In order to validate the results from the 2-DE and to investigate the possibility of the identified proteins becoming relevant biomarkers, we performed an immunoblot analysis on an expanded group of samples: 11 that were used for 2-DE as well as an additional 16 (*n* = 27). The selection of proteins subjected to the analysis was based on their putative relevance. GKN1 was the most abundantly underexpressed protein and was already validated at the protein level<sup>[19]</sup>, so it was chosen as a general control in our 2-DE and immunoblot experiments. MRPL12 has, to the best of our knowledge, not yet been found

**Table 2** Results of mass spectrometry identification

Protein name	Gene name	Swiss-Prot ID	pI/MW	Frequency <sup>1</sup>	Fold <sup>2</sup>	P value	Coverage <sup>3</sup>	No. of pep. <sup>4</sup>
Down-regulated								
Gastrokine-1 precursor	<i>GKN1</i>	Q9NS71	5.3/21.0	75% (9/12)	15.17	0.000	16%	6
15-hydroxyprostaglandin dehydrogenase isoform 1	<i>HPGD</i>	P15428	5.6/25.2	66% (8/12)	3.85	0.016	23%	5
Enoyl CoA hydratase, mitochondrial precursor	<i>ECHS1</i>	P30084	5.8/27.9	66% (8/12)	3.38	0.001	49%	15

<sup>1</sup>Frequency shows the number of patients where the protein was differentially expressed in two-dimensional gel electrophoresis analysis; <sup>2</sup>Fold stands for the average fold change in the relative spot volume between non-tumor and tumor (downregulated) or tumor and non-tumor (upregulated) tissue; <sup>3</sup>Coverage stands for the sequence coverage in mass spectrometry (MS) analysis; <sup>4</sup>No. of pep. stands for the number of matched peptides in MS analysis. MW: Molecular weight.

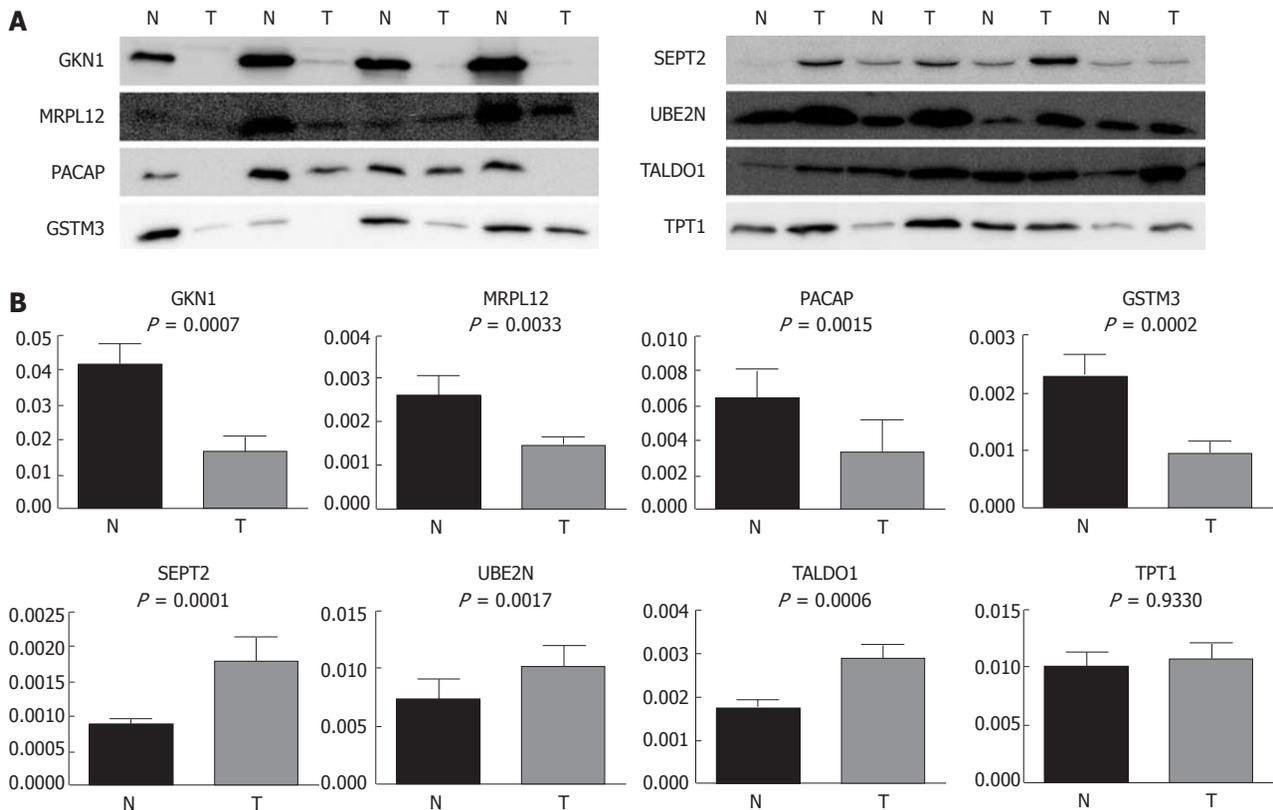

**Figure 3** Distribution of differentially expressed proteins according to the biological processes in which they are involved.

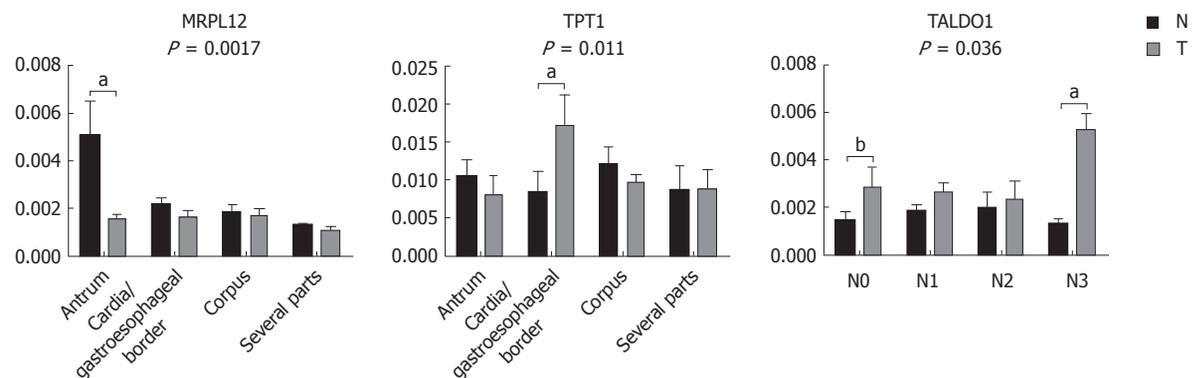

to be associated with gastric cancer, while SEPT2 (as the most abundantly overexpressed), UBE2N, TALDO1, TPT1, PACAP, and GSTM3 were already found to be

associated with gastric adenocarcinoma, but were not previously validated at the protein level.

Our results (Figure 4) show that GKN1 ( $P = 0.0007$ ), MRPL12 ( $P = 0.0033$ ), PACAP ( $P = 0.0015$ ), and GSTM3 ( $P = 0.0002$ ) were significantly underexpressed in gastric adenocarcinoma. SEPT2 ( $P = 0.0001$ ), UBE2N ( $P = 0.0017$ ), and TALDO1 ( $P = 0.0006$ ), on the other hand, were significantly overexpressed. The immunoblot results confirmed our results from the 2-DE analysis. TPT1, on the other hand, did not appear as generally differentially expressed in the tumor samples compared to the non-tumor samples. However, we also checked for a correlation of the differential expression with the histopathological parameters. We observed (Figure 5) significant differences in the MRPL12 expression and tumor location ( $P = 0.017$ ), as well as in TPT1 expression and tumor location ( $P = 0.011$ ). TALDO1 expression was observed to correlate with pN status ( $P = 0.036$ ). A higher rate of MRPL12 overexpression was found in the antrum ( $P < 0.001$ ) and a higher rate of TPT1 overexpression

**Figure 4** Examples of immunoblotting results on four pairs of non-tumor and tumor tissue for eight differentially expressed proteins (A) and densitometric results from immunoblotting for the same eight proteins (B). The x-axis represents non-tumor (N) and tumor (T) tissues and the y-axis represents relative band density. The *P* values are from the Wilcoxon signed-rank test. GKN1: Gastrin-1 precursor; MRPL12: 39S ribosomal protein L12 (mitochondrial precursor); PACAP: Plasma cell-induced resident endoplasmic reticulum protein; GSTM3: Glutathione S-transferase mu 3; SEPT2: Septin-2; UBE2N: Ubiquitin-conjugating enzyme E2 N; TALDO1: Transaldolase; TPT1: Translationally controlled tumor protein.

**Figure 5** Densitometric results from immunoblotting for three proteins describing potential associations of differential protein expression and clinical parameters. The x-axis represents different clinical parameters and the y-axis represents relative band density. The *P* values are from the repeated measures analysis of variance. <sup>a</sup>*P* < 0.01 and <sup>b</sup>*P* < 0.05 are from the Bonferroni post-test. MRPL12: 39S ribosomal protein L12 (mitochondrial precursor); TPT1: Translationally controlled tumor protein; TALDO1: Transaldolase; N: Non-tumor; T: Tumor.

was found in the cardia/gastroesophageal border (*P* < 0.01). A higher rate of TALDO1 overexpression was found in pN0 (*P* < 0.05) and pN3 (*P* < 0.01) tumors.

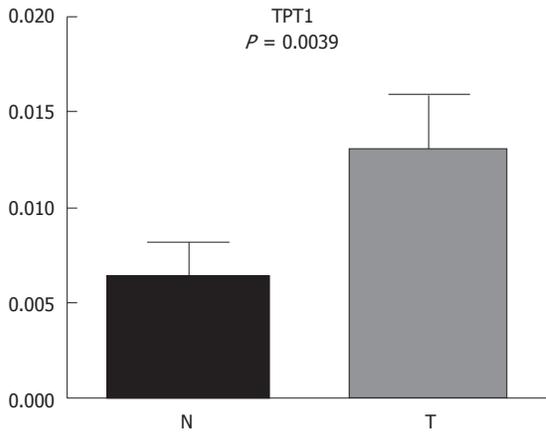

Due to the interesting results of TPT1 and cardia/gastroesophageal border correlation, we used additional tissue samples from four patients with cardia/gastroesophageal border adenocarcinoma to confirm it. The trend remained the same: TPT1 was upregulated. When combining tissues from all 10 patients with cardia/gas-

troesophageal border adenocarcinoma (six from before and four additional), Wilcoxon signed-rank test confirmed the differential expression (Figure 6).

## DISCUSSION

### General observations

Using a gel-based proteomic approach, we aimed to find and validate the differentially expressed proteins in a set

**Figure 6** Densitometric results from immunoblotting of 10 pairs of non-tumor and tumor tissue from cardia/gastroesophageal border adenocarcinoma patients. The x-axis represents non-tumor (N) and tumor (T) tissues and the y-axis represents relative band density. The *P* value is from the Wilcoxon signed-rank test. TPT1: Translationally controlled tumor protein.

of gastric adenocarcinoma patients. A total of 30 different proteins were identified in the study. They belonged to different biological processes, including metabolism, development, death, response to stress, cell cycle, cell communication, transport, and cell motility. The largest group, metabolism, contained 20 proteins with at least some role in cell metabolism.

A set of these proteins has already been found in similarly conducted experiments for GC. Among those downregulated in the tumor, enoyl CoA hydratase, mitochondrial precursor<sup>[20,21]</sup>, acyl-CoA dehydrogenase<sup>[22]</sup>, NADH dehydrogenase (ubiquinone) flavoprotein 2, mitochondrial precursor<sup>[22]</sup>, phenazine biosynthesis-like domain-containing protein isoform a<sup>[22]</sup>, and ATP synthase subunit d, mitochondrial<sup>[23]</sup> have been reported with the same alterations as in our study. In contrast to our observation, ATP synthase subunit d was reported to be upregulated in another study<sup>[22]</sup>. Among the proteins upregulated in the tumor, phosphoglycerate kinase 1<sup>[19]</sup>, pyruvate kinase isozymes M1/M2<sup>[24,25]</sup>, heat shock 70 kDa protein 1A/1B<sup>[24,25]</sup>, cathepsin D precursor<sup>[22,24,26]</sup>, annexin A4<sup>[26]</sup>, alpha-enolase<sup>[24,25]</sup>, nicotinamide N-methyltransferase<sup>[20,27,28]</sup>, annexin A5<sup>[20,29]</sup>, and actin, cytoplasmic 1 in rat GC metastases<sup>[30]</sup> have been found elsewhere with the same trend as in our study. However, other studies have reported that pyruvate kinase<sup>[22]</sup>, alpha-enolase<sup>[26]</sup>, and actin<sup>[26,31]</sup> have the opposite expression patterns compared to our results. This discrepancy could perhaps result from the heterogeneity that is often present in studies of human tumor tissue. In this paper, we present and discuss eight putative biomarkers for gastric carcinogenesis that were identified in our study, among which seven were validated for the first time by means of immunoblotting.

### Specific protein alterations

GKN1 has already been identified as a downregulated gene in GC<sup>[32]</sup>. It is suggested to maintain gastric mu-

cosal integrity and mediate repair after injury<sup>[33]</sup>. The protection of the mucosal barrier is thought to be due to the ability of GKN1 to alter the distribution of specific tight-junction proteins and to stabilize perijunctional actin<sup>[34]</sup>. It was later demonstrated to bind with F-actin in smooth muscle cells, suggesting a role in cell-cell adhesion and the assembly of actin stress fibers<sup>[35]</sup>. Recently, GKN1 has been shown to be a modulator of apoptotic signals<sup>[36]</sup>. It has been confirmed as a secreted protein and as being present in native and metaplastic gastric epithelium, but absent from the gastric carcinoma and the precursor lesion of intestinal metaplasia, making it a possible tumor suppressor in gastric carcinogenesis<sup>[37]</sup>.

GKN1 expression is downregulated in *Helicobacter pylori*-positive patients<sup>[38]</sup>. In another study, a loss of GKN1 occurred, especially in the diffuse-type tumor, but was associated with a significantly worse outcome in the intestinal type<sup>[39]</sup>. It has been found to be downregulated in GC, using 2-DE<sup>[20,23,25,27]</sup>, and these results have been validated at the protein and mRNA levels<sup>[19]</sup>. Consistently, we found that GKN1 was underexpressed in tumor tissue, using 2-DE, and we also validated the results by immunoblotting. Our result is in agreement with other reports and, like other research groups, we were also unable to find any correlation with histopathological parameters at the protein level. The overlapping of both steps of the biomarker identification with a number of other studies in this case contributed to the confidence in the approach for the analysis of additional biomarkers found in our proteomic analysis.

MRPL12 is the first cloned and characterized mammalian mitochondrial ribosomal protein encoded by the nucleus<sup>[40]</sup>. It accumulates in cells at the mRNA and protein levels upon growth-factor stimulation. The enhanced expression later contributes to transcriptional activation<sup>[41]</sup>. *MRPL12* mRNA levels have been detected in different organs, being especially high in the colon and skeletal muscle<sup>[41]</sup>. Besides being a component of the mitochondrial ribosome (its dimers bind the large ribosomal unit), MRPL12 binds to mitochondrial RNA polymerase and enhances transcription *in vitro*<sup>[42]</sup>. It has been speculated that it may either directly couple transcription and translation by binding simultaneously to polymerase and ribosomes, or alone bind to polymerase and activate its transcriptional activity in some way<sup>[43]</sup>. However, Litonin *et al*<sup>[44]</sup> have observed no such stimulation, so further experiments are necessary to clarify the possible role of this protein in transcription.

MRPL12 is differentially expressed, and it has previously been observed by 2-DE to be overexpressed in prostate cancer<sup>[45]</sup> and in hepatitis B virus (HBV)-associated hepatocellular carcinoma<sup>[46]</sup>. This is not in accordance with our results because we showed that MRPL12 was downregulated in gastric adenocarcinoma. We also observed its correlation with location: higher rates of underexpression were found in the antrum. In the context of cancer, the knockdown of MRPL12 decreases mitochondrial activity, increases glycolysis and accelerates

tumor growth<sup>[47]</sup>. We speculate that it may also be the case in gastric adenocarcinoma.

PACAP was found as an expressed sequence tag from a microarray analysis where it exhibited downregulation in intestinal-type GC<sup>[48]</sup>. The protein was found in the endoplasmic reticulum of lymphocytes, where it exhibited upregulation in the course of B-cell differentiation<sup>[49,50]</sup>. It was found to assist in the oxidative folding of Ig domains; however, both research groups were uncertain as to whether it acted as an oxidoreductase or as a chaperone. In a very recent report<sup>[51]</sup>, PACAP was described as helping to diversify peripheral B-cell functions by regulating Ca<sup>2+</sup> stores, antibody secretion and integrin activation.

A patent application<sup>[52]</sup> has disclosed the use of PACAP as a universal marker of different types of cancer, GC included. However, they claim that increased concentrations of the protein and/or its fragments are associated with cancer, whereas we discovered just the opposite for GC. The same was reported by Huang *et al.*<sup>[31]</sup> in a 2-DE experiment (although this was without validation), by Hasegawa *et al.*<sup>[48]</sup> and Katoh *et al.*<sup>[53]</sup>. However, in the latter two cases, this was at the non-protein level. We validated our results by immunoblotting. Due to its downregulation in the tumor, we strongly support the previous speculation that PACAP might be a candidate tumor-suppressor gene<sup>[53]</sup>.

GSTM3 is a glutathione S-transferase (GST) that belongs to the mu class<sup>[54]</sup>. It is rather unusual; it is not only about 70% identical in its protein sequence to the other mu-class transferases, but it is also considerably shorter and transcribed in the reverse orientation<sup>[55]</sup>.

Several polymorphisms have been found in GSTs, which can alter the susceptibility to carcinogens and toxins and influence the toxicity and efficacy of drug treatment<sup>[54]</sup>. They have been studied in relation to several cancers, GC included. For example, Martinez and colleagues have found no association with the *GSTM3* genotype and GC risk<sup>[56]</sup>, whereas Tatemichi and co-workers have described a possible association between *GSTM3* polymorphisms and Ig titer levels in serum against *H. pylori*<sup>[57]</sup>.

*GSTM3* is found in several normal tissues, including the stomach<sup>[58]</sup>. A comparison of the differential *GSTM3* expression in cancers is made rather difficult by the fact that many studies have focused on the whole GST family or class, but not on individual isoforms. For instance, antral GST enzyme activity has been found to be significantly lower in the stomach of *H. pylori*-infected patients<sup>[59]</sup>, but the contributions of separate isoforms has not been studied. For *GSTM3* specifically, the gene is highly expressed in a subgroup of patients with head and neck squamous cell carcinoma<sup>[60]</sup>. The protein is upregulated in neuroblastoma<sup>[61]</sup> and in polycystic ovary syndrome<sup>[62]</sup>. We found that *GSTM3* was downregulated in gastric adenocarcinoma. Our results are in agreement with a study reporting downregulation in the seminomatous germ cell tumor, where the changes were also reflected at the transcriptional level<sup>[63]</sup>. This reduced expression could be indicative of the decreased detoxification capacity of tumor cells<sup>[59]</sup>.

Septins belong to a family of conserved GTP-binding proteins<sup>[64]</sup>. They have been implicated in many cellular processes. SEPT2 is thought to be involved in cytokinesis,

as well as chromosome congression and segregation<sup>[65,66]</sup>. Its fibers appear to contact actin bundles and focal adhesion complexes physically, thereby linking it to a functional interaction with actin-based cytoskeletal systems in interphase cells<sup>[65]</sup>. It has also been found in the microtubule spindle during metaphase and is proposed to form a mitotic scaffold for different effectors to coordinate cytokinesis with chromosome congression and segregation<sup>[66]</sup>. Several other binding partners and functions have been proposed for SEPT2, such as the DNA damage response, the regulation of the efficiency of vesicular transport, and FCγR-mediated phagocytosis<sup>[64]</sup>. Recently, it has been reported that SEPT2 is part of a diffusion barrier between the primary cilia and the cell and it is essential for retaining receptor-signaling pathways in primary cilia<sup>[67]</sup>. Also, in response to physiological and pathological stimuli, SEPT2 redistributes and its interaction with actin increases, which allows for the dynamic modulation of the airway epithelial barrier function<sup>[68]</sup>. Despite all the progress, the exact molecular mechanisms, cellular, and physiological functions of septins are still poorly understood and interactome studies could help<sup>[69]</sup>.

Septins have been linked to diseases such as neurodegeneration and cancer<sup>[70]</sup>. It is proposed that altered SEPT2 expression can lead to disordered chromosomal dynamics and underlie the development of the aneuploidy common to cancers<sup>[66]</sup>. SEPT2, among others, has been found to be a fusion partner of the mixed lineage leukemia (*MLL*) gene in therapy-related acute myeloid leukemia<sup>[71]</sup>. Such fusion is associated with downregulation of *SEPT2* and *MLL* in myeloid neoplasia<sup>[72]</sup>. It has also been shown to be downregulated in glioblastoma<sup>[73]</sup>. On the other hand, it has been identified as upregulated in hepatoma carcinoma cells, where its phosphorylation on Ser218 by casein kinase 2 has been determined as crucial for hepatoma carcinoma cell proliferation<sup>[74]</sup>. In a 2-DE experiment, SEPT2 was, in agreement with our results, determined to be upregulated in GC<sup>[22]</sup>; however, no validation was carried out. The same expression pattern was found in renal cell carcinoma<sup>[75]</sup> and in late-stage human colon cancer tissue<sup>[76]</sup>, and it is abundantly expressed in several brain tumors and brain-tumor cell lines<sup>[77]</sup>. Taken as a whole, these results suggest its possible role as an oncogene.

Ubiquitination is a post-translational modification carried out in several steps<sup>[78]</sup>, one of them being conjugation of an activated ubiquitin to an ubiquitin-conjugating enzyme (E2) *via* a highly conserved catalytic cysteine residue. By directly influencing the type of lysine used to label the substrates, they influence the fate of the substrates. One of the E2s is UBE2N, which acts as part of a complex that enables the formation of the non-canonical Lys63-mediated polyubiquitin chains<sup>[79]</sup>. As opposed to Lys48-mediated ones, these do not target proteasome degradation but mediate other processes. Among other functions, it has been shown that UBE2N in a complex with Mms2 functions *via* Lys63-mediated polyubiquitination in DNA repair, whereas in a complex with Uev1A, it functions in activating nuclear factor-κB signaling<sup>[78,80]</sup>. Both of the partner proteins, however, are dispensable for the RNF8-dependent propagation of DNA damage signals *via* ubiq-

uitination<sup>[81]</sup>, although there are some questions as to the importance of this activity<sup>[82]</sup>.

UBE2N is differentially expressed between different types of leukemia and lymphoma cell lines<sup>[83]</sup>. It has significantly lower transcriptional expression levels in non-small-cell lung cancer and is correlated with pN and the stage of the disease<sup>[84]</sup>. In a breast-cancer metastatic model using iTRAQ technology, UBE2N was downregulated when comparing cells with the most metastatic potential and non-metastatic cells<sup>[85]</sup>. On the other hand, it was observed in a 2-DE experiment to be overexpressed in HBV-associated liver cancer<sup>[46]</sup>, which is consistent with our results. It has already been shown to be differentially expressed in GC<sup>[86]</sup>; however, it has not been validated whether it is up- or downregulated. UBE2N-dependent Lys63-mediated polyubiquitination regulates processes that often enhance cell survival in response to certain forms of stress<sup>[87]</sup>, therefore, our result supports its implication in the regulation of similar processes in gastric cancerogenesis.

TALDO1 is an almost ubiquitous cofactor-less enzyme of the pentose phosphate pathway<sup>[88]</sup>. Its activity is tissue specific and, in the brain, it is selectively expressed in oligodendrocytes, thus connecting it to different autoimmune diseases, such as multiple sclerosis<sup>[89]</sup>. Its expression is developmentally controlled<sup>[88]</sup>.

TALDO1 is the rate-limiting enzyme of the non-oxidative part of the pentose phosphate pathway<sup>[88]</sup> that catalyzes the reversible transfer of a three-carbon unit between various sugar phosphates (from ketose to aldose sugar phosphates). It has a role in regulating the balance between the two branches of the pentose phosphate pathway and its overall output, as measured by NADPH and glutathione production, and thus influences the sensitivity to cell-death signals<sup>[90]</sup>.

When comparing tumor and normal TALDO1, its activity is increased in neoplastic liver<sup>[91]</sup>. Its gene is highly expressed in a subgroup of patients with squamous cell carcinoma of the head and neck<sup>[60]</sup>. Furthermore, it is up-regulated in late-stage human colon-cancer tissue<sup>[76]</sup> and in the sera of colorectal cancer patients<sup>[92]</sup>. In metastatic, compared to non-metastatic GC cell lines<sup>[93]</sup> and in GC tissue<sup>[86]</sup>, TALDO1 was overexpressed, as shown by 2-DE. However, in both studies, again, no validation was performed. All these studies are consistent with our results, which were also validated by immunoblotting. We also found that TALDO1 correlated with pN status at stages pN0 and pN3. A higher TALDO1 expression in the tumor tissue could reflect an increased metabolism of glucose for the synthesis of nucleic acids in malignant cells<sup>[92]</sup>.

TPT1 is a ubiquitously expressed and highly conserved protein. It is associated with various cellular processes, such as cell-cycle progression, release of histamine and various interleukins, apoptosis, malignant transformation, and tumor reversion<sup>[64,95]</sup>. Very recently, it was also discovered as a glucose-regulated protein, important for the survival of pancreatic beta cells<sup>[96]</sup>.

It has been implicated in cancer, although it is not tumor-specific. It is upregulated in various tumor tissue cell lines when compared to normal tissue cell lines<sup>[97]</sup>, in breast<sup>[98]</sup> and colon cancer<sup>[99]</sup>. As for the gastric tissue,

TPT1 has been reported as cDNA present in libraries only from normal gastric tissues<sup>[100]</sup>. In our study, TPT1 was not validated as generally differentially expressed in the whole group of samples. Instead, its expression was location-correlated; TPT1 was upregulated in gastric adenocarcinoma from the cardia/gastroesophageal border. In contrast to the general worldwide decline of GC rates, an increasing incidence of gastric cardia cancer has been observed in several countries<sup>[1]</sup>. This suggests that it is a distinct clinical entity<sup>[26]</sup>. Therefore, it is possible that TPT1 is implemented only in gastric cardia/gastroesophageal border carcinogenesis.

Comparison of tumor and adjacent, non-tumor gastric tissues by means of proteome analysis, including differential 2-DE coupled to MS analysis, revealed 30 protein alterations. Some of the differentially expressed proteins had already been observed in GC in previous studies, which supports the reliability of our analysis. Several other proteins were found with the same trend of differential expression in other types of cancer, which could suggest that they are commonly involved in carcinogenesis. The high mortality rate from GC is due to delayed detection and surgical resection at advanced stages of the disease. A breakthrough in the early diagnosis of GC has not occurred yet and there are currently very few markers that are clinically in use; however, advances in proteomic research are facilitating the identification of novel diagnostic, prognostic, or therapeutic biomarkers. It is apparent that a collection of protein biomarkers will be necessary for reliable cancer detection and monitoring, as single biomarkers often have an inadequate predictive value<sup>[101]</sup>. There is, therefore, a need for the expedited development of new, validated biomarkers to be added to the list of clinically relevant tumor-associated proteins in the proteome databases of gastric tissue and cell lines. To the best of our knowledge, we are the first to observe aberrant expression of MRPL12 in gastric adenocarcinoma, and, in addition, aberrant expression of PACAP, GSTM3, SEPT2, UBE2N, TALDO1 and TPT1 for the gastric cardia/esophageal border were validated in gastric adenocarcinoma, also for the first time. Future experiments are planned to use these biomarkers in the design of a combinatory microarray and to translate the obtained results to blood samples, so the proteins would ultimately be useful as biomarkers for early detection.

## ACKNOWLEDGMENTS

We would like to thank Imagif, La Plateforme du Vivant, France, for their major contribution to the MS analysis.

## COMMENTS

### Background

Gastric cancer (GC) is the fourth most common cancer worldwide. Despite declining incidence rates, it is still the second leading cause of cancer death and thus remains a major health problem. The majority of patients are diagnosed at an advanced stage when the 5-year survival rate is very low.

### Research frontiers

Current diagnosis is invasive, whereas blood biomarkers lack sensitivity and

specificity. This study investigated proteome changes in gastric cancerous vs non-cancerous tissue in the hope of discovering new biomarker candidates. It reports the validation of seven aberrantly expressed proteins, one of them being reported as a novel candidate biomarker.

### Innovations and breakthroughs

This is believed to be the first study that reports aberrant expression of 39S ribosomal protein L12 in gastric adenocarcinoma, and for the first time, validates aberrant expression of plasma cell-induced resident endoplasmic reticulum protein, glutathione S-transferase mu 3, septin-2, ubiquitin-conjugating enzyme E2 N, transaldolase, and translationally controlled tumor protein for the cardia/gastroesophageal border at the protein level.

### Applications

Future work will be focused on using the validated biomarkers in the design of a diagnostic protein microarray and on translating the research to blood samples, so that the proteins would ultimately be useful as biomarkers for early detection. By showing their differential expression, this work might contribute to the efforts to understand GC carcinogenesis, as well as present a set of possible diagnostic biomarkers for gastric adenocarcinoma.

### Peer review

Proteomic analysis was done in the present study. And several potential biomarkers were selected as an important protein for gastric cancer carcinogenesis. These fields are very important for further developments of the clinical treatment in patients with various malignancies including gastric cancer.

### Abstract

**AIM:** To assess attitudes and trends regarding the use of high-dose infliximab among pediatric gastroenterologists for treatment of pediatric ulcerative colitis (UC).

**METHODS:** A 19-item survey was distributed to subscribers of the pediatric gastroenterology (PEDSGI) listserv. Responses were submitted anonymously and results compiled in a secure website.

**RESULTS:** A total of 113 subscribers (88% based in the United States) responded (101 pediatric gastroenterology attendings and 12 pediatric gastroenterology fellows). There were 46% in academic medical institutions and 39% in hospital-based practices. The majority (91%) were treating >10 patients with UC; 13% were

treating >100 patients with UC; 91% had prescribed infliximab (IFX) 5 mg/kg for UC; 72% had prescribed IFX 10 mg/kg for UC. Using a 5-point Likert scale, factors that influenced the decision not to increase IFX dosing in patients with UC included: "improvement on initial dose of IFX" (mean: 3.88) and "decision to move to colectomy" (3.69). Lowest mean Likert scores were: "lack of guidelines or literature regarding increased IFX dosing" (1.96) and "insurance authorization or other insurance issues" (2.34). "Insurance authorization or other insurance issues" was identified by 39% as at least somewhat of a factor (Likert score  $\geq 3$ ) in their decision not to increase the IFX dose. IFX 10 mg/kg was more commonly used for the treatment of pediatric UC among responders based in the United States (75/100) compared to non-United States responders (6/13,  $P = 0.047$ ). Induction of remission was reported by 78% of all responders and 81% reported maintenance of remission with IFX 10 mg/kg. One responder reported one death with IFX 10 mg/kg.

**CONCLUSION:** IFX 10 mg/kg is more commonly used in the United States to treat pediatric UC. Efficacy and safety data are required to avoid insurance barriers for its use.

Nattiv R, Wojcicki JM, Garnett EA, Gupta N, Heyman MB. High-dose infliximab for treatment of pediatric ulcerative colitis: A survey of clinical practice. *World J Gastroenterol* 2012; 18(11): 1229-1234 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i11/1229.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i11.1229>

## INTRODUCTION

In the last decade, infliximab has become an alternative treatment for moderate to severe ulcerative colitis (UC). The landmark ACT1 and ACT2 trials in adults showed that infliximab (IFX) successfully induced remission in patients with corticosteroid sensitive and corticosteroid resistant UC<sup>[1]</sup>. More recently, the Pediatric Inflammatory Bowel Disease Collaborative Research Group showed that children with corticosteroid-dependent or corticosteroid-refractory UC treated with IFX have a significant decrease in corticosteroid dependency and avoidance of colectomy in 72% after 1 year and 61% after 2 years of treatment<sup>[2]</sup>.

The Food and Drug Administration (FDA) has approved the use of IFX for treatment of moderate to severe UC for adult patients at a dose of 5 mg/kg<sup>[3]</sup>. However, in patients who lose responsiveness, the dose of IFX is commonly increased up to 10 mg/kg. The ACT1 and ACT2 trials demonstrated a response at this higher dose<sup>[1]</sup>. No studies have documented a benefit at this higher dose in pediatric patients.

Given the increased use of IFX for treatment of UC and the ongoing issues regarding efficacy, safety and insurance approval, we conducted a survey of pediatric gastroenterologists to collect information regarding dosing practices of IFX for the treatment of UC in the pediatric population. The results of this survey provide a glimpse into the attitudes of pediatric gastroenterologists regarding the use of high-dose IFX for pediatric UC.

## MATERIALS AND METHODS

An anonymous survey was created using the web-based survey software SurveyMonkey.com® (Portland, OR). The survey was distributed to all United States based and international pediatric gastroenterologists participating in the pediatric gastroenterology (PEDSGI) listserv with the approval of the listserv administrator. This survey included an electronic consent form and was free of identifiers. In addition, the survey forms were secured using secure sockets layer encryption to maintain the Health Insurance Portability and Accountability Act compliance. An "Opt Out" link was available at any point during the survey. This survey was approved by the University of California, San Francisco Committee on Human Research.

Demographic information was obtained by asking responders to provide data regarding their specialty (pediatric gastroenterology attending, pediatric gastroenterology trainee, or other specialty), practice type (academic, private, hospital based or other), practice size (< 10, 10-50, 51-100, 101-200 or > 200 patients) and location (Western United States, Midwest United States, Northeast United States, South United States, Europe, Middle East, Asia or "Other").

To determine the extent of IFX use among pediatric gastroenterologists, responders were asked, "Have you ever prescribed IFX at 5 mg/kg?" Those pediatric gastroenterologists that responded positively were asked, "What were the diagnoses for those patients receiving

IFX 5 mg/kg (Crohn's, UC, inflammatory bowel disease- unspecified (IBD-U) or other)?" Responders were then asked, "Have you ever prescribed IFX at 10 mg/kg?" Those that responded positively were again asked, "What were the diagnoses for those patients receiving IFX 10 mg/kg (Crohn's, UC, IBD-U or other)?" Responders who listed UC as a diagnosis were subsequently asked to specify all indications for which they prescribed IFX 10 mg/kg (steroid refractory UC, mild-to-moderate UC for induction or maintenance of remission, moderate-to-severe UC for induction or maintenance of remission, severe UC for induction or maintenance of remission).

Difficulty in achieving dose escalation was evaluated by asking those with experience in prescribing IFX 5 mg/kg: "... was an increase in IFX dosing considered at any point?" Responders who answered positively were subsequently asked: "...was an increase in IFX dose achieved?"

To further evaluate barriers to IFX dose escalation, a 5-point Likert scale was created whereby responders were asked to rank (scale of 1-5) factors that may have influenced their decision not to increase IFX to 10 mg/kg. The factors listed included: (1) patient improvement on the initial dose of IFX; (2) patient improvement on alternate medical therapy; (3) decision to move to colectomy; (4) lack of guidelines or literature regarding dose escalation; and (5) insurance authorization or other insurance issues. Responders were also asked to list other reasons that may have influenced their decision not to increase IFX dosing.

To evaluate the variation in administration of concomitant immunosuppressive medications, responders were asked to specify all medications instituted prior to IFX 10 mg/kg. In a separate question, responders were asked to specify all medications instituted concomitant with IFX 10 mg/kg for the treatment of UC. Answer choices included: corticosteroids, aminosaliclates, azathioprine (AZA), 6-mercaptopurine (6-MP), and methotrexate. Responders were also asked to specify any other medications that were not listed.

Methods for administration of IFX 10 mg/kg such as dosing interval and continuous or episodic treatment were not surveyed.

Responders were also asked to select any adverse events their patients experienced as a result of IFX 10 mg/kg. Answer choices included: worsening UC, headache, arthralgia, profound anemia, infection, oncologic process, neurologic event, antibodies against IFX or other autoimmune antibodies and infusion reactions. Responders were asked to specify any other adverse event that was not listed.

Finally, responders were asked to list all outcomes their patients experienced as a result of IFX 10 mg/kg (clinical remission, maintenance of remission, colectomy, continued or worsening colitis, death). Again, responders were asked to specify any other unlisted outcome.

Response frequencies were tabulated and expressed as percentages of total responses. Differences among groups with regard to frequency and Likert scale variables were assessed for significance using a Wilcoxon

Table 1 Indication for initiation of infliximab 10 mg/kg

Answer options	Percentage (n)
Steroid refractory UC	70.5 (55)
Severe UC for maintenance of remission	64.1 (50)
Moderate-to-severe UC for maintenance of remission	62.8 (49)
Severe UC for induction of remission	55.1 (43)
Moderate-to-severe UC for induction of remission	38.5 (30)
Mild-to-moderate UC for maintenance of remission	9.0 (7)
Mild-to-moderate UC for induction of remission	2.6 (2)
Other	6.4 (5)

78 respondents. UC: Ulcerative colitis.

Rank Sum test for comparing two groups, or a Kruskal-Wallis test for more than two groups as the data were not normally distributed. Differences between categorical variables were tested using  $\chi^2$  and Fisher exact tests. Differences were considered significant for  $P \leq 0.05$ .

## RESULTS

### Demographics

Our survey yielded 113 responders (5.7%) out of a total of 1993 subscribers to the PEDGI listserv. Of those responders, 101 were pediatric gastroenterology attendings and 12 were trainees in pediatric gastroenterology programs. Most responders identified themselves as based in an academic medical institution (46.0%) or a hospital-based practice (38.9%). A minority of respondents identified themselves as working in a private practice (12.4%). Most responders also identified themselves as practicing within the United States (88.5%). Ninety-one percent of responders reported practices that treat at least 10 patients with UC, 23.0% reported 50 to 100 patients, and 13.3% reported over 100 patients with UC.

### Initiation of IFX

Ninety-one percent (103/113) of respondents had prescribed IFX 5 mg/kg for treatment of UC, while 71.7% (81/113) had prescribed IFX 10 mg/kg for treatment of UC. The indications for prescribing IFX 10 mg/kg are listed in Table 1. A large majority of respondents selected steroid refractory UC as an indication for IFX 10 mg/kg (70.5%). In addition, a majority of respondents listed severe UC for induction and maintenance of remission as an indication for prescribing IFX 10 mg/kg (55.1% and 64.1%, respectively). A large number of respondents had also used IFX 10 mg/kg for treatment of moderate-to-severe UC, both for induction and maintenance of remission (38.5% and 62.8%, respectively).

The overall use of IFX 10 mg/kg to treat UC did not differ significantly when comparing responders in academic and non-academic practices. However, more responders working in non-academic practices had prescribed IFX 10 mg/kg for maintenance of remission for severe UC (29/39) compared with those in academic practices (19/39,  $P = 0.034$ ).

Responders based in the United States were more likely

Table 2 Therapies introduced prior to infliximab 10 mg/kg

Answer options	Percentage (n)
Corticosteroids	96.2 (75)
Infliximab 5 mg/kg	92.3 (72)
Aminosalicylates	89.7 (70)
Azathioprine <sup>1</sup>	76.9 (60)
6-mercaptopurine <sup>1</sup>	70.5 (55)
Methotrexate	25.6 (20)
Other	14.1 (11)
None	1.3 (1)

<sup>1</sup>Reported use by physicians included either azathioprine or 6-mercaptopurine in different patients. 78 respondents.

to use IFX 10 mg/kg to treat UC (75/100) compared with non-United States responders (6/13,  $P = 0.047$ ). However, the indication for initiation of IFX 10 mg/kg for UC did not differ between these two groups.

### Increasing the IFX dose

Pediatric gastroenterologists will often increase IFX dosing in patients that respond poorly to IFX 5 mg/kg. Respondents who had prescribed IFX 5 mg/kg for the treatment of UC were subsequently asked, "Have you ever considered an increase in IFX dosing above 5 mg/kg?" Overwhelmingly, 87.4% (90/103) of those using IFX had at least considered an increase in IFX dosing.

Using a 5-point Likert scale, respondents were asked to rank factors that may have influenced their decision not to increase IFX dosing in patients with UC (Figure 1). Among the 82 respondents, "improvement on initial dose of IFX" and "decision to move to colectomy" had the highest mean Likert scores (3.88 and 3.69, respectively). "Lack of guidelines or literature regarding increased IFX dosing" and "insurance authorization or other insurance issues" had the lowest mean Likert scores (1.96 and 2.34, respectively). Of note, however, 39.0% (32/82) identified "insurance authorization or other insurance issues" as at least somewhat of a factor (Likert score  $\geq 3$ ) in their decision not to increase the IFX dose in patients with UC.

Respondents were asked to list all medical therapies that may have been instituted prior to IFX 10 mg/kg (Table 2). Many of the respondents selected all the alternative medical therapies listed, and only one reported prescribing IFX 10 mg/kg without attempting any prior medical therapy. "Other" medications that were specified included tacrolimus, probiotics, metronidazole and other antibiotics.

Respondents were also asked what therapies they had instituted concurrently with IFX 10 mg/kg (Table 3). Most used corticosteroids with IFX 10 mg/kg. In addition, aminosalicylates were commonly administered with IFX 10 mg/kg. Conversely, fewer prescribed AZA or 6-MP along with IFX 10 mg/kg. A small minority administered IFX 10 mg/kg alone. Methotrexate was also noted to be used concurrently with IFX 10 mg/kg.

No significant differences in practice patterns with regards to medications initiated prior to and concurrent with IFX 10 mg/kg were observed between those in

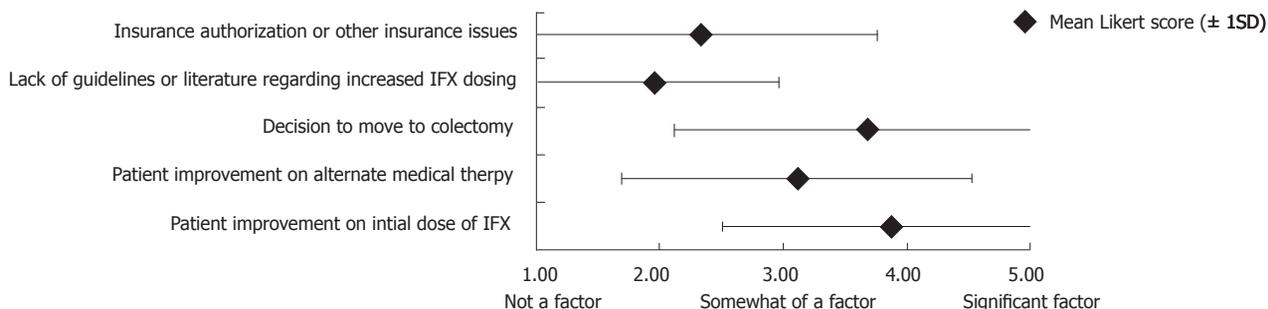

Figure 1 Factors that influenced pediatric gastroenterologists to not increase infliximab dosing depicted as a 5-point Likert scale. IFX: Infliximab.

Answer options	Percentage (n)
Corticosteroids	70.5 (55)
Aminosalicylates	61.5 (48)

academic and non-academic practices.

A larger number of United States based responders had prescribed 6-MP prior to instituting IFX 10 mg/kg to treat UC (54/75, 72.0%) compared with non-United States based responders (1/6, 16.7%,  $P = 0.012$ ). In addition, more United States based responders had prescribed 5-aminosalicylates concurrently with IFX 10 mg/kg (47/75, 62.7%) compared with non-United States responders (1/6, 16.7%,  $P = 0.039$ ). Similarly, antibiotics was more commonly prescribed concurrently with IFX 10 mg/kg among United States responders (35/75, 46.7%) compared with non-United States responders (0/6,  $P = 0.034$ ).

### Outcomes with high-dose IFX

Table 4 lists the outcomes reported by respondents as a result of using IFX 10 mg/kg. A majority of pediatric gastroenterologists surveyed reported either clinical remission (61/78, 78.2%) or maintenance of remission

Answer options	Percentage (n)
None	64.1 (50)
Antibodies to infliximab	17.9 (14)
Infusion reaction or delayed hypersensitivity reaction	16.7 (13)
Worsening ulcerative colitis	14.1 (11)
Infection	12.8 (10)

Profound anemia	1.3 (1)
Oncologic process	0 (0)
Neurologic event (e.g., neuritis, neuropathy)	0 (0)

78 respondents.

with this dose (63/78, 80.8%). Over half of the surveyed pediatric gastroenterologists who used 10 mg/kg IFX had patients who continued to suffer worsening colitis (40/78, 51.3%) or who moved to colectomy (47/78, 60.3%).

Most pediatric gastroenterologists (50/78, 64.1%) reported no adverse effects of the higher dose (Table 5). The most common adverse events reported by prescribers were antibodies to IFX (14/78, 17.9%) and infusion reactions (13/78, 16.7%); 14.1% (11/78) respondents reported discontinuing IFX 10 mg/kg as a result of these adverse reactions. No oncologic or major neurologic events were reported as a consequence of administering IFX 10 mg/kg. However, a single respondent reported one death while using IFX 10 mg/kg.

## DISCUSSION

This survey was designed to understand the attitudes and driving forces of pediatric gastroenterologists regarding the use of high-dose IFX for the treatment of UC. In our sample, a majority of the pediatric gastroenterologists surveyed had experience treating pediatric UC with IFX 10 mg/kg.

One of the strengths of this study is that the respondents were evenly split between academic institutions and non-academic practices, capturing the major practice settings of pediatric gastroenterologists.

One of the weaknesses of this study is the low response rate, which may represent a non-response bias. However, it should be noted that a large number of the 1993 PEDSGI listserv subscribers are not pediatric gastroenterologists. Many of the listserv subscribers are surgeons, pathologists, nurse practitioners and other healthcare professionals. Although the exact number of pediatric gastroenterologists that subscribe to the listserv is unknown, the response rate is likely much higher among this particular group. According to the American Board of Pediatrics, at the time this survey was conducted, 974 board certified pediatric gastroenterologists were registered in the United States<sup>[4]</sup>. Based on these numbers, our survey results represent the opinions of 9.3% (91/974) of the registered pediatric gastroenterologists practicing within the United States.

In addition, the results of this survey study are subject to recall bias. Respondents who have experienced more extreme outcomes with IFX or difficulty with insurance approval for higher doses of IFX are more likely to respond in an exaggerated manner.

While the results of this uncontrolled study are subject to various biases, they may also be indicative of the trends regarding the use of high-dose IFX among pediatric gastroenterologists.

IFX is effective for both induction and maintenance of remission for steroid-refractory and steroid-dependent UC<sup>[1,2,5]</sup>. Predictably, most of the pediatric gastroenterologists surveyed indicated steroid refractoriness as an indication for prescribing IFX 10 mg/kg. In addition, nearly all pediatric gastroenterologists surveyed indicated that both corticosteroids and IFX 5 mg/kg had been employed prior to increasing the IFX dose to 10 mg/kg. IFX 10 mg/kg may also be a corticosteroid-sparing agent as reflected in the response that fewer pediatric gastroenterologists reported using corticosteroids after the 10 mg/kg dose was instituted.

While nearly three-quarters of pediatric gastroenterologists surveyed have prescribed 6-MP or AZA therapy prior to instituting IFX, only about one-third of pediatric gastroenterologists surveyed have administered 6-MP or AZA concurrently with IFX 10 mg/kg. This practice may be in flux, as recent reports suggest improved disease responsiveness and lower risk of antibodies to IFX with concomitant immunomodulators, despite concerns of hepatosplenic T-cell lymphoma<sup>[6-10]</sup>. In our survey, no oncologic or serious neurologic adverse outcomes were reported. Future studies should further clarify the risk *vs* benefits of concomitant immunomodulator therapy.

Our results also suggest that pediatric gastroenterologists in the United States are more likely to prescribe IFX 10 mg/kg to treat UC compared with those working outside the United States. The only difference found for responders in academic compared with non-academic settings was an increased use of high-dose IFX for maintenance of remission for severe UC among non-academic pediatric gastroenterologists.

These differences highlight the lack of universal guidelines and need for further studies regarding the optimal use of IFX 10 mg/kg for the treatment of UC.

The most common reported side effects were antibodies to IFX and infusion reactions. Infections were also reported by 12.8% of responders. One respondent reported death as an adverse outcome. The events that lead to this death are not known. It is thought, however, that this fatality was not a result of oncologic, neurologic or infectious complications as the same respondent did not report experiencing any of these adverse effects while using IFX 10 mg/kg.

Most pediatric gastroenterologists surveyed reported improved outcome as a result of prescribing IFX 10 mg/kg, documenting a benefit of the higher dose in pediatric UC. However, over half of the respondents reported worsening disease and the need for colectomy, possibly due to loss of responsiveness, or in some cases a lack of any response to the increased dose.

IFX is approved by the FDA for the treatment of moderate to severe UC at a dose of 5 mg/kg<sup>[3]</sup>. Insurance companies have often rejected appeals for reimbursement for increased doses of IFX due to lack of published data showing efficacy and safety for pediatric patients with UC. Despite this, however, our survey suggests that insurance approval or other insurance issues did not uniformly prevent pediatric gastroenterologists from prescribing IFX 10 mg/kg.

Insurance approval for higher doses of IFX is achieved *via* an exception process or appeal process. An exception process involves an initial request for a health plan to consider coverage for a prescribed medication therapy or to reevaluate the possible benefits. An appeal is a request for an insurance carrier to reconsider a coverage decision that was initially denied<sup>[11]</sup>. The exception and appeal processes require letters of support from the prescribing physician. The time-consuming processes to initiate higher doses of IFX provide some patients with potentially lifesaving therapy. On the other hand, this litigious process is often unsuccessful and may delay alternative intervention for some patients.

Modification of UC treatment often becomes necessary in patients who lose responsiveness to an initial dose or standard maintenance regimen of IFX. Modification may consist of an increase in dose, decrease in dosing interval (not queried here), or addition of alternative medical or surgical therapy<sup>[12]</sup>. Treatment strategies with IFX should optimize drug pharmacokinetics to maximize dose response and minimize the development of antibodies to IFX. This may delay the need to increase IFX dose and reduce the risk of complications. Among pediatric gastroenterologists who prescribe IFX, IFX 10 mg/kg has a recognized role and perceived benefit in the treatment of some pediatric UC patients. Future prospective controlled clinical trials using high-dose IFX and other anti-tumor necrosis factor- $\alpha$  antibody agents, and testing of specific dose increases may provide more

standardized guidelines for the treatment of pediatric patients with UC.

## COMMENTS

### Background

In the last decade, infliximab (IFX) has become an alternative treatment of moderate to severe ulcerative colitis (UC) in both the adult and pediatric population. Based on current Food and Drug Administration recommendations the use of IFX for treatment of moderate to severe UC in adults is started at a dose of 5 mg/kg. However, in patients who lose responsiveness, the dose of IFX is commonly increased up to 10 mg/kg.

### Research frontiers

No studies have documented benefit at this higher dose in pediatric patients. The efficacy, safety and insurance approval for high-dose IFX have also been of growing concern in the medical community. The authors conducted a survey of pediatric gastroenterologists to collect information regarding the use of IFX for the treatment of UC in the pediatric population.

### Innovations and breakthroughs

Recently, the Pediatric Inflammatory Bowel Disease Collaborative Research Group (PIBDCRG) showed that children with corticosteroid-dependent or corticosteroid-refractory UC treated with IFX have a significant decrease in corticosteroid dependency and improved rates of colectomy. In the PIBDCRG study, dose escalation and decreased dose interval was at the discretion of prescribing physicians. The survey study conducted here is the first to report the extensive use of IFX 10 mg/kg by pediatric gastroenterologists for treatment of UC in the pediatric population.

### Applications

This study offers a glimpse in the attitudes and practice patterns of pediatric gastroenterologists regarding the use of high-dose IFX for the treatment of pediatric UC. The results highlight the recognized role of IFX 10 mg/kg for the treatment of UC in the pediatric population and the need for more standardized guidelines regarding dose escalation.

### Terminology

IFX is a biologic therapy used to treat autoimmune diseases such as UC. IFX is a monoclonal immunoglobulin G antibody that is genetically engineered to target tumor necrosis factor-alpha (TNF- $\alpha$ ). By selectively targeting specific players in the inflammatory cascade such as TNF- $\alpha$ , biologic agents may spare the need for treatment with systemic corticosteroids and thereby reduce the number of side effects associated with such treatment.

### Peer review

The authors examined the practice patterns of pediatric gastroenterologists regarding the use IFX for the treatment of UC. They found that a majority of those pediatric gastroenterologists surveyed have experience using IFX 10 mg/kg. In addition, significantly more pediatric gastroenterologists based in the United States have used IFX 10 mg/kg compared to those not based in the United States. Over one-third of pediatric gastroenterologists surveyed indicated insurance issues as a barrier to increasing IFX dosing.

### Abstract

**AIM:** To investigate toll-like receptor 2 (*TLR2*) -196 to -174 del, and *TLR4* (+896A/G rs4986790 and +1196C/T rs4986791) polymorphisms at risk of chronic gastritis and gastric cancer in a Brazilian population and association of gastric lesions with risk factors such as smoking, alcohol intake and *Helicobacter pylori* infection.

**METHODS:** In this case-control study, polymorphism at *TLR2* -196 to -174 del was investigated by using the allele-specific polymerase chain reaction (PCR) method, while the PCR-restriction fragment length polymorphism technique was carried out to identify the *TLR4* (rs4986790 and rs4986791) genotypes in 607 Brazilian individuals (208 with chronic gastritis-CG, 174 with gastric cancer-GC and 225 controls -C).

**RESULTS:** The single nucleotide polymorphisms *TLR4*+1196C/T was not associated with risk of chronic gastritis or gastric cancer and the homozygous genotypes *TLR4*+896GG and *TLR4*+1196TT were absent in the studied population. However, the frequency of *TLR2* -196 to -174 ins/del + del/del and *TLR4*+896AG

genotypes was significantly higher ( $P < 0.01$  and  $P = 0.01$ , respectively) in the cancer group (33.4% and 11.5%, respectively) than in the control group (16.9% and 4.5%, respectively). It was also observed that the G-C haplotype of the *TLR4*+896A/G+1196C/T ( $P = 0.02$ ) and the combination of variant alleles of the *TLR2*/*TLR4*+896G ( $P = 0.02$ ) are associated with susceptibility to gastric cancer. In addition, the multiple logistic regression showed that male gender [odds ratio (OR) = 2.70; 95% CI: 1.66-4.41;  $P < 0.01$ ], alcohol intake (OR = 2.93; 95% CI: 1.76-4.87;  $P < 0.01$ ), *TLR2* -196 to -174 del (OR = 2.64; 95% CI: 1.56-4.44;  $P < 0.01$ ) and *TLR4*+896G (OR = 3.19; 95% CI: 1.34-7.61;  $P < 0.01$ ) polymorphisms were associated with a higher susceptibility to developing this neoplasm.

**CONCLUSION:** Our data indicate that *TLR2* -196 to -174 del and *TLR4*+896G may increase the risk of gastric cancer in a Brazilian population.

de Oliveira JG, Silva AE. Polymorphisms of the *TLR2* and *TLR4* genes are associated with risk of gastric cancer in a Brazilian population. *World J Gastroenterol* 2012; 18(11): 1235-1242 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i11/1235.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i11.1235>

## INTRODUCTION

Gastric cancer is one of the most serious health problems in many countries, including Brazil, which ranks third in incidence and mortality, and with an estimated incidence in 2010 of about 21 500 new cases, with an incidence of 14.25 per 100 000 males and 7.70 per 100 000 females<sup>[1]</sup>. The *Helicobacter pylori* (*H. pylori*) is the major etiological risk factor for this malignancy, which progresses through a multi-step process, developing from gastritis, to gastric atrophy, intestinal metaplasia, dysplasia, and finally to carcinoma<sup>[2]</sup>. It is widely accepted that chronic *H. pylori* infection induces a gastric atrophy and hypochlorhydria, which are precursors of all pathophysiological changes of gastric carcinogenesis<sup>[3]</sup>. However, colonization with *H. pylori* can lead to various outcomes. Nearly all *H. pylori* positive subjects have chronic gastritis, and only 1%-2% development of stomach cancer among infected<sup>[4]</sup>. Hence, other factors are likely to be involved in gastric tumorigenesis such as host genetic factors, as well as the diversity of *H. pylori* virulence genes.

Host genetic factors, as polymorphisms in inflammatory and immune response genes, are mainly related to the recognition of the bacteria by the immune system and the variation in the level of cytokine response<sup>[5]</sup>. Among host factors, several inflammatory proteins including cytokines, growth factors, and chemokines have been known to control immune response against *H. pylori* infection<sup>[6,7]</sup>. Therefore, many studies have focused on the analyses of polymorphisms in genes associated with the inflammatory response in the gastric mucosa and risk for malignancy<sup>[8-11]</sup>. Other mediators also have polymorphic variants that modulate the innate immune response pattern, as the toll-like receptors (TLRs), which provide first line of host defense against harmful pathogens<sup>[12]</sup>.

Among the TLRs, it has been reported that the TLR2, lipoproteins bacterial receptor and the TLR4, the lipopolysaccharide (LPS) receptor, are involved in the response to infection by *H. pylori* on gastric epithelial cells<sup>[3,13-15]</sup>. Both the TLR2 and the TLR4 promote transcription of genes involved in immune activation including nuclear factor kappa B (*NF-κB*) and also mitogen-activated protein (*MAP*) kinase pathways<sup>[16]</sup>. *TLR4* is up regulated in gastric epithelial cell lines infected with *H. pylori* and in macrophages and expression of TLR4 protein has been demonstrated in chronic active gastritis, in precancerous lesions, and also in gastric tumor cells. TLR2 activates *NF-κB* in epithelial cells, in response to *H. pylori* infection, causing the expression of interleukin (IL)-8, macrophage inflammatory protein-3α and growth-regulated oncogene alpha<sup>[7]</sup>. Thus, it is conceivable that functionally relevant polymorphisms in *TLR* genes can alter the host immune response to pathogens as infection induced by *H. pylori*.

Single nucleotide polymorphisms (SNPs) in *TLR2* have been associated with susceptibility to various infectious and inflammatory diseases such as leprosy<sup>[17]</sup>, increased risk of Gram-negative sepsis<sup>[18]</sup>, asthma<sup>[19]</sup>, recurrent bacterial infections<sup>[20]</sup> and sporadic colorectal cancer

susceptibility<sup>[21]</sup>. The specific polymorphism *TLR2* -196 to -174 del/del genotype has been reported to show decreased transcriptional activity of the *TLR2* gene<sup>[22]</sup>. Such fact aroused the interest for this polymorphism, and previous studies in the Japanese population demonstrated its association with increased susceptibility to non-cardia gastric cancer<sup>[23]</sup> and intestinal metaplasia<sup>[24]</sup>.

Likewise, the *TLR4* presents some polymorphisms implicated in increased susceptibility to various diseases such as atherosclerosis<sup>[25]</sup>, asthma<sup>[3]</sup>, malaria<sup>[26]</sup>, and also infection with the *H. pylori* associated with gastric cancer and its precursors<sup>[27]</sup>. Two SNPs in *TLR4*+896A/G (rs4986790) and +1196C/T (rs4986791) have received special attention in some studies, although the results are still controversial<sup>[6,28,29]</sup>.

Therefore, the aim of this study was to evaluate the influence of the 22-bp nucleotide deletion -196 to -174 del, in the promoter region of the gene *TLR2* and +896A/G and +1196C/T polymorphisms (Asp299Gly and Thr399Ile) respectively in *TLR4* gene on the risk of chronic gastritis and gastric cancer in a Brazilian population and whether there is an association of gastric lesions with risk factors such as smoking, alcohol intake and *H. pylori* infection.

## MATERIALS AND METHODS

### Subjects

This was a case-control study on chronic gastritis and gastric cancer, in which a total of 607 DNA samples from peripheral blood leukocytes were genotyped. The case groups comprised 208 individuals (102 men and 106 women) with a histopathologically confirmed diagnosis of chronic gastritis - CG (Sidney System)<sup>[30]</sup>, with a mean age of 52.8 + 14.5 years (range 19 to 84 years), and 174 individuals (134 men and 40 women) with a histopathologically confirmed diagnosis of gastric cancer - GC (Lauren's classification)<sup>[31]</sup>, with a mean age of 62.2 ± 12.2 years (range 28 to 93 years). All subjects were recruited from the Hospital de Base in São José do Rio Preto, SP, and from the Pio XII Foundation in Barretos, SP, Brazil. *H. pylori* infection was histologically established either by the Giemsa staining technique or by the urease test, performed at the Pathology Services of the Hospital de Base and the Pio XII Foundation. Results of *H. pylori* infection were obtained for the available cases. The cancer-free control group (C) with no previous history of gastric disease was composed of 225 healthy individuals (112 men and 113 women), mainly blood donors, with a mean age of 56.5 + 18.1 years (range 20 to 93 years). Epidemiological data on the study population were collected using a standard interviewer-administered questionnaire, with questions about current and past occupation, smoking habits, alcohol intake and family history of cancer. All the individuals were ethnically classified on their visual appearance as Caucasians in the three groups evaluated. The few cases of African descent were excluded from the study (about 10%).

The National Research Ethics Committee approved this work, and written informed consent was obtained from all individuals.

### Genotyping

About 5 mL of whole blood were collected from all study participants in sterile EDTA-coated vacutainers. DNA was extracted according to a previous report<sup>[32]</sup>, and stored at -20 °C until use for genotyping.

Polymorphism at *TLR2* -196 to -174 del was investigated using the allele-specific polymerase chain reaction (PCR) method<sup>[24]</sup>, and the PCR-restriction fragment length polymorphism (RFLP) technique was carried out in order to identify the *TLR4* (rs4986790 and rs4986791) genotype<sup>[33,34]</sup> in cases and control groups. In brief, the procedure was carried in a total reaction volume of 25  $\mu$ L, containing 2.5  $\mu$ L 10  $\times$  PCR buffer, 2  $\mu$ L deoxyribonucleotide triphosphatess (1.25  $\mu$ mol/L), 0.5  $\mu$ L MgCl<sub>2</sub> (25 mmol/L), 1.25  $\mu$ L of each primer (25 mmol/L, Sigma-Aldrich, United States), 15.3  $\mu$ L dH<sub>2</sub>O, 2  $\mu$ L DNA (100 ng/ $\mu$ L), and 0.2  $\mu$ L Taq DNA polymerase (5 U/ $\mu$ L, Invitrogen, United States). PCR for *TLR2* -196 to -174 del was as follows: initial denaturation step at 95 °C for 5 min, amplification was carried out by 35 cycles at 95 °C for 30 s, at 60 °C for 40 s, and at 72 °C for 40 s, followed by a final elongation cycle at 72 °C for 7 min (Table 1). PCR for both *TLR4* polymorphisms were as follows: after an initial denaturation step at 94 °C for 3 min, amplification was carried out by 30 cycles at 94 °C for 30 s, at 62 °C for 30 s, and at 72 °C for 30 s, followed by a final elongation cycle at 72 °C for 7 min. Then, 10  $\mu$ L of *TLR4* +896 A/G and *TLR4* +1196 C/T polymorphism PCR products were digested with 0.5  $\mu$ L (5 U/ $\mu$ L) of the *Bst*XI and *Hinf*I specific enzymes, respectively in a 10  $\mu$ L volume including 2.5  $\mu$ L 10  $\times$  buffer 1 (New England Biolabs, United States) and 7.0  $\mu$ L dH<sub>2</sub>O (Table 1). The products were then electrophoresed on a 3% agarose 1000 (Invitrogen, United States) gel, to allow

detection by ethidium bromide staining.

In order to confirm the veracity of the results, one confirmed polymorphic case was used as positive control for every RFLP procedure, to attest the good functioning of the restriction enzyme. For the *TLR4*+896A/G (rs4986790) and +1196C/T (rs4986791) polymorphisms, we also used other fragments of the *TLR2* and *IL-1 $\beta$*  gene that was known to have the enzyme recognition site to verify the correct functioning of the enzymes *Bst*XI and *Hinf*I (Table 1), considering we did not detect any polymorphic homozygous subjects.

### Statistical analysis

Fisher's exact test was used to compare the groups regarding genotype and allele frequencies, and the chi-square test for determining Hardy-Weinberg equilibrium. Multiple logistic regression models were used to determine the effects of the variables in gastric cancer and chronic gastritis. The models included age (reference: < 61 and 53 years old - median of the groups), gender (reference: female), smoking habits (reference: nonsmokers), drinking habits (reference: nondrinkers), and *H. pylori* infection (reference: *H. pylori*-negative). The results are shown as odds ratio (OR), showing 95% CI. ORs were calculated using a dominant model due to low frequency of polymorphic homozygous (i.e., combining heterozygous and homozygous for the minor allele *vs* homozygous for the major allele) for all SNPs. The haplotype frequencies of *TLR4* were inferred by Haploview program (4.0 version). Statistical analyses were performed using the GraphPad InStat, and SPSS (11.5 version) computer software programs. A probability level (*P*) of less than 0.05 was adopted as a significance criterion.

## RESULTS

The samples of the 607 subjects were genotyped for the *TLR2* -196 to -174 del and *TLR4* (+896A/G rs4986790

**Table 2** Genotype and allele frequencies of toll-like receptor 2 (-196 to -174 *del*) and toll-like receptor 4 (rs4986790 and rs4986791) polymorphisms in gastric cancer, chronic gastritis and control groups

and +1196C/T rs4986791). The genotype and allele frequencies for these polymorphisms are presented in Table 2. The genotype and allele frequency distribution of the three polymorphisms complied with Hardy-Weinberg equilibrium in both cases and control groups (data not shown). The banding patterns of these SNPs are represented in Figure 1.

For *TLR2* -196 to -174 *del*, the genotype (*ins/del* and *del/del*) and allele (*del*) frequencies were increased statistically ( $P < 0.01$ ) in gastric cancer group (33.4% and 19% respectively) than in control group (16.0% and 8.5% respectively). In addition, among the groups of chronic gastritis (13.0%) and control (8.5%), the allele frequencies (*del*) was statistically significant ( $P = 0.02$ ).

Similarly, for *TLR4*+896A/G (rs4986790), the genotypes (A/G) and allele (G) frequencies were increased statistically in gastric cancer group (11.5% and 6.0%, respectively;  $P = 0.01$ ) and chronic gastritis (10.1% and 5.0%, respectively;  $P = 0.02$ ) than in control group (4.5% and 3%, respectively). This results due to the higher

frequency of polymorphic allele (*TLR4* +896G) in the gastric cancer and chronic gastritis groups.

In contrast, for *TLR4*+1196C/T (rs4986791), no significant difference was found between gastric cancer and control group (Table 2). Homozygous genotypes *TLR4*+896GG and *TLR4*+1196TT were absent in the studied population. We also compared the genotype and allele frequencies between gastric cancer and gastritis groups and no significant difference was found for the polymorphisms studied (data not shown).

The *TLR4* haplotype analysis (Table 3) demonstrated higher frequency of both wild alleles (haplotype A-C) in control subjects compared with gastric cancer (95.7% and 91.4%, respectively;  $P < 0.01$ ). However, the opposite was observed for frequency of variant haplotype

F: Frequency of individual (%); OR: Odds ratio; GC: Gastric cancer; CG: Chronic gastritis; C: Control; TLR: Toll-like receptor.

G-C, which was higher in the gastric cancer group compared with control group (63.0% and 31.0%, respectively;  $P = 0.02$ ).

In another statistical analysis, which evaluated the combined effect between the three polymorphisms (*TLR2* -196 to -174 *del*, *TLR4*+896A/G and +1196C/T), the combination of variant alleles of the polymorphisms *TLR2* ins/del and del/del with *TLR4* +896 AG showed a higher risk of gastric cancer compared to healthy individuals (OR = 4.13; 95% CI: 1.26-13.50;  $P = 0.02$ ). The other combinations of variant alleles did not show any significant difference (Table 4). The combination of the three variant alleles was found in only one individual of the group of chronic gastritis (data not shown).

The potential associations between the distributions of *TLR2* -196 to -174 *del* and *TLR4* (+896A/G and +1196C/T) genotypes adjusting for risk factors for gastric cancer and chronic gastritis in comparison of con-

trol group are presented in Table 5.

In the gastric cancer group, the multiple logistic regression shows that male gender (OR = 2.7; 95% CI: 1.66-4.41;  $P < 0.01$ ), alcohol intake (OR = 2.93; 95% CI: 1.76-4.87;  $P < 0.01$ ), *TLR2* -196 to -174 ins/del+del/del (OR = 2.64; 95% CI: 1.56-4.44;  $P < 0.01$ ) and *TLR4* +896AG (OR = 3.19; 95% CI: 1.34-7.61;  $P < 0.01$ ) were associated with a higher susceptibility to developing this neoplasm. The comparison between gastritis and control group showed that only *TLR4*+896AG polymorphism was associated with risk of chronic gastritis (OR = 2.29; 95% CI: 1.02-5.13;  $P = 0.04$ ), while age above 53 years (OR = 0.64; 95% CI: 0.43-0.95;  $P = 0.03$ ) and smoking (OR = 0.57; 95% CI: 0.37-0.87;  $P = 0.01$ ) were negatively associated with the development of gastritis. In another multiple logistic regression analysis considering also the individuals tested for *H. pylori* infection (95 with gastric cancer and 177 with gastritis), there was no statistically

significant association (OR = 0.73, 95% CI: 0.29-1.78;  $P = 0.49$ , data not shown in Table 5). There was also no association of three polymorphisms with *H. pylori* when evaluated negative and positive individuals within a group of gastric cancer and gastritis (data not shown).

## DISCUSSION

TLRs participate in *H. pylori* bacterium recognition in gastric mucosa, and SNPs in TLRs are associated with impaired immune response, inducing a potent inflammatory response. Therefore, it is relevant to carry out studies on host genetic factors that can be associated with susceptibility of gastric diseases. Hence, we investigated whether *TLR2* -196 to -174 del and *TLR4* (+896A/G rs4986790 and +1196C/T rs4986791) polymorphisms affect the risk of developing gastric cancer and chronic gastritis in a Brazilian population. Our results have demonstrated for the first time in this population, an association of *TLR2* -196 to -174 del and of *TLR4*+896 G polymorphisms with susceptibility to gastric cancer. The polymorphism *TLR4*+1196 T was not associated with risk to the gastric lesions evaluated, and the homozygous genotypes *TLR4*+896GG and *TLR4*+1196TT were absent in the studied population.

Some studies that investigated the association of *TLR2* -196 to -174 del polymorphisms at risk of developing diseases related to an inflammatory process have shown conflicting results. For instance, del allele or del/del genotype of *TLR2* -196 to -174 polymorphism was significantly associated with cervical cancer susceptibility<sup>[35]</sup> and risk of non-cardia gastric cancer in a Japanese population, but not for gastritis, gastric ulcer and duodenal ulcer<sup>[23]</sup>, while *TLR2* -196 to -174 ins allele was associated with more severe intestinal metaplasia in older patients<sup>[24]</sup>. However, Wang *et al.*<sup>[36]</sup> failed to show association of *TLR2* -196 to -174 del/del and ins/del carriers with ulcerative colitis.

The -196 to -174 del polymorphism in *TLR2* gene located on chromosome 4, causes a 22-bp nucleotide deletion that alters the promoter activity of gene. The *TLR2* del/del genotype is reported to show decreased transcriptional activity this gene<sup>[22]</sup>. In our study, we observed significantly higher frequencies of genotypes *TLR2* ins/del and del/del in the gastric cancer group compared to the healthy individuals, emphasizing its role in the gastric carcinogenesis.

The *TLR4* gene is mapped on chromosome 9 and consists of three exons. In exon 3, two non-synonymous SNPs *TLR4*+896A/G and +1196C/T allows the substitution of amino acids Asp299Gly and Thr399Ile, respectively. In the analysis by Haploview, the frequencies of *TLR4* G-C (299Gly-399Thr) and G allele were higher in patients with gastric cancer indicating an association of this haplotype with increased risk of gastric cancer to its carriers. The substitution of Asp299Gly amino acids disrupt the normal structure of the extracellular region of the TLR4 and may cause decreased ligand recogni-

tion or protein interaction, and decreased responsiveness to lipopolysaccharide, disrupting transport of *TLR4* to the cell membrane<sup>[13,37]</sup>. This change leads to an exaggerated inflammatory response with severe tissue destruction, likely due to a failure in stimulating regulatory cells and production of IL-10 cytokine<sup>[38]</sup>. Arbour *et al.*<sup>[13]</sup> were the first to report that individuals having either the Asp-299Gly and/or Thr399Ile polymorphisms had a blunted response towards inhaled LPS. Thus, during the cascade of progression of gastric carcinogenesis, the subjects with this polymorphism can have an increased risk of severe inflammation followed by development of hypochlorhydria and gastric atrophy, which are regarded as important precursor alterations of gastric cancer<sup>[12]</sup>.

Both SNPs in *TLR4* are presented in about 10% of Caucasian and African populations and are reported to have a positive correlation with susceptibility to infectious diseases, whereas studies in Asian populations have shown the absence of these polymorphisms<sup>[26,39]</sup>. However, in our study with a Southeastern Brazilian population, we found that both SNPs *TLR4* (+896A/G and +1196C/T) were present in heterozygous in about 4.5% to 11.5% and 2.7% to 5.2% respectively in the gastric cancer and control groups. Other studies in the Brazilian population found similar frequencies of heterozygous *TLR4*+896A/G polymorphism in Chagas disease (5.6%), ulcerative colitis (7.1%) and Crohn's disease (7%)<sup>[40,41]</sup>. But, to the best of our knowledge, there are not studies on *TLR2* and *TLR4* polymorphisms in gastric cancer of Brazilian population.

With regards to *TLR4*+896A/G and +1196C/T polymorphisms, Garza-Gonzalez *et al.*<sup>[29]</sup> showed no association with the risk of gastric cancer in the Mexican population, while Trejo de la O *et al.*<sup>[7]</sup> observed that both SNPs in *TLR4* had an association with duodenal ulcer and gastric cancer also in Mexican patients. Yet, other studies have demonstrated association with only one of these polymorphisms and risk of gastric cancer and precancerous lesions, either *TLR4*+1196C/T (Thr399Ile)<sup>[6,42]</sup> or *TLR4*+896A/G (Asp299Gly) polymorphisms<sup>[3]</sup> are associated with susceptibility to gastric carcinogenesis. In addition, in this study in Caucasian population<sup>[3]</sup>, homozygous polymorphic *TLR4*+896 GG was not found, corroborating our results.

Concerning *H. pylori* infection, we evaluated the association between *TLR2* and *TLR4* polymorphisms in the case groups with the available information in their medical records (95 with gastric cancer and 177 with gastritis) and no association was found. The reduced number of samples available for statistical analysis may have harmed these results. Rad *et al.*<sup>[8]</sup> studied the role of various TLRs (2/4/7 and 9) in response to *H. pylori* using mice mutants lacking these receptors. The results demonstrated the importance of the TLR2 in response to this bacterium, unlike the TLR4. TLR4-receptor lacking mice had little or no change in response to *H. pylori* compared with controls. Although the role that the effect of polymorphism in *TLR2* in the activity of this receptor in

gastric cells is not fully understood, this deletion is likely to alter their activity. Since *TLR2* has an important role in immune response against the *H. pylori* bacterium, the change of its function becomes relevant in carcinogenesis of the stomach<sup>[8]</sup>.

Besides the influence of the *H. pylori*, other risk factors as gender, age, smoking and alcohol intake were analyzed. There are statistically significant results for male gender and alcohol intake in the gastric cancer group compared with the control group. According to the National Cancer Institute the highest incidence of gastric cancer occurs in men around age 70 years, and about 65% of patients diagnosed with this type of cancer were over 50 years<sup>[1]</sup>. Another risk factor well established in the literature in relation to gastric carcinogenesis is the excessive consumption of alcohol<sup>[43-45]</sup>. Really, ethanol oxidation generates acetaldehyde, which presents carcinogenic effects, since it interferes with many DNA synthesis and repair sites, leading to tumor development<sup>[46]</sup>.

In conclusion, our findings indicate a significant role of both *TLR2* -196 to -174 del and *TLR4*+896G (Asp299Gly) polymorphic variant with susceptibility to gastric cancer in the Southeastern Brazilian population evaluated, whereas no association was observed for *TLR4* +1196T polymorphism. Thus, it is feasible to highlight that host genetic factors as the interaction of polymorphisms in genes of toll-like receptors can play an important role in gastric carcinogenesis.

## COMMENTS

### Background

Gastric cancer (GC) has high rate of incidence and mortality in Brazilian population. Thus is important to establish host genetic factors, as polymorphisms in genes related with inflammatory and immune response associated with higher risk of development of this neoplasia. In this study, authors have shown, for the first time association of toll-like receptor (*TLR*)2 -196 to -174 del and *TLR4*+896AG (Asp299Gly) polymorphisms with gastric cancer in a sample of Brazilian population.

### Research frontiers

Epidemiological studies on association of polymorphisms with susceptibility to disease as cancer frequently present conflicting results, possibly due to different factors as ethnicity, sample number, population sub-sampling, which can contribute to this discrepancy. Thus, are relevant studies in different populations that help clarify these aspects.

### Innovations and breakthroughs

In this study it was possible to make the combined analysis of three polymorphisms (*TLR2* -196 to -174 del, *TLR4*+896A/G and +1196C/T) and to show that the combination of single nucleotide polymorphisms *TLR2* ins/del and del/del with *TLR4* +896 AG led to a higher risk of gastric cancer.

### Applications

Considering the high incidence of gastric cancer in the Brazilian population, the data show that carriers of polymorphisms in genes involved with immune response as *TLR2* ins/del and del/del and *TLR4* +896 AG, together with other genetic and environmental factors constitute a risk group to gastric carcinogenesis.

### Peer review

This is a cross sectional study on the role of the *TLR2* and *TLR4* polymorphisms in GC in a Brazilian population. The main point that needs to be further clarified is the ethnic composition of the population. An important observation is that the *TLR4* variants are at similar frequencies on the African and Caucasian populations.

polypectomy, the incidence of adenoma decreases with age.

**METHODS:** Consecutive patients with colonic adenomas identified at index colonoscopy were retrospectively selected if they had undergone three or more complete colonoscopies, at least 24 mo apart. Patients who had any first-degree relative with colorectal cancer were excluded. Data regarding number of adenomas at each colonoscopy, their location, size and histological classification were recorded. The monthly incidence density of adenomas after the index examination was estimated for the study population, by using the person-years method. Baseline adenomas were excluded from incidence calculations but their characteristics were correlated with recurrence at follow-up, using the  $\chi^2$  test.

**RESULTS:** One hundred and fifty-six patients were included (109 male, mean age at index colonoscopy  $56.8 \pm 10.3$  years), with follow-up that ranged from 48 to 232 mo. No significant correlations were observed between the number, the presence of villous component, or the size of adenomas at index colonoscopy and the presence of adenomas at subsequent colonoscopies ( $P = 0.49, 0.12$  and  $0.78$ , respectively). The incidence of colonic adenomas was observed to decay from 1.4% person-months at the beginning of the study to values close to 0%, at 12 years after index colonoscopy.

**CONCLUSION:** Our results suggest the sporadic formation of adenomas occurs within a discrete period and that, when these adenomas are removed, all neoplasia-prone clones may be extinguished.

### Abstract

**AIM:** To investigate whether, under the influence of pol-

Rosa I, Fidalgo P, Soares J, Vinga S, Oliveira C, Silva JP, Ferro SM, Chaves P, Oliveira AG, Leitão CN. Adenoma incidence decreases under the effect of polypectomy. *World J Gastroenterol* 2012; 18(11): 1243-1248 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i11/1243.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i11.1243>

## INTRODUCTION

It has long been believed that initiation of sporadic colorectal cancer (CRC) increases over time, due to toxicity or loss of fidelity of DNA replication. Therefore, it is believed that the risk of adenoma formation is a function of age<sup>[1]</sup>, which justifies lifelong colonoscopy surveillance. However, current evidence has started to challenge these perceptions.

The data that have suggested that incidence of adenoma increases with age were mostly collected from autopsy studies<sup>[2,3]</sup>. Although relevant, these studies are prone to bias because the age-specific incidence rates do not adequately represent the time trend for newly formed lesions after removal of index lesions. Moreover, the rather important information of family aggregation of CRC was lacking in all of them.

More recent studies, based on surveillance colonoscopies<sup>[4-6]</sup>, have been mainly limited by short follow-up (3-5 years), which may lead to the inclusion, as new adenomas, of polyps that were missed at a previous examination. These time intervals are also likely to be too short to predict the lifelong dynamics of adenoma formation.

The notion that the formation of colon adenomatous polyps peaks at a certain age and then rapidly declines was first presented in 1975 by Henry *et al*<sup>[7]</sup>. He stated that: "some undefined stimulus to continuous polyp formation persists for up to 4 years in about one-third of patients who develop a colonic polyp. Thereafter, either the stimulus to neoplasia is no longer present, or the colonic mucosa adapts so that polyp formation does not persist." We propose that this undefined stimulus corresponds to the presence of a limited number of mutated clones that are scattered in the colonic epithelium and evolve through cumulative critical gene events selected over several decades. This sequence of events ends at a specific time window, in which most adenomas become endoscopically detectable and after which its incidence declines.

A study in Germany<sup>[8]</sup> has shown that individuals with negative findings at colonoscopy had a reduced risk of CRC for at least 20 years. Furthermore, when the examination was performed at 55-64 years of age and older, the risk of CRC was even lower. Additionally, according to the latest Guidelines for Colonoscopy Surveillance after Polypectomy issued by the American Gastroenterological Association (AGA)<sup>[9]</sup>, age is not considered to be a reliable predictor of subsequent advanced adenomas.

Taking these data into account and considering the

possibility of only a limited time window for sporadic adenoma expression, we aimed to study the temporal trend for adenoma formation, in a standard-risk population under colonoscopic surveillance. According to our hypothesis, which stated that a discrete number of mutated clones were scattered in the colon, we expected the adenoma incidence to decrease under the effect of polypectomy.

## MATERIALS AND METHODS

### *Patients and procedures*

Consecutive patients from three Portuguese hospitals (a tertiary oncology center, a tertiary general hospital and a regional hospital) with colonic adenomas who were identified at an index colonoscopy were retrospectively reviewed. These patients were included if they had undergone three or more complete colonoscopies that were at least 24 mo apart. The index colonoscopies were performed between 1978 and 2000, for screening or diagnostic purposes. The subsequent colonoscopies were performed according to the assistant physicians' choice, based on surveillance guidelines that changed during the time of the study (data were collected until 2007). Only colonoscopies reaching the cecum, with adequate bowel preparation and complete removal of all of the identified polyps were considered for inclusion in the present study.

The patient files were reviewed, and the patients were excluded if they had a previous history of CRC or adenomas, inflammatory bowel disease, hereditary non-polyposis CRC, familial adenomatous polyposis syndrome, a family history of CRC in any first-degree relative, or CRC at the index colonoscopy.

The location and size of all of the polyps had been recorded and the specimens had been sent for pathological evaluation and were classified according to the criteria of the World Health Organization<sup>[10]</sup>. All of the colonoscopies were performed by certified gastroenterologists, and sedation using intravenous midazolam (with or without pethidine association) or intravenous propofol (performed by an anesthesiologist) was administered on a case-to-case basis. The bowel preparation methods varied among the centers and over time, but were based on oral solutions that contained polyethylene glycol or senna.

The endoscopic and pathological reports were reviewed by the authors, for the results of the index colonoscopy, and of each colonoscopy reported thereafter. The left colon was defined as the splenic flexure and the segment distal to it.

The baseline adenoma characteristics were recorded and correlated with recurrence of adenomas at follow-up. However, these adenomas were specifically excluded from incidence ratio evaluation, because the time frame for their formation was unknown.

### *Data analysis*

The data regarding number of adenomas observed at each colonoscopy, along with their location, size and

Table 1 Outcomes of first four colonoscopies

Outcomes	Mean	SD
Index colonoscopy: 156 patients studied		
Adenomas	1.68	1.01
Tubular adenomas	1.49	1.13
Tubulo-villous/villous adenomas	0.14/0.05	0.35/0.22
Size of the larger adenoma (mm)	15.51	10.36
Adenomas in the left colon/remaining colon	1.34/0.35	0.93/0.69
Second colonoscopy: 156 patients studied (41.6 ± 21.0 mo since the first)		
Adenomas	0.54	0.86
Tubular adenomas	0.51	0.85
Tubulo-villous/villous adenomas	0.02/0.01	0.14/0.11
Size of the larger adenoma (mm)	8.02	7.39
Adenomas in the left colon/remaining colon	0.36/0.17	0.67/0.49
Third colonoscopy: 156 patients studied (83.7 ± 27.7 mo since the first)		
Adenomas	0.47	0.92
Tubular adenomas	0.46	0.92
Tubulo-villous/villous adenomas	0.02/0.0	0.18/0.0
Size of the larger adenoma (mm)	6.19	4.22
Adenomas in the left colon/remaining colon	0.21/0.26	0.47/0.71
Fourth colonoscopy: 44 patients studied (116.9 ± 34.1 mo since the first)		
Adenomas	0.32	0.74
Tubular adenomas	0.32	0.74
Tubulo-villous/villous adenomas	0.0/0.0	0.0/0.0
Size of the larger adenoma (mm)	5.78	1.92
Adenomas in the left colon/remaining colon	0.16/0.16	0.43/0.48

histological classification were recorded. The analysis of adenoma incidence over time was based on the person-years method. We assumed that the incidence rate of adenomas was constant between two consecutive colonoscopies in each individual and, in that time interval, the monthly incidence of adenomas in each patient was estimated by dividing the number of adenomas found at colonoscopy by the number of months that had elapsed since the previous examination. The incidence of adenomas in a given month after the index colonoscopy was determined for the entire sample by summing the incidence for that month across all of the patients that had been observed up to that time. The monthly incidence density of adenomas was then obtained by dividing the estimated incidence in that month by the population that was still at risk.

The statistical analysis was performed using Excel XP (Microsoft Inc) and Stata 10.0 (Stata Corporation, College Station, TX, United States). The baseline adenoma characteristics were correlated with recurrence at follow-up using the  $\chi^2$  test.

### Ethics

The present study was a retrospective observational study, in which no experimental intervention was used, and all of the data were kept anonymous. Therefore according to the local regulations, no approval by the Ethics Committee was necessary. All of the patients signed an informed consent document before each endoscopic examination.

## RESULTS

The present study included a total of 156 patients (109 male and 47 female). The mean age at the time of the

Table 2 Correlation between baseline adenoma characteristics and presence of adenomas in the second colonoscopy

Index colonoscopy	Second colonoscopy		$\chi^2$ test
	0 adenomas (n)	≥ 1 adenoma (n)	
> 1 adenoma	39	28	<i>P</i> = 0.24
≥ 3 adenomas	14	10	<i>P</i> = 0.57
≥ 1 TV adenoma	8	14	<i>P</i> = 0.004
≥ 1 villous adenoma	5	3	<i>P</i> = 0.95
≥ 1 TV or V adenoma	13	17	<i>P</i> = 0.01
≥ 1 adenoma > 1 cm	67	42	<i>P</i> = 0.43

TV: Tubulo-villous; V: Villous.

index colonoscopy was  $56.8 \pm 10.3$  years. No procedural complications were recorded. All 156 patients underwent three colonoscopies and 44 of them underwent a fourth examination. The outcomes of these colonoscopies are summarized in Table 1. The index colonoscopy was performed for screening in 31 patients and for diagnostic purposes in the remaining patients (and the symptoms were considered to be unrelated to the adenomas in the majority of cases).

The total number of adenomas and the numbers of each adenoma subtype (according to the histology or location) declined over the course of the four colonoscopies. Additionally, 12 patients underwent a fifth examination ( $162.3 \pm 32.7$  mo after the first), and two of these had a sixth examination ( $211.5 \pm 20.5$  mo after the first). No adenomas were found in any of these last examinations.

Of the initial 156 patients, who underwent three colonoscopies, 107 presently have scheduled colonoscopies, in agreement with the latest guidelines for surveillance after polypectomy; 27 patients have been released from follow-up due to advanced age or significant comorbidity; two patients have died of unrelated causes; and 20 have been lost from follow-up.

There was no significant correlation between the number of adenomas at the index colonoscopy and the presence or absence of adenomas at the second or all subsequent colonoscopies (*P* = 0.68 for the second colonoscopy, *P* = 0.49 for all subsequent colonoscopies). The presence of three or more adenomas at the index colonoscopy did not correlate with the presence of adenomas at the subsequent colonoscopies (*P* = 0.57 for the second, *P* = 0.21 for all subsequent colonoscopies), nor did the presence of adenomas > 1 cm at the index colonoscopy (*P* = 0.43 for the second colonoscopy, *P* = 0.78 for all subsequent colonoscopies). The presence of adenomas with a villous component at the index colonoscopy correlated with the presence of adenomas at the second colonoscopy (*P* = 0.01), but there was no significant correlation when all of the subsequent colonoscopies were considered together (*P* = 0.12) (Tables 2 and 3).

The presence of adenomas of the left colon at the index colonoscopy did not predict recurrence in the same segment in the second or all subsequent colonoscopies, and the same was true for the right colon (data not shown).

The incidence of colonic adenomas was found to

**Table 3** Correlation between baseline adenoma characteristics and presence of adenomas in all subsequent colonoscopies

Index colonoscopy	Subsequent colonoscopies		$\chi^2$ test
	0 adenomas ( <i>n</i> )	≥ 1 adenoma ( <i>n</i> )	
> 1 adenoma	31	36	<i>P</i> = 0.5
≥ 3 adenomas	9	15	<i>P</i> = 0.2
≥ 1 TV adenoma	7	15	<i>P</i> = 0.08
≥ 1 villous adenoma	4	4	<i>P</i> = 0.97
≥ 1 TV or V adenoma	11	19	<i>P</i> = 0.12
≥ 1 adenoma > 1 cm	53	56	<i>P</i> = 0.78

TV: Tubulo-villous; V: Villous.

decline from 1.4% person-months, at the beginning of the study, to values close to 0%, 12 years after the index examination (Figure 1).

Eight years after the index colonoscopy (with 65 patients evaluated), a peak in the incidence of adenomas was observed, that approached the baseline values, which was then followed by a steady decline until the end of follow-up (with 37 patients evaluated at 10 years and 19 patients evaluated at 12 years).

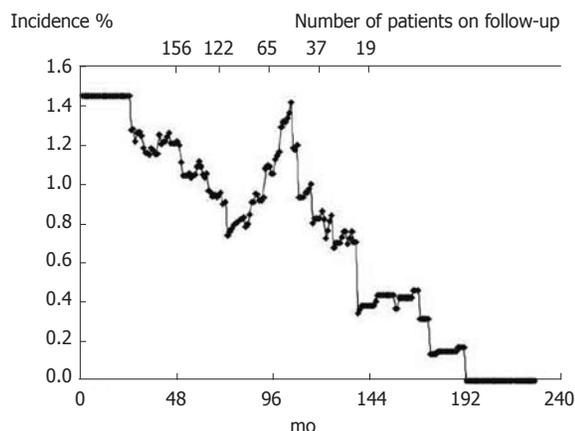

There were no reports of flat lesions of the colon in any of these examinations, and there were no colorectal adenocarcinomas reported in these patients during the study period.

## DISCUSSION

To explain the predominant CRC expression in the sixth and seventh decades of life, a necessary sequence of 4–7 known mutations fits a model of a stable mutation clock that ends in full-blown neoplasia at consistent time-intervals. The predominant molecular pathway responsible for CRC begins with the selection of cells with an *APC* gene loss or a  $\beta$ -catenin mutation, which is followed by the cumulative selection of subsequent critical events in other genes. Estimations of the time taken to acquire such a sequence of mutations suggest that full-blown neoplasia can take several decades to occur. According to recent estimations, to obtain the necessary sequence of mutations, the first event may need to occur at an early age<sup>[11–13]</sup>; most likely during the exponential phase of embryonic development, when *APC* is well known to play a key role<sup>[14]</sup>.

In 2007, human colon cancer stem cells were identified by two separate research groups<sup>[15,16]</sup>. More recently, the location of normal colon stem cells, at the crypt base, has also been demonstrated<sup>[17]</sup>, and these cells seem to be the origin of colon cancer stem cells<sup>[18]</sup>. It has been proposed that mutations in stem cells are much more likely to occur during the exponential phase of early growth, as opposed to later in life<sup>[19]</sup>.

Accordingly, the results of the present paper strongly suggest that the sporadic formation of adenomas occurs during a limited time period and, when these adenomas are removed, virtually all of the neoplasia-prone clones may be extinguished. If this model is shown to be true,

**Figure 1** Variation of colonic adenomas monthly incidence (person-month percentage) with time, since the index colonoscopy.

then the concept of a field carcinogenic defect, which progresses with continuous adverse environmental exposure and/or failure of the tight controls that assure DNA replication fidelity, should be replaced by a concept of limited colonic mosaicism. When the endoscopically visible neoplastic expression of this limited mosaicism is removed, the putative carcinogenic impulse no longer compromises colonic epithelia homeostasis.

Our study was limited mainly by its retrospective nature and by the small number of patients reaching longer follow-up. However, this sample was probably representative of the population at risk for sporadic CRC, because it included both symptomatic and asymptomatic individuals who had no relevant family histories, who underwent initial colonoscopy mostly during the sixth decade of life, and who were followed for at least 4 years.

In contrast to traditional beliefs, we did not observe a correlation between baseline adenoma characteristics and the risk of recurrence at follow-up. Although the AGA still takes baseline predictors of future adenomas or cancer into consideration, in their latest Guidelines for Colonoscopy Surveillance After Polypectomy<sup>[9]</sup>, several limitations of the available evidence have been raised. van Stolk *et al.*<sup>[20]</sup> have reported a study in which the number of adenomas at first colonoscopy was a significant predictor of having recurrent adenomas; however, these authors noted that missed polyps were a possible explanation for this relationship. Furthermore, that previous study only included 4 years of follow-up, and the presence of a family history of CRC was not taken into account at all. In another study, by Martínez *et al.*<sup>[21]</sup>, multiple adenomas at baseline, large adenomas (> 1 cm) or adenomas in the proximal colon were predictors of recurrence. However, the maximum follow-up of that study was 2 years, and the baseline colonoscopy was not the first examination for several of the patients. In addition, and although this relationship was not statistically significant, a family history of CRC in first-degree relatives was associated with a higher risk of recurrence in the study population. The initial National Polyp Study also included a follow-up of only 3 years, and investigated the incidence of colorec-

tal cancer but not adenoma<sup>[2,22]</sup>. The authors included patients regardless of their family history (other than established genetic syndromes)<sup>[2]</sup> and they admitted that, as a result of the short follow-up, three of the diagnosed cancers may have been missed polyps<sup>[23]</sup>. A more recent study, by Martinez *et al.*<sup>[24]</sup>, has revealed that the age of the patient and the number and size of prior adenomas were associated with the risk of advanced colorectal neoplasia after polypectomy. However, that study was also limited by a median follow-up of only 4 years and a maximum follow-up of < 6 years<sup>[24]</sup>. Our study had the advantages of a minimum follow-up of 4 years and exclusion of patients with any family history of CRC in first-degree relatives. This might explain why we did not find that baseline adenoma characteristics were predictive of recurrence, and why we were able to show a decreasing incidence of adenomas with time, after an age peak and under the influence of polypectomy.

At Digestive Disease Week 2007, Zauber *et al.* presented new data regarding the National Polyp Study population indicating that, after a mean follow-up of 14 years, CRC mortality was markedly reduced in all of the patients with adenomas at baseline, when compared to the general population. This was observed even when patients who refused follow-up were considered in the analysis. This finding supports the hypothesis that the major benefit is derived from the first colonoscopy and also brings into question the notion of increasing recurrence of adenomas over time.

With regard to the unexpected second peak that was observed for the incidence of adenomas in our study, after 8 years, we may speculate whether this peak is related to the type of the second hit in the *APC* gene. It has been reported that, when the first hit happens close to codon 1300, the second hit is most likely loss of heterozygosity, a faster and more efficient mutation process. In all other cases, point mutation is the most common mechanism for the second hit, thus driving a more sluggish development<sup>[25]</sup>. This confers different selective advantages to each colonic adenoma, according to the specific first hit-second hit combination and may explain why some adenomas appear earlier and why others are only apparent towards the end of the adenoma time window. We acknowledge that, during a limited period of embryonic development, a small number of stem cells may acquire different first mutations, and that these mutations are expressed along incidence waves during a restricted time window.

The results of the present study reinforce the importance of colonoscopy with polypectomy during the fifth to sixth decades of life, and the feasibility of increasing the time for re-examination after a normal examination. Furthermore, our study indirectly supports the concept of a relatively stable mutation clock, which is possibly initiated during the developmental phase of embryogenesis.

tuto Português de Oncologia de Lisboa Francisco Gentil, EPE and Dr. Celeste Fátima Viveiros, from Serviço de Gastrenterologia, Hospital do Espírito Santo - Évora, EPE for assisting with the acquisition of data.

## COMMENTS

### Background

Colorectal cancer (CRC) and adenomas are thought to have an increasing incidence with age, and this has led to almost lifelong surveillance colonoscopy. This view has recently started to be challenged.

### Research frontiers

*APC* is a crucial gene in colorectal carcinogenesis. If the first hit on this gene occurs in a colonic stem cell precursor early in life, it could lead to only a few colon crypts that are prone to originate adenoma and cancer, in a restricted time window. If these clones were removed, by polypectomy, the potential for colon cancer could be eradicated in that individual.

### Innovations and breakthroughs

Colon cancer stem cells have recently been identified, apparently originating from colonic stem cells, at the crypt base. Stem cells seem more prone to mutation during embryogenesis than later in life. Reports have shown that a single colonoscopy with polypectomy reduces CRC incidence. The study shows that, under the influence of polypectomy, adenoma incidence decreases with age.

### Applications

If the study results are confirmed, surveillance colonoscopy intervals may safely be lengthened, and some people may even be released from surveillance after a few examinations.

### Terminology

*APC* acts as a tumor suppressor gene by regulating the intranuclear concentration of  $\beta$ -catenin, a protein involved in the transcription of genes that promote proliferation. These genes and proteins are part of the Wnt pathway, which is involved in > 80% of sporadic CRC.

### Peer review

The authors do a nice job to expand on a current line of questioning the need for continuing surveillance and indirectly questioning the concept of age appropriateness for surveillance as well as cost-advantageous practice. This is a very relevant study and well written.

### Abstract

**AIM:** To investigate how a complex network of CC chemokine ligands (CCLs) and their receptors influence the progression of tumor and metastasis.

**METHODS:** In the present study, we used immunohistochemistry to examine the expression of CCL7, CCL8 and CCL21 in 194 gastric cancer samples and adjacent normal tissues. We analyzed their correlation with tumor metastasis, clinicopathologic parameters and clinical outcome.

**RESULTS:** We found that the higher expression of CCL7 and CCL21 in cancer tissues than in normal tissues was significantly correlated with advanced depth of wall invasion, lymph node metastasis and higher tumor

node metastasis stage. Moreover, Kaplan-Meier survival analysis revealed that CCL7 and CCL21 overexpression in cancer tissues was correlated with poor prognosis.

**CONCLUSION:** These results suggest that overexpression of these two CC chemokine ligands is associated with tumor metastasis and serves as a prognostic factor in patients with gastric cancer.

### INTRODUCTION

Chemokine ligands (CCLs) belong to the small molecule chemoattractive cytokine family and are grouped into CC and CXC chemokines ligands on the basis of the characteristic presence of four conserved cysteine residues<sup>[1-3]</sup>. Chemokines mediate their chemical effect on target cells through G-protein-coupled receptors, which are characterized structurally by seven transmembrane spanning domains and are involved in the attraction and activation of mononuclear and polymorphonuclear leukocytes. CCLs and their receptors play an important role

in angiogenesis and tumor growth, however the role of CCLs in metastasis has only recently been explored<sup>[4,5]</sup>. CCL7 promoted the invasion and migration of oral squamous cell carcinoma<sup>[4]</sup>. CCL21 was significantly highly expressed in breast tumor cells with lymph node metastasis and prognosis<sup>[5]</sup>.

Gastric cancer is one of the commonest malignant tumors of the alimentary tract and is characterized by late clinical presentation, rapid progression, and poor survival<sup>[6]</sup>. The reason for this poor prognosis is that, at the time of diagnosis, gastric cancer usually shows extensive local tumor invasion and frequent spread to metastatic sites, particularly lymph nodes. Spread of malignant tumors is a multistep process and many of the stages of tumor invasion require degradation or breakdown of the extracellular matrix and connective tissue surrounding tumor cells<sup>[7,8]</sup>. The matrix metalloproteinases (MMPs) are a family of zinc containing enzymes which are involved in the degradation of different components of the extracellular matrix, and there is considerable evidence to indicate that individual MMPs have important roles in tumor invasion and tumor spread<sup>[9-11]</sup>. A recent study showed that increased levels of CCL recruit immature myeloid cells that carry the chemokine ligand receptor (CCR) from the blood to the tumor invasion front. These immature myeloid cells produced MMP9 and MMP2 and help the tumor cells to migrate and invade<sup>[12]</sup>.

In the present study, we used immunohistochemistry to examine the expression of CCL7, CCL8 and CCL21 in 194 gastric cancer samples and adjacent normal tissues. We analyzed their correlation with tumor metastasis, clinicopathologic parameters and clinical outcome.

## MATERIALS AND METHODS

### Patients and specimens

A consecutive series of 194 tissue specimens were collected from patients with gastric cancer who received subtotal or total gastrectomy resection in Chang Gung Memorial Hospital (CGMH) in Taiwan. All operations were performed between January 2001 and December 2002. Written informed consent was obtained before sample collection and this study was approved by the Institutional Review Board of CGMH. There were 114 males and 80 females with a mean age of 62 years (range, 24-90 years). The age and gender of patients, tumor location, tumor size, cell differentiation, depth of wall invasion, status of lymph node metastasis, vascular invasion, lymphatic invasion and desmoplastic reaction were obtained from histopathology records. Stage of gastric cancer was described according to the 1997 tumor node metastasis (TNM) classification of malignant tumors by the American Joint Committee on Cancer. All patients were followed until December 2007 with a minimum 5 years of follow-up. All tissue specimens were formalin-fixed and paraffin-embedded. Formalin fixed tissue sections were stained with haematoxylin and eosin and classified by a pathologist. These results were compared with

the histopathology records from CGMH. Final pathology was determined by consensus and review if necessary.

### Immunohistochemistry

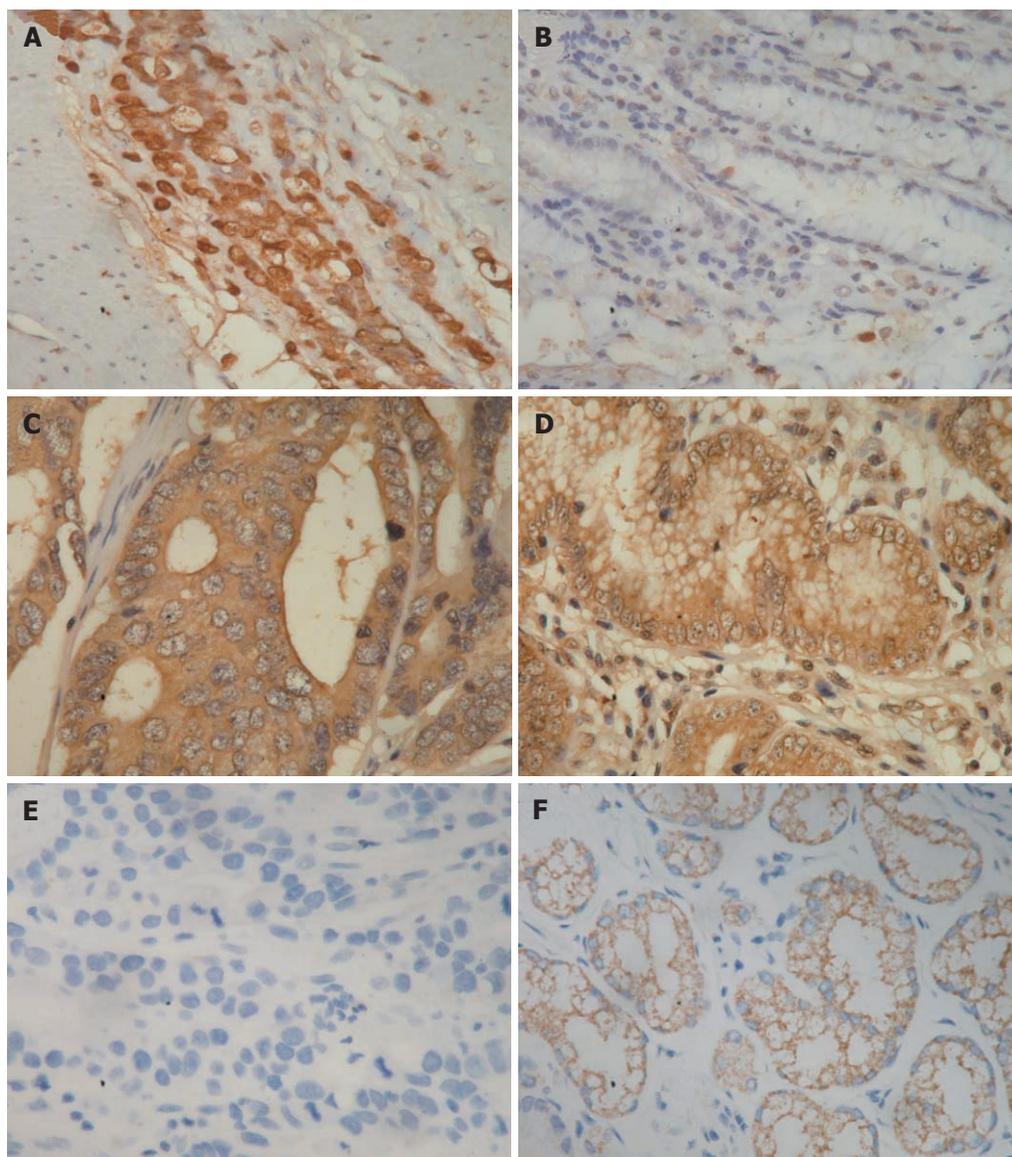

The tissue blocks were constructed according to the method of Schraml *et al.*<sup>[13]</sup> and the best representative morphological areas of tumors were used in this study. The specimen sections were deparaffinized, treated with 3% hydrogen peroxide and microwaved after pretreatment in 10 mmol/L citric acid to retrieve antigenicity. The sections were incubated with blocking solution containing phosphate buffered saline and 1% bovine serum albumin for 20 min at room temperature, and then incubated overnight at 4 °C with an anti-CCL7 antibody (1:100, R and D), an anti-CCL8 monoclonal antibody (1:50, R and D), or an anti-CCL21 monoclonal antibody (1:50, R and D), respectively. After washing 4 times with Tris Buffered Saline, the sections were incubated with biotinylated secondary antibody (Santa Cruz Biotechnology). The immuno-complex was visualized by the immunoglobulin enzyme bridge technique using the DAKO LSAB 2 System, HRP kit (DAKO corp. Carpinteria, CA) with 3,3' diaminobenzidine tetrachloride as a substrate. The sections were counterstained with haematoxylin, dehydrated with graded alcohols, cleared with xylene and mounted with a coverslip.

### Scoring of the immunohistochemical staining

The immunostaining results were scored as follows, according to a previous report<sup>[14]</sup>. The immunostaining reaction was evaluated by subjective assessments of the median staining intensity (0, no stain; 1, weak; 2, moderate; and 3, strong stain) and by the fraction of stained cells in percentage categories (0, 0%-9%; 1, 10%-49%; 2, 50%-89%; and 3, ≥ 90%). This scoring system was previously shown to be reproducible<sup>[15]</sup>. The scores of 0 to 3 were obtained as follows: percentage categories and staining were each ranked as indicated above. The ranks for percentage and staining intensity were multiplied by each other, divided by 3, and rounded up to the nearest whole number<sup>[15]</sup>. The results of immunostaining in tumor and normal tissues were divided into three groups, higher (rank of tumor tissue > rank of normal tissue), equal (rank of tumor tissue = rank of normal tissue), and lower (rank of tumor tissue < rank of normal tissue) (Figures 1-3).

### Statistical analysis

$\chi^2$  or Fisher's exact test was used to test for an association between CCL7, CCL8 and CCL21 expression and patient clinicopathologic parameters. Disease-free survival was defined as the time from surgery to the first relapse of cancer, occurrence of a second primary tumor, or death from any cause. Univariate survival analysis was assessed by the Kaplan-Meier method and significance of difference between groups was analysed using log rank test or log rank test for trend. Stepwise multivariate survival analysis was performed by the Cox proportional hazards model. All reported *P* values were two-sided and a *P* value < 0.05 was considered significant.

**Figure 1** Immunohistochemistry of chemokine ligand 7 in gastric cancer and adjacent normal tissues. Chemokine ligand 7 (CCL7) staining is higher in the cytoplasm of gastric cancer cells (A) than in the cytoplasm of adjacent normal cells (B); CCL7 staining is equal in the cytoplasm of gastric cancer cells (C) and in the cytoplasm of adjacent normal cells (D); CCL7 staining is lower in the cytoplasm of gastric cancer cells (E) than in the cytoplasm of adjacent normal cells (F). (magnification,  $\times 400$ ).

## RESULTS

### **CCL7, CCL8 and CCL21 expression in gastric cancer and adjacent normal tissues**

The percentages of the higher expression of CCL7, CCL8 and CCL21 in cancer tissues than in normal tissues were 42.3% (82 of 194), 29.9% (58 of 194) and 44.8% (87 of 194), respectively (Figures 1-3 and Table 1). The percentages of the equal expression of CCL7, CCL8 and CCL21 in cancer tissues and in normal tissues were 35.6% (69 of 194), 33% (64 of 194) and 32.5% (63 of 194), respectively (Figures 1-3 and Table 1). The percentages of the lower expression of CCL7, CCL8 and CCL21 in cancer tissues than in normal tissues were 22.2% (43 of 194), 37.1% (72 of 194) and 22.7% (44 of 194), respectively (Figures 1-3 and Table 1).

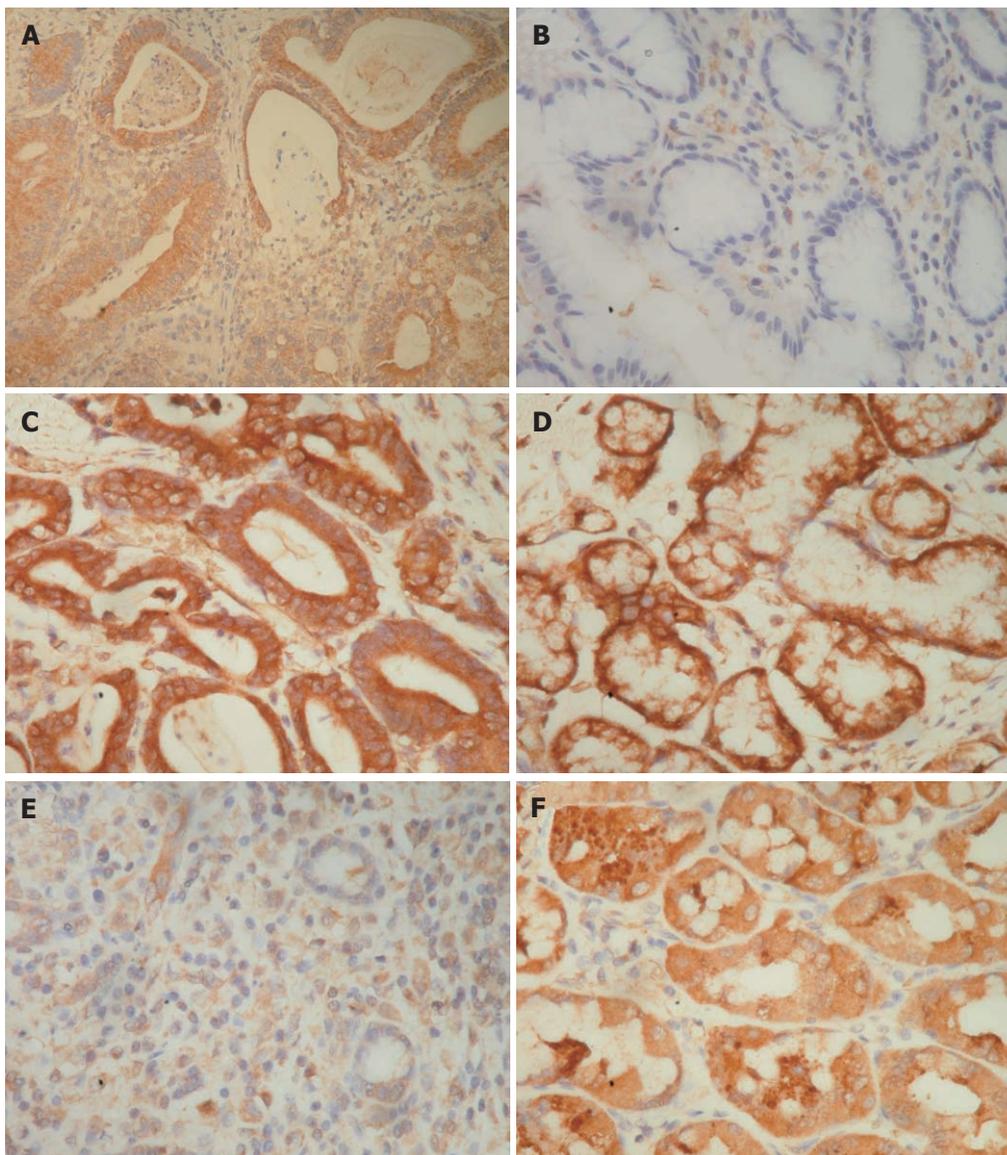

### **CCL7, CCL8 and CCL21 overexpression in relation to clinicopathologic parameters**

The overexpression of CCL7 in cancer tissues compared with normal tissues was significantly correlated with tu-

mor location ( $P = 0.025$ ) and tumor size ( $P = 0.001$ ). The overexpression of CCL7 was significantly higher in gastric cancer with advanced depth of wall invasion ( $P = 0.001$ ), lymph node metastasis ( $P = 0.020$ ), desmoplastic reaction ( $P = 0.006$ ) and higher TNM stage ( $P = 0.008$ ), but was not correlated with age, gender, differentiation, vascular invasion or lymphatic invasion (Table 1).

The overexpression of CCL8 was significantly correlated with age ( $P = 0.026$ ) and tumor location ( $P = 0.004$ ), but not with gender, tumor size, differentiation, depth of wall invasion, lymph node metastasis, vascular invasion, lymphatic invasion, desmoplastic reaction or TNM stage.

The overexpression of CCL21 was significantly higher in females than in males ( $P = 0.041$ ) and was correlated with tumor location ( $P = 0.026$ ), tumor size ( $P = 0.043$ ) and lymphatic invasion ( $P = 0.006$ ). As with CCL7, the overexpression of CCL21 was significantly higher in gastric cancer with an advanced depth of wall invasion ( $P < 0.0001$ ), lymph node metastasis ( $P = 0.003$ ), desmoplastic reaction ( $P < 0.0001$ ) and higher TNM stage ( $P < 0.0001$ ), but was not correlated with age, differentiation or vascular

**Figure 2** Immunohistochemistry of chemokine ligand 8 in gastric cancer and adjacent normal tissues. Chemokine ligand 8 (CCL8) staining is higher in the cytoplasm of gastric cancer cells (A) than in the cytoplasm of adjacent normal cells (B); CCL8 staining is equal in the cytoplasm of gastric cancer cells (C) and in the cytoplasm of adjacent normal cells (D); CCL8 staining is lower in the cytoplasm of gastric cancer cells (E) than in the cytoplasm of adjacent normal cells (F). (magnification,  $\times 400$ ).

invasion (Table 1).

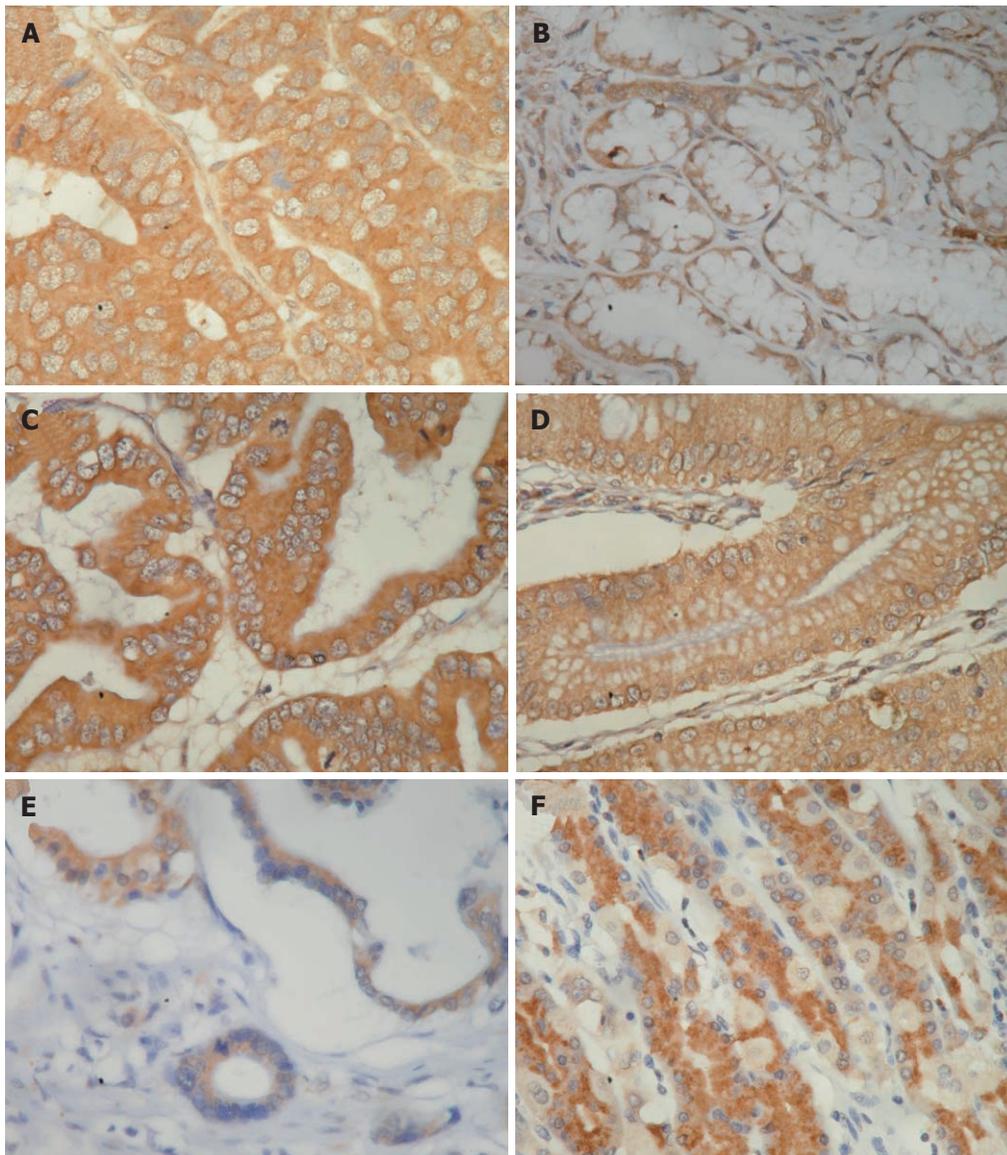

### Prognostic implications of CCL7, CCL8 and CCL21 overexpression in gastric cancer

CCL7 and CCL21 overexpression was correlated with a poor prognosis ( $P = 0.002$  and  $0.001$ , Table 2 and Figure 4A and C). CCL8 overexpression was not correlated with survival (Table 2, Figure 4B). Other significant prognostic factors were tumor location, tumor size, differentiation, depth of invasion, lymph node metastases, vascular invasion, lymphatic invasion, marked desmoplastic reaction and higher TNM stage. In multivariate analysis, depth of invasion, lymph node metastasis and desmoplastic reaction were independent prognostic factors (Table 3).

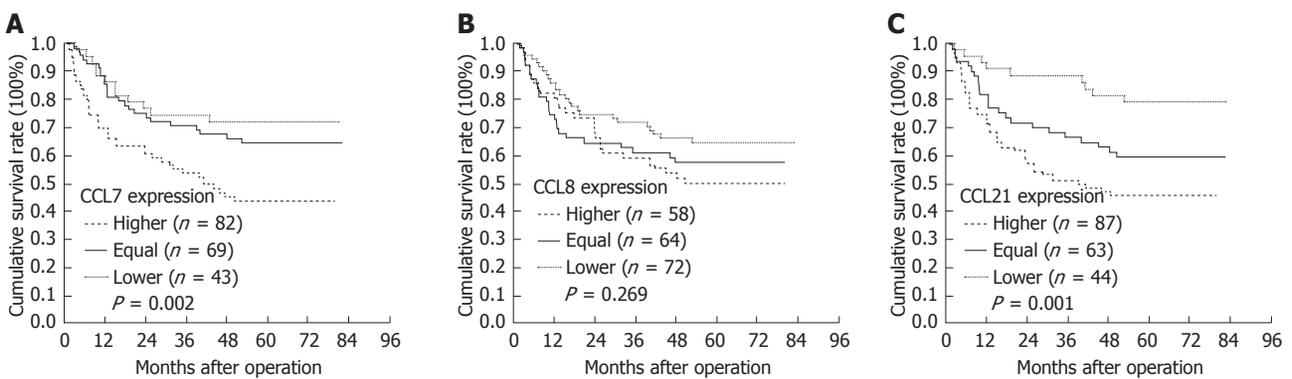

## DISCUSSION

In this study, CCL7, CCL8 and CCL21 expression levels were examined in 194 cases of gastric cancer for correlation with patient clinicopathologic factors. We found that the higher expression of CCL7 and CCL21 in cancer

tissues than in normal tissues was significantly correlated with advanced depth of wall invasion, lymph node metastasis and higher TNM stage. The mechanism for chemokine ligand promotion of tumor invasion and metastasis is not clear. Using a model of colorectal tumor progression, Kitamura *et al.*<sup>[12]</sup> showed that tumor-stromal interaction could promote tumor invasion. The colonic tumor can promote the production of CCL9. Increased levels of CCL9 recruited immature myeloid cells that carry the CCL9 receptor CCR1 from the blood to the tumor invasion front. The immature myeloid cells produce MMP2 and MMP9 and help the tumor epithelium to migrate and invade into the stroma. Jung *et al.*<sup>[4]</sup> also showed the importance of tumor-stromal crosstalk in invasion of oral squamous cell carcinoma (OSCC) *via* CCL7<sup>[4]</sup>. To identify key molecular regulators expressed by carcinoma-associated fibroblasts (CAF) that promote cancer cell invasion, Jung *et al.*<sup>[4]</sup> used microarrays to compare cocultured OSCC and CAF with monoculture controls. Microarray and real-time polymerase chain reaction analysis identified marked upregulation of CCL7 in cocultured CAF. Enzyme-linked

**Figure 3** Immunohistochemistry of chemokine ligand 21 in gastric cancer and adjacent normal tissues. Chemokine ligand 21 (CCL21) staining is higher in the cytoplasm of gastric cancer cells (A) than in the cytoplasm of adjacent normal cells (B); CCL21 staining is equal in the cytoplasm of gastric cancer cells (C) and in the cytoplasm of adjacent normal cells (D); CCL21 staining is lower in the cytoplasm of gastric cancer cells (E) than in the cytoplasm of adjacent normal cells (F). (magnification,  $\times 400$ ).

**Figure 4** Kaplan-Meier survival curves for disease-free survival of 194 patients with gastric cancer. A: Categorized by chemokine ligand 7 (CCL7) expression, survival was significantly worse for patients with higher CCL7 expression than those with equal or lower CCL7 expression ( $P = 0.002$ ); B: Categorized by CCL8 expression, no significant difference was observed among the three groups ( $P = 0.269$ ); C: Categorized by CCL21 expression, survival was significantly worse for patients with higher CCL21 expression than those with equal or lower CCL21 expression ( $P = 0.001$ ).

immunosorbent assay showed an elevated level of CCL7 secretion from CAF stimulated by coculture with OSCC cells. CCL7 promoted the invasion and migration of

OSCC cells, and the invasiveness was inhibited by treatment with CCL7 neutralizing antibody.

However, other studies have shown that CC chemokine

ligands promote T cells to kill the tumor cells. Wu *et al.*<sup>[6]</sup> investigated the effect of exogenous CCL21 expressed in breast cancer MCF-7 cells on human monocyte-derived dendritic cells (DCs). Stimulation of CCL21-transfected MCF-7 cells prompted DC function: migration, antigen uptake and presentation. The stimulated DCs facilitated Th 1 type cytokine production, perforin-forming CD8<sup>+</sup> T cell transformation and final T cell-associated clearance of MCF-7 cells. Wetzel *et al.*<sup>[7]</sup> showed that human CCL7 can reduce tumorigenicity and augment infiltration of dendritic cells and neutrophils toward mouse mastocytoma; it also inhibits mouse melanoma growth through activation of T lymphocytes and natural killer cells.

The differences between the expression of CCL7 and CCL21 correlated with clinicopathologic parameters were gender and lymphatic invasion. The overexpression of CCL7 in gastric cancer was not correlated with gender and lymphatic invasion, but that of CCL21 was correlated with these two parameters. The overexpression of CCL21 was significantly higher in females than in males. The reason for the significance is not clear and more studies are necessary to clarify the significance. The overexpression of CCL21 was also correlated with lymphatic invasion. Recently, metastatic gastric carcinoma cells have been shown to express the receptor for chemokine CCL21, chemokine receptors CCR7, a prop-

CCL: Chemokine ligand.

erty that may allow them to access the lymphatic system and spread to regional lymph nodes<sup>[18]</sup>. Thus the “chemoattraction” theory of metastasis may be reflected by malignant cells expressing functional chemokine receptors that can respond to organ-specific chemoattractant molecules and migrate directionally along chemokine gradients to set up site-specific metastases in the target organs. Such chemotactic migration of tumors would mirror the physiologic mechanisms of lymphocyte homing into lymphoid organs.

Kaplan-Meier survival analysis revealed that CCL7 and CCL21 overexpression in cancer tissues was correlated with poor prognosis. If tumor-infiltrating leukocytes are able, in some instances, to promote cancer, then the local production of chemokines that attract leukocytes could be a poor prognostic sign. This is the case in human breast cancer, where levels of CCL5 and CCL2 correlate with tumor progression and there is a positive correlation between the extent of the macrophage infiltrate, lymph-node metastasis and clinical aggressiveness<sup>[19-21]</sup>. In esophageal squamous cell carcinoma, CCL2 expression has been associated with the extent of macrophage infiltration, tumor cell invasion and tumor vascularity<sup>[22]</sup>.

In conclusion, the higher expression of CCL7 and CCL21 in gastric cancer tissues than in normal tissues was significantly correlated with advanced depth of wall invasion, lymph node metastasis and higher TNM stage. Moreover, Kaplan-Meier survival analysis revealed that CCL7 and CCL21 overexpression in cancer tissues was correlated with poor prognosis. These results suggest that overexpression of these two CC chemokine ligands is associated with tumor metastasis and serves as a prognostic factor in patients with gastric cancer.

## COMMENTS

### Background

Gastric cancer is one of the commonest malignant tumors of the alimentary tract and is characterized by late clinical presentation, rapid progression, and

poor survival. The reason for this poor prognosis is that, at the time of diagnosis, gastric cancer usually shows extensive local tumor invasion and frequent spread to metastatic sites, particularly lymph nodes. Spread of malignant tumors is a multistep process and many of the stages of tumor invasion require degradation or breakdown of the extracellular matrix and connective tissue surrounding tumor cells.

### Research frontiers

The matrix metalloproteinases (MMPs) are a family of zinc containing enzymes which are involved in the degradation of different components of the extracellular matrix, and there is considerable evidence to indicate that individual MMPs have important roles in tumor invasion and tumor spread. A recent study showed that increased levels of chemokine ligand (CCL) recruit immature myeloid cells that carry chemokine ligand receptor from the blood to the tumor invasion front. These immature myeloid cells produced MMP9 and MMP2 and help the tumor cells to migrate and invade.

### Innovations and breakthroughs

In the present study, the authors used immunohistochemistry to examine the expression of CCL7, CCL8 and CCL21 in 194 gastric cancer samples and adjacent normal tissues. The authors analyzed their correlation with tumor metastasis, clinicopathologic parameters and clinical outcome. They found that the higher expression of CCL7 and CCL21 in cancer tissues than in normal tissues was significantly correlated with advanced depth of wall invasion, lymph node metastasis and higher tumor node metastasis (TNM) stage. Moreover, Kaplan-Meier survival analysis revealed that CCL7 and CCL21 overexpression in cancer tissues was correlated with poor prognosis.

### Applications

These results suggest that overexpression of CCL7 and CCL21 is associated with tumor metastasis and serves as a prognostic factor in patients with gastric cancer.

### Peer review

The authors used immunohistochemistry to examine the expression of CCL7, CCL8 and CCL21 in 194 gastric cancer samples and adjacent normal tissues. They found that the higher expression of CCL7 and CCL21 in cancer tissues than in normal tissues was significantly correlated with advanced depth of wall invasion, lymph node metastasis and higher TNM stage. Moreover, Kaplan-Meier survival analysis revealed that CCL7 and CCL21 overexpression in cancer tissues was correlated with poor prognosis.

### Abstract

**AIM:** To investigate the non-*Helicobacter pylori* (*H. pylori*) bacterial flora concurrent with *H. pylori* infection.

**METHODS:** A total of 103 gastric biopsy specimens from *H. pylori* positive patients were selected for bacterial culture. All the non-*H. pylori* bacterial isolates were identified by matrix-assisted laser desorption ionization time-of-flight mass spectrometry (MALDI-TOF MS).

**RESULTS:** A total of 201 non-*H. pylori* bacterial isolates were cultivated from 67 (65.0%) of the 103 gastric samples, including 153 isolates identified successfully at species level and 48 at genus level by MALDI-TOF MS. The dominant species were *Streptococcus*, *Neisseria*, *Rothia* and *Staphylococcus*, which differed from

the predominantly acid resistant species reported previously in healthy volunteers. The prevalence of non-*H. pylori* bacteria was higher in non-ulcer dyspepsia group than in gastric ulcer group (100% vs 42.9%,  $P < 0.001$ ). Six bacterial species with urease activity (*Staphylococcus epidermidis*, *Staphylococcus warneri*, *Staphylococcus capitis*, *Staphylococcus aureus*, *Brevibacterium spp.* and *Klebsiella pneumoniae*) were also isolated.

**CONCLUSION:** There is a high prevalence of the non-*H. pylori* bacteria concurrent with *H. pylori* infection, and the non-*H. pylori* bacteria may also play important as-yet-undiscovered roles in the pathogenesis of stomach disorders.

## INTRODUCTION

Stomach is generally regarded as an environment that is not conducive to bacterial colonization. A notable exception is *Helicobacter pylori* (*H. pylori*), which may cause chronic gastritis, peptic ulcer and is correlated with gastric adenocarcinoma<sup>[1,2]</sup>. However, gastritis also occurs in *H. pylori* negative human subjects or mouse models, suggesting that *H. pylori* is just one of the organisms causing gastritis.

With the reduced level of acid induced by *H. pylori* dissipates or antiulcer medications, the stomach becomes more susceptible to the colonization of other organisms<sup>[3]</sup>, which may complicate the development of gastric disorders. In recent years, considerable interest has emerged in the interactions among *H. pylori*, non-*H. pylori* bacteria and acid-suppressive therapy. Some studies have shown that the co-infection of *H. pylori* and non-*H. pylori* bacteria enhances the development of atrophic corpus gastritis<sup>[4]</sup>. But up till now, there are only a limited number of studies regarding the stomach bacterial flora and all are based on a small size of a few patients or volunteers. The aim of this study was to investigate the non-*H. pylori* bacterial flora concurrent with *H. pylori* infection.

Matrix-assisted laser desorption ionization-time-of-flight mass spectrometry (MALDI-TOF MS) is a new technology for bacterial identification<sup>[5]</sup>. Its performance has been evaluated in different studies, and a higher accuracy was obtained compared with phenotypic methods<sup>[6,7]</sup>.

## MATERIALS AND METHODS

### Patients and materials

A total of 104 patients, who underwent upper gastrointestinal endoscopy because of dyspeptic symptoms and yield positive results in rapid urease test (RUT), were selected for the further *H. pylori* detection and bacterial examinations. Among the 104 patients, 103 were *H. pylori* positive and ultimately entered into this study, including 63 from Jiangxi Province and 40 from Beijing, China. No subject had received anti-secretory drugs, antibiotics, or probiotics two wk prior to entry into this study and no one had *H. pylori* eradication history. Diseases included gastritis ( $n = 23$ ), gastric ulcer ( $n = 21$ ), duodenal ulcer ( $n = 42$ ), reflux esophagitis ( $n = 4$ ), and non-ulcer dyspepsia (NUD) ( $n = 13$ ). There were 81 (78.6%) patients aged less than 50 years. The study was reviewed and approved by the Ethics Committee of the National Institute for Communicable Disease Control and Prevention. Each subject gave informed oral consent before entering into the study.

Upper gastrointestinal endoscopy was performed after an overnight fast in all patients. Mucosal samples were taken from the greater curvature of gastric antrum and corpus using sterile disposable biopsy forceps. All the samples were placed into sterile brain-heart infusion broth for transport to the cultural laboratory.

### Bacterial culture and polymerase chain reaction detection for *H. pylori*

After biopsies were taken, the samples were dispersed using a homogenizer. Each homogenate was inoculated onto three plates, two Columbia blood agars (CM0331, OXOID) and a Campylobacter agar (CM0935, OXOID) supplemented with 5% sheep blood, polymyxin B, vancomycin, trimethoprim, and amphotericin B. One of the Columbia blood agar was incubated under aerobic condition at 37 °C, the other one and the Campylobacter agar were incubated under microaerophilic condition at 37 °C.

The *H. pylori* status was assessed with culture and polymerase chain reaction (PCR) detection. Small (0.5 to 2 mm) translucent colonies were selected to gram-stain and tested for urease, catalase and oxidase activity. Microscopy of gram-stained smears with curved gram-negative rods resembling *Helicobacter*, together with positive in all the tree enzyme activity tests were identified as *H. pylori*.

*H. pylori* culture-negative samples were further detected by *ureA*, *vacA* and *cagA* PCR analysis, using the primers described previously<sup>[8,9]</sup>. *H. pylori* status was defined as negative only if all the three PCR detections were negative.

### Mass spectrometry identification of non-*H. pylori* bacteria

**Preparation of samples:** Appropriate amount (5-10 mg) colony was scraped by inoculating loop and suspended in 300  $\mu$ L distilled water, and 900  $\mu$ L ethanol was added and mixed. Then the sample was centrifuged at 12 000 r/min for 2 min, and the pellets were dried. Fifty  $\mu$ L formic acid (70% in water) was added to the dried bacterial pellet and mixed thoroughly, and then added with 50  $\mu$ L acetonitrile. After centrifugation at 12 000 r/min for 2 min, 1  $\mu$ L of the supernatant containing the bacterial extract was transferred onto the MSP 96 target ground steel plate (Bruker Daltonics, Bremen, Germany) and dried, then 1  $\mu$ L of matrix solution (saturated solution of a cyano-4-hydroxycinnamic acid in 50% acetonitrile + 2.5% trifluoroacetic acid) was added and crystallized by air-drying at room temperature. Each isolate was analyzed on the day of isolation.

**Measurement with spectrometer:** Measurement was performed with Microflex LT mass spectrometer (Bruker Daltonics) equipped with a 200 Hz smart-beam laser. The parameter settings were as follows: delay 320ns; ion source 20 kV; ion source 18.5 kV; lens voltage 8.5 kV; and mass range 2-15 kDa. Each run was validated with an *E. coli* control sample where the presence of 10 specific proteins insured that the spectrometer was set properly. Raw spectra of the strains were analyzed by MALDI Biotyper 2.0 software (Bruker Daltonics) using the default settings. A list of peaks up to 100 was generated. The threshold for peak acceptance was a signal-to-noise (S/N) ratio of 3. After alignment, peaks with a mass-to-charge ( $m/z$ ) ratio difference of less than 250 ppm were considered to be identical. The peak lists generated were used for matches against the reference library, by directly

<sup>1</sup>The number of bacterial strains isolated in I: Columbia blood agar incubated under aerobic condition; II: Columbia blood agar incubated under microaerophilic condition; III: Campylobacter agar under microaerophilic condition; <sup>2</sup>The number of patients colonized by the same genus is shown in parentheses; <sup>3</sup>The number of bacterial isolates with urease activity.

using the integrated pattern matching algorithm of the software. All parameters were the same regardless of the bacteria analyzed. Spectra were obtained in the positive linear mode after 500 shots. A score was attributed to each identification. When this score was > 2.00, the identification was considered correct at the species level; between 1.7 and 1.999, the identification was considered correct at the genus level; and < 1.7, the identification was not similar enough to draw a conclusion.

#### Urease activity test of non-*H. pylori* bacteria

Each non-*H. pylori* bacterial culture was subjected to urease test. The medium used for the test was urea broth containing dipotassium hydrogen phosphate, 9.5 g/L; potassium dihydrogen phosphate, 9.1 g/L; urea 20 g/L; phenol red, 0.01 g/L; and yeast extract, 0.1 g/L, final pH 6.8. Any change in the indicator from pale yellow to pink in 24 h was taken as positive.

#### Statistical analysis

Continuous data were described with mean (minimum, maximum), categorical data with number and proportions. Difference between the groups for age and sex was analyzed using analysis of variance and  $\chi^2$  test. Fisher exact test was conducted to compare non-*H. pylori* prevalence data. *Post hoc* tests were conducted by the Bonferroni method.  $P < 0.05$  was considered as statistically significant. All analyses were performed with SPSS 12.0 software.

## RESULTS

A total of 92 (88.5%) samples were *H. pylori* culture positive. Only one of the 12 culture-negative cases was PCR negative. As result, 103 *H. pylori* positive patients were eventually enrolled into the analysis.

#### Non-*H. pylori* bacteria isolation

A total of 201 non-*H. pylori* bacterial isolates were cultivated from gastric samples of 67 (65.0%) of the 103 *H. pylori* positive patients. All the isolates were identified by mass spectrometry, including 153 identified at species level and 48 at genus level (Table 1). Some species isolated from more than two culture plates were shown in Table 1. A total of 168 isolates was obtained with the exception of the repeat identification of the same patient, and 39 patients harbored more than 2 non-*H. pylori* species. Overall, a total of 18 non-*H. pylori* bacterial genera (43 species) were isolated from the stomach biopsy specimen (Table 1), most of them were gram-positive bacteria (73.8%). The dominant bacterial species were *Neisseria flavescens* (13.7%), *Streptococcus salivarius* (9.5%), *Rothia mucilaginosa* (8.9%) and *Streptococcus pneumoniae* (6.6%). Twelve gram-negative bacilli isolates (7.14%) belonged to 6 genera obtained in this study, which were discovered from 10 patients (9.7% of all the patients and 14.9% of the non-*H. pylori* positive patients). Concurrent colonization by gram-positive and/or gram-negative

**Table 2** Demographic, non-*Helicobacter pylori* bacterial colonization and clinical characteristics of 103 patients

Diseases	Enrolled patients (n)	Age (yr) <sup>1</sup>	Gender (male:female)	Colonized patients
Duodenal ulcer	42	39 (20-56)	2:1	28 (66.7%)
Gastric ulcer	21	42 (20-62)	0.75:1	9 (42.9%)
Gastritis	23	39 (10-75)	0.44:1	13 (56.5%)
Non-ulcer dyspepsia	13	34 (22-57)	0.63:1	13 (100%) <sup>a</sup>
Reflux esophagitis	4	52 (41-63)	1:1	4 (100%)
Total	103	39 (10-75)	0.96:1	67 (65.0%)
P value		0.079 <sup>2</sup>	0.074 <sup>3</sup>	0.0028 <sup>4</sup>

<sup>1</sup>Data are expressed as median (range); <sup>2</sup>By analysis of variance; <sup>3</sup>By  $\chi^2$  test; <sup>4</sup>By Fisher exact test; <sup>a</sup> $P = 0.00006$  vs gastric ulcer group by Bonferroni method.

coccus occurs in 10 of them.

The demographic and relevant clinical characters of the patients are described in Table 2. The patients were subdivided into five groups based on the clinical diseases. There were no significant intergroup differences in age and sex ratio, but the prevalence of non-*H. pylori* flora was significantly different ( $P = 0.0028$ ) among different clinical diseases, as shown in Table 2. *Post hoc* tests were conducted and statistical difference was found between the gastric ulcer group (42.9%) and the NUD group (100%) ( $P = 0.00006$ ). In addition, significant difference was also presented between the 50-plus age group and the younger age (< 50 years old) group (45.5% vs 69.1%,  $\chi^2$  test,  $P = 0.048$ ).

### Urease activity of non-*H. pylori* isolates

All the 201 non-*H. pylori* isolates were screened for urease activity, 14 isolates belonged to 6 species (*S. epidermidis*, *S. warneri*, *S. capitis*, *S. aureus*, *Brevibacterium spp.* and *K. pneumoniae*) and were urease positive (Table 1), which could benefit in the bacterial overgrowth in the stomach. Interestingly, not all the isolates of the 6 species were urease-positive except *S. warneri*. Especially in a 26-year-old patient with non-ulcer dyspepsia, two *Staphylococcus epidermidis* isolates were isolated under aerobic and microaerobic conditions, respectively, but only the microaerobic isolate was urease-positive.

## DISCUSSION

It has been suggested that non-*H. pylori* bacteria and their by-products may act as a persistent antigenic stimulus, and thereby augment the inflammatory response induced by the *H. pylori* infection<sup>[4]</sup>. The current study documented a high prevalence (65.0%) of the non-*H. pylori* bacterial flora in the *H. pylori* positive patients, which indicate that the upper gastrointestinal disorders may enable non-*Helicobacter* bacteria to survive and colonize in the human stomach. Further studies should be done to elucidate the role of the co-infection of the stomach with *H. pylori* and non-*H. pylori* bacteria in the pathogenesis process.

Most of the non-*H. pylori* bacteria isolated in this

study were upper respiratory tract microflora, which was in agreement with other researches<sup>[10]</sup>. The major species were *Streptococcus*, *Neisseria*, *Rothia* and *Staphylococcus*, that was different from the previous reports of healthy volunteers, which was predominantly acid resistant species - *Veillonella sp.*, *Lactobacillus sp.*, and *Clostridium sp.*<sup>[11]</sup>.

Gram-negative bacilli are uncommon in the upper gut of healthy individuals, but in patient populations with gastric hypochlorhydria, gram-negative bacilli are recovered in a minor proportion<sup>[12,13]</sup>. Gram-negative bacilli were discovered in 9.7% of the patients in this study. Concurrent colonization by gram-positive and/or gram-negative coccus occurs in 10 of the 12 gram-negative bacilli. *Acinetobacter lwoffii* was the only gram-negative bacilli species that was found as the only non-*H. pylori* bacteria in the patients. The two *A. lwoffii* carriers were a 42-year-old male patient with duodenal ulcer and a 25-year-old female patient with non-ulcer dyspepsia. *A. lwoffii* has been proved to cause the same histologic gastritis as *H. pylori* infection in a murine model<sup>[14]</sup>. And outer membrane protein (OmpA-like protein) of *A. lwoffii* was reported to activate interleukin 8 and gastrin promoter activity *in vitro*<sup>[15]</sup>. Moreover, a case of *A. lwoffii* bacteremia associated with acute gastroenteritis was reported recently<sup>[16]</sup>, which stimulate more interest in the contribution of *A. lwoffii* to gastrointestinal diseases.

It has been well known that gastric acid secretion declines with age which may increase the sensitivity of the stomach to the bacterial colonization. Surprisingly, a higher non-*H. pylori* prevalence was found in the younger age group (less than 50 years old,  $P = 0.048$ ). The result must be interpreted with caution.

The pathogenesis of NUD was not well understood and a number of hypotheses have been proposed. The role of *H. pylori* infection in NUD remains controversial too<sup>[17]</sup>. A high prevalence of non-*H. pylori* bacteria in NUD group observed in this study gave us a new clue that non-*H. pylori* bacteria may play a role in the pathogenesis of NUD.

Urease is a major virulent factor for *H. pylori*, which aids in neutralizing hydrochloric acid and allows *H. pylori* to colonize the gastric mucosa. Some rapid methods for *H. pylori* diagnosis, <sup>13</sup>C urea breath test (UBT) and RUT, were also based on the urease activity. But *H. pylori* is not the only bacteria which can produce urease. It has been reported that the colonization and overgrowth of urease-producing bacteria other than *H. pylori* induced false-positive UBT results<sup>[18,19]</sup>. All the 104 patients were RUT-positive, but one of them was *H. pylori*-negative based on the further detection and no urease-positive non-*H. pylori* bacteria was isolated. So role of the urease-positive non-*H. pylori* bacteria to cause false-positive results in RUT was not definite in this study.

Overall, a high prevalence of non-*H. pylori* bacteria obtained in this study, the major of which were *Streptococcus*, *Neisseria*, *Rothia* and *Staphylococcus*, differed from the previous report of healthy volunteers. It should be noted that this study only examined cultured bacteria. But not all flora can be cultivated due to the harsh culture condi-

tion, so the prevalence of the non-*H. pylori* bacteria may underestimate here. The remained question is whether these non-*H. pylori* species contribute to the pathogenesis of gastric disorders. Further studies should be done to elucidate it in the future.

## COMMENTS

### Background

*Helicobacter pylori* (*H. pylori*) infection has been known to trigger a variety of gastric disorders. Recent years, non-*H. pylori* bacteria have also been reported to play roles in the development of upper gastrointestinal disease, but little is known about the stomach bacterial flora. Analysis of stomach bacterial flora was performed in order to stimulate future research in this area.

### Research frontiers

The pathogenesis of gastric disorders is complicated. Besides *H. pylori*, considerable interest has emerged in the co-infection in the stomach with non-*H. pylori* bacteria.

### Innovations and breakthroughs

To date, there has only a limited number of studies regarding the stomach bacterial flora and all are based on a few patients or volunteers. In this study, the authors enrolled 103 *H. pylori* positive patients with upper gastrointestinal diseases and employed forefront matrix-assisted laser desorption/ionization time-of-flight mass spectrometry (MALDI-TOF MS) bacterial identification technique, which is more accurate and rapid than the routine methods or genotypic identification. Furthermore, the authors confirmed a high prevalence of the non-*H. pylori* bacteria concurrent with *H. pylori* in the patients.

### Applications

A high prevalence of the non-*H. pylori* bacteria and the evaluation of the bacterial species found in gastric tissues from *H. pylori* infected patients would stimulate future research to elucidate the role of the mixed infection of the stomach in the pathogenesis of the upper gastrointestinal diseases.

### Terminology

MALDI-TOF MS fingerprinting is a fast and reliable method for the classification and identification of micro-organisms. The BioTyper™ MALDI-TOF MS fingerprinting system allows researchers to perform this process for the unambiguous identification of bacteria, yeasts and fungi in minutes by measuring the exact sizes of peptides and small proteins, which are assumed to be characteristic for each species.

### Peer review

The study provided an interesting evaluation of the bacterial species found in gastric tissues from *H. pylori* infected persons.

### Abstract

**AIM:** To investigate the incidence and mortality of gastric cancer (GC) in Zhuanghe region, northeast China and the influencing factors for their changing trends.

**METHODS:** All new cancer cases and deaths registered from 2005 to 2010 in Zhuanghe County were reviewed. The annual GC cases, constituent ratio, crude rates,

age-standardized rates, their sex and age distribution and temporal trends were assessed. The method of annual percentage change (APC) was used to estimate the trends of GC.

**RESULTS:** Altogether 2634 new cases of GC and 1722 related deaths were registered, which accounted for 21.04% and 19.13% of all cancer-related incidence and deaths, respectively. The age-standardized incidence rate steadily decreased from 57.48 in 2005 to 44.53 in 2010 per 10<sup>5</sup> males, and from 18.13 to 14.70 per 10<sup>5</sup> females, resulting in a APC of -5.81% for males and -2.89% for females over the entire period. The magnitude of APC in GC mortality amounted to -11.09% and -15.23%, respectively, as the age-standardized mortality rate steadily decreased from 42.08 in 2005 to 23.71 in 2010 per 10<sup>5</sup> males, and from 23.86 to 10.78 per 10<sup>5</sup> females. Females had a significantly lower incidence (a male/female ratio 2.80,  $P < 0.001$ ) and mortality (a male/female ratio 2.30,  $P < 0.001$ ). In both genders, the peak incidence and mortality occurred in the 80-84 years age group. The age-standardized mortality/incidence ratio also decreased from the peak of 0.73 in 2005 to 0.53 in 2010 for males, and from 1.32 to 0.73 for females.

**CONCLUSION:** Encouraging declines of incidence and mortality of GC were observed in Zhuanghe region between 2005 and 2010, possibly due to the economic development and efficient GC control strategies.

## INTRODUCTION

Gastric cancer (GC) is one of the most frequently occurring cancers globally; a total of 989 600 new GC cases and 738 000 deaths are estimated to have occurred in 2008, accounting for 8% of the total cases and 10% of total cancer-related deaths, respectively<sup>[1]</sup>. The geographical distribution of GC exhibits wide international variation and over 70% of new cases and deaths occur in developing countries<sup>[1,2]</sup>. Although a notable decreasing trend has been recently observed in the developed countries, the incidence of GC is still high<sup>[3]</sup> and it remains an important public health burden in China. Moreover, there is a significant regional disparity in the distribution of GC in China. People in rural areas are supposed to have a higher risk of GC than those in cities<sup>[4]</sup>, thus, strategy of GC control in China should be implemented specifically based on the different distribution patterns.

Zhuanghe is a county of northern China with a total population of approximate 900 000, of whom approximately 87.2% are agricultural residents. It is located along the coast of the Huanghai Sea and occupies an area of approximately 4034 km<sup>2</sup><sup>[5]</sup>. Zhuanghe has been recognized for its high GC mortality since 1984, the mortality rate being 49.55/10<sup>5</sup> in males and 22.23/10<sup>5</sup> in females<sup>[6]</sup>. The high risk of GC in this region aroused the interest of researchers, and a series of investigations regarding the potential risk factors and corresponding etiological intervention methods and screening measures were conducted in representative villages<sup>[7]</sup>. To date, the population in Zhuanghe County has been surveyed through census for 28 years. Various risk factors, such as salted pork, *Helicobacter pylori* (*H. pylori*) infection with a specific strain, and genetic polymorphisms in the etiology of GC in local residents have been found to play a role<sup>[8-12]</sup>. In addition, several pilot surveys regarding incidence and mortality were also conducted. The GC mortality rates fluctuated between 63.29/10<sup>5</sup> and 38.98/10<sup>5</sup> during the period of 1996-2003 and the incidence rate was 35.42-41.03/10<sup>5</sup> from 1998 to 2004<sup>[7,13,14]</sup>.

Despite some epidemiological surveys in pilot areas, a population-based investigation concerning the incidence and mortality of GC in Zhuanghe has not been previously reported. Monitoring and studying the incidence as well as mortality provides important information, enabling effective assessment of potential cancer prevention and control. Therefore, the aim of the present study is to examine the GC patterns and temporal trends of incidence and mortality at the population level in Zhuanghe region and to elucidate the factors that

influence the changing trends, in an attempt to establish future general and specific strategies for the prevention and control of cancers.

## MATERIALS AND METHODS

### Cancer registry

The preliminary cancer surveillance was conducted in Zhuanghe as a high-risk GC research base in 1984. However, previous cancer data were obtained from limited populations and sample surveys. Over the past two decades, a cancer registry was developed along with an expanding research scope, with coverage of only several villages initially in the 1980s which increased to 70 villages in the 1990s. Since 2001, a population-based cancer registry has been gradually established, in collaboration with the Cancer Registration Office of Liaoning Province, China that has collected information on all deaths and all cancer cases in Zhuanghe County and has functioned well since 2005.

The framework of this registry consisted of three parts: village clinics that served as basic units, rural administration units, and Center of Disease Prevention and Control (CDC) of Zhuanghe County. Village clinic doctors were required to report each new case of cancer using a standard card to the rural administration unit. The cards were then submitted to the CDC of Zhuanghe, registered and processed on a regular basis. These cards were checked, analyzed, coded and stored at the CDC. All data were coded according to the manual "National Criteria of Cancer Registry in China", which describes the cancer inclusion and exclusion criteria, and provides definitions and coding for cancer cases. The accuracy of the data was assured through the comprehensive training of doctors and registrars by the Cancer Registration Office of Liaoning Province, and by computerized consistency checks. At the end of each year, a sample survey was conducted to check the quality of the registration. The cancer occurrence data were compared one by one with the death registry database data to supplement cases of cancer death which were not registered for cancer occurrence.

### Data collection

Annual GC cases data were provided by the CDC of Zhuanghe County. All data were coded and checked for eligibility and validity prior to analysis. Data collected on each patient included demographics and native origins, primary cancer site/type, morphology, and pathological diagnosis confirmation, stage of the disease, and active patient follow-up. The 10th revision of International Classification of Diseases (ICD-10) was used for cancer classification. Data concerning age and sex in the Zhuanghe population were provided by the local police station.

### Statistical analysis

All of the data were checked and analyzed by SPSS 13.0 software (SPSS, Chicago, Illinois, United States). Incidence and mortality rates were calculated as the mean annual number per 100 000 residents. Age-standardized

CR: Constituent ratio; ICD-10: The 10th revision of International Classification of Diseases; GC: Gastric cancer; LC: Lung cancer; HCC: Liver cancer; CRC: Colon/rectum cancer; BC: Breast cancer; EC: Esophageal cancer; TC: Thyroid cancer; BLC: Bladder cancer; PC: Pancreatic cancer; CNC: Cancers of brain and nervous system; PRC: Prostate cancer; KC: Renal cancer; CC: Cervical cancer; EMC: Endometrial carcinoma; OC: Ovarian cancer.

incidence rates (ASRs) and age-standardized mortality rates (ASMRs) were calculated using a direct method<sup>[15]</sup> by weighting age-specific incidence and mortality rates in accordance with the World Standard Population (World Health Organization, published in 2000) and the China Standard Population (2000). The Chi-squared test was used to determine whether the differences between sexes were statistically significant, and the test was also used to examine trends of annual change in crude rates.

The average annual percent change (APC)<sup>[16,17]</sup> was estimated by fitting a regression line to the natural logarithm of the rates using the calendar year as the regression variable, i.e.,  $y = mx + b$  in which  $y = \ln(\text{rate})$  and  $x = \text{calendar year}$ . The estimated APC =  $100(e^m - 1)$  and 95% CI of APC =  $100(e^{m \pm SE_m} - 1)$ , where the standard error of  $m$  (SEM) was obtained according to the fit of the regression line. To test the hypothesis that the APC equals zero is equivalent to the hypothesis that the slope of the regression line is zero, the  $t$ -distribution of  $m/SEM$  was used. The number of degrees of freedom is equivalent to the number of calendar years minus two. This calculation assumes that the rate increased/decreased at a constant rate over the entire period. Statistical significance was assessed by the two-sided Student's  $t$  test, and  $P < 0.05$  was considered statistically significant.

### Ethical consideration

Ethical approval for this study was obtained from the Human Ethics Review Committee of China Medical University (Shenyang, China). Written informed consents were obtained from the participants in accordance with the Declaration of Helsinki and its later revisions.

## RESULTS

### Incidence

From 2005 to 2010, a total of 2634 new cases of GC were registered in Zhuanghe, including 1950 males and 684 females. We analyzed the constituent ratios for incidence according to various types of cancer (Table 1).

GC ranked first among all types of cancers in males, whereas it ranked the second among females and both sexes combined. The ten most common types of cancer in the Zhuanghe population were lung, stomach, liver, colon/rectum, breast, esophageal, thyroid, bladder, pancreatic cancers, and cancer of brain and nervous system. These cancers comprised 80.74% of all cases of cancer. The five predominant primary cancer sites in males were stomach, lung, liver, and esophagus; whereas in females, the leading sites were lung, stomach, breast, colon/rectum, and thyroid.

The incidence rate of GC occurring over different years was analyzed. We initially calculated the annual crude incidence rate according to sex. The average crude incidence rate of GC in males was  $70.23/10^5$ , which was 2.80-fold higher than in females ( $25.12/10^5$ ). The difference was statistically significant ( $\chi^2 = 584.31$ ,  $P < 0.001$ ). Over the past 6 years, no obvious increasing or decreasing trend was observed concerning crude incidence ( $P = 0.404$  in males,  $0.061$  in females and  $0.101$  in both sexes) (Table 2).

To adjust for the effect of age differences over different time periods, age-standardized incidence rates were calculated in accordance with the China Standard Population (ASR1) and World Standard Population (ASR2). As shown in Figure 1, over the past 6 years, the incidence rate of GC has gradually decreased. For both genders, the ASR2 decreased from 37.67 to 29.83 per  $10^5$  with an APC of  $-4.82\%$  (95% CI:  $-3.58\%$  to  $-6.04\%$ ;  $P = 0.019$ ) and for males the rate decreased from 57.48 to 44.53 per  $10^5$  with an APC of  $-5.81\%$  (95% CI:  $-4.67\%$  to  $-6.94\%$ ;  $P = 0.008$ ). The ASR2 decreased from 18.13 to 14.70 per  $10^5$  with an APC of  $-2.89\%$  (95% CI:  $0.06\%$  to  $-5.75\%$ ) in females; however, the change had no statistical significance ( $P = 0.383$ ) (Table 2).

In both genders, GC was very rare among populations younger than 20 years, but the rate rose sharply to a peak at approximately 80 years of age, and it declined afterwards. The median age of GC patients was 67 years and the average age was 65.78 years. The cases above 50

years old accounted for 88.65% of all GC cases.

**Mortality**

There were a total of 1722 GC deaths between 2005 and 2010 in Zhuanghe, including 1207 males and 515 females. Table 3 shows the constituent ratio of malignant tumors leading to death, in which GC accounted for 19.13% (21.58% in males and 15.11% in females) of the total cancer deaths, making it the second leading cause of cancer death.

The crude mortality rate during this period due to

GC in Zhuanghe was 31.31 per 10<sup>5</sup>; 43.47 per 10<sup>5</sup> in males and 18.91 per 10<sup>5</sup> in females. The difference in sex-specific incidence rates was statistically significant ( $\chi^2 = 264.82, P < 0.001$ ); a higher rate was observed in males than in females with a ratio of 2.30. A decreasing trend in crude mortality rate was observed over the past 6 years ( $P < 0.001$  in both sexes;  $P = 0.046$  in males,  $P < 0.001$  in females) (Table 4).

A progressive decrease in the world age-standardized mortality rate was noted in both genders (Figure 2 and Table 4); ASMR2 decreased steadily from 42.08/10<sup>5</sup> in

2005 to 23.71/10<sup>5</sup> in 2010 for males, and from 23.86/10<sup>5</sup> to 10.78/10<sup>5</sup> for females, with an average reduction of -11.09% for males (95% CI: -9.65% to -12.50%;  $P = 0.002$ ) and -15.23% for females (95% CI: -11.71% to -18.62%;  $P = 0.015$ ) per year. In general, ASMR2 decreased from 32.74 to 17.28 per 10<sup>5</sup> with an APC of -12.23% (95% CI: -10.94% to -13.90%;  $P = 0.001$ ).

The minimum age group for GC death was 15-20 years. With increasing age, the mortality rate increased sharply, reaching a peak at approximately 80 years of age and declining thereafter. The median age was 71.00 years and the average age was 69.17 years. The cases in subjects over 50 years of age accounted for 91.70% of all deaths (Table 5).

In addition, we calculated the age-standardized mortality-incidence ratio (M/I ratio: ASR2/ASMR2) during different time periods. The M/I ratio decreased from 0.87 to 0.58 over a 6-year period. The worst ratio was recorded in 2005: 0.73 for males and 1.32 for females, followed by a steady decrease over the subsequent years with the M/I ratio falling to 0.53 for males and 0.73 for

**Table 6** Mortality to incidence ratio of gastric cancer

Year	Age-standardized mortality to incidence ratio <sup>1</sup>		
	Total	Male	Female
2005	0.87	0.73	1.32
2006	0.67	0.64	0.77
2007	0.68	0.67	0.75
2008	0.56	0.57	0.53

females in 2010 (Table 6).

## DISCUSSION

GC is one of the most common cancers worldwide. There is substantial geographic variation regarding the incidence and mortality of GC. Studies specifically examining the population in high-risk areas should be very useful in potentially controlling this disease. Zhuanghe County, which is situated in the coastal area of the eastern Liaoning peninsula, is a rural area exhibiting a high GC mortality in north China. A series of epidemiological investigations and comprehensive preventive measures for GC have been conducted since 1984. Surveillance of cancer incidence and mortality rates has provided a guideline to identify the etiology and aid in the evaluation of the impact of intervention on the population. Our previous sampling data indicated the initial effects of GC intervention. However, the lack of an overall picture of GC remains due to the unavailability of cancer registry data covering the entire region prior to 2005. In this study, we reviewed the data regarding the incidence and mortality of GC in Zhuanghe County during the period of 2005-2010 based on the population-based registry in order to analyze the changing trends and to elucidate the underlying causes.

The results about the organ distribution of all can-

cers in Zhuanghe indicated that 80.74% of new cases originated from ten primary organ sites, the two major sites being lung (21.35%) and stomach (21.04%). Moreover, the ten major cancers accounted for 88.77% of all cancer-related deaths, with lung and stomach as the top two positions (29.81% and 19.13%). GC was the most common type of cancer in males and the second most common in females in the Zhuanghe region, and was the second leading cause of cancer death for both genders. All of the data indicated that GC remained a major health burden for the local population.

Globally, the incidence rate of GC is nearly twice as high in males as in females<sup>[1]</sup>; the male-to-female incidence ratio in Zhuanghe county was 2.80 ( $\chi^2 = 264.82$ ,  $P < 0.001$ ), and the mortality of GC in males was 2.30 times higher than in females ( $\chi^2 = 584.31$ ,  $P < 0.001$ ). There were gender differences in many types of cancer, which may be related to the different risk level for exposure to diet, smoking, drinking and occupation<sup>[18]</sup>. Investigation of genetic factors together with other intrinsic and extrinsic differences between the genders could potentially help reveal the relevant factors in oncogenesis, and lead to more effective prevention measures and disease control.

Regarding age-specific incidence and mortality, we found an overall increasing trend that corresponded with increasing age, peaking at age 80-84 years, and a declining trend for older men and women during this period. According to the data collected from 2001 to 2003, the peak in GC incidence and mortality occurred earlier<sup>[13]</sup> and the median and the average age were also increased. These differences were hypothesized to be related to preventive measures as well as the change of population composition such as population growth and aging.

In our study, we specifically analyzed the changing trends in GC rates in Zhuanghe, China, and found encouraging declines in both incidence and mortality. Between 2005 and 2010, GC incidence decreased with an APC of 4.82% in Zhuanghe. Moreover, a similar but more noticeable trend was observed in mortality (APC = -12.23%). The decreasing trends were in concordance with the results from various other reports in China. Wang *et al.*<sup>[19]</sup> found that the estimated annual percentage change in GC incidence in Yangzhong was -2.96% in males and -2.86% in females. The APC change for GC incidence in Changde was reported to be -3.44% in men and -2.21% in women<sup>[20]</sup>. The report by Cui *et al.*<sup>[21]</sup> demonstrated an APC of GC mortality in Kaifeng of approximately -2.92% in males and -3.37% in females. Although similar trends were observed, the amplitudes of the declines were not similar to those demonstrated by our data, which indicated a far more significant decrease among the comparable studies.

The descending trends of GC rates in other regions were mostly reported to be attributed to the “unplanned triumph” of improvement in sanitation, fresh fruit and vegetable consumption, and reduced *H. pylori* infection. It is commonly accepted that the incidence and mortality of GC in a region are related to both the economic sta-

tus of the population and dietary habits<sup>[22-24]</sup>. In the past, residents in Zhuanghe had a low standard of living and were accustomed to eating highly salted food. However, currently, with economic development and increased knowledge regarding tumor prevention, residents have changed their dietary habits, and this potentially plays an important role in the descending trends of the disease. In 2010, Gross Domestic Product of Zhuanghe average per capita reached 54 348 RMB *yuan* - a 5.2-fold increase since 2000. Meanwhile, the rural health investment including environmental sanitation for water and housing has been increased by 23.8 times in the past decade<sup>[25]</sup>, and the consequentially improved sanitary conditions may help reduce the prevalence of *H. pylori* infection, and the risk of GC development. Therefore, further research regarding preventive factors, such as eating habits, foods, prevalence of *H. pylori* infection, environmental factors, *etc.*<sup>[26-28]</sup> is warranted.

In addition to the above causes for the decreasing trends in GC, prevention and control measures were also taken in Zhuanghe, and these measures also play an important role in the encouraging declines of GC incidence in our study. In Zhuanghe, comprehensive control and etiological intervention through mass behavior interference and chemoprophylaxis in the high-risk populations have been conducted in pilot villages for many years by a research group from the First Affiliated Hospital of China Medical University (FAHCMU). With professional guidance by the researchers, knowledge of prevention and treatment of GC was disseminated for general residents by means of broadcasting, video, brochures and face-to-face conversation. In addition, the targeted high-risk population was treated promptly with antibiotics, Chinese herbal medicine and nutritional therapy based on *H. pylori* detection and gastroscopic and pathological examinations<sup>[29]</sup>. Our previous pilot survey demonstrated that these strategies are feasible and cost-effective for the treatment of gastric premalignant lesions and carcinoma in early stages, and a decrease in the mortality rate was observed in the intervened population at the initial period of prevention. The average mortality rate in the intervention groups (34.97/10<sup>5</sup>) during the post-intervention period (1997-2000) was significantly lower than (59.31/10<sup>5</sup>) in the pre-intervention period (1996) ( $P < 0.05$ )<sup>[30]</sup>. In the present study, we focused on trends at the population level. Interestingly, the same downward trend seen in the intervention groups was observed in the entire population. This study demonstrates that the preventive activities potentially contributed to alleviating the adverse effects of GC on the health and life of patients, even in the population as a whole.

Despite declines in both incidence and mortality of GC, we noted a dissociation phenomenon, i.e., an APC decrease was greater for mortality compared with incidence. It was hypothesized that early diagnosis and early treatment would play an important role in the dissociation phenomenon between incidence and mortality. The data suggested the need for further promotion of GC screening to enable early diagnosis. In this study,

we also analyzed the M/I ratio in Zhuanghe. The M/I ratio, which compares the number of deaths attributed to a specific cancer and the number of incident cases in the same time period, can be interpreted as an indirect indicator of general survival if registration is complete and there are no marked temporal changes in incidence rates<sup>[31]</sup>. The age-standardized M/I ratio steadily decreased in both genders, which indicated a prolonged survival; hence the decrease in mortality was not caused by the fall in incidence rate alone, but by other factors, including earlier diagnosis or improved treatment. Since 1997, more than 15 000 people have received GC screening by the research group from FAHCMU through a two-round GC screening strategy, and this large-scale population screening program extensively covered 70 villages of Zhuanghe region. Through unremitting efforts for years, the detection rate of early GC reached 60%-80% and has been increasing yearly. The GC patients screened with pathological confirmation will be sent to hospitals for treatment, and their postoperative five-year survival rate was above 90%<sup>[7]</sup>. Thus, such a population screening program may contribute to the above-mentioned dissociation phenomenon and prolonged survival of the patients. Furthermore, the age-standardized M/I ratio was lower in the male population, suggesting that the survival rate was higher in males than in female patients after treatment.

This study describes the changes in incidence and mortality rates in the entire population of Zhuanghe over the past 6 years, which may not fully reflect broader population trends; however, our observations of the short-term changes potentially form the basis for future analysis. In concert with our previous studies, we described a general picture of GC patterns and changing trends in Zhuanghe. In addition, despite a significant declining trend, the age-standardized incidence (ASR1:  $26.84/10^5$  vs  $17.06/10^5$ ) and mortality (ASMR1:  $14.92/10^5$  vs  $11.67/10^5$ ) remained higher than the national level in China<sup>[32,33]</sup>. Therefore, in future studies, continuous monitoring over a longer period of time is needed to not only identify whether the declining trends persist, but also to acquire a more comprehensive understanding of GC in this region. Accordingly, effective prevention and treatment strategies would be further developed, which will greatly benefit the residents in high-risk areas. Moreover, researches regarding the impact of genetics, the environment, and their interaction are warranted to fully elucidate the disease etiology.

## COMMENTS

### Background

Gastric cancer (GC) is one of the most common cancers worldwide. The geographical distribution of GC is characterized by wide regional disparity. Monitoring and studying the incidence as well as mortality at the population level in high-risk areas should be very helpful in controlling this disease in the future.

### Research frontiers

Surveillance of cancer incidence and mortality provides important epidemiological information, enabling development of cancer prevention and control strategies. Several population-based cancer registries provided data on cancer rates

in China, however, most of which were established in the affluent big cities rather than in the poor rural counties. In this study, the data regarding the incidence and mortality of GC in Zhuanghe County, a rural area of China, were reviewed based on the population-based registry, which provided a general picture of the GC distribution in a rural high-risk area.

### Innovations and breakthroughs

The distribution of GC has substantial geographic variation, thus, studies concerning the population in high-risk areas should be more meaningful in potentially controlling this disease. The present study, for the first time, examined all-cancers distribution and temporal trends of GC in Zhuanghe and explored the possible influencing factors. Based on the findings in the registry studies, the control strategies of GC could be further developed in local areas, which may be also instructive and meaningful to cancer prevention of other similar areas in China.

### Applications

There is a significant global variation in the distribution of GC. The findings of the study would be helpful for the development of general and specific cancer prevention and control strategies to benefit the residents in the high-risk areas both locally and nationally.

### Terminology

Age-standardized incidence rates and age-standardized mortality rates are used to compare the incidence or mortality rates of places without being skewed by the difference in age distributions from place to place.

### Peer review

The authors studied the patterns and time trends of gastric cancer in terms of incidence and mortality in Zhuanghe region at population level and investigated the influencing factors of the changing trends. Findings from this study showed a downward trend of both incidence and mortality that may be due to the raised economic level along with implementation of prevention and control measures. It enriched epidemiological data of GC and offered reference to the other high-risk areas of China to control the disease based on population-level evidences.

### Abstract

Esophageal duplication cysts are rare inherited lesions usually diagnosed in early childhood. Most of them are found in the mediastinum and manifest themselves as separate masses along or in continuity with the native esophagus. Their prevalence remains unknown and they are treated either surgically or endoscopically. In this report we describe a series of four adult patients in whom esophageal duplication cysts were localised intramurally as masses pressing on the esophageal lumen and who were diagnosed with endoscopic ultrasonography. All patients were initially referred to other centres for upper gastroduodenoscopy due to non-specific dyspeptic symptoms. After finding suspicious lesions in the esophagus their endoscopists referred them for endoscopic ultrasound examination at our centre. In two of the cases lesions mimicked esophageal varices and the other two submucosal tumours. In all four patients endoscopic ultrasonography has shown esophageal duplication cysts. Patients had no symptoms suggesting disease of the esophagus

and required no treatment. As the true prevalence of esophageal cysts is unknown, it is very likely that in many patients, like in these four described by us, they may cause no symptoms, remain undetected and require no intervention. Increasing availability of new diagnostic modalities such as endoscopic ultrasonography may change the current view regarding the prevalence of esophageal duplication cysts and prove that they may, in fact, not be such rare findings.

### INTRODUCTION

Esophageal duplication cysts are congenital anomalies of the foregut resulting from aberration of the posterior division of the embryonic foregut at 3-4 wk gestation<sup>[1]</sup>. They represent either simple epithelial-lined cysts, or true esophageal duplication, which is a duplication of the muscularis mucosa and externa without epithelial duplication.

Esophageal cysts are considered rare, usually described in single case reports, and their true prevalence remains

unknown<sup>[2]</sup>. Up to 80% of cases are diagnosed during childhood<sup>[1-5]</sup>. Most of them are found in the mediastinum and manifest themselves as separate masses along or in continuity with the native esophagus. Intramural esophageal cysts are considered very uncommon in adults<sup>[6,7]</sup>.

Symptoms are caused by compression or displacement of surrounding mediastinal structures and comprise dysphagia, respiratory distress, failure to thrive and retrosternal pain<sup>[7,8]</sup>. Malignant progression is considered extremely rare<sup>[9]</sup>. Diagnosis is usually made by computed tomography scan or endoscopic ultrasonography (EUS).

Treatment of symptomatic esophageal cysts can be either surgical or endoscopic. Surgical resection of the cyst is usually carried out in childhood or in adults, in cases of lesions impossible to treat endoscopically. Surgical treatment is currently moving from thoracotomy to less-invasive procedures, such as video-assisted thoracoscopic surgery<sup>[7]</sup> and to endoscopic treatments which, however, still remain challenging interventions<sup>[10]</sup>.

We present a series of 4 patients with esophageal cysts which caused no symptoms and required no intervention.

## CASE REPORT

All patients were initially referred to other centres for upper gastroduodenoscopy due to non-specific, dyspeptic symptoms. They gave no history of dysphagia. After finding suspicious lesions in the esophagus their endoscopists referred them for EUS examination. Written informed consent was obtained from each patient.

### Case 1

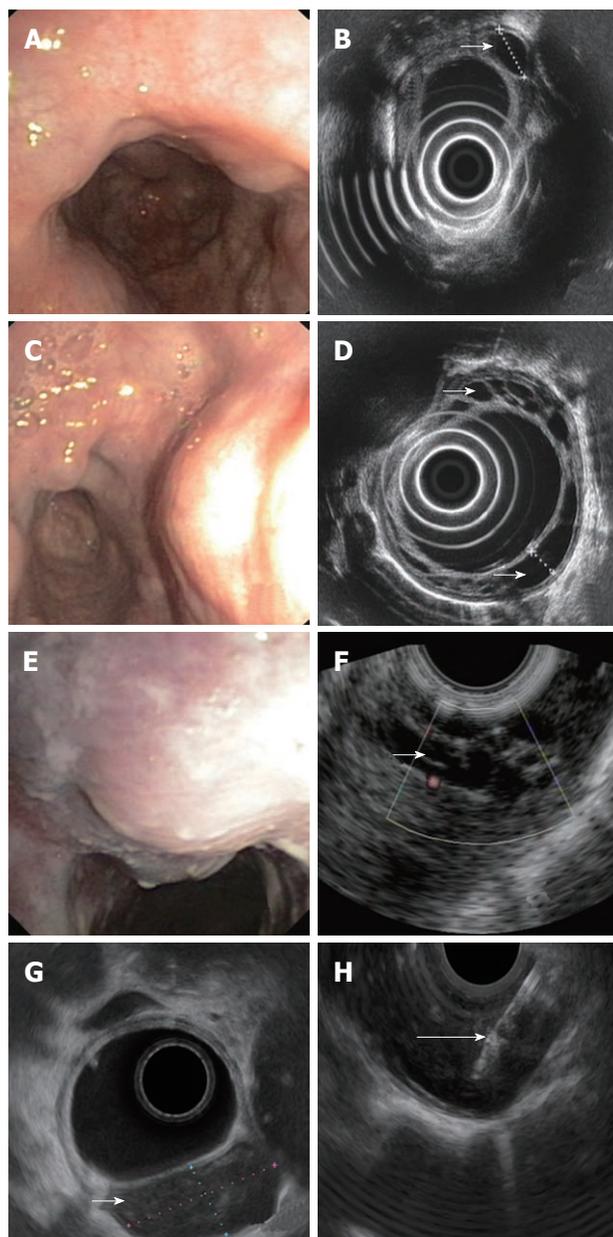

A 60-year old female: On endoscopy, multiple impressions, covered with normal mucosa and localized to the middle and lower third of the esophagus were seen (Figure 1A). They could be easily passed by the endoscope. No other abnormality was found on endoscopy. On EUS multiple cystic fluid-filled intramural lesions were detected (Figure 1B). They were avascular on Doppler study and their size varied from 3 mm × 5 mm to 11 mm × 25 mm.

### Case 2

A 51-year old male: Endoscopy revealed multiple impressions, covered with normal mucosa and localized in the lower third of the esophagus (Figure 1C). The prepyloric area showed features of atrophic gastritis subsequently confirmed with histology. On EUS, multiple cystic, fluid-filled, intramural lesions were detected (Figure 1D). Their size varied from 4 mm × 6 mm to 8 mm × 16 mm. They showed no vascular pattern on Doppler examination.

### Case 3

A 57-year old female: Endoscopy showed a solitary impression, localized 25 cm from the incisor teeth and covered with unchanged mucosa (Figure 1E). Examination was otherwise unremarkable. EUS revealed a cluster of anechoic fluid-filled intramural lesions showing no

**Figure 1** Endoscopic and endosonographic images of described patients.

A: Multiple impressions to middle and lower third of esophagus seen in endoscopy; B: Multiple cystic fluid-filled intramural lesions detected on endoscopic ultrasonography (EUS); C: On endoscopy multiple impressions, covered with normal mucosa, localized in the lower third of esophagus; D: On EUS multiple cystic, fluid-filled, intramural lesions; E: Solitary impression, localized 25 cm from the incisor teeth and covered with unchanged mucosa seen in endoscopy; F: On EUS a cluster of anechoic fluid-filled intramural lesions; G: On EUS an anechoic fluid-filled intramural lesion 24 x 12 mm large; H: Aspiration of the fluid with 19G needle. Small arrows show duplication cysts in D, F and G and big arrow shows the biopsy needle in H.

vascular pattern on Doppler examination (Figure 1F).

### Case 4

A 47-year old male: Endoscopy revealed a solitary lesion, size approximately 25 mm localized 30 cm from the incisor teeth and covered with unchanged mucosa (Figure 1G). No other abnormality was found on endoscopy. EUS demonstrated an anechoic fluid-filled intramural lesion

24 mm × 12 mm large. The lesion showed no vascular pattern on Doppler examination (Figure 1H). Aspiration with 18G needle revealed a clear fluid with no malignant or suspicious cells.

## DISCUSSION

In this paper we describe a series of 4 patients who were referred to our centre for further investigation of esophageal lesions found on routine gastroduodenoscopy. In two cases, where there were multiple lesions, referring doctors suspected unusual looking varices or vascular lesions. In view of our interest in EUS of portal hypertension<sup>[11-13]</sup> a more detailed study of both the lesions and intrinsic para- and peri-esophageal circulation was performed. However, these patients had no clinical, laboratory or imaging features suggesting liver cirrhosis or portal hypertension. In the other two cases the initial diagnosis was submucosal tumours. These findings were expected to be confirmed using EUS. All these patients turned out to have esophageal duplication cysts.

Esophageal cysts do not usually communicate with the esophageal wall but occur as a separate malformation along or in continuity with the native esophagus. In the presented cases they were localized intramurally as a mass pressing on the esophageal lumen and this is why they resembled esophageal varices or submucosal tumours.

Treatment of esophageal duplication cysts in asymptomatic patients is controversial with no clear clinical guidelines. As all our patients remained asymptomatic we arbitrarily decided to schedule them for follow up EUS/gastroduodenoscopy in a period of 2 years. An earlier intervention will be performed if they become symptomatic.

As the true prevalence of esophageal cysts is unknown<sup>[2]</sup>, it is very likely that in many patients, like in these four described by us, they cause no symptoms, remain undetected and require no intervention at all. Increasing availability of new diagnostic modalities such as EUS may change the current view regarding the prevalence of esophageal duplication cysts and prove that they are not rare findings.

### Abstract

Non-hepatocellular carcinoma (non-HCC) with macroscopic bile duct tumor thrombus (BDTT) formation is rare, few radiological studies have been reported. In this case report, we retrospectively analyzed the imaging findings of three cases of non-HCC with macroscopic BDTT on dynamic enhanced multislice computed tomography (MSCT) scan. One case of primary hepatic carcinosarcoma was presented as a solitary, large well-defined tumor with significant necrotic changes. One case of liver metastasis from colon cancer was presented as a lobulated, large ill-defined tumor. One case of intraductal oncocytic papillary neoplasm involved the entire pancreas, presented as a cystic and solid mass with multilocular changes (the individual loculi were less than 5.0 mm in diameter). The bile duct was dilated due to expansible growth of the BDTT in all three patients. The BDTT was contiguous with hepatic or pancreatic

tumor, and both of them showed the same enhancement patterns on dynamic contrast-enhanced computed tomography scan: early enhancement in the hepatic arterial phase and a quick wash-out of contrast agent in the portal and equilibrium phases. Macroscopic BDTT in non-HCC patient is rare, dynamic enhanced MSCT scan may be valuable in the diagnosis of non-HCC with BDTT.

### INTRODUCTION

Hepatocellular carcinoma (HCC) associated with bile duct invasion and subsequent bile duct tumor thrombus (BDTT) formation occurs in only 0.79%-4% of patients with primary HCC<sup>[1,2]</sup>. Because HCC is one of the most prevalent malignant tumors, HCC with BDTT is not uncommonly encountered in clinical practice and its

clinical characteristics have been well described<sup>[3]</sup>. Non-HCC liver tumor can also invade the biliary tree, such as combined hepatocellular and cholangiocellular carcinoma and liver metastasis<sup>[4-10]</sup>. However, only few cases of non-HCC with BDTT have been reported in the radiological literatures<sup>[5-7]</sup>. In this study, we report three cases of macroscopic BDTT: one case of primary hepatic carcinosarcoma, one case of liver metastasis from colon cancer, and one case of intraductal oncocytic papillary neoplasm (IOPN) of the pancreas. The cases of primary hepatic carcinosarcoma or IOPN of the pancreas associated with macroscopic BDTT have not been previously reported.

## CASE REPORT

### Patients

All three non-HCC patients with macroscopic BDTT were treated in our hospital. They had jaundice on admission. Liver function tests showed that aspartate aminotransferase, alanine aminotransferase, gamma-glutamyl transpeptidase and alkaline phosphatase were elevated. Total serum bilirubin (TBil) was significantly increased mainly due to direct bilirubin (DBil). Serum markers of hepatitis B and hepatitis C and tumor markers alpha-fetoprotein (AFP), carcino-embryonic antigen (CEA) and CA125 were all normal. However, CA19-9 was elevated in a patient with primary hepatic carcinosarcoma and a patient with IOPN of the pancreas. All three cases of non-HCC with macroscopic BDTT were pathologically confirmed. We retrospectively analyzed the dynamic enhanced multislice computed tomography (MSCT) findings in these three cases.

### Computed tomography imaging protocols

The computed tomography (CT) examination was performed using a 64-slice spiral CT scanner (Sensation 64, Siemens Medical Solutions), the technical parameters were as follows: 120 kVp tube voltage, 200 effective mAs, 64 mm × 0.6 mm beam collimation, pitch of 0.9, rotation time of 0.5 s, 5 mm reconstruction slice thickness. After acquisition of unenhanced images, nonionic iodinated contrast agent (iodipamide, 370 mg I/mL, Bracco) was injected through a dual-head injector at a rate of 3.5 mL/s and followed by a 20-mL saline flush, with a dose of 2.0 mL/kg body weight. To determine the timing for the hepatic arterial phase (HAP) scanning, a bolus-tracking technique was used with a region of interest in the descending aorta. After achieving enhancement of the descending aorta up to 100 HU, the HAP images were acquired with the scanning delay of 5 s. Portal venous phase (PVP) and equilibrium phase (EP) images were obtained with a delayed time of 30 s and 120 s, respectively.

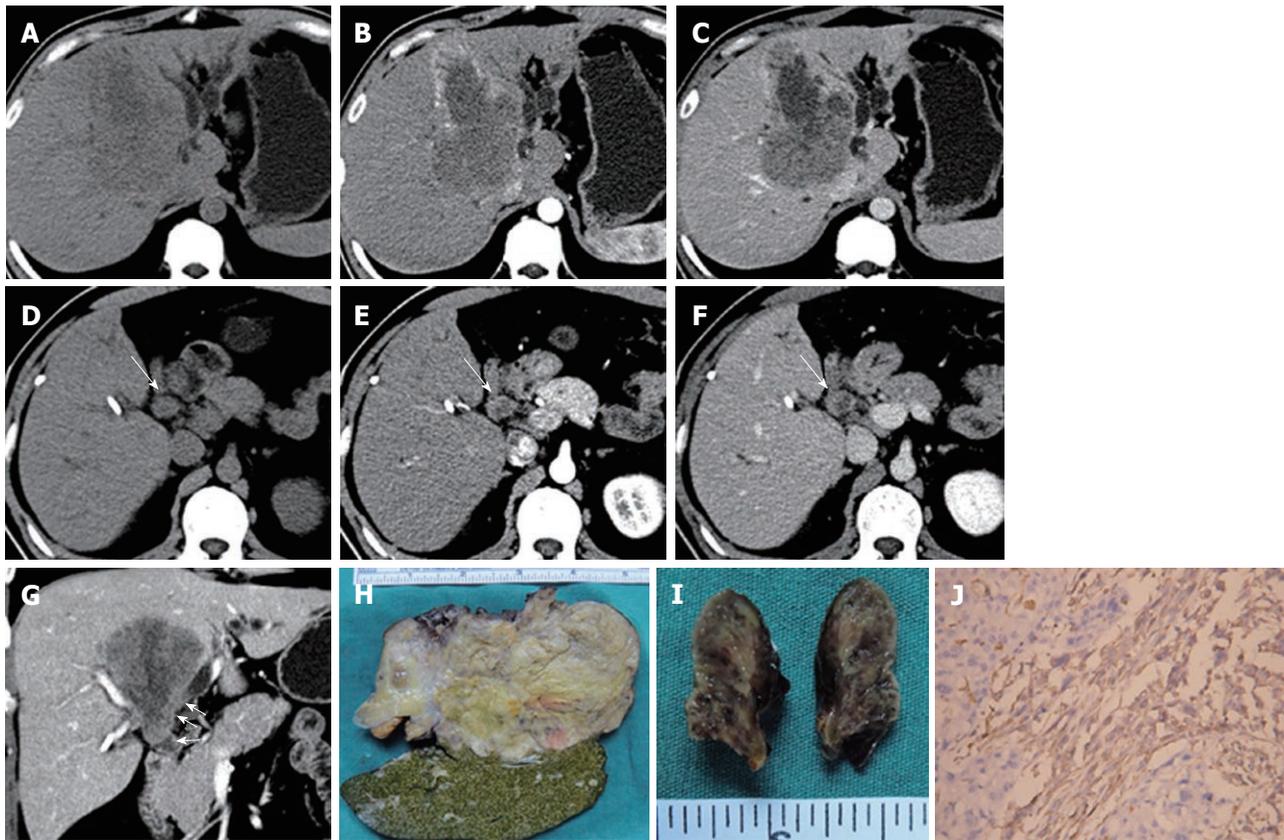

### Case 1

A 41-year-old man was admitted to our hospital on November 18, 2010 with a history of jaundice and right upper abdominal discomfort for one month. Laboratory examination showed that serum TBil was 282.1 μmol/L (normal range: 5-24 μmol/L), DBil was 221.4 μmol/L

(normal range: ≤ 11 μmol/L), and tumor marker CA19-9 was 953.4 U/mL (normal range: ≤ 35 U/mL). A well-defined tumor with a size of 10.8 cm × 6.9 cm in the middle hepatic lobe (Segments IV, V and VIII) was revealed on CT scan. The tumor showed hypo-attenuation (relative to normal liver parenchyma) on pre-contrast CT scan, early rim enhancement in the HAP images and hypo-attenuation in the PVP and EP images. A large necrotic area was noted in the tumor, and showed no enhancement after contrast administration. A tumor thrombus was revealed in the dilated left and right hepatic duct and the common hepatic duct, which was contiguous with the hepatic tumor. No bile duct wall invasion was noted. The enhancement pattern of the intraductal mass was consistent with intrahepatic tumor on dynamic enhanced CT scan. Biliary tree dilation was seen distal to the intraductal mass. The patient underwent left trisectionectomy and right posterior hepatic bile duct-jejunum anastomosis, and intraductal mass was removed through resection of the extrahepatic bile duct. The intrahepatic tumor was not encapsulated. The intraductal mass was not adhered to the bile duct wall, and was easily removed. Primary hepatic carcinosarcoma with BDTT was pathologically confirmed. The carcinomatous and sarcomatous elements were HCC and fibrosarcoma, respectively. The immunohistochemical results revealed that the sarcomatous elements were Vimentin positive, and negative results for cytokeratin, epithelial membrane antigen, hepatocyte, CD34, AFP, AAT, S-100, actin and CD117 (Figure 1). The patient died two months after surgery due to hepatorenal syndrome.

### Case 2

A 75-year-old woman was admitted on November 19, 2010 with epigastric pain and progressive jaundice for seven days. The patient underwent radical resection of colon cancer six years ago. Laboratory results showed significantly elevated serum TBil (196.5 μmol/L) and DBil (131.3 μmol/L). The tumor markers AFP, CEA, CA125 and CA19-9 were all in the normal range. A large lobulated tumor of 8.7 cm × 9.5 cm was displayed on CT scan in the left hepatic lobe with an ill-defined margin. The tumor demonstrated hypo-attenuation on precontrast CT scan, early mild enhancement in the HAP images and inhomogeneous hypo-attenuation in the PVP and EP images. An intraductal tumor thrombus was seen extending from the dilated left intrahepatic bile duct to the upper common bile duct, and was contiguous with intrahepatic tumor. The intraductal thrombus showed similar enhancement patterns with intrahepatic tumor on dynamic enhanced CT scans. Intrahepatic ductal dilation was found distal to the intraductal mass. Tumor thrombi were also seen in the inferior vena cava, the middle hepatic vein and the left hepatic vein. No enlarged lymph node was observed. The patient received percutaneous transhepatic biliary drainage instead of surgery due to poor liver reserve. However, jaundice was not effectively relieved, thus palliative thrombectomy through choledochotomy was performed. The intraductal tumor thrombus was easily removed as it was not adhered to the bile duct wall. Resection specimen

**Figure 1** A 41-year-old man with primary hepatic carcinosarcoma. A large hypodense tumor in the hepatic middle lobe appears on precontrast computed tomography (CT) scan (A), which shows early rim enhancement in the hepatic artery phase (B) and a low density in the portal phase with large areas of necrosis (C). The bile duct tumor thrombus (BDTT) (arrow) shows similar enhancement patterns with the intrahepatic tumor on pre-contrast CT scan (D), hepatic artery phase (E) and portal phase scan (F). Coronal reconstruction image in the portal phase shows that BDTT (arrows) is contiguous with the intrahepatic tumor (G). The resected hepatic tumor (H) and BDTT (I) specimens. The sarcomatous component of the primary hepatic carcinosarcoma is vimentin positive on the immunohistochemical staining (J),  $\times 200$ .

revealed to be metastatic adenocarcinoma pathologically, and was positive for CDX2 and CEA, and negative for hepatocyte, AFP, HBsAg, and CD34 on immunohistochemical staining (Figure 2). The patient was still alive 10 months after the operation.

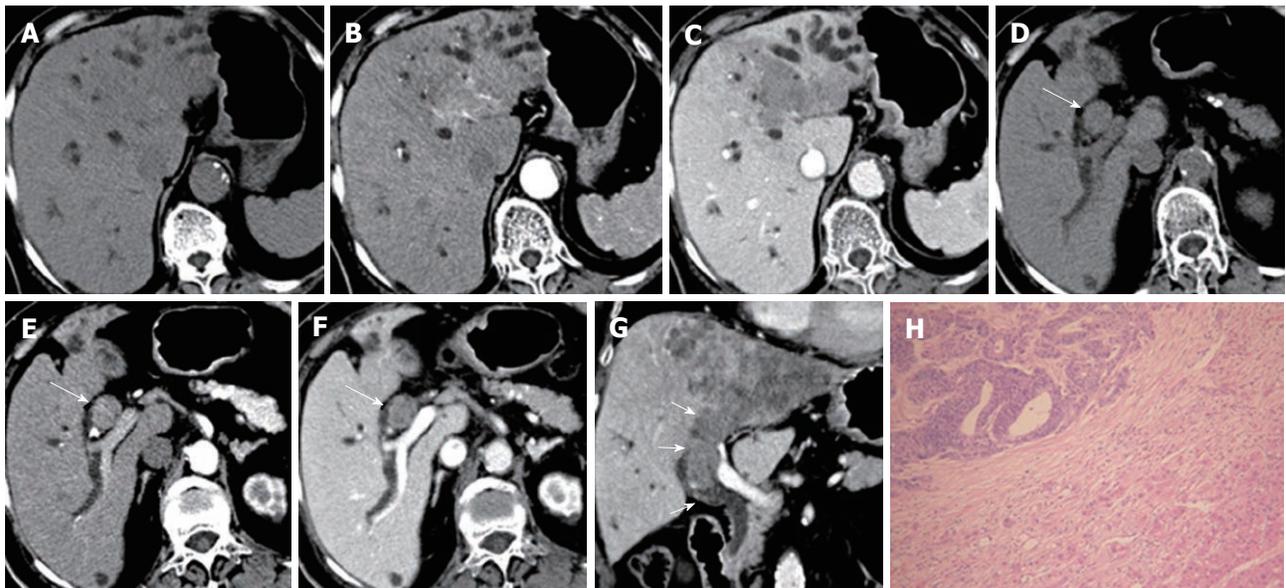

### Case 3

A 43-year-old woman was admitted on December 29, 2009 with a history of jaundice for 10 d. The laboratory results showed a high level of serum TBil (174.6  $\mu\text{mol/L}$ ) and DBil (141.3  $\mu\text{mol/L}$ ). The tumor marker CA19-9 was slightly elevated, with a level of 36.5 U/mL. CT scan showed enlargement of the pancreas which consisted of a mixed solid and cystic tumor. The solid components showed hypo-attenuation on precontrast CT scan, early enhancement on the HAP images and hypo-attenuation on the PVP and EP images. The cystic components were multilocular, with the loculi less than 5.0 mm in diameter, and showed no enhancement after contrast administration. The main pancreatic duct was mildly dilated and communicated with pancreatic tumor. An intraductal tumor thrombus appeared in the dilated right hepatic duct and the common bile duct on CT scan, and it was contiguous with the pancreatic tumor. The enhancement patterns of the intraductal thrombus were consistent with pancreatic tumor on dynamic enhanced CT scans. No en-

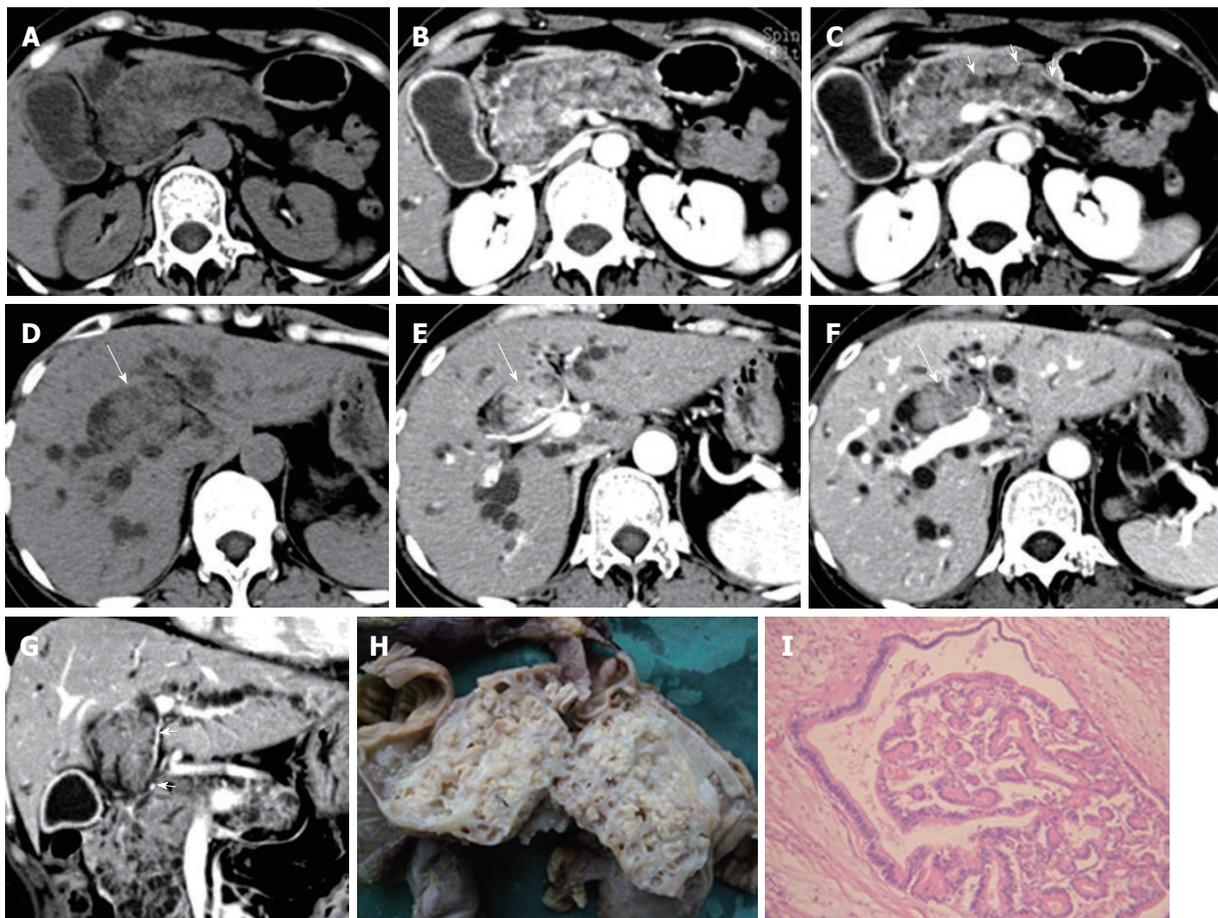

larged lymph node was detected. Thrombectomy through choledochotomy and pancreatic-duodenal resection was performed in this patient. IOPN of the pancreas with BDTT formation was confirmed pathologically. Tumor invasion was only observed in the lower segment of the common bile duct wall (Figure 3). The patient was still alive 21 mo after the operation.

## DISCUSSION

Macroscopic BDTT secondary to liver tumors is not commonly seen clinically and may occur in HCC, combined hepatocellular and cholangiocellular carcinoma and hepatic metastasis<sup>[4-10]</sup>. The mechanism of tumor thrombus formation in the bile duct is unclear. It is widely accepted that hepatic tumors (primary or secondary) can directly invade the bile duct, even extrabiliary malignant tumors can directly metastasize to the bile duct<sup>[10]</sup>. Consequently, tumors can develop along the bile duct and form intraductal thrombus. However, Peng *et al*<sup>[11]</sup> indicated that the tumor cells in HCC with BDTT might be originally derived from the canals of Hering and hepatic stem cells or primitive progenitor cells. We retrospectively analyzed three cases of BDTT secondary to primary hepatic carcinosarcoma, hepatic metastasis from colon cancer and IOPN of the pancreas and reviewed their

**Figure 2** A 75-year-old woman with liver metastasis from colon cancer. A lobulated, ill-defined hypodense tumor in the left hepatic lobe is noted on pre-contrast computed tomography (CT) scans (A), which shows early enhancement in the hepatic artery phase (B) and a low density in the portal phase (C). The bile duct tumor thrombus (BDTT) (arrow) shows similar enhancement patterns with the intrahepatic tumor on precontrast CT scan (D), hepatic artery phase (E) and portal phase scan (F). The coronal reconstruction image in the portal phase shows that BDTT (arrows) is contiguous with the intrahepatic tumor (G). Intraductal tumor thrombus is proved to be metastatic adenocarcinoma pathologically (H), hematoxylin and eosin stain,  $\times 100$ .

**Figure 3** A 43-year-old woman with intraductal oncocytic papillary neoplasm of the pancreas. An inhomogeneous hypodense tumor involving the entire pancreas is noted on precontrast computed tomography (CT) scan (A), which shows early enhancement in the hepatic artery phase (B) and a low density in the portal phase with mild dilation of the pancreatic duct (arrows) and multilocular changes (C). The bile duct tumor thrombus (BDTT) (arrow) shows similar enhancement patterns with the pancreatic tumor on precontrast CT scans (D), hepatic artery phase (E) and portal phase scan (F). The coronal reconstruction image in the portal phase shows that BDTT (arrows) is contiguous with the pancreatic tumor (G). Resected pancreatic tumor specimen shows multilocular changes with papillary growth in the loculi (H). Pancreatic tumor is proved to be intraductal oncocytic papillary neoplasm pathologically (I), hematoxylin and eosin stain,  $\times 100$ .

clinical and imaging findings.

World Health Organization defined primary hepatic carcinomas as tumors containing both carcinomatous (either hepatocellular or cholangiocellular) and sarcomatous components and without obvious transition zone between them<sup>[12]</sup>. Primary hepatic carcinomas are extremely rare and aggressive. To our knowledge, only about 20 cases have been reported in the English literature, and the pathogenesis is still controversial<sup>[12,13]</sup>. This tumor occurs between 34 and 84 years of age and presented no specific clinical manifestations<sup>[12,13]</sup>. More than half of the patients had a background of hepatic cirrhosis or fibrosis<sup>[12-14]</sup>. Elevated serum AFP and CA19-9 could be observed in some cases<sup>[14]</sup>. Patients usually have poor prognosis due to the highly invasive and metastatic features of the tumors<sup>[14]</sup>.

The CT characteristics of primary hepatic carcinomas reported in the literature include a solitary mass with central necrosis and myxoid changes, round, oval or lobulated in shape, and without capsule formation. They show iso-attenuation or hypo-attenuation on precontrast CT scan. Dynamic enhanced CT scan revealed early rim or peripheral ring enhancement in the HAP images, hypo-attenuation in the PVP images and iso-attenuation in the EP images<sup>[12,13,15]</sup>. If the sarcomatous components were osteosarcoma or chondrosarcoma, dense rocky calcifications or bone formations may be presented within the mass radiologically<sup>[15]</sup>. The case of primary hepatic carcinoma described here has similar CT findings as reported in the literature. Interestingly, this case was also associated with BDIT, which has not been previously reported. The BDIT grew expansively without invasion of the bile duct wall, and was contiguous with the hepatic carcinoma. Both of them showed the same enhancement pattern on dynamic enhanced CT scan as they shared the same blood supply. We found similar phenomena in HCC with BDIT, i.e., the enhancement pattern of BDIT was the same as HCC on dynamic enhanced CT scan, intraductal tumor thrombus was continuous with the main intrahepatic HCC mass, no thickened bile duct wall adjacent to the thrombus was observed<sup>[16]</sup>. The differential diagnosis of primary hepatic carcinoma with BDIT from HCC with BDIT is difficult. In the presence of large amounts of tumor necrosis, tumor calcification or ossification and negative serum AFP, hepatic carcinoma should be considered in the differential diagnosis.

Macroscopic intrabiliary tumor growth is a peculiar mode of intrahepatic spread in patients with colorectal liver metastasis. Metastatic hepatic tumors from colorectal cancer demonstrated macroscopic BDIT in approximately 5.8%-12.1% of resected tumors<sup>[6,8,9]</sup>. The growth of BDIT included two components: intraluminal and intraepithelial extension<sup>[8]</sup>. The diagnosis of metastatic hepatic tumors from colorectal cancer associated with macroscopic BDIT is important because macroscopic BDIT is an independent indicator of favorable prognosis in such patients. Aggressive surgical treatment can improve the chances of long-term survival<sup>[8,9]</sup>. Currently, there are few radiological studies about hepatic metastasis from colorectal cancer with bile duct invasion<sup>[5-7]</sup>. Okano *et al*<sup>[6]</sup>

reported the following radiological findings on CT scan in detecting the presence of intrabiliary tumor growth in patients with liver metastases from colorectal cancer: intrahepatic bile duct dilatation, thickened portal tract and wedge-shaped area with enhancement. A thickened portal tract around the tumor corresponded to intrabiliary thrombus itself, and the presence of this sign depended on the length of the intraductal thrombus. If the length of the thrombus is larger than 30 mm, thickened portal tract will likely be observed<sup>[6]</sup>. However, in our cases and in 8 cases of hepatic metastasis with BDIT from colon cancer reported by Lee *et al*<sup>[5]</sup>, no such sign was observed. This discrepancy was likely due to the use of an obsolete CT scanner as reported by Okano *et al*<sup>[6]</sup>, which was limited by low spatial resolution and thicker slice scanning (7-10 mm), thus the intraductal thrombus itself could not be clearly detected. The wedge-shaped area with enhancement is assumed to be caused by reduced portal flow and a compensatory increase in arterial blood flow caused by tumor compression or arteriportal shunt in the involved portal venous branch<sup>[6]</sup>. Jinzaki *et al*<sup>[7]</sup> reported four cases of liver metastasis from colorectal cancer with intraductal invasion. Two of the cases revealed hypo-dense hepatic tumors with bile duct dilation on an enhanced CT scan without presence of intraductal thrombus, while in the other two cases, intraductal thrombus itself appeared on CT scans, which were contiguous with the main intrahepatic tumors. The intraductal thrombus was isodense on unenhanced and enhanced CT compared with the main intrahepatic tumor. In our case of liver metastasis from colon cancer with macroscopic BDIT, the BDIT showed similar expansible growth pattern, and was contiguous with the hepatic metastatic tumor. Both of them showed the same enhancement pattern on CT scan as they shared a common blood supply.

In clinical practice, it is important to differentiate metastatic tumor from primary intraductal cholangiocarcinoma in patients with a history of colorectal cancer when an intraductal mass is presented in the bile duct. The expansible growth of intraductal mass and its direct connection with hepatic tumors are very valuable features in the differential diagnosis<sup>[5]</sup>. The diagnosis of liver metastasis with BDIT should also be differentiated from HCC with BDIT. Hepatic cirrhosis background and a rise in AFP level may aid in the diagnosis of HCC<sup>[16]</sup>.

The term "intraductal oncocytic papillary neoplasm" was proposed by Adsay *et al*<sup>[17]</sup> in 1996 to describe a rare type of pancreatic tumor. Currently, only about 20 cases of IOPN of the pancreas have been reported, but the accurate incidence and etiology of these cases are still unknown<sup>[18,19]</sup>. One of the distinguishing features of IOPN of the pancreas is the abundant, finely granular, eosinophilic cytoplasm of the cells. The tumors usually form complex, branching, and arborizing papillaries<sup>[17,18]</sup>. IOPN of the pancreas is often found in the elderly (mean age, 63.9 years), with no gender predilection and specific clinical features<sup>[18]</sup>. Tumors mainly involve the main pancreatic duct. They are more commonly observed in the head of the pancreas although they can occur in any part of the pancreas. Multiple sites involved have also been reported

in the literature<sup>[17-20]</sup>. In general, IOPN of the pancreas usually presents as either unilocular or multilocular cystic tumor with individual loculi ranging from 0.2 to 4.0 cm. The cystic loculi are filled with mucin and have prominent papillary growth. Cystic tumors usually communicate with the pancreatic duct system<sup>[17-20]</sup>. Most IOPNs of the pancreas exhibit severe dysplasia histopathologically to warrant the term intraductal oncocytic papillary carcinoma, and therefore they should be surgically resected completely<sup>[17]</sup>.

Radiologically IOPN of the pancreas can be presented as a well-defined mass with unilocular or multilocular cystic changes and with mural or solid nodules. The tumors always communicated with the dilated pancreatic duct<sup>[18-20]</sup>. Mural nodules or solid tumor components may show enhancement on CT or magnetic resonance imaging<sup>[19,20]</sup>. Adsay *et al.*<sup>[17]</sup> reported one case of IOPN of the pancreas with common bile duct involvement, and Fischer *et al.*<sup>[19]</sup> reported one case of IOPN of the pancreas with dilation of the common bile duct and intrahepatic ducts. However, no further description has been mentioned in both cases. Currently, no case of IOPN of the pancreas with macroscopic BDTT has been reported. The case we reported here has the following features: tumor involved the entire pancreas with multilocular, mixed cystic and solid changes, and the individual loculi were less than 5.0 mm in diameter. The pancreatic tumor invaded the lower segment of the common bile duct, and hence intraductal thrombus was formed, extending upward along the bile duct with expansible growth pattern. On dynamic enhanced CT scans, pancreatic tumor and BDTT have the same enhancement patterns, which might be due to direct connection of BDTT with main pancreatic tumor, and both sharing the same blood supply. Intraductal papillary mucinous neoplasm (IPMN) of pancreas has similar radiological features as IOPN. A fluorodeoxyglucose (FDG) positron emission tomography scan can help differentiate between IOPN and IPMN of the pancreas. A strong uptake of FDG was reported in IOPN of the pancreas, which suggested high glucose metabolic activity of tumor cells<sup>[19,20]</sup>.

In conclusion, non-HCC with macroscopic BDTT is a rare clinical entity. All three cases in this study shared the following imaging features: expansible growth of the BDTT; the intrahepatic tumor or pancreatic tumor contiguous with the BDTT, and both showing the same enhancement patterns on CT scans; and intrahepatic bile duct dilation distal to the BDTT. MSCT may be a valuable modality in the diagnosis of non-HCC with BDTT.

## Acknowledgments to reviewers of *World Journal of Gastroenterology*

Many reviewers have contributed their expertise and time to the peer review, a critical process to ensure the quality of *World Journal of Gastroenterology*. The editors and authors of the articles submitted to the journal are grateful to the following reviewers for evaluating the articles (including those published in this issue and those rejected for this issue) during the last editing time period.

**Christa Buechler, PhD**, Regensburg University Medical Center, Internal Medicine I, Franz Josef Strauss Allee 11, 93042 Regensburg, Germany

**Kevin E Behrns, MD, Professor, Chairman**, Department of Surgery, University of Florida, PO Box 100286, Room 6174, 1600 SW Archer Road, Gainesville, FL 32610-0286, United States

**Sung-Gil Chi, Professor**, School of Life Sciences and Biotechnology, Korea University, No. 301, Nok-Ji Building, Seoul 136-701, South Korea

of Liver Diseases  
Boston, MA 02298, United States

December 1-4, 2012  
Advances in Inflammatory Bowel  
Diseases  
Hollywood, FL 33028, United States

## GENERAL INFORMATION

*World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

### Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the “priority” and “copyright” of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers’ names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid

evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

### Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

### Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systematically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensus and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

## SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

### Biostatistical editing

Statistical review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc.* The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only

homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word ‘significantly’ should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

### Conflict-of-interest statement

In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read “Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest” from International Committee of Medical Journal Editors (ICMJE), which is available at: [http://www.icmje.org/ethical\\_4conflicts.html](http://www.icmje.org/ethical_4conflicts.html).

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

### Statement of informed consent

Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

### Statement of human and animal rights

When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator’s national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

## SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/1007-9327/office>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS ([http://www.wjgnet.com/1007-9327/g\\_info\\_20100315215714.htm](http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm)) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [wjg@wjgnet.com](mailto:wjg@wjgnet.com), or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

## MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically

for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. [montgomery.bissell@ucsf.edu](mailto:montgomery.bissell@ucsf.edu)

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

### Abstract

There are unstructured abstracts (no less than 256 words) and structured abstracts (no less than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no less than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections.

## Instructions to authors

AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/..."; MATERIALS AND METHODS (no less than 140 words); RESULTS (no less than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ; CONCLUSION (no more than 26 words).

### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

### Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315215714.htm](http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm).

### Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A...; B...; C...; D...; E...; F...; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

### Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  should be noted ( $P > 0.05$  should not be noted). If there are other series of *P* values, <sup>c</sup> $P < 0.05$  and <sup>d</sup> $P < 0.01$  are used. A third series of *P* values can be expressed as <sup>e</sup> $P < 0.05$  and <sup>f</sup> $P < 0.01$ . Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be la-

beled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that...".

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

### PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

## Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

## Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\nu$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

## Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h; blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum can be found at: [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315223018.htm](http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm).

## Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

## Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H. pylori*, *E. coli*, etc.

---

## RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be re-submitted online (<http://www.wjgnet.com/1007-9327/office/>). The author should send the copyright transfer letter, responses to the reviewers, English language Grade B certificate (for non-native speakers of English) and final manuscript checklist to [wjg@wjgnet.com](mailto:wjg@wjgnet.com).

### *Language evaluation*

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

### *Copyright assignment form*

Please download a Copyright assignment form from [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315222818.htm](http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm).

### *Responses to reviewers*

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315222607.htm](http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm).

### *Proof of financial support*

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

### *Links to documents related to the manuscript*

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

### *Science news releases*

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

### *Publication fee*

*WJG* is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1300 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.

### Abstract

Chronic atrophic gastritis (CAG) is an inflammatory condition characterized by the loss of gastric glandular structures which are replaced by connective tissue (non-metaplastic atrophy) or by glandular structures inappropriate for location (metaplastic atrophy). Epidemiological data suggest that CAG is associated with two different types of tumors: Intestinal-type gastric cancer (GC) and type I gastric carcinoid (T I GC). The pathophysiological mechanisms which lead to the development of these gastric tumors are different. It is accepted that a multistep process initiating from *Helicobacter pylori*-related chronic inflammation of the gastric mucosa progresses to CAG, intestinal metaplasia, dysplasia and, finally, leads to the development of GC. The T I GC is a gastrin-dependent tumor and the chronic elevation of gastrin, which is associated with CAG, stimulates the growth of enterochromaffin-like cells with their hyperplasia leading to the development of T I GC. Thus, several events occur in the gastric mucosa before the development of intestinal-type GC and/or T I GC and these take several years. Knowledge of

CAG incidence from superficial gastritis, its prevalence in different clinical settings and possible risk factors associated with the progression of this condition to gastric neoplasias are important issues. This editorial intends to provide a brief review of the main studies regarding incidence and prevalence of CAG and risk factors for the development of gastric neoplasias.

### INTRODUCTION

Chronic atrophic gastritis (CAG) is an inflammatory condition characterized by the loss of gastric glandular structures which are replaced by connective tissue (non-metaplastic atrophy) or by glandular structures inappropriate for location (metaplastic atrophy)<sup>[1]</sup>. Epidemiological data suggest that CAG is associated with two different types of tumors: Intestinal-type gastric cancer (GC) and type I gastric carcinoid (T I GC). The pathophysiological mechanisms which lead to the development of these gastric tumors are different. It is accepted that a multistep process initiating from *Helicobacter pylori* (*H. pylori*)-related chronic inflammation of the gastric mucosa progresses to CAG, intestinal metaplasia, dysplasia, and finally leads to

the development of GC<sup>[2]</sup>. T I GC is a gastrin-dependent tumor and the chronic elevation of gastrin, which is associated with CAG, stimulates the growth of enterochromaffin-like (ECL) cells with their hyperplasia leading to the development of T I GC<sup>[3-5]</sup>.

Considering that several events occur in the gastric mucosa before the development of GC and/or of T I GC, and that these events take several years, the knowledge of CAG incidence from superficial gastritis, its prevalence in different clinical settings and possible risk factors associated with the progression of this condition to gastric neoplasias are important issues.

## EPIDEMIOLOGY OF CHRONIC ATROPHIC GASTRITIS

A recent systematic review was performed with the aim of evaluating the CAG incidence in patients free of CAG at moment of inclusion in the study<sup>[6]</sup>. From published studies, the authors selected only 14 follow-up studies in which CAG diagnosis was carefully made by histology (12 studies) or by serum pepsinogen (PG) levels (2 studies). The CAG incidence rates ranged from 0% to 10.9% per year. This wide CAG incidence range is explained by the particular settings in which the CAG diagnoses were made. In fact, the lowest incidence rates (0%) were found in patients with reflux esophagitis<sup>[7]</sup> and in patients successfully treated for *H. pylori* infection<sup>[8]</sup>. The highest incidence rate was observed in an older study conducted on patients who underwent vagotomy because of ulcer disease<sup>[9]</sup>. Regarding *H. pylori* infection, the CAG incidence rate was higher in *H. pylori*-positive patients than in *H. pylori*-negative ones<sup>[7,10-13]</sup> and the meta-analysis on the association between *H. pylori* infection and CAG incidence presented a rate ratio of 5 (95% CI: 3.1-8.3).

The prevalence of CAG was evaluated by serological screening using surrogate markers of gastric function (PG I or PG I/PG II ratio) or by gastroscopy/histology. In the vast majority of cases, the serological and histological screenings were both made in a general population. Serological studies reported CAG prevalence rates between 3% and 7%, which were lower than those reported by histological ones. Studies on CAG prevalence subdivided on the basis of diagnostic tools used for CAG diagnosis (histology or serology) are shown in Table 1<sup>[14-23]</sup>. The observed differences between serological and histological studies could be explained by the fact that it is likely that symptomatic patients accepted more easily to undergo gastroscopy. Higher rates of CAG prevalence found in the Asian countries may be justified by the fact that these areas are at higher risk of GC and by the fact that the definition of CAG diagnosis may be different between Western and Asian countries. In studies reporting from Asian countries, CAG diagnosis included all atrophic lesions irrespective of the atrophy localization in the gastric mucosa (antrum and/or corpus); in the vast majority of the studies conducted in Western countries, CAG diagnosis included only patients with a corpus atro-

phic involvement such as corpus-atrophic gastritis or a multifocal atrophic gastritis (i.e., patchy areas of atrophic-metaplastic changes in the antral and corpus mucosa), because it is maintained that only corpus atrophic changes can lead to the development of gastric cancer.

## ATROPHIC GASTRITIS AND GASTRIC CANCER

Nowadays, GC represents one of the most challenging tumors due to the fact that its diagnosis is often late and, in the advanced stage, the therapeutic options are scarce with consequent high rate of mortality<sup>[24]</sup>. In fact, although a reduction of global incidence for this neoplasm is reported, it remains the second cause of cancer-related death. The knowledge of precursor lesions for the development of intestinal-type GC could contribute to anticipating GC diagnosis at an early stage when surgery or chemotherapy offers a better prognosis. Several studies have estimated the risk of GC in patients with CAG<sup>[25-33]</sup>. Although the vast majority of these were performed on small numbers of patients and were based on older histological classifications, the progression rate of CAG to GC fluctuates from 0% to 10% with annual incidence (person-year) lower than 1% (Table 2). It is interesting to observe that, although the incidence rate of CAG in patients with superficial gastritis is higher in populations with higher risk of GC (Table 1), the progression rate of CAG towards GC is similar irrespective of different geographic areas.

Some studies have attempted to identify risk factors linked with the progression of precancerous lesions (CAG or intestinal metaplasia) towards GC to select those patients who should undergo endoscopic surveillance.

### Age

Age has been identified as a possible risk factor in several studies. In the study by Leung *et al.*<sup>[40]</sup>, *H. pylori*-positive patients with intestinal metaplasia were followed up for 5 years to evaluate the progression or the improvement of histological lesions after *H. pylori* eradication treatment compared with placebo. At multivariate analysis, the presence of age > 45 years showed an approximate two-fold increased risk of progression of intestinal metaplasia compared to younger subjects<sup>[40]</sup>. This same age limit had already been identified in a screening survey performed on 3386 subjects from a rural Chinese population that showed an approximate three-fold increased risk of progression to GC<sup>[28]</sup>. In a large cohort study, increasing age at initial diagnosis was associated with higher hazard ratio (HR) for the progression to GC (for age > 55 years, HR > 2.38)<sup>[32]</sup>. In a recent work, patients with CAG who were aged > 50 years at the moment of initial diagnosis presented HR = 8.8 for the progression to gastric neoplastic lesions<sup>[33]</sup>.

### Pernicious anemia

<sup>1</sup>This number refers to biopsies taken in 144 patients and includes chronic atrophic gastritis (CAG) with type I, II, III intestinal metaplasia; <sup>2</sup>this number refers to CAG patients with or without intestinal metaplasia. GC: Gastric cancer.

included patients with pernicious anemia, the risk of GC in this particular clinical setting seems to be generally low (Table 2). In fact, this clinical condition is often associated with corpus-restricted gastritis and, as a consequence, with less extensive atrophy in the gastric mucosa. In a recent study, the presence of atrophic pangastritis increased the risk of progression to gastric neoplastic lesions by 4.5 times, in keeping with previous works<sup>[33,41,42]</sup>. The apparent contrast between older and more recent works about pernicious anemia can be explained by the difficulty in comparing studies with methodological differences linked to adopted gastritis classification or small number series. It is interesting to underline the fact that studies on the relationship between pernicious anemia and GC are lacking in Asian countries where the risk of GC is higher, thus it remains to be established whether pernicious ane-

mia has low prevalence in the Asian geographic area or if this condition is overlooked.

### Intestinal metaplasia

Parallel with more extensive atrophy in the gastric mucosa, the extensive replacement of this by intestinal metaplasia is considered a hallmark of severity of CAG. In the literature, the intestinal metaplasia extension was widely related to a higher risk of GC<sup>[32,33,40,42]</sup>. In particular, type III intestinal metaplasia was associated with an increased risk of GC in some studies<sup>[43,44]</sup>, but subsequent studies showed conflicting findings<sup>[45,46]</sup>, thus the clinical utility of different subtyping of intestinal metaplasia is limited.

### Helicobacter pylori

The role of *H. pylori* infection in progression from CAG

to GC is controversial. In the Leung study, *H. pylori*-positive patients who had not undergone eradication therapy had a progression rate of intestinal metaplasia higher than cured patients<sup>[40]</sup>. However, in this study, the vast majority of patients had only a superficial gastritis at baseline and, after 5 years of follow-up, the rate of patients with intestinal metaplasia increased significantly. It is maintained that the effect of eradication therapy on the progression to GC in patients with precancerous lesions is limited. A previous large prospective study demonstrated that *H. pylori* eradication may be beneficial in arresting the progression to GC only in patients without CAG or intestinal metaplasia<sup>[47]</sup>. Two recent meta-analyses showed a beneficial long-term effect of *H. pylori* eradication therapy on atrophic gastritis, but not on intestinal metaplasia<sup>[48,49]</sup>. Up till now, although the possibility of histological improvement of CAG is accepted after *H. pylori* cure, the efficacy of *H. pylori* eradication in reducing GC incidence needs to be demonstrated.

## ATROPHIC GASTRITIS AND TYPE I GASTRIC NEUROENDOCRINE TUMOR

T I GC derives from ECL cells which are localized in the gastric fundus and corpus. ECL cells are specialized in the secretion of histamine that, in turn, stimulates acid secretion by parietal cells<sup>[50]</sup>. Gastric carcinoids have been classified into three subgroups, type I to type III, with different outcomes<sup>[51-53]</sup>. Type I lesions are associated with atrophic gastritis and constitute up to 80% of all gastric carcinoids<sup>[54]</sup>. Gastrin, released by G-cells in the gastric antrum, stimulates the release of histamine and produces trophic effects upon ECL cells<sup>[5]</sup>. In CAG, the loss of appropriate glands in the body leads to achlorhydria, and the consequent chronic hypergastrinemia stimulates ECL hyperplasia and sometimes the development of T I GC<sup>[4,5]</sup>.

The prevalence rate of T I GC in patients with CAG is reported to be between 1% and 12.5% in different studies<sup>[36,37,55-58]</sup>. The wide range of the prevalence rates of T I GC among several studies can be explained by different settings where patients were selected, such as type of hospital (secondary, tertiary center) or symptoms/signs of presentation. CAG can have a wide range of clinical presentations such as dyspepsia, iron deficiency anemia or pernicious anemia<sup>[59]</sup>. In particular, in a recent observational study in which the T I GC incidence and prevalence were evaluated, pernicious anemia was present in almost 50% of patients, while previous studies included exclusively patients with this condition<sup>[60]</sup>.

Long-term observational studies assessing incidence of T I GC in CAG patients are scarce<sup>[35,56,61]</sup>. We recently followed up a cohort of CAG patients for 1463 person-years reporting an annual incidence rate (person-year) for T I GC of 0.4%<sup>[60]</sup>. An old study by Kokkola *et al.*<sup>[35]</sup> reported an annual incidence of 2%, observing 8 new cases of T I GC in 416 patient-years. Sjöblom *et al.*<sup>[61]</sup> studied 196 patients with pernicious anemia and after

1397 patient-years, 2 new cases of T I GC were reported in hospital registries among the initial group of patients. This figure should correspond to an annual incidence rate of 0.1%, but in this study only 70 patients (35.7%) underwent gastroscopy and the incidence rate can only be obtained indirectly. Furthermore, although there are small fluctuations in the reported incidence rates, only a small group of CAG patients develop T I GC showing that factors other than gastrin are necessary for the progression of ECL cells to T I GC.

Few studies have attempted to identify risk factors associated with the development of T I GC. In a recent work, we found higher baseline levels of gastrin and chromogranin A in CAG patients with T I GC compared to those without T I GC. However, all patients with CAG present high plasma values of chromogranin A<sup>[62]</sup> and gastrin, thus these markers have limited clinical utility because of low specificity<sup>[63]</sup>.

An accepted risk factor for T I GC is the presence of ECL dysplasia, which is often associated with T I GC. This lesion is considered as the true gastric carcinoid precursor lesion and it can represent the sign of a concomitant carcinoid lesion<sup>[56,64]</sup>. CAG patients with a diagnosis of ECL cell dysplasia could benefit from a shorter endoscopic follow-up time to exclude concomitant T I GC lesions or to identify newly arisen lesions in the gastric mucosa.

Although T I GC lesions can also be present on flat mucosa, in the vast majority of cases they are associated with the presence of body polyps. In CAG patients, hyperplastic or adenomatous polyps are very common; however, the presence of body polyps increases the risk of having a T I GC<sup>[60]</sup>. Unfortunately, no feature of endoscopic appearance of the gastric polyps (size, number, sessile/pedunculated presentation) seems useful to differentiate histology of polyps, thus all polyps should be removed and histologically examined<sup>[65,66]</sup>.

## CONCLUSION

The risk of development of GC or T I GC appears higher in CAG patients with respect to the general population. In geographic areas with low risk of GC, a surveillance program for all CAG patients may be not cost-effective considering that the vast majority of CAG patients will not develop a gastric neoplasm<sup>[67]</sup>. A subset of CAG patients at higher risk for GC should be identified allowing the selection of those CAG patients in whom gastroscopic/histologic surveillance may be warranted. Recently, an international consensus developed evidence-based guidelines on the management of precancerous conditions and lesions of the stomach, recommending an endoscopic surveillance every 3 years after diagnosis in all patients with extensive atrophy and/or intestinal metaplasia in the antrum and corpus<sup>[68]</sup>. New systems for histopathological staging (OLGA, OLGIM) have been developed with the aim of combining pathological findings with the risk of GC for the patient and to iden-

tify a subgroup of those at higher risk<sup>[69,70]</sup>. The OLGA system includes gastritis grading and staging<sup>[69]</sup>. Grading measures the severity of acute and chronic inflammatory infiltrate in the antrum and body. Staging refers to the extent of atrophy with or without intestinal metaplasia. The OLGIM system is based on intestinal metaplasia which is considered a more reproducible histopathological diagnosis with respect to atrophy diagnosis. Further studies are necessary to validate these new classifications and to establish their real clinical value. Regarding T IGC, although risk factors for its development have not been identified, ENETS guidelines suggest an endoscopic follow-up every 6-12 mo after T IGC diagnosis. This interval allows the identification of recurrent lesions or new lesions (incidence-case) at an early stage when they can easily be removed by polypectomy without complications<sup>[71]</sup>. This approach seems safe for T IGC, a neoplasm with an excellent outcome<sup>[60,72]</sup>.

### Abstract

Pancreatic cancer is one of the most lethal of human malignancies ranking 4th among cancer-related death in the western world and in the United States, and potent therapeutic options are lacking. Although during the last few years there have been important advances in the understanding of the molecular events responsible for the development of pancreatic cancer, currently specific mechanisms of treatment resistance remain poorly understood and new effective systemic drugs need to be developed and probed. *In vivo* models to study pancreatic cancer and approach this issue remain limited and present different molecular features that must be considered in the studies depending on the purpose to fit special research themes. In the last few years, several genetically engineered mouse models of pancreatic exocrine neoplasia have been developed. These models mimic the disease as they reproduce genetic alterations implicated in the progression of pancreatic cancer. Genetic alterations such as activat-

ing mutations in KRas, or TGF $\beta$  and/or inactivation of tumoral suppressors such as p53, INK4A/ARF, BRCA2 and Smad4 are the most common drivers to pancreatic carcinogenesis and have been used to create transgenic mice. These mouse models have a spectrum of pathologic changes, from pancreatic intraepithelial neoplasia to lesions that progress histologically culminating in fully invasive and metastatic disease and represent the most useful preclinical model system. These models can characterize the cellular and molecular pathology of pancreatic neoplasia and cancer and constitute the best tool to investigate new therapeutic approaches, chemopreventive and/or anticancer treatments. Here, we review and update the current mouse models that reproduce different stages of human pancreatic ductal adenocarcinoma and will have clinical relevance in future pancreatic cancer developments.

### INTRODUCTION

Infiltrating ductal adenocarcinoma of the pancreas (PDAC) accounts for over 85% of all pancreatic malignancies and has a poor prognosis as less than 5% of patients survive 5 years after diagnosis with a median survival period of 4-6 mo<sup>[1-3]</sup>. During the last few years there have been important advances to better understand the molecular mechanisms regulating the development of PDAC<sup>[4,5]</sup>. However, prog-

ress in prevention, early diagnosis and treatment needs major advances<sup>[6]</sup>.

Some of the recent advances have been possible by employing mouse models which have provided an important model system to better understand the molecular mechanism underlying pancreatic cancer. However, in stark contrast to the successful murine models of most common human tumors, the generation and use of appropriate mouse models of pancreatic cancer has remained an area of significant frustration and not always well established. Currently, there are several different genetically modified mouse tumors and xenograft models available that offer the possibility of experimental and preclinical model systems to evaluate different strategies for targeting this disease, early detection, chemoprevention, treatment and finally improve the outcome for pancreatic cancer patients<sup>[7]</sup>.

These models use a variety of approaches to target the expression of mutant or endogenous specific genes and as a result they develop a broad spectrum of pathologic changes, some of them mimic human disease while others are not equivalent to human pancreatic neoplasia. According to the cancer progression model postulated by Fearon and Vogelstein<sup>[8]</sup> in 1990, at least 4-5 genetic events are required for the progression from normal epithelium to carcinoma. Since, the genetic basis of pancreatic ductal adenocarcinoma was revealed, with activation of *Kras* and inactivation of the p16INK4a, p53 and Smad4 tumor suppressors<sup>[9]</sup>, several mouse models of invasive pancreatic cancer have been developed and modified. Also, regarding the role of pancreatic intraepithelial neoplasia (PanIN) as a direct noninvasive neoplastic precursor to human pancreatic cancer<sup>[10]</sup>, different mouse models are currently available, some of these models reproduce only PanIN lesions and others progress to invasive pancreatic carcinoma. Most of these models were previously presented and evaluated at the International Workshop sponsored by the National Cancer Institute and the University of Pennsylvania in 2004. Twelve genetically engineered mouse models were included and have been considered models for the study of pancreatic disease including PanINs and carcinomas<sup>[11-18]</sup>. Since then, several new models have been introduced in the basic and translational research fields and previous models have been re-evaluated. Here, we will focus only on pancreatic cancer mouse models as PanIN lesions are considered preinvasive.

Since an activating mutation of the *Kras* oncogene is the most frequent genetic alteration associated with pancreatic cancer, having been identified in up to 90% of all pancreatic adenocarcinomas<sup>[19-21]</sup>, most of the genetically engineered mouse models are based on the *Kras* oncogene. As mice expressing mutant *Kras* develop early and advanced forms of the most common pancreatic cancers in humans, these *Kras*-based models provide preclinical model systems to analyze the molecular biology of this disease and measure the benefit of new therapies<sup>[7,22]</sup>.

In these review, we update and describe the most common genetically engineered mouse and xenograft models of PDAC that could be useful for assessing the

role of genes and pathways, environmental conditions, co-morbidities and response to new adjuvant, neoadjuvant and anti-metastatic therapies.

## TRANSGENIC MOUSE MODELS

As *Kras* mutations are not sufficient to induce progression to the invasive stage of pancreatic adenocarcinoma, different transgenes have been used to generate combined models that progress to invasive PDAC and metastatic disease.

The common genetically engineered models are based on *Kras* mutations and also include PDX-1-Cre/Lox-Stop-Lox (LSL)-*Kras* or p48/LSL-*Kras* mice which have been modified with deletions or mutations of *Ink4*<sup>[23]</sup>, *p53*<sup>[24]</sup>, *Mist*<sup>[25]</sup>, *Smad4*<sup>[26]</sup> or *TGFβ*<sup>[27]</sup> (Table 1).

These *Kras*-mutated models can be induced using inducible alleles of Cre recombinase, such as estrogen receptor-Cre fusion genes (*CreER* or *CreERT*) and cycline-responsive Cre expression alleles (TRE-Cre) which are temporally expressed and initiate the expression in adult pancreata reflecting the somatic mutation as it occur in humans<sup>[28,29]</sup>. Also, some models that only develop PanIN lesions are available as *Ela-LSL-Kras*<sup>G12D</sup><sup>[12]</sup>, *Nestin-Cre, LSL-Kras*<sup>G12D</sup><sup>[30]</sup>, *PDX-1-CRE<sup>ERT</sup>, LSL-Kras*<sup>G12D</sup>, *R26Notch<sup>NIC</sup>*<sup>[31]</sup> and *PDX-1-CRE, LSL-Kras*<sup>G12D</sup>, *Tif1β<sup>lox/lox</sup>*<sup>[32]</sup>, however, these are not the purpose of our review.

### ***PDX1-Cre, LSL-Kras<sup>G12D</sup> and P48<sup>+/Cre</sup>, LSL-Kras<sup>G12D</sup> transgenic model***

After different studies identified PDX-1 and p48 as critical transcription factors in the developmental program of the pancreas<sup>[21,33]</sup>, these genes have been used in almost all transgenic mouse models to study pancreatic cancer. It is well known that the first identifiable pancreatic progenitor cell in the pancreas arises in the dorsal and ventral endoderm at embryonic day 8 in the fetal mouse: expression of PDX-1 occurs around E8.5<sup>[34]</sup> and P48 is expressed slightly later and is required to commit cells to a pancreatic fate<sup>[35]</sup>.

In addition, Ptf1a, a component of the pancreas transcription factor 1 complex (Ptf1) which plays an important role in mammalian pancreatic development has been used in some mouse models. Pdf1a determines whether cells allocated to the pancreatic buds continue towards pancreatic organogenesis or revert to duodenal fates<sup>[36,37]</sup>. To target the expression of oncogenic *Kras* in pancreatic progenitor cells, a conditionally expressed allele was constructed as previously described by Jackson *et al*<sup>[38]</sup>.

Briefly, the targeting vector contains genetic elements inhibiting transcription and translation flanked by functional LoxP sites. This Lox-Stop-Lox (LSL) construct was inserted into the mouse genomic *Kras* locus upstream of locus 1 to contain G-A transition in codon 12 (G12D). This transition mutation results in a glycine to aspartic acid substitution in the expressed protein that activates constitutive downstream signaling of Ras effector pathways and is one of the most common mutations found in human pancreatic tumors.

Table 1 Mouse models of pancreatic adenocarcinoma

Genotype (reference)	Time of expression	Time to tumor development (mo)	Pancreatic cancer phenotype	Survival (mo)
PDX-1-Cre; LSL-Kras <sup>G12D</sup> [22]	E8.5	6	PDAC; penetrant PanIN; age dependent increase severity; occasionally PDAC with long latency	16
P48 <sup>+/-Cre</sup> ; LSL-Kras <sup>G12D</sup> [22]	E9.5	8	PDAC; penetrant PanIN; age dependent increase severity; occasionally PDAC with long latency	16
PDX-1-Cre; LSL-Kras <sup>G12D</sup> ; LSL-Trp53 <sup>R172H/-</sup> [8]	E8.5	2-3	PDAC	5-6
Mist1 <sup>KrasG12D/+</sup> [9]	E10.5	2	Accelerated PanIN; well differentiated PDCA	10.8
KPCB <sup>wt/wt</sup> [25]	E8.5	2-3	PDAC	5.6

PDAC: Ductal adenocarcinoma of the pancreas; PanIN: Pancreatic intraepithelial neoplasia; IPMN: Intraductal papillary mucinous neoplasia.

Hingorani *et al.*<sup>[39]</sup> developed a mouse model expressing a Cre-activated Kras<sup>G12D</sup> allele inserted into the endogenous Kras locus, and these mice were crossed with mice expressing Cre recombinase in pancreatic tissue, either by virtue of a PDX-1 promoter-driven transgene or by Cre knockin at the Ptf1-p48 locus. Prior lineage studies suggest that both of these lines express Cre in a common endocrine/exocrine precursor cell during development, while expression in adults is retained in mature islet cells in the case of PDX-1-Cre transgenics and in mature acinar cells in the case of the Ptf1-p48+/Cre knockin<sup>[35]</sup>.

The subsequent recombination resulted in interbreeding LSL-Kras<sup>G12D</sup> mice with animals that express Cre recombinase from the pancreatic-specific promoters PDX-1 or P48 is a heterozygous mutant condition (KRAS<sup>+G12D</sup>). Note that only genomic DNA isolated from pancreata and not from tails evidence the recombination. The mutant mice PDX-1-Cre, LSL-Kras<sup>G12D</sup> and P48<sup>+/-Cre</sup>, LSL-Kras<sup>G12D</sup> have increased Kras oncogenic protein and their pancreata are larger than their wild type littermate controls.

The pancreata of compound mutant mice develop ductal lesions identical to all three stages of human PanINs. PanIN-1A lesions are observed in compound mutant mice as young as 2 wk old. As the mice age, higher-grade PanINs were observed with increasing frequency and in many of the older mice, the pancreata contained extensive ductal lesions and the acinar parenchyma was replaced by stromal or desmoplastic fibroblasts and inflammatory cells. This fibroinflammatory reaction is highly reminiscent of that seen in human pancreatic cancers. PanIN lesions show evidence of histologic progression and it has been demonstrated that these PanINs activate quiescent pathways such as Notch. These mice have increased Hes1 and Cox2, components of the prostaglandin pathway involved in the inflammatory response and increased ma-

trix metalloproteinase-7. Finally, at low frequency these mice progress to invasive and metastatic ductal adenocarcinoma within one year. In these mice, profuse hemorrhagic ascites was noted, the pancreas was large, firm and fibrotic and nodular densities were observed in liver, diaphragm, pleural surfaces and adrenal cortex.

This model developed by Hingorani *et al.*<sup>[39]</sup> shows progressive PanIN lesions and low-frequency progression to invasive and metastatic adenocarcinoma following activation of oncogenic K-Ras in mouse pancreas. The physiopathology and the sites of metastases observed in these mice are precisely found in human pancreatic ductal adenocarcinoma and further underscore the applicability of this model to study the human disease.

#### **PDX-1-Cre, LSL-Kras<sup>G12D</sup>, LSL-Trp53<sup>R172H/-</sup> transgenic model**

This mouse model was generated based on the previously described PDX-1-Cre, LSL-Kras<sup>G12D</sup> mouse. Using similar methods, Hingorani *et al.*<sup>[24]</sup> generated a conditionally expressed point mutant allele of the Li-Fraumeni human ortholog, Trp53<sup>R175H</sup><sup>[40]</sup>. Activation of both the Kras<sup>G12D</sup> and the Trp53<sup>R172H</sup> alleles occurs in tissue progenitor cells of the developing mouse pancreas through interbreeding with PDX-1-Cre transgenic animals. The presence of each rearranged, activated allele can be detected in the pancreata but not in tails. Thus, tissues not expressing Cre recombinase (non-pancreatic tissue) remain functionally heterozygous for these loci.

Four to six weeks old mice PDX-1-Cre, LSL-Kras<sup>G12D</sup>, LSL-Trp53<sup>R172H/-</sup> present early PanIN lesions similar to what it is observed in single PDX-1-Cre, LSL-Kras<sup>G12D</sup> mice. A significant disease burden is observed in animals by ten weeks of age at the earliest and the full spectrum of preinvasive lesions is apparent. Histological analyses reveal a predominant moderately well-differentiated to well-differentiated morphology organized as is observed

in the human disease. The carcinomas express CK19 and frequently contain mucin. Metastasis to the liver and lungs are similar to the pancreatic primaries. Finally, PDX-1-Cre, LSL-Kras<sup>G12D</sup>, LSL-Trp53<sup>R172H/-</sup> mice have dramatically shortened median survival of approximately 5 mo, significantly less than wild type, PDX-1-Cre, LSL-Trp53<sup>R172H/-</sup> and PDX-1-Cre, LSL-Kras<sup>G12D</sup>.

The triple mutant mice succumb earlier than PDX-1-Cre, LSL-Kras<sup>G12D</sup> animals which spontaneously develop PDA with a proscribed latency after manifesting preinvasive neoplasia. These triple mutant animals develop cachexia, abdominal distension, and hemorrhagic ascites. They also present metastasis in the liver, diaphragm and adrenals and all of them die before 12 mo.

### **PDX-1-Cre, Brca2<sup>F11</sup>, LSL-Kras<sup>G12D</sup>, Trp53 F2-10 transgenic model**

This transgenic mouse is a conditional Brca2<sup>F11</sup>, LSL-Kras<sup>G12D</sup>, Trp53 F2-10 and PDX-1-Cre and has been used as a model of pancreatic cancer, although the role of Brca2 in pancreatic cancer development is still unclear<sup>[41,42]</sup>. Brca2 plays a key role in the maintenance of genomic integrity, particularly through regulation of DNA repair by homologous recombination repair<sup>[43]</sup>, a process that is also controlled by another tumor suppressor protein, Brca1<sup>[44]</sup>. However, the significance of Brca2 in pancreatic cancer is not clear<sup>[45]</sup>.

While Rowley *et al.*<sup>[41]</sup> demonstrated that the inactivation of Brca2 promotes Trp53-associated but inhibits Kras<sup>G12D</sup>-dependent pancreatic cancer development in mice, Skoulidis *et al.*<sup>[42]</sup> showed that Brca2 heterozygosity promotes Kras<sup>G12D</sup>-driven carcinogenesis in the murine model of familial pancreatic cancer. In this model, the mouse expressed a functional wild type *Brca2* gene, in which exon 11 of Brca2 is flanked by loxP sites (B2<sup>F11</sup>). Conditional rearrangement of this allele in the developing pancreas in response to PDX-1-Cre expression results in the deletion of Brca2 exon 11, and the generation of a functionally null Brca2 allele (B2<sup>Δ11</sup>). These authors crossed CB2<sup>Δ11/Δ11</sup> mice with conditional Trp53F2-10/F2-10 (P) mice, in which exons 2 and 10 are flanked by loxP sites to generate Trp52 null CPB2<sup>Δ11/Δ11</sup>, CPB2<sup>wt/Δ11</sup> and CPB2<sup>wt/wt</sup> mice.

CPB2<sup>Δ11/Δ11</sup> mice develop pancreatic cancer at high frequency and their median survival is 300 d, showing substantially reduced pancreatic cancer-free survival relative to CB2<sup>wt/Δ11</sup>. However, in contrast, CB2<sup>Δ11/Δ11</sup>, CB2<sup>wt/Δ11</sup> and CB2<sup>wt/Δ11</sup> mice expressing wild type Trp53 alleles failed to develop pancreatic cancer.

This mouse model shows that the inactivation of Brca2 alone does not promote pancreatic cancer, but the disruption of Trp53 signaling in combination with the inactivation of Brca2 promotes pancreatic cancer formation. CPB2<sup>Δ11/Δ11</sup> mice display severe acinar cell dysplasia and a reduced number of islets. The pancreas is atrophic with acini replaced by mature adipose tissue, inflammatory infiltrates and little evidence of fibrosis. In contrast, in CPB2<sup>wt/Δ11</sup> and CPB2<sup>wt/wt</sup> mice the dysplasia, atrophy

and chronic inflammatory infiltrate is less severe and frequent<sup>[41]</sup>. The mouse model combining Brca2<sup>F11</sup> and LSL-Kras<sup>G12D</sup> (K) shows that CKB2<sup>Δ11/Δ11</sup>, CKB2<sup>Δ11/Δ11</sup> and CKB2<sup>wt/wt</sup> mice display normal development although CKB2<sup>wt/Δ11</sup> and CKB2<sup>wt/wt</sup> present PanINs and metaplastic lesions at 8 mo but not CKB2<sup>Δ11/Δ11</sup>. This mouse model showed that the loss of Brca2 tumor suppressor inhibits the development of premalignant lesions and pancreatic tumors that are induced by activated Kras. Only 13% of CKB2<sup>Δ11/Δ11</sup> mice develop tumors, whereas 66% of CKB2<sup>wt/Δ11</sup> and 61% of CKB2<sup>wt/wt</sup> develop pancreatic tumors with an average latency of 366 and 406 d, respectively<sup>[41]</sup>.

Skoulidis *et al.*<sup>[42]</sup> described a mouse model PDX-1-Cre-Kras<sup>G12D</sup> with two distinct mutant alleles of Brca2. The first encodes a germline truncating allele Brca2<sup>Tr</sup> (Tr), that mimics Brca2 human mutations in pancreatic cancer, and the second is a conditional deletion (F11) in which LoxP sites flank Brca2 exon 11 and emulates the loss of heterozygosity observed in human cancers.

Homozygous Brca2 inactivation in KPCB2<sup>Tr/Δ11</sup> mice displays pancreatic cancer in high penetrance with rapid and predictable clinical decline. The median survival was 84 d compared with the KPCB cohort whose median survival was 168 d. Mice with germline heterozygosity for Brca2<sup>Tr</sup> display pancreatic carcinogenesis, as even KCB<sup>Tr/wt</sup> mice with wild type Trp53 and mutant Kras-G12D in which pancreatic cancer is reported to develop less readily<sup>[39]</sup>. There is a reduction in PDAC-free survival of KCB<sup>Tr/wt</sup> mice in comparison with KCB controls with wild type Brca2. The pancreatic tumors observed in these mice display histological features similar to human pancreatic cancers with desmoplastic stroma. These tumors evolved with pancreatic intraepithelial neoplasia and metastatic behavior.

Interestingly, the KPCB<sup>Tr/Δ11</sup> mice which carry biallelic Brca2 mutations uniquely develop an acinar cell carcinoma component in 18% of cases, not observed in the other cohorts with Brca2 heterozygosity. This model shows that Brca2 inactivation promotes Kras-driven pancreatic malignancies<sup>[42]</sup>.

### **Mist1<sup>KrasG12D/+</sup> transgenic model**

To generate this transgenic model, Tuveson *et al.*<sup>[25]</sup> used homologous recombination to target the expression of Kras<sup>G12D</sup> to the Mist1 locus, a gene known to be expressed at earlier stages of pancreatic exocrine development. Mist1 is a basic helix-loop-helix transcription factor that is expressed at low levels in the embryonic pancreas at day 10.5<sup>[43,46,47]</sup> and in the adult, Mist protein is restricted to mature pancreatic acinar cell and is not found in ductal or islet cells<sup>[48,49]</sup>. Mist1<sup>KrasG12D/+</sup> mice have a diminished median survival of 10.8 mo compared with 24.2 mo in control wild type mice. Newborn mice show acinar hyperplasia with an increased proliferative index and acinar adenomas at 2 mo known as “acinar-ductal metaplasia”. Metaplastic ductal structures with mucinous cytoplasm that resemble murine PanIN-IA are found in the pancreas in close association with metaplastic acini. These metaplastic ducts are

characterized by the presence of CK19 and acidic mucin staining with alcian blue. At three months of age they become cachectic with pancreatic tumors and metastasis. Most of these tumors are acinar although some of them are cystic papillary neoplasms with acinar differentiation. Surprisingly, these mice also develop early and advanced hepatocellular carcinoma and some of them succumb before invasive pancreatic carcinoma.  $Mist1^{KrasG12D/+}$  mice die of advanced pancreatic exocrine carcinoma.

#### **PDX1-Cre, $Kras^{G12D}$ , $Ink4a/Arf^{flox/flox}$ transgenic model**

As the loss of function of the G1 cyclin-dependent kinase inhibitor, INK4A, appears to be a near universal event in pancreatic adenocarcinoma when there is an alternate reading frame or distinct first exon in the INK4A/ARF locus<sup>[50-52]</sup>, transgenic mice with this modification have been studied.

It was shown that mice with a constitutive deletion of both or either component of the  $Ink4a/Arf$  locus do not develop spontaneous pancreatic cancer<sup>[53]</sup>. Aguirre *et al.*<sup>[23]</sup> demonstrated the cooperative interaction between  $Ink4$  and  $Kras$  using mice engineered with Cre-mediated activation of mutant  $Kras$  ( $Kras^{G12D}$ ) and the deletion of a conditional  $Ink4/Arf$  tumoral suppressor allele.

In this model, the LSL- $Kras^{G12D}$  allele is expressed at the endogenous level after Cre mediates the expression of a transcriptional stopped element. The conditional  $Ink4a/Arf$  allele ( $Ink4/Arf^{flox}$ ) was engineered to sustain Cre-mediated excision of exon 2 and 3, thereby eliminating p16<sup>Ink4</sup> and p19<sup>Arf</sup> proteins. The double engineered mouse expressed the  $Kras^{G12D}$  allele and lack of both copies of the conditional  $Ink4/Arf$  allele specifically in the pancreas after using the PDX-1-Cre transgene. Between 7 and 11 wk of age, PDX-1-Cre,  $Kras^{G12D}$   $Ink4a/Arf^{flox/flox}$  mice show weight loss, ascites, jaundice and pancreatic tumors ranging in diameter from 4 to 20 mm. These pancreatic tumors are highly invasive, frequently involving the duodenum, stomach and spleen but no liver or lung metastasis. Furthermore, invasion of the lymphatic and vascular system is detected, an observation suggestive of metastatic potential of these neoplasms.

Consistent with a ductal phenotype, the tumors are positive for CK-19, DBA lectin and show stromal collagen deposition. In contrast, they do not show reactivity for amylase and insulin.

In conclusion,  $Kras^{G12D}$  expression in combination with  $Ink4a/Arf$  deficiency resulted in an earlier appearance of PanIN lesions and these neoplasms progressed rapidly to highly invasive and metastatic cancers, resulting in death in all cases by 11 wk.

#### **PDX1-Cre, $Kras^{G12D}$ , $Smad4^{flox/flox}$ transgenic model**

Although selective SMAD4 has no discernable impact on pancreatic development or physiology, when combined with the activated  $KRAS^{G12D}$  allele, SMAD4 deficiency enabled rapid progression of  $Kras^{G12D}$ -initiated neoplasms including pancreatic tumors. The combination of  $Kras^{G12D}$  and SMAD4 deficiency resulted in the rapid development

of tumors resembling intraductal papillary mucinous neoplasia (IPMN), a precursor to PDAC in humans. The SMAD4 tumor suppressor gene encodes a transcription factor that is a central effector of transforming growth factor- $\beta$  (TGF- $\beta$ )<sup>[50]</sup> and inactivating mutations in this gene are common in PDAC<sup>[54]</sup>. Bardeesy *et al.*<sup>[55]</sup> generated a conditional knockout allele of  $Smad4$  ( $Smad4^{lox}$ ) harbouring loxP sites flanking exons 8 and 9 in the mouse germline. They crossed  $Smad4^{lox}$  homozygous mice to either the PDX1-Cre or Ptf1a-Cre transgenic mice. Mice with a homozygous deletion of  $Smad4$  in the pancreas showed no evidence of any gross anatomic or physiological abnormalities, and exhibited normal pancreatic cytoarchitecture and differentiation.

In contrast, LSL- $Kras^{G12D}$ - $Smad4^{lox/lox}$  mice showed low-grade PanINs and acinar-ductal metaplasia from 4 wk of age, an abdominal mass between 7 and 12 wk and reached terminal morbidity between 8 and 24 wk of age and a tumor-free survival of 13-15 wk. The pancreatic tumors were positive for cytokeratin 19, Shh, Hes1, phospho-stat3, mucin, Muc1, Muc4 and Muc5AC, but lacked acinar (amylase) and islet (insulin) marker expression. Mice showed palpable abdominal masses between 7 and 12 wk of age, and reached terminal morbidity between 8 and 24 wk of age.

Since the combination of  $Kras^{G12D}$  expression and  $Smad4$  deletion showed a rapid onset of IPMN and advanced PanIN lesions, but exhibited only moderate pancreatic malignant progression, and since SMAD4 loss occurs with concurrent INK4A loss and  $Kras$  activation in human PDAC, the authors developed a transgenic mouse PDX1-Cre,  $Kras^{G12D}$   $Ink4a/Arf^{flox/lox}$   $Smad4^{lox/lox}$ . These mice have significantly reduced survival, around 8 wk associated with PDAC and a small number of them also have IPMN and liver metastasis.

#### **Ptf1a<sup>cre/+</sup>, LSL- $Kras^{G12D/+}$ , $Tgfb2^{flox/flox}$ transgenic model**

TGF- $\beta$  signaling plays an important role in PDAC progression, as indicated by the fact that  $Smad4$ , which encodes a central signal mediator downstream from TGF- $\beta$ , is deleted or mutated in 55% of human PDAC<sup>[54,56-58]</sup>. Pancreas-specific  $Tgfb2$  knockout mice have also been generated, alone or in the context of active  $Kras^{G12D}$  expression. Ijichi *et al.*<sup>[27]</sup> crossed the LSL- $Kras^{G12D/+}$  mice with  $Tgfb2$  knockout mice<sup>[59]</sup> (previously developed) and generated mice of the genotype Ptf1a<sup>cre/+</sup>, LSL- $Kras^{G12D/+}$ ,  $Tgfb2^{flox/flox}$ . These mice had active  $Kras^{G12D}$  expression plus  $Tgfb2$  knockout both in a pancreas epithelium-specific manner.

Ptf1a<sup>cre/+</sup>,  $Tgfb2^{flox/flox}$  mice did not have pancreas development effects or discernable pancreatic cancer phenotype during 1.5 years.

In contrast, Ptf1a<sup>cre/+</sup>, LSL- $Kras^{G12D/+}$ ,  $Tgfb2^{flox/flox}$  mice had abdominal distension due to ascites, weight loss, and jaundice at 6-7 wk of age. Finally, these mice developed well-differentiated PDAC with 100% penetrance and a median survival of 59 d. Tumors are always accompanied by a whole panel of mPanINs and acinar-ductal metapla-

sia lesions from 3.5 wk and mice frequently have liver and lung metastases, direct invasion to the duodenum, and peritoneal dissemination.

While Ptf1a<sup>cre/+</sup>, LSL-Kras<sup>G12D/+</sup>, Tgfr2<sup>fllox/+</sup> mice show normal pancreas histology, tumors from Ptf1<sup>acre/+</sup>, LSL-Kras<sup>G12D/+</sup>, Tgfr2<sup>fllox/fllox</sup> mice exhibited uniformly well-differentiated glandular architecture, which occupied the entire pancreas, resulting in almost complete loss of normal pancreatic tissue. Tumoral cells show positive ductal markers, CK19 and mucin, and are negative for the acinar and islet markers, amylase and insulin, indicating ductal adenocarcinoma. In addition, these tumors are rich in stromal component, positive for vimentin and smooth muscle actin staining.

In conclusion, Tgfr2 knockout mice combined with Kras<sup>G12D</sup> expression developed well-differentiated PDAC with 100% penetrance and a median survival of 59 d. Moreover, a distinct and important feature of this mouse model is that the Ptf1a<sup>cre/+</sup>, LSL-Kras<sup>G12D/+</sup>, Tgfr2<sup>fllox/fllox</sup> tumors did not show sarcomatoid architecture, which was seen in one-third of the KrasG12D, Ink4a/Arf knockout model<sup>[23]</sup>.

## XENOGRAFT MOUSE MODELS

Tumor xenograft mouse models have been commonly used in preclinical studies for the last few years<sup>[60-62]</sup>. Human tumor xenograft models are created by the injection of human tumor cells grown from culture into a mouse or by the transplantation of a human tumor mass into a mouse. The xenograft may be readily accepted by immunocompromised mice such as athymic nude mice or severely compromised immunodeficient mice<sup>[63]</sup>. Xenografts show different advantages as they mimic genetic and epigenetic abnormalities that exist in tumors, can be used in the development of individualized molecular therapeutic approaches and can be implanted into the same organ to reproduce the organ microenvironment or the tumor<sup>[63]</sup>.

There are two main types of human xenograft mouse models used for pancreatic cancer research, heterotopic and orthotopic, defined by the location of the implanted xenograft.

### Heterotopic xenograft model

For heterotopic subcutaneous models, the xenograft is implanted between the dermis and underlying muscle and is typically located on the flank, on the back or the footpad of the mice. For many years, the subcutaneous xenograft model has been the most widely used preclinical mouse model for cancer research because it is rapid, inexpensive, reproducible, and has been considered sufficiently preclinical to test anti-cancer drugs. The subcutaneous model also has the advantages of providing visual confirmation that mice used in an experiment have tumors prior to therapy; and provides a means of assessing tumor response or growth over time, compared to intracavitary models where animal survival is the sole measure

of response<sup>[64]</sup>.

Different studies have used tumor engraftment in nude mice to study the possible response to chemotherapy treatment such as gemcitabine<sup>[65]</sup> or new pharmacological blocking agents<sup>[66]</sup> obtaining good results and suggesting new potential treatment options for pancreatic cancer.

One of the disadvantages of the heterotopic model is that it was observed that drug regimens that are curative in these models often do not have a significant effect on human disease as the subcutaneous microenvironment is not relevant to that of the organ site of primary or metastatic disease. Additionally, subcutaneous tumor models rarely form metastases. These observations suggest that heterotopic tumor models that do not represent appropriate sites for human tumors are not predictive when used to test responses to anti-cancer drugs<sup>[60,67,68]</sup>.

### Orthotopic xenograft model

Orthotopic tumors are transplanted to the appropriate organ in the mouse. For example, human pancreatic cancer cells are injected into the mouse pancreas and not into the skin on the mouse's back. Advantages of orthotopic models include use of the relevant site for tumor-host interactions, the development of metastases, the ability to study site-specific dependence of therapy, organ-specific expression of genes and the clinical scenario can be replicated. Major disadvantages are that orthotopic tumor xenograft generation is labor intensive, technically challenging, expensive, requires longer healing and recovery time and that monitoring tumor volume requires relatively lower throughput imaging methods<sup>[67]</sup>. Nonetheless, orthotopic tumor models are emerging as the preferred model for cancer research due to the increased clinical relevance.

To study pancreatic cancer, the standard procedure uses anesthetized mice 6-8 wk old. The abdominal skin and muscle are incised just off the midline and directly above the pancreas to allow visualization of the pancreatic lobes; the pancreas is gently retracted and positioned to allow direct injection of tumoral cells. The pancreas is replaced within the abdominal cavity; and both the muscle and skin layers are closed with surgical glue. Following recovery from surgery, mice are monitored and weighed daily to evaluate the tumor or response to treatment<sup>[61]</sup>.

These models have been employed to study gene expression profiling of liver metastases and tumour invasion in pancreatic cancer<sup>[69]</sup> in basic research. In translational medicine, orthotopic models have been used to evaluate the antitumor efficacy of gemcitabine plus emodin<sup>[70]</sup>.

In conclusion, different *in vivo* models of pancreatic cancer have been developed for the evaluation of multiple chemotherapeutic drugs and to study the molecular mechanisms implicated in resistance to different treatments.

These models are now available to investigate basic and translational aspects, but multiple considerations should be kept on mind for model selection depending on the purpose. The optimal model system should investigate

**Table 2** Comparison of mouse models for the clinical approach in pancreatic cancer

Mouse model	Cost	Time consuming	Clinical approach	Clinical reproducibility (human disease)
Transgenic engineered	++++	++++	+	++++
Xenograft heterotopic	+	+	++++	+
Xenograft orthotopic	++	++	+++	++

+: Low; ++: Medium; +++: High; ++++: Very high.

invasiveness or metastasis, the criteria for assessing response and altered molecular pathways, expression of markers and time expression and tumor development are some of the most important factors (Table 2).

### Abstract

Any prognosis of gastrointestinal (GI) cancer is closely related to the stage of the disease at diagnosis. Endoscopic submucosal dissection (ESD) and *en bloc* endoscopic mucosal resection (EMR) have been performed as curative treatments for many early-stage GI lesions in recent years. The technologies have been widely accepted in many Asian countries because they are minimally invasive and supply thorough histopathologic evaluation of the specimens. However, before engaging in endoscopic therapy, an accurate diagnosis is a precondition to effecting the complete cure of the underlying malignancy or carcinoma *in situ*. For the past few years, many new types of endoscopic techniques, including magnifying endoscopy with narrow-band imaging (ME-NBI), have emerged in many countries because these

methods provide a strong indication of early lesions and are very useful in determining treatment options before ESD or EMR. However, to date, there is no comparable classification equivalent to "Kudo's Pit Pattern Classification in the colon", for the upper GI, there is still no clear internationally accepted classification system of magnifying endoscopy. Therefore, in order to help unify some viewpoints, here we will review the defining optical imaging characteristics and the current representative classifications of microvascular and microsurface patterns in the upper GI tract under ME-NBI, describe the accurate relationship between them and the pathological diagnosis, and their clinical applications prior to ESD or *en bloc* EMR. We will also discuss assessing the differentiation and depth of invasion, defying the lateral spread of involvement and targeting biopsy in real time.

### INTRODUCTION

Gastrointestinal (GI) cancer is a major medical and economic burden worldwide. Esophageal and gastric cancers remain a considerable source of morbidity and mortality in Asian countries. For instance, in Linxian, Henan province (China), cancer of the upper GI tract is endemic.

Mortality rates for esophageal cancer in Linxian exceed the American average (for white men) one hundredfold<sup>[1]</sup>. The prognosis of GI cancer is closely related to the stage of disease at diagnosis, and most cases are still detected at advanced stages and result in a relevantly poor outcome<sup>[2]</sup>. Early detection of these neoplasms or their precursors may be the only chance to reduce this high mortality.

Early GI cancers - such as Barrett's esophagus (BE) with high-grade dysplasia and early gastric cancer (EGC)- whose invasion is limited to the mucosa or submucosa regardless of the size or the presence of regional lymph-node and distant metastasis<sup>[3]</sup>, confer a survival rate of greater than 90% in 5 years in many centres<sup>[4,5]</sup>.

The screening program for gastric cancer in Japan indicates that 53% of diagnosed gastric cancers are localized lesions. Additionally, the accumulated clinical experience and formal outcome studies have shown that the majority of early-stage neoplastic lesions is localized with a low risk of lymph node metastasis. Recent data from 3261 patients who underwent gastrectomy with meticulous D2-level lymph node dissection over a 30-year period show that lymph node invasion was observed in only 2.7% of mucosal tumors and 18.6% of EGC invading the submucosa<sup>[6]</sup>. Clinical experience suggests that complete resection of the cancer is possible, and a cure can be achieved as long as the potential for metastatic spread is definitively excluded<sup>[7,8]</sup>.

Based on the above knowledge, the doctors began to try to use endoscopes for local excision with GI early tumors *in situ*, invading lamina propria or submucosa. More than a decade ago, endoscopic mucosal resection (EMR) technique emerged first in Japan as a critical tool in the management of patients with both high-grade dysplasia and superficial carcinomas<sup>[9]</sup>. But the indication of EMR is generally limited to mucosal tumors less than 2 cm in size even with the series of improvements that have been most widely used in recent years, such as using a transparent cap-fitted endoscope to suck targeted lesions into the cap and resect them with a snare (EMR-C) or a ligation device (EMR-L). All above EMR technologies are difficult to resect *en bloc* tumors larger than 2 cm in size, which is required for accurate and reliable pathological examination. However, though some endoscopists adopt piecemeal EMR techniques in order to cure the larger lesions, further investigation has revealed it involves problems such as remnants or high recurrent rates due to incomplete resections<sup>[10]</sup>. Thus, to overcome the problem of EMR techniques, a recent key issue in the field of therapeutic endoscopy is the development of a new therapeutic strategy for early GI cancers using endoscopic submucosal dissection (ESD). In this procedure, submucosal dissection is carried out by using an electrocautery knife to acquire a single-piece specimen, which is the gold-standard technique for offering *en bloc* resection of large superficial tumors in the GI tract, especially when R0 resection cannot be performed with other resection techniques. Within only a few years, ESD has become widespread in Asian countries - such as Japan, Korea and China - where there is a large volume of early upper GI

lesions that need endoscopic treatment. However, there are hardly any reports about long-term results after ESD, and the procedure involves a much higher complication rate and requires much higher skills<sup>[11,12]</sup>.

The two endoscopic local procedures are increasingly accepted by many patients and doctors mainly because they (1) **provide new alternatives for minimal invasiveness**; (2) **are perhaps the first approximations to true intraluminal resection of superficial malignant GI neoplasms**; and (3) **yield results that are comparable to surgery**. They also result in lower morbidity rates, lower costs and better quality of life than traditional surgery because of tissue preservation. But the difficulty lies in achieving *en bloc* or R0 resection and getting improved survival that precisely assesses resection margins and the depth of malignant invasion prior to performing EMR or ESD. The lesions with undifferentiated histology, lymphatic or vascular involvement and submucosal invasion were excluded due to possible lymph node metastases<sup>[5]</sup>.

Therefore, a thorough preoperative endoscopic examination is considered necessary for selecting the appropriate therapeutic modality. Due to this requirement, endoscopic equipment has improved markedly with respect to resolution in recent years. However, in 1967, Okuyama *et al*<sup>[13]</sup> produced a magnification endoscope for viewing the gastric mucosa. At present, magnification endoscopes have the ability to enlarge the image from 1.5 × to 150 × and produce images that have pixel densities as high as 850 000, allowing the discrimination of objects that are only 10-71 μm in diameter<sup>[14]</sup>. The newest magnification endoscopes permit magnification without loss of resolution<sup>[15]</sup>. Nevertheless, it was reported recently that some GI disorders, such as intestinal metaplasia, often appear translucent when observed with magnification endoscopy alone. Thus, the mucosal surface cannot be easily examined without staining<sup>[16]</sup>. Methylene blue, Lugol's iodine, and indigo carmine are several topical stains or pigments that have been used in conjunction with magnification endoscopy to improve tissue localization, characterization, or diagnosis during endoscopy<sup>[17]</sup>. The technique known as magnification chromoendoscopy (MCE) has been applied in a variety of clinical settings and throughout the GI tract for more than 10 years. In addition, other newer technologies, including narrow band imaging (NBI), that have proved particularly helpful during gastrointestinal endoscopic examinations have been developing in recent years. This shows that the two techniques have a similarly high sensitivity for detecting early neoplasia in the upper GI tract<sup>[18,19]</sup>. However, compared with MCE, the "electronic dyeing endoscopy," such as NBI, that are based upon the phenomenon that the depth of light penetration depends on its wavelength, are more user-friendly because their filters can be manually enabled and disabled during endoscopy, making it easy to switch them between the standard mode and the "electronic dyeing" mode, and no staining agents are required. Beyond these practical advantages, NBI reveals the superficial capillary network with a high contrast due to absorption of the blue light by hemoglobin, whereas the vascular pattern is

often less visible in chromoendoscopy<sup>[20]</sup>. When magnifying endoscopy is combined with narrow band imaging (ME-NBI), the combination has been shown to enhance visualization of the micromucosal and microcirculatory structure for a more detailed assessment of the early lesions<sup>[21]</sup>.

Hence, in many institutions, especially in Japan, MCE or the ME-NBI technique has been extensively included in standardized procedure and is performed in addition to conventional white-light endoscopy prior to ESD or EMR<sup>[22]</sup>. For the colorectum, “Kudo’s Pit Pattern Classification” has begun to be widely adopted by many endoscopists because it appeared valuable in the histological prediction from the observation of five-types pit patterns by MCE or NBI-although the microvascular observation is helpful as well<sup>[23]</sup>. In the upper GI, despite numerous studies from investigators around the world and especially in some Asian countries, there is still no consistent classification diagnosis system for ME-NBI before the endoscopic removal of esophageal and gastric lesions; each medical institution tends to adopt its own classification<sup>[24-36]</sup>. Therefore, here we will comprehensively review the literature in recent years on the main characteristics of microsurface (MS) and microvascular patterns, introduce their classifications that have become relatively popular in some Asian countries under ME-NBI, describe the accurate relationship between them, the pathological diagnosis for early lesions in the upper GI tract, and their clinical utility in ESD or *en bloc* EMR. We do this to help build consensus on observation flowcharts of ME-NBI and to help endoscopists recognize the classification of early upper GI lesions more clearly so that they can select the most appropriate therapeutic intervention.

## DEFINING OPTICAL IMAGING CHARACTERISTICS VISUALIZED UNDER MAGNIFYING ENDOSCOPY WITH NARROW BAND IMAGING IN UPPER GASTROINTESTINAL

In general, the doctor inspects the patient first under white-light endoscopy without magnification. He then slowly moves the scope, washes the tissue well, and pays special attention to areas containing slight differences. The key endoscopic finding by using white light (WL) has been reported to be a change of color (slight redness) and pallid mucosa<sup>[37]</sup>. However, the margin is difficult to identify by conventional WL. Then, the NBI model was employed to make it easier to detect the change in colors and structure of the mucosa. Moreover, with magnification, the microvascular (MV) pattern and MS pattern can be evaluated. So, what will be seen under ME-NBI if the cancerous lesion is suspected within the area?

### Esophagus

**Brownish area:** A brownish area can often be recognized by NBI observation as distinct boundaries are formed between the tumor lesion and normal epithelium (Fig-

ure 1)<sup>[38]</sup>. An intraepithelial papillary capillary loop (IPCL) appears as brown dots under NBI-enhanced observation. For example, in the esophagus, if the lesion appears brownish under magnifying NBI observation, it will predict the possibility of mucosal squamous-cell carcinoma as a result of assessing the morphologic changes in the IPCL. The brownish areas in the esophagus visualized by NBI generally correspond to the Lugol chromoendoscopy displayed the lesions as unstained areas<sup>[39]</sup>.

**Intraepithelial papillary capillary loop:** It is well known that angiogenesis plays a critical role in the transition from premalignant to malignant lesions. Consequently, early detection and diagnosis based on morphological changes to the microvessels are crucial<sup>[40]</sup>. Superficial blood vessels in the esophageal mucosa consist of branching vessels and IPCL. However, in some cases, only the former can be observed under the WL that extend to the horizontal plane and exist immediately above the muscularis mucosa while IPCL that rises perpendicularly from a branching vessel can be observed through ME-NBI (Figure 2)<sup>[41]</sup>. In these cases, Muto *et al.*<sup>[43]</sup> have reported that a well-demarcated brownish area or an area of scattered brownish dots under NBI is connected with the proliferation of IPCL. This is a useful indicator for early esophageal squamous-cell carcinoma or high-grade intraepithelial neoplasia.

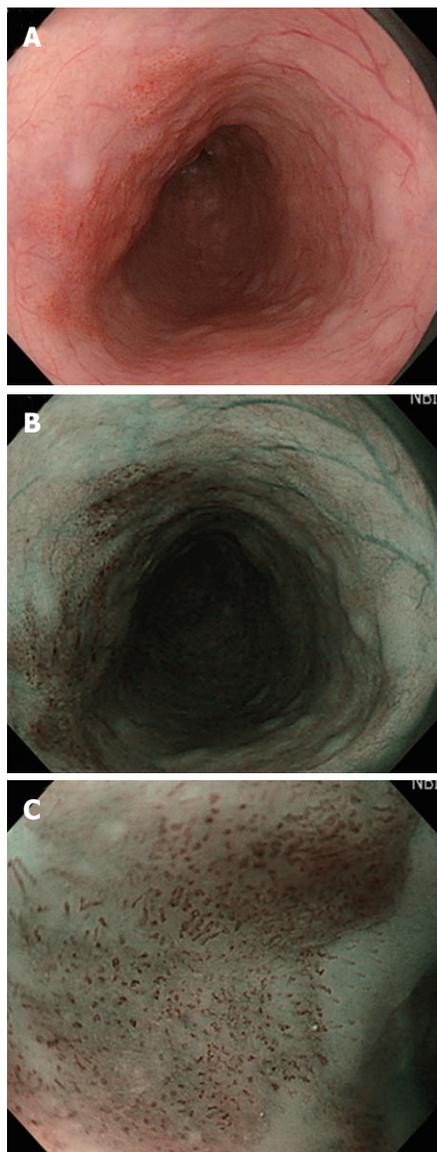

### Stomach

Besides the MV architecture, the imaging characteristics of the MS structure of mucosa the so-called pit or crypt patterns can be obtained by ME-NBI in the stomach (Figure 3).

### Subepithelial capillary network and collecting venule:

By ME-NBI, the subepithelial capillary network (SECN) and the collecting venule (CV) can be clearly visualized. A polygonal-shaped subepithelial capillary loop surrounding each pit forms a network in a regular arrangement, and this capillary network drains into a CV. SECN and CV are basic anatomical components for analysis of the MV architecture. The SECN shows two distinct patterns depending on the region of the normal stomach being imaged: The body mucosa demonstrates a regular honeycomb-like SECN pattern with a CV, whereas the gastric antrum shows a coil-shaped SECN but the CVs are rarely observed. This might be because the CVs in the antral mucosa are relatively deeper from the surface epithelium than those of the gastric body mucosa<sup>[44]</sup>.

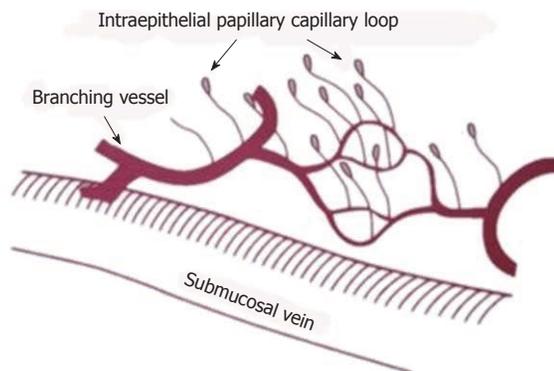

For the abnormal stomach, there are two characteristics of MV that can be identified by ME-NBI: the first is a relatively regular “fine network pattern” (Figure 3A), which is more likely to be observed in well-differentiated adenocarcinoma and appears as mesh and abundant microvessels connected with each other; the second is a “corkscrew pattern” (Figure 3B) as with isolated and tortuous microvessels, which often represents the low density of MV and corresponds to poorly-differentiated, depressed (0-IIc), early gastric adenocarcinoma<sup>[45]</sup>.

**Figure 1** The carcinoma visualized in esophagus. A: Carcinoma in esophagus is difficult to identify by conventional white light; B: Carcinoma in esophagus can be easily recognized by narrow-band imaging (NBI) as well-demarcated brownish area; C: Intraepithelial papillary capillary loop can be observed by magnifying endoscopy with NBI at the edge of the tumor.

Intrastructural irregular vessel (ISIV) (Figure 3C) also has an irregular MV pattern but often appears in the superficial flat gastric lesion (0-II b) as well as the marginal flat area of an elevated or a depressed lesion. This is a cancerous indication. Differing from the fine network pattern and corkscrew pattern shown in the areas where fine mucosal structure (FMS) disappear or are unclear in 0-II c gastric lesions, the ISIVs are found enclosed in villous or papillary FMSs and have characteristics of dilation, heterogeneity, abrupt caliber or tortuousness of shape<sup>[46]</sup>.

**Microsurface:** Applying ME-NBI is helpful for clearly visualizing not only some of the MV characteristics introduced above but also the gastric mucosal MS structures, namely pit or crypt opening patterns. The MS structures

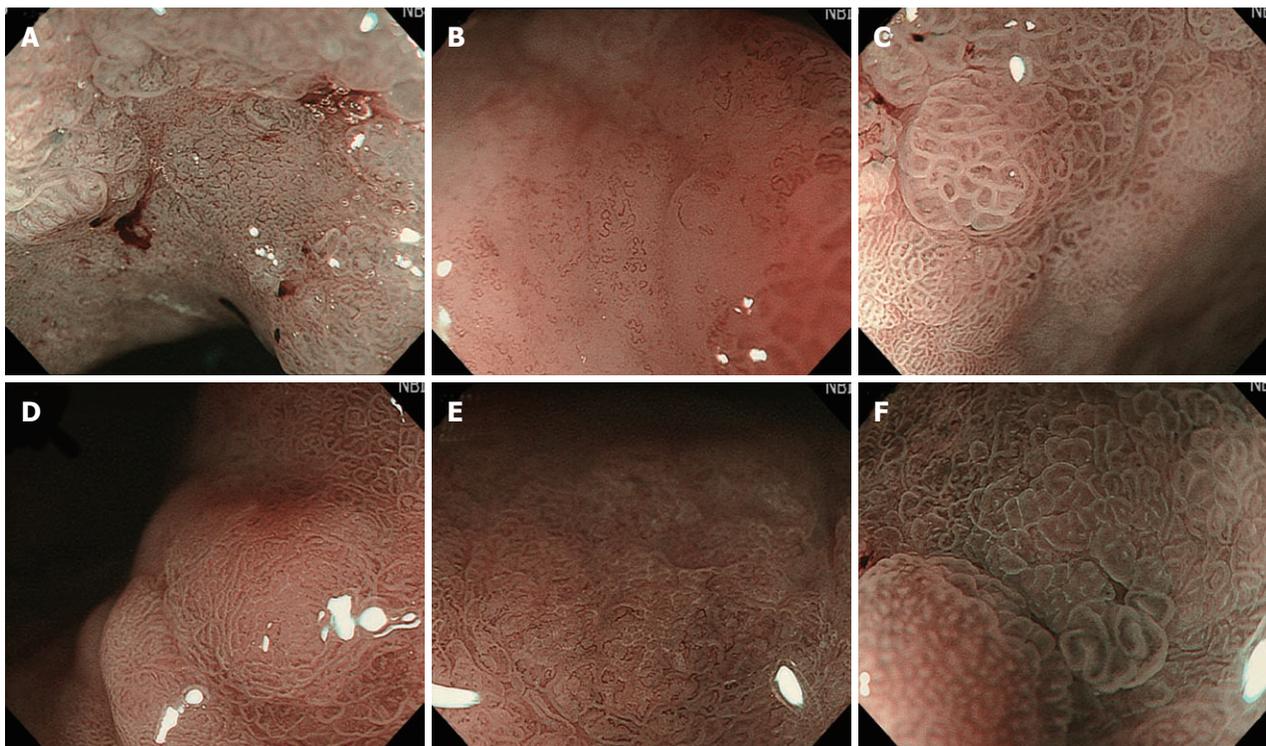

**Figure 2** The superficial blood vessels in the squamous esophagus (from Inoue *et al*<sup>[42]</sup>; with permission, making a little change for the original graph), the intraepithelial papillary capillary loop rises from the branching vessel and terminates in a diffuse.

include the FMS in a normal stomach as well as the irregular or loss of pit pattern that occurs with early gastric carcinomatous lesions.

Although it is necessary to assess a neoplasm in the stomach by the MV and MS patterns simultaneously, it is sometimes impossible to visualize the subepithelial MV pattern on account of overcurtaining by the white opaque substance (WOS). In most adenomatous lesions, the WOS is frequently observed more clearly under ME-NBI than WL and is speculated to be some intracellular component within the neoplastic epithelium of the intervening part between the crypts, obscuring the morphology of the subepithelial MV and causing difficulty in assessing the MV pattern. In such cases, rather than assessing the MV pattern, the morphology of the WOS could be an alternative new optical microstructure sign for distinguishing adenomas from adenocarcinomas. Yao *et al*<sup>[47]</sup> reported that only about 6% of the WOS was found in II b and II c lesions. For 0-II a type neoplasms, the WOS was more frequently visualized in adenomas (78%) than in carcinomas (43%) and showed a well-organized and symmetrical distribution of the dense WOS of a regular reticular/maze-like/speckled pattern (Regular WOS) (Figure 3D) within adenomas (100%), but showed a disorganized and asymmetrical distribution of the fine WOS of irregular reticular/speckled pattern (Irregular WOS) (Figure 3E) within carcinomas (83%). That is to say, the regular WOS is characteristic of adenomas, whereas its irregular distribution is characteristic for carcinomas.

Similar to the WOS, the light blue crest (LBC) (Figure 3F) is another characteristic optical microstructure under ME-NBI caused by the dense reflection of 400 to 430 nm short-wavelength light at the ciliated tissue. The LBC is defined as a fine, blue-white line on the crests of the epithelial surface/gyri, just at the edge of crypts. It has been suggested that the appearance of the LBC on the epithelial surface of the gastric mucosa may be a distinctive endoscopic finding associated with the presence of histological intestinal metaplasia in high sensitivity (89%), high specificity (93%), and high accuracy (91%)<sup>[48]</sup>. The LBC was also demonstrated to have a significant associa-

**Figure 3** Some typical microvascular and microsurface imaging characteristics visualized in stomach under magnifying endoscopy with narrow band imaging. A: Fine network pattern, mostly corresponding to well-differentiated adenocarcinoma (0-II c, gastric); B: Corkscrew pattern, mostly corresponding to the poorly-differentiated adenocarcinoma (0-II c, gastric); C: Intrastructural irregular vessel, enclosed in villous or papillary fine mucosal structure, had irregular shape characters such as dilation, heterogeneity, abrupt caliber or tortuosity (0-II b, gastric); D: Regular white opaque substance (WOS), that shows well-organized and symmetrical distribution with a regular reticular pattern and obscures the subepithelial microvascular (MV) pattern (0-II a adenoma, gastric); E: Irregular WOS, that is present within the cancerous epithelium with an irregular speckled pattern and makes the subepithelial MV pattern cannot be clearly visualized (0-II a cancer, gastric); F: Light blue crest, defined as a fine, blue-white line on the crests of the epithelial surface in the gastric mucosa may be a distinctive endoscopic finding associated with the presence of histological intestinal metaplasia.

tion with gastric atrophy and a high occurrence of gastric cancer<sup>[49]</sup>.

As noted above, the strategies for diagnosing upper GI lesions by ME-NBI are specific to different organs. Under a magnifying endoscope, an esophageal neoplasia could be diagnosed solely according to the findings from the MV pattern, namely IPCL, because the esophageal squamous epithelium does not show FMS. In contrast, a gastric neoplasia could be diagnosed with the findings of the MV pattern as well as the MS pattern<sup>[50,51]</sup>. Of course, sometimes the WOS or LBC is more useful for the diagnosis.

## CURRENT REPRESENTATIVE CLASSIFICATIONS OF MICROVASCULAR AND MICROSURFACE PATTERNS IN THE UPPER GASTROINTESTINAL UNDER MAGNIFYING ENDOSCOPY WITH NARROW BAND IMAGING

### *Classifications of intraepithelial papillary capillary loops in the esophagus*

IPCLs beneath the basement membrane of the esophageal squamous epithelium can be observed by ME-NBI.

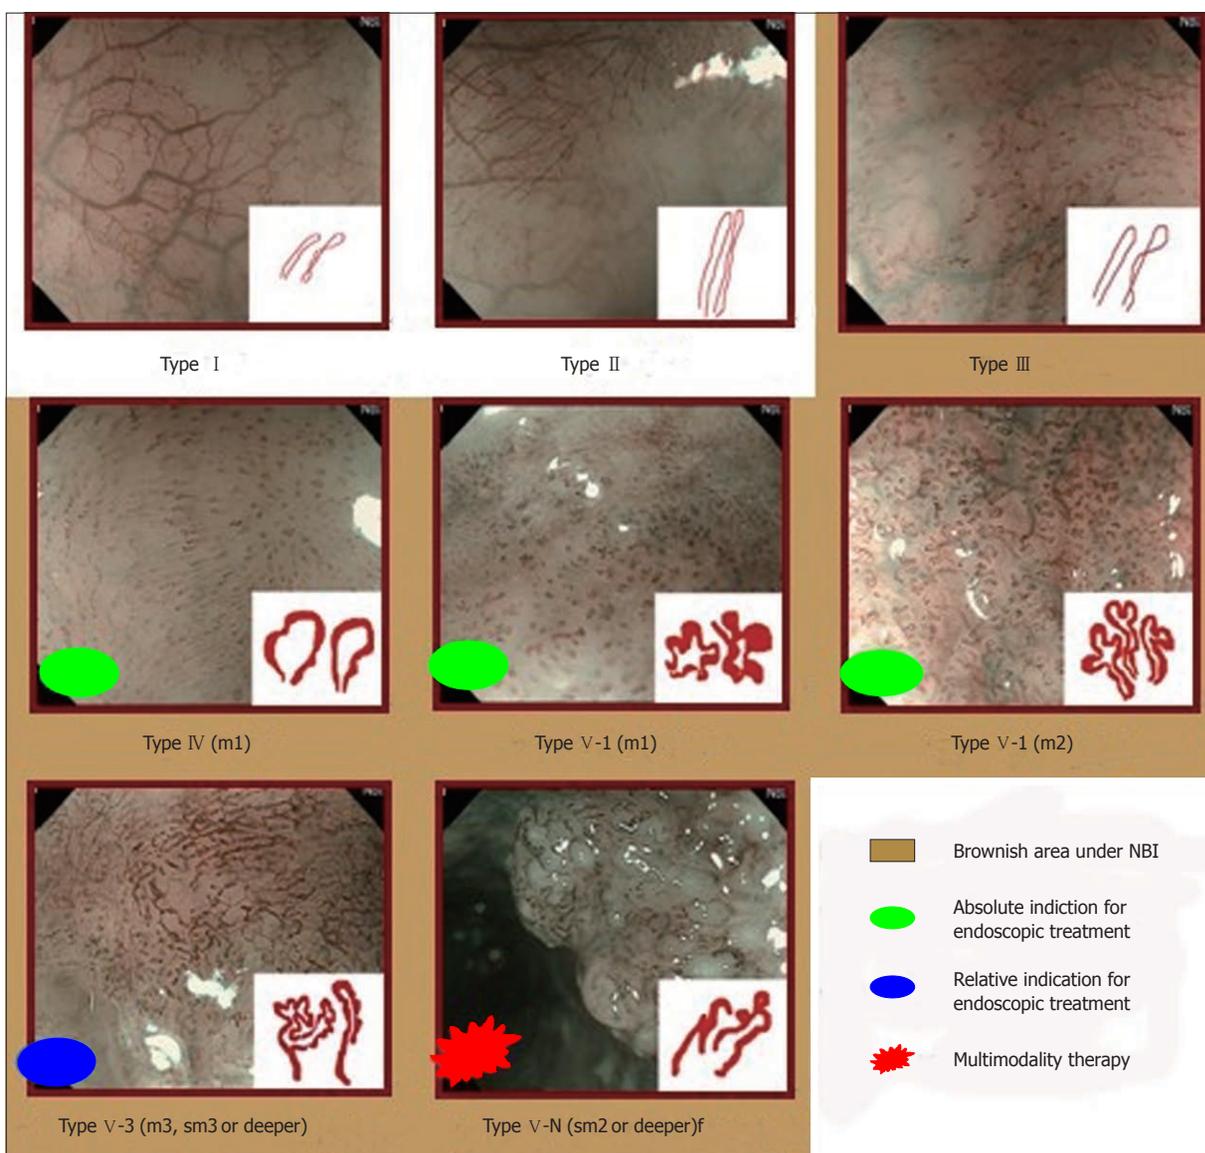

It has been shown that identifying IPCL changes is very important in predicating early lesions of the esophagus. Regarding the classifications of IPCLs, there have been several systems adopted by different researchers<sup>[26-28]</sup>, but in Japan, Inoue's classification and Arima's classification of IPCLs have been relatively popular.

**Inoue's classification of intraepithelial papillary capillary loop:** Under NBI, the IPCLs are easily recognized as brown spots, and the normal patterns appear as a smooth-running, small-diameter capillary vessel in the normal epithelium. The abnormal shapes appear as four typical changes: **Dilation, tortuous weaving, irregular caliber and form variation.** Inoue *et al.*<sup>[24,52]</sup> classed them into five types and several subtypes from type I to type V-N as below (Table 1 and Figure 4). IPCLs in type I is no different from the normal pattern. IPCLs in type II has one or two different characteristics: elongation and/or dilation is often seen. IPCLs in type III have no or few differences from the normal pattern, but this type differs from type I mainly in the features of color changes under NBI and iodine staining. Under NBI, the lesions of type I and type II often show no change or negligible change, but the types between type III and type V-N appear brownish. **In addition, type I and type II lesions are often positively stained with iodine while the types from**

**Table 1** Inoue's classification of intra-papillary capillary loop in esophagus

Typing	IPCL	Iodine staining	Under NBI	Pathological assessing	Treatment
Type I	Smooth running small diameter capillary vessel with no difference from the normal pattern	Stained		Normal epithelium	
Type II	Elongation and/or dilation capillary is often seen	Slightly stained		Esophagitis or re-generative tissue	
Type III	No or minimal change from the normal	Unstained	Brownish	HGIEN	Further follow-up
Type IV	Showing two or three of four patterns among dilation, meandering, caliber changes and different shapes	Unstained	Brownish	HGIEN or m1 carcinoma <i>in situ</i>	ESD/ <i>en bloc</i> EMR
Type V	Demonstrating all four characteristic changes: dilation, tortuous weaving, irregular caliber and form variation	Unstained	Brownish	M1 carcinoma <i>in situ</i>	
Type VI	Elongation basing on the shapes of type V IPCL, keeping IPCL partly	Unstained	Brownish	M2 carcinoma <i>in situ</i>	
Type VII	Destructuring dramatically and running on horizontal plane	Unstained	Brownish	M3-Sm1 deeper carcinoma	Relatively indicated for ESD/EMR
Type VIII	New tumor vessel appear	Unstained	Brownish	Sm2 deep carcinoma	Surgery, chemoradio-therapy

IPCL: Intraepithelial papillary capillary loop; NBI: Narrow-band imaging; ESD: Endoscopic submucosal dissection; EMR: Endoscopic mucosal resection; HGIEN: High-grade intraepithelial neoplasia.

**Figure 4** The case examples of Inoue's intraepithelial papillary capillary loop classification from type I to type V-N. NBI: Narrow-band imaging.

type III to type V-N are negatively stained. IPCLs in type IV appear to have two or three of the four abnormal characteristic changes. IPCLs in type V-1 demonstrate all the four typical changes. IPCLs in type V-2 are elongated on the base of the four shapes and only keeping part of the original IPCL. IPCLs in type V-3 are further degraded and run on a horizontal plane. As for type V-N, the most remarkable feature is the appearance of new tumor vessels.

According to the grade of the changes of IPCL, the depth of invasion can be assessed. Type I mainly appears in normal epithelium. Type II corresponds to inflammatory changes or regenerative tissue. Type III often reflects low-grade intraepithelial neoplasia. Type IV is linked to with high-grade intraepithelial neoplasia (HIN) or M1 carcinoma *in situ*. Type V-1 is definitively diagnosed as M1 carcinoma *in situ*. The appearance of Type V-2 strongly suggests m2 carcinoma. Type V-3 often indicates m3 to sm1 deep lesions. Type V-N is often associated with sm2 invasion cancer. In short, type I to type V-1 demonstrate the characterization for flat lesions while type V-1 to type V-N reflect invasive cancers.

With treatment, lesions of type III IPCLs need further follow-up, and type IV to type V-2 should be considered for ESD or *en bloc* ESD. Type V-3 lesions are thought to be an indication for ESD or EMR because of the depth of invasion ranges between m3 and sm1. A complete biopsy should be applied before deciding on a treatment strategy. For type V-N, it is taken for granted that the surgical treatment or chemoradiotherapy should be recommended to counteract the significantly increasing risk of lymph node metastasis.

**Arima's classification of intraepithelial papillary capillary loop:** In 2005, Arima *et al*<sup>[25]</sup> reported another classification of the microvasculature of esophageal IPCLs under magnifying endoscopy. The microvascular patterns are categorized into four types (Figure 5). The thin, liner capillaries in subepithelial papillae are recognized as type I, resembling the shapes in normal mucosa. The vessels of type II become distended and dilated in subepithelial papillae, and the structure of capillaries is preserved. Most of them are usually found in lesions with inflammatory changes and are also associated with intraepithelial neoplasia. Spiral vessels with an irregular caliber and crushed vessels with red spots are characteristics of type III, which are often seen in m1 or m2 cancers. Type IV usually appears to be irregularly multilayered, irregularly branched, reticular vessels with an irregular caliber as generally observed in cancers with an m3 invasion or deeper. Avascular areas as well as stretched vessels are seen in cancers with downward growth. In addition, reticular vessels are commonly seen in poorly differentiated cancers, and the size of a vascular area surrounded by distended vessels is related to the depth of tumor invasion.

Comparing to the above two classification systems on the morphologic changes of IPCL and predicting the depth of the tumor invasion, it can be argued that type I

of Arima's classification partly corresponds to type I -type III of Inoue's classification. Furthermore, type II of Arima's classification partly corresponds to Inoue's type IV, Arima's type III partly to Inoue's type V-1 or V-2, and Arima's type IV partly to Inoue's type V-3 or V-N. However, the two systems do not always have such clear corresponding links. The invasion depth diagnosis by Inoue's classification is possible for most lesions, and the correct ratio is about 78%<sup>[24,52]</sup>. By contrast, when using Arima's type III and type IV classifications as diagnostic criteria for HIN and cancers, the rate of differential diagnosis goes up to 99%<sup>[25]</sup>. Recently, it has been reported<sup>[53]</sup> that some flat areas are not able to be predicted by Inoue's classification. However, combining the two classification systems could result in greater accuracy of the preoperative diagnosis, which is proved by the pathological diagnosis after ESD. Therefore, it is recommended for clinical endoscopists using Inoue's classification and Arima's classification together to make an invasion depth diagnosis of esophageal cancer under ME-NBI.

### Stomach

As for the MS of the stomach, in 1978, Sakaki *et al*<sup>[54]</sup> described the gastric pit appearances under magnifying endoscopy and classified them into five types: (1) foveolar pattern; (2) foveo-intermediate pattern (FIP); (3) foveolousulciform pattern; (4) sulciform pattern; and (5) mesh pattern. Although "Sakaki's classification" is still currently the most widely adopted classification by many Japanese endoscopists, not all gastric pathological changes can be expressed by this system because it is not consistent with structural changes under some pathological conditions<sup>[55]</sup>, which were found to have round and long elliptical gastric pits. The width of the FIP band seems to be related to the severity of atrophic gastritis, and the FIP is considered to indicate the position of the atrophic border.

Therefore, in 2002, Yagi *et al*<sup>[56]</sup> first reported a new modified classification system named the "A-B classification system," which is useful to describe typical micromucosal structures related to the development of *Helicobacter pylori* (*H. pylori*) gastritis. They classified the morphological changes in the glandular structure and microvascular architecture obtained by WL magnifying endoscopy into four types: (1) type Z-0: Gastric round pits resembling pinholes surrounded by a regular arrangement of collecting venules with SECN forming a network; (2) type Z-1: Irregular true capillaries but no collecting venules observed; (3) type Z-2: White gastric pits and sulci with neither collecting venules nor true capillaries being seen; and (4) type Z-3: Dilated pits with surrounding redness. Type Z-0 specifically indicated the *H. pylori*-negative mucosa and differed significantly from types Z-1, Z-2 and Z-3 with regard to the grade of inflammation, activity and presence of *H. pylori*.

More recently, with the development of brand new optical techniques, such as ME-NBI, which can clearly visualize not only the glandular structure but also the mucosal microvascular architecture in units as small as the capillary, the prior diagnostic classification system seemed

less able to meet clinical needs, especially for early diagnosing of premalignant lesions and assessing the relationship between microvessel patterns, pit patterns and histological patterns ahead of endoscopic *en bloc* resection. In recent years, many researchers modified the above classifications but varied individually<sup>[45,57-61]</sup>, and there is still no set of consistent classification guidelines. Nonetheless, the key characteristic findings of all the current classifications for ME-NBI with respect to early gastric carcinomatous lesions are based on the types of abnormal MV patterns and irregular MS patterns. Among these, the representative diagnostic system is advocated by Yagi *et al.*<sup>[62]</sup>, who established a flowchart for ME-NBI diagnosis in early gastric cancerous lesions as below: first, the “white zone” should be imaged, which is Yagi’s term for the border of the uniform or heterogeneous papillae in the mucosal MS structure that appears as a bold white line. Next, microvessels should be observed. A regular MV pattern means the microvessels appear regular in shape and arrangement and look like closed or open loops of uniform size caliber. An irregular MV pattern means the microvessels appear irregular in shape and arrangement, looking like tortuous or irregular branches of various sizes or abnormal caliber<sup>[47]</sup>. Then, according to the white zone, the MV pattern, the WOS, and the LBC, the histological imaging of entire mucosa should be done. (1) Fine network patterns and loop patterns are mostly associated with well- or moderately-differentiated adenocarcinoma; (2) irregular MV patterns, namely ISIVs, enclosed in villous or papillary FMSs can often be observed in II b gastric cancerous lesions; (3) corkscrew patterns or wavy microvessels mostly correspond to the poorly-differentiated adenocarcinoma; (4) regular WOSs often appear in II a gastric adenoma lesions while irregular WOSs often present in II a gastric cancerous lesions; (5) LBC is mostly connected with intestinal metaplasia<sup>[47,48,63]</sup>.

As a matter of course, with regard to the classification of early gastric lesions under ME-NBI, more in-depth studies are needed to address the more morphologically-complex microstructures of the stomach relative to the other parts of the GI system. Some features described previously are not general enough to apply to each lesion, and the number of cases in the studies is limited as well. At present, it is reasonable to use ME-NBI as a supplementary diagnostic tool to normal endoscopy with chromoendoscopy in the stomach before deciding on therapy strategies. The current strategies require new additions and some modifications.

### Barrett’s esophagus

BE is thought to be a complication of longstanding gastroesophageal reflux and a condition of the distal esophagus where normal squamous lining is replaced by columnar epithelium containing specialized intestinal metaplasia (SIM), which has the tremendous potential for developing esophageal adenocarcinoma with generally poor prognoses and a median survival rate of less than one year. Short BE is defined as < 3 cm and long BE as ≥ 3 cm<sup>[64]</sup>.

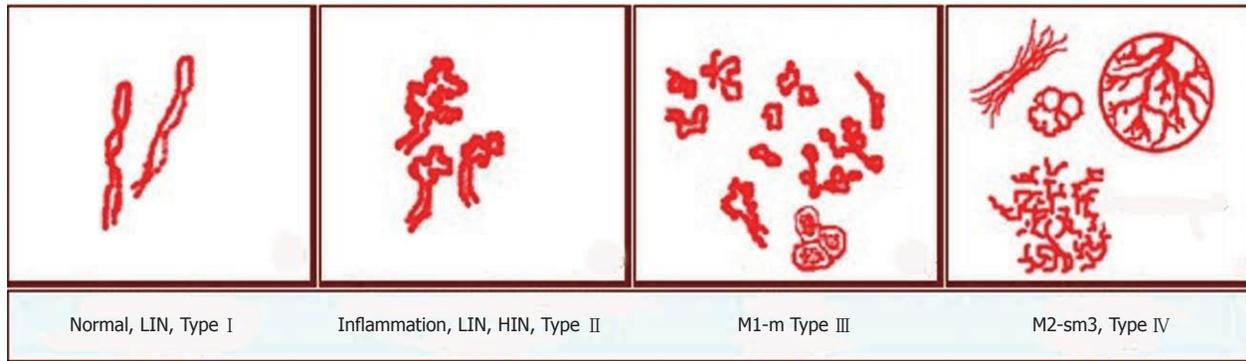

Using ME-NBI allows clear visualization of micro-mucosal and vascular patterns in BE. Now, depending on which targeted biopsy technique can be performed, improved distinction of nondysplastic SIM from HIN is possible. Recently, several pieces of literature<sup>[16,33,65,66]</sup> have reported their own classification systems, of which the principal features are summarized as follows: SIM is characterized by the mixing of villous, tubular and linear patterns with mostly regular arrangements and having regular vascular patterns or appearing as long, branching vessels in a flat mucosa. In addition, absent microstructural patterns also have a very high correlation to and predictive power for SIM. HIN is characterized by irregular/disrupted microstructural and irregular microvascular patterns, and the frequency of abnormalities shows a significant rise with increasing grades of dysplasia.

## USEFULNESS OF MAGNIFYING ENDOSCOPY WITH NARROW BAND IMAGING PRIOR TO ENDOSCOPIC SUBMUCOSAL DISSECTION OR EN BLOC ENDOSCOPIC MUCOSAL RESECTION

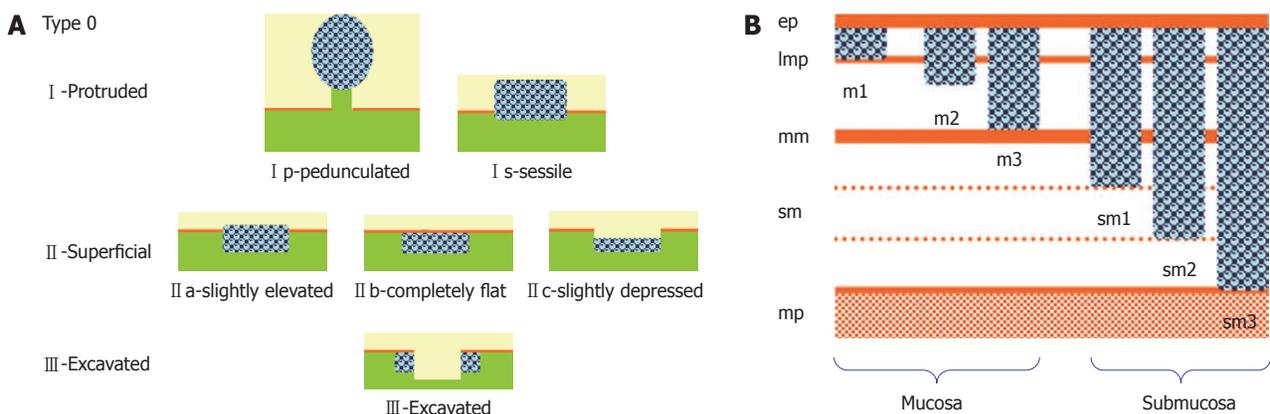

### To assess the differentiation and depth of invasion

**Criteria for endoscopic submucosal dissection/endoscopic mucosal resection:** Only some differentiation and invasion limited to sm1 lesions should be considered for endoscopic removal. Nowadays, in Asian countries, one of the widely adopted guidelines for ESD or *en bloc* EMR is that the histology of the tissues must be intramucosal, well-differentiated, early carcinoma, and the minute invasion of submucosal lesions must be limited to sm1—namely, with a depth less than 200 μm in the squamous epithelium of the esophagus and less than 500 μm in the stomach. If the lesion is recognized as undifferentiated, surgery should be recommended<sup>[6,67]</sup>.

Japan’s data show that the five-year cancer-specific survival rates of EGC limited to the mucosa and submucosa are 99% and 96%, respectively<sup>[67]</sup>. In other words, *en bloc* endoscopic treatment should be mainly applied to some category 0 superficial GI neoplastic lesions with the invasion limited to the mucosa or submucosa. These are divided into three subtypes according to the “Paris classification”: 0-I include I p and I s, referring to polypoid pedunculated and sessile respectively; 0-II are non-polypoid and non-excavated, and they are further subdivided into 0-II a for slightly elevated lesions, 0-II b for completely flat lesions, and 0-II c for slightly depressed lesions; 0-III are non-polypoid with an ulcer (Figure 6, left side)<sup>[68]</sup>. In order to get a more precise evaluation for choosing the appropriate therapy, endoscopists classify early GI cancer into the following subdivisions according to the depth of invasion: M1, carcinoma with questionable invasion carcinoma limited to the epithelium; m2, cancer invasion to the lamina propria; m3, cancer infiltration into the muscularis mucosa; sm1, to the upper third of submucosa; sm2, to the middle third; and sm3, to

**Figure 5** The morphology of Arima's intraepithelial papillary capillary loop classification in esophagus. LIN: Low-grade intraepithelial neoplasia; HIN: High-grade intraepithelial neoplasia.

**Figure 6** The Paris classification of early lesion of gastrointestinal tract (A) and the depth of tumor infiltration (B). ep: Epithelium; Imp: Lamina propria; mm: Muscularis mucosa; sm: Submucosa; mp: Muscularis propria.

the lower third. (Figure 6, right side)<sup>[69]</sup>. The distribution of subtypes in category 0 differs in the esophagus and stomach. As an example, the respective proportions of subtypes 0- I and 0- II c are 16% and 45% in the squamous epithelium of the esophagus, and they are 17% and 78% in the glandular epithelium of the stomach, respectively<sup>[70]</sup>.

Presently, the most critical factor in the decision of whether to perform ESD or *en bloc* EMR is the probability of unexpected lymph node metastasis. Studies have shown that early cancer without lymphovascular involvement could be cured by endoscopic removal. Intramucosal, moderately- or well-differentiated early carcinomas that have been proved do not have submucosal lymphovascular involvement. In contrast, poorly differentiated squamous-cell carcinoma, adenocarcinoma and/or signet-ring cell carcinoma have a high incidence of lymph node metastasis. M1 and m2 carcinomas have no metastasis, whereas less than 10% of m3 carcinomas and about 15%-20% of sm1 have lymph node metastasis. The risk increases to more than 50% of sm2 and sm3 carcinomas<sup>[7,67,71,72]</sup>. Therefore, before performing ESD or EMR, an accurate histological evaluation of the resected specimens is essential to avoid recurrence.

Magnified images obtained with the ME-NBI system could be a useful, non-invasive method of histologically predicting for early lesions in clinical practice, especially

with regard to the IPCL pattern in the esophagus and MV and MS patterns in the stomach, based on which alone usually could help us perform a successful endoscopic therapy. Many researchers focused on the relations between the ME-NBI classifications categories with the characteristics of the histopathological types. For example, regarding the depth of superficial esophageal cancer, the accuracy rate of diagnosis is about 83.3%, according to the Inoue's classification of IPCL<sup>[73]</sup>. And in the stomach, differentiated-type adenocarcinomas are mainly observed as fine-network patterns in about 15.7% of cases or loop patterns in about 83.8% of cases. Undifferentiated-type lesions are primarily characterized by the cork-screw pattern in approximately 58.8% of cases<sup>[57]</sup>. For HIN of BE, without the need for staining, the ME-NBI images have a sensitivity of 94% and a specificity of 76% as well as a positively predictive value of 64% and a negatively predictive value of 98%<sup>[65]</sup>.

Comparing the diagnostic accuracy of ME-NBI and endoscopic ultrasonography (EUS) for estimating the depth of invasion of early cancers before removal, some endoscopists conclude that the overall accuracy of ME-NBI is a little higher than EUS, but the difference is not statistically significant. However, ME-NBI is at least as accurate as EUS for preoperative locoregional staging of early cancers. On the other hand, EUS can be used for observing lymph nodes, but the diagnostic capability of

EUS for lymph nodes is less reliable, which can affect therapy-related decisions before ESD. Regarding this point, a consensus is still required. For some cases that are difficult to diagnose, it is even necessary to combine two stool tests with computed tomography before ESD or *en bloc* EMR<sup>[74-76]</sup>.

### To define the margin and size of involvement

**Criteria for endoscopic submucosal dissection/endoscopic mucosal resection:** For differentiated lesions, a size of  $\leq 2$  cm in diameter is an indication for EMR; a size of  $\leq 3$  cm of mucosal cancer with ulcers or sm1 submucosal cancers, and any size of mucosal cancer without ulcer are indication for ESD.

In Japan and a few other Asian countries, another current guideline for ESD or *en bloc* EMR regarding well-differentiated lesions is based on data relating the size of the early lesion and the rate of lymph node metastasis. For mucosal cancers with ulcers or sm1 submucosal cancers, lesions that are 3 cm or smaller present a negligible risk of venous or lymphatic involvement. These are indications for ESD. For larger lesions, surgery should be recommended. For lesions confined to the mucosa but without ulcers, the risk of lymph node metastasis is not affected by the size of the tumor, so there is no consensus on a maximal size, although circumferential lesions in the esophagus are usually avoided because of the potential for strictures. Because a 2 cm diameter is the upper limit for resection by EMR in one piece, if the lesions simultaneously meet the conditions of ESD and are not more than 2 cm large, these should also be reasonable indications for *en bloc* EMR treatment because this technique is easier than ESD<sup>[6,67,77,78]</sup>.

Therefore, prior to endoscopic treatment, it is absolutely necessary to accurately identify the full lateral spread of the margins of the lesion, which leads to the determination of the lesion's final size and contributes to the next step of making well-reasoned treatment decisions. In the upper GI, *en bloc* endoscopic removal needs to be carried out 2 mm outside the margin outlined by the spots. This is the key to ensuring that the complete R0 resection has a negative margin for the tumor cells and that the risk of local recurrence is reduced.

ME-NBI allows a more detailed observation of the mucosal changes of microstructures and microvessel patterns of GI carcinoma and is extremely useful, not only for identifying EGC itself, but also for differentiating the borders of cancerous tumors from background non-cancerous mucosa. By ME-NBI, the following points can help determine precise horizontal margins in clinical practice<sup>[44]</sup>: (1) **recognize a demarcation line** by the difference between an irregular MV or MS pattern and the surrounding regular normal mucosa. This has been proven to correspond to the tumor margins determined by histopathological examination; (2) **pay close attention** to the areas disappearing from the regular SECN pattern as well as the appearance of an ISIV pattern. Sometimes, WOSs are helpful for identifying tumor margins that have not been determined. Also, LBC is a specific indicator for

tumors derived from intestinal metaplasia by ME-NBI.

However, for IIb flat reddened lesions that have the same color as the surrounding normal mucosa, it is still occasionally difficult to detect the margins. On the other hand, accurate marking of tumors by ME-NBI also relies on an operator's skill. Therefore, in order to improve the accuracy rate of marking margins, many endoscopists combine ME-NBI with conventional chromoendoscopy. For example, Lugol's solution can dramatically outline the boundaries of a squamous cell esophageal cancer in the esophagus. Although one recent article has concluded that tumor margins can be identified more clearly by ME-NBI than by indigocarmine chromoendoscopy in the stomach<sup>[79]</sup>, it is likely that in the majority of cases, a combination of these two methods prior to ESD or EMR will ensure there are no residual lesions.

### To perform a target biopsy in real time

Before local endoscopic *en bloc* resection, the histopathologic diagnosis is very important for making therapy decisions. For a surveillance biopsy to detect early tumors, multiple random biopsies under conventional WL endoscopy are quite time-consuming and may miss a small lesion<sup>[80]</sup>. For example, for monitoring BE so far, the present recommended strategy is to perform random four-quadrant biopsies at every 2 cm. However, this approach is still prone to sampling errors, inconsistent histopathological interpretations, and delays in diagnosis<sup>[81]</sup>.

Ultimately, the higher-accuracy pathological diagnosis as well as the ultrarapid *in vivo* diagnosis would be preferred in clinical practice<sup>[82]</sup>. It has been reported that chromoendoscopy could provide a good validity score for early cancer targeted biopsies<sup>[83]</sup>. However, it still has its limitations, including spending time lost in spraying and washing out the dye. Moreover, some dyes-such as methylene blue-might induce DNA damage in columnar cell-lined mucosa<sup>[84]</sup>.

To this end, in recent years, many researchers suggest using the ME-NBI technique as an "optical biopsy" to better target biopsies in real time. Because this approach can provide better details of mucosa MV and MS patterns that significantly correlate with pathological diagnosis, it has the potential to reduce the need for histological examination of mucosal biopsy specimens<sup>[47,49,85,86]</sup>. Additionally, some endoscopists even think that ME-NBI can sometimes be substituted for a biopsy before endoscopic therapy because a biopsy might only focus on some suspected, poorly-differentiated lesions under magnifying endoscopy. However, to date, ME-NBI cannot always replace biopsies for histological assessment. In addition, ESD or *en bloc* EMR can supply specimens that are resected in one piece and provide more accurate histopathological diagnosis for determining whether the patient should receive an operation or other treatments<sup>[36,87-89]</sup>.

## CONCLUSION

In conclusion, ME-NBI is a very promising endoscopic technique that can clearly reveal detailed micromorpho-

logical differences corresponding to histology and provide some information about layer, origin, size, and extramural extension of GI early lesions. All of these benefits may augment the endoscopic R0 resection of early cancers in the GI tract and help guide targeted biopsies in the surveillance of certain high-risk conditions<sup>[19]</sup>. To some extent, ME-NBI has now become an indispensable tool in ultra-rapid *in vivo* diagnosis and immediate clinical decision-making, such as when performing ESD or EMR.

In this topic review, most representative references come from the experience of Japanese endoscopists because Japan remains the country with the most ESD cases reported around the world by far. Outside Asia, more recently, techniques such as magnification, NBI and ESD have been increasingly used although viewpoints differ between Eastern and Western cultures, especially regarding extending indications for ESD, the classifications of MV and MS under ME-NBI in the upper GI tract, and partly substituting EUS or biopsy with ME-NBI. However, current data is limited, and we would need long-term outcome data to unify some assessments in order to conduct multicenter trials to develop clear, internationally accepted classification systems. This system review was intended to make a small contribution to some of the aforementioned debates.

Additionally, besides ME-NBI, it is necessary to combine various endoscopic techniques including EUS and chromoendoscopy in some difficult cases before *en bloc* endoscopic resection. It is important to emphasize here that the first step should always be to look carefully for the suspected area by conventional WL endoscopy before switching to the ME-NBI model.

## ACKNOWLEDGEMENTS

The authors thank for Professor Inoue H from Showa University Northern Yokohama Hospital, Japan, for his help in supplying the image of superficial blood vessels in the squamous esophagus (Figure 2) in this paper.

### Abstract

**AIM:** To investigate cytokine production and cell surface phenotypes of dendritic cells (DC) in the presence of epithelial cells stimulated by probiotics.

**METHODS:** Mouse DC were cultured alone or together with mouse epithelial cell monolayers in normal or inverted systems and were stimulated with heat-killed probiotic bacteria, *Bifidobacterium lactis* AD011 (BL), *Bifidobacterium bifidum* BGN4 (BB), *Lactobacillus casei* IB5041 (LC), and *Lactobacillus acidophilus* AD031 (LA), for 12 h. Cytokine levels in the culture supernatants were determined by enzyme-linked immunosorbent assay and phenotypic analysis of DC was investigated by flow cytometry.

**RESULTS:** BB and LC in single-cultured DC increased the expression of I-Ad, CD86 and CD40 (I-Ad, 18.51 vs 30.88, 46.11; CD86, 62.74 vs 92.7, 104.12; CD40, 0.67 vs 6.39, 3.37,  $P < 0.05$ ). All of the experimental probiot-

ics increased the production of inflammatory cytokines, interleukin (IL)-6 and tumor necrosis factor (TNF)- $\alpha$ . However, in the normal co-culture systems, LC and LA decreased the expression of I-A<sup>d</sup> (39.46 vs 30.32, 33.26,  $P < 0.05$ ), and none of the experimental probiotics increased the levels of IL-6 or TNF- $\alpha$ . In the inverted co-culture systems, LC decreased the expression of CD40 (1.36 vs -2.27,  $P < 0.05$ ), and all of the experimental probiotics decreased the levels of IL-6. In addition, BL increased the production of IL-10 (103.8 vs 166.0,  $P < 0.05$ ) and LC and LA increased transforming growth factor- $\beta$  secretion (235.9 vs 618.9, 607.6,  $P < 0.05$ ).

**CONCLUSION:** These results suggest that specific probiotic strains exert differential immune modulation mediated by the interaction of dendritic cells and epithelial cells in the homeostasis of gastrointestinal tract.

### INTRODUCTION

The gastrointestinal (GI) tract is an immunologic organ

with continuous antigen exposure in the form of food, normal bacteria and pathogens. Despite numerous antigenic challenges, the complicated mucosal immune system maintains GI homeostasis *via* the concerted actions of the various mucosal immune cells. Dendritic cells (DC), dedicated antigen-presenting cells, modulate the immune balance in the GI tract<sup>[1]</sup>. DC can take up antigens directly by extending their dendrites into the lumen or indirectly after transport of the antigens by M cells overlying Peyer's patch<sup>[2,3]</sup>. Antigen-carrying DC may traffic through the lymphatics to the mesenteric lymph nodes<sup>[4]</sup>, mediating the homing of activated effector/memory T cells and IgA-secreting B cells<sup>[5,6]</sup> and inducing regulatory T cells to produce interleukin (IL)-10 and transforming growth factor (TGF)- $\beta$ <sup>[7,8]</sup>. These roles depend on the regulation of cell surface expression of co-stimulatory molecules and production of inflammatory chemokines and cytokines<sup>[9-11]</sup>.

DC can recognize and present microbial components using pattern receptor system which includes toll-like-receptor (TLR). TLR can interact with microorganism-associated molecules such as peptidoglycan, lipoprotein, and lipopolysaccharide<sup>[12-16]</sup>. *Bifidobacterium* and *Lactobacillus* are major components of the commensal microbes of the GI tract and are frequently used as probiotics<sup>[17,18]</sup>. Probiotics, defined as live microorganisms which, when consumed in appropriate amounts in food, confer a health benefit on the host<sup>[19]</sup>, exert various host physiological responses such as immunomodulatory effect<sup>[20]</sup>. Recent experiments reported that DC could be modulated by probiotics. Several *Lactobacillus* species could regulate DC surface expression and cytokine production<sup>[21]</sup>. In addition, the probiotics mixture VSL No. 3 upregulated the expression of major histocompatibility complex (MHC) class II and co-stimulation molecules<sup>[22]</sup>.

DC are often located close to epithelial cells, populating the subepithelial dome of Peyer's patches, immediately adjacent to the follicle-associated epithelium and the lamina propria<sup>[23,24]</sup>. Intestinal epithelial cells secrete many mediators, including functional peptides such as defensins, mucins, chemokines, and cytokines such as IL 8<sup>[25-27]</sup>. TLR5 on the epithelium is a key mediator of pro-inflammatory responses to flagella from commensal bacteria<sup>[28,29]</sup>. Flagella also stimulate the maturation of responsive DC<sup>[30]</sup>.

Interaction between DC and epithelial cells is integral to the intestinal immune system. We hypothesized that epithelial cells stimulated by probiotics could regulate the maturation of DC. Accordingly, the present study investigated the pattern of cytokine production and the surface phenotype of DC in the presence of epithelial cells polarized by heat-killed probiotic bacteria.

## MATERIALS AND METHODS

### Preparation of probiotic bacteria

*Bifidobacterium bifidum* BGN4 (BB) was isolated from healthy infant fecal matter and identified in our laboratory<sup>[31]</sup>. *Bifidobacterium lactis* AD011 (BL), *Lactobacillus casei* IBS041 (LC), and *Lactobacillus acidophilus* AD031 (LA) were provided

by the Research Institute of Bifido Co. Ltd. (Hongchun, Gangwondo, South Korea). Four probiotic bacteria were anaerobically propagated in de Man, Rogosa, and Sharpe (Difco, Detroit, MI, United States) broth containing 0.05% L-cysteine (Sigma, St. Louis, MO, United States) at 37 °C until mid-log phase was reached. Subsequently, probiotics were inoculated at 1% and anaerobically cultured in de Man, Rogosa, and Sharpe (Difco) broth containing 0.05% L-cysteine (Sigma) at 37 °C. *Lactobacillus* species were incubated for 16 h, and *Bifidobacterium* species were incubated for 24 h to late log phase. The bacteria were collected by centrifugation at 1000 × *g* for 15 min at 4 °C and washed twice with phosphate-buffered saline (PBS). After washing, the bacteria were resuspended in 1 mL of PBS and incubated at 95 °C for 30 min to prepare heat-killed bacteria cells. The killed bacteria were collected by centrifugation at 1000 × *g* for 15 min and then lyophilized (Combi-514R, Hanil Science Industrial, Seoul, South Korea).

### Generation of CMT-93 monolayers

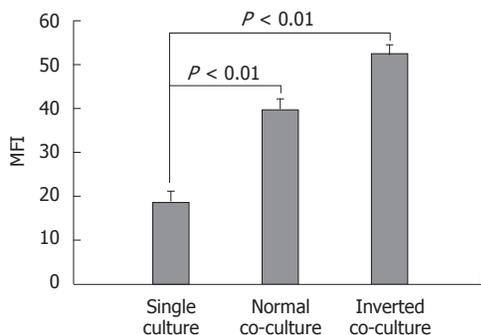

CMT93 was derived from carcinomas of C57BL mouse large intestine. The cells have an epithelial morphology and forms acini, junctional complexes, and microvilli with attached glycoprotein<sup>[32]</sup>. CMT-93 cells were maintained in DMEM (Gibco Life Technologies, United Kingdom) supplemented with 10% heat-inactivated fetal bovine serum (FBS) (Invitrogen, Paisley, United Kingdom) and 1% penicillin/streptomycin (Invitrogen), and were incubated at 37 °C in a humidified atmosphere of 5% CO<sub>2</sub>. Monolayers were grown in 24-well Corning Costar Transwell plates (Corning Inc., United States) with 3 μm pore-size filter inserts. In the normal co-culture system, 5 × 10<sup>5</sup> cells were seeded into the inserts, and the wells were filled with 1 mL medium. In the inverted co-culture system, inserts were removed and inverted in tissue culture dishes, and the cells of the same volume were seeded to the exposed filter membrane. The culture dishes were filled with enough medium to sink the inserts. The transwell inserts were cultured for 3-4 d until CMT-93 established monolayers. Confluence of the cells was confirmed when the trans-epithelial electrical resistance (TEER; Millicell ERS Ohmmeter, Millipore, Eschborn, Germany) exceeded the cut-off point of 250 Ω/cm<sup>2</sup>.

### JAWS II cell preparation

JAWS II, mouse bone marrow-derived immature DC<sup>[33]</sup>, were maintained in α-MEM (Gibco) supplemented with 5 ng/mL GM-CSF (Sigma, St. Louis, MO, United States), 20% heat-inactivated FBS (Invitrogen), and 1% penicillin/streptomycin (Invitrogen). The mixture was incubated at 37 °C in a humidified atmosphere of 5% CO<sub>2</sub>. The cells were cultured at a 1/2 subcultivation ratio for 5-6 d in complete medium.

### Co-culture experiment model

The co-culture experiment model is shown in Figure 1. JAWS II cells were harvested, washed, and resuspended in RPMI1640 complete medium (Gibco) containing 5 ng/mL GM-CSF (Sigma), 10% heat-inactivated FBS

**Figure 1** Effect of non-stimulated intestinal epithelial cells on surface phenotype of dendritic cells. Fluorescence activated cell sorter analysis of dendritic cells (DC) cultured alone or co-cultured with non-stimulated epithelial cell monolayers for 12 h showing DC surface phenotype by staining with I-A<sup>d</sup>. Data are shown as the mean fluorescent intensity (MFI) ± SEM of three representative experiments. Significant difference between the single culture and co-culture as determined by Student's *t*-test ( $P < 0.01$ ).

(Invitrogen), and 1% penicillin/streptomycin (Invitrogen). A total of  $1 \times 10^6$  JAWS II cells were added into lower chambers, and the normal and inverted cultured CMT-93 monolayer inserts were placed in the JAWS II seeded transwell plates. One hundred  $\mu\text{g}/\text{mL}$  of the experimental bacteria or 10  $\mu\text{g}/\text{mL}$  of LPS (Sigma) were added to the CMT-93 monolayer inserts. For comparison, JAWS II cells were also plated at the same concentration in 24 well tissue culture plates (Corning Inc.), and the same amount of the bacteria or LPS were added to the cells. The single- or co-cultured cells were incubated with 1 mL RPMI1640 complete medium at 37 °C in a humidified atmosphere of 5% CO<sub>2</sub> for 12 h.

### Flow cytometry analysis

Incubated JAWS II cells were harvested and washed three times in cold FACS buffer (Dulbecco's PBS; Gibco, 2% FBS) and then stained with the appropriate monoclonal antibodies: PE-conjugated anti-I-A<sup>d</sup>, anti-CD80, anti-CD86, and anti-CD40 at a final concentration of 10  $\mu\text{g}/\text{mL}$  for 30 min at 4 °C in the dark. Isotype control antibodies were hamster IgG2 k, rat IgG2a k, and mouse IgG2b. The stained cells were analyzed immediately by FACSCalibur (Becton Dickinson, San Diego, CA, United States). All of the antibodies used in this flow cytometry analysis were purchased from Pharmingen (San Diego, CA, United States).

### Cytokine measurement

JAWS II cell supernatants were harvested from the lower chamber of the Transwell or from the JAWS II cultured-alone plate following incubation, and were assayed for levels of IL-6, IL-10, IL-12p70, tumor necrosis factor (TNF)- $\alpha$  and TGF- $\beta$  using enzyme-linked immunosorbent assay. Briefly, Nunc-Immuno-Maxisorp plates (Nunc, Roskilde, Denmark) were coated with 2  $\mu\text{g}/\text{mL}$  of rat anti-mouse IL-6 and TGF- $\beta$  capture antibodies in coating buffer (1.6 g/L Na<sub>2</sub>CO<sub>3</sub>, 7.1 g/L NaHCO<sub>3</sub>, pH 9.5, or 2  $\mu\text{g}/\text{mL}$  of rat anti-mouse IL-10, IL-12p70, and TNF- $\alpha$  capture antibodies in coating buffer (11.8 g/L Na<sub>2</sub>HPO<sub>4</sub>, 16.1 g/L NaH<sub>2</sub>PO<sub>4</sub>, pH 6.5, overnight at 4 °C. After

washing and blocking, 100  $\mu\text{L}$  of 1:100 diluted (IL-6) or undiluted (IL-10, IL-12p70, TNF- $\alpha$  and TGF- $\beta$ ) supernatant was added to individual wells and incubated overnight at 4 °C. Plates were washed, and biotinylated rat anti-mouse IL-6, IL-10, IL-12p70, TNF- $\alpha$  and TGF- $\beta$  monoclonal antibodies (2  $\mu\text{g}/\text{mL}$ ) and HRP-conjugated streptavidin were added to the plates for cytokine detection for 1 h at room temperature. The reactions were developed with the 3,3',5,5'-tetramethylbenzidine substrate (Fluka, Neu-Ulm, Switzerland) for 30 min at room temperature. The color reactions were stopped with 2 N H<sub>2</sub>SO<sub>4</sub> and analyzed at 450 nm. Equivalent levels of IL-6, IL-10, IL-12p70, TNF- $\alpha$  and TGF- $\beta$  were measured for comparison with a reference curve generated using standards of these cytokines.

### Statistical analyses

Data are presented as the mean  $\pm$  SE, indicated by bars in the figures. All statistical analyses were performed using SPSS 12.0K for Windows (SPSS Inc., Chicago, IL, United States). Differences between the single culture and co-culture were determined by Student's *t*-test, and differences between cytokine levels were analyzed by analysis of variance followed by Duncan's multiple range test. The *P* values  $< 0.05$  were considered to be statistically significant.

## RESULTS

### Development of stable CMT-93 epithelial cell monolayers

To obtain stable CMT-93 intestinal epithelial cell monolayers, we monitored the culture every day for TEER using a Millicell-ERS ohmmeter for a period of 7 d. On day 3, normal insert monolayer integrity was obtained at 300-500  $\Omega/\text{cm}^2$ , and inverted insert monolayer integrity was obtained at 250-350  $\Omega/\text{cm}^2$ . In addition, the generation of epithelial cell monolayers was observed on the surface of the inserts by microscope (data not shown). Monolayers between day 3 and 4 were used for co-culture experiments. After co-culture with DC for 12, the integrity of CMT-93 monolayer was evaluated by TEER. There was no difference between before and after co-culture in terms of the resistances within the margin of error.

### Dendritic cells phenotype modulation during co-culturing with epithelial cells

DC surface phenotypes were compared in the presence and absence of epithelial cells. The expression of MHC class II I-A<sup>d</sup> on the normal and the inverted co-cultured DCs was upregulated compared with that of the single-cultured DC (single culture, 18.51  $\pm$  2.86; normal co-culture, 39.46  $\pm$  2.53; inverted co-culture, 52.03  $\pm$  2.41; Figure 1). Co-culture with epithelial cells did not alter the DC surface expression of CD80, CD86 and CD40 (data not shown).

### Effect of probiotics on the expression of major histocompatibility complex class II and costimulatory molecules

We performed flow cytometry analyses to examine the

effects of BL, BB, LC, LA, LPS and control on single- or co-cultured immature DC surface phenotypes. In the DC single culture, the expression of MHC class II I-A<sup>d</sup> was significantly increased by stimulation with BL, BB, and LC compared with the control (Figure 2). In the normal co-culture, the expression of I-A<sup>d</sup> was significantly decreased by the stimulation of LC and LA compared with the control. In the inverted co-culture, none of the experimental probiotics modulated the expression of I-A<sup>d</sup>.

BL and LA significantly downregulated the expression of CD80 in the single-cultured DC. However, none of the experimental probiotics regulated CD80 in the normal and inverted co-cultured DC (Figure 3A).

BB and LC upregulated the expressions of CD86 and CD40 in the single-cultured DC, whereas none of the experimental probiotics regulated the expression of CD86 in the normal or inverted co-cultured DC (Figure 3B). LC significantly downregulated the expression of CD40 in the inverted co-cultured DC compared with medium alone (Figure 3C).

#### **Cytokine profiles in dendritic cells supernatant by co-culturing with epithelial cells**

The levels of IL-6, IL-12p70, TNF- $\alpha$  and TGF- $\beta$  from the co-cultured system were significantly reduced compared with those from the single-cultured DC (Figure 4A and C-E); however, the production of IL-10 showed no decrease in the co-cultured DC.

#### **Effect of probiotics on the cytokine production in the co-culture system**

We quantified the cytokine levels in the single- and co-cultured DC supernatants to investigate the effect of the experimental probiotics on the production of cytokines. LPS was used as a stimulator control to compare with non-treated naïve control. In the single-cultured DC, stimulation with the experimental probiotic bacteria markedly increased the production of IL-6 and TNF- $\alpha$  compared with the control (Figure 4A and D). In the normal co-cultured DC, the levels of IL-6 stimulated by BB and LC and the level of TNF- $\alpha$  stimulated by LA were lower than those of non-stimulated control. In the inverted co-cultured DC, all of the experimental bacteria significantly decreased the production of IL-6 compared with the control, but had no significant effect on the production of TNF- $\alpha$ .

In the single-culture, the level of IL-10 in DC stimulated by BL, LC, and LA was higher than that in the control DC (Figure 4B). The levels of IL-10 from the normal co-cultured DC stimulated by BL, BB and LC were lower. IL-10 from the inverted co-cultured DC stimulated by BL was higher than that from the control.

In the single-cultured DC all of the experimental probiotics decreased the production of IL-12p70. In the normal co-cultured DC only BL increased the production of IL-12p70. In the inverted co-cultured DC the levels of IL-12p70 stimulated by all of the experimental probiotics were similar to that of control.

BL, BB and LC in the single-cultured DC decreased

the production of TGF- $\beta$ . The levels of TGF- $\beta$  in all of the treated groups in the normal co-culture system were similar to that from the non-stimulated control but in the inverted co-cultured system LC and LA significantly increased the production of TGF- $\beta$  (Figure 4C and E).

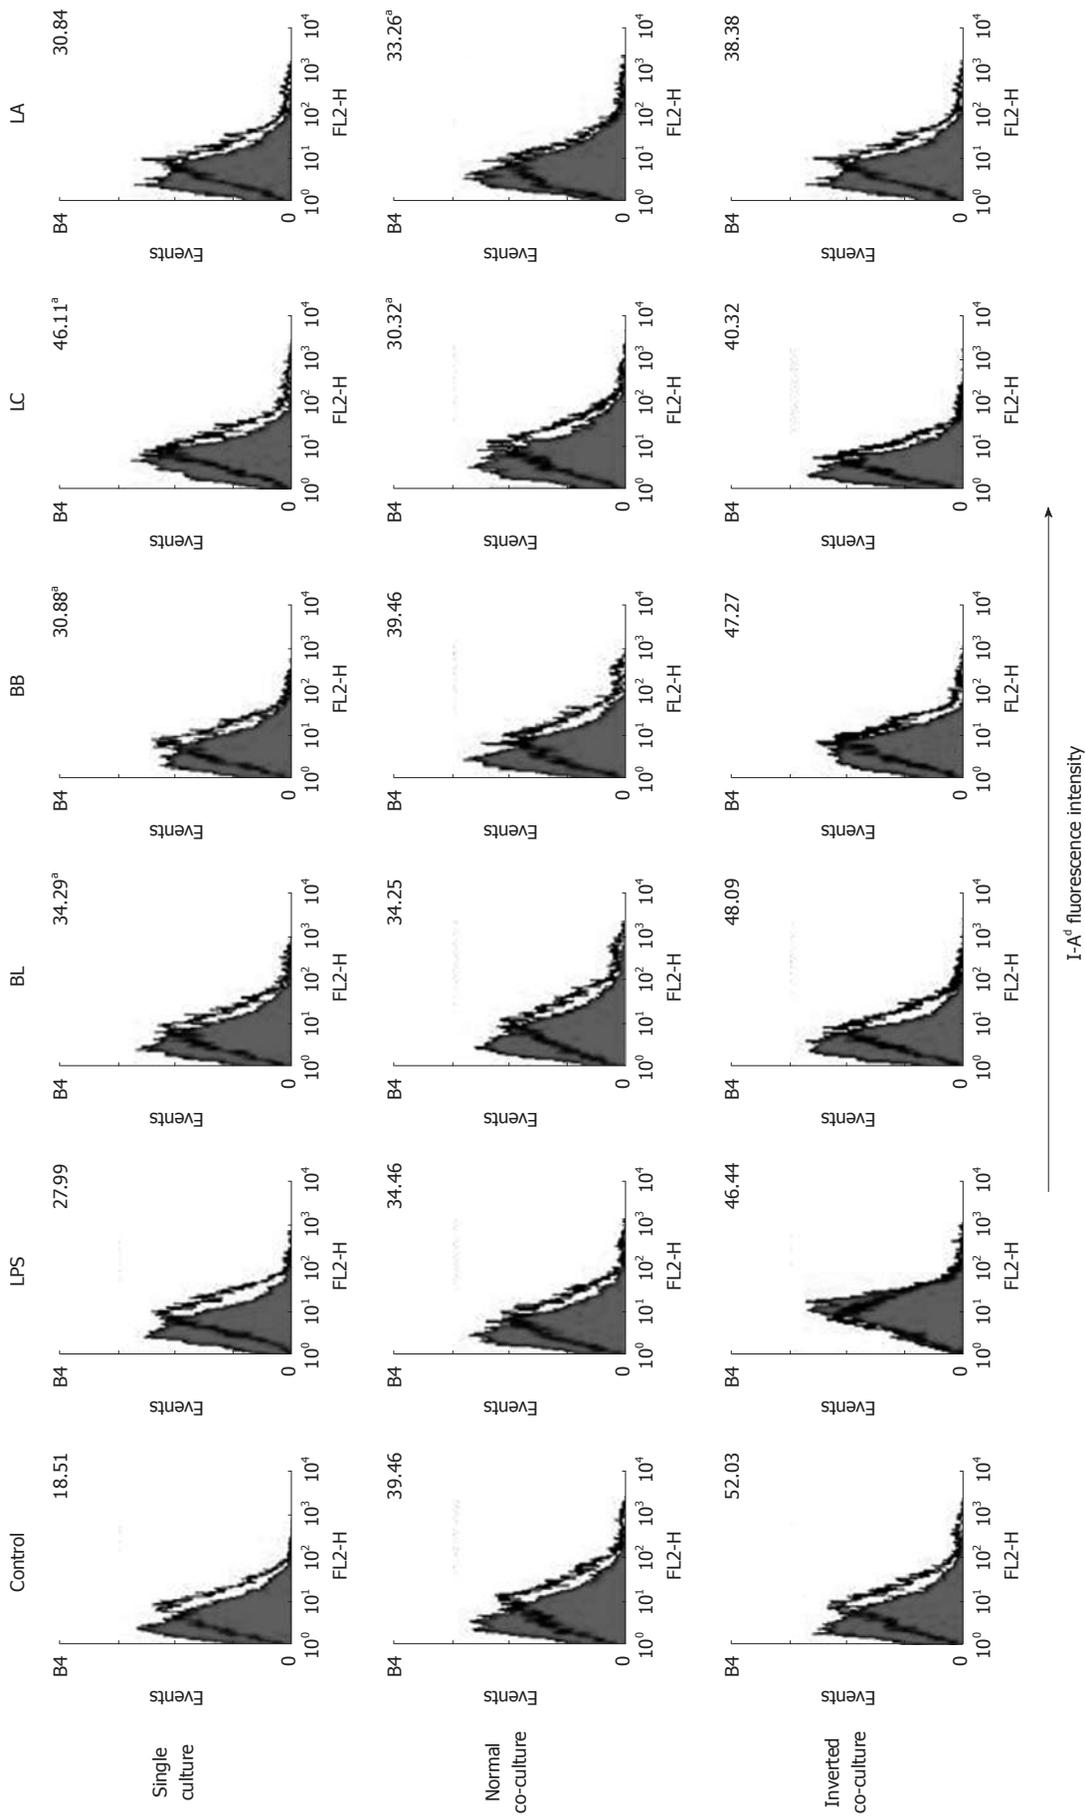

## **DISCUSSION**

The modulatory effect of probiotics on the host immune system was reported in *in vivo* experiments and clinical trials<sup>[34]</sup>. However, the exact mechanism of the immunomodulatory effect of probiotics, especially with respect to the interaction between DC and epithelial cells in the presence of probiotics, has not been well elucidated. In the present study, we investigated the effect of heat-killed BL, BB, LC and LA on the modulation of JAWS II (DC) using an *in vitro* co-culture model. *In vitro*, live bacteria grown by geometric progression exhausted culture nutrients, produced various acid metabolites, and induced necrosis of the cultured animal cells within a few hours. Therefore, the treatment of the host cells with live bacteria was inappropriate. The adhesive properties of heat killed bacteria might be differentially modified by the heat treatment depending on the specific strain of the experimental bacteria. However, a previous study reported that oral administration of heat-killed and lyophilized BB could suppress the occurrence of allergy by the immune regulatory actions in the mouse allergy model<sup>[35]</sup>, which implied that heat-killed and lyophilized bacteria could maintain their immunomodulatory effects.

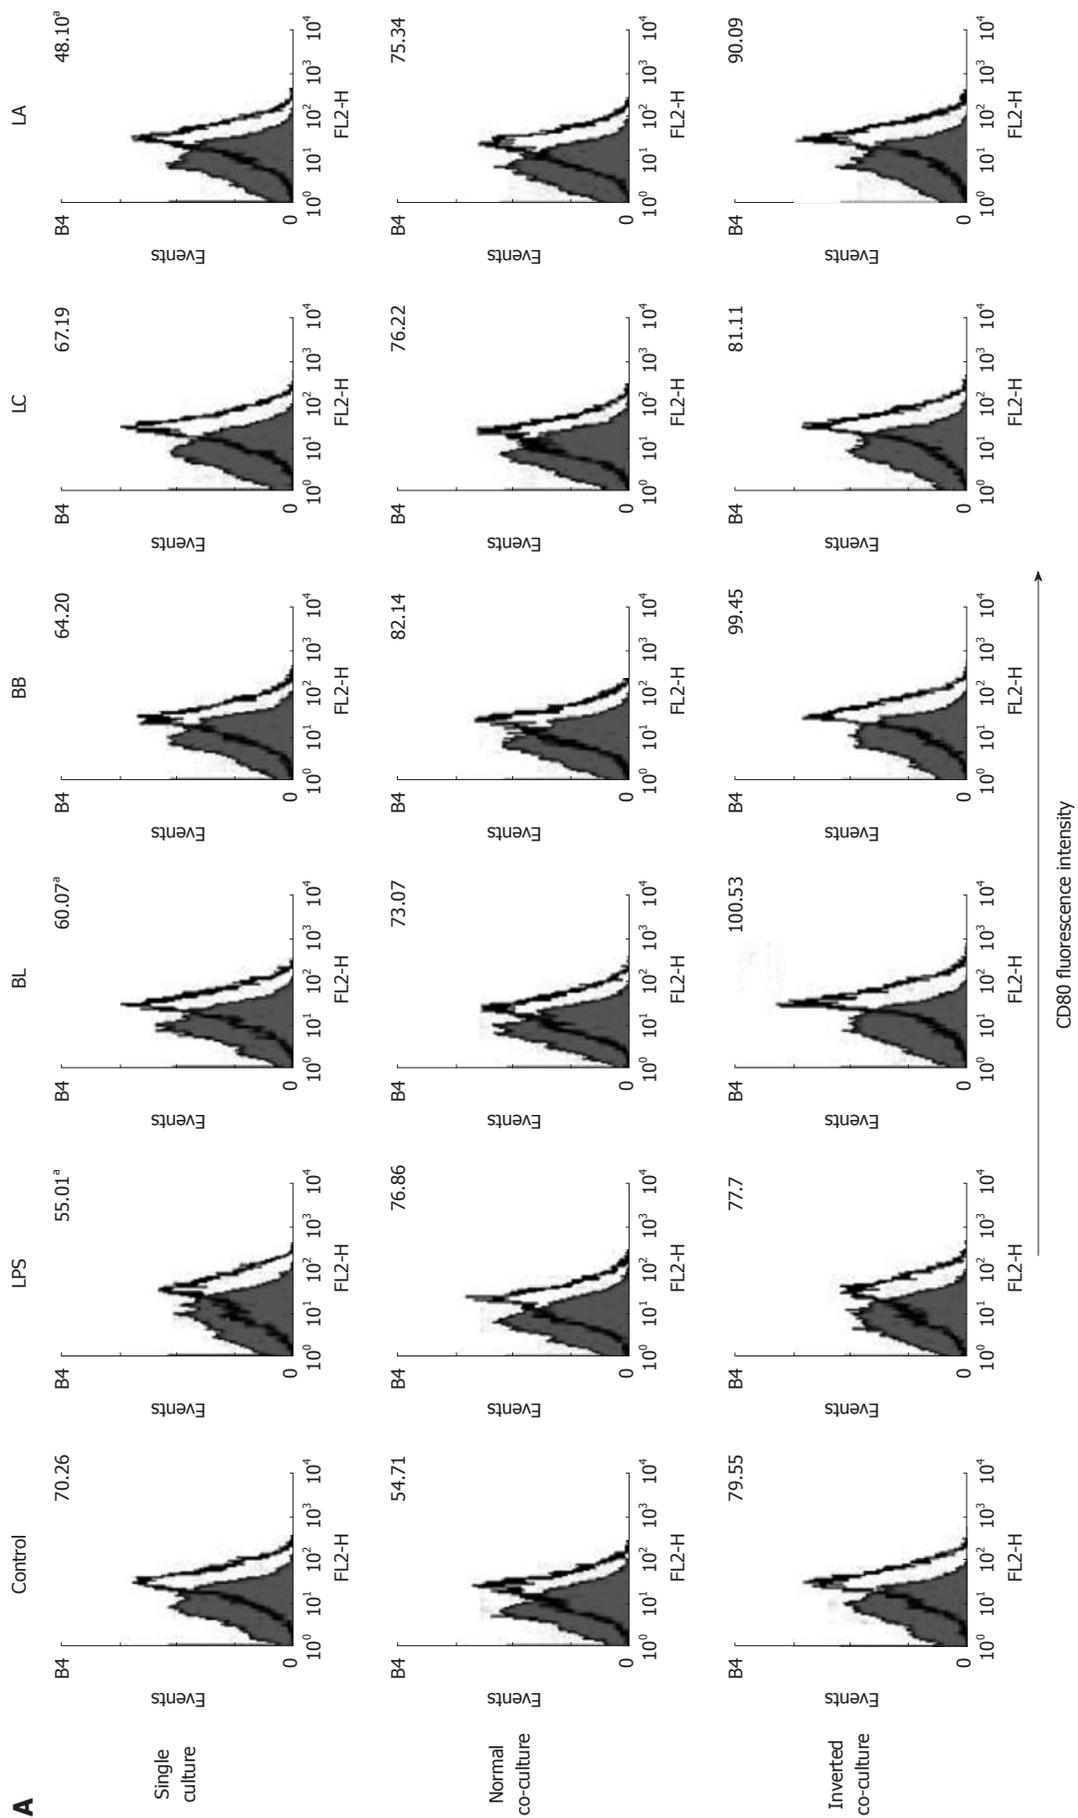

To simulate the interaction between DC and epithelial cells in the intestinal environment, we used a transwell co-culture system with CMT93 epithelial cell lines<sup>[32]</sup>. CMT93 was derived from the same mouse origins as JAWS II, C57BL mouse, and forms junction complexes. A previous study reported that there was a gap junctional communication between murine lymphocytes and CMT93 epithelial cells, and gap junctional communication might regulate cell functions<sup>[36]</sup>. Nonpathogenic intestinal bacteria can induce DC migration into the epithelial layer and recruit DC uptake of bacteria and apoptotic fragments derived from apoptotic epithelial cells to maintain peripheral self-tolerance<sup>[2,37]</sup>. In the normal co-culture system, there was an insert membrane and a gap of 1 mm between JAWS II and CMT93. On the other hand, an inverted co-culture model was established by the generation of a CMT93 monolayer on the underside of the inverted insert. A previous study demonstrated that DCs directly interacted with luminal bacteria using CX<sub>3</sub>CR1-mediated trans-epithelial dendrites<sup>[38]</sup>.

DC interact with microbes and distinguish gram positive, negative, or closely related organisms using TLR and present the processed antigens through MHC class II<sup>[12,16,39]</sup>. DC then mediate T cell activation, which is regulated by MHC class II molecules, co-stimulatory molecules such as CD80 and CD86, and cytokines<sup>[40]</sup>.

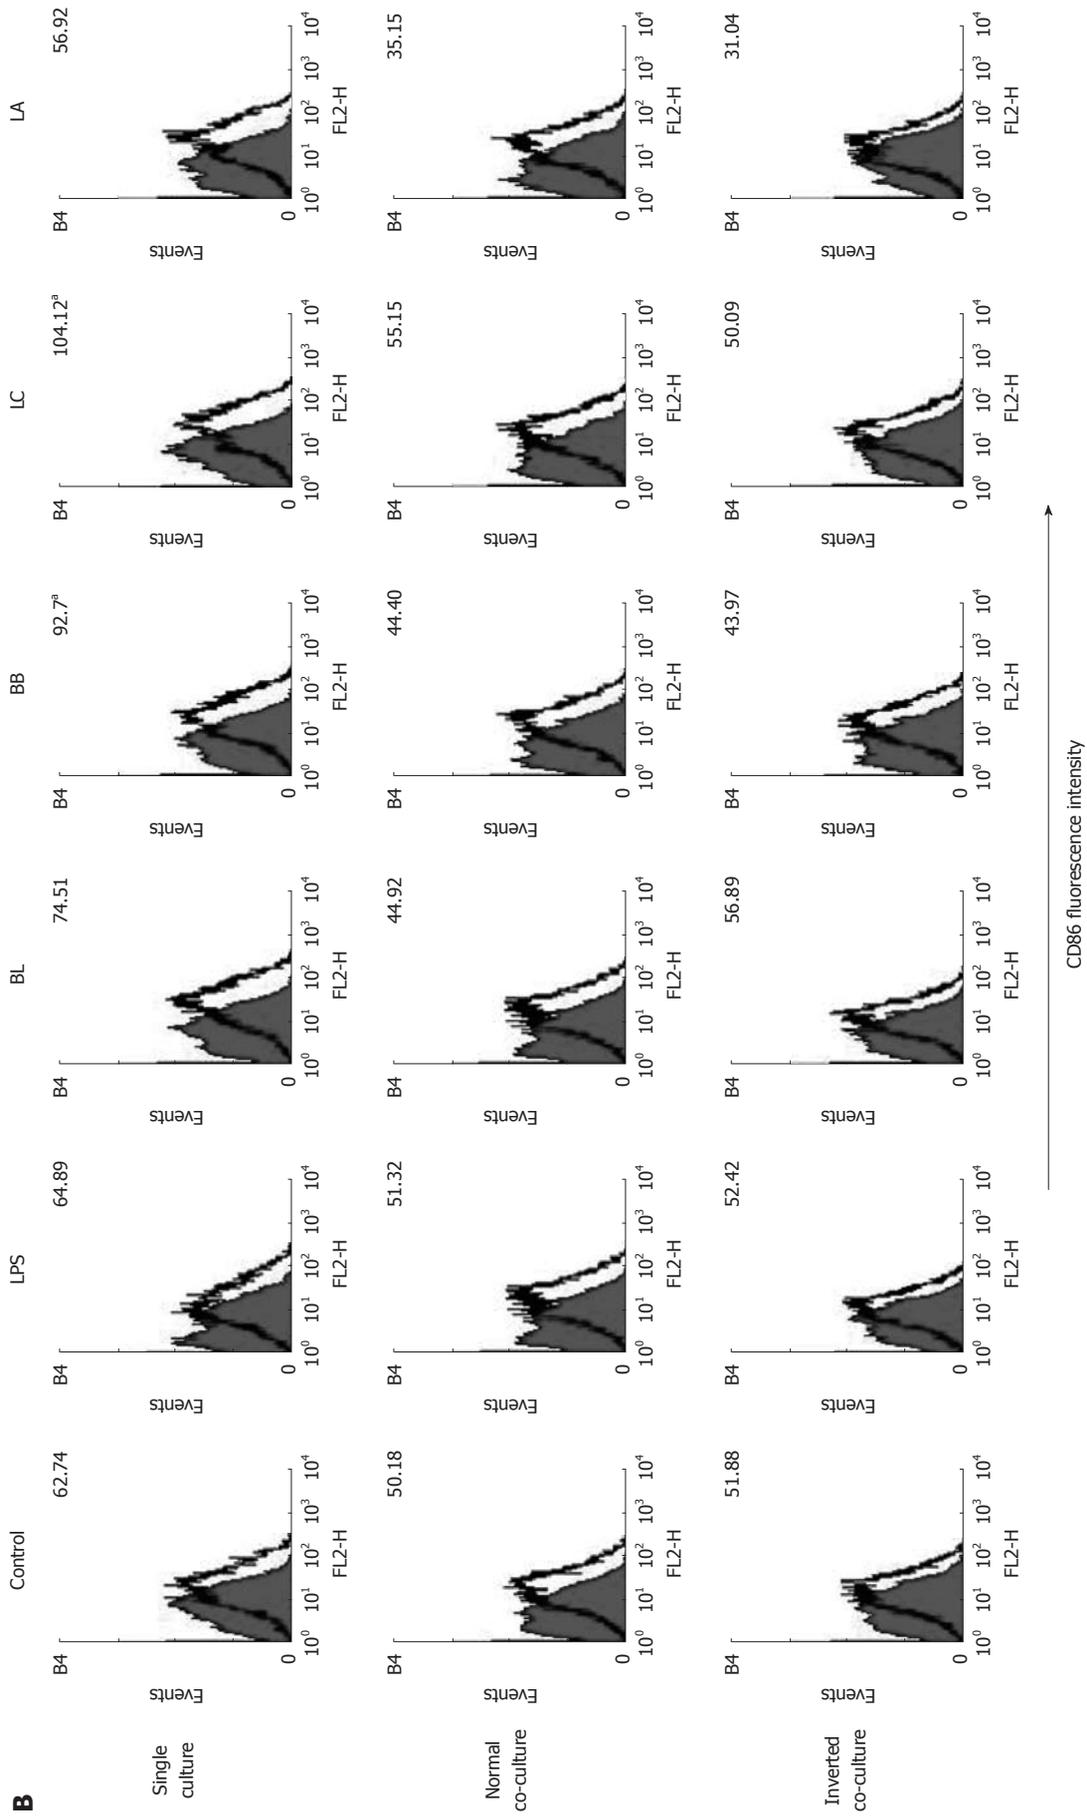

In the single-cultured systems BB and LC upregulated the expression of MHC class II I-A<sup>d</sup>, CD86, and CD40, while all of the experimental probiotics attenuated IL-

IL-12p70 secretion. IL-12 directed the differentiation of T cells to a Th1 phenotype<sup>[41]</sup>. Nier reported that *Bifidobacterium bifidum* enhanced the expression of CD86 and MHC class II in human neonatal DC, which led in turn to the polarization of IFN- $\gamma$ -producing T cells<sup>[42]</sup>. Mohamadzadeh *et al*<sup>[43]</sup> showed that *Lactobacillus gasseri*, *Lactobacillus johnsonii*, and *Lactobacillus reuteri* upregulated the expression of MHC class II, CD40, CD80 and CD86 in human myeloid DC and increased the level of IL-12p70 which induced the polarization from CD4(+) and CD8(+) T cells to T helper 1 and Tc1 cells. Meanwhile, Drakes *et al*<sup>[22]</sup> showed that probiotic products containing *Lactobacillus* and *Bifidobacterium* upregulated the expression of MHC class II, CD40, CD80 and CD86, and did not induce the production of IL-12p70 in mouse DC. Additionally, mouse bone marrow-derived DC treated with *Lactobacillus reuteri* induced Th2 immune response<sup>[21]</sup>. Taken together,

the results of these earlier studies suggested that probiotics upregulated the expression of MHC class II and differently modulated co-stimulatory molecules such as IL-12p70 and T cell polarization, depending on the DC origin and the strain of probiotics.

Interestingly, in the present study the effects of probiotics on cytokine production and the surface phenotype in co-cultured DC with epithelial cells were markedly different from those in single-cultured DC. All of the experimental probiotics induced the production of pro-inflammatory cytokines, IL-6 and TNF- $\alpha$ , in the single cultured DC. TNF- $\alpha$  mediated various immune responses<sup>[44]</sup>, and over-production of TNF- $\alpha$  could play a role in tissue damage and intestinal pathologies<sup>[45,46]</sup>. In contrast with the results from the single system the experimental probiotics reduced or did not affect the expression of I-A<sup>d</sup>, CD86 and CD40 or the production of IL-6, IL-12p70

and TNF- $\alpha$  in inverted co-cultured DC. These findings suggest that epithelial cells are essential components of the immune system to be considered in assessing the effects of probiotics on the regulation of the gastrointestinal immune system. Consequently, previous studies which employed only DC cells without epithelial cells might have provided only partial pictures or sometimes misleading information about the interaction of the probiotics with DC cells.

Previously, Haller *et al.*<sup>[47]</sup> showed that *Lactobacillus johnsonii* increased the production of TGF- $\beta$  in human epithelial cell lines co-cultured with leucocytes. In our study, BL, LC and LA induced IL-10 secretion from single-cultured DC. In an inverted co-culture system, BL increased IL-10 secretion, and LC and LA increased TGF- $\beta$  secretion. IL-10 was known to activate regulatory T cells<sup>[48]</sup>. TGF- $\beta$  which is an important factor in enhancing the differentiation of regulatory Th3 cells was reported to have wide-ranging immunomodulatory properties<sup>[49,50]</sup>. Th3 cells suppress Th1 and other immune responses and maintain oral tolerance<sup>[40,50,51]</sup>. Conceivably, enhanced secretion of IL-10 or TGF- $\beta$  observed in the co-culture systems by BL, LC and LA might contribute to the activation of regulatory T cells in the intestinal tracts. The present study is novel since we assessed the effect of probiotics on immunomodulation in a co-culture model. We suggest that a co-culture model better reflects the environmental status of the *in vivo* immune system. Our model supports the hypothesis that the interaction of DC and epithelial cells stimulated with probiotics may help maintain intestinal homeostasis by downregulating the production of inflammatory cytokines and expression of MHC class II in DC.

## COMMENTS

### Background

It is known that dendritic cells (DCs) modulate the immune balance in the intestinal tract by mediating the activation of different subsets of T cells. The functions and differentiation of the DCs may be modulated by probiotics. To better understand the role of the probiotics in the intestinal immune system the interactions of probiotics in the context of epithelial cells and DCs need to be assessed.

### Research frontiers

Intestinal epithelial cells secrete various immunological mediators, but the interactions between probiotics, intestinal epithelial cells, and DCs were not fully known. The present study investigated the pattern of cytokine production and the surface phenotype of DCs in the presence of epithelial cells polarized by heat-killed probiotic bacteria.

### Innovations and breakthroughs

The present study showed the differential effects of probiotics between the single cultured and the co-cultured DCs. We suggest that a co-culture model better reflects the environmental status of the *in vivo* immune system. The interaction of DCs and epithelial cells polarized with probiotics may contribute to the homeostasis of the immune system in the intestinal tracts.

### Applications

The employment of the co-culture system may facilitate the development of probiotic bacteria with immunomodulatory effects for people with hypersensitive or imbalanced immune symptoms.

### Peer review

The study is well-conducted and results are interesting. However, the results are curiously reported in a confusing manner. Moreover, some controls are needed and the positive control used should be more justified.

### Abstract

**AIM:** To investigate whether hepatitis B virus (HBV) could induce a hepatitis B virus core antigen (HBcAg)-specific cytotoxic T lymphocyte (CTL) response *in vitro* by dendritic cells (DCs) transduced with lentiviral vector-encoding ubiquitinated hepatitis B virus core antigen (LV-Ub-HBcAg).

**METHODS:** Recombinant LV-Ub-HBcAg were transfected into highly susceptible 293 T cells to obtain high virus titres. Bone marrow-derived DCs isolated from BALB/c mice were cultured with recombinant granulocyte-macrophage colony-stimulating factor and recombinant interleukin (IL)-4. LV-Ub-HBcAg, lentiviral vector-encoding hepatitis B virus core antigen (LV-HBcAg), lentiviral vector (LV) or lipopolysaccharide were added to induce DC maturation, and the DC phenotypes were analyzed by flow cytometry. The level of IL-12 in the supernatant was detected by enzyme-linked immunosorbent assay (ELISA). T lymphocytes were proliferated using Cell Counting Kit-8. DCs were cultured and induced to mature using different LVs, and co-cultured with allogeneic T cells to detect the secretion levels of IL-2, IL-4, IL-10

and interferon- $\gamma$  in the supernatants of T cells by ELISA. Intracellular cytokines of proliferative T cells were analyzed by flow cytometry, and specific CTL activity was measured by a lactate dehydrogenase release assay.

**RESULTS:** LV-Ub-HBcAg-induced DCs secreted more IL-12 and upregulated the expression of CD80, CD86 and major histocompatibility class II. DCs sensitised by different LVs effectively promoted cytokine secretion; the levels of IL-2 and interferon- $\gamma$  induced by LV-Ub-HBcAg were higher than those induced by LV-HBcAg. Compared with LV-HBcAg-transduced DCs, LV-Ub-HBcAg-transduced DCs more efficiently stimulated the proliferation of T lymphocytes and generated HBcAg-specific cytotoxic T lymphocytes.

**CONCLUSION:** LV-Ub-HBcAg effectively induced DC maturation. The mature DCs efficiently induced T cell polarisation to Th1 and generated HBcAg-specific CTLs.

### INTRODUCTION

Hepatitis B virus (HBV) infection is a serious public health problem, particularly in Asia and South Africa<sup>[1]</sup>. Notably,

an effective T cell response is critical for virus clearance, and defective cytotoxic T lymphocytes (CTLs) may lead to persistent HBV infection<sup>[2]</sup>. Moreover, the defective CTL response was ascribed to the impaired dendritic cell (DC) function<sup>[3]</sup>. Promoting and improving DC function is a promising approach to combating persistent HBV infection.

Various methods have been attempted to modify DC function, including the use of protein antigens, cytokines, costimulatory molecules, and signalling pathway ligands known to activate the immune response<sup>[4-7]</sup>. Nevertheless, these methods may be insufficient to induce a strong antigen-specific immune response. Further enhancement of the immune response to HBV-specific CTL may be more conducive to clear the HBV. Thus, a novel therapeutic approach is needed to activate T cell expansion and induce a strong antigen-specific T cell response.

Ubiquitin (Ub) is a highly conserved small regulatory protein, ubiquitous in eukaryotes, that usually serves as a signal for the target protein that is recognized and degraded in proteasomes<sup>[8]</sup>. The Ub-mediated processing of antigens is rapid and efficient and stimulates cell-mediated immune responses. Accordingly, Ub-mediated processing of antigens has been widely used in chronic infection and cancer studies to improve immune response. Wang *et al.*<sup>[9]</sup> found that an Ub-fused *Mycobacterium tuberculosis* antigen ESAT-6 DNA vaccine significantly increased the antigen-specific cellular immune response in BALB/c mice. That study confirmed that the Th1-type immune response and CTL activity were enhanced by changing the antigen processing. Zhang *et al.*<sup>[10]</sup> reported that Ub-fused melanoma antigens induced antigen proteins to execute proteasome-dependent degradation and created epitopes of major histocompatibility complex (MHC) class I, resulting in the preferential activation of antigen-specific CD8<sup>+</sup> T cells.

Retroviral and adenoviral vectors have been the focus of many studies because of their high efficiency. Lentivirus vectors (LVs) transfect both dividing and relatively quiescent cells and have been widely used to modify DCs<sup>[11,12]</sup>. The aim of this study was to investigate the capacity of DCs transfected with LVs encoding the ubiquitinated hepatitis B virus core antigen (LV-Ub-HBcAg-DC) to stimulate lymphocyte proliferation and to generate antigen-specific CTLs. The results may provide effective approaches to the control of persistent HBV infection.

## MATERIALS AND METHODS

### Animals

BALB/c mice (H-2<sup>d</sup>), 6-8 wk old, were purchased from the Shanghai Experimental Animal Centre of the Chinese Academy of Sciences and maintained under pathogen-free conditions. Mice were cared for and treated in accordance with the guidelines established by the Shanghai Public Health Service Policy on the Humane Care and Use of Laboratory Animals.

### Cell lines

HEK293T cells were cultured in Dulbecco's modified

Eagle's medium (Invitrogen, Gaithersburg, MD, United States) supplemented with 10% foetal bovine serum (Gibco, Grand Island, NY, United States), penicillin (100 U/mL), and streptomycin (100 mg/mL) at 37 °C in 5% CO<sub>2</sub>. The H-2<sup>d</sup> mastocytoma cell line P815/c (expressing the HBV core antigen) was maintained in our lab.

### Construction of lentiviral vectors

The plasmid pcDNA3.1(-)-Ub-HBcAg was constructed and maintained in our lab. The *Ub-HBcAg* gene was amplified by polymerase chain reaction (PCR). The primers used were: Ub-HBcAg: forward: CGTGGGATC-CATGCA GATCTTCGTGAAG, reverse: CGCAGC CGTCTAACATTGAGATTCCCGAG from plasmid pcDNA3.1(-)-Ub-HBcAg. The purified Ub-HBcAg fragment was cloned into the pWPLXd vector (provided by Prof. Jianming Li, Nanjing, China) using BamH I and Mlu I restriction sites. The recombinant pWPLXd-Ub-HBcAg plasmid was confirmed by restriction enzyme digestion and DNA sequencing. LV-Ub-HBcAg was derived by a combined transfection of three elements: 10 µg pWPLXd-Ub-HBcAg backbone plasmid, 5 µg psPAX2 packaging plasmid, and 5 µg PMD2.G envelope plasmid. We transiently transfected 293T cells with plasmids using Lipofectamine 2000 (Invitrogen, Carlsbad, CA, United States). Two days after the transfection, the viral supernatant was collected and filtered through a 0.45-µm filter. Concentrated vectors for the *in vitro* studies were prepared by ultracentrifugation at 25 000 rpm and 4 °C for 90 min. Viral pellets were resuspended in 2 mL sterile phosphate-buffered saline (PBS) and stored at -80 °C.

The control plasmid was constructed by inserting the HBcAg fragment into the BamH I and Mlu I site of the pWPLXd plasmid and named pWPLXd-HBcAg. LV particles (LV-HBcAg) were produced by Lipofectamine transfection into 293T cells.

To determine the titre of the green fluorescent protein (GFP)-expressing vector, 293T cells (1 × 10<sup>6</sup> cells/well) were infected with serially diluted viral supernatant. On day 2, the infected cells expressing GFP were counted by flow cytometry. The titre was calculated as: transduction units per mL (TU) = the number of infected cells/volume of virus supernatant.

### Western blotting

The 293T cells were seeded in six-well plates at 1 × 10<sup>6</sup> cells/well. LV-Ub-HBcAg, LV-HBcAg or LV was added at an multiplicity of infection (MOI) of 1. In some experiments, a specific inhibitor of proteasomes, MG132, was used at 10 µmol. The cells were harvested 48 h after infection, washed twice with PBS, gently dispersed into a single-cell suspension and homogenised using RIPA lysis buffer. Protein concentrations were determined using the Pierce BCA Protein Assay Reagent kit (Rockford, IL, United States). Homogenates were diluted to the desired protein concentration with 2 × SDS-PAGE loading buffer (Invitrogen). Samples were boiled and loaded onto polyacrylamide mini-gels (Invitrogen) for electrophoresis. Proteins from the gels were transferred to Im-

mobilon-PVDF membranes (Millipore Corp., Bedford, MA, United States) using a semi-dry apparatus (Bio-Rad, Hercules, CA, United States). A mouse anti-human HBcAg monoclonal antibody (Santa Cruz Biotechnology, Santa Cruz, CA, United States) was used as the primary antibody, and horseradish peroxidase-conjugated goat anti-mouse immunoglobulin-G antibody was used as the secondary antibody.

### **Dendritic cell generation**

Femurs and tibiae of Balb/c mice were removed and purified from the surrounding muscle tissues. Thereafter, intact bones were left in 70% ethanol for 5 min for disinfection and then washed with PBS. Both ends were cut with scissors and the marrow was flushed with PBS using a syringe with a 0.45-mm diameter needle. Clusters within the marrow suspension were disintegrated by vigorous pipetting. Bone marrow cells were cultured at  $2 \times 10^6$  cells/mL in complete RPMI 1640 culture medium (containing 10% FBS, 100 U/mL penicillin, and 100 mg/mL streptomycin) in the presence of 20 ng/mL murine granulocyte-macrophage colony-stimulating factor (GM-CSF) (PeproTech, Rocky Hill, United States) and 10 ng/mL murine IL-4 (mIL-4; PeproTech). Nonadherent single cells were gently removed, and fresh medium containing murine GM-CSF and mIL-4 was added on day 3 after beginning culture.

### **Dendritic cell immunophenotyping**

On day 5, immature DCs were cultured for an additional 96 h in the presence of LV-Ub-HBcAg, LV-HBcAg or LV (MOI = 20), and lipopolysaccharide (LPS, 0.5 mg/mL; Sigma-Aldrich, St. Louis, MO, United States) was used as a control group. On day 9, non-adherent and loosely adherent cells were harvested as DCs. The expression of DC surface molecules was analyzed by incubation with allophycocyanin-labelled anti-mouse CD11c, CD80, CD86 and MHC class II (eBioscience, San Diego, CA, United States). The stained cells were analyzed by flow cytometry.

### **Interleukin-12 production**

On day 5, immature DCs were infected with LV-Ub-HBcAg, LV-HBcAg, or LV (MOI = 20) for 72 h. On day 8, the IL-12 levels in harvested supernatants of mature DCs were measured using a standard sandwich enzyme-linked immunosorbent assay (ELISA) kit (R and D Systems, Minneapolis, MN, United States) according to the manufacturer's instructions.

### **Mixed leukocyte reaction**

On day 9, harvested mature DCs were pre-treated with 25  $\mu$ g/mL mitomycin C and 5% CO<sub>2</sub> for 30 min at 37 °C. Mouse spleens were dissociated on 200-gauge nylon mesh. Splenocytes were collected and treated with lysis buffer to eliminate red cells, washed, and resuspended in RPMI-1640 with 10% FBS. Lymphocytes were derived from splenocytes using nylon wool columns. Single-cell

suspensions of lymphocytes ( $5 \times 10^5$  cells/well) were grown in 96-well plates. Lymphocytes were co-cultured with mature DCs at different responder/stimulator (T cell/DC) ratios (5:1, 10:1 or 20:1) for 72 h. The cells were incubated in a final volume of 200- $\mu$ L complete RPMI 1640 for 72 h, and 10- $\mu$ L Cell Counting Kit-8 solution (Beyotime Institute of Biotechnology, Haimen, China) was added to the plates for 4 h at 37 °C. The absorbance was finally read at 450 nm.

### **Cytokine production**

Splenocytes from mice were cultured in 96-well culture plates in the presence of mature DCs for 4 d at a T-cell to DC ratio of 10:1, and the supernatants were collected. The levels of different cytokines [interferon (IFN)- $\gamma$ , IL-2, IL-4 and IL-10] in the supernatants of proliferating T cells were measured using commercial ELISA kits according to the manufacturer's protocol (R and D Systems). Data were expressed as pg/mL.

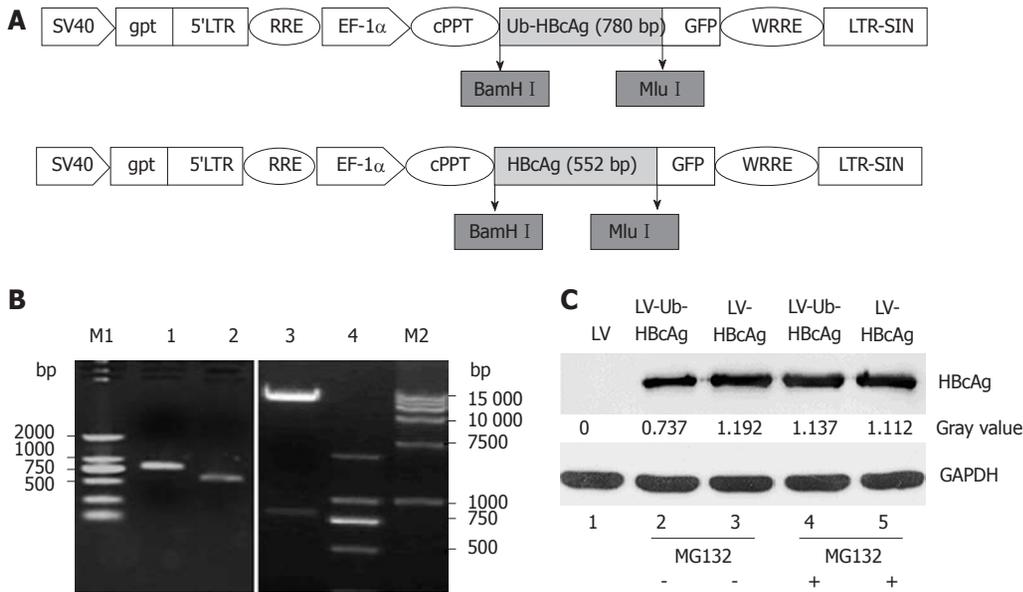

IFN- $\gamma$  production was detected by intracellular staining and flow cytometry. The above proliferative T cells were suspended in complete RPMI 1640 and stimulated for 6 h in the presence of 25  $\mu$ g/mL phorbol 12-myristate 13-acetate, 1  $\mu$ g/mL ionomycin and 1.7  $\mu$ g/mL monensin (Sigma). After washed with PBS, the cells were stained with FITC-conjugated anti-CD8 $\alpha$  mAb (eBioscience) for 30 min at 4 °C, washed with PBS, fixed with 4% paraformaldehyde, and permeabilised with PBS containing 0.5% saponin (both from BD, Shanghai, China). Cells were incubated with PE-labelled anti-INF- $\gamma$  McAb (eBioscience) for 30 min at 4 °C, washed with PBS, and analyzed by flow cytometry.

### **Hepatitis B virus core antigen-specific cytotoxic T lymphocytes activity**

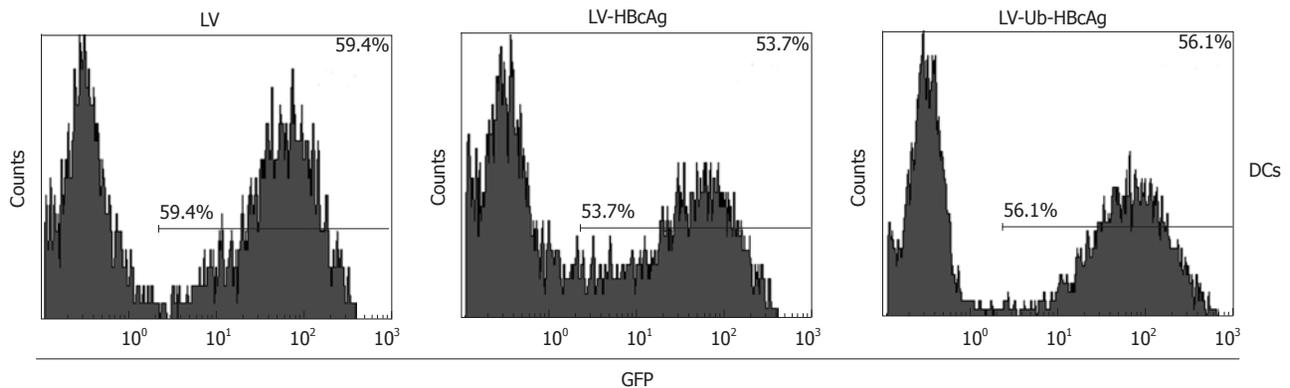

The former stimulated splenocytes ( $5 \times 10^6$ /mL) were used as effectors, and the P815/c cell line was used as target cells. P815/c cells were seeded at a density of  $5 \times 10^4$  cells/well in 96-well plates. Effector cells were incubated with P815/c at different effector and target (E/T) ratios (12.5:1, 25:1 or 50:1) at 37 °C under 5% CO<sub>2</sub> for 4 h. The HBcAg-specific CTL activity was measured using a Cyto-Tox 96<sup>®</sup> Non-Radioactive Cytotoxicity Assay (Promega, Madison WI, United States) for lactate dehydrogenase (LDH) release according to the manufacturer's instructions. The absorbance values of the supernatants were recorded at optical density 450 nm. Percent cytotoxicity was calculated as follows: [(Experimental release - Effector spontaneous release - Target spontaneous release)/(Target maximum release - Target spontaneous release)]  $\times$  100%.

### **Statistical analysis**

Results were expressed as mean  $\pm$  SD. Differences between groups was determined using Student's *t* test, and the differences between two or more groups were determined using a one-factor analysis of variance. Data were considered statistically significant at  $P < 0.05$ .

**Figure 1** Schematic diagram, electrophoresis of ubiquitinated hepatitis B virus core antigen and HbCag genes, pWPXLd-Ub-HBcAg digested by BamH I and Mlu I, and HbCag protein expression (about 21 kDa). A: Schematic diagram of pWPXLd vector; B: Lane 1, ubiquitinated hepatitis B virus core antigen (Ub-HBcAg) polymerase chain reaction (PCR) product (780 bp); lane 2, HbCag PCR product (552 bp); lane 3, The digested products pWPXLd-Ub-HBcAg by BamH I and Mlu I; lane 4 and lane M1, DNA marker 2000; lane M2, DNA marker 15 000; C: 293T cells were transduced with lentiviral vector (LV), LV-Ub-HBcAg or LV-HBcAg and cultured for 48 h. MG-132 (10 mmol) was added for 24 h before harvesting the cells. Cell lysates (10 mg) were analyzed by immunoblotting with an anti-HBc antibody. Relative expression of HbCag was calculated by a gray value.

**Figure 2** Transduction of dendritic cells with lentiviral vectors expressing green fluorescent protein was evaluated by flow cytometry. Dendritic cells (DCs) were seeded in six-well plates at  $1 \times 10^6$  cells/well. Lentiviral vectors ubiquitinated hepatitis B virus core antigen (LV-Ub-HBcAg), lentiviral vectors hepatitis B virus core antigen (LV-HBcAg) or lentiviral vector (LV) was added at an multiplicity of infection of 20. GFP: Green fluorescent protein.

## RESULTS

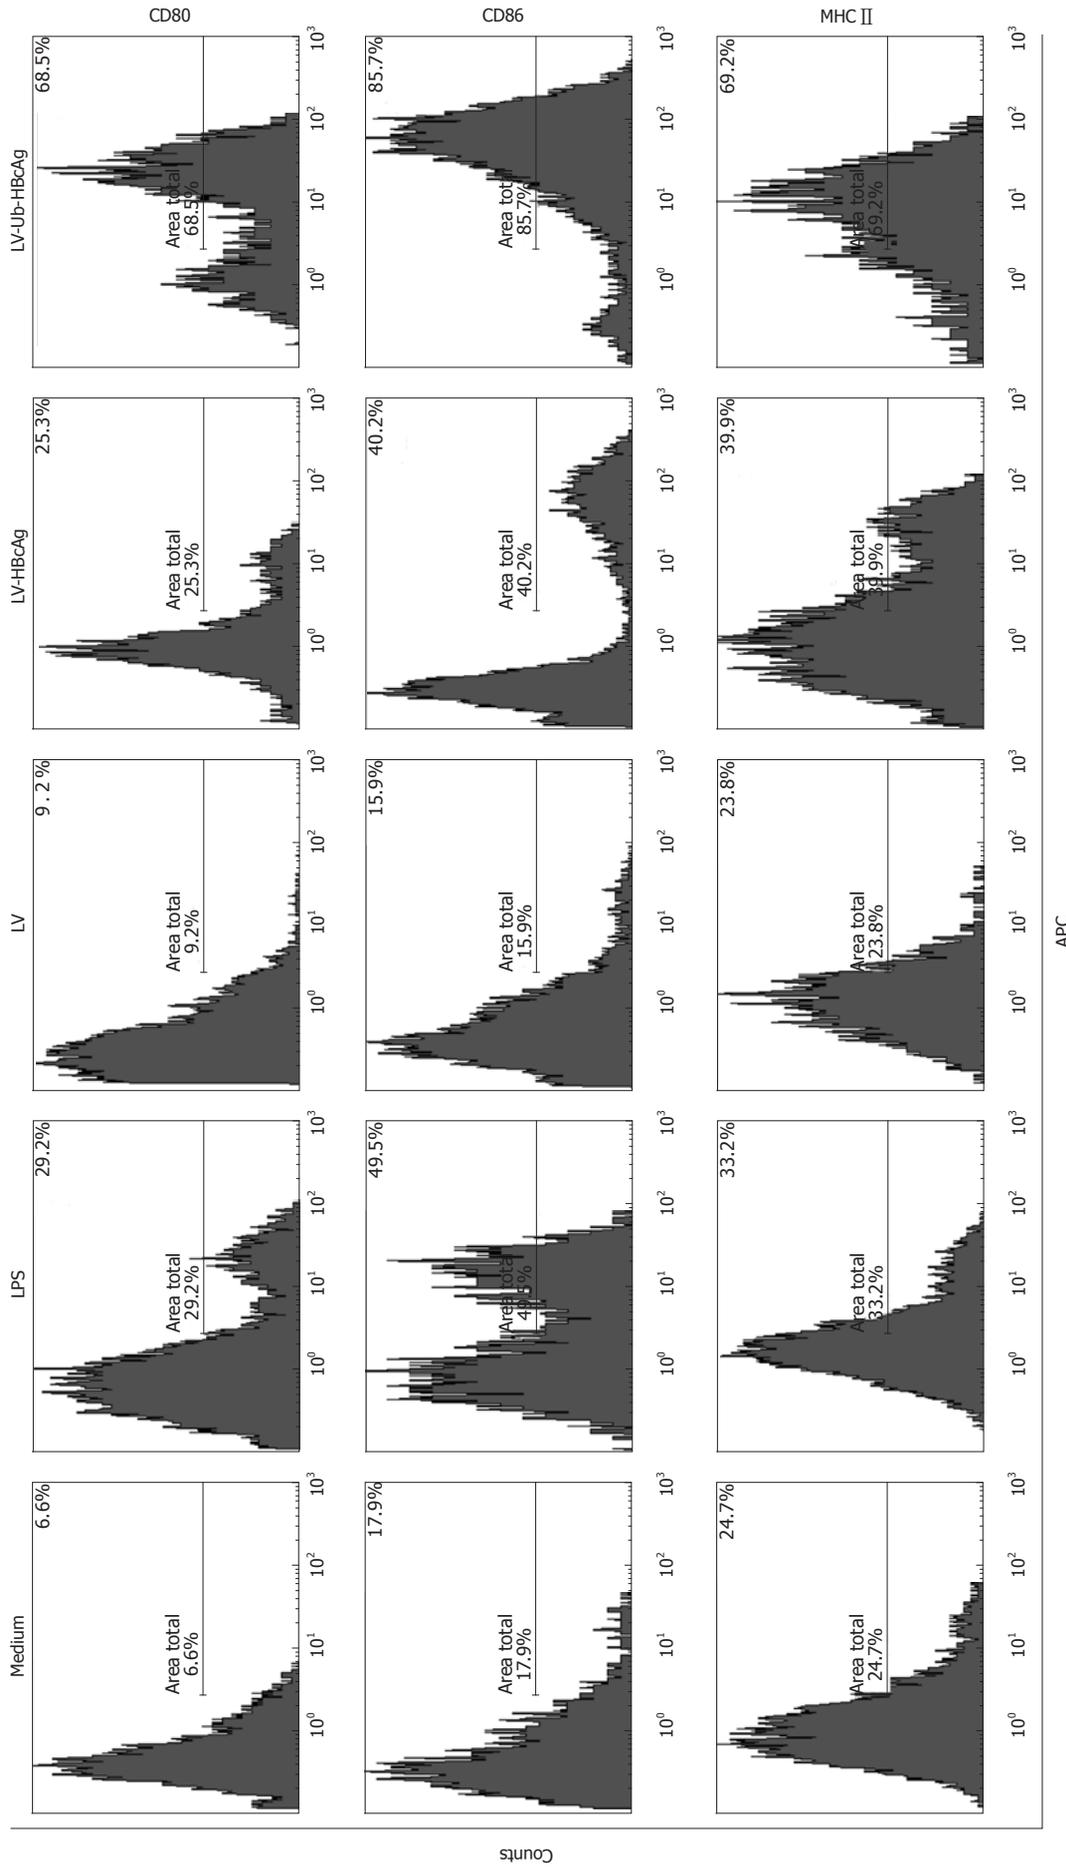

### Construction of lentiviral vectors and transduced dendritic cells

A 780 bp fragment of the *Ub-HBcAg* gene was cloned into pWPXLd (Figure 1B) and packed into LVs. The *HbCag* gene was similarly assembled as a control. After concentration, all vectors in the study achieved a titration of approximately  $7.5 \times 10^8$  transducing units/mL. The construction procedure is shown in Figure 1A. As expected, Ub-HBcAg expression was lower than that of HbCag and recovered to the same level as that of HbCag when MG-132 was added to the culture (Figure 1C). The transduction efficiency of LVs into DCs was evaluated using flow cytometry by detecting GFP expression

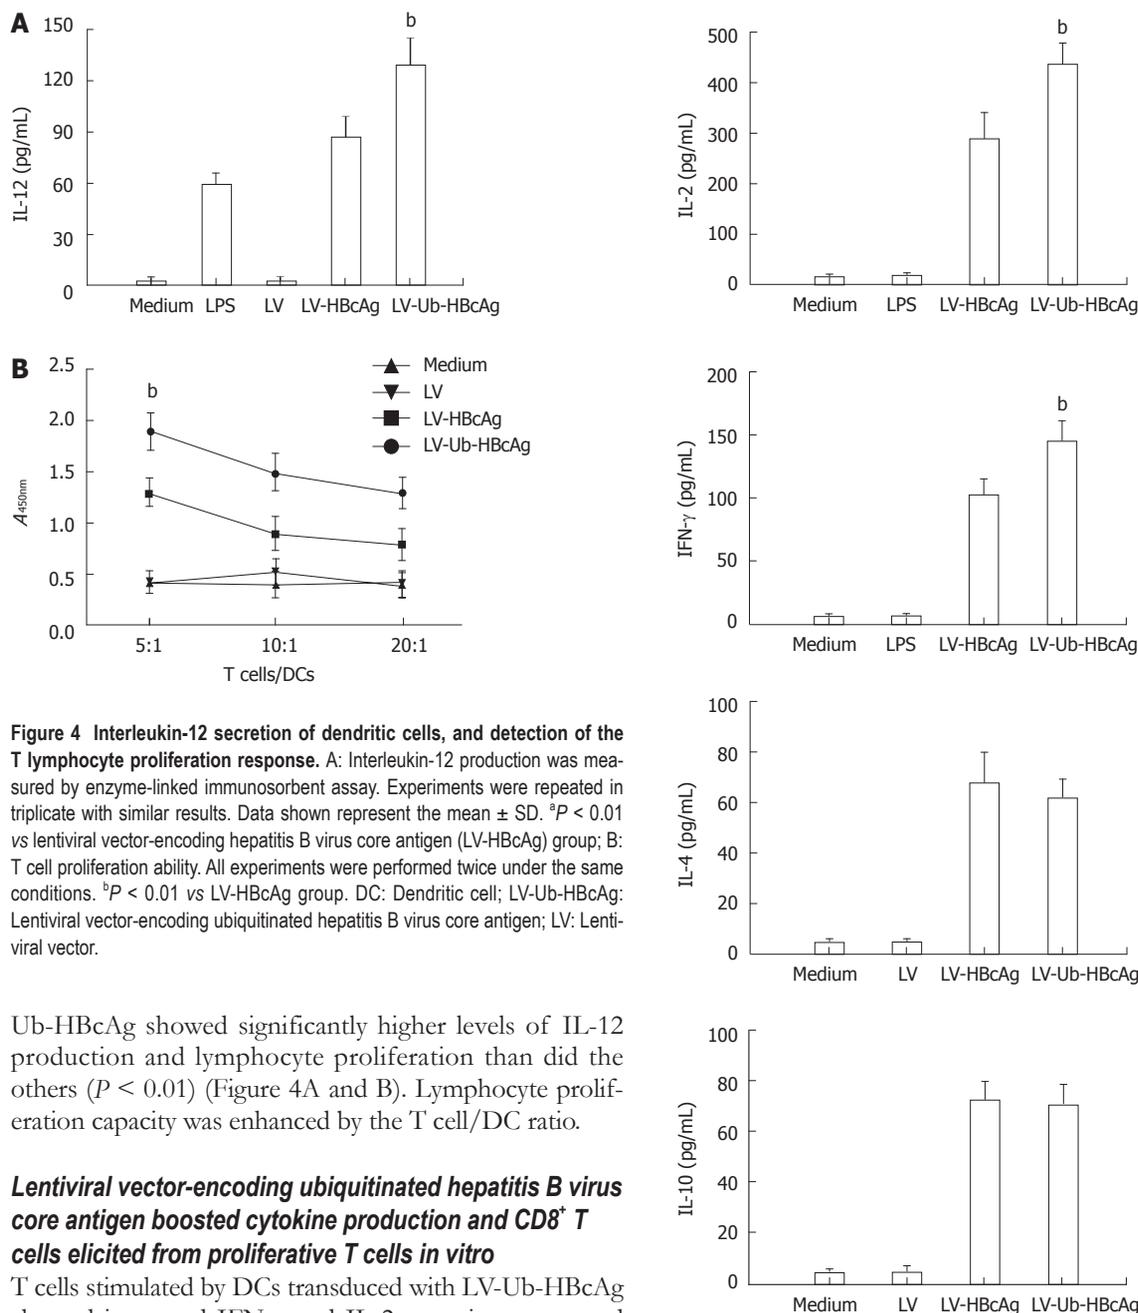

(Figure 2). On day 4 after infection, 56.1% of GFP-expressing DCs were detected.

### Lentiviral vector-encoding ubiquitinated hepatitis B virus core antigen-induced dendritic cell maturation increased IL-12 production and enhanced lymphocyte proliferation

At the end of the treatment, the amount of DCs (CD11c<sup>+</sup>) was 75% by fluorescence-activated cell sorting analysis. MHC II, CD80 and CD86 molecules, which are characteristic of DCs, were used to evaluate DC differentiation and maturation. These molecules were highly expressed in DCs transduced with LV-Ub-HBcAg compared with those transduced with the alternatives (Figure 3). DC function was evaluated by IL-12 secretion and promotion of lymphocyte proliferation. DCs transduced with LV-

**Figure 3 Percentage of dendritic cell surface molecules.** In the lentiviral vectors ubiquitinated hepatitis B virus core antigen (LV-Ub-HBcAg) group, the expression of major histocompatibility complex (MHC) class II, CD80 and CD86 molecules characteristic of dendritic cells (DCs) was significantly higher than that in the lipopolysaccharide (LPS) or lentiviral vectors hepatitis B virus core antigen (LV-HBcAg) group. The results represent one of three experiments. LV: Lentiviral vector; APC: Antigen-presenting cell.

**Figure 4 Interleukin-12 secretion of dendritic cells, and detection of the T lymphocyte proliferation response.** A: Interleukin-12 production was measured by enzyme-linked immunosorbent assay. Experiments were repeated in triplicate with similar results. Data shown represent the mean  $\pm$  SD. <sup>a</sup> $P < 0.01$  vs lentiviral vector-encoding hepatitis B virus core antigen (LV-HBcAg) group; B: T cell proliferation ability. All experiments were performed twice under the same conditions. <sup>b</sup> $P < 0.01$  vs LV-HBcAg group. DC: Dendritic cell; LV-Ub-HBcAg: Lentiviral vector-encoding ubiquitinated hepatitis B virus core antigen; LV: Lentiviral vector.

Ub-HBcAg showed significantly higher levels of IL-12 production and lymphocyte proliferation than did the others ( $P < 0.01$ ) (Figure 4A and B). Lymphocyte proliferation capacity was enhanced by the T cell/DC ratio.

**Lentiviral vector-encoding ubiquitinated hepatitis B virus core antigen boosted cytokine production and CD8<sup>+</sup> T cells elicited from proliferative T cells in vitro**

T cells stimulated by DCs transduced with LV-Ub-HBcAg showed increased IFN- $\gamma$  and IL-2 secretion compared with DCs transduced with LV-HBcAg (Figure 5). No significant difference between the two groups was observed for IL-4 and IL-10 production. CTLs were analyzed by intercellular IFN- $\gamma$  and CD8 $\alpha^+$  levels. The levels and intensities of IFN- $\gamma$  expression were higher in the LV-Ub-HBcAg than in the LV-HBcAg samples (Figure 6A and B), suggesting that DCs transduced with LV-Ub-HBcAg were effective for inducing CTLs.

**Enhancement of cytotoxic T lymphocyte activity in dendritic cells transduced with Lentiviral vector-encoding ubiquitinated hepatitis B virus core antigen**

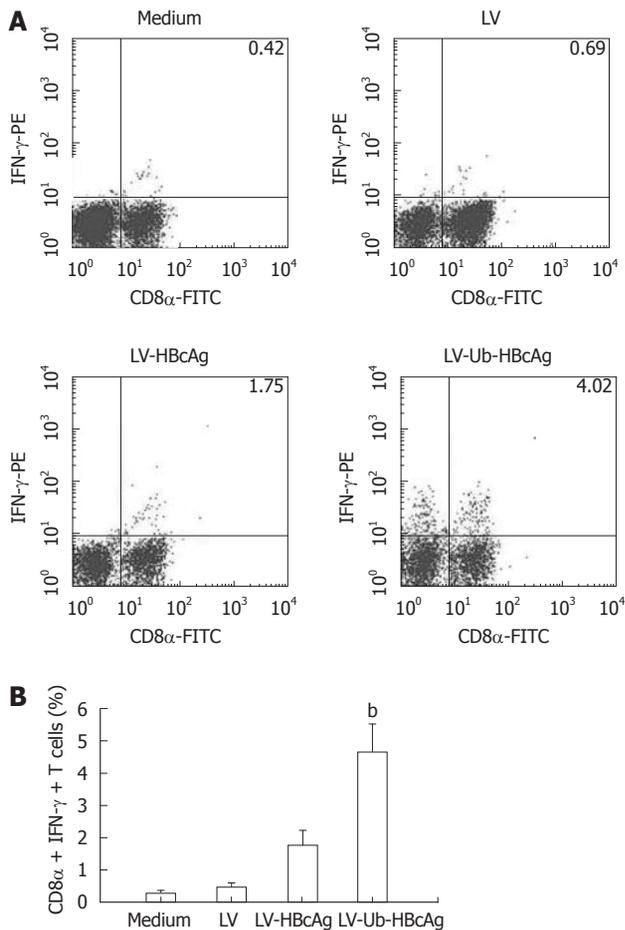

The LDH relaxation index was determined to evaluate the specific cytotoxicity of T lymphocytes in response to different LV-transduced DCs. HBcAg-specific CTL activities with different effector/target ratios are shown in Figure 7. T lymphocytes from the LV-Ub-HBcAg-

**Figure 5 Cytokine production.** Cytokine secretion of proliferative T cells. transduced DCs killed  $55.0\% \pm 4.3\%$  target cells at an effector and target ratio of 50:1, which was significantly higher than that of the LV-HBcAg-transduced DC group ( $32.4\% \pm 5.2\%$ ) ( $P < 0.01$ ). Accordingly, these results indicated that LV-Ub-HBcAg-transduced DCs induced strong specific CTL responses.

**DISCUSSION**

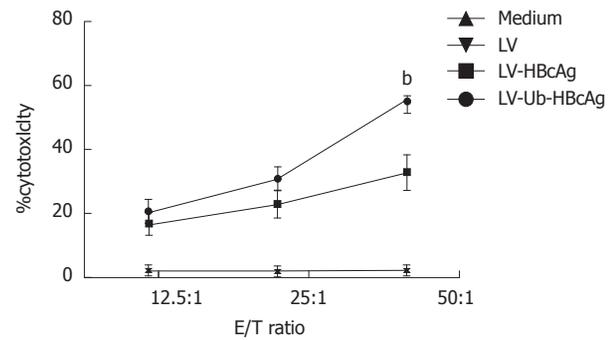

The development of novel immunotherapies has been highly anticipated because HBV infection is one of the

**Figure 6 Intracellular cytokine analysis.** A: The proliferative T cells were suspended in complete RPMI 1640 ( $2 \times 10^6$ /mL), intracellular cytokine analysis by flow cytometry using CD8 $\alpha$ -FITC and Interferon (IFN)- $\gamma$ -PE antibodies. LV-Ub-HBcAg: Lentiviral vector-encoding ubiquitinated hepatitis B virus core antigen; LV-HBcAg: Lentiviral vector-encoding hepatitis B virus core antigen; LV: Lentiviral vector.

leading causes of cancer or hepatocellular carcinoma-related death. Several studies have demonstrated that the main cause of viral persistence during HBV infection is an inadequate antiviral immune response to the viral antigens<sup>[13,14]</sup>. The viral-specific CD8 $^+$  T cell response plays an important role in the process of viral clearance. Patients with **chronic hepatitis B (CHB) or therapeutic failure** show deficient Th1 immunity associated with inefficient CD8 $^+$  T cell cytotoxicity<sup>[15]</sup>. Therefore, induction of CTL responses specific to HBV represents a promising strategy to protect against HBV infection.

DCs are key antigen-presenting cells that induce primary and memory immune responses. Impaired DC function is found in chronic HBV infection, in which patients are generally in an immunocompromised state of immune tolerance<sup>[16-18]</sup>. Considerable effort has been made to introduce antigens into DCs in the forms of peptides, proteins, or transgenic protein antigens using viral vectors<sup>[19,20]</sup>. Various viral vectors, including poxvirus and adenovirus, have been used to genetically modify DCs, but low transduction efficiencies have limited their ap-

**Figure 7 Cytotoxic response of proliferative T cells.** Effector cells were incubated with P815/c at different effector/target (E/T) ratios (12.5:1, 25:1 or 50:1) for 4h. Experiments were repeated three times with similar results. Data represent the mean  $\pm$  SD. <sup>b</sup>*P* < 0.01 vs lentiviral vector-encoding hepatitis B virus core antigen (LV-HBcAg) group. LV-Ub-HBcAg: Lentiviral vector-encoding ubiquitinated hepatitis B virus core antigen; LV: Lentiviral vector.

plication. We chose LVs as a gene transfer vector because they can transduce non-dividing, monocyte-derived DCs and bone marrow-derived DCs with very high transduction efficiencies<sup>[21,22]</sup>. Several reports have demonstrated that immunizing mice with LVs by delivering viral or tumor model antigens mice elicited broad and long-lasting specific immune responses. For example, lentiviral transduction of DCs expressing ovalbumin effectively processed and presented the ovalbumin antigens and induced ovalbumin-specific T cell responses<sup>[23]</sup>. Our results confirmed that lentivirus-mediated gene transfer could offer the unique opportunity to investigate the biologic activity of DCs.

The ubiquitin-proteasome system (UPS) is a highly selective adenosine-5'-triphosphate-dependent proteolytic system present in all eukaryotic cells and plays a key role in antigen presentation<sup>[8]</sup>. It is well established that short antigenic peptides must be presented on MHC class I molecules of target cells to be recognized by specific CTLs. Proteasomes are responsible for the proteolysis of intracellular proteins, including viral antigens, to generate MHC class I ligands.

Attachment of Ub to a protein is the initial signal for targeted protein degradation. To prevent fusion gene (*Ub-HBcAg*) cleavage by deubiquitination enzymes, we constructed a pWPXLd vector encoding HBcAg fused with Ub, in which the Ub C-terminal glycine was replaced with alanine<sup>[24]</sup>. Additionally, HBcAg with a modified N-terminal Met residue was replaced by Arg. By this method, the fusion protein can be quickly recognized by the UPS, resulting in a promotion of HBcAg degradation<sup>[25-27]</sup>. In our study, Western blotting analyses identified efficient expression of HBcAg from the 293T cells transduced with recombinant LVs. Ub-fused HBcAg was converted into an excellent substrate for the UPS. We found that the 293T cells transduced with LV-Ub-HBcAg showed low levels of protein expression in the absence of MG-132.

Immature DCs expressed low levels of surface MHC molecules, producing almost no expression of CD40, CD80 or CD86. Fully matured DCs showed strong surface expression of MHC class II and co-stimulatory mo-

lecules (CD80 and CD86). In our study, the surface molecules CD80, CD86, and MHC class II DCs were markedly upregulated by LV-Ub-HBcAg stimulation, whereas no significant change was observed after LPS or LV-HBcAg stimulation. An important sign of mature DCs is IL-12 secretion. Mature DCs secrete high levels of IL-12 that promote activation of effector cells (e.g., natural killer cells, lymphokine-activated killer cells, tumor-infiltrating lymphocytes and macrophages) and induce a variety of cytokines (e.g., IFN- $\gamma$ , GM-CSF, IL-2 and IL-8)<sup>[28]</sup>. IL-12 is produced by mature DCs in response to infection by various intracellular pathogens. This response plays a critical role initiating a specific T cell-mediated immune response and drives Th1 cell activation and differentiation<sup>[29,30]</sup>. We examined IL-12 production after adding different maturation factors to the culture medium. As expected, IL-12-induced LV-Ub-HBcAg production of DCs was markedly elevated compared with that produced by other treatments. In this study, LV-Ub-HBcAg-transduced DCs not only promoted DC surface molecule expression, but also promoted further secretion of IL-12, which helped stimulate the immune response.

Higher rates of intracellular antigen traffic should increase the number and varieties of peptides available for MHC class I binding, which may result in an increase in the cell immune response to the expressed antigen. DCs pulsed with HBV antigens effectively abrogated CTL tolerance in HBV transgenic mice. Chen *et al.*<sup>[4]</sup> demonstrated that DCs loaded with HBcAg not only induce the production of HBV-specific T cells but also restore the impaired function of such cells. The DCs generated by transfection of LV-Ub-HBcAg were able to stimulate proliferation of naive allogeneic T lymphocytes and to increase the number of antigen-specific CD8<sup>+</sup>/IFN- $\gamma$ <sup>+</sup> T cells *in vitro*. Th1 cells primarily secrete IL-2 and IFN- $\gamma$ , whereas Th2 cells secrete type II cytokines IL-4 and IL-10. Th1/Th2 immune balance plays a key role in the outcome of HBV infection. Dominant Th1 cells tend to lead to an acute self-limited HBV infection; dominant Th2 cells tend to occur with a chronic persistent HBV infection. In our study, we observed that the LV-Ub-HBcAg group had higher levels of both IL-2 and IFN- $\gamma$  in the lymphocyte supernatant compared with those in the LV-HBcAg group. This was further supported by enhanced levels of IFN- $\gamma$ -producing CD8<sup>+</sup> T cells. These results clearly indicate that the immune responses were directed toward a Th1 type rather than a Th2 type. Th1 cells are correlated with the induction of CTL activity, which is beneficial for viral or tumor eradication<sup>[31,32]</sup>. In this study, the LV-Ub-HBcAg-transfected DCs stimulated T lymphocytes and generated antigen-specific cytotoxic T lymphocytes more efficiently than those of the LV-HBcAg-transfected DCs. Thus, LVs carrying Ub-fused HBcAg effectively activated antigen-specific CD8<sup>+</sup> T cells. Inadequate endogenous antigen presentation by MHC class I molecules to CD8<sup>+</sup> T cells is one of the reasons for the failure of the immune system to eliminate pathogens. Patients with CHB or therapeutic failure showed deficient Th1 immunity associated with inefficient CD8<sup>+</sup> T cell cytotoxicity. In

our study, enhanced antigen presentation increased the number of antigen-specific CD8<sup>+</sup>/IFN- $\gamma$ <sup>+</sup> T cells in the LV-Ub-HBcAg-transfected DC group. Ub-fused HBcAg was rapidly degraded by the proteasome, resulting in efficient production of a variety of peptides, including many CTL epitopes that may be presented by many types of MHC class I molecules.

In summary, we have successfully transfected murine bone marrow-derived DCs with LVs encoding the Ub-HBcAg fusion gene. The Ub-HBcAg-transfected DCs proliferated and generated HBcAg-specific CTLs more efficiently than did the HBcAg-transfected DCs. Therefore, this novel strategy may have therapeutic value that can be applied to the treatment of infectious diseases.

## COMMENTS

### Background

Hepatitis B virus (HBV) infection is a serious public health problem. Defective cytotoxic T lymphocytes (CTLs) may lead to persistent HBV infection, and the defective CTL response was ascribed to the impaired dendritic cell (DC) function. Promoting and improving DC function is a promising approach to combating persistent HBV infection. Ubiquitin (Ub) is a highly conserved small regulatory protein, and the Ub-mediated processing of antigens is rapid and efficient and stimulates cell-mediated immune responses.

### Research frontiers

Ub-fused melanoma antigens could induce antigen proteins to execute proteasome-dependent degradation and created epitopes of major histocompatibility complex (MHC) class I, resulting in the preferential activation of antigen-specific CD8<sup>+</sup> T cells.

### Innovations and breakthroughs

The study reported for the first time the capacity of DCs transfected with lentivirus encoding the ubiquitinated hepatitis B virus core antigen (Ub-HBcAg) to stimulate lymphocyte proliferation and to generate antigen-specific CTLs.

### Applications

The authors found that lentivirus encoding Ub-HBcAg effectively could induce DC maturation. The mature DCs efficiently induced T cell polarization to Th1 and generated HBcAg-specific CTLs. These results may be helpful in seeking novel approaches to the control of persistent HBV infection.

### Terminology

Ubiquitin is a highly conserved small regulatory protein, ubiquitous in eukaryotes, that usually serves as a signal for the target protein that is recognized and degraded in proteasomes.

### Peer review

The topic is novel, with very few articles published in this field till now. The manuscript is well organized with objectives, methods, results being adequately described, and the conclusions are based on the results found. Tables and figures are appropriate. Statistical analysis needs better description by providing *P* values through the text where comparisons between groups are present.

### Abstract

**AIM:** To investigate the expression and clinical significance of Wnt member 5a (Wnt5a) and receptor tyrosine kinase-like orphan receptor 2 (Ror2) in hepatocellular carcinoma (HCC).

**METHODS:** In HCC tissues obtained from 85 patients, the protein expressions of Wnt5a, Ror2,  $\beta$ -catenin, and Ki-67 *via* immunohistochemical staining using the Envision Plus System. The antibody binding was visualized with 3, 3'-diaminobenzidine tetrahydrochloride (DAB) before brief counterstaining with Mayer's hematoxylin. The degree of immunohistochemical staining was recorded using a semiquantitative and subjective grading system. The mRNA expression of Ror2 was examined by real-time reverse transcription polymerase chain reaction, including nineteen of the 85 HCC and three nor-

mal liver tissues. The ratios of Ror2 to the housekeeping gene GAPDH represented the normalized relative levels of Ror2 expression. To determine the prognostic factor, the outcome of the 82 patients was determined by reviewing their medical charts. The overall and disease-free survival rates were estimated using the Kaplan-Meier method and compared with the log-rank test. The prognostic analysis was carried out with univariate and multivariate Cox regressions models.

**RESULTS:** Compared to nontumorous (hepatitis or cirrhotic) tissues, Ror2 mRNA expression was clearly decreased in HCC. Ror2 and Wnt5a protein expressions in the majority of HCC patients (63% and 77%, respectively) was significantly less in tumor tissues, as compared to adjacent nontumorous tissues, and this reduction was correlated with increasing serum  $\alpha$ -fetoprotein and tumor stage. In 68% (58/85) of the HCC cases, the expression of  $\beta$ -catenin in tumor tissues was either downregulated in the cellular membrane, upregulated in the cytoplasm, or both. Survival analysis indicated that Wnt5a and Ror2 protein expressions could be regarded as independent prognostic factors for HCC; HCC patients with decreased Wnt5a or Ror2 protein expression had a poorer prognosis than those with elevated Wnt5a and Ror2 expression ( $P = 0.016$ ,  $P = 0.007$ , respectively).

**CONCLUSION:** Wnt5a and Ror2 may serve as tumor suppressor genes in the development of HCC, and may serve as clinicopathologic biomarkers for prognosis in HCC patients.

## INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most frequently occurring tumors worldwide. It develops mostly in cirrhotic livers, and risk factors include chronic infection by the hepatitis B and C viruses (HBV and HCV), as well as nonviral liver diseases<sup>[1,2]</sup>. Unfortunately, the cellular mechanisms of hepatocarcinogenesis remain poorly understood. Recent advances have shown that apart from autocrine stimulation by growth factors such as insulin-like growth factor-II and transforming growth factor- $\alpha$ , the dysregulation of at least four different growth regulatory pathways is frequently involved in hepatocarcinogenesis<sup>[3,4]</sup>. These signaling pathways include the retinoblastoma, the transforming growth factor- $\beta$ , the tumor protein 53, and the wingless-type murine-mammary-tumor virus integration site family (Wnt). These pathways also interfere with each other at different levels<sup>[2,5,6]</sup>.

The Wnt family of genes encodes a large and diverse group of signaling molecules involved in the patterning, proliferation, and differentiation of a variety of organs and cell types<sup>[7,8]</sup>. The Wnt ligand binds to its receptor Frizzled and the low-density lipoprotein receptor-related proteins (Lrp) 5 and 6 to activate the canonical Wnt/ $\beta$ -catenin signaling pathway, or functions through  $\beta$ -catenin-independent (noncanonical) pathways which include the planar cell polarity and Wnt/ $\text{Ca}^{2+}$  pathways<sup>[9]</sup>. Wnt ligands are typically classified into canonical and non-canonical Wnts by the pathways they work through<sup>[9-11]</sup>.

The Wnt member 5a (Wnt5a) is one of the most highly investigated non-canonical Wnts and has been implicated in almost all aspects of non-canonical Wnt signaling<sup>[12-14]</sup>. In terms of cancer developmental research, Wnt5a has lived in the shadow of its better-characterized relatives. This was largely because of its apparent inability to transform cells or signal through the canonical  $\beta$ -catenin pathway that is so important in cancer<sup>[15-18]</sup>. Recent work with a wide of human tumors has indicated that Wnt5a has a critical role in malignant progression, but there is conflicting evidence as to whether that role is tumor-promoting or tumor-suppressing<sup>[17-22]</sup>. We have shown that Wnt5a has a tumor suppressing effect in HCC and is probably associated with HBV infection<sup>[23,24]</sup>. Emerging evidence suggests that the functions of Wnt5a can be drastically altered depending on the availability of key receptors<sup>[17,18,25]</sup>. It was recently reported that an alternative Wnt receptor, receptor tyrosine kinase-like orphan

receptor 2 (Ror2), an orphan tyrosine kinase, mediates Wnt5a-initiated noncanonical signaling and is required for the Wnt5a-mediated inhibition of canonical signaling<sup>[25,26]</sup>.

The Ror2 receptor belongs to the receptor tyrosine kinase superfamily<sup>[25]</sup>. This large protein family is involved in regulating diverse cellular processes such as the cell cycle, cell migration, proliferation and differentiation<sup>[27]</sup>. In addition, the Ror2 protein and its homolog Ror1 play essential roles during development. Mutations of the Ror2 receptor, resulting in protein misfolding or premature truncation, have been associated with human diseases such as dominant Brachydactyly type B and recessive Robinow syndrome<sup>[28]</sup>. Currently, investigations to elucidate the role of Ror2 in cancer have shown paradoxical results, indicating that Ror2 was overexpressed in oral and renal cell cancer and metastatic melanoma, but downregulated in colon cancer<sup>[29-31]</sup>. These different effects appear to be dependent on the cancer type and signaling pathway<sup>[32]</sup>.

Here, we investigate the expression and clinical significance of Ror2, Wnt5a and  $\beta$ -catenin in HCC.

## MATERIALS AND METHODS

### Patients and specimens

We collected tumors from 85 consecutive patients who had undergone surgery for HCC at the Jinan Military General Hospital from January 2006 to September 2010. The Ethics Committee of the Jinan Military General Hospital approved the protocol of this study. Among the 85 patients, 55 had serum  $\alpha$ -fetoprotein (AFP)  $\geq 30$   $\mu\text{g/L}$ , and 73 were sera positive for hepatitis B surface antigen (HBsAg). On gross examination, 3 cases had tumor sizes that were  $\leq 2$  cm, and 82 had tumor sizes  $> 2$  cm (median tumor size, 6.1 cm; range, 1.0-16 cm). Histopathological diagnoses were made according to the pathological classification system of the World Health Organization (2000), and the tumor was staged following the tumor-node-metastasis classification of the International Union Against Cancer<sup>[33]</sup>. Nine cases were well differentiated; 60 cases were moderately differentiated; and 16 cases were poorly differentiated. In total, 56 HCC cases had liver cirrhosis; 25 cases had chronic hepatitis; and 4 cases had basically normal liver tissue. We also collected 3 cases of lung metastasis. Furthermore, tissues of comparative normal liver obtained during surgery for liver cholelithiasis ( $n = 3$ ) and HBV-infected liver biopsies ( $n = 5$ ) were studied.

Nineteen of the 85 cases included chronic ( $n = 8$ ) and cirrhotic ( $n = 11$ ) HCC. From these, fresh tissues were obtained immediately after resection, including HCC tumor and adjacent nontumorous liver tissues. In addition, normal liver tissues ( $n = 3$ ) with no HBV infection were obtained during surgery for liver cholelithiasis. In these 22 cases, one portion of the fresh tissue was snap frozen in liquid nitrogen immediately and stored at  $-80$   $^{\circ}\text{C}$ ; the remainder portion was fixed in 10% buffered formalin and embedded in paraffin.

The available patient clinicopathological information

included gender, age, serum AFP, serum HBsAg, tumor size, tumor stage, histological grade and cancer-specific survival time.

### **Extraction of RNA and real-time reverse transcription-polymerase chain reaction**

Total RNA was extracted from 10-mm frozen HCC tissue sections. To isolate the RNA from defined areas containing  $\geq 80\%$  tumor cells, all tumors were manually microdissected under direct visual control through a dissecting microscope. Total RNA in the frozen tissues was extracted using Trizol (Invitrogen) following the manufacturer's recommendations. Total RNA was digested with DNase I (Invitrogen) and was used for the first-strand cDNA reaction. The reaction mixture consisted of 5  $\mu\text{g}$  of DNase I-treated RNA, 1  $\times$  reverse transcriptase buffer, 2.5 mmol dNTP mix, 3.5  $\mu\text{mol}$  oligo primer, and 2.5 U/mL MultiScribe™ reverse transcriptase (PE Applied Biosystems). Each sample was handled using the same protocol, with the exception that reverse transcriptase was added to exclude the presence of interference from genomic DNA.

Real-time reverse transcription polymerase chain reaction (qRT-PCR) was carried out using SYBER green dye in a Rotor Gene 3000 Detection System (Corbett Research, Sydney, Australia). Each SYBER green reaction (25  $\mu\text{L}$ ) contained one microliter diluted cDNA and 10.5  $\mu\text{L}$  SYBR Green PCR Master Mix, as well as 5 pmol forward and reverse primer (Ror2: forward 5'-AGGT-GCCTATGCAAGTTCA-3', reverse 5'-TGTGCGAG-GTTTAAGGTCTA-3'). Samples were activated by incubation at 95 °C for 5 min and denatured at 95 °C for 20 s. This was followed by annealing at 60 °C for 20 s and extension at 72 °C for 20 s, for 40 cycles. In all of the cDNA samples, gene expressions of Ror2 and glyceraldehyde-3-phosphate dehydrogenase (GAPDH) (forward 5'-GAAGGTGAAGGTCGGAGTC-3'; reverse 5'-GAA-GATGGTGATGGGATTC-3'), an internal quantitative control, were determined by SYBR green fluorescence using the Rotor-Gene 3000; the ratios of Ror2 to the housekeeping gene *GAPDH* represented the normalized relative levels of Ror2 expression. A non-template negative control was also included in each experiment. Analyses of all tumor samples were carried out at least twice, and the mean value was calculated.

### **Immunohistochemistry**

Immunohistochemical staining was performed on thin sections (4  $\mu\text{m}$ ) of paraffin-embedded archival tissue. The samples were dewaxed with xylene/ethanol before antigen retrieval (i.e., pressure cooked for one minute at full pressure, 15 psi, in 0.001 mol/L EDTA buffer, pH 8.0). The primary antibodies used were: Wnt5a (LS-C47384, Lifespan, 1:200), Ror2 (PAB3386, Abnova, 1:200),  $\beta$ -catenin (C19220, BD Transduction Laboratories, 1:400) and Ki-67 (MIB-1, Dako, 1:100). Immunohistochemical staining of antibodies was done using the Dako Envision Plus System (K5007, Dako). The anti-

body binding was visualized with 3, 3'-diaminobenzidine tetrahydrochloride (DAB) before brief counterstaining with Mayer's hematoxylin. For monoclonal antibodies of mouse origin, negative controls were obtained using isotypic mouse immunoglobulin in the same dilution as the primary antibody of concern. All control experiments gave negative results.

### **Evaluation of immunostaining**

Two authors (Cao YC and Jiang H) who had no knowledge of the patients' clinical status reviewed all of the immunostained sections. Cases with discrepant results were re-evaluated jointly until agreement was reached. For expression of Wnt5a, Ror2 and  $\beta$ -catenin protein, in cases with multiple areas of low intensity that occurred during evaluation of immunostaining, five areas were selected at random and scored.

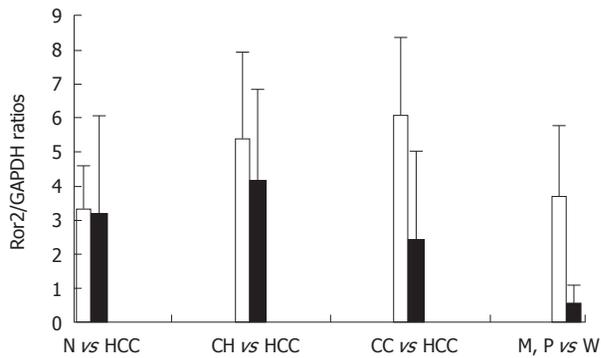

The degree of immunohistochemical staining was recorded using a semi-quantitative and subjective grading system that considered both the intensity of staining and the proportion of tumor cells that had an unequivocal positive reaction. Grades for stain intensity were: 0: No staining; 1: Weak staining; 2: Positive staining; and 3: Strong staining. For rating stained areas: 0: No staining; 1: Positive staining in  $< 10\%$  of tumor cells; 2: Positive staining in 10% to 50% of tumor cells; 3: Positive staining in  $> 50\%$  of tumor cells. The staining index was calculated as the staining intensity multiplied by the positive area.

Ki-67-positive cells were counted by viewing  $\geq 200$  HCC cells from  $\geq 10$  randomly selected fields. The percentage of antigen-positive nuclei among the total number of nuclei counted was calculated to obtain the nuclear labeling index (LI).

In the subsequent statistical analysis, the cutoff points for the staining index categories were mainly based on median values, as well as each marker's frequency distribution curve and the size of the subgroups. Therefore, cytoplasmic Wnt5a and Ror2 and membranous  $\beta$ -catenin staining indices were categorized by their median value as high ( $> 4$ ) or low (0-4), and the cytoplasmic  $\beta$ -catenin staining index was categorized as high ( $> 3$ ) or low (0-3). However, nuclear  $\beta$ -catenin expression was categorized based on the absence (staining index = 0) or presence (staining index  $\geq 1$ ) of staining. The Ki-67 labeling indices were divided into two groups (LI  $< 10\%$  and LI  $\geq 10\%$ ).

### **Follow-up and statistical analysis**

To determine the prognostic factor, the outcome of the 82 patients was determined by reviewing their medical charts. The follow-up period ranged from one to 54 mo (average: 31.3 mo; median: 27.0 mo). The end point in the analysis was HCC-related death. The overall and disease-free survival rates were estimated using the Kaplan-Meier method and compared with the log-rank test. The prognostic analysis was carried out with univariate and multivariate Cox regressions models.

**Figure 1** Real-time reverse transcription-polymerase chain reaction analysis of *Ror2* gene (mRNA) expression in hepatocellular carcinoma, chronic hepatitis, cirrhotic and normal liver tissue. Ror2: Receptor tyrosine kinase-like orphan receptor 2; HCC: Hepatocellular carcinoma; GAPDH: Glyceraldehyde-3-phosphate dehydrogenase; Bars: mean; Columns: SD; N: Normal; CH: Chronic hepatitis; CC: Cirrhosis; M, P, W: Moderately, poorly, and well differentiated tumor tissues, respectively.

The differences in *Ror2* mRNA expression between HCC and nontumorous liver tissue was statistically analyzed using Student's *t*-test and one-way analysis of variance (ANOVA) for multiple comparisons. The correlations between the clinicopathological parameters and Wnt5a, *Ror2* and  $\beta$ -catenin protein expression were analyzed using the  $\chi^2$  or Fisher's exact tests.

Pearson's correlation was used to determine the correlation between mRNA and protein expression, as well as between the expressions of different proteins. All statistical calculations were carried out using SPSS software (for Windows, version 13.0). A significant difference was defined at  $P < 0.05$ .

## RESULTS

### *Ror2* gene and protein expression in hepatocellular carcinoma

The *Ror2* gene (mRNA) expression levels relative to that of GAPDH in normal, HCC, chronic hepatitis, cirrhotic liver and adjacent nontumorous liver tissues are shown in Figure 1. *Ror2* mRNA levels were elevated in chronic hepatitis ( $5.420 \pm 5.492$ ,  $n = 11$ ) and cirrhotic liver tissues ( $6.128 \pm 5.252$ ,  $n = 8$ ) compared to that of normal ( $3.381 \pm 1.182$ ,  $n = 3$ ) and HCC ( $3.189 \pm 3.856$ ,  $n = 19$ ). Based on Student's *t*-test, statistically significant differences were found between the *Ror2* mRNA levels in HCC *vs* adjacent nontumorous (chronic hepatitis or cirrhotic) liver tissues ( $P = 0.029$ ), but not between HCC and normal liver tissues ( $P = 0.934$ ) or normal and adjacent nontumorous liver tissues ( $P = 0.094$ ). The *Ror2* mRNA level in moderately and poorly differentiated tumor tissues ( $n = 16$ ) was greater by 7.2-fold ( $P = 0.014$ ) than the level in well-differentiated tumor tissues ( $n = 3$ ). No significant differences were found between *Ror2* gene expression levels and other clinicopathological findings such as age, serum AFP concentration, tumor size, and HCC tumor stage.

Immunohistochemistry was performed to evaluate *Ror2* protein expression in tumor and non-tumorous liv-

er cells. In non-tumorous liver cells and HCC tumor cells, *Ror2* protein expression was displayed in the cytoplasm, but in stromal cells *Ror2* protein was not observed. In comparative normal liver cells *Ror2* was negative or weakly expressed (Figure 2A and B), whereas all chronic hepatitis, cirrhotic, and dysplastic liver cells exhibited positive immunostaining for *Ror2* (Figure 2C and D). In 62/85 (72.9%) of the HCCs, *Ror2* immunostaining was reduced or absent (Figure 2E and F).

A significant correlation was found between the normalized *Ror2* gene expression ratio and the protein expression level in normal, tumor and non-tumorous liver tissues ( $r = 0.254$ ,  $P = 0.021$ ). Furthermore, statistical comparisons between *Ror2* mRNA expression and patients' clinicopathological features revealed a significant negative association between *Ror2* mRNA and tumor stage ( $P < 0.001$ ), and between *Ror2* mRNA and serum AFP ( $P < 0.001$ ). However, there were no significant differences between *Ror2* protein expression and the other clinicopathological findings in HCC (Table 1).

### Wnt5a protein expression in hepatocellular carcinoma

Wnt5a protein expression was observed in the cytoplasm of non-tumorous liver and tumor cells, but nowhere in stromal cells. There was little or no Wnt5a seen in normal liver cells. However, all chronic hepatitis, cirrhosis and

**Figure 2** Immunohistochemical staining for Ror2 in hepatocellular carcinoma. Patient-matched normal liver cells showed negative (A) or weak expression (B) of receptor tyrosine kinase-like orphan receptor 2 (Ror2). Liver cirrhosis cells (C) and dysplastic liver cells (D) exhibited strong positive immunostaining for Ror2. Tumor cells (E, F) showing negative Ror2 staining in hepatocytes, while strong cytoplasmic staining is seen in adjacent nontumorous cells. Original magnification, 200 × in A; 400 × in B and D; 100 × in C.

dysplastic liver cells exhibited strong positive immunostaining for Wnt5a. In contrast, in 65/85 (76.5%) of HCC patients, Wnt5a immunostaining was reduced or absent compared to the levels in adjacent nontumorous (hepatitis and cirrhotic) tissues (Figure 3A). There was a significant negative correlation between Wnt5a expression and tumor stage ( $P < 0.001$ ), and between Wnt5a and serum AFP ( $P = 0.016$ ). However, there were no significant associations between Wnt5a protein expression and the other clinicopathological features of HCC patients.

#### ***β-catenin protein expression in hepatocellular carcinoma***

In non-neoplastic liver tissue, a thin membranous β-catenin signal delineated the hepatocytes, and strong membranous and pale cytoplasmic staining of bile ductules

was observed. As shown in Figure 3B and C, altered expressions of β-catenin were found in 68.2% (58/85) of HCC cases. These alterations included reductions in the cellular membrane, increases in the cytoplasm, or both, and nuclear accumulation (in 7%, 6/85). However, no evidence of altered β-catenin expression was found in cirrhotic nodules or dysplastic liver cells in adjacent non-cancerous liver tissue. In tumor tissues, altered β-catenin expression was significantly associated with a worsening histopathological tumor grade ( $P = 0.041$ ) and was not significantly associated with the other clinicopathological parameters.

#### ***Correlations among the protein expressions of Wnt5a, Ror2 and β-catenin***

Associations among the protein expression levels of Wn-

High	23	11	12		12	11	
$\beta$ -catenin							
N	27	16	11	0.019			
A	58	48	10				

N: Normal membranous staining; A: Abnormal non-membranous staining; Wnt5a: Wnt member 5a; Ror2: receptor tyrosine kinase-like orphan receptor 2.

t5a, Ror2 and  $\beta$ -catenin are shown in Table 2. Low cytoplasmic Wnt5a expression was positively associated with low cytoplasmic Ror2 expression ( $r = 0.411$ ,  $P < 0.001$ ) and abnormal  $\beta$ -catenin expression ( $r = 0.254$ ,  $P = 0.019$ ) in HCC tissue. Similarly, there was a statistically significant correlation between low cytoplasmic Ror2 expression and abnormal  $\beta$ -catenin expression ( $r = 0.267$ ,  $P = 0.014$ ).

#### Tumor cell proliferation in hepatocellular carcinoma

To investigate the biological functions of proteins in HCC, the Ki-67 LI was assessed in relation to Ror2, Wnt5a and  $\beta$ -catenin status. A strong correlation between a high Ki-67 LI and the reductive loss of Ror2 ( $r = -0.344$ ,  $P = 0.002$ ), or Wnt5a ( $r = -0.278$ ,  $P = 0.010$ ), but not  $\beta$ -catenin ( $r = 0.095$ ,  $P = 0.386$ ) was found (Figure 3D).

#### Immunohistochemistry for tumor tissues from patients with lung metastasis of hepatocellular carcinoma

A previous study reported that Wnt5a and Ror2 were expressed predominantly in metastatic but not primary lesions of metastatic melanoma, suggesting that Wnt5a and Ror2 might be closely correlated with tumor invasiveness and metastasis<sup>[31,34]</sup>. To determine whether a similar phenomenon occurs in the metastasis of HCC, three cases of lung metastasis of HCC were included in this study. Immunohistochemical analysis showed that Wnt5a and Ror2 were not expressed in either primary or metastatic lesions (Figure 4A and B), whereas  $\beta$ -catenin-positive staining were detected in the cellular membrane (Figure 4C and D). The Ki-67 LI in tumor tissues was 10%.

#### Statistical analysis

The median follow-up was 27.0 mo for survivors (range, 1-54 mo). Three patients were lost to follow-up after surgery and were excluded from the survival analyses. The overall survival curve for the remaining 82 HCC cases is shown in Figure 5A. The estimated 1- and 3-year overall rate of survival was 75% and 44%, respectively. Kaplan-Meier analysis was used to compare the survival rates of HCC patients with tumors expressing low or high levels of Wnt5a and Ror2 and normal or abnormal  $\beta$ -catenin (Figure 5B-D).

In a univariate Cox proportional hazard regression model analysis (Table 3), tumor stage ( $P < 0.001$ ), serum AFP ( $P = 0.036$ ), and the expressions of Wnt5a ( $P = 0.024$ ) and Ror2 ( $P = 0.011$ ) were significantly associated

with overall survival. Therefore, patients with tumors having a low expression of Wnt5a and Ror2 had a poorer prognosis than those with tumors of high Wnt5a and Ror2 expression.

Multivariate Cox regression analysis (Table 3), the expression levels of Wnt5a ( $P = 0.020$ ), and  $\beta$ -catenin ( $P = 0.013$ ) showed a significant association with overall survival. However, a significant correlation between the expression levels of Ror2 and overall survival ( $P = 0.144$ ), serum AFP and overall survival ( $P = 0.343$ ) were not demonstrated.

## DISCUSSION

Consistent with previous reports<sup>[23,24]</sup>, in this study immunohistochemical analysis showed that the loss of Wnt5a protein expression in HCC tumors frequently occurred in patients with HCC (71%-81%), and this also correlated with increased AFP and poor histologic grade. Wnt5a may act as a tumor suppressor gene in the development of HCC. Similar results were obtained in colon carcinoma, breast cancer and thyroid carcinoma<sup>[17,18,35,36]</sup>. We also performed a survival analysis for 82 patients with HCC. Our results demonstrated that HCC patients with low expression of Wnt5a had a poorer prognosis than those with high Wnt5a expression, and Wnt5a was an indepen-

dent prognostic factor for HCC.

Recent studies have indicated that the upregulation of Wnt5a was associated with tumor invasiveness and metastasis in metastatic melanoma, gastric cancer, and non-small-cell lung carcinoma<sup>[17-19]</sup>. Wnt5a was expressed predominantly in the metastatic but not primary lesions of metastatic melanoma<sup>[34]</sup>. Therefore, three cases with lung metastasis of HCC were recruited in the present study. Immunohistochemical analysis with anti-Wnt5a antibody showed that Wnt5a was not expressed in either primary or metastatic lesions, which confirmed our hypothesis that Wnt5a acts as a tumor suppressor gene in HCC. These observations suggested that the complex Wnt5a-regulated signal pathways and the functional role of Wnt5a depends on cell type as well as stimulus factors during the development of HCC tumor.

Previous reports showed that Ror2 shared a similar structure with the Wnt receptor<sup>[25]</sup>. Mikels *et al.*<sup>[25,37]</sup> revealed that Wnt5a suppressed Wnt/ $\beta$ -catenin activity via the Ror2-mediated signal pathway, and confirmed that the Ror2 receptor required tyrosine kinase activity to mediate Wnt5A signaling. He *et al.*<sup>[38]</sup> demonstrated that Wnt5a levels correlated with those of Ror2 during mammalian palate development. Similar to Wnt5a, Ror2 plays different roles in different human tumor tissues. There is evidence that the enhanced expression of Ror2 is associ-

ated with tumor invasiveness and metastasis in metastatic melanoma, renal cell carcinoma, and squamous cell carcinoma<sup>[29-31]</sup>. In contrast, the mRNA and protein expression of Ror2 was reduced in colon cancer tissues compared with adjacent nontumorous liver tissue, which might be due to the hypermethylated Ror2 promoter<sup>[32]</sup>.

Our current study showed that *Ror2* gene transcription and protein translation were both suppressed in tumor tissues of HCC as compared with tissue adjacent to the tumor. This reduced expression of Ror2 in tumor tissues was correlated with decreased Wnt5a expression ( $P < 0.001$ ), a high Ki-67 LI, increased AFP, high differentiation, and poor prognosis. The consistency of Wnt5a and Ror2 expression in tumor tissues as well as in lung metastasis of HCC implies that Ror2 may be active downstream of Wnt5a and participate in the regulation of the noncanonical Wnt signal pathway. Moreover, the mRNA and protein expression of Ror2 is increased in chronic hepatitis livers and is greatly enhanced in cirrhotic livers as compared with normal liver tissues, suggesting Ror2 may play important roles in regulation of cell repair. The expression of Ror2 is reduced in tumor tissues and is associated with poor prognosis, indicating the impaired regulatory effect of Ror2 in cells, and Ror2 may also serve as an anti-tumor gene. In addition, in this present study, the mRNA expression of Ror2 was decreased in highly differentiated HCC as compared with moderately or poorly differentiated HCC ( $P < 0.05$ ), whereas similar results were not obtained in the protein expression of Ror2. The underlying mechanism needs to be further elucidated. However, due to the limited sample size in highly differentiated HCC (3 cases), future study will be continued by enlarging the sample size.

$\beta$ -catenin is recognized as the key mediator in the canonical Wnt signal pathway. Evidence indicates that Wnt5a inhibits the abnormal expression of  $\beta$ -catenin through the Ror2-mediated pathway<sup>[25,39,40]</sup>. The involvement of  $\beta$ -catenin in tumorigenesis has been intensively researched. In colon carcinoma, the nuclear localization of  $\beta$ -catenin induced by gene mutation contributes to tumorigenesis. However, in HCC associated with HBV infection,  $\beta$ -catenin mutations are rarely seen, and  $\beta$ -catenin mainly accumulates in the cytoplasm<sup>[41,42]</sup>. Consistent with these observations, statistically reduced membrane expression and elevated cytoplasmic expression of  $\beta$ -catenin were detected in HCC tumor tissue, compared with the  $\beta$ -catenin expression in cell membranes in the adjacent liver tissue. Among 85 HCC cases, 6 exhibited condensed nuclear staining of  $\beta$ -catenin, suggesting that this protein is involved in the development of HCC. Nevertheless, we could not rule out the possibility that the loss of Wnt5a and Ror2 protein expression may decrease  $\beta$ -catenin degradation, which contributes to disease progression. Additionally, the lining shape of  $\beta$ -catenin expression in cell membranes was observed in lung metastasis of HCC, which was different from their cytoplasmic expression in the primary lesion. Since  $\beta$ -catenin not only acts as the key mediator of the canonical Wnt signal pathway, but also binds to E-cadherin and together they contribute to

the cell adhesion and migration process<sup>[43]</sup>, we hypothesize that the lung metastasis expression of  $\beta$ -catenin benefits the accumulation and adhesion of tumor cells in metastatic lesions.

In summary, in patients with chronic hepatitis or cirrhosis, loss of Wnt5a and Ror2 protein expression in HCC tumor tissue frequently occurs during the progression of HCC and is associated with patient prognosis. We hypothesize that Wnt5a acts upstream of Ror2. Wnt5a and Ror2 synergistically execute an anti-tumor effect during the development of HCC. The decreased expression of Wnt5a and Ror2 in HCC tissues may be directly or indirectly correlated with the abnormal activity of  $\beta$ -catenin. It is possible that the Wnt5a-mediated noncanonical Wnt signal pathway and the  $\beta$ -catenin-mediated canonical signal pathway contribute to the pathogenesis and progression of HCC. These critical mediators may be novel promising targets for gene therapy. Our study showed that HCC patients with reduced Wnt5a and Ror2 expression had poorer prognosis, indicating that protein expression of Wnt5a and Ror2 might be used as clinicopathological biomarkers for prognosis of HCC.

## COMMENTS

### Background

Hepatocellular carcinoma (HCC) is one of the most common cancers in the world. Understanding the molecular biological features of HCC is necessary for early diagnosis and better prognosis. The potential role of Wnt member 5a (Wnt5a) and receptor tyrosine kinase-like orphan receptor 2 (Ror2) in human HCC is receiving increasing attention.

### Research frontiers

Recent work in a wide of human tumors has indicated that Wnt5a and Ror2 have a critical role in malignant progression. However, little is known about the association of Wnt5a expression with Ror2 and canonical Wnt in HCC. In this study, the authors demonstrate that Wnt5a, in conjunction with Ror2 and  $\beta$ -catenin, may take part in the progression of HCC.

### Innovations and breakthroughs

The loss of Wnt5a and Ror2 protein expression in HCC tumor tissue frequently occurs during the progression of HCC and is associated with patient poor prognosis. Wnt5a and Ror2 synergistically execute an anti-tumor effect during the development of HCC. The loss of Wnt5a and Ror2 protein expression was shown to be associated with abnormal  $\beta$ -catenin expression. This is the first study to report an association of Wnt5a expression with Ror2 and  $\beta$ -catenin in HCC.

### Applications

The study results suggest that protein expression of Wnt5a and Ror2 may be used as clinicopathological biomarkers for prognosis of HCC.

### Terminology

Wnt5a is a non-canonical member of the Wnt family of secreted glycoproteins that acts through the family of frizzled G-protein-coupled receptor, Ror2, to mediate important events during development and cancer.

### Peer review

This paper reported that the loss of Wnt5a and Ror2 protein expression in HCC was associated with poor patient prognosis. Based on reduction in tumors, the authors conclude these markers could be tumor suppressor genes and good prognostic markers for HCC patients. The work is purely descriptive and relevance to clinical practice is significant.

chronic hepatitis C virus (HCV) infection are treated or not.

**METHODS:** This prospective cohort study included 7658 untreated patients and 6341 patients receiving pegylated interferon  $\alpha$ 2a/ribavirin, involving 434 physicians/institutions throughout Germany (377 in private practice and 57 in hospital settings). A structured questionnaire had to be answered prior to the treatment decision, which included demographic data, information about the personal life situation of the patients, anamnesis and symptomatology of hepatitis C, virological data, laboratory data and data on concomitant diseases. A second part of the study analyzes patients treated with pegylated interferon  $\alpha$ 2a. All questionnaires included reasons against treatment mentioned by the physician.

**RESULTS:** Overall treatment uptake was 45%. By multivariate analysis, genotype 1/4/5/6, HCV-RNA  $\leq$  520 000 IU/mL, normal alanine aminotransferase (ALT), platelets  $\leq$  142 500/ $\mu$ L, age > 56 years, female gender, infection length > 12.5 years, concomitant diseases, human immunodeficiency virus co-infection, liver biopsy not performed, care in private practice, asymptomatic disease, and unemployment were factors associated with reduced treatment rate. Treatment and sustained viral response rates in migrants (1/3 of cohort) were higher than in German natives although 1/3 of migrants had language problems. Treatment rate and liver biopsy were higher in clinical settings when compared to private practice and were low when ALT and HCV-RNA were low.

**CONCLUSION:** Some reasons against treatment were medically based whereas others were related to fears, socio-economical problems, and information deficits both on the side of physicians and patients.

## INTRODUCTION

Approximately 170 million humans worldwide are estimated to have a chronic hepatitis C virus (HCV) infection including 400 000 in Germany<sup>[1,2]</sup>. More than 20 % of these patients will progress to cirrhosis, hepatocellular carcinoma, liver transplantation or death<sup>[3,4]</sup>. Therefore, all patients are candidates for antiviral therapy<sup>[5]</sup>. Its benefits need to be determined based on the individual's disease stage and on the likelihood of adherence and success<sup>[5,6]</sup>. Probably only 20 % of HCV-infected subjects know of their infection<sup>[3]</sup>. This diagnostic deficit is caused by various factors; e.g., physicians do not follow guidelines to screen for HCV infection when alanine aminotransferase (ALT) is elevated<sup>[7,8]</sup>. In addition only 11%-41% of known infections are treated<sup>[9-12]</sup>. Only some reasons for this therapeutic deficit have been identified including comorbidity, drug abuse and psychosocial factors<sup>[9,12-15]</sup>. Considering that therapy cures the disease in 50% of patients, treatment rate should be increased. The present study evaluates which factors influence the treatment decision in daily German practice.

## MATERIALS AND METHODS

The study which is ongoing was started in March 2003; the present data analyzes the treatment decision in patients included between March 2003 and May 2008. Throughout Germany 434 physicians (377 in private practice and 57 in hospital settings) contributed a mean number of 35 patients with chronic hepatitis C. The study included only one academic center. Basic data of the cohort have been published<sup>[16]</sup> and are only briefly mentioned here. The study was approved by health authorities and ethical committees. Due to its observational character it did not affect individual medical decisions. A structured questionnaire had to be answered prior to the treatment decision; a second part of the study analyzes patients treated with pegylated interferon  $\alpha$ 2a (Pegasy<sup>®</sup>, Roche Pharma AG) and ribavirin. This part is not fully analyzed here; only those aspects are analyzed which are relevant to the treatment decision. All questionnaires included rea-

**Table 1** Demographic data and basic characteristics

Characteristics	Not treated (n = 7658)	Treated (n = 6341)
% of the 13 999 patients	55.7	45.3
Genotypes 1/4/5/6 (%)	69.8	59.4
Genotypes 2/3 (%)	30.2	40.6
Age (yr, median)	44.0	41.0
BMI (kg/m <sup>2</sup> , median)	24.2	24.3
Gender (male %)	56.6	61.1
Regular employment (%)	35.3	50.2
Infection length (yr, median)	11.0	10.0
Ultrasound performed (%)	76.8	87.6
Liver biopsy performed (%)	12.8	30.2
Fibrosis score F 0-1	72.8	58.6
Fibrosis score F 2-4	27.2	41.4
Active drug or alcohol abuse (%)	28.3	13.8
HIV co-infection (%)	6.7	3.7
Psychiatric disease (%)	14.8	9.2
Severe language problems (%)	9.6	10.0
Initial HCV-RNA (IU/mL, median)	482 500	500 000
ALT (U/L, median)	61.0	78.0
Thrombocytes (/ $\mu$ L, median)	217 000	218 000
At least on concomitant disease (%)	62.3	42.6

BMI: Body mass index; HIV: Human immunodeficiency virus; HCV: Hepatitis C virus; ALT: Alanine aminotransferase.

sons against treatment mentioned by the physician. After July 2004 questionnaires also asked why patients denied therapy ( $n = 7658$ ). Language skills were assessed after January 2006. Fibrosis was staged according to Desmet and Scheuer from F0 to F4<sup>[17]</sup>. Among the total 15 137 patients 7658 subjects did not receive any treatment ("untreated patients") while 6341 received pegylated interferon  $\alpha$ 2a and ribavirin ("treated patients") and 1138 alternative treatments. Details on alternative therapies (92.5% silymarin, 2.8% ursodesoxycholic acid, 4.9% other interferons) are not given because their characteristics were similar to the group receiving pegylated interferon  $\alpha$ 2a/ribavirin. Thus, in the following text the total cohort consists of 13 999 patients separated by the treatment decision into "treated patients" ( $n = 6341$ ) and "untreated patients" ( $n = 7658$ ). Specific procedures were not mandatory for inclusion except for documentation of chronic hepatitis C. There were no exclusion criteria except for patients below age 18 years and those with Child B/C cirrhosis. Thus, the study represents a real life scenario of a rather unselected cohort including a significant fraction of all patients diagnosed with hepatitis C in Germany.

## Statistical analysis

For continuous variables, receiver operating characteristic analyses estimated the best cut-off point for treatment decision; these cut-off points were 56 years for age, 520 000 IU/mL for basal HCV-RNA,  $\geq$  one concomitant disease,  $\geq$  12.5 years for infection length, and 142 500/ $\mu$ L for platelets. Categorical variables were used for continuous variables using these cut-off points. Association of various factors with treatment decision and sustained virological response (SVR = negative HCV-RNA 24 wk after end of therapy) were analyzed in an

Table 2 Treatment and sustained virological response rates in various subgroups

univariate fashion using Fisher's exact test. Only those variables which were significant in the univariate analysis were included in the multivariate analysis.

## RESULTS

### Effects of various factors on treatment rate by univariate analysis

Basic characteristics of treated *vs* untreated patients are shown in Table 1. Many characteristics were similar for genotypes 1 (*n* = 8625), 4 (*n* = 440), 5 (*n* = 22) and 6 (*n*

= 27) and for genotypes 2 (*n* = 1000) and 3 (*n* = 3885) (data not shown); thus, further analyses were done in two subgroups, i.e., genotypes 1/4/5/6 *vs* 2/3. Table 2 summarizes treatment and SVR rates in the total cohort (45.3% and 49.6%, respectively) and in treated *vs* untreated patients.

By univariate analysis reduced treatment uptake and reduced SVR were seen in these groups: (1) genotypes 1/4/5/6 *vs* 2/3; (2) age > 56 years *vs* ≤ 56 years; (3) platelets ≤ 142 500/μL *vs* > 142 500/μL; (4) disease duration >12.5 years *vs* ≤ 12.5 years; (5) human im-

**Table 3** Treatment and sustained virological response rates *vs* socio-economic problems and concomitant diseases

Characteristics	Treatment rate %	SVR %	<i>n</i>
Drug abuse absent and employed without psychiatric disease or HIV co-infection	58.2	52.7	4382
Drug abuse absent and employed without psychiatric disease	58.2	52.4	4560
Drug abuse absent and employed	57.1	52.6	4929
Drug abuse absent	49.2	49.6	10 839
Drug abuse present	32.0	49.9	3160
Drug abuse present and unemployed	29.1	51.6	2203
Drug abuse present and unemployed with psychiatric disease	25.1	50.8	470
Drug abuse present and employed with psychiatric disease and HIV co-infection	7.1	0.0	56

HIV: Human immunodeficiency virus.

munodeficiency virus (HIV)/HCV co-infection *vs* HCV mono-infection; (6) presence *vs* absence of concomitant diseases; (7) German natives *vs* migrants; and (8) absence *vs* presence of regular employment.

Treatment uptake was reduced but SVR was higher in the following groups: (1) women *vs* men; (2) fibrosis F0-1 *vs* F2-4; and (3) basal HCV-RNA > 520 000 IU/mL *vs* ≤ 520 000 IU/mL.

Treatment uptake was reduced while SVR was similar in the following groups: (1) normal *vs* elevated ALT; (2) good *vs* reduced quality of life; (3) treatment in private practice *vs* clinical setting; (4) presence *vs* absence of psychiatric disease; (5) presence *vs* absence of alcohol or drug abuse; and (6) liver biopsy (and ultrasound) not performed *vs* performed.

History of *i.v.* drug abuse was the most frequent mode of infection (44.6%) followed by history of blood transfusions (17.0%). By multivariate analysis infection mode did influence neither treatment uptake nor SVR (data not shown). In the total cohort only 20.7 % of patients had a liver biopsy. Biopsy was done more often in genotypes 1/4/5/6 when compared to genotypes 2/3 (23.6% *vs* 15.3%,  $P < 0.001$ ) and in patients with elevated ALT (75.4% had elevated ALT) when compared to those with normal ALT (21.6% *vs* 18.4%,  $P < 0.05$ ). Biopsy rate was three-times higher in hospital settings when compared to practitioners (53.4% *vs* 17.4%,  $P < 0.001$ ). Alcohol or drug abuse was a frequent treatment barrier in particular in patients with psychiatric diseases or HIV co-infection and in jobless people (Table 2). Treatment rates were similarly low in drug abusers with or without substitution (data not shown). Patients with alcohol or drug abuse refused therapy less often compared to patients without abuse (50.2% *vs* 67.9%,  $P < 0.001$ ). Thus, the decision not to treat was made primarily by the physician. About 1/3 of all patients were migrants among whom 1/3 had severe language problems. Nevertheless, treatment and SVR rates were higher in migrants than in German natives while language problems did not affect treatment and SVR rates. Treatment uptake decreased with an increasing number of socio-economical and psychiatric problems; HIV infection on top of other problems reduced treatment uptake to 7 % (Table 3). SVR was unaffected even by presence of several socio-economical problems but was drastically reduced when there was a HIV co-infection on top of other problems.

### Multivariate regression analysis

Gender, age, genotype, HCV-RNA, ALT, platelets, symptoms, infection length, occupational status, concomitant diseases, HIV co-infection, alcohol and drug abuse, performance of liver biopsy and ultrasound, and quality-of-life significantly affected the treatment decision in the multivariate analysis (Figure 1). In patients with genotypes 1/4/5/6 the same factors as for the total cohort affected the treatment decision except for presence of symptoms; in patients with genotypes 2/3 the same factors as for the total cohort affected the treatment decision except for symptoms, platelets, employment, and performance of liver biopsy (data not shown). SVR was associated with various factors in the univariate analysis (Table 2). By multivariate analysis SVR was associated only with gender, genotype, HCV-RNA, age, platelets, symptoms, employment and HIV co-infection (data not shown).

### Analysis of specific reasons against treatment

The analysis looked at reasons mentioned by physicians and patients (Figure 2). The patients' wish was the most common reason against treatment (62.9 %). Among these patients lack of understanding the need of therapy, fear of side-effects, and problems with family and job were frequent reasons. Fear of side-effects was mentioned more often in women than in men (29.9% *vs* 18.8%,  $P < 0.001$ ). Alcohol or drug abuse and concomitant diseases (most commonly depression) were also frequent treatment barriers. Among patients who did not see a need for therapy reasons included lack of liver disease, symptoms, fibrosis and bad prognosis as well as normal ALT. In patients with normal ALT minor disease activity was mentioned by the physician as a reason to wait in 24.1% whereas this reason was mentioned in only 6.6% when ALT was elevated ( $P < 0.001$ ). In contrast, a similar percentage of patients mentioned the lack of disease activity as a treatment barrier irrespective of whether ALT was normal or elevated (27.1% *vs* 24.4%; NS). In patients with a HCV-RNA ≤ 520 000 IU/mL minor disease activity was mentioned by the physician as a reason to wait in 15.8% whereas this reason was mentioned in only 6.7% when HCV-RNA was > 520 000 IU/mL ( $P < 0.01$ ). The percentage of patients mentioning lack of disease activity as a treatment barrier was similar when looking at high or low HCV-RNA (data not shown). In patients who had liver biopsy minor disease activity was mentioned by the

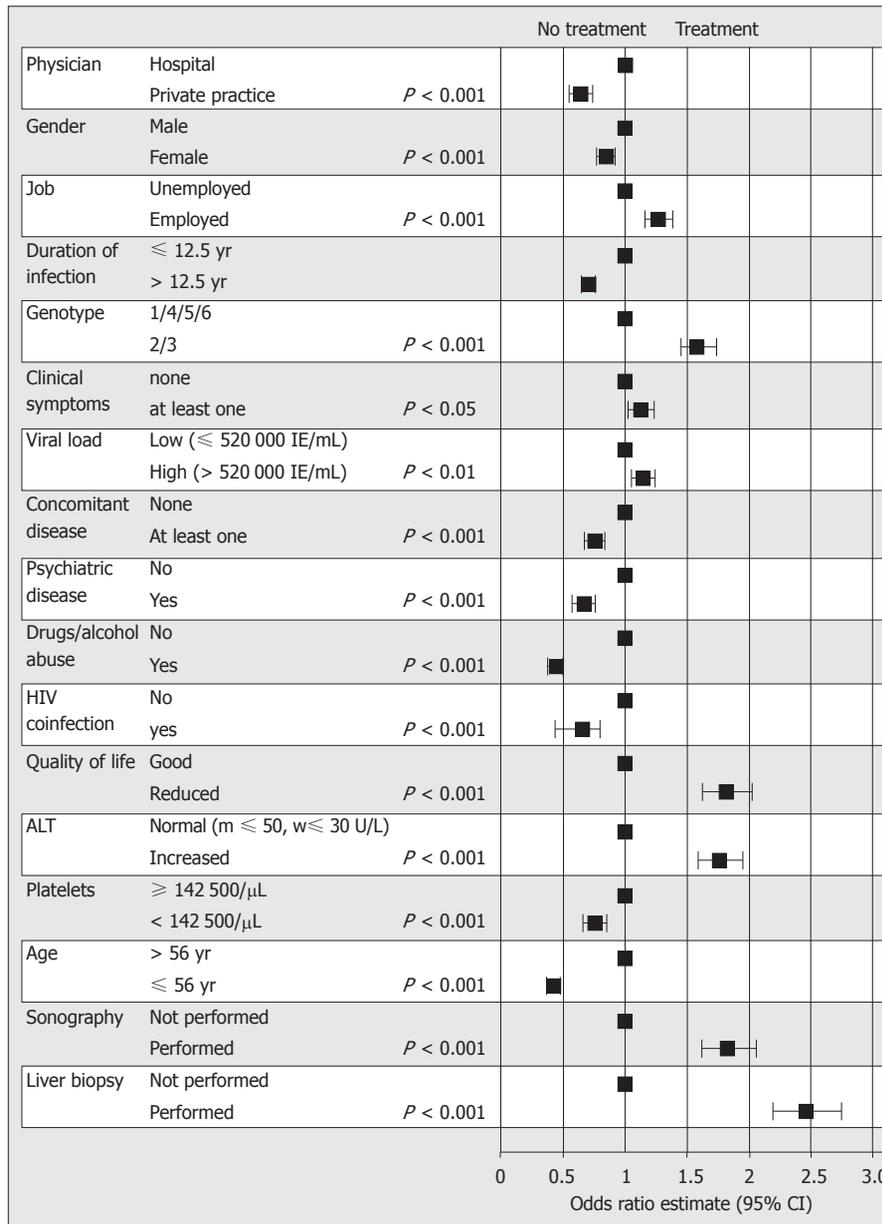

Figure 1 Multivariate regression analysis of treatment rates vs various factors. HIV: Human immunodeficiency virus; ALT: Alanine aminotransferase.

physician as a treatment barrier in 21.4 % whereas this reason was mentioned in only 10.3 % of patients without a liver biopsy ( $P < 0.01$ ). Patients mentioned fear of side effects and lack of understanding the need for therapy less often when treated in hospital settings as compared to private practice (18.5% vs 24.1% and 17.4% vs 25.9%,  $P < 0.01$ , respectively). In patients with drug/alcohol abuse, this abuse was the main treatment barrier mentioned by physicians (48.1 %). In contrast, patients with abuse refused therapy less often than those without (50.2% vs 67.9%,  $P < 0.001$ ). In HIV co-infection concomitant diseases and drug/alcohol abuse were more frequent treatment barriers than in mono-infection (25.0% vs 16.6% and 25.2% vs 16.4%,  $P < 0,01$ ). HIV co-infected patients refused therapy less often than mono-infected patients (59.1% vs 63.2%,  $P < 0.05$ ). Similarly, in patients with psychiatric diseases, the psychiatric disease was the main

treatment barrier (46.2%); among patients with psychiatric disease drug and alcohol abuse was another common barrier (24.5% vs 15.7% in patients without psychiatric disease;  $P < 0.001$ ). Older age was associated with a reduced treatment rate (49.0% vs 28.2% in patients ≤ 56 years vs patients > 56 years) (Table 2; Figure 1); in patients aged between 65 and 70 years treatment rate was 26.3% (158/600) and thus similar to the rate of 28.2% seen at ages > 56 years.

## DISCUSSION

Treatment uptake in the present cohort (45%) is one of the highest reported in the literature. Since the cohort included a significant fraction of all HCV-infected patients in Germany, the high treatment rate is probably not due to selection bias. In the literature treatment uptake

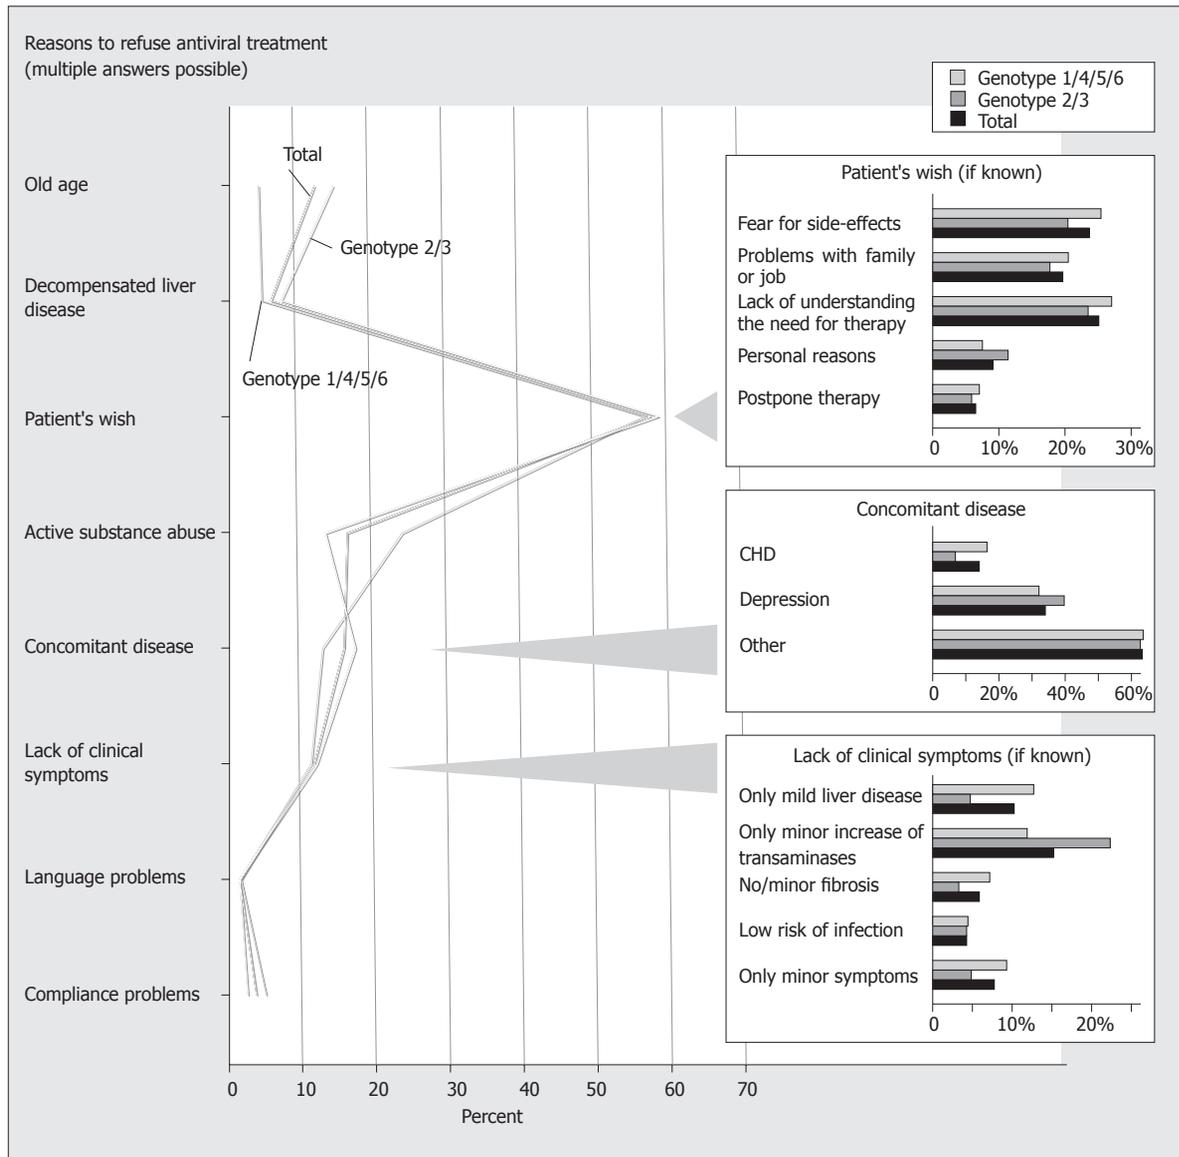

Figure 2 Reasons to refuse antiviral treatment.

tends to decrease with increasing number of subjects studied<sup>[9,12-15,18]</sup> with the lowest rate of 12% reported for the largest group of subjects studied<sup>[15]</sup>. There is little pre-selection in the present cohort; only patients with Child B/C cirrhosis were excluded as well as those under age 18 years. The present study did not include a relevant number of academic centers where most previous studies had been done. The community-based character of the present cohort incorporating 434 physicians and hospitals throughout the country reflects daily life in Germany probably better than looking at academic centres. However, one needs to keep in mind that most of the 434 physicians were not general practitioners, but gastroenterologists or at least physicians who treat hepatitis C. In general practitioners treatment rates may be lower than the 45% reported here. In the general United States community only 11% of all HCV-infected subjects had been treated<sup>[15]</sup>. This low treatment uptake suggests that therapeutic deficits are located on level of the general practitioner or

the health care system itself<sup>[7,8]</sup>. Recent studies show that knowledge deficits and misperceptions are main treatment barriers<sup>[19-21]</sup>. A high treatment rate might therefore reflect good knowledge among physicians and patients. In Germany most physicians who treat hepatitis C in private practice are organized in the Association of German Gastroenterologists (“bng”). Via their association gastroenterologists have been involved in the development of national HCV guidelines<sup>[6,22]</sup>. Many of them are members of the national “hepatitis competence network”. Recent studies have also shown that German patients with hepatitis C are well informed and better than patients with hepatitis B<sup>[23-25]</sup>. However, some practice aspects did not meet standards in the present cohort including the use of liver biopsy and interpretation of HCV-RNA values. Also, there were misperceptions among patients. Patients’ refusal was a common treatment barrier in the present cohort and in previous studies<sup>[9-11]</sup>. One of the highest treatment rates (41%) was published by Delwaide *et al.*<sup>[9]</sup>;

in that study only 17% of patients declined therapy. Thus, a high treatment uptake may be associated with low rate of refusal by patients<sup>[9]</sup>. This association may partly be explained by information deficits. In some subgroups, e.g., in patients with HIV co-infection and those with drug and alcohol abuse, the decision against treatment was often made by the physician whereas patients were rather willing to receive therapy.

Genotype and viral replication are major factors for estimating the chance for SVR and are therefore considered in the treatment decision. Correspondingly treatment rate and SVR were higher for genotypes 2/3 when compared to genotypes 1/4/5/6. In accordance with most previous studies<sup>[5,11,15,22]</sup> older age was associated with both reduced treatment uptake and reduced SVR in the present cohort. These results are in contrast to a recent study<sup>[18]</sup> in which being elderly was not associated with a low SVR. Surprisingly, treatment rate was low in patients with low HCV-RNA. This is a paradox because SVR is low at high replication in the present study and in the literature<sup>[26-28]</sup>. Thus, there may be misperceptions that high viral load indicates bad prognosis. All evidence shows this is not the case<sup>[22,29,30]</sup>. Further analyses suggested that physicians (and not patients) carry this misperception.

For many years normal serum aminotransferases were a common treatment barrier because they were thought to indicate good prognosis and reduced efficacy of therapy. In the meantime it has been shown that up to 30% of patients with normal ALT have major fibrosis and that SVR is not associated with ALT as also seen in the present study<sup>[22,29-31]</sup>. Despite this data, treatment rate was markedly lower in patients with normal ALT when compared to those with elevated ALT. We have reported a similar misperception of ALT for the decision to do HCV antibody tests<sup>[8]</sup>; many physicians just tested for HCV infection if ALT was markedly increased although most infections were associated with normal or slightly elevated ALT. Thus, ALT values are overestimated both in diagnostic<sup>[8]</sup> and treatment decisions<sup>[9,12]</sup>.

In contrast to academic trials, only 20% of patients had a liver biopsy in daily German practice. According to guidelines liver biopsy should be considered when the results will influence the treatment decision and in particular when treatment is not initiated<sup>[5,22]</sup>. However, treatment rate in patients with a liver biopsy was twice that seen in patients without a biopsy; according to guidelines it should be the other way around. Only a single previous study has also shown a positive association between performance of liver biopsy and treatment uptake<sup>[32]</sup>. It may be speculated that patients who refused liver biopsy may have a general problem to accept medical means. However, further analyses support other explanations. Biopsy rate in hospital settings was more than three-times higher than that in private practice. Although non-invasive means of assessing fibrosis are entering clinical routine, only a minority of community-based physicians use serum markers or sonographic stiffness in daily clinical routine as yet. Thus, physicians in private practice underestimate the value of liver biopsy more often than physicians in hospital

settings. The lack of immediate availability of biopsy may explain the low biopsy rate among practitioners. Also, treatment uptake was markedly lower for patients treated in private practice when compared to hospital settings. The analysis of specific reasons against treatment may partly explain this difference: patients mentioned fear of side effects and lack of understanding the need for therapy less often when treated in clinical settings when compared to private practice.

The treatment rate of HCV infection was considerably lower in HIV co-infected patients when compared to HCV mono-infection. Although SVR rates were also somewhat lower in co-infected patients, they were still in an acceptable range considering that end-stage liver disease is a common cause of death in HIV/HCV co-infection<sup>[33-35]</sup>. When compared with the literature the present rates of treatment and SVR (31% and 39%) look favorable. In other studies SVR ranged from 8% to 40% in co-infected patients<sup>[36-38]</sup>. Nevertheless HIV co-infection was a main treatment barrier also in the present cohort. Among co-infected patients drug and alcohol abuse as well as fear of side-effects were frequent treatment barriers. The present analysis also shows that HIV/HCV co-infected patients refused therapy less often than mono-infected patients; thus the low treatment rate is probably mainly caused by physicians and not by patients. In previous studies only 12%-33% of HIV co-infected patients initiated HCV therapy<sup>[36,39-40]</sup>; main barriers were non-adherence, patients' refusal, drug abuse and psychiatric problems. The present results demonstrate that the HIV infection on top of psychiatric and socio-economical problems may not only reduce treatment uptake but almost eliminates chances for SVR.

Recently it has been shown that HCV infection can successfully be treated in patients with drug and alcohol abuse and in those with HIV co-infection provided that there is a good management<sup>[35-38,41-43]</sup>. This is of great importance because alcohol abuse and co-infections accelerate fibrosis<sup>[34,35,44,45]</sup>. Although a history of drug abuse did not reduce treatment rate in the present cohort, active alcohol and drug abuse were associated with a markedly reduced treatment uptake as reported previously<sup>[10,11,14,15]</sup>; SVR was not affected by abuse. In 50% of abusers, physicians specified the abuse as the main treatment barrier. In contrast, patients with alcohol or drug abuse refused therapy less often than did patients without abuse. Thus, the decision not to treat was made primarily by the physician. A survey of 320 American Society of Addiction Medicine physicians showed that even among these specialists only a minority were providing HCV treatment or willing to provide treatment<sup>[46]</sup>. Treatment rates are even lower in the general community and may approach values of less than 1% in unselected drug addicts<sup>[47]</sup>.

Treatment rate was lower in unemployed patients when compared to those with a job while SVR was similar between these groups. Since jobless people tend to have a low educational state, these results fit to recent United States data showing that psychosocial factors and low education were associated with reduced treatment up-

take<sup>[12,14,48]</sup>. In the present cohort 1/3 of HCV infected patients were migrants among whom 1/3 had severe language problems. Unexpectedly, treatment uptake was not lower but higher in migrants when compared to German natives. These results can not be explained easily. Along this line women had a lower treatment rate when compared to men in this cohort as well as in another previous study<sup>[10]</sup>. This is also unexpected because men have a lower use of medical services than women both in the United States<sup>[49]</sup> and in Germany<sup>[50]</sup>. Thus, good knowledge and care about health issues *per se* do not necessarily increase treatment uptake for hepatitis C.

## ACKNOWLEDGMENTS

The following 20 physicians contributed the largest number of patients in addition to the authors: Thomas Lutz, 60311 Frankfurt; Solange Nzimegne Gözl, 10719 Berlin; Peter Geyer, 36088 Hünfeld; Petra Sandow, 14052 Berlin; Ralph Link, 77654 Offenburg; Henning Schnell-Kretschmer, 35392 Giessen; Oswald Burkhard, 67547 Worms; Stefan Pape, 33098 Paderborn; Bernd Bokemeyer, 32423 Minden; Willi Schiffelholz, 86150 Augsburg; Mathias Freitag, 76133 Karlsruhe; Andreas Zipf, 68161 Mannheim; Peter Buggisch, 20251 Hamburg; Maria Leuschner, 63065 Offenbach; Hanns Löhr, 65185 Wiesbaden; Jörg Cordes, 60596 Frankfurt; Christian Jellinek, 12043 Berlin; Klaus Boeker, 30161 Hannover; Gisela Felten, 44623 Herne; Christine John, 10117, Berlin; Germany (for all contributors).

## COMMENTS

### Background

In recent surveys only 20% of hepatitis C virus (HCV)-infected subjects know of their infection and only 20% of the latter are treated. Considering that therapy cures the disease in 50% of patients, treatment rate should be increased.

### Research frontiers

Bio-epidemiological research focuses to identify treatment barriers in patients with chronic hepatitis C. As yet only some reasons for the current large therapeutic deficit have been identified including co-morbidity, drug abuse and psychosocial factors. The present study evaluates which factors influence the treatment decision in daily German practice.

### Innovations and breakthroughs

Treatment uptake in the present cohort (45%) is one of the highest reported in the literature. A high treatment rate usually reflects good knowledge among physicians and patients. In Germany many physicians who treat hepatitis C are members of the national "hepatitis competence network" which is aimed to implement practice guidelines in the broad medical community. Despite the obvious success of the German hepatitis competence network some practice aspects did not meet standards in the present cohort including the use of liver biopsy and interpretation of HCV-RNA and alanine aminotransferase (ALT) values. Liver biopsy and thus knowledge about fibrosis stage were too low in particular in patients treated in private practice and in those with normal ALT. Also, there were misperceptions among patients as their refusal was a common treatment barrier. Unexpectedly, therapy uptake was higher in migrants despite language problems. Some further reasons against treatment appeared medically based whereas others seemed to be based on fears, socioeconomical problems and information deficits both on the side of physicians and patients.

### Applications

The present cohort study includes a significant fraction of all HCV-infected patients in Germany. The community-based character of the present cohort incorporating 434 physicians and hospitals throughout the country reflects daily

life in Germany probably better than looking at specialized academic centres.

### Terminology

Treatment barrier: Reasons why patients with chronic hepatitis C are not treated with antiviral drugs.

### Peer review

This is an important paper with a large HCV patient cohort from Germany including both academic and non-academic centres detailing reasons for treating and not treating HCV.

### Abstract

**AIM:** To investigate all patients referred to our center with non-responsive celiac disease (NRCD), to establish a cause for their continued symptoms.

**METHODS:** We assessed all patients referred to our center with non-responsive celiac disease over an 18-mo period. These individuals were investigated to establish the etiology of their continued symptoms. The patients were first seen in clinic where a thorough history and examination were performed with routine blood work including tissue transglutaminase antibody measurement. They were also referred to a specialist gastroenterology dietician to try to identify any lapses in the diet and sources of hidden gluten ingestion. A repeat small intestinal biopsy was also performed and compared to biopsies from the referring hospital where possible. Colonoscopy, lactulose hydrogen breath testing, pancreolauryl testing and computed tomography scan of the abdomen were undertaken if the symptoms persisted. Their clinical progress was followed over a minimum of 2 years.

**RESULTS:** One hundred and twelve consecutive patients were referred with NRCD. Twelve were found to have celiac disease (CD). Of the remaining 100 patients, 45% were not adequately adhering to a strict gluten-free diet, with 24 (53%) found to be inadvertently ingesting gluten, and 21 (47%) admitting non-compliance. Microscopic colitis was diagnosed in 12% and small bowel bacterial overgrowth in 9%. Refractory CD was diagnosed in 9%. Three of these were diagnosed with intestinal lymphoma. After 2 years, 78 patients remained well, eight had continuing symptoms, and four had died.

**CONCLUSION:** In individuals with NRCD, a remediable cause can be found in 90%: with continued gluten ingestion as the leading cause. We propose an algorithm for investigation.

### INTRODUCTION

Celiac disease (CD) is induced by ingestion of gluten and related proteins with consequent intestinal injury and varied clinical manifestations. The defining feature is the expectation that the intestinal lesion improves with strict

exclusion of gluten from the diet. However, a proportion of individuals do not respond to a gluten-free diet (GFD), in terms of clinical or histological recovery. Early analysis has indicated that as many as 30% of individuals prescribed a GFD do not experience symptomatic improvement<sup>[1]</sup>. Non-responsive CD (NRCD) is defined as continued symptoms (including lethargy, abdominal pain and diarrhea) in patients on a GFD. There have been no recent studies to provide robust epidemiological data to assess the incidence of NRCD, although in clinical practice it is a common occurrence, based on the authors' experience and several publications<sup>[2-5]</sup>. The investigation of NRCD has been reported<sup>[6]</sup>, however, there are no data on the management and longer term follow-up of these subjects. Most patients with CD experience a rapid symptomatic recovery with a strict GFD. In 30% of cases there may be a protracted ( $\geq 12$  mo) or incomplete phase of mucosal recovery<sup>[7]</sup>. An arbitrary period of 6-12 mo on a GFD before reassessment has been suggested but the urgency of further investigation is often dictated by the severity of continued symptoms or clinical manifestations. In this context, we define NRCD as failure of expected symptomatic response to a GFD. Accordingly, NRCD is not intended to be a diagnostic term but rather a clinical description to allow a pragmatic and systematic approach to be followed to evaluate and investigate these patients. The practical management of NRCD depends on establishing a cause for continued symptoms. The commonest reason for persistent symptoms in a previous study of 55 patients was failure to comply with a GFD<sup>[6]</sup>. Imposition of a strict gluten-free dietary regimen appears to abolish symptoms in the majority of CD patients with continued symptoms<sup>[8]</sup>.

Refractory CD (RCD) describes a distinct clinical entity and represents a subset of non-responsive patients. RCD is defined by symptomatic and persistent villous atrophy in patients despite a strict GFD<sup>[8]</sup>. RCD can be diagnosed after primary failure of GFD or occur as a secondary phenomenon in previously treated CD. It can be subdivided into types I and II. This clinical definition has been refined by the discovery that 80% of individuals with true RCD possess an abnormal population of intraepithelial lymphocytes (IELs) detectable in their small intestinal mucosa (CD103<sup>+</sup>, intracellular CD3<sup>+</sup>, CD4<sup>-</sup>, CD8<sup>-</sup>, surface CD3<sup>+</sup>)<sup>[8]</sup>. These IELs may demonstrate a monoclonal T cell receptor (*TCR*)- $\gamma$  gene rearrangement, detectable by polymerase chain reaction (PCR) analysis of biopsy specimens. The presence of this aberrant T cell phenotype has been termed type II RCD (as opposed to type I RCD in which this anomaly is not present). Studies have shown that type II RCD is associated with a significantly greater mortality than type I RCD; 41% *vs* 14% at 2 years<sup>[9]</sup>, 42% *vs* 4%<sup>[10]</sup> and 56% *vs* 7% 5-year mortality<sup>[11]</sup>, with the major cause of death attributed to the development of enteropathy-associated T cell lymphoma (EATL). This is characterized by malignant lymphoid tissue with the same immunophenotype as described in type II RCD.

It has been postulated that the presence of this type II RCD T cell phenotype may represent a cryptic T cell lymphoma. In 41 patients with RCD, over 50% developed EATL during a mean of 2 years follow-up<sup>[9]</sup>. Survival from EATL remains abysmal. Thus, there are compelling clinical reasons to investigate CD patients with continued symptoms despite a GFD, in order to establish a treatable cause or identify cases of RCD or intestinal lymphoma. NRCD and RCD may both be present with weight loss, diarrhea, or malabsorption; all of which warrant expeditious investigation.

## MATERIALS AND METHODS

We maintain a prospective database of patients diagnosed with CD. We selected patients who were referred to our institution with a diagnosis of NRCD (defined as failure of expected symptomatic response to a GFD) between April 2002 and October 2003.

Initial evaluation included an appraisal of the original diagnosis of CD, history of symptoms (including lethargy, increased bowel frequency and weight loss), clinical examination, routine blood tests and assessment of dietary intake and GFD compliance. Patients were then investigated according to our usual clinical practice and subsequent findings; thus, some patients were investigated differently to others, however, all patients were followed for a minimum of 2 years; those who developed further symptoms were reinvestigated. Unless an obvious cause was immediately apparent, we undertook a further small bowel biopsy, which was performed by the authors to ensure a standard quality of biopsy specimen. Jumbo endoscopy forceps were used to obtain four samples that were carefully placed, mucosal surface upwards, onto paper to ensure optimal orientation.

Following standard preparation, histological examination was performed by our histopathology department, although in borderline or ambiguous cases, we often elected additionally to examine the slides within our department. An excess above 20 IELs per 100 enterocytes defined a pathological increase and villous atrophy was defined as being unequivocally present if the villous height to crypt depth ratio was below 2<sup>[12]</sup>. Direct visual comparison was made with any previous small intestinal specimens for the same patient. If there were any concerns regarding the validity of the diagnosis of CD, a gluten challenge was carried out. This involved ingestion of 10 g gluten (equivalent to four slices of white bread daily) for a minimum of 2 wk before repeat duodenal biopsy<sup>[13]</sup>. If colonoscopy was performed, random colonic biopsies were taken. In the diagnosis of microscopic colitis, we defined this condition as  $> 20$  lymphocytes per 100 epithelial cells in the superficial colonic mucosa in patients with diarrhea<sup>[14]</sup>.

Tests for small bowel bacterial overgrowth (SBBO) involved a lactulose hydrogen breath test. A positive test was indicated by an early rise in breath hydrogen  $>$

20 ppm from baseline after ingestion of 10 g lactulose. We note the low sensitivity and specificity of breath tests for bacterial overgrowth, including hydrogen and labeled carbon tests<sup>[15]</sup>. In order to validate a diagnosis of SBBO, we additionally required that symptoms resolved following rotating antibiotic treatment (ciprofloxacin 250 mg bd for 2 wk followed by metronidazole 200 mg tds fortnightly for 4 mo).

Lactose intolerance was diagnosed on dietary exclusion alone as tests are also unreliable. Exclusion of dairy products carries no risk and, if symptoms resolve, is reliable in establishing a confident diagnosis of lactose intolerance. Non-invasive testing of pancreatic function was performed in a number of patients (pancreolauryl test). False positives may occur in CD<sup>[16]</sup>, so the diagnosis could only be confirmed with symptomatic improvement with oral pancreatic supplements.

RCD was suspected in those with severe, symptomatic NRC with demonstrated villous atrophy, particularly those with pronounced weight loss. Urgent and extensive investigation was arranged in these individuals. This included computed tomography scanning of the abdomen and pelvis, colonoscopy and small bowel imaging. Video capsule endoscopy was not routinely performed at the outset of this study, although this now forms part of our assessment of suspected RCD. If appropriate, serological testing for anti-enterocyte antibody was performed to exclude autoimmune enteropathy.

Additionally, tissue analysis for IEL immunophenotyping and PCR reaction amplification for TCR clonality were undertaken; DNA was analyzed by a series of multiplex PCR assays, which amplified *TCR β* and *γ* gene rearrangements. PCR primer sequences were those used by the Biomed-2 consortium and have been shown to detect clonal signals in approximately 95% of all T cell clonal cases<sup>[17,18]</sup>.

The presenting symptoms, investigation process, results and outcome of subsequent management were recorded. We followed up patients for a minimum of 2 years and observed if patients remained symptom-free or suffered further relapses or related adverse events such as death or identification of malignancy. Any other tests deemed necessary, based on clinical history and examination, were performed, which resulted in a number of other diagnoses.

## RESULTS

One hundred and twelve patients were referred to our center and underwent assessment for NRC. The mean age of this group was 48.5 years (range 19-72 years) and 69% were female; CD had been diagnosed at a mean age of 31 years. The commonest presenting symptoms were diarrhea (65%), lethargy (43%), abdominal pain (27%) and weight loss (23%). The demographic details and clinical symptoms are shown in Table 1. The results are summarised in Figure 1

Twelve out of the 112 patients had been wrongly diagnosed with CD. Due to the doubt over the diagno-

sis, these 12 patients underwent gluten challenge and repeat biopsy which was normal in all cases. Additionally, anti-endomysial antibody (EMA) tests were all negative, although four patients had anti-gliadin antibodies detected. In four cases, initial duodenal biopsy had not been performed previously and diagnosis had been made based on dramatic reduction in symptoms with initial wheat exclusion. In the remaining eight, we were able to examine the original histology in five patients. Four of these were sufficiently normal to exclude CD in tandem with the subsequent negative gluten challenge. One patient did have villous atrophy on their original biopsy, which was felt to have been due to bacterial overgrowth, which had subsequently improved with antibiotic treatment. We were not able to examine previous specimens from three patients but the negative gluten challenge was deemed sufficient to exclude a diagnosis of CD. In total, six out of 12 patients had been previously shown to have supportive positive serology for CD in other institutions (mainly anti-gliadin antibody). Seven patients were diagnosed with irritable bowel syndrome; three with primary SBBO; and one each with anorexia nervosa and IgE-mediated wheat allergy. These individuals were subsequently removed from the analysis.

Forty-five of the remaining 100 patients were found to be ingesting sufficient gluten to cause their symptoms. Of these, 24 were discovered to be consuming gluten accidentally, and 21 admitted poor compliance with aspects of their prescribed diet. In total, 37 (23/24 accidental group and 14/21 poor compliance group) patients underwent repeat duodenal biopsy in order to establish this information. Of these specimens, 33/37 were abnormal (Marsh III a-c) which assisted in correlating the continued ingestion with the persisting histological abnormalities.

The majority (28/37) proceeded to have a further duodenal sample taken that showed comparative improvement in all but one case. In this case, further gluten ingestion was admitted on further questioning. In summary, all 45 patients in this group reported symptomatic improve-

**Figure 1** Flow chart showing the investigation and diagnoses of the patient cohort. RCD: Responsive celiac disease; SBBO: Small bowel bacterial overgrowth; EATL: Enteropathy-associated T cell lymphoma.

ment on a strict GFD, with 27/45 having demonstrable histological improvement.

Eleven patients were treated successfully for microscopic colitis. Diagnosis was made based on the presence of diarrhea and typical colonic histological features. All of these patients underwent simultaneous small bowel biopsy which was abnormal in 7/11 (64%) cases, mainly with an isolated intra-epithelial lymphocytosis. No alternative cause was established on enquiry or testing. These individuals were treated with a combination of mesalazine, loperamide, prednisolone and azathioprine (1-2.5 mg/kg). Five out of 11 required azathioprine for resolution of symptoms. Three patients suffered a relapse of diarrhea within 2 years; again treated successfully with oral steroids. When abnormal, patients had comparative improvement in their

duodenal histology following resolution of symptoms. We performed a total of 75 colonoscopies in NRCD patients with diarrhea and found significant lymphocytic infiltration in 15. This included four patients defined as having RCD who did not show histological or clinical improvement with immunosuppressive treatment.

Nine patients were successfully diagnosed and treated for bacterial overgrowth with sustained resolution of symptoms. There have been two relapses both in the same patient within 2 years; responding on each occasion to further courses of antibiotic treatment (metronidazole and ciprofloxacin). Interestingly, one patient was found to have combined variable immunodeficiency as an underlying cause for bacterial overgrowth and was referred for immunoglobulin infusions as part of further management.

Ten patients had normal investigations (all had duodenal biopsy and colonoscopy). This group was reassured and treated symptomatically for irritable bowel syndrome. At review after 2 years, 5/10 had continued functional symptoms with no new positive investigations. One patient had been diagnosed empirically with lactose intolerance. The remaining four patients were symptom free.

Lactose intolerance was diagnosed in six individuals; all of whom had dramatic symptomatic resolution when a lactose-free diet was commenced. All of these patients had primary NRCD.

We identified seven patients with coexisting inflammatory bowel disease (IBD); all of whom were suffering from ulcerative colitis. The predominant pattern was proctitis in five patients, and two had sigmoid colitis. Six responded to 5-ASA therapies, and one required azathioprine to control their IBD. All remained well and no surgical intervention has been required at 2 years follow-up.

After initial assessment and duodenal biopsy, 20 patients were considered to have a high suspicion of RCD. All of these patients had weight loss and diarrhea and a history of positive correlative celiac serology. After exhaustive investigation and assessment according to the United European Gastroenterology Week guidelines<sup>[11]</sup> (median duration 5 mo), a firm diagnosis of RCD was made in 9/20 patients; all of whom had a raised IEL count (> 20 per 100 enterocytes). Furthermore, all had marked villous atrophy (Marsh IIIa-c). None of this group was found to have a positive anti-enterocyte antibody. An alternative and remediable explanation for symptoms was identified in 11 patients (seven continued gluten ingestion; three with bacterial overgrowth; and one with microscopic colitis). RCD may be divided into those without aberrant T cells (type I) and those with aberrant T cells or ulcerative jejunitis (type II)<sup>[11]</sup>. Of the nine refractory patients, seven had type II RCD with positive clonality by  $\gamma$  TCR PCR. Three had ulcerative jejunitis; four were found to have or developed an enteropathy-associated intestinal lymphoma, two of whom have subsequently died, one from proven EATL and the other from suspected EATL (a post-mortem was refused by the relatives); both survived less than 1 year from diagnosis. The other two patients remain alive; one is on immunosuppressive medication and the other has been successfully treated with surgery. The remaining patients have continued to have symptoms over the follow-up period of 2 years (median 33 mo).

Of the two patients with type I RCD, one has died but we have no information available as to the precise cause of death, and the other patient has continued to have symptoms over the follow-up period of 2 years. In summary 3/9 (33%) patients diagnosed with RCD in our study have died.

Other diagnoses that were established are listed in Table 2. A diagnosis was only included if the symptoms were clearly attributable and symptomatic improvement occurred with appropriate treatment. Ten patients had more than one diagnosis established during the study

period (median 33 mo). This was largely as a result of ongoing investigation for additional symptoms during the study period.

Further assessment of patients' symptoms was conducted 2 years after their initial evaluation. Overall, four patients had died, with one from an unrelated cause. The vast majority (78%) reported being symptom-free at 2 years. A total of eight patients reported continued symptoms, with four describing them as moderate or severe. Those with continued symptoms included four diagnosed with RCD, two with irritable bowel syndrome and two with microscopic colitis. Ten patients could not be contacted.

In the 100 patients with NRCD, 73% had detectable anti-tissue transglutaminase (tTG) antibodies at varying titers. There was no statistical correlation between presence of antibodies, antibody titer and the established cause of NRCD. However, it was noted that 9/20 patients with RCD had positive celiac serological tests.

## DISCUSSION

Evaluation of patients referred to us with continued symptoms on a GFD concluded that 12 out of 112 patients did not actually have CD. The diagnosis of CD might appear straightforward but this indicates that errors are still made in clinical practice. The main difficulties appear to be basing the diagnosis on serology alone; where available tTG and EMA should be tested because these are most sensitive and specific<sup>[19,20]</sup>. DQ2/8 HLA typing may be useful to exclude CD in patients when tTG is negative but villous atrophy is present, and there is doubt over the diagnosis. In this study, DQ2/8 was not performed given difficulty in availability; furthermore, it adds little in patients who have a positive tTG and villous atrophy. In experienced hands, serology testing is highly specific but,

there can be discordant results between different laboratories. The limitations of celiac serology have previously been reported<sup>[21]</sup>. Accordingly, duodenal biopsy remains mandatory for a clear diagnosis of CD to be made and this is supported by current recommendations. We feel it is important to reassess the initial biopsy, as failure to orientate the small intestinal mucosal biopsy can result in a false interpretation of villous atrophy.

When the diagnosis of CD is secure, investigation of continued symptoms yields a remediable cause in 90% of cases, with continued gluten ingestion as the leading diagnosis. This parallels the findings of a previous study in an NRCD group<sup>[6]</sup>. In our study, the commonest culprit for inadvertent intake was malted breakfast cereals, although beer, cooking sauces, pizza, and biscuits - the latter two of which were clearly labeled as containing gluten - were also identified as sources of continued gluten ingestion. The diagnosis of continued gluten ingestion was only accepted, if after dietary modification, the patients' symptoms were reported to have resolved at a later follow-up appointment. It is of interest that nearly half of those failing to adhere to a GFD were aware that their compliance was suboptimal but withheld this information at initial assessment. It appears that some CD patients are reluctant to acknowledge that a minor intake of gluten could account for their continued symptoms. It is therefore important that appropriate dietary advice is provided at the outset to avoid unnecessary investigation at a later date. Celiac societies have a useful role in advising on GFD. However, some patients in our study were following a recommended GFD but improved when certain "safe" foods were removed from their diet. There has been considerable debate as to the acceptable safe threshold for gluten in foods, with 200 ppm being initially recommended. Some individuals do appear to suffer ongoing symptoms with persistent duodenal injury, even with trace quantities of gluten ingested in certain foods. Therefore, a lower limit of 20 mg/kg (20 ppm) has been accepted for labeling of gluten-free foods with 100 mg/kg labeled as gluten-reduced. These regulations will be introduced in 2012<sup>[22]</sup>. We advise patients that appear to be exquisitely sensitive to traces of gluten to adhere to a wheat-free GFD. This involves avoidance of products that are made by extraction of wheat proteins from flour because this process is usually incomplete to some degree, with traces of residual gluten remaining.

The association of microscopic colitis has been reported in CD patients<sup>[6,13]</sup>. It has been postulated that the lymphocytic infiltrate is part of the same autoimmune pathogenesis that is seen in the small bowel and that this infiltrate improves with a GFD. Similarly, microscopic colitis appears to be linked with RCD, which again suggests an aberrant immunological process. In our study, we suggest that there may have been an overlap between the groups diagnosed with microscopic colitis and RCD. It may be difficult to differentiate the two conditions, especially when duodenal abnormalities are marked. We based our diagnosis on the predominant abnormality be-

tween colonic and duodenal histology, severity of clinical manifestations, and the response to treatment. In practice, once lymphoma has been exhaustively excluded, the management of resistant symptoms may be largely similar with recourse to immunosuppressive therapy. Treatment of microscopic colitis is currently suboptimal but overall, the natural history is benign. We do not attempt here to discuss the validity of treatments for microscopic colitis in CD; only that sustained symptomatic improvement was achieved in these cases. In our experience, a trial of oral mesalazine may prove sufficient, although this is frequently ineffective. Following this, moderate-dose oral systemic steroids (20 mg/d prednisolone) usually provides rapid complete symptomatic response. The dose should be tapered gradually, although in a few cases it may be necessary to maintain 5-7.5 mg/d; in such instances, azathioprine as a steroid-sparing agent should be considered.

SBBO is associated with CD and is probably underdiagnosed<sup>[23]</sup>. The mucosal abnormalities may theoretically disrupt the innate defenses of the small intestine and predispose to this condition. In our study, patients all responded to antibiotic therapy but relapse was common. A second longer course of rotating antibiotic therapy was prescribed, which appeared to eradicate symptoms in the long term. If suspected, the diagnosis can be difficult to confirm, either by duodenal aspiration or breath test because these tests have a low sensitivity and specificity<sup>[15]</sup>. The duodenal histology may be normal, abnormal or exhibit patchy changes that are difficult to detect<sup>[24]</sup>. Treatment may be reasonably advised empirically if this diagnosis is suspected<sup>[23]</sup>. Although there is minimal data from clinical trials, it is our practice to treat patients with ciprofloxacin 250 mg twice daily, rotating fortnightly with metronidazole 200 mg three times daily for 3 mo. Symptomatic response is assessed to determine success of treatment. Duration of treatment depends on the conviction that SBBO is the underlying course. In our experience, patients may require treatment with alternating antibiotics for up to 4 mo if symptoms are resistant or recur after discontinuation of a short course of empirical antibiotics.

Acquired lactose intolerance is widely recognized to be a potential problem in CD. Exclusion of dairy produce is often recommended in the first 3-6 mo of GFD to allow disruption of the brush-border disaccharidase activity to recover. IBD can coexist with CD, because both are common and not mutually exclusive. One study has previously reported an increased incidence of IBD in patients with CD compared with the general population<sup>[25]</sup>. Two patients in our cohort had evidence of concomitant pancreatic insufficiency. Abnormal exocrine function, as tested with fecal elastase, was demonstrated in 13 (42%) subjects in one series of 31 CD patients, although only in three was this clinically significant<sup>[26]</sup>. A trial of treatment with pancreatic supplements may be advisable in those in whom pancreatic insufficiency is suspected.

Continued symptoms in CD patients may be functional because the symptoms are often indistinguish-

able<sup>[27]</sup>. In 10% of our NRCD patients, further investigations, including duodenal biopsy, were normal and the symptom pattern was consistent with standard criteria for irritable bowel syndrome. It is possible that the original symptoms at presentation were functional and that the CD was an incidental diagnosis. Additionally, a GFD frequently fails to provide adequate fiber intake that may exacerbate constipation and symptoms of irritable bowel syndrome, for which we advise supplementary fiber with either an ispaghula or psyllium seed husk preparation. Clearly, the GFD should be continued if the diagnosis of CD has been confirmed. Patients with CD may also suffer from a range of other conditions that affect the general population and they should be investigated accordingly. It is not satisfactory to attribute any subsequent symptoms to a previous diagnosis of CD, particularly in cases in which symptoms initially responded to a GFD.

### Responsive celiac disease

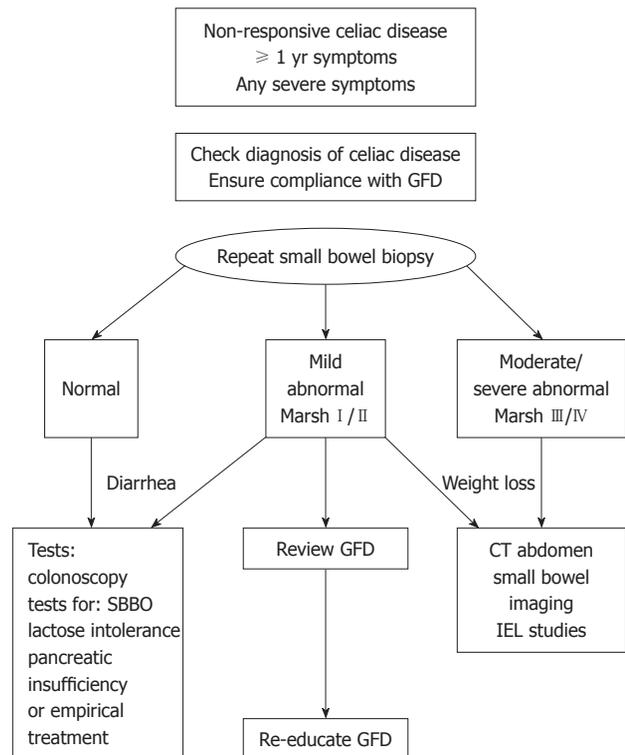

In our study of NRCD, nine patients were characterized as having RCD. Three were diagnosed with intestinal lymphoma, but one survived following treatment. At 2 years, 3/9 had died (33%), which is comparable to pre-existing cohorts<sup>[9,28]</sup>. There are no controlled trials but there are reports of symptomatic improvement with use of oral steroids and azathioprine. It is our practice to manage RCD and ulcerative jejunitis with moderate-dose prednisolone (20 mg/d), with initiation of azathioprine as a steroid-sparing agent (2-2.5 mg/kg). The steroid dose is tapered according to symptomatic response. We continue to monitor for the development of EATL. It is our practice to repeat duodenal biopsy after 4-6 mo to assess the small bowel inflammation and correlate this to ongoing symptoms and treatment.

### Celiac serology

We test for serum IgA EMA and tTG antibodies in all patients with suspected CD, because these are the most sensitive and specific. We also test for IgA deficiency because this is over-represented in CD patients and can lead to a false-negative EMA result. We no longer recommend using anti-gliadin antibody testing because of poor specificity<sup>[19]</sup>. Initial reports have suggested that celiac serology is a good indicator of response to GFD<sup>[29]</sup>. However, a further study has indicated that serology correlates poorly with histological recovery<sup>[30]</sup>. In our experience of NRCD, there was a high rate of low titer positive serology and this disappointingly failed to correlate with specific causes. Although celiac antibody testing should be performed routinely in symptomatic CD, we do not feel that this should deter further investigation of the non-responsive patient.

### Prognosis at two years

We have followed up this group of NRCD patients to provide information on longer-term outcome of NRCD. Only eight patients reported continued symptoms after 2 years, which included patients with RCD, as one might

**Figure 2** Algorithm for investigating non-responsive celiac disease. Moderate to severe abnormalities were defined by villous atrophy (Marsh III-a-c, or IV)<sup>[20]</sup>. GFD: Gluten-free diet; SBBO: Small bowel bacterial overgrowth; IEL: Intraepithelial lymphocytes; CT: Computed tomography.

expect, and microscopic colitis. This is reassuring in that NRCD has a good prognosis if evaluated and managed appropriately.

### Investigation algorithm

This algorithm (Figure 2) has been used as a basic guide in the investigation of patients referred to our institution with NRCD. It reflects the pivotal role of repeat duodenal biopsy. It recognizes that mild histological abnormalities are more likely to indicate continued trace gluten intake or be present in the context of a secondary diagnosis. More severe histological changes or significant weight loss warrant more urgent investigation for RCD or intestinal lymphoma. In our study, all nine patients with RCD had significant weight loss and severe histological abnormalities on duodenal biopsy.

The management of NRCD depends on confirming the diagnosis of CD and establishing a cause for the symptoms, which should be possible in 90% of cases. We suggest that those with RCD should be evaluated for lymphoma and subsequently managed with immunosuppressive therapy. Alternative strategies involving treatment with cyclosporine<sup>[31]</sup>, cladribine<sup>[32]</sup>, or fludribine and melaphan, stem cell transplantation for type II RCD<sup>[33]</sup> have been reported, although their use is not generally accepted. Continued gluten ingestion accounts for 45% of persistent symptoms in patients with CD and a thorough and honest dietary assessment should be encouraged. Microscopic colitis and SBBO are impor-

tant causes of persistent ongoing symptoms that should respond to treatment. The longer-term prognosis of NRC D is good, with a 90% prospect of sustained symptom resolution.

## COMMENTS

### Background

Celiac disease (CD) is a common disease that affects approximately 1% of Northern Europeans and North Americans. It is an inflammatory condition predominantly involving the proximal small bowel in genetically susceptible individuals. Treatment involves a life-long gluten-free diet (GFD) with avoidance of dietary gluten present in wheat, rye and barley. Thirty percent of CD patients fail to improve or may relapse while on a GFD, which is termed non-responsive CD (NRC D).

### Innovations and breakthroughs

The investigators report that the commonest cause of NRC D is continued gluten ingestion, either deliberately or by accidental ingestion. This cause is easily remediable by simple dietary measures. The authors also describe how other diagnoses can also contribute to the persistent symptoms: this includes microscopic colitis, a disease that causes diarrhea with a normal visual examination of the large bowel, and small bowel bacterial overgrowth; both of which occur more commonly in CD than previously reported.

### Applications

This article helps investigation of NRC D through provision of an investigative algorithm for physicians to investigate the persistent symptoms in individuals with CD who have been prescribed a GFD. It also highlights that continued gluten intake and other diagnoses can be concomitant, such that they should be considered in the diagnostic work up.

### Peer review

This is a good descriptive study in which authors investigate all patients referred to our centre with non-responsive celiac disease to establish a cause for their continued symptoms. The results are interesting and suggest that an algorithm for managing patients with non-responsive celiac disease.

a second-line therapy among 206 patients who had initially received first-line treatment with a gemcitabine-based regimen. Median number of cycles was 4 (range: 1-12) and the median duration of treatment was 2.6 mo (range: 0.3-7.4). The overall disease control rate was 40.0%. The median overall survival and progression-free survival from the start of second-line therapy were 5.8 (95% CI: 4.1-6.6) and 3.4 mo (95% CI: 2.4-4.2), respectively. Toxicity was generally acceptable. Median overall survival of patients with a CA 19-9 level declining by more than 20% was 10.3 mo (95% CI: 4.5-11.6) vs 5.2 mo (95% CI: 4.0-6.4) for others ( $P = 0.008$ ).

**CONCLUSION:** A large proportion of patients could benefit from second-line therapy, and CA 19-9 allows efficient treatment monitoring both in first and second-line chemotherapy.

### Abstract

**AIM:** To investigate second-line chemotherapy in gemcitabine-pretreated patients with advanced or metastatic pancreatic cancer [(frequency, response, outcome, course of carbohydrate antigen 19-9 (CA 19-9)].

**METHODS:** This retrospective study included all patients with advanced or metastatic pancreatic cancer (adenocarcinoma or carcinoma) treated with second-line chemotherapy in our center between 2000 and 2008. All patients received first-line chemotherapy with gemcitabine, and prior surgery or radiotherapy was permitted. We analyzed each chemotherapy protocol for second-line treatment, the number of cycles and the type of combination used. The primary endpoint was overall survival. Secondary endpoints included progression-free survival, response rate, grade 3-4 toxicity, dosage modifications and CA 19-9 course.

**RESULTS:** A total of eighty patients (38%) underwent

### INTRODUCTION

Pancreatic cancer is the tenth most common cause of cancer in the United States and the fourth leading cause

of cancer death, with an estimated 42 000 new cases and 35 000 associated deaths in 2009<sup>[1]</sup>. In France, over 7200 patients were diagnosed with a pancreatic cancer in 2008, and almost the same number died from their disease<sup>[2]</sup>. At the time of diagnosis, most of patients present with advanced or metastatic pancreatic cancer, thereby precluding surgical resection<sup>[3]</sup>. Gemcitabine has been considered as the standard treatment for advanced pancreatic cancer ever since a randomized trial demonstrated significant improvement in survival and clinical benefit over 5-FU<sup>[4]</sup>. However, its efficacy remains moderate with median overall survival (OS) times ranging from 5 to 8 mo, and one-year survival rates varying between 17% and 25%. Numerous studies have attempted to increase efficacy of chemotherapy by combining gemcitabine with other drugs, but most of the regimens evaluated in phase III trials failed to show any improvement in overall survival<sup>[5-18]</sup>. Only one randomized trial<sup>[6]</sup> ( $n = 569$  patients) comparing gemcitabine alone *vs* gemcitabine combined with erlotinib showed a modest but significant increase in OS in the erlotinib arm (6.2 mo *vs* 5.9 mo,  $P = 0.025$ ). Actually, the rate of patients receiving second-line chemotherapy varied from 16% to 57% in the trials evaluating a gemcitabine-based combination therapy<sup>[7-18]</sup>. This difference can be explained by both the deterioration in performance status after gemcitabine and the absence of recommended standard treatment in second-line<sup>[19]</sup>. Despite limited clinical data in this situation, a phase II trial comparing oxaliplatin/folinic acid/5-FU (OFF) combination *vs* best supportive care as second-line treatment in gemcitabine-pretreated patients with advanced pancreatic cancer showed substantial benefit in the chemotherapy arm, with an overall survival prolonged by 2.6 mo ( $P = 0.008$ )<sup>[20]</sup>.

Serum carbohydrate antigen 19-9 (CA 19-9), the sialylated Lewis blood group antigen defined by the monoclonal antibody 1116 NS 19-9<sup>[21]</sup>, is the most common tumor marker in Europe and in the United States for patients with pancreatic cancer, both as a prognostic factor and an early marker of response to treatment. To date, the reliability and prognostic value of CA 19-9 levels to monitor first-line chemotherapy of advanced pancreatic cancer patients is well established<sup>[3]</sup>.

In this context, this study aimed to describe the frequency of gemcitabine-pretreated patients with advanced or metastatic pancreatic cancer receiving second-line chemotherapy, their overall survival and progression-free survival. We also investigated response rates, outcome and potential correlations between the level and course of CA 19-9 and survival.

## MATERIALS AND METHODS

### Patients

This retrospective study included all adult patients with an advanced or metastatic histologically proven pancreatic cancer (adenocarcinoma or carcinoma) initially treated with gemcitabine in our center between 2000 and 2008. All patients received first-line chemotherapy with gemcitabine at a dose of 1000 mg/m<sup>2</sup> once weekly for 7 wk

followed by 1 wk of rest; thereafter, gemcitabine was given once weekly for 3 wk followed by 1 wk of rest until progression of disease. Prior surgery or radiotherapy for local disease was permitted. All patients' medical records were registered within a computerized database [following national registry council (CNIL) authorization]. While there was no standard treatment used in second line, the treatment decision regarding a second-line therapy was systematically made by a multidisciplinary oncology committee according to the performance status, age and comorbidities.

### Methods

We assessed each second-line chemotherapy protocol for the duration, the number of cycles and the type of drug combinations. The primary endpoint was OS. Secondary endpoints included progression-free survival (PFS), response rates, grade 3-4 toxicity, dosage modifications and CA 19-9 course. We stratified overall survival and progression-free survival according to the response to gemcitabine treatment (duration of treatment  $\geq$  or  $<$  4 mo) and the performance status (0-1 *vs* 2-3). Response rates and disease progression were evaluated after 2 mo of treatment by Response Evaluation Criteria in Solid Tumors<sup>[22]</sup> and clinical examination. Toxicity was assessed at every visit using the National Cancer Institute Common Toxicity Criteria v.2.0 (CTC AE v2.0). The CA 19-9 levels were determined from serum samples collected at baseline (maximum one month before starting treatment) and at final treatment evaluation. A value of 60 IU/mL was accepted as the upper limit of normal. A reduction in CA 19-9 level was considered as relevant when serum concentrations decreased by more than 20% after the completion of treatment.

### Statistical analysis

In this retrospective study, information relating to identification, treatment, available biological material, surgery, response to therapy and outcome were collected for each patient. The primary objective was to evaluate the efficacy of a variety of second-line regimens in a large series of advanced pancreatic adenocarcinoma after first-line treatment with a gemcitabine-based regimen. Categorical variables were reported by contingency tables. Continuous variables were expressed as medians and ranges. The objective response rate was presented with a 95% CI. Survival rates and median values were estimated according to the Kaplan-Meier method. Patients alive at the time of analysis were censored at their last follow-up examination. Overall survival duration was measured from the date of first infusion until death from any cause. Progression-free survival duration was calculated from the date of first infusion until the first disease progression. Survival curves were drawn, and the log rank test was performed to assess differences between groups. All reported  $P$  values are two-sided. For all statistical tests, differences were considered as significant at the 5% level. Statistical analyses were performed using the STATA 9.0 software.

**Table 1** Baseline patient characteristics in second line therapy

Clinical features	80 patients
Sex	
Male	38
Female	42
Median age (yr)	61.0
Histological diagnosis	67 (83.8)
OMS	
0	31 (38.7%)
1	40 (50.0%)

Gemcitabine	
Median number of cycle	3.0 (1.0-12.0)
Median duration (mo)	3.3 (0.5-18.9)
Duration ≥ 4 mo	29 (36.2%)
Metastatic disease	77 (96.3%)
Hepatic	70.1%
Peritoneal	29.9%
Nodal	23.4%
Pulmonary	16.9%
Carbohydrate antigen 19-9	
Initial median concentration (IU/mL)	741 (2.0-> 2000)
Elevated (> 60 IU/mL)	57 (89.1%)

Data are expressed as median values (range).

## RESULTS

### Patient characteristics

Baseline characteristics of the study population are detailed in Table 1. Of 206 patients receiving a first-line gemcitabine-based treatment for advanced or metastatic pancreatic cancer, 80 patients (38%) underwent a second-line therapy between January 2000 and May 2008. The median age was 61 years (range 36-81 years), and 38 patients were male (47.5%). The diagnosis of cancer was histologically confirmed in 67 patients (83.8%). Thirty-seven patients had undergone surgery including a pancreatoduodenectomy (*n* = 25) and palliative operation (*n* = 12) before first-line chemotherapy. Three other patients had received external radiation therapy. An endoscopic biliary prosthesis had been inserted prior to chemotherapy in eight patients. All patients received first-line chemotherapy with gemcitabine, with a median of 3 cycles (range: 1-12) and a median duration of 3.3 mo. Twenty-nine patients (36.2%) were treated for more than 4 mo. A total of 77 patients (96.3%) had evidence of metastatic disease, for most of them localized in the liver (70.1%). Despite the advanced stage of disease, patients generally showed good performance status before initiating second-line treatment, the WHO PS was of 0-1 in 71 patients (88.7%) and ≥ 2 in nine patients (11.3%).

From the CA 19-9 analyses performed in 64 patients, fifty-seven (89.1%) showed an elevated level, and initial median serum concentration was 741.5 IU/mL (range: 2-2000 IU/mL).

### Treatment

**Table 3** Chemotherapy regimens in second line

	Cisplatin group	Irinotecan group	Oxaliplatin group	Other group	<i>P</i> value
Number of patient	23 (28.8%)	22 (27.5%)	21 (26.3%)	14 (17.5%)	NS
Median number of cycle	5.0 (1.0-10.0)	5.0 (1.0-12.0)	4.0 (1.0-12.0)	2.0 (1.0-5.0)	NS
Median duration of treatment (mo)	2.7 (0.5-6.9)	3.2 (0.3-7.4)	2.3 (0.6-7.1)	2.3 (0.3-7.4)	NS
Disease control rate	10 (43.5%)	9 (40.9%)	9 (42.9%)	4 (28.6%)	NS
OS (mo)	6.7 (3.2-9.3)	4.5 (3.2-6.4)	4.5 (2.6-9.6)	5.2 (3.8-15.8)	NS
PFS (mo)	4.1 (1.9-6.7)	3.0 (2.0-6.1)	2.6 (1.8-5.4)	2.4 (2.1-10.1)	NS

OS: Overall survival; PFS: Progression-free survival; NS: Not significant.

was 4 (range: 1-12) and the median duration of treatment was 2.6 mo (range: 0.3-7.4).

All treatment regimens are described in Table 2. Different drug combinations were used in second-line. Twenty-three patients (28.8%) received a treatment with cisplatin (cisplatin group), 22 patients (27.5%) with irinotecan (irinotecan group) and 21 patients (26.3%) with oxaliplatin (oxaliplatin group). Fourteen patients (17.5%) were given other treatment, including a single agent for four of them. The duration of treatment did not significantly differ between groups (Table 3).

**Figure 1** Survival from the start of second-line therapy. A: Overall survival; B: Progression-free survival.

**Response and survival**

There was no complete response. Six patients (7.5%) achieved a partial response, 26 patients (32.5%) a disease stabilisation, 44 patients (55.0%) experienced disease progression and 4 patients could not be assessed. The overall disease control rate (complete response, plus partial response, plus stable disease) was 40.0% (median follow-up was 6.0 mo).

The median OS from the start of second-line therapy was 5.8 mo (95% CI: 4.1-6.6 mo). The 1-year and 2-year OS rates were 13.6% (95% CI: 6.9-22.7 mo) and 6.1% (95% CI: 2.0-13.5 mo), respectively (Figure 1A). The median PFS from the start of second-line therapy was 3.4 mo (95% CI: 2.4-4.2 mo). The one-year and two-year PFS rates were 6.0% (95% CI: 1.8-13.9 mo) and 4.0% (95% CI: 0.8-11.5 mo), respectively (Figure 1B). There was no significant difference between the four chemotherapy groups for overall disease control rates, overall survival and progression-free survival ( $P > 0.05$ ) (Table 3).

The median OS was 6.3 mo (95% CI: 4.3-7.2 mo) in patients with a performance status of 0-1 (71 patients) *vs* 1.8 mo (95% CI: 0.3-5.9 mo) in patients with a PS  $> 1$  (9 patients) ( $P < 0.001$ ). The one-year OS rates were 16.0% and 0%, respectively. The median PFS was 3.4 mo (95% CI: 2.6-4.9 mo) in patients with a performance status of 0-1 *vs* 2.1 mo (95% CI: 0.5-3.0 mo) in patients with a PS  $> 1$  ( $P = 0.004$ ). The one-year PFS rates were 7.0% and 0%, respectively.

The median OS times were 7.2 mo (95% CI: 4.5-10.5 mo) in patients treated for more than 4 mo with gem-

citabine as first-line therapy (29 patients) and 4.2 mo (95% CI: 3.2-5.9 mo) in those treated less than 4 mo (51 patients) ( $P = 0.046$ ). The one-year PFS rates were 10.0% and 4.0%, respectively.

**Toxicity and dosage modifications**

Toxicity was generally acceptable. The incidence of severe adverse events (grade 3-4) is reported on Table 4. Twenty-seven patients (33.7%) experienced at least one grade 3-4 toxic event. Neutropenia was the most frequent haematological toxicity, occurring in 14 patients (17.1%). There were 5 chemotherapy-related deaths. Two deaths were attributed to sepsis, and three to a combination of cancer and treatment-related complications. There was no difference in the incidence of toxicity and treatment-related deaths between the four chemotherapy groups (Table 5).

Forty-one patients (51.3%) had dosage modifications, including treatment suppression for 7 patients, dose reduction for 17 patients and cycle delay for 33 patients. Dose reductions were caused by haematological (9 patients, 53%) or clinical toxicities (8 patients, 47%) (Table 6). In thirty-one patients (41.3%), the chemotherapy was discontinued before evaluation because of disease progression (74.2%), toxicity (9.7%) or death (16.1%). There was no significant difference between groups for dose modification and chemotherapy discontinuation before evaluation.

**Carbohydrate antigen 19-9 measurement and survival**

Reduction in CA 19-9 levels during treatment was associated with improved survival. The median OS was significantly higher in patients whose level of CA 19-9 declined by more than 20% when compared to other patients 10.3 mo (95% CI: 4.5-11.6) *vs* 5.2 mo (95% CI: 4.0-6.4) ( $P = 0.008$ ) (Figure 2A). In this subgroup of patients, the median PFS was 6.7 mo (95% CI: 3.3-8.8 mo) *vs* 3.4 mo (95% CI: 2.6-4.2 mo) ( $P = 0.031$ ) (Figure 2B). All patients who experienced a CA 19-9 reduction  $> 20\%$  achieved disease control (3 partial responses and 5 cases of stable disease).

**DISCUSSION**

If gemcitabine-based chemotherapy is the current standard of care for first-line treatment of advanced pancreatic cancer, there are limited data to support a standard second-line chemotherapy regimen<sup>[23]</sup>. Indeed, the true survival benefit from first-line therapy is small, and few patients can endure a second line as their performance status deteriorates with disease progression. In our study, the rate of patients treated with second-line chemotherapy was 38.8%, in accordance with most published data regarding gemcitabine-pretreated pancreatic cancer (16%-57%). Median overall survival from the start of second-line setting was 5.8 mo (4.1-6.6 mo), and median progression-free survival was 3.4 mo (2.4-4.2 mo). These results are similar to those obtained in first-line with gemcitabine by Burris *et al*<sup>[4]</sup> or Heinemann *et al*<sup>[1]</sup>.

Neutropenia	6 (27.3)	6 (33.4)	2 (9.5)	0	NS
Thrombocytopenia	1 (4.5)	0	0	0	NS

NS: Not significant.

Table 6 Dose reduction <i>n</i> (%)	
Dose reduction	Patients
Neutropenia grade 2 or 3-4	5 (6.2)
Thrombocytopenia grade 2	4 (5.0)
Hand-foot skin reaction grade 2	5 (6.2)
Neuropathy grade 2	2 (2.4)
Diarrhea grade 3-4	1 (1.2)

Moreover, patients with good performance status (0-1) and who had benefited from gemcitabine chemotherapy in first line (duration of treatment  $\geq$  4 mo) had a significantly greater duration of overall survival than those who had not (6.3 mo *vs* 1.8 mo,  $P < 0.001$ ; and 7.2 mo *vs* 4.2 mo,  $P = 0.046$ , respectively). The rate of grade 3-4 toxicity was determined to be 33.7% (27 patients), but there were no unexpected side effects. Consequently, our experience demonstrates that a selected population of

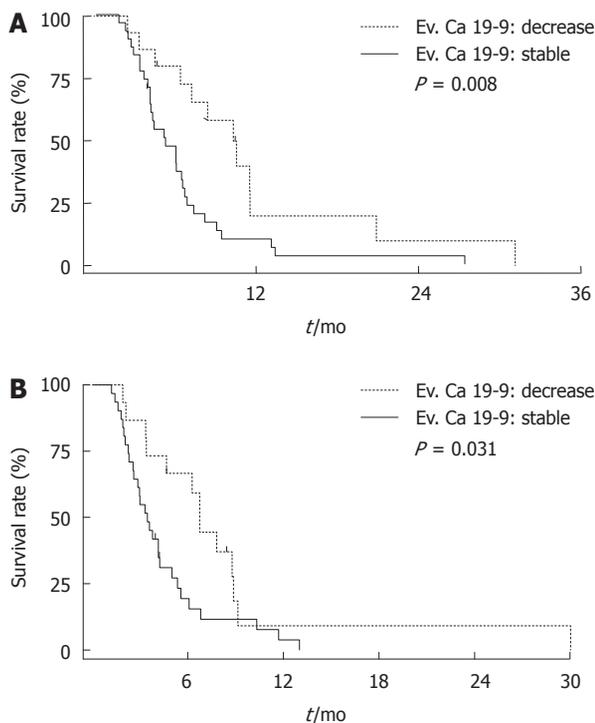

Figure 2 Overall survival and carbohydrate antigen 19-9 evolution in second line. A: Overall survival; B: Progression-free survival. Ev. Ca 19-9: Course of carbohydrate antigen 19-9.

patients with good performance status can benefit from second-line chemotherapy after first-line gemcitabine-based treatment, with appreciable overall and progression-free survivals. This retrospective study included a large population, while most of data published over the last ten years involved relatively small samples in monotherapy (from 13 to 52 patients) as well as in bithery (from 12 to 46 patients)<sup>[24]</sup>. The disease control rate was 40%, as described by many authors for both monotherapy and bithery regimens, and median overall and progression-free survivals were superior to those reported in monotherapy studies, but were not different from bithery<sup>[24]</sup>.

In daily practice, second-line therapies are regularly used in gemcitabine-pretreated patients with pancreatic carcinomas, but the efficacy and benefit in terms of survival or quality of life have never been validated. A randomized phase III trial conducted in second line was presented by Pelzer *et al*<sup>[25]</sup>. One hundred and sixty-five gemcitabine-pretreated patients with pancreatic cancer were randomly assigned to receive either FF (5-FU 2 g/m<sup>2</sup> for 24 h plus folinic acid or leucovorin 200 mg/m<sup>2</sup> on days 1, 8, 15 and 22) or OFF (FF plus oxaliplatin 85 mg/m<sup>2</sup> on days 8 and 22). Median overall survival and progression-free survival were significantly improved with OFF protocol (20 wk *vs* 13 wk,  $P = 0.014$ ; and 13 wk *vs* 9 wk,  $P = 0.012$ , respectively), with an acceptable tolerance profile. This study illustrated the effectiveness of this protocol which may become the standard second-line therapy. Currently, the National Comprehensive Cancer Center pancreatic cancer guidelines encourage the participation of patients with satisfactory performance status in

clinical trials, and recommend the use of oxaliplatin and fluoropyrimidine if enrolment in trials is not possible<sup>[26,27]</sup>. Finally, the XELOX regimen<sup>[28]</sup> showed comparable efficacy to FOLFOX (or OFF) regimen, while offering the advantage of oral fluoropyrimidine treatment. Even so, more large randomized controlled trials are required in second line before a new standard of care can be established.

Interestingly, the CA 19-9 measurement was correlated with OS and PFS in our study. Patients whose level of CA 19-9 declined by more than 20% had a significantly greater duration of survival. The prognostic value of CA 19-9 level and course is well established for patients with pancreatic cancer treated with surgery<sup>[29-31]</sup>, radiotherapy and chemoradiotherapy<sup>[32,33]</sup>. Some studies also correlated the level and the course of CA 19-9 with OS and PFS of pancreatic cancer patients treated with gemcitabine as first-line chemotherapy<sup>[3,34-36]</sup>. These studies showed improved median OS for patients with a decrease of CA 19-9 > 20% after two months of treatment with gemcitabine. Saad *et al.*<sup>[37]</sup> reported an increase in the median OS for patients with a reduction of CA 19-9 at any time after treatment. In second-line, only one study demonstrated that a CA 19-9 value > 400 IU/mL was a significant independently negative prognostic factor<sup>[38]</sup>. To our knowledge, it was the second report which showed a correlation between OS and CA 19-9 course<sup>[39]</sup>, and the first report for PFS and CA 19-9 course in second-line chemotherapy for gemcitabine-pretreated patients with pancreatic cancer.

In summary, treatment of metastatic pancreatic cancer remains a major challenge and requires new chemotherapeutic and targeted agent combination to be compared to gemcitabine in first-line. It should be noted that a new therapeutic alternative could merge in first-line for selected patients according to the recent results obtained in a randomized Phase III study comparing FOLFIRINOX regimen to gemcitabine<sup>[40]</sup>. A significant longer overall survival, progression-free survival, and higher response rates were obtained with FOLFIRINOX than with gemcitabine alone, associated with manageable toxicities.

The present study focused on second-line therapy in gemcitabine-pretreated patients with advanced pancreatic cancer. From our experience, second-line chemotherapy is a valuable treatment option after progression on gemcitabine-based regimen, because 30% to 40% of patients could benefit from this therapy, especially those with good performance status (1-2) and who gained benefit from first-line therapy. Further randomized clinical trials are necessary to provide a standard treatment in this situation. Additionally, measurement of the CA 19-9 level was confirmed to be an efficient marker for treatment monitoring in first-line as well as in second-line treatment.

## COMMENTS

### Background

Most of patients have advanced or metastatic pancreatic cancer at the time of

diagnosis, and cannot benefit from surgery. Gemcitabine-based chemotherapy is the standard treatment in first-line, but there are limited data to support standard second-line chemotherapy.

### Research frontiers

In practice, second-line therapies are regularly used in gemcitabine-pretreated pancreatic carcinomas, but the efficacy and benefit in terms of survival or quality of life have never been validated. Most of published studies in second line involved small samples, in monotherapy as well as in bitherapy.

### Innovations and breakthroughs

In our study, the rate of patients treated with second-line chemotherapy was 38.8%, and median overall and progression-free survivals from the start of second-line were similar to those obtained in first-line with gemcitabine. Carbohydrate antigen 19-9 (CA 19-9) course was correlated with prolonged overall and progression-free survival.

### Applications

Second-line chemotherapy is a valuable treatment option after progression on gemcitabine-based regimen, because 30% to 40% of patients could benefit from this therapy. Measurement of the CA 19-9 level was confirmed to be an efficient marker for treatment monitoring, in first-line as well as in second-line treatment.

### Peer review

The study is very interesting because there is no consensus about second-line therapy after disease progression while patients are receiving gemcitabine. The paper is well written. However, the authors should revise several points in the entire text.

**METHODS:** One hundred and fifty three patients with a clinical and ultrasonographic diagnosis of gallstones filled out a structured questionnaire on abdominal pain symptoms and functional gastrointestinal disorder (FGID) before and at six months after cholecystectomy. Symptom frequency groups (SFG) were categorized according to frequency of pain attacks. According to certain pain characteristics in gallstone patients, a gallstone symptom score was accorded on a scale from one to ten. A visual analogue scale was used to quantify pain. Operative specimens were examined for size and magnitude of stone contents as well as presence of bacteria. Follow-up took place after six months with either a consultation or via a mailed questionnaire. Results were compared with those obtained pre-operatively to describe and analyze symptomatic outcome.

**RESULTS:** SFG groups were categorized as severe (24.2%), moderate (38.6%), and mild (22.2%) attack frequency, and a chronic pain condition (15%). Pain was cured or improved in about 90% of patients and two-thirds of patients obtained complete symptom relief. Patients with the most frequent pain episodes were less likely to obtain symptom relief. FGID was present in 88% of patients pre-operatively and in 57% post-operatively ( $P = 0.244$ ). Those that became asymptomatic or improved with regard to pain also had most relief from FGID ( $P = 0.001$ ). No pre-operative FGID meant almost complete cure.

**CONCLUSION:** Only one third of patients with FGID experienced postoperative relief, indicating that FGID was a dominant cause of post-cholecystectomy symptoms.

## INTRODUCTION

It is commonly accepted that removal of the gallbladder is the best treatment for symptomatic gallstone disease. However, less focus has been on patient selection and typical or common symptoms of this disease in order to understand prevailing symptoms after surgery<sup>[1-4]</sup>. Although disease severity has been used<sup>[5-7]</sup>, these efforts have not been united into useful and widely accepted working terms for preoperative clinical use and outcome assessment. As a consequence, the indication for cholecystectomy is sometimes vague and assessment of outcome suffers accordingly<sup>[8]</sup>.

Pain is a key element in gallstone symptoms but pain is a general symptom. Therefore pain characteristics and additional symptoms reported in classical descriptions of the disease has expanded the interpretation<sup>[9-11]</sup>. Functional gastrointestinal disorder (FGID) is quite common in the population and the two diseases often appear together<sup>[12]</sup>. FGID may go away or appear more distinct to the patient after cholecystectomy and thus distort the sense of postoperative relief. Up to 30% of patients have some symptoms following cholecystectomy<sup>[13,14]</sup>. No consistent physiological substrate for such pain has been documented<sup>[2]</sup>. It is somewhat unclear to what degree post-cholecystectomy symptoms resemble the exact symptoms before removal of the gallbladder<sup>[13]</sup>. Most studies are retrospective with follow-up periods commonly ranging from a few weeks to a couple of years<sup>[6,14,15]</sup>. A recent, prospective study lacked clinically useful working terms with a mixture of both pain associated symptoms and FGID<sup>[3]</sup>.

Our aim was to categorize gallstone disease according to the severity of clinical symptoms, pain characteristics, and quantify FGID to define postoperative outcome in terms of new or persistent symptoms.

## MATERIALS AND METHODS

One hundred and fifty-three patients with an ultrasonographic diagnosis of gallstones admitted for elective laparoscopic treatment of symptomatic, uncomplicated gallstone disease in a Norwegian ( $n = 100$ ) and a US ( $n = 53$ ) institution.

### Questionnaire

The patients filled out a structured questionnaire on pain

characteristics and functional abdominal symptoms before and at six months after surgery. The questionnaire was assembled after a large experience with pre-operative interviews in two randomized trials and modeled as a simplified version of the Rome II questionnaire<sup>[16,17]</sup>. Symptoms were classified according to appearance ranging from never to almost always in four steps: never, occasionally, very often, and almost always. Only those symptoms that were present more than 50% of the time (i.e. the last two) was counted as a positive answer (Table 1).

Follow-up was conducted at the outpatient clinic for all Norwegian patients at six months at which time the questionnaire was filled out. The American patients were mailed the questionnaire for logistic reasons.

Gallstone pain attacks were categorized as symptom frequency groups (SFG) according to the frequency experienced during the last three months. Patients that were unable to define exact time periods for pain attacks or had a dominant pattern of ubiquitous pain or had symptoms dominated by severe nausea or food intolerance were classified as a chronic symptom group.

A visual analogue scale score (VAS) was used to quantify the severity of pain in the symptom questionnaire. A 100 mm long horizontal line was to be marked vertically at the point consistent with the pain experienced by the patient. The left end was marked "No pain" and the right end "Unbearable pain".

### Gallstone symptom score

According to certain pain characteristics in gallstone patients, a Gallstone symptom score (GSS) was accorded from 1 to 10 (Tables 2 and 3).

In our practice, patients were found to have symptomatic, uncomplicated gallstone disease if ultrasonography detected gallbladder stones and the patients had relevant clinical symptoms. Endoscopy was neither a routine part of the pre-operative work-up nor planned as a diagnostic aid in case of persistent symptoms.

### Pathology

Operative specimens were prepared for examination of bacterial contents, stone size and routine histology on the back table immediately after the operation finished.

Bile was aspirated with a syringe from the gallbladder and sent for culture together with a piece of the wall. Stone size was measured with a caliper after the gallbladder had been opened on the back table. Finally the specimen was put on formalin and sent to the pathologist for routine (hematoxylin and eosin) staining and histological assessment.

### Ethics

The Regional Ethical Committee of Western Norway and The National Data Inspectorate approved the study. The Institutional Review Board (IRB) of Cleveland Clinic approved the study (IRB 7000/04). The study was registered with [clinicaltrials.gov](http://clinicaltrials.gov) as part of NCT01190280.

Difficulty swallowing, food sticking in the lower esophagus
Nausea
Loss of appetite (anorexia)
Feeling full after eating very little (early satiety)
Feeling of abdominal fullness or bloating
Abdominal distension, which requires loosening of the belt
Frequent loose bowel movements (or more often than usual)
Constipation (or less bowel movements than usual)
Alternating constipation and loose bowel movements
Difficulty passing stools with straining, urgency or feeling of incomplete evacuation
Abdominal pain or discomfort is relieved by bowel movements (passing of stool)

Rate the frequency of the following symptoms associated with abdominal pain during the last 3 mo or longer, using the following scale: 0: Not at all or rarely (less than 10% of the episodes); 1: Occasionally (less than 50% of the episodes); 2: Very often (more than 50% of the episodes); 3: Almost always (more than 80% of the episodes).

### Statistical analysis

The  $\chi^2$  test was used to compare the level of improvement between groups, and to compare the presence of FGID between patients with different symptom alleviation before and after operation. Logistic regression for dependent paired data was used to analyze the difference in FGID before and after surgery between different GSS-groups. The statistical software used was PASW Statistics version 18.0 and Intercooled Stata 9.2 for Macintosh.

## RESULTS

The patient demographics are shown in Table 4.

### Symptom frequency groups and visual analogue scale score

Four SFG were categorized according to frequency of pain attacks: severe (24.2%):  $\geq 1$  pain attack per week, moderate (38.6%):  $\leq 3$  pain attacks per month, mild (22.2% of the patients):  $\leq 2$  pain attacks per 3 months, or chronic pain condition (15%): no discernable pain attack pattern.

The VAS was equally distributed between all patients, mean VAS preoperatively was 82.8 with variation from 17 to 100 (Table 5).

### Gallstone symptom score

Mean preoperative GSS in pair-wise comparisons showed a significant difference preoperative between chronic and moderate disease patients ( $P = 0.022$ ). There was a non-significant trend towards a greater rate of cure or symptom relief measured with GSS among patients with less severe disease ( $P = 0.651$ ). Patients in the most severe SFG had the highest GSS and experienced more remaining symptoms, for details see Tables 5 and 6.

**Table 2** Assessment of pain symptoms

Had an abdominal pain attack at least once for the last 3 mo or longer?
Experienced either pain or discomfort in the abdomen of a continuous steady nature at least once per week for the last 3 mo or longer?
For women: Did the onset of pain begin during pregnancy or soon after pregnancy?
Evaluated in the Emergency Department or seek medical attention for the abdominal pain?
Admitted to the hospital for the abdominal pain?
Estimate how often pain medications are required for the pain:
Not at all or rarely (less than 10% of the episodes)
Occasionally (less than 50% of the episodes)
Very often (more than 50% of the episodes)
Almost always (more than 80% of the episodes)
Time-interval during which the pain most often occurs:
7 am - 12 pm
12 pm - 6 pm
6 pm - 11 pm
11 pm - 7 am
Highly variable and unable to predict time of onset
Rate how often the pain occurs in the following abdominal areas:
Right upper quadrant <sup>1</sup>
Left upper quadrant <sup>1</sup>
Right lower quadrant <sup>1</sup>
Left lower quadrant <sup>1</sup>
Midline or center of the upper abdomen <sup>1</sup>
Is there often an area where the pain is strongest (able to point with one or two fingers):
Right upper quadrant
Left upper quadrant
Right lower quadrant
Left lower quadrant
Midline or center of the upper abdomen
Highly variable and unable to predict one area
No
Experience discomfort in the right upper quadrant when bending forward?
Abdominal pain radiates from where it started?
If yes, where does it radiate most often?
Right upper back beneath the right shoulder blade
Upper back between the shoulder blades
Lower back
None of these places mentioned
Highly variable and unable to predict a dominant area
Estimate the number of pain attacks over the last 3 mo
Estimate the usual duration of a pain attack in hours and minutes
Experience urge to move around during a pain attack <sup>1</sup>
Choose one of four patterns describing pain attacks (depicted by graphs):
Low-grade warning pain followed by a steady rise to a maximal constant pain, gradually getting better after a while
Low-grade warning pain followed by a steady rise to a maximal degree with occasional waves of pain, gradually getting better after a while
Pain begins suddenly with maximal intensity and improves over time
Pain begins suddenly with maximal intensity and persists with waves of pain until it goes away
Rate level of maximal pain intensity by 100 mm visual analogue scale score-scale

Pain attacks are defined as suddenly appearing pain that is distinct from, and stronger than any continuous, steady pain or discomfort. <sup>1</sup>The pain occurrence in each area is rated as: not at all or rarely (less than 10% of the episodes), occasionally (less than 50% of the episodes), very often (more than 50% of the episodes) or almost always (more than 80% of the episodes).

### Functional gastrointestinal disorder symptoms

A FGID was present in 87.6% before surgery and in 57.6%

**Table 3** Assignment of a clinical gallstone symptom score to different preoperative symptom frequency groups (%)

Symptom	Score	Percent of patients with symptoms according to pain presentation			
		Severe	Moderate	Mild	Chronic
Pain in upper abdomen: Pain most common in right upper quadrant or intensifies when bending forward or lying on the right side	2	100	96.6	94.1	88.2
Pain attacks commonly last more than one hour	1	73.0	66.7	76.5	46.2
Pain in a "plateau fashion"	1	62.2	72.9	67.6	64.3
Urge to move during pain attacks	1	51.4	69.0	58.8	84.6
Pain commonly occurs at night	1	43.2	61.0	50.0	29.4
Pain radiation to the back	1	40.5	47.5	38.2	58.8
Nausea during pain attacks	1	61.1	48.3	52.9	50.0
Use of analgesics in > 50% of pain attacks	1	54.0	54.3	44.1	41.2
Perspiration during pain attacks	1	36.1	41.4	41.2	60.0

**Table 4** Demographics of the study population of 153 patients and 115 follow-up responders *n* (%), mean age (range, yr)

Symptom frequency group	Females	Males	Total
All groups	122 (79.7), 47 (17-81)	31 (20.3), 51 (28-85)	153 (100), 48 (17-85)
Severe disease	31, 45 (17-81)	6, 44 (25-64)	37 (24.2), 45 (17-81)
Moderate disease	47, 44 (20-72)	12, 53 (39-70)	59 (38.6), 46 (20-72)
Mild disease	26, 53 (25-78)	8, 52 (34-85)	34 (22.2), 53 (25-85)
Chronic disease	18, 53 (23-81)	5, 55 (30-80)	23 (15.0), 54 (23-81)
Responders to follow-up	89 (77.4), 49 (20-81)	26 (22.6), 52 (25-85)	115 (75.2), 50 (20-85)

$\chi^2$  for gender;  $P = 0.889$ .

**Table 5** Changes in gallstone severity score by symptom frequency group in 115 responding patients from the study population of 153 patients *n* (%)

Preoperative SFG	Patients	Preoperative		Responders	Postoperative		mean % reduction in GSS
		mean GSS	mean VAS		mean GSS	mean VAS	
Severe disease	37 (24.2)	6.11	81.1	29 (78.4)	1.76	33.0	69.1
Moderate disease	59 (38.6)	6.47	86.6	41 (69.5)	1.32	15.8	78.7
Mild disease	34 (22.2)	6.09	81.3	26 (76.5)	1.04	12.8	87.0
Chronic disease	23 (15.0)	4.35	76.8	19 (82.6)	1.00	8.9	62.7

SFG: Symptom frequency groups; GSS: Gallstone symptom score; VAS: Visual analogue scale score.

at follow-up after surgery. No difference was seen between the different SFG ( $P = 0.244$ ). There was a trend that patients with FGID before surgery were less likely to experience improvement of their pain or complete relief. Likewise, patients without FGID after surgery were more likely to report improvement or complete relief of pain (Table 7).

#### Gallbladder specimen examination

Histology of the gallbladder showed that 85% had chronic and 10% subacute inflammation while 5% were normal. Bacteriological examination in 79 patients discovered bacteria in 12 (15.2%) without difference between the groups. The distribution of bacteria was: gram-negatives 3.8%, gram-positive cocci 8.9%, and mixed cultures 2.5%. Stone type was not examined.

The number of stones was measured in 66 patients and size in 64 patients. The mean number was 2.5 (range 1-9) with variation between SFG from 2.3 to 2.8. The

stone size was mean 13 mm (range 1-40) with variation between groups from 12.5 to 13.2 mm. There were no statistically significant differences between the groups.

## DISCUSSION

Gallstone symptoms are still classified simply as biliary colic long after a variety of pain characteristics have been described for these pain attacks<sup>[9,10]</sup>. Thus, studies of outcome of gallstone disease are usually hampered by lack of scientifically acceptable definitions and designs<sup>[3,5,6,16]</sup>. This includes an inadequate definition of gallstone symptoms, lack of proper recognition of FGID as a concomitant complaint, prospective design and defined follow-up methods. Freedom of pain attacks is a major outcome measure after cholecystectomy. Complete cure of a biliary type pain in contrast to a persisting dull aching pain, has been reported as a reasonable goal for surgery<sup>[18]</sup>. Previous studies have reported that so-called

biliary colic remained in only 8%-9% of patients in contrast to non-colicky pain in 18%-32%<sup>[13,19]</sup>. Others have found an incidence of around 20% of persistent pain of the same character as before the operation<sup>[20,21]</sup>. Lublin and coworkers<sup>[6]</sup> reported presence of pain in 25% and non-pain symptoms in 43%. It seems that distinct or marked pain is present in up to 4%-9%<sup>[12,13]</sup> whereas pain or "discomfort" connected with dyspeptic symptoms are not clearly categorized<sup>[22]</sup>. Around 25% of our patients improved without being completely cured after removal of the gallbladder. This corresponds to previous figures of 18%<sup>[13]</sup> and the frequency of more diffuse intestinal symptoms found by others during post-operative examination<sup>[12]</sup>. One author mentioned similar findings without giving figures but did not find interference with quality of life measurements<sup>[23]</sup>. Up to 93% satisfaction has been reported after removal of the gallbladder<sup>[13,15,22,24,25]</sup>.

FGID consists of two main subgroups, functional dyspepsia and irritable bowel syndrome (IBS), with overlapping features making them both symptomatic of an irritable or dysfunctional gut<sup>[26,27]</sup>. The criteria in the Rome II and the more recent Rome III questionnaire give a formal definition of FGID<sup>[17,28]</sup>. In the West, there tends to be a female predominance. FGID appears as a real condition of gallstone disease<sup>[3,12,22,29]</sup>. The pathological connection is still obscure but a common dysfunctional trait has been shown<sup>[30]</sup>. A diagnostic problem arises only when gallstone disease becomes vague with regard to pain expression<sup>[3,5,22]</sup>. Lublin and coworkers<sup>[6]</sup> reported that 80% of patients had so-called non-pain symptoms pre-opera-

tively in accordance with an 88% incidence of FGID in our patients. In our practices, nearly all gallstone patients coming to surgery have upper abdominal pain either in the right upper quadrant or epigastrium although a small percentage has intolerable nausea or food intolerance that dominates over pain. FGID was therefore judged a concomitant condition in most cases. Our outcomes are quite similar to those of others who have attempted to classify pre-operative symptoms<sup>[5,6]</sup>. It could be perceived that freedom of pain with an attack pattern was the decisive factor when cure or relief was achieved, whereas FGID of various intensities caused the bulk of the persistent symptoms, because FGID persisted in 57% of the patients. The post-operative GSS and VAS were markedly decreased and it is therefore likely that the patients were cured of the pain attacks that led to cholecystectomy. Besides, even so-called biliary colic, even if it resembles pre-operative symptoms, needs a substrate when the gallbladder has been removed. It has not been proved that this stems from the common bile duct (CBD) or the sphincter of Oddi, even though symptoms caused by CBD disease, such as a stone, may be quite similar. Therefore, we will argue that there is reasonable evidence pointing to FGID as a cause of persisting symptoms after surgery.

Some investigators have reported that patients with the most severe, frequent or bothersome pre-operative symptoms are less likely to be cured<sup>[5,6,13,22]</sup>. The present study corroborated this as results showed that only frequency of pain attacks expressed as SFG separated the patients with regard to severity in the pre-operative evalu-

ation. GSS only separated the pain attack groups against the chronic group. This is broadly correlated with a Swedish study but differed insofar that we amalgamated what were their two most severe groups into one<sup>[5]</sup>. Lublin and coworkers<sup>[6]</sup> used frequency without a more specific definition. The disease may wax and wane and this may influence the response to the questionnaire<sup>[5,5]</sup>. A minority of 15% had chronic symptoms with daily occurrence as the rule. We suspect that some of the patients with daily symptoms reported by Halldestam and coworkers<sup>[5]</sup> might have been classified as a chronic symptom group by our definition. This would distort comparison of outcome because these two groups responded differently to operative treatment in our study. It is also difficult to ascertain the meaning of “atypical” or multiple locations of pain<sup>[5]</sup>. Pain in the right upper quadrant or epigastrium is a core issue in the diagnosis of gallstone disease but admittedly in a small minority of patients other symptoms dominate. However, as long as these symptoms can be assigned to gallstone disease, they are not a contraindication to surgery in such cases.

Although patients with the highest pre-operative mean GSS had the largest relative score reduction, this group retained a higher post-operative score and had the highest VAS score. The reason for that was largely assumed as being caused by persistent symptoms of FGID even though this could not be established with certainty because of overlapping symptoms in gallstone patients. It was, however, consistent with the observation that the severe SFG had more patients with no relief and also had a slightly larger GSS burden and consequently higher post-operative GSS and VAS score, indicating that a larger disease burden or more symptoms was in concert with a higher VAS. This may be interpreted as more persistent pain. One study found that patients with the most bothersome symptoms before surgery had less chance of cure<sup>[22]</sup>. The highest odds ratio for persistence was obtained by “gas/flatulence”, a common symptom of IBS or FGID. This could easily be interpreted as caused by FGID but it has been unusual to explicitly label post-cholecystectomy symptoms as FGID even though many symptoms fit this diagnosis<sup>[22]</sup>. One explanation may be that these symptoms has for too long been discerned as part of a wider range of gallstone symptoms while we will argue that they are two concomitant disease expressions with many overlapping features making it difficult to separate them.

Compared with measurements before surgery VAS has reached levels of around 68 (of 100) pre-operatively to levels of 35 to 45 post-operatively<sup>[13,15,19,21]</sup>. In the present study, VAS was similar across all four GSS groups and it fell after surgery to a mean of 18 (range 9 to 33). Therefore, it could not by itself be used to distinguish between the patients before or after surgery. Our post-operative median score value indicates no more than mild to moderate pain<sup>[31]</sup>.

Theoretically, a bile duct focus might cause pain quite similar to that originating in the gallbladder but only

about 2% has common bile duct stones after removal of the gallbladder<sup>[6,13]</sup>. Psychometric testing has shown that a psychosomatic disturbance may influence outcome after cholecystectomy<sup>[8,32]</sup>. It has been observed that women tend to have more postoperative pain<sup>[33]</sup> while some have reported that gender is irrelevant<sup>[15,20,34]</sup>. Women under the age of 60-years have been found to have significantly more pain of the diffuse, more continuous type that is also described in functional dyspepsia, and satisfaction has been greater for men<sup>[15]</sup>. We found that women were less likely to become asymptomatic. Age of the patient has not influenced outcome<sup>[20,34]</sup>, whereas the opposite was found when 50 or 55-years-of-age was used as cut off value<sup>[4,22]</sup>. In contrast to previous studies, patients more than 60-years-of-age fared slightly worse in the present study<sup>[5,13]</sup>. Stone size and number, bacteriology, or histology<sup>[2]</sup> did not impact the symptom presentation in this study.

We recommend a follow-up period of 6 mo before assessing outcome after cholecystectomy<sup>[8,22]</sup>. Whether qualified personnel should interview a study object or a questionnaire be used, remains open for discussion<sup>[8,16,22,29]</sup>. It may be a point of concern whether a self-assessment questionnaire will make the patient report more complaints than will be revealed by a professional interview<sup>[35]</sup>.

Approximately 10% of patients did not improve or even got worse whereas the condition of 25% improved and the rest was cured. Patients with the most SFG were less likely to be completely cured and this group also had a higher pre-operative symptom score (GSS). Post-operative FGID persisted in 57% of patients and indirect evidence suggests that persistent symptoms were caused mainly by FGID. The main indication for elective cholecystectomy in uncomplicated gallstone disease should be pain attacks. Patients should be informed about the chance of persistent symptoms.

## COMMENTS

### Background

Patients with gallstones often have various abdominal symptoms that may be caused by the gallstones or are present as a separate condition but with a common physiology. The accompanying abdominal symptoms are called functional gastrointestinal disorders (FGID). Because of its common nature and presence of pain or discomfort it is difficult to separate a functional condition from the gallstone disease itself. Lack of a clear distinction between the two and a poor understanding of the physiology that causes both conditions, especially FGID, makes it difficult to treat these symptoms if they remain after the operation. The article characterizes symptoms caused by gallstone disease in order to define which symptoms remain after removal of the gallbladder. Hope of improving understanding of their character and origin will subsequently have a potential bearing on treatment.

### Research frontiers

Current treatment methods may not be satisfactory due to limited insight in physiological mechanisms. Therefore, FGID causes a major health problem with a large amount of sick-leave days. Because of this burden on both patient and society it is important to conduct proper research to gain insight in disease mechanisms and offer effective treatment.

### Innovations and breakthroughs

The study tried to characterize gallstone disease according to intensity and frequency of pain attacks as well as concomitant functional symptoms. The pre-

operative condition has then been compared to persisting symptoms after surgery. Such methodical studies of the character of gallstone disease are scarce.

### Applications

An understanding of disease expression may give better insight into why complete symptom relief does not occur in some patients after cholecystectomy. Thus, it may be possible in the future to decide which patients will have the greatest chance of cure as well as offer efficient treatment of persisting symptoms after cholecystectomy.

### Terminology

Gallstone disease is characterized by bouts of pain or pain attacks in about 85% of patients. The rest have a combination of more consistent pain, strong food intolerance or nausea. FGID is present in about 88% of gallstone patients. This condition may have particular symptoms but a clear-cut physiologic mechanism or organic origin has not been decisively described for it. The diagnosis is sometimes made by exclusion of other diseases. It is difficult to separate clinically from gallstone disease when both are present in the same patient.

### Peer review

The authors have nicely analyzed the existing preoperative functional disorder in patients of gallstones to substantiate its correlation with post-operative symptoms.

### Abstract

**AIM:** To evaluate the usefulness of the microcatheter techniques in balloon-occluded retrograde transvenous obliteration (BRTO) of gastric varices.

**METHODS:** Fifty-six patients with gastric varices underwent BRTOs using microcatheters. A balloon catheter was inserted into gastrosplenic or gastrocaval shunts. A microcatheter was navigated close to the varices, and sclerosant was injected into the varices through the microcatheter during balloon occlusion. The next morning, thrombosis of the varices was evaluated by contrast enhanced computed tomography (CE-CT). In patients with incomplete thrombosis of the varices, a second BRTO was performed the following day. Patients were followed up with CE-CT and endoscopy.

**RESULTS:** In all 56 patients, sclerosant was selectively injected through the microcatheter close to the varices. In 9 patients, microcoil embolization of collateral veins

was performed using a microcatheter. In 12 patients with incomplete thrombosis of the varices, additional injection of sclerosant was performed through the microcatheter that remained inserted overnight. Complete thrombosis of the varices was achieved in 51 of 56 patients, and the remaining 5 patients showed incomplete thrombosis of the varices. No recurrence of the varices was found in the successful 51 patients after a median follow up time of 10.5 mo. We experienced one case of liver necrosis, and the other complications were transient.

**CONCLUSION:** The microcatheter techniques are very effective methods for achieving a higher success rate of BRTO procedures.

### INTRODUCTION

Balloon-occluded retrograde transvenous obliteration (BRTO) is a treatment for gastric varices that has a high success rate<sup>[1-5]</sup>. However, there are three major problems with BRTO procedures such as overdose of the sclerosant,

leakage of the sclerosant into the systemic circulation, and incomplete thrombosis of large gastric varices<sup>[6-10]</sup>. We introduced the microcatheter techniques<sup>[11-13]</sup> in 1999 to solve these problems, and we have been using three major beneficial techniques for BRTO procedures such as selective injection of the sclerosant, microcoil embolization of collateral veins and additional injection of the sclerosant. Since 1999 we have collected a great deal of data and are now able to accurately report on the long-term results of these techniques in a large number of cases.

## MATERIALS AND METHODS

BRTO using 2.9Fr microcatheters was performed in 56 patients with liver cirrhosis-related gastric varices between August 1999 and December 2008. The subjects consisted of 35 males and 21 females, with a mean age of 65.3 years (range: 33-83 years). Liver cirrhosis was associated with hepatitis B in 3 patients, hepatitis C in 29 patients, alcohol in 15 patients, and unknown factors in 9 patients. According to the Child-Pugh classification, liver function was evaluated as A in 19 patients, B in 31 patients, and C in 6 patients. Prophylactic BRTO was performed in 31 patients with large tumor-like gastric varices or growing varices in danger of rupture. Elective BRTO was performed in 12 patients with a history of hemorrhage related to gastric varices. Emergency BRTO<sup>[16,17]</sup> was performed in 13 patients within 24 h after hematemesis or tarry stool. Informed consent for BRTO was obtained from all patients.

Gastric varices were confirmed by endoscopy. The presence and diameter of gastroduodenal shunt or gastrocaval shunt were evaluated by contrast enhanced computed tomography (CE-CT). An 8Fr sheath (Cobra type; Medikit, Tokyo, Japan) was inserted into the left renal vein or inferior vena cava through the right internal jugular vein or right femoral vein, and a 6Fr balloon catheter (Cobra type; Clinical Supply, Gifu, Japan) was inserted into the gastroduodenal shunt or gastrocaval shunt. The balloon diameter was 13 or 20 mm. In patients with a shunt diameter of 13 mm or more, a balloon measuring 20 mm in diameter was used. A 2.9Fr microcatheter was navigated close to the gastric varices. A sclerosant, 5% ethanolamine oleate iopamidol (EOI), was infused slowly and intermittently through a microcatheter during balloon occlusion. 5% EOI was prepared by making a 20 mL solution consisting of 10 mL contrast medium and 10 mL of 10% ethanolamine oleate (Oldamin; Grelan Pharmaceutical, Tokyo, Japan). The infusion of 5% EOI was continued until the entire gastric varices and feeding veins were opacified. The mean volume of sclerosant (5% EOI) was 22.9 mL per one procedure (range: 1.5-47 mL). The balloon occlusion time ranged from 12 to 48 h. To fix the sheath and catheters, sterilized tape (Hogy Medical, Tokyo, Japan) was used. The next morning after the BRTO procedure, thrombosis of gastric varices was evaluated by CE-CT. In patients with incomplete thrombosis after the first BRTO, a second BRTO was performed the following day. After complete thrombosis of gastric varices

was confirmed on CE-CT, all catheters were removed. To prevent renal damage due to EOI-induced hemolysis, 4000 units of haptoglobin (Mitsubishi Pharma, Osaka, Japan) was administered intravenously during and after the infusion of EOI in all patients<sup>[18,19]</sup>. Patients were followed up with endoscopy and CE-CT 1 d, 1 wk and 1, 3, 6 mo after the procedure and every 6 mo thereafter.

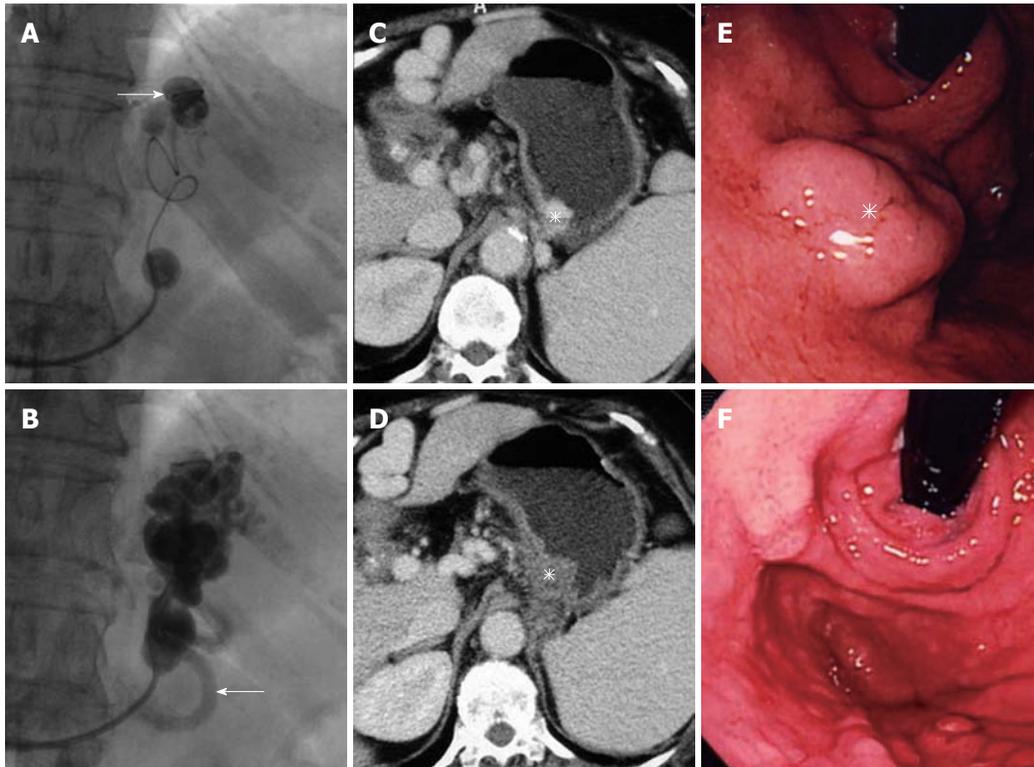

## RESULTS

In all (100%) of 56 patients, the sclerosant was selectively injected through the microcatheter close to the gastric varices (Figures 1 and 2). In 9 (16%) of 56 patients, microcoil embolization of dilated collateral veins was performed using the microcatheter (Figure 3). In 12 (21%) of 56 patients, CE-CT the next day after the first BRTO showed incomplete thrombosis of the varices, and additional injection of the sclerosant was performed in the second BRTO through the microcatheter which remained inserted overnight (Figure 4). Complete thrombosis of the varices was achieved in 51 of 56 patients after all BRTO procedures, and the remaining 5 patients showed incomplete thrombosis of the varices. Endoscopic treatments were performed in 4 of the 5 patients<sup>[20-24]</sup>, and a surgical treatment was performed in the other patient. No cases of recurrence or variceal bleeding of the gastric varices were found in the successful 51 patients after a median follow up time of 10.5 mo (range one day-7 years). Esophageal varices with red color sign appeared in 5 of the 51 patients<sup>[25-28]</sup>. Red color sign indicates a high risk of variceal bleeding<sup>[29]</sup>. These patients' varices were treated by endoscopic treatment.

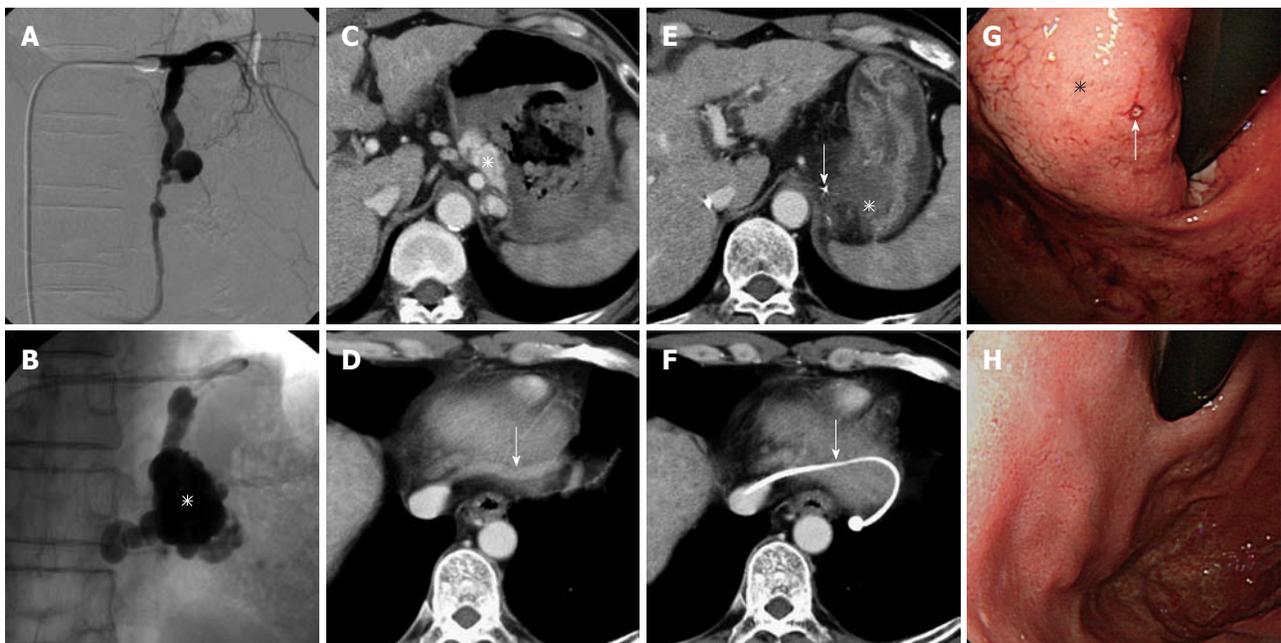

Most complications were transient and minor. These include: hematuria due to the sclerosant (8 of 56 patients), high fever (8 of 56), abdominal pain (5 of 56), elevation of blood pressure during infusion of the sclerosant (3 of 56), pleural effusion (35 of 56), ascites (33 of 56)<sup>[30]</sup>, and extravasation of the sclerosant during the procedure (3 of 56). In the three patients with extravasation, BRTO was continued, and complete thrombosis of the varices was achieved in 2 patients. We experienced one case of liver necrosis after the BRTO procedure<sup>[31]</sup>. No other major complications such as renal failure, pulmonary embolism, or acute respiratory distress syndrome (ARDS) were experienced.

## DISCUSSION

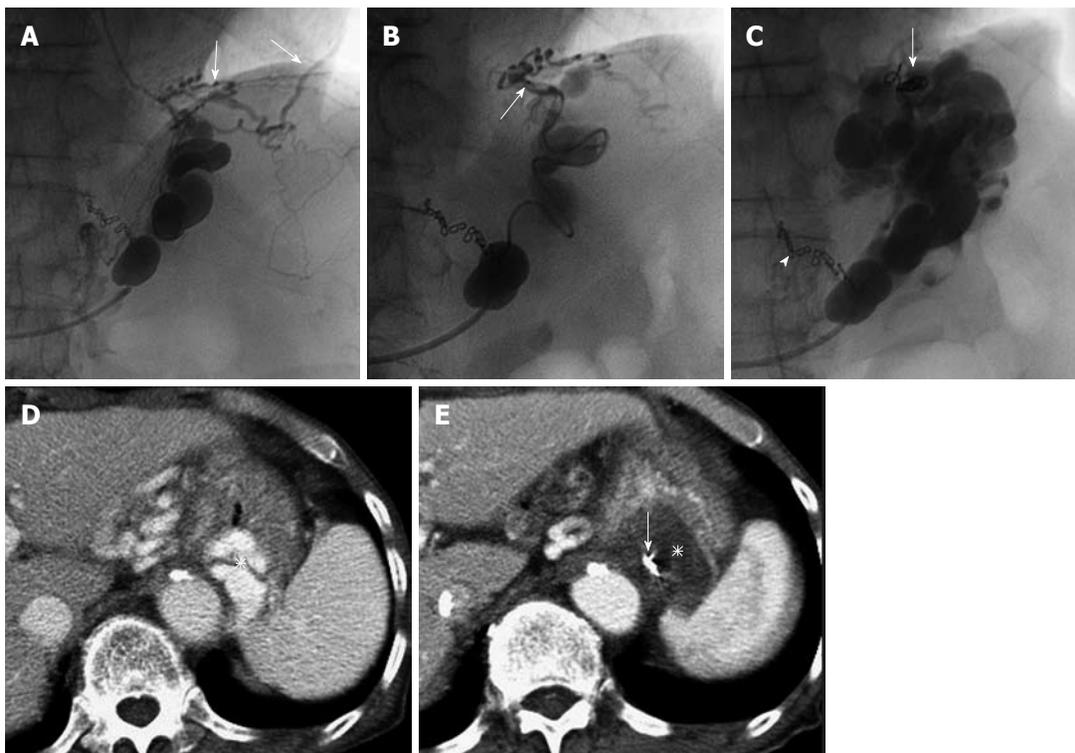

Microcatheters have three major benefits in BRTO for gastric varices. The first benefit is a selective injection of the sclerosant through a microcatheter<sup>[11-13]</sup>. Infusion of the sclerosant with a microcatheter, which is inserted close to the gastric varices, enables a decrease in the dose of the sclerosant, preventing sclerosant-related complications. We consider that the optimal volume of the sclerosant used for one BRTO procedure is 40 mL or less. To decrease the sclerosant volume of 5% EOI, 50% glucose solution may be infused before injection of 5% EOI during BRTO<sup>[32]</sup>.

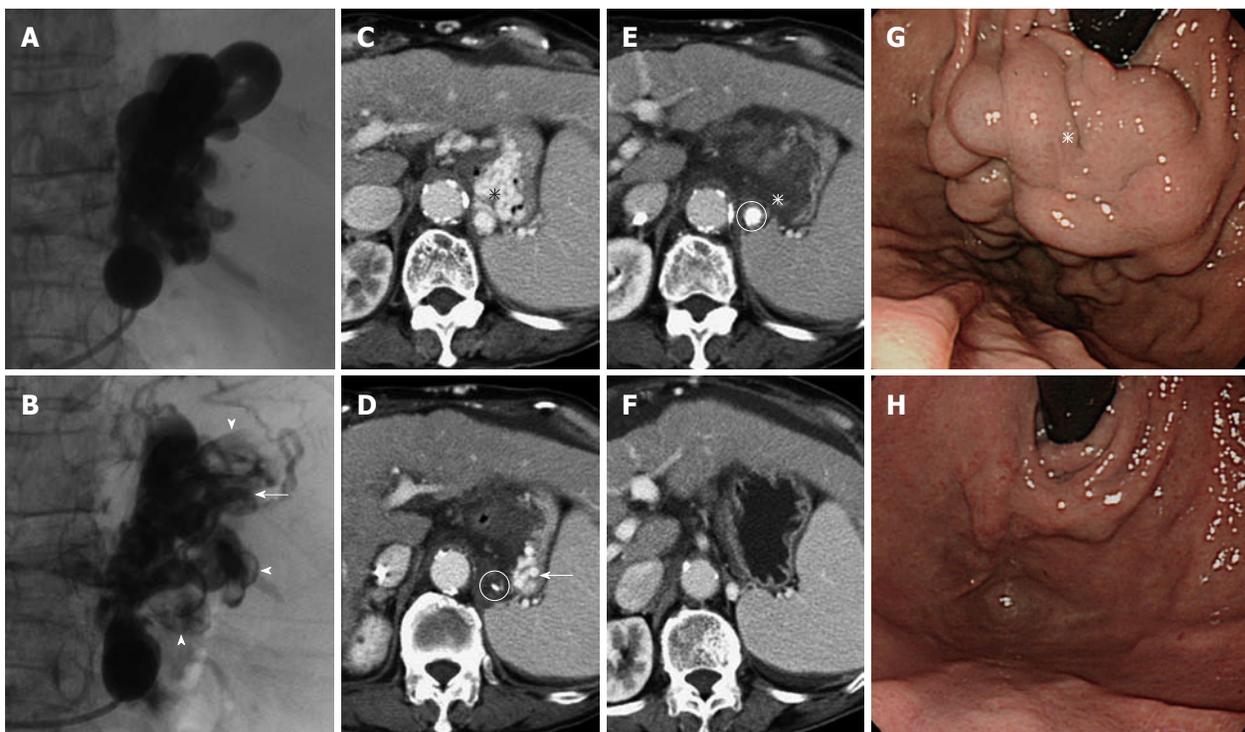

**Figure 1** Selective injection of the sclerosant. A: A microcatheter is navigated close to the gastric varices, and the sclerosant is selectively injected through the microcatheter (arrow); B: The gastric varices and gastrorenal shunt are fully filled with the sclerosant with contrast medium, and the afferent vein (arrow) is opacified; C: Contrast-enhanced computed tomography (CE-CT) before balloon-occluded retrograde transvenous obliteration (BRTO) shows gastric varices (asterisk); D: CE-CT one week after BRTO shows complete thrombosis of the varices (asterisk); E: Endoscopy before BRTO shows tumor-like varices (asterisk) in the fornix of the stomach; F: Endoscopy 3 mo after BRTO shows complete disappearance of the varices.

**Figure 2** Selective injection of the sclerosant. A: A balloon catheter is inserted into the gastrocaval shunt. Balloon-occluded venography shows no gastric varices; B: The balloon catheter is advanced further into the shunt, and the sclerosant is selectively injected through the microcatheter which is navigated close to the gastric varices. The varices (asterisk) are opacified sufficiently; C: Contrast-enhanced computed tomography (CE-CT) shows the varices (asterisk) and a large amount of hematomas in the stomach; D: The gastrocaval shunt (arrow) flows into the inferior vena cava; E: CE-CT next day shows complete thrombosis of the gastric varices (asterisk) and the tip of the microcatheter (arrow) close to the varices; F: CE-CT shows the balloon catheter in the shunt (arrow); G: Endoscopy before balloon-occluded retrograde transvenous obliteration (BRTO) shows large gastric varices (asterisk) with a bleeding site (arrow); H: Endoscopy 3 mo after BRTO shows complete disappearance of the varices.

**Figure 3** Microcoil embolization of collateral veins. A: Pericardiophrenic veins (arrows) develop as collateral draining veins; B: A microcatheter (arrow) is navigated into the pericardiophrenic vein and microcoil embolization is performed; C: The sclerosant is selectively injected through the microcatheter which is withdrawn a little, and the gastric varices are opacified sufficiently. Microcoils (arrow) from embolization and surgical clips from previous operation of gastric cancer. (arrowhead) are seen; D: Contrast-enhanced computed tomography (CE-CT) before balloon-occluded retrograde transvenous obliteration (BRTO) shows gastric varices (asterisk); E: CE-CT next day after BRTO shows complete thrombosis of the varices (asterisk) and microcoils close to the varices (arrow).

**Figure 4** Additional injection of the sclerosant. A: Fluoroscopic image obtained during the first balloon-occluded retrograde transvenous obliteration (BRTO) shows full opacification of the gastric varices and gastrorenal shunt; B: Fluoroscopic image obtained during the second BRTO (next day) shows partial opacification of the varices and shunt, suggesting residual varices (arrow) and thrombosis of the varices and shunt (arrowheads); C: Contrast-enhanced computed tomography (CE-CT) before BRTO shows large varices (asterisk); D: CE-CT after the first BRTO shows residual varices (arrow) in the lateral portion of the stomach. The microcatheter tip (circle) is in the gastrorenal shunt close to the varices; E: CE-CT after the second BRTO shows complete thrombosis of the varices (asterisk). The sclerosant with contrast medium (circle) is detected in the gastrorenal shunt; F: CE-CT 3 mo after BRTO shows complete disappearance of the varices; G: Endoscopy before BRTO shows bulky varices (asterisk); H: Endoscopy 3 mo after BRTO shows complete disappearance of the varices.

The second benefit is a microcoil embolization of dilated collateral veins<sup>[33]</sup> using a microcatheter<sup>[11,12,14]</sup>. Obliteration of collateral veins prevents renal failure, pulmonary embolism, and ARDS induced by leakage of the sclerosant into the systemic circulation. Haptoglobin was intravenously administered as a counteragent of ethanolamine oleate, which is a sclerosant that damages the endothelial cell of the vessel and induces thrombus formation in the vessel.

The third benefit is an additional injection of the sclerosant through the microcatheter that remained inserted overnight<sup>[15]</sup>. To achieve complete thrombosis of gastric varices, the balloon occlusion time was prolonged from 30 min (original BRTO) to 12 h or more<sup>[1]</sup>. After a complete thrombosis of gastric varices was confirmed on CE-CT done the next morning after the first BRTO, all catheters were removed. When complete thrombosis of gastric varices was not achieved, a second BRTO was performed, and additional sclerosant was injected through the microcatheter. Insertion of a microcatheter close to the gastric varices until the next day allows for an additional injection of the sclerosant into the varices through the microcatheter, even when occlusion of a shunt occurs.

Another minor benefit is that microcatheters can be a safer and more accurate guidance tool for balloon catheters than the 0.035 inch guidewires. The stiff guidewires sometimes induce venous damage. On the other hand, it's easy to insert a soft microcatheter into the shunts and advance a balloon catheter into the shunts over the microcatheter and microguidewire, because we can check the position of the microcatheter tip by test injection of the contrast material.

In the Kanagawa *et al*<sup>[1]</sup> on use of BRTO without the microcatheter technique, complete eradication of gastric varices was not achieved after a single BRTO procedure in 7 (22%) of 32 patients. This is compatible with our results that show 21% of patients with incomplete thrombosis of the varices and 16% of patients having microcoil embolization.

BRTO procedures for gastric varices may be difficult to conduct when varices lack a gastroduodenal shunt<sup>[34-37]</sup>. However, gastric varices without the gastroduodenal shunt are rare.

We experienced one case of liver necrosis. It is supposed that the liver necrosis was due to leakage of the sclerosant into the portal vein through afferent veins. So we must be careful in order to prevent leakage of the sclerosant into the portal vein.

Esophageal varices with red color sign appeared in 5 patients<sup>[25-28]</sup>. Occlusion of a gastroduodenal shunt and/or gastroduodenal shunt may have induced esophageal varices as another collateral route. Esophageal varices can be readily treated by endoscopic treatment. Therefore, the status of esophageal varices should be endoscopically checked at 6-month intervals after BRTO.

Three major beneficial techniques of microcatheters for BRTO of gastric varices are selective injection of the sclerosant, microcoil embolization of collateral veins and additional injection of the sclerosant. Microcatheters are

useful for achieving a higher success rate of BRTO procedures.

## COMMENTS

### Background

Gastric varices have a larger blood flow compared with esophageal varices, so when they are ruptured, there is a high mortality rate. Therefore, prophylactic treatment is necessary in patients with gastric varices in danger of rupture. Balloon-occluded retrograde transvenous obliteration (BRTO), is a treatment for gastric varices that is minimally invasive and has a high success rate. However, there are three major problems with BRTO procedures such as overdose of the sclerosant, leakage of the sclerosant into the systemic circulation, and incomplete thrombosis of large gastric varices. We introduced the microcatheter techniques to solve these problems

### Innovations and breakthroughs

Microcatheters have three major benefits in BRTO for gastric varices. The first benefit is a selective injection of the sclerosant through a microcatheter. The second benefit is a microcoil embolization of dilated collateral veins using a microcatheter. The third benefit is additional injection of the sclerosant through the microcatheter that remained inserted overnight. When complete thrombosis of gastric varices was not achieved, a second BRTO was performed, and additional sclerosant was injected through the microcatheter.

### Applications

Patients with large gastric varices and/or dilated collateral veins can be treated with BRTO procedures using the microcatheter techniques.

### Peer review

In this study, the authors described three major beneficial techniques of microcatheters for BRTO of gastric varices. Microcatheters are useful for achieving a higher success rate of BRTO procedures.

### Abstract

**AIM:** To examine the significance of branched-chain amino acid (BCAA) treatment before transcatheter arterial chemoembolization (TACE) for hepatocellular carcinoma (HCC).

**METHODS:** This study included 99 patients who underwent TACE therapy for HCC at our hospital and were followed up without treatment for at least 6 mo between January 2004 and January 2010. They were divided into 2 groups: those receiving BCAA granules ( $n = 40$ ) or regular diet ( $n = 59$ , control). Data obtained were retrospectively analyzed (prior to TACE, and 1 wk, 1, 3, and 6 mo after TACE) in terms of nutritional condition and clinical laboratory parameters (serum albumin level and Child-Pugh score), both of which are determinants of hepatic functional reserve.

**RESULTS:** The BCAA group comprised 27 males and 13 females with a mean age of  $69.9 \pm 8.8$  years. The patients of the BCAA group were classified as follows: Child-Pugh A/B/C in 22/15/3 patients, and Stage II/III/IVA HCC in 12/23/5 patients, respectively. The control

group comprised 32 males and 27 females with a mean age of  $73.2 \pm 10.1$  years. In the control group, 9 patients had chronic hepatitis, Child-Pugh A/B/C in 39/10/1 patients, and Stage I/II/III/IVA HCC in 1/11/35/12 patients, respectively. Overall, both serum albumin level and Child-Pugh score improved significantly in the BCAA group as compared with the control 3 and 6 mo after TACE ( $P < 0.05$ ). Further analysis was performed by the following categorization: (1) child-Pugh classification; (2) liver cirrhosis subgroup with a serum albumin level  $> 3.5$  g/dL; and (3) epirubicin dose. A similar trend indicating a significant improvement of all variables in the BCAA group was noted ( $P < 0.05$ ).

**CONCLUSION:** Treatment with BCAA granules in patients who have undergone TACE for HCC is considered useful to maintain their hepatic functional reserve.

### INTRODUCTION

Hepatocellular carcinoma (HCC) is the most common

carcinoma worldwide<sup>[1]</sup>. Treatment for HCC varies depending on the disease stage and liver function, and includes radiofrequency ablation, percutaneous ethanol injection therapy, hepatic resection, liver transplantation, transcatheter arterial chemoembolization (TACE), and molecular target therapy<sup>[2-4]</sup>.

TACE is a procedure whereby an embolizing agent is injected into the hepatic artery to deprive the tumor of its major nutrient source *via* embolization of the nutrient artery, resulting in ischemic necrosis of the tumor. Hepatic arterial embolization, which had been used until early in the 1990s, is divided into two treatment methods: injection of an embolizing agent after intra-arterial injection of an anticancer drug and intra-arterial injection of a mixture of an embolizing agent and an anticancer drug<sup>[5,6]</sup>. Subsequently, it was revealed that an oil contrast medium or iodized oil (Lipiodol) accumulates within the tumor after injection. This led to introduction of TACE, in which an embolizing agent is injected after injection of a mixture of Lipiodol and an anticancer drug (Lipiodol emulsion)<sup>[7,8]</sup>. Until the middle of the 1990s TACE had been performed in a large majority of patients with unresectable HCC. With the subsequent introduction of local treatment, however, TACE is now mainly indicated for treatment of an HCC measuring 3 to 5 cm in diameter or treatment of 4 or more HCCs less than 3 cm in diameter that are both unresectable and not indicated for local treatment.

Takayasu *et al.*<sup>[9]</sup> reported that independent prognostic factors in relation to survival in patients who underwent TACE include (1) degree of hepatic damage, (2) tumor staging and (3) serum  $\alpha$ -fetoprotein level, and recommended TACE, which can sufficiently maintain the volume ratio of a chemoembolized tumorous liver to the entire tumor-free liver as well as of residual hepatic functional reserve, while emphasizing the importance of maintenance of hepatic functional reserve in these patients.

Branched-chain amino acids ( BCAAs) are three amino acids possessing branched side chains (*i.e.*, valine, leucine, and isoleucine). Patients with liver cirrhosis are known to have decreased plasma BCAA levels, which can lead to protein-energy malnutrition (PEM). PEM is associated with a high morbidity and mortality due to an increased risk of life-threatening complications, resulting in poor survival and quality of life (QoL)<sup>[10]</sup>.

A considerable proportion of patients with HCC have concurrent liver cirrhosis. In those patients with underlying PEM, interventional therapy such as TACE may further worsen their nutritional condition and even occasionally cause development of ascites and jaundice, resulting in an irreversible outcome<sup>[11]</sup>.

Supplementation with BCAAs in patients with liver disorder has been attracting attention. BCAA treatment can correct malnutrition associated with liver cirrhosis in animals and humans<sup>[12-14]</sup>, and long-term nutritional BCAA supplementation may also be useful for prevention of hepatic failure while it also improves surrogate markers in patients with advanced cirrhosis<sup>[15,16]</sup>. BCAA

supplementation is also effective in down-regulating protein metabolism in liver cirrhosis patients by reducing ammonia (NH<sub>3</sub>) level, thus improving the nitrogen balance and resulting in better clinical outcomes<sup>[17,18]</sup>. The mechanism underlying these beneficial effects of BCAAs might be mediated by stimulation of hepatocyte growth factor activity that induces liver regeneration<sup>[19]</sup>. Therefore, nutritional support may play an important role in management of liver cirrhosis in patients with unresectable HCC. Studies dealing with the effect of treatment with BCAA granules before TACE in patients with HCC, nevertheless, are few as yet to our knowledge. This study was thus performed to investigate the significance of BCAA treatment in HCC patients who had undergone TACE.

## MATERIALS AND METHODS

### Patients

This retrospective study included 99 patients who underwent TACE alone for treatment of HCC at our hospital and were followed up thereafter without treatment for at least 6 mo between January 2004 and January 2010. Patients were divided into two groups: those receiving BCAA treatment ( $n = 40$ ) or regular diet ( $n = 59$ , control). BCAA therapy had been started at least one month before the day TACE was performed, and treatment compliance was good in all patients receiving BCAAs.

### Diagnosis of hepatocellular carcinoma

Dynamic computed tomography (CT) and abdominal echography were performed in all patients. A lesion visualized as a tumor blush in the early phase scan and as a defect area in the late phase scan on dynamic CT was diagnosed as HCC. It has been verified that such lesions appear as blushes on CT hepatic angiography and as defect areas on CT arterial portography during TACE. Two radiologists proficient in diagnostic imaging of the liver made a diagnosis of HCC. No pathological examination was conducted.

### Branched-chain amino acid granules

BCAA granules, containing 952 mg of L-isoleucine, 1904 mg of L-leucine and 1144 mg of L-valine per sachet, were orally administered to subjects at a dose of one sachet three times daily after meals. The control patients received no such treatment.

### Transcatheter arterial chemoembolization procedure

Written informed consent was obtained from each patient prior to TACE. The protocol for TACE was approved by the independent ethics committee of the hospital. TACE for HCC was performed in conformity with Japanese guidelines for this therapy<sup>[20]</sup> and consisted of catheterization *via* the femoral artery with super-selective cannulation to the hepatic artery feeding the target HCC. Farnorubicin (epirubicin hydrochloride, Pfizer) emulsion was infused at 10 to 60 mg, and Lipiodol (iodine addition products of ethyl esters of fatty acids obtained from pop-

py seed oil; Mitsui, Japan) was also injected at 2 to 10 mL according to the tumor size and tumor number. This was followed by embolization with gelatin (Spongel; Yamanouchi, Japan), which was injected slowly to prevent reflux into untreated segments. The sites of injection of the embolizing agents were segmental or subsegmental in all patients.

#### Follow-up after transcatheter arterial chemoembolization

At 1 wk and 1, 3 and 6 mo after TACE, patients underwent hematological and blood biochemical tests and were assessed for their hepatic functional reserve and development of any adverse events. Dynamic CT was carried out to assess for any ascites or recurrence of HCC at 1, 3 and 6 mo after TACE.

#### Statistical analysis

Student *t* test,  $\chi^2$  test and Fisher's exact test were used to compare data between BCAA patients and the control. Serum albumin level and Child-Pugh score constituted parameters for assessment of hepatic functional reserve. Absolute changes in serum albumin level observed at 1 wk and 1, 3 and 6 mo after TACE were compared between the two groups and evaluated using Student *t* test,

**Figure 1** Overall comparison of changes in Child-Pugh score between the branched-chain amino acids group and the control group over time. There was a significant difference in changes in Child-Pugh score 3 and 6 mo after transcatheter arterial chemoembolization. <sup>a</sup>*P* < 0.05 vs control group. BCAA: Branched-chain amino acid.

and the absolute change was defined as the difference found at each assessment time point from the baseline (pre-TACE level). Changes in Child-Pugh score were also evaluated similarly using Student *t* test at 1, 3 and 6 mo after TACE.

Data were analyzed using SPSS software, version 9.0 (SPSS Inc., Chicago, IL, United States) for Microsoft Windows. Data are expressed as mean  $\pm$  SD. Values of *P* < 0.05 were considered to be statistically significant.

## RESULTS

Patient demographic characteristics are summarized in Table 1. Significant differences were noted for the following parameters: Child-Pugh score, serum albumin level, prothrombin time, and dose of epirubicin at the time of TACE. A patient in the control group had stage I HCC, for which percutaneous therapy is indicated, but TACE alone was performed because the patient refused percutaneous therapy.

#### Overall comparison of hepatic functional reserve between the branched-chain amino acid group and the control group over time

A significant difference in serum albumin level was observed at all assessment time points (*P* < 0.05). Also, there was a significant difference in Child-Pugh score 3 and 6 mo after TACE (*P* < 0.05) (Table 1, and Figure 1).

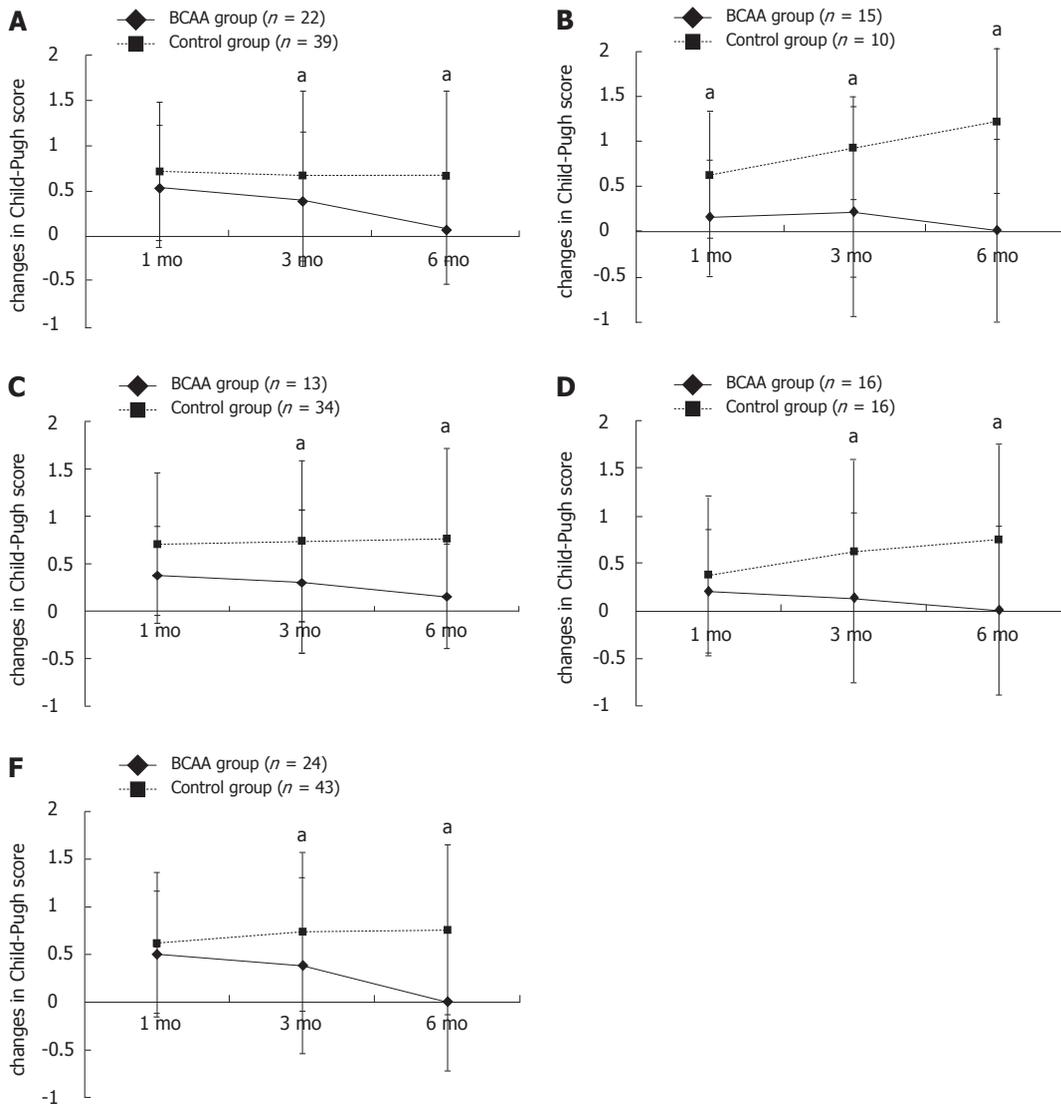

The categorized analysis results are presented below.

#### Comparison of hepatic functional reserve in Child A patients

There were 22 Child A patients in the BCAA group and 39 in the control group. A significant difference was noted in serum albumin level 1, 3 and 6 mo after TACE and in Child-Pugh score 3 and 6 mo after TACE (*P* < 0.05) (Table 1, and Figure 2A).

#### Comparison of hepatic functional reserve in Child B patients

There were 15 Child B patients in the BCAA group and 10 in the control group. A significant difference was

**Figure 2 Comparison of changes in Child-Pugh score in Child A and Child B patients: patients with a serum albumin level of 3.5 g/dL or more, low-dose epirubicin subgroups, high-dose epirubicin subgroups.** A: A significant difference was noted in changes in Child-Pugh score 3 and 6 mo after transcatheter arterial chemoembolization; B: A significant difference was noted in changes in Child-Pugh score 1, 3 and 6 mo after transcatheter arterial chemoembolization; C: A significant difference was observed in changes in Child-Pugh score 3 and 6 mo after TACE; D: A significant difference was noted in changes in Child-Pugh score 3 and 6 mo after TACE; E: A significant difference was noted in changes in Child-Pugh score 3 and 6 mo after TACE. BCAA: Branched-chain amino acids; TACE: Transcatheter arterial chemoembolization. <sup>a</sup> $P < 0.05$  vs control group.

noted in serum albumin level 3 and 6 mo after TACE and in Child-Pugh score 1, 3 and 6 mo after TACE ( $P < 0.05$ ) (Table 1 and Figure 2B).

### Comparison in patients with a serum albumin level of 3.5 g/dL or more

There were 13 and 34 patients who fell in this category in the BCAA group and the control group, respectively. A significant difference was observed in both serum albumin level and Child-Pugh score 3 and 6 mo after TACE ( $P < 0.05$ ) (Table 1, and Figure 2C).

As it is thought that antineoplastic agents used during TACE may cause hepatic impairment in a dose-dependent fashion, the data were further evaluated in patients classified into two subgroups: those treated with low-dose epirubicin (less than 40 mg) or a high-dose epirubi-

cin (40 mg or more).

### Comparison in low-dose epirubicin subgroups

Sixteen patients each received low-dose epirubicin in the BCAA group and the control group. Serum albumin level was significantly different 1, 3 and 6 mo after TACE and Child-Pugh score 3 and 6 mo after TACE ( $P < 0.05$ ) (Table 1 and Figure 2D).

### Comparison in high-dose epirubicin subgroups

Twenty-four and 43 patients received high-dose epirubicin in the BCAA group and the control group, respectively. A significant difference was noted in serum albumin level at all assessment time points and in Child-Pugh score 3 and 6 mo after TACE ( $P < 0.05$ ) (Table 1 and Figure 2E).

## DISCUSSION

PEM occurs frequently in patients with liver cirrhosis and represents an important predictive factor for the prognosis of liver cirrhosis patients with HCC<sup>[18,21]</sup>. Supplementation with BCAA formula is reportedly useful for improving PEM and QoL in these patients. However, few studies have assessed the importance of such nutritional intervention in patients with HCC who underwent nonsurgical therapies such as TACE. The purpose of the present study was to investigate to what extent BCAA treatment can contribute to maintaining hepatic functional reserve in HCC patients after TACE.

A significant difference was observed in the overall patient population in terms of change in serum albumin level at all assessment time points. As seen in Table 1, hepatic functional reserve was relatively well maintained in the control group; therefore, anticancer chemotherapy was given at relatively high doses (60% of patients treated with BCAA received epirubicin at 40 mg or more whereas the corresponding percentage for the control group was 72.9%). Patients receiving high-dose anticancer chemotherapy are often unable to sufficiently ingest food over several weeks after TACE. This may account for lower serum albumin levels observed in the control group compared with the BCAA group. Other possible causes of decreased serum albumin levels after TACE include (1) impaired ability of the liver to synthesize serum albumin due to decreased hepatocyte count; (2) inhibition of the synthesis of albumin by inflammatory cytokines; and (3) leakage of albumin due to inflammation of the cauterized areas<sup>[22,23]</sup>.

The assessments in Child-Pugh A patients revealed a significant difference in serum albumin level 1, 3 and 6 mo after TACE and in Child-Pugh score 3 and 6 mo after TACE. TACE is best indicated for Child-Pugh A HCC. In patients undergoing TACE, caution should be exercised to minimize depression of hepatic functional reserve in preparation for the next treatment session. The above results thus suggest the usefulness of BCAA treatment in this regard.

The assessments in the Child-Pugh B subgroup showed a significant difference in Child-Pugh score 1, 3 and 6 mo after TACE. Once hepatic functional reserve has worsened from Child-Pugh B to Child-Pugh C following TACE, the next TACE cannot be performed according to the Barcelona Clinic Liver Cancer guidelines<sup>[24]</sup>. Therefore, particular caution should be exercised in maintaining hepatic functional reserve at the time of TACE in patients with Child-Pugh B HCC, indicating the indispensability of BCAA therapy.

In Japan, BCAA granules are indicated for the treatment of liver cirrhosis in patients with a serum albumin level of 3.5 g/dL or less. However, conversely, the present study demonstrated similar results between patients with a serum albumin level of more than 3.5 g/dL and those in other categories of serum albumin level. Therefore, treatment with BCAA proved to improve hepatic functional reserve even in cirrhotic patients with HCC

whose serum albumin level exceeds 3.5 g/dL. It is thus recommended to actively provide BCAA treatment in such patients.

There was a conspicuous difference between the BCAA and control groups in respect of response to BCAA therapy when assessed in patients receiving high-dose epirubicin compared to those treated with low-dose epirubicin. TACE may cause a marked damage to the liver in HCC patients, eventually leading to a considerable impact on their hepatic functional reserve<sup>[9]</sup>. BCAA treatment is thus recommended at sufficient doses prior to TACE in patients with advanced HCC in whom high-dose anticancer chemotherapy is anticipated.

TACE is often repeated because a single session of therapy seldom provides complete necrosis of a tumor. The procedure is commonly repeated once every 2 to 3 mo<sup>[25-27]</sup>. In the present study, however, many patients failed to attain recovery of hepatic functional reserve to a pre-TACE level, particularly in the control group, within 2 to 3 mo of TACE. It is thus estimated that every repeated session of TACE may worsen hepatic functional reserve and thereby shorten the prognosis for survival. Treatment with BCAA would therefore be essential in order to allow for providing TACE periodically while securely maintaining hepatic functional reserve.

One of the findings commonly noted in regard to all the variables assessed in this study is that a significantly greater improvement was noted in both serum albumin level and Child-Pugh score for the BCAA group 6 mo after TACE in comparison to the control group. What is suggested by this fact is simply the usefulness of long-term BCAA treatment prior to TACE. It is also important that patients should be fully instructed on the use of BCAA granules to maintain their treatment compliance.

The present study has several limitations. Firstly, it is a retrospective study. Furthermore, there was a bias in patient demographic characteristics between the BCAA and control groups since BCAA is usually used for patients showing low serum albumin levels. Therefore, pertinent data were evaluated for improvement or exacerbation using absolute serum albumin change as a parameter. The present study did not include assessment for the prognosis for survival, which should be addressed by a prospective study using comparable demographic characteristics among patients.

In conclusion, treatment with BCAAs before TACE in HCC patients is extremely useful in maintaining their hepatic functional reserve.

## COMMENTS

### Background

Patients with hepatocellular carcinoma (HCC) due to liver cirrhosis are known to have decreased plasma branched-chain amino acid (BCAA) levels, which can lead to protein-energy malnutrition (PEM). BCAA treatment can correct malnutrition associated with liver cirrhosis.

### Research frontiers

Studies dealing with the effect of treatment with BCAA granules before transcatheter arterial chemoembolization (TACE) in patients with HCC are few as

yet. In this study, the authors analyzed the effect of BCAA treatment before TACE for HCC patients.

### Innovations and breakthroughs

Recent studies imply that by BCAA supplementation, malnutrition associated with liver cirrhosis is corrected and liver function improves. The present study shows that in HCC patients who underwent TACE, liver function was maintained by BCAA supplementation.

### Applications

This study emphasizes the importance of BCAA treatment before TACE for HCC patients with regard to maintaining liver function.

### Peer review

This is a very good and novel study in which authors analyze the effect of BCAA treatment before TACE for HCC patients. The results are interesting and suggest the usefulness of BCAA treatment before TACE in HCC patients in maintaining their hepatic functional reserve.

### Abstract

**AIM:** To evaluate the relationship between liver stiffness and duration of infection in blood transfusion-associated hepatitis C virus (HCV) patients with or without hepatocellular carcinoma (HCC).

**METHODS:** Between December 2006 and June 2008, a total of 524 transfusion-associated HCV-RNA positive patients with or without HCC were enrolled. Liver stiffness was obtained noninvasively by using Fibroscan (Echosens, Paris, France). The date of blood transfusion was obtained by interview. Duration of infection was derived from the interval between the date of blood

transfusion and the date of liver stiffness measurement (LSM). Patients were stratified into four groups based on the duration of infection (17-29 years; 30-39 years; 40-49 years; and 50-70 years). The difference in liver stiffness between patients with and without HCC was assessed in each group. Multiple linear regression analysis was used to determine the factors associated with liver stiffness.

**RESULTS:** A total of 524 patients underwent LSM. Eight patients were excluded because of unsuccessful measurements. Thus 516 patients were included in the current analysis (225 with HCC and 291 without). The patients were 244 men and 272 women, with a mean age of  $67.8 \pm 9.5$  years. The median liver stiffness was 14.3 kPa (25.8 in HCC group and 7.6 in non-HCC group). The patients who developed HCC in short duration of infection were male dominant, having lower platelet count, with a history of heavier alcohol consumption, showing higher liver stiffness, and receiving blood transfusion at an old age. Liver stiffness was positively correlated with duration of infection in patients without HCC ( $r = 0.132$ ,  $P = 0.024$ ) but not in patients with HCC ( $r = -0.103$ ,  $P = 0.123$ ). Liver stiffness was significantly higher in patients with HCC than in those without in each duration group ( $P < 0.0001$ ). The factors significantly associated with high liver stiffness in multiple regression were age at blood transfusion ( $P < 0.0001$ ), duration of infection ( $P = 0.0015$ ), and heavy alcohol consumption ( $P = 0.043$ ).

**CONCLUSION:** Although liver stiffness gradually increases over time, HCC develops in patients with high stiffness value regardless of the duration of infection.

## INTRODUCTION

Hepatitis C virus (HCV) is a leading cause of chronic liver diseases, presenting serious public health problems worldwide<sup>[1,2]</sup>. HCV infection generally shows an asymptomatic onset and slow fibrosis progression, with cirrhosis developing after 20-50 years<sup>[3-7]</sup>. Progression of disease is known to depend on patients' characteristics at the onset of infection<sup>[8-12]</sup>. Infection at old age, male gender and heavy alcohol consumption are reported to be independently associated with rapid disease progression.

The onset of HCV infection can be reliably estimated in transfusion-associated chronic hepatitis C patients, in contrast to repeating injecting-drug users. In Japan, about 40% of chronic hepatitis C patients and HCV-related HCC patients have a history of blood transfusion typically in 1950s and 1960s<sup>[13]</sup>, when blood supply depended on paid blood donors. Not a few of the blood donors were also injecting-drug users, mainly methamphetamine, among whom HCV spread first after the end of World War II. Viral spread started to decline in Japan after commercial blood banks were entirely abolished in 1969<sup>[14]</sup>.

Chronic hepatitis C with cirrhosis is a strong risk factor for hepatocellular carcinoma (HCC)<sup>[15,16]</sup>. It has been shown that the risk of HCC increases with the degree of liver fibrosis<sup>[17]</sup>. Until recently, however, the degree of liver fibrosis could be reliably assessed only with liver biopsy, an invasive procedure with the possibility of serious complications<sup>[18,19]</sup>.

Liver stiffness, which can be noninvasively measured with transient elastography, has been recently reported to be well correlated with histologically assessed liver fibrosis stage<sup>[20]</sup>. We previously reported that liver stiffness is strongly associated with the risk of HCC<sup>[21,22]</sup>. The calculated stratum-specific likelihood ratio indicated that the post-test odds for the presence of HCC increase five-fold when liver stiffness is higher than 25 kPa and decrease to one-fifth when lower than 10 kPa. Furthermore, we have confirmed in a prospective study that liver stiffness is a significant risk factor for HCC development, together with male gender, clinical cirrhosis and serum albumin level. However, in those studies we did not fully consider the duration of HCV infection and the age at the onset of infection, which are indicated in several studies to be

associated with disease progression.

The aim of this study is to evaluate the association between liver stiffness and the duration of infection in blood transfusion-associated hepatitis C patients with and without HCC, focusing on the risk of HCC development.

## MATERIALS AND METHODS

### Patients

This study conformed to the ethical guideline of the 1975 Helsinki Declaration and the ethical guidelines for epidemiologic research designed by Japanese Ministry of Education, Culture, Sports, Science and Technology and Ministry of Health, Labor and Welfare. The study design was approved by the ethics committee of the authors' institution. Between December 2006 and June 2008, a total of 1562 patients positive for HCV RNA visited the liver clinic of authors' institution. Among these patients, those with a history of receiving blood transfusion were consecutively enrolled (229 with HCC and 295 without). We excluded from the present study those patients with concomitant hepatitis B virus surface antigen positivity, patients with uncontrollable ascites, patients on interferon therapy, and patients who received multiple blood transfusions.

### Transient elastography

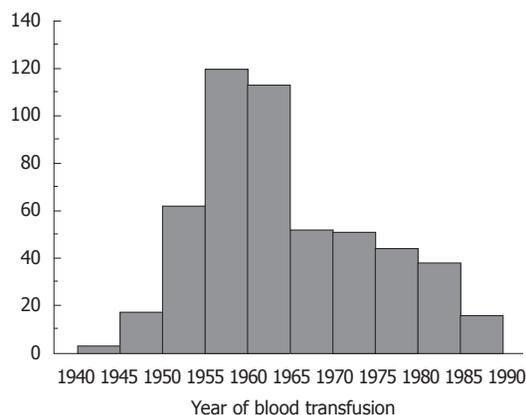

Liver stiffness was obtained noninvasively by using Fibroscan (Echosens, Paris, France), a newly developed medical device based on elastometry. Liver stiffness measurement (LSM) was considered valid only when at least eight acquisitions were successful with a success rate of at least 60% and the ratio of inter-quartile range (IQR) to the median value was larger than 30%.

### Diagnosis of hepatocellular carcinoma

In patients with HCC, the cancer was diagnosed by dynamic computed tomography (CT), where intrahepatic nodules with hyperattenuation in the arterial phase with washout in the late phase were considered as definite HCC<sup>[23,24]</sup>. Histopathological diagnosis, using ultrasound-guided biopsy samples, was also performed when required. In patients without HCC, the cancer was ruled out by ultrasonography. No HCC was detected in the subsequent six-month follow-up period among these patients.

### Laboratory tests

We determined the following parameters on the day of LSM: serum albumin and total bilirubin concentrations, serum aspartate aminotransferase (AST) and alanine aminotransferase (ALT) levels, prothrombin activity and platelet count. Serogrouping of HCV was assessed by enzyme-linked immunosorbent assay (ELISA) (Immucheck F-HCV Gr Kokusai; Sysmex, Kobe, Japan)<sup>[25]</sup>. Based on the prevalence of each HCV genotype in Japan, serogroup 1 was assumed to represent genotype 1b and serogroup 2 to represent genotype 2a or 2b.

<sup>1</sup>Data are expressed as median (25th-75th percentiles). ALT: Alanine aminotransferase; IQR: Inter-quartile range; HCC: Hepatocellular carcinoma; M: Male; F: Female.

### Duration of infection and liver stiffness progression

The date of blood transfusion was obtained by interview. Duration of infection was derived from the interval between the date of blood transfusion and the date of LSM. The rate of liver stiffness progression was calculated as follows: present liver stiffness-minimal stiffness value in the cohort (kPa)/interval after blood transfusion (years).

### Statistical analysis

Data were expressed as median and 25th-75th percentiles in parenthesis unless otherwise indicated. The categorical variables were compared by  $\chi^2$  tests, whereas continuous variables were compared with unpaired Student's *t* test (parametric) or Mann-Whitney *U* test (non-parametric). A *P* value < 0.05 on two-tailed test was considered significant.

The correlation between liver stiffness and the interval from blood transfusion was assessed by Spearman's rank correlation. The duration of infection was arbitrarily stratified into 4 groups, 17-29 years; 30-39 years; 40-49 years; and 50-70 years. The difference in liver stiffness according to the presence of HCC was assessed in each group. Multiple linear regression analysis was used to determine the factors associated with liver stiffness. Processing and analysis were performed by using the S-plus Version 7 (TIBCO Software Inc., Palo Alto, CA, United States).

## RESULTS

### Patients' profile

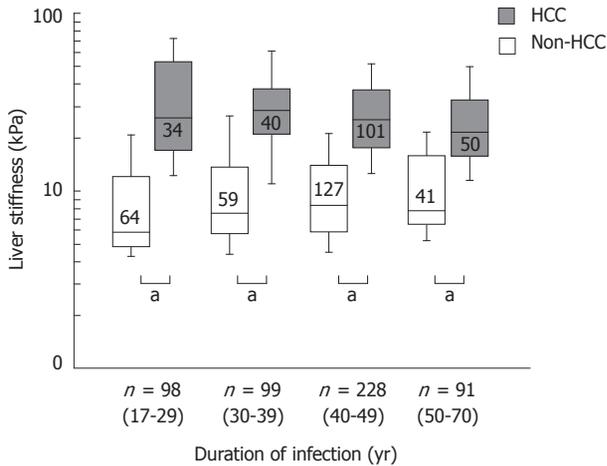

A total of 524 patients underwent LSM. Eight patients were excluded because of unsuccessful measurements, mostly due to obesity (four patients had IQR/median > 30% and four had a success rate lower than 60%). Thus 516 patients were included in the current analysis (225 with HCC and 291 without). Their characteristics at the time of LSM are summarized in Table 1. The patients were 244 men and 272 women, with a mean age of 67.8 ± 9.5 years. The median liver stiffness was 14.3 kPa (25.8 in HCC group and 7.6 in non-HCC group). Figure 1 shows the frequency distribution of the year of receiving blood transfusion among the subjects. A peak is noted around the year 1960.

### Characteristics of patients according to the duration of infection

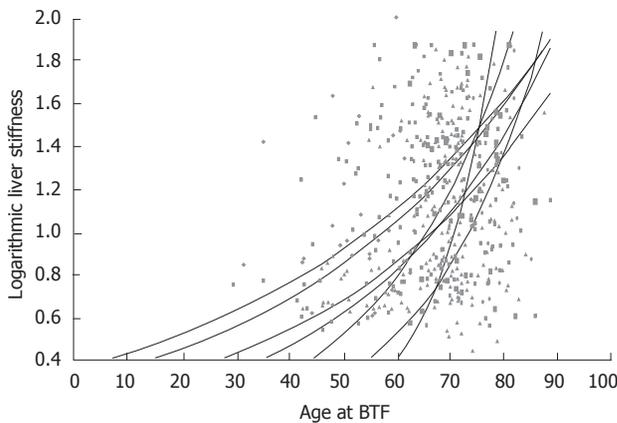

Characteristics of patients were compared between patients with and without HCC in each duration of infection group (Table 1). The patients who developed HCC in short duration of infection were male dominant, having low platelet count, with a history of heavier alcohol consumption, showing higher liver stiffness, and receiving blood transfusion at an older age.

### Correlation between liver stiffness and duration of infection

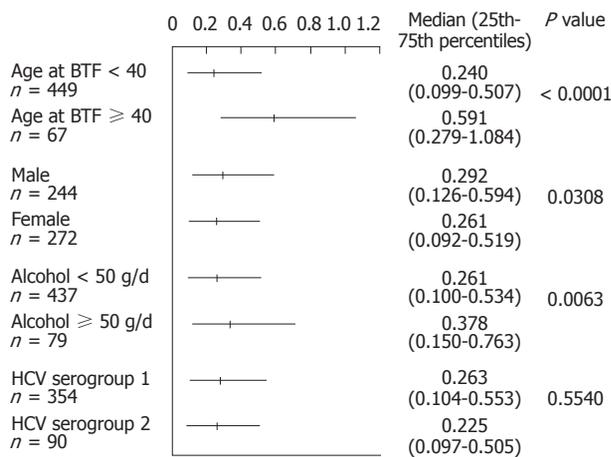

The correlation between liver stiffness and duration of

**Figure 2 Duration of infection and liver stiffness.** Liver stiffness was higher in patients with HCC than in patients without in each infection duration group ( $P < 0.0001$  by Mann-Whitney *U* test).

**Figure 3 Age at blood transfusion and liver stiffness.** Stiffness at present (each dot) and stiffness at BTF (assumed to normal value) were connected approximate logarithmic curve. Stiffness progressions become rapid in older age at BTF.

**Figure 4 Liver stiffness progression rate.** The progression rate is significantly higher in patients who were older than 40 at the time of blood transfusion, whose alcohol consumption is more than 50 g/d, and who are male. There is no significant difference according to hepatitis C virus (HCV) serotypes. Horizontal bar represents median value and 25th-75th percentiles.

infection was significant in patients without HCC ( $r = 0.132$ ,  $Z = 2.256$ ,  $P = 0.024$ ) but not in patients with HCC ( $r = -0.103$ ,  $Z = -1.54$ ,  $P = 0.123$ ). When the duration of infection was stratified into 4 groups, 17-29 years; 30-39 years; 40-49 years; and 50-70 years, liver stiffness was higher in patients with HCC than in patients without in each group ( $P < 0.0001$ , Figure 2).

### Multiple regression analysis

The relationship between present liver stiffness and patients' characteristics, i.e., the age at blood transfusion, duration of infection, gender, and alcohol consumption (alcohol > 50 g/d) was analyzed with multiple linear regression analysis. The results showed that the age at blood transfusion was positively correlated with liver stiffness, with a coefficient of +0.336 per year for kPa,  $P < 0.0001$ , independently of the duration of infection (coefficient +0.272 per year for kPa,  $P = 0.0015$ ). This suggests that fibrosis progression is more rapid when infection is acquired at older ages. Alcohol consumption was also significantly correlated with a positive coefficient (coefficient +4.183 for kPa,  $P = 0.043$ ).

### Stiffness progression and the age at blood transfusion

The progression of liver fibrosis, as represented by the increase in liver stiffness, must have been rapid in patients who have high liver stiffness in spite of short duration of HCV infection. We assumed that the liver stiffness was normal, that is, 2.9 kPa, when patients received blood transfusion. In Figure 3, the slopes represent the estimated increase rates of liver stiffness. In accordance with the results of multiple regression, the estimated increase rate was higher when patients received blood transfusion at older ages.

The progression rate of liver stiffness was assessed in subgroups according to three parameters (Figure 4). The progression rate was significantly higher in patients who were older than 40 at the time of blood transfusion ( $P < 0.0001$ ), which is in accordance with the results of multiple regression. Heavy alcohol consumption (more than 50 g ethanol/d,  $P = 0.0308$ ) and male gender ( $P = 0.0063$ ) also showed significant difference by Mann-Whitney *U* test. There was no significant difference among HCV genotypes.

## DISCUSSION

The natural history of chronic hepatitis C concerning liver fibrosis progression has been vigorously studied using liver biopsy specimens. The extent of liver fibrosis is usually evaluated as categorical stages. For example, METAVIR Score uses five stages, F0-F4, for fibrosis evaluation<sup>[26]</sup>. The fibrosis progression in hepatitis C patients, calculated by using paired liver biopsy, was reported to be 0.1-0.133 Unit per year<sup>[12,13]</sup>. Liver stiffness measured by transient elastography is now widely accepted as a surrogate marker of liver fibrosis<sup>[27]</sup>. Liver stiffness is expressed as a continuous variable in kPa unit. The cut-

off for cirrhosis is reportedly 13-17 kPa, and the upper limit of measurement is currently 75 kPa. Thus LSM has a wider dynamic range than histological staging, and the rate of fibrosis progression may be more accurately analyzed with LSM.

In the present study, the increase rate of liver stiffness was positively correlated with the age at blood transfusion, as shown by the steeper slopes of approximation curves when patients received BTF at older ages. The cause of this phenomenon is not clear but age-related changes in immunity may be involved. If this is the case, the increase rate is likely to become higher in the same patient with age. Indeed, each approximation curve in the figure apparently becomes steeper with age, suggesting age-related acceleration. This is to be confirmed in future longitudinal studies.

LSM is useful not only as a surrogate of liver biopsy but also as a risk indicator of HCC development. Indeed, in the present study, liver stiffness is high in patients with HCC regardless of duration of infection. The patients who developed HCC with short duration of infection received blood transfusion at an older age and were older at the time of LSM, male dominant, and showed higher liver stiffness than patients without HCC with similar duration of infection. The difference between patients with and without HCC became smaller with longer duration of infection, as the average liver stiffness in patients with HCC became lower and that in patients without HCC became higher. We speculated that patients with high liver stiffness who received blood transfusion in the early period have already died of HCC or liver failure and were eliminated from the study population. Another possibility is that HCC may develop in patients with relatively low liver stiffness when infection has lasted a long time.

In the present study, the median increase in liver stiffness was calculated as 0.275 kPa per year. Using 13.01 kPa as a cut-off for cirrhosis<sup>[28]</sup>, it will take around 40 years on average to develop cirrhosis, which is consistent with previous reports based on liver biopsy<sup>[29]</sup>. Admittedly, the present study is basically cross-sectional, and prospective longitudinal LSM will be obviously superior in understanding the natural course of liver fibrosis progression. However, the estimated average increase rate of liver stiffness indicates that such studies will require repeated LSM at an interval of at least five years.

Age at viral infection, alcohol consumption, and male gender were reported to be associated with accelerated fibrosis progression<sup>[8-11]</sup>. In the present study, we performed subgroup analysis and indeed found that blood transfusion at an age older than 40, male gender, and alcohol consumption more than 50 g ethanol/d were significantly associated with rapid increase in liver stiffness. There is consensus that heavy alcohol consumption is associated with fibrosis progression<sup>[30]</sup>. Alcohol, which by itself can cause liver disease and fibrosis, may affect liver stiffness and worsen fibrosis in hepatitis C<sup>[31]</sup>. We did not find a difference in liver stiffness increase rate between HCV genotypes 1 (mostly 1b) and 2 (2a/2b), although we could not evaluate genotypes 1a, 3 or 4.

This study has some limitations. First, since this is a cross-sectional study performed after LSM became available, patients with more rapid disease progression may have died and been excluded from the study. Second, because transfusion-associated HCV infection has been virtually eliminated in Japan since 1992, we could not include patients with shorter duration of infection. Lastly, we did not perform paired LSM but assumed that liver stiffness was normal at the time of infection. Longitudinal observation is now on-going but will take several years to obtain results.

In conclusion, although liver stiffness gradually increases over time from the onset of infection in general, HCC develops in patients with high liver stiffness regardless of the duration of infection. Patients who acquired HCV infection at older ages showed higher increase rate of liver stiffness and probably more rapid disease progression.

## COMMENTS

### Background

Liver stiffness, which can be noninvasively measured with transient elastography, has been recently reported to be well correlated with histologically assessed liver fibrosis stage.

### Research frontiers

This study evaluated the association between liver stiffness and the duration of infection in blood transfusion-associated hepatitis C patients with and without hepatocellular carcinoma (HCC), focusing on the risk of HCC development.

### Innovations and breakthroughs

Liver stiffness is expressed as a continuous variable in kPa unit. The cut-off for cirrhosis is reportedly 13-17 kPa, and the upper limit of measurement is currently 75 kPa. Thus liver stiffness measurement (LSM) has a wider dynamic range than histological staging, and the rate of fibrosis progression may be more accurately analyzed with LSM.

### Applications

Although liver stiffness gradually increases over time from the onset of infection in general, HCC develops in patients with high liver stiffness regardless of the duration of infection. Patients who acquired hepatitis C virus (HCV) infection at older ages showed higher increase rate of liver stiffness and probably more rapid disease progression.

### Terminology

Transient elastography (Fibro-Scan<sup>®</sup>; EchoSens, Paris, France) is a rapid, reliable and well-tolerated imaging technique for the assessment of liver fibrosis by measuring liver stiffness.

### Peer review

This is an interesting and timely study on liver stiffness in patients with transfusion associated HCV. The authors show that HCC develops in patients with high liver stiffness regardless of the duration of infection. Patients who acquired HCV infection at older ages showed higher increase rate of liver stiffness. Co-exposure to alcohol is critical. The methodology is sound and the paper is well and clearly written.

### Abstract

**AIM:** To investigate the role of opioid  $\mu$ -receptor subtype in opiate-induced constipation (OIC).

**METHODS:** The effect of loperamide on intestinal transit was investigated in mice. Ileum strips were isolated from 12-wk-old male BALB/c mice for identification of isometric tension. The ileum strips were precontracted with 1  $\mu$ mol/L acetylcholine (ACh). Then, decrease in muscle tone (relaxation) was characterized after cumulative administration of 0.1-10  $\mu$ mol/L loperamide into the organ bath, for a concentration-dependent study. Specific blockers or antagonists were used for pretreatment to compare the changes in loperamide-induced relaxation.

**RESULTS:** In addition to the delay in intestinal transit, loperamide produced a marked relaxation in isolated ileum precontracted with ACh, in a dose-dependent manner. This relaxation was abolished by cyprodime,

a selective opioid  $\mu$ -receptor antagonist, but not modified by naloxonazine at a dose sufficient to block opioid  $\mu$ -1 receptors. Also, treatment with opioid  $\mu$ -1 receptor agonist failed to modify the muscle tone. Moreover, the relaxation by loperamide was attenuated by glibenclamide at a dose sufficient to block ATP-sensitive  $K^+$  ( $K_{ATP}$ ) channels, and by protein kinase A (PKA) inhibitor, but was enhanced by an inhibitor of phosphodiesterase for cyclic adenosine monophosphate (cAMP).

**CONCLUSION:** Loperamide induces intestinal relaxation by activation of opioid  $\mu$ -2 receptors via the cAMP-PKA pathway to open  $K_{ATP}$  channels, relates to OIC.

### INTRODUCTION

Opiate-induced constipation (OIC) is widely observed among patients receiving chemotherapy<sup>[1,2]</sup>. In the gastrointestinal system, the opioid peptides are released and activate opioid receptors, which regulate the enteric circuitry by controlling motility and secretion, resulting in an increase in sphincter tone, inhibition of gastric emptying, and induction of stationary motor patterns. Together with the inhibition of ion and fluid secretion, these effects result in constipation, one of the most troublesome

side effects of opiate analgesic treatment<sup>[3]</sup>. The development of a better therapy for treating OIC is urgent and necessary.

Loperamide is widely used clinically to treat a variety of diarrheal syndromes, including acute and nonspecific (infectious) diarrhea<sup>[4,5]</sup>. Loperamide is a peripheral agonist of opioid  $\mu$ -receptors with poor ability to penetrate the blood-brain barrier<sup>[6,7]</sup>. Some analgesic agents have been shown to have relaxant effects on smooth muscle<sup>[8,9]</sup>. (+)-Tramadol activates peripheral opioid  $\mu$ -receptors, inducing concentration-dependent relaxation of the aorta<sup>[10]</sup>. Opioid  $\mu$ -receptors are divided into three subtypes:  $\mu$ -1,  $\mu$ -2 and  $\mu$ -3<sup>[11]</sup>. The activation of opioid  $\mu$ -1 receptors has been reported to be associated primarily with the phospholipase C (PLC)-protein kinase C (PKC) pathway<sup>[12]</sup>. PLC-PKC signals can increase the intracellular calcium concentration, inducing gastrointestinal or bladder contraction<sup>[13,14]</sup>. Therefore, it is unlikely that intestinal relaxation is induced by the activation of opioid  $\mu$ -1 receptors.

ATP-sensitive  $K^+$  ( $K_{ATP}$ ) channels are involved in the regulation of intestinal smooth muscle<sup>[15]</sup>. In addition, the opening of  $K_{ATP}$  channels has been reported to reduce intracellular  $Ca^{2+}$  concentration<sup>[16-18]</sup>. The  $K_{ATP}$  channel opener diazoxide has been shown to have the ability to attenuate indomethacin-induced small intestinal damage in rats<sup>[19]</sup>. However, the role of  $K_{ATP}$  channels in loperamide-induced gastrointestinal transit remains obscure.

In an attempt to determine the subtype of opioid  $\mu$ -receptors involved in the regulation of intestinal tone, we used loperamide as an agonist to induce intestinal relaxation in the present study. In addition, specific blockers or antagonists were applied to investigate the potential mechanisms of action of loperamide.

## MATERIALS AND METHODS

### Experimental animals

We obtained 12-wk-old male BALB/c mice from the Animal Center of National Cheng Kung University Medical College. Mice were maintained in a temperature-controlled room ( $25 \pm 1$  °C) under a 12-h light-dark cycle (lights on at 06:00 h). All mice were given water and fed standard chow (Purina Mills, LLC, St Louis, MO, United States) *ad libitum*. All animal-handling procedures were performed according to the Guide for the Care and Use of Laboratory Animals of the National Institutes of Health, and the guidelines of the Animal Welfare Act.

### Gastrointestinal transit assay

Gastrointestinal tract (GIT) in mice was measured according to the method used in a previous study<sup>[20]</sup>. Briefly, 18 h before the experiment, food was withheld from the animals but free access to water was allowed. The mice received 0.25 mL of a suspension of charcoal consisting of 10% vegetable charcoal in 5% gum acacia (Sigma-Aldrich, St Louis, MO, United States) that was administered by an intragastric cannula. In subsequent experiments, the effects of loperamide or other compounds on GIT were evaluated 20 min after administration of the marker. At

that time, the animals were sacrificed, the stomach and small intestine removed and the omentum was separated, avoiding stretching. The length of the intestine from the pyloric sphincter to the ileocecal junction and the distance travelled by the charcoal front were measured and recorded. We also recorded the time at which the mice started to drain stool after the administration of the charcoal meal.

We evaluated the effects of loperamide, stevioside (an agonist of opioid  $\mu$ -1 receptor) or vehicle on GIT using subcutaneous injection into mice. Loperamide, stevioside and vehicle were given 30 min before the charcoal meal. The opioid antagonists cyprodime and naloxonazine were intraperitoneally injected at 60 min before the charcoal meal.

### Preparation of isolated ileum

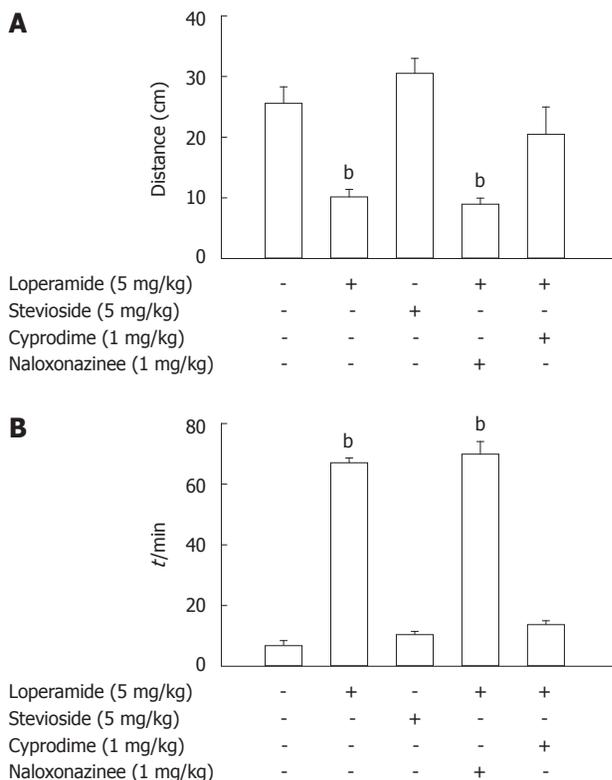

In the *in vitro* experiments, isolated ileum from BALB/c mice was used. Each mouse was killed by decapitation under anesthesia with pentobarbital (50 mg/kg). After the ileum strips had been carefully freed from the fat and connective tissue, the strips were mounted in organ baths filled with 10 mL oxygenated Krebs' buffer (95%  $O_2$ , 5%  $CO_2$ ) at 37 °C containing: 135 mmol/L NaCl; 5 mmol/L KCl; 2.5 mmol/L  $CaCl_2$ ; 1.3 mmol/L  $MgSO_4$ ; 1.2 mmol/L  $KH_2PO_4$ ; 20 mmol/L  $NaHCO_3$ ; and 10 mmol/L D-glucose (pH 7.4). Each preparation was connected to strain gauges (FT03; Grass Instruments, Quincy, MA, United States). The isometric tension was recorded using chart software (MLS023, Powerlab; ADInstruments, Bella Vista, NSW, Australia). Strips were mounted and allowed to stabilize for 2 h. Each preparation was then gradually stretched to achieve an optimal resting tension of 0.5 g.

### Intestinal relaxation induced by loperamide

After the resting tension had stabilized, a solution of acetylcholine (ACh; Sigma-Aldrich) prepared in distilled water was added to the bathing buffer to induce a rapid increase in ileum tone followed by stable constriction (tonic contraction). The final ACh concentration in the organ bath was 1  $\mu$ mol/L. Ileum strips in the treatment group were exposed to loperamide (0.1-10  $\mu$ mol/L) to observe the decrease in the tonic contraction (ileum relaxation). In addition, stevioside, an opioid  $\mu$ -1 receptor agonist<sup>[21]</sup>, was also used to investigate the effect on tonic contraction. Relaxation was expressed as the percentage decrease in the maximum tonic contraction. Concentration-relaxation curves were generated in a cumulative fashion.

### Effects of antagonists on loperamide-induced intestinal relaxation

Ileum strips were exposed to glibenclamide (Research Biochemicals, Wayland, MA, United States), a specific opioid  $\mu$ -1 receptor antagonist (naloxonazine) or a general opioid  $\mu$  receptor antagonist (cyprodime) (Tocris Cookson, Bristol, United Kingdom), for 15 min before addition of loperamide to the organ bath. The strips were treated with an inhibitor of cyclic adenosine monophosphate (cAMP) phosphodiesterase (3-isobutyl-1-methylxanthine; IBMX) or an inhibitor of protein kinase A (PKA) (H-89)

**Figure 1** Role of opioid  $\mu$ -receptors in gastrointestinal tract using charcoal as an indicator. The data represent the distance (A) and time (B) for the transit of charcoal. Data represent the mean  $\pm$  SEM of eight animals. <sup>b</sup> $P < 0.01$  vs the distilled water (vehicle)-treated control.

in the same manner. Forskolin (Sigma-Aldrich) was used as a control. The changes in the relaxation caused by antagonists or blockers were compared with those of the vehicle-treated control.

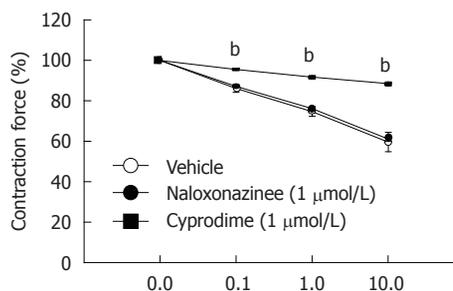

### Statistical analysis

All values are presented as the mean  $\pm$  SEM for a given number of animals or samples. Analysis of variance and Dunnett's post hoc test were used to evaluate the significance between groups.  $P < 0.05$  was considered significant.

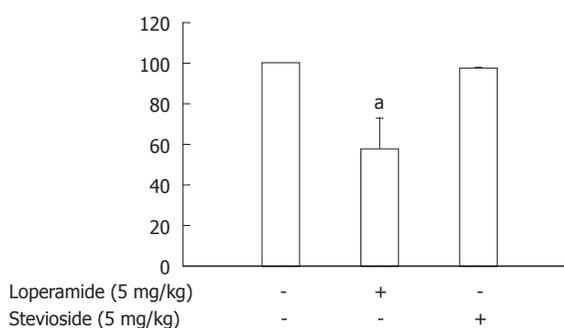

## RESULTS

### Role of opioid receptor in loperamide-induced gastrointestinal transit

As shown in Figure 1A, the distance travelled by charcoal in the loperamide-treated group (5 mg/kg) was shorter than that in the vehicle-treated group. However, the distance travelled in the stevioside-treated (5 mg/kg) group was similar to that in the vehicle-treated group. In addition, pretreatment with cyprodime (1 mg/kg) significantly abolished the effect of loperamide on GIT, but naloxonazine (1 mg/kg) failed to produce the same effect. Moreover, the time for transit of charcoal from the stomach to the anus stool drain in the loperamide-treated group (5 mg/kg) was longer than that in the vehicle-treated group. The transit time of the stevioside-treated (5 mg/kg) group was the same as that of the vehicle-treated group. In addition, pretreatment with cyprodime (1 mg/kg) at-

**Figure 2** Inhibitory effect of cyprodime or naloxonazine on relaxation induced by loperamide (10  $\mu$ mol/L) in isolated ileum contracted with 1  $\mu$ mol/L acetylcholine. Data represent the mean  $\pm$  SEM of the percentage changes in the acetylcholine (ACh)-induced tonic contraction of ileum from eight animals. <sup>b</sup> $P < 0.01$  vs the distilled water (vehicle)-treated control.

**Figure 3** Effect of stevioside on the tone of isolated ileum strips contracted with 1  $\mu$ mol/L acetylcholine. tenuated the loperamide-induced delay in charcoal transit, but naloxonazine (1 mg/kg) failed to exhibit the same action (Figure 1B).

### Effect of opioid receptor blockade on loperamide-induced intestinal relaxation

Ileum strips strongly contracted in response to the application of ACh at 1  $\mu$ mol/L. As shown in Figure 2, loperamide relaxed the ACh-contracted ileum strips in a concentration-dependent manner. At the maximum concentration tested (10  $\mu$ mol/L), loperamide significantly attenuated the tonic contraction of ileum strips to 63.59%  $\pm$  5.60% of the contraction induced by ACh. Cyprodime (1  $\mu$ mol/L) produced a marked attenuation of the relaxation induced by loperamide. However, naloxonazine failed to modify the action of loperamide, even at a higher concentration (1  $\mu$ mol/L). In addition, treatment with stevioside at a dose sufficient to activate the opioid  $\mu$ -1 receptor<sup>[21]</sup> failed to modify the intestinal tone in ACh-contracted ileum (Figure 3).

### Role of cyclic adenosine monophosphate and protein kinase A in loperamide-induced intestinal relaxation

In the present study, forskolin (5  $\mu$ mol/L), a direct activator of adenylate cyclase, was used as a positive control to increase the activity of cAMP, based on the findings of a previous study<sup>[22]</sup>. In ileum strips contracted with

**Table 1** Effects of inhibitors of cyclic adenosine monophosphate-phosphodiesterase or protein kinase A on the relaxation

H-89 (1 $\mu\text{mol/L}$ )	91.31 $\pm$ 3.47 <sup>b</sup>
Glibenclamide (1 $\mu\text{mol/L}$ )	92.45 $\pm$ 3.29 <sup>b</sup>

Effects of inhibitors of cyclic adenosine monophosphate-phosphodiesterase or protein kinase A on the relaxation induced by loperamide (10  $\mu\text{mol/L}$ ) or forskolin (5  $\mu\text{mol/L}$ ) in isolated ileum contracted with 1  $\mu\text{mol/L}$  acetylcholine (ACh). IBMX: 3-isobutyl-1-methylxanthine. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs vehicle treated control.

ACh (1  $\mu\text{mol/L}$ ), forskolin-induced relaxation was also abolished by pretreatment with glibenclamide (1  $\mu\text{mol/L}$ ). Moreover, intestinal relaxation induced by forskolin was increased by the addition of IBMX at a concentration (10  $\mu\text{mol/L}$ ) sufficient to inhibit cAMP-phosphodiesterase<sup>[23]</sup>, and was decreased by addition of H-89 at a concentration (1  $\mu\text{mol/L}$ ), which was sufficient to inhibit the activity of PKA<sup>[24]</sup>. The loperamide-induced intestinal relaxation was also modified by these agents in the same manner. Our results showed that intestinal relaxation induced by loperamide was increased by IBMX and attenuated by H-89 (Table 1).

## DISCUSSION

In the present study, we found that loperamide caused a dose-dependent delay in GIT using charcoal as an indicator in mice. In addition, loperamide induced relaxation in the ileum strips contracted with stimulant. This action of loperamide seems to be related primarily to the activation of opioid receptors in peripheral tissue, because loperamide does not cross into the central nervous system<sup>[7]</sup>. The loperamide-induced action was effectively abolished by cyprodime, suggesting that opioid  $\mu$  receptors were involved. However, this action of loperamide was not reversed by naloxonazine even at a dose sufficient to block opioid  $\mu$ -1 receptors. In addition, as shown in Figure 2, relaxation was not induced by stevioside, which is an agonist specific for opioid  $\mu$ -1 receptors<sup>[21]</sup>. The involvement of opioid  $\mu$ -1 receptors in the intestinal relaxation mechanism of loperamide seems unlikely.

Thus, another opioid  $\mu$  receptor must be involved in this action of loperamide. There is no doubt that loperamide is an agonist of peripheral opioid  $\mu$  receptors<sup>[7,25]</sup>. Opioid  $\mu$  receptors have been divided into three subtypes<sup>[11]</sup>:  $\mu$ -1,  $\mu$ -2 and  $\mu$ -3<sup>[26-28]</sup>. The analgesic action mediated by the activation of opioid  $\mu$ -1 receptors has been report-

ed to exert spinal antinociception<sup>[29,30]</sup>. In addition, the activation of opioid  $\mu$ -1 receptors seems to be related to smooth muscle contraction *via* the PLC-PKC pathway<sup>[14,31]</sup>. Moreover, opioid  $\mu$ -3 receptors are present predominantly in endothelial cells associated with the production of nitric oxide to induce vasodilatation<sup>[32]</sup>. Therefore, the involvement of opioid  $\mu$ -1 or  $\mu$ -3 receptors in intestinal relaxation seems unlikely. Taken together, our results suggest that the activation of opioid  $\mu$ -2 receptors is more likely to participate in the action of loperamide with respect to intestinal relaxation. The activation of opioid  $\mu$ -2 receptors has been reported to be involved in the relaxation of guinea pig ileum and in the inhibition of GIT<sup>[33,34]</sup>. In addition, opioid  $\mu$ -receptor-expressing myenteric neurons are distributed primarily in the small intestine, followed by the stomach and the proximal colon<sup>[35]</sup>. Although constipation is predominantly a large bowel disorder, the presence of opioid  $\mu$  receptors in the colon and the longer GIT time of charcoal to the anus stool drain in mice that received loperamide support the role of opioid  $\mu$ -2 receptors in opiate-induced constipation. Unfortunately, there is no suitable tool or agent that can be used to provide further evidence supporting this hypothesis. Therefore, we focused on the subcellular signals as an alternative experimental approach.

Potassium channels play an important role in the regulation of intestinal smooth muscle cells<sup>[36,37]</sup>. ATP-sensitive  $\text{K}^+$  ( $\text{K}_{\text{ATP}}$ ) channels are composed of four inwardly rectifying  $\text{K}^+$  channel subunits and four regulatory sulfonylurea receptors<sup>[38]</sup>. The activation of  $\text{K}_{\text{ATP}}$  channels induces hyperpolarization of the cell membrane and consequently relaxes the smooth muscle. Thus, we focused on the involvement of  $\text{K}_{\text{ATP}}$  channels in the intestinal relaxation induced by loperamide. We used forskolin as a positive control because forskolin is a direct activator of adenylate cyclase that can increase intracellular cAMP concentration to activate cAMP-dependent PKA, resulting in the opening of  $\text{K}_{\text{ATP}}$  channels<sup>[24]</sup>. As shown in Table 1, we observed that forskolin-induced intestinal relaxation was also blocked by glibenclamide. The intestinal relaxation induced by forskolin was abolished by H-89 at a concentration sufficient to block the activity of PKA<sup>[24]</sup> and was enhanced by IBMX at a concentration sufficient to inhibit the activity of cAMP-phosphodiesterase<sup>[23]</sup>. Similar changes were also observed in ileum strips relaxed by loperamide (Table 1). These data suggest that the potential mechanism responsible for loperamide-induced intestinal relaxation is mediated *via* the cAMP-PKA pathway to open  $\text{K}_{\text{ATP}}$  channels. Therefore, the results provide a novel insight into the mechanism of action of loperamide and increase our understanding of intestinal relaxation. It is reasonable to consider that similar results will be obtained for the parts of the colon that have opioid  $\mu$  receptors. Further investigations are required in the future.

In conclusion, we suggest that the activation of opioid  $\mu$ -2 receptors, which induce the opening of  $\text{K}_{\text{ATP}}$  channels, is responsible for loperamide-induced intestinal relaxation. Therefore, peripheral opioid  $\mu$ -2 receptors will

be a new target in the development of agents for treating OIC.

## ACKNOWLEDGMENTS

## COMMENTS

### Background

Opioid-induced constipation (OIC) is a frequent disorder in tumor patients receiving morphine-like compounds. Thus, it is important to prevent this disorder. To date, it is still unclear which subtype of opioid receptors should be used for development of suitable agents. Loperamide is a well-known agonist of opioid receptors, without the ability to enter the brain. Many studies have reported that loperamide can be used to treat diarrhea, but the receptor site has not been established.

### Research frontiers

Loperamide is a widely used agent in clinics and its effectiveness is believed to arise from peripheral action. In the area of prevention of constipation with loperamide, the research hotspot is how to distinguish the receptor subtype to improve its adverse reactions. Then, it will be useful for prevention of OIC.

### Innovations and breakthroughs

In previous studies of loperamide for treatment of diarrhea, it was found that intestinal motility was significantly decreased. In order to decrease the side effects of loperamide, the authors investigated the receptor subtype that is selectively activated, and the results will be useful for the development of new agents with similar side effects. Thus, the authors compared loperamide with stevioside, which is mainly effective against opioid  $\mu$ -1 receptors. We found that opioid  $\mu$ -2 receptors linked with ATP-sensitive K<sup>+</sup> channels are responsible for intestinal relaxation. Therefore, agents with less effect on opioid  $\mu$ -2 receptors will be useful to decrease the side effects of constipation.

### Applications

The results suggest that opioid  $\mu$ -2 receptors are mainly responsible for intestinal relaxation. Clinical application of agents showing less affinity than loperamide to opioid  $\mu$ -2 receptors could be useful for prevention of constipation.

### Terminology

OIC is a frequent side effect in cancer patients who received morphine-like compounds to reduce pain. Loperamide is a widely used agent for treatment of diarrhea in clinics, and it has no effect in the brain. Opioid receptors are the action site of opioids and related agents. Receptors are generally expressed in various tissues and located on the cell membrane. Subtypes of opioid receptors have been established.

### Peer review

This is a good descriptive study in which the authors analyzed the subtype of opioid  $\mu$  receptors in the intestine of mice. The results are interesting and suggest that opioid  $\mu$ -2 receptors are responsible for intestinal relaxation, which could be useful in preventing constipation by agents with less affinity for this receptor site.

### Abstract

**AIM:** To investigate whether Notch signaling is involved in liver fibrosis by regulating the activation of hepatic stellate cells (HSCs).

**METHODS:** Immunohistochemistry was used to detect the expression of Notch3 in fibrotic liver tissues of patients with chronic active hepatitis. The expression of Notch3 in HSC-T6 cells treated or not with transforming growth factor (TGF)- $\beta$ 1 was analyzed by immunofluorescence staining. The expression of Notch3 and myofibroblastic marker  $\alpha$ -smooth muscle actin ( $\alpha$ -SMA) and collagen I in HSC-T6 cells transfected with pcDNA3.1-N3ICD or control vector were detected by Western blotting and immunofluorescence staining. Moreover, effects of Notch3 knockdown in HSC-T6 by Notch3 siRNA were investigated by Western blotting and immunofluorescence staining.

**RESULTS:** The expression of Notch3 was significantly up-regulated in fibrotic liver tissues of patients with

chronic active hepatitis, but not detected in normal liver tissues. Active Notch signaling was found in HSC-T6 cells. TGF- $\beta$ 1 treatment led to up-regulation of Notch3 expression in HSC-T6 cells, and over-expression of Notch3 increased the expression of  $\alpha$ -SMA and collagen I in HSC-T6 without TGF- $\beta$ 1 treatment. Interestingly, transient knockdown of Notch3 decreased the expression of myofibroblastic marker and antagonized TGF- $\beta$ 1-induced expression of  $\alpha$ -SMA and collagen I in HSC-T6.

**CONCLUSION:** Notch3 may regulate the activation of HSCs, and the selective interruption of Notch3 may provide an anti-fibrotic strategy in hepatic fibrosis.

### INTRODUCTION

Hepatic fibrosis is a reversible wound-healing response characterized by the accumulation of extracellular matrix (ECM) to liver injury<sup>[1]</sup>. In the process of hepatic fibrosis, activated hepatic stellate cells (HSCs) synthesize a large amount of ECM and then change into myofibroblasts<sup>[2]</sup>, which is characterized by the expression of  $\alpha$ -smooth

muscle actin ( $\alpha$ -SMA) and ECM, particularly collagen I. Myofibroblast is one of the key cellular components involved in liver fibrosis, therefore, the majority of anti-fibrotic therapies are designed to inhibit the activation, proliferation, or synthetic products of HSCs<sup>[3]</sup>.

Notch signaling is an ancient cell signaling that regulates cell fate specification, stem cell maintenance, and initiation of differentiation in embryonic and postnatal tissues<sup>[4,5]</sup>. More recently, some researches reported that Notch signaling was implicated in human fibrosis diseases, such as pulmonary, renal and peritoneal fibrosis<sup>[6-8]</sup>. Several researches suggested that the Jagged/Notch pathway may selectively mediate fibrogenic properties of transforming growth factor- $\beta$ 1 (TGF- $\beta$ 1) which was essential to promote the production and deposition of ECM<sup>[9-11]</sup>.

Notch receptors (Notch1, Notch2 and Notch4) were present at the mRNA level in freshly isolated HSCs, and the synthesis of Notch1 decreased during culture and development of HSCs into myofibroblast-like cells<sup>[12]</sup>. However, the expression of Notch3 in phenotype activated HSCs remains unknown. Ono *et al.*<sup>[13]</sup> reported that Notch3 was required for TGF- $\beta$ 1-induced myofibroblastic differentiation of myoblasts. Based on the studies above, the present study was undertaken to investigate whether Notch3 was expressed in fibrotic liver tissues of patients with chronic active hepatitis and in activated HSCs, and sequentially contributed to liver fibrosis by regulating the activation of HSCs.

## MATERIALS AND METHODS

### Patients and liver biopsy samples

Liver tissue samples were obtained by biopsy from 11 patients with chronic active hepatitis (5 women and 6 men; median age 43 years, range 31-55 years). Control liver biopsy specimens were obtained from healthy volunteers ( $n = 6$ ). All patients and controls signed consent forms approved by the Ethics Committee of Tongji Medical College, Huazhong University of Science and Technology. Tissue samples were fixed in 10% formalin and paraffin-embedded for immunohistochemical analysis.

### Antibodies and reagents

Rabbit polyclonal to  $\alpha$ -SMA and Notch3 were obtained from Abcam (Cambridge, United States). Rabbit polyclonal anti-collagen I antibody was purchased from Bioss Corporation (Beijing, China). Horseradish peroxidase (HRP)-conjugated anti-rabbit IgG was obtained from Santa Cruz Biotechnology (Santa Cruz, United States). Recombinant human transforming growth factor (TGF)- $\beta$ 1 was purchased from PeproTech EC Ltd (London, United Kingdom). Lipofectamine™ 2000 transfection reagent was obtained from Invitrogen (Carlsbad, United States).

### Cell line and culture conditions

HSC-T6 cells, an immortalized rat HSC line, purchased from Cancer Institute and Hospital, Chinese Academy of Medical Sciences (China), were cultured in Dulbecco's

-modified Eagle's medium (DMEM; Gibco, United States) supplemented with 100 U/mL penicillin, 100  $\mu$ g/mL streptomycin, and 10% fetal bovine serum (FBS) (Gibco, United States). TGF- $\beta$ 1 (2 ng/mL) was incubated in growth medium for 24 h.

### Immunohistochemistry and immunocytofluorescence analysis

Liver tissue sections were incubated with 3% H<sub>2</sub>O<sub>2</sub> followed by serum blocking with 10% goat serum in 5% bovine serum albumin (BSA). The Notch3 was detected by staining with polyclonal rabbit anti-Notch3 (1:250) overnight at 4 °C. Irrelevant isotype antibodies (Santa Cruz Biotechnology, United States) at the same concentration were used as control. The staining was carried out using SABC kit (Boster, China).

Cells were fixed in phosphate buffered saline (PBS) containing 4% paraformaldehyde at room temperature for 30 min and were penetrated in blocking solution (Amresco, United States) containing 0.3% Triton X-100, and incubated overnight with either anti-Notch3 (1:250), anti- $\alpha$ -SMA (1:100) or anti-collagen I (1:100) antibody in 1% BSA solution. Then, cells were incubated with secondary antibodies for 1 h at 37 °C. After incubation, cells were stained with nuclear stain marker 4',6-diamidino-2-phenylindole. The reaction was examined under confocal microscope (Nikon, Japan).

### Transfection of siRNA and plasmid

HSC-T6 was seeded into 6-well plates at a density of  $1 \times 10^5$  cells 12 h before transfection. siRNA was mixed with 5  $\mu$ L lipofectamine 2000 in 250  $\mu$ L Opti-MEM I medium for 20 min. The transfection mixture was then added to each well with 1.5 mL FBS free DMEM at a concentration of 100 nmol/L. After 6-h incubation, liquid mixture containing siRNA was disposed. Two mL DMEM containing 10% FBS was added and incubated for another 72 h. The following siRNA sequences were used: Notch3 siRNA: 5' ACAAGAUCAAUACAGGAGCTT 3'; the control siRNA sequence: 5' UUGUAC UACACAAAAGUACUG 3'. These siRNA were synthesized by Shanghai Genepharma Co. Ltd. (Shanghai, China).

HSC-T6 was transfected with Notch3 intracellular domain (Notch3-ICD) cDNA cloned into pcDNA3.1 (pcDNA3.1-N3ICD) vector, which was a gift from Dr. Tao Wan. The control (pcDNA3.1-empty) vector was purchased from Shanghai Genepharma Co. Ltd. (Shanghai, China). All transfections were performed using Lipofectamine 2000 following the manufacturer's instructions.

### TaqMan quantitative reverse transcription polymerase chain reaction

Total RNA from each sample was extracted using Trizol (Invitrogen) according to the manufacturer's instructions. Real-time polymerase chain reaction (RT-PCR) was performed using a StepOne/StepOne-Plus (ABI) and the TaqMan PCR Reagent (Genepharma). Primer sequences are summarized in Table 1. Comparative threshold (Ct)

**Table 1** Primer sequences for TaqMan real-time reverse transcription polymerase chain reaction

method was used for calculating the relative amount of mRNA of treated sample compared with control samples.

### Western blotting assay

Cells were washed with PBS and lysed. The extracts were cleared by centrifugation at  $12\,000 \times g$  for 15 min. After blocking with 5% non-fat milk in PBS containing 0.1% Tween 20 for 1 h at room temperature, membranes were incubated with either anti-Notch3 (1:1000), anti- $\alpha$ -SMA (1:300) or anti-collagen I (1:200) antibody in tris-buffered saline (TBS) containing 0.05% Tween 20 at 4 °C overnight. Then membranes were incubated with HRP-conjugated secondary anti-rabbit IgG (1:2000) antibody in TBS and Tween 20 for 1 h at room temperature, and visualized by chemiluminescence using an electrochemiluminescence immunoblotting kit (Cell Signaling Technology) with a digital luminescent image analyzer Bio-Spectrum600 (UVP, United States). Band intensity was assessed using Gel-Pro analyzer.

### Statistical analysis

All experiments were repeated three times, and data recorded as mean  $\pm$  SD and analyzed by Student's *t* test using SPSS12.0 software.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Expression of Notch3 in fibrotic liver tissues of patients with chronic active hepatitis

All patients were positive for the Notch3 in fibrotic liver tissues (Figure 1A). In contrast, Notch3 was not detected by immunohistochemistry in normal liver tissues (Figure 1C).

### Expression of Notch3 in hepatic stellate cell-T6 cells

To detect expression of Notch3 in HSCs, immunofluorescence staining analysis was performed to examine the expression of Notch3 in HSC-T6 cells. The result showed that Notch3 protein was localized in the cytoplasm and nucleus of HSC-T6 cells (Figure 2).

### Up-regulation of Notch3 expression by transforming growth factor- $\beta$ 1 in hepatic stellate cell-T6 cells

We investigated the effect of TGF- $\beta$ 1 on Notch signaling in HSC-T6 treated with TGF- $\beta$ 1 (0.5, 1, 2 and 4 ng/mL) for 24 h. RT-PCR analysis showed that the expression of Notch signaling components including Notch3, Jagged1 and Hes-1 were obviously increased in HSC-T6 treated with 2 ng/mL TGF- $\beta$ 1 as compared with the control group without TGF- $\beta$ 1 treatment ( $P < 0.05$ , Figure 3).

### Over-expression of Notch3 increased the expression of myofibroblastic marker in hepatic stellate cell-T6

To investigate the effect of Notch3 in activation of HSCs, we examined if overexpression of Notch3 in HSC-T6 would enhance the activation. The results showed that the increased expression of Notch3 in pcDNA3.1-N3ICD introduced HSC-T6 cells as compared with cells transfected with pcDNA3.1-empty vector ( $P < 0.05$ , Figure 4A). Western blotting and immunofluorescence staining analyses demonstrated that over-expression of Notch3 led to increased expression of  $\alpha$ -SMA and collagen I compared with control group ( $P < 0.05$ , Figure 4A and B).

### Knockdown of Notch3 by siRNA downregulated the expression of myofibroblastic marker in hepatic stellate cell-T6

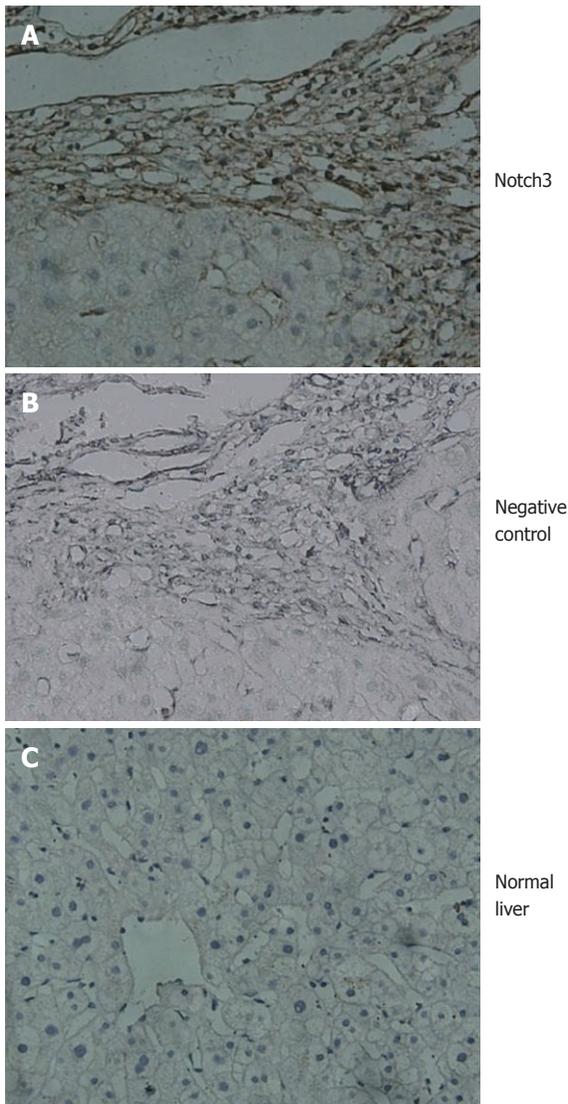

To further confirm the role of Notch3 in regulating activation of HSCs, siRNA was employed to specifically knockdown Notch3. Western blotting analysis showed that siRNAs targeting Notch3 reduced Notch3 protein levels by approximately 80%. Seventy and two hour after transfection in HSC-T6 ( $P < 0.05$ , Figure 5A). We also observed that knockdown of Notch3 in HSC-T6 down-regulated the expression of  $\alpha$ -SMA and collagen I detected by Western blotting and immunofluorescence staining 72 h after siRNA transfection ( $P < 0.05$ , Figure 5A and B).

To investigate the relationship between Notch3 and TGF- $\beta$ 1, TGF- $\beta$ 1 (2 ng/mL) was added into HSC-T6 24 h before transfection with siRNAs targeting Notch3 or control siRNAs. Western blotting and immunofluorescence staining analyses demonstrated that knockdown of Notch3 antagonized TGF- $\beta$ 1-induced expression of  $\alpha$ -SMA and collagen I in HSC-T6 ( $P < 0.05$ , Figure 5A and B).

## DISCUSSION

Liver fibrosis is the result of the wound-healing response to repeated injury in liver. It is well known that HSCs activation plays an important role in fibrosis because these cells become the primary source of extracellular matrix in liver upon injury. TGF- $\beta$ 1 is known to promote fibrogenesis *in vivo* and *in vitro*, however, development of anti-fibrotic strategies targeting the TGF- $\beta$  axis is problematic owing to the pleiotropic nature of TGF- $\beta$  action<sup>[1]</sup>.

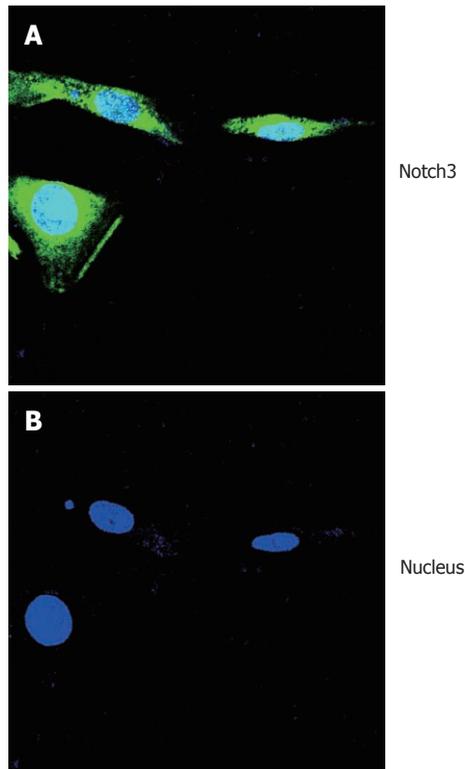

Notch signaling is an evolutionarily conserved local cell-signaling that functions in the determination of cellular identity during developmental stages<sup>[14]</sup>. Four Notch proteins (Notch1, Notch2, Notch3 and Notch4) have

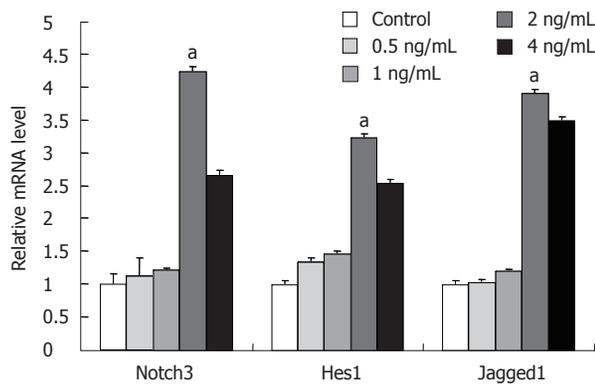

**Figure 1** Immunohistochemical staining of Notch3 in liver tissues of patients with chronic active hepatitis and normal livers. A: Intense staining of Notch3 in fibrotic tissues of livers from patients with chronic active hepatitis; B: Negative control; C: Notch3 was not detected in normal liver tissues (x 400).

been identified in vertebrates, while membrane-bound proteins (Delta and Jagged) have been recognized as Notch ligands<sup>[15]</sup>. Activation of the pathway usually occurs via expression of the ligand in signal-giving cells. Upon interaction with the ligand, Notch undergoes a series of proteolytic cleavages in the signal-receiving cells. Finally, the cytoplasmic domain, referred to as the Notch intracellular domain (NICD), translocates to the nucleus, where it binds with the transcription factor CSL [CBF-1/RBP-Jk, Su (H) and Lag-1] and co-activator Mastermind-like to trigger downstream target genes expression, such as HES1 and HEY which act as transcription factors<sup>[16-20]</sup>.

Notch signaling is essential for the regulation of cell differentiation, and its aberrant activation was implicated in human fibrosis diseases. Notch1 signaling in response to inflammatory zone 1 may play a significant role in myofibroblast differentiation during lung fibrosis<sup>[6]</sup>. Active Notch pathway in tubular epithelial cells was demonstrat-

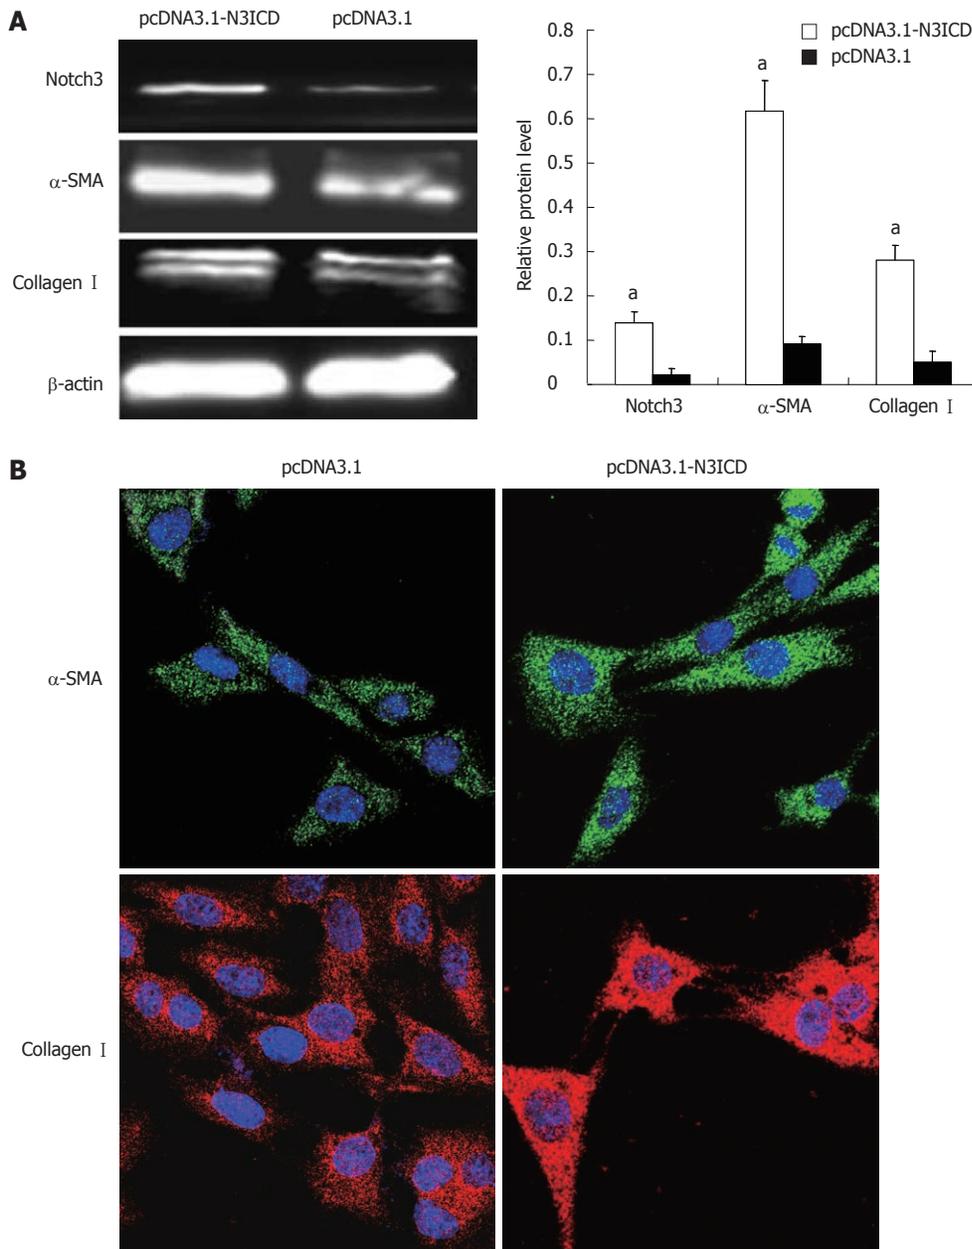

**Figure 2** Immunofluorescence staining analysis was performed to examine expression of Notch3 in hepatic stellate cell-T6 cells. A: The green fluorescence represents the expression of Notch3; B: Blue one represents nucleus of hepatic stellate cell-T6 cells (x 400).

**Figure 3** TaqMan reverse transcription polymerase chain reaction analysis was performed to detect expression of Notch3, Jagged1 and Hes1 in hepatic stellate cell-T6 cells treated or not with transforming growth factor- $\beta$ 1 (0.5, 1, 2 and 4 ng/mL) for 24 h. <sup>a</sup>*P* < 0.05 vs control group.

ed as a critical regulator of tubulointerstitial fibrosis<sup>[7]</sup>. It was reported that Notch signaling was highly activated in rats with fibrotic peritoneum induced by peritoneal dialysis fluid, as indicated by increased expression of Jagged1, Notch1, and HES1. Blocking Notch signaling activation by intraperitoneal injection of a  $\gamma$ -secretase inhibitor significantly attenuated peritoneal fibrosis as indicated by the decreased expression of  $\alpha$ -smooth muscle actin and collagen I<sup>[8]</sup>.

In this study, the Notch3 was not detected in normal liver tissues. In contrast, intense staining of the Notch3

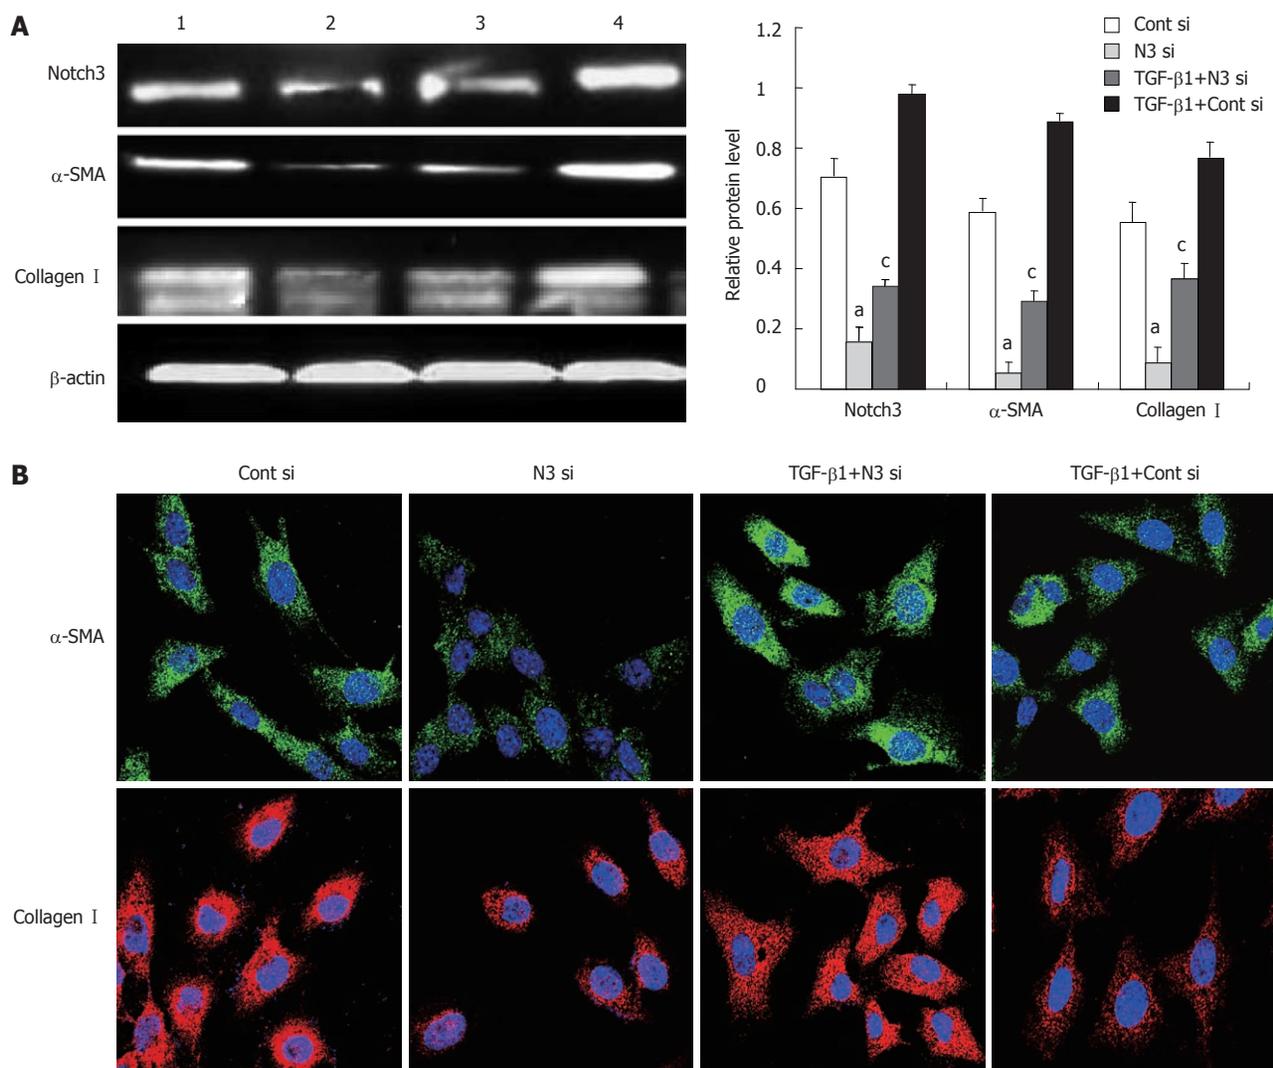

**Figure 4** Over-expression of Notch3 intracellular domain increased the expression of myofibroblastic marker in hepatic stellate cell-T6. A: The expression of Notch3,  $\alpha$ -smooth muscle actin (SMA) and collagen I were detected by Western blotting; B: The expression of  $\alpha$ -SMA and collagen I was also detected by immunofluorescence staining (x 400), <sup>a</sup> $P < 0.05$  vs control group.

was observed in fibrotic liver tissues of patients with chronic active hepatitis, which suggested that Notch3 was involved in liver fibrosis. Furthermore, several lines of evidence clearly confirmed that Notch3 contributed to liver fibrosis by regulating activation of HSCs. First, the expression of active Notch3 was found in the nucleus of HSC-T6. Second, the expression level of Notch signaling components was elevated including Notch3, Jagged1 and Hes1 in HSC-T6 after TGF- $\beta$ 1 treatment. More importantly, we also found that specific knockdown of Notch3 by siRNA antagonized TGF- $\beta$ 1-induced expression of myofibroblastic marker  $\alpha$ -SMA and collagen I in HSC-T6, and on the contrary, over-expression of Notch3 increased the expression of myofibroblastic marker in HSC-T6.

Inhibition of the  $\gamma$ -secretase complex required for release of the active NICD is the most common method for targeting Notch signaling<sup>[21,22]</sup>. Two different inhibitors are being evaluated in clinical trials for the treatment of resistant T cell acute leukemia and advanced breast cancer (www.clinicaltrials.gov). However, targeting of  $\gamma$ -secretase would result in several adverse events when Notch receptors from Notch1 to Notch4 are affected<sup>[23,24]</sup>. In this study, we found that the selective interruption of Notch3 by siRNA decreased the expression of myofibroblastic marker in HSC-T6 cells, which provided a potential novel therapeutic target for liver fibrosis.

However, further studies are required to elucidate how do other members of Notch family, such as Notch1, Notch2 and Notch4, play a part in activated HSCs as

**Figure 5** Knockdown of Notch3 decreased the secretion of myofibroblastic marker in hepatic stellate cell-T6. A: Effects of Notch3 knockdown in HSC-T6 using Notch3 siRNA (N3 si), and control siRNA (Cont si) were investigated. Expression of Notch3,  $\alpha$ -smooth muscle actin (SMA) and collagen I was detected by Western blotting; B: The expression of  $\alpha$ -SMA and collagen I was also detected by immunofluorescence staining (x 400). <sup>a</sup> $P < 0.05$  vs control siRNA group, <sup>c</sup> $P < 0.05$  vs transforming growth factor (TGF)- $\beta$ 1+control siRNA group. 1: Cont si; 2: N3 si; 3: TGF- $\beta$ 1+N3 si; 4: TGF- $\beta$ 1+Cont si.

well as the mechanism underlying the Notch signaling in liver fibrosis. In addition, the contribution of Notch and TGF- $\beta$ 1 signaling to the liver fibrosis should also be further investigated.

In conclusion, we demonstrated for the first time that Notch3 plays a role in regulating the activation of HSCs (HSC-T6). Therefore, the selective interruption of Notch3 may have a potential anti-fibrogenic effect in liver fibrosis.

## COMMENTS

### Background

It is well known that hepatic stellate cell (HSC) activation plays an important role in fibrosis because these cells are the primary source of extracellular matrix in liver upon injury. Notch signaling regulates many aspects of morphogenesis through diverse effects on differentiation, proliferation, and cell survival. Recently, some researches reported that Notch signaling was implicated in human fibrosis diseases, such as pulmonary, renal and peritoneal fibrosis.

### Research frontiers

This study was undertaken to investigate whether Notch signaling is activated in HSCs and sequentially contributed to liver fibrosis by regulating the activation of HSCs.

### Innovations and breakthroughs

This is the first study to characterize the role of Notch signaling in liver fibrosis. This finding indicated that Notch3 may contribute to liver fibrosis by regulating the activation of HSCs.

### Applications

This study showed that the selective interruption of Notch3 by siRNA decreased the expression of myofibroblastic marker in hepatic stellate cell-T6 cells, which provided a potential novel therapeutic target for liver fibrosis.

### Peer review

This is a very interesting study aimed at investigating the role of the Notch signaling pathway in liver fibrosis. The text is generally well written, with structured abstract and organized sections. The manuscript has scientific value since it includes original information about a relevant topic.

### Abstract

**AIM:** To evaluate the role of endoscopic stenting with or without concurrent 3-dimensional conformal chemoradiotherapy (3D-CRT) in patients with inoperable esophageal cancer.

**METHODS:** Advanced esophageal cancer patients indicated for esophagectomy received esophageal stents. A part of patients completed 3D-CRT after stenting. Efficacy was assessed by endoscopy and computed tomographic scan before and 4 wk after completion of the treatment. The median survival, 3D-CRT toxicity and complications were compared between 3D-CRT and control groups.

**RESULTS:** From 1999 to 2008, 99 consecutive patients with T3/T4 disease and unsuitable for esophagectomy were placed with esophageal stents. Sixty-seven patients received 3D-CRT, while 36 patients treated with

endoscopic stents alone were recruited as controls. After 3D-CRT treatment, the median tumor volume of 3D-CRT patients were reduced significantly from  $43.7 \pm 10.2 \text{ cm}^3$  to  $28.8 \pm 8.5 \text{ cm}^3$  ( $P < 0.05$ ). The complete and partial response rate was 85.1%, and no response was 14.9%. After 3D-CRT, the incidence rate of T2 and T3 disease evident on CT scan increased to 78.4% while T4 decreased from 66.7% to 21.6% ( $P < 0.05$ ). 3D-CRT Karnofsky Performance Status improved in 3D-CRT patients compared with the control group ( $P = 0.031$ ). 3D-CRT patients had a longer survival than the control group (251.7 d vs 91.1 d,  $P < 0.05$ ). And the median half-year survival rate in 3D-CRT group (91%) was higher than in the control group (50%,  $P < 0.05$ ). The most common toxicity was leukocytopenia in the 3D-CRT group (46.7% vs 18.8%,  $P = 0.008$ ). The control group had a higher rate of restenosis than the 3D-CRT group (81.3% vs 9.0%,  $P < 0.05$ ). The rate of nephrotoxicity was increased in 3D-CRT as compared with the control group (31.3% vs 15.6%,  $P < 0.05$ ).

**CONCLUSION:** 3D-CRT can improve dysphagia in patients with inoperable esophageal carcinoma. 3D-CRT combined with stenting results in better survival as compared with endoscopic stents used alone.

## INTRODUCTION

Esophageal cancer is one of the most common malignant tumors with a high mortality rate in almost a half of the cases, and is the fourth leading cause of cancer-related deaths in China<sup>[1,2]</sup>. Most patients have been already in an advanced stage at the diagnosis of this aggressive malignancy. At least 60% of patients are unsuitable for surgical resection either due to the advanced stage or their comorbidity<sup>[3]</sup>. At this stage, esophageal carcinoma has infiltrated surrounding tissues and caused esophageal stenosis, and even esophagotracheal fistula in some cases. These patients could only be treated with palliative procedures which play an important role in improving the patient's life quality. The current palliative means include radiotherapy, chemotherapy and esophageal stent placement. However, esophagitis is usually unavoidable after radiotherapy, and once esophagitis occurred, dysphagia would be exacerbated<sup>[4]</sup>. Some patients even can not swallow liquid diet, some can not endure the chemotherapy and radiotherapy for their poor nutritional status. Stents placement has become a safe and effective palliation for dysphagia due to malignant esophageal obstruction or strictures after radiotherapy<sup>[5]</sup>. A randomized trial demonstrated that the combination of endoscopic stenting with additional radiation and chemotherapy could improve the survival of advanced esophageal cancer patients<sup>[6,7]</sup>. We evaluated the feasibility and efficacy of esophageal stenting combined with simultaneous radiotherapy and chemotherapy in the treatment of advanced esophageal cancer.

## MATERIALS AND METHODS

### Patients

All esophageal cancer patients treated in Qingdao Municipal Hospital from January 1999 to September 2008 were identified. The care of esophageal cancer patients was planned under the auspices of a multidisciplinary gastrointestinal disease management team which includes surgical oncologists, medical oncologists, gastroenterologists, pathologists, interventional radiologists, and radiation oncologists. This study was approved by the Ethics Committee of our institution and informed consent was obtained from all the patients before enrollment.

Clinical staging was performed with endoscopy and endoscopic ultrasound and computed tomography (CT). The tumor, node, metastasis and staging classification used for this analysis were defined according to the American Joint Committee on Cancer staging system version 6.0<sup>[8]</sup>.

Inclusion criteria for the study were: (1) esophageal cancer at stage III or IV unsuitable for esophagectomy; (2) symptoms of dysphagia  $\geq$  grade 3 (Table 1); (3) tumors were mainly located in the esophagus; (4) adequate bone marrow (white blood cell  $> 3.5 \times 10^9/L$ , hemoglobin  $> 90$  g/L, platelet count  $> 100 \times 10^9/L$ ), and hepatic (bilirubin 1.5 times the upper limit of the normal value) and renal functions (calculated creatinine clearance  $> 50$  mL/

Inability to swallow anything, including saliva

min or creatinine  $< 2$  mg/dL) were examined before administration of chemotherapy; (5) a minimum life expectancy of 5 mo; and (6) stay in hospital during the entire chemoradiotherapy treatment course.

Patients were excluded because: (1) with tumors predominantly located in the stomach; (2) with prior treatment, including surgery, chemotherapy, or radiotherapy; and (3) with tumors infiltrating the tracheobronchial tree found on CT.

Data collected included patient clinical demographics, Karnofsky Performance Status, dysphagia grade, 76% meglumine diatrizoate compound swallow esophagogram (esophageal strictures) findings, endoscopic findings (tumor length at initial endoscopy, primary tumor, and lymphadenopathy location), tumor histology, and results of CT scan of the chest and abdomen with intravenous contrast.

### Procedure of stenting

The procedure was performed under local anesthetic spray, with intravenous sedation when required. Endoscopy was done to determine precisely the site and length of stenosis. All patients with strictures underwent dilation with 12-14 mm flexible rubber Savary-Guillard dilators before stent placement. Once this stricture was successfully dilated, a distal hemoclip (resolution clip, Boston Scientific, United States) was placed 2 cm below the area of stricture. Then endoscope was advanced farther and a flexible guidewire was placed into the second portion of the duodenum. The covered self-expanding Titanium Nickel alloy mesh stent (MTN, Nanjing Microinvasive Medical Inco., Nanjing, China) has a polyester at its mid-section and its proximal end is flared to a diameter of 25 mm. The stent was loaded onto a dedicated applicator (12-14 mm depending on the diameter of stent) with an atraumatic dilator tip and was placed under continuous fluoroscopic guidance using the distal hemoclip as a mark. The length chosen was at least 2 cm longer than the stenosis. An 18 mm-diameter stent was used for severe strictures; and a 21 mm-diameter stent was used for moderate strictures.

### Three-dimensional conformal chemoradiotherapy

Three-dimensional conformal chemoradiotherapy (3D-CRT) protocol was used. CT scans displayed isodose distributions and directly obtain dose-volume histograms. The primary tumors as well as the loco-regional lymph nodes were irradiated with an International Commission on Radiation Units and Measurements reference dose of 45.0 Gy in 25 fractions with 1.8 Gy/d using a LINAC

SCC: Squamous cell carcinoma; 3D-CRT: 3-dimensional conformal chemoradiotherapy.

6-MV X-ray unit (Varian, CA, United States), and the total dose was adjusted according to patients' tolerance. Chemotherapy regimens consisted of cisplatin 60 mg/m<sup>2</sup> infusion on day 1 and day 22, plus continuous infusion of 5-fluorouracil at 200 mg/m<sup>2</sup> per day from day 1 to day 42.

### Clinical response criteria

The clinical response to treatment was categorized as a clinically complete response (CR), partial response (PR), stable disease (SD), or progressive disease (PD). CR was defined as the disappearance of all clinically detectable lesions; CR of primary tumors was defined as the disappearance of all visible lesions, including ulceration, with no microscopic evidence of tumor in randomly obtained biopsy specimens from the previous lesion sites. PR was defined as either a reduction exceeding 50% of the initial sizes (products of dimensions) of all measurable tumors according to CT or esophagography. A new lesion or more than a 25% increase of the original tumor size was defined as PD. All other conditions were categorized as SD. Chest CT was repeated every 4 wk to assess the response of the tumor. Endoscopy or abdominal CT was repeated if necessary.

### Statistical analysis

The data was analyzed using SPSS 13.0, mean ± SD were calculated. Continuous variables were analyzed using Student's *t* test. Categorical variables were compared using  $\chi^2$  test or Fisher's exact test, whichever applicable. Repeated measure analysis (two-way ANOVA) was also used. Sur-

vival curves were estimated by the Kaplan-Meier method. A *P* value of 0.05 or less was considered significant.

## RESULTS

### Patient characteristics

Among the 146 patients who were diagnosed as having inoperable esophageal cancer, 111 (76.0%) were eligible for treatment with palliative 3D-CRT. Nine patients did not complete 3D-CRT because of disease progression. One patient died of severe bleeding 12 d after 3D-CRT. Two patients developed febrile neutropenia, and stopped the chemotherapy. Thirty-two patients did not undergo 3D-CRT after stents placement because their preference, these patients were regarded as the control group. Sixty-seven patients completed the 3D-CRT segment with a total radiation dose over 40Gy. Among these patients, 38 received 40Gy, and 29 received 50-55Gy. These patients were enrolled as the 3D-CRT treatment group. The clinical and demographic characteristics of the patients in 3D-CRT and control groups are shown in Table 2. There was no obvious difference in the dysphagia grade, tumor type, tumor stage and tumor size between the two groups.

### Response after 3-dimensional conformal chemoradiotherapy

After 3D-CRT treatment, the median tumor volume of the 67 patients measured by CT scan reduced significantly from 43.7 ± 10.2 cm<sup>3</sup> to 28.8 ± 8.5 cm<sup>3</sup> (*P* < 0.05). The complete or partial response (> 50% reduction of tumor volume) was observed in 57 patients (85.1%), and no response in 10 patients (14.9%). The cases of T2 and T3 disease evident on CT scan had increased from 0 to 40 (78.4%) after 3D-CRT, and that of T4 decreased from 34 (66.7%) to 11 (21.6%) (*P* < 0.05). After 3D-CRT, the number of cases of dysphagia at grade ≤ 3 among the 67 patients increased significantly from 6 (9.0%) to 55 (82.1%), while the number of dysphagia at grade ≥ 4 reduced from 61 (91.0%) to 12 (17.9%), (*P* < 0.05). Karnofsky Performance Status improved in the 3D-CRT patients compared with the control group (*P* = 0.031). The result of response assessed by CT scan and endoscopy is listed in Table 3.

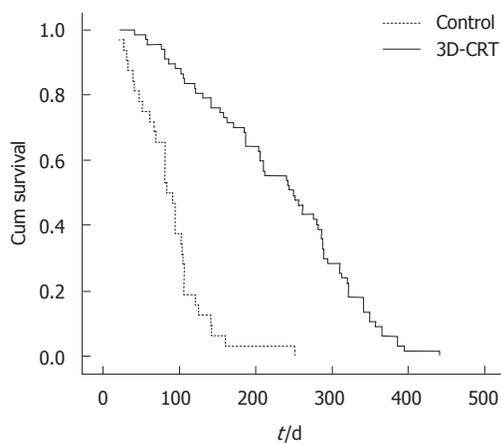

### Survival comparison

Patients treated with 3D-CRT seemed to have a better prognosis, with a longer survival duration (251.7 d *vs* 91.1 d, *P* < 0.05; Figure 1). The median six-month survival rate in 3D-CRT group (91%) was higher than in the control group (50%, *P* < 0.05, Table 4). The overall 1-year survival rate after 3D-CRT was 25%; none of the control patients survived more than 1 year. Although the mean number of hospital admissions was significantly higher in patients who received 3D-CRT (146 ± 48 d *vs* 87 ± 29 d, *P* < 0.05), the overall survival of the 3D-CRT group without hospitalization was statistically significantly higher than that of the control group (186 ± 33 d *vs* 59 ± 18 d, *P* < 0.05).

**Table 3 Radiological and clinical evaluation after 3-dimensional conformal chemoradiotherapy**

	Before 3D-CRT	After 3D-CRT	P value
Tumor staging			
T2 and T3	0	40 (78.4%)	< 0.05
T4	34 (66.7%)	11 (21.6%)

3D-CRT: 3-dimensional conformal chemoradiotherapy.

**Figure 1 Comparison of overall survival between 3D-CRT and control groups.** 3D-CRT: 3-dimensional conformal chemoradiotherapy.

**Toxicity and complications**

The toxicity profile is presented in Table 5. After 3D-CRT, the most common toxicity was leukocytopenia as compared with the control group without 3D-CRT treatment (46.7% *vs* 18.8%, *P* = 0.008). However, in the control group, the most common non-hematologic toxicities included a higher rate of restenosis compared with 3D-CRT group (81.3% *vs* 9.0%, *P* < 0.05). The incidence of nephrotoxicity in 3D-CRT was higher than in control group (31.3% *vs* 15.6%, *P* < 0.05).

**DISCUSSION**

About more than 90% of esophageal cancer patients are not clinically identified until at an advanced stage, their prognosis is the poorest among the patients with digestive carcinomas, with a 5-year survival rate below 10%<sup>[1]</sup>. Because of malnourishment due to comorbid conditions in advanced carcinoma, more than 50% of esophageal cancer cases are unresectable<sup>[9]</sup>. A case-control study showed that the median survival time for patients with advanced esophageal cancer was only 3-5 mo<sup>[10]</sup>. However, once

3D-CRT: 3-dimensional conformal chemoradiotherapy.

these inoperable patients' physical condition was permitted, effective therapies should be performed. No matter which therapy is used, the primary purpose is to prolong the patients' survival time and improve their quality of life. In this study, we relieved the dysphagia with minimal morbidity and mortality, and then choose the suitable management to prolong the patients' life span and improve their quality of life.

Recently, 3D-CRT appeared to be a promising treatment even for esophageal carcinoma patients with distant metastasis<sup>[11]</sup>. Because CDDP and 5-FU have synergistic effects and also act as radiosensitizers, these agents were considered to be particularly effective in combination with radiotherapy<sup>[12]</sup>.

In our study, we focused on the 3D-CRT effectiveness in the inoperable esophageal cancer patients. Ten years ago, we could only place stents to palliate dysphagia among these patients. And in recent years after stents placement, 3D-CRT could be performed as long as patient's physical condition allowed, and whenever their dysphagia was relieved, the malnutrition of the patients was ameliorated. For these inoperable patients, esophageal stents placement not only improved their quality of life, but made the 3D-CRT completion possible as well. In our study, compared with the patients treated with stenting only, at least 25% of the inoperable patients after 3D-CRT survived 1-year, and their six-month survival rate was also higher. 3D-CRT could reduce the tumor volume

and improve Karnofsky Performance Status in the inoperable patients. Combined with 3D-CRT, it seemed that the esophageal stent placement is the adjuvant therapy with CRT. We found that stenting combined with 3D-CRT could improve the inoperable patients' quality of life, and prolong their survival. Fietkau<sup>[4]</sup> thought that simultaneous CRT should be considered as the standard treatment for inoperable carcinoma of the esophagus with the median survival time between 13 and 18 mo. The reason why Fietkau's result<sup>[4]</sup> was better than ours may be that there were more inoperable stage III/IV patients in our study as compared with the stage II/III patients in Fietkau's study.

3D provides the superior dose distributions in the target volume with markedly reduced morbidity to the surrounding normal tissues. Minsky found that increasing the percutaneous radiation dose from 50.4 to 64.8 Gy did not result in better survival<sup>[13]</sup>. Part of the patients in our study received radiation dose of less 40Gy due to the complications such as perforation or esophagitis. Although there is still no consensus of the optimal dose of radiation within the framework of simultaneous RCT, there has been a common opinion that the higher dose of radiation the more therapy-related deaths. In our study, our therapeutic purposes were not to remit or downstage the tumor, but to alleviate the pain and improve the quality of life of the patients. Moreover, 3D-CRT with covered metal stenting would cause a relatively higher rate of late complications such as stent migration, hemorrhage, and gastroesophageal mucosal prolapse. The results from some studies about the safety of self-expandable metallic stents for patients who have undergone chemoradiotherapy were controversial<sup>[14-16]</sup>. Therefore, more studies should be conducted.

In our study, there was no difference of complications such as perforation, shift and brush off of stent and pectoralgia between the 3D-CRT group and the control group with only stenting. Because we did not determine whether lymph node metastasis occurred in these patients without biopsies from esophagectomy, we did not compare the patients with and without lymph node metastasis. Those who could not be treated by 3D-CRT due to poor physical conditions served as controls, and there might be selection bias in this study.

Fietkau<sup>[4]</sup> pointed out that CRT could increase the treatment-related toxicity, in particular, the hematological side effects. This result was in agreement with ours, which was caused by 3D-CRT such as leukocytopenia and nephrotoxicity. After 3D-CRT, more leukocytopenia and nephrotoxicity occurred, but less restenosis was found as compared with the control group. Therefore, among the patients with leukocytopenia and liver and renal dysfunctions, caution should be exercised in the application of 3D-CRT.

Furthermore, more patients were relieved from dysphagia during the later stages of life after 3D-CRT treatment. 3D-CRT is beneficial for the majority of patients with advanced esophageal cancer in the improvement of quality of life and survival. In our study, endoscopic stent-

ing with 3D-CRT for advanced esophageal cancer patients could relieve the dysphagia and prolong the survival, and decrease the incidence of restenosis as well. Therefore, more efficient and combined management should be explored and studied to improve the survival and quality of life of the patients with advanced esophageal cancer.

## COMMENTS

### Background

Placement of esophageal stents in patients with advanced esophageal cancer can improve the symptoms of dysphagia. However, the safety of esophageal stents for patients receiving chemoradiotherapy is controversial. The authors evaluated the morbidity and mortality after self-expandable metallic stent placement with and without 3-dimensional conformal chemoradiotherapy (3D-CRT) in advanced esophageal cancer patients unsuitable for surgery.

### Research frontiers

In this study, once the dysphagia in advanced esophageal cancer patients was alleviated, concurrent 3D-CRT was carried out. 3D-CRT combined with esophageal stenting could improve the symptoms of dysphagia in patients with inoperable esophageal carcinoma and could prolong their survival as well.

### Innovations and breakthroughs

This study showed that self-expandable metallic stent placement with concurrent 3D-CRT could improve the symptoms of dysphagia and result in better survival as compared with endoscopic stenting used alone in the patients with inoperable esophageal carcinoma.

### Applications

The combined treatment of endoscopic stenting and 3D-CR could be applied in patients with inoperable advanced esophageal cancer.

### Terminology

Three-dimensional conformal chemoradiotherapy (3D-CRT) is a mode of high precision radiotherapy. It is a complex process that begins with the creation of individualized, 3D digital data sets of patient tumors and normal adjacent anatomy. These data sets are then used to generate 3D computer images and to develop complex plans to deliver highly "conformed" (focused) radiation while sparing normal adjacent tissues. The radiation beam could focus on a higher radiation dose to the tumor while minimizing radiation exposure to healthy cells.

### Peer review

In this study, the authors examined the efficacy and toxicity/complication of esophageal stenting thereafter 3D-CRT for patients with inoperable esophageal cancer. The results of this study revealed that esophageal stenting after 3D-CRT induced no severe complication, prolonged their survival and effectively improved their symptoms of dysphagia than stenting alone in patients with inoperable advanced esophageal cancer.

### Abstract

Langerhans cell histiocytosis (LCH) is a group of idiopathic disorders characterized by the proliferation of specialized, bone marrow-derived langerhans cells and mature eosinophils. The clinical spectrum ranges from an acute, fulminant, disseminated disease called Letterer-Siwe disease to solitary or few, indolent and chronic lesions of the bone or other organs called eosinophilic granuloma. Involvement of the gastrointestinal tract is very rare in LCH. We present the case of a 53-year-old woman referred by her primary care physician for a screening colonoscopy. A single sessile polyp, measuring 4 mm in size, was found in the rectum. Histopathological examination revealed that the lesion was relatively well circumscribed and comprised mainly a mixture of polygonal cells with moderate-to-abundant pink slightly granular cytoplasm. The nuclei within these cells had frequent grooves and were occasionally folded. Immunohistochemical staining was positive for CD-1a which confirmed the diagnosis of LCH. On further workup, there was no evidence of involvement of any other organ. On follow up colonoscopy one year later, there was no evidence of disease recurrence. Review of the published literature revealed that LCH presenting as solitary colonic polyp is rare. However, with the increas-

ing rates of screening colonoscopy, more colonic polyps may be identified as LCH on histopathology. This underscores the importance of recognizing this rare condition and ensuring proper follow-up to rule out systemic disease.

### INTRODUCTION

Langerhans cell histiocytosis (LCH) is a group of idiopathic disorders characterized by the proliferation of specialized, bone marrow-derived langerhans cells (LCs) and mature eosinophils. The clinical spectrum of LCH ranges from an acute, fulminant, disseminated disease (called Letterer-Siwe disease) to solitary or few indolent and chronic lesions of the bone or other organs called (eosinophilic granuloma). The intermediate clinical form, called Hand-Schüller-Christian disease, is characterized by multifocal, chronic involvement and classically presents as a triad of diabetes insipidus, proptosis and lytic bone lesions.

LCH is a rare disease of the pediatric population,

with an estimated annual incidence of 4-5 per million. More than two-thirds of cases have single system disease with bones and skin as the most commonly involved sites<sup>[1,2]</sup>. Other organs involved are the lung, liver, spleen, bone marrow, lymph nodes and the hypothalamic-pituitary region<sup>[3]</sup>. Involvement of the gastrointestinal (GI) tract is very rare in LCH, especially in adults, with only a few isolated case reports available in English-language literature<sup>[4]</sup>.

The pathogenesis of LCH is unknown. An ongoing debate exists over whether this is a reactive or neoplastic process. From the histopathological viewpoint, the demonstration of LC (Birbeck) granules by electron microscopy remains the “gold standard” for diagnosis of the phenotype, but expression of the CD1a antigen on lesional cells also provides the basis for a definitive diagnosis<sup>[5]</sup>.

## CASE REPORT

We present a case of a 53-year-old woman with a history of hyperlipidemia who was referred by her primary care physician for a screening colonoscopy. She was essentially asymptomatic and did not report any abdominal pain, blood in stool, change in bowel habits, dysphagia, nausea, or vomiting. Findings of physical examination were unremarkable.

On colonoscopy, quality of bowel preparation was excellent. A single sessile polyp measuring 4 mm in size was found in the rectum (Figure 1). It was removed by cold snare polypectomy. The procedure was performed without complications.

Histopathological examination of the polyp revealed that the lesion was relatively well-circumscribed and comprised mainly a mixture of polygonal cells. These cells had moderate-to-abundant pink slightly granular cytoplasm. The lesion also contained inflammatory cells. The inflammatory populations included eosinophils, lymphocytes and neutrophils. The nuclei within the larger cells had frequent grooves and were occasionally folded, suggesting the presence of LCs (Figure 2). Immunohistochemical staining showed histiocytes with cytoplasmic and membranous staining for CD-1a (Figure 3). Histiocyte cytoplasm was positive for S-100 and negative for prekeratin on immunohistochemistry. Electron microscopy was not performed to document presence of Birbeck granules as staining for CD-1a was strongly positive and provided confirmation for the diagnosis<sup>[5]</sup>.

The patient was referred for medical oncology evaluation for this unusual pathologic finding with malignant potential. A computerized tomography (CT) scan of the chest, abdomen, and pelvis was performed to rule out any metastasis through staging evaluation. The CT scan showed no evidence of metastasis, although there were fibroids in the uterus and few cystic masses in the ovaries. Some prominent lymph nodes, which appeared to be benign, were observed in the right and left axillae and sub carina. Further evaluation by an oncologist and a gynecologist revealed that these lesions were benign.

Figure 1 Endoscopic view of the rectal polyp.

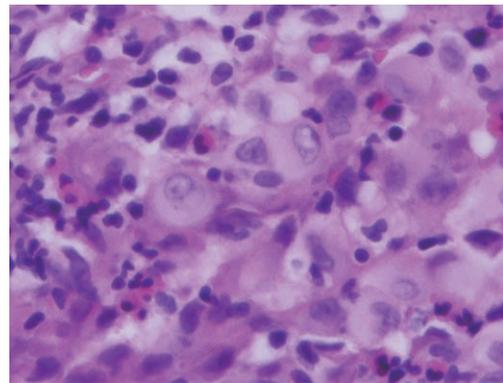

Figure 2 Rectal biopsy with histiocytic infiltrate in the lamina propria. Note eosinophils ( $\times 400$ ).

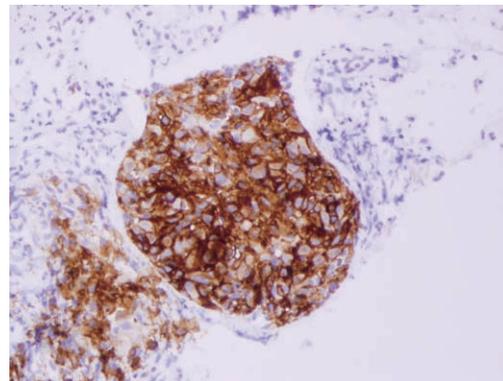

Figure 3 CD-1a immunostain. Histiocytes show positive cytoplasmic and membranous staining ( $\times 200$ ).

Therefore, we found no evidence of disseminated LCH.

The patient remained asymptomatic, and a follow-up colonoscopy was performed 1 year later. A single sessile polyp, measuring 4 mm, was found in the rectum. Another single sessile polyp, measuring 5 mm, was found in the proximal ascending colon. Histopathological examination showed that the polyps were hyperplastic and tubular adenomatous polyps, respectively.

## DISCUSSION

In the GI tract, LCH involvement of the stomach<sup>[6-8]</sup>,

small intestine<sup>[9-11]</sup>, colon<sup>[4,12,13]</sup> and perianal skin<sup>[14,15]</sup> has been reported. Rectal LCH, proven by histopathology, has been described in infants presenting with bloody diarrhea. In most cases, rectal LCH in infants is indicative of widespread, multisystem disease<sup>[16]</sup>.

Among the 6 reported cases of LCH of stomach, all patients were in the fourth and fifth decade of life, and the male-to-female ratio was 1:1; five patients presented with abdominal pain, and one was asymptomatic. The gastric lesion was described as a large, flat raised area in 1 case and a single polyp in 1 case. In other 2 cases, the gastric lesion was described as an ulcerating mass and multiple polyposis, respectively. Histopathological examination of lesions from 2 cases revealed malignant features<sup>[8,17]</sup>. In the case reported by Terracciano *et al.*<sup>[8]</sup>, the patient presented with abdominal pain and weight loss; the tumor was located on the lesser curvature of the stomach. During laparotomy, the tumor was found to have invaded the distal pancreas. Some areas of the tumor had high mitotic indexes and cytologic atypia. Most neoplastic cells were intensely positive for vimentin, S-100 and CD 1a on immunohistochemistry. Two months after surgical resection, the patient died at home. The cause of death was unclear. The remainder of the cases did not show histopathological or clinical malignant features.

Small bowel LCH is rare, with only 3 cases being reported in infants<sup>[10,18]</sup> and 1 in an adult<sup>[11]</sup>. All infants with small bowel LCH presented with diarrhea, weight loss, and failure to thrive. Laboratory findings were significant for anemia and hypoalbuminemia, and the duodenum was always involved. All patients simultaneously or subsequently developed widespread, multisystem involvement, requiring chemotherapy. Two patients responded well to chemotherapy with complete remission, but 1 succumbed to the disease after poor response to treatment and finally refusing chemotherapy<sup>[18]</sup>. In adults, only 1 proven case of small bowel LCH has been reported. LCH occurred in a patient who had undergone right hemicolectomy for steroid-refractory Crohn's disease; this patient presented with worsening diarrhea, abdominal pain, and weight loss. Barium follow-through showed extensive mucosal infiltration of the small bowel wall, and the duodenal biopsy result was consistent with a diagnosis of LCH. Results of bone marrow examination were consistent with chronic myelomonocytic leukemia. The authors concluded that in this case, LCH was a complication of Crohn's disease because of the increased incidence of myeloproliferative disorders in inflammatory bowel disease<sup>[11,19]</sup>.

In children, colonic involvement in LCH is extremely rare. Only 1 case of LCH has been reported in an infant who died of widespread multisystem disease consistent with Litterer-Siwe disease; LCH was diagnosed post-mortem in this case<sup>[13]</sup>. In adults, there have been only 2 reported cases of colonic LCH presenting as isolated polyps in English-language literature<sup>[4,12]</sup>. Both patients were essentially asymptomatic, and polyps were detected during screening colonoscopy. In both cases, diagnosis was confirmed by positive immunochemical staining for CD1a

antigen. Extensive workup in both cases did not reveal involvement of any other organ. In the case presented herein, a polyp was located in the rectum, and diagnosis was supported by the presence of an eosinophilic infiltrate and LCs. The diagnosis was confirmed by strong immunochemical staining for CD1a antigen. The workup to rule out involvement of other organs was negative, and repeat colon examination did not reveal recurrence.

In conclusion, LCH of the GI tract is extremely rare. Colonic involvement in adults usually presents as a solitary polyp without multisystem disease. With the increasing rates of screening colonoscopy, more colonic polyps may be identified as LCH on histopathology. This underscores the importance of recognizing this rare condition and ensuring proper follow-up to rule out systemic disease.

### Abstract

Pseudomelanosis duodeni (PD) is a rare dark speckled appearance of the duodenum associated with gastrointestinal bleeding, hypertension, chronic heart failure, chronic renal failure and consumption of different drugs. We report four cases of PD associated with chronic renal failure admitted to the gastroenterology outpatient unit due to epigastric pain, nausea, melena and progressive reduction of hemoglobin index. Gastroduodenal endoscopy revealed erosions in the esophagus and stomach, with no active bleeding at the moment. In addition, the duodenal mucosa presented marked signs of melanosis; later confirmed by histopathological study. Even though PD is usually regarded as a benign condition, its pathogenesis and clinical significance is yet to be defined.

### INTRODUCTION

Melanosis duodeni was first described in 1976 and refers to a rare endoscopic appearance of discrete speckled black pigmentation of duodenal mucosa, which was initially postulated to represent a form of stored iron<sup>[1]</sup>. The term melanosis gives a false idea that the pigment is produced by melanocytes, justifying renaming this endoscopic finding as pseudomelanosis duodeni (PD)<sup>[2]</sup>. Nevertheless, the clinical significance of this condition is yet to be established. PD is more common in the sixth and seventh decade of life with a female predominance. It has been postulated to be associated with gastric hemorrhage, certain chronic illnesses, such as diabetes mellitus, hypertension, as well as various medications, such as sulfur-containing antihypertensive agents and ferrous sulfate<sup>[3-5]</sup>.

### CASE REPORT

#### Case 1

A 66-year-old woman was admitted with a history of melena and a progressive decrease of hemoglobin index. She presented with a history of diabetes mellitus and

systemic arterial hypertension for > 30 years, with a diagnosis of chronic renal failure in the last 6 mo, treated with hemodialysis. She was on long-term treatment with angiotensin-converting enzyme inhibitors, furosemide, ferrous sulfate, folic acid and insulin. Gastroduodenal endoscopy was performed and revealed multiple superficial erosions in the stomach without signs of recent bleeding. In addition, in the duodenal mucosa, pigmented lesions with a speckled pattern were evident (Figure 1). Biopsies revealed numerous macrophages containing brown pigment granules in their cytoplasm within the lamina propria (Figure 2). Staining of the specimen with Masson Fontana stain revealed iron-containing deposits inside the macrophages (Figure 3).

### Case 2

A 37-year-old woman with a history of renal transplantation (hypertensive nephropathy) had been previously treated with furosemide, propranolol, hydralazine and ferrous sulfate. She was referred to the gastroenterology section due to classical gastroesophageal reflux disease symptoms. She was submitted to gastroduodenal endoscopy that revealed reflux esophagitis and diffuse, multiple, dark brown spots in the duodenum. Biopsies were taken and light microscopy confirmed the presence of brown pigment granules in the lamina propria.

### Case 3

A 70-year-old woman with diabetes and long-term systemic arterial hypertension developed chronic renal failure that was initially treated conservatively with calcium channel blockers, propranolol,  $\alpha$ -methyl dopa, furosemide and glibenclamide. She underwent a left nephrectomy due to nephrolithiasis. Progressive reduction of hemoglobin index was observed during follow-up, therefore, gastroduodenal endoscopy was performed, revealing multiple non-actively bleeding superficial gastric erosions and pigmented lesions in the duodenum. Biopsies were collected and histopathological examination showed features of PD.

### Case 4

A 30-year-old woman with diabetes started complaining of epigastric pain, nausea and vomiting 1 mo after renal and pancreatic transplantation (diabetic nephropathy). She had been previously taking insulin, and after the transplant, she started tracolumis, mycophenolate and corticosteroid therapy. Gastroduodenal endoscopy revealed cytomegalovirus (CMV) esophagitis and multiple small pigmented duodenal spots. Biopsies were taken and histopathological examination confirmed the diagnosis of PD. Another gastroduodenal endoscopy was performed after CMV treatment, and demonstrated total regression of the esophageal lesions but no changes in the aspect of the duodenal mucosa.

## DISCUSSION

PD represents a fine granular brown material inside the

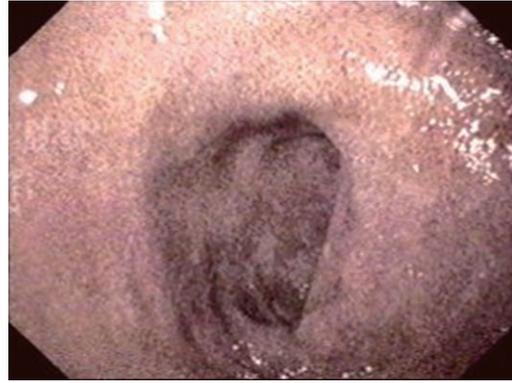

Figure 1 Endoscopic picture showing multiple dark brown spots in the duodenum.

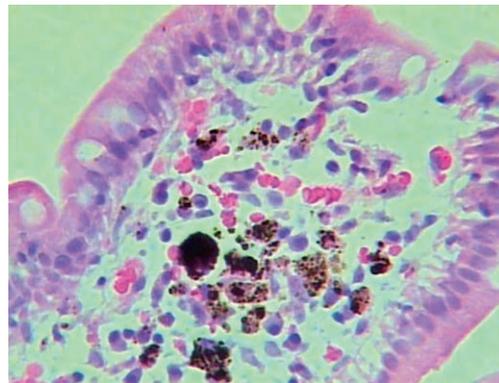

Figure 2 Many macrophages containing brown pigmented granules within the lamina propria (hematoxylin and eosin stain, x 200).

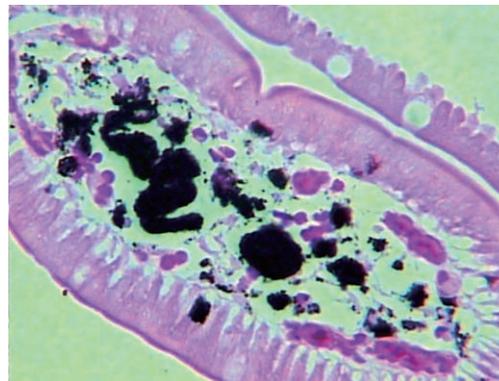

Figure 3 Iron deposits inside macrophage cytoplasm (Masson-Fontana stain, x 200).

macrophage lysosomes in the lamina propria around the tips of the duodenal villi, detected by histochemical staining and electron microscopy. It has been postulated that this heterogeneous pigment may represent a deposit of melanin-like substances, hemosiderin, lipomelanin and lipofuscin<sup>[6,7]</sup>. Even though iron (ferrous sulfide) is the main pigment compound, varying amounts of sulfur, calcium, potassium, aluminum, magnesium and silver can also be detected<sup>[5,8]</sup>. The color of the pigment could represent various degrees of auto-oxidation of ferrous sulfide<sup>[2,6]</sup>.

The pathogenesis still remains unclear. It could be related to iron deposition secondary to intramucosal hemorrhage or impaired intramucosal iron transport after oral ferrous sulfate supplementation<sup>[6,9]</sup>. Iron sulfide storage can also be a product of an acquired inherent defect in macrophage metabolism. In that regard, the pigment present in the duodenal mucosa has also been shown to be partially associated with impaired macrophage metabolism of drugs containing cyclic compounds such as phenols, indoles and skatoles<sup>[8]</sup>.

All four patients had undergone previous gastroduodenal endoscopy without any pathological findings, suggesting that this condition might be acquired rather than congenital, which is in keeping with previous reports<sup>[5]</sup>. Importantly, it must be stressed that this entity might be identified histologically even before it becomes endoscopically visible, making it difficult to establish a temporal association between disease onset and endoscopic manifestation<sup>[10]</sup>.

In this report, all patients were female, with chronic renal failure, and taking antihypertensive drugs. Of note, only two patients were taking oral iron supplements. The biopsy specimens were positive for hematoxylin and eosin and Masson-Fontana stains but not reactive for Pearl's stain, suggesting a melanin-like compound. Although Pearl's stain is a classic method for demonstrating iron in tissues, there is a possibility of a false-negative reaction if an iron oxide compound is present instead of iron sulfide<sup>[11,12]</sup>.

In conclusion, these findings suggest that the duodenal involvement can occur in the absence of a history of oral iron supplementation. Importantly, although the

long-term clinical impact of these depositions remains unclear, these endoscopic findings still do not require any specific treatment or recommended follow-up.

## GENERAL INFORMATION

*World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

### Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the “priority” and “copyright” of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers’ names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid

evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

### Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

### Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systematically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensus and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

Baishideng Publishing Group Co., Limited

## SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

### Biostatistical editing

Statistical review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc.* The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only

homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word ‘significantly’ should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

### Conflict-of-interest statement

In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read “Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest” from International Committee of Medical Journal Editors (ICMJE), which is available at: [http://www.icmje.org/ethical\\_4conflicts.html](http://www.icmje.org/ethical_4conflicts.html).

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

### Statement of informed consent

Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

### Statement of human and animal rights

When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator’s national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

## SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/1007-9327/office>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS ([http://www.wjgnet.com/1007-9327/g\\_info\\_20100315215714.htm](http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm)) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [wjg@wjgnet.com](mailto:wjg@wjgnet.com), or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

## MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically

for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. [montgomery.bissell@ucsf.edu](mailto:montgomery.bissell@ucsf.edu)

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

### Abstract

There are unstructured abstracts (no less than 256 words) and structured abstracts (no less than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no less than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections.

## Instructions to authors

AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/..."; MATERIALS AND METHODS (no less than 140 words); RESULTS (no less than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ; CONCLUSION (no more than 26 words).

### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

### Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315215714.htm](http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm).

### Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

### Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  should be noted ( $P > 0.05$  should not be noted). If there are other series of *P* values, <sup>c</sup> $P < 0.05$  and <sup>d</sup> $P < 0.01$  are used. A third series of *P* values can be expressed as <sup>e</sup> $P < 0.05$  and <sup>f</sup> $P < 0.01$ . Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be la-

beled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that...".

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

### PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

## Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

## Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\nu$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

## Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h; blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum can be found at: [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315223018.htm](http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm).

## Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

## Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H. pylori*, *E. coli*, etc.

---

## RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be re-submitted online (<http://www.wjgnet.com/1007-9327/office/>). The author should send the copyright transfer letter, responses to the reviewers, English language Grade B certificate (for non-native speakers of English) and final manuscript checklist to [wjg@wjgnet.com](mailto:wjg@wjgnet.com).

### *Language evaluation*

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

### *Copyright assignment form*

Please download a Copyright assignment form from [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315222818.htm](http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm).

### *Responses to reviewers*

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315222607.htm](http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm).

### *Proof of financial support*

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

### *Links to documents related to the manuscript*

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

### *Science news releases*

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

### *Publication fee*

*WJG* is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1300 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.

# World Journal of *Gastroenterology*

*World J Gastroenterol* 2012 April 7; 18(13): 1417-1554

## Editorial Board

2010-2013

The *World Journal of Gastroenterology* Editorial Board consists of 1352 members, representing a team of worldwide experts in gastroenterology and hepatology. They are from 64 countries, including Albania (1), Argentina (8), Australia (33), Austria (15), Belgium (14), Brazil (13), Brunei Darussalam (1), Bulgaria (2), Canada (21), Chile (3), China (82), Colombia (1), Croatia (2), Cuba (1), Czech (6), Denmark (9), Ecuador (1), Egypt (4), Estonia (2), Finland (8), France (29), Germany (87), Greece (22), Hungary (11), India (32), Indonesia (2), Iran (10), Ireland (6), Israel (13), Italy (124), Japan (140), Jordan (2), Kuwait (1), Lebanon (4), Lithuania (2), Malaysia (1), Mexico (11), Morocco (1), Moldova (1), Netherlands (32), New Zealand (2), Norway (13), Pakistan (2), Poland (11), Portugal (6), Romania (4), Russia (1), Saudi Arabia (3), Serbia (3), Singapore (11), Slovenia (1), South Africa (3), South Korea (46), Spain (43), Sri Lanka (1), Sweden (17), Switzerland (12), Thailand (1), Trinidad and Tobago (1), Turkey (30), United Arab Emirates (2), United Kingdom (95), United States (285), and Uruguay (1).

### Abstract

Despite improvements in surgical techniques and adjuvant chemotherapy, the overall mortality rates in pancreatic cancer have generally remained relatively unchanged and the 5-year survival rate is actually below 2%. This paper will address the importance of achieving an early diagnosis and identifying markers for prognosis and response to therapy such as genes, proteins, microRNAs or epigenetic modifications. However, there are still major hurdles when translating investigational biomarkers into routine clinical practice. Furthermore, novel ways of secondary screening in high-risk individuals, such as artificial neural networks and modern imaging, will be discussed. Drug resistance is ubiquitous in pancreatic cancer. Several mechanisms of drug resistance have already been revealed, including human equilibrative nucleoside transporter-1 status, multidrug resistance proteins, aberrant signaling pathways, mi-

croRNAs, stromal influence, epithelial-mesenchymal transition-type cells and recently the presence of cancer stem cells/cancer-initiating cells. These factors must be considered when developing more customized types of intervention ("personalized medicine"). In the future, multifunctional nanoparticles that combine a specific targeting agent, an imaging probe, a cell-penetrating agent, a biocompatible polymer and an anti-cancer drug may become valuable for the management of patients with pancreatic cancer.

### INTRODUCTION

Pancreatic cancer has an approximate incidence of 11.4/100 000 inhabitants per year, and is recognized as the fourth cause of cancer-related death, with an overall 5-year survival of less than 1%-2%<sup>[1-3]</sup>. Total costs, including care-related costs and loss of production (due especially to premature death) related to pancreatic cancer in Sweden in the year 2009 were 86-93 million euros (population 9.1 million), corresponding to a society cost in the West of up to 10 million euros per 1 million inhabitants per year<sup>[4]</sup>. Smoking and also family history (in about 5%-10% of cases) are established risk factors for the development of pancreatic cancer<sup>[5]</sup>. There is a weaker positive associa-

tion for other factors including obesity, diabetes mellitus, chronic pancreatitis, ABO genotype, race, periodontal disease, occupational exposures, dietary factors, *Helicobacter pylori* and gallstones<sup>[5,6]</sup>. It is to be stated that the median age at diagnosis is in general 66-68 years<sup>[7]</sup>, though early onset pancreatic cancer, i.e., occurring prior to 50 years of age, accounts for less than 6% of patients and is associated with more advanced disease at presentation and a tendency for shorter overall survival<sup>[8]</sup>. Gender-specific differences in the incidence of pancreatic cancer have been observed, including higher rates in males<sup>[9]</sup>.

Chemotherapy and to a lesser extent, radiotherapy, have emerged as valuable adjuncts to the management of pancreatic cancer. A few studies reported that “marginally resectable” pancreatic tumors shrink after radiochemotherapy and may become resectable<sup>[10-12]</sup>. Neoadjuvant treatment of resectable pancreatic cancer is associated with fewer positive lymph nodes and increased survival (median 34 mo *vs* 19 mo,  $P = 0.03$ )<sup>[13]</sup>. In the ESPAC-1 study, 6 mo of postoperative 5-fluorouracil (5-FU) and folinic acid (FA) increased median survival from 14 mo to 19.7 mo, but there was no effect provided by radiochemotherapy<sup>[14]</sup>. Long-term follow-up after adjuvant chemotherapy demonstrated even better results with a median 21-23 mo survival following adjuvant chemotherapy *vs* 8-16 mo for observation<sup>[15,16]</sup>. The validity of gemcitabine as an adjuvant agent has been confirmed<sup>[17]</sup>. The ESPAC-3 study reported similar outcomes between 5-FU and FA *vs* gemcitabine ( $n = 1088$ )<sup>[18]</sup>. In unresectable pancreatic cancer, most regimens are also gemcitabine-based. The use of gemcitabine has increased median survival from 3-4 mo to 5.5-7 mo<sup>[19-21]</sup>. Recently, FOLFIRINOX (oxaliplatin, irinotecan, leucovorin, fluorouracil) surpassed the effectiveness of gemcitabine by showing longer survival (11.1 mo *vs* 6.8 mo;  $P < 0.001$ )<sup>[22]</sup>. The utilization of molecular targeted treatment in pancreatic cancer outside of clinical trials has been limited. Erlotinib provided a modest survival benefit in advanced pancreatic cancer when used in combination with gemcitabine (6.2 mo *vs* 5.9 mo)<sup>[23]</sup>, but due to increased side-effects and increased costs it has not received wide clinical acceptance.

This paper will focus on clinical and molecular aspects of pancreatic cancer, discussing novel ways to improve early detection and prognostic prediction, as well as the design of future targeted therapy, which is imperative in this era of personalized medicine.

## MOLECULAR PATHOGENESIS

Pancreatic ductal adenocarcinoma (PDAC) is believed to arise from precursor lesions that develop into invasive carcinoma through a multistep carcinogenic process. Pancreatic intraepithelial neoplasia (PanIN) is the most common preneoplastic lesion in patients with pancreatic cancer, being observed in approximately 80% of cases<sup>[24]</sup>. Other precursor lesions of PDAC are intraductal papillary mucinous neoplasms (IPMN) and mucinous cystic neoplasms (MCN). The *KRAS* oncogene is the most commonly altered gene in pancreatic cancer. Inactivation

of the tumor-suppressor genes *CDKN2A*, *TP53*, *DPC4* and *BRC42*, as well as chromosomal losses, gene amplifications and telomere shortening have also been observed<sup>[6]</sup>. Reactivation of developmental pathways, such as hedgehog, notch and wnt/ $\beta$ -catenin, may be crucial for the development of PDAC<sup>[25]</sup>. In addition to genetic alterations, many lines of evidence indicate that epigenetic changes play a role in pancreatic carcinogenesis. DNA methylation and histone modification frequently alter gene function without changing the DNA sequence, and have the potential to be used as diagnostic markers in pancreatic cancer<sup>[26]</sup>. MicroRNAs are non-coding segments of RNA that can regulate gene expression. Aberrant expression of microRNAs contributes to tumor progression and has been associated with drug resistance<sup>[27]</sup>.

Because all three precursor lesions of PDAC possess ductal characteristics, it has been suggested that the lesions develop from ductal cells. However, the study of mouse models of pancreatic cancer has broadened the current understanding of pancreatic carcinogenesis by showing other cells to be the cancer-initiating cells. Differentiated acinar cells have been shown to cause PanIN and pancreatic cancer following activation of *KRAS in vivo*<sup>[28-30]</sup>. Moreover, insulin-positive endocrine cells and PDX1-expressing cells have been demonstrated to induce PDAC<sup>[31]</sup>. It should be noted that the cell of origin, in which tumorigenesis is initiated, could be different from the cancer stem cell, which propagates the tumor<sup>[32]</sup>. Identification of cells of origin in PDAC may allow earlier detection of malignancy and better preventive and treatment tools.

## Crosstalk tumor-stroma

Desmoplasia is a characteristic feature of pancreatic cancer and the stromal compartment has been considered to be a physical barrier for drug delivery<sup>[33]</sup>. The pancreatic stellate cell (PSC) has a key role in stroma formation. In addition to endogenous quiescent PSCs, bone marrow may also contribute to the population of activated PSCs<sup>[34]</sup>. PSCs are involved in tumor growth, invasion, metastasis and resistance to radiochemotherapy<sup>[35-37]</sup>. Furthermore, PSCs accompany cancer cells to distant metastatic sites, stimulate angiogenesis and have the capacity to migrate over the endothelial barrier to and from blood vessels<sup>[38]</sup>. A limited number of studies have attempted to block PSC activity in the setting of pancreatic cancer. For example, halofuginine, a smad3-phosphorylation-inhibitor, reduces PSC activation and prevents pancreatic xenograft tumor development<sup>[39]</sup>. Retinoic acid can also inhibit PSC activity and reduces wnt- $\beta$ -catenin signaling in cancer cells and their invasive ability<sup>[40]</sup>. Key signaling pathways between PSCs and cancer cells have been identified and involve e.g., sonic hedgehog, galectins, endothelins and platelet-derived growth factor<sup>[35]</sup>, which thereby represent potential therapeutic targets.

## Cancer stem cells and epithelial-mesenchymal transition

Pancreatic cancer stem cells constitute a minority of cancer cells (1%-5%) and have the ability to self-renew, and

are resistant to chemotherapy and radiation<sup>[41]</sup>. They are characterized by several surface markers including CD44, CD24, epithelial specific antigen, aldehyde dehydrogenase, CD133 and CXCR4<sup>[42]</sup>. Furthermore, it has been observed that pancreatic cancer cells that were cultured in gemcitabine demonstrated characteristics of epithelial-mesenchymal transition (EMT)<sup>[43]</sup>. They also showed increased expression of cell surface proteins associated with cancer stem cells. In pancreatic cancer xenografts, radiation or gemcitabine therapy leads to enrichment of the EMT cells<sup>[44]</sup>. Wnt, notch and hedgehog are important signaling events in cancer stem cells, and can become novel therapeutic targets<sup>[41]</sup>. Ongoing clinical trials are currently investigating PRI-724 (inhibitor of wnt), MK-0752 (inhibitor of notch) and GDC-0449 (inhibitor of hedgehog) in patients with advanced pancreatic cancer ([www.clinicaltrials.gov](http://www.clinicaltrials.gov)). Future therapeutic strategies may need to combine targeting of cancer stem cells and EMT cells with the targeting of other cells in the microenvironment, e.g., stromal cells, in order to achieve maximal benefit.

### Pro-inflammatory response

Inflammation is closely related to the development and progression of pancreatic cancer, and molecular factors such as STAT3 have been suggested to play a key role in creating a pro-inflammatory tumor microenvironment<sup>[45]</sup>. Clinical studies have shown that a pro-inflammatory response is both prognostically negative and promotes tumor proliferation<sup>[46]</sup>. Inflammatory factors may also contribute to the profound weight loss and cancer cachexia frequently seen in pancreatic cancer<sup>[47]</sup>. Elucidation of the mechanisms underlying the crosstalk between inflammation, cancer and stroma may improve the management of pancreatic cancer, as a frequent desmoplastic reaction is noted.

### Chemoresistance

Gemcitabine has represented the first-line of chemotherapeutic agents in pancreatic cancer. A frequent problem, though, is drug resistance and lack of response to therapy given. Nucleoside transporters, such as human equilibrative nucleoside transporter-1 (hENT-1), appear to regulate the intracellular uptake of gemcitabine<sup>[48]</sup>. One of the proposed mechanisms of chemoresistance is a reduction in hENT-1 expression. Determination of hENT-1 status at the time of cancer diagnosis, and also modifications of gemcitabine in order to bypass the nucleoside receptor, may represent novel types of targeted approaches in the management of patients with pancreatic cancer<sup>[48]</sup>. Multidrug resistance (MDR) proteins including ABC-transporters have also been implicated in drug resistance in pancreatic cancer and limit the efficacy of gemcitabine<sup>[49]</sup>. Another mechanism that contributes to chemoresistance is the tumor microenvironment surrounding the cancer cells, including cancer stem cells, EMT cells and stellate cells. Furthermore, the hypoxic stroma could be a physical barrier preventing chemotherapeutic drugs from

reaching pancreatic cancer cells, and depletion of the stroma could enhance cancer drug delivery<sup>[33]</sup>. Aberrant signaling pathways also have a role in drug resistance. The PI3K/Akt signaling pathway is commonly overactive in pancreatic cancer. PI3K stimulates proliferation and confers chemoresistance<sup>[50]</sup>. MicroRNAs have received increased attention in recent years. Targeting of microRNAs may help overcome drug resistance in pancreatic cancer and improve clinical outcome<sup>[27]</sup>.

## BIOMARKERS

Biomarkers can be applied in several areas of disease management including diagnosis, prognosis, staging and prediction and monitoring of therapeutic response. The different types of biomarkers include genes, proteins, metabolites, microRNAs and epigenetic modifications. CA 19-9 has some value for detection of recurrent disease<sup>[51]</sup>, but so far no other biomarker is recommended for routine clinical use in pancreatic cancer. Recently, a seven-gene panel was identified as being differentially expressed between pancreatic cancer ( $n = 36$ ) and normal samples ( $n = 19$ )<sup>[52]</sup>. Validation using two blood-based biomarkers from this panel, tenascin C and tissue factor pathway inhibitor, yielded a combined area under the curve (AUC) of 0.88 and, with addition of CA19-9, a combined AUC for the three-gene panel of 0.99 with 100% specificity at 90% sensitivity and 97% sensitivity at 90% specificity.

Proteomic profiling of pancreatic cancer serum has been promising. Most studies have used surface enhanced laser desorption (SELDI) or matrix assisted laser desorption/ionization (MALDI) yielding a sensitivity in the range of 78% to 100% and a specificity between 74% and 100%<sup>[53]</sup>. Immunohistochemistry (IHC) is the most practical method for evaluating protein expression changes in histopathology. It can be combined with tissue microarray technology to allow rapid testing of immunohistochemical markers on many tumors in a single experiment. During the past decade, a multitude of immunohistochemical biomarkers that are potentially involved in pancreatic carcinogenesis and drug responsiveness have been studied for their prognostic and predictive value, but none of them have yet proved to be sufficiently useful for use in routine clinical practice<sup>[54]</sup>. Apart from the tumor compartment, stromal tissue may also be analyzed and it has been discovered that stromal secreted protein acidic and rich in cysteine has been associated with outcome in pancreatic cancer<sup>[55]</sup>. A panel of IHC markers may prove clinically valuable in the future. Furthermore, metabolomic studies of pancreatic cancer are promising and may be useful in identifying benign from malignant conditions<sup>[56-58]</sup>. MicroRNA is a new class of biomarkers. Aberrant expression of miRNA-21 and miRNA-34a has been associated with survival in resectable pancreatic cancer<sup>[59]</sup>. Epigenetic changes, such as histone modification, may be used as novel biomarkers in pancreatic cancer<sup>[60]</sup>.

Although a multitude of investigational biomarkers have been identified, translation into routine clinical

practice has been difficult. To improve methodological reporting several guidelines have been developed. For diagnostic biomarkers, the STAndards for Reporting Diagnostic accuracy (STARD) guidelines are available<sup>[61]</sup>. For prognostic studies, the REporting recommendations for tumor MARKer prognostic studies (REMARK) guidelines are available<sup>[62]</sup>. The process of translating biomarkers is complex and the path from discovery to clinical application may be long and arduous. The effective demonstration of clinical utility of the biomarker will remain the key to its gaining widespread acceptance, but regulatory issues and budgetary constraints of the biomarker industry remain major challenges<sup>[63]</sup>.

## IMAGING

The detection of precursor lesions of pancreatic cancer would be a key factor in improving the prognosis. Non-invasive imaging techniques such as ultrasound, computed tomography and magnetic resonance imaging do not accurately identify PanINs. Positron emission tomography (PET) is a functional imaging modality that utilizes the principle that metabolic alterations in tumors occur prior to notable morphological alterations. The radioactive tracer <sup>18</sup>F-fluorodeoxyglucose (FDG) has been used extensively for PET imaging of malignant tumors. Malignant tissue has increased glucose metabolism as compared to its surrounding tissue, which leads to focal FDG-uptake visualized by PET. PET/CT has come to play an increasing role in pancreatic cancer, due to the ability to accurately detect small primary pancreatic lesions and distant metastases, as well as recurrences following surgery<sup>[64-67]</sup>. It has been shown that an elevated glucose metabolism occurs already in precursor lesions of pancreatic cancer, with the opportunity of detecting these changes with PET/CT, and thus improving diagnosis and outcome<sup>[68]</sup>. Eser *et al*<sup>[69]</sup> recently described a technique that could improve diagnosis and also grading of PanINs using *in vivo* molecular imaging based on catepsins.

## PANCREATIC CANCER AND DIABETES MELLITUS

Up to 80% of patients with pancreatic cancer have diabetes mellitus or pathologic glucose tolerance test at diagnosis<sup>[70]</sup>. Long-standing type II diabetes is a predisposing factor for pancreatic cancer, while new-onset diabetes may indicate subclinical cancer<sup>[71]</sup>. The molecular mechanisms linking long-standing diabetes to pancreatic cancer are incompletely understood. Diabetes may promote the neoplastic process by several mechanisms including hyperinsulinemia (endogenous or exogenous), hyperglycemia and chronic inflammation<sup>[72]</sup>. The insulin and insulin-like growth factor (IGF) receptors are frequently expressed in pancreatic cancer and contribute to neoplastic growth and progression<sup>[73]</sup>. The administration of the anti-diabetic agent metformin may reduce the incidence

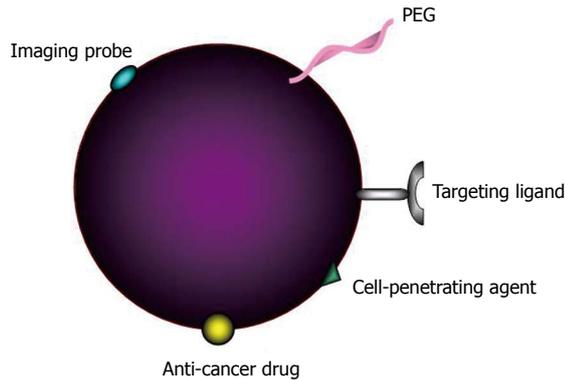

of pancreatic cancer in patients with type II diabetes<sup>[74,75]</sup>. In xenograft models, metformin inhibits the growth of pancreatic cancer cells by interfering with insulin/IGF-1 receptor and G-protein-coupled receptor signaling<sup>[76]</sup>. In addition, metformin can inhibit tumor growth by inactivating cancer stem cell-like cells<sup>[77]</sup>. Studies have sought to elucidate molecular alterations that link diabetes and cancer, and one such molecular connection could be TCF7L2 (T-cell factor 7-like 2) and p53<sup>[78]</sup>. In a recently published case-control study, rs780094 was selected as one of 10 diabetes-associated single-nucleotide polymorphisms related to increased pancreatic cancer risk<sup>[79]</sup>. However, diabetes in pancreatic cancer is mostly new-onset, i.e., occurring 24 mo prior to cancer diagnosis, and is likely related to secondary effects from the tumor, which is supported by the observation that glucose metabolism is improved following tumor resection<sup>[71,80]</sup>. Although the exact mechanisms behind pancreatic cancer-induced diabetes are yet to be disclosed, there is ample evidence for a tumor-derived influence on glucose metabolism, leading to disturbed  $\beta$ -cell function, peripheral insulin resistance, hyperglycemia and finally diabetes mellitus<sup>[70]</sup>.

## SCREENING

Pancreatic cancer develops over a long time span, providing a strong rationale for developing techniques for early detection. It may take ten years or more between the initial mutation and first non-metastatic tumor cell, and another five years for the development of metastatic capacity and death after an additional two years<sup>[81]</sup>. This implies a therapeutic window of opportunity for both early diagnosis and treatment. Chromothripsis is a new concept that involves the simultaneous acquisition of multiple mutations in a single catastrophic event. This phenomenon may be present in 2%-3% of all human cancers, but the incidence may be higher in certain tumors, such as osteosarcomas and chordomas<sup>[82]</sup>.

Patients with pancreatic cancer usually have generic symptoms and are often difficult to diagnose at an early stage. There are several risk groups where secondary screening for pancreatic cancer may be appropriate, e.g., patients with heredity, IPMN, or new-onset diabetes mellitus<sup>[70,83-85]</sup>. Distinguishing pancreatic cancer-associated diabetes from the more common general type 2 diabetes may identify individuals with a potentially resectable pancreatic cancer<sup>[70-71]</sup>. Huang *et al*<sup>[86]</sup> identified vanin-1 and matrix metalloproteinase 9 as useful biomarkers for the discrimination of pancreatic cancer-associated diabetes from type II diabetes.

Artificial neural networks represent non-linear pattern recognition techniques that simulate the analytic processes of the human brain. They have been utilized in complex medical decision-making, including diagnosis, prognosis and risk stratification<sup>[87]</sup>. A major benefit of these networks is the ability to recognize complex relationships between input and output data that may be hidden to conventional statistical methods. Initial reports on the use of artificial neural networks combined with proteomic

**Figure 1 Multifunctional nanoparticle.** PEG: Polyethylene glycol.

data have provided promising results concerning the detection of pancreatic cancer<sup>[88]</sup>. The future application of artificial neural networks based on parameters including age, smoking, heredity, chronic pancreatitis, new-onset diabetes mellitus, biomarkers and imaging findings imply promise for early detection of pancreatic cancer, and may be used as screening tools.

## NANOMEDICINE

Nanomedicine is defined as the application of nanotechnology to medicine. Nanoparticles are in the range of 1-100 nm. Examples of nanoparticles include liposomes (phospholipid vesicles), dendrimers (synthetic polymers), carbon nanotubes (fullerene), quantum dots (colloidal fluorescent semiconductor nanocrystals), magnetic nanoparticles (spherical nanocrystals with a  $Fe^{2+}$  and  $Fe^{3+}$  core) and gold nanoparticles (metallic nanoparticles). The application of nanoparticles in medicine include e.g., diagnostics, imaging and drug delivery.

Nanoparticles enable refined diagnostics at the level of single cells and molecules. For example, magnetic nanoparticles have been coupled with molecular targeting ligands to improve imaging of early pancreatic tumors *in vivo*<sup>[89]</sup>. Quantum dots conjugated with RGD peptides have been reported for *in vivo* imaging of pancreatic tumor vasculature<sup>[90]</sup>. Drug resistance is a recognized challenge in pancreatic cancer. Gemcitabine-squalene obtained by covalently coupling gemcitabine at the 4-amino group with squalene, a natural lipid, has been shown to make tumor cells more sensitive to gemcitabine<sup>[91]</sup>. Recently, polymeric nanoparticles encapsulating hedgehog-inhibitors or curcumin have been produced that inhibit the growth of orthotopic pancreatic cancer xenografts<sup>[92,93]</sup>. Gold nanoparticles have been utilized to induce intracellular hyperthermia in a murine model of pancreatic cancer after radiofrequency field exposure<sup>[94]</sup>. An ongoing phase I study (NCT00968604) of advanced pancreatic cancer is currently investigating the effects of intravenous injection of the liposome nanoparticle BikDD, which contains a pro-apoptotic agent. Several nanoparticle-based anticancer drugs are already on the market, e.g., Abraxane<sup>®</sup> (albumin-bound paclitaxel), Myocet<sup>®</sup> (liposomal doxorubicin) and

Oncaspar<sup>®</sup> (PEG-L-asparaginase)<sup>[95]</sup>.

While monofunctional nanoparticles only carry out one function, multifunctional nanoparticles have the ability to perform several tasks. Multifunctional nanocarriers using a specific targeting agent, an imaging probe, a cell-penetrating agent such as TAT peptide, a biocompatible polymer such as polyethylene glycol (PEG) and an anti-cancer drug, may result in effective tumor destruction with minimal toxicity (Figure 1).

## CONCLUSION

Pancreatic cancer is a condition with an almost total lethal outcome. Despite advancement in surgical techniques and adjuvant treatment, the prognosis has only marginally improved. Novel therapeutic interventions have been tested but with limited effect. Research should continue to focus on biomarkers for early diagnosis, prognosis and prediction and monitoring of therapeutic response. Screening of high-risk individuals using novel approaches such as artificial neural networks could be considered. Mechanisms of chemoresistance have been elucidated, including hENT-1 status, MDR proteins, aberrant signaling pathways, microRNAs and micro-environmental factors, which should underlie future development of targeted therapy. The identification of cancer-initiating cells represents a fundamental shift in our understanding of the intrinsic drug resistance of pancreatic cancer. Multifunctional nanoparticles have the potential to combine imaging, diagnosis and therapy in a single vehicle. It is expected that nanomedicine will have a prominent role in the quest for a successful therapy for this recalcitrant disease.

### Abstract

The worldwide incidence and prevalence of cystic echinococcosis have fallen dramatically over the past several decades. Nonetheless, infection with *Echinococcus granulosus* (*E. granulosus*) remains a major public health issue in several countries and regions, even in places where it was previously at low levels, as a result of a reduction of control programmes due to economic problems and lack of resources. Geographic distribution differs by country and region depending on the presence in that country of large numbers of nomadic or semi-nomadic sheep and goat flocks that represent the intermediate host of the parasite, and their close contact with the final host, the dog, which mostly provides the transmission of infection to humans. The greatest prevalence of cystic echinococcosis in human and animal hosts is found in countries of the temperate zones, including several parts of Eurasia (the Mediterranean

regions, southern and central parts of Russia, central Asia, China), Australia, some parts of America (especially South America) and north and east Africa. Echinococcosis is currently considered an endemic zoonotic disease in the Mediterranean region. The most frequent strain associated with human cystic echinococcosis appears to be the common sheep strain (G1). This strain appears to be widely distributed in all continents. The purpose of this review is to examine the distribution of *E. granulosus* and the epidemiology of a re-emerging disease such as cystic echinococcosis.

Worldwide epidemiology of liver hydatidosis including the Mediterranean area. *World J Gastroenterol* 2012; 18(13): 1425-1437 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i13/1425.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i13.1425>

### INTRODUCTION

Cystic echinococcosis (CE) is a near-cosmopolitan zoonosis caused by adult or larval stages of tapeworms (cestodes) belonging to the genus *Echinococcus* (family Taeniidae). Actually, six species of *Echinococcus* have been recognized, but the most important members of the genus in respect of their public health importance and their geographical distribution are *Echinococcus granulosus* (*E. granulosus*) (which causes cystic echinococcosis) and *Echinococcus multilocularis*

(which causes alveolar echinococcosis). Infection with *E. granulosus* results in the development of one or several unilocular hydatid cysts that in humans develop mainly in the liver (70%), but also lungs (20%) and 10% of cysts can occur almost anywhere in the body (e.g., brain, body musculature, wall of the heart, kidneys, orbit of the eye, marrow cavity of bones). *E. multilocularis* metacestodes develop as a series of small, interconnected cysts, growing as a metastasising lesion almost exclusively in the liver (98%-100%), but in the later phase of infection distant metastases in other organs may occur.

*E. multilocularis* is a cestode whose life cycle involves a tapeworm stage during which it lives in the small intestine of carnivores (definitive hosts, usually wild or domestic canids), and a tissue-invading metacestode (larval) stage during which echinococcal cysts develop in internal organs (mainly liver and lungs) of humans and other intermediate hosts as unilocular fluid-filled bladders surrounded by a host-produced layer of granulomatous adventitial reaction. Small vesicles called brood capsules bud internally from the germinal layer and produce multiple protoscolices by asexual division. In humans, the slowly growing echinococcal cysts may reach a volume of several litres and contain many thousands of protoscolices. Moreover, internal septations and daughter cysts may appear over time, disrupting the unilocular pattern typical of the young echinococcal cysts.

Infection of an intermediate host is due to accidental ingestion of tapeworm eggs passed into the environment with faeces from definitive hosts. Transmission of *E. granulosus* could be due to domestic and wildlife reservoirs, and is influenced by human activities, behaviour, and politics.

CE represents an increasing public health and socio-economic concern in many areas of the world<sup>[1-3]</sup> and is currently considered an endemic zoonosis in the Mediterranean region (MR), in addition to brucellosis, rabies, leishmaniasis and food-borne zoonotic infections<sup>[4]</sup>. Given a geographic distribution and extent greater than previously believed, several studies have shown that hydatidosis is currently considered an emerging or re-emerging disease<sup>[5,6]</sup>. The distribution and prevalence of CE depends on the presence in that country of large numbers of nomadic or semi-nomadic sheep and goat flocks that represent the intermediate host of the parasite, and their close contact with the final host, the dog, which mostly provides the transmission of infection to humans.

Molecular studies conducted on mitochondrial DNA (mtDNA) sequences, have shown that *E. granulosus* complex consists of three species and comprise ten defined strains (genotype G1-10), based on morphology, host specificity and molecular characteristics<sup>[7,8]</sup>. The intraspecific variants have substantial variation at the genetic level and DNA sequence<sup>[9]</sup>, conferring several characteristics such as life-cycle patterns, host specificity, development rate, antigenicity, transmission dynamics, sensitivity to chemotherapeutic agents, and pathology<sup>[10,11]</sup>. These characteristics may have important implications for the

design and development of vaccines, diagnostic reagents and drugs impacting on the epidemiology and control of echinococcosis<sup>[12,13]</sup>. Indeed, each *Echinococcus* species maintains a specific host-adapted genetic identity that only rarely overlaps in some geographical areas<sup>[5,11,14]</sup>.

In this review we discuss aspects of the current epidemiology of *E. granulosus* complex and highlight worldwide and specific distribution in recognised endemic areas.

## SPECIES AND DISTRIBUTION OF

### *E. GRANULOSUS* COMPLEX

*E. granulosus* has a worldwide geographical distribution with endemic foci present on every inhabited continent (Figure 1). The greatest prevalence of CE in human and animal hosts is found in countries of the temperate zones, including several parts of Eurasia (the Mediterranean regions, southern and central parts of Russia, central Asia, China), Australia, some parts of America (especially South America) and north and east Africa<sup>[2,15]</sup>.

The distinct genetic types of *E. granulosus* include two sheep strains (G1 and G2), two bovid strains (G3 and G5), a horse strain (G4), a camelid strain (G6), a pig strain (G7), and a cervid strain (G8). A ninth genotype (G9) has been described in swine in Poland<sup>[8,16]</sup> and a tenth strain (G10) in reindeer in Eurasia. Among these strains, we have available data for preliminary epidemiological analyses only for some strains. In fact, some of them are still poorly characterised and further research is needed to determine with higher detail their host and geographic ranges and whether their genetic characteristics are conserved between different endemic regions.

The most frequent strain associated with human CE appears to be the common sheep strain (G1). This strain appears to be widely distributed in all continents. Highest rates of infection are recorded in communities involved in extensive sheep farming and epidemiological studies suggest that this genetic variant is the principal strain infecting humans<sup>[2,5,9,17]</sup>. Consequently, its presence coincides with areas which have high prevalence of human CE such as in Morocco, Tunisia, Kenya, Kazakhstan, western China and Argentina.

The G2 strain is known to be transmitted among sheep and infect humans also, but genetic differences biologically distinguish it from the G1 strain, conferring a different life cycle<sup>[18]</sup>. It has been found in Australia and previously also documented in Tasmania.

The G3 strain which is diffused among buffalos and transmitted by water, has been recorded in South Asia<sup>[19]</sup>, but no susceptibility among humans has been found.

The G4 strain, formerly known as *Echinococcus equinus*, appears to infect exclusively equines as intermediate hosts and no human cases have been documented<sup>[9,20]</sup>. It is known to be diffused in the Mediterranean regions of Spain, Italy, Lebanon, and Syria, as well as in South Africa.

The former cattle strain (G5), known as *Echinococcus ortleppi*, is transmitted by cattle in Europe, Asia, parts of

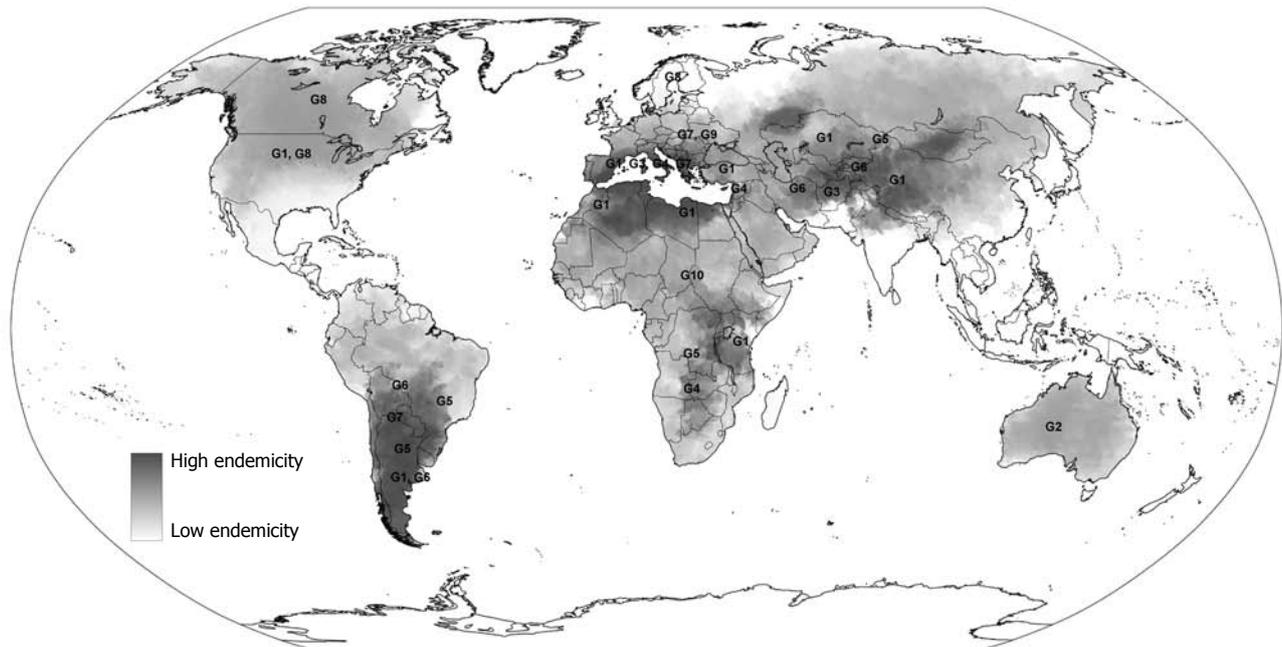

Figure 1 Worldwide distribution of the zoonotic strains of *Echinococcus granulosus* and geographical endemicity.

Africa and South America and only one case in humans has been isolated in past years<sup>[21]</sup>, suggesting a less pathogenic risk for humans than the sheep strain of *E. granulosus*.

G6-10 strains are poorly distinguished from each other but they are clearly distinct from the common sheep strain<sup>[5]</sup>. The G6 strain is known to principally affect camels and goats. Animal infection is diffused in the Middle East, Africa, southern Asia and South America<sup>[9]</sup> and cases of human infection have been found in Nepal, Iran, Mauritania, Kenya and Argentina<sup>[5,17]</sup>.

The G7 strain is transmitted by domestic pigs in Europe (Spain and Italy), Asia and South America, as well as the closely related genetic variant G9 that has been documented to affect Polish patients<sup>[16]</sup> although the animal reservoir is unknown.

The G8 strains are known to be transmitted between wolves and wild cervids in the northern regions of Europe, Asia and North America. Few cases of human infection have been documented with a lower severity of the disease than CE caused by other forms of *E. granulosus*<sup>[22]</sup>. However, transmission between humans of this genetic variant seems to be low and further data is needed to better assess its pathogenicity.

Finally, some other genetic variants which are poorly characterized have been found in several countries. For example, the wildlife “lion” strain transmitted among lions and wild ungulates has been documented in Africa but no human infection has been found.

## EPIDEMIOLOGY OF *E. GRANULOSUS* COMPLEX: WORLDWIDE DISTRIBUTION

### America

The most ubiquitous taxa of *E. granulosus* that occur in North America are the cervid strain (G8) and the sheep

strain (G1). The former is diffused in wildlife mainly in Canada, Alaska and Minnesota<sup>[23]</sup>. The wildlife reservoir was found to be largely diffused among cervids and wolves, coyotes and domestic dogs<sup>[24]</sup>. EC started to be diagnosed in Canada after the 1950s following the introduction of routine chest X-rays for tuberculosis in some tribes of native Americans (such as Indians and Eskimo) who were identified with pulmonary hydatidosis<sup>[24]</sup>. In the same period, a review of 101 autochthonous cases of *E. granulosus* infection in Alaska were documented<sup>[22]</sup>. It has been estimated that 50% of moose in Ontario and British Columbia are infected with the parasite<sup>[25]</sup> and that 28%-50% of dogs in the Canadian Northwest Territories are infected with *E. granulosus*<sup>[26]</sup>. In humans, pulmonary localization is quite diffuse. Indeed, a recent chart review performed in Alberta documented 22 definite and probable cases, of which 77% were female and 41% aboriginal; 40% had pulmonary involvement and 50% hepatic involvement<sup>[27]</sup>.

Sporadic autochthonous transmission among humans of the sheep strain in the western States of North America such as Arizona, California, New Mexico and Utah has been documented in reports from the 1960s<sup>[28]</sup>. The source of these *E. granulosus* infections was Australian sheep dogs imported into Utah in 1938 when the parasite diffused among sheep of this area as well as adjoining states through trading of live sheep<sup>[29]</sup>. Moreover, another source of infection were immigrants from countries in which echinococcosis disease is highly endemic, historically Icelanders, Italians and Greeks, but in more recent years, mostly persons of Middle Eastern and Asian origin. After the Second World War, foci of transmission involving swine and dogs were reported in several areas such the Mississippi valley due to the close relationship between humans and dogs<sup>[30]</sup> but transmission of infection ap-

peared to have ended by mid-century<sup>[31]</sup>. Then, an epidemic focus of sheep and human infection in western states including California, Utah, New Mexico and Arizona in the mid-1960s was traced<sup>[28]</sup>. Most infections occurred in high-risk groups such as sheep farmers and those involved in home slaughter including Basque-Americans in California<sup>[32]</sup>, Mormons in central Utah<sup>[33]</sup>, and Navajo and Zuni Indians in New Mexico and Arizona<sup>[33-35]</sup>.

As well as in the United States, all genetic variants of the *E. granulosus* complex have been introduced into South America with domestic animals imported from other regions, such as Europe. The principal strain of *E. granulosus* is the sheep strain (G1), widely diffused in Peru, Chile, Argentina and Brazil<sup>[2]</sup>.

In the central Peruvian Andes, the prevalence of hydatidosis in livestock has been noted to be 89% in sheep and 80% in cattle in a livestock raising community<sup>[36]</sup>. Among definitive hosts, the prevalence of infection in dogs in endemic areas has been reported to range from 32% to 46%<sup>[36-38]</sup> and from 46% to 88%<sup>[38-40]</sup>. The recorded surgical incidence of CE in the central and southern Peruvian Andes has been noted to be 1-2 cases per 100 000 inhabitants<sup>[36]</sup> and the prevalence of asymptomatic CE between 3% and 9.3% in rural villages in the central Peruvian highlands<sup>[38]</sup>. However, a study in a coastal city of Peru reported an annual surgical incidence of 32 per 10 000 for 1998<sup>[37]</sup> leading to the conclusion that incidence of CE is significantly under-reported. Recently, a re-emergence of transmission has been documented after the failure of previous control activities<sup>[41]</sup>.

Chile is an endemic area for *E. granulosus* infection. During 2000, the prevalence of bovine, sheep and canine hydatidosis for the entire country decreased to 22.3%, 6.3% and 11%, respectively<sup>[42]</sup>, after a control program<sup>[2,43,44]</sup>. With regard to human infection, although the overall incidence of diagnosed disease has been assessed as 2-2.5 cases per 100 000 inhabitants between 1992 and 2004, taking under-notification into account, the incidence has been estimated at 10 per 100 000. A major endemic area for EC is the southern part of Chile where annual surgical incidence ranged from 6 to 20 cases per 100 000 in August 2005 but reaching 162 per 100 000 in some regions<sup>[45]</sup>.

In Argentina, several strains of *E. granulosus* and *E. ortleppi* have been found in different host animals and humans such as the sheep strain (G1) (mostly infecting humans), the Tasmanian sheep strain (G2), the cattle strain (G5) and the camel strain (G6)<sup>[14,46]</sup>, while the pig strain (G7) has been detected in pigs and dogs but not humans<sup>[46]</sup>. The prevalence of EC affecting livestock has been documented as reaching 7% of cattle, 12.5% of sheep, 9.8% of pigs and 6.0% of goats<sup>[2]</sup>. In humans, prevalence rates depend on the endemicity of the area, ranging from 1.4 per 100 000 to 404, 260 and 30 cases per 100 000 in Neuquen, Chubut and Rio Negro (regions of Patagonia), respectively<sup>[42]</sup>.

In southern Brazil only sheep strain and *E. ortleppi* have been recorded<sup>[47,48]</sup>, although the most endemic area is the southern part of Brazil. Indeed, a recent analysis of

hydatidosis prevalence in animals in this area reported a prevalence of infection to be 25.5% of cattle, 30.2% of sheep<sup>[42]</sup> and from 11.4% to 38% of dogs<sup>[49]</sup>. Data about human hydatidosis documented a seroprevalence of 6% in the rural population and 3.5% in the urban population of Sena Madureira<sup>[50]</sup>. However, the few data available to allow conclusions on epidemiology of different taxa often depend on control activities that are inconsistent in their consideration of the economic and public health impact of echinococcosis in these areas.

## Australia

The most common strain currently found in Australia is the G1, while the G2 strain was previously also found in Tasmania<sup>[7,8,51]</sup>. This G2 strain probably evolved as a genetically modified variant after a Tasmanian hydatid control campaign aimed to strictly control helminthic diffusion among dogs. Thus, this genetic variant became dominant because of the limited gene pool on an island<sup>[18]</sup>. However, the absence of diffusion of the hydatid infection in wildlife and the intense hydatid control programmes allowed the eradication of *E. granulosus* from Tasmania in the middle 1990s<sup>[52]</sup>.

In Australia several areas have been documented at high risk of transmission of *E. granulosus*, especially in wildlife. The definitive hosts most commonly involved in transmission in south eastern Australia are represented by the wild dog<sup>[53,54]</sup>, while the most common intermediate hosts are grey kangaroos and wallabies<sup>[54]</sup>. Western Australia, south of Perth, is another active area of transmission of *E. granulosus*<sup>[55]</sup>. In this region, similar intermediate hosts have been found<sup>[10]</sup> while in northern Western Australia the source of infection has yet to be confirmed<sup>[56]</sup>.

However, wildlife reservoirs play the main role in maintaining a constant source of transmission for domestic livestock, domestic dogs and humans<sup>[53,54,57-60]</sup>. Recent analyses assessed infection in wild dogs caught in the outer suburbs of Townsville, Queensland<sup>[61]</sup>, and in those examined from the Maroochy Shire, eastern Queensland<sup>[62]</sup>. Sheep infection is still common in farms with a high number of poorly managed domestic dogs; additionally livestock are often hunted by wild dogs contaminating the pasture with eggs of *E. granulosus*<sup>[53]</sup>. However, dog and sheep infection prevalence seems to be decreasing over the last years<sup>[60]</sup>, although recent surveys reported a re-emergence of domestic transmission of *E. granulosus* in some rural areas of south eastern regions where it was found that 29% of 344 rural dogs in New South Wales and 18% of 218 Victorian dogs tested positive<sup>[63]</sup>.

Annually, new cases of human hydatidosis appear stable, numbering between 80 and 100 among the entire country<sup>[60,64]</sup>. Human transmission has traditionally been a public health problem of rural people due to *E. granulosus* infected domestic animals, but there is increasing potential for accidental exposure of urban residents due to the infiltration in urban centres by infected wildlife definitive hosts such as foxes and wild dogs. In fact, these animals are attracted to public recreation areas commonly fre-

quented by urban residents to scavenge food scraps<sup>[61,65]</sup>. Thus, urban residents could accidentally have direct contact with *E. granulosus* eggs through wild dog or fox faeces or *via* coprophagous flies when visiting parks and forests for recreational purposes. Furthermore, it has been documented that there has been a potential infection of the dogs of recreational pig hunters living in urban centres<sup>[66]</sup>.

The reporting of hydatidosis or echinococcosis does not depend on any monitoring system but only on individual case reports. Thus, assessing accurate prevalence and incidence, as well as trend changes over time, is still difficult to achieve.

### Western and Central Asia

The G1 strain, infecting sheep, goats, cattle and camels, is the most common genetic variant documented in Iran<sup>[67]</sup>. On the other hand, the G6 strain has also been found in camels, sheep and cattle in the same area<sup>[67]</sup>. Both of these were diagnosed in human hydatid infection confirming the pathogenicity of G6 for humans<sup>[67]</sup>.

In Kazakstan, it has been assessed that the prevalence of infection in sheep ranges between 20%-25% in 1-year-old sheep and 74%-80% in sheep 6 years old and over. Among wild and village dogs, the prevalence of infection is 23% and 6%, respectively<sup>[68]</sup>. Although the highest worm burdens have been recorded in rural dogs, only those closer to human habitation are responsible for transmitting disease to humans<sup>[68]</sup>. Human infection has increased since the middle 1990s till present time from 200 surgical cases annually to the current level of nearly 1000 cases per year<sup>[69,70]</sup>. Similar trends in human cases have been assessed in all other Central Asian countries. However, no detailed data is available about transmission and diffusion of *E. granulosus* infection in Central Asian countries.

Hydatidosis is a serious public health problem in Turkey where *E. granulosus* infection in dogs ranges between 0.32% and 40%<sup>[71]</sup>. The predominant genotype of *E. granulosus* in Turkey is the G1 strain with a prevalence infection rate in farm animals ranging from 26.6% to 50.9% in sheep, from 13.3% to 35.68% in cattle, and reaching 22.1% in goats, 44.31% in cows and 24.39% in bulls in the most endemic areas such the Budur region<sup>[72]</sup>, the Kirikkal region<sup>[73]</sup>, the Afyonkarahisar district<sup>[74]</sup>, and the Sivas region<sup>[75]</sup>. Lower rates in sheep (3.5%) and cattle (11.6%) have been found in less endemic areas such as Thrace region<sup>[76]</sup>. Surgical cases of human hydatidosis have been estimated to range from 0.87 to 6.6 per 100 000 inhabitants between 1987 and 1994<sup>[71]</sup>. A more recent survey based on hospital, regional and ministerial documents showed that, from 2001 to 2005, a total of 14 789 CE surgical cases were recorded with a higher incidence in the Middle Anatolian region (38.57%) and lower in the Black Sea region<sup>[77]</sup>.

Several regions of the Arab peninsula such as Syria, Israel and Palestine are considered endemic for *E. granulosus*. In fact, hydatidosis is mostly associated with main risk factors such as livestock production, raising of sheep

and nomadic tribal life that characterize northern Syria, northern Israel and western Palestine. Epidemiological evidence in Syria showed a prevalence of *E. granulosus* infection ranging between 9% and 15% in dogs and between 5% and 17% in livestock<sup>[78]</sup>; in Israel, ranging between 5.4% to 14.2% in dogs and between 4.56% and 10% in sheep<sup>[79,80]</sup>; and in Palestine, ranging between 7.9% and 14.3% in dogs<sup>[81]</sup>. Human infection rates have been assessed in individual studies. Annual surgical prevalence recorded from the Al-Maqased Hospital in Jerusalem was documented to be 1.76 per 100 000 inhabitants in the middle 1990s<sup>[81]</sup>, while in hospitals of the Palestinian West Bank this value was 3.1 per 100 000 inhabitants, with the highest rates of 4.9, 5.0 and 5.1 per 100 000 inhabitants found in Hebron, Jericho and Bethlehem, respectively<sup>[82]</sup>. In an epidemiological study conducted in northern Israel a cumulative infection rate of 1.5 per 100 000 inhabitants was found<sup>[83]</sup>, while in another study conducted in a Bedouin group from southern Israel this rate was 0.68%<sup>[83]</sup>.

### China

China is one of the most important endemic regions of CE<sup>[2]</sup>. The sheep strain (G1) and the camel strain (G6) are the only two *E. granulosus* strains found in China<sup>[84]</sup>, both of them infectious to humans<sup>[85]</sup>. The most endemic areas for *Echinococcus spp.* have been recognized as the provinces and autonomous regions stretching from western Xinjiang<sup>[86]</sup>, Ningxia and Inner Mongolia, with the highest prevalence rates occurring in pastoral communities of the eastern Tibetan plateau<sup>[87-89]</sup> (south western Qinghai and north western Sichuan) and the Tibetan autonomous area of south Gansu<sup>[90]</sup>, located in western and northwestern China<sup>[85,91-95]</sup>. Infection by cysts of *E. granulosus* can be found in organs of ungulate intermediate hosts<sup>[96-99]</sup>. High prevalence of hydatid infection has been reported in sheep and yaks (99%), cattle (88%) and pigs (70%)<sup>[90]</sup>. In fact, in the western and northwestern pastoral areas of China, livestock pastoralism is a major industry with a total of 350 million sheep and other domesticated large herbivores including horses, camels, and red deer<sup>[90]</sup>. On the other hand, the definitive host is mainly represented by canids, predominantly the domestic dog. Indeed, they are kept in large populations in northwestern China for pastoralism and cultural reasons<sup>[87]</sup>. Given the close contact with local people, dogs are considered the most important definitive host transmitting *E. granulosus* to humans<sup>[2,87]</sup>. However, in certain rural regions, wild canids such as wolves and foxes are involved in the sylvatic cycle<sup>[2]</sup>.

The first human CE was reported in China in 1905<sup>[86]</sup>. Over the last century, about 35 000 cases of human cystic echinococcosis have been treated surgically in China. However, given the documented 21 560 cases in Xinjiang alone with a prevalence of 80 cases/100 000 inhabitants<sup>[86]</sup>, it has been assessed that an underestimation occurred in past years. Now, it has been estimated that about one million existing cases of human echinococcosis occur in China<sup>[100]</sup>. Of these, about 70% present with chronic cystic lesions of the liver as well as in other organs includ-

ing the brain<sup>[101]</sup>. The infection rate of females has been assessed to be considerably higher than that of males because of their role in the home activities including feeding dogs, collecting yak dung for fuel, and milking livestock<sup>[87,102]</sup>. Thus, nomadic or seminomadic pastoral lifestyle is one of the most important risk factors for CE in China, especially in western and northwestern areas where livestock pastoralism is a major industry<sup>[90]</sup>, and women are more frequently exposed to the definitive hosts of CE. Consequently, adults have much higher infection rates than children<sup>[87]</sup>, and the infection rate increases with age<sup>[102]</sup>.

The increasing number of diagnosed cases may reflect improved diagnostic methods and improved outreach programs. In fact, China is now recognized as a new focus for echinococcosis research.

### Africa

Although most regions of Africa are poorly researched and limited information is available, several taxa have been found in the African countries<sup>[19,103,104]</sup>. The most common strain is the G1, highly diffused in the North and East African sheep raising areas. Moreover, the exclusive presence of the camel strain (G6) has been documented. In addition, wild strains such as the *E. equinus* (the "horse strain")<sup>[105]</sup> and the "lion strain"<sup>[106]</sup> have been found in South Africa. However, the nature of *Echinococcus* in African wildlife is poorly documented.

In a recent study carried out in Libya, 25.8% of stray dogs and 21% of owned dogs have been assessed to be positive for EC<sup>[107]</sup> while another study found a prevalence of 58% of hydatidosis in the same area<sup>[108]</sup>. Nevertheless, several surveys assessed that other animals also, especially camels, are frequently infected by *E. granulosus*<sup>[109,110]</sup>, while infection rates in livestock varied from 1.7% to 33.4% in sheep, 1.0% to 13.9% in cattle, 1.4% to 40.0% in camels and 0% to 18% in goats<sup>[111-113]</sup>, often associated with human cases<sup>[114]</sup>. The sheep strain has been considered the most common genetic variant diffused among humans in another survey, reporting a prevalence rate of 1.7% of 20 200 patients screened by ultrasound for hydatid cysts in 36 villages along the northern coast of Libya<sup>[115]</sup> and an incidence rate of 4.2 cases per 100 000 inhabitants in Eastern Libya<sup>[112]</sup>. Indeed, in a genetic survey conducted on 179 isolates from humans collected in the border area of northwestern Kenya and south-eastern Sudan, only one was associated with the camel strain (G6) while the remaining were the common sheep strain (G1)<sup>[117]</sup>. On the other hand, other surveys conducted in central Sudan<sup>[110,116]</sup> and Egypt<sup>[117]</sup> documented the presence of human echinococcosis cases diagnosed as G6 and at least two other distinct strains (camel and equine)<sup>[118]</sup>.

CE is currently of low endemicity in Egypt with a mean prevalence in dogs ranging between 3.2% in urban areas and 6% in rural areas<sup>[119]</sup>. Higher prevalence has been documented in Cairo with about 15% of dogs infected<sup>[120]</sup>. Among ruminants, confirming earlier re-

sults<sup>[121]</sup>, recent data demonstrated an overall prevalence infection rate of 0.3% in sheep and goats, 0.68% in pigs, 6.4% in cows and buffaloes, 2.53% in camels<sup>[121]</sup> and 10.62% in donkeys<sup>[122]</sup>. In humans, a retrospective hospital study showed an annual surgical incidence ranging between 1.34 and 2.60 per 100 000 inhabitants<sup>[123]</sup>.

In Tunisia, echinococcosis is a major public health problem due to its high prevalence and morbidity. Molecular analysis has demonstrated that the most common genetic variants of *E. granulosus* circulating in Tunisia are the G1 sheep strain and the G6 camel strain<sup>[124,125]</sup>. Sheep breeding is a significant risk factor, being practised by 94.7% of patients *vs* 58.3% of the farming population<sup>[126]</sup>. A series of studies carried out between 1999 and 2007 assessed that the prevalence of *E. granulosus* infection reached 10.41% in lambs (6-12 mo), 75.42% in sheep aged 1-2 years and 83.83 to 100% in sheep over 2 years old<sup>[127]</sup>; and 10.1% of camels<sup>[124]</sup> and 40% of sheep in a further analysis conducted in North-East Tunisia<sup>[128]</sup>. Despite the lack of recent published data, the last report of EC in humans reported an annual surgical incidence of hydatidosis of about 15 per 100 000 inhabitants<sup>[129]</sup>.

In Algeria similar strain distribution has been found, identifying the sheep strain G1 infecting sheep, cattle and humans and the camel strain G6 infecting camels<sup>[130]</sup>. Dogs likely represent the main source of infection for farm animals and humans<sup>[19]</sup> with a prevalence rate of 24.8% in camels, 13.9% in cattle and 6.0% in horses<sup>[131]</sup>. Despite poor data regarding recently reported human infection, it is documented that more than 700 surgical cases are notified each year to the Ministry of Health. Last published work assessed that the annual incidence of human EC reached 3.6-4.6 per 100 000 inhabitants<sup>[132]</sup>.

Morocco is considered an endemic area for echinococcosis. A genotype almost similar to the common G1 sheep strain with some nucleotide variations was found in camels and horses. Infection rate in dogs ranges from 22.0% to 62.8%, depending on the region<sup>[133]</sup>. In a more recent analysis, CE infection prevalence rates have been documented to be 10.58% in sheep, 1.88% in goats, 22.98% in cattle, 12.03% in camels and 17.80% in equines, mostly in Middle Atlas (48.72% in cattle) and in North West (37.61% in cattle and 31.65% in sheep)<sup>[134]</sup>. In humans, an annual rate of 4.55 surgical cases per 100 000 inhabitants has been documented in 2006, with a higher prevalence in the middle Atlas mountainous region<sup>[135]</sup>.

### Europe and the Mediterranean Basin

With the exception of Malta and the area controlled by the Government in southern Cyprus, where the disease has been practically eliminated, all the Mediterranean regions including the Arab peninsula countries are facing problems due to CE. Indeed, in Cyprus CE had an annual surgical incidence rate of 12.9 per 100 000 inhabitants before the first eradication program implemented in the 1970s and, subsequently, a second program in the 1990s<sup>[136]</sup>. In the northern part of Cyprus, disease rates

decreased from 1.95% in dogs examined in 1998-1999 to 0.012% in 2000-2003, from 23.58% to 6.61% in cattle, from 5.31% to 1.53% in sheep, while in goats rates were consistently below 0.5% and remained at 0.13%. On the other hand, the south part of Cyprus that maintained its control programme was able to keep positive testing levels at virtually 0%<sup>[137]</sup>.

In Europe, *E. granulosus* is present in most countries with the exception of Ireland, Iceland and Denmark. EC of animals is rare in northern and central Europe with the exception of cervid-transmitted echinococcosis in Finland and pig-transmitted echinococcosis in regions further east. The cervid strain in Finland was found to differ genetically from the previously described North American cervid strain G8, and was identified as a new strain, G10<sup>[138]</sup>. Transmission has been documented to occur mostly between wolves, reindeer and elks<sup>[139]</sup>.

The most endemic areas have been documented to be the Mediterranean regions where annual incidence rates for human CE of 4-8 per 100 000 have been reported, and parts of Eastern Mediterranean countries such as Bulgaria<sup>[2]</sup>. In some other eastern regions such as Poland, Slovakia and Ukraine, the pig strains (G6-G10) often occur as animal and sometimes human CE<sup>[140,141]</sup>. In Serbia and Montenegro the most frequent intermediate hosts for *E. granulosus* are pigs, with a percentage of infected animals ranging between 4.6% and 57.6%<sup>[142]</sup> but no information is available about human infection. Although several other countries such as Albania<sup>[78]</sup>, Bosnia and Herzegovina<sup>[143,144]</sup> are recognized as endemic for CE, none of them have available published data on the exact incidence of CE in livestock, carnivores or humans.

In Greece, investigation of the prevalence and the genotype of *E. granulosus* in sheep and goats in Peloponnese (southern Greece) revealed that sheep were infected by the G1 (sheep) strain and the G3 (buffalo) strain, while the 20 goats examined harboured the G7 (pig) strain<sup>[145]</sup>. The prevalence of CE in farm animals ranged from the mid 1980s to the mid 1990s between 82% and 56.6% in cattle, 80% and 100% in sheep, 24% and 15.4% in goats and 5% and 9.3% in pigs, while surgical human cases reached 12.9 per 100 000 inhabitants in 1984 and up to 29% in 1999<sup>[146]</sup>. Furthermore, surveillance in livestock species since 1998 has documented a prevalence of 31.3% in sheep, 10.3% in goats, 0.6% in pigs and 0% in cattle<sup>[146]</sup>. Finally, a more recent survey conducted on sheep in central Greece from 2002 to 2006, revealed an incidence rate of 39.3%<sup>[147]</sup>. In humans, the overall incidence rate was estimated to have increased from 9.77 per 100 000 in 1967<sup>[148]</sup> to 10.59 per 100 000 inhabitants in 1983<sup>[149]</sup>; results which were confirmed in another survey where an incidence of 12.7 per 100 000 inhabitants (varying from 11.6 to 13.35) has been reported<sup>[150]</sup>. Incidence rates steadily declined in the most recent survey carried out in 2007 where they have been documented to be 0.122 per 100 000 inhabitants<sup>[151]</sup>. Published data for the entire country are not available but according to personal communications with surgeons it is estimated that approxi-

mately 800 cases of cystic echinococcosis are diagnosed each year, of which between 300 and 400 of them were undergoing surgical treatment.

In Western Europe, the sheep strain (G1) is the principal cause of human CE. In the past, the cattle-based transmission cycle of *E. ortlepp* in Germany and Switzerland has been documented<sup>[2,152]</sup>, but now cases are reduced to sporadic occurrence and only a single case from a human patient in the Netherlands has been reported<sup>[21]</sup>.

In the United Kingdom, the parasite has a restricted distribution, being found mainly in mid and southern Wales<sup>[2,152]</sup>. Recently, a re-emergence of *E. granulosus* in Wales has been reported, noting a rise in prevalence in rural dogs between 1989 and 2002 of 3.4% to 8.1%<sup>[153]</sup>.

In Spain, CE is an endemic disease in north-eastern, central and western parts of the country, with prevalence rates rising in the last few years. The most common strains found in these areas were the sheep strain (G1) infecting sheep, cattle, goats, pigs, wild boars and humans, the pig strain (G7) infecting pigs, goats and wild boars, and *E. equinus* (old G4 strain) infecting horses<sup>[154]</sup>. In the province of Alava, two recent surveys documented prevalence of *E. granulosus* infection of 8% in the dog definitive hosts<sup>[155]</sup> and 15% in Iberian wolves<sup>[156]</sup>. In the municipality of Madrid, it has been assessed that hydatidosis affected 2.88% of sheep<sup>[157]</sup>. In Laroja region, the overall prevalence has been calculated to reach 20.3% in adult sheep and up to 23% in sheep and cows in the north-eastern, central and western parts of the country<sup>[158]</sup>.

With regard to human hydatidosis, a higher incidence of surgical cases occurs in Salamanca, with 10.8/100 000 inhabitants affected between the end of the 1980s and 2000<sup>[159]</sup>. On the other hand, in the Laroja region, prevalence of CE decreased from 19 to 4 cases per 100 000 inhabitants until 2000<sup>[158]</sup> and in the rest of the country it ranges between 1.1 and 3.4 cases per 100 000 inhabitants<sup>[159]</sup>.

In France, a surveillance system in the mid 1990s revealed a prevalence of hydatidosis of 2.5% in livestock and less than 0.28 per 100 000 in humans<sup>[160]</sup>. A higher annual incidence has been documented in Corsica (10/100 000) and eastern regions (4.5/100 000 inhabitants)<sup>[78]</sup>. In recent years, the European Centre for Disease Prevention and Control reported 17 human cases in 2005.

Italy is considered a medium to high risk country for echinococcosis. The G1 (sheep), G2 (Tasmanian sheep), G3 (buffalo), G4 (horse), and G7 (pig) genotypes of *E. granulosus* are commonly found in livestock of several regions of Italy, especially in the southern part (such as in the Campania region), in Sardinia and in Sicily<sup>[3]</sup>. Indeed, the prevalence rate of *E. granulosus* in sheep has been reported to be 5%-28% in Basilicata, 22% in Abruzzo and 47% in Tuscany<sup>[3]</sup>. In Sicily, CE was found in 67.1% of cattle, 11.13%-57.6% of sheep and 5.6%-19% of shepherd dogs<sup>[161,162]</sup>. CE prevalence of infection in Sardinia has been assessed to be 70%-92.8% of sheep, 9.4% of cattle, 9.4%-11.1% of pigs, 1% of horses and 3%-19% of dogs<sup>[3,163-166]</sup>. In Campania, the prevalence rate in cattle has been reported to range from 10.4%<sup>[167]</sup> to 14.8%<sup>[163]</sup> while in

buffalos this ranges from 10%<sup>[168]</sup> to 18.6%<sup>[169]</sup>.

Infection of *E. granulosus* in animals seems to occur also in several regions of the centre of Italy while north regions could be considered of low endemicity. Indeed, in Central Italy medium prevalence values usually range from 20.2% to 47%-81.18% in sheep, from 7.34% to 15.3% in cattle, and reach 71.97% in goats, and 0.82% in pigs<sup>[170-172]</sup>. In Abruzzo, prevalence infection rates in sheep and cattle are 20.2% and 15.3%, respectively<sup>[163]</sup>. On the other hand, in Emilia Romagna the prevalences were low for several animals: 0.39%-0.54% in cattle, 0.30% in sheep, 0.39% in goats, 0.34% in horses and 0.95 per million in pigs<sup>[173]</sup>. In dogs and wolves retrieved along the whole Apennines the prevalence of *E. granulosus* infection has been noted to be 31% and 15%, respectively<sup>[172,174]</sup>.

Despite these findings, the overall national occurrence of CE in farm animals can be considered low with prevalence rates of 0.52% of cattle, 1.30% of sheep, 0.6% of goats, 3.86% of sheep and goats, 0.0013% of pigs and 0.019% of horses<sup>[175]</sup>. On the other hand, human hydatidosis represents a serious public health problem, with an incidence of 1.3 cases per 100 000 inhabitants, a maximum of 4-8 cases per 100 000 inhabitants in Sardinia<sup>[176]</sup>, and the occurrence of over 1000 cases requiring surgery each year<sup>[177]</sup>. Endemic zones reflect animal infection, with higher incidence rates in Sardinia and Sicily, medium in the Central-South regions, and a sporadic diffusion in the northern part of the country where this disease plays a minor role (prevalence < 1%). Annual mean incidence rates of surgical cases have been reported to be 6.6-10.6 per 100 000 inhabitants in Sardinia<sup>[178,179]</sup>, 1.57-5.6 in Emilia Romagna<sup>[180,181]</sup>, 1.22 in Lombardia, 2.30 in Sicily<sup>[182]</sup>, 1.76 in Basilicata, 0.46 in Campania and 2.33 in Apulia<sup>[178]</sup>.

Risk factors for infection are now considered to be widespread use of extensive or semi-extensive sheep farming (echinococcosis being a work-related disease), illegal slaughtering, and high numbers of sheepdogs and other types of dogs<sup>[183]</sup>.

## CONCLUSION

Given the wide geographic distribution, CE caused by *E. granulosus* is a re-emerging disease in several countries and regions, even in places where it was previously at low levels. Evidence suggests this is a result of a reduction of control programmes due to economic problems and lack of resources, leading to severe disease, considerable economic loss and, definitely, a public health problem of increasing concern.

### Abstract

Liver hydatidosis is a parasitic endemic disease affecting extensive areas in our planet, a significant stigma within medicine to manage because of its incidence, possible complications, and diagnostic involvements. The diagnosis of liver hydatidosis should be as fast as possible because of the relevant complications that may arise with disease progression, involving multiple organs and neighboring structures causing disruption, migration, contamination. The aim of this essay is to illustrate the role of imaging as ultrasonography (US), multi detector row computed tomography, and magnetic resonance imaging (MRI) in the evaluation of liver hydatidosis: the diagnosis, the assessment of extension, the identification of possible complications and the monitoring the response to therapy. US is the screening method of choice. Computed tomography (CT) is indi-

cated in cases in which US is inadequate and has high sensitivity and specificity for calcified hydatid cysts. Magnetic resonance is the best imaging procedure to demonstrate a cystic component and to show a biliary tree involvement. Diagnostic tests such as CT and MRI are mandatory in liver hydatidosis because they allow thorough knowledge regarding lesion size, location, and relations to intrahepatic vascular and biliary structures, providing useful information for effective treatment and decrease in post-operative morbidity. Hydatid disease is classified into four types on the basis of their radiologic appearance.

### INTRODUCTION

Hydatid disease is a worldwide zoonosis caused by the larval stage of the echinococcus tapeworm, that is endemic in many parts of the world (in European, Middle Eastern, Mediterranean, South American and African countries)<sup>[1-4]</sup>. There are two types of Echinococcus infections: Echinococcus granulosus, the more common type, and Echinococcus multilocularis, the less common but more invasive. Hydatid disease is a relevant health problem in underdeveloped areas where veterinary control does not exist. The

most frequent location of hydatid cystic lesions is in the liver (up to 80% of cases), followed by the lung (about 20% of cases), and with a lower reported incidence in any other organ or tissue in the body<sup>[1-4]</sup>.

Dogs or other carnivores are definitive hosts, whereas sheep or other ruminants are intermediate hosts. Humans are secondarily infected by the ingestion of food or water contaminated by dog feces containing the eggs of the parasite. After the ingestion of the eggs, the freed embryo enters a branch of the portal vein by passing through the duodenal mucosa; most of these embryos become lodged in the hepatic capillaries where they either die or grow into hydatid cysts. Some embryos pass through the hepatic capillaries and become lodged in the lungs and other organs.

The definitive diagnosis of liver echinococcosis requires a combination of imaging, serologic, and immunologic studies<sup>[4]</sup>.

At biochemical analysis, there is usually eosinophilia, and a serologic test is positive in 25% of patients<sup>[5]</sup>. At histopathologic analysis, a hydatid cyst is composed of three layers: the outer pericyst, which corresponds to compressed liver tissue; the endocyst, an inner germinal layer; and the ectocyst, a translucent thin interleaved membrane<sup>[5]</sup>.

Imaging procedures are essential in diagnosis and evaluation of the extent of liver hydatidosis; ultrasound (US), computed tomography (CT), and magnetic resonance (MR) can depict hydatid disease<sup>[2-4,6]</sup>.

The imaging method used depends on the involved organ, and the radiologic findings range from purely cystic lesions to a completely solid appearance<sup>[3]</sup>. US is the screening method of choice and is also used to monitor efficacy of medical therapy<sup>[2-4,6]</sup>. CT is always performed because it has a high sensitivity (94%)<sup>[7]</sup>. It is an important preoperative diagnostic tool to determine vascular, biliary or extrahepatic extension, to recognize complications, such as rupture and infections, and therefore to assess respectability<sup>[8-10]</sup>. MR is the best imaging procedure to demonstrate a cystic component. It helps to determine vascular or biliary tree involvement, as well as extrahepatic extension<sup>[10,11]</sup>.

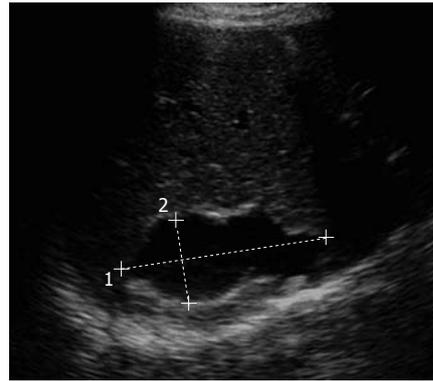

There are many potential complications such as exophytic growth, transdiaphragmatic thoracic involvement, peritoneal seeding, biliary communication, portal vein involvement, abdominal wall invasion and hematogenous dissemination in any anatomic location (lung, kidney, spleen, bone, brain)<sup>[6,10,11]</sup>.

## RADIOLOGIC FINDINGS

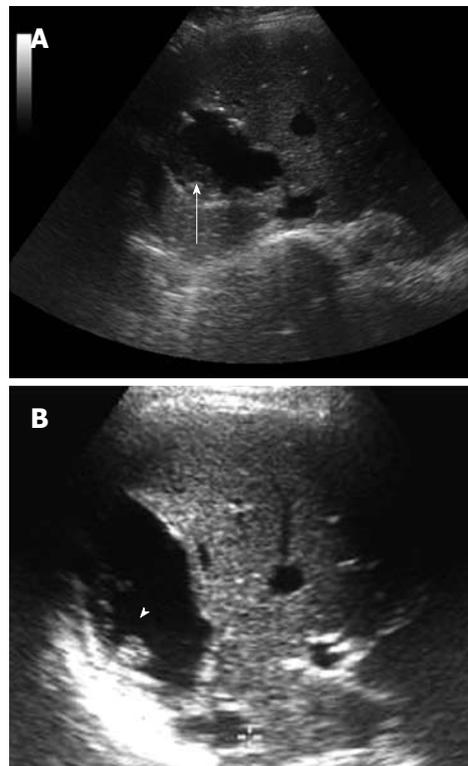

### Ultrasonographic findings

The ultrasonographic appearance of hydatid cysts may vary, from a simple aspect to a more complex one, in relation to the stage of evolution and maturity<sup>[5-7,10]</sup>. US can categorize cysts as solitary univesicular, solitary multivesicular, solid echogenic mass, multiple, either uni- or multivesicular, or collapsed, flattened and calcified<sup>[8]</sup>.

In the first stage, the hydatid cyst may manifest as a

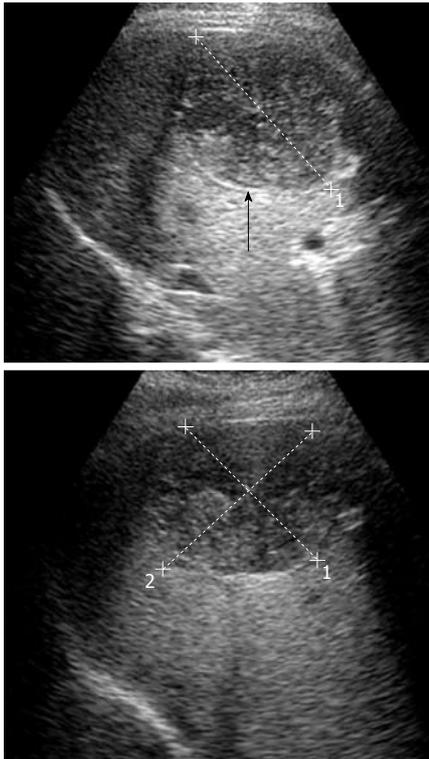

**Figure 1** Liver hydatid disease in a 50-year-old man appears as a well-defined anechoic mass without hydatid sand and septa (type I).

**Figure 2** Liver hydatidosis in a 27-year-old female. Ultrasonography images (A, B) show a lesion with mixed echogenicity, with hydatid sand (the arrow) and multiple echogenic foci (the arrowhead).

well-defined anechoic cyst (Figure 1), an anechoic cyst except for hydatid “sand”<sup>[2,6,7]</sup>. The more complex aspect is typical of the advanced stages and is related to the presence of multiple internal septa, daughter cysts, multiple echogenic foci and floating membranes inside the cavity (Figures 2 and 3)<sup>[7-9]</sup>. Membranes may appear as serpentine linear structures, a finding that is highly specific for hydatid disease<sup>[7,12,13]</sup>. The detachment of the membrane inside the cyst is considered the US “water lily sign”<sup>[13-16]</sup>. The cyst wall is visible as double echogenic lines separated by a hypoechoic layer (Figure 3)<sup>[16]</sup>.

Multivesicular cysts manifest as well-defined fluid collections in a honeycomb pattern with multiple septa representing the wall of the daughter cysts. Daughter cysts

**Figure 3** Ultrasonography images of hydatid disease show multiple internal septa and floating membranes inside the cyst. Note the cyst wall is visible as double echogenic lines (see the black arrow).

appear as cysts within a cyst<sup>[7-9]</sup>. Altering patient's position may change the position of daughter cysts.

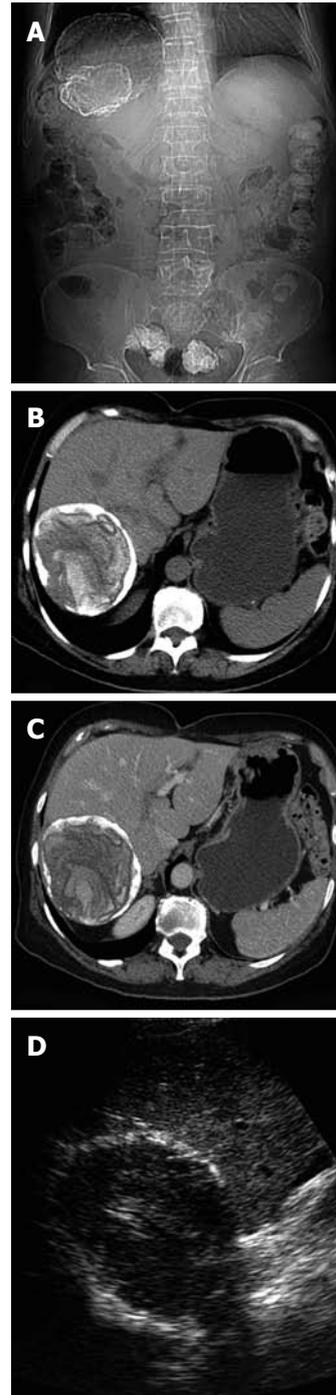

The more complex aspects of hydatid cyst may also mimic solid hepatic masses, and differential diagnosis becomes difficult but fundamental; it is important to look for daughter vesicles or membranes within the lesion that may help in differential diagnosis<sup>[7,8]</sup>. Cyst calcification is seen in dead hydatid cysts; US shows a hyperechogenic contour with a cone-shaped acoustic shadow<sup>[13,15,16]</sup>.

When the cyst wall is heavily calcified, only the anterior portion of the wall is visualized and appears as a thick arch with a posterior concavity. Partial calcification of the cyst does not indicate the death of the parasite, on the contrary densely calcified cysts may be assumed to be inactive<sup>[8,9]</sup>.

US is considered the preferred investigatory test to monitor efficacy of medical antihydatid therapy because of its low cost<sup>[12,14]</sup>. Positive response findings include reduction in cyst size, membrane detachment, progressive increase in cyst echogenicity and mural calcification<sup>[12]</sup>.

### Computed tomography findings

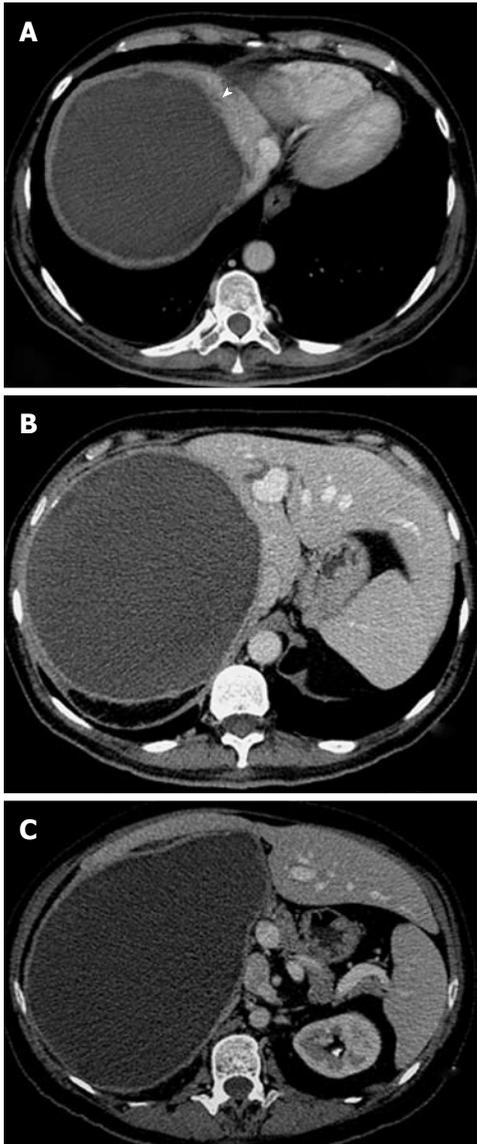

CT is indicated in cases in which US is inadequate due to patient-related difficulties (obesity, excessive intestinal gas, previous surgery<sup>[3,5-7]</sup>). CT has high sensitivity and specificity for hepatic hydatid disease<sup>[7]</sup>. Intravenous administration of contrast medium is useful to give a vascular map to the surgeon, and when complications (especially infection and communication with the biliary tree) and extra-hepatic diffusion are suspected.

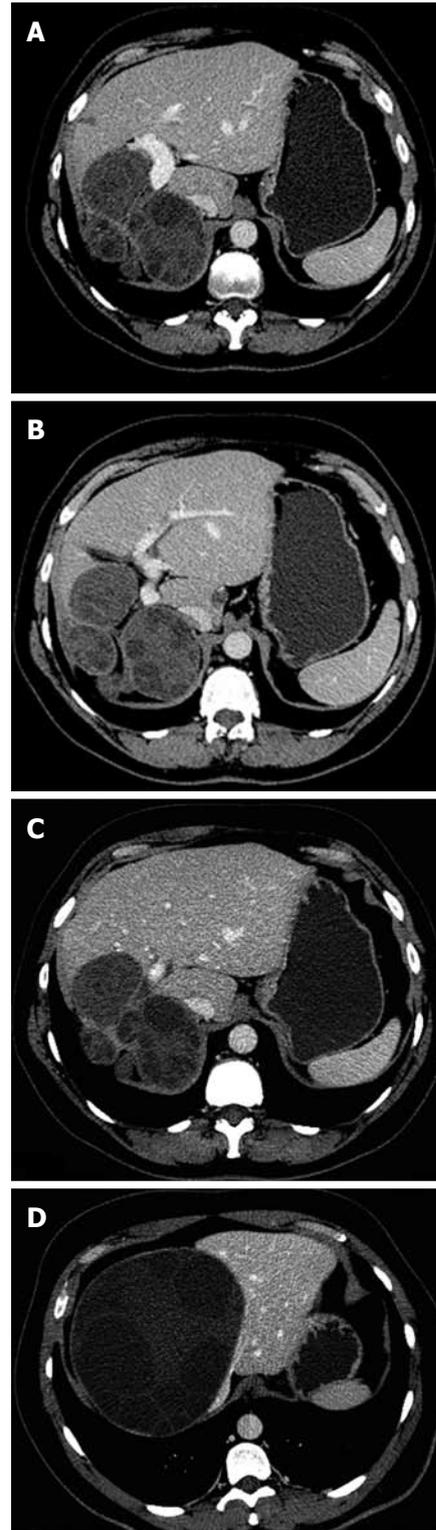

**Figure 4** Calcified unilocular hydatid cyst. Digital scout image (A) shows a round, densely calcified lesion supra-elevating the right diaphragm. Computed tomography basal (B) and contrast-enhanced (C) images reveal a hypoattenuating lesion with peripheral wall calcification in the right lobe. Membranes appear as serpentine linear structures. Note the complex ultrasonography aspect of the cyst and the hyperechoic wall (D).

CT may show the same findings as US<sup>[6,7]</sup>. Calcification of the cyst wall, internal septa, floating membranes and daughter vesicles are easily detected at CT<sup>[3,5]</sup>.

A hydatid cyst typically is seen as a round lesion with water attenuation density, surrounded by a calcified ring-like (Figure 4) or highly attenuated wall, representing the pericyst (Figure 5)<sup>[17]</sup>. Detachment of the laminated mem-

**Figure 5** Computed tomography scan shows a huge nonenhancing mass with regular contours and thickened wall representing the pericyst (the white arrowhead) occupying all the right lobe of the liver (type I); either the right portal vein or the right hepatic vein is completely replaced.

**Figure 6** Computed tomography scan (A, B, C, D) shows some unenhanced hypoattenuating masses with well defined borders occupying the right lobe of the liver; multiple round daughter cysts are seen peripherally inside the lesion (type II). Note the "rosette appearance".

branes from the pericyst are visualized as linear areas of increased attenuation within the cyst<sup>[17]</sup>.

At CT daughter vesicles are visible as round structures located peripherally within the mother cyst; they usually contain fluid with a lower attenuation than that of the fluid of the mother cyst (Figure 6)<sup>[5,7]</sup>.

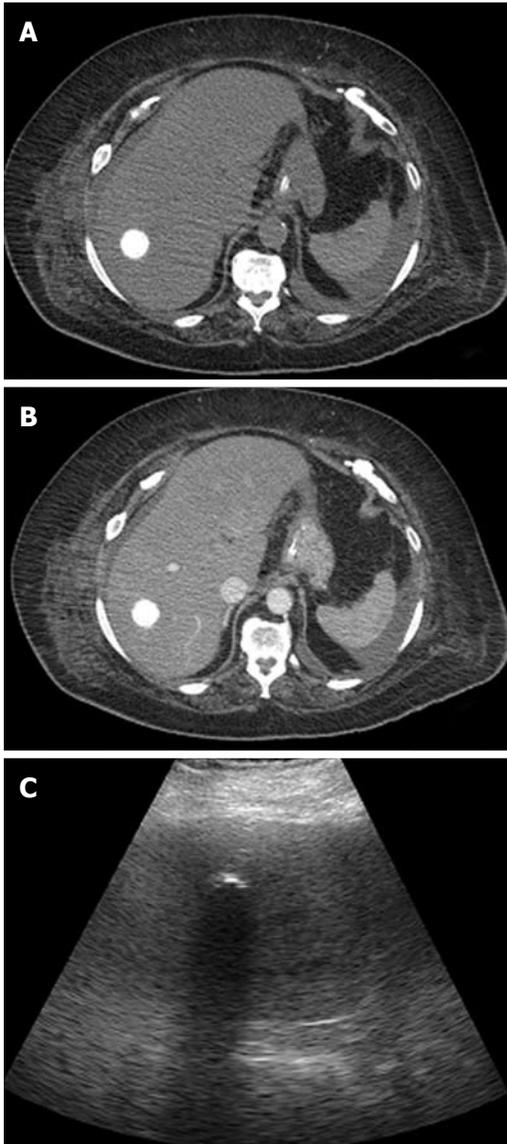

Contrast-enhanced CT may show the typical high-attenuation rim representing abscesses surrounding the lesion. Sometimes, patchy areas of contrast-enhanced liver parenchyma are seen in the vicinity of the lesion, representing inflammatory changes<sup>[18]</sup>.

The dead cysts are totally calcified and at CT they appear as round hyperattenuating areas (Figure 7)<sup>[5,7]</sup>.

CT also may depict gas or air-fluid levels or fat inside the hydatid cyst, indirect signs of infection and/or communication with the biliary tree (Figures 8 and 9)<sup>[6,10,11]</sup>.

CT is the modality of choice to study extra-hepatic diffusion because it allows imaging of the entire abdomen, pelvis and thorax.

Extra-hepatic diffusion may regard peritoneum, the

**Figure 7** Seventy-three year-old-woman with a dead hydatid cyst. Computed tomography scan basal and enhanced images (A, B) show a totally calcified cyst (type III). At ultrasonography (C) calcified cyst shows strong posterior shadowing.

diaphragm and the thorax cavity, the abdominal wall, the portal system, and the hematogenous dissemination<sup>[4,6,7]</sup>.

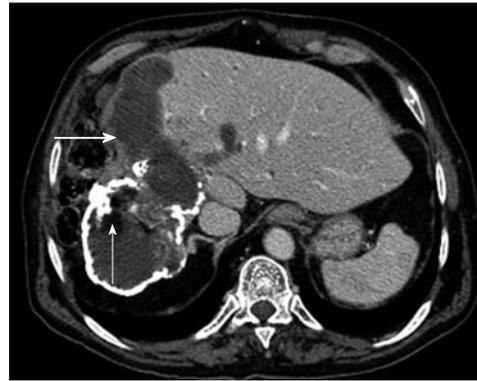

**Magnetic resonance findings**

MR may be performed to confirm the hypothesis of hepatic hydatidosis and visualize the lesion in different planes. It is the best diagnostic investigation to differentiate the cystic component from the others and to demonstrate a biliary tree involvement<sup>[13]</sup>.

The hydatid cysts may show variable signal intensities on T1- and T2-weighted images, according to the different components inside the lesion<sup>[13,17,18]</sup>.

The necrotic and the fluid components are hypointense on T1-weighted images and markedly hyperintense on T2-weighted images<sup>[13,18,19]</sup>.

When present the daughter cysts are seen as cystic structures attached to the germinal layer that are hypointense relative

**Figure 8** Contrast-enhanced upper abdominal computed tomography scan demonstrates a partially calcified hydatid cyst in direct communication with the biliary tree markedly dilated (the bold white arrow). The presence of fat components within the cyst derives from the lipid elements in bile (the thin white arrow) (type IV).

**Figure 9** Fifty-five-year-old male with acute abdominal pain, fever and leucocytosis. Contrast-enhanced computed tomography shows intracystic gas in the anterior part of a unilocular partially calcified hydatid cyst, suggesting super-infection; finding confirmed at surgery (type IV).

to the intracystic fluid on T1-weighted images (Figure 10)<sup>[13]</sup>.

The characteristic sign of hydatid disease is represented by the pericyst that usually appears as a low-signal-intensity rim on T2-weighted images (Figure 10)<sup>[17,19]</sup>.

In addition, there may be an intermediate-signal-intensity inner ring representing the detachment of the membranes<sup>[19]</sup>.

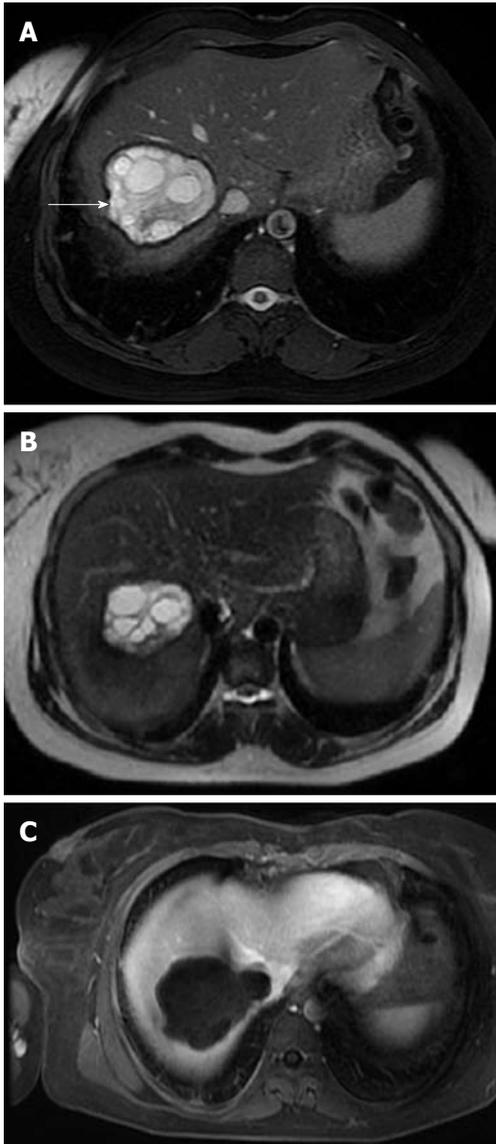

After the i.v. injection of gadolinium contrast agent the pericyst may show slight enhancement (Figure 11).

MR is the best diagnostic tool in demonstrating the floating membranes (Figure 12) and irregularities of the rim representing incipient detachment of the membranes (Figure 13)<sup>[17,19,20]</sup>. On the other hand MR is less sensitive than CT scan in showing cyst wall calcification.

The “snake sign” is another typical MR imaging feature: it represents collapsed parasitic membranes, secondary to damage or degeneration of the hydatid cyst: these membranes have low signal intensity with all sequences (Figure 13).

Intracystic air-fluid level may be visible on MR, as a possible sign of super-infection (Figure 14)<sup>[16,21]</sup>.

MR cholangiopancreatography (MRCP) is useful to

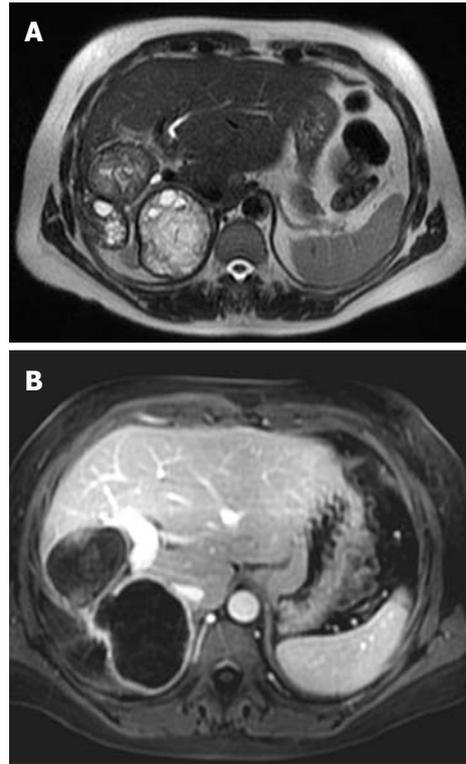

**Figure 10** Axial T1-weighted (A) and T2-weighted (B) images show a well defined cystic lesion and the typical peripheral location of the daughter cysts within the mother cyst. Note the marked hypointensity of the pericyst (the white arrow). After contrast administration (C) the cystic lesion does not show contrast enhancement (type II).

study potential involvement of the biliary tree: communication between the cysts and the biliary tree; dilatation of the biliary system secondary to compression of the hydatid cyst<sup>[20,21]</sup> (Figure 15).

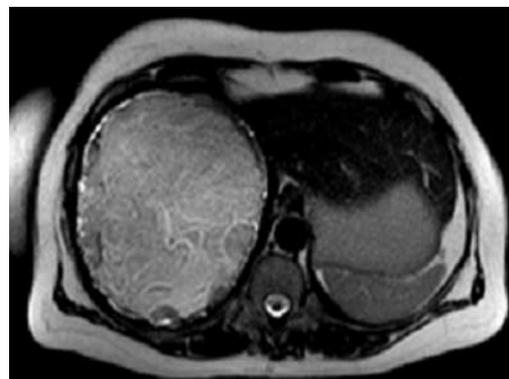

It is known that routine MRI does not adequately differentiate completely liquid hydatid cysts (type I, see following paragraph) from simple cysts: Inan *et al*<sup>[22,23]</sup> have demonstrated in their study that diffusion-weighted (DW-MRI), a recent MRI technique, can be helpful in the differential diagnosis.

DW-MRI has long been used exclusively in brain imaging due to technical problems and sensitivity to motion artifacts (caused by cardiac motion and respiration); with the advent of faster sequences, DW-MRI has been applied to abdominal imaging<sup>[22,23]</sup>.

Using DW MRI with a high b factor (1000 s/mm<sup>3</sup>) the

**Figure 11** Axial T2-weighted and post-contrast images show the exophytic growth of hydatid cyst (type II) (A). After the injection of contrast media the septa and cyst wall enhance (B). Note the proximity of the cyst to the diaphragm which facilitates transdiaphragmatic thoracic involvement and to main portal vein.

**Figure 12** 35-year-old woman living in an endemic region. Axial T2-weighted magnetic resonance image show the hydatid cyst that occupies almost the entire right lobe of the liver with thickened pericyst and multiple floating membranes inside the lesion (type II).

hydatid cysts are hyperintense, whereas none of the simple cysts show significant hyperintensity (Figure 16)<sup>[22-24]</sup>.

In addition, using DW MRI it is possible to calculate a parameter, called the apparent diffusion coefficients (ADCs), that measures the difference in cellular density of hepatic lesions<sup>[22-24]</sup>.

This quantitative parameter can be used to differentiate hydatid cysts from simple cysts. The difference between the ADCs of the hydatid cysts and those of simple cysts can be attributed to the difference in cyst contents<sup>[22-24]</sup>.

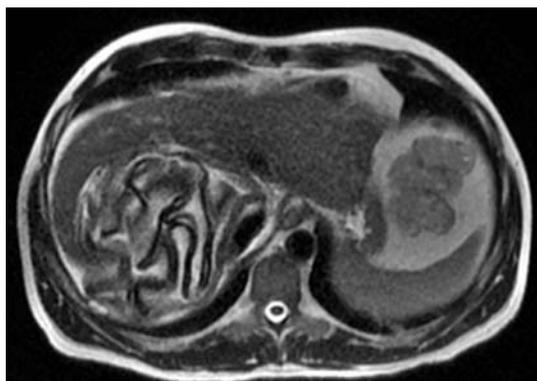

Figure 13 The detachment of the pericyst and the collapsed membranes inside the cyst due to damage or degeneration may give the hydatid cyst a serpentine linear aspect; this is the “snake sign”.

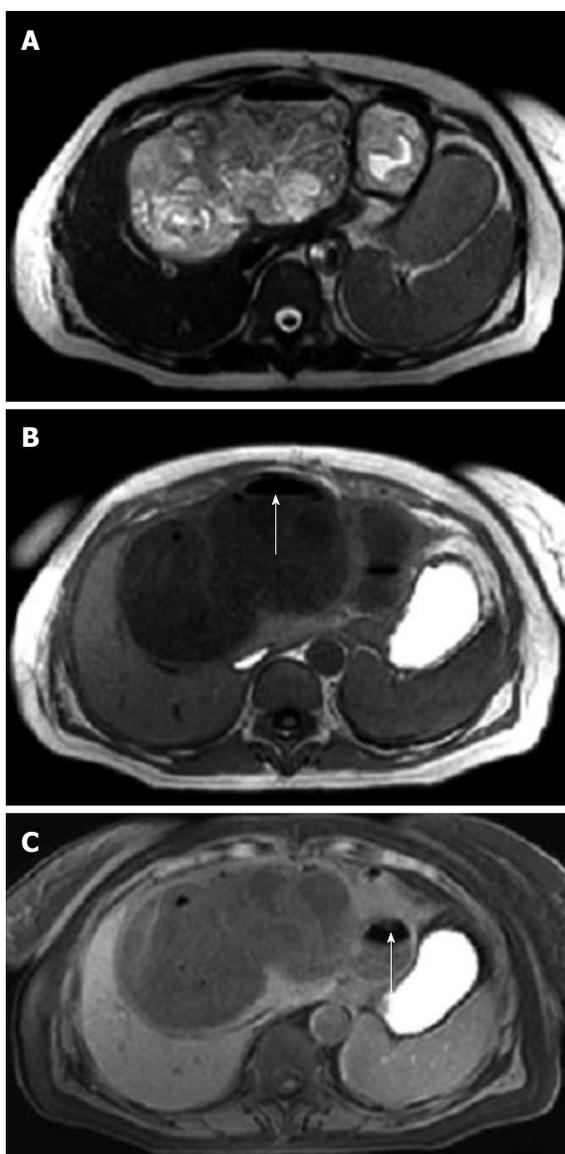

Figure 14 Axial T2-weighted (A) and T1-weighted (B, C) magnetic resonance images demonstrate a round, cystic lesion in the left hepatic lobe, with thickened pericyst, small daughter cysts, floating membranes and an air-fluid level within the cyst (white arrow). The diagnosis is an infected hydatid cyst (type IV).

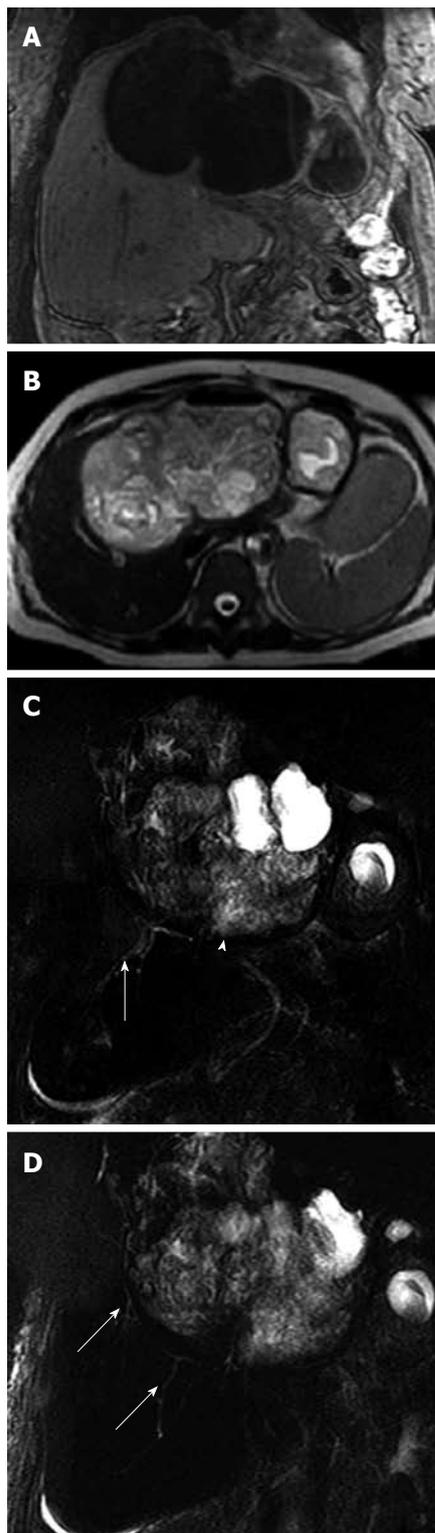

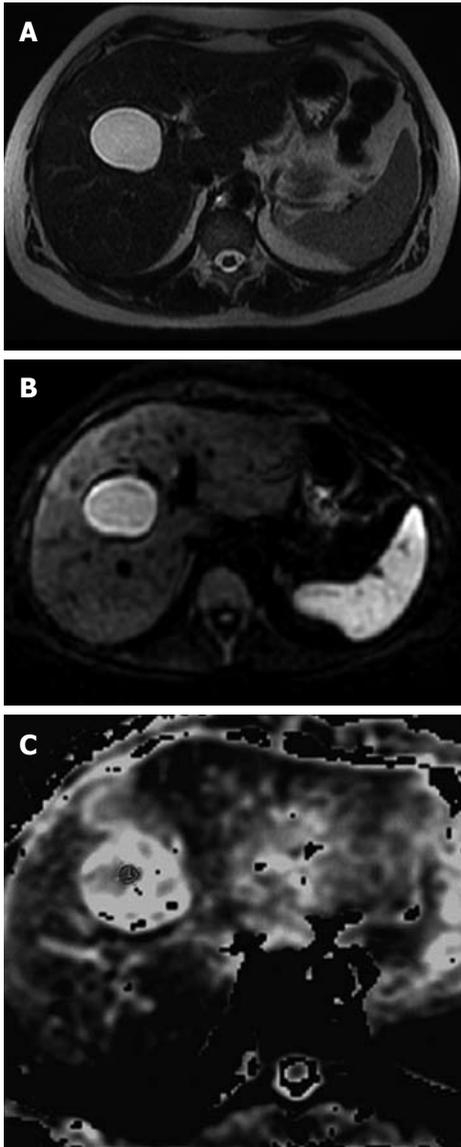

Figure 15 T1 coronal image and T2 axial image show a huge and multi-locular hydatid cyst occupying the entire left lobe, partially the right lobe (A, B) and protruding into the hepatic hilum. Magnetic resonance cholangiopancreatography (MRCP) sequences show the compression of the common bile duct at the confluence and of the right hepatic duct (the white arrowhead) and the consequent intrahepatic biliary tree dilatation (the white arrows) (C, D).

Because the hydatid cyst contains viscous hydatid sand that consists of scolices, sodium chloride, proteins, glucose, ions, lipids, and polysaccharides, the ADC of the hydatid

**Figure 16** A type I hydatid cyst. A: Axial T2 weighted magnetic resonance image depicts a round cystic mass in the anterior segment of the right lobe, with no septa or solid portions; B: On the diffusion-weighted image the lesion exhibits high signal intensity ( $b = 1000$ ); C: On apparent diffusion coefficient map, apparent diffusion coefficient value is  $2.4 \times 10^{-3}$ .

cyst is decreased; on the contrary the simple cyst has lower viscosity, hence the higher viscosity. In Inan's series the mean ADCs of the hydatid cysts was significantly lower ( $2.5 \times 10^{-3} \pm 0.9$ ) than that of the simple cysts ( $3.5 \times 10^{-3} \pm 0.5$ ) (Figure 16)<sup>[22-24]</sup>.

In patients affected by hepatic hydatidosis, contrast enhanced magnetic resonance angiography may be useful in detecting hepatic venous outflow obstruction or thrombosis or invasion<sup>[25]</sup>; in these patients, pulmonary embolism may be a possible complication (Figure 17)<sup>[26]</sup>.

## CLASSIFICATION OF HYDATID DISEASE ON THE BASIS OF IMAGING

Hydatid disease is classified into four types on the basis

of their radiologic appearance<sup>[27]</sup>:

### **Type I : Simple cyst with non internal architecture**

Hydatidosis appear at US as a well-defined anechoic mass with or without hydatid sand and septa. Unilocular cysts are considered to be an initial stage in the development of the parasite<sup>[28]</sup>. A solitary type I cyst may be difficult to distinguish from a simple epithelial cyst<sup>[8]</sup>.

At CT, a type I appears as a well-defined water-attenuation mass; after injection of contrast material the septa and cyst wall enhance, a finding that helps differentiate type I from a simple liver cyst<sup>[13,19]</sup>. MR images are also similar to those of a simple liver cyst, including hypointensity on T1-weighted images and marked hyperintensity on T2-weighted images; a low signal intensity rim (“rim sign”)<sup>[19,20]</sup>, which is more evident on T2-weighted images, has been described as typical of hydatidosis, and it can be used to differentiate hydatid cysts from simple cysts; this finding represents the pericyst.

Recently the emerging role of DW MRI may play a decisive role in the differential diagnosis of hydatid liver disease and simple cysts<sup>[22-24]</sup> (Figures 1, 5 and 16).

### **Type II : Cyst with daughter cysts and matrix**

Daughter cysts are inside the mother cyst, usually arranged at the periphery<sup>[15,18]</sup>. Floating membranes or vesicles can be also seen in the cyst. Multiple daughter cysts are enclosed together looking like an echogenic solid lesion. (Figures 6, 10, 11 and 12)

Type II may manifest as a well-defined fluid collection in a honeycomb pattern with multiple septa representing the walls of the daughter cysts, creating a “rosette” appearance<sup>[15]</sup>. Peripheral calcification may occur and involves the pericyst; it is easily detected in CT images as a curvilinear or ring-like structure. CT can distinguish the mother cyst: the average density attenuation of the mother cyst is higher than that of daughter cysts. At MR imaging, daughter cysts may appear hypointense or isointense relative to the maternal matrix on T1 and T2-weighted images<sup>[19,20]</sup>.

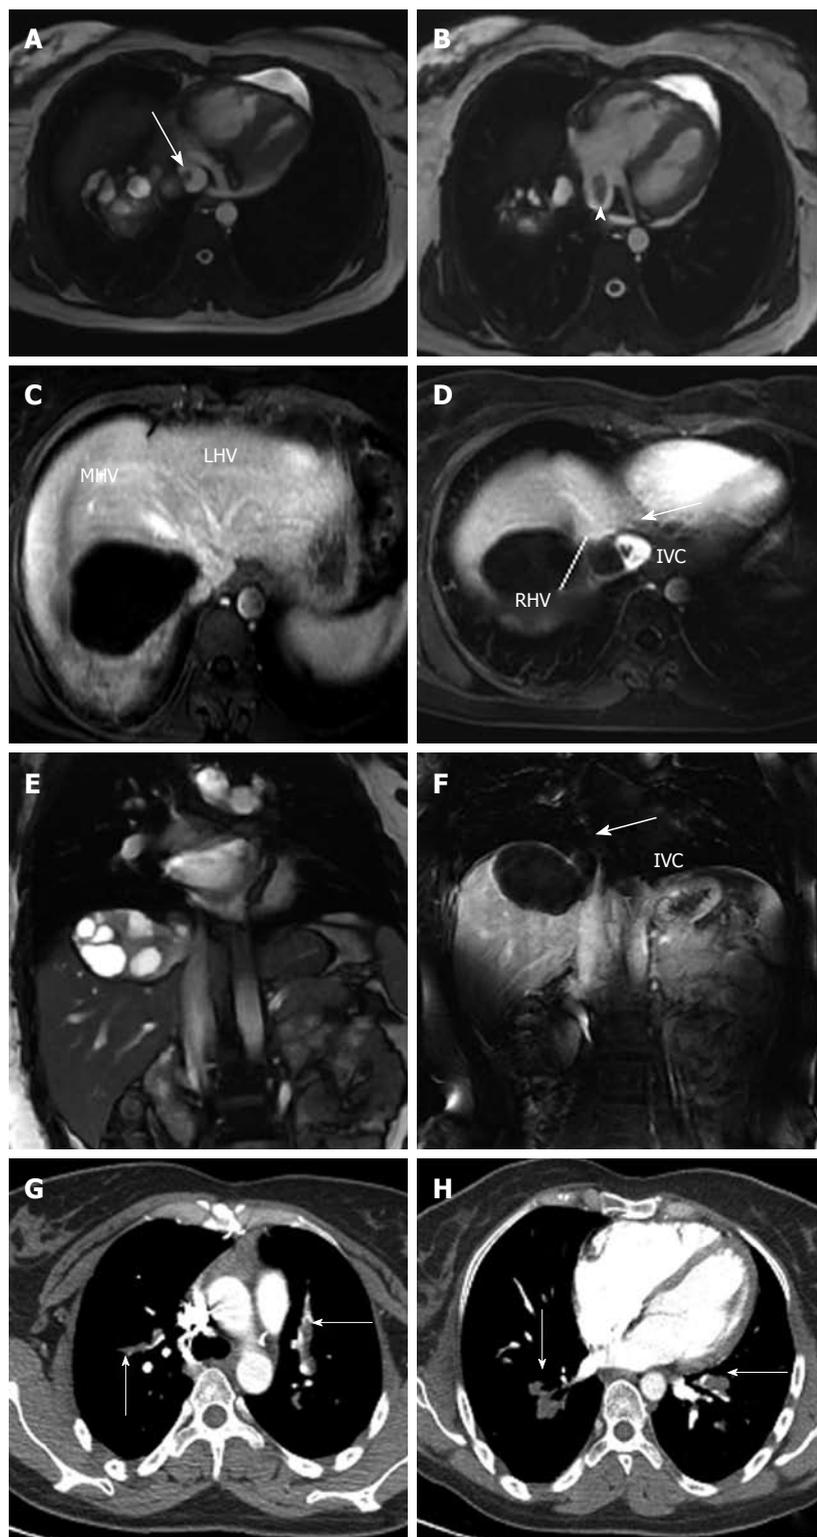

### **Type III : Calcified cyst**

Type III lesions are dead cysts with total calcification. At US calcified cysts show strong posterior shadowing, at CT they appear as round hyperattenuating areas, at MR they appear as hypointense areas (Figure 7).

### **Type IV**

Hydatid complications include rupture and superinfection and may be seen in both type I and type II. CT and MRI play a key role in recognizing the complications such as rupture and infection of cysts associated with hydatid disease.

Ruptures may occur in 50% of cases<sup>[6,9,11]</sup>; cyst rupture is mainly due to the degeneration of parasitic membranes. Cyst rupture is usually due to the degeneration of parasitic membranes, as a result of age, or a host defense mechanism<sup>[6,9,11]</sup>. The rupture may be contained, commu-

**Figure 17** Hepatic hydatidosis in a 30-year-old woman who presented with short of breath, fatigue and edema to the lower limbs. Magnetic resonance (MR) steady-state-free-precession sequences (A, B, E) and MR angiography (C, D, F) images showed the hydatid cyst invading the right hepatic vein (RHV), protruding in the inferior vein cava (IVC) (the bold white arrow) and in the right atrium (the white arrowhead). The mid hepatic vein (MHV) and the left hepatic vein (LHV) were normally patent (C). The multidetector computed tomography-angiography revealed diffuse pulmonary parasitic embolism (the thin white arrows) (G, H).

nicating or direct.

Fissures in the cyst wall can be visualized at both CT and MR imaging. Perforation to the biliary tree has been reported in up to 90% of hydatid cysts<sup>[7,10,11]</sup>. Hydatid cysts

may also rupture into pleural and peritoneal cavities. Up to 25% of ruptured cysts may become infected<sup>[10,11]</sup>. Signs of cyst infection include air-fluid or fluid-fluid levels<sup>[9,11]</sup> (Figures 8, 9 and 14).

## CONCLUSION

Imaging plays a primary role in liver hydatidosis. It is used for diagnosis, for assessment of extension, for identification of possible complications, for classification and for monitoring the response to therapy. US, MDCT and MR have different roles depending on accuracy in depicting the different goals.

alveolar and cystic forms, associated with *Echinococcus multilocularis* (*E. multilocularis*) and *Echinococcus granulosus* (*E. granulosus*) infection, respectively. Cystic echinococcosis (CE) has a worldwide distribution, while hepatic alveolar echinococcosis (AE) is endemic in the Northern hemisphere, including North America and several Asian and European countries, like France, Germany and Austria. *E. granulosus* young cysts are spherical, unilocular vesicles, consisting of an internal germinal layer and an outer acellular layer. Cyst expansion is associated with a host immune reaction and the subsequent development of a fibrous layer, called the pericyst; old cysts typically present internal septations and daughter cysts. *E. multilocularis* has a tumor-like, infiltrative behavior, which is responsible for tissue destruction and finally for liver failure. The liver is the main site of HD involvement, for both alveolar and cystic hydatidosis. HD is usually asymptomatic for a long period of time, because cyst growth is commonly slow; the most frequent symptoms are fatigue and abdominal pain. Patients may also present jaundice, hepatomegaly or anaphylaxis, due to cyst leakage or rupture. HD diagnosis is usually accomplished with the combined use of ultrasonography and immunodiagnosis; furthermore, the improvement of surgical techniques, the introduction of minimally invasive treatments [such as puncture, aspiration, injection, re-aspiration (PAIR)] and more effective drugs (such as benzimidazoles) have deeply changed life expectancy and quality of life of patients with HD. The aim of this article is to provide an up-to-date review of biological, diagnostic, clinical and therapeutic aspects of hepatic echinococcosis.

## INTRODUCTION

Echinococcosis or hydatid disease (HD) is a zoonosis caused by the larval stages of taeniid cestodes belonging to the genus *Echinococcus*. Six species of *Echinococcus* are known, but only four of them are responsible for human disease: *Echinococcus granulosus* (*E. granulosus*) (which causes cystic echinococcosis), *Echinococcus multilocularis* (*E. multilocularis*) (which causes alveolar echinococcosis), *E. vogeli* and *E. oligartbrus* (which cause polycystic echinococcosis). Recent studies have identified two new species, *E. felidis* and *E. shiquicus*, even if no data are available about their pathogenicity to humans.

Hepatic alveolar and cystic echinococcosis are both life-threatening diseases because of their medical and economical impact and their wide geographical distribution. Polycystic echinococcosis is, on the contrary, confined to Central and South America and only few cases of this condition have been reported in man<sup>[1,2]</sup>.

The liver is the major site of HD involvement (about 75% of cases) both in the alveolar and in the cystic form<sup>[3]</sup>. This review is focused on the biological, epidemiological, clinical and therapeutic aspects of hepatic echinococcosis, with particular reference to *E. granulosus* cystic and *E. multilocularis* alveolar hydatidosis (Table 1).

## HEPATIC ECHINOCOCCOSIS CAUSED BY *E. GRANULOSUS*

Cystic echinococcosis (CE) occurs as the result of infection by the larval stages of *E. granulosus*. CE is the most common form of HD, with a worldwide distribution, and it can be regarded as an emerging or re-emerging disease in several countries of the world.

### *E. granulosus*: The parasite biology and life cycle

*E. granulosus* is a small tapeworm (length of 2-7 mm), whose body is made up by a mean number of three proglottids. There are ten distinct genetic types (G1-10) within *E. granulosus*, with a different geographical distribution, and these have been identified by molecular studies based on mitochondrial DNA sequences<sup>[4,5]</sup>: 2 sheep strains (G1-G2), 2 bovid strains (G3 and G5), a horse strain (G4), a camelid strain (G6), a pig strain (G7), a cervid strain (G8), a swine strain (G9) and a reindeer strain (G10).

The parasite life cycle involves dogs and other canids (coyotes, dingoes, red foxes) as definitive hosts and un-

gulates (sheeps, pigs, goats, horses) as intermediate hosts. Definitive hosts are infected by ingestion of offal containing hydatid cysts; the adult worms reside in the canine small bowel and their eggs or gravid proglottids are shed in the feces. After oral uptake of eggs by intermediate hosts, an oncosphere larva is released from the egg and penetrates the intestinal lamina propria, reaching the blood and lymph vessels which transport it to liver, lungs and other organs, where oncosphere larvae can develop into metacestodes (also known as hydatid cysts). Humans can accidentally become "aberrant" intermediate hosts, after ingestion of *Echinococcus* eggs excreted by infected carnivores.

Hydatid cysts are spherical, fluid-filled, unilocular vesicles, consisting of an internal cellular layer (germinal layer) and an outer acellular, laminated layer. The parasite cysts gradually expand and cause a granulomatous host reaction, followed by the development of a fibrous tissue layer (pericyst). Brood capsules and protoscolices bud from the germinal membrane; with time, internal septations and daughter cysts usually develop, modifying the unilocular morphology that is typical of young hydatid cysts. When definitive hosts ingest the cyst-containing organs of intermediate herbivore hosts, the *Echinococcus* life cycle can restart, as the protoscolices evaginate, attach to the intestinal mucosa and develop to adult stage in 30-80 d<sup>[6,7]</sup>.

### Molecular crosstalk between human host and parasite

Several studies have focused on the mechanisms of host-parasite interplay in CE.

The immune response to *E. granulosus* infection has been investigated through both clinical studies on patients with hydatidosis and sheep and mouse experimental models<sup>[8]</sup>. In the early stage of hydatid cyst development, a cell-mediated response involving macrophages, neutrophils and eosinophils is established<sup>[9-11]</sup>; antibody response is usually undetectable during the first weeks after infection, but IgE, IgG2 and IgG4 levels subsequently significantly increase<sup>[8]</sup>. Elevated levels of IgE for echinococcal antigens are responsible for allergic reactions, such as itching, urticaria and anaphylactic shock<sup>[12]</sup>.

*E. granulosus* induces both TH1 and TH2 response: elevated levels of TH1 cytokines, especially interferon- $\gamma$  (IFN- $\gamma$ )<sup>[13]</sup>, but also TH2 cytokines, such as IL-4, IL-5 and IL-6, have been recorded in patients with HD<sup>[8,11]</sup>. The reason for this duplex cytokine secretion pattern is not known: TH1 and TH2 responses usually down-regulate each other, with a cross-inhibitory mechanism; it is assumed that the complex antigenic organization of *Echinococcus* may stimulate both T-cell subsets<sup>[14]</sup>. After chemotherapy treatment, surgical removal or natural death of a cyst, TH2 response quickly drops and TH1 response becomes predominant<sup>[15]</sup>.

The metacestode attempt to escape from the host protective response involves complex and intriguing strategies aimed at modulating host response and protecting itself from elimination. *Echinococcus* tries, in fact, to minimize host reaction by exposing several immunomodulatory molecules to its host<sup>[16]</sup>, interfering with complement

Table 1 Hydatid disease epidemiology and characteristics<sup>16,71</sup>

	Cystic echinococcosis	Alveolar echinococcosis
Causative agent	<i>E. granulosus</i>	<i>E. multilocularis</i>
Definitive hosts	Dogs and other canids (coyotes, dingoes, red foxes)	Red foxes, arctic foxes, coyotes, dogs and cats
Intermediate hosts	Ungulates	Rodents
Geographic distribution	Worldwide	North America, northern and central Eurasia
Worldwide incidence	1-200/100 000	0.03-1.2/100 000
Organ localization	Mainly liver and lungs	Mainly liver
Characteristics of hydatid lesions	Young cysts: spherical, fluid-filled, unilocular vesicles (diameter: 1-15 cm) Old cysts: internal septations, daughter cysts Three-layered structure: germinal layer, laminated layer, pericyst	Alveolar-like pattern, with numerous vesicles (< 1 mm up to 15 cm in diameter) and surrounding dense connective tissue, no cyst fluid, sometimes central necrosis
Type of growth in human organs	Concentric expansion	Tumor-like, infiltrative behaviour
Therapeutic options	Surgery, PT (especially PAIR), chemotherapy	Surgery, chemotherapy, EPIs

PTs: Percutaneous treatments; PAIR: Puncture, aspiration, injection, re-aspiration; EPIs : Endoscopic percutaneous interventions.

activity<sup>[17]</sup>, altering leukocyte function<sup>[18]</sup> or using molecular mimicry<sup>[19]</sup>.

### Epidemiology and infection risk

*E. granulosus* has a worldwide distribution; the highest prevalence is recorded in the Mediterranean countries, Russia and China (in Sichuan Province human CE had a prevalence of 2.1% in 1997-1998<sup>[20]</sup>). Other hyperendemic areas are North and East Africa (prevalence > 3%), South America and Australia<sup>[21]</sup>. CE infection has re-emerged in certain parts of the world where it was once believed to be controlled, including Israel, Central Asia and Eastern Europe<sup>[21,22]</sup>. In Bulgaria the annual incidence of CE in children has increased from 0.7 per 100 000 in 1971-1982 to 5.4 in 1995<sup>[23]</sup>; in Kazakhstan the annual surgical incidence of CE over the whole country was below 1.4 per 100 000 inhabitants from 1988 until 1995 but has increased to 5.9 in 2000<sup>[24,25]</sup>.

CE is typically a rural and occupational disease, since certain human activities, such as feeding dogs with the viscera of slaughtered livestock, increase the risk of infection. Humans acquire the parasite through fecal-oral contact, generally by handling infected domestic dogs or egg-containing feces. *Echinococcus* eggs adhere to the coat of animals, especially to hairs around the anus and on the muzzle and paws<sup>[26]</sup>. Eggs can also be ingested with contaminated water or vegetables; it is also possible that the contamination of surfaces and foodstuffs with *Echinococcus* eggs occurs *via* wind, flies, birds or beetles.

Some studies have evaluated several risk factors for infection: Campos-Bueno *et al.*<sup>[27]</sup> studied a Spanish cohort of 127 CE infected patients, matched with 127 healthy controls, associating an increased risk for CE with having a higher number of dogs in the family and with dogs' ease of access to raw viscera of slaughtered animals. In Tibet a rise of infective risk was associated with nomadic life, age, playing with dogs, not protecting food from flies and raising yaks or sheep. Water wells were suspected to be a source of infection in African arid lands, where animals and humans often share the same water points<sup>[28]</sup>.

### Clinical aspects

After infection, humans are usually asymptomatic for a long period of time, since cyst growth is usually slow; in the liver the growth rate is variable, ranging from 1 mm to 5 mm in diameter per year. Most primary infections consist of a single cyst, but up to 20%-40% of infected people have multiple cysts. Presenting symptoms depend not only on the size and number of cysts, but also on the mass effect within the organ and upon surrounding structures. The signs and symptoms of liver hydatidosis include hepatomegaly, right/epigastric pain, nausea and vomiting. Cyst leakage or rupture may be responsible for systemic immunological responses, causing anaphylaxis; in one series, anaphylaxis complicated 10% of all intra-peritoneal ruptures.

Cyst rupture in the peritoneal cavity may cause secondary CE, with the release of protoscolices and/or small cysts, which can grow to larger cysts.

Portal vein or bile duct obstruction, caused by the expanding cysts, may be responsible for segmental or lobar liver atrophy in the cyst-bearing lobes<sup>[29]</sup>.

Other complications are rupture in the biliary tree with secondary cholangitis<sup>[30]</sup>, biliary obstruction by daughter cysts, portal hypertension, ascites, intracystic or subphrenic abscess formation, development of a bronchobiliary fistula<sup>[31,32]</sup>. Hydatid cyst suppuration has been reported as occurring in 5% to 40% of patients<sup>[33]</sup>. Perforation in the biliary tree has been described in up to 90% of HD<sup>[34]</sup>.

### Diagnosis

Considering that the early stages of infection are usually asymptomatic, the diagnosis of liver CE may often be incidental, associated with an abdominal ultrasonography performed for other clinical reasons. In endemic areas, the presence of symptoms suggestive of CE in a person with a history of exposure to sheepdogs supports the suspicion of hydatidosis.

A non-invasive diagnosis of hepatic CE is usually accomplished with the combined use of radiologic imaging

and immunodiagnostic techniques. Abdominal ultrasonography is considered the gold standard for defining the number, site, dimensions and vitality of cysts<sup>[32,35,36]</sup> and it is also important to evaluate treatment options. A standardized ultrasonographic classification system for hepatic cysts has been developed by the World Health Organization (WHO)<sup>[37]</sup>, in order to update the older Gharbi classification<sup>[38]</sup>.

Ultrasonography is not always able to differentiate hydatid cysts from other space-occupying lesions, like tumors or liver abscesses, so that additional imaging techniques, such as magnetic resonance imaging (MRI) and CT scans, may be required. MRI should be preferred to CT, due to better visualization of liquid areas within the matrix<sup>[39]</sup>. MRI is also important for pre-surgical evaluation of CE.

Immunodiagnosis is useful to confirm a radiologic diagnosis and can also be an important tool for the follow-up after surgical or pharmacological treatment, even if not all patients with CE have a detectable immune response<sup>[40-42]</sup>. Serological test sensitivity is indeed inversely related to the degree of sequestration of the echinococcal antigens inside cysts; for instance, healthy, intact cysts can elicit a minimally detectable response, whereas previously ruptured or leaking cysts are associated with stronger immune responses.

Almost all traditional immunodiagnostic methods (e.g., Casoni intradermal test, complement fixation test, indirect hemagglutination test, indirect immunofluorescence antibody test, immunoelectrophoresis and latex agglutination test) have now been replaced by the enzyme-linked immunosorbent assay (ELISA) and/or immunoblotting<sup>[43]</sup>. In order to detect antibody response to parasite, several hydatid antigens have been extracted and used for serological diagnosis. Hydatid cyst fluid antigen B (AgB) and antigen 5 (Ag5) from *E. granulosus* are considered the most specific native antigens for the immunodiagnosis of CE<sup>[40,41]</sup>, even though lack of sensitivity and specificity, technique standardization and cross-reactivity with antigens of other parasites<sup>[44-46]</sup> are major problems associated with immunodiagnosis of CE.

In doubtful cases, for example undetectable anti-*Echinococcus* antibodies in patients with small lesions resembling hydatid cysts or in patients whose hepatic cysts cannot be differentiated from liver abscess or neoplasms, ultrasonography-guided fine needle puncture may represent an additional diagnostic option. The demonstration of protoscolices or hydatid membranes or echinococcal antigens/DNA in the aspirated cyst fluid can confirm, in fact, the diagnosis of CE. Anthelmintic coverage is important to minimize the risk of secondary CE: albendazole should be recommended for 4 d before the procedure and should be continued for at least 1 mo after having punctured a lesion recognized as an *E. granulosus* cyst<sup>[32,47]</sup>. Detection of parasite-specific IgE has no significant diagnostic advantages, even if eosinophilia is often present after rupture/leakage of the cyst<sup>[48]</sup>.

## Treatment

The goals of hepatic hydatid cyst treatment are a com-

plete elimination of the parasite and prevention of recurrence, minimizing mortality and morbidity risk. In order to achieve these aims, it is essential to choose the most appropriate treatment with regard to disease-specific characteristics (cyst number, size, site, presence of cystobiliary communication), to patient clinical conditions, availability of an experienced surgeon or an interventional radiologist.

Three therapeutic modalities are available to treat hepatic CE: chemotherapy, surgery (with open or laparoscopic approach) and percutaneous treatments (PTs). A stage-specific approach is recommended<sup>[49]</sup>.

**Surgery:** Until the 1980s, surgery was the only therapeutic option for patients with CE. Surgery is still the first choice for large CE2-CE3b cysts with multiple daughter cysts or for single superficial cysts, considering the likelihood of spontaneous or traumatic rupture, when PT is not available. Presence of complicated cysts, e.g., infected cysts or cysts communicating with the biliary tree, and cysts exerting pressure on other vital organs, are other indications for surgical approach. Surgery is contraindicated in patients whose preexisting medical conditions put them at risk or in patients having inactive asymptomatic cysts or multiple cysts which are difficult to access. If feasible, surgical removal of hydatid cysts has the best chance to completely remove cysts and to immediately cure CE.

Surgical options can be divided into radical (pericystectomy) and conservative approaches (for instance unroofing or capitonnage)<sup>[50-53]</sup>. Radical procedures are associated with a lower risk of recurrence, but also with a higher operative risk; conservative procedures, on the contrary, are easier to perform but have a higher likelihood of recurrence. Recurrence is usually due to either inadequate cyst removal or to previously undetected cysts; reported recurrence rates range from 2% to 25%<sup>[54]</sup>.

Whichever technique is used, a benzimidazole (BMZ) agent is usually used to reduce the risk of anaphylaxis and secondary CE<sup>[55]</sup>. BMZ is administered from 1 d before surgery to 1 mo after surgery but, again, no conclusive data about the best timing are available. Major complications of surgery are postoperative hemorrhage, cholangitis, sepsis and fistulae formation. Operative mortality varies from 0.5% to 4%<sup>[55]</sup>.

**Percutaneous treatments:** PTs of hepatic CE can aim at the destruction of the germinal layer [puncture, aspiration, injection, re-aspiration (PAIR)] or the evacuation of the entire endocyst ("modified catheterization technique").

PAIR is an acronym that stands for "puncture, aspiration, injection, re-aspiration". PAIR consists of four steps: (1) percutaneous puncture of the cyst using ultrasound guidance; (2) aspiration of the cyst fluid; (3) injection of a protoscolicidal agent (e.g., 95% ethanol or 20% NaCl) for at least 15 min; and (4) re-aspiration of the fluid<sup>[37,56]</sup>.

PAIR is indicated for CE1 and CE3a cysts > 5 cm<sup>[49,56]</sup>; CE2 and CE3b cysts treated by PAIR tend to relapse. PAIR has also been used for patients who refused surgery

or relapsed after surgical treatment. It is contraindicated for inaccessible or superficially located liver cysts and for inactive or calcified cystic lesions. The possibility of secondary echinococcosis can be minimized by concurrent treatment with benzimidazoles; indeed, combined treatment (PAIR plus albendazole) may yield better results than those of either chemotherapy or PAIR alone<sup>[57,58]</sup>. The length of administration of chemotherapy with albendazole usually ranges between 4 h before and 1 mo after PAIR, in order to reduce the risk of disease recurrence and intraperitoneal seeding of infection. PAIR must be avoided in patients with cystobiliary communications, to prevent the risk of sclerosing cholangitis.

**Chemotherapy:** Mebendazole (MBZ) and albendazole (ABZ) are the BMZ agents used for the treatment of hepatic CE. They interfere with the absorption of glucose through the wall of the parasite, causing glycogen depletion and degenerative changes in echinococcal mitochondria and endoplasmic reticulum. BMZ may be favorably used alone for the treatment of small (< 5 cm) CE1-CE3a liver cysts<sup>[59]</sup> or for inoperable patients; BMZs are also usually associated with PAIR or surgery to prevent secondary CE<sup>[55]</sup>. BMZs are not indicated for the treatment of inactive or calcified asymptomatic cysts, unless they are complicated lesions<sup>[49]</sup>.

Both ABZ and MBZ are effective, but ABZ is considered the drug of choice, because it is more active *in vitro* and it has a better gastrointestinal absorption and bioavailability<sup>[60,61]</sup>. The usual dose of orally-administered ABZ is 10-15 mg/kg per day in two divided doses; if MBZ, the daily dose is 40-50 mg/kg in three divided doses. Treatment with BMZ should be administered continuously, for 3-6 mo<sup>[49]</sup>.

Clinical and radiographic improvement (in most studies defined as > 25% reduction in cyst size, membrane separation, or cyst calcification<sup>[62]</sup>) is quite frequent and is favorably influenced by the duration of treatment. Unfortunately, complete cure (i.e., cyst disappearance) only occurs in approximately a third of patients treated with BMZ alone and, interestingly, the number of patients with cure does not significantly increase by extending the duration of treatment<sup>[60]</sup>. A recent systematic review<sup>[63]</sup> has confirmed that the size and stage of cysts are the key factors to evaluate the likelihood of response to chemotherapy.

Usual adverse effects include nausea, hepatotoxicity, neutropenia and occasionally alopecia. Thus, all patients should have regular monitoring of leukocyte counts and liver function tests. Contraindications to chemotherapy include pregnancy, chronic hepatic diseases and bone marrow depression.

Praziquantel has been used (40 mg/kg once a week) with ABZ for combined treatment of CE; this therapeutic association seems to be more effective than ABZ alone<sup>[64]</sup>.

For uncomplicated CE4 and CE5 cysts a “watch and wait” strategy is currently advised<sup>[49]</sup>.

## HEPATIC ALVEOLAR ECHINOCOCCOSIS CAUSED BY *E. MULTILOCULARIS*

Hepatic alveolar echinococcosis (AE) results from infection by the larval forms of *E. multilocularis*. The echinococcal metacestode develops in the liver and is characterized by an alveolar structure, made up by several vesicles surrounded by large granulomas. Human AE is a severe and emerging disease, whose prognosis is bleak in absence of treatment or if it is not diagnosed at an early stage of disease.

### *E. multilocularis*: The parasite life cycle

*E. multilocularis* is a small cestode (1.2-4.5 mm), whose definitive hosts are wild carnivores such as red fox and arctic fox (sylvatic cycle) or domestic dogs and cats (synanthropic cycle). The adult tapeworms, whose bodies are characterized by a mean number of five proglottids, reside in the small bowel of their definitive hosts, where gravid proglottids release eggs which are passed in the feces. Intermediate hosts, usually small rodents, or aberrant hosts such as humans, become infected by ingestion of embryonated eggs. Human infection can happen through direct contact with the definitive host or it can be indirect, through contamination of food or water with parasite eggs<sup>[7,65]</sup>. The echinococcal metacestode develops in the liver and is characterized by an alveolar structure, made up by several vesicles whose diameter varies from < 1 mm up to 15-20 cm<sup>[47,65]</sup>. Each vesicle has a wall structure similar to that of the *E. granulosus* cyst, consisting of a germinal and a laminated layer<sup>[66]</sup>. Brood capsules or protoscolices are only occasionally seen and lesions may be complicated by central necrosis, producing a cavity or pseudocyst after liquidization. Small cysts are surrounded by a dense connective tissue and they usually do not contain fluid but instead a semisolid matrix<sup>[6]</sup>.

### Host-parasite interaction

*E. multilocularis* is able to elicit a strong cellular immune response: in the liver, parasitic lesions appear to be surrounded by large granulomas made up by macrophages, T-lymphocytes and myofibroblasts<sup>[67-69]</sup>. Observations in humans and experiments with rodents have shown that cellular immunity, related to TH1 cytokine profile, has a crucial role in host defense against the parasite<sup>[70]</sup>. IL-12, a key factor in the induction of TH1 profile, has been shown to inhibit, in mice, the development of alveolar lesions, leading to the formation of abortive parasitic vesicles surrounded by fully efficient periparasitic immune cell infiltration and fibrosis<sup>[71]</sup>. In mice treated with IFN- $\gamma$ , a typical TH1 cytokine, a partial reduction in larval growth has been observed<sup>[72]</sup>. In contrast, a TH2 cytokine profile has been associated with disease progression: high levels of IL-5 and IL-10 have been detected in serum of patients with progressive disease, compared with individuals with abortive forms<sup>[73-76]</sup>. As in the case of *E. granulosus*, several mechanisms have been proposed

to explain *E. multilocularis* avoidance from host-protective responses, including antigenic disguise<sup>[77]</sup>, immunomodulation<sup>[78-80]</sup>, molecular mimicry<sup>[81]</sup>, antigen and DNA polymorphism<sup>[82,83]</sup>.

### Epidemiology and infection risk

Data on human AE are difficult to be evaluated due to its low prevalence<sup>[21]</sup>, which does not allow a reliable recognition of temporal developments or differences in spatial distribution. The long asymptomatic period also makes it difficult to determine time and place of infection<sup>[84]</sup>. *E. multilocularis* is endemic in the Northern hemisphere, including North America (Alaska, Canada), Asia (some of the newly independent states of the former Soviet Union<sup>[85]</sup>, China<sup>[86]</sup> and Japan) and some European countries<sup>[87]</sup> (mainly France, Switzerland, Austria, Germany)<sup>[21,22]</sup>. In endemic areas, annual incidence of AE ranges from 0.03 to 1.2/100 000 inhabitants<sup>[88,89]</sup>. Increasing fox population, increased fox encroachment into urban areas and *E. multilocularis* spillover from wild carnivores to domestic hosts, are all factors that may explain *E. multilocularis* spreading from endemic areas to previously non-endemic European countries<sup>[21,90]</sup>.

Considering the parasite life cycle, exposure of humans to echinococcal eggs may be influenced by occupational and behavioral factors. Hunters, trappers and persons who work with fox fur should be more frequently exposed to *E. multilocularis* eggs, but there is no evidence that these groups are at increased risk<sup>[91,92]</sup>.

### Clinical aspects

Slow larval growth results in an asymptomatic phase of several years (5-15 years). Initially, the liver, usually the right lobe, is the organ where the metacestodes establish themselves; then, later in the infection, it is possible to find blood metastasis to lung, brain, bones and local extension of the lesion (abdomen, retroperitoneum, diaphragm)<sup>[66]</sup>. First symptoms are usually vague: patients may complain of fatigue, weight loss or may have hepatomegaly. One third of them have cholestatic jaundice; one third present with abdominal pain<sup>[54,66,93]</sup>. In advanced stages, liver failure usually occurs and it is frequently associated with portal hypertension, ascites and splenomegaly. The prognosis in untreated or inadequately treated patients with AE is poor. Treatment has radically changed average life expectancy at diagnosis from 3 years in the 1970s to 20 years in 2005<sup>[94]</sup>.

### Diagnosis

As for CE, AE diagnosis is based on clinical and epidemiologic findings, imaging techniques, nucleic acid detection and serology.

Among the imaging techniques, ultrasonography is the method of choice to identify hydatid lesions: ultrasound (US) typical aspect shows a pseudotumoral mass, with irregular limits and scattered calcification, where hypoechogenic and hyperechogenic areas are juxtaposed; central necrosis may give to the mass the appearance of a cystic-

like structure, surrounded by a hyperechogenic ring<sup>[95,96]</sup>. Color doppler may be useful to evaluate biliary and vascular infiltration. Abdominal CT gives further anatomical details and information about the lesion pattern of calcification<sup>[65]</sup>. MR imaging is the best standard to study the invasion of adjacent structures and may help in unclear cases<sup>[97]</sup>. Pre-surgical percutaneous cholangiography is important to assess the presence of communication between the biliary tree and the alveolar lesions<sup>[96]</sup>; it is also fundamental to exclude extra-hepatic involvement, through pulmonary and cerebral radiological examination.<sup>[18f]</sup> Fluorodeoxyglucose positron emission tomography (FDG-PET) scanning gives indirect information on the parasite metabolic activity, especially if combined with MRI or CT scan; if negative, this finding does not mean that the parasite is not viable but that there is a suppressed periparasitic inflammatory activity<sup>[98]</sup>.

WHO classification of AE is based on imaging findings and it is useful to have an internationally recognized, uniform standard for disease diagnosis and treatment strategies. The WHO-IWGE PNM classification system<sup>[65,99]</sup> is similar to tumor TNM classification: "P" refers to the extent of parasite localization inside the liver, "N" establishes the involvement of neighboring organs, "M" evaluates the absence (M0) or presence (M1) of distant metastasis, after having performed a chest X-ray and a cerebral CT.

As in CE, immunodiagnosis has a complementary role to other procedures, not only in primary diagnosis but also for follow-up of patients after surgical treatment or chemotherapy<sup>[100,101]</sup> and for the specific differential diagnosis between AE and CE in those regions where the diseases are co-endemic<sup>[102,103]</sup>. Immunodiagnosis (with indirect hemoagglutination test or ELISA) is more reliable for the diagnosis of AE than for CE, because more specific antigens are available. For example, the Em2plus-ELISA, which is a mixture of affinity purified *E. multilocularis* metacestode antigens (Em2-antigen) and a recombinant antigen (Em II /3-10), has shown a great sensitivity and specificity<sup>[104]</sup>, but it is not able to discriminate between active and inactive lesions; in fact, Em2-ELISA may be positive for years after spontaneous or pharmacological-induced dying out of the metacestode in patients with calcified lesions, because the Em2 antigen main source is the laminated layer of the parasite which obviously persists in these inactive lesions. Surgical removal of the dried-out lesion results in an immediate seroconversion to negative anti-Em2 antibodies<sup>[105,106]</sup>. Considering that the protoscolex is the most active component of echinococcal tissues, protoscolex antigens Em16 and Em18 have been isolated and used for immunoblot tests, in order to discriminate between active and inactive lesions<sup>[107]</sup>; recombinant (r) Em18 appears to be a promising immunodiagnostic tool for serological differentiation between AE and CE<sup>[107,108]</sup>. Combining US and serological data, it is possible to classify seropositive patients into three groups: patients with active hepatic lesions, patients with calcified lesions and patients with no

evidence of hepatic lesions<sup>[49]</sup>. The latter cases are a consequence of immune system pressure, which can cause larval degeneration and death, so that the only radiological sign of the host-parasite interaction may be the US finding of calcifications<sup>[109]</sup>.

Some studies have shown that patients with AE have high levels of IgG1 and IgG4 antibodies and that after treatment they usually become seronegative for IgG4 antibodies<sup>[110-113]</sup>; IgG4 antibody reappearance can be considered a warning sign of disease reactivation.

Liver needle biopsy can be performed in uncertain cases and it can confirm AE diagnosis if histopathological examination identifies the presence of alveolar vesicles. RT-PCR on liver specimens, obtained by biopsy or surgery, has been used to assess parasite viability, while PCR can detect *E. multilocularis* DNA. These tests have a good positive predictive value, but a negative result does not exclude parasite activity and parasite presence in the liver, respectively<sup>[114]</sup>.

### Treatment

The key concept of AE treatment is to adopt a multidisciplinary approach to disease. Surgery and chemotherapy are the cornerstones of AE treatment and, as for CE, a stage-specific approach is recommended<sup>[49]</sup>.

**Surgery:** Surgery is the first-choice option in all operable patients. Radical resection of the entire hepatic parasitic lesions is the only curative procedure, even though it is often difficult to achieve because of echinococcal dissemination into host tissues. Palliative liver surgery is almost always contraindicated, because it does not offer advantages when compared with conservative treatment<sup>[115,116]</sup>. Pre-operative evaluation is important to establish lesions full resectability; WHO-IWGE PNM classification estimates quite well the likelihood to achieve radical resection<sup>[99]</sup>.

Liver transplant (LT) has been employed in otherwise terminal cases<sup>[117]</sup>. Indications for LT are the presence of severe liver failure or recurrent life-threatening cholangitis and the inability to perform a radical liver resection. The absence of extra-hepatic AE localizations is mandatory for LT<sup>[49]</sup>.

BMZ chemotherapy should be carried out for at least 2 years after surgery and patients should be monitored for at least 10 years, because of the risk of recurrence: in fact, unrecognized or invisible parasites can re-grow, even after some years, especially in post-LT immunosuppressed patients<sup>[118]</sup>.

**Chemotherapy:** Inoperable AE patients should receive continuous BMZ treatment for life; moreover, long-term BMZ administration (at least 2 years) is mandatory after surgical treatment. Pre-surgical BMZ therapy is advised only in the case of LT. ABZ is given orally at a dosage of 10-15 mg/kg per day, in two divided doses; if it is not tolerated, MBZ may be given at daily doses of 40-50 mg/kg per day, split into three divided doses with fat-rich meals<sup>[49]</sup>. Conventional and liposomal amphotericin B has

been used in patients who did not tolerate BMZ<sup>[119]</sup>. In a recent study nitazoxanide has not shown any efficacy for AE treatment<sup>[120]</sup>.

Therapy with BMZ has resulted in an increased 10-year survival rate of approximately 80% (6%-25% in untreated historical controls)<sup>[121]</sup>. BMZs are parasitostatic, not parasitocidal: after several years of BMZ treatment, in the absence of progression of AE lesions, it is possible to discuss whether treatment should be continued or not. Decision-making should be supported by the evaluation of parasite viability, usually by PET-CT<sup>[98]</sup>, and serum specific antibodies<sup>[101,102]</sup>. These tools may also be useful for the follow-up after BMZ withdrawal.

All AE patients should be monitored by US at frequent intervals and CT and/or MRI at intervals of 2-3 years, to evaluate disease recurrence or progression<sup>[49]</sup>.

**Endoscopic percutaneous interventions:** Interventional procedures may be considered in inoperable patients in the presence of complications such as liver abscesses, jaundice due to biliary duct obstruction, portal vein thrombosis or bleeding esophageal varices associated with portal hypertension<sup>[96]</sup>. EPIs with BMZ avoid palliative surgery and may improve the patient life expectancy and quality of life.

## CONCLUSION

Liver echinococcosis is a severe, neglected, often misdiagnosed disease; both AE and CE may be considered emerging public health problems, since CE is endemic in several countries in the world and AE is one of the most lethal helminthic diseases.

The last years have been characterized by significant advances in the knowledge of *Echinococcus* biology and interaction with the immune system; the development of more specific and sensitive immunological tests and the introduction of PCR for detection of parasite nucleic acid have increased the range of diagnostic tools. Furthermore, the improvement in surgical techniques, the introduction of effective drugs (e.g., BMZ) and minimally invasive treatments (e.g., PAIR) have deeply changed the life expectancy and quality of life of patients with HD.

Despite diagnostic and therapeutic progress, many unresolved problems are still waiting for a solution; for instance, there is a need for prevention programs able to monitor and control parasite spreading. Additionally, randomized, controlled trials comparing different therapeutic options, especially for CE, are urgently required, in order to provide new evidence to guide treatment decision-making.

### Abstract

**AIM:** To identify and characterize drosophila mothers against decapentaplegic (SMAD)3-dependent changes in immune cell populations following infection with *Helicobacter hepaticus* (*H. hepaticus*).

**METHODS:** SMAD3<sup>-/-</sup> (*n* = 19) and colitis-resistant SMAD3<sup>+/-</sup> (*n* = 24) mice (8-10 wk of age) were infected with *H. hepaticus* and changes in immune cell populations [T lymphocytes, natural killer (NK) cells, T regulatory cells] were measured in the spleen and mesenteric lymph nodes (MsLNs) at 0 d, 3 d, 7 d and 28 d post-infection using flow cytometry. Genotype-

dependent changes in T lymphocytes and granzyme B<sup>+</sup> cells were also assessed after 28 d in proximal colon tissue using immunohistochemistry.

**RESULTS:** As previously observed, SMAD3<sup>-/-</sup>, but not SMAD3<sup>+/-</sup> mice, developed colitis, peaking at 4 wk post-infection. No significant changes in T cell subsets were observed in the spleen or in the MsLNs between genotypes at any time point. However, CD4<sup>+</sup> and CD8<sup>+</sup>/CD62L<sup>lo</sup> cells, an effector T lymphocyte population, as well as NK cells (NKp46/DX5<sup>+</sup>) were significantly higher in the MsLNs of SMAD3<sup>-/-</sup> mice at 7 d and 28 d post-infection. In the colon, a higher number of CD3<sup>+</sup> cells were present in SMAD3<sup>-/-</sup> compared to SMAD3<sup>+/-</sup> mice at baseline, which did not significantly change during infection. However, the number of granzyme B<sup>+</sup> cells, a marker of cytolytic lymphocytes, significantly increased in SMAD3<sup>-/-</sup> mice 28 d post-infection compared to both SMAD3<sup>+/-</sup> mice and to baseline values. This was consistent with more severe colitis development in these animals.

**CONCLUSION:** Data suggest that defects in SMAD3 signaling increase susceptibility to *H. hepaticus*-induced colitis through aberrant activation and/or dysregulation of effector lymphocytes.

## INTRODUCTION

Individuals with inflammatory bowel disease (IBD), particularly ulcerative colitis (UC), are at a higher risk of developing colon cancer than the general population<sup>[1]</sup>. A meta-analysis of 116 studies indicated that the prevalence of colon cancer in patients with UC is approximately 3.7% (95% CI: 3.2-4.2), with the cumulative probability reaching 18% by 30 years regardless of disease severity<sup>[2]</sup>. Although the etiology of UC is poorly understood, there are indications that the immune system of individuals with UC reacts abnormally to bacteria in the digestive tract. This altered immune response leads to the inflammation-associated pathology of IBD<sup>[3-5]</sup>.

Imbalances in both innate and adaptive immune cells, such as natural killer (NK) cells and T cell subsets, including CD4<sup>+</sup> and CD8<sup>+</sup> T cells and CD4/CD25/Foxp3<sup>+</sup> T regulatory (Treg) cells, are associated with the pathogenesis of IBD<sup>[2]</sup>. The inflammation and damage caused by increased secretion of inflammatory cytokines during an active disease state is thought to be triggered by cytotoxicity against the commensal bacteria<sup>[6]</sup>. For example, levels of NK cytotoxicity in UC are related to the clinical stage of the disease<sup>[7]</sup>. In active disease states, NK cells are present in normal numbers, but are functionally defective, whereas NK cells exhibit normal cytotoxic activity in an inactive disease state<sup>[7]</sup>. Induction of inflammatory cytokines can also result from the disruption of the homeostatic balance between Treg and effector T helper (Th) cells. Elevated levels of pro-inflammatory CD4<sup>+</sup> T cells lead to excess cytokine/chemokine production, thereby recruiting additional leukocytes and influencing the severity of the inflammatory response<sup>[2]</sup>. CD8<sup>+</sup> T cells are also important in the pathogenesis of UC in humans, as demonstrated by extensive CD8<sup>+</sup> T cell infiltration within intestinal lesions contributing to mucosal damage<sup>[8,9]</sup>.

Transforming growth factor (TGF)- $\beta$  is a multifunctional cytokine that plays an important role in epithelial and immune cell homeostasis<sup>[10,11]</sup>. TGF- $\beta$  mediates many diverse biological functions on different cell types through receptor-mediated phosphorylation and activation of the drosophila mothers against decapentaplegic homolog (SMAD) family proteins, notably SMAD2 and SMAD3, which migrate to the nucleus and induce transcription of a targeted set of genes<sup>[12,13]</sup>. Dysfunctions in one or more components of TGF- $\beta$  signaling are commonly observed in human IBD and during colon cancer development. For example, loss of expression of the TGF receptor type II is observed in 90% of microsatellite instable colon

cancers, leading to loss of growth regulation in epithelial cells<sup>[14]</sup>. Additionally, although the TGF- $\beta$  isoform is overexpressed in the colon of individuals with IBD<sup>[15]</sup>, nuclear signaling is impaired due to increased levels of SMAD7<sup>[16]</sup>. SMAD7 normally inhibits TGF- $\beta$  signaling by blocking activation of SMAD2/3 in response to receptor-ligand binding. Normalizing SMAD7 expression restores TGF- $\beta$  signaling through SMAD3 and inhibits proinflammatory cytokine production by lamina propria mononuclear cells<sup>[16]</sup>.

Impairments in one or more components of the TGF- $\beta$  signaling pathway are implicated in intestinal inflammation in rodent models. For example, homologous knockout of the *TGF- $\beta$ 1* gene in mice causes an excessive inflammatory response in multiple organs, including the heart, lungs, and intestinal tract leading to premature death<sup>[17,18]</sup>. Additionally, Maggio-Price *et al.*<sup>[19]</sup> have demonstrated that disruption of the transcription factor SMAD3 modulates colitis susceptibility following infection with certain *Helicobacter spp.* Among these, *Helicobacter hepaticus* (*H. hepaticus*) is a Gram-negative spiral bacterium that colonizes the lower intestine and the hepatobiliary tract of mice<sup>[20]</sup>. Although generally asymptomatic, infection can lead to hepatic and intestinal inflammation in certain strains of immunodeficient mice<sup>[21-24]</sup>. In the complete absence of SMAD3 signaling, *H. hepaticus* induces a moderate inflammatory response in the cecum and colon, eventually leading to mucinous adenocarcinoma formation after 15-30 wk<sup>[19]</sup>. It is generally accepted that chronic low levels of inflammation lead to cancer promotion and progression<sup>[25-28]</sup>, therefore, the SMAD3 mouse model is very similar to the development of specific human cancers where pathogen-induced inflammation is necessary (but not sufficient) to cause dysplasia and tumor formation.

Using this model, the focus of the current study was to investigate the effect of SMAD3 deficiency on changes in local and systemic immune cell populations following infection with *H. hepaticus*. We hypothesized that colitis susceptibility in SMAD3<sup>-/-</sup> mice induced by *H. hepaticus* is associated with altered immune cell populations compared to colitis resistant SMAD3<sup>+/-</sup> mice. The aims of this study were to: (1) characterize the colitis induced by *H. hepaticus* in colitis-sensitive SMAD3<sup>-/-</sup> vs resistant SMAD3<sup>+/-</sup> mice; (2) compare the immune cell population changes in the spleen and mesenteric lymph nodes (MsLNs); and (3) compare local immune cell changes by immunohistochemistry in the colon.

## MATERIALS AND METHODS

### Murine model

SMAD3<sup>+/-</sup> and SMAD3<sup>-/-</sup> (129-Smad3<sup>tm1Par</sup>/J) mice were bred in-house. Homozygous males and heterozygous females were mated to obtain both SMAD3<sup>+/-</sup> and SMAD3<sup>-/-</sup> pups. Genotypes were confirmed by polymerase chain reaction (PCR). Animals were housed under specific pathogen-free (SPF) conditions in 60 square

inch plastic cages (maximum of five adult mice per cage) with microisolator lids in an Association for Assessment and Accreditation of Laboratory Animal Care-approved facility at Michigan State University. SPF conditions were assured through quarterly serology testing by Charles Rivers (Wilmington, MA, United States) and in-house testing for ectoparasites, endoparasites and fecal *Helicobacter* species (PCR). Full necropsies (including culture and sensitivity) were performed at least yearly on rodent breeding colonies. Animal rooms were maintained at  $23.3 \pm 2.2$  °C with a 12-h light/dark cycle. Mice were fed Harlan Teklad 7913 rodent chow and sterile water *ad libitum*. Animal protocols were approved by the Michigan State University Institutional Animal Care and Use Committee.

### Bacterial culture and infection

The wild-type *H. hepaticus* strain 3B1 (ATCC 51488) was utilized for these experiments. Isolates were aseptically streaked onto sheep blood agar and incubated at 37 °C for 24–48 h inside GasPak™ gas generating pouch systems (BD Diagnostic Systems, Sparks, MD, United States). Mice were infected as previously described<sup>[19]</sup>. Briefly, bacteria were collected and resuspended in tryptic soy broth at  $A_{600\text{ nm}} \geq 1.8$ . Animals were then gavaged with 0.3 mL doses of fresh bacterial suspension on two consecutive days. Previously, Maggio-Price *et al.*<sup>[19]</sup> have shown that *Helicobacter* infection is localized primarily in the cecum and proximal colon, and that bacterial DNA is still present in the tissue and luminal contents of the cecum at 12 wk post-infection. Bacterial presence was confirmed in the current study *via* DNA isolation at 3 d post-infection using a commercial kit (QIAGEN tissue kit; Valencia, CA, United States) as previously described<sup>[24]</sup>.

### Experimental design

In study 1, SMAD3<sup>-/-</sup> mice ( $n = 30$ ) at 8–10 wk of age were infected with *H. hepaticus* to determine onset and duration of colitis. At the time of necropsy, mice were asphyxiated with CO<sub>2</sub> and exsanguinated *via* cardiac puncture. Intestinal tissue was collected and processed for histopathology at 2–8 wk post-infection. In study 2, SMAD3<sup>+/-</sup> ( $n = 24$ ) and SMAD3<sup>-/-</sup> mice ( $n = 19$ ) at 8–10 wk of age were infected with *H. hepaticus* once per day for two consecutive days. At select time points after infection (0, 3, 7 and 28 d), the spleen and MsLNs were collected and processed for lymphocyte isolation as described below. Colon and cecum tissue was collected, fixed, and processed for immunohistochemistry.

### Histopathology

The colon and cecum were removed and flushed with phosphate-buffered saline (PBS). Tissues were fixed in 10% formalin overnight, embedded in paraffin, then sectioned and stained with hematoxylin and eosin (HE). Longitudinal sections were graded for inflammation and epithelial dysplasia/neoplasia by a pathologist using a blinded scoring system adapted from Maggio-Price *et al.*<sup>[29]</sup>. Cecum and colons were scored on a 1 to 4

scale both for inflammation (1, no inflammation; 2, mild inflammation; 3, moderate inflammation; 4, marked inflammation) and dysplasia (1, no dysplasia; 2, low-grade dysplasia; 3, high-grade dysplasia; 4, high-grade dysplasia with invasion/adenocarcinoma). The two scores for colon and two scores for cecum tissue in each animal were combined such that a score of 4 indicated no inflammation or dysplasia and a score of 16 reflected maximal inflammation and neoplasia.

Immunohistochemistry was performed on paraffin-embedded colon sections. Antibodies specific for CD3 and granzyme B were purchased from Abcam (Cambridge, MA, United States). Colons were sectioned at 5 µm, mounted on coated slides, deparaffinized in xylene, and rehydrated through graded ethanol-water baths. Antigen retrieval was performed using citrate buffer (10 mmol/L, pH 6.0) and a vegetable steamer. Tissues were incubated in 3% hydrogen peroxide to block endogenous peroxidase activity and then incubated overnight at 4 °C in primary antibody. On the following day, tissues were washed in Tris-buffered saline containing Tween-20 (0.05%), then incubated with biotinylated secondary antibodies followed by streptavidin horseradish peroxidase for 45 min each at room temperature (Dako, Carpinteria, CA, United States). After extensive washing, antigen-bound horseradish peroxidase was detected using the chromagen 3,3'-diaminobenzidine (0.5 mg/mL; Sigma-Aldrich, St. Louis, MO, United States) dissolved in PBS (10 mmol/L, pH 7.2). Identification of cellular infiltrate in the colons of mice was performed by a pathologist. CD3<sup>+</sup> and granzyme B<sup>+</sup> cells were identified under a light microscope using a 20 × objective. The occurrence of positively stained cells was scored in proximal colons of mice in five fields using a 1-cm<sup>2</sup> grid reticle as follows: 0 = average of 0 cells/grid, 1 = average of ≤ 1 cell/grid, 2 = average of 2–10 cells/grid, 3 = average of 11–20 cells/grid, 4 = average of > 21 cells/grid. Final values represent mean ± SE per group ( $n = 3$ –5/group).

### Lymphocyte isolation

Spleens and MsLNs were removed and placed in ice-cold RPMI medium at the time of necropsy. Spleens were processed with a dounce homogenizer, pelleted, and washed in RPMI. Cells were resuspended in ACK lysing buffer (Invitrogen, Carlsbad, CA, United States) and washed twice in RPMI. MsLNs were treated with 5 mL enzymatic digest [5% fetal bovine serum (FBS), 0.5 mg/mL collagenase, 0.05 mg/mL DNase I] for 30 min at 37 °C. Cells were passed through 70-µm filters and washed with RPMI. Cell counts were performed with a hemocytometer using trypan blue exclusion and resuspended to a concentration of one million cells per milliliter of medium.

### Flow cytometry

Lymphocytes were resuspended in fluorescence-activated cell sorting (FACS) buffer (0.1% sodium azide, 1% FBS, in dPBS) blocked with anti-Fc receptor R II / III [CD16/

CD32 (purified from clone 2.4G2 hybridoma; ATCC, Manassas, VA, United States)] for 10 min on ice, and subsequently incubated with combinations of the following fluorochrome-conjugated antibodies (E-bioscience, San Diego, CA, United States; or BD Bioscience, San José, CA, United States) at concentrations ranging from 1:100 to 1:300 in FACS buffer: CD3 (PerCP-Cy5.5), CD4 (eFluor450), CD8 (PE-Cy7), CD25 (PE), FoxP3 (FITC or Alexa Fluor488), CD62 (APC), Nkp46 (FITC) and DX5 (APC). Cells were incubated in staining cocktails (one million cells per cocktail) on ice in the dark for 30 min. Intracellular staining was performed using FoxP3 staining buffer set as per the manufacturer's instructions (E-bioscience). Briefly, after surface staining, cells were washed twice in FACS buffer, fixed in 4% paraformaldehyde for 25 min, and permeabilized for 30 min. Permeabilization was followed by incubation for 30 min with the appropriate antibodies diluted in permeabilization diluent. Samples were then acquired on a LSR II (BD Bioscience) and analyzed using FlowJo software (Tree Star Inc., Ashland, OR, United States). The number of cells in each population of interest was determined by multiplying cell percentages by the total cell number.

### Statistical analysis

Data for the colitis and immunohistochemistry scores were analyzed using the nonparametric Kruskal-Wallis test and Dunn's post-test for specific comparisons. Flow cytometric data was analyzed using a two-way analysis of variance in GraphPad Prism (GraphPad Software, La Jolla, CA, United States). When statistical differences were detected, Tukey's multiple comparison test was used to determine differences between the two groups.  $P < 0.05$  was considered significant. All data are represented as mean  $\pm$  SE.

## RESULTS

### SMAD3-deficient mice are susceptible to colitis 4 wk post-infection

Colitis severity in SMAD3<sup>-/-</sup> mice (Figure 1A) peaked at 4 wk post-infection, with an average colitis score of  $7.8 \pm 0.4$ . This value was significant compared to samples taken at all other time points ( $P < 0.05$ ). Colitis resolved to baseline levels in SMAD3<sup>-/-</sup> mice by 8 wk post-infection. In comparison, SMAD3<sup>+/-</sup> mice were resistant to colitis development at all time points (data not shown). There was no statistically significant change in colitis scores in SMAD3<sup>+/-</sup> mice compared to baseline at any time point post-infection. Representative HE images from SMAD3<sup>+/-</sup> and SMAD3<sup>-/-</sup> mice prior to and 4 wk following infection are presented in Figure 1B.

### SMAD3-dependent changes in lymphocyte populations following *H. hepaticus* infection

We next evaluated genotype- and time-dependent changes in lymphocyte populations in the spleen and MsLNs using flow cytometry. There were no significant changes

in total CD3<sup>+</sup>, CD4<sup>+</sup> or CD8<sup>+</sup> lymphocytes in the spleen at baseline or at any time point following infection (Figure 2A-C). Tregs (FoxP3<sup>+</sup>/CD25<sup>+</sup>/CD4<sup>+</sup>) and NK cells (Nkp46<sup>+</sup>/DX5<sup>+</sup>) increased in both genotypes following infection but returned to baseline by 28 d (Figure 2D and E).

In the MsLNs, CD3<sup>+</sup>, CD4<sup>+</sup> and Treg cells were significantly higher in both genotypes at 7 d and 28 d post-infection (Figure 3A, C, and D), whereas there were no significant changes in CD8<sup>+</sup> cells at any time point examined (Figure 3B). NK cells increased in SMAD3-deficient mice by 7 d post-infection, and were significantly different from baseline values at 28 d (Figure 3E). Comparably, NK cells were not significantly altered at any time point in SMAD3<sup>+/-</sup> mice (Figure 3E).

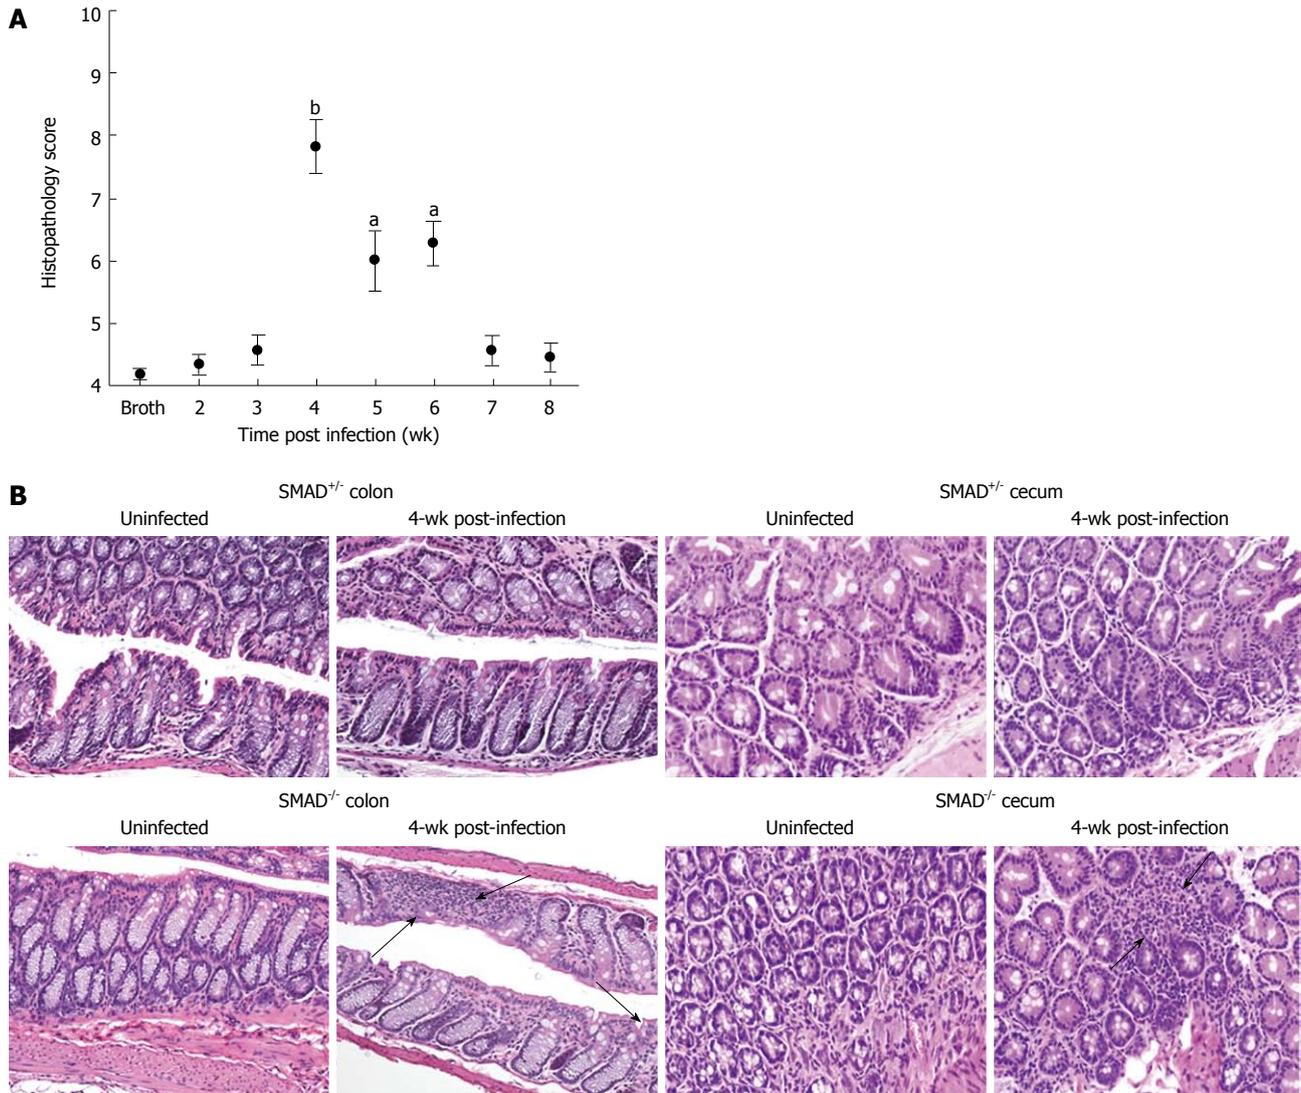

To determine activation status of the different T lymphocyte populations, we next evaluated surface expression of CD62L. L-Selectin (CD62L) is an adhesion marker expressed at high levels in naïve T cells and is cleaved from the surface (CD62L<sup>lo</sup>) in activated and/or in memory T cells. There were no statistically significant changes or observable trends in the proportion or total number of activated T cells in the spleen at any time point after infection (data not shown). However, the proportion of CD3<sup>+</sup>, CD8<sup>+</sup>, CD62L<sup>lo</sup> and CD3<sup>+</sup>, CD4<sup>+</sup>, CD62L<sup>lo</sup> cells was significantly higher in SMAD3<sup>-/-</sup> mice at 7 d and 28 d compared to baseline values and to SMAD3<sup>+/-</sup> mice (Figure 4A and D). Effector Treg cells increased in both strains at 7 d and 28 d compared to baseline values (Figure 4G). CD62L expression became dimmer at later time points in the SMAD3<sup>-/-</sup> mice for both CD8<sup>+</sup> and CD4<sup>+</sup> populations (Figure 4C and F) in the MsLNs, however, the intensity of CD62L expression was maintained consistently in SMAD3<sup>+/-</sup> mice through all time points (Figure 4B and E). No significant differences were observed in the percentage of Treg cells expressing reduced levels of CD62L between genotypes at any time point (Figure 4H and I).

### Immunohistochemical analysis of colon sections 28 d post-infection

We next evaluated local changes in CD3<sup>+</sup> cells and the serine protease, granzyme B, in the proximal colons of SMAD3<sup>+/-</sup> and SMAD3<sup>-/-</sup> mice 4 wk post-infection. The lamina propria in SMAD3<sup>-/-</sup> mice was moderately expanded by lymphocytic cells. Based on morphology and immunohistochemistry, these cells consisted primarily of CD3<sup>+</sup> lymphocytes (Figure 5A). Additionally, numerous granzyme B<sup>+</sup> cells were noted in the intestine of SMAD3<sup>-/-</sup> infected mice, primarily within the villous epithelium, but sometimes also within the lamina propria (Figure 5B).

## DISCUSSION

Functional TGF- $\beta$  signaling is crucial for maintaining immune cell homeostasis<sup>[30]</sup>. In the present study, we evaluated changes in local and systemic immune cell populations in colitis resistant SMAD3<sup>+/-</sup> and sensitive

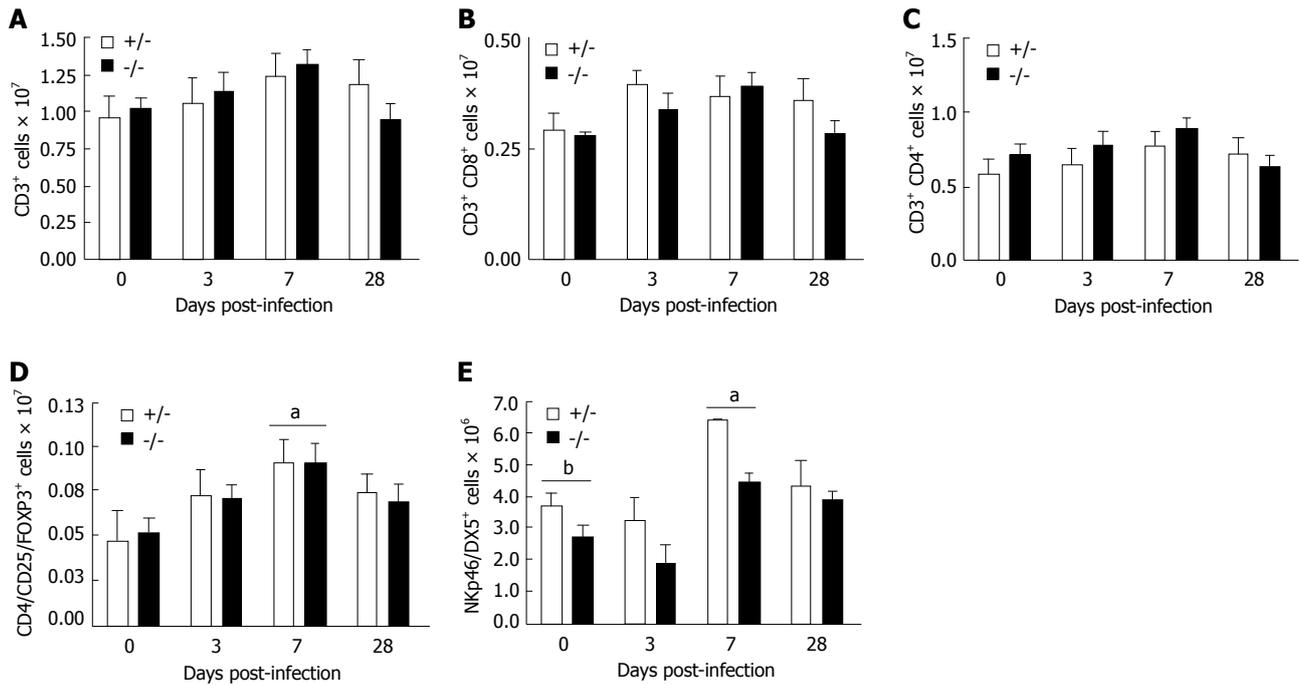

**Figure 1** *Drosophila* mothers against decapentaplegic 3<sup>+</sup> mice are more susceptible to colitis following infection with *Helicobacter hepaticus*. **A**: Inflammation and dysplasia scores in *drosophila* mothers against decapentaplegic (SMAD3)<sup>+/+</sup> mice post-infection (wk). The colon and cecum from each animal were given a separate score for inflammation and dysplasia (*n* = 30 animals/trt). Each animal received a total of four numerical scores for each of these criteria. The figure displays the average total of these scores with a lowest possible score of 4 and a highest possible of 16. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.001 vs control animals. There was no change in colitis scores among SMAD3<sup>-/-</sup> mice throughout the course of infection (data not shown); **B**: Hematoxylin and eosin-stained sections from the cecum and colon of SMAD3<sup>+/+</sup> (upper panel) and SMAD3<sup>-/-</sup> mice (lower panel) comparing uninfected and 4 wk after infection with *Helicobacter hepaticus* (*H. hepaticus*). Four weeks following infection, the number of inflammatory cells and primarily lymphocytes in the lamina propria was slightly increased in both tissues, consistent with mild inflammation (arrows denote infiltrate).

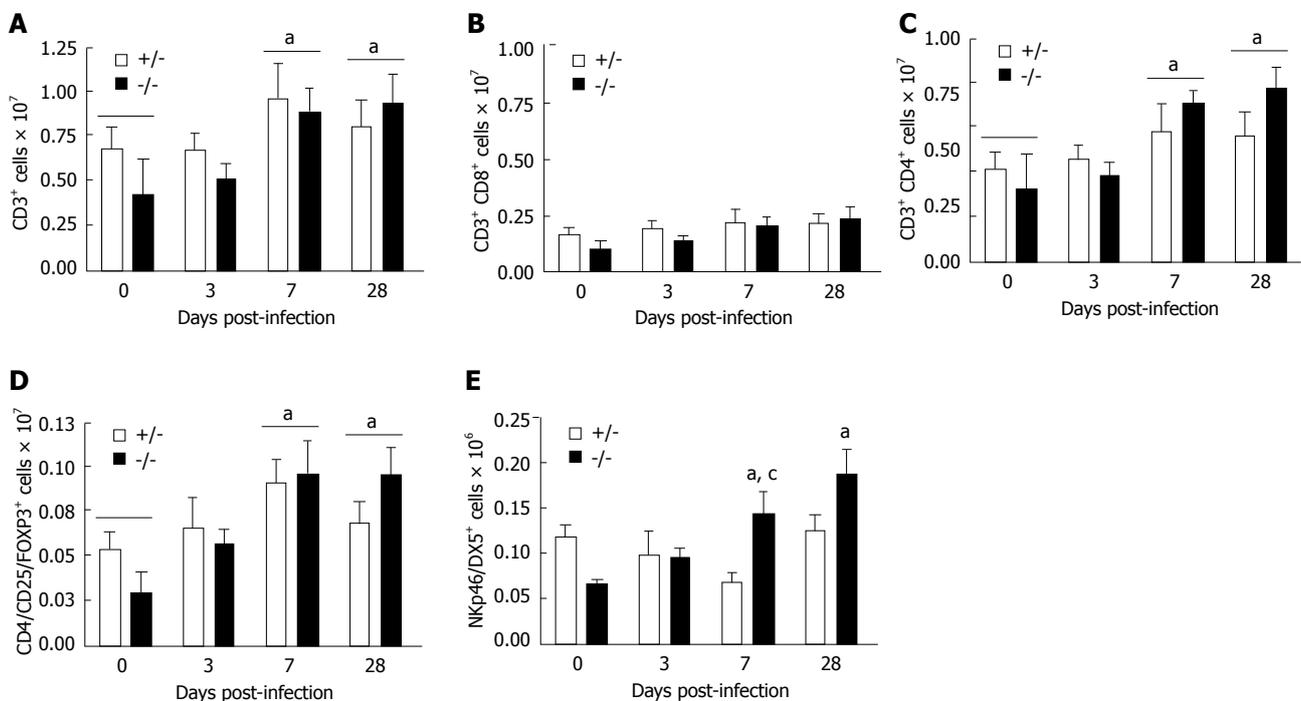

SMAD3<sup>-/-</sup> mice during the course of infection with the enteric pathogen, *H. hepaticus*. A major finding of this study was a significantly higher number of CD4 and CD8 effector cell populations in the mesenteric lymph nodes of SMAD3<sup>-/-</sup> mice at 7 d and 28 d post-infection compared to both baseline values and to SMAD3<sup>+/+</sup> mice. The number of granzyme B<sup>+</sup> cells, a marker of cytolytic lymphocytes, was also higher in proximal colon tissue at 28 d post-infection, consistent with colitis development in these animals. Our findings suggest loss of TGF-β signaling through SMAD3 leads to aberrant activation of colitogenic T cell subsets in response to *H. hepaticus*, whereas changes in specific T cell numbers were unaffected by genotype. These data are consistent with Maggio-Price *et al*<sup>[19]</sup>, who reported no significant T cell response to infection with *Helicobacter* *in vitro*, although

it is important to note that in that study only splenic lymphocytes were assessed, and that both *H. hepaticus* and *Helicobacter bilis* were used for infection. Additionally, Yang *et al*<sup>[31]</sup> reported no differences between SMAD3<sup>-/-</sup> and wild-type controls on development of T and B lymphocytes and NK cells, but found increased activated phenotype of T lymphocytes in SMAD3<sup>-/-</sup> mice that were resistant to TGF-β1 inhibition *in vitro*.

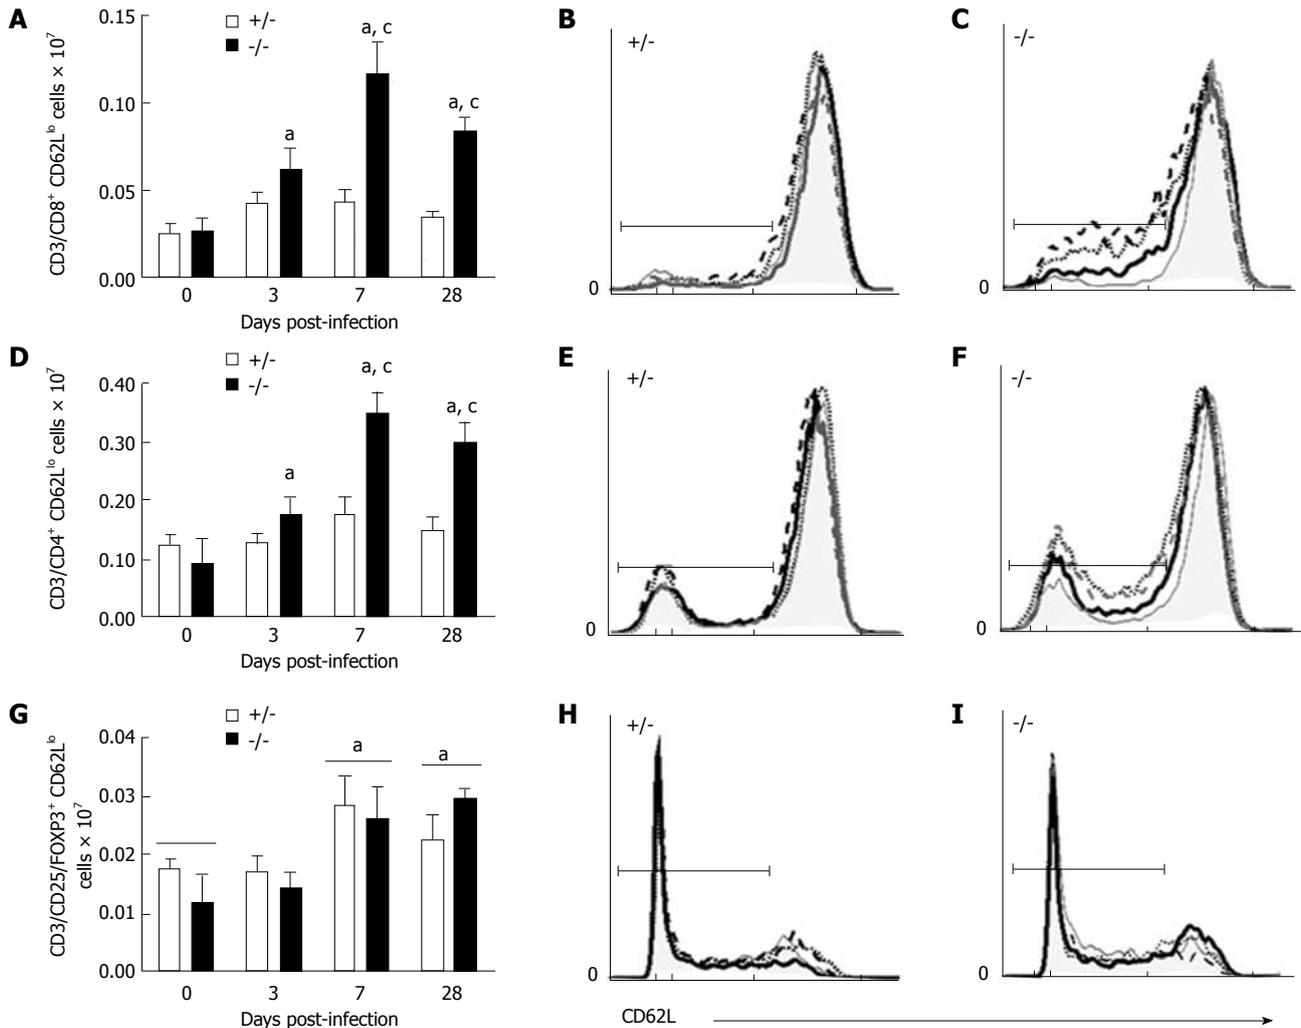

The inflammation associated with *H. hepaticus* infection in susceptible strains leads to a dysregulated Th1-type immune response, characterized by increased expression of interleukin (IL)-12 and interferon (IFN)-γ<sup>[19,32,33]</sup> as well as the proinflammatory cytokines IL-1α, IL-1β, IL-6 and tumor necrosis factor-α<sup>[19]</sup>. Treg cells normally function to control the inflammatory response by suppressing proliferation and activation of CD4<sup>+</sup> and CD8<sup>+</sup>

**Figure 2** Changes in T lymphocyte populations and natural killer cells in the spleen of drosophila mothers against decapentaplegic 3<sup>+/+</sup> and drosophila mothers against decapentaplegic 3<sup>-/-</sup> mice following infection with *Helicobacter hepaticus*. Flow cytometric analysis of lymphocyte populations at days 0, 3, 7 and 28 post-infection. Gates were drawn on viable cells using forward scatter vs side scatter parameters. A: Total CD3<sup>+</sup> lymphocytes gated on forward scatter vs CD3; B: Total CD8<sup>+</sup> lymphocytes gated on CD3<sup>+</sup> lymphocytes; C: Total CD4<sup>+</sup> lymphocytes gated on CD3<sup>+</sup> lymphocytes; D: Total CD25<sup>+</sup>/FOXP3<sup>+</sup> Treg cells gated on CD3<sup>+</sup>/CD4<sup>+</sup> lymphocytes; E: Total natural killer (NK)p46<sup>+</sup>/DX5<sup>+</sup> NK cells in spleen tissue (n = 4-6 animals per time point). <sup>a</sup>P < 0.05 vs baseline values (7 d vs 0 d); <sup>b</sup>P < 0.05 denotes significance between genotypes [drosophila mothers against decapentaplegic (SMAD)3<sup>+/+</sup> vs SMAD3<sup>-/-</sup>].

**Figure 3** Changes in T lymphocyte populations and natural killer cells in the mesenteric lymph nodes of drosophila mothers against decapentaplegic 3<sup>+/+</sup> and drosophila mothers against decapentaplegic 3<sup>-/-</sup> mice following infection with *Helicobacter hepaticus*. Flow cytometric analysis of lymphocyte populations at days 0, 3, 7 and 28 post-infection. Gates were drawn on viable cells using forward scatter vs side scatter parameters. A: Total CD3<sup>+</sup> lymphocytes gated on forward scatter vs CD3; B: Total CD8<sup>+</sup> lymphocytes gated on CD3<sup>+</sup> lymphocytes; C: Total CD4<sup>+</sup> lymphocytes gated on CD3<sup>+</sup> lymphocytes; D: Total CD25<sup>+</sup>/FOXP3<sup>+</sup> Treg cells gated on CD3<sup>+</sup>/CD4<sup>+</sup> lymphocytes; E: Total natural killer (NK)p46<sup>+</sup>/DX5<sup>+</sup> NK cells in mesenteric lymph nodes (n = 4-6 animals per time point). <sup>a</sup>P < 0.05 vs baseline values; <sup>c</sup>P < 0.05 denotes significant interaction between genotypes [drosophila mothers against decapentaplegic (SMAD)3<sup>+/+</sup> vs SMAD3<sup>-/-</sup>].

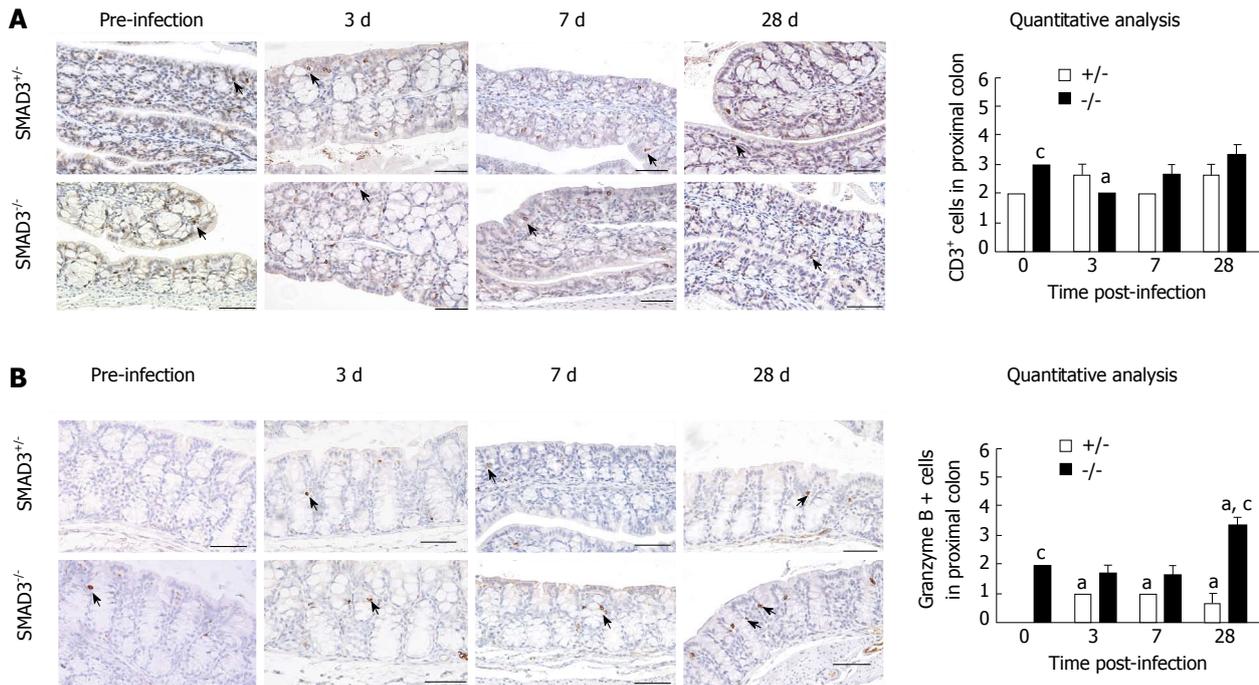

**Figure 4** Changes in effector T lymphocyte populations in the mesenteric lymph nodes of drosophila mothers against decapentaplegic 3<sup>-/-</sup> and drosophila mothers against decapentaplegic<sup>+/-</sup> mice following infection with *Helicobacter hepaticus*. Flow cytometric analysis of lymphocyte populations at days 0, 3, 7 and 28 post-infection. Gates were drawn on viable cells using forward scatter vs side scatter parameters. Histograms represent CD62L expression at 0 d (solid grey), 3 d (dotted black), 7 d (dashed black) and 28 d (solid black) post-infection. Y-axis represents relative cell frequency. X-axis is CD62L expression. Brackets indicate CD62L<sup>lo</sup> gate used to determine cell percentages. A: Total CD8<sup>+</sup> CD62L<sup>lo</sup> lymphocytes gated on CD3<sup>+</sup>/CD8<sup>+</sup> lymphocytes; B: CD62L expression in drosophila mothers against decapentaplegic (SMAD3)<sup>3<sup>-/-</sup></sup> CD8<sup>+</sup> lymphocytes; C: CD62L expression in SMAD3<sup>3<sup>-/-</sup></sup> CD8<sup>+</sup> lymphocytes; D: Total CD4<sup>+</sup> CD62L<sup>lo</sup> lymphocytes gated on CD3<sup>+</sup>/CD4<sup>+</sup> lymphocytes; E: CD62L expression in SMAD3<sup>3<sup>-/-</sup></sup> CD4<sup>+</sup> lymphocytes; F: CD62L expression in SMAD3<sup>3<sup>-/-</sup></sup> CD4<sup>+</sup> lymphocytes; G: Total CD25<sup>+</sup>/FOXP3<sup>+</sup> CD62L<sup>lo</sup> Treg cells gated on CD3<sup>+</sup>/CD4<sup>+</sup> lymphocytes (n = 4-6 animals per time point); H: CD62L expression in SMAD3<sup>3<sup>-/-</sup></sup> CD25<sup>+</sup>/FOXP3<sup>+</sup> lymphocytes; I: CD62L expression in SMAD3<sup>3<sup>-/-</sup></sup> CD25<sup>+</sup>/FOXP3<sup>+</sup> lymphocytes. <sup>a</sup>P < 0.05 vs baseline values; <sup>c</sup>P < 0.01 denotes significant interaction between genotypes (SMAD3<sup>3<sup>-/-</sup></sup> vs SMAD3<sup>3<sup>-/-</sup></sup>).

lymphocytes, inhibiting production of the cytokines IL-2 and IFN- $\gamma$ , as well as producing the anti-inflammatory cytokine IL-10<sup>[34,35]</sup>. Transgenic mice lacking T and B lymphocytes, including *scid* and *rag-2*-deficient mice exhibit a more severe colitis that can be partially alleviated by adoptive transfer of IL-10-producing Treg cells<sup>[36-40]</sup>. Additionally, adoptive transfer of wild-type Treg cells into *rag2*-deficient mice inhibits *H. hepaticus*-induced colon cancer development<sup>[38,40]</sup>, further establishing an important role for this cell type in suppressing inflammatory signaling.

Importantly, Treg cell development is intricately dependent on TGF- $\beta$  signaling, whereas Treg cells themselves are a major source of this cytokine, deriving much of their suppressive function from TGF- $\beta$  production as well as IL-10. Given the importance of this cell type

in suppressing colitis in other models, we next evaluated whether SMAD3-deficiency impaired the development and/or activation of CD4<sup>+</sup>/CD25<sup>+</sup>/Foxp3<sup>+</sup> T regulatory cells. We found no significant difference between genotypes at baseline, suggesting normal development of this cell type in the absence of SMAD3 signaling. Following infection, Treg cells increased proportionally in both genotypes in both the spleen and MsLNs at 7 d and remained elevated in the latter at 28 d. To assess further whether activation of Treg cells may be impaired, we evaluated L-selectin (CD62L) expression, which is required for migration to sites of inflammation and is cleaved from the surface upon activation<sup>[41,42]</sup>. Although the number of activated Tregs (CD4<sup>+</sup>/CD25<sup>+</sup>/FOXP3<sup>+</sup>CD62L<sup>lo</sup>) increased at 7 d and 28 d post-infection in the MsLNs, there was no further difference between genotypes. Thus,

**Figure 5** Immunohistochemical staining for (A) CD3 lymphocytes and (B) granzyme B in proximal colon tissue of drosophila mothers against decapentaplegic 3<sup>+/+</sup> and drosophila mothers against decapentaplegic 3<sup>-/-</sup> mice following infection with *Helicobacter hepaticus*. <sup>a</sup>P < 0.05 vs baseline values; <sup>b</sup>P < 0.01 denotes significant interaction between genotypes [drosophila mothers against decapentaplegic (SMAD3)<sup>+/+</sup> vs SMAD3<sup>-/-</sup>] (n = 4-5 animals per stain). Arrows denote areas of positive staining. Scale bars represent 100 μm.

our findings suggest that SMAD3 deficiency does not influence Treg cell numbers in peripheral lymphoid tissue; however, this does not rule out the possibility that the suppressive effect of this cell type is influenced in a SMAD3-dependent manner. This is further supported by recent findings of Fantini *et al*<sup>[43]</sup> who have reported that overexpression of SMAD7 in CD4 T lymphocytes, which blocks TGF-β-mediated activation of SMAD2/3, impairs the ability of Treg cells to suppress T cell proliferation and proinflammatory cytokine expression both *in vitro* and *in vivo*.

NK cells are generally acknowledged to be important for cell-mediated immunity, and play an important role in the control of cellular infections as well as in antitumor immunity<sup>[44]</sup>. For example, NK cells can directly lyse infected/dysplastic cells through perforin-granzyme-dependent mechanisms and induce apoptosis<sup>[45-51]</sup>. Additionally, NK cells activate other effector immune cells through local production of cytokines<sup>[52]</sup>. Fort *et al*<sup>[53]</sup> have demonstrated that NK cells exert a protective effect on colitis by controlling the responses of effector CD4 T cells through perforin-dependent mechanisms<sup>[53]</sup>. Other studies have provided evidence that NK cells are in fact an innate source of IL-22 in the colon; a cytokine that has proinflammatory properties but is also proposed to protect tissues during inflammation<sup>[54-56]</sup>.

Yang *et al*<sup>[31]</sup> previously have found no effect of SMAD3 deficiency on development of NK cells in the spleen or MsLNs. In the current study, we determined whether SMAD3 deficiency would influence NK cells in peripheral lymphoid tissue in response to infection with *H. hepaticus*. Surprisingly, we found higher numbers of NK cells

(NKp46<sup>+</sup>/DX5<sup>+</sup>) in SMAD3<sup>-/-</sup> mice both at 7 d and 28 d post-infection in the MsLNs, whereas no corresponding changes in population numbers were observed in SMAD3<sup>+/-</sup> mice. Our findings of increased NK cell populations are somewhat inconsistent with the previously established protective role of this cell type<sup>[53]</sup>; however, it is possible that SMAD3 signaling mediates the balance of NK cell subsets in response to infection and/or cytotoxicity of NK cells. For example, significant enrichment of lamina propria NK cells of the CD56<sup>+</sup>CD16<sup>+</sup> cytotoxic subset in individuals with IBD has been reported<sup>[57]</sup>. Additionally, individuals with Crohn's disease have been reported to have a higher proportion of NKp46<sup>+</sup> compared to NKp44<sup>+</sup> NK cells in the intestinal mucosa, which is suggested to mediate pathogenesis through increased production of IFN-γ<sup>[58]</sup>. Importantly, TGF-β inhibits INF-γ production by NK cells<sup>[30,59]</sup>, suggesting the possibility of altered balance of NK cell subsets in our model.

Our findings highlight that mice infected with *H. hepaticus* and deficient in SMAD3 signaling have elevated levels of effector lymphocyte subsets in the MsLNs and in the colon likely contributing to increased colitis severity. Although no genotype differences in numbers of natural Treg cells were found following infection, it is possible that defective TGF-β signaling through SMAD3 may impair suppressive function. Alternatively, the latent presence of effector T cells may indicate continuous antigen presenting cell stimulation which was not addressed in these studies. Given the pleiotropic role of TGF-β signaling in immune cell homeostasis, further evaluation of cytokine production by activated T cells

derived from infected SMAD3-deficient mice would lead to a more thorough understanding of SMAD3 in colitis susceptibility. Additionally, very little is known about the role of SMAD3 in NK cell function, however, the higher presence of NKp46<sup>+</sup>/DX5<sup>+</sup> NK cells in the MsLNs of SMAD3-deficient mice might indicate altered NK subsets present in the MsLNs due to different chemokines being released throughout the course of the infection. The signaling pathways involved in initiating the inflammatory response to *H. hepaticus* in susceptible mouse strains has also not been well characterized. *H. hepaticus* activates nuclear factor- $\kappa$ B and extracellular signal-regulated kinase signaling in bone-marrow-derived macrophages<sup>[60]</sup>, which can induce both pro- and anti-inflammatory pathways<sup>[33,36,60,61]</sup>. Given the importance of TGF- $\beta$  signaling in both IBD and colon cancer development in humans, further identifying innate targets involved in initiating the SMAD3-dependent inflammatory response to pathogenic stimuli would prove highly useful in understanding the pathogenesis of IBD as well as for designing interventions that may alter immune cell populations and/or activation. Future studies addressing some of these possibilities are currently under investigation.

## ACKNOWLEDGMENTS

The authors would like to thank Dr. Lillian Maggio-Price for providing SMAD3 knockout and heterozygous mice, Dr. Vince Young for donating the *H. hepaticus* strain, and Eric Gurzell, Dr. David Duriancik, Hillary Woodworth and Anita Gopalakrishnan for technical assistance with these experiments.

## COMMENTS

### Background

Individuals with inflammatory bowel disease (IBD) are at an increased risk of developing colon cancer. Imbalances in immune cells, such as natural killer (NK) cells and many T cell subsets, are important in the pathogenesis of IBD. These imbalances, in addition to an abnormal reaction to natural gut bacteria, lead to increased inflammation and create an environment favorable for tumor formation in the colon.

### Research frontiers

Previous studies using the drosophila mothers against decapentaplegic 3 (SMAD3) mouse model, in which SMAD3<sup>-/-</sup> but not SMAD3<sup>+/-</sup> mice develop colitis and colon cancer after infection with *Helicobacter* bacteria, highlight similarities to the development of specific human cancers in which pathogen-induced inflammation is necessary (but not sufficient) to cause dysplasia and tumor formation. This study used this model to investigate the effect of a SMAD3 deficiency on changes in both tissue-specific and systemic immune cell populations after bacterial infection.

### Innovations and breakthroughs

Novel findings from this study illustrate that changes in immune response, due to genetic alteration and/or specific susceptibility, can affect the severity of colitis and potentially contribute to the development of colon tumors.

### Applications

These data also suggest potential targets for prevention and treatment of chronic IBD-related inflammation. Furthermore, the SMAD3 model may also prove useful in identifying dietary and/or other interventions that alter immune cell functionality, thereby reducing inflammation and cancer.

### Terminology

SMAD3 is an intracellular protein that functions as a signal transducer and tran-

scription factor for the transforming growth factor  $\beta$  superfamily.

### Peer review

This is an interesting manuscript. Overall, the topic is complicated and the authors present it well. There of course was a great deal of interest at one time in the treatment of ulcerative colitis with anti-*Helicobacter* antibiotics.

### Abstract

**AIM:** To investigate the immunological repertoire in the peritoneal cavity of gastric cancer patients.

**METHODS:** The peritoneal cavity is a compartment in which immunological host-tumor interactions can occur. However, the role of lymphocytes in the peritoneal cavity of gastric cancer patients is unclear. We observed 64 patients who underwent gastrectomy for gastric cancer and 11 patients who underwent laparoscopic cholecystectomy for gallstones and acted as controls. Lymphocytes isolated from both peripheral blood and peritoneal lavage were analyzed for surface markers of lymphocytes and their cytokine production by flow cytometry. CD4<sup>+</sup>CD25<sup>high</sup> T cells isolated from

the patient's peripheral blood were co-cultivated for 4 d with the intra-peritoneal lymphocytes, and a cytokine assay was performed.

**RESULTS:** At gastrectomy, CCR7<sup>+</sup>CD45RA<sup>-</sup>CD8<sup>+</sup> effector memory T cells were observed in the peritoneal cavity. The frequency of CD4<sup>+</sup>CD25<sup>high</sup> T cells in both the peripheral blood and peritoneal cavity was elevated in patients at advanced stage [control *vs* stage IV in the peripheral blood: 6.89 (3.39-10.4) *vs* 15.34 (11.37-19.31), *P* < 0.05, control *vs* stage IV in the peritoneal cavity: 8.65 (5.28-12.0) *vs* 19.56 (14.81-24.32), *P* < 0.05]. On the other hand, the suppression was restored with CD4<sup>+</sup>CD25<sup>high</sup> T cells from their own peripheral blood. This study is the first to analyze lymphocyte and cytokine production in the peritoneal cavity in patients with gastric cancer. Immune regulation at advanced stage is reversible at the point of gastrectomy.

**CONCLUSION:** The immunological milieu in the peritoneal cavity of patients with advanced gastric cancer elicited a Th2 response even at gastrectomy, but this response was reversible.

## INTRODUCTION

Tumor progression is governed not only by the genetic changes intrinsic to cancer cells, but also by epigenetic and environmental factors. Therefore, neoplastic cell factors and biophylactic side factors such as immune reactions are interacting in the survival and development of micrometastasis. Increasing evidence gleaned from studies in immune-compromised hosts suggests that the cellular mechanisms of immunosurveillance influence tumor development. There are several lines of research which indicate the critical role of the immune system in controlling the growth of malignant cells<sup>[1-5]</sup>. Thus, impairment of anti-tumor immunity, which leads to immunologic toleration of malignant cells, contributes to the development and progression of peritoneal metastasis<sup>[6]</sup>. The elimination phase of the cancer immunosurveillance mechanism is thought to be a continuous process, and local control of metastatic invasion by the immune system may be critical for survival. However, the role of lymphocytes in the peritoneal cavity for anti-tumor immunity in gastric cancer patients is unknown<sup>[7]</sup>.

Studies in rodents have demonstrated that adoptive immunotherapy with antigen-specific CD8<sup>+</sup> T cells is effective for cancer, and there is evidence that this approach has therapeutic activity in humans<sup>[8-10]</sup>. Memory T cells circulate throughout all tissues of the body and are primed to rapidly produce secondary immune responses upon antigen challenge<sup>[11]</sup>. The nature of the cells that mediate the different facts of immunological memory remains unresolved. Natural killer T cells are a specialized subset of T cells. They express T-cell and natural killer-lineage cell surface markers and key cytokines, which regulate the course of the immune response. There are many mechanisms that regulate and dampen the immune response to cancers<sup>[12-15]</sup>. Regulatory T cells protect the host from autoimmune disease by suppressing self-reactive immune cells. As such, regulatory T cells may also block antitumor immune responses. Regulatory T cells have been an active research area in basic as well as in clinical immunology<sup>[16-18]</sup>. Th1 immune responses are considered to be essential for eradicating malignant cells. Based on the cytokine profile, interferon-gamma is a Th1 cytokine with an antitumor effect. Interleukin-10, a Th2 cytokine, inhibits Th1 immune responses and enhances the production of other Th2 cytokines<sup>[19-22]</sup>.

In order to clarify the clinical significance of the host immune response within the peritoneal cavity in patients with gastric cancer, we conducted an immunological analysis of the peritoneal lavage obtained from patients at the time of gastrectomy.

## MATERIALS AND METHODS

### Patients

A total of 75 patients (50 males and 25 females; mean age: 64.3 years) were included in this study. Sixty-four patients were histologically diagnosed as having gastric cancer. Among these, 56 had gastrectomy, 2 underwent bypass op-

eration, and 6 had exploratory laparotomy. Eleven patients who underwent laparoscopic cholecystectomy for benign disease acted as controls. The resected specimens were histologically examined by hematoxylin and eosin staining according to the general rules of the Japanese Classification of Gastric Carcinoma<sup>[23]</sup>. The investigation protocol was approved by the Institutional Review Board of the Nagasaki University School of Medicine (#14122694). Written informed consent was obtained from all patients. The stages of gastric cancer patients were as follows: stage I A, *n* = 25 patients; stage I B, *n* = 13; stage II, *n* = 7; stage III, *n* = 7; and stage IV, *n* = 12. The clinicopathological features of the patients are shown in Table 1.

### Isolation of mononuclear cells from peripheral blood and peritoneal lavage

Endotracheal general anesthesia was induced and 10 mL of peripheral blood was taken from all patients. Four hundred milliliter of physiological saline was poured into the peritoneal cavity prior to manipulation of the tumor, and was recovered after being gently stirred. Half of the peritoneal lavage was allocated for conventional cytology and carcinoembryonic antigen (CEA) analysis by an enzyme-linked immunosorbent assay. The other half of the peritoneal lavage was immediately centrifuged at 2000 rpm for 10 min, and the supernatants were assayed for CEA values. The peritoneal CEA levels were then measured using an enzyme immunoassay kit (IMx-SERECT CEA, Dainabot, Tokyo) and the protein concentration was determined using a protein assay kit (Bio-Rad, Richmond, CA, United States). The cell component was used for lymphocyte analysis. Lymphocytes from peripheral

blood were isolated by density centrifugation over Ficoll-Paque<sup>TM</sup> gradients (Amersham, Uppsala, Sweden).

### Flow cytometry

The following monoclonal antibodies were used in the present study: fluorescein isothiocyanate (FITC)-conjugated anti-CD8, FITC-CD25, FITC-CD45RA, phycoerythrin (PE)-conjugated anti-CD4, PE-CD56, PE-CCR7, PE-IFN- $\gamma$ , PE-IL-10, PE-Foxp3, cychrome (Cy)-conjugated anti-CD3, and Cy-CD8 (BD Pharmingen, San Diego, CA, United States). Single-cell suspensions were stained in phosphate-buffered saline-1% fetal calf serum at saturating concentrations according to standard procedures. Flow cytometry was performed on the BD Biosystems-FACSCanto II system (BD Biosciences, San Diego, CA, United States), and FACSDiva software (BD Biosciences, San Diego, CA, United States) was used for analysis. All analyses of T cells were carried out after gating by CD3. The ratio of the percentage of CD4 and CD8 cells was represented as the CD4/CD8 ratio.

### Intracellular staining for Foxp3

Intracellular staining for Foxp3 was performed using the Human Foxp3 Buffer set (BD Pharmingen, San Diego, CA, United States) according to the manufacturer's protocol.

### Cytokine assays

Anti-IFN- $\gamma$ -PE and anti-IL-10-PE mAbs were used for the intracellular analysis of cytokine production. Peripheral and intra-peritoneal lymphocytes were activated with 10 ng/mL phorbol 12-myristate-13-acetate (PMA), 0.5  $\mu$ g/mL Ionomycin, and 1  $\mu$ L/mL GolgiPlug (BD Pharmingen, San Diego, CA, United States) for 4 h. Cells were washed, fixed and permeabilized by Cytofix/Cytoperm solution (BD Pharmingen, San Diego, CA, United States), and stained with titrated amounts of cytokine-specific antibodies.

Next, the CD4<sup>+</sup> CD25<sup>+</sup> T cells were isolated from peripheral blood by magnetic beads (Miltenyi Biotech, BergischGladbach, Germany). These CD4<sup>+</sup> CD25<sup>+</sup> T cells

were mixed with intraperitoneal lymphocytes at a ratio of 1:10 and co-cultivated for 4 d in RPMI with 10% FBS. The CD4<sup>+</sup> CD25<sup>-</sup> T cells were co-cultivated with intraperitoneal lymphocytes as controls. The cytokine assay was performed by the intracellular cytokine method after 4 d of co-cultivation.

### Statistical analysis

The statistical analysis was performed using the Kruskal-Wallis test (non-parametric ANOVA) using a personal computer and the StatViewV.5.0 software package (SAS Institute, Cary, NC, United States). *P* values less than 0.05 were considered to indicate statistical significance.

## RESULTS

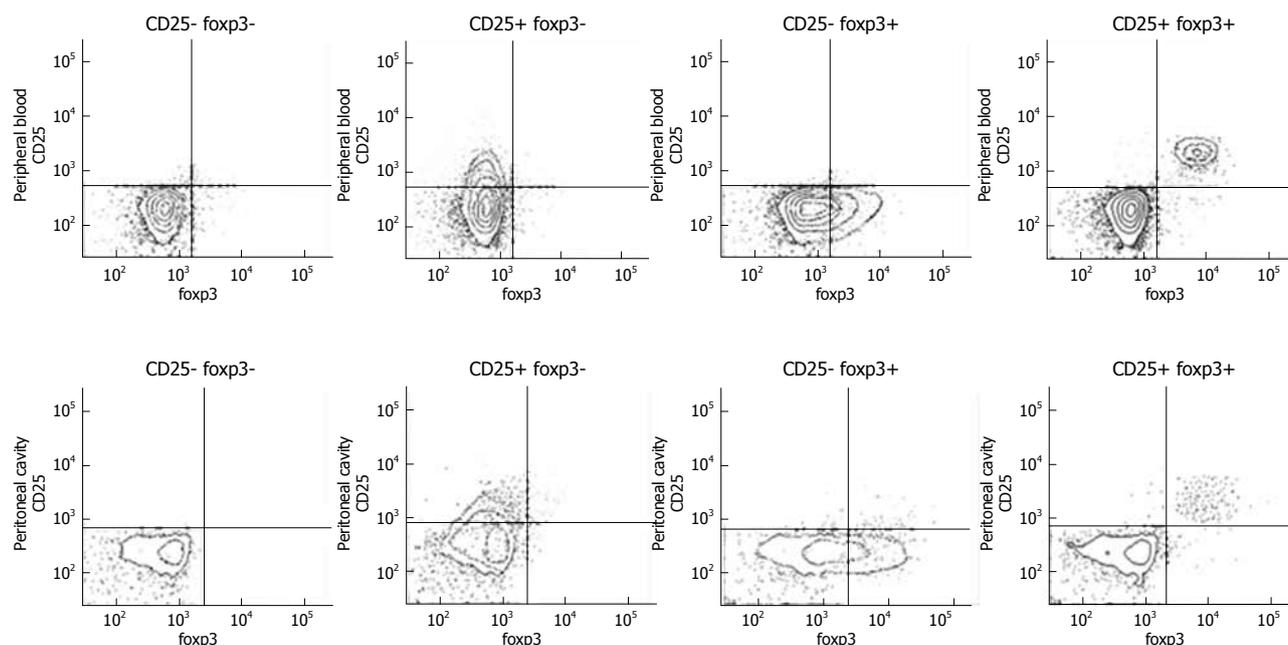

### Carcinoembryonic antigen values in sera and peritoneal lavage

For the interaction between peripheral blood and the peritoneal cavity, we investigated the CEA values in both serum and peritoneal lavage at the time of surgery. The serum CEA values were elevated only in patients with stage IV disease. On the other hand, the values in peritoneal lavage were found to be elevated even at stage III, and they were also related to the clinical stage (Table 2).

### Analysis of lymphocyte populations in peripheral blood and the peritoneal cavity

After purification of lymphocytes from peritoneal lavage, we investigated the phenotypes of lymphocytes in both peripheral blood and the peritoneal cavity. The mean value of the CD4/CD8 ratio for all patients was 2.17 in peripheral blood. The CD8<sup>+</sup> T cells were dominant in the peritoneal cavity and the CD4/CD8 ratio was reversed. The ratio in patients with stage III or IV was significantly higher than in stage I or control patients (Table 2).

The CCR7<sup>+</sup> CD45RA<sup>-</sup> CD8<sup>+</sup> T cells were counted as effector memory T cell subsets. The percentage of effector memory T cells in the peritoneal cavity was higher than that in peripheral blood. However, the percentage

**Figure 1** Co-staining with foxp3 and CD25 for CD4<sup>+</sup> T cells. High correlation was shown between both populations.

decreased in association with the clinical stage (Table 2). The CD3<sup>+</sup>CD56<sup>+</sup> cells were measured as natural killer T cells. The percentage of these cells in the peritoneal lavage was also low in patients with stage III or stage IV (Table 2). As the co-staining of foxp3 and CD25 revealed a high correlation between both populations, CD25<sup>high</sup> was used following cytokine producing assays (Figure 1). The frequency of CD4<sup>+</sup> CD25<sup>high</sup> T cells in patients with advanced stage cancer was higher than that in control patients in both peripheral blood and the peritoneal cavity (Figure 2A and B).

### Cytokine production by lymphocytes

The cytokine production from CD3<sup>+</sup> T cells after stimulation with PMA + ionomycin was evaluated by a cytokine production assay. The lymphocytes in the peritoneal cavity were more sensitive for the production of IFN- $\gamma$  than those in the peripheral blood. The ratio of IFN- $\gamma$  producing cells in the peritoneal cavity was significantly lower in patients with advanced stage disease in comparison to the controls (Figure 3A and B). The ratio of IL-10 producing cells in the peritoneal cavity in patients with advanced stages was higher in comparison to the controls (Figure 3C and D).

### Cytokine assays of intra-peritoneal lymphocytes after co-cultivation with self- CD4<sup>+</sup> CD25<sup>high</sup> T cells

In order to investigate whether the suppression of IFN- $\gamma$  production from T cells in the peritoneal cavity at advanced stages was caused by CD4<sup>+</sup> CD25<sup>high</sup> T cells, further assays were performed. The IFN- $\gamma$  production of CD8<sup>+</sup> T cells was suppressed in intra-peritoneal lymphocytes co-cultivated with isolated CD4<sup>+</sup> CD25<sup>high</sup> T cells from self-peripheral blood (Figure 4A). No inhibition was seen when the lymphocytes were co-cultivated with CD4<sup>+</sup>

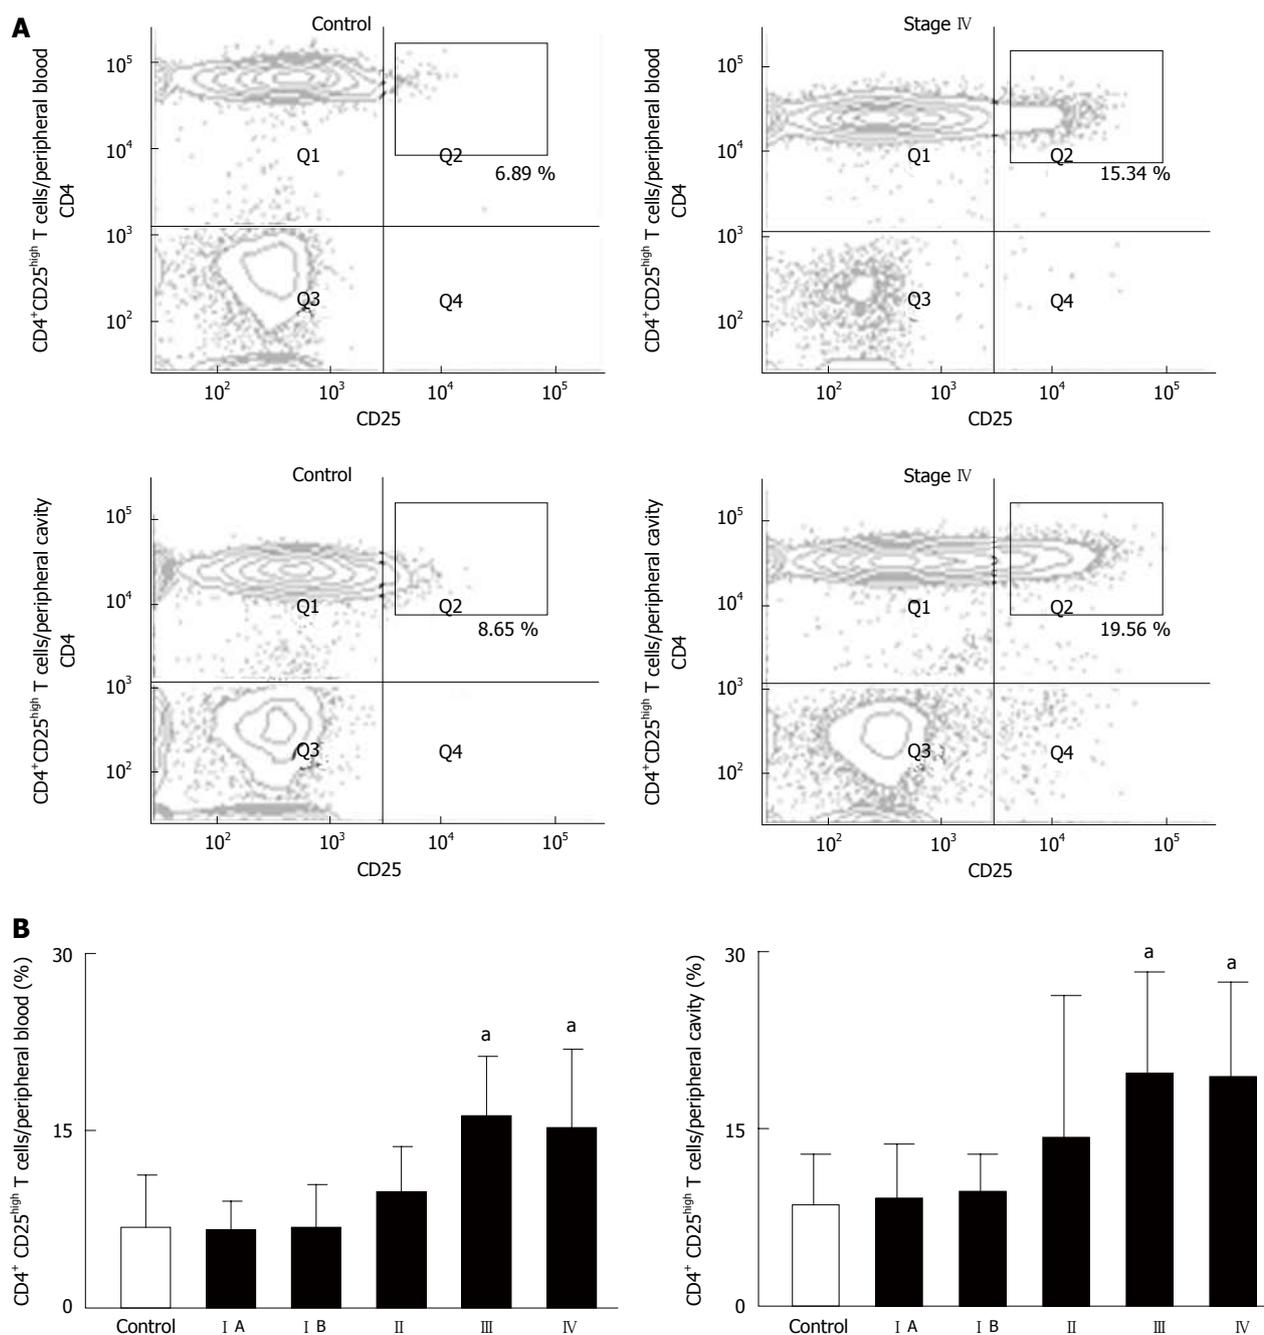

CD25<sup>-</sup> cells (Figure 4B).

## DISCUSSION

The peritoneal cavity is a compartment in which the immunological host-tumor interaction can occur<sup>[24]</sup>. This study investigated lymphocytes in the peritoneal cavity of patients with gastric cancer in relation to anti-tumor immunity. Some tumors can acquire the ability to down-regulate immune responses and exploit this action to promote tumor cell proliferation, survival, and invasion<sup>[10,25]</sup>. Therefore, the presence of leukocytes in the peritoneal cavity may be a consequence of an immune response that favors either dissemination of tumor cells or a protective host response. Malignant ascites has been used as a common source of immunological analysis in previous reports<sup>[11,26]</sup>. To the best of our knowledge, there are no reports describing the lymphocyte and cytokine production ability in peritoneal lavage from patients with gastric cancer at the time of gastrectomy.

In our initial experiments, the CEA values in peritoneal lavage were found to correlate with the clinical stages. Interestingly, the CEA values were elevated even in cases without serosal invasion. This result suggests that some fragments of cancer cells may spread throughout the peritoneal cavity and induce an immune reaction between the tumor and host<sup>[26,27]</sup>.

The frequency of CD4<sup>+</sup> T cells in all patients was higher than that of CD8<sup>+</sup> T cells in peripheral blood, but this pattern was reversed in peritoneal lavage fluid. CD8<sup>+</sup> T cells were dominant in the peritoneal cavity. Our data suggested that the immunological environment in the peripheral blood is different from that in the peritoneal cavity. There were significant differences in the CD4/CD8 ratio in the peritoneal cavity between gastric cancer

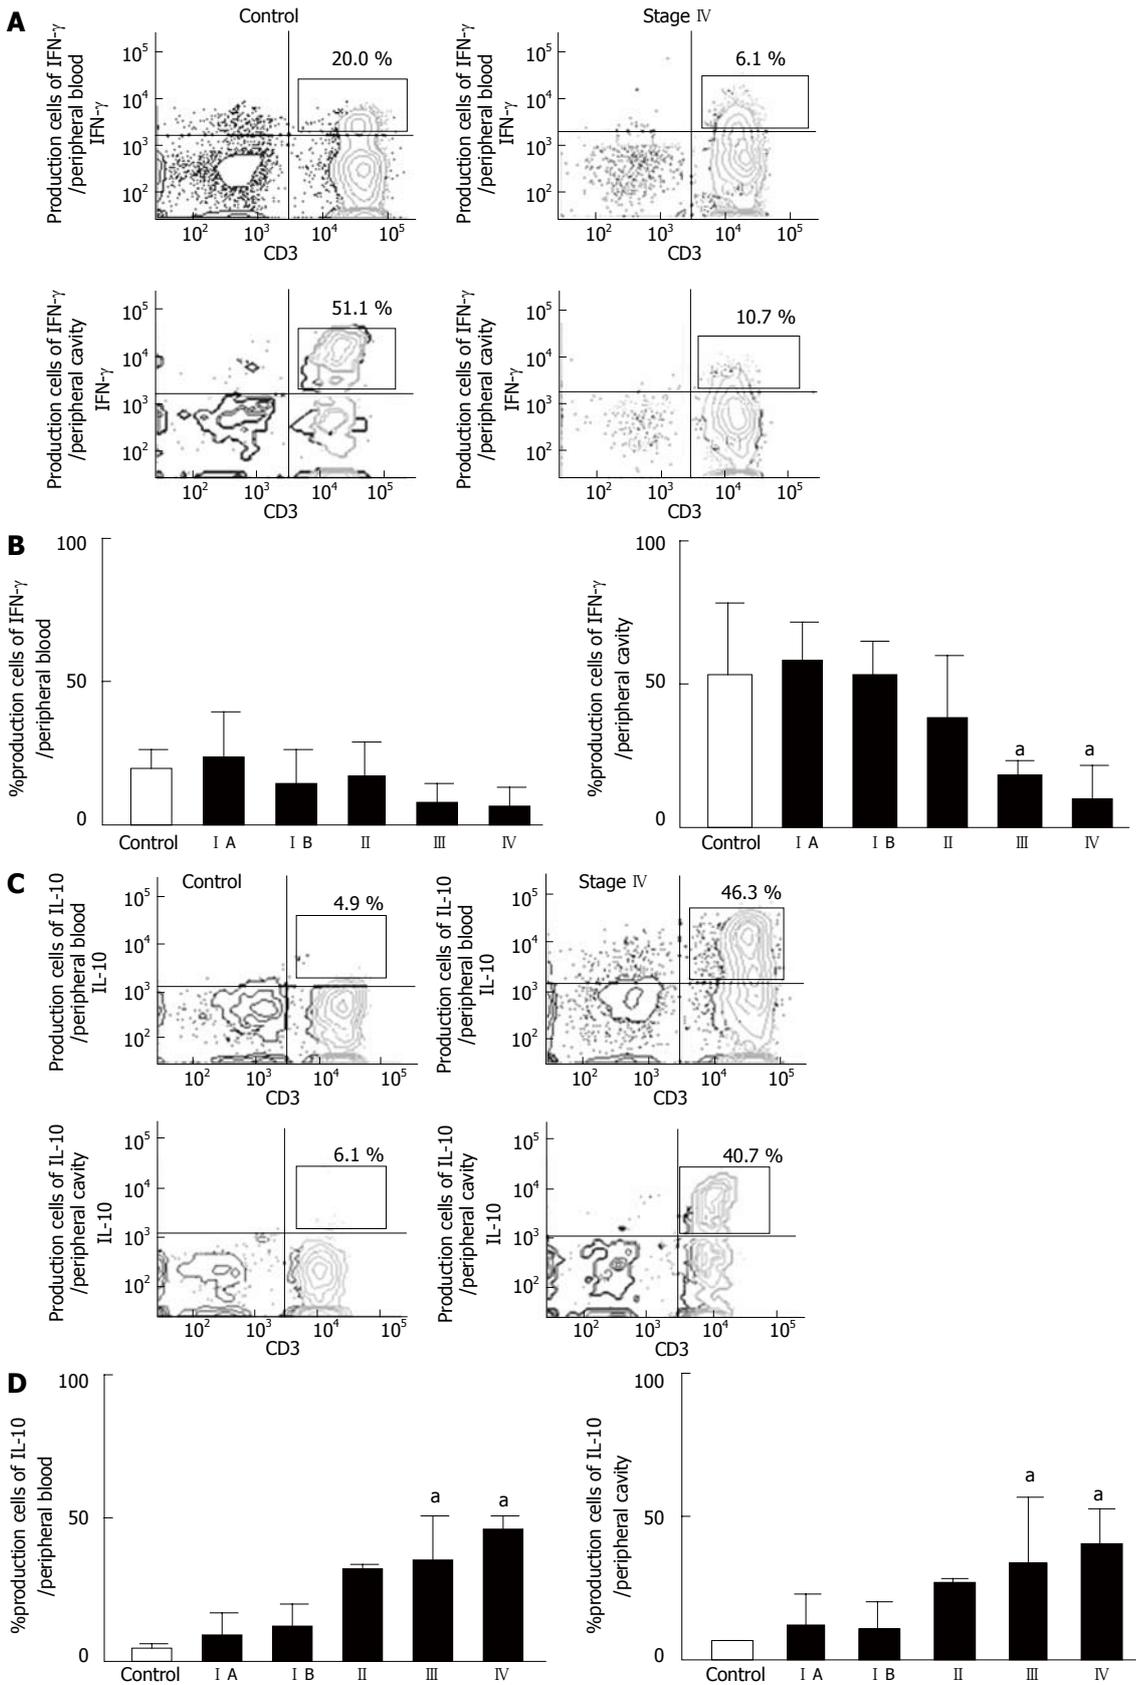

**Figure 2 Analysis of lymphocyte populations in peripheral blood and the peritoneal cavity.** A: The gating and counting of CD4<sup>+</sup> CD25<sup>high</sup> T cell population by flow cytometry; B: The percentage of CD4<sup>+</sup> CD25<sup>high</sup> T cells in the CD4<sup>+</sup> T cell population in peripheral blood and peritoneal lavage of patients at each stage of gastric cancer and control patients. Data are presented as the mean ± SD.

patients at advanced stage and control patients. Cancer progression may have an effect on the balance of the T cell population in the peritoneal cavity.

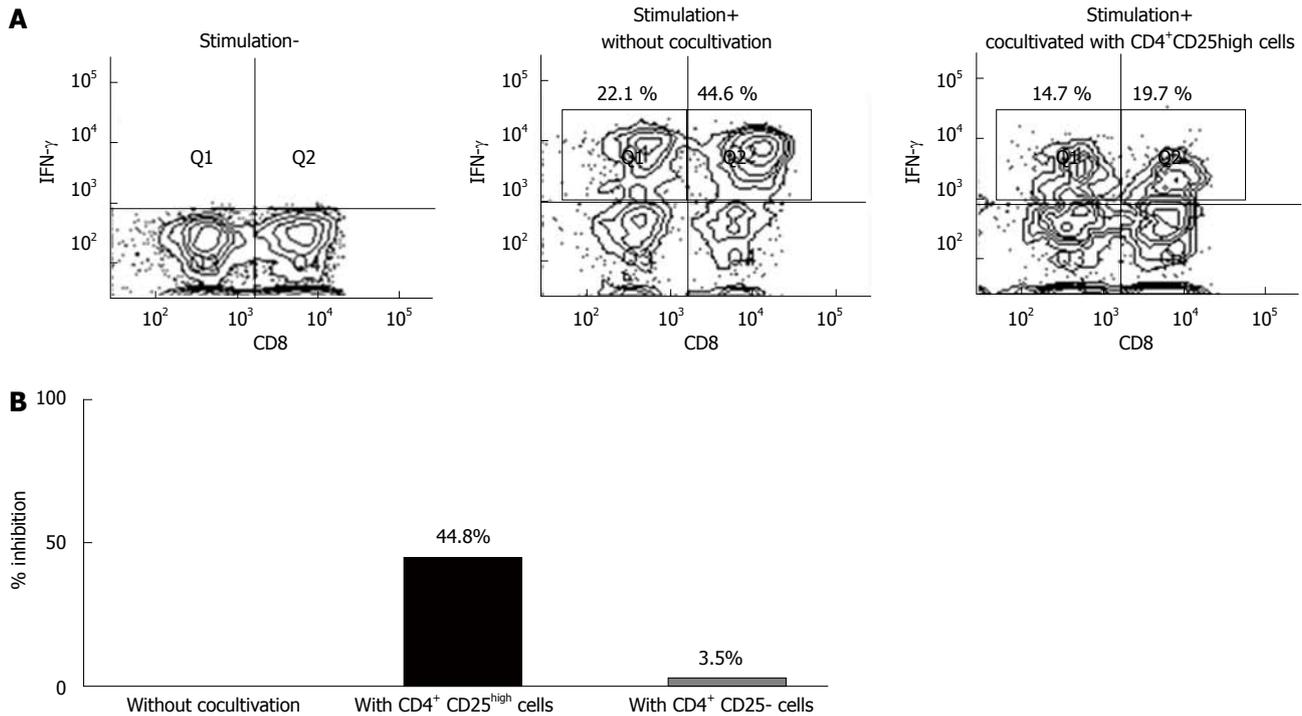

Immunological memory is demonstrated by following T cell subsets: lymph-node-homing cells lacking inflammatory and cytotoxic function (defined as central memory T cells, CCR7<sup>+</sup> CD45RA<sup>-</sup>) and tissue-homing cells endowed with various effector functions (defined as effector memory T cells, CCR7<sup>-</sup> CD45RA<sup>+</sup>). These two subsets allow for the division of labor among memory cells. Effector memory T cells represent a readily available pool of antigen-primed cells that can enter peripheral tissues

to mediate inflammatory reactions or cytotoxicity, thus rapidly containing invasive pathogens and cancer antigens<sup>[11,28-31]</sup>. Our data show that CD8<sup>+</sup> effector memory T cells were rich in the peritoneal cavity. This indicates the migration of effector memory cells from the peripheral blood to local sites. However, in advanced cases, the frequency of CD8<sup>+</sup> effector memory cells in the peritoneal lavage was low. These results suggest that the peritoneal cavity exerts the local immune response, more than peripheral blood.

Natural killer T cells, a unique lymphocyte subpopulation, are characterized by the expression of invariant an-

**Figure 3 Cytokine production by lymphocytes.** A: The gating and counting of the IFN- $\gamma$  producing cell population by flow cytometry; B: The percentage of IFN- $\gamma$  producing cells in the CD3<sup>+</sup> cell population stimulated with PMA + ionomycin in peripheral blood and peritoneal lavage of patients at each stage of gastric cancer and control patients. Data are presented as the mean  $\pm$  SD. The statistical analysis was performed by the Kruskal-Wallis test. After gating of CD3<sup>+</sup> T cells, 10 000 events were analyzed. The production of IFN- $\gamma$  in the peritoneal cavity was higher than that in the peripheral blood. The ratio of IFN- $\gamma$  production cells in the peritoneal lavage was significantly lower in patients with advanced-stage than in controls [control vs stage IV: 51.1 (35.1-67.1) vs 10.7 (2.6-22.1), <sup>a</sup> $P < 0.05$ ]; C: The gating and counting of the IL-10 producing cell population by flow cytometry; D: The percentage of IL-10 producing cells in the CD3<sup>+</sup> cells stimulated with PMA + ionomycin in peripheral blood and peritoneal lavage of patients at each stage of gastric cancer and control patients. Data are presented as the mean  $\pm$  SD. The ratio of IL-10 producing cells in peripheral blood and intra-peritoneal lymphocytes was significantly higher in patients at advanced stage than in controls [control vs stage IV: 6.1 (3.94-8.25) vs 40.7 (18.35-63.0), <sup>a</sup> $P < 0.05$ ].

**Figure 4** Cytokine assays of intra-peritoneal lymphocytes after co-cultivation with self-CD4<sup>+</sup>CD25<sup>high</sup>T cells. A: IFN- $\gamma$  production in intra-peritoneal lymphocytes co-cultivated with self- CD4<sup>+</sup> CD25<sup>high</sup> T cells; B: Either CD4<sup>+</sup> CD25<sup>high</sup> T cells or CD4<sup>+</sup> CD25<sup>-</sup> T cells.

tigen receptors<sup>[12,13]</sup>. Natural killer T cells have been suggested to serve as a bridge between innate and acquired immunity<sup>[14,15]</sup>. However, the mechanisms underlying the anti-tumor effect of human natural killer T cell-mediated immunotherapy remain unclear so far. The frequency of natural killer T cells was lower in patients with stages III and IV than in control patients. Therefore, a decrease in the number of natural killer T cells in the peritoneal cavity may be one aspect of the interaction between host-immunity and cancer progression.

Recent studies have shown that CD4<sup>+</sup> CD25<sup>high</sup> foxp3<sup>+</sup> T cells exhibiting regulatory/suppressive properties are naturally present in humans<sup>[16-18]</sup>. The roles of regulatory T cells have been active topics of research in both basic and clinical immunology. Naturally-occurring regulatory T cells represent a small fraction (5%-6%) of the overall CD4<sup>+</sup> T cell population, and play an important role in down-regulation of the response of T cells to foreign and self antigens<sup>[31]</sup>. The depletion of this subset of regulatory T cells in normal hosts results in various autoimmune diseases because the host immune system is unchecked and attacks the body's own tissues<sup>[28]</sup>. Despite the importance of these cells in preventing autoimmune disease, their presence in the tumor microenvironment diminishes anti-tumor immune responses<sup>[32-36]</sup>.

Within the CD4<sup>+</sup> T cell subset, there is a population of naturally occurring foxp3<sup>+</sup> T cells that are defined as regulatory T cells. These cells can be identified as CD4<sup>+</sup>foxp3<sup>+</sup> T cells by flow cytometry. However, because foxp3 is intracellular and requires permeabilization of cells for detection by flow cytometry, regulatory T cells are isolated as CD4<sup>+</sup>CD25<sup>high</sup> T cells, which were shown to

have functional suppressive abilities in our co-culture experiments<sup>[37]</sup>. In the present study, the mean percentage of CD4<sup>+</sup> CD25<sup>high</sup> T cells in the peritoneal cavity in advanced gastric cancer patients was higher than that of control patients. After the co-cultivation of the self-CD4<sup>+</sup> CD25<sup>high</sup> T cell population of intra-peritoneal lymphocytes, the production of IFN- $\gamma$  was inhibited.

IFN- $\gamma$ , a Th1 cytokine, not only exerts an anti-tumor effect, but also inhibits the proliferation of Th2 clones<sup>[19-20]</sup>. IL-10, a Th2 cytokine, suppresses the synthesis of Th1 cytokines such as IFN- $\gamma$ <sup>[21-22]</sup>. This study showed that the production of intracellular cytokines in the peritoneal cavity was higher than that in the peripheral blood after appropriate stimulation. IFN- $\gamma$  production was down-regulated in advanced cases, but not in the controls and stage I patients. On the other hand, IL-10 production was up-regulated, which revealed the switch of Th1 and Th2 responses in the peritoneal cavity of these patients. IFN- $\gamma$  production in intra-peritoneal lymphocytes was suppressed after co-cultivation with self-CD4<sup>+</sup> CD25<sup>high</sup> T cells, but not CD4<sup>+</sup> CD25<sup>-</sup> T cells. Interestingly, the replacement of CD4<sup>+</sup> CD25<sup>-</sup> T cells for CD4<sup>+</sup> CD25<sup>high</sup> T cells could recover the production of IFN- $\gamma$  in intra-peritoneal lymphocytes.

## COMMENTS

### Background

The peritoneal cavity is a compartment in which immunological host-tumor interactions can occur. Neoplastic cell factors and biophylactic side factors such as immune reactions are interacting in the survival and development of micro-metastasis. However, the role of lymphocytes in the peritoneal cavity of gastric cancer patients is unclear.

## Research frontiers

Clinical and experimental studies have established that leukocyte infiltrations around tumors promote the development or regression of solid tumors, but whether the organ-specific cellular and molecular programs promote tumor growth or exhibit anti-tumor immunity by leukocytes are incompletely understood. Recent studies have shown that CD4<sup>+</sup> CD25<sup>high</sup> foxp3<sup>+</sup> T cells exhibiting regulatory/suppressive properties are naturally present in humans. The roles of regulatory T cells have been active topics of research in both basic and clinical immunology.

## Innovations and breakthroughs

In most previous studies, malignant ascites have been a common source of immunological analysis. However, there are no reports describing the lymphocyte and cytokine production ability in peritoneal lavage from patients with gastric cancer at the time of gastrectomy. In the present study, CD4<sup>+</sup> CD25<sup>high</sup> T cells were found to be increased in the peritoneal cavity of advanced gastric cancer patients, but in the co-cultivation of the self- CD4<sup>+</sup> CD25<sup>high</sup> T cell population of intra-peritoneal lymphocytes, the production of IFN- $\gamma$  was inhibited.

## Applications

Peritoneal lavage samples from patients with gastric cancer are more susceptible than peripheral blood for monitoring the interaction between the host's immune system and tumor cells.

## Terminology

Regulatory T cells: Regulatory T cells contribute to the maintenance of immunologic self-tolerance. Recent reports underscore that regulatory T cells not only play a role in the maintenance of immunotolerance but are also potent inhibitors of antitumor immune responses.

## Peer review

The authors have investigated T-cells isolated from peripheral blood and peritoneal lavage in patients with gastric cancer and controls. Main findings are that in stage III and IV gastric cancers the lavage fluid contains less CD8 memory cells, NKT cells and more CD25<sup>high</sup> regulatory T cells.

### Abstract

**AIM:** To investigate the effects of curcumin on gastric microcirculation and inflammation in rats with indomethacin-induced gastric damage.

**METHODS:** Male Sprague-Dawley rats were randomly divided into three groups. Group 1 (control group,  $n = 5$ ) was fed with olive oil and 5%  $\text{NaHCO}_3^-$  (vehicle). Group 2 [indomethacin (IMN) group,  $n = 5$ ] was fed with olive oil 30 min prior to indomethacin 150 mg/kg body weight (BW) dissolved in 5%  $\text{NaHCO}_3^-$  at time 0th and 4th h. Group 3 (IMN + Cur group,  $n = 4$ ) was fed with curcumin 200 mg/kg BW dissolved in olive oil 0.5 mL, 30 min prior to indomethacin at 0th and 4th h. Leukocyte-endothelium interactions at postcapillary

venules were recorded after acridine orange injection. Blood samples were determined for intercellular adhesion molecule (ICAM)-1 and tumor necrosis factor (TNF)- $\alpha$  levels using enzyme linked immunosorbent assay method. Finally, the stomach was removed for histopathological examination for gastric lesions and grading for neutrophil infiltration.

**RESULTS:** In group 2, the leukocyte adherence in postcapillary venules was significantly increased compared to the control group ( $6.40 \pm 2.30$  cells/frame vs  $1.20 \pm 0.83$  cells/frame,  $P = 0.001$ ). Pretreatment with curcumin caused leukocyte adherence to postcapillary venule to decline ( $3.00 \pm 0.81$  cells/frame vs  $6.40 \pm 2.30$  cells/frame,  $P = 0.027$ ). The levels of ICAM-1 and TNF- $\alpha$  increased significantly in the indomethacin-treated group compared with the control group ( $1106.50 \pm 504.22$  pg/mL vs  $336.93 \pm 224.82$  pg/mL,  $P = 0.011$  and  $230.92 \pm 114.47$  pg/mL vs  $47.13 \pm 65.59$  pg/mL,  $P = 0.009$  respectively). Pretreatment with curcumin significantly decreased the elevation of ICAM-1 and TNF- $\alpha$  levels compared to treatment with indomethacin alone ( $413.66 \pm 147.74$  pg/mL vs  $1106.50 \pm 504.22$  pg/mL,  $P = 0.019$  and  $58.27 \pm 67.74$  pg/mL vs  $230.92 \pm 114.47$  pg/mL,  $P = 0.013$  respectively). The histological appearance of the stomach in the control group was normal. In the indomethacin-treated group, the stomachs showed a mild to moderate neutrophil infiltration score. Gastric lesions were erosive and ulcerative. In rats treated with indomethacin and curcumin, stomach histopathology improved and showed only a mild neutrophil infiltration score and fewer erosive lesions in the gastric mucosa.

**CONCLUSION:** The results indicate that curcumin prevents indomethacin-induced gastropathy through the improvement of gastric microcirculation by attenuating the level of ICAM-1 and TNF- $\alpha$ .

## INTRODUCTION

Nonsteroidal anti-inflammatory drugs (NSAIDs) are among the most commonly prescribed medications worldwide. However, NSAIDs have adverse effects on the gastric mucosa, resulting in various clinical presentations, ranging from nonspecific dyspepsia to ulceration, upper gastrointestinal bleeding, and death, summarized by the term "NSAID gastropathy"<sup>[1]</sup>. NSAIDs-induced gastric damage is the major side effect of this kind of drug<sup>[2]</sup>.

The main action of NSAIDs is to inhibit prostaglandin synthesis. There is substantial evidence supporting the view that the ulcerogenic effect of this medication correlates with its ability to suppress prostaglandin synthesis<sup>[3-5]</sup>. Endogenous prostaglandins normally regulate mucosal blood flow, epithelial cell proliferation, epithelial restitution, mucosal immunocyte function, mucus and bicarbonate secretion, and basal acid secretion<sup>[6]</sup>. Therefore, decreases in prostaglandins, protective factors for ulcer formation, lead to gastric mucosal injury.

Animal studies have shown that neutrophil adherence to the endothelium of the gastric microcirculation is critical in NSAIDs injury<sup>[7]</sup>. Neutrophil adherence damages the mucosa by producing oxygen-free radicals, releasing proteases, and obstructing capillary blood flow. NSAIDs might induce the synthesis of tumor necrosis factor (TNF)- $\alpha$  and leukotrienes<sup>[8,9]</sup>. These inflammatory mediators subsequently stimulate neutrophil adherence by the upregulation of adhesion molecules<sup>[10]</sup>.

NSAID administration in rats caused a rapid and significant increase in adhesion between neutrophils and vascular endothelial cells in both gastric and mesenteric venules<sup>[11-13]</sup>. This was dependent on intercellular adhesion molecule (ICAM)-1 expression on the endothelium and CD11/CD18 expression on the leukocyte<sup>[14,15]</sup>. Interestingly, Andrews *et al.*<sup>[10]</sup> recently reported that administration of aspirin or indomethacin to rats resulted in a significant increase in ICAM-1 expression in the gastric microcirculation.

Curcuma, a genus in the plant family of Zingiberaceae, is the biological source for curcuminoids, including curcumin. *Curcuma longa*, the yellow tuberous root re-

ferred to as turmeric, was taken from India to Southeast Asia<sup>[16]</sup>. The yellow pigmented fraction of *Curcuma longa* contains curcuminoids, which are chemically related to its principal ingredient, curcumin<sup>[16]</sup>. It possesses a broad range of pharmacological activities, including antioxidant, anti-carcinogenic, wound-healing, and anti-inflammatory effects<sup>[17-19]</sup>. There are currently limited studies investigating the effect of curcumin on NSAIDs-induced gastric damage. The aim of this study was to investigate the anti-inflammation effect of curcumin on indomethacin-induced gastric damage in rats.

## MATERIALS AND METHODS

### Animal preparation and curcumin preparation

Male Sprague-Dawley rats weighing 180-220 g, purchased from the National Laboratory Animal Center, Mahidol University, Salaya ( $n = 18$ ), Nakorn pathom, were used in this study. All rats were kept in a controlled temperature room at  $25 \pm 1$  °C under standard conditions (12 h day-night rhythm). They were cared for in accordance with the Ethical Committee, Faculty of Medicine, Chulalongkorn University, Thailand. Curcumin powder (Cayman Chemical Company, United States) was suspended in olive oil.

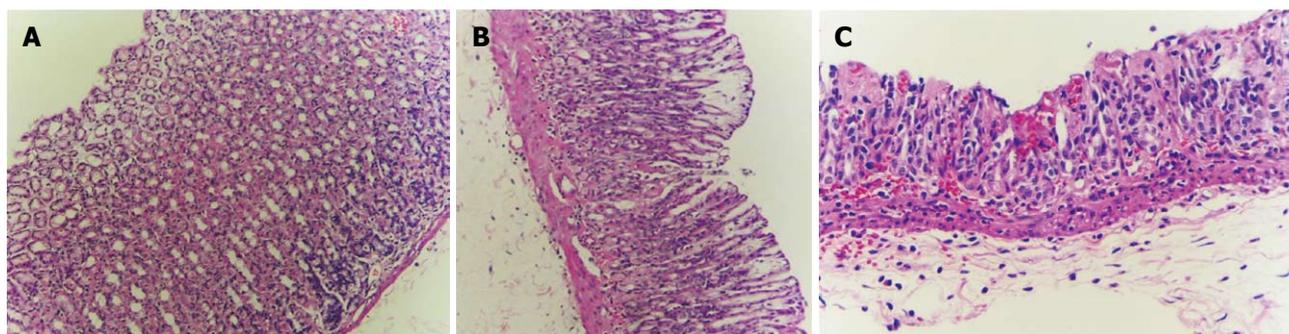

### Experimental protocol

All rats were fasted, with free access to water ad libitum, for 22-24 h before the experiment. They were randomly divided into three experimental groups. Group 1 (control,  $n = 6$ ): Rats were fed with olive oil 30 min prior to 5% sodium bicarbonate 1 mL orally *via* an intragastric tube at time 0th and 4th h. Group 2 [indomethacin (IMN),  $n = 6$ ]: Rats were fed with olive oil 30 min prior to indomethacin (150 mg/kg body weight in 5% sodium bicarbonate 1 mL orally *via* an intragastric tube) at time 0th and 4th h. Group 3 (IMN + Cur,  $n = 6$ ): Rats were fed with curcumin (200 mg/kg body weight dissolved in olive oil 0.5 mL) 30 min prior to indomethacin [150 mg/kg body weight (BW) dissolved in 5% sodium bicarbonate 1 mL orally *via* an intragastric tube] at time 0th and 4th h.

After 8 h 30 min, animals were anesthetized with intraperitoneal injection of thiopental (50 mg/kg body weight). After tracheostomy, the carotid artery and jugular vein were cannulated for blood pressure measurement using a polygraph and for the administration of a fluorescent marker; acridine orange was infused intravenously (Sigma chemical Co., United States, 0.5 mg/kg BW/min). The abdominal wall was incised and the stomach was extended and fixed. Leukocyte adherence in the stomach was observed by intravital fluorescence microscopy. At the end of the experiment, blood samples were collected for ICAM-1 and TNF- $\alpha$  determination using enzyme linked immunosorbent assay (ELISA) methods. The stomach was cut and fixed in 10% formalin solution to inspect the histopathology.

### Study of the interaction between leukocytes and endothelial cells in postcapillary venule

It has been stated that NSAIDs-induced leukocyte adherence could contribute to the pathogenesis of gastric

**Figure 1** Hematoxylin-eosin stained stomach sections ( $\times 200$ ). A: The control group showed normal stomach histopathology; B: The indomethacin treated group showed gastric ulcer formation and infiltration of inflammatory cells; C: The curcumin treated group showed a reduced degree of gastric ulcer formation and inflammation.

mucosal injury. To visualize leukocytes, acridine orange was infused intravenously (0.3 mg/kg body weight). The number of leukocyte adhesions was recorded using a video recorder. Videotape of each experiment was replayed and leukocyte adherence was monitored. Most leukocytes were adhered to the postcapillary venule (about 15-30  $\mu\text{m}$  in diameter). Leukocytes were considered adherent to the vessel endothelium if they remained stationary for 30 s or longer. Adherent leukocytes were expressed as the number of leukocyte adhesions per frame of view, as previously described<sup>[20]</sup>.

#### Determination of serum cytokine levels

After the experiment, blood samples were taken by cardiac puncture, and allowed to clot overnight before centrifuging at approximately 2000  $\times g$ . Serum was stored at -80  $^{\circ}\text{C}$  for determining ICAM-1 and TNF- $\alpha$  levels by ELISA kit (R and D systems).

#### Histopathological examination

Samples of the stomach were excised and transferred to formalin. The samples were subsequently processed by routine techniques before embedding in paraffin. Sections were cut at the thickness of 5  $\mu\text{m}$  and stained with hematoxylin and eosin (HE), as previously described<sup>[20]</sup>. One pathologist performed all the histopathological examinations. All histopathological changes were observed under a light microscope. The neutrophil infiltration score in each section was graded according previously determined criteria<sup>[21]</sup>.

#### Statistical analysis

All data were presented as mean  $\pm$  SD. To compare data among all groups of animals, one-way analysis of variance (one-way ANOVA) and Duncan comparisons were employed. All statistical tests were performed using SPSS for Windows version 13.0 (SPSS Inc., Chicago, IL, United States). Differences were considered statistically significant at  $P < 0.05$ .

## RESULTS

#### Histopathological examination

The histological appearance of the stomach in the con-

**Table 1** Summary of the infiltration of inflammatory cells and erosion in all groups ( $n = 6$ )

Experimental group	Neutrophil infiltration <sup>1</sup>				Pathology		
	0	1	2	3	No erosion	Erosion	Ulcer
Control	6	-	-	-	6	-	-
IMN	-	3	3	-	-	2	4
IMN + Cur	4	2	-	-	4	2	-

<sup>1</sup>The severity of neutrophil infiltration was graded as: 0: No neutrophil infiltration; 1: Neutrophil infiltration found in 1/3 of gastric mucosal layer; 2: Neutrophil infiltration found in 2/3 of gastric mucosal layer; 3: Neutrophil infiltration found in the muscularis mucosae of gasm. IMN: Indomethacin.

trol group (Figure 1) was normal. In the indomethacin treated group, the stomachs showed mild to moderate gastric mucosal injury. Gastric lesions were erosive and ulcerative. In rats treated with indomethacin and curcumin, the stomach histopathology improved and showed only mild gastric mucosal injury and reduced amounts of erosive lesions in the gastric mucosa. The summary of infiltration of inflammatory cells and gastric lesions are shown in Table 1.

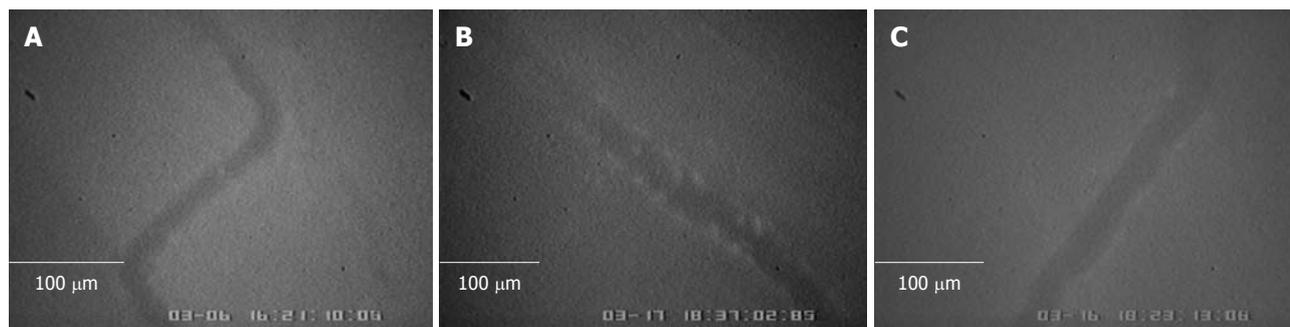

#### Interaction between leukocytes and endothelial cells

After gastric injury was induced by the administration of indomethacin, leukocyte adherence to endothelial cells of postcapillary venules (15-30  $\mu\text{m}$  in diameter) was observed under intravital fluorescence microscopy, 10-15 min after acridine orange injection (Figure 2). The number of leukocytes adhering to postcapillary venules for 30 s or longer was counted. The mean number of leukocyte adhesions in the IMN group without curcumin treatment was significantly higher than in the control group ( $6.40 \pm 2.30$  cells/frame *vs*  $1.20 \pm 0.83$  cells/frame,  $P = 0.001$ ).

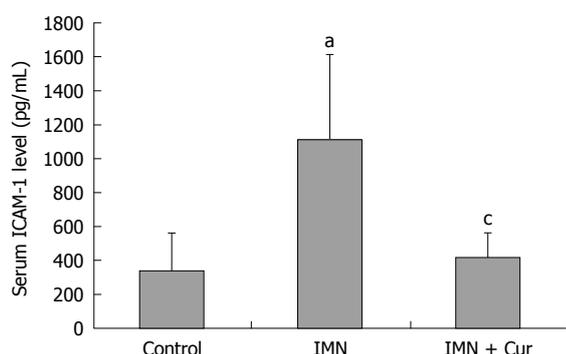

The number of leukocyte adhesions significantly decreased after pretreatment with curcumin as compared to the IMN group ( $3.00 \pm 0.81$  cells/frame *vs*  $6.40 \pm 2.30$  cells/frame,  $P = 0.027$ ).

#### Changes in ICAM-1 levels

The levels of ICAM-1 increased significantly in the indomethacin treated group compared with the control group

**Figure 2** Intravital microscopic ( $\times 40$ ) images of leukocyte adherence on vascular endothelium of postcapillary venules 10-15 min after acridine orange injection in the control group (A), IMN group (B), and IMN + Cur group (C). IMN: Indomethacin.

**Figure 3** Serum intercellular adhesion molecule-1 levels in all groups. All data are expressed as mean  $\pm$  SD. The mean intercellular adhesion molecule (ICAM)-1 levels were significantly higher in the indomethacin treated group (IMN) when compared with the control group ( $^aP < 0.05$ ). Pretreatment with curcumin significantly decreased ICAM-1 level when compared with indomethacin ( $^cP < 0.05$ ). IMN: Indomethacin.

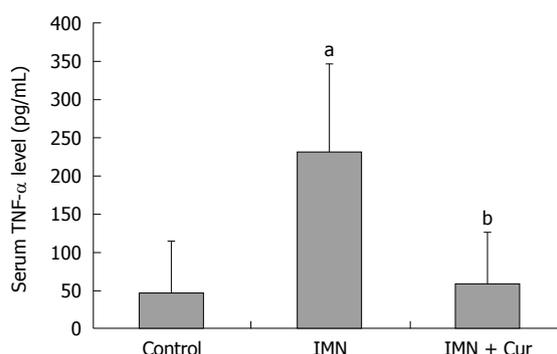

( $1106.50 \pm 504.22$  pg/mL *vs*  $336.93 \pm 224.82$  pg/mL,  $P = 0.011$ ). Pretreatment with curcumin markedly decreased the elevation of the ICAM-1 level compared with the indomethacin treated group ( $413.66 \pm 147.74$  pg/mL *vs*  $1106.50 \pm 504.22$  pg/mL,  $P = 0.019$ ) (Figure 3).

### Changes in TNF- $\alpha$ levels

The level of TNF- $\alpha$  markedly increased in the indomethacin treated group compared with the control group ( $230.92 \pm 114.47$  pg/mL *vs*  $47.13 \pm 65.59$  pg/mL,  $P = 0.009$ ). Pretreatment with curcumin decreased the elevation of TNF- $\alpha$  levels compared with the indomethacin treated group ( $58.27 \pm 67.74$  pg/mL *vs*  $230.92 \pm 114.47$  pg/mL,  $P = 0.013$ ) (Figure 4).

## DISCUSSION

In the present study, we investigated the effects of curcumin on indomethacin-induced gastric damage in rats. The results clearly demonstrated that curcumin administration prevented the ulcerogenic effect of indomethacin, possibly through its anti-inflammatory action. Evidence suggests that NSAIDs-induced gastric ulceration is a neutrophil-dependent process. NSAIDs administration to rats caused a rapid and significant increase in adhesion

**Figure 4** Serum tumor necrosis factor-alpha level in all groups. All data are expressed as mean  $\pm$  SD. The mean of tumor necrosis factor (TNF)- $\alpha$  levels increased in the indomethacin treated group when compared with the control group ( $^aP = 0.009$ ). Pretreatment with curcumin decreased serum of TNF- $\alpha$  when compared with indomethacin alone ( $^bP = 0.013$ ). IMN: Indomethacin.

between neutrophils and vascular endothelial cells in both the gastric and mesenteric venules<sup>[11,12]</sup>. Indeed, monoclonal antibodies that blocked NSAID-induced neutrophil adherence to vascular endothelium could significantly alleviate NSAID-induced gastric mucosal injury<sup>[7,15,22]</sup>. Neutrophils play an important role in the development of inflammation and tissue injury by releasing a variety of inflammatory mediators<sup>[23,24]</sup>. These inflammatory mediators are capable of producing tissue injury; therefore, they may be involved in the pathogenesis of indomethacin-induced gastric mucosal injury<sup>[25]</sup>. Furthermore, adhesion molecules expressed on activated neutrophils, such as CD11b and CD18, have been shown to play an important role in neutrophil-induced tissue injury<sup>[14]</sup>.

Moreover, NSAIDs are believed to have the effect on nuclear translocation of nuclear factor (NF)- $\kappa$ B, which modulates the expression of several adhesion molecules, including ICAM-1<sup>[26]</sup>. ICAM-1, one of the major adhesion molecules, plays a pivotal role in the inflammatory reaction by increasing leukocyte adhesion to endothelium and promoting transendothelial migration of leukocytes to inflammatory sites<sup>[27]</sup>. Another important mechanism that induces ICAM-1 expression is the increment of TNF- $\alpha$  levels<sup>[27,28]</sup>. The inhibitory effect of NSAIDs on COX-2 leads reduced prostaglandin E2 (PGE2) levels. Thus, TNF- $\alpha$  production, which is normally inhibited

by PGE<sub>2</sub>, increases<sup>[28]</sup>. TNF- $\alpha$  is an important mediator causing NSAIDs induced gastropathy. Apart from its effect on adhesion molecules, TNF- $\alpha$  may have the ability to activate pro-apoptosis caspases, which regulate gastric epithelial cells apoptosis in NSAID-treated rats<sup>[27]</sup>.

A previous study demonstrated that indomethacin administration caused significantly elevated TNF- $\alpha$  levels in rats<sup>[8]</sup>. Moreover, pretreatment with anti-TNF- $\alpha$ , dexamethasone, and PGE<sub>2</sub> could prevent the increases in gastric mucosal injuries and TNF- $\alpha$  levels. Similarly, we found significant rises in TNF- $\alpha$  and ICAM-1 levels in the serum of the indomethacin-treated group compared to the control. Other formulations of NSAIDs could also increase TNF- $\alpha$  production. A study by Jainu *et al*<sup>[29]</sup> noted a significant increase in TNF- $\alpha$ , IL-1 $\beta$  and NOS-2 activity in aspirin-administered rats. The elevations of inflammatory mediators and adhesion molecules in serum correlated with the pathological findings of gastric mucosa and the numbers of adhered leukocytes in the gastric microcirculation. These were also true for curcumin-treated group. Pretreatment with curcumin could significantly reduce TNF- $\alpha$  and ICAM-1 levels in the serum, accompanied by an improvement in gastric mucosal inflammation and leukocyte adhesion.

Curcumin, a substance rich in phenolics, is known to possess antioxidant properties. Curcumin reduces gastric injury induced by NSAIDs<sup>[30]</sup>. It has been reported that curcumin can decrease gastric injury by preventing the peroxidase inactivation effect of indomethacin and scavenging reactive oxygen produced by this enzyme<sup>[30]</sup>. Several studies showed that curcumin is also an anti-inflammatory substance, with an inhibitory effect on transcription factor NF- $\kappa$ B activation. NF- $\kappa$ B is required for the expression of many genes linked with the host immune response, such as ICAM-1, TNF- $\alpha$ , IL-1 $\beta$ , and iNOS<sup>[31]</sup>. Cytoplasmic NF- $\kappa$ B is complexed with its inhibitor I $\kappa$ B and is, therefore, inactive. The cytokine-mediated activation of NF- $\kappa$ B requires activation of various kinases, which ultimately leads to the phosphorylation and degradation of I $\kappa$ B. Several beneficial effects of curcumin are consistent with its ability to inhibit the activity of NF- $\kappa$ B<sup>[32-34]</sup>. Singh *et al*<sup>[31]</sup> observed that curcumin inhibited NF- $\kappa$ B activation pathway after the convergence of various stimuli mediated by protein tyrosine kinase, protein kinase, and ubiquitin conjugation enzymes, but before the phosphorylation and subsequent release of I $\kappa$ B complexed to NF- $\kappa$ B. Jobin *et al*<sup>[35]</sup> and Plummer *et al*<sup>[36]</sup> examined the modulatory potential of curcumin on NF- $\kappa$ B signaling pathways and found that curcumin prevented phosphorylation of I $\kappa$ B by inhibiting the activation of I $\kappa$ B-kinase (IKKs). Our previous study demonstrated that *Helicobacter pylori*-induced gastric inflammation in rats is associated with increased NF- $\kappa$ B activation and macromolecular leakage, which can be reduced by curcumin<sup>[37]</sup>. In this study, 200 mg/kg curcumin was a sufficient dose for reducing gastric epithelial NF- $\kappa$ B p65 expression and mucosal macromolecular leakage. Despite its inconclusive mechanism of action, we clearly demonstrated that curcumin has a protective and beneficial

effect on NSAIDs-induced gastropathy in rats. Further studies on the expression of inflammatory mediators and adhesion molecules in the gastric mucosa are necessary to demonstrate the exact curative effect of curcumin on NSAID-induced gastric pathology. Clinical studies might also be needed to verify the protective effect of curcumin in humans.

In conclusion, NSAIDs could induce gastric injury through increases in inflammatory cytokines and leukocyte adhesions. Curcumin, an anti-oxidant herbal substance, could prevent these adverse events and might be used as a preventive method for NSAIDs-induced gastropathy.

## COMMENTS

### Background

Nonsteroidal anti-inflammatory drugs (NSAIDs)-induced gastric damage is the major side effect of this kind of medication. Although the underlying pathogenesis of NSAIDs-induced gastric damage is unclear, neutrophils are believed to play an important role in the development of gastric inflammation and injury following NSAID administration. Curcumin possesses several biological activities, including an anti-inflammatory effect. Authors postulated that curcumin, acting through nuclear factor (NF)- $\kappa$ B inhibition, could reduce the production of adhesion molecules and inflammatory cytokines, resulting in the amelioration of gastric injury in NSAIDs-induced gastropathy in rats.

### Research frontiers

Curcumin (diferuloylmethane) is an active ingredient of *Curcuma longa* (turmeric), which exerts many biological activities by the inhibition of NF- $\kappa$ B-mediated reactions. NSAIDs can cause gastric mucosal damage through an increase in leukocyte-endothelial adhesions and the release of inflammatory mediators, leading to the free radical production. This study demonstrated an improvement in gastric mucosal damage and decreases in leukocyte adhesions, and intercellular adhesion molecule 1 and tumor necrosis factor (TNF)- $\alpha$  production after curcumin administration in the indomethacin-treated group.

### Innovations and breakthroughs

The previous study showed that curcumin is an anti-inflammatory agent and can inhibit NF- $\kappa$ B activation in an *in vitro* study. However, it is not known whether curcumin's anti-inflammatory effects will help prevent NSAIDs-induced gastropathy *in vivo*. In this study, authors investigated the protective effect of curcumin in indomethacin-induced gastric damage in rats. Authors found that curcumin could alleviate indomethacin-induced gastric injury *via* a decrease in leukocyte adhesions and TNF- $\alpha$  production.

### Applications

Curcumin might be used as a new protective agent for NSAIDs-induced gastric damage in clinical use.

### Terminology

NSAIDs gastropathy: NSAIDs are well-known for their adverse effects on gastric mucosa, resulting in various clinical presentations, ranging from nonspecific dyspepsia to ulceration, upper gastrointestinal bleeding and death, summarized by the term "NSAID gastropathy".

### Peer review

This is an interesting study of the effects of curcumin on indomethacin-induced gastric damage in rats. The results clearly demonstrated that curcumin administration prevented the ulcerogenic effect of indomethacin, possibly through its anti-inflammatory action.

### Abstract

**AIM:** To investigate the possible mechanism by which hepatitis B virus X protein (HBx) mediates apoptosis of HepG2 cells.

**METHODS:** HBx expression vector pcDNA3.1-X was transfected into HepG2 cells to establish an HBx high-expression cellular model as pcDNA3.1-X transfected group. The pcDNA3.1-X and pSilencer3.1-shHBX (HBx antagonist) were cotransfected into HepG2 cells to establish an HBx low-expression model as RNAi group. Untransfected HepG2 cells and HepG2 cells transfected with negative control plasmid were used as controls. Apoptosis rate, the expression of Fas/FasL signaling pathway-related proteins and the phosphorylation levels of MLK3, MKK7 and JNKs, which are upstream molecules of death receptor pathways and belong to the family of mitogen-activated protein kinases (MAPKs),

were measured in each group.

**RESULTS:** Compared with HepG2 cell group and RNAi group, apoptosis rate, the expression of Fas and FasL proteins, and the activation of MLK3, MKK7 and JNKs were increased in the pcDNA3.1-X transfected group. The activation of JNKs and expression of FasL protein were inhibited in the pcDNA3.1-X transfected group when treated with a known JNK inhibitor, SP600125. When authors treated pcDNA3.1-X transfected group with K252a, a known MLK3 inhibitor, the activation of MLK3, MKK7 and JNKs as well as expression of FasL protein was inhibited. Furthermore, cell apoptosis rate was also significantly declined in the presence of K252a in the pcDNA3.1-X transfected group.

**CONCLUSION:** HBx can induce HepG2 cell apoptosis *via* a novel active MLK3-MKK7-JNKs signaling module to upregulate FasL protein expression.

HBx activates FasL and mediates HepG2 cell apoptosis through MLK3-MKK7-JNKs signal module. *World J Gastroenterol* 2012; 18(13): 1485-1495 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i13/1485.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i13.1485>

### INTRODUCTION

Hepatitis B virus (HBV) is one of the major pathogenic causes of primary hepatocellular carcinoma (HCC),

among which, HBV X gene is considered as a key gene that plays a critical role in the occurrence and progression of HBV-related HCC<sup>[1]</sup>. It has been proposed that HBx is a cellular transactivator that may indirectly stimulate a variety of viral and host gene promoters by interacting with transcription factors, including AP-1, ATF/CREB, ERCC, and is involved in several signal transduction pathways, including mitogen-activated protein kinase, Ras-Raf-mitogen-activated protein kinase, and JAK/STAT signaling pathways, therefore HBx affects several cellular processes, such as proliferation and differentiation<sup>[2-4]</sup>. In contrast to its proliferative effects, HBx also participates in the apoptotic destruction of liver cells during the virus infection. Several mechanisms might be involved in this process: (1) HBx induces cell apoptosis on its own or sensitizes cells to apoptotic stimuli such as tumor necrosis factor  $\alpha$  (TNF- $\alpha$ ) or UV irradiation<sup>[5-8]</sup>; (2) HBx increases expression of IL-18 and enhances transcription activity of Egr-2 and Egr-3, which up-regulates FasL expression and induces the apoptosis of hepatic cells by the death receptor pathway<sup>[9,10]</sup>; (3) HBx may directly not only target to mitochondria to enhance translocation of Bax to mitochondria but also interact with the mitochondrial protein voltage-dependent anion channel (HVDAC3) to induce cell death by causing loss of mitochondrial membrane potential; and (4) HBx also interacts with heat shock protein 60 which is also localized in mitochondria to enhance HBx-mediated apoptosis<sup>[11-13]</sup>.

Cell death signals from the extracellular environment or internal sensors for the cellular response are major constituents of apoptotic machinery. Cell surface death receptors that transmit cell death signals are activated by specific death ligands. It is demonstrated that Fas is one of the best-characterized death receptors. Upon binding of FasL onto Fas, apoptotic signals are subsequently transmitted *via* death adaptor molecule FADD which can mediate the activation of caspase 8, and active caspase 8 can proteolytically activate downstream effector caspases, such as caspase 3, to trigger apoptosis<sup>[14,15]</sup>. It is reported that liver cell apoptosis is mediated by Fas<sup>[16-18]</sup>. Understanding the molecular mechanism responsible for the regulation of Fas and FasL may aid in developing novel therapeutic strategies for HCC.

The mixed lineage kinases (MLKs) are a family of serine/threonine protein kinases that function in a phospho-relay module to control the activity of specific mitogen-activated protein kinases (MAPKs). The family includes three subgroups: MLKs (mixed lineage kinases, including MLK1-4), dual leucine zipper-bearing kinases (DLKs), and Zipper Sterile-a-Motif Kinases (ZAKs). MLKs as mitogen activated protein kinase kinase kinases (MAP-KKKs) could activate MKKs, such as MKK4 and/or MKK7, which in turn, activate c-Jun N-terminal kinases (JNKs)<sup>[19-21]</sup>. Ischemic brain injury studies provide the evidence that the ischemia-stimulating factor can activate MLK3-MKK7-JNKs signaling module to activate death receptor pathway, leading to the neural cell apoptosis<sup>[22,23]</sup>. It is noteworthy that hepatic cells also express MLK3, MKK7, JNK proteins<sup>[24,25]</sup>. Therefore, it is of significance

to clarify whether the HBx can also activate MLK3-MKK7-JNKs signaling module and induce apoptosis of hepatic cells.

In this study, we demonstrated that HBx induces the apoptosis of hepatic cells depending on activating MLK3-MKK7-JNKs signaling module to upregulate FasL protein expression. On this basis, this study gives a new insight into a better understanding of how HBx mediates apoptosis in hepatocytes, and lays the foundation for further revealing the role of HBx in HBV-related liver oncogenesis and development.

## MATERIALS AND METHODS

### Reagents

The RPMI 1640 medium, liposome Lipofectamine 2000, and Trizol reagent were obtained from Invitrogen (Carlsbad, CA). Mouse monoclonal anti-HBx antibody was from Chemicon (Temecula, CA). Rabbit polyclonal anti-phospho-MLK3 and rabbit polyclonal anti-phospho-MKK7 were from Cell Signaling Technology (Beverly, MA). Mouse monoclonal anti-phospho-JNKs, rabbit polyclonal anti-Fas, and rabbit polyclonal anti-FasL were from Santa Cruz Biotechnology (Santa Cruz, CA). Mouse monoclonal anti-GAPDH antibody, goat anti-mouse IgG-AP, goat anti-rabbit IgG-AP, BCA Protein Assay Kit, BCIP/NBT Alkaline Phosphatase Color Development Kit, the BeyoECL Plus Western blotting detection System, Caspase3 activity assay kit, Caspase8 activity assay kit, and Hoechst33258 staining solution were from Beyotime Institute of Biotechnology (Jiangsu, China). *In situ* cell death detection kit was from Roche (Mannheim, Germany). Annexin V/PI apoptosis kit was from Biovision (Mountain View, CA). Primers were synthesized by Shanghai Sangon Biological Engineering Technology and Services (Shanghai, China). TIANScript RT Kit was from TIANGEN Biotech (Beijing, China). SP600125 and K252a were obtained from Sigma (St. Louis, MO). Twenty mmol/L stock solution of SP600125 and 20  $\mu$ mol/L stock solution of K252a were prepared in dimethyl sulfoxide (DMSO) and stored at -20 °C in the dark. SP600125 and K252a were prepared freshly for each experiment by serial dilution into 0.01% DMSO in RPMI 1640 medium. All other chemicals and reagents were of analytical grade.

### Plasmids construction

Plasmid pcDNA3.1-X containing the full length HBx sequence, was constructed in mammalian expression vector pcDNA3.1 (Invitrogen) as described previously<sup>[26]</sup>.

To construct the expression vector for shRNA targeting HBx, pSilencer3.1-shHBX, two chemically synthesized oligonucleotides encoding HBx specific shRNA with the following sense sequences: 5'-GATCCGGTCTTACATAAGAGGACTTTCAAGAG AAGTCCTCTTATGTAAGACCTTTTTTGAAA-3' and antisense sequences: 5'-AGCTTTTCCAAAAAAGGTCTTACATAAGAGGACTTCTCTTGAAAGTCCTCTTAT GTAAGACCG-3' were annealed and cloned into *Bam*H I -

Table 1 Primers for the reverse transcription polymerase chain reaction amplification

Gene	Sense	Antisense	Product length (bp)
HBX	5'-TGTAAGCTTATGGCTGCTAGGC-3'	5'-TGTTGAATTCCTTAGGCAGAGGTG-3'	465
Fas	5'-GTGAACACTGTGACCCCTT-3'	5'-TCATTGACACCATTCTTTCCG-3'	349
FasL	5'-CTGGGGATGTTTCAGCTCITC-3'	5'-CTTCACTCCAGAAAGCAGGAC-3'	304
Bax	5'-TTTGCTTCAGGGTTTCATCC-3'	5'-CAGTTGAAGTTGCCGTCAGA-3'	246
Bcl-2	5'-GTGGAGGAGCTCTTCAGGGA-3'	5'-AGGCACCCAGGGTGATGCAA-3	304
$\beta$ -actin	5'-GGCATCGTGATGGACTCCG-3'	5'-GCTGGAAGGTGGACAGCGA-3	607

HBx: Hepatitis B virus X protein.

*Hind*III sites of the linearized pSilencer3.1-H1-nero vector (Ambion, Austin, TX).

### Cell culture and transfection

Human hepatocarcinoma cell line, HepG2 cell, obtained from the Cell Bank of the Chinese Academy of Sciences (Shanghai, China) was cultured in RPMI 1640 medium supplemented with 100 mL/L fetal bovine serum, 2 mmol/mL L-glutamine, 100  $\mu$ g/mL streptomycin and 100 units/mL penicillin at 37 °C in 5% CO<sub>2</sub>. When the cell fusion rate reached 80%, HepG2 cells were transfected with negative control plasmid pcDNA3.1, pcDNA3.1-X, cotransfected pcDNA3.1-X with either pSilencer3.1-shHBX or pSilencer3.1-H1 in a ratio of 1:3, in the presence of the liposome Lipofectamine 2000 according to the manufacturer's instructions.

### Reverse transcription polymerase chain reaction analysis

The total RNA of HepG2 cells transfected with various plasmids was prepared with Trizol reagent according to the manufacturer's instructions. The reverse transcription was performed with TIANScript RT Kit. The specific primers used are shown in Table 1, the amplification condition was 94 °C for 45 s, 58 °C (55 °C-60 °C) for 35s, 72 °C for 1 min for 35 cycles and a final extension at 72 °C for 5 min each. The PCR products were subjected to electrophoresis in 1% agarose gel and visualized by ethidium bromide staining.

### Western blotting analysis

For protein extracts, cells were lysed using cell lysis buffer [20 mmol/L Tris pH 7.5, 150 mmol/L NaCl, 1% TritonX-100, 2.5 mmol/L sodium pyrophosphate, 1 mmol/L EDTA, 1% Na<sub>2</sub>VO<sub>4</sub>, 0.5  $\mu$ g/mL leupeptin and other phosphatase inhibitors, 1 mmol/L phenylmethanesulfonyl fluoride (PMSF)]. The lysates were collected, and centrifuged at 10 000  $\times$  g at 4 °C for 5 min. The bicinchoninic acid (BCA) Protein Assay Kit was used to measure the protein concentrations. Total protein of 100  $\mu$ g of each above lysate was subjected to sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) and transferred onto polyvinylidene difluoride (PVDF) membranes, which were blocked with 3% bovine serum albumin (BSA) in tris buffered saline (TBS) containing 0.01% Tween-20 for 3 h at room temperature, and then incubated with specific primary antibodies: mouse mono-

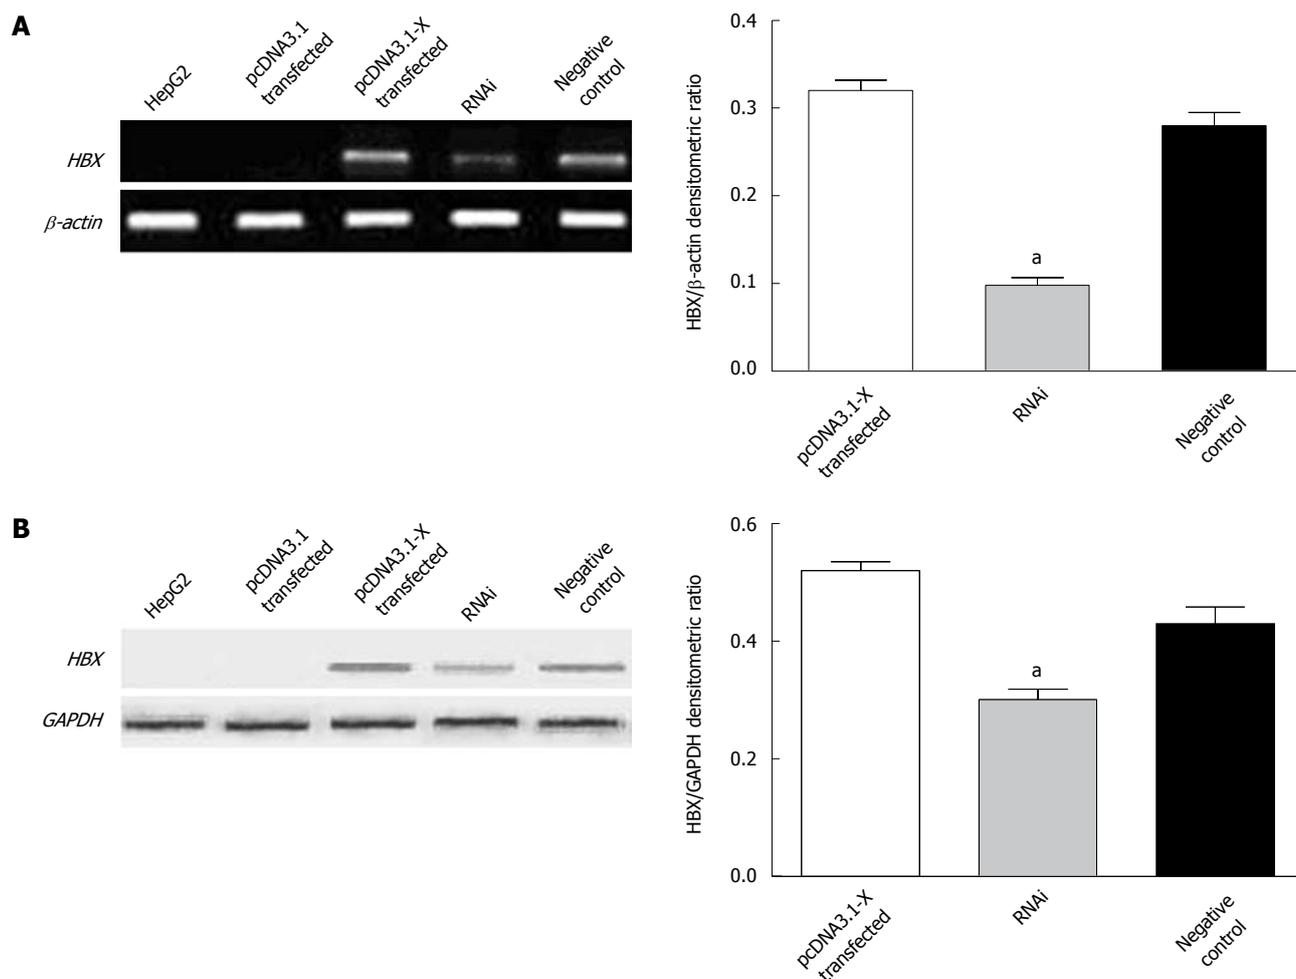

clonal anti-HBx antibody (1:250), rabbit polyclonal anti-phospho-MLK3 (1:500), rabbit polyclonal anti-phospho-MKK7(1:500), mouse monoclonal anti-phospho-JNKs (1:400), rabbit polyclonal anti-Fas (1:500), rabbit polyclonal anti-FasL (1:500), and mouse monoclonal anti-GAPDH antibody (1:500), respectively, overnight at 4 °C. The membranes were then incubated with goat anti-mouse IgG-AP (1:500), goat anti-rabbit IgG-AP (1:500), goat anti-mouse IgG-HRP (1:2000) and goat anti-rabbit IgG-HRP (1:2000) for 2 h at room temperature separately. The labeled bands were detected with NBT/BCIP Alkaline Phosphatase Color Development Kit or the BeyoECL Plus Western blotting detection system.

### Caspase activity assay

The enzyme activities of caspase3, caspase8 and caspase9 were quantified using caspase3, caspase8 and caspase9 activity assay kit, respectively. Adherent and floating cells were collected and lysed in caspase lysis buffer. Caspase3 enzyme activity in 30  $\mu$ g cell lysate was measured by cleavage of Ac-DEVD-pNA colorimetric substrate. Caspase8 enzyme activity in 30  $\mu$ g cell lysate was measured by cleavage of Ac-IETD-pNA colorimetric substrate. Caspase9 enzyme activity in 30  $\mu$ g cell lysate was measured by cleavage of Ac-LEHD-pNA colorimetric substrate. The absorbance at 405 nm was quantified in a microtiter plate reader after incubated at 37 °C for 2 h.

### Apoptosis analysis

Cells were adjusted to a density of 2  $\times$  10<sup>5</sup> cells/mL, added to 24-well plates in 0.5 mL each well. After transfection and incubation for 72 h, cell apoptosis was analyzed by three methods: (1) terminal deoxynucleotidyl transferase-mediated dUTP-biotin nick end labeling (TUNEL) staining: cell apoptosis was analyzed using the *in situ* cell death detection kit, according to the manufacturer's protocol. The number of TUNEL-positive cells was divided by the total number of cells to determine the ratio of TUNEL-positive cells. Five optical fields, about 200 cells were selected randomly and analyzed; (2) Hoechst 33258 staining: cells were fixed with 4% paraformaldehyde, washed twice with phosphate-buffered saline (PBS) and stained with Hoechst 33258 staining solution according to the manufacturer's instructions. The morphologic changes of apoptotic cells, including reduction in volume and nuclear chromatin condensation, were observed under a fluorescence microscope. Five optical fields containing about 200 cells were selected randomly and analyzed; and (3) flow

**Figure 1** Detection of hepatitis B virus X protein expression in transfected HepG2 cells. HepG2 cells were transfected with pcDNA3.1-X plasmids or cotransfected with pcDNA3.1-X and pSilencer3.1-shHBX plasmids. Forty-eight hours later, the expression of hepatitis B virus X protein (HBx) in HepG2 cells was determined by reverse transcription polymerase chain reaction (A) and Western blotting analysis (B). HepG2 group was not transfected with any plasmids. pcDNA3.1 transfected group was transfected with plasmid pcDNA3.1; pcDNA3.1-X transfected group was transfected with pcDNA3.1-X; RNAi group was cotransfected with pcDNA3.1-X and pSilencer3.1-shHBX in a ratio of 1:3; negative control group was cotransfected with pcDNA3.1-X and negative control plasmid pSilencer3.1-H1 in a ratio of 1:3. Data are expressed as mean  $\pm$  SD ( $n = 3$ ), <sup>a</sup> $P < 0.05$  vs pcDNA3.1-X transfected group.

cytometry: cell apoptosis was evaluated by double staining with fluorescein isothiocyanate (FITC)-conjugated Annexin V and propidium iodide (PI) using annexin V/PI apoptosis kit. Cells were washed with PBS twice and stained with Annexin V and PI for 5 min at room temperature in the dark. The level of apoptosis was determined by measuring the fluorescence of the cells with a flow cytometer (Becton-Dickinson, San Diego, CA).

### Statistical analysis

All experiments were performed three times. Semiquantitative analysis of the bands was performed with the Image J analysis software (Version 1.30v, Wayne Rasband, NIH, United States). The data were presented in mean  $\pm$  SD and analyzed by one-way ANOVA (SPSS version 13.0).  $P < 0.05$  was considered statistically significant.

## RESULTS

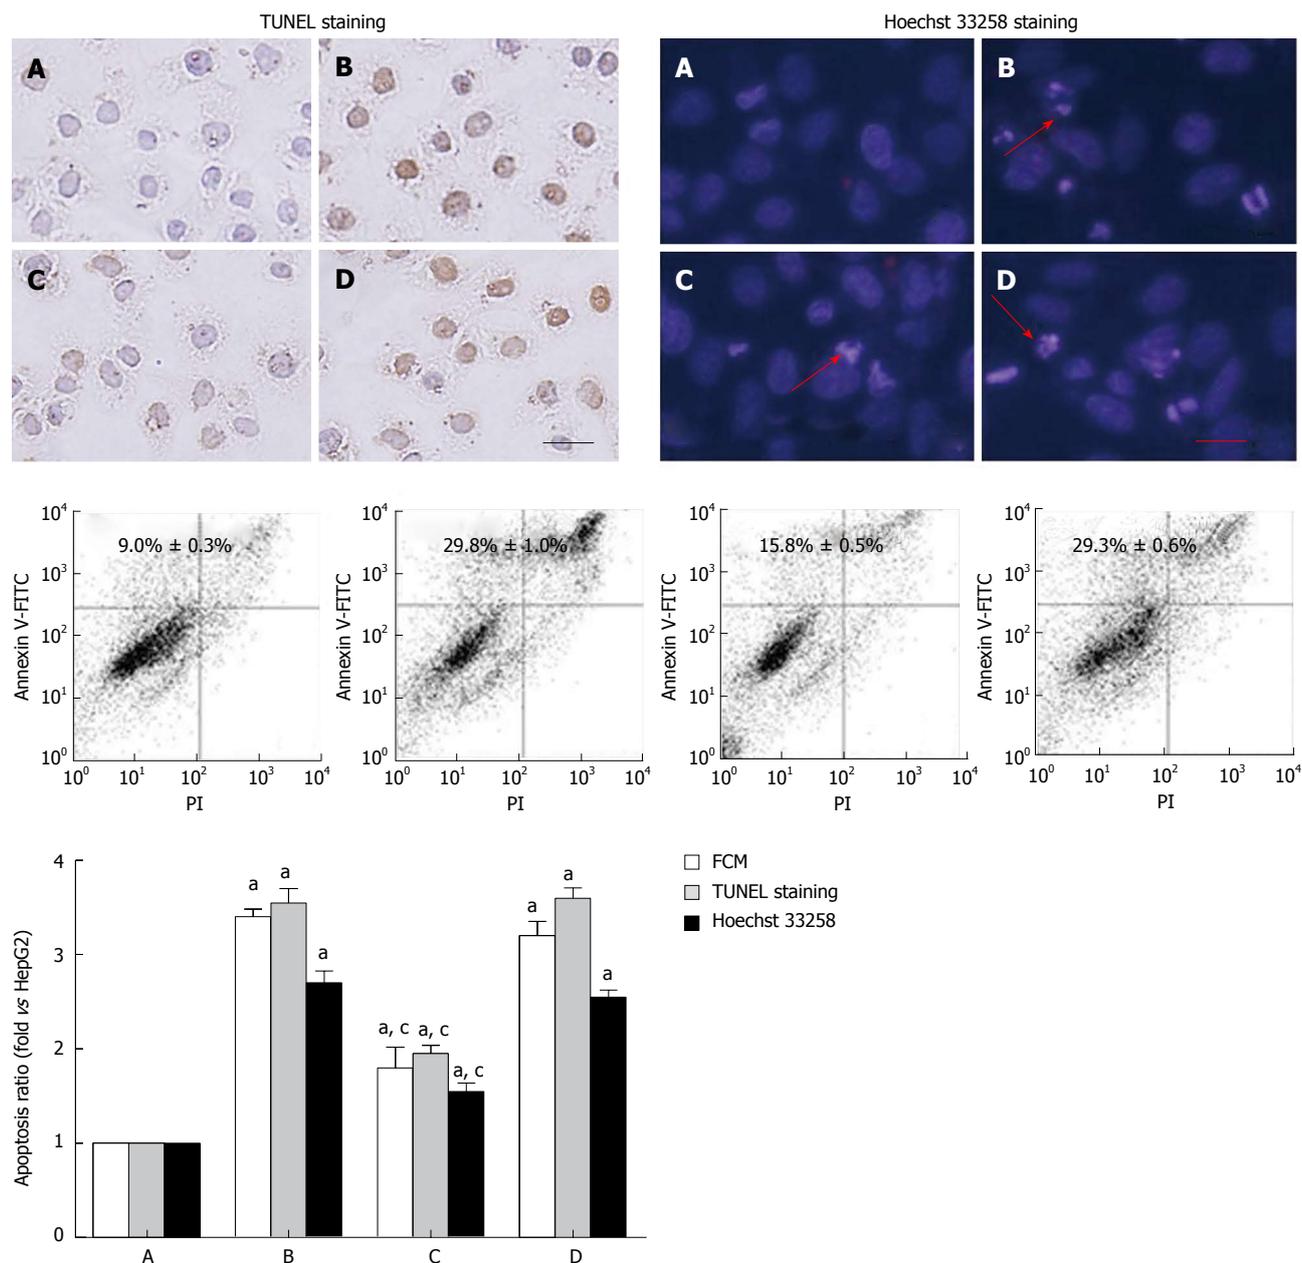

### Expression of hepatitis B virus X protein in HepG2 cells

To investigate the potential apoptotic ability of HBx,

HBx expressing plasmid pcDNA3.1-X was transiently transfected into a human HCC cell line, HepG2. RT-PCR and Western blotting analysis demonstrated that HepG2 cells transfected with pcDNA3.1-X could steadily express HBx. To further identify the function of HBx upon apoptosis of HepG2, the expression vector for shRNA targeting HBx named pSilencer3.1-shHBX was constructed. When the shRNA expression plasmid was transfected to HepG2 cells in combination with pcDNA3.1-X, the expression of HBx was specifically inhibited by shRNA against HBx, while universal negative control plasmid pSilencer3.1-H1 did not display any effect on HBx expression (Figure 1).

### Effects of hepatitis B virus X protein on induction of apoptosis in HepG2 cells

To investigate the roles of HBx in cell apoptosis, TUNEL assay was used to detect the presence of DNA strand breaks. The *in situ* TUNEL staining showed that the TUNEL-negative cells appeared with blue nucleus and TUNEL-positive cells with yellow nucleus. To fur-

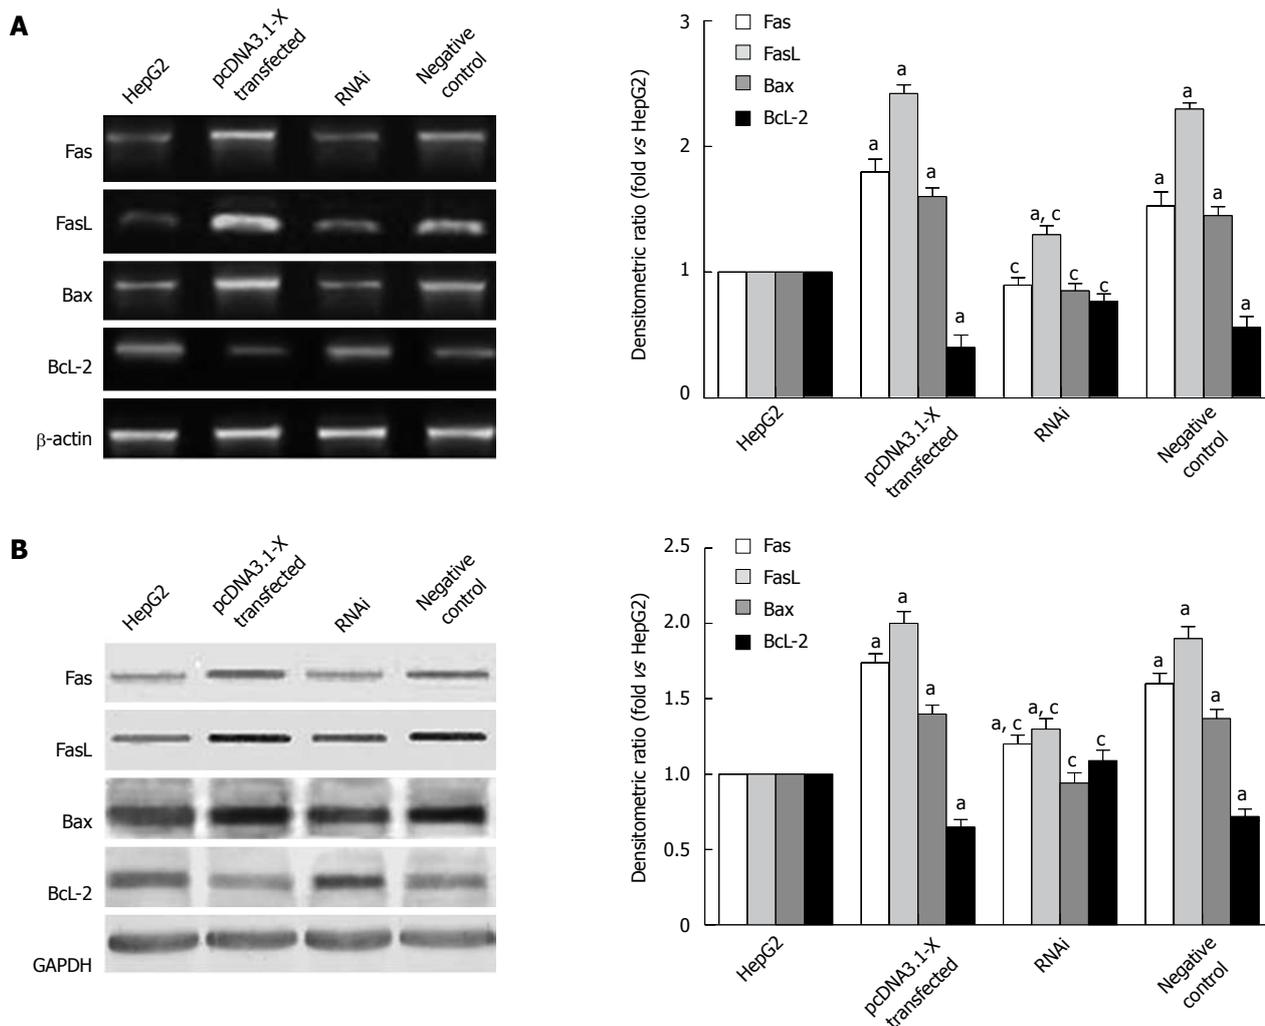

**Figure 2** Apoptosis of HepG2 cells induced by hepatitis B virus X protein. HepG2 cells were cotransfected with pcDNA3.1-X and pSilencer3.1-shHBX as RNAi group, and HepG2 cells were cotransfected with pcDNA3.1-X and pSilencer3.1-H1 plasmids as negative control. Cells were examined by TUNEL, Hoechst 33258 staining and flow cytometry as described in Materials and Methods. A: HepG2 group; B: pcDNA3.1-X transfected group; C: RNAi group; D: Negative control group. Data was expressed as mean ± SD ( $n = 3$ ),  $^*P < 0.05$  vs the HepG2 group;  $^*P < 0.05$  vs pcDNA3.1-X transfected group and negative control group. Scale bar value: 5  $\mu$ m. Red arrows indicate apoptotic nuclei. Apoptosis ratio = (apoptotic cells/total cells) × 100%. TUNEL: Terminal deoxynucleotidyl transferase-mediated dUTP-biotin nick end labeling.

ther confirm the occurrence of apoptosis, the apoptosis of HepG2 cells and HepG2 transfected with HBx were detected by Hoechst 33258 staining and flow cytometry (FCM). In Hoechst 33258 staining, reduced cell sizes and increased nuclear chromatin condensation were detected in the apoptotic cells. As it is shown in Figure 2, when compared with HepG2 cells group, the apoptosis rate of pcDNA3.1-X transfected group and negative control group was increased, while, in contrast, that of RNAi group was decreased. It indicated that the high expression of HBx could promote the apoptosis of HepG2 cells, and inhibiting the expression of HBx protein could

reduce the apoptosis rate of HepG2 cells.

**Hepatitis B virus X protein-induced apoptosis was attributed to the upregulation of Fas/FasL signaling pathway-related proteins**

To determine which signaling pathway was involved in cell apoptosis by HBx, expression of Fas, FasL and apoptotic regulators Bax, Bcl-2 in HBx-transfected HepG2 cells were examined by RT-PCR and Western blotting analysis. The results showed that the Fas, FasL, Bax mRNA and protein expression were increased induced by HBx, while the Bcl-2 mRNA and protein were decreased

**Figure 3** Expression of Fas, FasL, Bax, Bcl-2 mRNA and protein in HepG2 cells induced by hepatitis B virus X protein. Transfection of HepG2 cells is described in Figure 2. Forty-eight hours after transfection, the mRNA (A) and protein (B) expression levels of Bax, Bcl-2, Fas and FasL were determined by RT-PCR and Western blotting analysis. Data are expressed as mean ± SD (n = 3), <sup>a</sup>P < 0.05 vs the HepG2 group; <sup>b</sup>P < 0.05 vs pcDNA3.1-X transfected group and negative control group.

after transfection with HBx in HepG2 cells for 48 h (Figure 3). When HepG2 cells were cotransfected with pcDNA3.1-X and pSilencer3.1-shHBX for 48 h, the levels of Fas, FasL, Bax mRNA and protein were decreased. However, Bcl-2 mRNA and protein were increased after cotransfection with pcDNA3.1-X and pSilencer3.1-shHBX in HepG2 cells.

In order to determine the dynamic effect of HBx on the Fas/FasL signaling pathway, we detected the gene and protein expression of Fas and FasL at 24 h, 48 h, and 72 h after transfection with HBx, respectively, and found that the Fas and FasL mRNA expression was increased by HBx in a time-dependent manner (Figure 4A). In parallel, the levels of Fas and FasL proteins in pcDNA3.1-X transfected cells were increased by HBx in a similar manner (Figure 4B).

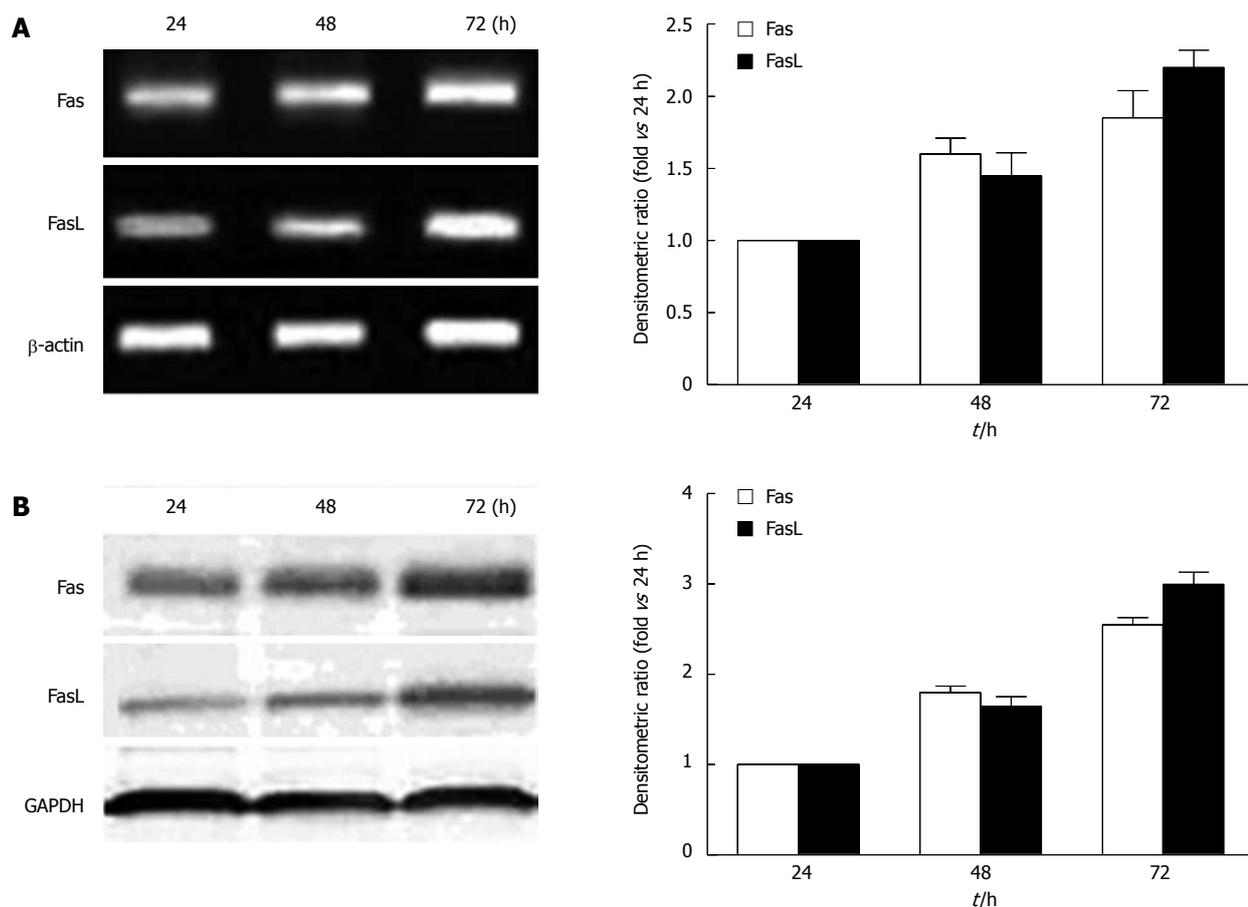

To further determine the effect of HBx on the Fas/FasL signaling pathway, enzyme activity of caspase8, caspase9 and caspase3 were also detected by spectrophotometric test. The results showed that the activation of caspase8, caspase9 and caspase3 was increased in HBx-

transfected HepG2 cells (Figure 5).

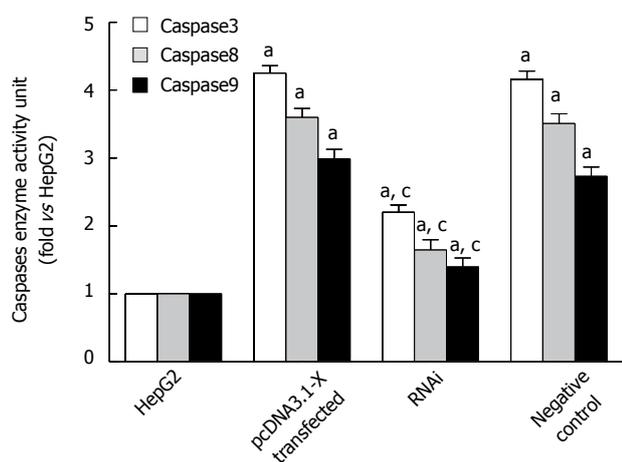

It could be concluded that HBx could mediate cell apoptosis by upregulating Fas/FasL signaling pathway-related protein expression to activate the Fas/FasL signaling pathway.

**Hepatitis B virus X protein upregulates FasL protein expression by activating MLK3-MKK7-JNKs signal module and induces apoptosis**

The upstream mechanisms of HBx on expression of Fas/FasL signaling pathway-related proteins were further investigated. Previous studies showed that MLK3, MKK7 and JNKs which belong to MAPK signaling pathways, could form MLK3-MKK7-JNKs signaling module and the activation of the signaling module could upregulate the expression of Fas/FasL signaling pathway-related protein, leading to cell apoptosis<sup>[22,23]</sup>. To find out whether the upregulation of Fas/FasL signaling pathway-related proteins induced by HBx was dependent on activation of MLK3-MKK7-JNKs signaling module, the phosphorylation levels of MLK3, MKK7 and JNKs

**Figure 4** Upregulation of Fas/FasL signaling pathway-related protein expression by hepatitis B virus X protein in a time-dependent manner. HepG2 cells were transfected with pcDNA3.1-X and incubated for various time periods as indicated. The levels of Fas, FasL mRNA (A) and proteins (B) were determined by reverse transcription polymerase chain reaction and Western blotting analysis. Data are expressed as mean  $\pm$  SD ( $n = 3$ ).

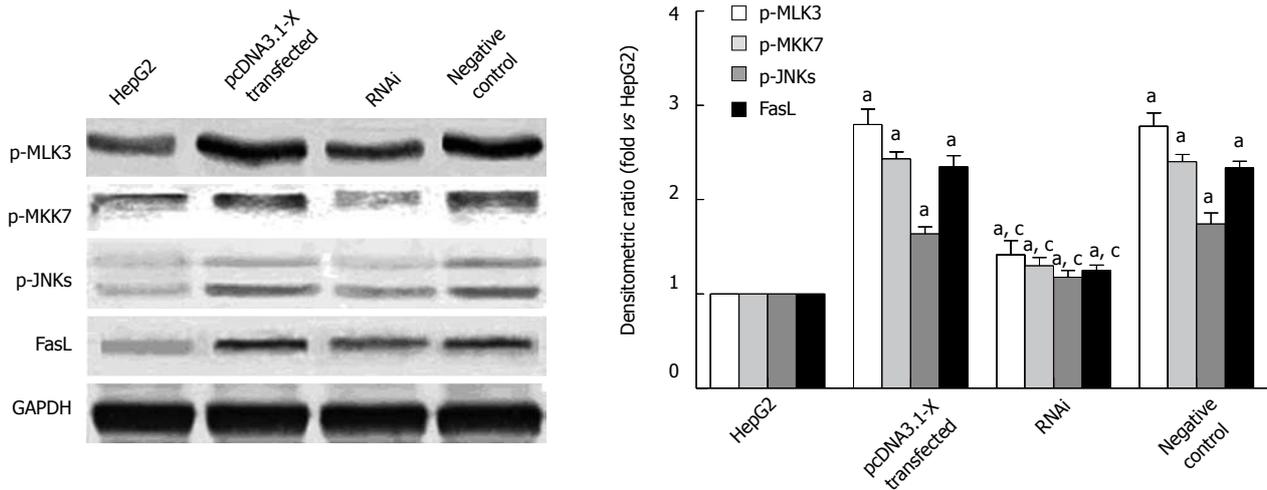

**Figure 5** Detection of activated caspases in HepG2 cells transfected with hepatitis B virus X protein. Transfection of HepG2 cells is described in Figure 2. Forty-eight hours after transfection, the enzyme activity of caspase3, caspase8 and caspase9 was analyzed by spectrophotometric test. Data are expressed as mean  $\pm$  SD ( $n = 3$ ), <sup>a</sup> $P < 0.05$  vs the HepG2 group; <sup>c</sup> $P < 0.05$  vs pcDNA3.1-X transfected group and negative control group.

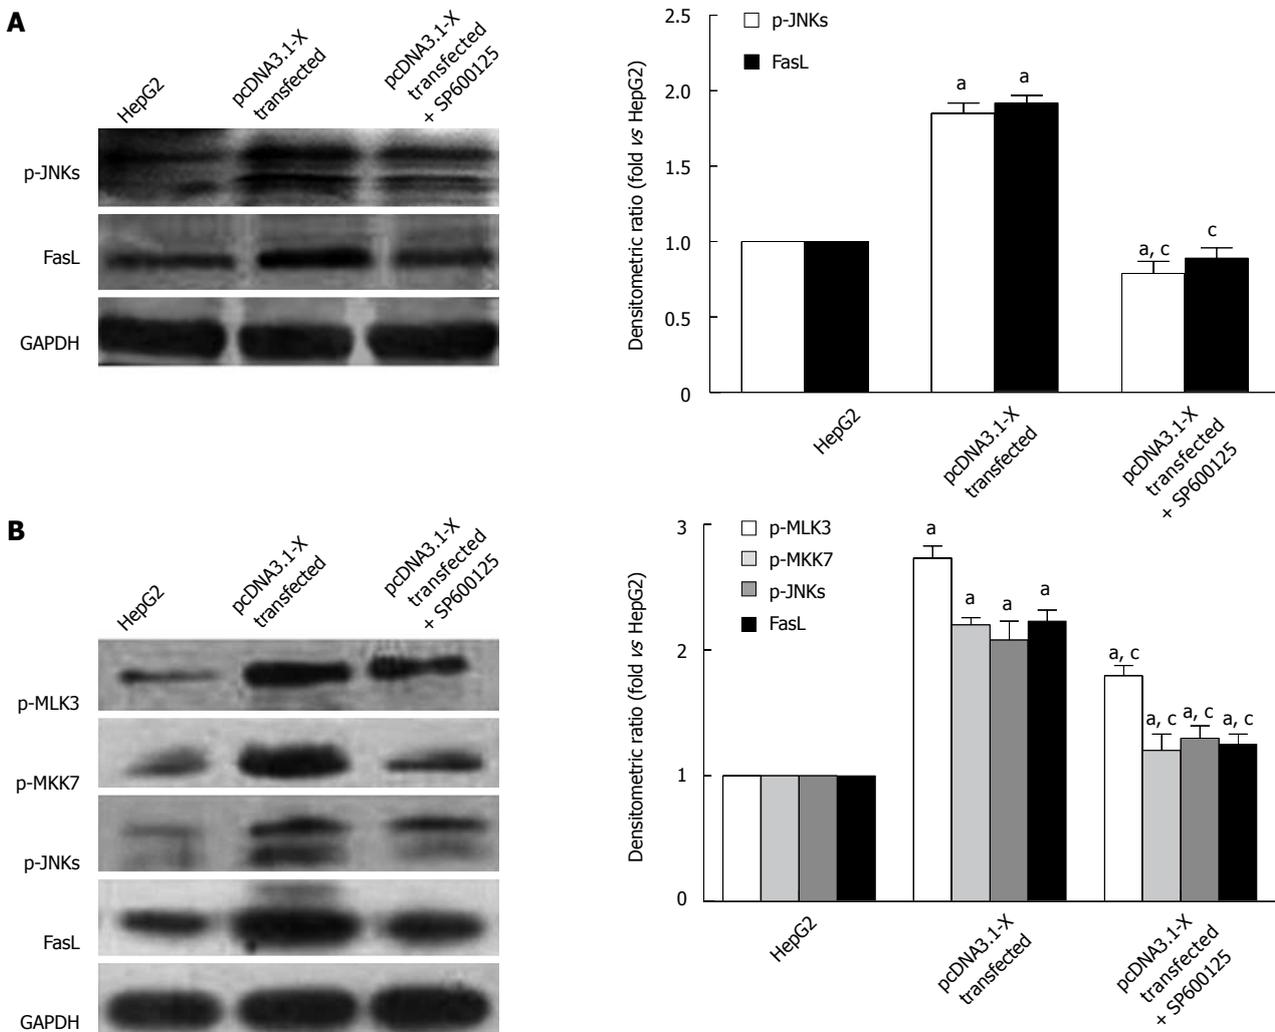

were detected. The phosphorylation levels of MLK3, MKK7 and JNKs proteins in pcDNA3.1-X transfected group were increased remarkably compared with the

HepG2 cells. When silencing HBx protein expressed by pSilencer3.1-shHBX, phosphorylation of MLK3, MKK7 and JNKs was inhibited (Figure 6). The changing tendency of expression level of FasL protein was consistent with phosphorylation levels of MLK3, MKK7 and JNKs proteins. When we treated HepG2 cells transfected with HBx with a known JNK inhibitor, SP600125, the activation of JNKs and expression of FasL protein were inhibited (Figure 7A). Furthermore, the phosphorylation levels of MLK3, MKK7 and JNKs and the protein expression of FasL also concomitantly decreased in pcDNA3.1-X transfected group when treated with K252a, a known MLK3 inhibitor<sup>[27,28]</sup> (Figure 7B). The results demonstrated that HBx could activate MLK3-MKK7-JNKs signal module and upregulate Fas/FasL death receptor pathway-related protein expression.

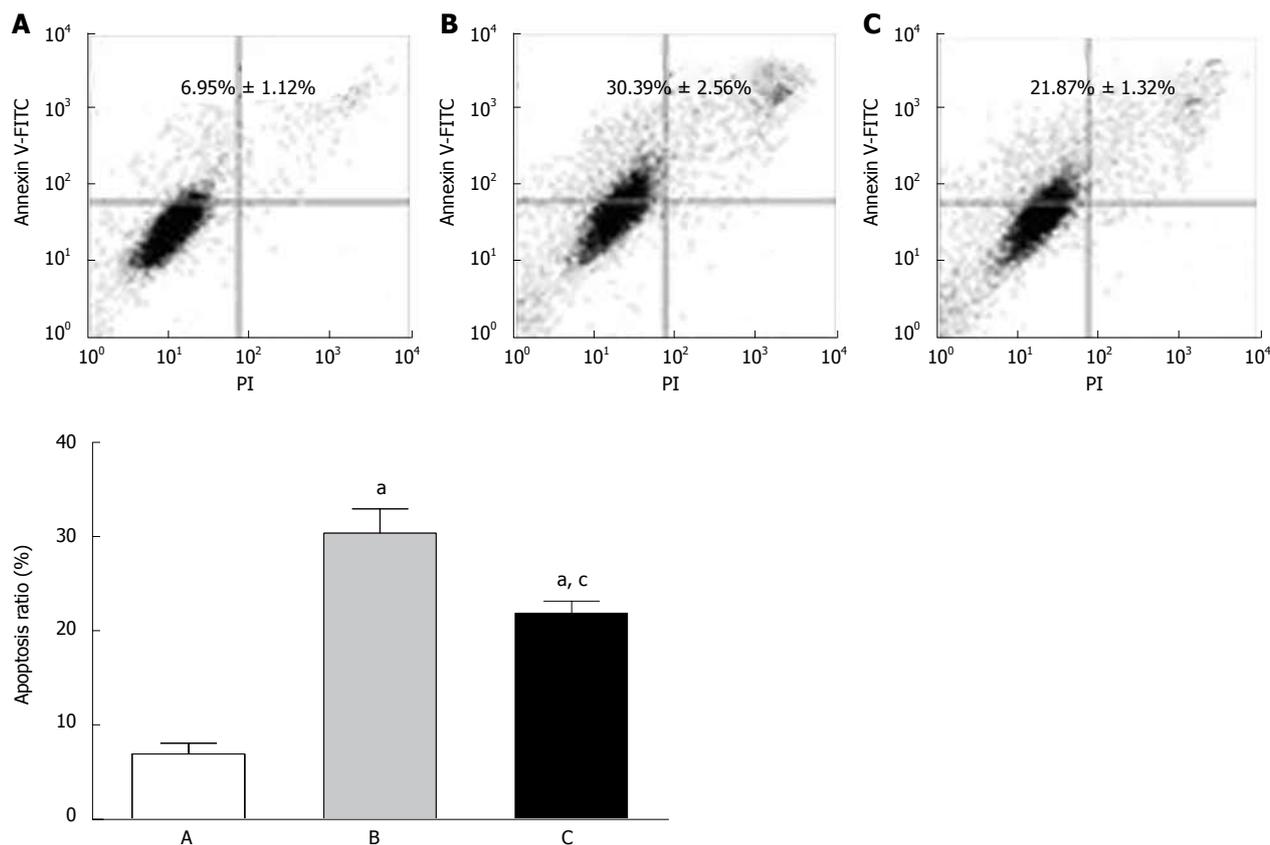

To determine the relationship between activation of MLK3-MKK7-JNKs signal module and HBx-stimulated cell apoptosis, the apoptosis rate of the pcDNA3.1-X transfected group treated with K252a or not was determined by flow cytometry. As expected, apoptosis rate of the HBx-transfected HepG2 cells was suppressed in the presence of the MLK3 inhibitor (Figure 8), indicating that HBx could activate the MLK3-MKK7-JNKs signaling modular and its downstream death receptor pathway, and

**Figure 6** Activation of MLK3-MKK7-JNKs signaling module in hepatitis B virus X protein-transfected HepG2 cells. Transfection of HepG2 cells is described in Figure 2. Forty-eight hours after transfection, the cells lysates were detected by Western blotting analysis. Data are expressed as mean  $\pm$  SD ( $n = 3$ ),  $^aP < 0.05$  vs the HepG2 group;  $^cP < 0.05$  vs pcDNA3.1-X transfected group and negative control group.

**Figure 7** Activation of MLK3-MKK7-JNKs signaling module on FasL expression mediated by hepatitis B virus X protein. A: HepG2 cells were cultured in 0.01% dimethyl sulfoxide (DMSO) in the absence or presence of 20  $\mu$ mol/L SP600125 after transfection with pcDNA3.1-X and incubated for 24 h; B: HepG2 cells were cultured in 0.01% DMSO in the absence or presence of 300 nmol/L K252a after transfection with pcDNA3.1-X and incubated for 24 h. Cell lysates were prepared and electrophoresed in SDS-PAGE and subsequently performed by Western blotting analysis. Data are expressed as mean  $\pm$  SD ( $n = 3$ ),  $^aP < 0.05$  vs the HepG2 group;  $^cP < 0.05$  vs pcDNA3.1-X transfected group.

**Figure 8** Inhibition of HBx-induced cell apoptosis by K252a. HepG2 cells were cultured in 0.01% dimethyl sulfoxide in the absence or presence of 300 nmol/L K252a after transfection with pcDNA3.1-X and incubated for 24 h, and the cell apoptosis was examined by flow cytometry. A: HepG2 group; B: pcDNA3.1-X transfected group; C: pcDNA3.1-X transfected + K252a group. Data are expressed as mean  $\pm$  SD ( $n = 3$ ), <sup>a</sup> $P < 0.05$  vs the HepG2 group; <sup>c</sup> $P < 0.05$  vs pcDNA3.1-X transfected group.

induce the apoptosis of the hepatocarcinoma cell line.

## DISCUSSION

HBx protein has been reported to be either a promoter or an inhibitor of cell apoptosis<sup>[11,29-31]</sup>. The dual activity of HBx protein on cell apoptosis suggests that the expression of HBx gene and its physiological role depend on cellular environments and infection stage<sup>[30,32-33]</sup>. Naturally, HBx shows extremely low levels of expression during the early stage of HBV infection, which may contribute to the activation of transcription and virus replication<sup>[33,34]</sup>. With the development of chronic HBV infection, expression of HBx protein increased and activated apoptosis to contribute to virus spread and the progression of chronic hepatitis and HCC<sup>[32,35,36]</sup>. It was reported that HBx could induce the apoptosis of hepatic cells by the death receptor pathway and the mitochondrial pathway. However, the question how HBx activates the death receptor pathway to induce the apoptosis of hepatic cells remains unclear. The further elucidation of signaling pathways that regulate apoptosis by HBx would help us understand the effectiveness of HBX in the development of HCC.

In this study, the regulation mechanism of apoptosis by HBx in HepG2 cells was investigated. First, the ability

of HBx to induce apoptosis using transient transfection of HBx was tested. As a result, after transfected with HBx, HepG2 cells exhibited more conspicuous apoptotic nuclear condensation and a higher level of cell death, which is in agreement with the previous reports that HBx could induce cell apoptosis on its own<sup>[5-6,37,38]</sup>. Second, the expression level of the Fas/FasL signaling pathway-related proteins was examined in HepG2 cells. The expression of Fas/FasL signaling pathway-related proteins were remarkably upregulated in pcDNA3.1-X transfected group. RNA interference targeting HBx in HepG2 cells could reduce the cell apoptosis and down-upregulate the Fas/FasL signaling pathway-related proteins at the same time. Based on the above results, it was reasonable to conclude that HBx is able to induce apoptosis by upregulating Fas/FasL signaling pathway-related protein expression in HepG2 cells, which was similar to the previous report that HBx played a role in inducing apoptosis of hepatocyte *via* Fas/FasL system<sup>[39,40]</sup>.

Recent studies have found that the MAPKs were involved in the signal transduction for apoptosis. The animal model experiments for cerebral ischemia demonstrated that MLK3-MKK7-JNKs signaling modules, a member of the MAPK family, could activate its downstream Fas/FasL signaling pathway and induce the apoptosis of nerve cells<sup>[22-23]</sup>. In addition, it was reported that hepatic cells

could also express MLK3, MKK7 and JNKs<sup>[24-25]</sup>. We supposed HBx protein could act as the stressor to activate the signal module of MLK3-MKK7-JNKs, and to induce the apoptosis of the hepatic cells.

On the basis of this hypothesis, the phosphorylation levels of MLK3, MKK7 and JNKs were detected in all groups. It was found that the phosphorylation levels of MLK3, MKK7 and JNKs were increased obviously in the pcDNA3.1-X group, indicating that the HBx might increase the phosphorylation levels of these proteins. When we treated pcDNA3.1-X group with SP600125, the activation of JNKs and expression of FasL were significantly inhibited. Moreover, when pcDNA3.1-X group was treated with K252a, the expression levels of p-MLK3, p-MKK7, p-JNKs and FasL were also significantly decreased, and then cell apoptosis rate obviously declined, suggesting that the HBx protein could act as a stressor and activate the MLK3-MKK7-JNKs signaling module and its downstream Fas/FasL death receptor pathway to induce the apoptosis of HepG2 cells. This would provide us a new research target and a novel concept for blocking the HBx-induced apoptosis process.

The ratio of Bax and Bcl-2 could change the mitochondrial membrane potential and result in the release of cytochrome C, the activation of caspase9, and then further activate caspase3 to induce apoptosis<sup>[41,42]</sup>. As shown in Figures 3 and 5, HBx up-regulated the expression of Bax, down-regulated the expression of Bcl-2, and increased the activation of caspase9 at the same time. This data indicated that the apoptosis induced by HBx also referred to the mitochondrial pathway. Nevertheless, effects of activating the mitochondrial pathway on apoptosis needs to be further investigated.

In conclusion, this study demonstrated that the high expression level of HBx protein could activate MLK3-MKK7-JNKs module and upregulate FasL protein. It has provided a novel insight into the mechanism of HBx-induced hepatocarcinoma cell apoptosis.

## COMMENTS

### Background

Hepatitis B virus (HBV) infection is one of the most widely spread viral diseases and strongly associated with the development of hepatocellular carcinoma (HCC). However, the mechanism of HBV-mediated HCC development is not clearly elucidated. Although it has been shown that HBx, the protein encoded by the X gene of the HBV genome, could induce cell apoptosis on its own or sensitize cells to apoptotic stimuli, such as tumor necrosis factor  $\alpha$  (TNF- $\alpha$ ) or UV irradiation, the mechanism of HBx-mediated apoptosis remains controversial.

### Research frontiers

HBx, the protein encoded by the X gene of the HBV genome, is a multifunctional regulatory protein and has been implicated in HBV-mediated hepatocarcinogenesis. In this study, the authors further investigated the regulation mechanism of apoptosis mediated by HBx in HepG2 cells.

### Innovations and breakthroughs

Previous researches showed that HBx participated in the apoptotic destruction

of liver cells during the virus infection. Although some studies found that HBx could mediate apoptosis by the death receptor pathway or affecting mitochondrial physiology, the mechanism of HBx-mediated apoptosis is still not clear. In the present study, the authors showed that HBx could induce HepG2 cells apoptosis via a novel active MLK3-MKK7-JNKs signaling module and upregulate Fas/FasL signaling pathway-related protein expression.

### Applications

This study provided a new insight into a better understanding of how HBx mediated apoptosis, and lay the foundation for further clarifying the role of HBx in HBV-related liver oncogenesis and development.

### Terminology

Apoptosis is a common form of cell death and often referred to as programmed death. The characteristics of apoptosis include activation of cysteine proteases (caspases) and endonucleases, condensation of the nuclear chromatin and cytoplasm, cleavage of the DNA into oligonucleosomal fragments, and segmentation of the dying cell into membrane-bound apoptotic bodies. Fas is one of the best-characterized death receptor. Upon binding of FasL (Fas ligand) onto Fas, apoptotic signals are subsequently transmitted in cytoplasm to trigger apoptosis. The mixed lineage kinase 3 (MLK3) is a member of the mixed lineage kinases (MLKs), a family of serine/threonine protein kinases functioning in a phosphorelay module to control the activity of specific mitogen-activated protein kinases (MAPKs).

### Peer review

In this manuscript, the authors demonstrate that hepatitis B virus X protein induced apoptosis through Fas/FasL signaling via MLK3-MKK7-JNKs signaling module in HepG2 cells. A series of experiments are well-planned and well-performed and this manuscript is well written. Although interesting, this manuscript could be strengthened if several points were addressed.

### Abstract

**AIM:** To define the evolution of ischemic lesions with 7T magnetic resonance imaging (7T-MRI) in an animal model of acute colonic ischemia.

**METHODS:** Adult Sprague-Dawley rats were divided into two groups. Group I underwent inferior mesenteric artery (IMA) ligation followed by macroscopic observations and histological analysis. In group II, 7T-MRI was performed before and after IMA ligation and followed by histological analysis.

**RESULTS:** Morphological alterations started to develop 1 h after IMA ligation, when pale areas became evident in the splenic flexure mesentery and progressively wors-

ened up to 8 h thereafter, when the mesentery was less pale, and the splenic flexure loop appeared very dark. The 7T-MRI results reflected these alterations, showing a hyperintense signal in both the intraperitoneal space and the colonic loop wall 1 h after IMA ligation; the latter progressively increased to demonstrate a reduction in the colonic loop lumen at 6 h. Eight hours after IMA ligation, MRI showed a persistent colonic mural hyperintensity associated with a reduction in peritoneal free fluid. The 7T-MRI findings were correlated with histological alterations, varying from an attenuated epithelium with glandular apex lesions at 1 h to coagulative necrosis and loss of the surface epithelium detected 8 h after IMA ligation.

**CONCLUSION:** MRI may be used as a substitute for invasive procedures in diagnosing and grading acute ischemic colitis, allowing for the early identification of pathological findings.

### INTRODUCTION

Ischemic colitis (IC) was first described by Boley *et al*<sup>[1]</sup>

and Theodoropoulou *et al.*<sup>[2]</sup>, and is a relatively common disease, being the most frequent form of intestinal ischemia<sup>[3]</sup> and the second-most frequent cause of lower gastrointestinal bleeding<sup>[4]</sup>. IC is the consequence of an acute interruption or chronic decrease in the colonic blood supply<sup>[5]</sup>, which may be either occlusive or non-occlusive in origin<sup>[2]</sup>. This disease results in ischemic necrosis of variable severity that can range from superficial mucosal involvement to full-thickness transmural necrosis<sup>[5,6]</sup>.

Clinically, IC presents in either a gangrenous (acute fulminant) or non-gangrenous form (acute transient; chronic)<sup>[2]</sup>, with a mortality rate ranging from 10% for the non-occlusive disease to 90% for occlusive mesenteric infarction due to embolus or thrombosis<sup>[5]</sup>. The left colon is involved in 75% of cases and the right colon in the remaining 25%; the splenic flexure and the sigmoid colon are the areas most frequently affected<sup>[3,7]</sup>.

The presentation of IC is not specific and is highly variable, therefore, its diagnosis largely depends on clinical suspicion<sup>[7]</sup>. In this context, the role of imaging techniques is controversial. Standard radiology and computed tomography (CT), the latter considered the best diagnostic modality in acute settings<sup>[8,9]</sup>, yield non-specific and late findings, whereas the advantages of magnetic resonance imaging (MRI) are still a matter of debate<sup>[5]</sup>.

The functional and morphological responses to ischemia produced by inferior mesenteric artery (IMA) ligation have been studied in the canine, porcine and rat colon<sup>[10-13]</sup>. However, to date, nothing is known about the histological evolution of the colonic ischemic injury or the relationship between these lesions and MRI findings. Therefore, the aim of our study was to define the evolution of histological ischemic lesions and to compare anatomopathological features with T2-weighted MRI in an animal model of colonic ischemia.

## MATERIALS AND METHODS

### Animal preparation

All procedures performed on animals were approved by our Institutional Animal Care and Use Committee. Nine adult male Sprague-Dawley rats (250-340 g; Harlan Laboratories, Indianapolis, IN, United States) were used in this study. The rats were maintained on a 12/12 h light/dark cycle and allowed free access to food and water. They were anesthetized with ketamine (100 mg/kg i.m.) and medetomidine (0.25 mg/kg i.m.) injections. Butorphanol (0.1 mg/kg s.c.) was used immediately before the intervention to ensure intraoperative analgesia. Further injections of these drugs were provided throughout the intervention to maintain a sufficient state of anesthesia. Each rat was allowed to breathe spontaneously. Body temperature was monitored with a rectal probe and maintained at  $37.0 \pm 0.5$  °C with a heating blanket regulated by a homeothermic blanket control unit (Harvard Apparatus Ltd., Holliston, MA, United States).

After drug injection, eight rats were prepared for surgery through thoracic and abdominal trichotomy. These areas were then washed with povidone iodine and

alcohol. These animals were divided at random into two groups of four rats each. Group I rats underwent IMA ligation followed by macroscopic observation and histological analysis. Before and after IMA ligation, group II rats underwent 7-tesla (7T) MRI followed by histological analysis of a colon specimen after euthanasia. A healthy rat underwent an MRI bowel enema without IMA ligation to enable us to study its bowel anatomy.

### Surgical procedures

After a midline laparotomy, the small and large bowel were exposed from the abdominal cavity and displaced to the left. A photograph of the physiological appearance of the bowel and mesentery was taken with a digital camera (Panasonic Lumix DMC-TZ8, 12.0 megapixels, ISO 2000; Osaka, Japan). The IMA was identified and ligated at the origin with Prolene 7/0 and sectioned.

### Macroscopic analysis

After IMA ligation, the anesthetized rats of group I were observed for 8 h. The bowel was exposed on gauze moistened with saline to prevent excessive evaporative loss. Photographs of the exposed bowel and mesentery were taken every 10 min for the first hour and every 30 min thereafter. At the end of the observation period, all rats were euthanized with an intrapulmonary injection of Tanax (0.5 mL), and the large bowel was excised for histological analysis.

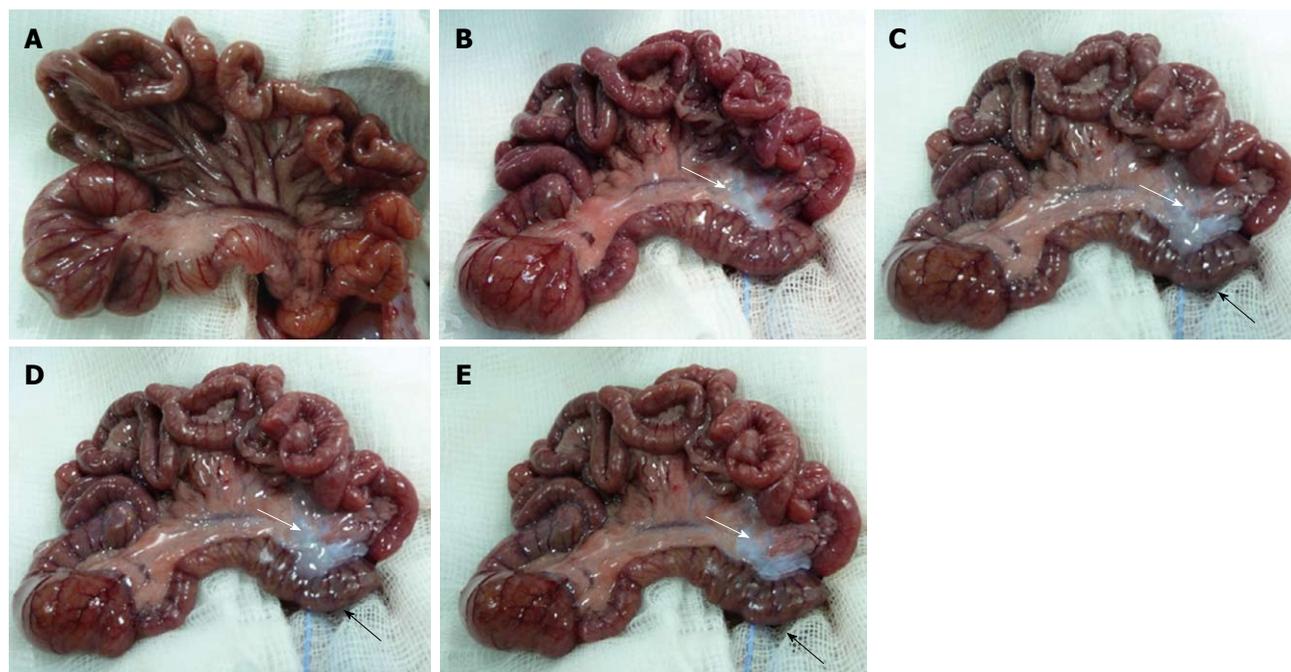

### MRI

Abdominal 7T-MRI scans were acquired in group II animals (Bruker BioSpec 70/16US; Bruker Medical Systems, Ettlingen, Germany) before IMA ligation to record the physiological appearance of the abdomen. After IMA ligation, the entire intestine was replaced in the abdomen, and the abdominal wall was closed with Vicryl 2/0 thread.

Each rat underwent 7T-MRI at 1 h, 4 h, 6 h and 8 h after IMA ligation as follows: Tripilot sequence, parameters: TR 100.0 ms; TE 6.0 ms; FOV 8.00 cm; IS 2.00 mm; N slice 3 and RareT2 sequence in axial section, parameters: TR 6060.3 ms; TE 36.0 ms; FOV 7.00 cm; matrix 256 × 256; IS 1.00/1.00 mm; N slice 52; acquisition time: 14 min, 32 s, 688 ms. To obtain bowels for histological analysis, selected rats were sacrificed at 1 h, 4 h, 6 h and 8 h after 7T-MRI.

### Histological analysis

For light microscopy, the large bowels in both groups of rats were excised from the cecum to the rectum, including the mesentery, and stored in 10% buffered formalin acetate for at least 2 d. The samples were divided into three segments: the cecum and proximal colon (first segment), the splenic flexure (second segment), and the distal colon and rectum (third segment). Sections 3 mm in size were obtained at 10-mm intervals from each segment and embedded in paraffin. Transverse sections 3 µm thick were cut and stained with hematoxylin-eosin. The sections were mounted on chrome alum/gelatin-coated slides,

**Figure 1 Macroscopic monitoring.** A: Physiological appearance of the rat bowel; B: Rat bowel 1 h after inferior mesenteric artery (IMA) ligation; C: At 4 h after IMA ligation; D: At 6 h after IMA ligation; E: At 8 h after IMA ligation.

dehydrated and coverslipped. Slides were imaged with a Zeiss Axio Skope microscope equipped with a high-resolution digital camera (ORCA-HR C4742-95-12HR, 10 MP; Hamamatsu Photonics, Hamamatsu, Japan)

### MRI bowel enema

This procedure was performed on one healthy rat to determine the large bowel anatomy and topography. Under anesthesia, a 16 G angiocatheter was inserted in the rectum and fixed to the anal skin by a purse-string suture. After the injection of 8-10 mL warm water, 7T-MRI was performed using the following protocol: Tripilot sequence, parameters: TR 100.0 ms; TE 6.0 ms; FOV 8.00 cm; IS 2.00 mm; N slice 3 and RareT2 sequence in axial section, parameters: TR 6060.3 ms; TE 36.0 ms; FOV 6.00 cm; matrix 256 × 256; IS 1.00/1.00 mm; N slice 44; acquisition time: 14 min, 32 s, 688 ms. These scans served as anatomic images of reference for comparison purposes to identify ischemic damage in group II rats.

## RESULTS

### Macroscopic evaluation

Figure 1A shows the appearance of a rat intestine immediately before IMA ligation; the colon and the ileum were of normal size and presented a uniform serous membrane and rose-colored mesentery. One hour after IMA ligation, pale areas appeared in the splenic flexure mesentery (indicated by a white arrow in Figure 1B); these areas progressively increased (white arrow) and were associated, four hours after IMA ligation, with a change in the color of the splenic flexure loop (black arrow), which appeared dark reddish blue (Figure 1C). Six

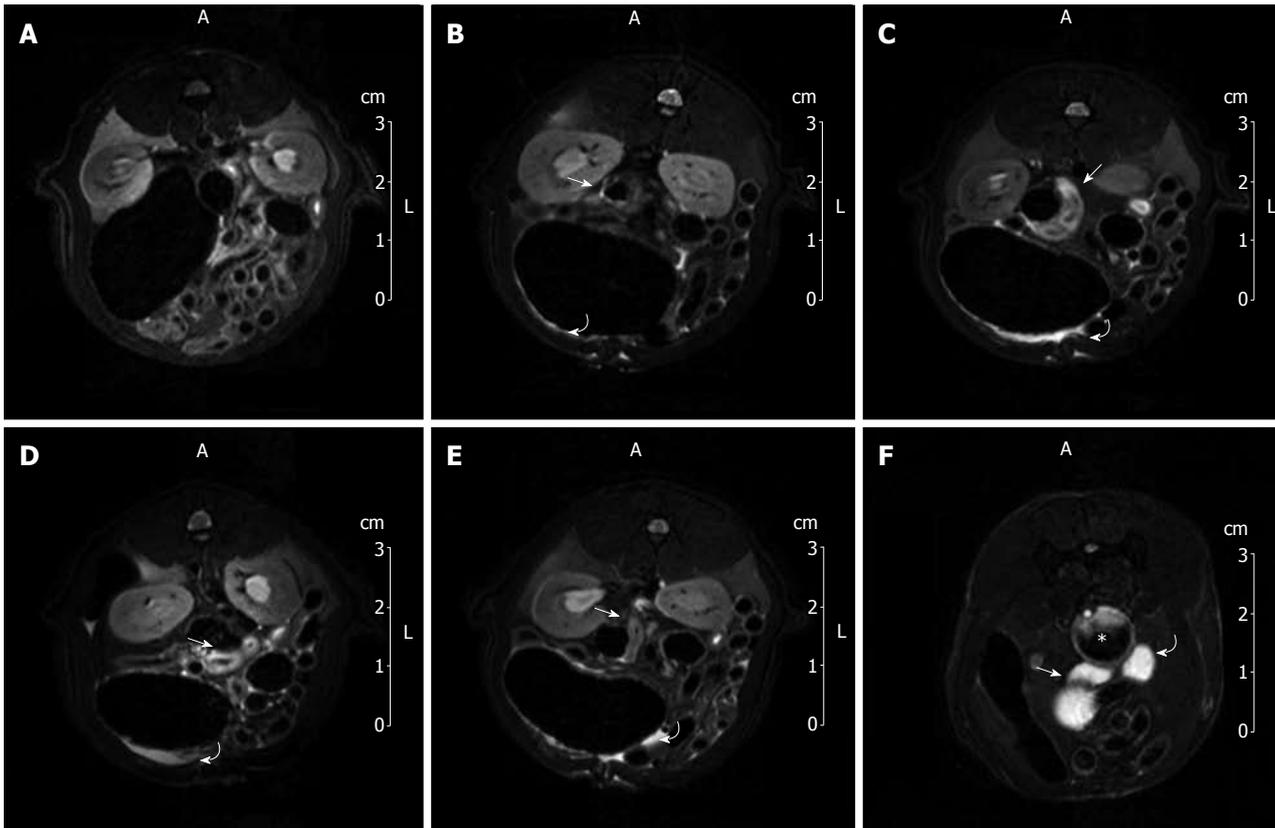

hours after IMA ligation, the splenic flexure mesentery was very pale (white arrow), and the loop was very dark (black arrow, Figure 1D). Eight hours after IMA ligation, although the loop was even darker (black arrow), the mesentery was less pale (white arrow, Figure 1E). No other macroscopic alterations were noted during the 8 h observation period, and the chronological sequence of the macroscopic morphological changes was the same in all group I animals.

### MRI

Figure 2A shows a 7T-MRI abdominal scan of a group II rat immediately before IMA ligation. No pathological findings related to ischemic damage were detected. One hour after IMA ligation, the T2 sequences showed minimal findings, namely, hyperintense signals in both the colonic loop wall (arrow) and the intraperitoneal space (curved arrow, Figure 2B). These MRI findings were more pronounced four hours after IMA ligation, suggesting colonic wall edematous thickening and a small amount of peritoneal free fluid (Figure 2C). Six hours after ligation, the amount of peritoneal free fluid increased (curved arrow), as did the colonic wall hyperintensity (arrow, Figure 2D). Eight hours after IMA ligation, MRI showed persistent colonic mural hyperintensity (arrow) associated with a reduction in the peritoneal free fluid (curved arrow), probably related to compensatory intraperitoneal drainage (Figure 2E).

### MRI colon enema

Figure 2F shows the hyperintense signals of the splenic flexure (arrow), descending colon (curved arrow) and rectum (star) distended by instilled water. Comparison

**Figure 2** 7T magnetic resonance imaging investigation. A: Image of a 7T magnetic resonance imaging (MRI) abdominal scan before inferior mesenteric artery (IMA) ligation; B: A 7T MRI abdominal scan 1 h after IMA ligation; C: At 4 h after IMA ligation; D: At 6 h after IMA ligation; E: At 8 h after IMA ligation; F: Image of 7T MRI colon enema.

of the 7T-MRI and MRI colon enema scans reveals that the splenic flexure was the colonic area most affected by ischemia.

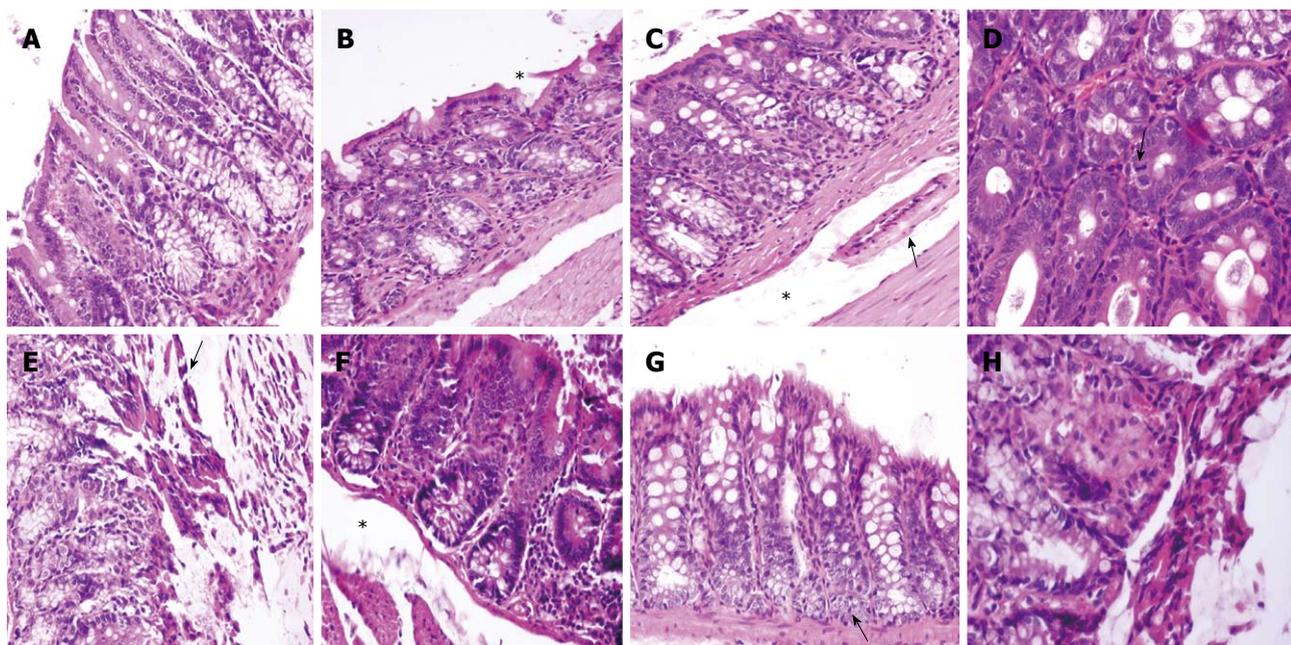

**Histological analysis**

Histology revealed anatomopathological alterations in the second segments (colonic splenic flexure), whereas the first and third segments were unaffected. The histology of the colonic sections obtained one hour after IMA ligation from the proximal colon and the splenic flexure are shown in Figure 3A and B, respectively. In contrast to the normal histological pattern of the proximal colon, the splenic flexure section showed an attenuated epithelium with glandular apex lesions (star). Four hours after IMA ligation, large ischemic lesions appeared at the splenic flexure level: superficial epithelium nuclear pyknosis and epithelium mucin depleted with submucosal edema (star) leading to vessel collapse (arrow, Figure 3C). Six hours after ligation, in the same colonic area, we found a further reduction in crypt goblet cells, clear signs of apoptosis such as nuclear pyknosis and hyper eosinophilia, and epithelial regeneration attempts, as shown by the presence of mitotic figures (arrow, Figure 3D). At the end of the observation (8 h), ischemic injury of the splenic flexure was more pronounced; necrosis and a loss of the surface epithelium, crypt drop-out (arrow) with a depletion of goblet cells (Figure 3E) and a

markedly edematous submucosa (star, Figure 3F) were observed. Signs of regeneration in response to the injury appeared at the bottom of the crypts (arrow, Figure 3G) near the images of coagulative necrosis (Figure 3H). Ischemic changes were related to vascular anatomy, and a sharp demarcation line often separated the involved from the uninvolved mucosa.

**DISCUSSION**

The availability of animal models in which to reproduce human diseases has increased our knowledge of human physiopathology and led to new diagnostic and therapeutic approaches<sup>[14]</sup>. This study, based on an animal model of colonic ischemic damage, was designed to define the evolution of histological ischemic lesions and to compare anatomopathological features with corresponding 7T-MRI findings. Thus far, the chronological sequence of early colonic ischemic damage has not been described, and the role of MRI is still widely debated. To the best of our knowledge, this is the first study using 7T-MRI for the instrumental evaluation of a human disease reproduced in a rat animal model. We decided to use T2-weighted MRI sequences because, as shown in a previous study<sup>[15]</sup>, they allow us to identify, without using contrast media, the hyperintensity of parietal edema, which is an early sign of intestinal ischemia.

**Figure 3 Histological analysis.** A: Normal histological pattern of the rat proximal colon; B: Histological pattern of the rat proximal colon 1 h after inferior mesenteric artery (IMA) ligation; C: At 4 h after IMA ligation; D: At 6 h after IMA ligation; E: At 8 h after IMA ligation; note the necrosis and loss of the surface epithelium; F: Markedly edematous submucosa (star); G: Active regeneration signs at the bottom of the crypts; H: Coagulative necrosis.

We identified anatomopathological alterations as early as one hour after IMA ligation, namely, a pale mesentery and mild surface epithelium damage at the colonic splenic flexure level. Additionally at one hour after ligation, the MRI study showed a small amount of peritoneal free fluid associated with mild edematous thickening of the colonic splenic flexure wall. Moreover, there was a relevant correlation between the MRI changes observed during the course of bowel ischemia and the pathological damage. Indeed, the morphological and MRI findings showed a progressive and parallel worsening with time up to eight hours when, despite the change in the color of the colonic loop, we observed a mild improvement in mesenteric color associated with a reduction in peritoneal free fluid. Therefore, MRI detected very early signs of colonic ischemia and allowed us to monitor the evolution of the ischemic damage. Consequently, although CT remains a valid diagnostic tool for the visualization of early signs of bowel ischemia and evaluation of colonic ischemic damage<sup>[8,9,16]</sup>, MRI, which does not require the use of a contrast medium or ionizing radiation, can play an important role in the diagnostic and therapeutic management of patients with acute colitis ischemia.

We performed MRI colon enema in a surgically untreated rat to define the large bowel anatomy and topography. We were thus able to identify the specific colonic hyperintensity area detected by MRI after IMA ligation as the colonic splenic flexure. In agreement with a previous study, although the superior mesenteric artery is more important than the IMA in maintaining the cecum and transverse colon perfusion, ligation of the IMA alone produced significant injury in a single, specific colonic area<sup>[10]</sup>. The major vulnerability of the splenic flexure to

ischemic damage may be related to the presence of more limited collateral networks in this region, apparently representing a “watershed” area where the two circulations meet<sup>[2]</sup>. In this context, the amount of ischemic injury depends on the high variability of the vascular anatomy<sup>[7]</sup>.

The rat model used in this study had several limitations: vascular occlusion was sudden and total, whereas partial occlusion is possible in humans; IMA ligation was performed at the emergence of the vessel, whereas in clinical practice, distal occlusions are also observed; the time window analysis was limited to 8 h, but these patients often reach the hospital a few days after the original occlusive event. However, despite the limitations of the animal model, this study shows that MRI is useful in the diagnosis of acute IC. Moreover, although our MRI scans were performed with a 7T-MRI machine, which is not yet available in clinical practice, both our results and those of previous studies suggest that 7T MRI machines are appropriate for clinical research on humans<sup>[17,18]</sup>.

In conclusion, the assumption of parallels between the experimental colonic ischemic damage in this animal model and humans is reasonable. Our results indicate that MRI allows for the identification of pathological findings of acute IC and their correlation with histopathological features. Therefore, MRI can play a relevant role in the diagnostic management of acute IC and may be substituted for other invasive surgical and endoscopic procedures in diagnosing and grading IC when ischemic injury is suggested. The possibility of assessing the evolution of IC over time and correlating the histological alterations with imaging patterns could result in a more accurate and earlier identification of imaging diagnostic features and thus facilitate more effective treatment.

**COMMENTS**

**Background**

Ischemic colitis (IC) is a relatively common disease, being the most frequent form of intestinal ischemia and the second-most frequent cause of lower gastrointestinal bleeding. Presentation of IC is not specific and is highly variable, therefore, the diagnosis largely depends on clinical suspicion. In this context, the role of imaging techniques remains controversial.

**Research frontiers**

The role of magnetic resonance imaging (MRI) in the diagnostic management of acute IC is still a matter of debate, and nothing is known about the histological evolution of the acute colonic ischemic injury or the relationship between these lesions and MRI findings.

**Innovations and breakthroughs**

To be known, this is the first study using 7T-MRI for the instrumental evaluation of a human disease reproduced in a rat animal model. In this study, authors established the chronological evolution of the early functional and morphological responses to ischemia produced by inferior mesenteric artery (IMA) ligation and compared their anatomopathological features with the corresponding 7T-MRI findings.

**Applications**

The possibility of detecting the early signs of colonic ischemic injury with MRI suggests that this technique can play an important role in diagnosing and grading acute IC.

**Terminology**

7T-MRI: A non-invasive method of demonstrating internal anatomy based on the principle that atomic nuclei in a strong magnetic field (7 Tesla) absorb pulses of radiofrequency energy and emit them as radio waves that can be reconstructed into computerized images. The concept includes proton-spin tomographic techniques; IC: Inflammation of the colon due to colonic ischemia resulting from alterations in systemic circulation or local vasculature.

**Peer review**

This is a good demonstration of the potential use of T2-weighted MRI for detecting edema in IC. In an experimental model, results of MRI are compared with physiological appearance and histology of the bowel at various times after IMA ligation.

### Abstract

**AIM:** To investigate whether the small bowel transit time (SBTT) influences the diagnostic yield of capsule endoscopy (CE).

**METHODS:** Six hundred and ninety-one consecutive CE procedures collected in a database were analyzed. SBTT and CE findings were recorded. A running mean for the SBTT was calculated and correlated to the diagnostic yield with a Spearman's correlation test. Subgroup analyses were performed for the various indications for the procedure.

**RESULTS:** There was a positive correlation between the diagnostic yield and SBTT (Spearman's rho 0.58,  $P < 0.01$ ). Positive correlations between diagnostic yield and SBTT were found for the indication obscure gastrointestinal bleeding ( $r = 0.54$ ,  $P < 0.01$ ), for polyposis and carcinoid combined ( $r = 0.56$ ,  $P < 0.01$ ) and for the other indications ( $r = 0.90$ ,  $P < 0.01$ ), but not for

suspected Crohn's disease ( $r = -0.40$ ).

**CONCLUSION:** The diagnostic yield in small bowel capsule endoscopy is positively correlated with the small bowel transit time. This is true for all indications except for suspected Crohn's disease.

### INTRODUCTION

Capsule endoscopy (CE) is a very sensitive diagnostic technique to detect small bowel pathology. It has a higher diagnostic yield than conventional diagnostic methods, i.e., push enteroscopy, small-bowel follow-through, conventional CT and angiography<sup>[1]</sup>. The reported diagnostic yield of CE varies between 38% and 83%<sup>[2-11]</sup>. In 15%-20% of all CE's the capsule does not reach the cecum within recording time. Risk factors for incomplete CE procedures include previous small-bowel surgery, hospitalization, moderate or poor bowel cleansing, and a gastric transit time longer than 45 min<sup>[12]</sup>.

For a good and complete evaluation of the small

bowel, the capsule should reach the cecum within recording time, which is eight to eleven hours depending on the manufacturer. Therefore, some investigators use a prokinetic agent to speed up the gastric and small bowel transit. However, the short bowel transit time (SBTT) may influence the diagnostic yield of CE. With colonoscopy, the detection rate of neoplastic lesions is higher when the time to withdraw the colonoscope is longer<sup>[13-15]</sup>. It is conceivable that a similar principle also applies for small bowel CE. We therefore hypothesize that the diagnostic yield of CE depends on the small bowel transit time. To study this, we analyzed the influence of small bowel transit time on the diagnostic yield of CE in 691 consecutive procedures performed in our department.

## MATERIALS AND METHODS

Data from all consecutive CE studies performed at the University Medical Center Groningen, the Netherlands, between September 2003 and January 2009 were collected. Data that were collected included patient demographics, indications for the procedure, procedural data, including gastric transit time (GTT) and SBTT, and findings of the procedure. The GTT was defined as the time, in minutes, from the first image of the stomach until the first image of the duodenum. The SBTT was defined as the passage time, in minutes, from the first image of the duodenum until the first image of the cecum. If the capsule did not reach the cecum within recording time, the SBTT was recorded as the time during which small bowel images were captured. CE was considered complete when the cecum was reached within recording time.

### CE procedure

During the study period, all patients received bowel preparation. Patients were given standardized instructions before the procedure, and informed consent was obtained. The patients were asked to stop iron supplements seven days before CE and to use a low-fiber diet three days before CE. The patients started a fasting period at midnight before the procedure. Bowel preparation consisted of the ingestion of four liters of a polyethylene glycol solution (Colofort<sup>®</sup>), 3 L the evening before the procedure and 1 L in the morning. The capsule (Pillcam; Given Imaging Ltd, Yoqneam, Israel) was swallowed in the morning. The patients were allowed to drink fluids after three hours and to consume a light meal after five hours. Before capsule ingestion, 10 mL of antifoam and a prokinetic agent was given, 10 mg of domperidone (before July 1st 2008,  $n = 641$ ) or 250 mg of erythromycin (after July 1st 2008,  $n = 50$ ). All CE recordings were reviewed by two gastroenterologists, experienced with CE (RKW and JJK). Controversial findings were discussed, and consensus was reached upon the final diagnosis. The most relevant findings obtained from CE were documented and categorized according to standard terminology<sup>[16]</sup> as angiectasia(s); ulcer(s); bleeding of unknown origin; erosion (s); polyp(s)/tumor(s); incidental abnormality of

esophagus, stomach, or colon; no abnormality; or unable to make a diagnosis.

### Statistical analysis

The SBTT was not normally distributed (tested with a Kolmogorov-Smirnov test) in the study population. To demonstrate the correlation between average diagnostic yield and average SBTT, the average yield was calculated of 50 consecutive transit times and plotted. Diagnostic yield was expressed as 0 for absence of abnormalities and 1 for presence of abnormalities. In this way, a running mean for the SBTT was calculated for 50 consecutive patients and correlated to the diagnostic yield with a Spearman's correlation test. A rho's correlation coefficient was calculated. Comparison of SBTT between groups was performed using a Mann-Whitney *U* test.

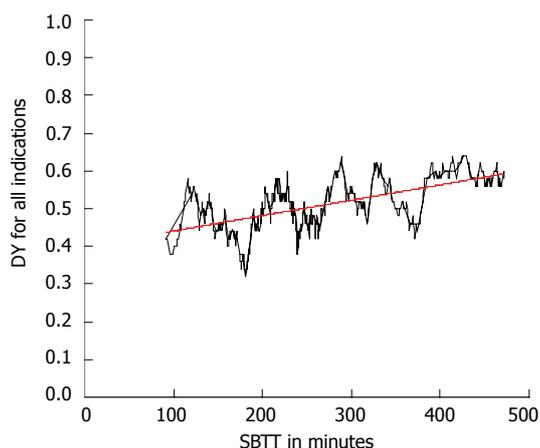

Subgroup analyses were performed for the various indications for the procedure. *P*-values below 0.05 were considered significant. SPSS 14.0 for Windows software (SPSS Inc., Chicago, IL, United States) and Microsoft Office Excel 2003 were used for statistical analyses.

## RESULTS

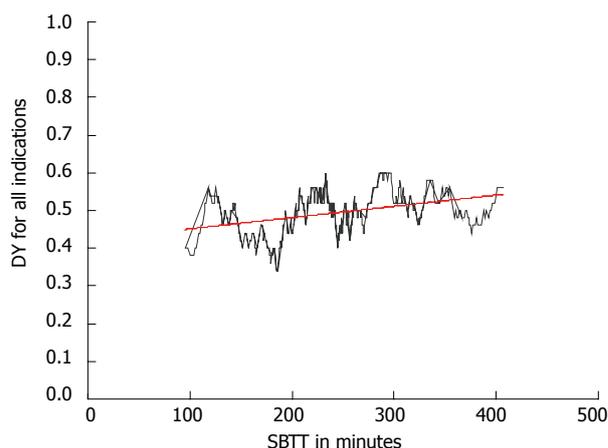

Six hundred and ninety-one consecutive CE procedures were analyzed. The mean age of the patients was 54 years (range 9-93, SD 18 years). 55% of the patients were male. Indications for CE were obscure gastrointestinal bleeding (OGIB) (67%), suspected Crohn's disease (22%), polyposis (4%), carcinoid (3%) and other (4%). CE findings were as follows in the investigated patients: angiectasia(s) in 121 cases (18%), ulcer(s) in 42 (6%), erosion(s) in 83 (12%), bleeding of unknown origin in 30 (4%), polyp(s)/tumor(s) in 56 (8%), abnormality of esophagus, stomach, or colon in 15 (2%), stenosis in 2 (0.3 %), unable to make a diagnosis in 6 (1%) and no abnormalities in 336 cases (48%). Overall, the diagnostic yield was 51%.

The cecum was reached in 82% of all procedures. The overall median small bowel transit time was 246 min (25 and 75 percentiles: 190 and 342). In CE cases with positive findings, the median SBTT was 254 min (25 and 75 percentiles: 200 and 361), in negative CE procedures, the median SBTT was 239 (25 and 75 percentiles 178 and 320), this difference was significant ( $P = 0.012$ ). There was a positive correlation between the diagnostic yield and SBTT (Figure 1) indicating that the longer the SBTT, the higher the diagnostic yield (Spearman's rho 0.58,  $P < 0.01$ ).

Next, patients were excluded in whom the cecum was not reached ( $n = 125$ ) within recording time, leaving 566 procedures with complete visualization of the small intestine. The overall median SBTT was 233 min (25 and 75 percentiles: 178 and 295). In cases with positive findings, the median SBTT was 236 (25 and 75 percentiles: 186 and 300), in negative CE procedures the median SBTT was 229 min (25 and 75 percentiles: 121 and 281), this difference was not significant ( $P = 0.078$ ). A positive correlation was again observed between the diagnostic yield and SBTT (Spearman's rho 0.40,  $P < 0.01$ , Figure 2).

**Figure 1** Correlation between the small bowel transit time in minutes and the diagnostic yield for all patients. Spearman's rho coefficient 0.58 ( $P < 0.01$ ) shown by the black line. The trend of this correlation is shown by the red line. DY: Diagnostic yield; SBTT: Small bowel transit time.

**Figure 2** Correlation between the small bowel transit time in minutes and the diagnostic yield in patient with complete capsule endoscopy. Spearman's rho coefficient 0.40 ( $P < 0.01$ ) shown by the black line. The trend of this correlation is shown by the red line. DY: Diagnostic yield; SBTT: Small bowel transit time.

Subgroup analysis for the different indications was performed for OGIB, suspected Crohn's disease, polyposis and carcinoid combined and other indications. The indications polyposis and carcinoid were taken together because both groups were too small for separate subgroup analysis. For these indications, positive correlations between diagnostic yield and SBTT were found for OGIB ( $r = 0.54$ ,  $P < 0.01$ ), for polyposis plus carcinoid ( $r = 0.56$ ,  $P < 0.01$ ) and for the other indications ( $r = 0.90$ ,  $P < 0.01$ ). However this was not observed for Crohn's disease ( $r = -0.40$ ). These results are depicted in Figure 3.

## DISCUSSION

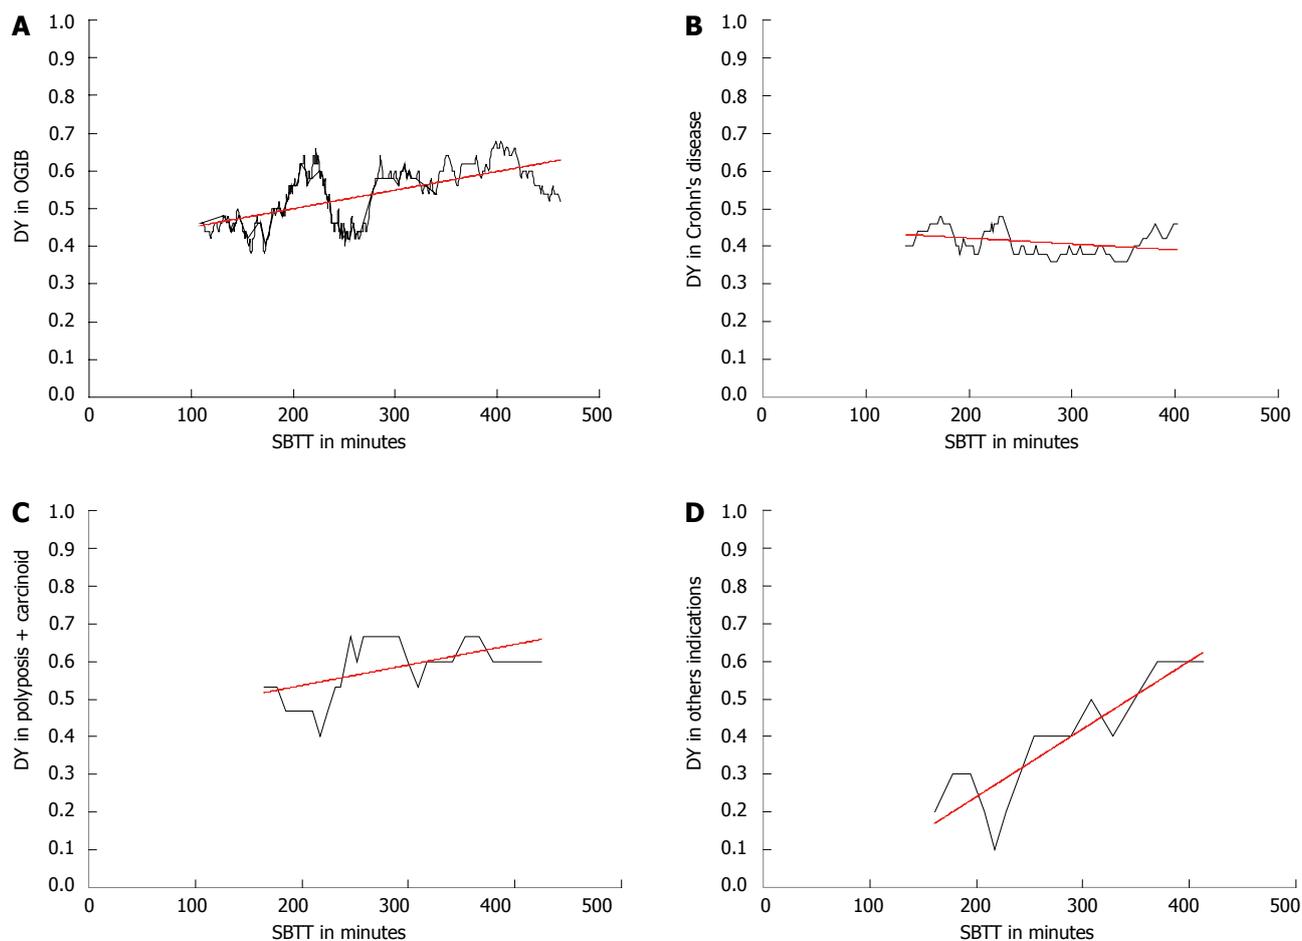

In this study, we found a positive correlation between the diagnostic yield of CE and small bowel transit time, irrespective of whether the capsule had reached the cecum within recording time. These findings are in accordance with those from colonoscopy studies, which show higher diagnostic yields for detecting neoplastic lesions when the withdrawal time during colonoscopy is longer<sup>[10-13]</sup> and from one previous study on the effect of SBTT on the diagnostic yield of CE<sup>[17]</sup>. Most of these colonoscopy studies divided the withdrawal time into more or less than a chosen number of minutes. In CE there are no known standard SBTT times, so we judged that it would not be correct to randomly divide the SBTT in two or more randomly chosen groups. Therefore we calculated a running mean to determine whether the diagnostic yield correlated with the SBTT. We found a positive correlation between the two, meaning that a longer transit time, implicating more images of the small bowel, resulted in a higher diagnostic yield.

For colonoscopy, the correlation between diagnostic yield and withdrawal time was only investigated in subjects undergoing screening for neoplastic lesions. In this study we looked at all indications for CE. We found a positive correlation between the diagnostic yield and

SBTT for the indications OGIB and polyposis/carcinoid and for other indications, but not for the indication suspected Crohn's disease. The latter is probably due to the multiple and widespread small bowel lesions usually seen in Crohn's disease. Therefore the endoscopist may be less dependent upon the mucosal inspection time to make the diagnosis. Furthermore, a previous study showed reduced capsule transit times in Crohn's disease<sup>[18]</sup>.

What does this positive correlation between diagnostic yield and SBTT mean for clinical practice? CE is less valuable when the cecum is not reached within recording time, but on the other hand our study indicates that the diagnostic yield is lower when the SBTT is shorter. So, ideally, the SBTT should be as long as possible, yet the capsule should reach the cecum within recording time. The development of capsule systems with longer battery times may be helpful. One important issue in this matter is whether there is a role for prokinetic agents in CE. In this way, one could influence the small bowel transit time. There is no consensus on this subject<sup>[1]</sup>. In most of the available studies, there are no data on the influence of prokinetics on the diagnostic yield of CE. Taking our data into account, it may not be wise to use prokinetics that speed up the SBTT. However this must be weighed against the fact that a prolonged GTT is a risk factor for incomplete CE<sup>[12]</sup>. It may therefore be useful to use an agent which shortens GTT without influencing SBTT.

A well known prokinetic agent is erythromycin. It induces high amplitude gastric propulsive contractions by activating gastric interdigestive migrating motor complexes, thereby accelerating gastric emptying<sup>[19-22]</sup>. The effects of erythromycin on SBTT are unclear. In the most recent publication on this subject, erythromycin reduced the GTT but had no significant effect on SBTT, total bowel transit time and CE completing rates<sup>[22]</sup>. Previous studies found similar results<sup>[23,24]</sup>, but in one at the cost of visibility<sup>[24]</sup>. Others found no effect of erythromycin on either GTT or SBTT<sup>[25]</sup>. Overall, the data are not very ro-

**Figure 3 Correlations between small bowel transit time and diagnostic yield.** A: Obscure gastrointestinal bleeding (OGIB;  $r = 0.54$ ,  $P < 0.01$ ); B: Suspected Crohn's disease ( $r = -0.40$ ); C: Polyposis plus carcinoid ( $r = 0.56$ ,  $P < 0.01$ ); D: Other indications ( $r = 0.90$ ,  $P < 0.01$ ), shown by the black line. The trend of this correlation is shown by the red line. DY: Diagnostic yield; SBTT: Small bowel transit time.

bust. If erythromycin mainly influences GTT, it might be an interesting prokinetic agent to use prior to small bowel CE.

Other prokinetics that have been studied in CE are metoclopramide and mosapride. Both prokinetic agents accelerated GTT and increased capsule completion rates, but had no influence on SBTT<sup>[26,27]</sup>. In our study, we used domperidone as a prokinetic agent in the majority of patients. Domperidone has shown to be effective in treating diabetic gastroparesis<sup>[28]</sup>, but there are no data on the use of this agent in CE.

Another way to use prokinetics may be with the aid of a real-time viewer system. In this way, prokinetics (or water or additional PEG) can be administered when the real-time viewer shows delayed gastric emptying. There are three studies that show a higher diagnostic yield of CE when a real-time viewer is used with on-demand administration of prokinetics, water, PEG or endoscopic-assisted duodenal placement<sup>[29-31]</sup>.

The strength of this study is that this is the first study that investigated the relation between diagnostic yield of CE and SBTT in a large study population. This allowed for a subgroup analysis for the different indications of CE. Another strong point of our study in our view is the

use of an appropriate statistical method for determining the relation between diagnostic yield and SBTT by using a running mean.

A limitation of this study is that all patients in our population received a prokinetic agent, which might have changed the SBTT and with that also the diagnostic yield. The diagnostic yield might have been higher in this study population when we would not have used a prokinetic agent. Another limitation of this study is that during this study period we switched our prokinetic agent from domperidone to erythromycin. One should realize that this is a retrospective study. Prospective studies are necessary to establish the effect of the use of prokinetics on SBTT and diagnostic yield.

There may be many factors that influence SBTT and thereby diagnostic yield in small bowel CE. In this study we did not analyze such other factors, mainly because the main goal of this study was to determine whether there was a relation between diagnostic yield and SBTT at all. A previous study on the effect of SBTT on diagnostic yield found an independent association between diagnostic yield and SBTT<sup>[17]</sup>. In that study, no relation was found between diagnostic yield and other potential risk factors such as age, gender, study indication, hospital status, and

quality of bowel preparation<sup>[17]</sup>. Since we also found a positive correlation between diagnostic yield and SBTT it might be very interesting to look further into factors influencing SBTT and thereby diagnostic yield in future studies.

In conclusion, in this study with a large group of patients, we found a positive correlation between the diagnostic yield of small bowel CE and small bowel transit time for all indications except for suspected Crohn's disease. For clinical practice, these data implicate that it may not be advisable to use prokinetic agents which accelerate small bowel transit although this remains to be proven in future studies.

## COMMENTS

### Background

Capsule endoscopy (CE) is a very sensitive diagnostic technique to detect small bowel pathology. For a good and complete evaluation of the small bowel, the capsule should reach the cecum within recording time which is eight to eleven hours depending on the manufacturer. Some investigators advocate the use of a prokinetic agent to speed up the gastric and small bowel transit. However, a short bowel transit time (SBTT) may influence the diagnostic yield of CE. With colonoscopy, the detection rate of neoplastic lesions is higher when the time to withdraw the colonoscope is longer. It is conceivable that a similar principle also applies for small bowel CE. Therefore the question is whether the diagnostic yield of CE depends on the small bowel transit time.

### Research frontiers

This the first study that investigated the relation between diagnostic yield of CE and SBTT in a large study population. This possible relation was also investigated for different indications for CE.

### Innovations and breakthroughs

Six hundred and ninety-one consecutive CE procedures were analyzed. This study found a positive correlation between the diagnostic yield of CE and small bowel transit time, irrespective of whether the capsule had reached the cecum within recording time. These findings are in accordance with those from colonoscopy studies. This means that a longer transit time, implicating more images of the small bowel, resulted in a higher diagnostic yield. We found a positive correlation between the diagnostic yield and SBTT for all indications except for suspected Crohn's disease. The latter is probably due to the multiple and widespread small bowel lesions usually seen in Crohn's disease.

### Applications

What does this positive correlation between diagnostic yield and SBTT mean for clinical practice? CE is less valuable when the cecum is not reached within recording time, but on the other hand our study indicates that the diagnostic yield is lower when the SBTT is shorter. So, ideally, the SBTT is long, but not so long that the capsule does not reach the cecum within recording time. One important issue in this matter is whether there is a role for prokinetic agents in CE to influence small bowel transit time. There is no consensus in the literature on this subject. For clinical practice, these data implicate that it may not be advisable to use prokinetic agents which accelerate small bowel transit, although this remains to be proven in future studies.

### Peer review

It is a nice and interesting work. It values an important aspect of the capsule endoscopy not well studied until now: the relation between the diagnostic yield of capsule endoscopy and small bowel transit time.

### Abstract

**AIM:** To clarify the efficiency of the criterion of metabolic syndrome to detecting non-alcoholic fatty liver disease (NAFLD).

**METHODS:** Authors performed a cross-sectional study involving participants of a medical health checkup pro-

gram including abdominal ultrasonography. This study involved 11 714 apparently healthy Japanese men and women, 18 to 83 years of age. NAFLD was defined by abdominal ultrasonography without an alcohol intake of more than 20 g/d, known liver disease, or current use of medication. The revised criteria of the National Cholesterol Education Program Adult Treatment Panel III were used to characterize the metabolic syndrome.

**RESULTS:** NAFLD was detected in 32.2% (95% CI: 31.0%-33.5%) of men ( $n = 1874$  of 5811) and in 8.7% (95% CI: 8.0%-9.5%) of women ( $n = 514$  of 5903). Among obese people, the prevalence of NAFLD was as high as 67.3% (95% CI: 64.8%-69.7%) in men and 45.8% (95% CI: 41.7%-50.0%) in women. Although NAFLD was thought of as being the liver phenotype of metabolic syndrome, the prevalence of the metabolic syndrome among subjects with NAFLD was low both in men and women. 66.8% of men and 70.4% of women with NAFLD were not diagnosed with the metabolic syndrome. 48.2% of men with NAFLD and 49.8% of women with NAFLD weren't overweight [body mass index (BMI)  $\geq 25$  kg/m<sup>2</sup>]. In the same way, 68.6% of men with NAFLD and 37.9% of women with NAFLD weren't satisfied with abdominal classification ( $\geq 90$  cm for men and  $\geq 80$  cm for women). Next, authors defined it as positive at screening for NAFLD when participants satisfied at least one criterion of metabolic syndrome. The sensitivity of the definition "at least 1 criterion" was as good as 84.8% in men and 86.6% in women. Separating subjects by BMI, the sensitivity was higher in obese men and women than in non-obese men and women (92.3% vs 76.8% in men, 96.1% vs 77.0% in women, respectively).

**CONCLUSION:** Authors could determine NAFLD effectively in epidemiological study by modifying the usage of the criteria for metabolic syndrome.

Identification of individuals with non-alcoholic fatty liver disease by the diagnostic criteria for the metabolic syndrome. *World J Gastroenterol* 2012; 18(13): 1508-1516 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i13/1508.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i13.1508>

## INTRODUCTION

Nonalcoholic fatty liver disease (NAFLD) is a common clinical condition with histological features that resemble those of alcohol-induced liver injury, but occurs in patients who do not drink an excessive amount of alcohol (ethanol > 20 g/d)<sup>[1,2]</sup>. This disease is often associated with obesity<sup>[3]</sup>, type 2 diabetes mellitus<sup>[4,5]</sup>, dyslipidemia<sup>[6]</sup>, and hypertension<sup>[7]</sup>. Each of these abnormalities carries a cardiovascular disease risk, and together they are often categorized as the insulin resistance syndrome or the metabolic syndrome<sup>[8-15]</sup>.

NAFLD is now considered to be the hepatic representation of the metabolic syndrome<sup>[10-15]</sup>.

Conventional radiology studies used in the diagnosis of fatty liver include ultrasound (US), computed tomography, and magnetic resonance (MR) imaging. Other than these radiological studies, we have no sensitive and low invasive screening method for NAFLD. Alanine aminotransferase (ALT) > 30 IU/L was usually used as the cut off level of screening NAFLD<sup>[16,17]</sup>. This threshold had a sensitivity of 0.92 for detecting the fatty-fibrotic pattern proven by ultrasound among obese children<sup>[18]</sup>. However, ALT was within normal levels in 69% of those who had increased liver fat<sup>[19]</sup>. Similarly, in the Dallas Heart Study, 79% of the subjects with a fatty liver (liver fat content > 5.6%) had normal serum ALT<sup>[20]</sup>. This implies that a normal ALT does not exclude steatosis. Aspartate aminotransferase (AST) and gamma glutamyltransferase (GGT) also correlate with liver fat content independent of obesity<sup>[21]</sup>, but are even less sensitive than serum ALT.

It was well known that NAFLD was associated with the metabolic syndrome and patients with NAFLD tend to be accompanied with the abnormal component of the metabolic syndrome. However, the efficiency of the criterion of metabolic syndrome for detecting NAFLD has not yet been clarified. We aimed to clarify the efficiency and perform a cross sectional study among apparent healthy Japanese.

## MATERIALS AND METHODS

### Study design

We performed a cross-sectional study involving partici-

pants of a medical health checkup program including abdominal ultrasonography. The program was conducted in the Medical Health Checkup Center at Murakami Memorial Hospital, Gifu, Japan. The purpose of the medical health checkup program is to promote public health through early detection of chronic diseases and the evaluation of their underlying risk factors. Known as a “human dock”, medical services of this kind are very popular in Japan.

### Study population

All the subjects participating in such health checkup programs at Murakami Memorial Hospital between January 2004 and December 2008 were invited to join this study. The study was approved by the ethics committee of Murakami Memorial Hospital.

Data collection and exclusion criteria were described previously<sup>[8]</sup>. In short, we collected the data from urinalysis, blood cell counts, blood chemistry and abdominal ultrasonography. The medical history and lifestyle factors were collected by using a self-administered questionnaire. Exclusion criteria were an alcohol intake of more than 20 g/d, known liver disease, or current use of medication which could influence the metabolic syndrome such as anti-diabetic drugs, anti-hypertensive drugs, anti-dyslipidemic drugs, anti-gout drugs, and/or anti-obesity drugs<sup>[8,10]</sup>.

According to the revised National Cholesterol Education Program Adult Treatment Panel III (NCEP-ATP III)<sup>[22]</sup> or the new International Diabetes Federation (IDF) definition<sup>[23]</sup>, subjects who had three or more of the following criteria were diagnosed as having the metabolic syndrome. Fatty liver was defined on the basis of ultrasonographic findings<sup>[24]</sup>. Of 4 known criteria (hepatorenal echo contrast, liver brightness, deep attenuation, and vascular blurring), the participants were required to have hepatorenal contrast and liver brightness to be given a diagnosis of fatty liver<sup>[24]</sup>.

During study period, we invited 20 012 participants in the health checkup program to enroll in the study. Of those, a total of 17 262 Japanese participants (10 329 men and 6933 women) were enrolled after giving informed consent to be included in the study. We excluded 621 participants (420 men and 201 women) who had known liver disease. In addition, 3330 participants (3042 men and 288 women) who consumed more than 20 g of ethanol per day and 1579 participants (1056 men and 541 women) who were currently receiving medication were excluded. As a result, this study ultimately consisted of 11 714 participants (5811 men and 5903 women). The mean  $\pm$  SD age was  $45.5 \pm 9.4$  years (range: 18 years to 83 years) for men and  $44.3 \pm 9.3$  years (range: 18 years to 79 years) for women, respectively. The mean body mass index (BMI) was  $23.2 \pm 3.1$  kg/m<sup>2</sup> (range: 14.3 to 41.0 kg/m<sup>2</sup>) in men and  $21.1 \pm 3.0$  kg/m<sup>2</sup> (range: 14.0 to 58.3 kg/m<sup>2</sup>) in women, respectively. The mean abdominal circumference was  $81.2 \pm 8.1$  cm (range: 57.3 cm to 127.5 cm) in men and  $71.4 \pm 8.2$  cm (range: 49.0 cm to 145.0 cm) in women, respectively.

**Table 1** The basic characteristics of the study population and the association of nonalcoholic fatty liver disease with gender difference

Men	Total <i>n</i> (%)	Obese <i>n</i> (%)	Non-obese <i>n</i> (%)

NAFLD: Nonalcoholic fatty liver disease; US: Abdominal ultrasonography; BMI: Body mass index; HDL: High density lipoprotein; MS: Metabolic syndrome; rNCEP-ATP III: Revised National Cholesterol Education Program Adult Treatment Panel III definition; IDF: International diabetes federation definition; ALT: Alanine aminotransferase.

### Statistical analysis

The R version 2.9.0 (available from <http://www.r-project.org/>) was used for statistical analyses. Two groups of subjects were compared by using the unpaired *t*-test and the chi-square test, and a *P* < 0.05 was accepted as a significant level.

## RESULTS

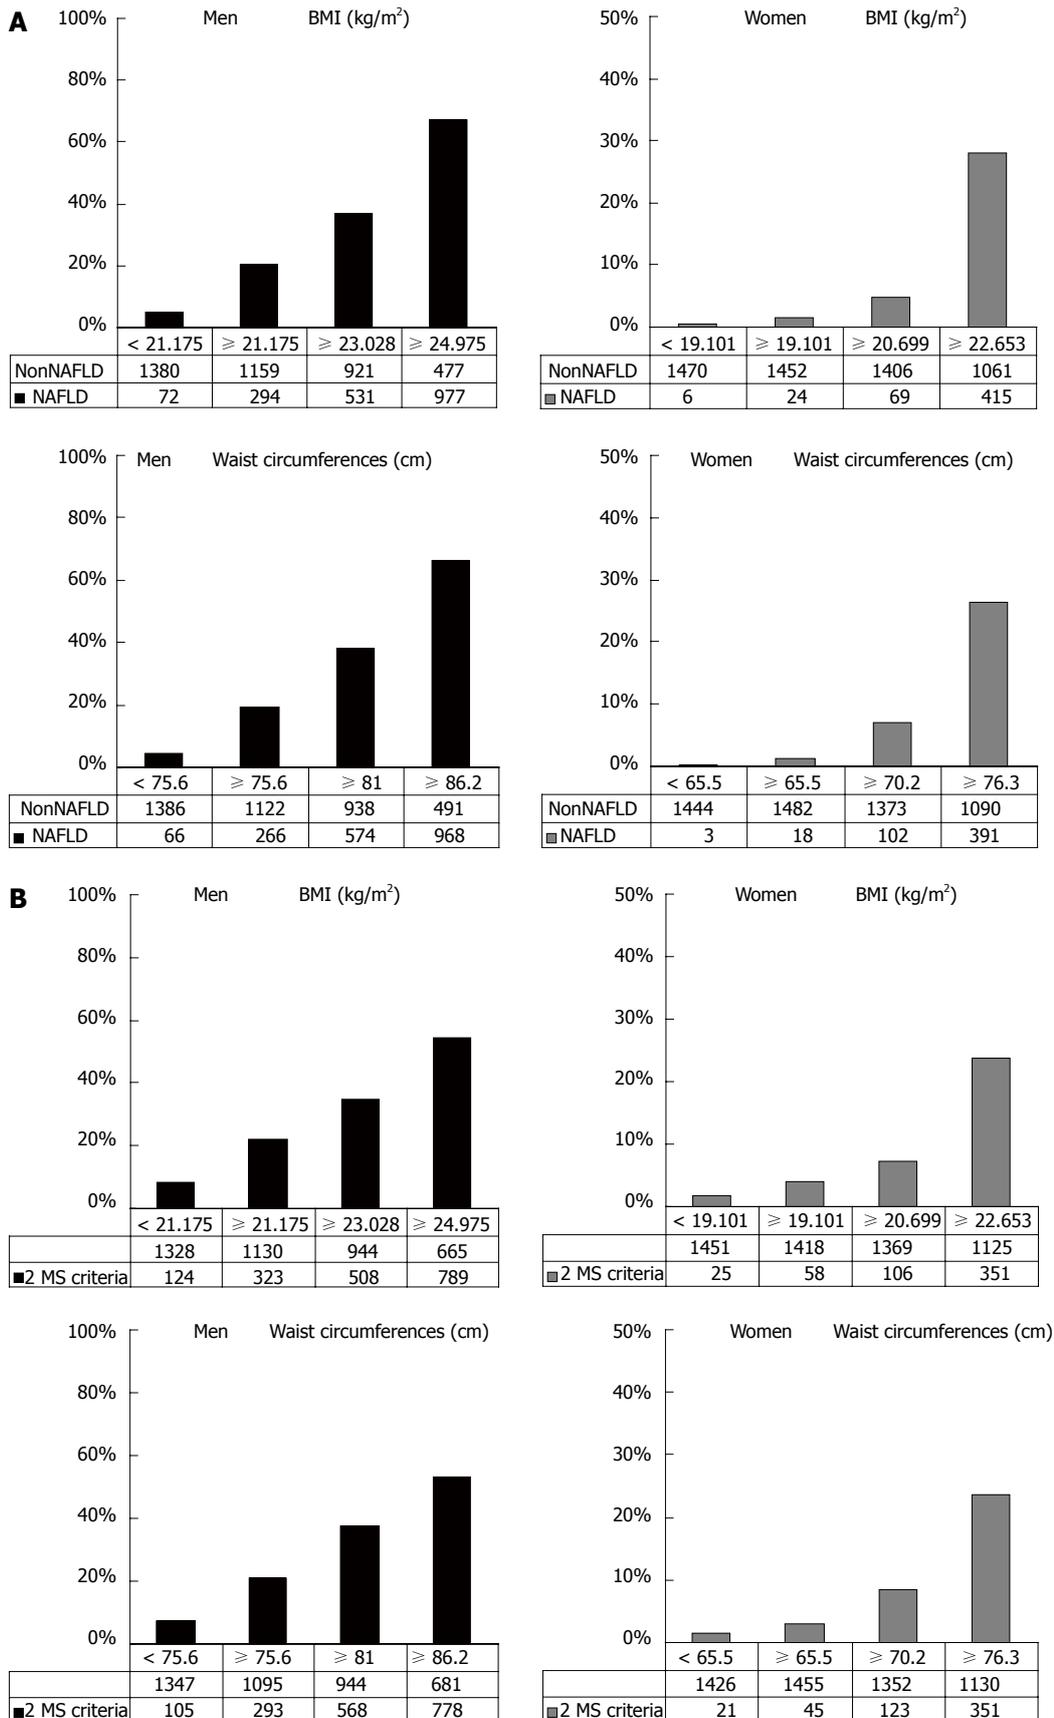

### Basic characteristics of study population

The metabolic syndrome defined by revised NCEP-ATP III definition was detected in 15.0% (95% CI: 14.1%-16.0%) of men (*n* = 873 of 5811) and in 5.1% (95% CI: 4.5%-5.7%) of women (*n* = 300 of 5903). The metabolic syndrome defined by IDF definition was detected in 8.2% (95% CI: 7.5%-9.0%) of men (*n* = 479 of 5811) and in 4.3% (95% CI: 3.8%-4.8%) of women (*n* = 254 of 5903) (Table 1). Among obese people, the metabolic syndrome defined by revised NCEP-ATP III definition was detected in 40.1% (95% CI: 37.6%-42.7%) of men and in 30.9% (95% CI: 27.1%-34.9%) of women, and the metabolic syndrome defined by IDF definition was detected in 30.7% (95% CI: 28.4%-33.2%) of men and in 28.8% (95% CI: 25.1%-32.7%) of women, respectively (Table 1).

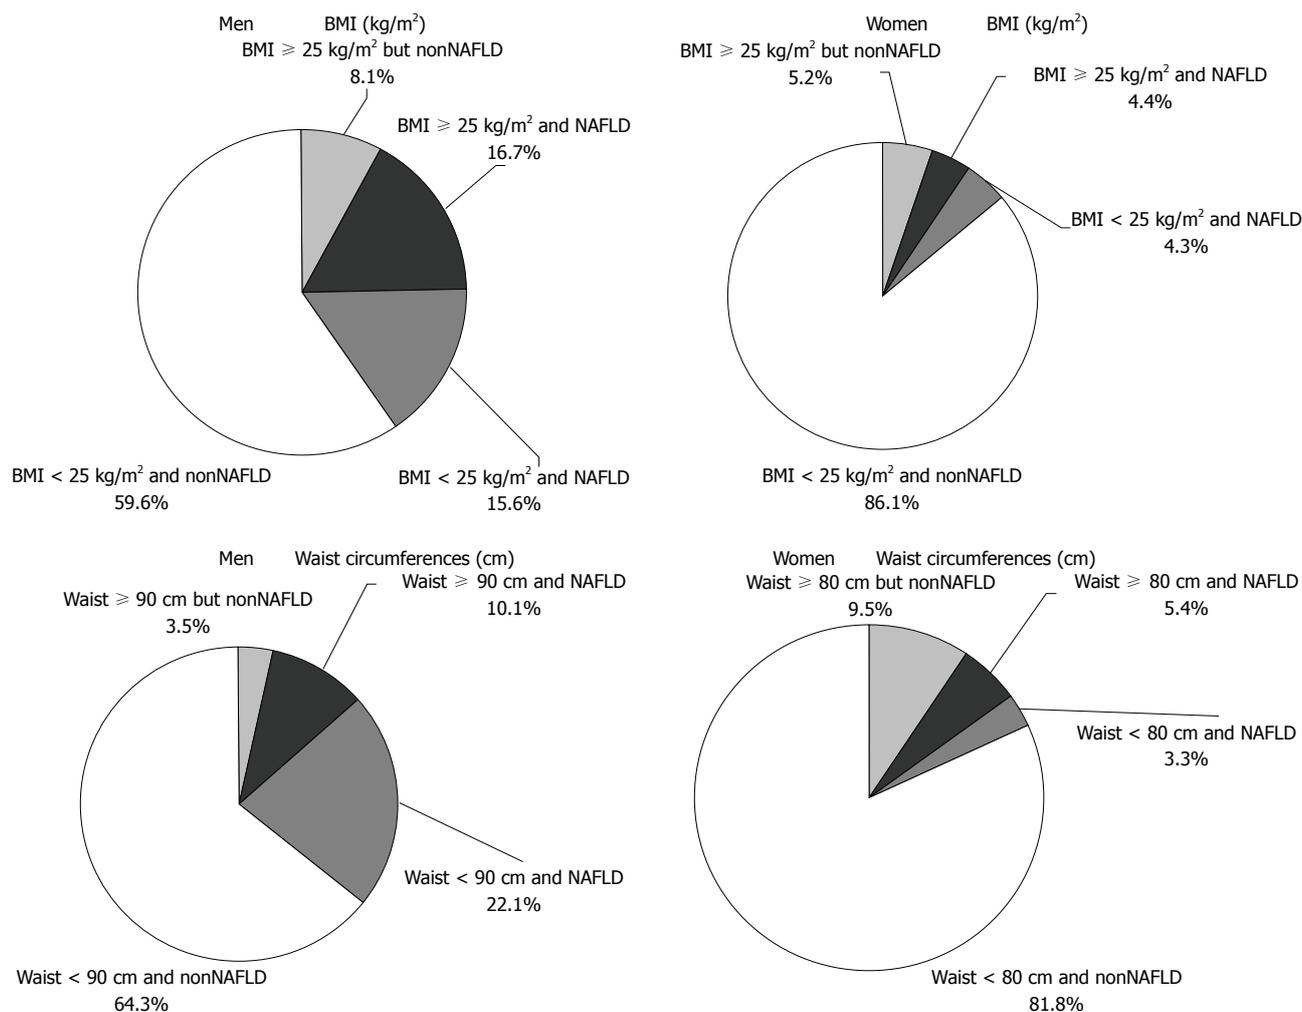

### Association of NAFLD with gender difference, or body fat accumulation

NAFLD was detected in 32.2% (95% CI: 31.0%-33.5%) of men (*n* = 1874 of 5811) and in 8.7% (95% CI: 8.0%-9.5%) of women (*n* = 514 of 5903). The prevalence of NAFLD in men was four times higher than those in women (Table 1). Among obese people, the prevalence of NAFLD was as high as 67.3% (95% CI: 64.8%-69.7%) in men and 45.8% (95% CI: 41.7%-50.0%) in women (Table 1). NAFLD was associated with body fat accumulation strongly both in men and women.

When we separated by quartile the subjects according to their BMI or abdominal circumference, half of NAFLD men and three quarters of NAFLD women were classified in the superior quartile. The prevalence of NAFLD was increased according to the increase of BMI or abdominal circumference (Figure 1A). The role of BMI for NAFLD was equal to that of abdominal circumference both in men and women. The ratio of NAFLD in the superior quartile/total NAFLD was higher in women than in men. The prevalence of individuals who met two or more of the MS criteria other than waist circumference was increased according to the increase of BMI or abdominal circumference (Figure 1B).

**Figure 1** We separated the subjects by quartile according to their body mass index or abdominal circumference. A: The bar indicated the prevalence (%) of individuals with NAFLD; B: Individuals who meet two or more of the MS criteria other than waist circumference according to BMI or waist circumference quartiles. 2 MS criteria means individuals who meets two or more of the MS criteria other than waist circumference. NAFLD: Nonalcoholic fatty liver disease; BMI: Body mass index; MS: Metabolic syndrome.

**Figure 2** This figure indicates the prevalence of non-alcoholic fatty liver disease and alcoholic fatty liver disease with or without patients being overweight (BMI  $\geq 25$  kg/m<sup>2</sup>) or having elevated abdominal circumferences ( $\geq 90$  cm for men and  $\geq 80$  cm for women). Data was expressed as prevalence (%). NAFLD accompanied with being overweight occurred in 51.8% of NAFLD men (970/1874) and 50.2% of NAFLD women (258/514). NAFLD accompanied by elevated abdominal circumference occurred in 31.4% of NAFLD men (588/1874) and 62.1% of women (319/514). NAFLD: Non-alcoholic fatty liver disease; BMI: Body mass index.

**Role of the criteria of the metabolic syndrome in detecting or diagnosing NAFLD in obese or non-obese population**

Although NAFLD was associated with obesity or body fat accumulation strongly, the population that was neither overweight (BMI  $\geq 25$  kg/m<sup>2</sup>) nor had elevated abdominal circumference was not small (Figure 2). Actually, 48.2% of men with NAFLD and 49.8% of women with NAFLD were not overweight (BMI  $\geq 25$  kg/m<sup>2</sup>). Similarly, 68.6% of men with NAFLD and 37.9% of women with NAFLD did not satisfy increased abdominal circumference classification. Half of the NAFLD group was classified as non-obese, but the prevalence of NAFLD among the non-obese population was lower. These facts means an effective method is needed to detect NAFLD among the non-obese population. Then, we separated the subjects into two groups, obese group or non-obese group, and investigated the efficacy of the criteria of metabolic syndrome for detecting NAFLD in each group.

Among the criteria for metabolic syndrome, the cri-

terion of abdominal circumferences ( $\geq 80$  cm) had high sensitivity (87.6%) for detecting NAFLD in women who were overweight (BMI  $\geq 25$  kg/m<sup>2</sup>) (Table 2). In other words, abdominal circumference was effective for detecting NAFLD in obese women. However, the criterion of abdominal circumference had low sensitivity (36.3%) in non-obese women. The sensitivity of abdominal circumference ( $\geq 90$  cm) was very low (5.8%) in non-obese men. Even in obese men the sensitivity was not high (55.3%). Other criteria for metabolic syndrome had higher sensitivity in obese men and women than in the non-obese population but sensitivity never exceeded 60%.

As a screening tool for NAFLD, the sensitivity of elevated ALT (ALT > 30 IU/L) was 49.7% in men, which exceeded the sensitivity of the criteria of metabolic syndrome, but it was 17.7% in women, which was lower than all metabolic syndrome criteria were. On the other hand, the specificity of elevated ALT was as high as 90.6% in men and 98.0% in women, but the criteria of metabolic syndrome had equally high specificity.

Next, we defined it as positive at screening for NAFLD

**Table 2** The role of the criteria of the metabolic syndrome in detecting or diagnosing nonalcoholic fatty liver disease in obese or non-obese population

	Men				Women			
	Total %	Obese %	Non-obese %	P value	Total %	Obese %	Non-obese %	P value

NAFLD: Nonalcoholic fatty liver disease; US: Abdominal ultrasonography; BMI: Body mass index; HDL: High dense lipoprotein; MS: Metabolic syndrome; rNCEP-ATP III: Revised National Cholesterol Education Program Adult Treatment Panel III definition; IDF: International Diabetes Federation definition; ALT: Alanine aminotransferase.

when participants satisfied at least one or two components of metabolic syndrome. The sensitivity of the definition “at least 1 criterion” was 84.8% in men and 86.6% in women. Separating subjects with BMI, the sensitivity was higher in obese men and women than in non-obese men and women (92.3% *vs* 76.8% in men, 96.1% *vs* 77.0% in women, respectively).

The prevalence of subjects with NAFLD who also had the metabolic syndrome is indicated in Figure 3. Although NAFLD was thought of as being the liver phenotype of metabolic syndrome, the prevalence of the metabolic syndrome among subjects with NAFLD was low both in men and women. Among men with NAFLD, 66.8% were not diagnosed with the metabolic syndrome defined by revised NCEP-ATP III definition, and 79.0% were not diagnosed with the metabolic syndrome as defined by revised IDF definition. Even in women, 70.4% and 67.5%, respectively, were not diagnosed with metabolic syndrome by revised NCEP-ATP III definition and revised IDF definition. These results mean that a large number of participants diagnosed with the metabolic syndrome have NAFLD, but a large number of participants with NAFLD were not diagnosed with the metabolic syndrome, whether we used revised NCEP-ATP III criteria or IDF criteria.

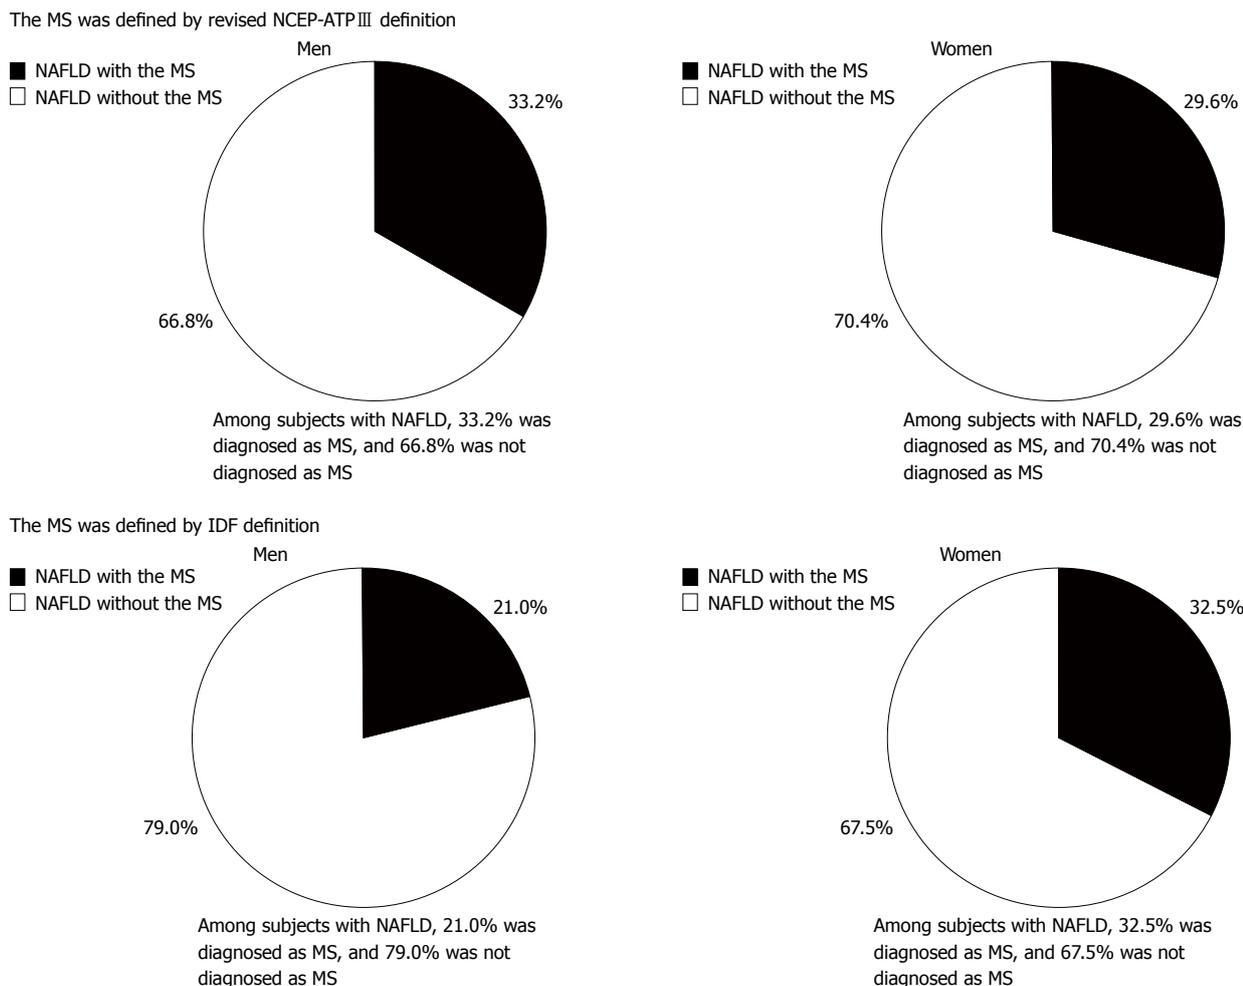

## DISCUSSION

In this study, we clarified the impact of the criteria of the

metabolic syndrome for diagnosing NAFLD in a healthy population. The metabolic syndrome was associated with abdominal obesity and its criteria include waist circumference<sup>[22,23,25,26]</sup>, and NAFLD was reported to be associated with abdominal obesity. However, our results indicated there was no significant difference between BMI and waist circumferences as the strength of association with NAFLD or the accumulation of metabolic syndrome criteria.

The presence of multiple metabolic disorders such as diabetes mellitus, obesity, dyslipidaemia and hypertension is associated with a potentially progressive, severe liver disease<sup>[15,27]</sup>. Previous reports demonstrated that prevalence of NAFLD increased to 10%-80% in individuals with obesity, 35%-90% in individuals with type 2 diabetes mellitus, 30%-56% in individuals with hypertension, and 26%-58% in individuals with dyslipidemia<sup>[9,28-30]</sup>. Another study in a Japanese population showed that prevalence of NAFLD increased to 43% in individuals with impaired fasting glucose and 62% in individuals with type 2 diabetes mellitus<sup>[28]</sup>. Some studies estimate the prevalence of NAFLD be up to 15%-30% of the general population<sup>[8,31,32]</sup>, and the prevalence of metabolic syndrome was estimated to be up to 25% of the general population<sup>[33]</sup>. In those patients with the metabolic syndrome, liver fat content is significantly increased up to 4-fold higher than those without the metabolic syndrome<sup>[34]</sup>, and the incidence of NAFLD has been shown to be increased 4-fold in men and 11-fold in women with the metabolic syndrome<sup>[8]</sup>.

Our data clearly indicated that 21% to 33% of sub-

**Figure 3** The prevalence of subjects with or without the metabolic syndrome among 1874 men and 514 women with non-alcoholic fatty liver disease. Data was expressed as prevalence (%). The metabolic syndrome (MS) was diagnosed using revised IDF. Among men with NAFLD, 66.8% and 79.0% were not diagnosed with the MS defined by revised NCEP-ATP III definition and revised IDF definition, respectively. In women, 70.4% and 67.5%, respectively, were not diagnosed with the MS by revised NCEP-ATP III definition and revised IDF definition. IDF: International Diabetes Federation; NCEP-ATP III: National Cholesterol Education Program Adult Treatment Panel III; NAFLD: Non-alcoholic fatty liver disease.

jects with NAFLD, depending on gender and the criteria used, were diagnosed with the metabolic syndrome. Several previous studies reported how many subjects with NAFLD were diagnosed with the metabolic syndrome, but almost all previous studies were hospital studies. Three population based studies mentioned the prevalence of subjects with NAFLD who were diagnosed with the metabolic syndrome among the general population<sup>[8,35,36]</sup>. In these studies, the prevalence of the metabolic syndrome among subjects with NAFLD was 17% to 36% depending on gender and the criteria used. The reported prevalence was similar to ours.

There has been no report regarding the sensitivity and specificity of the metabolic syndrome for detecting NAFLD. Among the criteria for metabolic syndrome, the criterion of abdominal circumference had high sensitivity in obese women. However, it had low sensitivity (36.3%) in non-obese women and was very low (5.8%) in non-obese men and low (55.3% in obese men. Other than the criterion of abdominal circumference, none of the sensitivities exceeded 60%. In our study, the specificity

of elevated ALT (ALT > 30 IU/L) was 90.6% in men and 98.0% in women. However, the sensitivity was as low as 47.9% in men and 17.7% in women. The specificity of elevated ALT was significantly higher among obese subjects than among non-obese subjects, and sensitivity was higher among obese subjects than among non-obese subjects.

When we investigated the predictability of each component of metabolic syndrome such as abdominal circumference, fasting blood sugar, serum lipid, and blood pressure, each component had high specificity but low sensitivity, similar to elevated ALT. Therefore, we defined it as screening positive for NAFLD, when subjects satisfied at least one criterion of metabolic syndrome; the sensitivity was 84.8% in men and 86.6% in women. Additionally, we defined it as positive when subjects satisfied at least one criterion of metabolic syndrome or elevated ALT. The sensitivity of “at least 1 criterion or elevated ALT” was 90.4% in men and 87.4% in women. However, the specificity of “at least 1 criterion or elevated ALT” was lower -44%-63%.

The result of our study means that we could identify NAFLD effectively in epidemiological study by modifying the usage of the criteria for metabolic syndrome. It is clinically critical evidence that a large part of patients with NAFLD were not diagnosed with the metabolic syndrome, when we used today's definition for the metabolic syndrome. However, our subject population consisted only of Japanese, thus, the generalizability of our study to non-Japanese populations is uncertain. It is one of our study limitations that we used abdominal ultrasonography for diagnosing NAFLD, although the validation ultrasonography had a sensitivity of 91.7% and a specificity of 100%<sup>[24]</sup>.

## COMMENTS

### Background

It is well known that non-alcoholic fatty liver disease (NAFLD) is associated with the metabolic syndrome and patients with NAFLD tend to also have the metabolic syndrome.

### Research frontiers

The impact of overlap between NAFLD and the metabolic syndrome has not been evaluated yet.

### Innovations and breakthroughs

It is clinically critical evidence that a large number of patients with NAFLD were not diagnosed with the metabolic syndrome in a healthy Japanese population.

### Applications

The authors could identify NAFLD effectively by modifying the usage of the criteria for metabolic syndrome.

### Peer review

It is a relatively large population study. The conclusion is consistent with recent observations showing the dissociation between NAFLD and other parameters of metabolic syndrome. The readers of this journal will be interested in the findings of this study.

(PPIs) with H<sub>2</sub>-receptor antagonists (H<sub>2</sub>RAs) plus prokinetics (Proks) for dysmotility-like symptoms in functional dyspepsia (FD).

**METHODS:** Subjects were randomized to receive open-label treatment with either rabeprazole 10 mg od ( $n = 57$ ) or famotidine 10 mg bid plus mosapride 5 mg tid ( $n = 57$ ) for 4 wk. The primary efficacy endpoint was change (%) from baseline in total dysmotility-like dyspepsia symptom score. The secondary efficacy endpoint was patient satisfaction with treatment.

**RESULTS:** The improvement in dysmotility-like dyspepsia symptom score on day 28 was significantly greater in the rabeprazole group ( $22.5\% \pm 29.2\%$  of baseline) than the famotidine + mosapride group ( $53.2\% \pm 58.6\%$  of baseline,  $P < 0.0001$ ). The superior benefit of rabeprazole treatment after 28 d was consistent regardless of *Helicobacter pylori* status. Significantly more subjects in the rabeprazole group were satisfied or very satisfied with treatment on day 28 than in the famotidine + mosapride group ( $87.7\%$  vs  $59.6\%$ ,  $P = 0.0012$ ). Rabeprazole therapy was the only significant predictor of treatment response ( $P < 0.0001$ ), defined as a total symptom score improvement  $\geq 50\%$ .

**CONCLUSION:** PPI monotherapy improves dysmotility-like symptoms significantly better than H<sub>2</sub>RAs plus Proks, and should be the treatment of first choice for Japanese FD.

## INTRODUCTION

Functional dyspepsia (FD) is a condition characterized by persistent upper abdominal symptoms in the absence of any causative organic disease<sup>[1]</sup>. It is thought to be caused by a combination of different factors, including dysmotility or hypersensitivity of the gastrointestinal (GI) tract, gastric acid secretion, inflammation of the gastric mucosa, altered sympathetic or parasympathetic activity, altered secretion of GI hormones, and psychological factors<sup>[2,3]</sup>. Treatments vary according to the symptoms, and include gastroprokinetic agents, suppressors of gastric acid secretion, antidepressants, anxiolytics and Chinese herbal medicines. Although it has been shown that gastric acid secretion is normal in patients with FD<sup>[4]</sup>, a subset of these patients will benefit from strong acid suppression by a proton pump inhibitor (PPI)<sup>[5]</sup>. Inhibitors of acid secretion are therefore widely prescribed to patients with FD worldwide. Although treatment with acid suppression produces symptom relief in a proportion of patients with FD, this effect has not been reported consistently in all studies<sup>[6-8]</sup>. A Japanese study surveyed the prescribing habits of primary care physicians for functional GI symptoms and evaluated the efficacy and indications of the medications prescribed<sup>[9]</sup>. It was found that H<sub>2</sub>-receptor antagonists (H<sub>2</sub>RAs) are the treatment of first choice for ulcer-like symptoms such as epigastric pain, and prokinetics (Proks) for dysmotility-like symptoms such as epigastric discomfort, heaviness, and bloating. In other words, Japanese primary care physicians prefer H<sub>2</sub>RA + prokinetic combination therapy for FD symptoms.

For FD patients with at least mild heartburn and/or regurgitation at baseline, omeprazole is associated with higher treatment success rates at 4 wk than ranitidine, cisapride and placebo<sup>[10]</sup>. In those patients who have either no or minimal heartburn and/or regurgitation at baseline, omeprazole and ranitidine are superior to placebo, although no significant difference is seen between omeprazole and ranitidine<sup>[10]</sup>. The question of whether more effective acid suppression is efficacious in Japanese patients with FD has yet to be adequately tested.

It is reasonable to think that H<sub>2</sub>RAs provide adequate relief for FD symptoms in Japanese patients, who have a higher rate of *Helicobacter pylori* (*H. pylori*) infection than their western counterparts, as well as lower levels of gastric acid secretion<sup>[11]</sup>.

Complete relief of symptoms is significantly more common with omeprazole than with placebo in subgroups of

patients with ulcer-like and reflux-like dyspepsia, whereas, as might be expected, there is no indication of benefit with omeprazole in patients with dysmotility-like dyspepsia<sup>[5]</sup>. In addition, meta-analyses suggest that H<sub>2</sub>RA and Proks are superior to placebo in non-ulcer dyspepsia (NUD)<sup>[12,13]</sup>.

In this study, we concentrated on dysmotility-like symptoms in patients with FD, and compared the efficacy of PPI monotherapy and combination therapy with H<sub>2</sub>RAs and Proks, which is widely prescribed by Japanese primary care physicians for FD symptoms.

## MATERIALS AND METHODS

### Selection of patients

This study was a randomized open-label trial conducted in three hospitals (Moriguchi Keijinkai Hospital, Osaka Saiseikai Nakatsu Hospital, and Arisawa General Hospital) and nine general medical clinics (Murotani Clinic, Majima Clinic, Morikawa Clinic, Hashimoto Clinic, Kiyota Clinic, Arisawa General Hospital, Amemoto Clinic, Isowa Clinic, and Mii Clinic) in Japan from January 2009 until April 2010.

The subjects were patients of at least 18 years of age with at least 1 mo of dyspepsia symptoms and no clinically significant findings at endoscopy. The main exclusion criteria were: (1) history of erosive esophagitis, peptic ulcer disease, GI malignancy, primary esophageal motility disorder, previous upper GI surgery; (2) maintenance treatment with a PPI or H<sub>2</sub>RA within 2 wk of enrollment; and (3) severe concurrent disease. PPI, H<sub>2</sub>RA and Prok use were not permitted during the 14 d prior to endoscopy, nor during the study. Nonsteroidal anti-inflammatory drugs, acetylsalicylic acid or steroids were not permitted at any time during the study. The study protocol was approved by the relevant Institutional Review Board and/or an Independent Ethics Committee, and informed written consent was obtained from each participating subject.

### Study design

The investigators referred each enrolled subject for esophagogastroduodenoscopy. After endoscopy, eligible patients underwent a validated <sup>13</sup>C urea breath test to determine their *H. pylori* status. Subjects were randomly allocated to receive one of the following treatments for 4 wk: (1) rabeprazole 10 mg *od* (PPI); or (2) famotidine 10 mg *bid* plus mosapride 5 mg *tid* (H<sub>2</sub>RA + Prok). Group allocations were assigned in equal numbers using a central computer-generated randomization list stratified for each participating institution. Subject compliance was assessed by counting the returned medication. Subjects were considered to have complied with treatment if they took at least 75% of the dispensed medication. Subjects attended their clinic at randomization and after 4 wk of treatment.

### Symptom assessment

Subjects were asked to assess their dyspepsia symptoms at baseline and after 3 d, 7 d, 14 d and 28 d of treatment using a self-completed questionnaire for dyspepsia symp-

toms. Dysmotility-like dyspepsia symptoms were assessed using five questions (upper abdominal bloating, postprandial fullness, early satiation, belching, vomiting/nausea), and each response was graded on a five-point frequency scale as follows: 0, never; 1, occasionally; 2, sometimes; 3, often; 4, always. The scores for each question were totaled to give the total symptom score for dysmotility-like dyspepsia symptoms. The total symptom scores at each assessment time point were then expressed as a percentage of the baseline total symptom score.

### Subject satisfaction

After 14 d and 28 d of treatment, subject satisfaction was evaluated using a four-grade scale as follows: very satisfied (symptoms disappeared); satisfied (symptoms improved considerably); somewhat satisfied (symptoms improved somewhat); unsatisfied (no improvement or symptoms worse).

### Endpoints

The primary efficacy endpoint was the change (%) from baseline in total dysmotility-like dyspepsia symptom score. The secondary efficacy endpoint was subject satisfaction.

### Sample size

The sample size calculation was based on the anticipated difference in symptom improvement rates between the PPI and H<sub>2</sub>RA + Prok groups. Due to the lack of clinical trials of H<sub>2</sub>RA + Prok combination therapy, we based our calculations of the sample size on the results of comparative trials of PPIs *vs* Proks.

The estimated success rate after 4 wk treatment was 23.7% for omeprazole, and 7.5% for cisapride<sup>[10]</sup>. Assuming a two-tailed  $\alpha$  error rate of 0.05 and a power of 80%, with a 30% dropout rate during screening, 77.5 patients were required for each treatment arm.

### Statistical analysis

Data are presented as mean  $\pm$  SD. The intention-to-treat analysis included all randomized subjects. A subject who withdrew at any time was considered a dropout. We used the Wilcoxon single rank test for paired intra-individual comparisons, the Mann-Whitney *U* test for comparisons of continuous variables, and the  $\chi^2$  test for comparisons of categorized variables between the two treatment groups. In addition, we stratified primary endpoint results for differences between treatment groups according to *H. pylori* status. We performed multiple logistic regression analysis to determine factors (age, sex, *H. pylori* status, and baseline dysmotility-like dyspepsia symptom score) associated with treatment response (defined as change in total dysmotility-like dyspepsia symptom score of  $\geq$  50% after 28 d of treatment).  $P < 0.05$  was considered to signify statistical significance for all analyses.

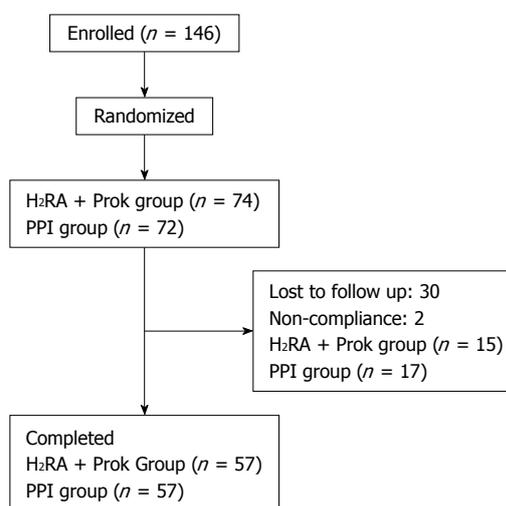

## RESULTS

A total of 146 patients were randomized. Thirty-two patients were excluded in the follow-up period (30 lost to follow-up, two for non-compliance), leaving 114 patients

**Table 1** Baseline demographic characteristics and total symptom scores for study completers

	H <sub>2</sub> RA + Prok ( <i>n</i> = 57)	PPI ( <i>n</i> = 57)	<i>P</i> value
Age (mean $\pm$ SD, yr)	51.5 $\pm$ 14.8	52.9 $\pm$ 13.8	0.6120
Sex (male/female)	17/40	12/45	0.3899
<i>Helicobacter pylori</i> infection (%)	43.8	43.8	> 0.9999
Symptom scores			
Upper abdominal bloating	1.6 $\pm$ 1.2	1.8 $\pm$ 1.3	0.6160
Postprandial fullness	2.1 $\pm$ 1.2	2.0 $\pm$ 1.2	0.7747
Early satiation	1.7 $\pm$ 1.3	1.3 $\pm$ 1.2	0.1934

Vomiting/nausea	1.5 $\pm$ 1.3	1.4 $\pm$ 1.3	0.8361
Total symptom score (dysmotility-like dyspepsia symptoms)	8.6 $\pm$ 3.9	8.2 $\pm$ 4.7	0.5330

PPI: Proton pump inhibitor. H<sub>2</sub>RA: H<sub>2</sub>-receptor antagonist; Prok: Plus prokinetic.

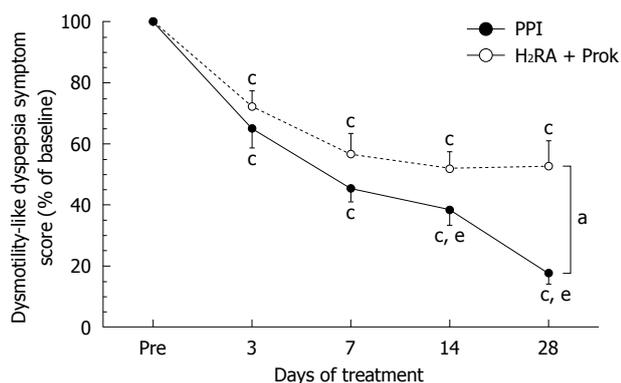

**Figure 1** Study flow chart. This study enrolled 146 subjects with functional dyspepsia and, after excluding 30 subjects for non-attendance and two for non-compliance, 57 subjects in each treatment group completed the study.

for inclusion in the analysis. Fifty-seven patients were randomized to receive PPI treatment, and 57 to receive H<sub>2</sub>RA + Prok treatment (Figure 1). Baseline demographic characteristics and symptom scores of the patients who completed the treatment period are given in Table 1. There were no significant differences between the characteristics of the two treatment groups at baseline.

### Change in dysmotility-like dyspepsia symptom score

No significant differences were seen between groups in the change in dysmotility-like dyspepsia symptom score from baseline to 3 d or 7 d of treatment. After 28 d of treatment, the change in symptom score was significantly greater in the PPI group (22.5%  $\pm$  29.2% of baseline) than in the H<sub>2</sub>RA + Prok group (53.2%  $\pm$  58.6% of baseline) ( $P < 0.0001$ ), indicating greater improvement in symptoms with PPI treatment (Figure 2). A significant improvement in total symptom score was seen over time in both groups, but in the H<sub>2</sub>RA + Prok group, the im-

**Figure 2** Change in dysmotility-like dyspepsia symptom score over time. Significantly greater improvement was seen in dysmotility-like dyspepsia symptom score on day 28 of treatment in the proton pump inhibitor (PPI) group than in the H<sub>2</sub>-receptor antagonist (H<sub>2</sub>RA) + prokinetic (Prok) group. No significant additional symptomatic improvement was seen after day 7 of H<sub>2</sub>RA + Prok treatment, whereas further symptomatic improvements were seen over time in the PPI group. <sup>a</sup>*P* < 0.05, PPI vs H<sub>2</sub>RA + Prok; <sup>c</sup>*P* < 0.05 vs pre-Rx in each group; <sup>e</sup>*P* < 0.05 vs 7 d Rx in each group.

Improvements in total symptom score on days 14 and 28 were not significantly greater than at day 7, whereas in the PPI group, the improvements in total symptom score at day 14 (38.4% ± 37.8% of baseline, *P* = 0.0034) and day 28 (*P* < 0.0001) were both significantly greater than on day 7 (45.1% ± 33.8% of baseline) (Figure 2).

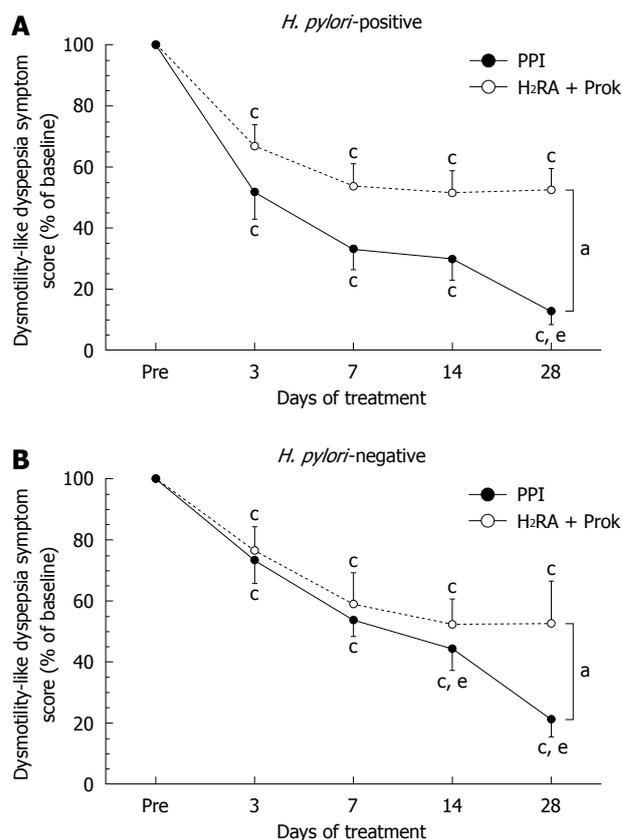

### Change in dysmotility-like dyspepsia symptom score according to *H. pylori* status

Among *H. pylori*-positive subjects, a significantly greater improvement in total symptom score was seen in the PPI group (13.4% ± 26.2% of baseline) than in the H<sub>2</sub>RA + Prok group (53.4% ± 34.7% of baseline) (*P* < 0.007) by the end of the treatment period. Significant symptomatic improvement was seen over time in both treatment groups, although in the H<sub>2</sub>RA + Prok group, no further improvement was observed after day 7 (35.7% ± 31.6% of baseline). In the PPI group, there was no significant difference between the changes in total symptom score for days 7 and 14, although there was a statistically significant difference between days 7 and 28 (*P* = 0.0277) (Figure 3A).

Among *H. pylori*-negative subjects, a significantly greater improvement in total symptom score was seen in the PPI group (24.1% ± 31.7% of baseline) than in the H<sub>2</sub>RA + Prok group (53.1% ± 72.2% of baseline, *P* < 0.0001) on day 28. Significant symptomatic improvement was seen over time in both treatment groups, although the improvements seen in the H<sub>2</sub>RA + Prok group on days 14 and 28 were not significantly superior to those observed on day 7. In the PPI group, the reductions in total symptom score on days 14 (44.2% ± 42.0% of baseline, *P* = 0.0177) and 28 (*P* = 0.0002) were both significantly greater than on day 7 (52.4% ± 34.1% of baseline) (Figure 3B).

### Subject satisfaction on days 14 and 28 of treatment

Although no significant difference was seen between

**Figure 3** Change in dysmotility-like dyspepsia symptom score over time according to *Helicobacter pylori* status. Significantly greater symptomatic improvement was seen in the proton pump inhibitor group than in the H<sub>2</sub>-receptor antagonist (H<sub>2</sub>RA) + prokinetic (Prok) group after 28 d of treatment, regardless of *Helicobacter pylori* (*H. pylori*) status. No additional significant symptomatic improvement was seen after day 7 of H<sub>2</sub>RA + Prok treatment, regardless of *H. pylori* status. <sup>a</sup>*P* < 0.05, PPI vs H<sub>2</sub>RA + Prok; <sup>c</sup>*P* < 0.05 vs pre-Rx in each group; <sup>e</sup>*P* < 0.05 vs 7 d Rx in each group.

the groups on day 14, the proportion of subjects who were satisfied or very satisfied with their treatment was significantly higher in the PPI group than in the H<sub>2</sub>RA + Prok group on day 28 (87.7% vs 59.6%, *P* = 0.0012). No significant increase was seen in subject satisfaction in the H<sub>2</sub>RA + Prok group between days 14 and 28, whereas a significant increase was seen in the proportion of subjects in the PPI group answering satisfied or very satisfied between day 14 (63.2%) and 28 (*P* = 0.0042) (Figure 4).

### Factors associated with treatment response

In this study, treatment response was defined as an improvement in dysmotility-like dyspepsia symptom score of ≥ 50% after 28 d of treatment. The only factor identified by logistic regression analysis as a positive predictor of treatment response was PPI therapy (Table 2).

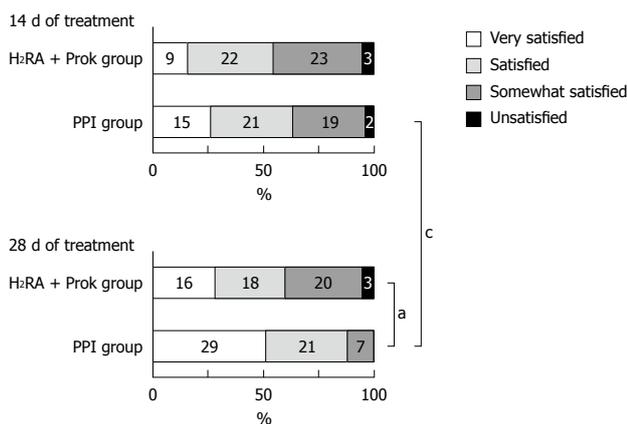

## DISCUSSION

The Rome III criteria define FD as “the chronic presence of one or more dyspepsia symptoms (bothersome postprandial fullness, early satiation, epigastric pain, epigastric burning) that are considered to originate from the

**Table 2** Multiple logistic regression analysis of treatment response

Variable	Estimated OR	95% CI	P value
Age (yr)	0.999	0.962-1.036	0.9493
Sex: male	0.853	0.312-2.332	0.7563
<i>Helicobacter pylori</i> infection	0.521	0.191-1.419	0.2019
Treatment: PPI	9.055	3.231-25.376	< 0.0001
Dysmotility-like symptom score	1.062	0.940-1.200	0.3368

OR: Odds ratio; PPI: Proton pump inhibitor.

**Figure 4** Subject satisfaction after 14 d and 28 d of treatment. Subject satisfaction was significantly higher in the proton pump inhibitor (PPI) group than in the H<sub>2</sub>-receptor antagonist (H<sub>2</sub>RA) + prokinetic (Prok) group on day 28 of treatment. No significant increase in subject satisfaction was seen in the H<sub>2</sub>RA + Prok group between days 14 and 28, whereas a significant increase was seen in the PPI group between days 14 and 28. <sup>a</sup>*P* < 0.05, PPI vs H<sub>2</sub>RA + Prok; <sup>c</sup>*P* < 0.05 vs 14 d Rx.

gastroduodenal region, with no evidence of structural disease (including at upper endoscopy) that is likely to explain the symptoms<sup>[14,15]</sup>. FD is a common condition<sup>[14,15]</sup>, with considerable adverse impact on quality of life<sup>[16]</sup>, and represents a serious problem in everyday clinical practice. Patients with FD present with a variety of symptoms<sup>[17,18]</sup>, so based on the symptom profile, they may be prescribed gastroprokinetic agents, suppressors of gastric acid secretion, antidepressants, anxiolytics or Chinese herbal medicines<sup>[19]</sup>. A Japanese survey of the prescribing habits of primary care physicians for upper GI symptoms has found that H<sub>2</sub>RAs are prescribed for epigastric pain and heartburn, and Proks for epigastric discomfort, nausea and loss of appetite<sup>[9]</sup>. In other words, H<sub>2</sub>RAs rather than PPIs are prescribed for epigastric pain syndrome<sup>[1]</sup>, characterized by the two symptoms of epigastric pain and epigastric burning, unrelated to meals and considered mainly related to gastric acid. Proks are widely prescribed for postprandial distress syndrome<sup>[1]</sup>, characterized by the two symptoms of postprandial fullness and early satiation, and considered to be strongly related to dysmotility of the GI tract; in particular, gastric accommodation of adaptive relaxation. H<sub>2</sub>RA + Prok combination therapy is widely prescribed in Japan, where dyspepsia is not a

recognized diagnosis for insurance purposes.

It has recently become clear that gastric acid secretion is strongly associated with the onset of dysmotility-like symptoms. Lee *et al*<sup>[20]</sup> have examined the influence of acid on gastric hypersensitivity and motility in healthy subjects, and have found that duodenal acidification significantly induces gastric hypersensitivity and impairs gastric motility. Compared with saline, infusion of acid into the duodenum causes not only ulcer reflux symptoms such as heartburn, but also dysmotility-like symptoms such as epigastric discomfort, belching and abdominal bloating<sup>[20]</sup>. When Miwa *et al*<sup>[21]</sup> infused acid into the stomach of Japanese subjects, they induced a variety of dyspeptic symptoms, with no significant change in acid-reflux-related symptoms such as heartburn and epigastric pain, but a significant increase in dysmotility-like symptoms such as epigastric discomfort, stomach fullness, nausea and belching. Samsom *et al*<sup>[22]</sup> have reported that decreased acid clearance and increased sensitivity to acid in patients with dyspepsia may lead to dyspeptic symptoms. There have in fact been a number of recent studies reporting the effectiveness of PPIs<sup>[7]</sup> and H<sub>2</sub>RAs<sup>[23]</sup> in the treatment of FD. Empirical omeprazole therapy induces symptom improvement in a higher proportion of patients with uninvestigated dyspepsia (defined as epigastric pain or discomfort with or without heartburn or regurgitation) than ranitidine or cisapride does, but this effect is more marked in patients with gastroesophageal reflux disease<sup>[10]</sup>. The prevalence of pathological pH monitoring (4%-6% of time at pH < 4) is significantly higher in FD patients with heartburn than those without<sup>[17]</sup>. In other words, PPIs are more effective than H<sub>2</sub>RAs in the treatment of FD associated with heartburn and regurgitation.

It is unclear, however, how important suppression of acid secretion is in Japanese patients, who have a high prevalence of *H. pylori* infection and low levels of gastric acid secretion<sup>[11]</sup>. A Japanese clinical trial found that H<sub>2</sub>RA therapy was more effective than mosapride for treatment of FD<sup>[24]</sup>, suggesting that suppression of gastric acid secretion by an H<sub>2</sub>RA may be sufficient to treat FD in Japanese patients, with no need for a PPI. In this study, we compared PPI monotherapy with H<sub>2</sub>RA + Prok combination therapy; the therapy most commonly prescribed by Japanese clinicians<sup>[9]</sup>. In consideration of the superior acid secretion suppression of PPIs over H<sub>2</sub>RAs, we combined an H<sub>2</sub>RA with a Prok, and examined only dysmotility-like symptoms, considered less responsive to PPI therapy.

Our results showed no differences between treatment groups for changes in dysmotility-like dyspepsia symptom score on days 3 and 7 of treatment, but significantly greater symptom improvement was seen in the PPI group than the H<sub>2</sub>RA + Prok group on days 14 and 28 of treatment. The proportion of subjects reporting that they were satisfied or very satisfied was significantly higher in the PPI group than in the H<sub>2</sub>RA + Prok group on day 28. PPI therapy was the only significant predictor

of treatment response, defined as a total symptom score improvement of  $\geq 50\%$ .

In a recent meta-analysis of PPI treatment for FD, the dysmotility-like subgroup did not respond to PPI therapy, unlike the reflux and ulcer-like subgroup<sup>[25]</sup>. The severity of heartburn at baseline in FD patients influences treatment response to PPI or H<sub>2</sub>RA therapy<sup>[10]</sup>. We assessed heartburn symptoms at baseline in a separate study, finding no difference between groups in the pretreatment heartburn symptom score (data not shown). Our results suggest that powerful suppression of acid secretion by PPIs is also important in the treatment of dysmotility-like symptoms in Japanese patients with FD. We saw similar symptom score improvements in both groups until day 7 of treatment. This may represent a placebo response, because it is well known that the placebo response can be substantial in trials of GI disorders, including FD<sup>[10]</sup>. There have been reports of a placebo effect until day 7 of treatment with a PPI<sup>[26]</sup>, and of the need for a 7-d run-in period to minimize the placebo effect in FD clinical trials<sup>[27-29]</sup>, so a similar placebo response lasting until day 7 of treatment was also possible in this study. The absence of any further improvement in dysmotility-like dyspepsia symptoms between day 7 and days 14 or 28 in the H<sub>2</sub>RA + Prok group, and the lack of significant change in subject satisfaction rates from day 14 to 28, indicates the development of H<sub>2</sub>RA tolerance<sup>[30]</sup>.

Stratifying the study sample by *H. pylori* status showed that significantly better symptom improvement was seen in the PPI group than the H<sub>2</sub>RA + Prok group in both *H. pylori*-positive and -negative subjects. No influence of *H. pylori* status was seen in either treatment group in our study. In the studies by Talley *et al.*<sup>[5]</sup>, no significant difference was seen in the rate of complete symptom resolution after 28 d of treatment between *H. pylori*-positive and -negative subjects in the ulcer-like, reflux-like, or dysmotility-like symptom subgroups in either treatment arm, although these were only exploratory analyses. Although *H. pylori* status did not significantly influence the response to omeprazole, this does not exclude the possibility of a small true difference between *H. pylori*-positive and -negative patients in the effect of acid inhibition on FD. Intra-gastric pH is higher in patients taking a PPI who are infected with *H. pylori*<sup>[31]</sup>. PPI therapy may therefore be more effective in *H. pylori*-positive patients with NUD, as one study has suggested<sup>[28]</sup>. Pooling all trial data suggests that symptom responses are similar in *H. pylori*-positive and -negative patients with NUD. *H. pylori* status is unlikely to have a clinically important impact on the efficacy of treatments in this patient group.

In this study, symptoms improved over time regardless of *H. pylori* status in the PPI group, whereas no further symptom improvement was seen in the H<sub>2</sub>RA + Prok group after day 7 of treatment in both *H. pylori*-positive and -negative subjects, indicating tolerance to treatment. Loss of the suppressive effect on acid secretion by H<sub>2</sub>RAs has been reported in *H. pylori*-negative patients as the duration of treatment increases<sup>[32]</sup>, whereas in this

study tolerance was seen from day 7 of treatment in the H<sub>2</sub>RA + Prok group.

Limitations of this study include the small number of subjects and the fact that it was not a placebo-controlled trial. Consideration of the Japanese medical system tells us that clinical trials of treatments for FD, a condition not covered by medical insurance, conducted with the participation of general medical clinics will be limited in scope. Nevertheless, this is the first published report of a randomized comparative trial of PPI monotherapy and H<sub>2</sub>RA + Prok combination therapy in the treatment of FD in Japanese subjects.

We demonstrated that, even in Japan with its high proportion of *H. pylori*-positive patients, PPI monotherapy significantly improves not only ulcer and reflux-like symptoms, but also dysmotility-like symptoms, better than H<sub>2</sub>RA + Prok combination therapy. In particular, tolerance to H<sub>2</sub>RA + Prok combination therapy was seen regardless of *H. pylori* status. The prevalence of *H. pylori* infection is expected to decline in Japan in the future<sup>[33]</sup>, leading to increased gastric acid secretion, so suppression of acid secretion will likely become even more important. The American College of Gastroenterology guidelines for the management of dyspepsia recommend a PPI as the treatment of first choice in regions with a low prevalence of *H. pylori* infection, with investigations and other therapies for those who fail to respond<sup>[29]</sup>. In Japan, where the prevalence of *H. pylori* infection remains high, upper GI endoscopy is considered mandatory for the exclusion of malignancy. Powerful suppression of acid secretion, such as a PPI provides, is the most effective therapy for treatment of all dyspeptic symptoms in Japanese patients, both ulcer- and reflux-like and dysmotility-like symptoms. Of particular interest is our finding that PPI therapy is useful in the treatment of dysmotility-like symptoms, usually considered less responsive to PPIs. In other words, dysmotility-like symptoms of FD are also an acid-related disorder, for which suppression of acid secretion is the most effective therapy. PPIs are extremely effective in the treatment of all symptoms of FD, and should be the treatment of first choice in Japanese patients with FD.

## COMMENTS

### Background

Many people suffer from functional dyspepsia (FD). The disease has a substantial negative effect on quality of life, therefore, daily care is of the utmost importance. However, because there are many causes of FD, including gastrointestinal motility disorders and hypersensitivity of the digestive tract, gastric acid secretion, inflammation of the mucous membrane of the stomach, nervous system and digestive tract hormone disorders, and psychological factors, no method of treatment has been established.

### Research frontiers

It has recently been clarified that gastric acid secretion plays a major role in the onset of FD symptoms. In Japan, however, where there are many *Helicobacter pylori* (*H. pylori*)-positive patients, epigastric pain, epigastric burning and other acid-related symptoms are treated with acid-secretion blockers. In contrast, dysmotility-like symptoms such as painful stomach heaviness after eating and soon feeling full are mainly treated with prokinetic agents and/or antiulcer agents, and the significance of acid secretion suppression is not clear. For this reason, we conducted a prospective randomized treatment study to examine

the importance of acid-suppressing drugs for the treatment of various FD symptoms.

### Innovations and breakthroughs

Regardless of whether cases were *H. pylori*-positive or -negative, the improvement rate for dysmotility-like symptoms as well as ulcer and acid-reflux-related symptoms in a proton pump inhibitor (PPI) single therapy group was significantly better compared to a group concomitantly administered histamine H<sub>2</sub> receptor antagonists (H<sub>2</sub>RAs) and prokinetic drugs (Proks). Logistic analysis (multivariable analysis) of factors related to improvements in dysmotility-like symptoms also showed that PPI therapy was the only significant factor. Patient satisfaction was also significantly higher in the PPI single therapy group than in the H<sub>2</sub>RA and Prok groups. In other words, in Japan, as well as other countries, regardless of whether a patient is *H. pylori*-positive or -negative, the importance of acid secretion suppression for the treatment of not only ulcer and acid-reflux-related symptoms but also digestive motility disorder symptoms has been established.

### Applications

It is thought that the *H. pylori* infection rate in Japan will gradually decrease. Assuming this will lead to more patients with increased acid secretion, acid secretion suppression will become an increasingly important issue. It has been concluded that, regardless of whether a patient is *H. pylori*-positive or -negative, PPI therapy is extremely effective as a first-choice treatment for not only ulcer and acid-reflux-related symptoms but also dysmotility-like symptoms, in other words, for all FD symptoms.

### Terminology

In the Rome III classification, FD is defined as "one or more of the chronic symptoms of painful postprandial fullness, early feeling of satiety, epigastric pain and epigastric burning for which no causal organic disease is observed during endoscopic and other examinations". This definition is divided into the subcategories of epigastric pain syndrome, indicated by the two symptoms of epigastric pain related to dietary intake and epigastric burning related to gastric acid, and postprandial distress syndrome (PDS), indicated by the two so-called dysmotility-like symptoms of early satiation and fullness. Many cases of FD are thought to be due to PDS. In Japan, Proks, drugs that improve gastrointestinal motility, are the first-choice treatment for dysmotility-like symptoms. *H. pylori*, a bacterium that exists in the mucous membrane of the stomach, is thought to cause stomach and duodenal ulcers, and stomach cancer. In *H. pylori*-positive patients, the bacterium causes chronic atrophic gastritis, progressing to gastric cancer, and low gastric acid output. The *H. pylori*-positive rate in Japan is tending to decrease, which could result in more Japanese patients with excessive gastric acid output.

### Peer review

A good paper and can be accepted for publication. Only problem is the number of patients recruited for the study was too low.

### Abstract

**AIM:** To evaluate the noninvasive parameters and hepatic fibrosis scores in obese children with nonalcoholic fatty liver disease (NAFLD).

**METHODS:** A total of 77 children diagnosed with NAFLD *via* liver biopsy were included and divided into 2 subgroups according to the histopathologic staging of hepatic fibrosis: mild (stage 0-1) *vs* significant fibrosis (stage 2-4). Clinical and laboratory parameters were evaluated in each patient. The aspartate aminotransferase (AST)/alanine aminotransferase (ALT) ratio, AST/platelet ratio index (APRI), PGA index, Forns index, FIB-4, NAFLD fibrosis score, and pediatric NAFLD fibrosis index (PNFI) were calculated.

**RESULTS:** No clinical or biochemical parameter exhib-

ited a significant difference between patients with mild and significant fibrosis. Among noninvasive hepatic fibrosis scores, only APRI and FIB4 revealed a significant difference between patients with mild and significant fibrosis (APRI:  $0.67 \pm 0.54$  *vs*  $0.78 \pm 0.38$ ,  $P = 0.032$  and FIB4:  $0.24 \pm 0.12$  *vs*  $0.31 \pm 0.21$ ,  $P = 0.010$ ). The area under the receiving operating characteristic curve of FIB4 was 0.81, followed by Forns index (0.73), APRI (0.70), NAFLD fibrosis score (0.58), AST/ALT ratio (0.53), PGA score (0.45), and PNFI (0.41).

**CONCLUSION:** APRI and FIB4 might be useful noninvasive hepatic fibrosis scores for predicting hepatic fibrosis in children with NAFLD.

Noninvasive Parameters and hepatic fibrosis scores in children with nonalcoholic fatty liver disease. *World J Gastroenterol* 2012; 18(13): 1525-1530 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i13/1525.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i13.1525>

### INTRODUCTION

The disease spectrum of nonalcoholic fatty liver disease (NAFLD) ranges from simple steatosis to nonalcoholic steatohepatitis (NASH), fibrosis, and cirrhosis; NASH progresses towards cirrhosis, even in children<sup>[1,2]</sup>. Therefore, accurate diagnosis and early detection of hepatic fibrosis are required in obese children suspicious of NAFLD.

Percutaneous liver biopsy is the gold standard for the diagnosis of NASH<sup>[3]</sup>. However, histopathologic investigation has some limitations because of its invasiveness and high costs, especially in children; moreover, the histopathologic findings of NAFLD in children are somewhat different from those in adults, revealing portal inflammation and portal fibrosis mainly in pediatric NASH in contrast to lobular inflammation, perisinusoidal fibrosis, ballooning, and Mallory's hyaline in adult NASH<sup>[4,5]</sup>.

Noninvasive markers of hepatic fibrosis and noninvasive hepatic fibrosis scores have been evaluated in previous studies, mostly in adult patients with NAFLD<sup>[6]</sup>. Although pediatric NAFLD shows peculiar histopathologic features as described above<sup>[4,5]</sup>, there have been only limited studies of noninvasive biochemical markers of hepatic fibrosis related to NAFLD in pediatric populations<sup>[7-10]</sup>, and no validation studies in children on the previously suggested noninvasive hepatic fibrosis scores excluding 1 study on the enhanced liver fibrosis panel<sup>[11]</sup>. Only 1 pediatric noninvasive score has been developed up to date<sup>[12]</sup>.

Therefore, the present study aimed to evaluate the noninvasive clinical and laboratory parameters and noninvasive hepatic fibrosis scores indicating the presence of hepatic fibrosis and its severity in obese children with NAFLD.

## MATERIALS AND METHODS

A total of 77 obese children with NAFLD under the age of 18 years who visited the Pediatric Obesity Clinic were included and divided into 2 subgroups according to the grading and staging of NAFLD. Obesity was defined as a body mass index (BMI) value higher than the 95th percentile for the child's age and sex, and overweight as a BMI between the 85th and 95th percentiles. NAFLD was diagnosed on the basis of histopathologic findings compatible with NAFLD on liver biopsy<sup>[13]</sup>. This study was approved by the Institutional Review Board of the Seoul National University Bundang Hospital.

### Laboratory tests

Serum levels of fasting glucose, insulin, total cholesterol, TGs, high-density lipoprotein cholesterol, low-density lipoprotein cholesterol, and apoprotein A1 and B levels were measured after a 12-h fast at the same time of liver biopsy. Insulin resistance was determined by the homeostatic model assessment of insulin resistance. Serum aspartate aminotransferase (AST), alanine aminotransferase (ALT), total bilirubin, albumin,  $\gamma$ -glutamyl transpeptidase ( $\gamma$ GT), alkaline phosphatase (ALP) levels, prothrombin time (PT), and tumor necrosis factor- $\alpha$  were also measured.

For the differential diagnosis of chronic hepatitis, creatine phosphokinase, lactate dehydrogenase, ammonia, lactate, pyruvate, anti-HAV IgM antibody, HBs antigen and anti-HBs antibody, anti-HCV antibody, EBV VCA IgM antibody, CMV IgM antibody, serum ceruloplasmin, and anti-nuclear antibody were evaluated.

### Radiologic investigations

The presence of fatty liver was evaluated in each patient

using either abdominal sonography or noncontrast abdominal computed tomography (CT). Using abdominal sonography, fatty liver was detected and the degree of fatty liver was defined as mild, moderate, and severe fatty liver<sup>[14]</sup>. Regarding abdominal CT, fatty liver was diagnosed when the difference between CT numbers of the liver and spleen was greater than 10<sup>[15]</sup>.

### Histopathologic examination

Percutaneous needle liver biopsy was performed in all patients. Histopathologic grades of steatosis, lobular and portal inflammation, and hepatocyte ballooning and the histopathologic stages of fibrosis were evaluated in each patient to diagnose NAFLD and to assess the stages of hepatic fibrosis<sup>[16]</sup>. The histological scoring system of Kleiner *et al.*<sup>[13]</sup> was also applied to the liver biopsy specimens to assess the histologic stages of hepatic fibrosis and the NAFLD activity score (NAS). Fibrosis was staged as follows: stage 0: none; stage 1: perisinusoidal or periportal fibrosis (stage 1a: mild perisinusoidal; stage 1b: moderate perisinusoidal; stage 1c: portal/periportal); stage 2: perisinusoidal and portal/periportal fibrosis; stage 3: bridging fibrosis; stage 4: cirrhosis<sup>[14]</sup>.

### Noninvasive hepatic fibrosis scores

The AST/ALT ratio was calculated as the ratio of AST to ALT<sup>[10]</sup>; AST/platelet ratio index (APRI) as follows: (AST level/AST upper level of normal/platelet counts)  $\times$  100<sup>[17]</sup>; PGA index as the sum of 3 scores based on the test results of PT,  $\gamma$ GT activity, and apoprotein A1 and ranged from 0 to 12<sup>[18]</sup>; Forns index as follows:  $[7.811 - 3.131 \times \ln(\text{platelet count}) + 0.781 \times \ln(\gamma\text{GT}) + 3.467 \times \ln(\text{age}) - 0.014 \times \text{cholesterol}]$ <sup>[19]</sup>; FIB-4 as  $(\text{age} \times \text{AST level}/\text{platelet count} \times \sqrt{\text{ALT}})$ <sup>[20]</sup>; NAFLD fibrosis score as follows:  $[-1.675 + 0.037 \times \text{age (years)} + 0.094 \times \text{BMI (kg/m}^2\text{)} + 1.13 \times \text{impaired fasting glucose/diabetes (yes = 1, no = 0)} + 0.99 \times \text{AST/ALT ratio} - 0.013 \times \text{platelet count} - 0.66 \times \text{albumin}]$ <sup>[21]</sup>. Pediatric NAFLD fibrosis index (PNFI) was calculated using a formula suggested by Nobili *et al.*<sup>[12]</sup>.

### Statistical analysis

The results are expressed as mean  $\pm$  SD. The data were analyzed using the SPSS 18.0 software program (SPSS Inc., Chicago, IL, United States). Frequency data were compared using Fisher's exact test for nonparametric analysis. The Mann-Whitney *U* test was used for comparisons of means between 2 groups. Multivariate logistic regression analysis was performed to determine potential variables predicting significant hepatic fibrosis. *P*-values less than 0.05 were considered statistically significant.

Receiver operating characteristic (ROC) curves and the area under the ROC curve (AUROC) were applied to assess and compare the diagnostic accuracy of each noninvasive hepatic fibrosis scores.

## RESULTS

### Patient characteristics

A total of 77 children (M:F = 66:11; mean age 12.2  $\pm$

AC: Abdominal circumference; ALP: Alkaline phosphatase; ALT: Alanine aminotransferase; AST: Aspartate aminotransferase; BMI: Body mass index;  $\gamma$ GT:  $\gamma$ -glutamyl transpeptidase; DBP: Diastolic blood pressure; HDL: High density lipoprotein; HOMA-IR: Insulin resistance determined by homeostasis model assessment; LDL: Low density lipoprotein; NAFLD: Non-alcoholic fatty liver disease; NAS: NAFLD activity score; Ob: Obesity; Ow: Overweight; PT: Prothrombin time; SBP: Systolic blood pressure; TNF- $\alpha$ : Tumor necrosis factor- $\alpha$ .

2.2 years, range 8-18 years) diagnosed as NAFLD were included. The clinical characteristics of children with NAFLD are shown in Table 1.

### Histopathologic findings and hepatic fibrosis in NAFLD

Histopathologic findings of the liver in children with NAFLD are listed in Table 2. Staging for hepatic fibrosis revealed the prevalence of stage 0 (*n* = 12), stage 1A (*n* = 12), stage 1B (*n* = 7), stage 1C (*n* = 20), stage 2 (*n* = 21), and stage 3 (*n* = 5). There was no patient with stage 4 of hepatic histology. Fibrosis stages were grouped into 2 subgroups: mild hepatic fibrosis (stage 0 to 1) (*n* = 51); and significant hepatic fibrosis (stage 2 to 3) (*n* = 26). The histopathologic findings for these 2 groups are compared in Table 2. There were no differences in steatosis, lobular inflammation, and NAS between 2 fibrosis groups (Table 2). Only hepatocyte ballooning was significantly different between the 2 groups (*P* = 0.018) (Table 2).

### Noninvasive clinical and biochemical parameters in children

Clinical data of the patients and the results of laboratory tests for obesity and obesity-related complications are listed in Table 1. None of these noninvasive clinical and

biochemical parameters exhibited a significant difference between the 2 fibrosis groups based on histopathologic findings (Table 1).

### Multivariate logistic regression analysis for hepatic fibrosis in NAFLD

The result of multivariate logistic regression analysis for clinical or biochemical factors to predict significant hepatic fibrosis in children with NAFLD is shown in Table 3.

### Comparisons of noninvasive hepatic fibrosis scores and hepatic fibrosis in children with NAFLD

The results of hepatic fibrosis scores including the AST/ALT ratio, APRI, PGA index, Forns index, FIB4, NAFLD fibrosis score, and PNFI were compared between the 2 groups based on the stage of hepatic fibrosis (Table 2).

Among the hepatic fibrosis scores, APRI and FIB4 revealed statistically significant differences between patients with mild fibrosis and significant fibrosis (APRI, *P* = 0.032; FIB4, *P* = 0.010) (Table 2). The other hepatic fibrosis scores were not significantly different between the 2 groups (AST/ALT ratio, *P* = 0.808; PGA index, *P* = 0.710; Forns index, *P* = 0.097; NAFLD fibrosis score, *P* = 0.532; PNFI, *P* = 0.314) (Table 2).

**Table 2** Comparison of hepatic fibrosis scoring systems between mild fibrosis and significant fibrosis regarding the hepatic histology of children with non-alcoholic fatty liver disease (mean ± SD)

Parameters and hepatic fibrosis scores	Total (n = 77)	Mild fibrosis (stage 0-1) (n = 51)	Significant fibrosis (stage 2-3) (n = 26)	P value
Invasive histopathologic NAFLD scores <sup>1</sup>				
Steatosis (grade 0/1/2/3)	0/13/36/28	0/7/22/22	0/6/14/6	0.085
Inflammation (grade 0/1/2/3)	9/43/25/0	7/29/15/0	2/14/10/0	0.325
Ballooning (grade 0/1/2)	27/33/17	22/21/8	5/12/9	0.018
NAS	4.3 ± 1.4	4.18 ± 1.48	4.46 ± 1.14	0.470
Noninvasive hepatic fibrosis scoring systems				
AST/ALT ratio	0.53 ± 0.22	0.52 ± 0.16	0.57 ± 0.31	0.802
AST/platelet ratio index	0.71 ± 0.49	0.67 ± 0.54	0.78 ± 0.38	0.032
PGA index	3.78 ± 1.80	3.85 ± 1.89	3.68 ± 1.70	0.710
Forns index	-0.94 ± 1.18	-1.06 ± 0.21	-0.69 ± 1.09	0.097
FIB4 score	0.27 ± 0.16	0.24 ± 0.12	0.31 ± 0.21	0.010
NAFLD fibrosis score	-4.95 ± 1.32	-5.07 ± 1.27	-4.73 ± 1.41	0.532
Pediatric NAFLD fibrosis index	7.67 ± 2.48	7.71 ± 2.79	7.61 ± 2.08	0.314

<sup>1</sup>Histopathologic non-alcoholic fatty liver disease (NAFLD) scoring on liver biopsy specimens was based on the definition by Kleiner *et al*<sup>[13]</sup>. ALT: Alanine aminotransferase; AST: Aspartate aminotransferase; NAS: Non-alcoholic fatty liver disease activity score.

**Table 3** Multivariate logistic regression analysis for significant hepatic fibrosis in children with non-alcoholic fatty liver disease

Variables	OR	95% CI	P value
Age	1.357	1.027-1.793	0.032
ALP	1.006	1.000-1.011	0.035

ALP: Alkaline phosphatase; OR: Odds ratio.

**Comparison of the diagnostic accuracy of the hepatic fibrosis scoring systems**

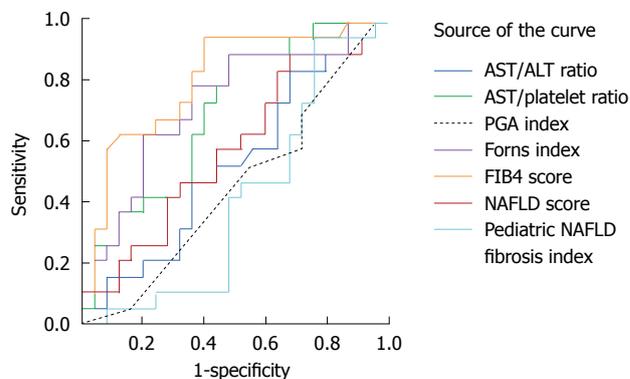

ROC curves of the hepatic fibrosis scoring systems are shown in Figure 1.

When the AUROC of each scoring system was compared, the AUROC of FIB4 was 0.81 (95% CI: 0.68-0.94), followed by the Forns index (AUROC = 0.73, 95% CI: 0.58-0.88), APRI (AUROC = 0.70, 95% CI: 0.55-0.86), NAFLD fibrosis score (AUROC = 0.58, 95% CI: 0.41-0.75), AST/ALT ratio (AUROC = 0.53, 95% CI: 0.35-0.70), PGA score (AUROC = 0.45, 95% CI: 0.28-0.62), and PNFI (AUROC = 0.41, 95% CI: 0.24-0.58).

**DISCUSSION**

Due to the invasiveness of histopathologic diagnosis based on liver biopsy, noninvasive methods including the measurement of various clinical parameters or laboratory markers have been applied to clinical practice and research, mostly in adults, to facilitate the diagnosis of NAFLD and to predict hepatic fibrosis in obese patients.

In our study performed in children with biopsy-proven NAFLD, both clinical and biochemical parameters were evaluated on the basis of the histopathologic findings of liver biopsy specimens, particularly focused on biochemical parameters. However, all of these clinical and biochemical parameters failed to distinguish significant fibrosis from no/mild fibrosis in children with NAFLD

**Figure 1** Receiver operating characteristic curves for the noninvasive hepatic fibrosis scoring systems used to diagnose clinically significant fibrosis (stage 2-3) in children with non-alcoholic fatty liver disease. ALT: Alanine aminotransferase; AST: Aspartate aminotransferase; NAFLD: Non-alcoholic fatty liver disease.

by univariate analysis, although the result of multivariate analysis suggested age and ALP as possible prognostic factors that predict significant hepatic fibrosis.

Regarding the clinical markers in children with NAFLD, 1 multicenter study reached the same conclusion as our study, revealing no significantly different clinical parameters for significant fibrosis (stage 2 or more), and the serum AST level was the only biochemical parameter associated with the severity of hepatic fibrosis<sup>[9]</sup>. In contrast, another pediatric study reported that BMI was the only clinical parameter that significantly differentiated NAFLD with hepatic fibrosis from NAFLD without fibrosis, and there were no biochemical parameters predictive of hepatic fibrosis<sup>[10]</sup>. From these results, it appears that more developed noninvasive tools beyond simple parameters are needed to detect hepatic fibrosis in children suspicious of NAFLD.

To this point, a number of noninvasive hepatic fibrosis scores have been developed and applied to chronic liver diseases, such as hepatitis B, hepatitis C, alcoholic fatty

liver disease, and NAFLD<sup>[22,23]</sup>. These scores include indices based on indirect biochemical markers and/or clinical parameters developed for adults, such as the AST/ALT ratio<sup>[10]</sup>, APRI<sup>[17]</sup>, PGA index<sup>[18]</sup>, Forns index<sup>[19]</sup>, FIB-4<sup>[20]</sup>, and NAFLD fibrosis score<sup>[21]</sup>. These scores have been validated in a number of previously published studies in adults<sup>[22]</sup>, but no validation studies have been performed in children with NAFLD, excluding the AST/ALT ratio, which did not differentiate hepatic fibrosis from no fibrosis in children<sup>[10]</sup>.

In our study, only APRI and FIB4 exhibited statistically significant differences between patients with mild fibrosis and those with significant fibrosis among these noninvasive scores. Regarding APRI, no studies have been reported in children with NAFLD. However, a study on APRI in children with chronic viral hepatitis revealed that the AUROC of APRI was 0.71 for hepatic fibrosis, and the sensitivity and the specificity of APRI were 47% and 90%, respectively, at the cutoff of 0.5<sup>[24]</sup>. In addition, another study comparing APRI with FibroScan and FibroTest in children with chronic liver disease reported the AUROC of APRI to be 0.73<sup>[25]</sup>. In our study on children with NAFLD, the AUROC of APRI was 0.70, which was similar to those of previous studies on children with chronic liver diseases.

FIB4, comprising age in addition to AST, ALT, and platelet counts, also differentiated significant hepatic fibrosis from mild fibrosis in our study, with the highest AUROC of 0.81. In previous studies on FIB4 in adult patients with NAFLD, the AUROCs of FIB4 were 0.802 and 0.86, respectively, which were higher than those of the AST/ALT ratio, APRI, NAFLD fibrosis score, and the BMI, AST/ALT ratio, diabetes score in both studies<sup>[26,27]</sup>. FIB4 was significant in distinguishing advanced fibrosis (stage 3 to 4) from mild fibrosis (stage 0 to 2) in these 2 studies<sup>[26,27]</sup>. These results were similar to those of our study, indicating that FIB4 had the highest AUROC among a variety of hepatic fibrosis scores using standard laboratory tests. Thus, FIB4 also appears to be a desirable noninvasive hepatic fibrosis score, even in children, with the application of age-appropriate cutoffs.

Up to date, PNFI was the only noninvasive hepatic fibrosis scoring system developed for children with NAFLD, which revealed the AUROC for significant fibrosis (stage 2 to 3) was 0.663<sup>[28]</sup>, and according to previous studies, PNFI was significant in differentiating children with hepatic fibrosis from children without fibrosis<sup>[12,28]</sup>. However, in our study, PNFI failed to distinguish significant hepatic fibrosis from no/mild fibrosis in children with the lowest AUROC of 0.41.

Because histopathologic findings of pediatric NASH are to some extent distinct from adult NASH<sup>[4,5]</sup>, the application of noninvasive hepatic fibrosis scores to children with NAFLD should be considered from a different point of view. More validation studies may be required in the future to apply noninvasive hepatic fibrosis scoring systems to clinical fields in pediatric population.

In conclusion, it appears that no single clinical or labo-

ratory parameter can reflect the presence of hepatic fibrosis or the severity of fibrosis in children with NAFLD. Therefore, APRI and FIB4 might be regarded as useful noninvasive methods to evaluate hepatic fibrosis even in children with NAFLD.

## COMMENTS

### Background

Although liver biopsy is the gold standard for the diagnosis of nonalcoholic fatty liver disease (NAFLD), it has some limitations in children because of its invasiveness and high costs, and moreover, the histopathologic findings of pediatric nonalcoholic steatohepatitis (NASH) are somewhat different from adult NASH. Thus, noninvasive methods to predict hepatic fibrosis are required in children suspicious of NAFLD.

### Research frontiers

The application of noninvasive hepatic fibrosis scores to detect liver fibrosis may be useful in detecting and predicting significant hepatic fibrosis in pediatric NAFLD.

### Innovations and breakthroughs

There have been only limited studies of noninvasive markers or hepatic fibrosis scores of hepatic fibrosis related to NAFLD in pediatric populations. This is the first study applying noninvasive clinical or biochemical markers and various noninvasive hepatic fibrosis scores together to the detection of hepatic fibrosis. Our study suggests that AST/platelet ratio index and FIB4, among hepatic fibrosis scores, might be useful to detect hepatic fibrosis even in children with NAFLD.

### Applications

The study may represent a future diagnostics for NAFLD in pediatric population, suggesting APRI and FIB4 as noninvasive tools to evaluate hepatic fibrosis in children possibly instead of invasive liver biopsy.

### Terminology

NAFLD is a form of chronic liver disease with histopathologic features of alcohol-induced liver disease occurs in persons who do not consume a significant amount of alcohol. Because the main etiology of NAFLD is obesity, the prevalence of NAFLD is increasing in children as the prevalence of pediatric obesity is increasing.

### Peer review

In this study, authors investigate several non-invasive scores for liver fibrosis in children with established and histology-proven NAFLD. This study is of interest, as today only view reports about the diagnostic accuracy of these scores in children are available.

examined by real-time quantitative RT-PCR in gastric tumors and their matched non-neoplastic gastric tissue samples.

**RESULTS:** Authors observed a significant reduction of 14-3-3 $\epsilon$  protein expression in gastric cancer (GC) samples compared to their matched non-neoplastic tissue. Reduced levels of 14-3-3 $\epsilon$  were also associated with diffuse-type GC and early-onset of this pathology. Our data suggest that reduced 14-3-3 $\epsilon$  may have a role in gastric carcinogenesis process.

**CONCLUSION:** Our results reveal that the reduced 14-3-3 $\epsilon$  expression in GC and investigation of 14-3-3 $\epsilon$  interaction partners may help to elucidate the carcinogenesis process.

### Abstract

**AIM:** To evaluate for the first time the protein and mRNA expression of 14-3-3 $\epsilon$  in gastric carcinogenesis.

**METHODS:** 14-3-3 $\epsilon$  protein expression was determined by western blotting, and mRNA expression was

### INTRODUCTION

Although gastric cancer (GC) rates have decreased substantially in most parts of the world, it is still the fourth most frequent cancer type and the second highest cause of cancer mortality worldwide. A total of 989 600 new

stomach cancer cases and 738 000 deaths are estimated to have occurred in 2008, accounting for 8% of the total cases and 10% of total deaths by cancer<sup>[1]</sup>.

About 90% of stomach tumors are adenocarcinomas<sup>[2]</sup>. However, the etiology and disease evolution may vary among populations, primary tumor location, histological subtypes of adenocarcinoma, and other variables<sup>[3]</sup>.

GC, as with other neoplasms, is a multifactorial disease that results from a combination of environmental factors and accumulation of generalized and specific genetic and epigenetic alterations. Chromosomal instability is characterized by changes in chromosome copy number (aneuploidy) and alterations in chromosomal regions, which may induce oncogene activation, tumor suppressor gene inactivation, or both<sup>[4]</sup>. The chromosomal aberrations that are constantly found in GC include gains of 3q, 7p, 7q, 8q, 13q, 17q, 20p and 20q and losses of 4q, 9p, 17p and 18q (for a review, see<sup>[5]</sup>). Our research group previously reported that the loss of one copy of *TP53* locus (17p13) is commonly found in gastric tumors of individuals from a Brazilian population<sup>[6]</sup>, as well as in GC cell lines<sup>[7-9]</sup>. Although *TP53* is a key tumor suppressor gene in the carcinogenesis process<sup>[10]</sup>, additional genes at 17p13 may play a role in gastric carcinogenesis.

The *YWHAE* gene is located at 17p13.3 and encodes the 14-3-3 $\epsilon$  protein, one of the mammalian 14-3-3 protein family members that are highly conserved in eukaryotes. There are at least seven distinct *14-3-3* genes in vertebrates, giving rise to nine isoforms ( $\alpha$ ,  $\beta$ ,  $\gamma$ ,  $\delta$ ,  $\epsilon$ ,  $\zeta$ ,  $\eta$ ,  $\sigma$  and  $\tau/\upsilon$ , with  $\alpha$  and  $\delta$  being phosphorylated forms of  $\beta$  and  $\zeta$ , respectively)<sup>[11,12]</sup>. The 14-3-3 proteins are predominantly dimeric within the cell and bind either to multiple sites within single proteins or act as a bridge between two targets<sup>[13-15]</sup>. Up to now, > 300 proteins have been reported to interact with 14-3-3 proteins, including key signaling components, such as p53, Raf-1 kinase, Bcl-2 antagonist of cell death, protein kinase C, phosphatidylinositol 3-kinase, and cdc25 phosphatase (*RASGRF1*)<sup>[12,13,15,16]</sup>. Although the exact 14-3-3 protein functions are not fully known, these proteins may act as a molecular scaffold, bringing together proteins that interact functionally and effecting phosphorylation-dependent cell regulation<sup>[12]</sup>. This protein family is involved in several biological processes and plays a regulatory role in processes such as apoptotic cell death, mitogenic signal transduction, and cell cycle control<sup>[13,17,18]</sup>.

The isoform 14-3-3 $\epsilon$  is the most highly conserved member of the 14-3-3 family, with conserved sequence in plants, yeast, and mammals<sup>[19,20]</sup>. Abnormal expression of 14-3-3 $\epsilon$  has been found in some types of cancers. However, the role of 14-3-3 $\epsilon$  in the carcinogenesis process is ambiguous and contradictory. Low expression of 14-3-3 $\epsilon$  occurs in small cell lung cancer<sup>[21]</sup>, laryngeal squamous cell carcinoma<sup>[22]</sup>, and medulloblastoma<sup>[23]</sup>, which suggest its role as a tumor suppressor gene. On the other hand, high expression of 14-3-3 $\epsilon$  has been detected in renal carcinoma<sup>[24]</sup>, astrocytoma<sup>[25]</sup>, meningioma<sup>[26]</sup> and subependymomas<sup>[27]</sup>, and, thus, probably it acts as an oncogene.

To the best of our knowledge, no study has evaluated

the role of 14-3-3 $\epsilon$  in gastric carcinogenesis until now. In the present study, we analyzed the *14-3-3 $\epsilon$*  gene and protein expression in GC and matched non-neoplastic gastric samples. We also evaluated the possible associations between 14-3-3 $\epsilon$  and clinicopathological characteristics.

## MATERIALS AND METHODS

### Tissue samples

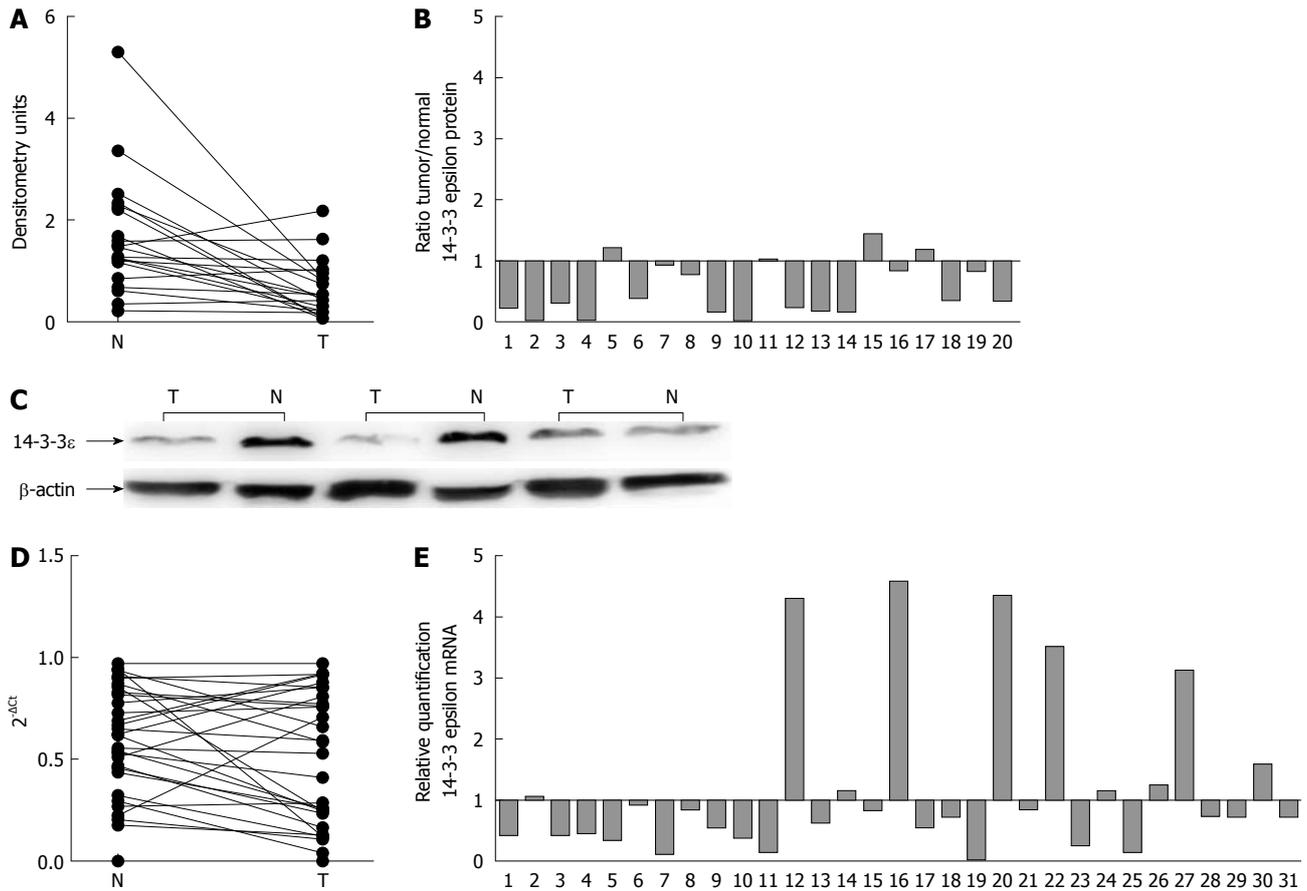

14-3-3 $\epsilon$  protein expression was evaluated in 20 pairs of GC samples and corresponding non-neoplastic gastric tissues (distant location of primary tumor). The mRNA expression was evaluated in 31 pairs of GC samples and corresponding non-neoplastic gastric tissues. Dissected tumor and paired non-neoplastic tissue specimens were immediately cut from stomach samples, frozen in liquid nitrogen, and stored at -80 °C until use for protein and RNA extraction. All the gastric samples were obtained surgically from João de Barros Barreto University Hospital (HUIBB) in Pará State, Northern Brazil. Informed consent with approval of the ethics committee of HUIBB was obtained. All patients had negative histories of exposure to either chemotherapy or radiotherapy before surgery and there was no other co-occurrence of diagnosed cancers. All samples were classified according to Laurén<sup>[28]</sup> and tumors were staged using standard criteria by TNM staging<sup>[29]</sup>.

### Protein and mRNA purification

Total protein and total mRNA were simultaneously isolated from gastric tissue samples using the AllPrep DNA/RNA/Protein Kit (Qiagen, Hilden, Germany) according to the manufacturer's instructions. To allow greatest solubilization, the protein pellet was dissolved in buffer containing 7 mol urea, 2 mol thiourea, 4% CHAPS, 50 mmol dithiothreitol, 1% Protease Inhibitor Cocktail (Sigma, St Louis, MO, United States), and 0.5% of each Phosphatase Inhibitor Cocktail 1 and 2 (Sigma-Aldrich, St Louis, MO, United States). Protein concentration was determined by the method of Bradford (Sigma-Aldrich). RNA concentration and quality were determined using a NanoDrop spectrophotometer (Kisker, Germany) and 1% agarose gels. Samples were stored at -80 °C until use.

### 14-3-3 $\epsilon$ expression by western blotting

Reduced protein (30  $\mu$ g) of each sample was separated on 12.5% homogeneous SDS-PAGE gel and electroblotted to a polyvinylidene fluoride (PVDF) membrane (Hybond-P; GE Healthcare, Uppsala, Sweden). The PVDF membrane was blocked with PBS containing 0.1% Tween 20, 5% low-fat milk, and incubated overnight at 4 °C with corresponding primary antibodies to anti-14-3-3 $\epsilon$  (sc-31962, 1:100; Santa Cruz Biotechnology, Santa Cruz, CA, United States) and anti- $\beta$ -actin (Ac-74, 1:3000; Sigma-Aldrich). After extensive washing, a peroxidase-conjugated secondary antibody was incubated for 1 h at room temperature. Immunoreactive bands were visualized using western blotting Luminol reagent and the images were acquired using an ImageQuant 350 digital image system (GE Healthcare, Uppsala, Sweden). The  $\beta$ -actin was used as a loading reference control.

**Figure 1** Expression of 14-3-3ε in tumor and non-neoplastic gastric tissue. A: Protein expression normalized by β-actin (ACTB); B: Ratio of protein expression between tumor and matched non-neoplastic gastric tissues; C: Western blotting using anti-14-3-3ε and anti-β-actin antibodies; D: mRNA expression normalized by the internal controls ACTB and glyceraldehyde-3-phosphate dehydrogenase; E: Relative mRNA quantification-gastric tumor samples normalized by matched non-neoplastic gastric tissues. T: Tumor samples; N: Non-neoplastic samples.

### 14-3-3ε mRNA expression by real-time quantitative RT-PCR

First, cDNA was synthesized using High-Capacity cDNA Archive kit (Applied Biosystems, Warsaw, Poland) according to the manufacturer's protocol. All real-time qRT-PCR reactions were performed in triplicate for both target gene (YWHAE: Hs00356749\_g1, Applied Biosystems, United States) and internal controls (β-actin: Hs03023943\_g1; glyceraldehyde-3-phosphate dehydrogenase: Hs99999905\_m1; Applied Biosystems, United States). To compare 14-3-3ε mRNA expression between GC and non-neoplastic gastric samples, we converted  $\Delta\text{Ct}$  ( $\Delta\text{Ct} = \text{Ct of YWHAE} - \text{Ct of internal controls}$ ) to linear form ( $2^{-\Delta\text{Ct}}$ ). Relative quantification of the gene expression was calculated according to Pfaffl method<sup>[30]</sup>. Non-neoplastic gastric samples were designated as a calibrator of each paired tumor sample.

### Statistical analysis

We first evaluated the normal distribution of all data using the Shapiro-Wilk normality test to determine subsequent use of appropriate tests for statistical comparison. Since 14-3-3ε mRNA and protein data did not present with a normal distribution, we performed parametric tests with bootstrapping, a re-sampling method. The re-sampling methods are relatively powerful and can control

a type I error (false positive), reducing over-fit bias and internally validating the accuracy estimates. Bootstrapping methods also produce confidence intervals (CIs) around the observed effects. Paired *t* test was performed to compare the mean of 14-3-3ε expression between neoplastic and matched non-neoplastic samples. The associations between clinicopathological parameters and the mean of 14-3-3ε expression were assessed using a *t* test for independent samples. The correlation among the 14-3-3ε mRNA and protein expression was analyzed by Pearson test. All the analyses performed in this article were based on 1000 bootstrap samples. In all analyses, the CI was 95% and  $P < 0.05$  was considered significant.

## RESULTS

14-3-3ε protein expression was significantly reduced in GC samples (densitometry units:  $0.656 \pm 0.552$ ) compared to matched non-neoplastic gastric samples ( $1.656 \pm 1.158$ ) ( $P = 0.005$ , 95% CI: -1.59 to -0.53). 14-3-3ε protein was 1.5-fold lower in 60% of GC samples compared to their paired non-neoplastic gastric tissues. However, 14-3-3ε mRNA expression did not differ between GC ( $2^{-\Delta\text{Ct}}$ :  $0.492 \pm 0.325$ ) and corresponding non-neoplastic gastric tissue ( $0.579 \pm 0.272$ ) ( $P = 0.075$ , 95% CI: -0.18 to 0.003) (Figure 1). Although mRNA and protein were simultaneously purified,

Differentially expressed between groups, <sup>a</sup>*P* < 0.05. T: Tumor gastric samples; N: Non-neoplastic gastric samples.

no correlation was observed between 14-3-3 $\epsilon$  mRNA and protein expression (*R* = 0.236, *P* = 0.345).

The associations between clinicopathological characteristics and 14-3-3 $\epsilon$  expression are summarized in Table 1. A significant decrease in 14-3-3 $\epsilon$  mRNA level was observed in early-onset GC (at age  $\leq$  45 years<sup>[31]</sup>) compared to late-onset GC (*P* = 0.028, 95% CI: -1.49 to -0.25). Moreover, a tendency towards 14-3-3 $\epsilon$  protein down-expression was also observed in early-onset compared to late-onset GC (*P* = 0.052, 95% CI: -0.69 to -0.05).

The 14-3-3 $\epsilon$  mRNA level was reduced in early GC compared to advanced GC (*P* = 0.046, 95% CI: -1.41 to -0.16) and tended to present reduced levels with less invasive tumors (*P* = 0.052, 95% CI: -1.40 to -0.13). In contrast, these observations were not observed for protein level.

Concerning the 14-3-3 $\epsilon$  protein, we observed that the diffuse-type GC presented reduced expression compared to intestinal-type GC (*P* = 0.024, 95% CI: 0.12-0.65). However, a significant difference was observed between non-neoplastic gastric tissues and intestinal-type GC (*P* = 0.045, 95% CI: -1.55 to -0.29) and diffuse-type GC (*P* = 0.024, 95% CI: -2.22 to -1.14).

## DISCUSSION

Cancer cells have defects in regulatory circuits that govern normal cell proliferation and homeostasis<sup>[32]</sup>. The 14-3-3 proteins continue to generate intense interest due to their roles in signal transduction pathways that control

cell cycle checkpoints, mitogen-activate protein kinase activation, apoptosis, and regulation of gene expression. 14-3-3 stabilizes non-native conformations of bound ligands to promote their interactions with downstream targets, or facilitates their subsequent modification by kinases and phosphatases<sup>[18]</sup>.

In the present study, we evaluated the 14-3-3 $\epsilon$  mRNA and protein expression in gastric carcinogenesis. To the best of our knowledge, no study has evaluated 14-3-3 $\epsilon$  expression in this neoplasm. Here, we observed that 14-3-3 $\epsilon$  protein expression was reduced in GC samples compared to matched non-neoplastic gastric tissue. Low expression of 14-3-3 $\epsilon$  has also been reported in small cell lung cancer<sup>[21]</sup>, laryngeal squamous cell carcinoma<sup>[22]</sup>, and medulloblastoma<sup>[23]</sup>, suggesting a tumor suppressor function. The reduced 14-3-3 $\epsilon$  expression may be in part due to the loss of its locus (17p13), which is a common finding in gastric tumors of individuals from the studied population<sup>[6]</sup>.

Little is known about the role of 14-3-3 $\epsilon$  in carcinogenesis. One of the major partners of 14-3-3 $\epsilon$  is the CDC25 protein. CDC25 protein is virtually inactive during interphase, but undergoes a strong activation at mitosis due to phosphorylation of its N-terminal regulatory domain<sup>[33]</sup>. 14-3-3 $\epsilon$  acts as a negative regulator of CDC25<sup>[33,34]</sup>. The overexpression of CDC25 proteins has previously been described in GC<sup>[35-37]</sup>. Thus, the reduced expression of 14-3-3 $\epsilon$  in GC cells may enhance the ability of CDC25 to induce mitosis, contributing to the gastric carcinogenesis process.

Several classification systems have been described for

GC. According to the Laurén classification, one of the most used, gastric adenocarcinoma is classified mainly into intestinal and diffuse types<sup>[28]</sup>. Intestinal-type GC progresses through a number of sequential steps, beginning with atrophic gastritis followed by intestinal metaplasia, intraepithelial neoplasia, and carcinoma<sup>[38]</sup>. In contrast, diffuse-type GC generally does not evolve from precancerous lesions<sup>[39,40]</sup>. In the present study, we observed that the expression of 14-3-3 $\epsilon$  protein was lower in diffuse-type than in intestinal-type GC, confirming that these two histological GC subtypes follow different genetic pathways and may be two distinct entities<sup>[39]</sup>.

MYC deregulation is a frequent finding in GC<sup>[41]</sup>. Moreover, MYC immunoreactivity seems to be more frequently detected in intestinal-type than diffuse-type GC<sup>[42,43]</sup>. Gene amplification is the main mechanism of MYC deregulation in GC<sup>[41]</sup>, and we have previously described a higher frequency of *MYC* locus amplification in intestinal-type than diffuse-type GC<sup>[44,45]</sup>. Interestingly, one of the MYC target proteins is CDC25, which is negatively regulated by 14-3-3 $\epsilon$ . A correlation between MYC and CDC25 has previously been reported in GC<sup>[46]</sup>. Here, we hypothesize that the relative increase of 14-3-3 $\epsilon$  in the subset of tumors of the intestinal-type may be a compensatory mechanism to control the increase of cell proliferation due to MYC and CDC25 action. Moreover, MYC overexpression also induces the production of reactive oxygen species, which may lead to double-stranded DNA breaks and point mutations resulting in genomic instability<sup>[47]</sup>. Thus, the relative increase in 14-3-3 $\epsilon$  in the intestinal-type GC may be also a compensatory response to other oncogenic mutations accumulated in cancer cells, which lead to genomic instability and initiate a DNA damage check-point in cells that contain some functional p53 alleles, as already proposed for other 14-3-3 isoforms<sup>[18]</sup>.

Here, we also described a decrease in 14-3-3 $\epsilon$  expression in early-onset compared to late-onset GC. Early-onset GC is observed in < 10% of GC patients, and only 10% of these patients have a positive family history<sup>[31]</sup>. Most young patients present at an advanced clinical stage similar to elderly patients, so the prognosis in both age groups is poor. However, early-onset GC shows different clinicopathological and molecular profiles compared to late-onset GC, suggesting that they represent a separate entity within gastric carcinogenesis, with genetic factors probably presenting a more important role in early-onset GC patients<sup>[48-50]</sup>. 14-3-3 $\epsilon$  deregulation may have a direct or indirect function in early-onset GC because this protein interacts with several others.

In addition, no correlation was observed between 14-3-3 $\epsilon$  mRNA and protein expression, corroborating a previous study of laryngeal squamous cell carcinoma<sup>[22]</sup>. The lack of correlation between 14-3-3 $\epsilon$  protein and mRNA expression patterns indicates the post-translational regulation mechanism involved in this protein expression, and highlights the complexity of the relationship between protein and mRNA expression.

In conclusion, our data suggest that, for the first time, reduced 14-3-3 $\epsilon$  may have a role in gastric carcinogenesis, mainly in diffuse-type and early-onset GC. Moreover, further investigations are necessary to understand which proteins interact with 14-3-3 $\epsilon$  in these subtypes of GC.

## COMMENTS

### Background

Gastric cancer (GC) is the fourth most frequent cancer type and the second highest cause of cancer mortality worldwide. Although this neoplasm is a serious public health problem due to its high incidence and mortality, little is known about the molecular events involved in gastric carcinogenesis.

### Research frontiers

GC, as with other neoplasms, is a multifactorial disease that results from a combination of environmental factors and the accumulation of generalized and specific genetic and epigenetic alterations. The 14-3-3 protein family has been recently associated with carcinogenesis, but not in the stomach. In this study, the authors evaluated mRNA and protein expression of 14-3-3 $\epsilon$  in gastric neoplasms and corresponding non-neoplastic samples.

### Innovations and breakthroughs

No previous study has evaluated the gene and protein expression of 14-3-3 $\epsilon$  in gastric carcinogenesis. This study demonstrates that 14-3-3 $\epsilon$  has a role in gastric carcinogenesis, especially in diffuse-type and early-onset GC.

### Applications

14-3-3 $\epsilon$  may have a role in gastric carcinogenesis as a tumor suppressor protein.

### Terminology

The *YWHAE* gene is located at 17p13.3, a region frequently deleted in gastric neoplasms. This gene encodes the 14-3-3 $\epsilon$  protein, one of the mammalian 14-3-3 protein family members that are highly conserved in eukaryotes. This protein family is involved in several biological processes and plays a regulatory role in processes such as apoptotic cell death, mitogenic signal transduction, and cell cycle control.

### Peer review

The results report for the first time the expression of 14-3-3 $\epsilon$  in GC, both at the protein and mRNA level, and the data obtained reveal reduced 14-3-3 $\epsilon$  protein expression in GC. The data contribute to the biology of GC with possible future clinical implications to be tested in a subsequent study in a larger number of GC patients.

### Abstract

Pancreatic schwannomas are rare neoplasms. Authors briefly describe a 64-year-old female patient with cystic pancreatic schwannoma mimicking other cystic tumors and review the literature. Databases for PubMed were searched for English-language articles from 1980 to 2010 using a list of keywords, as well as references from review articles. Only 41 articles, including 47 cases, have been reported in the English literature. The mean age was 55.7 years (range 20-87 years), with 45% of patients being male. Mean tumor size was 6.2 cm (range 1-20 cm). Tumor location was the head (40%), head and body (6%), body (21%), body and tail (15%), tail (4%), and uncinate process (13%). Thirty-four percent of patients exhibited solid tumors and 60% of patients exhibited cystic tumors. Treatment included pancreaticoduodenectomy (32%), distal pancreatectomy (21%), enucleation (15%), unresectable (4%), refused operation (2%) and the detail of resection was not specified in 26% of patients. No patients died of disease with a mean follow-up of 15.7 mo (range 3-65 mo), although

5 (11%) patients had a malignancy. The tumor size was significantly related to malignant tumor ( $13.8 \pm 6.2$  cm for malignancy vs  $5.5 \pm 4.4$  cm for benign,  $P = 0.001$ ) and cystic formation ( $7.9 \pm 5.9$  cm for cystic tumor vs  $3.9 \pm 2.4$  cm for solid tumor,  $P = 0.005$ ). The preoperative diagnosis of pancreatic schwannoma remains difficult. Cystic pancreatic schwannoma should be considered in the differential diagnosis of cystic neoplasms and pseudocysts. In our case, intraoperative frozen section confirmed the diagnosis of a schwannoma. Simple enucleation may be adequate, if this is possible.

### INTRODUCTION

Pancreatic schwannomas are rare neoplasms that originate from Schwann cells. The Schwann cells line the nerve sheath and can generate either schwannoma or neurofibroma<sup>[1]</sup>. Schwannoma usually occur in the extremities, but can also be found in the trunk, head and neck, retroperitoneum, mediastinum, pelvis and rectum<sup>[2,3]</sup>. Pancre-

atic schwannomas are even more unusual neoplasms that affect adults with an equal gender distribution<sup>[4,5]</sup>. These tumors vary considerably in size and approximately two-thirds are reported to undergo degenerative changes including cyst formation, calcification, hemorrhage, hyalinization and xanthomatous infiltration<sup>[4,5]</sup>. As a result, they may radiographically mimic cystic pancreatic lesions (e.g., mucinous cystic neoplasms, solid and pseudopapillary neoplasms, serous cystic neoplasms, and pseudocysts).

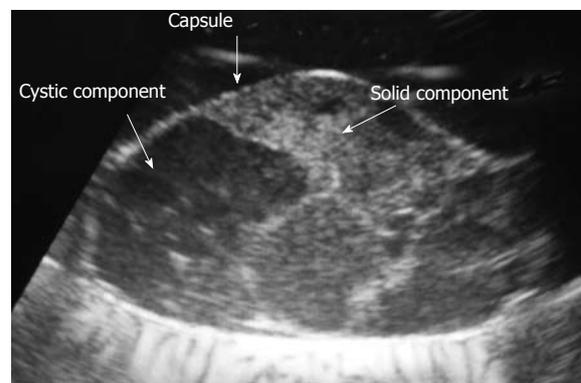

Only 47 cases have been reported in the English literature in the last three decades<sup>[2-42]</sup>. In this report, we present a case of pancreatic schwannoma and provide a pertinent review of literature with emphasis on clinical presentation, diagnosis, treatment options, and outcome.

## CASE REPORT

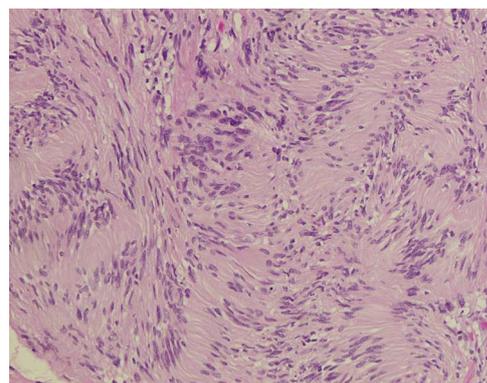

A 64-year-old previously healthy woman was incidentally discovered to have a cystic tumor in the pancreas during an ultrasound examination for a health check. She was referred to our institution for further investigation. The abdominal physical examination did not detect any marked finding and all laboratory data were normal, including tumor markers. The computed tomography (CT) scan demonstrated a well-encapsulated tumor, which was composed of solid and cystic areas (Figure 1), and neither liver mass nor peripancreatic lymph node swelling was detected. Magnetic resonance imaging (MRI) showed a mass, with hypointensity on T1-weighted images and hyperintensity on T2-weighted images. Magnetic resonance cholangiopancreatography (MRCP) showed a hyperintense mass in the pancreatic head with no dilatation of the main pancreatic duct. Endoscopic retrograde cholangiopancreatography revealed no communication between cystic tumor and pancreatic duct. Endoscopic ultrasonography showed that the tumor was composed of cystic part and solid part. We performed surgery under the diagnosis of cystic tumor of the pancreas as mucinous cystic tumor, solid pseudo papillary tumor or gastrointestinal stromal tumor. The laparotomy disclosed a well-encapsulated 4-cm mass in the uncinate process of the pancreas that had no signs of inflammation. Intraoperative ultrasound confirmed a solitary mass composed of solid and cystic components (Figure 2). The mass was enucleated and an intraoperative frozen section demonstrated a benign schwannoma. No further resection was performed based on these findings. The tumor was 4 cm × 4 cm × 3 cm in size, and was composed of a mixture of solid and hemorrhage areas. On microscopic examination, the tumor was composed of spindle cells strongly positive for S-100 proteins and foci of hemorrhage (hematoxylin and eosin, × 100) (Figure 3). The tumor cells were negative for smooth muscle actin and CD-34. The tumor was therefore histologically diagnosed as benign schwannoma. The patient was discharged uneventfully on postoperative day 17. At a 65-month follow up after resection, the patient is doing well without any recurrent disease.

**Figure 1** Contrast-enhanced computed tomography scan obtained in the arterial phase showing a multilocular cystic mass in the uncinate process of the pancreas. No pancreatic ductal dilatation or invasion into adjacent arteries or portal vein are identified.

**Figure 2** Intraoperative ultrasound showing the well-encapsulated pancreatic mass that is composed of solid and cystic components.

**Figure 3** Microscopic examination demonstrating spindle cells without nuclear atypism (HE × 100). Immunohistochemical staining for S-100 protein was positive. HE: Hematoxylin and eosin.

## DISCUSSION

A review of the patient's chart was performed along with a review of English-language articles using a PubMed search for the last three decades. We found 41 articles including 47 patients with pancreatic schwannoma. Details of the cases are summarized in Table 1 along with the current patient. Table 2 summarizes the important

available facts regarding all patients. We examined the correlation between tumor size and malignancy, as well as tumor size and cystic degeneration. Continuous data are presented as mean  $\pm$  standard deviation and range. Student *t*-test was used for all comparisons among continuous variables. A *P* < 0.05 was considered statistically significant.

A PubMed search of the literature indicated 41 reports including 47 patients with pancreatic schwannoma in the English literature. Details of all the 47 cases are summarized in Table 1. Table 2 summarizes the important available clinicopathological factors. The mean age of the patients was 55.7  $\pm$  15.1 years (range 20-87 years) and the male-female ratio was 21:26. Thirty percent of patients were asymptomatic and 70% of patients were symptomatic. Symptoms included abdominal pain (57%), weight loss (13%), back pain (6%), nausea/vomiting (4%), abdominal mass (4%), melena (4%), and jaundice (4%). The symptoms did not correlate with tumor size and tu-

**Figure 4** Analysis for relation between tumor size and malignant potential and tumor nature (solid or cystic) in all 47 cases of pancreatic schwannoma. A: Relationship between tumor size and malignancy. Larger tumor size is related to malignant tumor (13.8  $\pm$  6.2 cm for malignancy vs 5.5  $\pm$  4.4 cm for benign, *P* = 0.001); B: Relationship between tumor size and nature of tumor. Larger tumor size is related to cystic degeneration (13.8  $\pm$  6.2 cm for cystic tumor vs 5.5  $\pm$  4.4 cm for solid tumor, *P* = 0.005).

mor location. The lesion was located in the pancreas head in 19 patients (40%), head and body in 3 patients (6%), body in 10 patients (21%), body and tail in 7 (15%), tail in 2 patients (4%), and uncinate process in 6 patients (13%). Mean tumor size was 6.2  $\pm$  5.1 cm (range 1-20 cm). Treatment included pancreaticoduodenectomy for 15 patients (32%) including one portal vein reconstruction, distal pancreatectomy for 10 patients (21%) including combined transverse colon resection, enucleation for 7 patients (15%), unresectable for 2 patients (4%), refused operation for 1 patient (2%) and the detail of resection was not specified in 12 patients (26%). Enucleation was performed for 7 patients, and out of these, 3 lesions were located in the head, 2 lesions were in the uncinate process and 2 lesions were in the body. The mean tumor size in the patients who underwent enucleation was 2.7 cm (range 1.5-4.0 cm). Regarding gross appearance, 34% of patients exhibited solid tumors and 60% of patients exhibited cystic tumors. No patient died of disease with a follow-up of 15.7 mo (range 3-65 mo), although 4 (9%) patients had a malignancy. The tumor size was related to malignant tumor (13.8  $\pm$  6.2 cm for malignancy vs 5.5  $\pm$  4.4 cm for benign, *P* = 0.001) (Figure 4A) and cystic for-

mation ( $7.9 \pm 5.9$  cm for cystic tumor *vs*  $3.9 \pm 2.4$  cm for solid tumor,  $P = 0.005$ ) (Figure 4B).

In 1910, Verocay reported a schwannoma as a true neoplasm which originated from Schwann cells, and which did not contain neuroganglion cells<sup>[1]</sup>. Since then, schwannomas have become well known as benign spindle cell tumors derived from Schwann cells that line the nerve sheaths. Schwannomas usually occur in the extremities, but can also be found in the trunk, head and neck, retroperitoneum, mediastinum, pelvis and rectum<sup>[2-4]</sup>. Pancreatic schwannomas are rare neoplasms that arise from either autonomic sympathetic or parasympathetic fibers, both of which course through the pancreas as branches of the vagus nerve<sup>[2-4]</sup>.

Microscopically, a typical schwannoma is composed of 2 areas, namely Antoni A and Antoni B areas. The Antoni A area is hypercellular and characterized by closely packed spindle cells with occasional nuclear palisading and Verocay bodies, whereas the Antoni B area is hypocellular and is occupied by loosely arranged tumor cells<sup>[43]</sup>. Most of the pancreatic schwannomas reported had both Antoni A and Antoni B areas in various proportions. Degenerative or cystic changes such as calcification or hemorrhage are often recognized in the Antoni B area. These changes result from vascular thrombosis and subsequent necrosis<sup>[43]</sup>. Cystic pancreatic schwannomas can mimic the whole spectrum of cystic pancreatic lesions including: intraductal mucinous-papillary neoplasms, mucinous cystic neoplasms, serous cystic neoplasms, solid and pseudo-papillary neoplasms, lymphangiomas, and pancreatic pseudocysts. Immunohistochemically, schwannomas stain strongly positive for S-100 protein, vimentin and CD 56, while negative for other tumor markers including cytokeratin AE1/AE3, desmin, smooth muscle myosin, CD 34 and CD 117<sup>[43]</sup>.

The symptoms of the reported patient cases of pancreatic schwannoma vary. Seventy percent of patients were symptomatic. Abdominal pain was the most common symptom reported (57%). Symptoms such as back pain (6%), nausea/vomiting (4%), weight loss (13%), melena (4%) and jaundice (4%) have been also reported. Thirty percent of patients were asymptomatic and the lesions were incidentally discovered on CT scans performed for other reasons.

The preoperative diagnosis of pancreatic schwannoma is very difficult, especially in cystic schwannomas. Suzuki *et al*<sup>[8]</sup> reviewed imaging features of pancreatic schwannomas. The most characteristic feature on CT scan was the presence of an area of low density and/or cystic images reflecting the Antoni B component or degenerative cystic areas of the schwannoma. Contrast-enhanced CT scan showed the difference between the Antoni A and the Antoni B areas based on their vascularity, i.e., well-enhanced areas corresponding to Antoni A, and unenhanced areas corresponding to Antoni B. The CT findings correlated well with pathological features<sup>[8,19]</sup>. The MRI findings usually showed hypointensity on T1-weighted images and hyperintensity on T2-weighted images<sup>[21]</sup>. However, other

pancreatic tumors often share those imaging features, and differential diagnoses should always be considered. Ultrasound-guided Fine Needle Aspiration (EUS-FNA) biopsy has been used increasingly commonly at many institutions. This procedure may be useful for accurate preoperative diagnosis. Cytologically, schwannomas are characteristically composed of spindle-shaped cells, which possess indistinct cytoplasmic borders and wavy nuclei embedded in a fibrillary and occasionally myxoid or collagenous matrix. The Antoni A (cohesive cellular clusters) and Antoni B (loosely cohesive or poorly cellular sheets) areas are occasionally found. Immunohistochemical staining is useful for accurate diagnosis of schwannoma<sup>[12,14]</sup>. It is diffusely and strongly positive for S-100 protein. There has only been one previous report of pancreatic schwannoma diagnosed preoperatively by EUS-FNA cytology combined with immunohistochemistry<sup>[12]</sup>.

Although malignant pancreatic schwannomas have been reported in 5 articles<sup>[7,38,40-42]</sup>, in 3 of 5 the methods of diagnosing malignancy were inconsistent, as some previous reports pointed out<sup>[4,5]</sup>. Immunohistochemical examination was not used or was not available in these 3 patients. Walsh and Bradspigel<sup>[40]</sup> described a case of pancreatic schwannoma eroding into the bowel wall and presenting with gastrointestinal bleeding that mimicked a recurrently bleeding duodenal ulcer. Another two patients reported had disease associated with von Recklinghausen's disease<sup>[41,42]</sup>. These could represent misdiagnosed neurofibromas that underwent malignant degeneration<sup>[4,5]</sup>. Stojanovic *et al*<sup>[7]</sup> reported malignant pancreatic schwannoma with node metastasis and infiltrating serosa of transverse colon. This tumor was confirmed using immunohistochemical examination. This may be the first definite report of malignant schwannoma with subsequent radical resection.

Since malignant transformation of pancreatic schwannomas is uncommon, simple enucleation is usually sufficient. A review of the treatment showed that the most common resection was pancreaticoduodenectomy (32%), followed by distal pancreatectomy (21%) and enucleation (15%). This result may account for the difficulty in accurate diagnosis of pancreatic schwannoma and relate to larger size of this tumor. Enucleation was performed for 7 patients for whom 3 lesions were located in the head, 2 lesions were in the uncinate process and 2 lesions were in the body. The mean tumor size of the patients who underwent enucleation was 2.7 cm (range 1.5-4.0 cm). Intraoperative consultation with the pathologist was carried out in most of the enucleated cases. An intraoperative frozen section should be performed, as it helps to establish the diagnosis of a benign schwannoma and avoid more radical resection. Large tumors, tumors involving portal vein, ampulla, or splenic hilum, may require a more radical resection than simple enucleation.

The present report shows the correlation between tumor size and malignant formation (Figure 4A), and tumor size and cystic degeneration (Figure 4B). Malignant schwannomas were more likely to be larger-sized compared to many other tumors. On the other hand, the par-

ticular feature of pancreatic schwannoma was that larger tumor size was related to cystic degeneration, as shown in Figure 4B. Cystic degeneration could make it difficult to diagnose pancreatic schwannoma preoperatively, because of mimicking other cystic neoplasms. Caution should be applied when diagnosing cystic neoplasm. An intraoperative frozen section may help to establish the diagnosis of a schwannoma and avoid more radical resection. To our knowledge, the present report is the first to analyze the relation among tumor size, malignant formation and cystic degeneration. Our results suggest that pancreatic schwannoma might be resected even though diagnosed preoperatively, because if schwannomas are smaller, enucleation should be oncologically adequate. However, when tumors become larger with associated bleeding risk, more invasive resection such a PD or DP might be necessary. In particular, in cases of tumors more than 10 cm in size, we should pay special attention to malignant degeneration and should perform a more extended resection. To avoid extended resection, earlier resection and accurate diagnosis are very important.

In conclusion, pancreatic schwannomas deserve attention with regard to the differential diagnosis of pancreatic lesions. Preoperative diagnosis is very difficult. Simple enucleation is adequate if this is possible to achieve. Intraoperative frozen section is useful to diagnose schwannoma.

### Abstract

Primary esophageal combined carcinoma is very rare. The authors herein report 2 cases. Case 1 was a combined squamous cell carcinoma and small cell carcinoma, and case 2 was a combined squamous cell carcinoma, adenocarcinoma, and small cell carcinoma. Case 1 was a 67-year-old man with complaints of dysphagia. Endoscopic examination revealed an ulcerated tumor in the middle esophagus, and 6 biopsies were obtained. All 6 biopsies revealed a mixture of squamous cell carcinoma and small cell carcinoma. Both elements were positive for cytokeratin, epithelial membrane antigen, and p53 protein, and had high Ki-67 labeling. The small cell carcinoma element was positive for synaptophysin, CD56, KIT, and platelet-derived growth factor- $\alpha$  (PDGFRA), while the squamous cell carcinoma element was not. Genetically, no mutations of *KIT* and *PDGFRA* were recognized. The patient died of systemic carcinomatosis 15 mo after presentation. Case 2 was a 74-year-old man presenting with dysplasia. Endoscopy revealed a polypoid tumor in the distal esophagus. Seven biopsies were taken, and 6 showed a mixture of squamous cell carcinoma, small cell carcinoma, and adenocarcinoma. The 3 elements were positive for cytokeratins, epithe-

lial membrane antigen, and p53 protein, and had high Ki-67 labeling. The adenocarcinoma element was positive for mucins. The small cell carcinoma element was positive for CD56, synaptophysin, KIT, and PDGFRA, but the other elements were not. Mutations of *KIT* and *PDGFRA* were not recognized. The patient died of systemic carcinomatosis 7 mo after presentation. These combined carcinomas may arise from enterochromaffin cells or totipotent stem cell in the esophagus or transdifferentiation of one element to another. A review of the literature was performed.

### INTRODUCTION

Combined esophageal carcinomas are very rare and interesting tumors. A full review of the English literature revealed 24 reporting combined carcinoma of the esophagus<sup>[1-24]</sup>. Most were small cell carcinomas, and a few were non-small cell carcinomas<sup>[1-24]</sup>. The author herein reports 2 cases of combined carcinoma of the esophagus. One case is a combined squamous cell carcinoma and small cell carcinoma, and another case is a combined squamous cell carcinoma, adenocarcinoma, and small cell carcinoma

## CASE REPORT

### Case 1

A 67-year-old man was admitted to our hospital with dysphagia. An endoscopic examination revealed an ulcerated tumor (3 cm × 4 cm × 3 cm) in the middle esophagus (Figure 1A), and 6 biopsies were obtained. All 6 biopsies revealed a mixture of squamous cell carcinoma (Figure 1B) and small cell carcinoma (Figure 1C). The squamous element was composed of malignant cells arranged in a layer with focal keratinization (cancer pearls). The small cell carcinoma element consisted of malignant small cells with hyperchromatic nuclei, nuclear molding, absent nucleoli, and very scant cytoplasm. There was a gradual merging of the 2 elements.

The authors performed an immunohistochemical study using Dako Envision method, as previously described<sup>[25,26]</sup>. The immunohistochemical antibodies used were as follows: cytokeratins (AE1/3, Dako; CAM5.2 Becton-Dickinson, CA, United States), epithelial membrane antigen (E29, Dako), neuron-specific enolase (BBS/NC/VI-H14, Dako), chromogranin (DAK-A3, Dako), synaptophysin (polyclonal, Dako), CD56 (UJ13A, Dako), p53 protein (DO-7, Dako), Ki-67 (MIB-1, Dako), KIT (polyclonal, Dako), and platelet derived growth factor receptor- $\alpha$  (PDGFRA) (polyclonal, Santa Cruz, CA, United States). The squamous cell carcinoma element was positive for cytokeratin, epithelial membrane antigen, p53 protein, and Ki-67 antigen (57% labeled), but negative for other antigens examined. The small cell carcinoma element was positive for cytokeratin (Figure 1D), p53 protein, Ki-67 (96% labeled), synaptophysin (Figure 1E), CD56, and chromogranin, KIT (Figure 1F), and PDGFRA (Figure 1G).

The authors performed a molecular genetic study for *KIT* (exons 9, 11, 13 and 17) and *PDGFRA* (exons 12 and 18) genes in paraffin sections using microdissection and the polymerase chain reaction-direct sequencing method, as previously described<sup>[27-30]</sup>. There were no mutations of the *KIT* (exons 9, 11, 13 and 17) and *PDGFRA* (exons 12 and 18) genes.

The patient was diagnosed with combined carcinoma of esophagus (stage II, T2 N0 M0). Surgery was not considered because the tumor contained small cell carcinoma. The patient was treated with cisplatin-based chemotherapy and radiation, but died of systemic carcinomatosis 15 mo after presentation.

### Case 2

A 74-year-old man presented with dysplasia, and attended our hospital. An endoscopy revealed a polypoid tumor (2 cm × 2 cm × 3 cm) in the middle esophagus (Figure 2A). Seven biopsies were taken, and 6 showed a mixture of squamous cell carcinoma (Figure 2B), small cell carcinoma (Figure 2C), and adenocarcinoma (Figure 2D). The squamous cell carcinoma element showed malignant cells in a layer with focal keratinization. The small cell carcinoma element was composed of small malignant cells with hy-

perchromatic nuclei, inconspicuous nucleoli, and scant cytoplasm. The adenocarcinoma element showed sheet-like tumor cells with focal acinar formations, in which mucins were identified. The 3 elements were positive for cytokeratins, epithelial membrane antigen, p53 protein, and Ki-67 (labeling: squamous cell carcinoma element, 34%; adenocarcinoma element, 29%; small cell carcinoma element 87%). The squamous cell carcinoma and adenocarcinoma elements were negative for CD56, chromogranin, synaptophysin, neuron-specific enolase, KIT and PDGFRA. In contrast, the small cell carcinoma element was positive for CD56 (Figure 2E), synaptophysin, KIT (Figure 2F), and PDGFRA (Figure 2G). Mutations of *KIT* and *PDGFRA* were not found.

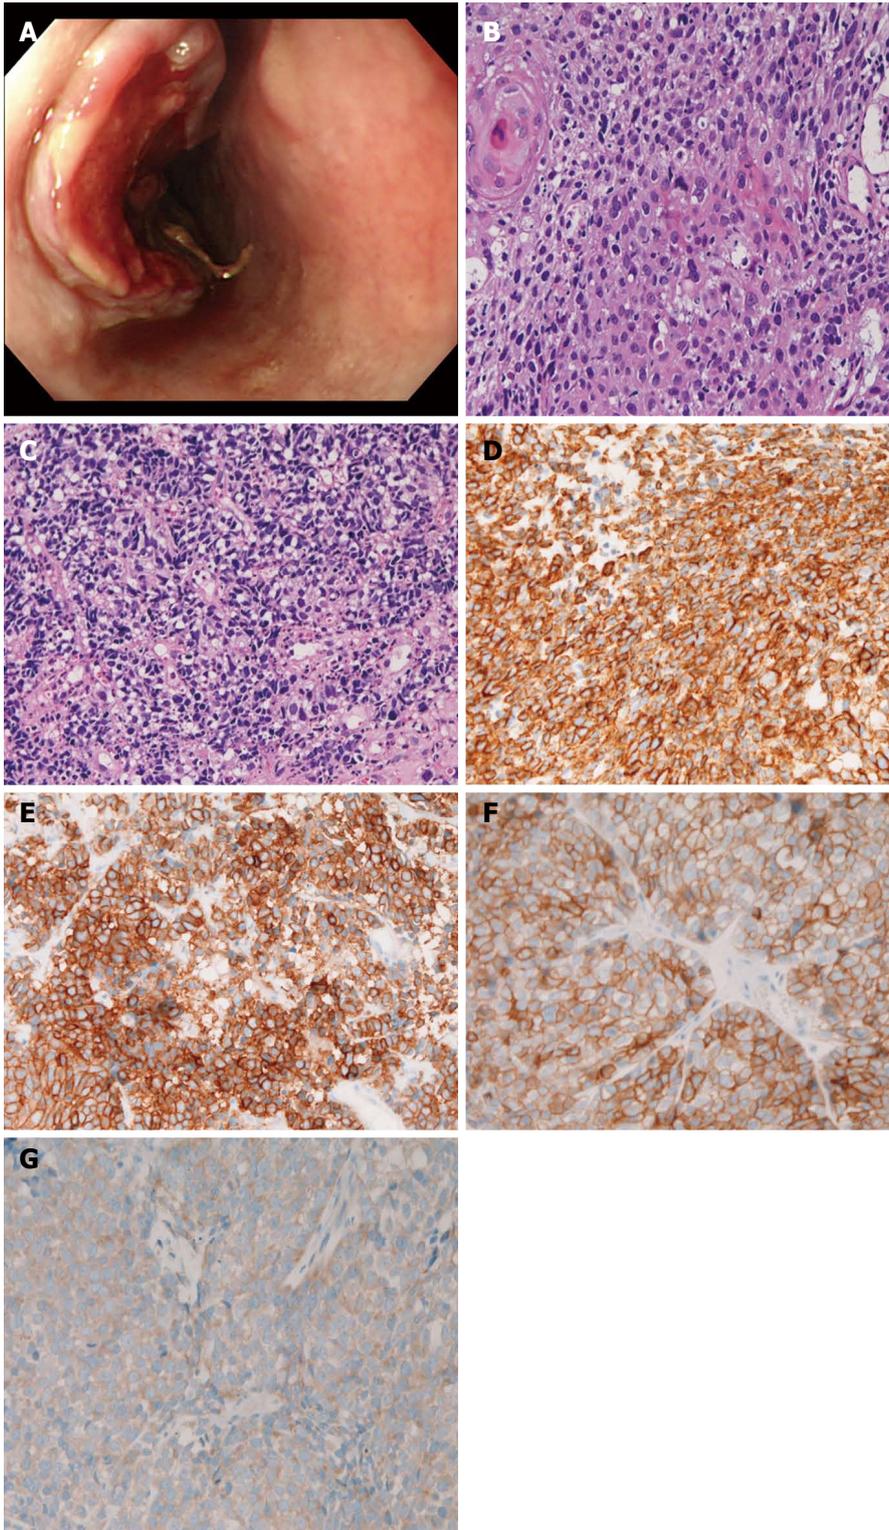

The patient was diagnosed with combined carcinoma of the esophagus (stage II, T2 N1 M0). Surgery was not considered because the tumor contained small cell carcinoma. The patient received chemoradiation, but died of systemic carcinomatosis 7 mo after presentation.

## DISCUSSION

The present 2 cases of combined carcinoma of the esophagus were associated with small cell carcinoma. Small cell carcinoma is diagnosed with hematoxylin and eosin (HE) staining and is defined as an undifferentiated carcinoma consisting of small cells with characteristic cellular and nuclear features, such as small-sized cells, scant cytoplasm, hyperchromatic, finely granular, and molded nuclei, and inconspicuous nucleoli, according to the World Health Organization Blue Book<sup>[31]</sup>. Neuroendocrine features are recognized in more than 90% of small cell carcinoma<sup>[31]</sup>. Squamous cell carcinoma is characterized by a squamoid cell arrangement and the presence of intercellular bridges and keratinization. Adenocarcinoma is characterized by tubular formations and the presence of mucins. Case 1 in the present study fulfilled these criteria, and was definitely combined small cell carcinoma and squamous cell carcinoma. Likewise, Case 2 was an apparently combined small cell carcinoma, squamous cell carcinoma, and adenocarcinoma. The presence of p53 protein and high Ki-67 labeling supports the above diagnosis.

In the present study, there was gradual merging of the 2 elements in case 1 and of the 3 elements in case 2. These findings may indicate that each element is derived from transdifferentiation of other elements. Traditionally, small cell carcinoma of the esophagus is thought to be derived from enterochromaffin cells or APUD cells present in the normal esophagus. Otherwise, this esophageal tumor arises from totipotent stem cells of the esophagus, as suggested by Ho *et al.*<sup>[2]</sup>. The present study could not determine the histogenesis of the combined carcinomas associated with small cell carcinomas.

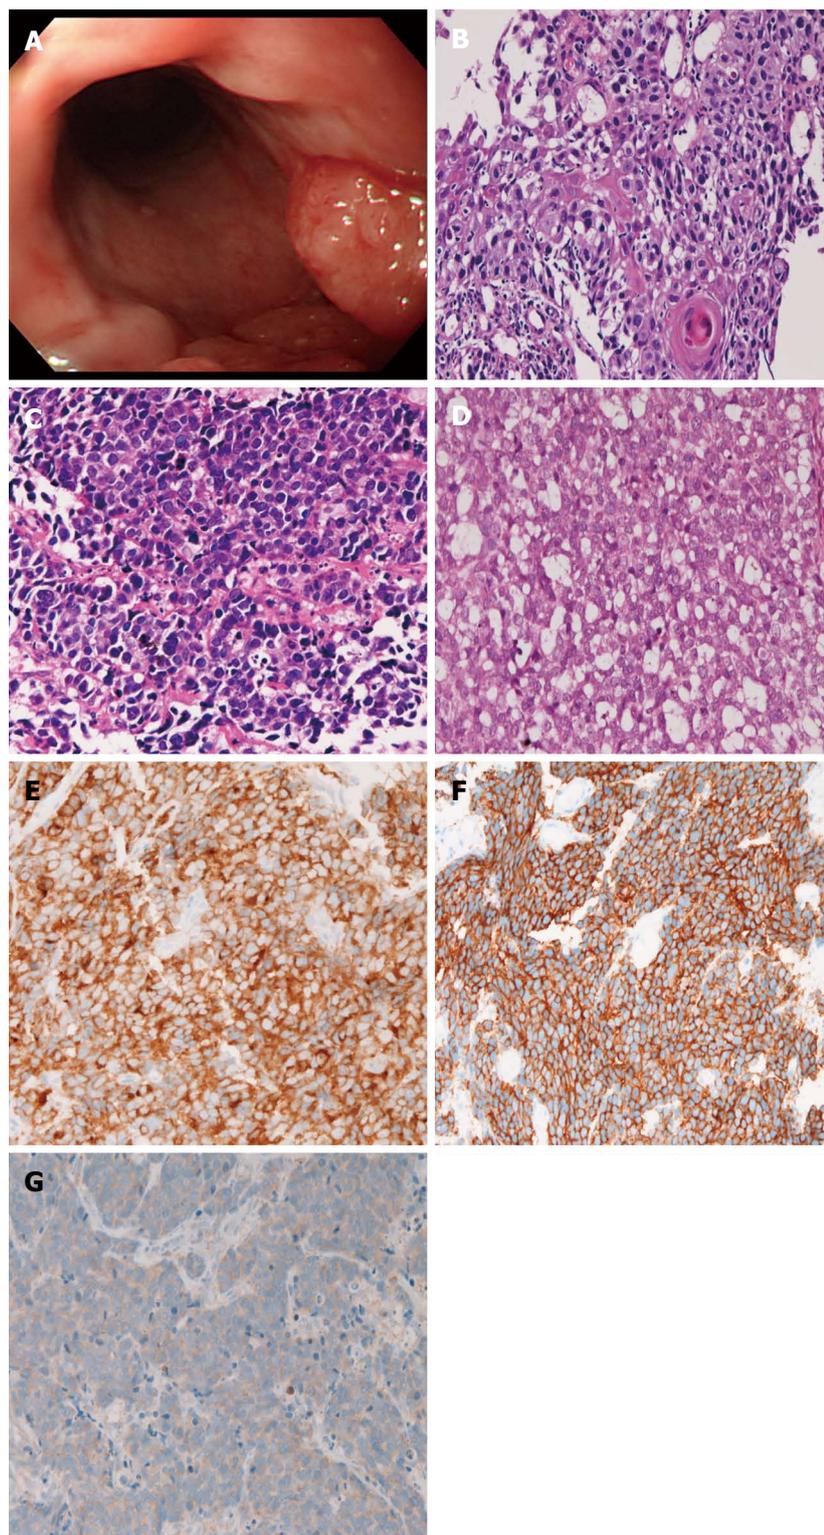

Most of esophageal tumors with multiple differentiation (combined carcinoma) are associated with small cell carcinoma<sup>[1-15,17-24]</sup>, although basaloid cell squamous cell carcinoma also shows multiple differentiation<sup>[16]</sup>. The cel-

ular origin of small cell carcinoma is unknown. In the full review of the English literature on combined carcinomas of esophageal cancers, Rosen *et al*<sup>[1]</sup> reported an epidermoid carcinoma simulating oat cell carcinoma. Ho *et al*<sup>[2]</sup> reported that 2 of 4 cases of esophageal small cell carcinoma contained foci of squamous cell carcinoma. Reid *et al*<sup>[3]</sup> described a case of esophageal small cell carcinoma with foci of squamous cell carcinoma. Reyes *et al*<sup>[4]</sup> reported that foci of squamous cell carcinoma were seen in 4/16

esophageal small cell carcinoma. Sarma<sup>[5]</sup> mentioned that there were oat cell carcinomas with squamous cell carcinoma foci and adenocarcinoma foci. Doherty *et al*<sup>[6]</sup> reported that there were oat cell carcinomas with squamous cell carcinoma *in situ*, with squamous cell carcinoma, with adenocarcinoma, and with carcinoid. Sato *et al*<sup>[7]</sup> reported a case of small cell carcinoma with invasive squamous cell carcinoma. Sasajima *et al*<sup>[8]</sup> demonstrated one case of esophageal carcinoma showing multiple differentiations into oat

**Figure 2 Case 2.** A: Endoscopy. An elevated tumor is seen in the esophagus; B: Histology of the squamous cell carcinoma element of the esophageal tumor. A cancer pearl is seen [hematoxylin and eosin (HE), x 200]; C: Small cell carcinoma element of the esophageal carcinoma. The tumor cells show characteristic morphologies of small cell carcinoma (HE, x 200); D: Adenocarcinomatous element shows focal tubular formations (HE, x 200); E: CD56 is expressed in the small cell carcinoma component (x 200); F: KIT is expressed in the small cell carcinoma component (x 200); G: Platelet-derived growth factor- $\alpha$  is expressed in the small cell carcinoma component (x 200).

cell carcinoma, adenoid cystic carcinoma, adenocarcinoma, and squamous cell carcinoma. Mori *et al*<sup>[9]</sup> reported that 7 squamous cell foci and 2 adenocarcinoma foci were recognized in 10 small cell carcinomas. Attar *et al*<sup>[10]</sup> showed concomitant squamous cell carcinoma in small cell carcinoma. Beyer *et al*<sup>[11]</sup> mentioned that there was considerable histological heterogeneity in small cell carcinoma. Fujiwara *et al*<sup>[13]</sup> reported a case of small cell carcinoma with concomitant squamous cell carcinoma.

Takubo *et al*<sup>[14]</sup> found a combination of small cell carcinoma and squamous cell carcinoma in 11 of 21 cases, and a combination of small cell carcinoma and mucoepidermoid carcinoma in 1 of 21 cases. Medgyesy *et al*<sup>[15]</sup> found a combination of small cell carcinoma and adenocarcinoma in 1 of 8 cases, and a combination of small cell carcinoma and squamous cell carcinoma in 1 of 8 cases. Cho *et al*<sup>[16]</sup> identified a combination of basaloid squamous cell carcinoma and squamous cell carcinoma in 8 of 18 cases, a

combination of basaloid squamous cell carcinoma and adenocarcinoma in 3 of 18 cases, a combination of basaloid squamous cell carcinoma and small cell carcinoma in 2 of 18 cases. Uğraş *et al*<sup>[18]</sup> reported a combined carcinoma composed of small cell carcinoma and squamous cell carcinoma. Ishihara *et al*<sup>[19]</sup> found an esophageal combined carcinoma consisting of Pagetoid squamous cell carcinoma, choriocarcinoma, and mucoepidermoid carcinoma. Yamamoto *et al*<sup>[20]</sup> reported *in situ* and invasive squamous cell carcinomas were present in 3 of 6 cases of small cell carcinoma. Wu *et al*<sup>[21]</sup> reported that small cell carcinoma with squamous cell carcinoma was found in 3 of 9 cases. Yun *et al*<sup>[22]</sup> identified squamous differentiation in small cell carcinoma in 2 of 21 cases. Bilbeau *et al*<sup>[23]</sup> reported a case of small cell carcinoma with adenocarcinoma in a Barrett's esophagus. Maru *et al*<sup>[24]</sup> reported that a combination of small cell carcinoma and adenocarcinoma was seen in 15 of 40 cases, and a combination of small cell carcinoma and squamous cell carcinoma in 1 of 40 cases. Therefore, this literature review showed that combined carcinoma of the esophagus is not so rare among small cell esophageal carcinomas, and that the majority of combined carcinoma is associated with small cell carcinoma. The review also confirmed that esophageal combined carcinoma composed of small cell carcinoma and squamous cell carcinoma is the most common, followed by a combination of small cell carcinoma and adenocarcinoma. The present 2 cases also are the common type of combined esophageal carcinoma.

As mentioned above, small cell carcinoma is diagnosed by HE staining<sup>[31]</sup>. About 90% of small cell carcinoma has neuroendocrine features<sup>[31]</sup>. The neuroendocrine features can be demonstrated by immunohistochemical demonstration of neuroendocrine antigens such as chromogranin, synaptophysin, CD56, and neuron-specific enolase or by ultrastructural demonstration of neuroendocrine secretory vesicles<sup>[32]</sup>. Yamamoto *et al*<sup>[20]</sup> described that CD56, neuron-specific enolase, and chromogranin were positive in a small cell carcinoma component while they were negative in the squamous cell carcinoma component in 3 cases of combined esophageal carcinoma. They also demonstrated that both components were positive for cytokeratins and epithelial membrane antigen. Wu *et al*<sup>[21]</sup> described that esophageal small cell carcinomas were positive for neuron-specific enolase, chromogranin A, and synaptophysin in all 9 cases investigated. Yun *et al*<sup>[22]</sup> described that the percentage of endocrine markers in 21 esophageal small cell carcinomas was as follows: synaptophysin, 95%; CD56, 76%; chromogranin A, 62%; neuron-specific enolase, 62%; TTF-1, 71%; epithelial membrane antigen, 62%; cytokeratins, 57%; S100 protein, 19%. Maru *et al*<sup>[24]</sup> described that chromogranin was positive in 31 of 40 and synaptophysin in all 40 esophageal neuroendocrine carcinomas. In the present case, synaptophysin, CD56 and chromogranin were positive in the small cell carcinoma component in case 1, and CD56 and synaptophysin were positive in the small cell carcinoma component in case 2.

In both cases in the present study, all the elements were positive for cytokeratin and epithelial membrane antigen. The non-small cell carcinoma components were negative for the neuroendocrine carcinoma. These findings are compatible with those of previous studies.

The present study has new findings: it showed positive expression of *KIT* and *PDGFRA* in the small cell carcinoma element of the 2 combined esophageal carcinomas. The present study also revealed that the squamous cell carcinoma and adenocarcinoma components were negative for *KIT* and *PDGFRA* protein and were negative for *KIT* and *PDGFRA* mutations in the esophageal combined carcinoma. *KIT* and *PDGFRA* are transmembrane receptor tyrosine kinase oncoproteins involved in carcinogenesis<sup>[33-35]</sup>. The vast majority of small cell carcinoma develops in the lung. In small cell lung carcinoma, *KIT* is frequently expressed, but no mutations of *KIT* gene have been recognized<sup>[36-46]</sup>. In small cell lung carcinoma, protein expression and mutations of *PDGFRA* are unknown. In extrapulmonary small cell carcinoma, *KIT* and *PDGFRA* proteins are frequently expressed, but there have been no mutations of *KIT* and *PDGFRA* genes found<sup>[46-48]</sup>. Many more studies of the *KIT* and *PDGFRA* gene status in esophageal combined carcinomas are necessary to elucidate the molecular mechanism of the carcinogenesis.

The biological behavior of these combined carcinomas of the esophagus is not known. However, it is thought that these combined carcinomas behave like small cell carcinoma, because the great majority of these combined carcinomas contain a small cell carcinoma element<sup>[1-24]</sup>. The option for treatment is not surgery but chemotherapy and radiation as in pulmonary small cell carcinoma<sup>[1-24]</sup>. The chemotherapy employed was cisplatin and etoposide<sup>[1-24]</sup>. Adjuvant radiation therapy may be effective. The combined carcinomas of the esophagus have a higher propensity for systemic metastases<sup>[1-24]</sup>. The survival rate is not clear because of a limited number of cases. However, survival was thought to be similar to that of pulmonary small cell carcinoma<sup>[1-24]</sup>.

In summary, the authors presented 2 rare cases of esophageal combined carcinoma with double (squamous cell carcinoma and small cell carcinoma) and triplicate differentiation (squamous cell carcinoma, small cell carcinoma, and adenocarcinoma). The authors speculate that the combined carcinomas are basically small cell carcinomas with squamous and/or adenocarcinomatous differentiation. The present esophageal combined carcinomas may arise from enterochromaffin or totipotent stem cell of the esophagus. It is also possible that each element of the esophageal combined carcinomas may be derived from transdifferentiation of other elements. There were expressions of *KIT* and *PDGFRA* in the small cell carcinoma component of the esophageal combined carcinomas, but were negative for mutations of *KIT* and *PDGFRA*.

### Abstract

*Ascaris lumbricoides* is the largest intestinal nematode parasite of man, which can lead to various complications because of its mobility. As the esophagus is not normal habitat of *Ascaris*, the report of esophageal ascariasis is rare. An old female presented with dysphagia after an intake of several red bean buns and haw jellies. The barium meal examination revealed a spherical defect in the lower esophagus. Esophageal bezoar or esophageal carcinoma was considered at the beginning. The patient fasted, and received fluid replacement treatment as well as some oral drugs such as proton pump inhibitor and sodium bicarbonate. Then upper gastrointestinal endoscopy was done to further confirm the diagnosis and found a live *Ascaris lumbricoides* in the gastric antrum and two in the duodenal bulb. The conclusive diagnosis was ascariasis. The esophageal space-occupying lesion might be the entangled worm bolus. Anthelmintic treatment with mebendazole improved patient's clinical manifestations along with normalization of the radiological findings during a 2-wk follow-up. Authors report herein this rare case of *As-*

### INTRODUCTION

*Ascaris lumbricoides* is the giant intestinal roundworm, causing infection of the gastrointestinal tract and affects approximately one quarter of the world's population. In clinical observations, the majority of patients are infected with intestinal ascariasis. Adult roundworms can be stimulated to migrate to any orifice by stressful conditions such as gastrointestinal disease, fever, anesthesia and anthelmintic drugs, so some complications such as acute cholecystitis, acute cholangitis, and acute pancreatitis caused by ascariasis of bile or pancreatic ducts have been reported. However, demonstration of the worms in esophagus is extremely rare. A case of esophageal ascariasis in a 15-year-old boy was reported by an Indian author in 1999<sup>[1]</sup>, but it did not discuss the possible mechanism. Herein, we describe a case that showed a space-occupying lesion of the esophagus in an old woman caused by *Ascaris* and discuss the likely causes.

## CASE REPORT

A 70-year-old female presented with recurrent dysphagia for 4 years, and was admitted to our hospital with complaints of symptoms worsening in the past 3 d. The patient complained that the dysphagia often occurred when she ate too fast, which was unrelated to the position or season and relieved by inducing vomiting through physical stimulation. She also had abdominal distension and frequent belching. Three days before admission, the symptoms of dysphagia could not be relieved by inducing vomiting after an intake of several red bean buns and haw jellies. Barium meal examination in a local hospital revealed a spherical defect in the lower esophagus allowing little barium to pass through (Figure 1). She had no specific past medical history which included digestive system disease. Upon physical examination, her general condition was normal, temperature 37 °C, blood pressure 120/75 mmHg, heart rate 64 beats/min, and respiratory rate of 18 breaths/min. She was thin but no signs of anemia. The abdomen was soft with normal bowel sounds and no peritoneal signs. The laboratory results were as follows: Hb 139 g/L, white blood cell  $11.54 \times 10^9/L$ , neutrophils 77.8%, eosinophils 0.3%. Markers for hepatitis A, B, C were negative. Kidney and liver function tests and serum electrolytes were normal. Fecal examination was not available due to absence of stools in the hospital. X-ray films of the chest and abdomen were performed immediately upon admission to our hospital and showed a globular high density shadow on the right side of trachea in the mediastinum, as well as a strand-like high density shadow in the right upper quadrant of abdomen, and excess barium remained in the colon, and lumbar spondylosis. We considered the following diagnoses: hiatal hernia, esophageal bezoar or esophageal carcinoma on the basis of the radiological appearance.

The patient fasted and was given fluid replacement treatment. Other oral drugs such as proton pump inhibitor (PPI) and sodium bicarbonate were also administered considering the possible existence of hiatal hernia and esophageal bezoar, while soybean oil was taken orally to help the barium pass with the feces. To further confirm the diagnosis, the patient underwent upper gastrointestinal endoscopy on the second day of admission. Endoscopy showed the mucous membrane of esophagus to be smooth and clear except for some slight congestion in the lower part; the body of stomach was normal and a live *Ascaris lumbricoides* worm was seen in the gastric antrum, where mucosa was thinner; there was a diverticula approximately 0.6 cm × 0.6 cm in size in the posterior wall of duodenal bulb and another two live worms were present (Figure 2). The congestion of duodenal mucosa also appeared. Endoscopic diagnoses were esophagitis, atrophic antral gastritis, duodenitis with diverticulum, and ascariasis.

The patient reported a history of passage of worms in stools, and a history of eating raw vegetables. She received mebendazole for anthelmintic treatment along with PPI therapy. The patient improved symptomatically during a 2-wk follow-up, and did pass 5-6 worms with

Figure 1 Barium meal examination revealed a spherical filling defect in the lower esophagus.

Figure 2 A live *Ascaris* worm appeared in the duodenal bulb, which was extracted with a grasper.

Figure 3 The defect filling disappeared in repeated barium examinations.

feces. Repeated barium examination for upper gastrointestinal tract was unremarkable (Figure 3).

## DISCUSSION

*Ascaris lumbricoides*, the largest intestinal nematode parasite of man, are commonly seen in rural areas of China, especially among people with poor hygienic conditions and/or having a habit of eating raw food. However, the prevalence of ascariasis has declined with improvement of sanitation and the application of pesticides and chemi-

cal fertilizers. The serious harm and complications of this round worm should be stressed. *Ascaris* larvae can cause transient eosinophilic pulmonary infiltrates (Loeffler's syndrome) when they migrate through the lungs, which is characterized by pulmonary infiltrates and peripheral blood eosinophilia. Infection of adult *Ascaris lumbricoides*, which mostly inhabit the jejunum and ileum, usually presents with anorexia, nausea and vomiting, intermittent periumbilical pain, and malnutrition. More serious complications of *Ascaris* infection may occur when a large worm burden is present in the lumen of the intestine, such as intestinal obstruction, intussusception, volvulus or even gangrene. Intestinal hemorrhage<sup>[2]</sup> and perforation by *Ascaris* have also been reported, with the latter being able to lead to acute diffuse peritonitis or peritoneal granuloma<sup>[3]</sup>. In addition, *Ascaris* infection can cause allergic reactions, presenting with urticaria, skin itch, angio-neurotic edema or even eosinophilic cholecystitis<sup>[4]</sup>.

When the living environment becomes unfavorable such as gastrointestinal disease, hunger, fever, failed deworming therapy or impaction of a mass of worms in the intestinal lumen, adult *Ascaris* will try to enter into any orifice and advance into any channel leading off from it. Then various complications are encountered. The worms commonly enter the biliary or pancreatic ducts, causing cholecystitis, cholangitis, liver abscess, and pancreatitis. *Ascaris* may migrate into appendix as well, resulting in appendiceal colic and appendicitis. *Ascaris* has also been found in the lacrimal passage by being regurgitated into the nasolacrimal duct when they accidentally enter nasopharynx; in the air way causing mechanical asphyxia; and in the urethra and urinary bladder through vesico-intestinal fistulae or transanal migration causing urinary retention. Moreover, the emergence of an *Ascaris* from mouth, nostrils and external auditory meatus has been documented. Esophagus ascariasis is extremely rare, because the esophagus is not normal habitat of *Ascaris* as it prefers an alkaline environment and rarely travels from the jejunum and duodenum to the stomach (an acid environment) and then to esophagus.

The patient in our case is at high risk of ascariasis as she is from rural area and in favor of eating fresh vegetables. This old woman was admitted to the hospital due to dysphagia with an abnormal barium study of the esophagus. In Figure 1, we can find several high-density string shadows and globular shadows in the esophageal spherical filling defect, which actually are *Ascaris* worms. The most likely explanation in our case is that the worms were forced to migrate by gastroduodenal antiperistalsis, which is induced by eating too many red bean buns and haw jellies. Subsequently these worms became entangled with each other to form a small worm bolus in the alkaline esophagus, resulting in the symptom of dysphagia. The patient received treatment of soybean oil after admission, and she drank lidocaine hydrochloride mucilage before endoscopic examination, which relaxed the lower esophageal sphincter, possibly stimulating the worms. All of these measures induced the migration of the *Ascaris* bolus to the gastrointestinal tract. Therefore, the esophagus ap-

peared normal except for some slight mucosal congestion on endoscopy. After anthelmintic therapy, more ascarides were passed out with feces, and a repeated barium study of upper gastrointestinal showed that the former defect filling had disappeared, which confirmed that the abnormal radiological appearance in the esophagus was a worm bolus. In a previous case<sup>[1]</sup> with similar radiographic appearance in the esophagus, the boy later vomited out six live *Ascaris* worms, and his esophageal lumen and mucosa were normal on the barium examination done the next day. Because of lack of exact causative factors in this case, we consider that children's anatomically smaller intestine and larger worm loads caused the rapid transit of worms across the esophagus. This kind of anti-peristaltic migration of *Ascaris* is truly uncommon.

As our patient had a history of recurrent dysphagia and eating too many haw jellies before admission, we highly suspected that hiatal hernia combining with esophageal bezoar might cause this kind of space-occupying lesion at the beginning. However, bezoars rarely form in the esophagus and are often associated with structural and functional abnormalities of the esophagus, such as achalasia and hiatal hernia. Esophageal bezoar is also a complication of enteral feeding and the predisposing factors include mechanical ventilation, supine position, neurological diseases, diabetes mellitus, hypothyroidism, obesity and history of partial gastrectomy<sup>[5]</sup>. Therefore, we performed the gastrointestinal endoscopy to clarify the diagnosis. The unexpected result suggests that careful history-taking and complete examinations are necessary.

In conclusion, we reported a case of an old woman with esophageal ascariasis and discussed the possible causes. We often lack of awareness of *Ascaris* infection because of the dramatically decreasing incidence and several different and unspecific symptoms of this infection. This report also listed some other common and rare complications, and we would like to warn all medical workers that we should pay more attention to such a disease and reduce any misdiagnosis in the future work.

## Events Calendar 2012

January 13-15, 2012  
 Asian Pacific *Helicobacter pylori*  
 Meeting 2012  
 Kuala Lumpur, Malaysia

January 19-21, 2012  
 American Society of Clinical  
 Oncology 2012 Gastrointestinal  
 Cancers Symposium  
 San Francisco, CA 3000,  
 United States

January 19-21, 2012  
 2012 Gastrointestinal Cancers  
 Symposium  
 San Francisco, CA 94103,  
 United States

January 20-21, 2012  
 American Gastroenterological  
 Association Clinical Congress of  
 Gastroenterology and Hepatology  
 Miami Beach, FL 33141,  
 United States

February 3, 2012  
 The Future of Obesity Treatment  
 London, United Kingdom

February 16-17, 2012  
 4th United Kingdom Swallowing  
 Research Group Conference  
 London, United Kingdom

February 23, 2012  
 Management of Barretts  
 Oesophagus: Everything you need  
 to know  
 Cambridge, United Kingdom

February 24-27, 2012  
 Canadian Digestive Diseases Week  
 2012  
 Montreal, Canada

March 1-3, 2012  
 International Conference on  
 Nutrition and Growth 2012  
 Paris, France

March 7-10, 2012  
 Society of American Gastrointestinal  
 and Endoscopic Surgeons Annual  
 Meeting  
 San Diego, CA 92121, United States

March 12-14, 2012  
 World Congress on  
 Gastroenterology and Urology  
 Omaha, NE 68197, United States

March 17-20, 2012  
 Mayo Clinic Gastroenterology and  
 Hepatology  
 Orlando, FL 32808, United States

March 26-27, 2012  
 26th Annual New Treatments in  
 Chronic Liver Disease  
 San Diego, CA 92121, United States

March 30-April 2, 2012  
 Mayo Clinic Gastroenterology and  
 Hepatology  
 San Antonio, TX 78249,  
 United States

March 31-April 1, 2012  
 27th Annual New Treatments in  
 Chronic Liver Disease  
 San Diego, CA 92121, United States

April 8-10, 2012  
 9th International Symposium on  
 Functional GI Disorders  
 Milwaukee, WI 53202, United States

April 13-15, 2012  
 Asian Oncology Summit 2012  
 Singapore, Singapore

April 15-17, 2012  
 European Multidisciplinary  
 Colorectal Cancer Congress 2012  
 Prague, Czech

April 18-20, 2012  
 The International Liver Congress  
 2012  
 Barcelona, Spain

April 19-21, 2012  
 Internal Medicine 2012  
 New Orleans, LA 70166,  
 United States

April 20-22, 2012  
 Diffuse Small Bowel and Liver  
 Diseases  
 Melbourne, Australia

April 22-24, 2012  
 EUROSON 2012 EFSUMB Annual

Meeting  
 Madrid, Spain

April 28, 2012  
 Issues in Pediatric Oncology  
 Kiev, Ukraine

May 3-5, 2012  
 9th Congress of The Jordanian  
 Society of Gastroenterology  
 Amman, Jordan

May 7-10, 2012  
 Digestive Diseases Week  
 Chicago, IL 60601, United States

May 17-21, 2012  
 2012 ASCRS Annual Meeting-  
 American Society of Colon and  
 Rectal Surgeons  
 Hollywood, FL 1300, United States

May 18-19, 2012  
 Pancreas Club Meeting  
 San Diego, CA 92101, United States

May 18-23, 2012  
 SGNA: Society of Gastroenterology  
 Nurses and Associates Annual  
 Course  
 Phoenix, AZ 85001, United States

May 19-22, 2012  
 2012-Digestive Disease Week  
 San Diego, CA 92121, United States

June 2-6, 2012  
 American Society of Colon and  
 Rectal Surgeons Annual Meeting  
 San Antonio, TX 78249,  
 United States

June 18-21, 2012  
 Pancreatic Cancer: Progress and  
 Challenges  
 Lake Tahoe, NV 89101, United States

July 25-26, 2012  
 PancreasFest 2012  
 Pittsburgh, PA 15260, United States

September 1-4, 2012  
 OESO 11th World Conference  
 Como, Italy

September 6-8, 2012  
 2012 Joint International

Neurogastroenterology and Motility  
 Meeting  
 Bologna, Italy

September 7-9, 2012  
 The Viral Hepatitis Congress  
 Frankfurt, Germany

September 8-9, 2012  
 New Advances in Inflammatory  
 Bowel Disease  
 La Jolla, CA 92093, United States

September 8-9, 2012  
 Florida Gastroenterologic Society  
 2012 Annual Meeting  
 Boca Raton, FL 33498, United States

September 15-16, 2012  
 Current Problems of  
 Gastroenterology and Abdominal  
 Surgery  
 Kiev, Ukraine

September 20-22, 2012  
 1st World Congress on Controversies  
 in the Management of Viral Hepatitis  
 Prague, Czech

October 19-24, 2012  
 American College of  
 Gastroenterology 77th Annual  
 Scientific Meeting and Postgraduate  
 Course  
 Las Vegas, NV 89085, United States

November 3-4, 2012  
 Modern Technologies in  
 Diagnosis and Treatment of  
 Gastroenterological Patients  
 Dnepropetrovsk, Ukraine

November 4-8, 2012  
 The Liver Meeting  
 San Francisco, CA 94101,  
 United States

November 9-13, 2012  
 American Association for the Study  
 of Liver Diseases  
 Boston, MA 02298, United States

December 1-4, 2012  
 Advances in Inflammatory Bowel  
 Diseases  
 Hollywood, FL 33028, United States

**GENERAL INFORMATION**

*World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

**Maximization of personal benefits**

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copy-right" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid

evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

**Aims and scope**

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

**Columns**

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systematically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensus and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

### Published by

Baishideng Publishing Group Co., Limited

## SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

### Biostatistical editing

Statistical review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Redit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc.* The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only

homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

### Conflict-of-interest statement

In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: [http://www.icmje.org/ethical\\_4conflicts.html](http://www.icmje.org/ethical_4conflicts.html).

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

### Statement of informed consent

Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

### Statement of human and animal rights

When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

## SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/1007-9327/office>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS ([http://www.wjgnet.com/1007-9327/g\\_info\\_20100315215714.htm](http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm)) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [wjg@wjgnet.com](mailto:wjg@wjgnet.com), or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

## MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically

for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. [montgomery.bissell@ucsf.edu](mailto:montgomery.bissell@ucsf.edu)

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

### Abstract

There are unstructured abstracts (no less than 256 words) and structured abstracts (no less than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no less than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections.

## Instructions to authors

AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of “To investigate/study/...”; MATERIALS AND METHODS (no less than 140 words); RESULTS (no less than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ; CONCLUSION (no more than 26 words).

### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

### Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315215714.htm](http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm).

### Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: ...etc. It is our principle to publish high resolution-figures for the printed and E-versions.

### Tables

Three-line tables should be numbered 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  should be noted ( $P > 0.05$  should not be noted). If there are other series of *P* values, <sup>c</sup> $P < 0.05$  and <sup>d</sup> $P < 0.01$  are used. A third series of *P* values can be expressed as <sup>e</sup> $P < 0.05$  and <sup>f</sup> $P < 0.01$ . Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be la-

beled with ●, ○, ■, □, ▲, △, etc., in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, “Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>”. If references are cited directly in the text, they should be put together within the text, for example, “From references<sup>[19,22-24]</sup>, we know that...”.

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

### PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

eases. *Emerg Infect Dis* serial online, 1995-01-03, cited 1996-06-05; 1(1): 24 screens. Available from: URL: <http://www.cdc.gov/ncidod/eid/index.htm>

**Patent (list all authors)**

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

**Statistical data**

Write as mean  $\pm$  SD or mean  $\pm$  SE.

**Statistical expression**

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as *v* (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

**Units**

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4  $\pm$  2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum numbers can be found at: [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315223018.htm](http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm).

**Abbreviations**

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

**Italics**

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kbo I*, *Kpn I*, etc.

Biology: *H. pylori*, *E. coli*, etc.

## RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be re-submitted online (<http://www.wjgnet.com/1007-9327/office/>). The author should send the copyright transfer letter, responses to the reviewers, English language Grade B certificate (for non-native speakers of English) and final manuscript checklist to [wjg@wjgnet.com](mailto:wjg@wjgnet.com).

### Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

### Copyright assignment form

Please download a Copyright assignment form from [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315222818.htm](http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm).

### Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315222607.htm](http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm).

### Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

### Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

### Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

### Publication fee

*WJG* is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1300 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.

## Contents

*World Journal of Gastroenterology*  
Volume 18 Number 14 April 14, 2012

**ACKNOWLEDGMENTS** I Acknowledgments to reviewers of *World Journal of Gastroenterology*

**APPENDIX** I Meetings  
I-VI Instructions to authors

**ABOUT COVER** Editorial Board Member of *World Journal of Gastroenterology*, Mauro Bernardi, Professor, Internal Medicine, Cardioangiology, Hepatology, University of Bologna, Semeiotica Medical, Policlinico S. Orsola, Malpighi, Via Massarenti, 9, 40138 Bologna, Italy

**AIM AND SCOPE** *World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access, peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.  
The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

**FLYLEAF** I-IX Editorial Board

### Abstract

Chronic constipation is a common and extremely troublesome disorder that significantly reduces the quality of life, and this fact is consistent with the high rate at which health care is sought for this condition. The aim of this project was to develop a consensus for the diagnosis and treatment of chronic constipation and obstructed defecation. The commission presents its results in a "Question-Answer" format, including a set of graded recommendations based on a systematic review of the literature and evidence-based medicine. This section represents the consensus for the diagnosis. The history includes information relating to the onset and duration of symptoms and may reveal secondary causes of constipation. The presence of alarm symptoms and risk factors requires investigation. The physical examination should assess the presence of lesions in the anal and perianal region. The evidence does not support the routine use of blood testing and colonoscopy or barium enema for constipation. Various scoring systems are available to quantify the severity of constipation; the Constipation Severity Instrument for constipation and the obstructed defecation syndrome score for obstructed defecation are the most reliable. The Constipation-Related Quality of Life is an excellent tool for evaluating the patient's quality of life. No single test provides a pathophysiological basis for constipation. Colonic transit and anorectal manometry define the pathophysiologic subtypes. Balloon expulsion is a simple screening test for defecatory disorders, but it does not define the mechanisms. Defecography detects structural abnormalities and assesses functional parameters. Magnetic resonance imaging and/or pelvic floor sonography can further complement defecography by providing information on the movement of the pelvic floor and the organs that it supports. All these investigations are indicated to differentiate

between slow transit constipation and obstructed defecation because the treatments differ between these conditions.

## INTRODUCTION

The mission of the Italian Association of Hospital Gastroenterologists (AIGO) is to advance the knowledge of digestive pathologies, to promote progress in the prevention, diagnosis, care and rehabilitation of gastrointestinal diseases, and to promote research.

The aim of the Italian Society of Colo-Rectal Surgery (SICCR) is to ensure the highest therapeutic standards through the evaluation and introduction into medical practice of the latest advances in the areas of prevention, diagnosis and care of pathologies involving the colon, rectum and anus.

The Joint Committee AIGO/SICCR is made up of members of these two scientific societies, elected on the basis of their experience in treating functional and organic problems of the colon and rectum.

The objective of the committee was to develop a consensus statement on the most important diagnostic and therapeutic aspects of functional constipation and obstructed defecation, including a set of graded recommendations based on a review of the literature and on evidence-based medicine.

## LITERATURE SEARCH

A search of the literature was carried out using the online databases of PUBMED, MEDLINE and COCHRANE to identify articles published in English before April 2011 and reporting trials conducted on adult subjects with chronic constipation. The key words used were: Rome criteria, constipation, slow transit constipation,

Table 1 Levels of evidence<sup>[1]</sup>

## LEVELS OF EVIDENCE AND GRADING OF RECOMMENDATIONS

The recommendations of the committee were defined and graded based on the current levels of evidence and in accordance with the criteria adopted by the American College of Gastroenterology's Chronic Constipation Task Force<sup>[1]</sup>.

Five evidence levels were defined (Table 1). The recommendations were graded A, B and C (Table 2).

The committee wishes to underline that insufficient evidence does not automatically imply "evidence against" a statement. Many decisions in daily practice are based on clinical experience. Sometimes, it is difficult to find scientific papers supporting a widespread clinical practice, but this difficulty does not mean that we need to refute or abandon therapies that clinicians have been using for years with their patients. Evidence-based medicine is a useful tool to guide clinical practice, but if applied mechanically and without the application of common sense and personal experience, it can lead to erroneous conclusions<sup>[2]</sup>.

In the development of this consensus statement, the committee identified five key areas (Table 3) and divided

Table 2 Grading of the recommendations<sup>[1]</sup>

Grading of the recommendations	
A	Recommendation supported by two or more level I trials, without conflicting evidence from other level I trials
B	Recommendation based on evidence from a single level I trial OR, evidence from two or more level I trials with conflicting, evidence from another level I trial OR, evidence from two or more level II trials
C	Recommendations based on levels of evidence III-V

OR: Odds ratio.

them into subsections. Each subsection was researched, and recommendations were prepared by one or more members of the committee in accordance with specific themes defined by the committee.

The process of drafting the consensus statement involved constant communication and evaluation conducted online and during four face-to-face working meetings held at 3-mo intervals. During these meetings, the levels of evidence and the grading of the recommendations were discussed to reach a consensus in all the areas covered in the consensus statement.

The commission presents its results here in a “Question-Answer” format, which will allow clinicians to find concise responses to their specific questions quickly and easily and to peruse the full text at their leisure.

## DEFINITION OF CONSTIPATION

Constipation can be either primary or secondary. The commission adopted the definition of primary functional constipation outlined in the Rome III criteria<sup>[3]</sup>. This set of criteria was developed by an international group of experts through a process of consensus, and it has been reviewed and revised more than once since it was first published<sup>[5-5]</sup>.

Stool form was defined using the Bristol stool form score<sup>[6]</sup>; constipation may involve slow intestinal transit and/or abnormal defecation; the definition of abnormal defecation from the Rome III criteria was adopted<sup>[7]</sup>.

## CLINICAL EVALUATION AND SCORING SYSTEMS

### Clinical evaluation

Is a patient history useful in the evaluation of chronic constipation? A thorough medical history should always be taken in patients with chronic constipation. This process constitutes the first approach to the patient and is designed to detect events that may be directly or indirectly linked to the patient's symptoms<sup>[8-11]</sup>.

The patient history can identify conditions responsible for secondary constipation<sup>[11,12]</sup>, such as the following: (1) alarm symptoms, such as weight loss, bloody stools, anaemia, or a family history of colon cancer; (2) conditions and/or diseases potentially associated with

Table 3 Areas defined by the committee for the consensus statement

Area	
1	Clinical evaluation and scoring systems
2	Diagnostic techniques
3	Medical and rehabilitative treatment
4	Surgery for slow transit constipation
5	Surgery for obstructed defecation with or without associated pelvic diseases

constipation, such as inappropriate diet<sup>[13]</sup>, low physical activity<sup>[10]</sup>, the use of constipating drugs, and metabolic, psychiatric or neurological diseases; and (3) the negative outcome of perineal-pelvic-abdominal or obstetric-gynaecological surgery<sup>[14,15]</sup>.

Can the medical history distinguish among the different subtypes of chronic constipation? No, there are as yet no specific criteria that can distinguish among the subtypes of chronic constipation based on anamnesis<sup>[7,16-18]</sup>. Level I evidence, Grade A recommendation.

Are there specific symptoms that are present only in patients with functional constipation? No, there are no specific symptoms that distinguish patients with functional constipation from normal subjects<sup>[3]</sup>. Level I evidence, Grade A recommendation.

The occurrence of two or more symptoms during at least 25% of bowel movements distinguishes patients with chronic constipation from normal subjects<sup>[3,19]</sup>.

Should a physical examination be performed in patients with chronic constipation? A physical examination is essential in the initial workup of a patient with chronic constipation<sup>[11]</sup>. The examination should include inspection of the anorectal region and exploration of the rectum. This process can detect external signs of anal disease, pelvic organ prolapse, or descending perineum syndrome. A digital rectal examination should detect any signs of organic disease or obstructed defecation. The examination is particularly important if functional alterations in defecation are suspected.

Is blood testing useful in the diagnostic algorithm of functional constipation? Blood testing does not provide useful input. Functional constipation is defined as a primitive condition and is not accompanied by any organic or biochemical alterations, being associated instead with a “functional” pathology of visceral motility. For this reason, there are no laboratory tests for the diagnosis of functional constipation<sup>[3,9]</sup>. Level I evidence, Grade A recommendation.

Blood tests can, however, be performed to exclude conditions of secondary chronic constipation<sup>[12]</sup>.

Should morphological investigations (colonoscopy, barium enema, or computerised tomographic colonography) be performed in all patients with chronic constipation? Prospective studies on this point are lacking in the literature<sup>[20,21]</sup>. There is no clear evidence to support the usefulness of colonoscopy in patients with chronic constipation. Level IV evidence, Grade C recommendation.

However, morphologic investigations should always be performed in patients with alarm symptoms, in patients > 50 years of age, and in patients with a family history of colon cancer.

## SCORING SYSTEMS IN CHRONIC CONSTIPATION

### Scoring systems to quantify disease severity

Various scoring systems have been developed to quantify the severity of constipation. These systems are particularly important in a subjective, functional disease, such as constipation, to evaluate the results of therapy.

An early scoring system, the chronic idiopathic constipation index (CICI), was published in *Techniques of Coloproctology* in 1996<sup>[22]</sup>. It is based on seven variables (scored from 0 to 3, with a maximum score of 21) and was designed to detect chronic idiopathic slow transit constipation. The CICI was the first evaluation system that took into consideration signs of autonomic neuropathy. However, it has never been validated in a prospective study.

In 1999, the Patient Assessment of Constipation Symptoms<sup>[23]</sup> was published. This 12-item, patient-administered questionnaire has been validated and found to be effective, but it is rarely used in clinical studies.

The most widely adopted instrument is the Cleveland Clinic Constipation Score<sup>[24]</sup>. It is easy to understand and administer and therefore has won broad acceptance, although it has not been formally validated. It consists of 8 items scored from 0 to 4 for a maximum score of 30. It should be noted that one of the items, "duration of symptoms", cannot be modified by therapy.

In 2002, a new, prospectively validated score, the symptom scoring system for constipation<sup>[25]</sup>, consisting of 11 items scored from 0 to 3 or 4 for a maximum possible score of 39, was published, but it is rarely used.

More recently the Constipation Severity Instrument (CSI)<sup>[26]</sup> was developed. It is a well-designed scoring system consisting of 78 items that can identify and quantify different types of constipation (IBS, slow transit and obstructed defecation).

In 2008, the first instrument specifically designed for obstructed defecation syndrome, the obstructed defecation syndrome (ODS) score, was published in *Colorectal Disease*<sup>[27]</sup>. It consists of 7 items scored from 0 to 4 with a maximum score of 27, and it has been prospectively validated.

### Measuring quality of life in constipation

Three Quality of Life (QoL) questionnaires for constipation have been published. The gastrointestinal QoL questionnaire<sup>[28]</sup> was designed to address all gastrointestinal symptoms and therefore is not specific for constipation. It includes 36 items with 5 possible answers, and it has a maximum possible score of 180.

In 2005, the first disease-specific questionnaire on constipation appeared, the Patient Assessment of Constipation Quality of Life<sup>[29]</sup>. It consists of 28 items

scored from 0 to 4 with a maximum score of 112.

Recently, a new, statistically validated QoL questionnaire, the Constipation-Related Quality of Life (CRQOL)<sup>[30]</sup>, was published. It includes 4 domains: social impact (11 items), distress (11 items), usual diet (11 items), and defecation features (4 items).

## Conclusions

Several scoring systems for constipation can be found in the medical literature. The consensus of the committee is that the most reliable instruments for scoring disease severity are the CSI for constipation in general and the ODS score for obstructed defecation. The CRQOL is an excellent tool for evaluating the effects of constipation on the patient's quality of life. The use of these instruments is recommended for clinical trials.

## DIAGNOSIS OF FUNCTIONAL CONSTIPATION

### Imaging in chronic constipation and obstructed defecation syndrome

Currently available imaging techniques for chronic constipation and ODS include the following: (1) transit time (TT) studies<sup>[31,32]</sup>; (2) X-ray videoproctography<sup>[33]</sup> and colpo-cysto-entero-defecography<sup>[34,35]</sup>; (3) magnetic resonance (MR)-defecography<sup>[36]</sup>; and (4) ultrasonography (US) of the pelvic floor<sup>[37-40]</sup>.

Can a TT study differentiate slow transit constipation from obstructed defecation? Depending on the site of accumulation of the radiopaque markers along the large bowel, an initial TT study can differentiate between patients with total or segmental colonic slow transit constipation and patients with outlet obstruction. Unfortunately, lack of standardisation in the procedure makes it difficult to compare results among centres. Level V evidence, Grade C recommendation. In the case of distal obstruction, X-ray defecography is recommended as a second-line examination. The fact that this examination has been universally adopted makes it the benchmark against which to test newer modalities.

When should defecography be performed as opposed to colpo-cysto-entero-defecography? Defecography is indicated to rule out a variety of conditions that could play a role in the aetiology of the presenting symptom(s), such as paradoxical contraction of the puborectalis muscle<sup>[41,42]</sup>, a rectocele, recto-anal intussusception and complete external rectal prolapse. Colpo-cysto-entero-defecography should be performed when multiple compartment defects are suspected, including cystocele, enterocele, or descending perineum syndrome<sup>[43]</sup>.

Because their clinical significance remains a matter of debate, there is general agreement<sup>[44-46]</sup> that the results of contrast radiography should not be relied on exclusively when making decisions regarding the treatment of a patient (including surgery).

When should MR defecography be considered as an alternative to X-ray examination? Due to the panoramic

view that they provide and the absence of ionising radiation, MR imaging of the pelvic floor and MR defecography are now frequently recommended as a valid alternative to contrast radiography, especially in young patients, female patients of reproductive age, pregnant patients, and those patients at risk for adverse reactions to the contrast medium.

Are the findings commonly observed on defecography captured equally well by MR defecography? Despite the less natural (horizontal) position of the patient during the exam, MR imaging can provide similar, and sometimes better, results than conventional X-rays, with the added advantage (especially in the case of defects affecting multiple compartments) of the superior reproducibility of the results<sup>[47,48]</sup>. Consequently, while MR defecography is widely recommended as a tool to increase diagnostic confidence in cases of evacuation dysfunctions, MR neurography of the pelvic floor can be extremely useful in detecting pudendal nerve entrapment neuropathy in patients with chronic pelvic pain<sup>[49]</sup>. Level V evidence, Grade C recommendation.

Can defecographic findings be assessed and measured by perineal, endovaginal and endoanal sonography? There has been a reappraisal of the use of perineal, introital, endoanal and endovaginal US (conventional 2-D and 3-D images recorded using a variety of probes: convex, end-fire, linear and axial 360° rotating models) in the evaluation of the pelvic floor anatomy in patients with evacuation dysfunctions<sup>[50-55]</sup>. With the exception of rectal evacuation<sup>[56]</sup>, the presence and severity of the most common ODS abnormalities visible on defecography can be equally well documented by any one of these sonography techniques. Level V evidence, Grade C recommendation.

What is the role of endovaginal sonography in chronic constipation? Currently, 2-D and 3-D endovaginal sonography are recommended as alternatives to defecography and MR imaging, respectively, when assessing the overall anatomic configuration and movement of the urogenital hiatus in patients with multiple defects affecting the muscular and fascial components of various compartments (anterior, middle and posterior), which are possibly indicative of descending perineum syndrome or pelvic organ prolapse<sup>[53,54]</sup>. Level V evidence, Grade C recommendation.

What is the role of endoanal sonography in chronic constipation? Given the inherently static nature of this examination and the presence of a foreign object in the anal canal (i.e., the endocavitary probe), endoanal sonography is of limited value in the diagnosis of chronic constipation. Recently, however, the advent of 3-D reconstruction has significantly increased the diagnostic confidence associated with this technique<sup>[55]</sup>, which can provide detailed imaging of abnormalities, such as the extent of anal sphincter defects, the anatomy of fistulous tracts in complex perianal sepsis, and submucosal invasion in early anorectal cancers.

In summary, general agreement exists among authors

that the first-line examination remains TT, followed by X-ray defecography. When the appropriate instruments and trained personnel are available, MRI and/or pelvic floor sonography can further complement defecography by providing information on the movement of the pelvic floor and the organs that it supports.

### **Anorectal manometry**

Anorectal manometry measures anal canal pressures. Perfusion catheters are generally employed, rather than solid-state microtransducers, which are more reliable but too expensive for routine use<sup>[57]</sup>. Vector volume manometry has been developed to provide a 3-D view of the anal sphincter, but its clinical utility is still under evaluation<sup>[58]</sup>. Recently, the high-resolution manometry has been shown to provide greater details than water-perfused manometry, but it is still in the experimental stage<sup>[59]</sup>.

The reproducibility of anal manometry is high<sup>[60]</sup>, but its reliability depends on the operator's experience, and its utility is limited by the absence of standardised protocols<sup>[61,62]</sup> and of data from large numbers of normal subjects<sup>[57,63]</sup>. Moreover, most of the parameters measured by anorectal manometry (anal canal pressure, sensory thresholds) are influenced by sex and age<sup>[64]</sup>.

Should anorectal manometry always be performed in patients with chronic constipation and/or obstructed defecation? The main indication for anorectal manometry is the presence of obstructed defecation<sup>[65,66]</sup>. It should also be performed in patients who do not improve with first-line treatments for chronic constipation (a defecation disorder is reported in 51% of such patients)<sup>[12,67]</sup>.

Anorectal manometry, together with other tests, can provide essential information on the rectoanal function defects involved in the physiopathology of obstructed defecation, including increased pressure in the anal canal, rectoanal inhibitory reflex defects, lower rectal sensitivity, and increased rectal compliance<sup>[7]</sup>. Level II evidence, Grade B recommendation.

Is anorectal manometry sufficient for the diagnosis of obstructed defecation? There is no gold standard for the diagnosis of obstructed defecation, and manometry alone does not provide sufficient grounds for the diagnosis. A comprehensive evaluation of anorectal function is necessary and should include tests to evaluate various aspects of defecation, including the balloon expulsion test, imaging techniques, and perhaps electromyography, in addition to manometry<sup>[7]</sup>. Defecography can evaluate the morphological and dynamic factors of defecation; anorectal manometry measures anorectal sensitivity and motility; and electromyography can provide information on electrical activity in the external anal sphincter muscle during straining. The balloon expulsion test can confirm the diagnosis of obstructed defecation<sup>[68,69]</sup>. Level II evidence, Grade B recommendation.

Anorectal manometry consists of several tests; which of them are most useful in the diagnosis of obstructed defecation? At a minimum, the following tests should be performed<sup>[70]</sup>: resting anal pressure, squeezing pressure,

Table 4 Interpretation of the manometric data

Test	Parameter evaluated	Interpretation
Resting pressure	IAS (70% of resting pressure) and EAS (30% of resting pressure)	<i>P</i> increased: Hypertonic sphincters (IAS and/or EAS). Oral nitroglycerin can identify the sphincter involved because it relaxes IAS, but not EAS
Squeeze pressure	EAS	The fatigue rate index can be calculated based on the pressure and duration of the contraction. However, the usefulness of the test in both constipated and incontinent patients is disputed <sup>[112,113]</sup>
Rectoanal inhibitory reflex	IAS relaxation during rectal inflation	Absent: Possible hirschsprung; If present with elevated volume inflation: Megarectum <sup>[57]</sup>
Rectal sensitivity	Rectal sensory function at different volumes	Elevated sensory thresholds may be linked to changes in rectal biomechanics (megarectum) or to afferent pathway dysfunction <sup>[114,115]</sup>
Rectal compliance	Mechanical rectal function	Increased compliance: megarectum <sup>[57]</sup>
Attempted defecation	Synchronisation between the increase in rectal pressure and the decrease in anal pressure during attempts to defecate	Three types of dysfunction may be detected <sup>[65]</sup> : Type 1: Adequate rectal <i>P</i> increase but associated with anal <i>P</i> increase; Type 2: Inadequate rectal <i>P</i> increase associated with anal <i>P</i> increase or inadequate anal <i>P</i> decrease; Type 3: Adequate rectal <i>P</i> increase but inadequate anal <i>P</i> decrease

IAS: Internal anal sphincter; EAS: External anal sphincter; *P*: Pressure. Modified from Azpiroz *et al*<sup>[57]</sup>.

rectoanal inhibitory reflex, rectal sensations (first sensation, maximum tolerable volume), rectal compliance, and rectal and anal pressure during attempted defecation (straining)<sup>[57,71]</sup>. The results will vary with age and sex; normal values based on a large cohort of healthy individuals are still lacking<sup>[57]</sup>. Level III evidence, Grade C recommendation.

How should I interpret the results of anorectal manometric tests for obstructed defecation? The interpretation of the manometric data in clinical and physiopathologic terms is summarised in Table 4.

Are there typical manometric abnormalities in chronic constipation and/or obstructed defecation? The main abnormality in obstructed defecation is absent or inadequate relaxation of the anal sphincter, sometimes associated, paradoxically, with contraction during straining (dyssynergia). Obstructed defecation may also be associated with absent or inadequate rectal pressure<sup>[65,67]</sup>. The “defecation index”, or the ratio of maximal rectal pressure to minimal anal residual pressure<sup>[65]</sup>, quantifies recto-anal coordination during attempted defecation. Abnormalities have also been reported in anal canal resting pressure, anal canal squeezing pressure (external anal sphincters exhaustion), rectoanal inhibitory reflex (RAIR), rectal sensitivity, and compliance. Level III evidence, Grade C recommendation.

How can anorectal manometry be used to guide choices regarding therapy? Anorectal manometry can shed light on the physiopathologic mechanisms of obstructed defecation and help to develop a pelvic floor rehabilitation program for the patient<sup>[72]</sup>. It should be included in the pre-operative evaluation when a surgical reduction in rectal capacity is planned<sup>[73,74]</sup>. If RAIR is absent, Hirschsprung disease should be suspected. Elevated sensory thresholds, increased compliance, and rectal motor dysfunction are frequent in constipated patients<sup>[75,76]</sup> and can be treated with sensory retraining biofeedback therapy, based on sensory values obtained by means of anorectal manometry<sup>[77]</sup>. The results of bio-

feedback and electrical stimulation can be measured with anorectal manometry, and in fact, a reduction in rectal sensory thresholds has been demonstrated<sup>[78,79]</sup>. Level III evidence, Grade C recommendation.

### Balloon expulsion test

The balloon expulsion test is a simple, inexpensive test that can identify patients with abnormal defecation.

What is the usefulness of the balloon expulsion test to diagnose dyssynergic defecation? The balloon expulsion test has not yet been standardised; the filling volume of the balloon, the position of the patient, and the expulsion time have differed in various studies.

Trials including healthy controls. Two trials performed the test with the patient seated and the balloon filled with 50 mL of water; 59%<sup>[67]</sup> and 25%<sup>[80]</sup> of the constipated patients and 16%<sup>[67]</sup> of the controls were unable to expel the balloon within 5 min.

In the third trial<sup>[81]</sup>, the expulsion time was not specified, and the test was performed with a balloon filled with different volumes of water; 100% of patients with idiopathic megarectum, 53% of patients with a normal colonic transit time, 36% of patients with a slow transit colonic time, and 7% of controls were unable to expel the balloon.

Other trials. Some trials<sup>[82-84]</sup> have assessed patients with pelvic floor dyssynergia and have reported positive results in 23% to 57% of patients. However, different methods were used, so the results are not comparable.

In one trial<sup>[85]</sup>, the balloon was filled to the point at which the need to defecate was triggered, and the balloon had to be expelled within one minute. The authors concluded that a negative test is useful “to identify patients who do not have dyssynergia” and resulted in a specificity of 89%, a sensibility of 88%, a positive predictive value of 67%, and a negative predictive value of 97%.

The balloon expulsion test cannot be used as a gold standard for the diagnosis of “dyssynergic defecation” and should be integrated with other anorectal tests. Level

III evidence, Grade C recommendation.

### Colonic manometry

Slow transit constipation (STC) is characterised by prolonged colonic transit, generally measured in terms of intestinal transit time using radiopaque markers<sup>[86]</sup>. Colon manometry shows the daily patterns of bowel activity, identifying high amplitude waves, which correspond to mass movement in the intestine, and low amplitude waves<sup>[87,88]</sup>. Manometric studies<sup>[89,90]</sup> in STC patients have shown that propagating activity may be altered in frequency, amplitude and duration; segmental activity can be maintained or drastically lost, but there is, above all, a subversion of the periodicity of motor activity in the colon. Recently, a new method of evaluating propagated motor activity or “propagating sequences” has been developed, but it is still in the experimental stage<sup>[91]</sup>.

What are the clinical applications of colonic manometry? In patients with serious STC symptoms, colonic manometry can be helpful in the diagnosis and in decisions regarding therapy (whether conservative or surgical)<sup>[61]</sup>. Level IV evidence, Grade C recommendation.

How should colon manometry be performed in patients with slow transit constipation? In the clinical setting, the bisacodyl test should be used. This procedure tests the stimulation of residual colonic propulsive activity, and it can be used to identify the subgroup of patients with severe slow transit constipation or “inertia coli”, one incontrovertible indication for total colectomy<sup>[92-94]</sup>. Thus, colonic manometry may help to diagnose an underlying myopathy or neuropathy and to differentiate slower transit due to neuromuscular function<sup>[95]</sup>. Level V evidence, Grade C recommendation.

### Pathologies of the colon

The pathophysiology of slow transit constipation is not known<sup>[96]</sup>, but there is evidence to indicate that certain subtypes of idiopathic constipation are secondary to visceral neuropathy<sup>[97-99]</sup>, such as aberrant regulation of the nervous enteric system or parasympathetic alterations<sup>[100]</sup>.

What STC alterations can be verified on histology? Qualitative and quantitative alterations in the enteric nervous system can be observed on histology, from alterations in the neurotransmitters to the loss of argyrophilic neurons and neurofilaments and myenteric plexus hypoganglionosis<sup>[101]</sup>. More recently, reductions in the number of cells of Cajal have been described<sup>[102,103]</sup>. Level III evidence, Grade C recommendation.

Is an endoscopic biopsy sufficient, or is a full-wall thickness biopsy necessary? Endoscopic biopsies only provide information on the mucosa and cannot detect other histological alterations; therefore, they are not useful in the pathogenetic evaluation of STC. Given the nature of the alterations, it is necessary to conduct biopsies that reach the muscle layer.

What is the role of the suction biopsy in STC? Suction biopsy is the gold standard for the diagnosis of intestinal neurodysplasia, particularly in children. In the

differential diagnosis, four biopsy samples should be taken between 2 cm and 10 cm from the pectinea line<sup>[104]</sup>. The histological findings can distinguish STC from Hirschsprung disease and contribute to the diagnosis of intestinal neurodysplasia and other degenerative diseases of the colon (i.e., amyloidosis, desmosis, elastosis)<sup>[105]</sup>. Level II evidence, Grade B recommendation.

What is the role of immunohistochemistry? Immunohistochemistry is the main tool for the histological evaluation of nerves and connective tissues. There are no clinical studies in the literature that focus on this particular examination. Pathologists recommend that immunohistochemical analysis be undertaken in suspected cases of STC<sup>[106]</sup>.

The Consensus Committee therefore recommends that immunohistochemistry be performed to document patterns of slow transit constipation.

### Gastrojejunal manometry

There is evidence that slow transit constipation subtends diffuse enteric neurological involvement, probably of the myenteric plexus and, above all, the system of interstitial cells of Cajal<sup>[107]</sup>. Various studies have highlighted different ileal dysfunctions: in two retrospective analyses, 20.6% of patients with chronic constipation showed gastrojejunal abnormalities<sup>[61,108]</sup>. Cardiovascular tests for dysautonomia, which are widely used in diabetic neuropathy, are not applicable in the diagnostic workup of slow transit constipation.

The most meaningful test for myopathic or neuro-pathic involvement (especially in the pre-surgical evaluation) in patients with chronic constipation is gastrojejunal manometry, as stated recently by the American Neurogastroenterology and Motility Society<sup>[109-111]</sup>.

What are the clinical applications of gastrojejunal manometry? Gastrojejunal manometry can be used to analyse antro-duodenal activity and fasting jejunal motility, particularly in patients with autonomic dysfunctions, such as diabetic neuropathy. In a recent study of 61 subjects undergoing gastrojejunal manometry, all STC patients and 94% of those patients with normal transit constipation exhibited alterations in small bowel motility in the postprandial and fasting phases, but there were no significant differences between the two groups<sup>[109]</sup>.

When should gastrojejunal manometry be performed in STC patients? In cases of STC, gastrojejunal manometry is recommended before surgery<sup>[93,109]</sup>. Level III evidence, Grade C recommendation.

### Abstract

Pancreatic adenocarcinoma is one of the most aggressive human malignancies, ranking 4th among causes for cancer-related death in the Western world including the United States. Surgical resection offers the only chance of cure, but only 15 to 20 percent of cases are potentially resectable at presentation. Different studies demonstrate and confirm that advanced pancreatic cancer is among the most complex cancers to treat and that these tumors are relatively resistant to chemotherapy and radiotherapy. Currently there is no consensus around the world on what constitutes "standard" adjuvant therapy for pancreatic cancer. This controversy derives from several studies, each fraught with its own limitations. Standards of care also vary somewhat with regard to geography and economy, for instance chemo-radiotherapy followed by chemotherapy or *vice versa* is considered the optimal therapy in North America while chemotherapy alone is the current stan-

dard in Europe. Regardless of the efforts in adjuvant and neoadjuvant improved therapy, the major goal to combat pancreatic cancer is to find diagnostic markers, identifying the disease in a pre-metastatic stage and making a curative treatment accessible to more patients. In this review, authors examined the different therapy options for advanced pancreatic patients in recent years and the future directions in adjuvant and neoadjuvant treatments for these patients.

### INTRODUCTION

Pancreatic ductal adenocarcinoma (PDAC) is one of the most aggressive human malignancies, ranking 4th among causes of cancer-related death in the Western world<sup>[1]</sup>.

Unlike most of the more frequent causes of cancer mortality (lung, colon, prostate and breast cancers) whose death rates are declining, the death rate for pancreatic cancer is relatively stable.

The poor prognosis is reflected by a median survival of 5-8 mo and a 5-year survival of less than 5% when all stages are combined<sup>[1-3]</sup>.

PDAC is characterized by a rapid disease progression

and absence of specific symptoms, largely precluding an early diagnosis and curative treatment<sup>[5,4]</sup>.

In most cases, PDAC is already locally advanced at time of diagnosis and only approximately 10%-20%<sup>[1,5]</sup> of patients are considered candidates for curative resection. The majority of patients (50%-60%) present with metastatic disease, and thus palliative chemotherapy remains the only option for almost all of these patients<sup>[6]</sup>. Owing to the high recurrence rate, surgical PDAC patients require adjuvant chemotherapy with or without radiotherapy providing a 5-year survival rate of 15%-25%<sup>[7]</sup> (Table 1).

Due to the described overall prognosis for all pancreatic cancer patients, systemic chemotherapy, radiation therapy or a combination of both is used following surgical resection (adjuvant therapy) and also prior to the tumor resection (neoadjuvant therapy) to improve cure rates.

Although the benefit of adjuvant and neoadjuvant therapy has been improved in recent years, the best choice of treatment modality still remains highly controversial.

The objective of this review is to examine therapies received by advanced pancreatic cancer patients in recent years and to examine the principal chemotherapeutic agents or molecular-targeted therapies useful for clinicians.

## ADJUVANT THERAPY

In an effort to improve the outcome in patients undergoing potentially curative resection, systemic chemotherapy (Table 2), radiotherapy or a combination of both have been applied following surgery.

## SYSTEMIC THERAPY

### Chemotherapy

The first randomized controlled trial of adjuvant therapy in pancreatic cancer was designed by the Gastrointestinal Tumor Study Group, which concluded that treatment with 5-fluorouracil (5-FU) plus radiation followed by two years of weekly 5-FU maintenance provided better outcomes than surgery alone<sup>[8]</sup>. Although this trial was criticized for many reasons, it served to establish 5-FU as the only standard adjuvant therapy for many years in pancreatic cancer. Different drugs and combinations have emerged and been incorporated for the best treatment of these patients (Table 2).

**5-FU:** 5-FU is a thymidylate synthase inhibitor that blocks the synthesis of pyrimidine thymidine, a nucleotide required for DNA replication.

5-FU had been considered the only chemotherapeutic option for about 20 years until the registration of gemcitabine. Several trials conducted in the late 1970s and early 1980s demonstrated that adjuvant chemotherapy using bolus 5-FU therapy conferred a survival benefit in patients with resected pancreatic cancer<sup>[8]</sup>.

Different studies in the last years have demonstrated a survival benefit from six months of postoperative leucovorin-modulated 5-FU in patients with resected pan-

Table 1 Staging of pancreatic cancer

Stage	TNM classification	Clinical classification	5-year percent survival (mo)
Stage 0	TisN0M0	Resectable	
Stage I A	T1N0M0	Initial	31.4
Stage I B	T2N0M0		27.2
Stage II A	T3N0M0		15.7
Stage II B	TXN1M0	Locally advanced	7.7
Stage III	T4NXM0		6.8
Stage IV	TXNXM1	Metastatic	2.8

Tis: Cancer *in situ*; T: Size and/or extent of invasion; N: Extent of lymph node involvement; M: Whether distant metastases are present.

creatic cancer, compared to those receiving no adjuvant chemotherapy (median overall survival 19.7 mo *vs* 14 mo respectively, statistically significant)<sup>[9-11]</sup>.

Although for locally advanced and metastatic patients this drug leads to an improved survival compared to the best supportive care<sup>[12,13]</sup>, the combination of 5-FU with other drugs such as doxorubicin or mitomycin did not prove superior to the antimetabolite alone. Similar results were obtained comparing single agent 5-FU to 5-FU plus cyclophosphamide, methotrexate and vincristine<sup>[14]</sup> as the combination did not offer a survival advantage over 5-FU alone.

Only the combination of 5-FU/irinotecan/oxaliplatin (FOLFIRINOX) has been associated with a high objective response rate based on imaging study, and this finally is the preferred regimen for patients who have good performance status and a normal serum bilirubin level<sup>[15]</sup>.

In the last years, new fluoropyrimidines that mimic the effect of a continuous infusion of 5-FU have been approved. One of the most common but not available in all countries is S-1, an orally active fluoropyrimidine, with favorable antitumor activity in gemcitabine-refractory disease<sup>[16,17]</sup>.

**Capecitabine:** Capecitabine is an orally administered fluoropyrimidine that is absorbed intact through the intestinal wall and then converted to 5-FU in three sequential enzymatic reactions: carboxylesterases, cytidine deaminase and thymidine phosphorylase. The last enzyme is present at consistently higher levels in tumor rather than normal tissue, thereby providing the basis for enhanced selectivity and better tolerability<sup>[18]</sup>. The efficacy of capecitabine in monotherapy was shown with high clinical response rate (24%) but low objective response (7%)<sup>[19]</sup>; however, no advantage using capecitabine in monotherapy over gemcitabine alone has been demonstrated.

**Gemcitabine:** The development of gemcitabine may be considered a major advance in the treatment of pancreatic cancer. This drug is a difluorinated analog of deoxycytidine. As a prodrug, gemcitabine must be phosphorylated by cytoplasmic and mitochondrial enzymes to its active metabolites, gemcitabine diphosphate and gemcitabine triphosphate. The cytotoxic effect of this drug is attributed to a combination of two actions of the

Table 2 Mode of action of principal drugs used in pancreatic cancer

Agent	Mode of action
5-FU	5-FU is a folate antimetabolite that forms a ternary complex involving 5-fluoro-2-deoxyuridine-5-monophosphate, thymidylate synthase, and 5,10-methylene THF. The formation of this complex thereby inhibits thymidylate synthase activity, which subsequently depletes intracellular thymidylate levels and ultimately suppresses DNA synthesis
Gemcitabine (Gemzar®)	Also, two metabolites of 5-FU, 5-fluoro-2-deoxyuridine-5-triphosphate and 5-fluorouridine-5-triphosphate, can be incorporated into DNA and RNA, respectively, resulting in DNA instability and interfering with RNA processing and function Gemcitabine is an S-phase nucleoside analogue (difluorodeoxycytidine) that is phosphorylated to difluorodeoxycytidine triphosphate by deoxycytidine kinase. Gemcitabine also stimulates deoxycytidine kinase and inhibits both ribonucleotide reductase and deoxycytidine monophosphate deaminase. Gemcitabine triphosphate is incorporated into nascent DNA to inhibit DNA synthesis
Capecitabine (Xeloda®)	Capecitabine an oral, tumor-selective fluoropyrimidine carbamate that is sequentially converted to 5-FU by three enzymes located in the liver and in tumors. The final step is the conversion of 5'-deoxy-5-fluorouridine to 5-FU by thymidine phosphorylase in tumors
Platinum analogues	Platinum forms adducts with DNA inhibiting transcription and replication causing cell death. Oxaliplatin is a third-generation platinum analogue (a diaminocyclohexane platinum derivative) that may have activity in tumors resistant to cisplatin or carboplatin and may have an additive/synergistic activity in doublet or triplet therapy
Taxanes	The taxanes include paclitaxel and docetaxel (Taxotere®) and are semi-synthetic microtubule inhibitors with a different mechanism of action from the vinca alkaloids. Taxanes bind to $\beta$ -tubulin, promoting microtubule assembly and preventing depolymerisation thus forming stable non-functional complexes and inhibiting the function of the mitotic spindle; This results in cell cycle arrest and increased sensitivity to radiation
Irinotecan (CPT11, Camptosar®)	Irinotecan is a topoisomerase I inhibitor that impedes the DNA helix torsional stress-relieving activity of DNA topoisomerases and also prevents their release from the DNA thus prompting apoptosis

5-FU: 5-fluorouracil.

diphosphate and triphosphate nucleosides, which leads to inhibition of DNA synthesis<sup>[20,21]</sup>.

The first pivotal trial found that gemcitabine is more effective than 5-FU in alleviation of some disease-related symptoms in patients with advanced, symptomatic pancreatic cancer, conferring a modest survival advantage over treatment with 5-FU. As the treatment with gemcitabine was associated with significant clinical response and better survival, this drug was approved for first-line therapy of metastatic pancreatic cancer. This pivotal phase III trial demonstrated improvement in median overall and 1-year survival compared to 5-FU (5.7 mo *vs* 4.4 mo and 18% *vs* 2%, respectively)<sup>[22]</sup>.

Many phase II studies have demonstrated the efficacy of gemcitabine combination treatments, but not all of the phase III trials confirmed the improvement in overall survival (OS) of gemcitabine-based regimens compared to gemcitabine alone. However, an improvement in six-month survival was seen by combining gemcitabine-fluoropyrimidine analogues and gemcitabine-platinum analogues, as demonstrated in the meta-analysis of Heinemann and colleagues<sup>[2]</sup>.

Due to the results obtained in monotherapy, gemcitabine has been combined with many other active cytotoxic agents including 5-FU, cisplatin, docetaxel, oxaliplatin and irinotecan, in an attempt to improve the response in pancreatic cancer patients and each will be discussed here separately.

**Gemcitabine and 5-fluorouracil:** Based on the complementary pharmacology of their mechanisms of action, the combination of 5-FU and gemcitabine has been evaluated in phase I, II and III trials. Finally, phase III trials showed that there is no significant improvement in

median OS and median progression-free survival when evaluating the combined regimen compared to that of gemcitabine alone<sup>[23-26]</sup>.

**Gemcitabine and capecitabine:** Different phase III trials have shown that patients who received gemcitabine and capecitabine compared to gemcitabine alone have a significant improvement in survival<sup>[27,28]</sup>.

These data and the meta-analysis performed by these authors suggest that the combination of gemcitabine plus capecitabine should be considered a standard first-line option for locally advanced and metastatic pancreatic cancer.

**Gemcitabine and platinum combinations:** Since gemcitabine enhances the formation of cisplatin-DNA adducts, an effect that may be due to suppression of nuclear excision repair by gemcitabine, and the platinum may augment the incorporation of gemcitabine triphosphate into DNA<sup>[29]</sup>, the gemcitabine and platinum combination has been assessed in different trials.

Although in preclinical studies the combination of gemcitabine and cisplatin is synergistic, at least three phase III trials comparing gemcitabine to the combination of gemcitabine plus cisplatin showed no significant survival advantage for this approach<sup>[30-32]</sup>. Furthermore, the combination of gemcitabine and platins has not shown improvement in terms of response and is not a considered option for pancreatic cancer patients.

**Gemcitabine and irinotecan:** As irinotecan (a topoisomerase inhibitor) had minimal clinical activity in patients with advanced pancreatic cancer, combined therapy with gemcitabine is not recommended<sup>[33,34]</sup> and in some

cases the combination could lead to major toxicity.

**Gemcitabine and taxanes:** Antitumoral action of taxanes is due to their mechanism of microtubule stabilization and consequently to cell cycle arrest. The association of gemcitabine with paclitaxel or docetaxel in advanced pancreatic patients was studied in different trials and has shown encouraging response rates<sup>[35,36]</sup>. A phase III trial has not yet been completed. Thus, whether this regimen represents an improvement over gemcitabine alone is unclear.

The available data suggest that if there is a benefit to gemcitabine combination therapy compared to gemcitabine alone, it is modest and best documented for capecitabine plus gemcitabine. Today, only gemcitabine alone and the combination of gemcitabine plus capecitabine represent good options for initial therapy.

In summary, adjuvant fluorouracil has been shown to be of benefit for patients with resected pancreatic cancer but gemcitabine is the most effective agent in advanced disease. Compared with the use of fluorouracil, gemcitabine does not result in improved overall survival in patients with completely resected pancreatic cancer<sup>[37]</sup>.

### Combined therapies

As compared with gemcitabine, FOLFIRINOX was associated with a survival advantage and had increased toxicity. FOLFIRINOX is an option for the treatment of patients with metastatic pancreatic cancer and good performance status<sup>[38]</sup>.

### Targeted molecular therapy

Based on the biological properties of pancreatic cancer, new systemic therapies have been tried. The most common molecular targets have been epidermal growth factor receptor (EGFR)/KRAS, human epidermal growth factor receptor type 2 (HER2) and vascular endothelial growth factor (VEGF), as these genes are overexpressed or mutated in pancreatic tumors.

**Targeting EGFR:** Currently, there are two approaches targeting the EGFR system: monoclonal antibodies (i.e., cetuximab/Erbitux<sup>®</sup>) and small molecule tyrosine kinase inhibitors. In spite of promising preclinical trials, cetuximab as monotherapy, or in combination with other cytotoxic agents such as gemcitabine or with radiotherapy, has failed to improve the outcome of PDAC patients<sup>[39,40]</sup>.

Up to now, the only EGFR targeting demonstrating a clinical benefit is erlotinib (Tarceva<sup>®</sup>, OSI 774), a tyrosine kinase inhibitor that inhibits ErbB-1 phosphorylation. One phase III trial of erlotinib with gemcitabine was able to show at least a small gain in the survival of patients with advanced PDAC<sup>[41]</sup>. Although erlotinib obtained Food and Drug Administration approval and access in clinical application in 2005, the therapeutic benefit for patients with advanced PDAC remains poor.

**Targeting HER2:** In several studies, HER-2 overexpression in pancreatic cancer has been reported to vary widely (10%-82%)<sup>[42,43]</sup> and it does not correlate with poor prognosis<sup>[44]</sup>. Although studies in a mouse model have shown that combination of anti-HER2 antibodies (i.e., trastuzumab) and other chemotherapy may be effective for HER2-overexpressing pancreatic cancer patients<sup>[45]</sup>, the clinical significance is uncertain. A phase II clinical trial of trastuzumab for pancreatic cancer has been conducted and showed only 6% response to combined therapy with trastuzumab and gemcitabine in patients with metastatic pancreatic cancer, which is not superior to therapy with gemcitabine alone<sup>[46]</sup>.

Currently, anti-Her2 therapy is experimental and still under investigation for the treatment of pancreatic cancer.

**Targeting VEGF:** A phase III trial concluded that there is no benefit for the addition of bevacizumab to gemcitabine *vs* gemcitabine alone and *vs* gemcitabine and cetuximab<sup>[47]</sup>.

Also some studies have failed to demonstrate a benefit for adding axitinib (an oral inhibitor of VEGF receptors 1, 2 and 3) to gemcitabine<sup>[48,49]</sup>. Currently, the anti-VEGF approach is not recommended in pancreatic cancer.

### Hormonal therapy

Tamoxifen and octreotide are not indicated in metastatic pancreatic cancer because both of them have failed to demonstrate any survival advantage for treated patients<sup>[50,51]</sup>.

## RADIOTHERAPY

The use of adjuvant radiotherapy for pancreatic cancer is controversial and the role of radiation therapy continues to be investigated. Currently, the addition of radiotherapy depends on the country in which a patient is being treated<sup>[52]</sup>.

Chemo-radiotherapy followed by chemotherapy is considered the optimal therapy in North America (Gastrointestinal Tumor Study Group; Radiation Therapy Oncology Group) while chemotherapy alone is the current standard in Europe (European Study Group for Pancreatic Cancer; Charité Onkologie)<sup>[10,53,54]</sup>.

The rationale for adjuvant radiotherapy for pancreatic cancer is to improve loco-regional control. Modern radiation delivery techniques, such as intensity-modulated radiation therapy or image-guided and stereotactic body radiation therapy, permit dose escalation in order to reduce normal tissue toxic effects and simultaneously deliver increased doses of radiation to affected areas<sup>[55,56]</sup>. It is clear that breakthroughs in the treatment of this devastating disease will come mostly from advances in systemic therapy, so radiotherapy should not be abandoned, but rather, intensified.

Intraoperative radiotherapy has also been considered, since local recurrence rates are very high. In general, intraoperative radiotherapy can slightly increase survival rates among patients with pancreatic cancer in localized

stages. There is no clear evidence to indicate that intraoperative radiotherapy is more effective than other therapies in treating pancreatic cancer in locally advanced and metastatic stages<sup>[57]</sup>.

## CHEMORADIO THERAPY

Some studies demonstrated improved survival when radiotherapy was combined with 5-FU chemotherapy compared with radiotherapy alone, in patients with locally advanced unresectable pancreatic cancer<sup>[58]</sup>. This combined therapy has been applied to patients undergoing RO resection to improve surgical cure rate.

In locally advanced pancreatic cancer, recent evidence using modern radiotherapy techniques and dosing suggests a continued role for radiotherapy. In both resected and unresected disease, further studies are needed to define optimal radiation dose, field size, and technique, and to assess the effect of radiotherapy not only on survival, but also on local disease control and quality of life<sup>[59]</sup>.

## NEOADJUVANT THERAPY

The low rate of resectability and the poor outcomes following pancreaticoduodenectomy have led to the investigation of preoperative and postoperative therapies to identify those patients who are not candidates for surgery and who could benefit from neoadjuvant chemotherapy and/or radiotherapy.

The initial reports using radiation therapy with or without 5-FU did not demonstrate an obvious improvement in either resectability or overall survival<sup>[60,61]</sup>. Subsequent studies improved the treatment by increasing radiotherapy dose, adding intraoperative radiotherapy and using combined chemotherapy. The drugs tested were mitomycin, 5-FU, 5-FU and cisplatin, and paclitaxel, but their efficacy remains uncertain<sup>[62-64]</sup>.

Subsequent reports used gemcitabine-based chemotherapy which provided an enhanced local effect, although with potentially more toxicity than 5-FU-based regimens. Gemcitabine has also been combined with radiotherapy and cisplatin<sup>[65,66]</sup>.

Currently, neoadjuvant radiation is associated with improved survival in patients with resectable pancreatic cancer<sup>[67]</sup> but chemotherapy alone without radiotherapy is beginning to be studied and the experience is limited<sup>[68,69]</sup>.

## ADJUVANT VS NEOADJUVANT THERAPY

Although the median survival times reported from some uncontrolled trials of neoadjuvant therapy compare favorably to those reported with adjuvant therapy approaches<sup>[65,70,71]</sup>, the question as to whether preoperative therapy is better than postoperative therapy is uncertain as there are no randomized trials comparing the two approaches.

One advantage of neoadjuvant therapy is that it avoids the morbidity of pancreaticoduodenectomy in patients who have occult, micrometastatic disease that

becomes evident during therapy. A second advantage is that in patients undergoing surgery, prolonged recovery prevents the delivery of postoperative adjuvant chemotherapy in about a quarter of them<sup>[72]</sup>.

Recent studies have shown that neoadjuvant therapy is associated with a lower rate of lymph node positivity and improved overall survival and should be considered an acceptable alternative to the surgery-first paradigm in operable pancreatic cancer<sup>[73]</sup>.

## SECOND-LINE THERAPY

There are few trials of second-line therapy in patients who have failed chemotherapy, and there is no widely accepted standard of care.

For patients who retain a good performance status after failing initial gemcitabine therapy, benefit has been suggested from a second-line therapy based on oxaliplatin/fluoropyrimidine combination such as 5-FU and oxaliplatin<sup>[65,70,71]</sup>. Other oxaliplatin combinations are also acceptable with the agents gemcitabine, irinotecan or capecitabine<sup>[74-76]</sup>.

There are no data for patients who fail initial 5-FU and oxaliplatin, but a reasonable option is gemcitabine as monotherapy.

## CONCLUSION

All the treatment options examined in this review demonstrate and confirm that advanced pancreatic cancer is among the most complex cancers to treat.

Currently there is no consensus regarding the optimal management of patients after resection of an exocrine pancreatic cancer, and the approach is different in Europe and in the United States. Most European clinicians use chemotherapy alone after resection of a pancreatic neoplasm. The American approach more often includes chemoradiotherapy as well as adjuvant chemotherapy.

Although it is mainly accepted that a 6-mo course of systemic chemotherapy with gemcitabine or 5-FU should be part of any adjuvant treatment, there is no single adjuvant regimen of chemotherapy or chemoradiotherapy that can claim unequivocal superiority over others. Among these options there are no differences in outcome but fewer side effects occur with gemcitabine, and this is nowadays the preferred regimen.

Based on current data, it is clear that treatment with gemcitabine or 5-FU results in a median survival of just a few months<sup>[77,78]</sup>. The limitation of this treatment is mainly due to the profound resistance of PDAC cells towards anti-cancer drugs, emerging from the efficient protection against chemotherapeutic drugs by an altered balance of pro- and anti-apoptotic proteins which results in a markedly reduced apoptotic responsiveness<sup>[79,80]</sup>.

Currently there are around 1070 clinical trials focusing on studying new biomarkers, different drug combinations and vaccines designed for pancreatic cancer ([www.clinicaltrial.gov](http://www.clinicaltrial.gov)).

Regardless of these efforts in adjuvant and neoadjuvant therapy, the major goal to combat PDAC is to find diagnostic markers, identifying the disease in a pre-metastatic stage and making a curative treatment accessible to more patients. Given an earlier diagnosis, surgical interventions together with adjuvant radio/chemotherapy are the most promising options. Considering such evidence, the urgent need for an individualized and more effective adjuvant therapy is evident.
