### Abstract

Antimicrobial management of severe intra-abdominal infections (IAIs) involves a delicate balance of optimizing empirical therapy, which has been shown to improve clinical outcomes, while simultaneously reducing unnecessary antimicrobial use. Two sets of guidelines for the management of intra-abdominal infections were recently published. In 2010, the Surgical Infection Society and the Infectious Diseases Society of America (SIS-IDSA) created guidelines for the diagnosis and management of complicated IAIs. The new SIS-IDSA guidelines replace those previously published in 2002 and 2003. The World Society of Emergency Surgery (WSES) guidelines represent additional contributions, made by specialists worldwide, to the debate regarding proper antimicrobial drug methodology. These guidelines represent the conclusions of the consensus conference held in Bologna, Italy, in July 2010 during the first congress of the WSES.

### INTRODUCTION

Intra-abdominal infections (IAIs) encompass a variety of pathological conditions, ranging from uncomplicated appendicitis to fecal peritonitis. Cases of IAI are further subcategorized as being either uncomplicated or complicated<sup>[1]</sup>.

In the event of an uncomplicated case of IAI, the infection only involves a single organ and does not extend to the peritoneum. Patients with such infections can be treated with either surgical resection or antibiotics. When the infection is effectively resolved by surgical excision, 24-h perioperative prophylaxis is typically sufficient. Patients with IAIs, including acute diverticulitis and certain forms of acute appendicitis, may be treated non-operatively by means of antimicrobial therapy.

In the event of complicated IAI, the infectious process proceeds beyond the organ, causing either localized or diffuse peritonitis. The treatment of patients with complicated IAIs involves both source control and antibiotic therapy.

Antimicrobial therapy plays an integral role in the management of IAIs, especially in critically ill patients who require immediate empiric antibiotic therapy. An insufficient or otherwise inadequate antimicrobial regimen is one of the variables most strongly associated with unfavorable outcomes<sup>[2,3]</sup>.

Various studies have demonstrated that inappropriate

antimicrobial use is common. Excessive antimicrobial use has contributed to the emergence and spread of drug-resistant microorganisms and has simultaneously increased overall treatment costs<sup>[4-9]</sup>.

An antimicrobial-based approach to treating IAIs always involves a delicate balance between the optimization of empirical therapy, which has been shown to improve clinical outcomes, and the reduction of excessive antimicrobial use, which has been proven to increase the rate of emergence of antimicrobial-resistant strains.

The threat of antimicrobial resistance has been identified as one of the major challenges in the management of complicated IAIs.

In the past few decades, an increased prevalence of infections caused by antibiotic-resistant pathogens, including methicillin-resistant *Staphylococcus aureus*, vancomycin-resistant *Enterococcus* species, carbapenem-resistant *Pseudomonas aeruginosa* (*P. aeruginosa*), extended-spectrum  $\beta$ -lactamase (ESBL)-producing *Escherichia coli* (*E. coli*) and *Klebsiella* species, and multidrug-resistant *Acinetobacter* species, has been observed, especially in IAIs.

To resolve the medical community's tendency to over-use antibiotics, a set of guidelines outlining the proper use of antimicrobial therapy has been implemented, which contains specific directions for addressing IAIs.

Two different sets of guidelines outlining the clinical management of IAIs were recently published.

In 2010, the Surgical Infection Society (SIS) and the Infectious Diseases Society of America (IDSA) instituted standardized guidelines for the diagnosis and management of complicated IAIs<sup>[10]</sup>.

The new SIS and IDSA guidelines replace those previously published in 2002 and 2003.

The World Society of Emergency Surgery (WSES) guidelines<sup>[11]</sup> represent an additional contribution to the debate by specialists worldwide. These guidelines represent the conclusions reached by the consensus conference held in Bologna, Italy, in July 2010, during the first congress of the WSES; in attendance at this event were surgeons, infectious disease specialists, pharmacologists, radiologists and intensivists, all of whom wished to define and streamline a standardized set of recommendations for the early treatment and management of IAIs<sup>[11]</sup>.

## **GUIDELINES BY SIS AND IDSA: ANTIMICROBIAL MANAGEMENT FOR COMPLICATED INTRA-ABDOMINAL INFECTIONS**

In the SIS and IDSA guidelines, selection of the appropriate antimicrobial regimen is based primarily on the "risk factor" of the potential failure of the treatment in question.

"High risk" describes patients with an increased likelihood of treatment failure and a greater potential severity of infection according to clinical assessment criteria. Such patients include those with anatomically unfavorable infections or health care-related infections<sup>[10]</sup>.

Clinical factors predicting failure of treatment for IAIs include: (1) delay in the initial stages of intervention (24 h); (2) high severity of illness (Acute Physiology and Chronic Health Evaluation II score > 15); (3) advanced age of patient; (4) comorbidity involving organ dysfunction; (5) low albumin levels; (6) poor nutritional status; (7) peritoneal involvement or diffuse peritonitis; (8) inability to achieve adequate debridement or control of drainage; (9) presence of malignancy; and (10) health care-related infection.

Health care-related infections refer to a spectrum of adult patients treated in acute care hospitals or monitored in chronic care settings. These patients increase their risk of infection due to the emergence of multidrug-resistant bacteria. Health care-related infections have higher risks of complication and mortality than community-acquired disease.

Guidelines developed by the SIS and the IDSA have recommended various single-agent and combination regimens for patients with different levels of risk.

### **Extra-biliary community-acquired intra-abdominal infections**

In the treatment of patients with community-acquired IAIs, empiric antimicrobial therapy should protect against common gram-negative and anaerobic enteric bacteria.

The SIS and IDSA guidelines classify community-acquired IAIs as being mild, moderate, or severe on the basis of the patient's assessed risk factors.

For high severity infections, those cases for which adequate empirical therapy helps reduce the rate of mortality, regimens having a broader spectrum of antimicrobial activity are recommended.

For adult patients with mild-to-moderate community-acquired infections, the SIS-IDSA guidelines recommend the use of ticarcillin-clavulanate, cefoxitin, ertapenem, moxifloxacin, or tigecycline as single-agent therapies; the guidelines also advocate combinations of metronidazole with cefazolin, cefuroxime, ceftriaxone, cefotaxime, or levofloxacin, as opposed to single agents featuring broader antimicrobial activity.

The empiric use of antimicrobial regimens with broad-spectrum activity against gram-negative organisms, which include meropenem, imipenem-cilastatin, doripenem, piperacillin-tazobactam as single-agent therapies, or ciprofloxacin, levofloxacin ceftazidime, cefepime each combined with metronidazole, is recommended by the SIS-IDSA guidelines for treating high-severity community-acquired IAIs.

(Due to the increasing resistance of *E. coli* to fluoroquinolones, local population susceptibility profiles and, if available, isolate susceptibilities should be reviewed).

The SIS-IDSA guidelines do not recommend the routine use of agents effective against enterococci in community-acquired infections, even if infections caused by these organisms may be associated with poorer clinical outcomes<sup>[10]</sup>.

Additionally, antifungal protection is not required for community-acquired infections.

According to the guidelines, Aminoglycosides should be reserved for patients allergic to  $\beta$ -lactam agents and, even in these cases, they are “last resort” options that should be used only when quinolone-based regimens are unavailable. That said, depending on the local susceptibility patterns of nosocomial gram-negative bacilli, Aminoglycosides may be a reasonable choice for the empiric or definitive treatment of certain patients with health care-related IAIs.

#### **Health care-associated intra-abdominal infections**

Health care-related infections are commonly caused by more resistant strains, which may include the non-fermenting gram-negative *P. aeruginosa*, *Acinetobacter* species, *E. coli*, *Enterobacter* species, *Proteus* species, methicillin resistant *Staphylococcus aureus*, enterococci, *Candida* species, and extended spectrum  $\beta$ -lactamase-producing *Klebsiella*. For these infections, given that adequate empiric therapy appears to be a crucial factor affecting postoperative complications and mortality rates, complex multidrug regimens are recommended.

According to the SIS-IDSa guidelines, antibiotic selection should always be tailored to address the nosocomial microorganisms known to be present at the facilities in which the patient developed the infection.

#### **Biliary intra-abdominal infections**

For patients with complicated biliary IAIs, selection of a specific antimicrobial therapy should be based on the origin of the infection (community versus health care), on the severity of illness, and on the presence or absence of a biliary-enteric anastomosis.

For biliary infections, anaerobic therapy is not recommended unless a biliary-enteric anastomosis is present.

Regarding community-acquired biliary infections, antimicrobial activity against enterococci is not required because such strains have not proven to be pathogenic. For certain immunosuppressed patients, however, particularly for those who have undergone extensive hepatic-related procedures or liver transplants, enterococcal infections can be clinically significant and may require treatment.

For community-acquired acute cholecystitis of mild-to-moderate severity, the SIS and IDSA guidelines recommend treatment regimens of cefazolin, cefuroxime, or ceftriaxone. On the other hand, for community-acquired acute cholecystitis causing severe physiologic disturbance, advanced age, and/or immunocompromise, the IDSA guidelines recommend Imipenem-cilastatin, meropenem, doripenem, piperacillin-tazobactam as single-agent therapies, or ciprofloxacin, levofloxacin, cefepime, each in combination with metronidazole. Contrastingly, for acute cholangitis of any severity grade following bilio-enteric anastomosis, the SIS-IDSa guidelines recommend Imipenem-cilastatin, meropenem, doripenem, piperacillin-tazobactam as single-agent therapies, or ciprofloxacin, levofloxacin, cefepime, each in combination with metronidazole. For health care-related biliary infection of any severity grade, the IDSA guidelines recommend Imi-

penem-cilastatin, meropenem, doripenem, piperacillin-tazobactam, or ciprofloxacin, levofloxacin, cefepime, each in combination with metronidazole, supplementing them with vancomycin.

(Due to the increasing resistance of *E. coli* to fluoroquinolones, local population susceptibility profiles and, if available, isolate susceptibilities should be assessed and systematically reviewed).

## **GUIDELINES BY WSES: ANTIMICROBIAL MANAGEMENT FOR INTRA-ABDOMINAL INFECTIONS**

Patients with IAIs are classified by SIS-IDSa guidelines into low risk and high risk.

However the definition of “risk” in IAIs remains too vague. Dividing patients with IAIs into lower and higher risk categories may be not easy, and attempting to assess a patient’s risk of treatment failure may be not sufficient to optimize an antimicrobial treatment plan.

In order to stratify the patients with IAIs, WSES guidelines stratify patients with IAIs according to the specific risk for antimicrobial resistant bacteria and to the clinical patient’s severity.

In order to better identify the pathogens present and evaluate the associated resistance patterns, infections are classified as being either community- or hospital-acquired.

In the past two decades, the incidence rate of hospital-acquired infections caused by resistant microorganisms has risen significantly, a finding that is probably correlated with higher levels of antibiotic exposure and an increasing number of patients with one or more predisposing conditions such as recent exposure to antibiotics, high severity of illness, advanced age, comorbidity, degree of organ dysfunction, low albumin level, poor nutritional status, immunocompromise, and the presence of malignancy.

In the last years, the level of resistance has become significant also in the community acquired infections. The main resistance problem in IAIs is represented by ESBL producers Enterobacteriaceae, even today frequently found in community acquired infections<sup>[12,13]</sup>.

The available therapeutic options for the treatment of ESBL-associated infections are limited by drug resistance conferred by the ESBLs<sup>[14,15]</sup>.

The third generation cephalosporins, recommended by SIS-IDSa for high risk patients in association with metronidazole, should not be used to treat suspected infections with ESBL producing organisms because clinical outcome is poor even in the presence of apparent susceptibility<sup>[14]</sup>.

Also cefepime should not be used as the first line therapy against ESBL-producing organisms<sup>[14]</sup>.

Piperacillin-tazobactam, recommended by SIS-IDSa guidelines for high risk patients, is not regarded as suitable first line therapy for serious infections caused by ESBL producer<sup>[14]</sup>.

Ciprofloxacin has been a potential antimicrobial option for the treatment of infections caused by ESBL-producing enterobacteriaceae; however, in recent years, the usage of ciprofloxacin has risen, and ESBL-producing isolates resistant to fluoroquinolones has increased over time also in *E. coli*<sup>[14]</sup>.

For two decades Carbapenems have been the antibiotics of first choice for ESBLs.

The increased carbapenem consumption has been associated to increasing of carbapenem-resistant bacterial species<sup>[13]</sup>.

The rapid spread of carbapenemases in *Klebsiella pneumoniae* (*K. pneumoniae*)<sup>[16]</sup> emphasizes the concept that the usage of carbapenems should be optimized in terms of indication and exposure.

Therefore, group 2 carbapenems should be used in community acquired IAIs only in critically ill patients where inadequate antimicrobial therapy may have a significant impact on the patients mortality, independently by the site of infection.

The choice of the antimicrobial regimen poses serious problems for the management of critically ill patients. In patients with severe sepsis or septic shock an early correct empirical antimicrobial therapy has a significant impact on the outcome, independently by the site of infection.

It is confirmed by a recent prospective observational study, involving 180 consecutive patients with secondary generalized peritonitis, by Riché *et al*<sup>[17]</sup> that demonstrated, a significantly higher mortality rate in septic shock (35% vs 8% for patients without shock).

Recently published international guidelines outlining the proper management of severe sepsis and septic shock (Surviving Sepsis Campaign)<sup>[3]</sup> recommend the intravenous administration of antibiotics within the first hour following diagnosis; the use of broad-spectrum agents that can effectively penetrate the presumed site of infection; and the daily reassessment of the antimicrobial regimen in order to optimize treatment efficacy, prevent the development of drug resistance, avoid drug-induced toxicity, and minimize the overall cost of hospitalization.

For years, antibiotics have typically been used as single-agent therapies; only once microbiological cultures and susceptibility tests had been performed were more potent compounds then administered. The traditional approach, however, may no longer be appropriate for critically ill patients in the current context of increasing antibiotic resistance.

Increasing rates of antibiotic resistance and a better understanding of the inflammatory process together prompted the medical community to begin advocating the use of broad-spectrum regimens initially when treating critically ill patients.

This two-stage approach, consisting of aggressive initial therapy followed by a less intense follow-up treatment, allows for the immediate and effective treatment of serious infections while simultaneously avoiding the overuse of antibiotics, potential microbial resistance, and excessive hospitalization costs.

### Community-acquired intra-abdominal infections

Empirical antibiotic treatment of community-acquired IAIs should be conducted in accordance with the most frequently isolated germs and the local trends of antibiotic resistance. The major pathogens involved in community-acquired IAIs are enterobacteriaceae, streptococci, and anaerobes. The primary problems with resistance stem from ESBL-producing enterobacteriaceae, which are frequently found in community-acquired infections<sup>[12,13]</sup>.

Many factors can increase the risk of ESBL selection, but prior exposure to antibiotics (mainly third generation cephalosporins) and comorbidities that continuously require antibiotic treatment regimens, are among the most significant predisposing criteria<sup>[18]</sup>.

In the event of community-acquired IAIs, antimicrobial therapy for enterococci should be considered on a patient-by-patient basis, mainly for critically ill and immunocompromised patients as well as patients with valvular heart disease or prosthetic implants.

Community-acquired IAIs may be treated with either single or multiple antimicrobial regimens depending on the patient's condition as well as the predominant risk factors for specific microorganisms and resistance patterns. For stable, non-critical patients presenting with no ESBL-associated risk factors, amoxicillin/clavulanate and ciprofloxacin plus metronidazole regimens are recommended. Contrastingly, for critically ill patients presenting with no ESBL-associated risk factors, treatments of piperacillin/tazobactam are recommended.

On the other hand, for stable, non-critical patients presenting with ESBL-associated risk factors, ertapenem or tigecycline treatments are recommended. Contrastingly, for critically ill patients presenting with ESBL-associated risk factors, meropenem or imipenem plus fluconazole regimens (the latter in the event of risk factors for *Candida*) are recommended.

Antimicrobial regimens recommended by WSES<sup>[11]</sup> for treating extra-biliary community-acquired IAIs was summarized in Table 1.

### Biliary intra-abdominal infections

Antibiotics are always recommended when treating complicated cholecystitis and advanced uncomplicated cholecystitis.

The most important factors for antimicrobial drug selection in biliary infections are the following: antimicrobial activity against causative bacteria, the clinical condition of the patient in question, and the biliary levels of the antimicrobial agents.

An antibiotic's in-bile efficacy as well as the manner in which it is ultimately secreted into the bile are also important selection criteria when choosing an appropriate drug regimen.

The microorganisms that are most often isolated in biliary infections are the gram-negative aerobes, *E. coli* and *K. pneumoniae*, and several anaerobes, especially *Bacteroides fragilis*. Activity against enterococci is not typically required since their pathogenicity in biliary tract infections remains unclear<sup>[19,20]</sup>.

**Table 1** Antimicrobial regimens recommended by the World Society of Emergency Surgery recommendations for treating extra-biliary community-acquired intra-abdominal infections

	Antimicrobial agents	Dosage
In stable, non-critical patients		
With no ESBL-associated risk factors	Amoxicillin/clavulanate	2.2 g every 6 h (2-h infusion time)
	Ciprofloxacin	400 mg every 8 h (30-min infusion time)
With ESBL-associated risk factors	+	
	Metronidazole	500 mg every 6 h (1-h infusion time)
	Ertapenem	1 g every 24 h (2-h infusion time)
	Tigecycline	100 mg LD then 50 mg every 12 h (2-h infusion time)
In critically ill patients presenting		
With no ESBL-associated risk factors	Piperacillin/tazobactam	9 g LD then 18 g per day <i>via</i> continuous infusion or 4.5 g every 6 h (4-h infusion time)
	Meropenem	500 mg every 6 h (6-h infusion time)
With ESBL-associated risk factors	or	
	Imipenem	500 mg every 4 h (3-h infusion time)
	+	
	Fluconazole	600 mg LD then 400 mg every 24 h (2-h infusion time)

ESBL: Extended-spectrum  $\beta$ -lactamase; LD: Loading dose.

**Table 2** Antimicrobial regimens recommended by the World Society of Emergency Surgery recommendations for treating biliary intra-abdominal infections

	Antimicrobial agents	Dosage
In stable, non-critical patients		
With no ESBL-associated risk factors	Amoxicillin/clavulanate	2.2 g every 6 h (2-h infusion time)
	Ciprofloxacin	400 mg every 8 h (30-min infusion time)

	Metronidazole	500 mg every 6 h (1-h infusion time)
	Tigecycline	100 mg LD then 50 mg every 12 h (2-h infusion time)
In critically ill patients		
With no ESBL-associated risk factors	Piperacillin/tazobactam	9 g LD then 18 g per day <i>via</i> continuous infusion or 4.5 g every 6 h (4-h infusion time)
	Piperacillin	8 g LD then 16 g/d <i>via</i> continuous infusion or 4 every 6 h (4-h infusion time)
With ESBL-associated risk factors	+	
	Tigecycline	100 mg LD then 50 mg every 12 h (2-h infusion time)
	+/-	
	Fluconazole	600 mg LD then 400 mg every 24 h (2-h infusion time)

ESBL: Extended-spectrum  $\beta$ -lactamase; LD: Loading dose.

The efficacy of antibiotics in treating biliary infections depends largely on the drugs' resulting biliary concentrations<sup>[21-23]</sup>.

However, there are no clinical or experimental data available from which to infer the antimicrobial dosage that would safely maximize biliary duct penetration, and as such, no standardized recommendations have been established.

For stable, non-critical patients presenting with no ESBL-associated risk factors, amoxicillin/clavulanate or ciprofloxacin plus metronidazole regimens are recommended.

For stable, non-critical patients presenting with ESBL-associated risk factors, Tigecycline is recommended.

For critically ill patients presenting with no ESBL-associated risk factors, Piperacillin/tazobactam is recommended.

For critically ill patients presenting with ESBL-associated risk factors, tygecycline plus piperacillin (plus flu-

conazole in the event of risk factors for *Candida*) is the recommended drug regimen.

Antimicrobial regimens recommended by WSES<sup>[11]</sup> for treating biliary IAIs was summarized in Table 2.

### **Hospital-acquired intra-abdominal infections**

Hospital-acquired IAIs are, by definition, infections that were not present upon hospital admission but become evident at least 48 h following admission in patients hospitalized for a reason other than IAIs.

The threat of antimicrobial resistance has been identified as one of the major challenges in the management of complicated IAIs.

Hospital-acquired infections are commonly caused by more resistant strains, and for these infections, complex multi-drug regimens are usually recommended.

The use of anti-enterococcal drugs in empirical antibiotic regimens to treat nosocomial IAIs is always warranted if directed against *Enterococcus faecalis*.

**Table 3** Antimicrobial regimens recommended by the World Society of Emergency Surgery recommendations for hospital-acquired intra-abdominal infections

	Antimicrobial agents	Dosage
In stable, non-critical patients	Piperacillin +	8 g LD then 16 g/d <i>via</i> continuous infusion or 4 every 6 h (4-h infusion time)
	Tigecycline +	100 mg LD then 50 mg every 12 h (2-h infusion time)
	Fluconazole	600 mg LD then 400 mg every 24 h (2-h infusion time)
In critically ill patients	Piperacillin +	8 g LD then 16 g/d <i>via</i> continuous infusion or 4 every 6 h (4-h infusion time)
	Tigecycline +	100 mg LD then 50 mg every 12 h (2-h infusion time)
	Echinocandin Caspofungin	(loading dose of 70 mg, then 50 mg daily)
	Anidulafungin	(loading dose of 200 mg, then 100 mg daily)
	Micafungin	(100 mg daily)
	Meropenem or	500 mg every 6 h (6-h infusion time)
	Imipenem or	500 mg every 4 h (3-h infusion time)
	Doripenem +	500 mg every 8 h (4-h infusion time)
	Teicoplanin +	1.6 g <i>via</i> continuous infusion or 400 mg every 6 h (4-h infusion time)
	Echinocandin Caspofungin	(loading dose of 70 mg, then 50 mg daily)
	Anidulafungin	(loading dose of 200 mg, then 100 mg daily)
	Micafungin	(100 mg daily)

LD: Loading dose.

The recently published IDSA guidelines for the treatment of invasive candidiasis don't explicitly address candidal peritonitis<sup>[24]</sup>. However, the use of echinocandins is generally favored as a first-line empirical therapy in treating critically ill patients, while fluconazole is typically used for patients with less severe conditions. Consequently, by applying these trends to the context of IAIs one might suggest the prescription of echinocandins as a first-line treatment for cases of severe nosocomial IAIs.

For stable, non-critical patients presenting with risk factors for multidrug-resistant pathogens, fluconazole and tigecycline plus piperacillin are recommended.

In critically ill patients presenting with risk factors presenting for multidrug-resistant pathogens meropenem, imipenem/cilastatin, and doripenem (plus an echinocandin and Teicoplanin) or Tigecycline (plus an Echinocandin and Piperacillin) are recommended.

Antimicrobial regimens recommended by WSES<sup>[11]</sup> for hospital-acquired IAIs was summarized in Table 3.

## CONCLUSION

Proper empiric antimicrobial therapy has an enormous effect on the morbidity and mortality rates of patients suffering from IAIs, especially those who are critically ill. Inappropriate antibiotic treatments of IAIs may result in poor patient outcome. Furthermore, the selection of an appropriate antimicrobial agent has become a significant challenge due to the emerging resistances of target organisms to commonly prescribed antibiotics.

To more effectively customize antimicrobial treatment

regimens, guidelines outlining the proper therapeutic protocol for administering antimicrobial drugs have been developed to help clinicians to better and more efficiently treat IAIs.

### Abstract

Crohn's disease and ulcerative colitis evolve with a relapsing and remitting course. Determination of inflammatory state is crucial for the assessment of disease activity and for tailoring therapy. However, no simple diagnostic test for monitoring intestinal inflammation is available. Noninvasive markers give only indirect assessments of disease activity. Histopathological or endoscopical examinations accurately assess inflammatory activity, but they are invasive, time consuming and expensive and therefore are unsuitable for routine use. Imaging procedures are not applicable for ulcerative colitis. The usefulness of ultrasound and Doppler imag-

ing in assessing disease activity is still a matter of discussion for Crohn's disease, and an increased interest in computed tomography enterograph (CTE) has been seen, mainly because it can delineate the extent and severity of bowel wall inflammation, besides detecting extraluminal findings. Until now, the available data concerning the accuracy of magnetic resonance enterography in detecting disease activity is less than CTE. Due to this, clinical activity indices are still commonly used for both diseases.

### INTRODUCTION

Inflammatory bowel disease (IBD) comprises two major disease entities: Crohn's disease (CD) and ulcerative colitis (UC). Its etiology is not completely understood, but it is characterized by chronic inflammation of the gastrointestinal tract. Treatment is generally effective in relieving symptoms, but is not curative. Typically, these diseases evolve with

a relapsing and remitting course. Exacerbations are characterized by diarrhea, abdominal pain and rectal bleeding.

Determination of inflammatory activity is crucial for the assessment of disease activity and for tailoring the therapy. Ideally, a disease marker must be disease specific, mirror the presence of activity, be easily applicable in clinical practice and identify patients at risk for relapse. However, no such disease markers have been described so far.

Numerous clinical activity indices and other noninvasive markers are used in IBD, but they all give only indirect assessments of disease activity and none are accurate in evaluating inflammatory activity as found by histopathological or endoscopic examination. On the other hand, endoscopic evaluation is difficult to perform, invasive, time consuming and expensive, and hence is unsuitable for routine use. In the biological era, mucosal healing in CD is associated with a longer duration of remission and fewer hospitalizations, so endoscopic evaluation becomes essential<sup>[1]</sup>. It is clear that treatment must have an impact in the natural course of the disease. In the pre-biological and pre-immunosuppressive era, more than 80% of patients with CD required some kind of surgery during their lifetimes and approximately 75% of patients displayed new lesions on endoscopy 1 year after surgery<sup>[2-4]</sup>. In UC, ultimately, up to a third of patients with extensive disease will require a colectomy at some point during the disease's course<sup>[4]</sup>.

Identifying whether patients are in a relapsing or remission phase is important to offer an adequate therapy and since intestinal symptoms are a frequent cause for referrals to gastroenterologists, it is crucial to distinguish between non-inflammatory functional problems such as irritable bowel syndrome (IBS) and IBD. IBD is characterized by unpredictable flare-ups of symptoms that impair the patient's quality of life. So, markers of inflammation are important in the follow-up of patients, especially during periods of low disease activity, when it is essential to detect sub-clinical intestinal inflammation and to predict relapsing disease. This could promote a refinement of therapy to the actual needs of each case.

This article aims to make a critical review of clinical, endoscopic, laboratory and image markers of disease with respect to their ability of establishing disease activity.

## CLINICAL ACTIVITY INDEX

The instrument most commonly used to quantify disease activity in CD has been the Crohn's disease activity index (CDAI). It is a scoring system derived from the sum of products from a list of 8 items that combines subjective symptoms, objective findings on examination and laboratory testing (Table 1)<sup>[5]</sup>. Index values of 150 or below are associated with non-active disease. Values between 151 and 220 indicate mild activity, and between 221 and 450 indicate moderate to severe activity. Values over 450 indicate extremely severe disease. However, reproducibility of the CDAI is limited by a great deal of inter-observer variation and, in fibrostenotic disease, it may reflect poorly on bowel inflammation as a cause of symptoms because it induces subjective measurements<sup>[6]</sup>. Other disease activ-

**Table 1** Crohn's disease activity index items and weighting factors

Item (daily sum per week)	Weighting factor
Number of liquid or very soft stools	2
Abdominal pain score in one week (rating, 0-3)	5
General well-being (rating, 1-4)	7
Sum of physical findings per week	
Arthritis/arthralgia	
Mucocutaneous lesions (e.g., erythema nodosum, aphthous ulcers)	
Iritis/uveiti	
Anal disease (fissure, fistula, etc.)	
External fistula (enterocutaneous, vesicle, vaginal, etc.)	
Fever over 37.8 °C	20
Antidiarrheal use (e.g., diphenoxylate)	30
Abdominal mass (no = 0, equivocal = 2, yes = 5)	10
47 minus hematocrit (males) or 42 minus hematocrit (females)	6
1-x (1-body weight divided by a standard weight)	1

ity indices include van Hees index, the Cape Town index, Oxford index and Talsted index, but none result in a better approach to identify relapses<sup>[7-10]</sup>.

In order to evaluate the overall state of well-being of patients, with a focus on various domains, the Inflammatory Bowel Disease Questionnaire is the most widely accepted disease-specific instrument and measures separate domains for bowel, social, systemic and emotional function<sup>[11]</sup>.

In UC, the clinical activity index most commonly used to define the severity of disease was established by Truelove and Witts<sup>[12]</sup>. It defines mild and severe disease activity, with moderate activity being present when there are intermediate symptoms. In the mild form there are fewer than four stools daily, with or without blood, with no systemic repercussion and a normal erythrocyte sedimentation rate (ESR). In moderate one, the number of stools daily is greater than four but with minimal systemic repercussion. In the severe form, there are more than six stools daily with blood and with evidence of systemic repercussion, as shown by fever, tachycardia, anemia, or an ESR greater than 30. Clinical remission was defined as 1 or 2 stools per day without blood, absence of fever and tachycardia, a normal hemoglobin or its tendency towards reference values, a normal erythrocyte sedimentation rate and weight gain. It is simple and easy to use, but lacks precision, especially in the definition of more severe cases. It is not clear how many systemic features are required, and, furthermore, an attack can be followed by fever, tachycardia or anemia, which would characterize it as severe, but the patient may look well. Not unrarely, patients can present moderately severe symptoms and that the original index did not predict. Additionally, neither the Truelove and Witts Severity Index nor the definitions, as clinical remission or improvement, have been validated, and also, not being quantitative, no disease severity score is generated. Various attempts to create a numerical index have been made, such as the St. Marks Index, the Clinical Activity Index (also known as the Rachmilewitz Index), the Physi-

cian Global Assessment, and the Lichtiger Index. None have been validated and there is no evidence that any of them are better than Truelove and Witts<sup>[13-16]</sup>.

Although not mentioned in the original classification of Truelove and Witts, the term fulminant is used to describe a particularly severe form and is defined by more than 10 evacuations per day, continuous presence of blood in stool, temperature above 37.5 °C, heart rate over 90 beats/min, erythrocyte sedimentation rate above 30 mm and a need for transfusion.

## NON-INVASIVE MARKERS

A great deal of research has been devoted to the search for a laboratory marker of disease activity in IBD in past decades. The reasons for this are firstly to overcome the subjectivity of symptoms by means of an objective evaluation and, secondly to avoid endoscopic and imaging procedures, which may be invasive, expensive and time-consuming<sup>[17]</sup>. With the introduction of newer biological therapies, there might be potential for laboratory markers in selecting responders along with their role in monitoring therapy<sup>[17]</sup>. Differential diagnosis with IBS and the follow-up of patients in periods of low disease activity, in order to detect sub-clinical intestinal inflammation and to predict disease relapses, are other important roles of these markers<sup>[18]</sup>.

### Serology markers

The acute phase response indicators ESR and C-reactive protein (CRP) have long been used as markers of inflammation and, consequently, of disease activity in IBD. CRP is the most studied among them and is considered to have the best performance. Produced by hepatocytes in low rates under normal circumstances, it rises rapidly in situations of systemic inflammation, under the influence of interleukin-6, tumoral necrosis factor- $\alpha$  and interleukin 1 $\beta$ <sup>[19]</sup>. It correlates well with clinical, endoscopic, radiological and cross-sectional activity markers in IBD, especially in CD, but not in UC<sup>[17,18,20,21]</sup>. CRP has the advantage of an early rise after onset of inflammation and a rapid decrease after its resolution, due to its short half-life of 19 h. In CD, ESR is hampered by its lack of specificity, slow increase and late decrease<sup>[17]</sup>. In UC there is a good correlation between ESR and disease activity, however it is not useful in distal proctitis because of the small area of inflammation involved<sup>[22,23]</sup>. In CD, ESR may correlate with colonic CD involvement<sup>[24]</sup>. Both polymerase chain reaction and ESR relate to systemic host responses but not with intestinal inflammation and, as a consequence, have no predictive value for the course of the disease<sup>[18]</sup>.

Leukocytosis, commonly found during disease activity, may be the consequence of a number of inflammatory conditions and stressful situations. It may also increase or decrease as a consequence of therapy (corticosteroids, azathioprine and 6-mercaptopurine). Thrombocytosis may occur in inflammatory states, but the range of normal values is too wide to allow for good sensitivity or specificity. Decreased levels of serum albumin may be found during activity of CD, but malnutrition, malabsorption, as well

as intestinal protein loss may also lead to albumin level reductions<sup>[17]</sup>.

Other classical acute phase proteins that can be detected in the serum of IBD patients are  $\alpha$ 1-acid glycoprotein (orosomucoid), fibrinogen, serum amyloid A,  $\beta$ 2-microglobulin,  $\alpha$ 2-globulin, and  $\alpha$ 1-antitrypsin. The levels of circulating orosomucoid correlate with disease activity of IBD as assessed by standard indices. Furthermore, circulating orosomucoid levels correlate with the protein loss into the gut, but its five day half-life in serum limits its usefulness as an indicator of improvement in disease activity<sup>[25]</sup>. Most of these acute phase markers have been sparsely studied and do not show advantages over CRP in detecting and monitoring inflammation in IBD<sup>[17,26]</sup>.

The search for an etiologic agent involved in the initiation of the immune-mediated bowel injury of IBD has led to the discovery of immune markers present in the sera of patients with CD and UC. The DNase-sensitive anti-neutrophil cytoplasmic antibody, with perinuclear highlighting (p-ANCA) on immunofluorescence, directed to a nuclear histone has been shown repeatedly to be present in the sera of 60% of UC and 20% of CD patients, with 5% of non-IBD patients being p-ANCA-positive. Anti-*Saccharomyces cerevisiae* (*S. cerevisiae*) IgA and IgG antibodies (ASCA), directed against a specific oligomannosidic epitope present on the cell wall of the yeast appears to represent an immune response to the antigens on the *S. cerevisiae* itself, or a cross reaction to an unidentified antigen present on the cell wall of a luminal bacteria<sup>[27-30]</sup>. ASCA is expressed in 60% of CD, 10% of UC, and 5% of non-IBD patients. Other microbial antigens recently identified to be involved in the IBD immune response [*Escherichia coli* outer membrane porin C (OmpC), the *Pseudomonas fluorescens* CD-related protein (I2), and anti-CBiR1 (anti-flagellin)] are present in 50% of CD patients and uncommon or not detected in the UC and non-IBD population. The role of these antigens in the diagnosis of IBD, in the differential diagnosis between CD and UC and in disease stratification and course are promising. The role of these emerging antigens as indicators of disease activity has not been established<sup>[26,30-33]</sup>.

Recently, it was observed that elevated serum levels of antibodies specific for certain carbohydrate structures might have a relationship with CD<sup>[34]</sup>. Malickova *et al.*<sup>[35]</sup> evaluated anti-chitobiose carbohydrate antibody, anti-laminaribiose, carbohydrate antibodies, and anti-mannobiose carbohydrate antibodies in Central European patients with IBD and concluded that a panel of anti-carbohydrate antibodies might provide additional help in distinguishing IBD from non-IBD disease patterns. However, anti-carbohydrate assays are not helpful for predicting CD behavior<sup>[35]</sup>. Another study, conducted by Rieder *et al.*<sup>[36]</sup>, showed the clinical value of serum anti-glycan antibodies for the prediction of a more complicated disease course in adult patients with CD.

The relationship between pro-inflammatory cytokine serum levels and IBD activity has been demonstrated. More recently, correlation between cytokines and endoscopically determined mucosal inflammation was demonstrated, suggesting the potential role of these markers in determining

disease activity<sup>[37-42]</sup>. IL-6 in active CD and IL-10 in recovery of CD have demonstrated a good correlation, which has been reproducible between studies<sup>[43]</sup>.

### Stool test

A number of reasons have led to the development of fecal markers of inflammation in IBD in addition to, or in substitution of, serum markers. As they are derived from stools, they may be of easy access. Also, they may have a higher specificity than serum markers, since they may reflect intestinal rather than systemic inflammation, a result of the close contact of stools with intestinal mucosa and of the possibility that it may wash out molecules related to inflammation or damage. Finally, they may avoid endoscopic examinations, since they are related to mucosal inflammation<sup>[17,18]</sup>.

Stool markers cannot be considered specific for IBD, since they can be increased in situations of mucosal inflammation, irrespective of an infectious or non-infectious etiology. Markers expressed by phagocytes may be more specific for inflammation, while markers found in epithelial cells may be more sensitive and can increase in conditions of non-inflammatory stress<sup>[18]</sup>.

Fecal occult blood (FOB) and  $\alpha$ -1 antitrypsin are markers of mucosal damage and/or disturbed barrier function. FOB determination lacks specificity for IBD and cannot be related to disease activity<sup>[44]</sup>.  $\alpha$ -1 antitrypsin is considered a sensitive but non-specific parameter reflecting enteric inflammation in IBD and has been replaced by other fecal markers<sup>[45]</sup>.

Substances related to phagocyte influx and activation comprises another group of IBD fecal markers with pathophysiological rationale. They appear as a result of leukocyte degranulation consequent to the activation of innate immunity which, in IBD, relates to phagocyte gathering and cytokine production in areas of inflammation. One interesting and already classic application of this rationale is the use indium-111-labelled granulocyte scintigraphy<sup>[46,47]</sup>. However, this technique is expensive, involves long-term stool sampling, exposure to radiation, and may not be applicable in clinical routine. This is why leukocyte degranulation markers have been studied. Even in situations of milder inflammation, products from activated phagocytes within the mucosa may spill over into the lumen and remain stable in single random stool samples, making them a more sensitive, cheaper and easier alternative to indium-111-labelled granulocyte scintigraphy<sup>[48]</sup>.

Lactoferrin, polymorphonuclear elastase, eosinophil cationic protein (ECP), eosinophilic protein X (EPX), myeloperoxidase and lysozyme are among the leukocyte degranulation markers better evaluated so far. ECP and EPX are eosinophil degranulation markers that have been described in IBD, but are considered inferior to other markers and more indicative of pathological processes that involve eosinophils<sup>[49-51]</sup>. Lactoferrin, polymorphonuclear (PMN) elastase, myeloperoxidase, and human neutrophil lipocalin are neutrophil degranulation markers detected in the stool. Lactoferrin is the most accurate among them, but it may be present in cells other than granulocytes (i.e., epithelial cells) and may have anti-inflammatory action. Also,

its pathogenetic link to IBD has not yet been elucidated.

Recently, a group of molecules with pro-inflammatory activity have been described as part of the innate immune system. The innate immunity starts our primary host defense by recognizing invading microorganisms through pathogen-associated molecular patterns (PAMPs). Activated or damaged cells can secrete the damage-associated molecular pattern proteins (DAMPs). The precise mechanism by which microorganisms activate inflammation in IBD is only partially known, but it seems that PAMPs and DAMPs have an important interaction. There are probably multiple positive feedback loops between both molecules and their overlapping receptors may amplify inflammatory processes. As DAMPs are related to the initiation of cell stress and inflammation and are found in areas of intestine affected by IBD, they are considered good candidates as markers of disease activity. S100A8, S100A9 and S100A12 are recently described DAMPs that are ligands to pattern recognition receptors, such as toll-like receptors 4 and receptors for advanced glycation end products and directly related with the amplification inflammatory processes<sup>[52-54]</sup>.

The complex S100A8/S100A9 was named calprotectin, and a strong correlation between it and indium-111-labelled granulocyte scintigraphy, the gold standard method for detecting inflammatory activity in IBD, has been demonstrated<sup>[47]</sup>. Calprotectin is commercially available and an assay for S100A12 is under development<sup>[55]</sup>. Calprotectin can be used in disease monitoring, showing a closer correlation to endoscopic and histological evidence of inflammation than clinical indices, and detecting inflammatory activity before the appearance of clinical signs<sup>[56-58]</sup>. However, calprotectin seems more predictive of relapse in UC than in CD<sup>[58,59]</sup>. Rapid, qualitative or semi-quantitative tests were developed and seem promising for discrimination of IBD from IBS. A recent meta-analysis involving 13 studies with 670 adults and 371 children and teenagers showed that fecal calprotectin is a useful screening tool for identifying patients who are most likely to need endoscopy for suspected inflammatory bowel disease<sup>[60]</sup>.

The performance of the fecal markers lactoferrin, PMN elastase and calprotectin, along with CRP and clinical indices, compared to endoscopic measures of inflammation has been evaluated. The three fecal markers are able to define disease activity both in UC and CD, and distinguish both IBDs from IBS in some situations depending on the marker, even in the absence of activity. None of the three markers seem superior in their ability to reflect endoscopic inflammation, but all three are superior to CRP in their diagnostic accuracy<sup>[19]</sup>.

Abnormalities in intestinal permeability using urinary concentration of sugar probes can be used as a predictor of imminent relapse of clinically inactive CD. Large sugar molecules (i.e., lactulose) and small molecules (i.e., mannitol), both with near 100% elimination in urine, are mixed in a drink and measured in urine as an index of tight junction function. Tight junctions are dynamic structures that respond to many stimuli and are particularly sensitive to cytokines in situations of inflammatory stress. Studies have shown that, in patients with CD in clinical remission, an increased intestinal permeability can predict the risk of

Table 2 Simple endoscopic score for Crohn's disease

Variable	Values			
	0	1	2	3
Size of ulcers	None	Aphthous ulcers (0.1 to 0.5 cm)	Large ulcers (0.5 to 2.0 cm)	Very large ulcers (> 2 cm)
Ulcerated surface	None	< 10%	10%-30%	> 30%
Affected surface	Unaffected surface	< 50%	50%-75%	> 75%
Presence of narrowing	None	Single, can be passed	Multiple, can be passed	Cannot be passed

relapse<sup>[61-63]</sup>. In all studies, the frequency of relapses was significantly different between those with normal and abnormal intestinal permeability tests.

## ENDOSCOPY

Endoscopy is usually useful to diagnose CD involving terminal ileum and colon and to distinguish it from UC. It is also important to determine the extent and severity of the disease, to assess response to treatment and to screen for dysplasia. Additionally, endoscopy allows for direct visualization of the mucosa and acquisition of biopsies, becoming the primary diagnostic tool.

An endoscopic scoring system has been developed and validated for monitoring activity in CD, and to assess severity of ileal and colonic disease. However, it is time consuming and complicated, due to the analysis of multiple aspects of lesions. It is named Crohn's disease endoscopic index of severity (CDEIS) and it is based upon the presence of four types of lesions: superficial ulcers, deep ulcers, ulcerated stenosis or non-ulcerated stenosis, all of which should be recorded in five different segments: terminal ileum, ascending colon, transverse colon, descending and sigmoid colon, and rectum<sup>[64]</sup>. The combination of values allows the calculation of a severity score, which ranges from between 0 and 30. Unfortunately, in a subsequent study, the same authors demonstrated that the use of endoscopy and the CDEIS to guide therapeutic decisions with regard to corticosteroid therapy was not helpful clinically<sup>[65]</sup>.

Years later, Dapermo *et al*<sup>[66]</sup> proposed a simplified model based on ulcer size, ulcerated surface, affected surface and narrowing of lumen present in the ileum, right colon, transverse colon, left colon and rectum, with a score ranging from 0 to 3 (Table 2). Reproducibility of these parameters was confirmed and it was highly correlated with both CDEIS and CDAI.

However, it must be asked if it is really necessary to establish an endoscopic scoring system, as objective as it is to evidentiate healing of mucosal lesions, which has become an important end point in clinical trials of CD treatment<sup>[67-69]</sup>. It remains to be defined if standardization of endoscopic evaluation can be useful in guiding therapy. Still of concern are possible pitfalls of the SES-CD index of activity including the presence of fistulas, for which endoscopy is not the best diagnostic test, and underestimation of stenosis and overestimation of non-specific lesions because of inexperience with endoscopy in patients with IBD.

In UC, endoscopy is necessary for diagnosis and for

determining disease extent. In order to evaluate the clinical disease activity, various endoscopic indices have been elaborated, such as Baron Score, Rachmilewitz Endoscopic Index, Mayo Score and Sutherland Mucosal Appearance Assessment<sup>[13,70-72]</sup>. All were based in granulation scattering, vascular pattern, vulnerability of mucosa and mucosal damage (mucus, fibrin, exudates, erosions and ulcer). However, no standardized model has been established. In an attempt to determine whether or not any endoscopic indices could be established as a standard, Hirai *et al*<sup>[73]</sup> compared the Baron score with the Rachmilewitz Endoscopic Index and demonstrated that both were almost equally useful for evaluating disease activity. In another study, inter- and intraobserver agreement were evaluated, using Matt's, Mayo Score, Baron, and Blackstone indices<sup>[74]</sup>. Two hundred and seventy nine endoscopic pictures of inflammatory lesions from 93 UC patients were displayed twice to 4 expert and 4 trainee endoscopists, with a one month interval. The Matt's and Mayo indices showed a good degree of concordance for expert endoscopists in terms of inter- and intraobserver agreements, but this was not so evident with the Baron and Blackstone indices. For trainee endoscopists, all weighted kappa values for inter- and intraobserver scores using established indices were lower than for the experts. In 2007, D'Haens *et al*<sup>[75]</sup> published a study that reviewed activity indices and efficacy end points for clinical trials of medical therapy in adults with UC and recommended that absence of friability, blood, erosions, and ulcers in all visualized segments are required components of genuine endoscopic healing.

## IMAGING TECHNIQUES

### Abdominal and doppler ultrasound

Transabdominal ultrasound is a very well established tool to examine the liver, hepatobiliary-pancreatic tree and urogenital tract; however, its use for imaging the intestinal tract has been considered more difficult. In the past two decades, improvements in technology, specially new high frequency probes, highly sensitive color and power Doppler units and development of new contrast agents, along with an increasing experience with sonographic findings in intestinal diseases, have all contributed to establishing the role of ultrasound as a clinically important, non-invasive, radiation free and widely available imaging modality for evaluation of these patients<sup>[76,77]</sup>.

Ultrasound has been successfully used as the imaging method of choice in screening patients with clinically suspected CD; it may be the first diagnostic tool employed

for young patients and can be used in the preliminary diagnostic work-up prior to further invasive tests. Another important application of bowel ultrasound is in the follow-up of patients already diagnosed with CD, in whom it may be useful to assess the site and extent of the lesions and to ensure early detection of intra-abdominal complications<sup>[78]</sup>.

Although it has an important role in the evaluation of CD patients, the usefulness of ultrasound and Doppler imaging in assessing disease activity is still a matter of discussion. Several studies attempted to correlate ultrasound and Doppler findings with clinical and biochemical activity, but the published results are controversial<sup>[78]</sup>.

Bowel wall thickening, bowel wall stratification and length of bowel wall involvement were all tested as sign of disease activity. Of these, only the degree of bowel wall thickening showed a significant, but weak, correlation with clinical CDAI and biochemical (erythrocyte sedimentation rate, C-reactive protein) parameters, and can be viewed as an indirect sign of disease activity<sup>[79]</sup>. Although a sensitivity of 80% has been reported for the cut-off value of 4 mm for the maximum thickness of bowel wall, the specificity of this finding alone is low due to the difficulty in differentiating inflammation from fibrosis<sup>[80,81]</sup>.

As neovascularization and hyperemia of the bowel wall are well established findings in active CD, much effort was also made trying to correlate Doppler sonography of the superior mesenteric artery and power Doppler study of the bowel wall with other markers of activity.

Regarding Doppler sonography of superior mesenteric artery, some authors state that the available results concerning this association are conflicting, but the disagreement seems to be due to crucial differences in methodology, especially in the adopted Doppler parameters<sup>[79,82]</sup>. Van Ostayen *et al.*<sup>[83-86]</sup> showed that superior mesenteric artery flow was the most reliable parameter to characterize disease activity and that the cut-off value of 500 mL/min had a sensibility between 80% and 83% and a specificity of 87% for this diagnosis. The association between increased superior mesenteric artery flow and disease activity was also supported by others<sup>[87-89]</sup>.

Intestinal wall vascularity has been studied for more than a decade and the results were consistent with a correlation between blood vessel density assessed by power Doppler sonography and the degree of local inflammation assessed by endoscopy or clinical and biochemical evaluation<sup>[90,91]</sup>. In this field, newer techniques such as harmonic imaging and the administration of echo-enhancing contrast agents have further improved the sensitivity and accuracy of power Doppler evaluation of the bowel wall in detecting inflammatory activity by showing increased perfusion in the affected bowel<sup>[92-96]</sup>. It has also been demonstrated that the assessment of intramural blood flow by means of power Doppler and intravenous contrast agents may discriminate inflammatory stenosis which are hypervascularized, of those cicatricially transformed, and characterized by fibrosis and hypovascularized scar tissue<sup>[97]</sup>.

Although sometimes helpful in evaluating the extent of the disease, the role of transabdominal ultrasound in UC is much less important than in CD, mostly due to the fact

that the disease affects only the mucosa, resulting in very subtle echographic findings, which are difficult to evaluate<sup>[76]</sup>. The mesenteric blood flow in inferior mesenteric artery, although seemingly related to clinical endoscopic disease activity, is technically much more difficult to measure by Doppler than it is in the superior mesenteric artery due to its smaller diameter<sup>[98]</sup>.

### Computed tomography and magnetic resonance enterography

Computed tomography (CT) in its conventional form has played a significant role in the evaluation of complications and extraenteric manifestations of CD, such as fistulas and abscesses, but it has a limited role for depicting bowel wall and luminal abnormalities. CT enterography (CTE) is a modification of the conventional CT technique, optimized for the evaluation of small bowel. This technique utilizes multidetector CT scanners with high spatial and temporal resolutions, thin sections, multiplanar reconstructions and large volumes of ingested neutral enteric contrast material, combined with the use of intravenously administered iodinated contrast, in order to permit visualization of the small bowel wall, mucosa and lumen<sup>[99]</sup>. Then, apart from detecting extraluminal findings, CTE can delineate the extent and severity of bowel wall inflammation<sup>[100]</sup>.

CTE findings of bowel wall thickening, mural stratification, mural hyperenhancement, increased attenuation in the perienteric fat and engorged vasa recta correlate with mucosal and mural inflammation and so, with active CD<sup>[99,101]</sup>.

Mural thickening refers to wall thickness of greater than 3 mm in a well distended bowel loop. It is the most frequently observed CT finding in CD, present in up to 82% of patients<sup>[102]</sup>.

Mural stratification is a distinction of the bowel wall layers on CT after intravenous contrast injection; mucosa and muscular/serosa layers show contrast enhancement and interposed submucosa has a decreased attenuation, giving the wall a trilaminar appearance<sup>[103]</sup>.

Mural hyperenhancement describes a segmental hyperattenuation of a distended bowel loop when compared to adjacent normal loops. This finding correlates significantly with histologic findings of active CD, being the most sensitive CTE finding of disease activity<sup>[103]</sup>. It has also been observed that the degree of bowel wall enhancement correlates with the severity of inflammation<sup>[104,105]</sup>.

Increased attenuation of mesenteric fat can be due to edema or engorged vasa recta, vessels that penetrate the bowel wall perpendicular to the bowel lumen; these two findings combined are the most specific sign of disease activity and correlate with the levels of C reactive protein<sup>[105]</sup>.

CTE can also depict signs of chronic manifestations of CD, such as submucosal fat deposition, sacculations and fibrofatty proliferation<sup>[101]</sup>. The presence of intramural fat indicates past or chronic inflammation. Sacculations result from the chronic inflammatory process, leading to fibrosis and asymmetric shortening of the mesenteric border of the wall (Table 3)<sup>[106]</sup>.

Many authors addressed the positive correlation between CTE findings and clinical and biochemical markers

**Table 3** Computed tomography enterography findings of Crohn's disease activity and chronic disease

Disease activity	Chronic disease
Bowel wall thickening	Submucosal fat deposition
Mural stratification	Sacculations
Mural hyperenhancement	Fibrofatty proliferation
Increased attenuation in the perienteric fat	
Engorged vasa recta	

of disease activity, such as CDAI and C-reactive protein and erythrocyte sedimentation rate, respectively, but the clinical relevance of these images is still a matter of discussion<sup>[105,107]</sup>. Higgins *et al*<sup>[108]</sup> reviewed the CTE scans and clinical data of 67 patients with CD presenting abdominal pain and a clinical suspicion of either small bowel inflammation or stricture. The authors showed that CTE can detect strictures not clinically suspected, rule out strictures that were radiologically insignificant and change the perceived likelihood of steroid benefit in up to 61% of cases. The CTE ability to detect small bowel strictures can be particularly helpful when considering using endoscopic capsules, which may themselves precipitate small bowel obstruction.

CTE has a major disadvantage: the use of ionizing radiation. The increased spatial resolution of CT with new multidetector CT scanners carries along with it a greater dose of ionizing radiation. In fact, effective doses of radiation are up to five times higher with CTE when compared with small bowel follow through<sup>[109]</sup>. Considering that many patients will undergo various examinations through their lifetime, efforts should be made to minimize the number of CT examinations, decrease CT dose or considering another diagnostic imaging modality, such as magnetic resonance enterography (MRE).

MR imaging also experienced the same technical advances seen in CT in the last ten years. In a similar way, the improvement in spatial and temporal resolution of images, combined with the use of large volumes of oral contrast agents to provide bowel distention, allows the evaluation of bowel wall contrast enhancement, wall thickening and edema; findings useful for the assessment of CD activity<sup>[110]</sup>.

The preference of MRE *vs* CTE has been geographical and based on expertise and public policy. With increasing awareness of radiation exposure risks, there has been a more global interest in implementing techniques that reduce or eliminate radiation exposure. Owing to this excellent soft tissue contrast, direct multiplanar imaging capabilities and lack of ionizing radiation, MRE is well suited to play an important role in the evaluation of small bowel disorders<sup>[111]</sup>.

Until now, the available data concerning accuracy of MRE in detecting disease activity is less than CTE, but early results are encouraging, showing a similar sensitivity and diagnostic effectiveness<sup>[112-114]</sup>, although image quality is still better with CT. Motion artifacts from small bowel motility are more severe with MRE<sup>[112]</sup>, but halting peristalsis by administering 1 mg of glucagon intramuscularly

before contrast-enhanced imaging reduces blurring and artifacts related to bowel motility<sup>[115]</sup>.

As they are imaging methods designed to assess small bowel, both CTE and MRE are not suited for evaluating UC.

In conclusion, in the last few years, a great deal of research and the development of diagnostic tools have been devoted to the task of diagnosing IBD, predicting its course and determining activity. Many of these tools show promising results, but a lack of specificity remains a problem that precludes routine use in clinical practice. Advances in molecular medicine towards a better understanding of genetic and other etiologic factors in IBD may result in better performance of markers of disease. Endoscopy displays direct evidence of mucosal injury. However, it is time consuming, invasive, expensive and, a good deal of endoscopic evaluation criteria lack validation, making it difficult to adopt endoscopic methods for routinely monitoring the course of IBD. Imaging techniques are useful as markers in CD, but they lack applicability in UC. Considering disease markers pitfalls, clinical activity indices still have their place in IBD monitoring. In conclusion, there is not yet an ideal marker, and determination of activity depends on clinical ability to manage information given by the available complementary exams.

### Abstract

DNA methylation is a type of epigenetic modification in the human genome, which means that gene expression is regulated without altering the DNA sequence. Methylation and the relationship between methylation and cancer have been the focus of molecular biology researches. Methylation represses gene expression and can influence embryogenesis and tumorigenesis. In different tissues and at different stages of life, the level of methylation of DNA varies, implying a fundamental but distinct role for methylation. When genes are repressed by abnormal methylation, the resulting effects can include instability of that gene and inactivation of a tumor suppressor gene. MicroRNAs have some aspects in common with this regulation of gene expression. Here we reviewed the influence of gene methylation on cancer and analyzed the methods used to profile methylation. We also assessed the correlation between methylation and other epigenetic modifications and microRNAs. About 55 845 research papers have been published about methylation, and one-fifth of these are about the appearance of methylation in cancer. We conclude that methylation does play a role in some cancer types.

### INTRODUCTION

The occurrence of many diseases, such as cancer, diabetes mellitus and scleroderma, is related to the dysregulated gene expression resulting from epigenetic and genetic abnormalities. Genetic abnormalities can be caused by point mutations, gene amplification, or changes in the promoter (typically caused by chromosomal rearrangements)<sup>[1]</sup>, whereas epigenetic modifications include methylation, deacetylation of genes, and methylation of histone proteins, resulting in the accurate regulation of gene expression, without changing the DNA sequence, in response to changes in the environment and to meet the demands of differentiation<sup>[2]</sup>. In fact, epigenetic modifications are as important as genetic modifications in regulating gene expression and controlling the onset of disease<sup>[3]</sup>. DNA methylation, as a crucial component of epigenetics, plays an important role in cell differentiation and embryogenesis and is also heritable. Since it was first described by Feinberg and Vogelstein in 1983, our knowledge of methylation has grown at a dramatic rate<sup>[4]</sup>. The recent development of methods to profile and study methylation in chromosomes has led to a deeper understanding of this process along with clinical applications to aid in the prognosis and treatment of disease<sup>[5]</sup>.

### DNA METHYLATION

#### Definition of methylation

In 1999, the modern conception of epigenetics was put forward by Jones *et al*<sup>[6]</sup>. Epigenetics is defined as the reg-

**Figure 1** DNA methylation machinery. NLS: Nuclear localization signal; PCNA: Proliferating cell nuclear antigen.

ulation of gene expression without changing the genetic sequence. It is a flexible, heritable process that regulates some genes<sup>[7]</sup>. DNA methylation and the modification of histones including acetylation and deacetylation are important components of epigenetics; however, the most common modification is DNA methylation.

DNA methylation is a type of covalent modification in which a methyl group is added to a cytosine in the genome *via* S-adenosylmethionine; this process occurs as an enzymatic reaction after DNA replication<sup>[8]</sup>. In mammalian cells, methylation of DNA is typically restricted to the 5-position of the pyrimidine ring of cytosine residues that are located in CpG dinucleotides<sup>[9]</sup>. CpG dinucleotides are frequently clustered into CpG islands, regions that are rich in CpG sites. These islands are generally about 0.5-3 kb, occur on average every 100 kb in the genome, and are found in approximately half of all genes in humans<sup>[10]</sup>. Methylation of other CpGs seems to have no biological functions<sup>[11]</sup>.

There are four types of DNA methyltransferases (DNMTs), including DNMT1, DNMT3A, DNMT3B, and DNMT3L. DNMTs control the degree of methylation of the genome: DNMT1 is responsible for the maintenance of methylation, and DNMT3A and DNMT3B carry out *de novo* methylation. The DNMT3L does not have enzymatic activity, but it does regulate the activity of the other methyltransferases<sup>[12,13]</sup>. DNMT1 is considered to be the maintenance methyltransferase because of its high activity and preference for hemimethylated DNA during DNA replication. All of the active DNA methyltransferases contain an active site motif in the C-terminal region (red box), whereas DNMT3L does not. DNMT1 contains other functional regions required for its interaction with proliferating cell nuclear antigen, which is adjacent to the nuclear localization signal. The N-terminal region of DNMT1 also contains a cysteine-rich HRX-like region and a lysine-glycine repeat [KG(5)] region. DNMT3A, DNMT3B, and DNMT3L contain a plant homeodomain; DNMT3A and DNMT3B contain a PWWP domain. These two domains are required for targeting DNMT3A and DNMT3B to pericentromeric heterochromatin and contribute to protein-protein interactions by recognizing histone modifications<sup>[14]</sup> (Figure 1).

### Normal and abnormal levels of methylation

The level of methylation changes during the growth of human beings and the development of diseases and, in different tissues, methylation varies substantially. Normally, about 50% of the CpG islands, which customarily are located in the promoter region of housekeeping genes, are unmethylated and thus are active. When those CpGs become methylated, the corresponding gene is silenced. There are, however, CpGs that are located elsewhere in genes and that do not influence transcription when they are methylated. DNA methylation is replicated with a high fidelity in mammalian cells and is almost at a stable state in a specified cell. It is regarded as having tissue and organ specificity<sup>[15]</sup>.

Once the rhythm of methylation is disturbed, many diseases develop<sup>[16,17]</sup> (Table 1). Customarily, the abnormal condition includes two aspects: Hypermethylation and hypomethylation<sup>[14]</sup>.

## DNA METHYLATION IN TRANSCRIPTIONAL CONTROL

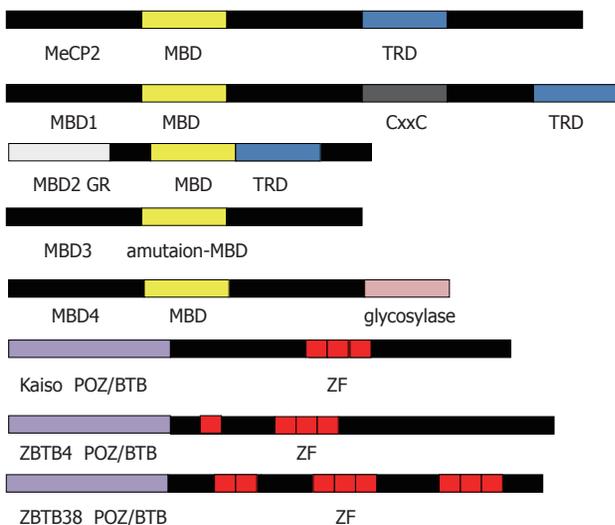

### The role of methylation in transcriptional control

When methylated, chromosomes become stabilized, and their activity is decreased. Gene expression is repressed by methylation in two separate mechanisms<sup>[18,19]</sup>. In direct inhibition, the methylated chromosome prevents the approach of the transcriptase, holding back transcription. The second method is indirect inhibition, in which two types of protein, methylation-binding proteins (MBDs) and histone deacetylase (HDAC) are recruited to the chromosome (Figure 2). MBD proteins display homology within their MBD domains, whereas the transcription repression domains (TRDs) described for MeCP2, MBD1 and MBD2 are nonhomologous. In addition to its MBD domain, MBD1 is able to bind unmethylated DNA *via* its third CxxC zinc-finger motif. MBD2 features a characteristic stretch of glycine and arginine residues in the MBD domain, which when mutated prevent the binding of MBD to methylated CpGs in mammals<sup>[20]</sup>. MBD3 is not able to bind methylated CpGs in mammals because of a mutation in the MBD domain. MBD4, a thymine glycosylase, contains a C-terminal glycosylase domain used for excision-based DNA repair. Three members of the Kaiso protein family which also influence the transcription, have been described so far. Kaiso, ZBTB4 and ZBTB38 share a triple zinc-finger domain and a BTB/POZ domain, which in the case of ZBTB4 contains a 60-amino-acid insertion. Furthermore, ZBTB4 and ZBTB38 contain, respectively, three and seven additional zinc-finger domains and have juxtaposed MBD and TRD domains<sup>[21]</sup>.

MBDs can also prevent the approach of transcription factor (TF) and cofactors, so that they cannot bind the promoter of the gene, thus stopping the transcription. The HDAC is also recruited to the region of methylated DNA, where it affects the activity of the promoter and deacetylates of the lysine of histone3/histone4 charged, and it then reacts with the negatively charged DNA. As a result, the chromosome becomes more tightly packed,

Table 1 Methylation and diseases		
AML	<i>hPer3</i> gene	Hypermethylation
Fragile X syndrome	Loss of FMR1/FMR2 function	Promoter methylation
ATR-X syndrome	Loss of ATRX function	Hypomethylation of certain repeat and satellite sequences
Immunodeficiency, centromeric region instability, and facial anomaly syndrome	DNMT3b mutation	Centromeric DNA hypomethylation
Beckwith-Wiedeman syndrome	Disruption of the imprinted IGF2/CDKN1C loci on 11p15.5	Loss of genomic imprinting
Williams syndrome	Loss of WSTF function	Condensed chromatin structures
Rubinstein-Taybi syndrome	Mutations in the gene encoding CREB-binding protein	Reduced histone H3 acetylation
Prader-Willi syndrome	Disruption of the imprinted SNRF/SNRPN locus on 15q11-13	Disruption of genomic imprinting
Coffin-Lowry syndrome	Mutation in RSK genes	Disrupted chromatin remodeling <i>via</i> activation of CREB-binding protein

CREB: cAMP-response element-binding protein; WSTF: Williams syndrome transcription factor.

**Figure 2** Proteins that bind the methylated DNA. MBD: Methylation-binding protein; TRD: Transcription repression domains.

blocking access to those proteins that are needed to start transcription. Genes with unmethylated (open lollipops), active CpG island promoters (Pro), have TFs (the radial pattern) at the transcription initiation site. Transcripts initiated here proceeding through the downstream elements even though they are methylated (closed lollipops) and presumably are coated with methyl CpG binding domain proteins (MBDs, the cylindrical cast) and HDACs (the trigon). The enhancer is functional because the silencer and insulator are methylated and, thus, not occupied by their respective cognate proteins. Methylation here is permissive for expression. For a permanently silenced gene such as an imprinted gene or a gene on the inactive X chromosome, the promoter is methylated, leading to binding of MBDs, HDACs, other transcriptional suppressors, and chromatin compaction. The TFs, which normally regulate gene expression, are not able to access the promoter. Figure 3 also shows how lack of methylation in a silencer or insulator can lead to binding of the cognate proteins, e.g., GCF2 (GC binding factor 2, the cube) or CTCF (CTC binding factor, the oblong), thus preventing the enhancer

from functioning<sup>[22]</sup> (Figure 3).

From what has been described above, we know that methylation and deacetylation work in conjunction to regulate gene expression, but methylation is the triggering event. Under some conditions, however, deacetylation appears first, followed by methylation<sup>[23]</sup>. The role of each process in the regulation of gene expression needs to be studied in more detail.

### How methylation is maintained and induced

Although methylation is known to be important and has been the focus of research, we are still not clear why abnormal methylation occurs. Because methylation is catalyzed by DNMTs, changes in these enzymes may have some association. When DNMT1 is removed, the level of methylation of the whole genome is reduced by 3%, and when DNMT3 is removed, it is reduced by 4%. When they are both removed, the level is lowered by 98%<sup>[14,24]</sup>. Thus, DNMTs are important for methylation. Their activity can, however, be influenced by many factors, such as ray, temperature. Because cells near the body surface are more easily influenced by the surrounding environment, the methylation of skin cells often becomes dysregulated. In addition, infection can lead to abnormal methylation. Infection with *Helicobacter pylori* (*H. pylori*) in the stomach can cause cancers, accompanied by changes in DNA methylation. Smoking is also a risk factor, as it can cause many genes to gain methylation<sup>[25]</sup>. One study has also shown that eating foods lacking in folic acid, which is the carrier of the one carbon unit, leads to more-complex methylation patterns and increases the likelihood of cancer<sup>[26]</sup>.

## DNA METHYLATION AND MICRORNAS IN CANCER

It is well accepted that cancer is a result of many events, including genetic and epigenetic and others. Since 1983, epigenetics has attracted the most attention of researchers, who have focused in particular on methylation. The appropriate DNA methylation within CpG dinucleotide islands plays a significant role in the regulation of gene

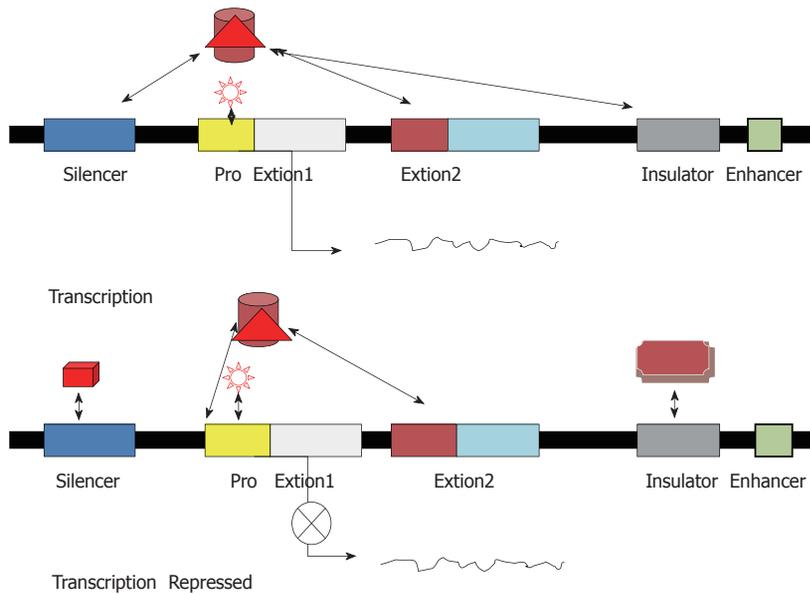

Figure 3 How methylation represses the gene expression..

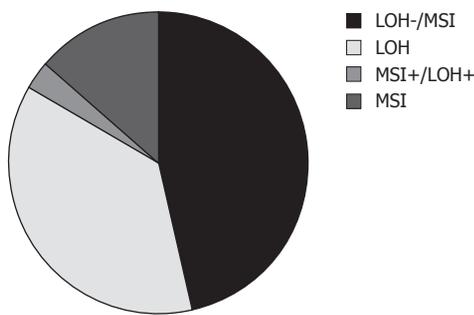

Figure 4 Factors for cancer development. LOH: Heterozygosity; MSI: Microsatellite instability.

expression. Abnormal patterns in DNA methylation often result in many diseases<sup>[27]</sup>. Either as a result of DNMT overexpression or the occurrence of aberrant hypermethylation of tumor cell-specific promoters, the pattern of cell cycle, apoptosis and DNA repair changes following the aberrances of differentiation and adhesion of cells which is often a hallmark of diseases<sup>[28]</sup>. It is reported that 48% of tumors had evidence of loss of heterozygosity (LOH), whereas 14% of tumors had microsatellite instability (MSI), including a minority of tumors (3%) that overlapped with LOH. Nearly one-third of tumors (38%) have neither MSI nor LOH<sup>[1]</sup> (Figure 4).

Four abnormal aspects, inactivation of mismatch repair, instability of chromosomes, hypomethylation of oncogenes, and hypermethylation of tumor suppressor genes, can be observed when abnormal DNA methylation appears. The four aspects often cooperate to cause cancers to happen. The first genes found to be methylated were p16, TSP-1, and IGF2. In colorectal cancer, there is a significant degree of methylation at the previously identified CIMP-associated loci (MINT-1, -2, -31; p16; p14; MLH1), as well as in six new tumor suppressors or gene markers (PTEN, TIMP3, RUNX3, HIC1, APC, and RARβ2), in combina-

tion with the chromosomal instability and microsatellites instability<sup>[1]</sup>.

In addition, it has been proposed that hypomethylation patterns of the genome exist and, more specifically, that hypomethylation and hypermethylation cooperate in cancer development<sup>[29]</sup>. Transcriptional silencing *via* DNA hypermethylation can often be associated with poor clinical outcome in several malignancies, indicating that hypermethylation of tumor-suppressor genes or hypomethylation of tumor genes are related to cancer<sup>[30,31]</sup>.

In addition, methylation can be a marker to judge whether the cancer has been transferred to other tissues. HIN-1, CDH13, RIL, RASSF1A, and RARβ2 were frequently methylated in both primary and metastatic tissues, whereas the methylation status of HIN-1, CDH13, RIL, and RARβ2 isolated from lymph nodes was correlated with that in primary tumors in breast cancer<sup>[32]</sup>.

Recently, small interfering RNAs (siRNAs) have been found to participate in gene regulation together with methylation. siRNAs are RNAs that consist of 21-25 nucleotides. They make up nearly 2% of the genome and can be found either in the host gene or other genes. siRNAs can induce the methylation of the promoter, thus silencing the gene. This factor has been conserved during evolution and has complicated functions. There are at least three kinds of small RNAs, siRNA, miRNA, and others. It has been known that some small RNA can repress gene expression *via* a complex of proteins named the RNA-induced silencing complex, thus regulating gene expression after transcription. miRNA-223 is located in the X chromosome, and its expression is controlled by the upper sequence CCAAT box. Two kinds of proteins, NFI-A and C/EBPα, participate in the process. Abnormal expression of miRNA223 can lead to acute lymphocytic leukemia and acute myelocytic leukemia (AML). The fusion gene *AML1/ETO* will cause down-regulation of the miRNA223 *via* methylation or recruiting of related

enzymes. When miRNA223 is silenced, diseases appear. In the primary carcinoma of liver, miRNA223 is notably down-regulated, reflecting the coordination of methylation and miRNA. The influence of methylation on the expression of miRNAs should be further studied and will be a hotspot of research in the next few years<sup>[33-37]</sup>.

## DNA METHYLATION AND MICRORNAS IN GASTRIC CANER

The roles of DNA methylation and miRNA in gastric cancer have been extensively studied recently. Many genes are methylated specifically in gastric cancer, as are miRNAs and siRNAs. Because oncogenes and tumor suppressor genes can have important roles in cancer and because methylation can repress gene expression, the level of methylation of a specific gene in gastric cancer may reflect whether that gene is an oncogene or tumor suppressor gene. Weak gene expression and loss of gene expression because of promoter hypermethylation may be a cancer-specific event<sup>[38]</sup>.

Ulcer-healing genes (*TFF1*, *TFF2*, *CDH1* and *PPARG*) are methylated in earlier gastric carcinoma, and methylation of hsa-miR-124 is involved in cervical cancer<sup>[39-41]</sup>. The gene encoding BMP3 has been found to cause gastric carcinoma in Chinese population<sup>[42]</sup>. If combined with other aspects, the situation may be more severe. For example, epigenetic inactivation of GATA-4 and GATA-5 by methylation of CpG islands is an early frequent event during gastric carcinogenesis and is significantly correlated with *H. pylori* infection<sup>[43]</sup>. If expression of DNMT is abnormal, methylation will be abnormal, leading to a disease state. It has also been reported that methylation can have an additive effect with other chromosomal abnormalities. This can result in a positive feedback loop that progresses to a disease state<sup>[11]</sup>. Infection with *H. pylori* induces IRX1 promoter methylation and downregulation of the promoter activity as well as a significant reduction in gene expression. Gene silencing of the IRX1 tumor suppressor by promoter CpG methylation, combined with LOH, has been identified in human gastric cancer<sup>[44]</sup>. SLC19A3 was epigenetically down-regulated in gastric cancer, and *via* the technique of quantitative real time polymerase chain reaction (RT-qPCR), it has been shown that aberrant SLC19A3 promoter hypermethylation in plasma may be a novel biomarker for breast and gastric cancer diagnosis<sup>[45]</sup>. Promoter hypermethylation of p16, Runx3, DAPK and CHFR is frequent in gastric cancer. DAPK and CHFR promoter hypermethylation may be important for evaluating the differentiation grade and lymph node status in patients with gastric cancer. Silencing of HIC1 and TOB1 expression is a common occurrence in gastric cancer and may contribute to the development and progression of the disease<sup>[46]</sup>.

Methylation silencing of *miRNA* genes, in addition to that of protein-coding genes, may contribute to the formation of a field defect for gastric cancers<sup>[47]</sup>. Down-regulation of miR-212 may be related to gastric carcinogenesis through its target genes, such as *MECP2*<sup>[48]</sup>.

Hypermethylation of hsa-miR-124a is present in gastric cancer<sup>[49]</sup>. miRNA-34b and miRNA-34c are novel tumor suppressors that are frequently silenced by DNA methylation in gastric cancer, and methylation of miR-34b/c is involved in an epigenetic field defect and that the methylation might be a predictive marker of gastric cancer risk<sup>[50]</sup>. The transformation from gastritis to lymphoma of mucosa-associated lymphoid tissue is epigenetically regulated by miR-203 promoter methylation, and ABL1 is a novel target for the treatment of this malignancy<sup>[51]</sup>. miR-10b methylation may be a useful molecular biomarker for assessing the risk of gastric cancer development, and modulation of miR-10b may represent a therapeutic approach for treating gastric cancer<sup>[52]</sup>.

## CLINICAL APPLICATIONS

Based on how methylation works to repress gene expression, several methods can be used to treat the related diseases. Current research has focused on methods to demethylate the gene of interest. Both HDAC inhibition and DNA demethylating agents have shown clinical efficacy respectively; yet a combination of the two agents has a strong synergistic effect on the reactivation of silenced genes and antiproliferative and cytotoxic effects on cancer cells<sup>[30,53]</sup>. The two compounds do not, however, reverse the methylation entirely<sup>[54]</sup>. Both nucleoside analogs and non-nucleoside analogs can be used to demethylate the gene of interest, but with severe side effects<sup>[55,56]</sup>. The first kind of agents includes 5-azacytidine, 5-aza-2-deoxycytidine (5-aza-CdR), 5,6-dihydro-5-azacytidine, and zebularine, among which 5-azacytidine has been clinically shown to reduce the degree of methylation and prolong the survival of the patients. The second includes procaine, mitoxantrone, N-acetyl-procainamide, procainamide, hydralazine, and the main polyphenol compound of green tea, (-)-epigallocatechin-3-gallate. Although the two kinds of agents are effective, their severe side effects cannot be ignored, for they both will make the whole genome hypomethylated which can cause many problems including the development of new diseases<sup>[57]</sup>.

For these reasons, these agents just acts as some assistance ones. To reduce the side effects, small molecules targeting DNMT are being developed. It has been reported that they are exquisitely S-phase specific, which makes them less toxic<sup>[58]</sup>. RG108 and MG98 are among them. They can apparently inhibit methylation with fewer side effects and activate the repressed genes, but clinical trials have not yet been carried out<sup>[59]</sup>.

Because we now have accurate ways to profile the methylation in a genome or in an individual gene, demethylation can be monitored frequently, which will allow the prompt correction of therapeutic agents, giving greater promise to this approach. It is, however, more important to prevent the occurrence of abnormal methylation.

## METHODS IN METHYLATION PROFILING

Methylation profiling can be approached in two ways:

analysis of genome-wide methylation and analysis of single CpGs. Both approaches can be carried out by the same methods: colorimetry, fluorescence, methylation-sensitive restriction endonuclease treatment and PCR.

The first step in the colorimetric method is to hydrolyze the target DNAs into nucleotides using hydrochloric acid and then test the resulting absorbance. Differences in absorbance suggest that there are differences in the level of methylation between the two chromosomes. This is used to test the whole-genome methylation of DNAs. The fluorescence method has something in common with the colorimetric approach. It uses chloroacetaldehyde to treat the chromosomes, so that the chromosomes will increase in fluorescence, and the fluorescence intensity reflects the level of methylation of the whole genome. The methylation-sensitive restriction endonuclease method is used to analyze single CpGs, and the enzyme pairs used include Hpa II -Msp I and Sma I -XmaI. These enzymes specifically degrade the unmethylated chromosomes into small pieces, whereas the methylated DNA will escape the shearing. The pieces then can be tested *via* PCR or Southern blotting<sup>[60]</sup>.

When treated with bisulfite, methylated cytosines are stable, whereas unmethylated cytosines are modified to uracils. The amplification results thus can indicate whether the CpG is methylated or not<sup>[61]</sup>.

## CONCLUSION

With every new discovery in the epigenetic landscape of tumors, there comes a new opportunity for producing targeted agents to cure cancer. As the understanding of the intricate machinery of tumor growth continues, there is greater hope that methylation-based therapies will prove successful. It is, however, essential to determine the safety of these treatments in the long run as we administer the agents to healthier populations of patients. It is also important to consider the context of all epigenetic processes, as the known treatments for blocking methylation are either non-specific or have severe side effects.

Our understanding of the relationship between DNA methylation and transcriptional control is being deepened but is still far from complete. It may be unrealistic to expect that any unified theory will encompass all the biological consequences of DNA methylation. It must be linked with deacetylation, siRNAs and phosphorylation. The mechanisms by which methylation patterns are generated are still not fully understood. After the human genome project comes into the post-genome period, methylation is of great importance. It is feasible to use the technique of methylation in the future to induce cell differentiation, guide clinical treatment and explore the early stages of cancer<sup>[62]</sup>.

### Abstract

**AIM:** To assess quantitative endoscopic ultrasound (EUS)-guided elastography in the nodal staging of oesophago-gastric cancers.

**METHODS:** This was a single tertiary centre study assessing 50 patients with established oesophago-gastric cancer undergoing EUS-guided fine needle aspiration biopsy (FNAB) of lymph nodes between July 2007 and July 2009. EUS-guided elastography of lymph nodes was performed before EUS-FNAB. Standard EUS characteristics were also described. Cytological determination of whether a lymph node was malignant or benign was used as the gold standard for this study. Comparisons of elastography and standard EUS characteristics were made between the cytologically benign and malignant nodes. The main outcome measure was the accuracy of elastography in differentiating between benign and malignant lymph nodes in oesophageal cancers.

**RESULTS:** EUS elastography and FNAB were performed

on 53 lymph nodes. Cytological malignancy was found in 23 nodes, one was indeterminate, one was found to be a gastrointestinal stromal tumor and 25 of the nodes were negative for malignancy. On 3 occasions insufficient material was obtained for analysis. The area under the curve for the receiver operating characteristic curve for elastography strain ratio was 0.87 ( $P < 0.0001$ ). Elastography strain ratio had a sensitivity 83%, specificity 96%, positive predictive value 95%, and negative predictive value 86% for distinguishing between malignant and benign nodes. The overall accuracy of elastography strain ratio was 90%. Elastography was more sensitive and specific in determining malignant nodal disease than standard EUS criteria.

**CONCLUSION:** EUS elastography is a promising modality that may complement standard EUS and help guide EUS-FNAB during staging of upper gastrointestinal tract cancer.

### INTRODUCTION

Endoscopic ultrasound (EUS) is an integral investigation in the staging of oesophageal and oesophago-gastric junctional tumours<sup>[1,2]</sup>. It provides both an accurate as-

assessment of the tumour (T) stage of a cancer and associated lymphadenopathy (N)<sup>[3-5]</sup>.

EUS lymph node assessment can be challenging. EUS-guided fine needle aspiration biopsy (FNAB) of lymph nodes remains the pre-operative gold standard for determining nodal involvement, with diagnostic accuracy of up to 95% reported in previous studies<sup>[6,7]</sup>. However, EUS-FNAB cannot be undertaken if the needle passes through the primary tumour, and there can be technical difficulties in obtaining lymph node material for analysis.

Using conventional grey-scale B-mode EUS, lymph nodes are characterised by size, shape, density and distinction of the border in an attempt to distinguish between benign and malignant nodes<sup>[8]</sup>. However, the sensitivity and specificity of these features in distinguishing malignant involvement only exceeds 80% when all four of these features are present<sup>[8]</sup>.

Elastography measures the stiffness of a structure and it is known that pathophysiological processes such as malignancy lead to stiffer tissue that deforms less. Over the past 15 years, elastography during ultrasound has been applied to measure tissue elasticity in breast, thyroid and liver disease<sup>[9-13]</sup>. Initial studies assessing nodes with elastography used processing to produce a colour elastography image<sup>[14-16]</sup>. More recent software technology allows quantification of the stiffness in the form of strain. Comparing two different areas of tissue allows calculation of a strain ratio between the two.

There have been several recent reports using EUS elastography to assess pancreatic lesions<sup>[17,18]</sup> as well as lymph nodes<sup>[13,18-20]</sup>. The results from these studies, using first wave software to produce descriptive colour elastograms, are encouraging, suggesting a high sensitivity and specificity for detecting malignant involvement. However, there is limited data on oesophageal cancer nodal staging. This study aimed to compare conventional EUS with quantitative EUS-guided elastography in the assessment of nodal staging in oesophageal and junctional cancers and to assess whether quantitative EUS could accurately distinguish malignant from benign lymph nodes.

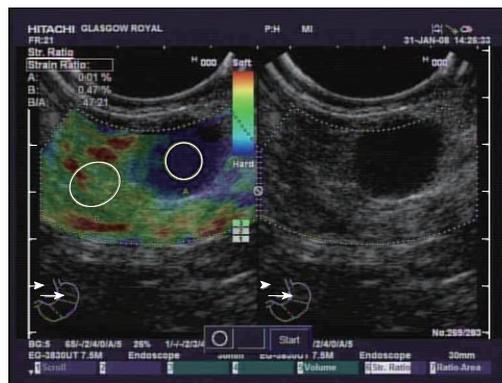

## MATERIALS AND METHODS

### Patients

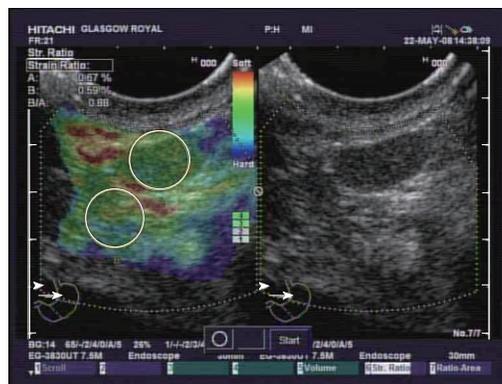

This was a prospective single centre study. Glasgow Royal Infirmary is a West of Scotland tertiary referral centre for EUS staging of upper gastrointestinal tract cancers. All patients who, as part of routine clinical care, were undergoing EUS-FNA lymph node biopsy for staging of upper gastrointestinal tract cancer, during the period July 2007 to July 2009, had elastography of the node prior to sampling.

### Instruments and technique

Initial staging EUS was undertaken by one of two endoscopists (SP/AJS) using a Pentax radial echoendoscope, attached to a Hitachi EUB-8500 ultrasound processor. Standard EUS grey-scale images of suspicious lymph nodes were obtained and conventional characteristics of size, shape, distinction of border and density were re-

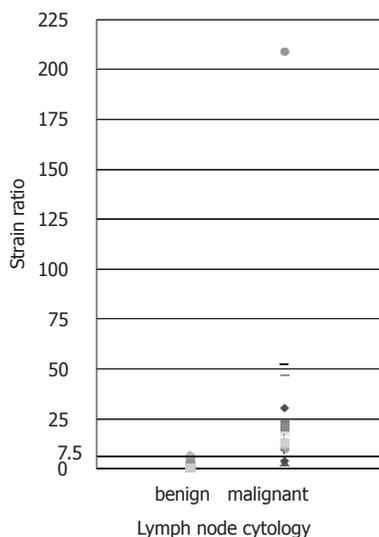

**Figure 1** Endoscopic ultrasound image of a malignant appearing lymph node. The right-hand side of the image displays all 4 of the conventional endoscopic ultrasound criteria characteristics of malignant nodes with regard to size (> 1 cm), shape (round), density (hypodense) and distinction of border (clear edge). The left-hand side of the image is a superimposed elastographic image with strain ratio measurement between an area of the lymph node and a surrounding area of tissue.

**Figure 2** Endoscopic ultrasound elastography of a benign lymph node. The right-hand side of the image displays standard grey-scale endoscopic ultrasound images while on the left is a superimposed elastography image. In the elastography image window the strain ratio measurements of the two areas outlined in the yellow circles is shown as a percentage in the top left-hand corner. The calculated strain ratio is shown as B/A. The elastographic signal is indicated by the bar column in the bottom right of the elastographic image window.

corded. After the decision was made to undertake a FNA biopsy, a Pentax linear array echoendoscope was then used with the same ultrasound processor.

Elastography is a standard function of the Hitachi EUB-8500 ultrasound processor. A conventional grey-scale image was displayed on the right-hand side of the monitor, while the superimposed elastography image was displayed on the left-hand side (Figures 1 and 2). The elastography image and measurements rely on compressions from vascular pulsation and respiratory movement. Measurements were only taken when there was good contact and appropriate compression of the transducer, as indicated on the elastography image on the ultrasound processor. Using the superimposed elastography image, the largest area possible of the node was outlined, as was a similar sized area of surrounding apparently normal tissue. The ultrasound processor measured the strain of each area as a quantitative figure and calculated a strain ratio between the two areas. The strain ratio was recorded a

**Figure 3** Plot of elastography strain ratio for cytologically proven benign or positive lymph nodes. The cut-off line of  $\geq 7.5$  is the optimal strain ratio for discriminating between benign and malignant lymph nodes.

**Table 1** Demographic data of the cytologically confirmed benign and malignant lymph node groups *n* (%)

	Benign node	Malignant node
Gender	M 20:F 5	M 18:F 5
Age (mean, yr)	66.8	67.9
Oesophageal adenocarcinoma	17 (68)	16 (70)
Oesophageal squamous cancer	5 (20)	7 (30)
Gastric adenocarcinoma	2 (8)	0 (0)
Barrett's oesophagus with HGD	1 (4)	0 (0)

HGD: High-grade dysplasia; M: Male; F: Female.

minimum of three times prior to EUS-FNAB. The mean of these recordings was calculated.

EUS-FNAB was performed using a Wilson Cook 22 gauge needle. Three passes were obtained, the samples stored in formalin and sent to the laboratory for later cytological analysis by specialist pathologists who were blinded to the elastography values.

**Statistical analysis**

Cytological determination of whether a lymph node was benign or malignant was used as the gold standard for the purposes of this study, as surgical resection specimens and follow up imaging were not available. Comparison of the demographic variables between cytologically proven benign and malignant nodes was carried out using either contingency table ( $\chi^2$ ) analysis or Mann-Whitney test, as appropriate. In order to assess the intra-observer variation, and hence the reproducibility, for strain ratio, 8 patients had 8 strain ratio values determined and the coefficient of variation was determined. In order to compare the relative sensitivity and specificity of the EUS elastography and 4 conventional EUS criteria (both individually and in combination) with EUS-FNAB for detecting malignant lymph nodes, the area under the receiver operator curve (ROC) was analysed. The area under an

ROC curve (AUC) for a measurement to discriminate between two disease conditions may be viewed as the probability that the measurement would correctly discriminate between two patients, one with and one without disease, each selected randomly from their group (those with and without disease). Note that the *P*-value cited with a single ROC curve is for the rejection of the null hypothesis that the expected value of the strain ratio AUC = 0.50, i.e., non-informative, equivalent to flipping a fair coin; whereas, the other *P*-values for AUCs other than the strain ratio ROC are for rejecting the null hypotheses that those expected values of AUCs are no different than that of the strain ratio AUC. Comparison between ROC curves AUC was undertaken by the statistics software package which uses the DeLong, DeLong, Clarke-Pearson methodology<sup>[21]</sup>. Because of the number of statistical comparisons, a *P* value of  $< 0.01$  was considered to be significant. Analysis was performed with the use of Analyse-It Statistical Package (Analyse-it Software, Ltd. <http://www.analyse-it.com/>; 2009).

**RESULTS**

**Total numbers**

EUS elastography, prior to lymph node EUS-FNAB, was performed in 53 patients undergoing EUS for oesophago-gastric cancer staging. Cytological evidence of malignant disease was found in 23 nodes, while 25 nodes were considered benign (Figure 3). On 3 occasions insufficient node material was sampled to allow cytological analysis and on one occasion the cytological analysis was indeterminate. The pathological analysis of one lesion in a patient with confirmed oesophageal adenocarcinoma revealed a gastrointestinal stromal tumor rather than a lymph node.

**Demographics**

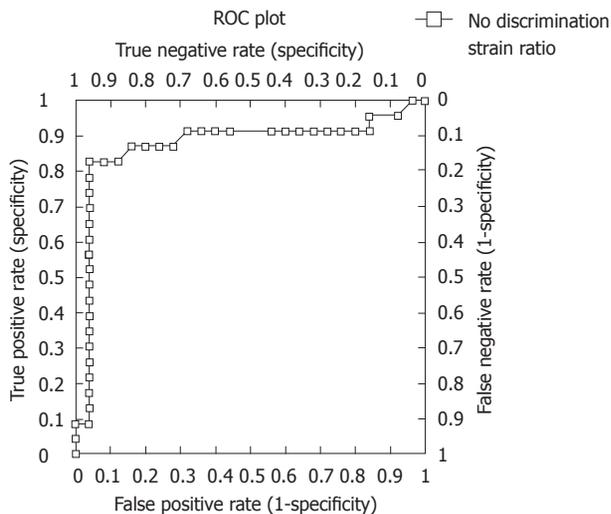

Patient demographics are shown in Table 1. There were no statistically significant differences between the cytologically benign and malignant node groups.

**Elastography strain ratio effectiveness and determination of strain ratio cut-off value**

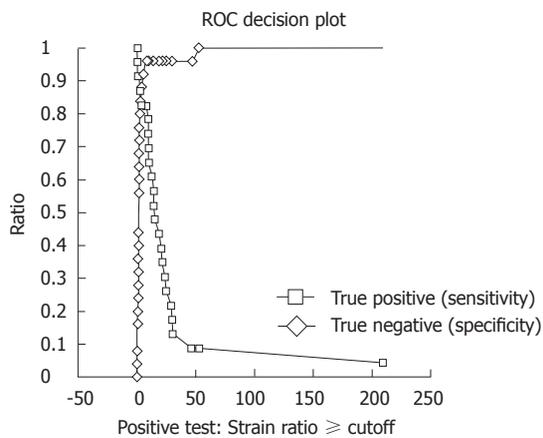

The ROC area under the curve, using elastography strain ratio, was 0.87 (95% CI: 0.75-1.00,  $P < 0.0001$ ) (Figure 4). The strain ratio which was the optimal cut-off point for distinguishing malignant from benign nodes was  $\geq 7.5$  as determined by a ROC sensitivity specificity decision plot (Figure 5), with a strain ratio above this indicating malignant involvement. The likelihood ratio was 20.65 for a strain ratio of 7.5. This gave sensitivity 83%, specificity 96%, positive predictive value (PPV) 95%, and negative predictive value (NPV) 86% (Table 2). The accuracy of elastography with a strain ratio  $\geq 7.5$  was 90%.

**Comparison of elastography strain ratio vs other endoscopic ultrasound methods of distinguishing benign from malignant lymph nodes**

ROC area under the curve comparisons showed that there

**Figure 4** Receiver operating characteristic curve for elastography strain ratio. The receiver operating characteristic area under the curve was 0.87 ( $P < 0.0001$ ).

**Figure 5** Receiver operating characteristic sensitivity, specificity based decision plot to determine the optimal elastography strain ratio cut-off point. The sensitivity and specificity lines cross at strain ratio 7.5.

was a trend for elastography strain ratio to be the best diagnostic test for distinguishing benign from malignant nodes when compared to standard EUS nodal assessment, i.e., size, shape, density, distinction of border and any combination of these four conventional characteristics, although statistical significance was reached for only individual comparisons of size and clear edge (Figure 6 and Table 3).

Elastography strain ratio assessment was more accurate than all other assessed EUS characteristics of lymph nodes, with an accuracy of 90% (Figure 6, Tables 2 and 3).

Elastography strain ratio was favourable compared to other nodal assessments with regard to sensitivity, specificity, PPV and NPV (Table 2).

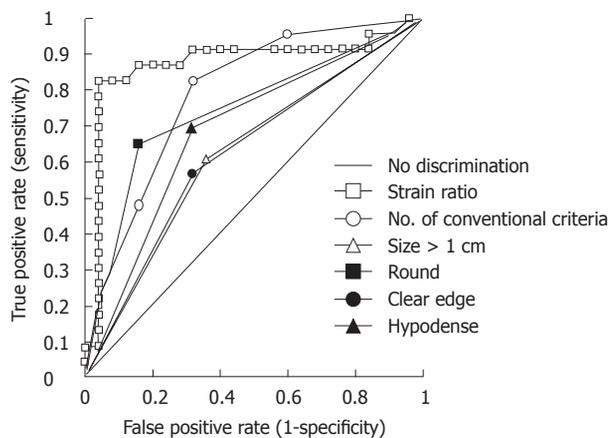

**Intra-observer variation**

The mean coefficient of variation (CV) for all recorded node strain ratio recordings was 44.8%. The mean CV for cytologically malignant nodes was 51.7%, while the mean CV for cytologically benign nodes was 34%.

**Table 2** Comparison of sensitivity, specificity, positive predictive value and negative predictive value for the ability of endoscopic ultrasound-based characteristics to differentiate benign from malignant lymph nodes (% , CI)

	Sensitivity	Specificity	PPV	NPV	Accuracy
Strain ratio	83 (61-95)	96 (80-100)	95 (75-100)	86 (67-96)	90 (77-97)
4/4 conventional criteria present	22 (07-43)	96 (80-100)	83 (36-99)	57 (41-72)	60 (45-72)
3/4 conventional criteria present	48 (27-69)	84 (64-96)	75 (45-92)	64 (45-80)	67 (52-80)
Size > 1 cm	61 (39-80)	64 (43-82)	61 (38-80)	64 (43-82)	62 (47-76)
Shape round	65 (43-84)	84 (64-96)	79 (54-94)	72 (53-87)	75 (60-86)
Clear border	56 (34-77)	68 (47-85)	62 (38-82)	63 (42-81)	62 (47-76)
Hypodense	70 (47-87)	68 (46-85)	67 (45-84)	71 (49-87)	69 (53-81)

PPV: Positive predictive value; NPV: Negative predictive value.

**Figure 6** Receiver operating characteristic curve comparison of elastography strain ratio against conventional endoscopic ultrasound criteria both in combination and individually (size > 1 cm, round, hypodense, clear edge).

**Table 3** The area under the curve for receiver operating curve characteristics for each endoscopic ultrasound-based modality for distinguishing benign from malignant nodes

	ROC AUC	P value <sup>1</sup>
Strain ratio	0.87 (0.75-1.00)	NA
Number of conventional criteria	0.79 (0.66-0.92)	0.2846
Size > 1cm	0.62 (0.48-0.76)	0.0078
Shape round	0.75 (0.62-0.87)	0.1329
Clear edge	0.62 (0.48-0.76)	0.0035
Hypodense	0.69 (0.55-0.82)	0.0100

<sup>1</sup>Comparison with strain ratio. The P value determined relates to the area under the curve (AUC) of an individual characteristic compared to elastography strain ratio receiver operating characteristics (ROC) AUC. NA: Not available.

**DISCUSSION**

This study has shown EUS-guided elastography to be ef-

fective for distinguishing between malignant and benign lymph nodes in patients with oesophago-gastric cancer and that it is more accurate than conventional EUS nodal characteristics.

Elastography of tissue is a new technology that has been successfully applied to several clinical fields. The specific modality of EUS-guided elastography has been developed over the past few years and first generation technology using elastographic colour imaging has shown promising results in the assessment of pancreatic disease<sup>[17,18]</sup>. There has also been encouraging, though limited, data on lymph node assessment<sup>[13,18-20]</sup>.

Conventional EUS lymph node assessment using size, shape, density and distinction of node border does not give adequate sensitivity and specificity to confidently distinguish between malignant and benign nodes. In this study, accuracy of these characteristics is poor (Table 3). This is consistent with previously published data<sup>[8,19,22]</sup>. However, using EUS elastography with a strain ratio cut off of  $\geq 7.5$  for malignancy, we found a sensitivity and specificity of 83% and 96%, respectively. The ROC AUC was highest for strain ratio compared to all of the conventional EUS criteria, either individually or in combination. The strain ratio cut-off point of  $\geq 7.5$  to distinguish malignant nodal involvement was derived from a ROC sensitivity and specificity decision plot. The specificity and the sensitivity using this strain ratio cut-off point were 96% and 83%, respectively.

Out of the 23 cytologically determined malignant cases, there were 4 cases where elastography strain ratio gave a false negative result. This may be explained by vascular or necrotic lymph nodes giving the elastographic appearance of soft tissue<sup>[19,23]</sup>. There were no surgical resection specimens in this study to confirm or refute this hypothesis.

The gold standard for determination of malignant cells within a lymph node at the time of pre-operative staging remains FNAB. However, there are challenges encountered during endosonography such as large peri-tumoural reactive lymph nodal assessment, targeting which suspicious nodes on which to perform FNAB, and avoiding passing the needle through interposed major neurovascular structures. Although EUS-FNAB is considered the gold standard for the purposes of this study, there are previous reports suggesting EUS-FNAB has a false negative rate of 5%-10%<sup>[24,25]</sup>. EUS-FNAB was used as the gold standard due to the lack of availability of routine imaging follow up or surgical resection specimens. This is a limitation of our study. In this study, there was only one patient who had an apparently striking falsely positive strain ratio value of 47.0. Despite radical chemotherapy this patient has not progressed well with rapid deterioration. It is possible that the EUS-FNA was cytologically falsely negative, rather than there being a falsely positive elastography strain ratio value.

Technical challenges were encountered in performing elastography during EUS. The technique relies on respiratory movement and vascular pulsation to generate appropriate compression displacement of the digitalised

radiofrequency echo lines. Obtaining consistent compression recordings was not always possible, leading to some variability in the elastogram produced, as has previously been described by other groups<sup>[26]</sup>. This will have led, in part, to the moderately large intra-observer variation calculated which is a limitation of this technique. It would have been desirable to have a coefficient of variance not exceeding 30%. It is, however, worth noting that the intra-observer variation was only significant when strain ratio values were high and none of the range of values obtained changed the likelihood of a node from being malignant to benign.

The method described relies on comparison of the strain within a node and surrounding tissue. This comparison assumes that the surrounding tissues are normal. It is recognised that the surrounding tissues may have different physical characteristics, which may influence the results. It is also worth noting that, as central necrosis and vascular invasion of a lymph node occur, the strain within the node may start to reduce as these "softer" components of the node are assessed. This is the basis of a fifth colour pattern analysis described by other authors<sup>[18,23]</sup>. However, the use of a strain ratio is an objective measure that is not limited by the inter-observer variability which is inherent in elastogram colour pattern analysis.

A limitation of this study is that it was undertaken within a single centre. However, there are supporting data from a recently reported large European multi-centre trial. Giovannini *et al.*<sup>[23]</sup> report on 38 cases of oesophago-gastric cancer staging EUS-guided elastography lymph node assessments in a larger cohort of lymph node analysis. The elastography sensitivity and specificity of 91.8% and 82.5% recorded from this multicentre study are similar to those presented in this paper. The sensitivity and specificity recorded from the data presented in our paper are also similar to those found when cervical lymph nodes were assessed by sonographic elastography<sup>[19]</sup>.

It is also recognised that there is the potential for selection bias within this study, in that all patients were having EUS-FNAB of nodes which were considered suspicious for malignancy. However, it is proposed that this modality is used in those very situations where EUS-FNAB will have been contemplated but may not be practical.

Patients undergoing staging of oesophago-gastric cancers are often subjected to several staging investigations. EUS-guided elastography offers an additional assessment of any suspicious lymph nodes that can be undertaken at the time of the standard EUS evaluation and is no more invasive. The recent change in the staging system for oesophago-gastric cancers means that the absolute number of involved malignant nodes becomes critical in determining the tumour stage<sup>[27-30]</sup>. Therefore, any modality that improves nodal staging is of critical importance. We believe EUS elastography is complementary to FNA in distinguishing between benign and malignant lymphadenopathy.

In conclusion, EUS elastography has been shown in this study to be superior to standard EUS assessment in characterising benign from malignant lymph nodes in

oesophago-gastric cancer. It appears complementary to current staging investigations and has the potential to improve the staging and management of this disease.

## ACKNOWLEDGMENTS

We would like to acknowledge Professor Donald McMillan of the University of Glasgow for his comments and guidance on writing the statistical analysis section of this paper.

## COMMENTS

### Background

Endoscopic ultrasound (EUS) is an integral investigation in the staging of oesophageal and oesophago-gastric junctional tumours. Determination of lymph node involvement in particular is of critical prognostic importance. At present, staging relies largely on EUS-fine needle aspiration biopsy (FNAB) of suspicious nodes after initial determination of standard EUS characteristics. However, the invasive process of FNAB is not always possible.

### Research frontiers

Elastography has been shown to be useful in distinguishing benign from malignant tissue in the pancreas. However, there are limited data assessing the accuracy of EUS elastography for nodal assessment in upper gastrointestinal malignancy.

### Innovations and breakthroughs

There have been recent reports of the use of elastography to distinguish between benign and malignant tissue, including lymph nodes. Earlier studies used qualitative descriptions of elastogram patterns. More recently, there have been technological advances allowing quantitative assessment of elastography strain ratio which measures, and compares, the stiffness of tissues.

### Applications

This study suggests that quantitative EUS elastography is accurate at distinguishing between malignant and benign lymph nodes in the staging of oesophago-gastric malignancy. Compared to standard EUS characterisation of lymph nodes, elastography is superior in this study. EUS elastography appears complementary to current staging investigations and has the potential to improve the staging and management of this disease.

### Terminology

Elastography is a measure of the stiffness, or strain, of tissue. This can be useful in many disease processes including malignancy where tissue is often "harder" or "stiffer" where there is cancerous tissue present. Measuring elastography relies on applying a mechanical compression and determining how much the tissue deforms. Harder tissue deforms less than soft tissue.

### Peer review

Overall, a very interesting article looking at something that remains a problem without tissue diagnosis. The paper is well written and reads well. The methodology is appropriate, the results presented well and the discussion is appropriate. This paper will add to our understanding and serve as a platform for further studies looking at the characteristics of lymph nodes, not just for the oesophago-gastric lymph nodes but other malignancies as well.

### Abstract

**AIM:** To test the efficiency of a recently proposed histotype-based grading system in a consecutive series of gastric cancers.

**METHODS:** Two hundred advanced gastric cancers operated upon in 1980-1987 and followed for a median 159 mo were investigated on hematoxylin-eosin-stained sections to identify low-grade [muconodular, well differentiated tubular, diffuse desmoplastic and high lymphoid response (HLR)], high-grade (anaplastic and mucinous invasive) and intermediate-grade (ordinary cohesive, diffuse and mucinous) cancers, in parallel with a previously investigated series of 292 cases. In addition, immunohistochemical analyses for CD8, CD11 and HLA-DR antigens, pancytokeratin and podoplanin, as well as immunohistochemical and molecular tests for microsatellite DNA instability and *in situ* hybridization

for the Epstein-Barr virus (EBV) *EBER1* gene were performed. Patient survival was assessed with death rates per 100 person-years and with Kaplan-Meier or Cox model estimates.

**RESULTS:** Collectively, the four low-grade histotypes accounted for 22% and the two high-grade histotypes for 7% of the consecutive cancers investigated, while the remaining 71% of cases were intermediate-grade cancers, with highly significant, stage-independent, survival differences among the three tumor grades ( $P = 0.004$  for grade 1 vs 2 and  $P = 0.0019$  for grade 2 vs grade 3), thus confirming the results in the original series. A combined analysis of 492 cases showed an improved prognostic value of histotype-based grading compared with the Lauren classification. In addition, it allowed better characterization of rare histotypes, particularly the three subsets of prognostically different mucinous neoplasms, of which 10 ordinary mucinous cancers showed stage-inclusive survival worse than that of 20 muconodular ( $P = 0.037$ ) and better than that of 21 high-grade ( $P < 0.001$ ) cases. Tumors with high-level microsatellite DNA instability (MSI-H) or EBV infection, together with a third subset negative for both conditions, formed the T8 cell-rich HLR group, the largest group among low-grade histotypes. Coexisting HLR proved to be a factor in improved prognosis in tumors with microsatellite instability ( $P = 0.0015$  vs HLR-/MSI-H tumors) or DR type human leukocyte antigen expression ( $P = 0.033$  vs HLR-/HLA-DR<sup>+</sup> tumors).

**CONCLUSION:** Identification of low- and high-grade histotypes can improve the prognostic assessment of a substantial proportion of gastric cancers in routine diagnostic practice.

## INTRODUCTION

The difficulty of assessing the prognosis of gastric cancer using histological methods is well known and this is also reflected in the essentially descriptive character of presently used classifications<sup>[1-4]</sup>. However, several histotypes characterized by lower malignant potential have been identified and separated from more common cohesive (so-called “intestinal”) or diffuse tumors. They include lymphocyte-rich cancer<sup>[5-7]</sup>, mucinodular cancer<sup>[8]</sup>, very-well-differentiated tubular cancer with an intestinal<sup>[9]</sup> or gastric<sup>[10]</sup> phenotype, and a low-grade subtype of diffuse desmoplastic cancer<sup>[11]</sup>. Similarly, various kinds of cancer with poor outcome have been identified, from poorly differentiated neuroendocrine carcinoma, small to large cell<sup>[12,13]</sup>, to anaplastic diffuse cancer<sup>[14]</sup> or hepatoid<sup>[14]</sup>, choriocarcinomatous<sup>[15]</sup> and adenosquamous carcinoma<sup>[16]</sup>. In addition, comparative genomic hybridization analysis has shown a clear relationship between the number and severity of genomic alterations and tumor histotype and prognosis<sup>[17,18]</sup>.

The different behavior of these histotypes offered an opportunity to develop a three-grade system of prognostic evaluation, which, when applied to a large tumor series, was highly predictive of patient outcome<sup>[19]</sup>. However, the tumor series used in that study was substantially selected (1) to be representative of all main stages (intramucosal cases apart) and histological types of the disease; and (2) to include uncommon histological subtypes or variants, as well as earlier invasive stages (submucosal or confined to muscularis propria). Therefore, in order to ascertain the effectiveness of the system in routine diagnostic work, a continuous, homogeneous series of advanced cancers needs to be evaluated.

In this study, we retrospectively identified prognostic histotypes according to previously reported criteria<sup>[19]</sup> in a consecutive series of advanced (muscularis propria invasion or beyond) gastric cancers collected at Varese General Hospital during 1980-1987, and we tested such histotypes as potential predictors of patient outcome and compared the results with those of the original Pavia series. During the study, we realized that we needed to investigate further mucinous and lymphocyte-rich can-

cers, due to discrepancies concerning: (1) the impact of histology or stage on mucinous cancer prognosis<sup>[20-23]</sup>; and (2) the contribution of tumor microsatellite instability, Epstein-Barr virus (EBV) infection and DR type human leukocyte antigen (HLA-DR) expression, rather than lymphoid cell response *per se*, to the natural history of lymphocyte-rich neoplasms<sup>[5-7,24-27]</sup>. Therefore, mucinous and lymphocyte-rich tumors from both series were combined to obtain tumor groups large enough to allow appropriate investigation.

## MATERIALS AND METHODS

### Tissue samples

A consecutive series of 200 invasive (T2-T4) gastric cancers were retrieved from the files of the Anatomic Pathology Service, for patients who had undergone potentially curative surgery at Varese General Hospital during 1980-1987. The clinicopathological and follow-up data of all the patients were carefully collected from hospital records, interviews with family doctors, and the Varese Province Tumor Registry. One hundred and eighty-five of the cases had already been the subject of a previous investigation<sup>[2]</sup>. Eight cases were operated on during January 1980-April 1987 and were not considered in the previous study because the available clinical or follow-up documentation was incomplete. This information was retraced, appropriately documented and added to the present study to ensure the continuous pattern of the patient series, together with seven more cases operated on in May-June 1987. The original tumor node metastasis (TNM) stage assessment of each tumor was revised according to the criteria of the 2002, 6th Edition American Joint Committee on Cancer system<sup>[28]</sup>. No antitumor therapy had been given to the patients. For survivors, the follow-up period was prolonged until 2008; a median follow-up of 159 mo was recorded.

### Immunohistochemical analysis

Archival and newly cut paraffin sections were stained with hematoxylin-eosin, Alcian blue-periodic acid Schiff or the immunoperoxidase procedure using antibodies directed against h-MLH1 (G-168.15 clone; Pharmingen, San Diego, CA, United States), hMSH2 (Fe11 clone; Oncogene, Cambridge, MA, United States), hPMS2 (clone A16-4; BD Pharmingen), hMSH6 (clone 44; BD Transduction Laboratories, Lexington, KY, United States), CD8 antigen (C8/144B clone; Dako, Glostrup, Denmark), CD11c antigen (5D11 clone; Novocastra Laboratories, Newcastle, United Kingdom), pancytokeratin (AE1/AE3 clone; Novocastra Laboratories), HLA-DR (LN3 clone; Biotest, Dreieich, Germany) and podoplanin (D2-40 clone; Biocare Medical, Concord, CA, United States) as previously reported<sup>[7,19,29]</sup>.

### Molecular analysis

*In situ* hybridization for the *EBER1* gene of EBV was performed as described previously<sup>[3,7]</sup>. Microsatellite instability was assessed at Bat 25, Bat 26, BAT40, D5S346 and D2S123 loci. Tumors with instability involving at

least two of the five loci were classified as highly instable (MSI-H), while those with only one instable locus were classified as low instable (MSI-L) and included in the MSI negative tumor group together with microsatellite stable cases<sup>[7,19,30]</sup>.

### Morphological analysis

Tumor histotypes were identified as described previously<sup>[8-11,19]</sup>. In particular, very-well-differentiated tubular (VWDT) cancer is characterized by glands with moderately atypical, polarized cells arranged in a monostratified epithelium, low-grade diffuse desmoplastic cancer shows fibroblast-rich desmoplasia surrounding individual (or minute groups of) moderately atypical tumor cells, while muconodular cancer forms extracellular mucin lakes with expansile borders in which isolated signet ring cells or cords of mucin-producing tumor cells are freely floating.

To increase the diagnostic accuracy of lymphocyte-rich tumors, as well as intratumor CD8<sup>+</sup> T cell counts, intraepithelial T8 cells (i.e., cells infiltrating tumor aggregates so as to contact neoplastic cells directly, with the exclusion of purely stromal T8 cells) were also counted<sup>[7,31]</sup>, and an evaluation of dendritic cells was added<sup>[27]</sup>. Thus, in this study, classification of a lymphocyte-rich tumor as high lymphoid response (HLR) required one of the following: (1) a lymphoepithelial type histological pattern with an overwhelming lymphocyte infiltrate dissecting tumor cells; or (2) > 400 intratumor and/or >200 intraepithelial CD8-positive cells in 10 high-power fields (HPFs), coupled with a band of lymphoid cells rich in CD8<sup>+</sup> T cells and CD11c<sup>+</sup> dendritic cells surrounding expansile tumor nodules.

Anaplastic cancers were characterized by small to large, cytokeratin-positive cells with highly atypical nuclei, with or without prominent nucleoli and with or without signs of poor neuroendocrine differentiation, high cellularity, scarce stroma, and high proliferative rates (> 20 mitoses/10 HPFs)<sup>[11,12]</sup>. During characterization of the mucinous infiltrative tumors, it was found that those showing local infiltration of peritumoral tissues in the absence of prominent lymphoinvasion or angioinvasion had a less severe prognosis. Therefore, in this study, infiltrative tumors lacking vascular invasion or with only sporadic lymphoinvasion were added to the grade 2 group, together with ordinary cohesive and diffuse cancers, while only prominently lymphoinvasive (two or more foci per microscopic tumor sections) or angioinvasive cases remained in the grade 3 group together with anaplastic cancers, as in the original classification<sup>[19]</sup>. Cases showing a coexistence of two or more histological patterns were classified according to their prevalent histotype, provided that all the components were low-grade; otherwise, they were classified according to their higher grade component.

A reproducibility test involving two senior pathologists (Solcia E and Capella C) gave a  $\kappa$  value of 0.84 concerning interobserver agreement for five main histotypes (cohesive, diffuse, mucinous, anaplastic and HLR), a  $\kappa$  of 0.81 agreement for nine subtypes (HLR, VWDT, ordinary cohesive, low-grade diffuse desmoplastic, ordinary

<sup>a</sup>P = 0.001 vs III + IV; <sup>b</sup>P = 0.015 vs II ; <sup>c</sup>P = 0.004 vs III. CI: Confidence intervals; HR: Hazard ratio.

diffuse, muconodular, ordinary mucinous, invasive mucinous and anaplastic), and a  $\kappa$  of 0.79 agreement for the three histotype-based grades (low, intermediate and high).

From the previously investigated Pavia series of 294 cases<sup>[19]</sup>, 292 cases (two tumors had to be excluded because there was no remaining tumor tissue) were considered for comparative analysis with the Varese series, as well as for a joint reinvestigation of both series looking at mucinous and HLR tumors according to the above criteria. In addition, the prognostic value of the histotype-based grading system was compared with that of the commonly used Lauren classification<sup>[1]</sup>.

### Statistical analysis

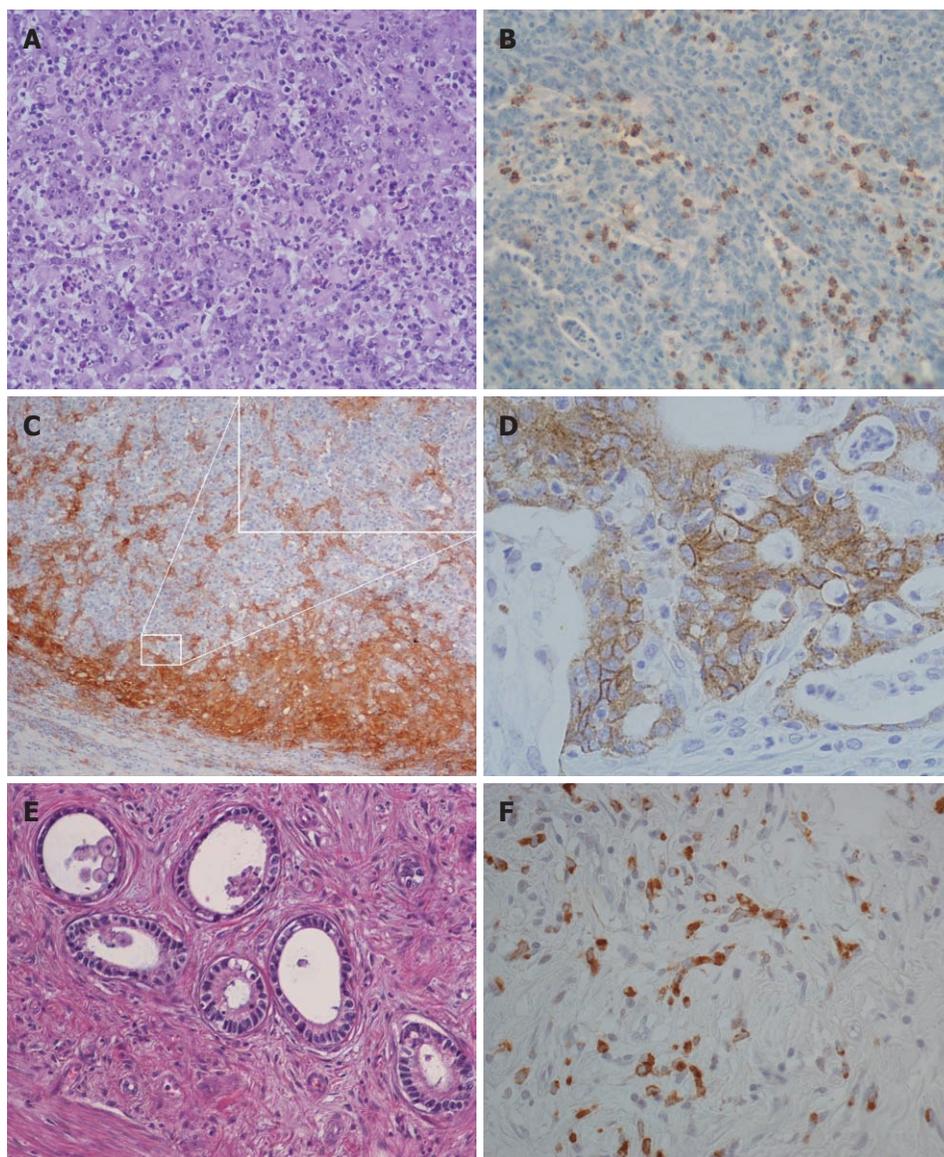

Statistical analysis was performed using Stata version 11 (Stata Corporation, College Station, TX, United States). All tests were two-sided. Categorical variables were described with counts and percentages and compared with the Fisher exact test. Continuous variables were described with median and quartiles, and compared with the Kruskal-Wallis test. Death rates per 100 person-years, with 95% confidence intervals (CIs), and Kaplan-Meier estimates were computed to describe survival. The Cox model was used to assess the prognostic role of the considered variables; both univariate and bivariate models (inclusive of stage) were fitted. The hazard ratio (HR) and 95% CI were reported. Proportional hazard assumptions were satisfied in all cases. The Harrell c statistic was computed to assess model performance (discrimination ability); a value of 0.5 indicating no discrimination and a value of 1 indicating perfect discrimination.

## RESULTS

### Characterization of the Varese continuous series

The Varese consecutive, non-selected series of 200 advanced (T<sub>2</sub> or above) gastric cancers is described in Table 1 according to stage and patient survival. Compared with the original Pavia selected series, which also included a substantial number (44 cases) of deeply submucosal (penetrating T1b) tumors, the present series showed more advanced tumors (Stages III + IV: 49.5% vs 39% of the original series; Stage II: 30.5% vs 25%). A clear step-wise, stage-dependent behavior emerges from the survival analysis.

Of the 200 tumors, 44 (22%) had low-grade, 14 (7%) high-grade and 142 (71%) intermediate-grade histotypes

**Figure 1** Histological and histochemical aspects of high lymphoid response cancers. A: Lymphoepithelioid pattern of an HLR EBV<sup>+</sup> tumor (hematoxylin-eosin,  $\times 200$ ); B: High intratumor T8 cells infiltration in an HLR EBV/MSI case (CD8 immunoperoxidase-hematoxylin,  $\times 200$ ); C: Peritumor dendritic cell rich demarcating band in an HLR MSI-H tumor (CD11c immunoperoxidase-hematoxylin,  $\times 100$ ); in the inset, focal enlargement of image C to show interaction of CD11c-reactive dendritic cells with unreactive neoplastic cells ( $\times 400$ ); D: HLA-DR reactivity of an HLR MSI-H case (immunoperoxidase-hematoxylin,  $\times 400$ ); E: Low-grade very-well-differentiated tubular carcinoma (hematoxylin-eosin,  $\times 200$ ); F: Low-grade desmoplastic tumor with spindle neoplastic cells interspersed among fibroblast rich stroma (CAR5, immunoperoxidase-hematoxylin,  $\times 200$ ).

(Figures 1 and 2). Survival analysis according to histotype-based grade is outlined in Table 2 and Figure 3. The more favorable behavior of grade 1 compared to grade 2 and of grade 2 compared to grade 3 tumors is evident.

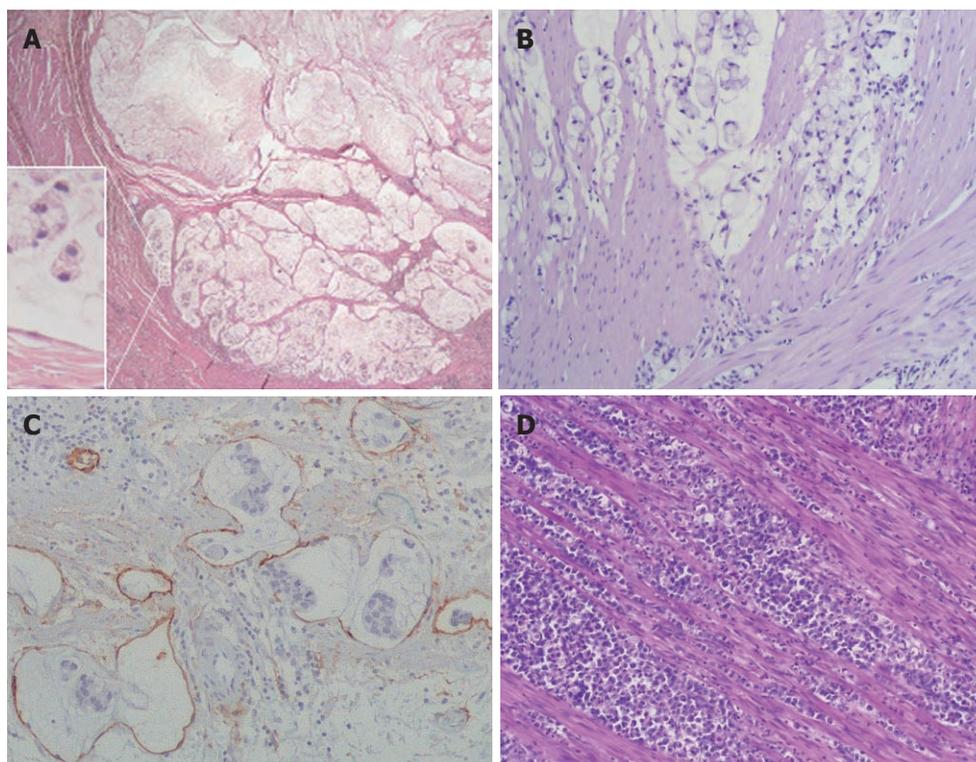

In Table 2, univariate analysis of the Varese series after reclassification according to Lauren<sup>[1]</sup> shows a significantly worse prognosis for the diffuse compared to intestinal and unclassified types [model:  $\chi^2(2\gamma) = 8.67$ ,  $P = 0.013$ ]. However no significant difference was observed among the same cases in the stage-inclusive bivariate analysis (model:  $P = 0.341$  for Lauren classification), while no difference was found by either univariate (model:  $\chi^2(2\gamma) = 4.87$ ,  $P = 0.087$ ) or bivariate (model:  $P = 0.342$ ) analysis among the 292 tumors in the Pavia series. In both the Varese and Pavia series, the Harrell's concor-

dance ( $c$ ) test showed a higher efficiency of the histotype-based grading ( $c = 0.63$  and  $0.73$ , respectively) compared to the Lauren classification ( $c = 0.57$  and  $0.55$ ).

Individual histotypes in the three grades are detailed in Table 3, first column. It appears that, while ordinary cohesive or diffuse and HLR tumors form a substantial group, the number of other histotypes is too low to allow appropriate statistical analysis.

#### **Joint analysis of 492 cases from both Varese and Pavia series**

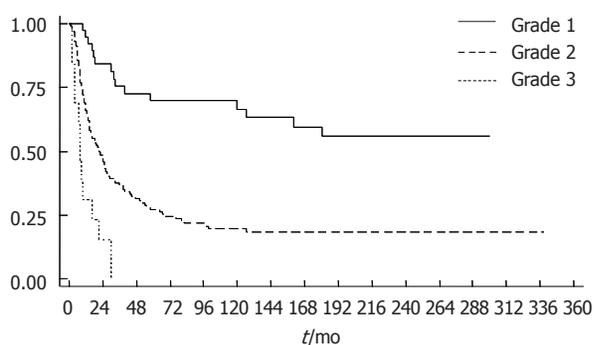

When corresponding tumors of the two series were analyzed jointly (Table 3), the more favorable behavior of grade 1 compared to grade 2 tumors and of the latter compared to grade 3 cases was confirmed. In addition,

**Figure 2 Muconodular, well-differentiated tubular, diffuse desmoplastic and high lymphoid response.** A: Low-grade muconodular cancer with expansile growth (hematoxylin-eosin, × 20); in the inset, note tumor cells floating inside mucin, free of contact with stroma (× 400); B: intermediate-grade, locally infiltrative mucinous cancer (hematoxylin-eosin, × 200); C: massive lymphoinvasion of a high-grade mucinous cancer (podoplanin immunoperoxidase-hematoxylin, × 200); D: Diffuse anaplastic cancer invading the muscularis propria (hematoxylin-eosin, × 200), in the inset the enlargement shows cellular pleomorphism (× 400) .

the resulting number of the rare histotypes was sufficient to allow survival analysis of each histotype. Thus, the prognostic similarity of types belonging to the same grade and their significant difference from those of other grades was assessed.

**Reinvestigation of mucinous and high lymphoid response tumors**

It also appears from Table 3 that mucinous neoplasms, when appropriately reclassified as muconodular, ordinary mucinous and highly invasive mucinous cancers, may form three prognostically different histological subsets, as confirmed by separate Cox univariate and stage-inclusive

HLR <sup>-</sup>							
MSI-H	38 (48.7) <sup>2</sup>	12.29	8.24-18.33	3.64	1.78-7.47	< 0.001	0.015

<sup>1</sup>One EBV<sup>+</sup>/MSI case omitted; <sup>2</sup>% of all MSI-H cases, HLR<sup>+</sup> or <sup>-</sup>. HLR: High lymphoid response; EBV: Epstein-Barr virus; MSI-H: High-level microsatellite DNA instability.

survival analyses, where ordinary mucinous cancers proved significantly worse than muconodular and better than highly invasive cancers (Table 3). Significant differences were also found between the three groups in terms of TNM stage, T level invasion and lymph node involvement (for all:  $P < 0.001$ , Fisher's exact test) and even diameter ( $P < 0.001$ , Kruskal-Wallis test). In contrast, only a nonsignificant trend (Cox univariate  $P = 0.126$  and stage-inclusive  $P = 0.102$ ) for better survival was noted among mucinous cancers as a whole; for those with cohesive vs diffuse or mixed histological patterns.

No survival difference was found between HLR and the three other low-grade histotypes or, among the HLR cases, between MSI-H and the EBV<sup>+</sup>/MSI subset, while a trend for worse behavior of the EBV<sup>+</sup> compared to the other subsets was noted by univariate analysis, which disappeared with stage-inclusive bivariate analysis (Table 4). EBV<sup>+</sup> tumors also differed from the other two HLR subsets in showing significantly higher proportions of lymphoepithelioid histology (17/24, 71%, vs 5/57, 9%,  $P < 0.001$ , Fisher's exact test) and median intratumor T8 (107.5 vs 58.5 per HPF,  $P < 0.001$ , Kruskal-Wallis test). In contrast, 40 HLR MSI-H cases obviously showed more

favorable behavior than their 38 non-HLR MSI-H counterparts (22 cohesive, 10 mucinous, three diffuse and anaplastic cancers), of which six were low-, 24 intermediate- and eight high-grade.

The proportion of mucinous neoplasms showing MSI-H (10/51; 19.6%) did not differ significantly from that of the whole tumor population (78/492; 15.9%) while remaining significantly lower than that of HLR cases (41/81; 50.6%). Notably, the 10 MSI-H cases were equally distributed among the three grades of mucinous cancers, being grade 1 [14/20 (20%)], grade 2 [1/10 (10%)], and grade 3 [5/21 (23.8%)].

For the combined analysis of HLR and HLA-DR status, 77 of the total 82 HLR tumors from both series had sufficient histological material left to allow reinvestigation, together with 202 randomly selected non-HLR tumors representative of all histotypes and stages. HLA-DR positivity in > 10% of tumor cells was found in 100/279 (35.8%) cases. Positive tumors showed a trend for lower death rate (5.97, 4.39-8.19 vs 9.41, 7.75-11.44) and improved survival (HR: 0.63, 0.44-0.91,  $P = 0.014$ ) compared with HLA-DR<sup>-</sup> cases, a behavior probably accounted for by the HLR<sup>+</sup>/HLA-DR<sup>+</sup> subset, in which

57 tumors showed a significantly lower death rate (3.21, 1.93-5.32 *vs* 11.84, 8.06-17.39) and better survival (HR: 0.35, 0.18-0.66,  $P = 0.001$ ) than their HLR/HLA-DR<sup>+</sup> counterparts.

## DISCUSSION

The present study confirms, in an independent patient series, the effectiveness of a recently proposed histotype-based grading system for the prognostic evaluation of gastric cancer<sup>[19]</sup>, despite substantial differences between the present series and the original one. Indeed, the present series differed in being consecutive rather than selected for uncommon histotypes and in lacking submucosal (T1b) cancers, while including more advanced cases, diagnosed and operated on about a decade earlier in another hospital serving a different territory. All these differences may help to explain the lower prevalence of low-grade cases (22% *vs* 31% in the original series), known to be more frequent in lower stages<sup>[19]</sup>. This is especially true for rare histotypes like muconodular<sup>[8]</sup>, VWD<sup>[9,10]</sup> or low-grade diffuse desmoplastic<sup>[11]</sup> cancers, which were specifically selected in the original series. However, the HLR histotype was confirmed to represent a fairly large (19%) population of low-grade gastric cancers, even after introducing more stringent diagnostic criteria. Thus, our consecutive Varese Hospital series suggests that only about 20% of all invasive (T2 or beyond) gastric cancers may be of low-grade, while < 10% may fit into the high-grade category. However, within these quantitative limits, the histotype-based three-grade system was confirmed to be highly predictive of patient outcome. This conclusion seems especially interesting considering the limited prognostic value of commonly used histological classifications<sup>[1-4]</sup>. Indeed, in this study the histotype-based classification and grading system showed superior Harrell's discriminative power when compared with the Lauren classification and, unlike the latter, outlined stage-independent prognostic differences.

Reinvestigation of the two series taken together increased the number of rare tumor subsets and allowed better characterization of their clinicopathological profile, with special reference to the HLR and mucinous tumors. The presence of three etiological subtypes among HLR tumors<sup>[19]</sup> was also confirmed in the new series. Joint analysis of the 82 HLR cases obtained from the two series allowed us to confirm the distinct clinicopathological pattern of EBV<sup>+</sup> (preferred proximal location in the stomach, higher frequency of lymphoepithelioid pattern, higher intratumor T8 cell counts, and a trend toward worse survival), as already illustrated in previous studies<sup>[6,7,32]</sup>, compared to both the MSI-H and the MSI/EBV<sup>-</sup> subsets, whose behavior was remarkably similar to each other. Among MSI-H tumors, the better prognosis of those associated with HLR compared with those lacking this association is of interest, because it suggests that cytotoxic T8 cell response, more than the MSI status itself, is a crucial factor in defining the behavior of this tumor subset, with potential implications for appropriate therapy<sup>[26]</sup>.

The cause of the T8-cell-rich lymphoid response in the EBV/MSI subset remains to be ascertained. Tumor cell overexpression of highly antigenic molecules like HLA-DR, as suggested in the present investigation, or of mutated p53 protein, as found in a previous study<sup>[19]</sup>, might be among its driving factors. Whatever its origin, it should be pointed out that the favorable prognostic implication of HLR deserves attention in clinical studies because, besides accounting for the better prognosis of MSI-H<sup>+</sup><sup>[5,7,19,26]</sup> and HLA-DR<sup>+</sup> cancers<sup>[24]</sup>, it might interfere with therapies potentially affecting antitumor immune response<sup>[26]</sup>.

In our cumulative series of 492 tumors, the proportion of mucinous cancers showing high MSI was not significantly higher than in the remaining neoplasms; a finding confirming recent observations<sup>[22]</sup>, although at variance with the behavior of mucinous cancers in the colon, where they represent in some series a dominant histotype among MSI-H cases<sup>[31,33]</sup>. Moreover, the few MSI<sup>+</sup> mucinous cancers that we found in the stomach lacked an HLR, and failed to show a preferential concentration in the low-grade, muconodular histotype, or evidence for more favorable survival compared to their MSI counterpart. This further outlines the limited prognostic value of MSI status in the absence of HLR, at least in the stomach. It should also be recalled that, at variance with gut cancers, in other cancers (e.g., breast and lung), MSI has more often been linked to adverse rather than favorable postoperative survival<sup>[25,34]</sup>.

Several studies have shown that mucinous gastric cancers have a worse prognosis<sup>[20-22]</sup>. However, it is uncertain whether a higher stage at diagnosis<sup>[23]</sup>, rather than mucinous type histology, may account for this. In this study we reinvestigated the issue with the help of an improved histological classification separating low-grade muconodular tumors from infiltrative mucinous cancers, among which grade 3 cases showing prominent vascular (especially lympho-) invasion were distinguished from grade 2 "ordinary" cases lacking it. Survival analysis showed that these may represent three prognostically distinct, stage-independent cancer subsets, despite the fact that they also show highly significant differences in stage and size. Thus, for the prognostic assessment of mucinous cancers both stage and histology should be carefully investigated.

In conclusion, our histotype-based grading system for gastric cancers proved to be an effective tool, at least for a minority (about 30%) of neoplasms. For the evaluation of grade 2 ordinary cancers, which form a very large, histologically heterogeneous group with a wide prognostic spectrum (e.g., a 95% CI 14-187 in our joint series), we should rely on common histological parameters (invasive pattern, proliferative rate, structural or cytological atypia, tumor cell phenotype)<sup>[4]</sup> or a variety of promising molecular tools<sup>[17,18,35]</sup>, as well as on carefully assessed stage.

## COMMENTS

### Background

Gastric carcinoma is a very heterogeneous tumor, often characterized by the

coexistence of two or more distinct histological components within the same tumor, and by different host responses in terms of stromal response. A detailed histopathological classification should enable us to identify tumor subtypes that could provide useful prognostic and therapeutic information. The efficacy of a recently proposed classification system in predicting survival needs to be tested in a non-selected series of gastric carcinomas.

### Research frontiers

This new histological classification takes advantage of the cytological, biological and architectural features of tumor cells to identify histological types (histotypes) of tumors with low, intermediate or high malignancy. Lymphoid and stromal reactions, which seem to play an important role in contrasting or favoring tumor growth, and consequently, resulting in a better or worse prognosis, also need to be taken into consideration.

### Innovation and breakthroughs

The proposed three-grade system proved to be highly predictive of patient outcome. It identified low-grade (muconodular, well-differentiated tubular, diffuse desmoplastic and high lymphoid response), intermediate-grade (ordinary cohesive, diffuse and mucinous) and high-grade (anaplastic and mucinous invasive) gastric cancers, with highly significant stage-independent survival differences and had a better prognostic value compared to the Lauren classification.

### Application

A careful histological examination of gastric cancers with the criteria proposed by the histotype-based prognostic classification was shown to be an effective tool in everyday diagnostic practice. Additional studies are necessary to identify histological and molecular parameters that could better characterize the large population of intermediate-grade cancers.

### Peer review

The manuscript fits well with the scope of the journal, and is well written. It addresses a relevant aspect of gastric cancer, the exact histopathological assessment of the tumor and correlation of these data to clinical and molecular alterations.

### Abstract

**AIM:** To determine if liver regeneration (LR) could be disturbed following radiofrequency (RF) ablation and whether modification of LR by steroid administration occurs.

**METHODS:** Sham operation, partial hepatectomy (PH), and partial hepatectomy with radiofrequency ablation (PHA) were performed on adult Fisher 344 rats. We investigated the recovery of liver volume, DNA synthetic activities, serum cytokine/chemokine levels and signal transducers and activators of transcription 3 DNA-binding activities in the nucleus after the operations. Additionally, the effects of steroid (dexamethasone) pretreatment in the PH group (S-PH) and the PHA group (S-PHA) were compared.

**RESULTS:** The LR after PHA was impaired, with high serum cytokine/chemokine induction compared to PH, although the ratio of the residual liver weight to body weight was not significantly different. Steroid pretreatment disturbed LR in the S-PH group. On the other hand, low-dose steroid pretreatment improved LR and suppressed tumor necrosis factor (TNF)- $\alpha$  elevation in the S-PHA group, with recovery of STAT3 DNA-binding activity. On the other hand, low-dose steroid pretreatment improved LR and suppressed TNF- $\alpha$  elevation in the S-PHA group, with recovery of STAT3 DNA-binding activity.

**CONCLUSION:** LR is disturbed after RF ablation, with high serum cytokine/chemokine induction. Low-dose steroid administration can improve LR after RF ablation with TNF- $\alpha$  suppression.

### INTRODUCTION

Liver resection is still one of the best curative therapies for primary or secondary liver tumors in most cases with

no extrahepatic metastasis<sup>[1,2]</sup>. Various techniques and devices for liver resection have been employed to improve the perioperative outcome<sup>[3-7]</sup>, although the clamp-crush technique used by a skilled surgeon still has the most favorable outcome according to recent systematic reviews<sup>[8,9]</sup>. Liver surgeons focus on reducing bleeding during liver resection, which leads to shorter operative time. Heat-assist devices such as the harmonic scalpel<sup>[10]</sup>, Ligasure<sup>[11]</sup>, saline-linked monopolar cautery<sup>[12]</sup>, microwave coagulator<sup>[13]</sup>, and radiofrequency (RF) devices<sup>[14]</sup>, can seal vessels and bile ducts to avoid postoperative bleeding and bile leakage. Because these heat-assist devices can achieve firm sealing of vessels and bile ducts, unnecessary ties and clips can be avoided without any adverse events<sup>[15]</sup>. Some randomized trials have indicated the merits and demerits of using heat-assist devices<sup>[4,7]</sup>.

The greatest merit is the sealing effect to reduce perioperative morbidity<sup>[7,16]</sup>. A second merit is enhancement of the surgical margins of tumors located near the cutting surface of the liver<sup>[17]</sup>. On the other hand, a necrotic zone remains in the cutting surface of the residual liver<sup>[14]</sup>. Although cryoablation causes lethal systemic responses with high levels of cytokines<sup>[18,19]</sup>, RF ablation may be safe and result in only minimal release of soluble factors causing systemic responses. However, it is not known whether RF manipulation, and the residual necrotic tissue during liver resection, is beneficial or harmful to liver regeneration (LR). In addition, the molecular events of LR after the use of heating devices for liver resection are also unknown.

LR is regulated by sequential molecular events in which various humoral factors such as tumor necrosis factor (TNF)- $\alpha$  and IL-6 prime and facilitate hepatocyte replication<sup>[20-22]</sup>. Although the humoral factors increase and influence each step of LR in a very short time<sup>[21]</sup>, each cytokine activates subsequent molecular signals to complete LR<sup>[22]</sup>. RF ablation, in particular, excessively increases plasma cytokines such as TNF- $\alpha$  and IL-6 compared to simple liver resection<sup>[23,24]</sup>. Due to superphysiological stimulation of these cytokines, the heat effect of RF ablation may impair liver regeneration<sup>[25]</sup>. On the other hand, fast recovery of liver function in LR after RF ablation has been reported in major clinical hepatectomy<sup>[6]</sup>. Therefore, the exact effect of RF ablation on LR remains unclear.

Steroid administration has been proved to attenuate surgical stress following liver resection<sup>[26,27]</sup>. In addition, steroid pretreatment has been proved to decrease plasma cytokine levels and the therapeutic dose of the steroid does not inhibit hepatocyte proliferation<sup>[28]</sup>. Although previous investigations showed that steroid treatment could ameliorate excessive surgical stress of extended hepatectomy<sup>[26-28]</sup>, the exact benefits of steroid administration in clinical LR are largely unknown. The main aim of this study was to determine whether liver regeneration could be disturbed following RF ablation. The second was to determine the effect of steroid pretreatment on LR after RF ablation.

## MATERIALS AND METHODS

Animal studies were performed in compliance with in-

stitutional and National Research Council guidelines for humane care of laboratory animals.

### Animals

Adult female Fisher 344 rats (250-350 g) were obtained from Charles River Japan (Kanagawa, Japan). They were housed in a climate-controlled (21 °C) room under a 12 h light-dark cycle and were given tap water and standard laboratory chow. All operations were performed between 9:00 a.m. and noon under general (ether) anesthesia using a sterile surgical technique.

### Surgical animal models

**Sham hepatectomy:** The sham hepatectomy consisted of laparotomy and mobilization of the liver.

**Partial hepatectomy:** The two anterior liver lobes were removed as previously described<sup>[29,30]</sup>. In this model, removal of the two anterior lobes (68% of the liver) is known to induce the optimal proliferative response in the remnant liver mass.

**Partial hepatectomy with radiofrequency ablation:** Preceding partial hepatectomy (PH), the two anterior liver lobes were ablated with saline-linked electric bipolar forceps (ERBE Elektromedizin GmbH, Tübingen, Germany). After complete ablation of the two anterior lobes, they were removed the same as PH operation.

### Experimental design

Groups of sham hepatectomy (SH), PH, and partial hepatectomy with RF ablation (PHA) rats were euthanized in batches of six at 1, 3, 5 and 7 d after surgery. A separate experiment was designed to determine the effect of steroid administration. All animals were pretreated with dexamethasone at 30 min prior to the operation. Groups of steroid pretreated PH rats (S-PH) and PHA rats (S-PHA) were euthanized in batches of six at 1 d after surgery. One hour before euthanasia, 5-bromo-2-deoxyuridine (BrdU) was injected intraperitoneally (50  $\mu$ g/kg body weight)<sup>[31]</sup>. When animals were killed, part of the liver tissue was immediately frozen in liquid nitrogen for molecular analysis and part of it was dipped into cold ethanol for immunohistochemical study.

### Blood chemistry and white blood cell counts

Blood samples were analyzed for activity of alanine transaminase (ALT), aspartate transaminase (AST), total protein levels, and albumin (ALB) in a clinical laboratory. White blood cells were counted with an autocalculator in the laboratory.

### Multiple cytokine detection

Serum obtained after euthanasia was kept at -80 °C until submission to a company (Upstate United States Inc., Charlottesville, VA, United States) for analysis. Briefly, multianalyte profiling was performed on a Luminex 100 system and the XY Platform (Luminex Corporation, Austin, TX, United States). Calibration microspheres for

classification and reporter readings as well as sheath fluid were obtained from Luminex Corporation. Acquired fluorescence data were analyzed using MASTERPLEX™ QT (Ver. 1.2; MiraiBio Inc., South San Francisco, CA, United States). Serum concentrations of TNF- $\alpha$ , IL-6, IL-10, and monocyte chemoattractant protein-1 (MCP-1) were measured with an Upstate Beadlyte Mouse Multicytokine Bead master kit (Upstate United States, Inc.)<sup>[31]</sup>. All analyses were performed according to the manufacturers' protocols.

#### **Immunohistochemistry for BrdU and BrdU labeling index**

The proliferative activity in the liver after hepatectomy was determined by measuring incorporation of BrdU as previously described<sup>[31]</sup>. Briefly, a mouse anti-BrdU antibody (X 100 dilution: DAKO A/S, Copenhagen, Denmark) was used as the primary antibody, followed by the ABC method (DAKO Co., Carpinteria, CA). Both labeled and unlabeled hepatocytes were counted in 20 fields in three different sections per time point from five different animals. Data are presented as means  $\pm$  SD from three independent experiments.

#### **Restitution of liver mass**

Growth of the residual liver lobes (right and omental lobes) was calculated as the ratio of residual liver weight/body weight (RLW/BW).

#### **Western blotting analysis**

Western blotting analysis was performed using the Invitrogen NuPAGE® electrophoresis system (Invitrogen, Carlsbad, CA, United States). The samples were homogenized in phosphate buffered saline and kept at -80 °C until use. Briefly, nuclear proteins were extracted using the NE-PER® nuclear and cytoplasmic extraction protocol (Pierce Chemicals, Rockford, IL, United States). A BCA protein assay kit® (Pierce Chemicals) was used to measure the protein concentrations. Proteins (5  $\mu$ g/lane) were separated on NuPAGE 4%-12% Bis-Tris gradient gels (Invitrogen). The gels were transferred to nitrocellulose membranes (Amersham Co., Buckinghamshire, United Kingdom) using an iBlot™ Gel Transfer Device (Invitrogen). Immunodetection of proteins was performed using a Western-Breeze® Chromogenic Immunodetection Kit (Invitrogen). Mouse monoclonal anti-proliferation cell nuclear antigen (PCNA) (Dako Co., Carpinteria, CA, United States) and rabbit polyclonal anti-ALB (Santa Cruz Biotechnology, Inc., Santa Cruz, CA) were used as the primary antibodies (1:250). The ECL western blotting analysis system (Amersham Co.) was used to detect signals.

#### **Densitometric analysis**

Scanning densitometry was performed using a Macintosh G4 computer (Apple Computer, Cupertino, CA) and an EPSON GT-9600 scanner (Seiko Epson, Suwa, Japan). The signals were quantified using the NIH Image 1.55 Densitometric Analysis Program<sup>[30]</sup>.

#### **STAT3 DNA-binding activation assay**

STAT3 activation was quantified using a TransAM™STAT3

Kit (Active Motif, Funakoshi Co., Tokyo, Japan)<sup>[32]</sup>. Briefly, 10 g/well of the nuclear cell extract from whole liver tissue (containing an activated transcription factor) was incubated in a 96-well plate on which double-stranded oligonucleotides containing the consensus sequence for the STAT3 DNA-binding site (5'-TTCCCGGAA-3') were immobilized. The primary antibody used to detect STAT3 recognized epitopes on both the alpha and beta forms of STAT3, which are accessible only when STAT3 is activated and bound to its target DNA. After incubation with horseradish peroxidase, absorbance was recorded at 450 nm using a reference wavelength of 655 nm.

#### **Statistical analysis**

The unpaired Student's *t*-test, Welch's *t*-test or one-way analysis of variance (ANOVA) was used as appropriate. Data are given as mean  $\pm$  SD. **Statistical analysis was performed** using the StatView 5.0 program (SAS Institute, Cary, NC, United States) and the difference between the means was considered significant when  $P < 0.05$ .

## **RESULTS**

All rats tolerated the operative procedures well and recovered uneventfully from anesthesia. Samples were collected immediately after each animal was euthanized.

#### **Liver regeneration after ablation**

Although the liver was ablated within a short time and most necrotic tissue was removed in the PHA group, postoperative serum AST and ALT levels in this group at one day after operation were significantly higher than in the PH group (Table 1). On the other hand, the white blood cell counts were not significantly different among the groups (Table 1). Total protein and albumin levels at two, three, and five days after operation in the PHA group were significantly lower than in the PH group.

Serum cytokine and chemokine levels are shown in Figure 1. TNF- $\alpha$  levels in the PHA group at one and two days after operation were significantly higher than in the PH group (Figure 1A). IL-6 (Figure 1B) and MCP-1 (Figure 1D) levels in the PHA group at two, three, and five days after operation were significantly higher than in the PH group. IL-10 levels in the PHA group at two and three days after operation were significantly higher than in the PH group (Figure 1C).

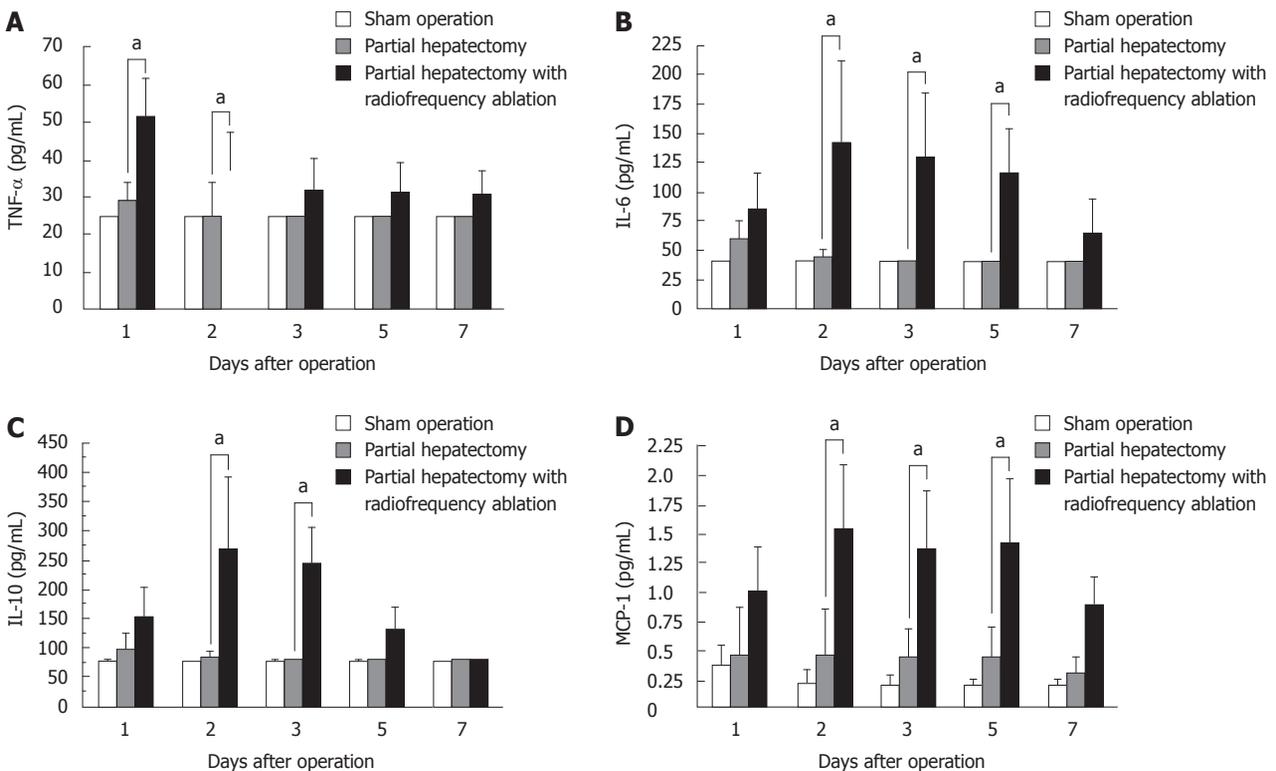

DNA synthetic activity was determined by immunohistochemistry for BrdU (Figure 2A-J) and labeling indices (LIs) (Figure 2K). **The LI at one day in the PHA group was significantly lower than in the PH group** ( $12.17 \pm 3.43$  vs  $29.02 \pm 8.47$ ,  $P = 0.001$ ). On the other hand, the LIs at two days and three days after operation in the PHA group were significantly higher than in the PH group ( $15.85 \pm 4.18$  vs  $7.05 \pm 1.54$ ,  $P < 0.001$ , and  $12.55 \pm 3.14$  vs  $6.03 \pm 2.11$ ,  $P = 0.002$ , respectively). Although DNA synthetic activities between the groups are significantly different, RLW/BW ratio was not greatly significantly different among the groups (Figure 2L).

Protein expression of nuclear PCNA and cytosolic

One-way analysis of variance was used for statistical analysis and  $P < 0.05$  is considered to be significant. WBC: White blood cell; PH: Partial hepatectomy; PHA: Partial hepatectomy with radiofrequency ablation; TP: Total protein levels; ALB: Albumin; AST: Aspartate transaminase; ALT: Alanine transaminase; NS: Not Significant.

**Figure 1** Changes in serum tumor necrosis factor- $\alpha$  (A), IL-6 (B), IL-10 (C), and monocyte chemoattractant protein-1 (D) levels after the operations.  $^aP < 0.05$  between groups. TNF- $\alpha$ : Tumor necrosis factor- $\alpha$ ; MCP-1: Monocyte chemoattractant protein-1.

albumin is shown in Figure 3A. Densitometric analysis of the expression of each protein is shown in Figure 3B. The pattern of PCNA expression was similar to the immunohistochemistry for BrdU and LIs. The peak of BrdU expression in the PH group was seen at one day after operation and in the PHA group at two and three

days after operation. ALB expression in the PH group dropped at one and two days after operation and recovered thereafter. In contrast, ALB expression in the PHA group dropped at three and five days after operation. STAT3 DNA-binding activity was also consistent with the results of BrdU, LIs, and PCNA expression (Figure 3C).

**Figure 2** Immunohistochemistry for 5-bromo-2-deoxyuridine in the partial hepatectomy group (A-E) and in the partial hepatectomy with radiofrequency ablation group (F-J) at 1 d (A and F), 2 d (B and G), 3 d (C and H), 5 d (D and I) and 7 d (E and J) after the operations. K: Comparison of labeling indices in the partial hepatectomy group and partial hepatectomy with radiofrequency ablation group; L: The ratio of liver weight/body weight shows restitution of the remnant liver. <sup>a</sup>*P* < 0.05 between groups. LIs: Labeling indices; RLW/BW: Residual liver weight/body weight.

The peak of STAT3 DNA-binding activity in the PH group was seen at one day after operation and in the PHA group at two and three days after operation.

### Response of liver regeneration after ablation with steroid administration

We found that LR was disturbed after RF ablation in hepatectomy, with high cytokine/chemokine induction. Because steroid treatment could block cytokine elevation after hepatectomy, we tested the effects of S-PH and S-PHA groups.

Immunohistochemistry values for BrdU (Figure 4A-P) and LIs (Figure 4Q) at 1 d after steroid administration at different concentrations are shown in Figure 4. BrdU uptake in the S-PH group (Figure 4A-H) gradually decreased when the steroid dose was increased. In contrast, that in the S-PHA group (Figure 4I-P) gradually increased when the steroid dose was increased by 0.04 mg/kg and then it decreased with further increases in dosage. Although the LI at 0.002 mg/kg steroid administration in the S-PH group was significantly higher than in the S-PHA group ( $29.62 \pm 8.28$  vs  $14.87 \pm 4.35$ , *P* = 0.003), the LIs at the other steroid doses were not significantly different between the groups (Figure 4Q). Among the examined cytokines and chemokines, only the TNF- $\alpha$  level at 0.002 mg/kg of steroid in the S-PH group (Figure 4R) was significantly lower than in the S-PHA group ( $27.5 \pm 4.18$  vs  $46.5 \pm 4.18$ ,

*P* = 0.001). In contrast, other levels were not significantly different at any steroid doses (data not shown).

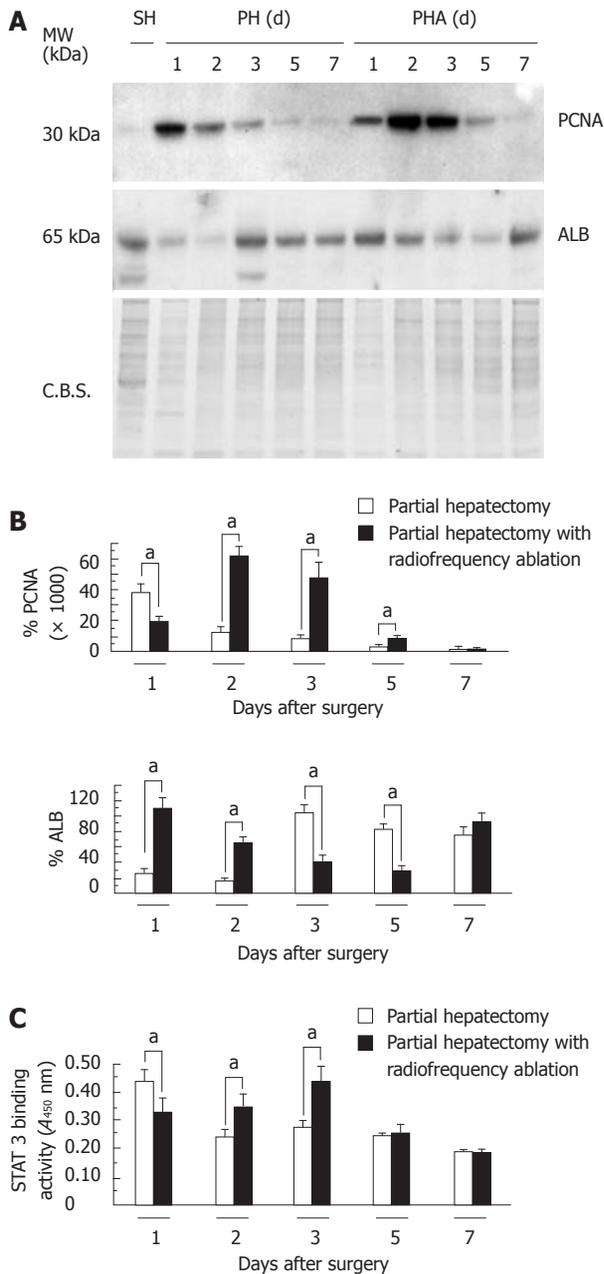

The pattern of PCNA expression in the nucleus (Figure 5A) was similar to that observed in the immunohistochemistry for BrdU and LIs (Figure 4). PCNA expression in the S-PH group gradually decreased when the steroid dose was increased. In contrast, that in the S-PHA group gradually increased when the steroid dose was increased by 0.04 mg/kg and then it decreased with further dosage. STAT 3 DNA-binding activities (Figure 5B) were also consistent with the BrdU staining, LIs and PCNA expression. Only STAT3 DNA-binding activity at 0.002 mg/kg of steroid was significantly different between the groups ( $0.406 \pm 0.042$  vs  $0.298 \pm 0.053$ , *P* = 0.019).

## DISCUSSION

We investigated the influence of RF ablation during hepatectomy on LR. We found that LR after RF ablation was disturbed, with high serum cytokine/chemokine induction. Low-dose steroid administration nearly restored LR after RF ablation during hepatectomy, and STAT3 DNA-binding activity supported this finding.

### Surgical model to investigate influence of radiofrequency ablation on liver regeneration

The method of liver resection should take into account

**Figure 3** Proliferation cell nuclear antigen expression in the nuclear protein and albumin expression in the cytosol after the operations. A: Western blotting analysis for proliferation cell nuclear antigen expression (PCNA); B: Densitometric analysis of each protein signal; C: STAT3 DNA-binding activity in the nuclear protein after the operations. <sup>a</sup>*P* < 0.05 between groups. SH: Sham hepatectomy; PH: Partial hepatectomy; PHA: Partial hepatectomy with radiofrequency ablation; MW: Molecular weight; C.B.S.: Coomassie blue staining; ALB: Albumin.

both perioperative safety and oncological curability. RF ablation is one of the less invasive strategies for small liver tumors<sup>[33]</sup> and can be used for hemostasis during liver resection<sup>[34]</sup>. The one concern is that some necrotic tissue will remain in the residual liver after RF ablation and may affect LR. In addition, thermal energy itself during the operation also may affect it. Most investigations have used large animal models to study the effects of RF ablation after hepatectomy on humoral and oncological activities<sup>[25]</sup>. The use of murine models to investigate RF ablation has been limited<sup>[25,35]</sup>. Large animal models

can be ideal to simulate the human response; however, they are time consuming and it is difficult to examine the molecular details compared to murine models. Although our model did not totally reproduce the human clinical situation, the postoperative course was very similar, as serum transaminases were strongly elevated at one day after operation<sup>[24]</sup>. Furthermore, high serum cytokine levels after ablation have been reported in human studies<sup>[24,36]</sup>. These clinical postoperative alterations of laboratory tests supported the idea that our model could represent the clinical phenomena of hepatectomy using RF ablation. Therefore, our model was suitable to examine the thermal effect of RF ablation after hepatectomy.

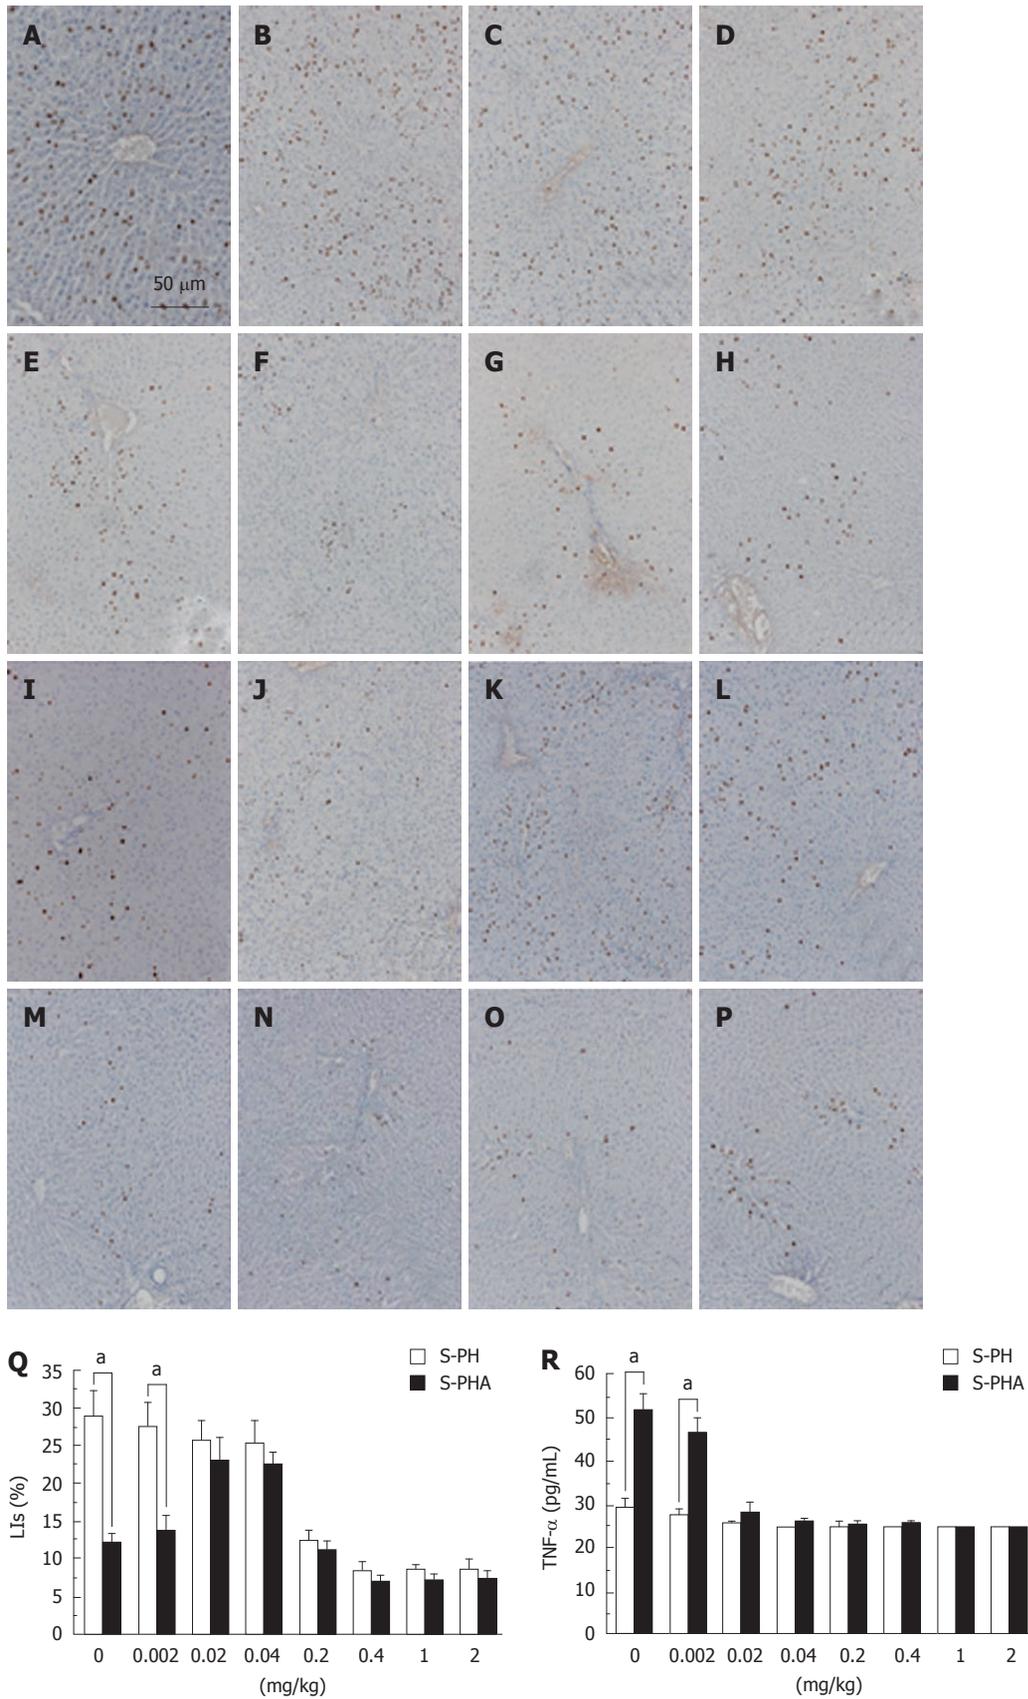

### Effect of radiofrequency ablation on the liver

Effects of RF ablation on cancer cells in the liver could modulate the systemic immune responses, including cytokine/chemokine production and the proliferative activity of the cancer cells<sup>[37,38]</sup>. Necrotic tissue after RF ablation could also modulate the systemic immune response to specific cancer cells<sup>[39]</sup>. On the other hand, Meredith *et al.*<sup>[40]</sup> reported that RF ablation itself did not accelerate tumor growth. In our study, RF ablation delayed the liver regenerative response, which was consistent with a previous study<sup>[25]</sup>. These differently reported proliferative responses may be due to the differences between cancer cells and normal cells. Other reasons could be differences in the amount of necrosis and the duration of the ablation. We could not distinguish between the exact effects of necrosis and ablation, but our results indicated that the heat effect of RF ablation, not necrosis, could delay LR, because most ablated tissues were removed in both groups, and the amounts of necrosis in the PH and the PHA groups were comparable in our model. Serum cytokines such as IL-6, IL-8, and IL-10 are elevated after RF ablation<sup>[24,35,36]</sup>, which is also consistent with our results. Therefore, regardless of how much necrotic tissue was removed after RF ablation, the heat effect during the ablation itself could activate cytokine/chemokine responses.

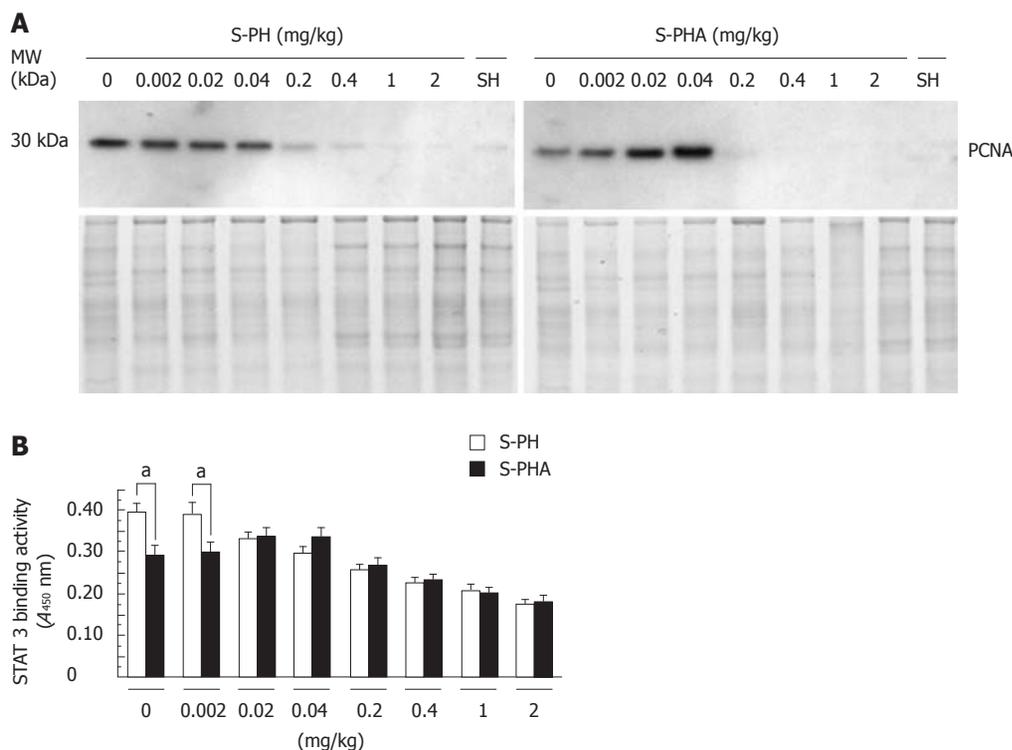

### Cytokine/chemokine signals in liver regeneration

LR after RF ablation was delayed without any difference in the RLW/BW ratio. This indicated that volume recovery after PH did not represent parenchymal cell proliferation itself, which was consistent with a previous report<sup>[41]</sup>. Delayed LR after RF ablation affected the serum albumin level. Albumin production was suppressed when hepatocytes began to proliferate<sup>[42]</sup>. The time lag between DNA synthesis and the serum albumin level could be due to the long half-life of serum albumin. Even though there was no critical event in our model, we need to pay attention to the albumin level, which could decrease in LR after RF ablation and be associated with delayed LR in the clinical setting.

A systemic cytokine/chemokine response was activated by RF ablation even within the short time during operation. We could not determine the specific cytokine/chemokine that disturbed hepatocyte proliferation. Excessively high levels of cytokines such as TNF- $\alpha$  and

**Figure 4** Immunohistochemistry for 5-bromo-2-deoxyuridine staining in the partial hepatectomy with dexamethasone pretreatment group (A-H) and partial hepatectomy after radiofrequency ablation with dexamethasone pretreatment group (I-P) at 1 d after the operations. Animals were pretreated with 0 mg/kg (A and I), 0.002 mg/kg (B and J), 0.02 mg/kg (C and K), 0.04 mg/kg (D and L), 0.2 mg/kg (E and M), 0.4 mg/kg (F and N), 1 mg/kg (G and O), or 2 mg/kg (H and P) dexamethasone. Q: The brown nuclei are positive for 5-bromo-2-deoxyuridine. The labeling indices were calculated from 20 fields in three different sections per treatment for five different animals; R: Serum tumor necrosis factor- $\alpha$  levels at 1 d after the operations. The horizontal axis presents each concentration of dexamethasone pretreatment. <sup>a</sup>*P* < 0.05 between groups. S-PH: Steroid pretreatment in the partial hepatectomy group; S-PHA: Steroid pretreatment in the partial hepatectomy after radiofrequency ablation group; LIs: Labeling indices.

**Figure 5** Proliferation cell nuclear antigen expression in the nuclear protein at 1 d after the operations. A: Western blotting analysis for proliferation cell nuclear antigen (PCNA) expression. Animals were pretreated with various concentrations of dexamethasone 30 min prior to the hepatectomy; B: STAT3 DNA-binding activity in the nucleus at 1 d after the operations. <sup>a</sup>*P* < 0.05 between groups. SH: Sham operation; S-PH: Steroid pretreatment in the partial hepatectomy group; S-PHA: Steroid pretreatment in the partial hepatectomy after radiofrequency ablation group; MW: Molecular weight.

IL-6 are desensitized from growth stimuli<sup>[43]</sup>, although knockout murine models targeting TNF- $\alpha$  receptor and *IL-6* genes have demonstrated that these cytokine signals are necessary to accomplish LR<sup>[44,45]</sup>. The lack of DNA-binding activity of STAT3 in our results supported the finding of growth suppression in the PHA group. Even though the peaks of most cytokine/chemokine levels in the PHA model were between two days and five days after operation, DNA synthesis in PHA continued in these periods. The only distinctive alteration seen was in the TNF- $\alpha$  level, which gradually decreased. In addition, steroid pretreatment in the PHA group showed that only the TNF- $\alpha$  level was different between the PH group and PHA group at one day after operation. Therefore, DNA synthesis after RF ablation could be more affected by TNF- $\alpha$  than by other cytokines/chemokines. Thus, TNF- $\alpha$  activation should be observed within a short time after simple hepatectomy<sup>[21]</sup>. However, it could be prolonged in LR after RF ablation, as shown in our results. Though we could not determine the mechanism of the TNF- $\alpha$  activation after RF ablation, our results strongly suggested that the TNF- $\alpha$  could play a major role in LR after RF ablation. Further study is needed to determine whether TNF- $\alpha$  could be a molecular target to control LR in the clinical setting.

### Steroid administration and liver regeneration

Steroids have been demonstrated to inhibit LR by inhibiting excessive TNF- $\alpha$  and IL-6 production<sup>[46-48]</sup>, although moderate stimulation by TNF- $\alpha$  and IL-6 is necessary

to complete LR<sup>[21]</sup>. Our results also showed that cytokine/chemokine levels decreased gradually depending on steroid administration in the S-PHA group. On the other hand, steroids can inhibit the DNA synthesis of hepatocytes directly<sup>[42]</sup>. The reason why DNA synthesis recovered after low-dose steroid administration in the S-PHA group could be related to the balance between the suppression of excessive cytokine production and the direct inhibition of DNA synthesis. In other words, LR after low-dose steroid administration could recover, escaping from the excessive cytokine production, and be nearly free from the direct inhibition by the steroid. Our results indicated the presence of an optimal threshold of the steroid concentration that facilitated LR when cytokines/chemokines were excessively activated. Therefore, our results strongly suggest that we need to pay careful attention to the clinical steroid concentration because the effects of steroid administration could be altered depending on the clinical condition.

In conclusion, LR was disturbed after RF ablation, with high serum cytokine/chemokine induction. Low-dose steroid administration could improve LR after RF ablation with TNF- $\alpha$  suppression. Further clinical study is needed to confirm that low-dose steroid administration has a clinical benefit for LR after RF ablation.

### ACKNOWLEDGMENTS

We thank Mr. Kim Barrymore for his help in preparing this manuscript.

## COMMENTS

### Background

Liver resection is still one of the best curative therapies for primary or secondary liver tumors. Various techniques and devices for liver resection have been employed to improve the perioperative outcome. Radiofrequency (RF) devices can seal vessels and bile ducts to avoid postoperative bleeding and bile leakage. Although some of its merits have been reported, its demerits are largely unknown.

### Research frontiers

The greatest merit of a RF device is the sealing effect to reduce perioperative morbidity. A second merit is enhancement of the surgical margins of tumors located near the cutting surface of the liver. On the other hand, a necrotic zone remains in the cutting surface of the residual liver. The research hotspot is whether RF manipulation, and the residual necrotic tissue during liver resection, is beneficial or harmful to liver regeneration (LR).

### Innovations and breakthroughs

The present study showed LR after RF ablation delayed the regenerative response with high serum cytokine/chemokine induction, and low-dose steroid administration could improve LR after RF ablation with TNF- $\alpha$  suppression. The results indicated that the heat effect of RF ablation, not necrosis, could delay LR, because most ablated tissues were removed. Serum cytokines such as IL-6, IL-8, and IL-10 are elevated after RF ablation, which is consistent with previous studies. Therefore, regardless of how much necrotic tissue was removed after RF ablation, the heat effect during the ablation itself could activate cytokine/chemokine responses.

### Applications

This study provides insights into the mechanism by which RF ablation could activate cytokines/chemokines in LR and found that steroids can be used for controlling LR. The results strongly suggest that they need to pay careful attention to the clinical steroid concentration because the effects of steroid administration could be altered depending on the clinical condition.

### Peer review

The aim of this study focused on liver regeneration after RF ablation is clear and interesting, and these data may provide a basis for RF ablation studies in the future. The impact of this study in this field is moderate.

### Abstract

**AIM:** To investigate a potential role of S100A4 in esophageal squamous cell carcinoma metastasis (ESCCs).

**METHODS:** Expression of S100A4 and E-cadherin were analyzed in frozen sections from ESCCs (metastasis,  $n = 28$ ; non-metastasis,  $n = 20$ ) by reverse transcription-polymerase chain reaction, quantitative polymerase chain reaction and immunohistochemistry. To explore the influence of S100A4 on esophageal cancer invasion and metastasis, S100A4 was overexpressed or silenced by S100A4 siRNA in TE-13 or Eca-109 cells *in vitro* and *in vivo*.

**RESULTS:** We found the mRNA and protein levels of S100A4 expression in ESCCs was significantly upregulated, and more importantly, that expression of S100A4 and E cadherin are strongly negatively correlated in patients who had metastasis. It was indicated that overexpression of S100A4 in TE-13 and Eca-109 cells downregulates the expression of E-cadherin, leading to

increased cell migration *in vitro*, whereas knockdown of S100A4 inhibited cell migration and upregulation of E-cadherin expression. Moreover, the loss of cell metastatic potential was rescued by overexpression of E-cadherin completely. In addition, nude mice inoculated with S100A4 siRNA-transfected cells exhibited a significantly decreased invasion ability *in vivo*.

**CONCLUSION:** S100A4 may be involved in ESCC progression by regulate E-cadherin expression, vector-based RNA interference targeting S100A4 is a potential therapeutic method for human ESCC.

### INTRODUCTION

Despite improvements in detection, surgical resection, and (neo-) adjuvant therapy, the overall survival for esophageal squamous cell carcinoma (ESCC), one of the most aggressive carcinomas of the gastrointestinal tract, remains lower than that of other solid tumors due to distant and lymph node metastasis<sup>[1]</sup>. Therefore, efforts are ongoing regarding exploration of novel targets and

strategies for the management of ESCC, and gene targeting therapies in particular are promising. Multiple studies focusing on the effects of various biological factors on the malignant potential of ESCC have been conducted<sup>[2-4]</sup>. One of those factors is E-cadherin as the loss of E-cadherin is an important step in the process of epithelial-to-mesenchymal transition (EMT) in cancer<sup>[5-8]</sup>. In ESCC, loss of E-cadherin expression is associated with tumor invasiveness, metastasis and prognosis<sup>[2,9,10]</sup>. Mechanisms involved in regulation of E-cadherin in ESCC are likely complex and poorly understood.

The S100 family of calcium binding proteins has been shown to be involved in a variety of physiological functions, such as cell proliferation, extracellular signal transduction, intercellular adhesion, and motility as well as cancer metastasis<sup>[11-13]</sup>. Of these, S100A4 (mts1, p9Ka, calvasculin) has been identified as a cytoplasmic protein in normal cells, which is associated with the actin/myosin cytoskeleton in fixed cells<sup>[14]</sup>. Interestingly, elevated levels of S100A4 are closely associated with the process of metastasis in several human solid cancers including gastric cancer<sup>[15,16]</sup>, colorectal adenocarcinoma<sup>[17,18]</sup>, and breast cancer<sup>[19]</sup>. Patients with S100A4 high expression often appear with advanced stage or lymph node metastasis suggesting correlation of the S100A4 expression and the invasion or metastasis of ESCC<sup>[20]</sup>. In this study, we investigated the expression of S100A4 and E-cadherin in ESCC patients and the potential functional relationship in tumor metastasis and proliferation.

## MATERIALS AND METHODS

### Cell lines

EC109 and TE13 were kindly provided by Dr. Zhang (Surgery, the affiliated Hospital of Medical College, Qingdao University, Qingdao, China)<sup>[21]</sup>. All the cells were maintained in 50 mL/L CO<sub>2</sub> atmosphere at 37 °C in RPMI 1640/Ham's F-12 mixed (1:1) medium containing 100 g/L fetal bovine serum.

### Tissue sample collection

A total of 48 cryostat sections of frozen ESCC tissue were enrolled in this study: 28 with lymph node ( $n = 25$ ) or distant metastasis ( $n = 3$ ) and 20 without metastasis. These patients did not receive any preoperative adjuvant radiation or chemotherapy. All research involving human participants was approved in written form by the patients studied and the ethics committee at the affiliated hospital of Tianjin medical university.

### Silencing of S100A4

siRNAs were commercially purchased from Qiagen (Valencia, CA). The sequence of selected regions to be targeted by siRNAs was 5'-AACGAGGTGGACTTCCAAGAG-3' for S100A4 and 5'-AATTCTCCGAACGTGTCTCG T-3' for a nonsilencing siRNA (control). siRNA cloning vector (pGB) was purchased from ABCAM (Shanghai). pGB-S100A4 siRNA and controls were constructed according to the manufacture's instruction. EC109 cells were transfected

with the siRNA plasmids in the presence of Lipofectamine. Stable transfectants were selected with 300 µg/mL G418.

### S100A4 cDNA and E-cadherin cDNA plasmid construction and transfection

The commercial pMD vector (produced by TAKARA) and Homo sapiens S100A4 transcript variant 1 DNA ORF (S100A4 cDNA) and Homo sapiens E-cadherin DNA ORF Clone (E-cadherin cDNA) were purchased from Sino Biological Inc. Beijing; The gene sequence is identical with the Gene Bank Ref. ID sequence: S100A4 cDNA: NM\_002961.2; E-cadherin DNA: NM\_004360.3. The S100A4 cDNA product was then cloned into pMD vector as the manufacture's instruction. The constructs were confirmed by DNA sequencing and restriction enzyme digestion. For transfection studies, EC109 and TE13 cells were plated at a density of  $1 \times 10^6$  cells per well in 6-well plates and incubated for 24 h in complete medium. The cells were then transfected with S100A4 cDNA (E-cadherin) construct by using an lipofectamine transfection kit for 48 h. For controls, the same amount of empty vector was also transfected. Stable transfected TE13 cells (pMD-S100A4 cDNA) were selected with 200 µg/mL G418.

### Real-time quantitative reverse transcription-polymerase chain reaction analysis of archival material or TE-13 and Eca-109 cell lines

Total RNA was extracted from cryostat sections of frozen tissue or TE-13 and Eca-109 cell lines using Trizol Reagent (Life Technologies, Inc.) according to the manufacturer's instructions. Real-time quantitative reverse transcription-polymerase chain reaction (Q-PCR) was performed using the ABI Prism 7 700 Sequence Detection System (Perkin-Elmer Applied Biosystems). Q-PCR assays were performed in triplicate, and the mean values were used for calculations of mRNA expression. Relative levels were determined using the 2<sup>-ΔΔCt</sup> method<sup>[22]</sup>.

### Reverse transcription-polymerase chain reaction analysis of archival material or TE-13 and Eca-109 cell lines

PCRs were carried out by using forward and reverse primer combinations for S100A4 (forward 5'-TCAGAACTA-AAGGAGCTGCTGACC-3', reverse 5'-TTTCTTCCT-GGGCTGCTTATCTGG-3'), E-cadherin (forward 5'-GGAAGTCAGTTCAGACTCCAGCC-3', reverse 5'-AGGCCTTTTGACTGTAATCACACC-3'), GAPDH (forward 5'-AATCCCATCACCACTTCCAGGAG-3', reverse 5'-GCATTGCTGATGATCTTGAGGCTG-3'). The cDNA was amplified with an initial denaturation at 94 °C for 3 min followed by the sequential cycles of denaturation at 94 °C for 50 s, annealing at 55 °C for 1 min, and extension at 72 °C for 1 min for 30 cycles, with final extension at 72 °C for 5 min.

### Western blotting

Whole-cell proteins were isolated, the lysates centrifuged, and the supernatant collected. 30 µg of total protein was loaded per well, separated by 7.5% to 12% sodium dodecyl sulfate polyacrylamide gel electrophoresis, and

transferred to polyvinylidene difluoride membranes at 150 mA for 16 h at 4 °C according to the manufacturer's instructions. The membranes were blocked and incubated with primary antibodies. Primary antibodies were as follows: anti-S100A4 (1:200 dilution) and anti-E-cadherin (1:200 dilution; all from Santa Cruz Biotechnology). The immunoblots were detected by using an electrochemiluminescence kit (Amersham, Piscataway, NJ) and exposed to X-OMATAR film.

### Immunohistochemistry staining

The paraffin-embedded sections were stained with primary anti-S100A4 or anti-Ecadherin (Abcam, Cambridge, United Kingdom) antibody and horseradish peroxidase-labeled immunoglobulin (Boshide Biotech Co., Ltd, Wuhan, China). Images were obtained at  $\times 200$  magnification. Stained slides were scored by 2 blinded, independent observers. The results of the immunohistochemical stainings were evaluated by the percentage of positively stained carcinoma cells. Expression of S100A4 was determined as positive when cytoplasmic and/or perinuclear staining was seen in more than 10% of the tumour cells. Expression of S100A4 was considered negative when no cells or less than 10% of the tumour cells were stained. Expression of E-cadherin was determined as described in a previous study<sup>[23]</sup>. Briefly, the tumor cells that stained as strongly as normal epithelial cells were considered to be "preserved expression" (positive), and those which exhibited weaker staining than normal epithelial cells or showed completely negative staining were considered to be "reduced expression" (negative).

### Cell invasion assays

Cell invasion assays were performed using 8- $\mu$ m pore size Transwell Biocoat Control inserts (Becton Dickinson). In brief,  $1 \times 10^4$  cells were seeded on a transwell containing numbers of 8- $\mu$ m pores for invasion assay. The chambers were put into the incubator at 37 °C, 50 mL/L CO<sub>2</sub>. Cells on the top surface of the transwell were removed by scrubbing 24 h after incubation. The cells were fixed by 950 mL/L ethanol, and stained in 30 min by 1 mL/L crystal violet. We counted the number of transmembrane cells under an optical microscope, chose five high power fields by random, and checked each field of vision to evaluate the invasion and metastasis of tumor cells *in vitro*. Such invaded cells were counted and compared among groups. Individual experiments were done in duplicate and repeated four times.

### Invasion study in vivo

All animals were maintained in a sterile environment and cared for within the laboratory animal regulations of the Ministry of Science and Technology of the People's Republic of China (<http://www.most.gov.cn/kytj/kytjz-cwj/200411>). Full details of the study approval by the ethics committee at the affiliated hospital of Tianjin medical university. After growth to subconfluency, transfected (pMD-S100A4 siRNA or mock siRNA) and nontransfected Eca-109 cells, stable transfected TE13 cells (pMD-S100A4

**Table 1** Immunohistochemistry staining of S100A4 and E-cadherin

Groups	n	S100A4			E-cadherin		
		Positive	Negative	P value	Positive	Negative	P value
Metastasis	28	19	9	0.027	10	18	0.036
Non-metastasis	20	7	13		12	8	

cDNA), mock transfected and nontransfected TE13 cells were injected into the pancreas under the envelope near spleen of nude mice ( $n = 8$  for each variant). Twenty-eight days later, the mice were killed following the operation. The number of the seeded tumor naked in the liver and lung is used for assessment of metastases.

### Statistical analysis

All statistical analyses were performed using SPSS 11.0 software. The results were presented as mean  $\pm$  SD of three replicate assays. Differences between various groups were assessed using ANOVA or Dunnett *t*-test. *P* value (of  $< 0.05$ ) was considered to indicate statistical significance.

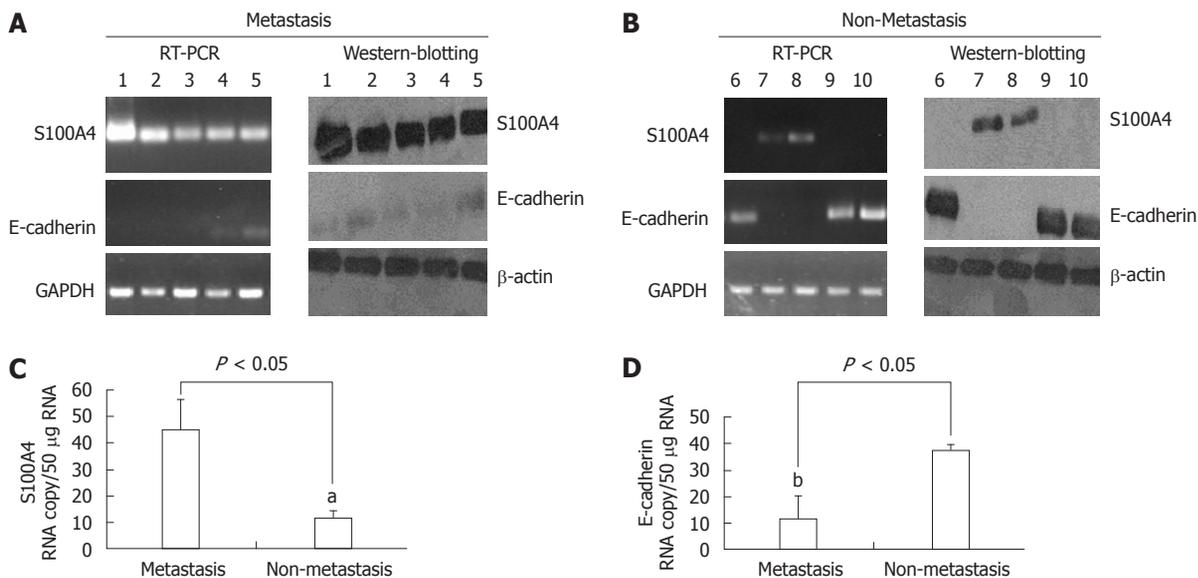

## RESULTS

### Increased expression of S100A4 and E-cadherin is associated with lymph node metastasis

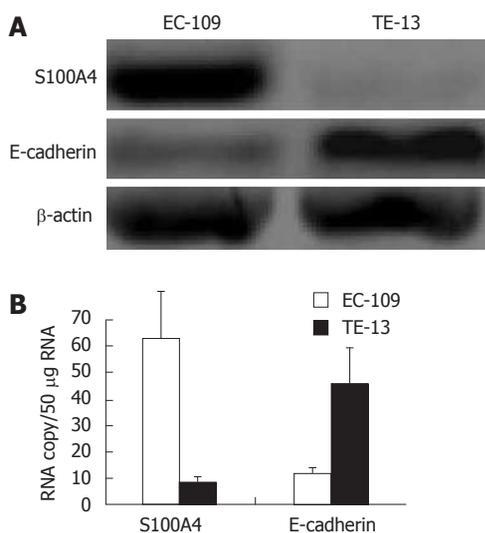

Results of immunohistochemistry (IHC) staining showed that S100A4 was weakly expressed in non-metastasis ESCC, whereas strongly expressed in metastatic ESCC (Table 1,  $P < 0.05$ ). On the contrary, E-cadherin expression was strongly expressed in non-metastatic ESCC, whereas weak E-cadherin expression was detectable in metastatic ESCC (Table 1) Significantly, negative relationship was found between S100A4 and E-cadherin expression. The Western blotting, Q-PCR and reverse transcription-polymerase chain reaction (RT-PCR) analysis has the same results as IHC analysis. A six representative (5 non-metastatic ESCC cases and 5 metastatic ESCC cases) western blotting and RT-PCR results was shown in Figure 1A and B. In the present study, we also detected the levels of transcripts of S100A4 mRNA and E-cadherin mRNA in metastasis (M) tumor samples and non-metastasis tumor (N) samples (expressed as transcript copy number per 50  $\mu$ g of messenger RNA and standardized with  $\beta$ -actin; Figure 1C and D). We found that transcript copy numbers for S100A4 were  $46.3 \pm 9.4$  for M tumor and  $10.5 \pm 3.6$  for N tumor ( $P = 0.036$ ); for E-cadherin, they were  $13.62 \pm 2.3$  for M tumor and  $40.17 \pm 3.91$  for N tumor ( $P = 0.018$ ); A significant negative relationship was observed between S100A4 mRNA and E-cadherin expression ( $P = 0.034$ ). These results above indicates that ESCC metastasis is associated with significantly decreased expression of E-cadherin and increased S100A4 expression.

### S100A4 and E-cadherin expression in EC109 and TE13 cell lines

Western blotting (Figure 2A) and RT-PCR (Figure 2B) analysis shown the levels of S100A4 were significantly

**Figure 1 S100A4 and E-cadherin expression in metastasis and non-metastasis tissue.** A: The representative reverse transcription-polymerase chain reaction (RT-PCR) and Western blotting results for S100A4 and E-cadherin in metastasis tissue; B: The representative RT-PCR and Western blotting results for S100A4 and E-cadherin in non-metastasis tissue; C and D: Levels of transcripts of S100A4 and E-cadherin in M tumor samples in comparison to N tumor (expressed as transcript copy number per 50 µg of messenger RNA and standardized with β-actin). The intensity of each band relative to the glyceraldehyde-3-phosphate dehydrogenase (GAPDH) (α-tubulin) band was represented as the mean ± SD, <sup>a</sup>*P* < 0.05 vs metastasis group and <sup>b</sup>*P* < 0.05 vs non-metastasis group.

**Figure 2 Analysis for S100A4 and E-cadherin in EC109 and TE13 cell lines.** A: Western blotting analysis for S100A4 and E-cadherin in EC109 and TE13 cell lines; B: Reverse transcription-polymerase chain reaction analysis for S100A4 and E-cadherin in EC109 and TE13 cell lines. The levels of S100A4 were significantly higher in EC109 cells than that of in TE13 cells, and the levels of E-cadherin were significantly lower in EC109 cells than that of in TE13 cells.

higher in EC109 cells than that of in TE13 cells, and the levels of E-cadherin were significantly lower in EC109 cells than that of in TE13 cells. IHC analysis shown the same result as Western blotting and RT-PCR (data not shown).

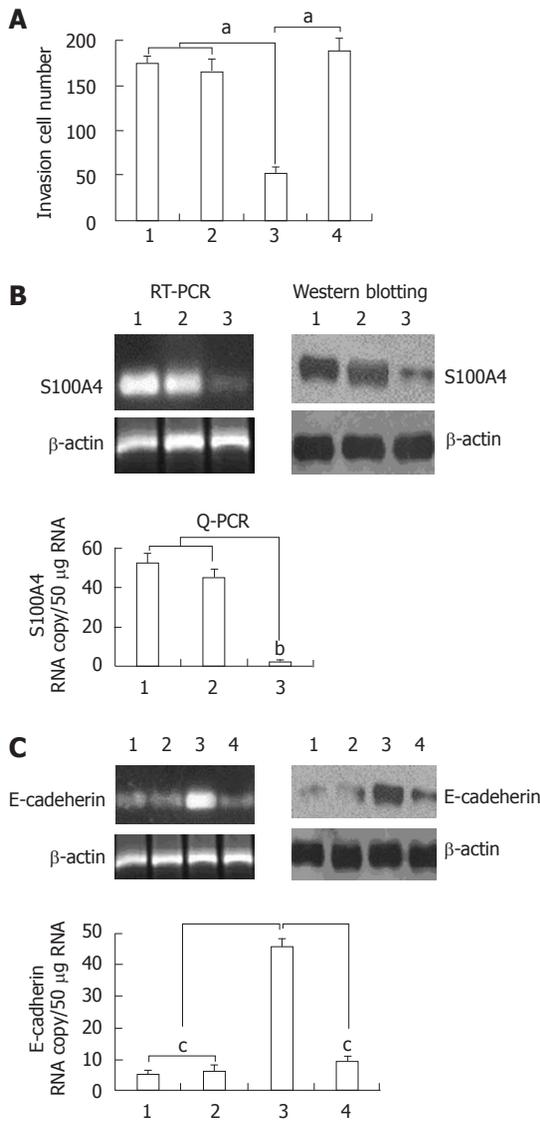

**Knockdown of S100A4 inhibits invasion in EC109 cell by upregulation of E-cadherin**

S100A4 has been implicated in the malignant phenotype of tumor cells, including cell motility, however the bio-

logical function is hardly known. Many studies found that S100A4-induced invasiveness in malignant tumor cells is caused or partially caused by down-regulation of E-cadherin<sup>[24-29]</sup>. Kwak *et al*<sup>[30]</sup> has reported there was no significant association between S100A4 and clinicopathological parameters such as tumor differentiation or TNM stage, and also no correlation between the reactivity and E-cadherin. In the present study, we found that knockdown of S100A4 inhibited invasion in EC109 cells, followed by increased E-cadherin expression in EC109 cells. As shown in Figure 3A, suppression of the S100A4 caused a over 60% reduction (*P* < 0.05) in the number of cells that traversed the membrane versus nonsilencing control or mock control in EC109 cells. Western blotting, RT-PCR and Q-PCR analysis shown E-cadherin mRNA and protein expression was upregulated when the S100A4 expression was knockdown (Figure 3B). When the stable transfectants (S100A4 siRNA) were transfected with S100A4 cDNA for 48h, S100A4 expression was observed to be very high 48 h after transfection (data not shown) to restore the expression of S100A4 in the stable transfected EC109 cells, only to find significantly increased invasion ability in EC109 cells (Figure 3A) followed by the downregulation of E-cadherin expression (Figure 3C). These data suggest that knockdown of S100A4 suppressed the invasion ability of human EC109 cells by upregulation of E-cadherin expression.

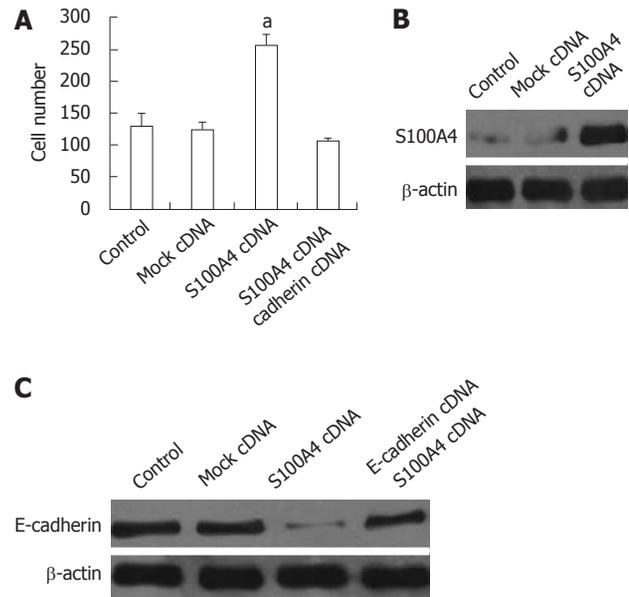

**Overexpression of S100A4 promotes invasion in TE-13 cell by downregulation of E-cadherin**

TE-13 cells stably transfected with pMD-S100A4 cDNA plasmid displayed a significantly increased S100A4 expression as compared with vector control. The overexpression of S100A4 was confirmed by performing Western

**Figure 3 Knockdown of S100A4 inhibits invasive capability of EC109 cells.** A: Transmigration cells of control, mock siRNA, S100A4 siRNA and S100A4 siRNA + S100A4 cDNA cells was calculated from three independent experiments. The indicated cells ( $1 \times 10^4$ ) were seeded on 8-mm porous transwell chambers. After 24 h of plating, transmigration cells were fixed and stained with crystal violet. Transmigration cells were counted for each of the indicated cells. Columns, mean number of cells obtained in three independent experiments; bars, SD; <sup>a</sup> $P < 0.05$  vs control or mock siRNA group; B: Western blotting, reverse transcription-polymerase chain reaction (RT-PCR) and quantitative real time PCR (Q-PCR) analysis for S100A4 and mRNA and protein expression, <sup>b</sup> $P < 0.05$  vs control or mock siRNA group; C: Western blotting, RT-PCR and Q-PCR analysis for E-cadherin and mRNA and protein expression. <sup>c</sup> $P < 0.05$  vs S100A4 siRNA group. 1: Control; 2: Mock siRNA; 3: S100A4 siRNA; 4: S100A4 siRNA + E-cadherin siRNA.

blotting analysis (Figure 4B). We analyzed the effect of S100A4 overexpression on the invasive ability of TE13 cells. As shown in Figure 4A, overexpression of S100A4 significantly increased the number of invasive cells ( $P < 0.05$ ), followed by the downregulation of E-cadherin (Figure 4C). However, when the stable transfectants (pMD-S100A4 cDNA plasmid) were transfected with pMD-E-cadherin cDNA for 48 h [E-cadherin expression was observed to be very high 48 h after transfection (data not shown)] to restore the expression of E-cadherin in the stable transfected TE-13 cells, only to find significantly

**Figure 4 S100A4 overexpression promotes invasive capability of TE13 cells.** A: Transmigration cells of control, mock cDNA, S100A4 cDNA and S100A4 cDNA + E-cadherin cDNA cells was calculated from three independent experiments. The indicated cells ( $1 \times 10^4$ ) were seeded on 8-mm porous transwell chambers. After 24 h of plating, transmigration cells were fixed and stained with crystal violet. Transmigration cells were counted for each of the indicated cells. Columns, mean number of cells obtained in three independent experiments; bars, SD; <sup>a</sup> $P < 0.05$  vs other 3 groups respectively; B: Western blotting, analysis for S100A4 protein expression; C: Western blotting analysis for E-cadherin protein expression.

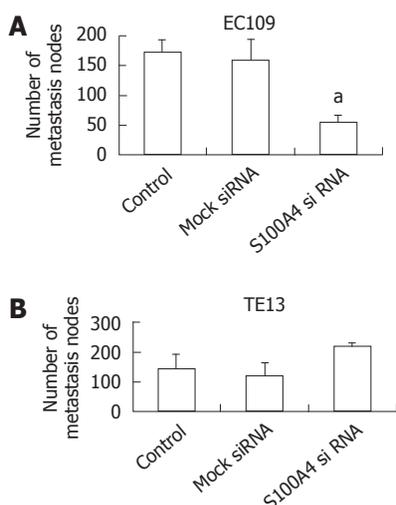

decreased invasion ability in the TE-13 cells (pMD-S100A4 cDNA plasmid-transfected) (Figure 4A). These data suggest that the *S100A4* gene controls the invasion ability of human TE-13 cells by regulation of E-cadherin. These data further support our hypothesis that S100A4 confers the invasive characteristics to cells during human ESCC development.

**Effect of S100A4 on metastasis in vivo model**

EC109 cells (S100A4 siRNA-transfected) or TE-13 cells (S100A4 cDNA-transfected) and their control cells were injected into the pancreas under the envelope near spleen of nude mice ( $n = 6$  for each variant). Twenty-one days later, the mice were killed, autopsy was carried out to remove organs. The number of the seeded tumor naked in the spleen, liver, pancreas and lung is used for assessment of metastases. Less sleep, liver, pancreas and lung metastasis nodes were found in S100A4 siRNA-transfected groups. The total nodes in S100A4 siRNA-transfected groups was significantly fewer than that of in mock siRNA or control ( $P < 0.01$ ) (Figure 5A). However, more seeded nodes were found in S100A4 cDNA transfected groups than that of in mock cDNA or control groups, although the difference was not significant (Figure 5B).

**DISCUSSION**

Metastasis is a complex cascade of events involving a finely tuned interplay between malignant cells and multiple host factors. The transition from benign tumor growth to

**Figure 5** Knockdown of S100A4 inhibits metastasis of xenograft tumors ( $n = 6$  per group). A: The total metastasis nodes in EC109 tumors ( $^*P < 0.05$  vs control or mock siRNA); B: The metastasis nodes in TE13 tumors.

malignancy is manifested by the ability of tumor cells to traverse tissue barriers and invade surrounding tissues<sup>[31]</sup>. Among a multitude of factors playing a role, the small calcium-binding protein S100A4 has been found to add to the invasive and metastatic capacity of cancer cells<sup>[32,33]</sup>. Recent studies have shown S100A4 is up-regulated in many types of epithelial cancers, including esophageal squamous cell<sup>[17-20]</sup>. S100A4S plays an important role in tumor progression and invasion. However, the exact molecular function or mechanism by which S100A4 exerts its putative metastasis-promoting effects has not been fully elucidated, and the protein is most likely involved in several aspects of tumor progression<sup>[34,35]</sup>.

EMT is a crucial process during morphogenesis of multi-cellular organisms. EMT not only is a normal developmental process but also plays a role in tumor invasion and metastasis<sup>[36]</sup>. Currently, EMT is thought to be a key step for cancer metastasis<sup>[37]</sup>. One of the key features of EMT is the down-regulation of the expression of the cell adhesion molecule E-cadherin, a critical event in tumor invasion. Many reports have found E-cadherin expression was significantly reduced in ESCCs, and lower expression of E-cadherin followed by increased lymph node metastasis and poor procession<sup>[2,38-40]</sup>. Several studies have recently described a direct interaction and/or reciprocal influence between S100A4 and E-cadherin<sup>[24-30]</sup>.

In the present study, we found that expression of S100A4 was significantly associated with nodal metastasis in ESCC. The ESCC tissue with a high S100A4 expression had a weak E-cadherin expression, and the expression of S100A4 was significantly associated with decreased E-cadherin. It is suggested S100A4 promotes migration and invasion may correlate with the downregulation of E-cadherin expression.

Several studies found knockdown of S100A4 inhibits invasion and proliferation in carcinoma cells, and overexpression of S100A4 promotes invasion and proliferation<sup>[41-44]</sup>. To test the significance of S100A4 expression

in ESCC, we transfected the S100A4 siRNA into EC109 cells to knockdown of S100A4. After transfection, the invasive ability of EC109 cells decreased dramatically. Our results were consequent with the resent report<sup>[45]</sup>.

We also observed that *S100A4* gene suppression significantly increased the expression of E-cadherin. When we restored the expression of S100A4 in the stable transfected EC109 cells, only to find significantly increased invasion ability in EC109 cells followed by the downregulation of E-cadherin expression. To prove that overexpression of S100A4 promotes invasion again, the TE-13 cells (less S100A4 expression) was transfected with S100A4 cDNA, only to find significantly increased the invasion ability of TE-13 cells, followed by the downregulation of E-cadherin. However, when the S100A4 cDNA transfected TE13 cells were transfected with E-cadherin cDNA to restore the expression of E-cadherin in the TE-13 cells, only to find significantly decreased invasion ability in the TE-13 cells. These data suggest that the *S100A4* gene controls the invasion ability of ESCC by regulation of E-cadherin.

*In vivo*, we found S100A4 knockdown can synergistically reduce the metastatic burden using a EC109 pseudometastatic model in immunodeficient mice, and the effects reached statistical significance. We also observed that overexpression of S100A4 increased the metastatic burden in a TE13 pseudometastatic model.

In summary, we demonstrated that the *S100A4* gene controls invasion ability of human ESCC cells through the regulation of *E-cadherin* gene. We suggest that control of invasion and metastasis through suppression of the *S100A4* gene may contribute to a novel therapeutic approach against ESCC. This approach could be realized through development of specific S100A4 inhibitors or use of a gene therapy approach.

## COMMENTS

### Background

Esophagus squamous cell carcinoma (ESCC) is one of the most deadly malignances because of its high frequency of metastasis. S100A4 possesses a wide range of biological functions, such as regulation of angiogenesis, cell survival, motility and invasion. In the study, the authors explored a potential role of S100A4 in ESCC metastasis.

### Research frontiers

S100A4 was overexpressed or silenced by S100A4 siRNA in TE-13 or Eca-109 cells *in vitro* and *in vivo*, and to explore the influence of S100A4 on esophageal cancer invasion and metastasis.

### Innovations and breakthroughs

It has reported S100A4 may play an important role in promoting metastasis and the early step of tumorigenesis of human cancers. Furthermore, S100A4 silencing could suppress invasion and metastasis in many cancer cells.

### Applications

S100A4 may be involved in ESCC progression, RNA interference (RNAi) targeting S100A4 is a potential therapeutic method for human ESCCs.

### Terminology

S100A4, also known as mts1, p9Ka, FSP1, CAPL, calvasculin, pEL98, metastasin, 18A2, and 42A, was cloned in the 1980s and early 1990s from various cell systems. S100A4 is localized in the nucleus, cytoplasm, and extracellular space and possesses a wide range of biological functions, such as regulation of angiogenesis, cell survival, motility and invasion.

**Peer review**

The study investigates the role of S100A4 oncoprotein in esophageal cancer samples and cell lines. The study clearly shows that the oncoprotein mediates tumor invasion by down-regulating CDH1.

### Abstract

**AIM:** To investigate whether high-fat-feeding is associated with increased intestinal permeability *via* alterations in bile acid metabolism.

**METHODS:** Male C57Bl/6J mice were fed on a high-fat ( $n = 26$ ) or low-fat diet ( $n = 24$ ) for 15 wk. Intestinal permeability was measured from duodenum, jejunum, ileum and colon in an Ussing chamber system using 4 kDa FITC-labeled dextran as an indicator. Fecal bile acids were analyzed with gas chromatography. Segments of jejunum and colon were analyzed for the expression of farnesoid X receptor (FXR) and tumor necrosis factor (TNF).

**RESULTS:** Intestinal permeability was significantly increased by high-fat feeding in jejunum (median 0.334 for control *vs* 0.393 for high-fat,  $P = 0.03$ ) and colon (0.335 for control *vs* 0.433 for high-fat,  $P = 0.01$ ), but not in duodenum or ileum. The concentration of nearly all identified bile acids was significantly increased by high-fat feeding ( $P < 0.001$ ). The proportion of ursodeoxycholic acid (UDCA) in all bile acids was decreased

( $1.4\% \pm 0.1\%$  in high-fat *vs*  $2.8\% \pm 0.3\%$  in controls,  $P < 0.01$ ) and correlated inversely with intestinal permeability ( $r = -0.72$ ,  $P = 0.01$ ). High-fat feeding also increased jejunal FXR expression, as well as TNF expression along the intestine, especially in the colon.

**CONCLUSION:** High-fat-feeding increased intestinal permeability, perhaps by a mechanism related to bile acid metabolism, namely a decreased proportion of fecal UDCA and increased FXR expression.

### INTRODUCTION

Intestinal permeability is a term for the paracellular and transcellular translocation of large molecules foreign to the body. Paracellular permeability is mediated by tight-junction proteins, which prevent uncontrolled transport through the epithelium<sup>[1]</sup>. Deterioration of tight-junction proteins may permit translocation of bacterial lipopolysaccharides into the serum, i.e., endotoxemia, which may then cause inflammation. In obesity, low-grade inflammation is a risk factor for type 2 diabetes and cardiovascular diseases<sup>[2,3]</sup>. Impaired gut barrier function is related to several disease states such as steatohepatitis, fatty liver dis-

ease and diabetes<sup>[4,6]</sup>. Furthermore, it may form the link between obesity and its related disorders<sup>[7-12]</sup>.

High dietary fat content may in part lead to barrier dysfunction, supported by cross-sectional data indicating that a diet high in energy and fat is associated with endotoxemia<sup>[13]</sup>. Dietary fat affects bile acid metabolism, because the absorption of fat requires an increase in bile flow. Consequently, a high-fat diet elevates the fecal concentration of bile acids<sup>[14,15]</sup>. In mice, an orally fed secondary bile acid deoxycholic acid (DCA) induces intestinal inflammation<sup>[16]</sup>, and *in vitro* bile acids provoke permeability of intestinal cell monolayers<sup>[17,18]</sup>. In contrast, the most hydrophilic bile acid, ursodeoxycholic acid (UDCA), may counteract increased intestinal permeability<sup>[19]</sup>.

Proteins involved in bile acid absorption are mediated by the intestinal farnesoid X receptor (FXR), also known as the bile acid receptor, which is highly expressed in intestinal and liver tissues<sup>[20]</sup>. Mice deficient in FXR show compromised barrier function and localization of neutrophils in their intestinal villi<sup>[21]</sup>.

The aim of this study was to investigate whether high-fat feeding is associated with increased intestinal permeability *via* alterations in bile acid metabolism.

## MATERIALS AND METHODS

### Animals

Male C57Bl/6 mice were obtained from Charles River (Sulzfeld, Germany) and acclimatized for a week prior to the experiment. At 6 wk of age, they were randomized into two groups equal in weight: High-fat ( $n = 26$ ; 60E% fat, D12492; Research Diets, New Brunswick, NJ, United States) and control ( $n = 24$ ; 10E% fat, D12450B; Research Diets). Diets were paired for fiber and protein content. Mice were housed six per cage in a standard animal laboratory with a dark/light cycle of 12/12 h, with free access to food and water. After 15 wk of feeding, mice were euthanized with a gas mixture of CO<sub>2</sub> (70%) and O<sub>2</sub> (30%) (AGA, Riihimäki, Finland), and cervical dislocation. Animal experiments were approved by the National Animal Experiment Board of Finland.

### Intestinal permeability measurements

Fresh segments of duodenum, jejunum, ileum and proximal colon were collected in duplicate, opened along the mesenteric border, pinned onto 0.3 cm<sup>2</sup> sliders and mounted into an EasyMount Ussing chamber system with a voltage-clamp apparatus (Physiologic Instruments, San Diego, CA, United States). Two intestinal segments were collected in duplicate from each mouse, because only four chambers were available. Tissues were surrounded by 5 mL Ringer solution (120 mmol/L NaCl, 5 mmol/L KCl, 25 mmol/L NaHCO<sub>3</sub>, 1.8 mmol/L Na<sub>2</sub>HPO<sub>4</sub>, 0.2 mmol/L NaH<sub>2</sub>PO<sub>4</sub>, 1.25 mmol/L CaCl<sub>2</sub>, 1 mmol/L MgSO<sub>4</sub>, 10 mmol/L glucose) on each side. The system was water-jacketed to 37 °C and carbonated with a carbogen (95% O<sub>2</sub>, 5% CO<sub>2</sub>; AGA) gas flow. After an equilibration period of 10 min, solutions were replaced with fresh Ringer, and 4 kDa FITC-dextran (TdB Cons, Uppsala, Sweden) was added

to the luminal side to a final concentration of 2.2 mg/mL. Resistance and short-circuit current were followed for 60 min, after which, serosal fluorescence was detected with a Wallac Victor<sup>2</sup> 1420 Multilabel counter (Perkin-Elmer, Waltham, MA, United States). Intestinal permeability was determined by comparing serosal fluorescence to luminal fluorescence as per mille of translocated dextran.

### Fecal bile acid analysis

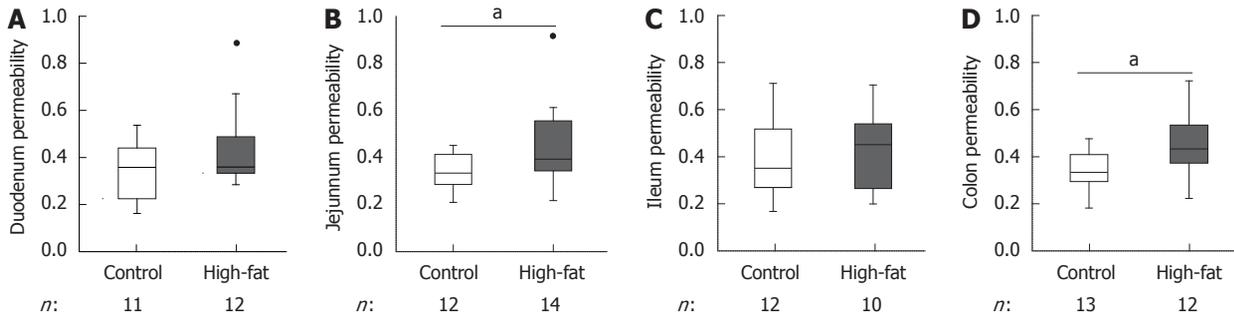

Feces were collected at 13 wk by placing mice individually in metabolic cages for 24 h. Feed and water was provided *ad libitum*. Feces were carefully separated from all other material and frozen at -20 °C. Upon analysis, feces of six mice from each group were dried overnight with nitrogen and pulverized. Bile acids were extracted and measured by gas-liquid chromatography according to the method by Grundy *et al*<sup>[22]</sup> in the laboratory of the Hospital District of Helsinki and Uusimaa. Internal standards were run for isolithocholic acid, lithocholic acid, epideoxycholic acid, DCA, chenodeoxycholic acid, cholic acid and UDCA.

### Farnesoid X receptor and tumor necrosis factor expression assays

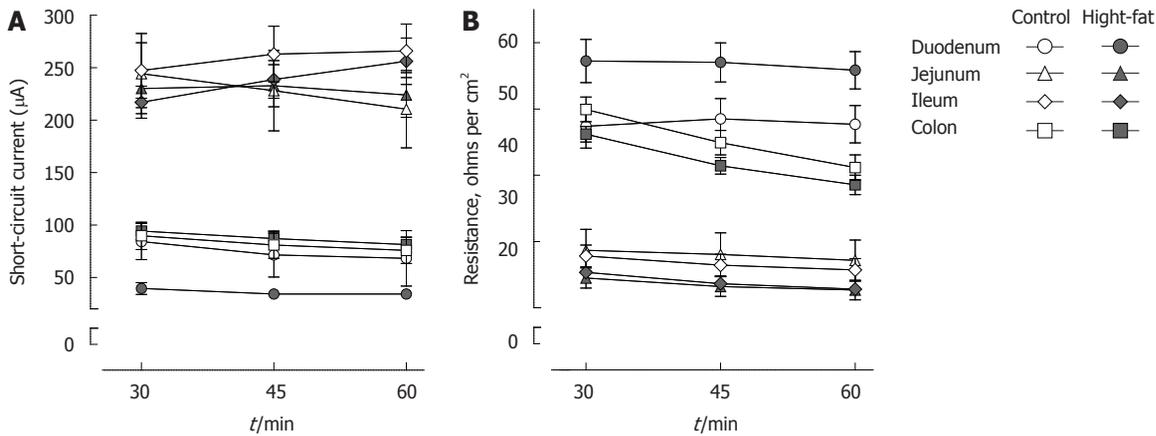

Segments of jejunum were collected from each mouse, snap frozen in liquid nitrogen, and stored at -80 °C. RNA was extracted with TRI Reagent (RT111; Molecular Research Center, Cincinnati, OH, United States) according to the manufacturer's protocol. Tissues were homogenized with Precellus24 (6500 rpm, 2 × 15 s; Bertin Technologies, Montigny-le-Bretonneux, France). Phase separation was performed with chloroform (34 854; Sigma-Aldrich, St Louis, MO, United States), and RNA precipitation with isopropanol (P/7507/15X, Fisher Scientific, United States). RNA concentration was measured with NanoDrop 8000 (Thermo Scientific, Waltham, MA, United States), and converted to cDNA with a SuperScript VILO cDNA synthesis kit (Applied Biosystems, Carlsbad, CA, United States) according to the manufacturer's instructions, using 1 µg RNA in a reaction volume of 20 µL. Reactions for quantitative real time polymerase chain reaction (qPCR) were run using TaqMan chemistry (Applied Biosystems) for FXR (Mm00436420\_m1) and tumor necrosis factor (TNF) (Mm00443258\_m1). Gene expression was normalized to beta-actin and beta-glucuronidase. Reactions were run on a CFX96 real-time PCR detection system (Bio-Rad, Hercules, CA, United States) in triplicate. Skeletal muscle was used as a non-expressing negative control. Gene expression was calculated with Bio-Rad CFX Manager software using the normalized expression  $\Delta\Delta C(t)$  method.

### Statistical analysis

Permeability results were statistically analyzed with a Mann-Whitney *U* test due to the uneven distribution of values around the means. In addition to calculating intestinal permeability for each segment (duodenum, jejunum, ileum and colon), a value for overall intestinal permeability was calculated for each mouse as an average of the permeability in its two measured intestinal segments. Bile acid and gene expression data were analyzed with a *t* test

**Figure 1** Effect of high-fat-feeding on intestinal permeability. Intestinal permeability in duodenum (A), jejunum (B), ileum (C), and colon (D) of high-fat-fed vs control mice. Permeability was measured in an Ussing chamber. Results are shown as per mille translocated dextran. Box plots show median, upper and lower quartiles, and Tukey's whiskers (highest and lowest values, outliers shown as black dots). <sup>a</sup>*P* < 0.05 between high-fat and control.

**Figure 2** Stability of Ussing chamber experiments. Short-circuit current (A) and resistance (B) in Ussing chamber experiments. Bars indicate mean and SEM. *n* = 9-15/group.

between control and high-fat groups. As there was a special focus on UDCA, the concentration of this bile acid relative to total identified bile acids was also calculated. The gene expression data had a setting of four groups, characterized by two factors possibly affecting intestinal FXR and TNF expression: intestinal segment and diet. The independent effects of these two factors were statistically analyzed with a factorial experiment. Groups were also compared with each other individually for both intestinal segments with a *t* test. Equality of variances was tested with Levene's test. All statistical analyses were performed with PASW Statistics version 18.0.2 (IBM, United States). All data are expressed as mean ± SE unless otherwise stated.

## RESULTS

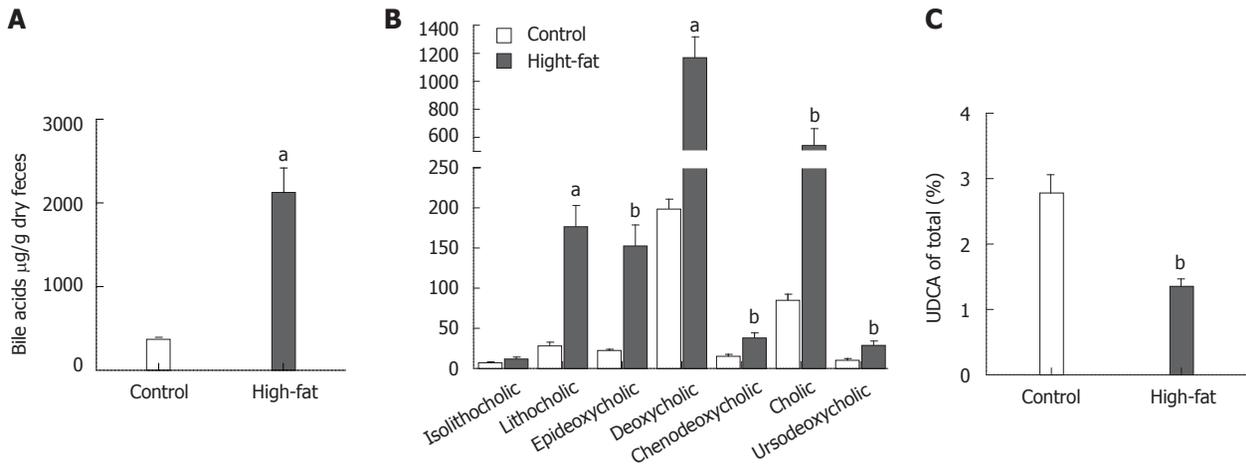

### Intestinal permeability

The weight of the high-fat-fed mice was significantly higher compared to control mice (49.5 ± 0.59 g *vs* 28.6 ± 0.36 g, *P* < 0.001). High-fat-feeding increased intestinal permeability significantly in the jejunum (median 0.334 per mille translocated dextran for control *vs* 0.393 for high-fat, *P* = 0.03) and colon (median 0.335 for control *vs* 0.433 for high-fat, *P* = 0.01), but not in the duodenum (median 0.359 for control *vs* 0.360 for high-fat, *P* = 0.33) or ileum (median 0.351 for control *vs* 0.452 for high-fat,

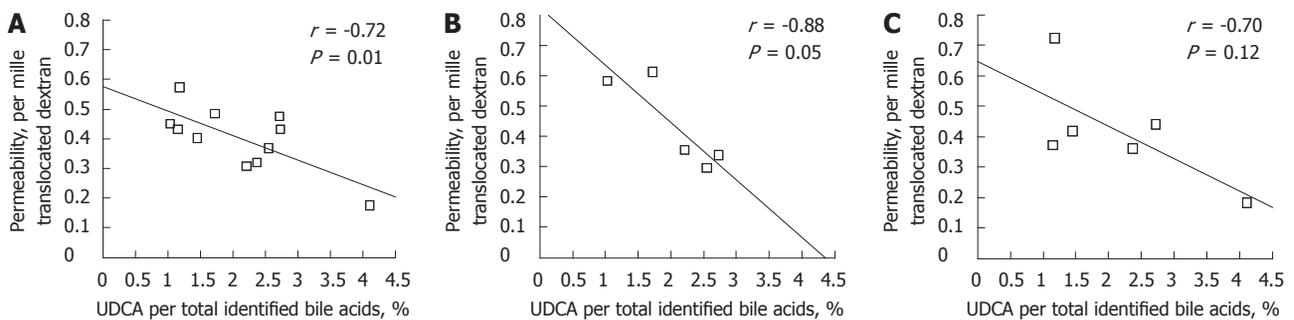

*P* = 0.69, Figure 1). Resistance and short-circuit current were measured during the Ussing chamber experiments to monitor tissue viability. The stability of these values indicates good viability of tissue segments throughout the experiments (Figure 2).

### Fecal bile acids

Feces from high-fat fed mice contained substantially more bile acids compared to feces from control mice (2.13 ± 0.29 mg/g dry feces *vs* 0.37 ± 0.03 mg/g dry feces, *P* < 0.001; Figure 3A). This was reflected as a significantly elevated concentration of each bile acid (*P* < 0.01) except isolithocholic acid (Figure 3B). We were especially interested in the effects of UDCA, which is considered cytoprotective, therefore, we calculated the ratio of UDCA to total bile acids. The proportion of UDCA in feces of high-fat-fed mice was nearly halved compared to that in control mice (1.4% ± 0.1% in high-fat *vs* 2.8% ± 0.3% in controls, *P* < 0.01, Figure 3C). There was also a marked inverse correlation of overall intestinal permeability to the proportion of UDCA in total fecal bile acids (*r* = -0.72, *P* = 0.01, *n* = 11, Figure 4A). The correlation remained significant even after controlling for body weight (partial correlation *r* = -0.64, *P* < 0.05, *n* = 11). A trend for a similar association was seen in the subgroups of jejunal and colonic permeability (*r* = -0.88, *P* = 0.05, *n* = 5 for jejunum and *r* = -0.70, *P* = 0.12, *n* = 6 for colon, Fig-

**Figure 3 Fecal bile acids.** A: Concentration of total measured bile acids; B: Concentration of measured bile acids in feces; C: Proportion of ursodeoxycholic acid (UDCA) in total measured bile acids. Bars indicate mean and SEM.  $n = 6/\text{group}$ ,  $^aP < 0.001$ ,  $^bP < 0.01$  between high-fat and control groups.

**Figure 4 Correlation of proportion of ursodeoxycholic acid with intestinal permeability.** Pearson's correlation of fecal proportion of ursodeoxycholic acid (UDCA) percentage to overall permeability of intestine (A), jejunal permeability (B), and colonic permeability (C). Each dot represents an individual animal.

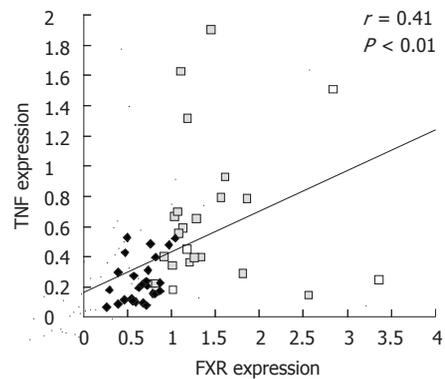

Table 1 Gene expression of farnesoid X receptor and tumor necrosis factor (mean $\pm$ SEM)					
	Control		High-fat		P value
	n	expression	n	expression	
FXR					
Jejunum	14	0.57 $\pm$ 0.051	12	0.74 $\pm$ 0.049	0.03
Colon	10	1.36 $\pm$ 0.234	14	1.49 $\pm$ 0.159	0.63
TNF					
Jejunum	14	0.21 $\pm$ 0.041	12	0.27 $\pm$ 0.040	0.30
Colon	10	0.42 $\pm$ 0.068	14	0.82 $\pm$ 0.148	0.02

FXR: Farnesoid X receptor; TNF: Tumor necrosis factor.

ure 4B and C). In addition, we correlated permeability to the ratio of UDCA to DCA, a cytotoxic bile acid. This was done to prevent bias by the unmeasured muricholic acid, which is a primary bile acid present in murine bile<sup>[23]</sup>, and is left unidentified by methods designed for clinical use. The relation of UDCA to DCA showed a similar halved concentration and inverse correlation to permeability ( $r = -0.70$ ,  $P = 0.02$ ).

### Intestinal farnesoid X receptor and tumor necrosis factor expression

The effect of high-fat-feeding on bile acid metabolism and

**Figure 5 Correlation of tumor necrosis factor and farnesoid X receptor expression.** Pearson's correlation of tumor necrosis factor (TNF) and farnesoid X receptor (FXR) expression. Jejunal values are shown as black diamonds and colonic values as grey squares. Each dot represents an individual animal.

intestinal inflammation was assayed as expression of intestinal FXR and TNF in the jejunum and colon. Jejunal FXR expression was increased 30% by high-fat feeding ( $0.74 \pm 0.049$  for high-fat *vs*  $0.57 \pm 0.051$  for control,  $P = 0.03$ ) and colonic TNF expression was doubled ( $0.82 \pm 0.148$  for high-fat *vs*  $0.42 \pm 0.068$  for control,  $P = 0.02$ ) but no significant differences were seen in jejunal tumor necrosis factor (TNF) ( $P = 0.30$ ) or colonic FXR ( $P = 0.63$ ,

Table 1). FXR and TNF expressions did, however, correlate with each other ( $r = 0.41$ ,  $P < 0.01$ ,  $n = 50$ , Figure 5).

A factorial experiment on the independent effects of diet and intestinal segment on gene expression revealed that overall intestinal TNF expression was elevated by high-fat-feeding ( $P = 0.02$ ). Moreover, both TNF and FXR expressions were higher in colon compared to jejunum ( $P < 0.001$  for both).

## DISCUSSION

The objective of this study was to see whether intestinal permeability was increased by high-fat-feeding *via* a mechanism related to bile acid metabolism. These data showed that permeability of jejunum and colon in high-fat-fed mice was increased. The animals were clearly obese solely due to dietary fat content (60E%), and not by genetic modification. Our results on increased permeability are supported by a similar previous study, which investigated the effects of obesity and a high-fat diet on rat intestinal permeability<sup>[12]</sup>. Also a carbohydrate-free diet containing an extremely high amount of fat (72E%) increased intestinal permeability in mice<sup>[9]</sup>. Our 60E% diet may be considered more physiologically relevant compared to carbohydrate-free diets. We also took care to pair the diets in protein and fiber content. Therefore, the barrier dysfunction in high-fat-feeding was not biased by any fiber-mediated effect. There is no conclusion on whether gut permeability may be affected by obesity alone, without modifications in diet composition<sup>[7,12]</sup>.

In the present study, we found that, in addition to increased fecal bile acid content, high-fat feeding also modulated fecal bile acid profile. Bile acids and bile juice are known to impair barrier function in enterocyte monolayers *in vitro*<sup>[12,17,18]</sup>, as well as recovery from tissue damage *ex vivo*<sup>[24]</sup>, and are elevated in serum of high-fat-fed rats<sup>[12]</sup>. Our data indicate that high-fat-feeding modifies gut permeability by a mechanism related to bile acids, as previously hypothesized<sup>[12]</sup>.

This is, to the best of our knowledge, the first study to show that high-fat-induced intestinal barrier dysfunction is related to increased intestinal FXR expression. Inagaki *et al.*<sup>[21]</sup> have shown in a FXR knockout mouse model that FXR is involved in tight junction integrity. It is unclear, however, what role FXR plays in the pathogenesis of high-fat-induced barrier dysfunction.

Both fecal bile acids and intestinal TNF expression were elevated by high-fat-feeding in the present study. Bile acids are linked to inflammatory pathways, because DCA is able to stimulate the nuclear factor- $\kappa$ B route<sup>[25]</sup>, which regulates TNF expression. A correlation between bile acids and TNF was not observed in our small set of fecal samples. Intestinal FXR and TNF were, however, correlated, which may reflect a link between intestinal bile acid concentration and inflammation. Incubation of jejunum in DCA (0.3 mmol/L) increased prostaglandin E2 in the supernatant, thus indicating a possible role for inflammation in increasing intestinal permeability (data not shown). Orally fed DCA induces intestinal inflammation

in mice<sup>[6]</sup>, which further supports the hypothesis that inflammation is involved in the pathogenesis of gut barrier dysfunction. In this study, we observed increased TNF expression in the intestine. TNF is known to increase intestinal permeability *in vitro*<sup>[26-29]</sup>, and anti-TNF antibodies restore barrier function *in vivo*<sup>[30,31]</sup>. However, these data do not permit us to draw conclusions on whether increased TNF expression, in this study, was a cause or a secondary event in increased intestinal permeability.

We observed a halved proportion of UDCA in fecal bile acids of high-fat-fed mice. Moreover, this proportion of UDCA correlated with increased permeability, even when controlled for body weight. These data suggest a barrier protective effect for UDCA in our study. Our results are in agreement with previous reports showing that, as a hydrophilic bile acid, UDCA does not increase epithelial permeability *in vitro* in comparison to other bile acids<sup>[18]</sup>. On the contrary, it is capable of counteracting intestinal barrier dysfunction<sup>[19]</sup>, protecting against chemically induced colitis<sup>[19,32,33]</sup> and colitis-associated adenocarcinoma<sup>[34]</sup> in rodents. Its role may be especially relevant in comparison to DCA, because UDCA protects mitochondria against DCA-induced reactive oxygen species production<sup>[35]</sup>. It may thus be suggested that, in addition to total bile acid concentration, the bile acid profile is relevant regarding bile-acid-related functions in the intestine.

Intestinal permeability was measured *ex vivo* with the Ussing chamber as the translocation of large dextrans. This direct method is more representative of intestinal permeability than the often used transepithelial resistance and tight-junction protein analysis. Furthermore, the Ussing chamber allows measurement of permeability from selected tissue segments, unlike direct *in vivo* methods.

The 4 kDa FITC-dextrans used here are generally believed to translocate through the paracellular spaces, although there are no reports to confirm this. Permeability to FITC-dextrans does, however, correlate with a decrease in tight-junction protein expression<sup>[10]</sup>. It has also been proposed that translocation of lipopolysaccharides occurs transcellularly *via* chylomicrons<sup>[36]</sup>. The methods used in the present study do not distinguish between these two pathways. Their importance in intestinal permeability needs further elucidation.

We evaluated modifications of bile acid metabolism by analyzing fecal bile acids. It must be noted that fecal bile acids only reflect alterations of bile acid metabolism, and this method does not allow us to draw conclusions about liver bile acid metabolism or bile composition. It is, however, an estimate of colonic bile acid concentrations.

In conclusion, high-fat feeding increases permeability in the jejunum and colon, elevates fecal bile acid concentration, and induces intestinal inflammation in mice. Alterations in bile acid homeostasis, namely UDCA synthesis and intestinal FXR expression, may relate to increased intestinal permeability. Our results show that alterations in bile acid metabolism may be associated with intestinal permeability and should be studied as a possible target in affecting the onset of barrier dysfunction.

## ACKNOWLEDGMENTS

We are grateful to Hanna Laurikainen for help with the Ussing chamber experiments. We are grateful to Professor Eero Mervaala, MD, and Professor (emeritus) Heikki Vapaatalo, MD, for critical discussion. We are grateful to Leena Kaipainen for analysis of bile acids. We are grateful to statistician Tuija Poussa for statistical advice.

## COMMENTS

### Background

Intestinal permeability has recently been linked to type 2 diabetes, steatosis and steatohepatitis. One proposed cause for increased permeability is a diet high in fat. A high-fat-diet increases excretion of bile. Secondary bile acids are known to increase permeability of epithelial monolayers *in vitro*. However, physiological concentrations of bile juice obtained from healthy rats have failed to increase epithelial monolayer permeability. This may be due to the fact that bile consists of a profile of several bile acids, which differ in cytotoxicity. It has not yet been addressed whether high-fat feeding alters the profile of fecal bile acids, and whether this profile plays a role in the onset of barrier dysfunction.

### Research frontiers

Proposed mechanisms for the dietary induction of increased intestinal permeability have mostly been related to alterations in gut microbiota. Only a few publications have mentioned other luminal factors affecting permeability. The research hotspot in this field is how diet modifies bile acid metabolism and leads to increased intestinal permeability.

### Innovations and breakthroughs

Although bile is considered detrimental to the gut epithelium, physiological concentrations have not increased epithelial monolayer permeability. We show that not only was bile excretion increased by high-fat feeding, but the profile of fecal bile acids had become more cytotoxic than in healthy control mice. The proportion of a hydrophilic bile acid, ursodeoxycholic acid (UDCA), was decreased by high-fat feeding and correlated inversely with intestinal permeability.

### Applications

The prevention of barrier dysfunction may decrease the risk of its associated diseases. The present results suggest that bile acid metabolism is a potential target for the prevention of a barrier dysfunction.

### Terminology

Intestinal permeability refers to how large molecules, such as inflammatory bacterial components, translocate through the intestinal epithelium into the circulation. Translocation may be paracellular, through tight-junction proteins, or transcellular, via chylomicrons. UDCA is a hydrophilic bile acid. Deoxycholic acid is a secondary bile acid produced from cholic acid by intestinal microbes.

### Peer review

The authors tested intestinal permeability in an *ex vivo* model (Ussing chambers; mucosal to serosal flux of FITC-labeled dextran) in mice on a high-fat diet; moreover, analysis of fecal bile acids and expression of mucosal tumor necrosis factor and farnesoid X receptor was performed.

### Abstract

**AIM:** To investigate the effect of drinking sulphate-bicarbonate-calcium thermal water (TW) on risk factors for atherosclerosis and cholesterol gallstone disease.

**METHODS:** Postmenopausal women with functional dyspepsia and/or constipation underwent a 12 d cycle of thermal ( $n = 20$ ) or tap ( $n = 20$ ) water controlled drinking. Gallbladder fasting volume at ultrasound, blood vitamin E, oxysterols (7- $\beta$ -hydroxycholesterol and 7-ketocholesterol), bile acid (BA), triglycerides, total/low density lipoprotein and high density lipoprotein cholesterol were measured at baseline and at the end of the study. Food consumption, stool frequency and body weight were recorded daily.

**RESULTS:** Blood lipids, oxysterols and vitamin E were not affected by either thermal or tap water consumption. Fasting gallbladder volume was significantly ( $P < 0.005$ ) smaller at the end of the study than at baseline in the TW ( $15.7 \pm 1.1$  mL vs  $20.1 \pm 1.7$  mL) but not in the tap water group ( $19.0 \pm 1.4$  mL vs  $19.4 \pm 1.5$  mL). Total serum BA concentration was significantly ( $P < 0.05$ ) higher at the end of the study than at baseline in the TW ( $5.83 \pm 1.24$   $\mu$ mol vs  $4.25 \pm 1.00$   $\mu$ mol) but not in the tap water group ( $3.41 \pm 0.46$   $\mu$ mol vs  $2.91 \pm 0.56$   $\mu$ mol). The increased BA concentration after TW consumption was mainly accounted for by glycochenodeoxycholic acid. The number of pasta ( $P < 0.001$ ), meat ( $P < 0.001$ ) and vegetable ( $P < 0.005$ ) portions consumed during the study and of bowel movements per day ( $P < 0.05$ ) were significantly higher in the TW than in the tap water group. Body weight did not change at the end of the study as compared to baseline in both groups.

**CONCLUSION:** Sulphate-bicarbonate-calcium water consumption has a positive effect on lithogenic risk and intestinal transit and allows maintenance of a stable body weight despite a high food intake.

## INTRODUCTION

Atherosclerosis, coledithiasis and obesity are very frequent and interrelated diseases among postmenopausal women<sup>[1-4]</sup>.

High serum triglycerides and total/low-density lipoprotein (LDL) cholesterol are important risk factors for atherosclerosis, heart attack and stroke<sup>[5]</sup>. Also oxidative stress, particularly the oxidation of LDL, plays a key role in atherogenesis due to the production of reactive oxygen species. New markers based on the detection of lipid peroxidation products by mass spectroscopy, such as oxysterols including 7- $\beta$ -hydroxycholesterol and 7-ketocholesterol, are specific, sensitive and reliable markers of systemic oxidative stress *in vivo*<sup>[6-8]</sup>. In addition, oxysterol coupled to vitamin E measurement in plasma can be used for estimating systemic oxidant stress/antioxidant balance<sup>[8]</sup>.

Cholesterol gallstone disease is very common in postmenopausal women, with incidence ranging from 22% to 30% in Western countries, and this disorder is one of the most common and costly of all digestive diseases<sup>[3]</sup>. Cholesterol gallstone pathogenesis is complex and multifactorial, involving genetic defects and environmental factors<sup>[9-11]</sup>. Changes in bile acid (BA), cholesterol and triglyceride metabolism, gallbladder reduced function and prolonged colonic transit time are critical factors in the pathogenesis of gallstones<sup>[12-15]</sup>.

Obesity and overweight are risk factors for both atherosclerosis and gallstone disease<sup>[16]</sup>. Some data suggest that body weight reduction can be achieved by acceleration of intestinal transit in humans and by BA feeding in animals<sup>[17-21]</sup>.

Thermal water (TW) consumption has been shown to ameliorate blood cholesterol patterns and systemic oxidative stress, and reduce oro-fecal transit time and gallbladder fasting volume<sup>[22-26]</sup>. No data are available on the effect of TW on BA pool composition and plasma oxysterols.

In the present study, we investigated in postmenopausal women the effect of drinking sulphate-bicarbonate-calcium TW on blood cholesterol, triglycerides, oxysterols, vitamin E and BA, and on gallbladder fasting volume, intestinal transit rate and body weight.

## MATERIALS AND METHODS

### Patients

The study protocol was approved by the Ethics Commit-

tee of the University of Rome Sapienza and informed written consent was obtained from all patients.

Forty postmenopausal (at least 1 year) women with functional dyspepsia and/or constipation participated in this study. Patients were divided into 2 groups: (1) TW group were 20 patients enrolled by the medical staff of Chianciano thermal centre (Tuscany, Italy); (2) control (CTRL) group were 20 patients enrolled by the medical staff of the Gastroenterology Division of Department of Clinical Medicine at the Sapienza University (Rome, Italy). Diagnosis of functional dyspepsia and/or constipation was made based on the Roma III criteria<sup>[27,28]</sup>.

Exclusion criteria were a history of liver, pancreatic, gallbladder (including sonographic evidence of gallstones) or other gastrointestinal diseases, lipid disorders, diabetes, severe high blood pressure (diastolic > 110 mmHg, systolic > 180 mmHg), cancer, surgical resection, and thyroid, neurological, muscular, rheumatological and immunological diseases. Patients were also excluded if they were heavy drinkers, heavy smokers or habitual drinkers of more than 3 cups of espresso coffee every day. Individuals enrolled were not receiving estrogen replacement therapy or any medication known to affect lipid metabolism, and were not taking vitamin, mineral, or phytoestrogen supplements. Participants had not consumed diets intended to cause weight loss within 1 year of selection.

Between 8 and 9 a.m. on days 1 and 13 after an overnight fast and before drinking water, all enrolled patients underwent blood sampling and abdominal ultrasonography, and they had daily body weight measurements, according to international standards, using a digital scale that was calibrated, having a capacity of up to 150 kg<sup>[29]</sup>.

Patients in the TW group underwent a 12 d cycle of TW treatment by drinking 500 mL of "Acqua Santa of Chianciano Terme" sulphate-bicarbonate-calcium water, at a temperature of 33 °C, every day in the morning in the fasted state, over a 30 min period. The control group drank Rome tap water at a temperature of 10-12 °C using the same schedule. The chemical composition of the "Acqua Santa of Chianciano Terme" sulphate-bicarbonate-calcium water and of the Rome tap water is reported in Table 1. Each day of the study all patients filled a stool diary<sup>[30]</sup> and a food and beverage frequency daily diary which asked for the number of portions consumed for the following items: Pasta, pizza, meat, fish, vegetables, bread, desserts, soft drinks, fruits, milk, dairy products, legumes and espresso coffee.

### Gallbladder volume and blood analyses

Fasting gallbladder volume was calculated by using the ellipsoid formula on the average of 2 sonographical gallbladder measurements<sup>[31]</sup>.

Plasma and serum were stored at -80 °C. Plasma levels of  $\alpha$ -tocopherol were analyzed by high performance liquid chromatography (HPLC), and 7- $\beta$ -hydroxycholesterol and 7-ketocholesterol were measured from the same sample by mass spectrometry using an isotope dilution method<sup>[8]</sup>. Serum triglycerides, total and high-density lipoprotein (HDL) cholesterol were measured by a colorimetric

**Table 1** Chemical composition of the sulphate-bicarbonate-calcium thermal water and of the Rome tap water, as consumed by the thermal water and by the control group, respectively

	Thermal water (TW)	Tap water (CTRL)

method. LDL cholesterol was calculated according to the Friedewald Formula<sup>[32]</sup>.

BA standards were obtained from Sigma Aldrich (St. Louis, United States). Total serum BA concentration was determined enzymatically by the 3 $\alpha$ -hydroxysteroid-dehydrogenase assay (Stereognost 3a, Pho, Nycomed, AS, Torsoy, Norway). The qualitative and quantitative BA composition was assessed by an HPLC-electrospray-mass spectrometry method, as previously reported with a slight modification<sup>[33]</sup>. Isolute C18 cartridges were obtained from International Sorbent Technology LTD (Hengoed, United Kingdom). The solid phase extraction cartridge was conditioned with 5 mL of methyl alcohol and 5 mL of water prior to the sample loading. Serum samples were diluted 1:6 (v/v) with 0.1 N solution of NaOH and heated to 64 °C for 30 min. Afterwards, the serum sample was loaded on the conditioned cartridge and then washed with 10 mL of water. The cartridge was then eluted with 5 mL of methyl alcohol. The eluate was dried under vacuum and then reconstituted with the mobile phase (70:30 v/v ammonium acetate buffer/acetonitrile) and injected into the HPLC-electrospray-mass spectrometry instru-

ment. The recovery of all BAs ranged from 80% to 96%. The chromatographic system consisted of a Waters Alliance 2695 HPLC system. The separation was obtained using a 150 mm × 2.00 mm, 4 µm Phenomenex Sinergy Hydro-RP C18 column with a mobile phase consisting of 15 mmol ammonium acetate buffer (pH 5)/acetonitrile. The mobile phase was delivered at a flow rate of 0.150 mL/min, with a total HPLC-electrospray-mass spectrometry run time of 30 min. Mass spectra were obtained with a Quattro LC mass spectrometer (Micromass, United Kingdom) equipped with electrospray source. All BA ions were monitored in a negative mode by the Multiple Reaction Monitoring mode. A seven point calibration curve, ranging from blank to 10 µmol was prepared by spiking BA-free serum with the analytes for serum analysis. Quantification of the analytes in the sample was performed on the peak area, by external calibration. The inter-assay precision and accuracy were determined by analyzing three calibration curves with quality control samples at one-concentration level (1 µmol) on 2 d. The value for the coefficient of variation (%) near the limit of detection was 1%-2%.

### Statistical analysis

Analysis of data was carried out using the “Statistical Package for Social Sciences (SPSS) for Windows (SPSS version 17.0, Chicago, IL, United States). Data are reported as mean ± SE. Intergroup differences between categorical variables were estimated by the  $\chi^2$  test. The non-parametric Kolmogorov-Smirnov test was used to verify the normal distribution of the continuous variables data set. When the data set was normally distributed, the Student *t* test for coupled or uncoupled data was used as appropriate. When the data set was not normally distributed, the variables were analyzed by the Mann-Whitney *U*-test and by the Wilcoxon test as appropriate. A significant level of 0.05 (*P* < 0.05) was chosen to assess the statistical significance.

## RESULTS

### Patient characteristics at enrollment

No intergroup difference was found in terms of age, weight, height, body mass index (BMI) and diagnosis (Table 2). Eight patients in each group had constipation either alone or associated with dyspepsia.

### Blood cholesterol, triglycerides, oxysterols and vitamin E

As shown in Table 3, we did not find any intergroup (TW vs CTRL) difference in serum levels of total, HDL and LDL cholesterol and triglycerides. Plasma 7- $\beta$ -hydroxycholesterol, 7-ketocholesterol,  $\alpha$ -tocopherol,  $\gamma$ -tocopherol and oxysterol to tocopherol ratio, both at baseline and at the end of the study, did not differ between the TW and the CTRL group. In addition, no change in blood lipids or oxidative stress was found at the end of treatment with respect to baseline when each group was considered separately.

Table 3 Serum lipids and plasma markers of oxidative stress in the thermal water and in the control groups

	TW		CTRL	
	Baseline	End	Baseline	End
Total cholesterol (mg/dL)	178.7 ± 5.8	182.4 ± 6.3	181.5 ± 7.6	177.4 ± 6.5
HDL cholesterol (mg/dL)	62.3 ± 4.7	63.7 ± 4.7	56.7 ± 5.0	59.4 ± 6.1

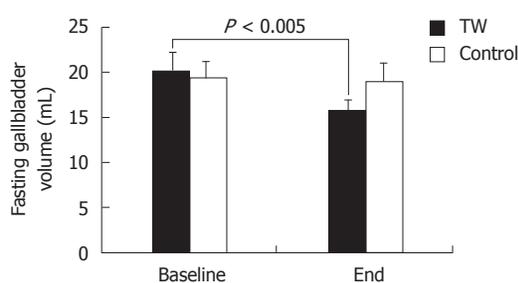

Figure 1 Fasting gallbladder volume at baseline and at the end of the study in the thermal water and in the control group. TW: Thermal water.

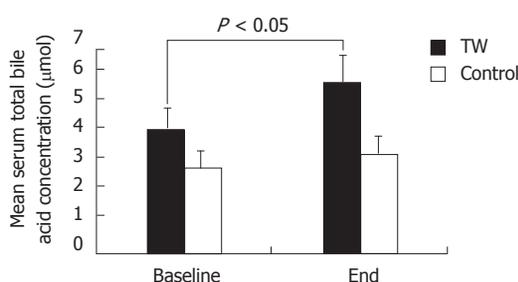

Figure 2 Mean serum total bile acid concentration at baseline and at the end of the study in the thermal water and in the control group. TW: Thermal water.

### Gallbladder volume and serum bile acids

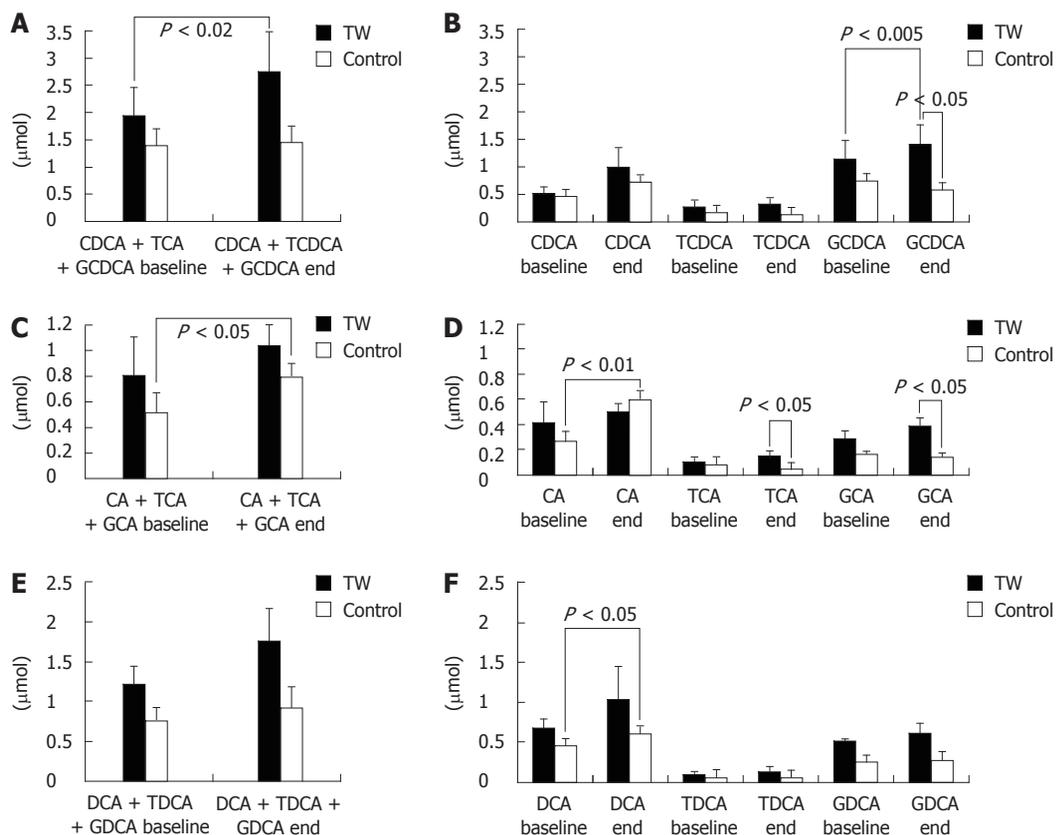

As shown in Figure 1, the mean fasting gallbladder volume did not differ between the TW and the CTRL group both at baseline and at the end of the study. Fasting gallbladder volume was significantly ( $P < 0.005$ ) smaller at the end of the study than at baseline in the TW ( $15.7 \pm 1.1$  mL *vs*  $20.1 \pm 1.7$  mL) but not in the CTRL group ( $19.0 \pm 1.4$  mL *vs*  $19.4 \pm 1.5$  mL).

As shown in Figure 2, although there was a trend for higher baseline values in the TW than in the CTRL group, the mean serum total BA concentration did not significantly differ between the TW and the CTRL group both at baseline and at the end of the study. Serum total BA concentration was significantly ( $P < 0.05$ ) higher at the end of the study than at baseline in the TW ( $5.83$

$\pm 1.24$   $\mu\text{mol}$  *vs*  $4.25 \pm 1.00$   $\mu\text{mol}$ ) but not in the CTRL group ( $3.41 \pm 0.46$   $\mu\text{mol}$  *vs*  $2.91 \pm 0.56$   $\mu\text{mol}$ ).

With regard to the serum BA molecular species, as shown in Figure 3, no intergroup difference was found at baseline. At the end of the study however, the TW as compared to the CTRL group had significantly ( $P < 0.05$ ) higher glycochenodeoxycholic acid (GCDCA) ( $1.41 \pm 0.35$   $\mu\text{mol}$  *vs*  $0.59 \pm 0.07$   $\mu\text{mol}$ , respectively), taurocholic acid (TCA) ( $0.15 \pm 0.04$   $\mu\text{mol}$  *vs*  $0.05 \pm 0.02$   $\mu\text{mol}$ , respectively) and glycocholic acid (GCA) ( $0.39 \pm 0.10$   $\mu\text{mol}$  *vs*  $0.14 \pm 0.02$   $\mu\text{mol}$ , respectively). No other intergroup difference was found at the end of the study.

When the BA molecular species serum concentrations were compared separately in each study group at the end of the study with regard to baseline, in the TW group the mean GCDCA concentration at the end of the study was significantly higher ( $P < 0.005$ ) than at baseline ( $1.41 \pm 0.85$   $\mu\text{mol}$  *vs*  $1.15 \pm 0.35$   $\mu\text{mol}$ ). On the contrary, in the CTRL group there was a trend ( $P = 0.062$ ) for a lower GCDCA concentration at the end with respect to baseline ( $0.59 \pm 0.07$   $\mu\text{mol}$  *vs*  $0.75 \pm 0.21$   $\mu\text{mol}$ ). The mean free cholic acid (CA) concentration was significantly ( $P < 0.01$ ) higher at the end of the study than at baseline in the CTRL ( $0.60 \pm 0.14$   $\mu\text{mol}$  *vs*  $0.27 \pm 0.09$   $\mu\text{mol}$ ) but not in the TW group ( $0.50 \pm 0.12$   $\mu\text{mol}$  *vs*  $0.42 \pm 0.18$   $\mu\text{mol}$ ). The mean free deoxycholic acid (DCA) concentration was significantly ( $P < 0.05$ ) higher at the end of the study than at baseline in the CTRL ( $0.60 \pm 0.16$   $\mu\text{mol}$  *vs*  $0.45 \pm 0.13$   $\mu\text{mol}$ ) but not in the TW group ( $1.03 \pm 0.44$   $\mu\text{mol}$  *vs*  $0.67 \pm 0.16$   $\mu\text{mol}$ ). The other BA molecular species did not change at the end as compared to baseline when each group was considered separately. The sum of free chenodeoxycholic acid (CDCA), GCDCA and taurochenodeoxycholic acid was significantly ( $P < 0.02$ ) higher at the end of the study than at baseline in the TW ( $2.75 \pm 0.70$   $\mu\text{mol}$  *vs*  $1.95 \pm 0.58$   $\mu\text{mol}$ ) but not in the CTRL group ( $1.46 \pm 0.20$   $\mu\text{mol}$  *vs*  $1.40 \pm 0.35$   $\mu\text{mol}$ ). The sum of CA, GCA and TCA was significantly ( $P < 0.05$ ) higher at the end of the study than at baseline in the CTRL ( $0.80 \pm 0.14$   $\mu\text{mol}$  *vs*  $0.52 \pm 0.11$   $\mu\text{mol}$ ) but not in the TW group ( $1.04 \pm 0.20$   $\mu\text{mol}$  *vs*  $0.81 \pm 0.27$   $\mu\text{mol}$ ).

**Figure 3** Mean serum bile acid molecular species concentration at baseline and at the end of the study in the thermal water and in the control group. A: Total chenodeoxycholic acid (CDCA); B: Free CDCA, glycochenodeoxycholic acid (GCDCA) and taurochenodeoxycholic acid (TCDCA); C: Total cholic acid (CA); D: Free CA, glycocholic acid (GCA) and taurocholic acid (TCA); E: Total deoxycholic acid (DCA); F: Free DCA, glycodeoxycholic acid (GDCA) and taurodeoxycholic acid (TDCA). TW: Thermal water.

Table 4 Number of food portions consumed by the thermal water and by the control group subjects during the study period			
	TW	Control	P value
Pasta	16.40 ± 1.22	8.80 ± 1.05	< 0.001
Bread	4.32 ± 1.40	8.90 ± 1.57	0.01
Pizza	0.58 ± 0.23	1.01 ± 0.31	NS
Sweets	9.57 ± 1.87	7.08 ± 1.02	NS
Soft drinks	4.82 ± 1.40	4.30 ± 1.59	NS
Fruits	17.60 ± 1.69	14.59 ± 2.24	NS
Meat	11.52 ± 1.00	5.90 ± 0.51	< 0.001
Fish	4.05 ± 0.75	3.20 ± 0.38	NS
Milk	6.00 ± 1.21	6.89 ± 0.87	NS
Dairy products	6.32 ± 1.23	4.04 ± 0.50	NS
Legumes	0.98 ± 0.36	0.84 ± 0.23	NS
Vegetables	22.80 ± 2.40	13.51 ± 1.08	0.002

TW: Thermal water.

**Meal consumption, bowel movements and body weight**

As shown in Table 4, the number of pasta ( $P < 0.001$ ), meat ( $P < 0.001$ ) and vegetable ( $P < 0.005$ ) portions consumed during the study period was significantly higher by approximately two-fold in the TW than in the CTRL group, while bread consumption was significantly ( $P < 0.05$ ) less frequent, being half the amount in the TW than in the CTRL group. No intergroup difference was found with regard to pizza, dessert, soft drink, fruit, fish, milk,

dairy product, legume and coffee espresso consumption.

During the study period, the TW group had a significantly ( $P < 0.05$ ) higher number of bowel movements per day than the CTRL group ( $1.077 \pm 0.057$  vs  $0.893 \pm 0.055$ , respectively). Body weight did not differ between the TW and the CTRL group both at baseline ( $64.4 \pm 2.4$  kg vs  $61.1 \pm 1.5$  kg, respectively) and at the end of the study ( $64.3 \pm 2.4$  kg vs  $61.3 \pm 1.4$  kg, respectively). In addition, no change in body weight was found at the end of the study with respect to baseline when each group was considered separately.

**DISCUSSION**

The main finding of the present study is that 12 d of sulphate-bicarbonate-calcium TW, but not tap water, administration to gallstone-free postmenopausal women with functional dyspepsia and/or constipation is associated with a reduction of fasting gallbladder volume and an increase in fasting serum BA concentration, especially GCDCA. The effects of sulphate-bicarbonate-calcium TW administration on fasting gallbladder volume and serum BA that we found can be considered protective from gallstone development. In fact, a relatively high fasting gallbladder volume, indicative of a gallbladder motility defect, has been shown to be associated with gallstones. Conversely, a beneficial effect of preserved gallbladder

motility on gallstone recurrence has been demonstrated after extracorporeal shock-wave lithotripsy<sup>[14,34-36]</sup>.

Since CDCA molar percent in serum has been shown to correlate with that in gallbladder bile, the increased concentration of serum GCDCA (the major form of CDCA in humans) that we found after sulphate-bicarbonate-calcium TW administration is likely to reflect bile enrichment with this BA<sup>[37,38]</sup>. Although a direct measurement of the qualitative and quantitative BA composition in bile is the best predictor of gallstone risk, our findings in serum suggest that sulphate-bicarbonate-calcium TW administration can be considered protective from gallstone development. In fact, it has been shown that cholesterol gallstone patients have a lower CDCA and a higher DCA content in gallbladder bile than gallstone-free controls<sup>[39]</sup>. In addition, pharmacological CDCA administration has been used as a litholytic/preventive treatment against gallstones and ameliorates cholesterol solubility in BA<sup>[40]</sup>.

The beneficial effect of sulphate-bicarbonate-calcium TW administration on gallbladder motility has been already demonstrated, but the underlying mechanisms are not clear<sup>[41]</sup>. The effect of sulphate-bicarbonate-calcium TW consumption on the BA pool has never been shown previously and our present data do not allow the clarification of the mechanisms. In fact, limitations of the present study are the lack of measurements of intestinal transit time and of BA hepatic synthesis and fecal losses. However, as indirectly suggested by the higher frequency of bowel movements that we found in the TW than in the CTRL group, it can be hypothesized that TW consumption accelerates intestinal transit. This change in intestinal transit is in agreement with the increased fecal scour score described in pigs ingesting a high mineral sulphated water<sup>[42]</sup> and should be secondary to an osmotic mechanism, although the warm temperature of the TW could also play a role<sup>[41]</sup>. The acceleration of intestinal transit, as well as the improved gallbladder motility, are likely to increase the frequency of BA enterohepatic circulation and fecal losses with a secondary stimulation of primary BA (especially CDCA) hepatic synthesis. The increased frequency of BA enterohepatic circulation and the enrichment of the BA pool with CDCA could then further accelerate colonic transit. The latter hypothesis is in agreement with previously published data showing: (1) a positive correlation between the rate of BA synthesis and colonic transit (the higher the synthesis the faster colonic transit)<sup>[43]</sup>; (2) a positive correlation between serum CDCA and intestinal transit (the higher the concentration the faster intestinal transit)<sup>[14]</sup>; and (3) that CDCA administration accelerates colonic transit in healthy volunteers and in female patients with constipation-predominant irritable bowel syndrome<sup>[43,44]</sup>. The second finding of the present study is that body weight and blood total, HDL and LDL cholesterol, triglycerides, oxysterols and vitamin E were not affected by 12 d of either sulphate-bicarbonate-calcium or tap water consumption. Interestingly, we found that the TW, as compared to the CTRL

group, showed a doubling of frequency of pasta, meat and vegetable consumption during the study period suggesting that drinking sulphate-bicarbonate-calcium TW allows maintenance of stable body weight and blood cardiovascular risk factors under conditions of overfeeding. Again, our present study does not allow clarification of the mechanisms for this unexpected finding. In fact, other than the lack of characterization of BA enterohepatic circulation, we did not assess gastric emptying and energy expenditure. However, the increased food intake in our TW group could be explained by an increased gastrointestinal emptying and more frequent BA enterohepatic circulation, with GCDCA enrichment. In agreement with this hypothesis, both the ingestion of a high mineral sulphated water in pigs<sup>[42]</sup> and the administration of CDCA in humans have been shown to increase food consumption. Furthermore, the increased serum BA concentration that we found during sulphate-bicarbonate-calcium TW consumption could directly avert weight gain, despite increased food consumption. In fact, serum BAs have been recognized as important modulators of whole-body metabolism, by increasing energy expenditure in brown adipose tissue and in muscles, through promotion of intracellular thyroid hormone activation secondary to the activation of the TGR5-signaling pathway<sup>[21]</sup>.

In conclusion, sulphate-bicarbonate-calcium TW consumption in postmenopausal women with functional dyspepsia and/or constipation has a positive effect on the lithogenic risk and intestinal transit and allows maintenance of a stable body weight despite a high food intake. Further studies are needed to confirm these effects of TW in asymptomatic subjects and to prove its potential benefit in weight loss treatments.

## COMMENTS

### Background

Atherosclerosis, gallstones and obesity are very frequent and interrelated diseases, with a very high socioeconomic impact worldwide. High triglycerides, total/low-density lipoprotein cholesterol and increased oxidative stress in blood are important risk factors for atherosclerosis and cardiovascular diseases. In addition to cholesterol and triglyceride metabolism, bile acid (BA) metabolism, gallbladder motility and intestinal motility are critical factors in the pathogenesis of gallstones. Obesity and overweight are risk factors for both atherosclerosis and gallstone disease.

### Research frontiers

Thermal water (TW), and especially sulphate-bicarbonate mineral waters, are used to treat several biliary and digestive tract diseases. In the present study, The authors investigated the effect of drinking sulphate-bicarbonate-calcium TW on risk factors for: (1) atherosclerosis (i.e., cholesterol, triglycerides and markers of oxidative stress in blood); (2) gallstones (i.e., BAs in blood, gallbladder and intestinal motility); and (3) diet and body weight.

### Innovations and breakthroughs

TW drinking has been shown to ameliorate intestinal and gallbladder motility and blood cholesterol and oxidative stress markers. However, in previous studies oxidative stress was evaluated by using methods with poor physiological significance *in vivo*. No data are available on the effect of TW on BA metabolism and body weight. In the present study, for the first time we investigated the effect of drinking sulphate-bicarbonate-calcium TW on BA metabolism and body weight. In addition, the authors evaluated the effect of drinking sulphate-bicarbonate-calcium TW on oxidative stress by measuring sensitive and specific markers of enhanced oxidant stress *in vivo*, such as oxysterols, or antioxidant defense by measuring  $\alpha$ -tocopherol.

### Applications

The results suggest that sulphate-bicarbonate-calcium water consumption has a positive effect on the risk of gallstone development and allows maintenance of a stable atherosclerosis risk and body weight despite a high food intake. This study might be useful in preparation of preventive strategies for atherosclerosis and gallstones in overweight and obese subjects.

### Terminology

Oxysterols are oxidation products of cholesterol, and among them 7- $\beta$ -hydroxycholesterol and 7-ketocholesterol are produced nonenzymatically via a free radical-mediated mechanism and, thus, are very good markers of oxidant stress *in vivo*. BAs are steroid acids found predominantly in the bile and, in lower concentrations, in serum of mammals. Besides their well-established roles in lipid absorption and homeostasis and cholesterol biliary solubilization, BAs also act as metabolically active signaling molecules.

### Peer review

The study is of particular interest to those involved in practical medicine. The authors' data might be used for the prevention of atherosclerosis development and gallstone disease in postmenopausal women and probably for the treatment of these diseases.

### Abstract

**AIM:** To evaluate the results of duodenal stenting for palliation of gastroduodenal malignant obstruction by using a gastric outlet obstruction score (GOOS).

**METHODS:** A prospective, non-randomized study was performed at a tertiary center between August 2005 and April 2010. Patients were eligible if they had malignant gastric outlet obstruction (GOO) and were not candidates for surgical treatment. Medical history and patient demographics were collected at baseline. Scheduled interviews were made on the day of the procedure and 15, 30, 90 and 180 d later or unscheduled as necessary.

**RESULTS:** Fifteen patients (6 male, 9 female; median age 61 years) with GOO who had undergone duodenal stenting were evaluated. Ten patients had metastasis

at baseline (66.6%) and 14 were unable to accept oral intake (93.33%), including 7 patients who were using a feeding tube. Laboratory data showed biliary obstruction in eight cases (53.33%); all were submitted to biliary drainage. Two patients developed obstructive symptoms due to tumor ingrowth after 30 d and another due to tumor overgrowth after 180 d. Two cases of stent migration occurred. A good response to treatment was observed, with a mean time of approximately 1 d (19 h) until toleration of a liquid diet and slightly more than 2 d for both soft solids (51 h) and a solid food/normal diet (55 h). The mean time to first failure to maintain liquid intake (GOOS  $\geq$  1) was 93 d. During follow-up, the mean time to first failure to maintain the previously achieved GOOS of 2-3 (solid/semi-solid food), considered technical failure, was 71 d. On the basis of oral intake a GOOS is defined: 0 for no oral intake; 1 for liquids only; 2 for soft solids only; 3 for low-residue or full diet.

**CONCLUSION:** Enteral stenting to alleviate gastroduodenal malignant obstruction improves quality of life in patients with limited life expectancy, which can be evaluated by using a GOO scoring system.

Duodenal stenting for malignant gastric outlet obstruction: Prospective study. *World J Gastroenterol* 2012; 18(9): 938-943 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i9/938.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i9.938>

## INTRODUCTION

Gastroduodenal strictures may be caused by malignant diseases of the stomach, pancreas and duodenum or by the mass effect of lymphonodal metastasis. Curative resections may not be possible in about 40% of such gastric lesions and in up to 80%-95% of pancreatic lesions, which makes clear the need to develop alternative means to achieve palliation and thus a better quality of life<sup>[1-3]</sup>.

The use of self-expandable metal stents (SEMS) for treatment of gastroduodenal malignancy as a surgical alternative for palliation in patients with high morbidity and limited life expectancy is a feasible, safe and effective method<sup>[4-7]</sup>.

In this study, we aimed to analyze the usefulness of a gastric outlet obstruction score to assess results of duodenal stenting for palliation of gastroduodenal malignant obstruction.

## MATERIALS AND METHODS

A prospective, non-randomized study was performed at a tertiary care center between August 2005 and April 2010. Patients over 18 years of age were eligible if they had gastric outlet obstruction (GOO) and were not candidates for surgical treatment due to high morbidity of the procedure, refusal or poor nutritional status. The main exclusion criteria were multiple lesions with enteral stenosis, suspected intestinal ischemia, impossibility of passing a guide-wire, gastric cancer presenting as *limitis plastica*, and contraindication to gastrointestinal endoscopy. All participants signed an informed consent approved by a review board.

Medical history and patient demographics were collected at baseline, and scheduled interviews were made on the day of the procedure and 15 d, 30 d, 90 d and 180 d later or unscheduled as necessary (Table 1). Patients were withdrawn from the study at the end of 180 d or if death occurred before that time.

The stent used was an uncovered SEMS with a 27 mm diameter (22 mm at the mid-body) and length of 60, 90 or 120 mm preloaded in a 10 Fr delivery system (Wallflex, Boston Scientific Corporation, MA, United States) (Figure 1). All of the procedures were conducted under sedation or general anesthesia, under radiologic guidance with iodine contrast.

## RESULTS

Fifteen patients (6 male, 9 female; median age 61 years) were submitted to duodenal stenting. The procedure was carried out under sedation in six cases, and under general anesthesia in nine patients due to poor clinical status. Most patients had metastasis at baseline (66.60%) and no acceptance of oral intake (93.33%), including seven patients who were using a feeding tube. Three patients had a gastric outlet obstruction score (GOOS)  $\geq 1$  (Figure 2).

Laboratory data showed biliary obstruction in 8 cases (53.33%), all of whom were submitted to biliary drainage (50.00% endoscopic and 50.00% surgical).

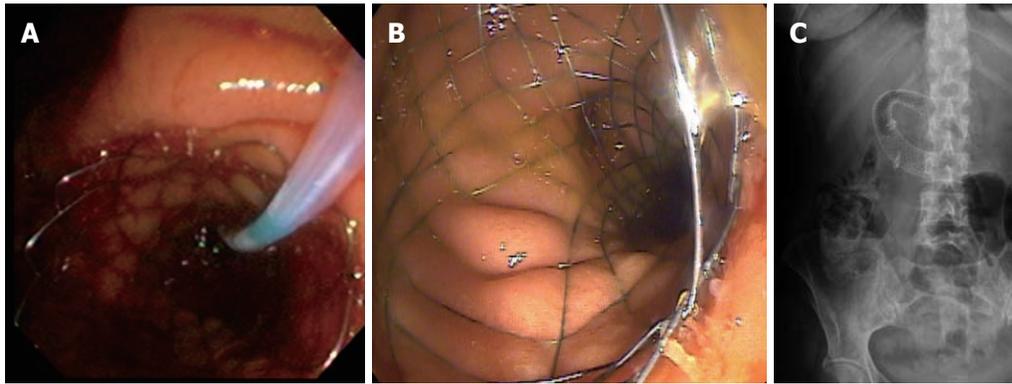

Table 1 Baseline demographic and clinical features of patients

Characteristic	Data (average)
Age (yr)	61.33
Gender	Male (6)/female (9)
Weight (kg)	55.93
Height (m)	1.61
Weight loss (kg)/(mo)	14.53/5.40
Previous chemotherapy/ radiation therapy	Yes (5)/no (10)
Previous biliary drainage	Yes (8)/no (7)
Only local cancer	Yes (5)/no (10)
Malignancy	
Pancreatic adenocarcinoma	9
Gastric adenocarcinoma	3
Cholangiocarcinoma	1
Metastatic disease	2
Location of the obstruction	
Stomach	3
Bulb	7
Second and third portion	5
Tumor extension (cm)	4.93
Biliary stenosis	Bismuth I (2)/bismuth II and III (6)

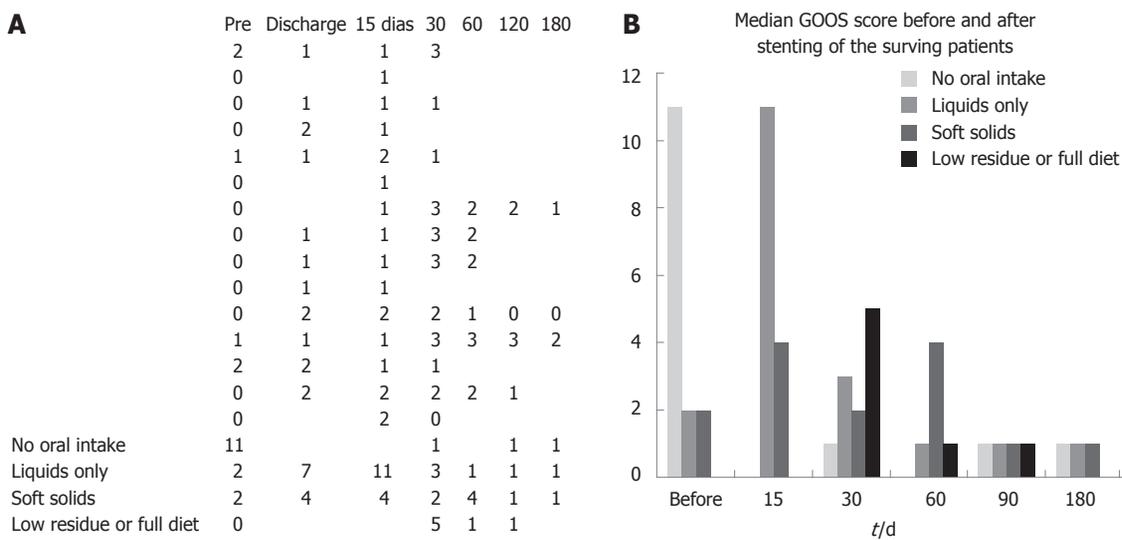

One patient developed obstructive symptoms after 1 mo of stent placement due to tumor ingrowth, which was treated by placing another stent inside the original one, with no recurrence of obstruction. Another patient developed obstructive symptoms after 6 mo due to tumor overgrowth, but it was not possible either to remove the stent or to bridge it because of bleeding and friability. This patient died 9 mo after stent placement.

There were two cases of stent migration. In the first case the patient had a duodenal metastasis from colonic cancer and presented obstructive symptoms after 8 d of stent placement. Two new stents were placed inside the original one, but the patient died 9 d later. The second patient was 53 years old with gastric cancer, liver metastasis and poor nutritional status who developed signs of obstruction within 3 mo after the procedure. Surgical removal of the migrated stent was done without complications and a surgical bypass was performed owing to better nutritional status at that time. One patient was submitted to removal of a foreign body, without complications.

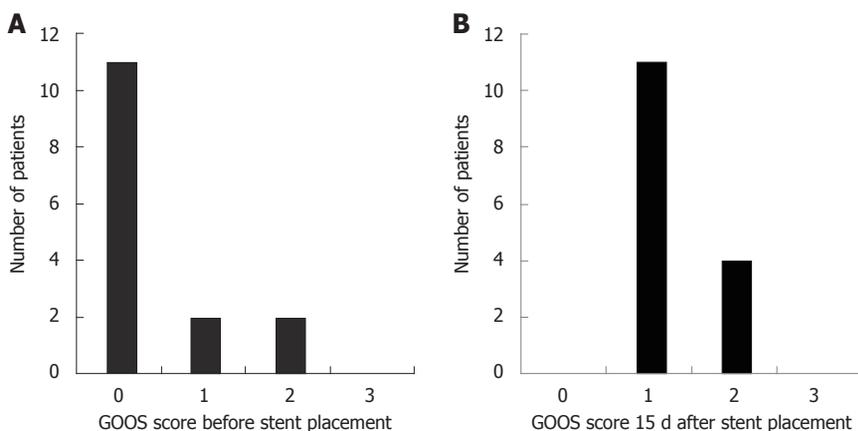

Regarding tolerance to oral diet, a good response to the treatment was observed, with a mean time of approximately 1 d (19 h) till toleration of a liquid diet and slightly more than 2 d for soft solids (51 h) and solid food/normal diet (55 h). These data differ from those of other studies, which showed a faster acceptance of solid food after the procedure, with return to solid food on the same day of the procedure in up to 52% of the cases<sup>[8]</sup>. During the present study, the prescriptions were made by the patients' physicians, mostly surgeons who prescribed liquids on the first day and, if they had good acceptance, prescribed solid food on the second day. The first failure to maintain liquid intake (GOOS  $\geq 1$ ) occurred at a mean of 3.1 mo. During follow-up, the first failure to maintain the previously achieved GOOS of 2-3 (solid/semi-solid food), considered technical failure, occurred at a mean of 2.35 mo (Figure 3).

**Figure 2** Bar graph showing median gastric outlet obstruction scores before the procedure and after 30 d, 60 d, 90 d and 180 d of stenting of the surviving patients.

**Figure 3** Bar graphs showing the gastric outlet obstruction scores. A: Before stent placement; B: 15 d after stent placement.

## DISCUSSION

Patients with gastroduodenal malignancies usually have limited prognosis with low life expectancy and also a poor quality of life due to inability to swallow at least

semi-solid food. Consequently, there is a high incidence of poor nutritional status and dehydration, which reduce the resources that can be used to palliate this scenario<sup>[9,10]</sup>. Surgical treatment has better results on long-term follow-up but it cannot be offered, initially, to patients with poor

clinical status because of increased morbidity and mortality. Based on the fact that less than 40% of patients who require palliative care are fit to undergo a surgical procedure, the need to achieve this objective with a less invasive, safer and effective method has been made clear<sup>[1,8,11]</sup>. The application of stents to the gastrointestinal tract has addressed this need, with attendant advantages of the surgical procedure although with a lesser long-term patency than desirable, mostly because of growth of tumoral tissue through the mesh (tumor ingrowth) or over the stent (tumor overgrowth) leading to recurrence of obstructive symptoms<sup>[7,12,13]</sup>.

In studies of malignancies it is important to assess each patient's quality of life and performance status, and several scales are used for this purpose such as the World Health Organization performance status (WHO status), the standard Short Form-36 questionnaire and the European Organization for Research and Treatment of Cancer scale. In GOO malignancies, however, the ability to ingest food seems to be the most important factor analyzed in terms of quality of life status, with the GOOS system being used most frequently for assessment<sup>[14]</sup>. A retrospective multicenter study enrolling 62 patients and using GOOS to evaluate the clinical success of enteral stenting, stated that all patients had resumed oral intake, although in 14.5% ( $n = 9$ ) there was no improvement in the score. Some patients had a maximum score prior to stenting, and in all of them relief of symptoms was observed<sup>[15]</sup>.

In a recent prospective study of 101 patients with incurable malignancies of the gastric outlet, three independent predictors of survival were identified: the ability to maintain self-care (WHO status), pain score, and the use of morphinomimetics. A 30-d survival rate of below 10% was found for patients who had all three prognostic indicators (WHO status of 3-4, pain score over 83 at baseline, the use of morphinomimetics stronger than tramadol), suggesting that a less invasive treatment should be considered for this group<sup>[1,15]</sup>.

Analysis of each individual's clinical status, associated diseases, and independent predictors of survival may provide objective data in helping to decide between surgical or endoscopic palliation. Patients with better prognosis and greater life expectancy should obtain more benefit from surgical treatment due to higher long-term patency rates, and patients with shorter life expectancy might benefit more from endoscopic treatment, enjoying a better quality of life, a quick return to oral diet, and less morbidity<sup>[16-18]</sup>.

The cost of gastrojejunostomy (GJJ) *vs* stent placement in GOO was compared in a recent randomized trial that considered both direct and indirect costs of the 2 treatments. The study concluded that, although GJJ had a higher total cost, largely due to longer hospital stays, the difference was small and of lesser importance when deciding on the kind of treatment<sup>[17]</sup>.

The choice of stent is also very important for achieving lower complication rates and higher patency leading

to better quality of life. Plastic stents are associated with higher migration (self-expandable plastic stents) and perforation (non-expandable plastic stents) than SEMs, which are used more often<sup>[19-21]</sup>. Metallic stents may be covered by a membrane made of various plastic materials (covered SEMs) which provide greater resistance to tumor ingrowth but they may lose functionality because of higher migration rates in the colon. Uncovered SEMs have lower migration rates because they are anchored by the tumor, but are associated with higher recurrence of symptoms due to tumor ingrowth; nevertheless, they are used more often than covered metallic stents in colon and gastroduodenal malignant obstruction because overall they bring better results<sup>[18,21-25]</sup>.

A recent randomized prospective study comparing the use of covered SEMs *vs* uncovered SEMs and enrolling 40 patients with gastric cancer in each group, demonstrated a higher stent migration rate within 8 weeks of stent placement in the covered SEMs group (25.8%) than in the uncovered SEMs group (2.8%). At the same time, the restenosis rate related to tumor ingrowth was higher in the uncovered SEMs group (25.0%) than in the covered SEMs (0.0%). In that study a routine endoscopy was performed independent of obstruction symptoms, which could explain the higher migration rates<sup>[25]</sup>.

The evaluation of obstructive biliary signs is crucial in patients with gastroduodenal malignant obstruction because there is an association between them in over 61% of cases<sup>[22,25]</sup>. When jaundice is present it is important to perform imaging exams to determine its cause and help in its characterization, such as excluding other causes like liver failure due to metastasis. Obstructive jaundice may be successfully treated by endoscopic procedures, interventional radiology or surgery with comparable results but with higher morbidity and longer hospitalization periods in the case of surgery. Treatment decision should be made based on the clinical status and tumor staging. Biliary endoscopic drainage can be accomplished with the use of plastic or metallic stents, the latter having lower rates of cholangitis and occlusion and shorter hospitalization stays but being more expensive. Both stents are equally effective in maintaining patency during the first 3 mo. If the patient has a short life expectancy, then plastic stents can be used safely and effectively at a lower cost, but they must be changed every 3 to 6 mo or in suspected cases of cholangitis<sup>[22,25-27]</sup>.

In conclusion, gastroduodenal malignancies are associated with gastric outlet obstruction symptoms and consequently with poor quality of life due to incapacity to swallow solid food, intractable nausea and vomiting, post-prandial epigastric tenderness and pain, and usually presenting with poor nutritional and clinical status that limit the options for treatment<sup>[18-20]</sup>. It has been shown that the use of SEMs for gastroduodenal malignancies is a feasible, safe and effective method, especially in those patients with limited life expectancy or in more critical conditions, allowing improvement not only in nutritional status but also in quality of life. SEMs placement may

serve as a bridge to definitive surgical treatment in high-risk patients<sup>[28,29]</sup>, as was conducted in one patient in the present study. We observed a quick return to an oral diet in our cohort after the procedure, and patency was estimated by the clinical efficacy to maintain an oral diet of solid/semi-solid food (GOOS  $\geq$  1), with a mean time to recurrence of obstructive symptoms of 3.1 mo.

The complications regarding the recurrence of symptoms observed in this study in two cases of stent migration, one case of tumor ingrowth and one of tumor overgrowth are similar to those reported in other publications and can be treated with a high success rate in most cases.

The association of GOO symptoms in gastroduodenal malignancies with biliary obstruction was shown in several published studies; therefore, we performed biliary stenting in eight of our patients (53.33%) prior to duodenal stenting. During the follow-up, three biliary stents were changed but there was no need to implant a new stent. In cases of biliary obstruction after duodenal stenting, biliary stents can be placed through the mesh of the duodenal SEMS to successfully palliate this condition.

Most published studies regarding endoscopic treatment of gastroduodenal malignancies have included only a limited number of patients, thus highlighting the need to perform more comparative studies between this method and surgery and to assess the costs involved.

## COMMENTS

### Background

Use of self-expandable metal stents in gastroduodenal malignancy as a surgical alternative for palliation in patients with high morbidity and limited life expectancy is a feasible, safe and effective method, allowing a quick return to oral intake and low morbidity.

### Research frontiers

Cost analyses comparing treatment of gastric outlet obstruction (GOO) malignancies by surgery or endoscopic procedures shows that any difference, considering direct and indirect costs, is small and should not have influence on patient's treatment.

### Innovations and breakthroughs

A prospective, non-randomized study was performed at a tertiary center between August 2005 and April 2010. Patients were eligible if they had GOO and were not candidates for surgical treatment. Medical history and patient demographics were collected at baseline. Scheduled interviews were made on the day of the procedure and 15, 30, 90 and 180 d later or unscheduled as necessary.

### Applications

Assessment of patient's quality of life and performance status is crucial to provide more accurate information on whether the treatment being offered to the patient is satisfactory. Gastric outlet obstruction score (GOOS) system is an important tool to achieve this goal when the ability to ingest food seems to be an important factor to patient's quality of life in GOO malignancies.

### Peer review

This is a good descriptive study in which authors analyze the results of duodenal stenting, by using a GOOS, for palliation of gastroduodenal malignant obstruction.

### Abstract

**AIM:** To investigate the safety and feasibility of our original single-incision laparoscopic cholecystectomy (SILC) for acute inflamed gallbladder (AIG).

**METHODS:** One hundred and ten consecutive patients underwent original SILC for gallbladder disease without any selection criteria and 15 and 11 of these were diagnosed with acute cholecystitis and acute gallstone cholangitis, respectively. A retrospective review was performed not only between SILC for AIG and non-AIG, but also between SILC for AIG and traditional laparoscopic cholecystectomy (TLC) for AIG in the same period.

**RESULTS:** Comparison between SILC for AIG and non-AIG revealed that the operative time was longer in SILC for AIG (97.5 min vs 85.0 min,  $P = 0.03$ ). The open conversion rate (2/26 vs 2/84,  $P = 0.24$ ) and complication rate (1/26 vs 3/84,  $P = 1.00$ ) showed no differences, but a need for additional trocars was more frequent in SILC for AIG (5/24 vs 3/82,  $P = 0.01$ ). Comparison between SILC for AIG and TLC for AIG revealed no differences based on statistical analysis.

**CONCLUSION:** Our original SILC technique was ade-

quately safe and feasible for the treatment of acute cholecystitis and acute gallstone cholangitis.

### INTRODUCTION

Single-incision laparoscopic cholecystectomy (SILC) has recently gained popularity, just as laparoscopic cholecystectomy (LC) became popular in the early 1990s. Although LC was initially established as the treatment of choice for symptomatic cholelithiasis, LC for acute inflammation of the gallbladder (AIG), such as that caused by acute cholecystitis and gallstone cholangitis, was considered to be a contraindication. The complication rate for LC was believed to be higher than that for AIG. Ultimately, LC was accepted as a safe procedure for AIG, when it was performed by an expert in laparoscopic techniques<sup>[1]</sup>. As with LC, SILC for AIG is currently considered to be a contraindication because of its technical difficulty and infancy. SILC is developing, and there are a wide variety of operative techniques. The safety and feasibility of these operative techniques also varies; some are adequate for the treatment of AIG, but others are not. In the near

future, SILC will probably be considered an acceptable treatment and the standard operative technique for AIG, effectively eliminating inappropriate operative techniques.

Here, we report our experience with SILC for AIG and explore the safety and feasibility of our original SILC technique.

## MATERIALS AND METHODS

A total of 110 consecutive patients underwent SILC for gallbladder disease from July 2009 to November 2010, without any selection criteria. Of these 110 patients, 15 and 11 were diagnosed with acute cholecystitis and acute gallstone cholangitis, respectively. We performed both SILC and traditional laparoscopic cholecystectomy (TLC) during the same period. There were four staff surgeons in our department, each of whom operated on or supervised the patients, who came to or were referred to their own outpatient clinics. Two of the four staff surgeons performed our original SILC technique routinely, and the other two performed a traditional four-port technique. All SILC operations were performed by staff surgeons only. However, several TLC procedures were performed by young surgical residents under the supervision of a staff surgeon. A surgical resident was considered eligible for performing TLC only if he/she had 2-6 years of experience in general surgery. Staff surgeons performed TLC in cases with severe inflammation or dense adhesions and in cases in which malignancy was suspected. There was no predesigned patient selection bias between the patients in the SILC and TLC groups.

A diagnosis of acute cholecystitis and the presence of acute cholangitis were determined based on the Tokyo guidelines and criteria for acute cholecystitis and cholangitis, as follows. Patients exhibiting one of the local signs of inflammation, such as a Murphy's sign or a mass, or tenderness in the right upper quadrant, as well as one of the systemic signs of inflammation, such as fever or elevated C-reactive protein (CRP) level, were diagnosed as having acute cholecystitis. Patients in whom suspected clinical findings were confirmed by diagnostic imaging were also diagnosed with acute cholecystitis (Table 1)<sup>[2]</sup>. Patients were classified as grade I (mild), grade II (moderate), or grade III (severe), according to the severity grading of the Tokyo guidelines for acute cholecystitis (Table 1)<sup>[2]</sup>. Acute cholangitis was diagnosed if the clinical manifestations of Charcot's triad, namely, fever and/or chills, abdominal pain (right upper quadrant or epigastric), and jaundice, were present. When not all components of the triad were present, then a definite diagnosis could be made if laboratory and imaging data supported the evidence of inflammation, and biliary obstruction was revealed (Table 2)<sup>[3]</sup>. We diagnosed patients with acute cholangitis due to gallstones and/or debris with gallstone cholangitis. Acute cholangitis patients were also classified as grade I, II or III, according to the severity grading of the Tokyo guidelines for acute cholangitis (Table 2)<sup>[3]</sup>.

The general policy for acute cholecystitis in our department is delayed surgery following medical treatment,

**Table 1** Tokyo guideline diagnostic criteria and severity assessment of acute cholecystitis

Diagnosis criteria
A: Local signs of inflammation
Murphy's sign
Right upper quadrant mass/pain/tenderness
B: Systemic signs of inflammation
Fever
Elevated C-reactive protein
Elevated white blood cell count
C: Imaging findings
Sonographic Murphy sign
Thickened gallbladder wall
Enlarged gallbladder
Pericholecystic fluid collection
Sonolucent layer in the gallbladder wall
Definite diagnosis
One item in A and one in B are positive
C confirms the diagnosis when acute cholecystitis is suspected clinically <sup>1</sup>
Severity assessment
Mild (grade I)
Acute cholecystitis does not meet the criteria of severe (grade III) or moderate (grade II) acute cholecystitis or acute cholecystitis in a healthy patient with no organ dysfunction and mild inflammatory changes in the gallbladder, making cholecystectomy a safe and low risk operative procedure
Moderate (grade II)
Elevated WBC count (> 18 000/mm <sup>3</sup> )
Palpable tender mass in the right upper quadrant
Duration of complains > 72 h <sup>2</sup>
Marked local inflammation (biliary peritonitis, pericholecystic abscess, hepatic abscess, gangrenous cholecystitis, emphysematous cholecystitis)
Severe (grade III)
Acute cholecystitis associated with dysfunction of any one of the following organs/systems
Cardiovascular dysfunction (hypotension requiring treatment with dopamine $\geq$ 5 $\mu$ g/kg per minute, or any dose of dobutamine)
Neurological dysfunction (decreased level of consciousness)
Respiratory dysfunction (PaO <sub>2</sub> /FiO <sub>2</sub> ratio < 300)
Renal dysfunction (oliguria, creatinine > 2.0 mg/dL)
Hepatic dysfunction (PT-INR > 1.5)

<sup>1</sup>Acute hepatitis, other acute abdominal disease, and chronic cholecystitis should be excluded; <sup>2</sup>Laparoscopic surgery should be performed within 96 h of the onset of acute cholecystitis. WBC: White blood cell; PT-INR: Prothrombin time and international normalized ratio.

such as antibiotics or percutaneous cholecystotomy. The general policy for acute gallbladder cholangitis in our department is delayed surgery following medical treatment, with endoscopic stone extraction. The timing of surgery depends upon the extent of inflammation, and we typically perform LC after inflammation has decreased considerably.

The definition of AIG in this study was acute cholecystitis, excluding acalculous cholecystitis; acute cholangitis with gallbladder stones or/and debris; and choledocholithiasis. Even if the patient had concomitant gallstone pancreatitis, we defined the condition simply as acute gallstone cholangitis. We defined the operation for AIG as surgery that was performed within 4 mo of the primary acute inflammation.

We performed magnetic resonance cholangiopancrea-

**Table 2 Tokyo guideline diagnosis criteria and severity assessment of acute cholangitis**

Diagnosis criteria (suspected diagnosis and definite diagnosis)
Severity assessment
A: Clinical context and clinical manifestations
History of biliary disease
Fever and/or chills
Jaundice
Abdominal pain (right upper quadrant or upper abdominal)
B: Laboratory data
Evidence of inflammatory response <sup>1</sup>
Abnormal liver function tests <sup>2</sup>
C: Imaging findings
Biliary dilation, or evidence of etiology (stricture, stone, stent, <i>etc.</i> )
Two or more items in A
Charcot's triad (2 + 3 + 4)
Two or more items in A + both items in B + C
Severity assessment
Mild (grade I)
Acute cholangitis that responds to initial medical treatment <sup>3</sup>
Moderate (grade II)
Acute cholangitis that does not respond to initial medical treatment and is not accompanied by organ dysfunction
Severe (grade III)
Acute cholangitis that is associated with the onset of dysfunction at least in any one of the following organs/systems
Cardiovascular system; hypotension requiring dopamine $\geq$ 5 $\mu$ g/kg per minute, or any dose of dobutamine
Nervous system: disturbance of consciousness
Respiratory system: PaO <sub>2</sub> /FiO <sub>2</sub> ratio < 300
Kidney: serum creatinine > 2.0 mg/dL
Liver: PT-INR > 1.5
Hematological system: platelet count < 100 000/ $\mu$ L

Compromised patients, for example, elderly (> 75 years old) and patients with comorbidity, should be monitored closely. <sup>1</sup>Abnormal white blood cell count, increased serum C-reactive protein level, and other changes including inflammation; <sup>2</sup>increased serum alkaline phosphatase,  $\gamma$ -glutamyltransferase, aspartate aminotransferase and alanine aminotransferase levels; <sup>3</sup>general supportive care and antibiotics. PT-INR: Prothrombin time and international normalized ratio.

tography for all patients undergoing LC to gain preoperative information about the anatomy of the biliary tree and the presence of common bile duct stones. Perioperative patient care was identical between patients undergoing TLC and SILC.

A retrospective review of prospectively collected data was performed to investigate the safety and feasibility of SILC for AIG. We compared multiple variables, not only between SILC for AIG and SILC for non-AIG, but also between SILC for AIG and TLC for AIG during the same period. A comparison between SILC for AIG and SILC for non-AIG was performed to reveal the influence of AIG on SILC. In this analysis, operative findings, such as intra-abdominal adhesion and gallbladder thickening, were evaluated by the same hepatopancreatobiliary specialist. Additionally, the comparison between SILC for AIG and TLC for AIG was performed to reveal the influence of the operative method of LC on AIG. In the comparison between SILC for AIG and TLC for AIG, the maximum white blood cell (WBC) count and CRP level during the acute inflammatory phase were categorized as follows: WBC > 14 000/mm<sup>3</sup> or not and CRP level > 10 mg/dL

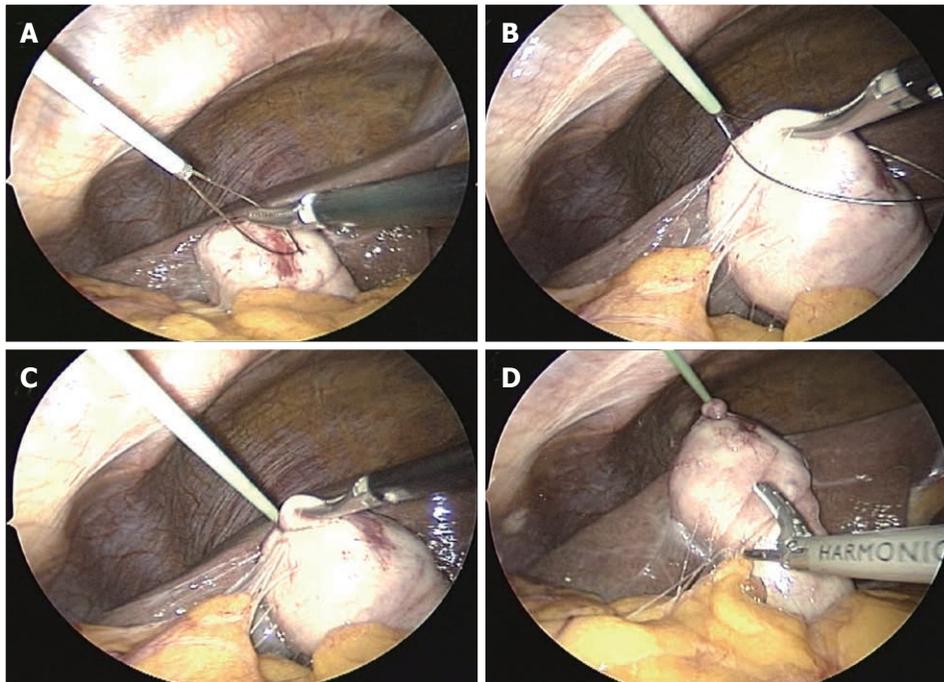

or not. These concrete cutoffs were determined to be indicators of severe inflammation according to the Japanese version of the Tokyo guidelines for acute cholecystitis and acute cholangitis<sup>[4]</sup>.

### Operative technique of our original single-incision laparoscopic cholecystectomy

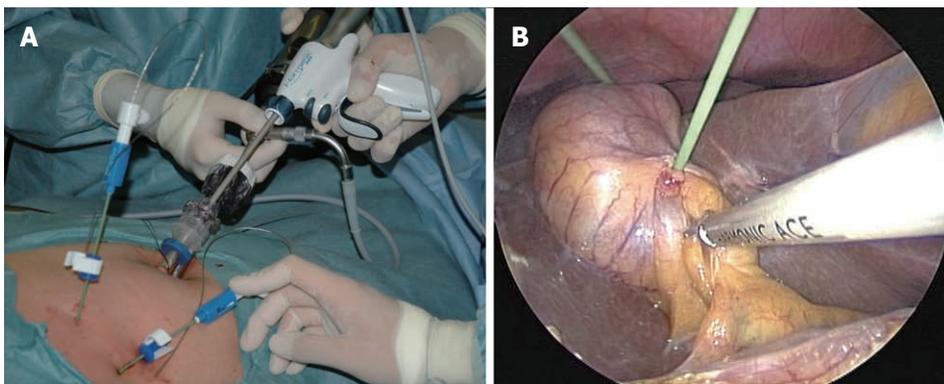

The operative technique and analysis of our original SILC technique have been described in another study<sup>[5]</sup>; here, we describe the procedure briefly as follows. The patients were placed in a low modified lithotomy position; the operator stood between the legs, the laparoscopist stood on the left side, and the second assistant stood on the right. A 10-20-mm skin incision was created by pulling out the umbilicus. After exposing the fascia, a 5-mm, 95-mm-long trocar was placed using an open approach. Pneumo-peritoneum was established, and another 5-mm, 70-mm-long trocar was placed through the same skin incision but through a separate fascial incision, which was created as far as possible above the first trocar. The first trocar was for the 30-degree laparoscope, and the second trocar was for the grasper and laparoscopic coagulating shears (LCSs). After inspection of adhesions and the gallbladder, a 2-mm wire loop retractor (WLR) (Mini Loop Retractor II, Covidien, Tokyo, Japan) was inserted from the right subcostal space, and the body or fundus of the gallbladder was retracted. The WLR was used as follows: (1) the grasper was inserted into the wire, and the tissue needing retraction was grasped; and (2) the wire was wrung, and retraction was performed (Figure 1). If the gallbladder was so distended that it could not be grasped, then bile was aspirated and decompressed using a 16-gauge needle for intraoperative cholangiography (IOC). Both the dissection of the adhesions and exposure of the infundibulum of the gallbladder were performed mainly by LCSs. The second WLR was then inserted obliquely above the first to retract the neck of the gallbladder; this WLR was used as the grasper for retraction in the lateral direction (Figure 2). After visualizing the so-called "critical view of safety," we performed routine IOC, using the catheter insertion technique. Closure of the cystic duct and dissection of the gallbladder from the liver bed were performed in the same manner as for TLC. The cystic duct was closed using a 5-mm laparoscopic clip. The gallbladder was extracted with a specimen bag through the umbilicus. The final appearances of the umbilical incision and the WLR insertion site at 3 mo after surgery were virtually scarless.

### Statistical analysis

All statistical analyses were performed with SPSS II for Windows software (SPSS, Chicago, IL, United States). Parametric summary statistics are presented as mean  $\pm$  SD, whereas nonparametric summary statistics are presented as medians with interquartile ranges. Categorical data were analyzed using the  $\chi^2$  test or Fisher's exact test, as appropriate. The two-sample *t* test was used to test the hypothesis of equality of means, and the Mann-Whitney *U* test was used to test the hypothesis of equality of medians. *P* < 0.05 was considered statistically significant.

## RESULTS

A total of 110 patients underwent attempted SILC and 191 patients underwent attempted TLC during the same period. A total of 23.6% (26/110) of SILCs and 28.3% (54/191) of TLCs were diagnosed and operated on as AIG. The comparison of the patients' demographics and operative outcomes between SILC for AIG and SILC for non-AIG are shown in Table 3. Patients' demographics between SILC for AIG and SILC for non-AIG showed no significant differences without ASA scores. SILC for AIG patients included more patients with complicated backgrounds, but there was only one ASA III patient who had severe systemic disease.

In the operative outcomes, intra-abdominal adhesions and gallbladder wall thickening were more frequently seen in SILC for AIG. The operative time was significantly

longer in SILC for AIG (97.5 min *vs* 85 min,  $P = 0.03$ ). The open conversion rate (2/26 *vs* 2/84,  $P = 0.24$ ) and complication rate (1/26 *vs* 3/84,  $P = 1.00$ ) showed no significant differences, but a need for additional trocars was significantly more frequent in SILC for AIG (5/24 *vs* 3/82,  $P = 0.01$ ). There were two cases of open conversion in SILC for AIG. The first case involved gangrenous cholecystitis with a cholecystocholedochal fistula, which we noticed when we dissected the gallbladder from the liver bed, and we converted to an open procedure to repair the fistula. This case also suffered wound infection, which was the only operative complication with SILC for AIG. The second case involved dense adhesions in a patient with severe bronchial asthma; in this case, we converted to laparotomy to shorten the operative time. Additional trocars were required in five cases of SILC for AIG; three required an additional 5-mm trocar in the

**Table 3** Comparison of patients' demographics and operative outcome between dingle-incision laparoscopic cholecystectomy for acute inflamed gallbladder and single-incision laparoscopic cholecystectomy for non-acute inflamed gallbladder

Patient demographics	SILC for AIG	SILC for non-AIG	P value

<sup>1</sup>Excluded open converted cases. BMI: Body mass index; ASA: American Society of Anesthesiologists; SILC: Single-incision laparoscopic cholecystectomy; AIG: Acute inflamed gallbladder; IOC: Intraoperative cholangiography.

right subcostal space, one required an additional 10-mm trocar in the epigastrium to perform intraoperative ultrasonography, and one required two 5-mm trocars in the subcostal spaces due to stone dissemination.

The comparison of patients' demographics and operative outcomes between SILC for AIG and TLC for AIG is shown in Table 4. The two groups were similar with respect to sex, age, body mass index, indication for surgery, preoperative inflammation findings, severity assessment following Tokyo guidelines, and time between onset and operation. In the severity assessment, SILC for AIG included five moderate cases: three showed WBC counts > 18 000/mm<sup>3</sup>, one showed gangrenous cholecystitis, and one acute cholangitis case did not respond to initial medical treatment and required emergency endoscopic stone extraction. Furthermore, SILC for AIG included two severe cholecystitis cases; both cases showed remarkable inflammation findings (WBC > 22 000/mm<sup>3</sup> and CRP > 25 mg/dL), cardiovascular dysfunction, and neurologic dysfunction, and required biliary drainage. Of 54 TLCs for AIG, 39 were performed by surgical residents under the supervision of staff surgeons. However, all SILCs were performed by staff surgeons.

Even when the operative outcome did not reach statistical significance, the operative time of SILC for AIG was 10 min longer than that of TLC for AIG (97.5 min *vs* 87.5 min, *P* = 0.12). The open conversion rate (2/26 *vs* 5/54, *P* = 1.00) and complication rate (1/26 *vs* 7/54, *P* = 0.26) showed no significant differences. All open

conversions in TLC for AIG were performed for unclear anatomic relationships due to severe adhesions. Complications in TLC for AIG were as follows: postoperative hemorrhage in two, fluid collection in two, paralytic ileus in one, intra-abdominal abscess formation in one, and wound infection in one.

## DISCUSSION

At our institution, we performed SILC with very liberal selection criteria. We performed SILC without any contraindications, and we adopted SILC for AIG. The above findings clearly showed that neither acute cholecystitis nor acute gallstone cholangitis were contraindications for our original SILC technique.

LC for AIG was considered to be an absolute contraindication in the early laparoscopic era. The fear of an increased risk of complications, compared with open cholecystectomy, was unfounded based on the results of randomized controlled trials<sup>[6]</sup>. However, the conversion and complication rates of LC for AIG were greater than those of elective LC for other indications<sup>[7,8]</sup>. In the present study, the open conversion rate of SILC for AIG was 7.7% (2/26), which was a favorable result when compared with the results of TLC for AIG<sup>[6-11]</sup>. Open conversion itself is not a complication, but failure of the operative procedure is; surgeons are frequently obliged to convert due to uncertain anatomy, uncontrollable bleeding, and difficulty with manipulating swollen and thick-

<sup>1</sup>Excluded open converted cases. ASA: American Society of Anesthesiologists; BMI: Body mass index; WBC: White blood cell; CRP: C-reactive protein; IOC: Intra-operative cholangiography; SILC: Single-incision laparoscopic cholecystectomy; TLC: Traditional laparoscopic cholecystectomy; AIG: Acute inflamed gallbladder.

ened gallbladders. The greater the open conversion rate is, the less safe the operative technique. Thus, our original SILC for AIG was proved to be sufficiently safe given the open conversion rate. The complication rate of our SILC for AIG was 3.8% (1/26), which was also more favorable than the reported complication rates of TLC for AIG<sup>[6-11]</sup>.

With regard to feasibility, even if we considered both open conversion and the requirement for additional trocars to be operative method failures, 73% (19/26) of AIG cases that fulfilled the Tokyo guidelines underwent virtually scarless operations. Considering that the reported open conversion rate in the initial experiences of TLC for AIG was 33.7%, and that it remained at 10%-25% after a decade of experience, our original SILC technique is sufficiently feasible for AIG<sup>[6-11]</sup>.

However, SILC for AIG required additional trocars significantly more frequently than SILC for non-AIG. Looking back over individual cases, we especially needed additional trocars in cases with thickened gallbladder walls. In the early cases, we were inexperienced in handling WLRs and could not grasp the thickened gallbladder walls; consequently, we required additional trocars to grasp and manipulate the inflamed gallbladders. After we gained experience and became familiar with using WLRs, we could grasp even severely thickened gallbladder walls. Of the first 12 cases, four required additional trocars, but only one of the next 12 cases required an additional trocar (excluding two open conversion cases). We are convin-

ced that, after the accumulation of another dozen cases, we will be able to perform SILC for AIG with a lower combined conversion rate (open conversion + requirement for additional trocars).

The analysis of SILC for AIG and TLC and AIG revealed no significant differences based on statistical comparison. However, all SILCs for AIG were performed by hepatopancreatobiliary specialists, and satisfactory operative results depended partly on the surgeons' experiences.

The sufficient safety and feasibility of SILC for AIG achieved in our study were derived from some unique characteristics of our original technique. First, we employed two WLRs, which were sufficient to accomplish retraction, even in severely thickened, inflamed gallbladder walls. Second, we inserted only two trocars into the umbilical incision, which resulted in good handling of the instruments and gallbladder manipulation, without interfering with the other instruments or the laparoscope. Third, almost all dissections were performed by LCS, which allowed us to operate easily in dense fibrosis and tissue with neovascularization secondary to inflammation. Fourth, inserting two WLRs from the subcostal margin and using LCS created a triangulation of devices that allowed us to manipulate the gallbladder, as we did in TLC. All of these characteristics allowed us to employ the same operative technique and anatomical knowledge as in TLC, and ultimately, we could perform SILC without selection criteria.

In this study, we adopted the Tokyo guidelines for the diagnosis and severity assessment of gallbladder inflammation. Many reports about TLC for AIG exist in the literature, but the diagnostic criteria and severity assessment were inconsistent among the studies. Employment of the guidelines, which are based on a systemic literature review and the consensus of experts, allowed us to compare each operative result. SILC is still developing, and it has not yet been standardized. Many original procedures exist, but some may not be suitable to perform in cases of AIG. Comparisons using complication and conversion rates under the same diagnostic criteria and severity assessments should become standards of the ideal operative technique.

There are some limitations to our study. First, we did not perform early operations for acute cholecystitis, even though several prospective, randomized, controlled studies comparing early and delayed LC have concluded that early LC is safe and decreases the length of hospital stay<sup>[12]</sup>. We prefer delayed elective surgery, not only for medical reasons but also for social reasons. In our experience, we struggled with difficult bleeding from inflamed tissue in the early phase of AIG; we also struggled with dense adhesions in the delayed phase of AIG. Meticulous dissection of fibrous tissue and sure exposure of Calot's triangle allowed us to operate safely for AIG, although the operative time was slightly longer. Regarding social reasons, our institution is a tertiary referral hospital with only four hepatopancreatobiliary specialists. Considering the availability of surgical staff, anesthesiologists, and operating rooms, we prefer to delay elective surgery unless a patient needs an emergency cholecystectomy. Similar to our institute, there has been a general reluctance to adopt this approach in the United Kingdom, despite increasing evidence supporting early cholecystectomy; currently, only 20% of surgeons perform cholecystectomies during acute cholecystitis<sup>[13]</sup>.

In this study, we showed sufficient operative results for the safety and feasibility of the operative technique, even though delayed surgery is generally considered technically difficult because of acute inflammation and subsequent fibrosis, dense adhesions, and neovascularization. We are convinced that our original SILC technique can be adapted to early operations for AIG if needed. The second limitation is that we evaluated only 15 cases of SILC for acute cholecystitis and 11 cases of SILC for acute gallbladder cholangitis. These numbers of cases were too small to conclude that our SILC is statistically safe and feasible, and we must continue to analyze cases. Third, the occupied percentages of acute gallstone cholangitis in AIG in this study were 42% in SILC and 46% in TLC, which were greater than the reported prevalence of acute gallstone cholangitis<sup>[14,15]</sup>. This finding may have been because our institution is a tertiary referral hospital and there were many referrals of acute gallstone cholangitis that required endoscopic stone extraction from other institutes.

In conclusion, the significant influence of AIG on SILC in this study was due to the longer operative time

and high rate of requirement for additional trocars. The open conversion rate of SILC for AIG was increased to a similar degree as that of TLC for AIG. In experienced hands, the influence of the operative method seemed to decrease, and SILC for AIG could be satisfactorily performed, comparable to TLC for AIG. Our original SILC technique was adequately safe and feasible for the treatment of AIG, with greater requirements for extra ports than non-AIG cases, and a slightly greater conversion rate. We are convinced that, in the near future, SILC will be one of the principal techniques for the management of AIG, just as TLC for AIG evolved from absolute contraindication to the first-choice standard treatment.

## COMMENTS

### Background

Single-incision laparoscopic cholecystectomy (SILC) has recently gained popularity, just as laparoscopic cholecystectomy (LC) became popular in the early 1990s. Although LC was initially established as the treatment of choice for symptomatic cholelithiasis, LC for acute inflammation of the gallbladder (AIG), such as that caused by acute cholecystitis and gallstone cholangitis, was considered to be a contraindication. The complication rate for LC was believed to be possibly higher than that of AIG. Ultimately, LC was accepted as a safe procedure for AIG, when it is performed by an expert at laparoscopic techniques. As with LC, SILC for AIG is currently considered to be a contraindication because of its technical difficulty and infancy.

### Research frontiers

SILC is developing, and there is a wide variety of operative techniques. There is also variety in the safety and feasibility of these operative techniques; some are adequate for the treatment of AIG, but some are not. In the near future, SILC will be considered an acceptable treatment and the standard operative technique for AIG, effectively eliminating inappropriate operative technique.

### Innovations and breakthroughs

The authors investigated the feasibility and safety of their original SILC technique for AIG. The original SILC technique was proven to be adequately safe and feasible for the treatment of AIG by statistical analysis. The sufficient safety and feasibility of SILC for AIG achieved was derived from some unique characteristics of the technique. First, the authors used two wire loop retractors, which were sufficient to accomplish retraction even in severely thickened, inflamed gallbladder walls. Second, they inserted only two trocars into the umbilical incision, which resulted in good handling of instruments and gallbladder manipulation, without interfering with other instruments or the laparoscope. Third, inserting two wire loop retractor from the subcostal margin and using laparoscopic coagulating shear maintained a triangulation of devices that allowed them to manipulate the gallbladder as they did with traditional laparoscopic cholecystectomy.

### Peer review

This is accepted for publication because this study represent a lot of experience of SILC for AIG.

### Abstract

**AIM:** To demonstrate the imaging findings of biliopancreatic and pancreatico-biliary reflux in patients with anomalous union of the pancreatico-biliary duct (AUPBD) on gadoxetic acid-enhanced functional magnetic resonance cholangiography (fMRC).

**METHODS:** This study included six consecutive patients (two men and four women; mean age 47.5 years) with AUPBD. All subjects underwent endoscopic retrograde cholangiopancreatography (ERCP); one subject also underwent bile sampling of the common bile duct (CBD) to measure the amylase level because his gadoxetic acid-enhanced fMRC images showed evidence of pancreatico-biliary reflux of pancreatic secretions. Of the five patients with choledochal cysts, four underwent pylorus-preserving pancreaticoduodenectomy.

**RESULTS:** The five cases of choledochal cysts were classified as Todani classification I. In three of the six patients with AUPBD, injected contrast media reached the distal CBD and pancreatic duct on delay images, suggesting biliopancreatic reflux. In two of these six patients, a band-like filling defect was noted in the CBD on pre-fatty meal images, which decreased in size on delayed post-fatty meal images, suggesting pancreatico-biliary reflux of pancreatic secretions, and the bile sampled from the CBD in one patient had an amylase level of 113 000 IU/L. In one of the six patients with AUPBD, contrast media did not reach the distal CBD due to multiple CBD stones.

**CONCLUSION:** Gadoxetic acid-enhanced fMRC successfully demonstrated biliopancreatic reflux of bile and pancreatico-biliary reflux of pancreatic secretions in patients with AUPBD with and without choledochal cysts.

### INTRODUCTION

Functional hepatocytes uptake a maximum of 50% of

the intravenous (IV) dose of gadoxetic acid (gadolinium ethoxybenzyl diethylenetriamine pentaacetic acid Primovist, Bayer Schering Pharma) administered. Gadoxetic acid is excreted into the bile ducts, allowing visualization of the bile ducts on hepatobiliary phase T1-weighted images. In patients with normal hepatic function, the hepatobiliary phase usually occurs within 20 min of gadoxetic acid administration<sup>[1-3]</sup>.

Hepatocyte-specific agents can be used in a wide range of hepatobiliary applications, and gadoxetic acid-enhanced T1-weighted magnetic resonance cholangiography (MRC) provides additional information to T2-weighted MRC<sup>[4,5]</sup>.

At our institution, we previously evaluated the time sequence of gadoxetic acid-enhanced MRC in 40 normal healthy subjects in 2009; the study was approved by the Korea Food and Drug Administration and our institutional review board. In this previous study, we performed gadoxetic acid-enhanced MRC 60 min after contrast administration and then another 30 min after a fatty meal. In all subjects, we found complete filling of the distal common bile duct (CBD) with contrast on 30-min delayed pre-prandial images, while 50- and 60-min delayed images showed better image quality of bile ducts than early images due to increasing signal-to-noise ratio of extrahepatic bile ducts and bile duct-to-liver contrast-to-noise ratio, and post-prandial images showed gall bladder contraction and more extension of contrast excretion into the small bowel. We found no evidence of contrast media in the pancreatic duct in any subjects (unpublished data). In light of these results, 50- and 60-min delay images after gadoxetic acid administration and 10-, 20- and 30-min delayed images after fatty meal oral uptake were included in the gadoxetic acid-enhanced MRC protocol when requested by the gastroenterologist majoring in pancreato-biliary disorders. In our experience, these images can help verify bile excretion and flow after gallbladder contraction. We were able to evaluate normal or pathological physiology of bile excretion of the liver and bile flow along the biliary tract. These experiences indicated that gadoxetic acid-enhanced functional magnetic resonance cholangiography (fMRC) could reveal the physiology of bile excretion in certain pathologic conditions, including biliopancreatic and pancreato-biliary reflux. In this study, we present six patients with anomalous union of the pancreato-biliary duct (AUPBD) who exhibited biliopancreatic bile reflux and pancreato-biliary pancreatic juice reflux on gadoxetic acid-enhanced fMRC.

The purpose of this study was to investigate the value of gadoxetic acid-enhanced fMRC in the evaluation of AUPBD, with emphasis on the detection of biliopancreatic bile reflux and pancreato-biliary pancreatic reflux.

## MATERIALS AND METHODS

### Patients

Our institutional review board approved this retrospective study and waived the requirement to obtain informed consent. AUPBD was diagnosed radiologically as a long

common channel (> 1.5 cm) or a perpendicular confluence of the CBD and the main pancreatic duct on T2-MRC images and endoscopic retrograde cholangiopancreatography (ERCP). Choledochal cysts were diagnosed when T2-MRC images and ERCP showed typical dilation of the CBD without an obstructive lesion<sup>[6-8]</sup>.

After reviewing 176 patients who underwent gadoxetic acid-enhanced fMRC at our institution for evaluation of biliary pathology due to increased serum bilirubin level, incidental detection of bile duct dilatation on other imaging studies, and right upper quadrant pain between March 2009 and May 2010, we enrolled 6 patients with AUPBD. Of these participants, five had a choledochal cyst. The study group consisted of four women and two men (mean age, 47.5 years; range, 35-64 years), all six of whom underwent ERCP.

We reviewed participant medical records for pertinent clinical features, including medical history, presenting symptoms, results of other imaging studies, and operative records. Of the five patients with both AUPBD and choledochal cysts, four underwent pylorus-preserving pancreaticoduodenectomy. We reviewed these pathology reports and correlated them with imaging findings. One subject underwent bile sampling of the CBD to evaluate the amylase level because his gadoxetic acid-enhanced fMRC showed evidence of pancreato-biliary reflux of pancreatic secretions.

### Imaging techniques

All magnetic resonance imagings (MRIs) were performed on a 3-Tesla MRI machine (Achieva; Philips Medical Systems, Best, the Netherlands). Patients underwent gadoxetic acid-enhanced fMRC with hepatocyte-specific contrast agents; we obtained both contrast-enhanced and un-enhanced fat-saturated 3D gradient-echo T1-weighted images during the arterial, portal venous, and equilibrium phases. We obtained images 50 and 60 min after administration of gadoxetic acid (Primovist, Bayer Schering Pharma, Berlin, Germany) at a dose of 0.025 mmol/kg of body weight at a flow rate of 1 mL/s, followed by a 10-mL saline flush at the same flow rate, using a IV power injector (Spectris Solaris; MedRad, Indianola, PA, United States). Patients then consumed a fatty meal, and post-prandial images were obtained at 10, 20 and 30 min. We used the enhanced-T1 High Resolution Isotropic Volume Examination technique to obtain 3D gradient-echo T1-weighted images. We performed 3D reconstruction using the Maximum Intensity Projection technique 60 min after gadoxetic acid administration and 30 min after the fatty meal. We obtained T2-MRC images as axial and coronal T2 single-shot sequences and maximum intensity projection (MIP) reconstruction images in all patients (Table 1).

### Image review

Two radiologists reviewed the image sequences of all six patients and classified choledochal cysts according to the Todani classification and AUPBD according to Kimura's classification (B-P type: a right angle between the bile duct

and pancreatic duct or the bile duct inserted into the pancreatic duct; P-B type: an acute angle between the bile duct and pancreatic duct or the pancreatic duct inserted into the bile duct)<sup>[9-11]</sup>.

The radiologists evaluated by consensus the extent of injected contrast media and recorded the presence of biliopancreatic and pancreatico-biliary reflux on all image sequences. The radiologic diagnosis of biliopancreatic bile reflux was made when biliary-excreted contrast media was visible in the main pancreatic duct on gadoxetic acid-enhanced fMRC. The diagnosis of pancreaticobiliary reflux of pancreatic secretions was made when a filling defect was present on pre-prandial images, which decreased in size or was absent on post-fatty meal images. Based on an unpublished study we conducted on normal volunteers, which found that the CBD was filled with excreted gadoxetic acid 30 min after contrast administration and a fatty meal uptake can make more extension of biliary excreted contrast media by contraction of the gallbladder, we therefore considered a filling defect in the distal CBD on 50 and 60 min delayed images as evidence of reflux of pancreatic secretions.

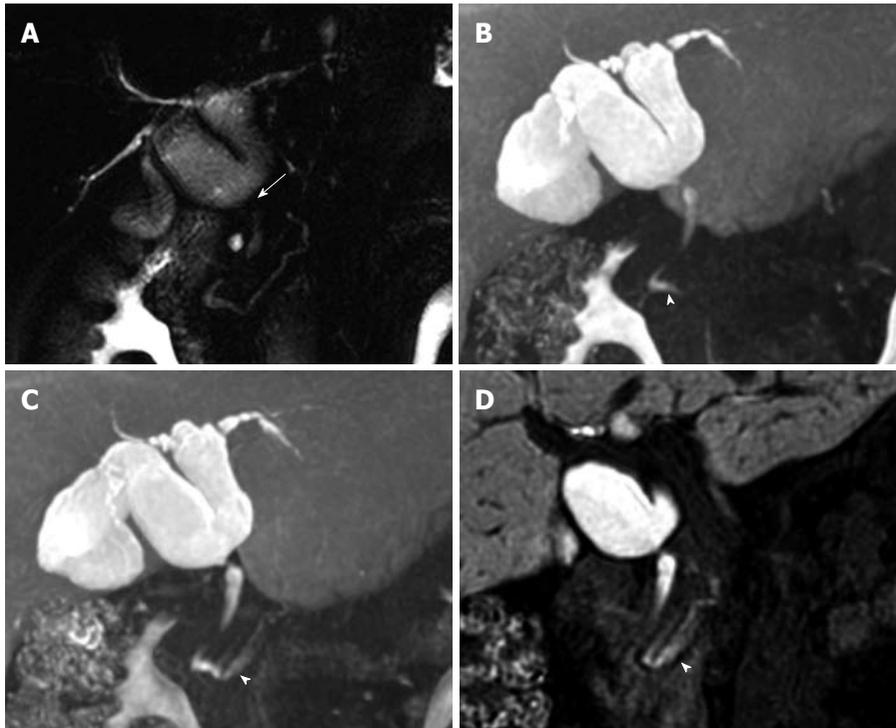

## RESULTS

The results of our study are summarized in Table 2. Of the six patients, four had B-P type AUPBD and two had P-B type AUPBD. All five choledochal cysts were Toda-

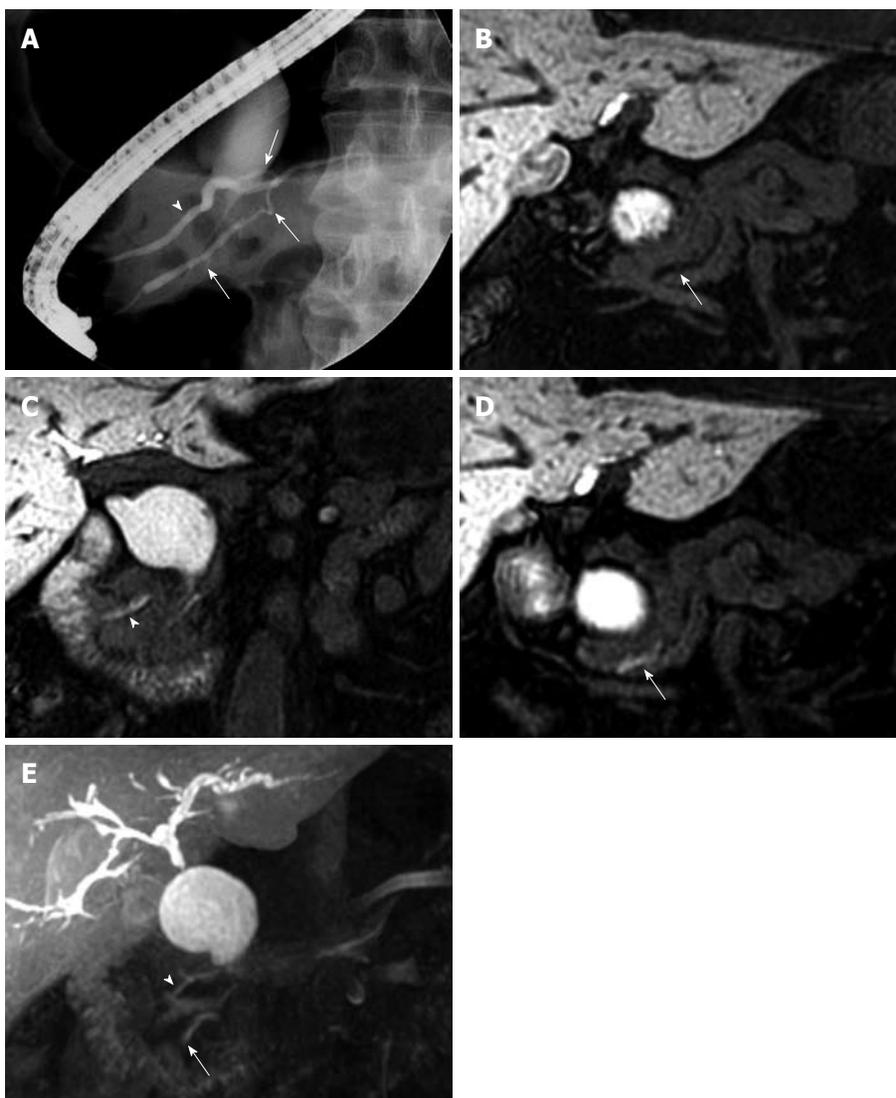

ni classification I (four patients with I a and one patient with I c), with confined dilation of the extrahepatic bile duct.

In three of the six patients with AUPBD, injected contrast media reached the distal CBD and pancreatic duct, suggesting biliopancreatic reflux. We observed extension of contrast to the pancreatic duct on images taken 20 min after a fatty meal in two patients (Figure 1). In one patient, we observed contrast extending to the pancreatic duct on images taken 50 min after contrast administration; later images showed contrast extending to the more distal portion of the pancreatic duct (Figure 2). These three patients all had Todani type I a choledochal cysts and B-P type AUPBD. The one patient with AUPBD without a choledochal cyst had a history of recurrent acute pancreatitis with no history of alcohol abuse.

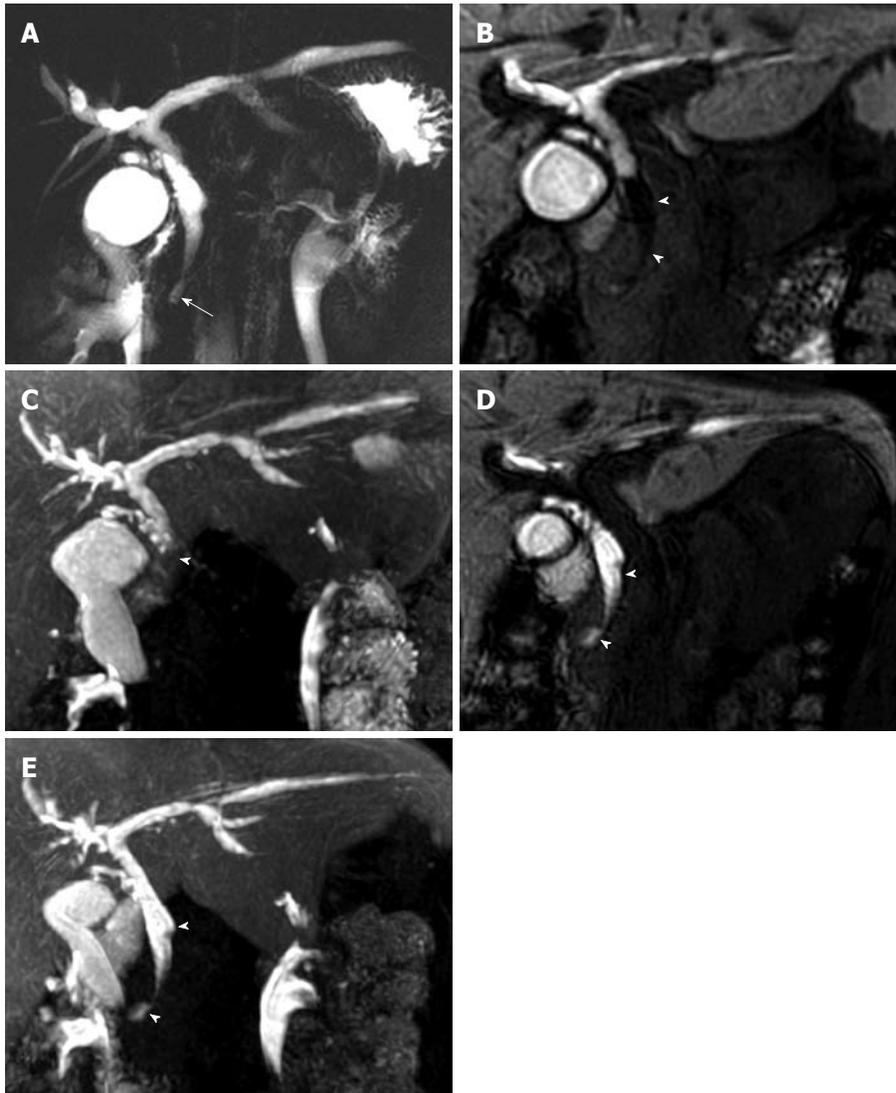

In two patients, we observed a band-like filling defect in the central portion of the distal CBD on pre-fatty meal images. The filling defect decreased in size on post-fatty meal images, which we considered evidence of pancreatico-biliary reflux of pancreatic secretions. One of these two patients had B-P type AUPBD with no combined bile duct dilatation, and the other had P-B type AUPBD with a Todani type I c choledochal cyst. A bile amylase level of 113 000 IU/L was measured from the CBD in the latter patient (Figure 3). In one patient with a choledochal cyst (Todani I a and Kimura P-B), contrast did not reach the distal CBD and did not appear to enter the

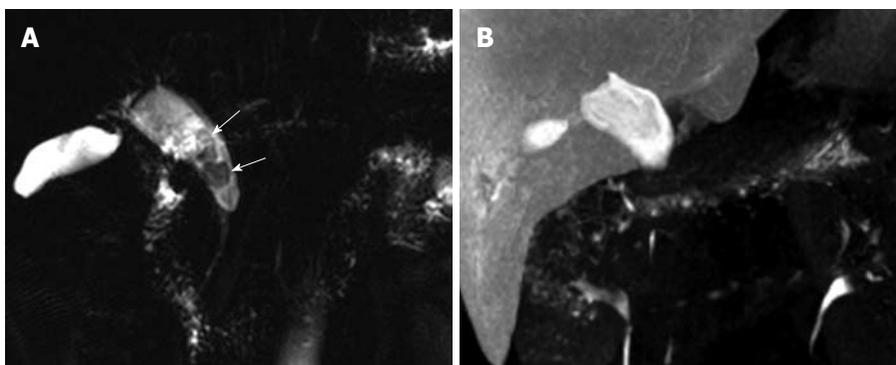

**Figure 1** A 52-year-old woman with anomalous union of the pancreatico-biliary duct and a type I choledochal cyst. A: Fusiform dilation of the common hepatic and cystic ducts with a focal stricture in the common bile duct (arrow) on T2-magnetic resonance cholangiography (MRC); B: Maximum intensity projection (MIP) reconstruction image of 60-min delayed gadopentetate acid-enhanced MRC shows the main pancreatic duct (arrowhead), indicating biliopancreatic reflux; C: MIP reconstruction image of 30-min delayed gadopentetate acid-enhanced MRC after a fatty meal shows progression of contrast media (arrowhead) along the main pancreatic duct; D: Gadopentetate acid-enhanced MRC coronal image taken 30 min after a fatty meal shows visualization of the main pancreatic duct (arrowhead) using contrast material.

**Figure 2** A 64-year-old man with anomalous union of the pancreatico-biliary duct and a type I choledochal cyst. A: Endoscopic retrograde cholangiopancreatography shows cystic dilation of the extrahepatic bile duct with a focal stricture in the distal common bile duct. The end of the long ventral pancreatic duct (duct of Wirsung, arrows) is fused with the dorsal pancreatic duct (duct of Santorini, arrowhead). The common bile duct inserts into the ventral pancreatic duct; B: Sixty-minute delayed gadopentetate acid-enhanced magnetic resonance cholangiography (MRC) coronal image does not visualize the main pancreatic duct (arrow); C and D: Gadopentetate acid-enhanced MRC coronal images taken 30 min after a fatty meal show the duct of Santorini (arrowhead) and duct of Wirsung (arrow), indicating biliopancreatic reflux of contrast material; E: Gadopentetate acid-enhanced MRC maximum intensity projection reconstruction images taken 30 min after a fatty meal show major and minor pancreatic ducts.

**Figure 3** A 40-year-old woman with anomalous union of the pancreatico-biliary duct and a type I c choledochal cyst. A: T2-magnetic resonance cholangiography (MRC) shows a long common channel (arrow), with diffuse bile duct dilation; B: Sixty-minute delayed gadoxetic acid-enhanced MRC coronal image; C: Maximum intensity projection (MIP) reconstruction image show a filling defect (arrow heads) in the central portion of the distal common bile duct (CBD); D: Gadoxetic acid-enhanced MRC coronal images taken 30 min after a fatty meal; E: MIP reconstruction images show a decreased filling defect (arrow heads) in the distal CBD, indicative of pancreatico-biliary reflux.

**Figure 4** A 35-year-old woman with a type I a choledochal cyst and multiple common bile duct stones. A: Fusiform dilatation of the extrahepatic bile duct is seen on T2-magnetic resonance cholangiography (MRC) and multiple nodular filling defects (arrows) are seen in the common bile duct (CBD) which represent CBD stones; B: Contrast media did not pass through the ampulla of Vater until 30 min after fatty meal ingestion and multiple CBD stones are not seen due to masking by contrast media with high signal intensity.

duodenum. We noted multiple CBD stones in this patient (Figure 4).

## DISCUSSION

AUPBD is defined as an anomalous union of the bile and pancreatic ducts outside the duodenal wall proximal to the sphincter of Oddi. The diagnostic criteria for AUPBD include the radiological and anatomical detection of the extramural location of the junction of the

pancreatic and biliary ducts in the duodenal wall, as well as radiological detection of a long common channel (> 1.5 cm). Detection of the extramural location is difficult in AUPBD patients with a short common duct (less than 1 cm in length)<sup>[6]</sup>. The sphincter of Oddi, which regulates the outflow of bile and pancreatic secretions, is deficient in AUPBD due to the long common channel, allowing two-way regurgitation: Pancreatico-biliary reflux of pancreatic secretions and biliopancreatic bile reflux. This reflux can result in various pathological condi-

tions including choledocholithiasis, cholangitis, gallstones, acute pancreatitis, bile duct cancer, gallbladder cancer, and pancreatic ductal carcinoma<sup>[12,13]</sup>. It is known that choledochal cysts are embryologically associated with AUPBD, and their various clinical signs and symptoms have been shown to be closely related to the presence of AUPBD<sup>[14]</sup>.

Various methods have been reported to confirm biliopancreatic reflux, including operative or postoperative T-tube cholangiography, computerized tomography combined with drip infusion cholangiography, histological detection of gallbladder cancer cells in the main pancreatic duct, and bile reflux on the cut surface of the pancreas<sup>[12,15,16]</sup>. Furthermore, pancreatico-biliary reflux of pancreatic secretions has been confirmed by measurement of bile amylase in the bile duct, secretin-stimulated dynamic MRC, and pancreatography *via* the minor duodenal papilla<sup>[15,17]</sup>. However, these methods are limited by their levels of invasiveness, the time required, patient discomfort, and adverse effects of contrast materials<sup>[18-20]</sup>.

Gadoxetic acid is widely used because of its diagnostic efficacy in focal lesions of the liver and its safety<sup>[21-24]</sup>. In our study, there were no serious adverse effects related to the use of contrast material that required medical management. Although our protocol for functional MR cholangiography to detect biliary reflux in AUPBD patients required an additional 90 min and 70 min when compared with non-contrast enhanced T2-MRC and Gd-enhanced T1-MRC, respectively, it is easy to perform and does not augment the risk of contrast agent-related adverse effects.

As previously described, AUPBD was diagnosed by identifying biliopancreatic bile reflux and pancreatico-biliary pancreatic reflux on gadoxetic acid-enhanced fMRC in addition to the detection of a long common channel on T2-MRC or the customary 20-min delayed gadoxetic acid-enhanced MRC. Delayed hepatobiliary MRC (greater than a 30 min delay) after contrast administration, and MRC of gallbladder contraction induced by a fatty meal were required to detect both types of reflux.

Some researchers report that, if the passage of contrast material through the ampulla of Vater takes longer than 30 to 60 min, it can be considered delayed. In comparison, excretion of contrast material past the ampulla in less than 20 to 30 min is considered normal<sup>[4-5]</sup>. There have been many reports on gadoxetic acid-enhanced MRC which showed that bile excretion could be visualized by capturing images during the hepatobiliary phase approximately 20 or 30 min after contrast administration<sup>[4,5,25,26]</sup>. Images taken one hour after contrast administration and again after a fatty meal allow bile to travel further along the normal or anomalous pathway, providing additional information about the patient's biliary system. Since there are no studies which looked into the optimal phase to observe AUPBD, further study is warranted to simplify the study protocol.

Our fMRC protocol requires additional time for delayed images compared with contrast enhanced T1-MRC. However, gadoxetic acid-enhanced fMRC allows the as-

essment of bile excretion and pancreas secretion physiology in addition to visualization of bile duct and pancreatic duct morphology, thus obviating the need for additional imaging studies such as hepatobiliary scan and ERCP.

It is difficult to generalize the results of our study due to its small sample size. Nonetheless, one patient in our study was found to have a filling defect in the distal CBD along with an abnormally high amylase level (113 000 IU/L) in the CBD. One study reported the biliary amylase levels of patients with biliopancreatic disease to range widely from less than 10 to 300 000 IU/L<sup>[27]</sup>. Sai *et al.*<sup>[28]</sup> reported a mean biliary amylase level of 238 IU/L in patients with no reflux of pancreatic secretions into the bile duct, while Horaguchi *et al.*<sup>[27]</sup> adopted 168 IU/L as the upper limit of a normal biliary amylase level. Our previous study of gadoxetic acid-enhanced MRC in 40 normal volunteers found no filling defects in the distal CBD up to one hour after contrast administration or after a fatty meal (unpublished data). Taken together, we used these data to presume pancreatico-biliary reflux in the case of a central filling defect in the CBD that diminished after a fatty meal.

In normal physiology, the pressure in the pancreatic duct exceeds the choledochal pressure, allowing pancreatic secretions to flow into the biliary tract rather than reflux into the pancreatic duct where they can cause biliary complications<sup>[29,30]</sup>. In the case of AUPBD, however, bile can reflux into the pancreatic duct under conditions such as increased pressure in the bile duct due to bile stasis in a choledochal cyst or cholangitis<sup>[31]</sup>.

A study of 2980 patients undergoing ERCP found a 1.7% prevalence of a long common channel. In that study, 13 patients underwent intraoperative cholangiography, 11 of whom were found to have biliopancreatic reflux with an elevated biliary amylase level<sup>[32]</sup>. In our study, all three patients with biliopancreatic reflux were found to have B-P type AUPBD as well as Todani type I a choledochal cysts. We hypothesize that bile duct stasis in the dilated bile duct resulted in elevated choledochal pressure, resulting in biliopancreatic bile reflux. Of the two patients with pancreatico-biliary reflux of pancreatic secretions, one had B-P type AUPBD and the other had P-B type AUPBD.

Our study had several limitations. First, the sample size is too small to allow for generalization. Second, the type of choledochal cysts in our study were limited to Todani classification type I, meaning a cystic or fusiform dilation of the extrahepatic bile duct. Further studies that include larger sample sizes and several types of choledochal cysts are required to generalize the imaging findings of biliopancreatic and pancreatico-biliary reflux, as well as to evaluate the diagnostic accuracy of these findings for AUPBD in patients with choledochal cysts.

In conclusion, gadoxetic acid-enhanced fMRC can show biliopancreatic bile reflux and pancreatico-biliary reflux of pancreatic secretions in patients with AUPBD with and without combined Todani type I choledochal cysts.

## COMMENTS

**Background**

Gadoxetic acid has both properties of extracellular contrast media, which make dynamic study possible, through the organic anion-transporting polypeptide and is excreted into the bile ducts, allowing visualization of the bile ducts on hepatobiliary phase T1-weighted images. In patients with normal hepatic function, the hepatobiliary phase usually occurs within 20 min of gadoxetic acid administration. From a previous study in normal healthy patients, we know that images obtained after a delayed time period and after a fatty meal allow bile to travel further along the normal or anomalous pathway, providing additional information about the patient's biliary system.

**Research frontiers**

Gadoxetic acid has hepatobiliary properties which mediate specific uptake of the agent into the hepatocytes. Gadoxetic acid-enhanced magnetic resonance cholangiography (MRC) can visualize the physiology of bile excretion directly, in contrast to conventional T2-weighted MRC which can visualize fluid filled space by heavily T2-weighted and fat-suppressed images. The usefulness of gadoxetic acid-enhanced MRC was demonstrated in many reports in a wide range of hepatobiliary applications including evaluation of biliary tract anomalies, the diagnosis of acute cholecystitis, assessment of postsurgical anatomy and complications, and to determine whether fluid collections communicate with the biliary tree.

**Innovations and breakthroughs**

The present study clearly showed that biliopancreatic bile reflux and pancreatico-biliary reflux of pancreatic secretions in patients with anomalous union of the pancreatico-biliary duct (AUPBD) could be easily diagnosed using the convenient and safe imaging method of gadoxetic acid-enhanced MR cholangiography.

**Applications**

The present study revealed that biliopancreatic bile reflux and pancreatico-biliary reflux of pancreatic secretions in patients with AUPBD could be diagnosed with gadoxetic acid-enhanced MRC. Further studies which include larger sample sizes and several types of choledochal cysts are required to generalize the imaging findings of biliopancreatic and pancreatico-biliary reflux, as well as to evaluate the diagnostic accuracy of these findings.

**Peer review**

Although gadoxetic acid-enhanced functional MRC is not a new method to observe the bile system, it is reasonable and interesting to use it to detect biliopancreatic and pancreatico-biliary reflux in patients with AUPBD.

### Abstract

**AIM:** To describe the clinical characteristics of patients with gastric or intestinal bezoars recently treated in our hospital.

**METHODS:** In this study, a retrospective chart review of consecutive patients with gastrointestinal bezoars, who were treated at the Samsun Education and Research Hospital between January 2006 and March 2011, was conducted. Data on demographic characteristics, clinical presentation, history of risk factors, diagnostic procedures, localization of bezoars, treatment interventions, and postoperative morbidity and mortality rates were collected and evaluated.

**RESULTS:** Forty-two patients [26 (61.9%) males and 16 (31.1%) females] with a mean  $\pm$  SD (range) age of  $55.8 \pm 10.5$  (37-74) years were enrolled in this study. Thirty-six patients (85.7%) had one or more predisposing risk factors for gastrointestinal bezoars. The most common predisposing risk factor was a history of previous gastric surgery which was identified in 18 patients (42.8%). Twenty three patients (54.8%) had multiple

predisposing risk factors. Phytobezoars were identified in all patients except one who had a trichobezoar in the stomach. Non-operative endoscopic fragmentation was performed either initially or after unsuccessful medical treatment in 14 patients with gastric bezoars and was completely successful in 10 patients (71.5%). Surgery was the most frequent treatment method in our study, which was required in 28 patients (66.7%). Intestinal obstruction secondary to bezoars was the most common complication ( $n = 18$ , 42.8%) in our study.

**CONCLUSION:** The presence of multiple predisposing factors may create a synergistic effect in the development of bezoars.

### INTRODUCTION

Bezoars can be defined as masses of indigestible, hard materials formed in the gastrointestinal tract. Etymologically, the word bezoar came from the Persian word "padzahr" meaning to expel poison. In some societies, animal bezoars were formerly considered a useful medicine and possessed certain magical properties<sup>[1]</sup>. In 1854,

Quain reported an intragastric alimentary mass in an autopsy and called it a "bezoar"<sup>[2]</sup>.

Bezoars can be classified as phytobezoars (undigested vegetables), trichobezoars (hairs), lactobezoars (milk) and pharmacobezoars (medications) according to their composition<sup>[3]</sup>. They usually form in the stomach and can pass into the small bowel where they occasionally cause obstruction. Phytobezoars are composed of undigested food fibers, such as cellulose, hemicellulose, lignin and fruit tannin. These fibers occur in fruits and vegetables such as celery, pumpkin, prunes, raisins, leeks, beets and persimmons.

The aim of this study was to describe the clinical characteristics of patients with gastric or intestinal bezoars recently treated in our hospital.

## MATERIALS AND METHODS

A retrospective chart review of consecutive patients with gastrointestinal bezoars, who were treated at the Samsun Education and Research Hospital between January 2006 and March 2011, was conducted. Data on the demographic characteristics, clinical presentations, history of predisposing risk factors, diagnostic procedures, localization of bezoars, treatment interventions, morbidity and mortality rates were collected and evaluated. In addition, the patients were contacted by phone to determine any recurrence of bezoars after treatment.

In this study, previous gastric surgery, excessive consumption of some types of fruit and vegetables, diabetes mellitus, mastication problems, long-term antacid treatment and mental disorders were considered predisposing risk factors in the development of bezoars.

All calculations were performed in Microsoft Office Excel 2007. Continuous variables were summarized as mean  $\pm$  SD or median when appropriate, and categorical variables as frequency and percentage (%).

## RESULTS

### Demographic characteristics and presentation

Forty-two patients [26 (61.9%) males and 16 (31.1%) females] with a mean  $\pm$  SD (range) age of 55.8  $\pm$  10.5 (37-78 years) were enrolled in this study. The peak incidence was in the 6th decade of life (51-60 years). Twelve patients (28.6%) were in the 6th decade.

The most common presenting symptom was abdominal pain which was noted in 40 patients (95.2%). Dyspeptic symptoms other than epigastric pain were found in 32 patients (76.2%). Mild to severe nausea and vomiting were observed in 29 cases (69%). Loss of appetite was found in 19 patients (45.2%) and a significant weight loss history was identified in 5 (11.9%) patients. Some degree of abdominal distention as a sign of intestinal obstruction developed in 18 patients (42.9%). Two patients presented with acute gastric outlet obstruction.

Twelve patients with intestinal or gastric outlet obstruction (47.6%) were admitted to our emergency service. Five patients (11.9%) were referred by gastroenterologists.

Table 1 Distribution of predisposing factors

Predisposing factors	n	%
Single predisposing factor	13	31.0
Only gastric surgery	4	9.5
Only persimmon consumption	3	7.1
Only mastication problems	3	7.1
Only diabetes mellitus	2	4.8
Trichotillomania	1	2.4
Multiple predisposing factors	23	54.7
Gastric surgery + persimmon consumption	3	7.1
Gastric surgery + diabetes mellitus	3	7.1
Gastric surgery + mastication problem	3	7.1
Gastric surgery + mastication problem + persimmon consumption	3	7.1
Gastric surgery + mastication problem + diabetes mellitus	2	4.8
Persimmon consumption + mastication problem	3	7.1
Persimmon consumption + diabetes mellitus	2	4.8
Mastication problem + diabetes mellitus	1	2.4
Diabetes mellitus + antacid drug	1	2.4
Persimmon consumption + antacid drug	1	2.4
Mastication problem + antacid drug + persimmon consumption	1	2.4
No predisposing factor	6	14.3

The remaining patients ( $n = 17$ , 40.4%) were admitted to the general surgery clinic.

During the study period, 257 patients with mechanical bowel obstruction due to various reasons were admitted to our emergency service. Bezoars were the cause of mechanical bowel obstruction in 18 of these patients (7%).

### History of predisposing factors

Thirty-six patients (85.7%) had one or more predisposing risk factors (Table 1). The most common predisposing risk factor was previous gastric surgery which was identified in 18 patients (42.8%). Excessive persimmon consumption was another significant predisposing risk factor in our study. A history of excessive persimmon consumption was observed in 17 patients (40.5%). Mastication problems and diabetes mellitus were identified in 16 (38.1%) and 12 (28.6%) patients, respectively. Twenty-three patients (54.8%) had multiple predisposing risk factors. All predisposing risk factors are summarized in Table 1.

### Diagnostic procedures

Initial diagnosis was made by gastroscopy in 15 patients (35.7%). Abdominal sonography was the first diagnostic method used in 7 patients (16.7%), which was carried out in 12 patients as the first imaging method. Plain abdominal radiography (PAR) showed air-fluid levels in 18 patients (40.5%). The typical bezoar image on PAR, involving a mottled air pattern, was identified in only two patients. Abdominal tomography was carried out in 16 patients and bezoars were revealed in 14 of these patients (87.5%).

### Localization and composition

A single bezoar was found in 38 (90.4%) patients. Four patients (9.6%) had multiple bezoars in different locations.

Bezoars were mainly located in the stomach ( $n = 28$ ). Other locations were the ileum, jejunum and colon ( $n = 14$ ,  $n = 3$  and  $n = 1$ , respectively). Phytobezoars were identified in all patients except one who had a trichobezoar in the stomach. The patient with the trichobezoar was a 43-year-old woman, who had a history of psychiatric problems and trichotillomania.

### Intervention

Medical treatment with various enzymatic agents (including cellulase and cola) was initially tried in 15 cases with small gastric bezoars, however, enzymatic treatment was completely successful in only 4 patients (26.7%). Non-operative endoscopic fragmentation was performed either initially or after unsuccessful medical treatment in 14 patients and was completely successful in 10 patients (71.5%).

Surgery was the most frequent treatment method in our study, which was required in 28 patients (66.7%). Bezoars were removed from the stomach by gastrotomy in 8 patients. Preoperatively diagnosed small bezoars which were located in the distal ileum were carefully milked into the cecum in 8 cases. In 9 cases, it was not possible to milk the bezoars into the large intestine and an enterotomy was required. The patient who had a colonic bezoar in the ascending colon was treated with colotomy. In these 18 patients with intestinal bezoars, the stomach was surgically explored for additional bezoars and additional gastric bezoars were found and extracted *via* gastrotomy in 4 patients.

Coexisting gastric ulcers were identified in 5 (20.8%) of the patients with gastric bezoars. While anti-ulcer medication was prescribed in endoscopically treated patients, ( $n = 3$ ), wedge resection of ulcers was added to the gastrotomy in operated patients ( $n = 2$ ). Histopathological examinations of the ulcers revealed benign findings in all 5 patients.

### Postoperative outcomes and complications

The mean postoperative hospital stay was  $6.1 \pm 1.7$  d (range, 3-12 d) in our study. Postoperative complications developed in 7 (25%) patients (surgical site infection in 3 (10.7%) cases, chest infection in 2 (7.1%) patients and prolonged ileus in 2 (7.1%) patients).

We were only able to contact 32 (76.2%) patients by phone. There were no clinical recurrences in these patients during a median follow-up time of 25 mo (range, 3-63 mo).

## DISCUSSION

A number of predisposing factors may contribute to the risk of bezoar formation. Previous gastric surgery was reported in 20% to 93% of patients with bezoars and the incidence of bezoar formation after gastric surgery ranged from 5% to 12%<sup>[4-8]</sup>. Similar to previous published studies, the most common predisposing risk factor was previous gastric surgery which was identified in 42.8% of the patients in our study. Altered anatomy and physiology of the gastric remnant after vagotomy and partial

gastrectomy are largely responsible for bezoar formation. Vagotomy and partial gastrectomy diminish the ability of the stomach to break up and digest food. Both the quantity and the acidity of the gastric juice are reduced and peptic activity is adversely affected<sup>[9,10]</sup>. Additionally, the antrum has an important role in the mechanical fragmentation of ingested material, and the pylorus prevents large boluses from reaching the small intestine. Resection of the antrum and pylorus may lead to the passage of a non-fragmented, large bolus to the small intestine. The interval between gastric surgery and bezoar detection was 9 mo to 30 years<sup>[4-7]</sup>. In our study, the mean interval between surgery and bezoar detection was  $7.4 \pm 2.3$  years (5-11 years).

Excessive consumption of persimmon was identified in 40.5% of our patients. Persimmon, which grows in many areas in our region and widely consumed, is the fruit of a number of species of trees belonging to the genus *Diospyros*. The word *Diospyros* means "the fruit of the gods" in ancient Greek. Persimmon bezoars are also known as diospyrobezoars. Unripe persimmons contain soluble tannin. Tannin polymerizes in an acidic environment to form a glue-like coagulum, which can affix to other materials in the stomach<sup>[11]</sup>. In 1986, Krausz *et al*<sup>[4]</sup> reported that 91.2% of 113 patients with phytobezoars had a history of persimmon intake. Erzurumlu *et al*<sup>[12]</sup> from our country reported that 17.6% of their 34 patients with bezoars had a history of persimmon or cherry laurel intake.

Mental retardation and trichotillomania are major risk factors for the development of trichobezoars<sup>[13]</sup>. In our study, there was only one patient with trichobezoar who had a history of psychiatric disorders and trichotillomania. The other predisposing factors observed in our study included mastication problems, diabetic gastroparesis and antacid drug use. Consequently, 85.7% of patients had one or more predisposing factors in our study. While about one third of our patients had only one predisposing risk factor, over fifty percent had multiple predisposing risk factors. In our opinion, these results may indicate that the presence of multiple predisposing risk factors creates a synergistic effect in the development of bezoars. On the other hand, 14.3% of the patients in our study had no apparent predisposing risk factors. Erzurumlu *et al*<sup>[12]</sup> reported that only 5.9% of the patients in their study had no apparent predisposing risk factors. Bezoar formation is postulated to be provoked by dietary and eating habits in patients without predisposing factors<sup>[14]</sup>.

Until only a few decades ago, the differential diagnosis of intestinal obstruction secondary to bezoars was difficult before surgery, because the clinical and radiographic findings are similar to those of intestinal obstruction attributable to other causes<sup>[11,15]</sup>. However, findings from recent studies suggest that sonography or computerized tomography (CT) can assist radiologists in diagnosing bezoars before surgery<sup>[6,16]</sup>. In our study, PAR showed air-fluid levels in 18 patients with intestinal obstruction. The typical bezoar image on PAR, involving a mottled air pattern, was identified in only two patients (11.1%). Abdom-

inal CT was carried out in 16 patients and bezoars were revealed in 14 (77.7%) of these patients before surgery. Although sonography was not the preferred imaging modality for the patients with intestinal obstruction in our study, it was carried out in 12 patients with gastric bezoar as the first imaging method and the presence of a bezoar was suspected in 7 (58.3%) of these patients before endoscopy.

Both mechanical and chemical procedures are used in the treatment of gastric bezoars. Bezoars can be endoscopically fragmented into pieces using polypectomy snares, endoscopic forceps, Dormia baskets, endoscopic lithotripsy, electrosurgical knives or YAG laser. However, this technique requires specific equipment and is not complication free. Bleeding, perforation or even migration of bezoar pieces causing intestinal obstruction are potential complications<sup>[17]</sup>. In our study, endoscopic fragmentation was performed either initially or after unsuccessful medical treatment in 14 patients and was completely successful in 10 patients (71.5%). Medical treatment may also be useful in the management of gastric bezoars. Several chemical agents have been tested; these are administered orally, through a nasogastric tube or injected directly into the bezoar *via* endoscopy. However, the development of these techniques usually takes time, is not free of complications such as electrolytic disorders, gastric ulcer and has indistinct results<sup>[17]</sup>. In our study, medical treatment was initially tried in 15 cases with gastric bezoars, but was completely successful in only 4 patients (26.7%).

Although bezoars are the most common type of foreign body lodged in any part of the gastrointestinal tract, the overall incidence of bezoar-induced intestinal obstruction remains relatively low. Epidemiological data show that 2% to 4% of intestinal obstructions are caused by bezoars<sup>[2]</sup>. This figure was 7% in our study. Although intestinal obstruction was reported to be the most frequent clinical presentation of bezoars in the majority of previous studies, it was observed in 42% of the patients in our study. Surgical management of intestinal obstruction secondary to bezoars entails milking the object into the cecum or performing enterotomy for retrieval in difficult cases. In our study, 47% of patients with intestinal obstruction were managed by milking. Enterotomy was performed in 53% of patients with intestinal obstruction. Although therapeutic laparoscopy has been demonstrated to be feasible in the management of intestinal obstruction secondary to bezoars<sup>[18]</sup>, all operations were conducted as open surgery in our study.

Intestinal bezoars are often found in association with gastric bezoars<sup>[6]</sup>. Coexisting gastric bezoars was reported in 17%-21% of patients<sup>[19,21]</sup>. In our study, a coexisting gastric bezoar was found in 22.2% of patients with an intestinal bezoar. Consequently, when an intestinal bezoar is diagnosed, the possible presence of coexisting gastric or intestinal bezoars should be investigated cautiously.

Major complications of bezoars other than intestinal obstruction include gastric ulcer, gastritis, gastric perforation and gastric outlet obstruction. In our study, coexisting

gastric ulcers were identified in 20.8% patients with gastric bezoars. While anti-ulcer medication was prescribed in endoscopically treated patients, wedge resection of ulcers was added to the gastrotomy in operated patients. Two patients with gastric outlet obstruction were treated with gastrotomy and extraction of bezoars.

Although, there was no clinical recurrence of bezoars during a median follow-up time of 25 mo after treatment in our study, Klamer *et al.*<sup>[22]</sup> reported recurrence in approximately 20% of patients with gastric bezoars after initial treatment. Therefore, patients should be instructed to avoid a high fiber diet, persimmons and certain medications to minimize the potential risk of recurrence.

In conclusion, over fifty percent of the patients in our study had multiple predisposing factors for gastrointestinal bezoars. In light of these results, it may be concluded that the presence of multiple predisposing factors create a synergistic effect in the development of bezoars. Intestinal obstruction is the most common complication of bezoars. Although the prevalence of intestinal obstruction secondary to bezoars is quite low, differential diagnosis of intestinal obstruction secondary to adhesions is important in patients with previous abdominal surgery; CT can help to make this differentiation. Therefore, CT should be obtained whenever possible in all patients with bowel obstruction to establish the diagnosis and avoid inappropriate treatment.

## COMMENTS

### Background

Bezoars have become increasingly recognized as a cause of acute mechanical intestinal obstruction. Bezoars are classified according to their composition. The major types are phytobezoars, trichobezoars, and pharmacobezoars. Phytobezoars, composed of undigested vegetable matter, are the most common type of bezoar. Trichobezoars, composed of hair, are often associated with psychiatric problems. *Pharmacobezoars* are composed of ingested medications.

### Research frontiers

Previous studies have shown that different types of predisposing factors may increase the risk of developing bezoars. During data extraction, the authors realized that most of their patients had more than one predisposing factor for bezoar formation. This result was of interest to them and they would like to emphasize this finding. The present study is the first to address the possible synergistic role of multiple predisposing factors in the development of bezoars.

### Innovations and breakthroughs

The results of the present study suggest that the presence of multiple predisposing factors may create a synergistic effect in the development of bezoars.

### Applications

Early recognition of high-risk individuals, who have multiple predisposing factors, may prompt early investigation and the prevention of potential life-threatening sequelae of intestinal obstruction due to bezoars.

### Terminology

Diospyrobezoar is a type of phytobezoar which is caused by unripe persimmons and it is considered to be harder than other types of phytobezoars. Trichotillomania is a disorder where people compulsively pull out their hair.

### Peer review

The manuscript has been written properly and clearly. Case reports are the most common types of articles considering this problem.

### Abstract

**AIM:** To investigate the genetic characteristics and pathogenicity of hepatitis E virus (HEV) and assess the potential risk factors for sporadic hepatitis E.

**METHODS:** Sixty-two serum samples from the patients with acute hepatitis E were collected, including 23 cases coinfecting with hepatitis B virus. Anti-HEV detection and partial HEV RNA amplification were performed by enzyme immunoassays and reverse transcription-nested polymerase chain reaction (RT-nPCR) method, respectively, and PCR products were sequenced. The isolated human HEV sequences were analyzed phylogenetically.

**RESULTS:** The positive rate of serum HEV RNA were 21.0% (13/62), including 5 cases of liver failure. All the 13 isolates shared a 82.1%-98.0% nucleotide homology with each other and had identities of 74.7%-81.0%, 75.3%-78.6%, 75.3%-80.0% and 82.1%-96.1% with

the corresponding regions of HEV genotypes 1-4, respectively. The human HEV strain GS-NJ-12 shared a 100% nucleotide identity with the swine HEV strain swIM6-43 isolated from Inner Mongolia, China.

**CONCLUSION:** Swine may be a principal risk factor for occurrence of sporadic hepatitis E in eastern China, and genotype 4 HEV can induce acute liver failure.

### INTRODUCTION

Hepatitis E virus (HEV) is a single-strand, positive-sense RNA, non-enveloped virus which is classified into the *Hep- eiviridae* family with a single serotype and at least 4 known main genotypes of mammalian HEV, one avian HEV and a new HEV genotype have been isolated from rabbits recently<sup>[1]</sup>. Genotype 1 and 2 of mammalian strains are predominant in humans and associated with large waterborne epidemics in endemic regions<sup>[2]</sup>. However, genotype 3 and 4, which were suggested to be zoonotically transmitted between animals and humans, are mainly responsible for sporadic cases of hepatitis E clinically ma-

nifested as icterus, malaise, anorexia, fever, hepatomegaly and pruritus. Additionally, increasing reports suggest that different HEV genotypes are associated with different disease severity. HEV genotype 1 and 2, which have similar epidemiological and sporadic features, can result in acute hepatitis, acute liver failure, and acute-on-chronic liver failure. However, HEV genotype 3 and 4, which were generally considered to cause acute, self-limiting illness followed by a complete recovery, seem to be less virulent in humans than genotype 1 and 2<sup>[3]</sup>, and do not cause severe liver diseases<sup>[4]</sup>. In mainland China, HEV genotype 4 has become the dominant genotype instead of genotype 1 since 2004<sup>[5]</sup>.

Since the first swine HEV strain was isolated in 1997, many strains of HEV have been identified from human and other mammalian reservoirs (swine, wild boar, deer, mongooses, rabbits and rats), and swine was considered to be the principal reservoir of HEV<sup>[6-10]</sup>. Accumulating data indicates that hepatitis E is a zoonotic disease. Transmissions through the consumption of contaminated food products such as pork have provided further direct evidence. Thus, zoonotic transmission of hepatitis E raises an important public health concern over food safety and zoonotic risk<sup>[11]</sup>.

In China, seroepidemiological studies in patients with viral hepatitis have shown a high superinfection rate (32.4%) with two or more types of hepatitis virus; and HEV superinfection in patients with chronic hepatitis B (CHB) accounts for 17.6%<sup>[12]</sup>. HEV could result in severe disease and a poor outcome in patients with pre-existing liver diseases<sup>[13,14]</sup>. However, there were few reports on the association between genetic characteristics and pathogenicity of HEV infection. In addition, whether genotype 3 and 4 HEV could induce liver failure in normal population and patients with chronic liver disease (CLD) is still unclear. This study was designed to investigate the genotype of HEV prevalent in eastern China, the pathogenicity of HEV in patients with or without CLD and the phylogenetic relationship between human and swine HEV.

## MATERIALS AND METHODS

### *Patients and serum samples*

A total of 62 serum samples were collected from the hospitalized patients with hepatitis E during the period from November 2008 to December 2010. The diagnostic criteria of hepatitis E are as follows: the elevation of alanine aminotransferase (ALT) level (> 2ULN); the positive result for anti-HEV IgM or at least 4-fold increase of IgG levels during hospitalization. Patients coinfecting with hepatitis B virus had positive serum HBsAg and HBV DNA. All patients were negative for anti-human immunodeficiency virus, anti-hepatitis A virus, anti-hepatitis C virus antibodies and autoantibodies. As some patients did not seek medical care in the early stages of their illness, the presence of HEV-IgG was used to diagnose acute hepatitis E in this study<sup>[14-16]</sup>. The clinical data of patients with acute liver failure or acute-on-chronic liver failure were recorded.

### *Enzyme immunoassay of serum anti-hepatitis E virus antibodies*

All the serum samples were detected for anti-HEV IgM, anti-HEV IgG, anti-HAV IgM, HBsAg, anti-HCV IgG using commercial enzyme immunoassay (EIA) kits (Beijing Wantai Biological Pharmacy Enterprise Co., Beijing, China). All assay procedures were carried out according to the manufacturer's instructions. All anti-HEV antibody positive specimens were confirmed by Wantai EIA kit one more time.

### *RNA extraction and reverse transcription-nested polymerase chain reaction*

All serum samples were tested for presence of HEV RNA by reverse transcription-nested polymerase chain reaction (RT-nPCR). RNA was extracted from 200 µL of serum according to the instructions of TRIzol reagent (Invitrogen). The viral RNA was reverse-transcribed to cDNA for 1h at 42 °C with M-MuLV reverse transcriptase (Promega) and specific external anti-sense primers in a 10 µL reaction volume. Nested PCRs for open reading frame (ORF) 2 and ORF1 were performed to detect HEV sequences using two sets of consensus oligonucleotide primers. The primer sequences and amplification parameters were as described previously<sup>[10]</sup>. The final PCR product was analyzed by 15 g/L agarose gel electrophoresis.

### *Sequencing and phylogenetic analysis*

The target second-round PCR products were purified and double-ends sequenced by ABI model 3730 sequencer. Nucleotide sequences were analyzed with the MEGA 4.0, ALIGNX and Bioedit v7.0.9 software. Phylogenetic trees were constructed by the neighbor-joining method and the interior branch test with the aid of MEGA 4.0 software package. One thousand resamplings of the data were used to calculate percentages of the branches obtained.

Designations and accession numbers of full-length reference sequences representing different genotypes for analysis of HEV ORF1 and ORF2 were retrieved from GenBank as follows: Genotype 1: Abb-2B (AF185822); Bur86 (D10330), Sar-55 (M80581), Uigh179 (D11093), FHF (X98292), Morocco (AY230202), T3-Chad (AY204877); Genotype 2: M1 (M74506); Genotype 3: US2 (AF060669), Osh-205 (AF455784), JBOAR-1Hy04 (AB189070), swArnell (AY115488), HE-JA10 (AB089824), JKN-Sap (AB074918), JMY-HAW (AB074920); Genotype 4: 4a: ChH-S-1 (EF077063), swGX32 (EU366959), JKO-ChiSai98C (AB197673); 4b: swGX40 (EU676172), swDQ (DQ279091); 4c: swJ13-1 (AB097811), HE-JA1 (AB097812), HE-JK4 (AB099347), JSN-SAP-FH02 (AB200239); 4d: T1 (AJ272108), swCH25 (AY594199); 4g: ccc220 (AB108537).

In addition, the reference sequences used for analysis of partial ORF2 regions included subtype 4e: IND-SW1 (AF324501), IND-SW2 (AF324502), IND-SW3 (AF324503); 4d: swIM6-26 (AB550622), swIM6-43 (AB550624); subtype 4f: HE-JA2 (AB082558).

I ascites, II dead, III hepatic encephalopathy; patient number 1, 5, 6, 7, 9 and 10 with underlying chronic liver disease, such as chronic hepatitis B, autoimmune hepatitis, alcoholic hepatitis. Patient number 4, 6, 7, 8 and 10 were positive for hepatitis E virus (HEV) RNA. Patient number 1, 2, 4, 6, 8, 9 and 10 were positive for anti-HEV IgM, and patient number 3, 4, 5, 7 and 8 were positive for anti-HEV IgG. All biochemical indices of liver function were recorded at peak level during treatment at our hospital. Because some patients were treated at other hospitals at early period of illness, the biochemical indices of liver function, such as alanine aminotransferase (ALT) and aspartate aminotransferase (AST) may not represent the actual peak level. TBIL: Total bilirubin; DBIL: Direct bilirubin; PA: Pre-albumin; ALB: Albumin; CHE: Cholinesterase; PTA: Prothrombin time activity; PT: Prothrombin time.

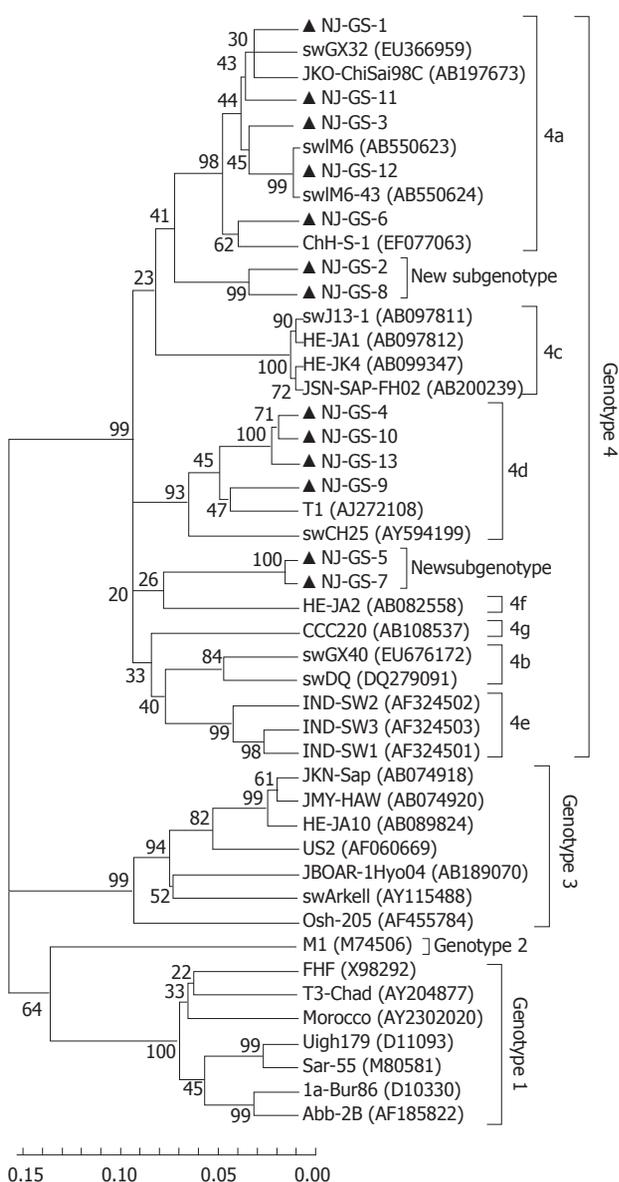

Figure 1 Phylogenetic tree based on 286 bp of open reading frame 2 of hepatitis E virus genotypes 1-4, 13 human sequences. Human hepatitis E virus isolated in this study were signed with solid triangle.

## RESULTS

### Clinical data of patients with liver failure

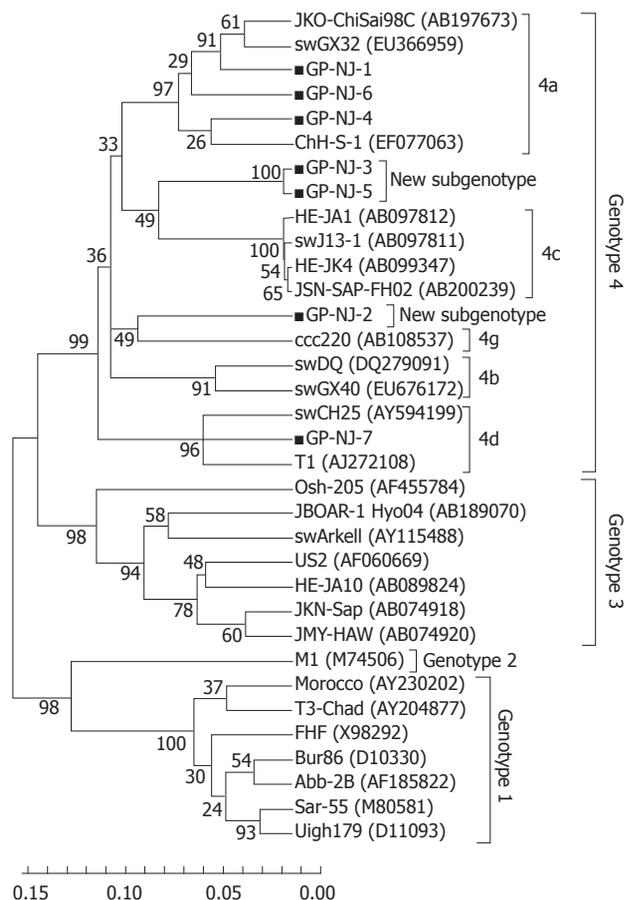

The clinical data of patients with liver failure is summarized in Table 1. Among 62 cases, 10 developed liver failure (4 with acute liver failure and 6 with acute-on-chronic failure), 5 with CLD died of acute-on-chronic liver failure, and one 21-year-old female patient died of acute liver failure.

### Detection of anti-hepatitis E virus and hepatitis E virus RNA

Out of 62 serum samples, 33 were positive for anti-HEV IgM but negative for anti-HEV IgG, while 23 were positive only for anti-HEV IgG, 6 were positive for both IgG and IgM. The overall positivity rate for HEV RNA was 21.0% (13/62).

### Phylogenetic analysis of hepatitis E virus genome isolated from patients

HEV cDNA was amplified from 13 serum samples using primer S4, and the 365nt PCR products of partial ORF2 sequences were determined. The 13 isolated strains were designated as GS-NJ-1 to GS-NJ-13 (GenBank accession numbers JF309208 - JF309220). These 13 isolates shared 82.1%-98.0% nucleotide homology, and had identities of 74.7%-81.0%, 75.3%-78.6%, 75.3%-80.0% and 82.1%-96.1% with the corresponding regions of HEV genotypes 1-4, respectively. Phylogenetic analysis based on partial ORF2 (286 bp) showed that the 13 sequences could be clearly grouped into four main clades (Figure 1), one of which consisted of 4 HEV isolates sharing an 88.4%-97.2% identity with HEV subtype 4d. The second clade included 5 isolates sharing a 90.6%-96.1% identity with HEV subtype 4a. The third clades were formed by GS-NJ-5 and GS-NJ-7 sharing a 98.0% identity with each other and 82.1%-87.3% nucleotide homology with subtypes 4a-4g. The last clade contained 2 isolates sharing a 94.2% identity with each other and 82.5%-89.0% identity with subtypes 4a-4g. Phylogenetic tree showed that both the last two branches were formed individually, separat-

**Figure 2** Phylogenetic tree based on 243 bp of open reading frame 1 of hepatitis E virus genotypes 1-4, 7 human sequences. Human hepatitis E virus isolated in this study were signed with solid square.

ing from the established subgenotypes 4a-4g, which indicated that they may belong to novel subgenotypes. The phylogenetic analysis based on partial ORF1 sequences confirmed the genotyping results (Figure 2).

### Sequence analysis of partial hepatitis E virus ORF1

To exclude the possibility of contamination and confirm the results of phylogenetic analysis based on partial ORF2 sequences, 13 positive samples were amplified using ORF1 primers (P primer) and 11 were positive. Sequence analysis of partial HEV ORF1 fragments showed that there were 7 groups, designated as GP-NJ-1 to GP-NJ-7 with GenBank accession numbers JF309201-JF309207. The 7 strains shared an 82.0%-99.1% sequence identity with each other, and had identities of 73.2%-78.1%, 75.3%-79.0%, 74.0%-82.7% and 80.6%-95.0% with the corresponding regions of HEV genotypes 1-4, respectively. Phylogenetic analysis (Figure 2) confirmed the subtyping result based on partial sequences of ORF2.

## DISCUSSION

In China, a substantial proportion of people had serological evidence of prior HEV exposure but no disease<sup>[17]</sup>. Moreover, according to the national investigation of 2002,

the positive rate of HBsAg was 9.09% in persons over 3 years of age and most of the HBsAg carriers were asymptomatic and under recognized. During the long period of CHB, there was a chance for patients to be sporadically superinfected by HEV. Studies had demonstrated that patients with CLD coinfecting with HEV had more severe liver diseases with higher rates of compensated cirrhosis, hepatic failure, and complications<sup>[13,14]</sup>. In present study, 10 of 62 patients suffered from hepatic failure and 6 patients died (1 died of acute liver failure and 5 died of acute-on-chronic liver failure) (Table 1). Therefore, all susceptible people, especially the patients with CLD should take appropriate strategies to decrease the incidence of HEV infection, such as consumption of boiled water and well-cooked food and hand washing with soap.

As many studies reported, HEV was transmitted primarily by fecal-oral route, usually *via* the consumption of contaminated water or food. However, recent investigations have not consistently found well-defined water sources of HEV, suggesting other possible modes of transmission<sup>[18,19]</sup>. Transmissions through blood transfusions, mother-to-fetus, and person-to-person were also reported<sup>[20,21]</sup>, but these routes of transmission were not thought to be frequent. In this study, a substantial proportion of patients had not consumed any raw meat in the recent past, and no clear source of infection was found, raising the suspicion of transmission through contaminated water or food. It is worth mentioning that in eastern China, where there are many rivers, water are usually contaminated by domestic pig feces and used to fertilize crops without special treatment. As HEV was isolated frequently from swine feces in most parts of the world, people who drink unboiled water or inadequately cooked food may be infected by HEV. Therefore, clinicians should be vigilant and should consider hepatitis E in the differential diagnosis of unexplained jaundice and clinical indications, such as the lack of evidence for other causes of abnormal liver failure, should increase the threshold for testing for HEV infection.

Phylogenetically, sequence analysis of partial ORF2 and ORF1 showed the highest identity with genotype 4, and phylogenetic tree conformed that all HEV strains belonged to genotype 4 and could further subdivided into 4 subgenotypes (Figures 1 and 2). These results indicate that patients in eastern China are currently infected with divergent genotype 4 HEV strains that may be indigenous; genotype 4 has emerged as the predominant genotype in this region with at least 4 subgenotypes. Additionally, further phylogenetic analysis showed a very close relationship and a high nucleotide identity between human and swine HEVs by blasting the partial human HEV sequences in Genbank (Table 2). The GS-NJ-12 strain shared a 100% nucleotide identity with two swine HEVs (swIM6-43 and swIM6-41) isolated from Inner Mongolia, China. Moreover, all swine HEVs showing the highest nucleotide identities comparable with human HEVs were isolated from different areas of mainland China, indicating that sporadic hepatitis E was acquired domestically,

HEV: Hepatitis E virus.

and swine may be a principal risk factor for occurrence of sporadic hepatitis E.

Among 62 serum specimens, 13 samples had positive result of HEV RNA using ORF2 primers. The ORF1 degenerate primer (P primer) set amplified 11 of 13 HEV sequences successfully, and 2 specimens positive for S primer were negative for P primer. While both primer sets could amplify human and animal HEV successfully<sup>[6,10,17,22]</sup>, multiple nucleotide substitutions in the primer-binding regions or a few bases mismatch in 3' end of primers, the narrow window of HEV incubation, low HEV RNA titer in sera and "false-positive" results from cross-reactivity with unknown antigens may result in a low detection rate of HEV RNA. Because the window for HEV diagnosis may be narrow, sample collection from the patients in due course is considered to be the key for HEV RNA detection.

Up until now, hepatitis E is diagnosed by detecting viral RNA in serum and/or feces during the incubation period or early acute phase of disease, or, more commonly, by demonstrating IgM anti-HEV or a rising titer of IgG anti-HEV in the serum during the late acute phase or convalescent phase of the illness<sup>[16]</sup>. However, there are still problems with the enzyme immunoassays used to detect current or previous HEV exposure. Commercial assays vary markedly in their sensitivity and specificity<sup>[14,23]</sup>. Recently, the Wantai kit used in this study was proved to be more sensitive than GeneLab kit (98% vs 56%)<sup>[24]</sup>, which has a high specificity for diagnosis of acute infection of HEV<sup>[25,26]</sup>. Detection of rising IgG or RNA was considered diagnostic with a specificity of 100%; the specificity of IgM was found to be 99.4%<sup>[15]</sup>. Yet, based on previous studies, it is still very hard for researchers to detect HEV RNA in all serum specimens positive for

anti-HEV. In present study, because some patients did not seek medical care in the early stages of their illness, and the period of viraemia is short<sup>[3]</sup>, only 5 of 10 cases with hepatic failure were confirmed by the presence of HEV RNA in serum samples. Although some cases negative for HEV RNA might be misdiagnosed as hepatitis E, 5 patients with liver failure (No. 4, 6, 7, 8, 10) were confirmed by detecting serum HEV RNA using S primers (designated as GS-NJ-11, GS-NJ-4, GS-NJ-6, GS-NJ-9, GS-NJ-5) and P primers (designated as GP-NJ-6, GP-NJ-7, GP-NJ-4, GP-NJ-7, GP-NJ-2). Patients 4 and 8 with no underlying liver diseases suffered from acute liver failure, and patient 4 died. Furthermore, 5 (No. 1, 5, 6, 7 and 9) out of 6 patients with CLD died of hepatic failure and relative complications, suggesting that it is imperative to develop a reliable hepatitis E vaccine.

In conclusion, this study presented the first finding that HEV genotype 4 could result in acute liver failure and acute-on-chronic liver failure. Genotype 4 was the dominant strain among the patients involved in this study, and there were at least 4 subgenotypes (4a, 4d and 2 new subgenotypes) prevalent in eastern China. Phylogenetic analysis showed a very close relationship between human and swine HEV, suggesting that swine may be a principal risk factor for occurrence of hepatitis E in eastern China. However, the implication for subgenotype classification and other issues such as the relationship between different genotypes/subtypes and different modes of transmission, pathogenicity, possibility of cross species transmission are still indistinct and remain to be understood.

## COMMENTS

### Background

Hepatitis E, caused by the hepatitis E virus (HEV), is the most important cause of acute viral hepatitis in adults throughout Asia, the Middle East and Africa where the sanitation conditions are usually substandard. HEV genotypes 1 and 2, which have similar epidemiological and sporadic features, can result in acute hepatitis, acute liver failure, and acute-on-chronic liver failure. However, HEV genotype 3 and 4, which were generally considered to cause acute, self-limiting illness followed by a complete recovery, seems to be less virulent for humans than genotypes 1 and 2 and have not been implicated in causing severe liver diseases. However, there were few reports on the association between genetic characteristics and pathogenicity of HEV infection. In addition, whether genotype 3 and 4 HEV could induce liver failure in normal population and patients with chronic liver disease (CLD) is still unclear.

### Research frontiers

HEV is widespread in swine and is likely to be endemic in many developed/developing countries. There is a very close relationship between human and swine HEV by phylogenetic analysis of partial/full-length genomic sequence. Accumulated evidences support the hypothesis that hepatitis E is a zoonosis, and swine may be a principal risk factor for occurrence of hepatitis E in many areas. HEV infection in healthy individuals are associated with a mortality rate of 0.04%-4%. Some studies have reported a high prevalence of HEV antibodies in patients with CLDs and others have suggested that cirrhotics were prone to HEV infection, and superinfection with HEV in patients with underlying CLD

can cause severe hepatic decompensation, leading to increased morbidity and mortality.

### Innovations and breakthroughs

In China, superinfection with genotype 4 HEV in patients with underlying CLD, especially in patients with chronic hepatitis B, can cause severe hepatic decompensation, leading to increased morbidity and mortality. This study presented the first finding that genotype 4 HEV can induce liver failure in normal population and patients with CLD. The GS-NJ-12 strain isolated from a case of sporadic hepatitis E shared a 100% nucleotide identity with two swine HEVs (swIM6-43 and swIM6-41) isolated from Inner Mongolia, China. Moreover, all swine HEVs showing the highest nucleotide identities comparable with human HEVs were isolated from different areas of mainland China, indicating that sporadic hepatitis E is acquired domestically, and swine may be a principal risk factor for occurrence of sporadic hepatitis E in eastern China.

### Applications

This study found that the dominant genotype of HEV prevalent in eastern China was genotype 4, which can induce liver failure in normal population and patients with CLD and swine may be a principal risk factor for occurrence of sporadic hepatitis E. Therefore, a standardized management of swine in stock farm is the key to prevent HEV transmission from swine to human.

### Peer review

The work investigated the genetic characteristics of the HEV in Eastern China and assessed the potential risk factors. Among acute infected patients, they found a seroprevalence of HEV RNA in 21%. The isolated HEV strains shared a high percentage of nucleotide homology with a HEV strain isolated from swine. The manuscript demonstrates a well performed study which hints one more time the direction that HEV may be acquired by the contact to swines/wild boars.

### Abstract

**AIM:** To investigate the expression of B7-H1 in human colorectal carcinoma (CRC) to define its regulating effects on T cells in tumor microenvironment.

**METHODS:** One hundred and two paraffin blocks and 33 fresh samples of CRC tissues were subject to this study. Immunohistochemistry was performed for B7-H1 and CD3 staining in CRC tissues. Ficoll-Hypaque density gradient centrifugation was used to isolate peripheral

blood mononuclear cells of fresh CRC tissues; flow cytometry and immunofluorescence staining were used for detection of regulatory T cells. Data was analyzed with statistical software.

**RESULTS:** Costimulatory molecule B7-H1 was found strongly expressed in CRC tissues, localized in tumor cell membrane and cytoplasm, while weak or none expression of B7-H1 was detected in paired normal colorectal tissues. Meanwhile, CD3 positive T cells were found congregated in CRC tumor nest and stroma. Statistic analysis showed that B7-H1 expression level was negatively correlated to the total T cell density in tumor nest ( $P < 0.0001$ ) and tumor stroma ( $P = 0.0200$ ) of 102 cases of CRC tissues. Among the total T cells, a variable amount of regulatory T cells with a clear Foxp3<sup>+</sup> (fork-head box P3) staining could be detected in CRC tissues and patients' blood. Interestingly, in the 33 samples (15 cases of B7-H1<sup>high</sup> CRC tissues and 18 cases of B7-H1<sup>low</sup> CRC tissues) of freshly isolated mononuclear cells from CRC tissues, the percentages of CD4<sup>+</sup>Foxp3<sup>+</sup> and CD8<sup>+</sup>Foxp3<sup>+</sup> regulatory T cells were found remarkably higher in B7-H1<sup>high</sup> CRC tissues than in B7-H1<sup>low</sup> CRC tissues ( $P = 0.0024$ ,  $P = 0.0182$ ), indicating that B7-H1 expression was involved in proliferation of regulatory T cell. No significant difference was found in CRC peripheral blood ( $P = 0.0863$ ,  $P = 0.0678$ ). PD-1 is the specific ligand for B7-H1 pathway transferring inhibitory signal to T cell, which is expressed by activated T cell. Our further analysis of PD-1 expression on T cells in CRC tissues showed that conventional T cells (CD4<sup>+</sup>Foxp3<sup>-</sup>/CD8<sup>+</sup>Foxp3<sup>-</sup>), which was thought to contribute to the anti-tumor immune response, highly expressed PD-1; while regulatory T cells (CD4<sup>+</sup>Foxp3<sup>+</sup>/CD8<sup>+</sup>Foxp3<sup>+</sup>) almost failed to express PD-1. The average percentage of PD-1 expression on regulatory T cells was significantly higher than the percentage of PD-1 on conventional T cells (CD4<sup>+</sup>Foxp3<sup>-</sup> T cell,  $P < 0.0001$ ; CD8<sup>+</sup>Foxp3<sup>-</sup> T cell,  $P < 0.0001$ ). The diverse expression of PD-1 might lead to different fate of T cell subsets in B7-H1 over-expression CRC tumor microenvironment.

**CONCLUSION:** B7-H1 expression in tumor cells can inhibit the conventional T cell proliferation in tumor microenvironment through the PD-1 expression on conventional T cells.

## INTRODUCTION

Tumor genesis is associated with a wide array of both genetic and epigenetic changes. Although host immune surveillance may prevent tumor outgrowth during the earliest stages of tumor growth, locally invasive or metastatic tumors must evade host immunity<sup>[1]</sup>. Immune escape is not merely a passive process of immune evasion but an active process in which tumor cells, stromal cells and immune cells within the tumor microenvironment actively suppress the antitumor immune response. Both myeloid-derived cells and lymphocyte subsets, most notably regulatory T cells (Treg), collaborate with their malignant counterparts to suppress the host immunity<sup>[2,3]</sup>. Recent evidence showed that experimental depletion of Tregs improves immune-mediated tumor clearance and enhances the response to immune-based therapy<sup>[4,5]</sup>. Tregs have been shown to suppress tumor-specific T cell immunity and therefore may contribute to the progression of human tumors<sup>[6,7]</sup>. Furthermore, tumor Tregs are associated with a reduced survival of the patients with ovarian carcinoma and brain tumors<sup>[8,9]</sup>. In contrast, it has been found in Hodgkin lymphoma that decreased number of infiltrating Foxp3<sup>+</sup> cells in conjunction with increased infiltration of cytotoxic T lymphocytes predicts an unfavorable clinical outcome<sup>[10]</sup>. Although previous studies have suggested that tumors could induce CD25<sup>+</sup>Foxp3<sup>+</sup>Tregs from naïve CD4 T cells in the absence of thymus, the cellular and molecular mechanisms for that, however, are still not well understood<sup>[11,12]</sup>. Optimal activation of antigen-specific lymphocytes requires specific antigen recognition by lymphocytes and costimulatory signals<sup>[13]</sup>. Up to date, a cohort of important costimulatory molecules, including B7 family ligands, and those which interact with known or unknown receptors, has been identified, namely B7-1 (CD80), B7-2 (CD86), B7-H1 (PD-L1), B7-DC (PD-L2), B7-H2 (ICOS ligand), B7-H3 and B7-H4 (B7x, B7-S1),

which essentially contribute to the T cell activation and tolerance<sup>[14-19]</sup>. B7-H1 was identified in 1999 as a member of B7 family that was described to negatively regulate T cell function by engagement with PD-1, a CD28 family member receptor. Besides antigen-presenting cells, B7-H1 mRNA was found in a variety of nonlymphoid parenchymal organs, including the heart, placenta, skeletal muscle, and lung<sup>[15]</sup>. B7-H1 was thought to inhibit T cell growth and cytokine production by ligation of the PD-1 receptor<sup>[20]</sup>, which is expressed on activated T and B cells<sup>[15,21]</sup>. Zou *et al*<sup>[22]</sup> reported the presence of B7-H1 protein by immunohistochemistry in a wide range of human cancers. Tumor-associated B7-H1 induced apoptosis of effector T cells and was thought to contribute to immune evasion by cancer. Other studies indicated that blockade of B7-H1 enhanced tumor immunity but had no direct effect on tumor cells<sup>[23-25]</sup>. To make the situation more complicated, B7-H1 can also function as a receptor to transmit signals to T cells and tumor cells<sup>[26,27]</sup>. In summary, B7-H1 can act as both ligand and receptor to execute immuno-regulatory functions. B7-H1 was reported to be involved in the induction of Tregs, dysfunctional dendritic cells that expressed up-regulated B7-H1 may lead to the generation of Tregs, and *in vivo* blocking of B7-H1 signaling abolished the conversion in a tumor-induced Treg conversion model<sup>[28]</sup>. Whether the tumor-associated B7-H1 could affect the Tregs generation in the tumor microenvironment deserves further exploration.

Colorectal carcinoma (CRC) is one of the most frequent malignancies worldwide, its incidence and mortality are especially high in Western developed counties, and it is the second leading cause of cancer-related death<sup>[29]</sup>. CRC is a multi-pathway disease since numerous pathological factors and polygene transformation are involved in its oncogenesis and progression. Within recent decades, varieties of therapeutic strategies including conventional surgery, chemotherapy, radiotherapy and immunotherapy, or even combination of these therapies have been available in the treatment of CRC patients. However, these therapies yielded different outcomes due to different physical conditions of the patients, which shaped the tumor microenvironment with immune suppressions<sup>[30-32]</sup>. Therefore, it is critical for clinicians to perform further analysis of the immune suppression and establish individualized strategy for CRC patients.

In the present study, we performed immunohistochemistry to characterize the B7-H1 expression in human CRC and examined its effect on infiltrating T lymphocytes in tumor tissues. The regulatory T cells were detected in the tumor tissues and peripheral blood of CRC patients, and the relationship between the B7-H1 expression and Tregs population was analyzed. The mechanism of regulatory T cell expansion related to B7-H1-PD-1 signal was also investigated.

## MATERIALS AND METHODS

### Patients

For B7-H1 expression and T cell infiltration analysis, 102

patients with CRC who underwent surgery from May 2004 to December 2007 were included in the present study. No patient received pre-operative chemotherapy or radiotherapy. The paraffin blocks of tumor tissues were assembled from the archival collections of the Department of Pathology, and all 102 specimens were identified as CRC by hematoxylin and eosin (HE) staining. For regulatory T cell and B7-H1 expression analysis, 33 CRC patients who underwent surgery from January 2008 to July 2009 were subjected to this study. No patient received pre-operative chemotherapy or radiotherapy. The freshly removed tumor tissues were identified as colorectal carcinoma by pathologist according to the HE staining. The blood samples were collected from the 33 CRC patients before the surgery by venipuncture. Thirty-three normal tissues from autologous non-malignant portion of colon or rectum were resected surgically for the analysis as well, and used as the normal tissue control.

The specimens were collected from the Third Affiliated Hospital and the Fourth Affiliated Hospital of Soochow University, China, with the approval of the Ethic Committees of these hospitals.

### Immunohistochemistry

Immunohistochemistry was performed using the Dako Elivision™ according to the manufacturer's instructions. Both tumor tissues and non-malignant tissues were fixed with formalin, and embedded in paraffin wax. Before immunohistochemical staining, 3- $\mu$ m-thick consecutive sections were cut by microtome, dewaxed in xylene and rehydrated through graded ethanol solutions. Antigens were retrieved by heating the tissue sections at 100 °C for 30 min with citrate solution (10 mmol/L, pH 6.0, for CD3 antigen retrieval) or ethylenediaminetetraacetic acid solution (1 mmol/L, pH 8.0, for B7-H3 antigen retrieval). Sections were cooled down and immersed in 0.3% hydrogen peroxide for 15 min to block endogenous peroxidase activity, and then rinsed in phosphate-buffered saline (PBS) for 5 min, blocked with 5% bovine serum albumin (BSA) at room temperature for 15 min, and incubated with primary antibodies against CD3 (Maixin Biotechnology Limited Corporation, Fuzhou, China) and B7-H1<sup>[21]</sup>, respectively, at 4 °C overnight. Negative controls were performed by replacing the specific primary antibody with PBS. The sections were then rinsed in PBS for 5 min for 3 times and were followed by incubation with HRP-labeled goat anti mouse/rabbit secondary antibody (Dako, Glostrup, Denmark). Diaminobenzene was used as the chromogen and hematoxylin as the nuclear counterstain. The sections were dehydrated, cleared and mounted.

### Evaluation of B7-H1 and CD3 immunohistochemical staining

Two independent observers who blinded to the clinicopathological parameters of the patients assessed the immunohistochemical staining sections. The B7-H1 immunostaining intensities were scored according to a scale as grade 0, negative; grade 1, weakly positive; grade 2, moderately positive; grade 3, strongly positive. The nega-

tive means no tumor cells showing positive immunostaining. Sections were considered as positive when the tumor cells showed cytoplasmic or membranous B7-H1 immunostaining with proper intensities and were extended as grades 1, 2 and 3. The sections of grade 0 and grade 1 were classified as low expression group, and other sections of grade 2 and grade 3 were classified as high expression group.

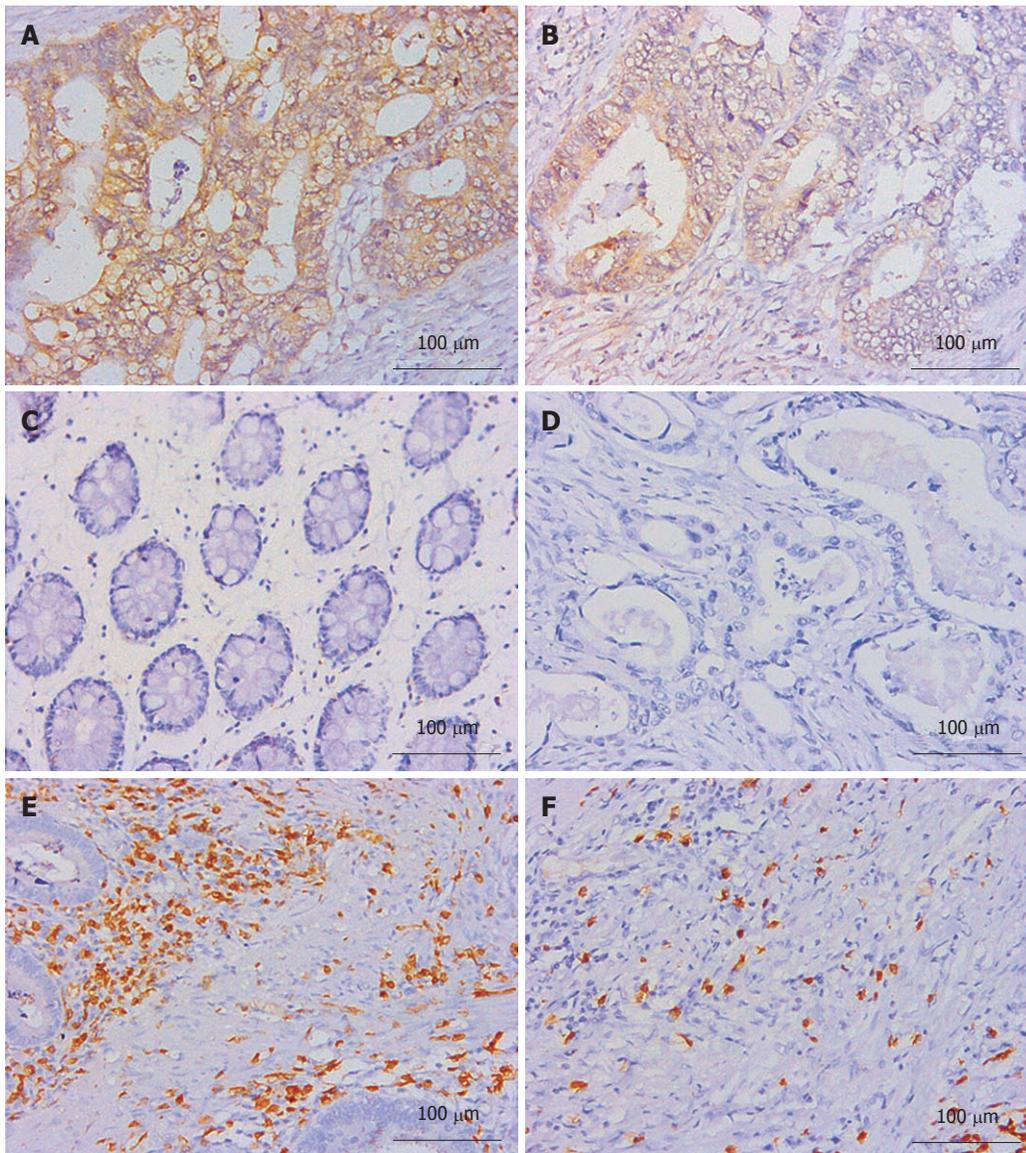

Infiltrating T lymphocytes in both tumor stroma and tumor nest were determined according to the CD3 immunolabeling. First, the infiltrating T lymphocytes in tumor stroma were examined at low magnification ( $\times 40$ ) and categorized according to the density as: grade 0, scanty; grade 1, moderate infiltration; grade 2, abundant infiltration; grade 3, the most abundant infiltration. The group of grade 0 and grade 1 was defined as low infiltration group, and another group of grade 2 and grade 3 was defined as high infiltration group. Second, the infiltrating T lymphocytes in tumor nest were counted as follows: five areas in tumor nest with the most intense infiltrating T lymphocytes were selected at low magnification ( $\times 40$ ), then the infiltrating T lymphocytes were counted and recorded at high power field (HPF,  $\times 200$  magnification). Results from the five areas were averaged and used in the statistical analysis. In the present study, the sections with the infiltrating T lymphocytes in tumor nest of less than 60 per HPF were defined as low infiltration group, and other sections with the infiltrating T lymphocytes in tumor nest of more than 60 per HPF were defined as high infiltration group. The cutoff point of 60 T lymphocytes per HPF for low/high infiltration assessment in tumor nest was set at the median value of the entire sections.

### Cell isolation from fresh tumor tissues and peripheral blood

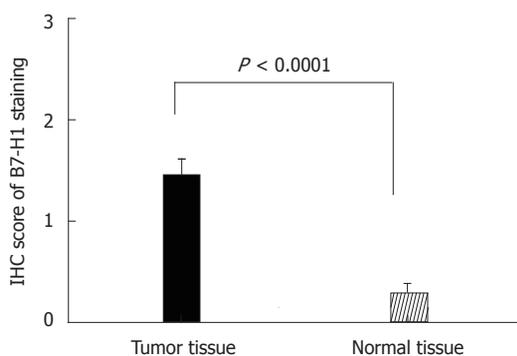

Fresh tumor specimens were gently minced on a wire mesh screen to obtain a cell suspension. The cell suspension was centrifuged over Ficoll-Hypaque (Amersham Biosciences, Sweden) at 1400 r/min for 25 min. After density gradient centrifugation, the mononuclear cells were collected and washed with RPMI 1640 media (Gibco, United States) containing 50 g/mL fetal bovine serum (Hyclone, United States) and 10 g/mL penicillin/streptomycin (Sigma-Aldrich, United States). Peripheral blood mononuclear cells were also isolated with Ficoll-Hypaque density gradient centrifugation, and the isolated mononuclear cells were subjected to the analysis immediately.

### Flow cytometry and intracellular staining

Cells were washed in PBS containing 5 g/mL BSA and incubated with the specific fluorochrome-conjugated antibodies identifying surface molecules on T cells for 30 min at 4 °C. The antibodies included CD4-FITC, CD8-FITC (Beckman Coulter, United States) and PD-1-PE (eBioscience, United States). For intracellular staining, washed cells were fixed with Foxp3 Fixation/Permeabilization Solution (eBioscience, United States) at room temperature, then incubated with PE-cy5 conjugated anti-Foxp3 anti-

**Figure 1** B7-H1 and CD3 immunostaining of colorectal carcinoma tissues. **Figure 2** B7-H1 expression level in colorectal carcinoma tissues and adjacent normal tissues from 33 patients evaluated by immunohistochemistry. IHC: Immunohistochemistry.

body (eBioscience, United States) at room temperature in the dark for 30 min. Labeled cells were re-suspended in

0.5 mL cell staining buffer, and then were analyzed with flow cytometry and the Beckman-Coulter's Expo32 Multicom software (Beckman Coulter, United States). Isotype controls were done for each staining.

### Statistical analysis

Statistical analyses were performed using GraphPad Prism 5.0 software package (GraphPad Software, United States). Paired or unpaired Student's *t* test, Wilcoxon signed rank test, and the Pearson  $\chi^2$  test were used where appropriate. A *P* value less than 0.05 was considered statistically significant.

## RESULTS

### **B7-H1 expression was found in colorectal carcinoma tissues but not in normal colorectal tissues**

Thirty-three cases of paired CRC tissues and adjacent nor-

Infiltrating T lymphocytes in colorectal carcinoma tissues	Cases	B7-H1 expression		$\chi^2$	P value
		Low	High		
Tumor stroma				9.549	0.0200
Low infiltration (scanty and moderate)	68	24	44		
High infiltration (abundant and the most abundant)	34	23	11		
Tumor nest				17.4	<0.0001
Low infiltration (less than 60 T lymphocytes per HPF)	51	13	38		
High infiltration (more than 60 T lymphocytes per HPF)	51	34	17		

HPF: High power field.

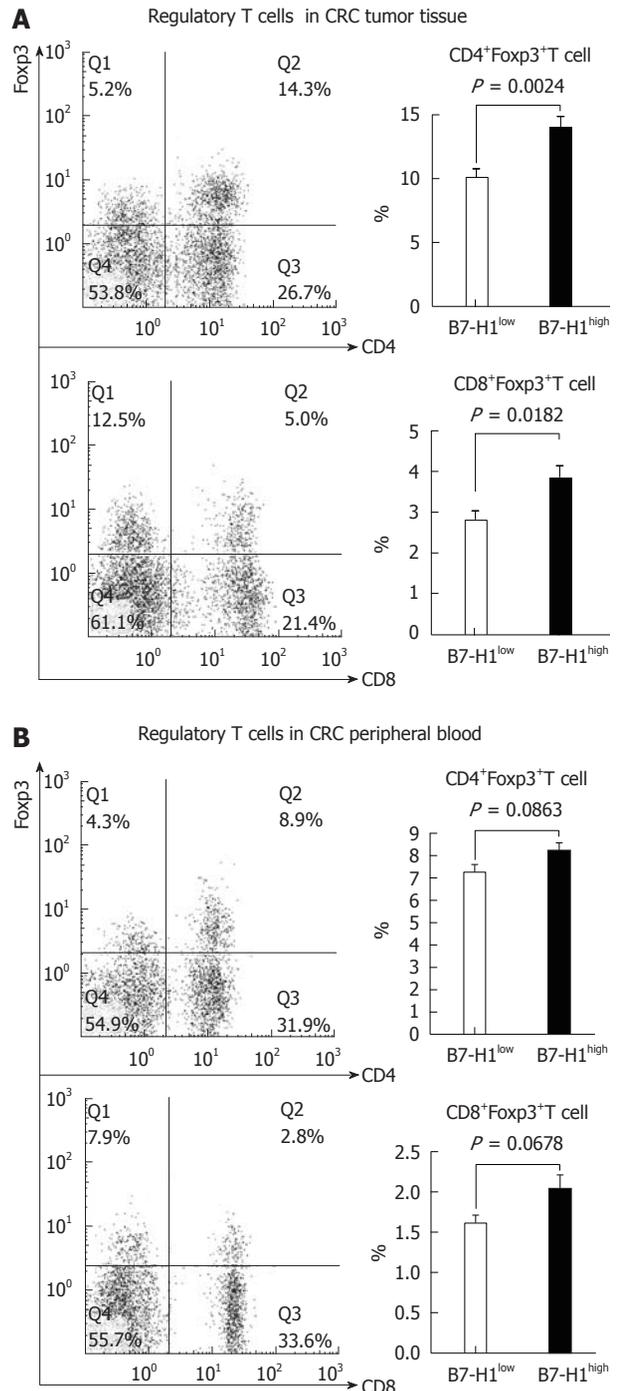

mal tissues resected surgically were used to investigate the B7-H1 expression. As we described in previous works in human gastric carcinoma<sup>[21]</sup>, B7-H1 was also found strongly expressed in tumor cells, localized in the membrane and cytoplasm (Figure 1A and B). Based on the immunohistochemical scores, 33 cases of tumor tissues showed B7-H1 expression (Score 1, 2 or 3), and 15 cases of tumor tissues had high B7-H1 expression (Score 2 or 3). In the normal tissues, 3 cases showed low B7-H1 expression (Score 1), and none showed high B7-H1 expression (Figure 1C). According to the statistical analysis, B7-H1 expression level in CRC tumor tissues was higher than in the adjacent normal colorectal tissues ( $P < 0.0001$ , Figure 2).

**B7-H1 expression level was negatively correlated to the total T cell infiltration density**

CD3 staining was considered as T cell labeling, and the number of positive cells represented the total T cell infiltration density<sup>[30]</sup>. CD3 positive T cells were found congregated in CRC tumor and stroma (Figure 1E and F). One hundred and two cases of paraffin embedded CRC tissues were used to study the B7-H1 expression and the T cell infiltration. As shown in Table 1, tumor cell B7-H1 expression was negatively and significantly correlated to the density of CD3 positive T cells in tumor nest ( $P < 0.0001$ , Table 1) and tumor stroma ( $P = 0.0200$ , Table 1). Thus, the data further implied an important role of B7-H1 in suppressing T cell-based cellular immune surveillance of CRC.

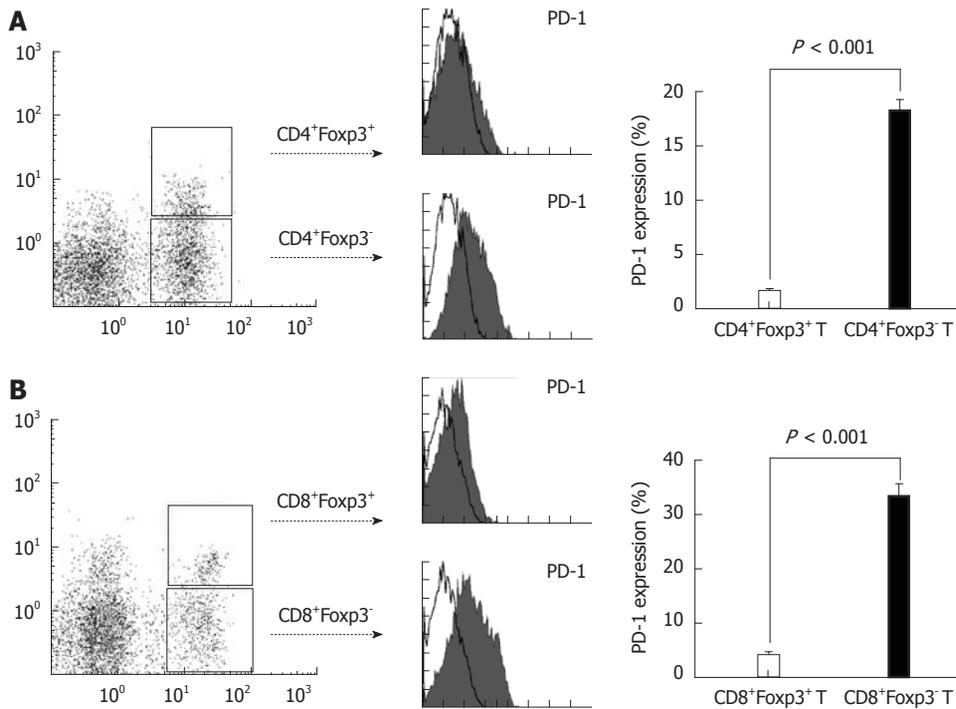

**B7-H1<sup>high</sup> colorectal carcinoma tissues were infiltrated with elevated numbers of CD4<sup>+</sup>/CD8<sup>+</sup> regulatory T cells**

To evaluate the effect of tumor B7-H1 on intratumoral regulatory T cells, we first characterized the percentage of CD4<sup>+</sup>Foxp3<sup>+</sup> T cells and CD8<sup>+</sup>Foxp3<sup>+</sup> T cells. Mononuclear cells isolated from resected specimens of CRC patients were stained with multicolor-labeled antibodies and analyzed by flow cytometry. The peripheral blood mononuclear cells were also analyzed in the regulatory cell population. Among the CD4<sup>+</sup> or CD8<sup>+</sup> T cells, a population with a clear Foxp3<sup>+</sup> could be detected (Figure 3).

**Figure 3** An elevated CD4<sup>+</sup>Foxp3<sup>+</sup> and CD8<sup>+</sup>Foxp3<sup>+</sup> T cell amount observed in B7-H1<sup>high</sup> colorectal carcinoma tissues. Mononuclear cells were harvested from fresh tumor tissues (A) and the peripheral blood (B) of the same colorectal carcinoma patient. The percentage of the Foxp3<sup>+</sup> T cells was determined by fluorescence-activated cell sorting analysis. A: The population of CD4<sup>+</sup>Foxp3<sup>+</sup> and CD8<sup>+</sup>Foxp3<sup>+</sup> T cells was increased remarkably in B7-H1<sup>high</sup> colorectal carcinoma (CRC) tissues compared with B7-H1<sup>low</sup> CRC tissues; B: In peripheral blood, there was no significant diversity of regulatory T cells between the B7-H1<sup>low</sup> and B7-H1<sup>high</sup> CRC patients.

A variable amount of regulatory T cells was found in CRC tissues and patients' blood. Next, to determine the correlation between the tumor cell B7-H1 expression and regulatory T cells, we divided the 33 CRC specimens into B7-H1<sup>high</sup> group ( $n = 15$ ) and B7-H1<sup>low</sup> group ( $n = 18$ )

**Figure 4** PD-1 expression on CD4<sup>+</sup>Foxp3<sup>+</sup> or CD8<sup>+</sup>Foxp3<sup>+</sup> regulatory T cells and conventional T cells in colorectal carcinoma tissues. Mononuclear cells were harvested from fresh tumor tissues of the same colorectal carcinoma patient. The PD-1 expression was determined by fluorescence-activated cell sorting analysis, gated on CD4<sup>+</sup>Foxp3<sup>-</sup> or CD8<sup>+</sup>Foxp3<sup>-</sup> T cells. A: CD4<sup>+</sup>Foxp3<sup>+</sup> regulatory T cells could hardly express PD-1 on the cell surface, while PD-1 expression level was significantly higher on the conventional CD4<sup>+</sup>T cells; B: CD8<sup>+</sup>Foxp3<sup>+</sup> regulatory T cells almost failed to express PD-1, while PD-1 expression was significantly higher on the conventional CD8<sup>+</sup>T cells as well.

according to the B7-H1 expression in tumor tissues. The results showed that in the CRC tumor tissues, the percentages of CD4<sup>+</sup>Foxp3<sup>+</sup> T cells and CD8<sup>+</sup>Foxp3<sup>+</sup> T cells in B7-H1<sup>high</sup> group were remarkably higher than in the B7-H1<sup>low</sup> group ( $P = 0.0024$ ,  $P = 0.0182$ ). On the contrary, in the CRC peripheral blood, there was no significant difference of the percentages of regulatory T cells between B7-H1<sup>high</sup> group and B7-H1<sup>low</sup> group ( $P = 0.0863$ ,  $P = 0.0678$ ).

**PD-1 expression was decreased on regulatory T cells and increased on conventional T cells in colorectal carcinoma tissues**

PD-1-B7-H1 ligation has been shown to have an inhibitory effect on T cells<sup>[33]</sup>. However, the effect of this pathway on regulatory T cells infiltrated in tumor tissues has not been investigated. The highly expressed B7-H1 on tumor cells could lead to a low amount of total T cell infiltration, but a high amount of regulatory T cell infiltration in the local tissues, which indicated that the PD-1-B7-H1 pathway could be different in the conventional T cells and regulatory T cells. Therefore, we assessed the surface PD-1 expression on CD4<sup>+</sup>Foxp3<sup>+</sup>/CD8<sup>+</sup>Foxp3<sup>+</sup> regulatory T cells and CD4<sup>+</sup>Foxp3<sup>-</sup>/CD8<sup>+</sup>Foxp3<sup>-</sup> conventional T cells in CRC tissues. We found a high percentage of CD4<sup>+</sup>Foxp3<sup>-</sup>/CD8<sup>+</sup>Foxp3<sup>-</sup> conventional T cells expressing PD-1 on the cell surface (Figure 4,  $P < 0.0001$ ). However, the CD4<sup>+</sup>Foxp3<sup>+</sup>/CD8<sup>+</sup>Foxp3<sup>+</sup> regulatory T cells could hardly express PD-1 (Figure 4,  $P < 0.0001$ ), which could allow the survival of regulatory T cells in B7-H1<sup>high</sup> tumor microenvironment.

**DISCUSSION**

B7-H1, with engagement of either of its receptor, PD-1, plays a critical role in suppressing T cell-based immunity and has emerged as an important mediator of tumor-associated immune suppression. B7-H1 was found in several solid tumors and evaluated as a potent prognostic factor. Our previous work has described the immunosuppressive effects of B7-H1 pathway in gastric carcinoma<sup>[33]</sup>. We demonstrated in this study that B7-H1 was over-expressed in human colorectal carcinoma, whereas B7-H1 was not expressed or expressed at a very low level in normal colorectal tissues. Furthermore, we found that the protein levels of B7-H1 in tumor cells were negatively correlated to the densities of total T cells, suggesting that it may encompass a mechanism of immune suppression in antitumor immunity in human CRC. This part of work is consistent with the previous studies of B7-H1 in other solid tumors, which again emphasize the important role of up-regulated B7-H1 expression in human tumors. Tumors have a specific microenvironment that contains many types of immune cells. Although the potent value of B7-H1 in tumor progression was confirmed repeatedly, the mechanism of tumor-associated B7-H1 involved in the regulation of these immune cells is still poorly understood.

Regulatory T cells have been identified in the lung, gastric and esophageal, ovarian, breast and pancreatic tumor specimens, and Hodgkin lymphoma. It has been suggested that CD4<sup>+</sup>CD25<sup>+</sup>Treg cells are involved in the mediation of antitumor immunity by suppressing tumor-specific T

cell immunity, thereby contributing to the growth of human tumors<sup>[6-10]</sup>. How regulatory T cells could survive and expand in the tumor microenvironment remains unclear, and how to regulate the regulatory T cells in microenvironment would be critical to tumor immunotherapy<sup>[34]</sup>. In the present study, we detected the CD4<sup>+</sup>Foxp3<sup>+</sup> and CD8<sup>+</sup>Foxp3<sup>+</sup> regulatory T cell population in the CRC tumor tissues and peripheral blood. The percentage of regulatory T cells was significantly elevated in B7-H1<sup>high</sup> CRC tissues, but not in the peripheral blood. These results indicated that the up-regulated B7-H1 expression could lead to a local congregation of regulatory T cells, which might promote the tumor progression. B7-H1 expression was positively related to the regulatory T cell expansion, but negatively related the total T cell infiltration in CRC tissues. This suggested that B7-H1 pathway could have different effects and functions on the subgroups of T cells. B7-H1 pathway could participate in the immune suppressions through multi-regulations of T cells.

T cells are a very diverse lymphocyte population with respective functions in tumor microenvironment. Understanding of their polarization toward stimulatory or inhibitory activity is important to know how they work in diseases<sup>[30,35]</sup>. Regulatory T cells expressing the hallmark forkhead transcription factor 3 (Foxp3) are of therapeutic value in cancer immunotherapy due to their potent immunosuppressive effects. The presence of regulatory T cells was determined by the complex tumor microenvironment. How to decrease the number of regulatory T cells and increase the conventional T cells is critical to obtain a desired outcome of immunotherapy. Here, we assessed the PD-1 expression on T cell subsets to explore the mechanism of B7-H1 pathway in regulation of tumor-infiltrated T cells. The data showed a very interesting phenomenon that conventional T cells (CD4<sup>+</sup>Foxp3<sup>-</sup>/CD8<sup>+</sup>Foxp3<sup>-</sup>) expressed PD-1 on the cell surface at a high level, while regulatory T cells (CD4<sup>+</sup>Foxp3<sup>+</sup>/CD8<sup>+</sup>Foxp3<sup>+</sup>) almost failed to express PD-1. Under these circumstances, the ligation of tumor-associated B7-H1 with PD-1 on conventional T cells would lead to the failure of T cell-mediated anti-tumor effect, and inhibit the conventional T cell proliferation and survival. At the same time, the loss of PD-1 expression could allow the existence and expansion of regulatory T cells, which could further inhibit the conventional T cells. B7-H1 expression in tumor cells could collaborate with its regulation outcomes on T cells, suppress the tumor immune response, and shape the tumor immune escape circumstance.

In conclusion, the inhibitory co-stimulatory molecule B7-H1 expression was found in CRC tissues, but not in normal colorectal tissues. B7-H1 expression in tumor cells could inhibit the conventional T cell proliferation in tumor microenvironment through the PD-1 expression on conventional T cells. Regulatory T cells could barely express PD-1, and consequently gain the survival and expansion in a B7-H1<sup>high</sup> microenvironment. Our works also support the efforts to develop immunotherapeutic approaches targeting B7-H1 pathway for the treatment of CRC.

## ACKNOWLEDGMENTS

We also thank Professor Jiang JT from the Third Affiliated Hospital of Soochow University, Dr. Jiang D and Dr. Chen Y from the First Affiliated Hospital of Soochow University for their instructions in the collection of experimental specimens.

## COMMENTS

### Background

Inhibitory co-stimulatory molecules from B7-family have been implicated in suppression of tumor immunity. B7-H1 was found to be over-expressed in many human malignancies, and was significantly correlated to the clinicopathological parameters and prognoses of various human tumors. B7-H1 was suggested to play an important role in tumor immune escape, while the full mechanism of tumor-associated B7-H1 pathway needs further studies.

### Research frontiers

B7-H1 expression in tumor tissues was evaluated as a potent target for tumor immune therapy. The mechanism of B7-H1 pathway was considered involving the suppressive effect on tumor-specific T cell immunity and therefore may contribute to the progression of human tumors. Previous studies have suggested that tumors could induce CD25<sup>+</sup>Foxp3<sup>+</sup> regulatory T cells (Treg) from naive CD4 T cells in the absence of thymus, while the key molecules and pathway are still unknown. In this study, the authors focus on the significance and function of tumor-associated B7-H1 in Tregs' expansion.

### Innovations and breakthroughs

The mechanism of B7-H1 pathway in tumor microenvironment is commonly considered as decreasing and suppressing of antigen-specific T cells. This article reported for the first time that tumor-associated B7-H1 was involved in the expansion of Tregs in colorectal carcinoma (CRC) tissues, which provided a new strategy for the future researches. Furthermore, B7-H1-PD-1 was found not responsible for the Tregs expansion, which offers a presumption of another receptor for B7-H1 on Tregs.

### Applications

Regulatory T cells are of therapeutic value in cancer immunotherapy due to their potent immunosuppressive effects. How to decrease the number of regulatory T cells and increase the conventional T cells is critical to obtain a desired outcome of immunotherapy. This study supports the efforts to develop immunotherapeutic approaches targeting B7-H1 pathway for immune therapy through regulating conventional and regulatory T cells in CRC.

### Peer review

The authors investigated the immunolocalization of the protein B7-H1 in colorectal cancer tissues using a standardized immunohistochemical approach. Furthermore, they compared the B7-H1 expression with the density of FOXP3 and CD3 immune cell infiltrate. They found that B7-H1 expression in tumor cells inhibits the proliferation of T cells, but allows the survival and expansion of T regulatory lymphocytes. The manuscript is interesting, and well done.

### Abstract

**AIM:** To investigate the relationship between Interleukin-8 (IL-8) and proliferation, adhesion, migration, invasion and chemosensitivity of gastric cancer (GC) cells.

**METHODS:** The IL-8 cDNA was stably transfected into human GC cell line MKN-45 and selected IL-8-secreting transfectants. The expression of IL-8 in human GC cell line KATO-III was inhibited by RNA interference. The expressions of mRNA and protein of IL-8 in GC cells were detected by real-time reverse transcription-polymerase chain reaction or enzyme-linked immunosorbent assay (ELISA).

**RESULTS:** The overexpression of IL-8 resulted in an increased cell adhesion, migration and invasion, and

a significant resistance to oxaliplatin in MKN-45 cells. Inhibition of IL-8 expression with small interfering RNA decreased the adhesion, migration and invasion functions and oxaliplatin resistance in KATO-III cells. IL-8 increased NF- $\kappa$ B and Akt activities and adhesion molecules ICAM-1, VCAM-1, and CD44 expression in GC cells.

**CONCLUSION:** Overexpression of IL-8 promotes the adhesion, migration, invasion, and chemoresistance of GC cells, indicating that IL-8 is an important therapeutic target in GC.

### INTRODUCTION

Gastric cancer (GC) is still a serious health problem and remains the second most common type of fatal cancer worldwide<sup>[1,2]</sup>. GC is one of the most aggressive tumors and is frequently associated with lymph node metastasis, peritoneal dissemination and hematogenous metastasis.

Interleukin-8 (IL-8), a cytokine of the CXC chemokine family that was originally classified as neutrophil

chemoattractant, is now reported to play an important role in tumor progression and metastasis in a variety of human cancers<sup>[3]</sup>. It has been suggested that tumor cells produce IL-8 as an autocrine growth factor, which promotes tumor growth, tissue invasion and metastatic spread<sup>[4,5]</sup>. Moreover, IL-8 expression correlates with vascularity in gastric carcinoma<sup>[6]</sup>. In human moderately differentiated gastric adenocarcinoma cancer cell line SCG-7901<sup>[7]</sup> and poorly differentiated adenocarcinoma cancer cell line TMK-1<sup>[8]</sup>, constitutive expression of IL-8 has been linked to tumorigenesis and angiogenesis *in vitro* and *in vivo*. However, the exact role of IL-8 in the progressive tumorigenesis of GC remains unclear.

The purpose of this study was to provide evidence for the role of IL-8 in determining the migration, invasion and chemosensitivity of human GC. We found that expression of IL-8 participated in the migration and invasion and was correlated with oxaliplatin resistance of GC cells *in vitro*. This study may provide the basis for the development of new therapies for GC by increasing chemosensitivity and decreasing the proliferation, migration and invasion of the cancer cells.

## MATERIALS AND METHODS

### Cell culture

Human GC cell lines MKN-45, and KATO-III, and human umbilical vein endothelial cells (HUVECs) were purchased from the cell bank of Chinese Academy of Sciences (Shanghai, China). GC cells were cultured in RPMI-1640 medium (Invitrogen, United States) supplemented with 10% fetal bovine serum (FBS) (Invitrogen), 100 IU/mL penicillin and 100 µg/mL streptomycin (Invitrogen). HUVECs were cultured in Human Endothelial-SFM (Invitrogen). Cells were maintained at 37 °C in a humidified chamber containing 5% CO<sub>2</sub>.

### Stable overexpression of interleukin-8 in MKN-45 cells

The empty plasmid vector pcDNA3.1 (Invitrogen) or the plasmid vector containing IL-8 cDNA was transfected into MKN-45 cells using Lipofectamine 2000 (Invitrogen). Multiple clones were selected in the presence of 0.75 mg/mL G418. IL-8-transfected clones were screened for IL-8 expression. Stably transfected clones were picked and maintained in the medium containing 0.1 mg/mL G418. To avoid clonal variations, six positive clones were pooled for further studies.

### Stable knockdown of interleukin-8 in KATO-III cells

The DNA sequence of RNAi of IL-8 was designed to hybridize and destroy human IL-8 mRNA (accession no. NM\_000584) using the Web-based siRNA target finder and design tool provided at the Ambion website (Ambion). The DNA sequence of RNAi of IL-8 (sense, 5' -ACCACCGGAAGGAACCAUCdTdT-3'; antisense, 5' -GAUGGUUCCUCCGGUGGdTdT-3') was synthesized and cloned into the pSilencer 2.1-U6 neo (Ambion) according to the manufacturer's instructions. The human

specific negative control siRNA was also designed with the sequences as follows: sense: 5'-UUCUCCGAACGU-GUACGUDtT-3'; antisense: 5'-ACGUGACACGUUC-GGAGAAdTdT-3'.

The negative control siRNA vector or the vector containing RNAi sequence of IL-8 was transfected into KATO-III cells using Lipofectamine 2000. Multiple clones were selected in the presence of 0.4 mg/mL G418. IL-8-RNAi clones were screened for IL-8 expression. Stable RNAi clones were picked and maintained in the medium containing 0.1 mg/mL G418. To avoid clonal variations, six positive clones were pooled for further studies.

### Enzyme-linked immunosorbent assay

Enzyme-linked immunosorbent assays (ELISAs) were performed using commercial IL-8 ELISA kits from R and D Systems. Cells ( $1 \times 10^6$  cells per well) were plated in a 6-well plate and incubated at 37 °C for 72 h. An equal volume of cell culture supernatants was collected. The assays were done in triplicate, and the concentration of IL-8 in culture supernatants was determined by comparing their optical density with the standard curve.

### 3-(4,5-cimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide assay

Cells growing exponentially were plated in 96-well plates at a density of  $1 \times 10^5$  cells per well for 7 d. One hundred microliters of 3-(4,5-cimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) stock solution (1 mg/mL) was added to each well daily, and the cells were further incubated at 37 °C for 4 h. The supernatant was discarded and 200 µL dimethyl sulfoxide was added. When the precipitates were completely dissolved, the absorbance at wavelength 595 nm was measured with a micro-ELISA reader.

### Growth inhibition assay

Growth inhibition was measured as previously described<sup>[9]</sup>. Cells were trypsinized and seeded at  $1 \times 10^4$  cells per well in 96-well plates. After 24 h, cells were exposed to oxaliplatin (Sigma, St. Louis, MO) for 72 h, at stepwise concentrations from 0 µg/mL to 10 µg/mL. The cells were quantified as described in MTT assay, to calculate the mean cell growth inhibition.

### Cell adhesion assay

To measure the cell adhesion, monolayer adhesion assay and extracellular matrix component (ECM) adhesion assay were performed. For the monolayer adhesion assay, HUVECs were seeded onto 24-well plates ( $1 \times 10^5$  cells/well) 48 h before adhesion assay. Cells ( $1 \times 10^5$  cells/well) were seeded onto HUVEC monolayers and incubated at 37 °C. After 2 h, non-adherent cells were removed by washing with phosphate-buffered saline (PBS).

For ECM adhesion assay, 96-well plates were coated with human fibronectin (BD Biosciences) at a final concentration of 2 µg/cm<sup>2</sup> overnight at 4 °C. Plates were washed with 1% bovine serum albumin in PBS to block

nonspecific cell adhesion. Cells were seeded and incubated for 2 h. Nonadherent cells were washed up to three times with PBS.

The adherent cells were quantified as described in MTT assay, to calculate the mean cellular adhesion capability. The absorbance at 570 nm was measured by the ELX-800 ELISA plate reader (Bio-Tek Instruments, Winooski, VT). After subtracting background absorbance, results were calculated as the mean cellular adhesion rate.

### Cell migration assay

To measure the cell migration activity, Transwell and wound-healing assays were performed. The Transwell cell migration assay was performed as previously described<sup>[10]</sup> using Transwells (8  $\mu\text{mol/L}$  pore size polycarbonate membrane) obtained from Corning. Cells ( $1 \times 10^5$ ) in 0.5 mL serum-free medium were placed in the upper chamber, whereas the lower chamber was loaded with 0.8 mL medium containing 10% FBS. The total number of cells that migrated into the lower chamber was counted after 24 h of incubation at 37 °C with 5% CO<sub>2</sub>. Nonmigratory cells were removed. Migratory cells were stained with 0.2% crystal violet in 10% ethanol. To quantitate migratory cells, three independent fields of migratory cells per well were photographed under phase contrast microscope. The number of cells per field was counted and averaged.

To carry out the wound-healing assay, cells ( $5 \times 10^5$  cells per well) were plated in 6-well plates. After 24 h, the confluent monolayer cells were scratched manually with a plastic pipette tip, and after being washed with PBS, wounded monolayers of the cells were allowed to heal for 12-24 h. Each migration assay was done for at least three times independently.

### Cell invasion assay

Cell invasion was measured using 8- $\mu\text{m}$  pore BD Bio-Coat Matrigel Invasion Chambers (BD Biosciences) according to the manufacturer's instructions. Cells ( $2.5 \times 10^5$ ) were added to chambers and incubated for 24 h at 37 °C. Matrigel and noninvasive cells were removed and chambers were stained as described above. To quantitate invasive cells, three independent fields of invasive cells per well were photographed under phase contrast microscope. The number of cells per field was counted and averaged. Each invasion assay was done at least three times independently.

### RNA isolation and reverse transcription polymerase chain reaction

Total RNA was purified from cells using a Trizol reagent (Life Technologies). First-strand cDNA was synthesized using 2.5  $\mu\text{g}$  RNA and AMVretroviridase (Promega). Quantitative real-time polymerase chain reaction (PCR) was performed using the Bio-Rad iCycler iQ real-time PCR system (Bio-Rad) and following primers: IL-8, IL8-L: 5'-ATGACTTCCAAGCTGGCCGTGGCT-3'; IL8-R: 5'-TCTCAGCCCTCTTCAAAAATTCT-3'. As a control, each cDNA sample was simultaneously subjected to glyceraldehyde-3-phosphate dehydrogenase (GAPDH) using

the primers: GAPDH-L: 5'-CCACCCATGGCAAATTCCATGGCA-3'; GAPDH-R: 5'-TCTAGACGGCAGGTCA GGTCCACC-3'. The threshold cycle (Ct) of each sample was determined, and the relative level of a transcript ( $2^{\Delta\text{Ct}}$ ) was calculated by obtaining  $\Delta\text{Ct}$  (test Ct - GAPDH Ct) and then expressed as arbitrary units ( $1/2^{\Delta\text{Ct}} \times 100$ ) = fold difference.

### Protein isolation and Western blotting

Cells at 80% culture confluence were harvested for Western blotting analysis. The harvested cells were lysed and their protein concentrations were determined using a bicinchoninic acid protein assay (Pierce, Rockford, IL). The cell lysates (50  $\mu\text{g}$  protein each lane) were separated by 10% sodium dodecyl sulfate-polyacrylamide gel electrophoresis and were transferred to nitrocellulose membranes (Hyclone, Logan, UT). The membranes were blocked with 5% (v/v) skim milk and probed with primary antibody at 4 °C overnight. Following washing, the membranes were incubated with horseradish peroxidase-conjugated secondary antibody at room temperature for 1 h. Primary antibodies were specific for phospho-NF- $\kappa\text{B}$ -p65, NF- $\kappa\text{B}$ -p65, phospho-Akt, Akt, ICAM-1, VCAM-1, CD44, and  $\beta$ -actin (Cell Signaling Technology, Inc., Danvers, MA). The bound antibodies were visualized using an electrochemiluminescence system (Amersham Pharmacia Biotech, Buckinghamshire, United Kingdom).

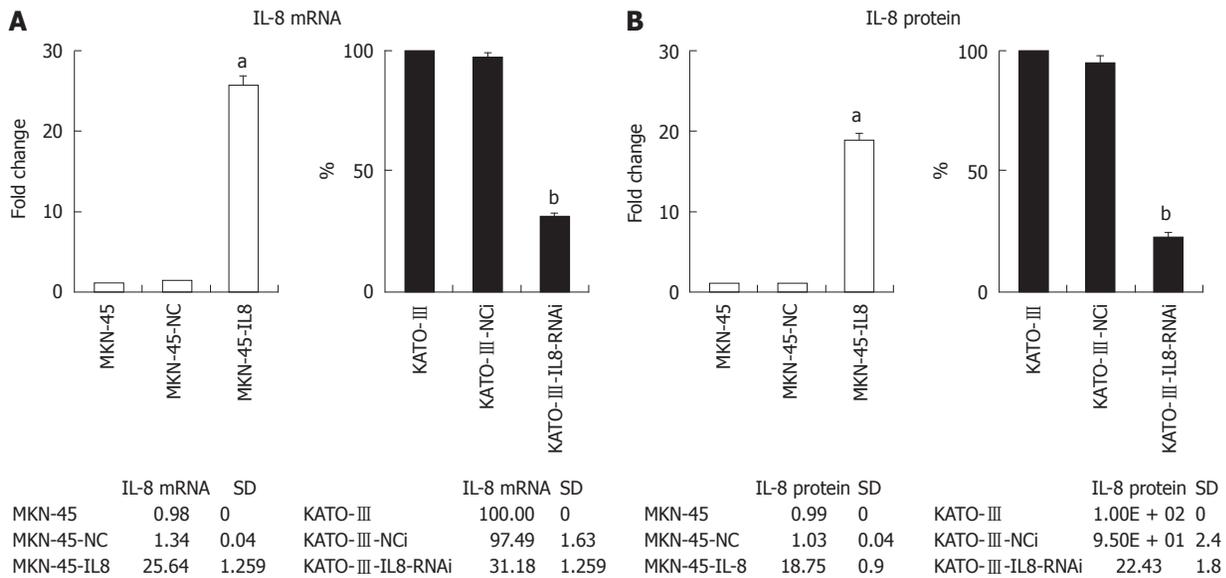

### Statistical analysis

Data were presented as means  $\pm$  SE. Differences of the variables between groups were analyzed by Student's *t* test. Differences were considered significant when  $P < 0.05$ .

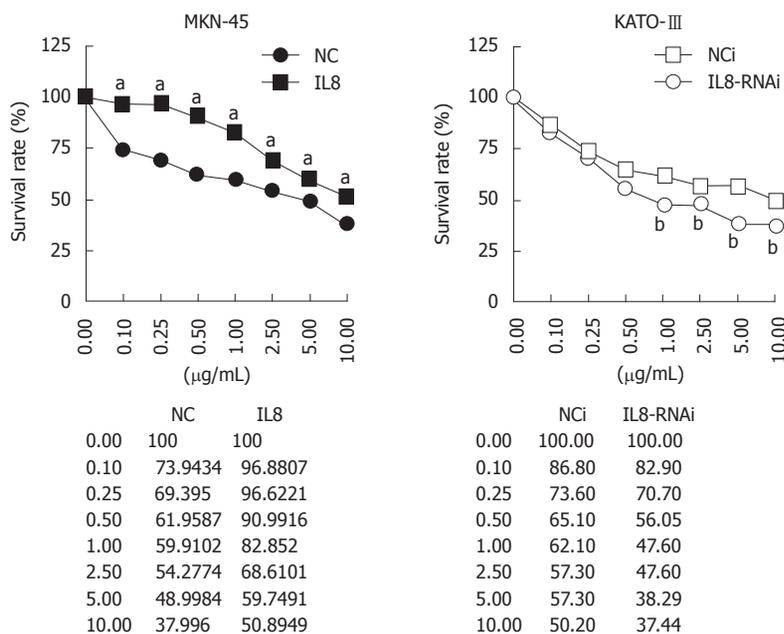

## RESULTS

### Stable overexpression and silencing expression of interleukin-8 in gastric cancer cells

To investigate the effect of IL-8 in GC, the mRNA expression of IL-8 was quantified in three GC cells (Figure 1A). MKN-45 cell lines had lower expression of IL-8 in comparison with KATO-III cells, which is consistent with a previous study by Kitadai *et al*<sup>[11]</sup>. To increase the IL-8 expression, MKN-45 cells were stably transfected with full-length IL-8 expression construct. The RNAi technology was employed in order to stably silence the IL-8 expression in KATO-III cells. The mRNA expression of IL-8 in cells was examined by real-time PCR. The ELISA assay was performed to quantify secreted IL-8 present in the cell culture medium. After transfection and G418 selection, IL-8 mRNA expression level in the stably IL-8 transfected MKN-45 cells (MKN-45-IL8) was 25.6-folds higher than in MKN-45 cells (Figure 1A). As shown in Figure 1B, the secretion levels of IL-8 in MKN-45-IL8 cells were 18.4-folds higher than in MKN-45 cells. Endogenous IL-8 mRNA expression and protein secretion levels were significantly lowered by RNAi in KATO-III cells (KATO-III-IL8-RNAi) when compared with control transfections (KATO-III-NCi) and KATO-III cells (Figure 1).

**Figure 1 Interleukin-8 expression of gastric cancer cells.** A: Real-time polymerase chain reaction determined the level of Interleukin-8 (IL-8) mRNA in gastric cancer (GC) cells. Expression levels were determined by the  $\Delta\Delta C_t$  method using glyceraldehyde-3-phosphate dehydrogenase as endogenous control. Histograms show fold change over the relative expression levels of IL-8 mRNA of control cells. Each bar represents the mean  $\pm$  SD (<sup>a</sup> $P < 0.05$  vs MKN-45, <sup>b</sup> $P < 0.05$  vs KATO-III); B: IL-8 production in GC cells measured by enzyme-linked immunosorbent assay. Histograms show fold change in the relative expression levels of IL-8 protein of control cells. All experiments were repeated three times with similar results. Each bar represents the mean  $\pm$  SD (<sup>a</sup> $P < 0.05$  vs MKN-45, <sup>b</sup> $P < 0.05$  vs KATO-III).

**Figure 2 Growth inhibition assay of gastric cancer cells treated with oxaliplatin.** Survival of gastric cancer cells is tested by 3-(4,5-cimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide assay. Each bar represents the mean  $\pm$  SD. All experiments were repeated three times with similar results (<sup>a</sup> $P < 0.05$  vs MKN-45-NC, <sup>b</sup> $P < 0.05$  vs KATO-III-NCi).

**Interleukin-8 insignificantly affects proliferation of gastric cancer cells**

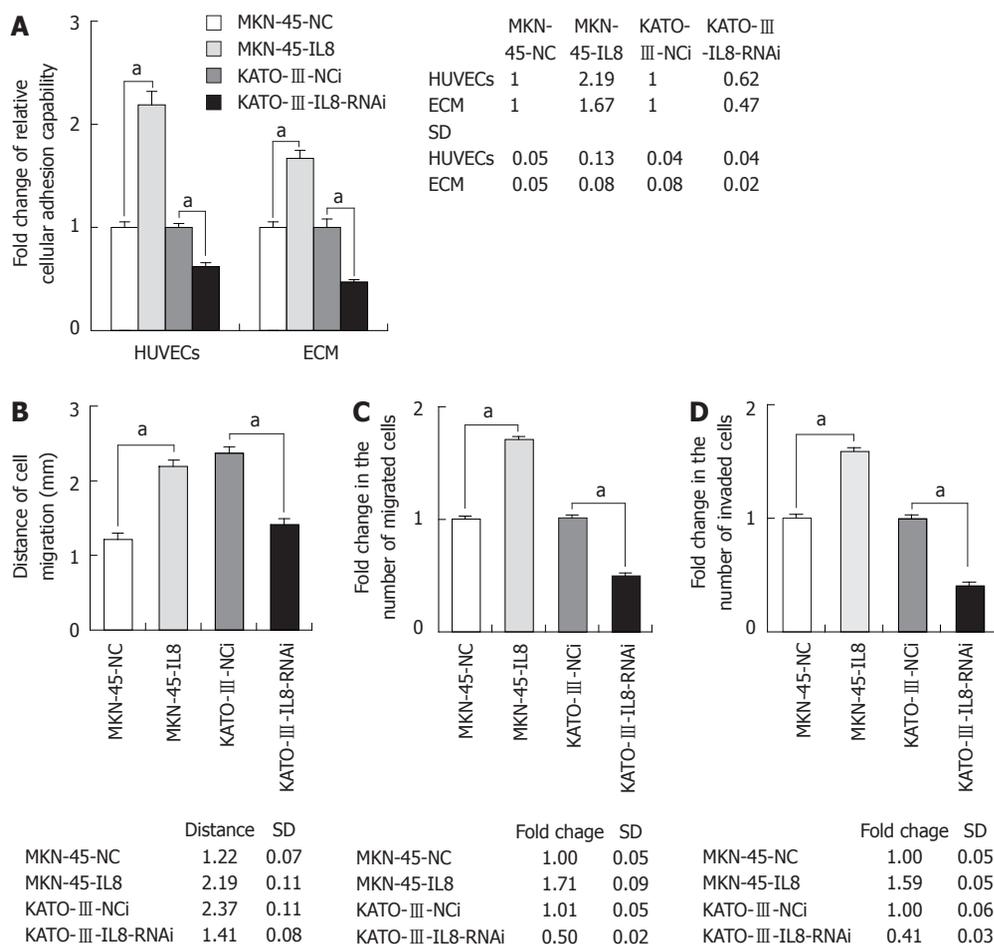

Since IL-8 has been reported to be an autocrine growth factor<sup>[12]</sup>, we examined its role in the growth of human GC cells. Overexpression or silencing expression of IL-8 in GC cells had insignificant effect on cancer cell proliferation as measured by the MTT assay (data not shown).

**Interleukin-8 increases resistance to oxaliplatin in gastric cancer cells**

Previous reports indicated that increased IL-8 was associ-

ated with chemoresistance, such as oxaliplatin<sup>[13-15]</sup>. To investigate whether IL-8 is associated with chemosensitivity in GC cells, the effects of IL-8 expression on oxaliplatin sensitivity in IL-8-overexpressed MKN-45-IL8 cells and IL-8-silenced KATO-III-IL8-RNAi cells were tested using growth inhibition analyses.

As shown in Figure 2, MKN-45-NC and KATO-III-NCi cells were sensitive to oxaliplatin. In MKN-45-IL8 cells, the survival rate significantly increased than in the control cells ( $P < 0.05$ ) after treatment with oxaliplatin at the concentrations from 0.1  $\mu\text{g/mL}$  to 10  $\mu\text{g/mL}$  ( $P <$

**Figure 3 Interleukin-8 involved in gastric cancer cell adhesion, migration and invasion.** A: Effect of Interleukin-8 (IL-8) on gastric cancer (GC) cell adhesion to human endothelial cells and extracellular matrix components. Histograms show fold change in the relative OD value of control cells quantified by cell proliferation assay to calculate the mean cellular adhesion capability; B: Effect of IL-8 on GC cell migration tested by wound-healing assays. Histograms show distances of cell migration; C: Effect of IL-8 on GC cell migration tested by Transwell assays. Histograms show fold change in the number of migrated cells vs the control cells; D: Effect of IL-8 on GC cell invasion. Histograms show fold change in the number of invaded cells vs the control cells. Each bar represents the mean  $\pm$  SD. All experiments were repeated three times with similar results ( $^{\#}P < 0.05$ ). HUVEC: Human umbilical vein endothelial cell.

0.05). On the contrary, when IL-8 expression was suppressed in KATO-III cells using RNAi, there was significant decrease in growth rate after treatment with 1.0-10  $\mu\text{g}/\text{mL}$  oxaliplatin ( $P < 0.05$ ). These results suggest that IL-8 expression in GC cells decreased the sensitivity to the cytotoxic effects of oxaliplatin.

#### Interleukin-8 is involved in gastric cancer cell adhesion

To determine the role of IL-8 expression in GC cell adhesion, adhesion capacity of GC cells to endothelium or extracellular matrix components was evaluated (Figure 3A). The 2-h adhesion capability of GC cells to a monolayer of HUVECs or ECM components was significantly increased in MKN-45-IL8 cells as compared with the control cells. Silencing expression of IL-8 in KATO-III cells significantly reduced the cell adhesion capability ( $P < 0.05$ ).

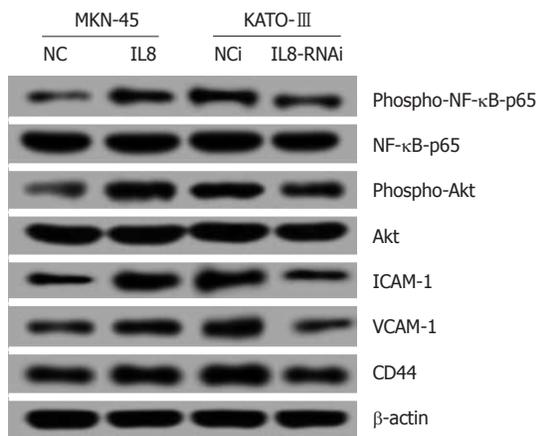

#### Interleukin-8 is involved in gastric cancer cell migration and invasion

To measure the cell migration activity, Transwell and wound-healing assays were performed. As shown in Figure 3B and C, expression of IL-8 could significantly promote

GC cell migration into the cell-free region and migration through cell culture inserts. The invasive potential of GC cells was investigated using *in vitro* Matrigel invasion assay. Cell invasion was similar to cell migration. MKN-45-IL8 cells exhibited significant increase in invasion capacity whereas KATO-III-IL8-RNAi cells exhibited significant decrease (Figure 3D). Therefore, IL-8 overexpression was sufficient to increase the rate of GC cell migration and *in vitro* invasion.

#### Interleukin-8 increases NF- $\kappa$ B and Akt activities, adhesion molecules ICAM-1 and VCAM-1, and CD44 expression in gastric cancer cells

Recent studies have reported that induction of IL-8 signaling increased NF- $\kappa$ B transcriptional activity, and activated the phosphoinositide-3-kinase and cascade. As shown in Figure 4, the levels of phospho-NF- $\kappa$ B-p65 and phospho-Akt were upregulated in IL-8 overexpressed MKN-45-IL8 cells compared with the control cells, and were downregulated in KATO-III-IL8-RNAi cells. These data suggest that constitutive IL-8 expression strongly increased NF- $\kappa$ B and Akt activation.

**Figure 4** Effect of Interleukin-8 on NF-κB and Akt activities and adhesion molecules ICAM-1 and VCAM-1, and CD44 expression in gastric cancer cells. The protein expression levels of phospho-NF-κB-p65, NF-κB-p65, phospho-Akt, Akt, ICAM-1, VCAM-1, and CD44 were determined by Western blotting. All experiments were repeated three times with similar results.

Adhesion molecules play an important role in cell-cell, cell-ECM interactions in cancer invasion and metastasis. As shown in Figure 4, IL-8 increased the protein expression levels of adhesion molecules ICAM-1 and VCAM-1, and CD44 expression in GC cells.

## DISCUSSION

It has been shown that IL-8 modulates proliferation and migration of tumor cells, including melanoma<sup>[16-18]</sup>, prostate cancer<sup>[14,19]</sup>, breast cancer<sup>[20]</sup>, and colon cancer<sup>[13]</sup>. A study confirmed that IL-8 increases angiogenesis of human gastric carcinoma<sup>[6]</sup>. Our goal was to evaluate whether IL-8 is involved in proliferation, adhesion, migration, invasion and the sensitivity to chemotherapeutics in human GC cell lines. We found that IL-8 overexpression in GC cells was associated with increased adhesion, migration, and invasion activity and resistance to oxaliplatin, suggesting that IL-8 is a promising therapeutic target.

In this study, we examined the biological role of IL-8 in adhesion, migration, and invasion of GC cells with either overexpression or knocked down expression of IL-8. The stable IL-8 transfectants and IL-8 RNAi were successfully generated in MGC803 cells. The constitutive expression of IL-8 in MGC803 cells increased cell adhesion, migration and invasion, which was opposed by silencing IL-8 expression in KATO-III cells using RNAi. Our findings suggest that expression of IL-8 plays an important role in modulating cell adhesion, migration, and invasion of GC cells. This observation is supported by the study of Ju *et al.*<sup>[7]</sup>, which showed that recombinant interleukin-8 promoted the adhesion, migration and invasion of GC SCG-7901 cells and up-regulated the expression of matrix metalloproteinase-9, intercellular adhesion molecule-1 and E-cad *in vitro*. However, IL-8 in GC cells had insignificant effect on cell proliferation according to the previous studies<sup>[6,7]</sup>.

The NF-κB and Akt signaling pathway activations are involved in cellular transformation, survival, prolifera-

tion, invasion, angiogenesis, metastasis and inflammation in cancers. It has been reported that NF-κB stimulates IL-8 production, and endogenous IL-8 causes constitutive activation of NF-κB (p65) in colon cancer<sup>[13]</sup> and prostate cancer cells<sup>[14]</sup>. In this study, we found that IL-8 overexpression caused activation of NF-κB and Akt signaling in GC cells.

It is widely accepted that the invasion and metastasis of cancer is dependent on the capacity of cancer cell adhesion and migration<sup>[21]</sup>. In this study, we found that GC cells overexpressing IL-8 produced increased adhesion and migration activity with upregulated ICAM-1, VCAM-1, and CD44. Further investigations are warranted to elucidate the regulative mechanism of IL-8 as a migratory and invasive factor in GC cells.

In conclusion, our studies provide significant evidence that IL-8 expression contributes to GC cell adhesion, migration and invasion, and leads to resistance to oxaliplatin. These findings may help develop novel IL-8-targeted therapies for GC.

## COMMENTS

### Background

Gastric cancer (GC) is still a serious health problem and remains the second most common type of fatal cancer worldwide. Interleukin-8 (IL-8), a cytokine of the CXC chemokine family that was originally classified as neutrophil chemoattractant, is now reported to play an important role in tumor progression and metastasis in a variety of human cancers.

### Research frontiers

The exact role of IL-8 in the progressive tumorigenesis of GC remains unclear. The purpose of this study was to provide evidence for the role and molecular mechanism of IL-8 in determining the migration, invasion and chemosensitivity of human GC.

### Innovations and breakthroughs

This study demonstrated that IL-8 expression is associated with cell adhesion, migration, and invasion in GC. Overexpression of IL-8 promotes invasion phenotype of GC cells with activated NF-κB and Akt and increased expression of adhesion molecules ICAM-1, VCAM-1, and CD44 *in vitro*.

### Applications

The findings help clarify the molecular mechanisms of IL-8 involved in GC invasion and indicate that IL-8 may be an important therapeutic target in GC.

### Peer review

The authors have shown that overexpression of IL-8 *in vitro* promotes the adhesion, migration, invasion, and chemoresistance of some gastric cancer cell lines, thus indicating IL-8 as possible therapeutic target in gastric cancer. The work addresses an interesting topic with the proper methodological approach.

### Abstract

**AIM:** To investigate the seroprevalence and molecular characteristics of hepatitis E virus (HEV) in the illegal blood donors (IBDs) of central China in the early 1990s.

**METHODS:** A total of 546 blood samples were collected from the IBDs in Maanshan city, a questionnaire was completed by each subject, detailing the age, sex, and periods of blood or plasma donation. Anhui Province and tested for the anti-HEV antibodies. The seropositive

samples were subjected to nested reverse transcription-polymerase chain reaction and sequencing to analyze HEV partial genome.

**RESULTS:** The prevalence of IgG and IgM HEV antibody in IBDs was 22.7% and 1.8%, and genotype 4 was the dominant circulating HEV type in IBDs. The prevalence of anti-HEV IgG was significantly related to sex (OR = 4.905,  $P = 0.004$ ) and increased with age (OR = 2.78,  $P = 0.022$ ), which ranged from 13.0% in those < 40 years old to 30.6% among older persons aged > 60 years. Moreover, frequency of blood donation was significantly associated with HEV seropositivity (OR = 2.06,  $P = 0.006$ ). HEV partial sequences of ORF2 and obtained 3 sequences in serum samples of 10 IBDs which developed HEV specific IgM.

**CONCLUSION:** This study helps define one of the possible routes of transmission of sporadic HEV infection and provides guidance to screen HEV in the blood donors so as to guarantee safe blood banks in China.

## INTRODUCTION

Hepatitis E virus (HEV) infection is an important public-health concern as a major cause of enterically transmitted hepatitis worldwide. Epidemiologic studies have shown that HEV is prevalent in most developing countries, such as southeast Asia, northern and central Africa, India and central America. In addition, a high incidence of sporadic HEV infection has been observed in several industrialized countries, including the United States, European countries and Japan<sup>[1-5]</sup>. Although the ingestion of contaminated drinking water contributes mainly to the spread of HEV, other routes of transmission should be considered, because some studies implicated that blood transfusion was the possible route of sporadic HEV infection in non-endemic developed countries<sup>[6-8]</sup>.

Between 1992 and 1995, illegal blood donation (IBDs) occurred frequently in several provinces in central China, including Henan, Anhui and Shanxi provinces. Although commercial blood donation was eradicated by the Chinese government by the end of 1995, the practice of using contaminated blood collection equipment caused the spread of some viruses, such as hepatitis C virus (HCV) and human immunodeficiency virus (HIV)<sup>[9,10]</sup>.

While many studies have reported the prevalence of HEV infection and the HEV genome characteristics in different groups in China, to date, there has been no report on the prevalence of HEV infection among the IBDs. The aim of this study was to investigate whether HEV can be transmitted by the blood transfusion route and analyze the partially conserved nucleotide sequences of HEV strains among the IBDs in Maanshan city in Anhui Province, one of the provinces with the illegal blood collection in the early 1990s.

## MATERIALS AND METHODS

### Ethics

This work has been carried out in accordance with the Declaration of Helsinki (2000) of the World Medical Association. The study was initiated after the study protocol was approved by the Institutional Review Board (IRB) of China Center for AIDS/STD Control and Prevention and the IRB of Maanshan Center of Disease Control and Prevention.

### Study population

A total of 546 samples were collected between January and August in 2005 from those who donated their blood or plasma frequently from 1992 to 1995. All participants were from Dangtu District in Maanshan city. A questionnaire was completed by each subject, detailing the age, sex, and periods of blood or plasma donation.

### Detection of antibodies against hepatitis E virus

Serum samples were tested by enzyme-linked immunosorbent assay (ELISA) for IgG and IgM with anti-HEV activity described previously<sup>[11,12]</sup>. All serum samples were

assayed at a 1:20 dilution. The absorbance of each sample was read at 450 nm. The cutoff value used for the anti-HEV IgG and IgM assay was 0.152. Then the serum positive for IgM antibody against HEV were tested for HEV RNA. All patients were previously tested for HBsAg (Diasorin, United States) and anti-HCV (third generation assay, Diasorin, United States) by ELISA.

### Extraction of RNA and reverse transcription-polymerase nested chain reaction

Viral RNA was extracted from serum samples using Qia-gen viral RNA kit (Qiagen) according to the manufacturer's instructions. The viral RNA was finally dissolved in 20  $\mu$ L RNase-free water. Reverse transcription-polymerase chain reaction (RT-PCR) was performed using TaKaRa RNA PCR kit (TaKaRa, Japan). The primers and the PCR protocol used were adapted from a previous study<sup>[13]</sup>. The external primers were P1 (5'-CCGACAGAAATTGATTTCGTCCGC-3') and P4 (5'-CCGTAAGTTCGACTGGTCTGTACTC-3'). The internal primers were P2 (5'-GTTGTCTCGCCAATGGCGAGCC-3') and P3 (5'-TCGGCGGCGGTGAGAGAGCCA-3'). The first-round and the second-round amplifications were carried out according to the following cycling program denaturation at 9  $^{\circ}$ C for 45 s, annealing at 52  $^{\circ}$ C for 60 s, extension at 72  $^{\circ}$ C for 60 s, for 35 cycles. The size of the first-round PCR product was 307 bp, and that of the second-round PCR was 236 bp.

### Sequencing and analysis of sequences

The PCR products were visualized on a 10 mL/L agarose gel, excised and purified using a gel extraction kit (Qiagen) and directly sequenced on an ABI model 3730 DNA Auto Sequencer (Shanghai, China). The 236 bp fragment amplified from ORF2 of HEV genome was sequenced for comparison with the corresponding regions of other known human, porcine and avian HEV strains available in the GenBank database (DNASTar). Sequences were aligned using ClustalX v1.8 (<http://www-igbmc.ustrasbg.fr/Bio-Info/ClustalX/Top.html>), and the phylogenetic analysis was performed using the MEGA program, version 3.1 (Pennsylvania State University).

### Statistical analysis

The Pearson  $\chi^2$  test was used to evaluate the difference in the prevalence between groups in the univariate analyses. Odds ratios (OR) with 95% confidence intervals were used to determine whether a variable was associated with HEV infection.

## RESULTS

### Hepatitis E virus seropositivity in illegal blood donors

A total of 546 IBDs in the 1990s were enrolled to this study. The IBDs were aged from 29 to 75 years with a mean of  $51 \pm 9$  years. Among them, 156 (28.6%) were males and 390 (71.4%) were females. While 124 IBDs developed HEV IgG antibody, only 10 IBDs developed HEV IgM antibody, therefore, the prevalence of IgG and

HEV: Hepatitis E virus; OR: Odd ratio; CI: Confidence interval.

IgM HEV antibody in this group was 22.7% and 1.8%, respectively.

The prevalence of HEV IgG seropositivity in the 546 IBDs is shown in Table 1. In the male group, 30.8% (48/156) were positive as against 19.5% (76/390) in the female group. The prevalence of HEV IgG seropositivity was significantly higher in men than in women (OR = 4.905,  $P = 0.004$ ). In addition, subjects over 60 years of age had a higher prevalence of HEV IgG seropositivity than those aged < 40 years (OR = 2.780,  $P = 0.022$ ). The frequency of plasma donation was also associated with HEV infection. The odds ratio was 2.06 among those who donated more than 20 times compared with those who donated 10 or fewer times.

The sex specific prevalence of HEV IgG in IBDs with different frequency of donation is shown in Table 2. HEV infection prevalence was significantly correlated with the increasing age in total participants ( $\chi^2 = 2.91$ ,  $P = 0.004$ ) and female participants ( $\chi^2 = 1.97$ ,  $P = 0.048$ ).

We also examined the relationship between HEV infection and HBV or HCV coinfection in these IBDs. The results showed no significant difference in HBsAg positive status (3.2% *vs* 3.1%) and HCV positive status (11.3% *vs* 11.1%) between HEV IgG positive and negative IBDs (Table 3).

#### Phylogenetic analysis of hepatitis E virus strains

We detected HEV partial sequences of ORF2 and obtained 3 sequences in serum samples of 10 IBDs which developed HEV specific IgM. Sequence analysis demonstrated that these 3 strains were 83.3%-93.6% identical to each other. When compared with the HEV reference isolates, the strains were closely related to Chinese strain T1 with an 82.6%-89.4% nucleotide homology, and demonstrated a 91.1% sequence homology to a Japanese strain JAK-Sai. The nucleotide homology of other Japanese HEV strains with the strains from IBDs ranged from 78.6% to 85.4%. The homology of strains from Burma, Mexico and the United States was 79.2%-80.2%, 80.5%-81.4% and 77.1%-78.0%, respectively.

In the phylogenetic tree generated, the Bur82 strain

≥ 20	15/45 (33.3)	16/55 (29.1)	0.648

**Table 3** Relationship between hepatitis E virus infection and hepatitis B virus or hepatitis C virus co-infection in commercial blood donors *n* (%)

Characteristics	HEV positive IgG ( <i>n</i> = 124)	HEV negative IgG ( <i>n</i> = 422)	<i>P</i> value
HBsAg positive	4 (3.2)	13 (3.1)	0.935
HCV antibody positive	14 (11.3)	47 (11.1)	0.962

HEV: Hepatitis E virus.

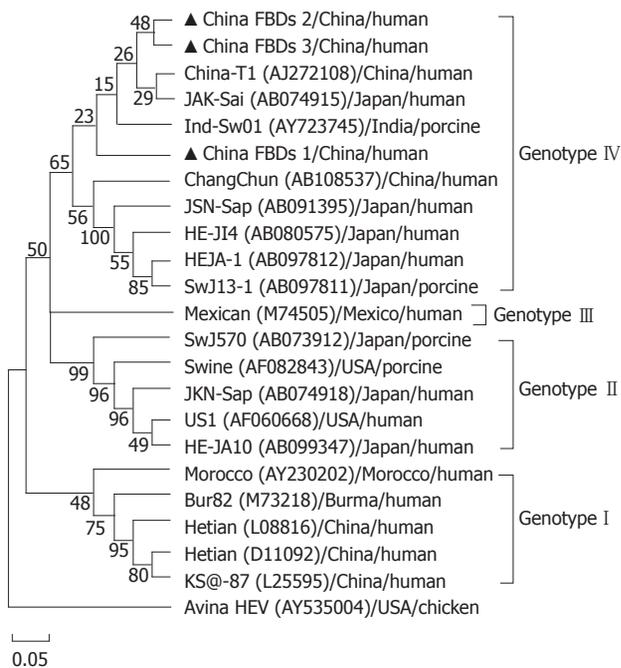

(genotype 1), the Mexican strain (genotype 2), the US1/swine strain (genotype 3), and the Chinese strain T1 (genotype 4) represent major branches. Phylogenetic analyses clearly illustrate that all HEV sequences except avian strain can be divided into these four distinct genotypes and the three HEV sequences isolated in our study were genotype 4. The IBDs 1 sequence we analyzed formed an exclusive cluster, and was bound to a new subgenotype within genotype 4, which was supported by the bootstrap values obtained from 1000 replicates resampling analysis (Figure 1).

## DISCUSSION

HCV and HIV infections were prevalent among the IBDs who donated blood in the early 1990s in China. However, data on HEV infection in this population have been unavailable so far. To our knowledge, the present study is the first seroepidemiological and molecular study on HEV infection in this unique population. Our results demonstrated that HEV infection had been introduced into this population in this area and that the prevalence was much higher (22.5%) than that in the normal population (4.76%) in this area<sup>[14]</sup>.

Our data indicated that 30.7% of males were HEV positive compared to 19.5% of females and the difference was statistically significant (OR = 1.84,  $P = 0.004$ ). In addition, we found that males with a history of blood transfusion had a high HEV seropositivity than females, suggesting that male IBDs are more likely to get infected by HEV than female donors. Our study also showed that HEV seropositivity increased with age of the first donating blood, consistent with previous studies demonstrating that age may be an important risk associated with HEV in other populations<sup>[15,16]</sup>.

Although no statistically significant association was observed between HEV seropositivity and blood-borne hep-

**Figure 1** A phylogenetic tree is constructed using the neighbor-joining method based on the 236-nt ORF2 sequences of four genotypes hepatitis E virus isolates. The isolates were named by the accession number in parentheses, the name of the country of origin and species from which it was isolated. Bootstrap values were indicated for the major nodes as a percentage of the data obtained from 300 replicates. Bar, 0.05 substitutions per site. Percent bootstrap support was indicated at the respective nodes. An avian hepatitis E virus strain is included as outgroup. The isolates identified in this study were marked with solid triangle.

atitis viruses such as HBV and HCV, our findings show that more frequent blood/plasma donation increased the risk of HEV infection, providing evidence that HEV can be transmitted by viremic blood units and have similar or overlapping routes of transmission with HCV<sup>[17]</sup>.

HEV IgM antibody is known as a marker of the early seroconversion period. In this study, HEV IgM antibody was detected in 10 samples in the population. We also tested the presence of serum HEV RNA in the IBDs. HEV has been classified into four genotypes based on the full sequence heterogeneity. These include genotypes 1 (mainly prevalent in Asia and Africa), 2 (mainly prevalent in Mexico, Nigeria), 3 (mainly prevalent in the US, Japan, Argentina, and Europe), and 4 (mainly prevalent in Taiwan, Japan, and mainland China)<sup>[18]</sup>. More recently, HEV genotype 4 has been isolated from various regions of China, ranging from the south (Guangzhou and Shanghai), the centre (Henan province) to the north (Liaoning Province and Beijing), and has been found to be responsible for a significant proportion of cases of sporadic acute hepatitis in China<sup>[19-21]</sup>. Schlauder *et al.*<sup>[22]</sup> reported that the analysis of small regions of HEV genome yields evolutionary distances similar to those produced from the full-length HEV genome. Therefore, we amplified and sequenced three HEV partial sequences in the serum samples of 10 IBDs positive for HEV IgM antibody. The three sequences share an 81.4%-88.1% identity

at the nucleotide level with each other, and 79.2%-80.2%, 80.5%-81.4%, 77.1%-78.0% and 83.3%-93.6% identity with HEV genotypes 1-4, respectively. Clearly, they belong to genotype 4 and resemble HEV genotype 4 sequences but form some new subgenotypes. These results indicate that there is great genetic variability in HEV genome of genotype 4, even within a certain region or population investigated in China. Previous data showed that a substantial proportion of voluntary blood donors (3/200 or 1.5%) was positive for HEV RNA and the isolates all had a high nucleotide sequence identity (> 90%) with swine HEV, which means that HEV may be zoonotically transmitted from viremic animals to humans<sup>[23]</sup>, however, in the present study, three isolates only shared a 77.5%-86.0% identity with swine HEV.

In conclusion, we report the first molecular and sero-epidemiological study on HEV infection in the IBDs in China in the 1990s. The results demonstrate that HEV is widely spread in this population and confined to genotype 4. Males, individuals aged beyond 60 years, and people who donated blood more than 20 times showed a higher rate of previous HEV infection. Our study may help define one of the possible routes of transmission of sporadic HEV infection in this population and provide guidance to screen HEV in the donors to guarantee safe blood banks in China.

## COMMENTS

### Background

Hepatitis E virus (HEV) infection is an important public-health concern as a major cause of enterically transmitted hepatitis worldwide. Epidemiologic studies have shown that HEV is prevalent in most developing countries and some industrialized countries. Although commercial blood donation was eradicated by Chinese government by the end of 1995, the practice of using contaminated blood collection equipment caused the spread of some viruses such as hepatitis C virus and hepatitis I virus, but there has been no report on the prevalence of HEV infection in the illegal blood donors (IBDs).

### Innovations and breakthroughs

This is a first serological and molecular study on HEV infection in IBDs. The results showed that the prevalence of HEV IgG antibody was higher (22.5%) in the IBDs than in general population, and the risks of HEV infection in IBDs were age, gender and times of donation. Additionally, phylogenetic analysis showed that 3 HEV strains isolated from IBDs belong to genotype 4. Therefore, the present study indicated that HEV is widely spread in the IBDs and the new possible modes of transmission of sporadic HEV infection in IBDs should be defined.

### Applications

As it was indicated in this study that HEV is widely spread among the IBDs, and age, gender and times of blood donation are the risk factors of HEV infection. Therefore, HEV should be detected regularly among the IBDs for the safety of transfusion.

### Terminology

Hepatitis E virus (HEV): Hepatitis E Virus 1 has a particle diameter of 32-34 nm, a buoyant density of 1.29 g/mL in KTar/Gly gradient, and is very labile. Serologically related smaller (27-30 nm) particles are often found in feces of patients with hepatitis E and are presumed to represent degraded viral particles. HEV has a single-stranded polyadenylated RNA genome of approximately 8 kb. Based on its physicochemical properties, it is presumed to be a calicivirus-like virus.

### Peer review

The molecular and sero-epidemiological study on HEV infection is presented in a proper way and this study could help in defining one of the possible modes of transmission of sporadic HEV infection in Chinese population and guide the

screening of HEV in the donors to guarantee safe blood banks. The manuscript is well presented and of interest and the design of this study is appropriate. The study was done well and their results can contribute to knowledge of this topic.

### Abstract

**AIM:** To evaluate the prophylaxis of chronic kidney disease (CKD) after liver transplantation (LT) with low-dose calcineurin inhibitor (CNI) and mycophenolate mofetil (MMF).

**METHODS:** From March 1999 to December 2009, a total of 572 patients (478 males and 94 females) underwent LT enrolled in the study. Initial immunosuppression was by triple-drug regimens that included a CNI, MMF, and prednisone. The initial dose of CNI was 0.05-0.10 mg/kg per day for tacrolimus (TAC) and 5-10 mg/kg per d for cyclosporine A (CSA) respectively, and was gradually reduced based on a stable graft function. The serum trough level of CNI was 6-8 ng/mL for TAC and 120-150 ng/mL for CSA 3-mo post-operation, 4-6 ng/mL for TAC and 80-120 ng/mL for CSA 1-year after transplantation

was expected with stable liver function. MMF was personalized between 1.0-1.5 g/d. Glomerular filtration rate (GFR) was estimated by an abbreviated Modification of Diet in Renal Disease formula. Risk factors of CKD were examined by univariate and multivariate logistic regression.

**RESULTS:** With a definition of GFR < 60 mL/min per 1.73 m<sup>2</sup>, the incidence of CKD was 17.3% 5-year after LT. There were 68.3% (293 of 429 cases) patients managed to control their TAC trough concentrations within 8 ng/mL and 58.0% (83 of 143 cases) patients' CSA trough concentrations within 150 ng/mL. Of the 450 recipients followed-up over 1 year, 55.5% (183 of 330 cases) of which were treated with TAC had a trough concentration ≤ 6 ng/mL while 65.8% (79 of 120 cases) of which were treated with CSA had a concentration ≤ 120 ng/mL. The incidence of CKD in the groups of lower CNI trough concentrations was significantly lower than the groups with CNI concentrations above the ideal range. Patients with CKD had much higher CNI trough concentrations than that of patients without CKD. MMF was adopted in 359 patients (62.8%). Patients administrated with MMF had a relatively low CNI trough concentrations but with no significant difference. The graft function remained stable during follow-up. No difference was found between different groups of CNI trough concentrations. Pre-LT renal dysfunction, ages, acute kidney injury, high blood trough concentrations of CNI in 3 mo (TAC > 8 ng/mL, CSA > 150 ng/mL) and hypertension after operation were associated with CKD progression, while male gender and adoption of MMF were protection factors.

**CONCLUSION:** Low dose of CNI combined with MMF managed to prevent CKD after LT with stable graft function.

## INTRODUCTION

Since the introduction of calcineurin inhibitor (CNI) in the 1980s, its use in clinical solid organ has greatly increased transplant recipient survival rates and reduced graft rejection rates<sup>[1]</sup>. More and more patients with end stage liver disease are benefiting from liver transplantation (LT) in the last three decades. However, although the number of long-term surviving recipients has increased, many of them suffer from chronic complications. Chronic kidney disease (CKD) is one such complication that has severely affected the quality of life and survival of organ recipients<sup>[2-7]</sup>. Cohen *et al*<sup>[8]</sup> reported that 27.5% of 191 patients had progressive renal dysfunction [glomerular filtration rate (GFR) < 40 mL/min] 5 years after LT. Ojo *et al*<sup>[9]</sup> found that GFR < 29 mL/min was in up to 18% of patients by 5 years post LT, and that chronic renal failure elevated the risk of death after transplantation (relative risk 4.55). Long duration of CNI-taken is one of the many factors adversely affecting renal function after transplantation<sup>[2,4,7]</sup>. Its nephrotoxicity is seen by kidney biopsy, which includes severe tubular atrophy, interstitial fibrosis and focal hyalinosis of small renal arteries and arterioles<sup>[10,11]</sup>. Lee *et al*<sup>[12]</sup> pointed out that rapid progression of kidney disease was associated with CNI nephrotoxicity which significantly increased the risk by a factor of 4.24.

There are two main strategies for CNI induced CKD, one is CNI withdrawal and conversion to a non-nephrotoxic immunosuppressant, such as sirolimus, mycophenolate mofetil (MMF) and azathioprine; the other is dose reduction in combination with an auxiliary immunosuppressant<sup>[4,6,7,13,14]</sup>. Shenoy *et al*<sup>[13]</sup> found no significant improvement in renal function after 12 mo' follow-up in a prospective trial of CNI withdrawal and replacement with sirolimus for renal insufficiency in liver transplant recipients. Cantarovich *et al*<sup>[15]</sup>, on the other hand, found significant improvement in the renal function of long-term liver-transplant recipients with renal dysfunction by introducing MMF and tapering cyclosporine A (CSA) to a very low dose (50 mg/d), however, this strategy may increase the risk of acute rejection (AR). No agreement has been reached on this issue. Since it has been proven that

the nephrotoxicity was associated with the dosage and duration of CNI, we can expect that administration of initial low-dose CNI and maintaining low blood concentrations after would prevent the progression of renal dysfunction. However, such a conclusion cannot be drawn yet because most researches were based on patients who had pre-existing renal dysfunction. Moreover, there is no consensus on the minimum CNI dose which is considered to be safe for LT recipients.

In our center, a protocol of combining CNI [tacrolimus (TAC) or CSA] with MMF was adopted after LT. The CNI initial dose and blood concentrations after were kept at a relatively low level. The purpose of this study was to delineate the risk factors for developing CKD, and more important, to find out whether the strategy of combination low-dose CNI and MMF can make a successfully prophylaxis of CKD after LT.

## MATERIALS AND METHODS

### Study population

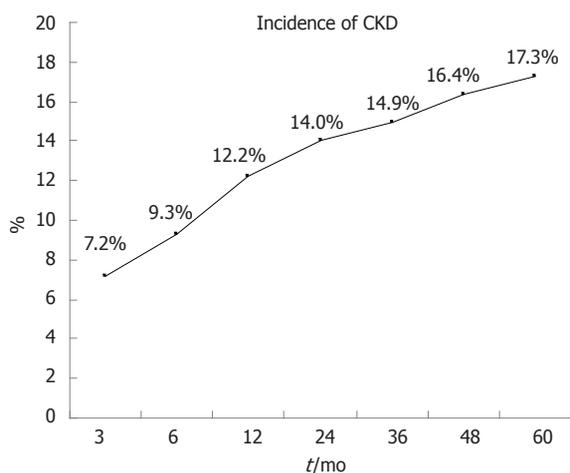

Data from the clinical records of 772 consecutive Chinese patients who underwent LT from March 1999 until December 2009 were retrospectively analysed. Patients were monitored till August 2010 or to their death. Recipients with a short follow-up (less than 3 mo), died within 3 mo after transplantation and younger than 18 years old were excluded. All the liver grafts were from brain-dead donors or living donors. Living and deceased donations were voluntary in all cases, approved by the West China Hospital Ethics Committee, and in accordance with the ethical guidelines of the Declaration of Helsinki.

### Evaluation of kidney function

Renal function was assessed by estimated glomerular filtration rate (eGFR) using the abbreviated Modification of Diet in Renal Disease formula:  $eGFR = 186 \times \text{creatinine (mg/dL)}^{-1.154} \times (\text{age})^{-0.203} \times (0.742 \text{ if female})$ . Acute kidney injury (AKI) was defined as more than 25% decrease of GFR in the first post-operative week compared with the pre-operative level by the RIFLE (risk, injury, failure, loss and end-stage renal failure) criteria<sup>[16]</sup>. CKD was defined as GFR < 60 mL/min per 1.73 m<sup>2</sup> for at least 3 consecutive months. Hepatorenal syndrome was defined as Salerno *et al*<sup>[17]</sup> reported: cirrhosis with ascites, serum creatinine > 1.5 mg/dL, no improvement of serum creatinine after at least 2 d with diuretic withdrawal and volume expansion with albumin, no current or recent treatment with nephrotoxic drugs, absence of parenchyma kidney disease. Renal dysfunction before LT was also defined as eGFR < 60 mL/min per 1.73 m<sup>2</sup>.

### Definitions of other clinical parameters

According to the latest guideline of prevention and treatment of plasma lipid abnormality for Chinese adults, hypercholesterolemia was defined as total plasma cholesterol  $\geq 6.22$  mmol/L, hypertriglyceridemia as triglyceride  $\geq 2.26$  mmol/L<sup>[18]</sup>. Diabetes mellitus (DM) was diagnosed if

**Figure 1** Incidence of chronic kidney disease 5 years after liver transplantation. The estimated glomerular filtration rate (eGFR) was calculated by the abbreviated Modification of Diet in Renal Disease formula after each visit of a patient. And once met the criterion of chronic kidney disease (CKD) (eGFR < 60 mL/min per 1.73 m<sup>2</sup>), they were registered into the CKD group. Seventeen point three percents of the whole population (99 cases) developed CKD during the 5-year's follow-up.

random blood glucose  $\geq$  11.1 mmol/L or fasting plasma glucose  $\geq$  7.0 mmol/L. AR was confirmed either by liver biopsy or recovery from high-dose methylprednisolone. If chronic rejection (CR) was suspected, liver biopsy was also carried out. Hypertension was defined as a systolic blood pressure over 140 mmHg or diastolic pressure over 90 mmHg twice at different time. Mayo end-stage liver disease (MELD) scores were calculated for each patient.

### Immunosuppressive protocols

Initial immunosuppression was by triple-drug regimens that included a CNI (TAC or CSA), MMF and prednisone. The initial dose of CNI was 0.05-0.10 mg/kg per day for TAC and 5-10 mg/kg per day for CSA respectively. MMF was personalized between 1.0-1.5 g/d. At the early phase in our center, patients were administrated with MMF only when they were diagnosed hypertension and DM; however, all recipients in the late period were administrated with it unless severe gastrointestinal side effects or myelosuppression happened. Prednisone was generally discontinued within 3 mo after transplantation.

### Adjustment of calcineurin inhibitor dose during follow-up

Observations of clinical indices including CNI trough concentrations were checked daily for the first week and weekly for the next three in the first month post-operation, monthly within 3-mo and every three months thereafter. The ideal serum trough level of CNI was 6-8 ng/mL for TAC and 120-150 ng/mL for CSA 3-mo post-operation. Liver function was monitored intensely while adjusting the CNI dose. If AR happened, prior dosage was restarted, together with the prednisone increase or high-dose methylprednisolone administration. Dose reduction was more carefully and slowly carried out. A trough level of 4-6 ng/mL for TAC and 80-120 ng/mL

for CSA one year after transplantation was expected with stable liver function.

### Statistical analysis

SPSS 17.0 statistical software (SPSS Company, Chicago, IL) was used to analyse the relevant data. Numerical data are presented as the mean  $\pm$  SD or as the median. Continuous data were compared using the independent *t*-test if data were normally distributed, or using the rank-sum test if data were non-normally distributed. Categorical data were compared using the  $\chi^2$  test. Univariate logistic regression analysis was used to discover risk factors for CKD. Variables reaching statistical significance were then included for multivariate analysis. Results were reported as odds ratios with 95% confidence intervals.

## RESULTS

### Patients population

The medical records of 572 patients [male:female 478:94, mean age 44 (20-69) years old] meeting the inclusion criteria were reviewed retrospectively. Mean follow-up duration was 28 (3-125) mo. Pre-operation baseline included DM in 36 (6.29%) patients, hypertension in 13 (2.27%) patients, renal dysfunction in 54 (9.44%) patients, and hepatorenal syndrome in 27 (4.72%) patients, 19 (3.32%) were given hemodialysis therapy within a 2-wk period before surgery. The main indications for LT were tumors and end stage liver diseases, with 268 (46.9%) and 276 (48.2%) patients respectively. More than 80% patients were found to be hepatitis B virus (HBV) related. The deceased donor transplantation rate was 75.5%.

### Incidence of chronic kidney disease

The eGFR was calculated after each visit of a patient. And once met the criterion of CKD, they were registered into the CKD group. As shown in Figure 1, 17.3% of the whole population (99 cases) developed CKD during the 5-year's follow-up.

Our analysis of the difference in over 20 clinical indices between patients with and without CKD showed that the CKD group had older age, higher MELD scores, more female, more patients with pre-operative renal dysfunction, more with hepatorenal syndrome and more received pre-operative hemodialysis. There was also a between-group difference in immunosuppression protocols, TAC and MMF was preferred in the non-CKD group. Of the 85 cases of AKI (14.9%), 32 progressed to CKD. In addition, the CKD group had more patients with post-operative DM, hypertension and hypertriglyceridemia (Table 1).

### Subgroups of calcineurin inhibitor trough concentrations

The CNI trough concentrations were recorded in each visit too. Mean concentrations of both TAC and CSA were calculated at different time points. A decreasing trend was discovered with lengthening of follow-up time (Figure 2).

As we mentioned before, an ideal concentration was expected at 3-mo and 1-year post LT. The results showed

**Table 1** Clinical features between chronic kidney disease and non-chronic kidney diseases recipients *n* (%)

CKD: Chronic kidney disease; Age: Age at transplantation; DDLT: Deceased donor liver transplantation; LDLT: Living donor liver transplantation; NS: No significance; LT: Liver transplantation; HBV: Hepatitis B Virus; DM: Diabetes mellitus; HRS: Hepatorenal syndrome; MELD: Mayo end-stage liver disease; CNI: Calcineurin Inhibitor; TAC: Tacrolimus; CSA: Cyclosporine A; MMF: Mycophenolate mofetil; AKI: Acute kidney injury; AR: Acute rejection; CR: Chronic rejection.

that there were 68.3% (293 of 429 cases) patients managed to control their TAC trough concentrations within 8 ng/mL and 58.0% (83 of 143 cases) patients' CSA trough concentrations within 150 ng/mL. Of the 450 recipients followed-up over 1 year, 55.5% (183 of 330 cases) of which were treated with TAC had a trough concentration  $\leq$  6 ng/mL while 65.8% (79 of 120 cases) of which were treated with CSA had a concentration  $\leq$  120 ng/mL. The incidence of CKD in the groups of lower CNI trough concentrations was significantly lower than the groups with CNI concentrations above the ideal range (Table 2). At the same time, we compared the CNI trough concentrations between patients with and without CKD. As shown in Figure 2A and B, the CKD group had much higher CNI trough concentrations than that of patients without CKD.

Also, recipients were grouped by whether MMF was used. We found its adoption in 359 patients (62.8%). It was used in 49.5% of the CKD group and 65.5% of the non-CKD group ( $P = 0.003$ ). Although patients administered with MMF had a relatively low CNI trough concentrations, but no significant difference was found

between groups (Figure 2C and D).

To assess the impact of CNI concentrations on the chronic complications and graft function post transplantation, patients were still grouped according to the CNI trough concentrations 3-mo post transplantation. The analysis showed between-group differences in these parameters were without statistical significance (Table 3).

### Risk factors for chronic kidney disease progression

Together with the different CNI concentrations and whether uses of MMF, over twenty parameters were examined by univariate logistic analysis to identify the risk factors of CKD (Table 4). All the factors with statistical significance were chosen for multivariate logistic analysis, and seven of them were singled out. Age at LT, pre-operative renal dysfunction, AKI, high CNI concentration 3 mo after LT (TAC > 8 ng/mL or CSA > 150 ng/mL), post-operative hypertension were risk factors of CKD; male, use of MMF were protective factors of CKD (Table 5).

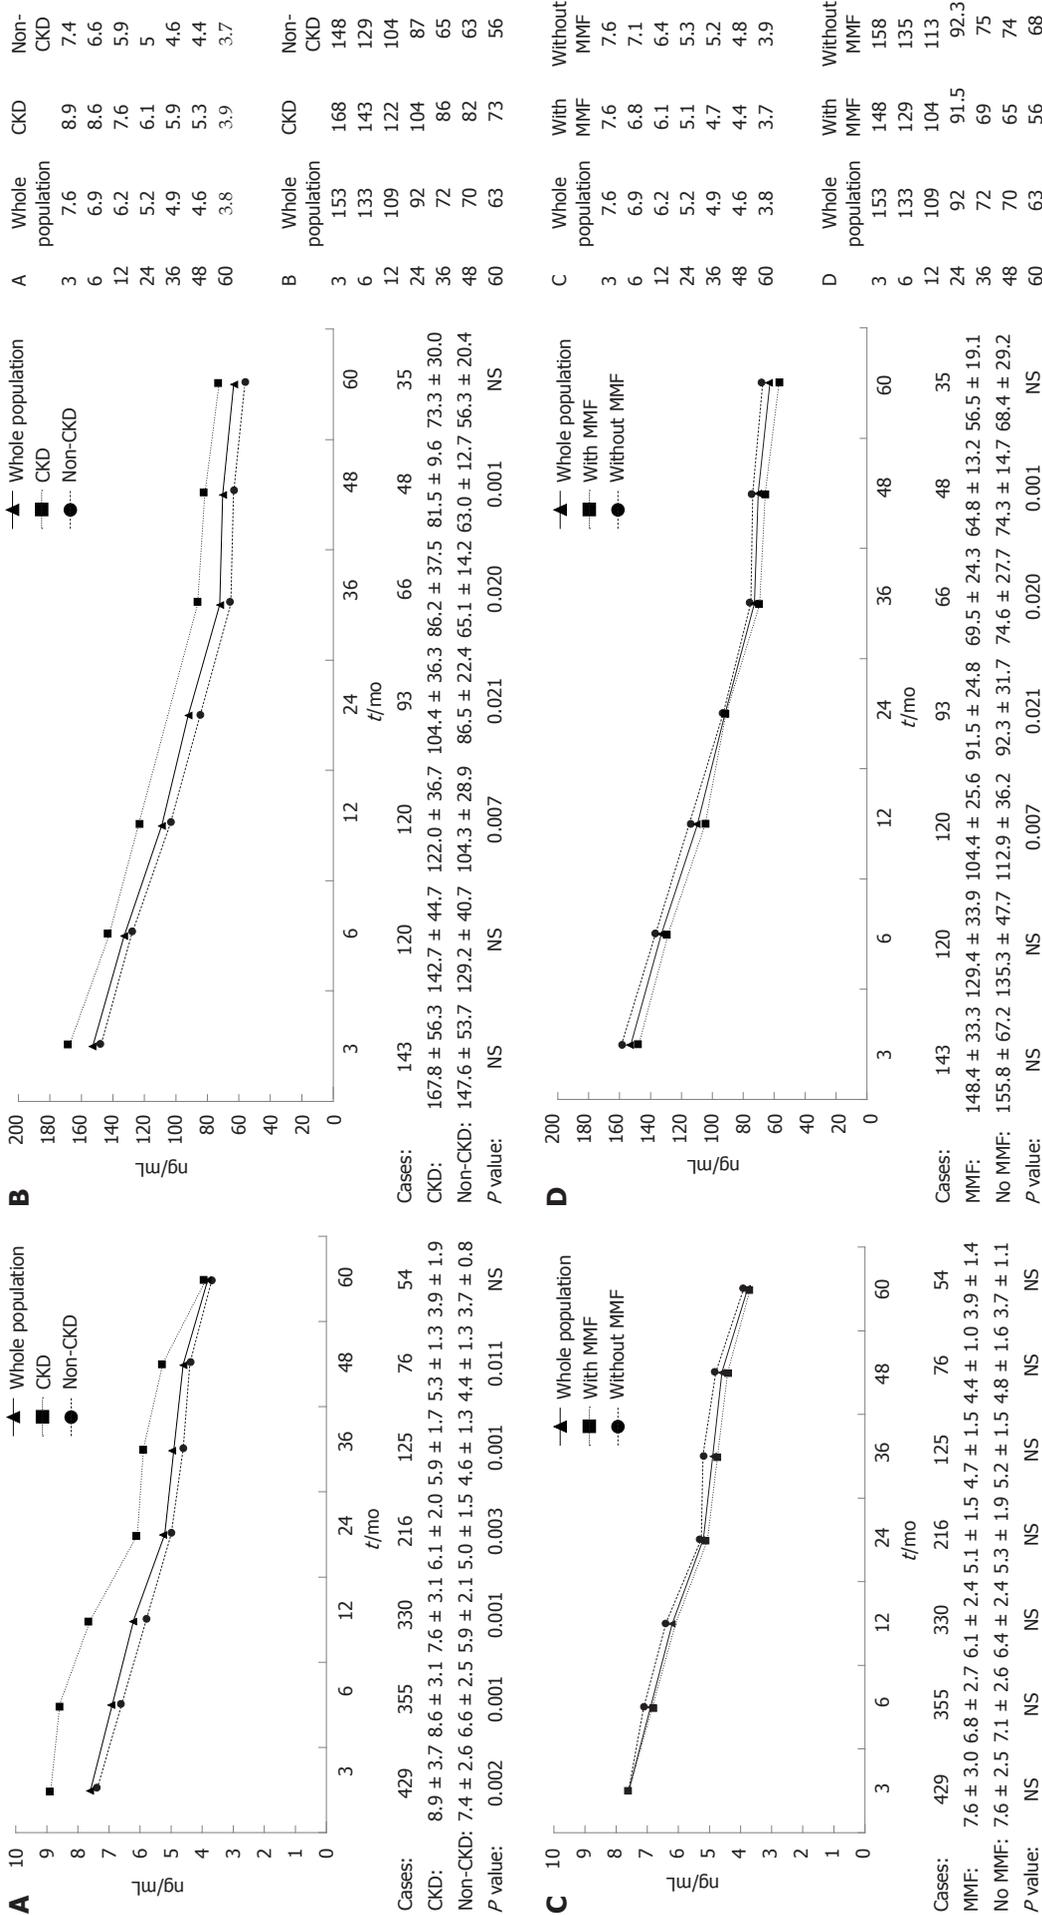

## DISCUSSION

The incidence of CKD increases with survival time after LT. As its nephrotoxicity proved by more researches, every center realized the importance of CNI dose adjustment. But how and when to adjust it still remains a question. There are two mainly strategies for CNI induced CKD, one is CNI withdrawal and conversion to a non-nephrotoxic immunosuppressant, such as sirolimus, MMF and azathioprine; the other is CNI dose reduction in combination with an auxiliary immunosuppressant<sup>[4,6,7,13,14]</sup>. Both were used. However, because of the CNI withdrawal time and dose reduction level differed among different centers, no agreement was reached.

Unlike the strategies mentioned above, in our center, an initial low CNI dose was administered. And by intensely monitoring of the graft function and gradually CNI dose reduction, a low blood concentration of CNI was maintained thereafter. The results displayed that over half the patients managed to maintain a CNI level within the target range in 3-mo and 1-year post LT and graft function remained stable compared with the high CNI level group. Moreover, groups of CNI concentrations within target range had significantly lower CKD incidence than the rest.

It was reported that CKD incidence varied to a great distance. Data from different centers varies partly because of different definitions of CKD<sup>[2-7]</sup>. We defined CKD as GFR < 60 mL/min per 1.73 m<sup>2</sup> in this research, a level at which the prevalence of complications of CKD begins to increase<sup>[19,20]</sup>. By this criterion, the incidence of CKD 5 years after LT was 17.3%, lower than many reports. Five factors have been incriminated as etiologic factors of CKD as demonstrated by the multivariate logistic analysis.

An important risk factor for CKD was CNI trough concentrations 3 mo after LT (OR = 2.935). Dose of CNI varies between different centers. Nevertheless, there is a consensus that the CNI concentration should be as low as

**Figure 2 Calcineurin inhibitor trough concentrations between different groups.** We compared the mean trough concentrations of tacrolimus (TAC) and cyclosporine A (CSA) at different time points between patients with and without chronic kidney disease (CKD) (A and B), between patients combined mycophenolate mofetil (MMF) use and no use (C and D). A: Trough concentrations of TAC grouped by CKD and non-CKD at different time points. Apart from 5 years after liver transplantation (LT), the CKD people had higher TAC trough concentrations than non-CKD people with statistical significance; B: Trough concentrations of CSA grouped by CKD and non-CKD at different time points. The CKD people had higher CSA trough concentrations than non-CKD people with statistical significance in 1, 2, 3, 4 years after LT; C and D: Trough concentrations of TAC (C) and CSA (D) grouped by combination with and without MMF at different time points. Patients with MMF combination had a lower calcineurin inhibitor trough concentrations but most without statistical significance. NS: Not significant.

**Table 2 Chronic kidney disease incidence between groups 3 mo and one year after liver transplantation**

Groups	Cases (CKD incidence %)	P value
Three months after LT		
CSA trough concentrations		
> 150 ng/mL	20/60 (32.3)	0.036
≤ 150 ng/mL	15/83 (18.1)	
TAC trough concentrations		
> 8 ng/mL	32/136 (23.5)	0.001
≤ 8 ng/mL	32/293 (10.9)	
One year after LT		
CSA trough concentrations		
> 120 ng/mL	19/41 (46.3)	< 0.001
≤ 120 ng/mL	12/79 (15.2)	
TAC trough concentrations		
> 6 ng/mL	36/147 (24.5)	< 0.001
≤ 6 ng/mL	17/183 (9.3)	

Patients were divided by the calcineurin inhibitor types and trough concentrations 3 mo post transplantation. Groups with ideal trough concentrations [cyclosporine A (CSA) trough concentrations ≤ 150 ng/mL, tacrolimus (TAC) trough concentrations ≤ 8 ng/mL] had much lower chronic kidney disease (CKD) incidence. Patients followed-up over 1-year (*n* = 450) were divided by the calcineurin inhibitor types and trough concentrations at one year post transplantation. Groups with ideal trough concentrations (CSA trough concentrations ≤ 120 ng/mL, TAC trough concentrations ≤ 6 ng/mL) had much lower CKD incidence. LT: Liver transplantation.

**Table 3 Chronic complications and graft function between different groups of calcineurin inhibitor trough concentrations**

Complications	Cases (CKD incidence %)	Group 1 (%)	Group 2 (%)	P value
DM	112 (19.6)	17.6	23.5	NS
Hypertriglyceridemia	107 (18.7)	18.1	19.9	NS
Hypercholesterolemia	76 (13.3)	12.8	14.3	NS
Hypertension	54 (9.4)	8.2	11.7	NS
AR	74 (12.9)	11.7	15.3	NS
CR	15 (2.6)	2.1	3.8	NS
Graft failure	17 (3.0)	2.7	3.6	NS
Re-transplantation	13 (2.3)	2.1	2.6	NS

Patients were divided according to the trough concentrations 3 mo after liver transplantation. Group 1: 376 cases, tacrolimus (TAC) ≤ 8 ng/mL or cyclosporine A (CSA) ≤ 150 ng/mL; Group 2: 196 cases, TAC > 8 ng/mL or CSA > 150 ng/mL. No statistical significance was found between groups. DM: Diabetes mellitus; AR: Acute rejection; CR: Chronic rejection; CKD: Chronic kidney disease.

possible to avoid CKD. Morard *et al*<sup>[21]</sup> identified trough levels of CSA ≥ 150 ng/mL or TAC ≥ 10 ng/mL at 1 year and CSA ≥ 100 ng/mL or TAC ≥ 8 ng/mL at 5 years as independent risk factors for impaired renal function. However, no agreement has yet been reached on what is the minimum and safe CNI dose for LT recipients.

Pre-LT baseline renal function has a major impact on that post-transplantation<sup>[3,6,7,22]</sup>. In this study, both renal dysfunction pre-operation and AKI post-operation proved to be important risk factors for CKD. Velidedeoglu *et al*<sup>[23]</sup> suggested that a combination of events during the first postoperative week after LT serve as a physiologic “stress test” for the kidneys. Patients who failed the test (peak creatinine > 2 mg/dL) were at increased risk of

chronic renal disease. Although both pre-operative renal dysfunction and AKI were considered to be reversible, with persistently nephrotoxication of CNI, the chance of recovery for kidney function is small and the injury could become irreversible and chronic finally. Induction therapy with both lymphocyte-depleting and non lymphocyte-depleting antibodies and delayed introduction of CNI (3-7 d) may preserve or ameliorate renal function in LT recipients with pre-transplant renal dysfunction without increasing the risk of rejection or compromising patient and graft survival<sup>[24-26]</sup>.

Hypertension commonly causes renal disease in general population, so it was not surprising that post-operative hypertension became risk factor of CKD. Once confirmed, recipients should receive active treatment. Administration of angiotensin-converting enzyme inhibitors and angiotensin receptor blockers were recommended, for they could theoretically protect these patients from both the acute hemodynamic component and chronic vascular and tubulointerstitial injury. The benefit of the former class of agents is conferred predominantly *via* reduction in CNI-induced afferent arteriolar vasoconstriction and that of the latter is conferred *via* the inhibition of angiotensin II effects of transforming growth factor- $\beta$  and other profibrotic mediators<sup>[27]</sup>.

Our finding showed use of MMF as a protective factor of CKD. And as an accessory immunosuppressant, MMF does not have nephrotoxicity and could reduce the CNI dosage. Strategies to alleviate CNI nephrotoxicity include use of MMF with CNI dose reduction or CNI-withdrawal and conversion to MMF<sup>[4,6,7,13,14,28]</sup>. We found that, with an 1.0-1.5 g/d administration, most people had no severe side effects, which proved to be safe and effective.

Another protective factor of CKD was male gender. In the general population, however, male gender is more closely associated with renal disease progression, but the reason for this inconsistency is unclear<sup>[5,29]</sup>.

HBV infection was not a significant risk factor compared to other causes in this research. This finding was similar to previous studies based on Asian people<sup>[12]</sup>. HCV infection was also not a significant risk factor for CKD progression. In western countries, HCV is the most common cause of liver failure, and it increases CKD risk in liver transplantation primarily because it may cause glomerulonephritis<sup>[9,30]</sup>. Nevertheless, only 7 patients had HCV related cirrhosis in this cohort. Lamivudine combined with individualized low-dose hepatitis B immunoglobulin was used as a prophylaxis against HBV recurrence after LT in our center. Adefovir, which is known to be nephrotoxic, was administered with only a few patients<sup>[31]</sup>. This could partly explain why our center has a relatively low incidence of CKD.

Posttransplantation DM is prevalent among LT recipients. It was reported earlier that the incidence of post-transplantation DM could reach 14.9% in the living donor liver transplantation<sup>[32]</sup>. However, in this study we found no relationship between DM and CKD. The proper explanation maybe that insulin was widely accepted and used among LT recipients. Most people had his blood sugar under the ideal range. Complications of DM were not as popular as usual.

While there is conflicting evidence in the literature on whether a TAC or CSA use is more beneficial<sup>[33,34]</sup>, we found a lower incidence of CKD in the TAC group and identified CSA as a risk factor for CKD by univariate logistic regression analysis. However, the analysis did not take into account a small number of patients ( $n = 20$ ) who switched CNIs during the follow-up. Therefore, the benefit of TAC over CSA remains inconclusive. Randomized, prospective studies with a large number of patients

will be needed to resolve this issue.

In conclusion, many factors have been associated with CKD progression. With few practical and validate strategy, we have shown that administration of low-dose CNI in combination with MMF could lower CKD incidence and did not increase AR rate, which provided as a successful experience for Chinese LT recipients. As mentioned above, there was part of the population left whose CNI concentration was above the target range. So the low dose was not adaptable for everyone. Closely monitoring of liver function during tapering the CNI dose was needed. Dose reduction must be based on a stable liver function. Limitation of this study is that data were collected retrospectively and that GFR was evaluated rather than measured. Study of prospective designed and CKD defined by measured GFR would be more convincing.

## COMMENTS

### Background

Use of calcineurin inhibitor (CNI) has greatly increased liver transplant recipient survival rates and reduced graft rejection rates in recent years. However, long duration of its use may cause chronic complications, like chronic kidney disease (CKD), which has severely affected the quality of life and survival of organ recipients.

### Research frontiers

There are two main strategies for CNI induced CKD, one is CNI withdrawal and conversion to a non-nephrotoxic immunosuppressant, such as sirolimus, mycophenolate mofetil (MMF) and azathioprine; the other is dose reduction combined with an auxiliary immunosuppressant. Both strategies were used, but no agreement has been reached.

### Innovations and breakthroughs

It has been proven that CNI nephrotoxicity was associated with its dosage and duration. However, no consensus was reached on the minimum CNI dose which is considered to be safe for liver transplantation (LT) recipients. Different with other centers, the authors carried out a strategy of initial low-dose CNI and maintaining low blood concentrations after. By closely monitoring of liver function and gradually tapering the CNI dose, the result was favorable with low incidence of CKD and acceptable graft functions.

### Applications

Administration of low-dose CNI in combination with MMF could lower CKD incidence and did not increase acute rejection rate, which provided as a successful experience for Chinese LT recipients. Limitation of this study is that data were collected retrospectively and that glomerular filtration rate (GFR) was evaluated rather than measured. Study of prospective designed and CKD defined by measured GFR is needed in the future.

### Peer review

The research proved a successful strategy to prevent CKD liver transplantation with ample data and strict design, which should be popularized by more centers.

### Abstract

Three cases of transient proximal small bowel angioedema induced by intravenous administration of nonionic iodinated contrast media (CM) are presented. Computed tomography (CT) images in the venous phase displayed the proximal small bowel with circumferential thickening of the wall including the duodenum and proximal segment of the jejunum. The bowel wall was normal in non-enhanced images, and normal or inconspicuous in arterial phase enhanced images. In one of the three cases, the bowel wall was thickened in venous phase but disappeared in the 40 s delayed phase images. No filling defect was seen in the lumen of the superior mesenteric artery and vein. No peritoneal effusion or mesentery abnormality was found. Each of these patients reported only mild abdominal discomfort and recovered without specific treatment within a short time. Only one patient suffered mild diarrhea after scanning which had resolved by the following day. The transient anaphylactic small bowel angioedema due to intravenous iodinated contrast media was easily diagnosed based on its characteristic CT findings and clinical symptoms. Differential diagnosis may include inflammatory and ischemic bowel disease, as well as neoplasms. A three-phase CT protocol and good under-

standing of this disorder are fundamentally important in the diagnosis of this condition. The supposed etiology behind the transient anaphylactic reaction to intravenous administration of iodinated CM in small bowel is similar to other CM-induced hypersensitive immediate reactions. The predilection location of transient anaphylactic bowel angioedema is the small intestine, particularly the proximal segment. A speculated cause may be the richer supply of vessels in the small intestine, ample mucous folds and loose connective tissue in the duodenum and the jejunum.

### INTRODUCTION

Anaphylactic reactions to intravenous nonionic iodinated contrast media (CM) range from mild flushing to severe cardiopulmonary arrest and occur in about 1% of patients<sup>[1,2]</sup>. Such anaphylactic reactions can occur in the gastrointestinal tract presenting as bowel angioedema. To our knowledge, only four cases of small bowel angioedema and one case of colon angioedema were previously reported in the literature<sup>[3-5]</sup>. Here we report three cases of proximal small bowel angioedema and discuss their computed tomography (CT) findings, clinical features and outcomes.

## CASE REPORT

### Case one

A 55 year-old man with upper abdominal pain for one month was referred for an upper abdominal multi-phase contrast-enhanced CT examination. The patient drank 400 mL of iso-osmotic mannitol solution 30 min before the study and 100 mL just before the scan. After a conventional plain CT scan, a total of 90 mL nonionic iodinated CM (370 mgI/mL, Ultravist, Bayer Schering Pharma) was administered intravenously at a rate of 3 mL/s using an automated injector. The patient suffered mild abdominal discomfort during the examination and mild diarrhea after scanning. No dermal rash or other disorders were reported. These symptoms had resolved by the following day.

CT images in the venous phase displayed the proximal small bowel with circumferential thickening of the wall of a long segment (Figure 1A), including the descending, horizontal and ascending duodenum. However, the bowel wall was normal in the non-enhanced (Figure 1B) and arterial phase (Figure 1C) images. The fat around the bowel was clear. No filling defect was seen in the lumen of the superior mesenteric artery and vein. No peritoneal effusion or other abnormality was found. Therefore, the patient was clinically diagnosed with bowel angioedema, and follow-up was recommended.

Four months later, the patient received a repeat abdominal enhanced CT scan using another nonionic CM (370 mgI/mL, Iopamidol Injection, Bracco Diagnostics). The proximal small bowel was normal.

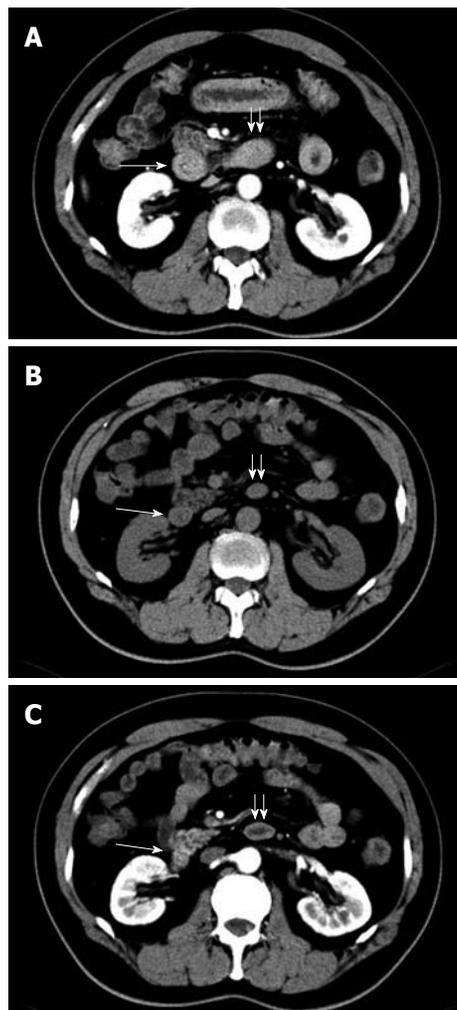

### Case two

A 46 year-old man with multiple colon polyps was referred for a complete abdominal contrast-enhanced CT exam. Prior to the CT scan, 1000 mL oral iso-osmotic mannitol solution was administered to distend the alimentary duct within one hour. The protocol for administering iodinated CM was the same as that in the first case, however, the CM (370 mgI/mL, Iopamidol Injection, Bracco Diagnostics) was different. The patient complained of mild abdominal discomfort after the CT examination. Symptoms resolved about thirty minutes later.

In non-enhanced CT images, no abnormality in the small bowel was found. The proximal segment of the small bowel showed slight thickening in arterial phase (Figure 2A) and marked circumferential thickening in venous phase (Figure 2B) CT images. The affected segment included the descending, horizontal and ascending duodenum. However, no extraluminal, mesenteric, or peritoneal pathological process was found.

### Case three

A 32-year-old woman with a mass in the right kidney was referred for a multi-phase abdominal enhanced CT exam. The examination protocol was the same as that in case one, except the CM was Omnipaque (350 mgI/mL, Iohexol Injection, GE Healthcare). An edematous proximal

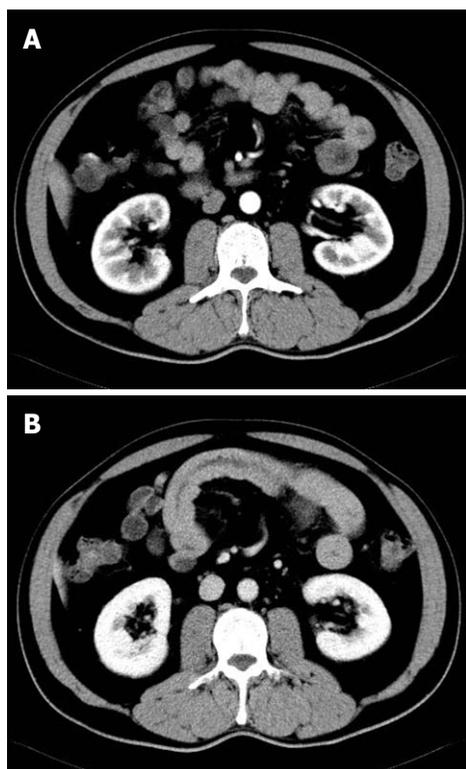

**Figure 1** A 55-year-old man. A: Circumferential thickening of the proximal small bowel in a long segment including the descending duodenum (long arrow) and horizontal duodenum (double short arrows) in venous phase image; B and C: This bowel segment appears normal in unenhanced image (B) and arterial phase image (C).

intestinal segment, including the second to fourth segment of the duodenum, was identified in venous phase CT images (Figure 3A). The intestinal wall was marked by circumferential thickening and the lumen was slightly dilated. Slight bowel edema was found in both arterial phase and 40-s delayed phase images (Figure 3B). However, the bowel segment was normal on the non-enhanced images (Figure 3C). Mild abdominal discomfort was the only symptom in this case and resolved spontaneously.

## DISCUSSION

Segmental bowel wall thickening is usually indicative of inflammatory bowel disease, mesenteric ischemia, or neoplastic disease. In the above-mentioned cases, thickening of the intestinal wall was most prominent on venous phase imaging. However, the bowel wall was normal in non-enhanced images and inconspicuous in arterial phase enhanced images. It is interesting that the bowel wall thickening disappeared in the 40-s delayed phase images in

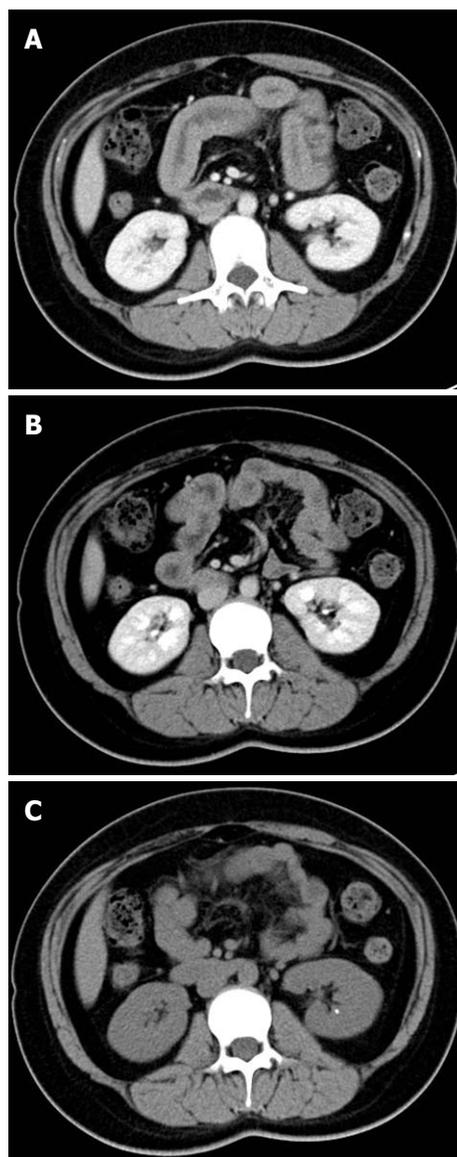

**Figure 2** A 46-year-old man. A: The proximal bowel segment is slightly thickened in arterial phase image; B: The proximal bowel segment shows marked circumferential thickening in venous phase.

the third case. A rapid change in bowel wall thickening may be an exclusive characteristic of anaphylactic small intestinal angioedema due to intravenous iodinated contrast. Although bowel wall angioedema can appear slightly thickened at an initially enhanced CT and be markedly edematous 4 h later, the majority of cases in the literature revealed that circumferential wall thickening of small bowel segments was found only at initial enhanced CT images<sup>[3,4]</sup>. In our cases, peak wall thickening appeared on the venous phase about 65 s after administration of intravenous contrast. Another feature of the CT findings in our cases was that there was no exudation, vascular engorgement, or lymphadenopathy around the thickened bowel segment, which is distinguishable from other pathological processes.

All three patients felt mild abdominal discomfort during scanning with contrast enhancement, but recovered after the CT examination without special treatment. Only one patient complained of mild diarrhea on the day of examination. Such symptoms may be caused by oral administration of iso-osmotic mannitol solution before examination for distending the stomach and small intestine<sup>[6]</sup>. Our findings, in accordance with previous reports, indicate that anaphylactic angioedema of the small bowel induced by iodinated CM was self-limiting and resolved quickly without additional intervention<sup>[4]</sup>.

To our knowledge, there have only been 4 cases reported in the literature with iodinated CM-induced small bowel anaphylactic angioedema. The incidence of CM-induced bowel anaphylactic angioedema is very low com-

**Figure 3** A 32-year-old woman. A: Venous phase image reveals an edematous proximal small bowel segment, including the descending and horizontal duodenum; B: The edematous wall resolved after the 40-s delayed image; C: This same bowel segment presented as normal on the unenhanced image.

pared with pruritus and mild urticaria in affected patients<sup>[1]</sup>. Due to high time resolution, CM-induced bowel anaphylactic angioedema may not be well displayed in CT images before or after the venous phase, about 65 s after administration of iodinated CM. A transient wall thickening without pathological CT findings around the bowel wall and/or obvious clinical symptoms may miss the diagnosis of CM-induced bowel anaphylactic angioedema. Occasionally, it may be misdiagnosed as inflammatory or ischemic bowel disease, especially if only the venous phase protocol is used for multi-detector CT enterography<sup>[7]</sup>. Based on the above-mentioned possibilities, we presume that such a condition may be clinically underestimated.

The exact etiology of the anaphylactic reactions to intravenous administration of iodinated CM is not completely understood. In our three cases, anaphylactic angioedema of the proximal small intestine was induced

by different brands of nonionic iodinated CM. In case one, the patient was hypersensitive to one type of commercial product, but not to another type. The concentration of iodinated CM we used was relative high (350 or 370 mgI/mL). However, anaphylactic small bowel angioedema can also be induced by iodinated CM at lower concentrations (300 or 282 mgI/mL) according to the literature<sup>[4,5]</sup>. Thus, the relationship between anaphylactic small bowel angioedema and the concentration of iodine in the CM was not assured. We propose that transient anaphylactic small bowel angioedema shares the same underlying etiology as the other non-allergic CM-induced hypersensitive immediate reactions<sup>[8,9]</sup>. With regard to the reason why most cases (including ours) of transient anaphylactic bowel angioedema occur in the small intestine, particularly the proximal segment, the speculated cause may be the richer supply of vessels in the small intestine than in the colon, as well as the ample mucous folds and loose connective tissue in the jejunum.

In conclusion, transient anaphylactic small bowel angioedema due to intravenous iodinated contrast media is easily diagnosed based on its characteristic CT findings. However, the three-phase CT protocol and a good understanding of this disorder are fundamentally important.

## GENERAL INFORMATION

*World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

### Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the “priority” and “copyright” of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers’ names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid

evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

### Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

### Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systematically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensus and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

### Name of journal

*World Journal of Gastroenterology*

## Instructions to authors

### ISSN and EISSN

ISSN 1007-9327 (print)

ISSN 2219-2840 (online)

### Editor-in-chief

**Ferruccio Bonino, MD, PhD, Professor** of Gastroenterology, Director of Liver and Digestive Disease Division, Department of Internal Medicine, University of Pisa, Director of General Medicine 2 Unit University Hospital of Pisa, Via Roma 67, 56124 Pisa, Italy

**Myung-Hwan Kim, MD, PhD, Professor, Head**, Department of Gastroenterology, Director, Center for Biliary Diseases, University of Ulsan College of Medicine, Asan Medical Center, 388-1 Pungnap-2dong, Songpa-gu, Seoul 138-736, South Korea

**Kjell Öberg, MD, PhD, Professor**, Department of Endocrine Oncology, Uppsala University Hospital, SE-751 85 Uppsala, Sweden

**Matt D Rutter, MBBS, MD, FRCP**, Consultant Gastroenterologist, Senior Lecturer, Director, Tees Bowel Cancer Screening Centre, University Hospital of North Tees, Durham University, Stockton-on-Tees, Cleveland TS19 8PE, United Kingdom

**Andrzej S Tarnawski, MD, PhD, DSc (Med), Professor of Medicine, Chief** Gastroenterology, VA Long Beach Health Care System, University of California, Irvine, CA, 5901 E. Seventh Str., Long Beach, CA 90822, United States

### Published by

Baishideng Publishing Group Co., Limited

## SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

### Biostatistical editing

Statistical review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc.* The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only

homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word ‘significantly’ should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

### Conflict-of-interest statement

In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read “Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest” from International Committee of Medical Journal Editors (ICMJE), which is available at: [http://www.icmje.org/ethical\\_4conflicts.html](http://www.icmje.org/ethical_4conflicts.html).

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

### Statement of informed consent

Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

### Statement of human and animal rights

When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator’s national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

## SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/1007-9327/office>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS ([http://www.wjgnet.com/1007-9327/g\\_info\\_20100315215714.htm](http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm)) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [wjg@wjgnet.com](mailto:wjg@wjgnet.com), or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

## MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically

for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. [montgomery.bissell@ucsf.edu](mailto:montgomery.bissell@ucsf.edu)

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

### Abstract

There are unstructured abstracts (no less than 256 words) and structured abstracts (no less than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no less than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections.

## Instructions to authors

AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/..."; MATERIALS AND METHODS (no less than 140 words); RESULTS (no less than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ; CONCLUSION (no more than 26 words).

### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

### Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315215714.htm](http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm).

### Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A...; B...; C...; D...; E...; F...; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

### Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  should be noted ( $P > 0.05$  should not be noted). If there are other series of *P* values, <sup>c</sup> $P < 0.05$  and <sup>d</sup> $P < 0.01$  are used. A third series of *P* values can be expressed as <sup>e</sup> $P < 0.05$  and <sup>f</sup> $P < 0.01$ . Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be la-

beled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that...".

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

### PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

**Statistical data**

Write as mean  $\pm$  SD or mean  $\pm$  SE.

**Statistical expression**

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\nu$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

**Units**

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h; blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315223018.htm](http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm).

**Abbreviations**

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

**Italics**

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H. pylori*, *E. coli*, etc.

---

## RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be re-submitted online (<http://www.wjgnet.com/1007-9327/office/>). The author should send the copyright transfer letter, responses to the reviewers, English language Grade B certificate (for non-native speakers of English) and final manuscript checklist to [wjg@wjgnet.com](mailto:wjg@wjgnet.com).

### *Language evaluation*

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

### *Copyright assignment form*

Please download a Copyright assignment form from [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315222818.htm](http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm).

### *Responses to reviewers*

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315222607.htm](http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm).

### *Proof of financial support*

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

### *Links to documents related to the manuscript*

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

### *Science news releases*

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

### *Publication fee*

*WJG* is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1300 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.

# World Journal of *Gastroenterology*

*World J Gastroenterol* 2012 March 14; 18(10): 1003-1140

## Editorial Board

2010-2013

The *World Journal of Gastroenterology* Editorial Board consists of 1352 members, representing a team of worldwide experts in gastroenterology and hepatology. They are from 64 countries, including Albania (1), Argentina (8), Australia (33), Austria (15), Belgium (14), Brazil (13), Brunei Darussalam (1), Bulgaria (2), Canada (21), Chile (3), China (82), Colombia (1), Croatia (2), Cuba (1), Czech (6), Denmark (9), Ecuador (1), Egypt (4), Estonia (2), Finland (8), France (29), Germany (87), Greece (22), Hungary (11), India (32), Indonesia (2), Iran (10), Ireland (6), Israel (13), Italy (124), Japan (140), Jordan (2), Kuwait (1), Lebanon (4), Lithuania (2), Malaysia (1), Mexico (11), Morocco (1), Moldova (1), Netherlands (32), New Zealand (2), Norway (13), Pakistan (2), Poland (11), Portugal (6), Romania (4), Russia (1), Saudi Arabia (3), Serbia (3), Singapore (11), Slovenia (1), South Africa (3), South Korea (46), Spain (43), Sri Lanka (1), Sweden (17), Switzerland (12), Thailand (1), Trinidad and Tobago (1), Turkey (30), United Arab Emirates (2), United Kingdom (95), United States (285), and Uruguay (1).

### Abstract

The liver is a common location of both primary and secondary malignancies. For unresectable liver cancer, many local ablative therapies have been developed. These include e.g., percutaneous ethanol injection (PEI), percutaneous acetic acid injection, radiofrequency ablation (RFA), cryoablation, microwave ablation, laser-induced thermotherapy, and high-intensity focused ultrasound. RFA has recently gained interest and is the most widely applied thermoablative technique. RFA allows more effective tumor control in fewer treatment sessions compared with PEI, but with a higher rate of complications. However, there are certain circumstances where PEI therapy represents a better strategy to control liver tumors than RFA, especially in situations where RFA is difficult, for example when large vessels surround the tumor. In the context of hepatocellular carcinoma (HCC), both RFA and PEI are feasible and of benefit in non-operable patients. RFA seems superior to PEI in HCC > 2 cm, and the combination of interventions may be of benefit in selected patients. Liver resection is superior to RFA for patients with HCC meeting the Milan criteria, but RFA can be employed in tumors ≤ 3 cm and where there is an increased expected

operative mortality. In addition, some lines of evidence indicate that RFA and PEI can be employed as a bridge to liver transplantation. The use of RFA in colorectal liver metastases is currently limited to unresectable disease and for patients unfit for surgery. The aim of this article is to summarize the current status of RFA in the management of liver tumors and compare it to the cheap and readily available technique of PEI.

### INTRODUCTION

Hepatocellular carcinoma (HCC) is the third highest cause of cancer-related death and the incidence appears to be rising<sup>[1,2]</sup>. Partial hepatectomy and liver transplantation are potential curative options, but only a minority (10%-20%) are candidates for these therapies<sup>[3]</sup>. For inoperable cases, sorafenib (Nexavar<sup>®</sup>) is now available, inhibiting tumor-cell proliferation and tumor angiogenesis, as well as increasing the rate of apoptosis. It acts by inhibiting the serine-threonine kinase Raf and the receptor tyrosine kinase activity of vascular endothelial growth factor receptors (VEGFRs) and platelet-derived growth factor receptor  $\beta$ <sup>[4,5]</sup>. Sorafenib increased median survival

and the time to radiological progression by nearly three months (7.9-10.7 mo and 2.8-5.5 mo, respectively) in patients with inoperable HCC<sup>[5]</sup>. The effect of sorafenib has been reproduced<sup>[6]</sup>. Furthermore, sorafenib has been reported to be cost-effective as compared to best supportive care in HCC<sup>[7]</sup>. Its multikinase inhibition, which is effective in RAS-mediated signal transduction pathways, is potentially applicable in other tumors<sup>[8,9]</sup>. Currently, the combination of sorafenib and various other chemotherapeutic agents in HCC is under investigation<sup>[10]</sup>. In the future, sorafenib might become an adjuvant following resection or local ablation of HCC<sup>[11]</sup>.

Liver metastases occur in almost half of cases with colorectal cancer<sup>[12]</sup>. Resection is the treatment of choice for the 20% to 30% that have metastatic disease limited to the liver<sup>[13]</sup>. Novel local treatment, embolization, and not least, neoadjuvant radiochemotherapy have increased the number of resectable cases<sup>[14,15]</sup>. For those with initially unresectable colorectal liver metastases (CLM), downstaging with chemotherapy followed by rescue liver resection is safe and effective<sup>[16]</sup>. The role of chemotherapy in resectable CLM is not entirely certain. The use of perioperative FOLFOX has been associated with improvement of 3-year progression-free survival<sup>[17]</sup>.

Over the years, local ablative methods have been developed for patients that are not surgical candidates because of multifocal disease, an inadequate liver remnant (size, function), or co-morbid conditions. These techniques include percutaneous ethanol injection (PEI), percutaneous acetic acid injection, radiofrequency ablation (RFA), cryoablation, microwave ablation, laser-induced thermotherapy, high-intensity focused ultrasound, and irreversible electroporation<sup>[18]</sup>. RFA has recently received increased attention, and is the most studied of the thermal ablation techniques<sup>[19]</sup>. This article reviews the current role of RFA in the treatment of liver tumors and compares it to PEI, which is a safe, cost-efficient, and readily available alternative to RFA.

## RADIOFREQUENCY ABLATION AND PERCUTANEOUS ETHANOL INJECTION

Modern RFA for the treatment of liver tumors has been available since the early 1990s<sup>[20,21]</sup>. RFA induces thermal injury to the target tissue using electromagnetic energy with a frequency < 900 kHz. An electrode is placed into the lesion and a high-frequency alternating current is delivered. The current causes ionic agitation and frictional heat, leading to irreversible cellular changes, such as protein denaturation and coagulative necrosis of tumor cells. Optimal ablation results are achieved when local temperatures of 60 °C to 100 °C are employed. At temperatures above 100 °C, the increase in the electrical impedance because of tissue carbonization and vaporization limits the amount of energy that can be delivered. Internally cooled-wet electrodes have been developed that combine interstitial saline infusion and intra-electrode cooling, thereby avoiding tissue desiccation around the electrode

tip and maintaining low impedance during treatment, while increasing the ablative zone<sup>[22,23]</sup>. RFA can be performed either percutaneously or intraoperatively with laparoscopy or laparotomy. The percutaneous approach is less invasive and may be associated with reduced postoperative pain, fewer complications, shorter hospital stay, and reduced costs<sup>[24-26]</sup>. However, surgical RFA allows more accurate cancer staging because of the direct macroscopic visualization of tumors and the use of intraoperative ultrasound. In patients with small HCC ( $\leq 3$  cm), percutaneous and surgical RFA had similar complete ablation rates and the overall and disease-free survival were comparable at 1 and 3 years<sup>[25]</sup>. However, for larger tumors (3.1-5 cm), the surgical approach was associated with better overall survival. In addition, surgical RFA may be preferred for HCC occurring in high-risk locations, defined as less than 5 mm from a large vessel or an extrahepatic organ<sup>[27]</sup>.

PEI was described for the first time in 1983<sup>[28]</sup>. PEI is performed under local anesthesia using a 21-gauge needle guided by ultrasound or computed tomography. Ethanol diffuses into the tumor cells and causes dehydration and protein denaturation, resulting in coagulative necrosis. This is followed by microvascular thrombosis and subsequent tumor ischemia. The amount of ethanol required can be calculated using the formula of a sphere, where 0.5 is added to provide extra safety margin:  $V = 4/3 \times \pi \times (r + 0.5)^3$ . The advantages of PEI are its relative safety, simplicity, and low cost. However, PEI is limited to small lesions and requires multiple sessions because of its reduced diffusion capacity over intratumoral septa.

Tumor seeding has occasionally been reported following RFA and PEI, but the risk remains low (< 2%) when an adequate ablation technique is employed and there is no previous biopsy<sup>[29-33]</sup>. Several studies have confirmed the safety of RFA and PEI in patients awaiting liver transplantation<sup>[34-41]</sup>. According to the practice guidelines from the American Association for the Study of Liver Diseases (AASLD), there is level II evidence to support the use of RFA and PEI as a bridge to liver transplantation<sup>[42]</sup>. However, the actual value of local therapies before liver transplantation remains controversial. It has been suggested that bridging therapies such as RFA or PEI should be reserved for patients with a predicted waiting list time of more than 6 mo<sup>[43,44]</sup>.

## RADIOFREQUENCY ABLATION VS LIVER RESECTION

Two recent systematic reviews<sup>[45,46]</sup> showed no significant differences in survival between RFA and resection for HCC within the Milan criteria, although RFA was associated with higher recurrence rates. When RFA was used for tumors outside the Milan criteria, overall and disease-free survival rates were significantly better after resection<sup>[46]</sup>. Zhou *et al.*<sup>[47]</sup> performed a meta-analysis of one randomized controlled trial (RCT) and nine controlled studies comparing RFA and liver resection for HCC

**Table 1 Summary of meta-analyses of radiofrequency ablation vs liver resection and radiofrequency ablation vs percutaneous ethanol injection**

Author	Diagnosis	Treatment	n	Tumor response (OR)	Complications (OR)	Local recurrence (OR)	Overall survival (OR)
Zhou <i>et al</i> <sup>[47]</sup>	HCC	RFA	744	-	0.29 (0.13-0.65)	4.50 (2.45-8.27)	0.60 (0.36-1.01) (5 yr)
		resection	667				
Wu <i>et al</i> <sup>[50]</sup>	CLM	RFA	273	-	0.32 (0.07-1.52)	4.89 (1.73-13.87)	0.41 (0.22-0.90) (5 yr)
		resection	574				
Bouza <i>et al</i> <sup>[63]</sup>	HCC	RFA	396	1.10 (1.04-1.17)	Total: 2.55 (1.8-3.65) Major: 1.85 (0.68-5.01)	0.37 (0.23-0.59)	1.24 (1.05-1.48) (4 yr)
		PEI	391				

PEI: Percutaneous ethanol injection; RFA: Radiofrequency ablation; OR: Odds ratio; HCC: Hepatocellular carcinoma; CLM: Colorectal liver metastases.

(Table 1). Seven hundred and forty-four patients treated with RFA and 667 treated with resection were included. The 5-year overall survival rate was borderline significant at 5 years [OR 0.60 (0.36-1.01)]. RFA was associated with higher local recurrence [OR 4.50 (2.45-8.27)] and the disease-free survival rates were significantly better for resected patients. A recently published RCT by Huang *et al*<sup>[48]</sup> based on 230 patients fulfilling the Milan criteria, confirmed the superiority of surgical resection. The benefits of liver resection are further supported by data concerning quality of life adjusted survival, which seem to favor resection over RFA, at least in cirrhotic patients<sup>[49]</sup>. However, although current evidence favors liver resection for the treatment of early HCC (within the Milan criteria), percutaneous RFA can be used as a first-line treatment when the tumor is ≤ 3 cm and the expected operative mortality rate is above 3%<sup>[45]</sup>.

Data concerning RFA vs resection for CLM are accumulating. A recent meta-analysis by Wu *et al*<sup>[50]</sup> compared RFA and liver resection for solitary CLM (Table 1). Liver resection was better than RFA in terms of 5-year overall survival, as well as local control of the disease. There were no statistically verified differences regarding the rate of adverse events. According to the study by Gazelle *et al*<sup>[51]</sup>, liver resection is more effective in terms of quality-adjusted life year (QALY) as compared to RFA.

### PERCUTANEOUS ETHANOL INJECTION VS LIVER RESECTION

PEI is suggested to be as safe and effective as resection in early-stage HCC (n = 76)<sup>[27]</sup>. On the other hand, Cho *et al*<sup>[52]</sup> reported that liver resection had a better survival profile as compared to PEI in 230 HCC patients (5-year overall survival 49% vs 19%). Repeated single-session PEI is effective in patients with advanced HCC and a combination of transcatheter arterial chemoembolization (TACE) and PEI results in longer survival<sup>[53]</sup>.

The effectiveness of PEI for the treatment of CLM is unclear. It was reported that in more than 50% of cases of liver metastases < 4 cm, complete necrosis can be obtained by means of PEI<sup>[54]</sup>. Giorgio *et al*<sup>[55]</sup> reported that the survival rates of patients with liver metastases who underwent PEI were 94%, 80%, 80%, and 44% at 12 mo, 24 mo, 36 mo, and 44 mo, respectively. However, Livraghi *et al*<sup>[56]</sup> reported that PEI was ineffective for

the treatment of colorectal metastases. The main difficulty is that liver metastases are typically scirrhous and the alcohol tends to spread into the “soft” adjacent liver parenchyma. HCC is often surrounded by a cirrhotic parenchyma and is more vascularized than CLM, allowing for a better local effect of PEI<sup>[57,58]</sup>.

### RADIOFREQUENCY ABLATION VS PERCUTANEOUS ETHANOL INJECTION IN HEPATOCELLULAR CARCINOMA

Giorgio *et al*<sup>[59]</sup> recently conducted an RCT of percutaneous RFA and PEI in 285 HCC patients with tumors ≤ 3 cm. The primary endpoint was 5-year survival. In the RFA and PEI groups, the 5-year survival rates were 70% and 68%, respectively (not significant). The local recurrence rates were also not significantly different. The overall costs of RFA and PEI were 171 000 Euros and 1359 Euros, respectively (P < 0.0001). According to pooled data from two previous RCTs<sup>[60,61]</sup>, RFA and PEI are equally effective for tumors ≤ 2 cm<sup>[62]</sup>. However, the effect of RFA is more predictable than PEI when considering all tumor sizes. The meta-analysis by Bouza *et al*<sup>[63]</sup> included a total of 396 patients treated by RFA and 391 treated by PEI (Table 1). RFA yielded a better overall survival (1 year, 2 year, 3 year, and 4 year), as well as disease-free survival (1 year, 2 year, and 3 year). The risk of local recurrence was reduced in the RFA group. Total complications were increased for RFA, but major complications were not significantly different. In terms of cost-effectiveness of PEI over RFA, data are still controversial. Brunello *et al*<sup>[64]</sup> reported that mean direct hospital costs were 6540 Euros for RFA treated patients and 4097 Euros for the PEI group (P < 0.001), whereas Seror *et al*<sup>[65]</sup> reported that RFA was the most cost-effective option.

### RADIOFREQUENCY ABLATION-IMPROVEMENT WHEN COMBINED WITH PERCUTANEOUS ETHANOL INJECTION

RFA enables more effective tumor necrosis in fewer treatment sessions, albeit with a higher rate of complications than with PEI therapy. Nevertheless, there are certain circumstances or clinical situations that PEI therapy

offers a better strategy to control liver tumors than RFA, especially in situations where RFA is difficult. PEI can be useful when tumors are in close vicinity (< 1 cm) to vital structures, including biliary ducts, stomach, intestinal loops, and kidney, and whose location make them difficult to treat with thermal ablative techniques<sup>[66]</sup>. In addition, PEI is useful for lesions that remain undetected by ultrasound, such as masses in the hepatic dome or small nodules, or when the tumor is located subcapsularly or exophytically or surrounded by major vessels<sup>[66]</sup>. The efficacy of RFA in HCC can be improved if combined with PEI. The combination of RFA and PEI was shown to be more effective than RFA alone for high risk locations<sup>[67]</sup>. The combination of RFA and PEI can also be used for recurrent HCC (diameter > 3 cm)<sup>[68]</sup>. Furthermore, RFA and PEI can be combined with other locoregional therapies. TACE and RFA were as effective as liver resection for HCC in a recent study, with similar 1-, 3-, and 5-year overall and recurrence-free survival rates<sup>[69]</sup>. The combination of microwave ablation and PEI was safe and effective for the treatment of liver tumors adjacent to the hepatic hilum<sup>[70]</sup>.

## CONCLUSION

Liver resection still remains the gold standard for the treatment of liver tumors. RFA and PEI are feasible and of benefit in non-operable patients, and as bridging therapies before liver transplantation. RFA seems superior to PEI in HCC > 2 cm and the combination of both interventions may be of benefit in selected patients. Liver resection is superior to RFA for patients with HCC meeting the Milan criteria, but RFA can be employed in tumors ≤ 3 cm and where there is increased expected operative mortality. Using RFA as the primary treatment of resectable CLM is still not recommended; however, RFA may have a role in unresectable lesions and for patients unfit for surgery. Newer advancements in the field of local ablative therapies are to be expected, requiring constant evaluation of the different techniques. In the future, local ablative approaches may be combined with systematically administered molecular targeted therapies (e.g., sorafenib) to further improve the outcomes of patients with liver malignancies.

### Abstract

Neuroendocrine tumors (NETs) are diagnosed with increasing frequency and patients often present with liver metastases at the time of diagnosis. Apart from treatment of the metastases, resection of the primary tumor at an early phase is recommended to prevent complications, although it may be difficult to locate, especially in patients with functionally inactive NETs. Small and multifocal tumors in the jejunum and ileum represent a particular challenge. Primary hepatic neuroendocrine carcinoma is extremely rare and is diagnosed only after exclusion of other primary tumors. Therefore, some uncertainty may remain, as small non-hepatic primary tumors may escape detection. Diagnostic work-up in these patients includes biochemical assays and imaging modalities (also comprising specific techniques of scintigraphy and positron emission tomography). This editorial highlights the contributions of endoscopy and operative exploration to the search for the primary tumor. Besides esophago-gastro-duodenoscopy, endoscopic ultrasonography, colonoscopy and bronchoscopy, special endoscopic techniques such as balloon enteroscopy or capsule endoscopy are used with growing experience. Compared with balloon enteroscopy, capsule endoscopy is non-invasive and better tolerated, but it cannot localize a lesion precisely and does not allow biopsy or removal

of lesions. Before proceeding to surgery, a discussion of the findings by a tumor board should be a standard procedure. Improvements in diagnostic tools have created new perspectives for the detection of obscure primary tumors in patients with neuroendocrine liver metastases, and these searches are best coordinated by a multidisciplinary team.

### INTRODUCTION

Neuroendocrine tumors (NETs)<sup>[1-9]</sup> are diagnosed with increasing frequency. The overall annual incidence of gastrointestinal NETs was recently reported to be 1.32 per 100 000 in men and 1.33 per 100 000 in women, with 12% of tumors in the stomach, 29% in the small intestine, 38% in the appendix, 13% in the colon, and

8% in the rectum<sup>[10]</sup>. After the lymph nodes, the liver is the second most common site of neuroendocrine metastases; in the study by Hlatky *et al*<sup>[11]</sup>, 39% of patients had liver metastases at the time of diagnosis. Resection of neuroendocrine liver metastases, if feasible, is the treatment of choice. In patients with advanced disease, an aggressive surgical approach, including staged procedures if required, is warranted as part of multimodal treatment<sup>[12-15]</sup>. Although resection of the primary tumor in an early phase is recommended to prevent complications<sup>[16,17]</sup>, the primary tumor may be difficult to locate<sup>[18]</sup>, especially in patients with functionally inactive NETs. If curative resection of liver metastases is not possible, however, it is unclear whether the primary tumor should also be removed. When possible, debulking, leaving < 10% of residual tumor volume, has proven helpful<sup>[19]</sup>. One argument for removing the primary tumor from patients with unresectable liver metastases is that these hepatic foci can be treated by interventional techniques, whereas the primary tumor is best treated by resection. Indeed, recent studies<sup>[20,21]</sup> have suggested that resection of the primary tumors, even from patients with unresectable neuroendocrine liver metastases, may be associated with improved survival.

About 11% to 14% of NET patients have metastatic disease with an unknown primary tumor<sup>[22]</sup>, and these primary tumors may also be multifocal. The most common primary location is the gastrointestinal tract, followed by respiratory and thymic carcinoids<sup>[23]</sup>. Primary tumors in the jejunum and ileum may be small, but they often cause a characteristic fibrosis in the mesentery (desmoplastic reaction), resulting in bowel obstruction, ischemia or perforation in approximately one-third of patients<sup>[24,25]</sup>. Primary hepatic neuroendocrine carcinoma is extremely rare<sup>[26,27]</sup> and is diagnosed only after exclusion of other primary tumors. Therefore, some uncertainty may remain, because small non-hepatic primary tumors may escape detection. As with metastases, the therapy of choice is resection<sup>[28]</sup>.

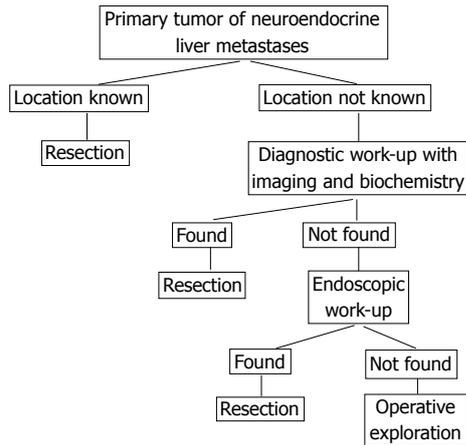

Diagnostic work-up in these patients includes biochemical assays and imaging modalities (Figure 1). Although ultrasonography is an important screening method with easy access and low costs, it remains operator dependent and its capacity for detecting primary tumors, especially in the small intestine, is limited. On contrast-enhanced ultrasonography using microbubbles, NETs of the small intestine and pancreas may present as hypoechoic, isoechoic, and/or hyperechoic liver lesions. Necrotic areas can also be identified, especially after treatment<sup>[29]</sup>. Computed tomography (CT) scans are very helpful in diagnosing NETs, especially larger foci in the mesentery or in the liver, but may not be useful in diagnosing small primary tumors. Magnetic resonance (MR) imaging is performed to determine the extent, anatomical relationships and resectability of the liver metastases but may also contribute to the detection and localization of intestinal primary tumors. On post-gadolinium T1-weighted fat-suppressed images, these primary tumors

can be visualized as nodular masses originating from the bowel wall, or as regional uniform bowel wall thickening with moderately intense enhancement<sup>[30]</sup>. Less is known about the uses of CT/MR enteroclysis. For example, CT enteroclysis in a small number of patients ( $n = 8$ ) had a sensitivity for detection of primary NETs of 50%, but false-positive results were also reported<sup>[31]</sup>. MR enteroclysis is an evolving technique that has shown promise in initial studies<sup>[30]</sup>.

Selective receptor-targeting radiopeptides have been developed for molecular imaging and therapy of NETs that overexpress peptide receptors on their cell membranes. The somatostatin analog <sup>111</sup>In-octreotide can be used to localize NETs expressing somatostatin receptors. Newer modified somatostatin analogs, including Tyr(3)-octreotide and Tyr(3)-octreotate, have been successfully used for diagnosis of these tumors, including the localization of primary tumors, and for radionuclide therapy and have therefore been named “theragnostics”. Radiopeptides targeting other receptors, including radiolabeled analogs of cholecystokinin, gastrin, bombesin, substance P, vasoactive intestinal peptide, and neuropeptide Y, may also be used<sup>[32]</sup>. As scintigraphy detects tumors not seen on CT and *vice versa*, these two imaging techniques can be seen as complementing each other. Imaging by <sup>18</sup>F-Dopa positron emission tomography (PET) is based on the decarboxylase contained in these tumors and is especially useful in patients with negative scintigraphy results. Due to better anatomical allocation of “hot spots”, PET can be combined with CT. Fluorodeoxyglucose (FDG) is taken up primarily by poorly differentiated tumors due to their enhanced glucose metabolism, making FDG-PET useful in depicting and identifying this group of tumors. <sup>68</sup>Ga-DOTATOC PET/CT is presently being investigated and has yielded promising results<sup>[33-35]</sup>. The combination of <sup>68</sup>Ga-DOTATOC with PET/CT was found to have an impact on the therapeutic management of 38% of patients with NET, including identifying the primary tumor for resection in about 8%; moreover, in 50% of these patients, the relevant findings were detected by a single imaging modality (i.e., CT or PET)<sup>[36]</sup>. These findings indicate that CT and PET have comparable sensitivity, provide complementary information and contribute equally to therapeutic decision making<sup>[36]</sup>.

## ENDOSCOPY

Upper and lower gastrointestinal endoscopy should be performed not only to identify the primary tumor, but also to rule out concomitant malignancies, which are present in a higher percentage (about 20%) of NET patients than in the normal population<sup>[37]</sup>. The importance of esophago-gastro-duodenoscopy (EGD) is emphasized by findings showing that the incidence of stomach NETs is increasing. Although one study<sup>[38]</sup> reported a 10-fold increase, this applies mainly to well-differentiated NETs and is probably due to increased rates of screening and associated diagnosis. Endoscopic ultrasonogra-

**Figure 1** Use of endoscopic and operative exploration in the search for primary tumors in patients with neuroendocrine liver metastases.

phy (EUS) is the method of choice for the assessment of tumor size and depth of infiltration<sup>[38]</sup> and is very helpful in the diagnosis of pancreatic NETs. A study of the EUS characteristics of cystic pancreatic NETs found that these tumors constitute 0.67% of all cystic pancreatic lesions and 9.5% of all confirmed pancreatic NETs<sup>[39]</sup>. Primary tumors in the colon can be detected by colonoscopy, and these examinations should include the terminal ileum, as far as possible. Figure 2 shows a resected small primary tumor in the terminal ileum that was detected by colonoscopy extending beyond the ileocecal valve. Intraoperatively, this tumor was not detectable, either by inspection from the serosal side or by palpation; rather, its removal was based on its endoscopic localization.

Bronchoscopy, in combination with thoracic CT or PET/CT, can help identify primary tumors in the bronchi/lungs.

Capsule endoscopy<sup>[40]</sup> is a practical technique, but analysis of the films requires expertise and time. Extraluminal tumor growth may limit this method. A comparison of CT, enteroclysis, nuclear imaging, and video capsule endoscopy (VCE) of the small bowel showed that CT and enteroclysis were unable to detect a primary tumor, whereas nuclear imaging identified abnormalities in the abdominal area in about two-thirds of the patients but was unable to relate this to an intestinal localization<sup>[16]</sup>. In contrast, VCE had a high diagnostic yield (45%) in identifying primary tumors in the small intestine. Although nuclear imaging had a comparable diagnostic yield, it could not differentiate between intestinal and mesenteric localization<sup>[16]</sup>. A study of 300 patients who underwent VCE for obscure bleeding following non-diagnostic EGD and colonoscopy showed that one had a neuroendocrine carcinoma, and nine had other small-bowel masses. Capsule retention occurred in two patients, with one requiring urgent surgery<sup>[41]</sup>.

An alternative for examination of the small bowel is balloon endoscopy, using either a single or double balloon technique<sup>[42,43]</sup>. This method, however, is time-consuming, and complications, including small bowel

perforation, ileus, and pancreatitis, have been reported in 0.8%–4.0% of patients<sup>[44]</sup>. A recent study<sup>[45]</sup> has shown that a single-balloon push-and-pull enteroscopy system was safe, useful, and highly effective in the diagnosis and treatment of several small-bowel diseases. Moreover, double balloon enteroscopy (DBE) in 12 consecutive patients with suspected NETs resulted in the detection of submucosal tumors in the ileum or jejunum in seven patients; in two patients with a submucosal ileum protrusion suspicious for NET, however, laparotomy and intraoperative endoscopy did not confirm that the protrusion was a tumor. The diagnostic yield of DBE for primary tumors in patients with metastatic or suspected NET was 33%, suggesting that DBE should only be performed in selected patients, possibly based on a previous positive work-up<sup>[46]</sup>.

Compared with balloon enteroscopy, capsule endoscopy is non-invasive and better tolerated, but it cannot localize a lesion precisely and does not allow biopsy or removal of lesions. The velocity of the transport of the capsule by peristalsis is irregular and there is no possibility of rinsing and suction; thus, a lesion may be missed. New technologies may expand the role of capsule endoscopy by, for example, controlling capsule movement, enabling this method to be used therapeutically or to obtain tissue biopsies and providing a transcatheter power delivery system<sup>[47]</sup>. A recent meta-analysis<sup>[48]</sup> found that capsule endoscopy and DBE had similar diagnostic yields in patients with obscure gastrointestinal bleeding.

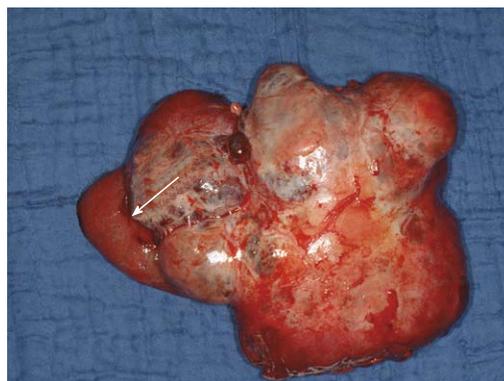

## OPERATIVE EXPLORATION

Intraoperative exploration may be performed as a self-contained procedure or in combination with other surgical goals such as resection of liver metastases or mesenteric masses, or cholecystectomy. Prophylactic removal of the gallbladder from NET patients during abdominal operations is recommended for two reasons. First, anticipating future long-term somatostatin analog therapy of these patients, removal of the gallbladder will prevent gallstone-associated complications associated with this treatment. Second, removal of the gallbladder will prevent gallbladder necrosis from hepatic artery embolization for liver metastases. In a recent study, preoperative identification of the primary tumor failed in 21% of patients, whereas laparoscopic exploration was successful in locating the primary tumor in 87%<sup>[49]</sup>. The presence of a mesenteric mass may indicate a primary tumor in the adjacent small bowel loop. Figure 3 shows the operative specimen from an NET patient with bulky disease in the mesentery; no primary tumor could be found pre- or intraoperatively. The adjacent loop of the ileum was resected *en bloc* with the mesenteric tumor (for reasons of blood supply), and its meticulous histopathological work-up yielded two foci of neuroendocrine carcinoma.

In contrast, if a small primary tumor is present in the small intestine without visible disease in the mesentery, a wide mesenteric dissection would be preferable, given

**Figure 2** Operative specimen of a small primary neuroendocrine tumor (arrow) in the terminal ileum detected by colonoscopy, extending beyond the ileocecal valve. Intraoperatively, this tumor was not detectable, either by inspection from the serosal side or by palpation; it was removed based on its endoscopic localization.

**Figure 3** Operative specimen from a neuroendocrine tumor patient with bulky disease in the mesentery; no primary tumor could be found pre- or intraoperatively. The mesenteric tumor was resected *en bloc*, along with the adjacent loop of the ileum (arrow); meticulous histopathological work-up of this ileal loop yielded two foci of neuroendocrine carcinoma.

the propensity of these tumors to cause mesenteric spread and desmoplastic masses.

During the course of laparoscopic exploration, exteriorization of the bowel and thorough palpation are recommended. Although these tumors may cause dimpling of the serosa, this is not a reliable feature and will not always be visible during laparoscopic exploration. Careful palpation, however, also allows identification of small and multifocal primary tumors.

Intraoperative ultrasonography (IOUS) is very helpful for liver resections and may be used to screen the pancreas, if no primary tumor is found in the intestine or at other locations. IOUS is also useful for measuring the distance between a pancreatic primary tumor and the pancreatic duct<sup>[50]</sup>. The pancreas was recently found to be the most common primary site (35%) for NET liver metastases but, as pancreatic tumors are well visualized on CT, all of them were detected preoperatively by CT<sup>[49]</sup>. Thus, occult primary tumors in the pancreas are highly unlikely in patients with NET liver metastases, limiting the use of EUS/IOUS of the pancreas in patients previously examined by CT.

During the course of the exploration, a biopsy can be taken of the liver metastases if they have not been identified histopathologically. Due to the rarity of these tumors, there have been few studies on the frequency and success of operative exploration, suggesting the need for multicenter studies using a standardized protocol. It is also unclear whether conversion to an open procedure is warranted if no primary tumor is found during laparoscopic exploration. If all laparoscopically visible parts of the abdominal cavity have been thoroughly inspected and the intestine has been exteriorized and meticulously palpated, open access by laparotomy will probably not yield any additional diagnostic benefit, although multiple tight adhesions may be an indication for conversion. To date, however, this has not been studied.

Before proceeding to surgery, a discussion of the findings by a tumor board should be a standard procedure.

In conclusion, improvements in diagnostic tools have

created new perspectives for the detection of obscure primary tumors in patients with neuroendocrine liver metastases, and these searches are best coordinated by a multidisciplinary team.

### Abstract

Autoimmune pancreatitis (AIP) is a newly described entity of pancreatitis in which the pathogenesis appears to involve autoimmune mechanisms. Based on histological and immunohistochemical examinations of various organs of AIP patients, AIP appears to be a pancreatic lesion reflecting a systemic "IgG4-related sclerosing disease". Clinically, AIP patients and patients with pancreatic cancer share many features, such as preponderance of elderly males, frequent initial symptom of painless jaundice, development of new-onset diabetes mellitus, and elevated levels of serum tumor markers. It is of uppermost importance not to misdiagnose AIP as pancreatic cancer. Since there is currently no diagnostic serological marker for AIP, and approach to the pancreas for histological examination is generally difficult, AIP is diagnosed using a combination of clinical, serological, morphological, and histopathological features. Findings suggesting AIP rather than pancreatic cancer include:

fluctuating obstructive jaundice; elevated serum IgG4 levels; diffuse enlargement of the pancreas; delayed enhancement of the enlarged pancreas and presence of a capsule-like rim on dynamic computed tomography; low apparent diffusion coefficient values on diffusion-weighted magnetic resonance image; irregular narrowing of the main pancreatic duct on endoscopic retrograde cholangiopancreatography; less upstream dilatation of the main pancreatic duct on magnetic resonance cholangiopancreatography, presence of other organ involvement such as bilateral salivary gland swelling, retroperitoneal fibrosis and hilar or intrahepatic sclerosing cholangitis; negative work-up for malignancy including endoscopic ultrasound-guided fine needle aspiration; and steroid responsiveness. Since AIP responds dramatically to steroid therapy, accurate diagnosis of AIP can avoid unnecessary laparotomy or pancreatic resection.

Strategy to differentiate autoimmune pancreatitis from pancreas cancer. *World J Gastroenterol* 2012; 18(10): 1015-1020 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i10/1015.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i10.1015>

### INTRODUCTION

Autoimmune pancreatitis (AIP) is a recently described entity of pancreatitis in which the pathogenesis appears

to involve autoimmune mechanisms<sup>[1,2]</sup>. Characteristic histopathological findings in AIP patients in Japan include dense infiltration of T lymphocytes and IgG4-positive plasma cells, storiform fibrosis, and obliterative phlebitis in the pancreas; this form is termed lymphoplasmacytic sclerosing pancreatitis (LPSP)<sup>[1-3]</sup>. Recently, another AIP variant having different histological findings has been described. It is called idiopathic duct-centric pancreatitis (IDCP), and is rare in Japan but more prevalent in Europe and the United States<sup>[4-6]</sup>.

Clinically, AIP patients and those with pancreatic cancer have many features in common, such as painless jaundice, development of new-onset diabetes mellitus (DM), and elevated levels of serum tumor markers. In both populations there is preponderance of elderly males. In North America, about 2.5% of pancreatoduodenectomies were performed in AIP patients following a mistaken diagnosis of pancreatic cancer<sup>[7]</sup>. Since AIP responds extremely well to steroid therapy, it is of utmost importance that it be differentiated from pancreatic cancer to avoid unnecessary laparotomy or pancreatic resection.

Other prominent features of AIP include a variety of extrapancreatic complications. Patients frequently have significantly elevated serum IgG4 levels<sup>[8-10]</sup>. Currently, AIP is recognized as a pancreatic lesion of IgG4-related systemic disease<sup>[2,11]</sup>.

In this review, we will summarize clinicopathological features of AIP and describe a strategy to differentiate it from pancreatic cancer.

## AUTOIMMUNE PANCREATITIS

### Clinical features

AIP occurs predominantly in elderly males<sup>[12]</sup>. Typical presentation with severe abdominal pain and clinically acute pancreatitis is rare; the major presenting complaint is painless obstructive jaundice due to associated sclerosing cholangitis. Failure of pancreatic exocrine or endocrine function is frequently seen. Up to 50% of AIP patients present with glucose intolerance. The diagnoses of DM and AIP are made simultaneously in many cases, but some patients experience exacerbation of preexisting DM with the onset of AIP<sup>[2,11]</sup>.

### Other organ involvement: IgG4-related sclerosing disease

In addition to symptoms resulting from pancreatic involvement, AIP patients often have other complications, such as biliary stricture and thickening of the gallbladder wall, swelling of salivary and lacrimal glands, and a retroperitoneal mass. Histological features in these other anatomical locations include dense fibrosis with abundant infiltration of T lymphocytes and IgG4-positive plasma cells and obliterative phlebitis. We have observed these features in the periportal area of the liver, gastric mucosa, colonic mucosa, dermis, lymph nodes, and bone marrow of AIP patients<sup>[11,13,14]</sup>. Based on histological and immunohistochemical examinations of various organs of AIP

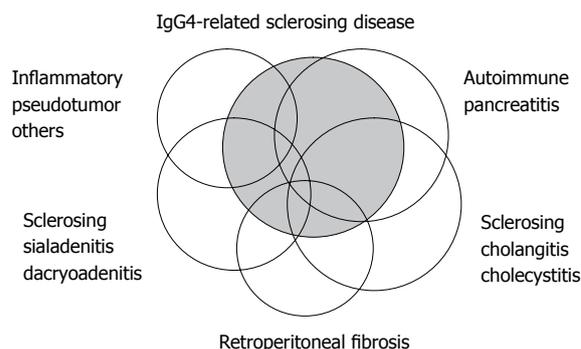

Figure 1 Schematic illustration of IgG4-related sclerosing disease.

patients, we proposed that a novel clinicopathological entity, an “IgG4-related sclerosing disease”<sup>[2,11,13]</sup> should be described.

IgG4-related sclerosing disease is a systemic disease affecting multiple organs with tissue fibrosis and obliterative phlebitis. We suggest that AIP appears to be a pancreatic lesion reflecting a systemic IgG4-related sclerosing disease, which can be manifest elsewhere to varying degree. In some cases, only 1 or 2 organs are clinically involved, while in others, 3 or 4 organs are affected (Figure 1)<sup>[2,11,13]</sup>. These extrapancreatic lesions can be synchronous or metachronous<sup>[15]</sup>.

### Histopathological features

Histological pancreatic findings in AIP patients with LPSP are characterized by dense infiltration of T lymphocytes and IgG4-positive plasma cells and storiform fibrosis. Obliterative phlebitis is frequently detected. The pancreatic duct is narrowed by periductal fibrosis and lymphoplasmacytic infiltration, but the ductal epithelium is usually preserved<sup>[1-3]</sup>.

American and European pathologists have described another unique histological pattern in AIP, which they have termed IDCP<sup>[4]</sup> or AIP with granulocyte epithelial lesion (GEL)<sup>[5]</sup>. Neutrophilic infiltration in the epithelium of pancreatic ducts is a characteristic feature of IDCP; this is not seen in LPSP. Infiltration of IgG4-positive plasma cells and obliterative phlebitis are uncommon in IDCP<sup>[4,5,16]</sup>. IDCP is seen mostly in Western countries, but it appears uncommon in Asia<sup>[6,17]</sup>. LPSP and IDCP are regarded as two distinct subtypes of AIP, and it has been proposed that LPSP be called “type 1 AIP” and IDCP “type 2 AIP”<sup>[6,16,18]</sup>.

### Diagnostic criteria for AIP

Since there is currently no diagnostic serological marker for AIP, and approach to the pancreas for histological examination is generally difficult, AIP is currently diagnosed on the basis of presence of a combination of abnormalities unique to AIP. The Japanese clinical diagnostic criteria for AIP were revised in 2006<sup>[19]</sup>. In 2006, new diagnostic criteria for AIP were proposed in Korea<sup>[20]</sup> and the United States<sup>[21]</sup>. In 2008, Asian diagnostic criteria for AIP were published by Japanese and Korean pancreatologists<sup>[22]</sup>.

**Table 1** Diagnosis of definitive and probable type 1 autoimmune pancreatitis using international consensus diagnostic criteria

Diagnosis	Primary basis for diagnosis	Imaging evidence	Collateral evidence
Definitive type 1 AIP	Histology	Typical/indeterminate	Histologically confirmed LPSP (level 1 H)
	Imaging	Typical indeterminate	Any non-D level 1/level2 Two or more from level 1 (+ level 2 D <sup>1</sup> )
Probable type 1 AIP	Response to steroid	Indeterminate	Level 1 S/OOI + Rt or level 1 D + level 2 S/OOI/H + Rt Level 2 S/OOI/H + Rt

AIP: Autoimmune pancreatitis; LPSP: Lymphoplasmacytic sclerosing pancreatitis; H: Histology of the pancreas; S: Serology; D: Ductal imaging; OOI: Other organ involvement. <sup>1</sup>Level 2 D is counted as level 1 in this setting.

**Table 2** Level 1 and level 2 criteria for type 1 autoimmune pancreatitis

Criterion	Level 1	Level 2
Parenchymal imaging	Typical: Diffuse enlargement with delayed enhancement (sometimes associated with rim-like enhancement)	Indeterminate (including atypia <sup>2</sup> ): Segmental/focal enlargement with delayed enhancement
Ductal imaging (ERP)	Long (> 1/3 length of the main pancreatic duct or multiple strictures without marked up stream dilatation)	Segmental/focal narrowing without marked upstream dilatation (duct size, < 5 mm)
Serology other organ involvement	IgG4, > 2x upper limit of normal value a or b a: Histology of extrapancreatic organs Any three of the following: (1) Marked lymphoplasmacytic infiltration with fibrosis and without granulocytic infiltration (2) Storiform fibrosis (3) Obliterative phlebitis (4) Abundant (> 10 cells/HPF) IgG4-positive cells b: Typical radiological evidence At least one of the following: (1) Segmental/multiple proximal (hilar/intrahepatic) or proximal and distal bile duct stricture (2) Retroperitoneal fibrosis	IgG4, 1-2x upper limit of normal value a or b a: Histology of extrapancreatic organs including endoscopic biopsies of bile duct <sup>3</sup> : Both of the following: (1) Marked lymphoplasmacytic infiltration without granulocytic infiltration (2) Abundant (> 10 cells/HPF) IgG-positive cells b: Physical or radiological evidence At least one of the following: (1) Symmetrically enlarged salivary/lachrymal glands (2) Radiological evidence of renal involvement described in association with AIP
Histology of the pancreas	LPSP (core biopsy/resection) At least 3 of the following: (1) Periductal lymphoplasmacytic infiltrate without granulocytic infiltration (2) Obliterative phlebitis (3) Storiform fibrosis (4) Abundant (> 10 cells/HPF) IgG4-positive cells	LPSP (core biopsy) Any 2 of the following: (1) Periductal lymphoplasmacytic infiltrate without granulocytic infiltration (2) Obliterative phlebitis (3) Storiform fibrosis (4) Abundant (> 10 cells/HPF) IgG4-positive cells
Response to steroid (Rt) <sup>1</sup>	Diagnostic steroid trial Rapid (≤ 2 wk) radiologically demonstrable resolution or marked improvement in pancreatic/extrapancreatic manifestations	

AIP: Autoimmune pancreatitis; LPSP: Lymphoplasmacytic sclerosing pancreatitis; HPF: High power field; ERP: Endoscopic retrograde pancreatography. <sup>1</sup>Diagnostic steroid trial should be conducted carefully by pancreatologists with caveats (see text) only after negative workup for cancer including endoscopic ultrasound-guided fine needle aspiration; <sup>2</sup>Atypical: Some AIP cases may show low-density mass pancreatic ductal dilatation, or distal atrophy. Such atypical imaging findings in patients with obstructive jaundice and/or pancreatic mass are highly suggestive of pancreatic cancer. Such patients should be managed as pancreatic cancer unless there is strong collateral evidence for AIP, and a thorough workup for cancer is negative (see algorithm); <sup>3</sup>Endoscopic biopsy of duodenal papilla is a useful adjunctive method because ampulla often is involved pathologically in AIP.

In 2011, international consensus diagnostic criteria for AIP were proposed<sup>[23]</sup>. According to these, AIP is classified into type 1 and 2. Five cardinal features of AIP are used: imaging of pancreatic parenchyma and ducts; serology; other organ involvement; pancreatic histology; and an optional criterion of response to steroid therapy. Each feature is categorized as a level 1 or 2 finding, depending on the diagnostic reliability. The diagnosis of type 1 and type 2 AIP can be definitive or probable (Tables 1 and 2).

### Treatment and prognosis

A multicenter study for steroid treatment of AIP was performed in Japan in 2009<sup>[24]</sup>, and Japanese consen-

sus guidelines for treatment of AIP were proposed in 2010<sup>[25]</sup>. According to the guidelines, steroid treatment is a standard therapy for AIP, as it is usually effective clinically, serologically, and radiologically in these patients, including for extrapancreatic lesions. It is most important to distinguish AIP from pancreatic cancer before starting steroid therapy. Indications for steroid therapy are symptoms such as obstructive jaundice, abdominal pain, and hydronephrosis. Before beginning steroid therapy, jaundice is usually managed by endoscopic or transhepatic biliary drainage in patients with obstructive jaundice, and the blood glucose level should be controlled with insulin in patients with DM. Initially, oral prednisolone (0.6 mg/

**Figure 2** Dynamic computed tomography of an autoimmune pancreatitis patient showing well-enhanced enlargement of the pancreas.

kg per day) is administered for 2-4 wk, and then the dose is tapered by 5 mg every 1-2 wk while carefully monitoring the patient's symptoms, as well as the biochemical, serological, and imaging findings, to a maintenance dose, a process usually requiring a period of 3-6 mo. Morphological and serological evaluation for effectiveness of steroid therapy is performed 2 wk after initiation. A poor response to steroid therapy should raise the possibility of pancreatic cancer and the need for re-evaluation of the diagnosis.

To prevent relapse, maintenance therapy (2.5-5 mg per day) is recommended for almost all patients for at least 6 mo. In patients showing complete remission 1 year after initial administration of steroids, maintenance therapy can be withdrawn. Maintenance therapy should be continued for a maximum of 3 years. In relapsed cases, re-administration or increasing the dose is effective.

AIP prognosis appears to be good over the short term with steroid therapy. However, long-term outcomes are unclear, because there are many unknown factors<sup>[26]</sup>. Pancreatic stone formation is observed in some relapsing AIP patients because of stenosis of the pancreatic duct system and facilitated pancreatic juice stasis<sup>[27,28]</sup>. AIP occurs predominantly in elderly males, and steroid therapy is immunosuppressive. It is reported that some patients develop malignancies during treatment, but it is unclear whether prolonged AIP is a risk factor for the malignancy<sup>[25,26]</sup>.

## STRATEGY TO DIFFERENTIATE AUTOIMMUNE PANCREATITIS FROM PANCREATIC CANCER

AIP should be included in the differential diagnosis for an elderly man presenting with obstructive jaundice and a pancreatic mass. Before therapy is initiated, it is of the utmost importance to differentiate AIP from pancreatic cancer.

### Obstructive jaundice

Obstructive jaundice induced by bile duct stenosis secondary to pancreatic cancer typically progresses steadily,

whereas the jaundice of AIP in IgG4-related sclerosing disease sometimes fluctuates or, in rare cases, improves spontaneously<sup>[2,11,25]</sup>.

### Serum IgG4 levels

AIP patients frequently have significantly elevated serum IgG4 levels<sup>[29]</sup>. In our series of 39 patients<sup>[30]</sup>, the median level was 301.5 mg/dL, and 30 (77%) had levels greater than 135 mg/dL. On the other hand, the median level was 34.0 mg/dL in 114 pancreatic cancer patients. However, 5 of these had levels  $\geq 135$  mg/mL; therefore, elevation of serum IgG4 levels alone cannot rule out pancreatic cancer. According to Ghazale *et al.*<sup>[31]</sup>, serum IgG4 levels were elevated in 13/135 (10%) of pancreatic cancer patients; however, only 1% had IgG4 levels  $> 280$  mg/dL, compared with 53% of AIP patients.

### Computed tomography imaging

Diffuse enlargement of the pancreas and effacement of the lobular contour of the pancreas, the so-called "sausage-like" appearance, is a typical finding in AIP, and is rarely seen in pancreatic cancer (Figure 2). On delayed-phase of dynamic computed tomography and magnetic resonance imaging (MRI), enhancement of an enlarged pancreas is characteristic of AIP. As fibroinflammatory changes involve the peripancreatic adipose tissue, a capsule-like rim surrounding the pancreas, is specifically detected in some AIP patients<sup>[32-34]</sup>.

### Diffusion weighted MRI

The clinical utility of diffusion weighted MRI (DW-MRI) for differentiating AIP from pancreatic cancer was reported<sup>[35]</sup>. AIP and pancreatic cancer were detected as high signal intensity areas. However, the high signal-intensity areas were found to be diffuse, solitary, and multiple in AIP patients, whereas all patients with pancreatic cancer had solitary areas. Additionally, the apparent diffusion coefficient (ADC) values were significantly lower in AIP than in pancreatic cancer patients or in individuals with a normal pancreas. Morphological differences seen in high signal intensity areas on DW-MRI and ADC values may prove useful to help distinguish AIP from pancreatic cancer.

### Endoscopic retrograde cholangiopancreatography

Irregular narrowing of the main pancreatic duct (MPD) on endoscopic retrograde cholangiopancreatography (ERCP) is a characteristic radiological feature of AIP, and is mandatory for meeting the Japanese diagnostic criteria for AIP<sup>[19]</sup>. In our study<sup>[36,37]</sup>, comparing the ERCPs of AIP and pancreatic head cancer patients, MPD findings that were highly suggestive of the former included no obstruction, skipped lesions, side branch derivation from the narrowed portion, narrowed portion  $> 3$  cm long, and a maximum diameter of  $< 5$  mm upstream (Figure 3). The histopathological differences around the ducts represent the different pancreatographic findings between AIP and pancreatic cancer (PC). Infiltrating cancer cells cause scirrhous changes, destroy ductal epithelium, and

**Figure 3** Endoscopic retrograde cholangiopancreatography of an autoimmune pancreatitis patient showing narrowing of the main pancreatic duct.

frequently obstruct main and branch ducts.

### Magnetic resonance cholangiopancreatography

Since magnetic resonance cholangiopancreatography (MRCP) has become popular as a non-invasive method for obtaining high quality images of the pancreaticobiliary tree, it is becoming preferable to diagnostic ERCP in many cases. However, the narrowest MPD seen on ERCP cannot be visualized by MRCP due to the inferior resolution of MRCP compared with ERCP, so distinguishing between narrowing of the MPD in AIP and stenosis of the MPD in pancreatic cancer is not possible. However, less upstream dilatation of the MPD on MRCP suggests AIP rather than pancreatic cancer. Furthermore, MRCP is useful for judging response to steroid therapy<sup>[37,38]</sup>.

### Other organ involvements

Presence of other organ involvements such as bilateral salivary gland swelling, retroperitoneal fibrosis and hilar or intrahepatic sclerosing cholangitis is highly suggestive of AIP rather than pancreatic cancer.

On 18F-Fluorodeoxyglucose (FDG)-Positron Emission Tomography (PET), pancreatic FDG uptake is observed in both, but abnormal extrapancreatic uptake, such as extensive lymph nodes or swollen salivary glands, is highly suggestive of AIP<sup>[39]</sup>.

### Endoscopic ultrasound-guided fine needle aspiration

In some cases, when diagnosis is difficult, especially when segmental-type AIP is involved, histopathological examination is necessary. Endoscopic ultrasound-guided fine needle aspiration (EUS-FNA) is useful to either diagnose or rule out pancreatic cancer. However, definitive diagnosis of AIP is sometimes difficult by EUS-FNA, because of the small sample size obtained<sup>[40]</sup>. Therefore, EUS-guided core biopsy is recommended<sup>[41]</sup>. Positive IgG4-immunostaining in biopsy specimens taken from the major duodenal papilla supports a diagnosis of AIP<sup>[42]</sup>.

### Steroid responsiveness

There is reversible improvement of AIP with oral steroid therapy. In patients with typical radiological findings

highly suggestive of AIP, a diagnosis cannot be made, according to Japanese criteria<sup>[19]</sup>, if there are no histological features and negative laboratory tests. Although it can be diagnostic, a steroid diagnostic trial is not generally recommended; it should only be performed with extreme caution by pancreatologists in carefully selected patients after obtaining negative results from a thorough work-up for pancreatic cancer, including EUS-FNA<sup>[22,23]</sup>.

## CONCLUSION

For an elderly male presenting with obstructive jaundice and a pancreatic mass, AIP should be considered as a differential diagnosis to avoid performance of unnecessary surgery for presumed pancreatic cancer. As it is sometimes difficult to obtain adequate biopsy material from the pancreas, AIP is currently diagnosed based on careful consideration of a combination of characteristic clinical, serological, morphological, and histopathological features.

### Abstract

**AIM:** To study the effect of botulinum toxin in patients with chronic anal fissure after biliopancreatic diversion (BPD) for severe obesity.

**METHODS:** Fifty-nine symptomatic adults with chronic anal fissure developed after BPD were enrolled in an open label study. The outcome was evaluated clinically and by comparing the pressure of the anal sphincters before and after treatment. All data were analyzed in univariate and multivariate analysis.

**RESULTS:** Two months after treatment, 65.4% of the patients had a healing scar. Only one patient had mild incontinence to flatus that lasted 3 wk after treatment, but this disappeared spontaneously. In the multivariate analysis of the data, two registered months after the treatment, sex ( $P = 0.01$ ), baseline resting anal pressure ( $P = 0.02$ ) and resting anal pressure 2 mo after treatment ( $P < 0.0001$ ) were significantly related to healing rate.

**CONCLUSION:** Botulinum toxin, despite worse results than in non-obese individuals, appears the best alternative to surgery for this group of patients with a high risk of incontinence.

### INTRODUCTION

Approximately two-thirds of individuals living in the United States are overweight, and of those, almost half are obese<sup>[1,2]</sup>. The incremented prevalence of obesity is associated with an increase in the frequency of obesity comorbidity<sup>[3,4]</sup>, which is responsible for > 2.5 million deaths per year worldwide<sup>[5-9]</sup>.

In 1991, the US National Institutes of Health established guidelines for the surgical therapy of morbid obesity (body mass index  $\geq 40$  or  $\geq 35$  in the presence of significant comorbidity), now referred to as bariatric surgery<sup>[10]</sup>. The literature on postoperative weight loss and the problems associated with various bariatric surgical procedures is extensive and has been summarized elsewhere.

Bariatric surgery in morbidly obese individuals re-

verses, eliminates, or significantly ameliorates diabetes, hyperlipidemia, hypertension, and obstructive sleep apnea<sup>[11]</sup>. These benefits occur in the majority of patients who undergo surgery. Biliopancreatic diversion (BPD) is a malabsorptive bariatric technique that is successful in achieving long-lasting weight lost in super-obese patients<sup>[12,13]</sup>. In fact, the diarrhea (steatorrhea) that is expected after any malabsorptive technique can sometimes cause significant nutritional changes and anal disease. These patients are frequently referred to a coloproctology clinic due to hemorrhoids, fissures, and anal sepsis and fistula due to changes in quality and quantity of their feces. The aim of this technique in maintaining long-term weight loss is to produce malabsorption for fats and starch, which will lead to an important qualitative change in the patient's feces<sup>[14-16]</sup>. In a recent long-term study of outcome after BPD, Marinari *et al*<sup>[17]</sup> found that 85.5% of patients scored good or better; however, little is known about the direct consequences of changes in defecation and flatulence after BPD. In addition, a change in the equilibrium of intestinal flora and bacterial overgrowth syndrome may also increase malodorous gas and discomfort. Changes in bowel habit may have a direct influence on quality of life reported by patients after BPD. Although many of the possible metabolic side effects can be controlled with vitamin complexes, micronutrients and protein prophylactics, chronic diarrhea can be the cause of different proctological disorders. These lead to an increase in the assistance required by these patients, who therefore need intervention and re-intervention, with a consequential increase in health expenditure.

The most commonly recorded anal disorders seen in this type of patient are hemorrhoids, fissures, abscesses, and anal fistulae mainly due to repeated, continuous diarrhea and changes in qualitative composition that are typical of steatorrhea in malabsorptive processes. The aim of this study was to analyze the results of botulinum toxin treatment in chronic anal fissure after BPD.

## MATERIALS AND METHODS

This was an open label study. We present the results of the treatment with type A botulinum toxin in patients affected by chronic anal fissure developed after BPD for morbid obesity, observed at the Department of Surgery of the University Hospital "A. Gemelli" in Rome. Patients were sent to our Proctological Center after 1 year follow-up after BPD. History and physical examination pre-BPD did not show any anal disorders that existed before the bariatric surgery. The diagnosis was based on the following clinical criteria: (1) evidence of circumscribed ulcer with a large sentinel tag of skin, induration at the edges and exposure of the horizontal fibers of the internal anal sphincter; and (2) symptoms (post-defecation and/or nocturnal pain, bleeding) persisting for > 2 mo.

The exclusion criteria were as follows: acute fissure; fissure associated with different pathologies (i.e., inflammatory bowel disease, human immunodeficiency virus

infection, anal or perianal cancer); previous surgical procedures on the anal canal; the existence of systemic diseases with alteration of the cholinergic transmission that could confound the evaluations; concomitant oral medications that could interfere with the action of type A botulinum neurotoxin, such as aminoglycosides, baclofen, dantrolene or diazepam; known hypersensitivity to any of the components of the formulations of type A toxin; pregnant or breast-feeding women.

The study protocol was reviewed and approved by the Institutional Ethical Committee of the Catholic University of Rome. All patients gave written informed consent to participate in the study.

### Treatment target

In every treated patient, the primary target was the complete healing of the fissure. The healing was documented by inspection, physical examination and reported symptoms. Treatment was considered satisfactory only when a complete cicatrization was obtained.

### Baseline assessment and operative technique

All patients underwent pretreatment evaluation, including clinical inspection and anorectal manometry. In all the patients, age and sex were registered. We divided the patients into four age groups to make the examined population more homogeneous ( $\leq 30$ , 31-40, 41-50 and > 50 years). Specific data relative to the anal diseases, association with other anal or systemic pathologies, allergies, and previous surgery have been registered in every patient. Defecation pattern, fecal consistency, evacuation frequency, and eventual utilization of laxatives or enemas have been particularly emphasized. As regards duration of symptoms, two groups have been identified ( $\leq 7$  mo or > 7 mo). Finally, we divided our population into two groups according to whether they had  $\leq 7$  or > 7 fecal evacuations/wk.

Anorectal manometry was performed at rest and after maximum voluntary contraction, and was compared with the normal range for our laboratory<sup>[18,19]</sup>. The resting anal tone and maximal squeeze pressure (i.e., the maximal voluntary increase above the resting tone) were measured according to a stationary pull-through technique. One and two months after treatment, patients underwent the same examination as performed at baseline.

Type A botulinum toxin was diluted with saline solution; after individuating the internal anal sphincter, the toxin was injected with a 27 gauge needle; during the procedure the patient was lying on the left side. The injection was given in the anterior or posterior midline. During the procedure, no local or systemic sedative was administered. The phials were containing 100 IU of botulinum toxin A (Botox, Allergan, Irvine, CA, United States) were stored at a temperature of -20 °C and diluted in saline solution at the moment of its utilization. As regards the treatment with botulinum toxin, there were three groups according to the number of units injected: low dose (20 IU injected for single treatment); middle dose (30 IU);

and high dose (50 IU). The patients received different doses of botulinum toxin to test which dose may have a lower complication rate and higher healing rate.

### Statistical analysis

Data have been analyzed with statistical standard methods. At the outset, we performed a univariate analysis with all the factors potentially influencing the course of disease using the  $\chi^2$  test or Fisher's exact test for categorical data and the ANOVA test for continuous data divided in more than two groups. Subsequently, we executed a logistic multivariate regression, constructing models with the factors potentially influencing the course of disease, which by univariate analysis had a *P* value < 0.25. Additionally, we inserted age and sex into our multivariate analysis. Data were processed using GraphPad® Prism Software (GraphPad, San Diego, CA, United States). *P* < 0.05 was considered statistically significant, regardless of the test used.

## RESULTS

Demographic data and parameters registered at the first observation are reported in Table 1. Specifically, we observed 21 (35.6%) male patients and 38 (64.4%) females, aged between 21 years and 61 years (average: 40.49 ± 10.63 years). We did not observe prevalence of the considered disease in patients of a particular age: we observed 12 (20.3%) patients aged ≤ 30 years, 19 (32.2%) aged 31-40 years, 15 (25.4%) aged 41-50 years, and 13 (22.0%) aged > 50 years.

The anal fissure was localized posteriorly in 91.5% and anteriorly in 5.1% of the patients. In 31 (52.5%) patients, symptoms started in the 7 mo before the clinical observation and treatment with botulinum toxin. 98.3% of cases (58 patients) were referred with post-defecatory pain, which tended to persist independently from the evacuation in 22 patients (37.3%) and during the night in 17 (28.8%). Bleeding, even mild, was reported in 44 patients (74.6%), and 22.0% complained of mucorrhea. The relaxation of puborectal muscle was documentable at the physical examination in almost all patients (98.3%). Associated anal or systemic pathology due to obesity was observed in only 11.9% and 39.0% of patients, respectively.

As regards defecation characteristics, 50 patients (84.7%) were referred for diarrhea and evacuation of feces with decreased consistency. In 89.8% of cases, the number of weekly evacuations was > 7. Only three patients (5.1%) were referred for forced evacuations, a sense of incomplete evacuation, and continuous utilization of laxatives and evacuative enemas.

In almost all patients, botulinum toxin was injected into the internal anal sphincter, at the anterior midline (56 cases). No patients received local anesthesia and/or systemic sedation, and in all patients, the internal sphincter was easily identified with digital palpation alone (Table 2).

### Healing after treatment with botulinum toxin

We observed 45 and 26 patients at 1 mo and 2 mo, re-

lasted 3 wk after treatment but disappeared spontaneously. Two months after treatment, no patient had incontinence. At the same time, the complete cicatrization of the fissure, with no residual specific symptoms, was evident in 65.4% of patients. Healing persisted for a period of 32.2 ± 33.9 mo (range: 0-141 mo).

**Manometric results**

At the first observation, before treatment, resting anal pressure was 107.1 ± 20.0 mmHg and maximal voluntary squeezing was 78.2 ± 17.0 mmHg. One month after treatment with botulinum toxin, the mean resting pressure and maximum voluntary squeeze pressure were 21.2% (84.4 ± 23.6 mmHg, *P* < 0.0001) and 9.3% (70.9 ± 18.3 mmHg, *P* = 0.03) lower, respectively, than the respective baseline values. Two months after treatment, the mean resting anal pressure was similar to the 1-mo value (*P* = 0.7) and was 23.2% lower than the baseline value (82.3 ± 22.7 mmHg, *P* < 0.0001). The maximum voluntary squeeze pressure did not differ significantly from the 1-mo value (*P* = 0.9) and was 10.4% lower than the baseline value (70.1 ± 19.2 mmHg, *P* = 0.05) (Table 3).

**Univariate analysis**

The considered parameters were compared with the healing rate at 1 mo and 2 mo after treatment with botulinum

toxin. No demographic parameter had a direct influence on healing rate (Table 4). Both age and sex did not show a statistically significant difference (*P* = 0.42 and *P* = 0.11, respectively). None of the clinical parameters had an influence on the results. Dose and site of injection did not have a significant effect on healing rate.

**Multivariate analysis**

One month after treatment (Table 5), no significant relationship was revealed with any parameter. Two months after treatment, sex (*P* = 0.01), baseline resting anal pressure (*P* = 0.02) and resting anal pressure 2 mo after treatment (*P* < 0.0001) were significantly related to healing rate (Table 6).

**DISCUSSION**

It has been shown that the more aggressive a bariatric technique is, the better are the results in terms of fat loss and maintenance of that fat loss over time. and although there is an improvement in comorbidity, the price paid by the patient, in relation to undesirable and adverse side effects and associated illnesses derived from these aggress-

sive techniques, is high<sup>[13,20]</sup>. The etiology of anal pathology in this group of patients is multifactorial. One trigger-factor present after the intervention (as well as poor dietary habits), is diarrhea (steatorrhea), due to chemical irritation of the liquid feces. BPD produces an increase in the number of bowel movements and a decrease in their consistency due to malabsorption of fat<sup>[21]</sup>. Diarrhea generally appears during the first months after intervention and then it stabilizes between the 18th and 24th months when in general, fat loss has also stabilized.

Fich *et al*<sup>[22]</sup> showed a significant increase in the frequency of phase 3 of the migrating motor complex in patients after Billroth II and Roux-en-Y operations. Change in consistency of bowel motions after BPD was even greater than after Roux-en-Y gastric bypass, with nearly 80% of patients reporting loose stools or diarrhea, even 6 years after the intervention.

A high prevalence of fecal incontinence in both women and men after bariatric surgery has been described<sup>[23-25]</sup>. Women with diarrhea were four times as likely to have fecal incontinence and over half perceived their fecal in-

tinence to be worse after surgery<sup>[26]</sup>. Furthermore, women who perceived their diarrhea to be worse after surgery were significantly more likely to have fecal incontinence. This suggests that fecal incontinence in this population may be due to an underlying weakness in continence mechanisms that is clinically expressed after surgery because of altered stool consistency and delivery or changes in diet. Roberson and colleagues highlighted, for the first time, that fecal incontinence may begin or worsen after bariatric surgery<sup>[14]</sup>.

In the general population, diarrhea, cholecystectomy, stress, and mixed urinary incontinence were risk factors for fecal incontinence in univariate analysis. However, only diarrhea remained a significant risk factor in multivariate analysis. Stool consistency is a critical factor affecting fecal continence. In addition to fat malabsorption resulting from BPD, an alteration in intestinal and colonic bacterial flora after bariatric surgery may also contribute to diarrhea<sup>[27]</sup>.

Bacterial overgrowth is one of the complications related to diarrhea caused by the excluding loop in patients who undergo bariatric surgery. It occurs when a lack of equilibrium between the colonic flora and pathogenic bacteria is present. When untreated, it can evolve into malnutrition, anemia, poor absorption syndrome and can worsen diarrhea<sup>[28,29]</sup>.

Anal fissure is a linear ulceration of the distal part of the anal canal, extending below the dentate line to the anal verge<sup>[30]</sup>. It is a very common pathology affecting the quality of life of subjects who, in most cases, do not have any other significant comorbidity. Most of the fissures are localized in the posterior midline; in 10% of females and 1% of males, they are localized anteriorly<sup>[31,32]</sup>.

The etiology of anal fissure is multifactorial and not completely understood. There is a general agreement that trauma of the anal canal represents the initial insult. Hard bowel movements are the most common antecedent, but diarrhea may also be associated with the onset of fissure symptoms<sup>[31]</sup>. Anal hypertonicity and subsequent decreased blood flow to the anoderm are now recognized as pivotal factors in the pathogenesis of anal fissures. The increased internal sphincter pressure in patients with fissures reduces the blood flow to this area even further. Sphincterotomy reduces the anal canal pressure and improves anodermal blood flow at the posterior midline, resulting in fissure healing, which provides further evidence that abnormal activity in the sphincter contributes to the development of a fissure.

Although anal fissures are generally associated with constipation, in 7%, diarrhea could be the trigger as passing irritant liquid feces is a factor in the deterioration of the situation more often than with the patients who are constipated. This appeared together with the increase in the number of bowel movements following dietetic transgressions. Diarrhea/steatorrhea, due to malabsorption, is one of the common consequences of this type of operation, which can become incapacitating. In the general population, the fundamental pathogenetic element

in anal fissure is high anal pressure; therefore, different therapeutic strategies are needed to resolve the internal sphincter spasm, temporarily or permanently. The most used surgical procedure is partial lateral internal sphincterotomy<sup>[33]</sup>. The procedure has been considered the most effective treatment for anal fissure, although up to 10% of patients have recurrence, and > 35% of patients may experience incontinence. In fact, continence mechanisms can be acutely unbalanced by the execution of sphincterotomy. To avoid the permanent sequences of sphincterotomy, especially in multiparous women with a high risk of incontinence, alternative treatments can be adopted, such as botulinum toxin injection or topical application of nitrates<sup>[31,34]</sup>. The advantage in using these therapeutic approaches is that they cause a significant decrease in anal resting tone, inducing fissure healing, without permanent damages to anal sphincters<sup>[30]</sup>.

We reported the results of observation and treatment with type A botulinum toxin of patients affected by chronic anal fissure who had undergone Scopinaro's BPD. We observed a prevalence of anal fissure in the female patients, but we did not observe any difference between the age groups. One month after treatment with botulinum toxin, healing was observed in 68.9% of patients. Two months after treatment, complete healing of the fissure without any specific symptoms was present in 65.4% of cases. Healing persisted for a mean  $32.2 \pm 33.9$  mo. The number of evacuations per week did not significantly relate to persistence of fissure at 1 mo and 2 mo follow-up. We think that not only the frequency of bowel movements but also the altered composition of feces can play a role in the development of anal disorders in these patients. Mild incontinence to flatus with botulinum treatment was probably related to the diffusion of botulinum toxin to the external anal sphincter. The multivariate analysis of the parameters registered at the first control revealed no statistically significant values, instead, at the second control, sex, baseline resting anal pressure and resting anal pressure 2 mo after treatment had a significant influence on healing, by multivariate analysis. In particular, male sex had a direct influence on healing and high resting anal pressure pre- and post-treatment was associated with persistent anal fissure.

Despite the high dose of botulinum toxin, the healing rate in this study, and the reduction of resting anal canal pressure and maximum anal canal squeeze pressure were lower than in our previous trials<sup>[18,19,30,34,35]</sup>. The results of the present study were different from our previous observation of 100 patients: 50 treated with 50 IU Botox (group I) and 50 with 150 IU Dysport (group II)<sup>[35]</sup>. We considered the difference in group I. One month after treatment, fissure healing was present in 82% of the patients in our previous study and in 68.9% of the patients in the present trial ( $P = 0.15$ ). In patients in previous trials, a 38.7% decrease of resting anal pressure, compared to pretreatment values, was registered; in the present study, we observed a lower decrease of resting anal pressure (21.2%). The reduction of maximal anal squeezing

was 22.4% and 9.3% in the previous and present study, respectively. Two months after treatment, 92% and 65.4% of the patients in the previous and present study, respectively, ( $P = 0.007$ ) had a healing scar. The reduction of resting anal canal pressure was lower than in our previous trial (23.2% *vs* 41.8%). The decrease of maximum anal canal squeeze pressure was lower than in our previous study (10.4% *vs* 20.2%)<sup>[35]</sup>.

We think that the increase of baseline resting anal pressure in bariatric patients is secondary to repeated, continuous diarrhea and changes in qualitative composition that are typical of steatorrhea in malabsorptive processes. The reduction of resting anal pressure and maximal anal squeezing after treatment, lower than in the general population, and the association between persistent high levels of resting anal pressure and a low healing rate can result from chronic irritation of the anal canal by liquid stools. The reduction of resting anal pressure favors healing but the results are worse than in the general population because the anal hypertonicity is not the principal pathogenetic factor of chronic anal fissure in bariatric patients.

In summary, we believe that, in patients who undergo BPD, chronic steatorrhea can be the cause of different anal disorders. It is of utmost importance to be conservative in the treatment of anal disorders for bariatric patients. It is also important to remember that the anatomy of the anal canal should be preserved as much as possible so as to avoid incontinence, because in these patients, at least one of the continence mechanisms is already altered. Botulinum toxin, despite worse results than in non-obese population, appears the best alternative to surgery for this group of patients with high risk of incontinence. The effectiveness of other treatments such as nitrates depends on patient compliance, which may be poor in bariatric patients. Moreover, repeated evacuations and altered fecal composition can decrease the pharmacological effect of nitrates. Botulinum toxin injection has the advantage of a good healing rate, can be repeated if necessary, and the possible incontinence is temporary.

## COMMENTS

### Background

Anal fissure is a split in the distal anal canal. It is a common problem that causes substantial morbidity in people who are otherwise healthy. There is accumulating agreement that bariatric surgery is currently the most efficacious and enduring treatment for clinically severe obesity, and as a result, the number of bariatric surgery procedures performed has risen dramatically in recent years. Biliopancreatic diversion (BPD) by Scopinaro is a malabsorptive technique that is successful in achieving long-lasting weight lost in super-obese patients. The diarrhea that is expected after the procedure can sometimes cause significant nutritional changes and anal disease.

### Research frontiers

Treatment of chronic anal fissure has undergone a transformation in recent years from surgical to medical, both approaches sharing the common goal of reducing spasm of the internal anal sphincter. Surgical sphincterotomy results in a healing rate up to 95%. Despite this, it carries a significant risk of persistent disturbance in anal continence. This is believed to be the first study of the use of botulinum toxin injection for treatment of chronic anal fissure in patients undergoing BPD. This article, unlike others that focus only on the positive effects

of bariatric surgery on improvement of comorbidity in obese patients, highlights the side effects that may affect the quality of life and draws new boundaries in the treatment of chronic anal fissure after BPD.

### Innovations and breakthroughs

Different types of bariatric operations might alter bowel habits as a consequence of the surgical technique used. Disordered bowel habits and anal diseases might influence quality of life after bariatric surgery. There are few papers in the literature devoted to the study of the anal disorders after bariatric surgery. Prospective randomized trials are needed to estimate the true incidence and to establish the etiology of proctological disorders in these patients.

### Applications

The treatment of chronic anal fissure in these high-risk patients should have the minimum risk of fecal incontinence. Botulinum toxin injection has the advantages of an excellent healing rate and can be repeated if necessary. Any incontinence, as a complication, however, is transient.

### Peer review

This is an interesting paper about the usefulness of botulinum toxin A in healing chronic anal fissure after BPD for morbid obesity. The authors report complete healing in 65.4% of patients.

### Abstract

**AIM:** To investigate the expression of 15-hydroxyprostaglandin dehydrogenase (15-PGDH) in human gastric cancer and its mechanism in apoptosis and cell cycle arrest.

**METHODS:** Expression of 15-PGDH mRNA and protein was examined by immunohistochemistry, immunocytochemistry, reverse transcriptase polymerase chain reaction (RT-PCR) and Western blotting in tissue from human gastric cancer, gastric precancerous state (gastric polyps and atrophic gastritis), normal stomach, and gastric cancer cell lines. The relationship between gastric cancer, gastric precancerous state and 15-PGDH

expression was determined. The association between expression of 15-PGDH and various clinicopathological parameters in gastric cancer was evaluated. Human gastric cancer cell line SGC-7901 was transfected with 15-PGDH expression plasmids. The effect of 15-PGDH on the cell cycle was examined by flow cytometry. The effect of 15-PGDH on apoptosis was examined by transmission electron microscopy, flow cytometry and transferase mediated nick end labeling (TUNEL) assay. Expression of cell cycle (p21, p27, p16 and p53) and apoptosis (*Survivin*, *BCL-2*, *BCL-X<sub>L</sub>*, *BAK* and *BAX*) genes was analyzed by RT-PCR.

**RESULTS:** Expression of 15-PGDH mRNA and protein in human gastric cancer tissues was significantly lower than in normal gastric tissues ( $P < 0.01$ ). Expression in human gastric cancer cell lines MKN-28 and MKN-45 was reduced, and absent in SGC-7901 cells ( $P < 0.05$ ). Reduction of 15-PGDH expression was also found in precancerous tissues, such as gastric polyps and atrophic gastritis ( $P < 0.01$ ). There was a significant difference in expression of 15-PGDH among various gastric cancer pathological types ( $P < 0.05$ ), with or without distant metastasis ( $P < 0.05$ ) and different TNM stage ( $P < 0.01$ ). Flow cytometry demonstrated a significant increase in apoptotic cells in SGC-7901 cells transfected with pcDNA3/15-PGDH plasmid for 24 h and 48 h ( $P < 0.01$ ), and an increased fraction of sub-G1 phase after transfection ( $P < 0.05$ ). TUNEL assay showed an increased apoptotic index in cells overexpressing 15-PGDH ( $P < 0.01$ ). After transfection, expression of proapoptotic genes, such as *BAK* ( $P < 0.05$ ), *BAX* and *p53* ( $P < 0.01$ ), was increased. Expression of antiapoptotic genes was decreased, such as *Survivin*, *BCL-2* and *BCL-X<sub>L</sub>* ( $P < 0.01$ ). Expression of cyclin-dependent kinase inhibitors p21 and p16 ( $P < 0.01$ ) was significantly upregulated in cells overexpressing 15-PGDH.

**CONCLUSION:** Reduction of 15-PGDH is associated with carcinogenesis and development of gastric carcinoma. 15-PGDH induces apoptosis and cell cycle arrest in SGC-7901 cells.

## INTRODUCTION

Gastric carcinoma is one of the most common malignant tumors in humans and continues to be a major unresolved health problem. New approaches for the management of gastric cancer are needed. NAD<sup>+</sup>-dependent 15-hydroxyprostaglandin dehydrogenase (15-PGDH) is the key enzyme responsible for the biological inactivation of prostaglandins (PGs) and related eicosanoids. It catalyzes the oxidation of the 15(S)-hydroxyl group of PGs and lipoxins. The products, 15-keto-metabolites, exhibit greatly reduced biological activities<sup>[1]</sup>. 15-PGDH is widely distributed in various mammalian tissues such as lung, breast, prostate, placenta and gut. The stomach is one of the most active tissues expressing 15-PGDH<sup>[2]</sup>. Recent studies<sup>[3-6]</sup> have shown a reduction of 15-PGDH in some cancers, such as colorectal, breast, prostate and lung. Some studies<sup>[3,4,6,7-9]</sup> have revealed that 15-PGDH may have tumor-suppressive properties. Recently, some studies<sup>[10-15]</sup> have indicated that 15-PGDH is downregulated in gastric cancer and is a suppressor of human gastric cancer. It provides a new target for the chemoprevention and treatment of cancer, especially in gastric carcinoma. However, to the best of our knowledge, there has been no study on 15-PGDH expression in gastric precancerous tissue. The association between 15-PGDH expression and various clinicopathological parameters of gastric cancer needs to be validated. Only a few studies have been published on its mechanism of tumor inhibition. Therefore, more studies on the mechanism of 15-PGDH suppression of gastric cancer are necessary.

In this study, we investigated the expression of 15-PGDH in human gastric cancer and gastric precancerous tissues, and determined the relationship between occurrence, development, infiltration, metastasis, cell differentiation of gastric carcinoma and 15-PGDH expression. We also examined the association of 15-PGDH with gastric cancer cell proliferation, apoptosis and the cell cycle. We studied the role of 15-PGDH reduction in carcinogenesis and de-

velopment of gastric cancer and the possible mechanism of gastric cancer inhibition of 15-PGDH. Our results suggest the use of 15-PGDH in chemoprevention and treatment of gastric cancer.

## MATERIALS AND METHODS

### Human gastric specimens

Human gastric carcinoma specimens ( $n = 30$ ) were obtained from surgical resections, with the approval of the Shanghai First People's Hospital Ethics Committee. The specimens were frozen and stored in liquid nitrogen and 10% formaldehyde solution. Each tumor sample was matched with adjacent tissues (3 cm and 6 cm from the border of tumor) collected during the process. Other gastric tissues, including normal gastric tissues ( $n = 10$ ), gastric polyps ( $n = 10$ ) and chronic atrophic gastritis ( $n = 10$ ), were obtained from gastroscopic biopsy and stored in liquid nitrogen and 10% formaldehyde solution. Specimens were dissected macroscopically by trained pathologists.

### Cell culture

Human gastric carcinoma cell lines MKN-45, MKN-28 and SGC-7901 (obtained from Shanghai Institute of Biochemistry and Cell Biology) were maintained in RPMI-1640 (Gibco, United States) medium supplemented with 10% fetal calf serum, 100 U/mL penicillin and 100 µg/mL streptomycin in a 5% CO<sub>2</sub> atmosphere at 37 °C. These cells were plated in six-well plates at about  $2 \times 10^5$  cells/well in duplicate, and grown for 24 h before transfection.

### Expression of wild-type 15-PGDH

The mammalian expression vector pcDNA3 containing the cDNA of the wild-type 15-PGDH and pcDNA3 expression vector were donated by Dr. Tai HH (Department of Pharmaceutical Sciences, College of Pharmacy, University of Kentucky, Lexington, United States). Both pcDNA3/15-PGDH and pcDNA3 (200 ng) plasmids were transfected into SGC-7901 cells by Lipofectamine 2000 reagent for 24 h and 48 h, according to the manufacturer's directions. Expression of the wild-type 15-PGDH mRNA and protein was monitored by reverse transcriptase polymerase chain reaction (RT-PCR), cellular immunohistochemistry and Western blotting.

### Immunohistochemistry and immunocytochemistry

Paraffin-embedded tissue sections (3 µm) were dried, deparaffinized, and rehydrated. Endogenous peroxidase was blocked with 3% hydrogen peroxide in ion-free water for 30 min. After nonspecific binding sites, tissue slides were blocked with 10% goat serum. Cellular slides were treated by 4% paraformaldehyde for 30 min. Both kinds of slides were incubated at 4 °C overnight with a 1:50 dilution of rabbit polyclonal 15-PGDH antibody (Cayman, United States), followed by a 30-min incubation in horseradish peroxidase (HRP)-conjugated sheep anti-rabbit IgG (Changdao, China), rinsed with PBS, developed with the DAB kit (DakoCytomation, United States), and then counterstained with haematoxylin. Each slide

was scanned at 100 and 400 × magnification. Immunohistochemistry score = intensity score (absent, 0; weak, 1; moderate, 2; strong, 3) × percentage score (< 5%, 0; 5%-25%, 1; 25%-50%, 2; 50%-75%, 3; > 75% of total tumor area, 4).

**Reverse transcriptase polymerase chain reaction analysis**

Total RNA of tissues and gastric cancer cells was extracted with TRIzol (Invitrogen, United States) following the manufacturer’s instructions. cDNA was synthesized from 2 µg total RNA using the M-MLV RT-PCR kit (Promega, United States) in a 20 µL volume, according to the manufacturer’s instructions. Two µL of cDNA, 2 µL each primer (50 pmol/L), 1 µL dNTP mix (10 mmol/L) and 1 µL Taq DNA polymerase (Sangon, China) were used for PCR analysis. The PCR amplification cycles consisted of denaturation at 94 °C for 5 min, 35 cycles of denaturation at 94 °C for 60 s, annealing for 60 s, extension at 72 °C for 60 s, and final elongation at 72 °C for 10 min. The PCR products were separated on a 1.5% agarose gel, stained with 0.5 mg/mL ethidium bromide, and visualized by UV light. Gene expression was normalized to glyceraldehyde-3-phosphate dehydrogenase and shown as the ratio of absorbance values. The primer sequences and annealing temperature are listed in Table 1.

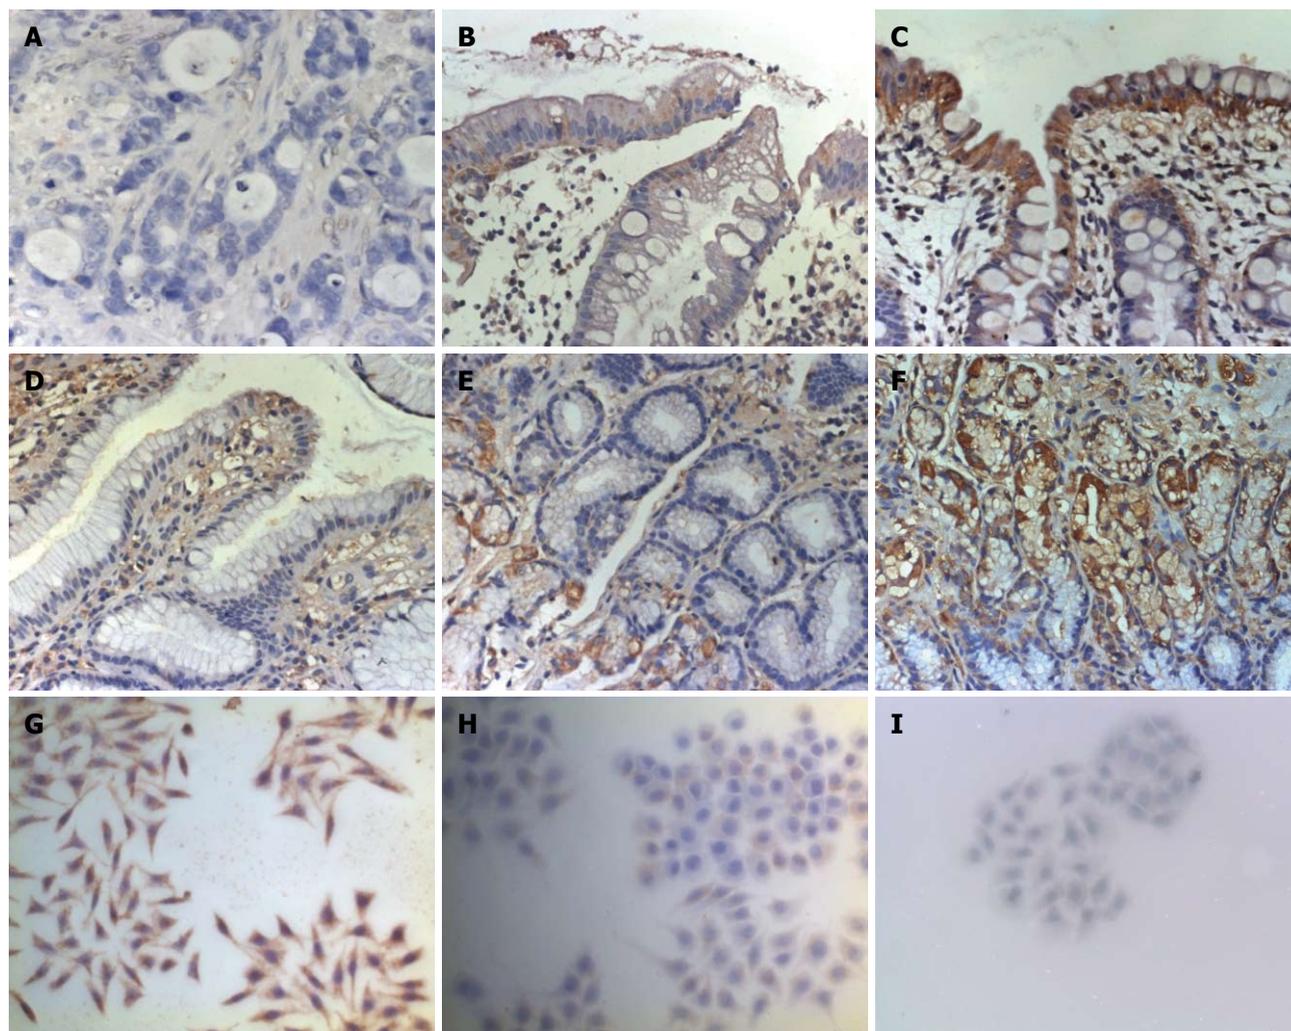

**Western blotting**

Tissues and gastric cancer cells were lysed with lysis buffer containing 0.5% NP-40, 40 mmol/L Tris-HCl (pH 8.0), 120 mmol/L NaCl, and a protease cocktail inhibitor (Complete Mini; Pierce, Rockford, IL, United States). Samples (40 µg protein per lane) were subjected to sodium

dodecyl sulfate-polyacrylamide gel electrophoresis, and then blotted onto polyvinylidene difluoride membranes. Membranes were blocked for 2 h at room temperature with 5% skimmed milk and then probed with 1:200 dilution of rabbit polyclonal 15-PGDH antibody overnight at 4 °C. Membranes were washed and incubated for 1 h at room temperature with anti-rabbit IgG-HRP. Results were visualized by ECL chemiluminescence detection kit (Kangcheng, China). Protein expression was normalized to ACTIN.

**Cell cycle analysis and apoptosis assays**

The effect of 15-PGDH on the cell cycle and apoptosis in SGC-7901 cells was analyzed by flow cytometry. Cells floating in medium combined with the adherent layer were trypsinized and fixed with 2 mL citrate buffer for 1 h. Cells were then incubated with RNase A (1500 µL) and stained with propidium iodide (1500 µL). Samples were immediately analyzed by flow cytometry for cell cycle and apoptosis assays. Cells were observed under transmission electron microscopy (TEM) at Shanghai Medical College of Fudan University. The number of apoptotic cells was counted per 100 cells. Terminal deoxynucleotidyl transferase mediated nick end labeling (TUNEL) assay, in which residue of digoxigenin-labeled dUTP was catalytically incorporated into the DNA by terminal deoxynucleotidyl transferase II, was performed according to the manufacturer’s instructions (Boster, Wuhan, China). The positive particles of DAB staining were viewed under an optical microscope. The number of apoptotic cells was counted under a microscope (400 ×) and expressed as the apoptotic index (AI = the number of apoptotic bodies/1000 cells).

**Figure 1 Immunohistochemistry image of 15-hydroxyprostaglandin dehydrogenase (400 ×).** A: Gastric cancer (IHC Score  $1.20 \pm 1.13$ ,  $P < 0.01$  vs B, C and F); B and C: Paracancerous tissue 3 cm ( $6.83 \pm 2.78$ ,  $P < 0.01$  vs C and F) and 6 cm ( $10.20 \pm 1.92$ ) distant from tumor; D: Gastric polyps ( $6.00 \pm 2.74$ ,  $P < 0.01$  vs F); E: Atrophic gastritis ( $5.14 \pm 1.57$ ,  $P < 0.05$  vs F); F: Normal gastric tissues ( $11.00 \pm 1.63$ ). G: MKN-28 ( $3.31 \pm 0.92$ ,  $P < 0.05$  vs H and I); H: MKN-45 ( $1.29 \pm 0.48$ ); I: SGC-7901 (absent).

### Statistical analysis

Quantitative results were expressed as mean  $\pm$  SD. Statistical analysis was assessed by Student's *t* test (between two groups) or Student-Newman-Keuls test (among three or more groups), with SAS version 8.02 software.  $P < 0.05$  was considered statistically significant.

## RESULTS

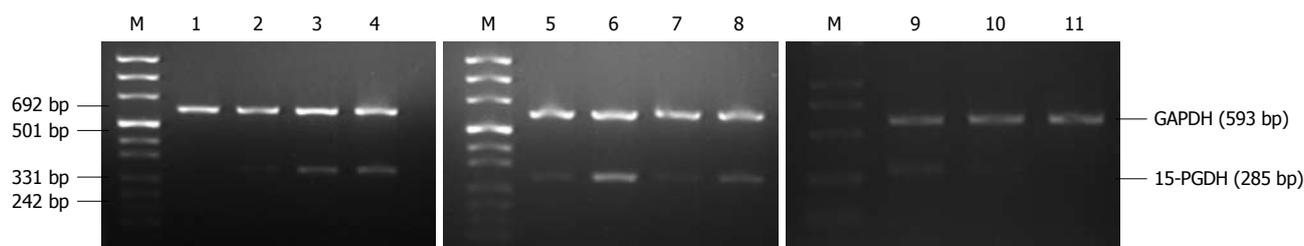

### Downregulation of 15-PGDH expression in gastric cancer, paracancerous and precancerous tissues and gastric cancer cell lines

Immunohistochemistry analysis confirmed that 15-PGDH protein was expressed mainly in the cytoplasm of epithelial, inflammatory and gastric cancer cells in the lamina propria. Of the 30 gastric cancer cases, 15-PGDH expression was undetectable in 10 tumors (33.3%). Immunohistochemistry score of 15-PGDH was decreased in gastric cancer, paracancerous tissues 3 cm and 6 cm from the tumor, gastric polyps and atrophic gastritis compared with normal gastric

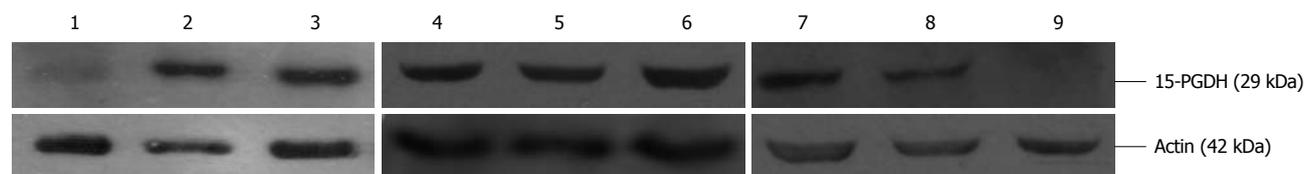

tissues. Immunocytochemical analysis showed that expression of 15-PGDH in various differentiated gastric cell lines was dissimilar. Poorly differentiated gastric cell line SGC-7901 displayed no 15-PGDH, whereas MKN-28 and MKN-45 displayed little 15-PGDH (Figure 1).

RT-PCR analysis showed that expression of 15-PGDH mRNA in gastric cancer, paracancerous tissues, gastric polyps and atrophic gastritis was significantly lower than in normal gastric tissues. We also found loss of 15-PGDH in nine tumors (30%). Expression of 15-PGDH was absent in SGC-7901 cells, and significantly decreased in MKN-45 and MKN-28 cells (Figure 2).

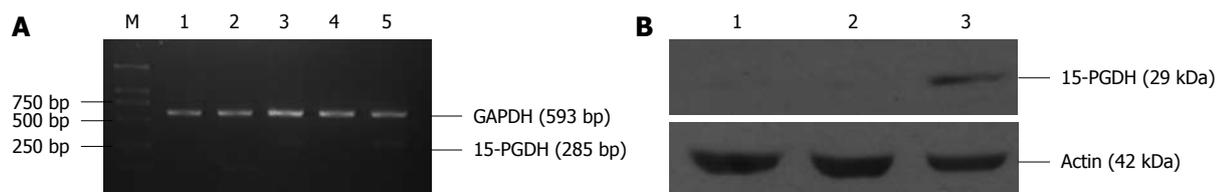

Western blotting demonstrated that 15-PGDH protein expression was absent in nine of 30 gastric cancer cases (30%), and an average 5.7- and 8.3-fold less 15-PGDH expression was found in cancer tissues compared with paracancerous tissues at 3 cm and 6 cm from the tumor. There was a twofold reduction in gastric polyps and 2.1-fold reduction in atrophic gastritis tissues compared with normal gastric mucosa. Expression of 15-PGDH

protein in gastric cancer cells was the same as shown by RT-PCR (Figure 3).

**Relationship between expression of 15-PGDH and clinicopathological parameters in gastric cancer**

Expression of 15-PGDH protein was significantly different among the various gastric cancer pathological types ( $P < 0.05$ ). Reduction of 15-PGDH was more distinct in gastric cancer with distant metastasis than in tumor without distant metastasis ( $P < 0.05$  at protein level,  $P < 0.01$  at mRNA level). There was also a significant difference in expression of 15-PGDH among tumors of different TNM stage ( $P < 0.01$  at both protein and mRNA level). More reduced 15-PGDH expression was associated with worse TNM stage (Table 2).

**Over-expression of 15-PGDH induced cell cycle arrest and apoptosis in SGC-7901 cells**

After transfection by pcDNA3/15-PGDH plasmid, SGC-7901 cells were induced to overexpress 15-PGDH (Figure 4). At the same time, an increased fraction of sub-G1 phase ( $57.21\% \pm 0.53\%$  for 24 h transfection

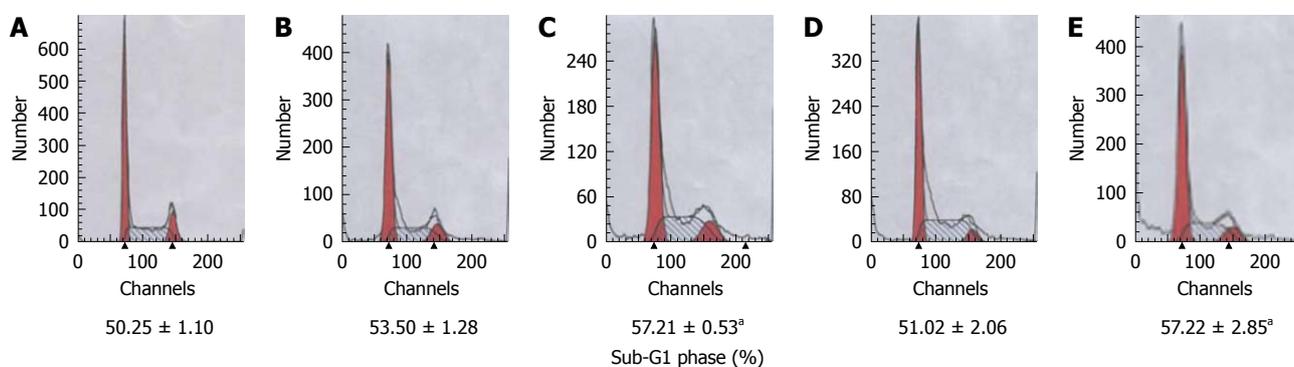

and  $57.22\% \pm 2.85\%$  for 48 h transfection,  $P < 0.05$ ) was found by flow cytometry (Figure 5). It showed that 15-PGDH promoted cell cycle arrest in the sub-G1 phase. To assess the effect of 15-PGDH on induction of cell apoptosis in gastric cancer, we observed SGC-7901 cells under TEM and by flow cytometry, and then performed a TUNEL assay. Under TEM, nuclear and cytoplasmic shrinkage, condensation and margination of chromatin against the nuclear membrane, and formation of apoptotic bodies were observed in SGC-7901 cells that overexpressed 15-PGDH (Figure 6). The proportion of apoptotic cells was significantly increased after transfection for 24 h and 48 h ( $12.33\% \pm 1.15\%$  and  $25.00\% \pm 1.00\%$  vs  $3.33\% \pm 0.58\%$ ,  $P < 0.01$ ). Flow cytometric analysis showed induction of apoptosis ( $10.49\% \pm 0.81\%$  and  $24.02\% \pm 0.37\%$  vs  $4.17\% \pm 0.68\%$ ,  $P < 0.01$ ), which was further confirmed by TUNEL assay (AI:  $25.27\% \pm 1.19\%$  and  $48.37\% \pm 2.67\%$  vs  $6.50\% \pm 0.30\%$ ,  $P < 0.01$ ) (Figure 7). It indicated that cell cycle arrest and increased apoptosis was one mechanism of cancer suppression of 15-PGDH in SGC-7901 cells.

Expression of genes associated with the cell cycle

**Table 2 Relationship between expression of 15-hydroxyprostaglandin dehydrogenase and clinicopathological parameters in gastric cancer**

(p21, p27, p16 and p53) and apoptosis (Survivin, BCL-2, BCL-X<sub>L</sub>, BAK and BAX) was determined by RT-PCR in SGC-7901 cells transfected with pcDNA3/15-PGDH plasmids. p21 (1.75 ± 0.51 for 24 h transfection and 1.76 ± 0.52 for 48 h transfection vs 0.46 ± 0.06 SGC-7901, P < 0.01), p16 (0.33 ± 0.12 and 0.32 ± 0.17 vs absence, P < 0.01) and p53 genes (0.19 ± 0.04 and 0.19 ± 0.06 vs 0.08 ± 0.02, P < 0.01) were significantly upregulated in cells treated with 15-PGDH for 24 h group and 48 h, whereas the level of p27 mRNA did not change (P > 0.05). Expression of the proapoptotic genes, such as BAK (0.92 ± 0.14 and 1.04 ± 0.27 vs 0.52 ± 0.24, P < 0.05) and BAX

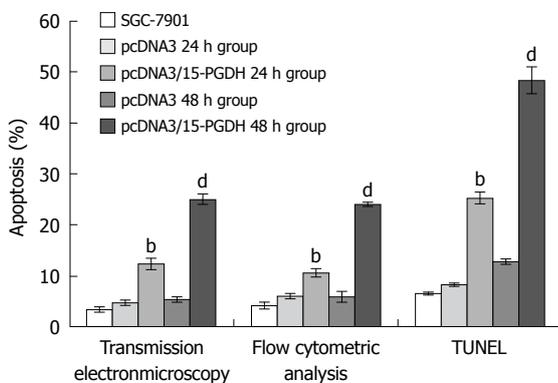

(1.73 ± 0.17 and 1.72 ± 0.07 vs 1.14 ± 0.11, P < 0.01) was significantly increased. The antiapoptotic genes, such as Survivin (0.14 ± 0.06 and 0.13 ± 0.02 vs 0.34 ± 0.06, P < 0.01), BCL-2 (0.02 ± 0.01 and 0.02 ± 0.01 vs 0.08 ± 0.03, P < 0.01) and BCL-X<sub>L</sub> (0.63 ± 0.11 and 0.63 ± 0.08 vs 1.12 ± 0.08, P < 0.01), were significantly down-regulated (Figure 8).

## DISCUSSION

These findings demonstrate that the reduction of 15-PGDH is related to occurrence and development of

**Figure 6** Transmission electron microscopy of gastric cancer cell apoptosis (5000 ×). gastric cancer in humans. 15-PGDH also induces cell cycle arrest and apoptosis in gastric cancer cells. It may be a suppressor of gastric cancer through these two pathways.

15-PGDH catalyzes the oxidation of the 15(S)-hydroxyl group of PGs and lipoxins. 15-PGDH is one of the target genes. Some cytokines, factors and cell signaling pathways affect carcinogenesis and tumor progression through 15-PGDH. It shows that epidermal growth factor (EGF) and EGF receptor tyrosine kinase inhibitor<sup>[16,17]</sup>, histone deacetylase inhibitors, transforming growth factor-β (TGF-β)<sup>[18]</sup>, hepatocyte nuclear factor 3β<sup>[7]</sup>, interleukin (IL)-4<sup>[19]</sup>, tumor necrosis factor α<sup>[20]</sup>, IL-1β<sup>[21]</sup>, peroxisome proliferator-activated receptor γ ligands<sup>[22]</sup>, hepatocyte growth factor receptor, Met<sup>[23]</sup>, bile acids<sup>[24]</sup> adjust tumor growth through 15-PGDH. Recent studies have shown an obvious reduction of 15-PGDH in some cancers, for example, colorectal, breast, prostate and lung<sup>[3-6]</sup>. It also has been reported that 10%-80% of gastric cancer exhibits downregulation of 15-PGDH expression<sup>[10,11-14]</sup>. Our finding that 15-PGDH expression is decreased in gastric cancer is consistent with these reports. 15-PGDH protein and mRNA expression is absent

in 33.3% of gastric cancer tissues, and reduced in almost all gastric cancer tissues and cell lines examined. There was also a significant reduction of 15-PGDH expression in paracancerous and precancerous tissues, for example, gastric polyps and atrophic gastritis. Downregulation of 15-PGDH expression was positively correlated with differentiation in gastric cancer tissues, distant metastasis and different TNM stages of gastric cancer. This result is similar to that in previous studies. It has also been reported that expression of 15-PGDH is reduced and associated with tumor differentiation, lymph node metastasis, clinical stage<sup>[11,13]</sup> and prognosis<sup>[10]</sup> in gastric cancer. We verified the relationship between differentiation of gastric cancer cells and 15-PGDH expression *in vitro*. We showed that poorer differentiation in carcinoma was associated with lower 15-PGDH expression. Taken together, reduction of 15-PGDH is related to the carcinogenesis and development of gastric cancer. Evaluation of 15-PGDH expression in tumor and precancerous tissues is a useful diagnostic or prognostic marker for gastric carcinoma.

After determining the relationship between 15-PGDH expression and gastric cancer, we suggest that reduction of 15-PGDH promotes occurrence and development of gastric cancer and that it is an inhibitor of human gastric cancer. Some studies have already demonstrated that 15-PGDH suppresses some tumors. Overexpression of 15-PGDH by transfection with plasmid or adenovirus vectors encoding 15-PGDH reduces occurrence and growth of tumor<sup>[3-5,8-10]</sup>, whereas silencing of 15-PGDH using siRNA enhances cell proliferation and growth of cancer<sup>[3,10]</sup>. 15-PGDH gene knockout increases the colon tumor incidence in the APC+/Min mouse model<sup>[25]</sup>. The antitumor effect in human gastric cancer has only been shown in one study<sup>[15]</sup>. However the mechanism is still not clear.

The mechanism of the antitumor effect of 15-PGDH can be explained by the following hypothesis. 15-PGDH substantially inhibits production of PGE2 and changes the microenvironment to suppress tumor formation by *Ras* gene<sup>[8]</sup>; controls growth of tumor by regulation of cyclooxygenase-2<sup>[21]</sup>; suppresses synthesis, secretion and

**Figure 8** Expressions of 15-PGDH, p21, p27, p16, p53, Survivin, BCL-2, BAX, BAK and BCL-Xl mRNA in SGC-7901 cells transfected by pcDNA3/15-PGDH plasmids for 24 h and 48 h by reverse transcriptase polymerase chain reaction. Lane M: DNA marker; 1: SGC-7901; 2: pcDNA3 24 h group; 3: pcDNA3/15-PGDH 24 h group; 4: pcDNA3 48 h group; 5: pcDNA3/15-PGDH 48 h group. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 vs SGC-7901, pc DNA3 24 h and 48 h group.

activation of matrix metalloproteinase-2, inhibits cell adhesion to extracellular matrix and reduces CD44 expression, which contributes to the inhibition of the growth, invasion and metastasis of cancer cells<sup>[4,9]</sup>; reduces expression of antiapoptotic protein Bcl-2, which indicates a role for Bcl-2 in mediating or triggering the event of apoptosis<sup>[4]</sup>; inhibits endothelial cell proliferation by 15-oxo-5,8,11,13-(Z,Z,Z,E)-eicosatetraenoic acid, a metabolite of 15-PGDH, suppressing DNA synthesis and implicating a potential antiangiogenic role<sup>[26]</sup>; and attenuates tumor-induced immune suppression and substantially reduces the secretion of immunosuppressive mediators and cytokines such as PGE2, IL-10, IL-13 and IL-6 to regulate the local antitumor immune response<sup>[27]</sup>.

Our present research showed that apoptosis occurred in gastric cancer cells overexpressing 15-PGDH. In SGC-7901 cells transfected with pcDNA3/15-PGDH plasmid, we found by TEM nuclear and cytoplasmic shrinkage, condensation and margination of chromatin against the nuclear membrane, and formation of apoptotic

bodies. Flow cytometric analysis and TUNEL assay showed that the proportion of apoptotic cells was increased by 15-PGDH. Previous research has found the same phenomenon in lung cancer<sup>[4]</sup>. Overexpression of this enzyme induces apoptosis in lung cancer cell line A549. When A549 cells overexpress 15-PGDH by transfection with Ad-15-PGDH, they become apoptotic, as shown by DNA fragmentation, activation of pro-caspase-3 and cleavage of poly ADP ribose polymerase<sup>[4]</sup>. Furthermore, we analyzed genes associated with apoptosis. There was a reduction in expression of antiapoptotic genes (*Survivin*, *BCL-2* and *BCL-Xl*) and increased expression of proapoptotic genes (*BAK*, *BAX* and *p53*). As we know, *Survivin*, *BCL-2* members and *p53* genes are crucial regulators of apoptotic cell death<sup>[28-32]</sup>. *BCL-2* prevents the release of apoptosis-inducing factor and cytochrome c from the mitochondria, which is assumed to be a key event during apoptosis<sup>[30,31]</sup>. Overexpression of 15-PGDH regulates expression of *Survivin*, *BCL-2* members and *p53*, indicating a role in mediating or trig-

gering apoptosis. The results are inconsistent with previous findings, in which apoptosis induced by 15-PGDH is independent of the p53 pathway. 15-PGDH only decreases expression of antiapoptotic protein BCL-2 in lung cancer<sup>[4]</sup>. The mechanism of apoptosis varies in different tumors. In gastric cancer, 15-PGDH induces apoptosis by Survivin, BCL-2 and the p53 pathway.

In our study, we also observed cell cycle arrest in SGC-7901 cells that overexpressed 15-PGDH. We showed an increased accumulation of cells in the sub-G1 phase compared with the control group, and upregulated expression of p21, p16 and p53 without altering p27 expression. p16, p21 and p27 all belong to the cyclin-dependent kinase (CDK) inhibitors<sup>[33-37]</sup>. The product of *p16* gene is an inhibitor of CDK4. Its function is to cyclin E and CDK2 complexes. p27 functions as a negative regulator of G1 progression and is a possible mediator of TGF- $\beta$ -induced G1 phase arrest<sup>[35]</sup>. *p53* is known as a suppressor gene that can adjust the cell cycle<sup>[29]</sup>.

In conclusion, our study provides evidence that loss or reduction of 15-PGDH is related to human gastric cancer. 15-PGDH induces cell cycle arrest and apoptosis of gastric cancer cells *in vitro*, and it may be the mechanism by which it suppresses human gastric cancer and other tumors. Further research is needed to establish the role of 15-PGDH as a target for treatment and chemoprevention of gastric cancer.

## COMMENTS

### Background

Gastric carcinoma is one of the most common malignant tumors in humans and continues to be a major unresolved health problem. New approaches for the management of gastric cancer are needed. Recent studies have shown a reduction of 15-hydroxyprostaglandin dehydrogenase (15-PGDH) in some cancers, such as colorectal, breast, prostate and lung. Some studies have revealed that 15-PGDH may have tumor-suppressive properties. It provides a new target for the chemoprevention and treatment of cancer, especially in gastric carcinoma. However, to the best of our knowledge, there has been no study on 15-PGDH expression in gastric precancerous tissue. The association between 15-PGDH expression and various clinicopathological parameters of gastric cancer needs to be validated. Only a few studies have been published on its mechanism of tumor inhibition.

### Research frontiers

NAD<sup>+</sup>-dependent 15-PGDH is the key enzyme responsible for the biological inactivation of prostaglandins (PGs) and related eicosanoids. It may have tumor-suppressive properties. The research hotspot is first study on 15-PGDH expression in gastric precancerous tissue. The association between 15-PGDH expression and various clinicopathological parameters of gastric cancer and its mechanism of tumor inhibition.

### Innovations and breakthroughs

We found that 15-PGDH expression in human gastric cancer was reduced and even absent. Reduction of 15-PGDH expression was also found in precancerous state tissues, e.g., gastric polyps and atrophic gastritis. There was significant difference in expression of 15-PGDH among various pathologic type, with or without distant metastasis and different TNM stage. Apoptosis and cell cycle arrest was found after transfected with pcDNA3/15-PGDH plasmid. In 15-PGDH over-expression cells, expression of the pro-apoptotic genes, such as *BAK* and *p53*, was increased. Expression of anti-apoptotic genes was decreased, e.g., *Survivin*, *BCL-2* and *BCL-X<sub>L</sub>*. Cyclin-dependent kinase inhibitors p21 and p16 expression was significantly up-regulated. The researchers drew a conclusion that reduction of 15-PGDH is associated with carcinogenesis and development of gastric carcinoma. 15-PGDH induces apoptosis and cell cycle arrest in gastric cancer. It will be a novel chemotherapy strategy in gastric cancer.

## Applications

The study results suggest the use of 15-PGDH in chemoprevention and treatment of gastric cancer.

## Terminology

NAD<sup>+</sup>-dependent 15-PGDH is the key enzyme responsible for the biological inactivation of PGs and related eicosanoids. It catalyzes the oxidation of the 15(S)-hydroxyl group of PGs and lipoxins. The products, 15-keto-metabolites, exhibit greatly reduced biological activities.

## Peer review

This is an interesting and well presented study, supported by primary data. It presents the studies on the expression of 15-PGDH in normal and cancerous gastric mucosal tissue, and its effect on apoptosis and cell cycle progression. Further, the authors examined the effect of 15-PGDH overexpression in gastric cell line, SGC-7901, on cell cycle progression and apoptosis. Based on the presented results, it is concluded that the loss or reduction in the mucosal cell 15-PGDH expression is associated with carcinogenesis and the development of gastric carcinoma.

## ACKNOWLEDGMENTS

We thank Dr. Tai HH (Department of Pharmaceutical Sciences, College of Pharmacy, University of Kentucky, Lexington, United States) for donating 15-PGDH expression vector.

### Abstract

**AIM:** To investigate pathological types and influential factors of chronic graft dysfunction (CGD) following liver transplantation (LT) in rats.

**METHODS:** The whole experiment was divided into three groups: (1) normal group ( $n = 12$ ): normal BN rats without any drug or operation; (2) syngeneic transplant group (SGT of BN-BN,  $n = 12$ ): both donors and recipients were BN rats; and (3) allogeneic transplant group (AGT of LEW-BN,  $n = 12$ ): Donors were Lewis and recipients were BN rats. In the AGT group, all recipients were subcutaneously injected by

Cyclosporin A after LT. Survival time was observed for 1 year. All the dying rats were sampled, biliary tract tissues were performed bacterial culture and liver tissues for histological study. Twenty-one day after LT, 8 rats were selected randomly in each group for sampling. Blood samples from caudal veins were collected for measurements of plasma endotoxin, cytokines and metabonomic analysis, and faeces were analyzed for intestinal microflora.

**RESULTS:** During the surgery of LT, no complications of blood vessels or bile duct happened, and all rats in each group were still alive in the next 2 wk. The long term observation revealed that a total of 8 rats in the SGT and AGT groups died of hepatic graft diseases, 5 rats in which died of chronic bile duct hyperplasia. Compared to the SGT and normal groups, survival ratio of rats significantly decreased in the AGT group ( $P < 0.01$ ). Moreover, liver necrosis, liver infection, and severe chronic bile duct hyperplasia were observed in the AGT group by H and E stain. On 21 d after LT, compared with the normal group ( $25.38 \pm 7.09$  ng/L) and SGT group ( $33.12 \pm 10.26$  ng/L), plasma endotoxin in the AGT group was remarkably increased ( $142.86 \pm 30.85$  ng/L) (both  $P < 0.01$ ). Plasma tumor necrosis factor- $\alpha$  and interleukin-6 were also significantly elevated in the AGT group ( $593.6 \pm 171.67$  pg/mL,  $323.8 \pm 68.30$  pg/mL) vs the normal ( $225.5 \pm 72.07$  pg/mL,  $114.6 \pm 36.67$  pg/mL) and SGT groups ( $321.3 \pm 88.47$  pg/mL,  $205.2 \pm 53.06$  pg/mL) ( $P < 0.01$ ). Furthermore, Bacterial cultures of bile duct tissues revealed that the rats close to death from the SGT and AGT groups were strongly positive, while those from the normal group were negative. The analysis of intestinal microflora was performed. Compared to the normal group ( $7.98 \pm 0.92$ ,  $8.90 \pm 1.44$ ) and SGT group ( $8.51 \pm 0.46$ ,  $9.43 \pm 0.69$ ), the numbers of *Enterococcus* and *Enterobacteria* in the AGT group ( $8.76 \pm 1.93$ ,  $10.18 \pm 1.64$ ) were significantly increased (both  $P < 0.01$ ). Meanwhile, compared to the normal group ( $9.62 \pm 1.60$ ,  $9.93 \pm 1.10$ ) and SGT group ( $8.95 \pm 0.04$ ,  $9.02 \pm 1.14$ ), the numbers of *Bifidobacterium* and *Lac-*

*tobacillus* in the AGT group ( $7.83 \pm 0.72$ ,  $8.87 \pm 0.13$ ) were remarkably reduced (both  $P < 0.01$ ). In addition, metabonomics analysis showed that metabolic profiles of plasma in rats in the AGT group were severe deviated from the normal and SGT groups.

**CONCLUSION:** Chronic bile duct hyperplasia is a pathological type of CGD following LT in rats. The mechanism of this kind of CGD is associated with the alterations of inflammation, intestinal barrier function and microflora as well as plasma metabolic profiles.

Chronic bile duct hyperplasia is a chronic graft dysfunction following liver transplantation. *World J Gastroenterol* 2012; 18(10): 1038-1047 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i10/1038.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i10.1038>

## INTRODUCTION

Liver transplantation (LT) has become an established therapy for various end-stage liver diseases for more than three decades<sup>[1-3]</sup>. Numerous advances in surgical technique, organ preservation, perioperative anesthesia, postoperative care, and clinical immunosuppression, as well as improved recipient selection and donor management have together significantly increased the survival rates of allograft and improved life quality of patients following LT<sup>[4]</sup>. Currently, approximately 90% of liver transplant patients are alive after 1 year and 75% after 5 years with majority living a full and near-normal life<sup>[3,5]</sup>. However, although early mortality rates after transplantation have fallen dramatically, long-term graft survival has barely improved over the last two decades<sup>[6,7]</sup>. That is to say, the incidence of chronic graft dysfunction (CGD) and the mortality of patients after LT have remained constant, and CGD has become the biggest obstacle for long-term function of allograft and better life quality of patients. Thus, it is essential to investigate the causes and relevant mechanisms of CGD to improve long-term outcomes of patients following LT.

In the early day after LT, common causes of hepatic allograft dysfunction include ischemia and reperfusion injury, infection, technical complications such as hepatic artery thrombosis and recipient diseases<sup>[3,5]</sup>. Thereafter the causes of allograft dysfunction are variable with dis-

ease recurrence and chronic rejection as major causes of graft loss<sup>[3,8]</sup>. Moreover, the biliary tract is still the most common site for postoperative complications. The importance of this condition lies in the fact that the biliary tract complications can be a serious source of morbidity and sometimes mortality<sup>[9,10]</sup>. These complications not only affect allograft survival but also have a major impact on the life quality for a hepatic allograft recipient.

However, so far little is known on biliary tract variation of CGD and its influential factors in recipients following LT. In this study, we want to explore hepatic graft pathology and the relevant mechanisms of CGD from aspects of inflammation, intestinal barrier function, intestinal microflora and metabonomics following LT.

## MATERIALS AND METHODS

### Animals

Specific pathogen-free (SPF) male inbred Lewis and BN rats (weight 220-250 g, 12-15 wk) were purchased from Beijing Vital River Laboratories (Beijing, China). All rats were housed in a SPF lab (Zhejiang Academy of Medical Sciences, China). The rats were caged in 21 °C, 12 h light/dark cycle, and fed with sterilized standard rat chow and water. All animals received humane care and the study was conducted according to the Guide for the Care and Use of Laboratory Animals (NIH publication No. 85-23, revised 1985).

### Experimental design

Sixty rats were raised in SPF animal facility. Twelve inbred BN rats were served as normal controls; 12 inbred Lewis and 12 inbred BN rats as donors; 24 inbred BN rats as recipients. All donors and recipients were randomly performed orthotopic LT under strict sterile conditions. The remaining 36 BN rats were divided into three groups: (1) normal group ( $n = 12$ ): normal BN rats without any drug or operation; (2) syngeneic transplant group (SGT of BN-BN,  $n = 12$ ): both donors and recipients were BN rats; and (3) allogeneic transplant group (AGT of LEW-BN,  $n = 12$ ): donors were Lewis and recipients were BN rats. In the AGT group, all recipients were subcutaneously injected by Cyclosporin A at 1 mg/kg daily in the first 30 d, and then at 2 mg/kg daily for the next 100 d after orthotopic LT. All the recipients in the SGT and AGT groups were received alanine (ALA) daily by gastric perfusion for preoperative 3 d and postoperative 130 d. Survival time was observed for 1 year.

### Surgery procedures

All rats were fasted for 12 h before the operation. The initial anesthesia of rats was performed by intraperitoneal injection of Ketamine Hydrochloride (100 mg/kg) and Atropine (1 mg/kg) (Shanghai No. 1 Biochemical and Pharmaceutical, China), and then ether was inhaled to maintain anesthesia. The profiles of rats with orthotopic LT were established according to the previous techniques<sup>[11,12]</sup>, with slight modifications. Briefly, after the

liver of the donor was dissociated, the graft was perfused with chilled saline containing 25 U/mL heparin *via* the portal vein, and then preserved in cold normal saline for no more than 1 h before being placed in the abdomen of recipient. After the anastomosis of suprahepatic vena cava and portal vein was finished, the graft was reperfused. The common bile duct was reconstructed by tying the duct over a stent. All recipients recovered in a short time, and no further treatment was performed.

### Sample collections

The survival conditions of rats were monitored continuously. When any rat was dying, the following samples were collected under strict sterile condition; the liver was fixed in 40 g/L neutral formaldehyde for later histological study and the biliary tract tissue for bacterial culture. Moreover, on 21 d after the surgery, biliary tract tissues of 4 rats selected randomly in the normal group were collected for bacterial culture. Eight rats were selected randomly in each group for sampling. Blood samples from the caudal veins were gained for measurements of plasma endotoxin, cytokines and analysis of ultra performance liquid chromatography-mass spectrometry (UPLC-MS), and faeces were collected for the determination of intestinal microflora.

### Graft histopathology

The sample from the left lobe of hepatic graft was fixed in 40 g/L neutral formaldehyde and embedded in paraffin, cut into 3  $\mu$ m slices, stained with hematoxylin and eosin (HE), and then observed under light microscopy by a pathologist.

### Plasma endotoxin and cytokines

The blood sample (100  $\mu$ L) was placed in the pyrogen-free heparin-containing tube, and then centrifuged at 3000 *g* for 15 min at 4 °C. Plasma endotoxin of the caudal vein was determined using a quantitative, chromogenic Limulus Amebocyte Lysate assay according to the manufacturer's instruction (Eihua Medical, Shanghai, China). The value was expressed as nanogram per liter of plasma (ng/L).

The levels of plasma tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) and interleukin-6 (IL-6) were tested with enzyme-linked immunosorbent assay (ELISA) (Groundwork Biotechnology Diagnostic Ltd, United States) according to the protocol of manufacturer. The result was expressed as ng/L.

### Bacterial culture and identification

Biliary tract tissues from the grafts were weighed and placed in a germ-free glass homogenizer containing a nine-fold amount of anaerobic buffer (phosphate buffered saline with 0.5 g cysteine HCl, 0.5 mL tween 80, and 0.5 g agar). They were homogenized and 50  $\mu$ L of 10% homogenate were placed on the agar base of Colombian culture medium within 30 min, incubated for 48 h at 37 °C. Bacterial colonies were evaluated qualitatively ac-

ording to their growth conditions respectively at the end of the culture. In addition, bacterial colonies from biliary tract tissues were identified by the Automatic analyzer of bacteria (Model Viger 60, France) to identify bacterial species according to the report<sup>[13]</sup>.

### Determination of intestinal microflora

Intestinal microflora was studied with 4 selected agar media according to the reports<sup>[14]</sup>. Samples from colorectal contents were placed in sterile tubes, weighed and transferred into other sterile tubes containing appropriate anaerobic buffer (as described above) to approach a 10-fold dilution of samples, and then serial decimal dilutions were taken in the same way from 10<sup>-2</sup> to 10<sup>-8</sup>. Within 30 min of sample collection, bacterial cultures were finished with placing 50  $\mu$ L dilutions on 4 agar media. According to the instructions, TPY agar medium, LBS agar medium, EC medium, and Eosin-Methylene Blue Agar (EMB) were used for Bifidobacterium, Lactobacillus, Enterococcus and Enterobacter, respectively. Anaerobic bacteria were incubated in Anaerobic Box System including AnaeroPack (MGC, Japan) and GENbox anaer (BioMérieux, France), and aerobic bacteria were incubated aerobically for 48 h at 37 °C, respectively. Bacterial colonies on every plate were counted and calculated at the primal weight of samples. The results were expressed as bacterial colony forming units per gram content (log<sub>10</sub> CFU/g).

### UPLC-MS analysis

Blood samples from caudal veins of rats were collected for metabonomics analysis according to the method of UPLC-MS described by Wang *et al.*<sup>[15]</sup> and Yang *et al.*<sup>[16]</sup>. Prior to analysis, blood samples were defrosted at room temperature and mixed with acetonitrile (ACN) at the ratio of 1:3 (v/v), the mixture was vortexed and centrifuged at 10 000 *g* for 10 min. The supernatant was transferred to sample bottles for UPLC separation. Chromatographic separations were performed at a 100 mm  $\times$  2.1 mm ACQUITY-1.7  $\mu$ m C18 column (Waters Co., Milford, United States) using an ACQUITY-Ultra Performance Liquid Chromatography system (Waters). Mass spectrometry was performed on a Premier-Q-ToF (Waters MS Technologies, Milford, United States).

### Partial least squares-discriminate analysis

The UPLC-MS data were analyzed with the SIMCA-P+ 12 Software (Umetrics, Sweden). An ApexTrack-peak detection algorithm was adopted in MarkerLynx V4.1 software (Waters, United States) to measure peaks and align retention times of the peaks for all chromatograms. The results were transferred into a single data matrix by aligning peaks with the same mass/retention time pair together from each data file in the dataset, along with their relevant intensities. The resulting dataset containing peak numbers (RT-m/z pair), sample names, and ion intensities was analyzed by partial least squares-discriminate analysis (PLS-DA) with the SIMCA-P+ 12 Software.

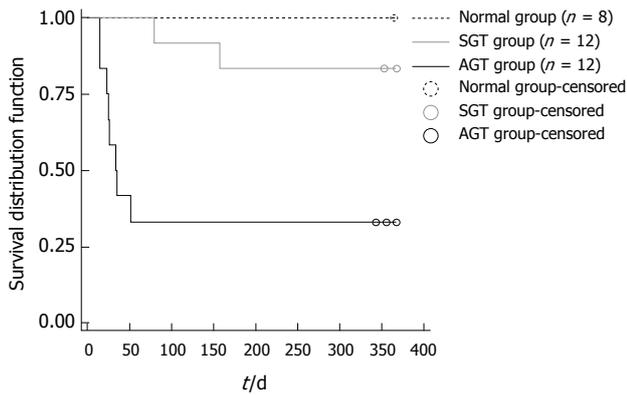

Figure 1 Kaplan-Meier survival curve in the different groups.

### Statistical analysis

All the data were presented as mean  $\pm$  SD. The survival distribution function was evaluated by the Kaplan-Meier survival curve and the others were determined using Students *T*-test. These analysis were performed with the statistical software SAS 9.1.3 (SAS Institute Inc., North Carolina State University, United States), and UPLC-MS data were analyzed by PLS-DA with the SIMCA-P+ 12 Software (Umetrics, Sweden). A *P*-value of less than 0.05 was considered statistically significant.

## RESULTS

During the surgery of LT, no complication of blood vessels or bile duct happened, and all rats in each group were still alive in the next 2 wk.

### Survival distribution function

The survival distribution function in each group was shown in Figure 1. A total 8 rats in the normal group were alive for more than one year. Two rats in the SGT group respectively died of hepatic necrosis and chronic bile duct hyperplasia on the 78th and 156th day post-operation. It was worth noting that a total of 8 rats in the AGT group were dead: two died of hepatic necrosis on the 25th and 26th day post-operation, respectively; two died of abdominal infection on the 15th and 23th day post-operation, respectively; the remaining 4 rats died of severe chronic bile duct hyperplasia on the 25th, 34th, 35th and 51th day post-operation, respectively. Compared to the rats in the SGT group and normal group, the survival ratio of rats significantly decreased in the AGT group ( $^aP < 0.01$ ,  $^bP < 0.001$ , respectively).

### Hepatic graft histopathology

As shown in Figure 2, the different characteristics of hepatic graft histology were observed in the rats of different groups. Under light microscope, rats' livers in the normal group showed the normal hepatic structure that the hepatocyte cords were presented the radial distribution around the central vein without the infiltration of inflammatory cells (Figure 2A). The rat dead of chronic

bile duct hyperplasia in the SGT group showed special pathological features that the proliferative epithelial cells of bile duct invaded into the hepatic parenchyma without lymphocyte infiltration (Figure 2B). However, the dead rats in the AGT group were presented unique pathological structures, including liver necrosis, liver infection, and severe chronic bile duct hyperplasia. Specifically, liver necrosis was presented the extensive destruction of hepatic structure, and the necrosis of lots of hepatocytes (Figure 2C). Liver infection was described as the destruction of hepatic structure, the excessive proliferation of ectogenic bacteria, and the infiltration of lots of inflammatory cells (Figure 2D). And severe chronic bile duct hyperplasia was expressed by some special points that the proliferative epithelial cells of bile duct extensively invaded into the hepatic parenchyma, and bile duct lumen was significantly extended with the destruction of hepatic structure (Figure 2E).

### Plasma endotoxin and cytokines

Plasma endotoxin, as a critical medium to aggravate graft injury, is a vital stimulus of CGD following allogeneic LT. As showed in Figure 3, there was no significant difference in plasma endotoxin between the normal group ( $25.38 \pm 7.09$  ng/L) and SGT group ( $33.12 \pm 10.26$  ng/L). By contrast, plasma level of endotoxin in the AGT group was remarkably increased ( $142.86 \pm 30.85$  ng/L) *vs* the other two groups ( $P < 0.01$ ).

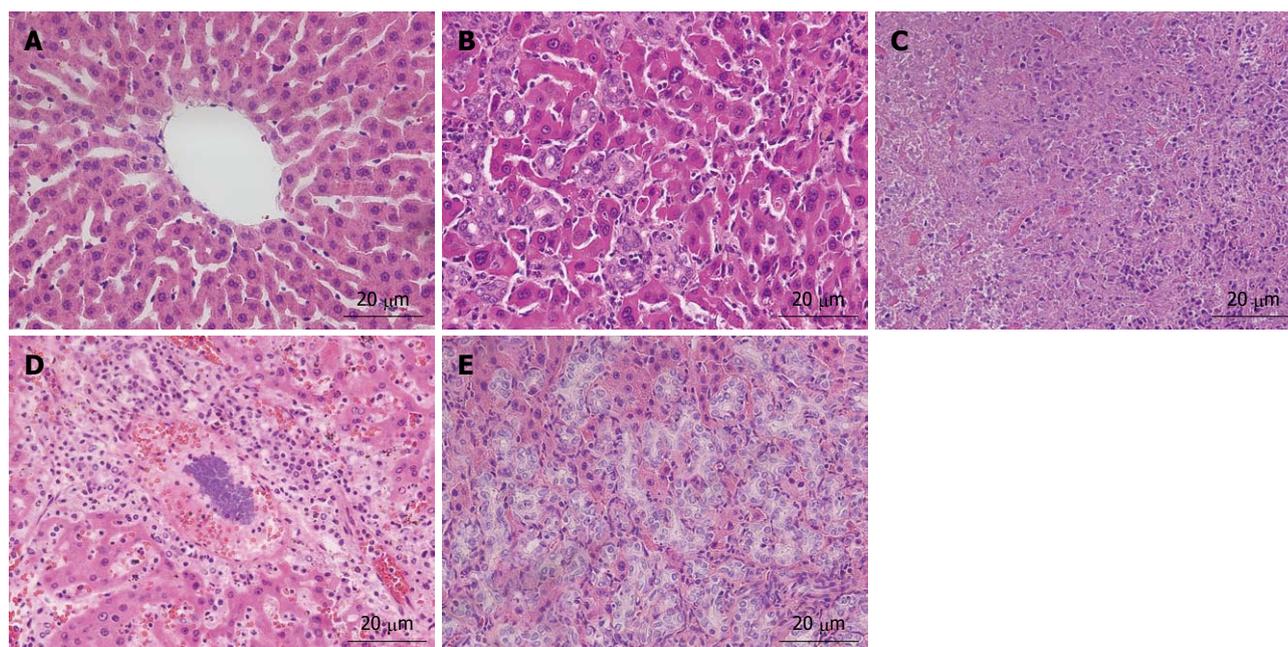

Both TNF- $\alpha$  and IL-6 are important pro-inflammatory cytokines and can directly or indirectly cause graft injury and CGD of recipients after LT. As shown in Figure 3 (pg/mL), compared to the normal group ( $225.5 \pm 72.07$  ng/L,  $114.6 \pm 36.67$  ng/L) and SGT group ( $321.3 \pm 88.47$  ng/L,  $205.2 \pm 53.06$  ng/L), the levels of plasma TNF- $\alpha$  and IL-6 were significantly elevated in the AGT group ( $593.6 \pm 171.67$  ng/L,  $323.8 \pm 68.30$  ng/L) ( $P < 0.01$ ). In addition, plasma levels of both TNF- $\alpha$  and IL-6 in the SGT group were also increased *vs* those in the normal group ( $^aP < 0.05$ ,  $^bP < 0.01$ , respectively).

### Bacterial culture and identification

Bacterial translocation may participate in some physiological and pathological procedures when recipient suffers from CGD. Samples from biliary duct tissues of hepatic graft were cultured and results were summarized in Table 1. There was rare bacterial colony in the 4 rats from the normal group, while bacterial culture of samples from the SGT and AGT groups were strongly positive. Bacterial identification revealed significantly increased aerobic bacteria, such as *Escherichia coli* and *Enterococcus* in the groups of LT. Moreover, *Protens vulgaris*, *Streptococcus agalactiae* and *Protens mirabilis* presented remarkably positive in the AGT group, which suggested that more kinds of bacteria translocated to biliary duct tissues when recipients suffered from CGD following allogeneic LT.

### Intestinal microflora

To determine the alterations of intestinal microflora when recipients suffered from CGD after LT, bacterial

**Figure 2** Light micrograph of hepatic histopathology stained with hematoxylin and eosin (HE, × 400). A: The normal group showed the normal hepatic structure; B: The SGT group revealed the chronic bile duct hyperplasia; C: The AGT group presented hepatic graft necrosis; D: The AGT group showed the infectious hepatic graft; E: The AGT group emerged severe chronic bile duct hyperplasia.

**Table 1** Bacterial culture of biliary duct tissues from hepatic graft in the different groups

Bacterial species	SGT group (n = 2)	AGT group (n = 8)
<i>Escherichia coli</i>	2/2	8/8
<i>Enterococcus</i>	2/2	8/8
<i>Staphylococcus aureus</i>	1/2	0/8
<i>Proteus vulgaris</i>	0/2	8/8
<i>Streptococcus agalactiae</i>	0/2	6/8
<i>Proteus mirabilis</i>	0/2	5/8

There is rare bacterial colony in the normal group (n = 4). SGT group (n = 2): Syngeneic transplant of BN-BN rats; AGT group (n = 8): Allogeneic transplant of LEW-BN rats.

**Table 2** Bacterial counts of colorectal contents in the different groups (log<sub>10</sub> CFU/g, mean ± SD)

Group	Normal group	SGT group	AGT group
<i>Enterococcus</i>	7.98 ± 0.92	8.51 ± 0.46	8.76 ± 1.93 <sup>a,d</sup>
<i>Enterobacteria</i>	8.90 ± 1.44	9.43 ± 0.69	10.18 ± 1.64 <sup>a,d</sup>
<i>Bifidobacterium</i>	9.62 ± 1.60	8.95 ± 0.04	7.83 ± 0.72 <sup>a,d</sup>
<i>Lactobacillus</i>	9.93 ± 1.10	9.02 ± 1.14	8.87 ± 0.13 <sup>a,d</sup>

CFU/g: Colony-forming unit per gram colorectal content; Normal group (n = 8): Normal BN rats without any drug or operations; SGT group (n = 8): Syngeneic transplant of BN-BN rats; AGT group (n = 8): Allogeneic transplant of LEW-BN rats. <sup>a</sup>P < 0.05 vs SGT group; <sup>d</sup>P < 0.01 vs normal group.

species and numbers in colorectal contents were analyzed. As shown in Table 2, compared to the normal group (7.98 ± 0.92, 8.90 ± 1.44) and SGT group (8.51 ± 0.46, 9.43 ± 0.69), the numbers of *Enterococcus* and *Enterobacteria* in the AGT group (8.76 ± 1.93, 10.18 ± 1.64) were significantly

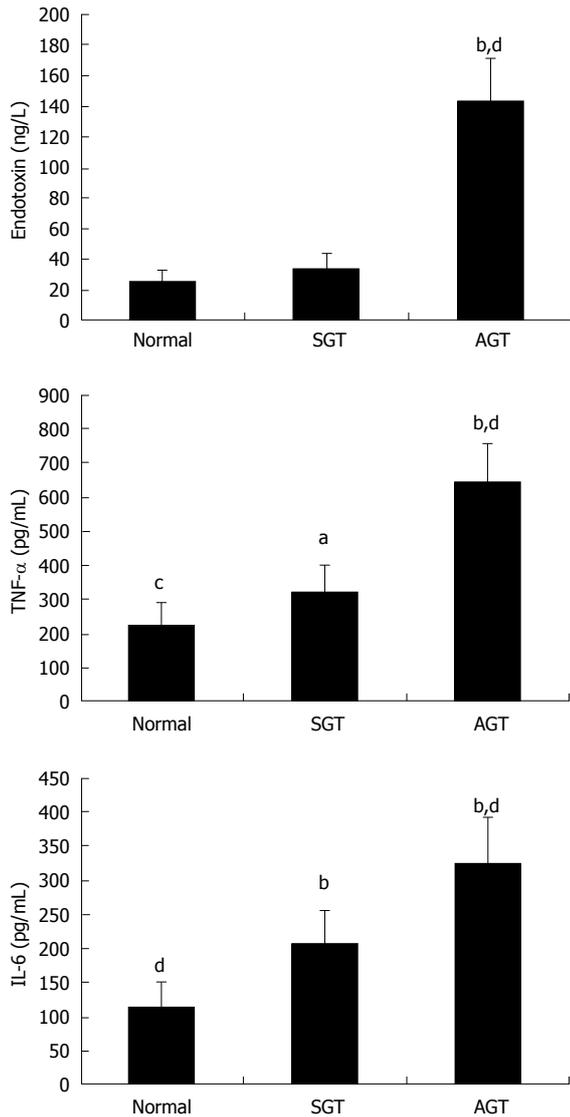

increased (both <sup>a</sup>P < 0.01, <sup>b</sup>P < 0.05, respectively). Meanwhile, compared to the normal group (9.62 ± 1.60, 9.93 ± 1.10) and SGT group (8.95 ± 0.04, 9.02 ± 1.14), the numbers of *Bifidobacterium* and *Lactobacillus* in the AGT group (7.83 ± 0.72, 8.87 ± 0.13) were remarkably reduced (both <sup>a</sup>P < 0.01, <sup>b</sup>P < 0.05, respectively). There were no statistical differences in bacterial species and counts between the normal group and the SGT group.

### UPLC-MS analysis and PLS-DA

In order to analyze the interactions between metabolic profile and CGD, caudal vein plasma was collected to perform metabonomics analysis by the method of UPLC-MS and PLS-DA. As shown in Figures 4-6, the metabolic profiles of plasma in rats from the SGT and AGT groups were deviated from those of the normal group gradually. We also found that metabolic alterations were more severely deviated in the AGT group vs the normal group, which suggested that the degree of metabolic change was positively associated with the severity of CGD in recipients following LT.

## DISCUSSION

Organ transplantation has become the radical method for treatment of many end-stage organic diseases<sup>[17,18]</sup>. Since the early experiences of the 1960s, liver transplant surgery has evolved over the decades and is now the standard of care in patients with end-stage liver diseases<sup>[19-21]</sup>. Although there has been consistent improvement in the overall survival rates for transplant recipients, organ shortages and CGD are still two major problems which hinder the development of organ transplantation.

**Figure 3** Plasma levels of endotoxin, tumor necrosis factor- $\alpha$ , and interleukin-6 in the different groups on the 21th day after liver transplantation. Normal group ( $n = 8$ ); SGT group ( $n = 8$ ); AGT group ( $n = 8$ ). <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs Normal group, respectively; <sup>c</sup> $P < 0.05$ , <sup>d</sup> $P < 0.01$  vs SGT group, respectively;  $P$  not significant in the remaining parameters. TNF- $\alpha$ : Tumor necrosis factor- $\alpha$ ; IL-6: Interleukin-6.

In general, chronic hepatic allograft dysfunction is defined as the declining of hepatic graft function irreversibly and gradually, expressed by increasing or persistent elevations in serum levels of alanine aminotransferase, alkaline phosphatase, or bilirubin (greater than two times the upper limit of normal)<sup>[5]</sup>. Chronic hepatic allograft dysfunction may result from a variety of causes including rejection<sup>[8]</sup>, vascular stenosis/thrombosis, *de novo* or recurrent infection, biliary complications<sup>[19]</sup> including stricture or stenosis, recurrent disease related to autoimmune mechanisms such as that seen in primary biliary cirrhosis, primary sclerosing cholangitis, and autoimmune chronic active hepatitis<sup>[5]</sup>. In addition, drug hepatotoxicity and the development of neoplasms such as a posttransplant lymphoproliferative disorder or the recurrences of hepatocellular carcinoma are important considerations<sup>[3]</sup>.

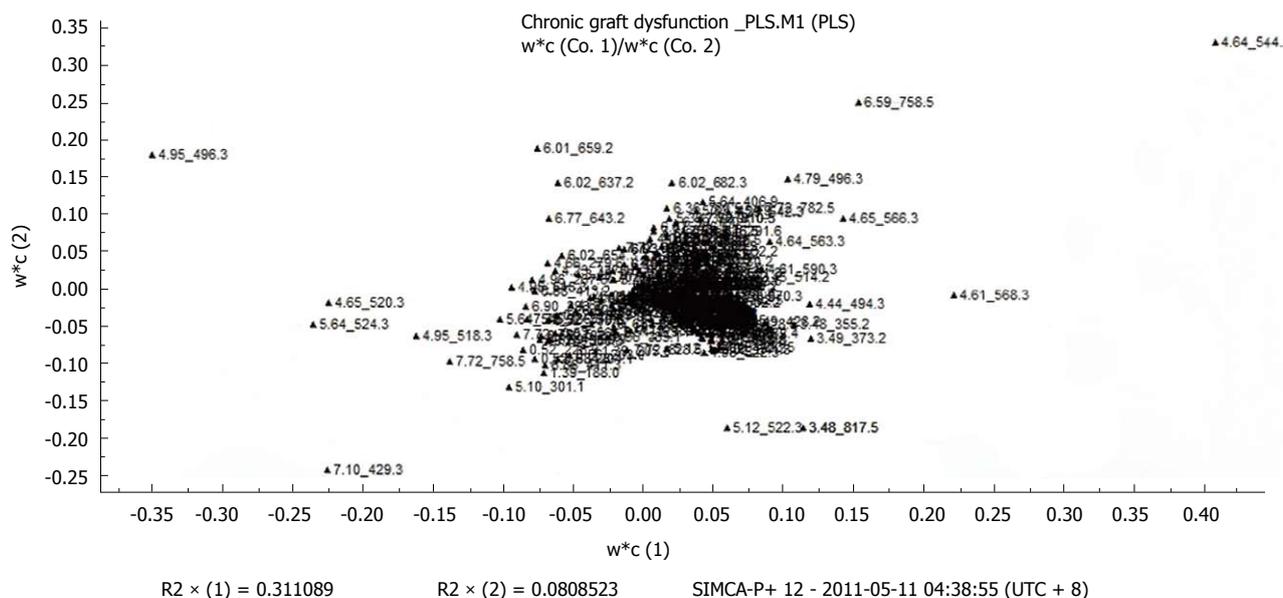

With the efforts in recent decades, survival after LT is 90% at 1 year and approximately 75% at 5 years<sup>[5]</sup>. However, biliary tract complications are still the “Achilles heel” of LT<sup>[22,23]</sup>. Despite great improvements in the surgical techniques and standardization of the method of biliary reconstruction, the biliary tract is still the most common site for postoperative complications. So far little is known about alterations of biliary tract when recipients suffer from CGD following LT. Thus, it has been indispensable to explore changes of biliary tract and relevant mechanisms of CGD to improve survival conditions of recipients following LT for a long time.

In our study, no rats died within 2 wk after LT since applications of immunosuppressants and sterile surgery in SPF-class laboratory. Life span of human is usually 60-90 years, while life expectancy of rats typically is 2-3 years, so we can define CGD of rats as loss of graft function after about one month post-operation. During the whole process of observation, a total of 8 rats in the LT groups died of hepatic graft diseases, such as partial hepatic necrosis and chronic bile duct hyperplasia, and the other 2 rats died of abdominal infection. Notably, 5 rats in these 8 rats that died of hepatic graft diseases died of chronic bile duct hyperplasia, which accounted for 5/8 (62.5%). We concluded that chronic bile duct hyperplasia was a pathological type of CGD and its occurrence frequency was closely associated with the causes of CGD following LT. This finding is consistent with the reports<sup>[24]</sup> that bile duct hyperplasia extending progressively is a pathology finding in a profile of auxiliary LT with portal vein arterialization in pigs.

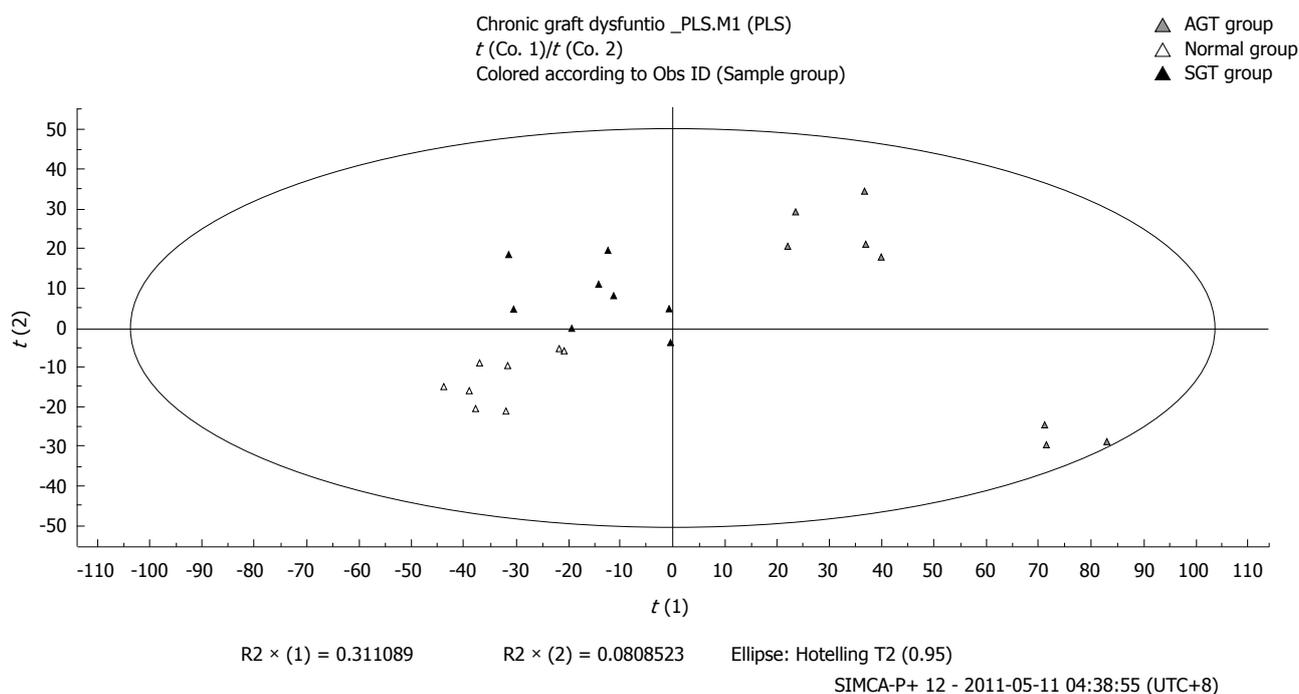

In order to explore influential factors and possible mechanisms of chronic bile duct hyperplasia, as a special type of CGD following LT, we further investigated alterations of serum endotoxin and cytokines, bacterial translocation, intestinal microflora, and metabolic profile in the different groups.

Endotoxin, which mainly originated from non-viable intestinal gram-negative bacteria, is a crucial medium to aggravate hepatic graft injury<sup>[25]</sup>. Plasma level of endotoxin not only can reflect intestinal barrier function<sup>[26]</sup>, but also can predict the defensive ability of body and the injury degree of hepatic graft. Our research found that plasma level of endotoxin in the AGT group remarkably increased compared to the other two groups, which suggested that intestinal barrier function was destroyed when recipients suffered from CGD following LT. Meanwhile, we also speculated that the elevation of plasma endotoxin was closely associated with the occurrence of CGD after LT in rats.

Inflammation plays a vital role in the progression of liver injury<sup>[27]</sup>. TNF- $\alpha$  and IL-6 are important proinflammatory mediators and can directly, or by inducing inflammatory cascades and enhancing the microvascular dysfunction of liver and intestine, aggravate the injury of hepatic graft<sup>[28]</sup>. Inflammatory mediators such as TNF- $\alpha$ , interferon- $\gamma$  (INF- $\gamma$ ) and interleukin (IL) have cytotoxicity, thus being considered as effectors of liver injury. Our results revealed that plasma levels of cytokines gradually

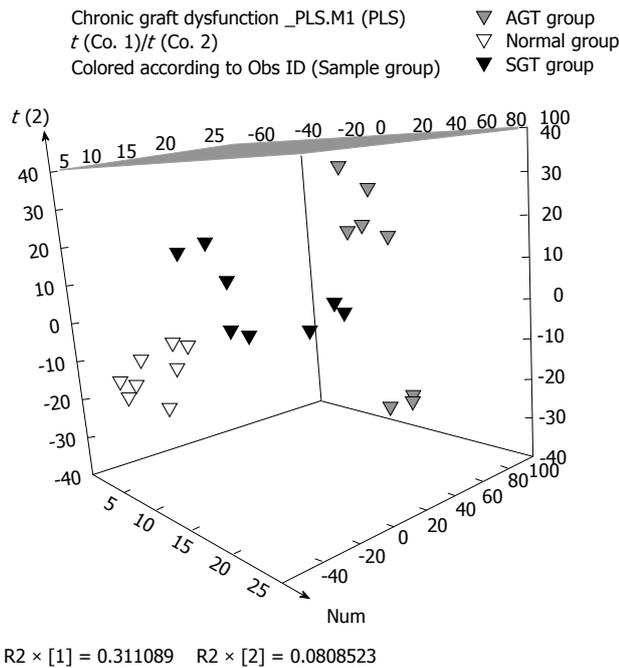

**Figure 4** Loading plot of all the different plasma samples. The marked numbers beside the points were the corresponding retention time and the mass-to-charge ratio (m/z) of each possible biomarkers.

**Figure 5** The partial least squares-discriminate analysis scores plot of the different groups. According to this plot, the metabolic profiles of the SGT and AGT groups deviated from those of the normal group gradually.

increased from the rats in the normal group to those in the syngeneic transplant group, and even to those in the allogeneic transplant group, suggesting that inflammatory reaction was positively associated with the severity of CGD in recipients. Thus, our findings support the concept that inflammation may be a component of the pathogenesis of CGD, which is in line with the report on inflammation and graft deterioration by Dahle *et al*<sup>[29]</sup>. However, the exact pathogenetic role of inflammatory cytokines in graft failure is still elusive.

Under certain conditions, the original bacteria in the intestine would cross a relatively complete intestinal epithelium to reach the sites of MLN, abdominal internal and external organs (such as liver, spleen and lung) as well as blood, and may cause the occurrence of infection, which is called “bacterial translocation”<sup>[30]</sup>. Normally, a small amount of bacteria and endotoxin can go through the intestinal wall, which may be associated with the maintenance of normal intestinal immune response and the activity of reticuloendothelial system<sup>[31,32]</sup>. In gen-

**Figure 6** The three-dimensional partial least squares-discriminate analysis scores plot of the different groups. According to this three-dimensional plot, the metabolic profiles of the AGT groups deviated more than those of the SGT group from those of the normal group. PLS: Partial least squares.

eral, three factors mainly attributed to the occurrence of BT: the destruction of intestinal barrier, the imbalance of intestinal microflora, and the reduction of immune defense<sup>[33]</sup>. There was rare bacterial growth in culture medium of biliary duct in the normal group, while bacterial counts significantly elevated in the AGT group. Bacterial identification mainly designated aerobic bacteria, including *Escherichia coli*, *Enterococcus*, *Protens vulgaris*, *Streptococcus agalactiae* and *Protens mirabilis*. This result suggested bacterial translocation occurred in recipients after LT under immunosuppression, which might aggravate the severity of CGD in some extent.

The commensal bacteria living in the human intestine play a pivotal role in the maintenance of intestinal homeostasis in their host<sup>[34]</sup>. The normal formation of intestinal microflora contributes not only to the prevention of enteritis caused by pathogens but also to immunological development and preservation<sup>[35]</sup>. Under physiological circumstances, intestinal bacteria keep an ecological balance of intestinal microflora. Many researches have indicated that some extrinsic factors, such as administration of abdominal surgery<sup>[36]</sup>, hepatic I/R injury<sup>[14]</sup>, gastrointestinal disorders<sup>[37]</sup> and LT<sup>[25]</sup>, can cause the imbalance of intestinal microflora. Our results also indicated that the imbalance of intestinal microflora was expressed by an increase in *Enterococcus* and *Enterobacteria*, and a reduction in *Bifidobacterium* and *Lactobacillus*, when recipients suffered from severe CGD in allogeneic transplant group. Thereafter we may speculate that the occurrence of CGD has some correlations with intestinal microflora.

In addition, we performed metabolomics analysis of

plasma in recipients following LT. As a system analysis approach, metabolomics can provide comprehensive information on the dynamic process of postoperative physiopathological development<sup>[15]</sup>. The systemic detection of chronic diseases can be obtained with metabolomics at an earlier stage compared to the clinical chemistry and histopathological assessment<sup>[15]</sup>. Our results on metabolomics analysis revealed that the metabolic profile of plasma gradually deviated from the normal parameters, from the rats in the syngeneic transplant group to those in the allogeneic transplant group. To some extent, this finding suggested that the mechanism of CGD might be explained by the alterations of plasma metabolic profile in recipients following LT. However, further exploration need to be taken for the accurate relationship between metabolic changes and CGD of recipients following LT.

In conclusion, according to the observation of one year for recipients following LT in rats, we have found that chronic bile duct hyperplasia is a pathological type of CGD following LT. The mechanism of this kind of CGD is associated with the alterations of inflammation, intestinal barrier function, intestinal microflora, and plasma metabolic profile, which will be the possible therapeutic targets for LT.

## ACKNOWLEDGMENTS

We wish to thank Dr. Xin-Hua Chen for her critical assessment of the manuscript, Dr. Wei Xu, Dr. Qing Xie, Ms. De-Ying Chen, and Dr. Jiang-Shan Lian for their help in the technique of UPLC-MS analysis and PLS-DA. We also thank Prof. Da Yu, Mr. Xiao-Ying Sa, Mr. Xian-Fu Ke, Mr. Qi Lou, Mr. Li Jiang, Mr. Yong He, and Ms. Qiao-Juan Shi for their help with the experiment.

## COMMENTS

### Background

Although early mortality rates after liver transplantation (LT) have fallen dramatically, the paradox is that long-term graft survival has barely improved over the last two decades. Chronic graft dysfunction (CGD) has become the biggest obstacle for long-term function of allograft and better life quality of patients. The biliary tract is still the most common site for postoperative complications. These complications not only affect allograft survival, but also have a major impact on the life quality for a hepatic allograft recipient.

### Research frontiers

So far little is known on biliary tract variation of CGD and its influential factors in recipients following LT. In our experimental study, according to the observation of one year for recipients following LT, we have found that chronic bile duct hyperplasia is a pathological type of CGD following LT. The mechanism of this kind of CGD is associated with the alterations of inflammation, intestinal barrier function, intestinal microflora and plasma metabolic profile.

### Innovations and breakthroughs

Chronic hepatic allograft dysfunction may result from a variety of causes including rejection, vascular stenosis/thrombosis, *de novo* or recurrent infection, recurrent disease related to autoimmune mechanisms such as that seen in primary biliary cirrhosis, primary sclerosing cholangitis, and autoimmune chronic active hepatitis. However, So far little is known about alterations of biliary tract when recipients suffer from CGD following LT. Through one-year observation of recipients following LT, we found that chronic bile duct hyperplasia is a pathological type of CGD following LT. Meanwhile, we elaborated the influential factors of this kind of CGD mainly including inflammatory response, intestinal

barrier function, intestinal microflora, and plasma metabolic profile. Furthermore, through the technique of ultra performance liquid chromatography-mass spectrometry analysis and partial least squares-discriminate analysis (PLS-DA), we explored the plasma metabolomics alterations during the period of CGD after LT, and indicated the relevance between plasma metabolomics and CGD after LT in rats.

### Applications

This study provides the experimental data for the research of CGD after organ transplantation in rats, and indicated that chronic bile duct hyperplasia is a kind of CGD following LT in rats. The relative influence factors will be the possible therapeutic targets to prevent or alleviate CGD after LT.

### Terminology

Chronic hepatic allograft dysfunction is defined as the declining of hepatic graft function irreversibly and gradually, expressed by increasing or persistent elevations in serum levels of alanine aminotransferase, alkaline phosphatase, or bilirubin (greater than two times the upper limit of normal). PLS-DA is a statistical method that can grasp the principal contradiction from the complexity, and thereby simplify something complexity, which can generate models that are tightly focused on the effects of interest.

### Peer review

This is a well designed experimental report on chronic allograft dysfunction after LT. The topic is of some interest due to the prolonged survival now being constantly achieved after LT. The authors described chronic bile duct hyperplasia as a type of chronic allograft dysfunction associated to inflammation of the intestinal mucosa

### Abstract

**AIM:** To compare the influence of different transplant sites in bone marrow mesenchymal stem cell (MSC)-based therapy for liver fibrosis.

**METHODS:** MSCs isolated from Sprague Dawley (SD) rats were induced into hepatocyte-like cells. Liver fibrosis in SD rats was induced with carbon tetrachloride. Following hepatocyte induction *in vitro*, 4',6-diamidino-2-phenylindole (DAPI)-labeled MSCs were transplanted by intravenous, intrahepatic, and intraperitoneal injection. Histopathological staining, immunohistochemistry, and biochemical analysis were used to compare the morphological and functional liver regeneration among different MSC injection modalities. The expression differences of interleukins, growth factor, extracellular matrix, matrix metalloproteinases, and tissue inhibitor of metalloproteinase were examined by real-time reverse transcription-polymerase chain reaction (RT-PCR) and

enzyme linked immunosorbent assay (ELISA).

**RESULTS:** Four days after exposure to hepatocyte differentiation medium, MSCs that did not express hepatocyte markers could express  $\alpha$ -fetoprotein, albumin, and cytokeratin 18. The results of histopathological staining, immunohistochemistry, and biochemical analysis indicated that intravenous injection is more effective at rescuing liver failure than other injection modalities. DAPI-labeled cells were found around liver lobules in all three injection site groups, but the intravenous group had the highest number of cells. PCR and ELISA analysis indicated that interleukin-10 (IL-10) was highest in the intravenous group, whereas *il1 $\beta$* , *il6*, *tnf $\alpha$*  and *tgf $\beta$* , which can be regulated by IL10 and are promoters of liver fibrosis, were significantly lower than in the other groups.

**CONCLUSION:** MSC administration is able to protect against liver fibrosis. Intravenous injection is the most favorable treatment modality through promotion of IL10 expression.

## INTRODUCTION

Liver injury caused by chemical damage or viral infection often leads to liver fibrosis, which can lead to an impairment of liver function that requires medical intervention<sup>[1,2]</sup>. Although liver transplantation is by far the most effective treatment for liver cirrhosis, extensive clinical application of the technique is limited by the lack of donor organ availability<sup>[3]</sup>. Thus, it is very important to investigate different treatments and therapies for cirrhosis. Cell-based hepatocyte transplantation, a potential interventional procedure, provides an effective strategy and holds great promise for the treatment of impaired livers<sup>[4]</sup>. When compared to orthotopic liver transplantation, cell transplantation has the advantages of lower cost, lower risk, and a simpler procedure<sup>[5]</sup>. A single donor could serve multiple recipients, and excess cells could be cryopreserved for future use. However, the type of hepatocyte necessary for transplantation is less common in mature liver cells because of the paucity of cadaveric livers. Furthermore, with hepatocytes cultured *in vitro*, it is difficult to obtain mature and intact hepatocytes<sup>[6]</sup>. Thus, it is very important to investigate alternative, appropriate therapies for liver cirrhosis.

Mesenchymal stem cells (MSCs) are adherent, fibroblast-like, pluripotent and non-hematopoietic progenitor cells. They have been found to reside in most organs and tissues investigated to date, including bone marrow, adipose, dermis, muscular tissue, hair follicles, the periodontal ligament and the placenta. Previous studies<sup>[7,8]</sup> have demonstrated that MSCs can be differentiated into osteogenic, chondrogenic, adipogenic, myogenic, cardiomyogenic, and hematopoietic potential stromal cells. Moreover, apart from their differentiative abilities, MSCs play a supportive role in organ regeneration processes. In addition, several studies<sup>[9]</sup> have suggested that the use of MSCs *in vivo* should be safer than that of embryonic stem cells due to their higher chromosomal stability and lower tendency to form neoplasms in the recipient host. These reports indicate that MSCs are an attractive cell source for regenerative medicine.

A large number of *in vitro* studies indicate that bone marrow-derived MSCs can express the liver-specific marker  $\alpha$ -fetoprotein (AFP), cytokeratin 18 (CK18), and albumin. In addition, they can be involved in urea production, show liver-specific functions of cytochrome P450 activity, and store glycogen when co-cultured with adult liver cells or cultured in the presence of cytokines, such as fibroblast growth factor and hepatocyte growth factor<sup>[10,11]</sup>. The functional hepatocyte-like cells derived from MSCs might serve as cell sources for liver-targeted cell therapy<sup>[12]</sup>.

Hematopoietic stem cells (HSCs), another type of bone marrow-derived stem cell, also have multi-potent differentiation capabilities. The transplantation of HSCs can act as a substitute for hepatocyte transplantation in a murine model of tyrosinemia, and HSC transplantation can correct this metabolic liver disease<sup>[13,14]</sup>. However, the fusion process of hematopoietic stem cells with hepatocytes and the difficulty in maintaining hematopoi-

etic stem cells hamper their wide application to human disease treatment<sup>[15,16]</sup>. Sato *et al.*<sup>[17]</sup> examined the ability of fractionated human bone marrow-component MSCs to differentiate into hepatocytes *in vivo* by directly inoculating the cells into rat livers that had sustained chronic damage from alcohol treatment. Their results indicated that MSCs had a great ability to differentiate into hepatocytes without any evidence of fusion.

Besides treating acutely damaged tissue, MSCs also have the potential to reduce chronic fibrogenesis through the modulation of inflammation, collagen deposition, and remodeling. Although numerous studies have reported that bone marrow (BM)-derived MSCs can reduce carbon tetrachloride (CCl<sub>4</sub>)-induced liver fibrosis in mice, the mechanism by which MSCs repair the fibrosis is unclear, and the results are controversial<sup>[18-23]</sup>. For therapeutic applications, it will be important to understand the potency and possible repair mechanisms of MSCs. In the present study, we aimed to find and compare the best therapeutic effects among three different protocols of MSC engraftment (intraperitoneal, intravenous and intrahepatic transplantation) to treat CCl<sub>4</sub>-induced liver injury, as well as to elucidate the mechanisms that explain the differences between the effects of the cell transplant site.

## MATERIALS AND METHODS

### Isolation and culture of MSCs

MSCs were prepared from rat bone marrow as described previously. In brief, whole BM was flushed from the tibia and femur of Sprague Dawley (SD) rats (six-week-old males); cultured in Dulbecco's Modified Eagle's medium (DMEM) supplemented with 10% fetal calf serum, 1% penicillin/streptomycin, 2 mmol/L L-glutamine; and purified for up to five passages. MSCs were grown to confluency before being detached by trypsin/ethylenediaminetetraacetic acid treatment. After detachment, cells were incubated with four phycoerythrin-conjugated antibodies: CD34, a hematopoietic progenitor marker; CD45, a leukocyte marker; CD90, which is also known as Thy-1; and/or CD29. Fluorescence-activated cell sorting was performed on at least 10 000 cells/sample using Cell Quest software (Beckman Coulter).

### Hepatocyte differentiation

Hepatic transplantation was performed as previously described<sup>[12]</sup>. Briefly, the cultured cells were harvested from the culture bottles with 0.25 g/L trypsin. Cultured cells at passage 3 were seeded in six-well cell culture plates. When the cells grew to 70% confluence, the control group was continuously cultured in DMEM supplemented with 10 mL/L fetal bovine serum (FBS), 100 U/mL penicillin, and 100 U/mL streptomycin. The hepatocyte differentiation group was cultured in  $\alpha$ -MEM supplemented with 10 mL/L FBS, 20 ng/mL hepatocyte growth factor (HGF), 20 ng/mL fibroblast growth factor (FGF)-4, 20 ng/mL epidermal growth factor (EGF), 100 U/mL penicillin and 100 U/mL streptomycin. each well, 2 mL of medium was added and changed every 4 d. The medium was stored at -20 °C until the albumin, AFP and urea assays were conducted. To determine the cell phenotype, the cultured cells were stained by anti-AFP and albumin (ALB) protein monoclonal antibodies according to the manufacturer's protocol<sup>[17]</sup>.

### CCl<sub>4</sub>-induced rat liver injury model

To establish the liver-damaged rat model, 0.5 mL/kg CCl<sub>4</sub> was injected subcutaneously into adult male SD rats (320 ± 20 g) twice a week for 4 wk. Control ("normal") animals were injected with the same volume of normal saline. The extent of hepatic damage was evaluated by biochemical analysis of blood samples and histopathological examination of liver tissue samples taken from sacrificed rats.

### Cell transplantation

For *in vivo* tracking of transplanted cells, MSCs from the SD rats were labeled with 4,6-diamidino-2-phenylindole (DAPI). Forty-five rats that suffered liver injury induced by CCl<sub>4</sub> were classified into three groups: intraperitoneal transplantation, intravenous transplantation, and intrahepatic transplantation. Each group's hepatocyte differentiated-MSCs were resuspended in 0.1 mol/L phosphate buffer solution (PBS) at a concentration of 10<sup>7</sup> cells/mL, and every rat was injected with 300 μL. Rats were sacrificed

at 28 d post-implantation. At that time, liver tissues and blood were obtained for analysis.

### Reverse transcription polymerase chain reaction and real-time polymerase chain reaction analysis

Total RNA was prepared using the RNeasy total RNA isolation kit (Invitrogen, United States). For cDNA synthesis, random hexamer primers (Invitrogen, United States) were used to prime reverse transcriptase reactions. The cDNA synthesis was carried out using Moloney-murine leukemia virus Superscript II reverse transcriptase (TaKaRa, Japan) following the manufacturer's instructions. For the semiquantitative polymerase chain reaction (PCR) detection of AFP, ALB, and CK18, 5 μL of cDNA-template was mixed with 2.5 μL of 10× PCR buffer, 0.5 μL of 10 mmol/L dNTPs, 0.5 μL of each primer (50 ng/μL), and 0.5 μL of polymerase (TaKaRa, Japan) in a total volume of 25 μL for each probe. PCR was performed in a programmable Biometra Uno-Thermobloc (Biometra, Germany). All samples were analyzed on 1% agarose gels. The size of the PCR fragments was estimated using a 100-base-pair ladder.

At three days post-MSC transplantation, quantitative PCR was carried out using standard protocols with the Quantitec SYBR Green PCR Kit (TaKaRa, Japan). The PCR mix contained SYBR Green Mix, 0.5 μmol/L primers (Table 1), 1 ng of DNA template and nuclease-free water to a final volume of 25 μL. PCR was performed in an ABI Prism 7000 Detection System (Applied Biosystems, United States). The percentage of gene expression was normalized as a function of *GAPDH* gene expression. Oligonucleotide primers for real-time PCR were obtained from TaKaRa (Japan), including matrix metalloproteinases (*mmp*2, *mmp*9), tissue inhibitor of metalloproteinase (*timp*1), *hgf*, *pdgf*, *il1β*, *il2*, *il6*, *il10*, *il13*, *infγ*, *tnfα* and *tgfb1*. Primer sequences are shown in Table 1.

### Biochemical analysis

Biochemical parameters including albumin, total bilirubin in serum (TBIL), and alanine aminotransferase (ALT) were analyzed with a biochemical analyzer (Roche Integra 800, Holliston, United States).

### Histopathological analysis and immunohistochemistry

At the time of sacrifice, liver tissue samples were collected and fixed in 3.7% formaldehyde for two days. Tissues were then dehydrated, cleared, and infiltrated with a histoprocessor for 16 h. Serial 3-μm sections were hematoxylin and eosin (HE) and Van Gieson's (VG) stained for histopathological analysis. For HE analysis, sectioned samples were stained with hematoxylin solution (Sigma-Aldrich, Germany) for 5 min followed by eosin for 5 min. For the VG stain, the sectioned samples were placed in hematoxylin solution for 5 min following a 10-min water wash, stained in VG (Biyuntian, China) solution for 3 min, and dehydrated in succession with 85%, 95% and 100% ethanol for 3 min.

Immunohistochemical staining was performed according to a previously reported method to evaluate

certain markers including alpha-smooth muscle actin ( $\alpha$ -SMA). After paraffin removal and microwave-based antigen retrieval, the sections were treated with 0.3% H<sub>2</sub>O<sub>2</sub> in PBS to quench endogenous peroxidase activity and then incubated with 5% goat serum to block the non-specific sites.  $\alpha$ -SMA (1:100) mAb was applied and incubated at 4 °C overnight (PBS was used as the negative control), followed by incubation with peroxidase-conjugated AffiniPure goat anti-mouse secondary antibody (Zhongshan Goldbridge, China) at 37 °C for 30 min. The specimens were then incubated with diaminobenzidine peroxidase substrate to obtain a brown stain and then subsequently counterstained with hematoxylin.

### Enzyme linked immunosorbent assay

Blood of the MSC- and CCl<sub>4</sub>-treated rats from the three different injection groups was collected at days 3, 7 and 14 post-transplantation. Serum samples were assayed for IL10 production with an IL10 enzyme linked immunosorbent assay (ELISA) Quantitation kit (Invitrogen, United States) according to the manufacturer's recommendation.

### Data analysis

Data are shown as the means and standard deviations. The statistical differences were analyzed using Student's *t* test for normally distributed values and by the *t* test for non-normally distributed values. Values of *P* < 0.05 were considered significant. The data represent mean  $\pm$  SD from at least three independent experiments.

## RESULTS

### Characterization of stem cell cultures

The cells were isolated by gradient density centrifugation. After approximately 3 d in culture, cells from the stromal fraction appeared as a monolayer of broad, flat cells (Figure 1A). As the cells approached 80% confluence, they differentiated into a more spindle-shaped, fibroblastic morphology (Figure 2B). More than 98% of cells expressed the MSC markers CD29 and CD90 (Figure 1C and D), and less than 5% of hematopoietic stem cells expressed leukocyte markers CD34 and CD45 (Figure 1E and F). They were easily expanded for up to 10 passages, maintaining the spindle-shaped, fibroblastic morphology and MSC markers of the undifferentiated state. Adipose-derived stem cells (ADSCs) did not spontaneously differentiate during *in vitro* culture.

### Differentiation to hepatocytes

When the cultured cells reached 70% confluence, they were treated with hepatocyte differentiation medium containing 20 ng/mL HGF, 20 ng/mL FGF-4, and 20 ng/mL EGF. After 4 d of hepatocyte induction, ADSCs displayed changes in cellular morphology including shrinkage of the cytoplasm and diameter, as well as the formation of round cells. The fibroblasts, as control cells, did not exhibit any change in morphology after being treated with differentiation medium. Before induction, the MSCs did not express hepatocyte markers. Four

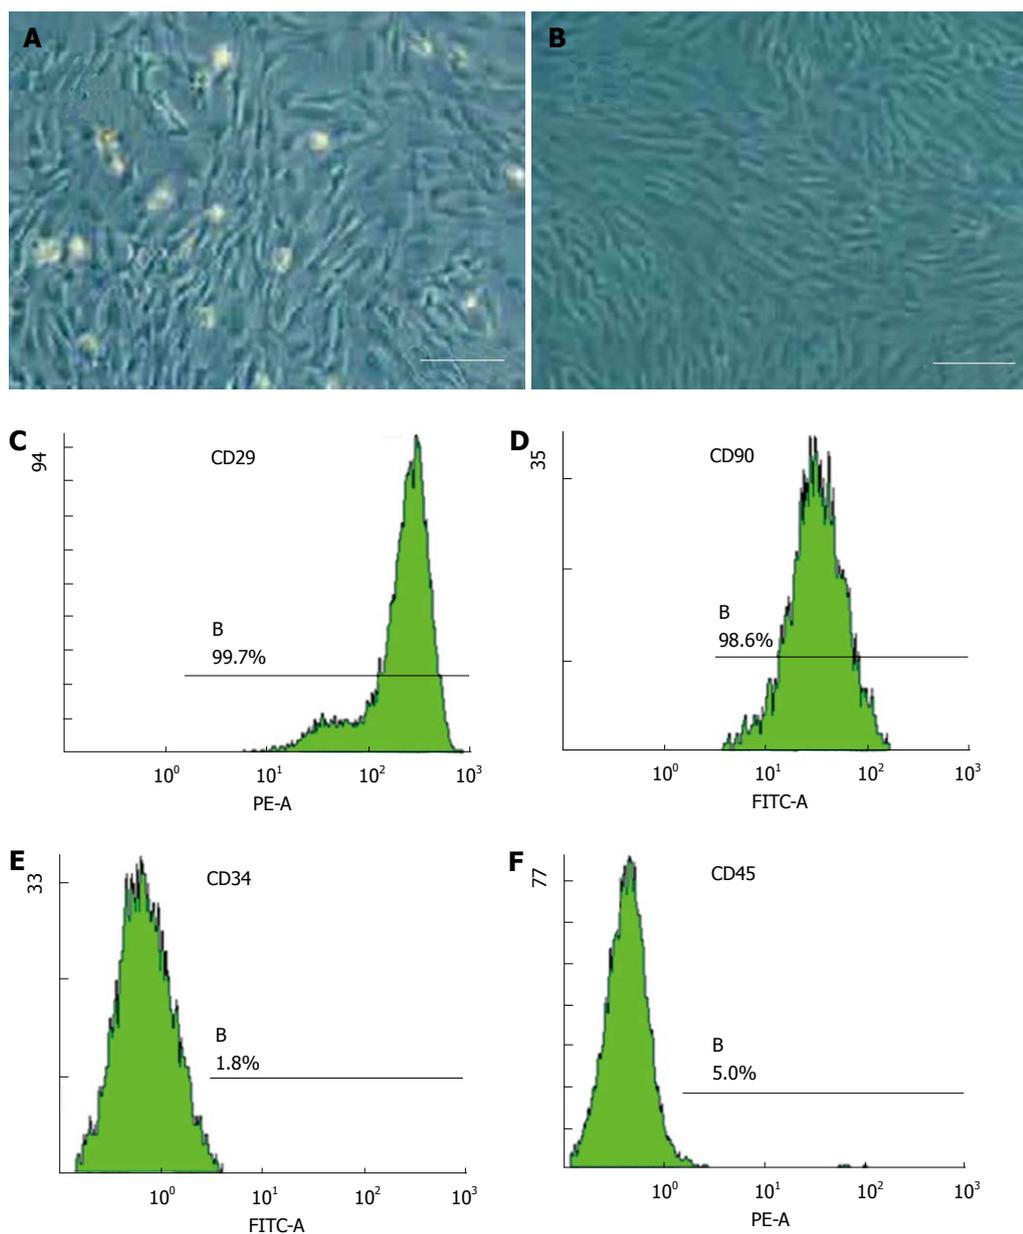

days after exposure to differentiation medium, the MSCs stained positive for the AFP and ALB hepatocyte markers (Figure 2A and B). Hepatocyte marker expression after hepatocyte induction was further confirmed by RT-PCR. In addition, *AFP*, *ALB* and *CK18* gene expression levels increased with prolonged exposure time in differentiation medium (Figure 2C). From these results, we can conclude that the MSCs differentiated into hepatocytes, and the proportion of differentiated cells account for approximately 70% of all induced cells.

### Intravenous injection of MSCs provides better treatment than other injection modalities

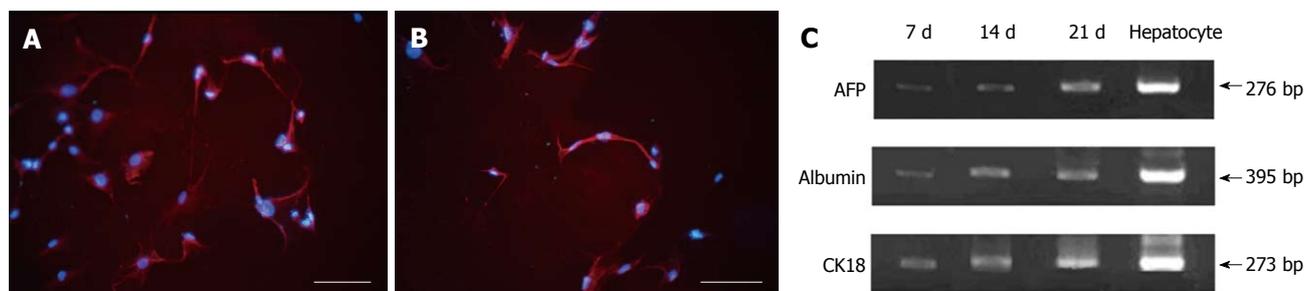

To explore cell homing, MSCs were labeled with DAPI before transplantation. Four days after transplantation, the number of surviving homing MSCs was highest in animals that received an intravenous injection. Surviving homing MSCs in animals that received an intrahepatic injection were more numerous than those observed in animals that received an intraperitoneal injection (Figure 3A-D). In addition, histological staining indicated that sham-injected, CCl<sub>4</sub>-treated rats suffered serious inflammation with non-normal liver lobules dispersed throughout the liver. The sham group also had large areas of collagen that were distributed along the edge of the liver lobules (Figure 3H and L). In the intraperitoneal and intrahepatic injection groups, the morphology of liver lobules was unclear, and collagen deposition was evident in the liver (Figure 3F, G, J and K). In the intravenous injection group, however, the liver lobules were normal (Figure 3E and I). Although there was mild inflammation in the portal or sinusoid areas, collagen accumulation was minimal in the liver. Immunohistochemistry of liver sections for  $\alpha$ -SMA expression revealed intense staining patterns in sham- and intraperitoneal-injected mice (Figure 3O and P). However,  $\alpha$ -SMA staining levels in intravenous- and intrahepatic-injected mice were significantly lower (Figure 3M and N). In addition, there were lower levels of  $\alpha$ -SMA staining in intravenous-injected mice than in intrahepatic-injected mice. To further compare the functional restoration of MSCs following intraperitoneal, intravenous, and intrahepatic injection, we quantitatively analyzed the levels of AFP, albumin, and TBIL production. The serum from rats given CCl<sub>4</sub> but not injected with MSCs, and from rats given neither MSCs nor CCl<sub>4</sub>, was used as control samples. Twenty-eight days post-injection, intravenously-injected MSCs were close to the level observed in normal rats. However, intraperitoneally-injected MSCs had not enough effective treatment when compared with MSCs intravenous injection group. The observed levels in the intrahepatic injection group fell between the other MSC-treated groups, but the levels were still closer to the levels observed in the intravenous injection group (Figure 4).

### Comparison of cytokine expression following intraperitoneal, intravenous and intrahepatic MSC treatment

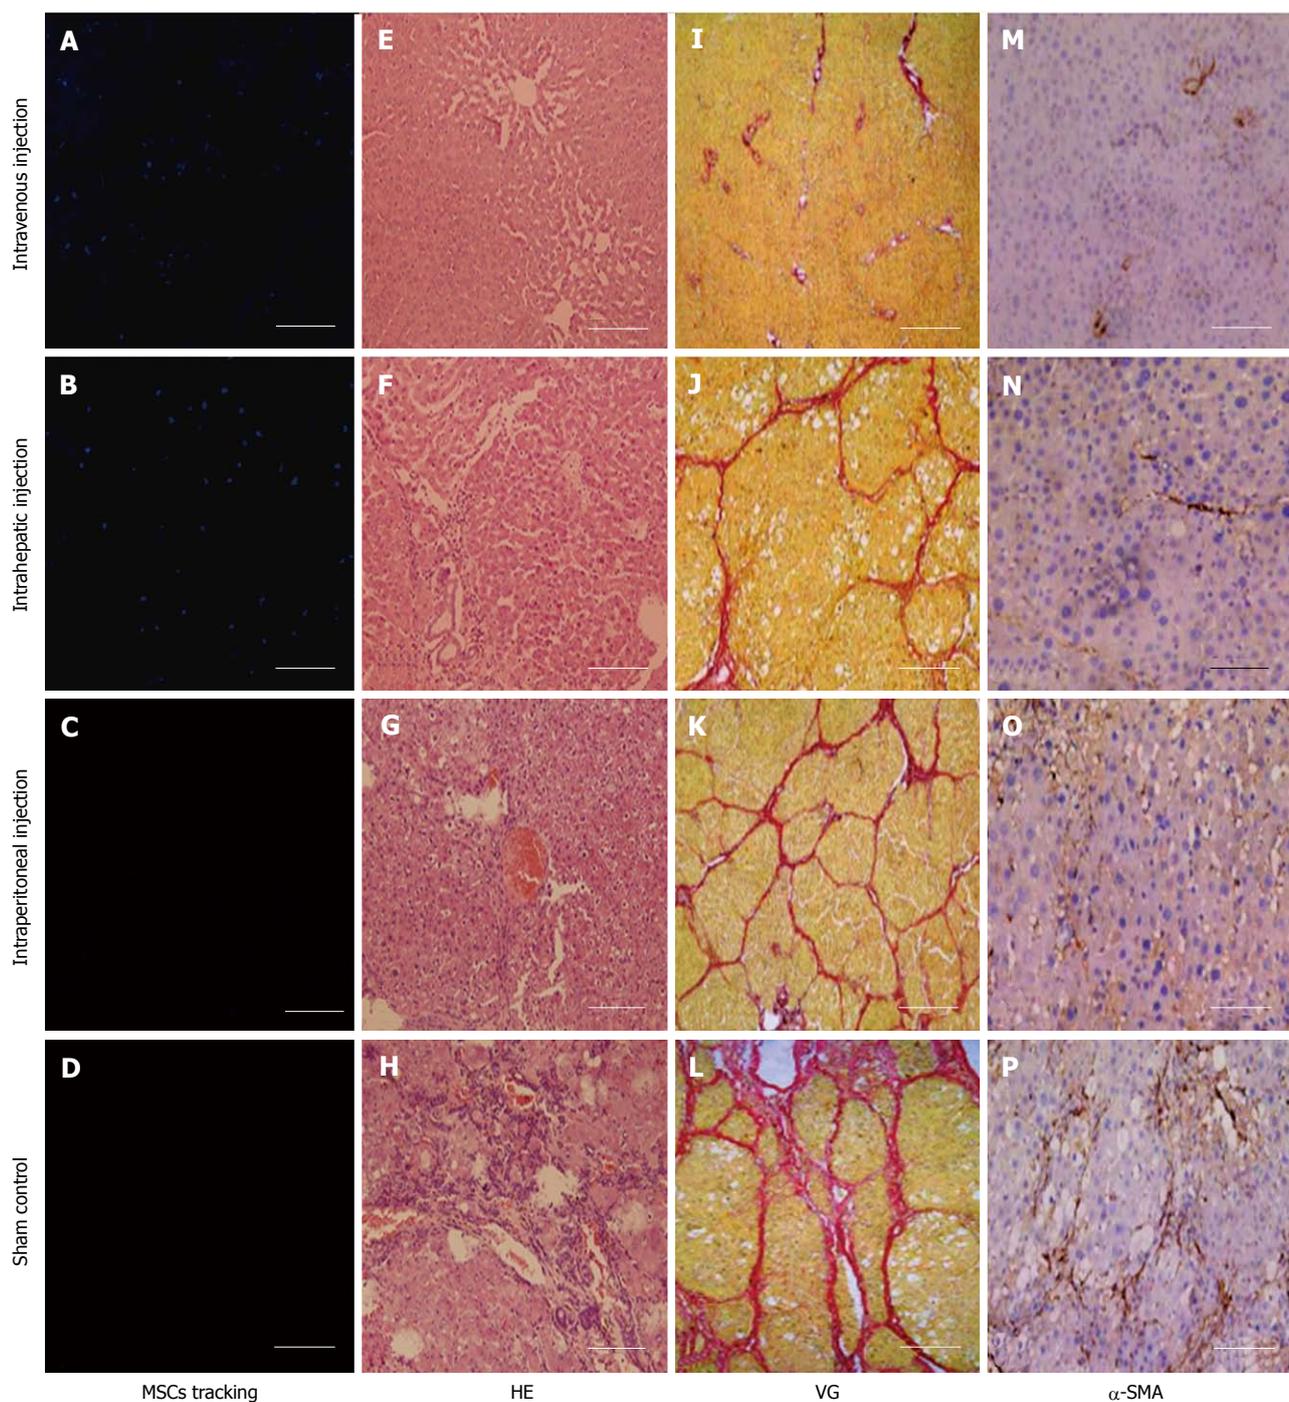

To further explore why intravenously-injected MSC treatment was more effective than either intraperitoneal or

intrahepatic injection, real-time PCR was used to quantitatively analyze the expression difference among the 3 transplant methods. As seen in Figure 5A and B, *mmp2*

and *mmp9* were expressed at their highest levels in the intravenous injection group, whereas *timp1* expression was the lowest in this group. The intraperitoneal injection

**Figure 4** Quantitative analysis for hepatocyte specific protein expression by biochemical analysis to compare the liver fibrosis treatment efficacy of intravenous, intrahepatic and intraperitoneal mesenchymal stem cell injection. Non-treated carbon tetrachloride (CCl<sub>4</sub>) group acted as normal control. Rats not injected with mesenchymal stem cells (MSCs) after CCl<sub>4</sub> processing were used as sham control. A: Analysis for albumin expression; B: Analysis for total bilirubin in serum (TBIL) expression; C: Analysis for alanine aminotransferase (ALT) expression.

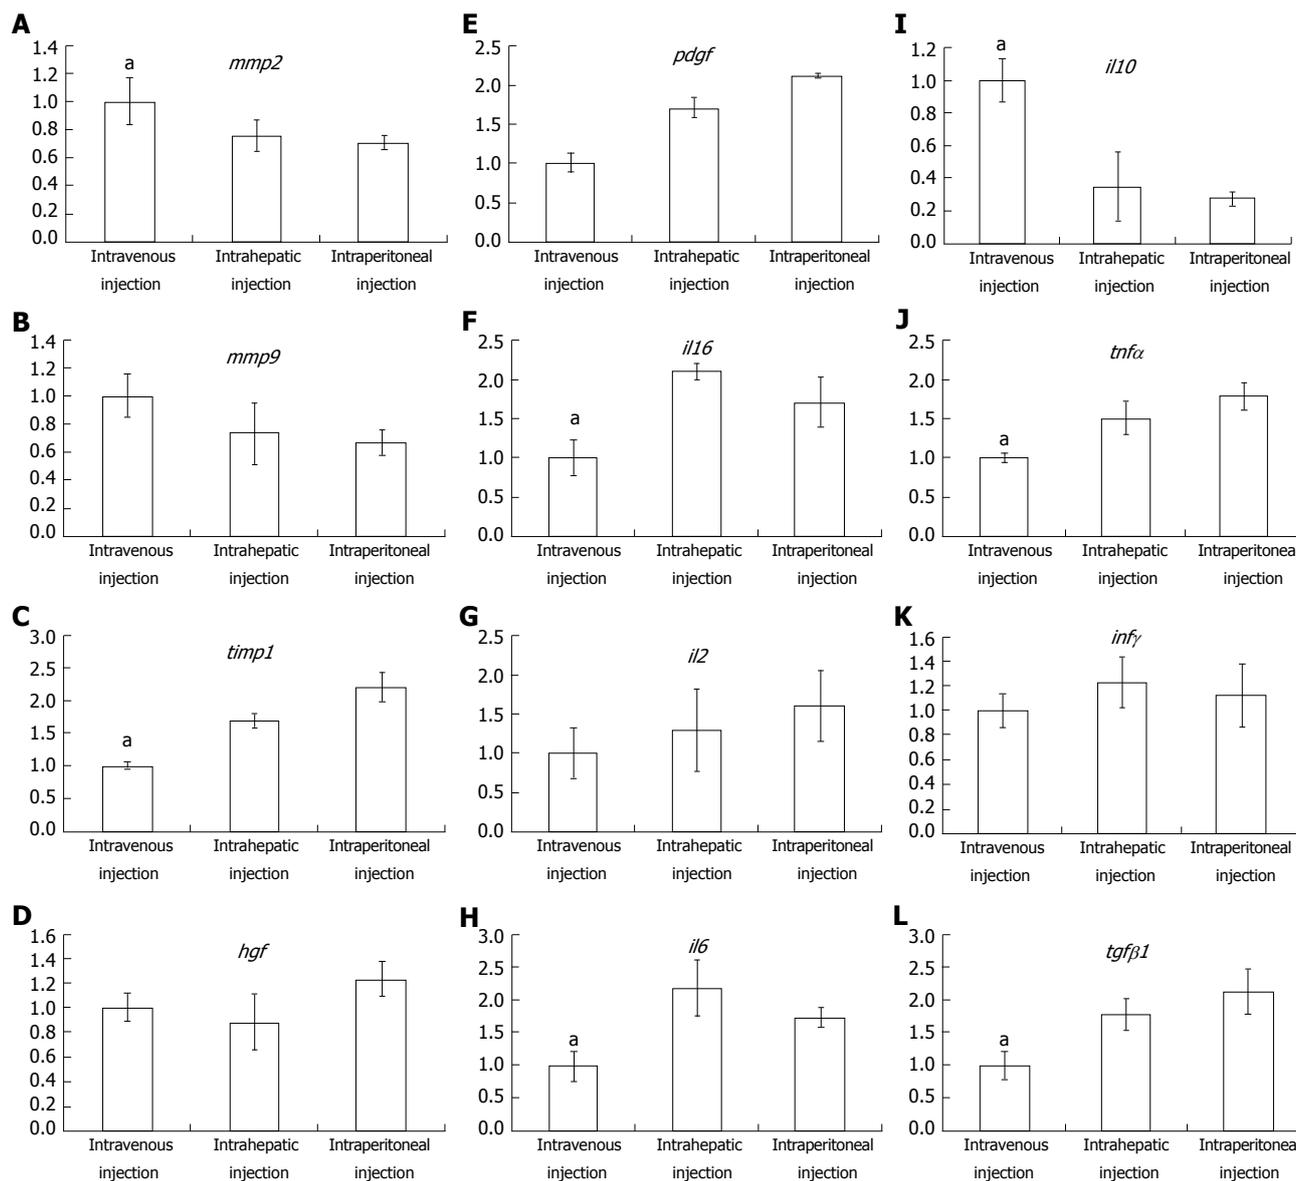

tion group, in contrast to the intravenous injection group, had the lowest *mmp2* and *mmp9* expression and the highest *timp1* expression. These results were in accordance with the observation that the fibrosis observed in the intravenous injection group was low relative to the two other groups. Besides assaying *mmp* and *timp* expression, cytokine expression was also assayed to detect whether the immune response played a pivotal role in the differential treatment response among the three experimental groups. The expression of *hgf* was slightly higher in the intravenous injection group than in the other two groups (Figure 5D). platelet-derived growth factor (PDGF), an important fibrosis enhancer, was not significantly different among the three groups. Similarly, expression levels of *pdgf*, *infγ* and *il2* were not significantly different among the three groups (Figure 5E, K and G). In the intravenous injection group, however, the expression levels of

*il1β*, *il6*, *tnfα* and *tgfβ* were significantly lower than in other groups, and the intraperitoneal injection group had the highest expression of these genes (Figure 5F, H, J and L). Interestingly, in the intravenous injection group, *il10*, a key factor in the regulation of the Th1-mediated immune response and homeostasis between matrix metalloproteinase (MMP) and the tissue inhibitors of the MMP (TIMP), was significantly higher when compared to the intrahepatic and intraperitoneal injection groups. Furthermore, the blood ELISA assay also indicated that IL10 production in the intravenous injection group was higher than in the other two groups (Figure 6).

## DISCUSSION

Liver fibrosis results from chronic injury to the liver in conjunction with excessive deposition of collagen and other components of the extracellular matrix (ECM), which is a characteristic of most types of chronic liver diseases<sup>[1]</sup>. If not effectively treated in time, liver fibrosis may transform into liver cirrhosis. Cirrhosis causes a number of complicating diseases, such as portal hypertension, hepatic encephalopathy, and gastrointestinal bleeding<sup>[2]</sup>. Thus, the discovery of a new approach to treating this disease would provide great clinical value. CCl<sub>4</sub>-induced hepatocyte necrosis has the ability to imitate human liver fibrosis disease in animals and has so far been a main method used in the development of animal treatment models<sup>[2,3]</sup>. In this study, CCl<sub>4</sub> was used to induce liver fibrosis in SD rats according to previous protocols. Histological staining indicated collagen deposition in the liver, an indicator of fibrosis. Further liver function testing revealed that ALB, TBIL and ALT levels changed from their normal, baseline levels of 3.65 ± 0.18, 0.049 ± 0.019, and 48.70 ± 9.86 to 3.02 ± 0.22, 1.018 ± 0.114, and 1458.78 ± 230.07, respectively. These findings, in accordance with previous reports, all indicate that liver fibrosis was induced by CCl<sub>4</sub>.

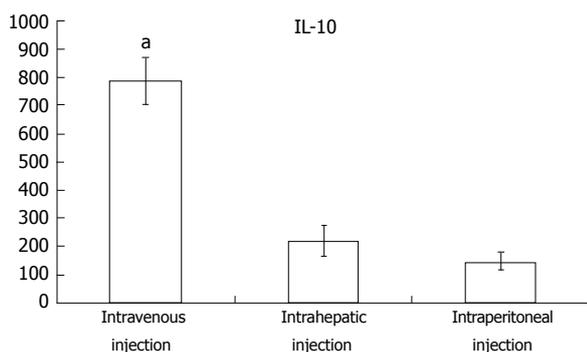

Liver transplantation is currently considered the best treatment for liver cirrhosis caused by fibrosis. However, there are some disadvantages that limit the expansive use of the procedure, such as liver shortages, high risks associated with surgery, and the risk of further post-surgery complications<sup>[3]</sup>. Although hepatocyte therapy has been proven to improve liver function, immune rejection and hepatocyte disorder in *in vitro* cultures have provided obstacles to the expansive use of this type of therapy. MSCs, in recent years, have shown potential as a post-transplantation fibrosis cure<sup>[24,25]</sup>. MSCs derived from bone marrow also contain HSCs and multipotent adult progenitor cells. Thus, fluorescence-activated cell sorting in this study was performed to identify the type of cultured cells obtained. More than 98% of cells stained positive for CD29 and CD90, which is in accordance with the diagnostic characteristics of MSCs. The cells stained negative for CD34 and CD45, which are indicative of hematopoietic cell lines. These results demonstrate that the cultured cells derived from the rat

**Figure 5** Real-time polymerase chain reaction analysis for detecting the expression difference of cytokines, growth factors and interleukin, which are involved in liver fibrosis progression, among different mesenchymal stem cell transplanted modalities. The histogram shows the relative expression level for intravenous, intrahepatic and intraperitoneal injections. Data represent the mean  $\pm$  SE, <sup>a</sup>*P* < 0.05. A and I: The expression of *mmp2* and *il10* in intravenous injection was significantly higher than other injection modalities; F, J, C, H and L: The expression of *il1β*, *tnfα*, *timp1*, *il6* and *tgfβ1* was significantly lower in intravenous injection than others; E, B, G, K and D: The expression of *pdgf*, *mmp9*, *il2*, *hgf*, *infγ* and *hgf* was not significantly different among the three mesenchymal stem cell injection modalities.

bone marrow consisted of more than 98% MSCs. HSCs that produce all of the blood lineages and liver epithelium have been previously shown to be capable of acting as a substitute for hepatocytes in transplantation in a murine model of tyrosinemia<sup>[26,27]</sup>. The benefits to the regenerating liver in the transplant recipients are derived from donor HSCs that fuse with host hepatocytes, rather than from transdifferentiating hematopoietic stem cells or hepatic stem cells present in bone marrow<sup>[15,16]</sup>. In a study by Sato *et al.*<sup>[17]</sup>, unlike HSCs, MSCs grafted directly to livers that had sustained chronic damage from allyl alcohol treatment were more successful than MSC+ and non-MSC/CD34- cells in differentiating into hepatocytes without any evidence of fusion. *In vitro*, multiple studies, including those of our group, indicate that MSCs can also

differentiate into hepatocytes when induced by cytokines, such as HGF, FGF-4 and EGF<sup>[28]</sup>. To assay the degree of hepatocyte differentiation of MSCs, real-time PCR and immunofluorescence staining were performed. High expression levels of AFP, ALB and CK18 were noted in induced MSCs when compared to non-induced MSCs. While some studies have examined only one marker, or a small number of them, most published data refer to multiple markers, of which expression is assessed at both the protein and mRNA levels. One of the most widely used markers is albumin secretion, together with the evaluation of AFP, metabolic enzymes, and cytoskeletal proteins<sup>[19]</sup>. AFP in the liver is a marker of immature liver cells or oval cells in adult livers. Albumin is a typical marker of mature hepatocytes. CK18 is expressed by several liver

**Figure 6** Enzyme linked immunosorbent assay analysis for detecting interleukin-10 protein expression in peripheral blood after intravenous, intrahepatic and intraperitoneal mesenchymal stem cell injection. Values shown are mean  $\pm$  SE,  $^aP < 0.05$ . IL-10: Interleukin-10.

cell types, including biliary epithelial cells and hepatic oval cells. In particular, a “cytokeratin switch” can be observed as a later process in the maturation of hepatocytes from bipotential progenitors. In fact, bipotential hepatoblasts express both CK-18 and CK-19, while mature hepatocytes express CK-18 alone, and CK-19 specifically identifies cholangiocyte populations<sup>[17]</sup>.

While MSCs are not the only reported adult stem cells that can treat liver fibrosis, they have advantages that make them more favorable for their use in clinical treatment, such as easy accessibility, minimal invasiveness, and fast proliferation<sup>[12]</sup>. In this study, we injected MSCs isolated from bone marrow into SD rats at three different body regions. We found that the liver function of the three groups was elevated compared to the control group. These observations were made by the biochemical analysis of ALB, TBIL and ALT and histological staining of collagen deposition. Although there was an elevation of liver function in all of the experimental groups, there were also differences among the groups. The expression of  $\alpha$ -SMA, which plays a pivotal role in liver fibrosis, was also significantly reduced after MSC transplantation. These results are similar to those seen in many previous reports and suggest that, apart from expressing specific markers, differentiated cells are capable of carrying out the functional activities of mature hepatocytes, which are involved in the supportive functions needed for regenerative medicine applications. These enzymatic functions should also be considered as more reliable “markers” of the successful differentiation of MSCs.

So far, there are two primary methods, non-induced and hepatocyte-induced MSC injection, for the treatment of livers with MSCs. Although these two methods have a potent ability to reverse liver fibrosis, the mechanism of treatment for non-induced MSCs is still unknown. There may be two factors by which MSCs protect against liver fibrosis. One is that MSCs which differentiate into hepatocytes, because of the *in vivo* niche, secrete numerous growth factors that promote liver regeneration<sup>[29,30]</sup>. Another possibility is that MSCs suppress hepatic stellate cell activity and secrete MMP, thereby eliminating ECM deposition<sup>[31]</sup>. In contrast to the primary rationale for us-

ing non-induced MSCs to treat liver fibrosis, some studies have demonstrated that MSCs injected into rats with cirrhotic livers differentiate mainly into myofibroblasts and hepatic stellate cells, both of which are promoters of liver fibrosis<sup>[32,33]</sup>. In the present study, to avoid liver fibrosis aggravation, transplanted MSCs were induced to differentiate into hepatocytes. The results of this method appear to promote improved liver regeneration, rather than liver cirrhosis aggravation, in CCl<sub>4</sub>-induced fibrotic rats.

In previous reports, Kuo *et al.*<sup>[12]</sup> demonstrated that intravenous MSC-derived hepatocyte transplantation was more effective in rescuing liver failure than intrasplenic transplantation. In this paper, we extended the effective comparison of MSC-engrafted sites, including intravenous, intraperitoneal, and intrahepatic transplantation. In agreement with the results of Kuo *et al.*<sup>[12]</sup>, intravenous transplantation in our experiments was better at rescuing liver fibrosis than transplantation *via* the other two methods. The effectiveness of intraperitoneal transplantation was better in the non-MSC-treated groups than in the other treated groups. The difference among the three groups was stratified by not only liver biochemical functional differences and collagen deposition but also by the distribution of MSC-derived hepatocytes in the recipient liver. Although the results of the present study and those of the Kuo group study are valuable for guiding MSC therapy for liver disease, they do not fully elucidate the causes of these transplant-site effectiveness differences.

Thus, we assayed for protein and mRNA expression differences of cytokines and interleukins that play an important role in fibrosis progression. HGF, a powerful mitotic promoter for hepatocytes, also has the ability to restrain collagen and transforming growth factor (TGF) $\beta$ 1 expression, thereby suppressing hepatic stellate cell activity<sup>[34,35]</sup>. PDGF can enhance liver fibrosis *via* stimulation of hepatic stellate cells expressing collagen and TIMP<sup>[36]</sup>. In this study, the mRNA expression of these two factors, however, was not significantly different among the three groups. Thus, they are not the factors leading to the observed difference caused by injection in different MSC transplant sites. Similarly, elevations of *hgf*, *pdgf*, *infy* and *il2* were also detected, but the differences did not reach statistical significance. *il1 $\beta$* , *il6*, *tnf $\alpha$* , and *tgf $\beta$*  were expressed at significantly lower levels after intravenous injection than after intraperitoneal or intrahepatic injection. The expression of *il10*, however, was highest in the intravenous injection group. These results demonstrate that IL10 expression may play a central role in mediating the superior effects of intravenously injected MSCs in ameliorating liver fibrosis. IL10 is an inhibitor of many cytokines that stimulate tissue fibrosis, such as IL6, tumor necrosis factor- $\alpha$  and TGF $\beta$ . In addition, IL10 can suppress TIMP-1 expression and thereby relieve MMP-1 to degrade liver collagen deposits<sup>[37,38]</sup>. The increased expression of *timp1* following intravenous injection is in contrast to the expression following other injection modalities, which supports such a viewpoint (Figure 5C). According to previous reports, an intravenous injection of MSCs can beneficially modulate

the host immune response by increasing the release of prostaglandin E2 from the BM-derived MSCs acting on the EP2 and EP4 receptors of the macrophages and by stimulating the production and release of IL10<sup>[39]</sup>. Blood ELISA assays indicated that IL10 expression in the intravenous injection group was higher than that in other groups. These results support the viewpoint that the main advantage provided by MSCs transplanted *via* injection into the venous blood is the stimulation of IL10 release, thereby supporting this method as an effective treatment of liver fibrosis.

In summary, MSC-derived hepatocytes are able to protect against liver fibrosis induced by CCl<sub>4</sub>. Intravenous injection, in contrast to the intraperitoneal and intrahepatic injection of MSCs, provides the most effective treatment to prevent fibrosis. These results are due to the fact that MSCs in the venous blood can stimulate IL10 release, which, in turn, can modulate the host immune response and homeostasis between TIMP and MMP.

## COMMENTS

### Background

Liver fibrosis causes many deadly diseases. Previous reports indicate that mesenchymal stem cells (MSCs) can facilitate recovery from chemically-induced liver damage and decrease liver fibrosis.

### Research frontiers

In recent years, MSCs have been reported in many studies to promote liver fibrosis regeneration at many different transplanted sites. However, there are no critical comparisons of how different transplant sites influence bone marrow MSC-based therapy for liver fibrosis, and the molecular mechanisms that influence the treatment differences are unknown.

### Innovations and breakthroughs

This study compares the treatment effectiveness of MSCs for intravenous, intrahepatic and intraperitoneal injection. The results suggest that intravenous injection, in contrast to intraperitoneal and intrahepatic MSC injection, provides the most effective treatment to prevent fibrosis. These results are due to the fact that MSCs in the venous blood can stimulate interleukin-10 (IL-10) release, which, in turn, can modulate the host immune response and homeostasis between tissue inhibitor of metalloproteinase and matrix metalloproteinases.

### Applications

This comparative study of treatment effectiveness influenced by transplanted sites supports the therapeutic principle of future MSC treatment.

### Terminology

Liver injury caused by chemical damage or viral infection often leads to liver fibrosis, which can lead to an impairment of liver function that requires medical intervention. MSCs that have been found to reside in most organs and tissues can be differentiated into hepatocyte-like cells *in vitro*, and rescue liver fibrosis. The authors found MSCs intravenously injected into the body impeded liver fibrosis caused by carbon tetrachloride more than intraperitoneal and intrahepatic injection. IL-10, which is a regulator of host immune response and metabolism homeostasis, may play an important role in mediating this phenomenon.

### Peer review

The authors compared the liver fibrosis treatment effectiveness among different MSCs injection modalities. The study revealed that MSCs intravenously transplanted evidently improved the functional protein expression and reduced the collagen deposition in injured liver more than other injection modalities. And further mechanism detection suggested intravenous injection of MSCs releases more IL10 that can ameliorate liver fibrosis by down-regulation of *il1β*, *il6*, *tnfα*, and *tgfb* expression. The results may represent a molecular mechanism of MSC therapy in liver injury.

### Abstract

**AIM:** To investigate the protective effect and mechanism of rebamipide on small intestinal permeability induced by diclofenac in mice.

**METHODS:** Diclofenac (2.5 mg/kg) was administered once daily for 3 d orally. A control group received the vehicle by gavage. Rebamipide (100 mg/kg, 200 mg/kg, 400 mg/kg) was administered intragastrically once a day for 3 d 4 h after diclofenac administration. Intestinal permeability was evaluated by Evans blue and the FITC-dextran method. The ultrastructure of the mucosal barrier was evaluated by transmission electron microscopy (TEM). Mitochondrial function including mitochondrial swelling, mitochondrial membrane potential, mitochondrial nicotinamide adenine dinucleotide-reduced (NADH) levels, succinate dehydrogenase (SDH) and ATPase activities were measured. Small intestinal mucosa was collected for assessment of malondialdehyde (MDA)

content and myeloperoxidase (MPO) activity.

**RESULTS:** Compared with the control group, intestinal permeability was significantly increased in the diclofenac group, which was accompanied by broken tight junctions, and significant increases in MDA content and MPO activity. Rebamipide significantly reduced intestinal permeability, improved inter-cellular tight junctions, and was associated with decreases in intestinal MDA content and MPO activity. At the mitochondrial level, rebamipide increased SDH and ATPase activities, NADH level and decreased mitochondrial swelling.

**CONCLUSION:** Increased intestinal permeability induced by diclofenac can be attenuated by rebamipide, which partially contributed to the protection of mitochondrial function.

## INTRODUCTION

It is well-known that traditional non-steroid anti-inflammatory drugs (NSAIDs) induce mucosal injuries in the lower gastrointestinal (GI) resulting in serious damage<sup>[1-5]</sup>. However, the mechanism of NSAIDs-related small intestinal mucosal injury is not yet clear. Bjarnason *et al*<sup>[6]</sup> suggested a hypothesis for the mechanism involved in the pathogenesis of NSAIDs-related enteropathy which was thought to be a multi-stage process, and included mitochondrial damage, increased intestinal permeability, decreased blood flow, and a reduction in prostaglandins. Several basic studies have supported the idea of increased permeability of the small intestinal mucosa as a central mechanism. Intestinal permeability regulates penetration of substances such as macromolecules, bile acids, bacteria and other intra-lumen toxins through the intestinal epithelial barrier. This may lead to low-grade intestinal inflammation by exposing the mucosa to luminal factors and might be the driving force in converting inflammation into ulcer<sup>[7]</sup>. Therefore, increased intestinal permeability was usually seen as the early stage of intestinal mucosal damage induced by NSAIDs. Many gastrointestinal inflammatory diseases, such as inflammatory bowel disease, can be detected through intestinal permeability tests, which can be used as an early predictor of relapse<sup>[8-11]</sup>. However, there are no effective drugs for the treatment of increased intestinal permeability induced by NSAIDs. Although proton pump inhibitors and prostaglandin analogues have a preventive effect in patients with traditional NSAIDs-induced upper GI adverse events, investigations into the preventive effects of drugs on NSAIDs-induced lower GI mucosal injury are inadequate.

Rebamipide is a mucosal protective agent which exerts a protective effect on NSAIDs-induced gastric injury through its antioxidant properties<sup>[12]</sup>. It was demonstrated that *Helicobacter pylori*-related macromolecular transepithelial transportation was reduced by the administration of rebamipide<sup>[13-14]</sup>, which was attributed to barrier integrity reinforcement. Kishimoto *et al*<sup>[15]</sup> reported that rebamipide prevented dextran sulfate sodium-induced ulcerative colitis in rats, which was related to mucosal barrier repair. In addition, rebamipide was shown to have a healing effect in a patient with corticosteroid-resistant ulcerative colitis<sup>[16]</sup>. However, few studies have evaluated the mechanism of rebamipide on intestinal permeability in NSAIDs enteropathy.

The aim of this research was to investigate the preventive effect and mechanism of rebamipide on intestinal permeability in a diclofenac-induced enteropathy model.

## MATERIALS AND METHODS

### Animals and reagents

Kunming mice, 6-8 wk old weighing  $20 \pm 2$  g were provided by the Laboratory Animal Center of Anhui Medical University. The mice were housed in animal facilities with 50% humidity and a 12:12-h light-dark cycle and

fed a standard pellet diet and tap water ad libitum. All experiments were performed in accordance with the institutional and national guidelines for the care and use of laboratory animals and were approved by the Ethics Committee of Anhui Medical University. Rebamipide was purchased from Zhejiang Otsuka Pharmaceutical Corporation, Zhejiang, China. Diclofenac sodium salt, Evans blue, rhodamine 123 and fluorescein isothiocyanate dextran (FITC-D) was purchased from Sigma Co. Acetylcysteine was obtained from Beijing Solarbio Science and Technology Co., Ltd, Beijing, China. Malondialdehyde (MDA), myeloperoxidase (MPO), ATPase and succinate dehydrogenase (SDH) detection kits were bought from Nanjing Jiancheng Institute of Biotechnology, Nanjing, China.

### Experimental protocol

Mice were randomly divided into the following five groups; control, diclofenac, rebamipide 100 mg/kg, 200 mg/kg, and 400 mg/kg<sup>[15]</sup>. Mice were administered diclofenac (2.5 mg/kg)<sup>[17]</sup> dissolved in 0.2% methylcellulose daily by oral gavage for 3 d, except the control group which received the vehicle. Rebamipide suspended in 0.2% methylcellulose dissolved in saline was dosed intragastrically once a day for 3 d 4 h after diclofenac administration. In the control and diclofenac groups, saline was given orally instead of rebamipide. At the end of the experiment, mice were sacrificed by decapitation, and the small intestine was quickly removed.

### Intestinal permeability

Small intestinal permeability was evaluated as previously described<sup>[18]</sup>. Briefly, mice were anesthetized with ether, the abdomen was opened and a 3 cm proximal portion of the ileum from the ileocecal junction was ligated by silk suture with care to prevent injury to the superior mesenteric vessels. The ileal luminal contents were washed out gently with 4-5 mL of phosphate buffered saline (PBS). The ileocecal end was ligated to prepare the ileal loop (3 cm), and then 0.2 mL of 1.5% (w/v) Evans blue in PBS was injected into the loop. Mice were warmed with an incandescent lamp and left undisturbed for 60 min without any signs of pain. Sixty min later, mice were sacrificed by decapitation. The ileal loop was rapidly dissected out, opened, rinsed with 6 mmol/L acetylcysteine, dried on filter paper at 37 °C for 24 h, and then weighed and incubated with 3 mL of formamide at 50 °C for 24 h. The amount of dye eluted was estimated using a spectrophotometer at a wavelength of 612 nm<sup>[19]</sup>. The amount of Evans blue permeating into the intestinal wall was calculated based on the standard curve of Evans blue in formamide.

Intestinal permeability to FITC-D with a molecular mass of 4000 Da was determined using a method previously described by Chen *et al*<sup>[20]</sup> with a minor modification. Mice were anesthetized and a 5 cm segment of the ileal loop was prepared by ligating the ileum at the 3 cm and 8 cm proximal portions from the ileocecal junction

with care to prevent injury to the superior mesenteric vessels. Then 0.2 mL of PBS (pH 7.4) containing 25 mg/kg FITC-D was injected into the loop. After 30 min, a blood sample (100  $\mu$ L) was taken by puncture of the portal vein under ether anesthesia and immediately diluted with 1.9 mL of 50 mmol/L Tris (pH 10.3) containing 150 mmol/L sodium chloride. The diluted plasma was centrifuged at 3000 g for 7 min and plasma FITC-D concentrations were determined by a fluorescence spectrophotometer at an excitation wavelength of 485 nm and an emission wavelength of 515 nm<sup>[21-22]</sup>.

#### Assessment of transmission electron microscopy

For transmission electron microscopy (TEM) assessment, an ileal specimen of about 1 cm in length from the ileocecal junction to the proximal portion was excised with a sharp scalpel and fixed in 2.5% glutaraldehyde for 4 h at 4°C, followed by fixation in osmic acid and embedding in Epon. Ultrathin sections were examined by a Hitachi TEM to detect ultrastructural injuries.

#### Intestinal MDA content and MPO activity

The dissected intestine was removed without any fat and mesenteries attached, and subsequently homogenized in physiologic saline for the detection of MDA content and MPO activity using commercial kits following the instruction procedures.

#### Preparation of liver mitochondrial and determination of mitochondrial functions

Mouse liver mitochondria were isolated as described by Johnson and Lardy<sup>[23]</sup>, as it was exceedingly difficult to obtain a high yield of mitochondria from intestinal tissue<sup>[24]</sup>. Briefly, the liver was rapidly removed and placed in medium containing 250 mmol/L sucrose, 10 mmol/L Tris and 1 mmol/L EGTA (pH 7.8) at 4 °C. The tissue was scissor minced and homogenized on ice. The homogenates was centrifuged at 600 g for 10 min and the resulting supernatant was centrifuged at 15 000 g for 5 min. The resulting mitochondrial pellet was then washed with the same medium without EGTA, and then centrifuged at 15 000 g for 5 min. The final mitochondrial suspension contained 5 mg/mL protein determined by Lowry's method.

#### Determination of mitochondrial membrane potential

Mitochondrial membrane potential (MMP) was evaluated from the uptake of rhodamine 123, which accumulates electrophoretically into energized mitochondrial in response to their negative-inside membrane potential<sup>[25]</sup>. Briefly, 1800  $\mu$ L of the phosphate buffer (pH 7.2) containing 250 mmol/L sucrose, 5 mmol/L  $\text{KH}_2\text{PO}_4$ , 3 mmol/L succinate and 0.3  $\mu$ mol/L rhodamine 123 was added to the cuvette, and the fluorescence was monitored by fluorescence spectrometry with excitation and emission wavelengths of 503 nm and 527 nm, respectively. After 30 s, the mitochondrial suspension (final concentration of 0.5 mg/mL protein) was added, and the fluores-

cence intensity was recorded continuously at 25 °C for 5 min. MMP was expressed by the relative value compared to the baseline intensity.

#### Measurement of mitochondrial swelling

Mitochondrial swelling was assessed by measuring the changes in absorbance of the suspension at 520 nm ( $\Delta$ ) by spectrophotometry according to Halestrap *et al.*<sup>[26]</sup>. The standard incubation medium for the swelling assay contained 250 mmol/L sucrose, 0.3 mmol/L  $\text{CaCl}_2$  and 10 mmol/L Tris (pH 7.4). Mitochondria (0.5 mg protein) were suspended in 3.6 mL of phosphate buffer. A quantity of 1.8 mL of this suspension was added to both sample and reference cuvettes and 6 mmol/L succinate was added to the sample cuvette only, and the  $A_{520\text{ nm}}$  scanning was started and recorded continuously at 25 °C for 10 min. Swelling of mitochondrial was evaluated according to decreased values in absorption at 520 nm.

#### Determination of mitochondrial nicotinamide adenine dinucleotide-reduced level

The mitochondrial pyridine nucleotide, nicotinamide adenine dinucleotide-reduced (NADH), was monitored by measuring its autofluorescence with excitation and emission wavelengths of 360 nm and 450 nm, respectively, using a fluorescence spectrometer according to Minezaki *et al.*<sup>[27]</sup>. Mitochondria (2 mg protein) were added to 1.8 mL of phosphate buffer containing 6 mmol/L succinate and the autofluorescence of NADH was determined.

#### Determination of mitochondrial SDH and ATPase activity

The activities of mitochondrial SDH and ATPase were detected using kits as described in the instruction manuals. The quantity of Pi production represented the activity of ATPase and was measured by the active unit mmol Pi h mg protein. SDH activity was expressed as units/mg.protein.

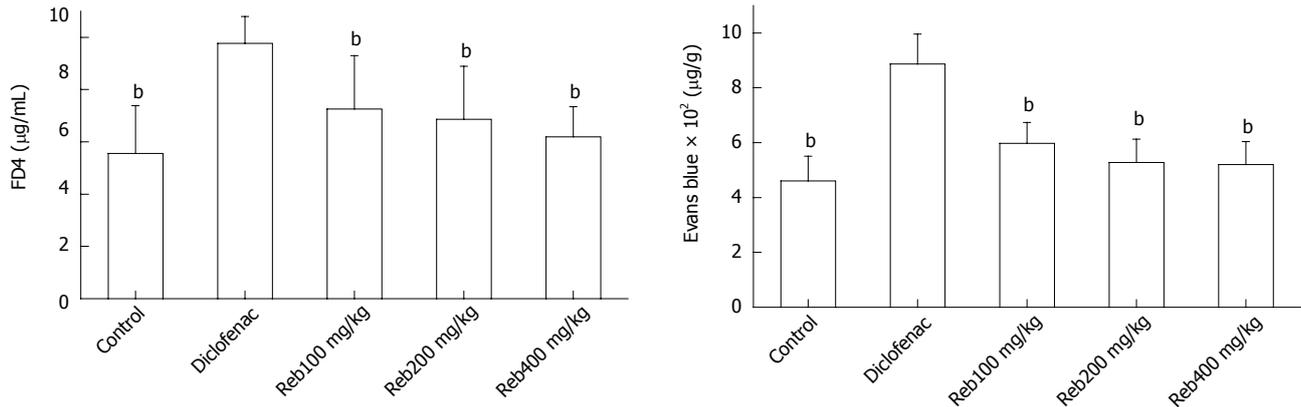

#### Statistical analysis

All results are expressed as mean  $\pm$  SEM. Statistical comparisons were made using the one-way analysis of variance (ANOVA) test. The level of significance was set to a *P*-value of 0.05. All tests were two-sided.

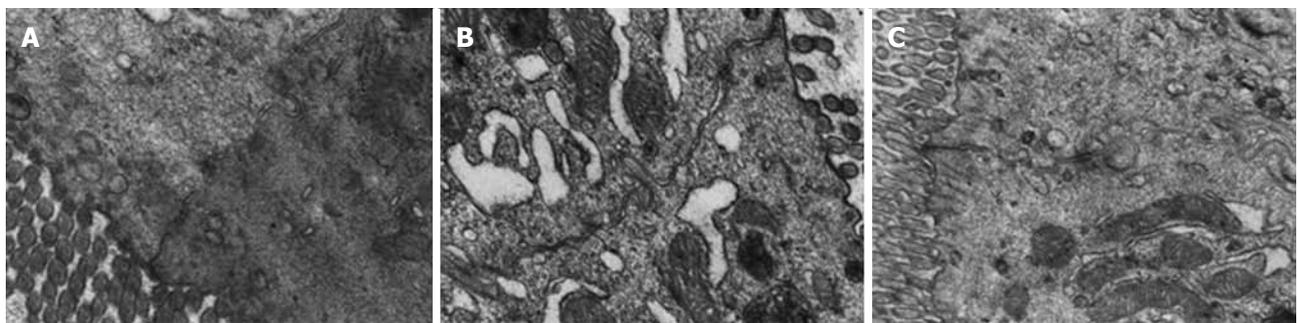

## RESULTS

### Effect of rebamipide on diclofenac-induced small intestinal permeability in mice

Non-absorbed macromolecules, such as EB and FITC-D, are often used as probes in intestinal permeability tests. The amount of Evans Blue which had permeated into the intestinal wall and the plasma FITC-D concentrations in the diclofenac group were significantly higher than those in the control group (*P* < 0.01, Figure 1). These results indicated that diclofenac damaged the small intestinal mucosal barrier, which resulted in an increase in intestinal permeability. Rebamipide significantly reduced Evans Blue and FITC-D permeation.

**Figure 1** Effects of rebamipide on diclofenac-induced small intestinal permeability in mice. Values are mean  $\pm$  SEM of data obtained from 8 mice in each group. <sup>b</sup> $P < 0.01$  compared with the diclofenac group.

**Figure 2** Transmission electron microscopic appearances of diclofenac-induced small intestinal injuries in mice (original magnification  $\times 20\,000$ ). A: Control group; B: Diclofenac group; C: Rebamipide group (400 mg/kg). In the diclofenac group, partial deformation of intestinal epithelial cells, intestinal microvillus reduction, disarrangement of the epithelial surface and broader junctional complexes, tight junction opening were seen. Rebamipide group showed regular and intensive microvillus, and ameliorated tight junction when compared with the diclofenac group.

### Effects of rebamipide on diclofenac-induced ultrastructure of the intestinal barrier in mice

TEM observations showed that the intestinal mucosa in the diclofenac group (Figure 2B) demonstrated visible injury and a portion of the intestinal epithelial cells were deformed, in addition, a significant reduction in intestinal microvilli, disarrangement of the epithelial surface, broader junctional complexes, and open tight junctions were observed when compared with the control group (Figure 2A). In contrast, the rebamipide group displayed nearly normal intestinal epithelial cells, regular and numerous microvilli, and clearly heightened tightness in the tight junctions (Figure 2C).

### Effects of rebamipide on small intestinal MDA content and MPO activity

Compared with the control group, the small intestinal MDA content and MPO activity were significantly increased in the diclofenac group ( $1.65 \pm 0.32$  vs  $0.97 \pm 0.28$  nmol/mg protein, and  $0.236 \pm 0.027$  vs  $0.159 \pm 0.025$  U/g, respectively, both  $P < 0.01$ ), indicating that diclofenac caused oxidative damage and inflammation in small intestinal mucosa. Rebamipide significantly reduced the MDA content and MPO activity demonstrating that the anti-oxidative and anti-inflammatory effects of rebamipide

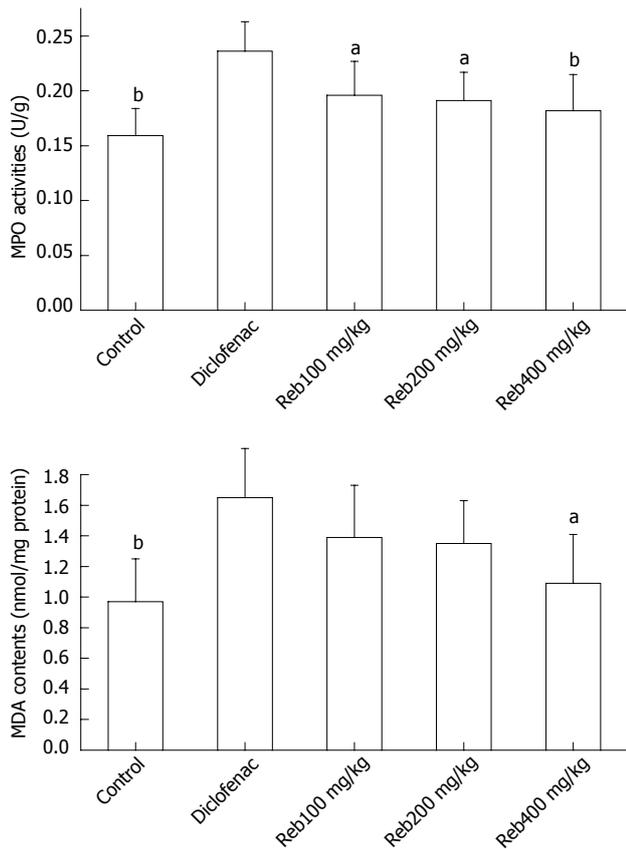

may be related to the reduction in small intestinal injury (Figure 3).

### Effects of rebamipide on diclofenac-induced impairment of liver mitochondrial functions, mitochondrial membrane potential

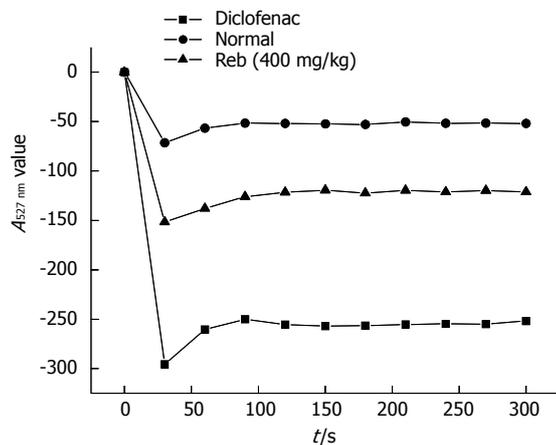

In the control group, the fluorescence intensity was rapidly reduced within 30 s after the mixture of mitochondria with rhodamine 123, it then began to rise and reached a steady-state within 90 s (Figure 4). Compared with the control group, the reduction in fluorescence intensity in the diclofenac group decreased slightly, indicating that the uptake of rhodamine 123 in mitochondria was smaller in the diclofenac group than in the control group. The reduction in mitochondrial rhodamine 123 uptake was reversed in the rebamipide group indicating that rebamipide significantly improved the impairment of MMP.

### Mitochondrial swelling

It has been shown that pH change and high calcium can cause mitochondrial swelling, which is detected by a reduction in mitochondrial absorbance at certain wavelengths. After adding the reaction buffer (at pH 7.2) or 0.3 mmol/L of  $\text{CaCl}_2$ , the mitochondrial absorbance at

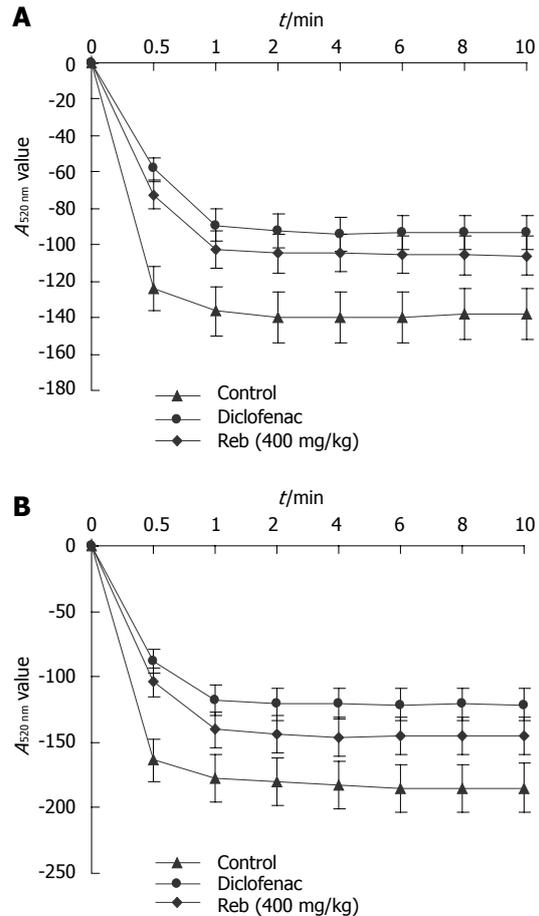

**Figure 3** Effects of rebamipide on small intestinal malondialdehyde content and myeloperoxidase activity. Values are mean  $\pm$  SEM of data obtained from 8 mice in each group. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  compared with the diclofenac group. MDA: Malondialdehyde; MPO: Myeloperoxidase.

**Figure 4** Effects of rebamipide on diclofenac-induced liver mitochondrial membrane potential. In the control group, the fluorescence intensity was reduced within 30 s, and then began to rise and reached a steady state within 90 s. The fluorescence intensity reduction in the diclofenac group was smaller than that in the control group, indicating that the liver mitochondrial membrane potential was decreased by diclofenac administration. The reduction in the fluorescence intensity in the rebamipide group was greater than that in the diclofenac group indicating that rebamipide improved the impairment in mitochondrial function induced by diclofenac.

520 nm declined, indicating mitochondrial swelling due to abnormal osmotic pressure. The extent of absorbance

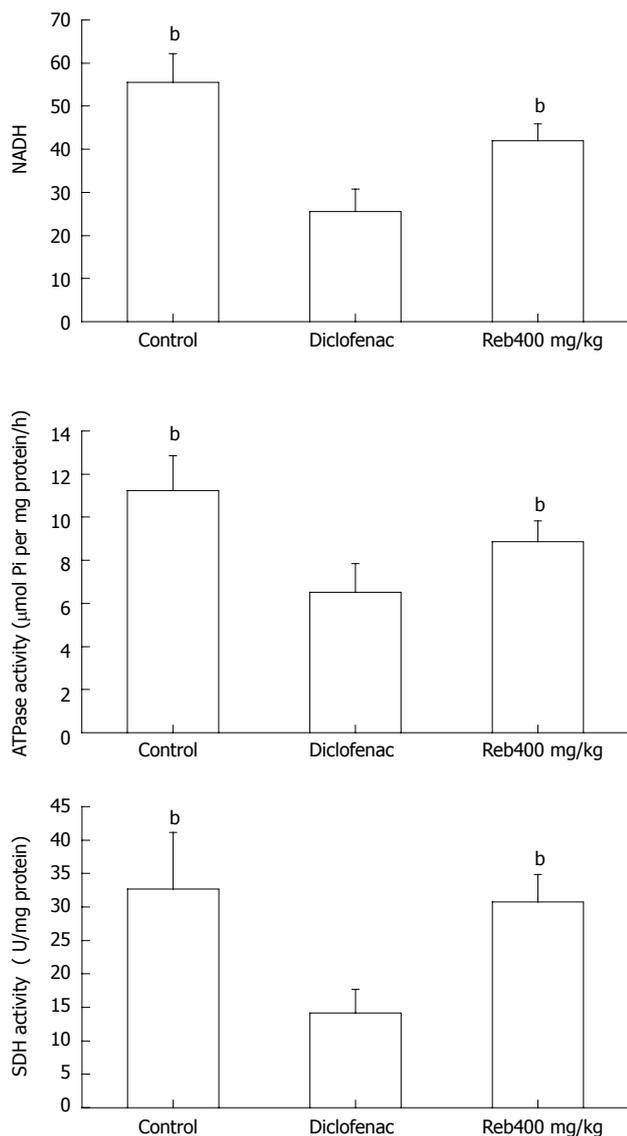

**Figure 5** Effects of rebamipide on diclofenac-induced liver mitochondrial swelling in mice. A: After adding the reaction buffer, the absorbance at 520 nm in the control mitochondria declined rapidly. The decrease was smaller in the presence of diclofenac compared with that in the control, demonstrating that liver mitochondrial dysfunction was induced by diclofenac administration. This reduction in absorbance was significantly increased in the presence of rebamipide, indicating that rebamipide improved impaired mitochondrial function; B: After adding 0.3 mmol/L CaCl<sub>2</sub> reaction buffer, the absorbance at 520 nm in the control mitochondria declined rapidly, suggesting significant swelling of mitochondria. The decrease was smaller in the presence of diclofenac compared with that in the control, demonstrating that liver mitochondrial dysfunction was induced by diclofenac administration. This reduction was significantly increased in the presence of rebamipide, indicating that rebamipide improved impaired mitochondrial function.

decrease in the diclofenac group was smaller than that in the control group (Figure 5A and B), demonstrating that liver mitochondrial dysfunction was induced by diclofenac administration. Compared with the diclofenac group, the absorbance of rebamipide was significantly increased, indicating that rebamipide improved impaired liver mitochondrial functions.

**Mitochondrial NADH levels, SDH and ATPase activities**

Compared with the control group, significant decreases in NADH levels, ATPase and SDH activities in liver mitochondrial were seen in the diclofenac group (Figure 6). Rebamipide significantly increased these levels and activities, demonstrating that rebamipide enhanced cellular stress response capacity and maintenance of mitochon-

**Figure 6** Effects of rebamipide on diclofenac-induced decreases in liver mitochondrial nicotinamide adenine dinucleotide-reduced levels, succinate dehydrogenase and ATPase activities in mice. Values are mean  $\pm$  SEM of data obtained from 8 mice in each group. <sup>b</sup> $P < 0.01$  compared with the diclofenac group. SDH: Succinate dehydrogenase; NADH: Nicotinamide adenine dinucleotide-reduced.

drial energy metabolism.

## DISCUSSION

Recently, several investigators have shown that the administration of NSAIDs induces small intestinal damage. Bjarnason *et al*<sup>[28]</sup> demonstrated that in 97 patients who took NSAIDs for more than 2 mo these agents caused enteropathy in 66% of these patients. Sigthorsson *et al*<sup>[29,30]</sup> demonstrated that intestinal adverse events, defined as hospitalization for intestinal perforation or hemorrhage, occurred in 72% of 286 patients who took 12 different NSAIDs. These trials showed that chronic NSAIDs use not only causes upper GI injury, but also lower GI injury. To date, there are no effective drugs to

prevent NSAID-induced lower GI complications.

Bjarnason *et al*<sup>[31]</sup> advocated that an increase in the permeability of small intestinal mucosa was an important factor in the mechanism of NSAID-induced small intestinal injury. Increased intestinal permeability leads to large molecules contained in food substances, bile acids, pancreatic juice, bacteria and other toxins within the lumen passing through the intestinal epithelial barrier, causing intestinal inflammation and injury. Therefore, the change in small intestinal permeability could directly reflect small intestinal mucosal integrity and barrier function, and help to identify early damage to intestinal mucosa.

In the present study, we investigated intestinal permeability induced by diclofenac and the protective effects of rebamipide. Because non-absorbed macromolecules, such as EB and FITC-D, are often used as probes in intestinal permeability tests, we investigated the amount of Evans Blue permeating into the intestinal wall ( $460.6 \pm 89.7$  *vs*  $887.1 \pm 108.3$ ) and the significant elevation in plasma FITC-D concentrations ( $5.56 \pm 1.82$  *vs*  $9.77 \pm 1.03$ ) (Figure 1). By using TEM technology, visible injury, deformed intestinal epithelial cells, a significant reduction in intestinal microvilli, disarrangement of the epithelial surface, broader junctional complexes, and opened tight junctions were observed in the diclofenac group (Figure 2B). Administration of rebamipide significantly improved small intestinal mucosal permeability and the ultrastructure changes showed more regular and numerous microvilli, and ameliorated tight junctions (Figure 1 and Figure 2C).

On the other hand, our results demonstrated that small intestinal injury induced by diclofenac was associated with increased permeability, ulcers and edema macroscopically, and small intestinal villi damage, partial epithelial denudation, and infiltration of inflammatory cells microscopically. Rebamipide reduced these small intestinal injuries both macroscopically and microscopically. Administration of rebamipide prevented small intestinal injury and histopathologic changes induced by diclofenac (data not shown).

Matysiak *et al*<sup>[13]</sup>, using HT29-19A intestinal epithelial cells, reported that rebamipide may exert its protective effect on gastric mucosa by reinforcing the epithelial barrier. Banan *et al*<sup>[32]</sup>, using human intestinal (Caco-2) cell monolayers, reported that rebamipide prevented oxidation of actin and led to the protection of actin cytoskeleton and intestinal barrier integrity against oxidant insult. These two reports show that rebamipide acts in the management of tight junctions in small intestinal mucosa. It is suggested that rebamipide improved intestinal mucosa integrity by reducing intestinal permeability.

Rebamipide removes oxygen free radicals in epithelial cells. It has been reported to promote healing and prevent relapse of gastric ulcers, which is attributed to inflammatory cell migration into the gastric mucosa<sup>[33]</sup>. Kim *et al*<sup>[34]</sup> reported that rebamipide significantly inhibited upper GI mucosal damage induced by NSAIDs in a randomized controlled trial carried out in healthy volun-

teers. In addition, rebamipide was protective in NSAID-induced lower GI injuries. Niwa *et al.*<sup>[35]</sup> reported that taking rebamipide plus diclofenac significantly prevented small intestinal injury compared with placebo plus diclofenac. However, the protective mechanism of rebamipide on intestinal mucosal injury remains unclear.

Many researchers have demonstrated that mitochondrial injury is part of the mechanism of intestinal damage induced by NSAIDs, which also includes dissipating the mitochondrial transmembrane potential, and inducing the mitochondrial permeability transition pore, which liberates cytochrome c, resulting in the caspase cascade and cellular lipid peroxidation, inducing cellular apoptosis. The fluorescent molecular probe, rhodamine 123, can enter the mitochondrial matrix through mitochondrial membrane potential dependent-substrate, and can reflect mitochondrial membrane potential by measuring the changes in optical density<sup>[25]</sup>. Research has shown that rebamipide exerted a protective effect on mitochondrial membrane stability in gastric epithelial cells<sup>[36]</sup>, however, the mechanism remains unknown. In our study, as it was exceedingly difficult to obtain a high yield of mitochondria from intestinal tissue<sup>[24]</sup>, mouse liver mitochondria were isolated to examine mitochondrial function instead of small intestinal mitochondria according to the method of Somasundaram. We found that rebamipide had a protective role in mitochondrial damage induced by diclofenac, which was related to the maintenance of mitochondrial membrane potential, an improvement in mitochondrial function, enhanced enzyme activities in the mitochondrial respiratory chain and the maintenance of energy metabolism, which indicated that the protective effect of rebamipide may be related to mitochondrial protection.

In conclusion, the administration of diclofenac in mice induced small intestinal mucosal damage and was associated with small intestinal hyperpermeation. Rebamipide showed a preventive effect on hyperpermeation, which was related to mitochondrial protection.

## COMMENTS

### Background

It is well-known that traditional non-steroid anti-inflammatory drugs (NSAIDs) induce mucosal injury in the lower gastrointestinal resulting in serious damage. However, the mechanism of NSAIDs-related small intestinal mucosal injury has not yet been clearly defined and the available protective drugs for NSAIDs enteropathy are inadequate.

### Research frontiers

Many researchers have demonstrated that mitochondrial injury is part of the mechanism of intestinal damage induced by NSAIDs, which also includes dissipating the mitochondrial transmembrane potential, and inducing the mitochondrial permeability transition pore, which liberates cytochrome c, resulting in the caspase cascade and cellular lipid peroxidation, inducing cellular apoptosis.

### Innovations and breakthroughs

The administration of diclofenac in mice induced small intestinal mucosal damage and was associated with small intestinal hyperpermeation. Rebamipide showed a preventive effect on the permeability induced by diclofenac, which was related to mitochondrial protection.

### Applications

These findings may provide experimental evidence for the clinical application of

rebamipide in the treatment of NSAIDs enteropathy.

### Terminology

NSAIDs enteropathy, mitochondria, rebamipide, intestinal mucosal permeability.

### Peer review

This is an interesting paper investigating the effects of NSAIDs on intestinal permeability and the protective effect of rebamipide on diclofenac-induced injury. However, for this kind of pharmacological study, a clear dose-dependency has not been found.

### Abstract

**AIM:** To investigate the clinical presentations associated

with bile acid synthesis defects and to describe identification of individual disorders and diagnostic pitfalls.

**METHODS:** Authors describe semiquantitative determination of 16 urinary bile acid metabolites by electrospray ionization-tandem mass spectrometry. Sample preparation was performed by solid-phase extraction. The total analysis time was 2 min per sample. Authors determined bile acid metabolites in 363 patients with suspected defects in bile acid metabolism.

**RESULTS:** Abnormal bile acid metabolites were found in 36 patients. Two patients had bile acid synthesis defects but presented with atypical presentations. In 2 other patients who were later shown to be affected by biliary atresia and cystic fibrosis the profile of bile acid metabolites was initially suggestive of a bile acid synthesis defect. Three adult patients suffered from cerebrotendinous xanthomatosis. Nineteen patients had peroxisomal disorders, and 10 patients had cholestatic hepatopathy of other cause.

**CONCLUSION:** Screening for urinary cholanooids should be done in every infant with cholestatic hepatopathy as well as in children with progressive neurological disease to provide specific therapy.

## INTRODUCTION

Inborn errors of bile acid synthesis can result in potentially treatable progressive cholestatic liver disease and neurological disease. Liver disease often presents in early childhood with jaundice, deficiency of fat-soluble vitamins, acholic stools and hepatomegaly. Serum aminotransferases and conjugated bilirubin are usually elevated and typically, gamma glutamyl transpeptidase activity is normal. Progressive neurological disease usually occurs later in childhood or early adulthood with pyramidal tract dysfunction, cerebellar signs, sensory-motor neuropathy and cognitive decline.

The synthesis of bile acids in the liver is the main pathway of cholesterol degradation. Many enzymes localized in different subcellular compartments of hepatocytes interact in the conversion of cholesterol to bile acids. Thus, defective functioning of one or more of these enzymes results in a deficiency of the final bile acids chenodeoxycholic acid and cholic acid (Figure 1) as well as the formation of atypical sterol intermediates (Table 1) including unusual bile acids and bile alcohols, which can be hepatotoxic or interfere with biliary secretion leading to cholestasis and malabsorption of fat-soluble vitamins. Severe liver disease in turn gives rise to serum aminotransferases and conjugated bilirubin levels while serum gamma glutamyl transpeptidase activity in patients with bile acid synthesis defects remains normal despite severe cholestasis<sup>[1]</sup>. This contributes to the fact that glutamyl transpeptidase is localized mainly at the luminal plasma membrane of bile duct epithelium cells. It increases if bile acids dissolve the glutamyl transpeptidase from this membrane. In patients with bile acid synthesis defects (and in those with a bile acid transporter defect) these bile acids are not produced. Therefore no increase in glutamyl transpeptidase is seen despite severe cholestasis<sup>[2]</sup>.

At the genetic level, 9 inborn errors in the bile acid biosynthetic pathways have been described to date: cerebrotendinous xanthomatosis, 3 $\beta$ -hydroxy- $\Delta^5$ -C<sub>27</sub>-steroid dehydrogenase/isomerase deficiency<sup>[3]</sup>,  $\Delta^4$ -3-oxosteroid 5 $\beta$ -reductase (5 $\beta$ -reductase) deficiency<sup>[4]</sup>, oxysterol 7 $\alpha$ -hydroxylase deficiency<sup>[5]</sup>, cholesterol 7 $\alpha$ -hydroxylase deficiency<sup>[6]</sup>, as well as the peroxisomally located defects 2-methylacyl-CoA racemase (AMCAR) deficiency<sup>[7,8]</sup>, D-bifunctional protein deficiency<sup>[9,10]</sup>, sterol carrier protein X (SCPx) deficiency<sup>[11]</sup>. The clinically most important errors are depicted in Table 1.

Several analytical techniques are available for the de-

termination of bile acid profiles in urine and plasma<sup>[12-15]</sup>, but the most useful screening test is analysis of urinary cholanooids (bile acids and bile alcohols) by electrospray ionization-tandem mass spectrometry (ESI-MS/MS)<sup>[2]</sup>.

However, patients with severely compromised liver function of different origin may show patterns of bile acid metabolites resembling those of bile acid synthesis defects and patients with disorders of bile acid synthesis may present with atypical clinical symptoms making a straightforward diagnosis impossible. In this study urinary bile acids of 363 patients with suspected defects in bile acid metabolism were determined and in 36 patients an abnormal bile acid pattern was recognized. This paper focuses on 2 groups of patients: those with proven defects of bile acid synthesis, who present with atypical clinical symptoms and those with cholanooid profiles pointing to a defect of bile acid synthesis who were later shown to have a different disorder. We describe clinical presentations, present differential diagnoses and analyze the diagnostic pitfalls of the ESI-MS/MS method in these patients.

## MATERIALS AND METHODS

### Ethics

This study has been carried out in accordance with the Declaration of Helsinki (2000) of the World Medical Association. Sample collection for this study was approved by the ethics committee of the medical faculty, University of Heidelberg, Germany (No. 071/2005).

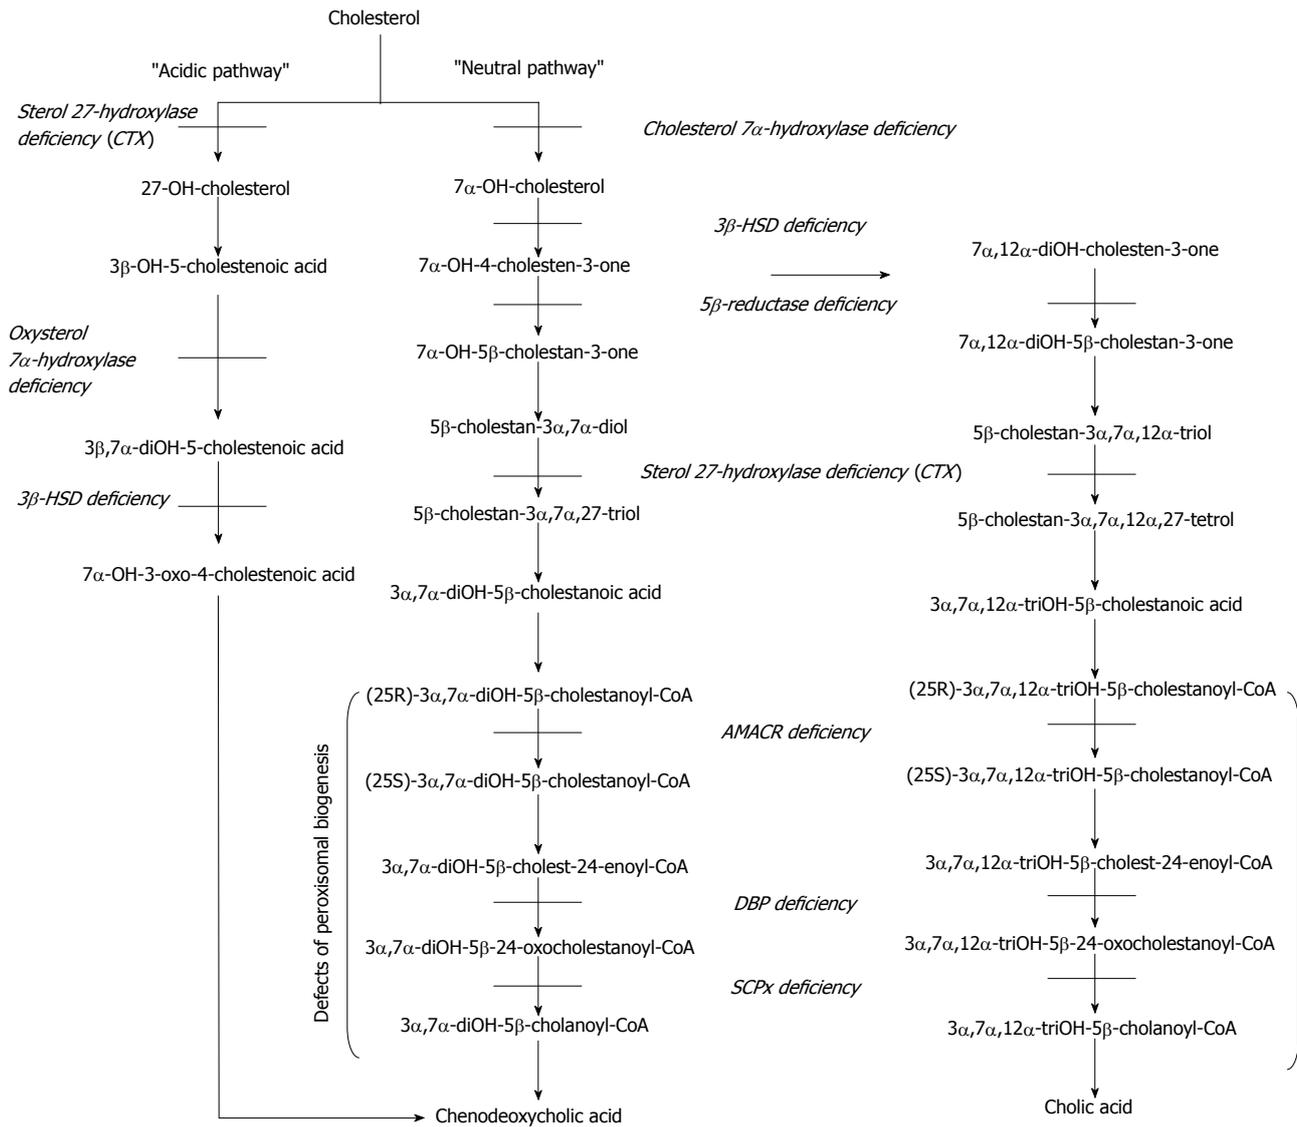

### Patients

The control population consisted of 100 healthy and non-symptomatic children, adolescents and young adults ranging in age from 10 d to 20 years. Urine specimens were collected in our hospital and used to establish the normal ranges of the 16 metabolites assayed. As positive controls, we additionally investigated patient samples collected previously at the UCL Institute of Child Health, London; these samples were obtained from patients with the following confirmed defects: 3 $\beta$ -hydroxy- $\Delta^5$ -C<sub>27</sub>-steroid dehydrogenase (3 $\beta$ -HSD) ( $n = 1$ ), 5 $\beta$ -reductase deficiency ( $n = 1$ ), peroxisomal biosynthesis disorders ( $n = 3$ ), and cerebrotendinous xanthomatosis ( $n = 3$ ).

After establishing reference ranges urine samples of patients with suspected bile acid synthesis defects were investigated in the clinical routine. To date samples of 363 patients have been analyzed. Thirty-six of those showed abnormal results and are further discussed in this study. The remaining 327 patients had normal or non-specific bile acid profiles. In the following, 3 clinically especially instructive histories from patients are briefly summarized.

### Patient MD

This girl, the second child of healthy Turkish parents who are first cousins, was born after 35 wk of an otherwise uneventful pregnancy. Shortly after birth a persistent

**Figure 1** The metabolic pathway of bile acid biosynthesis. The classical "neutral pathway" with chenodeoxycholic acid and cholic acid as end products is the main pathway in adults. In children, the alternative "acidic pathway" with chenodeoxycholic acid as major product is more active. The end products are exported as glycine or taurine conjugates into the bile canaliculi. Known metabolic blocks are displayed as bars and the specific defects in italic script. CTX: Cerebrotendinous xanthomatosis.

metabolic acidosis was observed, which was treated with bicarbonate supplementation. She also had nephrocalcinosis and failure to thrive. Because phosphate excretion was also elevated DeToni-Debré-Fanconi syndrome was suspected. At age 6 years she developed gait ataxia, muscle weakness, and external ophtalmoplegia. A severe deficiency of fat-soluble vitamins became evident (vitamin A: 0.89 μmol/L, reference range 1.09-3.07, vitamin E: 19.89 μmol/L, reference range 25-42). Aspartate aminotransferase (AST) was 66 U/L (reference range < 39), alanine aminotransferase (ALT) 46 U/L (reference range < 34), gamma glutamyltransferase (GGT) 22 U/L (reference range < 38), total bilirubin 24 μmol/L (reference range < 17), and conjugated bilirubin 12 μmol/L (reference range < 5). Abdominal ultrasound showed normal hepatic echotexture. Because multiple organ systems were involved a defect of mitochondrial energy metabolism

was suspected but lactate concentrations in blood and CSF (cerebrospinal fluid), determination of respiratory chain and pyruvate dehydrogenase complexes in frozen muscle as well as mutation analysis for pediatric mitochondrial disorders such as MERRF (myoclonic epilepsy with "ragged red fibres"), MELAS (encephalomyopathy, lactic acidosis, stroke-like episodes) and NARP (neuropathy, ataxia, retinitis pigmentosa) were all normal. After the diagnosis of the bile acid synthesis disorder 3β-hydroxy-Δ<sup>5</sup>-C<sub>27</sub>-steroid dehydrogenase deficiency was established by analysis of urinary bile acid metabolites, supplementation with vitamins A, E and K normalized her vitamin A levels but those of vitamin E remained below the normal range. After adding ursodeoxycholic acid and chenodeoxycholic acid, vitamin concentrations normalized quickly and remained so even after discontinuation of vitamin supplementation. Her gait improved significantly

**Table 1** Reference ranges of bile acid metabolites which accumulate in different bile acid biosynthesis defects

Defect	Metabolite	<i>m/z</i>	Median	Range

	Tauro-cholic acid	514	0.08	0.0-8.4

The disorders are listed with their Online Mendelian Inheritance in Man™ (OMIM) and their genetic defect, respectively. Reference ranges for bile acid metabolites which are increased in different bile acid synthesis defects were established in 100 healthy children, adolescents and young adults of age 10 d to 20 years. The metabolites are arranged to their appearance in different pathological conditions. Data are peak area ratios obtained for conjugates *versus* internal standard normalized to mol creatinine. The characteristic fragment ions used for detection of the metabolites are given as the mass-to-charge ratio (*m/z*).

and after a short period of treatment her muscle strength returned to normal.

### Patient AS

This baby girl was the first child of healthy non-consanguineous Tamil parents. At age 4 wk scleral icterus was observed. Additionally, she developed dark urine and pale stools, but her weight gain was within the normal range. Laboratory investigations at age 13 wk showed elevated AST (681 U/L, reference range < 74), ALT (344 U/L, reference range < 60) and normal GGT (99 U/L, reference range < 160). Total bilirubin was 268  $\mu$ mol/L (reference range < 21), conjugated bilirubin was 185  $\mu$ mol/L (reference range < 5). The gall bladder was not detectable in abdominal ultrasound, therefore biliary atresia was suspected. Explorative laparotomy showed a completely cirrhotic liver; there was no excretion of marker dye into the bile ducts. Due to the severe cirrhosis a Kasai procedure was not attempted. A primary liver transplantation was planned. Histological examination of a liver biopsy showed proliferating bile ducts and no giant cells consistent with biliary atresia; however, analysis of bile acids was suggestive of  $\Delta^4$ -3-oxosteroid 5 $\beta$ -reductase deficiency. Subsequent DNA sequencing of the exons of the patient's *AKR1D1* gene failed to reveal mutations, thereby excluding the diagnosis of primary 5 $\beta$ -reductase deficiency. She was treated with cholic acid and ursodeoxycholic acid but her condition deteriorated with progressive ascites, which led to refer-

ral for liver transplantation. Segments 2 and 3 of her mother's liver were transplanted successfully at age 4.5 mo. Examination of the explanted liver and biliary tree confirmed the diagnosis of biliary atresia. Several days after transplantation she developed rejection, which was successfully treated with immunosuppression. At age 10 mo the patient was doing well.

### Patient KS

This boy was the first child of non-consanguineous German parents. His mother suffered from a stroke at the age of 20 years. Follow-up investigations were not performed. At the age of 6 years attention deficit hyperactivity disorder (ADHD) was diagnosed in patient KS and treatment with methylphenidate was initiated. After primary school he attended a secondary school for children with learning difficulties. His parents noted recurrent diarrhea, especially after consuming sweets. At the age of 14 years bilateral cataracts were diagnosed. After surgery he was referred for metabolic workup. Galactose metabolites, homocysteine and urinary oligosaccharides were all normal. Cranial magnetic resonance imaging (MRI) showed increased signal intensity in cerebellar white matter in T2. Analysis of urinary bile acid metabolites was suggestive of cerebrotendinous xanthomatosis. Sterol analysis of plasma showed a clearly elevated concentration of cholestanol (0.24  $\mu$ mol/L, reference range < 0.01), together with positive results of mutation analysis confirming the diagnosis. Treatment with chenodeoxycholic

**Table 2** Electrospray ionization-tandem mass spectrometry operating parameters for bile acid intermediates

acid normalized bowel movements and the sterol profile. The patient has not developed ataxia or xanthomata. At the age of 19 years he is an apprentice landscaper.

### Analysis of bile acid conjugates

Urine samples were stored at -20 °C until analysis. Sample preparation was performed by solid-phase extraction (SPE) using a Oasis™ HLB cartridge as described previously<sup>[16]</sup>. In brief, the cartridge was preconditioned with 2 × 1 mL dichloromethane/methanol (2:1, v/v) and 1 mL purified water. To a fixed volume of 300 µL urine 10 µL internal standard solution (100 µmol/L D<sub>4</sub>-glycocholic acid) was added. The urine sample was then applied onto the preconditioned cartridge and washed with 2 mL each of purified water and n-hexane. The bile acid conjugates were eluted with 300 µL of 700 mL/L aqueous methanol (v/v). The eluate was directly used for injection to tandem mass spectrometer. The sample preparation time for a series of 20 samples takes about 1.5 h.

ESI-MS/MS measurement was carried out using a triple quadrupole IONICS EP 10+ upgraded Perkin Elmer Sciex API 365 mass spectrometer equipped with a turbo spray ion source. The mobile phase contained acetonitrile/purified water (1:1, v/v). 10 µL eluate of the SPE cartridge was directly injected. The flow rate was 80 µL/min over a total run time of 2 min.

The 16 urinary bile acid metabolites (glycine and taurine conjugates, sulfates and glucuronides) were identified with negative electrospray ionisation. Characteristic fragment ions used to determine the bile acid metabolites according to<sup>[17-22]</sup> are given in Table 1 as their mass-to-charge ratio (*m/z*). ESI-MS/MS operating parameters for

the four precursor ion scans are given in Table 2.

Data acquisition was carried out by Analysis 1.4.1 software. The determination of the 16 relevant analytes in urine was semi-quantitative since only one internal standard, D<sub>4</sub>-glycocholic acid, was used as a reference quantity. Therefore the resulting values were given as analyte/internal standard peak-area ratios normalized to mol creatinine. Creatinine determination in urine was performed on an Olympus AU 400 analyzer using the creatinine kit (Beckman Coulter, Krefeld, Germany).

### Determination of 3β-hydroxy-Δ<sup>5</sup>-C<sub>27</sub>-steroid dehydrogenase activity in fibroblasts

Patient and control fibroblasts were cultured in Dulbecco's modified eagle medium with 10% bovine serum, and antibiotic supplements. After 5-10 passages cells were trypsinized, washed with PBS and stored as pellets at -70 °C until required.

The activity of 3β-hydroxy-Δ<sup>5</sup>-C<sub>27</sub>-steroid dehydrogenase was determined as described previously<sup>[17,18]</sup>. Briefly, fibroblasts were thawed on ice, resuspended in potassium phosphate buffer (0.1 mol/L, pH 7.5) and sonicated. Cell suspensions containing 1 mg protein were preincubated with <sup>14</sup>C-labelled 7α-hydroxycholesterol (0.05 mmol/L in 5 µL acetone) and buffer for 5 min in a 37 °C shaking water bath. The reaction was initiated with the addition of 50 µL of nicotinamide adenine nucleotide (NAD) (1.5 mmol/L), with a final reaction volume of 0.5 mL. After 1 hour the reaction was stopped with the addition of 2 mL of ethanol, followed by 3 mL of water. Extractions were performed twice with *n*-hexane/ethyl acetate (1:1 v/v). Negative controls included a reaction with extract from control fibroblasts without the addition of NAD, and an assay with no cellular extract added.

The extracts were dried under argon, re-dissolved in toluene/ethyl acetate (1:1 v/v) and spotted onto a thin layer chromatography (TLC) plate, which was developed using a mobile phase of toluene/ethyl acetate (1:1 v/v).

Visualization of sterol products was performed using a phosphoimager according to the manufacturer's recommendations (Fuji Medical Systems, Stamford, United States).

### Mutation analysis of HSD3B7 and AKR1D1 loci

Genomic DNA was extracted from cultured fibroblasts or whole blood collected into EDTA-containing tubes by standard methods. Individual exons together with an average of 25 base pairs of 5'- and 3'-flanking intronic DNA from the 3β-hydroxy-Δ<sup>5</sup>-C<sub>27</sub>-steroid dehydrogenase gene (*HSD3B7*) and Δ<sup>4</sup>-3-oxosteroid 5β-reductase gene (*AKR1D1*) were amplified and subjected to DNA sequence analysis as described previously<sup>[18,19]</sup>.

## RESULTS

### Reference intervals and control ranges

Bile acid conjugates were extracted from urine and 16 metabolites (6 glycine conjugates, 6 taurine conjugates, 2 sulfates and 2 glucuronides) were determined semi-quantita-

**Table 3** Peak area ratios of specific glycine and taurine conjugates in controls, patients with cholestatic liver disease (cholestasis) and patients AS and MK with suspected 5 $\beta$ -reductase deficiency

Metabolite	<i>m/z</i>	Controls ( <i>n</i> = 100)	Cholestasis ( <i>n</i> = 10)	AS	MK	MK <sup>1</sup>
Glyco-hydroxy-oxo-cholenoic acid	444	0-0.4	1-210	34	104	14
Glyco-dihydroxy-oxo-cholenoic acid	460	0-2.4	8-251	15	1331	1

Tauro-cholic acid	514	0-8.4	6-749	9	10	1

Elevation of glycine and taurine conjugates of dihydroxy-oxo-cholenoic acid (*m/z* 460 and 510) and hydroxy-oxo-cholenoic acid (*m/z* 444 and 494) point to 3 $\beta$ -HSD. Elevation of glycine and taurine conjugates of cholic acid (*m/z* 448 and 464) and chenodeoxycholic acid (*m/z* 498 and 514) point to cholestatic liver disease. In patient AS, 5 $\beta$ -reductase and 3 $\beta$ -hydroxy- $\Delta^5$ -C<sub>27</sub>-steroid dehydrogenase deficiency were excluded by mutation analysis. The cholanoic profiles of patient MK with cystic fibrosis are in a decompensated state with severe cholestatic liver disease and after treatment with ursodeoxycholic acid, pancreatic enzymes and fat-soluble vitamins.

tively by ESI-MS/MS. We established reference ranges for these 16 metabolites studied here in 100 subjects ranging in age from 10 d to 20 years (Table 1); no age-dependency for any of these bile acid conjugates was found (data not shown).

### Bile acid metabolites in patient samples

**Cholestatic liver disease and cholanoic profiles mimicking 5 $\beta$ -reductase deficiency:** In patients with cholestatic liver disease analysis of urinary bile acid metabolites showed clearly increased excretion of glycine and taurine conjugates of cholic acid and chenodeoxycholic acid (*m/z* 448, 464, 498 and 514). In a subgroup of patients with non-specified cholestatic liver disease (*n* = 10) we additionally detected elevated excretion of glycine and taurine conjugates of dihydroxy-oxo-cholenoic acid (*m/z* 460, 510) and hydroxy-oxo-cholenoic acid (*m/z* 444, 494), however the elevation of cholic and chenodeoxycholic conjugates always exceeded the excretion of (di)-hydroxy-oxo-cholenoic acid conjugates (Table 3).

In patient AS with suspected biliary atresia excretion of glyco-(di)-hydroxy-oxo-cholenoic acid conjugates was elevated (Table 3). However, conjugates of cholic acid and chenodeoxycholic acid were very low for an infant with cholestasis. As some aspects of biliary atresia such

as absent gall bladder upon ultrasound and missing excretion of bile in the gut have been described previously in patients with 5 $\beta$ -reductase deficiency, we performed mutation analysis of the *AKR1D1* gene, which was normal, excluding 5 $\beta$ -reductase deficiency. Similarly, no mutations were detected in the 3 $\beta$ -hydroxy- $\Delta^5$ -C<sub>27</sub>-steroid dehydrogenase gene (*HSD3B7*).

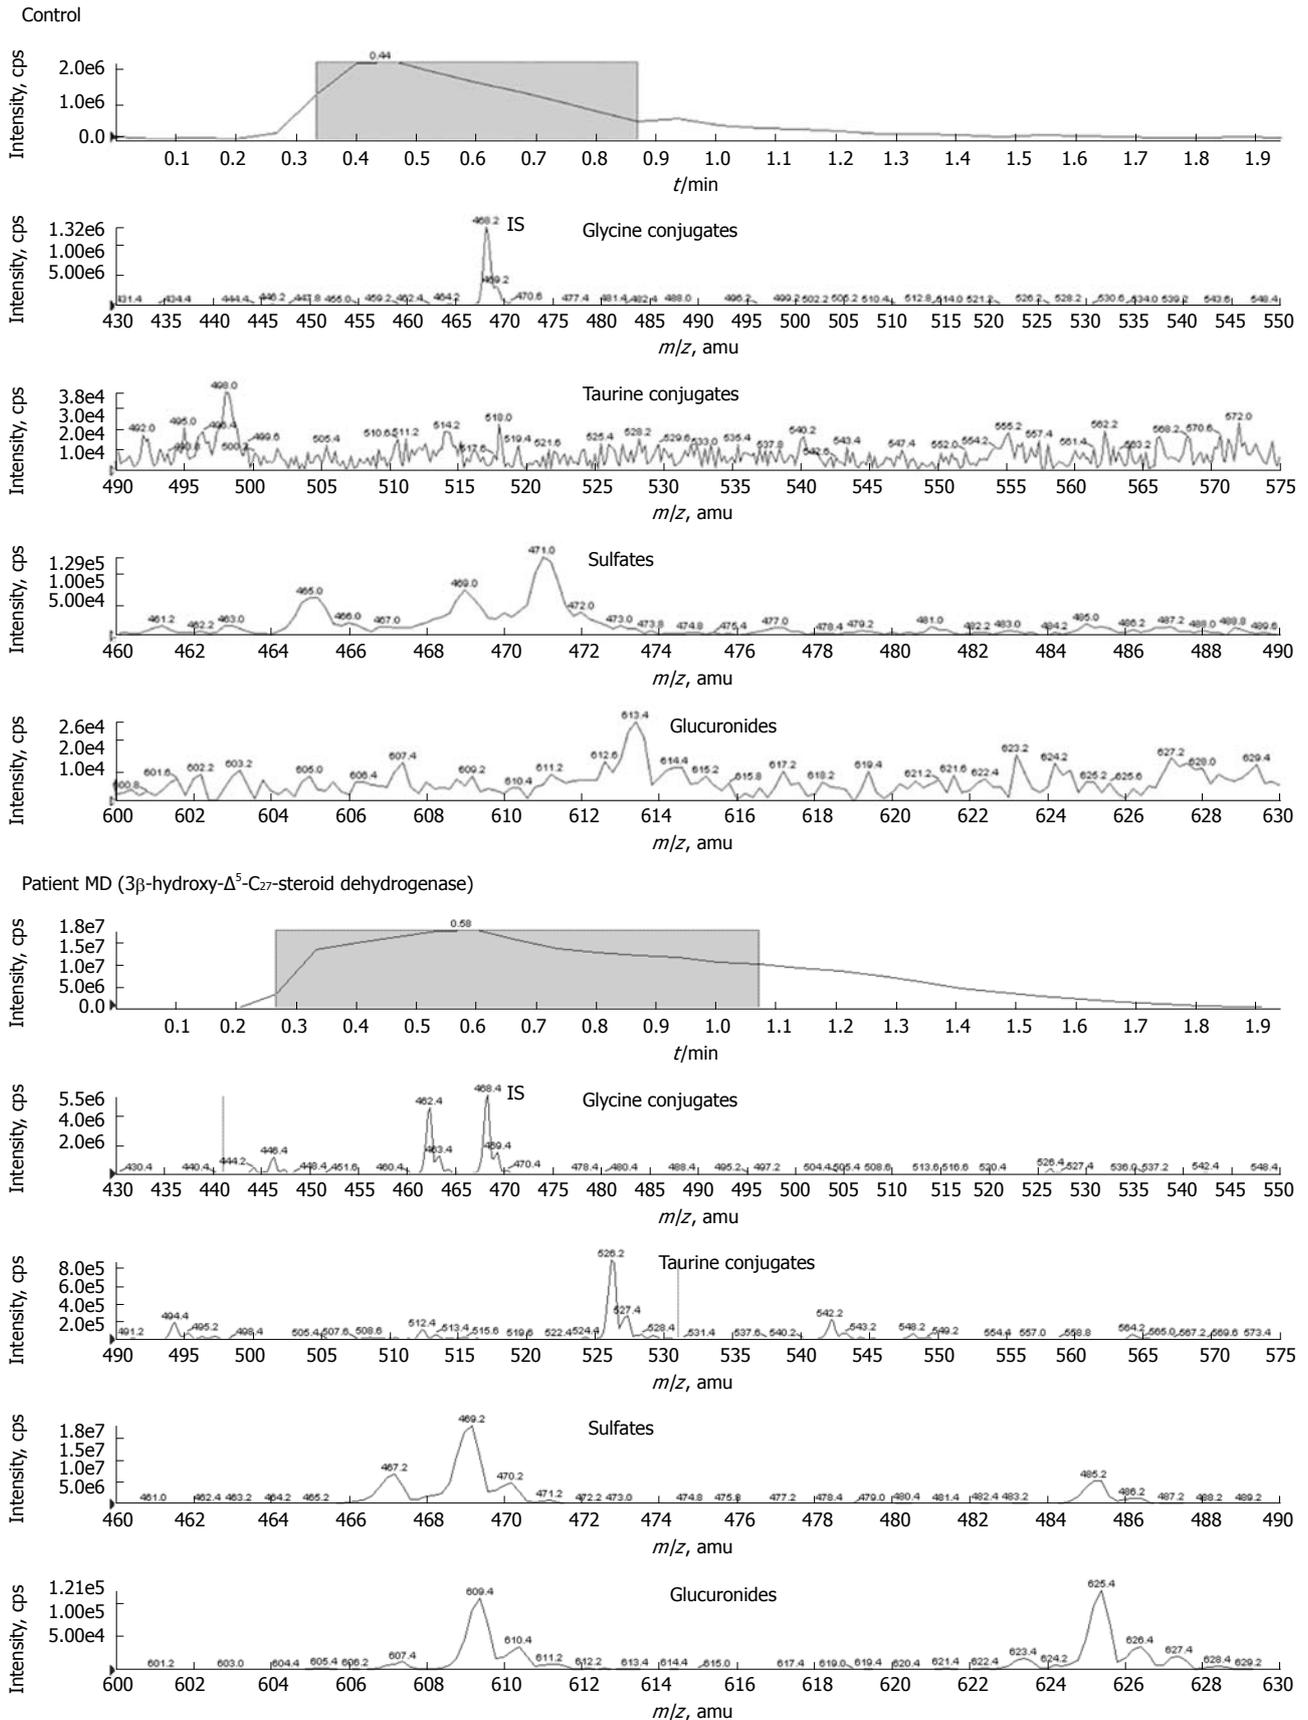

A quite similar cholanoic profile with low amounts of cholic and chenodeoxycholic acid conjugates was found in another patient, MK, a 7 mo old patient with failure to thrive and severe cholestatic liver disease (Table 3). In this patient cystic fibrosis was confirmed by an abnormal sweat test, abnormal ion transport in rectal epithelial cells and heterozygosity for the mutation  $\Delta$ F508 in the *CFTR* gene. Supplementation with ursodeoxycholic acid, pancreatic enzymes and fat-soluble vitamins completely normalized the cholanoic profile.

**3 $\beta$ -hydroxy- $\Delta^5$ -C<sub>27</sub>-steroid dehydrogenase deficiency-patient MD:** Analysis of urinary bile acid metabolites in patient MD revealed large quantities of sulphate conjugates of di- and trihydroxy-5-cholenoic acid metabolites characterized by *m/z* 469 and 485, respectively. Glycine conjugates of di- and trihydroxy-5-cholenoic acid (*m/z* 526 and 542) were less pronounced, but clearly increased compared to controls (Figure 2). Peaks attributable to the glycine and taurine conjugates of chenodeoxycholic acid and cholic acid (*m/z* 448, 464, 498 and 514, respectively) were small or present at near baseline levels. This constellation of metabolites is characteristic of 3 $\beta$ -hydroxy- $\Delta^5$ -C<sub>27</sub>-steroid dehydrogenase deficiency.

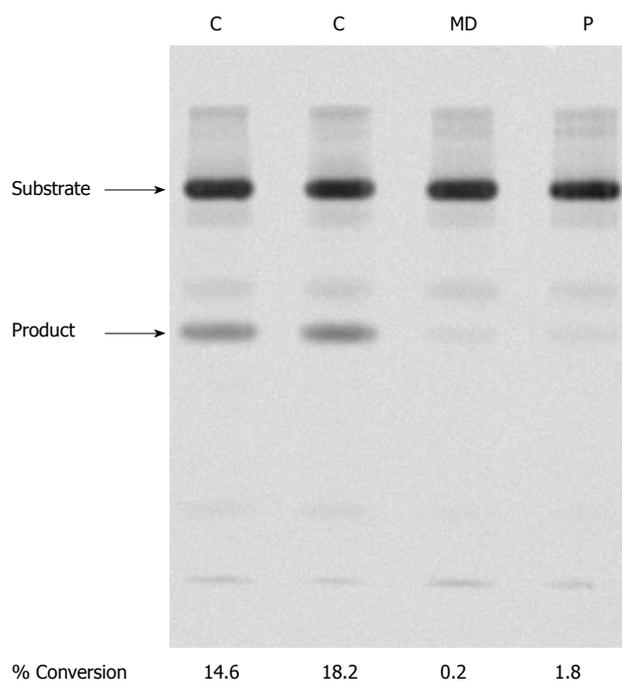

Mutation analysis of the *HSD3B7* gene showed homozygosity for a single base pair mutation (c.605G > C, GenBank Accession #AF277719) in exon 5 resulting in an amino acid substitution (p.G196A). This mutation has not been described before but has not been found in > 50 control DNAs.

To examine if this mutation affected enzyme activity we determined 3 $\beta$ -hydroxy- $\Delta^5$ -C<sub>27</sub>-steroid dehydrogenase activity in the patient's fibroblasts (Figure 3) as described in materials and methods. In control fibroblasts (C) two clear sterols were visualised after TLC developed under standard conditions. These sterols were identified by gas chromatography mass spectrometry as the substrate, 7 $\alpha$ -hydroxycholesterol and the product, 7 $\alpha$ -hydroxy-4-cholesten-3-one of the 3 $\beta$ -HSD enzyme. In fibroblasts of patient MD, little or no product was formed, indicative of severely reduced 3 $\beta$ -hydroxy- $\Delta^5$ -C<sub>27</sub>-steroid dehydrogenase activity. As a negative control, unaffected fibroblasts were incubated with substrate in the absence of NAD and the reaction subjected to TLC. In this case no product was observed on the silica plate (results not shown).

**Cerebrotendinous xanthomatosis-patient KS and others:** In patient KS analysis of urinary bile acid metabolites showed increased excretion of glucuronide-5 $\beta$ -cholestane-pentole (*m/z* 627) and less pronounced excretion of glucuronide-5 $\beta$ -cholestane-tetrole (*m/z* 611). Mutation

**Figure 2** Precursor ion spectra of urinary bile acid metabolites from patient MD with 3β-hydroxy-Δ<sup>5</sup>-C<sub>27</sub>-steroid dehydrogenase deficiency and control. The strongest signals were identified as sulphate conjugates of di- and trihydroxy-5-cholenoic acid scanning with *m/z* 469 and 485. Glycine conjugates of di- and trihydroxy-5-cholenoic acid (*m/z* 526 and 542) were less pronounced, but also increased.

**Figure 3** 3 $\beta$ -hydroxy- $\Delta^5$ -C<sub>27</sub>-steroid dehydrogenase activity in patient fibroblasts. In control cells (C) two sterols were observed after thin layer chromatography. These compounds were identified by gas chromatography mass spectrometry as the substrate, 7 $\alpha$ -hydroxycholesterol and product, 7 $\alpha$ -hydroxy-4-cholesten-3-one, of 3 $\beta$ -hydroxy- $\Delta^5$ -C<sub>27</sub>-steroid dehydrogenase. In fibroblasts of patient MD and another patient with known 3 $\beta$ -hydroxy- $\Delta^5$ -C<sub>27</sub>-steroid dehydrogenase deficiency (P), little or no 7 $\alpha$ -hydroxy-4-cholesten-3-one was formed.

analysis of the *CYP27A1* gene revealed compound heterozygosity for c.IVS6-1A and c.1213C > T (p.R405W) (University Medical Center Nijmegen, Department of Human Genetics, DNA-Diagnostics). These are known pathogenic mutations for cerebrotendinous xanthomatosis<sup>[20]</sup>.

Additionally we found elevated concentrations of 5 $\beta$ -cholestane-tetrol glucuronides (mean excretion 4, normal < 1.6) and -pentol glucuronides (mean excretion 28, normal < 4.3) in three adults unrelated to KS and to each other with previously confirmed cerebrotendinous xanthomatosis.

### Peroxisomal disorders

We analyzed urinary bile acid metabolites in 21 infants with suspected peroxisome biogenesis defects. All patients had profound neurological abnormalities and clearly elevated concentrations of hexacosanoic acid (C26:0). In 16 patients, tauro-tetra-hydroxycholestanic ( $m/z$  572) was elevated, consistent with a peroxisome biogenesis defect. Of these patients 12 additionally showed an elevation of tauro-tri-hydroxycholestanic acid ( $m/z$  556), but this increase was always lower than that measured for tauro-tetra-hydroxycholestanic acid. In two patients there was no elevation of tauro-tetra-hydroxycholestanic acid but increases of tauro-tetra-hydroxy-24-ene-cholestanic acid ( $m/z$  570) and tauro-penta-hydroxy-24-ene-cholestanic acid ( $m/z$  586) were detected, pointing to D-bifunctional protein deficiency (*HSD17B4* gene).

In a previously described 45-year old patient (HPH)<sup>[11]</sup> with dystonic head tremor, spasmodic torticollis and leucoencephalopathy in MR imaging we found increased excretion of 27-nor-5 $\beta$ -cholestanepentol-glucuronide ( $m/z$  613) and 27-nor-5 $\beta$ -cholestanhexol-glucuronide ( $m/z$  629). This patient was found to suffer from a defect of peroxisomal sterol carrier protein X (SCPx)<sup>[11]</sup>.

### DISCUSSION

Defects of bile acid synthesis can present with a wide variety of clinical symptoms from early infancy to adulthood. Cholestatic liver disease, which is often described as the leading symptom, may not be evident as in patient MD in the present cohort. Instead impaired absorption of fat-soluble vitamins may result in a multisystem disorder with predominantly neurological symptoms in early childhood. It is likely that vitamin E deficiency contributed to the ataxia seen in MD; spinocerebellar ataxia is a common feature of vitamin E deficiency (as seen in untreated abetalipoproteinemia). Myopathy has also been reported in vitamin E deficiency in both man and experimental animals.

Cataracts are often the first sign of cerebrotendinous xanthomatosis in school children and adolescents, with xanthomas and ataxia usually occurring later in life. Treatment with chenodeoxycholic acid positively influences neurological disease and avoids development of xanthomata and arteriosclerosis<sup>[21]</sup>, therefore determination of bile acid metabolites and sterols should be included in the diagnostic workup of cataract in this age group.

In patients with peroxisomal disorders determination of bile acid metabolites is helpful in distinguishing between defects of peroxisome biogenesis versus single enzyme deficiencies. An elevated excretion of tauro-tetrahydroxy-cholestanic acid is highly suggestive of a defect in peroxisome biogenesis whereas increased excretion of tauro-tetra-hydroxy-24-ene-cholestanic acid and tauro-penta-hydroxy-24-ene-cholestanic acid point to a D-bifunctional protein defect. It is important to note that a normal bile acid profile does not exclude peroxisome biogenesis disorders as some patients may present without urinary bile acid abnormalities. Importantly bile acid analysis may elucidate peroxisomal defects with predominantly neurological presentations as in peroxisomal SCPx or  $\alpha$ -methyl-acyl-CoA racemase deficiencies, in which analysis of very long-chain fatty acids is not of diagnostic value<sup>[11]</sup>.

Earlier studies<sup>[22]</sup> have indicated that non-specific cholestatic liver disease may result in elevated excretion of hydroxy- and dihydroxy-oxo-choleonic acids mimicking 5 $\beta$ -reductase deficiency. However, non-specific cholestatic liver disease can usually be distinguished from 5 $\beta$ -reductase deficiency by the finding of elevated urinary concentrations of the primary bile acids cholic acid and chenodeoxycholic acid. From our study cohort 2 examples of patients with elevated hydroxy- and dihydroxy-oxo-choleonic acids and low primary bile acids are de-

scribed, one presenting with biliary atresia (patient AS) and the other (patient MK) with cystic fibrosis, cholestasis and severe malabsorption.

Since one patient with 5 $\beta$ -reductase deficiency had a clinical presentation resembling biliary atresia 5 $\beta$ -reductase deficiency should be considered in the differential diagnosis of biliary atresia<sup>[19]</sup>. Although liver transplantation is curative for both biliary atresia and 5 $\beta$ -reductase deficiency, it is crucial to define the molecular basis of the diseases in these individuals prior to counselling of the parents regarding recurrence risk in further pregnancies. In our patient AS, mutation analysis of the 5 $\beta$ -reductase gene (*AKR1D1*) excluded a deficiency in bile acid synthesis leaving biliary atresia as the most likely diagnosis, so that she subsequently underwent successful liver transplantation.

In patient MK, the common  $\Delta$ F508 mutation was detected in the *CFTR* gene, and this individual experienced a normalization of her urinary cholanoic profile after supplementation with pancreatic enzymes, vitamins and ursodesoxycholic acid.

The mechanism underlying the aberrant cholanoic profiles in patients AS and MK is not clear. There may be secondary inhibition of 5 $\beta$ -reductase by an as yet undefined substance occurring in both conditions.

Because of the clinical variability associated with atypical presentations, as in the patients described in this article, the availability of a quick and reliable method for determination of bile acid metabolites is essential in the diagnostic work-up. The ESI-MS/MS method described is fast and reliable. However, in some patients cholanoic profiles suggesting 5 $\beta$ -reductase deficiency are obtained. In these cases mutation analysis of the *AKR1D1* gene is necessary. If 5 $\beta$ -reductase deficiency is excluded cystic fibrosis or biliary atresia should be considered in the differential diagnosis.

## ACKNOWLEDGMENTS

We thank Davis DL, Treiber DK, and Schmidt KV for their excellent technical assistance and the Department of Human Genetics, DNA-Diagnostics, University Medical Center Nijmegen for mutation analysis of the *CYP27A1* gene.

## COMMENTS

### Background

Bile acid synthesis defects can result in progressive cholestatic liver disease and neurological disease. They can be treated effectively with bile acid supplementation when determined early but result in permanent liver failure requiring liver transplantation or irreversible neurological damage when diagnosed at a late stage. Therefore knowledge of clinical symptoms and early diagnosis are important.

### Research frontiers

Analysis of urinary bile acids by electrospray ionization-tandem mass spectrometry (ESI-MS/MS) is the method of choice to screen for bile acid synthesis defects. However, patients with liver disease of other origin may show similar patterns of bile acid metabolites. Moreover patients with disorders of bile acid synthesis may present with atypical clinical symptoms.

## Innovations and breakthroughs

In the present study authors analyzed urinary bile acid metabolites in a large number of patients, in whom bile acid synthesis defects were suspected. In patients with abnormal bile acid profiles authors performed complete biochemical and molecular diagnostic workup. The pitfalls of the ESI-MS/MS method were evaluated and differential diagnoses discussed.

## Applications

To expand the knowledge about clinical presentation of bile acid synthesis defects and the differential diagnoses. To be aware of pitfalls of the ESI-MS/MS method and further diagnostic procedures to confirm or exclude defects of bile acid synthesis.

## Peer review

This work is well written. Although the group of patients with bile acid synthesis defects is small, it is important to make the clinical diagnosis. This paper will be particularly interesting for pediatricians.

### Abstract

**AIM:** To evaluate cut-off values and performance of acoustic radiation force impulse imaging (ARFI) using transient elastography [FibroScan® (FS)] as a reference.

**METHODS:** Six hundred and six patients were enrolled in this study. All patients underwent liver stiffness measurement with FS (FS-LS) and ARFI (with shear wave velocity quantification; ARFI-SWV) and the performance of ARFI in comparison to FS was determined. Sixty-eight patients underwent liver biopsy.

**RESULTS:** Significantly higher success rates for the determination of liver stiffness were found using ARFI

as compared to FS [604/606 (99.7%) vs 482/606 (79.5%),  $P < 0.001$ ]. ARFI-SWV correlated significantly with FS-LS ( $r = 0.920$ ,  $P < 0.001$ ). ARFI-SWV increased significantly with the stage of fibrosis ( $1.09 \pm 0.13$  m/s for patients with no significant fibrosis (FS-LS  $< 7.6$  kPa);  $1.46 \pm 0.27$  m/s for patients with significant liver fibrosis ( $7.6 < \text{FS-LS} \leq 13.0$  kPa); and  $2.55 \pm 0.77$  m/s for patients with liver cirrhosis (FS-LS  $> 13.0$  kPa)). ARFI-SWV cut-off values were identified for no significant fibrosis (1.29 m/s; sensitivity 91.4% and specificity 92.6%) and for liver cirrhosis (1.60 m/s; sensitivity 92.3% and specificity 96.5%). The optimal cut-off value for predicting liver fibrosis ( $F \geq 2$ ) was 1.32 m/s (sensitivity 87.0% and specificity 80.0%) and for liver cirrhosis (F4) 1.62 m/s (sensitivity 100% and specificity 85.7%), for patients who underwent liver biopsy. An excellent inter- and intraobserver reproducibility was observed for ARFI-SWV determinations.

**CONCLUSION:** An ARFI-SWV cut-off value of 1.29 m/s seems to be optimal for patients with no significant liver fibrosis and 1.60 m/s for patients with liver cirrhosis.

Evaluation of acoustic radiation force impulse imaging for determination of liver stiffness using transient elastography as a reference. *World J Gastroenterol* 2012; 18(10): 1077-1084 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i10/1077.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i10.1077>

## INTRODUCTION

Liver biopsy is currently considered the gold standard for assessing hepatic fibrosis or cirrhosis<sup>[1]</sup>. However, it is an invasive procedure with rare but potentially life threatening complications. In addition, the accuracy of liver biopsy for assessment of fibrosis may suffer from sampling errors and interobserver variability<sup>[2-6]</sup>. Therefore, research has been focused on the evaluation of non-invasive methods for assessment of liver fibrosis, such as routine biological and hematologic tests, surrogate serum fibrosis markers and measurement of liver elasticity<sup>[7-11]</sup>. Considerable experience exists for transient elastography<sup>[12]</sup>. Transient elastography [FibroScan<sup>®</sup> (FS)] is a rapid, non-invasive, and reproducible method for measuring liver stiffness (FS-LS). A strong association between FS-LS and the degree of liver fibrosis was demonstrated in patients with chronic hepatitis<sup>[13-15]</sup>. A cut-off value of 13 kPa has been established for the discrimination between liver fibrosis and cirrhosis<sup>[13]</sup>. For discrimination of fibrosis from no significant fibrosis a cut-off value of 7.6 kPa was suggested<sup>[16]</sup>. However, FS is limited in patients with ascites or a body mass index above 28 kg/m<sup>2</sup><sup>[17]</sup>. Further limitations of FS have been described in several studies<sup>[18-21]</sup>.

Another noninvasive tool for the detection of liver fibrosis is the acoustic radiation force impulse (ARFI) imaging technology<sup>[22-24]</sup>. ARFI imaging has been incorporated into a conventional ultrasonographic (US) device (Acuson S2000; Siemens Medical Solutions, Mountain View, CA, United States). ARFI imaging technology involves the mechanical excitation of tissue using short-duration acoustic pulses in a region of interest, producing shear waves that spread away from the region of interest<sup>[25-27]</sup>. By recording the shear wave-front and correlating these measurements with the elapsed time, the shear wave velocity-SWV (m/s) can be quantified (ARFI-SWV). The SWV increases with stiffness. Thus, the measured SWV is an intrinsic and reproducible property of the tissue<sup>[28-30]</sup>. A significant correlation between ARFI imaging, serum fibrosis marker tests, and the histologic fibrosis stage was reported in a few pilot studies<sup>[31-33]</sup>.

In this study, we compared FS-LS with ARFI-SWV. Using the known cut-off values of 7.6 kPa and 13 kPa for FS we established cut-off values for ARFI-SWV for discriminating no significant liver fibrosis from significant liver fibrosis and significant liver fibrosis from liver cirrhosis, respectively. Furthermore, inter- and intraobserver reproducibility was studied for ARFI.

## MATERIALS AND METHODS

### Patients

This study was approved by the ethics committee of Heinrich Heine University. A total of 606 patients who had consulted the Hepatology Unit of the University Hospital Düsseldorf, Germany were included in this study. Aetiology of the liver disease was determined according to standard diagnostic criteria. Patients' characteristics and aetiologies of liver diseases are shown in Table 1.

**Table 1** Characteristics of patients at the time of liver stiffness measurement (*n* = 606)

Patients, <i>n</i>	606
Male, <i>n</i> (%)	363 (59.9%)
Age (yr)	53 ± 17
ALT (IU/L)	59 ± 159
AST (IU/L)	53 ± 142
GGT (IU/L)	104 ± 218
AP (IU/L)	97 ± 84
Total bilirubin (mg/dL)	1.1 ± 0.4
Prothrombin time (% of normal)	96 ± 22
Chronic liver diseases, <i>n</i> (%)	
Non-alcoholic steatohepatitis	236 (38.9%)
Chronic hepatitis B	48 (7.9%)
Chronic hepatitis C	97 (16.0%)
Alcoholic liver disease	52 (8.6%)
Autoimmune hepatitis	18 (3.0%)
PBC/PSC	12 (2.0%)
Others	14 (2.3%)
Healthy controls	129 (21.3%)
Liver biopsy available, <i>n</i> (%)	68 (11.2%)

ALT: Alanine aminotransferase; AST: Aspartate aminotransferase; GGT:  $\gamma$ -glutamyl-transpeptidase; AP: Alkaline phosphatases; PBC: Primary biliary cirrhosis; PSC: Primary sclerosing cholangitis.

### Liver stiffness measured by FibroScan

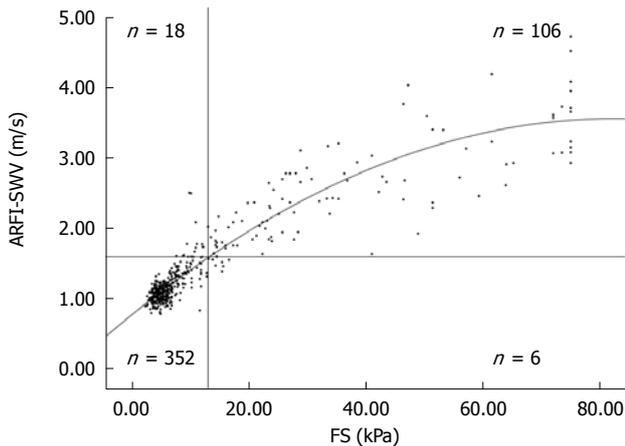

Details of the technical background and examination procedure have been described previously<sup>[12]</sup>. The tip of the probe transducer was placed on the skin between the ribs over the right liver lobe. The measurement depth was between 25 mm and 65 mm below the skin surface. Ten measurements were obtained in each patient. Determination of liver stiffness was considered valid, when a success rate of at least 60% was obtained. The results were expressed in kPa. The median value was taken as representative.

### Acoustic radiation force impulse-shear wave velocity determination

In all patients, ARFI imaging (Acuson S2000, Virtual Touch Tissue Quantification mode) and transient elastography (TE; FibroScan; Echosens, Paris, France) were performed on the same day. The examination was performed in the right lobe of the liver, through the intercostal space, at the same site as the transient elastography measurement. A measurement depth of 2 cm below the liver capsule was chosen to standardize the examination for ARFI-SWV. The mean value of ten measurements was taken as representative.

### Liver histology and quantification of liver fibrosis

A subgroup of 68 patients underwent liver biopsy in the previous six months. Patients with histological proven liver cirrhosis in the previous two years were also included. Liver biopsy specimens were fixed in formalin and embedded in paraffin. Liver fibrosis was evaluated semiquantitatively according to the METAVIR scoring system. Fibrosis was staged on a 0-4 scale as follows: F0: No fibrosis; F1: Portal fibrosis without portal septa; F2: Portal fibrosis with few septa; F3: Numerous septa with-

**Figure 1 Correlation of acoustic radiation force impulse with FibroScan ( $r = 0.920$ ;  $P < 0.001$ ).** The vertical line represents the cut-off value of 13 kPa for FS and the horizontal line represents the cut-off value of 1.60 m/s for acoustic radiation force impulse ( $n = 482$ ); using the cut-off value of 1.60 for the discrimination of liver fibrosis from liver cirrhosis for acoustic radiation force impulse imaging shear wave velocity, 458 of the 482 patients (95.1%) were classified correctly. Six (1.2%) patients were classified false-negative (FS-LS  $\geq 13$  kPa and acoustic radiation force impulse imaging shear wave velocity  $< 1.60$  m/s), and 18 (3.7%) were classified false-positive (FS-LS  $< 13$  kPa and ARFI-SWV  $\geq 1.60$  m/s. FS: FibroScan®.

out cirrhosis; and F4: Cirrhosis.

### Statistical analysis

Data were entered in SPSS (version 19.0, Inc., Munich, Germany). A  $\chi^2$  or Fisher's exact test ( $F$ -test) was used to compare categorical variables, and a Mann-Whitney test was used for the comparison of continuous variables. The significance level was set at 0.05, and all  $P$  values were two-tailed. A Pearson's test was performed to study the correlation between FS-LS and ARFI-SWV.

For no significant fibrosis (FS  $\leq 7.6$  kPa) and liver cirrhosis (FS  $> 13.0$  kPa), the diagnostic performance of ARFI was assessed using receiver operating characteristic (ROC) curves. The ROC curve is a plot of sensitivity *vs* 1-specificity for all possible cut-off values. The most commonly used index of accuracy is area under the ROC curve (AUROC). AUROC-values close to 1.0 indicated high diagnostic accuracy. ROC curves were generated for patients with FS  $\leq 7.6$  kPa, and patients with FS  $> 13$  kPa. Optimal cut-off values for ARFI were chosen to maximize the sum of sensitivity and specificity, positive and negative predictive values were computed for these cut-off values. Using this analysis SWV cut-off values were identified for patients with no significant fibrosis (FS  $\leq 7.6$  kPa) and patients with liver cirrhosis (FS  $> 13.0$  kPa).

Intraobserver and interobserver agreement was analysed using the intraclass correlation coefficient (ICC)<sup>[34]</sup>. ICC values range from +1 (100% agreement; all the variability being due to patient characteristics) to -1 (100% disagreement; all the variability being due to the rater's performance). Interobserver agreement was calculated as the agreement between the first liver ARFI measurements of the two observers. Intraobserver agreement was calcu-

lated as the agreement between the first and the second ARFI evaluation. The agreement of liver stiffness between the right liver lobe and left liver lobe was calculated using the ICC. Agreement was classified as poor (ICC = 0.00 to 0.20), fair to good (ICC = 0.40 to 0.75) or excellent (ICC = 0.75).

## RESULTS

A total of 606 patients were enrolled in this study. Their characteristics at the time of the FibroScan/ARFI examination are summarised in Table 1 (<http://www.ncbi.nlm.nih.gov/pmc/articles/PMC1856085/table/tbl1/>). Aetiologies of chronic liver diseases were non-alcoholic steatohepatitis ( $n = 236$ ), hepatitis C virus ( $n = 97$ ) or hepatitis B virus infection ( $n = 48$ ), alcoholic liver disease ( $n = 52$ ), primary biliary cirrhosis/primary sclerosing cholangitis ( $n = 12$ ), autoimmune hepatitis ( $n = 18$ ), and others ( $n = 14$ ). In addition, another 129 patients without any liver diseases were included in the study.

### Comparison of success rates for acoustic radiation force impulse and FibroScan

FS-LS ranged from 2.3 kPa to 75.0 kPa (median 6.0 kPa) and ARFI-SWV ranged from 0.77 m/s to 4.72 m/s (mean  $1.5 \pm 0.77$  m/s). Mean depth of the area where ARFI-SWV measurement was performed was  $4.51 \pm 0.56$  cm. The overall success rate was  $77.8\% \pm 28.5\%$  for FS compared to  $93.3\% \pm 9.87\%$  for ARFI ( $P < 0.001$ ). A liver stiffness measurement success rate of 100% was observed in 262 (43.2%) patients by FS compared to 373 patients (61.6%,  $P < 0.001$ ) by ARFI.

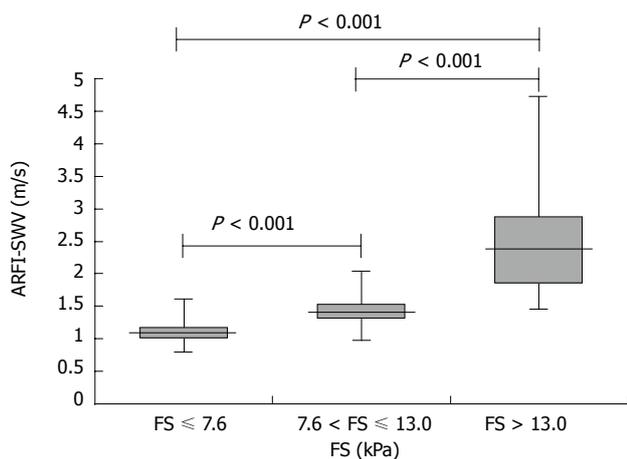

A valid liver stiffness determination (success rate of at least 60%) was observed in 482/606 (79.5%) by FS compared to 604/606 (99.7%) by ARFI ( $P < 0.001$ ). This difference was mostly due to a large distance between the skin surface and the liver capsule, which is associated with overweight. The success rate of FS was significantly dependent upon the distance between the skin surface and liver capsule (success rate 0%:  $3.27 \pm 0.34$  cm; success rate between 1% and 59%:  $2.81 \pm 0.56$  cm; and success rate  $\geq 60\%$ :  $2.41 \pm 0.52$  cm;  $P < 0.001$  for all differences).

After exclusion of all patients with an invalid liver stiffness determination (success rates below 60%) in one of the techniques, 482 patients remained for the following analysis.

### Correlation of acoustic radiation force impulse with FibroScan

To analyse the correlation between FS-LS and ARFI-SWV, a Pearson test was performed. There was a significant correlation between these two methods ( $P < 0.001$ ;  $r = 0.920$ ; Figure 1)

In consideration of the cut-off values for the different stages of liver fibrosis for FS, the following frequencies were observed: 297 (61.6 %) no significant fibrosis (FS-LS  $\leq 7.6$  kPa), 73 (15.2%) significant fibrosis ( $7.6$  kPa  $<$  FS-LS  $\leq 13.0$  kPa), and 112 (23.2%) cirrhosis (FS-LS  $> 13.0$  kPa). Mean ARFI-SWV was  $1.09 \pm 0.13$  m/s

**Figure 2** Acoustic radiation force impulse imaging shear wave velocity for the different stages of fibrosis. Box plots show median values with 25th and 75th percentiles of shear wave velocity determined by acoustic radiation force impulse. (FS ≤ 7.6 kPa: No significant fibrosis; 7.6 kPa < FS ≤ 13.0 kPa: Significant fibrosis; FS > 13.0 kPa: Liver cirrhosis).

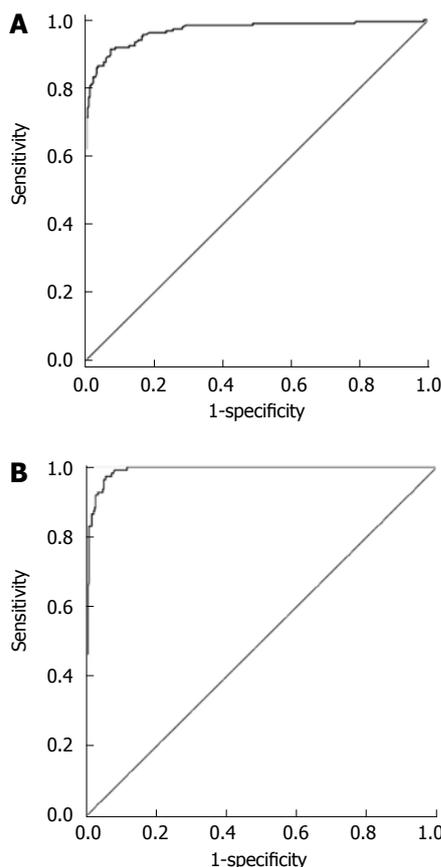

(range 0.80-1.61 m/s) for patients with no significant fibrosis (FS-LS < 7.6 kPa), compared to 1.44 ± 0.26 m/s (range 0.98-2.03 m/s) for patients with significant liver fibrosis, and 2.55 ± 0.77 m/s (range 1.47-4.72 m/s) for patients with liver cirrhosis. ARFI-SWV was significantly different between patients according to their fibrosis stage ( $P < 0.001$ ). Figure 2 shows box plots of ARFI-SWV for the three groups.

**Receiver operating characteristic analysis of acoustic radiation force impulse**

The diagnostic value (ROC curves) of liver stiffness measurement for patients with FS-LS < 7.6 kPa and patients with FS-LS > 13.0 kPa is shown in Figure 3. Corresponding AUROC values and 95% confidence intervals were 0.969 (95% CI: 0.952-0.985) for FS-LS < 7.6 kPa and 0.991 (95% CI: 0.985-0.997) for FS-LS > 13 kPa. Based on the ROC curves the optimal cut-off values for ARFI were chosen to maximize the sum of sensitivity and specificity. These cut-off levels were 1.29 m/s (sensitivity 91.4% and specificity 92.6% for FS-LS < 7.6 kPa) and 1.60 m/s (sensitivity 92.3% and specificity 96.5% for FS-LS > 13 kPa). The corresponding positive predictive value was 0.93 and the negative predictive value was 0.90 for FS-LS ≤ 7.6 kPa. When 1.60 m/s was chosen as the cut-off value for liver cirrhosis, the positive and negative predictive values were 0.85 and 0.98, respectively (Table 2).

Using these cut-off values for ARFI-SWV, 458 of the 482 patients (95.1%) were classified correctly. Six (1.2%) patients were classified false-negative (FS-LS ≥ 13 kPa and ARFI-SWV < 1.60 m/s), and 18 (3.7%) were classified false-positive (FS-LS < 13 kPa and ARFI-SWV ≥ 1.60 m/s; Figure 1).

After dividing the patients according to the aetiologies of chronic liver diseases [non-alcoholic steatohepatitis ( $n = 157$ ) vs others ( $n = 325$ )], the following cut-off values for ARFI were chosen (FS-LS > 13kPa): 1.52 m/s

**Figure 3** Receiver operator characteristic curve for acoustic radiation force impulse for the prediction of no significant fibrosis and liver cirrhosis ( $n = 482$ ). A: Receiver operator characteristic curve for acoustic radiation force impulse for the prediction of no significant fibrosis (FS < 7.6 kPa); B: Receiver operator characteristic curve for acoustic radiation force impulse for the prediction of liver cirrhosis (FS > 13.0 kPa).

for patients with non-alcoholic steatohepatitis (sensitivity 100% and specificity 96.6%; AUROC 0.990; 95% CI: 0.977-1.000) compared to 1.64 m/s for patients with liver diseases other than non-alcoholic steatohepatitis (sensitivity 94.2% and specificity 96.2%; AUROC 0.988; 95% CI: 0.980-0.996).

**Relationship between liver stiffness and liver histology**

68 patients underwent liver biopsy. A valid liver stiffness determination (success rate of at least 60%) was observed in 59/68 (86.8%) by FS compared to 68/68 (100%) by ARFI ( $P = 0.003$ ).

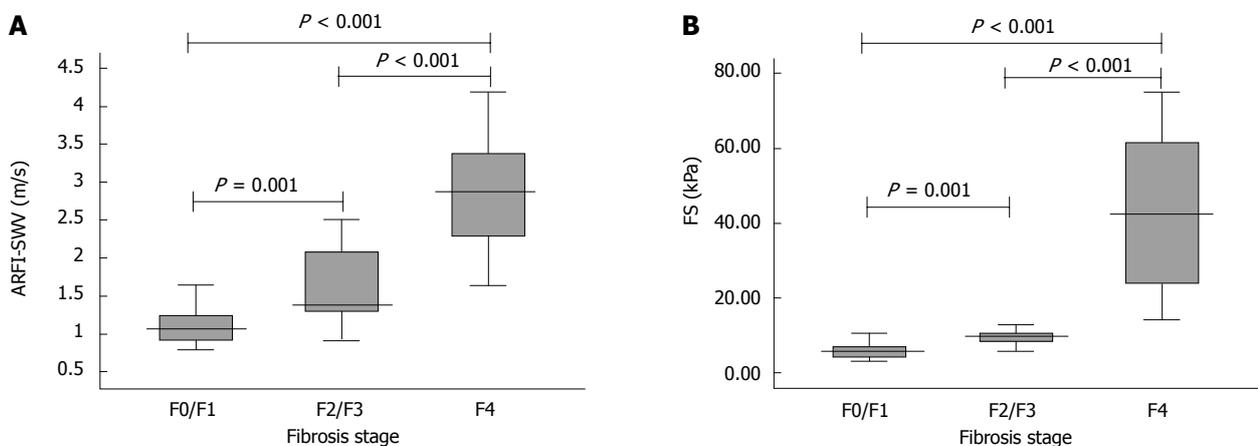

Liver stiffness measurements by ARFI ranged from 0.79 m/s to 4.17m/s. For patients without significant fibrosis ( $F \leq F1$ ,  $n = 23$ ), mean ARFI-SWV was 1.11 ± 0.24 m/s, 1.78 ± 0.88 m/s for patients with moderate fibrosis (F2 and F3;  $n = 17$ ), and 2.87 ± 0.76 m/s for liver cirrhosis (F4;  $n = 28$ ). Liver stiffness measured by ARFI was significantly different between patients according to their fibrosis stage ( $P = 0.001$  for  $F \leq F1$  vs F2/F3;  $P < 0.001$  for F2/F3 vs F4; and  $P < 0.001$  for  $F \leq F1$  vs F4; Figure 4A).

AUROC values and 95% confidence intervals were 0.934 (95% CI: 0.870-0.998) for liver cirrhosis (F4) and 0.929 (95% CI: 0.870-0.987) for  $F \leq F1$ . Based on the

**Table 2** Diagnostic accuracy of acoustic radiation force impulse imaging shear wave velocity and liver stiffness measured by transient elastography

	AUROC	Cut-off	PPV	NPV	Sensitivity (%)	Specificity (%)
Comparison to all patients [ARFI-SWV ( <i>n</i> = 482)]						
FS < 7.6 kPa	0.969	1.29 m/s	0.93	0.90	91.4	92.6
FS > 13.0 kPa	0.991	1.60 m/s	0.85	0.98	92.3	96.5
Comparison with liver biopsy [ARFI-SWV ( <i>n</i> = 68) and FS-LS ( <i>n</i> = 59)]						
Non significant liver fibrosis						
ARFI-SWV ( <i>n</i> = 23)	0.929	1.32 m/s	0.83	0.91	87.0	80.0
FS-LS ( <i>n</i> = 20)	0.920	7.6 kPa	0.85	0.95	94.9	85.0
Liver cirrhosis						
ARFI-SWV ( <i>n</i> = 28)	0.934	1.62 m/s	1.0	0.85	100	85.7
FS-LS ( <i>n</i> = 24)	0.958	13.0 kPa	1.0	0.91	100	91.4

AUROC: Area under the receiver operating characteristic curves; CI: Confidence interval; PPV: Positive predictive value; NPV: Negative predictive value; ARFI-SWV: Acoustic radiation force impulse imaging shear wave velocity; FS-LS: Liver stiffness measured by transient elastography.

**Figure 4** Acoustic radiation force impulse imaging shear wave velocity and liver stiffness measured by transient elastography for the different fibrosis stages in patients who underwent liver biopsy (F0/F1, F2/F3, and F4). A: ARFI-SWV for the different fibrosis stages in patients who underwent liver biopsy. Box plots show median values with 25th and 75th percentiles of shear wave velocity determined by ARFI (*n* = 68); B: FS-LS for the different fibrosis stages in patients who underwent liver biopsy (F0/F1, F2/F3, and F4). Box plots show median values with 25th and 75th percentiles of FS-LS (*n* = 59). ARFI-SWV: Acoustic radiation force impulse imaging shear wave velocity; FS-LS: Liver stiffness measured by transient elastography.

ROC curves, the discriminating cut-off values for ARFI were chosen to maximize the sum of sensitivity and specificity. These cut-off levels were 1.32 m/s for  $F \leq F1$  (sensitivity 87.0% and specificity 80.0%) and 1.62 m/s for liver cirrhosis (F4) (sensitivity 100% and specificity 85.7%). The corresponding positive predictive value was 0.83 and the negative predictive value was 0.91 for non-significant fibrosis and 1.0 and 0.85 for liver cirrhosis (Table 2).

Liver stiffness measurements by FS ranged from 2.9 kPa to 75 kPa. For patients without significant fibrosis ( $F \leq F1$ , *n* = 20), mean FS-LS was  $7.6 \pm 8.1$  kPa,  $13.8 \pm 17.1$  kPa for patients with moderate fibrosis (F2 and F3; *n* = 15), and  $42.6 \pm 20.5$  kPa for liver cirrhosis (F4; *n* = 24). Liver stiffness measured by FS was significantly different between patients according to their fibrosis stage ( $P = 0.001$  for  $F \leq F1$  vs F2/F3;  $P < 0.001$  for F2/F3 vs F4; and  $P < 0.001$  for  $F \leq F1$  vs F4; Figure 4B).

AUROC value for non-significant fibrosis (F0/F1) was 0.920 (95% CI: 0.841-0.998) with a sensitivity of 94.9% and specificity of 85.0% when 7.6 kPa was chosen

as the cut-off value. AUROC value and 95% confidence intervals were 0.958 (95% CI: 0.900-1.000) for liver cirrhosis (F4) with a sensitivity of 100% and specificity of 91.4% when 13.0 kPa was chosen as the cut-off value. The corresponding positive predictive value was 0.85 and the negative predictive value was 0.95 for non-significant liver fibrosis (F0/F1) and 1.0 and 0.91 for liver cirrhosis (F4; Table 2).

#### Inter- and intraobserver reproducibility; differences between the right and left liver lobes

In order to evaluate the reproducibility of ARFI-SWV measurements, 18 patients were examined repeatedly. For interobserver reproducibility, the patients were examined by two observers consecutively. An excellent agreement between the observers was found (ICC = 0.945; 95% CI: 0.844-0.981). For intraobserver reproducibility, one observer examined the patients twice directly in series. The intraobserver reproducibility was also excellent (ICC = 0.975; 95% CI: 0.906-0.993).

In order to study if there was a difference when ARFI

was performed in the right liver lobe or left liver lobe, 18 patients underwent measurement of ARFI-SWV in both liver lobes. The mean distance between skin surface and the liver capsule for the right and left liver lobes were  $2.24 \pm 0.52$  cm and  $2.54 \pm 0.62$  cm, respectively ( $P = 0.143$ ). ARFI-SWV did not differ significantly between the two liver lobes ( $1.36 \pm 0.41$  m/s *vs*  $1.51 \pm 0.53$  m/s,  $P = 0.143$ ). The agreement between both liver lobes, however, was moderate (ICC = 0.589; 95% CI: 0.135-0.851).

**Dynamics measured by FibroScan and acoustic radiation force impulse**

Fifty patients underwent liver stiffness measurement at least twice (mean  $\pm$  SD,  $2.3 \pm 1.2$ ). The mean interval between the two measurements was  $73.6 \pm 56.6$  d. FS-LS did not change in 24 patients, increased in 9 and decreased in 17 patients. ARFI-SWV changed in parallel to FS-LS. The behaviour of ARFI-SWV over time was assessed in 24 patients, in which FS-LS remained constant, increased or decreased over time (8 patients in each group) (Figure 5).

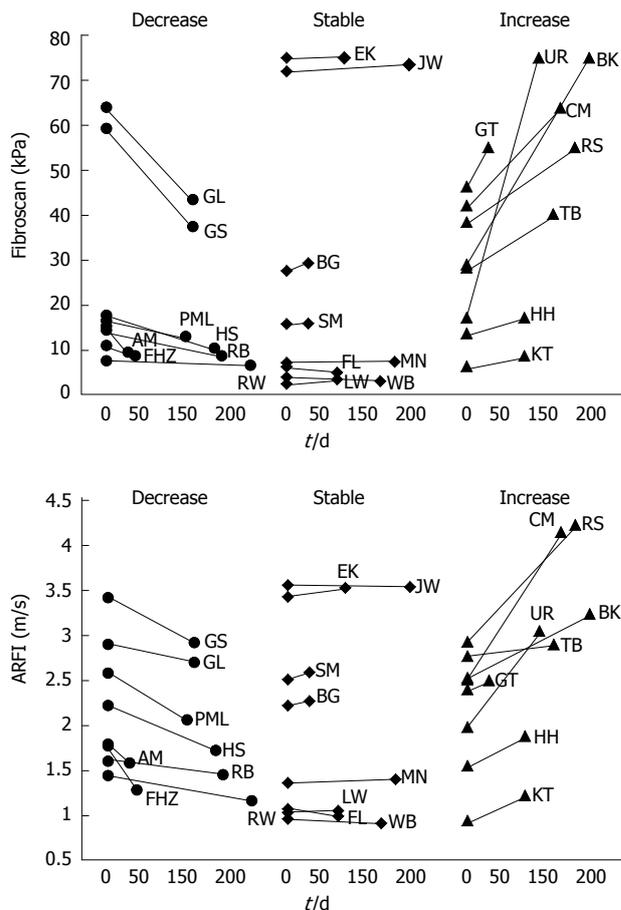

**DISCUSSION**

Liver biopsy is currently considered to be the gold standard for detection of liver fibrosis/cirrhosis, but is associated with serious complications<sup>[1]</sup>. On the other hand, cut-off values for FS-LS are available, which were evaluated in a meta-analysis including more than 8000 patients<sup>[16]</sup>. All these patients underwent liver biopsy, and these cut-off values were compared with the gold standard. Therefore, we used TE as the standard to evaluate ARFI technology. This allowed us to avoid any liver biopsy-associated complications.

The data in this study suggest that non-invasive fibrosis/cirrhosis assessed by measuring ARFI-SWV shows an excellent agreement with the established FS-LS measurements and can be successfully employed in patients, where FS-LS measurements were unsuccessful. Furthermore, as already reported for FS-LS determinations<sup>[35]</sup>, both intra- and interobserver variability were excellent for ARFI-SWV measurements.

A significantly higher success rate was observed for ARFI compared to FS ( $78.6\%$  *vs*  $99.8\%$ ,  $P < 0.001$ ). A significant inverse relationship between the success rate by FS and the distance between the skin surface and liver capsule was observed. ARFI is less dependent on this factor. Another advantage is that ARFI is performed under the control of conventional B-mode sonography. The observer can select and place the region of interest under visual control.

Mean ARFI-SWV increased significantly with the stage of fibrosis [ $1.09 \pm 0.13$  m/s (range 0.80-1.61 m/s)] for patients with no significant fibrosis (FS-LS  $< 7.6$  kPa);  $1.44 \pm 0.26$  m/s (range 0.98-2.03 m/s) for patients with significant liver fibrosis ( $7.6 < \text{FS-LS} \leq 13.0$  kPa); and  $2.55 \pm 0.77$  m/s (range 1.47-4.72 m/s) for patients with liver cirrhosis ( $13.0 < \text{FS-LS}$ ).

**Figure 5** Behaviour of acoustic radiation force impulse imaging shear wave velocity over time in 24 patients, in which FS-LS remained constant, increased or decreased over time (8 patients in each group). FS-LS: Liver stiffness measured by transient elastography.

We defined cut-off values for patients with no significant fibrosis and patients with liver cirrhosis. They were chosen so that the sum of sensitivity and specificity was maximal. A cut-off value for ARFI-SWV of 1.29 m/s was associated with a sensitivity of 91.4% and specificity of 92.6% for patients with FS-LS  $< 7.6$  kPa and a cut-off value of 1.60 m/s for patients with FS-LS  $> 13.0$  kPa with a sensitivity of 92.3% and specificity of 96.5%. Both cut-off values indicated high diagnostic accuracy for no significant fibrosis or liver cirrhosis, respectively. These cut-off values were confirmed by the subgroup-analyses. The cut-off values identified in patients who underwent liver biopsy did not differ significantly from the cut-off values taken from the correlation between both liver stiffness measurements ( $1.29$  m/s *vs*  $1.32$  m/s for patients without significant liver fibrosis;  $1.60$  m/s *vs*  $1.62$  m/s for patients with liver cirrhosis).

Experience with ARFI is limited and there are only a few published studies on small numbers of patients<sup>[31-33,36-40]</sup>. The largest study published by Palmeri *et al*<sup>[36]</sup> included 172 patients with non-alcoholic fatty liver disease. The present study included patients with different liver diseases and used FS-LS cut-off values from a meta-analysis of studies which included patients with different liver dis-

eases<sup>[16]</sup>. In the above-mentioned studies, ARFI-SWV cut-off values between 1.30 m/s and 1.37 m/s were reported for no significant liver fibrosis and 1.75–2.00 m/s for liver cirrhosis<sup>[31,32,38,40]</sup>. These cut-off values differ from those determined in our study, and may be due to differences in the liver diseases studied, sample size and the sensitivities and specificities chosen. In our substudy, which included patients with non-alcoholic steatohepatitis, the cut-off value was lower than for other patients, which may be due to the softening effect of steatosis. This effect has been described previously<sup>[41]</sup>. While liver stiffness measurement by FS is possible only in the right liver lobe, measurement of liver stiffness by ARFI is practicable in both liver lobes. Agreement of the measured liver stiffness between both liver lobes was moderate, but should be investigated in a larger study population. Thus, at present ARFI should be performed in the right liver lobe. Dynamics in the liver stiffness measured by FS have been described previously<sup>[18,19,21]</sup>. A congruent behaviour of ARFI-SWV and FS-LS dynamics over time was observed.

In conclusion, ARFI-SWV correlated significantly with FS-LS. ARFI can be performed in a significantly higher proportion of patients compared to FS. The most important advantage of ARFI over FS is the visual control by B-mode sonography and the variable depth of the measurement. A cut-off value of 1.29 m/s seems to be optimal for no significant fibrosis and 1.60 m/s for liver cirrhosis. ARFI-SWV did not depend on the observer. The sensitivity and specificity for the detection of liver cirrhosis seems to be comparable for both methods when liver biopsy is taken as the reference.

## COMMENTS

### Background

Liver biopsy is currently considered the gold standard for assessing hepatic fibrosis or cirrhosis, but is associated with complications. Thus, research has been focused on the evaluation of methods for the assessment of liver fibrosis. Transient elastography [FibroScan® (FS)] and acoustic radiation force impulse imaging (ARFI) are two methods used to detect liver fibrosis/cirrhosis.

### Research frontiers

A strong association between FS-LS and the degree of liver fibrosis was demonstrated in patients with chronic hepatitis. The experience with ARFI is limited. In this study the authors found a strong correlation between FS and ARFI. Using FS as a reference they evaluated cut-off values for ARFI. To evaluate the reproducibility of ARFI, an intra- and interobserver study was performed, without any significant results. It is known that liver stiffness shows a dynamic development, this point was also observed using ARFI.

### Innovations and breakthroughs

Non-invasive methods for the assessment of liver fibrosis are of great interest. FS and ARFI are two methods used to detect liver fibrosis/cirrhosis. The experience with ARFI is very limited. Significantly higher success rates for the determination of liver stiffness were found using ARFI as compared to FS. A strong correlation between liver stiffness measured by FS and ARFI was shown. An ARFI-SWV cut-off value of 1.29 m/s seems to be optimal for patients with no significant liver fibrosis and 1.60 m/s for patients with liver cirrhosis.

### Applications

ARFI is an additional non-invasive tool to detect liver fibrosis/cirrhosis. An ARFI-SWV cut-off value of 1.29 m/s seems to be optimal for patients with no significant liver fibrosis and 1.60 m/s for patients with liver cirrhosis.

### Terminology

FS and ARFI are two non-invasive methods to detect liver fibrosis/cirrhosis by

measuring liver stiffness. Both methods show a strong correlation between liver stiffness and the stage of liver fibrosis. These methods did not show any dependence on the observer. These tools can reduce the number of liver biopsies which is associated with complications.

### Peer review

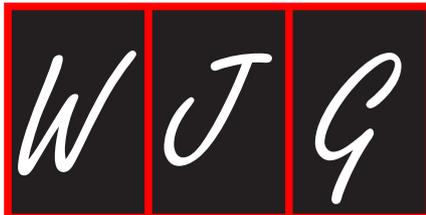

The authors reported the efficacy of acoustic radiation force impulse for determination of liver stiffness. The report is well written.

### Abstract

**AIM:** To create and apply a framework for quality assessment and improvement in care for inflammatory bowel disease (IBD) patients.

**METHODS** A framework for quality assessment and improvement was created for IBD based on two generally acknowledged quality models. The model of Donabedian (Df) offers a logistical and productive perspective and the Clinical Value Compass (CVC) model adds a management and service perspective. The framework creates a pedagogical tool to understand the

balance between the dimensions of clinical care (CVC) and the components of clinical outcome (Df). The merged models create a framework of the care process dimensions as a whole, reflecting important parts of the IBD care delivery system in a local setting. Clinical and organizational quality measures were adopted from clinical experience and the literature and were integrated into the framework. Data were collected at the yearly check-up for 481 IBD patients during 2008. The application of the quality assessment framework was tested and evaluated in a local clinical IBD care setting in Jönköping County, Sweden.

**RESULTS:** The main outcome was the presentation of how locally-selected clinical quality measures, integrated into two complementary models to develop a framework, could be instrumental in assessing the quality of care delivered to patients with IBD. The selected quality measures of the framework noted less anemia in the population than previously reported, provided information about hospitalization rates and the few surgical procedures reported, and noted good access to the clinic.

**CONCLUSION:** The applied local quality framework was feasible and useful for assessing the quality of care delivered to IBD patients in a local setting.

## INTRODUCTION

In modern healthcare, there is often a gap between the expected level of healthcare delivery and the actual healthcare provided, as shown by McGlynn *et al*<sup>[1]</sup>. This is also true for the care of inflammatory bowel disease (IBD), as highlighted recently in an editorial by Siegel<sup>[2]</sup> and previously by Reddy *et al*<sup>[3]</sup> as well as by the American Gastroenterology Association<sup>[4]</sup> several years ago. There is still no framework or general quality measures for IBD as noted by Kappelman<sup>[5]</sup>, who called for action and challenged the gastroenterology community to correct this.

IBD is a chronic disease with two primary subtypes; Crohn's disease (CD), and ulcerative colitis (UC)<sup>[6]</sup>. The incidence of CD and UC in Sweden is approximately 6 and 15 per 100 000 inhabitants, respectively, and the prevalence is approximately 150 and 300 per 100 000, respectively<sup>[7]</sup>. Because of the early age at onset and the absence of curative treatment, the vast majority of patients require lifelong medical care, which periodically leads to intensive outpatient contact, hospitalizations, and occasionally surgery. Improved quality of care aims to minimize the symptoms of the disease, improve quality of life, and meet the goal of delivering the best possible value of care to the patient<sup>[8]</sup>. These targets are well captured in the Institute of Medicine's mnemonic, stressing the need for safe, timely, efficient, evidence-based, effective, and patient-centered care (STEEEP)<sup>[9]</sup>.

During the first years of the new millennium, the structure of care for IBD patients within the Gastroenterology Unit at the Department of Internal Medicine, Highland Hospital, Eksjö, Sweden was significantly redesigned as previously reported<sup>[10,11]</sup>. Along with the redesign, the need to be able to monitor the changes and the quality of care became obvious. Obvious also was the absence of any known framework and quality measures for the assessment of quality of care for IBD. To bridge this gap, a selection of clinical and organizational parameters were integrated into two generally acknowledged quality models adopted from Donabedian (Df)<sup>[12]</sup> and the Clinical Value Compass (CVC)<sup>[13]</sup>, and were merged to form a quality framework. The collection of quality measures was accomplished as a part of the ordinary yearly check performed by a specialist nurse or by a gastroenterologist. The selected measures were integrated and applied to the quality framework as a means to assess the quality of IBD care in the local setting.

A quality assessment tool may be developed in several ways, and there are several critical steps when creating a quality framework; these include design, implementation,

and utilization. Each of these factors must be addressed before the framework can be used. Furthermore, before the process of introducing a framework begins, insight into the complexity of care, an understanding of the systems used, and sound professional knowledge, all coupled with both enthusiasm and leadership, are required<sup>[8,14,15]</sup>.

In this study, two generally acknowledged quality models were used. The first, according to Df<sup>[12]</sup>, has been discussed previously by Kappelman *et al*<sup>[5]</sup> and testing on IBD care was suggested. Donabedian advises that the following questions are to be asked before using a quality framework<sup>[12]</sup>: "who and what activities are to be assessed"; "how are these activities supposed to be conducted"; and "what are they to accomplish?" These are all important questions to raise and are possible to apply to health care institutions. The model according to Donabedian derives the quality of care from the components of structure, process, and outcome. Structure denotes the attributes of the setting and includes the facilities, equipment, human resources, and organizational structure. Processes are defined by what is actually done in delivering and receiving care. Furthermore, outcome denotes the effects of care on the health status of patients and populations, conveys a production management perspective, and frames a delivery-focused approach by the organization.

The second model is the CVC<sup>[13]</sup>. It was derived from a management customer area, and offers a flexible framework where the outcomes of health care are perceived in four dimensions as follows: (1) functional; (2) **economic**; (3) satisfaction with health care; and (4) **clinical outcome**. The use of already existing measures is favored to avoid add-on routines, making it possible to fulfill the intertwined assignment to both manage the patient and improve care by measuring outcomes<sup>[16]</sup>.

The Df offers a logistical, productive perspective to the studied case, and the CVC adds a management and service perspective. The framework creates a pedagogical tool to understand the balance between the dimensions of clinical care (CVC) and the components of clinical outcome (Df). Together they create a framework of the care process dimensions as a whole, reflecting important parts of the IBD care delivery system in a local setting.

Quality measures are valuable means of improving clinical practice. The use of quality measures may be defined as the process of collecting, computing, and presenting quantified constructs for the managerial purposes of following up, monitoring, and improving organizational performance<sup>[17]</sup>. The basis of this argument is that they play a significant role in the coordination of organizational activity<sup>[18]</sup>, decision-making, prioritization<sup>[19]</sup>, comparisons, and initiation of improvement processes<sup>[20]</sup>. In every effort to measure the performance, it is important to consider the desired application of the information obtained. The application of the information may be to control, budget, motivate, or improve the care<sup>[21]</sup>. As part of the explorative case study, well established measures such as hemoglobin, quality of life, medication, and

access to care, which were practical to perform and used in daily clinical life, were chosen after a review of relevant literature and from clinical experience<sup>[22-24]</sup>.

The aim of this study was two fold; firstly, to apply a generally acknowledged quality framework to the assessment and improvement of care for IBD, and secondly, to study and evaluate its application in a local clinical IBD care setting in Jönköping County, Sweden.

## MATERIALS AND METHODS

The measures in this study originate from the Gastroenterological Unit responsible for all IBD care in the area, which is a part of the Department of Internal Medicine at the Highland Hospital in Eksjö, Jönköping County, Sweden. The unit includes an outpatient clinic, an inpatient ward with 15 beds, and an affiliated unit for endoscopic examinations<sup>[11]</sup>. The Highland health care system consists of eight health care centers for primary care, and the 280-bed Highland Hospital responsible for secondary and acute care, in all serving 110 000 inhabitants. The health care delivered is tax financed, and the county council functions both as insurer and provider of the care.

To date, no quality measures for IBD care have been generally approved. Feasible and practical quality measures were selected in order to evaluate the quality of care delivered within the local setting. The first act was to organize a registry with information, including patient addresses, diagnosis, disease duration, smoking habits, weight, and sex. Further information about the current prescribed medication and whether any surgical intervention had been performed was added to the files. Hemoglobin was chosen as the clinical marker to find anemia in the population, which may go undetected in many patients<sup>[25]</sup>. Further quality measures assessing the access to care<sup>[10]</sup> and quality of life (QoL) were chosen and integrated into the framework. Access was measured as the number of days from the referral being sent from the primary care physician until the patient received a scheduled consultation at the outpatient clinic, as well as the clinic's ability to offer an acute visit within two days after contact by a known patient. QoL was measured by using the short health scale (SHS)<sup>[26,27]</sup>. SHS is a questionnaire consisting of four questions about symptoms, function, worry and general health associated with the disease, reported on a 6-point graded likert scale. Patients were diagnosed according to clinical, endoscopic, and microscopic findings, and were sub-typed as having UC or CD. A senior gastroenterologist confirmed the diagnosis and registration of each patient. The status of the disease, i.e., subjectively experienced activity, was reported by the patients on the day of the annual check-up. Tumor surveillance colonoscopy was offered and performed according to guidelines for more than 95% of relevant patients. At the end of 2008, 481 patients were included in the local registry.

During the year, all patients were offered an annual

check-up, which was preceded by a letter including a quality of life questionnaire and instructions for laboratory testing (hemoglobin) that could be performed at any of the primary care centers. An important part of the annual check-up was to remind the patient to contact the nurse by telephone with any questions or worries raised during the remainder of the year. Reinforcing this opportunity for telephone access was aimed toward avoiding misdirected care for IBD to other care settings such as the Emergency Department. In the redesigned clinical model, there was also a guarantee that access to an unscheduled visit for acute symptoms would be available within two days at all times. Data was collected by the specialist nurse or gastroenterologist at the time of the check-up, and computed every quarter but presented once a year.

In Table 1 an overview of the definitions, quality dimensions and components, purposes behind the measures, operational definitions, and data sources of the quality measures are integrated into the two quality models together creating the framework.

### Ethical considerations

The ethical committee at the University of Linköping, Sweden, approved this study.

## RESULTS

The first main finding is the presentation regarding how locally-selected clinical quality measures, integrated into two complementary models to create a framework, could be instrumental in assessing the quality of care delivered to patients with IBD. Further, the second main finding is the results presented in Table 2 for the local IBD population using the framework. The data describe the epidemiology of a patient population in the local care setting for IBD. To be stressed is the fact that more than 95% of the patients with IBD in the area are cared for by our care unit. The incidence of IBD was slightly below the expected level according to Swedish data<sup>[7]</sup>. This is probably explained by the older age distribution in the studied rural area. The prevalence of anemia is less than previously reported. Medication is presented for Crohn's disease and ulcerative colitis. Immunosuppressive medication, cortisone and anti-TNF-alpha are prescribed more for Crohn's disease compared to ulcerative colitis. Further, 5-aminosalicylic acid is prescribed more for ulcerative colitis compared to Crohn's disease. Table 2 show good access to care. Few surgical interventions were performed over the year. Three patients with ulcerative colitis underwent colectomy and three patients with Crohn's disease underwent incisions due to fistulas or strictures. No tumor was found in the population. Data was not processed statistically for differences between groups.

In the years before 2008, an average of 75% of the registered patients had a complete annual check-up documented, i.e., a telephone call or a visit in combination with QoL and/or laboratory tests. In 2008, patients without

	The clinic's ability to offer an acute visit within two days after contact for known IBD patients	< 2 d	< 2 d
	Contact route (before being admitted to hospital)		
	The ERS was searched to find out where the decision was either at the ER or from the outpatient clinic	50%/50%	50%/50%
Hospitalization	Hospitalization		
	ERS documented ICD code for IBD and hospitalisation	29	17

Data from the annual check-up 2008. IBD: Inflammatory bowel disease; ICD: International classification of diseases; 5-ASA: 5-aminosalicylic acid; ERS: Electronic record system; SHS: Short health scale.

complete annual check-ups were offered a new visit or telephone call at the end of the year. Using this approach,

98% (471/481) of the IBD population had a documented annual check-up during 2008. Of nine patients not receiving a check-up, four refrained from participating in the study and five were missing. One patient (with CD) was excluded from the study because of particularly severe disease demanding various levels of hospitalization on a more or less continuous basis.

## DISCUSSION

Quality improvement (QI) forms a link between the study of disease (science) and clinical care (management)<sup>[28]</sup> and provides better management of the planning, delivery, and assessment of care. The need for a general assessment tool for IBD care has been emphasized several times over a number of years<sup>[3,5]</sup>. This study is, to the best of our knowledge, one of the first to present how two generally acknowledged quality models<sup>[12,13]</sup> with integrated clinical quality measures can be applied as a quality framework and tested in clinical practice at a single center in an IBD population. The intent was to evaluate the quality of care delivered to a population of patients with IBD in the Highland health care area, Jönköping County, Sweden. Because there are few other frameworks currently available, there are problems with comparing results and usage, which needs to be done when future research is available.

The framework offers a map of the epidemiology of all patients affected by IBD in a local setting. This is a prerequisite and a foundation for any further analysis and improvement effort. Interesting results were found in the population as presented in the framework. Anemia is a well-known complication of IBD, caused by a combination of bone marrow suppression secondary to chronic inflammation and blood loss from intestinal bleeding. The reported prevalence of anemia from different IBD care settings and patient populations ranges from 9% to 74%<sup>[29]</sup>. In this study, anemia was detected in 4% of UC patients and 5% of CD patients, as shown in Table 1. Less than 1% had severe anemia. However, the mean hemoglobin for all study groups was comparable to that of a healthy control population. The detected prevalence of anemia has even improved compared to previous findings in the same population<sup>[10]</sup>. The clinic has used the findings of incipient anemia to offer extra visits to the outpatient clinic, and/or more thorough laboratory investigations to identify the reasons behind these findings. The analysis of hemoglobin is inexpensive, valid, and simple to perform. Treatment of anemia on an individual level is well established. Altogether, it is a feasible and useful finding to apply as a quality measure within a population.

Knowledge of how well guidelines for medication are implemented in an IBD patient population is sparse. The prescription pattern presented is in line with reports from centers in Norway<sup>[30,31]</sup> and Canada<sup>[32]</sup>. It provides an example of how quality measures can be directly related to guidelines and thus provides important information about the quality of care delivered<sup>[33]</sup>. The incidence and type of surgery is presented in Table

1. Surgical intervention rates were low in our study, and should be interpreted cautiously. The figures of access and number of hospital admittances for IBD could be used in future work as a benchmark for other clinics and as comparisons to national trends in Sweden or in America<sup>[34,35]</sup>.

The future use of the framework is associated with the way in which data retrieval could be improved. This could be done in several ways. One way would be to retrieve the data directly from the electronic medical record (EMR), and a second way would be to provide opportunities for the patient to deliver self-reported outcome measures directly into the EMR. In order to achieve this for additional quality measures, several steps are required. First, the suggested framework and measures need to be tested, discussed, and refined in a broader setting. Secondly, the measures need to be presented and followed as “real time” data on both an individual and a group/subgroup level in order to allow benchmarking. Thirdly, it should be possible to correlate quality measures with prescriptions, days off from work, and further changes in medication and/or treatment. An example of a “feed-forward” quality register<sup>[36]</sup> is already in place for patients with rheumatoid arthritis within the Swedish Rheumatoid Arthritis Registry (SRAR)<sup>[37,38]</sup>. In the SRAR register, it is possible to track individual patients as well as patient populations both locally and nationally and use this information to, for example, correlate their clinical status with the timing of newly prescribed biological drugs and days off from work<sup>[39]</sup>. The SRAR is regarded as one of the best quality registries in Sweden, and can serve as a model for future IBD registry work.

This study presents how locally-selected clinical quality measures, integrated into two complementary models to develop a framework, could be instrumental in assessing the quality of care delivered to patients with IBD. The selected quality measures noted less anemia in the population than previously reported, provided information about hospitalization rates and the few surgical procedures reported, and noted good access to the clinic. We believe that this approach of organizing and regularly utilizing data within our system is sustainable, and will enable future improvement in the quality and value of care for our IBD patients. We propose that the suggested framework and quality measures should be further tested, evaluated, and refined within the gastroenterological community.

## COMMENTS

### Background

In modern healthcare, there is often a gap between the expected level of healthcare delivery and the actual healthcare provided. This is also true for the care of inflammatory bowel disease (IBD) as highlighted by the American Gastroenterology Association. These stakeholders have called for action and challenged the gastroenterology community to find systems for quality assessment and improvement in IBD.

### Research frontiers

Since the publication “Crossing the Quality Chasm” by the Institute of Medicine in America on the brink of the new millennium, the urge to improve quality of care

has been one of the main focuses in health care research. Unfortunately, few publications connecting this area to IBD have been published since that time.

### Innovations and breakthroughs

The main outcome was the presentation of how locally-selected clinical quality measures, integrated into two complementary models to develop a framework, could be instrumental in assessing the quality of care delivered to patients with IBD. The selected quality measures of the framework noted less anemia in the population than previously reported, provided information about hospitalization rates and the few surgical procedures reported, and also noted good access to the clinic.

### Applications

The framework offers a map of the epidemiology of all patients affected by IBD in a local setting. This is a prerequisite and a foundation for any further analysis and improvement effort.

### Peer review

In this study, the authors created and applied a framework for quality assessment and improvement in IBD. They showed that the locally selected clinical quality measures, integrated into two complementary models to create a framework, could be instrumental in assessing the quality of care delivered to patients with IBD.

### Abstract

**AIM:** To investigate the correlation between autoimmune thyroid diseases (ATDs) and the prevalence of Cag-A positive strains of *Helicobacter pylori* (*H. pylori*) in stool samples.

**METHODS:** Authors investigated 112 consecutive Caucasian patients (48 females and 4 males with Graves' disease and 54 females and 6 males with Hashimoto's thyroiditis HT), at their first diagnosis of ATDs. Authors tested for *H. pylori* in stool samples using an amplified enzyme immunoassay and Cag-A in serum samples using an enzyme-linked immunoassay method (ELISA). The results were analyzed using the two-sided Fisher's exact test and the respective odds ratio (OR) was calculated.

**RESULTS:** A marked correlation was found between the presence of *H. pylori* ( $P \leq 0.0001$ , OR 6.3) and, in particular, Cag-A positive strains ( $P \leq 0.005$ , OR 5.3) in Graves' disease, but not in Hashimoto's thyroiditis,

where authors found only a correlation with Cag-A strains ( $P \leq 0.005$ , OR 8.73) but not when *H. pylori* was present.

**CONCLUSION:** The marked correlation between *H. pylori* and Cag-A, found in ATDs, could be dependent on the different expression of adhesion molecules in the gastric mucosa.

Autoimmune thyroid diseases and *Helicobacter pylori*: The correlation is present only in Graves's disease. *World J Gastroenterol* 2012; 18(10): 1093-1097 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i10/1093.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i10.1093>

### INTRODUCTION

Autoimmune thyroid diseases (ATDs) are represented, essentially, by Hashimoto's thyroiditis (HT) and its variants (postpartum and sporadic thyroiditis), Graves' disease (GD) and atrophic thyroiditis<sup>[1]</sup>. A typical marker of HT and GD is the presence of autoantibodies against thyroglobulin (TgAbs), thyroperoxidase (TPOAbs) and thyrotropin receptor (TRAbs)<sup>[2]</sup>. Both genetic and environmental factors are involved in the pathogenesis of ATDs. Some bacteria and viruses are suspected of being able to mimic the antigenic profile on the thyroid

cell membrane, and play an important role in the onset of autoimmune diseases<sup>[3-6]</sup>. *Helicobacter pylori* (*H. pylori*) infection is found worldwide and has an incidence of up to 50% in the population of developed countries<sup>[7]</sup>. A cohort effect has been demonstrated for such infection, and a higher prevalence rate is found in the elderly and in males<sup>[8]</sup>. *H. pylori* is a gram-negative, motile bacterium, which typically colonizes and infects the gastric mucosa; the most virulent strains can usually be identified by the presence of the cytotoxin-associated gene A (Cag-A) antigen<sup>[9]</sup>. Therefore, the microorganism is responsible for gastric diseases such as gastritis, gastric/duodenal ulcers and carcinomas.

Several studies<sup>[10-12]</sup> have shown a positive correlation between the presence of *H. pylori* and HT, although others did not find such an association<sup>[13,14]</sup>. Moreover, we recently demonstrated a noteworthy correlation between *H. pylori* infection and GD, independent of hormonal status<sup>[15]</sup>.

The aim of this study was to investigate the prevalence of *H. pylori* in ATDs and, in particular, HT, to help clarify the controversial results observed in previous studies. We detected the presence of *H. pylori* in fresh stool samples from our patients using an enzyme immunoassay method, and Cag-A positivity using a serological test.

## MATERIALS AND METHODS

### ATDs patients

We studied 112 consecutive Caucasian patients (48 females and 4 males with GD and 54 females and 6 males with HT), at their first diagnosis of ATDs, enrolled over a period of 18 mo (from October 2008 to March 2010). The mean age ( $\pm$  SD) of the ATDs patients was  $49.7 \pm 6.6$  years ( $48.8 \pm 3.9$  years for GD patients and  $50.2 \pm 9.7$  years for HT patients). The study inclusion criteria were previously reported<sup>[15]</sup>. Briefly, these criteria included the absence of other diseases, a negative anamnesis for antimicrobial drugs use for at least three months and the absence of dyspeptic symptoms (epigastric pain, nausea, heartburn) or gastric diseases. The study was approved by the ethical committee of our institution and informed consent was obtained from each patient.

GD diagnosis was defined by hormonal hyperthyroidism [suppressed thyrotrophin (TSH), elevated FT3 and FT4], diffuse and high iodine capture on thyroid scintigraphy, and positive titers of TPOAbs, TgAbs and TRAbs. To eliminate possible bias between subclinical and frank primary hypothyroidism, HT diagnosis was defined by a cut-off value higher than 35 mU/mL TSH, low FT3 and FT4 values, positive titers of TPOAbs and TgAbs and hypoechogenicity pattern on echography (Table 1).

### Controls

The control population was composed of 100 body mass index-, socio-economic- and inclusion criteria class-matched individuals (90 females and 10 males, mean age  $49.0 \pm 4.5$  years, Table 1). All of these subjects showed

Table 1 Clinical characteristics of the investigated groups

Group	n	Sex female/male	Age (yr) (mean $\pm$ SD)	Smokers yes/no	Ophthalmopathy yes/no
Control	100	90/10	49.0 $\pm$ 4.5	44/56	-
GD	52	48/4	48.8 $\pm$ 3.9	21/31	34/18
HT	60	54/6	50.2 $\pm$ 9.7	26/34	0/60
ATDs	112	102/10	49.2 $\pm$ 6.9	47/65	34/112

No significant statistical differences in sex and age were present among the different groups. ATDs: Autoimmune thyroid diseases; HT: Hashimoto's thyroiditis; GD: Graves' disease.

normal TSH, FT3 and FT4 values with absent titers of TPOAbs, TgAbs and TRAbs.

### Study of the presence of *H. pylori* in stool samples

The tests were performed by laboratory technicians blinded to the subject's diagnosis. Fresh stool samples were obtained and tested using an amplified enzyme immunoassay for the detection of *H. pylori* antigens (Amplified IDEIA *H. pylori* StAR, Oxoid, United Kingdom). This test is highly specific for *H. pylori* antigens (sensitivity 95%, specificity 95%), with no cross-reactivity with other microorganisms. An absorbance value  $> 0.150$  using a dual wavelength (450/620 to 650 nanometers) was considered positive for the presence of *H. pylori*.

### Detection of Cag-A antibodies

Fresh serum samples were tested with the enzyme-linked immunoassay method (ELISA, Radim, Pomezia, Italy, sensitivity 93.7%, specificity 100%). Anti-Cag-A immunoglobulin-G values greater than 15 units/mL were regarded as Cag-A positive.

### Statistical analysis

The relationship between the different studied groups, in terms of *H. pylori* and Cag-A positivity, was investigated with the two-sided Fisher's exact test and calculation of the respective odds ratio (OR, with 95% confidence interval, using the approximation of Woolf, Instat 3.06, Graphstat Software Inc., San Diego, CA, United States).  $P \leq 0.05$  was considered significant.

## RESULTS

### Detection of *H. pylori* in fresh stool samples

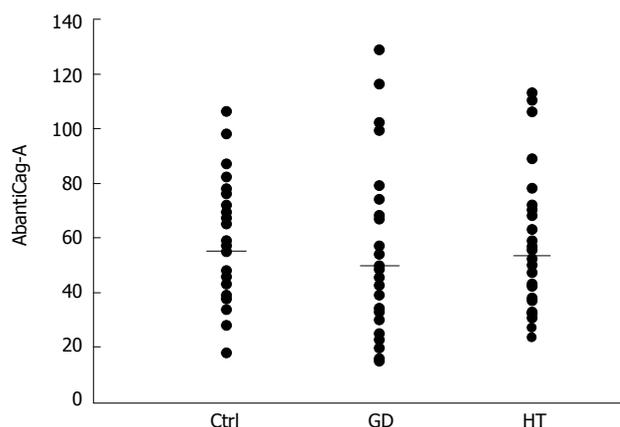

Of 112 ATDs patients, 43/52 (82%) in the GD group and 28/60 (46%) in the HT group were positive for *H. pylori* infection, *vs* 43 [43.0%,  $P \leq 0.0001$ , OR 6.3 (2.7-14.3)] *vs* the GD group, not significant *vs* the HT group] of 100 controls (Table 2).

Immunoassay testing on the stool samples confirmed that the observed *H. pylori* positivity was dependent on ongoing *H. pylori* presence in the gastric mucosa and not on past infection. Furthermore, no correlation was found between the presence of *H. pylori* and smoking habit in the two groups of ATDs patients (data not shown).

**Table 2** The HP- and CagA-positivity in patients in the different study groups

Group	n	HP-	HP+	CagA+	CagA-	Overall CagA+
Control	100	57	43	21	22	21/100
GD total	52	9	43 <sup>c</sup>	36 <sup>b</sup>	7	36 <sup>c</sup> /52
HT total	60	32	28 <sup>1</sup>	25 <sup>b</sup>	3	25 <sup>b</sup> /60
ATDs total	112	41	71 <sup>2</sup>	61 <sup>c</sup>	10	61 <sup>c</sup> /112

<sup>a</sup> $P \leq 0.05$  vs control, <sup>b</sup> $P \leq 0.005$ , <sup>c</sup> $P \leq 0.0001$ . <sup>1</sup>Not significant; <sup>2</sup>Not calculated.

**Figure 1** The AbantiCag-A levels are shown for the investigated groups. The bars show the different means. No significant difference was found among the different groups. GD: Graves' disease; HT: Hashimoto's thyroiditis.

### Cag-A positivity in the serum of *H. pylori*-positive patients

Thirty-six (83.7%) of 43 *H. pylori*-positive GD patients and 25/28 (89.2%) *H. pylori*-positive HT patients were positive for Cag-A antigens vs 21/43 [48.8%,  $P \leq 0.005$ , OR 5.3 (1.9-14.7) vs the GD group and  $P \leq 0.005$ , OR 8.73 (2.7-33.0) vs the HT group] of infected controls. Again, considering the overall prevalence of infection by Cag-A-positive *H. pylori* in the studied groups of ATDs patients, the results were statistically significant, [61 of 112 or 54.4% vs the controls, 21 of 100 subjects or 21%,  $P \leq 0.0001$  OR 4.5 (2.4-8.2), Table 2].

Cag-A antibody levels, expressed in mU/mL [control  $56 \pm 24.3$  (mean  $\pm$  SD), GD  $50.3 \pm 28.6$ , HT  $54.1 \pm 22.6$ ], were similar among the three groups of investigated subjects (Figure 1) and did not correlate with the respective titers of TgAbs, TPOAbs or TRAbs (data not shown).

## DISCUSSION

*H. pylori* infection is found world wide and affects up to 50% of the population of developed countries, such as Italy, and the most virulent strains are identified by the presence of Cag-A antigens<sup>[9]</sup>. Recently, a significant correlation was shown between the Cag-A carrier *H. pylori* strains and GD, independent of the hormonal status of the investigated patients<sup>[13]</sup>. Moreover, other studies have

investigated the association between such microorganisms and HT, however, the results are controversial. Some investigations point to a noteworthy correlation<sup>[10,11,12]</sup>, others do not<sup>[13,14]</sup>. The use of different techniques to assess *H. pylori* infection could explain these conflicting conclusions. For instance, serological detection of *H. pylori* antibodies can not discriminate between past and ongoing infection. Conversely, the <sup>13</sup>C-urea breath test and immunoassay test on fresh stool samples can only detect ongoing *H. pylori* infection, therefore these tests are currently considered the preferred non-invasive methods of investigation<sup>[7]</sup>. Moreover, the presence of similar antigenic sites for Cag-A and TPO could cause false positive results in the Abs titers against *H. pylori*, leading to a bias in group selection of the enrolled patients<sup>[16]</sup>. In addition, the different grade of thyroid function in HT patients, such as subclinical or frank hypothyroidism, could be a misleading factor.

Our results, using a stool antigen test, confirmed that a correlation was present between *H. pylori* and hyperthyroid GD patients, but this correlation was not seen in hypothyroid HT patients.

In accordance with the guidelines<sup>[7]</sup>, we did not perform further invasive exams, such as gastroscopy, in consideration of the age (usually under 45 years old in the investigated patients) and the absence of digestive symptoms in *H. pylori*-positive patients.

Several factors could be considered to explain the different results regarding *H. pylori* prevalence in GD and HT. Usually, the onset and/or progression of ATDs are dependent on different autoimmune mechanisms. Cellular autoimmunity with the TH1 profile of CD4 + T helper precursor cells is predominant in HT, whereas humoral autoimmunity (production of TRAbs or TSH-receptor blocking antibodies) with the TH2 profile is prevalent in GD and atrophic thyroiditis<sup>[17]</sup>. These different activated profiles in ATDs induce the expression of different panels of cytokines, such as interleukin (IL)-4, IL-5, IL-6 and IL-10 in GD and IL-2, interferon- $\gamma$  (IFN- $\gamma$ ) and tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) in HT<sup>[17]</sup>. Also, the opposite thyroid function, i.e., hyperthyroidism in GD vs hypothyroidism in HT, could be another factor leading to the controversial results on *H. pylori* prevalence in GD and HT patients.

In our study, both GD and HT show a comparable elevated prevalence of Cag-A positive strains in *H. pylori*-positive patients, in agreement with previous observations in TH patients<sup>[11]</sup>.

The involved factors could operate through a common pathway, such as the glycoconjugates-mediated adhesion of *H. pylori* to the gastric mucosa, which represents a crucial step in the establishment of successful infection. *H. pylori* glycan receptors include fucosylated ABO blood group antigens<sup>[18,19]</sup> and glycans with charged groups, such as sialic acid<sup>[20]</sup> or sulfate<sup>[21]</sup>, and neolacto core chains<sup>[22]</sup>. Two different *H. pylori* adhesins have been characterized on the basis of their interactions with the receptors: the

blood group antigen-binding adhesin (BabA) is specific for H type-1 and Lewis b antigens, admitting terminal blood groups A and B glycan determinants, whereas the sialic acid binding adhesin (SabA) recognizes the Sialyl-Lewis a and Sialyl-Lewis x antigens<sup>[20,23]</sup>.

In particular, the potential effect of the suggested factors, such as hyperthyroidism or the production of cytokines induced by humoral immunity, could modify the profile of the adhesion molecules expressed on the gastric mucosa, increasing *H. pylori* binding in GD and selecting the Cag-A positive strains in ATDs.

Regarding the pathogenetic role of HP in the onset of ATDs, it has been postulated that viral and bacterial infections could play a noteworthy role. Usually, elevated levels of antibodies against some bacteria have been found in GD patients<sup>[4,6]</sup> and, conversely, an antigen structure, such as TSH-binding protein, is described in many gram-positive and gram-negative bacteria<sup>[24]</sup>. Moreover, Cag-A positive *H. pylori* strains show some nucleotide sequence similarity to TPO sequence<sup>[25]</sup>. A positive linear regression between *H. pylori*-Abs titers and microsomal autoantibodies<sup>[9]</sup> and a significant reduction in these antibodies after *H. pylori* eradication have been demonstrated<sup>[26]</sup>. Therefore, cross-reactivity of the antibodies produced against thyroid antigen structures during *H. pylori* infections could potentially induce a biological effect<sup>[27]</sup>, in a similar way to that of *H. pylori* which triggers the onset of autoantibodies against the H<sup>+</sup>K<sup>+</sup>-ATPase in the gastric autoimmunity<sup>[28,29]</sup>. Moreover, the increased prevalence of *H. pylori* in GD, on first diagnosis, and the observation that, usually, *H. pylori* infection starts during childhood<sup>[30]</sup>, suggest that the bacterium could be present before the onset of the autoimmune disease. Larizza *et al*<sup>[31]</sup> proposed that *H. pylori* infection can induce and/or worsen the course of GD in susceptible young patients, carrying the human leukocyte DRB1\*0301 antigen. The authors also suggested that *H. pylori* eradication could prevent GD in these "at high risk" children.

Conversely, hyperthyroid GD patients could just be more susceptible to *H. pylori* infection, and the presence of the microorganism could represent an epiphenomenon, not involved in the onset of the autoimmune disease.

In conclusion, we report an increased *H. pylori* prevalence only in hyperthyroid GD patients, but not in hypothyroid HT patients, although the strains involved in both GD and HT are, prevalently, carriers of Cag-A antigens. These results suggest the execution of screening for *H. pylori* in ATDs patients, taking into account either the presence of virulent strains in autoimmune diseases and the increased *H. pylori* prevalence in GD. Therefore, a possible role of *H. pylori* infection might be postulated for GD, but further studies are needed to confirm such a hypothesis.

## ACKNOWLEDGMENTS

We thank Dr. Giovanna Allevato and Dr. Serena Leone for careful reading of the manuscript.

## COMMENTS

### Background

Autoimmune thyroid diseases (ATDs) are represented, essentially, by Hashimoto's thyroiditis (HT) and its variants (postpartum and sporadic thyroiditis) and Graves' disease (GD). *Helicobacter pylori* (*H. pylori*) infection is found worldwide with an incidence of up to 50% in the population of developed countries and a possible correlation has been suggested between the bacterium and ATDs.

### Research frontiers

A wide range of diseases are correlated with the presence of *H. pylori* and a possible pathogenetic role is suspected.

### Innovations and breakthroughs

A noteworthy correlation between *H. pylori* and GD, but not with HT, has been demonstrated. In contrast, the prevalence of Cag-A expression was increased in both ATDs.

### Applications

Screening for *H. pylori* in ATDs patients is suggested, taking into account either the presence of virulent strains in autoimmune diseases and the increased *H. pylori* prevalence in GD.

### Peer review

The manuscript is well written and the methods are adequate. The results justify the conclusions drawn.

### Abstract

**AIM:** To assess the necessity of esophagogastroduodenoscopy (EGD) to predict the outcome of caustic ingestion in children.

**METHODS:** The study included 206 children who underwent EGD because of ingestion of caustic substances between January 2005 and August 2010. Retrospective analysis of data of the patients was performed.

**RESULTS:** The male/female ratio was 1.6 and mean age was  $38.1 \pm 28.8$  mo. The caustic substances were acidic in 72 (34.9%) cases, alkaline in 56 (27.2%), liquid household bleach in 62 (30.1%), and unknown in 16 (7.8%). Fifty-seven (27.7%) patients were symptom-free. Significant clinical findings were observed in 149 (72.3%) patients. Upper gastrointestinal endoscopy findings of esophageal injury were grade 0 in 86 (41.7%) patients, grade 1 in 49 (23.8%), grade 2a in 42 (20.4%), grade 2b in 28 (13.6%), and grade 3a in 1 (0.5%) patient. 35 patients with grade 2a, 2b, and 3a injuries underwent esophageal dilation at second

week of ingestion. Esophageal stricture, which necessitated a regular dilation program developed in 13 of the aforementioned 35 patients. There is no statistically significant difference in the rate of development of esophageal stricture between the patients who ingested acidic (15.3%) and alkaline (8.9%) substances ( $P = 0.32$ ). Severe gastric injury was detected in 38 (18.5%) patients. The rate of development of gastric injury was significantly higher in the acidic group (14%) than in the alkaline group (2.9%) ( $P = 0.001$ ). Out of 149 patients with clinical findings, 49 (32.9%) patients had no esophageal injury and 117 (78.5%) patients had no gastric lesion. Esophageal and severe gastric injuries were detected in 20 (35.1%) and 8 (14%) of patients with no clinical findings respectively. Pyloric stenosis developed in 6 patients. Pyloric obstruction improved with balloon dilation in 2 patients. Mean hospitalization time were  $1.2 \pm 0.5$  d for grade 0 and  $2.3 \pm 5$  d for grade 1 and  $6.3 \pm 6.2$  d for grade 2a and  $15.8 \pm 18.6$  d for grade 2b. It was significantly longer for patients with grade 2a and 2b injuries ( $P = 0.000$ ).

**CONCLUSION:** Endoscopy is an effective technique for determining the presence of esophageal and gastric damage and to avoid unnecessary treatment in patients with no or mild injury.

## INTRODUCTION

Corrosive ingestion is an important social and medical problem due to associated early and long-term complications, including bleeding, perforation, systemic complications (renal insufficiency, hepatic dysfunction, and diffuse intravascular coagulation), esophageal stricture, fistula, gastric outlet obstruction, and cancer<sup>[1-4]</sup>. Corrosive injury may also lead to economic hardship due to medical costs and psychosocial problems in affected children, including behavioral and educational, as well as domestic problems<sup>[5]</sup>. Although the use of child proof packages or containers is increasing, caustic ingestion is still an important problem in children because of uncontrolled and cheaper cleaners which have been introduced through common uncontrolled markets in developing countries<sup>[6,7]</sup>.

Several studies<sup>[8,9]</sup> indicate that clinical signs are not always helpful in predicting the degree of injury and subsequent stricture formation. esophagogastroduodenoscopy (EGD) is the most effective method for establishing the severity of injury and treatment planning. However the reported studies<sup>[8-10]</sup> that investigated the role of endoscopy in caustic ingestion focused especially on esophageal injury. There are several studies with limited number of patients which emphasizes the gastric findings with detailed findings and results of caustic injury. The aim of the present study is to determine significance and necessity of the EGD to predict the esophageal and gastric outcome of caustic ingestion and its effect on planning the treatment strategies in children.

## MATERIALS AND METHODS

The study included 206 children that underwent EGD in a single institution because of accidental caustic substance ingestion between January 2005 and August 2010. We didn't perform EGD in patients with questionable history of ingestion if they were asymptomatic and had no oropharyngeal finding. Age and gender of the patients, chemical properties of the caustic substances, clinical findings, endoscopic findings, treatment modalities, feeding methods, and long-term complications were analyzed retrospectively. Hematemesis, oropharyngeal fibrinous lesions, severe mucosal edema, vomiting, drooling, oropharyngeal hyperemia and respiratory distress were considered positive clinical findings.

Ampicillin with sulbactam and ranitidine were routinely administered to all patients before EGD. EGD was performed in all patients under general anesthesia by a fiberoptic Pentax LH-150PC (Japan) endoscope. Endoscopy was performed within 48 h of initial injury. Endoscopic findings were graded by using a modification of the method of Di Costanza which was used by

Poley *et al*<sup>[4]</sup> as grade 0: normal; grade 1: mucosal edema and hyperemia; grade 2a: hemorrhagic, bullous mucosa, exudates, fibrinous membranes, or superficial ulceration; grade 2b: circumferential ulceration in addition to grade 2a; grade 3: scattered small necrotic areas, and black or brown mucosa. Grade 2a, 2b, and 3 were defined as severe lesions. Gastric injury was classified as normal (normal mucosal appearance, edematous or hyperemic mucosa) or severe (exudates, fibrinous membrane, superficial ulceration, scattered small necrotic area and hemorrhagic, black or brown mucosa).

Intravenous antibiotics and H<sub>2</sub> (histamin-2) receptor blocker were discontinued in patients with grade-0 and grade-1 injuries. Patients with grade-0 and grade-1 esophageal injury without severe gastric injury were fed orally and discharged after endoscopy. Gastric decompression and medical treatment which included steroid, intravenous antibiotics (ampicillin-sulbactam, netilmicin, and metronidazol) and H<sub>2</sub> receptor blocker were given in patients with grade 2 and 3 injuries or severe gastric injury. All patients who had grade-2 or 3 esophageal injury without severe gastric injury were fed *via* nasogastric tube after endoscopy. Enteral nutrition was not started and total parenteral nutrition (TPN) was given in patients who had severe gastric injury which was characterized with mucosal necrosis. A repeat endoscopy was performed for the reevaluation of the esophageal and gastric injury, and to start dilation within 7-13 d after caustic ingestion in patients with high suspicion about development of esophageal stricture and grade 2 or higher injury. Oral nutrition was initiated after detection of esophageal and gastric amelioration during the repeat endoscopy. Barium meal studies were performed in all patients with severe esophageal or gastric injuries at the end of the third week of ingestion to determine if esophageal or pyloric stricture was present. Dilation management was started in patients with esophageal or pyloric stricture.

### Statistical analysis

Statistical analysis was performed using SPSS v.11.5 software. Data were analyzed using descriptive statistical methods. Differences between groups were analyzed using the chi square test for categorical variables and Mann Whitney-U for continuous variables. *P* < 0.05 was considered statistically significant.

## RESULTS

The male/female ratio was 129/77 and mean age was 38.1 ± 28.8 mo (range: 4 mo-15 years). The caustic substances were acidic in 72 (34.9%) patients, alkaline in 56 (27.2%), liquid household bleach in 62 (30.1%), and unknown substance in 16 (7.8%) patients. Fifty-seven patients (27.7%) were symptom-free on admission. Positive clinical findings were observed in 149 (72.3%) patients. The median time of presentation was 1 h (range 10 min-7 d) and mean time of endoscopy was 1.56 ± 1.39 d (range: 1-10 d). Endoscopy was performed within 48 h of injury

**Table 1** Endoscopic findings of the patients number based on ingested caustic substance *n* (%)

Esophageal grade	Acidic	Alkaline	Liquid household bleach	Unknown content	Total
Grade 0	14	18	44	10	86 (41.7)
Grade 1	11	20	15	3	49 (23.8)
Grade 2a	25	12	2	3	42 (20.4)
Grade 2b	21	6	1	0	28 (13.6)

in 185 (89.8%) patients and was performed after 48 h in 21 (10.2%) patients because of late presentation. Esophageal findings according to the type of ingested substance are summarized in Table 1. One hundred and thirty-three patients with no or grade 1 esophageal injury were fed and discharged after endoscopy. Two patients who had grade 1 esophageal injury were hospitalized for 21 d and 30 d respectively because of severe gastric injury.

A repeat endoscopy and bouginage were performed within 7 d to 13 d after initial procedure in 35 patients with grade 2a and grade 2b esophageal injury and high suspicion about development of esophageal stricture. Esophageal stricture was detected in 16 patients with barium meal study. Thirteen of them needed more than 1 dilation. The correlation of degree of esophageal injury and stricture formation. The stricture rate was 15.3% (11 patients) and 8.9% (5 patients) among the patients with acidic and alkaline injuries, respectively (Table 2). No esophageal strictures developed in patients that ingested liquid household bleach or unknown caustic substances. Although 63.6% of patients who developed esophageal stricture ingested acidic substances, there is no statistically significant difference in the rate of development of esophageal stricture between the patients who ingested acidic and alkaline substances (*P* = 0.32).

Severe gastric injury was detected in 38 (18.4%) patients (Table 3). Gastroscopy could not be performed in 2 patients that ingested acidic substances because of severe esophageal edema. Gastric injury was more severe than esophageal injury in 7 (3.4%) patients. The rate of development of gastric injury was significantly higher in the acidic group than in the alkaline group (*P* = 0.001). Septicemia developed in four patients (1.9%) after oral feeding which was started after revealing the

normal esophageal appearance with partially improved initial severe gastric mucosal injury by control endoscopy. Pyloric stenosis developed in 6 patients. Five patients ingested acidic substances while one patient ingested liquid household bleach. Three of them had no clinical signs after ingestion. Endoscopy revealed grade 2a and grade 2b esophageal injuries in 2 and 4 of them, respectively. Severe gastric injuries, especially of the antral and pyloric areas, were observed in all 6 patients. Endoscopic balloon dilation of the pylorus was attempted in 4 of these patients and pyloric obstruction improved with dilation in 2 of them. One month following ingestion gastrojejunostomy and Heineke-Miculicz pyloroplasty were required in three and one remaining patients respectively.

Esophageal and gastric endoscopic findings according to clinical findings are summarized in Tables 4 and 5. The sensitivity and specificity of all clinical findings regarding severe esophageal injury were calculated as 80.6% and 32.8%, respectively. However sensitivity and specificity of all clinical findings regarding severe gastric injury were calculated as 75.7% and 29%, respectively. Tracheal injury was observed only in 1 patient. Duodenal injury was not detected in any of the patients. No complications related to endoscopy were observed in any of the patients.

TPN was required in 15 (7.3%) patients, of which 14 had severe gastric, antral or pyloric injury; six patients developed pyloric stenosis. One patient with esophageal injury without gastric injury required TPN because of enteral nutrition intolerance. Mean hospitalization time were 1.2 ± 0.5 d for grade 0 and 2.3 ± 5 d for grade 1 and 6.3 ± 6.2 d for grade 2a and 15.8 ± 18.6 d for grade 2b. It was significantly longer for patients with grade 2a and 2b injuries (*P* = 0.000).

**DISCUSSION**

Extent of injury following caustic ingestion depends on amount, concentration and pH of substance and tissue contact time<sup>[8,11]</sup>. Alkaline injury caused liquefaction necrosis which results in deep penetration of tissue<sup>[11]</sup>. Alkaline injury appears mostly in esophagus. However acidic injury causes coagulation necrosis which limits deep penetration. Acidic substance rapidly transit to the stomach because of their low viscosity and specific gravity. This condition results gastric injury more than esophageal injury<sup>[11]</sup>.

The late complications of caustic ingestion are closely related to the depth and extent of the esophageal or gastric injuries. Several clinical approaches and treatment modalities were recommended in injured children<sup>[6,12-15]</sup>. However, to estimate the risk of stricture formation, to begin early and appropriate treatment, and to prevent unnecessary malnutrition and medication use, the presence of esophageal and gastric damage should be documented. Several diagnostic trials were conducted for this purpose and included radiocontrast esophagography, scintigraphy, and esophageal ultrasound; however, the usefulness and prognostic value of these methods remain

**Table 3 Gastroscopic findings according to caustic substance n (%)**

	Substance				Total (n = 206)
	Acidic (n = 72 )	Alkaline (n = 56)	Liquid household bleach (n = 62 )	Unknown content (n = 16)

	Normal	Severe
Normal (n = 57) (27.7%)	49 (23.7)	8 (3.9)
Positive clinical findings (n = 149) (72.3%)	117 (56.8)	30 (14.6)

Gastroscopy could not be performed in 2 (1%) patients with positive clinical findings because of severe esophageal edema.

controversial<sup>[16,17]</sup>. The predictability of esophageal injury based on signs and symptoms, and the necessity of upper gastrointestinal endoscopy has been addressed in previous reports<sup>[1,2,4,8,9]</sup>. Although Gaudreault *et al*<sup>[9]</sup> considered vomiting, dysphagia, excessive salivation, abdominal pain, refusal to drink, and oropharyngeal burn specific clinical signs and symptoms of caustic injury, they observed severe esophageal burns in only 18%-33% of patients with these findings and concluded that clinical signs or symptoms cannot predict esophageal injury. Nonetheless, endoscopic evaluation was suggested as a mandatory intervention in symptomatic corrosive-injured patients, but it was not necessary for asymptomatic patients, especially those with a questionable history<sup>[3,18]</sup>. Lamireau *et al*<sup>[8]</sup> reported that vomiting, drooling, and oropharyngeal lesions were not predictors of esophageal injury; however, respiratory symptoms, hematemesis, or the presence of at least 3 symptoms were highly predictive of severe gastrointestinal injury, even though their sensitivity was low. However none of the authors stated the gastric injury in detail and its relation with symptoms and outcome of caustic injury.

We observed severe esophageal injury in 19.3% of our patients that did not have symptoms on the contrary 59.7% of the patients with positive clinical symptoms have no or grade 1 esophageal injury. Fifty percent of patients who developed pyloric stenosis did not have any clinical findings. We want to emphasize that clinical findings are not predictors of esophageal or gastric injury. Although sensitivity of clinical findings was relatively high; specificity of findings was low. Therefore these results support that the absence of any oropharyngeal lesion

does not rule out the severe esophageal or gastric injury.

Endoscopic evaluation is the most effective and widely used technique for establishing the severity of injury. The burned esophagus is weakest between the 7th and 21st d of injury<sup>[5]</sup>; the frequency of endoscopic complications such as fistulas, perforation, and bleeding usually increase in patients with high-grade injury during this period<sup>[5,5]</sup>. Early endoscopy is recommended, especially in the first 24-48 h<sup>[11,3,18]</sup>.

It is usually recommended to stop endoscopy at the first circumferential esophageal burn because of the risk of perforation beyond this point<sup>[19]</sup>; however; we think that this approach might cause a more severely burned esophagus or stomach to be missed. We observed severe gastric injury in 18.4% patients; gastric injury was more severe than esophageal injury in 3.4% of patients. We performed endoscopy after 48 h of injury in 10.2% of patients because of late presentation to the hospital. In contrary to the ordinary knowledge, we performed complete upper gastrointestinal endoscopy to reveal gastric injury even in patients in which severe esophageal injury was detected through endoscopy in all patients except two. However, there were no complications due to late or complete EGD.

The most frequent complication of corrosive substance ingestion is esophageal stricture. The rate of stricture formation is reported to be between 2% and 63%<sup>[5,6,9,13,20]</sup>. Baskin *et al*<sup>[20]</sup> reported that 4.7% of patients with grade 2a injury and 26% of those with grade 2b injury developed esophageal stricture. Huang *et al*<sup>[6]</sup> reported that all patients with grade 2 and 3 injury developed esophageal stricture. Overall, incidence of esophageal stricture was 7.8% in our study. Fourteen point three percent of our patients with grade 2a esophageal injury developed esophageal stricture. This rate was 32.1% and 100%, respectively, in patients with grade 2b and grade 3 esophageal injuries. We think that the partially low overall rate of esophageal stricture was related to the treatment strategies which were directed through the findings of EGD. Because we started early dilation within 7-13 d after initial procedure in patients who had grade 2 and 3 esophageal injury<sup>[3]</sup>. Therefore early dilation is suggested

to improve the outcome of esophageal injury and reduce the number of patients that develop esophageal stricture which was detected at the third week of ingestion.

We did not observe a significant statistical difference in the rate of development of esophageal injury between the acidic and alkaline ingestion groups in contrary to the literature, however esophageal and gastric injury occurred less frequently in the liquid household bleach and unknown content groups than in the acid and alkaline groups. Although 68.7% of the patients who developed esophageal stricture ingested acidic substances, there was no difference in the rate of stricture formation between the acidic and alkaline ingestion groups.

In the present study gastric injuries occurred with greater frequency in the acidic group than in the alkaline group [acidic (40.2%) *vs* alkaline (10.7%)]. Several studies<sup>[21-24]</sup> report that the overall incidence of gastric outlet obstruction is 5%-10% and that surgical correction is the preferred treatment modality in these patients. We observed gastric injury in 8.4% of our patients and gastric outlet obstruction occurred in 15.7% of them. Another advantage of EGD in patients with gastric injury is attempt of balloon dilation for pyloric stenosis.

We think that overlooking gastric injury distal to the upper circumferential esophageal injury is prevented by the gastroscopy which is completed even severe circumferential esophageal injury is detected. Also the widespread use of endoscopy and endoscopic dilation reduce the necessity for surgical procedures to treat corrosive-induced gastric outlet obstruction.

In conclusion, we think that endoscopy which is a mandatory and effective technique should be performed to prevent unnecessary hospitalization and medication use, to plan initial treatment and to predict the patients who are under the risk of developing esophageal stricture and/or gastric outlet obstruction. EGD can be performed without complications in experienced hands. Additionally EGD has advantages such as to establish treatment and follow-up strategies and improving the clinical outcome of the children with caustic ingestion.

## COMMENTS

### Background

Corrosive ingestion is still an important problem causing serious esophageal and gastric injuries which end up with esophageal strictures and pyloric obstruction in children. There are several studies with limited number of patients which emphasizes the gastric findings and results of caustic injury. Endoscopy is the most effective method for establishing the severity of injury.

### Research frontiers

There have been several studies which indicate that clinical signs are not always helpful in predicting the degree of injury and subsequent stricture formation of esophagus and pylorus. Endoscopy provides detailed information about the grade of corrosive injury thus helps to predict esophageal and gastric outcomes.

### Innovations and breakthroughs

The present retrospective study investigated the necessity of endoscopy to predict the outcome of caustic ingestion in children. This study suggests that endoscopy should be performed in all patients who experienced caustic ingestion except the patients with a questionable history and had no symptoms. Also severe gastric injury was observed in 18.4% patients and more severe than

esophageal injury in 3.4% of patients in this study. Therefore complete upper gastrointestinal endoscopy should be performed to prevent misdiagnosis.

### Applications

This article provides important data about significance and necessity of the endoscopy in patients with caustic ingestion. It is important to establish the severity, penetration and extent of injury to plan the treatment strategies in children with caustic ingestion.

### Terminology

Upper gastrointestinal endoscopy and esophagogastroduodenoscopy (EGD) are direct visual examination of mouth, esophagus, stomach and duodenum through an endoscope. Stricture is narrowing of the lumen. Total parenteral nutrition is defined as feeding of patient intravenously by bypassing of digestive system.

### Peer review

The manuscript is a reasonable retrospective review of 206 children who underwent EGD because of caustic ingestion. Severe gastric injury was noted in 18.5% and endoscopies proved safe even in the setting of severe esophageal injury.

### Abstract

**AIM:** To determine the efficacy of bevacizumab in patients with metastatic colorectal cancer (MCRC) who have failed prior chemotherapy without bevacizumab.

**METHODS:** Between March 2002 and June 2010, 40 patients in South Korea with MCRC who were treated with bevacizumab plus chemotherapy as a second or later-line treatment were analyzed retrospectively for their overall response rate (ORR), overall survival (OS), and progression-free survival (PFS). The tumor re-

sponses were assessed using the Response Evaluation Criteria in Solid Tumors guidelines.

**RESULTS:** All of the patients had progressed under prior chemotherapy without bevacizumab. Three patients (7.5%) exhibited an ORR, twenty one patients (52.5%) exhibited stable disease (SD), and fifteen patients (37.5%) exhibited disease progression. The median duration of the OS and PFS were 14.0 mo and 6.13 mo respectively. The median OSs were 16.60, 14.07 and 13.00 mo for second-line, third-line and fourth- or later-line treatments, respectively. The median PFSs were 7.23, 7.30 and 3.87 mo for the second-line, third-line and fourth- or later-line treatments, respectively.

**CONCLUSION:** In patients with MCRC, bevacizumab combined chemotherapy may be beneficial during second- or later-line treatment.

### INTRODUCTION

Metastatic colorectal cancer (MCRC) is a common can-

cer, and significant advances have been made in the treatment of this disease. The integration of oxaliplatin or irinotecan chemotherapies in combination with 5-fluorouracil (5-FU) and leucovorin (LV) as a front-line therapy for MCRC is associated with significant improvements in the time-to-progression and overall survival (OS)<sup>[1-3]</sup>.

The recent integration of bevacizumab in front-line therapy for MCRC has resulted in an additional positive impact on the outcome for colorectal cancer patients. Vascular endothelial growth factor (VEGF) is a diffusible, homodimeric glycoprotein this is produced by healthy and neoplastic cells and is a key promoter of angiogenesis under physiologic and pathologic conditions, including tumor progression<sup>[4]</sup>. The VEGF family includes six members [VEGF-A-E and placental growth factor (PIGF)]. The major mediator of tumor angiogenesis is VEGF-A<sup>[5]</sup>. Bevacizumab is a recombinant, humanized, monoclonal antibody directed against the VEGF ligand (VEGF-A); bevacizumab binds all isoforms of VEGF-A with a high affinity<sup>[6]</sup>. The inhibition of VEGF with bevacizumab has been shown to result in tumor reduction of colon cancer in xenograft models and acts in synergy with chemotherapy<sup>[7]</sup>. The addition of bevacizumab to 5-FU-based combination chemotherapy has been shown to result in a statistically significant and clinically meaningful improvement in survival among patients with MCRC<sup>[8-11]</sup>. The addition of bevacizumab to the FOLFOX chemotherapy regimen, consisting of 5-FU, LV, and oxaliplatin, provides a statistically significant and clinically meaningful improvement in OS, compared to FOLFOX alone, in patients with advanced or metastatic disease in whom the disease has progressed after adjuvant chemotherapy with FOLFIRI (5-FU, LV and irinotecan)<sup>[12,13]</sup>. However, based on the inconclusive results from multicenter studies, the role of bevacizumab in the treatment of patients with a disease that is refractory to 5-FU, irinotecan, and oxaliplatin is not yet known<sup>[14-16]</sup>.

The present retrospective study was designed to determine the efficacy and safety of bevacizumab combined with chemotherapy in patients with MCRC who have failed prior chemotherapy without bevacizumab.

## MATERIALS AND METHODS

### Patients

Between April 2005 and June 2010, 40 patients with MCRC were treated with bevacizumab plus chemotherapy as a second- or later-line treatment in Busan, South Korea. Patients who were eligible for the present study suffered from histologically-confirmed MCRC. Other inclusion criteria included an age of at least 20 years, and a life expectancy of > 3 mo. There were no limitations on the number of prior therapies or on the Eastern Cooperative Oncology Group (ECOG) performance status. However, adequate hematologic (an absolute neutrophil count > 1500/ $\mu$ L, hemoglobin > 9.0 g/dL, and a platelet count > 75 000/ $\mu$ L), hepatic (bilirubin < 2.0 mg/dL and transaminase levels < 3 times the upper normal limit), and renal

functions (creatinine < 1.5 mg/dL and urinary excretion  $\leq$  500 mg of protein per day) were required.

The exclusion criteria included the presence of clinically significant cardiovascular disease, uncontrolled hypertension, central nervous system metastasis, major surgery within 6 wk, pregnancy or lactation, non-healing wounds, bleeding diatheses, the regular use of aspirin (> 325 mg/d) or other non-steroidal anti-inflammatory agents, pre-existing bleeding diatheses or coagulopathies, the need for full-dose anticoagulation or prior bevacizumab therapy.

### Treatment schedule and dosing

Among the 40 patients in the present study, 12 patients received bevacizumab plus oxaliplatin-containing chemotherapy, 19 patients received bevacizumab plus irinotecan-containing chemotherapy, 8 patients received bevacizumab plus 5-FU and LV (FL), and 1 patient received bevacizumab alone. Bevacizumab plus FOLFOX or FOLFIRI chemotherapy was administered every 2 wk and consisted of the following: intravenous (IV) oxaliplatin (85 mg/m<sup>2</sup>) or irinotecan (150 mg/m<sup>2</sup>) over 2 h; IV LV (200 mg/m<sup>2</sup>) over 2 h, followed by a bolus of 5-FU (400 mg/m<sup>2</sup>); and infusional 5-FU (600 mg/m<sup>2</sup>) over 22 h, with FL repeated on day 1. The FL chemotherapy was administered every 4 wk [infusional 5-FU (375 mg/m<sup>2</sup>) over 24 h, and the IV LV (20 mg/m<sup>2</sup>)] was administered over 2 h for 5 d. Bevacizumab was administered intravenously at 5 mg/kg over 30 min to 90 min every 2 wk, prior to FOLFOX, FOLFIRI, or FL.

### Assessment

The objective of the present study was to evaluate the overall response rate (ORR), OS, progression-free survival (PFS), and toxicity of bevacizumab in patients who failed prior treatment. The tumor responses were assessed using Response Evaluation Criteria in Solid Tumors guidelines<sup>[17]</sup>. Progression was defined as a 20% increase at the time of disease progression.

The toxicities were graded using the NCI Common Terminology Criteria for Adverse Events (version 3.0)<sup>[18]</sup>. Radiographic assessments were performed at baseline (within 4 wk before starting chemotherapy) and every 6 wk to 8 wk. Radiologic evaluation consisted of a chest X-ray, bone scan, chest computed tomography (CT) scan, and abdominopelvic CT scan.

### Statistical analysis

All of the patients who received at least three dose of therapy were included in the PFS and OS analyses. The OS was defined as the time elapsed between the initiation of the study therapy to the date of death from any cause. The PFS was defined as the time elapsed between the initiation of the study therapy to the date of the progressive disease (PD). Patients who died without a documented PD were considered to have had a PD at the time of death. Patients who were removed from therapy for

ECOG: Performance status score.

toxicity without clinical or radiographic evidence of PD were censored. Patients who were lost to follow-up were censored at the last contact date. Survival curves were estimated using the Kaplan-Meier method.

## RESULTS

### Patient characteristics

The median age of the patients in the present study was 55.5 years. Forty patients received FOLFOX, FOLFIRI or FL, plus bevacizumab or bevacizumab alone, as a therapy. The metastatic sites were primarily located in the liver and/or lung (45.0%). Thirty one patients had previously undergone treatment with the FOLFOX regimen, twenty-five had undergone treatment with FOLFIRI, fifteen had undergone treatment with capecitabine alone and six had undergone treatment with FL. Seventeen patients (42.5%) were treated with bevacizumab combined

**Figure 1** Curves for the overall survival, and progression-free survival in patients with metastatic colorectal cancer after bevacizumab combined chemotherapy as a second- or later-line treatment. A: Curves for the overall survival in patients with metastatic colorectal cancer after bevacizumab combined chemotherapy as a second- or later-line treatment; B: Curves for progression-free survival in patients with metastatic colorectal cancer after bevacizumab combined chemotherapy as a second- or later-line treatment.

chemotherapy as a second-line treatment, thirteen (32.5%) were treated as a third-line treatment, and ten (25.0%) were treated as a fourth- or later-line treatment. The majority of the patients were treated with Bevacizumab combined chemotherapy, including oxaliplatin (30.0%), irinotecan (47.5%), and fluoropyrimidine (20.0%). One patient (2.5%) was treated using bevacizumab alone, without the addition of other chemotherapy regimens. Additional patient demographics are summarized in Table 1.

### Efficacy

Three patients had partial responses, resulting in an ORR of 7.5%. Twenty-one patients exhibited a stable disease (SD), and fifteen patients exhibited a PD. The response rates of second-line, third-line, and fourth- or later-line treatments were noted in Table 2.

The median duration of the OS and PFS was 14.0 mo and 6.13 mo, respectively (Table 3 and Figure 1). The median OSs were 16.60 mo, 14.07 mo and 13.00 mo for the second-line, third-line and fourth- or later-line treatments, respectively. The median PFSs were 7.23, 7.30, and 3.87 mo for the second-line, third-line and fourth- or later-line treatments, respectively.

Table 2 Response to treatment *n* (%)

Response	Patients	CR	PR	SD	PD	Unknown
Overall	40	0 (0.0)	3 (7.5)	21 (52.5)	15 (37.5)	1 (2.5)
2nd line	17	0 (0.0)	2 (13.3)	11 (64.7)	4 (23.5)	0 (0.0)
3rd line	13	0 (0.0)	1 (7.7)	6 (46.2)	5 (38.5)	1 (7.7)
4th or later-line	10	0 (0.0)	0 (0.0)	4 (40.0)	6 (60.0)	0 (0.0)

CR: Complete response; PR: Partial response; SD: Stable disease; PD: Progressive disease.

Table 3 Analysis of survival

End point	Median follow-up duration (range) (mo)	mOS (95% CI) (mo)	mPFS (95% CI) (mo)
Overall	23.87 (6.13-77.83)	14.00 (7.77-20.23)	6.13 (3.94-8.33)
2nd line	22.37 (6.13-56.10)	16.60 (3.22-29.98)	7.23 (6.45-8.02)

## DISCUSSION

In colorectal cancer, the use of bevacizumab has been shown to result in an improvement in survival rates and response rates. Bevacizumab was investigated after a randomized phase II study in combination with FL as part of the first-line of treatment of MCRC and resulted in a considerable improvement in efficacy when compared with the FL control<sup>[9,10,14]</sup>. Based on these data, phase III studies were conducted. Compared with irinotecan plus 5-FU/LV (IFL) alone, IFL plus bevacizumab improved the PFS, the ORR and the OS<sup>[8]</sup>. In the TREE-2 trial, previously untreated patients with MCRC were randomly assigned to bevacizumab and one of the three oxaliplatin- and 5-FU-containing regimens used in the TREE 1 trial (FOLFOX, oxaliplatin plus bolus 5-FU/LV, or capecitabine plus oxaliplatin). The bevacizumab-containing arms resulted in an improvement in the OS compared with the non-bevacizumab-containing groups in the TREE-1 study<sup>[19]</sup>. The administration of bevacizumab resulted in a superior response rate, PFS and OS in the

treatment of MCRC in the second-line setting. Supporting evidence was presented by the ECOG 3200, a phase III study randomizing patients who progressed after first-line IFL to FOLFOX plus bevacizumab *vs* FOLFOX alone<sup>[12]</sup>. In the second-line setting, another study showed that bevacizumab plus irinotecan was an active and safe treatment option for patients failing oxaliplatin-based therapy<sup>[20]</sup>. The role of bevacizumab in combination with FL as a third-line treatment was studied in a phase II trial of patients who failed irinotecan- and oxaliplatin-based chemotherapy regimens. Based on previous study, the use of third-line FL plus bevacizumab in chemoresistant patients is considered an ineffective treatment<sup>[14]</sup>. However, additional reports presented different results than this previous report after bevacizumab combined chemotherapy as a third-line treatment. Bevacizumab with FOLFIRI was reported to be well tolerated and to be a feasible treatment in patients with heavily treated advanced MCRC<sup>[21]</sup>. Two studies evaluated the efficacy and safety of bevacizumab plus FOLFIRI or FOLFOX in MCRC after failure with FOLFIRI and FOLFOX using a

retrospective analysis. These studies concluded that bevacizumab plus FOLFIRI or FOLFOX as third-line or later treatment in patients with MCRC resulted in a modest activity and was relatively tolerable<sup>[16,22]</sup>. A summary of the data during bevacizumab-combined chemotherapy as a second- or later-line treatment in patients with MCRC is shown in Table 4.

In the present study, the ORR was 7.5% for all of the patients, and the median duration of the OS and PFS was 14.0 mo and 6.13 mo, respectively. We suggest that bevacizumab combined chemotherapy as a second- or later-line treatment is an active and tolerable treatment in patients with MCRC after failure to response to previous chemotherapy.

## COMMENTS

### Background

The addition of bevacizumab to 5-fluorouracil (5-FU)-based combination chemotherapy as the first-line treatment results in a clinically meaningful improvement in the survival of patients with metastatic colorectal cancer (MCRC).

### Research frontiers

Based on the inconclusive results from multicenter studies, the role of bevacizumab in the treatment of patients with disease that is refractory to 5-FU, irinotecan, and oxaliplatin is unclear.

### Innovations and breakthroughs

In previous studies, bevacizumab combined chemotherapy as a second- or later-line treatment was shown to have controversial results. In the present study, three patients exhibited partial responses, resulting in an overall response rate of 7.5%. The median duration of the overall survival (OS) and progression-free survival (PFS) was 14.0 mo and 6.13 mo, respectively. The median OSs were 16.60, 14.07 and 13.00 mo for the second-line, third-line and fourth- or later-line treatments, respectively. The median PFSs were 7.23 mo, 7.30 mo, and 3.87 mo the second-line, third-line and fourth- or later-line treatments, respectively.

### Applications

The results of the present study suggest that bevacizumab combined chemotherapy as a second- or later-line treatment is an active and tolerable treatment option for patients with MCRC after failure to previous chemotherapy.

### Peer review

The present study is a good descriptive retrospective study that evaluated the efficacy of bevacizumab plus chemotherapy in patients with MCRC who have failed prior chemotherapy without bevacizumab.

### Abstract

**AIM:** To compare the clinical characteristics of pyogenic liver abscess (PLA) in patients with and without hepatic neoplasm (HN).

**METHODS:** Authors performed a retrospective analysis involving patients with PLA. The demographic, clinical features, laboratory and imaging findings, management and outcome of patients with and without HN were studied.

**RESULTS:** From January 2000 to December 2009 inclusive, 318 patients (35 with HN) had PLA, and mean age and comorbidity were comparable between the two groups. More patients with HN experienced right upper quadrant pain (68.6% vs 52.7%,  $P < 0.04$ ), developed jaundice (14.3% vs 5.7%,  $P < 0.03$ ) and hepatomegaly (17.1% vs 3.9%,  $P < 0.01$ ), and had higher serum total bilirubin level (43.3  $\mu\text{mol/L}$  vs 30.0  $\mu\text{mol/L}$ ,  $P = 0.05$ ). Most patients in both groups had PLAs in the right hepatic lobe, and biliary tract disorder was the most common underlying cause (71.4% and 61.8%). However, more PLAs in the HN group were associated with thicker abscess wall (37.1% vs 19.4%,  $P < 0.01$ ), septal

lobulation (77.1% vs 58%,  $P < 0.02$ ), gaseous cavitation (17% vs 7.8%,  $P = 0.03$ ), portal thrombophlebitis (11.4% vs 1.8%,  $P < 0.01$ ) and aerobilia (25.9% vs 5.5%,  $P < 0.01$ ). Mixed bacterial growth (40% vs 15.2%,  $P < 0.01$ ) and Gram-negative bacilli (22.8% vs 60.4%,  $P < 0.01$ ) were dominant isolates in PLAs with and without HN, respectively. Although incidence of the complications was comparable between the two groups, patients with HN had a higher mortality rate than those without (71.4% vs 8.8%,  $P < 0.01$ ). Multivariate logistic regression analysis revealed underlying active malignancy [odds ratio (OR): 40.45, 95% CI: 14.76-111.65], hypoalbuminemia (OR: 1.22, 95% CI: 1.14-1.38), disseminated intravascular coagulation (OR: 3.32, 95% CI: 1.19-9.69) and acute coronary syndrome (OR: 4.48, 95% CI: 1.08-17.8) were independent risk factors associated with mortality. However, several HN cases, presented concurrently with PLAs, were found to have curative resectable tumors and had good prognosis after surgery.

**CONCLUSION:** PLA associated with HN tends to form a distinct clinical syndrome with a different extent of clinical manifestations, radiological and microbiological features and complications.

Law ST, Li KK. Is hepatic neoplasm-related pyogenic liver abscess a distinct clinical entity? *World J Gastroenterol* 2012; 18(10): 1110-1116 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i10/1110.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i10.1110>

## INTRODUCTION

Pyogenic liver abscess (PLA) has been recognized since the time of Hippocrates<sup>[1-4]</sup>. It is the most common type of visceral abscess; in a report of 540 cases of intra-abdominal abscesses, PLA accounted for 48% of visceral abscesses. This condition is potentially life threatening, with a mortality rate ranging from 10% to 40%<sup>[5,6]</sup>. The previous reports have indicated that hepatic malignancy is the major risk and poor prognostic factor for PLA<sup>[7,8]</sup>. Clinically, it is mandatory for clinicians to rule in/out any coexisting tumor component in the PLA, so that appropriate neoadjuvant therapy or even surgical resection if localized can be offered promptly after treatment of the infection. However, to the best of our knowledge, the issue of the prediction of the presence of hepatic malignancy in PLA has never been investigated.

Thus, the aim of this study was to review the characteristics of patients with and without hepatic neoplasm (HN)-associated PLA in the following areas: risk factors, clinical features, characteristics features of liver abscess, treatment and outcome.

## MATERIALS AND METHODS

The records of patients discharged from Tuen Mun Hospital in Hong Kong with a diagnosis of PLA (International Classification of Diseases code 572.0) between January 2000 and December 2009 were reviewed. Cases were identified through searching the hospital database (Clinical Management System of Hospital Authority of Hong Kong). Underestimation of actual caseload is possible because coding might not have included patients suffering from an underlying disease.

The case definition of PLA required patients to have one or more filling defects on liver imaging [either ultrasound or computed tomography (CT)], together with either (1) complete resolution of radiological abnormalities following antimicrobial therapy with/without positive blood/pus culture, or (2) histological proof of microbiological infection without underlying neoplasm.

The diagnosis of hepatic tumor abscess was based on the presence of hepatic tumor of primary or secondary origin plus one or both of the following: (1) positive pus culture; and (2) partial resolution of radiological abnormalities following antimicrobial therapy.

The clinical records of these patients were retrospectively reviewed to obtain the demographic characteristics, clinical features, laboratory, imaging findings, treatment methods and final outcomes. Recurrence was defined as the development of new clinical and radiological changes subsequent to clinical and/or radiological resolution.

### Statistical analysis

The data were compiled and analyzed using SPSS for Windows version 17.0 (SPSS Inc., Chicago, IL, United States). All continuous variables were expressed as mean  $\pm$  SD. Categorical variables were reported as percentages. Student's *t* test,  $\chi^2$  test, Fisher's exact test and Mann-

## RESULTS

From January 2000 to December 2009 inclusive, a total of 318 patients were diagnosed with PLA, 35 (11%) of which were associated with HN. There were 29 cases of hepatopancreatobiliary (HPB) malignant disease and causes identified for the other patients were as follows: colonic cancers in three patients, and hepatocellular, gastric and breast cancer in one patient each. Among 29 cases of HPB neoplasms, there were 20 cases of cholangiocarcinoma (13 intrahepatic and seven extrahepatic cholangiocarcinoma), six cases of gallbladder cancer, and three of pancreatic cancer. In the HN group, 10 patients had neoplasms that presented concomitantly with the development of PLA, and they included four gallbladder cancers, two intrahepatic cholangiocarcinomas, two cancers of the head of the pancreas, and one each of breast and cecal cancer. Although they presented concurrently, most of them were found to be widely metastatic by imaging, and unable to undergo curative resection. Only four cases had localized tumors on presentation: two cases each of intrahepatic cholangiocarcinoma and cancer of the head of the pancreas. They remained stable after the resection of the tumors. For the patients whose HNs presented prior to PLAs, the median period of time was 5 mo (range: 2-17 mo).

### Demographic characteristics

The demographic characteristics of these patients are shown in Table 1. There was no sex dominance in the HN group (male to female ratio: 1.06). The mean age

HN: Hepatic neoplasm; CRP: C-reactive protein; ESR: Erythrocyte sedimentation rate.

was 67.7 years (range: 24-91 years; median: 72 years) in the HN group and 65 years (range: 24-97 years; median: 65 years) in the non-HN group (data not shown). There was no significant difference in age and sex between the two groups (*P* = 0.40). Major comorbidities of the two groups were similar and included hypertension, ischemic heart disease, diabetes mellitus and stroke.

### Clinical features

The clinical features of PLA in patients with and without HN are shown in Table 1. Patients with HN tended to have more acute onset of symptoms than did patients without HN. As shown in Table 1, the most common presenting features were fever, chills and right upper quadrant pain. The HN group experienced right upper quadrant pain (68.6% *vs* 52.7%, *P* < 0.04), jaundice (14.3% *vs* 5.7%, *P* < 0.03) and hepatomegaly (17.1% *vs* 3.9%, *P* < 0.01) more than did the non-HN group, with a significant difference between them. About 20% of patients in both groups experienced respiratory symptoms but only half of these patients had abnormalities in chest radiography.

### Laboratory and radiological features

The laboratory findings are summarized in Table 2. Anemia, leukocytosis, high erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP), hypoalbuminemia, and elevated total bilirubin and alanine aminotransferase were common in the two groups. The HN group tended to have a higher serum bilirubin level (43.3 μmol/L *vs* 30.0 μmol/L, *P* = 0.05). About 40% of the patients had positive bacterial growth in blood culture on admission. Ultrasonography (USG) and CT of the abdomen were performed in two (5.7%) and nine (25.7%) patients with HN, and 81 (28.6%) and 20 (7.1%) patients without HN, respectively. Combined imaging was performed in 24 (68.6%) and 182 (64.3%) patients with and without HN, respectively. The characteristics of PLA found by radiological imaging are shown in Table 2. The majority of the patients in both groups had right lobe PLA of comparable size. Most PLAs in the two groups appeared as hypoechoic nodules on USG imaging. Both groups had the following common features: rim enhancement, septal lobulation and fluid cavitation in CT imaging, with greater frequency in the HN group. In contrast, more patients in the HN group had thicker (37.1% *vs* 19.4%, *P* < 0.01) abscess walls (i.e., thickened abscess wall is defined as wall thickness > 1 cm<sup>[9]</sup>) than those in the non-HN group had, but both carried a similar risk of rupture. Moreover, aerobilia, gaseous cavitation and portal thrombophlebitis were experienced more in the HN group, with a significant difference between the two groups (*P* < 0.05).

### Underlying etiology

The etiologies of the two groups are summarized in Table 3. The pattern of the causative organisms was entirely different between the two groups. Most of the

**Table 4** Management and outcomes of pyogenic liver abscess with/without hepatic neoplasm *n* (%)

	HN group ( <i>n</i> = 35)	Non-HN group ( <i>n</i> = 283)	<i>P</i> value
Intervention

Recurrence	1 (2.9)	16 (5.7)	0.25
Death	25 (71.4)	25 (8.8)	< 0.01

<sup>1</sup>For disseminated intravascular coagulation; <sup>2</sup>For intensive care unit. HN: Hepatic neoplasm.

microorganisms isolated from the HN group were mixed growth (40%), followed by Gram-negative and Gram-positive isolates, whereas Gram-negative isolates were dominant in the non-HN group, followed by polymicrobial isolates and Gram-positive cocci. *Klebsiella* spp. were the dominant Gram-negative organisms in both groups.

Biliary tract disorder was the most common cause of disease in the two groups. In 14 (4.4%) patients PLA was due to portal pyemia: three patients were from the HN group and all had advanced colon cancer with multiple hepatic metastasis. The remaining 11 were from the non-HN group: seven with colonic diverticulitis shown by abdominal CT scan; two with active inflammatory bowel disease; and two with a recent history of acute appendicitis. Five patients from the HN group had PLAs caused by the direct spread of infection. One patient developed PLA after transarterial chemoembolization for hepatocellular carcinoma and the organism involved was *Staphylococcus aureus*, thus the infection was probably due to catheter delivery of the skin contaminant. The other four cases had advanced carcinoma of the gallbladder with local invasion into the liver parenchyma. Seven cases (two from the HN group) were caused by hematogenous spread: In the HN group, these were cases of advanced gastric and breast cancer and both had multiple liver metastases. Causes identified in the other group were as follows: urinary tract infection in two patients, and one each with pneumonia, right psoas abscess and continuous ambulatory peritoneal dialysis peritonitis. Lastly, > 20% of patients in the non-HN group had not been investigated for the underlying causes of PLA.

### Management and treatment outcomes

The management and outcomes of the two groups are summarized in Table 4. All patients received intravenous broad-spectrum antibiotics after assessment for sepsis. Antibiotic resistance was detected in 10 (28.6%) isolates from the HN group, but in only 49 (17.3%) from patients without HN, with a significant difference between the

two groups ( $P = 0.05$ ). Antibiotic therapy was the only treatment for seven and 32 patients in the HN and non-HN groups, respectively, and the reason for not performing image-guided aspiration and drainage was the small size of the lesion (< 3 cm in diameter). Among the HN group, USG-guided needle aspiration was performed in 27 (77.1%) patients and continuous catheter drainage in six (17.1%). In the non-HN group, 233 (82.3%) patients had USG-guided needle aspiration and among these, 206 (72.8%) patients had continuous catheter drainage, with a significant difference between the two groups. A pigtail catheter was not inserted in these 48 patients after percutaneous aspiration because the abscess was too solid or it was completely collapsed after aspiration, thus, further catheter drainage was not considered useful. Surgical drainage was required in one (2.9%) and 18 (6.4%) patients with and without HN, respectively. The main reason for laparotomy among these patients was the presentation of acute abdomen. There were no patients who failed to respond to antibiotics with/without percutaneous drainage.

No patients with HN had detectable metastatic infections, whereas 16 (5.7%) patients without HN experienced distant spread of the infection: urinary tract infection in eight, endophthalmitis in three, pneumonia in two, and right empyema, right psoas abscess and simultaneous endophthalmitis and urinary tract infection in one patient each. Septic shock developed in 40% of patients with HN but in only 25% of those without HN, with no significant difference between the two groups. Other complications, such as disseminated intravascular coagulation (DIC), acute coronary syndrome and respiratory/renal failure had comparable incidence between the two groups. The intensive care unit was offered to 31 (11%) patients without HN but only one (2.9%) patient with HN, with no significant difference between the two groups. Recurrence rate of PLA was low in both groups. Twenty-five (71.4%) patients with HN died during the management, all of which was attributed to the underlying HNs, in which all except one had the septic process under control. Only one case died due to uncontrolled *Clostridium perfringens* septicemia on day 7 of hospitalization. The non-HN group had only 25 (8.8%) deaths and causes were as follows: 17 with liver abscesses, six with hospital-acquired pneumonia, two with cerebrovascular accident, and one with uncontrolled bleeding duodenal ulcer, with a significant difference between the two groups (log rank test < 0.01) (Figure 1). By using multivariate logistic regression analysis, underlying active malignancy, hypoalbuminemia, DIC and acute coronary syndrome were independent risk factors associated with mortality for these two groups (Table 5). These combined risk factors accounted for 49% (Nagelkerke  $r^2$ : 0.49) of the mortality risk and HN was the most significant clinical variable in this model.

### DISCUSSION

PLA has been recognized since the time of Hippocrates. During recent decades, despite advances in microbiology,

Table 5 Summary of multivariate logistic regression analysis of mortality of pyogenic liver abscess

Variable <sup>1</sup>	Wald estimate <sup>2</sup>	$\beta$ coefficient (B)	OR <sup>3</sup> (95% CI)	P value
Hepatic malignancy	51.5	3.7	40.45 (14.76-111.65)	0.00
Hypoalbuminemia	15.2	0.2	1.22 (1.14-1.38)	0.00
DIC	5.2	1.2	3.32 (1.19-9.69)	< 0.05
Acute coronary syndrome	4.3	1.5	4.48 (1.08-17.80)	0.02
Impaired renal function	0.1	0	1.00 (0.82-1.12)	0.76

imaging-guided intervention and antibiotic therapy, PLA is still a potential life-threatening condition with a mortality rate ranging from 10% to 40%, and one of the reasons is the increasing number of patients with primary or secondary HNs<sup>[5-8]</sup>. In general, only 5% of malignant liver tumors are of primary origin, whereas the rest are assumed to be metastases<sup>[10]</sup>. In fact, the liver is the second most common site of metastasis next to lymph nodes. Our study revealed two important findings. First, the primary HNs, instead of liver metastases, were dominant in those PLAs associated with HN. The liver is resistant to infection because it is one of the reticuloendothelial systems in the body and harbors numerous lymphoid cells. Second, the primary site of the HN is also crucial for the development of PLAs because HBP malignant disease was dominant within the HN group.

In the present study, the mean age of the patients and the prevalence of their comorbidity were comparable with previous studies. Men and women were equally affected in patients with HN, whereas there was male dominance in patients without HN, as in most previous studies<sup>[11-17]</sup>. The duration of symptoms before admission was shorter in the HN group than the non-HN group. This is because a higher proportion of the cases in HN groups were due to the biliary tract pathology. Seeto *et al.*<sup>[18]</sup> have found that

PLA presents most acutely (3 d) if it is due to biliary tract disorder.

The patients in both groups presented with similar clinical features: fever, chill and right upper quadrant pain were frequent symptoms. Because of the presence of hepatic tumors of either primary or secondary, there was a higher incidence of right upper quadrant pain, jaundice and hepatomegaly on physical examination in patients with HN.

Abnormalities in laboratory parameters were similar in both groups, mainly anemia, leukocytosis, high ESR and CRP, deranged liver function test, with elevated serum bilirubin and alkaline phosphatase. However, the change in serum alanine aminotransferase was less pronounced in patients with HN, which may relate to the dominance of cancer of the biliary system among the HNs, thus reflecting the probable secondary biliary cirrhotic change in liver parenchyma. Right lobe involvement was dominant in both groups of patients, which is consistent with prior reports<sup>[19]</sup>. The right lobe dominance is due to its size and propensity to receive most of the portal blood flow. Bilobar involvement was only seen in 8.6% of the HN group. This is because bilobar tumors are more common in hepatic metastases of extra-HPB origin, which only contributed five (14.3%) cases in our series.

PLAs with and without HN had several similar radiological features in our study. USG appearance of both groups might range from hyperechoic to hypoechoic and this variation has a close relationship to the pathological stage of PLA. During the very early stage of abscess formation, the hepatocytes/tumor cells undergo acute inflammation and thus the abscess might appear solid, i.e., hyperechoic. When these cells start to become necrotic, the abscess liquefies with increasing fluid content and surrounding edema. This is also the stage most patients with PLA present clinically, and thus most PLAs, with or without HN, are hypoechoic by USG and are fluid-containing lesions with rim enhancement in CT contrast studies. In contrast, our study demonstrated that PLAs with and without HNs had several contrast features in imaging. First, within the hepatic tumor tissue, the tumor cells will secrete cytokine to stimulate the adjacent fibrous stroma tissue to grow, therefore, thickened abscess wall

and septation were more commonly seen in PLAs with HN<sup>[20]</sup>. Second, there was a higher incidence of aerobilia and portal thrombophlebitis in patients with HN that might be related to the high incidence of HPB malignancies in the HN group. Third, the gaseous cavitation was more commonly seen in PLAs associated with HN. This might be explained by the fact that the tumor cells have high energy demand for rapid duplication, and this leads to accumulation of lactic acid through their glycolytic pathway. Subsequently, the acidic environment stimulates the formic hydrogen lyase of the bacteria to produce carbon dioxide and hydrogen through mixed acid fermentation<sup>[21]</sup>. The comparable risk of rupture of PLA associated with/without HN might be explained by the combined counteracting effects of the wall thickness and the gaseous cavitation inside the abscess.

The bacteriological pattern in PLA was entirely different between the two groups in which there was a higher incidence of polymicrobial isolates in the abscesses of the HN group. This may be related to the mixture of microorganisms in the normal flora in the gastrointestinal and biliary tract. There are three possible mechanisms for the bacterial flora to develop PLA in the presence of HN: malignant biliary obstruction caused by HPB malignancies, portal venous suppuration, which usually happens in colorectal tumor, and bacterial seeding *via* hepatic artery following systemic chemotherapy<sup>[22]</sup>. Although only some patients were investigated by colonoscopy, endoscopic retrograde cholangiopancreatography and endoscopic ultrasound were performed, the biliary disease was still the most common identifiable cause of PLA in patients without HN as in other recent studies<sup>[18,23,24]</sup>.

In our study, most of the patients were managed by combination of antibiotic and imaging-guided aspiration with/without drainage. There was no difference in the complications between the two groups during the imaging-guided intervention. No tumor seedlings were reported in the HN group, and this might have been due to only minute quantities of tumor cells in the central region of the tumor mass. Thus, imaging-guided aspiration of the hepatic tumor abscess is regarded as a relatively safe procedure. Although both groups of patients responded similarly in the initial phase of management, the patients with HN tended to have a more fulminant clinical course with a higher incidence of septic shock, DIC and acute coronary syndrome. There was no detected metastatic infection in patients with HN and this might be explained by the difficulty for the bacteria to disseminate within the tumor tissue. Surprisingly, underlying active hepatic malignancy was less likely to be associated with the recurrence of PLA, because a considerable proportion of the patients with HN died. This would have made an apparently negative association between malignancy and recurrence.

In the present study, the overall mortality rate of PLA was 16%, which is comparable to other studies<sup>[25]</sup>. The higher mortality rate of patients with HN was due to underlying active malignancy and higher incidence of the complications mentioned previously. Half of the deaths

in the HN group happened within the first 12 wk. Although there were two cases each of intrahepatic cholangiocarcinoma and cancer of the head of the pancreas that presented concurrently with PLAs, these four cases were found to have localized tumors and thus curative resection could be performed after treatment of PLA. Thus, it is justifiable to have early follow-up imaging with/without biopsy for those PLAs that have a suspicion of malignancy. Despite the advanced stage of the disease, early diagnosis of the neoplastic component is warranted because neoadjuvant target therapy might modify its natural course. In our study, the most important determinants of mortality rate were underlying active hepatic malignancy, hypoalbuminemia, DIC and acute coronary syndrome. The prognostic value of underlying malignancy has been recognized in other studies<sup>[24,26]</sup>. Hypoalbuminemia reflects the duration of the growth of the liver abscess and the degree of impairment of hepatic synthetic function. DIC and acute coronary syndrome may relate to the severity of the septic process.

PLA associated with HN tends to have a distinct clinical syndrome with a different extent of clinical manifestations, radiological and microbiological features, and complications. The initial antibiotic of choice should be broad-spectrum with coverage of both Gram-positive and -negative microorganisms. These PLAs can be safely treated with image-guided aspiration with/without drainage, with negligible risk of tumor seedlings. Early follow-up imaging should be considered for those PLAs with potential risk of malignancy.

## COMMENTS

### Background

Hepatic neoplasm (HN) is a recognized cause of pyogenic liver abscess (PLA). It is well-known that HN can mimic PLA on presentation and it is difficult to identify the coexisting hepatic tumor component in PLA, thus, PLA associated with HN is a diagnostic challenge to clinicians. There have been few studies focused on this subject.

### Research frontiers

Due to the better understanding of carcinogenesis and the advancement of molecular medicine, treatments based on molecular targets are being developed and these might have the potential to modify the clinical course of these neoplasms.

### Innovations and breakthroughs

PLA associated with HN tends to have a distinct clinical syndrome with a different extent of clinical manifestations, radiological and microbiological features, and complications. Several cases, presented concurrently with PLAs, were found to have curative resectable tumors and had good prognosis after surgery.

### Applications

The initial antibiotic of choice should be broad-spectrum with coverage of both Gram-positive and -negative microorganisms. These PLAs can be safely treated with image-guided aspiration with/without drainage, with negligible risk of tumor seedlings. Early follow-up imaging should be considered for those PLAs with potential risk of malignancy.

### Peer review

This is a unique manuscript documenting the clinical course of liver abscess associated with/without malignancy. The authors report differences between two groups (liver abscess with and without malignancy) and liver abscess with malignancy was associated with unfavorable prognosis. The viewpoint of this manuscript is interesting, but the clinical impact of this study is not fully discussed.

### Abstract

**AIM:** To investigate the association between the polymorphism of *TBX21* gene and the risk of gastric cancer in a Chinese population.

**METHODS:** The -1993 polymorphism located in *TBX21* gene promoter region was identified by polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) method. The risk between *TBX21* gene genotype and gastric cancer was determined by multivariate logistic regression analysis in 220 gastric cancer patients and 262 cancer-free controls matched by age, sex and ethnicity.

**RESULTS:** Compared with the *TBX21* -1993TT geno-

type, the -1993CC genotype exhibited a significantly elevated risk for gastric cancer [Odds ratio (OR) = 3.42, 95% confidence interval (CI): 1.41-8.31]. The relationship between the -1993 polymorphic genotype and the invasive status such as lymph node and distant metastasis was found among the gastric cancer patients (OR = 4.02, 95% CI: 1.87-8.66; OR = 7.02, 95% CI: 3.44-14.34, respectively).

**CONCLUSION:** *TBX21* -1993 polymorphism might contribute to the risk of gastric cancer, especially to the distant metastasis.

Association between gastric cancer and -1993 polymorphism of *TBX21* gene. *World J Gastroenterol* 2012; 18(10): 1117-1122 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i10/1117.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i10.1117>

### INTRODUCTION

Gastric cancer is the fourth most common cancer, which approximately accounts for 12% of all cancer deaths and currently ranks second in global cancer mortality only behind the lung cancer<sup>[1]</sup>. Until recently, although the global incidence of gastric cancer has been dramatically

decreased in different regions, it still represents a leading cause of death worldwide, especially in China and other Asian countries<sup>[2]</sup>. It is estimated that more than 930 000 new cases of gastric cancer would be diagnosed each year in the world. Although the different management approaches were performed, a minimum of 700 000 patients would die from this malignant disease<sup>[3]</sup>.

In the previous study, the dietary factors, such as nitrates, smoked fish and salted meats, moldy foods containing aflatoxin, and the infection with *Helicobacter pylori* (*H. pylori*), were thought to be involved in the development of gastric cancer<sup>[4]</sup>, but the detailed mechanisms of gastric carcinogenesis are still unknown. In spite the new insight of the immune surveillance, the molecular elimination mechanism and host susceptibility to malignant gastric cell still remained largely unsolved. The susceptibility of the host genetic factor to malignant disease is a dynamic interactive process, which is thought to be involved in the balance between the host immune response and the malignant cell apoptosis. Moreover, multitudinous cytokines played crucial roles against the malignant transformation of normal cells in this process<sup>[5]</sup>.

Although the genetic basis of host susceptibility to the development of gastric cancer had not been clearly discovered, our previous study reported that the -1661A/G polymorphism located at *cytotoxic T lymphocyte-associated antigen-4* (*CTLA-4*) gene promoter might significantly increase the risk of gastric cancer development<sup>[6]</sup>. Similarly, in the immune-regulated area, researches demonstrated that the *TBX21* gene (NCBI OMIM nos.\*604895), which encoded the transcription factor T-bet (T-box expressed in T cells), was a key transcriptional activator to induce the differentiation from helper T cells to Th1 cells<sup>[7]</sup>. In the previous experiments, the expression of *TBX21* gene was proved to be associated with breast cancer and the T-bet protein played a key role in natural killer (NK) cell-mediated melanoma metastatic disease<sup>[2,8]</sup>. These evidences indicated that the expression of *TBX21* gene was closely associated with the development of cancer through the Th1 and NK cells pathway<sup>[9]</sup>. Moreover, the -1993 polymorphism located in *TBX21* gene promoter region had been verified to alter the transcription factor binding and regulating the *TBX21* gene expression<sup>[10]</sup>. Hence, in this study, we systematically scrutinized the -1993 genetic polymorphism and assessed the potent susceptibility of this *TBX21* gene (SNP) to gastric cancer in the Chinese population.

## MATERIALS AND METHODS

### Patients

This population-based case-control study was carried out in two hospitals: Beijing Friendship Hospital, Capital Medical University and Qianfoshan Hospital, Shandong University, China. Followed an identical protocol, each hospital was responsible to recruit the gastric cancer patients consecutively from 2005 through 2010. All patients were histopathologically confirmed by endoscopic biopsy

or surgical specimen. At the same time, a comparable group of normal controls without gastric cancer or other disease was included in this study from the two hospitals. Two hundred and twenty eligible patients with gastric cancer (124 males and 96 females) were enrolled in this study. The individuals who possessed secondary, recurrent malignancies, and accepted blood transfusion were excluded. There were eight cases of gastric cancers located in cardia, 117 in non-cardia, six in the upper third, 49 in the middle third, and 40 in the lower third. Two hundred and sixty two controls (143 males and 119 females) proved to be free from any malignant diseases by the physical examination were randomly and simultaneously recruited from the two hospitals. Except for matching the gastric cancer patients by gender and age (within 5 years), control subjects with severe clinical symptoms, previous diagnosis of cancer, and genetic disease were excluded. The mean age of the gastric cancer patients was  $41.14 \pm 7.10$  years (mean  $\pm$  SD) and the control group was  $41.69 \pm 8.83$  years. There were no statistically significant differences in current smoking or drinking status, age, sex, and race between the two groups. All participants were of Han nationality from Northern China. The minor distinct ethnic groups and migrants from other countries were not included. This study protocol was approved by the Institutional Review Boards of participating institutions, and each participant should provide a signed informed consent before the two mL peripheral blood sample was collected.

### DNA extraction and genotyping method

According to the standard protocol as described in a previous study<sup>[11]</sup>, genomic DNA was extracted from peripheral blood leukocytes using sodium dodecyl sulphate lysis and proteinase K digestion followed by the standard phenol-chloroform extraction. DNA samples were quantified and subjected to specific polymerase chain reaction (PCR) amplification as described below. The -1993 polymorphism within *TBX-21* gene promoter region was identified by the reaction-restriction fragment length polymorphism (PCR-RFLP) method. The primers which were used in PCR amplification for the promoter specific fragments were described previously<sup>[10]</sup>. The PCR was performed in a 20  $\mu$ L total reaction volume containing 2  $\mu$ L 10  $\times$  PCR buffer (Qiagen Inc., Hilden, Germany), 1.5 mmol/L MgCl<sub>2</sub>, 0.5  $\mu$ mol/L each primer, 0.2 mmol/L dNTP, 1.2 U Taq polymerase (Qiagen Inc., Hilden, Germany) and 200 ng of genomic DNA. After an initial denaturation at 95  $^{\circ}$ C for 5 min, the DNA was amplified by 35 cycles of 94  $^{\circ}$ C for 30 s, 62.0  $^{\circ}$ C for 40 s, and 72  $^{\circ}$ C for 45 s, with a final elongation at 72  $^{\circ}$ C for 10 min on the Gene-Amp PCR System 9700 (PE Applied Biosystems, Foster City, CA, United States). PCR products were purified using a Multi-Screen-PCR purifying plate (Millipore Company, Billerica, MA, United States). Under the condition recommended by the manufacturer's instruction, the purified PCR products were digested by the restrictive enzyme *Hha* I (New England Biolabs Beverly, MA, United States). The digest-

ed PCR products were fractionated on 4% agarose Tris-borate-EDTA gel (Agarose 1000; Gibco BRL, Rockville, MD, United States) and stained with ethidium bromide. All assays were conducted blindly by two researchers without the knowledge of case or control status. Additionally, about 10% of the samples were randomly selected and retested, and the results were 100% concordant.

### Statistical analysis

The frequency distributions of demographic variables and putative risk factors to gastric cancer, including age, gender, smoking or drinking status, and family history of cancer were examined in case and control groups by Mann-Whitney *U* test or Chi-square test. Multivariate unconditional logistic regression was used to determine the statistical significance of interaction between the certain variables and gastric cancer. Odds ratios (ORs) were adjusted by matching the variables. The Chi-square was used to compare the observed genotype distributions with the expected genotype by the Hardy-Weinberg equilibrium. All calculations were performed using the SPSS/Win statistical program (version 11.5.1 for Windows; SPSS Inc, Chicago, IL, United States). The statistical tests were two-sided, and the values of *P* < 0.05 were considered statistically significant.

## RESULTS

### Study population characteristics

In our experiment, *TBX21* gene -1993 loci within its promoter region were found in 482 Chinese individuals consisting of 220 gastric cancer patients and 262 controls, and the substitution of nucleotide from T to C was detected by PCR-RFLP method. The observed -1993 T/C genotypes of *TBX21* gene were in Hardy-Weinberg equilibrium (*P* > 0.05). There were no statistically significant

differences in age (*P* = 0.884) or gender distribution (*P* = 0.695) between patients and controls by the Mann-Whitney *U* test or Chi-square test (Table 1). The family cancer history in case group showed statistically significant difference from the control group (*P* = 0.002). The amounts of alcohol intake and tobacco smoking were similar between patients and controls.

### Association between *TBX21* -1993 polymorphism and gastric cancer

Under the subgroup analysis stratified by the confounding factors or as a whole group analysis in the gastric cancer cases, the association between the genotype frequencies of *TBX21* gene -1993T/C polymorphism and gastric cancer is shown in Tables 1 and 2. The distribution of the T allele at the -1993 loci was significantly different between the control and case groups (OR = 2.06, 95% CI: 1.44-2.96, Table 1). The -1993TC and -1993CC genotypes were associated with the risk of gastric cancer (OR = 1.84, 95% CI: 1.13-3.01; OR = 3.42, 95% CI: 1.41-8.31; respectively). When the data were stratified by gender, age, smoking or drinking status and the family history of cancer, the stronger association was revealed in the male patients aged less than 65 years with frequent smoking, especially in the patients who had family histories of cancer (OR = 3.99, 95% CI: 1.06-15.03, Table 2).

### Clinicopathological association between patients and *TBX21* -1993 polymorphism

The association between the clinicopathological characteristics of the gastric cancer and the genotype distributions is shown in Table 3. In the multivariate unconditional logistic regression analysis, the clinicopathological parameters did not show any significant relations to -1993TC genotype in age (*P* = 0.218), gender (*P* = 0.388), tumor size (*P* = 0.369), degree of differentiation (*P* =

CI: Confidence interval; OR: Odds ratio.

0.124), and the TNM stage ( $P = 0.370$ ). In contrast, the patients were dichotomized in TC + CC and TT genotypes, a significantly higher rate of pN<sub>1-3</sub>-category was detected in TC + CC allele carriers (38.03%). It showed that the -1993 SNP was significantly associated with the lymph node metastasis ( $P < 0.001$ , OR = 4.02, 95% CI: 1.87-8.66; Table 3). Moreover, the eventual statistical results revealed that the TC+CC genotype in gastric cancer patients was more closely associated with the tumor distant metastasis with respect to the frequency of wild genotype TT ( $P < 0.001$ , OR = 7.02, 95% CI: 3.44-14.34).

## DISCUSSION

In antitumor immunity, the local progression or distant

metastasis of primary tumors was extrinsically controlled by type 1 immune responses, particularly *via* the cytokine interferon (IFN)- $\gamma$  pathway<sup>[12-14]</sup>. The secretion of IFN- $\gamma$  was highly dependent on helper T cells, and then the helper T cell-dependent type 1 (IFN- $\gamma$ )-related responses promoted the tumor immunogenicity and inhibited the tumor cell progression. The transcription factor T-bet (*TBX21*; GenBank database accession number: AC003665) gene is a member of the T-box family, which is located on chromosome17q21.32, and plays a critical role in the development of type 1 helper T cells<sup>[15]</sup>. In the *T-bet* gene knockout mice, it exhibited a dramatic difference from the wild-type mice in the expression of IFN- $\gamma$ , TNF- $\alpha$ , IL-1 $\beta$ , IL-12, and IL-13<sup>[16,17]</sup>. The levels of these cytokines significantly decreased in T-bet knockout mice

compared with the wild-type mice. Because the infection of *H. pylori* is one of the major risk factors for gastric cancer, T-bet seemed to be important for *H. pylori*-induced gastric cancer in mice<sup>[18]</sup>. In mouse T-bet transgenic adenocarcinoma model, another study demonstrated that T-bet could affect the primary tumor incidence and lead to a moderate decrease in the rate of tumor progression. Meanwhile, T-bet not only possessed a moderate effect on the primary cancers but primarily exerted a significant suppressor capability in the metastasis of cancer<sup>[19]</sup>. These findings strongly supported that the T-bet regulation role in immune response was related to cancer risk and could account for a portion of this risk in cancer metastasis<sup>[20]</sup>.

This is the first epidemiologic study to evaluate the association between -1993 variant of *TBX21* gene and gastric cancer. A positive association was observed between -1993T/C and gastric cancer. When analyzed by genotypes, the CC genotype was strongly associated with the gastric cancer development after adjusting for potential confounders (OR = 3.42). When stratified by gender, age, smoking or drinking status, and the family history of cancer, the adjusted OR was 3.38 (95% CI: 1.31-8.71) for smokers and the adjusted OR was 3.99 (95% CI: 1.06-15.03) for the individuals with cancer family histories.

In our present experiment, when stratified by age and gender among gastric cancer patients, no positive association was found between the -1993 polymorphism and gastric cancer. Similarly, no clear difference was noticed between this polymorphic site and clinicopathological characteristics such as tumor size, degree of differentiation, and TNM stage status. Although no association was observed between -1993TC and the progression of gastric cancer, the invasive status of lymph node was related to the distant metastasis rate of tumor (OR = 4.02 and 7.02). The results revealed that the *TBX21* -1993T/C polymorphism played a crucial role in the process of gastric cancer metastasis. To our best knowledge, *TBX21* -1993T/C polymorphism has not been investigated in gastric cancer. However, the SNPs have often been observed to be amplified in virus infection<sup>[21-22]</sup>, systemic sclerosis<sup>[23]</sup>, asthma<sup>[24]</sup>, rheumatoid arthritis<sup>[25]</sup>, and systemic lupus erythematosus<sup>[26]</sup>, suggesting that our results are not by chance.

In summary, this population-based case-control study indicated that the host *TBX21* -1993T/C polymorphism was associated with an increased risk of gastric cancer, especially with the distant metastasis. The findings suggested that host *TBX21* -1993 polymorphism might be a potential marker to identify the individuals who were in the risk of gastric cancer, especially in China. Because of the limited sample size and single race for these genotypes, further replicated studies or pooled analyses are needed to confirm our results and the interaction study between the *H. pylori* infection and the genetic factors should be conducted as well.

## ACKNOWLEDGMENTS

We would like to thank Dr. Zi-Ping Chen and Dr. Kun Li

for their contributions to this study. We are also indebted to the participants in this study for their time and dedication.

## COMMENTS

### Background

*TBX21*, which played a critical role in modulating the development of naive T lymphocyte, has been thought to be a susceptibility gene in the progress of cancer. In this study, the authors investigated the association between the potentially functional polymorphism of *TBX21* gene and the risk of gastric cancer in the Chinese population.

### Research frontiers

Gastric cancer is the one of the most common cancers in the Chinese population, many studies have reported that the expression of *TBX21* gene is closely associated with the development of cancer through the Th1 and NK cells pathway. In this study the authors reported that the -1993 genetic polymorphism located in *TBX21* gene promoter region and assessed the potent susceptibility of this *TBX21* gene to gastric cancer in the Chinese population.

### Innovations and breakthroughs

This is one of the first studies of its kinds to investigate whether the host *TBX21* -1993T/C polymorphism was associated with an increased risk of gastric cancer, especially the distant metastasis. The findings suggested that host *TBX21* -1993 polymorphism might be a potential marker to identify the individuals who were at the risk of gastric cancer.

### Applications

This study provides the evidence of the association between gastric cancer and the -1993 polymorphism of *TBX21* gene. Because of the limited sample size and single race for these genotypes, further studies are needed to confirm the findings.

### Terminology

The *TBX21* gene (NCBI OMIM nos.\*604895), which encoded the transcription factor T-bet (T-box expressed in T cells), is a key transcriptional activator to induce the differentiation from helper T cells to Th1 cells. The gene polymorphism represents the different base substitution or replacement in the DNA sequence.

### Peer review

In the present study, the *TBX21*-1993 polymorphism was suggested to be associated with the risk of gastric cancer, in particular, the distant metastasis. The finding overall is interesting.

### Abstract

**AIM:** To investigate the value of interleukin-8 (IL-8), a pro-inflammatory chemokine, in predicting the prognosis of pancreatic cancer.

**METHODS:** Expression of IL-8 and its receptor CXCR1 was assessed by immunohistochemistry in pancreatic cancer and chronic pancreatitis samples. Enzyme-linked immunosorbent assay was used to detect the serum IL-8 levels in pancreatic cancer patients. Human pancreatic cancer tissues were heterotopically transplanted to the immune-deficiency mice to evaluate the effect of serum IL-8 on the tumorigenesis of the cancer samples.

**RESULTS:** IL-8 and CXCR1 proteins were both over-expressed in pancreatic adenocarcinoma samples (55.6% and 65.4%, respectively) compared with the matched para-cancer tissues (25.9% and 12.3%,  $P < 0.01$ ), or chronic pancreatitis (0% and 25%,  $P < 0.05$ ). Serum IL-8 levels in pancreatic cancer patients ( $271.1 \pm 187.7$  ng/mL) were higher than in other digestive system tumors, such as gastric cancer ( $41.77 \pm 9.11$  ng/mL,  $P = 0.025$ ), colorectal carcinoma ( $78.72 \pm 80.60$  ng/mL,  $P = 0.032$ ) and hepatocellular carcinoma ( $59.60 \pm 19.80$  ng/mL,  $P = 0.016$ ). *In vivo* tumorigenesis analysis further proved that tumor tissues from patients with higher serum IL-8 levels grew faster than those with lower IL-8 levels.

**CONCLUSION:** IL-8 can be a fine serum marker for predicting the prognosis pancreatic cancer.

### INTRODUCTION

Interleukin-8 (IL-8) is a pro-inflammatory factor, belonging to CXC chemokine family. It was initially named neutrophil-activating peptide-1 for its potent chemotactic activity on granulocytes in inflammatory and immune

diseases<sup>[1,2]</sup>. Recently, it has been shown that IL-8 plays a critical role in cancer invasion, angiogenesis and metastasis<sup>[3-6]</sup> and is considered as an important component of tumor microenvironment<sup>[7,8]</sup>. The significance of tumor microenvironment, which can be described as the “soil” of cancer cells, has been emphasized, especially the cancer-stroma interaction, which has become critical determinants of cancer behavior<sup>[9]</sup>. Stromal cells can produce IL-8 to influence the ability of invasion or metastasis of cancer cells, and the cancer cells themselves can also secrete IL-8 in an autocrine or paracrine manner, such as in breast cancer<sup>[10]</sup>, gastric cancer<sup>[4]</sup>, colon cancer<sup>[11]</sup>, cervical cancer<sup>[12]</sup>, pancreatic cancer<sup>[8,13]</sup> and leukemia<sup>[14,15]</sup>.

Pancreatic cancer is one of the most aggressive human malignancies and often with a dismal prognosis. The overall 5-year survival rate is only 5% or even less. Patients with pancreatic cancer have already been at advanced stage in their first visit to hospital. Around 15%-20% of the patients have the chance for tumor resection and the rest can only receive adjuvant therapies<sup>[16]</sup>. Although new drugs and techniques have been developed in treating pancreatic cancer, their therapeutic effects varied. Even the first-line anticancer drug, gemcitabine, still has not achieved satisfactory results in improving patients' outcome. The overall survival of pancreatic cancer patients is quite low, it is therefore, very important to predict the prognosis of the patients so as to enable more active treatment to prolong their lives.

Many studies<sup>[8]</sup> have revealed that pancreatic cancer highly produces IL-8, which can promote angiogenesis and invasion of tumors. Serum IL-8 levels were elevated in pancreatic cancer patients<sup>[17]</sup>, suggesting the feasibility of IL-8 to be a fine marker in predicting the outcome of the patients. The main aim of the present study is to investigate the prognostic value of IL-8 in pancreatic cancer patients. We examined the expression and secretion levels of IL-8 in both tumor tissue and human blood. Furthermore, we implanted the cancer tissues from patients with various serum IL-8 levels subcutaneously to the nude mice and observed the growth of each xenograft. Based on these *in vitro* and *in vivo* analyses, we aim to more precisely define the role of IL-8 in predicting the prognosis of pancreatic cancer patients.

## MATERIALS AND METHODS

### Sample collection

Eighty-one pancreatic ductal adenocarcinoma (PDC) specimens with matched para-cancerous pancreas were collected during resection in the surgically treated patients. Five cases of chronic pancreatitis (CP) served as controls. All patients with pancreatic cancer had been followed up for survival and outcome until October 2008. Except for four patients who were alive till the end of follow-up, the rest all died.

The clinical information of the patients is presented in Table 1. Besides the patients with PDC, patients with chronic and acute pancreatitis (AP) were also included.

**Table 1** Clinical data of patients subjected to enzyme-linked immunosorbent assay analysis for serum interleukin-8

Groups	Sex		Age (yr)	
	Male	Female	Range	Median
PDC	13	14	45-80	58
CP	13	2	9-58	40
AP	3	5	37-73	51
DA	3	5	47-65	58
GC	1	2	47-55	53
CRC	3	1	48-68	63
HCC	1	1	55-72	63.5

PDC: Pancreatic ductal carcinoma; CP: Chronic pancreatitis; AP: Acute pancreatitis; DA: Duodenal adenocarcinoma; GC: Gastric carcinoma; CRC: Colorectal carcinoma; HCC: Hepatocellular carcinoma.

**Table 2** Background information of cell lines for interleukin-8 detection

Cell lines	Cell origin	Number in cell line library
BxPC3	Primary adenocarcinoma	CRL-1687 (ATCC)
CFPAC-1	Liver metastasis from adenocarcinoma	CRL-1918 (ATCC)
SW1990	Spleen metastasis from adenocarcinoma	CRL-2172 (ATCC)
Patu 8988s	Liver metastasis from adenocarcinoma	ACC 204 (DSMZ)

ATCC: American Type Culture Collection; DSMZ: German Collection of Microorganisms and Cell Cultures.

Those with other carcinomas from gastrointestinal system such as stomach, large bowel and liver were also investigated as controls. Diagnosis for all these patients was pathologically confirmed by HE staining. Supernatant from four pancreatic cancer cell lines (BxPC3, SW1990, CFPAC-1 and Patu 8988s) was collected after the cells were cultured for 48 h. Detailed information of these cell lines is shown in Table 2.

### Ethics

This study was approved by the Ethics Committee of the Second Military Medical University (Shanghai, China). Informed consent was obtained from each patient before tissue specimen and blood samples were collected.

### Immunohistochemical analysis

Unstained 3- $\mu$ m sections were cut from the paraffin blocks and deparaffinized by routine procedures. Envision solution (K4065, DAKO, Denmark) was added to detect the primary antibody and 3,3'-diaminobenzidine was applied as chemicon. Sections were counterstained with hematoxylin. Primary antibodies against IL-8 (AHC0881) and CXCR1 (AHR1522Z) were purchased from BioSource (California, United States). In immunohistochemical (IHC) analysis, all the focal cases were considered negative and cases showing diffused expression were considered positive. Only the positive signals in epithelial cells were taken into account.

### Enzyme-linked immunosorbent assay

The concentration of serum IL-8 in the patients was determined quantitatively with human IL-8 enzyme-linked immunosorbent assay (ELISA) detection kit provided by BioSource following the manufacturer's instructions. The up-limit of the test was 500 ng/mL.

### Animal models and heterotopic implantation of human tumor tissues

Eleven severe combined immunodeficiency (SCID) nude mice aged 6-7 wk were housed under specific pathogen-free conditions. Animals were inoculated with subcutaneously (sc) transplanted fresh tissue cubes (1 mL) from pancreatic cancer patients with a detected serum IL-8 level. Animals were monitored daily by general clinical observation throughout the study period. Tumor volumes were calculated based on the following formula: tumor volume = (length × width<sup>2</sup>)/2. Animals were euthanized when their tumors reached an appropriate size (0.3 cm<sup>3</sup>) and the latent period was recorded. All experimental manipulations were undertaken in accordance with the NIH Guide for the Care and Use of Laboratory Animals, with the approval of the Biomedical Ethics Committee of the Second Military Medical University (Shanghai, China).

### Histological analysis of implanted tumor tissues

After implanted with human tumor tissues heterotopically, animals with growing tumor were sacrificed by craniocervical dislocation. The mice were then weighed, and the sc tumor tissues were excised. Part of the tumor tissues underwent routine histological examination and the rest was stored in liquid nitrogen for future use. Histology of the corresponding human tumor tissues was also reviewed.

### Statistical analysis

The IHC results were analyzed by  $\chi^2$  test. And the ELISA assay results were expressed as arithmetic mean ± SD. The comparisons between groups of patients were made using analysis of variance, and Fisher's Least Significant Difference test was used for animal models. The difference was considered significant at  $P < 0.05$ . SPSS 10.0 was applied as a statistical tool. Survival rates were calculated by the Kaplan-Meier method.

## RESULTS

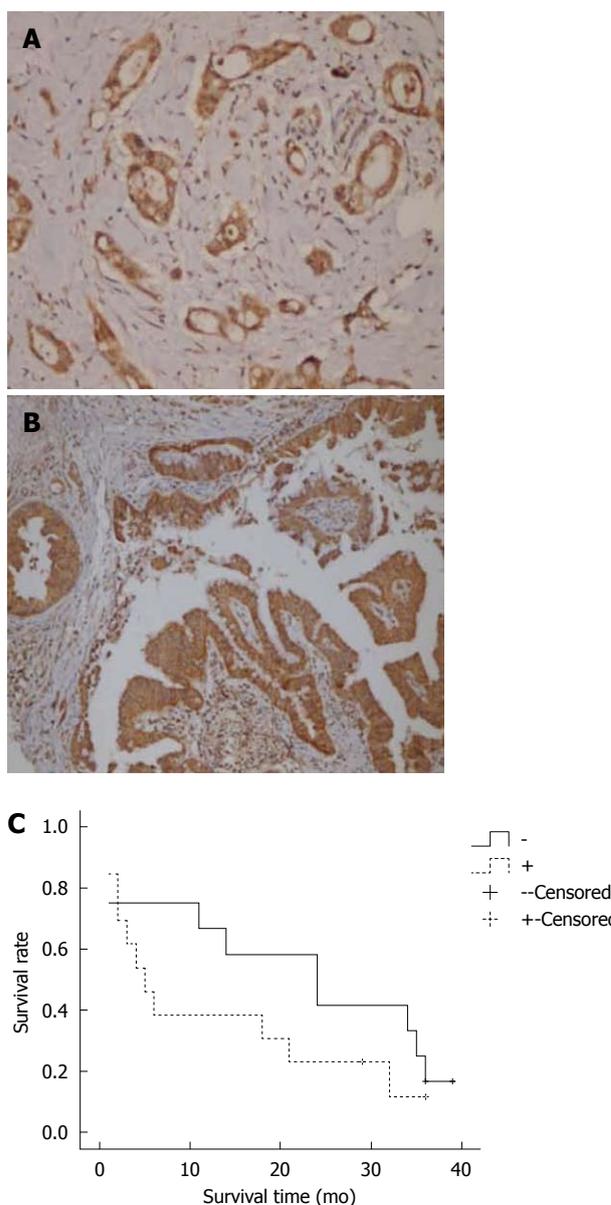

### IL-8 and CXCR1 expression in PDC

IL-8 was expressed in 55.6% (45/81) of pancreatic cancer specimens, whereas in 25.9% (21/81) of non-cancer tissues ( $P < 0.01$ ,  $\chi^2 = 14.727$ ) (Table 3). IL-8 immunoreactivity was absent in CP (0%, 0/5) ( $P = 0.016$ ,  $\chi^2 = 5.827$ ) (Table 3). The positive signal was localized in the cytoplasm of cancerous or normal ductal cells (Figure 1). Focal stromal cells could express both IL-8 and CXCR1. The relationship between the expression of IL-8 or CXCR1 and the histological grading of pancreatic cancer is shown in Table 3. The CXCR1 expression level was significantly higher in pancreatic cancer samples (65.4%,

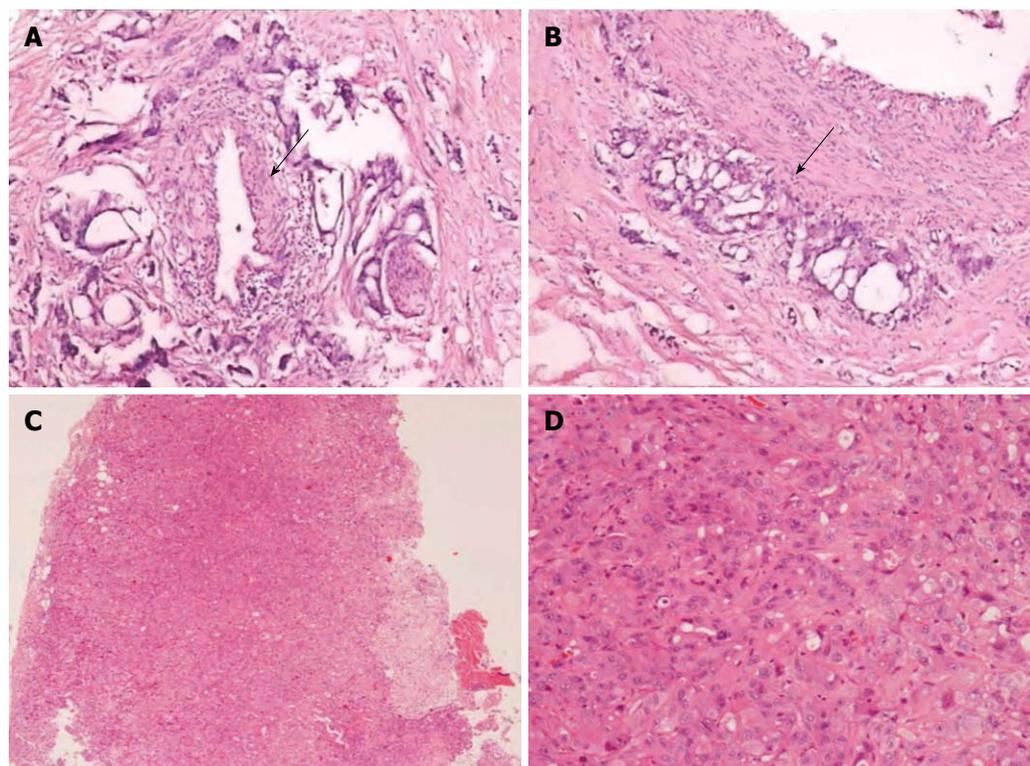

**Table 3** Interleukin-8 and CXCR1 expression in pancreatic cancer, matched para-cancer tissue and chronic pancreatitis

	Pancreatic cancer differentiation			Matched para-cancer tissue	Chronic pancreatitis
	Well	Moderate	Poor		
IL-8					
+	5	33	7	21	0
-	11	22	3	60	5
CXCR1					
+	10	35	8	10	1
-	6	20	2	71	4

IL-8: Interleukin-8.

**Figure 1** Interleukin-8 and CXCR1 expression in pancreatic cancer. A: Interleukin-8 (IL-8) expression in pancreatic cancer (× 200); B: CXCR1 expression in pancreatic cancer (× 200); The positive signals of IL-8 and CXCR1 were mainly located in the cytoplasm of cancer cells. For IL-8, focal positivity was found in the fibroblasts; C: Survival analysis of pancreatic cancer patients. "Censored" means patients were still alive till the end of follow-up study. The patients without IL-8 expression survived longer than those IL-8 positive.

**Figure 2** Histology of human pancreatic cancer tissue and transplanted tumor in SCID mice. A: Both vascular (arrow) and neural invasion (cross) were seen in the original human pancreatic ductal adenocarcinoma (PDC) ( $\times 100$ ); B: Cancer cells were infiltrating the medium-sized vessel in human PDC tissues ( $\times 100$ ) (arrow). Desmoplastic response was obvious in the human PDC tissues; C, D: Transplanted cancer tissue in SCID mice in low power (C,  $\times 40$ ) and in high power (D,  $\times 200$ ). Cancer cells were almost clustered and poorly differentiated. In some areas, primitive gland formation could be seen (arrow). Cells grew into sheet with very less stromal reaction than the original human tissues.

**Table 4** Interleukin-8 concentration in the supernatant of pancreatic cancer cell lines

Cell line	IL-8 concentration (ng/mL)
BxPC3	81.38
CFPAC-1	3.906
SW1990	> 500
Patu 8988s	498.9

SW1990 and Patu8988 originated from metastatic sites showed much higher levels of interleukin-8 (IL-8) than BxPC3 and CFPAC-1.

53/81) than in samples from the adjacent non-cancerous pancreas (12.3%, 10/81) ( $P < 0.001$ ,  $\chi^2 = 48.026$ ). No statistical difference was observed between histological grading and IL-8 or CXCR1 expression.

Overall survival analysis was performed in the patients. Most people died within 3 years after surgery and only four were alive till the end of follow-up. The median survival was 5 mo (range, 1-36 mo) in the IL-8 positive group and 24 mo (range, 1-39 mo) in the IL-8 negative group. Although IL-8 positive patients seemed to live shorter than IL-8 negative ones, no significant difference was observed by Kaplan-Meier method ( $P = 0.245$ ).

#### Serum IL-8 levels in pancreatic cancer patients and pancreatic cancer cell lines

Serum IL-8 level was measured in patients with PDC ( $n$

= 27), AP ( $n = 8$ ), CP ( $n = 15$ ) and other kinds of cancer from digestive system, such as duodenal adenocarcinoma (DA,  $n = 4$ ), gastric carcinoma (GC,  $n = 3$ ), rectal colonic carcinoma (CRC,  $n = 4$ ), and hepatocellular carcinoma (HCC,  $n = 2$ ). Blood was collected before surgery in the cancer patients. The serum IL-8 levels were significantly higher in PDC ( $271.1 \pm 187.7$  ng/mL) than in CP ( $97.02 \pm 130$  ng/mL,  $P = 0.002$ ), AP ( $133.6 \pm 162.9$  ng/mL,  $P = 0.041$ ), GC ( $41.77 \pm 9.11$  ng/mL,  $P = 0.025$ ), CRC ( $78.72 \pm 80.6$  ng/mL,  $P = 0.032$ ) or HCC ( $59.6 \pm 19.8$  ng/mL,  $P = 0.016$ ). No significant difference was observed between PDC and DA ( $168.7 \pm 212.4$  ng/mL,  $P = 0.247$ ). Two cancer cell lines originated from metastatic site (SW1990 and Patu 8988s) showed a much high level of IL-8 secretion (Table 4).

#### Histology of human tumor tissues implanted into SCID mice

Tumors subcutaneously implanted into the SCID mice were mostly composed of strands of cells, and glandular architectures were not very obvious (Figure 2). Intracellular vacuoles could be observed in some regions as immature or primary glands, indicating their adeno-epithelial origin. Unlike cancers growing in human pancreas, the desmoplastic reaction was not so remarkable and only several fibroblastoid spindle cells appeared in the implanted cancer tissues. Nerve and vessel invasion by can-

cer cells was easily observed in human cancer tissues, but none was detected in transplanted cancer tissues.

### ***In vivo* growth of heterotopically transplanted tumor tissues and its correlation with serum IL-8 levels**

Among all the 11 cases of human tumor tissues implanted into SCID mice, seven tumors grew subcutaneously in animals. We set the terminal goal of growth at 0.3 cm<sup>3</sup> and recorded the latent period. The slowest growing period was 93 d and the fastest was 44 d. Seven animals with tumors were divided into three groups based on the median latent period of 61 d for analysis: group 1, failed to form tumor,  $n = 4$ ; group 2, latent period < 61 d,  $n = 3$ ; and group 3, latent period  $\geq 61$  d,  $n = 4$ . Serum IL-8 level in group 2 ( $140.1 \pm 33.4$  ng/mL) was much higher than in group 1 ( $23.4 \pm 17.4$  ng/mL) and group 3 ( $23.2 \pm 16.1$  ng/mL) ( $P < 0.001$ ). There was no significant difference between group 1 and group 3 ( $P = 0.998$ ).

## **DISCUSSION**

In this study, the expression level of IL-8 and its receptor CXCR1 was elevated in pancreatic cancer and serum IL-8 level was significantly higher in patients with pancreatic cancer than in those with pancreatitis and also higher than in the patients with other kinds of tumors from digestive system. *In vivo* tumor tissues from pancreatic cancer patients with a higher serum IL-8 level grew faster and behaved more aggressively than those with low serum IL-8 levels. Follow-up data showed that patients with high serum IL-8 levels had a relatively lower survival than those with low serum IL-8 levels. Due to the insufficient number of patients involved in the follow-up analysis, no statistical difference was achieved in the two groups.

IL-8 is a member of the CXC chemokine family and is a chemotactic factor for T cells, neutrophils, and basophils. Besides its pro-inflammatory role, IL-8 has been evaluated as a pro-oncogenic effector in various types of human cancers, including leukemia, astrocytoma, melanoma, breast cancer, ovarian cancer, lung cancer, prostate cancer, colon cancer, renal cell carcinoma, gastric cancer and pancreatic cancer<sup>[18]</sup>. The most critical effect of IL-8 on cancer cells is its strong angiogenic potential and ability of promoting invasion and metastasis<sup>[19-21]</sup>. *In vitro* IL-8 can enhance the proliferation and survival of endothelial cells and through its receptor CXCR1 can upregulate the expression of matrix protein, MMP-2 and MMP-9<sup>[22]</sup>. IL-8 can mimic the role of vascular endothelial growth factor (VEGF), transactivate VEGFR2 and promote angiogenesis<sup>[23]</sup>. Various signals or pathways can induce IL-8 expression in cancers<sup>[24-26]</sup> and the whole IL-8-involved network is very complicated. It has been confirmed that nuclear factors, NF- $\kappa$ B and AP-1 are the upstream regulators of transcription of IL-8 mRNA, both of which may cooperate with each other in the production of IL-8. In our study, a higher expression level of IL-8 and CXCR1 was detected in pancreatic cancer tissues than in para-cancerous pancreas. Although IL-8 could be el-

evated in colon and gastric cancers, the serum IL-8 level in pancreatic cancer was remarkably higher than in colon and gastric cancers. Moreover, IL-8 level was even higher in acute pancreatitis, in which IL-8 is considered to be a reliable indicator in evaluating the severity of inflammation and necrosis<sup>[27]</sup>. These data suggest that pancreatic cancer cells have a higher capability to produce chemokines than inflammatory cells, and function in an autocrine manner, which fulfills the composition of tumor microenvironment.

We have no direct experimental information on which cells are responsible for the secretion of IL-8, but according to the IHC analysis, IL-8 expression occurred mostly inside cancer cells, indicating that they might be the main source of IL-8. Pancreatic cancer cell lines have been investigated for IL-8 secretion and its mRNA expression, and quite a number of these cell lines showed high levels of IL-8 in the supernatant and mRNA expression<sup>[28]</sup>. We also analyzed IL-8 levels in the cultured supernatant of four pancreatic cancer cell lines, and found that those cell lines originated from the primary tumor site produced less IL-8 than those selected from metastatic site. Nomura *et al.*<sup>[29]</sup> demonstrated similar results using two sublines of pancreatic cancer, both of which were sequentially selected from the parental cell line and possessed a high potential of organ metastasis, and the high IL-8 expression was closely correlated with the aggressive behavior of cancer cells. Besides cancer cells, inflammatory cells in the tumor stroma is also one of the important sources of IL-8 secretion. Neutrophils can not only promote tumor destruction<sup>[30]</sup>, but also increase the growth of tumor cells<sup>[31]</sup>. Neutrophil-dependent release of VEGF-A leads to subsequent recruitment of neutrophils, resulting in angiogenesis.

Our survival analysis showed that IL-8 positive pancreatic cancer patients had a lower survival than IL-8 negative ones, whereas no significant difference was observed between the two groups possibly due to the insufficient number of cases involved. *In vivo* preclinical experiments of animal models on IL-8 have been conducted by many labs using various tumor cell lines, such as prostate cancer, lung cancer, breast cancer and pancreatic cancer<sup>[18]</sup>. In these cell lines, a high level of IL-8 is directly correlated with tumor growth, angiogenesis and metastasis in nude mice. But in ovarian cancer, IL-8 was negatively involved during tumorigenesis in animal models. Lee *et al.*<sup>[30]</sup> demonstrated that the inverse regulation of IL-8 on xenograft growth was mainly mediated by its induction of neutrophil infiltration. In our animal model, we for the first time used the clinically resected pancreatic cancer tissues and transplanted them sc into SCID mice. The infiltration of inflammatory cells was not as evident as that observed by Lee *et al.*<sup>[30]</sup> in ovarian cancer. The growth rate of tumors was significantly correlated with the serum level of IL-8 of the corresponding patients. The higher serum IL-8 level in the patients, the faster the tumor grew, indicating the more aggressive phenotype of this tumor, the poorer prognosis of the patients. IL-8

level can be measured in the tumor tissues resected surgically and in the patients' sera, it can also be detected in other kinds of clinical samples, including pancreatic juice obtained from the duodenum. Moreover, IL-8 concentration in pancreatic juice could be used to discriminate between normal pancreas and pancreatic cancer<sup>[32]</sup>.

In summary, IL-8 was highly expressed in pancreatic cancer in both tumor tissues and blood samples. *In vivo* analysis showed that IL-8 would be a sensitive marker in predicting prognosis and monitoring disease progression of the pancreatic cancer patients. The patients with high serum levels of IL-8 should receive more active treatment due to the more aggressive biology of their cancer. Besides its prognostic value, IL-8 may represent a promising target for the development of adjuvant therapy for pancreatic cancer.

## COMMENTS

### Background

Many studies have revealed that pancreatic cancer highly produces IL-8 and IL-8 can promote angiogenesis and invasion of tumors. Serum IL-8 level was elevated in pancreatic cancer patients, suggesting the feasibility of IL-8 to be a fine marker in predicting outcomes of pancreatic cancer patients.

### Research frontiers

The present study is to confirm the prognostic value of IL-8 in pancreatic cancer patients. The authors examined the expression and secretion levels in tumor tissues and human blood, respectively. Cancer tissues from patients with various serum IL-8 levels were implanted subcutaneously into nude mice to observe the growth of each xenograft.

### Innovations and breakthroughs

ELISA was used to detect the serum IL-8 levels in pancreatic cancer patients. Human pancreatic cancer tissues were transplanted heterotopically into immune-deficiency mice to evaluate the effect of serum IL-8 on the tumorigenesis of cancer samples. Besides its prognostic value, IL-8 may represent a promising target for the development of adjuvant therapy for pancreatic cancer.

### Peer review

This issue is of great interest and is definitely offering the opportunity to more accurately predict prognosis of patients affected by pancreatic carcinoma and to monitor the disease progression.

### Abstract

**AIM:** To evaluate the feasibility of quantifying liver choline concentrations in both normal and apoptotic rabbit livers *in vivo*, using  $^1\text{H}$  magnetic resonance spectroscopy ( $^1\text{H}$ -MRS).

**METHODS:**  $^1\text{H}$ -MRS was performed in 18 rabbits using a 1.5T GE MR system with an eight-channel head/neck receiving coil. Fifteen rabbits were injected with sodium selenite at a dose of 10  $\mu\text{mol}/\text{kg}$  to induce the liver cell apoptosis. Point-resolved spectroscopy sequence-localized spectra were obtained from 10 livers once before and once 24 h after sodium selenite injection *in*

*vivo*. T1 and T2 relaxation time of water and choline was measured separately in the livers of three healthy rabbits and three selenite-treated rabbits. Hematoxylin and eosin and dUTP-biotin nick end labeling (TUNEL) staining was used to detect and confirm apoptosis. Choline peak areas were measured relative to unsuppressed water using LCModel. Relaxation attenuation was corrected using the average of T1 and T2 relaxation time. The choline concentration was quantified using a formula, which was tested by a phantom with a known concentration.

**RESULTS:** Apoptosis of hepatic cells was confirmed by TUNEL assay. In phantom experiment, the choline concentration (3.01 mmol/L), measured by  $^1\text{H}$ -MRS, was in good agreement with the actual concentration (3 mmol/L). The average T1 and T2 relaxation time of choline was  $612 \pm 15$  ms and  $74 \pm 4$  ms in the control group and  $670 \pm 27$  ms and  $78 \pm 5$  ms in apoptotic livers *in vivo*, respectively. Choline was quantified in 10 rabbits, once before and once after the injection with sodium selenite. The choline concentration decreased from  $14.5 \pm 7.57$  mmol/L before sodium selenite injection to  $10.8 \pm 6.58$  mmol/L (mean  $\pm$  SD,  $n = 10$ ) after treatment ( $Z = -2.395$ ,  $P < 0.05$ , two-sample paired Wilcoxon test).

**CONCLUSION:**  $^1\text{H}$ -MRS can be used to quantify liver choline *in vivo* using unsuppressed water as an internal reference. Decreased liver choline concentrations are found in sodium selenite-treated rabbits undergoing liver cell apoptosis.

Shen ZW, Cao Z, You KZ, Yang ZX, Xiao YY, Cheng XF, Chen YW, Wu RH. Quantification of choline concentration following liver cell apoptosis using <sup>1</sup>H magnetic resonance spectroscopy. *World J Gastroenterol* 2012; 18(10): 1130-1136 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i10/1130.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i10.1130>

## INTRODUCTION

Cell apoptosis is a form of programmed cell death. Compared with necrosis, cell apoptosis does not damage the neighboring cells. Primary tumors are thought to be a result of inadequate apoptosis<sup>[1]</sup>. Through detecting apoptosis, the progression of a tumor can be evaluated and drug effects can be determined so as to adopt appropriate therapies<sup>[2]</sup>. It is, therefore, essential to develop a non-invasive method that can be used to assess apoptosis of tissues *in vivo*.

Proton magnetic resonance spectroscopy (<sup>1</sup>H-MRS) is a powerful tool which can be used for non-invasive measurement of compounds *in vivo*. Several previous studies<sup>[3-6]</sup>, evaluated the role of <sup>1</sup>H-MRS in characterization of apoptosis with lipid signals. The most important non-lipid signals are from the choline-containing compounds at 3.2 ppm. However, changes in these signals were not universal, at least in the early stages of apoptosis<sup>[7]</sup>. One of our previous studies, using *in vitro* 9.4T high resolution magnetic resonance spectroscopy, has shown decreased total choline compounds and free choline in the rat apoptotic liver tissues as compared with the healthy rats<sup>[8]</sup>.

The liver is a particularly suitable and interesting organ for metabolic studies using *in vivo* magnetic resonance spectroscopy due to its rich metabolic activities and location at the body surface<sup>[9]</sup>. However, difficulties in measurement may mostly come from respiratory movement, which leads to limited spectral resolution, especially in the clinical environment. Several previous *in vivo* studies<sup>[10,11]</sup> focused on choline-to-lipid ratios in liver tumors. These studies have shown increased choline-to-lipid ratios with the progression of hepatocarcinogenesis<sup>[10]</sup>, and decreased choline-to-lipid ratios after treatment<sup>[11]</sup>. However, quantitative results are more suitable for horizontal and vertical comparison. Two preliminary reports<sup>[12,13]</sup> have quantified the choline concentrations in human hepatic tumors using separate reference standards of an external phantom and internal water signal. Tissue water reference method has been used for quantification of the choline level in <sup>1</sup>H-MR spectra of brain<sup>[14]</sup>, breast, muscle<sup>[15]</sup>, and ovary<sup>[16]</sup>, and is considered as a simple and practical approach in the clinical environment. Fischbach *et al*<sup>[17]</sup> applied LCMoDel to quantify choline relative to water, although the relaxation attenuation was not corrected. Accurate quantification requires correction for the relaxation attenuation, especially for point-resolved spectroscopy sequence (PRESS) sequence<sup>[18,19]</sup>.

The aim of this study was to use an *in vivo* rabbit model (1) to evaluate the feasibility of quantifying choline

concentrations of healthy and apoptotic livers with *in vivo* <sup>1</sup>H-MRS using the unsuppressed water signal as the internal reference, and to correct the relaxation attenuation, and (2) to compare the observed changes of choline with our previous *in vitro* results.

## MATERIALS AND METHODS

### Ethics

This study was approved ethically by the Animal Ethics Committee of Shantou University Medical College.

### Phantom and animal

A standard spectroscopy phantom provided by GE Medical Systems (25-cm-diameter MRS HD sphere; General Electric Company) was used. The metabolites in the phantom are 3.0 mmol/L choline chloride, 10.0 mmol/L creatine hydrate, 12.5 mmol/L N-acetylaspartic acid, 7.5 mmol/L myo-inositol, 12.5 mmol/L L-Glutamic acid and 5 mmol/L lactate, containing 0.1% sodium azide, 0.1% Magnavis, 50 mmol/L potassium dihydrogen phosphate and 56 mmol/L sodium hydroxide. This phantom was used in previous studies in the brain<sup>[20]</sup> and liver<sup>[13]</sup> as the quantification standard.

New Zealand white rabbits ( $n = 18$ ) weighing  $1.9 \pm 0.3$  kg were used in this study. In the control group, rabbits ( $n = 3$ ) were injected with saline and were sacrificed for the liver histological analysis after the <sup>1</sup>H-MRS measurement. In the experimental group, the rabbits ( $n = 15$ ) were injected with sodium selenite at a dose of 10  $\mu$ mol/kg. Spectra were obtained once before and once 24 h after sodium selenite injection, and the rabbits were sacrificed after MRS. Prior to the MRS, rabbits were fasted for six hours and anesthetized with 1 mL/kg sodium pentobarbital through ear vein injection. Shen *et al*<sup>[21]</sup> observed that Se was able to induce apoptosis in *in vitro* HepG2 cells and found that selenite-induced apoptosis was both time- and dose-dependent<sup>[22]</sup>. The duration and dose of sodium selenite were determined according to their studies. All the rabbits were supplied from the Laboratory Animal Center of Shantou University Medical College.

### Magnetic resonance imaging and MRS

All studies were performed on a 1.5-T HDxt MR scanner (Signa Systems, GE Healthcare) using an eight-channel head/neck receiving coil. At first, the phantom was used for the regular system stability check and served as a test to confirm the quantification strategy *in vivo*. For the phantom measurement, magnetic resonance imaging (MRI) consisted of axial and coronal localizer sequences for positioning the single voxel (20 mm  $\times$  20 mm  $\times$  20 mm) within the phantom solution. For *in vivo* measurement, rabbits were placed in the prone position and the liver region was situated in the center of the coil. The abdomen was immobilized with cushions to reduce respiratory movement. MRI consisted of images followed by the Propeller fast spin echo T2-weight sequence (TE/TR: 110 ms/6000 ms; field of view: 20 cm  $\times$  20 cm; slice thickness: 4 mm; slice space: 0.5 mm) to define the

position of volume of interest (VOI).

Proton MRS was performed using a PRESS (TE/TR: 35 ms/1500 ms; total scan number: 128; VOI: 15 mm × 15 mm × 15 mm). Water suppression was obtained with chemical shift selective saturation. The volume saturation suppression (VSS) pulse was oblique and placed on the edge of the voxel for shimming and reducing motion artifact. T1 and T2 relaxation time of choline and water was separately measured in the phantom, three rabbits in the control group, and three selenite-injected rabbits. For T1 measurement, the TE was kept constant at 35 ms and the TR varied from 1130 ms to 3000 ms for five measurements. For T2 measurement, the TR was kept constant at 1500 ms and the TE varied from 30 ms to 135 ms for five measurements.

### Data analysis

The raw spectral data were input into a SAGE software package (GE Healthcare). The peak amplitudes of the unsuppressed water signal at 4.7 ppm and choline compound signals at 3.2 ppm were measured with SAGE. The T2 relaxation time of MR-visible water and choline was measured in SAGE using the macro T2 fit. T1 time was obtained by fitting the data to a mono-exponential model as a function of TR, and TE to a mono-exponential model with an in-house program. The average T1 and T2 values for Cho and water were used for correcting the relaxation attenuation with the following equation.

Choline was quantified using commercially available LCModel (version 6.2-2B) software, according to Dr. Provencher<sup>[17]</sup>, which is suitable for fitting the spectra collected by PRESS sequence (TE = 35 ms) in a GE 1.5T scanner. The mode of only-choline-2 was selected for phantom analysis. Using the prior knowledge incorporated into the spectral fitting, phase and baseline correction were automatically processed with LCModel. The control parameters were adjusted according to the LCModel manual.

Spectra were discarded if the reported signal-to-noise ratio (SNR) from LCModel was less than 15, or if the SD of choline was more than 20%. The ratio of the choline resonance area to the unsuppressed water resonance area was acquired. These ratios were converted to approximate mmol/L units by setting the concentration of water in the phantom as 55 556 mmol/L according to the manual. This ratio was measured *in vivo* using the analysis mode of liver-6. The water concentration was assumed to be 47 778 mmol/L for an 86% water content of the liver. The absolute concentration of choline was measured by the following formula modified from the reference<sup>[15]</sup>.

$$[Cho] = A_{Cho/H_2O} \times \frac{n_{H_2O}}{n_{Cho}} \times \frac{fT1(H_2O)}{fT1(Cho)} \times \frac{fT2(H_2O)}{fT2(Cho)} \times CF_{Lipid}$$

Where  $A_{Cho/H_2O}$  = the area ratio of choline to unsuppressed water,  $n_{H_2O} = 2$ ,  $n_{Cho} = 9$  (from three CH<sub>3</sub> groups),  $fT1 = 1 - \exp(-TR/T1)$ , and  $fT2 = \exp(-TE/T2)$ .  $CF_{Lipid}$  represents a correction factor that is equivalent to  $A_{H_2O}/(A_{H_2O} + A_{Lipid})$  measured from the non-suppressed water.

### Histopathology

All animals were sacrificed under anesthesia after the

MRS. Livers were removed and washed with physiological saline. Macroscopic examination followed by visual inspection was performed, and representative sections were taken. Formalin fixed samples were embedded in paraffin and 2-mm thin sections were cut. Samples were stained with hematoxylin and eosin and examined under light microscopy to identify apoptotic characteristics of vacuolated hepatocytes and the degree of lipid deposition in the parenchyma.

Shen *et al.*<sup>[21]</sup> found that selenite-induced apoptosis could be evaluated by dUTP nick end labeling (TUNEL) assay and *in vitro* HepG2 cell morphological changes. The apoptotic cells were observed and analyzed in this study according to the reported methods. After the homogenized liver tissue was filtered through a 40 μm cell strainer, the cells were washed with PBS and then were centrifuged at 1500 r/min for 5 min to remove cell debris. After this procedure was repeated three times, the cells were fixed with 4% paraformaldehyde for 30 min. Apoptotic cells were stained with transferase-mediated TUNEL using a One Step TUNEL Apoptosis Assay Kit (Beyotime, China). The TUNEL reaction took place with the addition of reaction mixture (containing nucleotides and TdT enzyme), which was incubated for 60 min at 37 °C in the dark. After wash with phosphate buffer solution (PBS), cells were finally resuspended in PBS for flow cytometry analysis (XL MCL, Beckman Coulter, United States). The data obtained from flow cytometry were analyzed using Expo32 ADC Analysis software for calculating the percentage of apoptotic cells in each group.

### Statistical analysis

All data were presented as a mean ± SD. Statistical significance was calculated using two-sample relative Wilcoxon test and was accepted at  $P \leq 0.05$ . The relationship between the percentage of apoptotic cells and choline concentration was investigated using the linear regression analysis. All analyses were performed using SPSS version 13.0 (SPSS Inc, United States).

## RESULTS

### Phantom studies

T1 and T2 relaxation time of choline was 1129 ms and 236 ms, respectively, while T1 and T2 relaxation time of water was 3172 ms and 206 ms. The fitted data was acceptable for the low SD of choline (9%). The calculated choline concentration was 3.01 mmol/L, which was in agreement with the known choline concentration in the phantom (3 mmol/L).

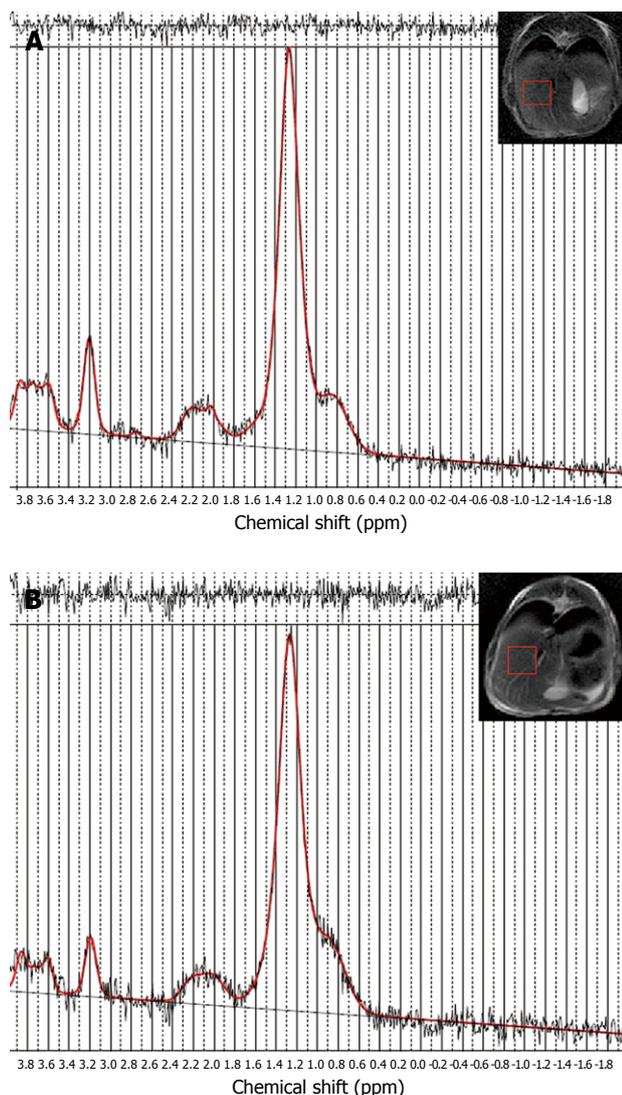

### In vivo studies

Choline spectra were obtained from all rabbits in the control group and 10/14 selenite-treated rabbits. Among the four failures in experimental group, one rabbit died during the model-making process, two failed in MRS after injection of sodium selenite due to prescan failure, and one spectrum was rejected after the injection of so-

**Table 1** Summary of data quality related parameters ( $n = 10$ , mean  $\pm$  SD)

	SD of choline (%)	SNR of spectra	FWHM (Hz)	WS (%)
Before injection	8.5 $\pm$ 4.1	46.4 $\pm$ 19.4	12.6 $\pm$ 2.0	94.3 $\pm$ 2.8
After injection	10.5 $\pm$ 4.6	26.9 $\pm$ 14.3	11.8 $\pm$ 7.0	95.4 $\pm$ 2.5

Standard deviation (SD) of choline and signal-to-noise ratio (SNR) of spectra were produced by LCMoel. Full-width at half-maximum (FWHM) and water suppression (WS) was provided by the magnetic resonance machine.

**Figure 1** LCMoel output of point-resolved spectroscopy-localized single-voxel  $^1\text{H}$  magnetic resonance spectra from the liver of one rabbit before (A) and after injection of sodium selenite (B). The locations of the spectroscopic volume of interest are indicated by the squares in the Propeller FSE T2W image. The decreased choline-to-water area was observed.

dium selenite with a full-width at half-maximum (FWHM)  $> 20$  and there was no metabolite resonance peak within a range from 0 ppm to 4.0 ppm. One spectrum of liver cell apoptosis induced by sodium selenite was excluded due to a higher choline SD ( $> 20\%$ ). The spectra from ten rabbits before and after the injection with sodium selenite were finally adopted (Table 1).

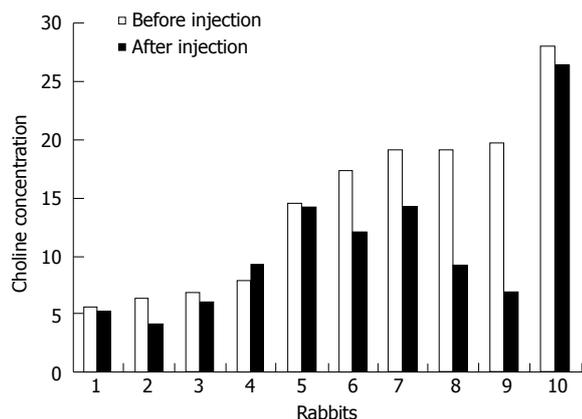

**Figure 2**  $^1\text{H}$  magnetic resonance spectra from a rabbit liver before (green line) and after injection of sodium selenite (black line). The decreased choline peak was observed at 3.2 ppm. However, the choline peak from the liver after injection of sodium selenite was too weak, with a choline SD  $> 20\%$ .

The average T1 and T2 relaxation time of choline was  $612 \pm 15$  ms and  $74 \pm 4$  ms in the control group ( $n = 3$ ) and  $670 \pm 27$  ms and  $78 \pm 5$  ms in apoptotic livers ( $n = 3$ ). The average T1 and T2 relaxation time of water was  $653 \pm 23$  ms and  $48 \pm 3$  ms in the control group ( $n = 3$ ), and  $719 \pm 37$  and  $50 \pm 5$  ms in apoptotic livers ( $n = 3$ ).

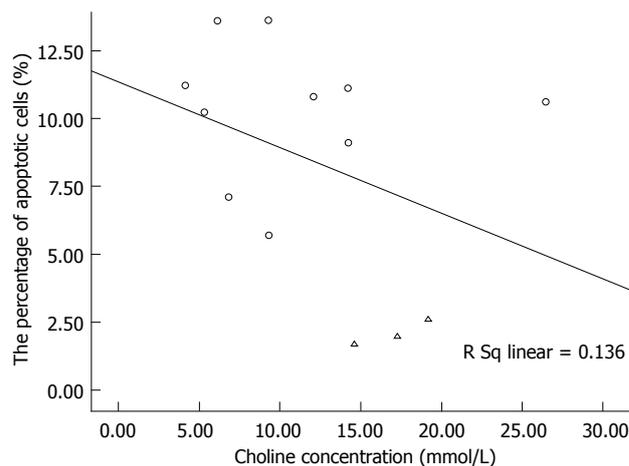

PRESS-localized single-voxel  $^1\text{H}$ -MR spectra from the liver of one rabbit before and after injection of sodium selenite can be well fitted using LCMoel (Figure 1). A decreased choline peak was observed at 3.2 ppm (Figure 2). The calculated average T1 and T2 relaxation time of choline and water in both normal and apoptotic livers were used to calculate the choline concentrations. Decreased choline concentrations ranged from  $14.5 \pm 7.6$  mmol/L ( $n = 10$ ) before injection of sodium selenite to  $10.8 \pm 6.6$  mmol/L ( $n = 10$ ) 24 h after that treatment ( $Z = -2.395$ ,  $P < 0.05$ , two-sample relative Wilcoxon test), although increased choline was also found in one rabbit (Figure 3). The calculated concentrations of choline varied from 5.5 mmol/L to 28.1 mmol/L in normal liver and 4.1 mmol/L to 26.4 mmol/L in apoptotic liver after injection of sodium selenite.

### Histopathology

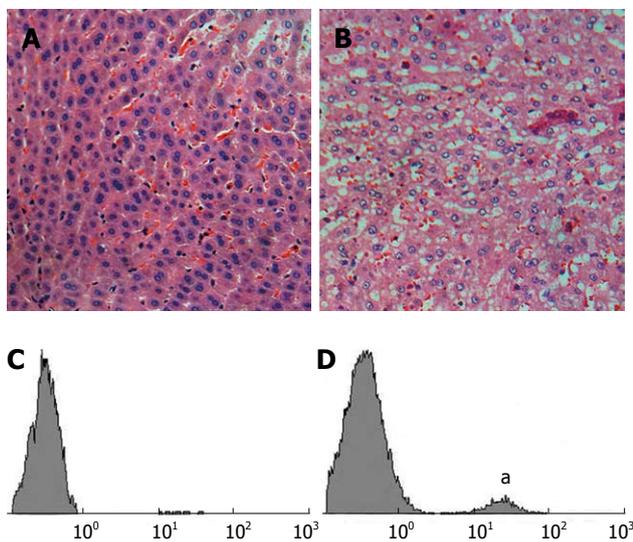

Histological differences between two groups were observed by hematoxylin and eosin staining. Normal liver had no observable effects on the microscopic distribution of vacuolated hepatocytes in liver tissues (Figure 4A and B). Apoptosis of hepatic cells in both groups was confirmed by TUNEL assay and the increased ratio of apoptotic to normal cells was detected by flow cytometry (Figure 4C and D). The average ratio was  $2.1\% \pm 0.5\%$  ( $n = 3$ ) *vs*  $10.3\% \pm 7.6\%$  ( $n = 10$ ), respectively. However, the linear regression analysis revealed no significant linear relationship between choline concentration and the

**Figure 3** Barplot shows the choline concentration of livers from 10 rabbits before and after injection of sodium selenite. The two-sample Wilcoxon test revealed significant differences between the groups ( $Z = -2.395, P < 0.05$ ).

**Figure 5** Scatter diagram shows the correlation between the percentage of apoptotic cells and choline concentration in the control group ( $\Delta$ ) and the experiment group after injection of sodium selenite ( $\circ$ ). The linear regression analysis revealed no significant linear relationship between variables ( $R = 0.369, F = 1.734, P > 0.05$ ).

**Figure 4** Light microscopy of representative hematoxylin and eosin stained histological sections of liver (A and B, x 200) and flow cytometry of liver apoptotic cells stained by dUTP-biotin nick end labeling assay (C and D). A, C: Normal rabbits; B, D: Rabbits injected with sodium. The elevated apoptotic cell peak labeled by A was observed.

percentage of apoptotic cells ( $R = 0.369, F = 1.734, P > 0.05$ ) (Figure 5).

## DISCUSSION

Noninvasive quantitative measurement of choline by proton MRS is important for the assessment of tumor characterization, grading, and post-treatment evaluation. The data in this study showed the feasibility of measuring choline concentration in rabbit liver *in vivo* using 1.5T MR by appropriate acquisition and quantification methods.

Choline spectra were obtained from three healthy rabbits and 10/14 selenite-treated rabbits. Phase and frequency shifts were found in some liver spectral frames. We deduced that this may be due to respiratory motion, which could also lead to inhomogeneous B0 and B1 fields and result in broadening of the spectral resonanc-

es. According to the data quality, the FWHM and water suppression of spectra in selenite-treated rabbits were better than those in normal rabbits due to decreased SNR and SD of choline. The possible reason is that rabbits injected with sodium selenite were quieter and therefore had reduced movement of the tissue. However, liver tissue necrosis may cause signal non-uniformity and worsen the effect of shimming, even leading to pleural effusion after injection of sodium selenite.

It is very important to make optimal choices about the spectroscopic sequence and parameters. The PRESS technique was used for its higher SNR and non-sensitivity to movement. The quality of MR spectra also relies on adequate technics, such as effective water suppression and prescan adjustment, such as the position of the VOI and adequate anesthetic dose. The VSS pulse was used to reduce the voxel misregistration leading to outer voxel contamination, and to improve the effect of shimming. Although it is a time-consuming process, it is of importance to obtain good quality spectra that allow for more accuracy of metabolite identification and quantification.

Absolute quantification remains a challenge due to the lack of relatively stable metabolites used as the standard. Therefore, metabolite concentrations were reported in terms of metabolite ratios such as choline/lipid under the assumption of constancy of the reference compound<sup>[23,24]</sup>. Unfortunately, variations in choline and lipid must be taken into account. The use of the lipid peak as an internal reference was not considered for this study, as the range of lipids is very variable<sup>[25]</sup>.

LCModel software is widely used in the field of quantitative analysis. Compared with other fitting programs, phase and baseline correction can be automatically processed and overlapping spectra can be better resolved. In this study, unsuppressed water was used as an internal reference to acquire the metabolite area ratio of choline to water. However, accurate choline quantification requires additional correction for some factors,

such as the concentration and relaxation attenuation of tissue water as well as the relaxation attenuation of choline. Otherwise, the measurement can only be presented as concentrations in arbitrary institutional units (a.u.).

T1 and T2 relaxation time of choline and water *in vivo* was measured in this study. A number of studies reported the relaxation time of human hepatic tumor metabolites. At 3T, T1 and T2 values of water in the phantom were measured by Li *et al.*<sup>[13]</sup> to be 3420 ms and 370 ms, respectively, and choline T2 relaxation time in HCC patients ranged from 88 ms to 161 ms. These values are similar to the T1 and T2 relaxation time of water (3172 and 206 ms) and T2 relaxation time of choline ( $78 \pm 5$  ms in apoptotic liver) in the present study. In the study by Goldberg *et al.*<sup>[26]</sup> T1 and T2 relaxation time of water in solid lesions was  $1004 \pm 234$  ms and  $80 \pm 18$  ms at 1.5T by MRI. These values are higher than our data ( $719 \pm 37$  ms and  $50 \pm 5$  ms in cell apoptotic livers). The differences of T1 and T2 relaxation time may be attributed to the magnetic field strength, subjects, and measurement methods. Enhanced field strength led to increase in T1 and minor decrease in T2. Moreover, this procedure was subject to failure caused by the movement. Due to individual differences, variable relaxation time should be taken into consideration.

The liver choline concentration *in vivo* seems not universal. In the report by Fischbach *et al.*<sup>[12]</sup>, it was  $7.7 \pm 7.3$  a.u. in normal liver parenchyma of volunteers and  $7.3 \pm 4.3$  a.u. in normal-appearing liver parenchyma of patients with hepatic tumors using LCMoel at 3T. However, Li *et al.*<sup>[13]</sup> reported that the choline concentrations in four patients ranged from 3.4 mmol/L to 14.0 mmol/L, and in healthy volunteers  $1.3 \pm 0.9$  mmol/L. It was  $1.0 \pm 0.7$  a.u. in the normal liver tissues of rats and  $5.6 \pm 1.5$  a.u. in tumor tissues reported by Chen *et al.*<sup>[27]</sup>. The choline concentration in our study ( $14.5 \pm 7.6$  mmol/L in normal and  $10.8 \pm 6.6$  mmol/L in apoptotic livers) is higher than the above values. In addition to field strength and different subjects as well as the quantification method, the assumed tissue water concentration may be the main reason leading to our higher values. The water concentration was assumed to be 47 778 mmol/L for an 86% water content of liver. This value may be slightly higher for including parts of MR-invisible water. However, the real water concentration of liver is hard to measure *in vivo* and might vary between individuals.

The basis set is another important issue in quantification with LCMoel. It included the metabolites of choline and lipid as well as glycogen in analysis mode of liver-6. Therefore, the above metabolites can be measured in our study. Nevertheless, a choline compound consists of glycerophosphorylcholine, phosphorylcholine and free choline, which can be resolved *in vitro* at 9.4T<sup>[8]</sup>. As for the much poorer spectral resolution and SNR of *in vivo* MRS, only choline is included in the basis set.

Se-induced apoptosis has been studied in a number of cancer cells *in vitro* and the results generally suggest the involvement of apoptosis in Se-induced cytotoxic and

anti-proliferative effects against cancer cells<sup>[21]</sup>. Choline is a nutrient essential for the normal function of cells and is usually considered as a marker of cell growth<sup>[28,29]</sup>. The data in our study support that choline concentrations are decreased with the elevated number of apoptotic liver cells. This result is consistent with the results of Blankenberg<sup>[30]</sup> and our results *in vitro*<sup>[8]</sup>. However, it is insufficient to use choline as a possible apoptosis biomarker in this study. High concentrations of selenite can induce oxidative stress and make tissue undergo necrosis, which also leads to a decreased choline concentration. Therefore, it is essential to confine the time window to early apoptosis in future studies. The increased choline after injection of sodium selenite may be caused by the experimental control. This phenomenon might be related to individual diversities.

In conclusion, this work demonstrates the feasibility of noninvasive measurement of liver choline concentrations using *in vivo* 1.5T clinical MR. Although there are limitations as outlined above, this method has the potential to characterize liver lesions and determine therapeutic responses. Moreover, it lays a foundation for future investigations of cell apoptosis *in vivo*<sup>[8,9,31]</sup>.

## ACKNOWLEDGMENTS

We thank Dr. Stephen Provencher for his useful suggestions about LCMoel control parameter settings, and thank Dr. Stanley Lin, Dr. Yan Lin and Dr. Darren Price for their English language editing of this paper.

## COMMENTS

### Background

Through detecting apoptosis, the progression of a tumor can be evaluated and drug effects can be determined. It is, therefore, essential to develop a non-invasive method that can be used to assess apoptosis of tissues *in vivo*. The liver is a particularly suitable and interesting organ for metabolic studies owing to its rich metabolic activities and location at the body surface. However, the difficulties in measurement *in vivo* may occur due to respiratory movement.

### Research frontiers

Changes in choline-containing compounds at 3.2 ppm seem not to be universal, at least in the early stages of apoptosis. In this study, the decreased choline concentrations were observed in the sodium selenite-induced rabbit liver cell apoptosis *in vivo*.

### Innovations and breakthroughs

Several previous *in vivo* studies focused on the choline-to-lipid ratios in liver tumors. This may be the first study to attempt to quantify the metabolite concentrations of both normal and apoptotic rabbit livers *in vivo* using single-voxel 1H-magnetic resonance spectroscopy (MRS) with unsuppressed water signal as the internal reference, and to correct the relaxation attenuation.

### Applications

This study demonstrates the feasibility of noninvasive measure of liver choline concentrations *in vivo* in a 1.5T clinical MR environment. Moreover, it lays a foundation for future investigations of cell apoptosis *in vivo*.

### Peer review

The authors have tried to evaluate the feasibility of quantifying liver choline concentrations in both normal and apoptotic rabbit livers *in vivo* using <sup>1</sup>H MRS. Based on the *in vitro* study using a phantom model and an *in vivo* study using 18 rabbits, the authors conclude that MRS can be used to quantify choline in rabbit liver *in vivo* using unsuppressed water as an internal reference. This is an interesting animal study and the authors needed to be lauded for their efforts.

### Abstract

Behçet's disease is characterized by recurrent oral ulcers, genital ulcers, uveitis and skin lesions. Myelodysplastic syndrome (MDS) is characterized by problems due to ineffective hematopoiesis. Several studies have identified a relationship between MDS and Behçet's disease, especially intestinal Behçet's disease. Trisomy 8 seems to play an important role in these disorders as well. The present case was a 24-year-old woman who had a huge tonsil ulcer with initial symptoms of odynophagia and intermittent fever. We also noted folliculitis on her upper back. Five days later, she began to experience diarrhea and abdominal pain. Abdominal computed tomography and subsequent surgery revealed ileum perforation and enterocolitis with multiple ulcers. Later, she was admitted again for a vulvar suppurative ulcer and suspicious Bartholin's cyst infection. The patient's clinical presentations met the criteria for Behçet's disease. Six months after the bowel perforation event, we noted the development of pancytopenia in a routine laboratory examination. All the examinations led to the diagnosis of MDS

with trisomy 8. The most unusual finding was that multiple large vessel thrombi developed during follow-up. Previous studies have suggested that trisomy 8 in MDS leads to concurrent intestinal Behçet's disease. Moreover, the inflammatory and immune genes related to thrombus formation are overexpressed in cases of MDS with trisomy 8. Trisomy 8 must play a role in thrombosis. Further studies are needed to help clarify the pathophysiology and pathogenesis of these disorders.

### INTRODUCTION

Behçet's disease is a multisystem inflammatory disease characterized by recurrent oral ulcers, genital ulcers, uveitis, and skin lesions. Many other systems can be involved, such as the gastrointestinal tract, central nervous system and cardiovascular system; the disease can also cause arthritic joints.

Myelodysplastic syndrome (MDS) is a blood disease that easily converts to acute leukemia. It is characterized by stem cell disorders, multi-lineage dysplasia, and pancytopenia due to ineffective hematopoiesis.

Behçet's disease and MDS are two different disease entities. However, an association between the two diseases has been reported in an increasing number of cases. Most of the patients who suffer from the two diseases have intestinal ulcers. Some previous studies have also identified a statistically significant relationship between trisomy 8 and intestinal Behçet's disease with MDS.

We report the case of a patient with trisomy 8 who was diagnosed with intestinal Behçet's disease and MDS. We incidentally found multiple thrombi in the major veins.

## CASE REPORT

A 24-year-old woman was admitted to our hospital due to odynophagia and intermittent fever for 1 wk. The initial findings were a huge tonsil ulcer with a pus-like coating. We also noted several spots of folliculitis on her upper back. The laboratory examination revealed the following: white cell count  $12.5 \times 10^3/\text{mm}^3$ , red blood cell count  $3.80 \times 10^6/\text{mm}^3$ , hemoglobin 14.1 g/dL, platelet count  $150 \times 10^3/\text{mm}^3$ , alanine aminotransferase 24 IU/L, creatinine 0.9 mg/dL, Na 141 mEq/L and K 3.3 mEq/L. She was initially treated for acute suppurative tonsillitis. However, the symptoms persisted after the administration of antibiotics. Five days later, she began to experience diarrhea, abdominal pain and dyspnea. We arranged for abdominal computed tomography (CT), and the results showed ileus, edematous bowels, right-side colon dilation, ascites and free air. She then underwent an operation, and ileum perforation and enterocolitis with multiple ulcers were found (Figure 1). The pathology report identified multiple ulcers with transmural necrotizing inflammation in the colon and ileum.

About 2 mo later, the patient returned to our hospital due to increased vaginal discharge, itching and pain. Fever and chills followed these symptoms. She was admitted again for a vulvar suppurative ulcer and a suspicion of Bartholin's cyst infection. After antibiotic treatment, these symptoms improved, and she then received outpatient clinical follow-up care.

The patient's clinical presentations met the International Study Group's criteria for Behçet's disease; these include recurrent oral ulcers (> 3 times in a year), frequent genital ulcers (twice in the past 3 mo), folliculitis on the upper back and multiple bowel ulcers with perforation.

Three months after the second hospitalization, the patient was admitted again due to adhesion ileus. Unexpectedly, abdominal CT found thrombi in the patient's bilateral internal iliac vein, common iliac vein and inferior vena cava (Figure 2); the multiple thrombi were not noted in the previous CT scan.

Six months after the bowel perforation event, we noted the development of pancytopenia in a routine laboratory examination. The initial hemogram showed the following: white cell count  $1.0 \times 10^3/\text{mm}^3$ , red blood cell count  $1.45 \times 10^6/\text{mm}^3$ , hemoglobin 5.8 g/dL and platelet count

Figure 1 Ileum perforation and multiple transmural ulcers.

Figure 2 Abdominal computed tomography image shows a dilated bowel loop and a large thrombus (arrow) in the inferior vena cava.

$13 \times 10^3/\text{mm}^3$ . The differential count of the white blood cells was as follows: neutrophil-seg 18%, neutrophil-band 13%, lymphocytes 62%, monocytes 1%, eosinophils 2%, metamyelocytes 2% and atypical lymphocytes 62%. Bone marrow biopsy was performed for further evaluation and revealed profound hypocellularity of the marrow with a marked decrease of trilinear hematopoietic elements and focal aggregates of lymphoplasmacytic cells. Cytogenetic analysis demonstrated the presence of two cell lines: 48, XX, +8, +9 (11)/46, XX (9). Of the 20 cells examined, 11 showed an abnormal female karyotype with extra 8 and 9 chromosomes, and the remaining nine cells had normal, complete sets of chromosomes. These findings led to the diagnosis of MDS and refractory anemia. The overall picture was compatible intestinal Behçet's disease with MDS and chromosomal abnormality.

## DISCUSSION

Behçet's disease is characterized by recurrent oral ulcers, genital ulcers, uveitis, and skin lesions. Other systems can be involved, such as the gastrointestinal tract, central nervous system and cardiovascular system, and the disease can lead to arthritic joints. The exact etiology and pathogenesis of Behçet's disease are still being investigated. From previous studies, we know that genetic factors play key roles in its pathogenesis. MDS, however, is character-

ized by stem cell disorders, multi-lineage dysplasia and pancytopenia due to ineffective hematopoiesis.

Behçet's disease is generally considered to be an immunological disease. MDS is related to many immunological abnormalities, and presently, several types of immunomodulatory therapies, such as antithymocyte globulin and cyclosporin A<sup>[1]</sup>, have been used to treat MDS. These two diseases are currently thought to share some immunological characteristics. For example, extensive intramedullary cell death in an MDS patient is proposed to be strongly related to tumor necrosis factor (TNF)- $\alpha$ . In addition, the concentration of TNF and soluble TNF receptors is increased in the serum of patients with active Behçet's disease<sup>[2]</sup>. We conclude that some correlation exists in the pathogenesis of the two diseases.

The co-occurrence of Behçet's disease and MDS has been reported in an increasing number of cases<sup>[3]</sup>. Most of the patients who suffer from the two diseases have intestinal ulcers. In light of the previous literature, intestinal Behçet's disease is believed to be partly derived from MDS<sup>[4-7]</sup>, and most of these patients have trisomy 8. Kimura *et al*<sup>[6]</sup> have identified a statistically significant relationship between trisomy 8 and intestinal Behçet's disease with MDS.

Chromosomal abnormalities are observed in about 40% of patients with MDS, but trisomy 8 is found in only about 5% of the MDS population<sup>[8]</sup>. The high frequency of trisomy 8 in cases of intestinal Behçet's disease complicated with MDS suggests that trisomy 8 plays an important role in the pathogenesis of intestinal ulcers in the context of Behçet's disease.

Most cases of trisomy 8 with intestinal Behçet's disease complicated with MDS have been reported in Japan. A single case or a few cases have been reported in Italy, Korea, the United States, Germany, Spain, Israel and the United Kingdom<sup>[3]</sup>. We reported the case of a young woman who was diagnosed with intestinal Behçet's disease with MDS and trisomy 8. There are many compositions of trisomy 8; our patient was 48, XX, +8, +9, which is one of the karyotypes reported previously.

The most unusual finding in our reported case was that multiple large vessel thrombi developed during follow-up. Thrombosis related to Behçet's disease usually occurs in veins, and involvement of the arteries is less common<sup>[9]</sup>. Our patient developed thrombi in the bilateral internal iliac veins, common iliac veins and inferior vena cava. Thrombosis related to Behçet's disease is found more frequently in men<sup>[9]</sup>, although our patient was a young woman.

Kimura *et al*<sup>[6]</sup> have found that MDS patients with trisomy 8 tend to develop thrombosis and intestinal ulcers, but no definite cause for the vessel thrombus has been identified. Other researchers have noted neutrophil function abnormality and inflammatory cytokine overproduction in cases of MDS<sup>[10,11]</sup>. These immunological disorders, particularly cytokine overproduction, may lead to injury and inflammation of the endothelium.

Chen *et al*<sup>[12]</sup> have found that inflammatory and im-

mune genes, such as transforming growth factor (TGF)- $\beta$ , TGF- $\beta$  receptor, interleukin (IL)-10, IL-7 receptor and vascular cell adhesion molecule (VCAM)-1, are overexpressed in MDS patients with trisomy 8. The exact role of TGF- $\beta$  is controversial. Some researchers have suggested that it exacerbates neointima formation by inhibiting endothelial regeneration and promoting fibrosis, and some have shown that it protects against lipid lesion formation in atherosclerosis<sup>[13]</sup>. IL-10 and IL-7 are thought to contribute to the formation of atherosclerosis<sup>[14,15]</sup>. VCAM-1 has the ability to facilitate thrombus formation.

These previous studies have suggested that the presence of trisomy 8 in MDS leads to the patient having concurrent intestinal Behçet's disease. Moreover, the inflammatory and immune genes related to thrombus formation are overexpressed in cases of MDS with trisomy 8. Trisomy 8 must play a role in blood vessel thrombosis. We therefore hypothesize that trisomy 8 induces the activation of an abnormal inflammatory process and immune gene expression, eventually leading to or even aggravating blood vessel injury and thrombus formation. This may explain why our patient, with Behçet's disease complicated with MDS and trisomy 8, developed multiple vessel thrombi. In the near future, trisomy 8 may become a helpful predictor of Behçet's disease prognosis or outcome, especially in the case of intestinal ulcers or blood vessel thrombosis. Further studies are needed to help clarify the pathophysiology and pathogenesis of these disorders.

## Acknowledgments to reviewers of World Journal of Gastroenterology

Many reviewers have contributed their expertise and time to the peer review, a critical process to ensure the quality of *World Journal of Gastroenterology*. The editors and authors of the articles submitted to the journal are grateful to the following reviewers for evaluating the articles (including those published in this issue and those rejected for this issue) during the last editing time period.

**Julian Abrams, MD, MS, Assistant Professor** of Clinical Medicine, Division of Digestive and Liver Diseases, Columbia University Medical Center, 622 W 168th Street, PH 20-303, New York, NY 10032, United States

**Akira Andoh, MD**, Department of Internal Medicine, Shiga University of Medical Science, Seta Tukiowa, Otsu 520-2192, Japan

**Mauro Bernardi, Professor**, Internal Medicine, Cardioangiology, Hepatology, University of Bologna, Semeiotica Medical, Policlinico S. Orsola, Malpighi, Via Massarenti, 9, Bologna 40138, Italy

## Events Calendar 2012

January 13-15, 2012  
 Asian Pacific *Helicobacter pylori*  
 Meeting 2012  
 Kuala Lumpur, Malaysia

January 19-21, 2012  
 American Society of Clinical  
 Oncology 2012 Gastrointestinal  
 Cancers Symposium  
 San Francisco, CA 3000,  
 United States

January 19-21, 2012  
 2012 Gastrointestinal Cancers  
 Symposium  
 San Francisco, CA 94103,  
 United States

January 20-21, 2012  
 American Gastroenterological  
 Association Clinical Congress of  
 Gastroenterology and Hepatology  
 Miami Beach, FL 33141,  
 United States

February 3, 2012  
 The Future of Obesity Treatment  
 London, United Kingdom

February 16-17, 2012  
 4th United Kingdom Swallowing  
 Research Group Conference  
 London, United Kingdom

February 23, 2012  
 Management of Barretts  
 Oesophagus: Everything you need  
 to know  
 Cambridge, United Kingdom

February 24-27, 2012  
 Canadian Digestive Diseases Week  
 2012  
 Montreal, Canada

March 1-3, 2012  
 International Conference on  
 Nutrition and Growth 2012  
 Paris, France

March 7-10, 2012  
 Society of American Gastrointestinal  
 and Endoscopic Surgeons Annual  
 Meeting  
 San Diego, CA 92121, United States

March 12-14, 2012  
 World Congress on  
 Gastroenterology and Urology  
 Omaha, NE 68197, United States

March 17-20, 2012  
 Mayo Clinic Gastroenterology and  
 Hepatology  
 Orlando, FL 32808, United States

March 26-27, 2012  
 26th Annual New Treatments in  
 Chronic Liver Disease  
 San Diego, CA 92121, United States

March 30-April 2, 2012  
 Mayo Clinic Gastroenterology and  
 Hepatology  
 San Antonio, TX 78249,  
 United States

March 31-April 1, 2012  
 27th Annual New Treatments in  
 Chronic Liver Disease  
 San Diego, CA 92121, United States

April 8-10, 2012  
 9th International Symposium on  
 Functional GI Disorders  
 Milwaukee, WI 53202, United States

April 13-15, 2012  
 Asian Oncology Summit 2012  
 Singapore, Singapore

April 15-17, 2012  
 European Multidisciplinary  
 Colorectal Cancer Congress 2012  
 Prague, Czech

April 18-20, 2012  
 The International Liver Congress  
 2012  
 Barcelona, Spain

April 19-21, 2012  
 Internal Medicine 2012  
 New Orleans, LA 70166,  
 United States

April 20-22, 2012  
 Diffuse Small Bowel and Liver  
 Diseases  
 Melbourne, Australia

April 22-24, 2012  
 EUROSON 2012 EFSUMB Annual

Meeting  
 Madrid, Spain

April 28, 2012

 Modern Technologies in  
 Diagnosis and Treatment of  
 Gastroenterological Patients  
 Dnepropetrovsk, Ukraine

November 4-8, 2012  
 The Liver Meeting  
 San Francisco, CA 94101,  
 United States

November 9-13, 2012  
 American Association for the Study  
 of Liver Diseases  
 Boston, MA 02298, United States

December 1-4, 2012  
 Advances in Inflammatory Bowel  
 Diseases  
 Hollywood, FL 33028, United States

**GENERAL INFORMATION**

*World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

**Maximization of personal benefits**

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copy-right" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid

evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

**Aims and scope**

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

**Columns**

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systematically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensus and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

### Published by

Baishideng Publishing Group Co., Limited

## SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

### Biostatistical editing

Statistical review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Redit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc.* The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only

homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

### Conflict-of-interest statement

In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: [http://www.icmje.org/ethical\\_4conflicts.html](http://www.icmje.org/ethical_4conflicts.html).

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

### Statement of informed consent

Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

### Statement of human and animal rights

When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

## SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/1007-9327/office>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS ([http://www.wjgnet.com/1007-9327/g\\_info\\_20100315215714.htm](http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm)) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [wjg@wjgnet.com](mailto:wjg@wjgnet.com), or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

## MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically

for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. [montgomery.bissell@ucsf.edu](mailto:montgomery.bissell@ucsf.edu)

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

### Abstract

There are unstructured abstracts (no less than 256 words) and structured abstracts (no less than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no less than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections.

## Instructions to authors

AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of “To investigate/study/...”; MATERIALS AND METHODS (no less than 140 words); RESULTS (no less than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ; CONCLUSION (no more than 26 words).

### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

### Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315215714.htm](http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm).

### Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: ...etc. It is our principle to publish high resolution-figures for the printed and E-versions.

### Tables

Three-line tables should be numbered 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  should be noted ( $P > 0.05$  should not be noted). If there are other series of *P* values, <sup>c</sup> $P < 0.05$  and <sup>d</sup> $P < 0.01$  are used. A third series of *P* values can be expressed as <sup>e</sup> $P < 0.05$  and <sup>f</sup> $P < 0.01$ . Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be la-

beled with ●, ○, ■, □, ▲, △, etc., in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, “Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>”. If references are cited directly in the text, they should be put together within the text, for example, “From references<sup>[19,22-24]</sup>, we know that...”.

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

### PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

**Statistical data**

Write as mean  $\pm$  SD or mean  $\pm$  SE.

**Statistical expression**

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as *v* (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

**Units**

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4  $\pm$  2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum numbers can be found at: [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315223018.htm](http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm).

**Abbreviations**

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

**Italics**

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kbo I*, *Kpn I*, etc.

Biology: *H. pylori*, *E. coli*, etc.

## RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be re-submitted online (<http://www.wjgnet.com/1007-9327/office/>). The author should send the copyright transfer letter, responses to the reviewers, English language Grade B certificate (for non-native speakers of English) and final manuscript checklist to [wjg@wjgnet.com](mailto:wjg@wjgnet.com).

### Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

### Copyright assignment form

Please download a Copyright assignment form from [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315222818.htm](http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm).

[www.wjgnet.com/1007-9327/g\\_info\\_20100315222818.htm](http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm).

### Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315222607.htm](http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm).

### Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

### Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

### Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

### Publication fee

*WJG* is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1300 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.

## Contents

Weekly Volume 18 Number 11 March 21, 2012

### EDITORIAL

- 1141 Genetically modified mouse models for the study of nonalcoholic fatty liver disease

*Nagarajan P, Mahesh Kumar MJ, Venkatesan R, Majundar SS, Juyal RC*

### TOPIC HIGHLIGHT

- 1154 Trends on gastrointestinal bleeding and mortality: Where are we standing?

*El-Tawil AM*

- 1159 Management of non-variceal upper gastrointestinal tract hemorrhage: Controversies and areas of uncertainty

*Trawick EP, Yachinski PS*

- 1166 Treatment of portal hypertension

*Bari K, Garcia-Tsao G*

- 1176 Management of portal hypertension in children

*Gugig R, Rosenthal P*

- 1185 Pros and cons of colonoscopy in management of acute lower gastrointestinal bleeding

*Lhewa DY, Strate LL*

- 1191 Angiographic evaluation and management of acute gastrointestinal hemorrhage

*Walker TG, Salazar GM, Waltman AC*

- 1202 Management of acute nonvariceal upper gastrointestinal bleeding: Current policies and future perspectives

*Holster IL, Kuipers EJ*

### ORIGINAL ARTICLE

- 1208 Expression of HER2 and bradykinin B1 receptors in precursor lesions of gallbladder carcinoma

*Toledo C, Matus CE, Barraza X, Arroyo P, Ehrenfeld P, Figueroa CD, Bhoola KD, del Pozo M, Poblete MT*

- 1216 Proteomic analysis of gastric cancer and immunoblot validation of potential biomarkers

*Kočevar N, Odreman F, Vindigni A, Grazio SF, Komel R*

**BRIEF ARTICLE**

- 1229 High-dose infliximab for treatment of pediatric ulcerative colitis: A survey of clinical practice

*Nattiv R, Wojcicki JM, Garnett EA, Gupta N, Heyman MB*

- 1235 Polymorphisms of the *TLR2* and *TLR4* genes are associated with risk of gastric cancer in a Brazilian population

*de Oliveira JG, Silva AE*

- 1243 Adenoma incidence decreases under the effect of polypectomy

*Rosa I, Fidalgo P, Soares J, Vinga S, Oliveira C, Silva JP, Ferro SM, Chaves P, Oliveira AG, Leitão CN*

- 1249 CCL7 and CCL21 overexpression in gastric cancer is associated with lymph node metastasis and poor prognosis

*Hwang TL, Lee LY, Wang CC, Liang Y, Huang SF, Wu CM*

- 1257 Bacterial flora concurrent with *Helicobacter pylori* in the stomach of patients with upper gastrointestinal diseases

*Hu Y, He LH, Xiao D, Liu GD, Gu YX, Tao XX, Zhang JZ*

- 1262 Gastric cancer incidence and mortality in Zhuanghe, China, between 2005 and 2010

*Jing JJ, Liu HY, Hao JK, Wang LN, Wang YP, Sun LH, Yuan Y*

**CASE REPORT**

- 1270 Esophageal duplication cysts: Endosonographic findings in asymptomatic patients

### Abstract

Nonalcoholic fatty liver disease (NAFLD) is associated with obesity, insulin resistance, and type 2 diabetes. NAFLD represents a large spectrum of diseases ranging from (1) fatty liver (hepatic steatosis); (2) steatosis with inflammation and necrosis; to (3) cirrhosis. The animal models to study NAFLD/nonalcoholic steatohepatitis (NASH) are extremely useful, as there are still many events to be elucidated in the pathology of NASH. The study of the established animal models has provided many clues in the pathogenesis of steatosis and steatohepatitis, but these remain incompletely understood. The different mouse models can be classified in two large groups. The first one includes genetically modified (transgenic or knockout) mice that spontaneously develop liver disease, and the second one includes mice that acquire the disease after dietary or pharmacological manipulation. Although the molecular mechanism leading to the development of hepatic steatosis in the pathogenesis of NAFLD is complex, genetically modified animal models may be a key for

the treatment of NAFLD. Ideal animal models for NASH should closely resemble the pathological characteristics observed in humans. To date, no single animal model has encompassed the full spectrum of human disease progression, but they can imitate particular characteristics of human disease. Therefore, it is important that the researchers choose the appropriate animal model. This review discusses various genetically modified animal models developed and used in research on NAFLD.

### INTRODUCTION

Nonalcoholic fatty liver disease (NAFLD) represents a histological spectrum of liver disease associated with obesity, diabetes and insulin resistance that extends from isolated steatosis to steatohepatitis and cirrhosis. Besides being a potential cause of progressive liver disease, steatosis has been shown to be an important cofactor in the pathogenesis of many other liver diseases. Mouse models have been developed and the different mouse models can be classified in two major groups. The first one includes genetically modified (transgenic or knockout) mice that spontaneously develop liver disease, and the second one

includes mice that acquire the disease after dietary or pharmacological manipulation. NAFLD and nonalcoholic steatohepatitis (NASH) are increasing due to the prevalence of the metabolic syndrome linked to visceral adiposity, insulin resistance, dyslipidemia and type two diabetes. In this context, research has been undertaken using animal models for human steatosis and NAFLD to NASH disease progression. Most of the animal models develop a fatty liver and many develop aspects of steatohepatitis. However, spontaneous development of fibrosis is very rare. Because it is highly unlikely that NAFLD in the human population is monogenic, study of animals with deletion or over-expression of a single gene may not mimic etiology of the human disease at the molecular level. Likewise, choice of experimental diet may not mimic the human diets associated with development of NAFLD in man. Although rodent models of hepatic steatosis and/or insulin resistance do not always perfectly reproduce the human pathology of NAFLD, the use of transgenic, knockout, and knockdown mouse models have helped over the past years to better our understanding of the molecular determinants of NAFLD. This literature review describes different genetically modified mouse models that exhibit histological evidence of hepatic steatosis or, more variably, steatohepatitis.

## GENETIC MODELS FOR NAFLD

### *ob/ob* mice

The *ob/ob* mice carry a spontaneous mutation in the leptin gene (leptin-deficient). These mice are hyperphagic, inactive, extremely obese and are severely diabetic, with marked hyperinsulinemia and hyperglycemia. *ob/ob* mice develop NASH spontaneously<sup>[11]</sup>, but unlike human NAFLD, *ob/ob* mice do not spontaneously progress from steatosis to steatohepatitis. *ob/ob* mice require a 'second hit' to be administered in order to trigger progression to steatohepatitis. This may be provided by exposure to small doses of lipopolysaccharide (LPS) endotoxin, ethanol exposure or hepatic ischemia-reperfusion challenge which all provoke a severe steatohepatitis and frequently acute mortality<sup>[2-5]</sup>. *ob/ob* mice require other stimuli such as a methionine choline deficient (MCD) diet or a high fat diet to trigger progression to steatohepatitis. The effects of leptin deficiency on several aspects of physiology increase the complexity of studies while using this strain<sup>[6]</sup>. Similarly, the limited fibrotic capacity of a leptin-deficient model means that it is best suited to studies investigating the mechanisms behind the development of steatosis and the transition to steatohepatitis. Recent work demonstrates that the apparent flaws in this model can be turned to advantage, providing new insights into stellate cell function and the progression to fibrosis.

### *db/db* mice

The *db/db* mice have a natural mutation in the leptin receptor (*Ob-Rb*) gene<sup>[7]</sup>. These mice are obese with insulin resistance, and are able to develop macrovesicular he-

patic steatosis. These mice readily develop symptoms of NASH upon induction with a second hit, such as feeding with an MCD diet<sup>[8]</sup>. These mice have normal or elevated levels of leptin but are resistant to its effects. Studies have shown that the *db* gene encodes the leptin receptor (OB-R) which is structurally similar to a class I cytokine receptor<sup>[9,10]</sup>. There are two isoforms; the short OB-Ra isoform has not been shown to have any signaling activity. In contrast, the OB-Rb isoform has a long intracytoplasmic region that contains signal transduction motifs which activate the JAK/STAT protein kinase signal transduction cascade<sup>[11]</sup>. *db/db* mice carry a sequence insertion at the 3' end of the mRNA transcript exactly where the OB-Ra and OB-Rb transcripts diverge. This insertion contains a stop codon that leads to the premature termination of the OB-Rb long intracellular signaling domain, loss of function and consequently leptin resistance<sup>[12]</sup>.

### *Yellow-obese agouti (Ay)* mice

KK-*A<sup>y</sup>* mice are a cross-strain of diabetic KK mice<sup>[13]</sup> and lethal yellow (*A<sup>y</sup>*) mice, which carry mutation of the agouti(a) gene on mouse chromosome 2<sup>[14]</sup>. KK-*A<sup>y</sup>* mice develop maturity-onset obesity, dyslipidemia, and insulin resistance, in part because of the antagonism of melanocortin receptor-4 by ectopic expression of the agouti protein<sup>[14]</sup>. Importantly, these mice present hyperleptinemia and leptin resistance without defects in the *ObR* gene, and the expression of adiponectin is conversely down-regulated<sup>[15,16]</sup>. The phenotype of KK-*A<sup>y</sup>* mice, including altered adipokine expression, quite resembles metabolic syndrome in humans indicating the potential usefulness of this strain as a model of metabolic syndrome NASH<sup>[17,18]</sup>. In fact, KK-*A<sup>y</sup>* mice are more susceptible to experimental steatohepatitis induced by MCD diet.

### *CD36<sup>-/-</sup>* mice

A valuable model for the study of the effects of alteration in fatty acid (FA) utilization on insulin responsiveness is the recently generated CD36-deficient mouse<sup>[19,20]</sup>. CD36, also known as fatty acid translocase (FAT)<sup>[21]</sup>, is a multispecific, integral membrane glycoprotein<sup>[22,23]</sup> that has been identified as a facilitator of FA uptake. Its function in binding and transport of FA was documented *in vitro* by affinity labeling with FA derivatives and by cell transfection studies<sup>[23,24]</sup>. The CD36-deficient mouse exhibits greater than 60% decrease of FA uptake and utilization by heart, skeletal muscle, and adipose tissues and thereby increases FA delivery to liver and exhibits increased plasma free fatty acid (FFA) and triglyceride (TG) levels<sup>[20]</sup>. The pathogenic role of FAT/CD36 in hepatic steatosis in rodents is well-defined<sup>[25]</sup>.

### *Phosphoenolpyruvate carboxykinase-sterol regulatory-element binding protein 1a-mice*

Sterol regulatory-element binding protein (SREBP) family members have been established as transcription factors regulating the transcription of genes involved in cholesterol and FA synthesis. *In vivo* studies have demonstrated that

SREBP-1 plays a crucial role in the dietary regulation of most hepatic lipogenic genes<sup>[26,27]</sup>. Physiological changes of SREBP-1 protein in normal mice by dietary manipulation such as placement on high carbohydrate diets, polyunsaturated FA-enriched diets, and fasting-refeeding regimens has been reported<sup>[28,29]</sup>. SREBP-1a transgenic mice, under the control of liver specific Phosphoenolpyruvate carboxykinase promoter (TgSREBP-1a), show a massively enlarged liver and atrophic peripheral white adipose tissue, and develop steatosis<sup>[30]</sup>.

#### **aP2-NSREBP-1c mice**

Leptin has similar effects in lipodystrophic rodents, most notably in aP2-nSREBP-1c transgenic mice. These animals express a truncated, constitutively active form of the SREBP-1c transcription factor under the control of the adipose tissue specific aP2 promoter and develop lipodystrophy with very low plasma leptin levels. These mice are also hyperphagic and have massive fat accumulation in peripheral tissues with hyperglycemia and hyperinsulinemia<sup>[31,32]</sup>. This mouse model has markedly reduced body fat and develops liver steatosis, profound insulin resistance, and increased levels of triglycerides<sup>[31,32]</sup>.

#### **aP2-diphtheria toxin mice**

The aP2/DTA mice have low serum leptin levels and are hyperphagic. These mice when fed a control diet are hyperlipidemic, hyperglycemic, and have hyperinsulinemia indicative of insulin-resistant diabetes. These mice are born normally and initially lack any distinguishing phenotypic features, but develop atrophy and necrosis of the adipose tissue at five to six months resulting in the complete absence of subcutaneous or intra-abdominal adipose tissue at eight to nine months of age<sup>[33]</sup>. This late onset of adipose tissue loss is associated with reduced leptin levels, increased food consumption, hyperlipidemia, hyperglycemia and insulin resistance. Monosodium glutamate-treated aP2/DTA mice develop gross hepatomegaly as a result of severe fatty changes in the liver<sup>[33]</sup>.

#### **A-ZIP/F-1 mice**

The A-ZIP/F-1 mice express a dominant negative version of the C/EBP $\alpha$  leucine zipper domain that potently interferes with adipocyte differentiation<sup>[34]</sup>. The A-ZIP/F-1 mouse (*A-ZIPTg/+*) is a model of severe lipotrophic diabetes and is insulin resistant, hypoleptinemic, hyperphagic, and shows severe hepatic steatosis. This mouse has essentially no white adipose tissue, reduced brown fat and severe metabolic phenotype with a reduced life span. These mice display massive hepatomegaly causing increased body weight, liver steatosis, severe diabetes (hyperglycemia, hyperinsulinemia, hyperphagic, polydipsia and polyuria), and are hypertensive<sup>[35]</sup>. They have increased triglycerides and FFA levels, alveolar foam cells and reduced leptin levels. These mice are unable to sustain glucose levels during fasting. The insulin resistance and much of the liver steatosis in the A-ZIP/F-1 mice can be reversed by transgenic over-expression

of leptin<sup>[36]</sup> or by transplanting normal adipose tissue<sup>[37]</sup>. By contrast, transplantation of adipose tissue from *ob/ob* mice did not reverse the phenotype of the A-ZIP/F-1 mice indicating that leptin deficiency strongly contributes to the metabolic complications in lipodystrophy<sup>[38]</sup>.

#### **Peroxisome proliferator-activated receptor alpha<sup>-/-</sup> mice**

Peroxisome proliferator-activated receptor alpha (PPAR $\alpha$ ) is expressed in the liver and other metabolically active tissues including striated muscle, kidney and pancreas<sup>[39,40]</sup>. Many of the genes encoding enzymes involved in the mitochondrial and peroxisomal FA beta-oxidation pathways are regulated by PPAR $\alpha$ . In wild-type mice, peroxisome proliferators are compounds that induce lipid catabolism and an associated intracellular increase in peroxisome number and enzymatic activity. PPAR $\alpha$  mutated mice exhibit alterations of intracellular lipid processing, particularly in response to peroxisome proliferators. Mice deficient in PPAR $\alpha$  exhibit severe hepatic steatosis when subjected to fasting for 24-72 h, indicating that a defect in PPAR $\alpha$ -inducible FA oxidation accounts for severe FA overload in liver, causing steatosis, in contrast to the wild-type mice<sup>[41,42]</sup>.

#### **Galactin-3 knockout mice**

Galectin-3, a beta-galactoside-binding animal lectin, is a multifunctional protein. Galectin-3 plays a role in the regulation of hepatic stellate cell (HSC) activation *in vitro* and *in vivo*, thereby identifying galectin-3 as a potential therapeutic target in the treatment of liver fibrosis. This model plays a role in investigating liver carcinogenesis based on a natural history of NAFLD<sup>[43]</sup>. Previous studies have also suggested that galectin-3 may play an important role in inflammatory responses. The livers of *gal3(-/-)* male mice at six months of age displayed mild to severe fatty change. The liver weight per body weight ratio, serum alanine aminotransferase levels, liver triglyceride levels, and liver lipid peroxide in *gal3(-/-)* mice were significantly increased compared with those in *gal3(+/+)* mice. Furthermore, the hepatic protein levels of advanced glycation end-products (AGE), receptor for AGE, and PPAR $\gamma$  were increased in *gal3(-/-)* mice relative to *gal3(+/+)* mice<sup>[43,44]</sup>.

#### **Acetyl CoA oxidase<sup>-/-</sup> mice**

Acyl-coenzyme A oxidase (AOX) is the rate-limiting enzyme in peroxisomal FA  $\beta$ -oxidation for the preferential metabolism of very long-chain FAs. AOX null (*AOX(-/-)*) mice have defective peroxisomal  $\beta$ -oxidation and exhibit steatohepatitis. Microvesicular fatty change in hepatocytes is evident at 7 d. At 2 mo of age, livers show extensive steatosis and they have clusters of hepatocytes at periportal areas with abundant granular eosinophilic cytoplasm rich in peroxisomes. At 4-5 mo there is increased PPAR $\alpha$ , cytochrome P450, Cyp 4a10, and Cyp4a14 expression. By 6 to 7 mo, however, there is a compensatory increase in FA oxidation and reversal of hepatic steatosis resulting from hepatocellular regenera-

tion<sup>[45,46]</sup>. The *AOX*<sup>-/-</sup> mice proceed to develop adenomas and carcinomas by 15 mo of age<sup>[46,47]</sup>.

### **Aromatase (CYP 19)-deficient mice**

Aromatase P450 (CYP19) is an enzyme catalysing the conversion of androgens into estrogens<sup>[48]</sup>. These models present dyslipidemia, central obesity, hypercholesterolemia, hyperinsulinemia, hyperleptinemia, and hypertriglyceridemia<sup>[49]</sup>, and importantly the male mice have hepatic steatosis. Aromatase knockout (ArKO) mice have a similar phenotype to that of estrogen receptor null mice with increased gonadal fat pad weight<sup>[50]</sup>. Only ArKO males have elevated hepatic triglyceride levels leading to hepatic steatosis partly due to an increase in expression of enzymes involved in *de novo* lipogenesis and transporters involved in FA uptake<sup>[51-53]</sup>.

### **MTP<sup>-/-</sup> mice**

Mitochondrial  $\beta$ -oxidation of FAs is the major source of energy for skeletal muscle and the heart, and it plays an essential role in intermediary metabolism in the liver and impairment of mitochondrial  $\beta$ -oxidation in pathogenesis of NAFLD. The fetuses of *Mtpa*<sup>-/-</sup> mice accumulate long chain FA metabolites and have low birth weight compared with the *Mtpa*<sup>+/-</sup> and *Mtpa*<sup>+/+</sup> littermates. *Mtpa*<sup>-/-</sup> mice suffer neonatal hypoglycemia and sudden death 6-36 h after birth. Analysis of the histopathological changes in the *Mtpa*<sup>-/-</sup> pups revealed rapid development of hepatic steatosis after birth and, later, significant necrosis and acute degeneration of the cardiac and diaphragmatic myocytes. However, studies by Ibdah *et al*<sup>[54]</sup> indicated that aged but not young *MTPA*<sup>+/-</sup> mice developed hepatic steatosis with elevated alanine aminotransferase (ALT), basal hyperinsulinemia, and increased insulin compared with *MTPA*<sup>+/+</sup> littermates. Significant hepatic steatosis and insulin resistance developed concomitantly in the *MTPA*<sup>+/-</sup> mice at 9-10 mo of age. The cause resides in heterozygosity for  $\beta$ -oxidation defects that predisposes to NAFLD and insulin resistance in aging mice<sup>[55]</sup>.

### **Phosphatase and tensin homologue -/- mice**

Phosphatase and tensin homologue (PTEN) is a multifunctional phosphatase whose substrate is phosphatidylinositol-3,4,5-triphosphate and which acts as a tumor suppressor gene that downregulates phosphatidylinositol kinases<sup>[56,57]</sup>. Hepatocyte-specific PTEN-deficient mice spontaneously develop steatosis, steatohepatitis, and hepatocellular carcinoma<sup>[58,59]</sup>. By 10 wk of age, these mice have increased concentrations of triglyceride and cholesterol esters, and a histological analysis displays micro- and macrovesicular lipid vacuoles. At 40 wk of age, they have macrovesicular steatosis, Mallory bodies, ballooning degeneration, and sinusoidal fibrosis<sup>[59-60]</sup>. Mice that are homozygous for this allele are viable, fertile, and normal in size and do not display any gross physical or behavioral abnormalities. When crossed to a strain expressing Cre recombinase in liver, this mutant mouse

strain may be useful in studies of fatty liver and insulin signaling. Piguet *et al*<sup>[61]</sup> have investigated the effects of hypoxia in the PTEN-deficient mouse, a mouse model that develops NAFLD. The authors also showed that a short period (7 d) of exposure to hypoxia aggravates the NAFLD phenotype, causing changes in the liver that are in keeping with NASH, with increased lipogenesis and inflammation.

### **Methionine adenosyl transferase 1A -/- mice**

Mice deficient in methionine adenosyl transferase 1A (the enzyme responsible for SAM synthesis in the adult liver) have a decrease in hepatic SAM levels and spontaneously develop steatosis, NASH, and hepatocellular carcinoma (HCC)<sup>[62]</sup>. By three months of age, these mice have hepatomegaly with macrovesicular steatosis. These mice also have increased mRNA levels of CYP2E1 and UCP2, and levels of glutathione. Also, these mice have changes in the expression of genes involved in cell proliferation of lipid and carbohydrate metabolism<sup>[63]</sup>. These mice are predisposed to liver injury and have impaired liver regeneration after partial hepatectomy<sup>[64]</sup>.

### **Adiponectin null mice**

Adiponectin is an adipokine abundantly produced from adipocytes<sup>[65,66]</sup>. Adiponectin is an anti-inflammatory adipocyte-derived plasma protein known to alleviate steatosis and inflammation in NAFLD<sup>[65-67]</sup>. Two adiponectin receptors (adipoR1 and adipoR2) have been identified and found to be expressed in various tissues<sup>[68]</sup>. AdipoR1 is abundantly expressed in skeletal muscles, whereas adipoR2 is present predominantly in the liver, suggesting a role of adipoR2 in hepatic adiponectin signaling<sup>[68,69]</sup>. The physiological roles of adipoR1 and adipoR2 have recently been investigated by several laboratories in *adipoR1/2* knockout mice. Both *adipoR1* and *adipoR2* knockout mice exhibit mild insulin resistance<sup>[70]</sup>. In *adipoR1/R2* double knockout mice the binding and actions of adiponectin are abolished, resulting in increased tissue triglyceride content, inflammation oxidative stress<sup>[70-73]</sup> and mice exhibit impaired liver regeneration and increased hepatic steatosis.

### **Bid null mice**

The protein Bid is a participant in the pathway that leads to cell death (apoptosis), mediating the release of cytochrome from mitochondria in response to signals from "death" receptors known as tumor necrosis factor (TNF) receptor 1/Fas on the cell surface. Genetic inactivation of Bid, a key pro-apoptotic molecule that serves as a link between these two cell death pathways, significantly reduced caspase activation, adipocyte apoptosis, prevented adipose tissue macrophage infiltration, and protected against the development of systemic insulin resistance and hepatic steatosis independent of body weight<sup>[74,75]</sup>. These mice can be used in research based on adipocyte apoptosis which is a key initial event that contributes to macrophage infiltration into adipose tissue, insulin resistance, and hepatic steatosis associated with obesity.

**Fas adipocyte-specific (AfasKO) null mice**

Fas (CD95), a member of the TNF receptor super family, is a major contributor to apoptosis in many cells. Fas activation may contribute to obesity-induced insulin resistance, since mice lacking Fas in adipocytes were partly protected from developing insulin resistance. In particular, Fas activation led to increased release of pro-inflammatory cytokines, and reduced insulin-stimulated glucose uptake in 3T3-L1 adipocytes<sup>[75]</sup>. Fas-deficient (Fas-def) mice show increased insulin-stimulated glucose incorporation when compared to wild type (WT) with higher expression levels of Akt<sup>[76,77]</sup>.

**Interleukin-6 KO mice**

Interleukin-6 (IL-6) is an adipocytokine associated with NAFLD and obesity that is secreted in larger amounts by visceral fat compared to subcutaneous fat in obese adults<sup>[78]</sup>. Increased systemic IL-6 is associated with increased inflammation and fibrosis in NAFLD patients<sup>[79]</sup>. Expression of IL-6, a major proinflammatory cytokine, is increased in animal models of NAFLD. Hepatic IL-6 production may also play an important role in NASH development, as well as in systemic insulin resistance and diabetes. IL-6 is elevated in the plasma and peripheral blood monocytes of patients with fatty diseases, including alcoholic liver disease and non-alcoholic steatohepatitis, and elevation of IL-6 correlates with the progression and severity of liver disease, suggesting that IL-6 may be involved in the pathogenesis of fatty liver disease<sup>[80,81]</sup>. Studies using *Il6*<sup>-/-</sup> mice show these animals display obesity, hepatosteatosis, liver inflammation and insulin resistance when compared with control mice on a standard chow diet<sup>[82]</sup>.

**TNF alpha KO mice**

TNF- $\alpha$  appears to play a central role in the development of hepatic steatosis. TNF- $\alpha$ , by mechanisms not completely defined, is over expressed in the liver of obese mice and is an important mediator of insulin resistance in both diet-induced and *ob/ob* models of obesity<sup>[83,84]</sup>. Data from animal and clinical studies indicate that TNF- $\alpha$  mediates not only the early stages of fatty liver disease but also the transition to more advanced stages of liver damage<sup>[85,86]</sup>. Mice homozygous for the TNF targeted mutation are viable and fertile. Further, male mutant mice at 28 wk old display lower insulin, triglyceride, and leptin levels compared to wild type controls.

**NEMO<sup>LPC-KO</sup> mice**

The I $\kappa$ B kinase (IKK) subunit NEMO/IKK $\gamma$  is essential for activation of the transcription factor nuclear factor kappa B (NF- $\kappa$ B), which regulates cellular responses to inflammation. NEMO-mediated NF- $\kappa$ B activation in hepatocytes has an essential physiological function to prevent the spontaneous development of steatohepatitis and hepatocellular carcinoma. These mice were generated with liver parenchymal cell-specific knockout of these subunits (*NEMO*<sup>LPC-KO</sup>, *IKK2*<sup>LPC-KO</sup>) by crossing mice carrying loxP-

flanked *Nemo*<sup>[87]</sup> or *Ikk2*<sup>[88]</sup> alleles with Alfp-cre transgenic mice that mediate efficient Cre recombination in liver parenchymal cells, including hepatocytes and biliary epithelial cells, but not in endothelial or Kupffer cells<sup>[89]</sup>. *NEMO*<sup>LPC-KO</sup> mice were born and reached weaning age at the expected Mendelian frequency<sup>[90]</sup>. These mice showed efficient ablation of the respective proteins in whole-liver extracts and NF- $\kappa$ B activity in the liver was completely abolished<sup>[91,92]</sup>. Hepatocytes are LPS sensitive. When fed a high-fat diet, mice had reduced  $\beta$ -oxidation and upregulated PPAR- $\gamma$ , SREBP1 and FA synthase causing increased *de novo* lipid synthesis and macrovesicular steatosis with increased HCC occurrence<sup>[91,92]</sup>.

**Jun N-terminal kinase 1 null mice**

Jun N-terminal kinase (JNK) 1 null mice have less hepatic inflammation and fibrosis when fed a choline-deficient, l-amino acid-defined (CDAA) diet due to the absence of JNK1 in immune cells. As JNK is activated by oxidants and cytokines and regulates hepatocellular injury and insulin resistance, this kinase may mediate the development of steatohepatitis. JNK promotes the development of steatohepatitis as MCD diet-fed *JNK* null mice have significantly reduced levels of hepatic triglyceride accumulation, inflammation, lipid peroxidation, liver injury, and apoptosis compared with wild-type and *JNK2*<sup>-/-</sup> mice<sup>[93,94]</sup>. Hence JNK1 is responsible for JNK activation that promotes the development of steatohepatitis in the MCD diet model<sup>[93]</sup>. *JNK1* KO produces lean, male *JNK1* KO mice which have decreased body weights, fasting blood glucose levels, and fasting blood insulin levels compared to their wild-type controls<sup>[94]</sup>. This model can be used to study a combination of genetic and dietary challenges that constitute the disease etiology for NASH development and mimic more closely the pathogenesis of human NAFLD/NASH.

**Toll-like receptor 9 KO mice**

Development of NASH involves the innate immune system and is mediated by Kupffer cells and HSCs. Toll-like receptor 9 (TLR9) is a pattern recognition receptor that recognizes bacteria-derived cytosine phosphate guanine-containing DNA and activates innate immunity. Mice deficient in TLR9 have reduced steatohepatitis and fibrosis<sup>[95]</sup>. Hence this model can be used to study NAFLD involving innate immunity.

**LDLR KO and farnesoid X receptor KO mice**

Farnesoid X receptor (FXR) is essential for regulating bile-acid synthesis and transport. Mice with FXR deficiency have severe impairment of bile-acid homeostasis and manifest systemic abnormalities including altered lipid and cholesterol metabolism features known to be associated with the metabolic syndrome and NASH. Kong *et al*<sup>[96]</sup> studied LDL receptor knockout (*LDLR*<sup>-/-</sup>) mice fed with a high-fat diet for 5 mo, and checked whether FXR deficiency contributed to NASH development. Both high-fat diet and FXR deficiency increased

serum ALT activity, whereas only FXR deficiency increased bile-acid and ALP levels. FXR deficiency and high-fat feeding increased serum cholesterol and triglycerides. Although high-fat diet led to macrosteatosis and hepatocyte ballooning in livers of mice regardless of genotype, no inflammatory infiltrate was observed in the livers of *LDLR*<sup>-/-</sup> mice. In contrast, in the livers of *LDLR*<sup>-/-</sup>/*FXR*<sup>-/-</sup> mice, foci of inflammatory cells were observed when they were fed with control diet and were greatly increased when fed with the high-fat diet<sup>[96,97]</sup>. This model can be used to study a combination of genetic and dietary challenges that constitute the disease etiology for NASH development and mimic more closely the pathogenesis of human NAFLD/NASH.

### **Myd88 KO mice**

Chemokines, strongly induced by TLR stimulation, play an important role in the development of metabolic syndrome including NAFLD. TLR4- and MyD88-deficient mice, which are resistant to metabolic syndrome, show reduced chemokine production compared with WT mice<sup>[98,99]</sup>. MyD88 is a key molecule in the development of metabolic syndrome including NAFLD<sup>[98,99]</sup>. MyD88, an adaptor protein for all TLRs except for TLR3, is required for the expression of various inflammatory cytokines and chemokines<sup>[100]</sup>. MyD88-deficient mice are protected from metabolic syndrome as well as atherosclerosis<sup>[98,99]</sup> and from liver injury induced by bile duct ligation or carbon tetrachloride<sup>[101,102]</sup>. Miura *et al*<sup>[100]</sup> demonstrated that MyD88-deficient mice on a CDAA diet show less steatohepatitis with less insulin resistance compared with wild type mice. Inflammatory cytokines and fibrogenic factors are also significantly suppressed in MyD88-deficient mice compared with wild type mice fed a CDAA diet<sup>[100]</sup>.

### **Fatty liver dystrophy knockout mice**

Fatty liver dystrophy (*fld*) is a spontaneous point mutation in *Lpin1* which occurred on C3H/HeJ in 1994. An unstable gait and tremor at 3 wk of age was initially observed in these mice. The pups from these mice have a fatty liver before reaching weaning age. Mice carrying mutations in the *fld* gene have features of human lipodystrophy, a genetically heterogeneous group of disorders characterized by loss of body fat, fatty liver, and hypertriglyceridemia and insulin resistance<sup>[103]</sup>. Homozygous *fld* mice have an enlarged, fatty liver and hypertriglyceridemia that resolve to normal during the weaning transition. However, decreased overall size, decreased lipid in the fat pads and a peripheral neuropathy persist throughout the lifespan. This peripheral neuropathy manifests as a tremor and an unsteady gait shortly after 10 d of age and worsens with age. As with the original mutation of *fld*, homozygous females will breed and raise their litters but homozygous males do not breed.

### **Platelet endothelial cell adhesion molecule-1 null mice**

Platelet endothelial cell adhesion molecule-1 (PECAM-1)

is a 130-kDa transmembrane glycoprotein expressed on blood and vascular cells. Goel *et al*<sup>[104]</sup> demonstrated that genetic deficiency of PECAM-1 potentiates the development and progression of NASH. After 3 wk on an atherogenic diet, these mice developed mild microvesicular steatosis predominantly in hepatic parenchymal cells in the centrilobular region. At 9 and 18 wk on the atherogenic diet, more severe steatosis with lobular and sinusoidal inflammation developed in the livers, which are consistent with the typical histological features of steatohepatitis<sup>[104]</sup>.

### **ApolipoproteinB 38.9 mutant mice**

Fatty liver is prevalent in apolipoproteinB (apoB)-defective familial hypobetalipoproteinemia (FHBL). Similar to humans, mouse models of FHBL produced by gene targeting (*apoB*<sup>+/38.9</sup>) manifest low plasma cholesterol and increased hepatic TG even on a chow diet due to impaired hepatic VLDL-TG secretive capacity. These mice will be useful to study the genetic and molecular mechanism of apoB defects and lipid metabolism/liver fat accumulation, the relationship between hepatic steatosis and insulin resistance, and the progression of advanced NAFLD and atherosclerosis<sup>[105]</sup>.

### **Cystathionine-synthase deficient mice**

Cystathionine-synthase (CBS) deficiency causes severe hyperhomocysteinemia, which confers diverse clinical manifestations, notably liver disease. Robert *et al*<sup>[106]</sup> reported that CBS-deficient mice showed inflammation, fibrosis, and hepatic steatosis. These mice also had pathological resemblance to steatohepatitis and a pattern of perivenous and pericellular hepatic fibrosis around lipid-laden hepatocytes. CBS KO mice develop hepatic steatosis more tardily than inflammation and fibrosis at 8-32 wk old.

In addition to the above KO animals, Postic *et al*<sup>[107]</sup> has demonstrated a few animal models modulating enzymes in FA synthesis.

### **Acc2KO mice**

Acetyl-CoA carboxylase (ACC) catalyzes the synthesis of malonyl-CoA, the metabolic intermediate between lipogenesis<sup>[108]</sup> and  $\beta$ -oxidation<sup>[109]</sup>; this lipogenic enzyme has garnered significant attention over recent years. In mammals, two ACC isoforms exist, each with distinct tissue distribution and physiological roles: ACC1 is highly expressed in liver and adipose tissue, whereas ACC2 is predominantly expressed in heart and skeletal muscle and, to a lesser extent, in liver<sup>[110]</sup>. It is believed that only ACC1, but not ACC2, is committed to *de novo* lipogenesis in liver. Targeting ACC has beneficial effects on both hepatic steatosis and insulin resistance. ACC1-knockout mice (*Acc1*<sup>-/-</sup> mice and *ACC2*<sup>-/-</sup> mice) have been developed to study the effect.

### **SCD KO mice**

SCD1 has recently become a target of interest for the reversal of hepatic steatosis and insulin resistance<sup>[111]</sup>.

**Table 1** Potential candidate genes in fatty liver disease

Category of genes	Examples
Genes affecting insulin resistance	ADIPOQ, AKT2, ENPP1, IRS1, PPARG, HFE, resistin
Genes affecting hepatic lipid synthesis and uptake	DGAT2, SLC25A13, ACC, ELOVL6, SCD1, GPAT, SREBP1
Genes affecting hepatic lipid uptake	APOC3
Genes affecting hepatic triglyceride hydrolysis	PNPLA2, CGI-58, LIPA
Genes affecting hepatic lipid export	APOB, MTTP, PEMT
Genes affecting hepatic oxidative stress	GCLC, NOS2, SOD2, HFE, UCP2, MAT1A, GST, GSH-Px
Genes affecting immune regulation	ADIPOQ, ADIPOR1, ADIPOR2, STAT3, TNF $\alpha$ , IL10, IL6, CTLA-4, IL-4, IL-18
Genes influencing disease progression and fibrosis	TGF- $\beta$ 1, 3, PPAR $\alpha$ , DDX5, CPT1A, angiotensin II
Genes influencing response to endotoxin	CD14, TLR4, NOD2

ADIPOQ: Adiponectin; AKT: Beta serine/threonine-protein kinase; ENPP1: Ectonucleotide pyrophosphatase/phosphodiesterase 1; IRS-1: Insulin receptor substrate 1; PPARG: Peroxisome proliferator-activated receptor gamma; HFE: Hemochromatosis gene; DGAT2: Diacylglycerol acetyltransferase-2; SLC25A13: Solute carrier family 25 Member 13 (citrin); ACC gene: Acetyl-CoA carboxylase alpha; ELOVL6: Elongation of very long chain fatty acids; SCD1 gene: Stearoyl-CoA desaturase gene; GPAT: Glycerol-3-phosphate acyltransferase; SREBP1: Sterol regulatory element-binding transcription factor 1; APOC3: Apolipoprotein C-III; PNPLA2: Patatin-like phospholipase domain containing 2; CGI58: Comparative gene identification-58; LIPA: Lipase A; APOB: Apolipoprotein B; MTTP: Microsomal triglyceride transfer protein; PEMT: Phosphatidylethanolamine N-methyltransferase; GCLC: Glutamate-cysteine ligase, catalytic subunit; NOS2: Nitric oxide synthases2; SOD2: Superoxide dismutase-2; UCP2: Uncoupling protein 2; MAT1A: Methionine adenosyltransferase I alpha; GST: Glutathione S-transferase; ADH: Alcohol dehydrogenase; ALDH: Aldehyde dehydrogenase; CTGF: Connective tissue growth factor; CTLA-4: Cytotoxic T-cell associated antigen-4; GSH-Px: Glutathione peroxidase; STAT3: Signal transducer and activator of transcription 3; IL: Interleukin; PPAR: Peroxisomal proliferator activated receptor; SCD-1: Stearoyl CoA desaturase-1; TLR: Toll-like receptor; TNFR: TNF- $\alpha$  receptor; DDX5: DEAD box protein 5; CPT1A: Carnitine palmitoyltransferase 1A (liver); NOD2: Nucleotide-binding oligomerization domain containing 2.

SCD1 catalyzes the synthesis of monounsaturated FAs, particularly oleate (C18:1n-9) and palmitoleate (C16:1n-7), which are the major components of membrane phospholipids, TGs, and cholesterol esters. Mice with SCD1KO (*Scd1*<sup>-/-</sup> mice) show decreased lipogenic gene expression and increased  $\beta$ -oxidation and are protected from diet-induced obesity and insulin resistance when fed a HC/HF diet<sup>[112,113]</sup>. Inhibition of SCD1 using an ASO strategy (targeting SCD1 in both liver and adipose tissues) prevents many of the HF/HC-diet metabolic complications, including hepatic steatosis and postprandial hyperglycemia<sup>[114,115]</sup>.

### ELOVL6 KO mice

*Elovl6*<sup>-/-</sup> mice are protected against the development of hepatic insulin resistance when fed a HF/HC diet, despite the accumulation of palmitate concentrations. Improvement in insulin signaling (as evidenced by the restoration in insulin-mediated Akt phosphorylation)

occurred despite hepatic steatosis and marked obesity in *Elovl6*<sup>-/-</sup> mice<sup>[116]</sup>. While these results are somewhat surprising given the role of palmitate as a potent inducer of insulin resistance (at least in primary cultures of hepatocytes)<sup>[117]</sup>, they are also interesting since they indicate that the hepatic FA composition, and particularly the conversion of palmitate to stearate, is crucial for insulin sensitivity. It should be noted that the reduced SCD1 expression observed in livers of *Elovl6*<sup>-/-</sup> mice could have also contributed to the amelioration of insulin resistance in these mice<sup>[116]</sup>.

### ChREBP knockdown mice

ChREBP knockdown led to the expected inhibition of L-PK, ACC, FAS and SCD1 as well as GPAT. While a carbohydrate-response element was previously identified in the promoter region of the *GPAT* gene<sup>[118]</sup>, its expression was found to be unaffected in the liver of ChREBP-knockout mice upon refeeding<sup>[119]</sup>. It is possible that the nutritional regulation of GPAT may be more sensitive to insulin *via* SREBP-1c than to glucose *via* ChREBP. Nevertheless, following ChREBP knockdown, a resultant decrease in lipogenic rates was observed in shChREBP-RNA-treated *ob/ob* mice, leading to a 50% reduction in hepatic and circulating TG concentrations<sup>[120]</sup>. ChREBP knockdown not only affected the rate of *de novo* lipogenesis but also had consequences for  $\beta$ -oxidation. Therefore, similarly to the liver-specific knockout of SCD1 (LKO mice)<sup>[121]</sup>, the coordinated modulation in FA synthesis and oxidation in liver led to an overall improvement of lipid homeostasis in ChREBP-deficient mice. The decrease in lipogenic rates observed in LKO mice was at least partially attributed to a decrease in ChREBP nuclear protein content<sup>[122]</sup>. Clearly, ChREBP needs now to be considered as a key determinant of the molecular regulation of the lipogenic pathway.

## CLASSIFICATION OF SOME ANIMAL MODELS WITH DISRUPTION OF GENES INVOLVED IN NAFLD

Table 1 presents a number of candidate genes that are involved in the pathogenesis of NAFLD and a few are discussed below.

### Genes affecting lipid metabolism

**Pemt KO animals:** *Pemt*<sup>-/-</sup> mice have two selectively disrupted alleles of the *Pemt-2* gene at exon 2<sup>[123]</sup>, which encode PEMT, and do not express any PEMT activity in liver. Therefore these mice completely depend on dietary choline intake to meet daily choline requirements. When fed a diet deficient in choline and insufficient in methionine, *Pemt*<sup>-/-</sup> mice develop decreased PtdCho concentrations in hepatic membranes, leading to severe liver damage and death; a choline supplemented diet prevents this<sup>[124]</sup> and, if provided early enough, can reverse hepatic damage.

**DGAT2 mice:** DGAT2, an isoform of the enzyme acylCoA: diacylglycerol acyltransferase, catalyses the final stage of triglyceride synthesis in the liver<sup>[125]</sup>. Overexpression of DGAT2 in mice led to a 2.4-fold increase in hepatic triglyceride content, but no effect on production of VLDL triglyceride or apoB<sup>[126]</sup>. In addition, mice on a high-fat diet that overexpress DGAT develop fatty liver but not glucose or insulin intolerance<sup>[127]</sup>, showing that hepatic steatosis can occur independently of insulin resistance. Interestingly, antisense therapy reducing DGAT improves hepatic steatosis, but not insulin sensitivity<sup>[128]</sup>.

**Apolipoprotein C-III:** Apolipoprotein C-III (apoC-III) is the most abundant C apolipoprotein in human plasma, where it is present as an 8.8-kDa mature protein on chylomicrons, VLDL and HDL. ApoC-III is synthesized in the liver and in minor quantities by the intestine<sup>[129]</sup>. Several lines of evidence have implicated apoC-III as contributing to the development of hypertriglyceridemia in the human population. Investigation in *apoC3*<sup>-/-</sup> mice supports the concept that apoC-III is an effective inhibitor of VLDL TG hydrolysis and reveals a potential regulating role for apoC-III with respect to the selective uptake of cholesteryl esters<sup>[130]</sup>.

#### Genes affecting insulin resistance/sensitivity

**IRS 1:** Studies on mice with targeted disruption of the *Irs* genes lend some support to both situations. *Irs1* knockout (*Irs1*<sup>-/-</sup>) mice show significant embryonic and postnatal growth retardation, suggesting that IRS-1 plays a key role in relaying the growth-stimulating effects of insulin and insulin-like growth factor. IRS-1-deficient mice also have insulin resistance and mild glucose intolerance, but do not develop diabetes<sup>[131,132]</sup>.

**Ecto-nucleotide pyrophosphate phosphodiesterase:** Ecto-nucleotide pyrophosphate phosphodiesterase (ENPP1) has been shown to negatively modulate insulin receptor and to induce cellular insulin resistance when over-expressed in various cell types. Systemic insulin resistance has also been observed when ENPP1 is over-expressed in multiple tissues of transgenic models and is largely attributed to tissue insulin resistance induced in skeletal muscle and liver. In the presence of a high fat diet, ENPP1 over-expression in adipocytes induces fatty liver, hyperlipidemia and dysglycemia, thus recapitulating key manifestations of the metabolic syndrome<sup>[133]</sup>.

**Transcription factor 7-like 2:** Transcription factor 7-like 2 (TCF7L2) is a receptor for  $\beta$ -catenin and regulates the expression of a multitude of genes involved in cellular metabolism and growth. Various studies<sup>[134-136]</sup> have linked TCF7L2 variation with impaired insulin secretion and risk of diabetes, possibly mediated by altered  $\beta$ -cell glucose response. In addition, it regulates adipokine secretion and triglyceride metabolism through effects on PPAR- $\gamma$ , CCAAT/enhancer-binding protein, and lipoprotein lipase; TCF7L2 SNPs are associated with serum

triglyceride concentrations in familial hyperlipidemia<sup>[137]</sup>.

#### Genes affecting oxidative stress

**Glutamate-cysteine ligase:** Glutamate-cysteine ligase (GCLC) is the first and rate-limiting enzyme in the synthesis of glutathione, the major antioxidant in the liver. Liver-specific deletion of GCLC in mice rapidly leads to hepatic steatosis and progressive severe parenchymal damage<sup>[138]</sup>.

**Nitric oxide synthase:** Yoneda *et al.*<sup>[139]</sup>, who studied associations of PPAR $\gamma$ C1 $\alpha$ , also examined the influence of SNPs in the inducible nitric oxide synthase (*NOS2*) gene on their NAFLD cohort. iNOS is expressed as part of the inflammatory response and in the presence of superoxide radicals forms peroxynitrite, which can cause endoplasmic reticulum stress and cell death<sup>[140]</sup>. iNOS-deficient mice develop NASH with high fat diets<sup>[141]</sup>.

**Superoxide dismutase-2:** Elevated hepatic reactive oxygen species play an important role in pathogenesis of liver diseases, such as alcohol-induced liver injury, hepatitis C virus infection, and nonalcoholic steatohepatitis. Satoshi *et al.*<sup>[142]</sup> observed significant increases in lipid peroxidation and TG in the liver of *Sod1* KO and double KO mice but not in the liver of *Sod2* KO mice.

#### Genes affecting immune regulation

**Signal transducer and activator of transcription 3:** Signal transducer and activator of transcription 3 (STAT3) is an acute-phase transcription factor; after hepatic necrosis it activates pathways associated with liver regeneration and acute inflammation<sup>[143]</sup>. STAT3 is also implicated in nutrient metabolism and developing metabolic syndrome. Transgenic mice with hepatic deficiency of STAT3 develop insulin resistance and disturbed glucose homeostasis; whereas the constitutive liver specific expression of STAT3 in diabetic mice reduces blood glucose and plasma insulin concentrations and downregulates gluconeogenic gene expression<sup>[144]</sup>.

## CONCLUSION

Inbred strains of mice provide convenient tools to study the pathogenesis of NAFLD because they provide the opportunity to control genetic and environmental factors that might influence the natural history of NAFLD. Various genetic alterations or environmental stressors producing a similar phenotype prove that many different immunological, neuronal and hormonal factors are involved in the pathogenesis of NAFLD<sup>[145,146]</sup>. Transgenic mouse models also represent gene mediation to NAFLD. Therefore, any one of these animal models could be used to clarify how altered cross talk among immune cells, neurons and endocrine cells promote NAFLD. In contrast to human genetic studies, animal studies have found genes that consistently produce disease-like phenotypes, and the underlying genetic basis for the phenotypes in these models have often been

elucidated. Animal studies on NAFLD frequently reveal significant single-locus effects that can be reproduced across species and/or strains. Such “disease genes” in animal models can be found relatively easily using linkage mapping techniques in crossed inbred lines. Similarly, transgenic animals or genetically manipulated animals for NAFLD can reveal significant effects of candidate alleles in well-defined genetic backgrounds. This review has explored some of the advantages and disadvantages of a few genetically modified mouse models of NAFLD that would be useful in understanding the connections between lipid metabolism, host defences, environmental triggers, genetic variability, inflammatory recruitment, and fibrogenesis. These models will also serve as important platforms for assessing therapeutic strategies, which is an essential area of study.

### Abstract

Bleeding from the gastrointestinal tract and its management are associated with significant morbidity and mortality. The predisposing factors that led to the occurrence of these hemorrhagic instances are largely linked to the life style of the affected persons. Designing a new strategy aimed at educating the publics and improving their awareness of the problem could effectively help in eradicating this problem with no associated risks and in bringing the mortality rates down to almost zero.

### INTRODUCTION

Gastrointestinal (GI) bleeding involves any bleeding in the GI tract from the mouth, oesophagus, stomach, small intestines, large intestines, to the anus. The degree of bleeding can range from microscopic levels detected only by lab tests, to perceptible amounts of bleeding that can be seen in the stool or vomit. However, any level of bleeding can lead to serious problems. Microscopic levels of bleeding can lead to anaemia over time, and more massive amounts of bleeding can lead to death.

How to manage these instances more effectively and to prevent the happening of the co-incident adverse would be discussed by colleagues whom I invited to carry out this task. But in this review, I am going to assess how practically these haemorrhagic instances could be avoided.

### TRENDS ON GASTROINTESTINAL BLEEDING AND MORTALITY

Upper GI bleeding involves bleeding from the mouth to the duodenum (common causes of upper GI bleeding are listed in Table 1). But lower GI bleeding involves bleeding from the small intestines to the anus and can be caused by haemorrhoids, cancer, polyps and colitis, among other causes (Table 2). Upper GI bleeding has been estimated to account for up to 20 000 deaths annually in the United States (international records are not available). The overall incidence of acute upper GI haemorrhage has been estimated to be 50 to 100 per 100 000 persons per year. The trends of hospitalization for GI bleeding in the United States in 1998 and in 2006 have

**Table 1 Causes of acute upper gastrointestinal bleeding**

Common	Gastric ulcer Duodenal ulcer Esophageal varices Malory-Weiss tear
Less common	Gastric erosive/gastropathy Esophagitis Cameron lesions Dieulatory lesion Telangiectasias Portal hypertensive gastropathy Gastric antral vascular ectasia (watermelon stomach) Gastric varices Neoplasms
Rare	Esophageal ulcer Erosive duodenitis Aortoenteric fistula Hemobilia Pancreatic disease Crohn's disease

**Table 2 Causes of acute lower gastrointestinal bleeding**

Common	Colonic diverticula Angioectasia
Less common	Colonic neoplasms (including post polypectomy bleeding) Inflammatory bowel disease Colitis Ischemic Raditation Unspecified (infectious or non specific) Haemorrhoids Small bowel source Upper gastrointestinal source
Rare	Dieulatory lesion Colonic ulcerations Rectal varices

been summarised in Table 3.

And the hospitals' discharge rates of the admitted subjects for different causes of GI haemorrhage in 1998 and 2006 in the United States have also been listed (Table 4).

The incidence rate for upper GI bleeding appears to be, in general, decreasing (Table 3). This may be due to the prescription of proton pump inhibitors and the skilled efforts to eradicate *Helicobacter pylori* infections (Table 4). But, the risk of upper GI bleeding appears to be increasing in particular groups of patients, such as those with a history of oesophageal varices (Table 5).

Regarding bleeding from the lower GI tract, it appears that haemorrhage from rectum and anus and the incidences of diagnosis of occult blood in stool are increasing (Table 5).

When the total number of discharges for cases of GI bleeding was investigated per age of the discharged patient, it appeared that incidences of GI bleeding are increasing in certain subgroups. The incidences of GI haemorrhage was, for example, found increasing in those who were less than 20 years old (Table 3).

Oesophageal varices form less than 10% of the all causes of GI haemorrhages. However, patients with variceal haemorrhage have a mortality rate of at least 30% during their initial hospitalization, with a one year mortality rate approaches 60%<sup>[11]</sup>. Patients who have bled once from oesophageal varices have a 70% chance of rebleeding, and approximately one third of further bleeding episodes are fatal<sup>[2]</sup>. The risk of death is maximal during the first few days after the bleeding episode and decreases slowly over the first 6 wk. Oesophageal varices are present in approximately 40% of patients with cirrhosis and in as many as 60% of patients with cirrhosis and ascites<sup>[3]</sup>. In cirrhotic patients who do not have oesophageal varices at initial endoscopy, new varices will develop at a rate of approximately 5% per year. In patients with small varices at initial endoscopy, progression to large varices occurs at a rate of 10%-15% per year and is related chiefly to the degree of liver dysfunction<sup>[4]</sup>. On the other hand,

improvement in liver function in patients with alcoholic liver disease who abstain from alcohol is associated with a decreased risk, and sometimes even disappearance of the varices<sup>[5]</sup>. It has been estimated that up to 25% of the patients with newly diagnosed varices would bleed within two years<sup>[4]</sup>. The risk of bleeding in patients with varices less than 5 mm in diameter is 7% by two years, and in patients with varices greater than 5 mm in diameter is 30% by two years<sup>[4]</sup>. Mortality rates in the setting of surgical intervention for acute variceal bleeding are high<sup>[6]</sup>. Associated abnormalities in the renal<sup>[7]</sup>, pulmonary<sup>[7]</sup>, cardiovascular<sup>[8]</sup>, and immune systems in patients with oesophageal varices contribute to 20%-65% of mortality<sup>[9]</sup>. In Western countries, alcoholic and viral cirrhosis are the leading causes of portal hypertension and oesophageal varices. Thirty percent of patients with compensated cirrhosis and 60%-70% of patients with decompensate cirrhosis have gastroesophageal varices at presentation<sup>[9]</sup>. The *de novo* rate of development of oesophageal varices in patients with chronic liver diseases is approximately 8% per year for the first 2 years and 30% by the sixth year<sup>[9]</sup>. A recently published survey<sup>[10]</sup> on consumption of alcohol by teenagers in the North West of England revealed that almost 90% of the participant school children (aged 15 and 16) drink alcohol at least occasionally. Of those, 38.0% usually binge drink (5+ drinks in one session), 24.4% are frequent drinkers (drinking two or more times a week) and 49.8% drinks in public settings (such as bars, clubs, streets and parks). It is worth to note that excessive drinking by young people, for example, has seen a 20% rise in hospital admissions in England over the last five years. The number of people taken to Accident and Emergency with alcohol-related injuries has also doubled to 148 477 a year. Alcohol-related conditions such as liver disease have doubled in less than a decade, to 262 844 a year as well.

But in developing countries, hepatitis B is endemic in the Far East and Southeast Asia, particularly, as well as South America, North Africa, Egypt and other countries in the Middle East. Schistosomiasis is an important cause of portal hypertension in Egypt, Sudan and other African countries<sup>[8]</sup>. Those that have been affected with bilharsiasis, they almost have additional complications from hepa-

titis B and C<sup>[11-14]</sup>. The instances of acute lower GI bleeding are mainly self-limited and affected patients do not require hospitalization care, approximately 21 per 100 000 adults in the United States require hospitalization for severe lower GI bleeding every year<sup>[15]</sup> (international records are not available). The hospitalization rate for lower GI bleeding is approximately one third of that for upper GI bleeding<sup>[16]</sup> and in a survey by the American College of Gastroenterology, lower GI haemorrhage accounted for 24% of all GI bleeding occasions<sup>[17]</sup>. It has been estimated that detection of occult blood in stools formed 7% of all instances of GI bleeding in the United States in 2007. But it is expected that the incidence rates of detection of occult blood in the stools of patients in developing countries exceed this figure by many times. Helminthic infestation is a common cause for occult blood in stools in developing countries (Table 6). It has been estimated that 80% of the population of most countries in Asia, Africa and south America are infected with helminths, such as

Ascaris and widespread infection has been demonstrated throughout Europe, Particularly, Romania, Hungary, Portugal and Turkey<sup>[18]</sup>. When 312 children in the age group of 4-15 years were examined for different intestinal helminths in three schools located in rural areas in Kupwara, Kashmir, India<sup>[19]</sup>, 222 of 312 (71.15%) tested positive for various intestinal helminths<sup>[20]</sup>. The various helminth parasites included *Ascaris lumbricoides*, *Trichuris trichiura*, *Enterobius vermicularis* and *Taenia saginata*. The highest frequency of 69.23% (216/312) was noted for *Ascaris lumbricoides* followed by *Trichuris trichiura* 30.76% (96/312), *Enterobius vermicularis* 7.69% (24/312) and *Taenia saginata* 7.69% (24/312). Single infection was found in 33.65% (105/312) and mixed infection was seen in 37.5% (117/312) children. Again, Chandrasekhar MR and others in 2003<sup>[21]</sup> collected faecal samples from 1000 children below 6 years of age. Six hundred and eighty children (68.0%) were detected to have intestinal helminthic infection. The incidence of intestinal helminthiasis in urban group of children was 56.8% (284 out of 500 tested) while in rural group of children was 79.2% (396 out of 500 tested) both in rural and urban population *Ascaris lumbricoides* was the single predominant species, whereas a combination of *A. Lumbricoides* and *Trichuris trichiura* was common multiple infection. All cultures of faecal samples were positive for hook worm ova. In Pakistan, out of 200 children examined, 132 (66%) were found positive for various intestinal helminths infestation<sup>[22]</sup>. There were 6 different types of helminths found in the specimens examined.

It has become visible from the above review that the main causes for the occurrence of haemorrhage from the GI tract are strongly linked to the life style of the affected persons. Educating the public is thus expected to solve this problem. However, when the effect of health education in the control of bilharzias is assessed the results were disappointing. In 2001, Garba *et al*<sup>[23]</sup> carried out a survey on two groups of endemic villages in the Niger. In one group of villages, there were health educa-

**Table 5 Underlying conditions of gastrointestinal in 1998 and 2006 n (%)**

Underlying condition	1998	2006	Discharge percentage change (principal diagnosis)	1998	2006	Discharge percentage change (all diagnosis)

Infection	Hockworm Whipworm Stroyloidosis Ascariosis Tuberculous enterocolitis Amoebiasis Cytomegalo virus

tion campaigns but there were no education campaigns in the second group. The people in the targeted areas received information on Bilharziasis and on how to fight against it. However, 46.6% of interviewed people in the project area couldn't mention any means for controlling bilharziasis. Behaviours that favour the illness were ignored by 1/3 of interrogated people in the project area. Yet, there was an increase in knowledge about the illness in the program zone in comparison with the control area. Despite this increase in knowledge level, changes in behaviour in relation to the illness remained low. Risky be-

haviour continued in about 2/3 of interrogated people. Only 33% of persons of the project area declared having adopted at least a single good behaviour. This means that changes of behaviour may take time to have effect.

In addition, areas endemic for helminthic infestation worldwide suffer from poor economic growth, poor sanitation and lack of appropriate toilet facilities.

Multiple studies demonstrated that in endemic areas re-infection is exceedingly common and mass chemotherapy alone is insufficient to prevent the spread of these diseases<sup>[24]</sup>.

Relatively little attention has been focused on the impact of personal attitude on the development of haemorrhagic episodes from the GI tract. This review emphasizes on the importance of designing a new strategy aimed at preventing the happening of these episodes.

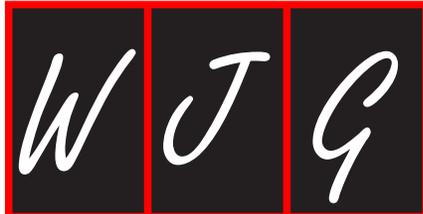

The occurrence of GI bleeding and its management are associated with significant harm; however, educating the publics through properly designed long term program and improving the general surrounding conditions are free from risk.

### Abstract

Upper gastrointestinal tract hemorrhage (UGIH) remains a common presentation requiring urgent evaluation and treatment. Accurate assessment, appropriate intervention and apt clinical skills are needed for proper management from time of presentation to discharge. The advent of pharmacologic acid suppression, endoscopic hemostatic techniques, and recognition of *Helicobacter pylori* as an etiologic agent in peptic ulcer disease (PUD) has revolutionized the treatment of UGIH. Despite this, acute UGIH still carries considerable rates of morbidity and mortality. This review aims to discuss current areas of uncertainty and controversy in the management of UGIH. Neoadjuvant proton pump inhibitor (PPI) therapy has become standard empiric treatment for UGIH given that PUD is the leading cause of non-variceal UGIH, and PPIs are extremely effective at promoting ulcer healing. However, neoadjuvant PPI administration has not been shown to affect hard clinical outcomes such as rebleeding or mortality. The optimal timing of upper endoscopy in UGIH is often debated. Upon completion of volume resuscitation and hemodynamic stabilization, upper endoscopy should be performed within 24 h in all patients

with evidence of UGIH for both diagnostic and therapeutic purposes. With rising healthcare cost paramount in today's medical landscape, the ability to appropriately triage UGIH patients is of increasing value. Upper endoscopy in conjunction with the clinical scenario allows for accurate decision making concerning early discharge home in low-risk lesions or admission for further monitoring and treatment in higher-risk lesions. Concomitant pharmacotherapy with non-steroidal anti-inflammatory drugs (NSAIDs) and antiplatelet agents, such as clopidogrel, has a major impact on the etiology, severity, and potential treatment of UGIH. Long-term PPI use in patients taking chronic NSAIDs or clopidogrel is discussed thoroughly in this review.

spread dissemination of flexible endoscopy and endoscopic hemostatic techniques have contributed to a paradigm shift in the treatment of complicated peptic ulcer disease, in particular, from predominantly surgical to predominantly endoscopic management. At the same time, an increasing proportion of patients presenting with UGIH are older or elderly patients<sup>[1]</sup>, and a significant number of patients with UGIH consume non-steroidal anti-inflammatory drugs (NSAIDs) and/or antiplatelet therapy to treat other medical comorbidities. Given the confluence of these factors, UGIH continues to have a considerable impact with respect to patient morbidity and mortality, as well as health care resource utilization. The annual incidence of UGIH has been estimated as low as 48 and as high as 165 cases per 100 000 population, and the mortality rate remains high somewhere between 7% and 14%<sup>[2-6]</sup>. UGIH accounts for > 300 000 annual hospitalizations in the United States, with an estimated cost of \$2.5 billion<sup>[3,5]</sup>. This article aims to review the management of UGIH, with an emphasis on discussion of areas of controversy or uncertainty in current practice.

## INITIAL ASSESSMENT

By definition, UGIH originates proximal to the ligament of Treitz. UGIH accounts for the preponderance of all gastrointestinal hemorrhage; estimated at 4-6 times more common than lower gastrointestinal (GI) hemorrhage<sup>[7]</sup>. Initial assessment of the pace and acuity of the bleeding episode has major bearing on the initial management of UGIH. For patients presenting with UGIH and evidence of hemodynamic compromise, the fundamental goal of initial management is adequate and appropriate volume resuscitation. Additional stratification of patients into high- and low-risk categories may be based on clinical and endoscopic criteria<sup>[8]</sup>. Predictors of poor prognosis include: age > 65 years, shock, poor overall health, comorbid conditions, low initial hemoglobin/hematocrit, active bleeding (red blood per rectum or hematemesis), sepsis, and elevated creatinine or serum transaminases<sup>[2,8,9]</sup>. Several scoring systems have been created and/or validated for this purpose, including APACHE II, Forrest Classification, Blatchford, pre-endoscopic Rockall, Baylor College, Cedars-Sinai Medical Center and Rockall indexes (Table 1 compares 6 commonly used scoring systems)<sup>[10,11]</sup>. Some of these may be cumbersome (APACHE II) or require data not immediately available based on initial clinical assessment (the Rockall Scoring System, for instance, requires endoscopic data) and therefore may be of limited utility in the acute setting<sup>[12]</sup>.

The role of nasogastric tube placement and aspirate inspection in the initial assessment of UGIH has fallen out of favor in many emergency room and acute care settings. In theory, the presence of bright red blood *via* nasogastric aspirate suggests active UGIH and should prompt urgent esophagogastroduodenoscopy (EGD)<sup>[3]</sup>. The absence of blood on nasogastric aspirate, however, does not exclude the presence of a culprit UGIH source. In a study by Aljebreen *et al*<sup>[13]</sup>, 15% of patients with UGIH and clear or bilious nasogastric aspirate were ultimately found to have an underlying high risk lesion during EGD.

## PHARMACOLOGIC THERAPY PRIOR TO ENDOSCOPY

Pharmacologic gastric acid suppression has changed the face of peptic ulcer disease (PUD) treatment, both by favoring hemostasis in the short term (platelet aggregation and clot formation are impaired at acidic gastric pH<sup>[14]</sup>), and enabling ulcer healing and remission over the longer term<sup>[3]</sup>. Proton pump inhibitors (PPIs) covalently bind to and inhibit the H-K ATPase pump of the gastric parietal cells, thus inhibiting the final common pathway of acid secretion. PPIs offer more durable and sustained acid suppression than histamine receptor antagonists, which are prone to tachyphylaxis<sup>[15]</sup>. For these reasons, PPIs have become the dominant acid suppressive therapy used in the treatment of UGIH.

An emerging area of importance is the optimal dose, route of administration, and timing of PPI therapy in patients presenting with UGIH. Administration of neoadjuvant PPI, prior to diagnostic endoscopy or endoscopic therapy, has become widespread, and this practice recommendation has been supported by consensus guidelines<sup>[2]</sup>. This approach may be particularly reasonable in instances when access to prompt EGD and/or availability of endoscopic therapeutic expertise is limited. Otherwise, however, it is uncertain whether neoadjuvant PPIs confer benefit with respect to meaningful clinical outcomes. In a controlled prospective study of patients with UGIH randomized to intravenous PPI *vs* placebo prior to endoscopy<sup>[16]</sup>, patients in the PPI arm were less likely to have active bleeding at the time of endoscopy and to require endoscopic hemostatic therapy. There was no difference in transfusion requirements, rates of rebleeding, requirement for surgery, or 30-d mortality when comparing patients receiving PPIs to those receiving placebo. A systematic meta-analysis, based on published controlled data in the medical literature, reported no benefit of neoadjuvant (pre-endoscopic) PPI therapy on rates of rebleeding, salvage surgery for failures of endoscopic hemostasis, or mortality<sup>[17]</sup>.

Adjuvant PPI therapy, administered following diagnostic and/or therapeutic EGD, has been proven effective, as well, leading to a decrease in recurrent PUD bleeding, need for blood transfusion, need for surgery, and duration of hospital stay<sup>[3,18,19]</sup>. Despite these major impacts, studies have not demonstrated an impact of PPIs on mortality due to UGIH<sup>[3,20,21]</sup>. Furthermore, whether in the neoadjuvant or adjuvant setting, the optimal dosing, route of administration, and duration of post-endoscopy PPI has not been clearly established. Current guidelines recommend the use of high-dose intravenous PPI therapy for 3 d following successful endoscopic hemostasis<sup>[2]</sup>. In many studies, high-dose PPI therapy is defined as an initial bolus (omeprazole 80 mg) followed by continuous infusion (omeprazole 8 mg/h) for up to 72 h. However, there has been limited direct comparison of this high-dose intravenous regimen in comparison to alternative regimens. Whether continuous intravenous infusion of PPIs is clearly superior to intermittent bolus dose is uncertain; similarly, whether intravenous PPIs are clearly superior to highly bioavailable oral PPIs in patients able to take oral medications is uncertain.

## TIMING OF ENDOSCOPIC EVALUATION

Endoscopic evaluation is an essential part of UGIH management. Urgent EGD has been proposed as the standard of care in patients with high-risk lesions, although the precise timing of urgent EGD has been variably defined. American Society for Gastrointestinal Endoscopy practice guidelines for the treatment of non-variceal UGIH suggest that early endoscopy (within 24 h) maximizes the impact on hospital length of stay and transfusion requirements, yet do not make formal recommendations regarding the optimal time for performing EGD within this 24-h window<sup>[22]</sup>.

In theory, the availability both of on-call physicians proficient in endoscopic hemostasis and on-call support staff with technical expertise in usage of endoscopic devices enable performance of EGD on a 24-h/7-d basis. Several studies have examined the timing of upper endoscopy and resultant impact on both patient outcomes and resource utilization. In a study by Sarin *et al*<sup>[23]</sup>, a retrospective review of > 500 patients who underwent upper endoscopy for non-variceal UGIH, the timing of endoscopy was stratified into three categories: < 6 h, 6-24 h and > 24 h. There was no significant difference in mortality or need for surgery between the < 6 h and 6-24 h groups. However, there was a difference between the two < 24 h groups and the > 24 h group. These findings were supported by a more recent retrospective review in 2007 that examined 169 patients with acute non-variceal UGIH with either systolic blood pressure < 100 mmHg or heart rate > 100 beats/min on presentation. Patients were divided into two groups: those who received endoscopy within 6 h *vs* 6-24 h. Again, there were no significant differences between the groups in any of the primary outcomes, including rebleeding, need for surgery, in-hospital mortality, or hospital readmission within 30 d<sup>[24]</sup>.

In a variation on this theme, Dorn *et al*<sup>[25]</sup> have examined the difference in clinical outcomes among patients admitted for UGIH on either a weekday or a weekend. Those admitted on a weekend had a slight but significant increase in mortality (hazard ratio of 1.09), hospital length of stay, and hospitalization cost. Although the weekend patients waited longer for EGD than their weekday counterparts, the entire effect on patient outcomes could not be accounted for by the delay in endoscopy timing alone. Further study is needed to elicit other potential causes of this weekend effect. Our practice is to perform EGD as soon as is feasible following hemodynamic resuscitation and stabilization of the patient, and within 12 h of clinical presentation.

In addition to offering hemostatic techniques to prevent continued or recurrent bleeding, a major benefit of endoscopy is the ability to risk stratify the lesion and triage patients to those who require inpatient or more intensive monitoring, *vs* those who are candidates for early hospital discharge. With respect to peptic ulcer hemorrhage, lesions at high risk for recurrent bleeding include ulcers > 2 cm, or ulcers with active bleeding, a visible vessel, or adherent clot. Such lesions warrant both endoscopic therapy, when feasible, and inpatient monitoring post-endoscopy. Conversely, clean-based ulcers or ulcers with flat pigmented spots are considered low risk and do not require endoscopic therapy<sup>[26]</sup>, and patients found to have such low-risk lesions may be candidates for early discharge, even from an emergency room setting.

Much improvement in current management of UGIH and resource allocation for treatment of UGIH could be achieved in this area. Numerous studies have shown that early endoscopy is not often followed by early discharge of appropriate low-risk patients. Bjorkman *et al*<sup>[27]</sup> have shown that EGD within 6 h of presentation to the emergency department versus 48 h did not change hospital utilization of resources, the study's primary endpoint. In

**Table 2** Areas requiring further investigation

Pharmacologic therapy prior to endoscopy	Determine optimal route and dosage of PPI in UGIH (continuous infusion <i>vs</i> intermittent IV bolus <i>vs</i> oral dosing)
Timing of endoscopic evaluation	Defining optimal timing of initial endoscopy, implementation of early discharge in low risk patients
Prokinetic agents as endoscopic adjuncts	Clearly define the role for prokinetics in UGIH with randomized controlled trials, specifically define the optimal agent, dose and timing prior to endoscopy
Long-term PPI management	Clarification of potential long-term sequelae of PPI including: osteoporosis, <i>c. difficile</i> infection and community-acquired pneumonia
PPI and thienopyridines	Consensus on the clinical importance of this interaction, a complete randomized controlled trial to support the truncated COGENT trial data
<i>H. pylori</i> and UGIH	<i>H. pylori</i> testing that allows accurate test results in the setting of acute UGIH

PPI: Proton pump inhibitor; *H. pylori*: *Helicobacter pylori*; UGIH: Upper gastrointestinal tract hemorrhage; IV: Intravenous; COGENT: Clopidogrel and the optimization of gastrointestinal events trial.

a recently published study, Chaparro *et al*<sup>[28]</sup> have formulated an early discharge algorithm using retrospective data and then examined this algorithm in a prospective cohort. Even at their institution using their algorithm, only 13/29 (45%) low-risk patients were discharged early. In view of these data, there is much room for improvement in clinical practice surrounding implementation of practice guidelines concerning early hospital discharge of low-risk UGIH patients and achieving the potential health care cost savings. Table 2 illustrates other areas in need of further investigation and improved recommendations.

## CHOICE OF ENDOSCOPIC HEMOSTATIC TECHNIQUE

Endoscopic therapies employed in the treatment of UGIH include: (1) pharmacologic therapies, including injection of epinephrine, sclerosants and even normal saline; (2) coagulation therapies, including monopolar or bipolar cautery and argon plasma coagulation; and (3) mechanical tamponade, including hemoclips and bands. Each of these therapies has demonstrated efficacy in different clinical settings. Often, the choice of which endoscopic therapy to employ is a clinical judgment based on provider preference and expertise.

Available data suggest that epinephrine injection plus a second endoscopic intervention is superior to epinephrine injection alone. Calvet *et al*<sup>[29]</sup> completed a systematic review and meta-analysis in 2004 which included 16 studies and > 1600 patients with UGIH secondary to PUD, and who underwent endoscopic therapy with epinephrine alone or epinephrine plus a second hemostatic modality. Adding an adjunct therapy reduced the rebleeding rate from 18.4% to 10.6% [odds ratio (OR): 0.53, 95% CI: 0.40-0.69], reduced the need for emergency surgery from 11.3% to 7.6% (OR: 0.64, 95% CI: 0.46-0.90), and reduced mortality from 5.1% to 2.6% (OR: 0.51, 95% CI: 0.31-0.84). Vergara *et al*<sup>[30]</sup> have confirmed these findings in a recent Cochrane review (2008). Rebleeding, need for surgical intervention, and mortality were all lower in groups receiving dual therapy. Additionally, there was no increased risk of significant complications or adverse events when dual therapy was used. In the above studies

and reviews, endoscopic therapy is usually reserved for high-risk lesions (active bleeding and visible vessels). Jensen *et al*<sup>[31]</sup> have additionally defined a role for removal of adherent clots in the treatment of PUD bleeding. In one study, removal of adherent clot and treatment with a second endoscopic intervention resulted in lower rebleeding rates when compared to not removing the adherent clot (35% *vs* 0%).

Even when endoscopy fails to provide durable and definitive hemostasis, endoscopy may provide a beneficial role in localization of the bleeding lesion to target salvage non-endoscopic intervention. Repeat endoscopy can assist both interventional radiology and/or surgery in the event that bleeding continues or recurs and alternative management is necessitated. Second-look endoscopy has also been shown to improve rebleeding rates in certain clinical situations, but without improvement in the need for surgery or mortality<sup>[3]</sup>. Current guidelines do not support routine use of second-look endoscopy.

## PROKINETIC AGENTS AS ENDOSCOPIC ADJUNCTS

The presence of retained blood in the UGI tract can limit the ability to identify definitively a bleeding source and/or deliver endoscopic hemostatic therapy. Prokinetic agents may promote UGI tract motility and facilitate gastric emptying of retained blood prior to endoscopy; however, the use of such agents may be highly physician dependent. American Society for Gastrointestinal Endoscopy guidelines<sup>[22]</sup> indicate that the use of erythromycin, when administered intravenously prior to EGD, may improve mucosal visibility. A recent meta-analysis published in *Gastrointestinal Endoscopy*<sup>[32]</sup> has shown that either erythromycin or metoclopramide given prior to endoscopy significantly reduced the need for repeat endoscopy to identify the bleeding source. However, use of a prokinetic agent led to no identifiable impact on total units of blood transfused, hospital stay, or need for surgical intervention<sup>[33]</sup>. As was germane to the discussion of pre-endoscopic PPI therapy, if there is a role of prokinetic agents in the endoscopic diagnosis and management of UGIH, the optimal agent,

dose and timing prior to endoscopy have not been defined. Metoclopramide has been assigned a “black box warning” by the United States Food and Drug Administration (FDA) due to risk of neurologic side effects, and caution should therefore be advised with use of this agent.

## LONG-TERM PPI MANAGEMENT

PPIs are recommended for 6-8 wk following UGIH and/or endoscopic treatment of PUD to allow for full mucosal healing. Several studies have shown a therapeutic benefit of PPIs in patients using NSAIDs chronically and/or patients with confirmed *H. pylori* infection<sup>[34,35]</sup>. After initial mucosal healing has been achieved, is there a benefit to long-term PPI use for secondary prophylaxis? Studies have shown that in patients who have PUD complicated by bleeding, there is a 33% risk of rebleeding in 1-2 years. Furthermore, there is a 40%-50% rebleeding risk over the subsequent 10 years following the initial episode of bleeding<sup>[13]</sup>. Randomized prospective trials have demonstrated a benefit to long-term acid-suppression therapy in two settings: chronic NSAID users and *H. pylori*-infected patients. As demonstrated in a 2001 *New England Journal of Medicine* article by Chan *et al*<sup>[34]</sup>, in patients taking NSAIDs other than acetylsalicylic acid (ASA) who were concomitantly infected with *H. pylori*, omeprazole provided added protection above bacterial eradication alone.

Although beneficial in both treatment and prevention of UGIH, PPI therapy is not without potential risks. Chronic PPI therapy has been associated with *Clostridium difficile* infection, community-acquired pneumonia, and calcium malabsorption resulting in osteoporosis and increased fracture risk<sup>[36]</sup>. These associations have originated largely from observational studies and no strong data exist to link PPI therapy directly as a causative factor in any of these outcomes. However, given these potential sequelae, long-term PPI therapy should only be used when justified by a clear medical indication<sup>[2]</sup>.

## PPIS AND THIENOPYRIDINES

Much recent attention has surrounded the concomitant use of PPIs and thienopyridines, particularly clopidogrel. This has included an FDA warning regarding combined use of these medications<sup>[36]</sup>. *In vitro* studies have suggested that omeprazole, which is metabolized predominately through the CYP2C19 isoenzyme of cytochrome P450, inhibits conversion of clopidogrel, a prodrug, to its active form, thus reducing its therapeutic margin<sup>[37]</sup>. Most of the original data were specific to omeprazole and subsequent experiments using pantoprazole, lansoprazole and esomeprazole have not shown an equal class effect<sup>[3,37,38]</sup>. Additionally, although a measurable change in platelet function occurred in patients concomitantly taking PPIs and clopidogrel, the data were mixed with regards to clinically significant cardiovascular outcomes.

Subsequent retrospective reviews and observational studies have attempted to define the true impact of PPIs on the therapeutic index of thienopyridines, but with mixed results. The French Omeprazole CLopidogrel As-

pirin study measured vasodilator-stimulated phosphoprotein phosphorylation; a measure of the inhibitory effect of clopidogrel on platelets *in vivo*. Patients taking both 75 mg ASA and 75 mg clopidogrel daily were randomized to either 20 mg omeprazole or placebo daily. One hundred and twenty-four patients were included and the results showed an 11.6% decrease in platelet inhibition by clopidogrel among those randomized to omeprazole, but no clinical outcomes were measured<sup>[38]</sup>. The TIMI Study Group at Brigham and Women’s Hospital in Boston have attempted to clarify the link between *in vitro* interactions, measures of platelet function, and clinical outcomes in patients on either of the thienopyridines and PPIs through the analysis of two trials: prasugrel in comparison to clopidogrel for inhibition of platelet activation and aggregation-TIMI 44, the primary endpoint of which was inhibition of platelet aggregation at 6 h, and trial to assess improvement in therapeutic outcomes by optimizing platelet inhibition with prasugrel-TIMI 38, with a primary composite endpoint of cardiovascular death, myocardial infarction or stroke. The first study demonstrated a reduction in the inhibitory effect of thienopyridines on platelet aggregation in patients taking PPIs after loading doses of either clopidogrel (12% decrease) or prasugrel (7.1% decrease). However, in the second trial, > 13 000 patients with acute coronary syndrome were randomized to prasugrel or clopidogrel, of which 33% of 4500 patients were on PPIs at randomization. PPI was continued without change in dosing or frequency. There was no association between PPI use and the primary endpoint, a composite cardiovascular event<sup>[39]</sup>. Additionally, when the data were assessed by specific PPI (omeprazole, lansoprazole, pantoprazole or esomeprazole), there was no correlation.

Most recently, the only prospective randomized controlled trial to address this important clinical question, the Clopidogrel and the optimization of gastrointestinal events trial (COGENT) Trial, was published in the *New England Journal of Medicine*. COGENT randomized patients with an indication for dual antiplatelet therapy to clopidogrel 75 mg plus omeprazole 20 mg daily or clopidogrel alone. In addition, every patient was given either 81 or 325 mg enteric coated aspirin. The primary cardiovascular endpoint was a composite of death from cardiovascular causes, non-fatal myocardial infarction, revascularization, or stroke. Over 3700 patients were included in the final analysis of events at 180 d after randomization. There were 109 cardiovascular events; 4.9% in the clopidogrel plus omeprazole arm, and 5.7% in the clopidogrel plus placebo arm (HR: 0.99; 95% CI: 0.68-1.44). The primary gastrointestinal endpoint was a composite of overt or occult bleeding, symptomatic gastroduodenal ulcers or erosions, obstruction or perforation. There were 51 gastrointestinal events; 1.1% in the clopidogrel plus omeprazole group, and 2.9% in the clopidogrel plus placebo arm (HR: 0.13; 95% CI: 0.03-0.56)<sup>[40]</sup>. These data suggest no association between omeprazole and clinically meaningful adverse cardiovascular outcomes when used in conjunction with clopidogrel. However, there was a significant reduction in adverse gastrointestinal events in patients receiving omeprazole. A significant limitation of this study

was premature study termination due to loss of funding, thereby attenuating the statistical power of the study.

The ambiguity of this matter is further demonstrated in the following consensus statements. The American College of Cardiology Foundation/American College of Gastroenterology (ACG)/American Heart Association (AHA) joint guidelines released in 2008 state, "In the interest of patient safety, the AHA/ACC and the ACG advise that patients who are currently taking these medications should not change their medication regimen unless advised by their healthcare provider". A revised joint statement was released in December 2010 stating, "Pharmacokinetic and pharmacodynamic studies, using platelet assays as surrogate endpoints, suggest that concomitant use of clopidogrel and a PPI reduces the antiplatelet effects of clopidogrel. The strongest evidence for an interaction is between omeprazole and clopidogrel. It is not established that changes in these surrogate endpoints translate into clinically meaningful differences. Observational studies and a single randomized clinical trial have shown inconsistent effects on (cardiovascular) outcomes of concomitant use of thienopyridines and PPIs. A clinically important interaction cannot be excluded, particularly in certain subgroups, such as poor metabolizers of clopidogrel. The roles of either pharmacogenomic testing or platelet function testing in managing therapy with thienopyridines and PPIs has not yet been established"<sup>[41]</sup>.

## NON-ACID DIRECTED PHARMACOLOGIC THERAPY

The role of *H. pylori* in PUD has been clearly elucidated over the years, beginning with Marshall and Warren's pioneering work. Since that time, many studies have demonstrated the beneficial effects of *H. pylori* eradication in the treatment of PUD. In a 1997 *Lancet* study, Chan *et al.*<sup>[34]</sup> reported that clearance of *H. pylori* in patients taking naproxen for 8 wk, irrespective of PPI use, significantly reduced the presence of PUD at time of repeat endoscopy: 26% *vs* 7%. Current guidelines support the test and treatment mantra for *H. pylori* in the setting of UGIH<sup>[2]</sup>. However, the appropriate timing of *H. pylori* testing is unclear given the potential for false-negative test results in the setting of UGIH and false negative results due to PPI use. In a 2001 study by Griño *et al.*<sup>[42]</sup>, 78 patients with endoscopically documented UGIH secondary to PUD underwent diagnostic testing for *H. pylori* in the acute setting by one of four modalities: histology, rapid urease test, urea breath test and serology. The sensitivity/specificity for each respective diagnostic test was as follows: 48.5/100 for the rapid urease test, 91/77.8 for the breath test, 89.5/80 for serology and 86.3/100 for histology. Additional support for questioning immediate *H. Pylori* test results was provided by Guell *et al.*<sup>[43]</sup>, who have reported a 79% false-negative rate with rapid urease testing and a maximum sensitivity of only 86% if both a rapid urease test and histological examination were performed on each biopsy specimen. Based on these data, a recommendation to retest at a later date all patients with negative immediate *H. pylori* test in the setting of acute UGIH may be reasonable<sup>[42,44]</sup>.

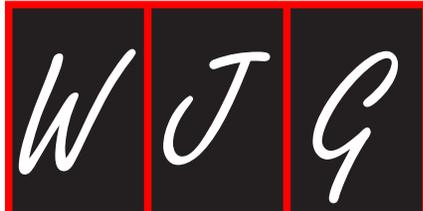

## CONCLUSION

UGIH requires early and accurate assessment, triage and resuscitation, in addition to well-coordinated care between generalist and sub-specialist to maximize patient outcomes. All patients with UGIH need upper endoscopy within 24 h of presentation to characterize further and potentially treat the bleeding source. Epinephrine plus a second modality of endoscopic therapy has proven superior to epinephrine alone. *H. Pylori* infection should be confirmed and treated when present. Negative *H. pylori* test in the acute setting should be followed by repeat testing to avoid false-negative results and minimize the risk of recurrent bleeding. Appropriate duration of PPI therapy is of critical importance to allow mucosal healing and to prevent rebleeding in the high-risk patient. Current data do not support a meaningful clinical interaction between PPIs and thienopyridines. Future clinical and research attention to the issues addressed in this review may serve to resolve current areas of uncertainty and controversy, and optimize clinical outcomes for patients presenting with UGIH.

### Abstract

Portal hypertension is the main complication of cirrhosis and is defined as an hepatic venous pressure gradient (HVPG) of more than 5 mmHg. Clinically significant portal hypertension is defined as HVPG of 10 mmHg or more. Development of gastroesophageal varices and variceal hemorrhage are the most direct consequence of portal hypertension. Over the last decades significant advancements in the field have led to standard treatment options. These clinical recommendations have evolved mostly as a result of randomized controlled trials and consensus conferences among experts where existing evidence has been reviewed and future goals for research and practice guidelines have been proposed. Management of varices/variceal hemorrhage is based on the clinical stage of portal hypertension. No specific treatment has shown to prevent the formation of varices. Prevention of first variceal hemorrhage depends on the size/characteristics of varices. In patients with small varices and high risk of bleeding, non-selective  $\beta$ -blockers are recommended, while patients with medium/large varices can be treated with either  $\beta$ -blockers or esophageal band ligation. Standard of

care for acute variceal hemorrhage consists of vasoactive drugs, endoscopic band ligation and antibiotics prophylaxis. Transjugular intrahepatic portosystemic shunt (TIPS) is reserved for those who fail standard of care or for patients who are likely to fail ("early TIPS"). Prevention of recurrent variceal hemorrhage consists of the combination of  $\beta$ -blockers and endoscopic band ligation.

### INTRODUCTION

Portal hypertension is the increase in porto-systemic pressure gradient in any portion of the portal venous system. Although portal hypertension could result from pre-hepatic abnormalities (e.g., portal or splenic vein thrombosis), post-hepatic abnormalities (e.g., Budd-Chiari syndrome) or intrahepatic non-cirrhotic causes (e.g., schistosomiasis, sinusoidal obstruction syndrome), cirrhosis is by far the most common cause of portal hypertension and, as such, has been the most widely investigated. In cirrhosis, the portosystemic gradient is assessed by measuring the wedged hepatic venous pressure (a measure of sinusoidal hepatic pressure) and subtracting the free hepatic venous pressure (systemic pressure) thus obtaining the hepatic

venous pressure gradient (HVPG). A normal HVPG is 3-5 mmHg. An HVPG above 5 mmHg defines portal hypertension, however an HVPG of 10 mmHg or greater defines clinically significant portal hypertension as this pressure gradient predicts clinical course in patients with cirrhosis including development of varices<sup>[1]</sup>, clinical decompensation (i.e., development of ascites, variceal hemorrhage and encephalopathy)<sup>[2]</sup>, decompensation or death after liver resection<sup>[3]</sup>, and hepatocellular carcinoma<sup>[4]</sup>.

The complications that most directly result from portal hypertension are the development of varices and variceal hemorrhage. This review summarizes the current standard management for varices and variceal hemorrhage in the context of cirrhotic portal hypertension.

Over the last decades, research on animal models and clinical trials have evolved and have led to our current management recommendations. The field has moved forward in large part through consensus conference among experts where events and endpoints have been defined and the existing evidence has been carefully reviewed leading to practice recommendations. The first such conference took place in 1986 in Groningen, the Netherlands and since then consensus conferences have been alternating between Europe (Baveno conference) and the United States [American association for the study of liver diseases (AASLD) or AASLD single topic conference (STC)], and are briefly summarized below (Table 1).

## HISTORY OF CONSENSUS CONFERENCES ON PORTAL HYPERTENSION

Baveno is a small town in Northern Italy located on the west shore of Lake Maggiore. It has become the epicenter of the portal hypertension consensus workshops aimed to reach a consensus on the definitions of key events related to portal hypertension and variceal bleeding and to provide guidelines for future research as well as reviewing the evidence, eventually leading to clinical practice guidelines. The first Baveno consensus workshop was held in April 1990<sup>[5]</sup> in which significant advances in diagnosis and management of varices and variceal bleeding including vasoactive drugs and endoscopic sclerotherapy were reviewed. In addition to defining certain terms including size of varices, clinically significant bleeding and rebleeding; this workshop also provided recommendations on diagnostic modalities, imaging and directions for future clinical trials. The therapeutic recommendations included  $\beta$ -blockers for primary prophylaxis of large varices, sclerotherapy and vasoactive drugs for acute hemorrhage and endoscopic sclerotherapy,  $\beta$ -blockers or surgical shunt to prevent recurrent hemorrhage.

The Baveno II workshop was held in April 1995<sup>[6]</sup>. Definitions of key clinical events were revised and new definitions were proposed. Based on multiple randomized controlled trials, non-selective  $\beta$ -blockers (NSBB) were recommended to be the treatment of choice for primary prophylaxis of variceal hemorrhage, while isosorbide-5 mononitrate (ISMN) was recommended in patients who

did not tolerate  $\beta$ -blockers. Endoscopic sclerotherapy was not recommended in the prevention of first hemorrhage. Treatment of acute hemorrhage was mainly based on endoscopic therapy, terlipressin was deemed the most effective of the vasoactive agents, with somatostatin showing some efficacy. The transjugular intrahepatic portosystemic shunt (TIPS) was recommended in case of treatment failure of endoscopic and pharmacologic therapy. The recommendations to prevent recurrent hemorrhage included  $\beta$ -blockers or endoscopic variceal ligation (EVL) that had been shown to be better than sclerotherapy<sup>[7]</sup>. TIPS and surgical shunts were to be used only for patients with frequent repeated episodes of variceal hemorrhage.

In June 1996, the AASLD STC took place in Reston, Virginia, United States, with the objective of identifying important areas in the treatment of variceal hemorrhage and future research<sup>[8]</sup>. Guidelines for initial variceal screening and follow-up endoscopy were described in detail depending on severity of liver disease and the size of varices on first endoscopy. Areas of further research were identified as the role of sequential portal pressure measurements and their timing, and defining new predictors of first hemorrhage. Primary prophylaxis recommendations were the same as in the Baveno II conference, with  $\beta$ -blockers as the mainstay of treatment and EVL requiring further studies. Vasoactive drugs in combination with endoscopic treatment (sclerotherapy or EVL) became the established treatment for acute hemorrhage, recognizing the advantage of initiating vasoactive therapy prior to diagnostic endoscopy<sup>[9]</sup>. For secondary prophylaxis EVL or  $\beta$ -blockers were recommended. TIPS or surgical shunts were considered acceptable therapies for failure to control acute hemorrhage or recurrent hemorrhage despite standard treatments.

The Baveno III conference was held in April 2000<sup>[10]</sup>, and introduced the concept of clinically significant portal hypertension (CSPH) which was defined as HVPG of 10 mmHg or more. The presence of varices, variceal hemorrhage or ascites is indicative of the presence of CSPH. Non-selective  $\beta$ -blockers remained the treatment of choice to prevent first hemorrhage from large/medium varices, while EVL required further assessment. The goals of therapy with  $\beta$ -blockers were defined (25% reduction in baseline heart rate or a heart rate of 55 beats/min). ISMN, previously recommended as an alternative to  $\beta$ -blockers, was no longer recommended<sup>[11]</sup>. For treatment of acute hemorrhage, the early administration of vasoactive drugs and continued use for up to 5 d along with endoscopic therapy (EVL or sclerotherapy) were considered standard. Additional measures included use of antibiotics to prevent bacterial infection<sup>[12]</sup>, and lactulose to treat hepatic encephalopathy. With regard to prevention of rebleeding,  $\beta$ -blockers were considered first-line therapy<sup>[13]</sup> as was EVL, with TIPS reserved for treatment failures. The complications of treatment of portal hypertension were also defined for use in clinical settings and in research trials.

The Baveno IV conference was held in April 2005<sup>[14]</sup>, and some of the key criteria (failure to control bleeding,

Table 1 Portal hypertension consensus conferences in the last two decades

AASLD: American association for the study of liver diseases.

failure of secondary prophylaxis) were revised. For primary prophylaxis,  $\beta$ -blockers remained the treatment of choice but endoscopic band ligation emerged as an excellent alternative for patients with medium or large varices, and contraindications or intolerance to  $\beta$ -blockers<sup>[15,16]</sup>. Isosorbide mononitrate as a single agent therapy was not recommended even in a combination of pharmacological therapies<sup>[17]</sup>. Primary prophylaxis of small varices could only be considered if they were high risk (red wale sign or Child C)<sup>[18]</sup>. There was no significant change in the recommendations of acute variceal hemorrhage from Baveno III. Small changes included the use of vasoactive drugs for at least 5 d, and the use of balloon tamponade only in massive bleeding as a temporary bridge until definitive treatment could be instituted. EVL was declared superior to sclerotherapy and as the endoscopic procedure of choice in the control of acute hemorrhage<sup>[16,19]</sup>. Secondary prophylaxis should be initiated 6 d after the index variceal bleed, and included the combination of EVL and  $\beta$ -blockers<sup>[20,21]</sup>. TIPS or surgical shunts were reserved for patients with failure of secondary prophylaxis.

The second AASLD STC was held in 2007 in Atlanta, Georgia<sup>[22]</sup>. The objective of this conference was to make clinical recommendations in areas that did not require further investigation and to identify research directions for the remaining areas. Compensated and decompensated cirrhosis were identified as separate entities to be studied separately both in clinical practice and in research<sup>[23]</sup>. The main differences compared with Baveno IV included the emergence of capsule endoscopy as a non-invasive alternative to esophagogastroduodenoscopy (EGD) for assessment of varices, a firm recommendation regarding use of  $\beta$ -blockers for primary prophylaxis of small varices with high-risk features, and consideration of  $\beta$ -blockers for small varices and no high-risk features<sup>[24]</sup>. EVL was considered as effective and safe as  $\beta$ -blockers for primary prophylaxis of medium to large sized varices. Early TIPS emerged as an option in patients at high risk of rebleeding<sup>[25]</sup>, but required further investigation.

The Baveno V conference in May 2010 revised the definitions of failure to control variceal bleeding, and fail-

ure of secondary prophylaxis<sup>[26]</sup>. Primary prophylaxis for small varices was the same as recommended in the 2007 AASLD STC. There was no significant change in the recommendations for primary prophylaxis of medium to large varices ( $\beta$ -blockers or EVL) with the choice of therapy dictated by local resources, expertise and patient preference<sup>[27]</sup>. The recommendations on the treatment of acute variceal bleeding were unchanged except that a stronger recommendation was made to consider early TIPS (within 72 h) in patients with high risk of treatment failure<sup>[28]</sup>. Recommendations for the prevention of recurrent hemorrhage, as in the AASLD STC, consisted of the combination of  $\beta$ -blockers and EVL.

Evidence-based guidelines endorsed by the AASLD<sup>[29]</sup> and the American College of Gastroenterology<sup>[30]</sup> as well as a recent comprehensive review<sup>[31]</sup> on the treatment of portal hypertension have been heavily based on these consensus conferences. These guidelines and review form the bases of the current recommendations that are described in the following section in which the advantages (pros) and disadvantages (cons) of these therapies are also discussed.

## CURRENT STANDARD TREATMENT OF PORTAL HYPERTENSION IN ADULTS

Therapy of varices and variceal hemorrhage in the adult patient with cirrhosis needs to be stratified depending on the different clinical stages in the natural history of portal hypertension: (1) the patient with cirrhosis and portal hypertension who has not yet developed varices and in whom the goal is to prevent the formation of varices (pre-primary prophylaxis); (2) the patient with gastroesophageal varices who has never had bleeding from them, and in whom the goal is to prevent their rupture (primary prophylaxis); (3) the patient with acute variceal hemorrhage in whom the goal is to stop the hemorrhage and prevent its early recurrence; and (4) the patient who has survived an episode of acute variceal hemorrhage, in whom the goal of therapy is to prevent late recurrence of hemorrhage (secondary prophylaxis).

### **Prevention of formation of varices (pre-primary prophylaxis)**

Every patient with a new diagnosis of cirrhosis should have an EGD to look for the presence and size of varices. In patients who do not have gastroesophageal varices, a large multicenter, randomized, controlled trial showed no differences between placebo and  $\beta$ -blockers in the prevention of varices<sup>[1]</sup>. Therefore, no specific treatment for portal hypertension is recommended in this setting. The main focus at this stage is to treat the underlying cause of cirrhosis which will reduce portal hypertension and may therefore prevent the development of clinical complications.

### **Prevention of first variceal hemorrhage (primary prophylaxis)**

First variceal hemorrhage occurs at an annual rate of about 15% and although current mortality from an episode of variceal hemorrhage is lower than in the past two decades, it still carries a significant mortality of 7%-15%<sup>[32-34]</sup>, and is still associated with significant morbidity and healthcare costs. Prevention of first hemorrhage, therefore, is an important part of treatment of portal hypertension. The size of varices, red wale signs on varices (visualized on EGD), and severity of liver disease (Child class C) identify the patients with highest risk of variceal hemorrhage<sup>[18]</sup>. Therefore, within this stage, patients need to be stratified by the risk of hemorrhage into (1) high-risk patients, i.e., those with medium/large varices or those with small varices that have red wale signs, or a Child C patient; and (2) low risk patients, i.e., those with small varices without red wale signs or occurring in a Child A or B patient.

In patients with medium/large varices, quality trials have shown that non-selective  $\beta$ -blockers (propranolol, nadolol) are as effective as EVL in preventing first variceal hemorrhage<sup>[35,36]</sup>, and the recommendation is to use therapy based on local resources, expertise and patient preference.

In patients with high-risk small varices the mainstay of treatment is NSBB because technically performing EVL in these varices may be challenging (although there is no clear evidence for this).

In patients with low-risk small varices, there is limited evidence that shows that their growth may be slowed by the use of NSBB<sup>[24]</sup>. Therefore, the use of NSBB in this setting is considered optional and should be discussed with the patient.

The doses are shown in Table 2, with therapeutic goals and follow-up procedures for each of the recommended therapies.

### **Pros**

NSBB decrease portal pressure through a reduction in portal blood flow. Their mechanism of action involves decreasing cardiac output *via*  $\beta$ -1 receptors and causing splanchnic vasoconstriction by blocking  $\beta$ -2 receptors, resulting in unopposed  $\alpha$ -1 activity. The latter is the most

important effect and therefore it is essential that NSBB (as opposed to selective  $\beta$ -blockers) be used. Advantages of NSBB include low cost, ease of administration and no requirement for specific expertise. As they act by decreasing portal pressure, NSBB may also reduce other complications of cirrhosis such as bleeding from portal gastropathy, ascites and spontaneous bacterial peritonitis<sup>[37,38]</sup>. In fact, a significant reduction in portal pressure has been related to an improvement in survival<sup>[38,39]</sup>. Additionally, once the patient is on NSBB there is no need for repeat EGD.

EVL has the advantage that the procedure can be done at the same time as screening endoscopy, although in some centers a screening EGD time slot will not allow for the performance of EVL, and a separate therapeutic EGD time slot is required. Also, there are relatively few contraindications to EVL and it has been associated with a lower incidence of side-effects compared with NSBB<sup>[15]</sup>.

### **Cons**

The main inconvenience of NSBB is that approximately 15% of patients may have absolute or relative contraindications to therapy, and that another 15% require dose-reduction or discontinuation due to its common side-effects (e.g., fatigue, weakness, shortness of breath) that resolve upon discontinuation but discourage patients from using these drugs<sup>[27]</sup>.

EVL requires specific expertise. The risks include that of the endoscopic procedure and conscious sedation (bleeding, aspiration, perforation and reaction to medications), plus the risk of bleeding from ligation-induced ulcers. In fact, although the quantity of side-effects is greater with NSBB than with EVL<sup>[15]</sup>, the severity of side-effects is greater with EVL. While no lethal side-effects have been reported with the use of NSBB<sup>[16]</sup>, three deaths resulting from EVL-induced bleeding ulcers have been reported<sup>[15,16]</sup>.

### **Recommendation**

The issue of which is the best treatment for primary prophylaxis (NSBB or EVL) has not yet been settled, and there are centers that perform predominantly EVL while others prefer the more rational approach of starting with NSBB and switching to EVL if there is intolerance to NSBB. Carvedilol is a NSBB with an added vasodilatory effect through anti- $\alpha$ -1 adrenergic activity that has recently been shown to be more effective than EVL in preventing first variceal hemorrhage<sup>[40]</sup>. Although considered a promising alternative, further research is necessary before it can be widely recommended.

## **MANAGEMENT OF ACUTE VARICEAL HEMORRHAGE**

Acute variceal hemorrhage is a medical emergency requiring intensive care. The basic medical principles of airway, breathing and circulation are followed to achieve hemodynamic stability. Blood transfusion is done conservative-

Table 2 Primary prophylaxis and secondary prophylaxis of variceal hemorrhage

Therapy	Starting dose	Therapy goals	Maintenance/follow-up
Propranolol	(1) 20 mg orally twice a day; (2) Adjust every 2-3 d until treatment goal is achieved; (3) Maximal daily dose should not exceed 320 mg	(1) Maximum tolerated dose; (2) Aim for resting heart rate of 50-55 beats per minute	(1) At every outpatient visit make sure that patient is appropriately $\beta$ -blocked; (2) Continue indefinitely; (3) No need for follow-up EGD
Nadolol	(1) 40 mg orally once a day; (2) Adjust every 2-3 d until treatment goal is achieved; (3) Maximal daily dose should not exceed 160 mg	As for propranolol	As for propranolol
EVL	Every 2-4 wk until the obliteration of varices	Obliteration of varices; Eradication of new varices following initial obliteration	First EGD performed 1-3 mo after obliteration and every 6-12 mo thereafter
Propranolol	(1) 20 mg orally twice a day; (2) Adjust every 2-3 d until treatment goal is achieved; (3) Maximal daily dose should not exceed 320 mg	(1) Maximum tolerated dose; (2) Aim for resting heart rate of 50-55 beats per minute	(1) At every outpatient visit make sure that patient is appropriately $\beta$ -blocked; (2) Continue indefinitely
Nadolol	(1) 40 mg orally once a day; (2) Adjust every 2-3 d until treatment goal is achieved; (3) Maximal daily dose should not exceed 160 mg	As for propranolol	As for propranolol
ISMN	(1) Only to be used in conjunction with propranolol or nadolol; (2) 10 mg orally at night every day; (3) Adjust every 2-3 d by adding 10 mg in am and then pm; (4) Maximal dose is 20 mg twice a day	(1) Maximal tolerated dose; (2) Systolic blood pressure remains over 95 mmHg	Continue indefinitely
EVL	Every 2-4 wk until the obliteration of varices	Obliteration of varices; Eradication of new varices following initial obliteration	First EGD performed 1-3 mo after obliteration and every 6-12 mo thereafter

Either one of the three therapies shown in the table are recommended. EGD: Esophagogastroduodenoscopy; EVL: Endoscopic variceal ligation; ISMN: Isosorbide-5-mononitrate.

ly for a target hemoglobin level between 7-8 g/dL<sup>[41]</sup>, because excessive blood volume restitution can increase portal pressure<sup>[42,43]</sup>. There are no definite recommendations on management of coagulopathy and thrombocytopenia, as randomized controlled trials of recombinant factor VIIa have not shown any advantages<sup>[44,45]</sup>. Antibiotic prophylaxis is provided by quinolones with consideration of iv ceftriaxone in patients with advanced cirrhosis or previous therapy with quinolones<sup>[12,46]</sup>. Safe vasoactive drugs are started as soon as possible, prior to diagnostic endoscopy. Endoscopy is done as soon as possible and not more than 12 h after presentation. If a variceal source is confirmed, EVL is the procedure of choice, but sclerotherapy is an option when EVL is technically difficult. TIPS is recommended in patients who fail standard combination therapy with endoscopic and pharmacological therapy, however salvage TIPS is accompanied by a very high mortality. Predictors of failure are Child class C, HVPG > 20 mmHg and active bleeding at endoscopy<sup>[47]</sup>. The use of early (pre-emptive) TIPS (within about 48 h of admission) in patients at high risk of failing standard therapy has been shown to reduce mortality<sup>[28]</sup>. These patients are specifically those who are Child C (score of 10-13 points) or are Child B with active hemorrhage (at the time of diagnostic endoscopy), and constitute < 20% of the patients admitted for variceal hemorrhage. In these patients it is recommended to consider early preemptive TIPS. All others should continue standard therapy with vasoactive drugs continued for 2-5 d depending on control of bleeding and severity of liver disease. Vasoactive drugs can be discontinued once the patient has been free of bleeding for at least 24 h. Balloon tamponade is

only used as a temporary measure (inflated for 12 h or less) to control bleeding while a definitive therapy (TIPS or endoscopic therapy) is planned. A new self-expanding esophageal stent is being tested that may replace balloon tamponade<sup>[48]</sup>.

Although there are pros and cons for each of these first-line therapies (pharmacological and endoscopic), the current recommendation is to use them jointly in the control of acute hemorrhage.

### Pros

Vasoactive agents improve the control of variceal hemorrhage when combined with endoscopic therapy and when compared to endoscopic therapy alone<sup>[49]</sup>. However there appears to be no significant difference among the different vasoactive agents regarding control of hemorrhage and early rebleeding. Vasopressin, a powerful vasoconstrictor, is associated with more adverse events<sup>[50]</sup>, and should not be considered a first-line vasoactive drug. Terlipressin is the only agent that, in small studies and when compared to no treatment, improved survival<sup>[50]</sup>. In practice, the choice of pharmacological agent is usually based on availability and cost. Octreotide, a somatostatin analogue, is the only safe vasoactive drug available in the United States. Doses and schedules for the different vasoconstrictors are shown in Table 3. Except for vasopressin that must be administered with nitroglycerin, the administration of these agents does not require any special procedure or expertise and can be started in the emergency room setting.

Endoscopic therapy in the acute setting is very effective in controlling variceal hemorrhage, particularly when

Table 3 Vasoactive agents used in the management of acute hemorrhage

Drug	Standard dosing	Duration	Mechanism of action
Somatostatin	Initial iv bolus 250 µg (can be repeated in the first hour if ongoing bleeding); continuous iv infusion of 250 to 500 µg/h	Up to 5 d	Inhibits vasodilator hormones like glucagon causing splanchnic vasoconstriction and reduced portal blood flow
Octreotide (somatostatin analogue)	Initial iv bolus of 50 µg (can be repeated in first hour if ongoing bleeding); continuous iv infusion of 50 µg/h	Up to 5 d	Same as somatostatin, longer duration of action
Vapreotide (somatostatin analogue)	Bolus: 50 µg; continuous iv infusion of 50 µg/h	Up to 5 d	Similar to somatostatin with higher metabolic stability
Vasopressin + nitroglycerine	0.2-0.4 units/min continuous iv infusion intravenously, may titrate to a maximum of 0.8 units/min; always use in combination with nitroglycerine	Maximum of 24 h at lowest effective dose	Causes direct vasoconstriction on splanchnic circulation resulting in decreased portal blood flow
Terlipressin (vasopressin analogue)	Initial 48 h: 2 mg iv every 4 h until control of bleeding; maintenance: 1 mg iv every 4 h to prevent re-bleeding	Up to 5 d	Splanchnic vasoconstriction; the active metabolite lysine-vasopressin is gradually released over several hours thus decreasing typical vasopressin side effects

a spurting varix is observed. However, in a meta-analysis comparing sclerotherapy *vs* vasoactive drugs, no differences in efficacy were observed between treatments, with more side-effects with sclerotherapy<sup>[51]</sup>. EVL has replaced sclerotherapy as the endoscopic procedure of choice due to more effective control of bleeding, obliteration of varices in fewer treatment sessions, a lower rebleeding rate, and lower mortality<sup>[19,33]</sup>. How EVL compares with vasoactive drugs alone remains to be determined. There is no added benefit of a combination of EVL and sclerotherapy over band ligation alone.

### Cons

Vasoactive drugs often require placement of central lines and require close monitoring for ischemic complications. Vasopressin is the most potent vasoconstrictor, but its use is limited by multiple side-effects related to splanchnic vasoconstriction (e.g., bowel ischemia) and systemic vasoconstriction (e.g., hypertension, myocardial ischemia). Terlipressin is an analogue of vasopressin that, although safer, is still accompanied by more side-effects than somatostatin<sup>[52]</sup>. The main side effects of the somatostatin analogs octreotide and vapreotide are sinus bradycardia, hypertension, arrhythmia, and abdominal pain.

Endoscopic therapy during acute hemorrhage carries the usual risks of endoscopic procedures, with increased risk of aspiration due to active bleeding and the emergency nature of the procedure. In the setting of active hemorrhage, the band ligator limits the visibility, and it becomes technically difficult to maneuver the endoscope back into the stomach. Elastic bands can slip or can cause ulcers that can result in rebleeding. As mentioned previously, EVL has less side-effects than sclerotherapy and is the endoscopic therapy of choice.

### Recommendation

The specific treatment of choice for acute variceal hemorrhage is the combination of vasoactive drugs (started prior to EGD) and emergency endoscopic therapy (at the time of initial diagnostic EGD). The pharmacological therapy of choice is terlipressin (lower mortality in small placebo-controlled studies) or somatostatin (fewer side-

effects), however the choice is dependent on availability and cost. Octreotide is the only vasoactive drug available in the United States. The endoscopic therapy of choice is EVL.

Recommendations may vary depending on the severity of liver disease. In patients who are Child C (or Child B with active hemorrhage), the risk of failing recommended treatment (vasoactive drugs and EVL) is high and therefore proceeding to a “rescue” therapy (i.e., TIPS) before failure occurs should be considered. In patients who are Child A, mortality with the treatment of choice is essentially nil<sup>[32,34]</sup>, and these patients may respond to vasoactive therapy alone, although this requires further exploration.

## PREVENTION OF RECURRENT VARICEAL HEMORRHAGE (SECONDARY PROPHYLAXIS)

The risk of rebleeding in patients who survive an episode of variceal hemorrhage is high (median rebleeding rate 60%), with a mortality of up to 33%. Prevention of rebleeding is therefore an essential part of the management of the patient with variceal hemorrhage. Patients who had a TIPS performed during the acute episode do not require specific therapy for portal hypertension or for varices but should be referred for transplant evaluation. TIPS patency should be checked through Doppler ultrasound every 6 mo. For the majority (patients who do not have a TIPS performed during the acute episode), secondary prophylaxis with NSBB should be started as soon as the intravenous vasoactive drug is discontinued. NSBB significantly reduce the risk of recurrent hemorrhage<sup>[13]</sup>. Although the addition of ISMN to NSBB has a greater portal pressure-reducing effect<sup>[53]</sup>, in clinical trials the combination of NSBB and ISMN is no different from NSBB alone regarding the rate of overall rebleeding or mortality, but has a higher rate of side-effects<sup>[54]</sup>. Sclerotherapy decreases rebleeding rates and mortality, but is associated with serious complications (e.g., esophageal strictures, bleeding from ulcers). Sclerotherapy has been replaced by EVL, since it has significantly better outcomes

(rebleeding, mortality and side-effects) compared with sclerotherapy. Studies comparing pharmacological therapy (NSBB plus ISMN) *vs* EVL show no differences in recurrent hemorrhage, but there is a suggestion of a beneficial effect on survival with pharmacological therapy in the long term<sup>[54,55]</sup>. The combination of pharmacological (NSBB alone or NSBB + ISMN) plus EVL is associated with lower rebleeding rates than either therapy alone<sup>[51,56]</sup>, and constitutes the treatment of choice.

In patients who experience recurrent variceal hemorrhage despite the combination of pharmacologic and endoscopic treatment, TIPS with polytetrafluoroethylene-covered stents<sup>[57]</sup> or, where expertise is available, surgical shunts<sup>[58]</sup> should be provided.

Table 2 presents the doses, therapeutic goals and follow-up procedures for the recommended therapies. The pros and cons of each of these first-line therapies (pharmacological and endoscopic) are the same as those described for primary prophylaxis, with some additional considerations described below.

### Pros

Pharmacologic agents provide protection against rebleeding during the initial phase after index hemorrhage while esophageal varices are being obliterated by EVL. NSBB alone or in combination with ISMN should be used. The choice will depend on patient tolerability. Patients who are not candidates for EVL should receive combination NSBB + ISMN.

The lowest rates of recurrent variceal hemorrhage (approximately 10%) are observed in individuals who have a hemodynamic response to pharmacologic therapy, defined as a decrease in HVPG to < 12 mmHg or a decrease of > 20% from baseline levels<sup>[39,59]</sup>. The more rational approach would thus be to guide therapy based on hemodynamic response and, in those who achieve a hemodynamic response, endoscopic therapy would not be necessary. However there are cons (see below) to this approach.

Patients who are intolerant or have contraindications to pharmacological therapy should receive EVL alone.

### Cons

A recent study suggests that NSBB are associated with a poorer survival in patients with refractory ascites<sup>[60]</sup>, a condition that may be present in patients in this clinical stage. However, the study is retrospective and the groups were disparate at baseline, with patients on NSBB having more advanced disease as shown by a higher prevalence of varices and variceal hemorrhage, and there is evidence that indicates the contrary, that is, that NSBB may be beneficial for these patients<sup>[13,61]</sup>. Therefore, unless stronger evidence arises, the use of NSBB in patients with refractory ascites should not be contraindicated.

The combination of NSBB + ISMN has a higher incidence of side effects because of the added ones associated with ISMN, specifically headache and lightheadedness. As mentioned above, the lowest rebleeding rates are in patients who experience a hemodynamic response. Although

HVPG-guided therapy would appear rational, a small trial showed that outcomes with HVPG-guided therapy are no different from those in patients treated with combined pharmacological and endoscopic therapy<sup>[62]</sup>. Until the best treatment for non-responders is settled, larger clinical trials are performed, and HVPG measurements are standardized across centers, HVPG-guided therapy cannot be currently recommended<sup>[63]</sup>.

As mentioned above, EVL is associated with bleeding from EVL-induced ulcers. Treatment with proton pump inhibitors post ligation reduces the size of these ulcers, with a trend towards a lower risk of bleeding<sup>[64]</sup>, and can be considered in this setting.

### Recommendation

The treatment of choice to prevent rebleeding is the combination of pharmacological therapy (NSBB ± ISMN) and EVL. Contrary to other clinical stages, risk stratification has not been tested in this setting. The main predictor of recurrent bleeding and death is the Child classification. It is conceivable that patients who are Child A would only require one or other therapy, while patients who have more advanced disease require the combination therapy. Patients who fail this therapy should be considered for TIPS placement and, in centers where expertise is available, for a surgical shunt. Patients with recurrent variceal hemorrhage are in a category of “further decompensation” of cirrhosis and, as such, should be evaluated for liver transplantation.

## CURRENT STANDARD TREATMENT OF PORTAL HYPERTENSION IN CHILDREN

The most common causes of portal hypertension in children are biliary atresia and portal vein thrombosis. Data regarding the prevalence of esophageal varices in children with portal hypertension is very limited and to date there have been no randomized controlled trials comparing different treatments for primary and secondary prophylaxis<sup>[65]</sup>.

Regarding primary prophylaxis, there is currently no recommended treatment<sup>[22,66]</sup>. In a recent gathering of experts at the AASLD annual meeting, it was concluded that, before a randomized trial could be performed in children, pediatric research should focus on addressing questions of the natural history and diagnosis of varices, prediction of variceal bleeding, optimal approaches to β-blocker and ligation therapy, and alternative study designs to explore therapeutic efficacy in children<sup>[65]</sup>.

Regarding acute variceal hemorrhage, management in children is based on limited data comparing EVL and sclerotherapy<sup>[67]</sup>, and expert pediatric opinion based on adult Baveno IV guidelines<sup>[66]</sup>. These include vasoactive agents, antibiotic prophylaxis and endoscopic variceal ligation.

EVL is also recommended for secondary prophylaxis of variceal hemorrhage but it has not been compared with β-blockers<sup>[22,66]</sup>. In children with portal vein throm-

bosis, meso-rex bypass appears to be the best option for secondary prophylaxis<sup>[22,66]</sup>.

## CONCLUSION

In the last two decades significant advances in the field of portal hypertension have improved the clinical care and survival of patients with cirrhosis and portal hypertension. In addition to better treatment strategies and improved therapeutic options, the issue of risk stratification has become more important so that, within each clinical stage, different patient subpopulations have been identified that require a different management. Clearly, further research is necessary to explore new pharmacological options that would allow a majority of patients to be hemodynamic responders, thereby foregoing the need for HVPG measurements and even the need for endoscopic therapy. The identification of different risk populations within each stage also requires further definition. It is expected that future trials and Baveno and AASLD conferences will continue to advance the field.

### Abstract

Portal hypertension can be caused by a wide variety of conditions. It frequently presents with bleeding from esophageal varices. The approach to acute variceal hemorrhage in children is a stepwise progression from least invasive to most invasive. Management of acute variceal bleeding is straightforward. But data on primary prophylaxis and long term management prevention of recurrent variceal bleeding in children is scarce, therefore prospective multicenter trials are needed to establish best practices.

### INTRODUCTION

Normal portal pressure is between 5 and 10 mmHg. Once portal pressure rises to 12 mmHg or greater, complications such as varices and ascites may occur.

The portal system drains the capillaries of the mesenteric and splenic veins and ends in the hepatic capillaries. The portal vein supplies partially oxygenated blood to the liver, supplementing the highly oxygenated blood of the hepatic artery to the liver. Blood flow to the liver is finely tuned; any disturbance of the flow in one of these vessels can be offset to a certain degree by increased flow through the other vessel. This is known as the arterial buffer response. Blood from both the portal venous system and the hepatic arterial systems combine within the sinusoids.

Portal hypertension occurs when there is increased portal resistance and/or increased portal blood flow. Generally, the portal venous system has a low baseline portal pressure of 7-10 mmHg and the hepatic venous pressure gradient (HVPG) ranges from 1 to 4 mmHg. Portal hypertension is defined as a portal pressure greater than 10 mmHg or gradient greater than 4 mmHg. Pressure gradients above 10 mmHg have been associated with esophageal varices formation, and those above 12 mmHg are associated with ascites and variceal bleeding in adults<sup>[1]</sup>. To measure the portal pressure gradient, a catheter can be wedged into the hepatic vein *via* the femoral or transjugular approach and a wedged hepatic venous pressure (WHVP) measurement obtained. If the catheter is then retracted into a free flowing hepatic vein, a free hepatic venous pressure (FHVP) can be measured. The HVPG is the difference between the WHVP and the FHVP. The cause of portal hypertension can be suggested by the

HVPG value. In pre-sinusoidal obstruction, the HVPG is normal but the WHVP is raised, whereas in cirrhosis both HVPG and WHVP are increased.

## HEMODYNAMIC CHANGES

Clinically, portal hypertension causes splenomegaly with resulting hypersplenism and the formation of a collateral circulation. Despite formation of a significant collateral network, portal hypertension persists. This is a result of an increase in cardiac output (result from increased venous return and diminished afterload); and a decrease in splanchnic arteriolar tone (mediated by several factors including glucagon and nitric oxide). Retention of sodium and water *via* a hepato-renal reflex increases the circulating blood volume. There is also production of vasodilatory factors that cause arterial vasodilation of the splanchnic circulation. Increases in the intrahepatic resistance are due to hepatocyte swelling, fibrosis and inflammation within the portal tracts. Clinical studies and animal models have demonstrated the hemodynamic events that occur; however, most of these investigations have not been performed in children or in pediatric models. The hyperdynamic circulatory state has not been well characterized in any cohorts of children.

## GASTROINTESTINAL BLEEDING

The clinical presentation of portal hypertension can be dramatic because it may be the first symptom of long-standing silent liver disease. In several large series of children with portal hypertension, approximately two thirds presented with hematemesis or melena, usually from rupture of an esophageal varix<sup>[2]</sup>. Gastrointestinal hemorrhage also may be associated with bleeding from portal hypertensive gastropathy, gastric antral vascular ectasia, or gastric, duodenal, peristomal, or rectal varices. Variceal hemorrhage is the result of increased pressure within the varix, which leads to changes in the diameter of the varix and increased wall tension. When the wall tension exceeds the variceal wall strength, physical rupture of the varix occurs. The majority of patients reported in the series had splenomegaly at the time of hemorrhage; thus, the combination of gastrointestinal bleeding and splenomegaly suggests portal hypertension until proven otherwise. The sentinel bleeding episode in children may occur in a wide range of ages, starting as early as 2 mo of age<sup>[3]</sup>. The risk of first-time bleeding from studies in children with cirrhosis is 22%, but rises to 38% in children with known varices over a 5 year period<sup>[4]</sup>. Bleeding occurs in 15%-25% of patients with biliary atresia in long term follow up<sup>[5,6]</sup>. The age of bleeding is dependent on the underlying etiology of cirrhosis. Patients who have surgically corrected but progressive biliary atresia bleed for the first time at a mean age of 3 years while children with cirrhosis due to cystic fibrosis bleed at a mean age of 11.5 years<sup>[7]</sup>.

Variceal bleeding in children often follows an acute

upper respiratory infection, fever, or aspirin ingestion<sup>[8]</sup>. The combination of factors including increased abdominal pressure from coughing or sneezing, increased cardiac output from fever, and ulceration from medications such as nonsteroidal antiinflammatory drugs or aspirin contribute to the rupture of varices. Prolonged gastroesophageal reflux can contribute to erosions over the varices that could result in bleeding.

Triger *et al.*<sup>[9]</sup> followed 44 children aged 12 years for a mean follow-up of 8 years. At the time of portal venous obstruction diagnosis, no child had either abnormal liver enzymes or abnormal liver function. The actuarial probability of bleeding was 49% at age 16 years and 76% at 24 years of age. If the child bled before 12 years of age, the probability of bleeding was higher than in those who had not bled before aged 12. Further, there was no evidence of variceal regression over time. Instead, progression of varices occurred in the majority of children suggesting that the previous hypothesis that variceal bleeding decreased in adolescence due to development of spontaneous porto-systemic collaterals was incorrect.

## SPLENOMEGALY

Splenomegaly is the second most common finding in children with portal hypertension after gastrointestinal bleeding. In many instances, an enlarged spleen is first discovered on routine physical examination. Many children will admit to a vague fullness in the left upper quadrant for many years prior to the diagnosis. Occasionally, manifestations of hypersplenism including thrombocytopenia, leukopenia, petechiae, or ecchymoses will prompt evaluation, leading to the discovery of portal hypertension. Hematologists should consider a biochemical liver profile and a Doppler ultrasonographic examination in the evaluation of any child with thrombocytopenia, especially if leukopenia is also present. Rarely will associated cytopenias lead to clinically relevant disease. Although splenomegaly is a common finding in patients with portal hypertension, splenic size does not correlate well with portal pressure<sup>[10,11]</sup>. Hypersplenism rarely requires surgical intervention. Exceptions include symptoms of symptomatic anemia and severe physical discomfort<sup>[12]</sup>.

## ABDOMINAL VENOUS PATTERNING

Specific cutaneous vascular patterns are observed with portal hypertension. Prominent vascular markings on the abdomen are the result of porto-collateral shunting through subcutaneous vessels. The direction of flow through these veins may be indicative of the site of obstruction. When the inferior vena cava is occluded, drainage is usually cephalad, but caudad below the umbilicus if the inferior vena cava is patent. Portal hypertension decompression through the umbilical vein results in prominent periumbilical collaterals, referred to as caput medusae. An audible venous hum (Cruveilhier-Baumgarten murmur) may occasionally be heard. Caput

Ascites	17	21	8	7

medusae are rare in children, partly because of the high prevalence of portal vein obstruction associated with umbilical vein obliteration. Rectal varices are more common in children<sup>[13]</sup>. In children with short bowel syndrome, stomal varices which are a site of low resistance, are often present and a common site for hemorrhage<sup>[14]</sup>.

## ASCITES

Ascites arises when the hydrostatic and osmotic pressures within the hepatic and mesenteric capillaries result in a net transfer from blood vessels to lymphatics at a rate that overcomes the drainage capacity of the lymphatics. It is the presenting sign of portal hypertension in 7%-21 % of children (Table 1).

In patients with portal hypertension, increased sodium retention and raised portal pressure may cause accumulation of fluid within the abdomen. Impaired lymphatic drainage compounds the situation. Treatment includes salt and fluid restriction and the use of diuretics. Albumin infusions can be used to increase intravascular osmotic pressure, followed by diuretic dosing to facilitate urination. Paracentesis has been used safely in children and is reserved for use when the ascites is difficult to control resulting in respiratory compromise or if peritonitis is suspected for cell count and culture<sup>[15,16]</sup>.

## PULMONARY COMPLICATIONS

Hepatopulmonary syndrome (HPS) and portopulmonary hypertension are undoubtedly underdiagnosed in children. Barbé *et al*<sup>[17]</sup> reported on the presence of HPS in 29 pediatric patients of which 26 had cirrhosis and 3 had an extrahepatic cause of portal hypertension. HPS progresses more rapidly in patients with biliary atresia associated with polysplenia<sup>[18]</sup>. Patients with HPS have a higher incidence of dyspnea, cyanosis, clubbing and spider nevi<sup>[19-21]</sup>. There are two forms of HPS. In type I, the vessels enlarge such that the red blood cells traveling through the center of the vessel do not have significant contact time with the oxygen-rich alveoli. In type II HPS, the diffusion-perfusion mismatch is presumed to be due to arteriovenous communications completely bypassing alveoli<sup>[22,23]</sup>. HPS is thought to occur as a result of shunting of vasodilatory mediators from the mesentery away from the liver in portal hypertension. Liver transplantation reverses HPS in greater than 80% of patients. If large shunts are present and the arterial par-

tial pressure of oxygen is less than 50 mmHg on 100% oxygen, a poorer outcome may be expected.

Portopulmonary syndrome eventually leads to right-sided heart failure. Histologically there is pulmonary arteriopathy with concentric laminar intimal fibrosis consistent with a vasoconstrictive etiology. Pediatric cases have been reported<sup>[24,25]</sup>. The condition is defined by a pulmonary arterial pressure greater than 25 mmHg at rest and above 30 mmHg with exercise, raised pulmonary vascular resistance with pulmonary arterial occlusion pressure, or a left-ventricular end-diastolic pressure of less than 15 mmHg<sup>[26]</sup>. The most common symptom of pulmonary hypertension is exertional dyspnea. Other symptoms include fatigue, palpitations, and syncope or chest pains.

## THERAPY

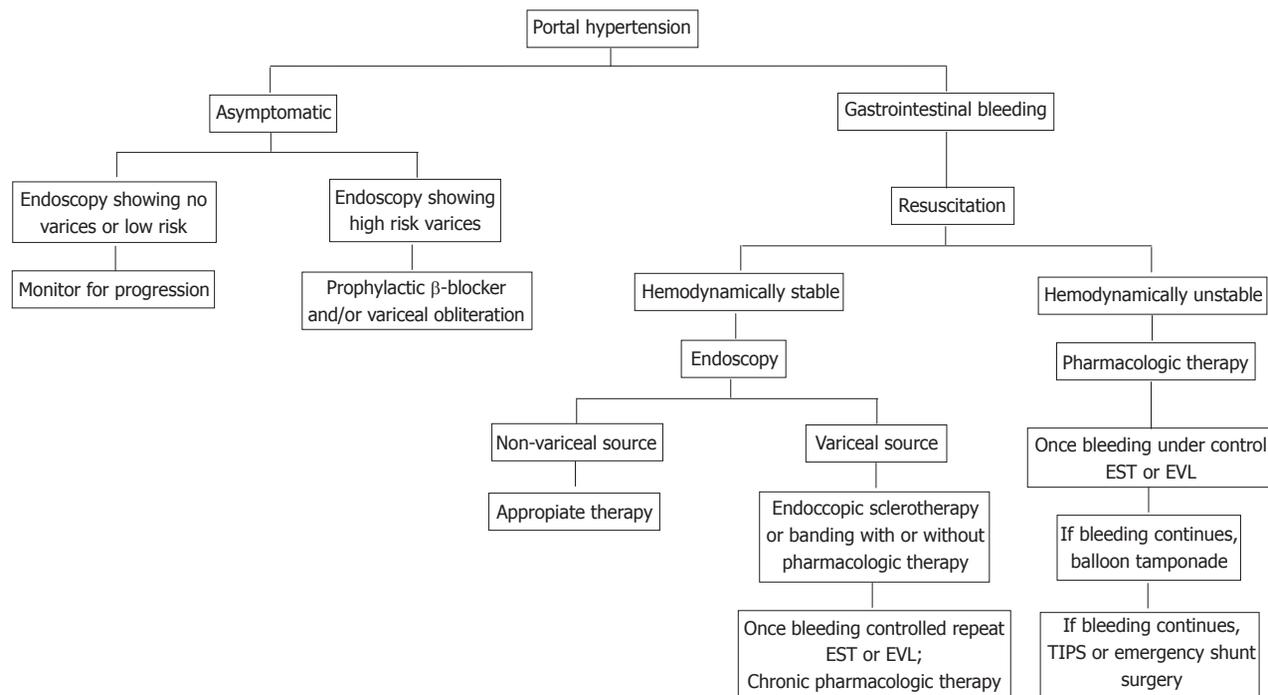

Therapy of portal hypertension is primarily directed at the management of its most dramatic manifestation, variceal hemorrhage. Variceal bleeding is a life threatening medical emergency, and patients with chronic liver disease should be instructed to seek immediate medical attention for any signs or symptoms of bleeding. The management can be divided into preprimary prophylaxis, prophylaxis (primary) of the first episode of bleeding, emergency therapy, and prophylaxis (secondary) of subsequent bleeding episodes. As with many other aspects of portal hypertension, almost all the modes of therapy are based on adult trials (Figure 1). Many of the trials are well-controlled randomized double-blinded studies, and comprehensive meta-analysis of these trials have been performed<sup>[27-30]</sup>. The literature on the management of variceal hemorrhage in children is predominantly descriptive and anecdotal. There have been few randomized trials of therapy for portal hypertension in children<sup>[31,32]</sup>.

### Preprimary prophylaxis

The concept is that early treatment of portal hypertension has the potential to delay or prevent the development of esophageal varices or other manifestations of portal hypertension. In a *S. mansoni* mouse model of portal hypertension, the administration of propranolol 5 wk into the infection resulted in a significant reduction in the development of portal hypertension, portosystemic shunting, and portal venous inflow<sup>[34]</sup>. A randomized controlled trial of timolol, a non-selective beta blocker, on the development of varices in adults did not show a significant benefit<sup>[35]</sup>. Currently, preprimary prophylaxis remains an interesting concept that is not applicable in clinical practice.

### Primary prophylaxis

The issue of prophylaxis of the first episode of variceal bleeding in children is controversial and is predicated on experience with adults who primarily have alcoholic cirrhosis. Surveillance endoscopy in children with liver disease and stigmata of portal hypertension is justified if the clinician anticipates recommending a prophylactic

**Figure 1 Portal hypertension.** EST: Endoscopic sclerotherapy; EVL: Endoscopic variceal band ligation; TIPS: Transjugular intrahepatic portosystemic shunt.

regimen. Prophylaxis may also be valuable in patients who live in remote areas far from emergency medical care. Given the unpredictable timing of the first episode of variceal bleeding, primary prophylaxis regimens need to be associated with relatively low morbidity and mortality. As such, beta blockade has been more extensively used in this setting. The improved risk-benefit ratio of endoscopic ligation therapy relative to sclerotherapy has led to reassessment of its role in primary prophylaxis<sup>[36,37]</sup>. Uncontrolled preliminary pediatric experience of variceal hemorrhage using beta blockade has recently been reported<sup>[38-40]</sup>. Beta blocker use in children has reduced the frequency of bleeding episodes, and in some trials has improved long-term survival in patients with esophageal varices. Initial randomized trials demonstrated efficacy in patients who had a previous bleeding episode<sup>[41]</sup>. Subsequently, propranolol was shown to be effective in patients with varices who had never bled. In a study of 230 subjects randomized to propranolol or placebo, the incidence of bleeding and mortality over a 14 mo period was reduced by almost 50%<sup>[42]</sup>. Several meta-analyses have demonstrated the success of propranolol<sup>[43-50]</sup>. It is clear that a goal of at least 25% reduction in resting heart rate needs to be achieved to realize these effects. In patients in whom HVPg drops below 12 mmHg, subsequent variceal bleeding is unlikely. Achieving such a large reduction in resting heart rate and achieving a HVPg below 12 mmHg may be problematic in children in whom baseline measurements may be difficult. A wide range of dosing (0.6-0.8 mg/kg per day) divided into two to four doses of propranolol has been required in children in order to observe a “therapeutic effect”.

Unfortunately, propranolol often does not reduce

HVPg below 12 mmHg, therefore a combination of beta blockade and vasodilatation therapies are now under investigation. Isosorbide-5-mononitrate, a long-acting vasodilator, may potentiate the effects of propranolol on the HVPg<sup>[51]</sup>. Combination pharmacologic agents, such as carvedilol, may have enhanced efficacy<sup>[52]</sup>. Unfortunately, there is little if any prospective data in children on the safety and effectiveness of beta blockade with or without vasodilators in patients with portal hypertension.

Endoscopic band ligation therapy has been used with greater frequency in adults with high risk varices<sup>[53,54]</sup>. As with beta blockade, endoscopic band ligation therapy cannot be recommended for routine use in children with varices. In fact, a small randomized trial of prophylactic endoscopic sclerotherapy in children showed no survival benefit<sup>[55]</sup>.

### **Emergency therapy of variceal bleeding**

The initial management of variceal bleeding is stabilization of the patient. Vital signs, particularly tachycardia or hypotension, can be especially helpful in assessing blood loss. Patients on beta blocker therapy may not manifest the usual compensatory tachycardia and are at higher risk of developing significant hypotension. Fluid resuscitation in the form of crystalloid initially, followed by red blood cell transfusion, is critical. One needs to administer these carefully to avoid overfilling the intravascular space and increasing portal pressure. Optimal hemoglobin levels in adults with variceal hemorrhage are between 7 and 9 g/dL<sup>[56]</sup>. Nasogastric tube placement is safe and may be an essential part of the management of these patients. It allows documentation of the rate of ongoing bleeding and removal of blood, a protein source that

may precipitate encephalopathy. In addition, blood in the stomach increases splanchnic blood flow and could aggravate portal hypertension and ongoing bleeding. Platelets should be administered for levels less than  $50 \times 10^9/L$ , and coagulopathy corrected with vitamin K and fresh frozen plasma. There may be a value to the use of recombinant factor VIIa in severe coagulopathy as the fluid requirements may be diminished<sup>[57]</sup>. Intravenous antibiotic therapy should be considered for all patients with variceal bleeding in light of the high risk of potentially fatal infectious complications<sup>[58,59]</sup>. Once the patient is stabilized, endoscopy should be performed to document that hemorrhage is indeed from variceal rupture. Continued bleeding at the time of endoscopy is a finding that portends poor prognosis. A significant percentage of both adults and children with chronic liver disease will have a source of bleeding other than varices, including duodenal or gastric ulceration<sup>[58]</sup>. Pharmacotherapy of acute hemorrhage should not be withheld until endoscopy can be performed. In fact, it may facilitate the procedure. At the time of initial endoscopy, management can begin in the form of sclerotherapy or band ligation. Bleeding that lasts more than 6 h or requires more than one red blood cell transfusion necessitates further investigation. A wide variety of therapeutic options exist in adults. Documentation of their efficacy in adults is fairly convincing, but data in children is scarce

### Pharmacology

The pharmacologic therapy of variceal bleeding usually consists of vasopressin or somatostatin (or their analogs) infusions. Vasopressin has the longest history of usage and acts by increasing splanchnic vascular tone and thus decreasing portal blood flow. Its use is often limited by the side effects of vasoconstriction, which include left ventricular failure, bowel ischemia, angina, and chest/abdominal pain<sup>[53]</sup>. In a study of 215 children with acute variceal hemorrhage, 184 had bleeding arrested by the combined use of fluid support and vasopressin. Vasopressin has a half-life of 30 min and is usually given as a bolus followed by continuous infusion. The recommended dose for children is 0.33 U/kg as a bolus over 20 min, followed by an infusion of 0.2 U/1.73 m<sup>2</sup> per minute (may be increased up to 3 times the initial rate). These recommendations are empiric, based on clinical practice, and derived from extrapolation of adult dosages. Terlipressin, a long-acting synthetic analogue of vasopressin, has shown similar effects and does not require continuous infusion<sup>[57]</sup>. Side effects appear to be reduced compared to vasopressin, but prospective data in children are lacking.

Alternatives to vasopressin have been investigated because of its poor side effect profile. Somatostatin and its synthetic homologue octreotide also have been shown to decrease splanchnic blood flow. Their effects on acute variceal hemorrhage appear to be similar to those of vasopressin, with fewer side effects<sup>[58,59]</sup>. Continuous infusion of 1-5 µg/kg per hour of octreotide appears to be effective but may need to be initiated by the ad-

ministration of a bolus. New longer-acting somatostatin analogues are currently under investigation<sup>[59]</sup>.

### Endoscopy

Approximately 15% of children will have persistent hemorrhage despite conservative management plus some form of splanchnic vasoconstriction. The most common secondary approach is endoscopic sclerotherapy or endoscopic band ligation. Endoscopic therapy is very effective in controlling bleeding, although it may be technically challenging. An extensive experience with emergency sclerotherapy exists in children, and it's rare for additional therapy to be required. A variety of agents have been used (sclerosants, chemically irritating compounds such as ethanolamine/tetradecyl sulfate). These sclerosants are injected either intra- or para-variceal, until bleeding has stopped. In the setting of emergency sclerotherapy it is important to be aware of the significant incidence of associated bacteremia and to consider antibiotic prophylaxis in most patients.

Endoscopic band ligation of varices may be a preferable approach because it is easier and safer. A randomized trial of band ligation versus sclerotherapy in adults demonstrated similar control of active bleeding and recurrence of hemorrhage with significantly lower overall complications and mortality). A potential concern of this technique in children (whose esophageal wall is thinner than adults), is entrapment of the full thickness of the esophageal wall by the rubber band with subsequent ischemic necrosis and perforation.

### Mechanical

The Sengstaken-Blackmore tube (SSBT) was designed to stop hemorrhage by mechanically compressing esophageal and gastric varices. The device consists of a rubber tube with at least two balloons. It is passed into the stomach, where the first balloon is inflated and pulled up snug against the gastroesophageal junction. Once the tube is secured in place, the second balloon is inflated in the esophagus at a pressure (60-70 mmHg) that compresses the varices without necrosing the esophagus. A channel in the rubber tube allows gastric contents to be sampled for evidence of bleeding. This therapy is very effective in controlling acute bleeding. Unfortunately, it is associated with significant number of complications and high incidence of re-bleeding when the tube is removed. Most patients find the treatment uncomfortable, and its use in children requires significant sedation. Use of the SSBT increases the risk of aspiration pneumonia, which can be a life threatening complication in a patient with liver failure. Re-bleeding has been reported in 33%-60% of patients. Given these problems it is reserved for severe uncontrollable hemorrhage and generally serves as a temporizing measure until a more definite procedure can be performed.

### Surgical and interventional radiology

Surgical therapy is usually a last resort approach to acute

**Table 2** Major complications of endoscopic sclerotherapy in children<sup>[61]</sup> (%)

Bleeding before treatment	39
Esophageal ulceration	29
Stricture formation	16
Recurrent varices	8

variceal hemorrhage. The reluctance to perform emergency surgery partly stems from its associated high mortality but also from concerns of an increased incidence of encephalopathy and greater difficulty for subsequent liver transplantation. The surgical procedures available can be divided into transection, devascularization, and portosystemic shunting. The first two techniques are rarely used and work by interrupting blood flow through the esophagus. Liver transplantation may be an effective means of treating esophageal variceal bleeding if an acceptable organ can be procured quickly enough. Variceal embolization *via* a percutaneous transhepatic or transsplenic approach has been advocated by some hepatologists as another method of controlling acute hemorrhage. Transjugular intrahepatic portosystemic shunt (TIPS) placement may be the optimal approach for intractable bleeding since it does not require surgery or puncture of an organ that is predisposed to hemorrhage. A catheter is inserted into the jugular vein and is advanced into the hepatic vein where a needle is used to form a tract between the portal vein and the hepatic vein. This tract is expanded with a balloon angioplasty catheter, and a stent is then placed forming a permanent portosystemic shunt. The experience in children is limited. Size limitations and local expertise may be limiting factors in some cases, but given the high risk associated with emergency surgery or the use of SSBT, TIPS may be the treatment of choice in the emergent setting, especially when liver transplantation is imminent.

**Secondary prophylaxis:** The long term management of portal hypertension in children with a previous episode of variceal bleeding is complex. One must take into consideration several factors; first the natural history; as discussed earlier, there are significant differences in the setting of minimal and inactive versus active and progressive hepatic disease. As a result, certain individuals may have the possibility of outgrowing their portal hypertension through the development of spontaneous portosystemic shunts, whereas other might be expected to develop end-stage liver disease and ultimately be candidates for liver transplantation. The second issue stems from the great diversity in therapeutic modalities. The physiologic goal of pharmacologic therapy varies from program to program (i.e, change in heart rate, hepatic portal venous gradient pressures, *etc*). Sclerotherapy may be administered with a wide variety of agents and by two different techniques (i.e, intra or para variceal). Endoscopic band ligation offers an important and generally safer alternative. Finally, at least six different portosys-

temic shunting procedures have been described, all with their own advantages and disadvantages.

**Sclerotherapy and ligation therapy:** Sclerotherapy and band ligation therapy work by physical obliteration of esophageal varices. Bleeding may occur during the several weeks required to complete the obliteration. Most importantly the principal problem of portal hypertension is not addressed. Despite these problems, endoscopic therapy has been a mainstay of the treatment of esophageal varices, and there is significant amount of clinical experience with these therapies in children.

The effectiveness of sclerotherapy has been studied for both prevention of initial and subsequent bleeding episodes. Sclerotherapy, which has in general been supplanted by band ligation, with the exception of very young or small children in which band ligation may not be feasible. Intravariceal, paravariceal, and some combination injection protocols have been used. A wide variety of sclerosing agents have been used without a clear cut difference in their efficacy or adverse side effects. A meta analysis of seven studies and 748 patients revealed mortality rates of 47% in the sclerotherapy group and 61% in the conservatively managed group. A variety of complications have been reported (Table 2).

Retrosternal pain, bacteremia, and fever post treatment are common. Esophageal ulceration may occur after sclerotherapy, and the associated symptoms may be ameliorated with sucralfate slurry therapy.

The range of complications associated with sclerotherapy has prompted the development of alternative endoscopic methods such as band ligation. This technique involves suctioning of a varix into the end of an endoscope so that a rubber band can be placed around the varix leading to thrombosis. Direct comparisons of endoscopic sclerotherapy and variceal ligation in adult patients have yielded results in favor of ligation. Similar results have been reported in children by Zargar *et al.* The major advantage of variceal ligation is avoidance of needle injection of varices, which appears to reduce the rate of complications. In addition, variceal ligation appears to lead to obliteration in fewer sessions and is associated with lower rate of rebleeding.

**Portosystemic Shunting:** A variety of procedures have been used to divert portal blood flow and decrease portal blood pressure: (1) Mesocaval Shunts: formed with the insertion of a graft between the superior mesenteric vein and the inferior vena cava; (2) Portacaval Shunts: formed by side-to-side anastomosis of the portal vein and the inferior vena cava; and (3) Distal Splenorenal Shunt: formed by end-to-side anastomosis of the splenic vein and the left renal vein.

The portacaval shunt diverts nearly all the portal blood flow into the subhepatic inferior vena cava. This is very effective decompressing the portal system, but also diverts a significant amount of blood from its normal hepatic metabolism, predisposing to the development

**Table 3** Results of portosystemic shunting in children<sup>[63,64]</sup>

Type of portal hypertension	No. of patients	Rebleeding	Mortality
Extrahepatic	292	45%	5%
Intrahepatic	76	50%	53%

of hepatic encephalopathy. Decreased hepatic blood flow theoretically also may lead to worsening of underlying liver disease. An intermediate shunt can be made by placing a graft between the mesenteric or portal vein and the vena cava. This decompresses the portal system while allowing a greater amount of portal blood flow into the liver. The use of grafts unfortunately is associated with increased risk of thrombosis and many times with worsening retrograde flow.

Another approach involves diversion of splenic blood flow into the left renal vein, which can be done nonselectively (central) or semiselectively (distal splenorenal shunt).

A substantial pediatric experience with surgical portosystemic shunting has been accumulated over the past 20 years. The results are clearly different in patients with extra- or intrahepatic portal hypertension (Table 3).

An alternative shunting procedure for children with extrahepatic portal vein thrombosis is the meso-Rex bypass, this procedure involves the placement of an autologous venous graft from the mesenteric vasculature to the left intrahepatic portal vein. One of the major advantages of this approach is the restoration of normal portal blood flow, which eliminates the risk of hepatic encephalopathy and should preserve hepatic function. The selection of patients for this procedure is not clear both from a clinical indication and surgical feasibility, and some have advocated that this procedure be considered in all children with portal vein thrombosis. Standard diagnostic imaging may not clearly indicate whether there is patency of the intrahepatic portal vein, and the potential in this group of children for hypercoagulable states must be kept in mind.

In stark contrast to the excellent results in portal vein thrombosis, there are generally poor results of portosystemic shunts in children with decompensated liver disease. The incidence of recurrent bleeding and death approaches 50%. Hepatic encephalopathy is a frequent and serious complication of portosystemic shunting in decompensated liver disease, and studies have failed to show improvement in long-term survival in patients with intrahepatic disease.

Overall, surgical portosystemic shunting is an excellent approach to the long-term management of children with intractable variceal bleeding in the setting of compensated cirrhosis. In addition, significant gastric variceal hemorrhage in children may be an indication to consider surgical shunting. TIPS may be an alternative shunting procedure for children with refractory bleeding and serves as an effective bridge to transplantation. The procedure is typically feasible, with published success in children as small as 14 kg, although special

procedural modifications must be undertaken in small children. Long term shunt occlusions limit the overall application of this efficacious therapy, although newer data with coated stents may improve long-term patency rates for TIPS.

## CONCLUSION

The approach to acute variceal hemorrhage in children is a stepwise progression from least invasive to most invasive. Surveillance endoscopy is predicated on the availability of an efficacious primary prophylactic therapy. Beta-blocker therapy is accepted primary prophylactic therapy in adults, and endoscopic ligation therapy is also gaining acceptance. Preliminary data in children appear to indicate that this approach is feasible, but further studies are needed before a wide-spread recommendation for children can be endorsed. Therefore, surveillance endoscopy and primary prophylaxis are not generally be indicated in children with portal hypertension who have not had a variceal bleed. Special medical and or social circumstances in which an initial bleeding episode may be particularly dangerous could justify this approach.

Management of acute variceal bleeding is more straightforward. Initial interventions should include stabilization of the patient, placement of a nasogastric tube, and institution of antibiotic therapy. Diagnostic and/or therapeutic endoscopy should be scheduled as soon as it is safe and feasible. In the interim, pharmacologic treatment with either a vasodilator or octreotide is indicated and may facilitate endoscopic therapy. Intractable and severe hemorrhage should be treated by TIPS.

The long term approach to prevention of recurrent variceal bleeding in children must be adapted for the etiology of portal hypertension, the needs of the specific patient, and the particular skills of the institution. The approach to extrahepatic portal vein obstruction is evolving. In general, the unpredictability of the timing of the sentinel bleeding episode and the low incidence of mortality associated with that episode make prophylactic therapy inadvisable. Enthusiasm for the utilization of the meso-Rex shunt is increasing because of the physiologic nature of the procedure, and should be considered for children with extrahepatic portal vein thrombosis and cavernous transformation and a normal liver. The long term management of portal hypertension in the child with biliary atresia is more complex. In patients with incomplete bile drainage, liver transplantation appears to be inevitable and should be the major focus of therapeutic intervention. Temporizing measures for these children may include band ligation therapy and TIPS. Biliary atresia patients who have a more successful response to Kasai portoenterostomy, have a more favorable long term outlook. Variceal hemorrhage may be followed by a relatively long term survival with medical intervention. Recurrent bleeding might be amenable to portosystemic shunting as opposed to transplantation.

The approach to patients with more slowly progressive intrahepatic disease is more difficult to generalize.

Well-conceived multicenter trials are required to determine whether the principals that have been developed in adults can be extrapolated to children.

in the hospitalization, can decrease hospital length of stay, rebleeding and the need for surgery. However, results from available small trials are conflicting and larger, multicenter studies are needed. Compared to other management options, colonoscopy is a safe procedure with complications reported in less than 2% of patients, including those undergoing urgent examinations. The requirement of bowel preparation (typically 4 or more liters of polyethylene glycol), the logistical complexity of coordinating after-hours colonoscopy, and the low prevalence of stigmata of hemorrhage complicate the use of colonoscopy for LGIB, particularly in urgent situations. This review discusses the above advantages and disadvantages of colonoscopy in the management of acute lower gastrointestinal bleeding in further detail.

### Abstract

Acute lower gastrointestinal bleeding (LGIB) is a frequent gastrointestinal cause of hospitalization, particularly in the elderly, and its incidence appears to be on the rise. Endoscopic and radiographic measures are available for the evaluation and treatment of LGIB including flexible sigmoidoscopy, colonoscopy, angiography, radionuclide scintigraphy and multi-detector row computed tomography. Although no modality has emerged as the gold standard in the management of LGIB, colonoscopy is the current preferred initial test for the majority of the patients presenting with hematochezia felt to be from a colon source. Colonoscopy has the ability to diagnose all sources of bleeding from the colon and, unlike the radiologic modalities, does not require active bleeding at the time of the examination. In addition, therapeutic interventions such as cautery and endoclips can be applied to achieve hemostasis and prevent recurrent bleeding. Studies suggest that colonoscopy, particularly when performed early

## INTRODUCTION

Acute lower gastrointestinal bleeding (LGIB) is a disorder frequently encountered by gastroenterologists, surgeons and internists. Hospitalization for LGIB in the 1990s was estimated to occur at an incidence of 20.5 per 100 000 person-years<sup>[1]</sup>. The incidence of LGIB may be rising concomitant with the aging of our population and the increasing use of aspirin/non-steroidal anti-inflammatory drugs and anticoagulants<sup>[2]</sup>. LGIB is associated with significant mortality, health care costs and increased length of hospitalization, emphasizing the need for effective evaluation and treatment<sup>[2-4]</sup>.

Currently, physicians managing LGIB have a number of different diagnostic and therapeutic options to choose from, ranging from radiographic interventions such as radionuclide scintigraphy and angiography to colonoscopy and flexible sigmoidoscopy. Although no modality has emerged as the gold standard in the management of LGIB, colonoscopy has several advantages and is generally regarded as the preferred initial test in the majority of cases. The advantages are as follows: (1) ability to identify bleeding source regardless of rate or presence of bleeding; (2) multiple therapeutic possibilities; (3) efficiency given diagnostic and therapeutic potential; (4) irrespective of initial testing, colonoscopy is required for definitive diagnosis; and (5) safety. Disadvantages are as follow: (1) requirement for colon preparation; (2) need for sedation, experienced staff and endoscopy facilities; (3) low prevalence of stigmata of hemorrhage; (4) invasive nature; and (5) rare but serious complications.

This article will explore the advantages and disadvantages of colonoscopy in the management of LGIB.

## PROS OF COLONOSCOPY

### **Potential for diagnosis and therapeutic intervention**

A major advantage of colonoscopy over other management options is the potential for diagnosis and therapeutic intervention even in the absence of ongoing bleeding. This is important given the often intermittent nature of LGIB and slow bleeding from diffuse mucosal sources such as colitis. In contrast, the radiographic alternatives including angiography, radionuclide scintigraphy and computed tomography (CT) require active bleeding at the time of the examination in order to identify and treat the source of bleeding, and are useful only in a subset of patients with severe ongoing bleeding. It is therefore not surprising that the diagnostic yield of colonoscopy exceeds that of the radiographic modalities.

Studies have shown a diagnosis is made in 74%-100% of patients with LGIB undergoing colonoscopy (Table 1)<sup>[5-11]</sup>. A pooled analysis by Strate *et al*<sup>[12]</sup> of six recent studies of colonoscopies following bowel preparation for LGIB found a composite diagnostic yield of 91% for colonoscopy. In comparison, in radionuclide scanning, a commonly used radiological diagnostic modality in LGIB, scans were positive in 40%-70% of patients with accuracy ranging from 35%-100%<sup>[13-17]</sup>. In small case series, multidetector

row CT scanning (MDCT) has shown promising results with localization of bleeding in 50%-100% of select cases<sup>[16,18,19]</sup>. Angiography is less sensitive than radionuclide or MDCT scan and therefore is infrequently utilized as a front line test. In a collected series of 247 patients reported by Browder *et al*<sup>[20]</sup>, angiography demonstrated a bleeding site in 72% of patients whereas a retrospective chart review study by Cohn *et al*<sup>[21]</sup> yielded only 35% positive angiographic findings. In addition, it is important to note that colonoscopy is generally required following radiographic tests, whether positive or negative, to confirm the source of bleeding and to exclude colorectal malignancy or other serious diagnoses. Therefore, colonoscopy is the most efficient initial test for the majority of patients with LGIB who can be stabilized and can undergo colon preparation.

Few studies have directly compared colonoscopy to radiographic interventions. In a study by Jensen *et al*<sup>[22]</sup>, emergency colonoscopy and upper endoscopy as well as emergency angiography were performed in 22 patients with severe bleeding. In the 17 patients with lower intestinal sources of bleeding, the diagnostic yield of colonoscopy was 82% *vs* 12% for angiography<sup>[22]</sup>. Similarly, in a retrospective study by Strate *et al*<sup>[23]</sup>, initial colonoscopy within 24 h of admission offered a diagnostic yield of 85% *vs* 45% for initial scintigraphy and angiography.

The timing of colonoscopy also may have an effect on diagnostic and therapeutic outcomes. Several studies indicate that urgent colonoscopy, or colonoscopy within 12-24 h of presentation, may improve the diagnostic and therapeutic yield of colonoscopy in LGIB. In a prospective study, Jensen *et al*<sup>[6]</sup> identified stigmata of hemorrhage in approximately 20% of patients with diverticular bleeding undergoing urgent colonoscopy. Subsequent endoscopic treatment significantly reduced the rate of rebleeding and surgery compared to historical controls. In a trial by Green *et al*<sup>[7]</sup> of colonoscopy following bowel preparation within 12 h *vs* elective colonoscopy (within 74 h), a definitive bleeding source was identified in 42% of patients undergoing urgent colonoscopy *vs* 22% in those undergoing elective colonoscopy. Most recently, in a trial of colonoscopy within 12 h *vs* colonoscopy in 36-60 h, Laine *et al*<sup>[24]</sup> found no differences in outcomes including the number of diagnoses. However, 78% of colonoscopies were diagnostic in the urgent group compared to 67% in the elective group, and the only 2 stigmata of hemorrhage were both identified in patients with diverticulosis undergoing urgent colonoscopy<sup>[24]</sup>.

For patients undergoing colonoscopy, once a diagnosis is made, endoscopic hemostasis can be carried out depending on the source. Epinephrine or saline injection, thermal contact, argon plasma coagulation, clipping and band ligation are available therapeutic modalities. A review of published series by Strate *et al*<sup>[12]</sup> showed that endoscopic therapy was applied to 10% to 40% of patients undergoing colonoscopy for LGIB and the most common intervention was thermal contact plus injection. Their review of 71 cases of diverticular bleeding treated with endoscopically placed hemoclips showed

Table 1 Comparison of management options for lower gastrointestinal bleeding (%)

Procedure	Diagnosis	Therapy	Early rebleeding	Major complications	Colon preparation	Requires active bleed
Colonoscopy <sup>[5-8]</sup>	74-100	8-37	0-24 <sup>1</sup>	0-2	Yes	No
Sigmoidoscopy <sup>[9-11]</sup>	About 10	0-20	0	Rare	Minimal	No
Angiography <sup>[20,21,26-29]<sup>2</sup></sup>	23-72	14-100	1-57	0-60	No	Yes
Radionuclide scan <sup>[13-15]</sup>	40-73	N/A	N/A	Rare	No	Yes
Multi-detector CT scan <sup>[16,18,19]</sup>	24-94	N/A	N/A	0%-11%	No	Yes

N/A: Not available; CT: Computed tomography. <sup>1</sup>Early rebleeding in patients who had undergone endoscopic therapy for diverticular bleeding; <sup>2</sup>Therapy, rebleeding and complications refer to superselective embolization only. It is difficult to determine the frequency of superselective embolization use because most series only report patients who receive therapy.

particular promise with a homeostasis success rate of 100% and with no complications.

### Improved outcomes

It is important to note that in most cases, diagnosis needs to be followed by therapeutic maneuvers in order to alter outcomes in patients with LGIB. Early colonoscopy has shown particular promise in this regard in patients with diverticular bleeding. In a study by Jensen *et al*<sup>[6]</sup>, patients undergoing endoscopic hemostasis for diverticular stigmata with epinephrine plus/minus thermocautery had significantly lower rates of rebleeding and surgery when compared to historical controls who did not receive endoscopic treatment. Indeed, none of the endoscopically treated patients experienced re-bleeding. In addition, length of hospital stay was significantly shorter in the colonoscopy treatment group ( $P < 0.001$ ).

Subsequent randomized trials for all sources of severe LGIB have yielded less positive results. However, these trials were small and the lack of significant findings may have been the result of inadequate power or other methodological issues. In the Green *et al*<sup>[7]</sup> trial, patients were randomized to urgent colonoscopy within 8 h or standard of care which was elective colonoscopy within 4 d of admission. As noted above, the diagnostic yield was superior in the urgent colonoscopy group. Other outcomes such as rebleeding, surgery and number of blood transfusions showed a trend in the favor of urgent colonoscopy but did not reach statistical significance. Also of note, only 36% of colon preparations were noted to be “excellent”, which may also have affected the efficacy of urgent colonoscopy. Laine *et al*<sup>[24]</sup> also did not find that urgent colonoscopy improved major outcomes compared to delayed colonoscopy. In addition to the small number of patients in their study (the study was stopped early with only 36 patients in each arm *vs* the planned 134 patients), patients in the urgent colonoscopy arm also appeared to have more severe bleeding which may have made it more difficult to detect a favorable difference.

A number of observational studies indicate that urgent colonoscopy reduces hospital length of stay. In a retrospective study of patients admitted with LGIB, Strate *et al*<sup>[25]</sup> looked at the impact of time to colonoscopy on hospital length of stay in patients presenting with LGIB. They found that earlier performance of colonos-

copy was associated with a shorter length of stay [hazard ratio (HR) 2.02, 95% CI: 1.5-2.6,  $P < 0.0001$ ] even when adjusted for other factors. Similarly, Schmulowitz *et al*<sup>[30]</sup> also showed that having a colonoscopy was associated with reduced hospital length of stay (HR 1.54, 95% CI: of 1.2-1.8), and mean length of hospital stay was significantly shorter in patients undergoing colonoscopy within 24 h compared to more than 24 h (5.4 d *vs* 7.2 d,  $P < 0.008$ ). Since hospital days are a major source of charges in LGIB this could have a significant economic impact. In a cost analysis study, Jensen *et al*<sup>[31]</sup> estimated that urgent colonoscopy was associated with an average savings of \$10 065 per patient compared with medical, angiography and surgical management; although this number likely overestimates the degree of cost savings due to other trends in care such as shorter hospital stay, and a recent randomized trial found no difference in hospital charges in patients undergoing urgent *vs* elective colonoscopy<sup>[24]</sup>. Overall, colonoscopy, particularly when performed early in the hospital course, has the potential to improve outcomes such as rebleeding, surgery and length of stay, but larger randomized trials are needed to better define its efficacy.

### Safety

Colonoscopy with or without intervention for LGIB is considered a safe procedure. In a review of 4 studies with 664 patients, there were 2 perforations for an overall complication rate of 0.3% for colonoscopy and 0.6% for colonoscopy performed urgently<sup>[12]</sup>. Other potential risks in addition to bowel perforation include congestive heart failure secondary to volume overload, electrolyte abnormalities and aspiration pneumonia. Also of note, in a review of 137 cases of endoscopic treatment for diverticular hemorrhage using a variety of modalities, there were no reported complications<sup>[12]</sup>. Complications are noted more frequently in patients undergoing angiography. The risks of bowel ischemia and cardiac arrhythmia seen with vasopressin infusions have been ameliorated with newer superselective embolization techniques. However, in a review of 20 studies utilizing superselective embolization for control of LGIB, minor complications were seen in 26% of patients and major complications requiring surgery or resulting in death were seen in 17%<sup>[12]</sup>. Another significant concern for both angiography and MDCT is renal compromise

secondary to contrast dye load. In the small amount of literature on MDCT there have been 2 reports of renal failure in patients with diabetes who also underwent angiography<sup>[19]</sup>.

## CONS OF COLONOSCOPY

### **Colon preparation**

Cleansing the colon of stool and blood prior to colonoscopy for management of LGIB is imperative, difficult to accomplish, and unique to endoscopic interventions for LGIB. Colonoscopy preparation is necessary for complete examination to the cecum. Studies of unprepped colonoscopy in LGIB report examinations to the cecum in only 55%-70% of cases<sup>[32-34]</sup>. Unprepped colonoscopy may increase the risk of perforation due to poor visualization. The identification of subtle bleeding sites, which are often among multiple lesions as is the case in diverticular hemorrhage, the most common source of LGIB, is contingent on removal of excess debris. In a prospective study by Jensen *et al*<sup>[6]</sup> on urgent colonoscopy in severe diverticular bleeding, active bleeding was detected in 21% of cases in the urgent colonoscopy arm and endoscopic hemostasis was achieved in 100% of the cases. The excellent results may have been due, in part, to their aggressive bowel preparation regimen. This regimen required 5-6 liters of sulfate purge over 3-4 h with 33% receiving the purge through a nasogastric tube. However, achieving consistently excellent bowel preparations, particularly in the urgent setting for LGIB, is difficult. The 4 or more hour time frame required for preparation may delay colonoscopy examinations until after-hours when nursing support and endoscopic facilities are not available. Thus, colon preparation makes urgent colonoscopy logistically complicated. Even under highly regulated study situations, colon preparations have been suboptimal in a high percentage of patients. In Green *et al*<sup>[7]</sup>'s study, endoscopic view was rated poor to fair in 62%-64% of patients (62% in elective arm and 64% in urgent arm). Laine *et al*<sup>[24]</sup> did not comment on the quality of the colon prep in their study but did report that 7% of their patients required a second colonoscopy due to poor bowel prep (2 in the urgent arm and 3 in the elective arm). In these two studies poor colon preparation has been cited as a reason for the lack of significant findings in favor of the colonoscopy arm<sup>[35,36]</sup>.

As mentioned above, aggressive bowel preparation requires a large volume of bowel preparation, often up to 6-8 liters. Rarely, this can lead to volume overload and electrolyte abnormalities such as hyponatremia<sup>[37]</sup>. There is also the risk for aspiration, especially when the prep is rapid or the patient is at risk for aspiration. The need for colon preparation makes colonoscopy for LGIB more complicated than esophagogastroduodenoscopy (EGD) for upper gastrointestinal bleeding, and is likely one of the main reasons it has not been equally embraced. Also, the need for colon prep clearly sets colonoscopy for management of LGIB apart from radiological interven-

tions for LGIB.

### **Sedation, experienced staff and procedure facilities**

Colonoscopy generally requires sedation given by trained professionals in a monitored location such as an intensive care unit or an endoscopy suite. Specialized support staff is also helpful to aid the gastroenterologist with the colonoscopy. These factors add to the complexity of coordinating the procedure, particularly on nights and weekends. However, angiography also requires sedation, an interventional radiologist, support staff and a specialized procedure suite. Indeed, in their study of utilization of early colonoscopy *vs* radiography in severe lower intestinal bleeding, Strate and Syngal found that the median times from admission to colonoscopy or angiography were similar (median of 17 h for colonoscopy *vs* 14 h for angiography)<sup>[23]</sup>.

### **Urgent vs delayed performance of colonoscopy**

The optimal timing of colonoscopy remains an area of controversy. As noted above, some studies suggest that performing colonoscopy within the first 12-24 h of hospital admission aids in the identification and treatment of the bleeding source. However, the two published randomized controlled trials of LGIB showed no difference in important clinical outcomes such as rebleeding and surgery<sup>[7,24]</sup>. Unfortunately, none of these studies was adequately powered to detect a statistically significant difference in important clinical outcomes, and the utility of urgent colonoscopy remains uncertain. The conflicting, albeit flawed, evidence paired with the practical issue of colon preparation make it difficult for clinicians to embrace urgent colonoscopy. Based on available literature, there is no specific time threshold for colonoscopy, but rather colonoscopy should be performed after a thorough bowel preparation, and more urgently in patients with signs of significant or ongoing bleeding as stigmata are rarely identified in delayed examinations<sup>[7,24]</sup>.

### **Low prevalence of stigmata of hemorrhage**

The identification and treatment of the bleeding source is the goal of urgent interventions for GI bleeding particularly when severe. Diagnostic interventions alone are unlikely to alter significant outcomes such as rebleeding and need for surgery. However, stigmata are infrequently identified in the colon. Studies report stigmata of hemorrhage in 7.7% to 43% of cases<sup>[5,30]</sup>. The colon has a large and complex surface area, often with multiple potential sources. In addition, bleeding tends to be intermittent in nature and it can be difficult to differentiate fresh blood from old blood and stool. Therefore, the effort entailed in orchestrating an urgent colonoscopy may be perceived as great in relation to the gain. Decision aids and predictive models have the potential to improve the utility of urgent colonoscopy for LGIB by identifying patients who are most likely to have ongoing bleeding and stigmata of hemorrhage and hence benefit from intervention. Three studies to date have aimed at

identifying high risk patients with LGIB with reasonable accuracy<sup>[38-40]</sup>. However, the use of these tools in routine practice has not been studied and they have not been widely embraced.

In addition to the low prevalence of stigmata, a substantial subset of patients (up to 20%) presenting with hematochezia and presumed LGIB will ultimately be found to have bleeding from the upper or small bowel<sup>[22,24]</sup>. An EGD or nasogastric lavage is necessary in briskly bleeding patients to begin to exclude these possibilities. In small bowel bleeding, colonoscopy and upper endoscopy serve only to exclude these areas of the bowel as bleeding sources, and these patients generally require a number of procedures for diagnosis<sup>[41]</sup>.

### Complications

As mentioned earlier, the complication rate of colonoscopy is low, 0.3% and 1.3% in two comprehensive reviews<sup>[12,42]</sup>. Safety is generally thought of as a relative strength of colonoscopy over other modalities. Radionuclide scanning and CT scanning are the only noninvasive option and these modalities do not provide therapeutic opportunities. However, complications of colonoscopy when they occur can be severe. Colon perforation is the most common complication and generally requires urgent surgical intervention. Other complications are mainly due to colon preparation and can be minimized with proper and careful administration of colon purge. For example, rapid preps should be avoided in patients with altered mental status, difficulty swallowing, delayed gastric emptying or bowel obstruction. Fleets Phosphosoda has been associated with renal compromise and is no longer available. Balanced electrolyte solutions are considered safer and less likely to result in fluid and electrolyte shifts<sup>[43]</sup>. However, there have been case reports of patients with decreased left ventricular systolic function experiencing exacerbation of their symptoms, thought to be secondary to fluid shifts in the setting of bowel preparation with polyethylene glycol (Golytely)<sup>[44]</sup>. These patients should hence be monitored closely while undergoing their prep.

### CONCLUSION

Colonoscopy offers many advantages in the management of acute lower gastrointestinal bleeding. All sources and severities of LGIB can be diagnosed with colonoscopy and the overall diagnostic yield of this procedure is high. Endoscopic hemostasis can be utilized to stop or prevent bleeding, and therefore colonoscopy offers the potential to improve important clinical outcomes such as rebleeding, although the data from existing small studies are conflicting. The need for bowel preparation, the logistical difficulty of coordinating the procedure after-hours and the infrequent identification of stigmata of hemorrhage deter the widespread use of urgent colonoscopy in LGIB. However, most of these difficulties also apply to other modalities such as angiography and radio-

nuclide scan. Albeit imperfect, current data indicate that colonoscopy offers more advantages than other management options and should be the initial modality in the majority of patients with LGIB. Further prospective randomized studies are needed to more clearly define the optimal timing of colonoscopy in LGIB and its role relative to other available options including radionuclide scanning, angiography and MDCT scanning.

### Abstract

Although most cases of acute nonvariceal gastrointestinal hemorrhage either spontaneously resolve or respond to medical management or endoscopic treatment, there are still a significant number of patients who require emergency angiography and transcatheter treatment. Evaluation with noninvasive imaging such as nuclear scintigraphy or computed tomography may localize the bleeding source and/or confirm active hemorrhage prior to angiography. Any angiographic evaluation should begin with selective catheterization of the artery supplying the most likely site of bleeding, as determined by the available clinical, endoscopic and imaging data. If a hemorrhage source is identified, superselective catheterization followed by transcatheter microcoil embolization is usually the most effective means of successfully controlling hemorrhage while minimizing potential complications. This is now well-recognized as a viable and safe alternative to emergency surgery. In selected situations transcatheter intra-arterial infusion of vasopressin may also be useful in controlling acute gastrointestinal bleeding. One must be aware of the various side effects and potential complications associated with this treatment, however, and recognize the high re-bleeding rate. In this article we

review the current role of angiography, transcatheter arterial embolization and infusion therapy in the evaluation and management of nonvariceal gastrointestinal hemorrhage.

### INTRODUCTION

Most cases of acute nonvariceal gastrointestinal hemorrhage resolve spontaneously and of those that do not, the majority respond to conservative medical management measures such as fluid resuscitation, correction of any coagulopathy and administration of blood products<sup>[1]</sup>. In those cases that are refractory to medical management, endoscopy is the mainstay for diagnosis and treatment. However, there is a subset of patients in whom endoscopic management is ineffective, and imaging evaluation with an accompanying alternative intervention is necessary for bleeding control because

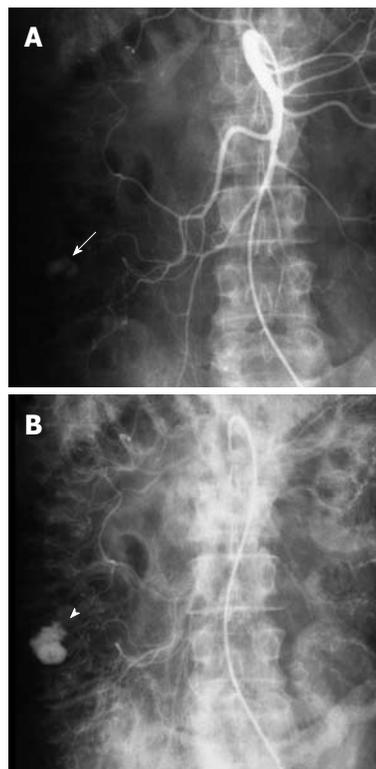

of recurrence or massive hemorrhage<sup>[1]</sup>. Localization and characterization of the bleeding source are important in determining the appropriate intervention, as treatment options range from minimally invasive catheter-directed therapy to extensive surgical resection. Although there has generally been a decline in the number of patients who present with acute gastrointestinal hemorrhage requiring angiography and/or transcatheter intervention, there are still patients who are unresponsive to either medical or endoscopic management and thus require emergency angiographic evaluation and possible transcatheter treatment.

The alimentary system is subdivided into the upper and lower gastrointestinal tracts and thus gastrointestinal hemorrhage is subcategorized according to the location of bleeding. The upper gastrointestinal system extends from the esophagus to the ligament of Treitz, while the latter includes the small bowel, colon and rectum. The distinction is important, as there are some characteristics that are relatively unique to each location and these may affect and determine the therapeutic approach to the particular bleeding source. Thus establishing the specific location of the bleeding as well as the etiology is critical to the treatment of patients with massive or recurrent gastrointestinal hemorrhage. Unfortunately the diagnosis can often be challenging because of the intermittent nature of gastrointestinal bleeding.

## PATIENT EVALUATION AND MANAGEMENT

The initial management of a patient with acute gastrointestinal hemorrhage should be directed at stabilization through administration of fluids and blood products, correction of coagulation abnormalities, placement of appropriate intravenous access lines and insertion of a nasogastric tube if needed. The vital signs should be closely monitored for signs of active bleeding that may manifest as tachycardia, hypotension and potential hypoxemia. Although persistent melena, hematochezia or hematemesis may provide direct clinical evidence of active hemorrhage, hemodynamic instability despite vigorous resuscitation is the best indicator of active bleeding that may be angiographically demonstrable.

Acute gastrointestinal hemorrhage far more frequently involves an upper than a lower gastrointestinal source, with the former most commonly due to either peptic ulcer disease or gastritis. The most common etiology of lower gastrointestinal hemorrhage, in young adults, is inflammatory bowel disease, while in patients older than 50 years, the cause is diverticulitis (Figure 1) and to a lesser extent, angiodysplasia. The colon is the source of lower gastrointestinal hemorrhage in 80% of individuals, with the bleeding site originating in the ascending colon in one-third, the transverse colon in another one-third, and the remainder in the descending colon and recto-sigmoid. A small bowel source of lower gastrointestinal hemorrhage occurs in only 20% of patients.

**Figure 1** Example of a bleeding colonic diverticulum. A: Arterial phase of a superior mesenteric artery arteriogram, obtained in a patient with acute lower gastrointestinal (GI) bleeding and a prior history of diverticulitis shows a rounded contrast collection (white arrow) arising from a branch of the right colic artery; B: In the later arterial phase the collection (white arrowhead) has increased in size but maintains the rounded configuration. The extravasated contrast medium is pooling in a colonic diverticulum, indicating that diverticular hemorrhage is the etiology of the lower GI bleeding.

If an upper gastrointestinal bleeding source seems most likely, endoscopy should be the initial diagnostic study, as the source can usually be identified and treated by the endoscopist. Unfortunately the endoscopic detection and treatment success rates in patients with lower gastrointestinal hemorrhage are generally less than with an upper source, particularly if rapid and significant bleeding is present.

## IMAGING PRIOR TO ANGIOGRAPHY

If a bleeding site cannot be identified endoscopically, or if a catheter-based intervention is being considered as a treatment option, obtaining imaging studies may be helpful. In order to successfully demonstrate bleeding by angiography, there must be active ongoing hemorrhage at the time of the examination. Bleeding rates of 0.5-1.0 mL/min have traditionally been considered necessary in order to angiographically demonstrate contrast extravasation<sup>[2]</sup>, but digital subtraction angiography (DSA) may be far more sensitive in detecting active extravasation than was previously thought<sup>[3]</sup>. Given the well-recognized intermittent nature of gastrointestinal bleeding, many advocate obtaining other imaging before proceeding directly to angiography unless there is massive ongoing

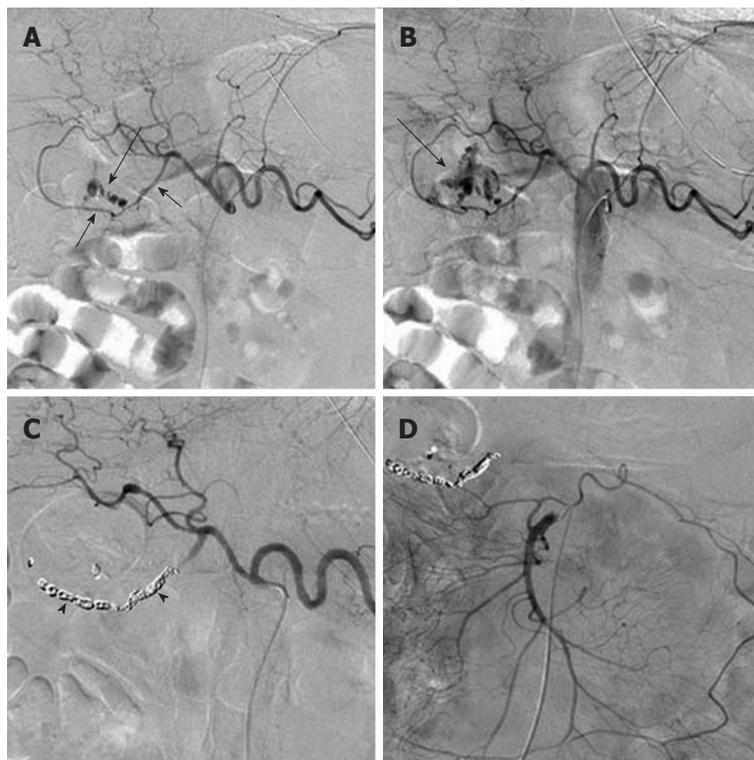

**Figure 2** A radionuclide Tc<sup>99m</sup>-labeled red blood cell scan obtained in a patient with acute lower gastrointestinal hemorrhage shows radioisotope accumulation in the left abdomen at 25 min (black arrow), which by 35 min has a small bowel location (black arrowhead) and by 50 min has distributed throughout much of the small intestine (short black arrows). The study demonstrates that the bleeding source is in the small bowel, and thus serves to appropriately direct either angiography or surgery.

hemorrhage or the patient is hemodynamically unstable. Thus a patient may be first evaluated with a radionuclide technetium<sup>99m</sup>-tagged red blood cell scan, as the nuclear scintigraphy study can demonstrate active bleeding at rates as low as 0.1 mL/min<sup>[4-6]</sup>. An arteriogram can be obtained following a positive bleeding scan (Figure 2), as a positive scintigram increases the likelihood of a positive angiogram from 22% to 53%<sup>[7]</sup>. The potential disadvantage of first obtaining a radionuclide study while there is clinical evidence of active bleeding is that prior to angiography the bleeding may cease during the delay necessitated by the nuclear medicine scan. A potentially useful algorithm to consider is to immediately perform angiography in hemodynamically unstable patients, and to first obtain nuclear medicine imaging in hemodynamically stable patients. This approach may potentially decrease the negative angiography examination rate.

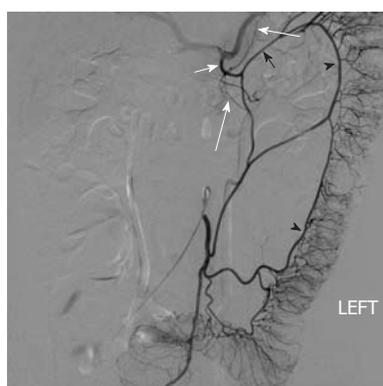

## ANGIOGRAPHIC EVALUATION OF ACUTE GASTROINTESTINAL HEMORRHAGE

Any angiographic evaluation of a patient with acute gas-

trointestinal hemorrhage should begin with the selective catheterization of the artery supplying the most likely site of bleeding, as determined by the available clinical, endoscopic and imaging data. Thus for suspected upper gastrointestinal hemorrhage, the celiac artery should first be evaluated (Figure 3), followed by the superior mesenteric artery (SMA), as the latter may contribute to a site of upper gastrointestinal hemorrhage through the pancreaticoduodenal arcade. The lower gastrointestinal tract, however, is the primary territory within the distribution of the SMA. It supplies the small bowel and the ascending and transverse portions of the colon, while the inferior mesenteric artery (IMA) supplies the splenic flexure, descending and sigmoid colonic segments as well as the rectum and anus. An additional arterial supply to the rectosigmoid and anus arises from the internal iliac arteries and this may become a dominant vascular pathway if there is IMA occlusion. The SMA becomes another collateral pathway in the presence of IMA occlusion and may provide the entire arterial supply to the descending and sigmoid colon *via* either the Arc or Riolan or the marginal artery of Drummond. One should be aware of the numerous mesenteric circulatory variations that may

**Figure 3** Angiographic diagnosis and transcatheter treatment of duodenal hemorrhage. A: Celiac digital subtraction angiography (DSA) arteriogram obtained in a patient with copious bleeding seen endoscopically in the duodenum shows focal contrast extravasation (black arrow) arising from the gastroduodenal artery (GDA); B: An image slightly later in the arterial phase of the DSA shows increasing extravasation (black arrow); C: The GDA was successfully coil embolized using microcoils (black arrowheads) through a microcatheter; D: An superior mesenteric artery DSA arteriogram was performed after the coil embolization in order to exclude any additional contribution to the duodenal hemorrhage from the pancreaticoduodenal arcade, as the duodenum has a rich collateral blood supply.

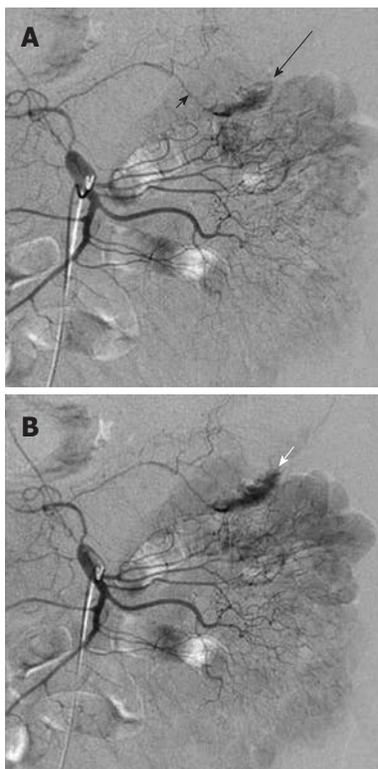

**Figure 4** Inferior mesenteric artery digital subtraction angiography arteriogram shows the marginal artery of Drummond (black arrowheads), which courses along the mesenteric border of the colon. There is retrograde filling of the left branch of the middle colic artery (black arrow), which arises from the dorsal pancreatic artery (white arrow) as an anatomic variant. There is also filling of pancreatic branches (long white arrows) along with partial opacification of the splenic and hepatic arteries.

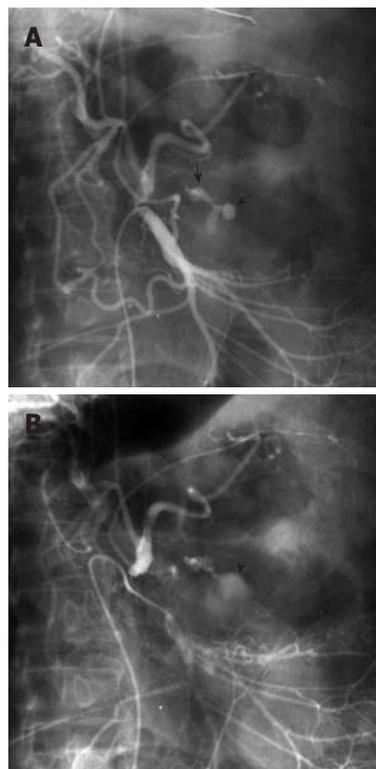

occur in the presence of occlusive disease. Furthermore, congenital variant vascular anatomy must be considered during the angiographic evaluation of gastrointestinal bleeding. For example, the entire middle colic artery may originate from the dorsal pancreatic artery in up to 2% of patients (Figure 4). If this situation exists, a celiac arteriogram may be required when investigating lower gastrointestinal bleeding, in order to fully evaluate the

colonic arterial supply, particularly in the presence of negative SMA and IMA arteriograms. If SMA, IMA, celiac, and internal iliac arteriography fail to either localize active hemorrhage or to demonstrate all the mesenteric vascular segments, then variant anatomy must be considered. There are known anomalous vessels that may arise directly from the abdominal aorta, such as an anomalous ileocolic artery or a middle mesenteric artery.

The classic angiographic finding denoting active gastrointestinal bleeding is extravasation of contrast material (Figure 5). Extravasation signifies a breach in the integrity of the arterial wall that permits the angiographic contrast to freely exit from the vessel. Extravasated contrast, therefore, does not have the typical tubular appearance of a vascular structure but instead distributes irregularly and often without a pattern. It may sometimes pool within the gastric rugae or within bowel folds or haustra so that the contrast assumes the appearance of a vein, the “pseudo-vein sign” (Figure 6). This may be differentiated from a true venous structure by the unusual location and appearance, as well as by the persistence beyond the venous phase of the contrast injection. Extravasation must also be differentiated from entities that mimic its appearance, such as a hypervascular bowel mucosa, adrenal gland vascular blush and DSA misregistration artifacts from bowel peristalsis or respiratory motion. There are also angiographic findings other than contrast extravasation that may be seen in certain patho-

**Figure 5 Contrast extravasation demonstrating location of lower gastrointestinal bleeding.** A: Superior mesenteric artery arteriogram shows an amorphous contrast collection (black arrow) arising from the left branch (long black arrow) of the middle colic artery; B: Later in the arterial phase the collection has increased and is layering dependently in the colon, assuming the configuration of the haustra. This extravasated contrast medium denotes the site of lower gastrointestinal bleeding.

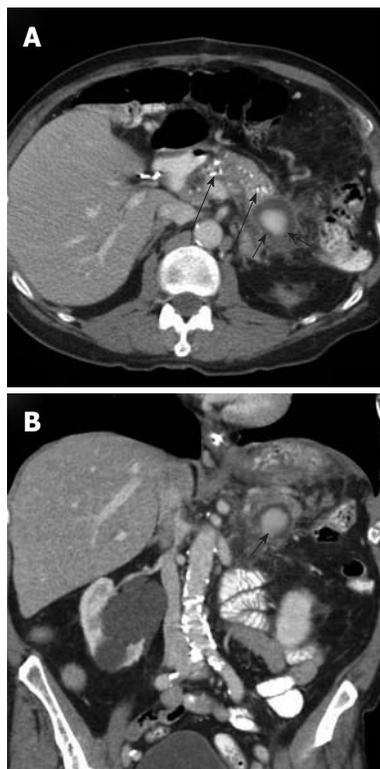

**Figure 6 The pseudovein sign in gastrointestinal hemorrhage.** A: Superior mesenteric artery arteriogram shows a branching contrast collection (black arrows), overlying the gastric air shadow. The collection has the appearance of a vascular structure such as a vein; B: A later image in the arterial injection shows that the collection (black arrowhead) has a more amorphous appearance, and represents extravasation. The former appearance is an example of the "pseudovein sign".

logic conditions and are suggestive of the cause and/or source of the gastrointestinal bleeding. In peptic ulcer disease, for example, small contrast collections may be seen within an ulcer crater, or may outline the gastric or duodenal mucosa. The angiographic demonstration of a gastric ulcer usually requires subselective catheterization of celiac arterial branches such as the left gastric artery, although the bleeding source may also potentially arise from the right gastric artery, the short gastric artery, or either the left or right gastroepiploic arteries. Additionally, the gastroduodenal artery may supply a bleeding pyloric or duodenal ulcer.

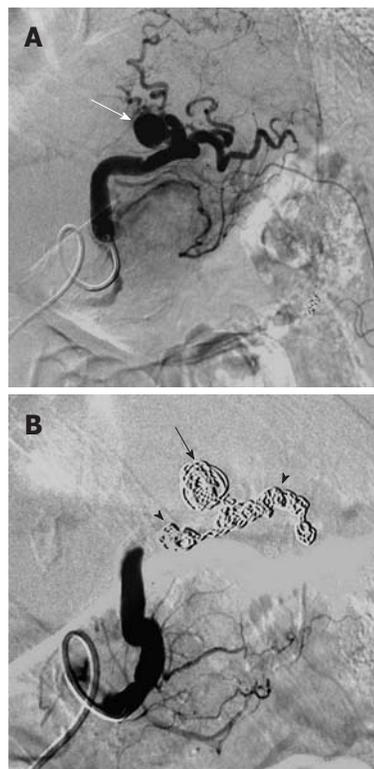

Arterial pseudoaneurysm is another angiographic abnormality that may be identified as a source of gastrointestinal hemorrhage. These occur most frequently in patients who have chronic pancreatitis. Hemosuccus pancreaticus refers to bleeding through the pancreatic duct, and may be caused by an arterial pseudoaneurysm that has resulted from chronic exposure of the arterial wall to the inflammatory effects of the pancreatic digestive enzymes<sup>[8]</sup>. The weakened arterial wall may permit the intermittent bleeding that characterizes hemosuccus pancreaticus, or the pseudoaneurysm may catastrophically rupture and cause acute massive, life-threatening intra-abdominal hemorrhage. Contrast enhanced computed tomographic angiography can be very effective in demonstrating these

characteristic pseudoaneurysms (Figure 7) and thus has an increasingly important role in the diagnosis of acute gastrointestinal hemorrhage that is secondary to pancreatitis, while angiographic transcatheter therapy provides the best treatment option in these patients (Figures 8 and 9). Given both the diffuse nature of the inflammatory process seen in pancreatitis, and the pancreatic arterial supply from both the celiac artery and SMA, pseudoaneurysms may be present involving either or both of these arteries or their branches. The angiographic evaluation must thus include both the celiac and SMA and transcatheter treatment may involve multiple sites. Surgical intervention is very difficult in these patients because of the extensive inflammatory process that characterizes this cause of bleeding (Figure 10).

Arterial pseudoaneurysms may also be seen in patients with chronic occlusive disease of the celiac artery, and involve the pancreaticoduodenal arteries (Figure 11). These pseudoaneurysms are rupture-prone and may cause massive acute upper gastrointestinal hemorrhage. Because of the occlusion of the origin of the celiac artery, the angiographic evaluation involves the selective catheterization of the SMA, in order to image the pancreaticoduodenal arcade. Any intervention, such as coil embolization, must typically also be performed *via* an SMA access, although there are cases in which a percutaneous route has been

**Figure 7** Upper gastrointestinal hemorrhage from pancreatitis related pseudoaneurysm. A: Axial contrast-enhanced computed tomography (CECT) scan, obtained in a patient who presented with hematemesis, shows pancreatic calcifications (long black arrows) indicating chronic pancreatitis and an enhancing mass (black arrows) in the pancreatic tail; B: Coronal CECT shows the rounded enhancing mass (black arrow) with surrounding inflammatory changes. This is suspicious for a pancreatitis-related pseudoaneurysm as the source of the upper gastrointestinal hemorrhage.

**Figure 8** Transcatheter treatment of a pancreatitis related pseudoaneurysm. A: Selective splenic artery digital subtraction angiography arteriogram shows that the pseudoaneurysm (white arrow) arises directly from the splenic artery; B: Coil embolization of the pseudoaneurysm (black arrow) and of the splenic artery (black arrowheads) both proximal and distal to the pseudoaneurysm was successful in controlling the hemorrhage. Arterial pseudoaneurysms associated with pancreatitis have a significant risk of rupture; if this occurs there is an extremely high mortality rate.

used to treat such an abnormality.

Angiodysplasia and arteriovenous malformations (AVMs) of the bowel are characterized by the early and prolonged opacification of a draining vein, accompanied by an abnormal tangle of vessels that may appear as a blush (Figure 12). The simultaneous filling of the feeding artery and the draining vein may give a characteristic “tram-track” sign. Although up to 80% of angiodysplastic lesions are in the right colon, other parts of the gut, particularly the lower small intestine, may be affected. Angiodysplasia is relatively common in older patients, aged 60 to 80 years, and may be an asymptomatic incidentally noted lesion identified at colonoscopy. Because the dilated vessels are superficial, however, they may bleed spontaneously and patients can either present acutely with overt hemorrhage or insidiously with iron deficiency anemia. Once bleeding has begun, recurrent episodic hemorrhage or persistent iron deficiency anemia requiring repeated transfusion is not uncommon. Symptomatic lesions may be effectively treated endoscopically with laser or heat coagulation or with sclerotherapy. These procedures are not risk-free in the thin cecal wall and have been known to cause serosal irritation and post-treatment bleeding. For patients with repeated bleeding from intestinal vascular malformations,

pharmacological treatment using estrogens (e.g., 0.05 mg ethinyl estradiol and 1 mg norethisterone) can be effective in reducing transfusion requirements. Although transcatheter arterial embolization of colonic angiodysplasia can be an effective treatment in emergencies<sup>[8-11]</sup>, it carries a significant risk of inducing colonic ischemia<sup>[12]</sup>. Definitive and curative treatment usually requires surgical resection.

## ANGIOGRAPHIC MANAGEMENT OF ACUTE GASTROINTESTINAL HEMORRHAGE

### ***Transcatheter arterial embolization***

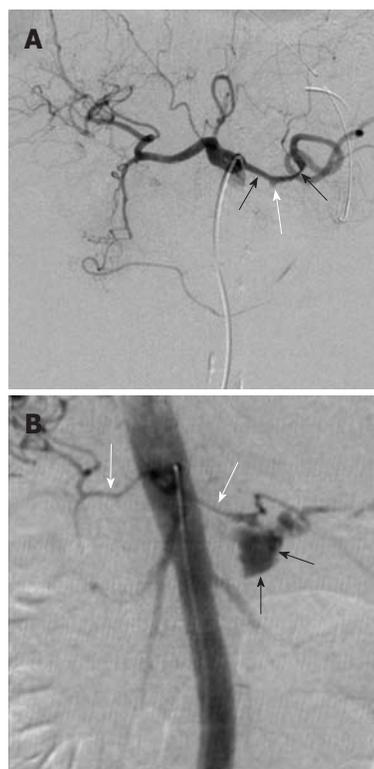

Transcatheter arterial embolization is an effective means of interrupting blood flow to the bleeding source, while maintaining bowel viability. Although there is a risk of bowel ischemia and/or infarction, the coaxial catheter systems and the variety of available embolic agents that are now used for embolotherapy allow for very selective and precise treatment, and thus have decreased the incidence of these complications. Additionally, the gastrointestinal tract has a rich collateral blood supply, with extensive vascular arcades that permit safe embolization

**Figure 9 Treatment of ruptured pseudoaneurysm with covered intravascular stent.** A: Digital subtraction angiography arteriogram obtained in a patient with upper gastrointestinal bleeding and a history of pancreatitis shows irregular dilatation of the proximal superior mesenteric artery (black arrows) and contrast extravasation (black arrowhead) consistent with pseudoaneurysm rupture; B: The hemorrhage was successfully controlled with covered stent (white arrows) placement.

if certain principles are observed. The objective of embolization therapy is to achieve a compromise between selective arterial inflow reduction and maintenance of collateral arterial blood flow. Arterial inflow must be sufficiently decreased to allow for hemostasis, but not to an extent that causes complete devascularization. Achieving a superselective embolization<sup>[11]</sup> in the presence of an intact coagulation cascade is key to attaining a successful outcome using this form of treatment.

In most of the early literature, embolization was performed proximally in the visceral arteries because microcatheters facilitating superselective embolization were not yet available. The technique that is currently used for transcatheter arterial embolization involves the initial placement of a larger caliber diagnostic catheter (4 or 5 Fr) into the main trunk of the feeding artery, followed by coaxial introduction of a microcatheter. The latter is the crucial step in modern embolization and requires the superselective catheterization of the target artery using a 3-Fr coaxial microcatheter over a 0.018 inch or 0.014 inch guidewire. The guidewire tip must be carefully advanced under fluoroscopic monitoring in a smooth and controlled fashion in order to avoid vasospasm, dissection, or vessel perforation. Vasodilators such as verapamil (100-200  $\mu$ g) or nitroglycerin (100-300  $\mu$ g) may be used to treat any vasospasm that may be induced by

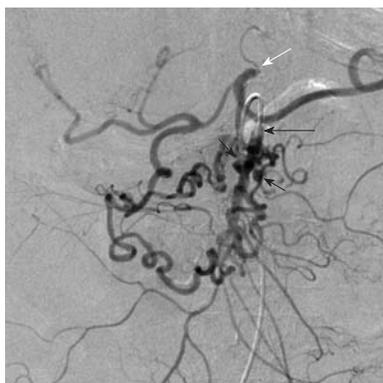

**Figure 10 Life-threatening hemorrhage from pancreatitis related pseudoaneurysm.** A: Celiac digital subtraction angiography arteriogram obtained in a patient with intermittent upper gastrointestinal bleeding and a history of chronic pancreatitis shows an irregular caliber to the splenic artery (black arrows) and a small pseudoaneurysm (white arrow). No intervention was performed at the time of this examination; B: Two weeks after the celiac arteriogram the patient presented with acute onset of severe abdominal pain and profound hypotension. Repeat angiography showed brisk contrast extravasation (black arrows) from the splenic artery. Note the marked vasoconstriction (white arrows) of the hepatic and splenic arteries due to the life-threatening hemorrhage.

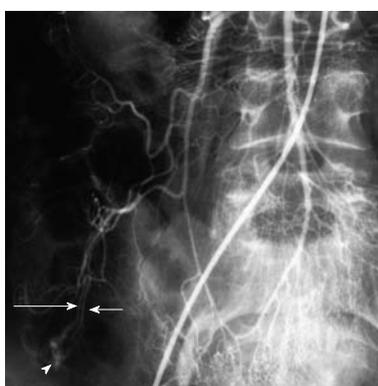

guidewire and/or microcatheter passage. Using the wire as a guide, the catheter should travel closely behind and eventually engage the target vessel.

The optimal level of embolization varies according to the bleeding site. In general, embolization should not be routinely attempted unless a microcatheter has been advanced close to the bleeding point so that the embolic agent can be deployed as selectively as possible. The risk of infarction is related to both the embolic agent and the proximity of embolization. In the colon, for example, ischemia and infarction may result from embolization of proximal branches supplying a large area of bowel or embolization of multiple distal arteries that do not have sufficient collateral flow. Submucosal collateral blood flow may be preserved only when arteries to a short segment of bowel are embolized, so one should attempt to occlude arteries to as limited a segment of bowel as possible. One must be aware that embolization in the setting of prior gastrointestinal surgery or radiation therapy may impose a greater risk of infarction because of the associated interruption of collaterals.

Various agents may be used for transcatheter embolization. The most commonly used agents include pledgets of absorbable gelatin sponge (Gelfoam<sup>®</sup>, Pfizer, Inc., NY,

**Figure 11** Digital subtraction angiography obtained with the catheter tip (long black arrow) in the superior mesenteric artery shows tortuous and dilated inferior pancreaticoduodenal arteries with at least two small pseudoaneurysms (black arrows). There is retrograde filling of the celiac arterial branches via the inferior pancreaticoduodenal arteries arcade, because the celiac origin is occluded (white arrow). The pseudoaneurysms are at risk of rupture.

**Figure 12** Magnified view from a superior mesenteric artery arteriogram shows an area of abnormal vascularity (white arrowhead) in the cecal area, with an early draining vein (long white arrow) paralleling the arterial inflow (white arrow). This simultaneous filling of the feeding artery and draining vein is known as the “tram-track” sign and is characteristic of angiodysplasia.

United States), particulate agents such as polyvinyl alcohol (e.g., Bead Block™, Biocompatibles International, Farnham, United Kingdom) and other spherical agents (e.g., Embospheres® BioSphere Medical, Inc., Rockland, MA, United States; Embozene™ microspheres Celonova BioSciences, Inc., Newnan, GA, United States) and microcoils of various sizes and configurations. Microcoils have the advantage of good radiopacity that allows for a precise deployment permitting reduction of the arterial perfusion pressure to the bleeding site while preserving sufficient collateral flow. The wide range of coil sizes allows one to appropriately match the coil to the target vessel diameter. Each microcoil is delivered sequentially, until hemostasis has been achieved. Intra-arterial microcoil placement is analogous to placement of a surgical ligature. The coil physically occludes the vascular lumen and causes a decreased perfusion pressure, while the attached synthetic fibers maximize thrombogenicity.

Gelfoam pledgets and particulate agents may also be used successfully, but are more difficult to control than

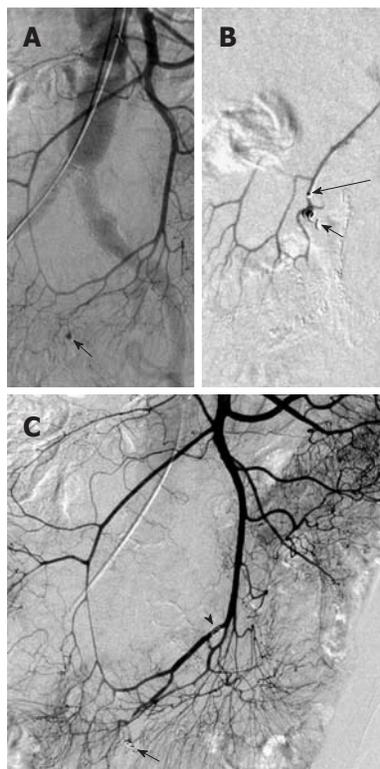

microcoils. Gelfoam is a temporary agent and often cannot easily be deployed superselectively. A disadvantage of the particulate agents is that small diameters may reach the intramural circulation distal to the collaterals, thereby risking bowel infarction, or may reflux into non-target arteries.

The liquid embolic agents n-butyl cyanoacrylate, known by the proprietary name Trufill® (Cordis Neurovascular, Miami Lakes, FL, United States), and liquid polyvinyl alcohol copolymer (Onyx®, ev3 Neurovascular, Irvine, CA, United States) have also been used successfully in treating gastrointestinal hemorrhage<sup>[13,14]</sup>. An advantage of liquid agents is that they may be used effectively in very small caliber vessels. However, the operator must be very familiar with the use of these agents, in order to achieve optimal outcomes and minimize complications.

### **Technical challenges of transcatheter arterial embolization**

Because of the intermittent nature of gastrointestinal hemorrhage, arteriography fails to demonstrate a distinct bleeding site in a considerable number of patients, and thus embolization is not possible. Furthermore, a negative arteriogram fails to guide emergency surgery and delays operative decision-making. In such circumstances, some investigators have advocated provocation of bleeding with vasodilators, anticoagulants, and/or thrombolytics in association with tagged red blood cell scans or angiography<sup>[15,16]</sup>. This may be appropriate for a patient who has undergone multiple blood transfusions and a prior exhaustive work-up that has failed to localize the occult bleeding site. Additionally there must be no contraindications to the administration of a thrombolytic agent. If provocative angiography is undertaken, one should arrange for surgical backup in the event that uncontrollable bleeding occurs.

Different methods of inducing bleeding and different rates of success have been reported. An optimal protocol has yet to be established and the procedure has also yet to become accepted by clinicians as part of the evaluation of gastrointestinal bleeding. The technique continues to evolve as experience and comfort with the use of thrombolytic agents in the setting of nonlocalized bleeding increases. One reported protocol used a combination of intravenous heparin, intra-arterial tolazoline, and intra-arterial tissue-type plasminogen activator (t-PA) to provoke bleeding. Doses used included 3000-10 000 U heparin, 25-100 mg intra-arterial tolazoline, and 10-50 mg intra-arterial t-PA (mean, 20.3 mg). The investigators also noted that more patients had bleeding provoked after smaller rather than larger doses of t-PA<sup>[16]</sup>. Tolazoline (Priscoline) was formerly used for a vasodilatory effect, but was withdrawn from the United States market in 2002 by Novartis Pharmaceuticals, the sole manufacturer of this drug. Alternative intra-arterial vasodilators that may be used include verapamil (100-200 µg) and nitroglycerin (100-300 µg), with the former showing the greater vasodilatory effects. In the authors' practice, we have occasionally used a similar transcatheter regimen, in

**Figure 13** Example of nontarget embolization during treatment of lower gastrointestinal bleeding. A: Superior mesenteric artery arteriogram obtained in a patient with lower gastrointestinal bleeding shows a focal contrast collection (black arrow) arising from a branch of the ileocolic artery; B: A microcatheter was introduced and was subselectively positioned with the tip (long black arrow) immediately proximal to the focal extravasation and a microcoil (black arrow) was placed; C: While attempting to place a second microcoil, the microcatheter tip was displaced proximally resulting in coil placement in a nontarget location (black arrowhead). Repeat digital subtraction angiography shows that the second coil is nonocclusive and the initially placed coil has successfully controlled the bleeding source.

which a vasodilator and a dose of 5000 U intra-arterial heparin and 5-10 mg intra-arterial t-PA were administered, with resultant provocation of bleeding that allowed for subsequent successful transcatheter embolization.

Superselective embolization of the arterial supply to the bleeding source may be technically demanding, particularly in older patients who may have significant atherosclerotic disease. The mesenteric vasculature and the various arterial arcades are often tortuous, and the smaller arteries are prone to vasospasm and care must be taken to avoid dissection.

An arterial bleeding site may receive a dual blood supply as a result of the rich collateral arcades that characterize the mesenteric circulation. One must therefore catheterize and inject both potential sources of perfusion to the lesion and be prepared to embolize two separate vessels if necessary. Although this dual approach will control the hemorrhage, it will also increase the risk of bowel ischemia<sup>[17]</sup>.

While angiodysplasia and AVMs may initially respond to embolization, recurrent hemorrhage is frequent and, as noted, surgical resection of the involved bowel segment is often required. A small bowel AVM is much more eas-

ily localized at surgery if an embolization coil has been placed distally in the arterial branch that supplies the lesion, so that it is palpable or visible to the surgeon<sup>[18]</sup>.

### **Results of transcatheter arterial embolization**

The current technique of embolization in the treatment of acute gastrointestinal hemorrhage successfully controls bleeding in about 80%-90% of patients<sup>[19-23]</sup>. Recurrent hemorrhage is infrequent, with the exception of angiodysplasia, AVMs and inflammatory lesions. Recurrences can usually be angiographically re-evaluated and, if a bleeding source is identified, treated with repeat embolization.

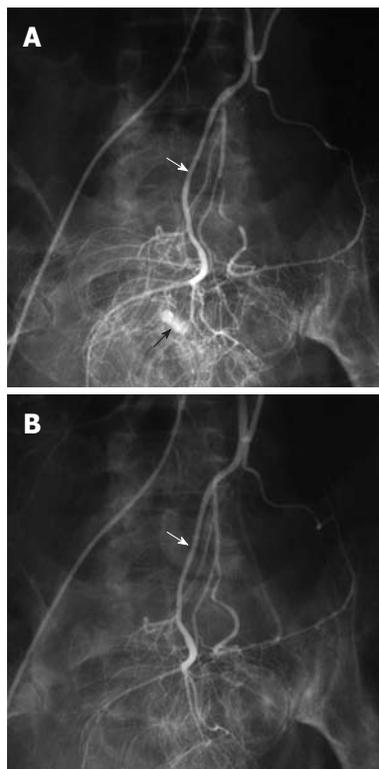

### **Complications of transcatheter arterial embolization**

Transcatheter arterial embolization for the treatment of acute gastrointestinal hemorrhage is safe, with major adverse events occurring in less than 2% of patients. A fraction of patients embolized superselectively will develop minor, asymptomatic and self-limited ischemic changes such as small ulcers that can only be detected incidentally *via* objective follow-up methods such as endoscopy, pathologic surgical specimen or by a radiographic imaging examination. Additionally, superselective microcoil embolization is unlikely to result in delayed infarction. If major bowel ischemia occurs several months to years later, it is more likely to be attributable to a new and acute insult such as thromboembolic disease affecting the mesenteric arterial bed.

Non-target embolization with microcoils is rare, as the coils are introduced only after a microcatheter has been successfully negotiated into the target vessel. One must carefully choose appropriate sized microcoils however, as a coil that is oversized relative to the target vessel may displace the microcatheter from its superselective position. This could lead to deployment of the microcoil in a non-target location (Figure 13). Similarly, undersized coils may fail to adequately occlude the target vessel or may lodge distal to the lesion that is to be treated.

### **Vasopressin infusion therapy**

Vasopressin (Pitressin) is a naturally occurring hormone that causes constriction of both the mesenteric arteries and of the smooth muscle of the bowel wall. The intra-arterial transcatheter infusion of vasopressin proximal to a mesenteric arterial bleeding site will reduce blood flow, thereby lowering the perfusion pressure and permitting clot formation at the lesion (Figure 14). There are several situations in which this form of treatment for gastrointestinal bleeding should not be used. These include bleeding that originates from a large diameter artery such as the gastroduodenal, splenic or proximal SMA or which occurs at a site with a dual blood supply such as the duodenum. It is also contraindicated in patients who have severe coronary artery disease, extreme hypertension, limb ischemia or cardiac arrhythmias. Superselective embolotherapy is now used preferentially over vasopressin infusion for treating gastrointestinal hemorrhage because embolization poses fewer risks and can

**Figure 14 Vasopressin infusion therapy for lower gastrointestinal hemorrhage.** A: Inferior mesenteric digital subtraction angiography arteriogram shows contrast extravasation (black arrow) in the rectosigmoid colon, arising from a branch of the superior hemorrhoidal artery (white arrow); B: Following trans-catheter arterial vasopressin infusion, there is no longer any evidence of active bleeding from the superior hemorrhoidal (white arrow) arterial distribution.

be completed more rapidly than a vasopressin infusion protocol. Vasopressin may still be useful in certain situations, despite the numerous side effects and the high re-bleeding rates. One may consider using vasopressin for treating lesions that are inaccessible to a microcatheter, for diffuse mucosal oozing, and for controlling multiple sites of hemorrhage in high-risk surgical patients.

#### **Technique of vasopressin infusion therapy**

Vasopressin is typically infused into the central vessel (e.g., celiac artery, SMA or IMA) that supplies the bleeding site *via* a catheter that has been placed proximally; to avoid bowel ischemia and potential infarction, a distal infusion should not be attempted. Vasopressin (100 U) is mixed in 500 mL of normal saline and the infusion is started at 0.2 U/min for 20 min using an arterial infusion pump set at 60 mL/min. If there is no cessation of bleeding, the dose is increased by 0.1 U/min up to a maximum of 0.4 U/min; each dosage change is followed by a repeat angiogram 20 to 30 min later to assess the effectiveness<sup>[24]</sup>. If the bleeding stops, the catheter is left in place for a 24-h infusion at the effective dosage, with monitoring in the intensive care unit. After another repeat angiogram shows control of bleeding, the vasopressin infusion is gradually reduced over 24 to 48 h and then vasopressin is replaced with an infusion of normal saline or 5% dextrose in water for 6-12 h.

#### **Results of vasopressin infusion therapy**

This form of therapy is particularly effective in controlling diverticular and gastric mucosal hemorrhage, with initial success rates ranging from 60%-90%<sup>[24-27]</sup>. As previously noted, however, there is a very high rate of re-bleeding that may be up to 50%.

#### **Complications of vasopressin infusion therapy**

Mild abdominal pain may occur at the initiation of the infusion and should be closely monitored, as persistence and/or worsening can be an indicator of bowel ischemia. If side effects develop during treatment, the vasopressin can be tapered to a lower dose or may need to be discontinued. Additional side effects and potential complications of vasopressin therapy include angina, myocardial infarction, hypertension, volume overload, abdominal cramps, and mesenteric ischemia. Some of the potential adverse effects may be treated or even pretreated. The simultaneous administration of intravenous, sublingual or transdermal nitroglycerin may prevent or reverse the cardiotoxic side effects of vasopressin infusion<sup>[28]</sup>.

#### **CONCLUSION**

Technical refinements and advances both in diagnostic angiography and in transcatheter arterial embolization have strengthened these options for the evaluation and management of acute gastrointestinal hemorrhage that is refractory to medical and endoscopic therapy. Highly sensitive noninvasive imaging modalities such as nuclear scintigraphy and contrast-enhanced computed tomography are extremely useful adjuncts to angiography as they often can localize and characterize the bleeding source, confirm active hemorrhage and aid in planning an appropriate transcatheter intervention. Superselective catheterization using a coaxial system that allows for microcoil embolization is an effective and safe alternative to emergency surgery. Other embolic agents such as gelatin sponge, spherical particles and liquids also have a role in transcatheter management of gastrointestinal bleeding as do transcatheter therapies such as covered stent placement and vasopressin infusion.

### Abstract

Acute upper gastrointestinal bleeding (UGIB) is a gastroenterological emergency with a mortality of 6%-13%. The vast majority of these bleeds are due to peptic ulcers. Nonsteroidal anti-inflammatory drugs and *Helicobacter pylori* are the main risk factors for peptic ulcer disease. Endoscopy has become the mainstay for diagnosis and treatment of acute UGIB, and is recommended within 24 h of presentation. Proton pump inhibitor (PPI) administration before endoscopy can downstage the bleeding lesion and reduce the need for endoscopic therapy, but has no effect on rebleeding, mortality and need for surgery. Endoscopic therapy should be undertaken for ulcers with high-risk stigmata, to reduce the risk of rebleeding. This can be done with a variety of modalities. High-dose PPI administration after endoscopy can prevent rebleeding and reduce the need for further intervention and mortality, particularly in patients with high-risk stigmata.

### INTRODUCTION

Acute upper gastrointestinal bleeding (UGIB) is the most common gastroenterological emergency and has a considerable morbidity and mortality. Management strategies have changed dramatically over recent decades due to the introduction of acid suppressive therapy [histamine-2 receptor antagonists and especially proton pump inhibitors (PPIs)] and endoscopic therapy. This review deals with the current standards and future perspectives in management of acute nonvariceal UGIB.

### EPIDEMIOLOGY

The incidence rates of UGIB demonstrate a large geographic variation ranging from 48 to 160 cases per 100 000 population, with consistent reports of higher incidences among men and elderly people<sup>[1-5]</sup>. Possible

None	3-19

explanations for the reported geographic variation in incidence are differences in definition of UGIB in various studies, population characteristics, prevalence of ulcerogenic medication, in particular aspirin and nonsteroidal anti-inflammatory drugs (NSAIDs), and *Helicobacter pylori* (*H. pylori*) prevalence. Some but not all time-trend studies have reported a significant decline in incidence of acute UGIB, especially peptic ulcer bleeding, in recent years<sup>[1,3,6]</sup>. This decline is likely due to a combination of factors, including decreasing prevalence of gastric colonization with *H. pylori*<sup>[1]</sup>, the use of eradication therapy in patients with ulcer disease, and the increased use of PPI therapy, both in general and in patients using aspirin and NSAIDs in particular.

Despite the introduction of therapeutic endoscopy and acid-suppressive therapy, the overall mortality of UGIB has remained stable over recent decades and is still 6%-14% in most studies (Table 1)<sup>[1,3-5,7]</sup>. The majority of deaths do not directly result from exsanguination, but are related to poorly tolerated blood loss and resultant shock, aspiration, and therapeutic procedures. As such, mortality from UGIB is strongly associated with advanced age and presence of severe comorbidity. The risk of mortality increases with rebleeding, which is thus another major outcome parameter<sup>[5]</sup>. The incidence of rebleeding in patients with UGIB shows a wide range from 5% to more than 20%, depending on several factors<sup>[3,4]</sup>. These firstly include the etiology of the bleeding, with rebleeding being more common in patients with variceal bleeding (25%) and uncommon in patients with small mucosal lesions such as Mallory-Weiss lesions. A second factor that determines the frequency of rebleeding is the timing and use of adequate endoscopic therapy. There is strong evidence that the risk of rebleeding is highest in the initial period of admission, and a 24-h time frame for endoscopic therapy is internationally

recommended as the optimal window of opportunity<sup>[8,9]</sup>. Mortality amongst those with recurrent bleeding is considerably higher, therefore, rebleeding must be prevented whenever possible<sup>[8]</sup>.

Peptic ulcer bleeding (PUB) is the most common cause of UGIB, accounting for 31%-67% of all cases, followed by erosive disease, variceal bleeding, esophagitis, malignancies and Mallory-Weiss tears (Table 2)<sup>[1,3-5,7,10]</sup>. In 2%-8% of cases, uncommon causes such as Dieulafoy's lesion, hemobilia, angiodysplasia, vasoenteric fistula, and gastric antral vascular ectasia have been found. In the remainder of this paper, we mainly focus on PUB, yet the approach to and treatment of any patient with nonvariceal UGIB is for the most part comparable. Possible differences will be discussed in the section on endoscopic therapy.

In the subgroup of patients with PUB, bleeding from duodenal ulcers is slightly more frequent than from gastric ulcers<sup>[1,4]</sup>. NSAID use and *H. pylori* infection are independent risk factors for UGIB, especially PUB<sup>[8,11]</sup>. The prevalence of *H. pylori* infection in PUB patients varies between 43 and 56%<sup>[12-14]</sup>, and treatment of *H. pylori* significantly reduces the rebleeding rate according to some randomized controlled trials<sup>[15,16]</sup>.

## PRE-ENDOSCOPIC MANAGEMENT

### Initial resuscitation and risk stratification

Patients with UGIB can present with various symptoms such as hematemesis, hematochezia, melena, or progressive anemia. Immediate evaluation and appropriate resuscitation is of major importance in these patients. Stratification of patients in low- and high-risk categories for rebleeding and mortality can be done using the Blatchford and initial Rockall scores (before endoscopy), or complete Rockall score (after endoscopy) (Table 3)<sup>[17,18]</sup>. The Blatchford score is more focused on clinical symptoms and laboratory results, whereas the Rockall score considers age as a parameter.

Resuscitation includes intravenous administration of fluids, and supplemental oxygen, correction of severe coagulopathy, and blood transfusion when needed. The threshold for blood transfusion depends on the underlying condition, rate of bleeding, and vital signs of the patient, but is generally set at a hemoglobin level of  $\leq 70$  g/L<sup>[19]</sup>. A recent meta-analysis regarding outcomes following red blood cell transfusion in patients with UGIB, however, suggests that red blood cell transfusion is associated with

**Table 3** Comparison of Blatchford and Rockall risk scoring systems

Risk factor	Blatchford score		Initial Rockall score	
	Parameter	Score	Parameter	Score
Age (yr)	-		60-79	1
			≥ 80	2
Systolic blood pressure (SBP) (mmHg)	100-109	1	< 100	2

higher mortality and rebleeding rate. The conclusions of this study were limited by the small size of the studies and the large volume of missing data. In addition, the possibility that patients who present with more severe and active bleeding are more rapidly transfused, acted as a potential major confounder in these analyses<sup>[20]</sup>. This means that prospective studies need to be done with strict predetermined transfusion protocols, and that for now, the risks and benefits of blood transfusion must be carefully weighed individually.

**Pre-endoscopic pharmacotherapy**

Administration of PPIs before endoscopy has become common practice in patients suspected with PUB. A strongly acidic environment leads to inhibition of platelet aggregation and plasma coagulation as well as to lysis of already formed clots<sup>[21]</sup>. PPIs quickly neutralize intraluminal gastric acid, which results in stabilization of blood clots. In the longer term, antisecretory therapy also promotes mucosal healing. A recent systematic review has shown that pre-endoscopic PPI administration significantly reduces high-risk stigmata at index endoscopy (37% *vs* 46% respectively, OR: 0.67; 95% CI: 0.54-0.84) and need for endoscopic therapy (9% *vs* 12%

respectively, OR: 0.68; 95% CI: 0.50-0.93). However, no effect on clinically important outcome measures such as rebleeding, mortality and need for surgery was seen<sup>[22]</sup>.

Another pharmacotherapeutic approach includes the use of prokinetics before endoscopy, in particular, erythromycin or metoclopramide. A meta-analysis of five studies assessing a total of 316 patients with acute UGIB has found a significant reduction in the need for repeated endoscopy (OR: 0.55; 95% CI: 0.32-0.94) in the prokinetic treatment group compared to the reference group (placebo or no treatment). The groups did not differ in the need for blood products, hospital stay, and need for surgery<sup>[23]</sup>. Therefore, prokinetics are not routinely recommended, but can be useful in patients who are suspected of having substantial amounts of blood in the stomach<sup>[9]</sup>. Administration of PPIs and prokinetics should however not delay endoscopy.

**ENDOSCOPY**

**Time to endoscopy**

Endoscopy has become a valuable and indispensable tool for diagnosis and treatment of UGIB<sup>[24,25]</sup>. It allows for identification of the bleeding source and application of treatment in the same session. The optimal timing for endoscopy remains under debate. Emergency endoscopy allows for early hemostasis, but can potentially result in aspiration of blood and oxygen desaturation in insufficiently stabilized patients. In addition, extensive amounts of blood and clots in the stomach can hinder targeted treatment of the bleeding focus, which results in repeated endoscopic procedures. International consensus guidelines recommend early endoscopy within 24 h of presentation, because it significantly reduces the length of hospital stay and improves outcome<sup>[19]</sup>. Very early endoscopy (< 12 h) has so far not been shown to provide additional benefit in terms of reduction of rebleeding, surgery and mortality, compared with later endoscopy (within 24 h)<sup>[26-29]</sup>. However, emergency endoscopy should be considered in patients with severe bleeding.

**Endoscopic therapy for PUB**

The aim of therapeutic endoscopy is to stop any ongoing bleeding and prevent rebleeding. Several techniques, including injection therapy, ablative therapy and mechanical therapy have been studied over recent decades<sup>[24,30,31]</sup>. Depending on the appearance of the bleeding focus and the related risk for persistent or recurrent bleeding, a suitable technique should be chosen. In PUB, patients with active bleeding ulcers or a nonbleeding visible vessel in an ulcer bed are at highest risk of rebleeding and therefore need prompt endoscopic hemostatic therapy (Figures 1 and 2)<sup>[32]</sup>. Patients with low-risk stigmata (a clean-based ulcer or a pigmented spot in an ulcer bed) do not require endoscopic therapy.

The role of endoscopic therapy for ulcers with adherent clots has been a topic of debate<sup>[19]</sup>. The risk of rebleeding depends on underlying lesions, so that clot re-

Figure 1 Ulcer with visible vessel.

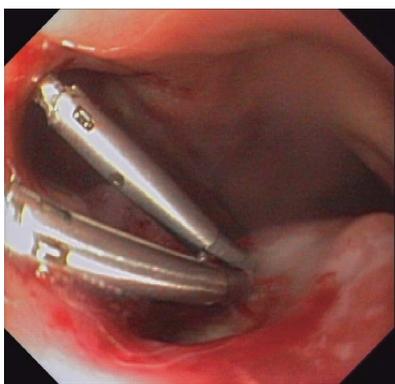

Figure 2 Ulcer with visible vessel after hemoclip placement.

removal should be attempted by vigorous irrigation. Stigmata revealed after clot removal are of high risk in about 70% of cases<sup>[33]</sup>. In a meta-analysis including 240 patients from six different studies, comparing endoscopic *vs* medical therapy for peptic ulcers with adherent clots, rebleeding was significantly lower in the endoscopic therapy group compared with the control group (8% *vs* 25%,  $P = 0.01$ )<sup>[34]</sup>. Another meta-analysis, however, has shown no benefit of endoscopic therapy for bleeding peptic ulcers with adherent clots<sup>[35]</sup>. These discrepancies could be attributed to inclusion of different studies and heterogeneity in statistical analysis. At present, endoscopic therapy should be considered, although intensive PPI therapy alone might be sufficient in ulcers with adherent clots<sup>[19]</sup>.

Epinephrine injection therapy promotes initial hemostasis by a combination of vasospasm and local tamponade. This effect declines after 20 min, and requires additional treatment with a more durable technique. In several meta-analyses, no superiority of one specific technique was proven; in particular, hemoclip placement, thermocoagulation (e.g., heater probe), and electrocoagulation (e.g., Gold probe, BICAP probe) all seem equivalent alternatives<sup>[24,30,31,36]</sup>. Patients with recurrent bleeding can usually be managed by endoscopic therapy. However, emergency surgery or angiographic embolization is required on occasion. There have been no randomized trials that have compared surgery and angiographic em-

bolization.

A new promising endoscopic application is the use of a chemical compound which, when sprayed as nanopowder on active bleeding, can lead to immediate hemostasis, with coverage of the bleeding ulcer with a powder layer. In a pilot study of 15 patients with active ulcer bleeding treated with this nanopowder, immediate hemostasis was achieved in 93%, and one patient had recurrent bleeding. No adverse events were reported during the 30-d follow-up<sup>[37]</sup>. Further studies with this product are ongoing and will elucidate if application is also beneficial for other causes of nonvariceal UGIB.

### Endoscopic therapy for other causes of nonvariceal UGIB

Treatment and prevention of (bleeding from) erosions depends upon the cause (e.g., drug-induced, mechanical, or inflammatory). Most cases respond well to PPIs. The offending agent should be discontinued whenever possible and, if present, *H. pylori* should be eradicated. Acute bleeding sometimes needs endoscopic therapy, similar to that for PUB<sup>[38]</sup>.

Hemorrhage due to neoplastic lesions is often difficult to manage because of the diffuse character of the bleeding and vulnerability of the mucosa. Primary endoscopic therapy is recommended, but additional surgical consultation is sometimes necessary. In cases with diffuse tumor bleeding in a palliative setting, radiotherapy is often the treatment of choice.

Most bleeding from Mallory-Weiss tears stops spontaneously. Patients with stigmata of active bleeding, however, might require interventional endoscopy<sup>[39]</sup>. Endoscopic therapy is the first choice in bleeding Dieulafoy's lesions and is usually performed with clipping or banding of the lesion<sup>[40]</sup>.

The current standard for endoscopic treatment of bleeding angiodysplasia consists of coagulation therapy. Sometimes, pharmacological agents such as estrogen and progesterone, octreotide or thalidomide are given, but their effects remain controversial.

Gastric antral vascular ectasia responds best to endoscopic ablation of the lesion.

## POSTENDOSCOPIC MANAGEMENT

### Antisecretory therapy

Pharmacotherapy plays a second major role in the treatment of UGIB. PPI therapy is superior over histamine-2 receptor antagonists<sup>[19]</sup>. PPIs can be administered orally or intravenously depending on the rebleeding risk. In a randomized placebo-controlled trial of 767 multiethnic PUB patients treated with endoscopic therapy because of high-risk stigmata, high-dose intravenous PPI (80 mg esomeprazole bolus, 8 mg/h continuous infusion for 72 h) significantly reduced rebleeding (5.9% *vs* 10.3%,  $P = 0.03$ ) and the need for endoscopic retreatment<sup>[41]</sup>. Similar results were found by meta-analysis; high-dose intravenous PPI after endoscopic therapy significantly reduced rebleeding [relative risk (RR): 0.40; 95% CI: 0.28-0.59], need for sur-

gery (RR: 0.43; 95% CI: 0.24-0.58) and mortality (RR: 0.41; 95% CI: 0.20-0.84) compared with placebo/no therapy<sup>[35]</sup>. These data support the guideline recommendation to give high-dose continuous intravenous PPI therapy to patients with PUB with high-risk stigmata.

Additionally, all patients with PUB should be discharged with a prescription for a single-daily-dose oral PPI to reduce the risk of recurrent bleeding. The duration and dose of the PPI depend on the underlying etiology and additional medication use<sup>[19]</sup>.

### ***H. pylori* eradication therapy**

Testing for *H. pylori* is recommended in all patients with PUB<sup>[19]</sup>. This should be followed by eradication therapy for those who are *H. pylori*-positive, with subsequent assessment of the effect of this therapy, and renewed treatment in those in whom eradication fails. The efficacy of eradication therapy and maintenance antisecretory therapy for the prevention of rebleeding has been assessed in a meta-analysis of randomized trials. This revealed a significantly lower risk of rebleeding in the *H. pylori* eradication group, that is, 1.6% *vs* 5.6% within a median follow-up of 12 mo. When only patients with successful *H. pylori* eradication were included, the rebleeding rate was even lower (1%)<sup>[42]</sup>. Therefore, confirmation of eradication is recommended. Diagnostics tests for *H. pylori* have a low negative predictive value in the setting of acute UGIB. This might be due to technical difficulties to collect a sufficient number of representative biopsies, or inaccuracy of the test in a more alkaline environment caused by the blood<sup>[43]</sup>. Initial negative results on biopsies obtained in the acute setting must therefore be interpreted with caution and repetition of the test during follow-up is recommended<sup>[19]</sup>.

### **CONCLUSION**

The management of UGIB has changed dramatically over recent decades. Endoscopic therapy and pharmacotherapy have become the mainstay in management. Early endoscopy within 24 h of presentation, or earlier in selected cases with signs of ongoing bleeding, improves outcome and reduces length of hospital stay. Endoscopic epinephrine injection in combination with another endoscopic technique reduces the risk for rebleeding and related mortality in patients with high-risk ulcers. Adequate *H. pylori* eradication and PPI therapy after discharge can bring the rebleeding and mortality rates further down.

Ongoing development is expected especially in the area of development of transfusion policies, and new tools for endoscopic hemostasis. Further studies are needed to clarify the optimal approach for patients with adherent clots. These developments should help to reduce the persistent high mortality rate of UGIB, a disease which nowadays in particular occurs in elderly patients with comorbidity and medication use.

### Abstract

**AIM:** To determine the expression of HER2 and bradykinin B<sub>1</sub> receptors (B<sub>1</sub>R) in the two pathogenic models of gallbladder cancer: the metaplasia-dysplasia-carcinoma and the adenoma-carcinoma pathways.

**METHODS:** Receptor proteins were visualized by immunohistochemistry on 5- $\mu$ m sections of paraffin-embedded tissue. Expression of both receptors was studied in biopsy samples from 92 patients (6 males and 86 females; age ranging from 28 to 86 years, mean 56 years). High HER2 expression in specimens was additionally investigated by fluorescence *in situ* hybridiza-

tion. Cell proliferation in each sample was assessed by using the Ki-67 proliferation marker.

**RESULTS:** HER2 receptor protein was absent in adenomas and in normal gallbladder epithelium. On the contrary, there was intense staining for HER2 on the basolateral membrane of epithelial cells of intestinal metaplasia (22/24; 91.7%) and carcinoma *in situ* (9/10; 90%), the lesions that displayed a significantly high proliferation index. Protein up-regulation of HER2 in the epithelium with metaplasia or carcinoma *in situ* was not accompanied by *HER2* gene amplification. A similar result was observed in invasive carcinomas (0/12). The B<sub>1</sub>R distribution pattern mirrored that of HER2 except that B<sub>1</sub>R was additionally observed in the adenomas. The B<sub>1</sub>R appeared either as cytoplasmic dots or labeling on the apical cell membrane of the cells composing the epithelia with intestinal metaplasia (24/24; 100%) and carcinoma *in situ* (10/10; 100%) and in the epithelial cells of adenomas. In contrast, both HER2 (4/12; 33%) and B<sub>1</sub>R (1/12; 8.3%) showed a low expression in invasive gallbladder carcinomas.

**CONCLUSION:** The up-regulation of HER2 and B<sub>1</sub>R in precursor lesions of gallbladder carcinoma suggests cross-talk between these two receptors that may be of importance in the modulation of cell proliferation in gallbladder carcinogenesis.

## INTRODUCTION

Gallbladder carcinoma is an aggressive cancer of the gastrointestinal tract with incidence three times greater in the female population of Chile, India and Japan when compared to men<sup>[1,2]</sup>. The most common type of gallbladder cancer is adenocarcinoma. However, early diagnosis is difficult because most of the cases are detected only at an advanced stage following laparotomy.

Successive bouts of inflammation cause continuous and long lasting damage to the gallbladder epithelium, which thereby transforms into an architecturally abnormal regenerative epithelium very similar to low grade dysplasia. Injury and repair are also related to well known metaplastic changes of the mucosa, such as pyloric and intestinal metaplasia, and to other rare types of metaplasia<sup>[3]</sup>. Intestinal metaplasia usually develops into dysplasia and is frequently observed adjacent to carcinoma. Pyloric and intestinal metaplasias are associated with gallbladder carcinoma, but intestinal metaplasia show a greater relationship with malignancy<sup>[4,5]</sup>. Analysis of serial sections indicates the presence of microinvasion foci in the lamina propria next to carcinoma *in situ* and also that dysplasia and carcinoma *in situ* occur close to areas of intact mucosa in nearly all invasive carcinomas<sup>[6]</sup>.

Among the pathogenic models that explain the neoplastic transformation of gallbladder epithelium are the metaplasia-dysplasia-carcinoma and the adenoma-carcinoma pathways<sup>[5]</sup>. Morphological and molecular studies have shown that these two entities correspond to independent biological events. Therefore, we have used representative gallbladder samples of both putative pathways to investigate the expression of two receptor molecules involved in cell proliferation, namely the HER2 and bradykinin B<sub>1</sub> receptors (B<sub>1</sub>R). The HER2 (c-erbB-2) receptor is recognized to be of clinical importance because of its prognostic value in determining progression of some types of breast tumors. Similarly, B<sub>1</sub>R has recently been shown to induce the proliferation of estrogen-sensitive breast cancer cells by turning on the transactivation of the epidermal growth factor receptor (EGFR), a signal-transduction pathway involved also in the activation of HER2<sup>[7]</sup>. As with breast cancer, expression of HER2 in gallbladder carcinoma has been associated with progression of malignancy and linked to poor patient survival<sup>[8-11]</sup>. Furthermore, constitutive expression of HER2 in transgenic mice causes adenocarcinoma of the gallbladder<sup>[12]</sup> suggesting a key role for this member of the EGFR family in such neoplasia. Although the expression levels of HER2 have been

previously investigated in invasive gallbladder cancer<sup>[13]</sup>, so far no studies appear to have examined its expression in the putative precursor lesions of gallbladder carcinoma.

The B<sub>1</sub>R belongs to the family of G protein-coupled rhodopsin-like receptors which, upon stimulation by analogues that lack the Arg<sup>9</sup> from the carboxy terminus of the bradykinin molecule, trigger several second messenger signaling systems that control cell differentiation, proliferation and/or migration<sup>[14,15]</sup>. The kinin B<sub>1</sub>R agonists belong to a family of bioactive peptides produced locally and with paracrine activity, that are formed from precursor molecules by the proteolytic action of enzymes called kallikreins (kininogenases)<sup>[14,15]</sup>. So far, only a few studies have evaluated the role of B<sub>1</sub>R as well as the underlying molecular mechanisms that trigger its activation in cancer cells. Recent reports have suggested that the B<sub>1</sub>R is an important player in lung, prostate and breast cancer by regulating tumoral growth, migration and invasion<sup>[7,16,17]</sup>. In addition, some of the cellular actions of B<sub>1</sub>R stimulation are a consequence of EGFR transactivation<sup>[7]</sup>. However, the status of B<sub>1</sub>R in other neoplastic disorders such as gallbladder carcinoma has not been investigated previously. Thus, the primary aim of our study was to perform a comprehensive evaluation of the expression values for HER2 and B<sub>1</sub>R in the metaplasia-dysplasia-carcinoma and adenoma-carcinoma pathways.

## MATERIALS AND METHODS

### Ethics

This study was performed in accordance with the Declaration of Helsinki of the World Medical Association. The designated experiments were approved by the Ethical Committees of Hospital Base Valdivia, Universidad Austral de Chile and the National Fund for Development of Science and Technology in Chile (FONDECYT) that included guidelines for the protection of human subjects.

### Patient tissue

The study was performed on 92 routinely resected gallbladders retrieved from the surgical pathology archive of the Servicio de Patología, Hospital Base Valdivia, Chile. Of the 92 specimens, 6 were from males, and 86 were from females; the patients ranged in age from 28 to 86 years (mean, 56 years). The data on age, sex of patients bearing adenomas, gallbladder adenocarcinomas and their putative precursor lesions are summarized in Table 1. The following categories were recorded: (1) normal mucosa ( $n = 5$ ), gallbladders that were resected due to lithiasis and elective surgery; (2) pyloric-type adenoma ( $n = 15$ ); (3) intestinal-type adenoma ( $n = 6$ ); (4) pyloric metaplasia ( $n = 20$ ); (5) intestinal metaplasia ( $n = 24$ ); (6) carcinoma *in situ* ( $n = 10$ ); and (7) invasive carcinoma ( $n = 12$ ) (Table 1). Invasive adenocarcinomas examined histologically were classified into well-differentiated with a papillary pattern of growth (8 cases), poorly differentiated (2 cases), mucinous well-differentiated (1 case) and signet ring (1 case) adenocarcinomas.

**Table 1** Clinical and pathological data of patients with gallbladder adenomas, adenocarcinoma and its putative precursor lesions

Lesion	Sex	Age (yr, mean $\pm$ SD)
Normal mucosa ( <i>n</i> = 5)	F (5)	54.6 $\pm$ 9.0
Pyloric adenoma ( <i>n</i> = 15)	F (13)/M (2)	55.2 $\pm$ 3.5
Intestinal adenoma ( <i>n</i> = 6)	F (6)	68.5 $\pm$ 1.7
Pyloric-type metaplasia ( <i>n</i> = 20)	F (20)	51.5 $\pm$ 3.2
Intestinal metaplasia ( <i>n</i> = 24)	F (24)	50.0 $\pm$ 3.4
Carcinoma <i>in situ</i> ( <i>n</i> = 10)	F (9)/M (1)	65.8 $\pm$ 2.5
Invasive carcinoma ( <i>n</i> = 12)	F (9)/M (3)	66.0 $\pm$ 3.8

According to WHO classification. F: Female; M: Male.

Each gallbladder was fixed in 10% buffered formalin and embedded in paraffin according to conventional protocols. Sections from each block were stained with hematoxylin and eosin for precise histopathological classification before immunostaining. In all cases, two to four blocks were used for immunohistochemical evaluation.

### Immunohistochemistry

This method was performed as previously described by Molina *et al*<sup>71</sup>. Briefly, paraffin sections were incubated with primary antibodies overnight at 22 °C in a water bath that was used as a moist chamber. The primary antibody sources, dilutions, antigen retrieval and incubation conditions are listed in Table 2. Bound primary antibodies were localized by the biotin/streptavidin immunoperoxidase technique using the LSAB+ kit (Dako, Carpinteria, CA, United States). Peroxidase was developed with diaminobenzidine and hydrogen peroxide. Sections were counterstained with Harris hematoxylin. Negative controls included omission of primary antibody and its replacement by non-immune immunoglobulins of the same species or isotype matched immunoglobulins under identical conditions.

Immunolabeling was scored as positive (presence of staining) or negative (absence of staining) and then expressed as percentage of total number of normal mucosa, metaplasia, carcinoma *in situ* and invasive carcinoma cases examined. Staining was considered positive when over 30% of the gallbladder epithelium was immunostained. Only cell membrane immunoreactivity was considered positive for HER2 staining. Cell proliferation index was determined by recording the immunolabeled Ki-67 antigen in gallbladder carcinoma and its putative precursor lesions. For this purpose, nuclei were counted at x40 magnification in three different fields selected at random. The procedure was repeated twice by two independent observers for each lesion and the counts were averaged. The Ki-67 cell proliferation index was derived by dividing the average Ki-67 count by the average total number of nuclei in one field.

### Fluorescence *in situ* hybridization

Fluorescence *in situ* hybridization (FISH) technique for

HER2 was performed on 3- $\mu$ m thick tissue sections according to the protocol of HER2 FISH PharmDx™ Kit (Dako). Hybridization was performed with a mixture of HER2-Texas Red and cen-17 labeled with fluorescein isothiocyanate. A breast cancer sample classified as HER2 (+3) was used as positive control. For each condition at least two samples were analyzed using a fluorescence Nikon Labophot-2, and at least 50 nuclei were visualized in each sample.

### Statistical analysis

Differences in the occurrence of immunolabeling were evaluated using Fischer's exact probability test with the aid of the software JMP Statistical Discovery Software 8.0 (SAS Institute, Cary, NC, United States). Probability values less than 0.05 were considered to be statistically significant.

## RESULTS

### Histopathological features

Normal, non-metaplastic epithelium was comprised of regular segments of tall columnar cells with basal nuclei and sporadic small apical vacuoles. Pyloric-type adenomas showed their typical morphology that was comprised of tightly packed pyloric or antral-type mucous glands similar to mucous glands of the stomach (Figure 1). Intestinal-type adenomas consisted of papillary structures lined by columnar epithelium with elongated and pseudostratified nuclei (Figure 1). Pyloric-type metaplasia was distinguished by glands lined by columnar cells with vacuolated cytoplasm and flattened nuclei located basally; the glands formed small lobular structures throughout the lamina propria. Epithelium with intestinal metaplasia was composed of tall columnar cells with a brush border and variable proportions of goblet cells. This type of metaplasia was often seen adjacent to invasive adenocarcinoma. Carcinoma *in situ* was characterized by the presence of epithelial cells that showed frequent mitosis and marked alterations in the size and shape of the nuclei such as hypercromasia, overlapping and crowding.

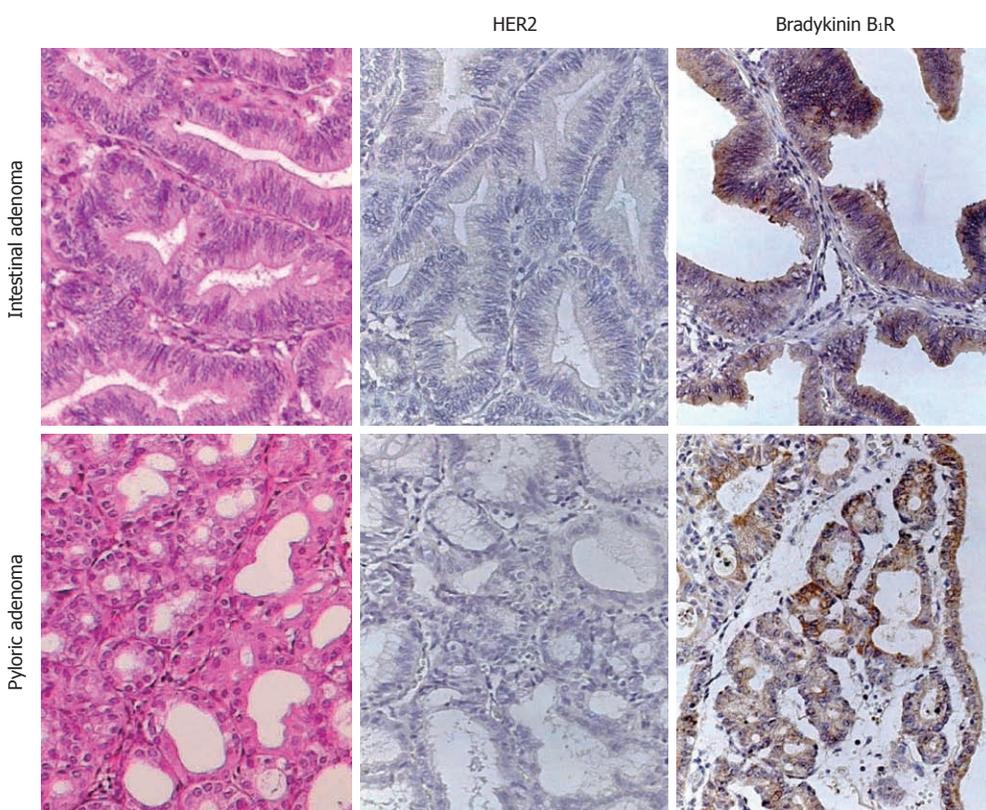

### Expression of HER2

No immunolabeled HER2 receptor was visualized in normal gallbladder epithelium and no significant expression of the protein was visualized in adenomas of either pyloric- or intestinal-type (Table 3; Figures 1 and 2). In contrast, an intense immunoreactivity was observed in the epithelium with intestinal metaplasia (22/24) and carcinoma *in situ* (9/10), with decreased staining in invasive carcinomas (4/12) (Table 3; Figure 2) and none in pyloric metaplasia and non-epithelial tissues (not shown). The HER2 immunolabeling was confined to the basolateral cell membrane region of all metaplastic epithelial cells, whereas the luminal membrane was devoid of staining (Figures 2 and 3). At a higher magnification, the boundary between the two segments was clearly delineated by the different immunoreactivity of the cells in the apical

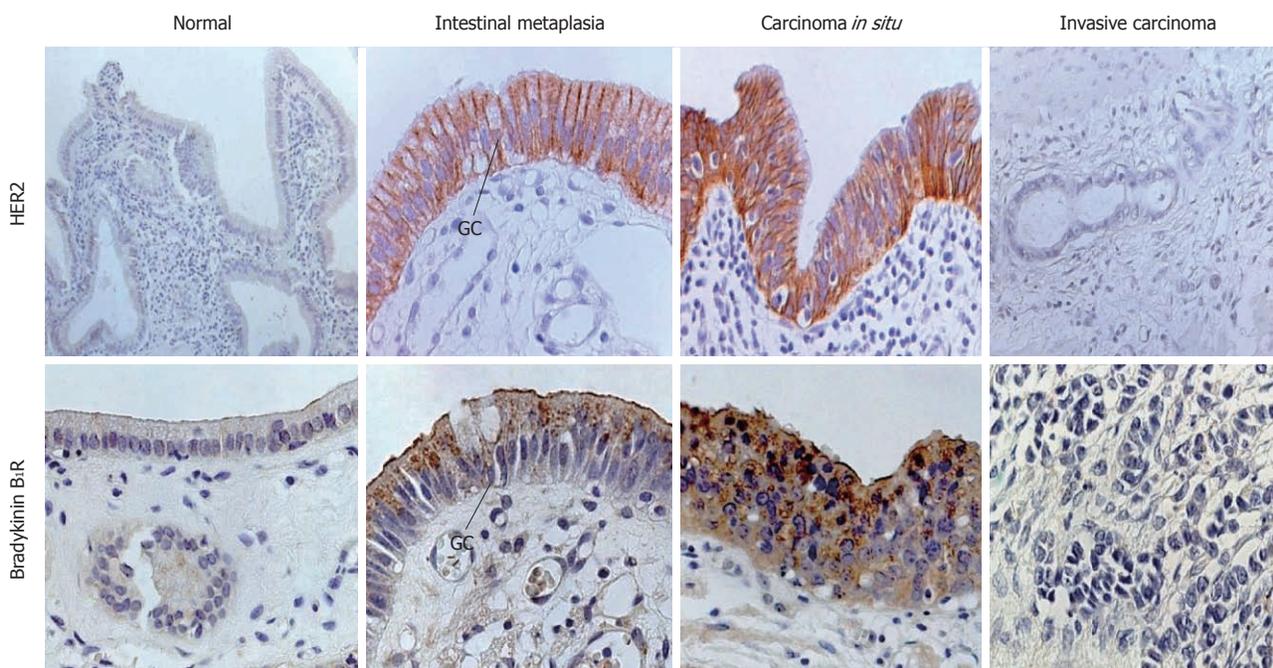

**Figure 1** Expression of immunoreactive HER2 and bradykinin B<sub>1</sub> receptor in pyloric- and intestinal-type adenomas. Tissue sections were incubated with each antibody and then the biotin/streptavidin-peroxidase technique was followed. B<sub>1</sub>R: B<sub>1</sub> receptor.

membrane when compared to those of the basolateral cell membrane (Figure 3). Loss of polarity in the epithelia with carcinoma *in situ* resulted in a complete membrane staining of some of the neoplastic epithelial cells. With FISH staining, *HER2* gene appeared as two red signals in normal and metaplastic epithelia and two to four signals in carcinoma *in situ* and invasive carcinoma, accompanied by the corresponding green signals pointing out the chromosome 17 centromeres (*HER2/CEN-17* < 1.8) that indicated lack of amplification (Figure 3C-F).

On the contrary, a clear amplification of *HER2* gene was observed in *HER2* (+3) breast cancer samples that were used as positive controls (Figure 3G).

**Expression of bradykinin B<sub>1</sub>R**

The B<sub>1</sub>R protein also followed a cell membrane distribution pattern. Immunolabeled B<sub>1</sub>R was visualized only in one case of the invasive carcinomas (Table 3). In contrast, samples with intestinal metaplasia and carcinoma *in situ* showed an intense staining for B<sub>1</sub>R that appeared as cy-

**Figure 2** Immunoreactive HER2 and bradykinin B<sub>1</sub> receptor receptors in normal gallbladder, invasive carcinoma and in epithelia with intestinal metaplasia and carcinoma *in situ*. Biotin/streptavidin-peroxidase technique. B<sub>1</sub>R: B<sub>1</sub> receptor; GC: Goblet cell.

toplasmic dots or labeling in the apical cell membrane region of metaplastic cells and in the epithelium with carcinoma *in situ* (Figures 2 and 3). Furthermore, B<sub>1</sub>R immunolabeling was observed in epithelial cells of pyloric- and intestinal-type adenomas, including the surface epithelium of adenomas (Figure 1 and Table 3).

### **Ki-67 cell proliferation marker**

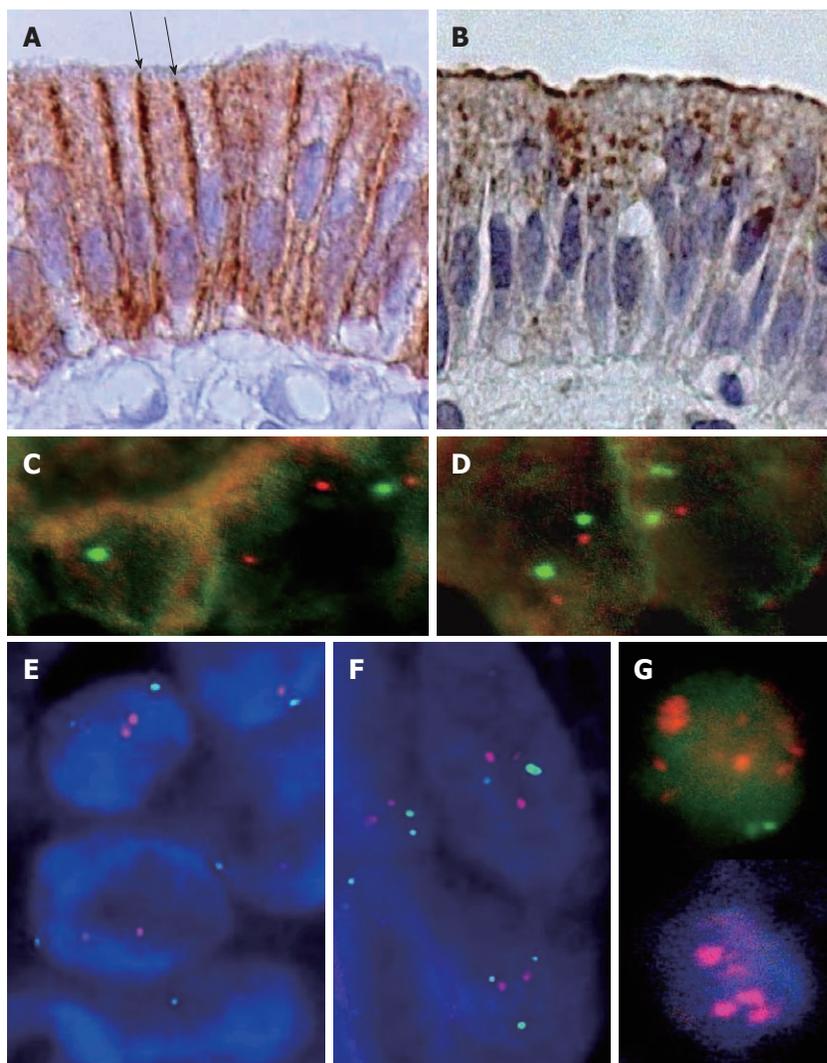

By using Ki-67, we confirmed that the observed cell proliferation was significantly higher in epithelia with metaplasia, carcinoma *in situ* and in cells of invasive gallbladder carcinomas than in normal epithelium and in epithelial cells of both pyloric- and intestinal-type adenomas (Table 3).

## **DISCUSSION**

Two pathogenic models designated as adenoma-carcinoma and metaplasia-dysplasia-carcinoma have been used to explain neoplastic transformation of the gallbladder epithelium. However, intestinal metaplasia is considered as the major precursor lesion that later progresses into carcinoma *in situ* and invasive adenocarcinoma. The question of whether expression of receptors such as HER2, a tyrosine kinase orphan receptor, and the B<sub>1</sub>R, a G protein-coupled receptor, are enhanced in such carcinogenic changes of the gallbladder epithelium formed the focus of the current study<sup>[7,15,16,18,19]</sup>.

Remarkably, the expression of HER2 and bradykinin B<sub>1</sub>R followed a similar pattern of distribution in invasive carcinoma and in its putative precursor lesions. Both receptors were absent in the normal epithelium but were strongly expressed in carcinoma *in situ* and the epithelia

with intestinal metaplasia. Absence of HER2 staining in normal gallbladder epithelium is in agreement with previous studies performed using normal breast tissue<sup>[20]</sup>. Two previous reports failed to demonstrate expression of HER2 protein in gallbladder dysplasia<sup>[15,21]</sup>. The discrepancy between these findings and our results may be explained by the use of different immunostaining procedures (e.g., monoclonal *vs* polyclonal antibodies and sensitivity of the technique), time of fixation, preservation of antigenic sites and number of samples analyzed. In our study, HER2 receptor protein stained intensely along the basolateral plasma membrane of the metaplastic and carcinoma *in situ* cells. A similar pattern of staining has been observed in apocrine metaplasia of the breast where HER2 immunoreactivity appeared restricted to the basolateral plasma membrane of the metaplastic cells<sup>[22]</sup>. It is well known that tight junctions morphologically divide cell membranes of non-neoplastic polarized epithelial cells into two regions: an apical one which faces the lumen and often has specialized features such as cilia or a brush border of microvilli; and a basolateral region, which covers the rest of the cell<sup>[23]</sup>. Further, tight junctions prevent proteins and lipids from diffusing between the basolateral and apical regions, so that not only the protein but also the lipid composition of the two membrane regions is different<sup>[23]</sup>. Therefore, the HER2 immunoreactivity, observed in the basolateral cell membrane domain of metaplastic gallbladder epithelium, is not comparable to that scored by the Hercep Test<sup>TM</sup> staining protocol, which is based on the immunoreactivity present on the cell membrane of invasive breast cancer cells that are not supported by a basement membrane, i.e., neoplastic non-polarized cells. Despite over-expression

**Figure 3** High magnification of gallbladder metaplastic epithelium showing immunoreactivity for HER2 (A) and bradykinin B<sub>1</sub> receptor (B). Arrows show the limit between apical and basolateral cell membrane domains. C-G: Fluorescence *in situ* hybridization for HER2. Tissue sections were hybridized with a mixture of HER2-Texas Red and cen-17 labeled with fluorescein isothiocyanate. C: Normal gallbladder epithelium; D: Epithelium with intestinal metaplasia; E: Carcinoma *in situ*; F: Invasive carcinoma; G: Positive control corresponding to a breast cancer sample classified as HER2 + 3.

of HER2 receptor protein in metaplastic epithelia and carcinoma *in situ*, our results using FISH revealed that this event was not accompanied by *HER2* gene amplification suggesting that this change may not be relevant for gallbladder cancer. Studies using FISH, but restricted to invasive carcinomas of the gallbladder, have shown amplification of the *HER2* gene only in approximately 10% of the cases investigated<sup>[8]</sup>. Absence of *HER2* gene amplification in our tissue samples with invasive carcinoma may be due to our low number of cases compared with other published studies<sup>[8]</sup>. Some authors suggest that *HER2* over-expression is due to gene deregulation rather than gene amplification because in some reports there is no strict correlation between receptor protein expression and gene amplification<sup>[24]</sup>. The HER2 receptor seems to be a key player since its constitutive expression leads to the development of gallbladder adenocarcinoma in 100% of transgenic mice<sup>[12]</sup>. Moreover, increased HER2/EGFR (erbB-1) heterodimer formation, hyperphosphorylation

of tyrosine residues of both HER2 and EGFR (but not erbB-3 or erbB-4) and activation of the mitogen-activated protein kinases (MAPK) signaling pathway were observed in the gallbladder epithelium of the transgenic mice<sup>[12]</sup>. Over-expression of the HER2 receptor protein, detected immunohistochemically in nearly all breast specimens showing carcinoma *in situ* of high grade, has been interpreted as an expression of rapid growth since its presence is related to cellular proliferation<sup>[25,26]</sup>. Our results show that the epithelia with intestinal metaplasia and carcinoma *in situ* display the higher values for Ki-67 cell proliferation marker. The fact that the *HER2* gene shows amplification only in 10% of the invasive gallbladder carcinomas<sup>[8]</sup> contrasts with the high levels of protein expression observed by us in intestinal metaplasia and carcinoma *in situ*, and suggests that major activity of HER2 may occur in these precursor lesions. Further, the expression of HER2 in other invasive tumors of the gastrointestinal tract such as gastric cancer has revealed

that less than 10% of all invasive tumors showed HER2 expression and that there is no relationship between its expression, patient survival or TNM stage<sup>[27]</sup>.

Members of the EGFR family are activated not only by direct binding of their corresponding ligands but also by transactivation triggered after stimulation of G protein-coupled receptors such as the B<sub>1</sub>R<sup>[13,19]</sup>. We have recently reported B<sub>1</sub>R binding sites in breast carcinoma and showed that B<sub>1</sub>R stimulation induces the proliferation of MCF-7 and ZR-75 breast cancer cells, an effect that depends on the transactivation of the EGFR and the subsequent activation of the MAPK signaling pathway<sup>[7]</sup>. Moreover, stimulation of the B<sub>1</sub>R increases the release of metalloproteases-2 and -9 from breast cancer cells<sup>[28]</sup>. Both metalloproteases are considered key enzymes for tumor invasion and metastasis, because they have the capacity to degrade type IV collagen, the major protein component of basement membranes. Here, we have described, for the first time, the expression of B<sub>1</sub>R in precursor lesions of gallbladder carcinomas (i.e., intestinal metaplasia and carcinoma *in situ*), conditions in which its expression is maximal and associated with high proliferation rates of the epithelial cells.

The kinin B<sub>1</sub>R agonists are short-lived peptides that exert most of their actions in a paracrine fashion for which the presence of kallikreins, kinin precursors and expression of the appropriate receptor is required<sup>[14]</sup>. In a previous report, we showed that both tissue kallikrein and the kinin precursors are present in the human gallbladder suggesting that kinin formation is feasible in this tissue<sup>[29]</sup>. Tissue kallikrein (*KLK1/hK1*, kininogenase) is expressed by gallbladder epithelial cells whereas the kininogens, substrates of hK1, diffuse from submucosal blood vessels to fill the interstitial space between epithelial cells<sup>[29]</sup>. A further source of tissue kallikrein is the neutrophil that infiltrates the inflamed gallbladder during acute episodes of cholecystitis and thereby releases hK1 in the vicinity of epithelial cells<sup>[29]</sup>. Additionally, the natural B<sub>1</sub>R agonist induces migration of glioma cells *via* up-regulation of cyclooxygenase-2 expression<sup>[30]</sup>; whether the B<sub>1</sub>R produces a similar effect in gallbladder cancer cells remains to be investigated using gallbladder cancer cell lines.

The identical pattern of expression observed for B<sub>1</sub> and HER2 receptors in precursor lesions of gallbladder carcinoma suggests a cooperative relationship, orientated towards promoting functional cell signaling that may result in an increased proliferation of the gallbladder epithelium.

## ACKNOWLEDGMENTS

The authors (Poblete MT and Figueroa CD) wish to record our deepest gratitude and appreciation for the conceptual support and advice given during our entire career by Drs Norambuena L and Caorsi I. We also wish to thank Ms Johana Mejia for her assistance with statistical procedures and Merck and Co Inc, West Point, PA, United States for the kind gift of anti-B<sub>1</sub> receptor antibody.

## COMMENTS

### Background

Gallbladder carcinoma is an aggressive malignancy of the gastrointestinal tract, and its early diagnosis is difficult, because most of the cases are detected at an advanced stage at laparotomy. It is well known that the HER2 receptor is involved in the carcinogenesis of many malignancies. Further, recent reports show that the bradykinin B<sub>1</sub> receptor (B<sub>1</sub>R) stimulates the proliferation of breast cancer cells. It is not known whether HER2 and B<sub>1</sub>R are overexpressed in precursor lesions of gallbladder carcinoma and whether they serve as biomarkers for early neoplastic transformation of gallbladder epithelium.

### Research frontiers

Most studies related to HER2 and gallbladder cancer have been focused on advanced stages of the disease, but not in their precursor lesions. So far, there have been no investigations on the expression levels of B<sub>1</sub>R in this neoplasm. Because HER2 has a low expression in invasive gallbladder cancer, it has been proposed by some authors that it is not relevant to gallbladder carcinoma.

### Innovations and breakthroughs

The novel finding of high expression of HER2 and B<sub>1</sub>R in precursor lesions of gallbladder carcinoma suggests that they enhance cell proliferation and play a significant role in gallbladder carcinogenesis.

### Applications

Because of the high HER2 and B<sub>1</sub>R expression data in precursor lesions of gallbladder carcinoma, and the therapeutic efficacy of anti-HER2 treatments in breast tumors, future studies should focus on HER2 and B<sub>1</sub>R as biomarkers for the detection of early neoplastic transformations in the gallbladder epithelium.

### Terminology

The HER2 is a tyrosine kinase receptor, member of the epidermal growth factor receptor family. Growth factors bind to receptors and initiate cell proliferation, migration, invasion, resistance to apoptosis and angiogenesis. B<sub>1</sub>R belongs to the family of G protein-coupled receptors, which upon stimulation by analogues trigger cell proliferation and secretion of metalloproteases in cancer cells: proteases that assist cancer cells to invade normal human tissue. The results clearly indicate that both HER2 and the B<sub>1</sub>R play a significant role in transformation of epithelial cells through the metaplasia-dysplasia-carcinoma pathway.

### Peer review

This article has very well explored the HER2 and B<sub>1</sub>R in gallbladder carcinoma. While HER2 and B<sub>1</sub>R are scarcely expressed in invasive gallbladder carcinoma, their expression is upregulated in precursor lesions of this neoplasm which may help in early diagnosis and also provide some pathways of carcinogenesis. This study is worthy.

### Abstract

**AIM:** To search for and validate differentially expressed proteins in patients with gastric adenocarcinoma.

**METHODS:** We used two-dimensional gel electrophoresis and mass spectrometry to search for differentially expressed proteins in patients with gastric adenocarcinoma. A set of proteins was validated with immunoblotting.

**RESULTS:** We identified 30 different proteins involved in various biological processes: metabolism, development, death, response to stress, cell cycle, cell communication, transport, and cell motility. Eight proteins

were chosen for further validation by immunoblotting. Our results show that gastrokine-1, 39S ribosomal protein L12 (mitochondrial precursor), plasma cell-induced resident endoplasmic reticulum protein, and glutathione S-transferase mu 3 were significantly underexpressed in gastric adenocarcinoma relative to adjacent non-tumor tissue samples. On the other hand, septin-2, ubiquitin-conjugating enzyme E2 N, and transaldolase were significantly overexpressed. Translationally controlled tumor protein was shown to be differentially expressed only in patients with cancer of the gastric cardia/esophageal border.

**CONCLUSION:** This work presents a set of possible diagnostic biomarkers, validated for the first time. It might contribute to the efforts of understanding gastric cancer carcinogenesis.

## INTRODUCTION

Gastric cancer (GC) is the fourth most common cancer worldwide<sup>[1]</sup>. However, incidence rates have steadily declined; this is largely determined by trends in the fundus and distal stomach<sup>[1]</sup>. Gastric cardia cancer, on the other hand, is on the increase, and is usually of the diffuse histological type<sup>[2]</sup>. However, despite declining incidence rates, GC is still the second leading cause of cancer death and thus remains a major health problem<sup>[1]</sup>. Radical surgery still offers the only chance of a cure for GC that invades the muscular layer, but only half of patients qualify for this at the time of their diagnosis<sup>[2]</sup>. The majority of patients are diagnosed at an advanced stage, where a systemic spread of the tumor cells has to be anticipated. The 5-year survival rate is very low and despite consistent improvements the prognosis remains poor<sup>[3]</sup>. On the other hand, the 5-year survival rate exceeds 90% for patients in an early stage of the disease<sup>[4]</sup>.

A definitive diagnosis of GC requires a gastroscopic or surgical biopsy<sup>[5]</sup>, which means there is a need for a non-invasive test, e.g., the detection of serum/plasma biomarkers. The most widely investigated serum markers include carcinoembryonic antigen, carbohydrate antigen (CA) 19.9, CA 72.4, cytokeratins and the  $\beta$  subunit of human chorionic gonadotropin. However, their low sensitivity and specificity precludes their use in screening and early diagnosis. Therefore, a search for more appropriate biomarkers is necessary.

One possible source of potential new biomarkers is the proteome. As opposed to static genomic data, the proteome is necessary for understanding the dynamic processes in cells<sup>[6]</sup>. It is also more complex, e.g., due to alternative splicing and post-translational modification, and the protein levels often do not correlate with the mRNA<sup>[7]</sup>. Proteomics is a rapidly developing field and is now applied to all areas of the life sciences<sup>[8]</sup>. Gel-based approaches, for example, belong to the most frequently used assays in protein separation and analysis<sup>[9]</sup>. Two-dimensional gel electrophoresis (2-DE) is still the method of choice for complex protein samples, although, due to its limitations with hydrophobic and large proteins, alternative or complementary methods based on mass spectrometry (MS) are gaining popularity.

2-DE, dating back to the 1970s<sup>[10,11]</sup>, in conjunction with MS, has allowed the identification of differentially expressed proteins in various diseases, including GC<sup>[12-17]</sup>. However, the process of translating basic proteomic discoveries to the clinic is very time consuming and expensive, and despite all the efforts put into biomarker research, very few diagnostic protein biomarkers have been approved by the United States Food and Drug Administration<sup>[8]</sup>. The lack of specific and sensitive biomarkers thus creates a persistent need for the expedited development of biomarkers and their use in improving the diagnosis and treatment of cancer. Furthermore, the validity of potential biomarkers, as found by proteome analysis, needs to be investigated and incorporated as the second step of the research, e.g., by immunohisto-

chemical and/or western blot analyses, in order to fulfill the criterion of a systematic investigation of the protein biomarkers in GC.

In this study, we used 2-DE and MS to search for differentially expressed proteins in patients with gastric adenocarcinoma: a total of 30 different protein alterations were found. Gastroskine-1 precursor (GKN1), 39S ribosomal protein L12 (mitochondrial precursor) (MRPL12), plasma cell-induced resident endoplasmic reticulum protein (PACAP), glutathione S-transferase mu 3 (GSTM3), septin-2 (SEPT2), ubiquitin-conjugating enzyme E2 N (UBE2N), transaldolase (TALDO1), and translationally controlled tumor protein (TPT1) were further validated with the immunoblot analysis, making them a set of possible biomarkers for gastric adenocarcinoma.

## MATERIALS AND METHODS

### Subjects and tissues

A total of 32 pairs of gastric adenocarcinoma tissues and adjacent control tissue from 32 patients were obtained from the tissue bank of the Institute of Oncology Ljubljana after the National Medical Ethics Committee's approval. They were stored at -70 °C until further use. The patients' and tumors' parameters are listed in Table 1.

### Sample preparation

The tissues were ground with a mortar and pestle in the presence of liquid nitrogen and then lysed with 7 mol/L urea, 2 mol/L thiourea, 40 g/L 3-[(3-cholamidopropyl)-dimethylammonio]-1-propane sulfonate (CHAPS), 20 mmol/L dithiothreitol (DTT) and a protease inhibitor cocktail (Sigma-Aldrich, St. Louis, MO, United States). For every 10 mg of tissue, 50  $\mu$ L lysis buffer was added. After sonication on ice, three times for 10 s, the samples were incubated for 1 h on ice with occasional vortexing and then centrifuged for 1 h at 20 000  $\times g$  at 4 °C. The supernatant was collected and the protein concentration was determined according to a commercial Bradford reagent (Thermo Fisher Scientific, Waltham, MA, United States) with bovine serum albumin as the standard.

### 2-DE

2-DE was conducted on 12 pairs of tissues and repeated in triplicate. For the isoelectric focusing, 100  $\mu$ g protein was diluted in 450  $\mu$ L rehydration solution (7 mol/L urea, 2 mol/L thiourea, 20 g/L CHAPS, 20 mmol/L DTT, 0.5% immobilized pH gradient (IPG) buffer, pH 4-7), loaded by in-gel rehydration onto IPG strips with an acidic pH range of 4-7 (GE Healthcare, Stockholm, Sweden), and focused in an Ettan IPGphor II isoelectric focusing system (GE Healthcare) to a total of 63.5 kVh. Next, the IPG strips were equilibrated for 15 min in 6 mol/L urea, 30% glycerol, 20 g/L sodium dodecyl sulfate (SDS), 50 mmol/L Tris-HCl, pH 8.8, with 10 g/L DTT, and for another 15 min in the same solution with DTT replaced by 25 g/L iodoacetamide. The strips were then transferred to 12% polyacrylamide gels and the

second dimension was carried out in an Ettan DALTsix electrophoresis unit (GE Healthcare) under constant power in a Laemmli buffer system until the bromophenol blue reached the end of the gel.

### Silver staining

The gels were silver stained according to Mortz *et al.*<sup>18</sup>. Briefly, they were fixed overnight in 50% methanol, 12% acetic acid, and 0.05% formalin, washed for 2 × 20 min with 35% ethanol and sensitized for 2 min with 0.02% sodium thiosulfate. Next, they were washed for 3 × 5 min with water and stained for 20 min in 0.2% silver nitrate and 0.076% formalin. Then they were washed again for 2 × 1 min with water and developed with 6% sodium carbonate, 0.05% formalin and 0.0004% sodium thiosulfate. The reaction was stopped with 50% methanol and 12% acetic acid and the gels were left in 1% acetic acid until the scanning.

### Image acquisition and analysis

The gels were scanned with an ImageScanner II (GE Healthcare) at 300 dpi and analyzed with an ImageMaster 2D Platinum v7 (GE Healthcare). The spots were detected, matched and quantified by relative volume. The normalization of the spot values (relative spot volumes) was based on the total spot volume. Next, the data were analyzed with Excel. The spots of interest were determined using a pair-by-pair comparison. The spots were considered to be differentially expressed if they matched the following criteria: at least a twofold change in the relative spot volume, the occurrence of this change in at

least three patients, and statistical significance.

### In-gel digestion

The enzymatic digestion of the excised spots was performed using a Progest robot (Genomic Solutions, Holliston, MA, United States). Briefly, the protein spots were excised from the gel, placed into 96-well plates and washed with 50  $\mu$ L acetonitrile ( $\text{CH}_3\text{CN}$ ) for 3 min and then with 50  $\mu$ L 25 mmol/L ammonium bicarbonate ( $\text{NH}_4\text{HCO}_3$ ) for 3 min. This washing step was repeated three times to eliminate SDS, Tris and glycine. After the washing procedure, the excised spots were treated with 100  $\mu$ L 10 mmol/L DTT for the reduction step and the reaction was left to proceed at 57 °C for 1 h. After DTT removal, 100  $\mu$ L 55 mmol/L iodoacetamide was added for the cysteine carbamidomethylation and the reaction was left to proceed at room temperature (RT) for 1 h. After removal of the supernatant, the washing procedure was repeated three times and the gel slices were dried with a SpeedVac (5 min). Based on the gel-slice volume, 5-10  $\mu$ L 12 ng/ $\mu$ L Porcine Trypsin (Promega, Madison, WI, United States) was added. The enzyme was freshly diluted in 25 mmol/L  $\text{NH}_4\text{HCO}_3$  and the digestion was performed overnight at RT. Trypsin was the protease of choice for the MS protein identification because of its reliability and its substrate specificity, yielding peptides with C-terminal basic residues (Arg and Lys), which facilitated positive ionization and subsequent MS detection. Finally, 10  $\mu$ L of 39%  $\text{H}_2\text{O}/60\%$   $\text{CH}_3\text{CN}/1\%$   $\text{HCOOH}$  was added and the samples were left for 3 h at RT to favor the extraction of peptides from the gel.

### MS and database search

Trypsin-generated peptide mixtures were analyzed by matrix-assisted laser desorption ionization coupled with a time-of-flight analyzer (MALDI-TOF) (Voyager, Applied Biosystems, Carlsbad, CA, United States). Samples that provided an ambiguous identification with MALDI-TOF were analyzed by tandem MS (MS/MS) using nanoliquid-chromatography electrospray ionization coupled with the quadrupole and time-of-flight analyzer (nanoLC-ESI-Q-TOF) (nanoAcquity, Q-TOF Premier; Waters, Milford, MA, United States).

For MALDI-TOF MS, the peptide extracts (0.5  $\mu$ L) were mixed with an equal volume of 2,5-dihydroxybenzoic acid (10 mg/mL; Sigma-Aldrich) dissolved in 20%  $\text{CH}_3\text{CN}$ . Trypsin-digested ovalbumin was used for external calibration. Crystals were obtained using the dried-droplet method on a 100-spots metallic plate and approximately 500 MALDI mass spectra were averaged per spot to optimize the signal-to-noise ratio. The laser fluency was adjusted to the threshold to achieve the best resolution and mass accuracy. The MS measurements were carried out at a maximum accelerating potential of 20 kV, in the positive reflectron mode. The acquisition range was set to  $m/z$  800-3500 with a low-mass gate at  $m/z$  700. For  $m/z$  values of about 1500, the mean mass resolution was 15 000.

Proteins were identified by peptide mass fingerprinting with two search programs: Mascot and ProFound. The following search parameters were applied: SWISS-PROT and NCBI were used as the protein-sequence databases; a mass tolerance of 50 ppm and one missed cleavage were allowed; the alkylation of cysteine by carbamidomethylation was considered complete; while the oxidation of methionine was considered as a possible modification.

For nanoLC-ESI-Q-TOF MS/MS analysis, peptide mixtures were SpeedVac-treated for 10 min to eliminate CH<sub>3</sub>CN, then 25 mmol/L NH<sub>4</sub>HCO<sub>3</sub> was added before injection into the nanoAcquity/Q-TOF system equipped with a trapping column (Symmetry C18, 180 μm × 20 mm, 5 μm particle size) and an analytical column (BEH130 C18, 75 μm × 100 mm, 1.7-μm particle size) (Waters). The aqueous solvent (buffer A) was 0.1% formic acid and the organic phase (buffer B) was acetonitrile with 0.1% formic acid. A 2%-40% B gradient was set for 25 min. The MS parameters were as follows: positive ion mode; capillary voltage, 3 kV; cone voltage, 40 V; ion-source block temperature, 80 °C; and collision energy ramping from 15 to 40 eV. For the exact mass measurements, the glufibrinopeptide reference ( $m/z = 785.8426$ ) was continuously supplied during the nanoLC-MS/MS experiments using the lockspray device. The peptide mass measurements were corrected by the PLGS software (ProteinLynx Global Server; Waters) during data processing. Peak lists were generated by PLGS and the processed data were submitted to Mascot searching using the following parameters: data bank, NCBI; peptide tolerance, 15 ppm; fragment tolerance, 0.1 Da; number of missed cleavages, one; variable modifications, oxidation; and fixed modifications, carbamido methylation.

### Immunoblot analysis

To validate the differential expression from the 2-DE gels, an immunoblot analysis was performed on an expanded number of samples, on 27 pairs. For TPT1, additional four pairs of cardia/gastroesophageal border adenocarcinoma were used. A total of 30 μg protein per sample was loaded on 12% or any kD gels (Bio-Rad, Hercules, CA, United States), transferred onto PDVF membranes (Millipore, Billerica, MA, United States), and blocked in 50 g/L skimmed milk overnight at 4 °C. Primary antibodies were used in the following dilutions: anti-GKN1 at 0.5 μg/mL (WH0056287M1; Sigma-Aldrich), anti-MRPL12 at 1 μg/mL (WH0006182M1; Sigma-Aldrich), anti-PACAP at 1:1000 (ab96308; Abcam, Cambridge, United Kingdom), anti-GSTM3 at 0.75 μg/mL (ab74749; Abcam), anti-SEPT2 at 1 μg/mL (ab88657; Abcam), anti-UBE2N at 0.5 μg/mL (ab25885; Abcam), anti-TALDO1 at 1:1000 (ab67467; Abcam), and anti-TPT1 at 1 μg/mL (WH0007178M1; Sigma-Aldrich). Horseradish-peroxidase-conjugated secondary antibodies were used in the following dilutions: goat anti-mouse at 1:5000 (115-035-062; Jackson ImmunoResearch, Newmarket, Suffolk, United Kingdom) and goat anti-rabbit

at 1:10 000 (111-035-003; Jackson ImmunoResearch). The proteins were detected chemiluminescently with an LAS-4000 CCD camera (Fujifilm, Tokyo, Japan) at 10-s intervals. The blots were then quantified with Multi Gauge software (Fujifilm) and the intensity values were exported to Excel. Differential expression was determined after normalization to Ponceau S-stained membranes for loading and transfer differences and statistical significance was assessed.

### Statistical analysis

To assess the statistical significance of differential protein expression (tumor *vs* non-tumor) in 2-DE as well as in immunoblotting, Wilcoxon signed-rank test was used. The test was double-sided and values with  $P < 0.05$  and a 95% CI were considered to be statistically significant. To assess the correlation of the differential protein expression from immunoblotting with the histopathological parameters, repeated-measures analysis of variance was used. The values with  $P < 0.05$  and a 95% CI were considered to be statistically significant. Bonferroni post-test was used to narrow down where the differences were significant. All analyses were performed using Microsoft Office Excel 2007 (Microsoft Corporation, Redmond, WA, United States) and GraphPad Prism 5 (GraphPad Software, Inc., La Jolla, CA, United States).

## RESULTS

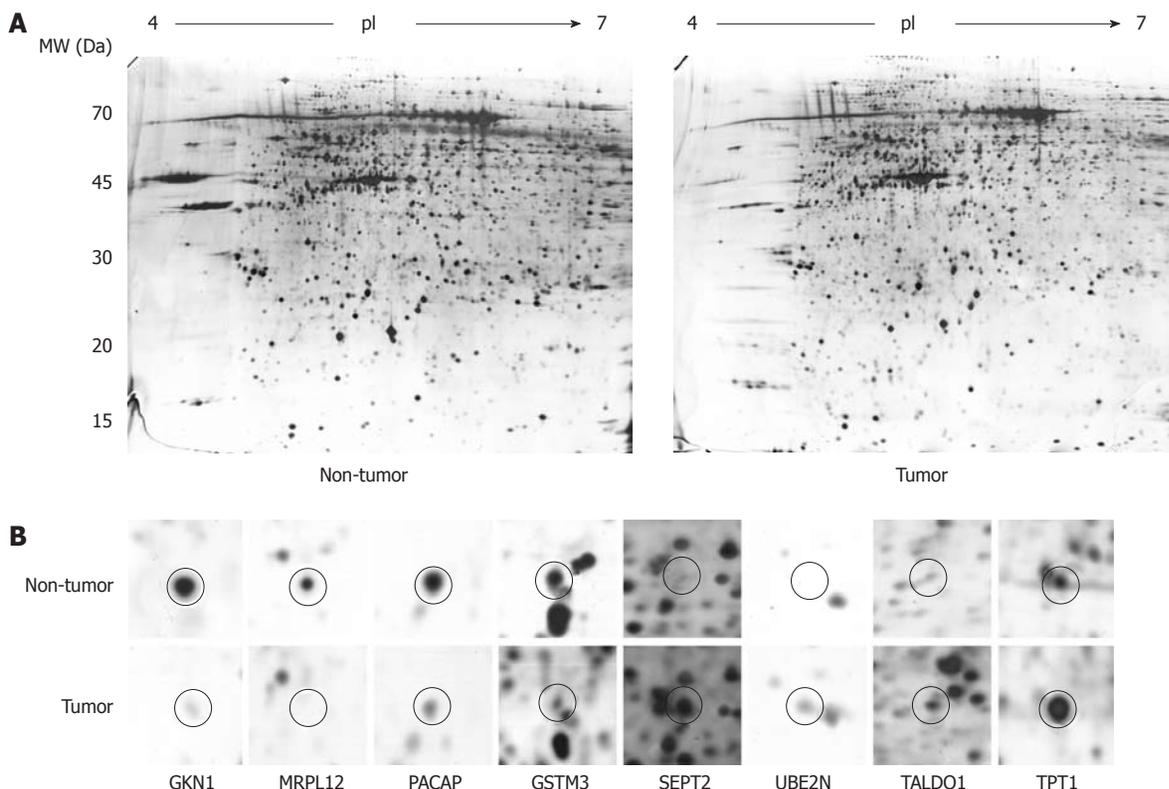

### Subject parameters

Altogether, we used 32 pairs of human gastric adenocarcinoma and adjacent normal tissue samples from 32 patients. The mean age of the patients was  $68.3 \pm 10.5$  (range 40-84) years. The subject group contained predominantly males (59.4%). According to Lauren's classification, the majority of tumors were intestinal (62.5%) and the largest part was located in the cardia/gastroesophageal border (31.2%). The tumors were mainly moderately (37.5%) and poorly (37.5%) differentiated. According to the TNM classification, most were pT2b (46.9%) and pN1 (50%). The data on pM were only available for some patients and were thus not included in any further analysis. For more details, refer to Table 1.

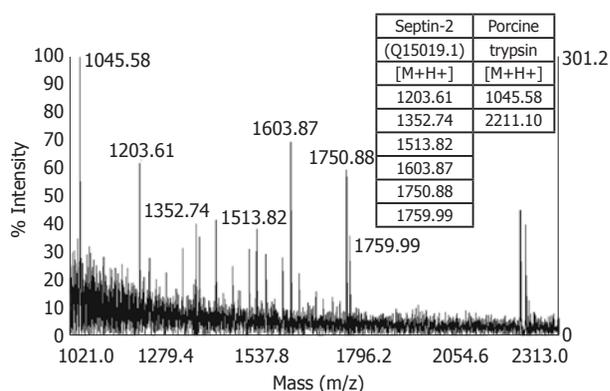

### 2-DE and MS

To determine the differentially expressed proteins in the gastric adenocarcinoma patients, we first performed 2-DE on 12 pairs of human gastric tissue samples. For good resolution we used large (24 cm) IPG strips with an acidic pH gradient (4-7). We performed the experiments in triplicate, which produced well-resolved spots and reproducible 2-DE patterns. On average,  $1197 \pm 150$  spots per gel were detected after silver staining. Figure 1 shows a typical image of a tumor- and a non-tumor-sample-derived gel. In the lower part of the figure, one can see differentially expressed spots from the tumor/non-tumor pairs, obtained from a pair-by-pair comparison.

After the proteolytic digestion of 32 excised spots,

**Figure 1** Results of two-dimensional gel electrophoresis from gastric adenocarcinoma patients. A: Examples of silver-stained two-dimensional gel electrophoresis gels for non-tumor and tumor tissue; B: Examples of differentially expressed spots (circled) for the non-tumor and tumor tissue that were chosen for immunoblot validation. MW: Molecular weight; GKN1: Gastrokine-1 precursor; MRPL12: 39S ribosomal protein L12 (mitochondrial precursor); PACAP: Plasma cell-induced resident endoplasmic reticulum protein; GSTM3: Glutathione S-transferase mu 3; SEPT2: Septin-2; UBE2N: Ubiquitin-conjugating enzyme E2 N; TALDO1: Transaldolase; TPT1: Translationally controlled tumor protein.

**Figure 2** An example of mass spectrometry identification results for septin-2.

we identified 30 different proteins by MALDI-TOF MS or nanoLC-ESI-Q-TOF MS/MS. Eleven proteins were found to be underexpressed, while 19 were found to be overexpressed in the gastric adenocarcinoma relative to adjacent non-tumor tissue samples. These results are summarized in Table 2 and an example of the MS identification is shown in Figure 2.

The identified differentially expressed proteins could be classified into eight groups according to the biological process in which they are involved (Figure 3), by information from the GO Classification for *Homo sapiens* from European Molecular Biology Laboratory - European

Bioinformatics Institute (<http://www.ebi.ac.uk/integr8/GOAnalysisPage.do?orgProteomeID=25>). These groups were: metabolism (*HPGD, ECHS1, MRPL12, ACADS, NDUFV2, PBLD, PACAP, ATP5H, GSTM3, PGK1, ACTB, HSPA1, CBX3, UBE2N, TALDO1, MTPN, ENO1, NNMT, EIF2S1, NME1*), development (*HPGD, NDUFV2, GSTM3, SEPT2, SERPINB5, ACTB, NGFR, MTPN, NME1*), death (*PACAP, PKM2, NGFR, CTSD, ANXA4, TPT1, ANXA5, NME1*), response to stress (*ACTB, HSPA1, UBE2N, ENO1, EIF2S1, ANXA5*), cell cycle (*GKN1, HPGD, SEPT2, NGFR, HSPA1, NME1*), cell communication (*GSTM3, ACTB, NGFR, ANXA4, ANXA5*), transport (*ATP5H, TTR, SEPT2, TPT1*), and cell motility (*SERPINB5, ACTB*).
