cases, according to the revised scoring criteria of HercepTest™ as used in the ToGA trial. Correlations between HER2 expression and clinicopathologic variables of proximal ( $n = 513$ ) and distal ( $n = 444$ ) GC were investigated.

**RESULTS:** Our results showed that HER2 expression was significantly higher in the proximal than in distal GC ( $P < 0.05$ ). Overall, HER2 expression was significantly higher in male patients ( $P < 0.01$ ), the Lauren intestinal type ( $P < 0.001$ ), low-grade ( $P < 0.001$ ) and pM1 ( $P < 0.01$ ) diseases, respectively. There was a significant difference in HER2 expression among some pTNM stages ( $P < 0.05$ ). In contrast, HER2 expression in the distal GC was significantly higher in male patients ( $P < 0.001$ ), low-grade histology ( $P < 0.001$ ), the Lauren intestinal type ( $P < 0.001$ ), and pM1 ( $P < 0.001$ ). In the proximal GC, however, higher HER2 expression scores were observed only in tumors with low-grade histology ( $P < 0.001$ ) and the Lauren intestinal type ( $P < 0.001$ ).

**CONCLUSION:** HER2 over-expression in GC of Chinese patients was significantly more common in proximal than in distal GC, and significantly correlated with the Lauren intestinal type and low-grade histology in both proximal and distal GC, and with pM1 disease and male gender in distal GC.

### Abstract

**AIM:** To investigate HER2 expression and its correlation with clinicopathological variables between proximal and distal gastric cancers (GC) in the Chinese population.

**METHODS:** Immunostaining of HER2 was performed and scored on a scale of 0-3 in 957 consecutive GC

**Core tip:** In this study, immunostaining of HER2 was performed and scored according to the revised scoring criteria of HercepTest™ used in the ToGA trial in a very large cohort of gastric cancers (GC) patients (957 cases). Our results revealed that HER2 over-expression in GC of Chinese patients was significantly more common in proximal than in distal GC, and was significantly cor-

related with the Lauren intestinal type and low-grade histology in both proximal and distal GC, and with pM1 disease and male gender in distal GC.

## INTRODUCTION

HER2 gene amplification and over-expression, which possibly represents a negative prognostical factor<sup>[1,2]</sup> but a potential therapeutic target<sup>[3-7]</sup>, has been found in 6%-53.4% of gastric cancer (GC) in patients from Western countries<sup>[3,8]</sup>. As such, it is now recommended that all patients with GC should have their tumors tested for the HER2 status at the time of initial diagnosis<sup>[9]</sup>. At present, the tests for HER2 over-expression by immunohistochemistry (IHC) and HER2 gene amplification by fluorescence in situ hybridization (FISH) are the most common methods. As demonstrated in the phase III ToGA trial, patients with IHC 2+/FISH-positive or IHC 3+ tumors benefited from trastuzumab treatment, but cases with HER2 gene-amplified tumors, revealed by the FISH test, without HER2 over-expression (IHC 0 or 1+) did not show any survival gain<sup>[5]</sup>. The characteristics of HER2 expression in GC are different from those in breast cancer<sup>[5,10]</sup>. Therefore, in the phase III ToGA trial, the HER2 expression scoring system for breast cancer, which was proposed by the American Society of Clinical Oncology (ASCO)/College of American Pathologists (CAP), was modified for evaluation of HER2 expression in GC<sup>[11]</sup>, requiring IHC for HER2 testing before use of the FISH test<sup>[9,12,13]</sup>, because IHC seems to be more predictive of trastuzumab therapeutic responses than the FISH test alone in GC, compared with breast cancers<sup>[14]</sup>.

In China, GC remains one of the leading cancers. Despite recent advances in treatment, the outcome of patients with advanced GCs is poor. Because there exist considerable differences in GC histopathology, environmental factors, and the *Helicobacter pylori* status between Western and Chinese patients<sup>[15]</sup>, the need for a comprehensive investigation of the HER2 expression profile in GC of Chinese patients is urgent for better clinical management. Therefore, we carried out this study to fully investigate differences in HER2 expression and clinicopathologic features between proximal and distal GC with the same assessment criteria of IHC as used in the ToGA trial<sup>[11]</sup>.

## MATERIALS AND METHODS

### Case selection

We retrospectively searched a prospectively established

electronic pathology database for GC resection cases with HER2 immunostaining results over the period from January 2007 to August 2009 at the affiliated Nanjing Drum Tower Hospital, Nanjing University Medical School in Nanjing, China. A total of 957 consecutive cases were identified, including 513 proximal and 444 distal GC, according to the surgical resection methods of GC and gross specimen description. Because our recent research results in the same group of Chinese GC patients suggested that almost all proximal GC with esophageal involvement also included Siewert II-III GC, which are regarded as esophageal origin and stage-grouped as esophageal cancers<sup>[16,17]</sup>, they might be more accurately staged as gastric rather than esophageal cancers<sup>[18,19]</sup>. Therefore, the proximal GC in this study included both GC with epicenters entirely below the gastroesophageal junction (GEJ) and those invading through the GEJ into the distal esophagus as a minor component. Distal GC was defined as tumors with epicenters in the region from the incisura angularis to the antrum-pylorus. The Lauren classification of GC was followed to subgroup all cases in histopathology. All cases were staged, according to the staging rules for GC set out in the 7<sup>th</sup> edition of the American Joint Committee on Cancer Staging<sup>[20]</sup>. The patient demographics and pathologic information were retrieved from each pathology report. The patient private identification information was deleted and the study protocol was approved by the Medical Ethics Committee of the Hospital.

### Immunohistochemistry

A conventional immunostaining protocol was used for all cases. Briefly, paraffin-embedded tumor tissue blocks were cut at 4- $\mu$ m in thickness. Sections were deparaffinized, dehydrated, subjected to the antigen retrieval procedure, and then incubated with the primary rabbit antihuman HER2 polyclonal antibody (clone A0485, dilution: 1:2500, Dako, Denmark) for one hour at 37 °C. The HER2 immunoreactivity was visualized after a brief treatment with the EnVision Plus system kit (Dako). Both positive and negative controls were included in each run.

Three experienced pathologists independently evaluated HER2-stained slides blindly without the knowledge of patient clinicopathologic information. The HER2 immunoreactivity of neoplastic cells was scored according to the revised ToGA scoring criteria of HercepTest<sup>TM</sup> for GC<sup>[5,11]</sup>, which was based on the intensity of membrane staining and quantity of positive neoplastic cells on a scale of 0-3. In brief, no membranous reactivity in less than 10% of tumor cells was scored as 0; faint/barely visible complete or basolateral membranous reactivity in 10% or more of tumor cells was scored as 1+; weak-to-moderate complete or basolateral membranous reactivity in 10% or more of tumor cells was scored as 2+; strong complete or basolateral membranous reactivity in 10% or more of tumor cells was scored as 3+. A score of 0 or 1+ was considered negative while scores 2+ and 3+ were positive.

**Table 2 Comparison of HER2 expression between proximal and distal gastric adenocarcinoma**

| Group    | n   | HER2 score |     |    |    | $\chi^2$ | P     |
|----------|-----|------------|-----|----|----|----------|-------|
|          |     | 0          | 1   | 2  | 3  |          |       |
| Proximal | 513 | 260        | 126 | 72 | 55 | 6.691    | 0.011 |
| Distal   | 444 | 255        | 108 | 45 | 36 |          |       |

**Statistical analysis**

The absolute and relative frequencies of qualitative variables were calculated in percentages.  $\chi^2$  tests for categorical variables were used and the differences were considered to be statistically significant if P values were less than 0.05. All analyses were performed using the SPSS version 20.0 software for Windows (SPSS Inc., Chicago, IL, United States).

**RESULTS**

**Clinicopathologic features**

The mean patient age was 63 years (range: 17-89 years). As shown in Table 1, most patients were male (75%) with a male-female ratio of 3.0; 29% of patients were older than 70 years. Most tumors were the Lauren intestine type (59%), high-grade histology (66%), and at advanced stages of pIII and pIV (61%). About 54% of GC was located in the proximal stomach (Table 2). None of the patients received neoadjuvant therapy before surgical resections.

**Overall HER2 immunoreactivity in GC**

In general, HER2 immunoreactivity of neoplastic cells

in GC was characterized by basolateral, lateral, and/or circumferential membranous, heterogeneous or diffuse, staining patterns (Figures 1-3). HER2 over-expression with score 3, and scores 2 and 3 were found in 9.5% (91/957) and 21.73% (208/957) of cases, respectively. Overall, HER2 expression with score 3 was significantly higher in male patients (10.24% *vs* 7.38% in females, *P* < 0.01), the proximal GC (8.11% *vs* 10.72% in distal GC, *P* < 0.05), the Lauren intestine type (14.79% *vs* 1.8% in the Lauren diffuse/mixed type, *P* < 0.001), histological low-grade histology (17.6% *vs* 5.37% in high-grade histology, *P* < 0.001), and pM1 (36.36% *vs* 8.88% in pM0, *P* < 0.01). Although there was a significant difference in HER2 expression between advanced and early GC, especially in stage pIV (p I : 2.7%; p II : 10.86%; p III : 9.12%; p IV : 38.1%; *P* < 0.05), the correlation between HER2 and pTNM stage was not statistically significant (*P* > 0.05) (Table 1).

**Differences in HER2 immunoreactivity between proximal and distal GCs**

HER2 expression was higher in proximal GC than in distal GC (10.7% *vs* 8.1% with score 3; 25% *vs* 18.2% with scores 2 and 3; *P* < 0.05) (Table 2). In the proximal GC, higher expression of HER2 with score 3 was found only in tumors with low-grade histology (17.24% *vs* 6.45%, *P* < 0.001), the Lauren intestine type (15.88% *vs* 0.58%, *P* < 0.001) than those with high-grade histology and the Lauren diffuse/mixed type (Table 3). In the distal GC, however, HER2 over-expression with score 3 was significantly higher in male patients (9.09% *vs* 5.88%, *P* < 0.001), distant metastasis (50% *vs* 6.94%, *P* < 0.001), histological low-grade (18.18% *vs* 4.33%, *P* < 0.001), the Lauren in-

testine type (13.16% *vs* 2.87%,  $P < 0.001$ ) GC than in female patients, pM0, high-grade histology, and the Lauren

diffuse/mixed type (Table 4).

## DISCUSSION

In this retrospective study using the revised IHC scoring criteria of HercepTest<sup>TM</sup> for HER2 expression in GC of Chinese patients, we compared HER2 protein expression profiles along with clinicopathologic features between 513 proximal and 444 distal GC in Chinese patients. The data showed that HER2 over-expression was significantly more common in proximal GC than in distal GC, and significantly correlated with the Lauren intestine type and low-grade histology in both proximal and distal GC, and with pM1 disease and male gender in distal GC.

In the recent literature, the frequency of HER2 over-expression in GC, determined by IHC, ranges widely from 6.8% to 26.8%<sup>[21]</sup>. In this study, HER2 over-expression

pTNM: Pathological tumor-node-metastasis; M: Male; F: Female.

with score 2 and 3 was found in 21.73% of cases, which was higher than that (15.9%) in another recent study using the same antibody and scoring criteria in Korean patients<sup>[8]</sup>. The discrepancy appears to result from the differences in tissue preparations because they used tissue microarray for HER2 immunostaining, which has a much lower sensitivity for HER2 immunoreactivity because of

the well-known heterogeneous expression of HER2 in GC<sup>[14,21-24]</sup>. In addition, different primary antibody clones, various immunostaining protocols, and diverse immunoreactivity scoring schemes may also contribute to variations described among recent studies<sup>[8,12,25]</sup>. This inconsistency indicates an urgent need for standardized HER2 immunostaining in GC for better reporting and comparison of

HER2 IHC results among different centers.

HER2 expression is known to differ among various clinicopathologic factors, such as patient gender, age, ethnicity, tumor location, type, and differentiation, *etc.*, as shown in this and previous studies<sup>[26-28]</sup>. Our data showed high HER2 expression in GC with low-grade histology and advanced pTNM stages. Similar to our results, a recent study in Japanese patients also described higher HER2 expression in male patients, tumors with the Lauren intestine type, and pM1 stage<sup>[26]</sup>. With a multivariate analysis, Janjigian *et al.*<sup>[29]</sup> reported a significantly higher frequency of HER2 immunopositivity in GC with liver metastasis and the Lauren intestine histology, but did not find significant differences in HER2 immunopositivity between resections and biopsies, or primaries and metastases. In that study, approximately 20% (78/381) of distant metastatic GC or GEJ cancers in Western patients were HER2-immunopositive (score 3+ or FISH-positive)<sup>[29]</sup>, a figure which is much lower than ours (36.4%, 8/22). However, the number of GC cases with distant metastasis was limited in this study and our results should be verified in studies with more qualified cases. Nonetheless, our data suggested that HER2 over-expression was more often seen in GC with the Lauren intestine type, low-grade histology, advanced pTNM stage, and in male patients.

In this study, we found a significantly higher frequency of HER2 over-expression in proximal GC than in distal GC. The result is similar to those reported recently in most other studies<sup>[30]</sup>. It must be pointed out that the vast majority of GEJ cancers in Chinese patients are not Barrett's esophagus-related and originate primarily in the proximal stomach, invading into the distal esophagus with clinicopathologic features of GC, as we reported previously<sup>[31]</sup>. Despite similar HER2 over-expression characteristics between Western GEJ cancers and Chinese proximal GC, there exist a number of differences in HER2 over-expression features between proximal and distal GC of Chinese patients in the present study. For example, in distal rather than proximal GC, HER2 over-expression in GC was more common in male patients and in tumors staged at pM1 than in female patients and in pM0 cases, respectively.

A major limitation in this observational study is the absence of the confirmatory FISH test for *HER2* gene amplification. However, unlike in breast cancer, HER2 expression with an IHC score of 0 or 1+ but with FISH positivity in GC tumors does not play a statistically significant role with regard to trastuzumab therapy<sup>[5]</sup>. GC with IHC 3+ HER2 status responds well to this treatment. Thus, the ToGA trial recommended testing *HER2* gene amplification by the FISH method only in GC cases with an IHC score of 2+<sup>[5]</sup>. Therefore, a confirmation FISH test might not be performed in GC with IHC 0, 1+ or 3+. However, our cohort is large with 957 GC resection cases and differences in HER2 expression are dramatically significant in many important clinicopathologic parameters. Therefore, the validity of our results should be

reasonably sound.

In summary, our data showed a significantly higher frequency of HER2 over-expression in proximal GC than in distal GC. HER2 over-expression was significantly correlated with low-grade histology and the Lauren intestine type in both proximal and distal GC, and with male gender and distant metastasis in distal GC.

This work was presented as a poster in an abstract form at the annual meeting of United States and Canadian Academy of Pathology in 2011 and Digestive Disease Week in 2011.

## COMMENTS

### Background

*HER2* gene amplification and over-expression is a potential therapeutic target and is found in 6%-53.4% of gastric cancer (GC) in patients from Western countries. As such, it is now recommended that all patients with GC should have their tumors tested for HER2 status at the time of initial diagnosis. In China, GC remains one of the leading cancers. Because there exist considerable differences in GC between Western and Chinese patients, the need for a comprehensive investigation of the HER2 expression profile in GC of Chinese patients is urgent for better clinical management.

### Research frontiers

The purpose of the present study was to investigate HER2 expression with the same assessment criteria of IHC as used in the ToGA trial and its correlation with clinicopathological variables between proximal and distal GC in the Chinese population.

### Innovations and breakthroughs

Our study represented a very large cohort of GC. In this study, HER2 expression in the overall GC was significantly higher in male patients, the Lauren intestinal type, low-grade and pM1 diseases. There was a significant difference in HER2 expression among some pTNM stages. Similar to some Western study results, our data showed that HER2 expression was significantly higher in proximal GC than in distal GC. Also, HER2 expression in the distal GC was significantly higher in male patients, low-grade histology, the Lauren intestinal type, and pM1. In the proximal GC, however, higher HER2 expression scores were observed only in tumors with low-grade histology and the Lauren intestinal type.

### Applications

Our data, derived from a comprehensive investigation of HER2 expression profile with the same ToGA criteria in GC resection specimens in a large cohort of homogeneous Chinese patients, provide pathologists and oncologists with more accurate study results than tissue microarray regarding HER2 over-expression characteristics in both proximal and distal GC, which is essential for better clinical management of patients with GC in the Chinese population.

### Terminology

ToGA trial: An international, open-label, randomized, controlled, phase III trial of Herceptin (Trastuzumab) in combination with chemotherapy compared with chemotherapy alone in patients with HER2-positive advanced gastric cancer, which was undertaken in 122 centers in 24 countries; Lauren classification: the Lauren classification is based on the histological features of gastric adenocarcinomas, and divides gastric adenocarcinomas into 3 types: intestinal type (the tumor consists of neoplastic glands arranged in tubules, acini, and papillae), diffuse type (the tumor cells are discohesive and many show the signet-ring morphology) and mixed type.

### Peer review

The authors reported statistically more frequent HER2 over-expression in proximal than distal GC. HER2 over-expression was also associated with some clinicopathological characteristics, such as gender, the Lauren intestinal type, low-grade dysplasia, and pM1 diseases in GC. This is a valuable paper which represents a very large cohort of cancers (957 cases). This provides

some real strength and confidence in the HER2 expression values. The data are consistent with but extend (for the Chinese population) the information already available.

### Abstract

**AIM:** To investigate whether the reduction of stem cell factor (SCF) is mediated by decreased endogenous insulin-like growth factor (IGF)-1 in diabetic rat colon smooth muscle.

**METHODS:** Sixteen Sprague-Dawley rats were randomly divided into two groups: control group and streptozotocin-induced diabetic group. After 8 wk of streptozotocin administration, colonic motility function and contractility of circular muscle strips were measured. The expression of endogenous IGF-1 and SCF was tested in colonic tissues. Colonic smooth muscle cells were cultured from normal adult rats. IGF-1 siRNA transfection was used to investigate whether SCF expression was affected by endogenous IGF-1 expression in smooth muscle cells, and IGF-1 induced SCF expres-

sion effects were studied. The effect of high glucose on the expression of endogenous IGF-1 and SCF was also investigated.

**RESULTS:** Diabetic rats showed prolonged colonic transit time ( $252 \pm 16$  min vs  $168 \pm 9$  min,  $P < 0.01$ ) and weakness of circular muscle contraction ( $0.81 \pm 0.09$  g vs  $2.48 \pm 0.23$  g,  $P < 0.01$ ) compared with the control group. Endogenous IGF-1 and SCF protein expression was significantly reduced in the diabetic colonic muscle tissues. IGF-1 and SCF mRNA expression also showed a paralleled reduction in diabetic rats. In the IGF-1 siRNA transfected smooth muscle cells, SCF mRNA and protein expression was significantly decreased. IGF-1 could induce SCF expression in a concentration and time-dependent manner, mainly through the extracellular-signal-regulated kinase 1/2 signal pathway. High glucose inhibited endogenous IGF-1 and SCF expression and the addition of IGF-1 to the medium reversed the SCF expression.

**CONCLUSION:** Myopathy may resolve in colonic motility dysfunction in diabetic rats. Deficiency of endogenous IGF-1 in colonic smooth muscle cells leads to reduction of SCF expression.

**Key words:** Diabetes; Gastrointestinal motility function; Insulin-like growth factor-1; Stem cell factor; Smooth muscle cell

**Core tip:** Endogenous insulin-like growth factor (IGF)-1 levels in diabetic rat colonic tissues were decreased. Hyperglycemia may be involved in initiating this change. In colonic smooth muscle cells, IGF-1 had a direct effect on increasing stem cell factor mRNA and protein levels mediated by extracellular-signal-regulated kinase 1/2 signaling.

Effect of endogenous insulin-like growth factor and stem cell factor on diabetic colonic dysmotility. *World J Gastroenterol* 2013; 19(21): 3324-3331 Available from: URL: <http://www.wjg-net.com/1007-9327/full/v19/i21/3324.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i21.3324>

## INTRODUCTION

Approximately 75% of diabetic patients with any type of diabetes mellitus (DM) present gastrointestinal symptoms<sup>[1,2]</sup>, particularly those who have poor glycemic control. Constipation and the use of laxatives are relatively common in patients with DM<sup>[3]</sup>. This disorder involves the depletion of interstitial cells of Cajal (ICCs), dystrophic changes of smooth muscle cells (SMCs), and impairment of enteric nervous systems<sup>[4-6]</sup>. ICCs are electrical active cells that generate and propagate electrical slow waves and serve as a bidirectional interface between nerves and smooth muscle<sup>[5-7]</sup>. ICCs damage has been shown in the stomach, jejunum, and colon of patients suffering from either type 1 or type 2 diabetes. ICCs depletion has been demonstrated in both patients with DM and laboratory animal models<sup>[8]</sup>, and ICCs depletion is a consequence of stem cell factor deficiency<sup>[9]</sup>.

It is well established that ICCs survival and function depend on the activation of c-kit, a receptor tyrosine kinase integral to ICCs. SCF, as a c-kit ligand, is produced locally within the tunica muscularis<sup>[10-12]</sup>.

*In vitro* experiments showed insulin-like growth factor-1 (IGF-1) prevented ICC deletion in long-term cultured smooth muscle<sup>[9]</sup>. In intact tissues, a significant proportion of tissue IGF-1 is actually produced by SMCs<sup>[13]</sup>. Therefore, local IGF-1 signaling may play a significant role in SCF expression. The aim of this research is to study the local colonic IGF-1 expression in DM rats and the endogenous IGF-1 effects on SCF production.

## MATERIALS AND METHODS

### Animals

Male SD rats (weighing 200-250 g) were used for the experiments. Smooth muscle cells were obtained from SD rat colons. Diabetic rats (streptozotocin, STZ-D,  $n = 8$ ) were induced by a single intraperitoneal injection of streptozotocin (STZ, 60 mg/kg body weight) dissolved in a citrate buffer, and age-matched control rats ( $n = 8$ ) received equal volumes of buffer by *ip* injection. Diabetes was confirmed 1 wk later by measurement of tail vein blood glucose levels with an AccuChek Compact Plus glucometer (Roche, IN, United States). Rats with final blood glucose levels > 16.7 mmol/L were included in the study. At 8 wk after STZ administration, all the experimental rats were sacrificed by cervical dislocation. Food and water were given *ad libitum*. All animals were maintained in a controlled environment with alternating 12 h light/dark cycles. All animal care, use, and experimental

protocols were approved by the Institutional Animal and Use Committee of Nanjing Medical University.

### Distal colonic transit

Eight weeks after STZ injection, colonic transit was measured using a bead expulsion test as described<sup>[14]</sup>. A glass bead (5 mm in diameter) was inserted through the anus, and pushed with a plastic rod into the distal colon for a distance of 3 cm, while each rat was under transient ethyl ether anesthesia. The time until bead expulsion was measured.

### *In vitro* studies of colonic smooth muscle contractility

Eight weeks after STZ injection, freshly obtained full-thickness distal colon tissues (about 5 cm from the anus) from control and diabetic rats were stored on ice for less than 1 h and then immersed in warm, oxygenated (95% O<sub>2</sub> and 5% CO<sub>2</sub>) Krebs solution (in mmol/L: 118 NaCl, 4.7 KCl, 2.5 CaCl<sub>2</sub>, 1 NaH<sub>2</sub>PO<sub>4</sub>, 1.2 MgCl<sub>2</sub>, 11 D-glucose and 25 NaHCO<sub>3</sub>). The mucosal layers were removed by micro-dissection under a magnifying glass and discarded. Circular muscle strips (2 mm × 10 mm) were prepared. After connecting to an isometric force transducer (Alcott-Biotech), the strips were allowed to equilibrate for 30 min under an initial tension of 0.5 g. The bath temperature was maintained at 37 °C. Contractile responses to acetylcholine (Ach, 1 μmol/L, Sigma-Aldrich, St. Louis, MO, United States) were obtained. At least three muscle strips from the distal colon of each rat were used for muscle experiments. The mean of the three or more muscle strips exposed to Ach 1 μmol/L was determined for each rat.

### Cell culture and treatment

SMCs were isolated from colonic tissues and cultured as described previously<sup>[15]</sup>. Briefly, whole SD rat colons were dissected, and mucosa and serosa were quickly removed from muscle tissues. After digestion with type II collagenase, SMCs were cultured in DMEM medium (Gibco) with 10% fetal bovine serum. Cells of passage 2 or 3 were used for the studies. Before the experiments, cells were serum starved for 24 h and then stimulated with different concentrations of IGF-1 (R and D Systems, Minneapolis, MN, United States) for various time periods. Phosphorylated extracellular-signal-regulated kinase 1/2 (ERK1/2) and phosphorylated Akt were measured after IGF-1 (100 ng/mL) treatment for 15 min. ERK1/2 inhibitor PD98059 (50 μmol/L) and phosphoinositide 3-kinase inhibitor (PI3K) inhibitor LY294002 (50 μmol/L) (Cell Signaling, Danvers, MA, United States) were added to the medium 30 min before IGF-1 treatment. Culture medium containing 25 mmol/L D-glucose was used for high glucose stimulation, and mannitol (5 mmol/L D-glucose plus 19.5 mmol/L mannitol) was used for osmotic controls.

### siRNA transfection

IGF-1 siRNA was synthesized by GenePharma (Shanghai GenePharmaCo, China). The sequence for IGF-1 siRNA was as follows: anti-IGF-1-sense 5'-GCAG-

GAAACAAGACCUACATT-3', and anti-IGF-1-antisense 5'-UGUAGGUCUUGUUUCCUGCTT-3'. Negative control siRNA: sense 5'-UUCUCCGAACGUGUCAC-GUTT-3', and antisense 5'-ACGUGACACGUUCG-GAGAATT-3'. Primary colonic smooth muscle cells were grown in six-well plates to 30% confluence, washed with serum-free medium immediately before transfection, and 800  $\mu$ L serum-free medium was added to each well. siRNA (4  $\mu$ g) was mixed with 10  $\mu$ L of X-tremeGENE siRNA transfection reagent (Roche) in 200  $\mu$ L serum-free medium. The mixture was incubated for 20 min at room temperature and then added to cells, according to the manufacturer's instructions. Serum was added 4 h later to a final concentration of 10%. Cells were harvested at 72 h after transfection.

### Western blotting

Distal colonic tissues were dissected from the mucosa and serosa. The remaining tissues were mainly muscle layers and used for Western blotting<sup>[16]</sup>. Tissues and cultured cells were lysed and centrifuged at 12000 *g* for 20 min. Protein samples were run on a 12% polyacrylamide gel in Tris-HCl. Proteins were then transferred to nitrocellulose membranes for 1 h at 100 V. The membranes were blocked with 5% (w/v) skim milk for 1 h at room temperature, and probed with primary antibodies at 4 °C overnight, and then washed in Tris-buffered saline with 0.1% Tween 20 for 5 min three times. The membranes were probed with corresponding horseradish peroxidase-conjugated secondary anti-rabbit and anti-goat antibodies at 1:2000 dilutions. Protein bands were detected with enhanced chemiluminescence Western blotting reagents (Thermo Fisher Scientific, Rockford, IL, United States). The resulting bands were scanned with an Epson 2400 printer and analyzed using the ImageJ program. All the antibodies used in this study, except for IGF-1 (Abcam, Cambridge, MA, United States) and SCF (Santa Cruz, CA, United States), were from Cell Signaling Technology.

### Real-time polymerase chain reaction

Total RNA was isolated from colonic muscle layers and isolated SMCs, and quantified using Spectrophotometer Nanodrop 2000 (Thermo Scientific). RNA (500 ng) was submitted for cDNA synthesis using Prime Script RT Master Mix (Takara). The levels of isolated mRNA were measured by real-time polymerase chain reaction (PCR) using SYBR Premix Ex Taq (Takara) according to the manufacturer's instructions. PCR was initiated at 95 °C for 30 s, followed by 40 cycles of denaturing at 95 °C for 5 s, annealing and extending at 60 °C for 30 s. After PCR, a dissociation curve was constructed at 60-95 °C. PCR was performed in triplicate. The oligonucleotide primers used were as follows: IGF-1, forward, GGCATTGTGGAT-GAGTGTG, reverse, GTCTTGGGCATGTCAGT-GTG; SCF, forward, TTCGCTTGTAAATGGCTTTGC; reverse, CAACTGCCCTTGTAAAGAC TTGCA; and 18S rRNA, forward, GCGAAAGCATTTGCCAAGAA, reverse, GGCATCGTTTATGGTCGGAAC. Results were

shown to be relative to 18S rRNA mRNA.

### Statistical analysis

The results are expressed as the mean  $\pm$  SE. The SPSS statistical package (version 14.0; SPSS Inc, Chicago, IL, United States) was used for statistical analysis. The differences between the two groups were analyzed using Student's *t* test, and differences between the three groups were analyzed using analysis of variance. A *P* value < 0.05 was considered statistically significant.

## RESULTS

### Effects of diabetes on colonic motility function

All STZ-induced rats showed hyperglycemia at the time of experiments, with their blood glucose concentrations being significantly higher than those of the age-matched rats which were not injected with STZ (*n* = 8) (Figure 1A). The body weight of STZ-treated (STZ-D) rats was significantly lower than the age-matched normal rats (*n* = 8) (Figure 1B).

The distal colon transit time was significantly increased in STZ-D group 8 wk after induction of diabetes (Figure 1C). Colonic circular smooth muscle strips from STZ-D rats showed weak contractility to Ach (Figure 1D). The maximum contractile tension of the STZ-D group was significantly reduced compared with control group (*n* = 8 each group) (Figure 1E).

### SCF and IGF-1 expression in STZ-D rat distal colonic tissue

Eight weeks after STZ administration, the rats were sacrificed and distal colonic tissues were harvested. Because the mucosa/submucosa and serosa had been removed, the protein and mRNA were mainly from the muscle layer. The protein levels of SCF and IGF-1 were significantly decreased in STZ-D rat distal colons (Figure 2A). SCF and IGF-1 mRNA levels were consistent with the protein results. SCF mRNA levels of diabetic rats were lower than those of control rats, and IGF-1 mRNA levels were also decreased in diabetic rat colonic tissues (Figure 2B).

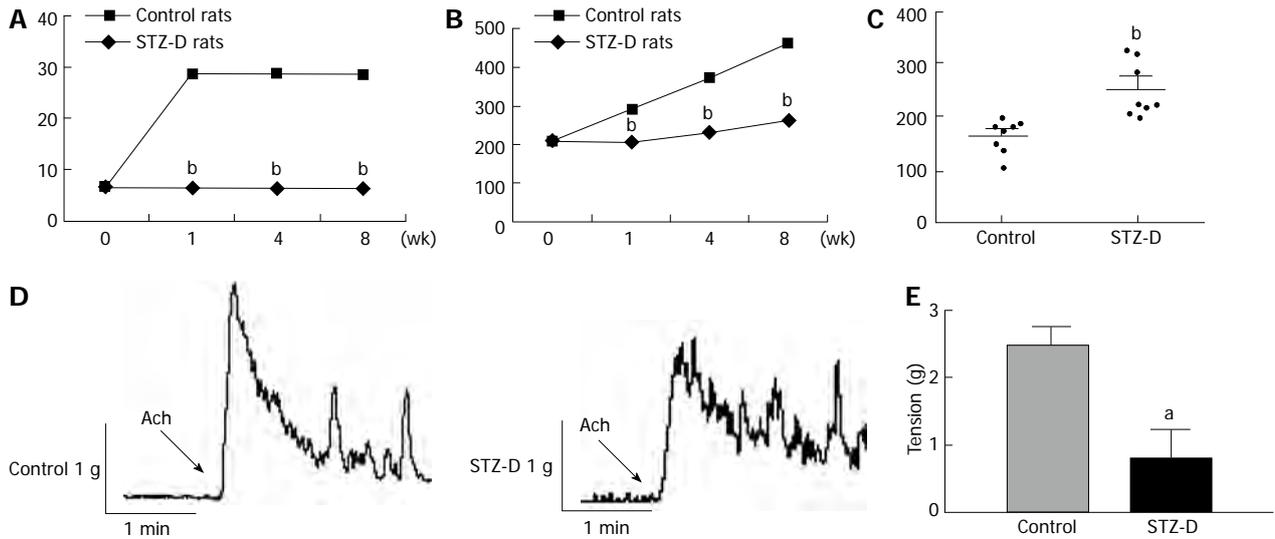

### Effects of IGF-1siRNA on SCF expression

siRNA knockdown of endogenous IGF-1 reduced SCF mRNA levels in SMCs, and SCF protein levels also showed a significant parallel reduction of IGF-1 levels compared with the controls (Figure 3).

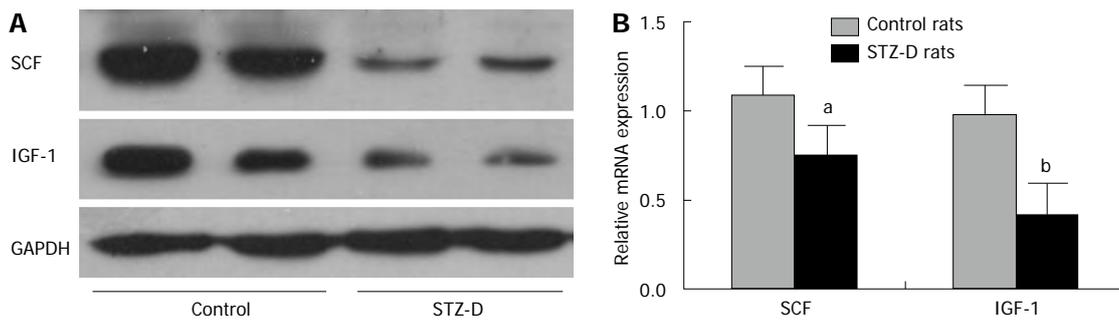

### IGF-1 increased expression of SCF in SMCs through ERK1/2 pathway

IGF-1 elicited a dose-dependent increase in the expression of SCF in rat colonic SMCs. The concentration of 50 ng/mL significantly increased the expression of SCF (*P* < 0.01). One hundred ng/mL and 150 ng/mL IGF-1 showed a maximal effect on the expression of SCF (*P* < 0.01); therefore, 100 ng/mL was used in subsequent experiments (Figure 4A).

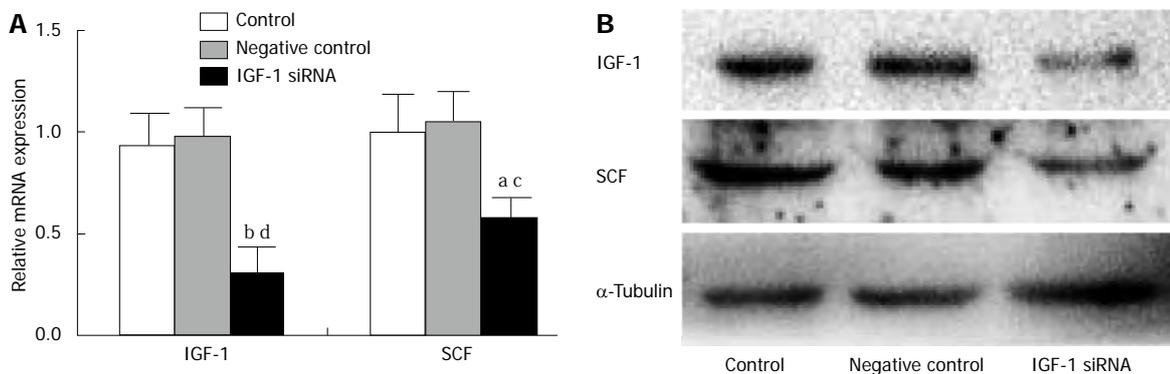

IGF-1 induced maximum SCF expression in SMCs at

**Figure 1** Colonic motility dysfunction in rats with streptozotocin-induced diabetes. A: Blood glucose levels of control group and rats with streptozotocin (STZ)-induced diabetes ( $n = 8$ ); B: The body weights of diabetic and age-matched control rats ( $n = 8$ ); C: Colonic transit time in STZ-D and control rats 8 wk after STZ injection ( $n = 8$ ); D: Circular muscle strip contractility from the representative distal colon of an STZ-D rats and control 8 wk after STZ injection and exposed to  $1 \mu\text{mol/L}$  ACh. Representative images are shown; E: Quantification of maximum contractile force of a circular muscle strip stimulated by  $1 \mu\text{mol/L}$  ACh ( $n = 8$ ). <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs the control group.

**Figure 2** Stem cell factor and insulin-like growth factor-1 expression in streptozotocin-D rat distal colon. A: Stem cell factor (SCF) and insulin-like growth factor-1 (IGF-1) protein levels in streptozotocin (STZ)-D rat distal colon ( $n = 8$ ). Images are representative of at least 4 independent Western blotting, glyceraldehyde-3-phosphate dehydrogenase (GAPDH) was used as a loading control; B: SCF and IGF-1 mRNA levels in colonic tissue of control rats and STZ-D rats ( $n = 8$ ). <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs the control group.

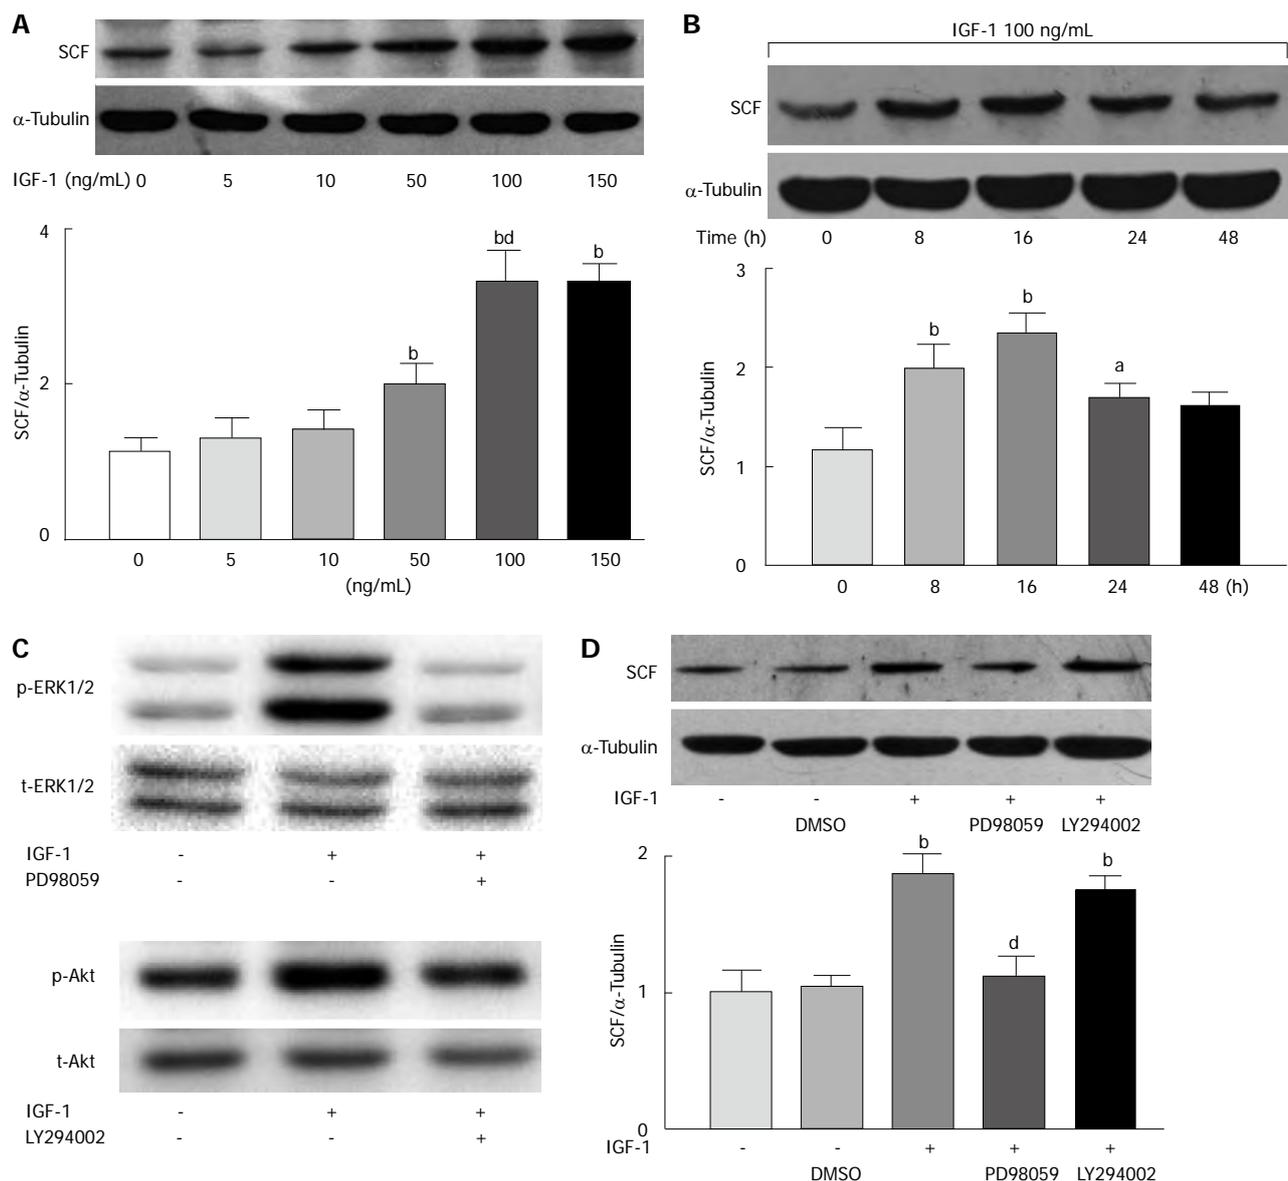

**Figure 3** Effects of insulin-like growth factor-1 siRNA on stem cell factor expression. A: Effects on stem cell factor (SCF) mRNA levels in colonic smooth muscle cells (SMCs) 72 h after of transfection with insulin-like growth factor-1 (IGF-1) siRNA (Each bar represents the mean  $\pm$  SE of 3 independent experiments). <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs controls; <sup>c</sup> $P < 0.05$ , <sup>d</sup> $P < 0.01$  vs negative controls; B: SCF protein expression in SMCs after IGF-1 knockdown for 72 h (figure is representative of 3 experiments).  $\alpha$ -Tubulin was used as a loading control.

16 h; while at 24 and 48 h, the stimulating effect of IGF-1 on SCF gradually diminished. By 48 h, the expression lev-

els had almost returned to baseline (0 h) (Figure 4B).

To determine whether IGF-1-induced SCF expression

**Figure 4** Insulin-like growth factor-1-induced stem cell factor expression through the extracellular-signal-regulated kinase 1/2 pathway in smooth muscle cells. **A:** Insulin-like growth factor-1 (IGF-1) effects on the expression of stem cell factor (SCF) as a function of concentration after treatment with IGF-1 for 24 h. <sup>b</sup>*P* < 0.01 vs 0 ng/mL IGF-1; <sup>d</sup>*P* < 0.01 vs 50 ng/mL IGF-1; **B:** IGF-1 effects on SCF expression as a function of time. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 vs 0 h; **C:** Phosphorylation of extracellular-signal-regulated kinase 1/2 (ERK1/2) and Akt after 100 ng/mL IGF-1 treatment for 15 min; **D:** Effects of PD98059 and LY294002 on SCF expression by IGF-1 treatment. <sup>b</sup>*P* < 0.01 vs the no treatment group; <sup>d</sup>*P* < 0.01 vs IGF-1 treatment group. Western blotting represent 3 independent experiments. α-Tubulin was used as a loading control (each bar represents the mean ± SE of 3 independent experiments).

was mediated by Akt-dependent or ERK1/2-dependent mechanisms, we measured the phosphorylation of Akt and ERK1/2. Both of them could be phosphorylated by IGF-1 (100 ng/mL). We then used a PI3K/Akt inhibitor (LY-294002, 50 μmol/L) and an ERK1/2 inhibitor (PD-98059, 50 μmol/L) before IGF-1 (100 ng/mL) was added to the media. Sixteen hours after IGF-1 stimulation, the ERK1/2 inhibitor significantly inhibited IGF-1-induced SCF expression (*P* < 0.01) while the PI3K/Akt inhibitor showed no effect (Figure 4C).

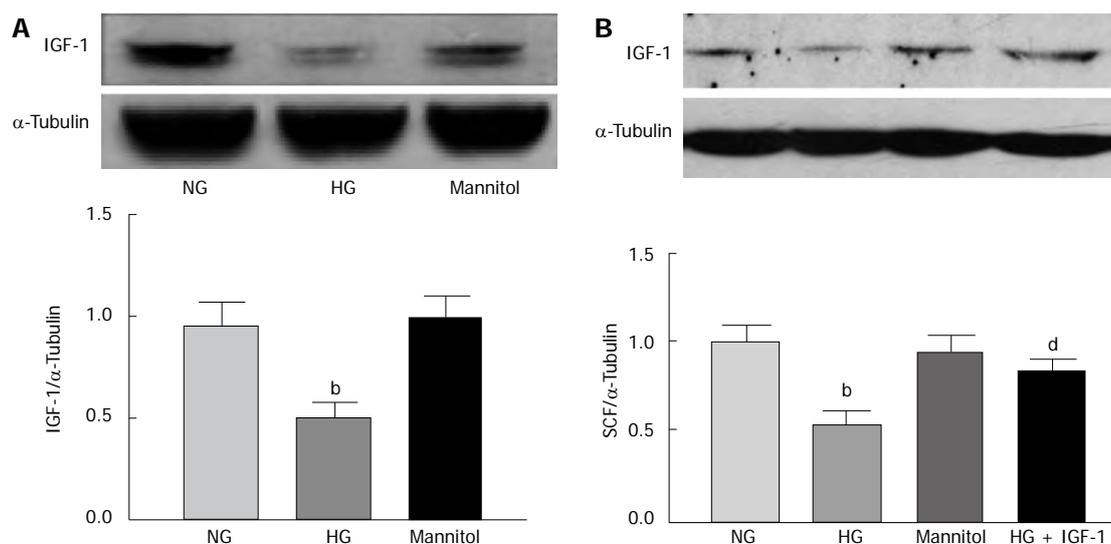

### High glucose suppresses endogenous IGF-1 and SCF expression

Compared with cultures for 24 h in normal glucose (5

mmol/L) medium, cultures in DMEM containing 25 mmol/L glucose significantly inhibited IGF-1 expression in cultured colonic SMCs. Mannitol was used as an osmotic control which did not have similar inhibitive effect (Figure 5A). High glucose concentrations also suppressed SCF expression, which was reversed by the addition of exogenous IGF-1 (100 ng/mL) (Figure 5B).

## DISCUSSION

Intestinal transit is often disturbed in diabetes (rapid or slow)<sup>[17]</sup>, and symptoms such as diarrhea and constipation occur more frequently than in the general population<sup>[18]</sup>. The prevalence of GI symptoms was found to be more

**Figure 5 High glucose inhibited endogenous insulin-like growth factor-1 and stem cell factor expression.** A: Expression of endogenous insulin-like growth factor-1 (IGF-1) in SMCs cultured in a high glucose (HG) medium for 24 h. <sup>b</sup> $P < 0.01$  vs the normal glucose (NG) group; B: Stem cell factor (SCF) expression in smooth muscle cells (SMCs) exposed to HG, and effects of the addition of exogenous IGF-1 (100 ng/mL). <sup>b</sup> $P < 0.01$  vs the NG group; and <sup>d</sup> $P < 0.01$  vs HG group. The Western blotting are representatives of 4 independent experiments.  $\alpha$ -Tubulin was used as a loading control (each bar represents the mean  $\pm$  SE of 3 independent experiments).

common in patients who had long histories of diabetes<sup>[19]</sup>. In diabetic animal models, it has been proven that 2 mo of DM is adequate to impair gastrointestinal motility. The spontaneously diabetic NOD/LtJ mouse, as a type 1 DM model, developed gastroparesis 2 mo after the onset of diabetes<sup>[20]</sup>, and a type 2 DM model *db/db* mouse developed disturbed motility of the stomach, small intestine, and colon 7 wk after the development of DM<sup>[21]</sup>.

Intestinal contractility is dependent on not only intact smooth muscle but also trophic factors, such as SCF and IGF-1, which protect the gastrointestinal slow wave generating ICCs<sup>[9]</sup>, and promote gastrointestinal growth<sup>[22]</sup>, respectively. In the present study, we found that SCF levels in colonic tissue of diabetic rats were significantly reduced, which is consistent with previous reports; in which NOD/LtJ mice had significantly reduced gastric mRNA levels of SCF<sup>[9]</sup> and diabetic *db/db* mice had lower mRNA levels of SCF in the small intestine and colon compared with age-matched control mice 7 wk after the development of type 2 DM<sup>[21]</sup>. Reduction of SCF production in the gastrointestinal tract of diabetic rats appears to play a significant role in decreasing ICCs network densities that have been described in human diabetes<sup>[9]</sup>. SCF has been shown to be produced locally by SMC and neurons within the tunica muscularis<sup>[9,23]</sup>. Decreases in IGF-1 signaling have been considered to be responsible for the decrease in SCF levels. Horváth *et al.*<sup>[9,24]</sup> have shown that IGF-1 treatment of murine gastric tunica muscularis tissues could reverse SCF reductions in long-term organ culture, and decreased levels of SCF were correlated with smooth-muscle atrophy. The observed pro-survival effects of insulin and IGF-1 on mature ICCs were probably indirect because ICCs do not express insulin or IGF-1 receptors<sup>[9]</sup>, while SMCs express both insulin and IGF-1 receptors. Therefore, both insulin and IGF-1 may induce SMCs to produce SCF.

IGF-1 is an endogenous growth factor that plays a central role in the growth and development of visceral and vascular smooth muscle<sup>[25,26]</sup>. Existing evidence suggests that mesenchymal cells, including  $\alpha$ -smooth muscle actin-positive myofibroblasts and smooth muscle cells, are primary sources of locally expressed IGF-1 in the intestine<sup>[27,28]</sup>. Local intestinal IGF-1 has autocrine effects on the growth of human intestinal muscle cells<sup>[29]</sup>. In this study, we found that endogenous IGF-1 was decreased in diabetic colonic tissues. Meanwhile, SCF expression in colonic tissue was paralleled by endogenous IGF-1, which suggested that a lack of endogenous IGF-1 might lead to low levels of SCF expression.

IGF-1 binds to the cellular membrane IGF-1 receptor leading to stimulation of proliferation and inhibition of apoptosis through PI3K/Akt and mitogen-activated protein kinase pathways<sup>[15,30]</sup>. In the present study, IGF-1 could cause both ERK1/2 and Akt phosphorylation, but IGF-1 promoted SCF expression mainly through ERK1/2-dependent signaling, not the PI3K/Akt pathway.

Both type 1 and type 2 diabetes patients have hyperglycemia as a basic feature, and chronic hyperglycemia is associated with dysfunction, damage, and failure of several organs<sup>[31]</sup>. This study showed that high glucose impaired the production of trophic factors in colonic SMCs. Whether the mechanism underlying the effects is oxidative stress caused by high glucose remains to be determined.

The current study is an extension of those described by Horváth *et al.*<sup>[9]</sup>. The significant differences between that study and the current one are: (1) we showed evidence supporting the presence of dysfunction of smooth muscle contractility in animals, which is more compelling evidence of myopathy than just a reduction of myh11 mRNA levels; (2) in cell culture studies, we demonstrated that IGF-1 had a direct effect on increasing SCF mRNA and protein levels, and this effect was mediated

by ERK1/2 signaling; additionally; and (3) we found that endogenous IGF-1 levels in diabetic rat colonic tissues were decreased, and that hyperglycemia may be involved in initiating this change.

In conclusion, we have demonstrated that the myopathy may resolve in colonic motility dysfunction in diabetic rats. Deficiency of endogenous IGF-1 in SMCs caused reduction in SCF expression, which is a critical developmental, growth, and survival factor for ICCs.

## COMMENTS

### Background

Most diabetic patients experience gastrointestinal symptoms, particularly those who are under poor glycemic control. Constipation is relatively common in patients with diabetes mellitus, and involves the depletion of interstitial cells of Cajal (ICCs), dystrophic changes of smooth muscle cell, and impairment of enteric nervous system.

### Research frontiers

ICCs are the primary electrical pacemakers for rhythmic contractile activity. ICC depletion has been demonstrated in both patients with diabetes mellitus and laboratory animal models, and is a consequence of stem cell factor (SCF) deficiency. Cell culture experiments have shown that addition of insulin-like growth factor-1 (IGF-1) prevented ICC deletion in long-term cultured smooth muscle cells.

### Innovations and breakthroughs

This study showed evidence supporting the presence of dysfunction of smooth muscle contractility in animals, which is compelling evidence of myopathy. In cell culture studies, the authors demonstrated that IGF-1 had a direct effect on increasing SCF mRNA and protein levels, and this effect was mediated by extracellular-signal-regulated kinase 1/2 signaling; and that endogenous IGF-1 levels in diabetic rat colonic tissues were decreased, and that hyperglycemia may be involved in initiating this change.

### Applications

The results of this study suggest that compensation of endogenous IGF-1 is a potential therapeutic option that could prevent the development of diabetic colonic dysmotility.

### Terminology

SCF is a cytokine that binds to the c-Kit receptor. SCF can exist both as a transmembrane protein and a soluble protein. This cytokine plays an important role in hematopoiesis, spermatogenesis, and melanogenesis. In gastrointestinal tract, SCF is mainly produced by smooth muscle cells and neurons.

### Peer review

This is a good descriptive study in which authors showed that myopathy may resolve in colonic motility dysfunction in diabetic rats, and deficiency of endogenous IGF-1 in colonic smooth muscle cells caused reduction of SCF expression. The results are interesting and suggest that endogenous IGF-1 is a potential therapeutic target for diabetic colonic dysmotility.

### Abstract

**AIM:** To describe protease serine 1 (*PRSS1*) gene mutations in patients with autoimmune pancreatitis (AIP) and the clinical features of AIP.

**METHODS:** Fourteen patients with AIP, 56 with other chronic pancreatitis, 254 with pancreatic cancer and 120 normal controls were studied. The mutations and polymorphisms of four genes involved with pancreatitis or pancreatic cancer, *PRSS1*, *SPINK1*, *CFTR* and *MEN1*, were sequenced. The pathogenic mechanism of AIP was investigated by comparing the wild-type expression system with the p.81Leu→Met mutant expression system.

**RESULTS:** Two novel mutations (p.81Leu→Met and p.91Ala→Ala) were found in *PRSS1* gene from four patients with AIP. *PRSS1*\_p.81Leu→Met mutation led to a trypsin display reduction (76.2%) combined with phenyl agarose (Ca<sup>2+</sup> induced failure). Moreover, the ratio of trypsin/amyase in patients with AIP was higher than in the patients with pancreatic cancer and other pancreatitis. A large number of lymphocytes and plasma cells were found in the bile ducts accompanied by hyperplasia of myofibroblasts.

**CONCLUSION:** Autoimmune pancreatitis may be related to *PRSS1* gene mutations.

© 2013 Baishideng. All rights reserved.

**Key words:** Autoimmune pancreatitis; Molecular mechanism; p.81Leu→Met; *PRSS1*

**Core tip:** Novel mutations (p.81Leu→Met and p.91Ala→Ala) were found in protease serine 1 gene from the patients with autoimmune pancreatitis. Trypsinogen abnormal activation resulted in multiple organ injuries. And this offers direct evidence in support of the trypsinogen gene mutation and abnormal immune system.

## INTRODUCTION

Most of the earlier literature about autoimmune pancreatitis (AIP) came from Japan<sup>[1-3]</sup>. AIP has been referred to a variety of names including sclerosing pancreatitis, tumefactive pancreatitis, and nonalcoholic destructive pancreatitis, depending in part on the specific pathologic findings and the presence of extrapancreatic manifestations. However, it is generally believed that the pathologic heterogeneity may reflect different stages or manifestations of the same disease. Immunoglobulin G4 (IgG4) positive plasma cells infiltration is considered a marker for the disease and can be detected in the pancreas and a variety of other tissues<sup>[3-7]</sup>. Unfortunately, serum IgG4 increase was not found in all patients with AIP and more than half of the patients with AIP had normal serum IgG4<sup>[8-10]</sup>. It is urgent to find some more specific diagnosis technology (including the molecular markers). Genetic mutation is often involved in immune system disorders, and protease serine 1 (*PRSS1*), cystic fibrosis conductance regulator (*CFTR*), serine protease inhibitor Kazal type 1 (*SPINK1*) and multiple endocrine neoplasia 1 (*MEN1*) mutation is followed by pancreatitis or pancreatic cancer<sup>[11-15]</sup>. We are keen on identifying these genes targeted by the inflammatory process in AIP. Although trypsin was historically believed to be immunologically active, it is now continued to be verified that abnormal activation of trypsin can be recognized by the immune system. This study aimed to determine whether *PRSS1* gene p.T81M mutation contributes to the functions of calcium-induced trypsinogen activation and to explore its role in autoimmune pancreatitis.

## MATERIALS AND METHODS

### Patients

This study was approved by the Fujian Medical University Ethics Committee and all study participants gave informed consent for DNA analyses. Clinical information for the survey was obtained by personal interviews using a structured questionnaire and/or clinical trials. AIP diagnostic criteria were as follows: (I) pancreatic imaging studies show diffuse narrowing of the main pancreatic duct with irregular wall (more than 1/3 of length of the entire pancreas); (II) laboratory data demonstrate abnormally elevated levels of serum gamma globulin and/or IgG, or the presence of autoantibodies; and (III) histopathologic examination of the pancreas shows fibrotic changes with lymphocyte and plasma cell infiltration. For diagnosis, criterion I (pancreatic imaging) must be presented with criterion II (laboratory data) and/or III (histopathologic

findings)<sup>[16-19]</sup>. Total one pedigree (Figure 1) and 12 unrelated patients with AIP, 56 with chronic pancreatitis, 254 with pancreatic cancer and 120 normal controls seen in the past six years were studied.

### DNA extraction and molecular genetic analysis

Genomic DNA was extracted from peripheral blood and other tissue specimens using a QIAamp DNA mini kit (Qiagen, Hilden, Germany). Primer pairs and experimental condition were used to generate specific fragments according to the references<sup>[12,15]</sup>. The polymerase chain reaction (PCR) products were purified for sequencing after electrophoresis on an agarose gel. For sequencing, a Perkin Elmer Big Dye Sequencing kit (Perkin-Elmer, Shelton, CT, United States) and an ABI PRISM7700 sequencer (Perkin-Elmer ABI, Foster, CA, United States) were used.

### Pancreatitis/pancreatic cancer-associated gene detection

Four genes involved in pancreatitis/pancreatic cancer, *PRSS1*, *SPINK1*, *CFTR* and *MEN1*, were sequenced according to references<sup>[12-15]</sup>. A 20  $\mu$ L mixture was prepared for each reaction and contained 1  $\times$  HotStarTaq buffer, 2.0 mmol/L  $Mg^{2+}$ , 0.2 mmol/L dNTP, 0.2  $\mu$ mol/L of each primer, 1 U HotStarTaq polymerase (Qiagen Inc., Valencia, CA, United States) and 1  $\mu$ L template DNA. The cycling program was 95  $^{\circ}C$  for 15 min; 11 cycles of 94  $^{\circ}C$  for 15 s, 62  $\pm$  0.5  $^{\circ}C$  per cycle for 40 s, 72  $^{\circ}C$  for 1 min; 24 cycles of 94  $^{\circ}C$  for 15 s, 57  $^{\circ}C$  for 30 s, 72  $^{\circ}C$  for 1 min, and 72  $^{\circ}C$  for 2 min. PCR purification was completed using SAP and *Exo* I 1 U SAP, and 6 U *Exo* I was added into 8  $\mu$ L PCR products. The mixture was incubat-

ed at 37 °C for 60 min, followed by incubation at 70 °C for 10 min.

### Pancreatic tissue pathology

Pancreatic tissues were stained with haematoxylin and eosin, modified gomori trichrome, periodic acid-Schiff stain and IgG4 special staining.

### Detection of serum trypsin and amylase

The serum trypsin was tested with ELISA kits (R and D Systems, Minneapolis, MN, United States) and amylase with latex-enhanced nephelometric immunoassay (Dade Behring Marburg GmbH, Germany).

### Functional experiments on mutants

The complete mutated (p.T81M) and wild-type *PRSS1* cDNA were introduced into plasmid pMD18-T (TaKaRa, China) and transformed into *Escherichia coli* DH5 competent cells. Primers were designed for PCR amplification. The forward primer was 5'-TGCAATTGTATGGCAC-CATTCGACGATGATGACAAGAT-3' and the reverse primer was 5'-GAGTCGACTCAGCTAATTAAGCT-TAGTG-3'. In addition, *Mun* I and *Sal* I digestion sites were designed in the forward and reverse primers, respectively. The expression products underwent isolation, purification and renaturation. Benzoyl L-arginine ethyl ester served as a substrate, and absorbance ( $A_{253}$ ) was measured at 253 nm within 30 min. The specific enzyme activity was calculated as follows: specific activity = enzyme activity/mg of protein =  $\Delta A_{253}/t \times 1000/(\epsilon \times t \times 0.001)$ , where t refers to time (min) and  $\epsilon$  refers to the amount of proteinase ( $\mu$ g) during the detection.

### $^{45}\text{Ca}^{2+}$ binding assay

Binding of  $^{45}\text{Ca}^{2+}$  to wild-type recoverin and the L81M mutant was investigated as described previously<sup>[20]</sup>. In brief, 100 mol/L protein was dissolved in 20 mmol/L HEPES-KOH, pH 7.5, 100 mmol/L NaCl and 1 mmol/L DTT, and then it was transferred to centricon 10 devices.  $^{45}\text{Ca}^{2+}$  was added, the samples were centrifuged for 1 min, and radioactivity of the filtrate was counted. Next, non-radioactive  $\text{Ca}^{2+}$  was added and the centrifugation procedure was repeated. Protein-bound  $\text{Ca}^{2+}$  versus free  $\text{Ca}^{2+}$  was determined from the excess  $\text{Ca}^{2+}$  in the protein

sample in the ultrafiltration.

### Treatment and follow-up

Informed consent was obtained before treatment. Glucocorticoids were administered empirically [oral prednisone (40 mg) once daily with a 5-mg taper every 2 wk]. At the same time, oral acid-suppressing agents and calcium were also given.

## RESULTS

### Clinical data of patients with AIP

The auxiliary test results of the patients with AIP (male/female = 7:7) are shown in Table 1. There was significant weight loss (2-9 kg/12 mo) and abnormally increased serum IgG4 level: 5/14 (+).

### Molecular genetic analysis

In the affected patients, novel mutations were found in the genes coding for *PRSS1* (Figure 2). They were *PRSS1\_c.247 C > A* (p.81Leu→Met) (No. 1, 2, 6 and 7) and *PRSS1\_c.279 C > A* (p.91Ala→Ala) (No. 7). None of these mutations were found in the normal controls and other patients with chronic pancreatitis and pancreatic cancer.

### Pathological analysis

Histopathologic examination of the pancreas revealed a characteristic lymphoplasmacytic infiltrate of lymphocytes and IgG4 positive plasma cells, and interstitial fibrosis and acinar cell atrophy in later stages. However, localization and the degree of duct wall infiltration were variable. It has been proposed that a cytologic smear is rich in inflammatory cells. The sensitivity and the specificity of these criteria for differentiating AIP from neoplasia are unknown. A large number of lymphocytes and plasma cells were found in the bile ducts accompanied by hyperplasia of myofibroblasts (Figure 3A). The number of pancreatic acini was markedly reduced (Figure 3B) (immunohistochemistry by CK, CD3, CD20, CD38, CD68 and vimentin).

### Monitoring of serum enzyme

Patients were treated with glucocorticoids for 3-6 mo,

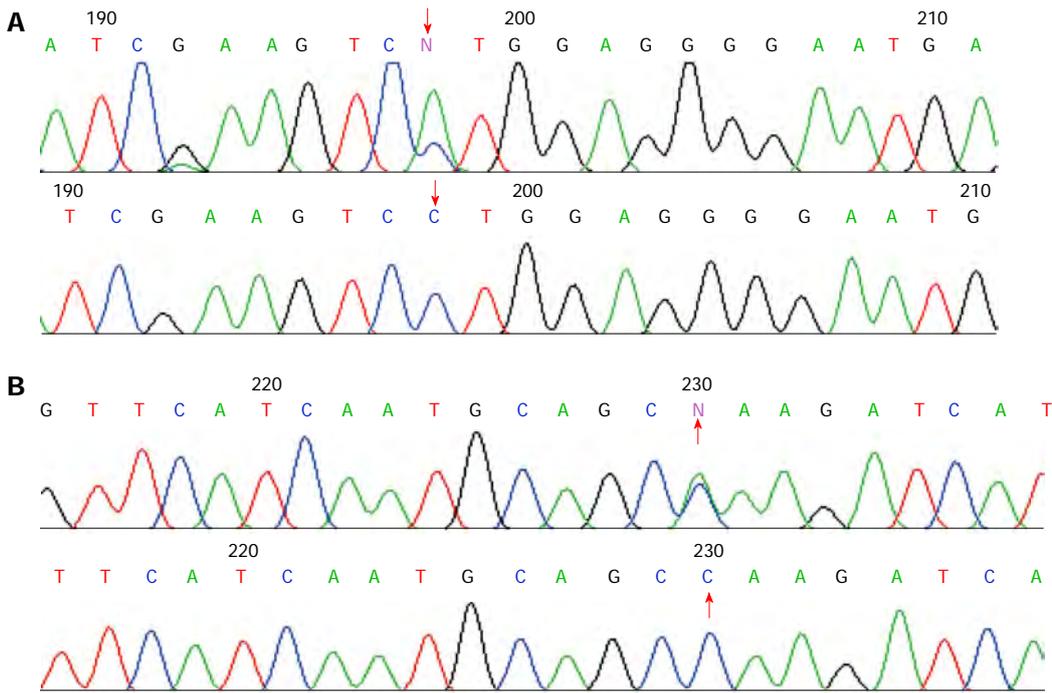

Figure 2 Sequencing of gene mutations from the patients with autoimmune pancreatitis. A: The sequencing c.247 C > A of *PRSS1* gene mutation (p.81Leu→Met); B: Sequencing c.279 C > A of *PRSS1* gene silent mutation (p.91Ala→Ala). The red arrow indicates the base mutation.

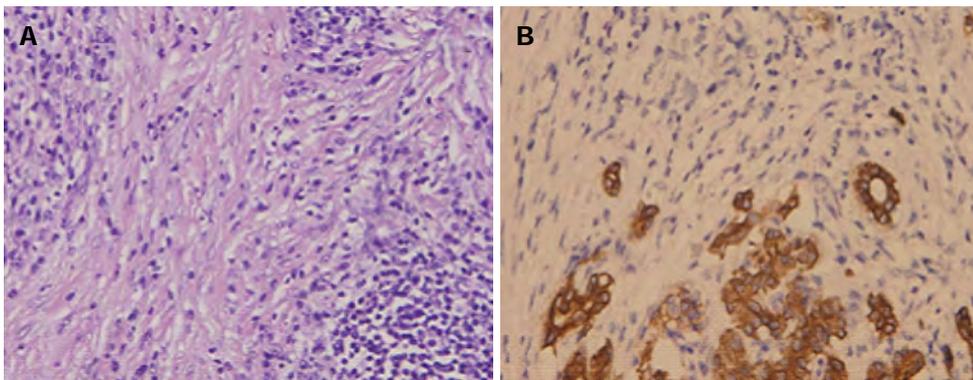

Figure 3 Histopathologic examination of the pancreas. A: A large number of lymphocytes and plasma cells were found in the bile ducts accompanied by hyperplasia of myofibroblasts (hematoxylin-eosin, × 20); B: The number of pancreatic acinar cells was markedly decreased (immunohistochemistry staining of cytokeratin, × 20).

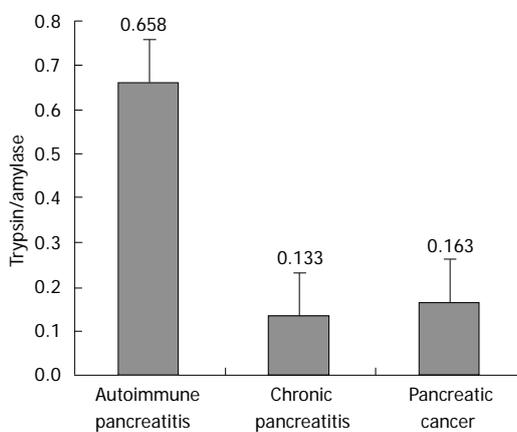

Figure 4 Ratio of trypsin/amyase among the three groups.

and the jaundice improved. Throughout the course of the disease, the trypsin (ng/mL)/amylase (U/L) ratio was higher in patients with AIP ( $0.658 \pm 0.309$ ) than in patients with pancreatic cancer ( $0.163 \pm 0.087$ ) or other types of chronic pancreatitis ( $0.133 \pm 0.095$ ) (Figure 4).

#### Radiologic features

Computed tomography found a diffusely enlarged hypodense pancreas or a focal mass and retroperitoneal lymph node enlargement that may be mistaken for a pancreatic cancer. Magnetic resonance imaging revealed diffusely decreased signal intensity and delayed enhancement on dynamic scanning. The characteristic endoscopic retrograde cholangiopancreatographic finding was segmental or diffuse irregular narrowing of the main pan-

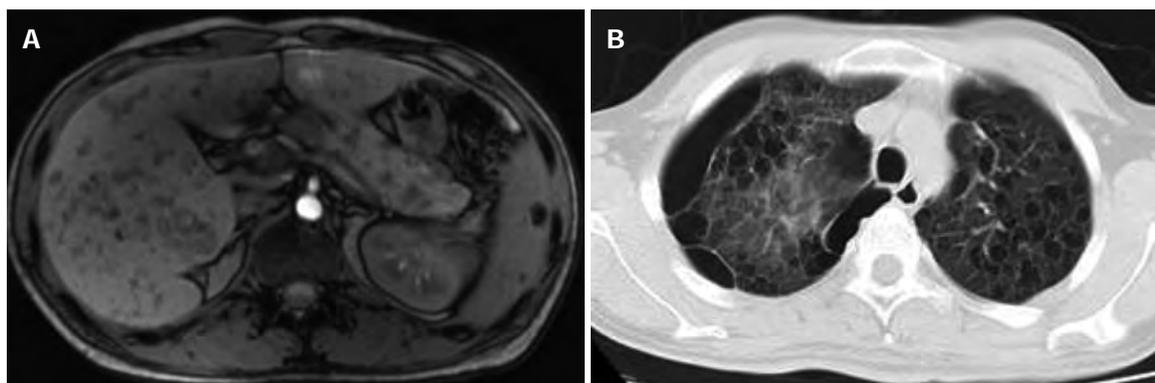

Figure 5 Polycystic lesions in the liver, gallbladder, pancreas, and spleen, and retroperitoneal lymphadenopathy and bullae. A: Abdominal magnetic resonance imaging figure showed diffuse swelling; B: Computed tomography findings image of lung.

creatic duct. The characteristic magnetic resonance cholangiopancreatographic finding was partial intrahepatic bile duct dilatation or narrowness and multiple focal high signal intensity in the liver. Multiple cysts occurred in the liver, pancreas, spleen and other organs (Figure 5).

#### Activity of the products of the mutated gene

A UV spectrophotometer was used to measure the activity of trypsinogen before and after enterokinase activation at 253 nm ( $\Delta OD_{253}$ ). The activity of products of the mutated gene remained unchanged after enterokinase activation. Using the aforementioned formula, the calculated specific activity of renatured recombinant trypsin was 126-183 BAEE U/mg, and the calculated specific activity of wild-type trypsin was 123-165 BAEE U/mg after enterokinase activation, showing that p.T81M mutation did not affect the activity of trypsin.

#### Interaction with phenyl-agarose

According to the literature<sup>[20]</sup>, the binding of recoverin to phenyl-agarose is thought to depend on the  $Ca^{2+}$ -induced exposure of hydrophobic residues and not on the presence of the myristoyl group. Could the non-myristoylated L81M variant bind to phenyl-agarose in a fashion similar to the wild-type? In fact, the binding capacity of the mutant protein was lower (76.2% of that of the wild-type protein).

#### Patient follow-up

Six patients (No. 2, 3, 5, 6, 7 and 10) were treated with glucocorticoids for 3-6 mo, and the jaundice improved. The serum levels of total and direct bilirubin were reduced significantly. Wheezing was markedly improved and the body weight increased (2-5 kg/mo). The symptoms of the other 8 patients were improved to different degrees.

## DISCUSSION

AIP shares many presenting symptoms with pancreatic carcinoma. Fortunately, AIP can be effectively treated and cured. Serum IgG4 levels are usually abnormally increased<sup>[6,9,21-24]</sup>, but increased serum IgG4 levels are

also found in patients with pancreatic cancer and some patients without AIP. Indeed, genetic analyses identified a specific gene, *PRSS1*, for hereditary pancreatitis and other types of chronic pancreatitis in 1996. Some *PRSS1* mutations enhance trypsinogen autoactivation, explaining the young age of patients at onset of AIP. Other mutations may render some patients more susceptible to pancreatitis in the presence of other insults to the pancreas<sup>[10-12]</sup>. In Japan, a strong association with the HLA-DRB1\*0405/DQB1\*0401 haplotype has been identified<sup>[25]</sup>. However, the relationship has not been reported in other ethnic groups, which prompted us to search for AIP-related genes<sup>[25-30]</sup>.

Although p.T81A mutant protein is not associated with functional activity, it binds to the sites that are quite dissimilar from 56Q-57W-58V-59V (*i.e.*, classical  $Ca^{2+}$ -binding sites)<sup>[20]</sup>. On the basis of this observation, a refined model of the role of the myristoyl group as an intrinsic allosteric modulator is proposed.  $Ca^{2+}$  stabilizes the hydrophobic pore structure of the trypsin molecule and increases folding to permit formation of two ionic bonds with  $\beta$  trypsin. Asp102, His57, Ser195 catalytic triad and Asp189, Gly216, Gly226 displayed by the substrate binding pocket of the trypsin are more stable, thereby improving the efficiency of the enzyme catalysis<sup>[20,31-33]</sup>.

There is no controversy that trypsinogen activation plays a very important role in early pancreatitis. However, what activates trypsinogen is not entirely clear. Recent researches have focused on the relationship between the original concentration of intracellular calcium and trypsin activation within acinar cells. Trypsinogen activation starts in the apical part of the acinar cells after supramaximal cholecystokinin stimulation. It is highly dependent on the release of calcium ions within subcellular structures<sup>[32-35]</sup> and on repetitive calcium transients. Normally, trypsin cannot be activated by calcium. Mutation at the trypsin calcium binding point blocks such a conventional activation pathway<sup>[20]</sup>. The gene mutation significantly increases the catalytic activity of trypsin but has no effect on the expression level of the mutant. Increased trypsin synthesis and secretion results in ectopic activation, leading to the occurrence of pancreatitis.

The abnormal increase in serum IgG4 is considered to be an indication of AIP. Unfortunately, serum IgG4 level is normal in more than half of the patients with AIP. In this study, most of our patients with AIP had normal serum IgG4 levels. Our findings suggest that patients with AIP can present with a variety of clinical phenotypes, and that genetic heterogeneity and clinical heterogeneity are features of AIP. In addition, studies of mutations in the *PRSS1* gene have helped elucidate the molecular mechanism underlying the pathogenesis of AIP. Furthermore, high trypsin/amyase ratio contributes to the diagnosis of AIP.

## COMMENTS

### Background

Autoimmune pancreatitis (AIP) is an autoimmune chronic pancreatitis which is characterized by infiltration of lymphocytes and plasma cells, and pancreatic fibrosis and dysfunction. AIP and pancreatic cancer have similar clinical manifestations and findings on imaging, thus AIP is often misdiagnosed as pancreatic cancer, resulting in unnecessary surgical intervention. AIP not only poses a diagnostic challenge for clinicians, but can lead to severe and irreversible injury to patients.

### Research frontiers

The etiology of AIP is poorly understood. It has been reported that genetic factors play an important role in the pathogenesis of AIP. Parkdo *et al* reported that substitution of aspartic acid at the 57<sup>th</sup> position of haploid DQβ1 of the histocompatibility leukocyte antigen is closely related to the recurrence of AIP. The trypsinogen genes are inserted in the TCR vβ site; thus, the trypsinogen gene and TCR vβ gene share the same loci, and this arrangement is conserved in humans, mice, and chickens.

### Innovations and breakthroughs

*PRSS1*<sub>p.81Leu→Met</sub> mutation leads to a trypsin display reduction (76.2% combined with phenyl agarose (Ca<sup>2+</sup> induced failure) which induced premature activation of trypsinogen and caused AIP-related polycystic lesions in the lungs, liver, gallbladder, pancreas, and spleen. Although trypsin was historically believed to be immunologically active, it is now continue to be verified that abnormal activation of trypsin can be recognized by the immune system.

### Applications

The authors' findings suggest that AIP can present with polycystic lesions in multiple organs, which can be found in patients with hereditary AIP, as well as those with sporadic AIP. In addition, functional studies have elucidated the molecular mechanisms underlying the pathogenesis of AIP due to the presence of mutations of the *PRSS1* gene. Additional clinical studies are required to investigate the clinical heterogeneity and molecular pathogenesis of AIP.

### Peer review

This paper reports the novel mutations (p.81Leu→Met and p.91Ala→Ala) found in *PRSS1* gene from patients with AIP. This finding is intriguing, but some of the cases described in the paper may not be AIP for the reasons written in major comments.

### Abstract

**AIM:** To identify peripheral blood mononuclear cell (PBMC) gene expression profiles of ulcerative colitis (UC) patients, using oligonucleotide microarrays, to gain insights into UC molecular mechanisms.

**METHODS:** The Human OneArray microarrays were used for a complete genome-wide transcript profiling of PBMCs from 12 UC patients and 6 controls. Differential analysis per gene was performed with a random variance model; *t* test and *P* values were adjusted to control the false discovery rate (5%). Gene ontology (GO) was deployed to analyze differentially expressed

genes at significant levels between patients and controls to identify the biological processes involved in UC.

**RESULTS:** Comparative analysis revealed that 4438 probes (4188 genes) were differentially expressed between the two groups, of which 3689 probes (3590 genes) were down-regulated whereas 749 probes (598 genes) were up-regulated. Many dysregulated genes in our data have been reported by previous microarray studies carried out on intestinal mucosa samples, such as *S100A8*, *CEACAM1* and *S100A9*. GO enrichment analysis revealed 67 high enrichment up-regulated categories and one significant down-regulated category. The up-regulated genes were mainly involved in immune and inflammatory response, cell cycle and proliferation, DNA metabolism and repair.

**CONCLUSION:** Gene expression profiling of PBMCs from patients with UC has highlighted several novel gene categories that could contribute to the pathogenesis of UC.

© 2013 Baishideng. All rights reserved.

**Key words:** Ulcerative colitis; Microarray; Gene ontology; Peripheral blood mononuclear cells

**Core tip:** Evidence indicates that peripheral blood immune cells play a vital role in the pathogenesis of ulcerative colitis (UC). This study identified genome-wide gene expression profiles of peripheral blood mononuclear cells in UC, and gene ontology analysis highlighted the significance of several categories related to immune and inflammatory responses, cell cycle and proliferation, and DNA repair. The gene enrichment analysis provides greater understanding of the processes that may be involved in UC.

## INTRODUCTION

Ulcerative colitis (UC) is a form of chronic inflammatory bowel disease (IBD) characterized by chronic and recurrent inflammation of the colonic mucosa, often resulting in intermittent bloody diarrhea and abdominal pain<sup>[1]</sup>. UC used to be considered western population-specific. However, recent investigation has revealed that the incidence and prevalence of the disease in Asia have increased significantly<sup>[2]</sup>. Taking China as an example, the number of 140120 cases of UC have been observed in the last 15 years, with an 8.5-fold increase during the last 5 years compared with the first 5 years<sup>[3]</sup>; conservative speculation from the reported cases indicate the incidence has reached 11.6/100000<sup>[4]</sup>.

Microarray analysis of global gene expression at the RNA level has generated new insights into the biological phenomena under investigation. Previous studies have successfully applied microarray technology to investigate the gene expression profile of resected specimens<sup>[5-7]</sup> and endoscopic pinch mucosal biopsies<sup>[8-15]</sup> from IBD, with the goal of identifying diagnostic or prognostic markers and therapeutic target genes of the diseases. The principal dysregulated genes revealed some similar biological processes, but there is little overlap between the individual genes among these data. In contrast to most studies utilizing intestinal tissue, taking peripheral blood mononuclear cells (PBMCs) is more accessible as this source of gene expression material offers the possibility of sampling any individual for future diagnosis. What is more important, PBMCs may be considered as a part of the intestinal immune system and contribute to the exacerbation and perpetuation of inflammation in UC. Firstly, PBMCs are found migrating between blood and intestine<sup>[14]</sup>, and labeled peripheral granulocytes and monocytes can be accumulated rapidly in the diseased gut of IBD patients<sup>[15]</sup>; this movement has a positive correlation to the disease activity<sup>[14]</sup>. Secondly, peripheral mononuclear cells in active IBD are found to release increased amounts of many proinflammatory mediators<sup>[16]</sup>. *In vitro* study found a cytotoxic effect in human fetal colon cells that was released by PBMCs in UC patients<sup>[17]</sup>. Leukocytapheresis therapy, through removing a portion of activated immunocytes from the peripheral blood<sup>[18]</sup>, indeed achieves a super effect and a lower incidence of adverse effects than high-dose steroids in a proportion of IBD patients<sup>[19]</sup>.

Given that PBMCs may play a vital role in the pathogenesis of UC and that the mechanism is still obscure, we hope to clarify the molecular processes involved in the etiopathogenesis of UC that are represented by differentially expressed genes. We recruited twelve UC patient and six healthy controls to compare gene expression profile differences in PBMCs and then, through system biology

tools, some useful information was found hidden behind the lists of significantly up- and down-regulated genes that may be further illustrate the pathogenesis of UC.

## MATERIALS AND METHODS

### *Patient selection and blood sample processing*

The diagnoses of patients were based on a combination of clinical features, endoscopy and pathology findings using standard diagnostic criteria<sup>[4,20]</sup>. Two groups of patient samples were recruited at the First Affiliated Hospital of Kunming Medical University. Group one was composed of 12 UC patients (half males and half females, mean age  $36.25 \pm 10.98$  years; range 19-60 years, Table 1) and 6 healthy controls (3 females, mean age  $35.17 \pm 14.88$  years; range 19-60 years) for microarray analysis. Median duration of disease was 4.33 years (range 1-12 years). At the time of recruitment, four patients were not receiving therapy, eight patients were receiving 5-aminosalicylic acid treatment, and none of them had taken corticosteroids or immunodepressants during the three months preceding their enrolment. The Sutherland Disease Activity Index was used to assess disease activity; all the patients were in active stage (scores ranging from 5 to 12). Group two was extended to 21 patients (mean age  $30 \pm 9.58$  years; range 20-46 years) and 21 age- and sex-matched healthy individuals (mean age  $32 \pm 11.3$  years; range 24-50 years) for the subsequent reverse transcription polymerase chain reaction (RT-PCR) analysis intending to verify and investigate the epidemiology of interesting markers.

To avoid the potential effect of diseases or conditions other than UC, which may lead to gene expression changes in PBMCs, the following strict exclusion criteria were implemented to screen combined diseases of (1) immune deficiency disease; (2) autoimmune-related diseases; (3) hematological diseases; and (4) any treatment or disease that would be an apparent factor affecting gene expression in these cells (*e.g.*, chronic obstructive pulmonary disease, allergy, smoking, chronic alcohol consumption, hormonal or other medications, *etc.*). Controls were persons who receiving a regular medical checkup at the First Affiliated Hospital of Kunming Medical University with the excluded diseases or factors mentioned above.

After obtaining approval of the Institutional Review Board and Ethics Committee, and informed consent of all 60 individuals, blood samples (10 mL) were collected at the Clinical Laboratory of First Affiliated Hospital of Kunming Medical University, and then PBMCs were isolated immediately. Each PBMC biopsy was added to 1 mL TRIzol Reagent (Invitrogen, CA, United States) and then kept at  $-80^{\circ}\text{C}$  until isolation of the RNA.

### *RNA isolation and microarray experiments*

The RNA amplification, labeling, hybridization, and data extraction were performed at the National Engineering Research Center for Biochip at Shanghai. Briefly, total RNA was extracted from PBMCs with Trizol Reagent (Invitrogen, United States), then purified to remove ge-

nomic DNA contamination and concentrated using an Rneasy Plus Mini kit (Qiagen, Hilden, Germany). RNA quality was assessed by determining the 26S/18S ratio using a Bioanalyzer 2100 (Agilent, CA, United States). Two micrograms of RNA from each subject of group one was converted into cyanine-5 labeled target cRNA, then hybridized to the Human OneArray microarray (Phalanx Biotech Group, Taiwan, China) containing 32050 oligonucleotides: 30968 human genome probes and 1082 experimental control probes. A complete description of the array is available at [www.phalanxbiotech.com](http://www.phalanxbiotech.com). The followed procedure was washing, scanning and extracting gene expression results (DNA Microarray Scanner G2565B, Agilent, United States) according to the manufacturer's protocol. Raw intensity values were normalized and log-transformed by GeneSpring GX 10 software (Agilent Technologies, United States).

### Statistical analysis

We applied the rostral ventromedial medulla (RVM) *t* test to filter the differentially expressed genes for the control and experimental groups because the RVM *t* test can raise degrees of freedom effectively in the cases of small samples. After the significant analysis and false discovery rate (FDR) analysis, we selected the differentially expressed genes according to the  $P < 0.01$  as a threshold. Gene ontology (GO) analysis was applied in order to organize dysregulated genes into hierarchical categories according to the key functional classification of the National Center for Biotechnology Information, and to uncover the gene regulatory network on the basis of biological process and molecular function<sup>[21]</sup>. Generally, Fisher's exact test and  $\chi^2$  test were used to classify the GO category, and the FDR<sup>[22]</sup> was calculated to correct the *P* value, since the smaller the FDR, the smaller the error in judging *P* value. We chose only GO categories that had a *P* of  $< 0.01$ . Within the significant category, the enrichment Re was given by  $Re = (m/n)/(N_r/N)$  where *m* is the number of differential genes within the particular category, *n* is the total number of genes within the same category, *N<sub>r</sub>* is the number of differential genes in the entire microarray, and *N* is the total number of genes in the microarray<sup>[23]</sup>.

### Validation of microarray results by semi-quantitative RT-PCR

For the second part of our study, mRNA from 21 UC patients and 21 age- and sex-matched controls was used for RT-PCR. Primers for PCR validations were designed using Primer-3 software<sup>[24]</sup>. Primer sequences are presented in Table 2. Total RNA was extracted from PBMCs and purified using the Rneasy Kit according to the manufacturer's instruction (Qiagen, United States) and converted to cDNA by moloney murine leukemia virus reverse transcriptase with oligo(dT) primer in the presence of RNasin (Stratagen, United States). After reverse transcription, 1/10<sup>th</sup> of the cDNA was used for each PCR reaction with 0.2  $\mu$ mol/L of each primer, 100  $\mu$ mol/L dNTPs, 2 mmol/L MgCl<sub>2</sub>, and 1 U Taq polymerase (Promega, Madison, WI, United States). Cycling conditions were the same for all primer pairs: 94 °C for 2 min, and then 30 cycles at 94 °C for 30 s followed by 55 °C for 45 s and 72 °C for 45 s.  $\beta$ -Actin served as a quantitative control and its sense primer is 5'-TTC-CAGCCTTCCTTCCTGG-3' and antisense primer, 5'-TTGCGCTCAGGAGGAGCAAT-3'. PCR products were fractionated by agarose electrophoresis, stained with ethidium bromide, and visualized under ultraviolet light. Densitometric analysis was done using Bio-Rad's Quantity One software. Statistical significance was tested using Student's *t* test.

## RESULTS

### Analysis of differentially regulated genes in UC

Identifying differential expression genes was achieved in 12 UC cases and 6 age- and sex-matched healthy controls by using RVM *t* test with a FDR of 0.5% and  $P < 0.01$ . Comparative analysis revealed that 4438 probes (4188 genes) were differentially expressed between the two groups, of which 3689 probes (3590 genes) were down-regulated whereas 749 probes (598 genes) were up-regulated. The data presented here confirm 10 (*SERPINB2*, *IGHG3*, *FUT4*, *Meis1*, *ZNF145*, *NFKB1A*, *APBB2*, *IGHM*, *COPG2*, *PTGDS*) of 71 reported genes identified by Burczynski *et al.*<sup>[25]</sup> with similar design of our study. Excepting *SERPINB2*, we also observed the up-regulation of another fundamental inhibitor of the fibrinolytic process: *SERPINE1* fold change (FC) 3.15,  $P = 3.8 \times 10^{-6}$ .

Some dysregulated genes found in mucosal biopsies of UC also appeared in the present PBMC study, such as genes for up-regulating of S100 family proteins (*S100A8*, FC 2.24,  $P = 0.0016$ ) and *S100A9* (FC 3.24,  $P = 0.00041$ ), as reported by Lawrance *et al.*<sup>[7]</sup> and Noble *et al.*<sup>[12]</sup>, and carcinoembryonic antigen-related cell adhesion molecule 1 (*CEACAM1*, FC 4.59,  $P = 0.00027$ ) observed by Costello *et al.*<sup>[8]</sup> and Dooley *et al.*<sup>[26]</sup>. In general, compared to four recently published papers that applied microarrays to explore gene expression profiles of endoscopic pinch mucosal biopsies with UC, our data confirmed 7 over-expressed (27%) and 14 down-regulated (22%) genes reported by Wu *et al.*<sup>[11]</sup>. Another microarray study found

**Table 2** Primers used for semiquantitative reverse transcription-polymerase chain reaction

| Genes   | Unique ID     | Forward primer sequence       | Reverse primer sequence       |
|---------|---------------|-------------------------------|-------------------------------|
| CEACAM6 | PH_hs_0020590 | 5'-GGGGACTTCTGTATTATGCTAAC-3' | 5'-GTGGTGCTAAATGCTACATACTC-3' |
| ELF4    | PH_hs_0009109 | 5'-CAGATGGGGTCTGATACTGG-3'    | 5'-ACGTGTGTATTGCATCATCG-3'    |
| MEFV    | PH_hs_0010414 | 5'-GGACATTGGAGACATCTGC-3'     | 5'-CGCAGGGTTCTGAGAAGTA-3'     |
| APAF1   | PH_hs_0024223 | 5'-AGAGACTGAGGCTGATGGTG-3'    | 5'-TTAAAGCCAGGCAGTGAATC-3'    |
| SLC1A6  | PH_hs_0032730 | 5'-CACCATGGTCATTGTGCTTA-3'    | 5'-GTGCCATGAGGGACTGTAG-3'     |
| KCNJ11  | PH_hs_0032311 | 5'-AGGAGGACGGACGTTACTCT-3'    | 5'-GGAATCTGGAGAGATGCTGA-3'    |

differences in 143 genes, of which our data confirmed 27 (18.9%)<sup>[12]</sup>. Twenty-six up- and 9 down-regulated genes out of 272 differentially regulated genes reported by Costello *et al.*<sup>[8]</sup> were seen in our data. Among the eight up-regulated genes reported by the only microarray study based on an Asian UC population carried out by Okahara *et al.*<sup>[10]</sup>, up-regulation of the *TFF1* gene was the only consistent finding. Although there is little overlap between the individual genes identified compared to those microarray studies due to different microarray platforms, specimens, and race, all the studies point to the involvement of one major biological process: the immune and inflammatory response.

To analyze functional differences represented by differentially expressed genes, we conducted a GO analysis. A  $P < 0.01$  in the Fisher's exact tests was selected as the significant criteria. Using this threshold, a total of 67 high-enrichment GOs targeted by over-expressed genes and one term corresponding to under-expressed genes (nucleosome assembly) were identified. Over-expressed genes were mainly segregated to three critical biological processes: (1) immune and inflammatory response (immune response, inflammatory response, innate immune response, positive regulation of natural killer cell-mediated cytotoxicity); (2) cell cycle and proliferation [cell cycle, cell proliferation, natural killer (NK) cell proliferation, natural killer T (NKT) cell proliferation, cell differentiation, cell division, cell cycle arrest]; and (3) DNA metabolism and repair (response to DNA damage stimulus, DNA repair, DNA recombination). The GO terms and enrichment are shown in Figure 1.

### Validation of selected microarray results

To validate the microarray data results, we chose six genes to quantify by RT-PCR in 21 UC cases and 21 controls. In agreement with the microarray data, of the four up-regulated genes, three were found to be expressed to a significantly greater extent in UC by RT-PCR (*CEACAM6*:  $0.0491 \pm 0.0353$  vs  $0.955 \pm 0.141$ ,  $P < 0.01$ ; *ELF4*:  $0.458 \pm 0.143$  vs  $0.185 \pm 0.0703$ ,  $P < 0.01$ ; *MEFV*:  $0.451 \pm 0.245$  vs  $0.161 \pm 0.0629$ ,  $P < 0.01$ ). Another up-regulated gene, *APAF1*, also showed the same tendency with microarray ( $0.253 \pm 0.168$  vs  $0.104 \pm 0.0308$ ,  $P < 0.05$ ). Of two down-regulated genes, *SLC1A6* was found to be significantly lower in UC than in controls ( $0.144 \pm 0.0749$  vs  $0.356 \pm 0.127$ ,  $P < 0.01$ ), and *KCNJ11* was not found to be significantly different between the two groups ( $0.227 \pm 0.0549$  vs  $0.294 \pm 0.0965$ ,

$P > 0.05$ ) (Figure 2).

## DISCUSSION

Clarifying the molecular mechanisms leading to UC remains a major challenge.

Definite diagnosis of UC mainly depends on colonoscopy and a following invasive biopsy due to deficiency of molecular markers for UC, and current first-line therapies generally target downstream of the inflammatory cascade. For these reasons, it is exigent to generate new biologic agents aimed at specific inflammatory processes and to explore disease specific molecular markers to facilitate diagnosis. To identify the molecules involved in activation behavior of PBMCs in UC, we compared the gene expression profiles of PBMCs between UC patients and healthy individuals using microarray technology. In addition, GO enrichment analysis, which was based on the significant dysregulated genes, has been developed to reveal whether particular functions were enriched.

To the best of our knowledge, there is only one published study on PBMC gene expression profiles in UC. Comparison of that study with the present Phalanx array screening on 30968 genes, which represents the first gene expression analysis in an Asian population, shows consistency with data from Burczynski *et al.*<sup>[25]</sup> who found that the most highly expressed gene commonly elevated in both IBDs was that for the protease inhibitor SERPINB2: we also observed the upregulation of *SERPINE1* in UC patients. Another gene for fundamental inhibitor of the fibrinolytic process, *SERPINE1* (also called *PAI-1*) showed upregulation in our data. Increased plasma levels of PAI-1 have been found in IBD patients<sup>[26]</sup>, this suggests that these molecules might contribute to the imbalance of the coagulation system and thromboembolic events in UC. Another consistent finding was the up-regulated expression of two immunoglobulin encoding sequences, *IgHG3* and *IGHM*. This correlates with the finding that elevated serum immunoglobulin G (IgG) levels are found in patients with UC, and is reminiscent of the finding that IgG antibodies to organ specific autoantigens such as colonic epithelial cells and antineutrophil cytoplasmic are identified in the colon of UC patients, and that these antibodies originate in the periphery.

A response to the peripheral antigens which have switched isotype to cross react with antigens of the flora or/and autoantigens which are normally segregated by the endothelial barrier<sup>[27]</sup> may result in mucosal inflamma-

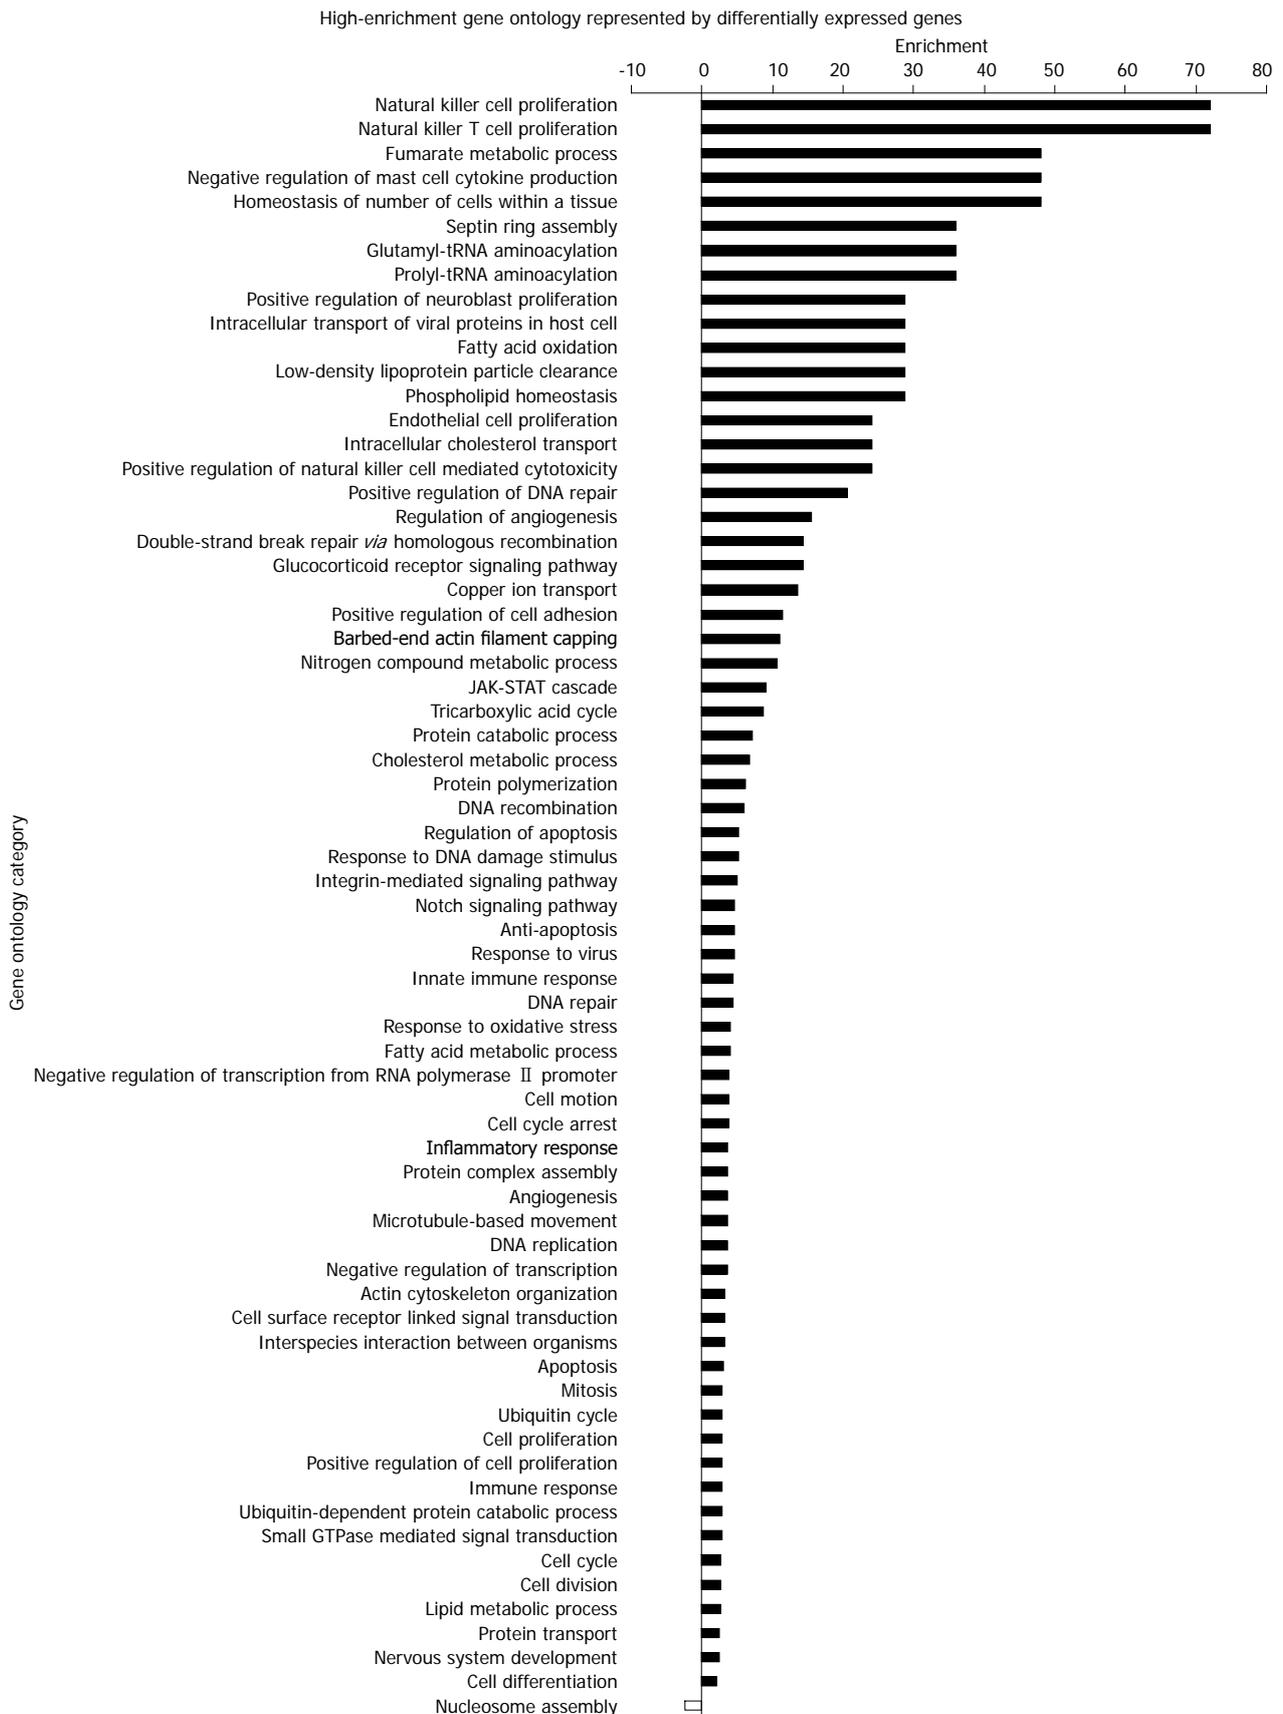

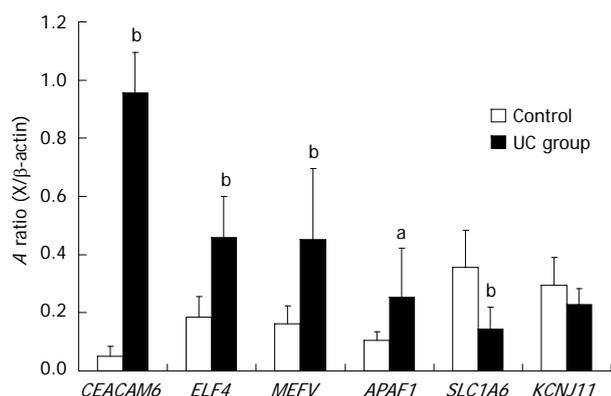

Figure 1 High-enrichment gene ontology represented by differentially expressed genes. A  $P < 0.01$  in the Fisher's exact test was selected as the significance criterion. Over-expressed genes were mainly segregated to three critical biological processes: immune and inflammatory response, cell cycle and proliferation, DNA metabolism and repair. JAK-STAT: Janus kinase-signal transducer and activator of transcription.

**Figure 2** Semiquantitative relative reverse transcription-polymerase chain reaction validation of 6 selected genes. The values were normalized against  $\beta$ -actin. Graph bars indicate the averaged absorbance (A) ratios between each gene and  $\beta$ -actin. Values represent the mean  $\pm$  SE. Significance levels were: <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs control subjects. UC: Ulcerative colitis.

tion. If this is the case, IgG-producing cells will expand through the antigen stimulation. This can explain the many up-regulated genes related to cell cycle and positive regulation of cell proliferation seen in our data.

It is of interest that many dysregulated genes in our data have been reported by previous microarray studies carried out on intestinal mucosa samples, such as genes for S100 family proteins (*S100A8* and *S100A9*) reported by Lawrence *et al*<sup>[7]</sup> and Noble *et al*<sup>[12]</sup>. In addition, another calcium binding protein, *S100A12*, has been demonstrated to be a novel noninvasive marker for IBD with high sensitivity and specificity<sup>[28]</sup>; this gene also showed upregulation in our data. Up-regulation of *CEACAM1* has been reported by Costello *et al*<sup>[8]</sup> and Dooley *et al*<sup>[26]</sup>. The up-regulation of another CEACAM family gene in our data, *CEACAM6*, has not been reported by any microarray study but has been found acting as a receptor for certain bacteria<sup>[29]</sup>.

Although there is little overlap between the individual genes identified compare to those other microarray studies due to different microarray platforms, specimens, and race, all the studies point to the involvement of one major biological process: immune and inflammatory response. GO enrichment analysis found several high-enrichment terms linked to immunity and inflammation, including immune response (33 genes), inflammatory response (17 genes), innate immune response (9 genes). The fact that the immune system and inflammatory mechanisms are activated in IBD is also well known<sup>[30]</sup>. It is not surprising that a general up-regulation of immune and inflammatory response genes is a feature of the intestine due to the nonsterile environment, but many up-regulated genes appear in PBMCs that had been ruled out by excluding patients with infections, malignancies, autoimmune disorders and so on that may impact the gene expression of PBMCs consistent with its role in the pathogenesis of UC. Evidently, not all of those genes involved in immune and inflammatory categories are UC specific. Other inflammatory conditions such as arthritis, dermatitis and atherosclerosis share common immunologic/inflamma-

tory mechanisms, although in different organ systems. Therefore, it is of importance to identify the profile of inflammatory genes that are differentially expressed in UC and compare it with those that characterize other inflammatory diseases. Although a crossover of some of these mechanisms is expected, it is highly plausible that differences between the diseases will also become apparent. Such differences have great potential as better diagnostic and prognostic biomarkers for these conditions.

NK cells and NKT cells are effector lymphocytes of the innate immune system and can limit or exacerbate immune responses<sup>[31]</sup>. Labeled peripheral blood granulocytes and monocytes have been shown to accumulate rapidly to the diseased intestine in IBD patients<sup>[15]</sup>, leading to increased numbers of NKT cells accumulating in the lamina propria<sup>[32]</sup>. This movement is correlated with the disease activity<sup>[14]</sup>. NK cells and NKT cells can contribute to tissue damage not only by their direct cytotoxic effects on the targets, but also by secretion of inflammatory cytokines, and those cytokines can enhance their cytotoxicity and attract much more leukocyte aggregation to release more chemokines that perpetuate and amplify this vicious circle<sup>[33,34]</sup>. Considering cell cycling is essential to induce tolerance and generate effector T cells<sup>[35]</sup>, a faster cycle will thus lead to an increased capacity for cellular expansion. It is tempting to speculate that up-regulated genes positively modulate proliferation of NK cells, NKT cells and cell cycling, playing a vital role in putting PMBCs as a source of effector immune cells in the inflamed intestine and magnifying the function of innate immunity and breaking the immune homeostasis. Therefore, it is a promising target to restrain the activation and proliferation of NK and NKT cells for treatment in active patients. However, the action of microflora and other factors which can activate these cells is complex and obscure. Accordingly, *ELF4* and *MEFV*, which are overexpressed genes from the categories that regulate the proliferation of NK and NKT cells, might be a focus of interest.

Studies have suggested that *ELF4* is a key transcriptional regulator of innate immune cells, affecting the number and function of NK cells and NKT development<sup>[36]</sup>. In a murine experiment<sup>[36]</sup>, the number of NKT cells was significantly reduced in the *ELF4*-deficient thymus. Similarly, NK cell development and function is impaired, with a 60% reduction in the number of NK cells in *ELF4* knock-out spleens and defects in their function. Another gene, *MEFV*, responsible for familial Mediterranean fever (FMF), also may contribute to the onset of IBD. One epidemiologic investigation of non-Askenazi Jews indicated that FMF patients have a high incidence and severity of both Crohn's disease (CD) and UC<sup>[37]</sup>, indicating the potential modifying effect of *MEFV* expressed in certain inflammatory diseases. The expression of *MEFV* was found to be significantly higher in the colonic mucosa of colitis mice models (trinitrobenzenesulfonic acid and dextran sodium sulfate) and CD and severe UC patients<sup>[38]</sup>. Apart from *MEFV* and *ELF4*, upregulated genes involved in categories that relate to cell growth and proliferation, including positive regulation of

cell proliferation, cell division, cell proliferation, also deserve further exploration.

Chromosome instability and microsatellite instability (MSI) have been proven to be associated with UC<sup>[39]</sup>, and further contribute to the carcinogenesis of UC-associated neoplasms<sup>[40]</sup>. Increased production of free radicals may impair cellular and DNA proteins and decrease the ability of the cell to repair DNA damage prior to replication. We have identified increased expression of transcripts involved in DNA repair in PBMCs (response to DNA damage stimulus, DNA repair, DNA recombination, double-strand break repair *via* homologous recombination, DNA replication, and positive regulation of DNA repair). Those categories positively regulating DNA repair seem to act as a defense role against carcinogenesis in UC, but opposite to this conjecture, a recent study observed that increased activity of base excision repair enzymes can contribute to increasing of MSI in inflamed UC mucosa<sup>[41]</sup>. Another study identified increased transcription involved in DNA repair in UC-associated colorectal cancer biopsies compared to UC mucosa<sup>[42]</sup>. In other words, increased expression of those categories involved in DNA repair may be injurious to the stability of the genome and may even increase neoplastic risk. Watanabe *et al.*<sup>[43]</sup> have identified 40 genes which are involved in categories such as in cell cycle, cell proliferation, and receptor activity to predict the development of cancer and/or dysplasia in UC with sensitivity and specificity of 100% and 83.7%, respectively. The dysregulated genes involved in categories of cell cycle and DNA repair identified in our study deserve in-depth studies to investigate the possibility of non-invasive markers for predicting the development risk of cancer in UC patients.

In conclusion, this study identified genome-wide gene expression profiles of PBMCs in UC, and GO analysis highlighted the significance of several categories related to the immune and inflammatory response, cell cycle and proliferation and DNA repair. The gene enrichment analysis provides greater understanding of the processes that may be involved in UC.

## COMMENTS

### Background

Evidence indicates that peripheral blood immune cells play a vital role in the pathogenesis of ulcerative colitis (UC). Microarray transcript profiling has the promise to clarify the molecular processes involved in the etiopathogenesis of UC.

### Research frontiers

Microarrays represent important tools to identify biomarkers of disease; biomarkers can be constituted by gene expression patterns or clusters of genes. Systems biology tools can find some useful information hidden behind the lists of differentially expressed genes at significant levels.

### Innovations and breakthroughs

In contrast to most studies utilizing intestinal tissue, the authors adopted more accessible specimens and carried out the research in Chinese UC patients for the first time.

### Applications

This study further elucidated the biological process that may lead to the pathogenesis of UC.

### Terminology

The gene ontology project is a major bioinformatics initiative to unify the repre-

sentation of gene and gene product attributes across all species.

### Peer review

The authors found some dysregulated genes in peripheral blood mononuclear cells of UC and further demonstrated biological processes represented by those differentially expressed genes. This is a very important study which could unravel the mechanisms of UC. The scientific content of the manuscript is original and novel.

### Abstract

Opportunistic viral infections are a well-recognized complication of anti-tumor necrosis factor (TNF) therapy for inflammatory bowel disease (IBD). Cases of severe or atypical varicella zoster virus infection, both primary and latent reactivation, have been described in association with immunosuppression of Crohn's disease (CD) patients. However, central nervous system varicella zoster virus infections have been rarely described, and there are no previous reports of varicella zoster virus meningitis associated with anti-TNF therapy among the CD population. Here, we present the case of a 40-year-old male with severe ileocecal-CD who developed a reactivation of dermatomal herpes zoster after treatment with prednisone and adalimumab. The reactivation presented as debilitating varicella zoster virus meningitis, which was not completely resolved despite aggressive antiviral therapy with prolonged intravenous acyclovir and subsequent oral valacyclovir. This is the first reported case of opportunistic central nervous system varicella zoster infection complicating anti-TNF therapy in the CD population. This paper also reviews the literature on varicella zoster virus infections of immunosuppressed IBD patients and the importance of vaccination prior to initiation of

anti-TNF therapy.

**Key words:** Varicella zoster virus; Meningitis; Crohn's disease; Adalimumab; Infliximab; corticosteroids; Anti-tumor necrosis factor

**Core tip:** Opportunistic viral infections can complicate anti-tumor necrosis factor (TNF) therapy for inflammatory bowel disease (IBD). Central nervous system varicella zoster virus (VZV) infections associated with the use of anti-TNF therapy have not been previously described in Crohn's disease patients. We present the first reported case of VZV meningitis in a 40-year-old male with Crohn's disease who developed reactivation dermatomal herpes zoster and VZV meningitis after treatment with adalimumab and prednisone. Despite aggressive antiviral therapy, he had significant morbidity, highlighting the risk of opportunistic viral infections in this population and the importance of vaccination before anti-TNF therapy.

Varicella zoster meningitis complicating combined anti-tumor necrosis factor and corticosteroid therapy in Crohn's disease. *World J Gastroenterol* 2013; 19(21): 3347-3351 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i21/3347.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i21.3347>

### INTRODUCTION

Biologic therapies which target tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), including infliximab, adalimumab, and certolizumab pegol, are increasingly common in the management of inflammatory bowel disease (IBD); however, their use is associated with opportunistic infections<sup>[1,2]</sup>. For Crohn's disease (CD) patients, infection risk is further

increased by combination treatment with immunosuppressants such as corticosteroids, methotrexate, azathioprine, or 6-mercaptopurine (6-MP)<sup>[3,4]</sup>.

As with the other herpes viruses, varicella zoster virus (VZV) infection risk is high for IBD patients<sup>[5,6]</sup>. VZV, an alpha-herpes virus, causes a primary infection (varicella/chickenpox), but the virus can also be reactivated from a latent state in which it sequesters in the dorsal root ganglia (herpes zoster/shingles)<sup>[7]</sup>. Evidence from the rheumatologic literature suggests an association between VZV and TNF inhibitors. Indeed, a large prospective cohort of 3266 rheumatoid arthritis patients on anti-TNF therapy found an adjusted hazard ratio for VZV of 1.82 (95%CI: 1.05-3.15), and these VZV cases were often severe enough to necessitate hospitalization<sup>[8]</sup>.

While cutaneous VZV is common, neurological VZV is rare; presentations include cerebellar ataxia, myelitis, radiculitis, Ramsay-Hunt syndrome, and meningitis or encephalitis<sup>[9]</sup>. VZV meningitis in association with anti-TNF therapy for Crohn's disease has not previously been reported. Here, we present the case of a 40-year-old male with CD who developed debilitating VZV meningitis while being treated with adalimumab and prednisone. The literature on VZV among anti-TNF immunosuppressed CD patients and on pre-treatment vaccination is reviewed in the Discussion which follows.

## CASE REPORT

A 40-year-old male presented to hospital with a four day history of increasing headaches. He had been diagnosed with medically refractory ileocecal CD in 2006. Initial treatment with azathioprine had to be discontinued because of acute pancreatitis. In 2007, he underwent an ileal resection and hemicolectomy; however, the disease recurred at the anastomosis by 2008. Despite treatment with post-operative mesalamine, disease activity persisted, and he began taking oral prednisone at 20 mg/d in September 2008. The disease became steroid-refractory, and infliximab 400 mg IV q8 weekly was started in 2009. With initiation of infliximab, the patient was able to wean off prednisone for a period of 8 mo. However, after one year, an allergic reaction to infliximab prompted a switch to adalimumab 40 mg SC q2 weekly at 25 mo prior to presentation. About 6 mo after the initiation of adalimumab, the patient experienced a disease flare and was restarted on prednisone. He experienced difficulties with weaning from the prednisone and was taking 15 mg *po* daily on presentation.

Four days prior to presentation, the patient developed insidious onset but constant bifrontal, progressively worsening headaches with photophobia. While the patient was experiencing unmeasured fever and generalized malaise, there was no history of neck pain, focal neurological deficits, seizures, or confusion. He had no recent infectious contacts or travel history. Though he had a history of childhood chickenpox, he had experienced no recent reactivation and he had not received a herpes zoster vac-

ination.

Two days prior to presentation, the patient developed increasing left upper quadrant abdominal pain, radiating to his back. The initial examination revealed voluntary guarding but no rash. Shortly after admission, the patient developed a vesicular maculopapular rash in the left T7 dermatome corresponding to the area of pain.

A detailed neurological examination demonstrated no focal motor or sensory deficits. Cranial nerve testing results were normal. Fundoscopy did not reveal papilledema. There was no nuchal rigidity; both Brudzinski's and Kernig's signs were negative, but jolt accentuation was positive.

Diagnostic investigations revealed an elevated white blood cell count of  $14 \times 10^9/L$ . Computer tomography of the head was unremarkable. Lumbar puncture was performed: the cerebrospinal fluid (CSF) revealed an elevated protein level [0.76 g/L, (normal range 0.15-0.45 g/L)], normal glucose [3.1 mmol/L, (normal range 2.2-4.4 mmol/L)], and a marked lymphocytic pleocytosis ( $391 \times 10^6$  WBCs with 98% lymphocytes). CSF polymerase chain reaction was subsequently positive for VZV. After consultation with the Infectious Disease specialist, we prescribed treatment for VZV meningitis: one month of intravenous acyclovir (10 mg/kg q8 h). Adalimumab was discontinued but, given the patient's severe CD, prednisone, 20 mg/d, was started. The patient has been unable to taper off this dose of prednisone.

Unfortunately, the patient's post-discharge course has been difficult. He continued to experience debilitating residual symptoms of post-meningitis syndrome, including intermittent headaches and cognitive slowing, and was unable to return to work 3 mo post-discharge. Given his ongoing symptoms and continuing immunosuppression, he was treated with an additional course of suppressive valacyclovir 1000 mg *po* daily for 3 mo.

## DISCUSSION

Although VZV reactivation in response to anti-TNF therapy has been described in the literature, central nervous system involvement is rare. This is the first reported case of VZV meningitis in a CD patient taking adalimumab, and it highlights the risk of atypical and severe VZV infection among immunosuppressed patients. As the long-term sequelae of central nervous system VZV can be debilitating, even with early detection and antiviral therapy, preventative strategies including vaccination are very important for this population.

VZV infection risk for IBD patients is high; a review of six global trials of adalimumab (CHARM, CARE, CLASSIC, GAIN, CHOICE, M04-729) involving 3160 CD patients found 46 cases of VZV, six of which required hospitalization<sup>[10]</sup>. Furthermore, severe disseminated and fatal VZV infections have been experienced by IBD patients on immunosuppression with steroids, thiopurines and anti-TNF therapy<sup>[11-14]</sup>. In one case, VZV caused fatal hepatic failure and disseminated intravascular

coagulation shortly after infliximab initiation<sup>[15]</sup>. As in the currently reported case, the VZV infection risk attributable to anti-TNF agents is confounded by combination immunosuppression with prednisone and adalimumab. Evidence from the prospective TREAT registry suggests corticosteroids are an especially strong independent risk factor for serious infection (OR = 2.21, 95%CI: 1.46-3.34)<sup>[3]</sup> and VZV reactivation among IBD patients taking corticosteroids is well-described. Marehbian *et al*<sup>[16]</sup> retrospectively evaluated 22310 CD patients and reported a zoster hazard ratio of 3.11 (95%CI: 1.57-6.17) if patients were on corticosteroids. The risk was even higher among patients on combination immunosuppression therapy. Similar findings have been corroborated by other authors<sup>[17]</sup>. For instance, Cullen *et al*<sup>[18]</sup> recently reviewed nine cases of primary VZV related to anti-TNF therapy for CD patients. As in the current case, all were taking concomitant immunosuppressive or corticosteroid therapy. Cases of severe disseminated VZV have been reported among IBD patients on steroid therapy alone<sup>[11,12]</sup>, while central nervous system VZV has been primarily described for immunosuppressive conditions such as HIV/AIDS or malignancies. Nonetheless, steroid therapy is recognized as a risk factor<sup>[7,19]</sup>, with several case reports describing varicella encephalitis or meningitis associated with corticosteroids in other patient populations<sup>[20-22]</sup>. In our case report, the clinical picture is complex; likely both adalimumab and prednisone contributed to this patient's increased susceptibility to VZV meningitis.

In the CD population, only two previous cases of central nervous system VZV infection have been reported. Cullen *et al*<sup>[18]</sup> described a case of meningoradiculitis in a 49-year-old male taking 6-MP; despite three weeks of acyclovir and discontinuation of 6-MP, his neurological deficits persisted. Salmon-Ceron *et al*<sup>[23]</sup> also identified one case of radiculitis in a CD patient on adalimumab in the large French RATIO registry documenting > 50000 patient-years of anti-TNF exposure; additional details were not provided. No cases of VZV meningitis or encephalitis in CD patients on anti-TNF therapy have been reported until now, but at least two cases have been identified in the rheumatology literature. One case is of a 38-year-old female with psoriatic arthritis treated with one year of adalimumab who developed VZV encephalitis that resolved with acyclovir<sup>[24]</sup>. The other case was of a patient on methotrexate and adalimumab; treatment details were not reported<sup>[25]</sup>.

Currently, there is no evidence on which to base a decision as to whether anti-TNF therapy should be restarted after VZV infection. Some authors have suggested that, in cases of mild, confined zoster, biologics can be restarted after complete lesion resolution<sup>[8,26]</sup>. However, discontinuation has been advocated in cases of severe or disseminated VZV<sup>[27]</sup>. Discontinuation, however, poses a therapeutic dilemma for IBD patients when step-up management strategies have been employed and biologic agents initiated only after failure of other immunosuppressants. In these cases, few options exist for non-

steroid maintenance therapy. In our case, adalimumab was discontinued but prednisone could not be further tapered off despite the possibility of its contributing to his VZV infection. In contrast, some experts have advocated for the use of steroid therapy as an anti-inflammatory in the management of central nervous system VZV infections<sup>[19]</sup>. Future management strategies in this setting may include consideration for granulocyte-macrophage colony-stimulating factor (sargramostim), but this is not yet an approved indication in our jurisdiction and would be accessible only through investigational trial.

Given both the likelihood of VZV infection and the seriousness of its potential sequelae, it seems obvious that CD patients should be vaccinated prior to initiation of steroid, immunosuppressive, or anti-TNF therapy. The varicella vaccine (VARIVAX<sup>®</sup>, PROQUAD<sup>®</sup>, Merck and Co., Inc)<sup>[28]</sup> and the herpes zoster vaccine (ZOSTAVAX<sup>®</sup>, Merck and Co., Inc)<sup>[29]</sup> are effective in reducing the incidence of VZV. Strong evidence from the Shingles Prevention Study Group, which evaluated > 38000 patients, demonstrated reduced herpes zoster incidence for vaccination (VZV dropped from 11.1 in the placebo group to 5.4 cases per 1000 person-years in vaccine treated patients)<sup>[30]</sup>, and the vaccine was safe and generally well-tolerated<sup>[31]</sup>. However, this particular study excluded immunocompromised patients due to the risk of iatrogenic infection from the live, attenuated virus in the vaccine. For IBD patients without a history of chickenpox, shingles, or previous vaccination, the 2009 European Crohn's and Colitis Organization guidelines, which are based on expert consensus opinion, recommend routine immunization with VZV vaccine at least three weeks prior to the onset of immunomodulation<sup>[32]</sup>. Nonetheless, routine immunization is not universal in clinical practice. Survey-based evidence suggests that < 50% of susceptible patients actually receive immunization<sup>[33]</sup>. At a minimum, the physician should discuss VZV prevention, including immunization, with the patient, and serology should be performed to confirm immunity if there is no documented history of past varicella infection<sup>[32]</sup>.

Even among IBD patients who have been previously vaccinated, evidence that post-vaccination immunity wanes over time argues for providing a second "catch-up" dose to adult patients. A retrospective review of 1080 breakthrough varicella cases found the annual rate increased from 1.6 (95%CI: 1.2-2.0) cases per 1000 person-years within 1 year of vaccination to 58.2 (95%CI: 36.0-94.0) cases per 1000 person-years 9 years post-vaccination<sup>[34]</sup>. Evidence in the pediatric literature also suggests that a two-dose vaccination regimen significantly decreases the risk of varicella infection<sup>[35]</sup>. Thus, immunosuppressed IBD patients, who are at higher risk for VZV infection, would benefit from a second vaccination in adulthood.

Vaccination timing presents another challenge in the case of IBD. Patients on other immunosuppressants or those started on rescue anti-TNF may not previously have had immunity evaluations, and the vaccine is con-

traindicated for patients already on immunosuppression therapy. This difficulty emphasizes the need for assessment of immunity at the time of CD diagnosis. In other patient populations, temporary 2-4 wk immunosuppression withdrawal to allow safe vaccination has been advocated<sup>[36]</sup>. However, such a temporary withdrawal of treatment is not usually feasible in the case of patients at risk of CD relapse. For susceptible CD patients already on anti-TNF agents, there may not be an ideal strategy for VZV prevention.

In conclusion, this paper presents the first reported case of VZV meningitis occurring opportunistically in association with adalimumab and corticosteroid therapy for CD. This case highlights this population's risk of severe, atypical opportunistic infections, the need for early recognition of VZV and aggressive management with antiviral therapy, and the potential confounders of this clinical picture, especially concomitant immunosuppression.

**Key words:** Fistula; Esophageal stent; Radiofrequency ablation; Endoscopy; Complication; Atrial fibrillation

**Core tip:** We report the successful endoscopic management of an esophagopericardial fistula induced by radiofrequency ablation for atrial fibrillation. Esophagopericardial fistulas are a complication of great significance, being extremely difficult to manage and having a very high mortality rate. In this case, the patient was treated with a fully covered esophageal stent combined with surgical pericardial drainage. It is important to be aware of the increasing incidence of post-radiofrequency esophageal complications for cardiologic applications. Furthermore, the possibility to place endoscopic stents as a potential therapeutic option for the occurrence of post-radiofrequency esophageal fistula is extremely important as part of a treatment plan for this complication.

### Abstract

A case is reported of a 76-year-old man with a past history of atrial fibrillation. A radiofrequency ablation procedure was suggested following several failed cardioversion attempts. However, an esophagopericardial fistula complicated the procedure. This life-threatening complication was successfully managed using both the placement of a covered esophageal stent and surgical pericardial and mediastinal drainage. In fact, no persisting fistula could be detected when the esophageal stent was removed seven weeks later. Atrioesophageal and esophagopericardial fistulas are two of the most severe complications associated with cardiologic radiofrequency ablation procedures. They are responsible for majority of the deaths associated with this procedure. Despite the extremely high morbimortality associated with cardiothoracic surgery in such conditions, this treatment is the gold-standard for the management of such complications. This case report emphasizes the importance and efficacy of the endoscopic approach as part of a multidisciplinary management approach to this serious adverse event following radiofrequency ablation for atrial fibrillation.

Quénéhervé L, Musquer N, Léauté F, Coron E. Endoscopic management of an esophagopericardial fistula after radiofrequency ablation for atrial fibrillation. *World J Gastroenterol* 2013; 19(21): 3352-3353 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i21/3352.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i21.3352>

### INTRODUCTION

With the increasing use of radiofrequency ablation (RFA) for the treatment of atrial fibrillation, cardiologists have to face the consequences of minor and major complications related to this procedure. One class of the most severe types of adverse events occurring during RFA is cardioesophageal fistulas, including atrioesophageal fistulas (AEF) and esophagopericardial fistulas<sup>[1]</sup>. Growing evidence supporting the efficacy and safety of conserva-

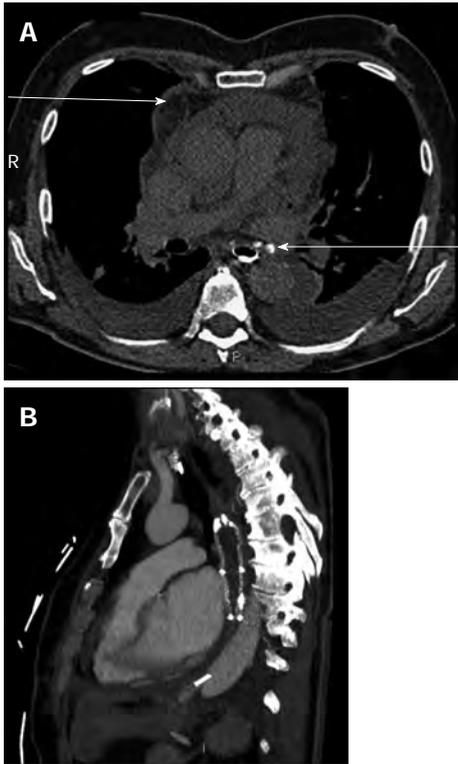

Figure 1 Computed tomography-scan. A: Computed tomography (CT)-scan with esophageal opacification. Pericardial effusion (upper arrow) and esophagopericardial fistula (lower arrow) were both present; B: CT-scan performed after esophageal stent placement and surgical drainage. Pericardial effusion was no longer present following esophageal stent insertion.

tive management has made digestive endoscopy one of the most important therapeutic options in the multidisciplinary treatment of such complications<sup>[2]</sup>.

## CASE REPORT

A 76-year-old man was admitted for chest pain. He had a medical history of chronic atrial fibrillation previously treated by several unsuccessful cardioversions. He finally underwent a radiofrequency ablation procedure. Although the electrocardiogram results showed evidence of pericarditis, no pericardial effusion was detected by echocardiography. However, a computed tomography scan revealed the presence of pleural effusion as well as pneumopericardium (Figure 1A).

A computed tomography-scan with esophageal opacification confirmed the presence of esophagopericardial fistula (OPF) and pericardial effusion. A combined surgical and endoscopic approach was performed,

consisting of surgical pericardial and mediastinal drainage immediately followed by the placement of an 8 cm fully covered self expanding metallic esophageal stent (Hanarostent Esophagus; MI Tech, Seoul, Korea) under both fluoroscopic and endoscopic (EG 530; Fujinon, Tokyo, Japan) guidance (Figure 1B). Seven weeks later, the stent was successfully removed during an upper gastrointestinal endoscopy, which also did not show persisting fistula. The patient was admitted for additional time due to multiple complications unrelated to the OPF, but was discharged 2 mo following his admission.

## DISCUSSION

Two types of cardioesophageal fistulas are AEF and OPF. AEF is a rare but dreadful complication of radiofrequency ablation with an overall mortality rate above 70%<sup>[1]</sup>. Currently, the best management option for AEF is surgery because of the risk of air embolism in case of an endoscopic approach<sup>[3]</sup>. In contrast, OPF can be managed either using conventional surgical or pericardioscopic drainage of the pericardium<sup>[2]</sup>. In addition, as in the patient cited here, endoscopic stenting has been used as a temporary treatment to seal off the fistula in cases of OPF<sup>[4]</sup>. Indeed, the ability for a gastroenterologist to diagnose AEF or OPF as potential complications of this increasingly common procedure is of pivotal importance to offer prompt treatment of the patient and multidisciplinary management of the condition.

such tumors in the literature, little can be said about the benefit of adjuvant therapy and prognosis for the rare cases with malignant histological findings.

© 2013 Baishideng. All rights reserved.

**Key words:** Malignant; Solitary fibrous tumor; Liver; Extrathoracic; Mesenchymal neoplasm; Surgical resection

**Core tip:** Solitary fibrous tumors are predominantly benign and most commonly found in the thoracic cavity and pleura, but occasionally show malignant characteristics and occur in extrathoracic organs. A malignant solitary fibrous tumor involving the liver that was diagnosed in a 62-year-old woman and treated by surgical resection is reported here. Solitary fibrous tumor is very rare in a hepatic location, and surgery is the mainstay of treatment. Due to limited reports of such tumors in the literature, little can be said about the benefit of adjuvant therapy and prognosis for the rare cases with malignant histological findings.

### Abstract

Solitary fibrous tumors are predominantly benign and are most commonly found in the thoracic cavity and pleura; while reports exist in the literature of malignant solitary fibrous tumors and those located in extrathoracic organs, these cases are considered extremely rare. Herein, a case is reported of a malignant solitary fibrous tumor involving the liver that was diagnosed and treated in a 62-year-old woman. The patient presented with complaints of upper abdominal pain and unintentional weight loss. Computed tomography scan of the abdomen revealed a remarkably large mass, measuring 15 cm × 10 cm × 20 cm, which appeared to be unrelated to any particular organ. The intraoperative finding of a wide communication with the left liver suggested hepatic origin, and served as an indicator for tumor resection *via* left hemihepatectomy. The diagnosis of solitary fibrous tumor and its malignant nature was confirmed by histological and immunohistochemical examination of the resected tissues. Hepatic solitary fibrous tumor is very rare, and surgery remains the mainstay of treatment. Due to limited reports of

### INTRODUCTION

Solitary fibrous tumor (SFT) is a rare mesenchymal neoplasm. Whereas most of the SFTs reported in the literature have occurred in the thoracic cavity and pleura, cases of SFTs involving extrathoracic organs exist<sup>[1-3]</sup>. The majority of SFTs are benign and patients commonly present as asymptomatic; however, excessive size or involvement of vital structures may lead to paraneoplastic and local symptoms<sup>[1,2,4,5]</sup>. Surgery remains the treatment of choice, and little is known about the benefits of adjuvant therapy for those rare cases with histological findings that indi-

Figure 1 Computed tomography scan of the abdomen showing a well-circumscribed, solitary, large mass (15 cm × 10 cm × 20 cm) adjacent to the left liver lobe. The claw sign of hepatic tissue suggests intrahepatic localization. Notable features include hypervascularity, heterogeneous enhancement, and smooth margins.

cate malignancy<sup>[6]</sup>. Herein, we report a very rare case of a malignant SFT involving the liver.

## CASE REPORT

A 62-year-old woman presented at our hospital with complaints of upper abdominal pain persisting for several days and unintended weight loss that had occurred over the past month approximately. The patient's surgical history included resection of the transverse colon in 1984 to remove an adenocarcinoma, for which the results of follow-up examinations were unremarkable.

Physical examination upon admission revealed cachexia and a palpable large, firm mass in the epigastrium region that was roughly the size of a coconut. Laboratory tests showed normal complete blood cell count and slight thrombocytosis (525 g/L *vs* normal range: 150-400 g/L), as well as normal levels of all liver function markers except for C-reactive protein, which was elevated (29 mg/L *vs* normal range: 0-5 mg/L).

Computed tomography (CT) scan revealed a remarkably large single circumscribed intraabdominal tumor (Figure 1) without evidence of lymphatic metastases; the imaging analysis provided no indication of tumor relation to any particular organ. The presence of distant metastases was excluded by findings from additional CT scanning of the thoracic cavity. A median laparotomy was performed. The intraoperative findings of a wide communication between the tumor and the left liver and absence of penetration into adjacent organs suggested hepatic origin, and a left hemihepatectomy was carried out. The gross specimen was a large, lobulated, sharply demarcated tumor with obvious intratumoral necrotic areas (Figure 2).

Histological examination revealed the specimen to be a well-circumscribed mesenchymal tumor adjacent to the hepatic parenchyma and capsule. The tumor was composed of short spindly and ovoid cells arranged in a random pattern amidst a variable collagenous background with hemangiopericytoma-like thin-walled ectatic blood

Figure 2 Gross specimen is a bulky neoplasm attached to the liver capsule.

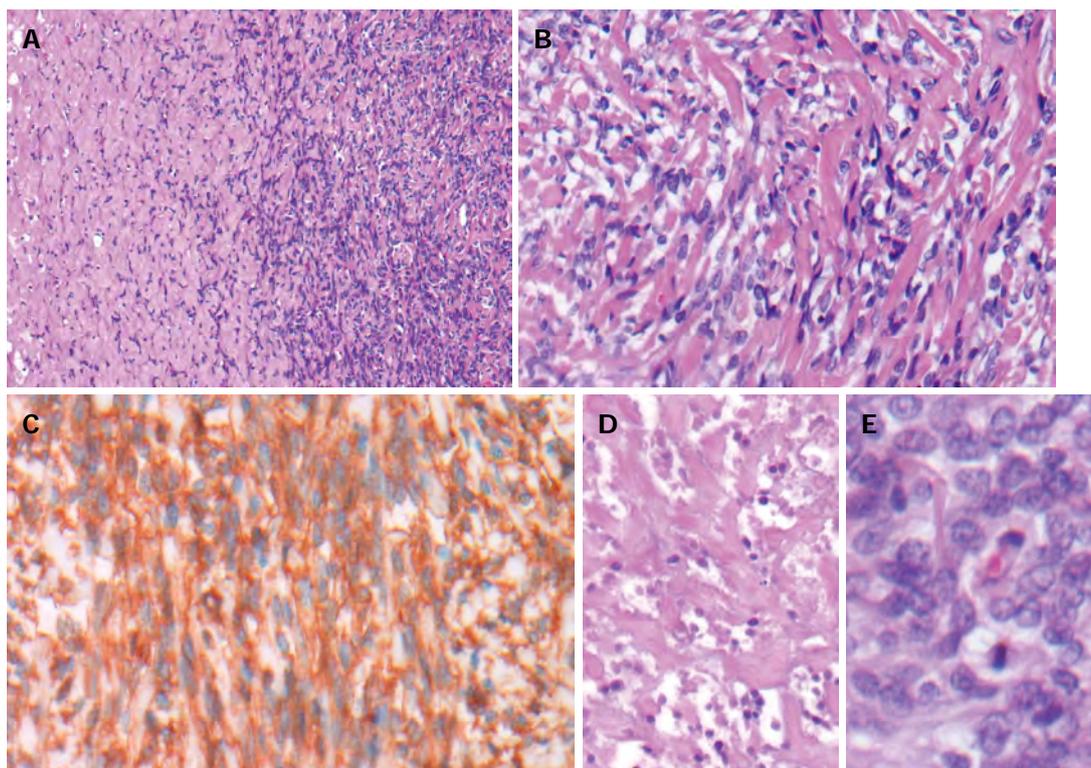

vessels (Figure 3). In addition, areas of high cellularity with nuclear crowding, cytological atypia, tumor necrosis, and increased mitotic rate (up to six mitotic figures per 10 high-power fields) were observed. Immunohistochemical analysis showed positivity for CD34, CD99 and Bcl-2, and negativity for cytokeratin, CD117, desmin, S-100 and actin. The diagnosis was made of a malignant SFT involving the liver.

The postoperative course was uneventful, although the recovery duration was slightly protracted because of the patient's poor nutritional status.

## DISCUSSION

SFTs are most commonly found in the thoracic cavity and pleura, but have also been reported in various extrathoracic organs, including the upper respiratory tract, orbits, soft tissue, abdomen, and breast<sup>[1-3]</sup>. Very rarely do SFTs involve the liver, and the incidence of these tumors is unknown<sup>[7]</sup>. The majority of hepatic SFT diagnoses have been in adults (mean age: 57.5 years) and there appears to be a strong bias towards the female sex (2:1)<sup>[4]</sup>. While most cases present as asymptomatic, some cases, such as our patient described herein, show abdominal fullness and a palpable mass<sup>[5]</sup>. Other symptoms that have been described include paraneoplastic hypoglycemia, fatigue, and weight loss<sup>[4]</sup>. From a biochemical perspective, the association of neoplasms with thrombocytosis and elevated C-reactive protein level is well known<sup>[8,9]</sup>, and the presence of a tumor may be suspected when these findings are present. However, definitive diagnosis of SFT is based on a characteristic panel of histological and immunohistochemical features. Histologically, SFT is composed of spindly to ovoid cells, possibly of fibroblastic origin, which are arranged in a haphazard "patternless" pattern and intimately intertwined by collagen fibers of various thicknesses, and associated with numerous hemangiopericytoma-like dilated thin-walled blood vessels. Immunohistochemically, SFT is positive for CD34, CD99 and Bcl-2<sup>[10]</sup>. The diagnosis of SFT was made in the present case according to these characteristic immunohistochemical findings and histological features.

Whereas most of the SFTs reported in the literature

**Figure 3** Histological findings indicative of malignant solitary fibrous tumor. A: Hypo- and hypercellular patternless growth patterns [hematoxylin and eosin (HE), × 40]; B: Short spindly to ovoid tumor cells in a collagenous background (HE, × 200); C: Immunohistochemical staining with positive detection of CD34 (HE, × 200); D: Multifocal areas of necrosis (HE, × 200); E: Hypercellularity, cytologic atypia, and increased mitotic activity (HE, × 400).

have been benign (> 80%), their malignant potential is largely unknown<sup>[2]</sup>. About 10%-15% of SFTs behave aggressively. Although no strict correlation has been found between the SFTs' morphological features and malignancy, the current World Health Organization (WHO) classification criteria of soft tissue tumors is used to identify malignant SFT; these criteria include hypercellularity, cytological atypia, tumor necrosis, high mitotic rate (four or more mitotic figures per 10 high-power fields), and/or infiltrative margins<sup>[10,11]</sup>. The resected tumor specimen from our case showed features of high cellularity with nuclear crowding, moderate to marked cellular atypia, up to six mitotic figures per 10 high-power fields and tumor necrosis, fulfilling the WHO criteria for malignant SFT. The imaging features previously reported for other benign and malignant SFTs involving the liver seem to overlap, and there is no distinctive radiological criterion for diagnosing malignancy, excepting the presence of distant metastases<sup>[12]</sup>.

Malignant SFTs involving the liver are currently treated by surgical resection, with the aim of obtaining a margin-negative specimen<sup>[6]</sup>. Because the number of cases reported to date is small, evidence of the benefit of adjuvant therapy is lacking and its use remains controversial<sup>[2,13]</sup>. As the biological behavior of these tumors and the patients' prognosis after treatment have not been well defined<sup>[5]</sup>, careful follow-up is mandatory.

In conclusion, malignant SFT involving the liver is very rare. Nevertheless, it should be considered as a po-

tential differential diagnosis when a single large hepatic mass is present. Definitive diagnosis is based on histopathological and immunohistochemical findings, and surgery remains the mainstay of treatment. The rarity of these cases and limited reports in the literature preclude any significant speculation regarding the benefit of adjuvant therapy and patient prognosis.

### Abstract

Solid pseudopapillary neoplasm (SPN) is a rare and low-grade malignant pancreatic neoplasm composed of poorly cohesive monomorphic neoplastic cells forming solid and pseudopapillary structures with frequent hemorrhagic-cystic degeneration. Intraductal papillary mucinous neoplasm (IPMN) is a pancreatic exocrine tumor composed of intraductal papillary growth of mucin containing neoplastic cells in the main pancreatic duct or its major branches. In the case presented here, a 53-year-old, Japanese man was found to have multiple

cystic lesions and dilatation of the main pancreatic duct in the neck of the pancreas. Histological examination revealed a main-duct and branch-duct type IPMN, of the gastric-type, involving the neck of the pancreas, associated with a 0.5 cm SPN in the caudal side of the IPMN. We diagnosed this case as synchronous SPN and IPMN. As far as we know, only one other case of synchronous SPN and IPMN has been reported. Both the present case and the previously reported case showed abnormal nuclear expression of  $\beta$ -catenin in SPN, whereas IPMN showed no abnormal nuclear expression. These results suggest that  $\beta$ -catenin abnormality is not a common pathogenetic factor of synchronous SPN and IPMN.

**Key words:** Intraductal papillary mucinous neoplasms; Solid pseudopapillary neoplasms; Pancreatic neoplasms; Synchronous neoplasms; Pancreas; Beta-catenin

**Core tip:** We report the second case of synchronous solid pseudopapillary neoplasm (SPN) and intraductal papillary mucinous neoplasm (IPMN) of the pancreas in a 53-year-old Japanese man. IPMN was classified as a "combined" type due to the involvement of both the main and branch ducts, and it showed a gastric subtype with low-grade dysplasia. Adjacent to the caudal side of IPMN, a 0.5-cm solid SPN was present. The SPN showed abnormal nuclear expression of  $\beta$ -catenin in SPN, whereas IPMN showed no abnormal nuclear expression. This result suggested that  $\beta$ -catenin abnormality is not a common pathogenetic factor of synchronous SPN or IPMN.

nous neoplasm. *World J Gastroenterol* 2013; 19(21): 3358-3363 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i21/3358.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i21.3358>

## INTRODUCTION

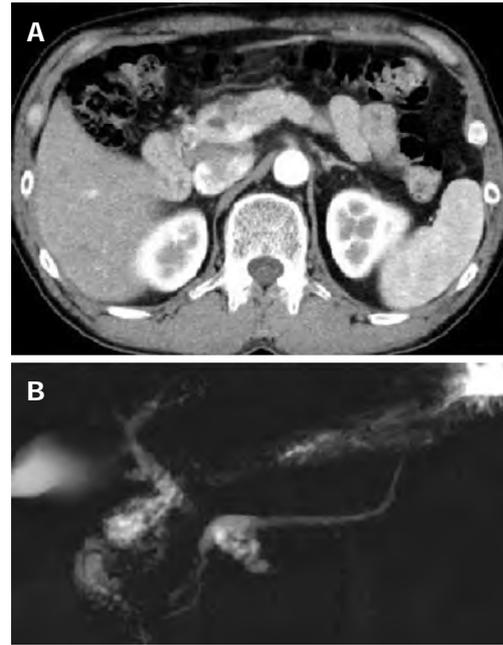

Solid pseudopapillary neoplasm (SPN) is a rare and low-grade malignant pancreatic neoplasm composed of poorly cohesive, monomorphic cells forming solid and pseudopapillary structures with frequent hemorrhagic-cystic degeneration, which predominantly occurs in young women. Immunohistochemically, SPN usually expresses vimentin,  $\alpha$ -1-antitrypsin, CD56, progesterone receptor, CD10, and nuclear/cytoplasmic  $\beta$ -catenin<sup>[1-3]</sup>.

Intraductal papillary mucinous neoplasm (IPMN) is a macroscopic pancreatic exocrine tumour that grows primarily within the main pancreatic duct or its major branches, and mainly occurs in older men. IPMNs are composed of intraductal papillary growth of mucin-containing neoplastic cells that are classified into 4 major subgroups: gastric, intestinal, pancreatobiliary, and oncocytic types<sup>[4,5]</sup>. Gastric-type IPMN consists of innocuous, tall columnar cells that resemble gastric foveolar epithelium and express mucin (MUC) 5AC, but are negative for MUC1, MUC2, and CDX2<sup>[4,5]</sup>. Intestinal-type IPMN consists of neoplastic cells that resemble intestinal villous neoplasms with MUC2, MUC5AC, and CDX2 expression, but without MUC1 expression<sup>[4,5]</sup>. Pancreatobiliary-type IPMN consists of thin, branching papillae with high-grade dysplasia and is at least focally positive for MUC1 and MUC5AC, but is negative for MUC2 or CDX2<sup>[4,5]</sup>. Oncocytic-type IPMN is characterised by complex and arborizing papillae lined by cuboidal cells with granular eosinophilic cytoplasm, which usually express MUC5AC and MUC6, but are negative for MUC2 and CDX2<sup>[4,5]</sup>.

Although IPMNs have been reported to occur synchronously with a variety of primary pancreatic neoplasms such as pancreatic ductal adenocarcinomas, endocrine neoplasms, or serous cyst adenomas<sup>[6-9]</sup>, the synchronous occurrence of SPN with other pancreatic neoplasms has only been reported in a single case report associated with an IPMN<sup>[10]</sup>. In the current study, we present the histological and clinical features of a second case of synchronous “early” SPN and IPMN, with a review of the literature.

## CASE REPORT

A 53-year-old Japanese man with multiple pancreatic cystic lesions, which were detected at a local hospital, was referred to the Tokai University Hospital for further examination. Upon inspection, he had no complaints, and no abnormal physical findings were reported. Laboratory data, including tumour markers, carcinoembryonic antigen, or carbohydrate antigen 19-9, showed no abnormal findings. Computed tomography showed multiple cystic

**Figure 1** Computed tomography and magnetic resonance cholangiopancreatography imaging. A: Multiple cystic lesions measuring 23 mm are indicated in the neck of the pancreas; B: Multiple cystic dilations of pancreatic branch duct connecting to the dilated main pancreatic duct are indicated in the neck of the pancreas.

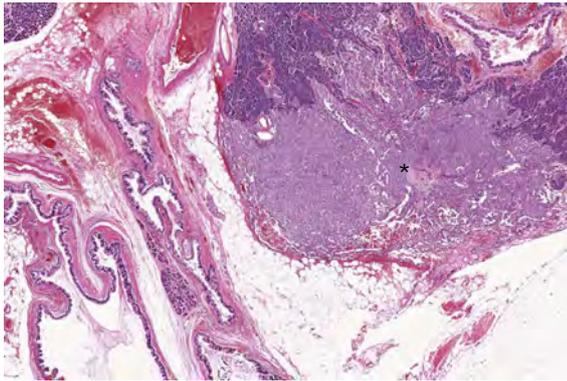

lesions measuring 2.3 cm in the neck of the pancreas (Figure 1A). Magnetic resonance cholangiopancreatography imaging showed multiple cystic dilations of the pancreatic branch ducts connecting to the dilated main pancreatic duct in the neck of the pancreas (Figure 1B). Endoscopic retrograde pancreaticography showed a dilated main pancreatic duct in the neck of the pancreas, measuring 6 mm in diameter, with multiple nodular defects. Distal pancreatectomy and splenectomy were performed. At present, the patient is alive and well 25 mo after the operation.

### Tissues

The resected specimen was fixed in 10% formalin, routinely embedded in paraffin, sectioned at 4- $\mu$ m, and stained with haematoxylin and eosin.

### Immunohistochemistry

The sections were deparaffinised in xylene and rehydrated in a graded ethanol series. The primary antibodies and their dilutions and sources are summarized in Table 1. If necessary, antigen retrieval was performed by autoclaving the samples for 15 min in a sodium citrate buffer at pH 6.0 ( $\beta$ -catenin, CD56, chromogranin A, E-cadherin, MUC1, MUC2, MUC5AC, MUC6, vimentin, and Ki67) or by treatment with 0.1% trypsin at 37 °C for 30 min (synaptophysin). The antibodies were detected using EnVision Plus (Dako, Glostrup, Denmark; for  $\beta$ -catenin, CD56, chromogranin A, E-cadherin, MUC1, MUC2, MUC5AC, MUC6, vimentin, synaptophysin, and Ki67), or Horseradish Peroxidase-conjugated polyclonal goat anti-rabbit

**Figure 2** Microscopic findings (low-power view). A small and irregularly shaped solid lesion of solid pseudopapillary neoplasm (asterisk) can be observed near the cystically dilated branch ducts of intraductal papillary mucinous neoplasm (hematoxylin and eosin stain, × 10).

immunoglobulin (Dako; for alpha-1-antitrypsin), with 3,3'-diaminobenzidine as the chromogen. Assays for pancytokeratin, progesterone receptor (PR), and CD10 were performed using Ventana Benchmark XT (Ventana Medical Systems, Tucson, AZ, United States) equipped with the Ultra View Detection Kit. Antigen retrieval was performed by treatment with CC1 (Ventana; for PR and CD10) or protease 1 (Ventana; for pancytokeratin).

On gross examination, the distal pancreatectomy specimen showed a dilatation of the main pancreatic duct, with multiple cystic dilatations of the branch ducts, filled with mucus and containing papillae, in the neck of the pancreas. A whitish and solid lesion measuring 0.5 cm × 0.3 cm in size, located adjacent to the caudal side of the cystically dilated branch ducts, was identified.

Microscopically, 2 distinct primary pancreatic neoplasms were present (Figure 2): (1) a typical central and branch-duct type IPMN, with the cyst lined by tall and pale columnar cells with only low-grade dysplasia, and pyloric-gland adenoma-like papillary projections (Figure 3A). Immunohistochemically, the neoplastic cells showed gastric-type phenotype with MUC5AC (Figure 3B) and MUC6 positivity, and MUC1 and MUC2 negativity. β-catenin immunostaining showed membranous expression, but did not show abnormal nuclear expression (Figure 3C). On the basis of current World Health Organization (WHO) criteria<sup>[4]</sup>, we diagnosed the patient with gastric-type IPMN with low-grade dysplasia; and (2) a small, SPN, adjacent to the IPMN, which showed an ill-defined demarcation, with focal extension to the pancreatic parenchyma. The tumor showed a prevalent solid pattern, with focal degenerative changes and rough pseudopapillary structures (Figure 3D). The neoplastic cells had eosinophilic cytoplasm and small, round nuclei with finely dispersed chromatin. We failed to find perineural infiltration, peripancreatic invasion, or calcification. Immunohistochemically, the neoplastic cells expressed CD56, vimentin, alpha-1-antitrypsin, CD10, progesterone receptor (Figure 3E), nuclear/cytoplasmic β-catenin (Figure 3F), focal positivity for synaptophysin and negativity

for chromogranin A, and E-cadherin and cytokeratin AE1 and 3. The immunohistochemical profiles of the 2 neoplasms are summarized in Table 1.

As our results show, the SPN was located near the IPMN. However, neither transition nor collision between IPMN and SPN were identified. Therefore, we diagnosed the present case as synchronous SPN and IPMN of the pancreas. The surgical margins were free of both types of tumors. No lymph node metastasis was identified.

## DISCUSSION

We reported a case of synchronous small, radiologically undetected SPN, in a patient operated on for a radiologically evident IPMN of the pancreas. To our knowledge, this association has only been previously reported by Imamura *et al*<sup>[10]</sup>. They reported a patient who presented with a 3-cm, solid SPN in the head of the pancreas that invaded the mesocolon with a synchronous IPMN constituted by 2 multilocular cystic lesions in the head of the pancreas. In other words, the 2 cases showed mirror clinicopathologic traits.

In general, SPN occurs predominantly in young women (91%) and is rare in men (9%)<sup>[11]</sup>. Interestingly, however, both our case and Imamura's occurred in men<sup>[10]</sup>. Several authors have reported the clinicopathologic correlations between genders and SPN. Takahashi *et al*<sup>[12]</sup> reported that the cases of SPN in men tend to exhibit solid components without prominent degenerative changes. Tien *et al*<sup>[13]</sup> reported no significant differences in patient age, size, neoplasm location, or malignancy rate between the genders in SPN. By contrast, Machado *et al*<sup>[14]</sup> reported that cases of SPN in men are more aggressive and that the patients are older. According to the literature review of 1014 SPN patients (women, 877; men, 137)

According to the current WHO classification<sup>[4]</sup>, the IPMN in the present case should be classified as low-grade dysplasia. Imamura *et al*<sup>[10]</sup> diagnosed the IPMN component in their case as intraductal papillary mucinous adenoma (IPMA). Under the current WHO classification guidelines, IPMA is now designated as IPMN with low-grade dysplasia<sup>[4]</sup>. Imamura *et al*<sup>[10]</sup> did not mention the subtype of IPMN applicable to their case. We assume that it might have been a gastric type, based on the features of their figures and the MUC5AC positivity, and MUC1 and MUC2 negativity.

In both our case and Imamura's case, the SPNs were adjacent to the IPMNs, without any transition or collision between the 2 neoplasms<sup>[10]</sup>.

The occurrence of SPN and IPMN offers an interesting opportunity to investigate the role of  $\beta$ -catenin gene mutation in the pathogenesis of both lesions. In fact, almost all SPNs harbour somatic point mutations in exon 3 of CTNNB1, the gene that encodes  $\beta$ -catenin, which results in abnormal nuclear expression of  $\beta$ -catenin on immunohistochemistry<sup>[1]</sup>. The role of  $\beta$ -catenin gene mutations in IPMN is more controversial.  $\beta$ -catenin nuclear protein accumulation has been reported in one patient with familial adenomatous polyposis<sup>[16]</sup> and in a small series of IPMNs. In the latter study, 7 of 18 IPMNs indicated abnormal  $\beta$ -catenin nuclear protein accumulation (1 of 8 adenomas, 2 of 3 borderline, and 4 of 7 carcinomas)<sup>[17]</sup>. Both the present case and Imamura *et al*<sup>[10]</sup> showed abnormal nuclear expression of  $\beta$ -catenin in SPN, whereas IPMN showed only membranous expression, but no abnormal nuclear expression. These results suggest that, at least in these 2 patients, there is no correlation between the  $\beta$ -catenin abnormalities, exclusively found in SPNs, and the development of synchronous IPMNs.

In conclusion, we present a second case of synchronous SPN and IPMN of the pancreas. Unlike SPNs that usually occur in adolescent girls or young women, the 2 synchronous SPNs and IPMNs occurred in old, male patients (53 and 66 years, respectively). It is still unknown whether SPN or IPMN neoplasms occur independently or are in some way linked. From the comparison of the 2 cases, it appears that the  $\beta$ -catenin gene abnormalities play a role exclusively in the development of SPN, whereas a different molecular pathogenesis has to be considered for the IPMN counterpart.

### Abstract

This case report describes a foreign body retained in the liver long after perihepatic gauze packing. A 64-year-old female patient had suffered a rib fracture and liver rupture during a traffic accident in 1973. She discovered a mass in her right hypochondrium. Her hepatic ultrasonography showed a round mass (20.3 cm × 17.3 cm × 16.0 cm in size) with fluid echogenicity in the right lobe of her liver, and a hepatic cystic-solid mass (19.7 cm × 18.5 cm × 15.6 cm in size) was identified in an abdominal computerized tomography scan. Several pieces of gauze were extracted, and brown

pus from the hepatic mass was suctioned during her exploratory laparotomy. Histology documented gauze remnants with necrotic material inclusions and fibrotic capsules. To our knowledge, this patient's case represents the longest time for which a foreign body has been retained in the liver. In addition, we conducted a comprehensive literature review of foreign bodies retained in the liver. Foreign bodies may be introduced into the liver via penetrating trauma, surgical procedures or the ingestion of foreign bodies (which then migrate from the gut). Thus, they can be classified into the following three categories: penetrating, medical and migrated foreign bodies. The details of the case are thoroughly described.

**Key words:** Liver; Foreign bodies; Foreign-body migration; Foreign-body reaction; Surgical sponges

**Core tip:** We reported a case of foreign body retained in liver 39 years post perihepatic gauze packing. To our knowledge, this seems to be the longest time and first report of gossypiboma post gauze packing in literature. We classified foreign bodies retained in liver as 3 categories: penetrating, medical and migrated foreign bodies. Also, we presented a comprehensive review, which may greatly help a surgeon make clinical decision when patients presented with hepatic mass.

### INTRODUCTION

Various foreign bodies retained in parts of the human body (such as the abdominal cavity and intrathoracic and

pericardial spaces) as a result of surgery, trauma or exposure to chemical substances (such as pigment or suture materials) have previously been described<sup>[1]</sup>. However, reports related to the liver are rare and had not been well-reviewed. In this report, we describe a case of a retained foreign body in the liver (gossypiboma) in which surgical gauze used for perihepatic packing had been retained for 39 years after an abdominal hepatorrhaphy following a traffic accident.

## CASE REPORT

A 64-year-old female patient was admitted to our department. She complained of slight intermittent chest pain and dyspnea on exertion for approximately 20 d associated with poor appetite and weight loss. A mass was present in her epigastrium and right hypochondrium. She has lived in a region in which schistosomiasis is epidemic and has had well-controlled hypertension with regular anti-hypertensive therapy for the last five years. She suffered rib fractures and liver rupture in a traffic accident 39 years ago and recovered post-laparotomy. Her general examination and laboratory parameters, including liver function tests, were within the normal limits. Upon abdominal examination, a large-sized vertical midline incision scar was identified, and a mass with restricted mobility and a smooth surface was palpable. Hepatic ultrasonography showed a round mass (20.3 cm × 17.3 cm × 16.0 cm in size) with fluid echogenicity in the right lobe of her liver. A hepatic cystic-solid mass (19.7 cm × 18.5 cm × 15.6 cm in size) was identified with the aid of an abdominal computerized tomography (CT) scan (Figure 1). Liver textiloma was highly suspected.

The patient was scheduled for an exploratory laparotomy under general anesthesia. After the abdomen was opened, a very large cyst was found in the right lobe of her liver protruding into the right chest cavity. All appropriate precautions were taken to prevent the cyst from rupturing. Thin, brown pus was suctioned after anhydrous alcohol was repeatedly infused into the cyst, and several pieces of gauze were found after the cyst was opened (Figure 2). Pus samples were collected in sterile syringes and sent for culture and sensitivity analyses. The surgical gauze was removed, and peritoneal lavage was performed. A double-lumen tube was used to drain the remaining fluid in the cyst and another rubber tube was inserted in hepatorenal recess. The abdomen was then closed after obtaining exact counts of sponges and instruments and taking all necessary precautions.

The culture of the pus was sterile. The histological analysis documented gauze remnants with necrotic material inclusions and a fibrotic capsule with old, calcified schistosome eggs that was attached to the foreign body granuloma. The postoperative period was uneventful; the patient was discharged with the double-lumen drainage tube in place and advised to return for follow-up visits. The double-lumen tube was extracted two months later, and the patient now lives a normal life.

## DISCUSSION

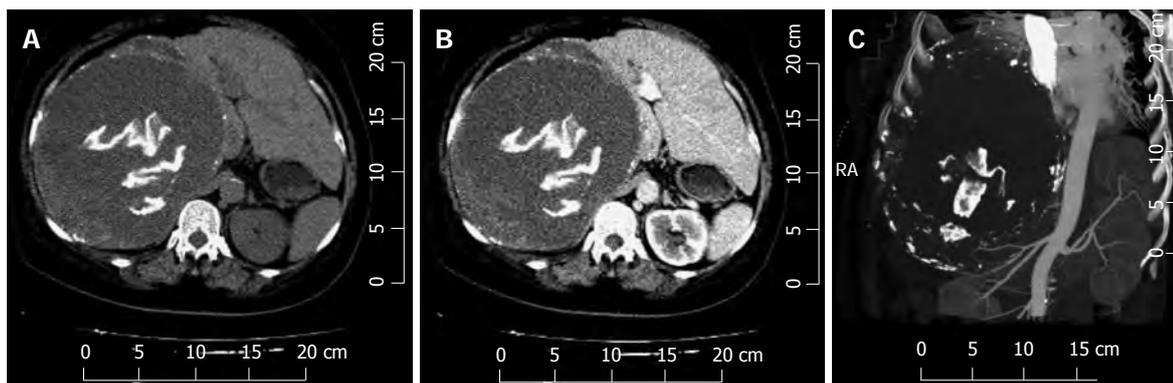

Foreign bodies may be introduced into the liver via penetrating trauma, surgical procedures or the ingestion of foreign bodies (which later migrate from the gut). Thus, these foreign bodies can be classified into the following three categories: penetrating, medical and migrated foreign bodies.

### *Penetrating foreign bodies*

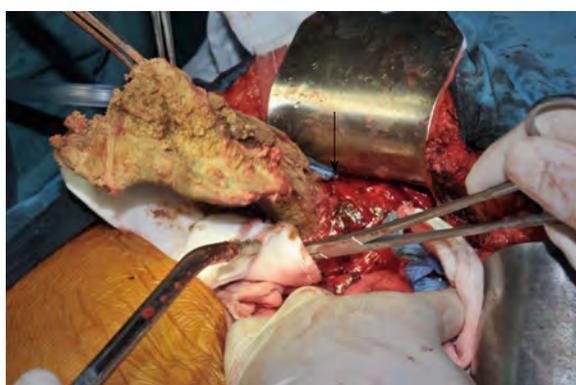

Penetrating foreign bodies, such as bullets, shell fragments, glass and wood, can become lodged in the liver via gunshot or stab wounds<sup>[2-7]</sup>. Although gunshot or stab injuries may not introduce penetrating foreign bodies into the liver<sup>[2,3]</sup>, they remain the most common causes. An immediate assessment with ultrasound or CT after a blunt or penetrating abdominal injury remains the gold standard method for identifying bleeding and foreign bodies<sup>[4]</sup>. Liver is the most commonly injured solid organ in blunt or penetrating abdominal or thoracic trauma, however, liver wounds associated with penetrating foreign bodies that are retained in the liver are rare<sup>[5]</sup>. Botoi *et al*<sup>[6]</sup> reported six cases of liver shotgun wounds that all resulted in metal foreign bodies being retained in the liver. The patients were all male, and most were young. Hunting rifles were involved in three of the cases. The wounds were complex in five of the six cases, and most of the injuries affected the right liver lobe. Hepatectomy was used in 40% of the cases<sup>[6]</sup>. Hepatic penetrating foreign bodies are surgical emergencies that should prompt prophylactic extraction through laparotomy; however, the tissue injury caused by the penetrating liver trauma and not the penetrating foreign bodies themselves require surgery<sup>[4,5]</sup>. Some penetrating foreign bodies, such as bullets, produce no clinical symptoms for many years.

Laparotomy remains the standard treatment for penetrating organ injuries with retained foreign bodies; however, non-operative management<sup>[7]</sup> is preferred for stable patients, especially those with penetrating organ injuries without retained foreign bodies. In the appropriate trauma center environment, selective non-operative management of penetrating abdominal solid organ injuries, especially liver injuries, has a high success rate and a low complication rate. Even high-grade liver injuries do not preclude non-operative management<sup>[8]</sup>.

Major complex surgical procedures, such as an anatomical resection, an irregular hepatotomy with direct suture and resectional debridement or atriocaval shunting, are thought to be indicated in the emergency setting in specialist units<sup>[7,8]</sup>. Fast and effective surgical damage control procedures (*i.e.*, temporary gauze packing and mesh wrapping of the fragmented liver with absorbable mesh (mesh hepatorrhaphy) combined with ipsilateral ligation of the bleeding vessel) are safe and effective for treating severe liver injuries, especially in non-specialist centers or in remote, rural settings. Interventional radiological techniques are becoming more widely used to more effectively manage severe liver injuries, particularly in patients

**Figure 1** Computed tomography images of the abdomino-thoracic region showing a cystic mass in the liver with filiform calcification inside and a small amount of pleural effusion. A: Plain; B: Contrast-enhanced; C: Reconstructive. RA: Right anterior.

**Figure 2** Surgical gauze (arrow) and the cyst wall (held with vessel forceps) in the right liver lobe following the evacuation of pus.

who are managed non-operatively or have been stabilized using perihepatic packing<sup>[8]</sup>. Liver transplantation for trauma is extremely rare; although this type of transplantation has been attempted<sup>[9]</sup>, it is very limited to date.

Although temporary perihepatic gauze packing was not used for decades, packing has been reintroduced because more aggressive attempts at controlling hemorrhaging without temporary packing failed to improve results. Packing is also recommended for inexperienced surgeons to control and stabilize patients before they are transferred to a tertiary center<sup>[4,5,7,8]</sup>. The patient in this case study suffered from blunt trauma in a traffic accident. Although the surgical details are obscure due to the passing of 39 years, perihepatic gauze packing saved the patient's life, and she lived a normal life for 39 years. Mesh hepatorrhaphy may control bleeding without many of the adverse effects of packing<sup>[4,7,8]</sup>.

### Migrated foreign bodies

Migrated foreign bodies are sharp objects that perforate the alimentary tract and migrate to the liver<sup>[10]</sup>. Ingested foreign bodies with sharp pointed end include sewing needles, dental plates, fish bones, chicken bones and office supplies. Foreign bodies are commonly ingested by elderly individuals, children, psychiatric patients, prison inmates, alcoholics, certain professionals (*e.g.*, carpenters

and dressmakers) and individuals wearing dentures<sup>[10-20]</sup>.

The migration of foreign bodies from the gut into the liver is often a slow process that encourages an inflammatory and fibrotic reaction that results in adhesion<sup>[11,12]</sup>. Clinical manifestations, such as perforation, bleeding and bowel obstruction, often do not occur with migrated foreign bodies<sup>[13]</sup>. Perforation of the gastrointestinal tract by a foreign body typically occurs at sites at which a physiological narrowing of the stomach<sup>[14,15]</sup> or duodenum<sup>[16,17]</sup> is present. Ingestion history is not often considered in the initial diagnosis<sup>[13-17]</sup>. Migrated foreign bodies in the liver often cause pyogenic liver abscesses or pseudotumors<sup>[18]</sup>.

Patients who present with a liver abscess or a pseudotumor may have a foreign body granuloma, which may be difficult to distinguish from a tumor upon radiological examination. Right upper-quadrant pain and cholangitis<sup>[11,12]</sup> are often the first symptoms, which may be mild initially but increase over time. An inflammatory mass mimicking a liver abscess or a pseudotumor that looks like hepatocellular carcinoma or cholangiocarcinoma may cause systemic symptoms, such as fevers and chills, anorexia, weight loss, abdominal pain, nausea and vomiting<sup>[12,13]</sup>. Abdominal ultrasonography and CT can reveal a hepatic abscess with a linear calcified foreign body and gas (which is often hyperechoic in ultrasonography and highly dense in the CT<sup>[18,19]</sup>) and are very helpful for establishing the correct diagnosis. A CT scan can demonstrate the location of the foreign body clearly and accurately, which may assist the clinician in selecting the appropriate treatment plan.

Conservative management has been described for asymptomatic patients with a stable, uncomplicated migrated foreign body<sup>[11,12,16]</sup>; however, in an emergency, a hepatic migrated foreign body should be extracted through laparotomy or laparoscopy<sup>[17,18]</sup> to avoid complications, such as hemorrhaging or the formation of an abscess or a fistula. Other strategies for removing the foreign body include endoscopy<sup>[19]</sup> and percutaneous abscess drainage under ultrasonographic guidance<sup>[20]</sup>.

### Medical foreign bodies

Medical foreign bodies in the liver include surgical objects,

such as surgical gauze (or gossypiboma/textiloma)<sup>[21-23]</sup>, surgical clips<sup>[24,25]</sup>, medical sutures<sup>[23,26]</sup>, shrapnel splinters<sup>[27]</sup> and T-tubes<sup>[28]</sup>, which are retained in the liver parenchyma or biliary tracts after surgical operations. These bodies can be grouped into two main categories: bodies in the biliary tract and bodies in the liver parenchyma.

Gossypibomas account for most of the malpractice claims for retained foreign bodies. They are most frequently observed in obese patients or patients in unstable conditions; during emergency surgeries, long operations or surgical procedures that include unexpected changes; and after laparoscopic interventions<sup>[29,30]</sup>. Gossypibomas in the liver parenchyma or the biliary tracts commonly follow cholecystectomy or liver surgery<sup>[28-30]</sup>. In our case, the patient underwent an emergent hepatorrhaphy that included perihepatic packing with surgical gauze. Typically, surgical gauze should be extracted when hemorrhaging stops; however, the gauze in the liver of our patient was not extracted and caused gossypiboma.

The symptoms of gossypiboma are usually non-specific and may appear years after surgery. Pain, irritation, a palpable mass, anorexia, fever and weight loss are the common signs and symptoms of gossypibomas in the liver parenchyma; however, some patients were asymptomatic or presented with foreign body granulomas mimicking liver metastasis<sup>[1]</sup>. The signs and symptoms of foreign bodies in the biliary tracts include jaundice and elevated liver enzymes<sup>[30]</sup>. The patient in this case complained of slight intermittent chest pain and dyspnea upon exertion, poor appetite and weight loss. The mass was palpable, but jaundice was absent.

Eguchi *et al*<sup>[27]</sup> reported a case of a shrapnel splinter in the common bile duct (CBD) that had migrated from the right thoracic cavity 36 years after the initial injury. It was serially documented that the shrapnel had migrated toward the diaphragm and then burrowed into the liver, settling in the CBD and causing obstructive jaundice. This timeframe represents the longest time reported in the literature that a foreign body remained in liver. In our case, the retained gauze was extracted 39 years later. To our knowledge, this is the longest time that a medical foreign body has been retained in the abdomen.

The most common detection methods are CT, radiography and ultrasound<sup>[22]</sup>. The most impressive imaging findings of gossypiboma are curved or banded radio-opaque lines on a plain radiograph. The ultrasound usually shows a well-defined mass with a wavy internal echogenic focus, a hypoechoic rim and a strong posterior shadow<sup>[31]</sup>. On a CT, a gossypiboma may manifest as a cystic lesion with an internal spongiform appearance with hyperdense capsules, concentric layering and mottled shadows as bubbles or mottled mural calcifications<sup>[32]</sup>. Magnetic resonance imaging pictures of gossypiboma in the abdomen and the pelvis reflect a well-defined mass with a peripheral wall of a low signal intensity on T1- and T2-weighted imaging, and T1-weighted imaging shows whorled stripes in the central portion and peripheral wall enhancement after intravenous gadolinium admin-

istration<sup>[33]</sup>. In our case, the patient's hepatic ultrasound showed a round mass with fluid echogenicity in the right liver lobe. The plain (Figure 1A), contrast-enhanced (Figure 1B) and reconstructive (Figure 1C) abdominal CT scans showed a cystic mass in the liver with filiform calcification inside, mottled mural calcifications and a small amount of pleural effusion.

Early diagnosis may be difficult, and the removal of a medical foreign body is crucial for preventing serious complications and medicolegal issues. The strategies for removing a medical foreign body include laparoscopy and laparotomy for foreign bodies in the liver parenchyma or in the CBD. If endoscopic retrograde cholangiopancreatogram is futile, percutaneous abscess drainage under ultrasonographic guidance will be useful<sup>[23]</sup>. The patient described in this case study underwent an exploratory laparotomy. The surgical gauze in her right liver was extracted, and double-lumen drainage was performed.

The retention of medical foreign bodies can be prevented with simple precautions, such as keeping a thorough pack count. The use of radiologically tagged materials is recommended, and radiofrequency chip identification with a barcode scanner will hopefully decrease the incidence of retained medical foreign bodies<sup>[34,35]</sup>.

In conclusion, retained foreign bodies in the liver can be classified into three categories: penetrating, medical and migrated foreign bodies. Any patient who presents with a hepatic mass and has a history of liver injury, surgery or an occult infection of unknown cause should arouse suspicion of a retained foreign body.

test, but is a public health issue: a national program is needed to ensure minimal participation, quality controls and evaluation of the results to improve the process.

Braillon A. Is the American Association for the Study of Liver Diseases recommendation for hepatocellular carcinoma screening a cul-de-sac? *World J Gastroenterol* 2013; 19(21): 3369-3370 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i21/3369.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i21.3369>

### Abstract

The American Association for the Study of Liver Diseases just confirmed a grade I recommendation for hepatocellular carcinoma (HCC) screening despite growing controversy. Why should HCC be an exception in the long list of other cancers where the feasibility and the efficacy of screening were investigated by randomized trials? Only 12.0% of United States patients are screened, a fact that precludes efficacy, and there are no relevant figures on the benefit-risk ratio. The ethics of belief is a treacherous reef. Screening is not just performing a test, but is a public health issue: a national program is needed to ensure minimal participation, quality controls and evaluation of the results to improve the process. There are also serious concerns regarding undisclosed potential conflicts of interest.

**Core tip:** Why should hepatocellular carcinoma be an exception in the long list of other cancers where the feasibility and the efficacy of screening were investigated by randomized trials? The ethics of belief is a treacherous reef. Screening is not just performing a

### TO THE EDITOR

A recent editorial from the American Association for the Study of Liver Diseases (AASLD) Practice Guidelines Committee on hepatocellular carcinoma (HCC) screening deserves comment<sup>[1]</sup>.

This recommendation for HCC screening, maintains a grade I (best evidence from randomized trials) despite the fact that it should have been downgraded to a grade III (experts statement) considering rising controversy<sup>[2,3]</sup>. Indeed, only two randomized trials are available, both from China, one is negative, the other is positive but has several major flaws<sup>[2]</sup>. In developed countries, only observational studies are available, concluding that screening improves survival despite raw data which consistently show that screened patients die younger than non-screened patients (length of time and lead time biases)<sup>[3,4]</sup>.

This is not a Byzantine comment on Evidence Medicine: this highest grade in the recommendation with flawed evidence blocks advances, is counterproductive and breaches patients' rights.

The grade I level blocks further advances as randomized controlled trials (RCT) are no longer acceptable. Moreover, the recommendation tries to justify why a RCT is not feasible. Among other arguments, it cites an Austra-

lian survey which showed that 90% of patients would refuse participation in a RCT, preferring to undergo screening (see 29 in 1). This did not provide evidence that a trial is not possible, it only showed that the patients did not receive balanced and unbiased information about screening. Randomized controlled trials are always difficult, however, why should HCC be an exception in the long list of other cancers where the feasibility and efficacy of screening were investigated by randomized trials? For example, French and United States urologists, whose associations have strongly promoted prostate cancer screening for a long time, did not hesitate to recruit patients for large multi-national trials. Everyone must support the trial recently submitted to the VA Cooperative Studies Program.

The maintenance of the grade I level cannot mask the fact that the recommendation has not been implemented. Only 12.0% of United States patients are screened, a fact that precludes efficacy<sup>[5]</sup>. Indeed, there are no relevant figures on screening to inform patients about the benefit-risk ratio, a pre-request for compliance. The benefit may be very limited, e.g., the 5-year HCC risk is 1.9% in patients with alcoholic cirrhosis<sup>[6]</sup>. With regard to harm, overdiagnosis is the inevitable trade-off involved in early cancer detection. Cancer overdiagnosis means that some cancers never progress or progress slowly and the patient dies of other causes before symptoms are apparent. Such patients, as patients with false-positive results, do not benefit from diagnostic procedures and unnecessary treatments, and can only be harmed by them<sup>[7]</sup>. The magnitude of overdiagnosis is estimated to be about 25% in mammographically-detected breast cancers and 60% in prostate-specific antigen-detected prostate cancers<sup>[7]</sup>. No data are available for HCC screening, and stating that “the risk of this is felt to be small” is not the best way to reassure patients<sup>[1]</sup>. Moreover, both the European Association for the Study of the Liver and AASLD noninvasive recall strategies for nodules of 10-30 mm in the cirrhotic liver, based on the vascular pattern, have a false-negative rate of approximately 20%<sup>[8]</sup>. Ultrasound screening is far from being a simple and non-invasive procedure, because the next step findings are frequently discordant on both computed tomography and magnetic resonance imaging, supporting the use of biopsy for the diagnosis of small HCCs<sup>[9,10]</sup>.

The ethics of belief is a treacherous reef when practiced at the bedside, and is without hope for improvement and progress. Screening is not just performing a blood test or a radiological exam, it is a complex issue which is beyond the scope of any clinical disciplines. It is a public health issue: a national program is needed to ensure minimal participation, quality controls (even more mandatory here as the algorithms are complex for recall strategies), and evaluation of the results to improve the process. Moreover, although on the rise, HCC is only the ninth leading cause of cancer deaths in the United States and has to compete with other priorities in a cost-constrained economy<sup>[11]</sup>.

Finally, the conflict of interest section is puzzling<sup>[1]</sup>.

It contrasts with a previous statement where both authors of the recommendation stated they served on the Speaker’s Bureau of Bayer<sup>[12]</sup>. Bayer markets sorafenib, the \$5000/mo drug for advanced HCC, which is now being investigated for the prevention of early HCC recurrence after local ablation (NCT01126645). Early HCC could be a huge market for Bayer. Moreover, AASLD which edits *Hepatology* receives grants from Bayer for its practice guidelines program and Bayer also held three different booth spaces during the last AASLD meeting. (see <http://www.aasld.org/practiceguidelines/Pages/ArchivePracticeGuidelines.aspx> and <http://www.aasld.org/lm2012/2012/exhibits/Pages/currentexhibitors.aspx>).

**ABOUT COVER** Editorial Board Member of *World Journal of Gastroenterology*, Giovanni Tarantino, Professor, Department of Clinical Medicine and Surgery, Federico II University Medical School of Naples, 80131 Naples, Italy

**AIMS AND SCOPE** *World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a peer-reviewed open access journal. *WJG* was established on October 1, 1995. It is published weekly on the 7<sup>th</sup>, 14<sup>th</sup>, 21<sup>st</sup>, and 28<sup>th</sup> each month. The *WJG* Editorial Board consists of 1352 experts in gastroenterology and hepatology from 64 countries.

The primary task of *WJG* is to rapidly publish high-quality original articles, reviews, and commentaries in the fields of gastroenterology, hepatology, gastrointestinal endoscopy, gastrointestinal surgery, hepatobiliary surgery, gastrointestinal oncology, gastrointestinal radiation oncology, gastrointestinal imaging, gastrointestinal interventional therapy, gastrointestinal infectious diseases, gastrointestinal pharmacology, gastrointestinal pathophysiology, gastrointestinal pathology, evidence-based medicine in gastroenterology, pancreatology, gastrointestinal laboratory medicine, gastrointestinal molecular biology, gastrointestinal immunology, gastrointestinal microbiology, gastrointestinal genetics, gastrointestinal translational medicine, gastrointestinal diagnostics, and gastrointestinal therapeutics. *WJG* is dedicated to become an influential and prestigious journal in gastroenterology and hepatology, to promote the development of above disciplines, and to improve the diagnostic and therapeutic skill and expertise of clinicians.

**INDEXING/ABSTRACTING** *World Journal of Gastroenterology* is now indexed in Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®), Journal Citation Reports®, Index Medicus, MEDLINE, PubMed, PubMed Central, Digital Object Identifier, and Directory of Open Access Journals. ISI, Journal Citation Reports®, Gastroenterology and Hepatology, 2011 Impact Factor: 2.471 (32/74); Total Cites: 16951 (7/74); Current Articles: 677 (1/74); and Eigenfactor® Score: 0.06035 (5/74).

### Abstract

Intraoperative blood salvage autotransfusion (IBSA) is used in various surgical procedures. However, because of the risk of reinfusion of salvaged blood contaminated by tumor cells, the use of IBSA in hepatocellular carcinoma (HCC) patients undergoing liver transplantation (LT) is controversial. The critical points include whether tumor cells can be cleared by IBSA, whether IBSA increases the risk of recurrence or metastasis, and what are the indications for IBSA. Moreover, is it warranted to take the risk of tumor dissemination by using IBSA to avoid allogeneic blood transfusion? Do the remaining tumor cells after additional filtration by leukocyte depletion filters still possess potential tumorigenicity? Does IBSA always work well? We have reviewed the literature and tried to address these questions. The available data indicate that IBSA is safe in LT for HCC, but randomized, controlled and prospective trials are urgently required to clarify the uncertainty.

**Key words:** Intraoperative blood salvage autotransfu-

sion; Liver transplantation; Hepatocellular carcinoma; Leukocyte depletion filters; Allogeneic blood transfusion

**Core tip:** The use of intraoperative blood salvage autotransfusion (IBSA) in hepatocellular carcinoma (HCC) patients undergoing liver transplantation is controversial as it may reinfuse salvaged blood contaminated by tumor cells. In this article, we reviewed the relevant literature and tried to address the critical questions about IBSA. The available data indicate that IBSA is safe in liver transplantation for HCC, but randomized, controlled and prospective trials are urgently required to clarify the uncertainty.

Controversy over the use of intraoperative blood salvage autotransfusion during liver transplantation for hepatocellular carcinoma patients. *World J Gastroenterol* 2013; 19(22): 3371-3374 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i22/3371.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i22.3371>

### COMMENTARY ON HOT TOPICS

We have read with great interest the recent article by Akbulut *et al*<sup>[1]</sup> describing the effects of intraoperative blood salvage autotransfusion (IBSA) during liver transplantation (LT) in patients with hepatocellular carcinoma (HCC) on tumor recurrence or metastasis, and would strongly recommend it to the readers.

HCC is often associated with chronic hepatitis B and C, particularly in East and Southeast Asia, Middle and Western Africa, and Northern and Eastern Europe, where as high as 85% of HCC patients simultaneously suffer from liver cirrhosis<sup>[2]</sup>. In view of the impaired liver function, elevated portal pressure and increased collateral circulation in these patients, LT has been recommended

as an optimal treatment for HCC as the tumor burden and the underlying liver disease are resolved at the same time<sup>[3]</sup>. However, the decreased synthesis of coagulation factors, elevated portal pressure and increased collateral circulation all increase the risk of hemorrhage during surgery. Intraoperative hemorrhage is currently recognized as a mortality risk and massive blood transfusion is necessary during LT<sup>[4]</sup>.

As a result of the underlying risk of transfusion of banked blood, IBSA has been used in various surgery procedures<sup>[5,6]</sup>. With this technique, blood lost during surgery is recovered and processed through a pump system called cell saver, then transfused back into the patient<sup>[7]</sup>. This requires a system that suctions the wound, separates the blood cells from the other blood products and debris, washes the cells, and returns them to the patient<sup>[1]</sup>. It is estimated that IBSA reduces the intraoperative blood requirement by up to 60%<sup>[1]</sup>. The main complication is dilutional or disseminated coagulopathy<sup>[8,9]</sup>. Another rare complication is pulmonary injury probably linked to leukoagglutinins and transient hemoglobinuria<sup>[10]</sup>. At present, the risk of complications during IBSA has declined due to technical advances, and IBSA has significantly lower adverse events than allogeneic blood transfusion<sup>[11]</sup>. However, the use of IBSA in surgical oncology involving LT in HCC patients is controversial, as it may result in reinfusion of salvaged blood contaminated by tumor cells<sup>[11]</sup>. To date, a few studies have investigated the effects of IBSA system on tumor recurrence in HCC patients undergoing LT<sup>[4,6,11]</sup>.

### Can tumor cells be filtered away by IBSA?

The process of IBSA involves collection of blood, filtration, washing, and reinfusion. The use of IBSA for cancer patients is always performed with caution as blood collected from the operating site is at a high risk of contamination with tumor cells. Tumor cells are detected in 91%-93% of blood samples from surgical sites during various cancer surgical procedures including liver resection for liver metastasis<sup>[12,13]</sup>. During LT for HCC patients, the detection rate of tumor cells in samples from surgical sites was as high as 62.5%<sup>[6]</sup>. Moreover, Hansen *et al*<sup>[13]</sup> has reported that in one-third of cases examined, tumor cells in blood collected from surgical sites showed proliferative capacity by forming cell colonies, invasive capacity by passing the collagen coated membrane *in vitro*, and one cell line displayed tumorigenicity *in vivo*, indicating the underlying hazards of salvaged blood.

The crucial consideration is whether IBSA can effectively filter out the tumor cells. Obviously, the use of IBSA alone is not satisfactory, as tumor cells are detected in 62%-91.2% of blood samples after filtration<sup>[6,11,14,15]</sup>. Leukocyte depletion filters (LDF) with smaller-diameter (3-8  $\mu\text{m}$ ) holes have been recommended to further clear away tumor cells from the collected blood. The high efficacy of LDF in removing tumor cells from blood collected from surgical sites has been reported in patients with HCC and prostate, bladder, lung, breast, endometrial, cervical and ovarian cancers<sup>[11,14-18]</sup>. Catling *et al*<sup>[15]</sup>

reported that LDF removed all the tumor cells in 91.2% of positive samples after LDF with IBSA. Considering the difference in diameters of tumor cells, Liang *et al*<sup>[6]</sup> further compared the positive cell rates by using the IBSA system with and without LDF in HCC patients undergoing LT, and the results showed that only 25% of the positive samples became negative after cell saver processing, while after additional filtration by LDF, only 2 out of 20 patients whose tumors were unexpectedly ruptured during surgery had the collected blood positive for  $\alpha$ -fetoprotein mRNA, and one of these patients was still positive after the second LDF<sup>[6]</sup>. These data indicate that LDF can render IBSA more efficient in eliminating tumor cells from blood collected from surgical sites, and thus reduce the risk of tumor cell reinfusion.

### Does IBSA increase the risk of recurrence or metastasis?

Although more evidence supports application of IBSA in surgical oncology, the fear of reinfusing tumor cells always troubles surgeons. However, in fact, a case report was the only evidence supporting the opinion up to now<sup>[19]</sup>. In 1975, a patient died from diffuse metastasis 4 wk after pneumonectomy. Because of the blood salvaged during surgery and tumor cells detected in salvaged blood, the metastasis was ascribed to the autotransfusion of blood<sup>[19]</sup>. Although the American Medical Association issued an alert about the use of IBSA in cancer surgery in 1986<sup>[11,13]</sup>, some organizations, including the National Institute of Clinical Excellence, the Association of Anaesthetists of Great Britain and Ireland, the Obstetric Anaesthetists Association, the American College of Obstetricians and Gynecologists, and the British Confidential Enquiry of Maternal and Child Health have developed guidelines to support the use of IBSA alone or in combination with LDF in cancer surgery<sup>[11,15,20,21]</sup>.

Notwithstanding the above facts, clinical investigations to clarify the correlation of IBSA with tumor recurrence or metastasis have been carefully conducted in the past few decades. The currently available results have failed to show that IBSA increases the risk of recurrence or metastasis; on the contrary, equivalent or even better outcomes have been reported in patients with various cancers who received IBSA during surgery<sup>[5,6,12,22-25]</sup>.

A study aimed at evaluating the long-term safety of IBSA in hepatectomy for HCC was conducted by Hirano and collaborators<sup>[22]</sup>. Significantly higher 10-year cumulative overall survival and disease-free survival rates were demonstrated in the patients receiving IBSA, particularly patients with stage I / II HCC, but the differences in cumulative survival and cancer-free survival rates of patients with stage III/IV HCC were not significant from those who did not receive IBSA<sup>[22]</sup>. Another study reported similar cumulative overall survival and recurrence rates in the IBSA group and IBSA-free group, but IBSA reduced the mean volume of infused allogeneic blood<sup>[26]</sup>.

To date, three studies have investigated the use of IBSA in LT for HCC<sup>[4,6,11]</sup>. One was to evaluate the efficiency of additional LDF in eliminating tumor cells from IBSA<sup>[6]</sup>; the other two investigated whether IBSA

increased the risk of recurrence or metastasis<sup>[4,11]</sup>. In the study by Muscari *et al*<sup>[4]</sup>, among the 47 HCC patients undergoing LT, 31 patients received IBSA while the other 16 did not. During a mean 34-mo follow-up period, both groups showed similar recurrence rates (6.4% in the IBSA group *vs* 6.3% in the IBSA-free group). In another study, Foltys *et al*<sup>[11]</sup> reported a similar recurrence rate and 5-year survival rate in the IBSA group of 40 patients compared with the IBSA-free group of 96 patients during a mean follow-up period of 1015 d. However, because the two studies lacked a randomized design, heterogeneities existed in age<sup>[11]</sup>, Child score<sup>[4,11]</sup>, the percentage of severe portal hypertension<sup>[4]</sup> and pre-treatment with transarterial chemoembolization<sup>[11]</sup>. In the study by Akbulut *et al*<sup>[11]</sup>, recurrence, overall survival and disease-free survival rates were comparable in the IBSA and non-IBSA groups, which were similar in age, gender, body mass index, underlying disease, donor type, graft-to-recipient weight ratio, Child-Pugh and model for end-stage liver disease scores, number of tumors, tumor size, alpha-fetoprotein level, Milan and University of California San Francisco (UCSF) criteria, tumor differentiation, macrovascular invasion, or median hospital stay.

Without results from prospective, randomized and controlled clinical trials in a large number of subjects, it is difficult at this stage to judge whether the use of IBSA during LT for HCC is more beneficial or not. However, the current available data may at least indicate that IBSA does not increase the risk of recurrence or metastasis.

### What are the indications of IBSA?

Although the current studies partially reduced the fear of the theoretical risk of IBSA during cancer surgery, there are still a series of problems urgently requiring attention.

First, is it justified to take the risk of tumor dissemination during IBSA to avoid or reduce allogeneic blood transfusion? Allogeneic blood transfusion is not a cost-effective method as it is associated with increased risk of transfusion reactions and transfusion-transmitted infections, and induction of immunosuppression<sup>[27]</sup>. In hepatectomy for HCC, autologous blood transfusion has shown benefits in simulating liver synthetic function<sup>[28]</sup>. Moreover, allogeneic blood transfusion also increased the tumor recurrence rate by nearly 2-fold in a dose-dependent manner<sup>[28]</sup>. From the prevailing evidence, it was concluded that the correlation of cancer recurrence and allogeneic blood carried more weight than the theoretical risk of utilizing blood salvage in cancer surgery<sup>[28]</sup>.

Second, do the remaining tumor cells after additional filtration by LDF still possess potential carcinogenicity? It is difficult to answer this question because of lacking of detailed and systemic studies, although the answer has been speculated by some authors<sup>[20,28]</sup>. Only 0.01%–0.000001% of circulating tumor cells have the potential to form metastatic lesions<sup>[20,25,28]</sup>. However, the effect of LDF in eliminating tumor cells is also limited<sup>[25]</sup>. In patients undergoing LT for HCC, a 10% remnant rate

of tumor cells was reported by Liang *et al*<sup>[6]</sup>. However, another fact is that tumor cells ubiquitously exist in circulating blood of cancer patients<sup>[28]</sup>. Although the theoretical risk of the remnant tumor cells after reinfusion has not been verified<sup>[5,6]</sup>, the correlation of circulating tumor cells and poor prognosis has been proved in various cancers<sup>[25,28]</sup>. In the study by Akbulut *et al*<sup>[11]</sup>, more than 50% of patients were beyond the Milan and UCSF criteria in the IBSA group, but the metastasis rate in the IBSA group was similar to that in the non-IBSA group. Based on the above facts, it is difficult to distinguish whether the recurrence or metastasis is caused by the reinfusion or circulating tumor cells, but the risk indeed exists. There is the point of view that if tumor cells are already in circulation, is there any significance to adding a few more<sup>[20,28]</sup>?

Third, does IBSA always work well? Although the scavenging capacity of LDF is far beyond the amount of tumor cells remaining in the reinfusion blood<sup>[6,13]</sup>, the remnant tumor cells appeared in all salvaged blood samples from the HCC patients with ruptured tumors<sup>[6]</sup>. Moreover, IBSA showed less benefit for patients with stage III/IV HCC than for those with stage I/II HCC, when compared respectively with corresponding patients without IBSA<sup>[22]</sup>. The results warn against the application of IBSA in patients with more tumor cells in salvaged blood, such as patients with ruptured tumors or advanced HCC, which may exceed the filtering capacity of IBSA.

In conclusion, IBSA is a safe procedure of blood salvage in LT for HCC based on the available evidence to date. However, well-designed, randomized, controlled, prospective trials are urgently required to clarify the existing concerns.

### Abstract

Non-alcoholic fatty liver disease (NAFLD) is currently not a component of the diagnostic criteria for metabolic syndrome (MetS); however, the development of NAFLD has some common mechanisms with the development of MetS, as they share the pathophysiologic basis of insulin resistance. It is also recognized that NAFLD is the hepatic manifestation of MetS. To define MetS, the presence of at least three of the proposed criteria is required, and sometimes it is sufficient to have only one laboratory value, modified by diet or drugs, for the classification of MetS. Ultrasonographically-detected NAFLD (US-NAFLD) is more stable, only changing during the middle- to long-term. Although controversies over MetS continue, and considering that abdominal ultrasonography for diagnosing NAFLD has high specificity and guidelines to modify the natural course of NAFLD by diet composition or lifestyle have not yet been established, why should we not introduce US-NAFLD as a new criterion to define MetS?

### INTRODUCTION

Non-alcoholic fatty liver disease (NAFLD) is characterized by the accumulation of fat in the liver when it exceeds 5%-10% of its weight<sup>[1]</sup>. In addition to leading to major histopathological alterations, it may be associated with elevated liver enzymes and abnormal liver function, ranging from steatosis to steatohepatitis, fibrosis, and cirrhosis<sup>[2,3]</sup>. Although diagnosed worldwide, its prevalence varies, reaching approximately 20%-30% in western countries<sup>[4]</sup>. In the United States, where 25% of the adult population is obese, the disease occurs in more than two-thirds of these individuals and in more than 90% of class III obese individuals<sup>[5]</sup>. It is estimated that 2% to 3% of the population has nonalcoholic steatohepatitis (NASH)<sup>[6,7]</sup>.

Approximately 74%-90% of patients who undergo liver biopsy show alterations due to triacylglycerol accumulation<sup>[8]</sup>. The disease is highly prevalent (88.7%) in obese patients undergoing bariatric surgery<sup>[9]</sup>, and the likelihood of developing steatohepatitis is increased in class III obesity, with 15%-20% of these patients diagnosed with NASH<sup>[10]</sup>.

Some studies have shown an increased prevalence and higher incidence of cardiovascular disease (CVD) in individuals with NAFLD. These studies have shown hepatic

steatosis as an independent risk factor for the development of this disease<sup>[11,12]</sup>.

Metabolic syndrome (MetS), which involves the combination of risk factors for CVD such as insulin resistance, abdominal fat, dyslipidaemia, glucose intolerance, and hypertension, has often been associated with more severe liver abnormalities<sup>[13]</sup>.

NAFLD is now considered to be the hepatic component of the MetS<sup>[14,15]</sup>.

Conventional radiology studies used in the diagnosis of fatty liver include ultrasonography (US), computed tomography, and magnetic resonance imaging. Other than these radiological studies, there are no sensitive and low invasive screening methods for NAFLD. Alanine aminotransferase (ALT) > 30 IU/L is usually used as the cut off level for screening NAFLD<sup>[16,17]</sup>. This threshold had a sensitivity of 0.92 for detecting the fatty-fibrotic pattern proven by ultrasound among obese children<sup>[18]</sup>. However, ALT was within normal levels in 69% of those who had increased liver fat<sup>[19]</sup>. Similarly, in the Dallas Heart Study, 79% of the subjects with a fatty liver (liver fat content > 5.6%) had normal serum ALT<sup>[20]</sup>. This implies that a normal ALT does not exclude steatosis. Aspartate aminotransferase and gamma glutamyltransferase also correlate with liver fat content independent of obesity<sup>[21]</sup>, but are even less sensitive than serum ALT.

It is well known that NAFLD mirrors insulin resistance, and patients with NAFLD tend to have the abnormal components of the MetS. However, the target for correctly detecting MetS has not yet been met.

## METABOLIC SYNDROME: DEFINITION, IMPORTANCE AND PATHOPHYSIOLOGY

### Definition

MetS identifies patients at increased risk of developing CVD and type 2 diabetes mellitus. As it is a clustering of different risk factors, and its pathogenesis is not well understood, this has given rise to the development of multiple concurrent definitions. Central obesity and insulin resistance are acknowledged as important causative

**Table 2 International Diabetes Federation: Definitions of metabolic syndrome**

| Central obesity plus any two of the following four factors |  |
|--|--|
| Raised triglyceride  | 150 mg/dL, or specific treatment for this lipid abnormality  |
| Reduced HDL-C  | < 40 mg/dL in men and < 50 mg/dL in women, or specific treatment for this lipid abnormality  |
| Raised BP  | Systolic BP 130 or diastolic BP 85 mmHg, or treatment of previously diagnosed hypertension   |
| Raised FPG   | 100 mg/dL, or previously diagnosed type 2 diabetes. If above 100 mg/dL, OGTT is strongly recommended but is not necessary to define presence of the syndrome |

OGTT: Oral glucose tolerance test; FPG: Fasting plasma glucose; HDL-C: High-density lipoprotein-cholesterol; BP: Blood pressure.

factors<sup>[22-24]</sup>, together with other associated conditions, including physical inactivity<sup>[25]</sup>, ageing<sup>[26]</sup> and hormonal imbalance<sup>[27,28]</sup> such as polycystic ovary syndrome or testosterone insufficiency.

The concept of clustering of risk factors was first described by Reaven<sup>[29]</sup>, when the term “insulin resistance syndrome” was conceived. However, as the mechanisms underlying the link to CVD risk factors remain uncertain and insulin resistance is not easily measured in clinical practice, the more recent consensus, *e.g.*, 2001 National Cholesterol Education Programme (NCEP) Adult Treatment Panel III (ATP III)<sup>[30]</sup> (Table 1) and the 2006 International Diabetes Federation (IDF) criteria<sup>[31]</sup> (Table 2), favours focusing on other clinical parameters that are easier to measure. It is, therefore, imperative to bear in mind that as the newer criteria do not include insulin resistance as one of its diagnostic criteria, individuals diagnosed as having the syndrome using these criteria may not necessarily be insulin resistant. This is in contrast to the 1999 World Health Organization (WHO)<sup>[32]</sup> and the 1999 European Group for the Study of Insulin Resistance<sup>[33]</sup> criteria, which emphasise insulin resistance. The IDF consensus, however, takes into account the importance of gender and ethnic differences in predicting early cardiovascular risk and may indeed be a better predictor for risk in women<sup>[34]</sup> and specific ethnic groups, *e.g.*, South Asians (Indians), who appear to be more susceptible to the development of MetS at waist circumferences below that of the NCEP/ATP III cutpoints<sup>[35]</sup> (Table 3). It is also worth noting that the NCEP/ATP III criteria were revised in 2004, where the threshold for fasting glucose was lowered to  $\geq 100$  mg/dL (5.6 mmol/L) in concordance with American Diabetes Association criteria for impaired fasting glucose (IFG)<sup>[36]</sup>. Hence, in view of the various diagnostic criteria used, care will need to be exercised when interpreting clinical studies related to MetS.

### Importance

MetS continues to be highly prevalent and contributes to a rapidly growing problem globally. About 40% of adults in the US population are estimated to have MetS by the

**Table 3** Central obesity defined according to the International Diabetes Federation

| Country/ethnic group  | WC              |
|---|-----------------|
| Europids (In the United States, the NCEP-ATP III values <sup>1</sup> are likely to continue to be used for clinical purposes) |                 |
| Male  | ≥ 94 cm (37 in) |
| Female  | ≥ 80 cm (32 in) |
| South Asians (based on a Chinese, Malay, and Asian-Indian population)   |                 |
| Male  | ≥ 90 cm (35 in) |
| Female  | ≥ 80 cm (32 in) |
| Chinese   |                 |
| Male  | ≥ 90 cm (35 in) |
| Female  | ≥ 80 cm (32 in) |
| Japanese  |                 |
| Male  | ≥ 85 cm (34 in) |
| Female  | ≥ 90 cm (32 in) |

<sup>1</sup>102 cm, 40 in, male; 88 cm, 35 in, female. NCEP: National Cholesterol Education Programme; WC: Waist circumference; ATP: Adult Treatment Panel.

age of 60 years<sup>[26,37]</sup>. At least one-fourth of the adult European population may have MetS<sup>[38-40]</sup>, with a similar prevalence in Latin America<sup>[41]</sup>. MetS is also considered an emerging epidemic in developing Asian countries, including Singapore, China, Japan and South Korea, with a prevalence of 8%-13% in men and 2%-18% in women, depending on the population and definitions used<sup>[42-44]</sup>.

### Pathophysiology

There have been several proposed hypotheses for the development of MetS. One such widely quoted hypothesis suggests that adipose tissue dysfunction is the underlying cause, resulting in abnormal metabolism of free fatty acids and the release of adipocytokines which are responsible for the observed inflammatory changes and insulin resistance<sup>[45-47]</sup>. Adipose tissue is in itself an endocrine organ that is metabolically active, rather than purely an energy storage organ<sup>[48-51]</sup>. Adiponectin is secreted exclusively by adipocytes in adipose tissue, and low levels in individuals have consistently predicted the presence of MetS and CVD risk<sup>[52-56]</sup>. In fact, adiponectin can be measured reliably in a clinical setting; its circulating values do not undergo diurnal fluctuation as much as other markers such as insulin, glucose or triglycerides, and only a small amount is required for its measurement, making this a potentially suitable biomarker for MetS<sup>[57,58]</sup>. Resistin<sup>[23,59,60]</sup> and visfatin<sup>[61-64]</sup> are the other adipocytokines implicated in the pathogenesis of MetS.

An alternative proposed aetiology suggests an underlying state of chronic, low-grade inflammation<sup>[65-67]</sup>, leading to endothelial dysfunction and the release of inflammatory cytokines, which induce insulin resistance in adipose tissue and muscle<sup>[67,68]</sup>. Indeed, insulin-resistant individuals manifest evidence of low-grade inflammation even without an increase in total body fat<sup>[69]</sup>.

Excess visceral fat accumulation may be causally related to the features of insulin resistance, but might also be a marker of dysfunctional adipose tissue which is unable to

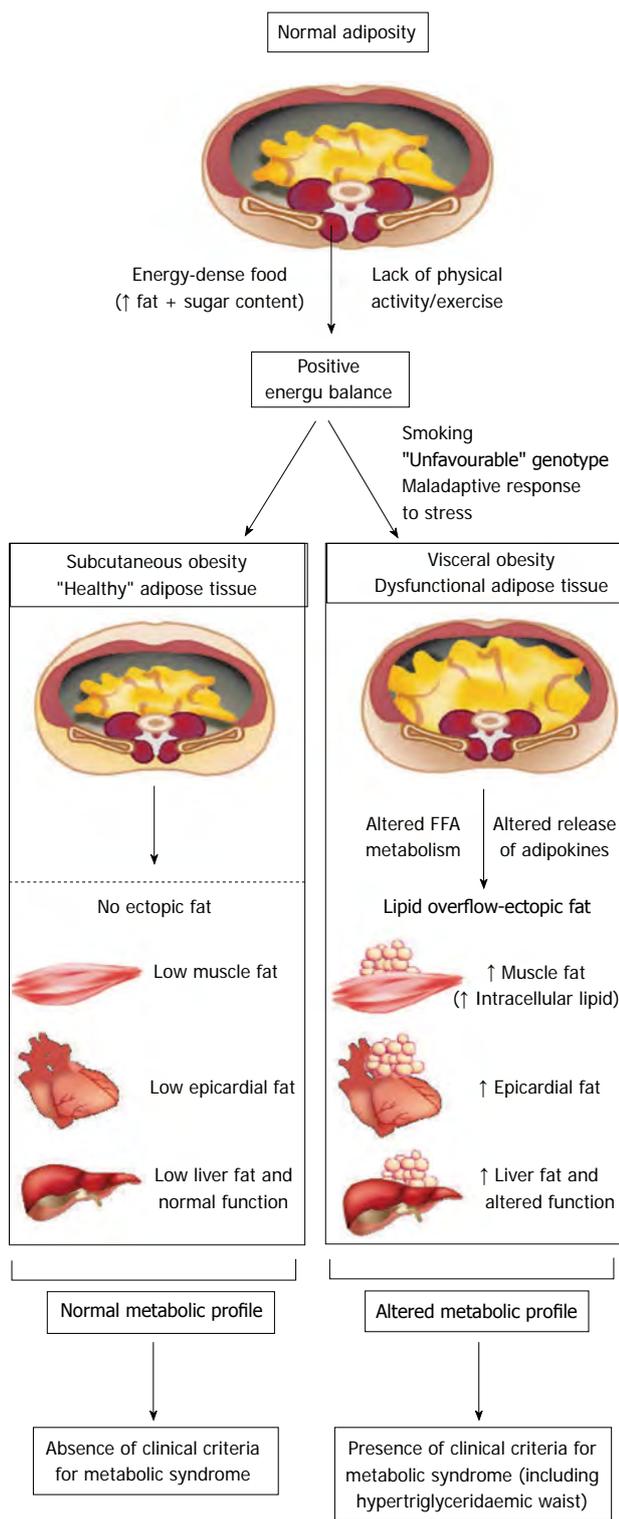

appropriately store the energy excess (Figure 1). According to this model, the body's ability to cope with the surplus of calories (resulting from excess caloric consumption, a sedentary lifestyle or, as is often the case, a combination of both factors) might, ultimately, determine the individual's susceptibility to developing MetS. There is evidence to suggest that if the extra energy is channelled into insulin-sensitive subcutaneous adipose tissue, the individual, although in positive energy balance, will be protected against the development of MetS. However, in cases in which adipose tissue is absent, deficient or insulin resistant with a limited ability to store the energy excess, the triacylglycerol surplus will be deposited at undesirable sites such as the liver, the heart, the skeletal muscle and in visceral adipose tissue - a phenomenon described as ectopic fat deposition. Factors associated with the preferential accumulation of visceral fat and with features of insulin resistance include, among others, smoking, the well documented genetic susceptibility to visceral obesity<sup>[70]</sup> and a neuroendocrine profile related to a maladaptive response to stress<sup>[71]</sup>. The resulting metabolic consequences of this "defect" in energy partitioning include visceral obesity, insulin resistance, an atherogenic dyslipidaemia and a pro-thrombotic, inflammatory profile. These are defining features of MetS.

This constellation of abnormalities can be detected by the clinical criteria for MetS, the two simplest being the simultaneous presence of increased waist girth and fasting triacylglycerol levels, a condition that has been described as "hypertriglyceridaemic waist"<sup>[72]</sup>.

It is noteworthy to stress that the identification of other risk factors might improve knowledge on the pathogenesis of NAFLD and open the way to new therapeutic approaches<sup>[73-75]</sup>. The debate surrounding the mechanisms inducing or favouring the presence/severity of NAFLD continues. In fact, some investigators have identified factors other than MetS to be associated with NAFLD<sup>[76-78]</sup>.

### RECENT CONTROVERSY

Although the MetS has existed in various forms and definitions for more than eight decades, only in the past 5 years has real controversy about its definition and significance emerged<sup>[79,80]</sup>. The main controversy is that the syndrome has had too many definitions and there is a lack of clarity about its role and value in clinical practice<sup>[81]</sup>. It is fair to say, with exceptions<sup>[82]</sup>, that most of the published reports indicate that the syndrome does not predict cardiovascular events or disease progression any better than the sum of its components<sup>[3,83,84]</sup>. The relative value in predicting type 2 diabetes remains uncertain<sup>[85]</sup>. The controversy, however, drove the need for a single global definition. Thus, came the initiative of the IDF and the American Heart Association/National Heart, Lung, and Blood Institute, joined by the World Heart Federation, International Atherosclerosis Society, and International Association for the Study of Obesity<sup>[79]</sup> to develop one unified definition<sup>[86]</sup>.

**Figure 1** The lipid overflow-ectopic fat model. FFA: Free fatty acid.

The main difference between the NCEP ATP III (National Cholesterol Education Program Expert Panel on Detection, Evaluation, and Treatment of High Blood Cholesterol in Adults)<sup>[87]</sup> and the IDF definitions<sup>[88]</sup> was that the IDF had a threshold value for waist circumference as obligatory. As a major step in consensus, this obligation has been reversed so that we now have a platform

for standardised reporting in epidemiological and clinical research<sup>[81]</sup>. Yet, because the relation between waist circumference and CVD and diabetes risk differs globally, the definition for the expanded waist circumference remains unsettled. In the meantime, national or regional cutpoints for waist circumference can be used.

Insulin resistance continues to explain most, if not all of the MetS. In fact, no other mechanisms have emerged that come close to justifying the individual components or their clustering. Evidence now indicates that the MetS begins with excess central adiposity<sup>[89]</sup>. When  $\beta$ -cell function is responsive, hyperinsulinaemia results but fasting and postprandial glycaemia often remain normal for years. However, in those genetically predisposed, defects in insulin secretion and IFG and/or impaired glucose tolerance follow<sup>[90]</sup>.

Most controversial has been the mechanism of hypertension under the tent of insulin resistance. However, not only are the effects of insulin on sodium reabsorption and sympathetic nervous system activation maintained despite insulin resistance, but increases in angiotensinogen, resistin, and leptin secretion from adipose tissue have also been implicated in the pathophysiology of hypertension in the syndrome<sup>[91]</sup>. Moreover, insulin resistance is closely associated with abnormalities in nitric oxide (NO) bioavailability and reduced phosphatidylinositol 3-kinase/protein kinase B signalling in the vascular wall, both of which have a crucial role in mobilisation of endothelial progenitor cells from bone marrow<sup>[91]</sup>. Not only do higher levels of free fatty acids directly reduce NO-dependent vasodilatation, but insulin resistance itself also results in structural or functional damage to the endothelium and apoptosis<sup>[91]</sup>. Reparative processes that regenerate injured endothelium might be increased by agents such as peroxisome proliferator-activated receptor  $\gamma$  agonists that enhance insulin sensitivity, an effect mediated by endothelial progenitor cells<sup>[92]</sup>.

Genetic predisposition also relates to the MetS. A recent study found that a polymorphism in the multi-PDZ domain-containing adaptor protein, a protein that regulates the high-density lipoprotein-receptor scavenger-receptor type B class 1, was associated with the MetS<sup>[93]</sup>. Shift work, sleep deprivation, and bright-light exposure at night also relate to increased adiposity and prevalence of the MetS; clock genes are expressed in adipose tissue, and both their levels of expression and their genetic variants correlate with different components of the syndrome<sup>[94]</sup>.

Another area of recent interest is vitamin D. Increasing evidence indicates that vitamin D deficiency is associated with the risk of CVD. Particularly relevant is a study that examined the association of serum vitamin D concentrations with risk factors for CVD in US adolescents<sup>[95]</sup>.

The hypothesis that the MetS is an outgrowth of insulin resistance provides a strategy for management. Weight loss often reduces insulin resistance; and caloric restriction, weight-loss drugs, and bariatric surgery have been proved to be effective.

Although long-term weight reduction through dietary and pharmacological means is theoretically possible, most dietary and weight-loss drug studies have only continued for a few years. In contrast, in one 10-year follow-up after bariatric surgery<sup>[96]</sup>, weight loss of 25% and improvement in the MetS were achieved; total mortality was also reduced. Even in the absence of weight loss, long-term physical activity, as measured by cardiorespiratory fitness, prevents the MetS<sup>[97]</sup>, reduces cancer incidence and related mortality, and all-cause mortality<sup>[98]</sup>.

Finally, one class of drugs that reduces insulin resistance and many of the components of the syndrome is the thiazolidinediones. These drugs act mainly in adipose tissue to favourably modify secretions of products that contribute to the pathophysiology of the MetS, including free fatty acids and adipocytokines. The major effect of thiazolidinediones is on dysglycaemia, which accounts for their use in the treatment of diabetes, yet the class as a whole has anti-inflammatory effects. At present, however, drug therapy for the MetS largely requires separate agents for the treatment of dysglycaemia, dyslipidaemia, and hypertension<sup>[99]</sup>.

The MetS is a widely accepted concept that identifies the centrally obese patient with increased risk for CVD and diabetes. A global definition has now been proposed, insights into aetiology and mechanisms have been furthered, and, despite the controversies, lifestyle interventions remain the primary therapy. After lifestyle, residual risk for CVD needs to be treated with appropriate drugs.

## US AND NAFLD

US is currently the most common method for screening asymptomatic patients with elevated liver enzymes and suspected NAFLD<sup>[100]</sup>. US findings of fatty liver include hepatomegaly, diffuse increases in the echogenicity of the liver parenchyma, and vascular blunting.

Nonsteatotic hepatic parenchyma exhibits an echotexture similar to that of renal parenchyma, but becomes “brighter” when infiltrated with fat<sup>[101]</sup>. This hepatorenal contrast can be used to detect hepatosteatosi<sup>[102,103]</sup>. However, bright liver contrast associated with fibrosis is discussed in the literature<sup>[103]</sup>. US is easily performed and has a low cost, however, it also has limitations. It is operator dependent and subject to significant intra- and inter-observer variability<sup>[104]</sup>. It is impossible for US to provide quantitative information about the degree of fat accumulation. The sensitivity of US to detect steatosis decreases with a degree of fat infiltration less than 30%<sup>[105]</sup>. In obese patients, sensitivity lower than 40% has been reported in the detection of hepatosteatosi<sup>[106]</sup>. Finally, US has failed to prove efficacious in the detection of inflammation and fibrosis, therefore, it cannot be utilized to diagnose NASH and hepatic fibrosis<sup>[107]</sup>. However, in a recent study, Iijima *et al.*<sup>[108]</sup> used an ultrasound contrast agent (Levovist; Sherling, Berlin, Germany) to distinguish between simple steatosis and NASH. Levovist contains galactose and palmitic acid and is taken up by hepatocytes<sup>[109]</sup>. These

moieties participate in sugar and fat metabolism<sup>[110]</sup>. The uptake of Levovist was observed to significantly decrease in NASH patients, thus correlating with fibrosis rather than steatosis<sup>[108]</sup>. Larger studies are needed to evaluate the use of contrast US in the diagnosis of NASH characterised by inflammation and fibrosis, although there is a no absolute consensus in separating NASH from simple fatty liver as two distinct entities.

## FUTURE REMARKS

The MetS is associated with abdominal obesity and its criteria include waist circumference<sup>[30,31]</sup>. In addition, NAFLD has been reported to be associated with abdominal obesity<sup>[110]</sup>.

The presence of multiple metabolic disorders such as diabetes mellitus, obesity, dyslipidaemia and hypertension is associated with a potentially progressive, severe liver disease<sup>[14,111-115]</sup>. Previous reports demonstrated that the prevalence of NAFLD increased to 10%-80% in individuals with obesity, 35%-90% in individuals with type 2 diabetes mellitus, 30%-56% in individuals with hypertension, and 26%-58% in individuals with dyslipidaemia<sup>[116-119]</sup>.

It is clinically critical that a large number of patients with NAFLD were not diagnosed with the MetS, when we used today’s definition of the MetS<sup>[120]</sup>. Why not change the approach and use the presence of NAFLD as a new criterion for detecting the MetS?

Recently, it was shown that ultrasonographically-detected NAFLD (US-NAFLD) is an independent predictor for identifying patients with insulin resistance in non-obese, non-diabetic middle-aged Asian adults<sup>[121]</sup>. Therefore, US-NAFLD may identify individuals with insulin resistance that cannot be identified by MetS in this population<sup>[121]</sup>.

On this basis, we believe that this suggestion, *i.e.*, the inclusion of NAFLD could help initiate weight control at the “earliest possible time” in the progression of disease, *i.e.*, obesity/MetS, which means diagnosing NAFLD earlier rather than later, using the simplest method possible, *i.e.*, at US<sup>[110]</sup>.

## CONCLUSION

NAFLD is highly prevalent and is considered the hepatic component of the MetS. The WHO, the NCEP-ATP III and the IDF have different criteria to define MetS. The MetS is associated with NAFLD, with the WHO definition being the best to determine its presence, probably due to the inclusion of insulin resistance as a main component. Unification of criteria is needed to adequately compare the prevalence of MetS and its relationship with NAFLD in different population, however, this is very hard task.

Further study will be needed to verify whether the inclusion of steatosis in the panel of MetS indicators will improve the predictive power of cardiovascular risk bet-

ter than the current MetS criteria.

To define MetS, the presence of at least three of the proposed criteria is required, however, sometimes it is sufficient to have only one laboratory value, modified by diet or drugs, for the classification. US-NAFLD detection is more stable, and changes in the middle-to-long term. Although the controversy surrounding the utility of the MetS continue, considering that abdominal US in the diagnosis of NAFLD has a sensitivity of 91.7% and a specificity of 100%<sup>[122]</sup> and guidelines to modify the natural course of NAFLD by diet composition or lifestyle have not been established<sup>[123]</sup>, why should we not introduce US-NAFLD as a new criterion to define MetS?

### Abstract

The discovery of induced pluripotent stem cells (iPSCs) unraveled a mystery in stem cell research, after identification of four re-programming factors for generating pluripotent stem cells without the need of embryos. This breakthrough in generating iPSCs from somatic cells has overcome the ethical issues and immune rejection involved in the use of human embryonic stem cells. Hence, iPSCs form a great potential source for developing disease models, drug toxicity screening and cell-based therapies. These cells have the potential to differentiate into desired cell types, including hepatocytes, under *in vitro* as well as under *in vivo* conditions given the proper microenvironment. iPSC-derived hepatocytes could be useful as an unlimited source, which can be utilized in disease modeling, drug toxicity testing and producing autologous cell therapies that would avoid immune rejection and enable correction of gene defects prior to cell transplantation. In this review, we discuss the induction methods, role of reprogramming factors, and characterization of iPSCs, along with hepatocyte differentiation from iPSCs and potential applica-

### INTRODUCTION

Patients suffering from chronic end-stage liver disease are currently receiving inadequate treatment due to the lack of organ donors for transplantation<sup>[1]</sup>. Alternatively, cell-based therapies are gaining importance as supportive therapy. Hepatocytes (adult, fetal) and liver stem cells form promising sources for cellular therapies in the treatment of liver diseases. However, inadequate proliferation, ethical issues and scanty numbers limit their applicability<sup>[2-5]</sup>. Therefore, it is essential to think outside the liver in favor of generating hepatocytes for drug screening, disease modeling and cell therapy applications. Identification of four reprogramming transcription factors revolutionized stem cell research in generating induced pluripotent stem cells (iPSCs). iPSCs generated from somatic cells can be utilized not only for cell-based therapies, but also for disease modeling and drug toxicity screening. Patient-specific iPSCs can be generated by reprogramming and differentiating somatic cells from the patient into the desired cell type. Key advantages of iPSCs over current transplantation approaches are that

they form an unlimited potential source and are patient-specific. In addition, the possibility of correcting genetic defects in liver diseases is currently under investigation<sup>[6]</sup>.

The identification of patient-specific pluripotent stem cells has long been an important goal for scientists working in the field of stem cells. In 2006, Takahashi *et al*<sup>[7]</sup> first reported that forced expression of four transcription factors [octamer-binding transcription factor (Oct) 3/4, SRY box-containing gene 2 (Sox2), Kruppel-like factor 4 (Klf4) and c-Myc] reprogrammed mouse somatic fibroblasts into embryonic stem cell (ESC)-like colonies, which were termed iPSCs. Later, human induced pluripotent stem cells (hiPSCs) were generated from embryonic, neonatal and adult fibroblasts<sup>[8-10]</sup>. In addition, derivation of patient-specific iPSCs for various diseases/disorders has also been reported<sup>[11-15]</sup>. Recently, several groups have investigated the possibilities of disease modeling using patient-derived iPSCs<sup>[6,16-23]</sup>. Apart from all these applications, hepatocytes derived from iPSCs will have larger implications in drug toxicity studies. Before iPSCs, several approaches were used to reprogram the differentiated cells to a pluripotent state. In the beginning, patient-specific human embryonic stem cells (hESCs) were derived using somatic cell nuclear transfer or therapeutic cloning. This technique requires the introduction of a nucleus from an adult donor cell into an enucleated oocyte to generate a nuclear transfer embryo. The objective of this technique is to produce pluripotent hESCs that carry the nuclear genome of the patient and then induce them to differentiate into cells which may be transplanted back into the patient<sup>[24-28]</sup>. Another method is the fusion of fibroblasts with ESCs<sup>[29,30]</sup>. However, the therapeutic application of either approach has been experiencing both ethical and technical difficulties, summarized in Table 1.

## METHODS TO GENERATE iPSCs

It was demonstrated that somatic cells can be re-programmed into pluripotent stem cells by ectopic expression of four transcription factors, namely Oct4, Klf4, Sox2, and c-Myc, using four independent retroviral vectors<sup>[7]</sup>. This achievement revolutionized stem cell research. Initially, iPSCs were derived from somatic cells by the retroviral or lentiviral transduction of transcription factors in which transgenes are randomly inserted into the genome of the hosts. Such integration of transgenes has the risk of tumorigenicity<sup>[31]</sup>. Later, trials to omit transgenic insertion of c-Myc resulted in low reprogramming efficiency and did not eliminate the risk of tumor formation<sup>[32]</sup>, as overexpression of Oct3/4 and Klf4 can also cause tumor formation<sup>[33]</sup>. In Table 2, we have summarized the advantages and disadvantages of various strategies used for inducing iPSCs generation<sup>[7,8,9,32,34-49]</sup>. Furthermore, combining all four factors (Oct4, Klf4, Sox2, and c-Myc) into a single vector allowed derivation of iPSCs with a single lentiviral stem cell cassette containing a loxP sequence in the long terminal repeat (LTR)<sup>[43]</sup>. Following this, transgenes were removed using Cre-mediated excision. Although it left an incomplete LTR in the iPS genome, this method mini-

mized the genomic alteration<sup>[44]</sup>. A transposon system encoding a reprogramming cassette has also been used for iPSC induction. The transduction of a plasmid-based transposon vector can integrate into the host genome with the help of transposase, and induces iPSC colony formation. The re-expression of the transposase after the establishment of iPSCs recognizes the terminal repeat of the integrated transposon vector, and excises it from the genome. The excision of the transposon does not leave a footprint in most cases, so it maintains the original endogenous sequences<sup>[45,46,50,51]</sup>. Several techniques have been used for obtaining transgene-free iPSCs.

The first integration-free iPSCs were generated from adult mouse hepatocytes using non integrating adenoviral vectors. However, this required repeated transduction to maintain transgene expression<sup>[34,38]</sup>. Another technique used is transduction with the Sendai virus, an RNA virus, to deliver the reprogramming factors<sup>[35]</sup>. The Sendai virus does not integrate into the genome, but working with this system requires more than 15 passages to eliminate viral transgene expression. This complexity limits the general use of this method<sup>[48]</sup>. Transient transfection of plasmids, episome-based DNA vectors and minicircle vectors has been used to generate transgene-free iPSCs. Mouse embryonic fibroblasts were reprogrammed by repeated transfection with two plasmid constructs carrying the reprogramming factors; the first plasmid expressed c-Myc, while the second expressed the other three factors Oct4, Klf4 and Sox2<sup>[36]</sup>. Furthermore, experiments with non-integrating episomal vectors have also been successful in iPSC generation<sup>[16]</sup>. Similarly, minicircle vectors lack the bacterial origin of replication and antibiotic resistance gene and offer higher transfection efficiencies and more prolonged transgene expression as compared to regular plasmids<sup>[52]</sup>. Moreover, iPSCs have been established by the direct delivery of recombinant reprogramming proteins<sup>[38]</sup> and small molecules<sup>[39]</sup>. More recently, one research group has utilized synthetic mRNA molecules to reprogram human fibroblasts to pluripotency and stimulate them into myogenic cells<sup>[32]</sup>. However, reprogramming using modified RNAs is technically difficult, sensitive to reagents and requires labor-intensive procedures. The efficiency of iPSC induction using transgene-free methods is lower than that with retrovirus vectors, possibly due to low transduction efficiency and unstable expression. Therefore, it is essential to develop methods that require less time and have higher efficiency of reprogramming involving viral and transgene-free techniques to generate iPSCs.

## REPROGRAMMING FACTORS

Takahashi *et al*<sup>[7]</sup> used a combination of four nuclear reprogramming factors, such as Oct4, Sox2, c-Myc and Klf4, for generating iPSCs from mice and reported an efficiency of 0.02%. Simultaneously, the Thomson group used a slightly different combination of factors, namely Oct4, Sox2, Nanog and Lin28, to reprogram human somatic cells at a similar efficiency (0.02%)<sup>[9]</sup>. Subsequently,

**Table 1** New approaches to reprogramming of differentiated cells to a pluripotent state

| Method  | Results of reprogramming   | Drawbacks   | Ref.    |
|---|--|---|---------|
| Transfer of the nucleus from a somatic cell to an enucleated oocyte   | The somatic cell nucleus is reprogrammed in the oocyte, and a whole organism develops as a result. Patient-specific hESCs can be derived | Low efficiency. Developmental abnormalities in cloned animals. Ethical and legal restrictions | [24-28] |
| Fusion of ESCs with differentiated cells  | Hybrids of differentiated cells and ESCs display all properties of pluripotent cells   | Cell hybrids lack a normal diploid chromosome set   | [29,30] |
| Reprogramming of somatic cells to a pluripotent state can be generated by the ectopic expression of 4 transcription factors, Oct4, Klf4, Sox2 and c-Myc | Somatic cells regain a pluripotent state and become similar in properties to ESCs  | Low efficiency of iPSC derivation. Viral integration. Tumor formation                         | [7]     |

ESCs: Embryonic stem cells; hESCs: Human embryonic stem cells; iPSC: Induced pluripotent stem cell; Oct: Octamer-binding transcription factor; Sox2: SRY box-containing gene 2; Klf4: Kruppel-like factor 4.

**Table 2** Various induction methods to generate induced pluripotent stem cells

| Methods                         | Advantages   | Disadvantages                                    | Ref.           |
|---------------------------------|--|--|----------------|
| Retroviral vectors              | High efficiency                                    | Genome integration, dividing target cells needed | [7-9,32,41,42] |
| Lentiviral vectors              | High efficiency, target cells need not be dividing | Genome integration                               | [47-49]        |
| Lentiviral vectors with Cre/Lox | High efficiency                                    | Minimize genomic integration                     | [43,44]        |
| Piggyback transposon            | Precise deletion is possible                       | Minimize genomic integration, laborious          | [45,46]        |
| Viral vectors                   | No genome integration                              | Low efficiency                                   | [34-37]        |
| Adenoviral vectors              |  |  |                |
| Sendai vectors                  |  |  |                |
| DNA vectors                     |  |  |                |
| Plasmid vectors                 |  |  |                |
| Episomal vectors                |  |  |                |
| Minicircle vectors              |  |  |                |
| Protein transduction            | No genome integration                              | Low efficiency                                   | [38]           |
| Small molecules                 | No genetic modification                            | Low efficiency                                   | [39]           |
| Synthetic mRNA                  | No genetic modification, high efficiency           | Multiple rounds of transfection are needed       | [40]           |

researchers have started to identify new reprogramming factors and usage of minimum factors for generating safe iPSCs. iPSCs have been established by 3 transcriptional factors without c-Myc (Oct3/4, Klf4, SOX2) at an efficiency of 0.002%<sup>[53,54]</sup>. It was also shown that using only Oct4 and Klf4 was enough to reprogram murine NSCs at an efficiency of 0.11%<sup>[55]</sup>. More recently, the forced expression of Oct4 alone was shown sufficient to reprogram murine NSCs, at a low efficiency of 0.014%<sup>[56]</sup>. However, the efficiency of iPSC generation has been significantly reduced with usage of minimum factors for generating safe iPSCs. The *Oct4*, *Sox2*, and *Nanog* genes code for transcription factors that activate the genes and signaling pathways responsible for the establishment and maintenance of the pluripotent state and repress the genes responsible for differentiation<sup>[57,58]</sup>. Others have reported that the expression of *Oct4* and *Sox2* genes is absolutely essential for iPSC generation. In addition, the products of the *Nanog*, *c-Myc*, *Klf4* and *Lin28* genes seem to act as catalysts which accelerate the reprogramming<sup>[59]</sup>. In Table 3, we have summarized the role of various reprogramming factors for iPSC generation<sup>[60-66]</sup>.

Recently, molecules have been used in combination with reprogramming factors to improve the efficiency of iPSC generation, including cotransduction of the catalytic subunit of human telomerase, human telomerase reverse transcriptase, along with SV40 large T antigen, or the

repression of the *Ink4a/Arf* locus (encoding cell cycle-dependent kinase inhibitors), or repression of the p53/p21 pathway. These efforts have led to dramatic increases in the efficiency of reprogramming<sup>[10,67-69]</sup>.

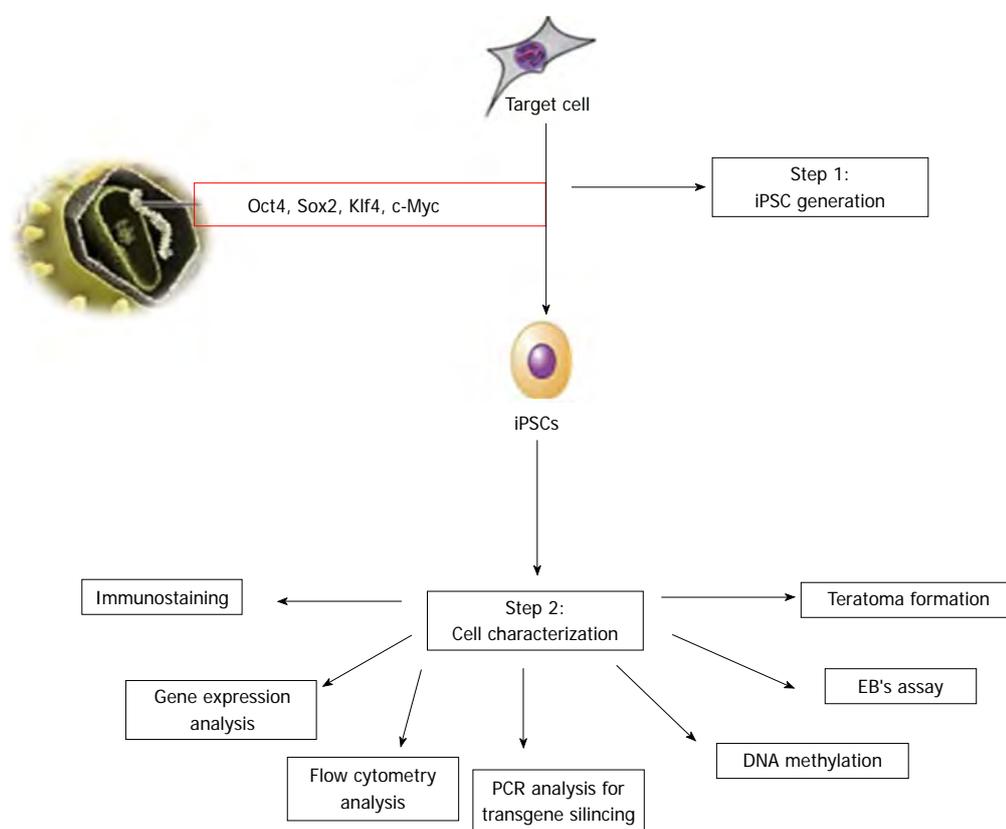

## CHARACTERIZATION OF iPSCs

The hiPSCs generated can be characterized for their pluripotency, as shown in Figure 1. In addition, assessment of their epigenetic status, silencing of transgene expression and DNA fingerprinting need to be established for confirmation. Assessment of pluripotency of iPSCs can be performed by checking the expression of protein and genes of Oct4, Sox2, Nanog, as well as for SSEA-1 (mouse) or SSEA-3/-4 and TRA-1-60/-81 (human) using flow cytometry, immunocytochemistry and reverse transcription-polymerase chain reaction (PCR) methods<sup>[70]</sup>. The pluripotent nature of iPSCs is routinely tested by two methods. The first is to determine the *in vitro* differentiation ability of iPSCs, where iPSCs can be allowed to differentiate spontaneously *in vitro* to form embryoid bodies. These embryoid bodies can be assessed for three embryonic germ layers, *i.e.*, mesoderm, endoderm and ectoderm. The second is to determine the *in vivo* differentiation ability of iPSCs<sup>[71]</sup>, where iPSCs can be injected into adult immune-deficient mice (SCID mice). In the host animal, injected iPSCs can form tumors called teratomas.

**Table 3 Role of reprogramming factors for induced pluripotent stem cell generation**

| Reprogramming factors | Description                            | Function  | Ref.    |
|-----------------------|--|---|---------|
| Oct4                  | Octamer binding transcription factor 4 | This transcription factor plays a role in embryonic development, especially during early embryogenesis, and it is necessary for embryonic stem cell pluripotency  | [7]     |
| Sox2                  | SRY box 2                              | In embryonic stem cells, Sox2 and Oct3/4 often co-occupy target genes, including own promoters. These proteins cooperate regulatory feedback loops to maintain pluripotency   | [60]    |
| Klf4                  | Kruppel-like factor 4                  | This transcription factor plays a role in upregulation of pluripotency gene <i>Nanog</i> and the modification of chromatin structure to facilitate the binding of Oct3/4 and Sox2 to their sequences. Klf4 itself is an oncogenic factor. This gene is over expressed in a variety of tumor types associated with advanced cancer | [61-63] |
| c-Myc                 | Proto oncogene protein                 | An oncogene that induces global histone acetylation, allowing Oct3/4 and Sox2 to bind to their specific target loci   | [60,63] |
| Nanog                 | Homeo box transcription factor         | A transcription factor critically involved with self-renewal of undifferentiated embryonic stem cells   | [64]    |
| Lin28                 | RNA binding protein Lin28              | The <i>Lin28</i> gene codes for an RNA-binding protein that selectively blocks the processing of microRNAs of the let-7 family, and possibly certain other microRNAs in ESCs, to prevent their differentiation  | [65,66] |

ESCs: Embryonic stem cells; Oct: Octamer-binding transcription factor; Sox2: SRY box-containing gene 2; Klf4: Kruppel-like factor 4.

**Figure 1** Flow diagram of generation and characterization of human induced pluripotent stem cells. Induced pluripotent stem cells (iPSCs) are derived through the introduction of stem cell factors into fibroblasts. After that, assessment of pluripotency of iPSCs can be studied by expression of protein and genes using various techniques such as immunocytochemistry, flow cytometry and reverse transcription-polymerase chain reaction (PCR) methods, respectively. *In vitro* and *in vivo* differentiation ability of iPSCs can be studied by embryoid body assay (EB assay) and teratoma formation assay, respectively. In addition, PCR analysis is required to demonstrate silencing of transgene expression in iPSCs and DNA methylation to confirm reprogramming of somatic cells. Oct: Octamer-binding transcription factor; Sox2: SRY box-containing gene 2; Klf4: Kruppel-like factor 4.

In addition to pluripotency assessment, it is important to confirm the silencing of exogenous transgene expression. PCR analysis can be used to demonstrate silencing of retro/lentiviral transgene expression using virus-specific primers<sup>[70]</sup>. Further, DNA fingerprinting can be performed to confirm iPSCs are genetically matched to

their parental somatic cells. DNA methylation analysis of the *Oct4*, *Sox2* and *Nanog* promoter regions using bisulfite sequencing can be used to reveal the different epigenetic states of the cells. Thus, the methylation status of promoter regions of pluripotency genes confirms successful reprogramming<sup>[70]</sup>.

## GENERATION OF HEPATOCYTES FROM iPSCs

To date, many protocols have been used to differentiate iPSCs into desired cell types. However, different iPSC lines have different outcomes under identical culture conditions. iPSC lines have a propensity to produce certain lineages or cell types when allowed to differentiate spontaneously, indicating that choosing a proper clone is also essential in differentiating iPSCs into a specific lineage<sup>[72-74]</sup>. A major issue in differentiation is to obtain hepatocytes from pluripotent stem cells that have an adult phenotype, and which stably express liver-like functions and reflect those *in vivo* functions<sup>[75]</sup>. Recently, a number of protocols have been developed to derive hepatocytes from hiPSCs. These protocols for hepatocyte generation are hampered by inefficient differentiation and maturation that lead to low yield and heterogeneous cell populations in cultures<sup>[76]</sup>. Recently, a homogenous population of hepatocytes from pluripotent stem cells has been isolated by sorting for surface asialoglycoprotein receptor marker; however, these enriched cells are found to retain immature fetal liver characteristics<sup>[77]</sup>. In Table 4, we have summarized various protocols used to differentiate hepatocytes from iPSCs<sup>[78-84]</sup>. Even after enriching the hepatocytes from culture prior to transplantation, the risk of teratoma formation may arise due to the presence of a few undifferentiated iPSCs. Therefore, further enriching hepatocytes using negative selection against pluripotent cells could be useful to avoid teratoma formation. Figure 2 summarizes the strategy on differentiation of human iPSCs into hepatocytes. Figure 3 depicts the hepatocytes generated from hiPSCs in our laboratory.

## POTENTIAL APPLICATIONS OF iPSC-DERIVED HEPATOCYTES

iPSCs represent a promising source of hepatocytes for a wide range of applications, including disease modeling, drug toxicity testing and cell transplantation (Figure 4).

### Disease modeling

iPSCs represent a novel tool for *in vitro* disease modeling. Traditionally, researchers rely on animal models, hepatic immortalized cell lines, or short-lived primary hepatocyte cultures to understand the mechanisms and pathogenesis of diseases and testing of drug candidates<sup>[85-87]</sup>. Each of these has limitations in functionality, reproducibility and availability. Disease-specific iPSCs derived from patients suffering from specific diseases may provide a more relevant model system because their properties closely resemble those found in the patient's own system, without the need for genetic manipulation. Several groups have successfully derived a wide range of iPSCs from patients with diseases<sup>[88]</sup> and inherited liver diseases<sup>[21]</sup>. These cells can be used as models to study the pathogenesis, disease mechanism(s) and possible cure for liver disorders. Therefore, human iPSC-derived hepatocytes could generate more accurate predictions of human physiological responses than animal models. iPSC-derived hepatocytes will overcome these limitations and provide a reliable source of highly reproducible and readily available human hepatocytes for disease modeling in pre-clinical drug development.

### Drug toxicity screening

Hepatotoxicity is the most common side effect of new candidate drugs under clinical trial, and is the leading cause of post approval drug recalls; for example, bromfenac and troglitazone<sup>[89]</sup>. The development of liver toxicity screening technologies utilizing iPSC-derived hepatocytes would allow investigation into the effects of single nucleotide polymorphisms on drug metabolism and toxicity<sup>[90]</sup>. An example of this is warfarin, a drug for which polymorphisms in cytochrome P-450 2C9 create problems with obtaining an appropriate pharmacotherapeutic range<sup>[91]</sup>. iPSC-derived hepatocytes could remain viable in culture for several months, enabling the assessment of acute and chronic toxicity of drugs due to their pluripotent ability. Drug toxicity assays will be performed in petri dishes which require small amounts of compound for a hepatic cytotoxicity profile. Terminally differentiated he-

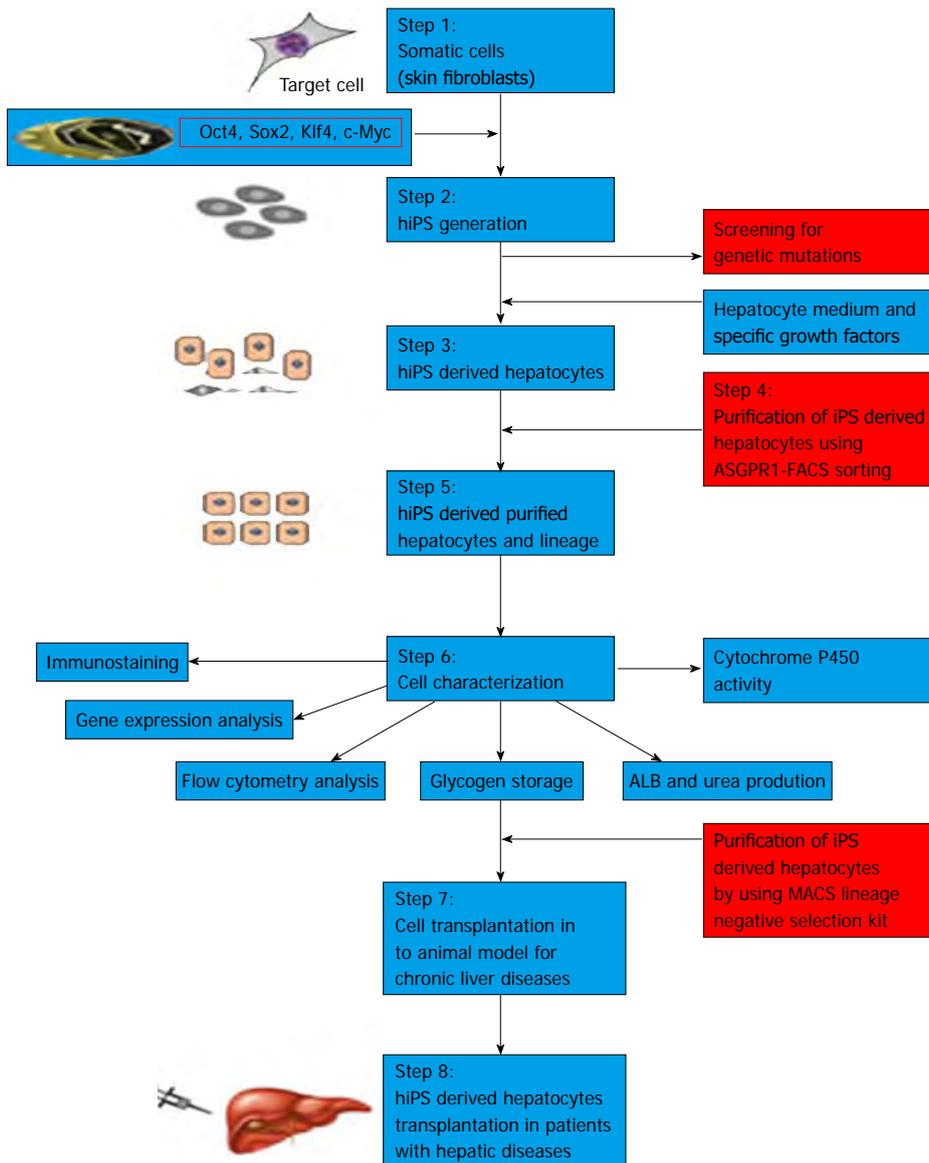

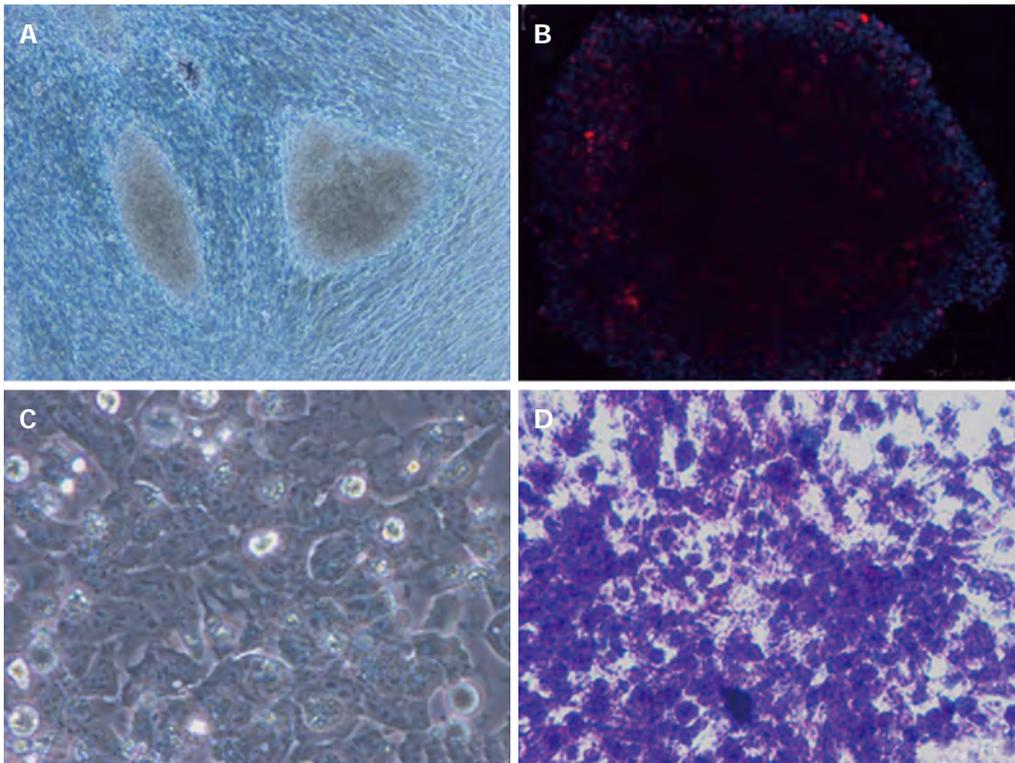

Figure 2 Flow diagram showing the strategy for human induced pluripotent stem cell-derived hepatocyte clinical applications. Steps 1 and 2, human induced pluripotent stem cells (hiPSCs) are generated from somatic cells using reprogramming techniques and screened for mutations; Step 3, hiPSCs are differentiated into hepatocytes using specific growth factors and medium; Step 4, enrichment of hiPSC-derived hepatocytes; Steps 5 and 6, characterization of enriched iPSC-derived hepatocytes for protein expression, gene expression and functional assays. Before clinical transplantation, hiPSC-derived hepatocytes are enriched again using negative selection against pluripotent cells to avoid teratoma formation; Step 7, transplantation of enriched hiPSC-derived hepatocytes into chronic liver failure animal model; Step 8, hiPSC-derived enriched hepatocytes could be transplanted into liver disease patients. Oct: Octamer-binding transcription factor; Sox2: SRY box-containing gene 2; Klf4: Kruppel-like factor 4; ASGPR: Asialoglycoprotein receptor; FACS: Fluorescence activated cell sorting; MACS: Magnetic-activated cell sorting; ALB: Albumin.

patocytes with cytochrome P-3A4 functional activity and scale-up of iPSC-derived hepatocytes will help in pharmaceutical industry drug toxicity applications.

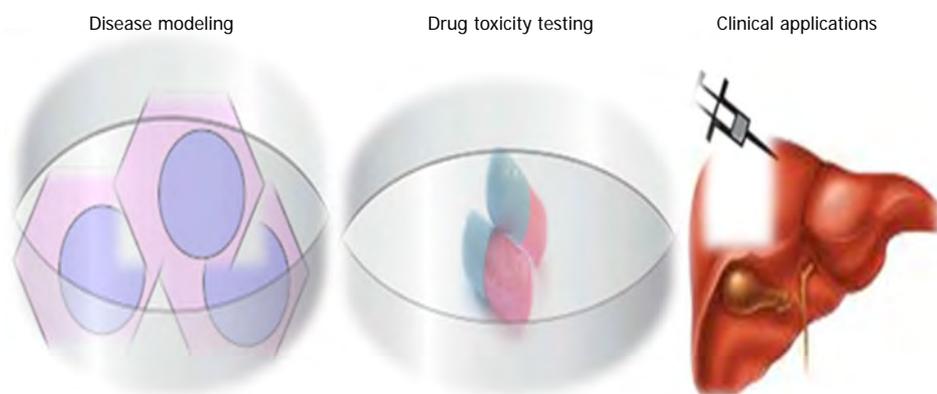

**Patient-specific iPSC-derived hepatocytes for cell transplantation**

Liver transplantation represents the only way to treat patients suffering from chronic liver failure, but this is associated with numerous problems, including shortage of donors, high cost, rejection and complications. Transplantation of hepatocytes derived from hiPSCs could represent an alternative cell source for liver failure and inborn liver diseases. The important issue is the generation of safe and functional cell types for therapy. Indeed,

the cell sources of iPSCs influence the safety of the established iPSCs. It has been demonstrated that hiPSCs retain certain gene expressions of the parent cells, and this suggests that iPSCs of different origins may possess different capacities to differentiate. A complete study using various mouse iPSCs has demonstrated that the origin of the iPSCs has a profound influence on the tumor-forming propensities in a cell transplantation therapy model<sup>[92]</sup>. Mouse tail-tip fibroblast iPSCs (mesoderm origin) have shown the highest tumorigenic propensity, whereas gastric epithelial cells and hepatocyte iPSCs (both are endoderm origin) have shown lower propensities<sup>[93]</sup>. The recent evidence suggests that epigenetic memory of the somatic cell of origin is retained in the iPSCs, and

**Figure 3** Human induced pluripotent stem cells generated from human foreskin fibroblasts using single lentiviral stem cell cassette kit (Millipore, United States) method. A, B: Human induced pluripotent stem cell (hiPSC) colonies resembling embryonic stem cells in morphology were observed, and iPSC with a flat, packed, tight colony morphology and a high nucleus to cytoplasm ratio (A,  $\times 40$ ) were positive for Oct4 marker on immunocytochemistry (B,  $\times 200$ ); C, D: hiPSCs were differentiated into hepatocytes. At day 13, these differentiated cells exhibited polygonal morphology (C,  $\times 400$ ) and showed pink color (glycogen storage) on periodic acid schiff staining (D,  $\times 200$ ).

**Figure 4** Flow diagram of potential applications of induced pluripotent stem cell-derived hepatocytes. Induced pluripotent stem cells (iPSCs) are capable of self-renewal and are able to differentiate into hepatocytes *in vitro*. iPSC-derived hepatocytes can be applied to disease modeling, drug toxicity screening assays, and clinical applications.

that may influence their directed differentiation potential into blood cells<sup>[94,81]</sup> or hepatocytes<sup>[92]</sup>. In the mouse, iPSCs have been generated from derivatives of all three embryonic germ layers, including mesodermal fibroblasts, epithelial cells of endodermal origin and ectodermal keratinocytes, whereas human iPSCs have been produced from mesoderm (fibroblasts and blood cells) or ectoderm (keratinocytes and neural stem cells) and endoderm (hepatocytes)<sup>[81]</sup>. It is therefore extremely important to establish human iPSC lines of multiple origins and thoroughly examine the source impact on both the safety issues and

their differentiation potentials.

Recently, it has been demonstrated that iPSC-derived hepatocytes can restore liver function in an animal model of liver failure<sup>[95]</sup>. These results indicate the utility of hiPSC-derived hepatocytes as an alternative treatment for patients with end-stage liver disease. Researchers investigated and analyzed the potential of hiPSC-derived hepatocytes to model inborn liver diseases such as  $\alpha_1$ -antitrypsin deficiency, familial hypercholesterolemia, glycogen storage disease type 1a, hereditary tyrosinemia, and Crigler-Najjar syndrome<sup>[6]</sup>. Genetic diseases of the liver modeled in hiPSC-

derived human hepatocytes create new opportunities to develop autologous cell transplantation therapy to correct genetic defects in liver diseases.

### Liver stem cells

The liver has a massive regenerative capacity. When liver regeneration is impaired, oval shaped cells emerge and are implicated in liver tissue repair<sup>[96]</sup>. These cells are derived from the canals of Hering, which are located in the periportal region of the liver and account for 0.3%-0.7% of the liver mass<sup>[97]</sup>. In rodents, these liver progenitor cells are called oval cells, while in humans they are known as hepatic progenitor cells<sup>[98]</sup>. These cells are phenotypically similar to fetal hepatoblasts and also have a bipotent differentiation potential. Oval cells or hepatic progenitors are difficult to isolate because of the lack of definitive markers. Various markers have been used to identify oval cells in adult liver, including liver stem cell and hematopoietic markers, such as OV6, Thy-1, CD34, c-kit, and Sca-1<sup>[99]</sup>. Hepatic progenitors have been isolated from fetal liver using the specific surface marker, epithelial cell adhesion molecule (EPCAM). These EPCAM<sup>+</sup> cells showed positive for hepatic progenitor markers such as CD29, CD49f and CD90<sup>[86]</sup>. Clinical studies have identified and confirmed the efficacy of fetal liver hepatic progenitors in end-stage liver diseases<sup>[100]</sup>. However, the clinical application of this cell source is limited due to the difficulty in obtaining large numbers of fetal liver cells, as well as ethical and immune rejection issues. Another stem cell population found in the fetal liver is side population cells which represents another potential source of liver progenitor cells<sup>[101]</sup>, but these cell numbers are very much fewer in fetal liver. There is increasing evidence in the literature suggesting that bone marrow is another source of hepatic progenitor cells<sup>[102,103]</sup>. Autologous bone marrow-derived stem cell transplantations have been performed in patients with liver diseases but it is difficult to assess overall clinical benefit from these therapies<sup>[104]</sup>.

In support of a role in liver regeneration, oval cell activation has been detected in chronic liver injury caused by inflammation, chronic hepatic necrosis, chronic alcoholism induced cirrhosis and hepatitis models<sup>[105,106]</sup>. Although the full complements of signals required for oval cell activation are still unknown, both continuous metabolic stress and chemical hepatotoxic substances have been implicated as potential oval cell activators when hepatocyte proliferation is inhibited<sup>[105,106]</sup>. A recent study reported the production of a chemokine known

as stromal derived factor-1 $\alpha$  in the liver following tissue damage<sup>[107]</sup>. The role of liver stem cells in physiology, pathophysiology and therapy is not yet exactly known; therefore, it needs to be further investigated<sup>[108]</sup>. Although a number of successful techniques have been developed, stem cell-derived hepatocytes from adult, fetal and embryonic sources are found to retain immature fetal liver characteristics, which are not similar in primary hepatocyte functionality. Therefore, the elucidation of other key developmental factors and tissue culture environments, together with iPSC technology, are essential in order to obtain functional hepatocytes for hepatic applications.

### DIRECT CONVERSION

Apart from the methods discussed above, overexpression of lineage-specific transcription factors in somatic cells is a new approach (direct conversion) to generate specific cell types including neurons, cardiomyocytes, blood progenitors and hepatocyte-like cells; as summarized in Table 5<sup>[109-112]</sup>. This method could be useful as an alternative approach for autologous cell-replacement therapies. Unlike iPSCs and ESCs, directly converted cells may not easily multiply in the lab since they do not have pluripotency properties. Therefore, this approach may have limitations. Choosing highly proliferative starting somatic cells is essential in the direct conversion approach.

### CONCLUSION

Thinking outside the liver explores the potential of iPSCs as an unlimited source for *in vitro* disease modeling and for drug toxicity studies and clinical applications. Patient-specific iPSCs or custom-made iPSCs may have future promising implications without immune rejection. However, iPSC technology has several technical issues to be addressed such as generation of iPSCs without viral integration, elimination of tumor formation and genetic mutations that need to be eliminated before the cells are put to clinical applications. Despite limitations, iPSC-derived hepatocytes are a very promising population for cell therapies in hepatology.

### Abstract

Endoscopic ultrasonography (EUS) has evolved into a useful therapeutic tool for treating a broad range of tumors since being introduced into clinical practice as a diagnostic modality nearly three decades ago. In particular, EUS-guided fine-needle injection has proven a successful minimally invasive approach for treating benign lesions such as pancreatic cysts, relieving pancreatic pain through celiac plexus neurolysis, and controlling local tumor growth of unresectable malignancies by direct delivery of anti-tumor agents. One such ablative agent, ethanol, is capable of safely ablating solid or cystic lesions in hepatic tissues *via* percutaneous injection. Recent research and clinical interest has focused on the promise of EUS-guided ethanol ablation as a safe and effective method for treating pancreatic tumor patients with small lesions or who are poor operative candidates. Although it is not likely to replace radical resection of localized lesions or systemic treatment of metastatic tumors in all patients, EUS-guided ablation is an ideal method for patients who refuse or are not eligible for surgery. Moreover, this treatment modality

may play an active role in the development of future pancreatic tumor treatments. This article reviews the most recent clinical applications of EUS-guided ethanol ablation in humans for treating pancreatic cystic tumors, pancreatic neuroendocrine tumors, and metastatic lesions.

**Key words:** Endoscopic ultrasonography; Ethanol; Tumor ablation; Pancreas cancer; Cystic tumor; Neuroendocrine tumors; Celiac plexus neurolysis

**Core tip:** Ethanol, a commonly used ablative agent, has been used to successfully and safely ablate solid and cystic hepatic lesions *via* percutaneous injection. Endoscopic ultrasonography (EUS)-guided ethanol ablation, a minimally invasive approach, was recently developed and has been successfully applied as treatment of pancreatic cysts, pancreatic neuroendocrine tumors, and abdominal metastatic lesions. Although it is not likely to replace radical resection for treating localized lesions or systemic therapy for managing metastatic tumors, EUS-guided ablation therapies represent an attractive alternative treatment modality for patients who refuse or are not eligible for surgery.

### INTRODUCTION

Endoscopic ultrasonography (EUS) has been used in clinical practice for more than 30 years<sup>[1,2]</sup> since its development for the original purpose of diagnosing pancre-

atic disease and carrying out malignancy staging. In the early 1990s, the introduction of curvilinear array echoendoscope made it possible to perform fine-needle aspiration (FNA) biopsy under direct endosonographic visualization. The minimally invasive and safe nature of FNA led to a boon in use of therapeutic EUS techniques, including EUS-guided fine needle injection (EUS-FNI). More recently, EUS-FNI has been applied as a pancreatic cancer treatment aimed at controlling pain through nerve blockade, as a solid tumor therapy for introduction of brachytherapy seeds and viral vectors, and as a tool for ablation therapy<sup>[3-6]</sup>.

Ethanol, a commonly used ablative agent, gained popularity according to its advantageous features of cost effectiveness, ready availability, and rapidly ablation function. The mechanism of ethanol ablation mainly involves cell death by causing cell membrane lysis, protein denaturation, and vascular occlusion<sup>[7]</sup>. Percutaneous ethanol injection has been used in the ablation of renal cysts, hepatic cysts, and solid tumors, such as liver or adrenal tumors<sup>[8-12]</sup>. EUS-guided ethanol injection is superior to the percutaneous application because it offers real-time image monitoring of the lesions located deep in the pancreas. In addition, EUS can provide precise measurement of lesions and identification of surrounding structures, and can readily deliver therapeutic agents to a target site, thereby minimizing damage to non-tumor tissue. Some EUS-guided ethanol ablation procedures for pancreatic tissue have been shown to be safe and feasible in animal models<sup>[13,14]</sup>.

In this review, the recent applications, features, and outcomes of EUS-guided ethanol injection treatment for pancreatic cystic tumors, pancreatic neuroendocrine tumors (pNETs), celiac plexus, and metastatic lesions in humans are summarized.

## EUS-GUIDED ETHANOL ABLATION THERAPY FOR PANCREATIC CYSTIC TUMORS

Pancreatic cysts are common, with the incidence of asymptomatic cysts being reported at about 2.5% in the general population<sup>[15]</sup>. The advances of various imaging modalities, such as computed tomography (CT) scanning, magnetic resonance imaging, and EUS, have been accompanied by an increase in detection of pancreatic cystic neoplasms (PCNs). Pancreatic cystic tumors are mainly classified as either mucinous cystic neoplasms (MCNs), serous cystic neoplasms (SCNs), or intraductal papillary mucinous neoplasms (IPMNs), according to histopathological features<sup>[16]</sup>. Some cystic tumors of the pancreas, such as MCNs and IPMNs, have the potential to become malignant and are often treated by surgical resection when malignancy is suspected. Although surgical resection is generally recommended, pancreatic cyst ablation is an increasingly popular treatment option, especially *via* injection of ethanol or other ablative agents into the cyst cavity under EUS guidance.

Recent studies have shown that EUS-guided ethanol injection into pancreatic cysts is safe and feasible, slows or inhibits growth, and avoids the risks associated with surgical resection. Gan *et al*<sup>[17]</sup> published the first report of safety and feasibility for the ethanol lavage and ablation of pancreatic cystic lesions using EUS-FNI. In that study, 25 patients with pancreatic cysts (MCNs,  $n = 13$ ; IPMNs,  $n = 4$ ; SCNs,  $n = 3$ ; pseudocysts,  $n = 3$ ; uncertain etiology,  $n = 2$ ) were treated with escalating doses (5%-80%) of ethanol for 3-5 min under EUS guidance. The results demonstrated that this procedure effectively reduced tumors without inducing complications, such as pancreatitis, in the short- and long-term follow-up periods. Eight patients (35%) had complete resolution of the cysts, and five patients undergoing surgical resection showed histological evidence of epithelial ablation.

To further determine whether EUS-guided ethanol lavage can decrease pancreatic cyst size, a multicenter, randomized, prospective trial was performed in 2009<sup>[18]</sup>. The primary aim of that study was to compare the change of pancreatic cyst size after EUS-guided lavage with 80% ethanol or saline solution alone. Of the 42 patients enrolled, 25 patients were initially treated with 80% ethanol lavage and 17 patients were administered saline solution lavage. Three months after the first lavage, a second pancreatic cystic lavage was performed. Patients who initially received an ethanol lavage received a second ethanol lavage, and those who received an initial saline solution lavage were then given an 80% ethanol lavage. The results indicated that EUS-guided 80% ethanol injection resulted in a greater decrease in size of pancreatic cystic tumors compared with the saline solution injection, and that the overall resolution rate of pancreatic cystic tumors was 33.3%. Incidences of major complications, such as abdominal pain, intracystic bleeding during lavage, and acute pancreatitis, were similar in the two groups. Furthermore, nine of the study patients (75%) were followed-up for two years after initial cyst resolution, and no evidence of cyst recurrence was found in any patient<sup>[19]</sup>.

To improve the effect of ethanol ablation therapy, Oh *et al*<sup>[20-22]</sup> performed EUS-guided ethanol lavage with a paclitaxel injection to treat cystic tumors of the pancreas. An initial study found that complete resolution of pancreatic cystic tumors was achieved in 11 of 14 patients after treatment with ethanol and paclitaxel injection; in addition, minor complications, including hyperamylasemia and abdominal pain, were observed in one patient<sup>[20]</sup>, but no cases of acute pancreatitis occurred. The study's collective findings demonstrated that ethanol lavage with paclitaxel injection is a safe, feasible, and effective method to treat pancreatic cystic tumors. However, only a small number of patients and only short-term outcomes were assessed in this study. A subsequent study by this group was carried out involving a larger population ( $n = 52$ ) with a longer-term follow-up period ( $n = 47$  for  $> 12$  mo). All patients underwent 99% pure ethanol injection into the collapsed cyst for a 3-5 min lavage. After the injected ethanol was aspirated, paclitaxel solution was injected into the cyst cavity. Ultimately,

complete resolution was achieved in 29 of the patients (62%). No treatment-related complications, including bleeding, bowel perforation, or severe pancreatitis, were observed<sup>[22]</sup>.

DiMaio *et al.*<sup>[23]</sup> retrospectively analyzed the effectiveness of multiple EUS-guided ethanol lavages for pancreatic cystic tumor treatment. The results showed that multiple ethanol lavage treatments resulted in a greater decrease in the size and surface area of PCNs compared with only one ethanol lavage treatment. Complete cyst resolution was not seen in any patient after the first EUS-ethanol lavage, but was achieved in 5 of the 13 patients (38%) who underwent two sequential EUS-ethanol lavage treatments. Again, no treatment-related complications were observed, with the exception of one patient complaining of minor abdominal pain.

Collectively, these preliminary studies suggest that ethanol ablation is relatively safe and feasible for clinical use in humans. Therefore, EUS-guided ablation of pancreatic cystic tumors *via* ethanol injection, a minimally invasive technique, may be an attractive choice to treat patients who refuse or are not eligible for surgery. However, there are a number of limitations in these studies. First, some studies only included a treatment group, and no control group was included. Second, there was not a definitive diagnosis made prior to application of the ethanol ablation procedure. Inclusive criteria were based on the imaging findings and some benign lesions might have been treated unnecessarily. Third, the patients were followed-up for a relatively short period of time for documentation of cyst resolution. Thus, EUS-guided cyst ablation is an experimental therapy modality that should be used with caution.

EUS-guided pancreatic cyst ablation is mainly used currently for the following indications: (1) patients who refuse surgery or are high-risk surgical candidates; (2) cysts that appear to be benign and are morphologically indeterminate; and (3) asymptomatic cysts that increase in size during the follow-up period. Before ethanol ablation for pancreatic cysts can be widely accepted, a prospective, randomized, controlled trial with a long follow-up period is required to determine the clinical efficacy of ethanol ablation therapy compared with surgical resection.

## EUS-GUIDED ETHANOL ABLATION THERAPY FOR PANCREATIC NEUROENDOCRINE TUMORS

pNET account for a small percentage of all pancreatic tumors (1.3%), but their incidence is increasing<sup>[24]</sup>. Although surgical enucleation or resection is considered as the treatment of choice for pNET, a few patients are not suitable candidates for surgery because of old age or comorbidities. Recently, successful application of EUS-guided ablation therapy using ethanol has been reported for the treatment of pNET. Jürgensen *et al.*<sup>[25]</sup> reported successful resolution of a 13 mm insulinoma by EUS-

guided ethanol ablation therapy in a 78-year-old woman (diagnosed by laboratory findings and EUS-FNA). Because the patient was in poor general condition and refused surgical resection, EUS-guided ethanol injection was performed. Although mild procedure-associated pancreatitis was experienced after the ethanol ablation procedure, complete resolution was achieved in the patient. The patient had durable glycemic control throughout the recovery and follow-up and no indications of insulinoma were observed by follow-up EUS.

Muscatiello *et al.*<sup>[26,27]</sup> described another case of successful ethanol ablation involving a patient with a pancreatic endocrine tumor. A female patient with multiple endocrine neoplasia type 1 (11 and 7 mm, respectively) underwent 40% ethanol ablation therapy. Two months after the ethanol ablation, EUS with contrast enhancement revealed areas of fibrosis. However, subsequent resolution of the accompanying perturbed levels of vasoactive intestinal peptide and chromogranin A was observed. The main complication in this case was a small pancreatic necrotic lesion, which was presumably caused by minimal ethanol effusion and managed by laparoscopic necrosectomy.

Deprez *et al.*<sup>[28]</sup> reported treatment of a patient with insulinoma of the pancreas head involving a 98% ethanol injection under EUS guidance. The patient achieved complete resolution (evidenced by imaging) at 3 mo after the procedure and remained asymptomatic and normoglycemic for more than two years later. Vleggaar *et al.*<sup>[29]</sup> reported an ethanol ablation operation for an 82-year-old patient with a pNET, for which 96% ethanol was delivered to under EUS guidance. Two months after the ablation therapy, EUS examination indicated that a significant reduction in the diameter of the tumor had been achieved. Finally, Levy *et al.*<sup>[30]</sup> retrospectively reviewed eight patients with insulinomas who received US-guided ethanol ablation. Five of those patients underwent EUS-guided ethanol injection and the remaining three underwent intra-operative ultrasound (IOUS)-guided ethanol injection. No complications occurred during or after the EUS-guided procedure. The IOUS-guided ethanol injection, however, was associated with minor peritumoral bleeding ( $n = 1$ ), pseudocyst ( $n = 1$ ), and pancreatitis with peri-pancreatic fluid ( $n = 1$ ). Hypoglycemia-related symptoms completely disappeared in five patients who underwent EUS-guided ethanol injection, and significantly improved in the three patients who underwent IOUS-guided ethanol injection.

Based on these case reports, EUS-guided ethanol ablation seems to be an alternative treatment option for pancreatic solid tumors. However, some issues remain that require further study, such as the choice of target area and adequate ethanol dose to achieve successful ablation without causing serious complications. In addition, EUS-guided ethanol ablation therapy for pNETs appears to harbor the possibility of late relapse requiring re-intervention, as well as incomplete ablation and risk of metastasis. While currently the strongest indication for intratumoral therapy is patients who refuse surgery

or are poor surgical candidates, a clinical trial enrolling more patients with longer follow-up is required to more definitively determine the particular physiological indications.

## EUS-GUIDED ETHANOL ABLATION THERAPY FOR CELIAC PLEXUS ABLATION

Pain is one of the major complications of advanced pancreatic cancer. It is estimated that pain is present in 80%-85% of pancreatic cancer patients at the time of diagnosis, and it can be difficult to control, even with high doses of analgesics<sup>[31,32]</sup>. Celiac plexus neurolysis (CPN), a chemical splanchnicectomy of the celiac plexus, has been well established as an effective method for controlling pain and decreasing morphine consumption in patients with locally advanced or unresectable pancreatic cancer<sup>[32,33]</sup>. Before the advent of EUS, CPN was performed by radiological guidance or intraoperative method, both of which are associated with a risk of the serious complications of paraesthesia, paraplegia, and pneumothorax<sup>[34,35]</sup>. With the development of the EUS technique, EUS-guided CPN (EUS-CPN) has become a novel option to treat cancer-related pain in patients with inoperable pancreatic cancer.

EUS-CPN consists of an injection of absolute alcohol, a neurolytic agent, into the celiac ganglia to permanently destroy neural tissue of celiac ganglia. The first applications of EUS-CPN were reported by Wiersema *et al*<sup>[36]</sup>. Thirty patients with pain due to intra-abdominal malignancies were injected with 98% dehydrated absolute alcohol under EUS guidance into the celiac plexus *via* the transgastric route. The majority of patients (79%-88%) experienced a significant decrease in pain scores at the 10 wk post-treatment (median follow-up time).

Subsequent studies have demonstrated that EUS-CPN is a safe and effective method to relieve severe pain from advanced pancreatic cancer<sup>[3,37-39]</sup>. In a meta-analysis of these EUS-CPN studies, pain relief was observed in about 80% of 289 patients with pain due to pancreatic cancer<sup>[40]</sup>. While EUS-CPN can be delivered on either or both sides of the aorta, a recent study showed that bilateral injection was more effective than a central single injection<sup>[41]</sup>. The common complications of EUS-CPN, transient diarrhea and hypotension, were observed in 9% and 10%-15% of cases, respectively, and both complications were self-limiting in most cases<sup>[37]</sup>.

## EUS-GUIDED ETHANOL ABLATION THERAPY FOR OTHER TUMORS

EUS-guided injection of alcohol is also used for ablation of other abdominal tumors, such as gastrointestinal stromal tumor (GIST) and intra-abdominal metastatic lesions located in the liver, adrenal glands, and pelvic lymph nodes. Günter *et al*<sup>[42]</sup> reported a case of EUS-guided

ethanol ablation of a GIST involving a 59-year-old man with a 4 cm lesion in the muscularis propria of the stomach that was diagnosed by EUS and EUS-guided FNA. Severe comorbidity precluded surgery and the patient was treated with an injection of 1.5 mL of 95% ethanol under EUS guidance. Seven weeks after the injection, no endosonographic evidence of residual tumor was seen, but a 1.5-cm ulcer at the treatment site was present, which was resolved by acid suppression therapy. Two years after the ethanol ablation treatment, a follow-up examination showed complete remission of the tumor. No severe complications were observed, except for self-limiting pain in the upper abdomen.

Recently, two cases of EUS-guided ethanol ablation of a solid hepatic metastasis carcinoma have been reported<sup>[43,44]</sup>. In the first, a 65-year-old man with a 3.3-cm lesion in the left liver and a markedly elevated carcinoembryonic antigen level was considered as having metastatic cancer from either a pancreatic adenocarcinoma or prior colorectal cancer. Multiple EUS-guided injections of absolute alcohol were administered over several years. The lesion size decreased over time, as well as the levels of corresponding tumor markers, indicating that this approach was effective in controlling tumor growth. Furthermore, the multiple EUS-guided hepatic tumor injections did not result in major complications, except for a small subcapsular hematoma that resolved spontaneously<sup>[43]</sup>.

Our group also reported a case of a 47-year-old man with a hepatic metastatic carcinoma from a pancreatic adenocarcinoma treated by injection of anhydrous ethanol under EUS guidance (Figure 1). One month later, an abdominal CT follow-up scan revealed a decrease in size of the lesion (Figure 2). No significant procedure-related complications were observed, except for a transient low fever<sup>[44]</sup>.

Artifon *et al*<sup>[45]</sup> described a case of EUS-guided alcohol ablation of a 5 cm left adrenal metastatic carcinoma in a 52-year-old man. For this patient, the main presenting complaint was abdominal pain and the diagnosis of left adrenal metastasis from non-small-cell lung carcinoma was made by EUS-FNA. Three days after the alcohol ablation therapy treatment (15 mL of 98% absolute alcohol), the symptom of abdominal pain disappeared. At the one-month follow-up, EUS revealed a hyperechoic nodule between the pancreas and the left kidney, which was presumed to represent alcohol ablation-induced fibrosis.

More recently, DeWitt *et al*<sup>[46]</sup> reported the successful EUS-guided alcohol ablation of metastatic pelvic lymph nodes in a patient with rectal cancer. The two injected metastatic pelvic lymph nodes received 4 and 2 mL of ethanol, respectively, which achieved local complete resolution at 10 mo post-treatment. No procedure-related complications were reported.

The basic characteristics and outcomes of the studies described herein of EUS-guided ethanol ablation therapy for pancreatic cystic tumors, pNETs, and other tumors are summarized in Tables 1-3, respectively.

## CONCLUSION

With the advent of curvilinear EUS, therapeutic EUS has emerged as an important approach to manage malignancies. While prominent advances have been made in applications of EUS-FNI for specific antitumor therapy, the field of EUS-guided ethanol ablation therapy for malignancies continues to evolve. Currently, our understanding of the safety and efficacy of EUS-guided ethanol ablation as a tumor therapy is primarily limited by the small sample sizes and short-term follow-up periods of related case studies. Prospective, large trials should be

performed to better evaluate this technique: its indications and complications before it is recommended for widespread use in clinical practice. For example, particular patient populations may receive more benefit than others from the EUS-guided ethanol ablation with or without systemic therapies, and prospective clinical trials will help to define these patients.

### Abstract

**AIM:** To study the interplay between butyrate concentration and butyrate-producing bacteria in fecal samples of ulcerative colitis (UC) patients *vs* control individuals.

**METHODS:** Fecal samples were collected from 14 control individuals (hemorrhoid patients only) and 26 UC patients (severe:  $n = 12$ , moderate:  $n = 6$ , remission:  $n = 8$ ), recruited by the gastroenterologist at the Department of Gastroenterology, All India Institute of Medical Sciences, New Delhi, India. Disease activity in UC patients was determined by clinical colitis activity index. We employed fluorescent *in situ* hybridization in combination with flow cytometry to enumerate the clostridium cluster population targeted by 16S rRNA gene probe. Major butyrate-producing species within this cluster were quantified to see if any change existed in control *vs* UC patients with different disease activity. This observed change was further validated by quantitative polymerase chain reaction. In addition to this,

we carried out gas chromatography to evaluate the changes in concentration of major short chain fatty acids (SCFAs), namely acetate, *n*-butyrate, *iso*-butyrate, in the above samples. Student *t* test and Graph pad prism-6 were used to compare the data statistically.

**RESULTS:** There was a significant decrease of *Clostridium coccooides* (control,  $25.69\% \pm 1.62\%$  *vs* severe,  $9.8\% \pm 2.4\%$ ,  $P = 0.0001$ ) and *Clostridium leptum* clusters (control,  $13.74\% \pm 1.05\%$  *vs* severe,  $6.2\% \pm 1.8\%$ ,  $P = 0.0001$ ) in fecal samples of UC patients. Furthermore, we demonstrated that some butyrate-producing members of the clostridial cluster, like *Fecalibacterium prausnitzii* (control,  $11.66\% \pm 1.55\%$  *vs* severe,  $6.01\% \pm 1.6\%$ ,  $P = 0.0001$ ) and *Roseburia intestinalis* (control,  $14.48\% \pm 1.52\%$  *vs* severe,  $9\% \pm 1.83\%$ ,  $P = 0.02$ ) were differentially present in patients with different disease activity. In addition, we also demonstrated decreased concentrations of fecal SCFAs, especially of *n*-butyrate (control,  $24.32 \pm 1.86$  mmol/ $\mu$ L *vs* severe,  $12.74 \pm 2.75$  mmol/ $\mu$ L,  $P = 0.003$ ), *iso*-butyrate (control,  $1.70 \pm 0.41$  mmol/ $\mu$ L *vs* severe,  $0.68 \pm 0.24$  mmol/ $\mu$ L,  $P = 0.0441$ ) and acetate (control,  $39.51 \pm 1.76$  mmol/ $\mu$ L *vs* severe,  $32.12 \pm 2.95$  mmol/ $\mu$ L,  $P = 0.047$ ), in the fecal samples of UC patients. The observed decrease of predominant butyrate producers of clostridial clusters correlated with the reduced SCFA levels in active UC patients. This was further confirmed by the restoration in the population of some butyrate producers with simultaneous increase in the level of SCFA in remission samples.

**CONCLUSION:** Our observations indicate that decreases in members of the clostridial cluster resulting in reduced butyrate levels contribute to the etiology of UC.

## INTRODUCTION

Inflammatory bowel disease (IBD), comprising of Crohn's disease and ulcerative colitis (UC), is a class of chronic inflammatory disorders of the intestine. An increasing trend in the incidence and prevalence of IBD in the Asian population has been recognized for the past two decades<sup>[1]</sup>. The dynamic balance between commensal microbiota and host defensive responses at the mucosal frontier has a pivotal role in the initiation and pathogenesis of chronic IBD<sup>[2]</sup>. Whether the exaggerated immune response is exerted to all commensal bacteria, or to a subset or a single strain of bacteria, is not known<sup>[3]</sup>. Differences in fecal microbiota of healthy subjects and IBD patients have been enumerated using different techniques<sup>[4-6]</sup>. Impaired cellular metabolism, such as butyrate oxidation and short chain fatty acid (SCFA) fermentation, has shown strong association with altered gut microbiota in UC patients<sup>[7,8]</sup>.

SCFAs, such as acetate, propionate and butyrate, are produced by intestinal microbial fermentation of mainly undigested dietary carbohydrates, specifically resistant starches and dietary fiber, but also in a minor part generated by dietary and endogenous proteins in the intestine<sup>[9]</sup>. SCFAs are important for normal intestinal biology<sup>[10]</sup>. They also stimulate colonic sodium and fluid absorption and exert proliferative effects on the colonocytes<sup>[11]</sup>. Therefore, monitoring the fluctuations in SCFA concentration may help in understanding the relation of dysbiosis with UC.

Members of *Clostridium leptum* (*C. leptum*) and *Clostridium coccoides* (*C. coccoides*) groups together constitute the majority of Firmicutes (low G + C content bacteria)<sup>[12]</sup>, producing large amounts of butyrate that function as an energy source for colonic epithelial cells and inhibit mRNA expression of proinflammatory cytokines in the mucosa by inhibiting nuclear factor- $\kappa$ B (NF- $\kappa$ B) activation<sup>[13]</sup>. Butyrate has been reported to help in prevention of colorectal cancer<sup>[14]</sup>. Evidence indicates that bacteria related to *Eubacterium hallii* (*E. hallii*), *Roseburia* species and *Eubacterium rectale* (*E. rectale*) within cluster XIVa and *Faecalibacterium prausnitzii* (*F. prausnitzii*)-related bacteria within cluster IV are normally the two most abundant groups of human fecal bacteria that produce butyrate<sup>[15]</sup>. These species-level probes account for a mean of 7.7% of the population of the total human fecal microbiota<sup>[16]</sup>. However, both the clostridial clusters harbor a diverse collection of several species of butyrate producers and non-butyrate producers as well<sup>[17]</sup>.

Dynamics of predominant butyrate producers at the species level during disease activity and their correlation with the fluctuation in SCFA have not been established

clearly. Here we explored the alteration in population of dominant butyrate-producing bacterial species present in fecal samples of UC patients at different disease stages. Abundance of the butyrate-producing clostridial cluster group was estimated by fluorescent *in situ* hybridization (FISH) in combination with flow cytometry and real time polymerase chain reaction (PCR). Further enumeration was carried out for known predominant members of butyrate-producing bacteria such as (1) *F. prausnitzii* as a member of the *C. leptum* group; and (2) *E. hallii* and *Roseburia intestinalis* (*R. intestinalis*) as members of the *C. coccoides* group. We also checked the level of butyrate, *iso*-butyrate and acetate in fecal samples to see if any correlation exists with butyrate-producing bacteria during different disease conditions.

## MATERIALS AND METHODS

### Fecal sample collection and processing

Disease activity in UC patients was determined by simple clinical colitis activity index<sup>[18]</sup> and the patients with total index score of 7-10, > 10 and 0-2 were assigned moderate, severe and remission category, respectively<sup>[19]</sup>. The patients were recruited by the gastroenterologist at the Department of Gastroenterology of the All India Institute of Medical Sciences, New Delhi, India. Clinical and demographic features of UC patients and controls are shown in Table 1. Patients who had hemorrhoids only and showed no evidence of small and large intestinal disease were enrolled as control individuals in this study. No study patient had received any antibiotic treatment in the past three months before sample collection. Patients under any antibiotic or probiotic treatments were excluded from this study. The fecal samples were collected in sterile stool specimen containers and stored at -80 °C within 3 h of sample collection until further processing.

### Probes and oligonucleotides

All probes were designed from the *16S rRNA* gene. EUB 338 conserved within the bacterial domain was used as a positive control probe<sup>[20]</sup>; conversely NONEUB338 (reverse of EUB)<sup>[21]</sup> was used as a negative control probe. The positive control probe was double labeled with fluorescein isothiocyanate (FITC) at both the 5' and 3' end<sup>[22]</sup>, whereas the negative control probe was labeled with FITC at the 5' end and Cy5 at the 3' end. We used two group-specific probes labeled with Cy5 at their 5' end (Sigma, India) and three species-specific probes labeled with FITC at their 5' end (Sigma, India). Two competitors (unlabeled) and 5 helper oligonucleotides (unlabeled) were used to increase the accessibility of the Clep 1156 probe<sup>[23]</sup> (Table 2).

### Analysis of fecal samples by FISH-flow cytometry

About 1 g of fecal sample was suspended in 9 mL of phosphate buffered saline (PBS) and vortexed with 10-15 glass beads for 5 min to homogenize the sample. This suspension was centrifuged at 1500 rpm for 1 min

**Table 1 Clinical and demographic features of ulcerative colitis patients and controls *n* (%)**

| Feature               | UC ( <i>n</i> = 26)   | Control ( <i>n</i> = 14) |
|-----------------------|-----------------------|--------------------------|
| Sex (F/M)             | 11 (42.30)/15 (57.69) | 7 (50)/7(50)             |
| Age at diagnosis (yr) |                       |                          |
| mean ± SD             | 38.35 ± 11.49         | 35.00 ± 14.14            |

to pellet down the debris and the supernatant was collected. To fix the cells, 1 mL of this supernatant was incubated with 4% paraformaldehyde (1:3 ratio) at 4 °C, overnight. The fixed cells were washed twice with PBS and incubated in ethanol-PBS solution (1:1 ratio) at -20 °C for 2 h. For each hybridization reaction, 60 µL of fixed cells were used. The fixed cells were washed twice with PBS and resuspended in 50 µL hybridization buffer (900 mmol/L NaCl, 20 mmol/L Tris-HCl of pH 8, and 0.01% sodium dodecyl sulfate at pH 7.2). All hybridizations were performed in the dark at 50 °C for 16 h in the hybridization solution containing 4 ng/µL of the appropriate labeled probe. One hundred and fifty microliter of hybridization solution (without probe) was added to stop the reaction and cells were pelleted at 1610 *g* for 10 min. Hybridized cells were further resuspended in prewarmed washing buffer [65 mmol/L NaCl, 20 mmol/L Tris-HCl, 5 mmol/L diaminoethanetetraacetic acid (EDTA), 0.01% sodium dodecyl sulfate, pH 7.2] and incubated at 50 °C for 20 min to remove non-specific binding of the probe. Finally, cells were pelleted down at 6000 rpm for 10 min and suspended in 200 µL PBS<sup>[5,24,25]</sup>. An aliquot of 100 µL was added to 0.5 mL of flow sheath solution (Becton Dickinson) for flow cytometry analysis.

#### Data acquisition by flow cytometry

Data acquisition was performed with a FACS calibur flow cytometer (Becton Dickinson) which is equipped with an air-cooled argon-ion laser providing 15 mW at 488 nm light combined with a 635 nm red-diode laser. The 488 nm laser was used to measure the forward angle light scatter (FSC, in the 488/10 nm band pass filter), the side angle light scatter (SSC, in the 488/10 nm band

pass) and the green fluorescence intensity conferred by FITC labeled probes (filter 1 in the 530/30 nm band pass filter). The red-diode laser was used to detect the red fluorescence conferred by Cy5 labeled probes (filter 4 in a 661/16 nm band pass filter). The acquisition threshold was set in the side scatter channel. All the parameters were collected as logarithmic signals. The rate of events in the flow was set at low (12 µL/s). A total of 25000 events were collected and subsequent analyses were conducted using the Cell Quest Software (Becton Dickinson).

#### Enumeration of bacterial groups in fecal samples

Enumeration of bacterial groups was performed by a double staining method in the same reaction tube where the hybridization of the EUB338 probe labeled with FITC and the genus-specific probe labeled with Cy5 were combined. This led us to estimate the abundance of bacterial groups targeted by the respective Cy5-labeled probe as a proportion of total bacteria labeled with the EUB338 FITC probe. Next, the abundance of known butyrate producers was enumerated as cells hybridized with the FITC-labeled species-specific probe as a proportion of total cells hybridized with the respective genus-specific Cy5-labeled probe. Each time, the proportion of hybridized bacteria was corrected by subtracting the background fluorescence obtained with hybridization of the negative control probe NONEUB338.

#### Quantitative polymerase chain reaction

Genomic DNA from human fecal samples (220 mg) was extracted using the Qiagen stool DNA kit and eluted in 50 µL of Tris-EDTA buffer. About 20 ng of DNA from each sample was used to analyze the bacterial population. All primer sets used in the study were designed from the *16S rRNA* gene as shown in Table 2. Genus-specific primers were used to amplify respective genus and species from genomic DNA of the fecal samples of healthy individuals. The amplified product was cloned and sequenced and sequences were deposited in the EMBL database to obtain the accession numbers (Table 3). These *16S rRNA* gene fragments containing plasmids were used as reference strains. The standard curves were constructed by serial dilutions of each reference clone prepared from 0.05 to 500000 pg/tube, corresponding to 1 × 10 to 1 × 10<sup>7</sup> copy numbers. The standard curve of the reference clones was used to extrapolate the numbers of bacteria present in the fecal samples. With the molecular mass of the plasmid and insert known, the copy number was calculated as follows: mass in Daltons (g/molecule) = [size of double-stranded (ds) product in base pairs (bp)] (330 Da × 2 nucleotides (nt)/bp)/Avogadro's number.

Thus, the precise number of molecules (molecules/µL) = Conc./mass in Daltons<sup>[26]</sup>.

#### Gas chromatography analysis of fecal SCFA

Fecal SCFAs were analyzed using gas chromatography/flame ionization detection (GC-FID). An aliquot of fecal

content (250 mg) was extracted with 1 mL of extraction buffer [0.1% (w/v) HgCl<sub>2</sub> and 1% (v/v) H<sub>3</sub>PO<sub>4</sub>] supplemented with 0.045 mg/mL 2,2-dimethylbutyrate (as internal standard). The resulting slurry was centrifuged for 30 min at 5000 g at 4 °C, and the supernatant was filtered through a 0.2-µm filter. SCFAs in the supernatant collected were analyzed using a GC (Shimadzu-2010) equipped with FID and a stabilwax column (Restek, United States) of 30 m length, 530 µm diameter and 1 µm film thickness. The system was run with nitrogen as carrier gas at an inlet constant pressure of 18.1 kPa. Samples were run at an initial temperature of 120 °C for 0.5 min, and then with 8 °C/min change in temperature till it reached 220 °C and was held at 220 °C for 8 min for a total program time of 20.5 min<sup>[27]</sup>. SCFAs were identified using external standards consisting of acetate, *iso*-butyrate, *n*-butyrate (Sigma, India) and the concentration was calculated using the area percentage method.

### Ethics statement

Ethical clearance for the study was obtained from the Institute Ethics Committee, All India Institute of Medical Sciences, New Delhi. Written informed consent was obtained from all the participants.

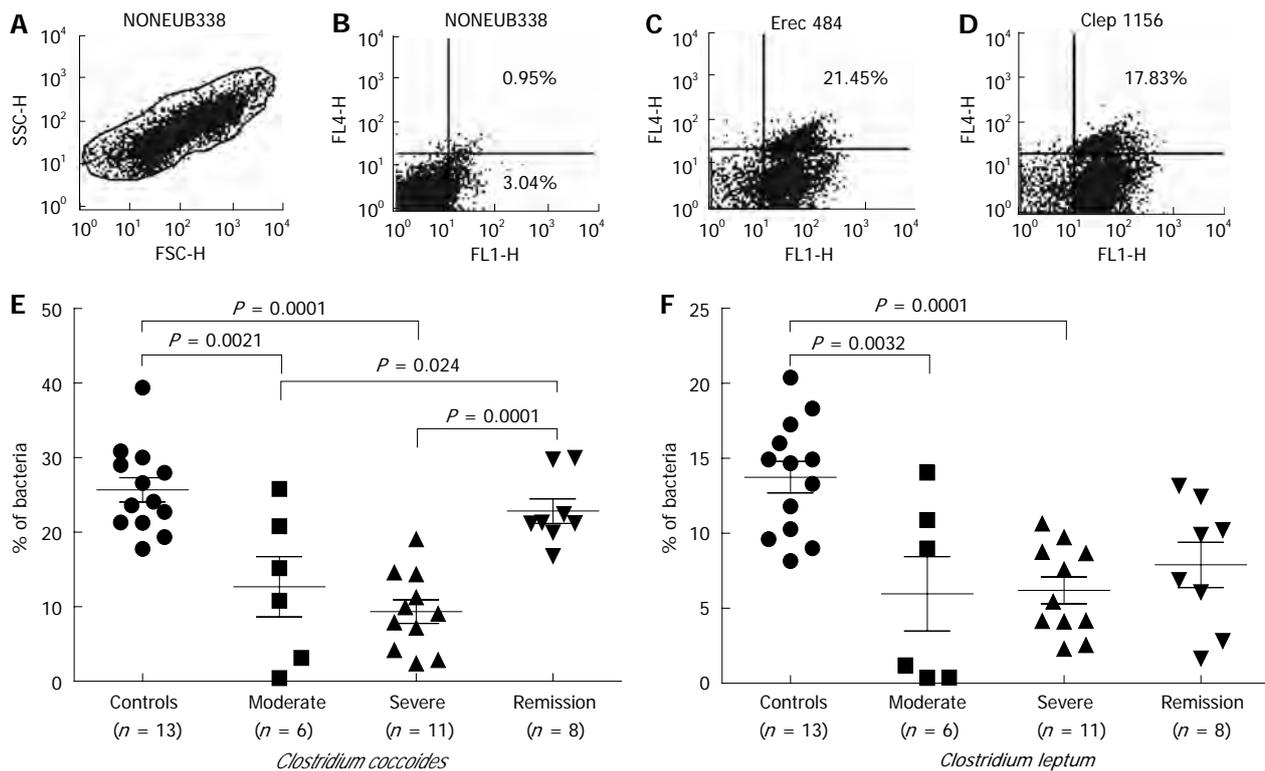

### Statistical analysis

The mean cell proportion and number of bacteria in fecal samples were estimated by FISH and qPCR in triplicate, and the results were expressed as a percentage of bacteria and number of bacteria, respectively. SCFA level was determined by GC, and the results were expressed in mmol/µL. Student's *t* test was employed to check any significant changes in the SCFA concentrations with the changes in the disease activity. Graphpad prism-6 was used to analyze FISH and qPCR data.

## RESULTS

### Analysis of *C. leptum* and *C. coccoides* groups

**FISH-flow cytometry:** In Figure 1A, the region R1 corresponds to relative size (FSC) with granularity (SSC) of the bacteria during flow cytometry with NONEUB338 hybridized cells. This region R1 was gated for further dot plots. Flow cytometric analysis of the hybridized samples gave a shift in signal of 1 log unit compared to the nonhybridized cells, enabling the specific detection and enumeration of the different bacterial groups (Figure 1B-D). Scoring of bacteria could not be achieved uni-

**Figure 1** Flow cytometric analysis of fecal microflora using 16S rRNA targeted probes. A: The region R1 corresponding to relative size (the forward angle light scatter)/granularity (the side angle light scatter) of the bacteria was delineated. This region R1 was gated for further dot plots; B: Bacteria from fecal samples were hybridized with NONEUB338 probe; C: EUB338 and Erec 482; D: EUB338 and Clep 1156. A shift in fluorescence to higher intensities was obtained upon hybridization with positive control or group-specific probe: right lower and upper quadrant compared to the lower left quadrant. The signal in lower left quadrant represents debris. The events in upper right quadrant represent the proportion of bacterial cells hybridized with the group-specific probe within the total bacterial cells hybridized with the universal bacterial probe EUB338-fluorescein isothiocyanate (FITC). The enumeration of targeted cells was corrected by subtracting the background fluorescence, which was measured using the negative control NONEUB338 probe. Fluorescent *in situ* hybridization (FISH)-flow cytometry data were expressed as the mean  $\pm$  SE as enumerated by FISH-flow cytometry in control, moderate, severe and remission samples of ulcerative colitis; E: Erec 482; F: Clep 1156.

formly; therefore, sample size differed in each category.

In UC patients belonging to the moderate and severe disease categories, we observed significant decreases in members of the *C. coccooides* and *C. leptum* groups compared to control individuals (Figure 1E and F). Among the *C. coccooides* cluster, decreases in moderate disease samples attained the *P* value of 0.0021, while there was a *P* value of 0.0001 in the case of severe patient samples in comparison to controls. However, in the case of *C. leptum*, the *P* values were 0.0032 in moderate and 0.0001 in severe categories of samples, respectively, as compared to controls. Samples in the remission stage showed significant restoration in the population of the *C. coccooides* group (*P* = 0.0001); although an increasing trend was observed in the members of the *C. leptum* group, this did not attain a significant value.

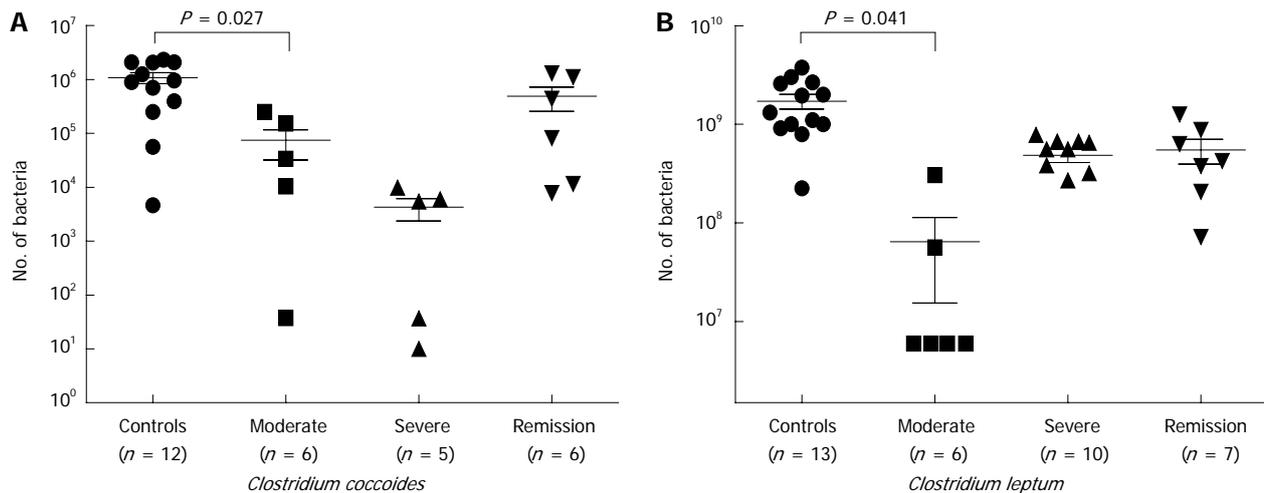

**Quantitative polymerase chain reaction:** In order to validate our FISH-flow cytometry data, we carried out a qPCR study (Figure 2A and B), where we observed significant decreases in both the members of *C. coccooides* group (*P* = 0.027) and *C. leptum* group (*P* = 0.041) in samples of moderate and severe disease stages. Members of both the clusters showed restoration of bacteria in

samples of remission category; however, this did not attain a significant *P* value.

**SCFA quantification by GC:** We further quantified the change in concentration of fecal SCFAs, namely acetate, *n*-butyrate and *iso*-butyrate, in control *vs* UC patient samples by GC. The concentrations of butyrate (*P* = 0.003), *iso*-butyrate (*P* = 0.044) and acetate (*P* = 0.047), were significantly reduced in severe UC samples when compared with control samples (Figure 3). As expected, during the remission stage *n*-butyrate level significantly restored back to normal level (*P* = 0.05) as seen in control individuals, confirming that the decrease observed during disease conditions reflects the loss of butyrate-producing bacteria (Figure 3C).

**Evaluation of predominant butyrate producers**

**FISH-flow cytometry:** Next, we evaluated the concentration of predominant members of both clostridial clusters (XIVa and IV). The population of *F. prausnitzii*, a member of the *C. leptum* group, was significantly low in UC samples of severe (*P* = 0.0001) category of disease in comparison to control samples (Figure 4A). Samples from the remission stage did not show significant restora-

**Figure 2** Quantitative polymerase chain reaction data showing the numbers of bacteria ( $\pm$  SE) in fecal samples of control vs ulcerative colitis patients. A: *Clostridium coccooides*; B: *Clostridium leptum*. The Y axis represents number of bacteria and X axis represents the sample category.

tion of *F. prausnitzii* in our FISH-flow cytometry experiment, as was observed for the *C. leptum* cluster during remission (Figures 1F and 2B).

*R. intestinalis*, a member of the *C. coccooides* group, was also significantly low ( $P = 0.02$ ) in patient samples of severe category disease (Figure 4B); however, this did not show significant restoration in the samples of remission stage. The population of *E. hallii*, another member of the *C. coccooides* group, decreased in disease conditions, but not significantly (Figure 4C). We failed to detect *E. hallii* in the majority of samples either by flow cytometry or qPCR, indicating low abundance of these bacteria in our study population. An increase in the population of *R. intestinalis* was recorded during remission stage in comparison to severe stage of the disease (Figure 4B and C). This was in agreement with our FISH-flow cytometry data of *C. coccooides* group. Abundance of *R. intestinalis*, *E. hallii* and *F. prausnitzii* was calculated out of total microbiota, as shown in Table 4. We detected a higher representation of *R. intestinalis* compared to *E. hallii* and *F. prausnitzii*. Therefore, we can infer that at the species level, abundance of the members of the *C. coccooides* cluster was higher in comparison to the members of the *C. leptum* cluster.

#### Quantitative polymerase chain reaction

As expected, the population of *F. prausnitzii* was significantly reduced in the samples of severe category of UC disease ( $P = 0.045$ ) (Figure 4D) as compared to control. In addition, abundance of the same species was restored at remission stage when compared to severe stage ( $P = 0.041$ ) (Figure 4D). Similarly, the *R. intestinalis* population showed significant reduction in samples of moderate ( $P = 0.015$ ) and severe ( $P = 0.001$ ) stage of the disease in comparison to control (Figure 4E). The recovery in the population of *R. intestinalis* was also seen in the remission category of samples when compared to severe category ( $P = 0.018$ ) (Figure 4E). However, qPCR analysis in the case of *E. hallii* did not show any significant reduction; in ad-

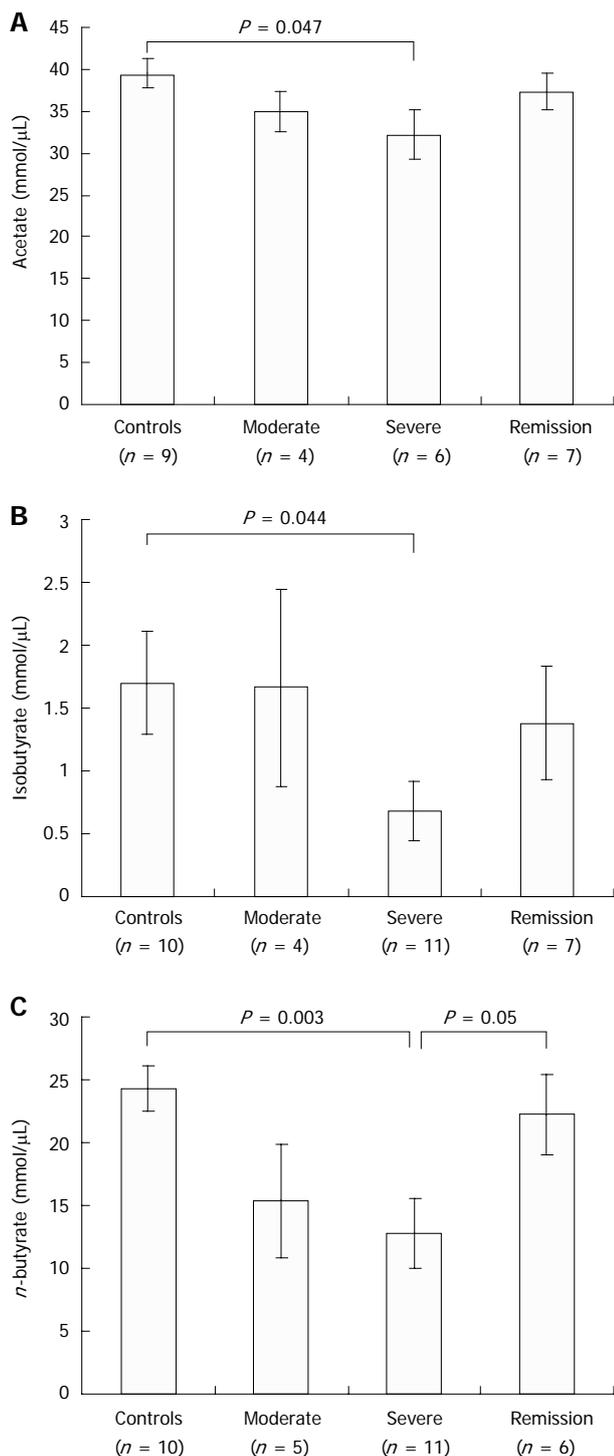

dition, *E. hallii* was undetected in the majority of samples observed by FISH-flow cytometry (Figure 4F).

## DISCUSSION

Our study revealed significant reduction in the members of both *C. coccooides* and *C. leptum* groups in fecal samples obtained from the severe disease category of UC patients in comparison to controls. FISH-flow cytometry and qPCR analysis of fecal samples belonging to the above groups supported the observations made by Takaishi *et al.*<sup>[4]</sup> and Sokol *et al.*<sup>[5]</sup>.

We quantified the abundance of predominant butyrate-producing species of clostridial clusters to see their association with acetate and butyrate. Since in most cases butyryl-CoA:acetate CoA-transferase rather than butyrate kinase appears to perform the final step in butyrate synthesis, we targeted bacteria possessing butyryl CoA:acetate CoA-transferase for butyrate synthesis, *e.g.*, *F. prausnitzii* and *Roseburia spp/E. rectale* which apparently lack butyrate kinase activity<sup>[15,28]</sup>. It is known that *Roseburia spp.* and *F. prausnitzii* strains contribute in butyrate production and many strains are associated with the net consumption of both acetate and carbohydrate<sup>[15]</sup>. Our study revealed that both the above species exhibited low abundance in the samples of severe category of UC and tended to restore their population during remission.

*F. prausnitzii* has been shown to exhibit anti-inflammatory effects on cellular and trinitrobenzenesulphonic acid-induced colitis models, partly due to secreted metabolites that are able to block NF- $\kappa$ B activation and interleukin 8 production<sup>[29]</sup>. In our observations (Table 4), *F. prausnitzii* accounted for 11.66%  $\pm$  1.55% of the *C. leptum* group, and *R. intestinalis* and *E. hallii* accounted for 14.48%  $\pm$  1.52% and 5.93%  $\pm$  0.54% of the *C. coccooides* group, respectively, in control individuals. In total these three species accounted for 6.83% of the total fecal flora. Previous studies have already reported low counts of *F. prausnitzii* in UC patients<sup>[30]</sup>.

**Figure 3** Short chain fatty acids in fecal samples of ulcerative colitis patients vs control samples, analyzed by gas chromatography. A: Acetate; B: Iso-butyrate; C: Butyrate. The Y axis represents concentration of respective short chain fatty acid and X axis represents the sample category.

We observed a significant decrease in concentrations of butyrate, iso-butyrate and acetate in UC fecal samples compared to controls through SCFA quantification by GC analysis, supporting earlier observations<sup>[4,31]</sup>.

An intriguing link between the level of SCFA and an intracellular energy sensor for the maintenance of intestinal barrier function has been suggested<sup>[10]</sup>. Our study

further substantiates a link between the fluctuations of butyrate production and the changes in the numbers of butyrate producers during UC. Lack of butyrate availability may lead to compromised intestinal barrier function resulting in increased exposure of luminal content to the host immune system, thus exaggerating the immune response<sup>[10]</sup>.

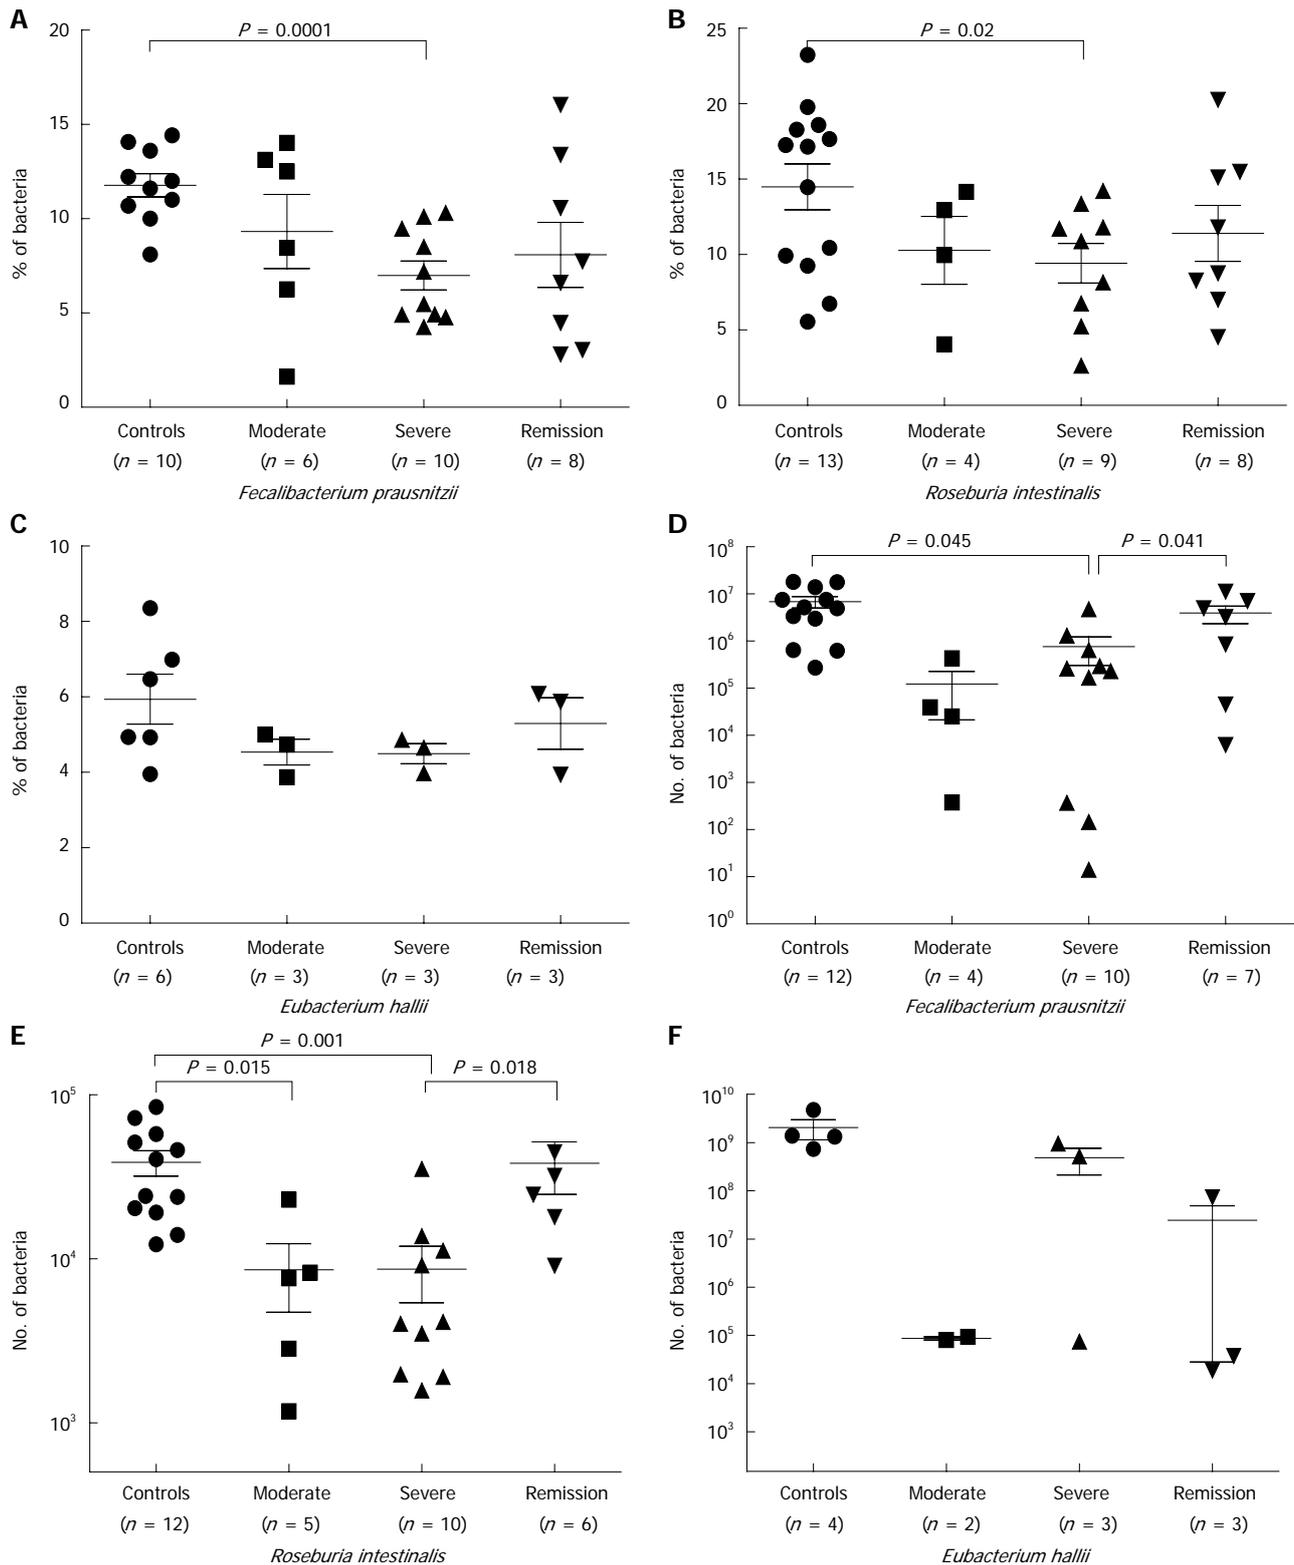

The reduced population of dominant butyrate producers and decreases in concentrations of butyrate and acetate in diseased samples indicate impaired butyrate supply in the colon, which may lead to energy deficiency for colonocytes. The resurgence of butyrate-producing bacteria at the remission stage and simultaneous increases in butyrate concentration, as observed here, show an association with UC and support the energy deficiency hypothesis of IBD<sup>[32]</sup>. Earlier studies have shown a requirement of acetate by *F. prausnitzii* and *R. intestinalis* for survival and other activities like production of butyrate<sup>[15,33]</sup>. Thus, major butyrogenic species depend on other bacteria, including net producers of acetate (*e.g.*, amyolytic bifidobacteria) and other bacterial species capable of degrading a variety of complex carbohydrates<sup>[15]</sup>. These bacteria play an important role in net butyrate production and may be associated with dysbiosis during UC.

Acetate and butyrate are major SCFAs and decreases in their concentration may affect the overall SCFA concentration. SCFAs in the colon maintain mild acidic conditions which boost the formation of butyrate by favoring growth of butyrate-producing bacteria and allowing them to compete against gram-negative bacteria such as *Bacteroides spp* to maintain the homeostasis<sup>[9]</sup>. Thus, a reduced butyrate level may lead to an increased Gram-negative bacteria population due to reduced competition. This was validated by our observation of increased representation of *Bacteroides* in UC samples (data not shown).

Our data showing reduced abundance of three predominant butyrate-producing species indicate that during UC, butyrate deficiency may not be solely due to reduced uptake of butyrate by the inflamed mucosa as reported by Canani *et al.*<sup>[9]</sup>, but also due to reduced abundance of predominant butyrate producers and conversely lower production of butyrate.

The limitation of our findings is that most of the microbial data are not presented in absolute values but in percentages; therefore, it is difficult to critically assess the real changes in the microbial composition. The study is performed in a very restricted number of subjects due to the exclusion criteria followed during sample collection.

In conclusion, our study shows a decreased abundance of predominant butyrate producers like *R. intestinalis* and *F. prausnitzii* belonging to clostridial clusters in the UC disease condition. This decrease was found to correlate with reduced SCFA concentration in UC patients. We thus provide evidence that reduced butyrate levels during the diseased state are due to less abundance of these species in UC. It is evident from our data that decreased levels of these species resulting in reduced butyrate levels may be associated with the etiology of UC.

**Figure 4** Analysis of predominant butyrate-producing bacteria. A-C: *Fecalibacterium prausnitzii* (A), *Roseburia intestinalis* (B), and *Eubacterium rectale* (C) by fluorescent *in situ* hybridization-flow cytometry; D-F: *Fecalibacterium prausnitzii* (D), *Roseburia intestinalis* (E), and *Eubacterium hallii* (F) by quantitative polymerase chain reaction. The Y axis represents number of bacteria and X axis represents the status of patients. Horizontal bars with asterisks represent comparison between ulcerative colitis and control conditions.

This was further demonstrated in our analysis of the samples from remission patients, where the targeted organisms tended to revert back to normal level. It would

be of interest in the future to extend this approach to studying the diversity of each member of the clostridial cluster, including changes in non-butyrate producers.

**Table 4** Enumeration of butyrate producers in fecal samples through fluorescent *in situ* hybridization-flow cytometry (mean  $\pm$  SE)

| Cluster or species                  | Out of total microbiota | Species                | Out of respective cluster |
|-------------------------------------|-------------------------|------------------------|---------------------------|
| Control fecal samples               |                         |                        |                           |
| <i>C. coccoides</i> cluster         | 25.69% $\pm$ 1.62%      | <i>R. intestinalis</i> | 14.48% $\pm$ 1.52%        |
|                                     |                         | <i>E. hallii</i>       | 5.93% $\pm$ 0.54%         |
| <i>C. leptum</i> cluster            | 13.74% $\pm$ 1.05%      | <i>F. prausnitzii</i>  | 11.66% $\pm$ 1.55%        |
| <i>R. intestinalis</i> <sup>1</sup> | 3.71% $\pm$ 0.39%       |                        |                           |
| <i>E. hallii</i> <sup>1</sup>       | 1.52% $\pm$ 0.13%       |                        |                           |
| <i>F. prausnitzii</i> <sup>1</sup>  | 1.60% $\pm$ 0.21%       |                        |                           |
| UC fecal samples (moderate)         |                         |                        |                           |
| <i>C. coccoides</i> cluster         | 12.70% $\pm$ 4.60%      | <i>R. intestinalis</i> | 10.00% $\pm$ 2.25%        |
|                                     |                         | <i>E. hallii</i>       | 4.03% $\pm$ 0.3%          |
| <i>C. leptum</i> cluster            | 6.40% $\pm$ 3.40%       | <i>F. prausnitzii</i>  | 7.5% $\pm$ 2.3%           |
| <i>R. intestinalis</i> <sup>1</sup> | 1.27% $\pm$ 0.10%       |                        |                           |
| <i>E. hallii</i> <sup>1</sup>       | 0.51% $\pm$ 0.01%       |                        |                           |
| <i>F. prausnitzii</i> <sup>1</sup>  | 0.48% $\pm$ 0.14%       |                        |                           |
| UC fecal samples (severe)           |                         |                        |                           |
| <i>C. coccoides</i> cluster         | 9.80% $\pm$ 2.40%       | <i>R. intestinalis</i> | 9% $\pm$ 1.83%            |
|                                     |                         | <i>E. hallii</i>       | 4.2% $\pm$ 0.2%           |
| <i>C. leptum</i> cluster            | 6.20% $\pm$ 1.80%       | <i>F. prausnitzii</i>  | 6.01% $\pm$ 1.6%          |
| <i>R. intestinalis</i> <sup>1</sup> | 0.82% $\pm$ 0.04%       |                        |                           |
| <i>E. hallii</i> <sup>1</sup>       | 0.41% $\pm$ 0.01%       |                        |                           |
| <i>F. prausnitzii</i> <sup>1</sup>  | 0.37% $\pm$ 0.02%       |                        |                           |
| UC fecal samples (remission)        |                         |                        |                           |
| <i>C. coccoides</i> cluster         | 12.99% $\pm$ 2.65%      | <i>R. intestinalis</i> | 11.40% $\pm$ 1.83%        |
|                                     |                         | <i>E. hallii</i>       | 5.07% $\pm$ 0.6%          |
| <i>C. leptum</i> cluster            | 7.89% $\pm$ 1.50%       | <i>F. prausnitzii</i>  | 7.40% $\pm$ 2.32%         |
| <i>R. intestinalis</i> <sup>1</sup> | 1.48% $\pm$ 0.04%       |                        |                           |
| <i>E. hallii</i> <sup>1</sup>       | 0.65% $\pm$ 0.01%       |                        |                           |
| <i>F. prausnitzii</i> <sup>1</sup>  | 0.58% $\pm$ 0.03%       |                        |                           |

<sup>1</sup>Abundance of *Roseburia intestinalis* (*R. intestinalis*), *Eubacterium hallii* (*E. hallii*) and *Fecalibacterium prausnitzii* (*F. prausnitzii*) were calculated out of total microbiota. *Clostridium coccoides* (*C. coccoides*) and *Clostridium leptum* (*C. leptum*) were enumerated as proportion of total bacterial cell hybridized with group-specific probe. *R. intestinalis*, *E. hallii* and *F. prausnitzii* were enumerated as proportion of cell hybridized with species-specific probe. UC: Ulcerative colitis.

## COMMENTS

### Background

Inflammatory bowel disease (IBD), comprising of Crohn's disease and ulcerative colitis (UC), is a class of chronic inflammatory disorders of the intestine and involves impaired barrier function. A rising trend in the incidence and prevalence of inflammatory bowel IBD in the Asian population has been recognized for the past two decades. IBD is considered as an exaggerated immune response, exerted either to all commensal bacteria or to a subset or to a single strain of bacteria.

### Research frontiers

Differences in fecal microbiota of healthy subjects and IBD patients have been identified. Commensal gut microbiota have been reported to exert various multiple beneficial effects on host gut epithelium. Short chain fatty acids (SCFAs), like butyrate, produced by microbial fermentation of undigested carbohydrates have been depicted to regulate transepithelial transport, colonocyte proliferation and differentiation, mucosal inflammation, intestinal motility and barrier function. The homeostasis between commensal microbiota and host defensive responses at the mucosal level has a pivotal role in the initiation and pathophysiology of chronic IBD. Therefore, monitoring the fluctuations in butyrogenic bacteria and SCFA level may help in understanding the relation of dysbiosis with UC.

### Innovations and breakthroughs

This work was carried out to study the fluctuations in butyrate-producing bacteria and simultaneous measurement of butyrate concentration in fecal samples of UC vs control individuals belonging to the northern part of India. The data were also correlated with patients differing in disease activity. Decreases in the level of butyrate producers in UC patients coincided with the changes in butyrate concentration during active stage disease. However, the levels reverted back to normal during remission stage showing the role of these bacteria in the disease etiology. Such comparisons have not been made so far to show the

above relationship with disease activity.

### Applications

It is speculated that by measuring the level of these species and concentration of SCFA in stool samples (a non-invasive method), authors can indicate the status of UC patients.

### Terminology

Dysbiosis (also called dysbacteriosis) refers to a condition with microbial imbalances on or within the body. Dysbiosis is most prominent in the digestive tract or on the skin, but can also occur on any exposed surface or mucous membrane such as the vagina, lungs, mouth, nose, sinuses, ears, nails or eyes. It has been associated with different illnesses, such as IBD, as imbalances in the intestinal microbiome may be associated with bowel inflammation and chronic fatigue syndrome.

### Peer review

This is a methodologically well performed, interesting report, addressing the potential role of gut commensal microbiota in the pathophysiology of UC.

### Abstract

**AIM:** To investigate the disruptions of interstitial cells of Cajal (ICC) in the remaining bowel in rats after massive small bowel resection (mSBR).

**METHODS:** Thirty male Sprague-Dawley rats fitting entry criteria were divided randomly into three experimental groups ( $n = 10$  each): Group A rats underwent bowel transection and re-anastomosis (sham) and tissue samples were harvested at day 7 post-surgery. Group B and C rats underwent 80% small bowel resection with tissue harvested from Group B rats at day 7 post-surgery, and from Group C rats at day 14 post-surgery. The distribution of ICC at the site of the resid-

ual small bowel was evaluated by immunohistochemical analysis of small intestine samples. The ultrastructural changes of ICC in the remnant ileum of model rats 7 and 14 d after mSBR were analyzed by transmission electron microscopy. Intracellular recordings of slow wave oscillations were used to evaluate electrical pace-making. The protein expression of c-kit, ICC phenotypic markers, and membrane-bound stem cell factor (mSCF) in intestinal smooth muscle of each group were detected by Western blotting.

**RESULTS:** After mSBR, immunohistochemical analysis indicated that the number of c-kit-positive cells was dramatically decreased in Group B rats compared with sham tissues. Significant ultrastructural changes in ICC with associated smooth muscle hypertrophy were also observed. Disordered spontaneous rhythmic contractions with reduced amplitude ( $8.5 \pm 1.4$  mV vs  $24.8 \pm 1.3$  mV,  $P = 0.037$ ) and increased slow wave frequency ( $39.5 \pm 2.1$  cycles/min vs  $33.0 \pm 1.3$  cycles/min,  $P = 0.044$ ) were found in the residual intestinal smooth muscle 7 d post mSBR. The contractile function and electrical activity of intestinal circular smooth muscle returned to normal levels at 14 d post mSBR (amplitude,  $14.9 \pm 1.6$  mV vs  $24.8 \pm 1.3$  mV; frequency,  $30.7 \pm 1.7$  cycles/min vs  $33.0 \pm 1.3$  cycles/min). The expression of Mscf and c-kit protein was decreased at 7 d ( $P = 0.026$ ), but gradually returned to normal levels at 14 d. The ICC and associated neural networks were disrupted, which was associated with the phenotype alterations of ICC.

**CONCLUSION:** Massive small bowel resection in rats triggered damage to ICC networks and decreased the number of ICC leading to disordered intestinal rhythmicity. The mSCF/c-kit signaling pathway plays a role in the regulation and maintenance of ICC phenotypes.

**Key words:** Interstitial cells of Cajal; c-kit; Slow wave; Massive small bowel resection; Intestinal dysfunction

**Core tip:** Several gastrointestinal motility diseases are associated with altered numbers of interstitial cells of Cajal (ICC). Short bowel syndrome is also characterized by disordered intestinal motility immediately after surgery. We have investigated the alterations in numbers and functional changes of ICC that occur as a result of short bowel syndrome. In summary, our study showed modifications of the ultrastructure morphology of ICC, altered numbers of ICC and subsequent altered electrophysiological functional activity in the ileum after massive small bowel resection. However, the association between motility disorders and the changes of ICC should be further evaluated.

Chen J, Du L, Xiao YT, Cai W. Disruption of interstitial cells of Cajal networks after massive small bowel resection. *World J Gastroenterol* 2013; 19(22): 3415-3422 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i22/3415.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i22.3415>

## INTRODUCTION

Short bowel syndrome (SBS) is characterized by disordered intestinal motility immediately after surgery<sup>[1]</sup>. After massive small bowel resection (mSBR), the remaining bowel undergoes a compensatory process termed adaptation. During the process of adaptation, the small intestine smooth muscle cells undergo dramatic changes in gross morphology and ultrastructure. Adaptation is associated with the hypertrophy of smooth muscle, which is a physiological response to the increased functional requirement placed on the residual small bowel<sup>[2]</sup>. In addition, hypertrophy of smooth muscle tissue produces distinct motility disorders in the intestinal remnant, resulting in malabsorption and loss of nutrients because of diarrhea. Therefore, there is a critical need for further investigation of the mechanisms regulating resection-induced adaptation and potential targets that could be developed as therapeutic strategies. In a previous study, we found that resection-induced intestinal adaptation in a rat SBR model involved both the mucosal and intestinal smooth muscle layers. However, the mechanisms regulating adaptation remain unclear<sup>[3]</sup>.

Interstitial cells of Cajal (ICC) reside in the tunica muscularis of the gastrointestinal tract<sup>[4]</sup>. ICC play a crucial role in gastrointestinal motility in concert with the enteric nervous system, which is composed of both the myenteric (inter-muscular) plexus and the submucosal plexus<sup>[5]</sup>. ICC are present in organs containing smooth muscle tissue and are pacemaker cells that provide the basal electrical rhythm, which controls peristalsis in the gastrointestinal tract<sup>[6]</sup>. After receiving inputs from motor neurons, ICC generate and propagate electrical activity<sup>[7,8]</sup>. ICC are specialized cells in the gastrointestinal tract smooth muscle organs that express the c-kit receptor tyrosine kinase<sup>[9]</sup>. ICC can be identified by the expression

of CD117 (c-kit), which is a membrane receptor with tyrosine kinase activity<sup>[5,10,11]</sup>.

Intracellular signaling *via* c-kit plays a key role in the development and maintenance of the ICC phenotype and functional activity of ICC in the gastrointestinal tract<sup>[7,12]</sup>. Maintenance of the ICC phenotype requires membrane-bound stem cell factor (mSCF) produced locally within the tunica muscularis<sup>[13-16]</sup>. To date, remarkably few studies have investigated the functional changes of ICC that occur as a result of SBS. We hypothesize that the disruption to ICC activity involves the downregulation of the mSCF/c-kit signaling pathway following massive mSBR. In the current study, alterations in ICC phenotype and pacemaker activity were evaluated in a model of mSBR.

## MATERIALS AND METHODS

### *Experimental design and animal model*

Thirty male Sprague-Dawley rats weighing 250-300 g were obtained from the Experimental Animal Center of Shanghai Jiaotong University School of Medicine. All animals were housed in metabolic cages with free access to food and water and acclimated to their environment for 5 d before experimentation. Animals were maintained under standardized temperature, humidity and 12 h light-dark cycles. The rats were divided randomly into three experimental groups ( $n = 10$  each): Group A rats underwent bowel transection and re-anastomosis (sham); Groups B and C rats underwent 80% small bowel resection; Group A and Group B (SBS1W) bowel tissues were harvested at day 7 post-surgery; Group C (SBS2W) bowel tissues were harvested at day 14 post-surgery.

Animals were fasted for 16 h prior to laparotomy, and intestinal surgery was performed the following morning, as previously described<sup>[17]</sup>. All operative procedures were performed under anesthesia by intraperitoneal (*ip*) injection of pentobarbital sodium (30 mg/mL), which was administered at doses of 33-40 mg/kg body weight. Briefly, during surgery, the abdomen was opened by a midline incision and the ligament of Treitz and the ileal-cecal junction was identified and marked. For SBR rats, enterectomy was performed by removing approximately 80% of the small intestine, leaving approximately 10 cm of the terminal ileum and 5 cm of the proximal jejunum, which were anastomosed. For sham-operated control rats, the laparotomy and all surgical manipulations were the same as above, but the resection procedure was not carried out. All animals received fluid resuscitation by *ip* injection of saline (10 mL 0.9% NaCl) before the abdominal wall was closed and surgery concluded. After recovery, rats were transferred back to individual cages and given water *ad libitum* overnight, after which their regular diet was reinstated.

All experimental protocols were approved by the local Animal Care Committee and conformed to the Guide for the Care and Use of Laboratory Animals published by the Science and Technology Commission of the People's Republic of China (STCC Publication No. 2, revised 1988).

### Immunohistochemistry

Immunohistochemical analysis was performed on tissue samples of smooth muscle at the same site of the ileum from both control and mSBR rats. The bowel was opened along the mesenteric border and the lumen contents were washed away with Krebs Ringer buffer. Segments of the bowel were pinned to the base of a Sylgard silicone elastomer dish and the mucosa was removed by sharp dissection. After dissection, the tunica muscularis were embedded in Tissue-Tek<sup>®</sup> OCT compound medium (Sakura Finetek United States, Inc., Torrance, CA, United States). The embedded tunica muscularis was cut at a thickness of 30  $\mu\text{m}$  with a freezing microtome (Leica Microsystems GmbH, Wetzlar, Germany) and stored at  $-20\text{ }^{\circ}\text{C}$  until use. The sections were fixed with iced acetone for 10 min. After endogenous peroxidase activity was quenched with 3% hydrogen peroxide, the sections were preincubated in 10% goat serum/0.2% Triton X-100/0.1 mol/L phosphate buffered saline (PBS) for 1 h at room temperature. The sections were incubated with antibodies against c-kit protein (1:50 dilution, rabbit polyclonal c-kit antibody, Santa Cruz Technologies, Santa Cruz, CA, United States) in 0.1 mol/L PBS containing 1% goat serum for 2 h. The sections were then incubated for 1 h at room temperature with biotinylated anti-rabbit immunoglobulin G (1:200; Vector Labs, Burlingame, CA, United States). Positive staining was visualized using an avidin-biotin-peroxidase complex system (Vectastain ABC Elite Kit, Vector Labs). The degree of expression of c-kit antibody was analyzed using image analysis software (Zeiss).

### Transmission electron microscopy

Tissue samples from intestinal smooth muscle at the same site of the ileum from both control and mSBR rats were fixed with 3% glutaraldehyde at room temperature. After fixation, the tissues were washed overnight in 0.1 mol/L sodium cacodylate buffer [6% sucrose and 1.25 mmol/L  $\text{CaCl}_2$  (pH 7.4)] at  $4\text{ }^{\circ}\text{C}$  and postfixed with 1% osmium tetroxide in 0.05 mol/L sodium cacodylate buffer (pH 7.4) at  $4\text{ }^{\circ}\text{C}$  for 2 h. The tissues were stained with saturated uranyl acetate for 3.5 h at room temperature, dehydrated in graded alcohol and embedded in Eponate 12 resin (Ted Pella, Inc., United States). The tissue was sectioned parallel and transverse to the long axis of the circular muscle layer. At suitable sites, 3  $\mu\text{m}$  sections were cut and stained with 2% toluidine blue. After examination of the toluidine blue stained sections, ultrathin sections of selected areas were obtained with the ultramicrotome using a diamond knife, mounted on 200-mesh grids, and stained with uranyl acetate and lead citrate. The grids were observed with a JEM1200EX electron microscope.

### Electrophysiological experiments

Following euthanasia, a 50 mm mid-segment of the remaining small bowel was removed and placed in Krebs solution (mmol/L; NaCl 117, KCl 4.7,  $\text{NaHCO}_3$  25,  $\text{KH}_2\text{PO}_4$  1.2,  $\text{MgSO}_4$  1.2, *D*-glucose 11,  $\text{CaCl}_2$  2.6). The bowel was opened along the mesenteric border, and the luminal contents were washed away with Krebs solution.

Segments of the bowel were pinned to the base of a Sylgard silicone elastomeric dish (Dow Corning, Midland, MI, United States), and the mucosa was removed by sharp dissection<sup>[18]</sup>. Strips of smooth muscle tissue (8 mm  $\times$  4 mm) were cut parallel to the longitudinal muscle oral to the site of the occlusion clips. The muscle was placed in a recording chamber with the submucosal aspect of the muscle facing upwards at  $37\text{ }^{\circ}\text{C}$  in an atmosphere of 95%  $\text{O}_2$  and 5%  $\text{CO}_2$ . Cells were impaled with KCl-filled glass microelectrodes with resistances of 50-90 M $\Omega$ . Electrical responses were recorded and amplified through a high input impedance amplifier (SYS-773 Duo 773 Electrometer, WPI, United States). Experiments were performed in the presence of nifedipine (1  $\mu\text{mol/L}$ ; Sigma, St Louis, MO, United States) in order to reduce contractions and facilitate the extended period of cell impalement. Slow waves in mouse intestine have been previously shown to be unaffected by nifedipine<sup>[19]</sup>.

### Western blotting

Smooth muscle tissues were lysed in radioimmunoprecipitation assay buffer [25 mmol/L Tris-HCl pH 7.6, 150 mmol/L NaCl, 1% NP-40, 1% sodium deoxycholate, 0.1% sodium dodecyl sulfate (SDS)] for the detection of protein expression levels. The Bradford method (Pierce, Rockford, IL, United States) was used to determine protein concentrations. Tissue lysates (20  $\mu\text{g}$  of total protein per lane) were subjected to electrophoretic separation by 10% SDS-polyacrylamide gel electrophoresis and transferred to nitrocellulose membranes (Hybond, GE Healthcare Biosciences, Pittsburgh, PA, United States). Nonspecific binding was reduced by incubation of the membrane in 5% milk. Western blots were performed using antibodies directed against c-kit (1:200 dilution, rabbit polyclonal c-kit antibody, Santa Cruz Technologies, Santa Cruz, CA, United States), murine stem cell factor (mSCF) (1:200 dilution, mouse monoclonal SCF antibody, Santa Cruz Technologies), and glyceraldehyde-3-phosphate dehydrogenase (GAPDH) (1:600 dilution, rabbit monoclonal antibody, CWbiotech company, Beijing, China). Alkaline phosphatase conjugated secondary antibodies (CWbiotech Company Beijing, China) were used to detect protein bands. TIFF images were captured by Adobe Photoshop and analyzed by Quantity one image software (NIH, MA, United States).

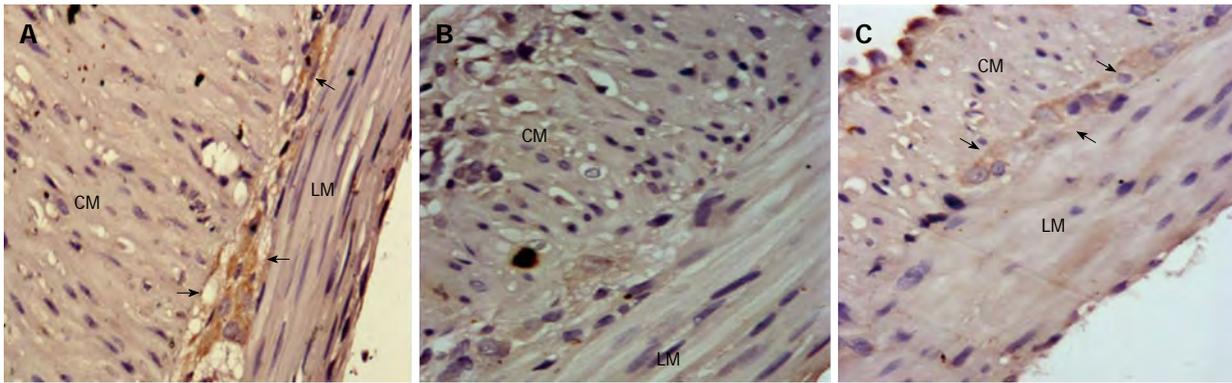

### Statistical analysis

The results are presented as mean  $\pm$  SE. Statistical differences between the groups were determined using a one-way analysis of variance with the SigmaStat program (SPSS, United States).  $P < 0.05$  was considered statistically significant.

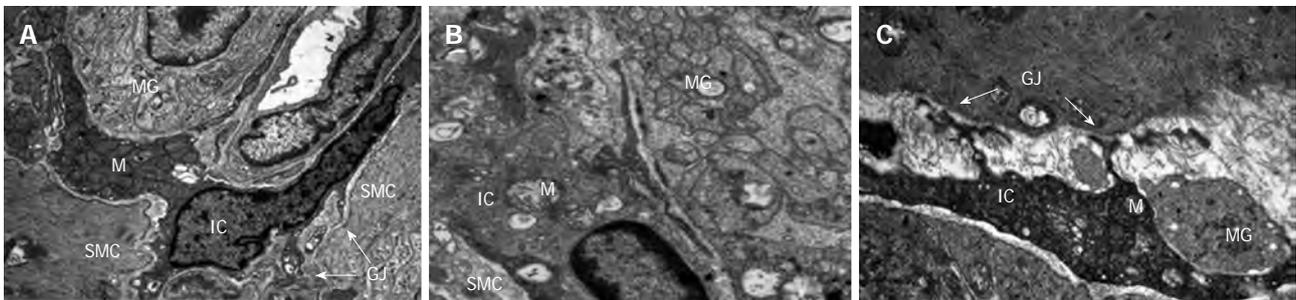

## RESULTS

### Distribution of c-kit(+) cells

Representative pictures of c-kit immunopositivity at the myenteric plexus are shown in Figure 1. In sham-operated rats, c-kit-positive cells were predominantly present

**Figure 1** c-kit immunopositivity at the level of the myenteric plexus in ileal whole-mount preparations. A: In the sham-operated group, c-kit-positive cells were predominantly present at the myenteric plexus level; B: Compared with sham-operated tissues, the number and density of c-kit immunopositive cells were significantly decreased in the short bowel syndrome (SBS) 1W group; C: In the SBS2W group, the number of interstitial cells of Cajal had returned to normal levels. The arrows showed c-kit immunopositivity is positive (original magnification  $\times 400$ ). LM: Longitudinal muscle; CM: Circular muscle.

**Figure 2** Ultrastructural morphological changes in interstitial cells of Cajal. A: At the ultrastructural morphological level, interstitial cells of Cajal (ICC) showed typical myofilaments and organelles of ICC, such as mitochondria and smooth sarcoplasmic reticulum in the sham-operated group; B: Ultrastructural changes of ICC were observed in the short bowel syndrome (SBS) 1W group, such as clear cytoplasm, sparse mitochondria, scarce smooth endoplasmic reticulum and a reduced number of contacts between nerves and ICC; C: In the SBS2W group, ultrastructural changes of ICC were ameliorated (original magnification  $\times 3750$ , 2.5 K). SMC: Smooth muscle cell; GJ: Gap junction; M: Mitochondria; MG: Myenteric ganglion.

at the myenteric plexus level. However, the number and density of c-kit immunopositive cells were significantly decreased in SBS1W rats ( $P < 0.05$ ) compared with sham tissues. However, after 2 wk, the number and density of ICC were clearly increased and approached sham levels, as indicated by c-kit positive cells (Figure 1).

### Ultrastructural morphological changes

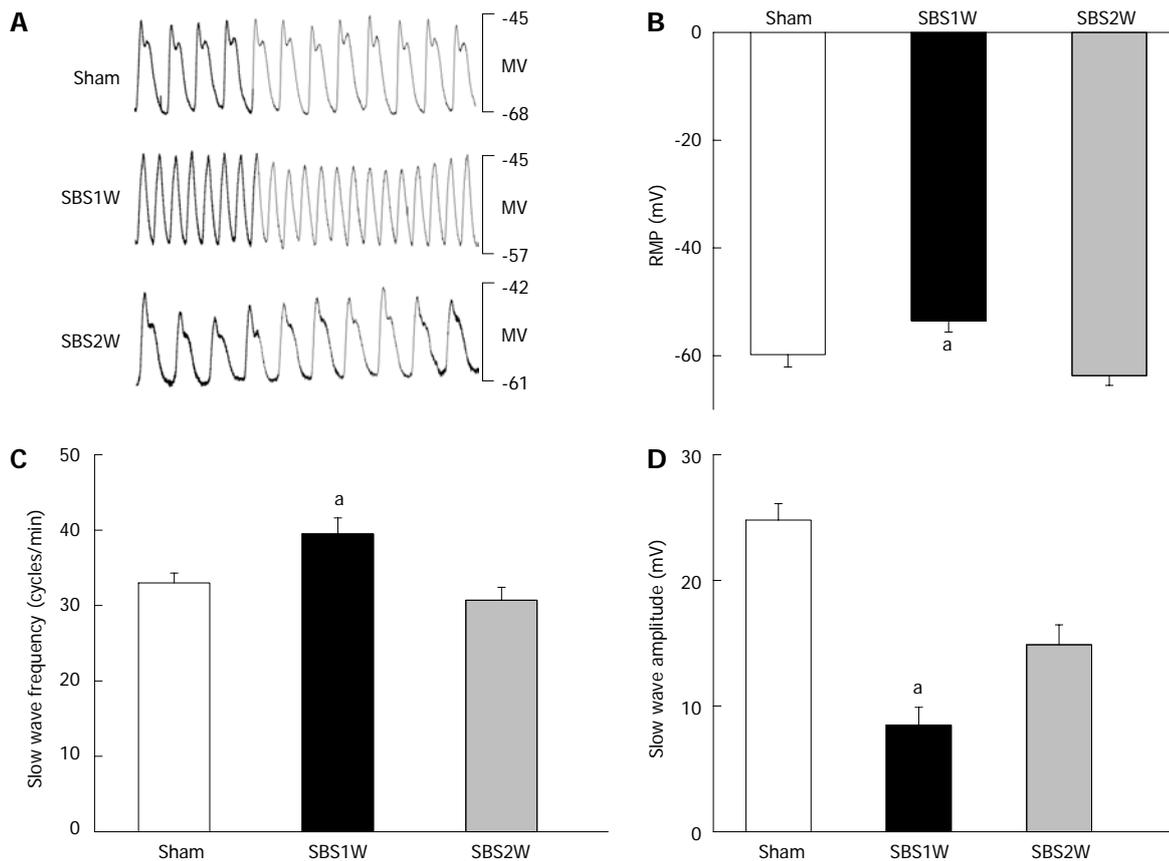

In sham rats, ultrastructural features of ICC in the small intestine were characterized by a less electron-dense cytoplasm and abundant mitochondria in sham rats (Figure 2A). However, the basal lamina or caveolae were not present. Intermediate filaments and thin filaments were apparent as thin processes. Along the length of overlapping processes, ICC predominantly formed large gap junctions between adjoining cells (Figure 2A). In certain areas, slender cytoplasmic processes of ICC were in close contact with a varicosity of the myenteric ganglion. Another part of the same cellular process was connected to a muscle cell *via* a gap junction, suggesting a functional relationship between these cell types.

Altered ICC ultrastructure was observed in the small intestine of SBS1W rats including clear cytoplasm, sparse mitochondria, scarce smooth endoplasmic reticulum,

and a reduced number of contacts between nerves and ICC (Figure 2B). The ultrastructural abnormalities of ICC in the small intestine of SBS2W rats exhibited some improvement compared to SBS1W rats, but the ultrastructural morphology had not returned to normal as observed in the sham-operated rats (Figure 2C).

### Electrophysiological studies

Electrophysiological studies were performed on circular muscles of the ileum in the remaining small bowel at day 7 or 14 following mSBR. The second component of slow waves was absent in SBS1W rats (Figure 3A). Circular muscle cells from the ileum of sham-operated rats ( $n = 7$ ) exhibited resting membrane potentials (RMP) averaging  $-63.7 \pm 1.8$  mV and slow waves of  $24.8 \pm 1.3$  mV in amplitude and a frequency of  $33 \pm 1.3$  cycles/min. The electrical activities of ileum circular muscle cells were markedly different in animals 7 d after mSBR. The slow waves had considerably reduced RMP and amplitude and increased in frequency (RMP,  $-53.5 \pm 2.1$  mV; amplitude,  $8.5 \pm 1.4$  mV; frequency,  $39.5 \pm 2.1$  cycles/min; Figure 3B-D, respectively;  $P < 0.05$ ) compared with sham-operated tissues. However, 14 d after mSBR, the electrical activity of the circular layer showed no significant chang-

**Figure 3** Electrical activity recorded from the small intestines (ileum) from sham-operated and short bowel syndrome rats. A: Slow waves in sham-operated group were biphasic, consisting of an upstroke and plateau component. Slow waves short bowel syndrome (SBS) 1W rats lacked an obvious secondary component; B: Resting membrane potentials (RMP) in each group were recorded, and a depolarized membrane potential appears to be a common feature of intestine smooth muscle in SBS rats; C: Slow wave frequency; D: Slow wave amplitude. <sup>a</sup> $P < 0.05$  vs sham group ( $n = 7$ ).

es ( $P > 0.05$ ) in RMP, amplitude and frequency (RMP,  $-59.8 \pm 2.3$  mV; slow wave amplitude,  $14.87 \pm 1.6$  mV; frequency,  $30.7 \pm 1.7$  cycles/min) compared with sham-operated tissues.

#### Expression levels of mSCF and c-kit are involved in the maintenance of the ICC phenotype and function after mSBR

In order to investigate the roles of mSCF and c-kit in the recovery process of the electrophysiological function of smooth muscle, we determined the expression of these two proteins in mSBR and sham rat intestinal smooth muscle tissues by Western blot (Figure 4A and C). The protein expression levels of mSCF and c-kit were normalized to the internal control GAPDH (Figure 4B and D). The protein expression levels of mSCF and c-kit were significantly decreased with mSBR in the SBS1W group ( $n = 4$ ;  $P < 0.05$ ). The protein expression levels returned to levels found in sham-operated rats by day 14 after mSBR, which coincided with the recovery of the electrical activities of ileal circular muscle cells.

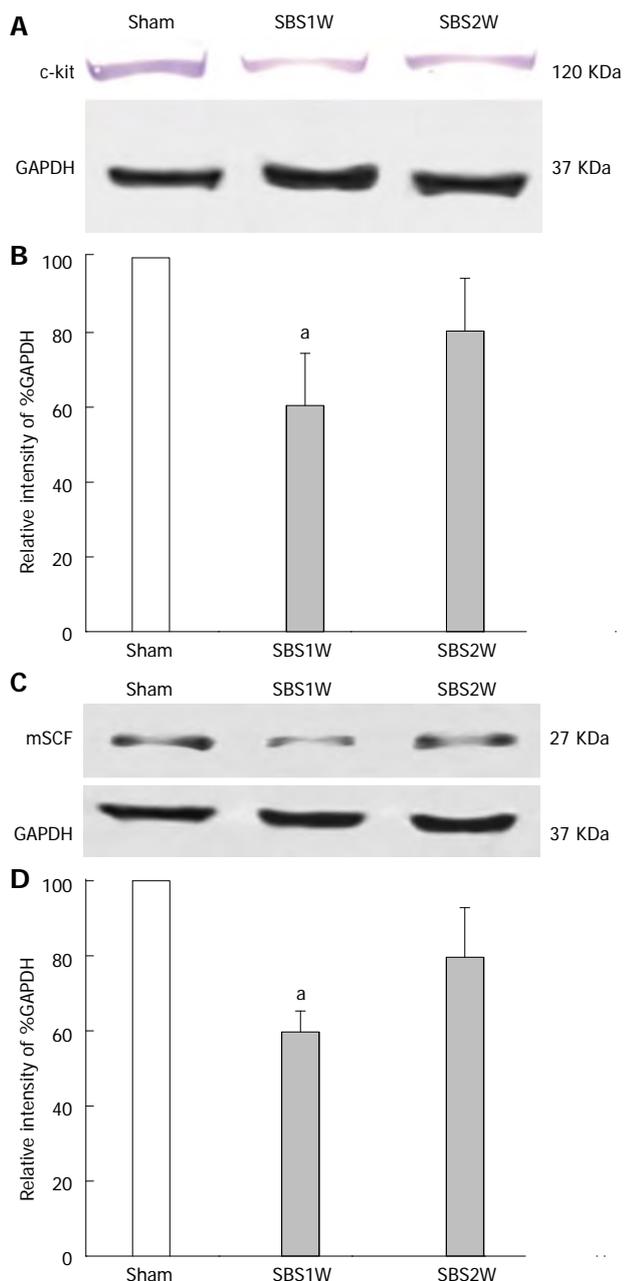

## DISCUSSION

After mSBR, adaptive alterations in the function of the remaining bowel are often accompanied by disorders of intestinal motility. However, the mechanisms regulating

the adaptation and motility disorders are not clear. A number of factors have been implicated in the pathogenesis of intestinal dysfunction, including changes in the number, density and ultrastructural morphology of ICC<sup>[11,20-22]</sup>. Alterations in the normal function of ICC have been reported in many intestinal disorders. In our previous studies, the unexpected finding of contractile dysfunction after mSBR prompted the investigation of whether intestinal dysfunction after mSBR was also mediated by ICC depletion<sup>[3]</sup>.

ICC are found between and within smooth muscle layers of the gastrointestinal tract from the esophagus to the internal anal sphincter<sup>[23,24]</sup>. ICC specifically express the proto-oncogene c-kit that encodes a receptor tyrosine kinase. *c-kit* expression can be clearly detected with the immunohistochemistry method and is a valuable tool for determining ICC structure, localization and distribution of cell networks.

Two separate functional groups of ICC exist in the lumen of the gastrointestinal tract: myenteric ICC (ICC-MY) and intramuscular ICC (ICC-IM). Networks of ICC-MY are located within the intermuscular space at the level of the myenteric plexus between the circular and longitudinal muscle layers. The plexus of ICC-MY, like the sino-atrial node, is the dominant pacemaker center that triggers the generation of slow waves, which are

**Figure 4** Changes in the expression profile of c-kit and membrane-bound stem cell factor in response to massive small bowel resection. A, C: The protein expression levels of c-kit and membrane-bound stem cell factor (mSCF) were downregulated in the first week after massive small bowel resection in the short bowel syndrome (SBS) 1W group and increased in the second week of the SBS2W group; B, D: Relative expression was determined by normalization to glyceraldehyde-3-phosphate dehydrogenase (GAPDH). <sup>a</sup> $P < 0.05$  vs sham group ( $n = 4$ ).

essential for orderly segmenting and peristaltic contractions in the tunica muscularis<sup>[25,26]</sup>. A second population of cells, ICC-IM, is localized within the muscle layers of the gastrointestinal tract and is innervated preferentially by enteric motor nerves. ICC-IM are closely associated with not only enteric motor nerves but also vagal afferent nerves. Elongated ICC-IM mediate efferent inputs to smooth muscle cells and the pacemaker apparatus, as well as relay afferent mechanical signals<sup>[27,28]</sup>.

We hypothesize that ICC depletion is central to the pathogenesis of many intestinal disorders. ICC are reduced or otherwise dysfunctional in several gastrointestinal tract dysmotilities, including achalasia, diabetic and idiopathic gastroparesis, mechanical ileus, intestinal pseudo-obstructions, slow-transit constipation, inflammations and malformations<sup>[29-31]</sup>. Rolfe *et al.*<sup>[30]</sup> reported that intestinal neuronal dysplasia was associated with loss or deficiency of ICC networks in the neonatal period. In addition, Chang *et al.*<sup>[32]</sup> reported that electrical slow waves were significantly disrupted and accompanied by disruption of ICC function and network in the obstructed ileum of mice.

In the current study, an absence or reduction in the number of ICCs was observed in the remaining bowel of an animal model of SBS. Utilizing intracellular recording of smooth muscle cells in isolated segments of the remnant ileal tissues, a reduction of rhythmic contractions and disruption of electrical slow waves were associated with the disruption of ICC and their network in the remnant ileum at 7 d in SBS rats. Slow waves are composed of two components: one produced by electrogenic propagation of driving potentials from the ICC-MY and the other formed by slow potentials from the ICC-IM<sup>[32,33]</sup>. In the current study, the frequency of slow waves changed in response to RMP changes as depolarization increased the frequency. Slow waves detected in SBS1W rats were lacking the secondary wave component compared with those in sham-operated and SBS2W rats. These differences suggested that alterations in the function of ICC account for the disruption of slow waves. This finding supports the concept that when ICC and their network were disrupted from the SBS ileum, the amplitude of slow waves decreased and the shape of slow waves and neural responses were lost due to the loss of ICC<sup>[12,32]</sup>.

Furthermore, c-kit signaling is essential for normal development of ICC and is required for long-term ICC survival and function<sup>[7,8]</sup>. This was first demonstrated by the blockade of c-kit signaling postnatally with an antagonistic anti-kit antibody. Inhibition of c-kit signaling resulted in a severe anomaly of gut motility with depletion of c-kit-positive ICC-MY cells in the myenteric regions of the small intestine<sup>[33]</sup>. Albertí *et al.*<sup>[34]</sup> also reported a deficient population of ICC in Ws/Ws rats harboring mutations in c-kit. In the gastrointestinal tract, c-kit expression on the cell surface of ICC is activated by mSCF produced by surrounding smooth muscle cells. Maintenance of ICC requires mSCF produced locally within the tunica muscularis. Another study reported a reduction in the content of mSCF in the stomach of non-obese diabetic mice<sup>[35]</sup>. These mice also exhibited marked depletion of ICC and a reduction in expression level of mSCF to one-third of that in normal mice. These studies support the hypothesis that reduced mSCF/c-kit signaling may underlie the decrease in ICC numbers and its network in obstructed mice<sup>[36]</sup>.

In our study, there was a reduction in mSCF/c-kit in the remnant ileum of SBS1W rats. The correlation

between the decrease in ICC numbers and reduction in mSCF/c-kit protein expression levels suggest that reduced mSCF/c-kit in the gastrointestinal tract may be involved in the disruption of ICC function in the remnant ileum of rats with SBS. Although previous work has shown that inflammatory diseases can induce the disruption of ICC and their network, the underlying mechanism by which the expression of mSCF in intestinal smooth muscle is decreased during SBS remains unclear. Additional studies are warranted to determine the role of mSCF and c-kit in the disruption of ICC.

In conclusion, the current study showed modifications of the ultrastructure morphology of ICC, phenotypic changes in ICC and subsequent altered electrophysiological functional activity in the ileum after mSBR, which may be associated with the mechanical alterations. In addition, the association between motility disorders after mSBR and the changes in ICC should be further evaluated.

## COMMENTS

### Background

Motility disorders are a prevalent condition observed in the residual small bowel after massive small bowel resection (mSBR). A number of factors have been implicated in the pathogenesis of intestinal dysfunction. A potential role for interstitial cells of Cajal (ICC) networks in intestinal disorders after mSBR has not previously been reported.

### Research frontiers

ICC are organized in distinct networks and serve several different functions. ICC generate the electrical slow wave and also set the smooth muscle membrane potential, are mechanosensors and modulate neuronal input to smooth muscle. Moreover, ICC play a protective role in gastrointestinal motility, although disruption of ICC networks are certainly not the only reason for intestinal dysfunction in some cases.

### Innovations and breakthroughs

The authors show that disruption of ICC networks is associated with intestinal dysfunction in rats after mSBR. This role of the ICC has not previously been reported and identifies a potential new therapeutic target intestinal disorders after mSBR.

### Applications

A greater understanding of mechanism of intestinal dysfunction after mSBR will help in utilizing its diverse effects more efficiently. Pharmacotherapy (such as glucagon-like peptide-2, which is supposed to improve the function of intestinal ileum in rats with short bowel syndrome) holds promise as an adjuvant treatment modality for short bowel syndrome.

### Terminology

Phenotypic changes in ICC refers to changes in the structure and function of ICC.

### Peer review

The authors investigate an attractive subject of Cajal network involvement in intestinal dysfunction after small bowel resection, using an experimental rat model. Experimental setup and methodology are appropriate and the study hypothesis and overall manuscript are well presented.

### Abstract

**AIM:** To select characteristic endogenous metabolites in hepatitis B virus (HBV)-related hepatocellular carcinoma (HCC) patients and to identify their molecular mechanism and potential clinical value.

**METHODS:** An ultra performance liquid chromatography and linear trap quadrupole-Orbitrap XL-mass spectrometry platform was used to analyze endogenous metabolites in the homogenate of central tumor tissue, adjacent tissue and distant tissue obtained from 10 HBV-related HCC patients. After pretreatment with Mzmine software, including peak detection, alignment and normalization, the acquired data were treated with Simca-P+software to establish multivariate statistical analysis based on a pattern recognition technique and characteristic metabolites highly correlated with changing trends in metabolic profiling were selected and further identified.

**RESULTS:** Based on data acquired using Mzmine software, a principal component analysis model ( $R2X = 66.9\%$ ,  $Q2 = 21.7\%$ ) with 6 principal components and an orthogonal partial least squares discriminant analy-

sis model ( $R2X = 76.5\%$ ,  $R2Y = 93.7\%$ ,  $Q2 = 68.7\%$ ) with 2 predicted principal components and 5 orthogonal principal components were established in the three tissue groups. Forty-nine ions were selected, 33 ions passed the 2 related samples nonparametric test ( $P < 0.05$ ) and 14 of these were further identified as characteristic metabolites that showed significant differences in levels between the central tumor tissue group and distant tumor tissue group, including 9 metabolites (*L*-phenylalanine, glycerophosphocholine, lysophosphatidylcholines, lysophosphatidylethanolamines and chenodeoxycholic acid glycine conjugate) which had been reported as serum metabolite biomarkers for HCC diagnosis in previous research, and 5 metabolites (betasitosterol, quinaldic acid, arachidyl carnitine, tetradecanal, and oleamide) which had not been reported before.

**CONCLUSION:** Characteristic metabolites and metabolic pathways highly related to HCC pathogenesis and progression are identified through metabolic profiling analysis of HCC tissue homogenates.

**Key words:** Hepatocellular carcinoma; Metabolomics; Characteristic metabolites; Potential biomarker; Ultra performance liquid chromatography-mass spectrometry

**Core tip:** An ultra performance liquid chromatography-mass spectrometry platform was used in the present study to identify characteristic metabolites in hepatitis B virus-related hepatocellular carcinoma tumor tissues. From an orthogonal partial least squares discriminant analysis model established to determine metabolic profiling in the central tumor tissue group, adjacent tissue group and distant tissue group, 49 ions were selected and 14 of these were identified as characteristic metabolites. The detection of these metabolites in tumor tissue not only confirmed the targeted traceability of previously reported serum biomarkers related to cancer diagnosis, but also provided novel targets for anticancer research.

## INTRODUCTION

Hepatocellular carcinoma (HCC) is currently an important research topic in basic and clinical investigations due to its high malignancy, fast development, high mortality, complicated pathogenesis and significant individual differences. There have been a number of previous investigations on the molecular biology and proteomics of HCC<sup>[1-3]</sup>. However, the occurrence and development of this disease are not simply determined by innate genetic differences. The introduction of metabolomics has provided more information in HCC investigations. Metabolomics is the study of biological systems where changes in metabolites after specific stimulation or interference are determined<sup>[4-7]</sup>. This type of study focuses on the end products of biological systems, which are a reflection of both the physiological and biochemical status, and are affected by both genotype and environment and are close to biological characteristics. Thus it has the advantage of investigating the objective basis and generative mechanism of individual differences in metabolites.

Current metabolomic investigations in HCC are mainly focused on identifying characteristic metabolites in serum or urine, revealing changes in the metabolic network, and finally selecting potential biomarkers with clinical application and exploring pathologic mechanisms<sup>[8,9]</sup>. For example, Wu *et al.*<sup>[10]</sup> used gas chromatography/mass spectrometry (MS) to analyze metabolic profiling in 20 male HCC patients and 20 healthy male volunteers. One hundred and three ions were detected and 66 ions were identified. Following *t* test analysis, 18 metabolites were significantly different between the central tumor tissue group and the distant tumor tissue group ( $P < 0.05$ ). The ability to distinguish these 18 ions combined with alpha-fetoprotein was analyzed by the receiver operating characteristic curve (0.9275). This non-invasive method was considered quite promising. Tan *et al.*<sup>[11]</sup> also used metabolic analytical methods to select serum biomarkers for small HCC diagnosis. Metabolic profiling was performed in a diethylnitrosamine-induced rat HCC model, which is similar to human HCC in the histopathology of liver disease development. The alterations in three metabolites, taurocholic acid, lysophosphoethanolamine 16:0 and lysophosphatidylcholine 22:5, were reported to be correlated with disease progression and considered as potential biomarkers. In addition, serum metabolic profiling was performed in 262 HCC patients, 76 liver cirrhosis patients and 74 HBV patients. The results showed that the sensitivity and specificity of these ions all reached 80%, which was better than alpha-fetoprotein in distinguishing HCC-

liver cirrhosis. This research laid the foundation for the clinical application of metabolic biomarkers. At the same time, Soga *et al.*<sup>[12]</sup> research group reported that gamma-glutamyl dipeptides were used as biomarkers for liver disease diagnosis. The metabolic profiling of 248 serum samples, including patients with 9 types of liver disease, was performed using a capillary electrophoresis-MS platform. Gamma-glutamyl dipeptides were selected and found to be predictive of a decrease in glutathione. Multiple regression analysis showed that the selected biomarkers had the ability to distinguish different liver diseases.

In animal models, serum and urine analysis and sample collection are easy to perform, and HCC serum and urine metabolic profiling can reflect specific signs and reveal pathological mechanisms, however, the targeting ability of these analyses is still limited. The present study used a ultra performance liquid chromatography and linear trap quadrupole (UPLC-LTQ)-Orbitrap XL MS analytical platform to perform metabolic profiling analyses on homogenates of hepatitis B virus (HBV)-related HCC tumors removed by surgery. A metabolic profiling model was established and metabolic pathways highly related to HCC were characterized for further investigations on the genesis and progression of HCC and the potential clinical value of characteristic metabolites.

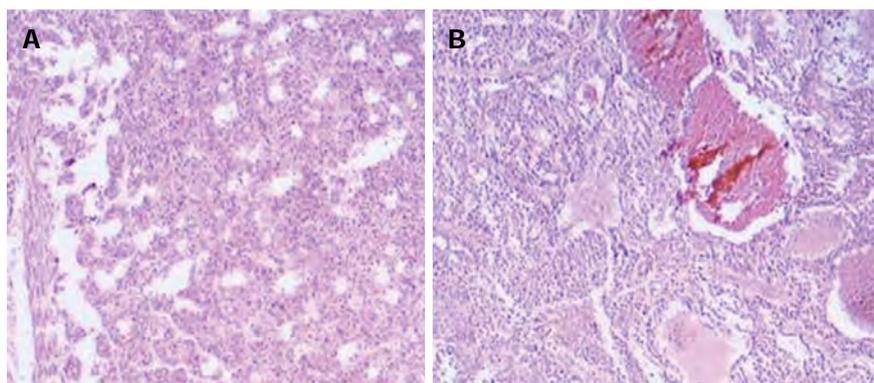

## MATERIALS AND METHODS

### Chemicals and instruments

All solvents were high performance liquid chromatography (HPLC) grade and used without modification. Formic acid and acetonitrile (ACN) were obtained from Merck (KGaA Merck, Germany). Distilled water was produced using a Milli-Q Reagent Water System (Millipore, Billerica, MA, United States). All standard [*L*-phenylalanine, glycerophosphocholine, chenodeoxycholic acid glycine conjugate and lysophosphatidylcholine (lysoPC) (18:0)] preparations were purchased from Sigma-Aldrich (St. Louis, MO, United States). Ultra performance liquid chromatography was performed on a Thermo Fisher Accela system (Thermo Fisher Scientific, Franklin, MA, United States). MS was performed on a Thermo Fisher (Thermo Fisher Scientific, Franklin, MA, United States) LTQ Orbitrap XL hybrid mass spectrometer. Other equipment included a Multifuge X1R high-speed centrifuge (Thermo Fisher Scientific, United States).

### Sample collection

The 10 HBV-related HCC patients included in this study were all from the Department of Hepatobiliary Surgery, Tianjin Third Central Hospital, and included 5 females and 5 males with average age of  $54.2 \pm 9.2$  years. All patients voluntarily joined this study and gave informed consent. Tissue from the central area of the tumor, adjacent tissue (1-2 cm from the tumor) and distant tissue (5 cm from the tumor) were collected. Thirty samples (10 samples in each group) were washed in hypothermic normal saline, dried using neutral filter paper and then stored at  $-80^{\circ}\text{C}$ .

**Figure 1** Pathological image of hepatocellular carcinoma tissues (hematoxylin-eosin staining,  $\times 100$ ). A: Moderately differentiated hepatocellular carcinoma (HCC), cancer emboli were observable in vessels; B: Moderately differentiated HCC, focal carcinoma tissue was observed in adjacent liver tissue.

Collection of samples was performed according to the following instructions: (1) all 10 patients had chronic persistent HBV (no other hepatotropic virus infection, no long-term drinking behavior, no autoimmune hepatitis, no schistosomiasis infection and no genetic metabolic liver disease); (2) all 10 patients had solitary tumors  $< 5$  cm in diameter, and Barcelona Clinic Liver Cancer stage A1; (3) tissue pathological immunohistochemistry examination diagnosed HCC using hepatitis B surface antigen (+); the pathological section is shown in Figure 1. Samples were all HCC grade II-III differentiation. Invasive growth was detected using the appropriate specific stain. No cancer cells were detected at the incisional edge; (4) no radiotherapy or chemotherapy was performed before surgery; (5) no evidence of endocrine or metabolic disease; (6) renal function, liver function, blood routine and hydropower solution pH were all in the normal range; (7) no severe infection was detected and parenteral nutrition was used; and (8) patients' dietary requirements were managed by the Nutrition Department of Tianjin Third Central Hospital to a relatively uniform standard, as a result, exogenous dietary influence on metabolic profiling was limited to the lowest level.

#### Sample pretreatment

Samples were thawed at room temperature and then weighed, 1:3 ultrapure water was added to each sample according to their weight before being homogenized. Tissue homogenate was subjected to ultrasonication at  $130\text{ W} \times 60\%$  for 3 cycles. One cycle included 10 s of ultrasonication and a 10 s interval (ultrasonication was performed in an ice-bath). Homogenate (400  $\mu\text{L}$ ) was centrifuged (4  $^{\circ}\text{C}$ , 15000  $g$ , 30 min). Supernatant (100  $\mu\text{L}$ ) was mixed with 400  $\mu\text{L}$  methanol to precipitate proteins. The mixture was centrifuged at 4  $^{\circ}\text{C}$ , 15000  $g$  for 30 min. The supernatant was filtered using a 0.22  $\mu\text{m}$  membrane. Quality control (QC) was the equivalent volume mixture in each sample.

#### Sample analysis

Chromatography conditions were as follows: Chromatography was performed on a Thermo Fisher Accela system

(Thermo Fisher Scientific, Franklin, MA, United States) which was equipped with a binary solvent delivery manager, and a sample manager. The analytical column was a Thermo Hypersil GOLD (2.1 mm *id*  $\times$  50 mm 1.9  $\mu\text{m}$ ) C18 reversed phase column.

**Mobile phase:** Phase A: 0.1% formic acid (volume ratio), 1 mL of formic acid was added to a 1 L bottle of HPLC-grade water; Phase B: 95% ACN and 0.1% formic acid. And 950 mL ACN, 50 mL HPLC-grade water, and 1 mL formic acid were combined.

**Chromatographic separation:** Chromatographic separation was performed isocratically within 15 min and the injection volume was 10  $\mu\text{L}$ . The flow rate was set at 200  $\mu\text{L}/\text{min}$ . The sample manager and column oven temperature were set at 4  $^{\circ}\text{C}$  and 20  $^{\circ}\text{C}$ , respectively. The chromatographic elution gradient was initialized at 5% Phase B and held for 3 min. In consecutive 10 min periods, Phase B was gradually escalated to 50%, and then a rapid increase in Phase B to 95% was completed within 3 min. After 4 min of maintaining the high volume of organic phase gradient, Phase B was immediately reduced to 5% and this elution gradient was used to balance the analytical column for the final 4 min.

MS was performed on a Thermo Fisher (Thermo Fisher Scientific, Franklin, MA, United States) LTQ Orbitrap XL hybrid mass spectrometer<sup>[13]</sup>, operating in the positive ion mode with an ion source voltage of 4.5 kV, a capillary voltage of 30 V, cone voltage of 150 V, desolvation temperature of 275  $^{\circ}\text{C}$ , sheath gas flow of 30 arb and assistant gas flow of 5 arb (99.999% nitrogen). Data were collected over 15 min in centroid mode over the mass range 50-1000  $m/z$ . The MS resolution was at 100000 full width half maximum (FMHW) and the calibration standards were provided by Thermo Fisher Scientific (caffeine, Ultramark 1621 and *L*-methionyl-arginyl-phenylalanylalanine acetate  $\text{H}_2\text{O}$ ). MS/MS analysis was carried out with collision-induced dissociation (CID) collision energy 35 (normalization collision energy) and the collision gas was 99.999% helium.

There were 14 QC samples throughout the test (equal

volume mixture of each analyzed sample). Before the samples were tested, 8 QC samples were analyzed continuously and the remaining QC samples were inserted into the sequence after every 5 samples were analyzed.

The sequence of samples was randomly generated by the excel function before and after sample analysis (including QC), and cross-contamination was avoided by inserting a blank between adjacent samples. The whole experiment lasted 780 min.

### **Ethics statement**

All samples were collected in accordance with the ethical guidelines and written consent protocols mandated by the Tianjin Third Central Hospital. The Institutional Review Board approved the collection of serum for comprehensive metabolite characterization. All patients and all control individuals were approached using approved ethical guidelines and those who agreed to participate in this study, were required to sign consent forms. Patients could refuse entry, discontinue participation, or withdraw from the study at any time without prejudice for further treatment or management. All participants provided written consent.

### **Statistical analysis**

MZmine 2.0 was used for peak detection, alignment and normalization. The filter conditions were: chromatography peak intensity signal/noise > 30, retention time tolerance =  $\pm 0.1$  min, and m/z tolerance =  $\pm 0.01$ .

One of the aims of this study was to establish a model to predict the tissue metabolic profile in HCC. With the help of Simca-P+12.0.1.0 (Umetrics, Sweden), software based on chemometrics methods, the OPLS-DA supervised model was established. The detailed process was as follows: The variables were firstly traded by Pareto scaling. The principal component analysis (PCA) and orthogonal partial least squares discriminant analysis (OPLS-DA) model of all the samples were established and checked by cross validation<sup>[14,15]</sup>. The preliminary selection of characteristic metabolites was accomplished using the corresponding variable importance (VIP) value, confidence interval and coefficient plot generated by the OPLS-DA model. The selected metabolites were then preliminarily confirmed by the S and SUS diagram. Finally, the variances were evaluated by SPSS 16.0 software (SPSS, United States), using the 2 related samples non-parametric test.

## **RESULTS**

### **Data pretreatment and QC analysis**

The total ion chromatogram of the central tumor tissue group, adjacent tissue group and distant tissue group acquired by the UPLC-MS platform are shown in Figure 2. After pretreatment and standardization using MZmine 2.0, there were 211 integral peaks following extraction ion chromatography detected in QC samples and 215 peaks in test samples.

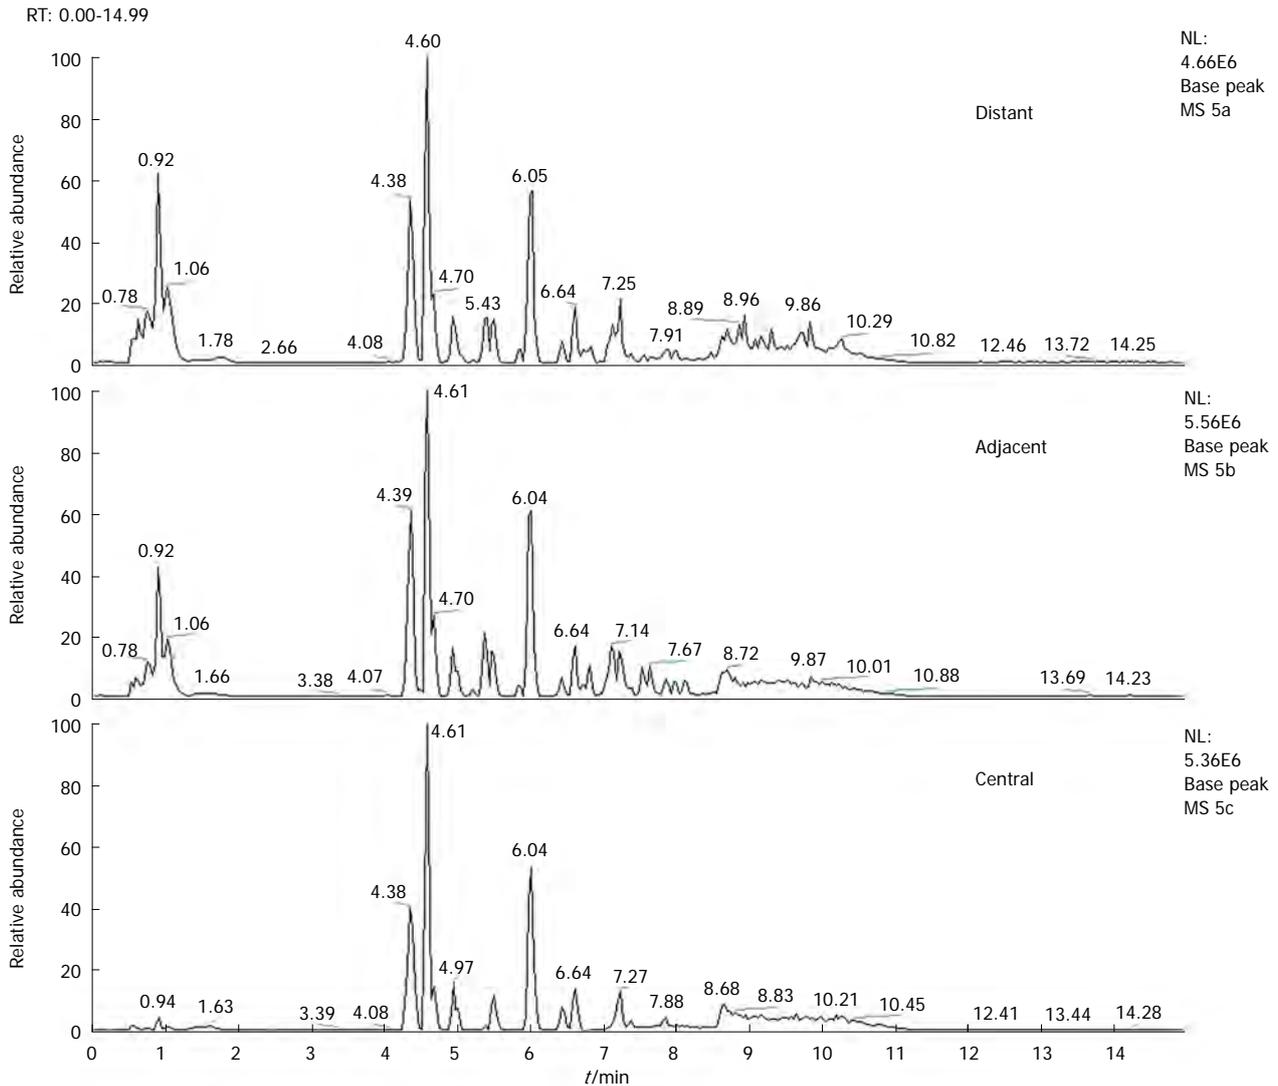

The stability of the UPLC-MS system was adequately assessed by the analysis of QC samples during the entire experimental period<sup>[16]</sup>. Through PCA of 14 data sets of QC samples, a PCA model with 2 principal components was established (Figure 3). Figure 3 shows the score plot of QC sample sequence versus first principal component (the most influential factor which varied with time). From the QC principal component score plot we found that the UPLS-MS system was stable after the first 8 continuous QC injections. In the test sample sequence, a QC sample was inserted after every 5 test samples to evaluate the stability of the system during the entire analytical process. The results showed that the detection system was stable throughout the experiment after the first 8 QC samples were injected (no outliers exceeding  $\pm 2$  SD were detected in the QC samples). According to a related article<sup>[17]</sup>, the QC standard was set as follows: (1) ion peaks were defined as reliable peaks when their intensity was in the range of  $\pm 30\%$  average ion intensity; (2) a QC sample was qualified if its 70% ion peaks were reliable; and (3) experimental data were accepted only when 60% QC was qualified. In the present experiment, 11 of 14 QC samples (reliable ion peaks distributed among 70.5%-86.3%) inserted into the test sample sequence qualified and the qualified ratio was 78.5%, which meant that the analytical results were trusted.

### **Ability of the metabolic profile to distinguish disease states**

A PCA model with 6 principal components was established (R2X = 66.9%, Q2 = 21.7%) and the score plot of its first two principal components is shown in Figure 4A. It can be seen that the central tumor tissue group and distant tissue group showed a clustering tendency in the direction of first predictive principal component (X axis). The adjacent tissue group was located between the central tumor tissue and distant tissue groups. Although the clustering tendency was not significant, its distribution could assess the development of HCC. An OPLS-DA model was established using all 30 samples. The model had 2 predictive principal components and 5 orthogonal principal components (R2X = 76.5%, R2Y = 93.7%, Q2 = 68.7%). As shown in Figure 4B, the score plot of the first predictive principal component and first orthogonal principal component showed significant clustering tendency. In the X axis direction, the changing tendency of metabolic profiling in the three groups reflected the development of HCC, at the same time differences between the three groups in metabolic profiling were significant. As a result, it was concluded that the first principal component could reflect the development of HCC.

### **Selection of characteristic metabolites**

Through metabolic profiling analysis of the homogenates of HCC tumor tissue, endogenous metabolites highly related to HCC were detected. The main focus of the present study was the metabolites which had an obvious impact on clustering tendency of the central tumor tissue group and distant tissue group. First, the OPLS-DA

**Figure 2 Total ion chromatogram of tissue metabolic profiling.** This was the total ion chromatogram of one single sample chosen randomly. Distant: Distant tissue group; Adjacent: Adjacent tissue group; Central: Central tumor tissue group; RT: Retention time.

model was established for the central tumor tissue group and distant tissue group (Figure 5A), which had 1 predictive principal component and 3 orthogonal principal components ( $R^2Y = 97.6\%$ ,  $Q^2 = 83.8\%$ ). The characteristic metabolites with the ability to distinguish disease were selected in the established OPLS-DA model after the following two processes: (1) Among ions with  $VIP > 1$ , excluded ions which included zero in the confidence interval in the VIP diagram (Figure 5B) and excluded ions which included zero in the confidence interval in the coefficient plot (Figure 5C, excluded ions were marked by black arrows)<sup>[18]</sup>, and (2) From the S-plot (Figure 5B), ions with a high degree of variation (high horizontal ordinate value) and reliability (high vertical ordinate value) were selected. After these two steps, 14 ions were selected. To limit the cover-up effect, a “blank” OPLS-DA model was established which excluded the 14 selected ions. The OPLS-DA model had 1 predictive principal component and 3 orthogonal principal components ( $R^2Y = 97.1\%$ ,  $Q^2 = 74.2\%$ ). Because the ability of the “blank”

model to distinguish disease was still high, other characteristic metabolites were selected following the two steps previously mentioned, and 35 ions were selected. Among the total 49 ions selected, 33 ions passed the 2 related samples nonparametric test ( $P < 0.05$ ).

#### Identification of characteristic metabolites

Some characteristic metabolites were identified by MS graphs when compared with the chromatographic peaks and mass spectrographic peaks of the standard (including MS1 and MS2). Identification of other selected ions was performed as follows: Firstly, because of the high resolution of the Orbitrap XL mass spectrometer (resolution set as 100000 FMHW), characteristic metabolites were preliminarily identified by checking accurate  $m/z$  on the Human Metabolome DataBase (<http://hmdb.ca/>). The matching metabolites were retained for further identification according to the rules that  $m/z$  deviation was below 0.01, with equal charge number and with suitable ionization mode. Secondly, after MS/MS scanning, MS2 graphs

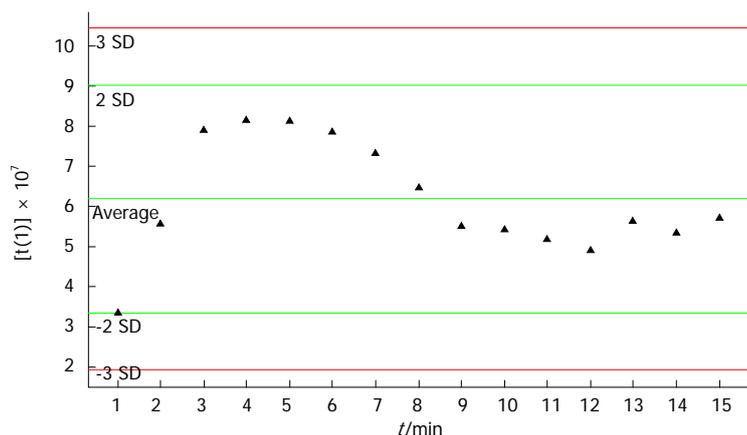

Figure 3 Score plot of principal component [t(1)] for quality control principal component analysis model. Each point represents a quality control sample.

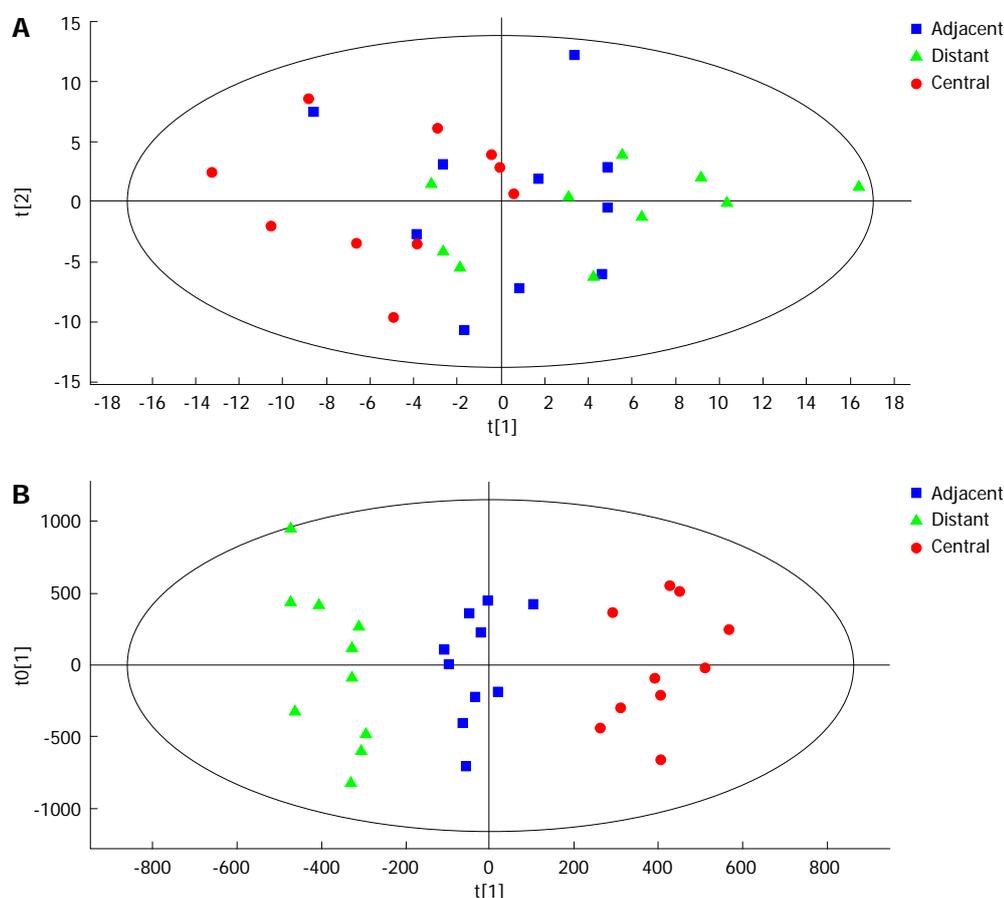

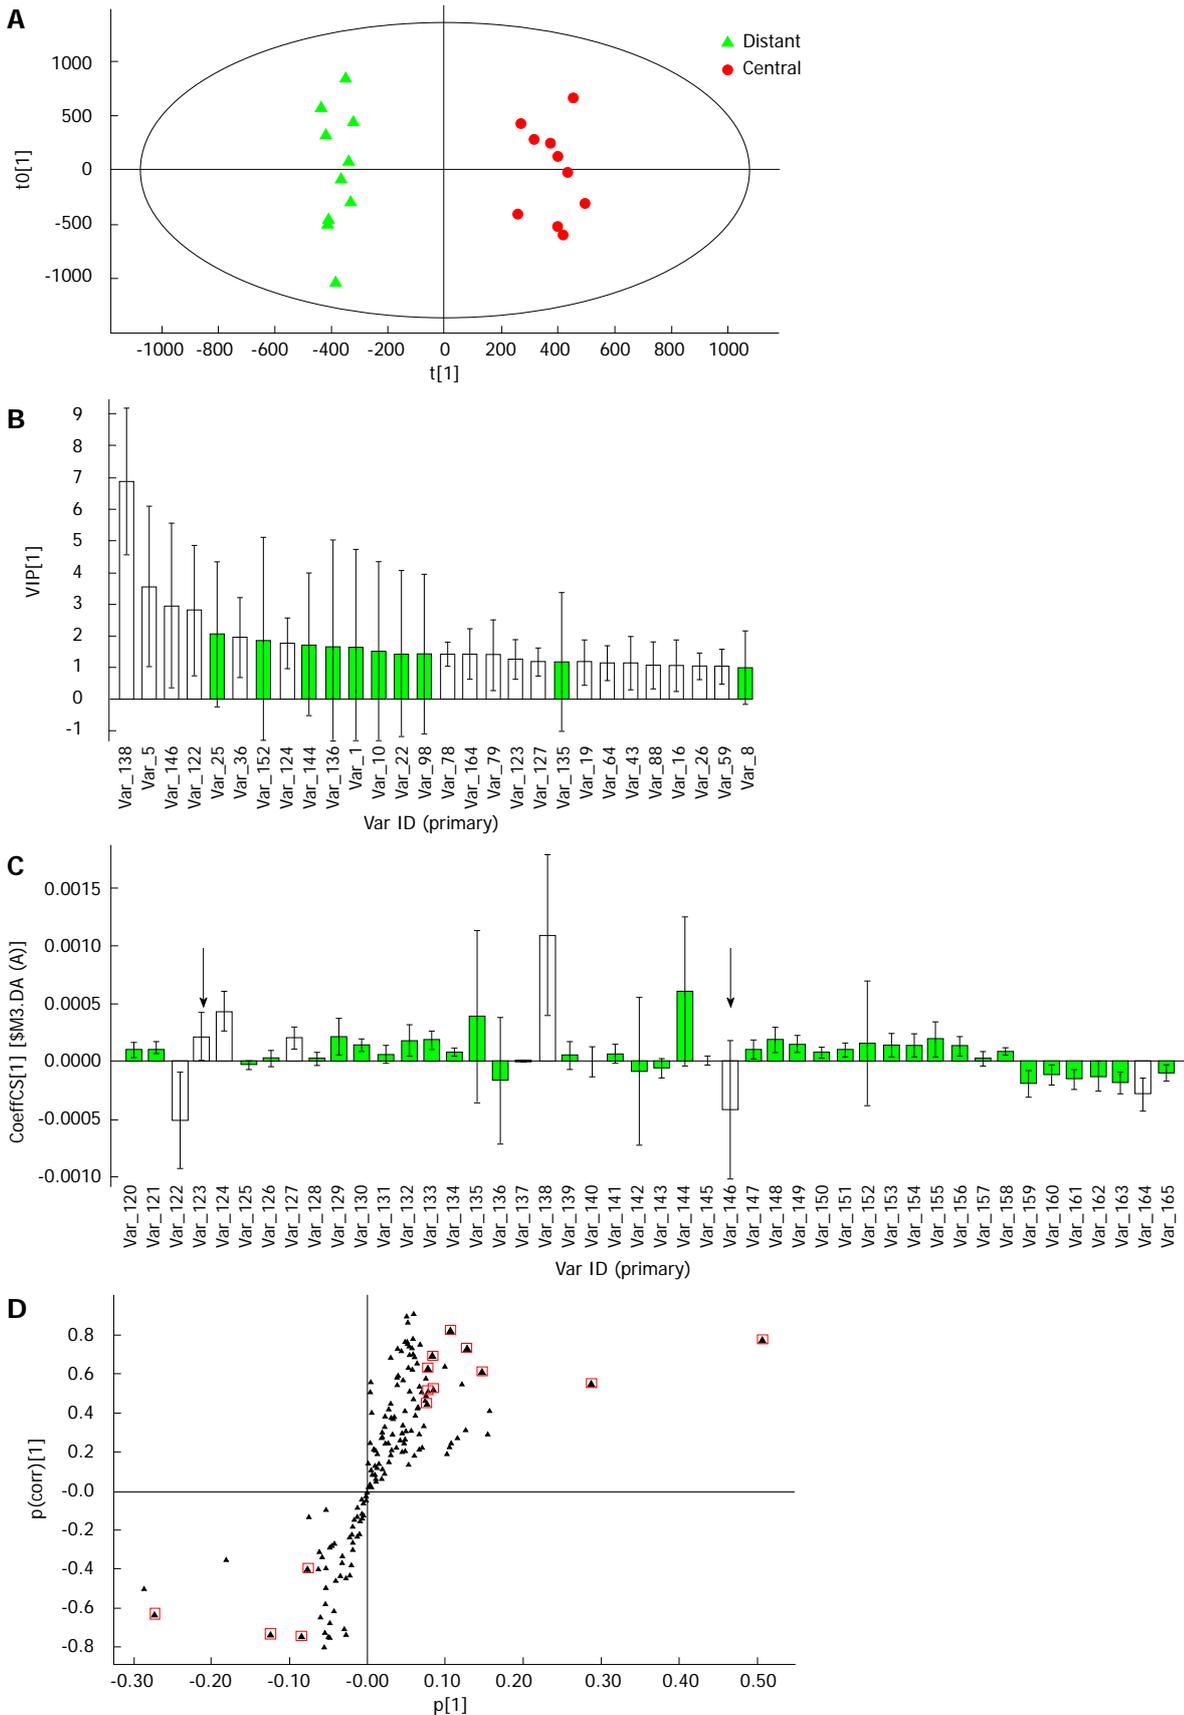

Figure 4 Ability of metabolic profiling to distinguish disease in tissue samples. A: Score plot of the first two components [t(1)]/[t(2)] of the tissue metabolic profiling principal component analysis model; B: Score plot of metabolic profiling orthogonal partial least squares discriminant analysis model. Each point in the figure represents a sample. Distant: Distant tissue group; Adjacent: Adjacent tissue group; Central: Central tumor tissue group.

of the characteristic ions were obtained and then compared with theoretical fragments of previous preliminary results according to the rules that MS2 *m/z* deviation was below 0.2, matching the top three peaks and at least 80% of secondary MS graphs (secondary MS fragments were generated by the ion trap CID model). The theoretical fragments were derived using Mass Frontier 6.0. The final identified results and statistical differences among

the three groups are shown in Table 1 (only 14 identified metabolites are listed).

## DISCUSSION

HCC, the fifth commonest cancer and the third most common cause of cancer-related death, accounts for 6% of all cancers worldwide<sup>[19,20]</sup>. Fifty percent of diagnosed

**Figure 5** Selecting process of characteristic metabolites. A: Orthogonal partial least squares discriminant analysis model of the central tumor tissue group and distant tissue group, each point in the figure represents a sample; B: Variable importance (VIP) diagram with confidence interval (green bars were excluded metabolites, the others were target metabolites); C: Coefficient plot of included variants in the VIP diagram (variants marked by arrows were excluded metabolites); D: S-plot of selected ions passed last two steps of filtering (points marked by red frame represent characteristic metabolites). Distant: Distant tissue group; Central: Central tumor tissue group.

HCC cases occur in China<sup>[21-23]</sup>. Because it takes a long time for HCC to occur in liver cirrhosis patients, early diagnosis of HCC is of great importance. Lots of effort has gone in discovering early biomarkers in human fluid, especially in serum, to monitor the occurrence and development of HCC<sup>[11,24,25]</sup>. Unfortunately, although the biomarkers discovered in serum have great potential value in clinical and subclinical areas, their targeting ability and specificity are still limited. The present study determined serum metabolic profiling of HCC and provided new research targets for molecular biology.

Tissue metabolic profiling, especially human tissue metabolic profiling has several advantages in metabolomics investigations<sup>[26,27]</sup>. For example, compared with serum metabolic profiling, tissue metabolic profiling reflects the metabolic changes in certain target lesions in tissues or organs instead of changes in the whole metabolic system. Thus, it has higher targeting ability, specificity and is affected by fewer exogenous influencing factors, such as psychological changes in patients. Compared with animal tissue metabolic profiling, where the model is generally induced by a single factor, human tissue metabolic profiling reflects the natural physiological changes of lesions and is trusted in investigations on the occurrence and development of certain diseases.

Following tissue metabolite profiling of HBV-related HCC, 215 ions were detected and after multivariate statistical analysis of their relative levels (integral peak area of extraction ion), 14 ions were selected as characteristic metabolites and then identified. Of these characteristic metabolites, 9 had been suggested as serum metabolite biomarkers for HCC diagnosis in previous reports, including *L*-phenylalanine, glycerophosphocholine, lysoPCs, lysophosphatidylethanolamines (lysoPEs) and chenodeoxycholic acid glycine conjugate<sup>[11,28-30]</sup>. The present results enhanced the targeting ability of these characteristic metabolites, as alterations in these metabolites occurred in HCC cells.

The remaining 5 identified characteristic metabolites have seldom been reported, including Beta-Sitosterol, Quinaldic acid, Arachidyl carnitine, Tetradecanal, and Oleamide. This was possibly due to alterations in these metabolites which were too small to be observed in serum or were masked by alterations in other metabolites. Although these metabolites did not show great value in clinical application as potential biomarkers, they still provided new targets for anticancer research.

Previous research has shown that the levels of 11 metabolites including beta-sitosterol, *L*-phenylalanine, lysoPCs, glycerophosphocholine, lysoPEs, chenodeoxycholic acid glycine conjugate and quinaldic acid were significantly high in the distant tissue group compared with the central tumor tissue group. In contrast, the levels of Arachidyl carnitine, tetradecanal and oleamide were significantly lower in the distant tissue group compared with the central tumor tissue group. A comparison of the levels of these metabolites in the adjacent tissue group showed that beta-sitosterol, quinaldic acid and oleamide were significantly lower in the central tumor tissue group, but relatively close to those in the central tumor tissue group. From these changes in metabolite levels, we can speculate that these endogenous metabolites correlate with the progression of adjacent tissue to central tumor tissue and contain important information on the occurrence and development of HCC. Further attention should be focused on these metabolites which will hopefully lead to the discovery of novel potential biomarkers for cancer diagnosis and disease course monitoring and provide new targets for tumor therapy.

In summary, the establishment of a metabolic profiling model and the analysis of the characteristic metabolites provided new perspectives for further research into the pathophysiology of HCC. Following investigations on homogenates of tumor tissue obtained during radical surgery of HCC, detection and identification of these previously reported potential biomarkers in human tissue

enhanced their targeted traceability and a comparison of the changes in these metabolites in the central tumor tissue group, adjacent tissue group and distant tissue group revealed metabolic information highly related to HCC development. More attention should be focused on these characteristic metabolites which will provide more potential biomarkers for HCC diagnosis and development. In addition, further research into the pathways related to these metabolites would provide new clinical targets for HCC therapy.

## ACKNOWLEDGMENTS

We would like to express my gratitude to Jie Gao and Yi-Jun Wang who helped with the sample collection and to Li Zhang who helped with the data collection. We also acknowledge the Liver Surgery Department of Tianjin Third Central Hospital for sample submission.

## COMMENTS

### Background

Hepatitis B virus (HBV)-related hepatocellular carcinoma (HCC) is the most common type of liver cancer in Asian populations with an extremely high incidence and poor survival rate. Unfortunately, there are no satisfactory definitive positive and negative markers for HCC diagnosis in clinical application at the present time.

### Research frontiers

Recently, metabolomics research provided a series of novel biomarkers in serum or urine with clinical value in the diagnosis and prognosis of HCC. However, the application of these biomarkers is still limited due to the lack of target traceability in the diseased organ. The detection of these previously reported characteristic metabolites in tumor tissue in the present research provided supporting proof for these novel biomarkers.

### Innovations and breakthroughs

The targeting ability of animal models, serum and urine analysis are limited although experiments and sample collection are easier to perform. The present research used homogenates of central, adjacent and distant HBV-related HCC tumor tissue removed by surgery to identify these metabolites. Thus, this method had higher targeting ability, specificity and was less affected by exogenous influencing factors. In addition, the analysis detected alterations in these metabolites that were barely observed in serum or urine.

### Applications

By detecting characteristic metabolites in tumor tissue, this research confirmed the traceability of 9 previously reported biomarkers detected in serum or urine provided supporting evidence for their potential clinical applications. The introduction of homogenates also suggested new avenues of research in metabolic analysis.

### Terminology

Principal component analysis (PCA) and orthogonal partial least squares discriminant analysis (OPLS-DA) analysis are data analysis methods based on projection technology. PCA can visually represent sample correlations (results distribution) such as clustering and migration. However, this method is easily affected by noise signals such as instrumental bias and operation error. In this situation, OPLS-DA analysis is often introduced in data analysis to focus experimental data in a particular direction according to a priori knowledge.

### Peer review

The manuscript selects 14 characteristic metabolites in liver tumor tissue that not only supports the clinical application of previous reported serum or urine biomarkers but also provides novel research targets for anticancer investigations.

### Abstract

**AIM:** To study sleep aspects and parameters in cirrhotic patients and assess the role of liver dysfunction severity in polysomnographic results.

**METHODS:** This was a case-control study. Patients with a diagnosis of liver cirrhosis were consecutively enrolled in the study. Clinical examinations and laboratory liver tests were performed in all patients, and disease severity was assessed using the Child-Pugh score. The control group consisted of age- and gender-matched healthy volunteers. All individuals answered a questionnaire about habits, behaviors, and complaints related to sleep and were submitted to polysomnography. Sleep parameters were compared between the two groups, and separate analyses were performed among classes

of Child-Pugh classification in the cirrhotic group.

**RESULTS:** Forty-two cirrhotic patients and forty-two controls were enrolled. Compared to the control group, the cirrhotic group exhibited lower sleep efficiency (mean  $\pm$  SD: 73.89%  $\pm$  14.99% vs 84.43%  $\pm$  8.55%,  $P < 0.01$ ), increased latency (151.27  $\pm$  93.24 min vs 90.62  $\pm$  54.74 min,  $P < 0.01$ ) and a lower percentage of rapid eye movement (REM) sleep (14.04%  $\pm$  5.64% vs 20.71%  $\pm$  6.77%,  $P < 0.05$ ) as well as a higher frequency of periodic limb movements (10.56  $\pm$  2.85/h vs 2.79  $\pm$  0.61/h,  $P < 0.01$ ). The comparison of sleep parameters among Child A, B and C cirrhotic patients revealed a significant reduction of REM sleep stage occurrence in individuals with severe liver disease (Child C patients) compared to Child A/B patients (polysomnography percentage of REM sleep stage of patients Child A: 16.1%  $\pm$  1.2%; Child B: 14.9%  $\pm$  1.2%; Child C: 8.6%  $\pm$  1.6%,  $P < 0.05$ ).

**CONCLUSION:** Cirrhosis was associated with shorter sleep time, reduced sleep efficiency, increased sleep latency, increased REM latency and reduced REM sleep. Additionally, disease severity influences sleep parameters.

## INTRODUCTION

Although modern sleep research has a short forty-year history, interest in the impact of sleep quality on bio-regulatory functions and human health dates back to ancient times<sup>[1-3]</sup>. The development of polysomnography (PSG) provided the ability to assess sleep structure and led to thorough characterizations of different sleep stages and sleep disorders<sup>[4]</sup>. The rapid eye movement (REM) sleep stage has acquired increasing relevance; it is considered fundamental to the maintenance of important intellectual functions such as memory, attention and mood<sup>[5]</sup>. The REM stage is characterized by cortical activation; this is evidenced by a rapid transition to higher frequency rhythms with rapid, low-voltage, irregular activity on electroencephalogram (EEG). It is also characterized by irregular breathing, heart rate and muscle atonia<sup>[2]</sup>. Time spent in REM sleep is markedly reduced in several organic dysfunctions and is associated with cardiovascular adverse events, such as systemic arterial hypertension<sup>[6-8]</sup>. Similarly, spontaneous or induced REM sleep deprivation was previously correlated with higher death rates<sup>[9]</sup>.

Sleep disturbances are commonly reported in liver cirrhosis (LC), particularly in patients with hepatic encephalopathy (HE)<sup>[10,11]</sup>. There are few clinical<sup>[12,13]</sup> and experimental<sup>[14]</sup> studies assessing the sleep patterns of LC patients without overt HE; however, to our knowledge, an approach based on full-night PSG (level 1) has never been performed<sup>[15-17]</sup>.

A study that used sleep questionnaires, neuropsychological tests and actigraph monitoring suggested that sleep complaints are an early sign of HE<sup>[17]</sup> and that insomnia and excessive daytime sleepiness (EDS) are often described in patients with liver disease<sup>[10,11,13,17]</sup>. Conversely, Vignatelli *et al.*<sup>[18]</sup> found only a small percentage of cirrhotic patients with EDS. Although clinical reports vary, one possible explanation for sleep dysfunction in LC patients is a disruption in melatonin circadian rhythms<sup>[13,14]</sup>; one study reported a delayed onset and peak of melatonin secretion, which caused a sleep phase delay and possibly EDS<sup>[19,20]</sup>.

Detailed information regarding PSG sleep aspects in LC patients is lacking. Moreover, no study to date has attempted to determine the influence of disease severity on sleep structure. This study aimed to characterize sleep patterns of LC patients using a full-night PSG-based approach focusing on the following: (1) sleep structure in LC; (2) sleep pattern variations associated with liver disease severity; and (3) detection of possible sleep disorders linked to LC. We then conducted a case-control study to compare PSG sleep aspects between LC patients and healthy volunteers.

## MATERIALS AND METHODS

### *Clinical and laboratory assessment*

Patients with a diagnosis of LC by either liver biopsy or analysis of clinical and laboratory data were enrolled in the cirrhotic group. They were invited to participate in

the study upon reporting to the Gastroenterology Out-patient Clinic of the Universidade Federal de São Paulo (UNIFESP). The exclusion criteria were the following: younger than 18 years, alcohol consumption or gastrointestinal bleeding in the last 6 mo, serum creatinine levels higher than 2.0 mg/dL, psychoactive drug intake in the last 2 wk and overt clinical HE in the initial assessment. Those who fulfilled the selection criteria had venous blood drawn, and a clinical evaluation was performed to determine liver disease severity according to the Child-Pugh score. At the same time, arterial blood was collected to determine arterial ammonia levels. LC etiology was determined in all patients. Selected patients were submitted to a full-night PSG examination in the same week as the initial assessment.

The control group was composed of age- and gender-matched volunteers from the UNIFESP-Instituto do Sono laboratories, who met the criteria listed above and were considered healthy according to clinical and laboratory evaluations. They also completed a PSG examination.

The research protocol was reviewed and approved by the institutional research ethics committee (protocol number 1503/04), and all participants provided informed consent before enrollment in the study.

### PSG

All PSG recordings were performed in the Instituto do Sono. Before PSG, all study participants completed a questionnaire about habits, behaviors, and complaints related to sleep. The questionnaire was developed by the internal staff of the Instituto do Sono<sup>[21]</sup> and validated for the local population.

Full-night PSGs were performed in all participants using the sleep laboratory digital system EMBLA S7000® (Embla Systems Inc., Broomfield, CO, United States). The subjects were instructed to go to sleep at their usual bedtime. The following physiological variables were simultaneously and continuously recorded during PSG: (1) four channels to EEG; (2) two channels to electrooculogram; (3) channels placed in the submentonian region, the anterior tibial muscle, the masseter region and the seventh intercostal space to the electromyogram; (4) electrocardiogram; (5) two channels for airflow monitoring (one for the thermocouple and the other for nasal pressure measurement); (6) the detection of respiratory efforts of the thorax (one channel) and the abdomen (one channel) for inductance plethysmography; (7) snore monitoring; (8) one channel for monitoring body position; and (9) oxy-hemoglobin saturation measurement.

All PSG sessions were monitored by trained technicians and visually scored according to standardized criteria<sup>[22]</sup>. EEG arousals and leg movement episodes were scored according to the "Manual for Scoring Sleep and Associated Events"<sup>[23,24]</sup>; apnea and hypopnea episodes as well as other detected sleep events were also scored and classified using recognized rules<sup>[25]</sup>.

The following PSG sleep parameters were recorded and systematically evaluated: (1) total recording time

BMI: Body mass index; LC: Liver cirrhosis; HCV: Hepatitis C virus; HBV: Hepatitis B virus.

(TRT): the entire period under PSG monitoring; (2) total sleep time (TST): the entire PSG recorded while sleeping; (3) wake: the entire PSG recorded while the patient was awake; (4) sleep efficiency: the TST/TRT ratio, expressed as percentage; (5) sleep latency: the length of time to sleep onset; (6) latency to REM sleep: the latency of REM sleep stage onset; (7) sleep stages 1, 2, 3 + 4 and REM sleep stage (S1, S2, S3 + 4 and REM): the percentage (%) of time patients spent in sleep stages 1, 2, 3 + 4 or REM sleep stage, respectively; (8) apnea-hypopnea index (AHI): an index to express the mean number of apneas or hypopneas in a 1-h period; (9) periodic leg movements of sleep per hour (PLMS/h): the average number of PLM events in a one hour period; (10) arousals/h: the average number of arousals in a one hour period; (11) mean SpO<sub>2</sub>: the mean oxy-hemoglobin saturation; and (12) nadir SpO<sub>2</sub>: minimal oxy-hemoglobin saturation recorded during PSG. These parameters were analyzed and scored by a blinded specialist before between-groups comparisons were made.

### Statistical analysis

Statistical analyses were performed using STATISTICA software, version 5.1. The Student's *t*-test was used to compare the quantitative PSG parameters between groups. Analysis of variance and Tukey's *post-hoc* test were used to compare the sleep parameters among the three classes of liver disease according to the Child-Pugh score. Results were considered statistically significant if *P* < 0.05.

## RESULTS

Forty-two cirrhotic patients and forty-two controls who satisfied the selection criteria were evaluated between May 2003 and August 2005. The cirrhotic group consisted of 29 males (69%) with a mean age of 50.0  $\pm$  8.5 years, and the general demographic characteristics of cirrhotic patients did not differ significantly from those of

**Table 2** Polysomnographic parameters of the two groups evaluated (mean  $\pm$  SD)

TRT: Total recording time; TST: Total sleep time; Wake: Minutes awake after sleep onset; SE: Sleep efficiency; Sleep Lat: Latency to sleep onset; REM: Rapid eye movement; REM Lat: REM sleep latency; S1: Stage 1; S2: Stage 2; S3: Stage 3; S3 + 4: Stages 3 and 4; AHI: Apnea-hypopnea index; PLMS/h: Number of periodic limbs movements of sleep per hour; Arousals/h: Number of arousals per hour of sleep; Mean SpO<sub>2</sub>: Mean oxy-hemoglobin saturation; Nadir SpO<sub>2</sub>: Minimal oxy-hemoglobin saturation.

the control group (Table 1). LC etiology and Child-Pugh scores are also shown in Table 1. The arterial ammonia measurements in cirrhotic patients were (mean  $\pm$  SD) 166.38  $\pm$  26.10 mol/L (normal value: 9-33 mol/L).

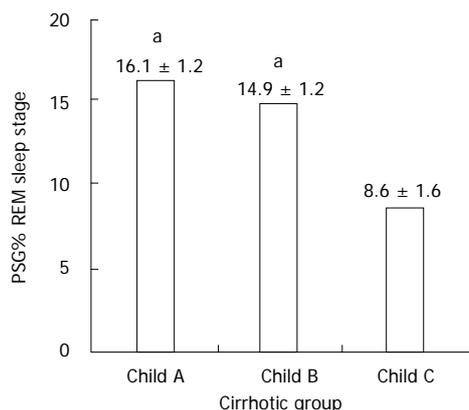

LC patients reported more sleep difficulties on the questionnaire, including trouble initiating sleep, non-restorative sleep and more episodes of napping during the day. Although the TRT and AHI were similar in both groups, a significant reduction in the TST, sleep efficiency and wake time were observed in the cirrhotic group. Increased sleep latency, REM latency, PLMS index and a decreased REM sleep percentage were also observed in the cirrhotic group (Table 2).

Comparison of sleep parameters among Child A, B and C cirrhotic patients revealed a significant reduction of REM sleep stage occurrence in individuals with severe liver disease (Child C patients) (Figure 1).

To assess the influence of alcoholism on sleep parameters, we divided the patients into two groups: those who had alcoholic etiology (alone or associated with viral hepatitis; *n* = 24) and those who had no history of alcoholism (*n* = 18). No significant differences were detected between the two groups in our study for any sleep parameter except sleep latency, which was longer in the group without alcoholic etiology (21.68  $\pm$  15.38 min *vs* 40.53  $\pm$  42.74 min for the alcoholic etiology group and without alcoholic etiology group respectively, *P* = 0.04).

## DISCUSSION

The sleep parameters evaluated by PSG in this study indicated worsening sleep in the cirrhotic group compared to the control group. This was due to decreased sleep

**Figure 1** Rapid eye movement sleep stage percentage comparison among different Child-Pugh score system classes. <sup>a</sup> $P < 0.05$  vs Child C group. Child A, B and C: Liver disease severity classes; PSG: Polysomnography; REM: Rapid eye movement.

efficiency, increased time to initiate sleep, increased latency of REM sleep, reduced REM sleep percentage and higher PLMS indices. As our data suggest, disease severity influenced sleep parameters, especially when data were classified by the patients' Child scale rating.

The sleep questionnaire results showed that the cirrhotic patients had more complaints about their sleep, such as difficulty initiating sleep and non-restorative sleep. These findings are consistent with the PSG results indicating lower sleep efficiency and higher sleep latency. Other studies have also described a higher number of sleep complaints in LC patients<sup>[12,26]</sup>. Moreover, LC patients report more episodes of napping during the day<sup>[10,19,27]</sup>. EDS appears to be attributable to a dysfunction of the neural circuit responsible for the maintenance of wakefulness and sleep states. The monoaminergic system, the systems of the locus coeruleus (noradrenergic) and the raphe nuclei (serotonergic) are important for directing attention and recruiting the cortex for processing external sensory stimuli<sup>[28]</sup>. High levels of ammonia can reduce serotonin and noradrenaline levels in the central nervous system, resulting in low alertness and attention<sup>[29,30]</sup>.

The higher incidence of PLMS in our sample of LC patients was not related to any clinical disorder or laboratory finding commonly associated with this phenomenon. This would include conditions such as anemia, renal failure, or low levels of iron or plasma transferritin<sup>[31]</sup>. PLMS is also associated sleep complaints, including difficulty falling asleep, multiple arousals and EDS<sup>[32,33]</sup>. These complaints were also reported by our group of patients and objectively confirmed by the PSG findings of higher sleep latency and higher arousal index.

This study did not find statistically significant differences between groups regarding AHI. This is in contrast with two previous studies<sup>[15,26]</sup>; however, it is consistent with the findings of Nikaina *et al.*<sup>[16]</sup>. Differing results may be explained by the presence or absence of ascites<sup>[34]</sup>. In fact, Nikaina *et al.*<sup>[16]</sup> found no significant differences in the index of respiratory events between controls and patients with compensated cirrhosis without ascites.

It is widely recognized that chronic alcohol abuse influences sleep parameters<sup>[35]</sup> and many patients in this study experienced cirrhosis of alcoholic etiology. However, in our study, we did not confirm this influence, perhaps due to the fact that patients had been in withdrawal for at least six months. The absence of differences suggests that LC may be seen as a determining factor of the sleep parameters observed for study in this group. The only difference that was found, in sleep latency, which was longer in the group without alcoholic etiology, cannot be easily explained; considering the effects of alcohol, the expected result would be the opposite of what was actually observed<sup>[35]</sup>.

The intense electrical and metabolic activity observed in REM sleep is the best argument supporting sleep as an active phenomenon<sup>[2,3]</sup>. The system responsible for the generation of REM sleep encompasses several specific nerve structures and follows a model of reciprocal interaction between the co-organizers and suppressor structures, which are located mainly in the brainstem and midbrain<sup>[2,3]</sup>. In the current study, both the latency and percentage of REM sleep of LC patients differed from those of controls, suggesting the hyperfunction of REM sleep suppressor mechanisms. Evidence from sleep deprivation studies suggests a role for dopamine during REM sleep<sup>[36]</sup>, and these studies have described the relationship of REM sleep in terms of dopamine D2 receptors<sup>[37]</sup>. Specific changes in the dopamine receptors of the brain of LC patients have been previously described<sup>[38,39]</sup>. Dopamine receptor dysfunction is associated with low concentrations of serotonin, which may suppress REM sleep and constitute a possible explanation for the PSG findings in our LC group.

It is possible that our findings of sleep impairment in subjects with cirrhosis are common to all forms of metabolic encephalopathy. However, our study's strength resides in the fact that we found differences in both subjective and objective parameters. In our observational study, LC patients had longer sleep latencies, shorter sleep time, worse sleep efficiency, increased REM sleep latencies and lower REM sleep percentages. The latter finding was negatively related to the severity of the disease. Therefore, we need to draw clinician's attention to the importance of sleep complaints and parameters regarding prognosis in cirrhotic patients.

## ACKNOWLEDGMENTS

The authors would like to thank Altay Lino de Souza and Ana Amelia Benedito Silva for their valuable suggestions and statistical analyses. All the efforts of the Associação Fundo de Incentivo a Pesquisa staff, particularly those of the sleep technicians, are deeply appreciated.

## COMMENTS

### Background

Liver cirrhosis (LC) is currently a serious clinical problem, and is considered a very common disease with a major impact on public health worldwide. It is a

chronic and irreversible process characterized by progressive replacement of the normal structure of the liver by fibrosis as a response to a continuous injury to this organ, leading to various clinical consequences, as alterations in sleep. In fact, sleep disturbances are commonly reported in LC.

### Research frontiers

Polysomnography provided the ability to assess sleep structure and led to a thorough characterization of sleep stages and sleep disorders. Sleep is divided into rapid eye movement (REM) and non-REM sleep stages. REM sleep has acquired increasing relevance because it is considered fundamental to the maintenance of important intellectual functions, such as memory, attention and mood. Time spent in REM is markedly reduced in several organic dysfunctions and is associated with cardiovascular adverse events, such as systemic arterial hypertension.

### Innovations and breakthroughs

There is a lack of detailed information regarding polysomnographic sleep aspects in patients with LC. Moreover, no study has attempted to determine the influence of disease severity on sleep structure. This study aimed to characterize the sleep patterns of patients with LC with a full-night polysomnographic based approach focusing on the following: (1) sleep structure in LC; (2) sleep pattern variations associated with liver disease severity; and (3) detection of possible sleep disorders linked to LC. Authors then compared polysomnographic sleep aspects between patients with LC and healthy volunteers.

### Applications

The study results suggest that hepatic cirrhosis was associated with shorter sleep time, reduced sleep efficiency, increased sleep latency, increased REM latency and reduced REM sleep. Additionally, disease severity influenced sleep parameters. Therefore, authors need to draw clinician's attention to the importance of sleep complaints and parameters regarding prognosis in cirrhotic patients.

### Peer review

In this paper, the authors study sleep aspects and parameters in cirrhotic patients and assess the role of liver dysfunction severity on polysomnographic results. This study is interesting and suggests that cirrhosis is associated with sleep disturbances and that disease severity influences sleep parameters.

### Abstract

**AIM:** To compare deep sedation with propofol-fentanyl and midazolam-fentanyl regimens during upper gastrointestinal endoscopy.

**METHODS:** After obtaining approval of the research ethics committee and informed consent, 200 patients were evaluated and referred for upper gastrointestinal endoscopy. Patients were randomized to receive propofol-fentanyl or midazolam-fentanyl ( $n = 100/\text{group}$ ).

We assessed the level of sedation using the observer's assessment of alertness/sedation (OAA/S) score and bispectral index (BIS). We evaluated patient and physician satisfaction, as well as the recovery time and complication rates. The statistical analysis was performed using SPSS statistical software and included the Mann-Whitney test,  $\chi^2$  test, measurement of analysis of variance, and the  $\kappa$  statistic.

**RESULTS:** The times to induction of sedation, recovery, and discharge were shorter in the propofol-fentanyl group than the midazolam-fentanyl group. According to the OAA/S score, deep sedation events occurred in 25% of the propofol-fentanyl group and 11% of the midazolam-fentanyl group ( $P = 0.014$ ). Additionally, deep sedation events occurred in 19% of the propofol-fentanyl group and 7% of the midazolam-fentanyl group according to the BIS scale ( $P = 0.039$ ). There was good concordance between the OAA/S score and BIS for both groups ( $\kappa = 0.71$  and  $\kappa = 0.63$ , respectively). Oxygen supplementation was required in 42% of the propofol-fentanyl group and 26% of the midazolam-fentanyl group ( $P = 0.025$ ). The mean time to recovery was 28.82 and 44.13 min in the propofol-fentanyl and midazolam-fentanyl groups, respectively ( $P < 0.001$ ). There were no severe complications in either group. Although patients were equally satisfied with both drug combinations, physicians were more satisfied with the propofol-fentanyl combination.

**CONCLUSION:** Deep sedation occurred with propofol-fentanyl and midazolam-fentanyl, but was more frequent in the former. Recovery was faster in the propofol-fentanyl group.

## INTRODUCTION

The routine use of sedation during endoscopic procedures is increasing worldwide<sup>[1,2]</sup>. In a survey conducted in the United States in 2006, > 98% of endoscopies and colonoscopies were performed under sedation<sup>[1,3]</sup>. A similar trend has been observed in Switzerland, Germany, and Australia<sup>[2,4-7]</sup>. The combination of a benzodiazepine and opioid is reportedly used at approximately 75% of all healthcare facilities in the United States<sup>[1,3]</sup> and considered the combination of choice by most endoscopists worldwide<sup>[1,2,4-9]</sup>. As a result of its anxiolytic and sedative properties, its ability to provide anterograde amnesia, and its short half-life, midazolam is the most widely used benzodiazepine. Fentanyl is the most widely used opioid, although meperidine is still frequently used<sup>[2-4,8,9]</sup>.

Propofol is a hypnotic agent that induces anesthesia almost immediately and has a short half-life. It also allows the patient to recover rapidly and be discharged. Patient and physician satisfaction is high with propofol. As a result of these properties, the use of propofol has been adopted at endoscopy centers worldwide<sup>[1-7,10]</sup>. However, its use has also been associated with deep sedation<sup>[11-14]</sup>.

During endoscopy, sedation and analgesia improve the efficiency of the procedure, quality of the results, and comfort of the patient<sup>[5,8]</sup>. However, sedation is also responsible for the majority of complications related to diagnostic endoscopy<sup>[15]</sup>. During sedation and analgesia, there is a continuum of states, ranging from mild sedation to general anesthesia. In the middle of this continuum is conscious sedation, which is the target level of sedation for patients undergoing upper or lower gastrointestinal endoscopy<sup>[4,5,10,11,13,14,16-19]</sup>. A level of sedation deeper than that intended is associated with a higher rate of complications<sup>[11,15,20]</sup>. The guidelines established in 2002 by the American Society of Anesthesiologists (ASA) task force on sedation and analgesia by non-anesthesiologists, which have also been endorsed by the American Society for Gastrointestinal Endoscopy, recommend that a distinction be made between conscious sedation and deep sedation and that one professional be dedicated to the assessment and monitoring of patients during sedation<sup>[11-13]</sup>.

The level of consciousness is typically assessed with the subjective clinical scale known as the observer's assessment of alertness/sedation (OAA/S) score, as validated by Chernik *et al*<sup>[21]</sup>, which ranks sedation as mild, conscious, or deep. Another means of assessing the level of consciousness is the calculation of the bispectral index

(BIS). Through the use of a BIS monitor, complex mathematical calculations of electroencephalography waves are transformed into numbers ranging from 0 (no brain activity) to 100 (fully conscious). This provides an objective measure of the level of consciousness. The BIS is considered a viable alternative for monitoring the level of consciousness in patients submitted to general anesthesia. Although its use in endoscopy is controversial, it has been investigated with increasing frequency, and further studies are recommended<sup>[22-27]</sup>.

In the past 10 years, new sedation guidelines have been established. Many of those guidelines state that propofol can be safely administered by an endoscopist or nurse under the supervision of a physician<sup>[1,3-5,8,10,12,14,17,25,28,29]</sup>. However, because propofol has been associated with deep sedation events and complications, some have recommended that propofol be administered exclusively by anesthesiologists<sup>[5,11-13,17]</sup>.

In view of these facts, we evaluated the use of propofol-fentanyl versus midazolam-fentanyl for sedation of patients undergoing upper gastrointestinal endoscopy. The primary endpoint of this study was to compare the frequency of deep sedation in each group. We also compared the two drug combinations in terms of time to induction, time to recovery, time to discharge, efficacy, and safety, as well as patient and endoscopist satisfaction.

## MATERIALS AND METHODS

This was a prospective, single-blind, randomized controlled trial carried out between January 2007 and October 2010 at the Gastrointestinal Endoscopy Clinic of the Department of Gastroenterology at the University of São Paulo Medical School - Hospital das Clínicas, Brazil.

### Patients

We recruited 262 patients from those scheduled to undergo upper gastrointestinal endoscopy at the Gastrointestinal Endoscopy Unit. The inclusion criteria were age > 18 years, physical status classified as ASA I, II or III, and having a contact telephone number. The exclusion criteria were as follows: pregnancy; a history of allergy to the medications to be administered; a history of allergy to soy or eggs; a psychotic disorder; being under treatment with psychoactive medications; being an illicit drug user or a heavy consumer of alcohol; Child-Pugh class C cirrhosis; presence of chronic kidney disease (being on dialysis); and being submitted to endoscopy as an emergency procedure. Of the 262 patients recruited, 62 were excluded (Figure 1). The final sample comprised 200 patients. Through a drawing of sealed envelopes, patients were randomized to two groups of 100: propofol-fentanyl and midazolam-fentanyl. The endoscopists scheduled to perform the procedures had no access to the envelopes.

### Drug administration

Drug infusion was performed by the nursing staff and attending endoscopist. In both groups, the objective was to

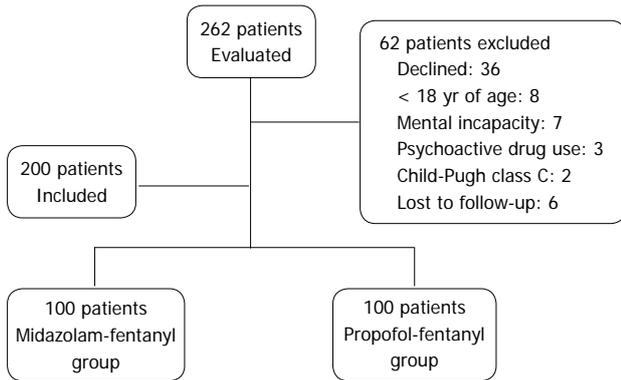

Figure 1 Flowchart of the study design.

achieve conscious sedation by using the dose calculated for that purpose (Table 1). The propofol and midazolam were administered by intravenous bolus and supplemented as necessary by the endoscopist to maintain the desired level of sedation. A single dose of fentanyl was used in both groups. The fixed maximum dose for midazolam was 10 mg or 0.1 mg/kg of body weight. If additional sedation became necessary, the endoscopist had the option of suspending the initial regimen and adding propofol.

### Patient evaluation and monitoring

Prior to the procedure, a clinical history and physical examination was performed for each patient. Additionally, the anesthetic risk was assessed with the ASA classification of physical status, and the patients completed a demographic questionnaire. Continuous monitoring during the procedure included the noninvasive measurement of blood pressure, heart rate, respiratory rate (thoracic excursion measurement), and oxygen saturation (SpO<sub>2</sub>). We defined the following evaluation time points: “baseline” (immediately before the procedure); “duodenum” (the approximate midpoint of the procedure, when the endoscopist was evaluating the duodenum or the jejunal loop in post-gastrectomy patients); and “recovery” (when the patient was awake and underwent the final evaluation).

### Evaluation of the level of sedation

During the procedure, the level of sedation was evaluated in two ways. We applied the OAA/S scale<sup>[21]</sup>, which is scored as 1 for deep sedation, 2-4 for conscious sedation, and 5 for mild sedation. In addition, after cleaning the skin with gauze and alcohol, we applied disposable electrodes to the forehead and connected the leads to a BIS monitor (A-2000 BIS XP; Aspect Medical Systems, Newton, MA, United States) (Figure 2). The BIS monitor output was evaluated continuously throughout the procedure and recovery period. BIS ≤ 65 indicates deep sedation, 66-85 indicates conscious sedation, and BIS > 85 indicates mild sedation. The OAA/S scale and BIS were determined simultaneously every 2 min.

An independent observer was responsible for the mo-

Figure 2 Bispectral index monitor.

onitoring, which included evaluating the level of consciousness, readout of other vital signs, collection of data regarding drugs and doses used, use of benzodiazepine or opioid antagonists, and occurrence of cardiorespiratory events, such as hypoxemia (defined as SpO<sub>2</sub> < 90% for > 30 s after application of the jaw thrust maneuver), hypotension (defined as ≥ 20% decrease in systolic or diastolic blood pressure), and bradycardia (heart rate < 50 bpm). Hypoxemia was classified as mild if it responded to supplemental oxygen delivered at 3-4 L/min; it was classified as severe if it did not respond to supplemental oxygen and the patient required noninvasive ventilatory support (*e.g.*, bag-mask ventilation) or intubation. The same observer also reported any other adverse events that occurred secondary to sedation. The observer was blinded to the randomization.

As described by Cohen *et al.*<sup>[30]</sup>, we compared the two groups in terms of the time to induction (interval between the first drug bolus administration and initiation of the procedure), time to recovery (interval between removal of the endoscope and final evaluation), and time to discharge (interval between removal of the endoscope and departure from the endoscopy unit). The final evaluation began when the BIS monitor indicated at least 90. Patients were discharged only when they had achieved an OAA/S score of 5 (the maximum), a BIS > 90, and reported no pain or any other type of discomfort.

### Visual analog scale and questionnaires

At discharge, patient satisfaction was assessed with a 10-point visual analog scale (1 = least satisfied and 10 = most satisfied). The patients also completed a satisfaction questionnaire before leaving the facility. At 24 h after discharge, the same observer who was responsible for the monitoring contacted the patients by telephone to administer a questionnaire that evaluated patient satisfaction with the procedure, adverse events and the resumption of domestic activities. All 200 patients completed both questionnaires. The visual analog scale was also applied to the endoscopists who performed the procedures to assess their level of satisfaction with the sedation regimen and was scored as follows: 1-3 = considerable difficulty in performing the procedure; 4-7 = minor difficulty in

**Table 1 Sedation regimens**

|                    |  |
|--------------------|--|
| Midazolam-fentanyl |  |
| Midazolam          |  |
| Initial dose       |  |
| ASA I              | 3-5 mg   |
| ASA II or III      | 2-3 mg   |
| Maintenance        | 0.5-1.0 mg every 2-3 min, up to a maximum cumulative dose of 10 mg or 0.1 mg/kg of body weight |
| Fentanyl           |  |
| Single dose        |  |
| ASA I              | 50 µg  |
| ASA II or III      | 20-30 µg   |
| Propofol-fentanyl  |  |
| Propofol           |  |
| Initial dose       |  |
| ASA I              | 0.5 mg/kg  |
| ASA II or III      | 0.25 mg/kg   |
| Maintenance        | 10-20 mg bolus at 60 s intervals   |
| Fentanyl           |  |
| Single dose        |  |

| ASA II or III      | 20-30 µg   |

ASA: American Society of Anesthesiologists.

performing the procedure (patient moved at the beginning or end of the procedure); and 8-10 = no difficulty in performing the procedure.

### Ethics

This work was conducted in accordance with the Declaration of Helsinki (2000) of the World Medical Association. The study was approved by the Hospital das Clínicas Research Ethics Committee, and all participating patients provided written informed consent.

### Statistical analysis

To calculate the sample size, we estimated the proportion of patients who received deep sedation by analyzing the BIS curve. We hypothesized that this proportion would be 10% for the midazolam-fentanyl group and 25% for the propofol-fentanyl group. By adopting an  $\alpha$  error tolerance (false-positive risk) of 5% and  $\beta$  error tolerance (false-negative risk) of 20%, we determined that 112 patients per group would be required to provide sufficient power to detect significant differences. It was agreed that we would perform an interim analysis involving 100 patients in each group.

The data were entered into a Microsoft Excel spreadsheet and analyzed with the assistance of the Statistics Sector of the University of São Paulo Medical School, Department of Gastroenterology. The statistical analysis was performed with the Statistical Package for the Social Sciences (SPSS Inc., Chicago, IL, United States). We applied the Mann-Whitney test to evaluate continuous variables and used the  $\chi^2$  test to evaluate categorical variables. To study the effects of the variable "group" at the various time points, we used repeated measures analyses of variance. We used the  $\kappa$  statistic to evaluate the degree of concordance between the OAA/S scale and BIS.

Data were collected by a researcher who was blinded

**Table 2 Patient characteristics**

| Variable                 | Group              |                   | Total      | P value |
|--------------------------|--------------------|-------------------|------------|---------|
|                          | Midazolam-fentanyl | Propofol-fentanyl |            |         |
| Sex                      |                    |                   |            |         |
| Female                   | 66 (60.0)          | 71 (71.0)         | 137 (68.5) | 0.543   |
| Male                     | 34 (34.0)          | 29 (29.0)         | 63 (31.5)  |         |
| ASA                      |                    |                   |            |         |

to each patient's group. However, such masking was not possible when we assessed endoscopist satisfaction with the sedation regimen.

## RESULTS

### Patient characteristics

Most patients presented with a low anesthetic risk (ASA class I or II), although one patient in the propofol-fentanyl group was classified as ASA III. There were no significant differences between the two groups regarding demographics, weight, height, body mass index, level of education, or ASA class (Table 2). All of the patients completed the procedure with adequate sedation throughout. None of the procedures were suspended or halted prematurely.

### Drug doses

Patients in the midazolam-fentanyl group received midazolam and fentanyl at mean doses of  $5.25 \pm 1.7$  mg and  $43.1 \pm 9.87$  µg, respectively. Patients in the propofol-fentanyl group received propofol and fentanyl at mean doses of  $70.3 \pm 38.9$  mg and  $41.0 \pm 10.25$  µg, respectively. Sixty minutes after the end of the procedure, a patient in the midazolam-fentanyl group presented with persistent drowsiness, despite normal cardiorespiratory function, and was given 0.2 mg flumazenil.

### Level of sedation

As seen in Table 3, the OAA/S classification of sedation in the midazolam-fentanyl group was mild in 1%, conscious in 88%, and deep in 11%, compared with 2%, 73%, and 25%, respectively, in the propofol-fentanyl group. There was a statistically significant difference between the two groups in terms of the OAA/S score ( $P = 0.014$ ). Based on the BIS values, sedation in the midazolam-fentanyl and propofol-fentanyl groups was classified

**Table 3** Level of sedation *n* (%)

| Variable    | Group              |                   | Total      | P value |
|-------------|--------------------|-------------------|------------|---------|
|             | Midazolam-fentanyl | Propofol-fentanyl |            |         |
| OAA/S score |                    |                   |            |         |
| 1           | 11 (11.0)          | 25 (25.0)         | 36 (18.0)  | 0.014   |
| 2-4         | 88 (88.0)          | 73 (73.0)         | 161 (80.5) |         |
| 5           | 1(1.0)             | 2 (2.0)           | 3 (1.5)    |         |
| BIS         |                    |                   |            |         |
| ≤ 65        | 7 (7.0)            | 19 (19.0)         | 26 (13.0)  | 0.039   |
| 66-85       | 75 (75.0)          | 67 (67.0)         | 142 (71.0) |         |
| > 85        | 18 (18.0)          | 14 (14.0)         | 32 (16.0)  |         |

OAA/S: Observer's assessment of alertness/sedation score; BIS: Bispectral index.

as mild in 18% and 14%, as conscious in 75% and 67%, and as deep in 7% and 19%, respectively ( $P = 0.039$ ). Comparing the BIS values obtained before, during, and after the procedure, we found that there was a trend toward a return to its initial value more rapidly in the propofol-fentanyl group than in the midazolam-fentanyl group (Figure 3). The OAA/S score showed good concordance with the BIS in the midazolam-fentanyl group ( $\kappa = 0.635$ ,  $P < 0.001$ ), the propofol-fentanyl group ( $\kappa = 0.710$ ,  $P < 0.001$ ), and the sample as a whole ( $\kappa = 0.696$ ,  $P < 0.001$ ).

### Satisfaction

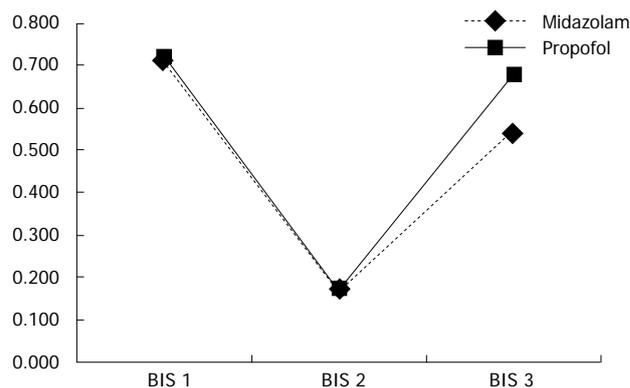

The mean score on the visual analog scale of patient satisfaction was  $9.84 \pm 0.4$  in the midazolam-fentanyl group and  $9.64 \pm 0.8$  in the propofol-fentanyl group ( $P = 0.178$ ). The mean score on the visual analog scale for endoscopist satisfaction was  $8.90 \pm 1.2$  for the midazolam-fentanyl regimen and  $9.30 \pm 0.9$  for the propofol-fentanyl regimen ( $P = 0.012$ ). The time to induction was significantly shorter in the propofol-fentanyl group ( $2.63 \pm 1.62$  min *vs*  $2.96 \pm 1.5$  min,  $P = 0.012$ ). The times to recovery and discharge were also shorter in the propofol-fentanyl group ( $P < 0.001$  and  $P < 0.001$ , respectively).

### Pre- and post-discharge questionnaires

We found no statistically significant differences between the two groups in terms of the patient-reported quality of sedation or pain/discomfort related to the procedure. The proportion of patients who remembered being awake at the beginning, middle, and end of the procedure was greater in the propofol-fentanyl group than the midazolam-fentanyl group ( $P < 0.001$  for all three time points). According to the results of the post-discharge questionnaire, none of the patients experienced any adverse reactions within the first 24 h after discharge. On average, the patients in the propofol-fentanyl group reported having resumed their domestic activities 60 min after discharge compared with 80 min after discharge for the midazolam-fentanyl group ( $P < 0.001$ ).

### Safety and complications

No serious complications were observed in either group. During the procedure, 42% of the propofol-fentanyl

**Figure 3** Bispectral values before, during, and after diagnostic upper gastrointestinal endoscopy according to group. Bispectral (BIS) 1: Before the procedure; BIS 2: During the procedure; BIS 3: After the procedure.

group patients developed mild transient hypoxemia ( $SpO_2$  of 85%-90% for  $> 30$  s after the jaw thrust maneuver), which also occurred in 26% of the midazolam-fentanyl group patients ( $P = 0.025$ ). In all of those cases, the hypoxemia responded to supplemental oxygen delivered by nasal cannula at 3-4 L/min. There were no instances of arrhythmia. Systolic hypotension was observed in 5% of the midazolam-fentanyl group and 10% of the propofol-fentanyl group, whereas diastolic hypotension was observed in 6% of the midazolam-fentanyl group and 16% of the propofol-fentanyl group. All of the variations in arterial blood pressure, heart rate, and respiratory rate were transient and required no mechanical or pharmacological intervention. There were no cases of perforation, bleeding, or death, and none of the patients required invasive ventilatory support, or hospitalization.

## DISCUSSION

Although there are abundant data in the literature and various guidelines on sedation during endoscopy<sup>[1-6,10,12,17,31]</sup>, few studies have compared propofol with midazolam for conscious sedation in patients undergoing diagnostic upper gastrointestinal endoscopy, especially when using the incidence of deep sedation events as the primary outcome. In the present study, we used the BIS and OAA/S scale in an innovative manner and assessed the frequency of deep sedation events for two sedation regimens frequently used during endoscopy<sup>[11,12,16,17,32,33]</sup>. In the midazolam-fentanyl group, deep sedation, defined according to the BIS and OAA/S score, occurred in 11% and 7% of the patients, respectively, compared with 25% and 19% of those in the propofol-fentanyl group. It was clear that despite the use of doses targeting conscious sedation, deep sedation events were common in the midazolam-fentanyl group. These findings are in agreement with those of Patel *et al*<sup>[20]</sup>, who evaluated the use of a benzodiazepine-opioid combination with the objective of achieving conscious sedation in patients undergoing diagnostic upper gastrointestinal endoscopy. The authors found that deep sedation, as evaluated by a modified OAA/S scale, occurred in 26% of the patients.

In the present study, the overall rates of deep sedation were 18% and 13% when assessed by the OAA/S score and BIS, respectively. However, we found that the frequency of clinically relevant complications was negligible, which is likely attributable to the relatively good overall health status of the patients. It is notable that the adverse effects arising from deep sedation were easily reversed with simple clinical maneuvers. There was a trend toward the BIS returning to its initial value more rapidly in the propofol-fentanyl group, which suggests faster recovery in those patients.

The principal complication that occurred in our study was hypoxemia, which was observed in 42% of the patients in the propofol-fentanyl group and 26% of the midazolam-fentanyl group. In all of those patients, hypoxemia responded to supplemental oxygen delivery. The close monitoring of the patients during sedation could explain the relatively high rates of transient mild hypoxemia found in both of the groups. These findings again raise the controversy regarding giving supplemental oxygen routinely during upper gastrointestinal endoscopy, which is our current practice. In addition, the small size of our sample prevented us from effectively evaluating the incidence of severe complications, which are rare in endoscopy.

In the pre-endoscopy, pre-medication period, patients typically have a BIS > 93, whereas a BIS of 60-70 is indicative of deep sedation<sup>[24]</sup>. There are some discrepancies between the data in the literature and information provided by the manufacturer in terms of the relationship between the numerical values and levels of consciousness<sup>[23,24,26,27]</sup>. Some authors define deep sedation as a BIS of 60-70 and conscious sedation as > 70<sup>[22]</sup>, while others define deep sedation as BIS < 75 in the presence of an OAA/S score of 1 or 2<sup>[27]</sup>. To improve the sensitivity and specificity of our evaluations, we defined deep sedation as BIS ≤ 65 and an OAA/S score of 1 and conscious sedation as BIS > 65 and an OAA/S score > 1. Bower *et al*<sup>[24]</sup> have suggested that a BIS of 75-85 indicates conscious sedation, which is an appropriate level of sedation for endoscopic procedures. In assessing the level of consciousness of patients undergoing endoscopic procedures, those authors demonstrated a strong temporal correlation between the BIS and OAA/S score ( $r = 0.59$ ,  $P < 0.0001$ ). In the present study, we observed good concordance between the BIS and OAA/S score ( $\kappa = 0.7$ ,  $P < 0.001$ ). However, the BIS has obvious advantages over the OAA/S. The primary advantage is that the BIS is a much simpler and more continuous measure. The BIS allows objective measurements of sedation in patients undergoing endoscopic procedures<sup>[26]</sup>.

The use of the BIS in monitoring the level of sedation of patients undergoing endoscopic procedures is controversial because its impact remains unclear<sup>[11,13,17,27]</sup>. In a study of patients undergoing colonoscopy, the sedation was administered by nurses under the supervision of gastroenterologists, and there was no reduction in the propofol dose used or the time to recovery<sup>[34]</sup>. Other au-

thors have shown that BIS monitoring leads to the use of a lower mean dose of propofol in endoscopic retrograde cholangiopancreatography<sup>[23]</sup>. In a study of BIS monitoring during sedation for endoscopic submucosal dissection, the propofol dose was not reduced, although there was increased satisfaction on the part of the patients and endoscopists<sup>[25]</sup>. Nevertheless, some authors question the accuracy of BIS monitoring in detecting deep sedation<sup>[27]</sup>. There is no evidence to support the routine use of BIS monitoring in the ambulatory setting of diagnostic endoscopic procedures. In the future, it may prove beneficial for more complex therapeutic endoscopic procedures.

The present study had some limitations. The fact that physical status was classified as ASA I or II in 99.5% of the patients might have limited the external validity of the study. However, the exclusion of patients with poor physical status allowed us to focus more closely on the relationship between propofol and deep sedation in the clinical setting most often encountered in endoscopy clinics. In fact, the inclusion of patients with more comorbidity who were undergoing endoscopic procedures of greater complexity would have shifted the discussion to the efficacy and safety of sedation in complex situations. Although that is an important topic and is currently being investigated by other authors<sup>[23,35]</sup>, it was not the focus of the present study. There were also some potential biases related to the difficulty of achieving full blinding of the sedation regimen. However, double blinding was achieved for the collection of data, such as the level of sedation (OAA/S and BIS), the time to induction, recovery, and discharge, and the level of patient satisfaction. All procedures were performed consecutively, respecting the sedation regimens initially proposed and with the observer present.

In the present study, we demonstrated that the times to induction, recovery, and discharge were significantly shorter in the propofol-fentanyl group. These findings replicate the results obtained by other authors who have demonstrated that propofol allows patients to resume their work activities sooner, thereby also increasing overall productivity<sup>[3,5,9,19,30,31,33,35-38]</sup>. We found no significant difference between the two regimens in terms of patient satisfaction, although there was a difference in terms of satisfaction on the part of endoscopists. The endoscopists expressed a preference for the propofol-fentanyl combination. This finding is in keeping with the global trend toward the use of propofol sedation by gastroenterologists and endoscopists<sup>[2,3]</sup>.

Our findings show that although the use of the midazolam-fentanyl regimen results in deep sedation less often than the propofol-fentanyl regimen does, the difference is not clinically relevant. In our opinion, there is little evidence to support the position that propofol should be administered only by anesthesiologists or that the use of propofol is disproportionately associated with the occurrence of unwanted deep sedation. In fact, deep sedation can also occur when the midazolam-fentanyl regimen is used. This underscores the importance of monitoring

the vital signs of patients under sedation. We could also add that both drug dosage and titration are crucial for the success of the sedation regimen.

In our opinion, patients classified as ASA I or II, if properly evaluated and monitored, can be safely subjected to diagnostic upper gastrointestinal endoscopy under sedation with the propofol-fentanyl combination at doses targeting conscious sedation. We also believe that the presence of an anesthesiologist is not mandatory in this setting. The use of this regimen can increase physician satisfaction and productivity.

## COMMENTS

### Background

The routine use of sedation during endoscopic procedures is increasing worldwide. The combination of a benzodiazepine (e.g., midazolam) and opioid (e.g., fentanyl) is reportedly used at approximately 75% of all healthcare facilities in the United States and considered the combination of choice by most endoscopists worldwide. Propofol is a hypnotic agent and its use has been adopted at endoscopy centers worldwide. However, its use has also been associated with deep sedation. In this study, authors evaluated the use of propofol-fentanyl versus midazolam-fentanyl for sedation of patients undergoing upper gastrointestinal endoscopy, comparing the frequency of deep sedation in each group. They also compared the two drug combinations in terms of time to induction, time to recovery, time to discharge, efficacy, and safety, as well as patient and endoscopist satisfaction.

### Research frontiers

Nowadays, propofol is only used routinely by anesthesiologists. The research hotspots are to find a secure way to provide safety and lower complications of propofol use by non-anesthesiologists.

### Innovations and breakthroughs

Although there are abundant data in the literature and various guidelines on sedation during endoscopy, few studies have compared propofol with midazolam for conscious sedation in patients undergoing diagnostic upper gastrointestinal endoscopy. In the present study, authors used the bispectral index (BIS) monitor and observer's assessment of alertness/sedation (OAA/S) scale in an innovative manner and assessed the frequency of deep sedation events for two sedation regimens frequently used during endoscopy.

### Applications

The results suggest that patients classified as low anesthetic risk, if properly evaluated and monitored, can be safely subjected to diagnostic upper gastrointestinal endoscopy under sedation with the propofol-fentanyl combination at doses targeting conscious sedation. Authors also believe that the presence of an anesthesiologist is not mandatory in this setting. The use of this regimen can increase physician satisfaction and productivity.

### Terminology

Deep sedation is represented by a BIS  $\leq$  65 and/or OAA/S scale = 1. The BIS monitors cerebral activity. BIS  $\leq$  65 indicates deep sedation, 66-85 indicates conscious sedation, and  $>$  85 indicates mild sedation. OAA/S scale was developed to measure the level of alertness in subjects who are sedated. It is scored as 1 for deep sedation, 2-4 for conscious sedation, and 5 for mild sedation.

### Peer review

An interesting study that assessed the differences and reliability between upper gastrointestinal endoscopies performed with midazolam-fentanyl versus propofol-fentanyl sedation. The main findings of the paper were that deep sedation was more frequent in the propofol-fentanyl group, however, this group had a more rapid recovery after the procedure.

### Abstract

**AIM:** To determine the technical feasibility and safety of an endoscopic gastrojejunostomy with a pure natural orifice transluminal endoscopic surgery (NOTES) technique using a T-anchoring device in a porcine survival model.

**METHODS:** An endoscopic gastrojejunostomy with a pure NOTES technique using a T-anchoring device was performed on 10 healthy female minipigs weighing approximately 40 kg each under general anesthesia. All procedures were performed with a transgastric approach using a 2-channel therapeutic endoscope.

**RESULTS:** The transgastric gastrojejunostomy was technically successful in all cases. A total of four to six

stitched pairs of a T-anchoring device were used to secure the anastomosis. The median time required to enter the peritoneal cavity and pull the small bowel into the stomach was 34 min (range: 19-41 min); the median time required to suture the anastomosis was 67 min (range: 44-78 min). An obstruction of the efferent limb occurred in one case, and a rupture of the anastomosis site occurred in another case. As a result, the functional success rate was 80% (8/10). Small bowel adhesion to the stomach and liver occurred in one case, but the anastomosis was intact without leakage or obstruction.

**CONCLUSION:** A transgastric gastrojejunostomy with a T-anchoring device may be safe and technically feasible. A T-anchoring device may provide a simple and effective endoscopic suturing method.

**Key words:** Natural orifice transluminal endoscopic surgery; Endoscopy; Pigs; Anastomosis

**Core tip:** Natural orifice transluminal endoscopic surgery (NOTES) have become part of the growing trend of minimally invasive surgery and have been gradually used in more diverse areas. An endoscopic gastrojejunostomy using a pure NOTES technique may be attractive because it can be a simple and less invasive method for bypassing a gastric outlet or duodenal obstruction. An endoscopic transgastric gastrojejunostomy with T-anchoring devices may be a technically feasible, useful alternative to invasive surgery. However, a great deal of care and further improvement is needed because of the risk of procedure-related complications.

Endoscopic gastrojejunostomy with a natural orifice transluminal endoscopic surgery technique. *World J Gastroenterol* 2013; 19(22): 3447-3452 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i22/3447.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i22.3447>

## INTRODUCTION

Gastric outlet obstruction or duodenal obstruction is one of the most serious problems that frequently occur in patients with advanced malignancies of the stomach or periampullary region<sup>[1-3]</sup>. In cases in which an oral diet was impossible due to gastric outlet obstruction or duodenal obstruction, open surgery using hand-sewn techniques, staplers, or compression devices, as well as laparoscopic surgery using staplers, have been the major treatment modalities thus far<sup>[4-8]</sup>. However, these obstructions usually occur in patients with unresectable malignancies of an advanced stage, and invasive surgery may be impossible or quite burdensome for these end-stage patients<sup>[9]</sup>. Therefore, less invasive methods to address malignant obstructions may be attractive to these patients<sup>[10,11]</sup>.

Various procedures using natural orifice transluminal endoscopic surgery (NOTES) techniques are part of the growing trend of minimally invasive surgery, and these NOTES techniques have been gradually used in more diverse areas<sup>[12-16]</sup>. Because NOTES techniques have proven to have many advantages in terms of being less invasive compared with existing surgical methods, they are considered to be effective treatment measures that are not burdensome for terminal-stage patients, particularly those with advanced-stage malignancies<sup>[17,18]</sup>. The first NOTES anastomosis, a cholecystogastrostomy, was reported in 2005, and subsequent studies have demonstrated that various forms of intraperitoneal surgery performed using laparoscopy could be conducted using a flexible endoscope<sup>[19,20]</sup>. Performing a gastrojejunostomy using a NOTES technique is attractive because it can be a simple and less invasive method for bypassing a gastric outlet obstruction or duodenal obstruction.

The aim of these experiments was to assess the technical feasibility and safety of an endoscopic peroral transgastric gastrojejunostomy procedure with a prototype T-anchoring device in a porcine model.

## MATERIALS AND METHODS

### Subjects

For this experiment, 10 minipigs, which were breeds of pig developed for medical research, weighing approximately 40 kg each were used. The anesthesia was performed by one veterinarian, and the gastrojejunostomy was performed by two endoscopists and two nurses. Permission for this study was obtained from the Animal Experiment Review Board of Asan Medical Center.

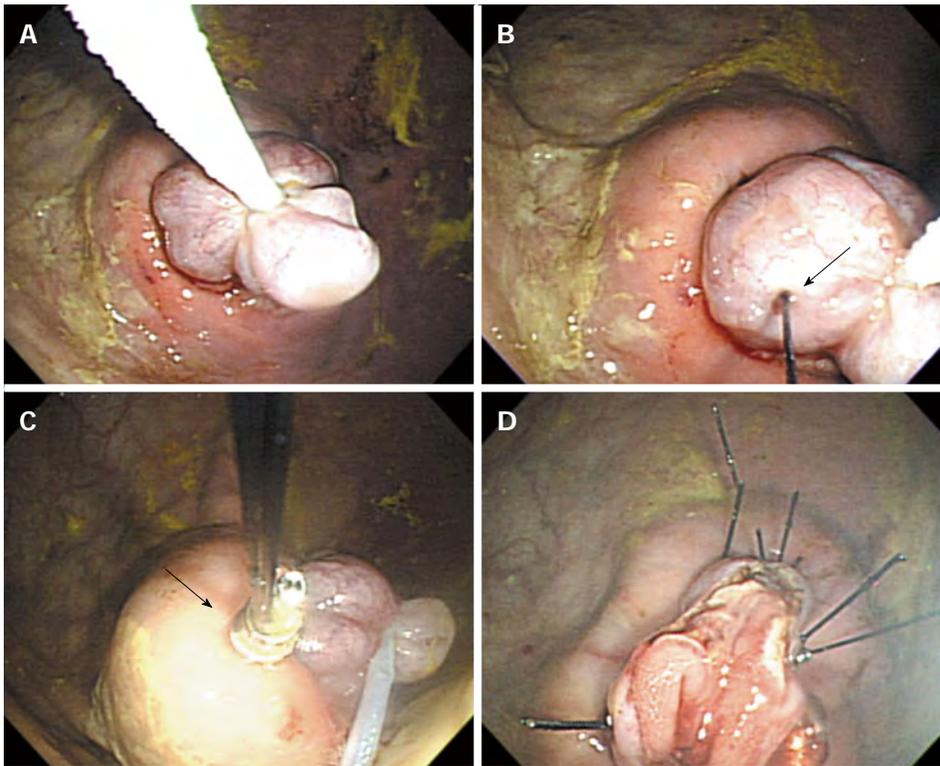

### Experiment method

**Pretreatment:** The animals were fed a soft liquid diet beginning 48 h before the procedure; then, they abstained from food-except for only a small quantity of water-beginning 24 h before the procedure. They were anesthetized with a combination of anesthetic agents, including tiletamine hydrochloride, zolazepam hypochloride (Zoletil<sup>®</sup>, Virbac do Brasil Ltda., Brazil), and xylazine (Rompun<sup>®</sup>, Bayer Korea Co. Ltd., South Korea) before the proce-

dures, and general anesthesia was maintained with 1.5% isoflurane (Forane<sup>®</sup>, Choongwae Pharma Co. Ltd., South Korea). Premedication was performed 30 min before anesthesia using an intramuscular injection of atropine sulfate (Bayer Korea Co. Ltd., South Korea).

**Procedure:** A multibending two-channel endoscope (2TQ260<sup>®</sup>, Olympus Optical Co. Ltd., Japan) was used for the procedures. The minipigs were placed in a supine position, and the endoscope was inserted into the stomach. The anterior wall of the body of the stomach was punctured with a needle knife (Micro knife<sup>®</sup>, Boston Scientific, Natick, MA, United States). After the puncture, a 0.035-inch guidewire (Jagwire<sup>®</sup>, Boston Scientific, Natick, MA, United States) was inserted into the peritoneal cavity through the needle knife, and the needle knife was then removed. A papillotome was inserted along the guidewire, and a 2-cm-long incision was made on the stomach wall. The incision was made in four directions-up, down, left, and right-while changing the direction of the papillotome. A dilating balloon with a diameter of 20 mm (CRE<sup>®</sup>, Boston Scientific, Natick, MA, United States) was inserted along the guidewire, and the puncture site was dilated twice for one minute each. After dilation, the dilating balloon was pushed inside the peritoneal cavity, together with the endoscope, while being deflated. After entry into the peritoneal cavity, the guidewire and inflating balloon were removed from the scope.

An appropriate loop of the small intestine was selected for the anastomosis. Usually, the mid-jejunum was selected using indications provided by the anatomic position relative to other structures. When the location of the anastomosis in the jejunum had been determined, grasping forceps were inserted into a channel of the endoscope, and a snare was inserted into another channel. After the snare was opened, the grasping forceps were pushed through the inside of the open snare, and the snare was slowly closed. Then, the predetermined antimesenteric site on the mid-jejunum was grasped using the grasping forceps, and the jejunum was drawn into the inside of the snare. Thereafter, the snare was closed to grasp the jejunum, which was brought into the stomach. The jejunum was grasped with care to avoid blocking the mesenteric vessel, and the air in the abdominal cavity was sufficiently aspirated before the jejunum was placed into the stomach. Because the small intestine would go back into the peritoneal cavity after being drawn into the stomach, the snare was held closed to hold the small intestine and prevent it from returning to the abdominal cavity while the grasping forcep was being removed. In the endoscopic channel (from which the grasping forceps had been removed), a needle, installed with the first T-anchoring tag, was inserted. Using the needle, the small intestine was punctured, and the first T-anchoring tag was detached through the inside of the needle. Then, the needle was removed, and the second T-anchoring tag was installed into the needle. This needle was inserted through the same channel, and the stomach wall (*i.e.*, the wall closest to the T-anchoring tag that was inserted first)

**Figure 1** Technique for endoscopic gastrojejunostomy using a T-anchoring device. A: After the gastric wall incision and balloon dilatation, the small intestine was held in the stomach; B: A needle installed with the first T-anchoring tag was used to start suturing. The first T-anchoring tag was attached to the small intestine (arrow), and then, the second was attached to the gastric wall; C: A pair of sutures was locked together using a locking device (arrow). The process was repeated four to six times to anchor the small intestine to the stomach; D: Finally, an incision using a needle knife was made on the jejunum.

was punctured. The second T-anchoring tag was detached through the inside of the needle, and the needle was removed. Then, a pair of T-anchoring tags was locked using a locking device. Thereafter, a pair of scissor forceps was inserted to cut the suture thread connected to the T-anchoring tag, thereby completing the suture. These processes were repeated four to six times to fix the jejunum to the stomach. Finally, the snare was opened, and an incision was made on the jejunum using a needle knife to open the jejunal lumen to the inside of the stomach (Figure 1).

**Postoperative care:** Third-generation cephalosporin and analgesics were administered intravenously after the procedures, and a liquid diet was administered after 24 h. All animals survived for seven days before they were euthanized. Then, autopsies were conducted. The health conditions and abnormal reactions of the animals were monitored for seven days. After seven days, the animals were euthanized, and the anastomosis site, afferent and efferent loops, and peritoneal cavity were observed.

## RESULTS

The detailed results of the endoscopic peroral transgastric gastrojejunostomy performed on the 10 animals are shown in Table 1. The transgastric gastrojejunostomy was technically successful in all cases (100%, 10/10). A total of four to six stitched pairs of T-anchoring devices were

used to secure the anastomosis. The median time from when the endoscope was inserted through the mouth to puncture the stomach, enter the peritoneal cavity, find an appropriate region of the small intestine, and draw it into the stomach was 34 min (range: 19-41 min). The median time required to complete the anastomosis using the T-anchoring devices was 67 min (range: 44-78 min). During the operations, there were no adverse events, such as bleeding or internal organ injury, and the vital signs of the animals were stable. On the postmortem examination, although the afferent limb was patent, the efferent limb was obstructed in one case. A rupture of the anastomosis site occurred in another case. As a result, the functional success rate was 80% (8/10). Mild adhesion of the short segment of the small intestine to the stomach and liver occurred in one case, but the anastomosis was intact without leakage or obstruction. In all other cases, the small intestine loops of the anastomosis reached the stomach without tension or abnormal rotation.

## DISCUSSION

In this study, the peroral transgastric gastrojejunostomy performed with a pure NOTES technique using a flexible endoscope and a T-anchoring device was technically feasible. Peroral transgastric gastrojejunostomy might be another potential therapeutic option for gastric outlet obstruction or duodenal obstruction in addition to surgical anastomosis. The method of using a pure NOTES

**Table 1** The results of an endoscopic peroral transgastric gastrojejunostomy on 10 animals *n* (%)

|  |            |
|--|------------|
| Technical success  | 10 (100)   |
| Functional success   | 8 (80)     |
| Number of stitched pairs of the T-anchoring device   |            |
| 4  | 4          |
| 5  | 4          |
| 6  | 2          |
| Median time required to enter the peritoneal cavity and pull the small bowel into the stomach (min, range) | 34 (19-41) |
| Median time required to suture the anastomosis (min, range)  | 67 (44-78) |
| Adverse events   |            |
| Rupture of anastomosis site  | 1          |
| Insufficient efferent limb opening   | 1          |
| Small bowel adhesion   | 1          |

technique to bypass a malignant obstruction is advantageous over surgical anastomosis because it does not require any abdominal incision; as a result, it induces less surgical stress<sup>[21]</sup>. Moreover, it can be easily performed using a flexible endoscope and accessories under a conscious sedation state without general anesthesia, which is required for the usual endoscopic procedures<sup>[22]</sup>. Therefore, this method is considered to be potentially applicable not only to the palliation of malignant obstructions but also to benign diseases in which conventional trans-abdominal and laparoscopic surgeries are unsuitable, such as bariatric surgery for morbidly obese patients<sup>[19]</sup>.

In this study, the anastomosis was performed using a T-anchoring device. Until recently, conventional hemoclips have been used for the closure of puncture sites during NOTES procedures<sup>[23]</sup>. Although existing hemoclips can be used easily in various types of conventional endoscopic procedures, they are disadvantageous as full-thickness sutures are impossible to secure, and the sutures may fail if two ends of an opening are distant from each other<sup>[24,25]</sup>. However, T-anchoring devices are advantageous because their use enables full-thickness sutures to be secured. Moreover, even in cases in which two ends of an opening are distant from each other, T-anchoring devices secure full-thickness sutures if only a needle puncture is possible. Therefore, T-anchoring devices can be used in diverse NOTES procedures, such as the closure of various incision sites or anastomosis, and also in the management of adverse events that may occur in conventional endoscopic procedures (*e.g.*, the closure of a bowel perforation and bleeding control).

In this study, room air, which is usually used in conventional endoscopic procedures, was used for the inflation of the stomach and the peritoneal cavity. During our pure NOTES procedures, air in the stomach may have leaked into the peritoneal cavity during the anastomosis to induce abdominal distension. Although air in the peritoneal cavity was sufficiently aspirated during the process of drawing the small intestine into the stomach, the air that leaked into the peritoneal cavity during the anastomosis was not removed by the suction of the stomach. Abdominal distension occurred immediately after the

anastomosis in two cases, and thus, percutaneous needle aspiration was performed after the procedures. When this procedure is performed on humans, CO<sub>2</sub> gas, which is easily absorbed and discharged through breathing, will be helpful in reducing this distension<sup>[26,27]</sup>. A great deal of care must be exercised to prevent pressure inside the stomach from rising too high during the procedure, and an endoscope installed with a pressure gauge at its fore-end should be developed to enable the easy measurement and constant maintenance of the pressure in the pneumoperitoneum<sup>[28,29]</sup>.

In our study, complications occurred with respect to the sizes of the initial incisions on the stomach wall. The case in which there was an obstruction in the efferent loop was the first, and we believe that the obstruction in the efferent loop occurred because the stomach wall incision was not sufficiently large. Although the incision site was further enlarged using a 20-mm dilatation balloon, openings enlarged by balloon dilatation may contract again, unlike direct incisions. Therefore, the initial incisions on the stomach wall are important. In one case in which a rupture occurred in the anastomosis site, the incision was large, exceeding 2.5 cm. Our speculation is that the suture site could not tolerate the pressure in the stomach after the diet because the incision was too large. Therefore, the size of the opening should be appropriate, and a great deal of care must be taken to ensure that it is not too small or too large. In our opinion, in the case of an endoscopic gastrojejunostomy, 2.0 cm is thought to be an appropriate incision size. In the event that a large incision exceeding 2.5 cm has been made, a greater number of sutures and a longer period of fasting after the procedure are necessary. In addition, the T-anchoring tag should be improved to ensure that the suture site can tolerate sufficiently high pressure.

The present T-anchoring device is a prototype. To secure one pair of sutures using this device, a needle should be inserted through an endoscopic channel at least twice, and then, a pair of scissor forceps should be inserted to cut the thread after installing two T-anchoring tags. Given these lengthy processes, coupled with the fact that more than four pairs of sutures are necessary for the anastomosis, the overall procedure time may become too long. In addition, the threads connected to the T-anchoring tags may occasionally become tangled, causing problems during the processes of inserting and removing the needle. Therefore, improving the T-anchoring device is necessary to simplify the suturing process. Many (but not all) of the limitations of the instruments that have been used for the NOTES technique can be overcome by innovative design and engineering improvements<sup>[20]</sup>.

In conclusion, a peroral transgastric gastrojejunostomy with T-anchoring devices may be a technically feasible, useful alternative to invasive surgery. However, a great deal of care is needed because of the risk of complications. The T-anchoring device is still in its early stage and needs further improvements; however, it may provide a simple and effective endoscopic suturing method.

## COMMENTS

### Background

Various natural orifice transluminal endoscopic surgery (NOTES) techniques have become part of the growing trend of minimally invasive surgery, and these NOTES techniques have been gradually used in more diverse areas.

### Research frontiers

Performing a gastrojejunostomy using a pure NOTES technique is attractive because it can be a simple and less invasive method for bypassing a gastric outlet obstruction or duodenal obstruction.

### Innovations and breakthroughs

The transgastric gastrojejunostomy was technically successful in all cases (100%, 10/10). A total of four to six stitched pairs of T-anchoring devices were used to secure the anastomosis. An obstruction of the efferent limb occurred in one case, and a rupture of the anastomosis site occurred in another case. As a result, the functional success rate was 80% (8/10). Small bowel adhesion to the stomach and liver occurred in one case, but the anastomosis was intact without leakage or obstruction in this animal.

### Applications

T-anchoring devices secure full-thickness sutures if only a needle puncture is possible. Therefore, T-anchoring devices can be used in diverse NOTES procedures, such as the closure of various incision sites or anastomosis, and also in the management of adverse events that may occur in conventional endoscopic procedures.

### Terminology

NOTES is a minimally invasive surgery technique that has been recently devised; the application of this technique has been gradually expanding.

### Peer review

The authors reported an animal study on the transgastric gastrojejunostomy using NOTES technique. This study provides a further potential advances in NOTES, with important potential advantages for use in human in due course.

### Abstract

**AIM:** To assess the clinical significance of incidental focal colorectal  $^{18}\text{F}$ -fluorodeoxyglucose ( $^{18}\text{F}$ -FDG) uptake on  $^{18}\text{F}$ -FDG-positron emission tomography/computed tomography (PET/CT).

**METHODS:** The records of all the cases which had undergone colonoscopy after PET/CT within a two weeks interval were reviewed. Adenomas were considered advanced when they were villous,  $\geq 10$  mm in size, or had high-grade dysplasia. Colorectal cancers and advanced adenomas are collectively referred to as advanced colorectal neoplasms. Receiver-operating characteristic curve analysis was used to determine the

significant predictive maximum standardized uptake value (SUVmax) cutoff value for advanced colorectal neoplasms and cancer.

**RESULTS:** Ninety-five colorectal lesions matched the site of incidental focal colorectal  $^{18}\text{F}$ -FDG uptake on PET/CT and 146 did not. Colonoscopy showed advanced colorectal neoplasms corresponding to the site of  $^{18}\text{F}$ -FDG uptake in 49 of the 95 (51.5%) lesions with incidental uptake. Of the lesions without incidental uptake, only 6 of 146 (4.1%) had advanced colorectal neoplasms on colonoscopy, indicating a statistically significant difference between the two groups ( $P < 0.001$ ). The sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and accuracy of incidental focal  $^{18}\text{F}$ -FDG uptake in identifying advanced colorectal neoplasms were 89.1%, 75.3%, 51.6%, 95.9%, and 78.4%, respectively. In detecting only CRC, these values were 89.2%, 69.6%, 34.7%, 97.3%, and 72.6%, respectively. The significant SUVmax cutoff value for advanced colorectal neoplasms (area under the curve 0.755,  $P < 0.001$ ) was 4.35, with a sensitivity, specificity, PPV, NPV, and accuracy of 75.5%, 65.2%, 69.8%, 71.4% and 70.5%, respectively. For CRC, 5.05 was the significant SUVmax cutoff value (area under the curve 0.817,  $P < 0.001$ ), with a sensitivity, specificity, PPV, NPV, and accuracy of 84.8%, 71.0%, 80.9%, 89.8%, and 75.8%, respectively.

**CONCLUSION:** The presence of incidental focal colorectal  $^{18}\text{F}$ -FDG uptake on PET/CT with a SUVmax  $\geq 4.35$  increases the likelihood of an advanced colorectal neoplasm.

**Key words:** Positron emission tomography; Adenomas; Computed tomography; Colorectal cancer; Colonoscopy

**Core tip:** Increased focal uptake of <sup>18</sup>F-fluorodeoxyglucose (<sup>18</sup>F-FDG) in the colon and rectum can be found incidentally during <sup>18</sup>F-FDG-positron emission tomography/computed tomography (PET/CT). The presence of incidental focal colorectal <sup>18</sup>F-FDG uptake on PET/CT indicated advanced colorectal neoplasms in more than half of the cases. Our study confirms the necessity of colonoscopy when incidental FDG uptake is detected on PET/CT to allow the early diagnosis and management of advanced colorectal neoplasms.

Incidental focal colorectal <sup>18</sup>F-fluorodeoxyglucose uptake on positron emission tomography/computed tomography. *World J Gastroenterol* 2013; 19(22): 3453-3458 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i22/3453.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i22.3453>

## INTRODUCTION

<sup>18</sup>F-fluorodeoxyglucose (<sup>18</sup>F-FDG)-positron emission tomography/computed tomography (PET/CT) is a technique used to reduce false-positive findings by combining two imaging modalities, and can distinguish physiological activity from pathology more readily than PET or CT alone. PET/CT is commonly used during the evaluation of malignant tumors, and an increased focal colorectal uptake of <sup>18</sup>F-FDG can be observed incidentally because of the capacity of PET/CT to detect the foci of tumors, which display increased glycolysis<sup>[1]</sup>.

Several previous studies have shown that not only is a high incidence of unexpected gastrointestinal malignancies associated with incidental <sup>18</sup>F-FDG avidity<sup>[2]</sup>, but also that the presence of these lesions can change patient management in up to 28% of cases<sup>[3]</sup>. And in symptomatic patients with proven or suspected colorectal cancer (CRC) recurrence PET detected additional sites of disease in up to 48.4% of patients<sup>[4]</sup>.

However, the significance of incidental focal colorectal <sup>18</sup>F-FDG uptake observed on PET/CT has not yet been fully clarified. Only one previous prospective study has demonstrated a requirement for colonoscopy when incidental FDG uptake was found with PET/CT imaging<sup>[5]</sup>. However, those researchers could not determine the statistically significant maximum standardized uptake value (SUV<sub>max</sub>) with which to detect advanced colorectal adenoma and cancer because of the broad overlapping SUV values among the patient groups.

As far as we know, we have evaluated the largest number of cases yet assessed to determine the value of colonoscopy when incidental FDG uptake is observed on PET/CT images. In this study, we investigated the clinical significance of incidental focal colorectal <sup>18</sup>F-FDG uptake detected on PET/CT, and determined the SUV<sub>max</sub> for detecting advanced adenoma and cancer.

## MATERIALS AND METHODS

### Patients

We analyzed the records of 583 consecutive colonoscopic lesions examined over a three-year period, from those who had undergone colonoscopy after PET/CT within a two weeks interval.

The exclusion criteria were an incomplete colonoscopic examination, insufficient biopsy specimen for pathological diagnosis, diffuse colorectal <sup>18</sup>F-FDG uptake on PET/CT, and proven or suspected CRC in a previous study. A surveillance PET/CT examination performed for clinical assessment after curative CRC resection was not an exclusion criterion. Based on these criteria, 342 lesions were excluded.

A total of 241 colonoscopic lesions (88 from women and 153 from men) were eligible for the study. The median age was 62 years (range: 29-86 years). The study was approved by the Institutional Review Board of Seoul St Mary's Hospital, Catholic University of Korea College of Medicine.

### PET/CT acquisition

The subjects were fasted for at least 6 h before the FDG injection. Their blood glucose levels were determined in capillary blood samples before the intravenous injection of FDG. At our institution, a cutoff blood glucose level of 8 mmol/L contraindicates FDG injection. PET/CT images were acquired 1 h after the injection of 370-570 MBq of <sup>18</sup>F-FDG. The subjects were scanned from the base of the skull to the upper thighs, with their arms raised above their heads.

The PET/CT scans (dual-section helical CT) were performed on a Biograph Duo scanner (Siemens Medical Solutions, Knoxville, TN, United States) with an axial spatial resolution of 6.5 mm. Neither intravenous contrast medium nor bowel preparations were used for the CT scan.

The PET/CT images were reviewed on a workstation with fusion software (Syngo, Siemens, Knoxville, TN, United States). An experienced nuclear medicine physician reviewed the PET/CT images. PET, CT, and fused whole-body images displayed in the axial, coronal, and sagittal planes were available for review. The PET data were also displayed in a rotating maximum-intensity projection. The intensity of the <sup>18</sup>F-FDG uptake can be analysed qualitatively and semiquantitatively by measuring the standardized uptake value, which is usually expressed as its maximum. The SUV is defined as the ratio of activity within the tissue (Bq/mL) and decay-corrected total activity injected divided by body weight (Bq/g) and it is calculated using the software provided by the workstation manufacturer. Abnormal FDG uptake, the SUV<sub>max</sub> of the primary tumor, and distant metastases were evaluated.

MUO: Metastasis of unknown origin; OBGY: Obstetrics and gynecology.

increased abdominopelvic <sup>18</sup>F-FDG uptake, localized by PET/CT images to the colorectum, and distinguishable from the background colonic uptake, were reviewed for interpretation<sup>[6]</sup>. The incidence of incidental focally increased <sup>18</sup>F-FDG uptake in the colorectum was calculated and the intensity of the uptake was measured by calculating SUVmax from the attenuation-corrected PET data, using the software provided by the workstation manufacturer. Lesion size on PET/CT was not part of the inclusion criteria. The PET/CT findings were correlated with the various colonoscopic and histopathological results.

### Colonoscopy and surgery

Two hundred forty-one colorectal pathological specimens obtained from 212 subjects who had undergone a total colonoscopy were studied. All colorectal lesions that appeared to be of neoplastic origin were biopsied and removed by polypectomy and/or surgery. Colonoscopy with a pathological examination was considered the gold standard diagnostic method.

Adenomas were considered advanced when they were villous, ≥ 10 mm in size, or had high-grade dysplasia. Colorectal cancers and advanced adenomas are collectively referred to as advanced colorectal neoplasms. If a subject had more than one detectable colorectal lesion, then each lesion was analyzed individually.

### Statistical analysis

The sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and accuracy of the incidental focal <sup>18</sup>F-FDG uptake in predicting advanced colorectal neoplasms and CRC were calculated. Receiver-operating characteristic (ROC) curve analysis was used to determine the significant predictive SUVmax cutoff value for advanced colorectal neoplasms and cancer. For all tests, a *P* value < 0.05 was considered statistically significant. All statistical analyses were performed with SPSS, version 16 (SPSS, Chicago, IL, United States).

## RESULTS

### Patient characteristics

Two hundred forty-one eligible colonoscopic lesions were obtained from 212 individual subjects. Of these, 95 lesions showed incidental focal colorectal <sup>18</sup>F-FDG uptake on PET/CT and 146 did not. The characteristics of the 241 colonoscopic lesions evaluated in this study are shown in Table 1. Of these, 153 were male and the mean age was 62 years (range: 29-86 years). The sex, age, and body mass index did not differ significantly between the <sup>18</sup>F-FDG positive and negative groups. The indications for PET/CT were as part of the initial staging of malignancies other than CRC in 99 cases, after the complete resection of malignancies other than CRC in 87 cases, and after chemotherapy for malignancies other than CRC in 12 cases. Thirty-one scanned cases were performed during health screening and 12 during screening for other purposes (Table 2).

The pathological diagnoses were 37 cancers, 24 acute or chronic inflammation, 140 non specific, and 18 advanced adenomatous lesions among a total of 40 adenomatous lesions (Table 1).

### Diagnostic accuracy of focal incidental uptake on PET/CT

In those lesions showing incidental uptake on PET/CT, 49 of 95 (51.5%) had advanced colorectal neoplasms on colonoscopy corresponding to the site of <sup>18</sup>F-FDG uptake, whereas in those lesions without uptake, only 6

of 146 (4.1%) were found to have advanced colorectal neoplasms on colonoscopy. This indicates a statistically significant difference between the two groups ( $P < 0.001$ ). Overall, the sensitivity, specificity, PPV, NPV, and accuracy of incidental focal <sup>18</sup>F-FDG uptake in predicting advanced colorectal neoplasms were 89.1%, 75.3%, 51.6%, 95.9%, and 78.4%, respectively. For detecting only CRC, the sensitivity, specificity, PPV, NPV, and accuracy of incidental focal <sup>18</sup>F-FDG uptake were 89.2%, 69.6%, 34.7%, 97.3%, and 72.6%, respectively.

### **SUVmax and colorectal neoplastic lesions**

The statistically significant SUVmax cutoff value that allowed the discrimination of advanced colorectal neoplasms from non advanced neoplastic and non neoplastic lesions was 4.35 (area under the ROC curve 0.755,  $P < 0.001$ ), with a sensitivity, specificity, PPV, NPV, and accuracy of 75.5%, 65.2%, 69.8%, 71.4%, and 70.5%, respectively. For CRC, 5.05 was the statistically significant SUVmax cutoff value (area under the curve 0.817,  $P < 0.001$ ), with a sensitivity, specificity, PPV, NPV, and accuracy of 84.8%, 71.0%, 80.9%, 89.8%, and 75.8%, respectively.

## **DISCUSSION**

PET/CT is a well-accepted technique for the diagnosis and staging of several malignancies because it provides more accurate functional and anatomical assessments than CT or other conventional imaging modalities<sup>[6]</sup>. Some researchers demonstrated that multidetector CT colonography has excellent sensitivity and specificity for lesions  $< 10$  mm. In fact, one study reported superior sensitivity compared to conventional colonoscopy for the detection of adenomas 10 mm or larger (93.8% *vs* 85.5%)<sup>[7]</sup>. A recent study looking at the feasibility of FDG-PET/CT colonography in patients with high clinical suspicion of colorectal carcinoma showed promising results in being an “all-in-one” staging modality, but was practically challenging and still required a formal colonoscopy for histopathological confirmation<sup>[8]</sup>.

Physiological <sup>18</sup>F-FDG uptake within the gastrointestinal tract, with variable intensities and localization patterns, has previously been described. Focal tracer uptake is frequently seen at the gastroesophageal junction, moderate uptake in the stomach, low-intensity uptake in the small bowel, and diffuse or focal uptake in the colon<sup>[9]</sup>. The mechanisms underlying this physiological activity are unclear. Muscular peristaltic activity, the presence of lymphoid tissue in the cecum, high concentrations of white blood cells in the bowel wall, and/or the presence within the bowel wall of cells secreting <sup>18</sup>F-FDG, especially in cases of cecum distention, have been hypothesized<sup>[10]</sup>. Increased FDG uptake can also be associated with inflammation, such as enterocolitis<sup>[11]</sup> or inflammatory bowel disease<sup>[12]</sup>. In our study, only focal or multifocal FDG findings were considered significant because diffuse uptake is considered to have a physiological origin.

Focal colorectal <sup>18</sup>F-FDG uptake indicates a high (70%-80%) probability of corresponding abnormal histopathological findings<sup>[13-15]</sup>. Despite this increase in confidence and reduction in the number of suggestive or equivocal lesions, the precise localization of increased <sup>18</sup>F-FDG foci using PET/CT cannot at present resolve the diagnostic dilemma of abnormal tracer uptake in the colorectum. For this reason, we assessed the clinical significance of incidental focal colorectal <sup>18</sup>F-FDG uptake on PET/CT and also determined a clinically useful SUVmax cutoff value for the detection of advanced adenoma and cancer. Our results are consistent with two large studies that showed that PET/CT is a sensitive tool with which to detect premalignant lesions<sup>[15,16]</sup>. In another previous study, PET/CT had a sensitivity of 74% and a specificity of 84% in the detection of colonic abnormalities<sup>[17]</sup>. However, that study was limited by its small sample size (39 patients).

Although previous studies have evaluated the etiology of incidental PET/CT findings in the colon<sup>[15,18]</sup>, we believe that our study contributes to the clinician's perspective by providing a SUVmax cutoff value that discriminates advanced colorectal neoplasms from non advanced lesions.

Larger series, with 3210 and 2000 patients, identified 20 (12 villous adenomas, six carcinomas, and two tubular adenomas) and 13 abnormalities (seven adenomatous polyps and six carcinomas), respectively, with colonoscopy<sup>[5,19]</sup>. However, they failed to determine a significant SUVmax cutoff value that would be clinically useful in discriminating advanced colorectal neoplasms from malignant carcinomas. In our study, the cutoff SUVmax value was higher in the CRC group than in the advanced neoplasms group (5.05 *vs* 4.35, respectively). We showed that the intensity of FDG uptake correlated with the severity of the lesion. This is consistent with the results of previous studies, although in those, the cutoff SUVmax value that allowed advanced and non advanced neoplasms to be distinguished was not determined, whereas this was one of the main goals of our study<sup>[3,20]</sup>. In the present study, a SUVmax  $\geq 4.35$  increased the likelihood of advanced colorectal neoplasms and a SUVmax  $\geq 5.05$  increased the likelihood of CRC.

One limitation of our study was a potential selection bias because we included those cases which had undergone PET/CT for the initial staging of a non colorectal malignancy and those in whom surveillance PET/CT had been performed for clinical assessments after curative CRC resection. However, we believe that our study more accurately reflects the real-life clinical situation by including them. The prevalence of focal colonic lesions in our study is also similar to that in previous studies that have used PET to detect colonic lesions<sup>[19,21,22]</sup>.

In conclusion, our study shows that advanced colorectal adenomas and malignant carcinomas should be suspected when focal <sup>18</sup>F-FDG uptake is detected by PET/CT and that this is clinically significant in most cases. Incidental focal colorectal <sup>18</sup>F-FDG uptake detected on PET/CT with a SUVmax  $\geq 4.35$  and a SUVmax

≥ 5.05 increases the likelihood of advanced colorectal neoplasms and CRC, respectively.

Our study confirms the necessity of colonoscopy when incidental FDG uptake is detected on PET/CT to allow the early diagnosis and management of advanced colorectal neoplasms.

## COMMENTS

### Background

Positron emission tomography (PET)/computed tomography (CT) is commonly used during the evaluation of malignant tumors. Increased focal uptake of <sup>18</sup>F-fluorodeoxyglucose (<sup>18</sup>F-FDG) in the colon and rectum can be found incidentally during FDG-PET/CT.

### Research frontiers

Several previous studies have shown that not only is a high incidence of unexpected gastrointestinal malignancies associated with incidental <sup>18</sup>F-FDG avidity, but also that the presence of these lesions can change patient management. However, the significance of incidental focal colorectal <sup>18</sup>F-FDG uptake observed on PET/CT has not yet been fully clarified.

### Innovations and breakthroughs

The authors have evaluated the largest number of cases yet assessed to determine the value of colonoscopy when incidental FDG uptake is observed on PET/CT images. In this study, the authors investigated the clinical significance of incidental focal colorectal <sup>18</sup>F-FDG uptake detected on PET/CT, and determined the maximal standardized uptake value (SUVmax) for detecting advanced adenoma and cancer.

### Applications

This study shows that advanced colorectal adenomas and malignant carcinomas should be suspected when focal <sup>18</sup>F-FDG uptake is detected by PET/CT and that this is clinically significant in most cases. This study confirms the necessity of colonoscopy when incidental FDG uptake is detected on PET/CT to allow the early diagnosis and management of advanced colorectal neoplasms.

### Terminology

FDG-PET/CT display increased sites of glycolysis and by increased focal colorectal uptake of <sup>18</sup>F-FDG and is capable to detect the foci of tumors. The SUVmax of <sup>18</sup>F-FDG is a way to measure the intensity of the <sup>18</sup>F-FDG uptake during FDG-PET/CT. It is measured using the software provided by the FDG-PET/CT workstation manufacturer.

### Peer review

The authors assessed the clinical significance of incidental focal colorectal <sup>18</sup>F-FDG uptake on FDG-PET/CT. The accuracy of incidental focal <sup>18</sup>F-FDG uptake in identifying advanced colorectal neoplasms and colorectal cancer (CRC) were 78.4% and 72.6%, respectively. In addition, they demonstrated higher cutoff SUVmax value in the CRC group than in the advanced neoplasms group (5.05 vs 4.35, respectively).

HCC was significantly correlated with their age. The participants' perceptions were also associated with their educational levels, household incomes and knowledge of hepatitis. Older patients and those with a lower socioeconomic status tended to have negative perceptions and less knowledge of hepatitis. Multivariate logistic regression further indicated that the participants' age ( $B = -0.044$ ,  $SE = 0.017$ , odds ratio = 0.957,  $P = 0.008$ , 95%CI: 0.926-0.989) and perceived barriers ( $B = -0.111$ ,  $SE = 0.030$ , odds ratio = 0.895,  $P < 0.001$ , 95%CI: 0.845-0.949) were correlated with their willingness to receive antiviral therapy.

**CONCLUSION:** Healthcare professionals should provide appropriate and effective guidance to increase their patients' awareness and to decrease the perceived barriers for continuing surveillance and antiviral therapy.

**Key words:** Antiviral therapy; Health perception; Hepatitis B; Hepatitis C; Hepatocellular carcinoma; Health knowledge

**Core tip:** Chronic hepatitis B/C carriers may benefit from regular surveillance for allowing an early diagnose of hepatocellular carcinoma (HCC). In addition, raising awareness of and health perceptions about HCC, and increasing willingness to receive antiviral therapy for preventing the development of HCC are crucial in patients with chronic hepatitis B/C, particularly in rural areas.

### Abstract

**AIM:** To measure patient perceptions about preventing hepatocellular carcinoma (HCC) and to predict the factors that influence patient willingness to receive therapy.

**METHODS:** A cross-sectional descriptive study was conducted at an outpatient clinic of a medical institution in southern Taiwan. Four hundred patients with chronic hepatitis B/C were recruited as participants. Two structured questionnaires based on the health belief model were utilized in this study, including the scales of perceptions about preventing HCC and knowledge of hepatitis B/C.

**RESULTS:** The statistical results demonstrated that the participants' perceived susceptibility ( $r = -0.22$ ,  $P < 0.001$ ), benefits ( $r = -0.11$ ,  $P = 0.028$ ) and cues to action ( $r = -0.12$ ,  $P = 0.014$ ) about the prevention of

## INTRODUCTION

Chronic liver disease is the eighth most common cause of death, and hepatocellular carcinoma (HCC) is the second leading cause of cancer-related death in Taiwan<sup>[1]</sup>. More than 80% of primary HCC is attributed to chronic infection with hepatitis B/C viruses<sup>[2,3]</sup>. To prevent further development of HCC, patients infected with hepatitis B/C should maintain a healthy lifestyle, reduce alcohol consumption, undergo regular liver function tests and abdominal sonography, and receive antiviral therapy, if necessary<sup>[4,5]</sup>. Chronic infection with hepatitis B/C is the most important cause of HCC. The early development of HCC is asymptomatic, and patients with chronic hepatitis are usually unaware of their carrier status, the symptoms and signs of HCC, and the importance of regular surveillance and treatment. During the early stage of HCC, when tumors are less than 2 cm in diameter, even expert radiologists have difficulty differentiating a cirrhotic nodule from a malignant tumor<sup>[4]</sup>. These tumors are highly heterogeneous, and HCC is nearly always fatal once the tumors cannot be eradicated by surgical or ablative approaches<sup>[4]</sup>. In addition, patients with HCC detected at the early asymptomatic stage have better survival rates than those who are diagnosed when symptomatic<sup>[6]</sup>. Therefore, increasing awareness of and health perceptions about HCC are crucial in patients with chronic hepatitis B/C, particularly in rural areas.

### Perceptions about preventing HCC

Henchoz *et al.*<sup>[7]</sup> defined perceived health as “an individual’s evaluation of his or her own health” which can determine personal health values and influence health behaviors<sup>[8]</sup>. Furthermore, Kartal *et al.*<sup>[9]</sup> stated that “self-perceived health is a subjective measure that can be calculated at an individual level. It gives an indication of how an individual feels about the condition of his/her own health.” To examine patient perceptions about preventing HCC, a health belief model was utilized as a theoretical framework in the present study. The health belief model was formulated using five concepts to explain attitudes and behaviors of individuals, including perceived susceptibility, perceived severity, perceived benefits of action, perceived barriers to action, and cues to action<sup>[10,11]</sup>. The model was developed to predict compliance with preventive health recommendations<sup>[6,12]</sup> and to specify the individuals’ values and beliefs about health and their influence on choices, especially for explaining screening behaviors<sup>[2,13]</sup>.

Perceived susceptibility refers to a person’s experience with a potentially harmful condition<sup>[11]</sup>. This concept measures whether patients with asymptomatic hepatitis perceive themselves as being at high risk and believe that they could acquire HCC. Perceived severity indicates individual concerns about the seriousness and consequences to the quality of life upon development of cancer, including the physical, mental, and social perspectives<sup>[11]</sup>. This concept can measure the impact of chronic hepatitis on a person’s life and his or her belief that people infected

could possibly die from liver cancer.

Perceived benefits of action refer to whether one believes the potential effectiveness of recommended health actions in preventing or reducing the risk or seriousness of a disease<sup>[11]</sup>. Perceived benefits of action can assess one’s beliefs that regular screening and antiviral therapy reduce the risks of progressing to liver cirrhosis and cancer.

Perceived barriers to action are the negative aspects of anticipated health behaviors that patients adopt for prevention or early detection of hepatic cancer, such as the inconvenience of seeing a doctor, the waiting time and pain involved in giving blood samples, and the side effects from taking medications. Patients may believe that regular screening of liver function and abdominal sonography are not necessary if they do not experience any symptoms of discomfort. Moreover, if patients receive antiviral therapy, they may develop physical and psychological side effects, such as fever, headache, fatigue, nausea, vomiting, anxiety and even depression. These adverse events often make patients feel uncomfortable, resulting in early withdrawal from therapy.

Cues to action measure the perceived social and environmental influences that stimulate an individual’s desire to take health-related action<sup>[11]</sup>. The concept can assess whether individuals with hepatitis have any family members, relatives or friends who are infected with hepatitis or whether the patients have ever followed the advice of healthcare professionals about regular check-ups of liver function, abdominal sonography, and antiviral therapy. Therefore, the five concepts of the health belief model were applied in the present study to explore health perceptions about preventing HCC among patients with chronic hepatitis B/C.

### Knowledge of hepatitis

Most people are not aware of the routes of viral transmission of hepatitis B/C and that these viruses spread more easily than the human immunodeficiency virus<sup>[14]</sup>. Ma *et al.*<sup>[15]</sup> found that populations with minimal education and low socioeconomic status are vulnerable to hepatitis infection. If high-risk groups with chronic hepatitis are not aware of the importance of regular surveillance and antiviral therapy, then their condition could gradually progress to liver cirrhosis and hepatic cancer. Wai *et al.*<sup>[16]</sup> identified that those hepatitis B carriers with high knowledge were significantly younger, and more likely to have received college education in Singapore. Treloar *et al.*<sup>[17]</sup> conducted a cross-sectional survey and indicated that knowledge is a precursor to decisions about treatment of hepatitis C, particularly for those patients who are less engaged with hepatitis C treatment and those with lower literacy.

The prevention of HCC in high-risk populations depends on regular serum screening, abdominal sonography and antiviral therapy. Regular screening of liver function, including assays to measure serum aspartate aminotransferase and alanine aminotransferase levels,  $\alpha$ -fetoprotein assays and abdominal sonography are strongly recom-

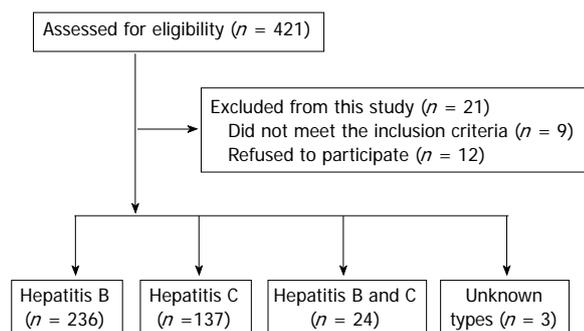

Figure 1 Sampling schema.

mended for patients with chronic hepatitis to ensure earlier detection of HCC and better survival<sup>[6,18]</sup>. Therefore, the purpose of the present study was to measure patient perceptions about the prevention of HCC, knowledge of hepatitis B/C, and frequency of hepatic check-ups, as well as to predict the factors that influence patient willingness to receive antiviral therapy.

## MATERIALS AND METHODS

### Participants

Four hundred patients with chronic hepatitis B/C from the outpatient clinic in a medical institution were recruited as participants. The teaching hospital is located in a rural area in southern Taiwan. The markers for hepatitis B are positive hepatitis B surface antigen (HBsAg) and positive antibody for hepatitis C (anti-HCV)<sup>[18]</sup>. The inclusion criteria for participants were (1) HBsAg (+) and anti-HBs (-), and/or (2) anti-HCV (+) in serum tests for more than 6 mo. The patients who were younger than 18 years and those who did not meet the inclusion criteria were excluded from this study. The sampling schema is shown in Figure 1.

### Instruments

This study had a cross-sectional, descriptive design. Two structured questionnaires developed by Chao *et al.*<sup>[19]</sup> and based on a health belief model were utilized in this investigation, namely, the scales of perceptions about preventing HCC and knowledge of hepatitis B/C. After obtaining permission from the original developers, a pilot test was conducted with 40 target adults (who did not participate in the main study) to examine whether there were any ambiguous statements in the questionnaires and to establish the reliability and validity of the instruments.

The scale of perceptions about preventing HCC consisted of five dimensions and 34 items, including the dimensions of perceived susceptibility (3 items), perceived severity (5 items), perceived benefits (3 items), perceived barriers (15 items), and cues to action (8 items). Each item was designed as a 5-point Likert scale, ranging from 1 “strongly disagree” to 5 “strongly agree.” Higher scores indicated greater degrees of perceived susceptibility, severity, benefits, barriers and cues to action. Cronbach’s alpha values were as follows: whole scale, 0.8; perceived suscep-

tibility, 0.71; perceived severity, 0.78; perceived benefits, 0.68; perceived barriers, 0.84; and cues to action, 0.77<sup>[19]</sup>. The internal consistency reliability with Cronbach’s alpha was 0.72 in this study. The values of Cronbach’s alpha for each dimension of perception indicated the reliability of the questionnaire utilized in this study.

The scale of knowledge of hepatitis B/C had 15 items, including liver function (2 items), blood tests for hepatitis (1 item), symptoms of hepatitis (2 items), definition of hepatitis (1 item), modes of viral transmission (4 items), screening to prevent liver cancer (2 items) and infectious status of hepatitis (3 items). Participants responded to these items using the following options: 0 = “do not know” or “false” and 1 = “true.” The total scores of 15 items represented a dimension of the participants’ knowledge. A higher score indicated a better understanding of hepatitis. The internal consistency with the Kuder-Richardson coefficient was previously determined to be 0.71<sup>[19]</sup>, whereas in the present study, the Kuder-Richardson coefficient was 0.62.

### Procedure

Approval to conduct this study was obtained from the institutional review board. This study was conducted between January and December of 2010. When patients visited the outpatient hepatic clinic and met the inclusion criteria, the researchers used convenient sampling to choose the participants. Subsequently, the participants were placed in another room to complete the questionnaires without interruption. All of the questionnaires were anonymous and separated from the consent forms. Prior to administering the questionnaires, the researchers informed the patients of the purpose of this study and explained that the responses would not influence their treatment.

### Statistical analysis

The Statistical Package for the Social Sciences (SPSS, Chicago, IL, United States) version 17.0 was used to analyze the data. The data analysis for this study included descriptive statistics, independent-samples *t*-tests, the chi-square test, a one-way analysis of variance (ANOVA), Pearson’s correlation, and logistic regression.

## RESULTS

### Participants’ demographics

Four hundred questionnaires were distributed and completed by 174 females (43.5%) and 226 males (56.5%). The average age of the respondents was 54 years (range: 18-89 years). The participants’ demographic information is summarized in Table 1.

### Participants’ hepatitis-related information

In this survey, 236 (59%) participants had hepatitis B, and 137 (34.3%) had hepatitis C. Twenty-four (6.0%) participants reported having both hepatitis B and C, and three (0.5%) did not know what types of hepatitis they had. In terms of vaccination, 298 patients (74.5%) responded

**Table 1** Participants' demographics (*n* = 400) *n* (%)

| Participants' demographics       | Value      |
|----------------------------------|------------|
| Gender                           |            |
| Female                           | 174 (43.5) |
| Male                             | 226 (56.5) |
| Marital status                   |            |
| Married                          | 353 (88.3) |
| Single                           | 27 (6.8)   |
| Widowed                          | 10 (2.5)   |
| Divorced/separated               | 9 (2.3)    |
| Educational level                |            |

| 21000-30000                      | 78 (19.5)  |
| 31000-40000                      | 47 (11.8)  |
| 41000-50000                      | 35 (8.8)   |
| Above 50000                      | 76 (19.0)  |

that they had never been vaccinated for hepatitis B. Thirty-eight patients (9.5%) had received the vaccine, and 64 (16.0%) did not know if they had been vaccinated.

Most of the patients (*n* = 292, 73.0%) reported that the virus had been found during a regular physical examination, 45 (11.3%) through the screening process for blood donation, 21 (5.3%) upon health screening in the community and 42 (10.5%) in other ways. Moreover, 332 patients (83.0%) were willing to receive antiviral therapy, 35 patients (8.8%) did not want to receive the therapy, and 33 patients (8.3%) were unaware that this antiviral therapy was available or whether they needed to receive this therapy.

Regarding the sources of hepatitis-related health information, 282 participants stated that they obtained this information from healthcare professionals, 189 from their relatives and friends, 220 from television, 173 from newspapers and magazines, and 70 from educational pamphlets or brochures. In addition, over one-half of the participants underwent regular blood screening every 3 mo (*n* = 247, 61.8%) and abdominal sonography every 6 mo (*n* = 183, 45.8%) according to the statistical results.

### Health perceptions and knowledge of hepatitis

The mean scores for each dimension of the health perceptions were as follows: perceived susceptibility,  $10.26 \pm 2.18$ ; perceived severity,  $20.43 \pm 3.53$ ; perceived benefits,  $12.07 \pm 1.63$ ; perceived barriers,  $37.60 \pm 7.06$ ; and cues

to action,  $27.01 \pm 4.73$ . The mean score for knowledge of hepatitis B/C in this study was  $7.36 \pm 1.87$ .

### Relationships among the patients' demographics, health perceptions, knowledge, screening, and willingness to receive antiviral therapy

Pearson's correlation revealed significantly negative correlations between the participants' age and their health perceptions, except for perceived severity and barriers. Likewise, the participants' age was significantly and negatively correlated with their level of knowledge ( $\gamma = -0.20$ ,  $P < 0.001$ ). The statistical results also suggested that the participants' perceptions had a significantly positive correlation with their knowledge of hepatitis. In addition, the patients' gender was not significantly correlated with their perceptions (except for perceived barriers) and knowledge, as presented in Table 2.

Moreover, a one-way ANOVA indicated that there were significantly positive correlations between the participants' educational levels and their perceptions (except for perceived severity) and knowledge of hepatitis. Significant relationships were found between the patients' frequency of blood screening for HCC prevention and the perceived severity ( $F = 3.67$ ,  $P = 0.001$ ) as well as between the frequency of abdominal sonography and perceived barriers ( $F = 3.66$ ,  $P = 0.001$ ).

Furthermore, the frequency of abdominal sonography was significantly correlated with the patients' knowledge ( $F = 2.74$ ,  $P = 0.009$ ) and with being vaccinated ( $F = 13.88$ ,  $P < 0.001$ ). A significant correlation existed between the participants' willingness to receive antiviral therapy and perceived barriers ( $F = 3.55$ ,  $P < 0.001$ ). The researchers further divided the participants into three groups by age (18-39 years, 40-64 years, and 65-89 years old). A significantly positive correlation was found between the participants' age and their willingness to receive antiviral therapy ( $\chi^2 = 13.97$ ,  $P = 0.007$ ), but there was no correlation between the participants' gender and their willingness to receive therapy ( $\chi^2 = 2.35$ ,  $P = 0.309$ ).

### Predictors for willingness to receive antiviral therapy

The participants' age, five dimensions of health perceptions and knowledge of hepatitis were analyzed as independent variables in the multivariate logistic regression. The results indicated that the participants' age ( $B = -0.044$ ,  $SE = 0.017$ , odds ratio = 0.957,  $P = 0.008$ , 95%CI: 0.926-0.989) and perceived barriers ( $B = -0.111$ ,  $SE = 0.030$ , odds ratio = 0.895,  $P < 0.001$ , 95%CI: 0.845-0.949) were significantly associated with their willingness to receive antiviral therapy, as presented in Table 3. Adjusting for other effects in the logistic regression model, for every one-year increase in age, the participants were 0.957 times less likely to have received antiviral therapy.

## DISCUSSION

Most of the participants in this study had elementary and high school educations, and their household in-

**Table 2 Relationships between the participants' demographics, health perceptions, and knowledge of hepatitis (*n* = 400)**

| Variables                                   | Perceived susceptibility | Perceived severity | Perceived benefits | Perceived barriers | Cues to action | Knowledge       |

comes were between \$10000 and \$ 30000 NT dollars. The patients in rural areas had lower educational levels and household incomes than those in urban areas. The results revealed that the participants' education levels were significantly correlated with their health perceptions and knowledge about hepatitis. This finding is consistent with the previous study<sup>[16,20]</sup>. The participants' education levels were not associated with the perceived severity in this study, which may be because the patients themselves might not have perceived the potentially severe consequences of being hepatitis carriers and might not have been aware of the asymptomatic development of HCC.

In addition, Hsu *et al.*<sup>[21]</sup> stated that educational attainment and knowledge of hepatitis B are associated with individual willingness to receive screening and vaccination. As previous studies have indicated, subjects with higher levels of knowledge were significantly more likely to receive blood screening for hepatitis B and to have received the vaccine<sup>[14,22-25]</sup>. However, the majority of the participants responded that they had never been vaccinated for hepatitis B prior to infection. Therefore, healthcare providers should educate patients with chronic hepatitis to increase their awareness and knowledge and to take action for prevention or early detection of HCC.

Likewise, household income was significantly and positively correlated with perceived susceptibility, benefits, barriers, cues to action, and knowledge. This finding revealed that patients with lower incomes perceived less susceptibility, benefits, and cues to action for preventing liver cancer, and they had less knowledge of hepatitis. These results were similar to those of a previous study<sup>[14]</sup>.

Thus, it is necessary to focus on the low socioeconomic population and to increase their perceptions and knowledge to reduce health disparities about liver cancer in the community.

Moreover, the vast majority of the participants usually obtained hepatitis-related health information and knowledge from healthcare professionals, public media (such as television, newspapers and magazines), and educational brochures and pamphlets. Cacoub *et al.*<sup>[26]</sup> indicated that the therapeutic education for those hepatitis patients can improve the probability of compliance with antiviral therapy. Hence, to raise perceptions and knowledge related to HCC, appropriate and effective instruction based on the individual's age and educational level is crucial, especially in rural areas.

Furthermore, the predictors for patient willingness to receive antiviral therapy were age and the perceived barriers. The participants' age was negatively associated with their health perceptions and knowledge of hepatitis. This finding indicates that elderly patients tend to have lower perceived susceptibilities, benefits, and cues to action for prevention of liver cancer; less knowledge about hepatitis; and less willingness to receive antiviral therapy. Similarly, Henchoz *et al.*<sup>[7]</sup> found that the paradox between health status and health perception diverges with advancing age.

Conversely, the participants' perceived barriers had a significantly negative relationship to their willingness to receive antiviral therapy. High barriers to screening and adverse consequences from antiviral therapy such as pain, high costs, and time expenditure may discourage patients from regular screenings and cause them to withdraw early from antiviral therapy. This finding is also consistent with previous studies<sup>[2,19]</sup>. Thus, identifying the patients' inherent barriers is the first crucial step for increasing participation in preventive behaviors<sup>[2]</sup>.

There were two limitations in the present study. Because the participants were restricted to an outpatient clinic of a rural medical institution, generalization beyond this population may be limited. Further research should be conducted in multiple diverse areas. In addition, this study had a cross-sectional descriptive design, and its analytic results do not indicate causality.

In conclusion, patient health perceptions about preventing HCC are related to their age, education levels, household income, and knowledge of hepatitis. Members of the high-risk population of hepatitis B/C carriers should be aware of the serious consequences of chronic active infection and should receive regular surveillance and treatment. To successfully complete a series of medical regimens, detailed explanation and communication regarding possible adverse effects are essential before starting antiviral therapy, especially in elderly individuals. In terms of the implications for clinical practice, health-care professionals should reduce patient discomfort and inconvenience as much as possible and should strive to remove barriers to screening and treatment. Moreover, clinicians may utilize educational programs as an intervention to increase patient perception, knowledge and willingness to receive antiviral therapy.

## ACKNOWLEDGMENTS

The authors sincerely appreciate the research assistants for data collection and entry and thank the participants who provided information.

## COMMENTS

### Background

Chronic liver disease is the eighth most common cause of death, and hepatocellular carcinoma (HCC) is the second leading cause of cancer-related death in Taiwan. More than 80% of primary HCC is attributed to chronic infection with hepatitis B/C viruses. The early development of HCC is asymptomatic, and patients with chronic hepatitis are usually unaware of their carrier status, the symptoms and signs of HCC, and the importance of regular surveillance and treatment.

### Research frontiers

The participants' educational levels were significantly correlated to their health perceptions (except for perceived severity) and knowledge about hepatitis. The elderly patients and those with lower household incomes tend to have lower perceived susceptibility, benefits, and cues to action for prevention of HCC, less knowledge about hepatitis and less willingness to receive antiviral therapy. The results indicated that the participants' age and perceived barriers were significantly associated with their willingness to receive antiviral therapy.

### Innovations and breakthroughs

Chronic hepatitis B/C carriers may benefit from regular surveillance for allowing an early diagnose of HCC. In addition, raising awareness of and health perceptions about HCC, and increasing willingness to receive antiviral therapy for preventing the development of HCC are crucial in patients with chronic hepatitis B/C, particularly in rural areas.

### Applications

In terms of the implications for clinical practice, health-care professionals should reduce patient discomfort and inconvenience as much as possible and should strive to remove barriers to screening and treatment. Moreover, clinicians may utilize educational programs as an intervention to increase patient knowledge and willingness to receive antiviral therapy.

### Terminology

Health perception is defined as "an individual's evaluation of his or her own health". Health perception can determine personal health values and influence health behaviors.

### Peer review

The authors conducted a cross-sectional descriptive study to identify several important factors of healthy perceptions about preventing HCC in Taiwan. The participants' age and perceived barriers were correlated with their willingness to receive antiviral therapy. The study was novel and well-constructed and the results have many implications in the field of preventive medicine.

### Abstract

**AIM:** To validate the clinical Rockall score in predicting outcomes (rebleeding, surgery and mortality) in elderly patients with acute upper gastrointestinal bleeding (AUGIB).

**METHODS:** A retrospective analysis was undertaken in 341 patients admitted to the emergency room and Intensive Care Unit of Xuanwu Hospital of Capital Medical University with non-variceal upper gastrointestinal bleeding. The Rockall scores were calculated, and the association between clinical Rockall scores and patient outcomes (rebleeding, surgery and mortality) was assessed. Based on the Rockall scores, patients were divided into three risk categories: low risk  $\leq 3$ , moderate risk 3-4, high risk  $\geq 4$ , and the percentages of rebleeding/death/surgery in each risk category were compared. The area under the receiver operating characteristic (ROC) curve was calculated to assess the validity of the Rockall system in predicting rebleeding, surgery and mortality of patients with AUGIB.

**RESULTS:** A positive linear correlation between clinical Rockall scores and patient outcomes in terms of rebleeding, surgery and mortality was observed ( $r =$

0.962, 0.955 and 0.946, respectively,  $P = 0.001$ ). High clinical Rockall scores  $> 3$  were associated with adverse outcomes (rebleeding, surgery and death). There was a significant correlation between high Rockall scores and the occurrence of rebleeding, surgery and mortality in the entire patient population ( $\chi^2 = 49.29, 23.10$  and  $27.64$ , respectively,  $P = 0.001$ ). For rebleeding, the area under the ROC curve was 0.788 (95%CI: 0.726-0.849,  $P = 0.001$ ); For surgery, the area under the ROC curve was 0.752 (95%CI: 0.679-0.825,  $P = 0.001$ ) and for mortality, the area under the ROC curve was 0.787 (95%CI: 0.716-0.859,  $P = 0.001$ ).

**CONCLUSION:** The Rockall score is clinically useful, rapid and accurate in predicting rebleeding, surgery and mortality outcomes in elderly patients with AUGIB.

**Key words:** Rockall score; Acute upper gastrointestinal bleeding; Prognosis; Elderly patients

**Core tip:** This study verified the advantages of the Rockall score in predicting the outcomes of the elderly patients with non-variceal upper gastrointestinal bleeding (UGIB) and assessed its clinical usefulness and prognostic value in rebleeding, surgery and mortality. The results suggest that the Rockall scoring system had satisfactory validity for the prediction of rebleeding, surgery and mortality in patients with acute non-variceal UGIB, and there was a positive linear correlation between the clinical Rockall scores and patient outcomes in terms of rebleeding, surgery and mortality.

Rockall score in predicting outcomes of elderly patients with acute upper gastrointestinal bleeding. *World J Gastroenterol* 2013; 19(22): 3466-3472 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i22/3466.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i22.3466>

## INTRODUCTION

Acute upper gastrointestinal bleeding (AUGIB) is common, costly, and potentially life-threatening and requires prompt assessment and aggressive medical management<sup>[1]</sup>. Despite changes in management, mortality has not significantly improved over the past 50 years. Elderly patients and those with chronic medical diseases withstand AUGIB less well than younger, fitter patients, and have a higher risk of death<sup>[2,3]</sup>. AUGIB is defined as hemorrhage that emanates proximal to the ligament of Treitz, which differentiates it from lower gastrointestinal bleeding involving the colon, and middle gastrointestinal bleeding involving the small intestine distal to the ligament of Treitz<sup>[4]</sup>. Clinically, AUGIB often causes hypodynamia, hematemesis (vomiting of blood), melena (passage of black tarry stools due to the presence of altered blood), and systemic shock typically ensues upon loss of 15% or more of the circulating blood volume. The color of the vomitus depends on its contact time with hydrochloric acid in the stomach<sup>[5,6]</sup>. If vomiting occurs early after the onset of bleeding, it appears red; with delayed vomiting, it is dark red, brown, or black. Coffee-ground emesis results from the precipitation of blood clots in the vomitus. Hematochezia (red blood per rectum) usually indicates bleeding distal to the ligament of Treitz. Occasionally, rapid bleeding from an upper gastrointestinal bleeding source may result in hematochezia<sup>[7]</sup>. The rate and extent of hemorrhage, coupled with the patient's comorbidities, determine the clinical presentation of UGIB. AUGIB is a common medical emergency, the annual incidence of hospitalization for AUGIB is 50-150 per 10000 people in China, and it has a mortality of 4%-14%<sup>[4]</sup>. Early predictors of adverse prognosis in AUGIB, include increasing age (above 60 years), an increased number of co-morbid conditions, the underlying cause of bleeding (*i.e.*, variceal), red blood cells (RBCs) in the emesis or stool, shock or hypotension on presentation, an increased number of units of blood transfused, active bleeding at the time of endoscopy, bleeding from large (> 2 cm) ulcers, onset of bleeding in the hospital, and emergency surgery<sup>[8-10]</sup>. Timely and effective assessment of the patient's condition and the degree of risk is very important, which could serve as a basis for the establishment of treatment procedures to reduce medical costs and improve prognosis<sup>[11]</sup>.

One of the major challenges in managing UGIB involves the identification of patients who are at high risk of rebleeding and death; conversely, the identification of patients who are suitable for early discharge and outpatient endoscopy is also important for effective resource use<sup>[12]</sup>. Similar to other common medical conditions, risk scores have been developed to try and identify those at lower or higher risk of poor outcome<sup>[13]</sup>. An ideal risk score is one that is easy to calculate, accurate for relevant outcomes and can be measured early after presentation with AUGIB. Several clinical scoring systems have been developed to help predict outcome in patients with a view to improving patient management and promoting

cost-effective use of resources. In most published scoring systems, a combination of clinical, laboratory, and endoscopic variables are weighted to produce a score that predicts the risk of mortality, recurrent hemorrhage, need for clinical intervention, or suitability for early discharge. The commonly used systems are the Rockall score, the Baylor bleeding score, the Cedars-Sinai Medical Centre Predictive Index, and the Blatchford score<sup>[14-17]</sup>. The most commonly used risk scoring system in UGIB is the Rockall score, which was described in 1996 following the analysis of data from a large English audit<sup>[12]</sup>. The score was developed to assess the risk of death following presentation with UGIB and incorporates patient age, hemodynamics, comorbidities and endoscopic findings. The clinical Rockall score, which relies on only clinical variables, is used to identify patients with AUGIB who have an adverse outcome, such as death or recurrent bleeding. The complete Rockall score, which relies on clinical and endoscopic variables, is also used to identify patients with AUGIB who died or have recurrent bleeding<sup>[18,19]</sup>. Rockall scores can be calculated both before and after endoscopy, but the post-endoscopic Rockall score provides a more accurate risk assessment. Patients at high-risk for rebleeding receive endoscopic therapy to achieve hemostasis and are subsequently treated with high-dose acid suppression to promote the formation of blood clots over the arterial defect responsible for bleeding. The aim of this study was to verify the advantages of the Rockall score in 341 patients with non-variceal upper gastrointestinal bleeding admitted to the emergency room and Intensive Care Unit (ICU) of Xuanwu Hospital, and to assess its clinical usefulness and prognostic value in rebleeding, surgery and mortality.

## MATERIALS AND METHODS

### Patients

This study included 341 patients with non-variceal UGIB admitted to the emergency room and ICU of Xuanwu Hospital of Capital Medical University. The median age of the patients was 72.85 ± 7.11 years (range: 60-85 years) and 181 were men and 160 were women. Patients admitted to hospital through the emergency department with a primary diagnosis of UGIB (hematemesis, melena or bloody nasogastric aspirate) were considered for inclusion, endoscopies were performed to confirm the diagnosis within 6-48 h after admission, and the characteristics of the patients are presented in Table 1. Patients were selected based on the following criteria: ≥ 60 years of age; patients with clinically significant UGIB (*i.e.*, signs of active UGIB including hematemesis, melena or hematochezia) confirmed by gastroscopy, surgery, blood or coffee grounds detected during nasogastric lavage; patients fulfilling the low-risk criteria such as having a low risk of requiring intervention (endoscopic therapy, blood transfusion, surgery) or death if they had a Rockall score ≤ 2 and were < 70 years old. Patients were excluded based on the following criteria: < 60 years of age; patients with a record of poor compliance, such as those

who did not undergo endoscopy; patients with acute variceal or obscure UGIB.

### Calculation of Rockall scores

The clinical Rockall score, which was calculated without endoscopic findings for each patient, was based on points assigned for clinical variables: patient age at presentation, shock status based on initial heart rate and systolic blood pressure, and presence of comorbid disease (Table 2). The associations between Rockall scores and rebleeding rate, mortality rate and surgical rate were evaluated. Scores ranged from 0 to 9 and were divided into three risk categories: low risk  $\leq 3$ , moderate risk 3-4, and high risk  $\geq 4$ . We used the observed percentages of rebleeding/death/surgery in each risk category in the original patient sample of Rockall as the predicted probabilities of rebleeding/mortality for both validation samples. Calibration and discrimination were assessed as measures of validity of the scoring system. Calibration was evaluated by a  $\chi^2$  goodness of fit test, and discrimination was evaluated by calculating the area under the receiver operating characteristic (ROC) curve.

Comorbidity was based on reference standard diagnostic criteria, including cardiovascular and cerebrovascular disease, chronic obstructive pulmonary disease, chronic liver disease and cancer.

Rebleeding or bleeding recurrence was defined as a separate episode of hematemesis or melena, or nasogastric evidence of new bleeding, occurring during admission and within 24 h of initial presentation, as witnessed by hospital staff. Hematemesis was defined as the vomiting of fresh or old blood, including "coffee grounds." Melena was defined as the passage of black or tarry stools. Mortality was defined as death occurring within 30 d of hospital admission.

Successful hemostasis was defined as endoscopic hemostasis or negative occult blood in the feces, and patients were hemostatically stable when no hematemesis or melena was observed.

Rebleeding manifestations were defined by at least one of the following: recurrent hematemesis or melena, bloody or red colored vomit, or bloody stools (blood in the stool that may appear as maroon or red), or the

patient had hyperactive bowel sounds; hemorrhagic peripheral circulatory failure (due to excessive blood loss and rapid bleeding) was not improved or hemodynamic status was temporarily improved after fluid infusion and blood transfusion, and the central venous pressure fluctuated and then decreased; RBC counts and hemoglobin levels continued to decline, and high reticulocyte count (increased RBC destruction such as bleeding or hemolysis) was observed; serum creatinine level increased when 24-h total volumes of fluid infusion and urinary output were normal; a relatively large amount of fresh blood was drained by nasogastric tube lavage.

Surgical treatment guidelines were as follows: conservative treatment was not sufficient and the bleeding continued, and patients suspected of having a perforated duodenal ulcer were transferred to the surgical ICU.

### Statistical analysis

SPSS statistical software version 19.0 (SPSS Inc., Chicago, IL, United States) was used for data analysis and management. The sensitivity and specificity of detecting patients who needed clinical intervention, had recurrent bleeding, or died were calculated for the clinical Rockall score and the complete Rockall score with confidence interval. The Rockall scores for all patients were calculated based on their pre-endoscopic variables. The correlation between the variables was analyzed using the Pearson product-moment correlation. Categorical variables were analyzed by  $\chi^2$  tests. We assessed the validity of the scoring systems by plotting ROC curves. A two-sided *P* value of less than 0.05 was considered statistically significant.

## RESULTS

### Rockall scores and clinical outcomes

Of 341 patients, 63 (18.47%) patients developed recurrent bleeding, 30 (8.79%) patients died and 31 (9.09%) patients required endoscopic treatment. The Rockall scores were calculated based on the collected data (Table 3). A positive linear correlation between the clinical Rockall scores and patient outcomes in terms of rebleeding, surgery and mortality ( $r = 0.962, 0.955$  and  $0.946$ , respectively,  $P = 0.001$ ) was observed. High clinical Rockall scores  $> 3$  were associated with adverse outcomes (rebleeding, surgery and death).

### Distribution of patients in the risk categories

The distribution of patients classified into the three risk categories (low, moderate, high), as determined by the Rockall risk scoring system, and the observed percentages of rebleeding, surgery and mortality in each risk category are shown in Table 4. The Rockall score identified 114 of 341 patients as low risk ( $\leq 3$ ), 110 of 341 patients as moderate risk (3-4) and 117 of 341 patients as high risk ( $\geq 4$ ). There were significant correlations between high Rockall scores and the occurrence of rebleeding, surgery and mortality in the entire patient population ( $\chi^2 = 49.29, 23.10$  and  $27.64$ , respectively,  $P = 0.001$ ).

### Predictive value of the Rockall score for rebleeding, surgery and mortality in patients with upper gastrointestinal bleeding

The discriminative ability of the Rockall score for the prediction of rebleeding and mortality were compared. The Rockall score was found to have good predictive value for rebleeding (area under the ROC curve was 0.788, 95%CI: 0.726-0.849,  $P = 0.001$ ), surgery (area under the ROC curve was 0.752, 95%CI: 0.679-0.825,  $P = 0.001$ ) and mortality (area under the ROC curve was 0.787, 95%CI: 0.716-0.859,  $P = 0.001$ ).

## DISCUSSION

Acute non-variceal UGIB remains a common and challenging emergency for gastroenterologists and general physicians<sup>[20]</sup>. The annual incidence is 50-150 per 100000 of the population, and although there have been significant improvements in endoscopic and supportive therapies, the overall mortality stubbornly remains around 10% (4%-14%), and may even reach 27% in hospitalized patients with serious co-morbidity<sup>[21]</sup>. AUGIB results in considerable patient morbidity and significant medical costs. Elderly patients (aged over 80 years) now account for around 25% of all AUGIB and 33% of AUGIB occurring in hospitalized patients, and therefore tend to account for much of the poor outcome associated with this condition<sup>[1]</sup>. Many risk factors are associated with bleeding, and these must be addressed. Pharmacists, physicians, and dentists should record patients' medical history and analgesic requirements. The initial evaluation of patients with AUGIB involves recognition of a range

of symptoms depending on the source, rate, and volume of blood loss<sup>[2]</sup>. Medical comorbidities and the use of antiplatelet medications can complicate the severity and management of bleeding, especially in the elderly. Symptoms of AUGIB include anemia, hematemesis (vomiting bright red blood or "coffee ground" material), and melena<sup>[5,6]</sup>. Other symptoms may include epigastric pain, dyspnea, and syncope (due to volume depletion). Bleeding may be obscure when the gastrointestinal blood loss is of unknown origin<sup>[7]</sup>. Certain prognostic factors in patients who present with AUGIB can increase the incidence of complications, including morbidity and mortality<sup>[22]</sup>. The patient should be admitted to the ICU if one or more of the following prognostic factors are present: age greater than 60 years; shock; comorbidities (*e.g.*, cardiac, renal and hepatic diseases); current bleeding; low systolic blood pressure; need for more than 6 units of blood; and endoscopy showing major signs of bleeding.

Several clinical scoring systems, *e.g.*, the Rockall score, the Blatchford score and Acute Physiology and Chronic Health Evaluation II score, have been developed to direct appropriate patient management and predict mortality as well as rebleeding. These systems weigh a combination of clinical, laboratory and endoscopic variables to produce a score that predicts the risk of mortality, recurrent hemorrhage, the need for clinical intervention or suitability for early discharge<sup>[23-25]</sup>. Factors commonly associated with poor outcome in patients with AUGIB may be related to presentation and co-morbidities, or to the behavior of the ulcer. Before endoscopy is performed, use of the Rockall risk scoring system is recommended. This assessment tool, which predicts the patient's outcome and estimates rebleeding risk, is the most widely

used scoring system and has been validated by several studies. The patient's age, systolic blood pressure, pulse rate and the presence of comorbidities are used for scoring. Patients with a score of 0 should be considered for non-admission or early discharge with outpatient follow-up; if the score is above 0, there is a significant risk of mortality, and endoscopy is recommended for a full assessment of bleeding risk<sup>[14-16]</sup>.

Rockall included 4185 cases of AUGIB from 74 hospitals in the United Kingdom over a four-month period in 1993. Their scoring system was based on multivariate analysis of information from history, examination, blood tests, and endoscopic investigation. The complete Rockall score makes use of both clinical and endoscopic criteria to predict the risks of rebleeding and death; the scale ranges from 0 to 11 points, with higher scores indicating higher risk. In the present study, we used Rockall's risk scoring system to classify patients and found that high clinical Rockall scores > 3 were associated with adverse outcomes (rebleeding, surgery and death), and the results obtained were widely corroborated in clinical practice. The complete Rockall score has been validated as a clinically useful score in predicting outcomes (rebleeding, mortality) of patients with acute non-variceal UGIB<sup>[26,27]</sup>. As the original study included only 180 of 4185 patients with esophagus-stomach fundus variceal hemorrhage, some investigators argued that the Rockall score might not be ideal or accurate in predicting rebleeding and mortality in patients with esophagus-stomach fundus variceal hemorrhage.

In the present study, we found that 63 (18.47%) patients developed recurrent bleeding, 30 (8.79%) patients died and 31 (9.09%) patients required endoscopic treatment. These results were consistent with earlier research<sup>[28]</sup>. A positive linear correlation between the clinical Rockall scores and patient outcomes in terms of rebleeding, surgery and mortality ( $r = 0.962, 0.955$  and  $0.946$ , respectively,  $P = 0.001$ ) was observed. High clinical Rockall scores > 3 were associated with adverse outcomes (rebleeding, surgery and death). Our results validated the clinical Rockall score in predicting patient outcome (*i.e.*, rebleeding, surgery and mortality) after acute non-variceal UGIB, which will help identify low-risk patients for delayed, elective or outpatient endoscopy, whereas those at high risk could have urgent endoscopy and a higher level of hospital care<sup>[29-33]</sup>.

Recurrence of bleeding is one of the most important factors affecting prognosis, and early prediction and treatment of rebleeding would improve the outcome in patients with acute non-variceal UGIB, as rebleeding is associated with high mortality<sup>[34-36]</sup>. The commonly used scoring systems are the Rockall score, the Baylor bleeding score, the Cedars-Sinai Medical Centre Predictive Index, and the Blatchford score<sup>[37]</sup>. The Cedars-Sinai Medical Centre Predictive Index was less accurate than the Rockall score in predicting patient outcome (*i.e.*, rebleeding, surgery and mortality), the Baylor bleeding score is commonly used in predicting the likelihood of rebleeding after endoscopic hemostasis of peptic ulcers, while the

complete Rockall score has been found to have good predictive value for mortality and in-hospital rebleeding. In this study, we showed that a low clinical Rockall risk score in patients with AUGIB without endoscopy was not associated with adverse outcomes (rebleeding or mortality), whereas a high clinical risk score was associated with adverse outcomes. A positive linear correlation between the clinical Rockall scores and patient outcomes in terms of rebleeding, surgery and mortality ( $r = 0.962, 0.955$  and  $0.946$ , respectively,  $P = 0.001$ ) was observed. The discriminative ability of the Rockall score for the prediction of rebleeding and mortality was compared. For rebleeding, the area under the ROC curve was 0.788 (95%CI: 0.726-0.849.  $P = 0.001$ ). For mortality, the area under the ROC curve was 0.787 (95%CI: 0.716-0.859.  $P = 0.001$ ). Our results were consistent with those of other studies and suggested that the Rockall score had good predictive value for mortality and in-hospital rebleeding, and was validated as a clinically useful scoring system for stratifying patients into high-risk and low-risk categories for mortality and in-hospital rebleeding<sup>[38,39]</sup>. However, other reports have suggested that the Rockall score showed inadequate sensitivity and poor specificity for outcome prediction in terms of rebleeding and mortality, thus, further clinical research is needed to confirm our observations<sup>[40]</sup>.

In conclusion, our results suggest that the Rockall risk scoring system had satisfactory validity for the prediction of rebleeding, surgery and mortality in patients with acute non-variceal UGIB, and a positive linear correlation between the clinical Rockall scores and patient outcomes in terms of rebleeding, surgery and mortality was observed. The problems associated with AUGIB are challenging for patients and physicians, and a combination of clinical and laboratory assessments (including the Cedars-Sinai Medical Centre Predictive Index and Baylor bleeding score) should be performed to comprehensively assess and correctly diagnose various conditions in patients in order to develop appropriate treatment programs and improve the prognosis of patients.

## COMMENTS

### Background

Acute upper gastrointestinal bleeding (AUGIB) is common, costly, and potentially life-threatening and requires prompt assessment and aggressive medical management. The most commonly used risk scoring system in UGIB is the Rockall score, which was described in 1996 following the analysis of data from a large English audit.

### Research frontiers

Rockall scores can be calculated both before and after endoscopy, but the post-endoscopic Rockall score provides a more accurate risk assessment. Patients at high-risk for rebleeding receive endoscopic therapy to achieve hemostasis and are subsequently treated with high-dose acid suppression to promote the formation of blood clots over the arterial defect responsible for bleeding.

### Innovations and breakthroughs

Several clinical scoring systems have been developed to help predict outcome in patients with a view to improving patient management and promoting cost-effective use of resources. In most published scoring systems, a combination of clinical, laboratory, and endoscopic variables are weighted to produce a score that predicts the risk of mortality, recurrent hemorrhage, need for clinical intervention, or suitability for early discharge. The commonly used systems are the Rockall score, the Baylor bleeding score, the Cedars-Sinai Medical Centre

Predictive Index, and the Blatchford score. This study verified the advantages of the Rockall score in predicting the outcomes of the elderly patients with non-variceal UGB and assessed its clinical usefulness and prognostic value in rebleeding, surgery and mortality.

### Applications

The authors found that the Rockall score is clinically useful, rapid and accurate in predicting rebleeding, surgery and mortality outcomes in elderly patients with acute upper gastrointestinal bleeding.

### Peer review

This manuscript is very interesting. The authors intended to validate the clinical Rockall score in predicting outcomes (rebleeding, surgery and mortality) in elderly patients with acute upper gastrointestinal bleeding. The study is well designed and the data well support the conclusion. Rockall score plays an important role in predicting the outcomes of the elderly patients with non-variceal upper gastrointestinal bleeding. This study will be informative for the readers.

### Abstract

**AIM:** To retrospectively assess the effect of comprehensive cryosurgery (ablation of intra- and extra-hepatic tumors) plus dendritic cell-cytokine-induced killer cell immunotherapy in metastatic hepatocellular cancer.

**METHODS:** We divided 45 patients into cryo-immunotherapy (21 patients), cryotherapy ( $n = 12$ ), immunotherapy ( $n = 5$ ) and untreated ( $n = 7$ ) groups. Overall survival (OS) after diagnosis of metastatic hepatocellular cancer was assessed after an 8-year follow-up.

**RESULTS:** Median OS was higher following cryo-immu-

notherapy (32 mo) or cryotherapy (17.5 mo;  $P < 0.05$ ) than in the untreated group (3 mo) and was higher in the cryo-immunotherapy group than in the cryotherapy group ( $P < 0.05$ ). In the cryo-immunotherapy group, median OS was higher after multiple treatments (36.5 mo) than after a single treatment (21 mo;  $P < 0.05$ ).

**CONCLUSION:** Cryotherapy and, especially, cryo-immunotherapy significantly increased OS in metastatic hepatocellular cancer patients. Multiple cryo-immunotherapy was associated with a better prognosis than single cryo-immunotherapy.

**Key words:** Cryoablation; Dendritic cell-cytokine-induced killer cell; Immunotherapy; Metastatic hepatocellular cancer; Survival time

**Core tip:** Forty-five patients of metastatic hepatocellular cancer were divided into cryo-immunotherapy, cryotherapy, immunotherapy and untreated groups. Median overall survival (OS) was higher following cryo-immunotherapy (32 mo) or cryotherapy (17.5 mo) than in the untreated group (3 mo); In the cryo-immunotherapy group, median OS was higher after multiple treatments (36.5 mo) than after a single treatment (21 mo). In a word, cryotherapy and, especially, cryo-immunotherapy significantly increased OS in metastatic hepatocellular cancer patients. Multiple cryo-immunotherapy was associated with a better prognosis than single cryo-immunotherapy.

Combination treatment with comprehensive cryoablation and immunotherapy in metastatic hepatocellular cancer. *World J Gastroenterol* 2013; 19(22): 3473-3480 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i22/3473.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i22.3473>

## INTRODUCTION

Hepatocellular carcinoma (HCC), which is the fifth most common cancer worldwide, is usually discovered late and has a poor prognosis<sup>[1]</sup>. In about 80% of patients, HCC is associated with chronic liver disease (*i.e.*, hepatitis and cirrhosis), with major implications for the prognosis and therapeutic options<sup>[2]</sup>. Many patients are unsuitable for tumor resection because of factors such as poor hepatic reserve (cirrhosis), multicentric tumors or extrahepatic disease<sup>[3,4]</sup>. Until recently, no systemic chemotherapy has significantly increased survival in patients with advanced HCC<sup>[5,6]</sup>. External beam radiation has had a limited role in the treatment of HCC because of radiation toxicity to the adjacent normal liver<sup>[7,8]</sup>. Percutaneous ablation is currently considered the best therapeutic modality for patients with early stage HCC who are not candidates for surgery; it principally involves percutaneous ethanol injection, radiofrequency ablation, microwave ablation, laser ablation or cryoablation<sup>[9]</sup>.

Because cryoablation forms an ice ball that can be visualized by many imaging methods, it has been an attractive option for reasons of safety. Technically, cryoablation of tumors in multiple organs (*i.e.*, liver, lung, kidney, breast, pancreas and prostate) has been proved to be safe and effective<sup>[10]</sup>. A long term study of medium to large tumors (more than 5 cm in diameter) treated with cryoablation and/or transarterial chemoembolization (TACE) showed a 5 year survival rate of 23% and local progression rate of 24%<sup>[11,12]</sup>. To our knowledge, there are currently no reports on the long term effects of simultaneous cryoablation of intra- and extra-hepatic tumors in metastatic HCC patients.

Another potential advantage of the *in situ* freezing of malignant disease is the cryo-immunologic response<sup>[13]</sup>, which is an antitumor immune response triggered by the natural absorption of malignant tissue<sup>[14]</sup>. Immunotherapy mediated by autologous dendritic cells (DCs) is a promising treatment option for long lasting control of unresectable HCC<sup>[15-17]</sup>. Increased knowledge regarding vaccination with DCs co-cultured with cytokine-induced killer (CIK) cells has led to improved clinical treatment strategies<sup>[18]</sup>. Whether slow release of tumor antigen after cryoablation can improve the effect of immunotherapy remains unknown.

Here, we retrospectively compared the effects of comprehensive cryosurgery (simultaneous cryoablation of intra- and extrahepatic tumors and of liver tumors of diameter greater than 5 cm, with TACE performed once or twice before cryoablation to reduce the tumor to 5 cm) and/or DC-CIK immunotherapy in patients with untreated metastatic HCC. To measure the survival time of patients with metastatic cancer, overall survival (OS) after diagnosis of metastatic disease was the main evaluation index.

## MATERIALS AND METHODS

### Patient selection

Between January, 2004 and October, 2011, 45 HCC pa-

tients with metastatic HCC met our inclusion criteria and were enrolled in this study. Surgery and chemotherapy were deemed unsuitable in any of the following situations: multifocal disease, unresectable HCC, patient refused to undergo surgery and chemotherapy or was seeking further treatment after failure of chemotherapy, severe complications (*i.e.*, hypertension and ascites) and advanced age. Ideal patients for comprehensive cryoablation are those with: Karnofsky performance status (KPS) score  $\geq 70$ ; platelet count  $\geq 80 \times 10^9/L$ ; white blood cell count  $\geq 3 \times 10^9/L$ ; neutrophil count  $\geq 2 \times 10^9/L$ ; hemoglobin  $\geq 90$  g/L; prothrombin time international normalized ratio  $\geq 1.5$ ; hepatic tumor not obviously invading the gallbladder, diaphragm or large vessels; absence of level 3 hypertension, severe coronary disease, myelosuppression, respiratory disease and acute or chronic infection; and adequate hepatic function (bilirubin  $< 30$   $\mu\text{mol/L}$ , aminotransferase  $< 60$  U/L and Child-Pugh score A or B) and renal function (serum creatinine  $< 130$   $\mu\text{mol/L}$ , serum urea  $< 10$  mmol/L).

The diagnosis of HCC was confirmed by liver pathology in 41 patients; in the remaining cases, HCC was diagnosed by classical imaging methods, including computed tomography (CT) or magnetic resonance imaging, or by biochemical markers such as increased alpha-fetoprotein. Twenty-four patients had only one mass in the liver, of 3.8-15 cm in diameter with an average of 6.5 cm. Twenty-one patients had two to four masses of 4.5-13 cm in diameter. There were a total of 71 masses in 45 patients. All except two cases had cirrhosis. Using the Child-Pugh score to assess the severity of cirrhosis, 25 patients were class A and 18 were class B. All patients received their final treatment in our hospital within an 8 year follow-up period.

### TACE

The preferred treatment for 25 patients with a hepatic tumor of long diameter  $\geq 5$  cm was TACE<sup>[19,20]</sup>, which was performed after cross-sectional imaging as previously described<sup>[21]</sup>. A French vascular sheath was placed into the femoral artery and a 0.035 inch diameter Mickaelson catheter was advanced into the celiac and superior mesenteric arteries. Contrast was injected into the arteries during rapid-sequence radiographic imaging. Arterial branches supplying the tumor were then located and the venous phase was examined carefully for patency of the portal veins. A 0.018 inch diameter Tracker catheter was advanced through the Mickaelson catheter to the arterial branches supplying the tumor. A mixture of doxorubicin (50 mg), mitomycin (10 mg) and lipiodol (4-15 mL) was injected into the arterial branches until hemostasis was achieved. If the tumor showed no shrinkage 2 wk after the procedure, a second TACE was performed.

### Cryoablation procedure

Comprehensive cryosurgery was performed on 33 patients, with complete cryoablation of obvious intra- and extrahepatic masses. Each procedure comprised two freeze/thaw cycles accomplished using an argon gas-

based cryosurgical unit (Endocare, Irvine, CA, United States). Cryoprobes (3, 5 or 8 mm) were inserted into the center of the tumor mass under ultrasonographic guidance and two freeze/thaw cycles were performed, each reaching a temperature of  $-180^{\circ}\text{C}$  at the tip of the probe. The duration of freezing was dependent on the achievement of an ice ball, visible as a hypoechoic region on ultrasonography. Generally, the maximal freezing time was 15 min, followed by thawing for 5 min; this cycle was then repeated. A margin of at least 1 cm of normal hepatic tissue was frozen circumferentially around the tumor. For masses larger than 5 cm in diameter, two or three cryoprobes were placed within the center and periphery of the tumor, to ensure freezing of the entire mass. The tracts formed were sealed with fibrin glue immediately after removal of the cryoprobes to ensure hemostasis.

### Immunotherapy

Twenty-six patients opted for immunotherapy (adoptive transfer of DC-CIK cells performed four times). DC-CIK cells were generated according to previously published protocols<sup>[22,23]</sup>; 70 mL peripheral blood was drawn before cryosurgery and the treatment was given 3-5 d after cryosurgery. Using Ficoll-Hypaque density centrifugation, we harvested peripheral blood mononuclear cells (PBMCs) from peripheral blood samples (80 mL) collected from the 48 patients 2 d before cryosurgery.

For DC culture, PBMCs were resuspended in DC medium [X-VIVO 15 (Lonza, Basel, Switzerland), 25 ng/mL interleukin (IL)-4 (Peprotech, Rocky Hill, NJ, United States) and 30 ng/mL granulocyte macrophage colony stimulating factor (GM-CSF; Peprotech)], at a concentration of  $1 \times 10^6$  to  $2 \times 10^6$ /mL. The cells were then allowed to adhere in two plastic flasks (T75; Corning Costa, Cambridge, MA, United States), each containing 50 mL DC medium and approximately  $10^8$  cells. After overnight culture at  $37^{\circ}\text{C}$  with 5%  $\text{CO}_2$ , the suspended cells were transferred to two fresh flasks. The cells sticking to the initial two flasks were continuously cultured in DC medium and a small amount of fresh medium was added daily to the cultures.

For culture of CIK cells, PBMCs were suspended in CIK medium [X-VIVO 15 (Lonza), 1000 U/mL IL-2 (Peprotech), 2.5  $\mu\text{g}/\text{mL}$  monoclonal antibody to CD3 (OKT-3; Jansen-Kyowa, Tokyo, Japan), 25  $\mu\text{g}/\text{mL}$  phytohemagglutinin (Peprotech) and 1000 U/mL interferon gamma (Peprotech)]. The CIK cells were allowed to grow and then continuously passaged. At approximately 7 d of culture, the CIK cells were passaged to fourteen T225 flasks. Cells adhering to the flasks were removed with a cell spatula, centrifuged and resuspended in DC-CIK medium [X-VIVO 15 (Lonza), 400 U/mL IL-2 and 0.5  $\mu\text{g}/\text{mL}$  monoclonal antibody to CD3]. All DCs were distributed evenly in the 14 T225 flasks containing CIK cells (approximately  $10^8$  DCs per flask). After co-culture for 24-48 h, almost 1 wk after cryosurgery, the DC-CIKs were harvested and suspended in 100 mL saline for intravenous injection (cells were collected on four consecutive days;  $6 \times 10^9$  to  $10 \times 10^9$  cells were collected on each

day). The final cell products were assessed for viability by the dye-exclusion test and checked twice for possible contamination by bacteria, fungi and endotoxins. All cell preparation processes were performed by the same technician and assessed by another technician.

Seven patients refused to undergo cryo- or immunotherapy owing to its cost or their health or age. These patients received no treatment and left the hospital.

### Ethics

The study protocol received ethical approval from the Regional Ethics Committee of Guangzhou Fuda Cancer Hospital and conformed to the provisions of the World Medical Association's Declaration of Helsinki in 1995 (as revised in Tokyo in 2004). Written informed consent was obtained from each participant.

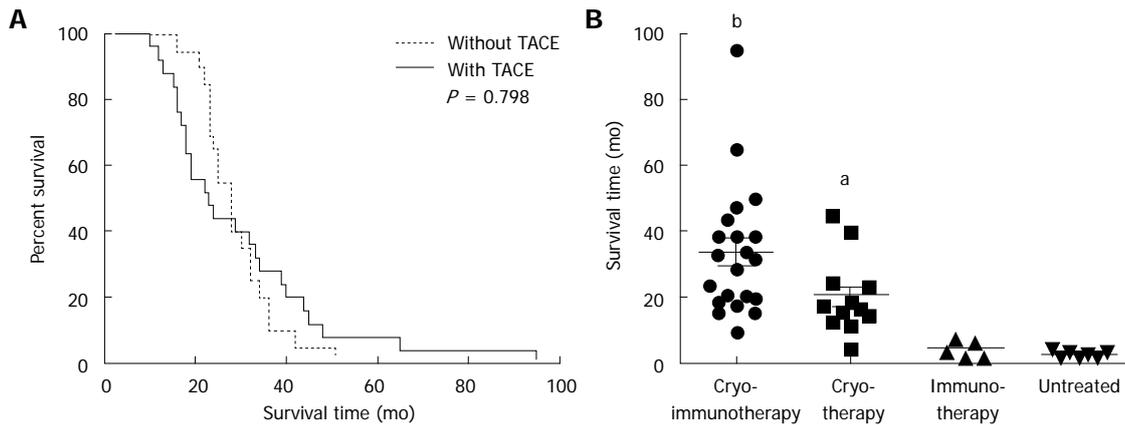

### Statistical analysis

Complications were recorded and classified in accordance with the Common Terminology Criteria of Adverse Events v4.0. Local tumor control and OS were also evaluated. Radiographic local tumor control was assessed using image-guided tumor ablation criteria<sup>[24]</sup>. Thoracic and/or abdominal ultrasonography was performed both 1 d and 1 wk after the minimally invasive treatment of primary and metastatic tumors. Follow-up dynamic CT was performed at 1 mo and then at 3-4 mo intervals. The revised Response Evaluation Criteria in Solid Tumors v1.1 were used to assess the response of the thoracic and abdominal tumors<sup>[25]</sup>. Three diagnostic radiologists reviewed CT scans for every case to determine whether progression or recurrence had occurred. Diagnoses were made independently, although the radiologists discussed cases over which they disagreed. Using the Dunnett test, we compared the OS of patients who had received cryo- and/or immunotherapy with that of untreated patients. The Kaplan-Meier test with log-rank analysis was used for comparison of OS between two groups. Significant differences were indicated by  $P < 0.05$  or  $P < 0.01$ . All analyses were conducted using GraphPad software (San Diego, CA, United States).

## RESULTS

### Clinical data

Twenty-eight men and five women underwent comprehensive cryoablation and/or TACE. Their ages ranged from 29 to 79 years, with a mean age of 53 years. Twenty-eight patients had histories of hepatitis B infection and two had hepatitis C infection. Fifteen patients were from China and 18 were from Southeast Asia. Of these patients, 18 had initially been treated with surgery and 13 with systemic chemotherapy in other centers; a total of 22 patients came to our hospital for further treatment 1-7 mo after metastases were found and 11 patients came to our hospital for first treatment. Bone metastases (17 lesions) were found in 11 patients, lung metastases (21 lesions) in 15 and multiple organ metastases (18 lesions) in seven. Moderate/severe abdominal pain, evaluated as 5-10

**Figure 1** Correlation of overall survival with type of treatment. All 45 patients with metastatic hepatocellular carcinoma died before June, 2012. There were 21 patients in the cryo-immunotherapy group, 12 in the cryotherapy group, five in the immunotherapy group and seven in the untreated group. The overall follow-up period was 8 years. **A:** Overall survival (OS) of patients who underwent comprehensive cryosurgery with or without transarterial chemoembolization (TACE). Thirty-three patients were enrolled; based on the long diameter of their hepatic tumors ( $\geq 5$  cm), 25 underwent TACE before hepatic cryoablation. Kaplan-Meier test with long-rank analysis; **B:** OS in the cryo-immunotherapy, cryotherapy and/or immunotherapy groups vs that in the untreated group using the Dunnett test. Horizontal lines represent the average and standard deviation. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs untreated group.

on a visual analog scale (VAS) (17 patients), and mild/moderate ascites (15 patients) were common complaints. For metastasis or recurrence of HCC after treatment, 16 patients received multiple treatments (10 in the cryo-immunotherapy group and 6 in the cryotherapy group); 17 patients refused to continue treatment (11 in the cryo-immunotherapy group and 6 in the cryotherapy group).

The untreated group (those who refused cryoablation, TACE and immunotherapy for reasons of treatment concept, age or economic ability) comprised 12 patients (47-77 years of age, median age 63 years; 8 male, 4 female). All of these patients had histories of hepatitis B or C infection. Five patients were from China and seven were from Southeast Asia. Of these patients, eight had initially been treated with surgery or systemic chemotherapy in other centers; a total of seven patients came to our hospital for further treatment 1-6 mo after metastases were found and five patients came to our hospital for first treatment. Bone metastases (5 lesions) were found in three patients, lung metastases (12 lesions) in seven and multiple organ metastases (6 lesions) in two. These patients had complaints similar to those of the comprehensive treatment group.

**Perioperative outcomes**

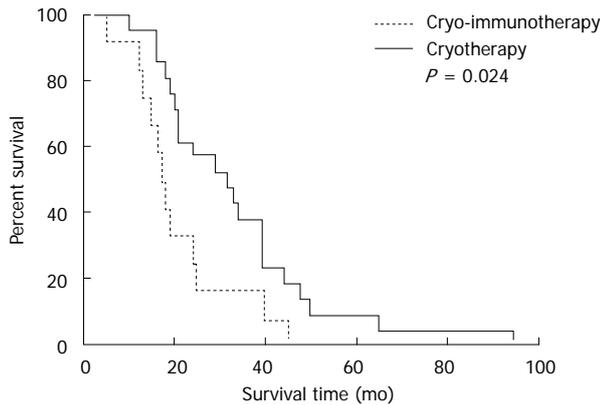

Percutaneous cryoablation of primary and metastatic HCC was successful in every case. No severe complications, such as liver cracking and failure or acute renal failure with myoglobinuria, were discovered post-cryoablation. After the first comprehensive cryosurgery in 33 patients, many slight side effects of cryoablation were observed but recovered with or without symptomatic treatment. Slightly hepatorrhagia was found in six patients (18%) but all healed within 5 d, after injection of a hemostatic agent. Liver capsular cracking was found in one patient (3%) who recovered after blood transfusion. Transient thrombocytopenia occurred in seven patients (21%) within 1 wk after cryoablation; two received

platelet transfusions. Two patients (6%) had tumor in the right lobe and developed asymptomatic right-sided pleural effusions close to the dome of the diaphragm; these disappeared spontaneously within 2-3 wk. Two patients (6%) developed liver abscess at the previous cryoablation site 2 and 4 d respectively following cryoablation, but recovered after antibiotic and drainage treatment. Four patients were found to have slight fever (body temperature less than 39 °C). No obvious side effects associated with TACE were found during the perioperative stage. In the first 2 wk after comprehensive cryosurgery, the VAS pain score decreased to 0-3 in 13 patients (76%) who had suffered pretreatment abdominal pain, with consumption of analgesics decreased by 50% and KPS score increased by  $\geq 20$ .

**Influence of treatment method and frequency on OS**

In our therapeutic protocol, large hepatic tumors (long diameter  $\geq 5$  cm) were treated by TACE first and considerably reduced in size before cryoablation. Whether patient life span is significantly affected by liver tumor size and additional TACE treatment remains to be determined. Of the 33 patients who received comprehensive cryosurgery, the median OS of those who underwent TACE first was 29 mo; those who received cryoablation directly had a median OS of 26 mo. There was no difference in the OS of these two groups according to the log-rank test ( $P = 0.798$ , Kaplan-Meier test with log-rank analysis; Figure 1A). Thus, a large hepatic tumor successfully shrunk by TACE can be treated as a small tumor, with no difference in the results of cryoablation.

To the date of the last follow-up, the median OS of all patients was 18 mo (25% percentile, 6 mo; 75% percentile, 33.5 mo). Median OS in the cryo-immunotherapy, cryotherapy, immunotherapy and untreated groups was 32, 17.5, 4 and 3 mo, respectively. OS was significantly higher in the cryo-immunotherapy ( $P < 0.01$ ) and cryotherapy ( $P < 0.05$ ) groups than in the untreated group (by

**Figure 2** Overall survival of patients who underwent comprehensive cryosurgery with or without immunotherapy. The Kaplan-Meier test with log-rank analysis was used to compare the overall survival of 21 patients in the cryo-immunotherapy group with that of 12 patients in the cryotherapy group.

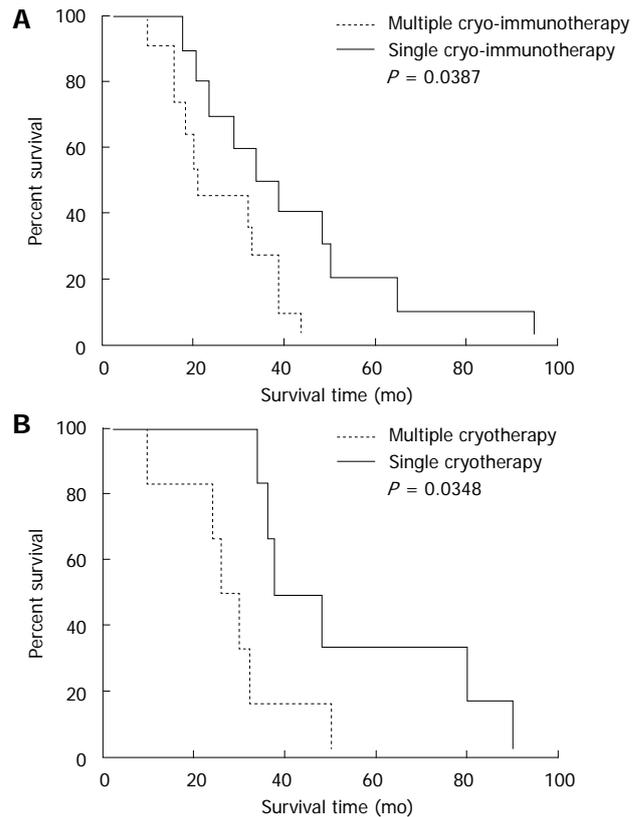

the Dunnett test, with the untreated group as the control group; Figure 1B).

Comparing the two groups in which there were obvious therapeutic effects, OS was higher in the cryo-immunotherapy group than in the cryotherapy group ( $P = 0.024$ , Kaplan-Meier test with log-rank analysis; Figure 2).

Repeated cryo- and immunotherapy for tumor progression and/or recurrence was performed in 10 patients in the cryo-immunotherapy group (twice in five patients, thrice in four patients and four times in one patient) and 6 patients in the cryotherapy group (twice in four patients and thrice in two patients); the remaining patients refused repeat treatments. Due to the shorter survival time, all patients in the immunotherapy group received one treatment. In the cryo-immunotherapy group, the median OS of the patients who underwent repeated treatment (36.5 mo) was higher than that of those who underwent a single treatment (21 mo;  $P = 0.039$ , Kaplan-Meier test with log-rank analysis; Figure 3A). In the cryotherapy group, the median OS after repeated treatment was 21.5 mo, whereas that after a single treatment was 14 mo ( $P = 0.035$ , Kaplan-Meier test with log-rank analysis; Figure 3B).

## DISCUSSION

In this study, we retrospectively reviewed our hospital's database to evaluate the survival time of patients with metastatic HCC. These patients had received various therapies in different medical centers before the metastases were found, and our treatment program directly determined their survival time in the metastatic stage. Increasing numbers of patients are undergoing cryoablation of their primary tumor and metastases, termed comprehensive cryoablation. With skilled operators and strict patient selection, this combined technology can be effective in preventing the occurrence of severe complications (*i.e.*, liver cracking and failure, acute renal failure with myoglobinuria), reducing the probability of side effects (*i.e.*, hepatorrhagia, liver capsular cracking, thrombocytopenia and liver abscess) and provide guar-

**Figure 3** Correlation of overall survival with number of cryo- and/or immunotherapy procedures, using the Kaplan-Meier test with long-rank analysis. A: Comparison of overall survival (OS) between 10 patients who underwent repeated treatments and 11 patients who underwent a single treatment in the cryo-immunotherapy group; B: Comparison of OS between six patients who underwent repeated cryoablation and six who underwent a single cryoablation in the cryotherapy group.

antee for the success of cryotherapy. Theoretically, most of the side effects can be further reduced, with the exception of thrombocytopenia. Development of systemic thrombocytopenia after cryosurgery is associated with excessive platelet trapping and destruction within the cryolesion<sup>[26]</sup>. This symptom is difficult to avoid simply through improved care, but can heal spontaneously or with platelet supplements.

It is increasingly clear that immunotherapy can be useful in cancer therapy, but there are also obstacles that need to be overcome. Due to their organ-like structural environment, these tumors are able to escape immune surveillance<sup>[27]</sup>, and immunotherapy for HCC must therefore be combined with additional therapy to disrupt this structure. Adoptive transfer of CIK cells along with DCs has been shown to be efficacious when the tumor burden is relatively low or when used as an adjuvant therapy rather than as a treatment for bulky tumors<sup>[18]</sup>, indicating the importance of cytoreductive cryoablation before immunotherapy. DCs have been the subject of much research in the last decade and are widely used in immunotherapy protocols. These bone marrow-derived cells have been identified as the most potent immune-stimulatory cells known and are specialized for the initiation and shaping of immune responses. Activated DCs after cryoablation

are potent stimulators of both CD4<sup>+</sup> and CD8<sup>+</sup> T cells, as supported by evidence from experimental<sup>[28]</sup> and human<sup>[29,30]</sup> studies. DCs are often pulsed with synthetic peptides derived from known tumor antigens<sup>[31]</sup>, tumor cell lysates<sup>[32]</sup>, apoptotic tumor cells<sup>[33]</sup> or RNA derived from tumor antigens<sup>[34]</sup> and transfected with whole tumor cell DNA<sup>[35]</sup> or RNA<sup>[36]</sup>. Moreover, DCs have been fused with tumor cells to induce antigen-specific, polyclonal cytotoxic T lymphocyte responses<sup>[37]</sup>.

On account of continued antigen release after cryoablation<sup>[14]</sup>, *in vitro* activation of DCs was omitted and the DCs were stimulated *in vivo* in the present study. We found that combined cryo- and immunotherapy extended the median OS of metastatic HCC patients from 3 to 32 mo (Figure 1B). Desirable results were achieved, and OS was longer in the cryo-immunotherapy group than in the cryotherapy group, demonstrating the synergistic effect of these two therapies (Figure 2). Owing to procedural costs, age or health, some of our patients underwent cryo-immunotherapy only once. We found that, compared with a single treatment, multiple cytoreductive cryoablation combined with immunotherapy was therapeutically valuable (Figure 3A) and prolonged survival time. Continued cryotherapy delayed disease progression, maintained function of multiple organs and improved quality of life and KPS scores, thereby achieving a better effect than single cryotherapy (Figure 3B).

In studies of the sequential use of TACE and percutaneous cryosurgery for unresectable HCC, pre-cryosurgical TACE was shown to increase the efficacy of cryoablation and decrease its adverse effects in patients with large HCCs (> 5 cm in diameter)<sup>[19]</sup>. It is well known that the presence of large HCCs often predicts rapid loss of liver function and a poor prognosis, and reducing their size before treatment is more effective than direct treatment of a large tumor. Data are available from two studies on the possible effect of TACE on immune stimulation<sup>[38,39]</sup>, which may further increase the therapeutic effect of combination therapy. Depending on whether single or multiple TACE is performed, a large HCC can first be reduced to 5 cm in diameter and then completely ablated by the combined application of multiple cryoprobes<sup>[19]</sup>. Consistent with the 2009 report of Shibata *et al.*<sup>[40]</sup>, treatment of larger tumors with sequential TACE and cryoablation can achieve significantly better effects than TACE or cryoablation alone. The findings of these authors and our own results indicate that not the frequency of TACE but the shrinkage of large HCCs contributed to the increase in median OS of about 30 mo, and differences due to HCC diameter can be eliminated by additional TACE procedures (median OS was 29 and 26 mo, respectively;  $P = 0.798$ ; Figure 1A).

In conclusion, we combined a minimally invasive procedure (percutaneous cryoablation of primary and metastatic tumors) with a common immunotherapy method (DC-CIK) to treat metastatic HCC. This new strategy extended the median OS from 3 to 32 mo. Better outcomes are expected as more patients undergo cryo-immunotherapy.

## COMMENTS

### Background

Hepatocellular carcinoma (HCC), which is the fifth most common cancer worldwide, is usually discovered late and has a poor prognosis. In about 80% of patients, HCC is associated with chronic liver disease (*i.e.*, hepatitis and cirrhosis), with major implications for the prognosis and therapeutic options. Many patients are unsuitable for tumor resection because of factors such as poor hepatic reserve (cirrhosis), multicentric tumors or extrahepatic disease. Until recently, no systemic chemotherapy has significantly increased survival in patients with advanced HCC. External beam radiation has had a limited role in the treatment of HCC because of radiation toxicity to the adjacent normal liver

### Research frontiers

The effects of comprehensive cryosurgery (simultaneous cryoablation of intra- and extrahepatic tumors and of liver tumors of diameter greater than 5 cm, with transarterial chemoembolization (TACE) performed once or twice before cryoablation to reduce the tumor to 5 cm) and/or dendritic cells - cytokine-induced killer (DC-CIK) immunotherapy in patients with untreated metastatic HCC.

### Innovations and breakthroughs

Cryotherapy and, especially, cryo-immunotherapy significantly increased overall survival in metastatic hepatocellular cancer patients. Multiple cryo-immunotherapy was associated with a better prognosis than single cryo-immunotherapy.

### Applications

For metastatic HCC, comprehensive cryotherapy and cryo-immunotherapy can help patients improve symptoms, reduce pain and prolong life.

### Terminology

Comprehensive cryotherapy: simultaneous cryoablation of intra- and extrahepatic tumors and of liver tumors of diameter greater than 5 cm, with TACE performed once or twice before cryoablation to reduce the tumor to 5 cm; cryo-immunotherapy: Immunotherapy is performed shortly after comprehensive cryosurgery, breaking products of tumor may continually stimulate immune cells to clean up the systemic metastases lesions.

### Peer review

In this study, authors combined a minimally invasive procedure (percutaneous cryoablation of primary and metastatic tumors) with a common immunotherapy method (DC-CIK) to treat metastatic HCC. This new strategy extended the median overall survival from 3 mo to 32 mo. Better outcomes are expected as more patients undergo cryo-immunotherapy.

### Abstract

**AIM:** To investigate the efficacy and safety of combined *de novo* lamivudine (LAM) and adefovir dipivoxil (ADV) therapy in hepatitis B virus (HBV)-related decompensated liver cirrhosis patients.

**METHODS:** One hundred and forty patients with HBV-related decompensated cirrhosis were recruited, 70 patients were treated with combined LAM and ADV *de novo* therapy, and the other 70 patients were treated with LAM alone as controls. The follow-up period was 144 wk. All patients with LAM resistance were shifted to ADV.

**RESULTS:** The percentage of HBV-related decompensated cirrhosis patients with undetectable HBV DNA in

*de novo* combination group was 51.6% (33/64), 84.2% (48/57), and 92.3% (49/53) by weeks 48, 96, and 144, respectively. In monotherapy group, HBV DNA negativity rate was 46.1% (30/65), 56.1% (32/57), and 39.2% (20/51) by weeks 48, 96 and 144, respectively. There was a significant difference between the two groups by weeks 96 and 144 ( $P = 0.012$  and  $0.001$ ). The hepatitis B e antigen seroconversion rate was 28.1% (9/32), 40.0% (12/30), and 53.6% (15/28) in the combination group by weeks 48, 96 and 144, respectively, and 24.2% (8/33), 31.0% (9/29), and 37.0% (10/27) by weeks 48, 96 and 144, respectively, in monotherapy group. A total of 68.6% (44/64), 84.2% (48/57), and 92.5% (49/53) patients achieved alanine aminotransferase (ALT) normalization by weeks 48, 96 and 144, respectively in the combination group. In monotherapy group, the ALT normalization rate was 64.6% (42/65) by week 48, 73.7% (42/57) by week 96, and 80.4% (41/51) by week 144. No patients in the combination group exhibited detectable resistance for at least 144 wk. The cumulative resistance rate in monotherapy group at weeks 48, 96, and 144 was 20.0%, 36.8%, and 56.9%. Both combination group and monotherapy group demonstrated an improvement in Child-Turcotte Pugh and Model for End-Stage Liver Disease scores at weeks 48, 96, and 144. All patients tolerated both combination and monotherapy. The ceratinine levels and glomerular filtration rate remained normal in all patients during the follow-up period.

**CONCLUSION:** In HBV-related decompensated liver cirrhosis patients, the combined *de novo* LAM and ADV therapy is more efficacious and safer compared to LAM alone.

© 2013 Baishideng. All rights reserved.

**Key words:** Liver cirrhosis; Lamivudine; Adefovir dipivoxil; Efficacy; Alanine transaminase

**Core tip:** Present treatment guidelines advocate oral nucleos(t)ide analogues in decompensated chronic hepatitis B (CHB) patients. Studies with lamivudine

(LAM) have demonstrated decreased mortality and improved liver function in CHB decompensated patients. However, LAM resistance mutations emerging during monotherapy can negate therapeutic benefit. Adefovir dipivoxil had no cross resistance with LAM. Consistent with outcomes in patients with LAM-resistance, no patient in *de novo* combination therapy group showed detectable resistance up to 144 wk in this study. The *de novo* combination therapy markedly improved liver function, reduced Child-Turcotte Pugh and Model for End-Stage Liver Disease scores in hepatitis B virus-related decompensated cirrhosis patients.

## INTRODUCTION

It is estimated that over 350 million people worldwide are chronically infected with hepatitis B virus (HBV). The majority of these individuals reside in the Asia-Pacific region<sup>[1]</sup>. Chronic hepatitis B (CHB) infection is the principal cause of liver cirrhosis and hepatocellular carcinoma (HCC). In cirrhotic patients, the 5-year probability of decompensation is 15%-20%, and the risk increases as the HBV DNA level increases<sup>[2]</sup>. The 5-year survival rate in decompensated cirrhosis patients is 14%-35%, compared to 84% for those with compensated cirrhosis<sup>[3]</sup>.

Previous studies have shown that high serum HBV DNA is a major risk factor for disease progression to cirrhosis or HCC. Lamivudine (LAM) is the first nucleoside analog widely prescribed for CHB patients due to its antiviral efficacy and safety profile. LAM is found effective for patients with HBV-related decompensated liver cirrhosis<sup>[4,5]</sup>. However, LAM is associated with a high risk of drug resistance and virological breakthrough<sup>[6]</sup>. Adefovir dipivoxil (ADV) exhibits specificity, low drug resistance, and no cross resistance with other nucleoside analogs, which has been strongly considered as a rescue therapeutic agent to combat resistance<sup>[7,8]</sup>. In China, as the first approved drug for CHB patients, LAM has been widely prescribed for its clinical efficacy and low cost. Clinical trials have demonstrated the superiority of combined LAM and ADV therapy compared to ADV monotherapy in LAM resistant patients<sup>[9,10]</sup>. In this study, LAM and ADV are utilized as *de novo* combination treatment. To date, no study has been performed to systematically evaluate the efficacy and safety of *de novo* combined therapy in patients with HBV-related decompensated liver cirrhosis.

In this study, we aimed to compare the efficacy and safety of *de novo* combination therapy with monotherapy in patients with HBV-related decompensated liver cirrhosis.

## MATERIALS AND METHODS

### Study population

From January 2007 to December 2008, 140 consecutive nucleoside analogs treatment-naïve patients with HBV-related decompensated cirrhosis were enrolled in this study in the First Affiliated Hospital of Zhejiang University.

**Diagnostic criteria:** The diagnosis of decompensated liver cirrhosis was based on clinical, laboratory, previous histological, ultrasonographic and radiological signs of cirrhosis with Child-Turcotte-Pugh (CTP) score. The inclusion criteria for this study were as follows: aged 18-65 years, with HBV DNA  $\geq 10^3$  copies/mL, a CTP score of 7-12 (inclusive), calculated serum creatinine clearance  $\geq 50$  mL/min, hemoglobin  $\geq 75$  g/L, total white blood cell  $\geq 2.5 \times 10^9$ /L, platelet count  $\geq 30 \times 10^9$ /L,  $\alpha$ -fetoprotein  $\leq 20$  ng/mL, and no evidence of HCC.

**Exclusion criteria:** Patients were excluded for resistance to LAM, co-infection with hepatitis C virus, hepatitis D virus, hepatitis E virus or human immunodeficiency virus, and autoimmune hepatitis, alcoholic cirrhosis, hepatorenal syndrome, grade 3 or 4 hepatic encephalopathy, or spontaneous bacterial peritonitis, and severe heart, renal, brain diseases.

### Study design

Among 140 patients with HBV-related decompensated cirrhosis, 70 patients were treated with *de novo* combination therapy of 100 mg/d LAM and 10 mg/d ADV; the other 70 patients were treated with 100 mg/d LAM alone as controls. The duration of the treatment was 144 wk. All patients who exhibited LAM resistance were administered ADV.

All patients were followed up every 3-6 mo with examinations of liver and renal function, prothrombin time (PT), international normalized ratio (INR), serum HBV DNA, hepatitis B surface antigen (HBsAg), hepatitis B surface antibody (anti-HBs), hepatitis B e antigen (HBeAg), hepatitis B e antibody (anti-HBe), and hepatitis B core antibody (anti-HBc), as well as ultrasonographic or computerized tomography examination. Routine biochemical and hematological tests, and clinical examination were performed at all clinical visits.

### Biochemical and virological analysis

Biochemistry, hematology, PT, INR, and urinalysis were analyzed immediately. Serum hepatitis B viral markers, including HBsAg, anti-HBs, HBeAg, anti-HBe, and anti-HBc were detected using commercially available enzyme immunoassays (Abbott Laboratories, Chicago, IL, United States). Serum HBV DNA was measured by polymerase chain reaction with a linear range between  $1 \times 10^3$  and  $5 \times 10^8$  copies/mL (Shanghai ZJ Bio-Tech Co., Ltd., China). LAM and ADV associated mutations were assessed by direct sequencing.

### Ethics

Informed consent for inclusion in the study was obtained

ALT: Alanine aminotransferase; TBIL: Total bilirubin; GFR: Glomerular filtration rate; HBV: Hepatitis B virus; HBeAg: Hepatitis B e antigen; CTP: Child-Turcotte-Pugh score; MELD: Model for End-Stage Liver Disease.

from all patients before recruitment. This study conformed to the ethical guidelines of the 1975 Declaration of Helsinki and was approved by the Clinical Research Ethics Committee of the First Affiliated Hospital of Zhejiang University.

### Statistical analysis

Statistical analysis was conducted using SPSS (version 16.0, IL, United States). Continuous variables were expressed as mean  $\pm$  SD. Continuous variables were examined using the Student's *t* test or Mann-Whitney *U* test. Categorical variables were compared by  $\chi^2$  test. A *P* value  $<$  0.05 was considered statistically significant.

## RESULTS

### Patients

A total of 140 patients were recruited: 70 received LAM and ADV *de novo* combination therapy and 70 received LAM monotherapy. Baseline characteristics were comparable between the two groups and are shown in Table 1. In *de novo* combination therapy group, 37 (52.9%) patients exhibited ascites, 9 (12.8%) exhibited episodes of hepatic encephalopathy, and 15 (21.4%) exhibited variceal bleeding. In LAM monotherapy group, 36 (51.4%) patients presented ascites, 8 (11.4%) presented episodes of hepatic encephalopathy, and 16 (22.9%) exhibited variceal bleeding. No patient in either group discontinued antiviral therapy during the study period. The characteristics of the patients during the 144 wk are shown in Figure 1.

### Virological, serological, and biochemical responses

The percentage of HBV related decompensated cirrhosis patients with undetectable HBV DNA in the *de novo* combination group was 51.6% (33/64), 84.2% (48/57) and 92.3% (49/53) by weeks 48, 96, and 144, respectively. In the monotherapy group, the rate of HBV DNA negativity was 46.1% (30/65), 56.1% (32/57) and 39.2% (20/51) by weeks 48, 96, and 144, respectively. A significant difference was observed between the two groups by weeks 96 and 144 (*P* = 0.012 and 0.001).

Patients who were HBeAg-positive at baseline, 34/70 (48.6%) in *de novo* combination group and 33/70 (47.1%) in monotherapy group, exhibited HBeAg seroconversion: 28.1% (9/32) *vs* 24.2% (8/33) by week 48 (*P* = 0.372), 40.0% (12/30) *vs* 31.0% (9/29) by week 96 (*P* = 0.021), and 53.6% (15/28) *vs* 37.0% (10/27) by week 144 (*P* = 0.014), respectively.

Of the 70 decompensated cirrhosis patients receiving *de novo* combination therapy, 68.6% (44/64), 84.2% (48/57) and 92.5% (49/53) of the patients achieved alanine aminotransferase (ALT) normalization by weeks 48, 96 and 144, respectively. In monotherapy group, the ALT

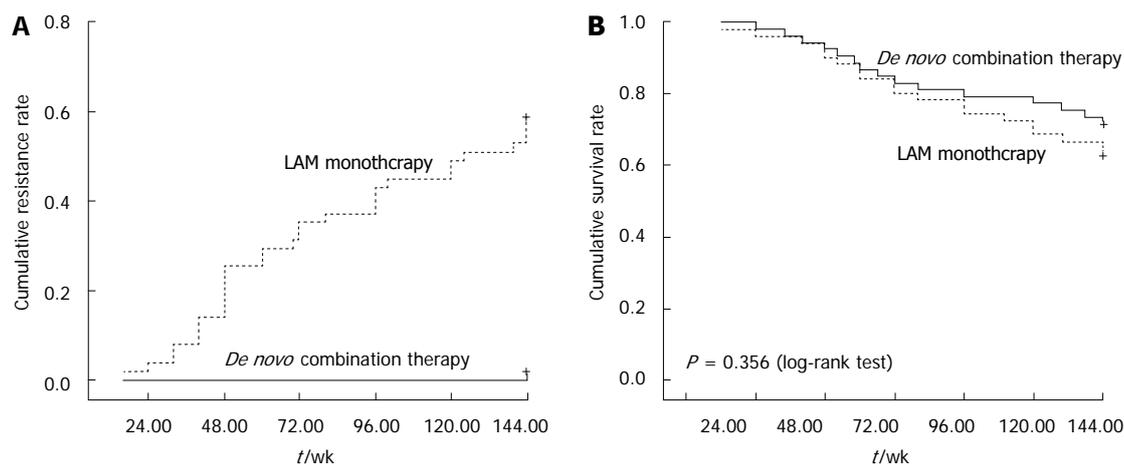

Figure 2 Kaplan-Meier analysis of cumulative resistance (A) and survival (B) rate in patients with hepatitis B virus-related decompensated cirrhosis on *de novo* lamivudine and adefovir dipivoxil combination therapy and lamivudine monotherapy. A: No resistance occurred in *de novo* combination group up to 144 wk. The cumulative resistance rate in lamivudine monotherapy group at weeks 48, 96 and 144 was 20%, 36.8% and 56.9%, respectively; B: The cumulative survival rate in *de novo* combination group was 91.4%, 81.6% and 75.7% at weeks 48, 96 and 144, respectively. The cumulative survival rate in lamivudine monotherapy group was 90.6%, 81.6% and 72.8%, respectively.

<sup>a</sup> $P < 0.05$  vs baseline combination group; <sup>c</sup> $P < 0.05$  vs lamivudine monotherapy group. TBIL: Total bilirubin; PT: Prothrombin time; CTP: Child-Turcotte-Pugh score, MELD: Model for End-Stage Liver Disease; BUN: Blood urine nitrogen; Cr: Creatinine; GFR: Glomerular filtration rate.

normalization rate was 64.6% (42/65) by week 48, 73.7% (42/57) by week 96, and 80.4% (41/51) by week 144, respectively. Compared to *de novo* combination therapy group, ALT normalization rates were lower in monotherapy group by weeks 96 and 144 ( $P = 0.026$  and  $0.037$ ).

### Drug resistance

No patient in the *de novo* combination group exhibited detectable resistance within 144 wk. The cumulative resistance rate in monotherapy group at weeks 48, 96 and 144 was 20%, 36.8%, and 56.9%, respectively as shown in Figure 2A, significantly higher compared to *de novo* combination group.

### Change in hepatic function

Through week 144, both *de novo* combination group and monotherapy group achieved improvement in hepatic function, as evaluated by change from baseline in serum albumin, total bilirubin, prothrombin time; the degree of improvement in *de novo* combination group for albumin and prothrombin at week 144 was superior to mono-

therapy group, as shown in Table 2.

Both *de novo* combination and monotherapy groups demonstrated an improvement in CTP and Model for End-Stage Liver Disease (MELD) scores at weeks 48, 96 and 144. The mean change from baseline in CTP scores was -1.9, -2.6, and -3.2 at weeks 48, 96 and 144, respectively, for *de novo* combination group, and -1.7, -2.2 and -2.7 at weeks 48, 96, and 144, respectively, for monotherapy group. As a result, 45 (84.9%) of cirrhosis patients in *de novo* combination therapy group achieved CTP class A (score 5 or 6) after 144 wk of treatment, whereas in monotherapy group 68.6% (35/51) of patients achieved CTP class A after 144 wk.

The mean change from baseline in MELD scores was -2.4, -3.2, and -4.0 at weeks 48, 96, and 144, respectively, for *de novo* combination group, and -1.8, -2.3, and -3.0 at weeks 48, 96 and 144, respectively, for monotherapy group as shown in Table 2.

The 70 patients with decompensated cirrhosis in *de novo* combination therapy group exhibited a cumulative HCC incidence of 3.1% at week 48, 5.3% at week 96,

and 7.5% at week 144, respectively; four patients developed HCC during the follow-up period. In monotherapy group, the cumulative incidence of HCC was 3.1%, 7.0% and 9.8% at weeks 48, 96 and 144, respectively; five patients developed HCC during the follow-up period. In addition, the cumulative mortality or orthotopic liver transplantation rate was 8.6%, 18.4% and 24.3% at weeks 48, 96 and 144, respectively in *de novo* combination group, and 9.4%, 18.4% and 27.2% at weeks 48, 96 and 144, respectively, in the monotherapy group, as shown in Figure 2B.

### Side effects

All patients in this study tolerated both the *de novo* combination therapy and monotherapy. No patient in either group discontinued the treatment during the follow-up period. In the *de novo* combination group, the blood urine nitrogen (BUN) of three patients increased to 8.6, 9.1 and 9.7 mmol/L respectively, without a concomitant increase in creatinine levels. BUN level of these patients were normalized during the follow-up period. The creatinine levels and glomerular filtration rate remained normal in all patients during the follow-up period, as shown in Table 2.

## DISCUSSION

A consensus on the benefit of antiviral therapy for HBV-related cirrhosis has been achieved. Liaw *et al.*<sup>[11]</sup> reported that continuous treatment with LAM delays clinical progression in patients with CHB and advanced fibrosis or cirrhosis by significantly reducing the incidence of hepatic decompensation and risk of HCC. However, LAM exhibits a high incidence of resistance mutations compared to other nucleos(t)ide analogs. The current CHB treatment guidelines advocate initial combination therapy or agents with a high genetic barrier for patients with a high risk of developing drug resistance and potentially life-threatening associated diseases, such as HBV-related liver cirrhosis<sup>[12-14]</sup>. A combination with other drugs that do not share cross resistance may promote or exhibit synergistic antiviral effects; most importantly, it may exhibit the potential to prevent resistance. Ghany *et al.*<sup>[15]</sup> recently reported that extended combined therapy with LAM and ADV was associated with a high rate of long-term virological and biochemical response; none of the 22 combination therapy treated CHB patients developed resistance for up to 192 wk. Fan *et al.*<sup>[16]</sup> demonstrated that *de novo* combination therapy with LAM and ADV was superior to add-on combination therapy in terms of CTP score, virus inhibition, and renal function. In this study, for patients with HBV-related decompensated liver cirrhosis, *de novo* combination therapy resulted in a superior virological response than monotherapy at weeks 96 and 144. The cumulative tyrosinemethionine-aspartic acid-resistance rate was higher in monotherapy group by weeks 48, 96 and 144, whereas none of the *de novo* combination therapy treated patients developed re-

sistance during the follow-up period.

Higher HBeAg seroconversion rates and ALT normalization rates were also observed in *de novo* combination group compared to LAM monotherapy group at weeks 96 and 144. It is well known that HBeAg seroconversion is accompanied by biochemical and histological regression of liver diseases. Previous studies have indicated that combination therapy is efficacious in preventing drug resistance, but does not improve virological and serological response<sup>[17]</sup>. Our results and other studies suggest that *de novo* combination therapy can not only prevent drug resistance, but also improve virological and serological response<sup>[15,16]</sup>. Further elucidation concerning the mechanisms underlying the higher negative rates of HBV DNA and higher rates of HBeAg seroconversion by *de novo* combination therapy is warranted. In general, patients with CHB-related liver cirrhosis exhibit lower levels of HBV DNA and HBeAg compared with patients with CHB. Alternatively, during the course of HBV-related liver cirrhosis, the antiviral immune response is vigorously activated. In concordance with the findings of previous studies, the results that we present in this study suggest that *de novo* combination therapy is potentially suitable as an initial treatment for HBV-related decompensated liver cirrhosis in order to reduce resistance.

Previous clinical studies have demonstrated the positive effects of LAM therapy on the functional improvement in patients with HBV-related decompensated liver cirrhosis<sup>[4,5,18]</sup>. However, these benefits were offset due to drug-resistance. The CTP and MELD scores, both of which reflect components of liver function, including serum albumin, total bilirubin, and prothrombin time, were markedly improved during *de novo* combination therapy. These results clearly indicate that due to inhibition of HBV replication, *de novo* combination treatment potentially prevents clinical progression to liver failure, reduces complication risk, and delays or avoids the need for liver transplantation.

Renal impairment is a known risk of severe liver disease and is considered a potential side effect of *de novo* combination therapy. In this study, both *de novo* combination and monotherapy were well-tolerated, with no case of renal failure attributable to combination therapy.

This study has several limitations. It was not randomized or blinded, as this would be difficult for patients with CHB-related decompensated liver cirrhosis. This may contribute to the discord in results among previous studies.

In conclusion, this study demonstrated that *de novo* combination therapy is superior to monotherapy in suppressing HBV DNA and achieving ALT normalization and HBeAg seroconversion by weeks 96 and 144. Both treatments improved liver function as measured by reduction of CTP and MELD scores. In HBV-related decompensated liver cirrhosis patients, *de novo* combination therapy has also been proven safe. Our findings strongly support *de novo* combination therapy as a viable and effective therapeutic strategy in patients with HBV-related decompensated liver cirrhosis.

## COMMENTS

## Background

The mortality rate of hepatitis B virus (HBV)-related decompensated cirrhosis is very high. Recommended treatment options are nucleos(t)ide analogues. There are few reports regarding the issue of treatment for these patients with *de novo* combination therapy or monotherapy.

## Research frontiers

In China, tenofovir is not available yet and entecavir is expensive for most patients. Combination therapy with lamivudine (LAM) and adefovir dipivoxil (ADV) is better than ADV in LAM-resistance chronic hepatitis B (CHB) patients. But in patients with HBV-related decompensated liver cirrhosis, it remains unclear whether *de novo* combination therapy is better than monotherapy. In this study, the authors demonstrate that LAM and ADV *de novo* combination therapy is more effective than LAM monotherapy for patients with HBV-related decompensated liver cirrhosis.

## Innovations and breakthroughs

Many clinical studies showed that the combined LAM and ADV therapy is more effective than ADV monotherapy after LAM-resistance. However, the efficacy of *de novo* LAM and ADV combination therapy in patients with HBV-related decompensated liver cirrhosis is unclear. This is the first study to report that *de novo* LAM and ADV is more effective than LAM monotherapy, especially the combination therapy can reduce the drug resistance.

## Applications

By understanding that LAM and ADV *de novo* combination therapy is more effective than LAM monotherapy in patients with HBV-related decompensated liver cirrhosis, this study may represent a future strategy for therapeutic intervention in CHB patients with HBV-related decompensated liver cirrhosis.

## Terminology

*De novo* combination therapy means combination with two or more drugs from the beginning of the treatment. The diagnosis of decompensated liver cirrhosis was based on clinical, laboratory, previous histological, ultrasonographic and radiological signs of cirrhosis with Child-Turcotte-Pugh (CTP) score. The CTP score is a system to assess the disease stage for decompensated cirrhotic patients.

## Peer review

This is a good clinical study in which the authors compared the effect of *de novo* LAM and ADV combination therapy with LAM monotherapy. The authors concluded that LAM and ADV should be combined at the beginning for treatment of the patients with HBV-related decompensated liver cirrhosis.

### Abstract

**AIM:** To explore the role of nesfatin-1 on irritable bowel syndrome (IBS)-like visceral hypersensitivity.

**METHODS:** The animal model of IBS-like visceral hypersensitivity was induced by intracolonic infusion of 0.5% acetic acid (AA) in saline once daily from post-natal days 8-21. Experiments were performed when rats became adults. The visceral sensitivity of rats was evaluated by abdominal withdrawal reflex (AWR) and electromyographic (EMG) activity of the external oblique muscle to graded colorectal distension. The content of nesfatin-1 in serum was determined using enzyme-linked immunosorbent assay. After implantation of an intracerebroventricular (ICV) cannula and two electrodes into the external oblique muscle, model rats were randomly divided into four groups. Animals then received ICV injection of 8  $\mu$ g of anti-nesfatin-1/nucleobindin-2 (NUCB2), 50  $\mu$ g of  $\alpha$ -helical cortico-

tropin releasing factor (CRF) 9-41 (non-selective CRF receptor antagonist), 50  $\mu$ g of NBI-27914 (selective CRF1 receptor antagonist) or 5  $\mu$ L of vehicle. After 1 h of ICV administration, visceral sensitivity of each group was measured again, and comparisons between groups were made.

**RESULTS:** Rats treated with AA showed higher mean AWR scores and EMG activity at all distension pressures compared with controls ( $P < 0.05$ ). On histopathologic examination, no evidence of inflammation or abnormalities in structure were noted in the colon of either control or AA-treated groups. Myeloperoxidase values were not significantly different between the two groups. The level of nesfatin-1 in serum was significantly higher in the AA-treated group than in the control group ( $5.34 \pm 0.37$  ng/mL vs  $4.81 \pm 0.42$  ng/mL,  $P < 0.01$ ). Compared with rats injected with vehicle, rats which received ICV anti-nesfatin-1/NUCB2,  $\alpha$ -helical CRF9-41 or NBI-27914 showed decreased mean AWR scores and EMG activity at all distension pressures ( $P < 0.05$ ).

**CONCLUSION:** Nesfatin-1 may be associated with IBS-like visceral hypersensitivity, which may be implicated in brain CRF/CRF1 signaling pathways.

**Key words:** Irritable bowel syndrome; Nesfatin-1; Visceral hypersensitivity; Corticotropin releasing factor; Intracerebroventricular injection

**Core tip:** This is a well conducted experimental study on the possible effect of nesfatin-1 in visceral hypersensitivity. Currently no reports have been published concerning the role of nesfatin-1 in irritable bowel syndrome (IBS). In a well-established visceral hypersensitivity animal model, we found an elevated nesfatin-1 level in the serum, and there was a reduction in evoked abdominal electromyography and abdominal withdrawal reflex scores after treatment with nesfatin-1 antibody, a non-selective corticotropin releasing factor (CRF) receptor antagonist, or a selective CRF1

receptor antagonist. These results suggest that nesfatin-1 may be associated with visceral hypersensitivity in model rats and implicated in brain CRF/CRF1 signaling pathways, which contribute to the visceral hypersensitivity of IBS.

## INTRODUCTION

Irritable bowel syndrome (IBS) is a common functional gastrointestinal disorder characterized by abdominal pain and alterations in bowel habits. The pathogenic mechanism of IBS remains incompletely understood. Visceral hypersensitivity is common in IBS patients and probably plays a major role in development of symptoms<sup>[1]</sup>. Nesfatin-1 is a newly discovered anorexigenic peptide derived from the precursor peptide nucleobindin-2 (NUCB2)<sup>[2]</sup>. Putative post-translational processing of NUCB2 by the enzyme pro-hormone convertase-1/3 results in nesfatin-1, nesfatin-2 and nesfatin-3<sup>[2]</sup>. Intracerebroventricular (ICV) injection of nesfatin-1 decreased dark phase food intake in freely fed rats, whereas injection of an antibody specific to nesfatin-1 potently stimulated appetite<sup>[2]</sup>. The hypothalamic selective corticotropin releasing factor-2 (CRF2) signaling system was also shown to be involved in the underlying mechanisms of nesfatin-1 induced reduction of dark phase food intake<sup>[3]</sup>. Nesfatin-1 is distributed in stress-related brain areas, such as the supraoptic nucleus, hypothalamic paraventricular nucleus (PVN), nucleus of the solitary tract, locus coeruleus and raphe pallidus nucleus<sup>[4,5]</sup>. Furthermore, nesfatin-1 is colocalized with CRF in the PVN<sup>[5]</sup>. The hormone CRF is the hallmark initiator of the stress response<sup>[6]</sup>. It exerts its biological actions by interacting with CRF1 and CRF2 receptors<sup>[7]</sup>. It has been well established that the brain CRF/CRF1 signaling system modulates pain responses although the exact sites mediating this modulation remain unidentified<sup>[8,9]</sup>. These observations suggest that nesfatin-1 may be involved in the autonomic regulation of visceral sensation. Given that visceral hypersensitivity is the major pathophysiology of IBS, nesfatin-1 may be an important contributor to the symptoms of IBS. Currently no reports have been published concerning the role of nesfatin-1 in IBS. The purpose of the present study, therefore, was to investigate the effect of nesfatin-1 on visceral sensitivity in IBS and the possible underlying mechanisms of this action. This was achieved by establishing a rat model of visceral hypersensitivity associated with IBS.

## MATERIALS AND METHODS

### Animals

Experiments were performed on male Sprague-Dawley

rats bought from the Experimental Animal Center of Nanjing Medical University (China). Rats were housed with *ad libitum* food and water in standard rodent cages at  $22 \pm 2$  °C in a 12-h light-dark controlled room. All animal procedures strictly adhered to the guidelines of the Institution Council of Animal Care and were approved by the Ethics Committee of Nanjing Medical University.

### Induction of chronic visceral hyperalgesia

Pups received an infusion of 0.3 mL of 0.5% acetic acid (AA) solution in saline into the colon 2 cm from the anus once daily on postnatal days 8-21<sup>[10]</sup>. Controls received an equal volume of saline. Experiments were conducted in these rats between 6 and 9 wk of age.

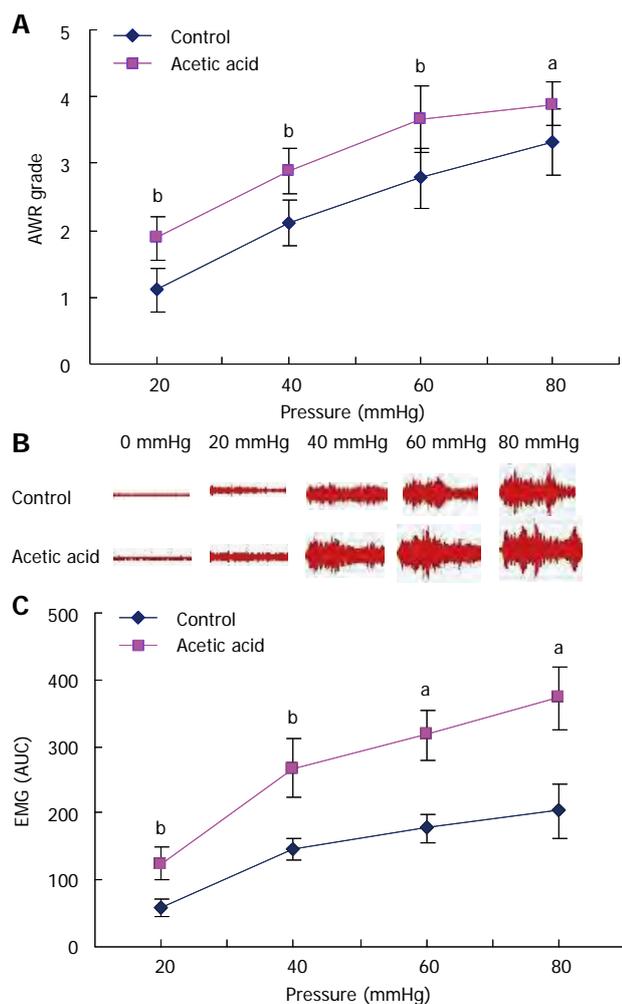

### Behavioral testing

We used a grading system based on the abdominal withdrawal reflex (AWR), as well as a measure of the electromyographic (EMG) activity of the external oblique muscle to evaluate visceral hypersensitivity 6 wk after treatment, by grading the response of rats to colorectal distention (CRD). Briefly, under mild sedation with ether, a flexible balloon (5 cm) constructed from a surgical glove finger attached to tygon tubing was inserted (8 cm) into the descending colon and rectum via the anus and held in place by taping the tubing to the tail. Rats were placed in small lucite cubicles (20 cm × 6 cm × 8 cm) and allowed to adapt for 30 min. CRD was performed by rapidly inflating the balloon to a constant pressure using a sphygmomanometer connected to a pressure transducer. The balloon was inflated to various pressures (20, 40, 60 and 80 mmHg) for 20 s followed by a 2-min rest. Behavioral responses to CRD were measured by visual observation of the AWR by a blinded observer. The assignment of an AWR score was as follows: 1 = normal behavior without response; 2 = contraction of abdominal muscles; 3 = lifting of abdominal wall; and 4 = body arching and lifting of pelvic structures<sup>[11]</sup>.

To obtain EMG measurements of visceromotor responses, two electrodes were implanted, under anesthesia with pentobarbital sodium (100 mg/kg, intraperitoneally), into the external oblique muscle and externalized behind the head. Rats were allowed 1 wk recovery from surgery. CRD was performed as described previously with 20 s of distention followed by 2-min rest between distentions of 20, 40, 60 and 80 mmHg. Wires were connected to a Bio Amp, which was connected to a power lab (AD Instruments, Australia) used as an EMG acquisition system with Chart 7 software. The area under the curve during the 20-s distention for the EMG signal was calculated by subtracting the area under the curve for the 20 s before distention<sup>[12]</sup>.

### Evaluation of the colon for inflammation/damage

After behavioral testing, 4 cm of colonic tissue proximal to the anus was removed and rinsed briefly with saline. The proximal half of each colon was placed in 4% paraformaldehyde, embedded in paraffin, cut into 4 μm sections, and used for histologic examination. The distal

**Figure 1** Evaluation of visceral sensitivity in neonatal acetic acid-treated rats when adults. **A:** Abdominal withdrawal reflex (AWR) scores were used as an index in response to distension pressure. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs control group,  $n = 9$ ; **B:** Typical electromyographic (EMG) activity in the external oblique muscle in response to graded colorectal distension; **C:** Area under the curve (AUC) of EMG activity in the external oblique muscle in response to graded colorectal distension. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs control group,  $n = 9$ .

half was snap-frozen and stored at  $-80^{\circ}\text{C}$  until use. Myeloperoxidase (MPO) activity was determined later by an enzyme-linked immunosorbent assay (ELISA) kit (RB, Minneapolis, MN, United States).

#### Blood sampling and processing

Under mild sedation with ether, approximately 1 mL blood was taken from the orbital canthus vein plexus. The blood was centrifuged, then the serum was separated and stored at  $-80^{\circ}\text{C}$  until assayed. Serum nesfatin-1 levels were measured using the ELISA kit (RD, CA, United States).

#### ICV cannula and external oblique muscle electrode implantation

Model rats were selected and anesthetized with pentobarbital sodium (100 mg/kg *ip*). A chronic guide cannula was implanted into the right lateral ventricle of the brain following coordinates from Bregma: anteroposterior,  $-0.8$  mm;

lateral,  $-1.5$  mm; dorsoventral,  $-3.5$  mm<sup>[13]</sup>. Two stainless steel screws were fixed to the skull, and then the cannula was secured with dental cement. Finally, two electrodes were implanted in the external oblique muscle as described above. After surgery, rats were housed individually and allowed to recuperate for 1 wk.

#### ICV injection

After ICV cannula and external oblique muscle electrode implantation, model rats were randomly divided into 4 groups and administered, by ICV injection, 8  $\mu\text{g}$  of anti-nesfatin-1/NUCB2<sup>[2]</sup> (Bioss, Beijing, China), 50  $\mu\text{g}$  of  $\alpha$ -helical CRF9-41<sup>[14]</sup> (Tocris, Minneapolis, MN, United States), 50  $\mu\text{g}$  of NBI-27914<sup>[13]</sup> (Tocris, Minneapolis, MN, United States) or 5  $\mu\text{L}$  of vehicle<sup>[2]</sup>. After 1 h, the visceral sensitivity of each group to CRD was measured and compared between groups.

#### Statistical analysis

Statistical analysis was performed using SPSS 16.0 software (SPSS Inc., Chicago, IL, United States). All data are expressed as mean  $\pm$  SE. For AWR behavioral grades, a Friedman analysis of variance (ANOVA) was used. Median AWR scores at each distension pressure were compared between treatment groups using the Mann-Whitney  $U$  rank sum test. EMG data were analyzed by two-way repeated-measures ANOVA. Other data were analyzed by the Student  $t$  test or one-way ANOVA where appropriate.  $P$  values  $< 0.05$  were considered statistically significant.

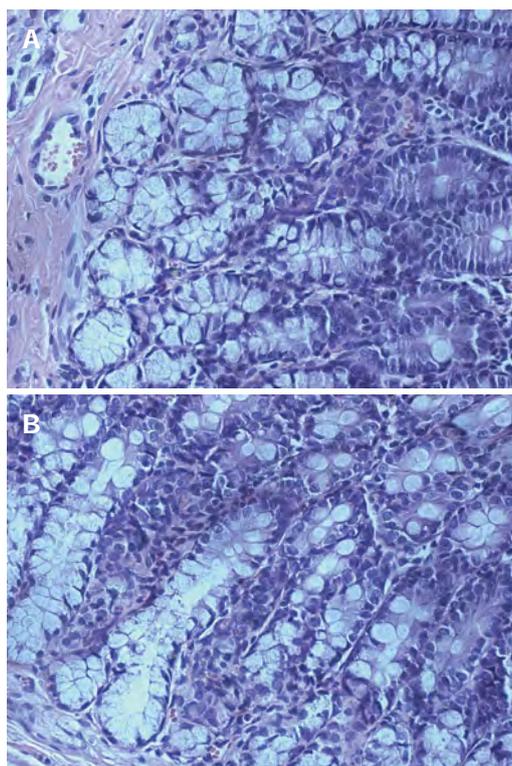

## RESULTS

### Neonatal AA treatment produced persistent visceral hypersensitivity

Visceral sensitivity to CRD was determined at 6 wk of age. Rats treated with AA exhibited higher mean AWR scores at all distension pressures tested than controls (Figure 1A,  $P < 0.05$ ). In a separate experiment, EMG activity, measured in response to graded CRD, was significantly higher in neonatal AA-treated rats than in controls (Figure 1B and C,  $P < 0.05$ ). Taken together, these data showed that rats treated with AA between postnatal days 8 and 21 were more sensitive to CRD than controls, suggesting that neonatal AA treatment produced persistent visceral hypersensitivity when animals became adults.

### Evaluation of adult colons for inflammation

To determine whether persistent visceral hypersensitivity achieved in adults of neonatal AA-treated rats was due to the development of chronic colitis in adults, hematoxylin and eosin-stained sections and MPO activity of the colons of adult rats were examined for histopathologic signs of inflammation. On examination, no significant inflammation or abnormalities in structure were noted in either saline- or AA-treated groups and no inflammatory infiltrates were observed (Figure 2). Likewise, there was

**Figure 2** Photomicrographs of hematoxylin and eosin-stained sections from colons of control adult rats (A) and neonatal acetic acid-treated adult rats (B). No significant inflammation or abnormalities in structure were observed in neonatal acetic acid-treated rats.

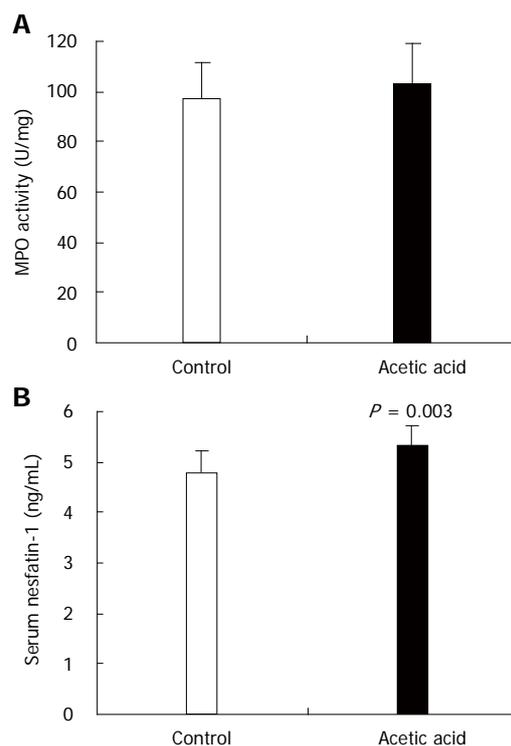

no significant difference in the level of MPO between control and neonatal AA-treated rats (Figure 3A,  $P > 0.05$ ). Thus, these data showed that inflammation/abnormalities were absent in our model, ruling out their involvement in persistent hypersensitivity. Therefore, we have a rat model of persistent visceral hypersensitivity caused by neonatal exposure to a mild acid in the absence of ongoing inflammation.

#### Serum nesfatin-1 levels in rats

The mean serum nesfatin-1 level in the neonatal AA-treated group ( $5.34 \pm 0.37$  ng/mL) was significantly higher than in the control rats ( $4.81 \pm 0.42$  ng/mL; Figure 3B,  $P = 0.003$ ).

#### Effect of ICV administration of antibody on visceral sensitivity

To determine the effect of nesfatin-1 on visceral sensitivity, adult model rats were given ICV injection of anti-nesfatin-1/NUCB2 or vehicle, and visceral sensitivity was measured 1 h later. The AWR scores of nesfatin-1 antibody-treated rats were significantly lower than those of vehicle-treated rats at 20, 40, 60 and 80 mmHg (Figure 4A). Similarly, in model rats, anti-nesfatin-1/NUCB2 treatment caused a significant decline in the EMG activity to graded CRD when compared with vehicle injection. To examine whether brain CRF/CRF1 signaling pathways were involved in visceral hypersensitivity in model rats,

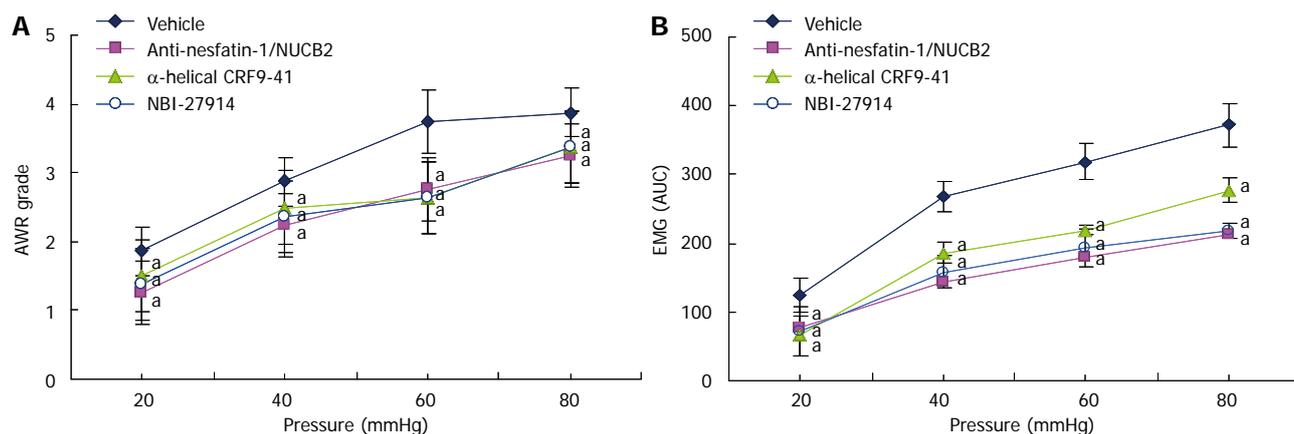

**Figure 3** Myeloperoxidase activity in rat colon (A) and nesfatin-1 levels in rat serum (B). A: There was no difference in myeloperoxidase (MPO) activity in neonatal acetic acid-treated rats compared with control rats; B: The average serum nesfatin-1 level was statistically higher in neonatal acetic acid-treated rats than in controls ( $n = 12$ ).

animals were injected intracerebroventricularly with non-selective CRF receptor antagonists ( $\alpha$ -helical CRF9-41), selective CRF1 receptor antagonist (NBI-27914) or vehicle 1 h before graded CRD. In comparison with model rats receiving a vehicle injection, model rats that received  $\alpha$ -helical CRF9-41 and NBI-27914 showed decreased mean AWR scores and EMG activity at all distension pressures (Figure 4B).

## DISCUSSION

IBS is one of the most common functional gastrointestinal disorders worldwide. The mechanism of this disease is not clear, but an important role for visceral hypersensitivity in the development of symptoms compatible with IBS has become evident. It has been confirmed that a lower pain threshold to colonic distention was observed in patients with IBS compared with healthy subjects<sup>[1]</sup>, and visceral hypersensitivity is a biological marker for IBS<sup>[15]</sup>.

Visceral hypersensitivity may be associated with intestinal irritation (pain or inflammation) in the neonatal period. Nociceptive neuronal circuits are formed during the embryonic and postnatal period when painful stimuli are normally absent or limited. Pain and inflammation during this critical period, particularly before the maturation of the descending inhibitory systems, can lead to prolonged structural and functional alterations in pain

**Figure 4** Effect of anti-nesfatin-1/nucleobindin-2,  $\alpha$ -helical corticotropin releasing factor 9-41 and NBI-27914 treatment on visceral sensitivity in model rats. **A:** Abdominal withdrawal reflex (AWR) scores were used as an index in response to distension pressure. Model rats receiving intracerebroventricular injection of anti-nesfatin-1/nucleobindin-2 (NUCB2),  $\alpha$ -helical corticotropin releasing factor (CRF) 9-41 and NBI-27914 showed decreased mean AWR scores compared with model rats receiving vehicle injection, at 20, 40, 60 and 80 mmHg,  $^aP < 0.05$  vs vehicle group,  $n = 8$ ; **B:** Electromyographic (EMG) activity in the external oblique muscle in response to graded colorectal distension. Compared with vehicle administration, EMG activity in model rats administered intracerebroventricularly with anti-nesfatin-1/NUCB2,  $\alpha$ -helical CRF9-41 or NBI-27914 was significantly decreased at 20, 40, 60 and 80 mmHg compared with model rats receiving vehicle injection,  $^aP < 0.05$  vs vehicle group,  $n = 8$ .

pathways that can last into adult life. This visceral hypersensitivity is associated with central neural sensitization, as well as central sensitization<sup>[16]</sup>.

In this study, a rat model of visceral hypersensitivity associated with IBS was established by intracolonic instillation of dilute AA between P8 and P21. In our model, dilute AA treatment of pups had no effect on the growth of rats. As adults, these rats showed no identifiable peripheral pathology, which was in line with the characteristics of IBS. These rats exhibited higher mean AWR scores and EMG activity at all distension pressures compared with controls. These findings suggest that neonatal AA treatment induced long-lasting visceral hypersensitivity without significant inflammation in the colon, which was in agreement with previous findings<sup>[17]</sup>. Therefore, this model can better reflect the chronic hyperesthetic state of IBS and is applicable to the study of visceral hypersensitivity.

Nesfatin-1 is a recently discovered 82-amino-acid satiety peptide and has a predicted molecular mass of 9.7 kDa. Nesfatin-1, injected intracerebroventricularly or peripherally in rats, reduced food intake in a dose-dependent manner<sup>[2,18]</sup>. As yet, however, the nesfatin-1 receptor has not been identified. Shimizu *et al*<sup>[18]</sup> reported that NUCB2 can be potentially processed into an active derivative, nesfatin-1. However, this mature peptide has not been detected in protein extracts from rat brain<sup>[2]</sup>. Likewise, the western blots of all tissues and cells studied here failed to show a band at 9.7 kDa<sup>[19,20]</sup>. It has been confirmed that nesfatin-1 exists in the blood of rodents and humans using a sandwich-type ELISA, but normal values have not yet been established for nesfatin-1<sup>[21]</sup>. Nesfatin-1 can cross the blood-brain barrier without saturation<sup>[22,23]</sup>, therefore the measurement of nesfatin-1 in the blood may partly reflect its level in the brain. The present study showed that the average serum nesfatin-1 level was significantly higher in neonatal AA-treated rats than in con-

trol rats, suggesting nesfatin-1 may be associated with a visceral hypersensitivity state in model rats.

Furthermore, we found that model rats receiving ICV injection of anti-nesfatin-1/NUCB2 showed decreased mean AWR scores and EMG activity at 20, 40, 60 and 80 mmHg compared with model rats receiving vehicle injection. Results suggest that ICV injection of nesfatin-1 antibody may neutralize endogenous nesfatin-1 and therefore dramatically attenuate visceral hypersensitivity in model rats.

Taken together, these results strongly suggest that nesfatin-1 may be involved in visceral hypersensitivity in model rats. To date, the evidence for the role of a brain CRF/CRF1 signaling system in the modulation of visceral sensitivity in rodents has been based on the study of visceral hypersensitivity in acute models of stress<sup>[24]</sup>. In this model, our results also showed that ICV administration of  $\alpha$ -helical CRF9-41 and NBI-27914 caused a significant decrease in mean AWR scores and EMG activity at 20, 40, 60 and 80 mmHg in comparison with ICV administration of vehicle, which was consistent with the previous studies<sup>[25,26]</sup>. These data demonstrate that brain CRF/CRF1 signaling pathways may be involved in visceral hypersensitivity in the present study.

Previous studies have shown that nesfatin-1 was colocalized with CRF in the PVN<sup>[5]</sup>. ICV administration of nesfatin-1 increased the incidence of c-Fos expression in CRF neurons, and nesfatin-1 increased cytosolic  $Ca^{2+}$  concentration in the CRF-immunoreactive neurons isolated from the PVN<sup>[27]</sup>. Taken together with our present study, these results suggested that nesfatin-1 may be implicated in brain CRF/CRF1 signaling pathways, which then contribute to visceral hypersensitivity in model rats.

In conclusion, nesfatin-1 may be associated with the visceral hypersensitivity state of IBS, and this may be mediated at least in part by brain CRF/CRF1 signaling pathways.

## COMMENTS

## Background

Irritable bowel syndrome (IBS) is a functional gastrointestinal disorder in clinical practice, but the pathophysiology of IBS has not been completely elucidated. Visceral hypersensitivity is common in IBS patients and has recently been considered as a biological marker for IBS. Nesfatin-1 is a recently discovered 82-amino-acid satiety peptide. Nesfatin-1 is co-localized with corticotropin releasing factor (CRF) in the hypothalamic paraventricular nucleus (PVN). Furthermore, intracerebroventricular administration of nesfatin-1 induced c-Fos expression in CRF neurons, and nesfatin-1 increased cytosolic Ca<sup>2+</sup> concentrations in single CRF neurons in the PVN. It is now well established that the brain CRF/CRF1 signaling system modulates pain responses. These observations suggest that nesfatin-1 may be involved in the autonomic regulation of visceral sensation.

## Research frontiers

Visceral hypersensitivity is a topic of intense research in gastrointestinal disorders. The research hotspot in terms of the visceral hypersensitivity mechanism is the signaling system and the exact sites mediating modulation.

## Innovations and breakthroughs

The authors found that the average serum nesfatin-1 level was significantly higher in neonatal acetic acid-treated rats than in control rats, suggesting nesfatin-1 may be associated with a visceral hypersensitivity state in IBS-like model rats. Currently, no reports have been published discussing the role of nesfatin-1 in IBS. The purpose of the present study, therefore, was to investigate the effect of nesfatin-1 on visceral sensitivity in IBS and the possible underlying mechanisms of this action.

## Applications

The study results suggest that nesfatin-1 may be associated with the visceral hypersensitivity state of IBS, and this may be mediated, at least in part, by brain CRF/CRF1 signaling pathways. This may provide new targets for the treatment of IBS.

## Peer review

The authors investigated serum nesfatin-1 in a rat model of visceral hypersensitivity associated with IBS to explore the role of nesfatin-1 in the pathogenesis of IBS-like visceral hypersensitivity. The study found that nesfatin-1 may be associated with visceral hypersensitivity in model rats and may be implicated in brain CRF/CRF1 signaling pathways. Overall, the study has been well designed and the results are of great scientific significance.

### Abstract

**AIM:** To evaluate psychometrics of the Chinese (mainland) chronic liver disease questionnaire (CLDQ) in patients with chronic hepatitis B (CHB).

**METHODS:** A cross-sectional sample of 460 Chinese patients with CHB was selected from the Outpatient Department of the Eighth Hospital of Xi'an, including CHB (CHB without cirrhosis) ( $n = 323$ ) and CHB-related cirrhosis ( $n = 137$ ). The psychometrics includes reliability, validity and sensitivity. Internal consistency reliability was measured using Cronbach's  $\alpha$ . Convergent and discriminant validity was evaluated by item-scale correlation. Factorial validity was explored by principal component analysis with varimax rotation. Sensitivity was assessed using Cohen's effect size (ES), and independent sample  $t$  test between CHB and CHB-related cirrhosis groups and between alanine aminotransferase (ALT) normal and abnormal groups after stratifying the disease (CHB and CHB-related cirrhosis).

**RESULTS:** Internal consistency reliability of the CLDQ was 0.83 (range: 0.65-0.90). Most of the hypothesized item-scale correlations were 0.40 or over, and all of such hypothesized correlations were higher than the alternative ones, indicating satisfactory convergent and discriminant validity. Six factors were extracted after varimax rotation from the 29 items of CLDQ. The eligible Cohen's ES with statistically significant independent sample  $t$  test was found in the overall CLDQ and abdominal, systematic, activity scales (CHB vs CHB-related cirrhosis), and in the overall CLDQ and abdominal scale in the stratification of patients with CHB (ALT normal vs abnormal).

**CONCLUSION:** The CLDQ has acceptable reliability, validity and sensitivity in Chinese (mainland) patients with CHB.

**Key words:** Chronic hepatitis B; Chronic liver disease questionnaire; Reliability; Validity; Sensitivity

**Core tip:** Chronic hepatitis B (CHB) is a common chronic liver disease in mainland China, and its adverse prognosis might impair the patients' health-related quality of life (HRQoL). The chronic liver disease questionnaire (CLDQ) is the first liver specific HRQoL instrument, however, few studies have examined psychometrics of the Chinese (mainland) CLDQ in CHB patients. This study tested psychometrics of the Chinese (mainland) CLDQ in patients with CHB (including CHB without cirrhosis and CHB-related cirrhosis). The findings will help find suitable disease-specific questionnaire in the management of CHB in mainland China and provide evidence for expanding the use of the CLDQ.

Zhou KN, Zhang M, Wu Q, Ji ZH, Zhang XM, Zhuang GH. Psychometrics of chronic liver disease questionnaire in Chinese chronic hepatitis B patients. *World J Gastroenterol* 2013; 19(22): 3494-3501 Available from: URL: <http://www.wjgnet.com>

## INTRODUCTION

Chronic hepatitis B (CHB), caused by persistent infection with hepatitis B virus (HBV), is a common chronic liver disease in mainland China. According to the latest national hepatitis B seroepidemiological survey<sup>[1]</sup>, the estimated current HBV carriers in mainland China run up to 93 million, including 20-30 million patients with CHB<sup>[2]</sup>. CHB patients suffer recurrent symptoms in the long disease natural history and are at a high risk of developing fatal complications of cirrhosis and hepatocellular carcinoma<sup>[3,4]</sup>. Therefore, CHB may result in a heavy disease burden not only in premature death but also in health impairment<sup>[5-8]</sup>.

Health-related quality of life (HRQoL) is defined as how the individual rates his/her life in terms of physical, psychological and social aspects<sup>[9]</sup>. In comparison with clinical parameters, HRQoL is a more holistic assessment of health status considering the individual's functional health and well-being, especially in chronic disease in which mortality is not an immediate concern<sup>[3]</sup>. Due to the complex natural history and phases of CHB<sup>[10]</sup>, it is particularly important to use HRQoL as the primary endpoint for evaluating health and treatment effects in patients with such disease.

Generally, HRQoL can be measured by generic and disease-specific instruments. Generic instruments are used to compare the HRQoL between groups of patients, but disease-specific questionnaires distinguish the impairment of a specific illness and are more sensitive to the change<sup>[11,12]</sup>. The 36-item short-form health survey version 2 (SF-36v2) performs well as a generic instrument in patients with CHB<sup>[13]</sup>. However, not every scale or summary component of the SF-36v2 has the required or eligible sensitivity<sup>[14]</sup>. Therefore, a disease-specific HRQoL instrument is recommended as a complement for clinical studies in CHB.

The chronic liver disease questionnaire (CLDQ) is the first liver specific instrument developed by Younossi *et al.*<sup>[15]</sup>. It has been translated into different languages for cross-cultural adaptation<sup>[16-23]</sup> and proved as a valid tool for HRQoL measurement and evaluation in patients with chronic liver disease<sup>[24,25]</sup>. The Chinese (Hong Kong, China) CLDQ has been validated in patients with CHB infection<sup>[14]</sup>. However, a dearth of study assessed psychometrics of the Chinese (mainland) CLDQ in mainland Chinese patients with CHB<sup>[26]</sup>.

The purpose of the study was to evaluate psychometrics including reliability, validity and sensitivity of the Chinese (mainland) CLDQ in CHB patients. The findings of this study will help find suitable disease-specific questionnaire in the management of CHB in mainland China and add to the body of evidence for expanding the use of the CLDQ.

## MATERIALS AND METHODS

### Patients and data collection

Participants were CHB outpatients from the Eighth Hospital of Xi'an, which is the only local infectious disease hospital in Xi'an, Shaanxi Province, China. Inclusion criteria were aged 18 years or over, Chinese-speaking, with diagnosis of CHB (CHB without cirrhosis) or CHB-related cirrhosis. The diagnosis was made following the standards in the Guideline of Prevention and Treatment for Chronic Hepatitis B (2005 version) issued by the Chinese Society of Hepatology and the Chinese Society of Infectious Diseases<sup>[27]</sup>. If the patients had other chronic diseases (including hypertension, diabetes, chronic obstructive pneumonia disease, cardiovascular disease, mental illness, arthritis, tuberculosis, or gallstone), non-hepatitis B related liver disease, malignancies of liver or other organs, liver transplantation, cognitive disorders, or co-infected with human immunodeficiency virus or other types of hepatitis virus (*e.g.*, hepatitis A virus, hepatitis C virus, hepatitis D virus or hepatitis E virus), or refused to give written informed consent, they would be excluded.

Data were collected from April to June 2010. An individual face-to-face interview was administered by the trained interviewers in a quiet and well-lit room. The patients answered questions of sociodemographics and the Chinese (mainland) CLDQ. In addition to this, a free alanine aminotransferase (ALT) test was provided for the patients immediately after the questionnaire survey. The test was conducted in the laboratory of the Eighth Hospital of Xi'an.

### Chinese (mainland) CLDQ

The Chinese (mainland) CLDQ was provided by the developers of the original CLDQ<sup>[15]</sup>. It consists of 29 items measuring six scales on abdominal symptoms (AB), fatigue (FA), systemic symptoms (SY), activity (AC), emotional function (EM) and worry (WO). Each item is rated on a 7-point Likert scale (1 = all of the time to 7 = none of the time). The six scale scores are calculated by the summated averages of corresponding endorsed item scores. The total score is calculated by the mean of all scale scores. Each scale and the total score ranged from 1 to 7, with a higher score indicating better HRQoL.

### Reliability and floor/ceiling effects

Cronbach's  $\alpha$  coefficient was used to assess the internal consistency reliability, with the value greater than 0.70 representing acceptable reliability<sup>[28]</sup>. Floor and ceiling effects were calculated as the number and percentage of CHB patients at the lowest and highest possible scores for each scale and the overall CLDQ. It should be less than 20% regarding both the floor and ceiling effect to ensure that the scales are capturing the full range of potential responses in the population and that changes over time can be detected<sup>[29]</sup>.

**Table 1 Social-demographic characteristics *n* (%)**

| Items                                     | Total<br>( <i>n</i> = 460) | CHB<br>( <i>n</i> = 323) | CHB-related<br>cirrhosis<br>( <i>n</i> = 137) |
|---|----------------------------|--------------------------|---|
| Age (yr)                                  |                            |                          |   |
| 18-35                                     | 240 (52.2)                 | 216 (90.0)               | 24 (10.0)                                     |

| No  | 85 (18.5)                  | 12 (14.1)                | 73 (85.9)                                     |

CHB: Chronic hepatitis B; ALT: Alanine aminotransferase.

### Validity

The hypothesized item-scale correlation ( $\gamma$  coefficient)  $\geq 0.40$  was considered as satisfactory convergent validity<sup>[30]</sup>. Discriminant validity was supported whenever the hypothesized item-scale correlation was significantly higher than the correlation of the item with other scales<sup>[31]</sup>. Factorial validity of the CLDQ was explored using the principal component analysis with varimax rotation. The predictive items with factor loading coefficient (FLC)  $\geq 0.45$ <sup>[32]</sup> and the extracted factors with an eigenvalue  $\geq 1.0$ <sup>[33]</sup> were considered to be relevant.

### Sensitivity

Sensitivity was evaluated by Cohen's effect size (ES), and independent sample *t* test between CHB and CHB-related cirrhosis groups and between ALT normal and abnormal groups after stratifying the disease (CHB and CHB-related cirrhosis). The ES value was calculated as the difference between group mean scores divided by overall standard deviation. According to Cohen, the ES of 0.2-0.5 is small, of 0.5-0.8 moderate, and those of 0.8 or above large<sup>[31]</sup>. Besides, multiple linear regression analysis was used to further prove sensitivity of the CLDQ under the influence of ALT (normal *vs* abnormal). The six scales and overall CLDQ scores were dependent variables, respectively, while the controlled independent variables were age, gender, marital status, education level,

<sup>1</sup>Floor and ceiling effect: The number and percentage of the chronic hepatitis B patients at the lowest and highest possible scores.

occupation, annual per capita household incomes and the disease (CHB and CHB-related cirrhosis).

### Ethics statement

The study protocol was reviewed and approved by the Human Research Ethics Committee of Xi'an Jiaotong University. The written informed consent was obtained from each recruited patient before the questionnaire survey.

### Statistical analysis

A database was built using the software EpiData 3.1 and the data were double-entered by two different persons to capture data entry errors. All analyses were performed with SPSS version 13.0 (SPSS Inc., Chicago, IL, United States).

## RESULTS

### Sociodemographics

A total of 460 patients were recruited. In the face-to-face interview, they understood the questions of the CLDQ well, and finished the questionnaire completely. The patients aged 35.75 ± 12.82 years (range: 18-76 years), with 305 (66.3%) males and 155 (33.7%) females. Three hundred and twenty-eight (71.3%) patients were married. Education levels of the patients were no schooling and primary (*n* = 63, 13.7%), secondary (*n* = 311, 67.6%) and tertiary (*n* = 86, 18.7%); 153 (33.3%) were peasants and the others were non-peasants. Annual per capita household incomes (RMB) of the patients were < 5000 (*n* = 236, 51.3%), 5000-9999 (*n* = 111, 24.1%) or  $\geq 10000$  (*n* = 113, 24.6%). With respect to the disease, the CHB and CHB-related cirrhosis patients accounted for 70.2% (*n* = 323) and 29.8% (*n* = 137) respectively. Three hundred and seventy five (81.5%) patients received ALT test immediately after the questionnaire survey, 311 (82.9%) with CHB and 64 (17.1%) with CHB-related cirrhosis. The detailed information of patients with CHB or CHB-related cirrhosis is shown in Table 1.

### Reliability and floor/ceiling effects

Cronbach's  $\alpha$  of the total CLDQ was 0.83, with the

| 29. Availability of a liver for transplant                | 0.19  | 0.15              | 0.24              | 0.18              | 0.22              | 0.35 <sup>2</sup> |

Convergent validity: <sup>1</sup>The hypothesized item-scale correlations  $\geq 0.40$ ; <sup>2</sup>correlations  $< 0.40$ . Discriminant validity: The hypothesized item-scale correlations are higher than the alternative ones. AB: Abdominal symptoms; FA: Fatigue; SY: Systemic symptoms; AC: Activity; EM: Emotional function; WO: Worry.

range from 0.65 to 0.90 in the six scales. Both floor and ceiling effect percentages of the six scales and total score of the CLDQ were less than 20% (Table 2).

### Validity

The hypothesized item-scale correlation of the six scales (range) were AB (0.79-0.91), FA (0.61-0.79), SY (0.59-0.71), AC (0.73-0.84), EM (0.67-0.81) and WO (0.35-0.89), all were higher than the range of the corresponding items with other scales, indicating better convergent and discriminant validity (Table 3).

Six factors were extracted from the 29 items of CLDQ, which explained 61.69% of the total variance. Factor loadings of the 29 items were not entirely consistent with the six scales. The items of EM scale loaded on factor 1, except for “difficulty in sleeping at night” (item 16) and “difficulty in falling asleep at night” (item 20), which loaded on factor 6. Factor 2 covered WO scale. The items of FA and AC scales loaded on factor 3, except for “tiredness or fatigue” (item 2), “feel sleepy during the day” (item 4) and “drowsiness” (item 13) loaded on fac-

tor 5. Both of AB scale and item 3 (bodily pain) loaded on factor 4 (Table 4).

### Sensitivity

Regarding the between-group comparison in CHB and CHB-related cirrhosis patients, the eligible ES was found in AC (0.71), SY (0.52), AB (0.33) scales and the overall CLDQ (0.37). After controlling the influences of the disease (CHB and CHB-related cirrhosis), the ES in AB (0.30) scale and the overall CLDQ (0.23) were satisfactory by comparison between the normal and abnormal ALT groups in the stratification of patients with CHB. Meanwhile, the corresponding between-group independent sample *t* test was statistically significant ( $P < 0.05$ ) (Tables 5 and 6). Other eligible ES was also found in patients with normal or abnormal ALT after stratification, including SY (0.22) scale (CHB), and AB (0.27), FA (0.23), AC (0.23) scales and the overall CLDQ (0.21) (CHB-related cirrhosis). However, the corresponding between-group *t* test was not statistically significant ( $P > 0.05$ ) (Table 6).

Based on controlling the influences of sociodemo-

**Table 4 Factor analysis of the chronic liver disease questionnaire (n = 460)**

| Items   | F 1 (EM) | F 2 (WO) | F 3 (AC + FA) | F 4 (AB + SY) | F 5 (FA) | F 6 (sleep) |
|---|----------|----------|---------------|---------------|----------|-------------|
| Abdominal symptoms  |          |          |               |               |          |             |

<sup>1</sup>The effect size (ES)  $\geq 0.20$ . Effect size is calculated as the difference between chronic hepatitis B (CHB) and CHB-related cirrhosis groups mean score divided by the overall standard deviation. Significant difference between CHB and CHB-related cirrhosis groups by independent sample *t* test: <sup>b</sup> $P < 0.01$ . AB: Abdominal symptoms; FA: Fatigue; SY: Systemic symptoms; AC: Activity; EM: Emotional function; WO: Worry.

graphics and the disease (CHB and CHB-related cirrhosis), multiple linear regression analysis detected differenc-

es (unstandardized coefficient, 95%CI) in AB scale [-0.39, (-0.63, -0.15),  $P = 0.001$ ], SY scale [-0.23, (-0.41, -0.06),  $P = 0.009$ ] and the overall CLDQ [-0.22, (-0.40, -0.04),  $P = 0.018$ ] with statistical significance under the influence of ALT (normal *vs* abnormal) (Table 7).

## DISCUSSION

The CLDQ is a non-generic, disease-specific instrument for assessing HRQoL in patients with chronic liver disease. We used the Chinese (mainland) CLDQ in patients with CHB and proved that this instrument has acceptable reliability, validity and sensitivity.

Internal consistency reliability of AB, FA, EM, WO scales and the overall CLDQ were satisfactory, with Cronbach’s  $\alpha$  coefficient greater than 0.70. It was consistent with the reports from similar studies using the original and other different language versions of CLDQ<sup>[15,16,19,34]</sup>. However, Cronbach’s  $\alpha$  of SY (0.65) and AC (0.66) scales were less than the recommended value of 0.70. This is probably due to heterogeneous manifestations of system-

**Table 6** Sensitivity of the chronic liver disease questionnaire in different alanine aminotransferase results after stratifying the disease

<sup>1</sup>The effect size (ES) ≥ 0.20. Effect size was calculated as the difference between alanine aminotransferase (ALT) normal and abnormal group mean scores divided by standard deviation of the total score. Significant difference by independent sample *t*-test between ALT normal and abnormal groups: <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01.

**Table 7** Multiple linear regression analysis (*n* = 460)

| Dependent variable | <i>B</i> | <i>SE</i> | <i>t</i> | <i>P</i> | 95%CI        |
|--------------------|----------|-----------|----------|----------|--------------|
| Abdominal symptoms | -0.39    | 0.12      | -3.22    | 0.001    | -0.63, -0.15 |
| Systemic symptoms  | -0.23    | 0.09      | -2.63    | 0.009    | -0.41, -0.06 |
| Overall CLDQ       | -0.22    | 0.09      | -2.37    | 0.018    | -0.40, -0.04 |

Independent variable: alanine aminotransferase (normal *vs* abnormal). The other controlled independent variables were age, gender, marital status, education level, occupation, annual per capita household incomes and the disease [chronic hepatitis B (CHB) and CHB-related cirrhosis]. CLDQ: Chronic liver disease questionnaire.

atic symptoms severity and activity limitations in patients with CHB or CHB-related cirrhosis and, consequently, influences the corresponding scoring. Percentages of the floor and ceiling effects regarding the six scales and total score of the CLDQ were less than 20%, indicating that this instrument can capture the full range of potential responses and detect small changes in CHB patients during treatment process.

The convergent and discriminant validity of the CLDQ was satisfactory, proving that the items of each scale can reflect the major characteristics consistently. Lam *et al*<sup>[14]</sup> and Mahmoudi *et al*<sup>[35]</sup> reported similar results in their studies. However, “availability of a liver for transplant” (item 29) in the present study did not better correlate to WO scale ( $\gamma = 0.35$ ), possibly due to few patients confronted with the problem of liver transplantation. Therefore, this item was less correlated to WO scale than the other four items within the same dimension.

The factor structure of the Chinese (mainland) CLDQ conform to the six scale structure of the original US version, with a new scale of “sleep” (factor 6) covering the item “difficulty in sleeping at night” (item 16) and “difficulty in falling asleep at night” (item 20) being the only major difference. Such new factor was also found in the Spanish, Italian and German population<sup>[19,20,34]</sup>. It was reasonable to believe that sleeping habits vary among cultures (napping habits and bedtimes), so it may not be surprising that these items clustered differently. For patients with CHB or CHB-related cirrhosis, they may have sleep difficulties due to various reasons other than emotional

problems, including pain or other disease-related factors. Except for the two items of “sleeping difficulty”, all other items of the EM scale loaded on factor 1 consistently.

The items of WO, AC and AB scales loaded on factor 2, 3 and 4. However, AC and AB scales also combined with other items. The finding showed that “decreased strength” (item 8) and “decreased energy” (item 11) of FA scale loaded on factor 3 (AC scale), whereas “bodily pain” (item 3) of SY scale loaded on factor 4 (AB scale), which demonstrated that decreased strength and energy highly correlate to activity<sup>[14]</sup>, and bodily pain may be better related to AB, especially abdominal pain in CHB patients. “Tiredness or fatigue” (item 2), “feel sleepy during the day” (item 4) and “drowsiness” (item 13) were found loading on factor 5 as measuring fatigue symptoms. However, the FLC of “shortness of breath” (item 6) (0.32), “muscle cramps” (item 21) (0.35), “dry mouth” (item 23) (0.32) and “itching” (item 27) (0.28) were less than the recommended value of 0.45. It was probably because that most of the patients were in CHB stage and did not have distinct clinical manifestations as the items reflected.

By comparison between CHB and CHB-related cirrhosis groups, the CLDQ was sensitive in detecting differences in the overall and AB, SY and AC scale scores. It suggests that, based on measuring the physical and psychological health, the CLDQ could further detect the difference of hepatitis-related physical symptoms in CHB patients with or without cirrhosis. After controlling for influences of the disease (CHB and CHB-related cirrhosis), the CLDQ was very good in measuring differences in the overall and AB and SY scale scores between normal and abnormal ALT groups in CHB patients without cirrhosis. Multiple linear regression analysis also confirmed this result through further controlling other confounding factors such as sociodemographics.

However, due to close scores, FA, EM and WO scales did not show significant difference in CHB patients with or without considering ALT test results and controlling for influences of the disease (CHB and CHB-related cirrhosis). Specifically, the difference of between-group comparison in AC scale changed from significant to not significant after stratification, indicating the confounding role of the disease (CHB and CHB-related cirrhosis).

Unlike such finding, Lam *et al*<sup>14</sup> used the Chinese (Hong Kong, China) CLDQ in patients with CHB infection and reported significant differences in FA, AC, EM and WO scales between uncomplicated and complicated CHB patients. Such discrepancy might be the result that CHB-related complications have impact on the patients' health regardless of the disease (CHB and CHB-related cirrhosis) and, subsequently, influence the scoring of the corresponding scales. Therefore, the sensitivity of FA, AC, EM and WO scales of the CLDQ in patients with CHB or CHB-related cirrhosis need further examination.

In patients with CHB-related cirrhosis, the ES values of AB (0.27), FA (0.23), AC (0.23) scales and the overall CLDQ (0.21) were greater than 0.20, confirming the major impact of ALT on the hepatitis-related physical health. Other scales including SY (0.16), EM (0.13) and WO (-0.06) did not have the required ES value, indicating the similar conditions of hepatitis-related symptoms and mental health under the influence of ALT (normal *vs* abnormal) in cirrhotic patients. However, no statistical significance of independent sample *t* test was found in any scales and the overall CLDQ in the present study. The probable explanation for this might be the small sample size ( $n = 64$ ). Different from such result, Lam *et al*<sup>13</sup> found significant differences in SY scale and the overall CLDQ between impaired liver function and cirrhosis groups in CHB patients. Accordingly, more attention should be paid to proving the sensitivity of the CLDQ in CHB-related cirrhosis patients under the influence of normal and abnormal ALT.

There were some limitations in the present study. First, the Chinese (mainland) CLDQ was administered using a face-to-face interview, the performance of the instrument by self-completion will need to be confirmed by future work. Second, the responsiveness of the Chinese (mainland) CLDQ in detecting changes with disease progression or ALT status will also need to be determined. Third, this study was conducted in the single-site of the Eighth Hospital of Xi'an. Therefore, it was limited to generalize the results to all of Chinese mainland CHB patients.

The Chinese (mainland) CLDQ has been proved as a valid tool for assessing HRQoL in patients with CHB. Both reliability and validity were demonstrated to be strongly satisfactory, and better sensitivity was confirmed in detecting the difference of AB, SY and AC scales and the overall CLDQ, especially the differences in AB scale and the overall CLDQ under the influence of ALT status. The Chinese (mainland) CLDQ can be a suitable disease-specific questionnaire for evaluating the change of HRQoL and treatment effects of CHB in clinical practice. Future work in a larger cohort of patients is needed to further prove the responsiveness of the Chinese (mainland) CLDQ.

The patients are at high risk of developing fatal complications of cirrhosis and hepatocellular carcinoma, which consequently lead to the impairments of the patients' health-related quality of life (HRQoL).

### Research frontiers

HRQoL should be used as the primary endpoint in the evaluation of treatment effectiveness for patients with CHB, since it is a more holistic assessment of health status considering the individual's functional health and well-being.

### Innovations and breakthroughs

The chronic liver disease questionnaire (CLDQ) has been translated into many different languages for cross-cultural adaptation and proved as a valid tool for HRQoL measurement and evaluation in patients with chronic liver disease. However, a dearth of study assessed psychometrics of the Chinese (mainland) CLDQ in mainland Chinese patients with CHB. This study determined that the Chinese (mainland) CLDQ has acceptable reliability, validity and sensitivity in patients with CHB. It can be applied to mainland Chinese CHB patients to evaluate their HRQoL.

### Applications

The Chinese (mainland) CLDQ can be used as a suitable disease-specific questionnaire for evaluating the change of HRQoL and treatment effects of CHB in clinical practice. The CLDQ can be used as a cross-cultural HRQoL measure in international studies that include mainland Chinese.

### Terminology

Reliability concerns the random variability associated with measurements. Validity refers to the extent to which a test measures what it is intended to measure. Sensitivity is the ability of measurements to detect differences between patients or groups of patients.

### Peer review

The authors tested psychometrics of the Chinese (mainland) CLDQ and proved that this questionnaire was reliable, valid and sensitive for Chinese mainland patients with CHB. The study was well done and used appropriate methodology to validate and test the questionnaire.

### Abstract

Nodular regenerative hyperplasia (NRH) of liver is a relatively rare liver disorder, but a frequent cause of noncirrhotic portal hypertension. We present a lady with common variable immune deficiency who presented with upper gastrointestinal bleeding and deranged liver function tests but preserved synthetic function. Upper gastrointestinal endoscope showed bleeding gastric varices and non-bleeding oesophageal varices. Although her oesophageal varices were eradicated by repeated endoscopic band ligation, the gastric varices failed to resolve after repeated endoscopic histocryl injection and she eventually needed transjugular intrahepatic portosystemic shunt placement. Liver biopsy showed NRH. We review the association of hypogammaglobulinaemia and NRH and discuss the appropriate management of portal hypertension in NRH.

**Key words:** Nodular regenerative hyperplasia; Liver; Portal hypertension; Hypogammaglobulinaemia; Gastro-oesophageal varices

**Core tip:** Nodular regenerative hyperplasia (NRH) is still an evolving concept. Although a rarely identified liver

disorder, it is a frequent cause of noncirrhotic portal hypertension. Liver involvement in primary hypogammaglobulinemia mainly consists of NRH leading to chronic cholestasis and portal hypertension. Optimal management of gastric variceal bleed remains unclear. Histoacryl injection is the endoscopic method of choice for gastric variceal bleed but one should keep a lower threshold for transjugular intrahepatic portosystemic shunt procedure for recurrent gastric variceal bleed.

### INTRODUCTION

Nodular regenerative hyperplasia (NRH) is the main cause of non-cirrhotic portal hypertension in the western world being responsible for 14%-27% of these cases<sup>[1-3]</sup>. It is characterized by diffuse regenerative hepatocytic nodules without fibrosis. Common variable immune disorder (CVID) is a heterogeneous group of primary immunodeficiency conditions involving formation of antibody production and various cellular immune system defects. NRH is the main liver pathology found in patients with CVID with abnormal liver function test (LFT). It is associated with intrasinusoidal T-cell infiltration, portal vein endothelitis, autoimmune disease and peripheral lymphocytic abnormalities which suggest an autoimmune mechanism.

### CASE REPORT

A 50-year-old lady presented with upper gastrointestinal bleeding. She had a history of bronchiectasis and idiopathic thrombocytopenic purpura and had previously

**Figure 1** Gastric varices. A: Gastric varices pre glue injection; B: Gastric varices post glue.

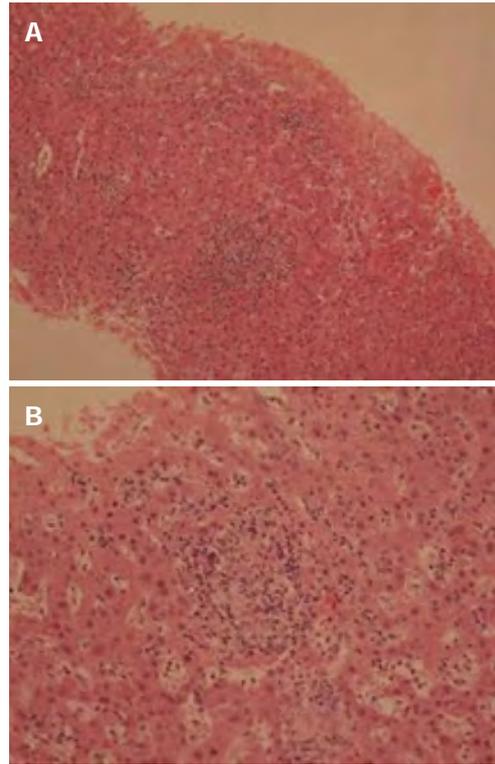

been diagnosed with CVID. She was taking regular intravenous immunoglobulin infusion.

She was haemodynamically stable on presentation with pulse 90 per minute and blood pressure 131/65 mmHg. She had further episodes of haematemesis after admission and emergency endoscopy revealed large gastric fundal varices with evidence of active bleeding (Figure 1) and non-bleeding oesophageal varices. Haemostasis was achieved by applying glue (Histoacryl) to the gastric varices and her esophageal varices were banded. She was given five days of antibiotics and started on oral propranolol for prevention of variceal rebleeding.

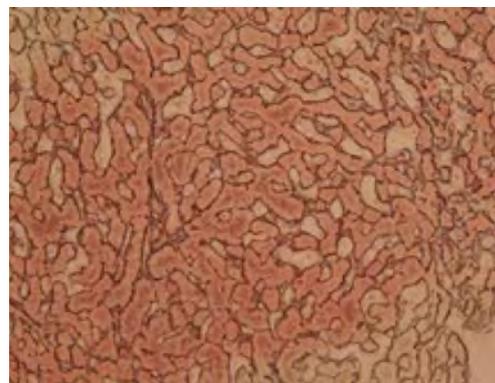

She had mildly elevated liver enzymes (bilirubin 22 mmol/L, aspartate aminotransferase 55 U/L, alanine aminotransferase 35 U/L, gamma-glutamyl transpeptidase 45 U/L) with preserved synthetic function (albumin 41 g/L and prothrombin time 16 s). Ultrasonography of the abdomen revealed a coarse liver echo texture and normal flow in all hepatic veins. There was some bidirectional flow noted in the portal vein suggestive of portal hypertension but no ascites was seen.

To investigate her mildly elevated liver enzymes and portal hypertension percutaneous liver biopsy was undertaken. This showed features suggestive of NRH (Figures 2 and 3). Inflammatory cell infiltrate with granulomas were seen with a reactive appearance and immunophenotype suggestive that the NRH was related to CVID.

Subsequently, her oesophageal varices were eradicated by repeated band ligation but her gastric varices failed to resolve despite of repeated histoacryl injection (Figure 1).

**Figure 2** Nodule formation and granuloma on liver biopsy. A: Nodule; B: Granuloma.

**Figure 3** Thick liver cell plates on reticulin, but no fibrosis on liver biopsy.

Eventually, she had transjugular intrahepatic portosystemic shunt (TIPS) procedure with a covered graft which was placed after 6 mo of initial presentation resulting into satisfactory reduction in the portosystemic gradient with reversal of flow in the varices. She had complete resolution of her gastric varices post procedure and has remained on 6-mo TIPS checks by portography since.

She remains under regular follow up jointly in the liver, immunology, respiratory and haematology clinics. After nine years follow-up she remains well with normal LFTs.

## DISCUSSION

NRH is usually associated with malignant, prothrom-

botic or rheumatologic conditions. Although liver disease and abnormal LFTs are found in approximately 10% of CVID patients<sup>[4,5]</sup> liver lesions associated with primary hypogammaglobulinaemia has been poorly described<sup>[6]</sup>. Two recent studies have identified NRH as the main histological correlate in patients with hypogammaglobulinemia<sup>[2-6]</sup>. Subsequent portal hypertension was frequently observed in only one patient cohort<sup>[6]</sup>. There has also been a case report which shows the association of hypogammaglobulinemia and major gastrointestinal bleeding from gastric varices as a result of cirrhosis of unknown cause (on biopsy)<sup>[7]</sup>.

Management of patients with NRH is aimed at the treatment of the underlying systemic disorder and any complications related to the portal hypertension. A fundamental concept is that the synthetic function of the liver is generally preserved in NRH, despite the potential for development of significant portal hypertension. Liver transplantation is therefore rarely needed for NRH<sup>[8]</sup>.

The immediate approach to variceal bleeding and ascites in patient with NRH does not differ from that of any other patients with the same condition. In the management of gastric varices or intractable or recurrent oesophageal variceal bleeding, TIPS should be considered<sup>[9]</sup>. Gastric variceal bleeding can be particularly challenging to the clinician. Histoacryl injection is the endoscopic method of choice for gastric variceal bleeding with immediate haemostasis figures of over 90% reported<sup>[9,10]</sup>. TIPS is used at a lower threshold for gastric compared with oesophageal variceal bleeding with uncontrolled studies demonstrating initial haemostasis obtained in over 90%, and rebleeding rates of 15%-30%<sup>[11]</sup>. As hepatic encephalopathy is rare in NRH because of preserved hepatic synthetic function, Porto systemic shunt surgery or TIPS is more suitable to treat and prevent refractory gastric variceal bleed in patients with NRH<sup>[11]</sup>. Balloon occluded retrograde transvenous obliteration is a technique for patients with gastric varices and gastrosplenic shunts, although it is rarely used outside Asia<sup>[12]</sup>. Non-cardioselective beta-blockers are an alternative to TIPS for secondary prophylaxis, although the evidence is limited<sup>[11]</sup>.

In conclusion, NRH is still an evolving concept. Although a rarely identified liver disorder, it is a frequent cause of noncirrhotic portal hypertension. Liver involvement in primary hypogammaglobulinaemia mainly consists of NRH leading to chronic cholestasis and portal hypertension. Optimal management of gastric variceal bleed remains unclear. Histoacryl injection is the endoscopic method of choice for gastric variceal bleed but one should keep a lower threshold for TIPS procedure for recurrent gastric variceal bleed.

### Abstract

Two percent of gastrointestinal hemorrhages are caused by Dieulafoy's lesions, which are located in duodenum in only 15% of cases. There are no recommendations regarding the prime endoscopic treatment technique for this condition. A 61-year-old woman presented with melena without signs of hemodynamic instability. During an urgent upper endoscopy, blood oozing from the normal mucosa of the duodenum was seen and this was classified as a Dieulafoy's lesion. A mini-loop was opened at the rim of a transparent ligation chamber, at the end of the endoscope, and after aspiration of the lesion, closed and detached. Complete hemostasis was achieved without early or postponed complications. In every day clinical practice, mini-loop ligation is rarely used because of possible complications, such as site ulceration, organ perforation, re-bleeding and possible inexperience of the operator. To the best of our knowledge this is the first case of successful treatment of bleeding duodenal Dieulafoy's lesion by mini-loop ligation.

**Key words:** Dieulafoy's lesion; Duodenum; Endoscopy; Mini-loop; Hemostasis

**Core tip:** This is a case of 61-year-old woman who presented with upper gastrointestinal hemorrhage caused by duodenal Dieulafoy's lesion that presented with blood oozing from the normal mucosa on upper endoscopy. Complete hemostasis was achieved using a mini-loop ligation without a mucosal lesion, such as ulceration, on two month follow-up endoscopy. Thus, mini-loop ligation is an effective, easy to use and safe method for the treatment of Dieulafoy's lesion. However, case reports with longer follow-up are needed for a definitive statement because of the substantial risk of re-bleeding from a residual aberrant artery.

Gomerčić Palčić M, Ljubičić N. Mini-loop ligation of a bleeding duodenal Dieulafoy's lesion. *World J Gastroenterol* 2013; 19(22): 3505-3507 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i22/3505.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i22.3505>

### INTRODUCTION

Dieulafoy's lesion (DL), a condition first reported in 1884, and named in 1898, refers to dilated submucosal arterial malformation (width of 1-3 mm) that protrudes through overlying epithelium erosion accompanied with normal surrounding mucosa<sup>[1]</sup>. It can be found in any segment of the gastrointestinal (GI) tract with a preference for the lesser curvature of the stomach, 6 cm distally from the esophagogastric junction<sup>[2]</sup>. The incidence of DL is unknown because it is usually an asymptomatic condition that is often undiagnosed; however, its most common complication, GI hemorrhage, accounts for 2%-3% of all GI hemorrhage. A combination of abundant arterial bleeding with an inapproachable site of the lesion implies urgent and reliable treatment; the available endoscopic hemostatic methods are thermal, mechanical and injection<sup>[3,4]</sup>. To the best of our knowledge mini-loop ligation has never been reported as a treatment option in a case of DL.

## CASE REPORT

A 61-year-old woman was admitted to our emergency unit because of melanic stool without abdominal pain, nausea or vomiting. Her previous history indicated that she did not have any serious health problems, just arterial hypertension and hyperlipoproteinemia, which were adequately regulated with chronic therapy. There was no history of alcohol abuse or excess intake of non-steroidal anti-inflammatory drugs (NSAIDs). She was anemic, but showed no signs of hemodynamic instability. Although a nasogastric tube aspirate was clear after insertion, a rectal examination showed evidence of melena. Laboratory tests revealed low levels of erythrocytes  $2.8 \times 10^9/L$  and hemoglobin 79 g/L with normal coagulation parameters. After signing an informed consent, the patient underwent an urgent upper endoscopy (GIF Q160, Olympus Optical Co., Japan). Blood oozing from a pin-point defect with normal surrounding mucosa of the duodenum was visualized and that was suggestive of DL (Figure 1A). A detachable nylon ring was opened at the rim of a transparent ligation chamber attached to the tip of the endoscope (Figure 1B). The lesion was aspirated into the chamber and subsequently the mini-loop was closed and detached, achieving complete hemostasis (Figure 1C). A blood transfusion was administered later, together with pantoprazole in the infusion over a 48 h period. A repeated endoscopy showed that the mini-loop was located at the site of the lesion with no visible sign of acute hemorrhage. The patient was discharged from the hospital on the fourth day with a satisfactory complete blood count (erythrocytes  $3.9 \times 10^9/L$  and hemoglobin 98 g/L). On follow up examination two months later, no pathology of a duodenal mucosa was observed, such as ulceration on the site, and values of her complete blood count were normal.

## DISCUSSION

DL of the duodenum is an uncommon cause of upper GI bleeding, currently experiencing an increase of its frequency because operators' increased awareness of this condition. The duodenum is the second commonest site of DLs, accounting for 15% of patients, second only to the lesser curvature of the stomach, which accounts for around 70%<sup>[3,5]</sup>. Although the incidence of DL is unknown, it accounts for 2%-3% of all GI hemorrhages. Clinical presentations of this condition are extremely wide-ranging: from symptom free, and therefore, frequently undiagnosed cases, to signs of severe and often fatal GI hemorrhage. These lesions usually appear among the elderly, predominantly in men, and are associated with multiple co-morbidities such as chronic renal and heart failure. Other risk factors include the usage of NSAIDs, and antiplatelet and anticoagulant therapy. The patient we treated was an elderly woman with a history of arterial hypertension and hyperlipoproteinemia.

Upper endoscopy, the gold standard, is diagnostic in 90% of the cases; other available diagnostic techniques are angiography and endoscopic ultrasound (EUS). Selective catheter-directed embolization, especially in patients

at high risk for surgery, is usually a salvage method in cases of unsuccessful endoscopic treatment, particularly if the lesion cannot be visualized because of excessive hemorrhage<sup>[6]</sup>. EUS is used to help detect the site of the submucosal vessel, especially in cases of spouting bleeding and to confirm ablation of a DL after therapy.

The endoscopic appearance of a DL is typically arterial spurting or oozing streaming from a minimal defect of the normal surrounding mucosa, or, less commonly, a protruding vessel without signs of active bleeding or with an adherent clot. In this case, blood oozing out of the normal mucosa was visualized without the possibility to distinguishing the underlying vessel. Once the diagnosis is established, several endoscopic techniques can be used, depending on the site of the lesion, severity of symptoms and previous operator experience. Available endoscopic procedures are electrocoagulation, heat probe coagulation, argon plasma coagulation, local epinephrine injection, sclerotherapy, banding and hemoclip. There is no consensus as to which is the most appropriate method. Based on the available data, endoscopic mechanical haemostatic methods seem to be superior to thermal or injection treatment methods<sup>[7,8]</sup>. However, the most commonly used methods are injection therapy and mechanical endoscopic therapy with hemoclips. In our case, a mechanical hemostatic method was used; the bleeding vessel with the surrounding mucosa was aspirated into the transparent ligation chamber and a preloaded nylon ring, called a mini-loop, was closed and detached with consequent complete hemostasis. A search of the published literature using PubMed with the phrase "Dieulafoy's lesion" resulted in 211 articles, of which the first was dated to early 1978 reporting two cases of DL of the jejunum<sup>[9]</sup>. First report of a duodenal DL was published in 1993<sup>[10]</sup> and to the best of our knowledge, there have been no reports of mini-loop ligation as a choice of endoscopic treatment for DL. Despite the fact that the first choice therapy for the bleeding duodenal DLs among most endoscopists includes injection of epinephrine and electrocoagulation<sup>[11]</sup>, mechanical techniques are used more frequently and endoscopic band ligation (EBL) has been demonstrated to be an effective treatment for bleeding esophageal, stomach, duodenal and rectal DLs<sup>[12,13]</sup>. Chung *et al.*<sup>[14]</sup> and Yanar *et al.*<sup>[15]</sup> demonstrated higher efficacy of mechanical hemostatic therapy in initial hemostasis and lowering re-bleeding rate with hemoclip and band ligation compared to injection therapy in patients with DL. On the other hand, EBL has been shown to be as effective as injection therapy with epinephrine, with or without thermal therapy, with a significantly longer length of hospitalization among patients treated with injection therapy or combined therapy with epinephrine and thermal therapy<sup>[16]</sup>. In a study that compared two mechanical methods, EBL and endoscopic hemoclip placement (EHP), no difference was detected in efficacy or safety in the management of bleeding gastric DLs and only one patient from each group experienced re-bleeding<sup>[17]</sup>. A larger study (66 patients) showed a lower recurrent bleeding rate in patients treated with EBL compared with EHP (3.1% *vs* 14.7%)<sup>[18]</sup>. A combined therapy, such as

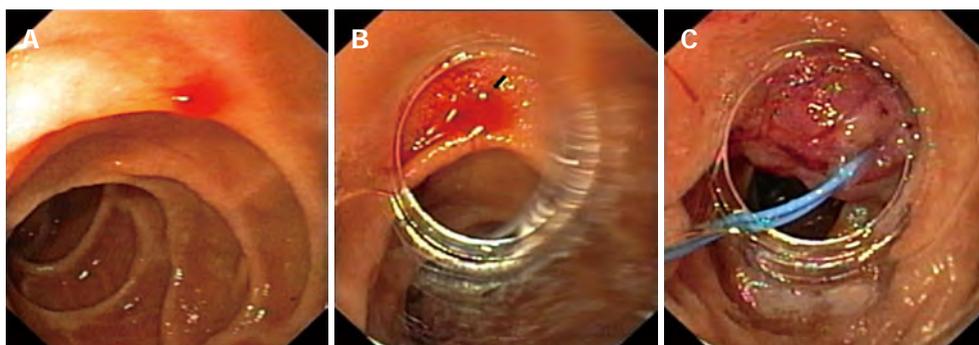

Figure 1 Sixty-one-year-old woman was admitted to our emergency unit because of melanic stool without abdominal pain, nausea or vomiting. A: Bleeding duodenal Dieulafoy's lesion; B: Visible bleeding Dieulafoy's lesion through the rim of a transparent ligation chamber attached to the tip of the endoscope; C: The mini-loop is closed and detached, achieving complete hemostasis.

EBL with EUS, promises a new era in diagnostic efficacy in terms of establishing accurate diagnosis, guiding EBL and confirming success of the treatment<sup>[19]</sup>.

Therapeutic endoscopy is the first line of treatment of DL. However, the choice of technique is not specified. In our case, endoscopic mini-loop ligation proved to be an effective, easy to use and safe method for the treatment of DL. Mini-loop ligation may become a method of choice in resolving bleeding DL; however, case reports with longer follow-up periods are needed for a definitive statement because of the substantial risk of re-bleeding from a residual aberrant artery.

### Abstract

Mucormycosis is an uncommon opportunistic fungal infection with high mortality in liver transplant recipients. Mucormycosis of the gastrointestinal tract can manifest with features similar to ischemic colitis. Typically signs and symptoms of non-gangrenous ischemic colitis resolve spontaneously within 24-48 h. On the other hand, the clinical course of the mucormycosis is commonly fulminant. We encountered a case of invasive fungal colitis presenting with abdominal pain and hematochezia in a liver transplant recipient. Endoscopic examination showed multiple shallow ulcerations and edema with mucosal friabilities on the sigmoid and distal descending colon, which was consistent with ischemic colitis. However, the histological examination obtained from endoscopic biopsies showed fungal hyphae with

surrounding inflammatory cells and mucosal necrosis. The patient was successfully managed with antifungal agent without surgical treatment. Thus, early diagnosis and treatment is essential for improving the prognosis of invasive fungal infection after liver transplantation.

### INTRODUCTION

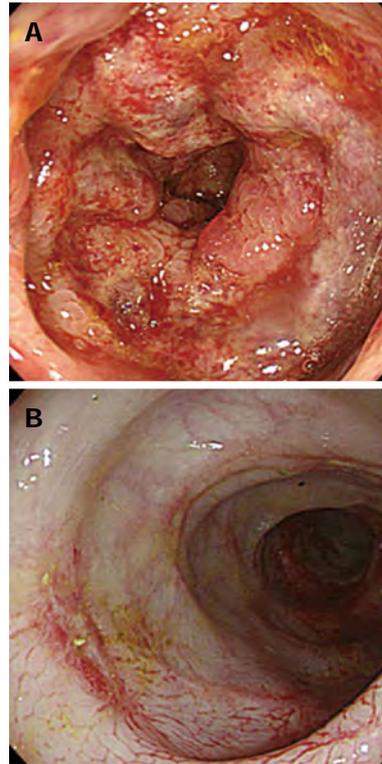

Mucormycosis is a rare but highly invasive opportunistic fungal infection in liver transplant recipients. Clinical manifestations can be rhino-sino-orbital, rhinocerebral, pulmonary, gastrointestinal, genitourinary, cutaneous and disseminated<sup>[1]</sup>. Mucormycosis of the gastrointestinal tract manifests with features similar to ischemic colitis<sup>[2]</sup>. *Mucor*, one of fungi that cause mucormycosis, has a special affinity for blood vessels<sup>[3]</sup>, which may explain the clinical presentation of colonic infection as an ischemic colitis pattern. Ischemic colitis is associated with inadequate blood flow in the colon leading to colonic inflammation, one of the most common vascular disorders of the intestinal tract. Most cases of ischemic colitis are transient and resolve spontaneously without complication<sup>[4]</sup>. However, a deteriorating course of ischemic colitis should warrant further investigation. Herein we present a case of colonic mucormycosis presenting with ischemic colitis in a liver transplant recipient with diabetes mellitus who had been on immunosuppressive agents.

**Figure 1** Abdominopelvic computed tomography scan. Mild to moderate symmetrical wall thickening with decreased mural attenuation was observed from the hepatic flexure to distal sigmoid colon.

## CASE REPORT

A 42-year-old man with chronic hepatitis B underwent deceased donor liver transplantation (DDLT) due to hepatocellular carcinoma in a background of liver cirrhosis. He suffered from diabetes mellitus for 26 mo and was treated with insulin. He had an extremely high blood glucose level after he stopped insulin therapy in the last few months on his own initiative. His general condition was good after transplantation and there were no immediate complications such as acute rejection or infection. Post-operative immunosuppressive agents with methylprednisolone, mycophenolate mofetil, and tacrolimus were used. On the fifth day after DDLT, the patient complained of abdominal pain and small amount of hematochezia. On physical examination, his vital signs were normal except slightly elevated pulse rate (101 beats/min). His abdomen was soft but diffusely tender without peritoneal irritation signs. Laboratory analysis revealed a leukocyte count of  $27800/\text{mm}^3$  with 92% segment form, hemoglobin of 12.1 g/dL, a platelet count of  $65000/\text{mm}^3$ , and C-reactive protein of 3.48 mg/dL. A computed tomography scan of the abdomen revealed mild to moderate symmetrical wall thickening with decreased mural attenuation was observed from the hepatic flexure to distal sigmoid colon (Figure 1). Because of suspected ischemic colitis, the patient was treated with bowel rest, intravenous fluid replacement, and antibiotics. However, the patient's symptoms continued to deteriorate. On the seventh day after DDLT, the decision was made to perform an endoscopic evaluation to elucidate the exact cause of abdominal pain and rectal bleeding. The sigmoidoscopic examination revealed multiple shallow ulcerations, edema with mucosal friabilities, and loss of the normal vascular appearance on the sigmoid and distal descending colon (Figure 2A). Microscopic examination showed several elongated fungal hyphae that stained light blue with haematoxylin and eosin (Figure 3A), were periodic acid Schiff positive and stained dark brown to black with the Grocott-Gomori methenamine silver method (Figure 3B). The fungal hyphae consisted of non-septated filaments, irregularly wide (6-9  $\mu\text{m}$  diameter) hyphae with frequent right angle

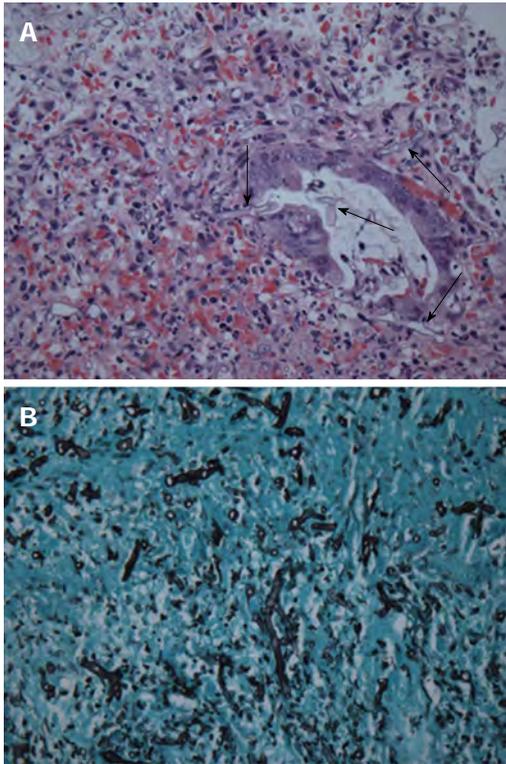

**Figure 2** Sigmoidoscopic findings. A: The mucosa shows multiple shallow ulcerations, edema with friability of the mucosa, and loss of the normal vascular appearance; B: Two weeks after anti-fungal therapy, the mucosal edema and ulcerative lesions are markedly improved and mucosal scar changes were seen on the sigmoid colon.

branching. These morphological features suggested infection by *Mucoraceae*. Based on the clinical findings and the morphological features of the fungal organisms, the diagnosis of mucormycosis was made. The patient was initially treated with intravenous high dose (1 mg/kg per day) amphotericin B, later replaced with liposomal amphotericin B due to azotemia. A follow-up sigmoidoscopy showed significant reduction in mucosal edema and inflammation compared to previous endoscopic findings (Figure 2B). The patient's symptoms disappeared and he made a good recovery.

## DISCUSSION

Mucormycosis is an uncommon fungal infection caused by fungi of the class *Zygomycetes*, order *Mucorales* and *Entomorphothorales*<sup>[5]</sup>. The following risk factors are associated with mucormycosis: neutropenia, history of diabetes mellitus, hyperglycemia, acidosis, preexisting renal impairment, deferoxamine therapy, immunosuppressive agents and steroid use<sup>[1]</sup>. Our patient was diagnosed with diabetes mellitus before this diagnosis and received postoperative immunosuppressive agents after liver transplantation. Mucormycosis manifests a variety of different syndromes in humans, particularly in solid organ transplant recipients<sup>[1,6]</sup>. Although unusual, mucormycosis of the gastrointestinal tract may occur as a result of ingesting fungal spores. A review of the 116 solid organ

**Figure 3 Histologic findings.** A: Microscopic examination of the biopsy specimen obtained by endoscopy shows several fungal hyphae (arrows) (hematoxylin and eosin stain, magnification  $\times 400$ ); B: Right-angle branching, non-septate hyphae of *Mucoraceae* are shown (Grocott's methenamine silver stain, magnification  $\times 400$ ).

transplant recipients with mucormycosis found that the site of involvement of gastrointestinal mucormycosis ( $n = 13$ , 11.2%), included stomach in 9 (69.2%), colon 1 (7.6%), esophagus 1 (7.6%) and liver 1 (7.6%)<sup>[1]</sup>. Non-specific abdominal pain and distention associated with nausea and vomiting are the most common symptoms. Fever and gastrointestinal bleeding may also occur<sup>[7]</sup>. In our case, the patient complained of abdominal pain and hematochezia. We performed a sigmoidoscopy to determine the exact cause of those symptoms. One previous study showed that endoscopic examination is a valuable diagnostic tool to establish an accurate diagnosis of transplant recipients with lower gastrointestinal complaints<sup>[8]</sup>. These symptoms occur typically in ischemic colitis<sup>[2]</sup>. In a review of 85 patients, endoscopic appearance of transient ischemic colitis included edematous and fragile mucosa, segmental erythema, scattered erosion, longitudinal ulcerations, petechial hemorrhages interspersed with pale areas, and purple hemorrhagic nodules<sup>[9]</sup>. The endoscopic findings for our patient resembled ischemic colitis. Successful current treatment for mucormycosis involves a combined approach; rapidity of diagnosis, the control of the underlying predisposing illness, appropriate surgical debridement of infected tissue and prompt initiation of antifungal therapy<sup>[5]</sup>. Until recently, only the polyene class of drugs, including amphotericin B deoxycholate and its lipid derivatives, demonstrated activity against the agents of mucormycosis. The lipid formulations of amphoteri-

cin are significantly less nephrotoxic than amphotericin B deoxycholate and can be safely administered at higher doses for a longer period of time<sup>[7]</sup>. Surgery is essential in decreasing the fungal burden by removing infarcted tissues, where amphotericin B cannot distribute. In a recent study, a patient who was precluded from extensive surgical intervention did not respond to amphotericin B but was treated successfully with a combination of posaconazole and liposomal amphotericin B without surgical treatment<sup>[10]</sup>. Mucormycosis is generally a severe infection with an overall survival rate of patients of approximately 50%<sup>[7]</sup>. Appropriate treatment must be instituted early if the clinical suspicion is high, even before the results of culture and/or histopathological studies have been obtained, and currently, the administration of systemic amphotericin B and/or surgical debridement of the lesions are considered standard therapy<sup>[7]</sup>.

In this case, the patient with diabetes mellitus had received immunosuppressive agents after liver transplantation and presumptive diagnosis of ischemic colitis was initially suspected. The patient was treated with supportive care including bowel rest, intravenous fluid replacement, and antibiotics. However, the patient's symptoms showed a deteriorating condition. Non-improving ischemic colitis warrants further inquiry into causes in an immunosuppressed patient, especially liver transplant recipients with risk factors of mucormycosis. He was finally diagnosed by endoscopic biopsies and successfully treated with strict control of blood sugar level and antifungal agent. Thus, early diagnosis and treatment are essential for improving the prognosis of invasive fungal infection such as colonic mucormycosis after liver transplantation.

### Abstract

This paper introduces an innovative treatment for extrahepatic metastasis of hepatocellular carcinoma. A 71-year-old patient had a stable liver condition following treatment for hepatocellular carcinoma, but later developed symptomatic mediastinal metastasis. This rapidly growing mediastinal mass induced symptoms including cough and hoarseness. Serial sessions of transarterial embolization (TAE) successfully controlled this mediastinal mass with limited side effects. The patient's survival time since the initial diagnosis of the mediastinal hepatocellular carcinoma was 32 mo, significantly longer than the 12 mo mean survival period of patients with similar diagnoses: metastatic hepatocellular carcinoma and a liver condition with a Child-Pugh class A score. Currently, oral sorafenib is the treatment of choice for metastatic hepatocellular carcinoma. Recent

studies indicate that locoregional treatment of extrahepatic metastasis of hepatocellular carcinomas might also significantly improve the prognosis in patients with their primary hepatic lesions under control. Many effective locoregional therapies for extrahepatic metastasis, including radiation and surgical resection, may provide palliative effects for hepatocellular carcinoma-associated mediastinal metastasis. This case report demonstrates that TAE of metastatic mediastinal hepatocellular carcinoma provided this patient with tumor control and increased survival time. This finding is important as it can potentially provide an alternative treatment option for patients with similar symptoms and diagnoses.

**Key words:** Embolization; Hepatocellular carcinoma; Lymphatic metastasis; Endosonography; Mediastinal neoplasm

**Core tip:** This report presents a patient with metastatic hepatocellular carcinoma localized to his mediastinum. The metastatic tumor grew rapidly, with  $\alpha$ -fetoprotein (AFP) elevation rates correlating with the size of the tumor and tumor growth. We used several sessions of transarterial embolization to control this metastatic tumor. After every successful intervention, the tumor had been stabilized and AFP levels were decreased significantly, resulting in a survival time of the patient that is much longer when compared to the mean survival times of others with similar diagnoses. Transarterial embolization could be an alternative treatment choice for patients with mediastinal metastasis of hepatocellular carcinoma.

Transarterial embolization of metastatic mediastinal hepatocellular carcinoma. *World J Gastroenterol* 2013; 19(22): 3512-3516 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i22/3512.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i22.3512>

## INTRODUCTION

Liver cancer in men is the fifth most frequently diagnosed cancer and the second most frequent cause of cancer death worldwide. In women, it is the seventh most commonly diagnosed cancer and the sixth leading cause of cancer death<sup>[1]</sup>. Although advances in treatment of hepatocellular carcinoma (HCC) have resulted in prolonged survival of HCC patients, the incidence of extrahepatic metastasis associated with HCC has also risen<sup>[2]</sup>. Patients with extrahepatic spread have a poor prognosis<sup>[3]</sup>. Current managements for these patients are oral sorafenib and possibly transarterial chemoembolization (TACE) for the hepatic tumors if the patient has enough remaining liver function<sup>[4]</sup>. There are few studies examining the efficacy of locoregional management for extrahepatic metastasis. Furthermore, there are even less reports of lymph node-directed therapy in distant lymph node metastasis<sup>[5]</sup>. In this report, a 71-year-old patient with symptomatic isolated progression of mediastinal lymphadenopathy of HCC was treated with transarterial embolization (TAE). The symptoms were controlled and survival time was longer than expected.

## CASE REPORT

A 71-year-old man visited the Taichung Veterans General Hospital for the management of his HCC. His HCC tumor was 3 cm, localized to the right lobe, and diagnosed by elevated  $\alpha$ -fetoprotein (AFP) levels and hypervascular appearance on abdominal computer tomography (CT). The patient was a hepatitis B carrier with a class A Child-Pugh score and had early stage HCC as assessed by the Barcelona Clinic Liver Cancer staging classification (stage A). However, this patient did not want to receive curative surgery due to old age and personal preference.

He received TACE treatment twice during the first year following his HCC diagnosis. His serum AFP level decreased from 1171 to 14.92 ng/mL following this TACE therapy. One year later, his serum AFP level increased again, but an abdominal CT scan and angiography of the liver did not reveal definite hepatic hypervascular tumors. Two years after the diagnosis of HCC, he started to experience hoarseness due to left vocal cord paralysis. A chest CT scan revealed a 5 cm tumor over the aortopulmonary window of the mediastinum (Figure 1). Metastatic HCC was identified pathologically with endosonography-guided fine needle aspiration. After discussions with the surgeon, radiation oncologist and interventional radiologist, he refused surgery and radiation.

Transarterial embolization of mediastinal tumor was adopted as the treatment modality. Although available now, molecular targeting agents for HCC were not yet a standard care option for patients at that time. The TAE procedure was performed as follows: the first branch of the right superior bronchial artery was identified as the main artery supplying the left hilar metastatic lesion during angiography. Lipiodol was administered *via* this artery as the embolizer, and a chest CT scan verified the

metastatic lymph nodes were mostly occupied by lipiodol (Figure 2). His AFP level decreased from 17089 to 1061 ng/mL and this TAE session was considered successful. There were no adverse effects like cough, chest pain, fever or dyspnea. Thereafter, he received another four sessions of TAE *via* several supplying arteries for viable or recurrent components. AFP levels decreased following each successful TAE, but these levels would rebound quickly due to recurrence of the tumor. During the 16-mo follow-up period, his AFP level was approximately 1000-4000 ng/mL. In addition, he began to have night coughs. On the sixth session of TAE, embolization was performed *via* a small branch of the left branch of internal mammary artery identified by high-resolution chest CT (Figure 3). AFP levels decreased significantly to 16.64 ng/mL and this session was considered successful and the patient remained in stable condition for seven months with no TAE-related complications. However, several months later, the patient began to experience progressive night cough and elevation of AFP levels. A chest CT scan showed progression of mediastinal tumors (Figure 4). A seventh TAE for recurrent mediastinal lymphadenopathy was performed for controlling of tumor. However, his lung condition deteriorated progressively eventually causing him to expire due to pneumonia-related respiratory failure. The patient's survival time since the initial diagnosis of mediastinal metastasis was 32 mo. During the follow up period, his hepatic tumor remained well embolized and his liver function remained stable without evidence of decompensation.

## DISCUSSION

The natural course of HCC is unique. Unlike cancers of the colon, breast, lung, and others, whose causes of death are typically due to systemic processes with development of disseminated diseases, HCCs usually present as local lesions and subsequent development of systemic diseases are relatively uncommon<sup>[6]</sup>. The causes of death from HCC may not only be due to progressive cancer, but may also be due to liver failure.

The prognosis of patients with extrahepatic metastases is usually very poor. The one year and three year survival rates of patients who underwent surgical resection of extrahepatic metastases of HCC was 24% and 7%, respectively. For patients who did not undergo resection, these rates dropped to 8% and 0%, respectively<sup>[7]</sup>. Poor prognostic factors of extrahepatic metastasis of HCC are poor performance status, a high Child-Pugh score, a large number and size of intrahepatic lesions, the presence of macroscopic vascular invasion, a symptomatic extrahepatic metastasis, and high AFP levels<sup>[8]</sup>. In this report, the patient exhibited two of these prognostic factors: high AFP level and symptomatic extrahepatic metastasis. He survived for 32 mo following the initial diagnosis of extrahepatic metastasis despite these poor prognostic factors and his decision not to have surgery. The mean survival time for HCC patients with a Child-Pugh class A score and who had developed extrahepatic

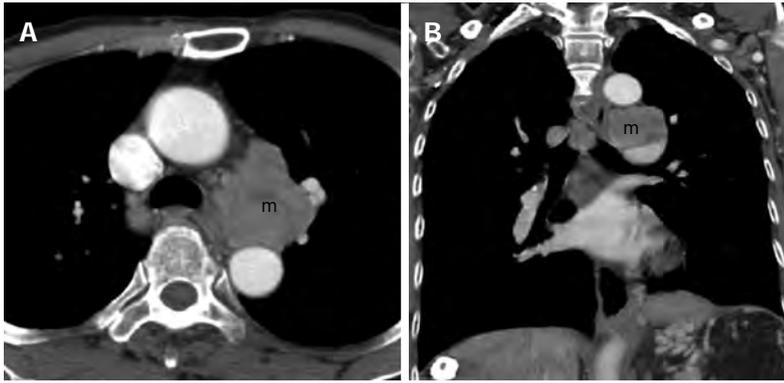

Figure 1 A chest computer tomography scan of the aortopulmonary window of the mediastinum revealed a 5 cm metastatic lymphadenopathy (m). A: Transverse view; B: Sagittal view.

Figure 2 First session of transarterial embolization for mediastinal tumor. A: An angiogram of the right superior bronchial arterial branch showed a metastatic hepatocellular carcinoma (M) in the left hilum supplying by the first branch of right superior bronchial artery. Embolization was performed by lipiodol only; B: Chest computer tomography (CT) scan: Lipiodol retention in posterior portion of the mass (T) over aortopulmonary window region and decreased in size, but the anterior portion of the mass (M) over aortopulmonary window region increased in size as compared with previous CT.

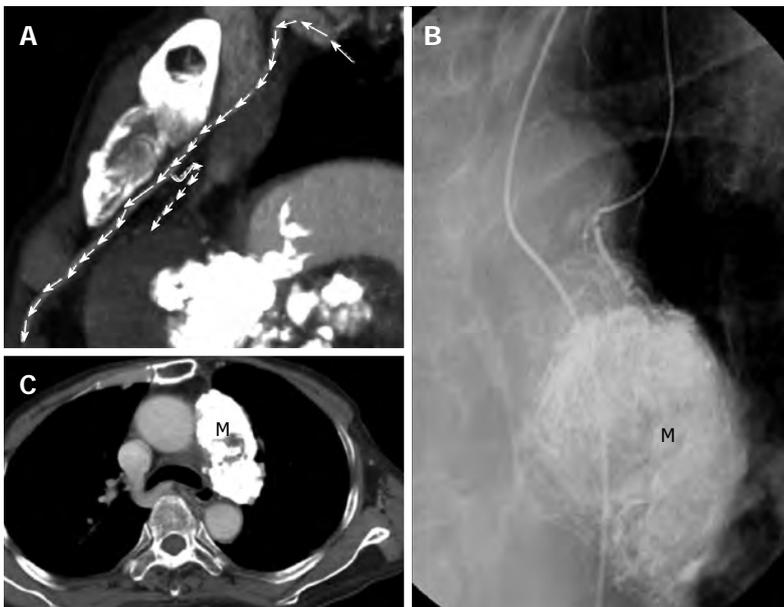

Figure 3 Successful control of mediastinal metastasis via selection of the supplying vessel. A: Multi-detector row computed tomography showed a supplying artery from small branch of left internal mammary artery to residual tumor (arrows); B: Tumor supplying artery of left internal thoracic (mammary) artery was selected via a 3 Fr microcatheter. Transarterial embolization for tumor (M) was done by using 6 mL of lipiodol; C: Follow-up chest computed tomography showed the metastatic tumor (M) in left anterior mediastinum was well embolized.

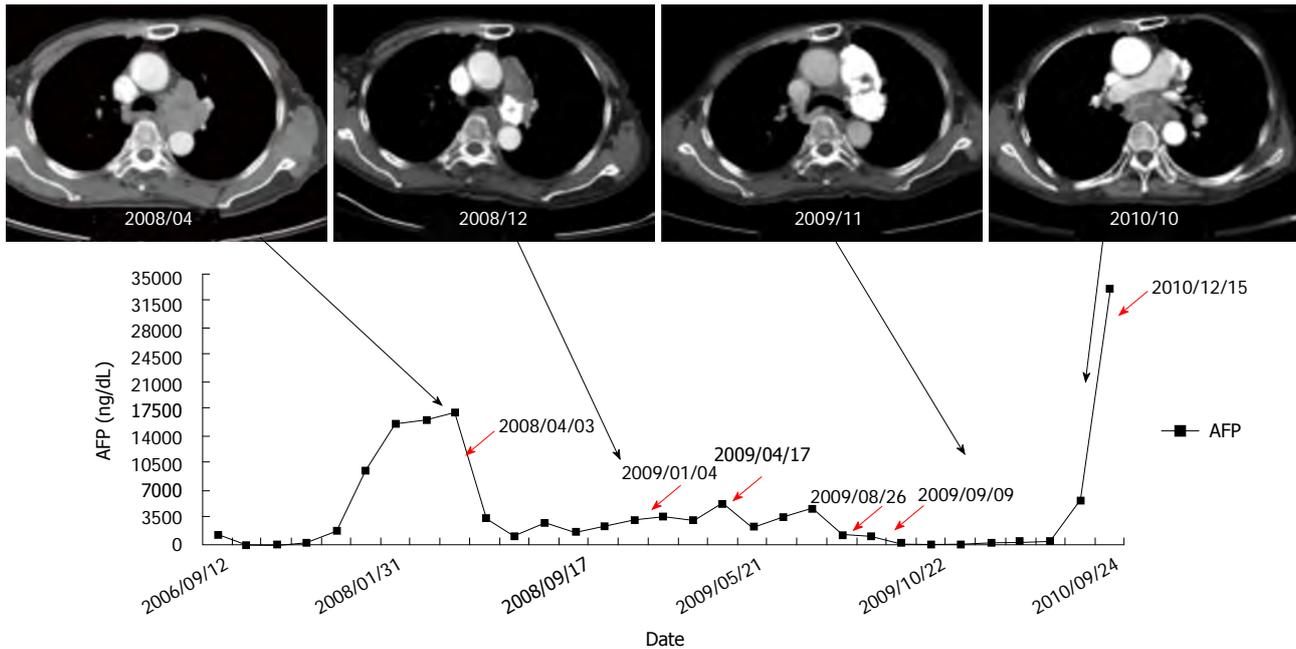

metastasis was recently reported to be 12.0 mo<sup>[6]</sup>. Therefore, this patient far exceeded the expected survival time for someone with his diagnosis.

Current management of metastatic HCC is TACE for primary tumor control and possible chemotherapy, radiation or molecular targeting with sorafenib for extrahepatic lesions<sup>[4]</sup>. Some evidence suggests that treatment of extra-hepatic metastasis of HCC can significantly improve the prognosis of patients whose hepatic lesions are under control<sup>[7,8]</sup>.

Previous studies indicate that surgery for HCC-

associated pulmonary<sup>[9]</sup>, adrenal<sup>[10]</sup> and local lymph node metastasis<sup>[11]</sup> may be beneficial when added to these traditional treatments. Many effective locoregional therapies for extrahepatic metastasis have also been reported, including irradiation for bone<sup>[12]</sup>, lymph node<sup>[13]</sup>, brain<sup>[14]</sup>, and adrenal<sup>[15]</sup> metastases, and percutaneous ablation for adrenal<sup>[16]</sup> and bone metastases<sup>[17]</sup>. Further, TAE has been used as a therapy for adrenal metastasis<sup>[18]</sup> while this is the first report of TAE for mediastinal metastasis.

The most common sites of lymph node metastasis of HCC are locoregional lymph nodes including paraaortic,

**Figure 4** Alpha-fetoprotein levels in time course of treatment. Every session of transarterial embolization is shown with a red arrow. The computed tomography (CT) images represented the progression of mediastinal tumor and treatment response of transarterial embolization. The CT image on the far right was taken about three months before death of the patient. The tumor compressed the left bronchus, which may explain the cause of the patient's pneumonia.

portohepatic, periceliac and peripancreatic nodes. The most common site of HCC-associated distant metastatic lymphadenopathy is the mediastinal lymph nodes<sup>[19]</sup>. Because lymph node metastasis or dissemination itself is not the usual cause of death<sup>[5]</sup>, there are relatively few studies examining the management of metastatic lymph nodes. Lymph node metastases that cause agonizing pain, or rarely life-threatening conditions like pericardial or esophageal invasion<sup>[20]</sup>, may be indications for locoregional treatment such as radiotherapy or surgical resection.

Excellent radiotherapy responsiveness was reported in patients whose intrahepatic HCC was concurrently under control<sup>[13]</sup>. However, radiation at the mediastinum is associated with cardiovascular toxicity, which may present with acute pericarditis, restrict cardiomyopathy, ischemic heart disease, congestive heart failure and valvular heart disease<sup>[21]</sup>. Moreover, radiation therapy at the mediastinum is also associated with a 5%-10% risk of symptomatic radiation pneumonitis<sup>[22]</sup>. Subtle lung function impairment induced by radiation injury may further reduce the capacity of a patient to deal with future cardiopulmonary stress. Surgical resection may be an option if the patient has good liver function and isolated lymph node metastasis<sup>[23]</sup>. However, the existence of possible occult metastasis and the variable degree of hepatic decompensation in HCC patients greatly reduce the benefits of surgery.

Currently, the mainstay treatment for metastatic HCC is sorafenib<sup>[4]</sup>, while options including heavy ion or proton radiotherapy also remain. TAE for mediastinal metastatic HCC may be an alternative option for certain patients with localized metastatic lymph nodes. Furthermore, TAE does not cost more than the other treatment mo-

dalities. In this report, the patient did not present significant side effects during several sessions of TAE and had satisfactory control of his tumor. However, several challenges associated with performing TAE in the mediastinum remain including: the considerable challenge of locating the supplying vessels, the close proximity to many critical arteries in this part of the body such as the spinal cord artery, and the risk of reflux of embolizer to other vital areas. Above all, the key challenge to providing a safe and successful TAE is selection of the supplying artery. Thus, it remains unclear whether this technique can be widely used.

In conclusion, this report showed that the use of TAE for treatment of a metastatic mediastinal HCC provided temporal tumor control and increased survival time. In the right environment, TAE should be an alternative option for well-selected patients with mediastinal metastasis of HCC.

### Abstract

The occurrence of adult intussusception arising from colorectal cancer is quite rare. We present the case of a 76-year-old man with sudden abdominal pain and vomiting. Clinical symptoms included severe abdominal distension and tenderness. Computed tomography scan of the abdomen revealed left-sided colocolic intussusception with a lead point. The patient underwent a left hemicolectomy with right transverse colostomy. Pathologic evaluation revealed moderately differentiated adenocarcinoma invading the muscularis propria; the regional lymph nodes were negative for cancer cells. The postoperative course was uneventful.

### INTRODUCTION

Intussusception is most often encountered in infants and children, and only 5% of cases occur in adults. It accounts for about 1% of all cases of adult bowel obstruction. Adult intussusception of the colon is rare and related to malignant lesions<sup>[1]</sup>. We describe a case of adult intussusception of the transverse colon caused by a malignant tumor in an elderly man preoperatively diagnosed by X-ray, barium enema and computed tomography (CT) scan.

### CASE REPORT

A 76-year-old male with no significant medical history was admitted as a surgical emergency with sudden abdominal pain and vomiting and 2 episodes of bright red bloody stool. Physical examination revealed severe abdominal distension and tenderness.

The abdominal X-ray showed distension of the ascending and right half transverse colon (Figure 1). A barium enema showed the meniscus sign in the contrast material-filled distal sigmoid (Figure 2). CT showed a giant mass at the transverse colon. CT also showed "bowel within bowel" consistent with colocolic component of the intussusception with distension of the ascending

Figure 1 Abdominal X-ray showing distension of the ascending and right half transverse colon.

Figure 2 Barium enema examination showing the meniscus sign in the contrast material-filled distal sigmoid.

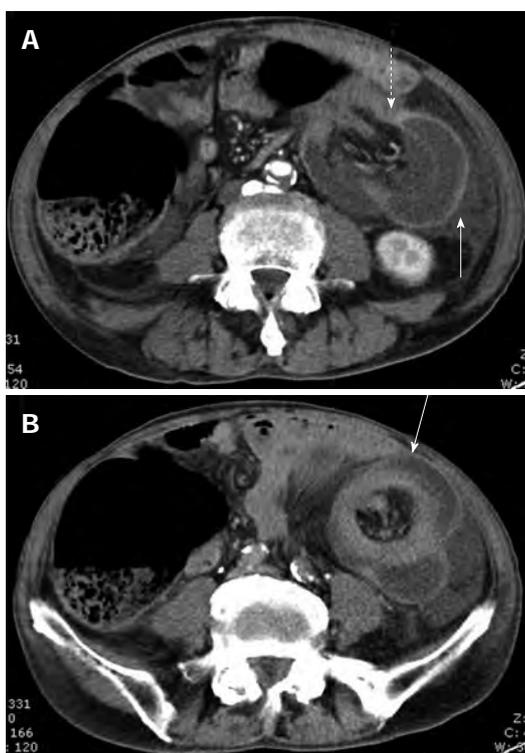

Figure 3 Abdominal computed tomography showing colocolic component of the intussusception (A, dashed arrow), thick-walled descending colon invaginated by transverse colon with mesenteric fat and vessels (A, solid arrow), and the typical "target sign" of colon within colon (B, solid arrow).

colon and invaginated left transverse colon into the descending colon with mesenteric fat and vessels (Figure 3).

The diagnosis of colocolic intussusception at the transverse colon was made. The patient was admitted and underwent emergency laparotomy, and radiologic findings were confirmed during the operation. A giant mass was palpable through the splenic flexure of colon which extended till the sigmoid colon. The mass comprised an intussusception of both the left part of the transverse colon and the great omentum (Figure 4). An extended left hemicolectomy with right transverse colostomy was performed. The patient had an uneventful recovery and was discharged 10 d after the surgery.

Figure 4 Abdominal computed tomography showing enlargement of the descending colon wall with the intussusception (arrow), suggesting the existence of a tumor in the head.

Gross examination of the resected specimen revealed a 25-cm colocolic intussusception which contained a 3.0 cm × 3.0 cm × 2.5 cm protuberant tumor originating from the splenic flexure of colon and the whole great omentum in the descending colon (Figure 5). The final pathological report showed moderately differentiated adenocarcinoma invading the muscularis propria; the regional lymph nodes were negative for cancer cells.

## DISCUSSION

Colo-colonic intussusception is rare in adults (< 5%), but it is the most common cause of intestinal obstruction in infants aged 6-18 mo<sup>[1]</sup>. The characteristic pediatric presentation triad of abdominal pain, palpable abdominal mass and bloody stool is rarely seen in adult cases. Most patients present with subacute (24.4%) or chronic (51.2%) symptoms of abdominal pain, nausea, vomiting and constipation; this is the main reason why preoperative diagnosis is difficult<sup>[2]</sup>. The best preoperative diagnosis method of intussusception is CT scan. Mostly, adult intussusception is related to bowel pathology and 38%-45% cases occur in the colon, while 52%-55% occur in the small intestine<sup>[3]</sup>. It has been reported that 33%-77% of adult colonic intussusception cases are associated with malignant lesions. Adult intus-

**Figure 5** Gross examination of the resected specimen reveals a 25-cm colocolic intussusception. A: Perioperative view after mobilization of the left colon with forceps inside the intussusception invaginated transverse colon with great omentum; B: Operative specimen showing about 25 cm overlapped colon in the intussusceptions; C: The specimen contained a 3.0 cm × 3.0 cm × 2.5 cm protuberant tumor, thought to be the lead point of the intussusception (arrow).

susception of the colon mostly occurs in the flexible regions such as the sigmoid and transverse colon and the cecum<sup>[4]</sup>. For the management of adult intussusception, most authors think that laparotomy is mandatory due to the high incidence of underlying malignancy in colonic intussusceptions and the inability to differentiate non-operatively benign from malignant causes in enteric intussusceptions<sup>[5]</sup>.

In this case, we report a relatively complete process for the diagnosis of adult intussusceptions with detailed medical pictures. Adult intussusception must be considered in the differential diagnosis of patients with abdominal pain and vomiting. The work-up must include X-ray, ultrasound and CT scan of the abdomen, and even a barium enema. Emergent surgical interventions are required once the diagnosis of intussusception is made, due to the high risk of malignancy.

### Abstract

We report a case of pancreatic hemolymphangioma. Hemolymphangioma is a malformation of both lymphatic vessels and blood vessels. The incidence of this disease in the pancreas is extremely rare. To the best of our knowledge, only seven cases have been reported worldwide (PubMed). A 39-year-old woman with a one-day history of abdominal pain was admitted to our hospital. There was no obvious precipitating factor. The preoperative examination, including ultrasonography and computed tomography, showed a cystic-solid tumor in the pancreas, and it was considered to be a mucinous cystadenoma or cystadenocarcinoma. Pancreatic

body-tail resection combined with splenectomy was performed. After the operation, the tumor was pathologically demonstrated to be a pancreatic hemolymphangioma. Although pancreatic hemolymphangioma is rare, we believe that it should be considered in the differential diagnosis of cystic-solid tumors of the pancreas, particularly when there is no sufficient evidence for diagnosing cystadenoma, cystadenocarcinoma or some other relatively common disease of the pancreas.

Hemolymphangioma: A rare differential diagnosis of cystic-solid or cystic tumors of the pancreas. *World J Gastroenterol* 2013; 19(22): 3520-3523 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i22/3520.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i22.3520>

### INTRODUCTION

Hemolymphangioma is a malformation of both lymphatic vessels and blood vessels. The incidence of pancreatic

hemolympangioma is extremely rare. To the best of our knowledge, only seven cases have been reported worldwide (PubMed)<sup>[1-7]</sup>. Macroscopically, it is a multilocular cystic mass with endothelium covering the connective septa<sup>[2,3]</sup>. The tumor typically presents as a mass with heterogeneous enhancement on computed tomography (CT)<sup>[1,6,7]</sup>. Here, we report a case of pancreatic hemolympangioma with different imaging findings.

## CASE REPORT

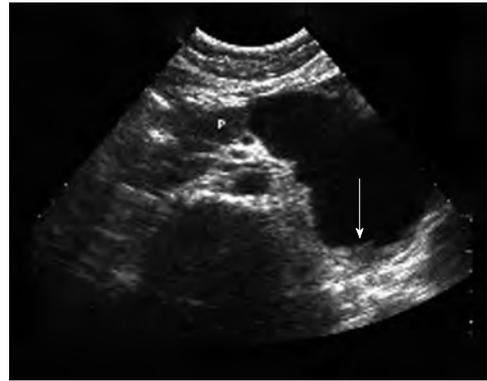

A 39-year-old woman was admitted to our hospital with a complaint of abdominal pain for one day. There was no obvious precipitating factor, no weight loss and no family history of cancer. A physical examination showed mild tenderness in the left hypochondrium. Laboratory tests, including serum tumor markers, were normal.

The ultrasonography and CT findings of the tumor were as follows: (1) Location: the tumor was located at the body and tail of the pancreas; (2) Shape: it was irregular, approximately 10 cm × 7 cm in size, and had a clear border (Figures 1 and 2); (3) Composition: it was a cystic-solid tumor. The cystic area, with a mean CT attenuation value of 30 Hounsfield units (HU), comprised the main part. There was a cord-like septum in the center of the cystic area (Figure 2A, arrow). The solid part was located at the back of the tumor, with a mean CT attenuation value of 68 HU (Figure 2E, arrow); (4) Enhancement: it showed almost no change on contrast-enhanced CT images (Figure 2B-D, Figure 2F-H) compared with pre-contrast images, as assessed with the CT attenuation value; and (5) Neighborhood: the adjacent organs were compressed, and no enlarged lymph nodes were found. Based on these findings, mucinous cystadenoma or cystadenocarcinoma was initially considered.

The patient underwent an exploratory laparotomy. During the operation, the mass was identified as a large dark red mass located at the body and tail of the pancreas, slightly adhering to the gastric wall, posterior peritoneum and left kidney, with bloody fluid inside. Pancreatic body-tail resection combined with splenectomy was performed. Microscopically, some dysplastic lymphatic vessels and blood vessels were observed in the tumor (Figure 3). The pathological diagnosis was hemolympangioma. Her postoperative course was uneventful. She is currently enjoying a normal life without signs of recurrence.

## DISCUSSION

Hemolympangioma is a congenital malformation of the vascular system. The formation of this tumor may be explained by obstruction of the venolymphatic communication between dysembryoplastic vascular tissue and the systemic circulation<sup>[1-3]</sup>. Only seven cases have been reported previously<sup>[1-7]</sup>. Most of these cases were women (6 of 7), and most of the tumors were located at the head of the pancreas (6 of 7). A patient with pancre-

**Figure 1 Ultrasonography.** The tumor is located at the body and tail of the pancreas and is irregularly shaped. The cystic part has a low-intensity echo level, and the solid part (arrow) displays an isointense echo.

atic hemolympangioma can be asymptomatic for a long time. Abdominal pain and awareness of an abdominal mass are the most common symptoms<sup>[7]</sup>.

The imaging findings of pancreatic hemolympangioma typically show a mass with heterogeneous enhancement<sup>[1,6,7]</sup>. In our case, the tumor showed different imaging findings. It presented as a cystic-solid tumor (a single large cyst and a small solid part), with no enhancement in the three-phase contrast scan. We believe that the cystic part might be due to the rupture and fusion of the vascular cavity and that the solid part represented the residual and compressed vascular tissue. The lack of enhancement in the three-phase contrast scan may be related to the relatively small number of blood vessels in the tumor and slow-moving blood flow in the dysplastic blood vessels.

The differential imaging diagnosis for this case includes other cystic-solid or cystic lesions of the pancreas. A mucinous cystadenoma typically shows a single large cyst with a smooth contour, fine septa, even wall, and potentially, small nodules. A thick wall and large nodules might suggest the diagnosis of cystadenocarcinoma. Both mucinous cystadenomas and cystadenocarcinomas can present septa, walls, and nodule enhancement. A solid pseudopapillary tumor of the pancreas is typically found in young women presenting a cystic-solid mass with enhancement of the solid part. A pancreatic pseudocyst typically shows a unilocular lesion with a history of pancreatitis. However, the definitive diagnosis of this tumor was made using histological evidence<sup>[1,3]</sup>.

An operation is required to treat this tumor. Two operative methods are available: tumor enucleation and partial pancreatectomy<sup>[2]</sup>. Because the diagnosis is made postoperatively, pancreatoduodenectomy is typically used for the suspicion of malignancy or invasion<sup>[1,6]</sup>.

Although rare, pancreatic hemolympangioma should be considered in the differential diagnosis when a cystic-solid tumor of the pancreas is found, particularly when there is no sufficient evidence for diagnosing cystadenoma, cystadenocarcinoma or some other relatively common disease.

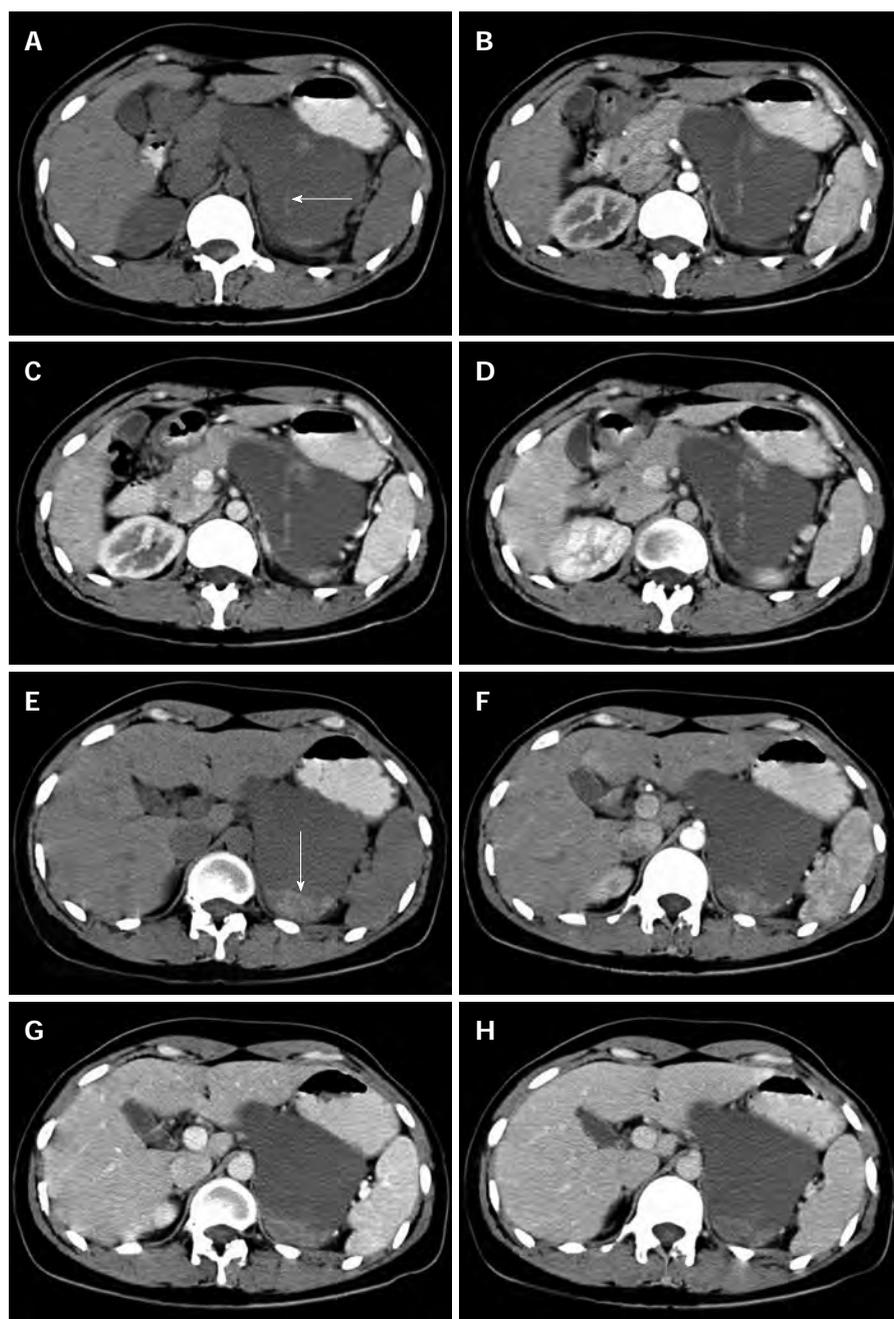

Figure 2 Computed tomography images. A-D: There is a septum (arrow) in the center of the cystic part. Neither the cystic part nor the septum shows enhancement in the arterial phase (20 s after contrast injection) (B), pancreatic phase (45 s after contrast injection) (C), or portal phase (80 s after contrast injection) (D) compared with the pre-enhanced phase (A); E-H: The solid part (arrow) shows no enhancement in the arterial phase (20 s after contrast injection) (F), pancreatic phase (45 s after contrast injection) (G), or portal phase (80 s after contrast injection) (H) compared with the pre-enhanced phase (E).

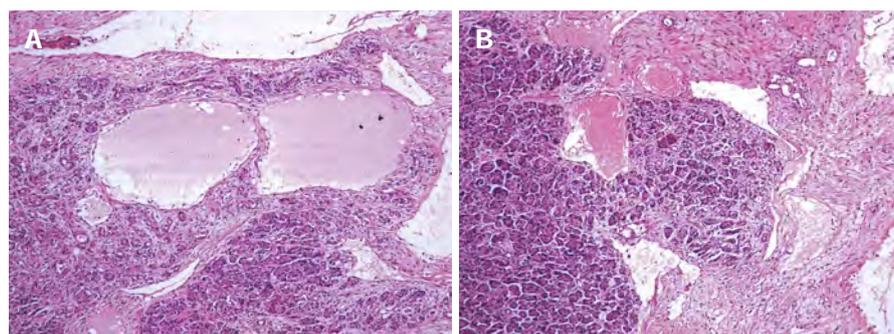

Figure 3 Pathological sections. Some dysplastic lymphatic vessels (A) and blood vessels (B) can be observed in the tumor. Hematoxylin and eosin stain,  $\times 100$ .

### Abstract

Hepatoid carcinoma is a unique type of extrahepatic tumor associated with hepatic differentiation and displays the morphological and functional features of hepatocellular carcinoma. Hepatoid carcinoma of the extrahepatic duct has rarely been reported in the literature. We report a 62-year-old man who presented with epigastric discomfort, xanthochromia, dull pain of the right shoulder, nausea and pruitus. Microscopic examination of the extrahepatic duct indicated that the tumor was primarily composed of "hepatoid cells", which were characterized by an eosinophilic cytoplasm, enlarged nucleus and prominent nucleoli. The cells were arranged in nests or proliferated in a trabecular pattern. Immunohistochemistry indicated that the tumor cells were positive for hepatocyte paraffin 1 and cytokeratins 8 and 18. Based on these findings, this case was diagnosed as hepatoid carcinoma of the extrahepatic duct.

**Key words:** Extrahepatic bile ducts; Hepatocellular;

Adenocarcinoma; Immunohistochemistry; Surgical pathology; Differential diagnosis

**Core tip:** Hepatoid adenocarcinoma (HAC) is a rare type of extrahepatic adenocarcinoma that resembles hepatocellular carcinoma. Although the stomach is the most common location for this tumor, the lung, pancreas, esophagus, papilla of Vater, colon, urinary bladder, renal pelvis, ovaries, uterus and cervix have also been reported as primary locations. To the best of our knowledge, HAC arising primarily from the extrahepatic duct has not previously been reported in the literature. This report presents a rare case of HAC of the hepatic duct and performs a differential diagnosis based on immunochemical results, detailed clinical history and endoscopic findings.

### INTRODUCTION

Hepatoid adenocarcinoma (HAC) of the stomach was first described by Ishikura *et al* in 1985. Carcinomas with hepatoid differentiation have since been described in a variety of locations, including the lung, kidney, female reproductive tract, pancreas, gallbladder and stomach (the most prevalent site)<sup>[1-6]</sup>. An adenocarcinoma of the papilla of Vater showing hepatoid differentiation has previously been reported<sup>[2]</sup>. This tumor was proposed to be a specific type of carcinoma of the Vater. HAC is characterized by hepatic differentiation, which is determined based on both morphological and functional features<sup>[7]</sup>.

To the best of our knowledge, cases of HAC of the extrahepatic duct have not previously been reported. Herein, we present a rare case of HAC of the hepatic duct, which may be proposed as a new site of this carcinoma.

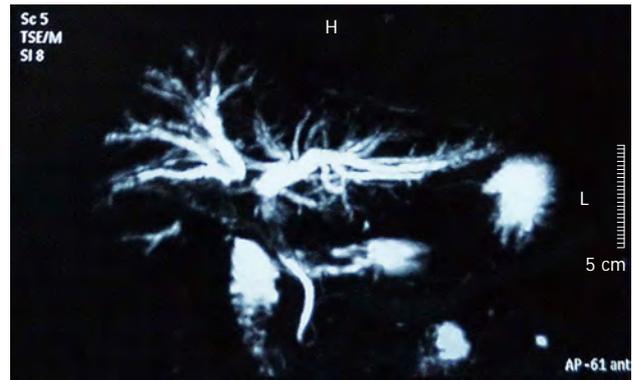

## CASE REPORT

A 62-year-old man presented with epigastric discomfort, xanthochromia, dull pain of the right shoulder, nausea and pruritus. A physical examination identified edema in both lower extremities and his feet. Epigastric tenderness to deep palpation was present but rebound tenderness was undetected. Muscular tension was negative. The liver and spleen were unreachable under the ribs. The hepatojugular reflux was negative. The patient denied any history of infection. Caput medusae, spider angioma and palmar erythema were not observed. Bowel sounds were detected twice per minute. Hepatitis B surface antigen (HbsAg) and hepatitis C-antibody were negative. Cholecystectomy, laparoscopic common bile duct exploration and cholangio-enterostomy were performed.

Abdominal ultrasonography revealed hepatic adipose infiltration, intrahepatic cholangiectasis, and choledochectasia. The above description included the possibility of upper hepatic duct obstruction. Magnetic resonance cholangiopancreatography (MRCP) demonstrated that the branches of the intrahepatic bile duct, the ductus hepaticus sinister and the ductus hepaticus dexter flowed normally. Intrahepatic cholangiectasis and aclasis of the ductus hepaticus sinister and the ductus hepaticus dexter were observed (Figure 1). The common hepatic duct, gall bladder and upper segment of the common bile duct could not be visualized. The imaging suggested obstructive jaundice of the upper segment of the bile duct. The obstruction was observed in the proximity of the hepatic portal area, and a lesion occupying the hepatic portal area was considered.

During the exploratory laparotomy, a small degree of abdominal dropsy and intrahepatic cholestasis were observed. The spleen was normal and the gallbladder wall was thickened. Foci of severe inflammation adhered to surrounding tissues were detected and the wall of the common bile duct was thickened and the lumen dilated (diameter of 3 cm). A solid space-occupying lump could be felt within the ampulla of the common bile duct. Therefore, cholecystectomy, laparoscopic exploration of the common bile duct and a cholangioenterostomy were performed. Intraoperative consultation reported a small number of malignant cells in the necrotic tissues, however, the origin of the cells could not be confirmed. A repeated search for the origin of the cells failed to identify a primary lesion in the liver, gastrointestinal tract or pancreas. A choledochojejunostomy was subsequently performed.

A gross examination revealed a purple and red solid mass in the hepatic duct corresponding to the occupying lesion observed by MRCP, measuring  $1.5 \times 1.2 \times 1.0 \text{ cm}^3$ . In addition, one tubular mass in the common hepatic duct (1 cm in diameter and 0.2 cm in depth), one tubular mass in the ductus hepaticus sinister ( $1.0 \times 0.6 \times 0.2 \text{ cm}^3$ ), one gray and yellow solid mass in the ductus hepaticus dexter ( $1.2 \times 1.2 \times 0.5 \text{ cm}^3$ ), a mass of fragmented red and purple contents in the hepatic duct ( $3.5 \times 3.0 \times 0.4 \text{ cm}^3$ ), one gallbladder containing bile (4 cm

**Figure 1** Magnetic resonance cholangiopancreatography. Magnetic resonance cholangiopancreatography revealed an obstruction in the proximity of the hepatic portal area and the absence of hepatic nodules within the liver lobes. L: Left; H: Height.

in diameter and 9 cm in length), and two lymph nodes attached to the mesentery were also observed.

Microscopically, the tumor was primarily composed of “hepatoid cells”, which were characterized by an eosinophilic cytoplasm, enlarged nucleus, and prominent nucleoli. The tumor cells were arranged in nests or proliferated in a trabecular pattern. The tumor consisted of marginal areas of dysplastic glands and well-differentiated intestinal-type adenocarcinomatous tissue, which formed the bulk of the tumor (Figure 2A-C). None of the lymph nodes dissected at surgery showed tumor metastasis. Immunohistochemistry indicated that the tumor cells were positive for hepatocyte paraffin 1 (HepPar-1), cytokeratins 8 and 18 (CK8/18), polyclonal carcino-embryonic antigen (pCEA) and S-100 (Figure 2D-G). Approximately 15% of the tumor cells were positive for Ki-67 (Figure 2H).

Based on the above findings, the case was diagnosed as HAC of the hepatic duct was made.

## DISCUSSION

HAC a rare variant of extrahepatic adenocarcinoma, consists of foci of both adenomatous and hepatocellular differentiation that behave morphologically and functionally similar to hepatocellular carcinoma (HCC)<sup>[8,9]</sup>. As previously mentioned, the primary characteristics of HAC are histopathological features that suggest hepatoid differentiation resembling HCC. The tumor is generally composed of large or polygonal cells with abundant eosinophilic cytoplasm and proliferates in a solid or trabecular pattern, although medullary proliferation is occasionally observed<sup>[10]</sup>. The hepatoid nature of the cells can be proven based on the detection of bile production<sup>[11]</sup>. Primary gastric HAC has been the most frequently analyzed type of HAC. Glandular and hepatocyte differentiation both have been observed and the explanation for this phenomenon is “enteroblastic differentiation”. Because the stomach and liver are derived from the primordial foregut, prosoplasia that occurs during the maturation of the cells may induce the formation described above.

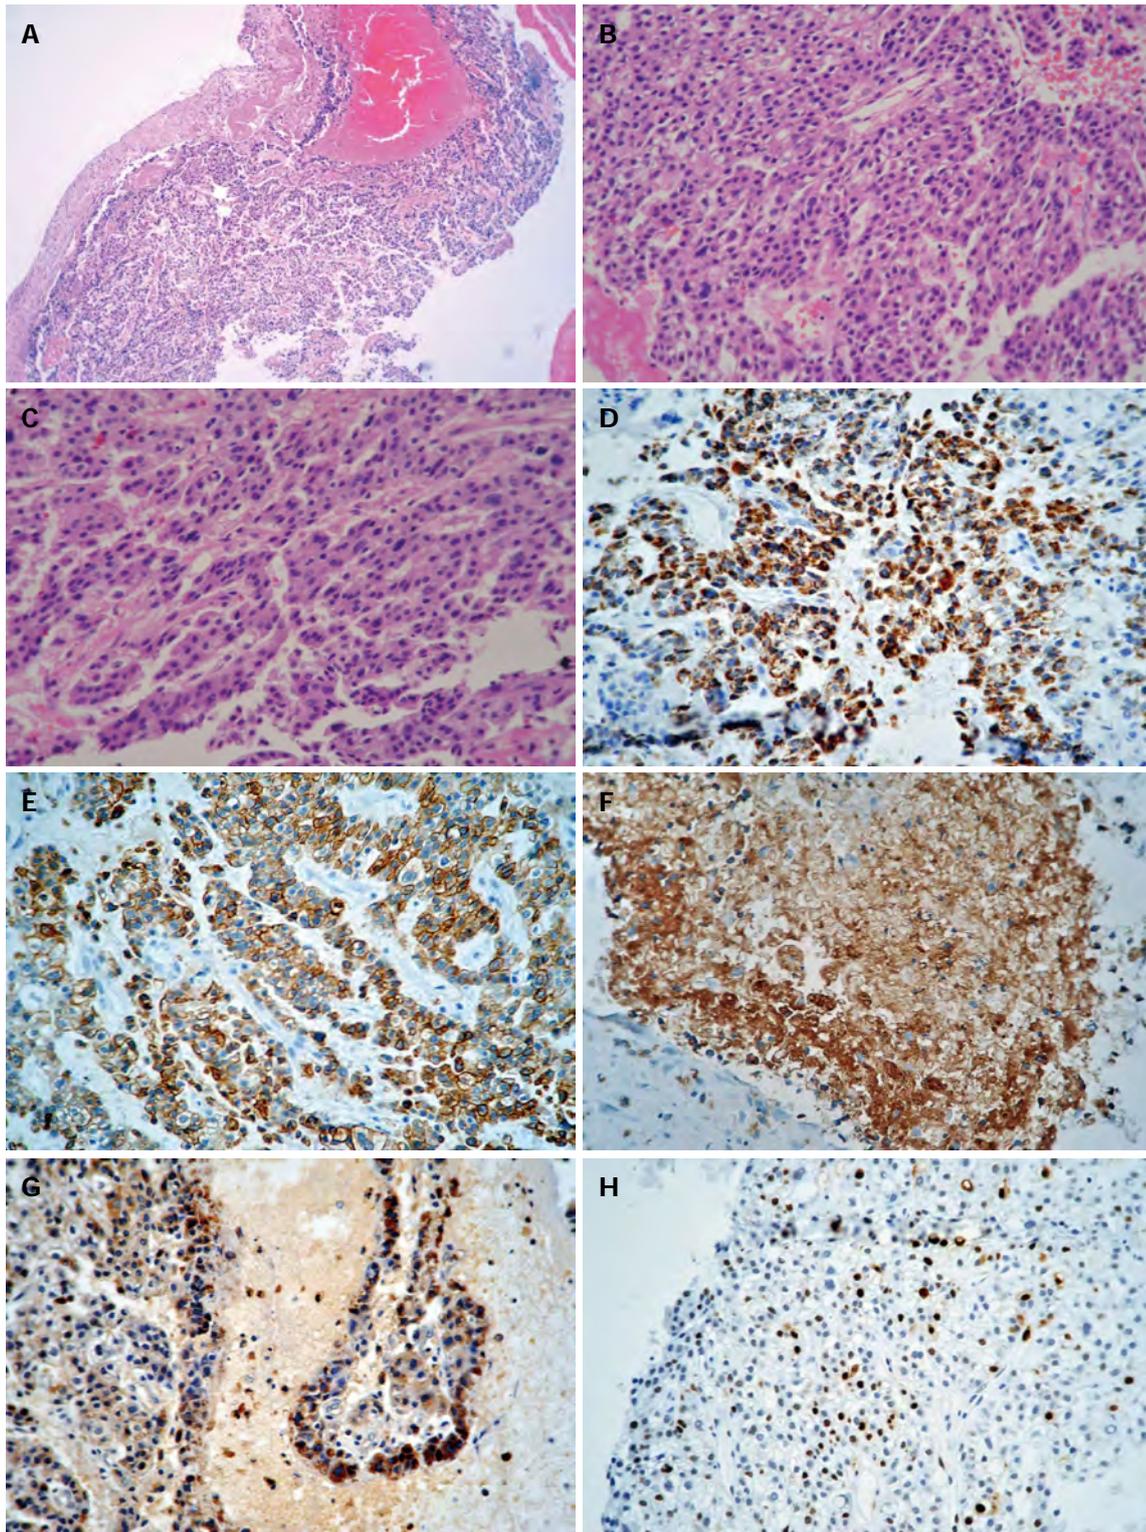

Figure 2 Histological and immunohistochemical features. A: Low-power microphotograph showing hepatoid areas (hematoxylin and eosin; original magnification,  $\times 100$ ); B, C: Hepatoid adenocarcinoma composed of cells with a clear cytoplasm arranged in a nested or trabecular pattern (hematoxylin and eosin; original magnification,  $\times 400$ ); D-H: Intracytoplasmic expression of hepatocyte paraffin 1, cytokeratin 8/18, polyclonal carcinoembryonic antigen and S-100 as well as Ki-67-positive nuclei (original magnification,  $\times 400$ ).

Clear cell carcinomas of the gallbladder with or without hepatoid differentiation are often associated with high serum  $\alpha$ -fetoprotein (AFP) levels<sup>[10]</sup>, however, not all HACs are associated with AFP overproduction<sup>[11]</sup>. In the present case, the preoperative serum AFP level was

6.84  $\mu\text{g/L}$ , and immunohistochemistry suggested that AFP protein was not expressed. However, focal positivity for HepPar-1 suggested the presence of hepatoid differentiation, and pCEA positivity indicated canalicular differentiation and hepatocellular origin. CK8/18 ex-

pression in this case resembled HCC and could also be considered to be as a marker of hepatocellular origin.

HCC generally arises in cirrhotic livers and with hepatitis virus infection, however, the preoperative examination revealed that this patient was negative for HBsAg. In the present case, the rough region of the ductus hepaticus sinister was observed by the operator during laparoscopic exploration of the common bile duct. Combined with the clinical findings, the extrahepatic ductal origin of the HAC was verified by the clinical presentation, its morphological similarity to HCC, the immunohistochemical identification of liver-synthesized proteins, and bile production<sup>[2]</sup>.

The differential diagnosis of HAC and HCC with invasion into the hepatic duct is primarily dependent upon tumor location. No primary lesion was identified in the liver, gastrointestinal tract or pancreas during surgery. In addition, MRCP and computed tomography angiography (not shown) did not reveal lumps in the liver. The literature has shown that HAC is generally found in elderly males, and poor outcomes are observed. The pathological findings in immunohistochemical analyses may also aid in the differential diagnosis of HAC from HCC: an evaluation using a panel of immunohistochemical markers (*e.g.*, cytokeratin 19, palate, lung and nasal epithelium clone, HepPar-1 and carcinoembryonic antigen), combined with detailed clinical history and endoscopic findings is essential for a definitive diagnosis.

### Abstract

Delayed liver laceration following transjugular intrahepatic portosystemic shunt (TIPS) is a serious and likely underdiagnosed complication. It is however an important complication following TIPS, which remains one of the most technically challenging interventional procedures performed. In addition to laceration, a number of complications regarding bleeding and perforation are well described following TIPS procedures. We feel the adoption of techniques such as ours and that of other authors described in the literature using an ultrasound-guided percutaneous transhepatic approach with a small caliber needle provides a safer and less traumatic procedure and should reduce complications of bleeding and almost completely eliminate the risk of liver laceration. Our procedure was successfully performed under conscious sedation rather than general anaesthesia further reducing the overall procedural risk to the patient.

Reducing risk of transjugular intrahepatic portosystemic shunt using ultrasound guided single needle pass. *World J Gastroenterol* 2013; 19(22): 3528-3530 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i22/3528.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i22.3528>

### TO THE EDITOR

We read with interest the excellent article by Liu *et al*<sup>[1]</sup> regarding the delayed liver laceration following transjugular intrahepatic portosystemic shunt (TIPS) for portal hypertension. This is a serious and likely underdiagnosed complication. It is however an important complication following TIPS, which remains one of the most technically challenging interventional procedures performed. In addition to laceration, a number of complications regarding bleeding and perforation are well described following TIPS procedures.

In their paper, Liu *et al*<sup>[1]</sup> correctly established a number of factors which contribute to bleeding and liver injury following TIPS: (1) liver cirrhosis with coagulopathy; (2) liver parenchyma and vascular injury during TIPS; and (3) early stent anticoagulation with low molecular weight heparin. While we fully agree with these postulations, we feel that another important factor is the

needle size used for percutaneous access and tract creation between the portal vein and the hepatic veins during TIPS. In our department, we have recently adopted a new technique utilising a 22-gauge microneedle and percutaneous liver puncture under direct ultrasound visualisation that dramatically decreases the risk of laceration.

This modification may help refine and improve the outcome of patients undergoing TIPS placement. The creation of the shunt between the portal and hepatic veins is traditionally performed under fluoroscopic guidance, and is considered the most difficult step in the establishment of a TIPS<sup>[2]</sup>, and is usually successful only after several punctures<sup>[3]</sup>. This “blind” fluoroscopic procedure can be refined with fluoroscopic methods including wedged hepatic venography<sup>[4]</sup> and superior mesenteric artery arterial portography<sup>[5]</sup>. Ultrasound assisted TIPS which facilitates the creation of the portosystemic shunt have also been described including placement of metallic overlying skin markers<sup>[6]</sup>, placement of metallic coils adjacent to or microwire placement within the portal vein<sup>[7]</sup>. These methods attempt to reduce the time spent achieving the portosystemic shunt and thus, the risk of bleeding complications.

More interestingly, the removal of the step requiring blind puncture of the portal vein has been described in the recent literature. Raza *et al*<sup>[8]</sup> described a single-pass technique to access the right portal and right hepatic veins under ultrasound guidance using an 18-gauge, 20-cm Chiba needle (Cook) with a technical success rate of 73% and no evidence of post-procedure puncture site haemorrhage. Liang *et al*<sup>[2]</sup> also achieved 100% technical success and no evidence of post-TIPS internal hemorrhage with a similar technique in patients with severely distorted liver parenchyma to obtain a left portal vein and inferior vena cava (IVC) shunt, using an 18-gauge, 20-cm needle. Whilst small in patient numbers, these studies highlight the feasibility of ultrasound guidance to reduce the number of punctures required to achieve a portosystemic shunt, which thus reduces the risk of bleeding.

To further reduce the risk of bleeding in these patients who are often coagulopathic, it is suggested to use a further modification of Raza *et al*<sup>[8]</sup> and Liang *et al*<sup>[2]</sup> technique using initial access with a 22-gauge, 20-cm Chiba needle (Cook) in an attempt to reduce the bleeding risk from the most challenging step of the TIPS procedure, especially in high risk patients. This method has also been described in a small series by Gazzera *et al*<sup>[9]</sup> in 8 patients with 100% technical success. This method requires pre-procedural drainage of ascites, if present, under ultrasound guidance with a 7-8 Fr pigtail catheter. Embolisation of the transhepatic needle tract can also be considered<sup>[8]</sup> especially in cases where ascites is present<sup>[2]</sup>. Where available, intravascular ultrasound may be useful to guide shunt creation especially in cases with portal vein thrombosis, distorted anatomy, Budd-Chiari syndrome or hepatic tumors<sup>[10]</sup>.

We recently adopted a modified transhepatic single-needle pass for TIPS in our institution. It involved a 53-year-old male with cirrhosis undergoing TIPS for refractory ascites. His pre-procedure work up revealed

a Child-Pugh B and Model for End-stage Liver Disease score of 14. Prior to the modified TIPS procedure, the ascites was drained under ultrasound guidance. Following this, both the neck and abdomen were prepared for a combined transjugular and transhepatic approach followed by administration of conscious sedation with intravenous midazolam and fentanyl. Using real time ultrasound guidance, the right portal vein (Figure 1) was punctured with a 22-gauge, 20-cm Chiba needle (Cook) close to the bifurcation of the main portal vein (MPV), with entry confirmed by aspiration of blood. Following this, the needle was advanced into the right hepatic vein under real-time ultrasound guidance, with confirmation of entry by blood aspiration. A 0.018-inch Nitinol guidewire was then advanced into the hepatic vein, IVC and right atrium. The tract was upsized with a 7-Fr co-axial introducer system. The introducer and stiffener was then removed allowing passage of a 0.035-inch Amplatz Ultrastiff guidewire (Cook) into the right atrium. The right internal jugular vein was the accessed under ultrasound guidance using a micropuncture set (Cook) comprising of a 21-gauge needle, 0.018-inch guidewire and 4-Fr co-axial catheter. This was then upsized to a 6-Fr long vascular sheath into the right atrium. At this point, a 25-mm diameter Amplatz Gooseneck Snare (ev3 Inc) was used to snare the transhepatic wire, achieving through and through access (Figure 2). The sheath was then advanced into the hepatic vein over the transhepatic-transjugular wire until resistance was met. A 6 mm × 20 mm and 8 mm × 20 mm angioplasty balloon catheter (Powerflex Pro, Cordis) was advanced over the wire and the hepatic and portal vein tract was dilated. The sheath was advanced into the dilated tract, and contrast was injected through the sheath to confirm intraportal position. A 0.035-inch, 260-cm long hydrophilic wire (Glide-wire Advantage, Terumo, Japan) and 5-Fr Berenstein catheter was then introduced through the transjugular sheath and manipulated into the MPV and then into the superior mesenteric vein (Figure 3). The transhepatic-transjugular wire was removed at this stage, and the 6-Fr sheath was replaced with a 10-Fr sheath. The procedure was completed as a conventional TIPS with deployment of a 10 mm × 70 mm (Viatorr, WL Gore and Associates) TIPS endoprosthesis stent (Figure 4). The patient remained stable with an uncomplicated post-procedural course and was discharged after 3 d with a satisfactory baseline post-TIPS ultrasound.

We feel the adoption of techniques such as ours and that of other authors described in the literature using an ultrasound-guided percutaneous transhepatic approach with a small caliber needle provides a safer and less traumatic procedure and should reduce complications of bleeding and almost completely eliminate the risk of liver laceration. Finally, our procedure was successfully performed under conscious sedation rather than general anaesthesia further reducing the overall procedural risk to the patient.

In conclusion, the authors should be commended for publication of this important complication of liver laceration following TIPS, which remains one of the most technically challenging interventional procedures but we hope that adoption of a microneedle controlled approach will potentially eliminate such complications.

Figure 1 The right portal vein was punctured with a 22-gauge, 20-cm Chiba needle (Cook) close to the bifurcation of the main portal vein, with entry confirmed by aspiration of blood.

Figure 3 A 0.035-inch, 260-cm long hydrophilic guidewire (Glidewire, Boston Scientific) and 5 Fr Berenstein catheter was then introduced through the transjugular sheath and manipulated into the main portal vein and then into the superior mesenteric vein.

Figure 2 A 25-mm diameter Amplatz Gooseneck Snare (ev3 Inc) was used to snare the transhepatic wire, achieving through and through access.

Figure 4 The procedure was completed as conventional transjugular intrahepatic portosystemic shunt with deployment of a 10 mm x 70 mm (Viatorr, WL Gore and Associates) transjugular intrahepatic portosystemic shunt endoprosthesis stent.

**AIMS AND SCOPE** *World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a peer-reviewed open access journal. *WJG* was established on October 1, 1995. It is published weekly on the 7<sup>th</sup>, 14<sup>th</sup>, 21<sup>st</sup>, and 28<sup>th</sup> each month. The *WJG* Editorial Board consists of 1352 experts in gastroenterology and hepatology from 64 countries.

The primary task of *WJG* is to rapidly publish high-quality original articles, reviews, and commentaries in the fields of gastroenterology, hepatology, gastrointestinal endoscopy, gastrointestinal surgery, hepatobiliary surgery, gastrointestinal oncology, gastrointestinal radiation oncology, gastrointestinal imaging, gastrointestinal interventional therapy, gastrointestinal infectious diseases, gastrointestinal pharmacology, gastrointestinal pathophysiology, gastrointestinal pathology, evidence-based medicine in gastroenterology, pancreatology, gastrointestinal laboratory medicine, gastrointestinal molecular biology, gastrointestinal immunology, gastrointestinal microbiology, gastrointestinal genetics, gastrointestinal translational medicine, gastrointestinal diagnostics, and gastrointestinal therapeutics. *WJG* is dedicated to become an influential and prestigious journal in gastroenterology and hepatology, to promote the development of above disciplines, and to improve the diagnostic and therapeutic skill and expertise of clinicians.

**INDEXING/ABSTRACTING** *World Journal of Gastroenterology* is now indexed in Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®), Journal Citation Reports®, Index Medicus, MEDLINE, PubMed, PubMed Central, Digital Object Identifier, and Directory of Open Access Journals. ISI, Journal Citation Reports®, Gastroenterology and Hepatology, 2011 Impact Factor: 2.471 (32/74); Total Cites: 16951 (7/74); Current Articles: 677 (1/74); and Eigenfactor® Score: 0.06035 (5/74).

### Abstract

The treatment of microscopic colitis is mainly based on the use of budesonide, the only drug found effective in controlled clinical trials. After an initial course at a dose of 9 mg daily, however, most patients relapse when the drug is discontinued, hence a maintenance therapy at doses of 6 mg daily or lower is necessary. In order to avoid steroid dependence and drug toxicity different pharmacological agents should be considered as an alternative to indefinite long-term budesonide treatment. Evidence-based guidelines are currently lacking due to the lack of conclusive data concerning the use of either immunosuppressive or anti-tumor necrosis factor agents. For the time being in clinical practice the skilled physician should therefore tailor long term management of microscopic colitis on the single patient.

**Key words:** Microscopic colitis; Budesonide; Mesalazine; Immunosuppressants

**Core tip:** The efficacy of short-term treatment of microscopic colitis with budesonide is confirmed. Long-term therapy is not advisable because of possible side effects, but the efficacy of alternative drugs such as immunosuppressants or anti-tumor necrosis factor agents remains to be established. For the time being prolonged budesonide treatment in minimal doses, tailored

on the single patient, appears to be the most sensible option.

### MICROSCOPIC COLITIS

Microscopic colitis (MC) is an intestinal inflammatory disorder the diagnosis of which relies on specific histopathological findings, namely an increased number of lymphocytes in the colonic epithelium and of subepithelial chronic inflammatory cells (lymphocytic colitis), in some cases with a thickening of the subepithelial layer (collagenous colitis)<sup>[1,2]</sup>.

Radiographic and endoscopic features are constantly normal. The main symptom is chronic watery diarrhea without bleeding, the disease being more common among older individuals, especially of female gender. Although a genetic cause has not been proven, familial occurrence has been reported.

Smoking is a risk factor and bile acid malabsorption is frequent (however, a bile acid binding drug such as cholestyramine may improve symptoms but not histopathology)<sup>[1-3]</sup>.

Medications such as nonsteroidal antiinflammatory drugs, proton pump inhibitor, ticlopidine, sertraline *etc.* can induce MC<sup>[4]</sup>. Hence, accurate information about pharmacological treatment history is mandatory in order to discontinue the supposedly responsible drug.

The only medication found effective in randomized, placebo-controlled trials is budesonide, which, at a dose of 9 mg per day is able to induce clinical remission and histological improvement in about 81% of cases<sup>[5]</sup>. The superior efficacy of budesonide compared with placebo has been shown in four controlled trials involving patients with either collagenous or lymphocytic form of MC<sup>[6-9]</sup>.

By contrast only a small trial comparing prednisolone and placebo for two weeks reported a trend toward clinical response<sup>[10]</sup>. At any rate, budesonide should be preferred to other steroids not only because of fewer side effects, but also because the success rate is higher and the incidence of clinical relapses is lower<sup>[11,12]</sup>.

When budesonide is withdrawn, symptomatic relapse of MC can occur in 60%-80% of cases<sup>[13,14]</sup>. In order to maintain remission budesonide can be successfully administered at a dose of 6 mg daily, up to six months<sup>[14,15]</sup>. After that period there is no published evidence that the drug continues to be effective, but clinical practice shows that budesonide 3-6 mg daily can prevent recurrence, although patients become at risk of becoming steroid dependent and to develop side effects due to long-term steroid therapy. The minimum dose of budesonide should be employed, even 3 mg every other day being occasionally sufficient to maintain clinical remission (Guslandi M, unpublished data), but in order to avoid steroid dependence and drug toxicity other therapeutic options must be considered.

Mesalazine, which is usually well tolerated, would represent an ideal long-term treatment, but evidence of its efficacy in MC is weak, retrospective series reporting benefit in fewer than half the patients as a short term therapy while data for periods exceeding 6 mo are lacking<sup>[16,17]</sup>.

Immunosuppressive agents can be taken into consideration, both in patients with severe symptoms who do not respond to full doses of budesonide or who are experiencing side effects and/or steroid dependence during long-term budesonide treatment. Unfortunately available data with either azathioprine (or 6-mercaptopurine) and methotrexate in MC are extremely limited and inconclusive<sup>[18-20]</sup> despite their not infrequent use in clinical practice by gastroenterologists.

In the attempt to avoid colectomy in severe cases of MC refractory to any other pharmacological treatment, the possible use of biological agents has been tested, with promising results<sup>[21,22]</sup> but more conclusive data are needed.

Thus, long-term management of microscopic colitis remains elusive, especially in patients refractory or intolerant to budesonide, but even in subjects where the drug is effective but continuous intake for an indefinite length of time is not advisable. In those cases physicians must take therapeutic decisions irrespective of evidence-based data, tailoring the treatment on the characteristics and needs of the single patient. Even a recent treatment algorithm proposed by the European Microscopic Colitis Group<sup>[23]</sup> includes drugs such as loperamide, mesalazine, cholestyramine and bismuth, the efficacy of which is questionable and uncertain, pointing out the fact that the use of those medication is empirical. The same applies to immunosuppressants and anti-tumor necrosis factor agents, although the former, in spite of the scarce controlled data, appear to be a sensible and comparatively safe approach. Needless to say, randomized, controlled

studies with azathioprine or methotrexate are eagerly awaited and sorely needed.

### Abstract

Spleen has been considered a neglected organ so far, even though is strictly linked to liver. The spleen plays an important role in the modulation of the immune system and in the maintenance of peripheral tolerance *via* the clearance of circulating apoptotic cells, the differentiation and activation of T and B cells and production of antibodies in the white pulp. Moreover, splenic macrophages are able to remove bacteria from the blood and protect from sepsis during systemic infections. We review the spleen function and its assessment in humans starting from the description of spleen diseases, ranging from the congenital asplenia to secondary hyposplenism. From the literature data it is clear that obesity in humans affects different compartments of immune system, even though there are still few data available on the implicated mechanisms. The intent is to enable clinicians to evaluate the newly recognized role of metabolic and endocrine functions of the spleen with special emphasis to obesity and nonalcoholic fatty liver disease in the context of the available literature.

Moreover, understanding the spleen function could be important to develop appropriate prevention strategies in order to counteract the *pandemia* of obesity. In this direction, we suggest spleen longitudinal diameter at ultrasonography, as simple, cheap and largely available tool, be used as new marker for assessing splenic function, in the context of the so-called liver-spleen axis.

### INTRODUCTION

In vertebrate evolution, spleen functions were performed by a spleen-like tissue scattered along the digestive tract, as seen in lamprey. Bony fishes and sharks are the first

vertebrates where it appears as individual organ<sup>[1]</sup>.

The spleen is a secondary peripheral lymphoid organ located in the abdominal cavity between the diaphragm and the fundus of the stomach of mammals. Its principal function was preserved during the evolution in all animal classes having that organ, while important differences can be observed histologically. For example, the red pulp is seen only from bony fishes upwards.

It is the largest lymphoid organ in the human body and it has a fundamental role as destruction of red blood cells and as actor in the immune response, filtering the blood from antigenic particles and from abnormal and aged cells. Table 1 summarizes the different functions of the spleen.

The spleen anatomical architecture is extremely sophisticated and little is still known about specific processes that are performed in its differentiation. Mesenchymal, hematopoietic and endothelial cells interact each other thanks to complex, organized and still undiscovered signals leading to the development of its complex micro-architecture<sup>[2-4]</sup>.

## WHAT EVIDENCE HAS SUGGESTED SPLEEN BE CONSIDERED A NEGLECTED ORGAN?

The congenital asplenia may occur with or without other clinically evident abnormalities. In the first case, with asplenia, other defects of organs of the thoracic and abdominal cavities can be found. One example is the heterotaxy syndrome, where there is a failure in the left-right axis specification<sup>[5]</sup>.

If the defect occurs before the ontogenesis of the spleen on the left side, it may not affect splenic development. The second type of congenital asplenia is less common<sup>[6-10]</sup> and includes subjects with no other obvious abnormalities that report recurrent infections from childhood. In those cases the diagnosis of asplenia often remains unravelled, due to the lack of necroscopy.

Studies in mice have highlighted that some genes are crucial for spleen development, such as *Tcf21*, *Bapx1*, *Pbx1*<sup>[11]</sup> and recently also *Tlx1*<sup>[12]</sup>. In this case it can be expected that asplenic animals suffer from additional several anomalies caused by the deficiency of specific genes. However, in the literature are not reported corresponding cases, probably because in humans and mice similar genes do not have overlapping functions, or these subjects die before or soon after birth and/or they were not extensively investigated.

A suitable example may be the Atrx syndrome, where the mutations of this gene result in athalassemia, myelodysplasia and mental retardation<sup>[13]</sup>. Individuals with this syndrome occasionally exhibit asplenia<sup>[14]</sup>, but the inactivation of Atrx similar gene in mice does not end up in asplenia<sup>[15]</sup>.

In individuals with congenital isolated asplenia are reported some mutations<sup>[16]</sup>, but the molecular mecha-

| Release of immunoglobulins upon antigenic challenge by splenic B lymphocytes   |

nisms and the etiology of spleen development are still unknown.

## ANATOMICAL AND HISTOLOGICAL COMPOSITION OF THE SPLEEN (ANIMAL VS HUMAN MODEL)

In the mice the spleen has a characteristic histological organization similar to a sponge, where the fibrous capsule form a reticular network with the trabeculae stemming from its internal side. The splenic artery enters the hilum of the spleen, divides itself into smaller branches and finally gives rise to “central arteriolar” of the white pulp and to the large sinusoids of the red pulp. The central arteriolar are surrounded by a sheath of small T lymphocytes, the so-called PeriArteriolar Lymphoid Sheath (PALS). They communicate with follicles, a highly organized accumulation of T and B lymphocytes. The red pulp, PALS and follicles are also surrounded by the marginal zone, filled with large memory B cells.

The human and mice spleen are not anatomically different. The fact that patients with autoimmune thrombocytopenia purpura and circulating antiplatelet antibodies improve after splenectomy<sup>[17]</sup>, supports the role of the red pulp of the spleen in the displacement of old and damaged platelets, aged erythrocytes and apoptotic cells in humans.

After apoptosis of aged erythrocytes, hemoglobin is digested and iron is released or stored by splenic macrophages. Thus, the spleen is fundamental in the recycling of iron<sup>[18]</sup>.

Interestingly, after abdominal surgery for trauma or neoplasia, the displacement of the spleen is often without immediate consequences. This is one of the reasons for which, until a recent past, the spleen was considered not a vital organ. Consequently, it was believed that the spleen could be removed without major consequences. Recently, Ozban *et al.*<sup>[19]</sup> have disproved this theory, because they have shown that exercise in splenectomized individuals can cause serious problems in form of decreasing splanchnic flow and increasing blood viscosity.

The spleen plays an important role in the modulation of the immune system and in the maintenance of peripheral tolerance *via* the clearance of circulating apoptotic cells, the differentiation and activation of T and B cells and production of antibodies in the white pulp<sup>[20,21]</sup>. Moreover, splenic macrophages are able to remove bacteria from the blood and protect from sepsis during systemic infections.

*Vice versa*, most important differences between mice and humans in the spleen organization and functionality are revealed in the immune response. The marginal sinus in mice and the perifollicular zone in humans are areas of particular activity. B cells in the marginal zone in mouse are highly reactive and specialized against pathogens invasion *via* a T-independent reaction<sup>[20]</sup>, however in humans, the same area contains memory B cells<sup>[22]</sup>. Several chemokines and adhesion molecules regulate the trafficking between the marginal zone and the white pulp.

## ROLE OF SPLEEN IN LIMITING BACTERIAL INFECTION

As seen before, congenital asplenic subjects have an increased risk of developing infective diseases and the lack of the spleen functionality causes more startling effects in the newborn.

Morris *et al.*<sup>[23]</sup> firstly described in 1919 that splenectomized patients are more susceptible to infections, especially caused by *Haemophilus influenzae*, *Streptococcus pneumoniae* and *Neisseria meningitidis* (so called encapsulated bacteria)<sup>[23-25]</sup>. The risk of sepsis is 10- to 20-fold higher than non splenectomized population and, especially in young children, death can result<sup>[26]</sup>. Overwhelming post-splenectomy infection can occur some hours after the first signs of deterioration of health and can degenerate to multi-organ failure and death<sup>[27]</sup>. Most asplenic children die of infection during the neonatal period. In fact, among the causes of sudden and unexpected infant death, the congenital asplenia can also be included<sup>[28]</sup>.

Another condition is functional asplenia, when in patients with haematological or metabolic disorders the splenic tissue organization is altered and, for this reason, equally they develop the same type of infections. In patients with functional or anatomical asplenia is quite impossible to quantify the risk of developing infections and sepsis. Therefore, a method to conserve some splenic tissue during abdominal surgery with deracination of the spleen is to transplant small spleen fragments

into the well vascularised greater omentum. Clinical data have shown that this procedure has an important effect in increasing specific antibody responses after pneumococcal vaccination, as well as normalizing IgM levels<sup>[29,30]</sup>, and probably can also reduce the risk of opportunistic infections in immunodeficient subjects<sup>[31]</sup>. The increased susceptibility of hypo or asplenic individuals to encapsulated bacterial infections is mostly due to the lack of IgM memory B cells and to their not adherent reaction to polysaccharide vaccines. The absence of splenic macrophages with the reduced number of B cells in asplenic patients can result in the establishment of a favorable environment to the development of overwhelming bacterial infections.

## SPLEEN AND NATURAL ANTIBODIES

A particular subtype of B-cell population is involved in the immune deficiency and in the reduced response to polysaccharide antigens seen in the asplenic or splenectomized mice. B cells may be divided in two main subpopulations on the basis of life development (fetal or adult), surface markers and functions. Asplenic mice lack B-1a B cells<sup>[32]</sup>, a distinct population from the more conventional B-2 B cells that are involved in the adaptive immunity and collaborating with T cells<sup>[33]</sup>.

Functions of B-1a B cells are mainly three: (1) they can act in an T-cell independent mode during the immune response; (2) they produce natural antibodies and co-operate with the innate immune system to contrast bacterial and viral infections; and (3) in the intestinal mucosa they can differentiate into plasma cells producing IgA<sup>[34]</sup>.

In the specific immune response, produced antibodies have a very high affinity for a particular epitope and they can prevent re-infection from the single pathogen that previously has caused their own production. *Vice versa*, the pentameric IgM isotype produced by B-1a B cells binds various antigens with high avidity and low affinity and is therefore able to neutralize many different antigens. IgM antibodies are the so called “natural antibodies” and in recent years, it has been demonstrated that they may play a role in the protection against malignancy<sup>[35]</sup> and atherosclerosis<sup>[36]</sup>. Asplenic mice not only have a reduced number of B-1a B cells but they have a decreased concentration of serum IgM<sup>[32]</sup>.

B-1a B cells produce IgA immunoglobulins, and in the intestinal mucosa about half of the IgA plasma cells derives from B-1a B cells<sup>[37]</sup>. The homeostasis of the intestine is finely regulated by mucosal IgA. These immunoglobulins interact with antigens presented by the intestinal microbiota and by pathogens, preventing their overgrowth and subsequent invasion.

The precise reason why B-1a B cells are absent in asplenic mice and why their number rapidly declines after splenectomy is not yet defined. B-1a B cells are produced in the fetal liver, contrarily to B-2 B cells that derive from adult bone marrow. It is noteworthy to stress that the

first subtype cannot be replaced after adult bone marrow transplant. Moreover, Ig-positive precursors of B-1a B cells have been detected in the spleen, but it is unknown if these cells persist in the spleen during the adult life and derive from precursors situated in the fetal liver. According to a recent theory the spleen might be central to their generation or survival and therefore splenectomy would lead to the depletion of the B-1a population<sup>[32]</sup>.

## OTHER FUNCTIONS OF THE SPLEEN

An interesting hypothesis relates the spleen to the activity of gut-associated lymphoid tissue (GALT). The dysfunction of GALT is known to predispose to inflammatory bowel diseases (IBD), above all for its role in T cell activation and trafficking in the gut. Moreover, the frequency of IgM memory B cells is decreased in IBD subjects<sup>[38]</sup> establishing a relationship among GALT and spleen in humans.

The spleen also has important hematological functions. The spleen picks up from the circulation platelets that subsequently are stored or can be destroyed by lymphocytes. As storage organ the spleen stores about one third of the human body's platelets.

The thrombocytopaenia is a result of hypersplenism, because of the heightened functions of the spleen in sequestering and break-downing platelets. Conversely, after splenectomy mild thrombocytosis can be observed<sup>[39]</sup> because of the lack of sequestering and destruction of platelets by the spleen, and at the same time it can be observed a slight increase in platelet production in the bone marrow<sup>[40]</sup>. Erythrocytes are stored and removed from the blood circulation in this organ. After splenectomy, the presence in the blood of many substances released from circulating damaged erythrocytes with procoagulant activity can lead to the establishment of a procoagulant state and therefore to the occurrence of thromboembolic events (for example pulmonary embolism, deep vein and portal vein thrombosis).

Beyond haematopoietic stem cells, stem cells of other differentiation lines, such as stromal cells with osteogenic differentiation properties, seem to be present in the spleen, confirmed by *in vitro* studies<sup>[41]</sup>. It would be interesting to explore if in the spleen these osteogenic precursors may represent a monocyte/macrophage lineage common precursor cell population with the ability to differentiate along the osteoclast lineage<sup>[42]</sup>. Animal studies have also shown that splenocytes can differentiate into pancreatic islets and ductal epithelial cells when injected into diabetic non-obese diabetic mice, thereby splenocytes may be useful in the treatment of type 1 diabetes, thanks to their ability of restoring normal glycaemia<sup>[43,44]</sup>. Subsequently, Chong *et al.*<sup>[45]</sup> have questioned the origin of these stem cells.

## ASSESSMENT OF SPLEEN FUNCTION

Over the years, several methods have been developed to

study the activity of the spleen. Because of its ability in purifying the blood from old erythrocytes, the amount of altered red blood cells can be used as index of functionality of the spleen. The detection of Howell-Jolly bodies is one of these, although the sensitivity and specificity are questionable for the hyposplenism<sup>[46,47]</sup>. Other haematological parameters are finding membranes pits, large vacuoles situated near to the plasma membrane, or other cellular changes as acanthocytes, target cells, Heinz bodies (remnants hemoglobin), Pappenheimer bodies (iron granulocytes) and siderocytes<sup>[48]</sup>.

The count of B cells derived from the marginal zone, which have fundamental action in innate immunity, and in particular as defense against the invasion by encapsulated bacteria, is otherwise a possible method for evaluating the immunological activity of spleen<sup>[49]</sup>. B cells derived from the marginal zone and the memory cells producing IgM are in fact reduced in patients with diminished splenic function<sup>[38]</sup>.

All the tests described above could be used with ease in clinical practice, on the other hand they have proved not to be very sensitive and specific, or they are needed to be further studied and validated<sup>[46,50]</sup>.

To date, the radioisotope method is definitely the best way to quantify the filtering activity of the spleen. The (99m) Tc-labeled, heat-altered, autologous erythrocyte scintigraphy with multimodality single photon emission computed tomography (CT) - technology is considered the best approach to gauge all the facets of the splenic function<sup>[51]</sup>. However, this is a method that has the highest cost and it is difficult to perform.

## SPLEEN AS A NEW PLAYER

Nonalcoholic Fatty Liver Disease (NAFLD), the most common cause of liver steatosis, is associated with obesity, mainly visceral type, and insulin resistance. The liver inflammation (nonalcoholic steatohepatitis, the so called NASH) can progress from the simple hepatic steatosis or fatty liver (FL) lasting risk factors, as type 2 diabetes mellitus, major obesity and Metabolic Syndrome (MS). In its natural history, NASH can end up in perisinusoidal fibrosis and cirrhosis. Hepatocytes, during steatosis, are fat-laden and swollen, and in steatohepatitis the hydropic change (ballooning) causes further swelling and also sinusoidal distortion, as visualized by *in vivo* microscopy studies. This evenience leads to the reduction of intrasinusoidal volume and microvascular blood flow, as clearly described by Farrell *et al.*<sup>[52]</sup>. Sinusoidal endothelial cells, Kupffer cells and stellate cells are also involved in the pathological process in conjunction with the activation of the immune system. The microcirculation is skewed by inflammatory cells and platelets recruited in the liver. Animal models confirm these data and evidence that these pathological changes lead to a marked reduction of sinusoidal space (approximately 50% of control), and a decrease in the number of normally perfused sinusoids, according to a review, recently published<sup>[51]</sup>. The micro-

vascular damage is necessary for developing further liver injury and causing disease progression as in NASH. The lipid peroxidation of unsaturated fatty acids by reactive oxygen species is one of the main causes of the sensitivity of hepatic steatosis to ischemia-reperfusion injury. During the whole 24-h-period the most part of time is spent in postprandial state in humans. Therefore, the liver has a fundamental role in maintaining the correct energy state balancing the input, secretion, and oxidation of fatty acids. In abdominally obese men the oxidation of dietary fatty acids, hepatic desaturation and elongation of palmitic acid occur to a greater extent than in non-obese<sup>[53]</sup>.

This means, therefore, that donor's fatty livers are an obstacle to transplantation<sup>[52]</sup>. Between other hepatic cells, the dysfunction of Kupffer cells gives a major contribution to NASH progression. It is noteworthy that the reticular-endothelial system also plays a key role in the spleen and a good method for study Kupffer cell activity is the colloid scintigraphy. Duman *et al*<sup>[54]</sup> have followed 22 patients with biopsy-proven NASH who underwent colloid liver scintigraphy. Liver right/left lobe ratio was altered in all patients after intravenous injection of 185 MBq Tc tin colloid. The shift of colloid to the spleen and a prolonged blood pool clearance time was observed in 55% of patients with NASH.

Previously, Tsushima *et al*<sup>[55]</sup> aimed to determine if there was an association between spleen enlargement and NAFLD, measuring spleen volume at CT. It must be observed that the values were weighted according to the patient's demographic data, the Liver/Spleen (L/S) ratio of CT Hounsfield unit measurements, and liver function tests. L/S ratio was also used to perform the diagnosis. The authors evidenced an increased mean spleen volume ( $P < 0.0001$ ) between NAFLD and controls  $73.0 \pm 24.4 \text{ cm}^3$  (range, 21.1-106.1) in normal subjects and  $141.2 \pm 54.1 \text{ cm}^3$  (range, 44.1-267.3) in NAFLD subjects. Only the L/S ratio ( $P < 0.0001$ ) and age ( $P < 0.01$ ) were significantly correlated to spleen volume at multivariate linear regression analysis and at forward selection stepwise regression.

Basing on the evidence that obesity and insulin resistance are inflammatory chronic diseases and therefore are associated with systemic markers of inflammation, some scholars have attempted to find a non invasive diagnostic method for NASH to help clinicians to decide whether and when to perform liver biopsy.

Patients with histology proven-NAFLD (43 patients with NASH and 40 with FL), compared with healthy subjects, were evaluated with ultrasonographic exams, with particular interest to ultrasonographic spleen longitudinal diameter (SLD) and splenic artery resistive index, and laboratory measurements, as serum interleukin (IL)-6 and vascular endothelial growth factor (VEGF) concentrations. The NASH group demonstrated higher IL-6 blood levels, SLD values, and VEGF concentrations than controls. In this study was estimated that the SLD is more sensitive than IL-6 and VEGF in discriminating NASH from FL, and the optimal cut-off value for SLD is 116 mm (specificity 95% and sensitivity 88%). NASH and FL

subjects have a similar splenic artery resistive index, but it differs when compared with controls. On the other hand, normal values of SLD and IL-6 were associated with FL and normal values of IL-6 could confirm the absence of NASH<sup>[56]</sup>. Further confirmation of these findings comes from another study which highlighted that spleen enlargement may be a distinct feature of NASH, especially early-stage NASH<sup>[57]</sup>. Therefore, we suggest that SLD could be used as new marker for assessing splenic function, independently from its use in distinguishing the simple FL, also called benign, from NASH, the more severe form of NAFLD, benignity not always shared<sup>[58]</sup>.

In this study<sup>[59]</sup>, SLD and blood pressure were significantly correlated with insulin resistance, moreover measures of SLD were well predicted by body mass index values.

To let Authors duplicate this finding, SLD was measured by postero-lateral scanning. It was used the average value obtained by measuring the maximum length and the cranio-caudal diameter. All the indices were measured thrice.

A subsequent study showed that spleen enlargement was found at significant levels (38%) in obese female rats as determined by Cavalieri volume calculation, an unbiased stereological method<sup>[60]</sup>. These recent results clearly indicated that high fat diet caused splenomegaly *via* sinusoidal dilatation and intracellular or intercellular deposits<sup>[61]</sup>. Although these data are encouraging to find a non-invasive method for NAFLD diagnosis, liver biopsy remains the only reliable method to differentiate simple steatosis or FL from NASH in NAFLD subjects<sup>[58]</sup>. On this line, Kikuchi *et al*<sup>[62]</sup> evaluate the efficacy of non-invasive (99m) Tc-phytate scintigraphy in the diagnosis of NASH in humans and in a rat model. In the first study, patients with suspected NAFLD underwent liver biopsy and (99m) Tc-phytate scintigraphy. As region of interest, signal intensities of the liver and spleen were measured. Subsequently, they observed that the L/S uptake ratio at scintigraphy was significantly decreased in NASH subjects when compared to patients with FL. The L/S ratio was an independent predictor in distinguishing NASH from FL. More interestingly, the decrease of L/S ratio was found in all NASH stages, from its earliest stages (stages 1 and 0). In the second study, the authors induced NASH in rats feeding them with a Methionine- and Choline-Deficient (MCD) diet. In this case, the L/S uptake ratio was also significantly decreased after 8 wk of a MCD diet in comparison with control diet-fed rats. From these data, the authors concluded that non-invasive (99m) Tc-phytate scintigraphy is able to discriminate NASH from FL.

GALT: Gut-associated lymphoid tissue; NAFLD: Nonalcoholic fatty liver disease; SLD: Spleen longitudinal diameter; VEGF: Vascular endothelial growth factor; IL-6: Interleukin-6; NASH: Nonalcoholic steatohepatitis.

found in patients with hypersplenism are observations that suggest a possible role for the spleen in lipid metabolism and in the etiology of atherosclerosis<sup>[63]</sup>. Previous studies showed that obese subjects, compared to non-obese, have an increased risk to develop cardiovascular disease, hypertension, cerebrovascular disease and type 2 diabetes mellitus. But, it is equally important that they have an impaired immune function, as demonstrated by the higher incidence of malignancies and infections. From the literature data it is clear that obesity in humans affects different compartments of immune system, even though there are still few data available on the implicated mechanisms. Elderly people (> 60 years of age) have

an increased risk of infection, showing their peripheral blood lymphocytes a decreased reactivity to mitogens and an impaired proliferative capacity<sup>[64,65]</sup>. The response of T lymphocytes to concanavalin A and response of B lymphocytes to pokeweed mitogen are decreased in obese subjects<sup>[66]</sup>. In addition to the T lymphocyte population, also natural killer cell activity is suppressed in obese men and women > 60 years of age, as mentioned in a report made by Moriguchi *et al*<sup>[66,67]</sup>. Moreover, the natural killer cells activity and percentage of body fat are negatively correlated in both elderly women<sup>[68]</sup>, and middle-aged men<sup>[69]</sup>. These data suggest that obesity is a risk factor for the progressive deteriorating of cellular immune functions. The pathophysiological mechanisms by which cellular immune functions are affected by obesity are still under investigation but the spleen may have an important role. In the splenic lymphocytes of obese mice, the expression of glucose transporter 1 (GLUT-1), analyzed by Western blot analysis, was lower compared to lean rats. The decreased expression of GLUT-1 in these rats is associated with a defective uptake of glucose into immune cells. It is probable that the decreased proliferation of splenic lymphocytes in obese rats is connected to the decreased expression of GLUT-1 and therefore to an impairment of glucose uptake<sup>[69]</sup>. An interesting report by Miyake *et al*<sup>[70]</sup> evaluates NAsFLD mice fed high-fat and high-calorie diet for 12 wk for assessing the extent of antigen-specific immunity response. NAFLD mice and control mice were immunized with hepatitis B vaccine containing hepatitis B surface antigen (HBsAg) and hepatitis B core antigen (HBcAg) and, subsequently, antibody to HBsAg (anti-HBs) blood levels, HBsAg and HBcAg-specific cellular immune response and functions of whole spleen cells, T lymphocytes, B lymphocytes and spleen dendritic cells (DCs) of NAFLD and control mice were assessed *in vitro*. Interestingly, in NAFLD mice levels of anti-HBs and the proliferation activity of HBsAg and HBcAg-specific lymphocytes were significantly lower compared to controls. Higher levels of inflammatory cytokines were produced and T cells have showed an increased proliferation rate in spleen cells of NAFLD than lean mice. Concurrently, DCs processing and presenting antigen activities were significantly decreased in the spleen of NAFLD mice compared to controls. Moreover, the administration of saturated fatty acids caused impaired antigen processing and presenting capacity of murine DCs. These data emphasize that the modification of antigen-specific immunity in NAFLD mice depends on the action different types of immunocytes, including DCs and lymphocytes, clarifying the role of the spleen in this specific pathological process.

## FUTURE PERSPECTIVES

This paper reports the studies on the use of simpler parameters in assessing the need for medical intervention with respect to healthy and non healthy overweight/obese individuals.

In a not too distant past, the spleen has been considered a neglected and expendable organ. In portal hypertension it was considered an ancillary organ<sup>[71-74]</sup> and it has some importance in infectious disease or as organ localization in lymphoproliferative diseases.

As described before, Table 2, now the spleen is deemed an important component of the immune system, crucial in immune response regulation<sup>[55,75,76]</sup>, and also it has a metabolic asset and it is involved in endocrine function with regard to NAFLD<sup>[51]</sup>.

It is suggested that adoption of a simpler tool to perform measurements could not only reduce the cost of medical care but also provide more reliable identification of patients in need of weight loss<sup>[77-80]</sup>.

Larger and well-implanted studies comprehending better characterized patients should be taken into account to ascertain the validity of this tool.

### Abstract

Hepatic cysts are increasingly found as a mere coincidence on abdominal imaging techniques, such as ultrasonography (USG), computed tomography (CT) and magnetic resonance imaging (MRI). These cysts often present a diagnostic challenge. Therefore, we performed a review of the recent literature and developed an evidence-based diagnostic algorithm to guide clinicians in characterising these lesions. Simple cysts are the most common cystic liver disease, and diagnosis is based on typical USG characteristics. Serodiagnostic tests and microbubble contrast-enhanced ultrasound (CEUS) are invaluable in differentiating complicated cysts, echinococcosis and cystadenoma/cystadenocarcinoma when USG, CT and MRI show ambiguous findings. Therefore, serodiagnostic tests and CEUS reduce the need for invasive procedures. Polycystic liver disease (PLD) is arbitrarily defined as the presence of > 20 liver cysts and can present as two distinct genetic disorders: autosomal dominant polycystic kidney disease (ADPKD) and autosomal dominant polycystic liver disease (PCLD). Although genetic testing for ADPKD and PCLD is possible, it is rarely performed because it does not affect the therapeutic management of PLD. USG screening of the liver and both kidneys combined with extensive family history taking are the cornerstone

of diagnostic decision making in PLD. In conclusion, an amalgamation of these recent advances results in a diagnostic algorithm that facilitates evidence-based clinical decision making.

### INTRODUCTION

Hepatic cystic lesions represent a comprehensive heterogeneous cluster with regard to pathogenesis, clinical presentation, diagnostic findings and therapeutic management (Table 1). Hepatic cystic lesions predominantly remain asymptomatic and are found as a mere coinci-

dence on abdominal imaging techniques, such as ultrasonography (USG), computed tomography (CT) and magnetic resonance imaging (MRI)<sup>[1,2]</sup>. The use of these techniques has greatly increased over the last years, and as a corollary, there has been an increase in incidental findings of asymptomatic hepatic cystic lesions<sup>[3]</sup>. In most cases, hepatic cystic lesions will follow a benign course<sup>[4]</sup>. However, it is essential to differentiate benign cysts from potentially harmful cysts, such as echinococcosis, cystadenoma and cystadenocarcinoma, which require specific treatment<sup>[5,6]</sup>. Currently, clinicians must also be aware of changes in the epidemiology of certain hepatic cystic lesions. Echinococcosis has spread to previously non-endemic Western European countries<sup>[7,8]</sup>. For this reason, the early and accurate diagnosis of cysts is crucial. To facilitate the diagnostic process, we provide an overview of the wide spectrum of mono- and polycystic liver diseases based on literature published over the last five years.

## LITERATURE SEARCH

We searched the electronic database PubMed using the following search terms: “liver” and “cyst” and “diagnosis”. We limited our search to articles that were written in English, published between November 2007 and November 2012 and available in full text. A total of 992 articles were identified. For the purpose of this review, we included articles with a main focus on the evaluation of hepatic cystic lesions in humans. Screening the titles and abstracts identified 252 articles meeting these inclusion criteria (Figure 1). Additionally, we searched the reference lists from all eligible reviews for additional leads.

## SIMPLE CYSTS

### Pathogenesis

Simple cysts arise congenitally from aberrant bile duct cells and contain a clear, bile-like fluid<sup>[9]</sup>. Because bile duct epithelium covers the simple cyst inner lining, it is hypothesised that simple cysts arise during embryogenesis when intrahepatic ductules fail to connect with extrahepatic ducts<sup>[4,10]</sup>.

### Clinical features

The prevalence of simple cysts ranges from 2.5% to 18% and increases with age<sup>[11,12]</sup>. More than half of individuals older than 60 years are likely to have one or more simple cysts. Cysts are small in most patients but can grow to over 30 cm in selected cases. In a small fraction of patients, symptoms, such as abdominal pain, early satiety, nausea and vomiting, arise as a result of a mass effect<sup>[3]</sup>. Physical examination may reveal a palpable abdominal mass or hepatomegaly<sup>[1]</sup>. Complications such as haemorrhage, rupture and biliary obstruction are uncommon but are more likely in larger cysts<sup>[13]</sup>. Intracystic haemorrhage is a rare complication of simple cysts and usually presents with severe abdominal pain<sup>[14]</sup>, although asymptomatic presentations are also observed<sup>[15,16]</sup>.

| Autosomal dominant polycystic kidney disease |
| Autosomal dominant polycystic liver disease  |

### Laboratory findings

Laboratory findings are predominantly normal, but a minority of patients have raised serum  $\gamma$ -glutamyl-transferase ( $\gamma$ GT)<sup>[17]</sup>. Several studies have shown that serum and cyst fluid levels of carcinoembryonic antigen (CEA) and cancer antigen 19-9 (CA 19-9) may be elevated<sup>[18]</sup>. CA 19-9 is expressed in the simple cyst inner epithelial lining and leads to elevated cyst fluid and serum CA 19-9 levels<sup>[17]</sup>. CA 19-9 is not helpful in the differential diagnosis of intracystic haemorrhage<sup>[19]</sup>.

### Diagnostic features

Most simple cysts are diagnosed incidentally on USG (Figure 2A), CT (Figure 2B) or MRI. The diagnosis of a simple cyst is based on the following USG criteria: anechoic (*i.e.*, fluid filled cavity), no septations, sharp smooth borders, strong posterior wall echoes (indicating a well-defined fluid/tissue interface), spherical or oval shaped and a relative accentuation of echoes beyond the cyst compared to echoes at a similar depth transmitted through normal adjacent hepatic tissue (Table 2)<sup>[20]</sup>. CT shows a sharply defined homogeneous hypodense lesion (Figure 2B)<sup>[21]</sup>. MRI T1-weighted sequence shows low signal intensity, whereas the T2-weighted sequence shows extremely high signal intensity, which does not enhance after contrast injection<sup>[22]</sup>. USG has a reported sensitivity and specificity of approximately 90% for diagnosing a simple cyst<sup>[23]</sup>, and recent advances in CT and MRI technology might result in even higher sensitivity rates<sup>[12,22,24]</sup>. However, because CT is accompanied with a radiation load and both CT and MRI come at a significantly higher cost, USG remains the most accurate, non-invasive and cost-effective imaging modality for diagnosing simple cysts.

In case of an intracystic haemorrhage (*i.e.*, complicated cyst), USG typically shows a hyperechogenic echo pattern combined with internal echoes that mimic septations or solid portions (Figure 3)<sup>[25]</sup>. In contrast, CT visualises intracystic haemorrhage as a high-density area<sup>[26]</sup>, whereas MRI depicts it as a high signal intensity on T1- and T2-weighted sequences<sup>[27]</sup>. Neither CT nor MRI has additional diagnostic value compared to USG in the diagnosis of cystic bleeding<sup>[15]</sup>. The recent development of microbubble contrast-enhanced ultrasound (CEUS) enables us to visualise vascular flow within septa or solid components of cysts, which is absent in simple cysts with intracystic

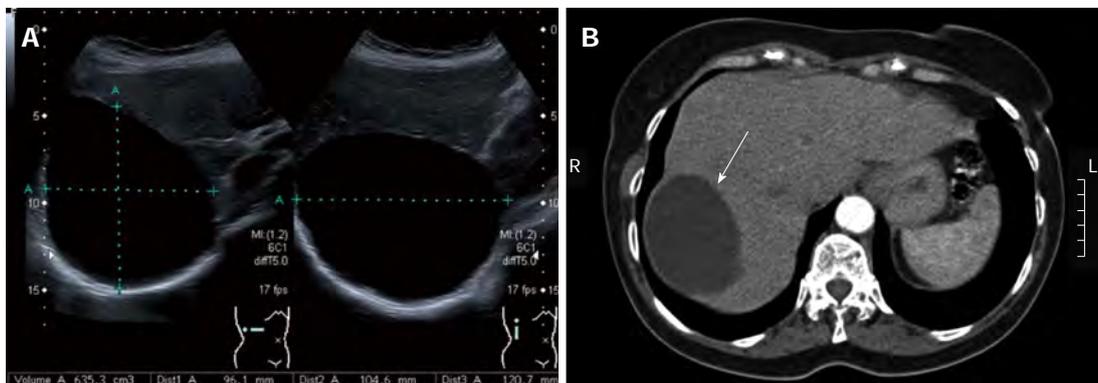

Figure 2 Simple cyst. A: On abdominal ultrasonography. Ultrasonography (USG) demonstrating a large simple cyst occupying the right hepatic lobe. Note the sharp and smooth border, oval shape, and anechoic echo pattern with the absence of septations and strong posterior wall echoes. The cyst size is indicated by the dotted lines; B: On abdominal computed tomography. Computed tomography demonstrating a sharply defined homogeneous hypodense cystic lesion (arrow) occupying the right hepatic lobe, which was diagnosed as a simple cyst.

haemorrhage<sup>[28]</sup>. Therefore, CEUS can accurately characterize these cysts when USG, CT and MRI show ambiguous findings<sup>[29-31]</sup>.

### Therapy

The management of most simple cysts relies on a “wait-and-see” policy, and no further treatment is required in these cases. If there are symptoms, aspiration-sclerotherapy is the preferred treatment<sup>[32,33]</sup>. Laparoscopic or open surgical fenestration techniques are similarly or even more effective in reducing symptoms<sup>[34,35]</sup> but have a significantly higher morbidity and mortality rate<sup>[36]</sup>.

## ECHINOCOCCOSIS

Echinococcosis is a zoonosis caused by larval stages of taeniid cestodes (tapeworms) belonging to the *Echinococcus* species. Two of the six known species cause solitary cystic lesions in humans: (1) *Echinococcus granulosus* (*E. granulosus*), responsible for cystic echinococcosis (CE); and (2) *Echinococcus multilocularis* (*E. multilocularis*), responsible for

alveolar echinococcosis (AE)<sup>[6]</sup>.

Echinococcosis-related deaths are uncommon in developed countries. For example, there were 41 echinococcosis-associated deaths in the United States over an 18-year study period<sup>[37]</sup>. However, echinococcosis is considered to be an emerging disease in Europe<sup>[38,39]</sup>. Thus, CE and AE are diseases with a considerable global disease impact, as indicated by a substantial loss in disability-adjusted life years<sup>[38,40]</sup>.

### Cystic echinococcosis

**Pathogenesis:** Humans become infected by acting as intermediate hosts of *E. granulosus* after ingestion of *Echinococcus* eggs, which are excreted by infected carnivores (dogs and other canids)<sup>[6]</sup>. Infection is typically observed in areas containing large numbers of the intermediate hosts of the parasite (sheep and goats) that are in close contact with the final host (herding dogs)<sup>[41-43]</sup>.

**Clinical features:** Although CE has a worldwide geographic distribution, the highest prevalence of CE is

**Table 2** Ultrasonography features for the diagnosis of monocytic diseases of the liver

|                            | Simple cyst                                  | Cystic echinococcosis             | Alveolar echinococcosis                            | Cystadenoma and cystadenocarcinoma                       |

<sup>1</sup>Fluid-filled cavity; <sup>2</sup>Snowflake-like inclusions or floating laminated membranes; <sup>3</sup>Compared to echoes at a similar depth transmitted through normal adjacent hepatic tissue.

**Figure 3** Complicated simple cyst on abdominal ultrasonography. Ultrasonography (USG) demonstrating a cystic lesion with a hyperechogenic echo pattern combined with internal echoes that mimic septations or solid portions (arrow) in a patient presenting with severe abdominal pain with a known history of multiple simple cysts (asterisks). Because of the known history of simple cysts, the lesion was diagnosed as a complicated simple cyst (*i.e.*, intracystic haemorrhage).

found in the temperate zones, including the Mediterranean, Central Asia, Australia and some parts of America<sup>[44]</sup>.

Because cyst growth in the liver is slow (ranging from 1-5 millimetres in diameter per year), CE can remain asymptomatic for a long time. In approximately 90% of cases, the primary presentation is a spherical, fluid-filled vesicle with an inner cellular layer and an outer laminated layer located in the liver, lungs or both<sup>[45]</sup>. Symptoms occur when cysts exert mass effects within the organ or surrounding tissues or rupture, often presenting as a sudden onset of abdominal pain. Secondary cholangitis (rupture into the biliary tree), biliary obstruction and intraperitoneal rupture followed by anaphylaxis are common complications of CE and require hospitalisation<sup>[6]</sup>. Worldwide mortality rate estimates vary between 2.2%-5.0%<sup>[45,46]</sup>, although the exact mortality rate of CE in developed countries remains unknown.

**Diagnostic features:** The diagnosis of CE is based on the following criteria: endemic region history, clinical findings (*e.g.*, abdominal pain, fever, chest pain, and dyspnea), pathognomonic USG features and positive

immuno diagnostic tests<sup>[47]</sup>. USG shows a round or oval-shaped, anechoic or atypical (*i.e.*, snowflake-like inclusions or floating laminated membranes) echo pattern with multiple septa confined by a laminated border (Table 2)<sup>[47]</sup>. USG has a reported specificity of 90% and is used in combination with CT when surgical treatment is considered. MRI has not been proven to be cost-effective and has no added value<sup>[48]</sup>. The currently used serodiagnostic tests to reveal *E. granulosus* antibodies have a sensitivity of 93.5% and specificity of 89.7%<sup>[49]</sup>.

**Therapy:** The treatment of CE, including surgery (open or laparoscopic), percutaneous treatments [*e.g.*, puncture aspiration injection re-aspiration (PAIR) method] and chemotherapy<sup>[50]</sup>, is indicated to reduce symptoms and prevent complications<sup>[51]</sup>. PAIR is the treatment of choice for CE, as a recent review showed that PAIR resulted in parasitological clearance (*i.e.*, negative serodiagnostic tests) in 95.8% of cases<sup>[52]</sup>.

### Alveolar echinococcosis

**Pathogenesis:** AE is endemic in the Northern hemisphere (*e.g.*, North America, Asia, China, Japan and Europe). AE occurs when *E. multilocularis* eggs, found in the excrement of foxes, are ingested. The spread from endemic areas to previously non-endemic Western European countries is most likely due to an increasing fox population and spillover from these wild carnivores to domestic hosts<sup>[7,8]</sup>.

**Clinical features:** The ingested eggs develop into an alveolar structure composed of numerous small vesicles that vary in diameter from smaller than 1 mm to 3 cm. Each vesicle has the same wall structure as CE. These vesicles grow slowly and are able to reach a maximum diameter of 15-20 cm, similar to simple cysts<sup>[53]</sup>. In approximately 99% of cases, the infection is initially confined to a solitary alveolar lesion in the liver<sup>[45]</sup>. After the primary infection, AE usually has an asymptomatic phase of 5-15 years prior to the development of symptoms. Symptoms are related to mass effect or are nonspecific, such as weight loss or fatigue<sup>[54]</sup>. In contrast to the encapsulated growth pattern of CE, AE eventually leads to liver failure

due to an infiltrative neoplastic growth with potential metastasis to adjacent and distant (*e.g.*, lungs, spleen, bone, and brain) organs<sup>[55,56]</sup>.

**Diagnostic features:** Typical USG aspects are observed in 70% of cases and include irregular shape and border, hyperechogenic outer ring and hypoechogenic centre, multivesicular appearance and dorsal shadowing due to calcified areas (Table 2)<sup>[47]</sup>. Atypical USG aspects include small hyperechogenic nodules (amorphous AE), large lesions with massive necrosis (pseudocyst) and small calcified lesions (inert AE)<sup>[57]</sup>. In contrast to CE, MRI is superior to CT in detecting AE lesion margins<sup>[58,59]</sup>. Similar to CE, high diagnostic sensitivity (90%-100%) and specificity (95%-100%) are attained with serodiagnostic tests, and in 80%-95% of cases, AE can be differentiated from CE with the help of serologically obtained purified *Echinococcus* antigens<sup>[60]</sup>.

**Therapy:** The approach to the management of AE resembles that of a hepatic malignancy. The cornerstone of treatment for AE includes radical surgery followed by a 2-year period of chemotherapy<sup>[6]</sup>. A recent study concluded that AE can be cured in 42% of cases by complete surgical removal of the parasitic mass. Early diagnosis could even improve this rate further<sup>[61]</sup>.

## CYSTADENOMA AND CYSTADENOCARCINOMA

### Pathogenesis

Cystadenoma and cystadenocarcinoma are biliary cyst tumours that originate from the biliary epithelium<sup>[62]</sup>. Analogous to simple cysts, cystadenoma is considered to be a congenital disorder<sup>[63]</sup>. The exact mechanism of carcinogenesis in cystadenoma remains unknown. Several studies have suggested that cystadenocarcinoma develops from the ectopic remnants of primitive foregut sequestered within the liver<sup>[63]</sup>. In contrast, the malignant transformation of cystadenoma into cystadenocarcinoma is considered to be an alternative mechanism of carcinogenesis, as some cystadenocarcinomas may co-exist with cystadenoma<sup>[64]</sup>. This hypothesis is supported by the observation that the presence of cystadenoma increases the chance of developing cystadenocarcinoma<sup>[65]</sup>.

### Clinical features

Less than 5% of all cystic lesions of the liver are cystic neoplasms<sup>[2]</sup>. The clinical presentation of cystadenoma and cystadenocarcinoma is asymptomatic or tends to mimic symptoms of simple cysts or echinococcosis<sup>[66,67]</sup>. Studies have reported a predominance in women, with a mean age of onset varying from 40-60 years<sup>[64,65]</sup>. Cystadenomas appear to be slow growing, but exact growth rates are unknown. One case series evaluated 75 patients and recorded a variability in cyst size from 1.5-35 cm<sup>[68]</sup>. One study involving 63 cases diagnosed with cystadenocarcinoma demonstrated infiltrative growth in neighbour-

ing organs in 33 cases (52%) and distant metastases in 15 cases (24%)<sup>[5]</sup>. For that reason, it is necessary to diagnose cystadenocarcinoma in an early stage.

### Laboratory findings

In general, liver function tests are normal. A review of 13 cases found that serum concentrations of  $\gamma$ GT and alkaline phosphatase (AP) were elevated in 3 cases<sup>[69]</sup>. One study reported a rise in serum levels of CEA in 3 of 22 cystadenocarcinoma cases (14%) and a rise in the serum concentration of CA 19-9 in 4 of 11 cases (36%)<sup>[5]</sup>. Similar results have been reported in cases with cystadenoma: one study showed elevated serum concentrations of CEA or CA 19-9 in 2 of 3 cases<sup>[63]</sup>. Consequently, laboratory studies are not helpful in differentiating cystadenoma and cystadenocarcinoma from complicated cysts or echinococcosis.

### Diagnostic features

The USG characteristics of cystic neoplasms for both cystadenoma and cystadenocarcinoma are the following: a round or oval shape, irregular border, hypoechogenic echo pattern with hyperechogenic septations or solid structures (*i.e.*, papillary projections), wall enhancement and dorsal shadowing due to calcified areas (Table 2)<sup>[2]</sup>. Because of these typical cystic neoplastic features, which are absent in simple cysts, USG is a useful technique to easily discriminate between cystic neoplasms and simple cysts<sup>[2]</sup>. Like USG, CT and MRI show markedly similar characteristics for cystadenoma and cystadenocarcinoma: internal septations, thickened and irregular wall, papillary projections, calcifications and wall enhancements<sup>[62]</sup>. Cystadenomas predominantly have thinner septa and more regular walls<sup>[70]</sup>, whereas solid structures, intracystic haemorrhage and vascularised septations on contrast-enhanced CT are more suspicious for cystadenocarcinoma<sup>[62]</sup>. However, in most cases, differentiation between cystadenoma and cystadenocarcinoma is not possible<sup>[1]</sup>. The same problem arises in differentiating echinococcosis and complicated cysts from cystadenoma and cystadenocarcinoma because in many cases, intracystic haemorrhage, calcifications and septations are present in these lesions<sup>[2,62]</sup>.

Recent advances in technology have made diffusion-weighted magnetic resonance imaging (DWI) a promising MRI technique for liver lesion detection and characterisation<sup>[71]</sup>. DWI depicts the rate of diffusion of water molecules between tissues, given as the apparent diffusion coefficient (ADC)<sup>[72]</sup>. Generally, high ADC values are measured in cystic and necrotic tissue, which allow a relatively free diffusion of water, whereas low ADC values are an indication of cell-rich tissue (*e.g.*, tumour tissue)<sup>[22,73,74]</sup>. However, because of an overlap of ADC values, differentiating cystic neoplasms, echinococcosis and complicated cysts is not possible with DWI<sup>[75]</sup>. Therefore, additional immunodiagnostic tests are needed to rule out echinococcosis. Fine needle aspiration (FNA) could be of additional help to exclude complicated cysts<sup>[76]</sup>; however, due to the risk of malignancy, FNA is generally

not performed. In contrast, CEUS can be helpful in differentiating cystadenoma and cystadenocarcinoma from complicated cysts when USG, CT or MRI is inconclusive. CEUS characterises the vascular flow within septa in cystadenoma and cystadenocarcinoma, which is absent in complicated cysts<sup>[29-31]</sup>. Nonetheless, surgical resection remains the golden standard for diagnosing cystadenoma and cystadenocarcinoma when CEUS is not available.

### Therapy

The primary treatment of cystadenoma and cystadenocarcinoma is hepatic resection. A study in which 66 cases of cystadenocarcinoma were subjected to hepatic resection described a 3-year survival rate of 74%<sup>[5]</sup>.

## PCLD AND ADPKD

### Polycystic liver disease

Polycystic liver disease (PLD) is arbitrarily defined as the presence of > 20 liver cysts<sup>[77]</sup>. Autosomal dominant polycystic liver disease (PCLD) and autosomal dominant polycystic kidney disease (ADPKD) are two distinct genetic disorders associated with the development of polycystic livers<sup>[78]</sup>. Liver function, as judged by parameters of liver synthesis, is not affected in PLD, as functional hepatic tissue remains unaffected<sup>[77,79]</sup>.

### Pathogenesis

During embryogenesis, the intrahepatic bile ducts are formed from a cylindrical layer of cells (*i.e.*, ductal plate) surrounding each portal vein. Incorrect involution of the ductal plate results in ductal plate malformation (DPM)<sup>[80,81]</sup>. DPM consists of excess embryonic bile duct structures in a ductal plate configuration that does not communicate with the normally developed intrahepatic bile ducts. The progressive dilatation of these excess intrahepatic structures during life results in multiple liver cysts<sup>[82]</sup>. Similar to simple cysts, these cysts contain a clear, bile-like fluid and an inner lining of cholangiocytes<sup>[83]</sup>.

### Genetics

PCLD was historically considered a phenotypic variant of ADPKD<sup>[84]</sup>. However, the presence of PLD in the absence of renal cysts led to the belief that PCLD should be regarded as a separate entity<sup>[85]</sup>. The discovery of a familial form of PLD<sup>[86]</sup>, genetically distinct from the heterozygous mutation in genes *PKD1* and *PKD2* identified in ADPKD<sup>[87]</sup>, ultimately led to the identification of heterozygous mutations in genes encoding *SEC63* and *PRKCSH*<sup>[88-90]</sup>. Mutation analysis identified a heterozygous mutation in *PRKCSH* (15%) and *SEC63* (5%) in approximately 20% of studied PCLD cases<sup>[91]</sup>. In contrast, a *PKD1* mutation was found in 85% of cases of ADPKD, and a *PKD2* mutation was found in the remaining cases<sup>[92]</sup>.

*PRKCSH* and *SEC63* encode hepatocystin and SEC63 proteins, respectively. Hepatocystin acts in the folding process of proteins, while SEC63 acts as part of

the endoplasmic reticulum translocon<sup>[93]</sup>. Unfortunately, the exact mechanism of cystogenesis in PCLD remains unclear. Polycystin 1 and 2, encoded by *PKD1* and *PKD2*, respectively, are important for adequate functioning of the primary cilium<sup>[94]</sup>. It is therefore suggested that primary cilia play a central pathogenic role in the mechanism of hepatic cystogenesis in ADPKD<sup>[78]</sup>.

### Clinical features

The extra polarisation of 137 identified PCLD cases in a specific adherence region (the Netherlands) led to an estimated PCLD prevalence of 1 per 158000<sup>[77]</sup>. This number is most likely an underestimation of the true prevalence because only symptomatic patients referred to tertiary centres were included in this study, and PCLD often remains asymptomatic<sup>[95]</sup>. ADPKD is the most common monogenetic disorder, with a world-wide estimated prevalence of 0.10%-0.25%<sup>[96]</sup>, and it is responsible for approximately 8%-10% of cases with end-stage renal disease<sup>[97]</sup>. Although ADPKD is primarily characterised by the presence of renal cysts<sup>[98]</sup>, liver cysts are considered the most prevalent extra-renal manifestation of ADPKD<sup>[99,100]</sup>. Indeed, one study involving 230 ADPKD cases found an overall prevalence of 83%<sup>[101]</sup>. However, the exact prevalence of PLD in ADPKD is still unknown. PCLD is predominantly confined to the liver, but a few renal cysts can also be present, which leads to difficulties in the accurate differentiation between PCLD and ADPKD<sup>[79,99]</sup>. Although renal cysts in ADPKD ultimately lead to renal failure, renal function remains unaffected in the presence of PCLD-associated renal cysts<sup>[102]</sup>.

PLD is predominantly discovered during the fourth or fifth decade of life and is more severe in females<sup>[77,96,103,104]</sup>. PCLD tends to lead to a higher number and greater volume of liver cysts<sup>[79]</sup>. The number of pregnancies, increased age and severity of renal disease are considered additional risk factors for liver cyst growth in ADPKD<sup>[105]</sup>. PLD is mainly asymptomatic, but mechanical complaints can arise in a subset of patients<sup>[79,106]</sup>. Complications such as intracystic haemorrhage and infection are rare and typically occur in large cysts<sup>[106]</sup>.

### Laboratory findings

PLD causes increased  $\gamma$ GT and AP levels in both PCLD and ADPKD patients<sup>[77]</sup>. Occasionally, increased serum aspartate aminotransferase (AST) is also found in ADPKD<sup>[79,107]</sup>. Renal function remains intact in PCLD, whereas ADPKD patients show a rise in serum creatinine due to impaired renal function<sup>[102]</sup>.

### Diagnostic features

PLD is detected with the use of USG, CT or MRI. USG, which is accurate, non-invasive and low cost, is the preferred imaging modality for both PCLD and ADPKD<sup>[108,109]</sup>. Currently, there are no generally accepted USG criteria for PCLD. One study suggested that the diagnosis can be made in case of a positive family history of PCLD and the presence of > 4 liver cysts<sup>[78]</sup>. However,

**Table 3** Ultrasonography criteria for the diagnosis of autosomal dominant polycystic kidney disease

| Family history positive <sup>1</sup>   |                            |
|--|----------------------------|
| Unknown genotype   |                            |
| Age (yr)   |                            |
| ≥ 15 and ≤ 39  | ≥ 3 unilateral renal cysts |
| ≥ 40 and ≤ 59  | ≥ 2 bilateral renal cysts  |
| ≥ 60   | ≥ 4 bilateral renal cysts  |
| Family history negative  |                            |
| > 10 bilateral renal cysts, with the exclusion of renal or extra-renal disease causing renal cysts |                            |

<sup>1</sup>Exclude autosomal dominant polycystic kidney disease when < 2 unilateral renal cysts and ≥ 40 years of age.

diagnosing ADPKD is usually relatively straightforward when enlarged bilateral cystic kidneys are present in combination with a positive family history for ADPKD<sup>[102]</sup>. In case of a negative family history, screening direct family members with USG can be helpful to reveal asymptomatic ADPKD. Because mutation analysis for ADPKD has no clinical implications, its use is limited to family members of ADPKD patients involved in kidney donation programs. In 2009, the Pei USG criteria were developed because the original Ravine USG criteria for diagnosing ADPKD appeared to be insufficient<sup>[110,111]</sup>. Table 3 gives an overview of the USG criteria for diagnosing ADPKD when the causative gene is unknown. For example, in case of a positive ADPKD family history, diagnosis can be made when ≥ 3 renal cysts are unilaterally present in individuals aged 15 to 39 years<sup>[110]</sup>. ADPKD should be considered when there are > 10 bilateral renal cysts present in the absence of other renal or extra-renal disease that can cause renal cysts<sup>[108]</sup>. When PCLD or ADPKD criteria are not met, multiple simple cysts are most likely responsible for the hepatic cystic lesions.

ADPKD is characterised by an increased risk of developing vascular manifestations. Hypertension occurs in approximately 50%-70% of patients, and almost half of these hypertensive patients are reported to have left ventricular hypertrophy (LVH)<sup>[112]</sup>. Mitral valve prolapse is observed in 25% of patients and intracranial aneurysms in 4%-12% of patients<sup>[112]</sup>. As a result, magnetic resonance angiography (MRA) must be performed when ADPKD patients have a positive family history of intracranial aneurysms because the rupture of aneurysms is reported to be responsible for 4%-7% of deaths in affected ADPKD families<sup>[113]</sup>. In contrast to ADPKD, several studies have shown that PCLD patients do not appear to have an increased risk of vascular malformations. One study involving 19 PCLD cases reported hypertension in 10.5% of cases, mitral valve prolapse in 0% and aneurysms in 5.3%<sup>[79]</sup>. Another study involving 38 PCLD cases found mitral valve prolapse in 1 case (2.6%)<sup>[114]</sup>. Subsequently, targeted screening is not advised for PCLD.

### Therapy

The main objective of therapy is to reduce liver cyst

volume to diminish mass effect-related symptoms<sup>[115]</sup>. Hence, the only indication for reducing cyst volume is when a PLD patient reports symptoms that can be linked to the polycystic liver<sup>[116]</sup>.

Surgical procedures, such as aspiration-sclerotherapy and fenestration, are indicated when PLD consists of large cysts confined to a limited part of the liver. In more extensive disease, segmental hepatic resection or even liver transplantation is imperative to relieve symptoms<sup>[117]</sup>. Future medical therapies include somatostatin analogues, as several clinical trials with lanreotide and octreotide achieved polycystic liver volume reduction in PCLD and ADPKD<sup>[118-123]</sup>.

## CONCLUSION

Cystic lesions of the liver encompass a wide spectrum of disorders. As a result of the frequent use of abdominal imaging techniques in recent years, the incidence of so-called coincidental cysts has increased. Simple cysts are the most prevalent and have a tendency to follow a benign course. However, complicated cysts, echinococcosis and cystic neoplasms (*e.g.*, cystadenoma and cystadenocarcinoma), which cause a diagnostic enigma, demand accurate diagnosis in the early stage because specific treatment could be required. Furthermore, the presence of multiple hepatic cystic lesions must raise the suspicion of PCLD or ADPKD and requires further screening.

USG remains the most accurate, non-invasive and cost-effective imaging modality for diagnosing simple cysts. Despite recent advances (*e.g.*, contrast-enhanced CT and DWI), distinguishing complicated cysts from echinococcosis and cystic neoplasms remains impossible with USG, CT or MRI alone. Because of an ever-increasing spread of *Echinococcus* to previously non-endemic regions and its initial quiescent phase after primary infection, it is necessary to exclude echinococcosis. Serodiagnostic tests have high sensitivity and specificity to reveal *Echinococcus* antibodies. Subsequently, CEUS can be used to accurately and reliably exclude cystic neoplasms by demonstrating the absence of any enhancement within the hepatic cystic lesion. Therefore, when CEUS is available, it reduces the need for surgical resection.

The detection of multiple liver cysts requires USG screening of both kidneys and extensive family history taking regarding the occurrence of ADPKD or PCLD. When PCLD or ADPKD criteria are not met, multiple simple cysts are most likely responsible for the hepatic cystic lesions. PCLD or ADPKD could eventually be diagnosed through USG follow-up.

To summarise, we developed a diagnostic algorithm by integrating recent advances with conventional diagnostic tools (Figure 4). Our diagnostic algorithm facilitates evidence-based clinical decision making when clinicians are confronted with coincidental hepatic cystic lesions on USG. Further development of USG- and MRI-based techniques, such as CEUS and DWI, will probably lead to further improvement of hepatic cystic lesion characterisation.

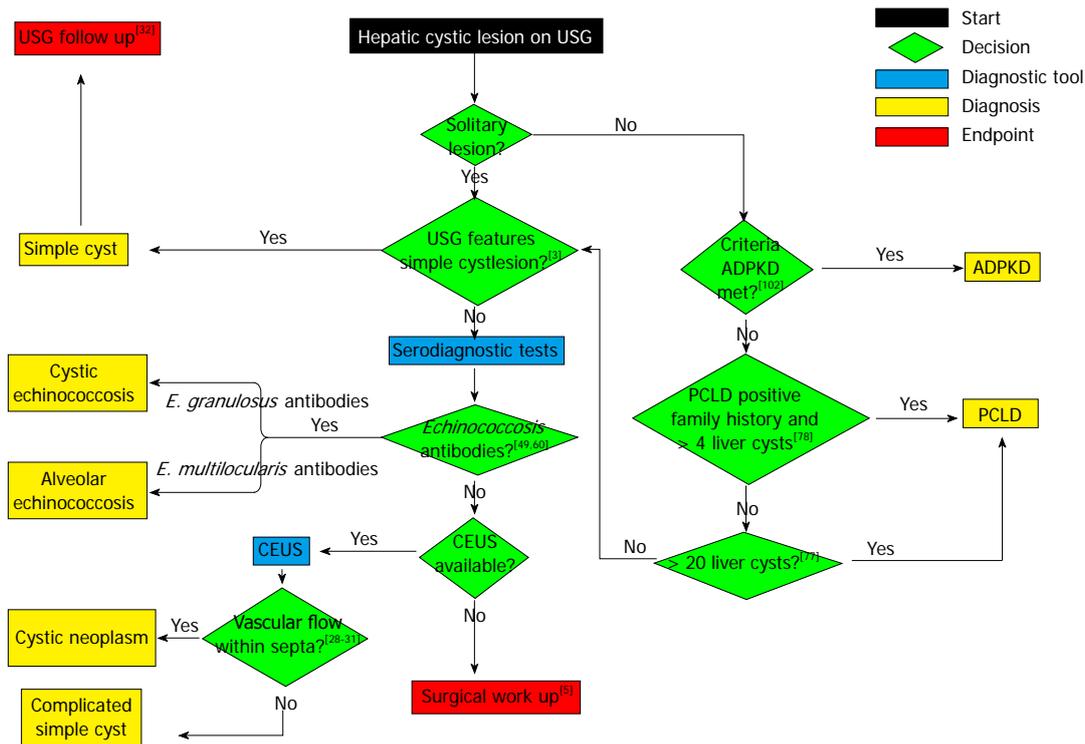

Figure 4 Diagnostic algorithm. Diagnosis of hepatic cystic lesions after detection on ultrasonography. *E. granulosus*: *Echinococcus granulosus*; *E. multilocularis*: *Echinococcus multilocularis*; CEUS: Contrast-enhanced ultrasound; PCLD: Polycystic liver disease; ADPKD: Autosomal dominant polycystic kidney disease.

## ACKNOWLEDGMENTS

The authors wish to thank Melissa Chrispijn from the Department of Gastroenterology and Hepatology Radboud University Nijmegen Medical Center, the Netherlands, for her expert advice.

### Abstract

Ischemia/reperfusion (I/R) injury of the gut is a significant problem in a variety of clinical settings and is associated with a high morbidity and mortality. Although the mechanisms involved in the pathogenesis of gut I/R injury have not been fully elucidated, it is generally believed that oxidative stress with subsequent inflammatory injury plays an important role. Heme oxygenase (HO) is the rate-limiting enzyme in the catabolism of heme, followed by production of CO, biliverdin, and free iron. The HO system is believed to confer cytoprotection by inhibiting inflammation, oxidation, and apoptosis, and maintaining microcirculation. HO-1, an inducible form of HO, serves a vital metabolic function as the rate-limiting step in the heme degradation pathway, and affords protection in models of intestinal I/R injury. HO-1 system is an important player in intestinal

I/R injury condition, and may offer new targets for the management of this condition.

**Key words:** Heme oxygenase; Ischemia/reperfusion injury; Oxidative stress; Cytoprotection; Gut

**Core tip:** In this review, we focused on the heme oxygenase (HO)-1 system and its possible roles and mechanisms in gut ischemia/reperfusion (I/R) injury studied to date. This review, for the first time, reviews in detail the relationship between HO-1 and gut I/R injury.

Liao YF, Zhu W, Li DP, Zhu X. Heme oxygenase-1 and gut ischemia/reperfusion injury: A short review. *World J Gastroenterol* 2013; 19(23): 3555-3561 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i23/3555.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i23.3555>

### INTRODUCTION

Ischemia/reperfusion (I/R) injury of the gut occurs frequently in a variety of clinical settings, including abdominal aortic aneurysm surgery, mesenteric artery occlusion, small bowel transplantation, cardiopulmonary bypass, strangulated hernias, trauma, and shock<sup>[1]</sup>; the exact mechanisms involved in the pathogenesis of which have not been fully elucidated. Gut I/R injury is associated with a substantial morbidity and mortality<sup>[2]</sup>.

Heme oxygenase (HO) is the rate-limiting enzyme in heme degradation, resulting in the formation of CO, biliverdin, and free iron<sup>[3]</sup>. There are three distinct HO isoforms (HO-1, HO-2, and HO-3) identified to date. HO-1 is the inducible form of the enzyme, and is expressed in relatively low amounts in most tissues<sup>[3]</sup>. HO-2 is the constitutive isoform, expressed mainly in brain and testis. HO-3 is identified only in rats, and its physiological

role remains unclear<sup>[4]</sup>.

HO-1, as an inducible form, also belongs to a member of the heat shock protein family and is highly inducible by a vast array of stimuli<sup>[3]</sup>. Many studies indicated that the induction of HO-1 plays a significant protective role against inflammatory processes and oxidative tissue injury<sup>[5-7]</sup>. In this review, we focus on the current understanding of the cytoprotective effects observed with the HO system during gut I/R injury. The implications for possible therapeutic manipulation of HO in gut I/R injury are elucidated.

## ISCHEMIA/REPERFUSION INJURY IN GUT

Interruption of blood supply results in ischemic injury which rapidly damages metabolically active tissues. Paradoxically, reintroduction of blood flow obtained following ischemia initiates a cascade of events that can potentially worsen the original injury. This effect is known as reperfusion injury<sup>[8]</sup>. The intestine is composed of labile cells that are very susceptible to I/R injury<sup>[9]</sup>. Multiple factors have been shown to be involved in the process of intestinal I/R injury. The primary pathophysiological events of this injury involve microcirculatory flow disturbances caused by the production of reactive oxygen species (ROS). Tissue ischemia and oxidative stress activate families of protein kinases that converge on specific transcriptional factors that regulate the expression of inflammatory genes. The resulting gene products include enzymes [*e.g.*, inducible nitric oxide synthase (iNOS); phospholipase A2, and cyclooxygenase-2 (COX-2)], cytokines [*e.g.*, tumor necrosis factor  $\alpha$  (TNF- $\alpha$ ); interleukin-1 (IL-1); interleukin-6 (IL-6)], prostaglandins (*e.g.*, PGE-2), and adhesion molecules [*e.g.*, intracellular adhesion molecule (ICAM-1); E-selectin]<sup>[10-14]</sup>. These initiate local inflammation, which is further amplified by the recruitment of circulating leukocytes<sup>[12]</sup>, which appear to be key effector cells in causing tissue injury. Furthermore, I/R injury induces widespread endothelial cell apoptosis and the loss of endothelial cells in the vessels serving the organ results in thrombosis<sup>[15,16]</sup> directly in the intestine<sup>[16]</sup>. This injury observed during I/R is believed to trigger a systemic inflammatory response leading to multiple organ failure<sup>[17,18]</sup>, which frequently involves the lungs<sup>[19,20]</sup> and liver<sup>[21]</sup>. Intestinal I/R injury is a complex, multifactorial pathophysiological process, dependent upon an understanding of which the optimal therapeutic approach is aimed at ameliorating I/R injury (Table 1). HO-1 system might be one of the most promising approaches among the potential therapeutic options.

## ROLE OF HO-1 IN ISCHEMIA/REPERFUSION INJURY IN GUT

HO-1 is expressed constitutively in normal gastric, intestinal, and colonic mucosa<sup>[22,23]</sup>, and is up-regulated in their inflamed tissue<sup>[23]</sup>. Many studies showed that HO-1 is involved in a variety of regulatory and protective cel-

lular mechanisms as a stress-responsive protein<sup>[5,6]</sup>. The normal expression and up-regulation of HO-1 suggest that activation of HO-1 could act as a natural defensive mechanism to alleviate inflammation and tissue injury in the gastrointestinal tract<sup>[24,25]</sup>. HO has been shown to have potent cytoprotective effects on intestinal I/R injury as well<sup>[26]</sup>. For example, induction of HO-1 by cobalt-protoporphyrin administration before intestinal I/R resulted in a significant reduction of intestinal tissue injury<sup>[27]</sup>. Another enhancer (pyrrolidine dithiocarbamate) of HO production improves intestinal microvascular perfusion and attenuates I/R injury of the intestine, possibly *via* HO production<sup>[28]</sup>. Similarly, administration with a HO inducer (hemin) results in lessened mucosal injury and improved intestinal transit following gut I/R<sup>[29]</sup>. Glutamine protects the intestine from warm ischemic injury, which was considered to be associated with inducible HO-1 expression through the interaction with cellular antioxidative activity and the inhibition of cytokines<sup>[30]</sup>. Several studies demonstrated that intraischemic hypothermia, hypertonic saline resuscitation, and whole-body hyperthermia decrease inflammation and protect against intestinal injury in a model of gut I/R<sup>[31-33]</sup>. Administration of IL-2, an immunoregulatory cytokine, resulted in clinical improvement of the study animals after intestinal I/R<sup>[34]</sup>. These protective interventions were associated with the induction of HO-1. Postischemic leukocyte-endothelial cell adhesive interactions are prevented by 5-aminoimidazole-4-carboxamide 1-beta-D-ribofuranoside preconditioning 24 h prior to I/R in the small intestine by HO-dependent mechanisms<sup>[35]</sup>. Furthermore, ischemic preconditioning of the intestine might prove to be an effective strategy for the amelioration of I/R injury, in which HO is involved<sup>[18,36,37]</sup>. Pretreatment with *Radix Paeoniae Rubra*<sup>[38]</sup>, or the anticancer drug doxorubicin<sup>[20]</sup>, can attenuate acute lung injury resulting from intestinal I/R. These results demonstrate that HO-1 is implicated in cytoprotection and may be an effective agent for the treatment of gut I/R.

## MECHANISMS OF ACTION

There is increasing evidence that HO-1 plays an important protective role in gut I/R injury. There are four factors that could be responsible for the protection of HO-1 in intestinal I/R, including: (1) removal of free heme; (2) CO; (3) biliverdin/bilirubin; and (4) Fe<sup>2+</sup>.

## REMOVAL OF FREE HEME

Heme, an essential iron chelate, is a potentially damaging species that not only provides a lipophilic form of iron, but also can directly attack and impair a multiplicity of intracellular targets<sup>[39]</sup>; production increases under conditions of oxidant stress, especially in I/R injury<sup>[39,40]</sup>. HO-1 is the key enzyme in heme degradation and plays a key role in regulating the intracellular heme level. HO-1 activity leads to rapid removal of free heme. Thus, in order

**Table 1** The role of heme oxygenase-1 for the protection of intestinal ischemia/reperfusion injury

|            | Treatment                   | I/R model                 | Ref.          |

AICAR: 5-aminoimidazole-4-carboxamide 1-beta-D-ribofuranoside; CORM: CO-releasing molecules; IL-2: Interleukin-2; I/R: Ischemia/reperfusion; HO: Heme oxygenase.

to prevent heme from both extracellular and intracellular sources reacting and producing ROS, the heme degradation step is an important consideration in the cytoprotection afforded by the HO system<sup>[40]</sup>.

## CO

CO is one of the three products of heme degradation by HO-1 and has profound effects as a signaling molecule that culminates in anti-inflammatory, antiapoptotic, and vasodilating effects<sup>[41,42]</sup>. A number of studies have revealed that CO mediates potent cytoprotective and anti-inflammatory effects in models of I/R injury of the heart, lung, kidney, and liver<sup>[43-46]</sup>. Some studies demonstrate that the efficacy of CO gas inhalation for the prevention of cold intestinal I/R injury using a small intestinal transplantation model, in which CO is able to effectively inhibit an early up-regulation of proinflammatory mediators such as IL-6, IL-1, TNF- $\alpha$ , ICAM-1, iNOS, and COX-2<sup>[11,13,14,47]</sup>. It has been reported that pre-treatment with CO-releasing molecules also markedly reduced intestinal inflammation induced by surgical manipulation of the small intestine<sup>[48]</sup> or by occluding the superior mesenteric artery<sup>[12]</sup>. Similarly, one study showed that cold storage in a preservation solution that was bubbled with 5% CO significantly reduced I/R injury associated with intestinal transplantation, which reduced

inflammatory mediator up-regulation and improved graft blood flow<sup>[49]</sup>. Moreover, CO-treated animals showed early up-regulation of the anti-apoptotic molecule Bcl-2, and down-regulation of the proapoptotic signal Bax, and reduced *in vivo* apoptosis of both vascular endothelial cells and intestinal epithelial cells<sup>[11]</sup>. The protective effects of CO are arbitrated by activating one or both of the two key signaling pathways. One of the pathways is soluble guanylate cyclase/cyclic guanosine monophosphate and the other one is the p38 mitogen-activated protein kinase pathway which transduces oxidative stress and inflammatory signaling<sup>[11,48-53]</sup>, through which CO exerts significant cytoprotection due to its anti-inflammatory, vasodilating, and anti-apoptotic properties in gut I/R injury.

## BILIVERDIN/BILIRUBIN

HO degrades heme into equimolar quantity of biliverdin. Biliverdin is, in turn, very rapidly converted to bilirubin by the enzyme biliverdin reductase<sup>[3]</sup>. Biliverdin and its reduced product, bilirubin, scavenge various ROS and are hence considered potent antioxidants<sup>[54,55]</sup>, which have been shown to confer cytoprotection against oxidative stress conditions in various cell types<sup>[56]</sup>. Several studies have also demonstrated that the administration of biliverdin and/or bilirubin is potently cytoprotective in I/R injury of the liver and heart, and in organ transplantation<sup>[57-59]</sup>. Evidence from an experimental small intestinal I/R injury model in rats describes a protective effect for bilirubin<sup>[60]</sup>, in which the bilirubin is infused *via* the jugular vein. Similarly, another study showed that increased serum bilirubin ameliorates the extent of intestinal IR injury<sup>[61]</sup>. Recent studies have suggested that biliverdin, in addition to its antioxidant properties, may have anti-inflammatory action. For example, treatment with biliverdin can significantly decrease mRNA expression of iNOS, COX-2, and ICAM-1, as well as the inflammatory cytokines IL-6 and IL-1, and decreased neutrophil infiltration into the jejunal muscularis in rat syngeneic small intestinal transplants<sup>[47]</sup>. These results suggest that bilirubin possesses complex immune-modulatory and antioxidant effects.

## Fe<sup>2+</sup>

Though HO activity is generally associated with cellular protection, Fe<sup>2+</sup>, the third product of heme decomposition, participates in the Fenton reaction to promote the generation of ROS and is believed to have potential deleterious effects. Increased iron levels, on the one hand, can upregulate an iron-transporter pump that removes intracellular Fe<sup>2+</sup> from the cell<sup>[62]</sup>. On the other hand, iron release from HO activity induces the expression of ferritin (an iron storing protein)<sup>[63,64]</sup>. Expression of ferritin was originally reported to protect endothelial cells against oxidant damage *in vitro*<sup>[64]</sup>. In addition, over-expression of H-ferritin (heavy chain ferritin) has also been shown to protect cultured endothelial cells from undergoing apop-

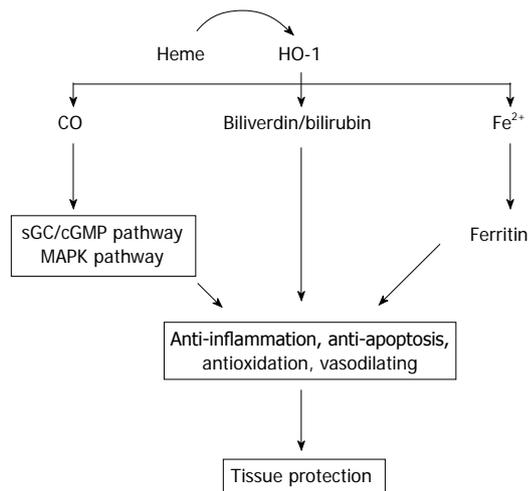

Figure 1 Schematic demonstration of the heme oxygenase-1 system and its biologic activities in gut ischemia/reperfusion injury. HO: Heme oxygenase.

osis and protects the liver from transplant-associated I/R injury<sup>[65]</sup>. Thus, ferritin seems to confer cytoprotection against oxidative challenge. There is no information about the roles of iron and ferritin in gut I/R injury, but in such a mechanism they could still be operative.

## CLINICAL EVIDENCE

As we mentioned above, the HO-1 system plays an important role in the cytoprotective process, up-regulation of which seems to be a potential therapeutic option for gut I/R injury. As far as we know, there have been no definitive trials designed to evaluate the efficacy of chemical HO-1 inducers in the clinical setting. Hemin, as an inducer of HO-1, has been used extensively in experimental studies, but has only been used by physicians experienced in the management of porphyrias clinically. However, there are increasing reports showing that hemin-induced HO-1 activity is a host defense mechanism in different animal models, such as the thrombosis vascular model<sup>[66]</sup>, in liver I/R injury<sup>[67]</sup>, acute pancreatitis with multi-organ failure<sup>[68,69]</sup>, human immunodeficiency virus-1 infection<sup>[70]</sup>, and spontaneously hypertension<sup>[71]</sup>. Such disease states share part or common physiopathological process with gut I/R injury, which suggests that hemin could offer a therapeutic benefit for gut I/R injury. A richer understanding of the cytoprotective mechanisms of hemin therapy will be necessary, which will also pave the way for clinical application in the treatment of gut I/R injury.

## CONCLUSION

Intestinal I/R injury is a complex, multifactorial pathophysiological process. Despite its complexity, the HO-1 system, owing to its antioxidative, anti-inflammatory, anti-apoptosis, and potent cytoprotective properties (Figure 1), may serve as promising potential therapeutic options for intestinal I/R injury.

The modulation of HO-1 expression using genetic or

pharmacological strategies may offer therapeutic strategies for intestinal I/R injury. Furthermore, HO-1-related molecules, including CO and biliverdin/bilirubin, might be employed as drugs in the management of intestinal I/R injury. More importantly, regulating the HO-1 system with different agents has already been demonstrated as important for attenuating I/R injury in other organs including the brain, liver, and kidney<sup>[40,72-74]</sup>. It is reasonable to assume that such a mechanism could also be operative in intestinal I/R injury. Research focused on the underlying mechanisms for the observed effects of HO-1 and its products will be necessary before their use can be evaluated in clinical applications for the prevention and/or treatment of human diseases such as intestinal I/R injury.

### Abstract

**AIM:** To determine the features of *Enterococcus* that contribute to the development and maintenance of the inflammatory process in patients with inflammatory bowel disease (IBD).

**METHODS:** Multiplex polymerase chain reaction (PCR) was applied to assess the presence of genes that encode virulence factors [surface aggregating protein (*asa1*), gelatinase (*gelE*), cytolysin (*cy1A*), extracellular surface protein (*esp*) and hyaluronidase (*hyl*)] in the genomic DNA of 28 strains of *Enterococcus* isolated from the intestinal tissues of children with IBD ( $n =$

16) and of children without IBD (controls;  $n = 12$ ). Additionally, strains with confirmed presence of the *gelE* gene were tested by PCR for the presence of quorum sensing genes (*fsrA*, *fsrB*, *fsrC*) that control the gelatinase production. Gelatinase activity was tested on agar plates containing 1.6% gelatin. We also analysed the ability of *Enterococcus* strains to release and decompose hydrogen peroxide (using Analytical Merckoquant peroxide test strips) and tested their ability to adhere to Caco-2 human gut epithelium cells and form biofilms *in vitro*.

**RESULTS:** A comparison of the genomes of *Enterococcus* strains isolated from the inflamed mucosa of patients with IBD with those of the control group showed statistically significant differences in the frequency of the *asa1* gene and the *gelE* gene. Furthermore, the cumulative occurrence of different virulence genes in the genome of a single strain of *Enterococcus* isolated from the IBD patient group is greater than in a strain from the control group, although no significant difference was found. Statistically significant differences in the decomposition of hydrogen peroxide and adherence to the Caco-2 epithelial cell line between the strains from the patient group and control group were demonstrated. The results also showed that profuse biofilm production was more frequent among *Enterococcus* strains isolated from children with IBD than in control strains.

**CONCLUSION:** *Enterococcus* strains that adhere strongly to the intestinal epithelium, form biofilms and possess antioxidant defence mechanisms seem to have the greatest influence on the inflammatory process.

**Key words:** *Enterococcus*; Virulence factors; Inflammatory bowel disease; Hydrogen peroxide; Biofilm

**Core tip:** In this research we have attempted to show

which features make *Enterococcus* strains contributing to the development and maintenance of the inflammatory process in patients with inflammatory bowel disease. The outcome of this research may have an impact on better understanding of the pathomechanisms of this disease, as its etiology is not fully known. The study results suggest that *Enterococcus* strains which adhere strongly to the intestinal epithelium, form biofilm as well as possess the enzymatic mechanisms protecting them against the effects of reactive oxygen species, seem to have the highest chances to survive and influence the inflammatory process.

## INTRODUCTION

Inflammatory bowel disease (IBD) refers to two disease entities: ulcerative colitis (UC) and Crohn's disease (CD). UC is a chronic inflammatory process of the mucous membranes of the rectum and colon. Inflammatory changes in the form of recurrent surface ulcerations are located along the whole length of the large intestine. The course of UC course ranges from mild disease activity, lasting for years, to severe disease that can result in death after only a few weeks. CD is a chronic inflammatory process that can affect any part of the alimentary system, from the oral cavity to the rectum.

The aetiology of IBD is not yet fully understood<sup>[1]</sup>. Based on numerous clinical observations and results of extensive *in vitro* and *in vivo* experiments, it is currently thought that this disease develops as a result of the concurrence of three factors: genetic predisposition, disorders of the immune system and the influence of the environmental factors. Among the environmental factors, changes in the composition of the bacterial flora that colonise the human alimentary tract are considered to be of great influence<sup>[2]</sup>. Consequently, a great deal of attention is currently devoted to the study of the bacterial species that constitute the normal alimentary tract flora compared to those found in the tract of the IBD patients.

From 2004 to 2006, research on the qualitative and quantitative changes in the microflora of the alimentary tracts of a group of children who had been diagnosed with CD or UC for the first time was performed in our department<sup>[3,4]</sup>. No single aetiological factor that could be responsible for the exacerbation of the progressing inflammatory process was confirmed based on the obtained results.

However, the analysis of the quantitative changes in the group of children with CD identified a significant

increase in the population of cocci (including *Streptococcus* and *Enterococcus*) and bacteria belonging to the genus *Lactobacillus* in the inflammatorily changed sites with a simultaneous decrease in the number of strictly anaerobic bacteria, particularly those belonging to the genus *Bifidobacterium*.

All of the above-mentioned bacteria are important members of the commensal flora of the human colon. Therefore, we must consider the mechanisms by which these bacteria may contribute to the development and/or maintenance of the inflammatory process in patients suffering from IBD. The virulence potential of the genus *Enterococcus* has been established in many publications, and it is this genus contributes to infections such as peritonitis, bloodstream and urinary tract infections and endocarditis<sup>[5,6]</sup>. Their potential role in the pathomechanisms leading to IBD has also been highlighted by research utilising *IL-10* gene knockout mice to show that *Enterococcus faecalis* (*E. faecalis*) can induce IBD<sup>[7]</sup>.

Recent studies on the pathogenicity of enterococci indicate that the genomes of strains that are able to cause tissue damage and inflammation contain a pathogenicity island that encodes aggregation substance (AS), gelatinase, extracellular surface proteins (Esp), cytolysin, hyaluronidase and other proteins<sup>[8,9]</sup>. Enterococci that express AS were found to resist phagocytosis significantly better than an isogenic AS-negative strain by inhibiting the respiratory burst of macrophages<sup>[10]</sup>. Gelatinase, a protease produced by enterococci, is capable of hydrolysing gelatin, collagen, casein, haemoglobin and other peptides<sup>[9]</sup>. The Esp enhance biofilm formation in *E. faecalis*<sup>[11]</sup>. Cytolysin produced by the enterococci is lethal for a broad range of prokaryotic and eukaryotic cells<sup>[12]</sup>. Hyaluronidase is mainly a degradative enzyme that is associated with tissue damage<sup>[13]</sup>.

Little attention has been devoted to the ability of enterococci to release hydrogen peroxide into the extracellular space<sup>[14]</sup>. Pursuant to the results obtained previously by our group, select members of several genera, including *Streptococcus*, *Enterococcus* and *Lactobacillus*, are, under aerobic conditions, able to produce amounts of hydrogen peroxide comparable to those released by cells of the immune system during the oxidative burst<sup>[15]</sup>. This additional source of hydrogen peroxide could help sustain, or even exacerbate, gut inflammation<sup>[16]</sup>. Notably, certain *Enterococcus* strains can defend themselves against the surplus of reactive oxygen species (ROS) by producing anti-oxidative enzymes to increase their chances of survival in unfavourable conditions<sup>[17]</sup>.

Thus, the main objective of this work was to compare the occurrence of genes encoding selected virulence factors [surface aggregating protein (*asa1*), gelatinase (*gelE*), cytolysin (*cytA*), extracellular surface protein (*esp*) and hyaluronidase (*hyl*)] in the genomes of *Enterococcus* strains isolated from patients suffering from IBD with the occurrence of these genes in the genomes of strains derived from the control group subjects. Additionally, strains confirmed positive for the *gelE* gene were tested for the presence of the quorum sensing genes *csrA-C*

that regulate gelatinase production, and gelatinase activity was tested on agar plates containing 1.6% gelatin. The adherence of the *Enterococcus* strains to Caco-2 epithelial cells and their ability to form biofilms were also tested. Furthermore, the ability of strains isolated from inflamed or non-inflamed gut mucosa to release and decompose extracellular hydrogen peroxide was assessed.

## MATERIALS AND METHODS

### Bacterial strains

*Enterococcus* strains were isolated from colon biopsies of 34 children who were diagnosed with IBD for the first time and 24 patients from the control group comprised of children with functional bowel disorders that were hospitalised in the same hospital during the same period of time. Neither the IBD patients nor the participants in the control group received antibiotics during the two weeks prior to the study. The diagnosis of CD or UC was based on endoscopic, histopathological, immunological and radiological criteria<sup>[3,4]</sup>. The biopsies were taken from both groups of patients during colonoscopy procedures carried out at the Clinic of Paediatrics, Gastroenterology and Nutrition of the Polish-American Institute of Paediatrics of the Jagiellonian University Medical College in Cracow pursuant to the approval of the Bioethical Committee (No. KBET/236/B/2002). The patients were prepared for the colonoscopy using routine washing procedures described by Gosiewski *et al.*<sup>[4]</sup>. During the colonoscopy, the location and intensity of the lesions was assessed, and tissue fragments were obtained for histopathological and microbiological examinations. The biopsy samples were transported to the microbiological laboratory in Schaedler broth (SAB, Difco, United States, + 10% glycerol) at -20 °C.

In the laboratory, the frozen samples were thawed, weighed and homogenised in 1 mL of SAB and quantitatively analysed for the main cultivable bacterial constituents of the colon microflora using differential media in aerobic and anaerobic conditions<sup>[3,4]</sup>. These steps were performed aseptically in an anaerobic chamber (MACS - MG 500 Work Station, DW Scientific, Shipley, United Kingdom) in N<sub>2</sub> (85%) + H<sub>2</sub> (10%) + CO<sub>2</sub> (5%) atmosphere. The homogenised samples were serially diluted with SAB and 100 µL aliquots plated on the following media: McConkey Agar (Oxoid, Basingstoke, United Kingdom) for *Enterobacteriaceae*, Columbia Blood Agar (Difco, Lawrence, Kansas, United States) with 5% sheep blood for streptococci, Enterococcosel agar (BBL, BD, Franklin Lakes, United States) for enterococci, MRS agar (Oxoid) for lactobacilli and other lactic acid bacteria, BL agar for bifidobacteria and Wilkins-Chalgren agar base (Difco) with supplements for *Bacteroides*.

The morphology of the grown colonies was analysed using a magnifying glass, and several colonies of each morphological type were subcultured on appropriate aerobic and anaerobic media and subsequently Gram-stained. After further incubation and culture purity checks, the phenotypic identification was conducted

with the use of commercial identification systems (API 20E, API20A, APIStaph, APIStrep, bioMerieux, Marcy l'Étoile, France; BBL Crystal ID System, BD, Franklin Lakes, United States). The identification was confirmed by species-specific multiplex polymerase chain reaction (PCR) as described by Jackson *et al.*<sup>[18]</sup>.

The selected strains were preserved at -80 °C on glass beads in BBL Nutrient Broth with the addition of 15% glycerol.

### Multiplex PCR

To detect presence of genes encoding selected virulence factors (*asa1*, *gelE*, *cylA*, *esp*, *hyl*) in the genomes of the tested strains, multiplex PCR was applied according to the methods of Vankerckhoven<sup>[19]</sup>.

### PCR

To investigate the presence of quorum sensing genes (*fsrA*, *fsrB*, *fsrC*) in the genomes of all the strains positive for the *gelE* gene, PCR was applied pursuant to Qin *et al.*<sup>[20]</sup>.

The reference strain *E. faecalis* ATTC29212 containing the gene *fsrC* was used as the positive control. The negative control was a reference strain of *E. faecium* (ATTC 35667) that did not possess any of the examined genes.

The product sizes for *fsrA*, *fsrB* and *fsrC* were 484 bp, 574 bp and 580 bp, respectively (BLAST).

### Detection of gelatinase activity

The production of gelatinase in *Enterococcus* strains was detected by the method described by Steck *et al.*<sup>[6]</sup>. Supernatants from overnight cultures were spotted onto tryptic soy agar supplemented with 0.5 g/L L-cysteine and 1.6% Difco gelatine. The zone of clearance was measured after 24 h of incubation.

### Adherence to human gut epithelium cells and evaluation of biofilm production

The ability of *Enterococcus* strains to adhere to Caco-2 human gut epithelium cells (ATCC HTB-37) was assessed using an *in vitro* assay according to Górska-Frączek<sup>[21]</sup>. Caco-2 cells were cultured for 24 h in a 12-well flat bottom tissue culture plate at a density of  $1 \times 10^6$  cells/mL (Iwaki, Japan) in Eagle's 1959 medium (MEM) with L-glutamine and NaHCO<sub>3</sub> (IITD, Wrocław, Poland) containing 5% foetal calf serum (Sigma-Aldrich Chemie, Germany) and antibiotics (penicillin 100 UI/mL, streptomycin 100 UI/mL, neomycin 200 µg/mL) (Sigma Aldrich Chemie, Germany) and were washed twice with PBS. Overnight cultures of bacteria were diluted with MRS+MEM to a concentration of about  $10^8$  CFU/mL. The Caco-2 cells were inoculated with the bacterial cultures. After incubating at 37 °C for 30 min, wells were washed twice with PBS to release unbound bacteria. Then, the cells were fixed with 3.7% formaldehyde for 1 h, washed twice with PBS and stained with crystal violet stain (Merck, Germany). The degree of adhesion was evaluated using a semiquantitative scoring system ranging from (-) to (+++). The adherent *Enterococcus* cells were

counted in 20 randomly selected microscopic fields, as we have previously described<sup>[22]</sup>.

Fifteen strains of enterococci collected from children with IBD and 10 strains from the control children were examined for biofilm formation in sterile plastic 96-well plates with an adherent surface (Greiner Bio-One, United States). Bacterial cells were grown in 10 mL of trypticase soy broth (TSB, Difco) at 37 °C for 24 h in aerobic conditions. The culture was then centrifuged (2000 r/min; 10 min) and washed with 10 mL of saline. A suspension of each strain ( $1 \times 10^5$  CFU/mL) was prepared by serial dilution of bacteria in saline using MacFarland's scale, and then 20 µL of the prepared suspension was added to a well followed by 180 µL of sterile TSB. The final concentration of bacteria was  $1 \times 10^4$  CFU/mL. The plates were centrifuged for 10 min at 2000 r/min to sediment the bacteria onto the bottom of each well and were then incubated for 48 h (37 °C, aerobic conditions). The biofilm quantity (total mass of bacterial polysaccharides) was measured using Congo red dye according to a modified procedure described by Reuter *et al.*<sup>[23]</sup>. Briefly, at two different time points (0 and 48 h), the plates were centrifuged, the culture medium was gently removed from the wells and 200 µL of 0.1% Congo red solution was immediately added. The plates were left at room temperature for 30 min and then washed twice with buffered saline to remove unbound dye. The absorbance was measured at a wavelength of 492 nm using a spectrophotometer (Awareness Technology, Inc.). All measurements were performed in triplicate, and the mean values  $\pm$  SD were calculated. The degree of biofilm production by the tested cocci was arbitrarily categorised as either highly positive ( $A_{492} \geq 0.81$ ) or weakly positive ( $A_{492} \leq 0.8$ ).

#### Measurement of hydrogen peroxide production

Analytical Merckoquant peroxide test strips (Merck, NJ, United States) were used to measure H<sub>2</sub>O<sub>2</sub> production by the tested strains on a detection scale between 0 and 100 mg/L. The tested bacteria were suspended in 2 mL of TSB broth (TSB) (Difco, Kansas, United States) and cultured at 37 °C in aerobic conditions. The measurements of H<sub>2</sub>O<sub>2</sub> were performed after 4 and 24 h according to the procedure provided by the manufacturer. The mean density of bacterial growth at 4 h was approximately  $3 \times 10^6$  CFU/mL and increased to  $1 \times 10^7$  CFU/mL after 24 h. Uninoculated TSB broth was used as a negative control. The amounts of H<sub>2</sub>O<sub>2</sub> are presented as mmol/L.

#### Kinetics of the decomposition of hydrogen peroxide

The bacterial strains were cultured in 10 mL of TSB for 24 h at 37 °C in aerobic conditions. Their final density was approximately 0.5 on the McFarland scale. After 24 h, chemically pure hydrogen peroxide (Sigma-Aldrich, United States) was added to each test culture at a final concentration of 2 mmol/L. The culture was incubated under the same conditions for 4 h, and the amount of hydrogen peroxide remaining in the test tube was then determined using Analytical Merckoquant peroxide test

strips (Merck, NJ, United States). The resulting amount of H<sub>2</sub>O<sub>2</sub> was converted from mg/L into mmol/L. Then, the number of bacterial cells in each culture was determined using the viable count method. These levels were comparable for all strains and equalled approximately  $8 \times 10^6$  CFU/mL. The negative control was sterile TSB containing 2 mmol/L H<sub>2</sub>O<sub>2</sub>.

#### Statistical analysis

The statistical analysis was focused on comparison of probabilities of the analyzed genes presence between the group of the bacteria isolated from IBD children and this from control group. Such comparison was done using frequency  $\chi^2$  test. If the given frequencies didn't fulfill the assumption of the test it's less strong equivalents: likelihood ratio of Fisher's exact test were used. The value  $P < 0.05$  was regarded as the threshold for statistical significance. All calculations were performed using JMP 7.0.2 (SAS, United States) software package.

## RESULTS

In total, 48 strains belonging to the genus *Enterococcus* were isolated. Of these, 34 strains originated from children diagnosed with IBD, including 21 from children diagnosed with CD and 13 from children with UC. In this group, 16 (47%) strains belonged to *E. faecalis*, 10 (29%) to *E. avium* and 8 (24%) to *E. faecium*. In the control group, 5 (36%) out of 14 strains were identified as *E. faecalis*, 4 (29%) as *E. avium*, 3 (21%) as *E. faecium* and 2 (14%) as *E. durans* (Table 1).

For further studies, 28 *Enterococcus* strains were randomly selected, including 16 strains from patients with IBD ( $n = 9$  CD,  $n = 7$  UC) and 12 strains from the control group (Tables 2, 3 and 4). Molecular typing of all *Enterococcus* isolates using PFGE procedure (not described here) was performed before selection to eliminate redundant pulsotypes. No clustering within individual species or across the entire set of strains was noted.

While identifying genes coding for selected virulence factors (*asa1*, *gelE*, *cylA*, *esp*, *hyl*) in the genomes of the *Enterococcus* strains isolated from the inflamed mucosa of IBD patients and from control group patients, statistically significant differences in the frequencies of the *asa1* gene, which encodes the surface aggregating proteins, and the *gelE* gene ( $P = 0.0091$ ), which encodes the gelatinase that is responsible for decomposing collagen and elastin, were confirmed (Tables 2 and 3; Figures 1 and 2).

The *cylA* gene, which encodes cytolysin, was detected in 2 strains of *E. faecalis* and 1 strain of *Enterococcus faecium* isolated from the inflamed sites. This gene was not detected in the control strains. The obtained results were at the limit of statistical significance ( $P = 0.0569$ ). The *esp* gene encoding the extracellular surface protein was present in 11 strains isolated from patients with IBD and in 5 strains isolated from the control group. None of the 28 strains examined, including strains from both research groups, contained the *hyl* gene that encodes hy-

**Table 1** List of *Enterococcus* strains used in the experiment

| Number of isolates | Strain number | Species (API 20 Strep/Multiplex PCR) | Disease entry/Patient number |

CD: Crohn's disease; UC: Ulcerative colitis; PCR: Polymerase chain reaction Species identification was conducted with the use of API Strep system (bioMérieux) and multiplex polymerase chain reaction assays.

aluronidase. No statistically significant differences were observed in the prevalence of *esp* or *hyl* between the two patient groups (Figures 1 and 2).

The cumulative occurrence of different virulence genes in the genome of a single strain of *Enterococcus* isolated from patients suffering from IBD was greater than that of a strain isolated from the control group (mean of 2.6 vs 2.0, respectively), but no significant difference was found. For instance, the strains *E. faecalis* 35A and *E. faecium* 57A were isolated from patients with IBD and pos-

sessed as many as 4 virulence genes (*cylA*, *esp*, *asa1* and *gelE*), but strains containing all four of these genes were not observed in *Enterococcus* isolates from the control group.

Further analysis was performed on strains in which the presence of the *gelE* gene was confirmed ( $n = 19$ ). Based on the results of a PCR assay for the presence of the regulator genes *fsrA-C*, statistically significant differences between the two groups were noted for the occurrence of *fsrC*. This gene was confirmed in 8 *Enterococcus* strains isolated from the study group, but it was detected in only 2 strains from the control group ( $P = 0.0195$ ). Furthermore, the presence of *fsrA* was confirmed in 3 strains from the study group and in 1 *Enterococcus* strain from the control group. The *fsrB* gene was detected in the genome of 3 strains isolated from the IBD children and in 2 strains from the control group children. These results are shown in Table 2.

Enterococci containing the gene encoding gelatinase also underwent an *in vitro* test in which the activity of gelatinase on agar plates containing 1.6% gelatin was examined. Zones of clearance were demonstrated only on plates inoculated with cultures of strains that had all three regulator genes (*fsrA*, *B* and *C*): 2 *Enterococcus* strains from the studied group and 1 strain from the control group. No statistically significant differences were shown between these two groups. The results are shown in Table 2.

While testing the ability of the enterococci to adhere to Caco-2 cells, statistically significant differences were demonstrated between the bacteria isolated from IBD children compared to controls. Ten of the 24 enterococcal strains from the IBD group strongly adhered to the Caco-2 cells ( $P = 0.0238$ ). Only 1 strain from the control group adhered to the epithelial cell line used in the study. It is important to note that adherence was demonstrated by all strains having the *asa1* gene, which encodes the surface aggregating protein and allows for increased adherence of the bacteria to the host's tissues. The results of this study are shown in Table 3. However, 6 strains from the control group and 1 strain from the study group with no confirmed presence of *asa1* gene also adhered to the cells. Therefore, there are other virulence factors that increase bacterial adherence to host tissues.

All of the tested *Enterococcus* strains were able to form biofilms structure within 48 h. However, the results demonstrated that profuse biofilm production was more frequent among strains isolated from children with IBD than in control strains. Among the enterococcal strains isolated from the studied group, 11 (73.3%) were abundant biofilm producers (high positive;  $A_{492} \geq 0.81$ ), and 4 (26.7%) were weak biofilm producers (low positive;  $A_{492} \leq 0.8$ ). Of the 10 strains isolated from the control group, 2 (20%) were classified as abundant biofilm producers and 8 (80%) were weak producers. The difference between the IBD and control groups was not statistically significant. The results of the biofilm formation analysis are shown in Table 3 and Figure 3.

While analysing the ability of the strains to produce

+: Presence of gene and/or gelatinase activity; -: Lack of gene and/or gelatinase activity Denotes significant ( $P = 0.0195$  vs control group) differences in the occurrence of the *fsrC* gene between the study group and the control group.

extracellular hydrogen peroxide, we observed that only *E. faecium* and *E. avium* species released hydrogen peroxide in amounts equal to or higher than 0.3 mmol/L. In total, 5 of the 16 *Enterococcus* strains isolated from patients with IBD and 3 of the 12 strains isolated from the control group were able to produce extracellular hydrogen peroxide, but this difference was not statistically significant (Table 4).

On the other hand, significant differences in the ability of the strains to decompose H<sub>2</sub>O<sub>2</sub> were observed upon examination of the 28 strains of *Enterococcus* isolated from both groups. Two subgroups could be distinguished based on the amount of decomposed hydrogen peroxide. The first group contained enterococci that decomposed 2 mmol/L of hydrogen peroxide to a level of 0-1 mmol/L in 4 h. The second group comprised strains that decomposed hydrogen peroxide to a level higher than 1 mmol/L. The difference in hydrogen peroxide decomposition ability was statistically significant between the *Enterococcus* strains isolated from patients with IBD and the strains isolated from control group patients ( $P = 0.04$ ; Figure 4).

## DISCUSSION

Recently, an important role has been ascribed to the

quantitative changes in the composition of the intestinal flora during inflammation<sup>[15,24]</sup>. These changes are likely related to the alterations in structure and function of the gut epithelium under inflammatory conditions that affect oxygenation, acidity and the functions of many enzymes and may lead to the preferential selection of microbial strains that are able to adapt to and/or interact with the inflamed epithelium.

In this work, *Enterococcus* strains were chosen for further studies because of their potential to be highly virulent. We sought to detect the differences between the virulence potential of the *Enterococcus* strains that colonised the intestines of children with IBD and control strains isolated from children without signs of gut inflammation.

The virulence of *Enterococci* can be linked to the presence of specific virulence factors encoded by specific genes, including cytolytic toxin, extracellular surface protein and AS, serine protease, gelatinase, cell wall adhesins, collagen-binding proteins and capsular polysaccharides<sup>[19,25]</sup>.

In the presented study, statistically significant differences were demonstrated for the occurrence of the *asa1* gene in the population of *Enterococcus* strains isolated from gut biopsies taken from patients with IBD in comparison to those cultured from those of the control

**Table 3** Presence of *asa1* gene, degree of adhesion to human gut epithelium cells and biofilm production among *Enterococcus* strains

Adhesion degree was assessed as +++ (strong adhesive abilities); ++ (average adhesive abilities) and - (lack of adhesive abilities). Biofilm formation was measured in triplicate at two time points (0 and 48 h). The differences between the time points were averaged, and the mean ± SD are shown.

group without gut inflammation. The *asa1* gene is responsible for bacterial aggregation on the surface of the host tissues (particularly enterocytes, neutrophil granulocytes and epithelial cells of the urinary tract), and it also enables conjugation between bacteria due to increased hydrophobicity of the cell wall surface<sup>[26]</sup>. Consequently, strains that possess the *asa1* gene can develop large aggregations of bacterial cells during an infection and may simultaneously increase the bacterial population<sup>[27]</sup>. This property is likely to be important in the pathomechanism underlying IBD because during episodes of diarrhoea, one of the main symptoms of IBD, the majority of the alimentary tract flora is removed with the intestinal contents. Enterococci that express the *asa1* gene are able to strongly adhere to intestinal surfaces lacking a mucous layer and are able to form biofilms for protection against unfavourable environmental factors.

Furthermore, experiments using a rat model of endocarditis have shown that enterococci equipped with the *asa1* gene are better able to survive inside stimulated immune cells, indicating that they may possess enzymatic mechanisms that protect them against the influence of ROS secreted by macrophages during the respiratory burst<sup>[10]</sup>.

The *gelE* gene was more frequently found in the genomes of enterococci isolated from the group of chil-

dren with IBD. However, the presence of the *gelE* gene alone is not sufficient for the production of gelatinase protein by bacteria. Therefore, we also detected the quorum sensing genes that regulate gelatinase production. Gelatinase is a zinc-dependent metalloproteinase that is capable of hydrolysing gelatin, collagen, casein, haemoglobin and human endothelin<sup>[28]</sup>. Its activity is one of the main causes of the pathological changes in the host's body upon infection with *E. faecalis*<sup>[25]</sup>. It is therefore possible that colonisation of the alimentary tract of patients with IBD with *Enterococcus* strains possessing the *gelE* gene can weaken the tight junction protein connections between the epithelial cells lining the intestinal walls of the host, thus leading to the disruption of the mucous barrier<sup>[6]</sup>.

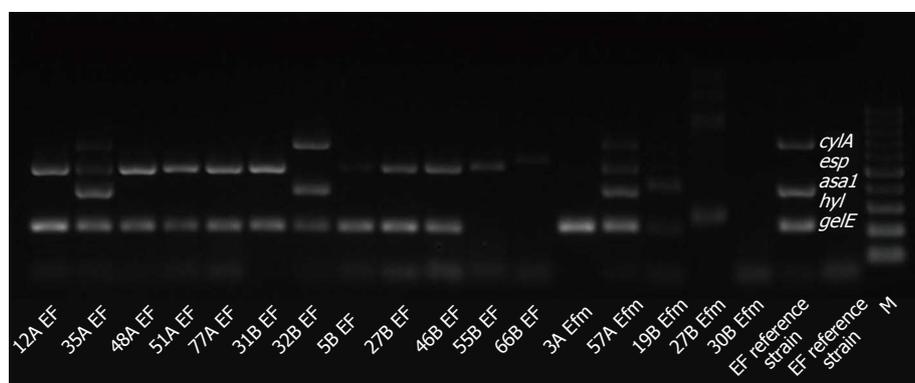

Cytolysin, encoded by the *cylA* gene, contributes to another pathomechanism of IBD that causes the excessive lysis of erythrocytes, leading to the uncontrolled release of large amounts of haemoglobin and subsequently heme and iron ions that influence the populations of *Enterobacteriaceae*, which are able to acquire iron<sup>[29]</sup>. Therefore, the increased number of enterococci that are able to decompose haemoglobin may be related to increases in the *E. coli* population observed in patients with IBD<sup>[30]</sup>.

Another *Enterococcus* virulence factor examined in this study was the *esp* gene, which encodes the extracellular

The measurement of H<sub>2</sub>O<sub>2</sub> was performed with the use of colorimetric method: Merckoquant peroxide test strips.

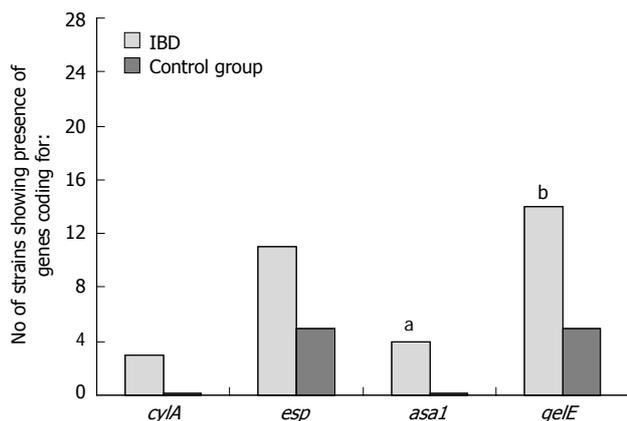

**Figure 1** Agarose gel electrophoresis of multiplex polymerase chain reaction amplification products from *Enterococcus* species isolates. The reference strain *Enterococcus faecalis* (*E. faecalis*) ATTC29212 (EF reference strain) possessing the genes *cylA*, *asa1* and *gelE* constituted the positive control. The negative control was a reference strain of *Enterococcus faecium* (*E. faecium*) ATTC 35667 Efm reference strain that did not possess any of the examined genes. Product sizes were as follows, *asa1*: 375 bp; *gelE*: 213 bp; *cylA*: 688 bp; *esp*: 510 bp; *hyl*: 276 bp. EF: Tested strains of *E. faecalis*; Efm: Tested strains of *E. faecium*; M: Mass marker 100-1000 bp.

surface protein (Esp). The *esp* gene was present in 11 strains of enterococci from the group of children with the IBD and in 5 strains from the control group. This finding may indicate that enterococci found in biopsy samples from ulcerations were able to adhere to and colonise the intestinal tissues more easily because Esp promotes primary attachment and biofilm formation in *E. faecalis*, as proved demonstrated by Toledo-Arana *et al*<sup>[31]</sup>.

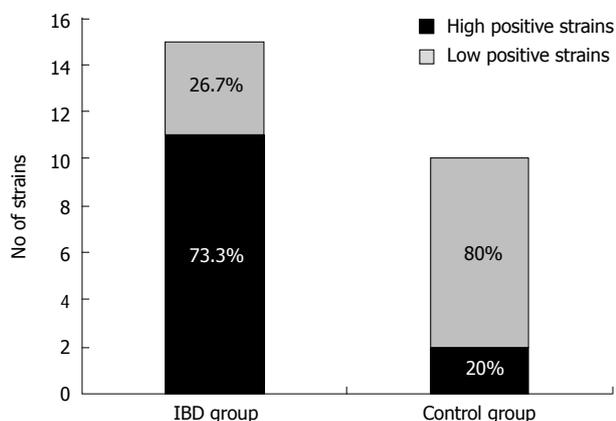

It should be noted here that our studies on the selected virulence factors were based only on the detection of

the specified genes that encode these factors, and more information could be obtained from the direct detection of these factors in bacteria using enterocytes in *in vitro* systems or in animal experiments because the expression of the studied genes may be specifically altered in inflamed tissues<sup>[32]</sup>.

In the alimentary tract of patients suffering from IBD, there can be a local accumulation of large amounts of ROS released by stimulated phagocytic cells, such as macrophages and neutrophils, due to the progressing

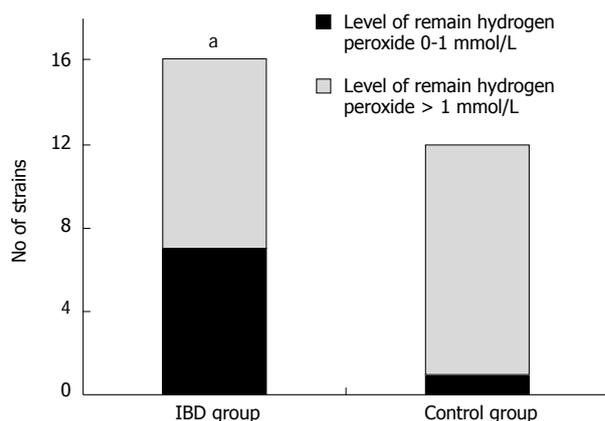

**Figure 2** Presence of virulence factors in *Enterococcus* strains. Significant differences in the occurrence of the *asa1* gene (<sup>a</sup>*P* = 0.0258 vs control group) and the *gelE* gene (<sup>b</sup>*P* = 0.0091 vs control group) were detected between strains isolated from children with inflammatory bowel disease (IBD) and strains from the participants in the control group.

**Figure 3** Comparison of the ability of the tested *Enterococcus* strains to form biofilms. The biofilm-forming abilities were assessed after 48 h, and all tested strains were classified as either abundant biofilm producers (high positive strains) or weakly adherent isolates (low positive strains). IBD: Inflammatory bowel disease.

acute and subsequently chronic inflammatory process. Additionally, some species of *Lactobacillus*, *Streptococcus* and *Enterococcus* that colonise the human intestinal tract are able to produce substantial amounts of superoxide (O<sub>2</sub><sup>-</sup>) and hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) that are comparable to those released by immune cells<sup>[33,34]</sup>. However, as has been shown by Al-Mushrif and Jones, the oxygen concentration present in the specific ecological niche regulates the bacterial production of hydrogen peroxide<sup>[35]</sup>. As we have previously demonstrated and discussed elsewhere (Strus *et al*<sup>[15]</sup>), the oxygen tension in inflamed tissues during the course of IBD enables the propagation of facultative aerobes such as *Enterococcus* spp. and the production of considerable amounts of hydrogen peroxide and other metabolites. Selected *Enterococcus* strains belonging to the species *E. avium* and *E. faecium* isolated from patients with IBD and children from the control group were able to produce extracellular hydrogen peroxide in our studies. This result may indicate that the production of hydrogen

**Figure 4** Decomposition of hydrogen peroxide by the tested strains. Statistically significant differences (<sup>a</sup>*P* = 0.04 vs control group) in the decomposition of H<sub>2</sub>O<sub>2</sub> (to a level higher than 1 mmol/L) were detected between strains isolated from patients with inflammatory bowel disease and from participants in the control group.

peroxide is due to certain *Enterococcus* species rather than the inflammatory conditions at the site of their isolation.

Bacteria belonging to the genera *Streptococcus*, *Lactobacillus* and *Enterococcus* occur in increased numbers in the alimentary tracts patients with IBD and can produce significant amounts of H<sub>2</sub>O<sub>2</sub> that can consequently limit the population of anaerobic flora, stimulate the cells of the immune system to release pro-inflammatory cytokines and stimulate the apoptosis of intestinal epithelial cells deprived of their protective mucous layer<sup>[36]</sup>. Denning *et al*<sup>[16]</sup> showed that hydrogen peroxide concentrations ranging from 0.5 up to 2 mmol/L were able to induce apoptosis in the cells of the abdominal lining and intestinal epithelium; similar amounts of H<sub>2</sub>O<sub>2</sub> were produced *in vitro* by the *Enterococcus* strains examined in this study. These observations support the studies by Kruidenier *et al*<sup>[37]</sup> and underline the importance of oxidative stress in the pathogenesis of IBD.

During the inflammatory process, the intestinal epithelial cells are exposed to the effects of ROS. If this is a short-term process, no significant damage or disruption of host cell function are observed due to the production of enzymes that inactivate ROS, such as catalase and peroxidase, and DNA repair mechanisms. A significant risk for the intestinal epithelium occurs when ROS are generated at variable concentrations for a longer period of time. Then, not only can the host cells be damaged, but the qualitative and quantitative composition of the specific bacterial species that comprise the commensal flora changes as well<sup>[35]</sup>.

In this work, we showed that enterococci isolated from patients with IBD were able to decompose hydrogen peroxide considerably faster than those isolated from the control group. This may indicate that these strains survived the selective pressures of the inflammatory process. It is likely that only bacterial species possessing a system capable of enzymatic deactivation of ROS were able to survive and subsequently increase their populations on the surface of the damaged intestinal epithelial

cells in patients with IBD. Until recently, bacteria belonging to the genera *Enterococcus*, *Lactobacillus* and *Pediococcus* were regarded as catalase negative. However, it appears that these bacteria have a very efficient system of hydrogen peroxide deactivation based on manganese-containing catalase or haeme-dependent catalase<sup>[38]</sup>.

In this study, we present data that suggest that processes in the alimentary tract of patients with IBD (most probably based on inflammatory background of this disease) may lead to the selection of certain bacterial species or strains from the constituents of the commensal flora. Our observations have been supported by recent studies on microbiota from biopsies taken from patients with UC and controls performed by Fite *et al.*<sup>[39]</sup>, who detected statistically significant differences in the bacterial populations of the UC mucosa and in the control group that varied over the study period. High clinical activity indices and sigmoidoscopy scores were associated with enterobacteria, desulfovibrios, Type E *Clostridium perfringens* and *E. faecalis*. We believe that in case of *Enterococcus*, the strains that adhere strongly to the intestinal epithelium, build three-dimensional biofilm structures and possess enzymatic mechanisms to protect against the effects of ROS produced by the immune cells and other bacterial species have the highest chances of survival.

## COMMENTS

### Background

Inflammatory bowel disease (IBD) is a chronic inflammation of all or part of the digestive tract. The aetiology of IBD is not fully known, but much attention is currently focused on the role of bacterial flora in the development and/or maintenance of the inflammatory process in patients suffering from this disease. Recent studies indicate that bacteria belonging to the genus *Enterococcus* play an important role in the pathomechanisms underlying IBD based on their virulence potential.

### Research frontiers

Changes in the composition of the bacterial flora colonising the human alimentary tract are considered influential in the maintenance of the inflammatory process in patients with IBD. The virulence potential the enterococci may be particularly important. It will be interesting to identify other factors that allow enterococci to develop and maintain the inflammatory process while increasing their chances of survival in unfavourable conditions.

### Innovations and breakthroughs

Recent studies have shown that no single aetiological factor could be responsible for the exacerbation of the inflammatory process in IBD. However, an analysis of the quantitative changes in the intestinal microflora of patients with Crohn's disease (CD) demonstrated a significant increase in the population of cocci (including *Enterococcus* and *Streptococcus*) at the sites of inflammation. In the present study, authors observed that virulence genes, such as *asa1* and *gelE*, occurred more frequently in the genomes of *Enterococcus* strains isolated from patients with IBD than in strains isolated from healthy patients. Moreover, authors demonstrated statistically significant differences in the ability of these strains to decompose hydrogen peroxide. Enterococci isolated from patients with IBD decomposed hydrogen peroxide considerably faster than those isolated from the control group. This result indicates that only select bacterial species with an efficient system of enzymatic deactivation of reactive oxygen species (ROS) are able to survive and subsequently increase their populations on the surface of the damaged intestinal epithelial cells.

### Applications

The results of this study suggest that *Enterococcus* strains that adhere strongly to the intestinal epithelium, form biofilms and possess enzymatic mechanisms that protect against the effects of ROS have the highest chances surviving and influencing the inflammatory process. Their research improves our understand-

ing of the pathomechanisms underlying IBD.

### Peer review

An interesting publication in which authors determine the features of *Enterococcus* that contribute to the development and maintenance of the inflammatory process in patients with IBD. The results are interesting and suggest that *Enterococcus* strains that adhere strongly to the intestinal epithelium, form biofilms and possess antioxidant defence mechanisms seem to have the greatest influence on the inflammatory process.

### Abstract

**AIM:** To study whether alterations in the glycosylation of immunoglobulin G (IgG) specific to the Thomsen-Friedenreich glycotope (TF) have diagnostic and prognostic potential in gastric cancer.

**METHODS:** Serum samples were obtained from patients with histologically verified gastric carcinoma ( $n = 89$ ), healthy blood donors ( $n = 40$ ), and patients with benign stomach diseases ( $n = 22$ ). The lectin-enzyme-linked immunosorbent assay-based glycoprofiling of TF-specific IgG (anti-TF IgG) was performed using synthetic TF-polyacrylamide conjugate as antigen, total IgG purified by affinity chromatography on protein G sepharose, and lectins of various sugar specificities: mannose-specific concanavalin A (ConA), fucose-specific *Aleuria aurantia* lectin (AAL) and sialic acid-specific

*Sambucus nigra* agglutinin (SNA). The sensitivity and specificity of the differences between cancer patients and controls were evaluated by receiver operator characteristic (ROC) curve analysis. Overall survival was analyzed by the Kaplan-Meier method. Time-dependent ROC curve statistics were applied to determine cut-off values for survival analysis. All calculations and comparisons were performed using the GraphPad Prism 5 and SPSS 15.0 software.

**RESULTS:** The level of TF-specific IgG was significantly increased in cancer patients compared with non-cancer controls ( $P < 0.001$ ). This increase was pronounced mostly in stage 1 of the disease. Cancer patients showed a higher level of ConA binding to anti-TF-IgG ( $P < 0.05$ ) and a very low level of SNA lectin binding ( $P = 0.0001$ ). No appreciable stage-dependency of the binding of any lectin to anti-TF IgG was found. A strong positive correlation between the binding of AAL and SNA was found in all groups studied ( $r = 0.71-0.72$ ;  $P < 0.0001$ ). The changes in ConA reactivity were not related to those of the fucose- or sialic acid-specific lectin. Changes in the SNA binding index and the ConA/SNA binding ratio demonstrated good sensitivity and specificity for stomach cancer: sensitivity 78.79% (95%CI: 61.09-91.02) and 72.73% (95%CI: 57.21-85.04); specificity 79.17 (95%CI: 65.01-89.53) and 88.64% (95%CI: 71.8-96.6), for the SNA binding index and the ConA/SNA binding ratio, respectively. The other combinations of lectins did not improve the accuracy of the assay. The low level of ConA-positive anti-TF IgG was associated with a survival benefit in cancer patients (HR = 1.56; 95%CI: 0.78-3.09;  $P = 0.19$ ), especially in stages 3-4 of the disease (HR = 2.17; 95%CI: 0.98-4.79;  $P = 0.048$ ). A significantly better survival rate was found in all cancer patients with a low reactivity of anti-TF IgG to the fucose-specific AAL lectin (HR = 2.39; 95%CI: 1.0-5.7;  $P = 0.038$ ).

**CONCLUSION:** The changes in the TF-specific IgG glycosylation pattern can be used as a biomarker for

stomach cancer detection, and to predict patient survival.

Kodar K, Izotova J, Klaamas K, Sergeyev B, Järvekülg L, Kurtenkov O. Aberrant glycosylation of the anti-Thomsen-Friedenreich glycotope immunoglobulin G in gastric cancer patients. *World J Gastroenterol* 2013; 19(23): 3573-3582 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i23/3573.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i23.3573>

## INTRODUCTION

The aberrant glycosylation often observed in cancer cells leads to the expression of tumor-associated carbohydrate antigens (TACA) which may be autoimmunogenic and recognized by autoantibodies<sup>[1-3]</sup>. This makes TACA a promising target for cancer immunotherapy. In cancer patients, an abnormal glycosylation pattern has also been observed for many circulating glycoconjugates, such as transferrin, MUC1 mucin, alpha1-acid glycoprotein, and immunoglobulins<sup>[6-10]</sup>. This suggests a systemic impact of malignancy on glycosylation machinery or possibly represents a specific feature of the host metabolism. In both cases, such changes might be considered as a biomarker of cancer, a premalignant state, or the disposition of the host to cancer (risk factors).

The Thomsen-Friedenreich antigen (TF, CD176, core-1) (Galβ1, 3GalNAcα/β-O-Ser/Thr) is expressed in many carcinomas and results from incomplete synthesis of O-linked glycans on glycoproteins and glycolipids<sup>[1,2]</sup>. The TF glycotope is known as a pancarcinoma antigen which is expressed in approximately 90% of all human cancers and in premalignant conditions<sup>[2,11]</sup>. TF expression is associated with more aggressive tumors and is related to the induction of invasion, metastasis and cancer surveillance mechanisms<sup>[12-16]</sup>. The TF antigen seems to play a crucial role in the adhesion of cancer cells to the endothelium through interaction with galectin-3, thereby promoting metastasis<sup>[17,18]</sup>.

Naturally-occurring TF antigen-specific immunoglobulin G (anti-TF IgG) autoantibodies are present in human serum in health and disease<sup>[3,19,20]</sup>. In cancer patients, their level is related to tumor progression and prognosis, being higher in patients with the early stages of the disease, in those with more differentiated tumors (G1-2), and in those with better survival<sup>[12,21,22]</sup>. This suggests an immediate impact of the humoral immune response on malignancy *via* direct or antibody-dependent cell-mediated effector pathways. However, the mechanisms behind these associations remain to be further elucidated.

Human serum IgG contains N-linked glycans attached to Asn297 on the fragment crystallizable (Fc) region. The Fc glycan structures are highly variable and differ in the level of terminal sialic acid, galactose (G0, G1, G2), core fucose and bisecting GlcNAc<sup>[23]</sup>. Changes in IgG Fc glycosylation strongly influence the Fc-receptor-mediated activities of antibody<sup>[23-25]</sup> and are associated with various pathologies, including cancer. However, little attention has been paid yet to the glycosylation of antibodies specific to tumor-associated antigens<sup>[26]</sup>. During the last decade, the diversity of IgG glycans has been thoroughly studied by the interaction of IgG with lectins<sup>[26-29]</sup>, as well as by mass spectrometry-based methodology<sup>[9,10,30]</sup>. Our recent studies demonstrated an increase in the level of the ConA lectin-positive glycoform of both total serum IgG and TF antigen-specific IgG in patients with cancer<sup>[8,31]</sup>. Moreover, the low level of this IgG glycoform was associated with an overall survival benefit in patients with gastric cancer<sup>[8]</sup>, indicating its functional relevance, as well as its potential clinical value. Similar changes in ConA reactivity have been reported for tumor-reactive IgG in patients with ovarian cancer<sup>[26]</sup>. However, the antigenic specificity of these antibodies remains unknown.

In an attempt to discover and evaluate potential biomarkers for stomach cancer diagnosis and patient prognosis, the TF antigen-specific IgG glycosylation profile was investigated using lectins of various sugar specificities. In this study, we demonstrate the aberrant glycosylation of anti-TF IgG in patients with stomach cancer, and the association of these changes with overall survival, indicating their potential clinical applicability.

## MATERIALS AND METHODS

### Subjects

Serum samples were obtained from healthy blood donors, patients with benign stomach diseases and patients with histologically verified gastric carcinoma (Table 1). The investigation was carried out in accordance with the ICH GCP Standards and approved by the Tallinn Medical Research Ethics Committee, Estonia. Written informed consent was obtained from each subject.

Tumor staging was based on the histopathological (pTNM) classification of malignant tumors. Serum samples were stored in aliquots at -20 °C until use.

### Serum IgG purification on protein G sepharose

To remove the anti-TF IgM and IgA isotype antibodies, preliminary purification of serum total IgG was performed on a Protein G HP Spin Trap column as described by the manufacturer (GE Healthcare, United States). The samples were immediately neutralized, dialyzed against phosphate buffered solution (PBS) - 0.1% NaN<sub>3</sub> and stored at + 4 °C until tested. About 8.5 mg of IgG was obtained from 1 mL of serum applied onto the Protein G Sepharose column.

**Table 1** Characteristics of the subjects tested<sup>1</sup>

| Groups                    | n  | Male | Female | M/F  | Median age (range), yr |
|---------------------------|----|------|--------|------|------------------------|
| Donors                    | 40 | 12   | 28     | 0.43 | 52.2 (23–70)           |
| Benign group <sup>2</sup> | 22 | 19   | 3      | 6.3  | 62.0 (44–76)           |
| Non-cancer <sup>3</sup>   | 62 | 31   | 31     | 1    | 59.5 (23–76)           |
| Cancer patients           | 89 | 53   | 36     | 1.47 | 66.0 (22–84)           |
| Stages 1–4                |    |      |        |      |                        |
| Stage 1                   | 18 | 8    | 10     | 0.86 | 65.0 (28–84)           |
| Stage 2                   | 19 | 14   | 5      | 1.67 | 66.5 (46–83)           |
| Stage 3                   | 42 | 22   | 20     | 0.83 | 65.0 (38–81)           |
| Stage 4                   | 10 | 9    | 1      | 9    | 65.0 (44–76)           |

<sup>1</sup>All subjects were tested for anti-Thomsen-Friedenreich glycotope IgG levels and the concanavalin A binding. *Aleuria aurantia* lectin and *Sambucus nigra* agglutinin binding test was performed in all donors and patients with benign gastric disease, and in 33 patients with stomach cancer (stage 1, *n* = 4; stage 2, *n* = 5; stage 3, *n* = 19; stage 4, *n* = 5); <sup>2</sup>Peptic ulcer disease, *n* = 6; chronic gastritis, *n* = 7; atrophic gastritis, *n* = 9; <sup>3</sup>Combined group of donors and patients with benign stomach disease. M/F: Male/female.

### Anti-TF IgG antibody assay

The anti-TF IgG level was determined by enzyme-linked immunosorbent assay (ELISA) as described elsewhere<sup>[21]</sup>, with minor modifications. Briefly, the plates (Maxisorp, Nunc, Roskilde, Denmark) were coated with a synthetic TF-polyacrylamide conjugate (Lectinity, Russia, 10 mol% of carbohydrate) in carbonate buffer, pH 9.6, 5 µg per well. After overnight incubation, triple washing and blocking with a Superblock solution (Pierce, United States) for 15 min at 25 °C, the purified IgG samples (50 µg/well) in PBS-0.05% Tween (Tw) were applied for 1.5 h at 25 °C. After subsequent washing with PBS-Tw, the bound anti-TF IgG was detected with alkaline phosphatase conjugated goat anti-human IgG (Dako, United States) and p-nitrophenylphosphate disodium hexahydrate (Sigma, United States). The absorbance values were read at 405 nm (Tecan Reader, Austria). The relatively high doses of total IgG were applied because of the low concentration of anti-TF IgG in the serum. These IgG doses correspond approximately to the 1:25–1:50 serum dilution used in our previous studies<sup>[21]</sup>.

### Lectin reactivity of the TF-specific IgG

The lectin reactivity of the TF glycotope-specific IgG was measured in a similar way, except that the binding of mannose-specific concanavalin A (ConA), fucose-specific *Aleuria aurantia* lectin (AAL) and neuraminic acid (sialic acid)-specific *Sambucus nigra* agglutinin (SNA) to the absorbed anti-TF IgG was measured as described by Kodar *et al.*<sup>[8]</sup>. Biotinylated ConA (Sigma, United States) in the ConA binding buffer (0.05 mol/L Tris-HCl buffer, pH 7.2, containing 0.2 mol/L NaCl and 3 mmol/L CaCl<sub>2</sub>, MgCl<sub>2</sub> and MnCl<sub>2</sub> each), AAL (Vector Laboratories Inc., United States) in 10 mmol/L HEPES, 0.15 mol/L NaCl buffer, pH 7.5, and SNA (Vector Laboratories Inc., United States) in 10 mmol/L HEPES, 0.15 mol/L NaCl, 0.1 mmol/L CaCl<sub>2</sub>, pH 7.5, were each applied at a concentration of 5 µg/mL, for 1.5 h at 25 °C.

The bound lectins were detected with a streptavidin-alkaline phosphatase conjugate (Dako, United States) and p-nitrophenylphosphate (Sigma, United States). The optical density value (*A*) of control wells (blank: the Superblock solution instead of TF-PAA for anti-TF or no sample for lectin binding testing) was subtracted from that of the IgG-coated wells to determine the binding of both IgG and lectin. Each sample was analyzed in duplicate.

To standardize the assay, standard IgG was included in each plate for IgG determination and lectin binding measurement. The interassay variations were minimized by using the correction factor (CF): CF = 1/(standard serum *A* values - blank) × 100. The results were expressed in relative units (RU): RU = sample *A* value × CF. The lectin reactivity of anti-TF IgG was calculated as the lectin index: (sample lectin binding RU)/(sample anti-TF IgG binding RU).

### Statistical analysis

Comparisons between the groups were performed using the nonparametric Mann-Whitney *U* test for unpaired data or regression analysis with the Spearman test. Survival analysis was carried out using the Kaplan-Meier method. The receiver operator characteristic (ROC) curve analysis as generated in SPSS 15.0 was used to evaluate the sensitivity and specificity of the changes found for stomach cancer. The area under the ROC curve and the *P* value of the ROC curve were calculated. The time-dependent ROC curve statistics were applied to determine cut-off values for survival analysis. The difference between the groups was considered to be significant when *P* ≤ 0.05. All calculations were performed using the GraphPad Prism 5 and SPSS 15.0 software.

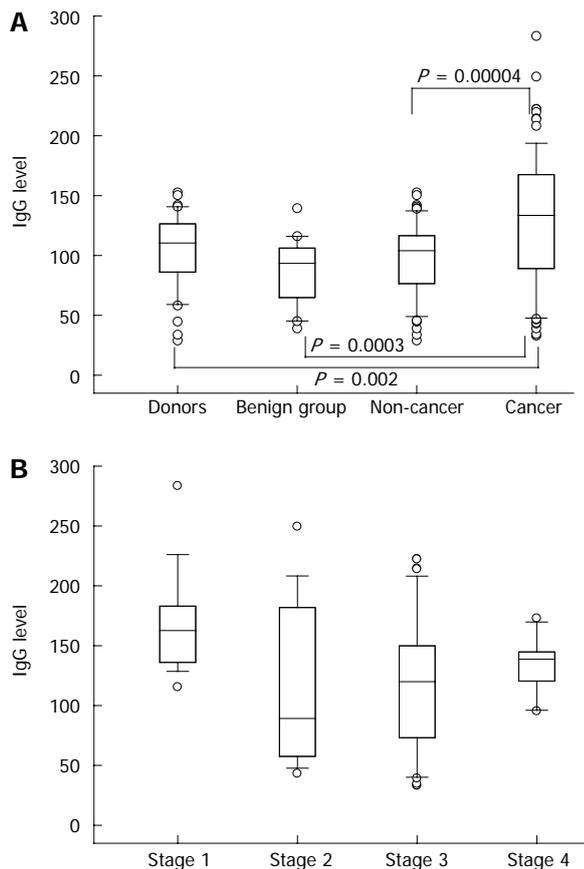

## RESULTS

### TF antigen-specific IgG antibody level in total IgG preparations

A significantly higher level of TF-specific IgG was found in purified total IgG preparations from the serum of patients with stomach cancer compared with that in controls: *P* = 0.002, 0.0003 and 0.00004 for donors, benign and combined non-cancer groups, respectively (Figure 1). This increase was mostly pronounced in stage 1 of the disease (*P* = 0.02, *P* = 0.0006, *P* = 0.01 compared with stages 2, 3 and 4, respectively). Up to 10-fold interindividual variations in anti-TF IgG antibody levels were observed in all the groups and especially in cancer patients.

### Lectin binding profile of TF-specific IgG

The anti-TF IgG of patients with cancer showed a significantly higher level of ConA-positive IgG glycoform than that of both controls: *P* = 0.013, 0.05 and 0.005 for donors, benign and non-cancer groups, respectively (Figures 2 and 3). In contrast, the binding of SNA was

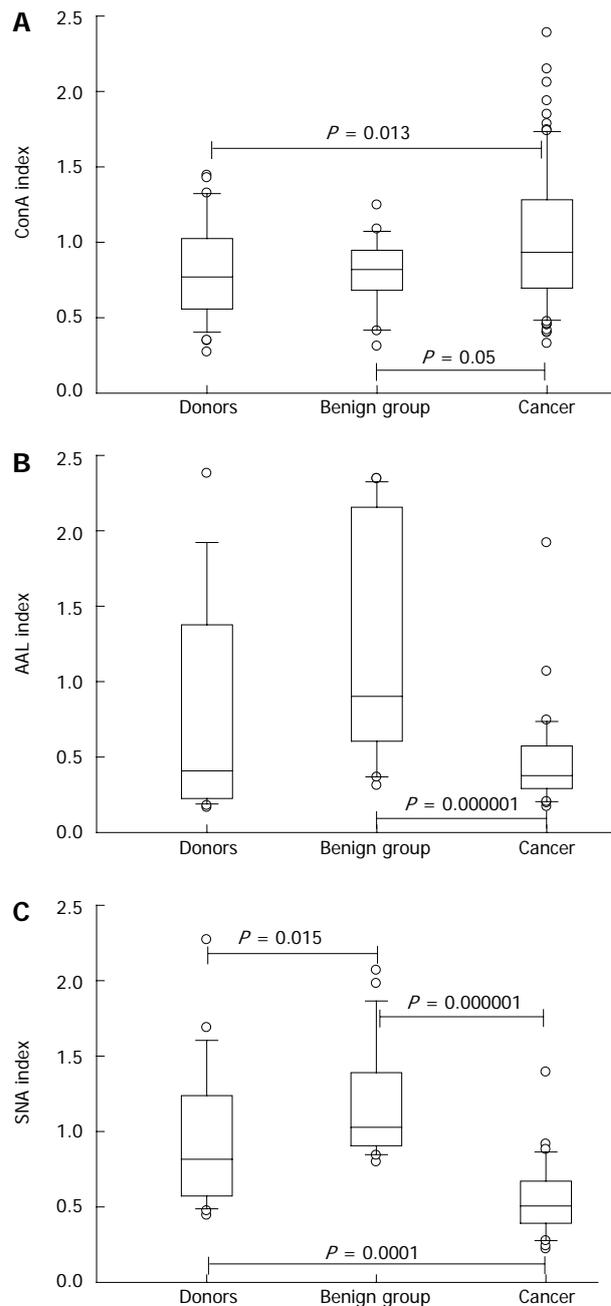

**Figure 1** Thomsen-Friedenreich glycotope-IgG level in patients with stomach cancer and controls. A: Box plots of anti-TF IgG levels (medians, ranges and quartiles) in controls and cancer patients; B: Anti-TF IgG levels in cancer patients by stage. Significantly higher in stage 1 compared with stages 2, 3 and 4 ( $P = 0.02$ ,  $0.001$  and  $0.01$ , respectively).  $P$  values were calculated by the Mann-Whitney  $U$  test.

significantly lower in cancer patients compared with that of blood donors and patients with benign gastric diseases ( $P < 0.0001$ ). In cancer patients, the binding of AAL did not differ from that of the donors ( $P = 0.64$ ), but was significantly lower than that of the benign group ( $P = 0.000008$ ) or non-cancer group ( $P = 0.005$ ). A group of patients with chronic gastritis ( $n = 7$ , one with atrophic gastritis), who showed very high AAL index values, accounted for this difference. This was the only exception in this study when the benign group differed significantly from the donors ( $P = 0.01$ ). Two of these patients also showed a high level of SNA binding. All patients with peptic ulcer disease ( $n = 6$ ) demonstrated a similar level of binding for all three lectins compared with that of blood donors.

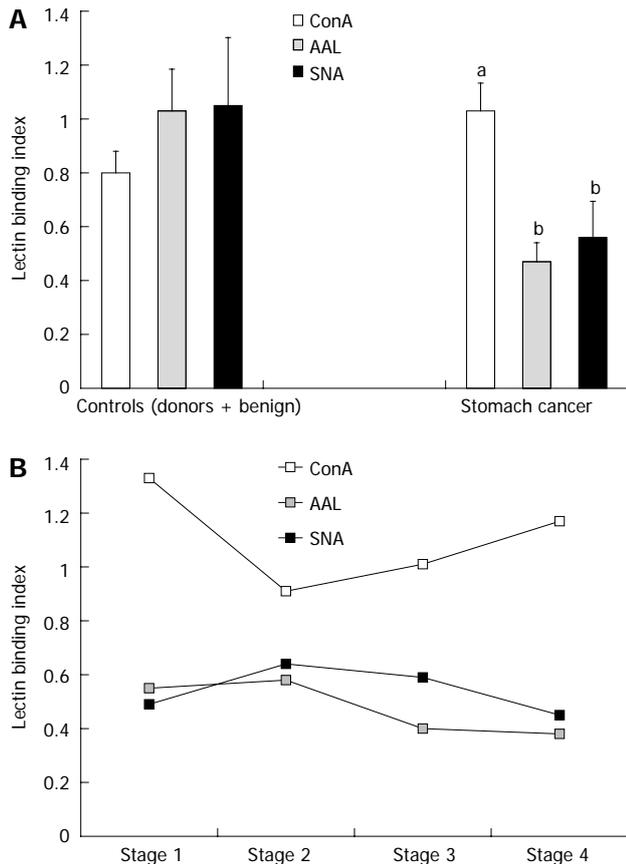

No appreciable stage-dependency of the binding of any lectin to the anti-TF IgG was found (Figure 3), though a slight trend towards higher ConA index values in stage 1 cancer patients was observed ( $P = 0.19$  compared with stage 3 patients).

A strong positive correlation between the reactivities of AAL and SNA was demonstrated in all groups: cancer

**Figure 2** Binding of lectins to the Thomsen-Friedenreich glycotope-specific IgG in gastric cancer patients and controls. A: Concanavalin A (ConA); B: *Aleuria aurantia* lectin (AAL); C: *Sambucus nigra* agglutinin (SNA). Box plots of lectin index values (medians, ranges and quartiles) in patients with stomach cancer, healthy blood donors and patients with benign stomach disease.  $P$  values were calculated by the Mann-Whitney  $U$  test and are shown for significant differences.

patients ( $r = 0.72$ ;  $P < 0.0001$ ); non-cancer group ( $r = 0.71$ ;  $P < 0.0001$ ) as well as the combined group of all tested subjects ( $r = 0.72$ ;  $P < 0.0001$ ). No significant correlation between the reactivities of ConA and the two other lectins was observed. Thus, the changes in ConA reactivity were not related to the modification of anti-TF IgG binding sites for the fucose- or sialic acid-specific lectins (AAL and SNA).

The results are depicted as mean with error bars representing SEM. *P* values were calculated by the Mann-Whitney *U* test: <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 vs controls for all lectins. ConA: Concanavalin A; AAL: *Aleuria aurantia* lectin SNA: *Sambucus nigra* agglutinin.

### Anti-TF IgG level and lectin binding profile: Sensitivity and specificity in stomach cancer

ROC curve analysis was used to evaluate changes in the level and glycosylation profile of anti-TF-IgG as possible biomarkers. The diagnostic accuracy and ROC curve statistics are presented in Figure 4 and Table 2. In the absence of a correlation between the binding of ConA and the two other lectins, we investigated a possible interactive effect of lectin combinations using the ratios of ConA/SNA, ConA/AAL and AAL/SNA in the ROC analysis.

Despite the significant difference in anti-TF IgG levels between cancer patients and controls these changes showed a low sensitivity and specificity for cancer, possibly due to great variations within each group. The same was true for the ConA and AAL lectin index values. In contrast, changes in the SNA binding index and, especially, ConA/SNA ratio values demonstrated rather good sensitivity and specificity reaching 78.8%-88.6% (Table 2). Since no notable cancer stage dependency of lectin binding was observed, the sensitivity and specificity values are presented for the combined cancer group and non-cancer

**Figure 4 Sensitivity and specificity of anti-Thomsen-Friedenreich glycotope-specific IgG glycosylation changes in stomach cancer.** A: Receiver operator characteristic (ROC) curve analysis by lectin binding index values; B: ROC curve analysis by lectin combinations using the ratios of concanavalin A (ConA)/*Sambucus nigra* agglutinin (SNA), ConA/*Aleuria aurantia* lectin (AAL) and AAL/SNA.

controls (Figure 4 and Table 2). Using the combination of ConA/AAL and AAL/SNA lectin ratios did not improve the accuracy of the assay and showed lower sensitivity and specificity values, usually below 70% (Table 2).

### Lectin binding of TF-specific IgG and survival of cancer patients

The subgroups of cancer patients with high and low levels of lectin binding to anti-TF IgG were compared. The cut-off levels were calculated using time-dependent ROC curve analysis for each lectin. Despite the opposite changes in the binding of ConA and AAL or SNA lectin in cancer patients (increase vs decrease) a similar association with survival was demonstrated for all three lectins tested, with a common trend in the early and advanced stages of the disease (Figure 5).

The low level of ConA-positive anti-TF IgG was associated with a survival benefit in cancer patients (HR = 1.56; 95%CI: 0.78-3.09; *P* = 0.19), especially in those with stages 3-4 of the disease (HR = 2.17; 95%CI: 0.98-4.79; *P* = 0.048). A significantly better survival rate was found in all cancer patients with low reactivity

**Table 2** Anti-TF IgG level and lectin binding profile: Sensitivity and specificity for gastric cancer

| Parameter   | Sensitivity % (95%CI) | Specificity % (95%CI) | ROC statistics   |          | Sensitivity at specificity 90% |
|-------------|-----------------------|-----------------------|------------------|----------|--------------------------------|
|             |                       |                       | Area under curve | P value  |                                |
| Anti-TF IgG | 65.17 (51.34-76.26)   | 67.74 (56.66-76.98)   | 0.70             | < 0.0001 | 50.56                          |
| ConA        | 62.92 (48.37-74.49)   | 56.90 (46.37-67.74)   | 0.64             | 0.004    | 24.72                          |
| SNA         | 78.79 (61.09-91.02)   | 79.17 (65.01-89.53)   | 0.87             | < 0.0001 | 57.58                          |
| AAL         | 69.70 (51.29-84.41)   | 64.58 (49.46-77.84)   | 0.68             | 0.006    | 12.12                          |
| ConA/SNA    | 72.73 (57.21-85.04)   | 88.64 (71.80-96.60)   | 0.91             | < 0.0001 | 63.64                          |
| AAL/ConA    | 84.85 (68.10-94.89)   | 68.18 (52.42-81.39)   | 0.78             | < 0.0001 | 33.33                          |
| AAL/SNA     | 84.85 (72.24-93.93)   | 47.92 (30.80-66.46)   | 0.68             | 0.006    | 3.03                           |

ConA: Concanavalin A; AAL: *Aleuria aurantia* lectin; SNA: *Sambucus nigra* agglutinin; Anti-TF IgG: Anti-Thomsen-Friedenreich glycotope immunoglobulin G; ROC: Receiver operator characteristic.

of anti-TF IgG to the fucose-specific AAL lectin (HR = 2.39; 95%CI: 1.0-5.7;  $P = 0.038$ ). The association of SNA lectin reactivity with survival showed a similar trend. Considering that no correlation between the binding of ConA and the two other lectins was found, a possible interactive effect of the combination of the two lectins was investigated using the ratios of ConA/SNA, ConA/AAL and AAL/SNA. However, no additional information regarding association with survival was obtained (data not shown).

## DISCUSSION

The role of autoantibodies against tumor-associated glycans in cancer surveillance has been mostly considered for IgM<sup>[2,4]</sup>. These antibodies are not affinity-matured which argues in favor of their inherent natural origin. In contrast, the presence of IgG anti-glycan antibodies suggests an adaptive immune response. The origin of anti-glycan autoantibodies of both isotypes is still unclear though the available evidence suggests that at least anti-TF and anti-alpha Gal antigen-specific antibodies may be induced by bacterial glycans or, possibly, by cross-reactivity with these antigens<sup>[3,32]</sup>. In any case, large and unexplained interindividual variations in their level in health and disease exist<sup>[21,22]</sup>, possibly reflecting the distinct immunological histories of each individual. Moreover, the anti-TF IgG level is rather stable over time at an individual level in both patients and controls<sup>[22,33]</sup>.

In this study, a significantly higher level of TF-specific IgG in purified total IgG preparations from the serum of patients with stomach cancer than in both control groups was observed. This increase was mostly pronounced in stage 1 of the disease, suggesting that an adaptive immune response cannot be excluded in the early stages of tumor with a subsequent decrease in the anti-TF IgG level in advanced cancer as a result of tumor-induced immunodepression. If this is the case, the population of anti-TF IgG should be expected to be heterogeneous and to include both naturally-occurring TF glycotope-specific antibodies, whose presence precedes tumor development, and those triggered by disease, *i.e.*, induced by the tumor-derived TF glycotope. Because of

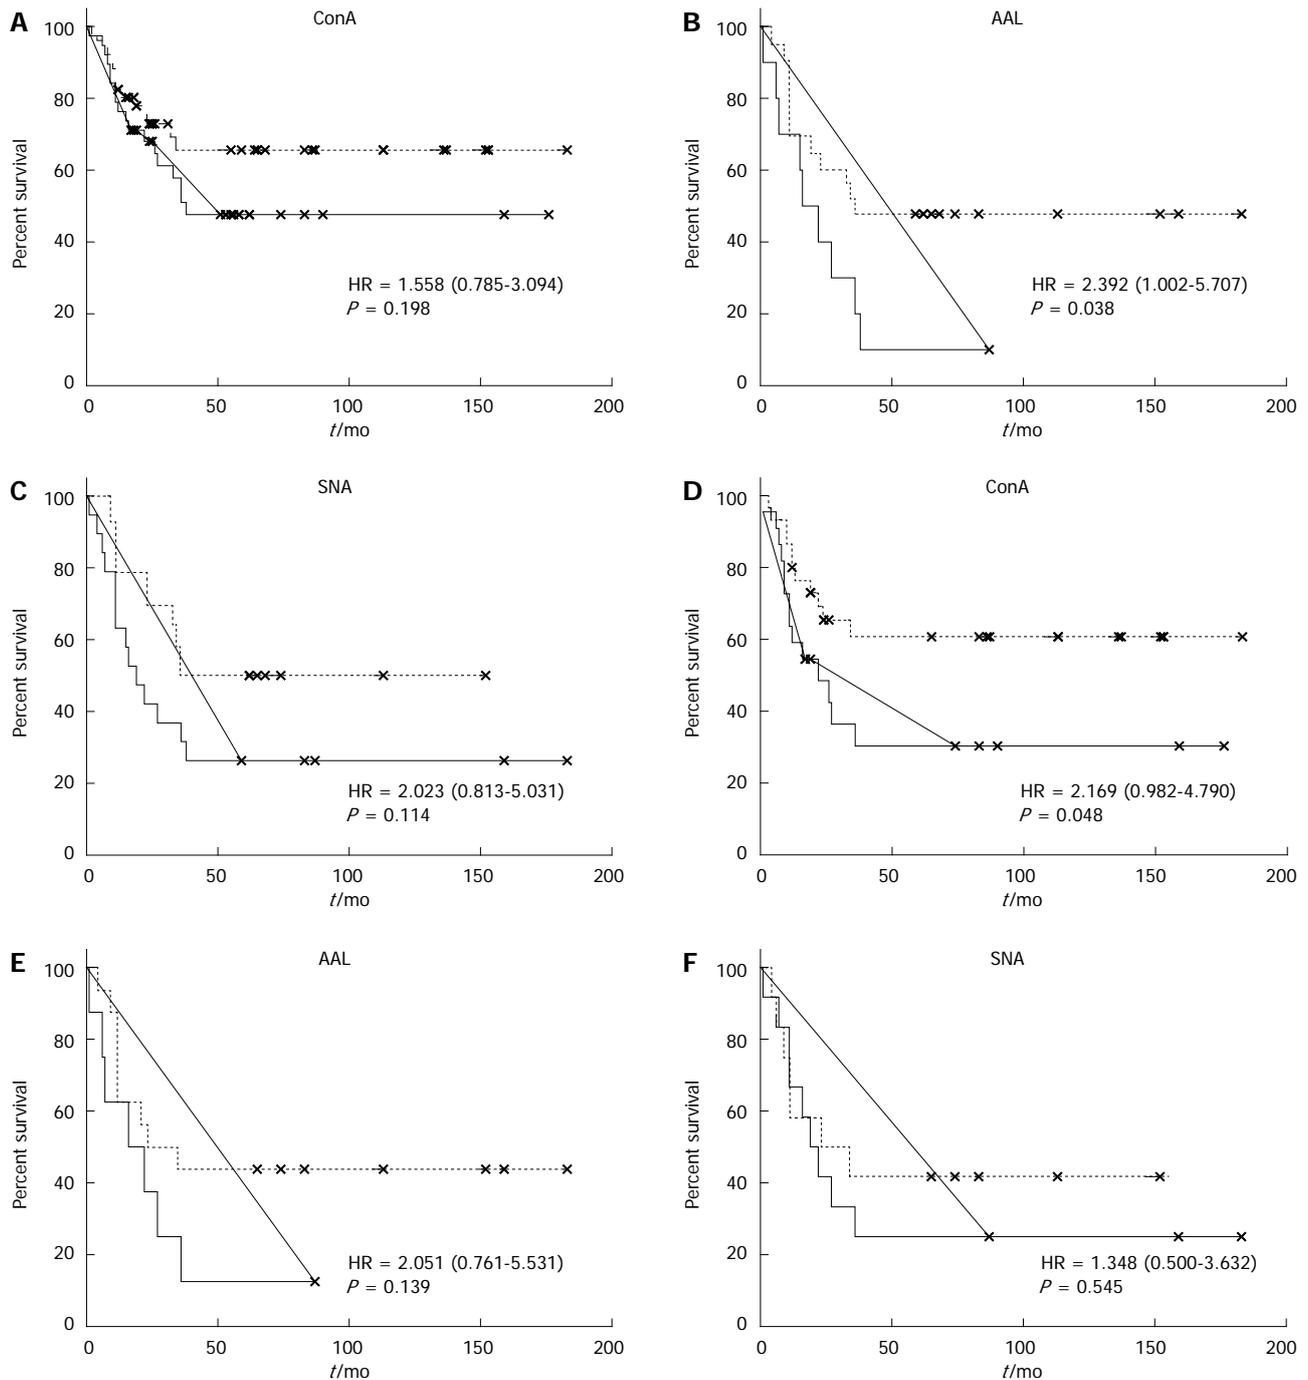

large interindividual variations in anti-TF IgG level, the human population may be divided into low and strong responders to the TF glycotope. Notably, donors and the benign group showed a more compact distribution. Further characterization of anti-TF IgG subpopulations is needed to determine their structural and functional diversities, and clinical significance.

A significantly higher binding of ConA ( $P = 0.005$ ) and a highly significant ( $P = 0.00000003$ ) decrease in SNA lectin binding was characteristic of the anti-TF IgG from the samples of cancer patients compared with those of the non-cancer group (Figure 3). The ConA binding index was higher in stage 1 patients, whereas the SNA and AAL lectin binding index values were low irrespective of the disease stage. We previously found similar changes in the binding of ConA to the total IgG from the serum of patients with gastric cancer.

The changes in anti-TF IgG glycosylation showed rather a high level of sensitivity and specificity in cancer and non-cancer group discrimination (Table 2). It appears that the SNA binding index and, in particular, the ConA/SNA ratio are promising as diagnostic markers to differentiate stomach cancer from controls, including benign gastric diseases. As there are no reliable markers for gastric cancer yet, these findings may be of clinical value.

We reported recently that the level of agalactosylated IgG (G0 glycoform) in the total IgG of gastric cancer patients was significantly higher than that of controls<sup>[9]</sup>. Interestingly, this shift positively correlated with the binding of ConA to the total serum IgG, and was also observed in purified TF-specific IgG samples (unpublished data). This indicates that IgG asialylation/agalactosylation is associated with an increased ConA binding possibly due to a better accessibility of the d-mannose residue to the ConA because of conformational changes in the Fc G0 glycoform. The absence of a correlation between the binding of ConA and SNA may be a reason for a positive interactive effect of using the ConA/SNA binding ratios for cancer *vs* non-cancer group discrimination.

Despite the opposite changes in the binding of ConA and the two other lectins to anti-TF IgG in pa-

**Figure 5 Binding of lectins to Thomsen-Friedenreich glycotopes-specific IgG and the survival of patients with stomach cancer.** The probability of survival (Kaplan-Meier method) of stomach cancer patients in relation to lectin binding to Thomsen-Friedenreich glycotopes (TF)-specific IgG. A: Concanavalin A (ConA) lectin binding of all cancer patients; B: *Aleuria aurantia* lectin (AAL) binding in all cancer patients; C: *Sambucus nigra* agglutinin (SNA) binding in all cancer patients; D: ConA binding in patients with stage 3-4 cancer; E: AAL binding in patients with stage 3-4 cancer; F: SNA binding of patients with stage 3-4 cancer. Patient lectin index values, which were either lower, equal to (dashed line) or higher (solid line) than the cut-off are compared. The cut-off levels were calculated using time-dependent receiver operator characteristic curve analysis.

tients with cancer (Figure 2), a better survival rate was associated with lower reactivity of anti-TF IgG to AAL and ConA. The SNA reactivity revealed no significant association with survival, though a similar slight trend was observed. It seems that IgG desialylation alone is not sufficient for the impact on survival, and further degalactosylation is needed to attain this effect. In this study, the patients were subjected to follow-up for more

than 10 years. The association of the binding of ConA and AAL with survival became evident after 2.5-3 years of observation, reaching a maximum after 5 years.

Several studies have demonstrated that agalactosylated IgGs show an increased inflammatory activity<sup>[34-37]</sup> that may promote tumor growth<sup>[38,39]</sup>. In addition, the IgG<sub>1</sub> lacking the branching fucose or with an additional bisecting GlcNAc shows an enhanced ADCC activity

through an increased interaction with Fc gamma receptors<sup>[36,40-42]</sup>. The association of the high level of the G0 IgG glycoform with a lower survival rate we reported recently<sup>[9]</sup>, and the decreased anti-TF IgG fucosylation associated with better survival in the present findings may be related to these mechanisms.

It has been shown that sialylated glycans predominate in glycosylated antibody binding fragments (Fab) whereas the Fc fragment N-glycans are mostly monosialylated<sup>[30,43]</sup>. Our findings cannot answer the question of whether the Fc or Fab fragment sialylation is responsible for the changes observed in anti-TF IgG glycosylation.

In addition, it remains unclear whether changes in the sialylation and core fucosylation of anti-TF IgG glycans in both IgG fragments may be independent or concordant events, despite the positive correlation observed between the binding of SNA and AAL lectin to the whole molecule of the TF-specific IgG. Given that an active immunization reduces the sialylation of IgG, especially the antigen-driven IgG<sup>[36]</sup>, we hypothesize that the decreased sialylation of anti-TF IgG observed in cancer patients may be an indicator of an adaptive immune response to tumor-derived TF antigen, in addition to naturally-occurring anti-TF IgG antibodies, which are present in every individual in different amounts.

In conclusion, the results show the glycosylation of TF-specific IgG antibodies in patients with gastric cancer to undergo significant changes when compared with that of controls. The appearance of these alterations already in the early stages of cancer and their association with survival suggest that they play a significant role in cancer development and progression. The lectin-based glycoprofiling ELISA assay is an informative and clinically applicable tool for the analysis of IgG glycans. The results imply that changes in the TF-specific IgG glycosylation have diagnostic and prognostic potential for stomach cancer. However, a further study is needed to support these findings on a larger scale using different control groups. Mass spectrometry-based methodology might help to further specify different subsets of anti-TF IgG of clinical importance.

## COMMENTS

### Background

Gastric cancer is the second leading cause of cancer deaths worldwide. Yet there are still no reliable serum biomarkers for gastric cancer diagnostics and prognostics. Previous studies have demonstrated that naturally-occurring antibodies (Ab) to tumor-associated glycans are involved in natural tumor immunity, being associated with tumor progression and cancer patients survival.

### Research frontiers

Recent findings about the impact of Ab glycosylation on their effect or functions suggest that the evaluation of not just the level of antibodies but rather their structural diversity might improve the clinical potential of the antibody-based approach in the disease diagnostics and prognostics. With this purpose in mind, a research team from Estonia led by Kurtenkov O aimed to evaluate whether the glycosylation profile of immunoglobulin G (IgG) antibody to the so-called tumor-associated Thomsen-Friedenreich antigen (TF) could serve as a marker of gastric cancer and the disease outcome. The study is based on the analysis of a long-term (for more than 10 years) survival of cancer patients.

## Innovations and breakthroughs

This study demonstrates for the first time that the glycosylation of anti-TF antibodies reveals gastric cancer-related changes with a diagnostic sensitivity and specificity of about 80%. It is striking that the stage of cancer had little effect on these parameters, thus allowing one to diagnose the disease in its early stages. Besides, the authors show that some Ab glycoforms may predict patient survival. Based on these results, the authors conclude that this serology-based approach may be of clinical importance for gastric cancer diagnostics and prognostics.

## Applications

The results indicate that changes in the TF-specific IgG glycosylation have diagnostic and prognostic potential for stomach cancer. The lectin-based glycoprofiling of anti-TF IgG antibodies is an informative and clinically applicable tool to specify sets of tumor-associated antibody glycoforms which can be used as a biomarker for stomach cancer detection and follow-up. It is plausible that the elevated level of a specific antibody glycoform might serve as a marker for a stronger immune response, providing protection against cancer. The findings may eventually lead to the development of novel forms of cancer immunotherapy based on vaccination with TF as target and the manipulation of Ab glycosylation machinery. This will need further work, in particular performance of functional tests using tumor cells and different Ab glycoforms, to understand the biological relevance of the results.

## Terminology

Glycans: The chains of sugars that coat the outer surface of cells or are attached to other molecules (proteins, lipids). Glycosylation is the enzymatic process in which sugars are attached to other molecules.

## Peer review

This important study extends findings from studies of the same authors published previously and make a great contribution to the understanding of the molecular mechanisms that underline aberrant glycosylation in gastric carcinogenesis, and to the evaluation of potential biomarkers for gastric cancer diagnosis and patient prognosis.

### Abstract

**AIM:** To investigate the effect of bone-marrow mesenchymal stem cells (BM MSCs) on the intestinal mucosa barrier in ischemia/reperfusion (I/R) injury.

**METHODS:** BM MSCs were isolated from male Sprague-Dawley rats by density gradient centrifugation, cultured, and analyzed by flow cytometry. I/R injury was induced by occlusion of the superior mesenteric artery for 30 min. Rats were treated with saline, BM MSCs (*via* intramucosal injection) or tumor necrosis factor (TNF)- $\alpha$  blocking antibodies (*via* the tail vein). I/R injury was assessed using transmission electron microscopy, hematoxylin and eosin (HE) staining, immunohistochemistry, western blotting and enzyme linked immunosorbent assay.

**RESULTS:** Intestinal permeability increased, tight junctions (TJs) were disrupted, and zona occludens 1 (ZO-1) was downregulated after I/R injury. BM MSCs reduced intestinal mucosal barrier destruction, ZO-1 downregulation, and TJ disruption. The morphological abnormalities after intestinal I/R injury positively correlated with serum TNF- $\alpha$  levels. Administration of anti-TNF- $\alpha$  IgG or anti-TNF- $\alpha$  receptor 1 antibodies attenuated the intestinal ultrastructural changes, ZO-1 downregulation, and TJ disruption.

**CONCLUSION:** Altered serum TNF- $\alpha$  levels play an important role in the ability of BM MSCs to protect against intestinal I/R injury.

**Key words:** Bone marrow mesenchymal stem cells; Zona occludens 1; Ischemia-reperfusion injury; Intestinal mucosa; Tumor necrosis factor- $\alpha$

**Core tip:** Intestinal ischemia/reperfusion (I/R) injury is clinically important. Bone-marrow mesenchymal stem cells (BM MSCs) can protect against I/R injury; however, the mechanism is unclear. This study demonstrates that submucosal infusion of BM MSCs decreased intestinal permeability and preserved intestinal mechanical barrier function after I/R injury in rats, *via* a mechanism linked to reduced serum tumor necrosis factor (TNF)- $\alpha$  levels and increased expression of the intestinal tight junction protein zona occludens 1. Altered serum TNF- $\alpha$  levels play an important role in the ability of BM MSCs to protect against intestinal I/R injury.

## INTRODUCTION

Digestive organ transplantation and other abdominal surgical procedures can result in different degrees of intestinal ischemia/reperfusion (I/R) injury, which can delay patient recovery and lead to systemic organ failure. Therefore, intestinal I/R injury is an important clinical issue. The small intestine is composed of labile cells that are easily injured by I/R; however, the mechanisms responsible for intestinal I/R injury are unclear. Previous studies have reported that the serum level of tumor necrosis factor (TNF)- $\alpha$  is elevated in patients with severe intestinal I/R injury<sup>[1]</sup>. TNF- $\alpha$  is a cytokine with broad-spectrum physiological and pathological responsiveness, which is primarily secreted by monokaryons and macrophages. In addition to participating in the humoral and cellular immune responses, TNF- $\alpha$  also plays an important role in diseases such as severe hepatitis, septic shock and inflammatory bowel disease<sup>[2-6]</sup>; however, it is not known whether TNF- $\alpha$  affects the intestinal barrier function during I/R injury.

Bone-marrow mesenchymal stem cells (BM MSCs) are fibroblast-like, pluripotent adult stem cells. BM MSCs can adhere to plastic and grow readily in the laboratory. BM MSCs give rise to mesoderm cells<sup>[7,8]</sup>, and have been reported to differentiate into all three germ cell lines<sup>[9]</sup>, liver and neural cells<sup>[10,11]</sup>, which have potential to be used for the treatment of various diseases. Allogeneic MSCs were transplanted into primates *via* an intravenous route and distributed to the gastrointestinal tract where they proliferated<sup>[12]</sup>. MSCs have also been shown to have immunomodulatory capabilities due to the secretion of several growth factors<sup>[13,14]</sup>. BM MSCs reduce intestinal I/R injury in rats<sup>[15]</sup>. Studies in I/R rodent models have demonstrated that MSCs can beneficially produce paracrine growth factors and anti-inflammatory cytokines<sup>[16]</sup>. It should be noted that MSCs respond to TNF- $\alpha$ , but do not produce TNF- $\alpha$ <sup>[17]</sup>.

The intestinal mucosa is the physical and metabolic barrier against toxins and pathogens in the gut lumen. Tight junctions (TJs) are the main structures responsible for restricting the paracellular movement of compounds across the intestinal mucosa. Structurally, TJs are composed of cytoplasmic proteins, including the zona occludens proteins, ZO-1-3<sup>[18,19]</sup> and two distinct transmembrane proteins, occludin and claudin<sup>[20,21]</sup>, which are linked to the actin-based cytoskeleton<sup>[22]</sup>. TJs function as occlusion barriers by maintaining cellular polarity and homeostasis, and by regulating the permeability of paracellular spaces in the epithelium<sup>[23]</sup>. ZO-1, a member of the membrane-associated guanylate kinase family of proteins, acts as a scaffold for the organization

of transmembrane TJ proteins, and also recruits various signaling molecules and the actin cytoskeleton to TJs<sup>[24]</sup>. Although previous studies have provided an insight into the molecular structure of TJs, much less is known about TJ functionality under physiological or pathophysiological conditions. Few studies have described the intestinal mucosa ultrastructure or changes in TJs during I/R injury.

In this study, we used a rat model of intestinal I/R injury to investigate the effect of BM MSCs on intestinal mucosa ultrastructure, with an emphasis on the mechanisms of intestinal barrier dysfunction.

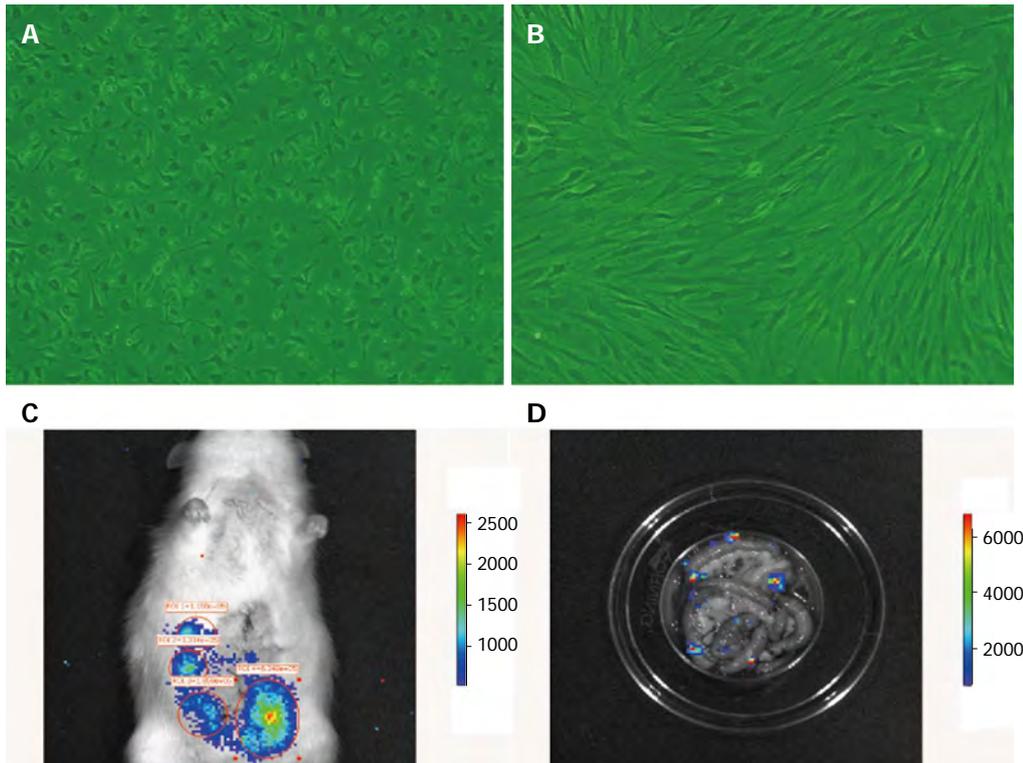

## MATERIALS AND METHODS

### Animals and I/R injury model

Male Sprague-Dawley rats (180-200 g) were obtained from the Military Medical Science Academy of China People's Liberation Army (PLA; Beijing, China), housed at a constant temperature and humidity, and provided with food and water *ad libitum*. All animal experimental procedures were approved by the Ethics Committee of the Military Medical Science Academy of the PLA before commencement of the study.

One-hundred and eight male rats were fasted for 12 h with free access to water before surgery and randomly assigned to five experimental groups. The operative procedures were performed using standard sterile technique under general anesthesia using 5% chloral hydrate (10 mL/kg). All rats were subjected to laparotomy using a midline incision that was approximately 3 cm, and the principal branches of the superior mesenteric artery (SMA) were identified. In the Sham group, the SMA was isolated using blunt dissection, without clamping the vessel. In the BM MSCs + I/R injury group, the SMA was occluded for 30 min using an atraumatic microvascular clamp. Immediately after the clamp was released,  $1 \times 10^7$  male rat BM MSCs suspended in 0.5 mL serum-free Dulbecco's Modified Eagle's Medium (DMEM) were injected into the intestinal submucosa at five different locations. Animals in the normal saline (NS) + I/R injury group underwent I/R followed by the injection of 0.5 mL normal saline into the intestinal submucosa at 10 different locations. The anti-TNF- $\alpha$  + I/R injury group and the anti-TNF- $\alpha$ R1-IgG + I/R injury group were administered with anti-TNF- $\alpha$  IgG (1000  $\mu$ g per rat; United States Biological, Swampscott, MA, United States) or anti-TNF- $\alpha$  R1 antibody (1000  $\mu$ g per rat; R and D Systems, Minneapolis, MN, United States), respectively. Injections were given *via* the tail vein after induction of I/R injury.

The abdomen was closed and the animals were allowed to recover with free access to tap water and standard pellet rat chow. Rats in the I/R injury, BMSCs + I/R injury and Sham groups were euthanized at 2, 6, 24, 72 and 144 h after I/R injury ( $n = 6$  at each time point). Rats in the anti-TNF- $\alpha$  IgG + I/R and anti-TNF- $\alpha$  R1

**Figure 1** Morphology of bone-marrow mesenchymal stem cells *in vitro*, and *in vivo* cell tracing of bone-marrow mesenchymal stem cells colonization in rat intestine. A: First-passage bone-marrow mesenchymal stem cells (BM MSCs); B: Third-passage BM MSCs ( $\times 200$ ); C: Homing of fluorescently labeled BM MSCs (B16-F10-Luc-G5) to the rat intestine 6 h after transplantation; D: After the intestine was removed and washed repeatedly, fluorescently labeled BM MSCs were still observed, confirming the cells homed to the intestine and survived.

antibody + I/R injury groups were euthanized at 6 h after I/R injury ( $n = 6$  each). Blood samples and approximately 5 cm of the ileum were collected from each rat. The plasma was separated by centrifugation and stored at  $-80^{\circ}\text{C}$  until analysis. The intestinal samples were fixed for histopathological analysis and transmission electron microscopy.

#### Isolation and characterization of BM MSCs

BM MSCs were isolated from the femur and tibia of male Sprague-Dawley rats (100-120 g). Red blood cells were lysed using 0.1 mol/L  $\text{NH}_4\text{Cl}$ , and the remaining cells were washed, resuspended, and cultured for 4 wk in DMEM/F12 (Gibco, Carlsbad, CA, United States) containing 100 U/mL penicillin, 100 mg/mL streptomycin, and 15% fetal bovine serum. BM MSCs were cultured in an incubator at  $37^{\circ}\text{C}$ , 5%  $\text{CO}_2$  with saturated humidity. The medium was changed every 72 h.

When the third-passage cells reached 80% confluence, the cells were trypsinized, washed, centrifuged, and resuspended at  $1 \times 10^7$  cells/mL in phosphate-buffered saline (PBS). BM MSCs were stained using antibodies against CD29, CD90, RT1A, CD45 and RT1B (Biolegend, San Diego, CA, United States) and CD34 (Santa Cruz Biotechnology, Santa Cruz, CA, United States). They were analyzed by flow cytometry (FACSCalibur; BD, Alaska, MN, United States). The proportion of CD29<sup>+</sup>, CD90<sup>+</sup> and RT1A-positive cells, and CD34<sup>-</sup>

CD45<sup>-</sup> and RT1B-negative cells was  $> 98\%$  (Figure 1A). BM MSCs were also confirmed as plastic-adherent cells with a spindle-shaped morphology under standard culture conditions by microscopy (Figure 1B). The purity of BM MSCs was  $> 95\%$ .

#### Detection of donor BM MSCs in recipient intestines

BM MSCs ( $1 \times 10^7$  cells) were incubated with  $3.5 \mu\text{g}/\text{mL}$  1,1'-dioctadecyl-3,3,3',3'-tetramethyl indocarbocyanine iodide (DIR) in 10 mL PBS containing 0.5% ethanol for 30 min at  $37^{\circ}\text{C}$ , and washed twice with PBS. Sprague-Dawley rats weighing 180-200 g were anesthetized using 5% chloral hydrate, subjected to a midline laparotomy, and  $1 \times 10^7$  labeled BM MSCs suspended in 1 mL PBS were injected into the intestinal submucosa at five different points. At 2, 6, 24, 72 and 144 h later, luciferin was injected abdominally using a 25-gauge needle and, 7-8 min later, the animals were anesthetized and imaged using a high-sensitivity optical molecular imaging and high-resolution digital X-ray system (IVIS Lumina II, Alameda, CA, United States).

#### Histological measurement of intestinal mucosal injury

Serial 2-cm samples were taken from the terminal ileum and fixed with 10% neutral formalin. Tissues were processed, embedded, and stained with hematoxylin and eosin. Three paraffin sections were prepared from each tissue sample. Two pathologists who were blinded to the

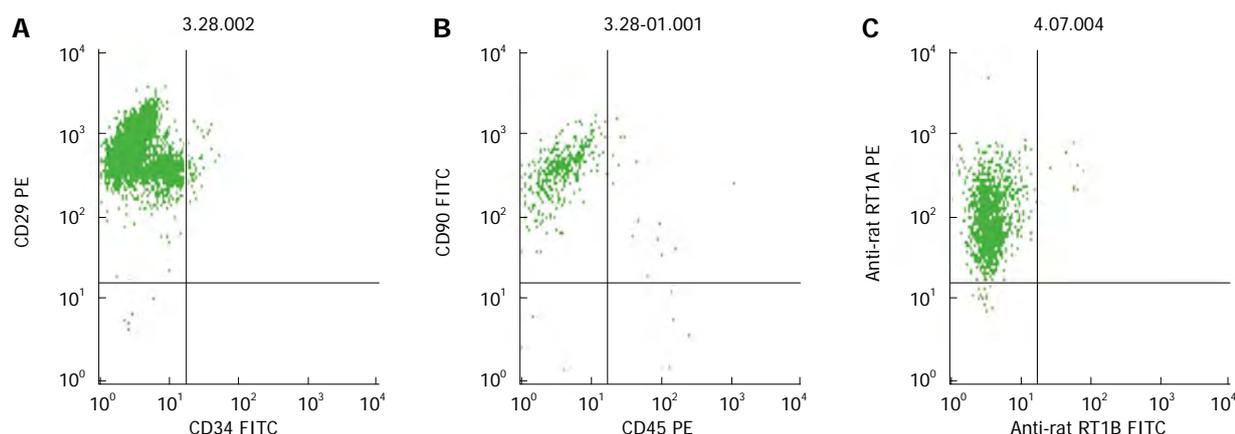

Figure 2 Flow cytometric analysis of third-passage bone-marrow mesenchymal stem cells. A: The proportion of CD29-positive and CD34-negative cells was approximately 96%; B: The proportion of CD90-positive and CD45-negative was approximately 98%; C: The proportion of RT1A-positive and RT1B-negative cells was > 98%.

source of the slides analyzed. The degree of histopathological changes was graded semiquantitatively using the histological injury scale previously described by Chiu *et al.*<sup>[25]</sup>, as follows: 0, normal mucosal villi; 1, development of a subepithelial space, usually at the apex of the villi with capillary congestion; 2, extension of the subepithelial space with moderate lifting of the epithelial layer from the lamina propria; 3, massive epithelial lifting down the sides of the villi and ulceration at the villous tips; 4, denuded villi with dilated capillaries and increased cellularity of the lamina propria; and 5, degradation and disintegration of the lamina propria, hemorrhage, and ulceration. A minimum of six randomly chosen fields from each rat were evaluated and averaged to determine the degree of mucosal damage.

#### Serum D-lactate, diamine oxidase and TNF- $\alpha$ assay

The serum levels of TNF- $\alpha$ , D-lactate and diamine oxidase (DAO) were determined using enzyme linked immunosorbent assay kits (R and D Systems) according to the manufacturer's protocol.

#### Detection and observation of intestinal mucosal ultrastructure

Ultrathin (70-nm) intestinal sections were prepared using standard techniques and examined using a transmission electron microscope (Hitachi H-600, Tokyo, Japan).

#### Immunohistochemical detection of ZO-1 in frozen tissue sections

Frozen intestinal tissue sections (5  $\mu$ m) were fixed on glass slides by incubation in acetone for 10 min at 4  $^{\circ}$ C, and then incubated with 3% H<sub>2</sub>O<sub>2</sub> for 20 min at room temperature, blocked in goat serum for 30 min at 37  $^{\circ}$ C, and then indirectly immunolabeled with a rabbit anti-mouse polyclonal ZO-1 antibody (1:50; Santa Cruz Biotechnology) using an ABC kit at 4  $^{\circ}$ C overnight (Takara, Dalian, China), according to the manufacturer's instructions. For the negative controls, the primary antibody was replaced with PBS. The sections were then incubated in biotinyl-

ated goat anti-rabbit IgG (1:300 in PBS; Histostain-Plus kit, Zymed Laboratories, South San Francisco, CA, United States) for 2 h at room temperature, rinsed in PBS, rinsed in distilled water, then the staining was developed using 3,3'-diaminobenzidine and the sections were counterstained using hematoxylin.

#### Western blotting of tissue ZO-1 content

Intestinal tissue samples were homogenized in lysis buffer [20 mmol/L Tris-HCl (pH 7.5), 1% Triton  $\times$  100, 0.2 mol/L NaCl, 2 mmol/L EDTA, 2 mmol/L EGTA, 1 mol/L DTT and 2 mol/L aprotinin]. The protein samples (50  $\mu$ g) were electrophoresed on 8% SDS-PAGE gels, transferred to nitrocellulose membranes, blocked with non-fat dried milk in TBS containing 0.05% Tween-20 (TTBS) for 1 h at room temperature, and incubated with a rabbit anti-mouse polyclonal ZO-1 antibody (1:400; Santa Cruz Biotechnology) at 4  $^{\circ}$ C overnight. After three washes in TTBS, the membranes were incubated with alkaline-phosphatase-labeled goat anti-rabbit IgG (1:2000; Santa Cruz Biotechnology) for 2 h at room temperature. The bands were visualized using  $\alpha$ -dianisidine and  $\beta$ -naphthyl acid phosphate (Sigma, St Louis, MO, United States).

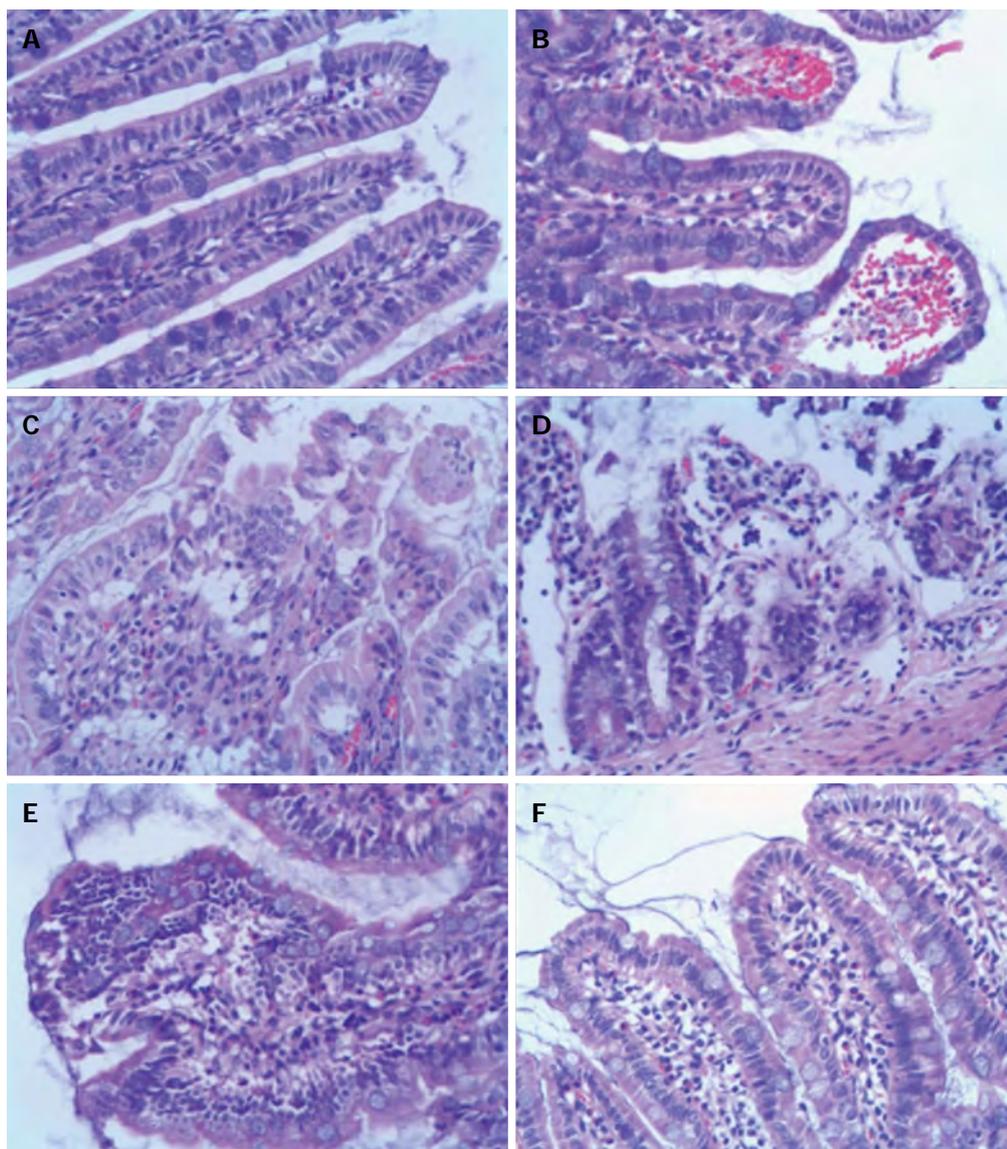

#### Statistical analysis

SPSS version 10.0 (SPSS, Chicago, IL, United States) was used for the statistical analysis. Normally distributed data were shown as the mean  $\pm$  SD. Different groups of data were compared by analysis of variance (ANOVA). The degree of relationship between TNF- $\alpha$  and the Chiu risk score was evaluated by a bivariate correlation. The results was statistically significant when  $P < 0.05$ , and was highly significant when  $P < 0.01$ .

## RESULTS

### Culture of BM MSCs

The cells were confirmed as BM MSCs based on their spindle-shaped morphology, adherence to plastic (Figure

**Figure 3** Histopathology of ileum sections at different time points after intestinal ischemia/reperfusion injury (hematoxylin and eosin,  $\times 200$ ). A: Sham group; the intestine showed normal villous architecture and glands, with no vascular congestion; B: In the ischemia/reperfusion (I/R) injury 2 h group, the degree of intestinal mucosa injury was marked with massive epithelial lifting down the sides of the villi and ulceration at the villous tips; C: At 6 h, there was intestinal mucosa degradation and disintegration of the lamina propria, hemorrhage, and ulceration; D: At 24 h, the damaged mucosa showed denuded villi with dilated capillaries and increased cellularity of the lamina propria; E: In the I/R injury group at 72 h, there was massive epithelial lifting down the sides of the villi and ulceration at the villous tips; F: However, at 144 h, the damaged mucosa had recovered.

1A and 1B), ability to differentiate hepatocytes *in vitro* (data not shown), and flow cytometry results (Figure 2). Most of the third-passage adherent cells were positive for CD90, CD29 and RT1A, and negative for the MSC markers, CD45, CD34 and RT1B. Furthermore, over the first three passages, the percentage of CD90<sup>+</sup> and CD45<sup>-</sup> cells rapidly increased from 80% to > 98% (Figure 2), which was in agreement with a previous study<sup>[26]</sup>.

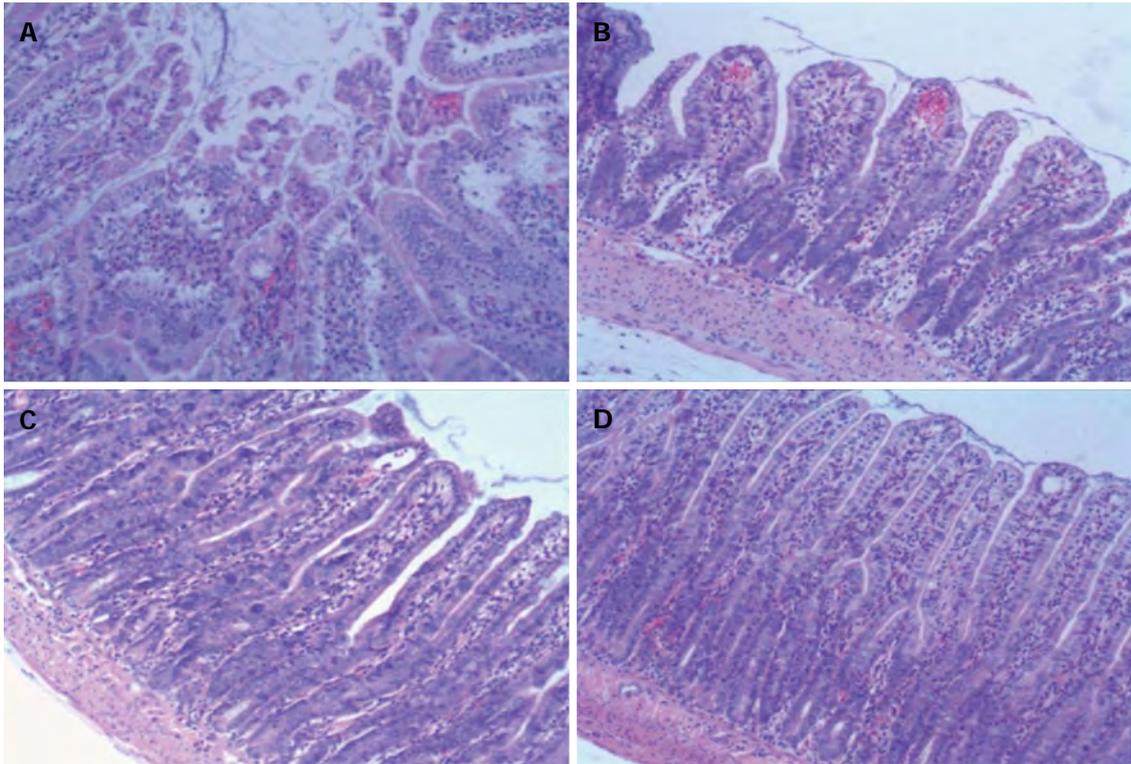

#### Confirmation of donor-derived BM MSCs

Labeled BM MSCs homing to the intestine were visible 2, 6, 24, 72 and 144 h after transplantation (Figure 1C). After the intestine was washed repeatedly with PBS, the labeled BM MSCs were still visible (Figure 1D), which indicated that the transplanted BM MSCs could home to

the intestine and survive long term.

#### Histopathological examination

The histopathological findings showed intact villi with no epithelial disruption in the Sham groups. In the NS + I/R injury group, massive destruction of the villi and inflammatory cell infiltration into the lamina propria were evident. In contrast, intestinal samples in the BM MSCs + I/R injury group (BM MSCs group) had significantly less damage in the small intestine. Major pathological changes observed were slight hyperemia, edema, and inflammatory cell infiltration in the mucosa and submucosa, with most of the intestinal villi intact (Figures 3 and 4). Chiu's grade scores of the three groups are shown in Table 1.

**Figure 4** Histopathology of ileum sections of different groups at 6 h after ischemia/reperfusion injury (hematoxylin and eosin, × 100). A: In the ischemia/reperfusion (I/R) injury group there was marked intestinal mucosa injury at 6 h, with intestinal mucosa degradation and disintegration of the lamina propria, hemorrhage, and ulceration. B: In the bone-marrow mesenchymal stem cells + I/R injury group at 6 h, the damaged mucosa had recovered and there was extension of the subepithelial space with moderate lifting of the epithelial layer from the lamina propria, massive epithelial lifting down the sides of the villi, and ulceration at the villous tips. C and D: In the anti-tumor necrosis factor (TNF)-α + I/R injury group and the anti-TNF-αR1-IgG + I/R injury group at 6 h, the damaged mucosa had almost recovered to resemble that in the Sham control group.

**Table 1** Grade of intestinal mucosal injury after intestinal ischemia/reperfusion in the different groups

| Group                         | Chiu's score              |                           |                           |                          |                          |
|-------------------------------|---------------------------|---------------------------|---------------------------|--------------------------|--------------------------|

All values are mean ± SD (*n* = 6, three paraffin sections were prepared from each tissue sample. Two pathologists who were blinded to the source of the slides analyzed each slide); <sup>b</sup>*P* < 0.01 *vs* the Sham group, <sup>d</sup>*P* < 0.01 *vs* the saline (NS) + ischemia/reperfusion (I/R) injury group, <sup>f</sup>*P* < 0.01 *vs* bone-marrow mesenchymal stem cells (BM MSCs) + I/R injury group. TNF-α: Tumor necrosis factor-α.

### Serum D-lactate and DAO

The levels of D-lactate and DAO significantly increased, reaching a peak at 6 h in the NS + I/R injury and BM MSCs + I/R injury groups, compared to the Sham group. This confirmed that I/R injury increased intestinal permeability.

The serum D-lactate and DAO levels in the NS + I/R injury group increased more than twofold compared to the Sham group at 2, 6 and 24 h after I/R (*P* < 0.01). However, the serum DAO levels in the BM MSCs + I/R injury group were significantly lower than in the NS + I/R group at 2, 6 and 24 h, and the serum D-lactate levels in the BM MSCs + I/R injury group were significantly

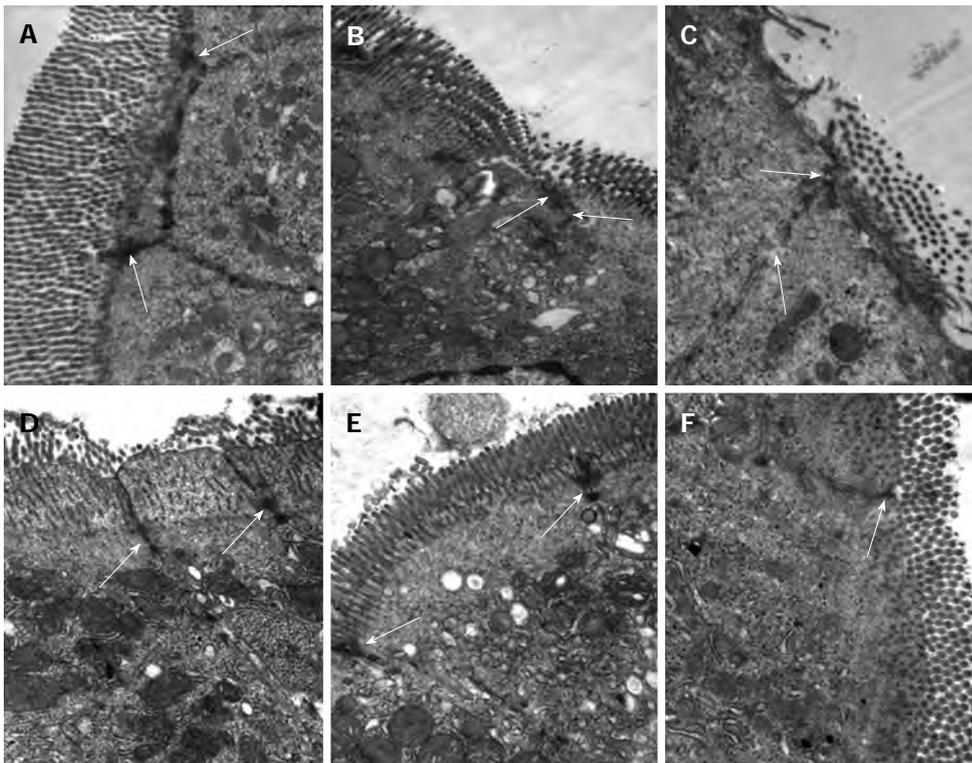

lower than in the NS + I/R group at 6 and 24 h. At 6 h, the serum D-lactate and DAO levels in the anti-TNF-α + I/R injury and anti-TNF-αR-IgG + I/R injury groups were lower than in the NS + I/R injury group (*P* < 0.01; Table 2). At 72 and 144 h, the serum DAO levels in the NS + I/R and BM MSCs + I/R injury groups had reduced, but remained higher than in the Sham group, whereas D-lactate levels were not significantly different in the NS + I/R, BM MSCs + I/R and Sham groups at 144 h.

These data indicate that serum DAO is a more sensitive marker of intestinal permeability than D-lactate, and also that the administration BM MSCs or TNF-α block-

**Table 2 Serum levels of diamine oxidase and D-lactate in a rat model of ischemia/reperfusion injury**

| Group                                  | DAO (IU/mL)                    |                                 |                                |                              |                              | D-lactate ( $\mu\text{g/mL}$ ) |                                 |                                |                              |                 |

**Figure 5** Bone-marrow mesenchymal stem cells and tumor necrosis factor- $\alpha$  blockade prevent ultrastructural pathological damage after intestinal ischemia/reperfusion injury. Transmission electron microscopy of the rat intestine after ischemia/reperfusion (I/R) injury. A: Epithelial cells and tight junctions (TJs) (arrows) were intact in the Sham group,  $\times 30000$ ; B: At 2 h after I/R injury, epithelial cells were swollen and shrunken, microvilli and organelles were normal, and TJs (arrows) were disrupted in the saline (NS) + I/R injury group,  $\times 25000$ ; C: At 6 h after I/R injury in the NS + I/R injury group, some microvilli were loose, TJs (arrows) were disrupted, and organelles were swollen with reduced electron density,  $\times 30000$ ; D: At 6 h after I/R injury and administration of bone-marrow mesenchymal stem cells, the microvilli and mitochondria of the endothelial cells were almost normal and TJs (arrows) were not disrupted,  $\times 30000$ ; E and F: TJs (arrows) between endothelial cells were intact 6 h after I/R injury in rats that received anti-tumor necrosis factor (TNF)- $\alpha$  IgG + I/R antibody (E,  $\times 25000$ ) or anti-TNF- $\alpha$  R1 antibody; (F,  $\times 30000$ ) before I/R injury.

ade reduced the permeability of the small intestine and accelerated the recovery of intestinal barrier function after I/R injury in rats.

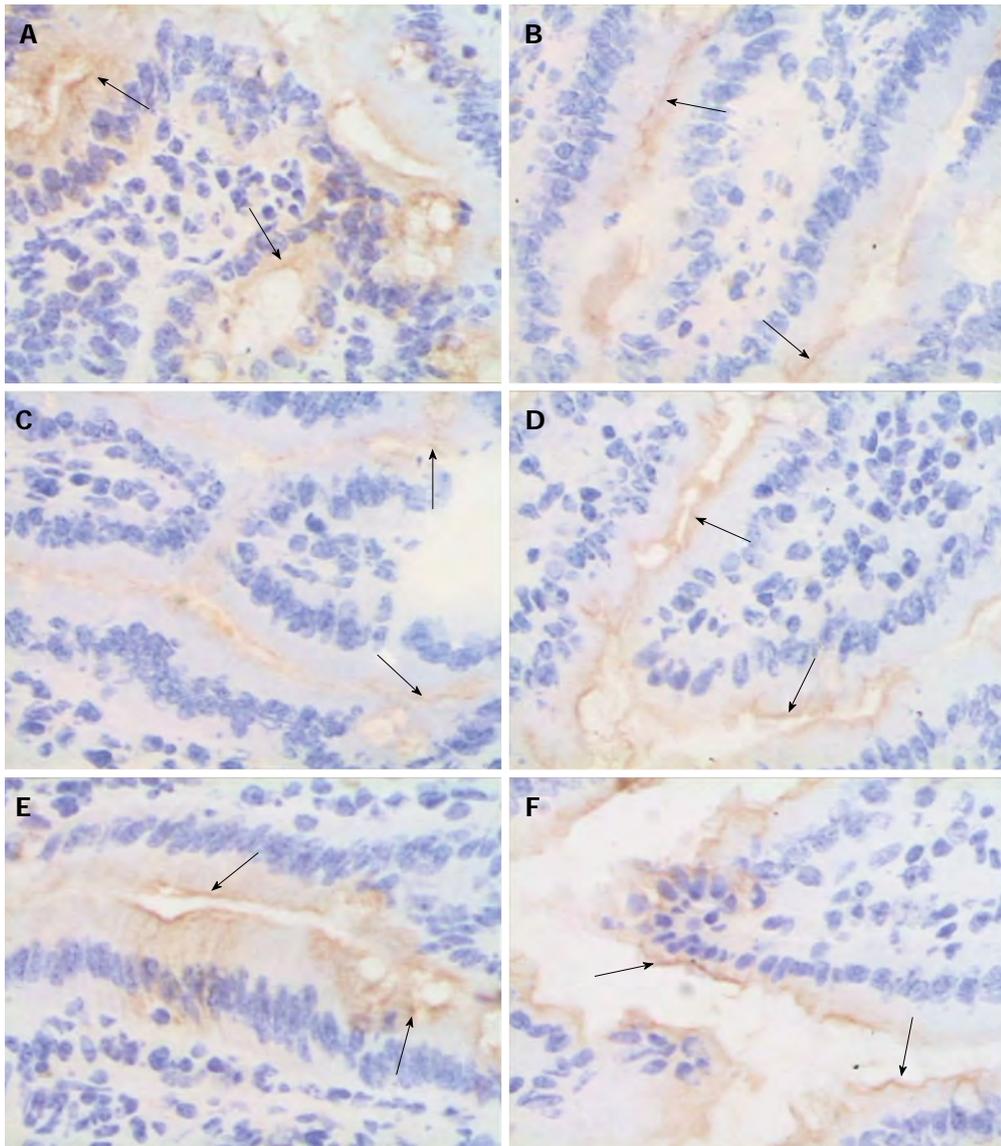

#### Ultrastructural characteristics of the intestinal mucosa

Compared to the Sham group, we observed obvious ultrastructural changes in the intestinal mucosa after I/R injury in the rats from the NS + I/R group. Epithelial cell microvilli were sparsely distributed, disarranged and distorted, and the epithelial cells were swollen or shrunken. The mitochondrial matrices were swollen, cristae were broken, and numerous TJs were disrupted.

There was no disruption of TJs in the BM MSCs + I/R injury group, and only swelling of the epithelial cells was observed. The ultrastructural pathological changes in the groups treated with anti-TNF- $\alpha$  and anti-TNF- $\alpha$ R-IgG were also less severe than in the NS + I/R injury group (Figure 5).

#### Expression of ZO-1 protein

Immunohistochemical analysis revealed strong ZO-1 expression in the intestinal tissue of the Sham group. In the intestinal tissue of the NS + I/R injury group, ZO-1 was expressed at low levels 2 h after injury, slightly in-

**Figure 6** Bone-marrow mesenchymal stem cells and tumor necrosis factor- $\alpha$  blockade attenuate zona occludens 1 downregulation after intestinal ischemia/reperfusion injury. The mucosal tissue sections after ischemia/reperfusion (I/R) injury were immunohistochemically labeled for zona occludens 1 (ZO-1) (brown) and counterstained with hematoxylin (blue). A: Sham group; B and C: In the normal saline + I/R injury group, decreased ZO-1 staining (arrows) was observed in the epithelial cells 2 h (B) and 6 h (C) after I/R; D-F: ZO-1 was not obviously affected in the bone-marrow mesenchymal stem cells + I/R injury group (D), anti-tumor necrosis factor (TNF)- $\alpha$  + I/R injury group (E), or anti-TNF- $\alpha$  R1 antibody + I/R injury group (F) at 6 h; original magnification,  $\times 400$ .

creased at 6 and 24 h, and by 72 h, ZO-1-positive signals were detected throughout the entire intestine (Figure 6). Western blot analysis confirmed that ZO-1 expression decreased more significantly in the NS + I/R group than the BM MSCs + I/R injury group, particularly at 6 h (Figure 7). Consistent with the immunohistochemical results, western blotting indicated that ZO-1 expression was significantly higher in the BM MSCs + I/R injury group and the two antibody-treated groups at 6 h than in the NS + I/R injury group (Figure 8).

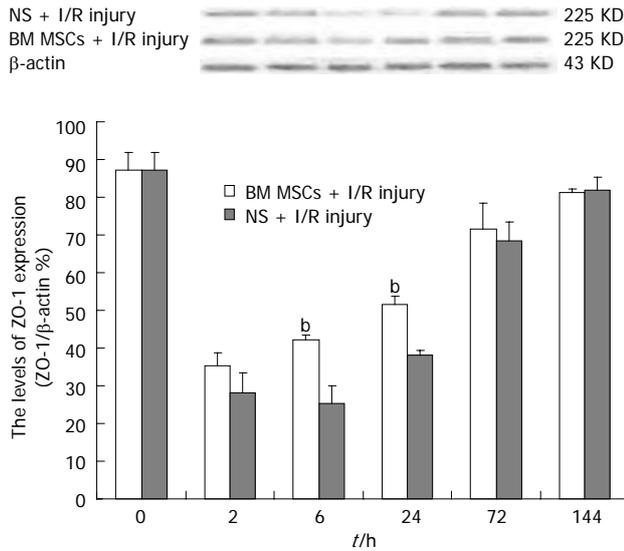

#### **Effect of I/R injury on serum TNF- $\alpha$ levels**

Compared to the Sham group, the serum TNF- $\alpha$  levels increased significantly, peaking at 6 h, in the NS + I/R injury group. The serum level of TNF- $\alpha$  was significant-

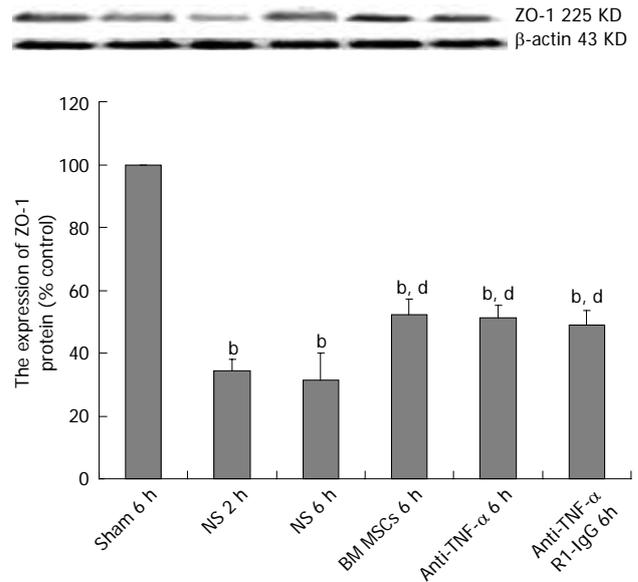

ly lower in the BM MSCs+ I/R injury group at 6 and 24 h than the NS + I/R injury group ( $P < 0.05$ , Table 3). The morphological abnormalities after intestinal I/R injury were positively correlated with serum TNF- $\alpha$  levels (Table 4).

## **DISCUSSION**

I/R injury to the gut is a common event in a variety of clinical conditions, such as trauma, burn injuries, septic shock, heart and aortic surgery, and liver and small bowel transplantation<sup>[27,28]</sup>. Intestinal I/R results in edema, apoptosis, necrosis of epithelial cells, disruption of mucosal integrity and small intestine function, which in turn increases mucosal and vascular permeability, bacte-

**Figure 7** Bone-marrow mesenchymal stem cells attenuate zona occludens 1 downregulation after intestinal ischemia/reperfusion injury. Representative western blots and quantification of zona occludens 1 (ZO-1) protein expression in the intestinal mucosa. ZO-1 expression was significantly lower in the saline (NS) + ischemia/reperfusion (I/R) injury group than the bone-marrow mesenchymal stem cells (BM MSCs) + I/R injury group at 6 h ( $25.35 \pm 4.58\%$  vs  $42.32 \pm 1.26\%$ ;  $P < 0.01$ ). Actin was used as a loading control. Values are shown as the mean  $\pm$  SD ( $n = 3$  rats per group); <sup>b</sup> $P < 0.01$  BM MSCs +I/R injury group vs the NS + I/R injury group [one-way ANOVA followed by the least significant difference (LSD) test].

**Figure 8** Bone-marrow mesenchymal stem cells and tumor necrosis factor- $\alpha$  blockade attenuate zona occludens 1 downregulation after intestinal ischemia/reperfusion injury. Representative western blots and quantification of zona occludens 1 (ZO-1) protein expression in the intestinal mucosa. Actin was used as a loading control. Values are the mean  $\pm$  SD ( $n = 3$  rats per group); <sup>b</sup> $P < 0.01$  vs Sham group; <sup>d</sup> $P < 0.01$  vs the saline (NS) + ischemia/reperfusion (I/R) injury group (one-way analysis of variance followed by the LSD test). rial translocation, as well as the risk of systemic inflammation response syndrome, multiple organ dysfunction and death<sup>[29,30]</sup>. Until recently, no effective treatments existed for intestinal I/R injury. Research has suggested that BM MSCs could possibly play a role in the treatment of I/R injury in the heart, kidney and brain<sup>[31-33]</sup>; however, studies of the effects of BM MSCs in intestinal disorders are scarce. In the current study, the therapeutic potential of BM MSCs was evaluated in an experimental rat model of I/R injury, which led to disruption of intestinal mechanical barrier function. The results of this study suggest that BM MSCs can effectively reduce both the intestinal permeability and pathological damage associated with I/R injury. BM MSCs have the potential for multidirectional differentiation. They participate in colonic mucosal regeneration<sup>[34]</sup>. In this study, intestinal I/R injury lead to necrosis and the loss of a large number of intestinal epithelial cells. BM MSCs could reduce I/R injury and protect the intestine.

Stem cell homing processes are thought to play a crucial role in the success of cell therapy for organ function disorders. Intravenous or intra-arterial infusions of BM MSCs often result in the entrapment of the administered cells in organ capillary beds, especially in the lung and the liver<sup>[35]</sup>. The transplantation of BM MSCs by intravenous or intra-arterial routes usually results in a low engraftment rate; therefore, increasing the number of MSCs within the injured area would improve the efficacy of cell therapy. Zhang *et al*<sup>[36]</sup> used gene-modified MSCs to enhance the homing rate of BM MSCs to the

irradiated intestine by 20% using an intravenous delivery route. However, using viral vectors to transfect MSCs may decrease the viability of MSCs. In this study, we directly injected MSCs into the wall of the intestine after I/R injury, which significantly increased the homing of MSCs into the I/R damaged intestinal mucosa. This indicated that the direct injection of BM MSCs into the intestine may provide a better method to enhance the homing rate.

The intestinal mucosal barrier is composed of mucosal fluid, microvilli, epithelial mucosal cell TJs, and other special structures. TJs are the most important structures in the mucosal barrier. The mechanisms responsible for intestinal I/R injury include cytotoxic effects and alterations in the structure of the intestinal mucosa<sup>[15]</sup>. However, few studies have examined the intestinal mucosa and TJ ultrastructure during I/R injury, and the role and mechanism of action of BM MSCs in intestinal I/R injury are unclear. In the present study, we found that severe intestinal mucosal damage occurred 2, 6 and 24 h after I/R injury. The morphological alterations to the intestinal mucosa included the shedding of epithelial cells, fracturing of villi, fusion of adjacent villi, mucosal atrophy and edema. Disruption of TJs between enterocytes, and damage to the mitochondria and endoplasm were also observed. Although damage to the intestinal mucosa plays a significant role in the permeability of the intestine, the mechanisms which cause this damage are poorly characterized. Moreover, we observed that the intestinal permeability increased 2, 6 and 24 h after I/R

The degree of relationship between tumor necrosis factor (TNF)- $\alpha$  and the Chiu risk score was evaluated by bivariate correlation. The results were statistically significant when  $P < 0.05$ , and was highly significant when  $P < 0.01$ . I/R: Ischemia/reperfusion.

injury, with simultaneous disruption in TJ integrity. Additionally, the administration of BM MSCs significantly attenuated the histological damage due to I/R injury (Figure 4) and reduced intestinal permeability (Table 2), compared with the NS + I/R injury group. Therefore, we hypothesized that changes in intestinal permeability may occur due to the disruption of TJs between intestinal mucosa epithelial cells.

To understand the mechanism of TJ disruption, we investigated the expression of ZO-1. ZO-1 was the first TJ-related protein to be identified<sup>[37]</sup>, and it connects the actin cytoskeleton to the transmembrane occludin proteins<sup>[38]</sup>. ZO-1 plays a vital role in the maintenance of intestinal mucosal barrier integrity and TJs during pathological insults<sup>[39]</sup>. In this study, ZO-1 expression in the intestinal mucosa significantly decreased after I/R injury; thus, we concluded that decreased ZO-1 expression lead to TJ disruption and possibly increased gut permeability.

Next, we examined the mechanism of TJ disruption and reduced ZO-1 protein expression during I/R injury. We observed that TNF- $\alpha$  increased at 2, 6 and 24 h after I/R injury, and correlated with ZO-1 downregulation and TJ disruption. The pathophysiological processes of I/R injury *in vivo* are complex, and it is thought that TNF- $\alpha$  may play an important role. Inflammation involves the sequential activation of signaling pathways which result in the production of pro- and anti-inflammatory mediators during I/R injury. Amongst the proinflammatory mediators, the TNF- $\alpha$  and TNF- $\alpha$ R1 systems play central roles in the physiological regulation of intestinal barrier function<sup>[40,41]</sup>, and both TNF- $\alpha$  and interferon (IFN)- $\gamma$  can induce intestinal epithelial barrier

dysfunction<sup>[42]</sup>. Some cytokines can induce endocytosis<sup>[43]</sup> and internalization of epithelial TJ proteins<sup>[44]</sup>. In mice with fulminant hepatic failure, reduced expression of occludin in intestinal epithelial cells was linked to increased TNF- $\alpha$  production<sup>[4]</sup>. TNF- $\alpha$  can also induce an increase in Caco-2 cell TJ permeability *via* nuclear factor- $\kappa$ B activation, leading to downregulation of ZO-1 protein expression and altered junctional localization<sup>[38,45]</sup>. We hypothesize that TNF- $\alpha$  acts as an initiator, which can induce expression of other cytokines such as IL-6 and IFN- $\gamma$ , which then initiate and aggravate the development of I/R injury, and disrupt intestinal TJs.

After the transplantation of BM MSCs, the serum TNF- $\alpha$  level significantly decreased, the damaged mucosa recovered, ZO-1 expression increased and intestinal permeability significantly improved. TNF- $\alpha$  is known to inhibit the expression of ZO-1<sup>[44]</sup>, and if the TJs are damaged, intestinal barrier dysfunction will occur. Research has confirmed that BM MSCs can inhibit the generation of TNF- $\alpha$  in dendritic cells *in vitro*<sup>[46,47]</sup>, and therefore we hypothesized that BM MSCs could repair intestinal I/R injury by inhibiting the release of TNF- $\alpha$ . In order to further study the role of TNF- $\alpha$ , we used anti-TNF- $\alpha$  and anti-TNFR antibodies. The TNF- $\alpha$  antibody neutralizes TNF- $\alpha$ , whereas the anti-TNFR antibody blocks the binding of TNF- $\alpha$  to the TNF- $\alpha$  receptor. TNF- $\alpha$  blockade significantly decreased the severity of I/R injury, which indicates that TNF- $\alpha$  is an important mediator of intestinal mucosa damage during I/R injury. These findings suggest that I/R injury increases TNF- $\alpha$ , leading to downregulation of ZO-1 protein expression, whereas BM MSCs can inhibit pro-

duction of TNF- $\alpha$ , leading to increased expression of ZO-1 and reduced intestinal mucosa damage. These effects were observed over a relatively short observation period, and long-term studies are required to elucidate if TNF- $\alpha$  exerts long-lasting effects during I/R injury.

In summary, this study demonstrates that the submucosal infusion of BM MSCs decreased intestinal permeability and preserved intestinal mechanical barrier function after I/R injury in rats, in a mechanism linked to reduced serum TNF- $\alpha$  levels and the increased expression of the intestinal TJ protein ZO-1. Future studies using exogenous or autologous BM MSCs to prevent or modulate intestinal I/R injuries are required to assess the clinical potential of BM MSCs. The mechanisms by which BM MSCs and TNF- $\alpha$  blockade protect against I/R-induced disruption of intestinal barrier function remain to be further investigated.

Disruption of the intestinal mucosa and the consequent increase in permeability after I/R injury may be due to reduced levels of the TJ-associated protein, ZO-1. BM MSCs restored the epithelial structure, promoted the recovery of intestinal permeability, increased ZO-1 protein expression and protected against intestinal I/R injury. TNF- $\alpha$  plays an important role in the ability of BM MSCs to protect against intestinal I/R injury, as the epithelial structure remained normal, and changes in intestinal permeability and ZO-1 protein expression were reduced when rats were treated with anti-TNF- $\alpha$  IgG antibody or anti-TNF- $\alpha$  R1 antibodies before I/R injury. This study confirms that high levels of TNF- $\alpha$  damage TJs and downregulate ZO-1 protein expression *in vivo*. The mechanism of TNF- $\alpha$ -induced change during I/R injury is complex and requires further study.

## COMMENTS

### Background

Digestive organ transplantation and other abdominal surgical procedures can result in different degrees of intestinal ischemia/reperfusion (I/R) injury, which can delay patient recovery and lead to systemic organ failure. Therefore, intestinal I/R injury is an important clinical issue. Bone-marrow mesenchymal stem cells (BM MSCs) can protect against I/R injury; however, the mechanism is unclear. Although previous studies have provided an insight into the molecular structure of tight junctions (TJs), much less is known about TJ functionality under physiological or pathophysiological conditions. Few studies have described the intestinal mucosa ultrastructure or changes in TJs during intestinal I/R injury. In this study, the authors used a rat model of intestinal I/R injury to investigate the effect of BM MSCs on the intestinal mucosa ultrastructure, with an emphasis on the mechanisms of intestinal barrier dysfunction.

### Research frontiers

In this study, the authors demonstrated that the submucosal infusion of BM MSCs decreased intestinal permeability and preserved intestinal mechanical barrier function after I/R injury in rats, in a mechanism linked to reduced serum tumor necrosis factor (TNF)- $\alpha$  levels and the increased expression of the intestinal TJ protein zona occludens (ZO)-1. Altered serum TNF- $\alpha$  levels play an important role in the ability of BM MSCs to protect against intestinal I/R injury.

### Innovations and breakthroughs

Recent reports have highlighted the importance of BM MSCs reducing intestinal I/R injury in rats. Although previous studies have provided an insight into the molecular structure of TJs, much less is known about TJ functionality under physiological or pathophysiological conditions. Few studies have described the intestinal mucosa ultrastructure or changes in TJs during intestinal I/R injury.

This is believed to be the first study to report that BM MSCs reduce rat intestinal I/R injury, ZO-1 downregulation, and TJ disruption *via* a TNF- $\alpha$ -regulated mechanism.

### Applications

By understanding how BM MSCs reduce rat intestinal I/R injury, this study may represent a future strategy for therapeutic intervention in the treatment of patients with digestive organ transplantation and other abdominal surgical procedures that result in different degrees of intestinal I/R injury, which can delay patient recovery and lead to systemic organ failure.

### Terminology

TJs are the main structures responsible for restricting the paracellular movement of compounds across the intestinal mucosa. Structurally, TJs are composed of cytoplasmic proteins, including ZO-1-3 and two distinct transmembrane proteins, occludin and claudin, which are linked to the actin-based cytoskeleton. ZO-1, as a scaffold for the organization of transmembrane TJ proteins, also recruits various signaling molecules and the actin cytoskeleton to TJs.

### Peer review

This paper shows the impact of BM MSCs on rat intestinal I/R injury. This study will be of interest and the paper is clearly written.

### Abstract

**AIM:** To assess the incidence and risk factors associated with colonic perforation due to colonoscopy.

**METHODS:** This was a retrospective cross-sectional study. Patients were retrospectively eligible for inclusion if they were 18 years and older and had an inpatient or outpatient colonoscopy procedure code in any facility within the Geisinger Health System during the period from January 1, 2002 to August 25, 2010. Data are presented as median and inter-quartile range, for continuous variables, and as frequency and percentage for categorical variables. Baseline comparisons across those with and without a perforation were made using the two-sample *t*-test and Pearson's  $\chi^2$  test, as appropriate.

**RESULTS:** A total of 50 perforations were diagnosed out of 80118 colonoscopies, which corresponded to an incidence of 0.06% (95%CI: 0.05-0.08) or a rate of 6.2 per 10000 colonoscopies. All possible risk factors associated with colonic perforation with a *P*-value < 0.1 were checked for inclusion in a multivariable log-binomial regression model predicting 7-d colonic perforation. The final model resulted in the following risk factors which were significantly associated with risk of colonic perforation: age, gender, body mass index, albumin level, intensive care unit (ICU) patients, inpatient setting, and abdominal pain and Crohn's disease as indications for colonoscopy.

**CONCLUSION:** The cumulative 7 d incidence of colonic perforation in this cohort was 0.06%. Advanced age and female gender were significantly more likely to have perforation. Increasing albumin and BMI resulted in decreased risk of colonic perforation. Having a colonoscopy indication of abdominal pain or Crohn's disease resulted in a higher risk of colonic perforation. Colonoscopies performed in inpatients and particularly the ICU setting had substantially greater odds of perforation. Biopsy and polypectomy did not increase the risk of perforation and only three perforations occurred with screening colonoscopy.

**Key words:** Colonoscopic perforation; Colon cancer; Endoscopy

**Core tip:** This study is unique because we have used state of the art electronic medical records to collect information about risk factors which can predispose patient to a high risk of perforation. We have looked into multiple risk factors including but not limited to serum albumin, serum creatinine, body mass index (BMI), inpatient and outpatient colonoscopy and intensive care unit (ICU) patients. Limited literature is available about the above mentioned risk factors and there propensity

to cause perforation. The important findings deduced from this research can have important implication in day to day practice of colonoscopy. The findings of Albumin, BMI, and Inpatient and out patient colonoscopy particularly performing colonoscopy in ICU setting predisposing to higher risk of perforation are crucial piece of information that can help physician in considering available alternatives which in turn may help to reduce the number of colonoscopic perforations.

## INTRODUCTION

Colorectal cancer is the third most commonly diagnosed cancer and the second leading cause of cancer-related death in the United States<sup>[1]</sup>. Early detection benefits patients and increases their quality of life, but also reduces health care expenditures. The ability of colonoscopy to detect polyps and colorectal cancer has been shown to reduce mortality and morbidity associated with this cancer<sup>[2,3]</sup>. In July 2001, Medicare began covering screening colonoscopy for individuals over the age of 50 at average risk for colorectal cancer and depending on the detection of polyps, at variable intervals thereafter. Since that time, the use of colonoscopy has been increasing<sup>[4-6]</sup>.

Colonoscopy is generally regarded as a safe procedure; potential complications include perforation, post-polypectomy bleeding and post-polypectomy syndrome<sup>[7]</sup>. The incidence of colonic perforation ranges from 0.005% and 0.63% with the majority of patients requiring laparotomy for repair<sup>[8-12]</sup>. Colonoscopic perforation occurs due to one of three mechanisms; mechanical forces from the endoscope, barotrauma from air insufflation, or as a direct result of a therapeutic procedure (*e.g.*, polypectomy). To better understand the risk factors associated with colonoscopic perforation, we conducted a large cross-sectional study to estimate the incidence of this serious complication, and to examine potential contributing effects of demographic and medical characteristics of patients.

## MATERIALS AND METHODS

### Study cohort, design, and setting

This was a retrospective cross-sectional study. Patients were retrospectively eligible for inclusion if they were 18 years and older and had an inpatient or outpatient colonoscopy procedure code in any facility within the Geisinger Health System (GHS) during the period from January 1, 2002 to August 25, 2010. GHS is a primary care and multispecialty medical practice located in central and northeast Pennsylvania and is the largest rural not-

for-profit health system in the nation. GHS uses health information technology infrastructure for managing and using patient data. Colonoscopy procedures were identified by the presence of current procedural terminology (CPT) 2005 codes 45378-45387, 45391, and 45392.

The study outcome was the diagnosis of colonic perforation using International Classification of Disease, 9<sup>th</sup> revision (ICD-9) codes 569.83 and 998.2, defined as perforation of intestine and accidental puncture or laceration during a procedure, 7 d after the day of colonoscopy. We specifically looked at the 7 d post colonoscopy for perforation since previous studies have shown that almost all post-colonoscopy perforations were detected within this time frame<sup>[13,14]</sup>. Both inpatient and outpatient procedures were included.

Variables obtained from the electronic health record included age at colonoscopy, gender, body mass index (BMI), albumin, serum creatinine, operator specialty (surgeon or gastroenterologist), and indications for the colonoscopy (identified by procedure codes in the colonoscopy report). Race was not assessed for analysis since the primary care population seen in Geisinger Health System is > 95% Caucasian.

Data on comorbid health conditions were also collected including history of coronary artery disease, congestive heart failure, peripheral arterial disease, cerebrovascular disease, dementia, chronic obstructive pulmonary disease, connective tissue disease, peptic ulcer disease, liver disease, diabetes mellitus, hemiplegia, chronic kidney disease, leukemia, lymphoma, metastatic cancer, and acquired immune deficiency syndrome.

### Statistical analysis

Data are presented as median and inter-quartile range, for continuous variables, and as frequency and percentage for categorical variables. Baseline comparisons across those with and without a perforation were made using the two-sample *t*-test and Pearson's  $\chi^2$  test, as appropriate. The incidence of 7-d post-colonoscopy perforations was calculated as the number of colonic perforations divided by the total number of colonoscopies, and expressed as both percentage and as an incidence rate (*e.g.*, number of perforations per 10000 colonoscopies). The count of comorbid conditions was summarized as a general indicator of health.

The log-binomial model was used to estimate the incident rate ratios (IRR) for risk factors found to vary across the two groups. A fully adjusted model was then developed to identify those risk factors predictive of perforation. Variables were considered for inclusion in the model if they were found to vary between groups at a significance level of  $P < 0.10$ . Backward elimination was performed to obtain a final model that retained clinically meaningful predictors. Results are presented as RR and corresponding 95%CI. The analysis was performed using SAS v9.2 (SAS Institute, Inc., Cary, NC, United States) and R v2.13 (R Development Core Team, [www.r-project.org](http://www.r-project.org))<sup>[15]</sup>.

<sup>1</sup>Includes foreign body removal, hemostasis; <sup>2</sup>Info to ascertain type of colonoscopy in one perforation not available; <sup>3</sup>Two body mass index (BMI) in perforation group not available; <sup>4</sup>Operator specialty of 4 perforations are other than gastroenterology and general surgery; <sup>5</sup>Number of interventions includes biopsy, polypectomy, dilations and hemostasis. ICU: Intensive care unit; CP: Cerebral palsy; IQR: Interquartile range.

## RESULTS

A total of 50 perforations were diagnosed out of 80118 colonoscopies, which corresponded to an incidence of 0.06% (95%CI: 0.05-0.08) or a rate of 6.2 per 10000 colonoscopies. Thirty-nine patients underwent emergent exploratory laparotomy and 11 were managed conservatively.

Patients that had a perforation within 7 d of their procedures were more likely to be older, female gender,

lower BMI, have more comorbidities, and a lower albumin value (Table 1). Indications for colonoscopy including abdominal pain, anemia, and bleeding were reported more in those with a perforation as compared to the non-perforation group. Operator specialty and creatinine values were not found to vary between groups. The presence of end stage renal disease (ESRD) and prior abdominal surgeries also were not associated with colonic perforations in our cohort.

Based on the findings in Table 1, those risk factors meeting the criteria of a *P* < 0.1 were further described. Table 2 reports the number of perforations and the incidence rate per 10000 patients stratified by these important factors. For every year increase in age, the risk of a perforation increased by 7% (95%CI: 5-9) with the incidence of perforation increasing from 2.6 cases per 10000 in the 50-64 year old age group to 31.7 cases per 10000 in the 80+ year old age group. Females were twice as likely to have a perforation compared to males. Lower BMI resulted in a higher risk of perforation. Decreased albumin levels ( $\leq 4.0$ ) (closest prior to colonoscopy) were associated with an increased risk of colonic perforation (IRR = 7.8, 95%CI: 4.1-14.6). There was also a significant difference of perforation rate between colonoscopy performed in an inpatient and outpatient setting. Inpatients were much more likely to have perforation compared with outpatients (55.4 and 3.6 cases per 10000, respectively). Similarly, the risk of perforation increased in intensive care unit (ICU)-patients compared to non-ICU patients.

All possible risk factors associated with colonic perforation with a *P*-value < 0.1 were checked for inclusion in a multivariable log-binomial regression model predicting 7-d colonic perforation. The final model resulted in the following risk factors which were significantly associated with risk of colonic perforation: age, gender, BMI, albumin level, ICU patients, inpatient setting, and abdominal pain and Crohn's disease as indications for colonoscopy. Approximately 21% of the patients did not have an albumin laboratory result available for analysis. Therefore, a model was fit with and without including albumin. Also, based on the descriptive results albumin was categorized at 4.0. The estimates from the final models are displayed in Table 3.

## DISCUSSION

In reviewing literature from 1975 onward, we observed that the incidence rate of colonic perforation ranges between 0.005% to 0.63%. We noticed a gradual decline in the incidence of colonic perforation which has reached a plateau in the last 10 years. The differences in the incidence rates in this study compared to those in the literature can possibly be attributed to the way the studies were conducted. For example Sieg *et al*<sup>[16]</sup> and Rathgeber *et al*<sup>[17]</sup> both reported low incidence rate of perforation (0.005 and 0.01 respectively). Sieg *et al*<sup>[16]</sup> looked prospectively at 82, 16 colonoscopies but there was a selection

**Table 2** Incidence of 7-d colonic perforation risk by important risk factors

| Patient variable                     | Frequency | Perforations | Incidence per 10000 | Incident rate ratio (95%CI)       |
|--------------------------------------|-----------|--------------|---------------------|-----------------------------------|
| Total                                | 80118     | 50           | 6.2                 | -                                 |

<sup>1</sup>Variable was treated as continuous in the estimation of the incident rate ratio. ICU: Intensive care unit; CP: Cerebral palsy; BMI: Body mass index.

bias since only perforations that required surgical intervention were included in the study. Similarly, Rathgaber and Wick's study of 12407 colonoscopies, complications were gathered by monthly retrospective review of all hospitalizations and patient phone calls. Anderson *et al*<sup>[18]</sup> reported an incidence 0.19% in 10486 colonoscopies and Gatto *et al*<sup>[13]</sup> found 0.196% in 39286 colonoscopies. Both studies primarily looked at an older patient population which may have contributed to the higher rate of colonoscopic perforations.

This study looked at patients 18 years or older. By

including a wider range of patients, the current findings are likely to be more representative of the true incidence of perforation. We found that age greater than 65 years was a significant predictor for risk of perforation. This finding is in congruence with other studies<sup>[12-14,19]</sup> that found increased age as an independent risk factor for perforation.

We found that the female gender is predisposed to a higher risk of perforation as compared to the male gender. Anderson *et al*<sup>[18]</sup> and Korman *et al*<sup>[12]</sup> also found female gender to be an independent risk factor for perforation. In contrast, Arora *et al*<sup>[19]</sup> did not find female gender as a significant risk factor for perforation in 277434 colonoscopies.

We found lower BMI to be another statistically significant predictor of perforation. Literature on the relation between BMI and risk of colonic perforation is sparse. Takahashi *et al*<sup>[20]</sup> postulated lower BMI as a predictor of pain and difficult colonic intubation during colonoscopy. Patients with low BMI may have sharper angulation of the sigmoid colon which theoretically can predispose these patients to a higher chance of mechanical injury during colonoscopy.

Increasing number of comorbidities resulted in increased risk of colonic perforation. Our findings are in congruence with other studies Gatto *et al*<sup>[13]</sup> and Arora *et al*<sup>[19]</sup> that demonstrated an increased risk of perforation with two or more co-morbidities.

Imai *et al*<sup>[21]</sup> studied the risk of perforation in patients with ESRD on hemodialysis (HD) undergoing colonoscopy. The study looked at 1106 HD patients and 13992 controls, and the authors found a higher risk of perforation among HD patients. Our study looked at patients with ESRD on hemodialysis, and also at patients with chronic kidney disease who were not on HD. There were no perforations among the 321 patients with ESRD in our cohort. We did not find any statistically significant relationship with increasing creatinine level and risk of perforation.

Low albumin has been shown to be a predictor for failure to complete colonoscopy<sup>[22]</sup>. Hypoalbuminemia is

a well-documented marker of morbidity and is a strong predictor of mortality in elderly patients<sup>[22,23]</sup>. We found low albumin level to be associated with a higher risk for perforation. It is possible that a low albumin may decrease the tensile strength of the colonic wall and also generally indicates poor health status that can theoretically predispose to higher risk for perforation.

We did not find any significant difference in the rate of perforation between colonoscopies performed by gastroenterologists or surgeons. This is in congruence with a prospective study of 13580 colonoscopies done by surgeons Wexner *et al.*<sup>[24]</sup>, which found that colonoscopy performed by surgeons are safe with low morbidity and mortality.

We did not find performance of biopsy or polypectomy as significant risk factors for perforation. Similar findings were noted by Arora *et al.*<sup>[19]</sup>, but are in contrast to Levin *et al.*<sup>[4]</sup> and Misra *et al.*<sup>[25]</sup> who found increased risk of perforation after polypectomy. We found that the performance of invasive procedures such as foreign body removal, hemostasis increase the risk of perforation, similar findings were noted by Arora *et al.*<sup>[19]</sup>. We also found dilation as a significant risk factor for perforation in our cohort.

A potential limitation of this study is the validity of coding and capturing of all perforations. We used ICD-9 and CPT codes to capture perforations and co-morbidities. It is possible that we may have missed perforations due to incorrect coding. Also, if a patient went outside of our health care system, then some perforations would not have been reported and thus, not identified. Therefore, underestimation of the incidence of perforation is possible in this study.

In conclusion, the cumulative 7 d incidence of colonic perforation in this cohort was 0.06%. Advanced age and female gender were significantly more likely to have perforation. Increasing albumin and BMI resulted in decreased risk of colonic perforation. Having a colonoscopy indication of abdominal pain or Crohn's disease resulted in a higher risk of colonic perforation. Colonoscopies performed in inpatients and particularly the ICU setting had substantially greater odds of perforation. Biopsy and polypectomy did not increase the risk of perforation and only three perforations occurred with screening colonoscopy.

The increased risk of perforation during inpatient colonoscopy among the elderly and very elderly (> 80 years), and ICU patients is not inconsequential. On the basis of this data, we have restricted inexperienced operators (such as first year gastroenterology fellows) from performing these types of cases. Additionally those over 80 years referred for diagnostic colonoscopy should also be advised of their increased risk of perforation. By understanding which patient populations are at greatest risk for colonoscopic perforation, considering available alternatives, and adjusting patient selection criteria balancing for those at highest risk, may help to reduce the number of colonoscopic perforations.

## COMMENTS

### Background

This study is unique because we have used state of the art electronic medical records to collect information about risk factors which can predispose patient to a high risk of perforation. The authors have looked into multiple risk factors including but not limited to serum albumin, serum creatinine, body mass index (BMI), inpatient and outpatient colonoscopy and intensive care unit patients. Limited literature is available about the above mentioned risk factors and there propensity to cause perforation. The important findings deduced from this research can have important implication in day to day practice of colonoscopy.

### Research frontiers

Authors found lower BMI to be another statistically significant predictor of perforation. Literature on the relation between BMI and risk of colonic perforation is sparse. Yuuichi postulated lower BMI as a predictor of pain and difficult colonic intubation during colonoscopy. Patients with low BMI may have sharper angulation of the sigmoid colon which theoretically can predispose these patients to a higher chance of mechanical injury during colonoscopy.

### Innovations and breakthroughs

This was a retrospective cross-sectional study. Patients were retrospectively eligible for inclusion if they were 18 years and older and had an inpatient or outpatient colonoscopy procedure code in any facility within the Geisinger Health System during the period from January 1, 2002 to August 25, 2010. Data are presented as median and inter-quartile range, for continuous variables, and as frequency and percentage for categorical variables.

### Peer review

This is an interesting paper on a clinically important topic and with good numbers. By understanding which patient populations are at greatest risk for colonoscopic perforation, considering available alternatives, and adjusting patient selection criteria balancing for those at highest risk, may help to reduce the number of colonoscopic perforations.

### Abstract

**AIM:** To study an assessment of the number of enterochromaffin cells and expression of hydroxyindole-O-methyltransferase in colonic mucosa and urine excretion of 6-sulfatoxymelatonin in patients with ulcerative colitis.

**METHODS:** The study included 30 healthy subjects (group I -C), 30 patients with ulcerative proctitis [group II -ulcerative proctitis (UP)] and 30 patients with ulcerative colitis [group III -ulcerative colitis (UC)] in acute phases of these diseases. The number of enterochromaffin cells (EC) was estimated in rectal and colonic mucosa. Biopsies were assembled from many different parts of the large intestine. Immunoreactive cells

collected from various parts of the colon were counted according to the Eurovision DAKO (Dako A/S, Copenhagen, Denmark) System in the range of 10 fields in each biopsate at  $\times 200$  magnification. The level of mRNA expression of hydroxyindole-O-methyltransferase (HIOMT) in colonic mucosa was estimated with RT-PCR. Urine 6-sulfatoxymelatonin (6-HMS) excretion was determined immunoenzymatically using an IBL (IBL International GmbH, Hamburg, Germany) kit (RE 54031).

**RESULTS:** The number of EC cells in healthy subjects (C) was  $132.40 \pm 31.26$ . In patients of group II (UP) and group III (UC) the number of these cells was higher -  $225.40 \pm 37.35$  ( $P < 0.001$ ) and -  $225.24 \pm 40.50$  ( $P < 0.001$ ) respectively. Similar differences were related to HIOMT expression, which was  $1.04 \pm 0.36$  in group C,  $1.56 \pm 0.56$  ( $P < 0.01$ ) in group UP and  $2.00 \pm 0.35$  ( $P < 0.001$ ) in group UC. Twenty-four hour 6-HMS urinary excretion was as follows: C -  $16.32 \pm 4.95$   $\mu\text{g}/24$  h, UP -  $26.30 \pm 7.29$   $\mu\text{g}/24$  h ( $P < 0.01$ ), UC -  $42.30 \pm 12.56$   $\mu\text{g}/24$  h ( $P < 0.001$ ). A correlation between number of EC cells and 6-HMS excretion was noted in all groups:  $r = 0.766$  in patients with UP,  $r = 0.703$  with UC and  $r = 0.8551$  in the control group; the correlation between the results is statistically significant.

**CONCLUSION:** In the acute phases of both UP and UC, proliferation of EC cells and high expression of HIOMT and urine excretion of 6-HMS is noted. These changes may represent a beneficial response in the anti-inflammatory and defense mechanism.

**Key words:** Enterochromaffin cells; 5-hydroxyindole-O-methyltransferase; 6-sulfatoxymelatonin; Ulcerative proctitis; Ulcerative colitis

**Core tip:** In the gastrointestinal tract melatonin is secreted mainly by enterochromaffin cells (EC). It appears

that hydroxyindole-O-methyltransferase (HIOMT) is enzyme determining melatonin synthesis. This indoleamine exerts, antioxidant, and anti-inflammatory effects. Its synthesis can be disturbed by pro-inflammatory cytokines. The obtained results noted the proliferation of EC cells and the increase of HIOMT expression in ulcerative colitis (UC). Positive correlation between the amount of EC cells and urinary 6-sulfatoxymelatonin excretion points to the increase of melatonin secretion in the colon, but its beneficial anti-inflammatory effect was insufficient. The results indicate that the supplementation of melatonin may be useful in complex treatment of UC.

## INTRODUCTION

Ulcerative colitis (UC) is a chronic disease with periods of exacerbation and remission. Its pathogenesis is complex and inflammatory and immune factors, as well as toxic forms of oxygen produced in this condition, play a major role in the destruction of colonic mucosa<sup>[1]</sup>.

The phase of exacerbation is characterized by, inter alia, the increased production of pro-inflammatory cytokines, cell adhesion molecules and acute-phase proteins. In addition, various defense mechanisms are activated, including increased production of specific antibodies and antioxidants. Melatonin is also a potent agent in antioxidative defense through its antioxidant and anti-inflammatory properties<sup>[2,3]</sup>.

Melatonin (N-acetyl-5-methoxytryptamine) is a hormone produced by the cells of the neuroendocrine system located throughout the body amine precursor uptake and decarboxylation (APUD). It is produced from L-tryptophan, an exogenous amino acid, which is first converted in the body into serotonin with the involvement of tryptophan hydroxylase and 5-hydroxytryptophan decarboxylase. The serotonin is then converted to melatonin by arylalkylamine N-acetyltransferase (AANAT) and 5-hydroxyindole-O-methyltransferase hydroxyindole-O-methyltransferase (HIOMT)<sup>[4]</sup>.

This indoleamine is secreted by pineal cells according to circadian rhythms, which are regulated mainly by light stimuli<sup>[5]</sup> and by enterochromaffin cells (EC) which are distributed throughout the whole gastrointestinal tract<sup>[6]</sup>. Melatonin from the gut is transported *via* the portal vein to the liver, where it is metabolized to 6-sulfatoxymelatonin (6-HMS)<sup>[7]</sup>. The amounts of urinary 6-HMS excretion are known to be indices of the synthesis and metabolism of this hormone<sup>[8]</sup>.

Melatonin is secreted from the gastrointestinal tract under the influence of a range of stimuli, including nutritional factors, but the precise mechanisms regulating its release have not been recognized thoroughly. This hormone, released from enterochromaffin cells, fulfills important enteroprotective functions *via* the paraendocrine mechanism<sup>[9]</sup>.

In inflammatory processes, melatonin inhibits nitric oxide and cyclooxygenase-2 synthesis and decreases the concentration of endogenous oxidants<sup>[10]</sup>. Furthermore, it induces other systems which in turn reduce oxygen free radicals: Superoxide dismutase and glutathione peroxidase. It also exerts a beneficial effect on microcirculation and tissue blood supply by inhibiting COX-2<sup>[11]</sup>.

In experimental colitis in animals, the administration of exogenous melatonin decreased lipid, protein and nucleic acid oxidation, and also ameliorated epithelial damage and inflammatory infiltration<sup>[12,13]</sup>. In our studies, carried out on patients with ulcerative colitis, melatonin was demonstrated to reduce DNA damage and to stimulate the repair of hydrogen-peroxide-induced oxidative DNA damage in enterocytes<sup>[14]</sup>. Melatonin also has an influence on beneficial immune processes. Melatonin receptors have been identified on immunologically active cells. It also stimulates Th lymphocytes to produce IL-2 and IFN- $\gamma$ , monocytes to produce IL-1, IL-6 and IL-12 and decreases TNF- $\alpha$  concentration and the expression of adhesion molecules (ICAM-1, P-selectin and MAdCAM-1)<sup>[15,16]</sup>.

All these properties of melatonin can have a beneficial effect on the course of ulcerative colitis, as the mentioned pro-inflammatory factors play a significant role in the pathogenesis of this disease. Melatonin deficiency has been suggested to be one of the causes of upper digestive tract mucosal defects<sup>[17]</sup>, whereas the results related to the colon are not consistent. The amount of melatonin secreted in an organism depends on the number of EC cells and their activity. Spiller *et al.*<sup>[18]</sup> found an increased number of EC cells in rectal mucosa in patients with diarrhea predominant IBS. Similar observations were made by Osadchuk *et al.*<sup>[19]</sup>. However, El-Salhy *et al.*<sup>[20]</sup> demonstrated that patients with constipation-predominant IBS have a decreased number of EC cells in the colonic mucosa.

Some authors have tried to relate the changes observed in IBS patients to inflammatory bowel diseases but no reliable results have been obtained, either. Most of the researchers demonstrated that the number of EC cells increases in colonic mucosa in patients with ulcerative colitis<sup>[21-23]</sup>. In turn, others have detected a decreased number of EC cells in this group of patients<sup>[24,25]</sup>. These differences may result from a heterogeneous clinical and morphological evaluation of colonic mucosa.

The aim of the present study was to evaluate the number of EC cells, HIOMT expression in colonic mucosa and urinary 6-HMS excretion in patients with acute phase of ulcerative proctitis (UP) and ulcerative colitis (UC).

## MATERIALS AND METHODS

### Patients

The study included 30 healthy subjects (control group I (C)-aged  $32.4 \pm 9.8$  years), 26 patients with an acute phase of ulcerative proctitis [group II (UP)-aged  $31.9 \pm 11.6$  years] and 30 patients with ulcerative colitis (group III (UC)-aged  $33.0 \pm 16.9$  years). The severity of the disease was classified according to modified Mayo Clinic Score<sup>[26]</sup>. Biopsates were collected from many different parts (10-16) of the rectum and colon close to erosions and ulcerations. Histopathological activity was expressed according to the criteria of truelove and richards<sup>[27]</sup>.

### Methods

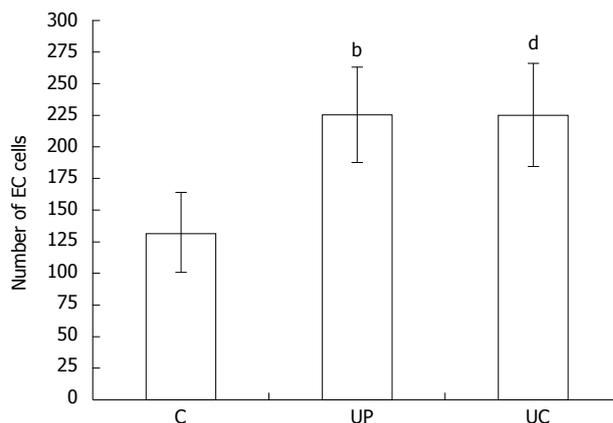

To determine the number of enterochromaffin cells in the biopsates, an immunohistochemical method was used with rabbit polyclonal antibodies (PSE) at a dilution of 1:200 (Eurodiagnostica). Immunoreactive cells were counted with a computer according to the Eurovision DAKO system, in the range of 10 fields in each biopsate at  $\times 200$  magnification.

The level of mRNA expression of HIOMT was estimated with RT-PCR, and for this purpose, 50 mg of colonic tissue was used. Total RNA was isolated with trizol (Gibco) reagents, and then purified with DNase using gigagen *RNeasy* mini kit. The quantity and quality of RNA was estimated by using spectrophotometry. The obtained extract was used as a matrix in analyses of gene expression. cDNA synthesis was performed with Oligo (dT) 12-18 in an MJ Research PTG-1000 thermocycler. cDNA was obtained in reverse transcription and applied as the matrix for a PCR reaction incorporating selected fragments of the analyzed gene. The hypoxanthine phosphoribosyltransferase gene was the quantitative marker for the evaluation of the activity of the selected genes.

The reaction products were first separated on 6%-10% polyacrylamide gel stained with ethidium bromide and then subjected to densitometry to determine the reaction efficacy and the level of mRNA of the investigated genes. The expression of the investigated genes was compared to *HPRT* gene product to normalize the expression.

The urine concentration of 6-HMS was determined immunoenzymatically using an IBL kit (RE54031).

On the day of testing excretion of 6-HMS through the urine, the patients remained in a room in which white light was off at night, and they received condensed liquid meals (Nutridrink-400 mL three times a day) with a total energy value of 1800 kcal and drank 1500 mL non-carbonated isotonic mineral water. After completion of 24-hour urine collection, the urine was centrifuged and the samples were stored at  $-70^\circ\text{C}$ . The 6-HMS concentration of the urine was determined immunoenzymatically using an Immuno-Biological Laboratories kit (No. RE54031). The measurements were performed by photometry at a wavelength of 450 nm using an Expert 96 reader (Biogent).

**Figure 1** Number of enterochromaffin cells in colonic mucosa in healthy subjects (C), patients with ulcerative proctitis and ulcerative colitis. The number of enterochromaffin cells was counted in 10 fields in each biopsate at  $\times 200$  magnification; Healthy subjects [control group (C);  $n = 30$ ]; Patients with acute phase of ulcerative proctitis (UP;  $n = 30$ ); Patients with acute phase of ulcerative colitis (UC;  $n = 30$ ); Differences between group C and UP <sup>b</sup> $P < 0.01$ ; Differences between group C and UC <sup>d</sup> $P < 0.01$ . EC: Enterochromaffin cells.

### Ethics

The study was conducted in accordance with the Declaration of Helsinki and the principles of Good Clinical Practice. Written consent was obtained from each patient enrolled in the study and the study protocol was approved by Bioethics Committee of the Medical University of Lodz (RNN/242/06/KB).

### Statistical analysis

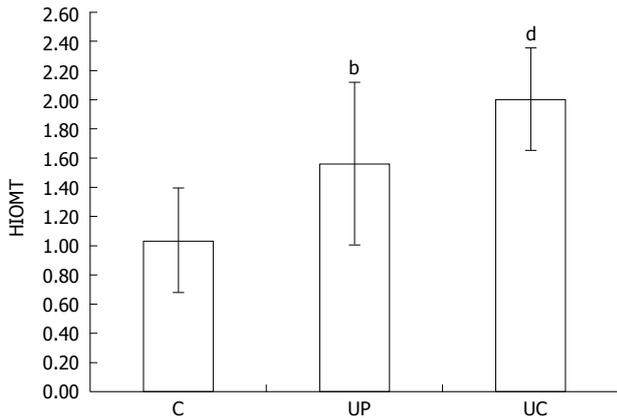

The non-parametric Krushal-Wallis test was used to evaluate the number of enterochromaffin cells, as well as the expression of HIOMT and urinary 6-HMS excretion in the three groups: C, UP and UC. The Mann-Whitney Test was used for comparison of median values. The correlation between the number of EC cells and urinary 6-HMS excretion was estimated by the determination of Pearson's correlation coefficient and linear regression equation. The differences between the results was regarded as significant at a  $P$  value 0.05-0.001. Statistica 9.0 (StatSoft, Inc., United States) and MS Excel 2007 (Microsoft Co, United States) were used for statistical analysis.

## RESULTS

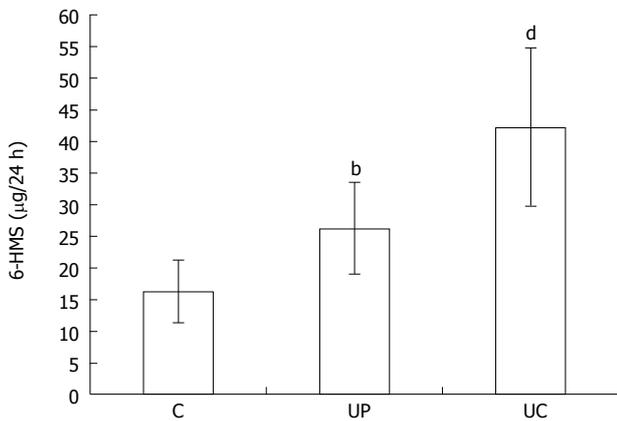

The mean number of colonic EC cells in 10 fields of view in healthy subjects (group I) was  $132.40 \pm 31.26$ . However, in patients with ulcerative colitis, the number was twice as high:  $225.40 \pm 37.35$  ( $P < 0.001$ ) in the rectal mucosa (group II) and  $225.24 \pm 40.50$  ( $P < 0.001$ ) in patients with pancolitis (group III) (Figure 1).

Similar differences were related to HIOMT expression:  $1.04 \pm 0.36$  in healthy subjects,  $1.56 \pm 0.56$  ( $P < 0.01$ ) in proctitis and  $2.00 \pm 0.35$  ( $P < 0.001$ ) in pancolitis (Figure 2).

Urinary 6-HMS excretion in healthy subjects was  $16.32 \pm 4.95$  and it was lower than in patients with proc-

**Figure 2** Expression of hydroxyindole-O-methyltransferase in colonic mucosa in healthy subjects (C), patients with ulcerative proctitis and ulcerative colitis. Healthy subjects [control group (C);  $n = 30$ ]; Patients with acute phase of ulcerative proctitis (UP;  $n = 30$ ); Patients with acute phase of ulcerative colitis (UC;  $n = 30$ ); Differences between group C and UP  $^bP < 0.01$ ; Differences between group C and UC  $^dP < 0.01$ . HIOMT: Hydroxyindole-O-methyltransferase.

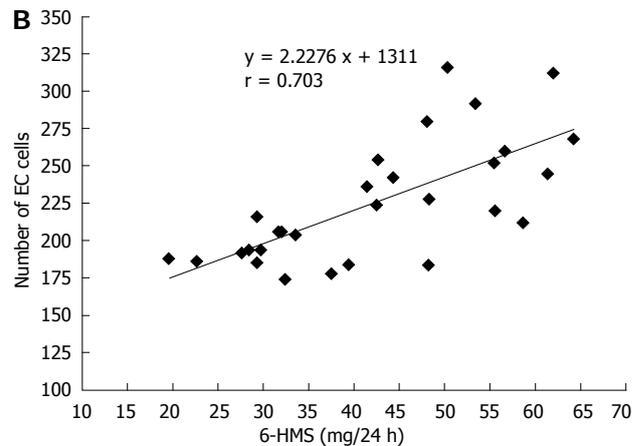

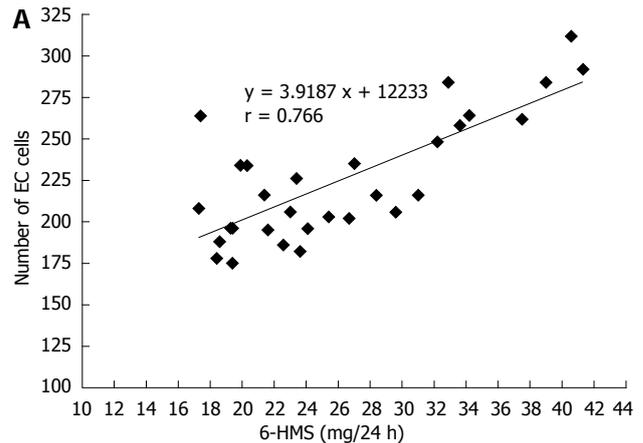

**Figure 3** Urinary excretion of 6-sulfatoxymelatonin in healthy subjects (C) and patients with ulcerative proctitis and ulcerative colitis. The number of enterochromaffin cells was counted in 10 fields in each biopate at  $\times 200$  magnification; Healthy subjects [control group (C);  $n = 30$ ]; Patients with acute phase of ulcerative proctitis (UP;  $n = 30$ ); Patients with acute phase of ulcerative colitis (UC;  $n = 30$ ); Differences between group C and UP  $^bP < 0.01$ ; Differences between group C and UC  $^dP < 0.01$ . 6-HMS: 6-sulfatoxymelatonin.

titis -  $26.30 \pm 7.29$  ( $P < 0.01$ ) and with pancolitis -  $42.30 \pm 12.56$  ( $P < 0.001$ ; Figure 3).

Urinary 6-HMS excretion was found to be dependent on the number of EC cells in all groups: In healthy subjects,  $r = 0.855$ , and in patients with proctitis,  $r = 0.766$  (Figure 4A). The number of EC cells was found to have a particularly strong positive correlation with urinary 6-HMS excretion in patients with pancolitis  $r = 0.703$  (Figure 4B).

## DISCUSSION

The obtained results confirm earlier observations, which indicate that EC cell proliferation is present in the active phase of ulcerative colitis, regardless of the location of

**Figure 4** Correlation between the number of enterochromaffin cells and excretion of 6-sulfatoxymelatonin in patients. A: With ulcerative proctitis (group II); B: with ulcerative colitis (group III). The number of enterochromaffin cells was counted in 10 fields in each biopate at  $\times 200$  magnification; y: Linear regression equation; r: Pearson's correlation coefficient; 6-HMS: 6-sulfatoxymelatonin; EC: Enterochromaffin cells.

inflammatory changes in colonic mucosa<sup>[21-23]</sup>. Additional observations found in this group of patients are firstly, an increase of HIOMT expression in the colon and secondly, a high level of urinary 6-HMS excretion. All these observations indicate increased activity of the melatonergic system in patients with ulcerative colitis. The increase of urinary 6-HMS excretion, in particular, is recognized to be the correct indicator of total melatonin production and content in the whole organism.

This pool of melatonin, which includes both the intestinal and pineal components, which represent nearly the whole amount, is metabolized in the liver. Nevertheless, the positive correlation between the number of EC cells and level of urinary 6-HMS excretion indicates an increase of melatonin production mainly in the colon, as confirmed by the high HIOMT expression, compared to healthy subjects. However, it should be emphasized that melatonin catabolism both in the liver and in the colon can be modified by other factors; an excessive increase of pro-inflammatory cytokines in the colonic wall can disturb metabolism of this hormone.

Furthermore, due to the “consumption” of melato-

nin in the reaction with oxygen free radicals at the infection site, and its metabolism in the cells of the immune system, other metabolites such as 2-hydroxymelatonin, 3-hydroxymelatonin can be formed<sup>[28,29]</sup>. In turn, amino salicylates and immunosuppressive drugs applied in the treatment of ulcerative colitis exert a hepatotoxic effect and can also impair the melatonin metabolism in hepatocytes.

Due to these reasons, and probably also to the profound destruction of the colonic mucosa, decreased urinary 6-HMS excretion was observed in patients with severe ulcerative colitis. In less severe forms of the disease, these values were higher<sup>[30]</sup>. Therefore, it should be acknowledged that inflammatory processes in the colon are accompanied by increased secretion of enteral melatonin. This hormone plays a crucial enteroprotective role and its increase in ulcerative colitis is an important defense mechanism.

However, these beneficial changes in melatonin homeostasis are not sufficient to inhibit the inflammatory process and to obtain spontaneous remission of the disease. Remission requires the administration of many medications, including anti-inflammatory ones and immunosuppressants, because the pathogenesis of ulcerative colitis is complex and conditioned by numerous pro-inflammatory factors.

Serotonin is one such factor. It is secreted by the same EC cells and it is the precursor of melatonin. EC cell proliferation can, at the same time, lead to increase of serotonin secretion. The balance between serotonin and melatonin depends on the expression of enzymes regulating their synthesis and catabolism. Previous studies have not given unequivocal results. Carpuso *et al.*<sup>[31]</sup> and Magro *et al.*<sup>[32]</sup> found decreased serotonin concentration in colonic mucosa in patients with ulcerative colitis. However, in experimental animals with ulcerative colitis, a significant increase was observed both of EC cells and serotonin concentration in the colonic mucosa<sup>[33,34]</sup>.

Regardless of the factors which contribute to the maintenance of the inflammatory process, the increase of melatonin secretion is a beneficial reaction. In our earlier studies, exogenous melatonin was also found to exert a positive effect on maintaining the remission of ulcerative colitis<sup>[35]</sup>, which is the main goal of pharmacotherapy in this disease.

In conclusion, EC proliferation, HIOMT expression and increased urine excretion of 6-HMS is seen in the acute phases of ulcerative proctitis and ulcerative colitis. Consequently, the increase of enteral melatonin secretion is a beneficial response in antiinflammatory and defense mechanisms.

## COMMENTS

### Background

Melatonin is synthesized mainly by pinealocytes and by enterochromaffin cells in the gastrointestinal tract. This indoleamine displays endocrine and paracrine properties which account for enteroprotective action. Particular, melatonin and its metabolites are powerful antioxidants.

### Research frontiers

It is known that melatonin deficiency plays an important role in the pathogenesis of certain gastrointestinal diseases, such as gastroesophageal diseases, duodenal ulcer and functional disorders, dyspepsia, irritable bowel syndrome and others. Melatonin homeostasis in inflammatory bowel diseases is not determined and the results of some researches are not unequivocal.

### Innovations and breakthroughs

It is believed to be the first study of report an association between the number of enterochromaffin cells, expression of hydroxyindole-O-methyltransferase (HIOMT) and urine excretion of 6-sulfatoxymelatonin (6-HMS) in patients with ulcerative colitis.

### Applications

Evaluation of 24-h urinary excretion of 6-sulfatoxymelatonin may be a useful method for the estimation of melatonin secretion and intensity of inflammatory process in colon mucosa in patients with acute phase of ulcerative colitis. During non active phase of this disease secretion of melatonin is probably decreased and the supplementation of melatonin may be useful in complex treatment to maintain the remission.

### Terminology

Melatonin is secreted by enterochromaffin cells (EC) in the gastrointestinal tract under the effect of HIOMT but the mechanism regulating its release have not been recognized thoroughly. In the gastrointestinal tract melatonin fulfils important enteroprotective role *via* paraendocrine activity. Melatonin from the gut is transported *via* portal vein to the liver where is metabolized mainly to 6-HMS. The amounts of the urinary 6-HMS excretion are recognized indices of the synthesis and metabolism of this hormone.

### Peer review

The authors evaluated the melatonin synthetic pathway in EC in the colonic mucosa in patients with ulcerative proctitis and ulcerative colitis. This is novel paper reporting an important role of melatonin in the injured gastrointestinal tract. The role showed that during acute phase of this disease there was a proliferation of EC cells accompanied with elevated expression of HIOMT and urinary excretion of 6-HMS. The authors concluded that the response of melatonin synthesis may account for a beneficial response against the inflammatory process.

nohistochemical (IHC) staining in gastrointestinal Kaposi's sarcoma (GI-KS) in relation to endoscopic tumor staging.

**METHODS:** Biopsy samples ( $n = 133$ ) from 41 human immunodeficiency virus-infected patients were reviewed. GI-KS was defined as histologically negative for other GI diseases and as a positive clinical response to KS therapy. The receiver operating characteristic area under the curve (ROC-AUC) was compared in relation to lesion size, GI location, and macroscopic appearances on endoscopy.

**RESULTS:** GI-KS was confirmed in 84 lesions (81.6%). Other endoscopic findings were polyps ( $n = 9$ ), inflammation ( $n = 4$ ), malignant lymphoma ( $n = 4$ ), and condyloma ( $n = 2$ ), which mimicked GI-KS on endoscopy. ROC-AUC of HE, D2-40, blood vessel markers, and HHV-8 showed results of 0.83, 0.89, 0.80, and 0.82, respectively. For IHC staining, the ROC-AUC of D2-40 was significantly higher ( $P < 0.05$ ) than that of HE staining only. In the analysis of endoscopic appearance, the ROC-AUC of HE and IHC showed a tendency toward an increase in tumor staging (*e.g.*, small to large, patches, and polypoid to SMT appearance). D2-40 was significantly ( $P < 0.05$ ) advantageous in the upper GI tract and for polypoid appearance compared with HE staining.

**CONCLUSION:** The diagnostic value of endothelial markers and HHV-8 staining was found to be high, and its accuracy tended to increase with endoscopic tumor staging. D2-40 will be useful for complementing HE staining in the diagnosis of GI-KS, especially in the upper GI tract and for polypoid appearance.

### Abstract

**AIM:** To clarify the diagnostic values of hematoxylin and eosin (HE), D2-40, CD31, CD34, and HHV-8 immu-

**Key words:** Gastrointestinal Kaposi's sarcoma; Hematoxylin and eosin; CD31; CD34; D2-40; Human herpesvirus-8

**Core tip:** Diagnosis of gastrointestinal Kaposi sarcoma (GI-KS) is important because treatment specifics depend on the extent of the disease. Endoscopic biopsy is a definitive diagnostic method for GI-KS, but its diagnostic accuracy has not been fully studied. In the current study, receiver operating characteristic area under the curve of hematoxylin and eosin (HE) staining, lymphatic and blood vessel endothelial cell markers, and HHV-8 was found to be high ( $> 0.80$ ), and its accuracy tended to increase with endoscopic tumor staging. D2-40 will be useful for complementing HE staining in the diagnosis of GI-KS, especially in the upper GI tract and for polypoid appearance.

Diagnostic value of endothelial markers and HHV-8 staining in gastrointestinal Kaposi sarcoma and its difference in endoscopic tumor staging. *World J Gastroenterol* 2013; 19(23): 3608-3614 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i23/3608.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i23.3608>

## INTRODUCTION

Kaposi sarcoma (KS) is a rare cancer that was highly prevalent in the early stages of the acquired immune deficiency syndrome (AIDS) endemic<sup>[1]</sup>. Although the rate of KS has shown a marked reduction since the introduction of highly active antiretroviral therapy (HAART)<sup>[1-3]</sup>, KS remains the most common malignancy in patients with AIDS<sup>[4]</sup>.

KS primarily involves the skin but can also involve the viscera<sup>[5-7]</sup>. Because the need for treatment and choice of treatment depend on visceral involvement<sup>[1-3,8-11]</sup>, diagnosis of the gastrointestinal (GI) tract, a common site of visceral involvement<sup>[11-13]</sup>, is important. Definitive diagnosis of GI-KS requires endoscopic biopsy<sup>[6,7,14-16]</sup>, but GI-KS often presents on endoscopy with submucosal or small protruded appearance<sup>[17,18]</sup>, which can lead to false-negative biopsy results<sup>[14-16]</sup>.

Recently, immunohistochemical (IHC) staining with D2-40, CD31, CD34, and HHV-8 has been reported as useful for distinguishing cutaneous KS from other diseases<sup>[19-28]</sup>. However, no IHC studies have reported on the utility of KS diagnosis in the GI tract. In addition, it is not known how well such staining methods provide additive effects compared with HE staining alone.

With regard to the diagnosis of cutaneous KS, there may be subtle differences in the staining patterns for endothelial markers between different histologic stages (patch, plaque, and nodular) of KS<sup>[19,21,22,25]</sup>. In the GI tract, KS has various macroscopic presentations<sup>[13-15,17,18,29]</sup> and KS may affect any part of the GI tract<sup>[7,13,14,17,18]</sup>. However, the effect of IHC-positive staining in the diagnosis of GI-KS on the basis of lesion appearance has not been fully investigated.

The purpose of this study was to clarify the diagnostic value of IHC staining in the diagnosis of GI-KS and to assess the difference in accuracy between HE and IHC

staining in relation to endoscopic tumor staging.

## MATERIALS AND METHODS

### Subjects

We retrospectively reviewed histologic slides from 103 consecutive lesions for which IHC staining was performed between 2006 and 2012 at the National Center for Global Health and Medicine (NCGM). Lesions were obtained from 41 human immunodeficiency virus (HIV)-infected patients who had not received anti-KS therapy. The institutional review board at NCGM approved this study.

### Clinical factors

Sexual behavior was classified subjects into two groups: men who have sex with men (MSM); and heterosexual. CD4<sup>+</sup> cell counts and HIV-RNA viral load (VL) determined by real-time quantitative polymerase chain reaction (PCR) were reviewed within 1 mo of endoscopy. A positive result for real-time HIV-RNA was defined as  $\geq 40$  copies/mL. History of HAART was collected from medical records prior to endoscopy. GI symptoms were assessed by the physician who interviewed each patient. Those without GI symptoms and negative screening endoscopy were considered to be symptom-free.

### Diagnosis of GI-KS

Confirmed GI-KS lesions were defined as those that fulfilled with following criteria. (1) Histologically negative biopsy for other GI diseases; (2) A positive response to KS therapy (HAART or systemic therapy of liposomal anthracycline); and (3) partial or complete resolution was confirmed on follow-up endoscopy after KS therapy (Figure 1). We usually perform endoscopy after 1 mo, 2 mo, or 6 mo of KS therapy to evaluate GI-KS regression.

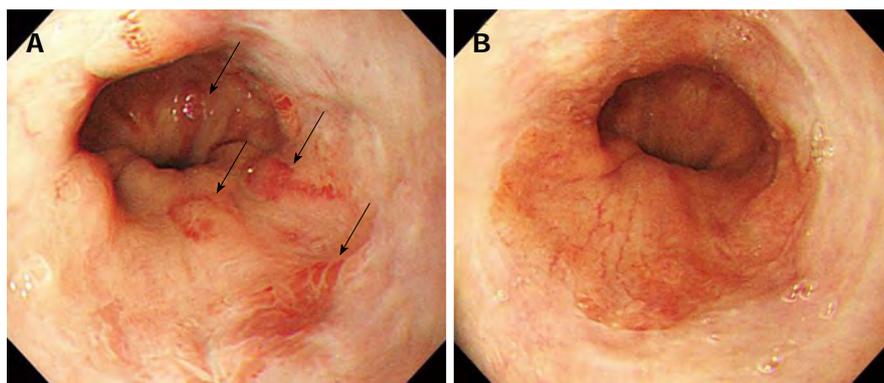

All 103 lesions were suspected to be GI-KS on endoscopy, as they exhibited properties such as reddish with patches, polypoid appearance, submucosal tumor (SMT)-like lesions, and ulcerative SMT, as previously reported<sup>[13-15,17,18,29]</sup>. Therefore, IHC staining in addition to HE staining was performed.

### Endoscopic assessment

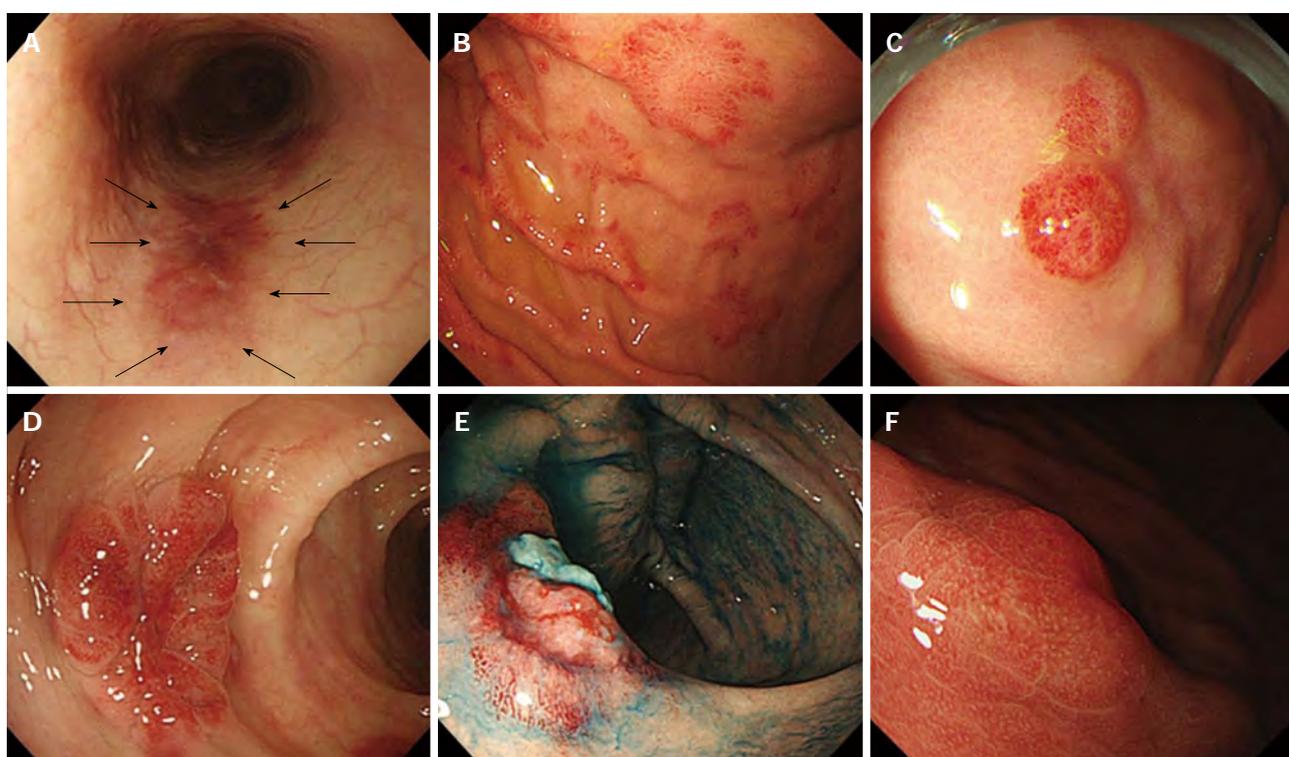

Endoscopic images were taken using a high-resolution scope (model GFH260, CFH260AI; Olympus Optical, Tokyo, Japan) in all patients. We performed a biopsy using biopsy forceps (FB-240U, FB230-K, Olympus Co., Tokyo, Japan).

Size ( $< 10$  mm or  $\geq 10$  mm), GI location, and macroscopic findings were assessed endoscopically. Locations of GI involvement were classified as upper GI (esophagus, stomach, and duodenum) and lower GI (ileum, colon, and rectum).

Macroscopic findings were evaluated as the presence of reddish mucosa with patches (Figure 2A), polypoid lesions (Figure 2B), submucosal tumor (SMT) (Figure 2C), and ulcerative SMT (Figure 2D), as previously reported<sup>[13-15,17,18,29]</sup>. Ulceration was defined endoscopically as a distinct, visible crater  $> 5$  mm in diameter with a slough base.

**Figure 1** Confirmation of clinical response on follow-up endoscopy before and after Kaposi's sarcoma therapy. A: Gastrointestinal Kaposi sarcoma (arrows) in the esophagogastric junction before Kaposi's sarcoma (KS) therapy; B: After four months of KS therapy with liposomal anthracycline.

**Figure 2** Gastrointestinal Kaposi sarcoma and mimicking lesions on endoscopy. A: Kaposi sarcoma, dark reddish patch (arrows) in the esophagus; B: Kaposi sarcoma, multiple patch appearance in the stomach; C: Kaposi sarcoma, small (< 10 mm) and polypoid appearance in the stomach; D: Kaposi sarcoma, submucosal tumor (SMT) appearance with large size ( $\geq 10$  mm) in the sigmoid colon; E: Kaposi sarcoma, submucosal tumor (SMT) appearance with ulceration in the ileo-cecal valve with indigo-carmin dye; F: Hyperplastic polyps mimicking Kaposi sarcoma with small size (< 10 mm) in the stomach.

### Histological assessment

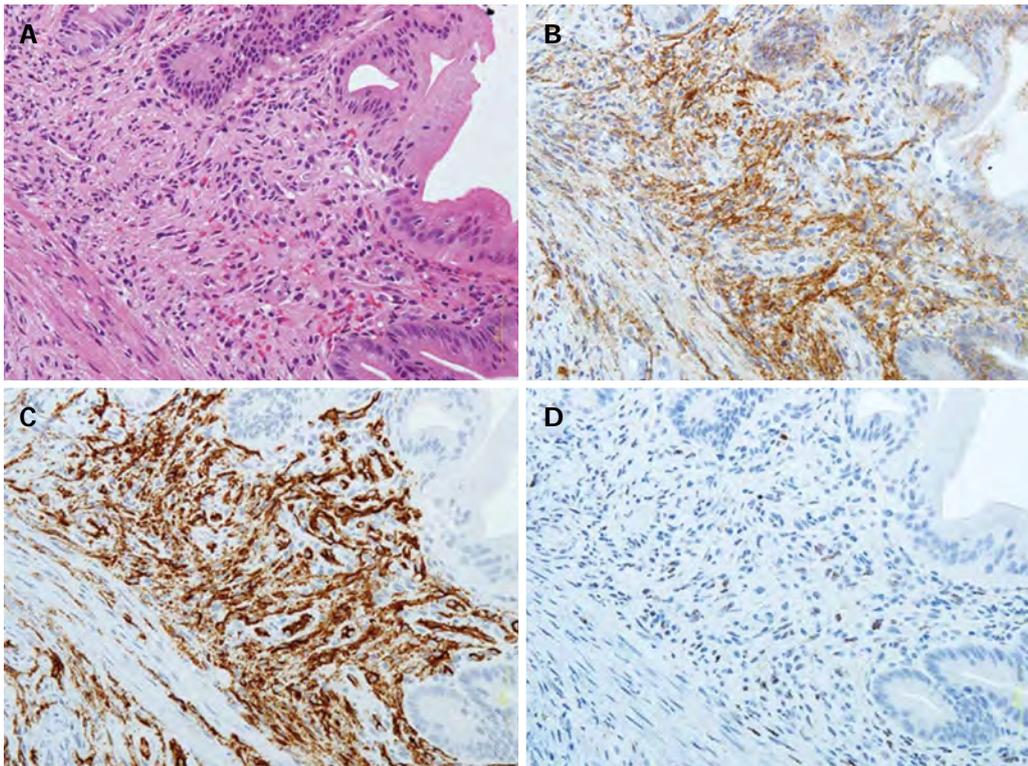

The presence of proliferating spindle cells with vascular channels filled with blood cells (Figure 3A) from biopsy specimens was evaluated with HE staining by an investigator blinded to IHC staining results. IHC staining for the lymphatic vessel endothelial cell marker D2-40 (Dako North America, Carpinteria, CA) (Figure 3B) and the blood vessel endothelial cell markers CD31 (Dako North America) or CD34 (Dako North America) (Figure 3C), and the use of the mouse monoclonal antibody against HHV-8 LNA-1 (Novocastra Laboratories Ltd, Newcastle upon Tyne, United Kingdom) (Figure 3D), were also evaluated on formalin-fixed, paraffin-embedded tissue sections as previously reported<sup>[19-28]</sup>. IHC slides were

evaluated at  $\times 200$  and  $\times 400$  magnification by expert GI pathologists.

### Statistical analysis

To elucidate the accuracy of HE and IHC staining for the diagnosis of GI-KS, the sensitivity, specificity, positive and negative likelihood ratio (LR+ and LR-, respectively), and area under the receiver operating characteristic curve (ROC-AUC) were calculated and estimated with a 95%CI.

The difference of the ROC-AUC of the four specific stains (HE, D2-10, vessel markers, and HHV-8) was compared. Subgroup analysis was performed to identify differences in four specific stains according to gross ap-

**Figure 3** Pathological features of gastrointestinal Kaposi sarcoma. A: Spindle cell proliferation in the submucosa on hematoxylin and eosin (HE) staining; B: Vascular gaps are lined with endothelial cells when staining with D2-40; C: Vascular gaps are lined with endothelial cells when staining with CD34; D: Some endothelial cells are positive for human herpesvirus 8.

**Table 1** Definitive diagnosis of gastrointestinal lesion from endoscopic biopsy samples ( $n = 103$ )  $n$  (%)

| Diagnosis                                 | No.       |
|---|-----------|
| GI-KS                                     | 84        |
| Upper GI tract                            | 57 (67.9) |
| Esophagus                                 | 7 (8.3)   |
| Stomach                                   | 38 (45.2) |
| Duodenum                                  | 12 (14.3) |
| Lower GI tract                            | 27 (32.1) |
| Cecum                                     | 8 (9.5)   |
| Ascending colon                           | 1 (1.2)   |
| Transverse colon                          | 2 (2.4)   |
| Descending colon                          | 1 (1.2)   |
| Sigmoid colon                             | 7 (8.3)   |
| Rectum                                    | 8 (9.5)   |
| Non-KS lesion                             | 19        |
| Hyperplastic polyp                        | 8         |
| Fundic gland polyps                       | 1         |
| <i>Helicobacter</i> -associated gastritis | 1         |
| Malignant lymphoma                        | 4         |
| Anorectal condyloma                       | 2         |
| Non-specific colitis                      | 3         |

GI-KS: Gastrointestinal Kaposi sarcoma.

pearances, and the ROC-AUC was compared in each group. ROC-AUC differences between HE staining and specific IHC staining in each groups were also compared.

Values of  $P < 0.05$  were considered significant. All statistical analysis was performed using Stata version 10 software (StataCorp, College Station, TX).

## RESULTS

### Baseline clinical characteristics

All 41 HIV-infected patients were male and the HIV infection route was MSM in all cases. The median CD4 cell count (interquartile range; IQR) was 77 (33, 157) cells/mL and the median HIV viral load (IQR) was 48500 (< 40, 150000) copies/mL. There were 18 (43.9%) patients with a history of HAART. GI symptoms were noted in 10 patients (24.4%). No notable gastrointestinal bleeding or perforation, either spontaneously or after endoscopic biopsy, was noted.

Table 1 provides details on the definitive diagnosis of GI lesions. Of the 103 lesions, 84 (81.6%) were confirmed as GI-KS while the remainder were other GI lesions (19) consisted of hyperplastic polyps (8), fundic gland polyps (1), *Helicobacter*-associated gastritis (1), malignant lymphoma (4), anorectal condyloma (2), and non-specific colitis (3).

### Diagnostic value of specific staining for the diagnosis of GI-KS

Sensitivity, specificity, LR+, LR-, and ROC-AUC of specific staining for the diagnosis of GI-KS are shown in Table 2. The ROC-AUC values of four specific stains (HE, D2-40, blood vessel marker, and HHV-8) were significantly different ( $P < 0.01$ ) in the diagnosis of GI-KS (Table 2). The ROC-AUC of D2-40 staining was only significantly higher ( $P < 0.05$ ) than that of HE staining (Table 2).

**Table 2** Diagnostic value of endoscopic biopsy in gastrointestinal Kaposi sarcoma (*n* = 103)

| KS/non-KS (84/19)          | Sensitivity, % (95%CI) | Specificity, % (95%CI) | Positive LR (95%CI)           | Negative LR (95%CI)           | ROC area <sup>1</sup> (95%CI) |
|----------------------------|------------------------|------------------------|-------------------------------|-------------------------------|-------------------------------|
| HE (59/1)                  | 70.2 (59.3-79.7)       | 94.7 (74.0-99.9)       | 9.33 (1.99-43.8) <sup>2</sup> | 0.32 (0.23-0.46) <sup>2</sup> | 0.83 (0.75-0.90)              |
| D2-40 (65/0)               | 77.4 (67.0-85.8)       | 100 (82.4-100)         | 30.8 (1.99-477) <sup>2</sup>  | 0.24 (0.16-0.35) <sup>2</sup> | 0.89 (0.84-0.93) <sup>a</sup> |
| Blood vessel marker (68/4) | 81 (70.9- 88.7)        | 78.9 (54.4- 93.9)      | 3.85 (1.6-9.24)               | 0.24 (0.15-0.40)              | 0.80 (0.70-0.90)              |
| HHV-8 (53/0)               | 63.1 (51.9-73.4)       | 100 (82.4-100)         | 25.2 (1.62-391) <sup>2</sup>  | 0.38 (0.29-0.51) <sup>2</sup> | 0.82 (0.76-0.87)              |

LR: Likelihood ratio; HE: Hematoxylin and eosin; HHV: Human herpesvirus. <sup>1</sup>Receiver operating characteristic (ROC) area is significantly (*P* < 0.01) different in this category; <sup>2</sup>LR estimated using the substitution formula. A value of 0.5 was added to all cell frequencies before calculation; <sup>a</sup>*P* < 0.05 for comparisons of lesions by HE staining.

**Table 3** Diagnostic values of gastrointestinal Kaposi sarcoma in relation to size, location, and macroscopic appearances on endoscopy (*n* = 103)

| Subgroup               | Specific stain      | No. of lesions (KS/non-KS) | ROC-AUC (95%CI)               | <i>P</i> value <sup>1</sup> |
|------------------------|---------------------|----------------------------|-------------------------------|-----------------------------|
| Size                   | Size < 10 mm        | 26/7                       |                               |                             |
|                        | HE                  | 14/0                       | 0.77 (0.67-0.87)              |                             |
|                        | D2-40               | 16/0                       | 0.81 (0.71-0.90)              |                             |
|                        | Blood vessel marker | 18/4                       | 0.56 (0.34-0.78)              |                             |

<sup>1</sup>*P* values of receiver operating characteristic (ROC) area in each category were compared. <sup>a</sup>*P* < 0.05 for the comparison with lesions by hematoxylin and eosin (HE) staining. GI-KS: Gastrointestinal Kaposi sarcoma; ROC-AUC: ROC area under the curve; SMT: Submucosal tumor.

### Diagnostic value of GI-KS according to size, location, and macroscopic appearance

The ROC-AUC of four specific stains showed a tendency toward an increase in tumor staging on endoscopy (*e.g.*, small to large, flat, protruded, and SMT appearance) (Table 3). The ROC-AUC of blood vessel marker in polypoid appearance was extremely low compared with other lesions (Table 3).

The ROC-AUC of four specific stains was significantly different in size, GI tract location, appearance of patches, and polypoid lesion for the diagnosis of GI-KS (Table 3). No significant differences were noted in the ROC-AUC of four specific stains for SMT lesions (*P* = 0.15) or ulcerative SMT lesions (*P* = 0.34) (Table 3).

### Comparison of the ROC-AUC between HE staining and specific staining

The ROC-AUC of the D2-40 stain was higher than that of the HE stain for lesions < 10 mm, lesions ≥ 10 mm, upper GI tract, lower GI tract, patches, polypoids, and SMT (Table 3). Of these, upper GI tract and polypoid appearance were statistically significant (*P* < 0.05). The ROC-AUC of blood vessel marker or HHV-8 stain was higher than that of HE staining for lesions ≥ 10 mm, patches, and ulcerative SMT (Table 3), with no statistical significance (*P* > 0.05).

## DISCUSSION

Previous IHC studies have shown the utility of differential diagnosis between cutaneous KS and vascular tumors such as hemangioma, lymphangioma, hemangioendothelioma, and angiosarcoma<sup>[19-28]</sup>. However, development of vascular tumor in the GI tract is extremely rare<sup>[30]</sup>. Therefore, differential diagnosis for GI-KS can be different for cutaneous and GI tract sites. In the present study, lesions that were difficult to distinguish from GI-KS are inflammation-associated protruded lesions with reddish color. The reason for this is that GI-KS can appear as a strong reddish mucosa and vary from flat maculopapular or polypoid masses to SMT, ulceration, or bulky tumor masses on endoscopy<sup>[14,17,18,29,31]</sup>.

Previous studies investigated only GI-KS cases, and

only sensitivity can be elucidated<sup>[14-16]</sup>. In the current study, the ROC-AUC values of the four IHC stains and HE stain were > 0.8, demonstrating that all had good diagnostic accuracy. However, it is not feasible in clinical practice to diagnose KS using all stains. Based on the results of this study, we conclude that D2-40 is the only stain capable of complementing HE staining.

We found that the ROC-AUC of four specific stains tended to increase with endoscopic tumor staging (*e.g.*, small to large, flat, protruded, and SMT). Previous studies, particularly those on cutaneous KS, have also shown that diagnostic accuracy varies according to tumor staging<sup>[19,21,22,25]</sup>. Although it is not feasible to apply staging classification of cutaneous KS to the evaluation of the macroscopic appearance of GI-KS, it is important--based on their results and our findings--to take tumor appearance and staging into consideration for the pathological diagnosis of KS.

We further performed subgroup analysis of four stains to reveal differences in diagnostic accuracy. No significant differences were noted in the ROC-AUC of four specific stains in SMT lesions ( $P = 0.15$ ) and ulcerative SMT lesions ( $P = 0.34$ ), indicating that HE staining alone is sufficient for diagnosing lesions with SMT appearance. Although we attempted to find lesions that can be better diagnosed with the addition of other IHC stains, polypoid lesions, and location of upper GI tract attained significant ROC-AUC ( $P < 0.05$ ) scores with D2-40. The ROC-AUC of D2-40 was always > 0.8, regardless of the size, location, or macroscopic appearance of lesions, indicating its utility as an additional staining modality.

One of the characteristic findings of this study is that the ROC-AUC of the blood vessel marker for polypoid appearance was extremely low compared with other lesions. This was due to the presence of hyperplastic polyps, meaning that CD34 staining produces positive results due to vessel proliferation. This can result in higher false-positive cases ( $n = 38$ ) and lower diagnostic accuracy of KS.

There are several limitations of the present study. First, we assessed IHC staining as positive or negative instead of using a scoring system; a semi-quantitative system might provide more accurate or available results in clinical practice. Second, positive vessel marker staining was defined as CD31- or CD34-positive because CD31 or CD34 was used by each pathologist. However, because 80% (82/103) of the lesions were examined using CD34, and because CD34 is reportedly a more accurate marker than CD31<sup>[25]</sup>, we believe the results of the vessel marker staining in the present study are reliable.

In conclusion, endoscopic biopsy for diagnosing GI-KS can be performed safely. The diagnostic accuracy of HE staining, lymphatic and blood vessel endothelial cell markers, and HHV-8 was found to be high. Among these, D2-40 had the highest accuracy. The diagnostic accuracy of four specific stains tended to increase with endoscopic tumor staging. In particular, polypoid lesions and those in the upper GI tract respond well to HE staining complemented by D2-40 staining.

## COMMENTS

### Background

Diagnosis of Kaposi sarcoma (KS) involving the gastrointestinal (GI) tract is important because treatment specifics depend on the extent of the disease. Definitive diagnosis of GI-KS requires endoscopic biopsy with hematoxylin and eosin (HE) or immunohistochemical (IHC) staining. IHC staining for the differential diagnosis of cutaneous disease has been extensively studied, but the diagnostic value of GI-KS remains unknown.

### Research frontiers

GI-KS often presents various endoscopic appearances, which can lead to false-negative biopsy results. Furthermore, the difference in accuracy of IHC staining in relation to endoscopic appearances has not been fully investigated. In the current study, the authors demonstrate the diagnostic value of IHC staining for GI-KS and to assess the difference in accuracy between HE and IHC staining in relation to endoscopic tumor staging.

### Innovations and breakthroughs

Previous reports have highlighted the accuracy of IHC for diagnosing cutaneous KS. This is the first study to report that the receiver operating characteristic area under the curve (ROC-AUC) of HE staining, lymphatic and blood vessel endothelial cell markers, and HHV-8 for diagnosing GI-KS was found to be high (> 0.80), and its accuracy tended to increase with endoscopic tumor staging. In particular, polypoid lesions and those in the upper GI tract respond well to HE staining complemented by D2-40 staining.

### Applications

In the current study, the ROC-AUC values of the four IHC stains and HE stain were good, but it is not feasible in clinical practice to diagnose KS using all stains. Based on the results of this study, the authors conclude that D2-40 is the only stain capable of complementing HE staining.

### Terminology

The ROC is a diagnostic testing modality that presents its results as a plot of sensitivity vs 1-specificity (false-positive rate). The ROC-AUC indicates the probability of a measure or predicted risk being higher for patients with disease than for those without disease.

### Peer review

This is an excellent paper describing novel findings of IHC in diagnosing GI-KS.

cancerous lesions in *Helicobacter pylori* (*H. pylori*)-susceptible ethnic Malays.

**METHODS:** Twenty-three Malay subjects with *H. pylori* infection and gastric precancerous lesions identified during endoscopy were included as "cases". Thirty-seven Malay subjects who were *H. pylori* negative and had no precancerous lesions were included as "controls". Venous blood was collected for genotyping with Affymetrix 50K Xba1 kit. Genotypes with call rates < 90% for autosomal single nucleotide polymorphisms (SNPs) were excluded. For each precancerous lesion, associated SNPs were identified from Manhattan plots, and only SNPs with a  $\chi^2$  *P* value < 0.05 and Hardy Weinberg Equilibrium *P* value > 0.5 was considered as significant markers.

**RESULTS:** Of the 23 *H. pylori*-positive subjects recruited, one sample was excluded from further analysis due to a low genotyping call rate. Of the 22 *H. pylori*-positive samples, atrophic gastritis only was present in 50.0%, complete intestinal metaplasia was present in 18.25%, both incomplete intestinal metaplasia and dysplasia was present in 22.7%, and dysplasia only was present in 9.1%. SNPs rs9315542 (*UFM1* gene), rs6878265 (*THBS4* gene), rs1042194 (*CYP2C19* gene) and rs10505799 (*MGST1* gene) were significantly associated with atrophic gastritis, complete intestinal metaplasia, incomplete metaplasia with foci of dysplasia and dysplasia, respectively. Allele frequencies in "cases" vs "controls" for rs9315542, rs6878265, rs1042194 and rs10505799 were 0.4 vs 0.06, 0.6 vs 0.01, 0.6 vs 0.01 and 0.5 vs 0.02, respectively.

**CONCLUSION:** Genetic variants possibly related to gastric precancerous lesions in ethnic Malays susceptible to *H. pylori* infection were identified for testing in subsequent trials.

### Abstract

**AIM:** To identify genes associated with gastric pre-

© 2013 Baishideng. All rights reserved.

**Key words:** Gastric precancerous lesions; Gene polymorphisms; Genome-wide association; *Helicobacter pylori*; Malays

**Core tip:** Gastric cancer and its precancerous lesions are exceptionally rare among ethnic Malays. Gene variants may be associated with precancerous lesions in *Helicobacter pylori*-susceptible Malays. Genome-wide association was performed to identify gene variants in Malays with a spectrum of gastric precancerous lesions. Results indicated that at different phases of the Correa cascade, different gene variants were manifest, but they followed a pattern of progression similar to their histological and clinical stages. It is possible that, in addition to histological staging, gene variant markers may serve to identify different phases of gastric cancer progression in the near future.

Gastric precancerous lesions are associated with gene variants in *Helicobacter pylori*-susceptible ethnic Malays. *World J Gastroenterol* 2013; 19(23): 3615-3622 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i23/3615.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i23.3615>

## INTRODUCTION

Gastric cancers are thought to arise from a cascade of histological changes or precancerous lesions (atrophic gastritis, intestinal metaplasia and dysplasia) before developing into full-blown malignancy<sup>[1]</sup>. In Japan, studies have shown that surveillance of these precancerous lesions is associated with increased detection of early gastric cancers and improved survival rates<sup>[2,3]</sup>.

These precancerous lesions are associated with *Helicobacter pylori* (*H. pylori*) infection acquired since childhood<sup>[4]</sup>. In populations with a high prevalence of *H. pylori* infection, including those in China and Japan, precancerous lesions can be detected in up to 80% of adults<sup>[5]</sup>. Eradication of *H. pylori* infection at this stage has not been shown to be effective in these high risk populations<sup>[6]</sup>.

Ethnic Malays residing in the north-eastern region of Peninsular Malaysia (state of Kelantan) have an exceptionally low prevalence of *H. pylori* infection<sup>[7,8]</sup>. Exact reasons for this low prevalence are unknown, but it could be a combination of unique environmental, host and strain virulence factors shaped by the population's evolutionary history<sup>[9-12]</sup>. Due to the extremely low acquisition of *H. pylori* infection, gastric cancer and its precancerous lesions are extremely rare in this population<sup>[13-15]</sup>.

In a survey of 234 subjects undergoing upper endoscopy in a tertiary hospital from the state of Kelantan, the reported rate of atrophic gastritis was 42.3% and intestinal metaplasia was present in 7.7% (14/234) of all biopsies, but was only present in 1.4% (2/146) of the ethnic Malays<sup>[15]</sup>. This low rate of gastric precancerous lesions

observed was a result of a low prevalence of *H. pylori* infection in the studied population of only 6.8%. As shown in a multivariable analysis, the risk of intestinal metaplasia and dysplasia was only significant in the presence of *H. pylori* infection<sup>[15]</sup>.

A minority of this Malay population is genetically susceptible to *H. pylori* infection, and *DCC* gene polymorphism has recently been found to be responsible<sup>[16]</sup>. An aberrant methylation of this tumor suppressor gene has been observed to occur in the course of gastric carcinogenesis<sup>[17]</sup>. As such, this population may also be genetically susceptible to the development of gastric precancerous lesions.

The current study aimed to determine the gene polymorphisms associated with gastric precancerous lesions in the Malay population from north-eastern region of Peninsular Malaysia using the genome-wide association approach.

## MATERIALS AND METHODS

### Study subjects

Only those ethnic Malay subjects (age range 20-80 years) whose gastrointestinal symptoms required upper endoscopy were screened for study eligibility. To avoid ascertainment bias, subjects had upper gastrointestinal symptoms (including dyspepsia and/or abdominal discomfort) and required upper endoscopy to exclude gastro-duodenal diseases before being included into the study.

All Malay subjects included in the study were born in the state of Kelantan, had resided within the region for at least 3 generations and were from different families but had similar socio-economic and socio-cultural backgrounds. Subjects positive for *H. pylori* infection according to a urease test and histology and with gastric precancerous lesions identified during endoscopy were categorized as "cases", while those negative for *H. pylori* infection and precancerous lesions were categorized as "controls". "Cases" and "controls" were matched for age and gender. Subjects satisfying the above inclusion criteria were recruited into the study. Exclusion criteria included an intake of antibiotics 3 mo prior to the upper endoscopy test, upper gastrointestinal bleeding, a positive family history of *H. pylori* infection and gastric cancer, a previous history of *H. pylori* infection and chronic psychiatric and medical conditions, including cancer. Informed consent was obtained from all subjects prior to their enrolment into the study.

Cases with *H. pylori* infection and positive for precancerous lesions were extremely limited in number due to an exceptionally low rate of *H. pylori* infection among ethnic Malays. Only 23 Malay subjects were eventually included as "cases". A larger sample size for the "controls" was sought to compensate for the low sample size in "cases". Furthermore, stringent criteria were set to ensure that only subjects of similar age, socio-economic and socio-cultural backgrounds were included in the study. From a total of 45 screened subjects, 37 Malay subjects

were recruited as “controls” with eight subjects being excluded as they did not meet the inclusion criteria, they did not give consent or blood samples were poor.

The study was approved by the Human Research and Ethics Committee of Universiti Sains Malaysia (USM).

### **Endoscopic diagnosis and histological definitions of precancerous lesions**

All upper endoscopies (model GIF-140 and GIF-160; Olympus Medical Systems, Tokyo, Japan) during this period were performed by one endoscopist with at least 5 years’ experience. If needed, patients were sedated accordingly. Subjects who did not stop proton pump inhibitors 2 wk before endoscopy, those who had received antibiotics prior to study, and patients who had upper gastrointestinal bleeding shortly before the study were excluded.

Endoscopic findings of gastritis and atrophy were recorded and classified based on established Sydney criteria<sup>[18]</sup> and Atrophy Club criteria<sup>[19]</sup>. Biopsies were taken using standard biopsy forceps at the antrum, incisura and body. A minimum of 2 to 4 biopsies (size between 2 to 4 mm) were taken in each sites and these gastric biopsies, preserved in formalin containers, were transported to the pathology laboratory on the same day.

Only one histopathologist was involved in reviewing all the slides. All biopsies were stained with routine hematoxylin and eosin (HE) stain followed by Alcian blue-periodic acid Schiff stain for the detection of intestinal metaplasia. The Warthin Starry stain would be used in sections where the *H. pylori* bacterium was not detected in the routine HE stain.

Chronic atrophic gastritis was identified based on the updated 1994 Sydney system<sup>[20]</sup> and Atrophy Club definitions<sup>[19]</sup>. Intestinal metaplasia was identified by replacing glandular epithelium with goblet cells<sup>[21]</sup>. Intestinal metaplasia was classified into complete or incomplete types. Complete type resembled the small intestinal phenotype with well-formed goblet cells while incomplete type resembled the colonic phenotype with irregular mucin droplets and absence of a brush border. Dysplasia was identified by epithelium disarray and increased nucleocytoplasmic ratio<sup>[22]</sup>.

For the purpose of the genotyping study, subjects were grouped as follows: atrophic gastritis only, complete intestinal metaplasia, incomplete metaplasia with foci of dysplasia, or dysplasia only.

### **Genomic DNA preparation**

All recruited subjects were called up by one of the investigators (SM) to have 1 mL of venous blood taken during the study day. Unlike conventional methods of DNA extraction, 1 mL of blood was sufficient for the commercially available kits. The blood was collected in an EDTA tube and was transported immediately to a facility (Human Genome Centre, USM, Kubang Kerian, Malaysia) to be stored at 4 °C. Subsequently, DNA for all recruited cases and controls was isolated using QIAamp DNA Blood

Mini Kit (QIAGEN, Hilden, Germany).

### **Genotyping with Affymetrix 50K Xba1**

The isolated DNA from all recruited cases ( $n = 23$ ) and controls ( $n = 37$ ) were processed and genotyped using Affymetrix 50k Xba1 array (Affymetrix, United States) following the instructions provided in the Affymetrix GeneChip Human Mapping 100K Assay Manual<sup>[23]</sup>. Genotypes with call rates  $< 90\%$  for autosomal single nucleotide polymorphisms (SNPs) were excluded. SNPs that had a minor allele frequency  $< 5\%$ , that failed to genotype in  $> 5\%$  of samples, or had a Hardy-Weinberg Equilibrium (HWE)  $P$ -value  $< 0.5$  were also excluded from the analysis.

### **Statistical analysis**

Genotype calling to assess the normalization of the SNPs was performed with the Bayesian Robust Linear Model with Mahalanobis distance classifier (BRLMM) algorithm from the Affymetrix<sup>®</sup> Genotyping Console<sup>™</sup> software version 4.0 (Affymetrix, United States). Quality control for genetic markers was assessed using the Genotype filtering tool in the SVS Golden Helix Bioinformatics Tools version 7.4 (Golden Helix Inc., Bozeman, MT, United States).

Association was evaluated for every single SNP in each gene with SVS Golden Helix Bioinformatics Tools. False Discovery Rate, and Bonferroni adjustments were used for multiple-testing corrections. A Manhattan plot for each phenotype was generated to determine SNPs with the highest significant value associated with that phenotype using SVS Golden Helix Bioinformatics Tools (version 7.4). A significant genomic threshold of  $3 \times 10^{-7}$  in Manhattan plots was set in this study and a  $\chi^2$   $P$  value for each SNP was calculated based on Fisher’s exact  $\chi^2$  test. For each type of precancerous lesion studied, of which a group of associated SNPs were identified from Manhattan plots, only a SNP with  $\chi^2$   $P$  value  $< 0.05$  and HWE  $P$  value  $> 0.5$  was considered as a significant marker.

## **RESULTS**

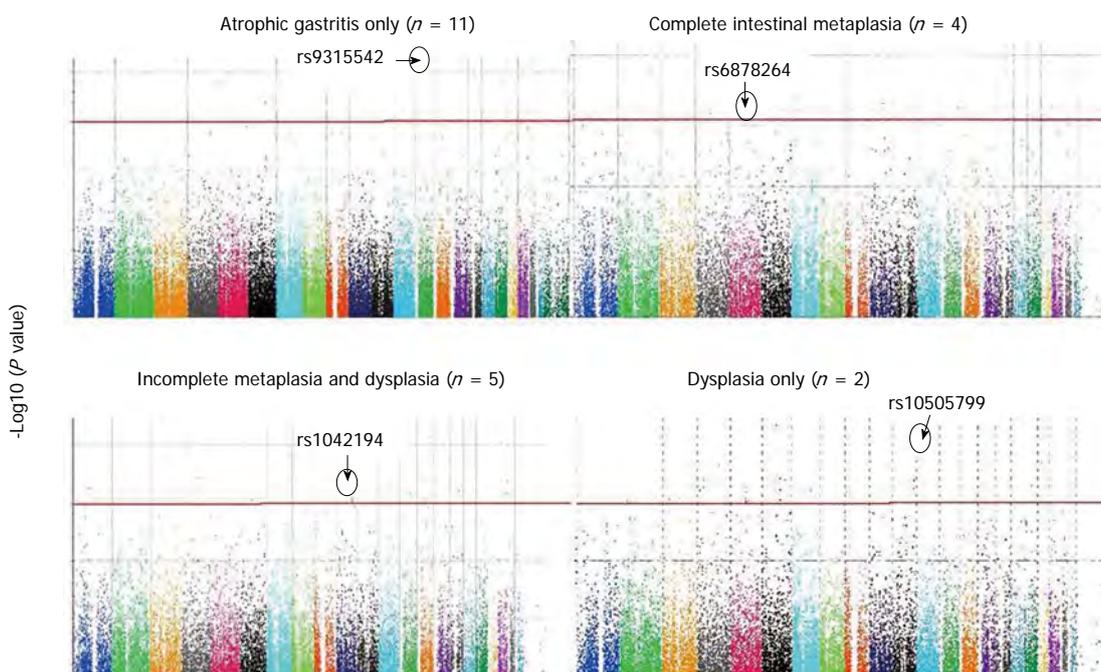

Of the 23 *H. pylori*-positive subjects recruited, one sample was excluded from further analysis due to a low genotyping call rate ( $< 90\%$ ). The mean age of the remaining 22 “cases” was  $56.5 \pm 16.5$  years, and was  $53.2 \pm 15.2$  years for the 37 “controls”. Cases were 54.5% (12/22) male compared with 50% (17/37) in “controls”. Of subjects positive for *H. pylori* infection (cases), atrophic gastritis only was present in 50.0% (11/22), complete intestinal metaplasia was present in 18.2% (4/22), both incomplete intestinal metaplasia and dysplasia was present in 22.7% (5/22) and dysplasia only was present in 9.1% (2/22). None of the gastric precancerous lesions were present in subjects negative for *H. pylori* infection (controls).

In 10 “cases” with atrophic gastritis only, compared with controls, 26 SNPs were above the significant ge-

rs ID: The unique ID for the identified single nucleotide polymorphisms; HWE: Hardy-Weinberg Equilibrium. <sup>1</sup>All markers were run using the FAMHAP (Haplotype Association Analysis) program. The P value represents the simulated overall significance for the particular marker corrected for multiple testing and P < 0.05 was considered statistically significant.

**Figure 1** Manhattan plots for different gastric precancerous lesions (phenotype) in susceptible Malays with *Helicobacter pylori*. Red line indicates genomic threshold ( $3 \times 10^{-7}$ ) set to determine single nucleotide polymorphisms (SNPs) in Hardy-Weinberg Equilibrium associated with the studied phenotype. The most significant SNP, as determined by the  $\chi^2$  P value, for each phenotype is shown by an arrow.

genomic threshold. Five of the identified 26 SNPs were in HWE, of which rs9315542, located in chromosome 13 q13.3 (*UFM1* gene), was the most significant associated SNP ( $\chi^2$  P value = 0.007) (Table 1, Figure 1). The allele frequency for rs9315542 in cases *vs* controls was 0.4 *vs* 0.06.

In 4 “cases” with intestinal metaplasia only, compared with controls, 13 SNPs were above the genomic threshold and were in HWE, of which rs6878264, located in intron 4 of the *thrombospondin 4* (*THBS4*) gene, was the most significant associated SNP ( $\chi^2$  P value = 0.01) (Table 2, Figure 1). The allele frequency for rs6878264 in cases *vs* controls was 0.6 *vs* 0.01.

In 6 “cases” with both intestinal metaplasia and dysplasia, compared with controls, 17 SNPs were above the genomic threshold and in HWE, of which rs1042194, located in exon 8 of the *CYP2C19* gene, was the most significant associated SNP ( $\chi^2$  P value = 0.00536) (Table 3, Figure 1). The allele frequency for rs1042194 in cases *vs*

controls was 0.6 *vs* 0.01.

Finally, in 2 “cases” with dysplasia only, compared with controls, 2 SNPs were above the genomic threshold and in HWE, of which rs10505799, located in chromosome 12p12.3 (*MGST1* gene), was the most significant associated SNP ( $\chi^2$  P value = 0.006) (Table 4, Figure 1). The allele frequency for rs10505799 in cases *vs* controls was 0.5 *vs* 0.02.

## DISCUSSION

In this Malay population with an extremely low risk of *H. pylori* infection, gastric cancer and its precancerous lesions are very rare. However, in the current study of subjects susceptible to *H. pylori* infection and those who developed precancerous lesions, certain gene polymorphisms were found to be more commonly associated with precancerous lesions. Notwithstanding the low sample size, resulting from the extremely rare occurrence of gastric

rs ID: The unique ID for the identified single nucleotide polymorphisms; HWE: Hardy-Weinberg Equilibrium.

precancerous lesions in this population, the current study, with the use of the genome-wide association approach, allowed identification of genetic markers that can be tested in a larger cohort in the near future<sup>[24]</sup>.

In the 50% of *H. pylori*-infected subjects with atrophic gastritis, the earliest lesion in the Correa cascade, rs9315542, located in chromosome 13 q13.3 (*UFM1* gene), was the identified marker. A recently identified expressed protein, ubiquitin-fold modifier 1 or *UFM1*, is a member of a large family of ubiquitin-like proteins or Ubls<sup>[25]</sup>. Ubiquitin, a small protein, is associated with the process of “ubiquitination”, a target of proteins for degradation by the proteasome. At the moment, the exact cellular functions of proteins modified by *UFM1* remain elusive. A recent report indicated that components of the *UFM1* conjugation pathway are highly expressed in the beta cells of the pancreas and some other protein secretory tissues<sup>[26]</sup>. In the same report, *UFM1* conjugate

prevented endoplasmic reticulum (ER) stress-induced apoptosis. While *UFM1* in gastric tissue has not been investigated, it is known that gastric mucosa secretes a number of peptides and hormones, including pepsinogen and ghrelin, whose levels are reduced in atrophic gastritis<sup>[27]</sup>. Speculatively, *UFM1* may be a marker of the secretory status of the gastric mucosa, similar to pepsinogen, and remains to be tested and validated.

Complete-type or type I intestinal metaplasia, considered as the benign version compared with the incomplete-type, was present in 18.2% of *H. pylori*-infected subjects. In these subjects, rs6878264 located in intron 4 of the *THBS4* gene, was the identified marker. THBS4 is a member of the THBS protein family, a glycoprotein in the extracellular matrix, which mediates cell-to-cell and cell-to-matrix interactions. Although the exact physiological functions of THBS4 are unknown, the published literature indicate that it promotes neurite outgrowth,

**Table 4** Single nucleotide polymorphisms associated with dysplasia among Malays with *Helicobacter pylori*

rs ID: The unique ID for the identified single nucleotide polymorphisms; HWE: Hardy-Weinberg Equilibrium.

stimulates proliferation of erythroid cells, skin fibroblasts and kidney epithelial cells, as well as myoblast adhesion and interaction with other extracellular matrix proteins<sup>[28-30]</sup>. Recently, *THBS4* has been found to be associated with gastric adenocarcinomas especially of the diffuse type<sup>[31]</sup>. While *H. pylori* infection is associated with atrophic gastritis and intestinal metaplasia, it is not commonly associated with diffuse-type gastric adenocarcinoma<sup>[32]</sup>. Complete-type intestinal metaplasia represents a reparative process of the epithelium following *H. pylori*-induced gastritis, and in this context, *THBS4* may act as an early proliferative marker but may have a more aggressive pro-oncogenic role in advanced stages. Again, this is speculative in the absence of any published studies, but it is a worthwhile marker for further studies.

Incomplete type intestinal metaplasia is more advanced compared with complete type, and therefore is more closely associated with dysplasia. In 22.7% of cases with both incomplete type intestinal metaplasia and dysplasia, rs1042194 located in exon 8 of *CYP2C19* gene was the identified marker. Cytochrome (CYP) P450 2C19, one of the isoforms of the CYP enzyme (phase I detoxification enzyme), plays an important role in metabolism of drugs and also detoxification of potential carcinogens<sup>[33]</sup>. Several studies indicated that *CYP2C19* gene polymorphism is associated with increased cancer susceptibility including hepatocellular carcinoma, and lung, esophageal and gastric cancer, especially in patients having a poor metabolizer (PM) genotype<sup>[34-36]</sup>. A study from Malaysia found that the PM genotype was uncommon among ethnic Malays (5.9%), compared with Chinese (19.1%) and Indians (10%)<sup>[37]</sup>. This may be one of the reasons for reduced susceptibility to gastric cancer and its precancerous lesions among ethnic Malays. The finding of *CYP2C19* in incomplete type intestinal metaplasia and dysplasia in a group of Malay subjects susceptible to *H. pylori* infection is therefore important and merits further study.

Dysplasia, a histological stage with high risk of malignant transformation, was present in only 9.1% or 2/23 subjects infected with *H. pylori*. Compared with controls, rs10505799 located in chromosome 12p12.3 (*MGST1* gene) was found to be the SNP marker associated with dysplasia. Microsomal glutathione S-transferase 1 (*MGST1*) is one of the glutathione S-transferase (GST) family of enzymes, and GSTs are phase II detoxification enzymes, which, similar to CYP enzymes, are involved in the detoxification of potential carcinogens<sup>[38,39]</sup>. Recently, *MGST1* gene polymorphism was found to be involved in

colorectal carcinogenesis in the Chinese population but there is no data as yet on gastric cancer<sup>[40]</sup>. However, since *MGST1* and *CYP2C19* are both carcinogen detoxification enzymes, with evidence supporting their involvement in gastrointestinal tract carcinogenesis, the role of *MGST1* in gastric precancerous lesions is likely to be valid. The limited number of cases with dysplasia in the current study means that the results need to be interpreted cautiously, but the potential of *MGST1* as a marker for dysplasia should not be disregarded.

There are a number of studies on gene polymorphisms associated with gastric precancerous lesions in high prevalence populations, but our study covered the entire spectrum of the Correa cascade in a population with an extremely low burden of gastric cancer and *H. pylori* infection. Development of gastric cancer is thought to involve multi-step carcinogenesis and follows a progressive pattern of pathological stages described by Correa. Our results indicated that, at different phases of the Correa cascade, different gene variants are manifest, but they follow a pattern of progression similar to their histological and clinical stages. During the stage of atrophic gastritis, *UFM1* expression reflects the secretory status of epithelium. With early development of intestinal metaplasia, *THBS4* acts as a proliferative marker but at more advanced stages, incomplete intestinal metaplasia and dysplasia involve polymorphisms of detoxification enzymes, *CYP2C19* and *MGST1*. Based on the current study, it is possible that, in addition to histological staging, gene variant markers may also serve to identify different phases of progression of gastric cancer in the near future. Recently, epigenetic silencing of *FOXD3* has been shown to be an early event in gastric carcinogenesis<sup>[41]</sup> and, together with genomic changes, it would allow a greater understanding of the pathogenesis of gastric cancer.

We acknowledge from the outset that the current study, based upon a genome-wide approach, was extremely limited in sample size, as gastric precancerous lesions are extremely rare among ethnic Malays from the north-eastern region of Peninsular Malaysia. In this respect, bioinformatics and statistical approaches were taken into consideration for a more reliable analysis of the data. To reduce false-positive results, a more stringent significance threshold of  $3 \times 10^{-7}$  was set for Manhattan plots in the current study. Only SNPs in HWE  $P$ -value  $> 0.5$  were selected to reduce occasionality. In addition to being long-term residents within the studied region, cases and controls were similar in age, socio-cultural and economic backgrounds. The current study only identified

SNPs associated with gastric precancerous lesions, and further validation studies are in progress to confirm their regulatory role in carcinogenesis.

In conclusion, we have shown that, compared with controls, susceptible ethnic Malays with *H. pylori* infection expressed different SNP markers at different spectrums of gastric precancerous lesions. These markers may allow efficient screening of precancerous lesions in larger cohorts of *H. pylori*-infected individuals.

## COMMENTS

### Background

Gastric cancer and its precancerous lesions are exceptionally rare among ethnic Malays. Gene variants may be associated with precancerous lesions in *Helicobacter pylori* (*H. pylori*)-susceptible Malays.

### Research frontiers

In a case-control study, genome-wide association was performed to identify gene variants in the Malay population with a spectrum of *H. pylori*-associated gastric precancerous lesions.

### Innovations and breakthroughs

Results indicated that at different phases of the Correa cascade, different gene variants were manifest, but they followed a pattern of progression similar to the histological and clinical stages.

### Applications

It is possible that, in addition to histological staging, gene variant markers may also serve to identify different phases of progression of gastric cancer in the near future.

### Terminology

The genome-wide approach utilises microarray technology to identify thousands of single nucleotide polymorphisms (SNPs). Using novel bioinformatics and statistical approaches, the association between SNPs and the studied disease can be determined reliably.

### Peer review

Current study indicates that different gene variants exist that reflect different stages of progression during different spectrums of gastric carcinogenesis. These gene variants, appropriately confirmed in later studies, may be useful markers, in addition to histological staging, of gastric precancerous lesions.

frequencies, variant allele C was associated with a significantly increased risk of CRC (OR = 1.375; 95%CI: 1.050-1.802;  $P = 0.020$ ). Moreover, the risk was markedly higher for those who were carriers of the Gln/Gln variant genotype and were also cigarette smokers (OR = 3.409; 95%CI: 1.061-10.949;  $P = 0.032$ ).

**CONCLUSION:** The XPC Gln/Gln genotype alone and in combination with smoking increases the risk of CRC among Malaysians.

Ahmad Aizat AA, Siti Nurfatimah MS, Aminudin MM, Ankathil R. XPC Lys939Gln polymorphism, smoking and risk of sporadic colorectal cancer among Malaysians. *World J Gastroenterol* 2013; 19(23): 3623-3628 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i23/3623.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i23.3623>

### Abstract

**AIM:** To investigate the risk association of xeroderma pigmentosum group C (XPC) Lys939Gln polymorphism alone and in combination with cigarette smoking on colorectal cancer (CRC) predisposition.

**METHODS:** Peripheral blood samples of 510 study subjects (255 CRC patients, 255 controls) were collected. DNA was extracted and genotyping was performed using polymerase chain reaction-restriction fragment length polymorphism. The association between polymorphic genotype and CRC predisposition was determined using the OR and 95%CI.

**RESULTS:** The frequency of the homozygous variant (Gln/Gln) genotype was significantly higher in cases compared with controls (16.0% vs 10.2%,  $P = 0.049$ ). The Gln/Gln genotype of XPC showed a significantly higher association with the risk of CRC (OR = 1.884; 95%CI: 1.082-3.277;  $P = 0.025$ ). In the case of allele

### INTRODUCTION

Colorectal cancer (CRC) is a major public health problem worldwide, being the third most common cancer and the fourth most common cancer causing death<sup>[1]</sup>. In Malaysia, CRC has become the most common cancer among males and the second most common among females<sup>[2]</sup>. The development of CRC is a complex, multistep process involving interaction between environmental and genetic factors. Environmental factors such as dietary and lifestyle habits, smoking, alcohol consumption, and obesity interact with host's genetic factors, especially genetic variations, and may modulate the risk of CRC<sup>[3]</sup>. Genetic variations, such as single nucleotide polymorphisms (SNPs), may increase the sensitivity to environmental

carcinogens and may act as cancer predisposition factors. Environmentally sensitive genetic polymorphisms acting together with environmental factors are well documented candidates influencing cancer susceptibility.

DNA damage repair genes maintain the integrity of the genome against endogenous and exogenous factors. The xeroderma pigmentosum group C (*XPC*) gene is a DNA repair gene involved in the nucleotide excision repair (NER) mechanism which repairs bulky DNA lesions such as pyrimidine dimers, ultraviolet light-induced damage, photoproducts, intrastrand crosslinks, larger chemical adducts and other genotoxic agents<sup>[4]</sup>. Genetic variations in the *XPC* gene have been reported to modulate an individual's susceptibility to developing cancer<sup>[5,6]</sup>. The *XPC* Lys939Gln polymorphism, which leads to an amino acid change from lysine to glutamine at codon 939, is the most common SNP studied in the *XPC* gene and has been shown to be associated with increased risk of several cancers such as skin<sup>[7]</sup>, breast<sup>[8]</sup> and bladder cancers<sup>[9,10]</sup>.

However, there are only limited reports on the association of this polymorphism with CRC susceptibility. A case-control study was undertaken in order to investigate the association of this polymorphism alone and also in conjunction with cigarette smoking on the risk of CRC. This polymorphism is believed to alter the gene expression and modulate the DNA repair function of the protein product, as it is located at the coding sequence of the *XPC* gene. Thus, we hypothesized that *XPC* Lys939Gln polymorphism may have an effect on modulating the susceptibility to CRC, and cigarette smoking may further enhance the effect on CRC risk.

## MATERIALS AND METHODS

### Study subjects

The study was approved by the Research Review Board and Ethics Committee of Universiti Sains Malaysia, Kelantan and the Ministry of Health, Malaysia. For this hospital-based case control study, subjects were recruited from various hospitals in Malaysia, including Hospital Universiti Sains Malaysia, Hospital Raja Perempuan Zainab II and Hospital Sultanah Bahiyah, Kedah, Malaysia. Genotyping was carried out at the Human Genome Center, Universiti Sains Malaysia. Two hundred and fifty five sporadic CRC patients and 255 healthy normal controls were recruited as study subjects. Cases were histopathologically confirmed sporadic CRC patients, aged > 25 years, who did not have previous colon/rectal or other cancers. Cases with known (as indicated in the pathology reports) familial adenomatous polyposis, ulcerative colitis or Crohn's disease or any other previous malignancy were excluded. Controls were normal healthy individuals who were biologically unrelated to the study patients, aged > 25 years and had no history of cancer. Epidemiological data was collected from patients using a pre-structured questionnaire, which included sociodemographic status, physical status, dietary factors, occupation, tobacco/alcohol habits, previous illness, radiation exposure, *etc.*

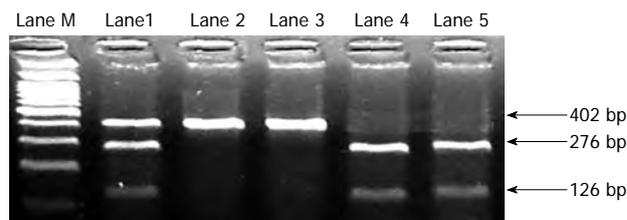

Figure 1 Gel picture showing the different categories of xeroderma pigmentosum group C Lys939Gln polymorphism genotype. Lane M: 100 bp DNA ladder; Lanes 2 and 3: Homozygous wildtype; Lane 1: Heterozygous; Lanes 4 and 5: Homozygous variant.

### Genotyping

Genotyping of *XPC* Lys939Gln polymorphism was carried out using polymerase chain reaction (PCR)-restriction fragment length polymorphism. Briefly, PCR primers for *XPC* Lys939Gln (F: 5'-GGCTTCCTGGTATCTGAT-TACT-3'R: 5'-CTCAGTTTGCCTTCTCAGCA-3') were used to generate a 402 bp product containing the polymorphic site. The PCR reactions were carried out in a 25  $\mu$ L volume of 1  $\times$  PCR Buffer, 2.0 mmol/L of MgCl<sub>2</sub>, 0.5 mmol/L dNTPs, 0.4 mmol/L of each primers and 1 U of AmpliTaq Gold Polymerase with a denaturation of 94  $^{\circ}$ C for 5 min, followed by 35 cycles at 94  $^{\circ}$ C for 30 s, 57  $^{\circ}$ C for 30 s, 72  $^{\circ}$ C for 30 s and finally 5 min at 72  $^{\circ}$ C. Following amplification, the PCR products were digested using *PvuII* restriction enzyme for 1 h at 37  $^{\circ}$ C and electrophoresed on 2% agarose gel. The homozygous wild-type genotype was identified by a single band at 402 bp level, the heterozygous genotype by 3 bands at 402, 276 and 126 bp levels and the homozygous variant by 2 bands at 276 and 126 bp levels (Figure 1).

### Statistical analysis

The sample size was calculated with power and sample size (PS) software version 2.1.31 using the uncorrected  $\chi^2$  test with 80% power and 95%CI. The difference in distribution of genotypes, gender and age between cases and controls were assessed using the  $\chi^2$  test. The ORs and 95%CI were calculated using binary logistic regression to evaluate the risk association. All statistical tests were two-sided, and statistical significance was determined as  $P < 0.05$ . SPSS v.18 (SPSS Inc., Chicago, IL, United States) was utilized for statistical analysis.

## RESULTS

The demographic characteristics of the study subjects are shown in Table 1. This case-control study recruited 510 study subjects, including 255 histopathologically confirmed sporadic CRC patients and 255 healthy normal controls. Of the 255 CRC patients, 139 (54.5%) were male and 116 (45.5%) were female. Of the 255 normal controls, 115 (45.1%) were male and 140 (54.9%) were female. The ages of the sporadic CRC patients ranged from 27 to 93 years (mean age: 53.17  $\pm$  7.07 years) and of the healthy normal controls ranged from 26 to 84

years (mean age: 46.47 ± 12.02 years).

The frequencies of the homozygous wildtype (Lys/Lys), heterozygous (Lys/Gln) and homozygous variant (Gln/Gln) genotypes were 108 (42.4%), 106 (41.6%) and 41 (16.0%), respectively, among CRC cases. In controls, the frequencies were 129 (50.6%) for homozygous wildtype, 100 (39.2%) for heterozygous and 26 (10.2%) for homozygous variant genotypes. The frequency of the homozygous variant (CC) genotype was significantly higher in cases compared with the controls (*P* = 0.049). Table 2 shows the genotype and allele frequencies of *XPC* Lys939Gln polymorphism in cases and controls.

Binary logistic regression analysis was performed in order to find the risk association. Table 3 shows the association between the *XPC* Lys939Gln polymorphism and risk of CRC. It can be clearly seen that the homozygous variant genotype was significantly associated with increased risk of CRC (OR = 1.884; 95%CI: 1.082-3.277; *P* = 0.025). The variant allele C was found to be significantly associated with increased risk of CRC (OR = 1.375; 95%CI: 1.050-1.802; *P* = 0.020). Furthermore, the study subjects were stratified into smokers and non-smokers and the risk association was evaluated. Results showed that, for those with the homozygous variant genotype (CC) and who were smokers, the risk was significantly increased (OR = 3.409; 95%CI: 1.061-10.949; *P* = 0.032). In the non-smoking group, no significant association was observed between the *XPC* Lys939Gln polymorphism and the risk of CRC.

## DISCUSSION

To date, a variety of chemical carcinogens have been identified to cause DNA damage in humans. DNA damage repair genes are responsible for maintaining the integrity of the human genome through different pathways, locations and types of damage by base excision repair, NER, double strand break and mismatch repair pathways<sup>[4]</sup>. Genes involved in the NER pathway, such as *XPC*, commonly repair lesions induced by numerous exogenous agents such as those derived from food and smoking, including 2-amino-1-methyl-6-phenylimidazo-[4,5-β]-pyridine and benzo-[α]-pyrenediol-epoxide<sup>[11]</sup>.

The *XPC* gene, located on chromosome 3p25, contains 16 exons and 15 introns and encodes a 940 amino acid protein<sup>[12]</sup>. Several polymorphic variants in the *XPC* gene have been identified and *XPC* Lys939Gln is one of the three most common SNPs. This case-control study investigated the genotype and allele frequencies of the *XPC* Lys939Gln polymorphism, and the risk association with sporadic CRC susceptibility. Results from the present study showed that the frequency of the *XPC* homozygous variant genotype was significantly higher in cases compared with controls (16.0% *vs* 10.2%, *P* = 0.049). On evaluation of the risk association, the homozygous variant genotype (CC) was associated with significantly increased risk of CRC (OR = 3.409; *P* = 0.032). This result conforms with a study by Yasuda *et al*<sup>[13]</sup>, which demonstrated that a single amino acid alteration could be sufficient to compromise *XPC* function, thereby enhancing the risk of CRC development. Our results are in agreement with a few other reports by Qiu *et al*<sup>[5]</sup>, Zhang *et al*<sup>[6]</sup> and Gil *et al*<sup>[14]</sup> which revealed that *XPC* is one of the most important genes modulating an individual's risk of developing sporadic cancer.

Carcinogens consumed through dietary and lifestyle habits as well as from the environment play a major role

in damaging DNA. Cigarette smoking is one of the life-style factors that play an important role in the exposure of an individual to the carcinogens present in cigarette smoke. Carcinogens contained in tobacco smoke, such as polycyclic aromatic hydrocarbons, heterocyclic amines, nitrosamines and aromatic amines, are harmful to the human colon and rectum. Cigarette smoking has been reported to lead to the formation of DNA adducts and cause damage to the DNA in the human colon<sup>[15,16]</sup>. All these carcinogens can reach the colorectal mucosa, through direct ingestion or via the circulatory system, and has been demonstrated to induce bulky adducts in crypt cells and contribute to the formation of mutations in the colon<sup>[17,18]</sup>. In the present study, a combination of smoking and a variant genotype of *XPC* enhanced the risk of CRC 3-fold, indicating that smoking further enhanced the risk of CRC. Although non-smokers showed an OR of 1.256, this was not statistically significant.

The *XPC* gene encodes an important protein involved in the recognition of DNA damage in the NER pathway. This protein binds to HR23B protein to form XPC-HR23B that recognizes a DNA lesion and repairs the DNA damage along with other DNA repair proteins<sup>[19,20]</sup>. Polymorphism in the coding sequence of the *XPC* gene has been demonstrated to alter the gene expression and thereby modulate the DNA repair function<sup>[21]</sup>. The *XPC* Lys939Gln polymorphism is located in the coding sequence of the *XPC* gene. The nucleotide change from A to C leads to an amino acid change from lysine to glutamine in the coding sequence of the *XPC* gene and has been reported to lead to reduced repair capacity. This genetic variation has also been reported to result in reduced specificity of this gene in recognition and repair of the DNA damage as well as in protein expression, thus allowing more somatic DNA mutations or alterations to occur<sup>[21,22]</sup>.

The XPC protein plays a crucial role in repairing the DNA damage caused by tobacco smoke. Individuals with the *XPC* variant genotype may possess deficient DNA repair capability. Accordingly, the XPC protein product may be less efficient in repairing the DNA lesions induced by tobacco smoke, and thereby could enhance the susceptibility, favoring the development of CRC.

Previous studies focusing on the role of the *XPC* variant in the modulation of an individual's risk of developing CRC are scarce, and reported results are inconsistent. Berndt *et al.*<sup>[22]</sup>, in an American population, found an OR of 1.19 for the variant genotype's association with risk of CRC, but the result was statistically insignificant ( $P = 0.50$ ). In contrast, a study conducted by Hansen *et al.*<sup>[23]</sup>, in a Polish population, observed no significant risk association between this polymorphism and CRC susceptibility. However, when the variant genotype in conjunction with red meat consumption was evaluated, the risk was reported to be significantly higher (OR = 3.7) in those who carried the homozygous variant (CC) genotype and consumed 100 g red meat per day.

A recent study by Wu *et al.*<sup>[24]</sup> on 421 CRC patients and

845 controls, showed that the homozygous variant (CC) genotype was significantly associated with higher risk of CRC in a Chinese population (OR = 1.5; 95%CI: 1.0-2.2;  $P = 0.035$ ). Moreover, combination (AC + CC) genotypes in the homozygous wildtype model also showed a significant association with risk of CRC (OR = 1.3; 95%CI: 1.0-1.7;  $P = 0.039$ ). When the study subjects were stratified into tea drinkers and non-tea drinkers, the results showed that individuals who were non-tea drinkers and carried combination (AC + CC) genotypes, had increased risk of CRC (OR = 3.0; 95%CI: 1.9-4.7;  $P < 0.001$ ).

Apart from CRC, *XPC* polymorphism was reported to be associated with the risk of other cancers, such as head and neck<sup>[25]</sup>, lung<sup>[10]</sup>, breast<sup>[8]</sup> and bladder<sup>[26]</sup>. In addition, abnormal expression of the *XPC* gene has been shown in hepatocarcinogenesis<sup>[27]</sup>. The variant allele of the *XPC* gene is associated with lower DNA repair capacity (DRC). Several studies showed that the Lys939Gln polymorphism had an interaction with other SNPs located in the same gene, such as Ala499Val, PAT (-/+ ) and IVS11 C/A polymorphisms. According to Khan *et al.*<sup>[28]</sup>, the *XPC* Lys939Gln polymorphism is in linkage disequilibrium with the *XPC* PAT polymorphism as well as the C/A polymorphism at 25 positions of intron 11 of *XPC*. This causes exon 12 to be skipped and deleted, resulting in the loss of *XPC* cDNA function, thus reducing the DNA repair activity.

Researchers have shown that carriers of the C variant allele of the *XPC* Lys939Gln polymorphism exhibited significantly more DNA damage induced by BPDE<sup>[21,29,30]</sup>. Moreover, combinations of haplotype C + C (Lys939Gln, PAT +, Ala499Val) have been reported to cause poor DRC, thus increasing the risk of CRC. In contrast, haplotype T-A (Ala499Val-PAT-Lys939Gln) has been demonstrated to be associated with the least DNA damage<sup>[21,24]</sup>. Also, another study has shown that accumulation or the presence of alleles in the *XPC* gene associated with increased risk might reduce DRC and thus increase CRC susceptibility<sup>[31]</sup>.

The difference in results on the risk association between the present study and other previous studies might be explained by differences in genetic background of study subjects groups or populations, and also differences in exposure to environmental and lifestyle factors. Small sample sizes and/or inadequate control for certain confounder factors such as gender and age might also have contributed to the differing results and lack of association.

From the present study, it is reasonable to suggest that the *XPC* gene, especially the *XPC* variant genotype, may modulate the DRC of the host cell and thus play an important role in sporadic colorectal carcinogenesis. The risk could be much higher in individuals who possess the variant genotype and who are also cigarette smokers. The results also highlight the potential role of the NER pathway (especially of *XPC*) in modulation of an individual's risk of sporadic CRC. Further studies to explore the interaction of *XPC* Lys939Gln with other SNPs of

the XPC gene and with other genes involved in DNA repair pathways, either singly or in combination, and to examine the correlation with environmental factors such as alcohol consumption and dietary habits, as well as clinicopathological characteristics, would be beneficial in deriving more accurate risk predictive markers.

## ACKNOWLEDGMENTS

We would like to thank Dr. Muhammad Radzi Abu Hassan (Hospital Sultanah Bahiyah, Kedah), Prof Dr. BM Biswal, Dr. VMK Bhavaraju (Hospital Universiti Sains Malaysia), Dr. Ahmad Shanwani and Dr. Zaidi Zakaria (Hospital Raja Perempuan Zainab II, Kota Bharu) for their cooperation in patient recruitment.

## COMMENTS

### Background

Colorectal cancer (CRC) which is the most common cancer among males and the second most common among females in Malaysia, has become a major public problem. Environmental factors, such as dietary carcinogens and tobacco smoke, interacting with the host's genetic factors may modulate the risk of CRC. However, the genetic predisposition factors associated with colorectal carcinogenesis remain largely undetermined. Identification of the host's genetic predisposition factors may help in understanding the carcinogenic process. Thus, it was of interest to explore the contribution of single nucleotide polymorphisms (SNPs) in a DNA repair gene, alone and in combination with tobacco smoke, as a predisposition factor for CRC susceptibility.

### Research frontiers

Exposure to mutagens and carcinogens through diet, tobacco smoke, etc can cause varying degrees of DNA damage and can cause mutations in humans if left unrepaired. The xeroderma pigmentosum group C (XPC) gene is a DNA repair gene involved in the nucleotide excision repair (NER) pathway. The SNP, Lys939Gln, located at the coding region of the XPC gene has been associated with lower DNA repair capacity and has been shown to be associated with increased risk of cancers of the skin, breast and bladder. This study was designed to determine the frequencies and influence of the XPC Lys939Gln polymorphic genotype, alone and in combination with smoking, on sporadic CRC susceptibility risk in a Malaysian population.

### Innovations and breakthroughs

Only limited reports are available on the association of XPC Lys939Gln polymorphism with CRC susceptibility risk. To the best of our knowledge, this is the first report of an association between the genetic variant of XPC with CRC susceptibility risk in the Malaysian population. The observation that genetic variation of the XPC gene influences susceptibility to CRC implies the importance of the NER pathway in modulation of an individual's risk of CRC. This study provides support for the hypothesis that genetic variation in the XPC gene, acting together with environmental factors, contributes to CRC development and may be considered as a candidate marker for CRC predisposition risk in the Malaysian population.

### Applications

The present study observed that the genetic variation Lys939Gln of the XPC gene influences the risk of CRC in the Malaysian population. Further SNP mapping studies utilizing high throughput genotyping methods could facilitate the analysis of multiple polymorphisms within DNA repair genes. Genotyping of Malaysian CRC patients for polymorphism(s) in DNA repair genes will help in understanding the specific polymorphism(s), which act as predisposing genotype(s) in CRC susceptibility. In future, the study can be extended to a population level, to identify individuals with high risk predisposition genotypes. Appropriate surveillance programs could then be developed in order to reduce the morbidity and mortality of CRC at the population level.

### Peer review

This case-control study investigated the association between SNPs and cigarette smoking on sporadic CRC susceptibility risk in Malaysian population. The

genotype and allele frequencies of XPC Lys939Gln were investigated in 255 CRC patients and 255 healthy controls. Homozygous variant (CC) genotype frequency was found to be significantly higher in CRC cases compared to controls. When the risk association was evaluated singly, the homozygous variant XPC CC genotype was associated with an increased risk of CRC susceptibility. Moreover, when the risk was evaluated after stratifying the study subjects into smokers and non-smokers, the combination of smoking habits and variant genotype of XPC was found to enhance the CRC susceptibility risk to 3-fold times higher. These results prompt us to suggest that genetic variation Lys939Gln in XPC gene might modify the effect of smoking and contribute to sporadic colorectal cancer etiology.

### Abstract

**AIM:** To study the clinical and laboratory characteristics of autoimmune hepatitis (AIH), and compare them with International Autoimmune Hepatitis Group (IAHG) criteria.

**METHODS:** Sixty consecutive patients with AIH attended the University Clinic at Tabriz University of Medical Sciences, Iran for a 12 mo period and were assessed in a case series study. Serological and biochemical evaluations were carried out in all patients. Autoantibodies, such as antinuclear antibody (ANA), anti-smooth muscle antibody (ASMA), anti-liver-kidney microsomal antibody (ALKM-1) type 1, and perinuclear anti-neutrophil cytoplasmic antibodies (P-ANCA) were evaluated in these patients. A liver biopsy was performed after diagnosis of the disease. Patients were evaluated in terms of their signs and symptoms, and laboratory results and the degree to which they corresponded with the diagnostic criteria of IAHG. In this study, both a comprehensive diagnostic scoring system and a simplified diagnostic scoring system were employed for AIH.

**RESULTS:** Sixty patients, 20 male, 40 female, mean age  $39.45 \pm 17.50$  years, participated in the study. Treatment began immediately after enrolment into the study. The percent distribution of the study population into definite and probable did not change after the treatment. The most common symptoms in descending order were fatigue (100%), icter (66.7%), abdominal discomfort (33.3%), abdominal distension (28.3%), dark urine (23.3%), edema (23.3%), hematemesis (20.0%), pruritus (20.0%), melena (11.7%) and pale stool (10.0%). At the physical examination, splenomegaly, ascites, hepatomegaly, epigastric tenderness and an abdominal mass were found in 50.0%, 16.7%, 13.3%, 5.0% and 3.3% of patients, respectively. Hypergammaglobulinemia was detected in 95.0% of cases. ALKM-1, P-ANCA, ANA and ASMA were positive in 71.4%, 66.7%, 42.4% and 19.4% of cases, respectively. Portal hypertensive gastropathy (45.0%), esophageal varices (41.7%) and cirrhosis (40.0%) were the most prevalent complications of AIH, and there was no evidence of primary sclerosing cholangitis, ulcerative colitis and overlap syndrome in these patients. According to IAHG criteria, 80.0% of cases had a definite diagnosis, 15.0% had a probable diagnosis and 5.0% had no AIH. The percent distribution of the study population into definite, probable and no AIH did not change after using the simplified diagnostic scoring system for AIH.

**CONCLUSION:** This research showed that the majority of cases in our study were appropriately diagnosed according to the IAHG criteria and simplified scoring system. Thus, these criteria are very useful.

## INTRODUCTION

Autoimmune hepatitis (AIH) is a chronic inflammation of the liver, the cause of which is unknown. It is characterized by the presence of interface hepatitis on histological examination, hypergammaglobulinemia, and autoantibodies<sup>[1]</sup>. Autoimmune hepatitis occurs predominantly in women and affects all ages<sup>[2]</sup>. Autoimmune hepatitis afflicts 100000 to 200000 persons in the United States<sup>[3]</sup>, and accounts for 2.6% of transplant recipients in Europe<sup>[4]</sup> and 5.9% in the United States<sup>[5]</sup>. Among Northern European Caucasians, the mean annual incidence of AIH is 1.9 per 100000 population, and its point prevalence is 16.9 per 100000 population<sup>[6]</sup>. Three types of AIH have been proposed based on immunoserologic markers<sup>[7]</sup>. The International Autoimmune Hepatitis Group (IAHG) devised and subsequently revised scoring systems to aid in the diagnosis of AIH<sup>[8,9]</sup>. The revised 1999 criteria evaluated up to 12 patient variables to derive a score which identified individuals as “not AIH”, “probable AIH” or “definite AIH”<sup>[8]</sup>. Despite a high degree of sensitivity and specificity, these criteria have proven cumbersome in day-to-day clinical practice. Subsequently, the IAHG published simplified diagnostic criteria, evaluating just four parameters<sup>[10]</sup>. This study was designed to determine a standard and reliable method for early diagnosis and close follow-up by using the IAHG simplified diagnostic criteria and comparing clinical and laboratory characteristics in Iranian AIH patients.

## MATERIALS AND METHODS

All patients who had been diagnosed with autoimmune hepatitis and had been referred to the outpatient clinic of Tabriz University of Medical Sciences from 2010 to 2011 were evaluated for clinical and laboratory parameters and compared with the diagnostic criteria of IAHG. Patient evaluation started by recording their medical history, and performing a physical examination and complete blood count. Serological and biochemical evaluation included aspartate aminotransferase, alanine aminotransferase, alkaline phosphatase, serum  $\gamma$ -globulin, serum albumin, total and direct bilirubin, erythrocyte sedimentation rate, prothrombin time, serum creatinine, triglyceride, total cholesterol and fasting blood sugar. The researchers also evaluated the autoantibodies such as antinuclear antibody (ANA), anti-smooth muscle antibody (ASMA), anti-liver-kidney microsomal antibody (ALKM-1) type 1 and perinuclear anti-neutrophil cytoplasmic antibodies (P-ANCA) by indirect immunofluorescence. A titer of  $\geq 1:40$  was considered to be positive. Chronic viral hepatitis, Wilson's disease and hemochromatosis were also assessed using

hepatitis B core antibody, hepatitis B surface antibody, hepatitis C antibody, serum ceruloplasmin, urine copper, serum iron and total iron-binding capacity. Hepatitis B surface antigen was detected by enzyme-linked immunosorbent assay (Stat Fax Awareness Technology Inc., Palm City, FL, United States) and hepatitis C virus (HCV) antibody was analyzed using a third generation enzyme linked immunosorbent assay test (Ortho-Clinical Diagnostics, Amersham, United Kingdom).

A percutaneous liver biopsy was taken from all patients for histology after diagnosis of the disease. Specimens were fixed in 10% formalin, embedded in paraffin, and stained with hematoxylin and eosin, Masson's trichrome, and reticulin. All specimens were evaluated by a single pathologist. Liver biopsies were adequate if there were at least 6 portal tracts per high-power field. A modified Hepatitis Activity Index was used to score specimens, in which necroinflammation was graded from 0 to 18 and fibrosis from 0 to 6<sup>[11]</sup>.

An abdominal ultrasound examination was performed in all patients, and liver size and echogenicity, splenomegaly, gallstones and ascites were assessed. The exclusion criteria were having viral (hepatitis B and C), metabolic (Wilson's disease, hemochromatosis), or drug-induced liver disease or overlap syndrome. Continuous variables are expressed as mean  $\pm$  SD. Statistical analysis was carried out using SPSS, version 16.0 (SPSS Inc., Chicago, IL, United States). The study protocol was approved by the Ethics Committee of the Liver and Gastrointestinal Diseases Research Center of Tabriz University of Medical Sciences, and informed consent was procured from all patients before enrolment in the study.

## RESULTS

Sixty patients with AIH were evaluated, of whom 40 (66.7%) were female. The mean age was  $39.45 \pm 17.50$  years (range, 19-75 years). Twelve patients had a familial history of liver disease (20.0%) and 8 patients had a familial history of AIH (13.3%). Four patients (6.7%) were diagnosed with other simultaneous autoimmune diseases. None of the patients had a history of hepatotoxic drug use. Patient characteristics are described in Table 1.

The most common symptoms in descending order were fatigue (100%), icterus (66.7%), abdominal discomfort (33.3%), abdominal distension (28.3%), dark urine (23.3%), edema (23.3%), hematemesis (20.0%), pruritus (20.0%), melena (11.7%) and pale stools (10.0%). At the time of physical examination, splenomegaly, ascites, hepatomegaly, epigastric tenderness and abdominal mass were found in 50.0%, 16.7%, 13.3%, 5.0% and 3.3% of the patients, respectively. Portal hypertensive gastropathy (45.0%), esophageal varices (41.7%) and hepatic cirrhosis (40.0%) were the most common complications in the patients.

The proportion of patients seropositive for ALKM1, P-ANCA, ANA and ASMA patients was 71.4%, 66.7%,

**Table 1 Characteristics of patients with autoimmune hepatitis**

| Parameter                    | n (%)     |
|------------------------------|-----------|
| Female                       | 40 (66.7) |
| Male                         | 20 (33.3) |
| Single                       | 22 (36.7) |
| Married                      | 38 (63.3) |
| Educated                     | 46 (76.7) |
| Uneducated                   | 14 (23.3) |
| Alcohol intake               | 3 (5)     |
| Smoking                      | 11 (18.3) |
| History of blood transfusion | 17 (28.3) |
| History of hospitalization   | 48 (80)   |

**Table 2 Serological, biochemical and histologic findings in patients with autoimmune hepatitis**

| Parameter                                    | Result          | Range     |
|--|-----------------|-----------|
| AST, IU/L                                    | 127.8 ± 108.6   | 17-812    |
| ALT, IU/L                                    | 146.0 ± 98.4    | 14-916    |
| Total bilirubin, mg/dL                       | 2.7 ± 2.2       | 0.5-8.6   |
| Direct bilirubin, mg/dL                      | 1.3 ± 1.2       | 0.05-4.3  |
| Alkaline phosphatase, IU/L                   | 499.9 ± 386.2   | 71-997    |
| White blood cell, No./mm <sup>3</sup>        | 6052.4 ± 2461.5 | 800-13500 |
| Hemoglobin, g/dL                             | 12.1 ± 3.0      | 7-17      |
| ESR  | 40.0 ± 28.7     | 3-95      |
| Platelet count (× 1000), No./mm <sup>3</sup> | 139.2 ± 91.4    | 36.4-464  |
| Prothrombin time                             | 15.8 ± 3.3      | 12.5-31   |
| Creatinine, mg/dL                            | 0.8 ± 0.3       | 0.5-2.1   |
| FBS, mg/dL                                   | 106.9 ± 48.6    | 68-302    |
| Triglyceride, mg/dL                          | 163.2 ± 109.5   | 50-506    |
| Total cholesterol, mg/dL                     | 208.1 ± 106.3   | 47-472    |
| Albumin, g/dL                                | 3.8 ± 0.7       | 2.1-5.1   |
| Grade  | 5.5 ± 2.7       |           |
| Stage  | 3.2 ± 1.5       |           |

All values are mean ± SD. ALT: Alanine aminotransferase; AST: Aspartate aminotransferase; ESR: Erythrocyte sedimentation rate; FBS: Fasting blood sugar.

42.4% and 19.4% respectively. Simultaneous seropositivity for ASMA/ANA occurred in 6.7%, ANA/P-ANCA in 6.7%, ANA/ALKM1 in 5.0%, and ALKM1/ASMA and/or ANA in 3.3%. Hepatitis C virus antibody was assessed in all patients, and all were negative. There was no evidence of primary sclerosing cholangitis, ulcerative colitis or overlap syndrome in these patients.

Liver biopsy and histological assays were performed in all the patients, and all had interface hepatitis. Forty-five cases of pathology reports were descriptive and the rest showed autoimmune hepatitis. The researchers found portal fibrotic expansion (stage 1-2) in 15 patients (33.3%), bridging fibrosis (stage 3-4) in 17 patients (37.8%) and cirrhosis (stage 5-6) in 13 patients (28.8%).

Blood proteins (electrophoresis analysis) were assessed in patients whose mean level of α1 protein was 3.0 ± 1.6 g/dL (0-7.1 g/dL). The mean level of α2 protein was 10.0 ± 3.2 g/dL (0.3-16.6 g/dL). The mean level of β protein was 11.4 ± 4.4 g/dL (0.5-17.0 g/dL). The mean level of γ protein was 25.8 ± 11.4 g/dL (3.7-44.1 g/dL). Hypoalbuminemia was found in 20 (33.3%) patients. Further serological and biochemical data are shown in Table 2.

**Table 3 Autoimmune hepatitis diagnosis using simplified score and revised International Autoimmune Hepatitis Group criteria**

| AIH score      | Probable AIH | Definite AIH | No AIH    |
|----------------|--------------|--------------|-----------|
| Revised IAHG   |              |              |           |
| Pre-treatment  | 17.7 ± 1.7   | 12.8 ± 1.4   | 7.7 ± 1.5 |
| Post-treatment | 19.7 ± 1.4   | 14.8 ± 1.4   | 9.7 ± 1.5 |
| Simplified     | 7.5 ± 0.5    | 5.6 ± 0.5    | 3.3 ± 0.6 |

Data are mean scores ± SD. AIH: Autoimmune hepatitis; IAHG: International Autoimmune Hepatitis Group.

Liver and bile duct ultrasonic imaging was performed in all patients and increased echogenicity in liver was found in 36 (60.0%). Splenomegaly was found in 32 patients (53.3%). Increased liver size (hepatomegaly) was found in 12 patients (20.0%), decreased liver size in 20 (33.3%) and normal liver size in 28 (46.7%). A gallstone was found in 11 patients (18.3%) a dilated bile duct in 9 (15.0%), and ascites in 13 (21.7%).

There was a good outcome during the 1-year follow-up in 58 patients (96.7%), one patient (1.7%) had no response to treatment and one patient with complications died while the research was being conducted. The 1-year mortality rate was 1.7%.

According to the revised IAHG criteria, 80.0% of cases had a definite diagnosis of AIH, 15.0% of cases had a probable diagnosis and 5.0% of cases had no AIH. Using the simplified diagnostic scoring system for AIH, the percent distribution of the study population into definite, probable and no AIH did not change. The mean scores and standard deviations for both the revised IAHG and simplified scoring criteria are presented in Table 3.

## DISCUSSION

The researchers surveyed 60 patients with AIH. The most common symptoms were fatigue, icterus, abdominal discomfort, abdominal distension, dark urine, edema, hematemesis, pruritus, melena and pale stools. At the physical examination, splenomegaly, ascites, hepatomegaly, epigastric tenderness and abdominal mass were discerned in 50.0%, 16.7%, 13.3%, 5.0% and 3.3% of the patients, respectively.

Koay *et al*<sup>121</sup> had performed a similar study in Taiwan, and the most common clinical findings of AIH were fatigue, icterus and loss of appetite. Another study conducted by Choudhuri *et al*<sup>131</sup> in India reported icterus (55.2%), edema (44.7%), fatigue (44.7%), encephalopathy (23.6%), pruritus (23.6%), abdominal pain (23.6%), fever (21.0%), arthritis (18.4%), hepatomegaly (44.7%), splenomegaly (34.2%) and ascites (34.2%) in their clinical findings. In a study by Gupta *et al*<sup>141</sup> in India (2001), the most common manifestations were fatigue, icterus and loss of appetite.

Variable findings can be seen in the studies reported above. Nevertheless, there is a similarity between the

general findings of the present study and those studies. The characteristic laboratory findings in the patients in the present study were an increase in bilirubin and abnormalities in liver enzyme levels. The pathologic found interface hepatitis in all patients, and 71.4%, 66.7%, 42.4% and 19.4% seropositivity for ALKM1, P-ANCA, ANA and ASMA, respectively.

Koay *et al.*<sup>[12]</sup> reported abnormalities in liver tests and increased bilirubin. Patients were 98.0% positive for ANA. Zhao *et al.*<sup>[15]</sup> in China reported interface hepatitis in all their AIH cases. In a study by Choudhuri *et al.*<sup>[13]</sup>, reported positivity for ANA in 39.4%, ASMA in 63.1% and P-ANCA in 2.6%. Johnson *et al.*<sup>[9]</sup> reported ANA or ASMA in 70.0%-80.0% and ALKM1 in 3.0%-4.0%. In a study by Nezu *et al.*<sup>[16]</sup> in Japan, 34.0% of patients were positive for ANA. In another study in Japan by Omagari *et al.*<sup>[17]</sup>, 34.0% of patients were positive for ANA. In another study by Terjung *et al.*<sup>[18]</sup> in 175 patients, 81.0% were positive for P-ANCA. Pavić *et al.*<sup>[19]</sup> in Serbia had reported ANA seropositivity in 15.0%-60.0%, ASMA in 34.0%-60.0% and ALKM1 in 0-6.0%. In a study by Adams *et al.*<sup>[20]</sup> in the United States, 20.0% of patients were positive for ANA and 3.0% for ASMA.

In summary, the range of antibody positivity in the above-mentioned studies were: ANA 15.0%-98.0%, ASMA 3.0%-80.0%, ALKM1 0%-6.0% and P-ANCA 2.6%-81.0%. The ranges in the present study are mostly in the reported ranges. Although technical differences in measurement of antibodies in different centers can produce some variability in the results, these wide differences may be a sign of racial differences in patients with AIH. This issue requires more controlled studies. Also, the present study had a small sample of patients and larger studies are required in future to examine the applicability of antibody measurements.

In the present study, 95.0% of patients were diagnosed using the diagnostic criteria of the IAHG. Several studies which had been conducted around the world that insisted on using these criteria, including Heurgué *et al.*<sup>[21]</sup> in Italy, Koay *et al.*<sup>[12]</sup> in Taiwan (China), Lee *et al.*<sup>[22]</sup> in Southern Korea, Michalska *et al.*<sup>[23]</sup> in Poland, Primo *et al.*<sup>[24]</sup> in Spain, Zhao *et al.*<sup>[15]</sup> in China, McFarlane *et al.*<sup>[25]</sup> in England and Yatsuji *et al.*<sup>[26]</sup> in Japan.

In conclusion, this research showed that the majority of cases in the present study were diagnosed according to the criteria of IAHG and the simplified scoring system. There were some deficiencies in the assessment of autoantibodies; therefore, recommendations are made for controlled studies to diagnose the probable causes of these deficiencies. The results of this study conform with reports in the literature. Further studies should be carried out in similar centers.

## COMMENTS

### Background

Autoimmune hepatitis (AIH) is an unresolving inflammation of liver, the cause of which is unknown. It is characterized by the presence of interface hepatitis on histological examination, hypergammaglobulinemia, and autoantibodies.

### Research frontiers

Despite a high degree of sensitivity and specificity, the diagnostic criteria have proven cumbersome in day-to-day clinical practice. Subsequently, the International Autoimmune Hepatitis Group (IAHG) have published simplified diagnostic criteria, evaluating just four parameters.

### Innovations and breakthroughs

This study was designed to determine a standard and reliable method for early diagnosis and close follow-up by using IAHG criteria and simplified diagnostic criteria and comparing clinical and laboratory characteristics in Iranian patients.

### Applications

This research showed that the majority of cases in the present study were diagnosed according to the criteria of IAHG and simplified scoring system. There were some deficiencies in autoantibodies assessment; therefore, recommendations are made for controlled studies to diagnose the probable causes of these deficiencies.

### Peer review

The authors collected data for one of the largest AIH cohort in the Middle East and compared laboratory and histologic findings with the international AIH Score. Using the score they found a definite AIH in 80% of their patients and a probable AIH in 15%. So the authors showed that the score is useful and can be used in patients of the Middle East without limitations. Altogether the achievement of the study is to collect such a cohort in a single center. The study was well performed.

### Abstract

**AIM:** To identify the radiological characteristics of focal autoimmune pancreatitis (f-AIP) useful for differentiation from pancreatic cancer (PC).

**METHODS:** Magnetic resonance imaging (MRI) and triple-phase computed tomography (CT) scans of 79 patients (19 with f-AIP, 30 with PC, and 30 with a normal pancreas) were evaluated retrospectively. A radiologist measured the CT attenuation of the pancreatic parenchyma, the f-AIP and PC lesions in triple phases. The mean CT attenuation values of the f-AIP lesions were compared with those of PC, and the mean CT attenuation values of pancreatic parenchyma in the three groups were compared. The diagnostic performance of

CT attenuation changes from arterial phase to hepatic phase in the differentiation between f-AIP and PC was evaluated using receiver operating characteristic (ROC) curve analysis. We also investigated the incidence of previously reported radiological findings for differentiation between f-AIP and PC.

**RESULTS:** The mean CT attenuation values of f-AIP lesions in enhanced phases were significantly higher than those of PC (arterial phase:  $60 \pm 7$  vs  $48 \pm 10$ ,  $P < 0.05$ ; pancreatic phase:  $85 \pm 6$  vs  $63 \pm 15$ ,  $P < 0.05$ ; hepatic phase:  $95 \pm 7$  vs  $63 \pm 13$ ,  $P < 0.05$ ). The mean CT attenuation values of f-AIP lesions were significantly lower than those of uninvolved pancreas and normal pancreas in the arterial and pancreatic phase of CT ( $P < 0.001$ ,  $P < 0.001$ ), with no significant difference at the hepatic phase or unenhanced scanning ( $P = 0.4$ ,  $P = 0.1$ ). When the attenuation value increase was equal or more than 28 HU this was considered diagnostic for f-AIP, and a sensitivity of 87.5%, specificity of 100% and an area under the ROC curve of 0.974 (95%CI: 0.928-1.021) were achieved. Five findings were more frequently observed in f-AIP patients: (1) sausage-shaped enlargement; (2) delayed homogeneous enhancement; (3) hypoattenuating capsule-like rim; (4) irregular narrowing of the main pancreatic duct (MPD) and/or stricture of the common bile duct (CBD); and (5) MPD upstream dilation  $\leq 5$  mm.

**CONCLUSION:** Analysis of a combination of CT and MRI findings could improve the diagnostic accuracy of differentiating f-AIP from PC.

**Key words:** Focal autoimmune pancreatitis; Pancreatic cancer; Computer tomography; Magnetic resonance imaging; Magnetic resonance cholangiopancreatography

**Core tip:** At present, focal autoimmune pancreatitis (f-

AIP) is still very difficult to differentiate from pancreatic cancer (PC). In this study, we compared the incidence of radiological features, investigated the differences in the triple-phase enhancement pattern of f-AIP and PC, and found that the combination analysis contributed to improve the diagnostic accuracy of f-AIP thus avoiding unnecessary surgery.

## INTRODUCTION

Autoimmune pancreatitis (AIP) is a rare form of immune-mediated chronic pancreatitis (CP) due to an autoimmune mechanism and is characterized by a marked infiltration of lymphocytes and plasma cells in pancreatic tissue (lymphoplasmacytic sclerosing pancreatitis) and was first described in 1961<sup>[1-5]</sup>. It can be classified into two radiological types: the diffuse form (the most frequent, 70% of cases) and the focal form (30% of cases), which is characterized by focal swelling of the pancreas, localized narrowing of the main pancreatic duct (MPD) with an irregular wall on imaging modalities<sup>[6-8]</sup>. Focal AIP (f-AIP) can be due to a mass formation or swollen pancreas located in one or two segments of the gland. AIP has a variety of manifestations, obstructive jaundice occurs in 76% and weight loss in 35% of patients, usually in combination with pancreatic enlargement, especially with focal pancreatic enlargement on imaging, making it very difficult to differentiate from pancreatic cancer<sup>[7,9,10]</sup>.

Treatment for AIP and pancreatic cancer (PC) are completely different. Autoimmune pancreatitis is a benign disease and steroid therapy can rapidly resolve symptoms; for PC, however, surgical resection is preferred, and if necessary, PC patients might receive combined radiotherapy or chemotherapy. However, about 3%-5% of patients undergoing pancreatic resection for presumed PC in fact have AIP<sup>[11]</sup>. Kamisawa *et al*<sup>[12]</sup> reported that 7 of 37 (18.9%) AIP patients had surgery because they were misdiagnosed as having PC or bile duct cancer. In particular, it is very difficult to differentiate between f-AIP and PC. Chang *et al*<sup>[13]</sup> reported that 8 of 26 (31.8%) AIP patients had f-AIP who were frequently treated with surgery because differentiating f-AIP from PC was so difficult. It was reported that approximately 2.2%-35.2% of f-AIP patients had undergone surgery due to a presumed diagnosis of PC<sup>[12,14-16]</sup>.

Here, we report the radiological features of 19 cases of f-AIP presenting as PC to: (1) increase the awareness and recognition of f-AIP; and (2) improve the diagnostic accuracy and avoid unnecessary surgery due to misdiagnosis.

## MATERIALS AND METHODS

### Patient sample

This study was approved by the hospital ethical committees. Consecutive patients with focal autoimmune pancreatitis (f-AIP,  $n = 19$ ) were recruited between November 2009 and October 2012. Patients with AIP were diagnosed according to the Asian Diagnostic Criteria for Autoimmune Pancreatitis (2008)<sup>[17]</sup>. A diagnosis of AIP was established when the criterion of (1) narrowing of the MPD with enlargement of the pancreas, as determined by a review of an imaging study, is met together with the criterion of (2) an increase in serum markers (g-globulin, IgG, or IgG4) and/or the criterion of (3) pathology. In this study, the diagnosis of AIP was established by the presence of criteria 1 and 2 in 4 patients; criteria 1 and 3 in 3 patients; and criteria 1, 2, and 3 in 12 patients.

The f-AIP group included 19 patients (14 men and 5 women; age range, 41-75 years; mean age, 54 years) with 21 lesions who had undergone contrast-enhanced computed tomography (CE-CT) ( $n = 19$ ), CE magnetic resonance imaging (MRI) ( $n = 11$ ), and magnetic resonance cholangiopancreatography (MRCP) ( $n = 16$ ). One patient had 3 lesions which were located at the pancreatic head, body and tail.

Identification of patients with focal pancreatic carcinoma was performed by reviewing patient records between March 2012 and December 2012 obtained from the hospital's pathology database. All 30 patients (21 men, 9 women; age range, 43-79 years; mean age, 58.2 years) with pathologically (histopathological examination of the surgically resected or biopsied tumor specimen) confirmed pancreatic ductal carcinoma ( $n = 30$ ) were included in this study. All 30 patients had undergone CE-CT, 26 had undergone MRCP, and 12 had undergone CE MRI using extracellular MR contrast agents (Gd-DTPA).

Thirty patients (20 men, 10 women; age range, 41-68 years; mean age, 53 years) with normal pancreas were also recruited. They were confirmed by reviewing the radiological images and followed-up for more than 6 months. All 30 patients had undergone CE-CT.

### CE-CT

In this study, all 79 patients underwent the triple-phase pancreatic CT protocol (Brilliance 16; PHILIPS Medical System) which included an unenhanced scan followed by triple-phase contrast-enhanced scans of the abdomen. The tube voltage was 120 kV, the tube current was 250 mA, and the rotation period was 0.75 s. A total of 90 mL of IV contrast material (iohexol, Omnipaque 300, GE Healthcare) containing 300 mg/mL iodine was intravenously administered as a bolus *via* a power injector. The injection rate was 3.5 mL/s. Images were obtained during the arterial, pancreatic and hepatic phases at 20, 40 and 80 s, respectively, after contrast medium injection. The median slice thickness for contrast-enhanced images was 3 mm.

### **MRI and MRCP**

MR imaging and MR cholangiopancreatography were performed using a 1.5-T MR imaging system (AVANTO; SIEMENS Medical Systems) and a pre-contrast coil. Pre-contrast T1-weighted MR imaging [repetition time msec/echo time msec, 150 (R) 200/2.1, 4.2] with and without fat saturation and respiratory-triggered T2-weighted MR imaging (5000-8000/80-135) were performed, followed by dynamic fat-suppressed T1-weighted MR imaging (150-200/2.1) after administration of a gadolinium-based contrast agent. MRCP was performed with a single-shot fast spin-echo thick-slab technique (25000-30000/800-1000).

### **Imaging analysis**

Three board-certified abdominal radiologists (with 9, 10 and 15 years of experience) reviewed all CT and MRI images retrospectively using a picture archiving and communication system (PACS) work station (General Electric Medical System). During analysis of the CT and MRI findings, all cases were randomly intermixed. The radiologists were blinded to the patients' clinical data, official reports, radiological examinations on other dates, and histopathological findings. Decisions were made by consensus.

For each patient, the radiologists were asked to make judgments on the following signs: (1) focal pancreatic enlargement and the location of the lesion; (2) capsule-like rim of the lesion; (3) localized irregular narrowing of MPD; (4) stricture of the distal common bile duct; and (5) other associated findings such as calcification, peripancreatic lymphadenopathy and vascular invasion.

When the lesion was confirmed, CT attenuation values of the f-AIP, PC, the apparently unaffected pancreatic parenchyma, and the normal pancreas were measured by one radiologist using a workstation (Advantage Version 4.2, GE Healthcare). The CT attenuation values were measured using unenhanced images and images obtained from arterial, pancreatic and hepatic phases after contrast administration. Following the placement of a region of interest (ROI) in each segment of the pancreas (head, body and tail), CT attenuation values of the pancreatic parenchyma were measured. The mean value of the three segments was used as the CT attenuation value of the pancreatic parenchyma. In f-AIP and PC patients, ROIs were placed both above the lesion and in the unaffected segments of the pancreas. The largest possible spherical ROI was marked, ruling out the pancreatic duct and partial volume averaging from the extrapancreatic structures. The smallest ROI was approximately 3 mm in diameter when the pancreas was atrophic. Delayed enhancement of the AIP and PC lesions was defined as the change in CT attenuation of the lesion between the arterial phase and the hepatic phase. CT attenuation values of the liver and spleen were similarly measured on unenhanced images (when available) and on images obtained in the arterial, pancreatic and hepatic phases.

The MRCP images were reviewed to identify changes

in the common bile duct (CBD) and MPD. The MPD and CBD observations were classified into 1 of 3 categories: as displaying (1) normal appearance; (2) stenosis; and (3) complete obstruction (nonvisualization of the obstructed segment). The MPD upstream diameter was evaluated by a review of MRCP images. The MPD upstream diameter and presence of distal pancreatic atrophy were not evaluated in patients with lesions in the pancreatic tail, while stenosis of CBD was not evaluated for patients with lesions in the pancreatic head.

### **Statistical analysis**

Statistical analysis was performed using the Fisher's exact test to compare the frequencies of imaging findings. The inter-reader agreement was evaluated by measurement of the kappa value. The mean CT attenuation value of the lesion in patients with f-AIP was compared with that of PC. Similarly, The mean CT attenuation values of unaffected segmental pancreas in f-AIP were compared with those of PC and normal pancreas. A comparison of the mean CT attenuation values of other organs (liver and spleen) was also performed in the three groups of patients.

Statistical analyses were performed with nonparametric tests due to the nongaussian distribution of the data and smaller sample sizes involved in some comparisons of interest. Wilcoxon's rank sum test was used to compare the CT attenuation values. When comparing two groups, the KruskalWallis test was performed before Wilcoxon's rank sum test. Fisher's exact test was applied to compare frequencies of delayed enhancement of the masses and focal enlarged segments. The diagnostic performance of attenuation value increase between the arterial and hepatic phase in the differentiation between f-AIP and PC was evaluated using receiver operating characteristic (ROC) analysis. From the ROC curves, the appropriate cutoff values were determined by selecting the point at which the Yoden index (sum of sensitivity + specificity - 1) was largest. All tests were two sided, and  $P < 0.05$  was considered statistically significant. Statistical analysis was performed with SPSS software (version 18.0, SPSS).

## **RESULTS**

The imaging characteristics of f-AIP and PC identified by reviewing the CE-CT and MRI/MRCP results are summarized in Tables 1 and 2.

### **Focal pancreatic enlargement**

Of the 49 f-AIP and PC cases, the affected segments of pancreas differed in the extent of enlargement. Of the f-AIP cases, the affected sites of the pancreas were the head in 5 patients, the body in 5 patients, and the tail in 9 patients. Of the PC cases, these values were 16, 6 and 8, respectively. The sausage-shaped enlargement of the affected segments of the pancreas was observed in 11 patients with f-AIP, but not in PC cases. Atrophy of

**Table 1 Comparison of imaging findings**

| Imaging features                 | Data of assessable patients |                  | Kappa | P       |
|----------------------------------|-----------------------------|------------------|-------|---------|
|                                  | f-AIP<br>(n = 19)           | f-PC<br>(n = 30) |       |         |

| Calcification                    | 0 (1/19)                    | 0 (0/30)         |       | NS      |

Data are percentages and numbers in parentheses refer to numbers of lesions. <sup>1</sup>The stenosis of common bile duct (CBD) was not evaluated for focal autoimmune pancreatitis (f-AIP) and pancreatic cancer (PC) patients with lesions in the pancreatic head. When the Kappa value was negative, the corresponding item was not suitable for differentiation. f-AIP: Focal autoimmune pancreatitis; MPD: Main pancreatic duct; NS: Not significant.

the pancreas was observed in 3 f-AIP and 20 PC cases whose lesions were located in the head and body.

### Density or signal abnormalities

CE-CT scans showed hypoattenuated or isoattenuated lesions in the involved segments of the pancreas in 4 and 15 f-AIP cases on precontrast scans, respectively. In all f-AIP patients, the affected pancreas appeared uniformly enlarged with the absence of pancreatic clefts and with a sharp outline (Figures 1-3). AIP and PC lesions all showed decreased enhancement on arterial phase and delayed enhancement on pancreatic and hepatic phases, however, the degree of delayed enhancement in f-AIP was greater than that in PC (Figures 2 and 4, Table 2). MRI imaging showed that the lesion was isointense or slightly hypointense in T1WI and slightly hyperintense in T2WI (Figure 3A and B). The MR enhancement patterns were similar to those of CE-CT.

### CBD and MPD Abnormalities

Of the AIP lesions ( $n = 21$ ), irregular narrowing of the MPD was observed in 13 lesions (Figure 3E), and the remaining 8 lesions did not display this MPD abnormality. Bile duct dilatation was observed in 5 cases which included 4 patients who had lesions at the pancreatic head

and 1 at the tail. The range of dilation was 9-14 mm (mean, 11 mm). The CBD showed a beak-like stricture (Figure 1C). In 3 patients with lesions in the pancreatic head, the upstream MPD was slightly dilated (less than 5 mm), distal pancreatic atrophy was not observed in 14 patients with lesions in the pancreatic body and tail.

Of the PC lesions ( $n = 30$ ), no irregular narrowing of the MPD was observed. Bile duct dilatation was observed in all 8 patients with lesions located in the pancreatic head, and the distal CBD showed an abrupt interruption sign.

### Capsule-like rim

Capsule-like rims were observed in f-AIP cases ( $n = 11$ ), which were shown continuously or discontinuously as hypodense peripancreatic strands on the precontrast CT and delayed enhanced on the delayed phase of dynamic CT (Figure 2). On MR imaging, the capsule-like rim appeared as a T1WI isointense and T2WI hypointense area surrounding the pancreas (Figure 3A and B).

### Other associated findings

Other associated findings included calcification (f-AIP,  $n = 1$ ; PC,  $n = 0$ ), peripancreatic lymphadenopathy (f-AIP,  $n = 3$ ; PC,  $n = 26$ ) and vascular invasion (f-AIP,  $n = 0$ ; PC,  $n = 4$ ).

### Comparison of CT attenuation values

The results of the mean CT attenuation values of the f-AIP lesions and uninvolved segments in f-AIP patients and normal pancreas are shown in Table 2. The mean CT attenuation values of f-AIP lesions in enhanced phases were significantly higher than those of PC ( $P < 0.05$ ,  $P < 0.05$ ,  $P < 0.05$ ) (Figure 5). The mean CT attenuation values of the f-AIP lesions were significantly lower than those of uninvolved pancreas and normal pancreas in the arterial and pancreatic phase of CT ( $P < 0.001$ ,  $P < 0.001$ ), however, there were no significant differences in the hepatic phase or unenhanced scanning ( $P = 0.4$ ,  $P = 0.1$ ). The mean CT attenuation values of normal and unaffected pancreatic parenchyma in the three groups showed no significant differences in the arterial, pancreatic, and hepatic phases ( $P = 0.1$ ,  $P = 0.8$ ,  $P = 0.2$ ). The mean CT attenuation values of the liver and spleen were not significantly different between the three groups. When the attenuation value increase was equal or more than 28 HU this was considered diagnostic for f-AIP, and a sensitivity of 87.5%, specificity of 100% and an area under the ROC curve of 0.974 (95%CI: 0.928-1.021) were achieved (Figure 6).

## DISCUSSION

Although the diagnosis of AIP has improved due to a growing awareness of the condition and proposed diagnostic criteria<sup>[18]</sup>, there is no practical strategy to differentiate PC from f-AIP. One must distinguish between the two disorders to prevent unnecessary surgery or delayed

Figure 1 A 55-year-old woman with focal autoimmune pancreatitis of the pancreatic head. A, B: Contrast-enhanced computed tomography images obtained during enhanced phases showing enhanced thickening of the common bile duct (CBD) wall (A, black arrow), narrowing of the main pancreatic duct (MPD) and distal CBD (B, black arrows); C: Bile duct dilation and irregular narrowing of the MPD in the pancreatic head can be observed on the magnetic resonance cholangiopancreatography image (white arrows).

Figure 2 A 59-year-old man with focal autoimmune pancreatitis of the pancreatic tail. Contrast-enhanced computed tomography image obtained during the arterial phase (A, white arrow) showing that a hypoattenuating capsule-like rim can be observed around the pancreatic tail, which manifested delayed enhancement during the pancreatic phase (B, white arrow) and hepatic phase (C, white arrow). Attenuation values of the autoimmune pancreatitis lesion were 36, 51, 76 and 89 HU during the pre-contrast and enhanced phases, respectively.

| Table 2 Mean computed tomography attenuation values |    |                     |                      |                     |                       |                    |
|---|----|---------------------|----------------------|---------------------|-----------------------|--------------------|
| Group   | n  | Condition           | Unenhanced scan (HU) | Arterial phase (HU) | Pancreatic phase (HU) | Hepatic phase (HU) |
| f-AIP   | 19 | Lesions             | 36 ± 4               | 60 ± 7              | 85 ± 6                | 95 ± 7             |

|   |    | Spleen              | 47 ± 4               | 107 ± 17            | 133 ± 23              | 99 ± 11            |

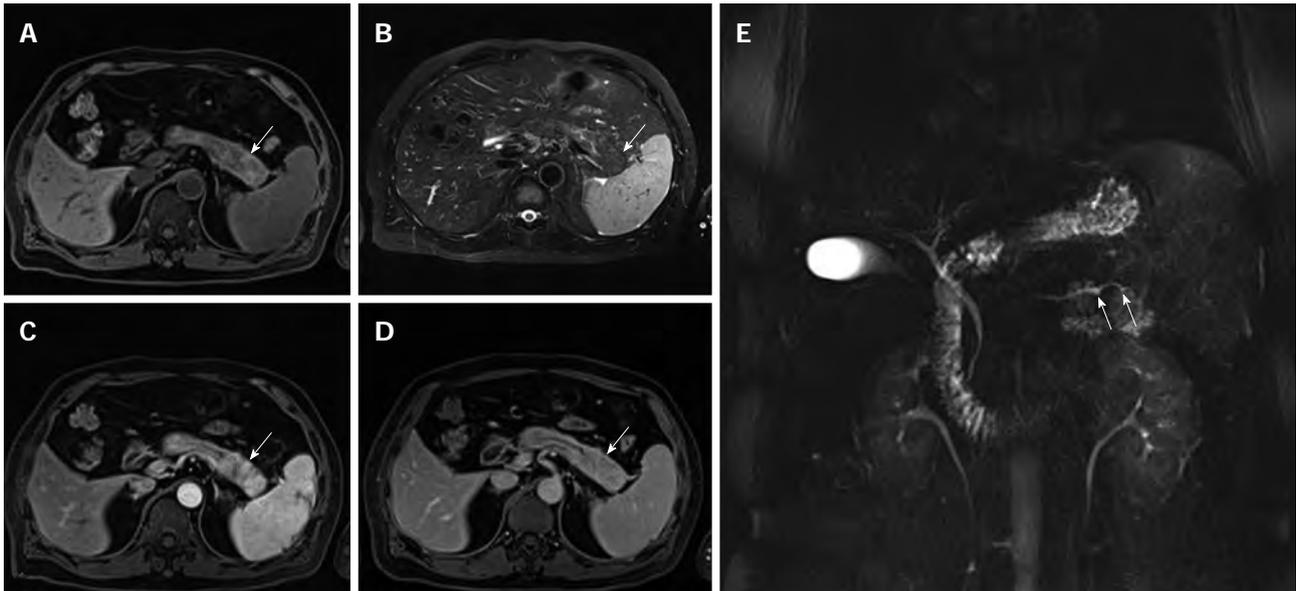

Data are computed tomography attenuation values (mean ± SD). f-AIP: Focal autoimmune pancreatitis; PC: pancreatic cancer.

initiation of corticosteroid therapy. A review of the CE-CT and MRI data indicated five imaging features of AIP: (1) delayed homogeneous enhancement; (2) hypoattenuating capsule-like rim; (3) the absence of distal pancreatic atrophy; (4) irregular narrowing of the MPD; and (5) stenosis of the CBD in patients with lesions in the body or/and tail. The analysis also indicated that those imaging features could be used to differentiate AIP from PC with high accuracy.

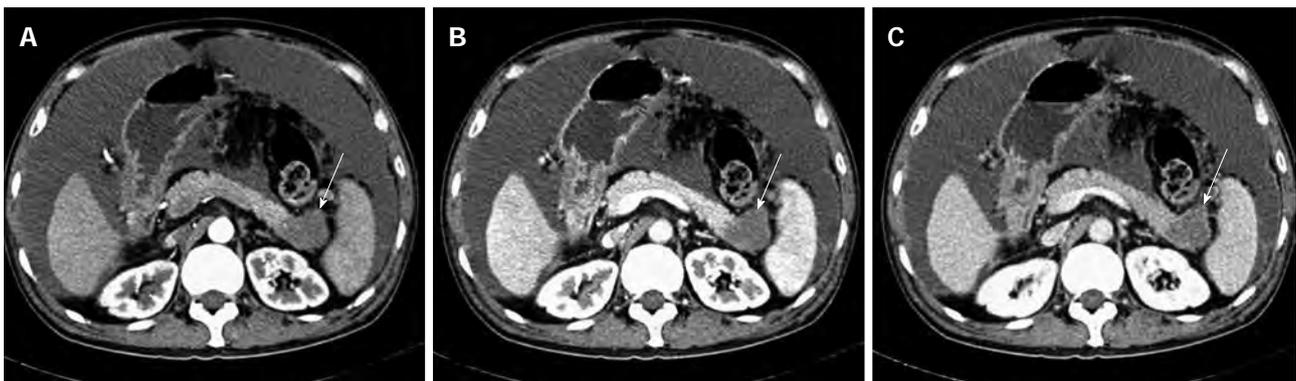

Some studies have reported that the head of the pan-

creas is involved in most AIP cases<sup>[19,20]</sup>, which is consistent with the study by Woo Ik Chang who showed that the affected site was the pancreatic head in 5 (62.5%) of 8 patients<sup>[13]</sup>. However, in our study, the affected site was the pancreatic head in only 4 patients (21.1%). This difference may be due to the following reasons: (1) the pancreatic head may not be the most commonly involved site in f-AIP; and (2) the number of patients studied may have been too small.

In our study, we identified the homogeneous good

**Figure 3** A 53-year-old man with focal autoimmune pancreatitis of the pancreatic tail. A-D: The lesion showed heterogenous T1WI hypointensity and heterogenous T2WI hyperintensity, which was delayed enhanced. The capsule-like rim appearing as a T1WI iso- or slight hyperintensity and a T2WI hypointensity area surrounding the pancreas (white arrow), which were delayed and moderately enhanced; E: Magnetic resonance cholangiopancreatography image shows the irregular narrowing main pancreatic duct in the pancreatic tail (white arrows).

**Figure 4** A 54-year-old man with pancreatic cancer of the pancreatic tail. Triple-phase computed tomography images show irregular enlargement of the pancreatic tail. Enhancement of the lesion is decreased (A, 39 HU) during arterial phase, and slightly increased enhancement during pancreatic phase (B, 48 HU) and hepatic phase (C, 62 HU), respectively (white arrows).

enhancement during the delayed phases as useful in differentiating between f-AIP and PC. Similarly, in the study by Kamisawa<sup>[12]</sup>, delayed enhancement was observed in 17 of 17 (100%) AIP patients, while Wakabayashi *et al*<sup>[20]</sup> described delayed homogeneous enhancement in 9 of 9 (100%) AIP patients. In addition, Chang *et al*<sup>[13]</sup> described homogeneous enhancement during the hepatic phase in six of seven AIP patients. The consistency of delayed homogenous enhancement in this and previous studies shows one of the common imaging features of AIP, but the absence of a further quantitative analysis.

We found that the attenuation values of AIP were significantly higher than those of PC in the enhanced phases, lower than those of unaffected pancreatic parenchyma in the arterial and pancreatic phase, however, no significant differences were observed in the hepatic phase ( $95 \pm 7$  HU *vs*  $95 \pm 7$  HU, 75 s). Takahashi found

significantly higher CT attenuation values for AIP ( $90 \pm 19$  HU) than for pancreatic carcinoma ( $64 \pm 19$  HU) during the hepatic phase (60-70 s)<sup>[21]</sup>. They also found greater enhancement during the pancreatic phase ( $71 \pm 22$  HU *vs*  $59 \pm 20$  HU), although the difference between the two groups was not statistically significant<sup>[10]</sup>. The difference between the CT attenuation values obtained in this study and those by Takahashi may be related to differences in the timing of scan acquisition, contrast injection rates and CT scanners.

Irregular narrowing of the MPD is one of the most important features of AIP. In our study, 79% of AIP patients (15 of 19) showed segmental irregular narrowing of the MPD, while the number was 6% (2 of 30) in PC patients. Moreover, no or minimal upstream dilatation can also be helpful to differentiate AIP from PC<sup>[10,22]</sup>. In the current study, upstream MPD dilatation ( $\geq 5$  mm)

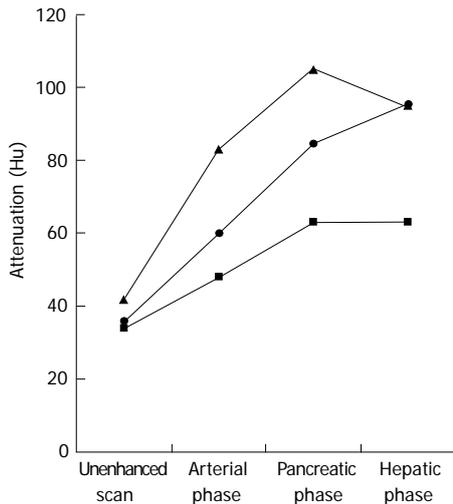

Figure 5 Graph shows mean computed tomography attenuation values of normal pancreatic parenchyma (triangle) and lesions in patients with focal autoimmune pancreatitis (circle) and pancreatic cancer (square) in relation to phase of contrast enhancement.

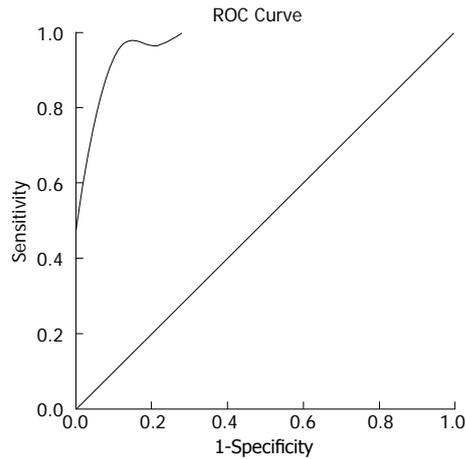

Figure 6 Receiver operating characteristic curve analysis result. Receiver operating characteristic (ROC) curve analysis revealed that when values were more than or equal 28 HU they were considered diagnostic for focal autoimmune pancreatitis, and a sensitivity of 87.5%, a specificity of 100%, and an area under the ROC curve of 0.974 (95%CI: 0.928-1.021) were achieved.

was observed in only 5% of patients (1 of 19), while the number was 86% in PC patients. Some studies reported that stricture of the distal CBD was often observed in AIP, and this occurred due to the combined effect of extrinsic compression by the inflamed pancreatic head and inflammatory changes in the CBD<sup>[10]</sup>. The f-AIP patients showed a smooth pattern, whereas the patients with PC showed an irregular pattern. In our study, CBD stricture of smooth pattern was seen in 8 of 19 patients, that is 4 of 5 patients with pancreatic head lesions and four with pancreatic tail lesions. Therefore, we suggest that the inflammatory changes in the CBD and AIP may be independent or have occurred one after another, and this might be useful for the diagnosis of f-AIP.

In the current study, the small number of patients may not represent all the characteristics of f-AIP according to radiological features only. Thus, we tried to identify radiological findings to diagnosis f-AIP, however, these findings were insufficient to exclude PC. Therefore, we recommend that IgG4 should be tested and histological findings should be obtained where possible to discriminate f-AIP from PC. We believe that future studies with more patients will clarify and validate the radiological features of f-AIP.

In conclusion, this study found that the analysis of a combination of imaging findings, either of delayed enhancement with more than 28 HU, or of three imaging findings (1) focal pancreatic enlargement with a capsule-like rim; (2) irregular narrowing of the MPD; and (3) stricture of the CBD in patients with lesions (not located in the pancreatic head) contribute to improve the diagnostic accuracy of f-AIP thus avoiding unnecessary surgery.

**COMMENTS**  
**Background**  
 Autoimmune pancreatitis (AIP), a rare form of chronic pancreatitis (CP), can

be classified as the diffuse form and the focal form. Although AIP is well-known among radiologists, focal AIP (f-AIP) is still very difficult to differentiate from pancreatic cancer (PC).

**Research frontiers**

f-AIP has a variety of manifestations and is very difficult to differentiate from PC. Improving the diagnostic accuracy can help avoid unnecessary surgery in f-AIP patients.

**Related publications**

The analysis of combined imaging with computed tomography and magnetic resonance to improve the diagnostic accuracy of differentiating f-AIP from PC has rarely been reported.

**Innovations and breakthroughs**

This is the first study to report that the triple-phase enhancement pattern of f-AIP is different from that of PC. Three imaging features are more frequently found in f-AIP, including focal pancreatic enlargement with a capsule-like rim, irregular narrowing of the main pancreatic duct and stricture of the common bile duct in patients with lesions not located in the pancreatic head. The combination of these findings could further improve the diagnostic accuracy of f-AIP and avoid unnecessary surgery.

**Applications**

The study results suggest that a combination of imaging findings will help improve the diagnostic accuracy of f-AIP and avoid unnecessary surgery.

**Peer review**

It is a good clinical study in which the authors analyzed the radiological characteristics of f-AIP. The results are interesting and suggest that the combination of triple-phase enhancement pattern and imaging features of f-AIP can help for the differential diagnosis of f-AIP from PC.

### Abstract

**AIM:** To assess the impact of fast-track surgery (FTS) on hospital stay, cost of hospitalization and complications after radical total gastrectomy.

**METHODS:** A randomized, controlled clinical trial was conducted from November 2011 to August 2012 in the Department of Digestive Surgery, Xijing Hospital of Digestive Diseases, the Fourth Military Medical University. A total of 122 gastric cancer patients who met the selection criteria were randomized into FTS and conventional care groups on the first day of hospitalization. All patients received elective standard D2 total gastrectomy. Clinical outcomes, including duration of flatus and defecation, white blood cell count, postoperative pain, duration of postoperative stay, cost of hospitalization and complications were recorded and evaluated.

Two specially trained doctors who were blinded to the treatment were in charge of evaluating postoperative outcomes, discharge and follow-up.

**RESULTS:** A total of 119 patients finished the study, including 60 patients in the conventional care group and 59 patients in the FTS group. Two patients were excluded from the FTS group due to withdrawal of consent. One patient was excluded from the conventional care group because of a non-resectable tumor. Compared with the conventional group, FTS shortened the duration of flatus ( $79.03 \pm 20.26$  h vs  $60.97 \pm 24.40$  h,  $P = 0.000$ ) and duration of defecation ( $93.03 \pm 27.95$  h vs  $68.00 \pm 25.42$  h,  $P = 0.000$ ), accelerated the decrease in white blood cell count [ $P < 0.05$  on postoperative day (POD) 3 and 4], alleviated pain in patients after surgery ( $P < 0.05$  on POD 1, 2 and 3), reduced complications ( $P < 0.05$ ), shortened the duration of postoperative stay ( $7.10 \pm 2.13$  d vs  $5.68 \pm 1.22$  d,  $P = 0.000$ ), reduced the cost of hospitalization ( $43783.25 \pm 8102.36$  RMB vs  $39597.62 \pm 7529.98$  RMB,  $P = 0.005$ ), and promoted recovery of patients.

**CONCLUSION:** FTS could be safely applied in radical total gastrectomy to accelerate clinical recovery of gastric cancer patients.

**Key words:** Fast-track surgery; Gastric cancer; Radical total gastrectomy; Perioperative care; Outcomes

**Core tip:** Fast-track surgery (FTS) is a promising program for surgical patients, and has been applied in several surgical diseases. The value of FTS in radical distal gastrectomy has been demonstrated recently, but the safety and efficacy of FTS for radical total gastrectomy requires further evaluation. The present study showed that FTS was feasible for perioperative care in radical total gastrectomy. Compared with conventional care, FTS could shorten the duration of flatus and defeca-

tion, accelerate the decrease in white blood cell count, decrease postoperative complications, shorten the postoperative stay, reduce the cost of hospitalization, and promote postoperative recovery of patients.

Fast-track surgery could improve postoperative recovery in radical total gastrectomy patients. *World J Gastroenterol* 2013; 19(23): 3642-3648 Available from: URL: <http://www.wjg-net.com/1007-9327/full/v19/i23/3642.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i23.3642>

## INTRODUCTION

Fast-track surgery (FTS) was initiated by the Danish surgeon H Kehlet in the field of elective colorectal surgery in the 1990s<sup>[1,2]</sup>, and has rapidly gained popularity around the world because of its significant benefits and safety<sup>[3]</sup>. The core elements of FTS include: epidural or regional anesthesia, perioperative fluid management, minimally invasive techniques, optimal pain control, early initiation of oral feeding and early mobilization<sup>[4]</sup>. The combination of these approaches has led to a significant reduction in complication rates, morbidity and mortality rates, duration of hospital stay and costs of hospitalization, and finally, greatly improved postoperative recovery<sup>[5-7]</sup>. In recent years, FTS has been applied in several surgical diseases, include radical prostatectomy<sup>[8]</sup>, cardiac surgery<sup>[9]</sup>, total knee replacement<sup>[10]</sup>, cesarean section<sup>[11]</sup>, coronary artery bypass grafting<sup>[12]</sup>, it has also been used for specific procedures in children<sup>[13]</sup> and the elderly<sup>[14]</sup>.

Gastric cancer is the fourth most common cancer worldwide but the second leading cause of cancer mortality<sup>[15]</sup>, and it is more common in men and in developing countries. Up to now, surgery has been the most common treatment. For radical gastrectomy, conventional elective gastric resection and perioperative care are associated with a morbidity of 20%-46%, a mortality of 0.8%-10%<sup>[16]</sup> and a postoperative hospital stay of 8-13 d<sup>[17]</sup>. The high rate of complications leads to prolonged duration of hospital stay and increased costs of hospitalization.

The value of FTS in radical distal gastrectomy has been demonstrated recently<sup>[18,19]</sup>, but the safety and efficacy of FTS in radical total gastrectomy still requires further evaluation. Therefore, we performed a slightly modified fast-track protocol in gastric cancer patients in our department. We evaluated the feasibility and safety of FTS in gastric cancer patients through a prospective, randomized comparative study.

## MATERIALS AND METHODS

### Patients

This study was performed in Xijing Hospital of Digestive Diseases affiliated to the Fourth Military Medical

University from November 2011 to August 2012. Selection criteria were: (1) diagnosis of gastric cancer based on clinical symptoms, imaging and pathology; (2) age between 18 and 75 years; (3) no preoperative radiotherapy or chemotherapy; (4) no distant metastasis; (5) no history of primary diabetes mellitus, bowel obstruction, severe cardiopulmonary diseases, and immune related diseases; (6) no pregnancy or breast feeding; (7) an American Society of Anesthesiologists (ASA) score of I or II; (8) undergoing elective standard D2 total gastrectomy; and (9) written informed consent was obtained from the patient and the family. Gastric cancer patients meeting the selection criteria were randomly divided into a FTS group and a conventional care group immediately after admission. The sample size of 122 patients (61 cases in each group) was calculated with an alpha level of 0.05 and 90% power for primary endpoints.

This study was approved by the Ethics Committee of Xijing Hospital. This study was registered under *chictr.org*, identifier number ChiCTR-TRC-11001440.

### Randomization and implementation

All the patients were clearly informed about the aims and details of the present study and signed consent forms. Random numbers were generated by computer. Eligible patients were randomly assigned in a 1:1 ratio. The specially trained investigator prepared allocation envelopes for the doctors of the enrolled patients. The investigator did not contact the patients throughout the clinical trial. The doctors and nurses administering the interventions and collecting the data had no role in the randomization process. Two specially trained doctors who were blinded to the treatment were in charge of evaluating postoperative outcomes, discharge and follow-up.

### Interventions

The patients were admitted to the hospital 1-2 d before surgery. A slightly modified fast-track protocol proposed by Kehlet *et al.*<sup>[20]</sup> was used in the present FTS group. Patients in the conventional surgery group received conventional perioperative care. Details of the interventions are listed in Table 1. Both groups were protocol-driven, with appropriate protocol details for patients, surgeons and nurses to ensure compliance.

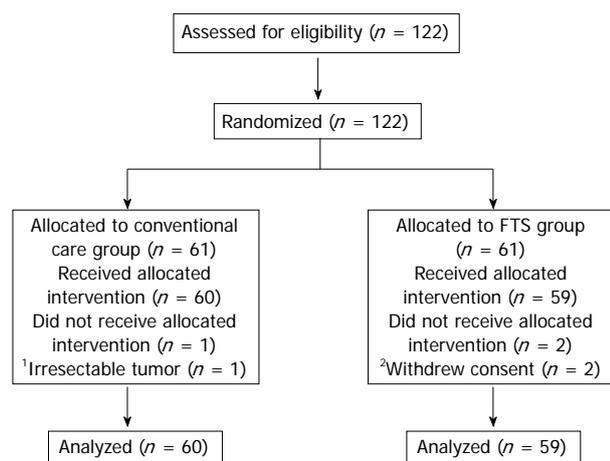

### Discharge criteria and readmission

Patients were considered dischargeable postoperatively if they met the following criteria: normal body temperature, pain controlled with oral analgesics, normal mobilization, no discomfort, normal oral diet, no parenteral nutrition, normal gastrointestinal function (normal flatus and defecation), Karnofsky Performance Status Scale score exceeding 80, and willing to go home.

After discharge, the patients were followed up by our specially trained surgeons through telephone within the first 24 h and once per week for 4 wk, and the patients could also contact us if they had any discomfort. The patients were readmitted if any of the following occurred:

**Table 1 Comparison of fast-track surgery and conventional perioperative intervention protocols**

| Perioperative intervention            | Conventional  | Fast-track surgery   |
|---------------------------------------|---|--|
| Diet before surgery                   | No intake of food and drink after supper the day before surgery   | Intake of 1000 mL 14% carbohydrate drink 12 h before and 350 mL 14% carbohydrate drink 3 h before surgery.   |
| Anesthesia                            | Tracheal intubation and general anesthesia  | Tracheal intubation and general anesthesia   |
| Thermal insulation during operation   | No thermal insulation, room temperature was maintained at 22 °C   | Thermal insulation of the body and extremities, body temperature was maintained at 36 °C   |
| Operation procedure                   | Standard laparotomy approach  | Standard laparotomy approach   |
| Placement of abdominal drainage       | Use of abdominal drainage tube  | No routine use of abdominal drainage tube  |
| Analgesia after operation             | Standard use of patient-controlled analgesic pump   | Infiltration of surgical wounds with ropivacaine at the end of surgery and 24 h after surgery. Oral intake of 200 mg celecoxib twice daily   |
| Mobilization after operation          | Mobilize out of bed on patients' own request  | Encourage patients to mobilize out of bed  |
| Diet after operation                  | Oral intake initiated after flatus (following a stepwise plan from water to other liquids to semi-fluids to normal food)  | Oral intake of 500-1000 mL glucose saline on the day of surgery. Intake of 2000-3000 mL liquid food containing 1000 kcal to 1200 kcal per day from the 1st day after surgery                   |
| Intravenous nutrition after operation | Infusion of glucose saline and amino acid injection <i>iv</i> on the day of surgery. Infusion of parenteral nutrition (25 kcal/kg of body weight) <i>iv</i> before oral intake. Appropriate level of <i>iv</i> fluid intake based on the volume of liquid intake and output, and physiological need | Infusion of parenteral nutrition <i>iv</i> if oral intake is not adequate. Appropriate level of <i>iv</i> fluid intake based on the volume of liquid intake and output, and physiological need |
| Removal of nasogastric tube           | Removal of nasogastric tube after flatus  | Removal of nasogastric tube within 24 h after surgery  |
| Removal of urine catheter             | Removal of urine catheter on the 3 <sup>rd</sup> or 4 <sup>th</sup> day after surgery   | Removal of urine catheter within 24 h after surgery  |
| Antibiotics                           | Standard use of antibiotics for 3 d after surgery   | Standard use of antibiotics before and once after surgery  |

**Figure 1** Flow diagram of the randomized control trial designed to compare the safety and efficacy of fast-track surgery and conventional care groups. <sup>1</sup>One patient had an irresectable tumor in the conventional care group; <sup>2</sup>Two patients withdrew consent in the fast-track surgery (FTS) group. All three patients were excluded from the analysis.

hyperpyrexia, abdominal pain, bowel obstruction, gastrointestinal hemorrhage, malnutrition, infection and poor healing of the wound.

### Data collection

The primary clinical endpoints were the duration of hospital stay and the cost of hospitalization. The second clinical endpoints were incidence of complications such as pneumonia, surgical site infection, abdominal infection, anastomotic leak, and bowel obstruction. We recorded preoperative data on age, sex, body mass index (BMI), nutritional risk screening (NRS) 2002 score, ASA

score, differentiation status, TNM classification, white blood cell (WBC) count, hemoglobin, albumin, alanine aminotransferase (ALT) and aspartate aminotransferase (AST). Surgical-related data such as operation time and blood loss were also recorded. Postoperative data such as timing of first flatus and defecation, duration of hospital stay, the cost of hospitalization and complications were recorded. WBC was measured from postoperative day (POD) 1 to POD 5. Pain intensity was evaluated from POD 1 to POD 5 using a visual analog scale (VAS).

### Statistical analysis

Data were processed using SPSS 16.0 for Windows (SPSS Inc., Chicago, IL, United States). Numerical variables were expressed as the mean  $\pm$  SD unless otherwise stated. Differences between the two groups were tested using a two-tailed Student *t* test. Discrete variables were analyzed using the  $\chi^2$  test or Fisher's exact test. A *P* value < 0.05 was considered statistically significant.

## RESULTS

### Clinical characteristics

A total of 119 patients finished the study, including 60 patients in the conventional care group and 59 patients in the FTS group. Two patients were excluded from the FTS group after withdrawing consent. One patient was excluded from the conventional care group because of an irresectable tumor (Figure 1). The preoperative baseline characteristics of the two groups are compared in Table 2. There were no significant differences between the two groups in age, sex, BMI, NRS 2002 score, ASA score, differentiation status, TNM classification, WBC count, he-

**Table 2** Comparison of baseline characteristics of the two groups (mean  $\pm$  SD)

| Characteristics           | Conventional        | Fast-track surgery  | P value |
|---------------------------|---------------------|---------------------|---------|
| Age, yr                   | 55.79 $\pm$ 10.06   | 54.98 $\pm$ 11.35   | 0.682   |
| Sex                       |                     |                     | 0.689   |
| Male/female               | 44/16               | 41/18               |         |
| BMI                       | 21.01 $\pm$ 1.78    | 22.44 $\pm$ 3.51    | 0.061   |
| NRS 2002 score            | 0.81 $\pm$ 1.10     | 1.08 $\pm$ 1.41     | 0.424   |
| ASA score                 |                     |                     | 0.364   |

| White blood cell count       |                  |                    |         |
| POD 1                        | 14.81 $\pm$ 5.34 | 14.55 $\pm$ 5.04   | 0.793   |
| POD 2                        | 15.36 $\pm$ 5.36 | 12.26 $\pm$ 4.78   | 0.002   |
| POD 3                        | 11.80 $\pm$ 4.80 | 9.35 $\pm$ 3.83    | 0.005   |
| POD 4                        | 8.56 $\pm$ 3.70  | 7.52 $\pm$ 3.57    | 0.223   |
| POD 5                        | 6.37 $\pm$ 2.34  | 6.91 $\pm$ 3.34    | 0.684   |

POD: Postoperative day.

hemoglobin, albumin, ALT, AST, operation time and blood loss (all  $P > 0.05$ ).

### Pain intensity

Pain intensity was evaluated from POD 1 to POD 5 in the two groups (Table 3). VAS analysis showed that pain intensity of patients in the FTS group was significantly lower than that of patients in the conventional care group on POD 1-3 ( $P < 0.05$ ).

### White blood cell count

The WBC counts of patients in the two groups were measured in the morning of POD 1 to POD 5 (Table 3). The WBC count in the conventional care group and FTS group were both elevated on POD 1. Although the WBC count in the conventional care group continued to rise on

**Table 4** Comparison clinical outcomes and postoperative complications between the two groups

|                              | Conventional           | Fast-track surgery     | P value |
|------------------------------|------------------------|------------------------|---------|
| Clinical outcomes            |                        |                        |         |
| First flatus, h              | 79.03 $\pm$ 20.26      | 60.97 $\pm$ 24.40      | 0.000   |
| First defecation, h          | 93.03 $\pm$ 27.95      | 68.00 $\pm$ 25.42      | 0.000   |
| Postoperative stay, d        | 7.10 $\pm$ 2.13        | 5.68 $\pm$ 1.22        | 0.000   |
| Cost of hospitalization, RMB | 43783.25 $\pm$ 8102.36 | 39597.62 $\pm$ 7529.98 | 0.005   |
| Postoperative complications  |                        |                        |         |
| Total cases                  | 17                     | 6                      | 0.019   |
| Pneumonia                    | 10                     | 5                      | 0.269   |

| Urinary infection            | 1                      | 0                      | 1.000   |
| Abdominal infection          | 1                      | 0                      | 1.000   |
| Gastric retention            | 0                      | 0                      |         |
| Anastomotic leak             | 0                      | 0                      |         |
| Deep-vein thrombosis         | 0                      | 0                      |         |
| Ileus                        | 1                      | 0                      | 1.000   |
| Reoperation                  | 1                      | 0                      | 1.000   |
| Readmission                  | 0                      | 0                      |         |
| Mortality                    | 0                      | 0                      |         |

POD 2, the WBC count in the FTS group began to drop ( $P < 0.05$ ). The WBC count in the conventional care group began to drop on POD 3, but was significantly higher than in the FTS group ( $P < 0.05$ ).

### Outcomes

The outcomes were summarized in Table 4. Compared with the conventional care group, the patients in the FTS group showed significantly accelerated recovery of gastrointestinal function in terms of time to first flatus and first defecation ( $P < 0.05$ ). The duration of postoperative stay of the FTS group was significantly shorter than that of the conventional care group ( $P < 0.05$ ) and the cost of hospitalization was also significantly lower ( $P < 0.05$ ).

### Complications and readmissions

Table 4 summarizes the complications and readmissions in each group. The overall complication rate in the FTS group (10.17%) was significantly lower than in the conventional group (28.33%,  $P = 0.019$ ). In the conventional care group, 10 patients suffered from pneumonia, 3 patients suffered from incision infection, 1 patient experienced urinary infection, 1 patient experienced abdominal infection, and 1 patient underwent reoperation because of ileus. In the FTS group, 5 patients suffered from pneumonia and 1 experienced incision infection. All the patients were cured by surgery or conservative treatment.

## DISCUSSION

The aim of the present study was to evaluate the safety, efficacy and outcome of FTS protocol employed in the perioperative treatment of gastric cancer in comparison with conventional perioperative treatment. The data of the present study showed that the FTS protocol was feasible for perioperative care of gastric cancer patients who underwent radical total gastrectomy. Compared with

conventional care, FTS could shorten the duration of flatus and defecation, accelerate the decrease in WBC, decrease postoperative complications, shorten the duration of postoperative stay, reduce the cost of hospitalization, and eventually promote postoperative recovery of the patients.

Optimal pain control is very important. Pain can not only result in stress<sup>[21]</sup>, but also affects the mobilization of patients after surgery. Early mobility or activity is recognized as a critical step in fast-track care. Bed rest not only increases muscle loss and insulin resistance, but also decreases pulmonary function and supply of oxygen to tissues<sup>[22]</sup>. It has been reported that opioids may result in nausea, vomiting and fatigue that counteract the benefits of FTS<sup>[23]</sup>. Therefore, routine use of opioids was avoided in the FTS group. In our present study, the infiltration of surgical wounds with ropivacaine and oral intake of celecoxib were applied instead of a patient-controlled analgesia pump. Pain intensity was evaluated from POD 1 to POD 5 after surgery using the VAS. The results showed that VAS in the FTS group was significantly lower than that of conventional care group. This indicated that ropivacaine combined with celecoxib had a better analgesic effect than an analgesic pump, and the better analgesic effect in the FTS group ensured a longer duration of mobilization out of bed.

Conventionally, the duration of antibiotic use is 2-3 d after gastrectomy. In the present study, the antibiotics were only applied before and after surgery in the FTS group (Table 1). We noticed that even with shorter use of antibiotics in the FTS group, the WBC decreased earlier and faster than in the conventional postoperative care group.

Nasogastric tubes have been used traditionally for decompression after gastric surgery and remain a routine part of postoperative care in many centers. Nasogastric tubes are often left for several days until the first flatus after gastric resection. This is based on the rationale that this can prevent aspiration, and reduce the risk of intestinal obstruction and anastomotic leak in clinical practice. Previous studies have shown that the small intestine might return to normal enterocinesia 6 h after abdominal surgery<sup>[24]</sup>. Recent studies comparing nasogastric decompression *vs* no decompression demonstrated that a gastric tube may induce pulmonary complications after gastric cancer surgery<sup>[25,26]</sup> and prolong the time to first flatus with no difference in anastomotic leak rate<sup>[27]</sup>. Therefore, placement of a nasogastric tube is unnecessary. In our present study, a nasogastric tube was not routinely used in FTS group and was removed within 24 h after surgery.

Multiple studies have demonstrated that drains are unnecessary after gastrointestinal surgery<sup>[28]</sup>. The placement of abdominal drainage is prone to increased feelings of pain, intra-abdominal fluid collection, infection, internal organ injuries and risk of fistulas, resulting in delayed recovery<sup>[17]</sup>. Alvarez Usler *et al*<sup>[29]</sup> reported that operative morbidity and hospital stay were significantly higher in patients who underwent total gastrectomy with abdomi-

nal drains than that in patients without drains. However, we refrain from abolishing use of abdominal drains for total gastrectomy in China. Since all the patients received D2 total gastrectomy, the degree of lymph node dissection could lead to a higher risk of chyle leakage. Therefore, the use of drains after total gastrectomy continues to be an issue for debate in the development of FTS.

An early postoperative oral diet can hasten the return of gut function, protect gut mucosal barrier function, and enhance portal circulation<sup>[30]</sup>. Early enteral nutrition with dietary fiber can alleviate intestinal barrier dysfunction and decrease the incidence of bacterial translocation<sup>[31]</sup>. Although early enteral nutrition increases the incidence of vomiting and flatulence, a series of reports showed that it can reduce the risk of postoperative complications and mortality<sup>[32]</sup>, facilitate postoperative restoration without increasing the incidence of fistulas<sup>[33]</sup>, and be safely applied in gastrectomy<sup>[34]</sup>. In the present study, the majority patients in the FTS group well tolerated an early oral diet or enteral nutrition by jejunal feeding tube. We noticed that nausea and vomiting was rare, but abdominal distension did occur in some patients, the symptoms only lasted for a short time based on adequate mobilization out of bed and did not result in severe complications.

It is reported that the postoperative hospital stay of gastric patients could be decreased to 3.8 d in FTS group<sup>[35]</sup>. In the present study, the mean postoperative stay of patients in FTS group was 5 d, which was longer than that reported in the literature. We found that the traditional Chinese concepts of patients are the main obstacles. They believe that surgery could cause great damage to their bodies, and they could not recover in a short time. Thus, they worried about their safety after discharge from hospital. Therefore, preoperative patient instruction and education is crucial to the outcome of FTS<sup>[36]</sup>. It will let the patients fully understand the safety, efficacy and benefits of FTS, and guarantee the compliance of patients with medical and FTS protocols.

From the view of the doctors, concern about anastomotic leakage was the main reason which affected early discharge. A series of studies showed that the FTS protocol did not increase the incidence of anastomotic leakage<sup>[37]</sup>, and revealed that education of FTS concepts was also very critical for doctors. Compliance with the FTS protocol is the main factor influencing the outcome of FTS<sup>[38]</sup>. Thus, we established a study group made up of a researcher, surgeons, anesthesiologists and nurses. We periodically conducted meetings with all staff about the details of FTS, in order to ensure the quality of the study.

The limitation of our present study was the inadequate adherence to the FTS protocol. Epidural analgesia was critical for FTS. Intraoperative application and postoperative use of epidural analgesia could block sympathetic activation to outside stimulation, inhibit hormone secretions of the hypothalamic-pituitary-adrenal axis, and finally attenuate responses to stress<sup>[39]</sup>. In our present study, tracheal intubation and general anesthesia were applied in both groups, which may partially decrease the

efficacy of FTS.

The present study indicates that FTS could promote postoperative recovery, decrease the rate of complications, shorten the duration of hospital stay, and reduce the cost of hospitalization. Our data indicate that FTS is a safe and efficient perioperative management strategy in patients undergoing radical total gastrectomy. Along with the further understanding of stress and development of FTS perioperative care, FTS could probably be safely applied in critically ill patients and emergency surgery, and major operations such as tumor resection may become day procedures in the near future.

## COMMENTS

### Background

Fast-track surgery (FTS) is a promising comprehensive program for surgical patients in elective surgery. In recent years, FTS has been applied in several surgical diseases, include radical prostatectomy, cardiac surgery, total knee replacement, cesarean section, and coronary artery bypass grafting. It has also been used for specific procedures in children and elderly. The value of FTS in radical distal gastrectomy has been demonstrated recently, but the safety and efficacy of FTS in radical total gastrectomy still requires further evaluation.

### Research frontiers

The value of FTS in radical distal gastrectomy has been demonstrated recently. Chen *et al* evaluate the safety and effectiveness of fast-track surgery combined with laparoscopy-assisted radical distal gastrectomy for gastric cancer. They found that a combination of FTS and laparoscopy-assisted radical distal gastrectomy in gastric cancer is safe, feasible, and efficient and can improve nutritional status, lessen postoperative stress, and accelerate postoperative rehabilitation.

### Innovations and breakthroughs

The present study showed that the FTS protocol was feasible for perioperative care of gastric cancer patients. Compared with conventional care, FTS could shorten the duration of flatus and defecation, accelerate the decrease in white blood cell count, decrease postoperative complications, shorten the duration of postoperative stay, reduce the cost of hospitalization, and eventually promote postoperative recovery of patients.

### Applications

The data indicate that FTS is a safe and efficient perioperative management strategy in patients undergoing radical total gastrectomy. Along with further understanding of stress, and development of FTS perioperative care, FTS could probably be safely applied in critically ill patients and emergency surgery, and major operations such as tumor resection may become day procedures in the near future.

### Terminology

FTS: Fast-track surgery, initiated by the Danish surgeon H Kehlet in the field of elective colorectal surgery in the 1990s, is a promising comprehensive program for surgical patients in elective surgery; the visual analogue scale is a psychometric response scale which can be used in questionnaires. It is a measurement instrument for subjective characteristics that cannot be directly measured.

### Peer review

This was a good study in which the authors indicates that FTS could promote postoperative recovery, decrease rate of complications, shorten duration of hospital stay, and reduce the cost of hospitalization. However, the author should think about the reason of more pneumonia in conventional care group although it is not significant.

### Abstract

**AIM:** To analyze the prognostic factors of 5-year survival and 10-year survival in hepatocellular carcinoma (HCC) patients, and to explore the reasons for long-term survival and provide choice of treatment modalities for HCC patients.

**METHODS:** From January 1990 to October 2012, 8450 HCC patients were included in a prospective database compiled by the Information Center after hospital admission. Long-term surviving patients were included in a 10-year survival group (520 patients) and

a 5-year survival group (1516 patients) for analysis. The long-term survival of HCC patients was defined as the survival of 5 years or longer. Clinical and biologic variables were assessed using univariate and multivariate analyses. The survival of patients was evaluated by follow-up data.

**RESULTS:** The long-term survival of HCC patients was associated with the number of lesions, liver cirrhosis and Child-Pugh classification. It was not found to be associated with tumor diameter, histological stage, and pretreatment level of serum  $\alpha$ -fetoprotein. The differences in clinical factors between the 5-year survival and the 10-year survival were found to be the number of lesions, liver cirrhosis, Child-Pugh classification, and time elapsed until first recurrence or metastasis. The survival period of different treatment modalities in the patients who survived for 5 years and 10 years showed significant differences: (in order of significance) surgery alone > surgery-transcatheter arterial chemoembolization (TACE) > TACE-radiofrequency ablation (RFA) > TACE alone > surgery-TACE-RFA. The 10-year survival of HCC patients was not associated with the choice of treatment modality.

**CONCLUSION:** This retrospective study elucidated survival outcomes, prognostic factors affecting survival and treatment modalities in HCC patients.

**Key words:** Hepatocellular carcinoma; Surgery; Radiofrequency ablation; Transcatheter arterial chemoembolization; Statistical analysis; Clinical study

**Core tip:** This manuscript was a retrospective analysis and it revealed that the long-term survival of hepatocellular carcinoma (HCC) patients was associated with the number of lesions, liver cirrhosis and Child-Pugh classification, while tumor diameter, histological stage, and pretreatment level of serum  $\alpha$ -fetoprotein

were not related. Conditions for long-term survival of HCC patients were: age over 50 years, no cirrhosis, a uninodular lesion, no vessel invasion, tumor-node-metastasis stage I or II, Child-Pugh classification Class A, and appropriate treatment. The best treatment modality for more than 10 years survival compared with 5 years survival were surgery alone > surgery-transcatheter arterial chemoembolization (TACE) > TACE-radiofrequency ablation (RFA) > TACE alone > surgery-TACE-RFA.

Hepatocellular carcinoma: Clinical study of long-term survival and choice of treatment modalities. *World J Gastroenterol* 2013; 19(23): 3649-3657 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i23/3649.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i23.3649>

## INTRODUCTION

Hepatocellular carcinoma (HCC) is the fifth most common cancer worldwide. The prognostic factors of primary HCC have been studied by many researchers worldwide. Several reports conducted in the 1990s in both Eastern and Western centers have documented a 5-year overall survival rate of 26% to 44% after HCC resection<sup>[1-5]</sup>. Studies performed from 1975 to the present<sup>[6-15]</sup> showed that age, gender, metastasis, bilirubin levels, ascites, tumor thrombus of the portal vein, neoplasm staging, Child-Pugh classification, and serum levels of  $\gamma$ -glutamyltransferase (GGT), alkaline phosphatase, and lactate dehydrogenase may all have significant effects on the prognosis of HCC patients.

There are many different modes of HCC treatment and types of primary HCC. The effects of treatment and survival rate have seen only limited improvements<sup>[16-21]</sup>. Curative surgical therapies have shown the best long-term survival rates. However, most patients do not meet the selection criteria for these treatments. Surgical resection is not available to HCC patients with severe liver cirrhosis, multiple lesions located in different parts of the liver, or lesions located near a large vein or the junctions of large portal veins<sup>[22,23]</sup>. For this reason, effective, minimally invasive therapeutic options are essential to improving the prognosis in HCC patients. Existing minimally invasive local treatments for primary HCC include radiofrequency ablation (RFA), microwave ablation, cryoablation, transcatheter arterial chemoembolization (TACE), percutaneous ethanol injection therapy, and high-intensity focused ultrasound ablation. In recent years, preliminary clinical trials have suggested that targeted drugs may have certain curative effects in the treatment of HCC<sup>[24-26]</sup>.

This study discusses the factors relevant to duration of survival in these primary HCC patients. The method of treatment, the tumor's general prognostic factors, and the tumor's own characteristics were found to determine duration of survival. Therefore, the purpose of the pres-

ent study was to analyze and compare the prognostic factors between 5-year survival and 10-year survival groups, to explore the clinical reasons for long-term survival and the choice of treatment modalities for HCC patients.

## MATERIALS AND METHODS

### Patients

From January 1990 to October 2012, 8450 HCC patients from Sun Yat-Sen University Cancer Center, First Affiliated Hospital of Jinan University, and Guangdong General Hospital were included in a prospective database after hospital admission. Long-term surviving patients were those who survived more than 5 years and they were identified and included in a 10-year survival group (520 patients) and 5-year survival group (1516 patients) for analysis. The long-term survival of HCC patients was defined as survival of 5 years or longer. This study was approved by the internal review board and ethics committee of the hospital. Informed consent was not required because of the retrospective and anonymous nature of the study, although these data were derived from prospective statistics for inpatients.

The diagnosis of HCC was confirmed in all patients either by histopathological findings or by the appearance of a liver tumor with arterial hypervascularization on contrast-enhanced computed tomography (CT) or magnetic resonance imaging (MRI) with a serum  $\alpha$ -fetoprotein (AFP) value exceeding 400 ng/mL. Liver cirrhosis was diagnosed by histological or clinical features and liver function was evaluated according to the Child-Pugh score. All patients were evaluated according to European Association for the Study of the Liver criteria up to 2005<sup>[27]</sup>, and to American Association for the Study of Liver Diseases criteria from January 2006<sup>[28]</sup>. We reviewed the patients' records for demographic parameters (age, sex), hepatitis B serology, Child-Pugh stage, AFP, tumor morphology and extension, including maximum diameter, tumor number, and vessel invasion determined by imaging studies (abdominal arteriography, CT during hepatic arteriography, and the portal phase of superior mesenteric arteriography), treatment modality, complications after treatment, hospital mortality, and time of recurrence. Patient characteristics of both survival groups are shown in Table 1.

### Treatment

**Surgical resection:** Surgery was performed with patients under general anesthesia using a right subcostal incision with a midline extension with the aid of intraoperative ultrasound. Anatomic resection was performed using a target resection margin of at least 1 cm. Pringle's maneuver was routinely used with a clamp time of 10 min and an unclamp time of 5 min. Suturing and fibrin glue were used to establish hemostasis on the surface of the liver<sup>[29]</sup>.

**TACE:** Chemoembolization involves the delivery of chemotherapeutic agents to liver tumors through the hepatic artery. Seldinger's method was used to insert a catheter

**Table 1** Baseline characteristics of the patients

| Characteristics                | 5-yr survival group                    | 10-yr survival group                   | P value |

<sup>1</sup>There is significant difference within each group. RFA: Radiofrequency ablation; TACE: Transcatheter arterial chemoembolization; AST: Aspartate aminotransferase; ALT: Alanine aminotransferase; HBsAg: Hepatitis B surface antigen.

through the femoral artery. Angiography of the celiac and superior mesenteric arteries was routinely performed to determine the tumor blood supply, distribution of hepatic arteries, and collateral circulation routes<sup>[30]</sup>. The tumor's primary artery was selected for catheter placement. Patients were given a standard drug regimen of emulsified THP (40-60 mg), DDP (20-60 mg) and lipiodol (5-40

mL) through the hepatic artery.

**Radiofrequency ablation:** The size and position of the tumors and the position and direction of the needle were confirmed by CT. RFA treatment was performed with patients under general anesthesia to prevent the patient from experiencing pain and to ensure immobilization. CT was used to guide the insertion of a radiofrequency electrode into each tumor. The diameter of the needle was adjusted for tumor size. The range of ablation was extended 0.5-1 cm into the non-cancerous tissue to ensure complete coverage<sup>[31]</sup>. Patients underwent enhanced CT scans 4 wk after TACE treatment to determine the distribution of lipiodol and the status of any remaining tumor. If living tumor tissue was found, RFA was repeated<sup>[32]</sup>.

### Follow-up and recurrence

Dual-phase spiral CT was performed 4 wk after treatment and every 2 mo thereafter for the next 2 years. Each of these follow-up visits included blood tests, including liver function tests and serum AFP tests. Residual viable tumor tissue was considered present upon the first CT assessment at 4 wk after treatment if enhancement areas were seen within the tumor at either the arterial or the portal venous phase. MRI was performed if CT results were unclear on whether residual viable tumor tissue was present. Additional treatment with RFA was given in these cases. If residual viable tumor was still present after repeated treatments, patients were given TACE<sup>[33]</sup>.

The level of serum AFP and CT scans were regularly assessed to determine tumor recurrence. Recurrence was defined as the presence of hypervascular or early wash-out tumors on dynamic CT, MRI or angiography, or by a diagnosis of HCC by a radiologist. In this way, the diagnosis of recurrence was based on typical imaging findings on CT or arteriography, and, if necessary, percutaneous fine-needle aspiration cytology. Treatment modalities for HCC included surgery alone, TACE alone, surgery-TACE, TACE-RFA and surgery-TACE-RFA.

### Statistical analysis

Patient characteristics are presented as mean ± SD.  $\chi^2$  tests and the Wilcoxon rank sum test were used to compare the characteristics of patients in the 5-year and 10-year survival groups. Overall survival was calculated by the Kaplan-Meier method from the beginning of treatment. Death from any cause was considered an event. The differences in survival between groups were compared by the generalized Wilcoxon's test. A stratified Cox's proportional hazards regression model was used for multivariate analysis of prognostic parameters identified by the survival analysis. SPSS statistical software, version SPSS 19.0 for Windows (IBM Corp., Armonk, NY, United States), was used. A *P* value < 0.05 was considered significant.

## RESULTS

### Patient characteristics and clinical features

As shown in Table 1, there were 520 patients in the 10-

**Table 2 Comparison of treatment modalities between 5-year survival group and 10-year survival group for hepatocellular carcinoma**

| Treatment modalities by tumor type   | 5-yr survival group       | 10-yr survival group      | P value between groups | P value between overall groups |

AFP: α-fetoprotein; TACE: Transcatheter arterial chemoembolization; RFA: Radiofrequency ablation; HCC: Hepatocellular carcinoma.

year survival group. Single lesions were present in 93.1% and multiple lesions in 6.7%. Lesions located in only one lobe of the liver were present in 93.1%, and lesions located in two lobes were present in 0.9%. A portal vein tumor thrombus was present in 2.3%. Child-Pugh classification class A applied to 97.1% and class B to 2.9%. tumor-node-metastasis (TNM) stage I or II applied to 98.5% patients. Among the 1516 patients who survived for 5 years, 84.8% had one lesion, 13.6% had two lesions, 1.6% had three lesions, 98.6% had lesions located in one lobe of the liver, 1.4% had lesions located in the two lobes, 1.1% had vessel invasion, 96.7% had Child-Pugh classification class A, 3.3% had class B, and 97.8% had TNM stage I or II. In this way, the survival period of both groups showed some correlation with the number of tumor lesions and liver cirrhosis. No statistically significant differences were observed with respect to maximum

tumor diameter in either group. In the 5-year group, vessel invasion appeared in 1.1% of patients. In the 10-year group, vessel invasion appeared in 2.1% of patients. This suggests that patients with vessel invasion seldom survived for 5 years. In the 10-year survival group, 97.1% of patients were described as Child-Pugh classification class A and 2.9% as class B. TNM stage I and II was applied to 98.5% of patients. In the 5-year survival group, 96.7% of patients were described as Child-Pugh classification class A, 3.3% as class B, and 97.8% as TNM stage I or II. The survival periods of both groups may be related to Child-Pugh classification class A and TNM stage I or II.

**Treatment modalities**

As shown in Table 2, treatment modalities such as surgery alone, TACE alone, surgery-TACE, surgery-TACE-RFA, and TACE-RFA, showed no statistically significant

**Table 3 Comparison of treatment efficacy between the 5-year survival group and 10-year survival group for hepatocellular carcinoma**

| Characteristics  | 5-yr survival group       | P value | 10-yr survival group     | P value | P value between groups |
|--|---------------------------|---------|--------------------------|---------|------------------------|

RFA: Radiofrequency ablation; TACE: Transcatheter arterial chemoembolization; AST: Aspartate aminotransferase; ALT: Alanine aminotransferase.

differences between the 5-year survival group and 10-year survival group, but there were significant differences in treatment modalities of uninodular lesions between the 5-year survival group and 10-year survival group. Surgery alone, TACE alone, surgery-TACE, TACE-RFA and surgery-TACE-RFA showed no statistical differences in the maximum diameter of the tumor for the two groups. The survival period had no relationship with tumor size. Similarly, the survival period had no relationship with the level of the serum AFP in patients treated with different modalities. The patients of the two groups showed statistically significant differences in survival period depending on the different treatment modalities, but only among patients with only one lesion. The patients of the groups showed statistically significant differences in survival period depending on liver cirrhosis. Survival period did not differ significantly across the 5-year survival and 10-year survival groups in patients multiple lesions. In short, different treatment modalities were found to have an effect on patients with only one lesion, and no effect on patients with multiple lesions.

### Effects of initial treatment

As shown in Table 3, serum levels of AFP and GGT differed significantly before and after the first treatment, but the levels of serum total bilirubin, aspartate aminotransferase, and alanine aminotransferase showed no statistically significant differences regardless of whether the first treatment was surgery or TACE and regardless of whether the patient survived for 5 or 10 years. The level of pre-surgery serum AFP showed statistically significant

differences between 5-year survival and 10-year survival groups. After the first surgery, the two groups showed no statistically significant differences from each other. The time of the first recurrence or metastasis showed significant differences between the 5-year and 10-year survival groups. Different treatments for each treatment group also showed statistically significant differences in the time of the first recurrence or metastasis: (in order of significance) surgery alone > surgery-TACE > TACE alone > surgery-TACE-RFA.

### Prognostic analysis

The influence of patient and tumor related factors on overall survival are shown in Table 4. Analysis of patients who survived for 5 years or longer showed that survival rates differed significantly with age, Child-Pugh classification, vessel invasion, liver cirrhosis, TNM stage, treatment method, and number of tumors. Statistical results also showed that, among patients who survived 5 years or longer, no significant differences could be attributed to sex, diameter of the largest tumor, or to pretreatment serum levels of AFP. Analysis of 10 years survival showed statistically significant differences in survival rates with respect to vessel invasion, number of tumors and Child-Pugh classification. No significant differences could be attributed to age, sex, tumor diameter, or pretreatment level of serum AFP. Multivariate analysis of patients who lived 5 years or longer showed survival rates to be related to age, vessel invasion, liver cirrhosis, TNM stage, Child-Pugh classification, treatment method, and number of tumors. Multivariate analysis of patients who survived

AFP:  $\alpha$ -fetoprotein; TNM: Tumor-node-metastasis.

10 years or longer showed survival rates to be related to Child-Pugh classification, liver cirrhosis and to the number of tumors.

### Overall survival

Table 1 show that patients with only one lesion, 2 lesions, or 3 lesions showed statistically significant differences with respect to duration of survival period in both groups. Patients who had only one lesion survived significantly longer than other patients. Patients who had 2 lesions seldom survived 5 years. Patients with 3 lesions seldom survived 5 years. Patients who survived more than 5 years were associated with more influencing factors than those in the 10-year survival group. Factors associated with long-term survival among HCC patients included age over 50 years, single rather than multiple lesions, no vessel invasion, TNM stage I or II, Child-Pugh classification Class A, and only 1-3 rounds of treatment. Long-term survival of patients for HCC was found to be related to the number of lesions, liver cirrhosis and methods of treatment, not to tumor diameter or level of serum AFP.

Statistical results showed that, among patients who survived 10 years or longer, no significant differences could be obtained from the different treatment modalities ( $P = 0.202$ ). The survival period of different treatment modalities in the patients who survived between 5 years and 10 years showed statistically significant differences: (in order of significance) surgery alone > surgery-TACE > TACE-RFA > TACE alone > surgery-TACE-RFA (Figure 1).

Therefore, the 10-year survival of HCC patients was not associated with the choice of initial treatment modality. However, different treatment modalities had a significant effect on the survival of HCC patients who survived between 5 and 10 years (Table 5).

## DISCUSSION

There is a variety of treatment methods and models of HCC. Surgical resection is the preferred treatment for HCC. TACE, however, has broader indications. RFA, microwave ablation, cryoablation, radiation therapy, and high intensity focused ultrasound therapy have been widely used in clinical treatment<sup>[34-37]</sup>. When HCC is diagnosed early, the curative effects enjoyed by some HCC patients improve, as does the prognosis. However, improvements to the survival rate are very limited and the prognosis remains poor. By evaluating criteria to more accurately predict prognosis, patients at high risk of recurrence would be identified more easily and effective prevention and control measures could be implemented.

The results of this study show the 5-year and 10-year survival groups to have the following common features: lesions located in only one lobe of the liver, single lesions, no vessel invasion, no liver cirrhosis, TNM stage I or II, Child-Pugh classification class A, and 1 to 3 treatments. Long-term survival factors are assessed by using univariate and multivariate Cox proportional hazard regression analyses. Multivariate analysis indicated that survival for more than 10 years was associated with treatment modal-

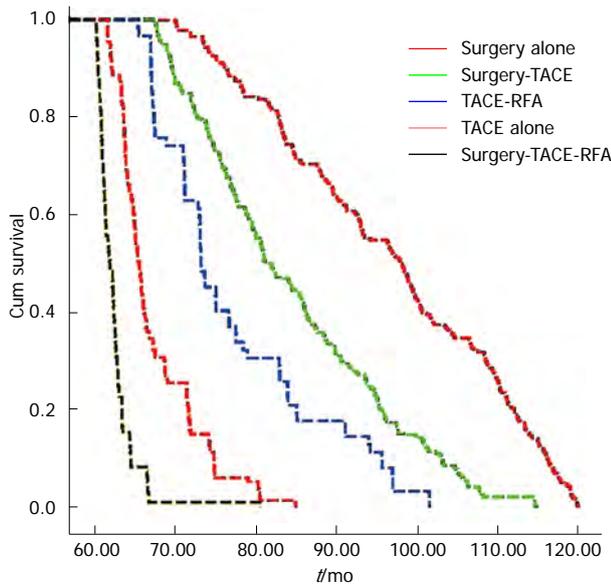

Figure 1 Kaplan-Meier curve shows overall survival rates of different treatment modalities in hepatocellular carcinoma patients who survived between 5 years and 10 years. Different treatment models showed statistically significant differences in the survival period: surgery alone > surgery-transcatheter arterial chemoembolization (TACE) > TACE-radiofrequency ablation (RFA) > TACE alone > surgery-TACE-RFA.

ity, number of lesions, vessel invasion, age, and Child-Pugh classification. Survival for more than 5 years was associated with number of lesions, no liver cirrhosis and treatment modalities. The independent prognostic factors of both groups included method of treatment, liver cirrhosis and number of lesions. The diameter of the largest tumor and serum level of AFP were not associated with survival period in either group.

Patients with multiple lesions or lesions located in more than one lobe of the liver showed poorer prognosis and did not always survive 5 years. The treatment modalities showed that the most effective type of treatment was surgery. The three types of combination therapy were used in 412/520 (79.2%) of the patients who survived for 10 years or longer and in 1244/1516 (82.1%) of the patients who survived for 5 years or longer. The survival period for different treatment modalities in both groups also showed statistically significant differences: surgery alone > surgery-TACE > TACE-RFA > TACE alone > surgery-TACE-RFA. When a single lesion is present and that lesion can be removed by surgery, surgical resection should be the preferred method. Surgical resection is the preferred treatment for HCC. TACE should be performed in the treatment of the relapse or metastatic lesions after surgical resection.

The initial effects of treatment in both 10-year and 5-year survival groups showed serum levels of AFP and GGT to be significantly different before and after the first treatment regardless of whether this first treatment was surgery or TACE. The level of serum AFP showed statistically significant differences between 10-year group and 5-year survival groups before the first surgical operation, but no statistically significant differences between

the two groups were detected after the first surgical operation. This suggests that the serum level of AFP decreased quickly after surgical resection in the 10-year survival group, an ideal curative effect. With all five kinds of treatment, surgery alone, surgery-TACE, TACE-RFA, TACE alone, or surgery-TACE-RFA, the first relapse or metastasis showed statistically significant differences between the 5-year and 10-year survival groups. The first relapse or metastasis tended to occur later in the 10-year survival group than in the 5-year survival group. The time to tumor recurrence or metastasis was found to significantly affect the patients' survival periods.

The prognosis of HCC here showed heterogeneity caused by the interactions between many factors and by the interplay between the tumor and the rest of the body. Factors that affect prognosis have been found to be different, but this may be because the studies evaluating them had different goals and factors<sup>[38-40]</sup>. Lau *et al*<sup>[41]</sup> reported that the factors that affect the curative effect of mid-to-late HCC are tumor type, portal vein tumor thrombus, treatment method, and hepatic function. Yamamoto *et al*<sup>[42]</sup> found that portal vein tumor thrombus, tumor type, traces of iodized oil, and hepatic function all influence the survival and prognosis of the HCC patients.

This study evaluated patient age, gender, TNM stage, Child-Pugh classification, portal vein tumor thrombus, serum AFP level, number of tumor lesions, tumor diameter, and treatment method, all of which may have some relationship with prognosis. The independent prognostic survival factors of both the patients who survived more than 10 years and those who survived 5 years can be said to be related to treatment method and to the number of lesions. The number of lesions was found to be a common risk factor in the 10-year and 5-year survival groups. One possible reason for this may be that most of the intrahepatic tumor lesions had undergone intrahepatic metastasis. Multiple lesions tended to be caused by intrahepatic metastasis. Even when tumors were completely removed, subclinical tumor lesions remained in the liver and the tumor cells may have entered the bloodstream. The survival period showed obvious differences in patients who received different treatments. The treatments, in decreasing order of favorability, were as follows: surgery alone > surgery-TACE > TACE-RFA > TACE alone > surgery-TACE-RFA. The patients who survived more than 10 years were found to have more influencing factors than those in the 5-year group. The patients who were more than 50 years old, who had no portal vein tumor thrombus, who had Child-Pugh class A tumors, who had only one lesion, and who underwent appropriate treatment tended to live longer than other patients.

## ACKNOWLEDGMENTS

Thanks to all patients who took part in this clinical research. We thank all the members of Department of Medical Imaging and Interventional Radiology of Cancer Center for discussion and comments.

## COMMENTS

**Background**

Hepatocellular carcinoma (HCC) is one of the most common digestive malignancies cancer, which do serious threat to the people's life and health. Therefore, it has been studied by many scholars, but people still do not know what is the reason for the long-term survival and whether it has an optimal treatment.

**Research frontiers**

There are various prognosis factors for HCC, some researchers suggesting that age, sex and  $\alpha$ -fetoprotein (AFP) level play a critical role, while others suggest that the long-term survival of HCC is related to treatment modality or the biological nature of the tumor.

**Innovations and breakthroughs**

This manuscript reveals the long-term survival of HCC patients was associated with the number of lesions, liver cirrhosis and Child-Pugh classification. It was not found to be associated with tumor diameter, histological stage, and pretreatment level of serum AFP. Conditions associated with long-term survival of HCC patients were: age over 50 years, no cirrhosis, uninodular lesion, no vessel invasion, tumor-node-metastasis stage I or II, Child-Pugh classification class A, and appropriate treatment. The clinical reasons for the differences between the 5-year survival and the 10-year survival were found to be the number of lesions, liver cirrhosis, Child-Pugh classification, and time elapsed until first recurrence or metastasis for HCC. The survival period of different treatment modalities in the patients who survived between 5 years and 10 years showed statistically significant differences: surgery alone > surgery-transcatheter arterial chemoembolization (TACE) > TACE-radiofrequency ablation (RFA) > TACE alone > surgery-TACE-RFA. The 10-year survival of HCC patients was not associated with the choice of treatment modality.

**Applications**

This study retrospectively studied HCC patients treated in the past 20 years, and the ultimate conclusion is that the long-term survival of HCC patients was associated with the number of lesions, liver cirrhosis and Child-Pugh classification, patients who survived for 5 and 10 years showed statistically significant differences in types of treatments. The 10-year survival of HCC patients was not associated with the choice of treatment modality. The results can provide information on the treatment choice of HCC patients.

**Terminology**

TACE is short for transhepatic arterial chemotherapy and embolization, used in the treatment of HCC patients especially for the terminal cancer patients; RFA is a treatment method for HCC patients which uses a RFA needle to send high radiofrequency waves to heat the tumor and cause cell degeneration and necrosis. It is widely used for small HCC tumor (diameter < 3 cm).

**Peer review**

This study was performed as a retrospective analysis of prognostic factors including individual therapy for patients with HCC who survived for 5 years or longer and 10 years or longer. A large population of more than 2000 patients was selected from over 8000 HCC patients, and thus this study is likely to give interesting and reliable data.

### Abstract

**AIM:** To investigate the expression patterns of long non-coding RNAs (lncRNAs) in gastric cancer.

**METHODS:** Two publicly available human exon arrays for gastric cancer and data for the corresponding normal tissue were downloaded from the Gene Expression Omnibus (GEO). We re-annotated the probes of the human exon arrays and retained the probes uniquely mapping to lncRNAs at the gene level. lncRNA expression profiles were generated by using robust multi-array average method in affymetrix power tools. The normalized data were then analyzed with a Bioconductor package linear models for microarray data and genes with adjusted *P*-values below 0.01 were considered differentially expressed. An independent data set was used to validate the results.

**RESULTS:** With the computational pipeline established to re-annotate over 6.5 million probes of the Affymetrix Human Exon 1.0 ST array, we identified 136053 probes

uniquely mapping to lncRNAs at the gene level. These probes correspond to 9294 lncRNAs, covering nearly 76% of the GENCODE lncRNA data set. By analyzing GSE27342 consisting of 80 paired gastric cancer and normal adjacent tissue samples, we identified 88 lncRNAs that were differentially expressed in gastric cancer, some of which have been reported to play a role in cancer, such as LINC00152, taurine upregulated 1, urothelial cancer associated 1, Pvt1 oncogene, small nucleolar RNA host gene 1 and LINC00261. In the validation data set GSE33335, 59% of these differentially expressed lncRNAs showed significant expression changes (adjusted *P*-value < 0.01) with the same direction.

**CONCLUSION:** We identified a set of lncRNAs differentially expressed in gastric cancer, providing useful information for discovery of new biomarkers and therapeutic targets in gastric cancer.

non-coding RNA expression profiles in gastric cancer. *World J Gastroenterol* 2013; 19(23): 3658-3664 Available from: URL: <http://www.wjnet.com/1007-9327/full/v19/i23/3658.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i23.3658>

## INTRODUCTION

Over the last decade, advances in genome-wide analysis of gene expression have revealed far more genomic transcription than previously anticipated, with the majority of the genome being transcribed into non-coding RNAs (ncRNAs)<sup>[1,2]</sup>. Much attention has focused on microRNAs (miRNAs), one class of small non-coding RNAs. MiRNAs are involved in specific regulation of both protein-coding and putatively non-coding genes by post-transcriptional silencing or infrequently by activation<sup>[3-5]</sup>.

More recently, long non-coding RNAs (lncRNAs), generally defined as having a size greater than 200 nucleotides, have risen to prominence with important roles in a broad range of biological processes. lncRNAs regulate gene expression at the level of post-transcriptional processing such as protein synthesis, RNA maturation, and transport. They also exert their effects in transcriptional gene silencing through the regulation of chromatin structure<sup>[6,7]</sup>. Dysregulation of lncRNAs is associated with many human diseases, including various types of cancers<sup>[8]</sup>. The well-studied lncRNA HOTAIR, for example, was found to be highly upregulated in both primary and metastatic breast tumors, and its expression level in primary tumors was a powerful predictor of eventual metastasis and death<sup>[9]</sup>. However, lncRNA expression patterns and their biological function in gastric cancer remain unknown.

In this study, we identified a set of lncRNAs that were differentially expressed in gastric cancer by analyzing publicly available data sets from the gene expression omnibus (GEO).

## MATERIALS AND METHODS

### Microarray data

Human exon arrays for gastric cancer and normal adjacent tissue were downloaded from the GEO. Two data sets were included: GSE27342 and GSE33335. GSE27342 consisted of 80 paired gastric cancer and normal adjacent tissue, including 4 stage I, 7 stage II, 54 stage III and 7 stage IV<sup>[10,11]</sup>. All samples were taken from three hospitals affiliated with Jilin University College of Medicine and Jilin Provincial Cancer Hospital, Changchun, China. GSE33335 consisted of 25 paired gastric cancer and normal adjacent tissue obtained from the tissue bank of Shanghai Biochip Center, Shanghai, China<sup>[12,13]</sup>. Three raw CEL files failed to be normalized and were excluded from our analysis, leaving 22 paired gastric cancer and normal adjacent tissue. GSE27342 was used as an experimental set to discover differentially expressed lncRNAs in gastric cancer while GSE33335 was used as a

validation set.

### Probe re-annotation pipeline

The sequences of protein-coding transcripts were retrieved from Ensembl release 67<sup>[14]</sup>, UCSC<sup>[15]</sup> and RefSeq release 54<sup>[16]</sup> in July 2012. Specifically, the protein-coding transcripts are a pool of transcripts with gene\_type as “protein\_coding” in Ensembl, transcripts with category as “coding” in UCSC and transcripts with an identifier beginning with NM\_ in RefSeq. The sequences of non-coding transcripts were compiled from Ensembl through Biomart. The probe sequences of the human exon array were downloaded from the Affymetrix website ([http://www.affymetrix.com/Auth/analysis/downloads/na25/wtexon/HuEx-1\\_0-st-v2.probe.tab.zip](http://www.affymetrix.com/Auth/analysis/downloads/na25/wtexon/HuEx-1_0-st-v2.probe.tab.zip)) and aligned to the sequences of protein-coding and non-coding transcripts using BLAST-2.2.26+<sup>[17]</sup>. The alignment results were then filtered by the following steps: (1) probes perfectly matched to a transcript were retained; (2) probes mapped to non-coding transcripts only were retained; (3) probes mapped to unique genes were retained; (4) probes mapped to known lncRNAs (genes annotated with processed\_transcript, lincRNA, antisense, non\_coding, sense\_intronic, ncrna\_host, sense\_overlapping and 3prime\_overlapping\_ncrna) were retained; and (5) genes with less than 3 probes were removed.

A new PGF file covering the re-annotated probe-lncRNA relationships was created. The official CLF file HuEx-1\_0-st-v2.r2.clf was downloaded from the Affymetrix website ([http://www.affymetrix.com/Auth/support/downloads/library\\_files/HuEx-1\\_0-st-v2.r2.zip](http://www.affymetrix.com/Auth/support/downloads/library_files/HuEx-1_0-st-v2.r2.zip)).

### Data analysis

Gene expression profiles were summarized by applying robust multi-array average (RMA)<sup>[18]</sup> normalization as implemented in affymetrix power tools (1.14.4 package apt-probeset-summarize), using the newly-created PGF file and the official CLF file.

The normalized data were analyzed with a Bioconductor package linear models for microarray data (LIMMA), a modified *t*-test incorporating the Benjamini-Hochberg multiple hypotheses correction technique<sup>[19]</sup>. Genes with adjusted *P*-values below 0.01 were considered differentially expressed. The heatmap of differentially expressed genes was generated using BRB-Array Tools Version 4.3.0 Beta 1 (<http://linus.nci.nih.gov/BRB-ArrayTools.html>)<sup>[20]</sup>.

## RESULTS

### Re-annotation of exon array probes

A computational pipeline was established to re-annotate over 6.5 million probes of the Affymetrix Human Exon 1.0 ST array (Figure 1). There were 315255 probes perfectly matched to non-coding RNAs but not to any protein-coding transcript. These probes were mapped from transcript level to gene level and 278918 probes matched to one gene were retained. Probes mapping to

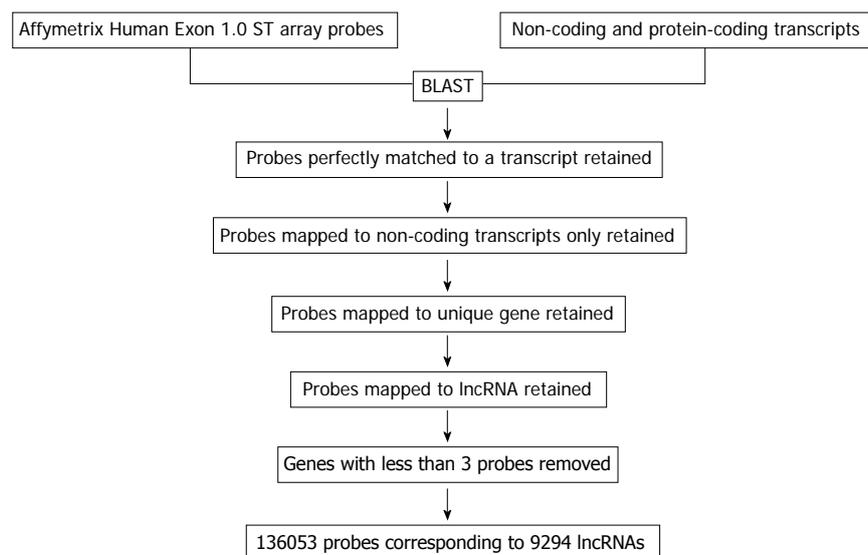

Figure 1 Computational pipeline for re-annotating the probes of the Affymetrix Human Exon 1.0 ST array. lncRNA: Long non-coding RNA.

short ncRNAs and pseudogenes were then discarded, leaving 136,533 probes mapping to lncRNAs, which were annotated with Ensembl (processed\_transcript, lincRNA, antisense, non\_coding, sense\_intronic, ncna\_host, sense\_overlapping and 3prime\_overlapping\_ncrna). To further increase accuracy, genes matched by less than three probes were discarded. Finally, we obtained 136053 probes uniquely mapping to lncRNAs at the gene level, corresponding to 9294 lncRNAs. The number of probes mapping to lncRNAs ranged from 3 to 257 and the average was 18.

### Identification of differentially expressed lncRNAs in gastric cancer

The CEL files were processed by Affymetrix Power Tools for background correction, normalization, and summarizations with RMA algorithm. Using LIMMA with an adjusted *P*-value of less than 0.01 as a threshold, we identified 88 lncRNAs that were differentially expressed in gastric cancer as compared to normal gastric tissue (Figure 2). The top 30 lncRNAs differentially expressed in gastric cancer are listed in Table 1. Of 88 differentially expressed lncRNAs, 71 lncRNAs were found to be upregulated and 17 to be downregulated. Most of these lncRNAs do not have an official Human Genome Nomenclature Committee symbol and their function is unknown. But some have been reported to play a role in cancer, including LINC00152<sup>[21]</sup>, taurine upregulated 1 (TUG1)<sup>[22]</sup>, urothelial cancer associated 1 (UCA1)<sup>[23,24]</sup>, Pvt1 oncogene (PVT1)<sup>[25]</sup>, small nucleolar RNA host gene 1 (SNHG1)<sup>[26]</sup>, and LINC00261<sup>[27]</sup>.

### Validation in an independent data set

To independently validate our results, we conducted the same analysis on GSE33335 and found that 59% of the differentially expressed lncRNAs identified by above analysis showed significant expression changes (adjusted *P* < 0.01) with the same direction. As shown in Figure 3,

the distribution of expression differentials between the experimental data set and the validation data set is significantly concordant, reflecting a high consistence in expression patterns of these genes among different sample sets.

## DISCUSSION

lncRNAs have comprehensive functions in biological processes through various mechanisms<sup>[6,7]</sup>. The expression patterns of lncRNAs are of great importance in the cancer field and are often investigated with tiling arrays<sup>[28,29]</sup>, RNA sequencing<sup>[30]</sup> or lncRNA-specific microarrays<sup>[31,32]</sup>, which are relatively expensive and inflexible. Recently, studies have suggested that lncRNA expression profiling may be achieved by mining existing microarray data because some probes uniquely mapping to lncRNAs are fortuitously represented on these arrays<sup>[33,34]</sup>. The Affymetrix Human Exon 1.0 ST array consists of over 6.5 million individual probes designed along the entire length of the gene as opposed to just the 3' end, providing a unique platform for mining lncRNA profiles<sup>[35,36]</sup>.

The lncRNA list used in this study was retrieved from Ensembl and is equivalent to the GENCODE lncRNA data set. This data set utilizes a combination of manual curation, computational analysis and targeted experimental approaches, and is the largest catalog of human lncRNAs to date<sup>[22]</sup>. To filter out potentially unrecognized probes mapping to protein-coding genes, we generated a merged known protein-coding gene list from RefSeq, UCSC and Ensembl. Still, some probes could potentially hybridize to other undiscovered transcripts or genes.

We identified 136053 probes from the Affymetrix Human Exon 1.0 ST array uniquely mapping to lncRNAs at the gene level. These probes correspond to 9294 lncRNAs, covering nearly 76% of the GENCODE lncRNA data set. This analysis revealed a set of lncRNAs that were differentially expressed between gastric cancer and normal gastric tissue, some of which have been pre-

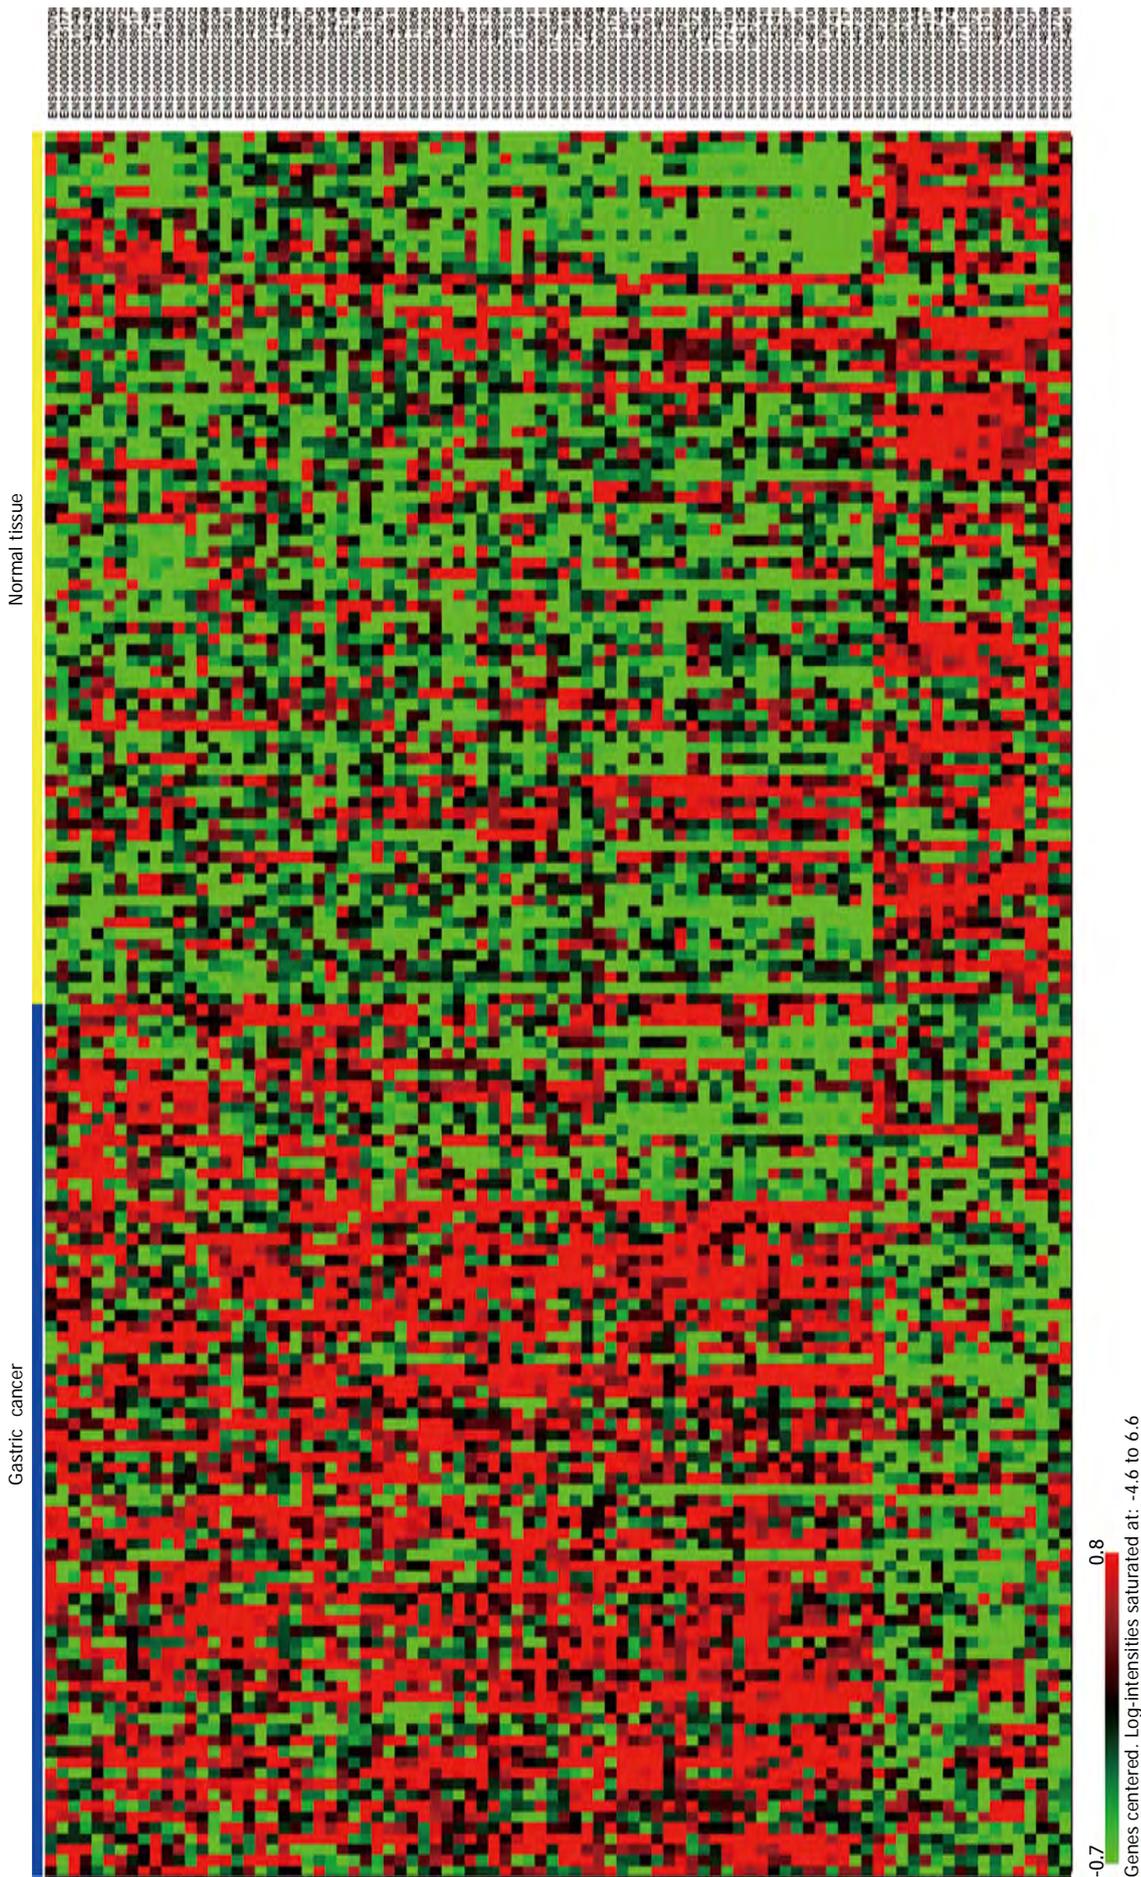

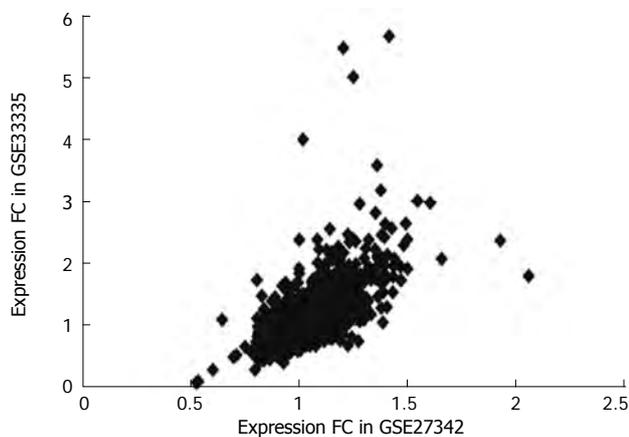

Figure 2 Clustering heatmap of 80 paired samples based on the 88 differentially expressed long non-coding RNAs. Each column represents one sample and each row represents one long non-coding RNA. Gene expression levels are indicated as follows: red, high expression; green, low expression.

viously reported in human cancers. For example, TUG1 is upregulated in bladder urothelial carcinoma and high TUG1 expression levels were associated with high grade and stage carcinomas<sup>[22]</sup>. Knockdown of TUG1 induced cell proliferation inhibition and apoptosis. Another candidate, UCA1, is dramatically upregulated in bladder cancer, suggesting it may be a very sensitive marker for bladder cancer<sup>[23]</sup>. Exogenous expression of UCA1 enhanced tumorigenicity, invasive potential, and drug resistance in

BLS-211 cells<sup>[24]</sup>. Also, PVT1, located in 8q24 and amplified and overexpressed in ovarian and breast cancer, increases cell proliferation and inhibits apoptosis<sup>[25]</sup>. In light of published results in other cancers, we hypothesize that these lncRNAs may play an important role in the development of gastric cancer and are potential candidates for new biomarkers and therapeutic targets in gastric cancer.

Recently, H19 was shown to be upregulated in gastric cancer and its overexpression contributes to proliferation of gastric cancer cells<sup>[37]</sup>. In our study, the fold change of H19 in gastric cancer versus normal tissue is 1.378 with an adjusted *P*-value of 0.043. Though the difference was not statistically significant with our threshold (an adjusted *P*-value less than 0.001), the trend is consistent with the early report. However, our analysis may miss some lncRNAs that other groups have demonstrated to be involved in the development of gastric cancer due to the different distributions of the patient populations in terms of age, gender and cancer subtype and stage. We are also interested in exploring which lncRNAs are differentially expressed in different stages of gastric cancer. Unfortunately, the majority of gastric cancer samples in GSE27342 are stage III (54/72), making it is challenging to identify differentially expressed lncRNAs based on the stage of disease.

In conclusion, we presented global lncRNA expression profiles in gastric cancer by mining existing microar-

ray data sets. We identified a set of lncRNAs that were differentially expressed in gastric cancer, revealing potential candidates for gastric cancer biomarkers, potentially improving diagnosis and therapy.

## COMMENTS

### Background

Long non-coding RNAs (lncRNAs) are an important class of regulatory transcripts involved in a variety of biological functions. While they are aberrantly expressed in many types of cancers, their expression patterns and biological functions in gastric cancer remain unknown.

### Research frontiers

lncRNA expression profiles are often investigated with tiling arrays, RNA sequencing or lncRNA-specific microarrays. Existing microarray data represent unique probes specific to lncRNAs, suggesting lncRNA expression profiling may be achieved by mining existing microarray data.

### Innovations and breakthroughs

The authors re-annotated the probes of the Affymetrix Human Exon 1.0 ST array and identified probes uniquely mapping to lncRNAs at the gene level. By analyzing a publicly available data set, a set of lncRNAs differentially expressed in gastric cancer were identified.

### Applications

The study results suggest lncRNAs play an important role in the development of gastric cancer and have the potential to be used as molecular diagnostic markers and therapeutic targets in gastric cancer.

### Terminology

lncRNAs are non-protein coding transcripts having a size greater than 200 nucleotides. This limit distinguishes lncRNAs from small non-coding RNAs such as microRNAs, short interfering RNAs, Piwi-interacting RNAs, and small nucleolar RNAs.

### Peer review

The authors investigated the expression patterns of lncRNAs in gastric cancer by mining existing microarray data sets. A set of lncRNAs differentially expressed in gastric cancer were identified. These results are interesting and suggest that lncRNAs may play an important role in gastric cancer.

### Abstract

**AIM:** To analyze the clinical characteristics of small bowel tumors detected by double-balloon enteroscopy (DBE) and to evaluate the diagnostic value of DBE in tumors.

**METHODS:** Four hundred and forty consecutive DBE examinations were performed in 400 patients (250 males and 150 females, mean age  $46.9 \pm 16.3$  years, range 14-86 years) between January 2007 and April 2012. Of these, 252 patients underwent the antegrade approach, and 188 patients underwent the retrograde approach. All the patients enrolled in our study were suspected of having small bowel diseases with a negative etiological diagnosis following other routine examinations, such as upper and lower gastrointestinal endoscopy and radiography tests. Data on tumors, such as clinical information, endoscopic findings and opera-

tion results, were retrospectively collected.

**RESULTS:** Small bowel tumors were diagnosed in 78 patients, of whom 67 were diagnosed using DBE, resulting in a diagnostic yield of 16.8% (67/400); the other 11 patients had negative DBE findings and were diagnosed through surgery or capsule endoscopy. Adenocarcinoma (29.5%, 23/78), gastrointestinal stromal tumor (24.4%, 19/78) and lymphoma (15.4%, 12/78) were the most common tumors. Among the 78 tumors, 60.3% (47/78) were located in the jejunum, and the overall number of malignant tumors was 74.4% (58/78). DBE examinations were frequently performed in patients with obscure gastrointestinal bleeding (47.4%) and abdominal pain (24.4%). The positive detection rate for DBE in the 78 patients with small bowel tumors was 85.9% (67/78), which was higher than that of a computed tomography scan (72.9%, 51/70). Based on the operation results, the accuracy rates of DBE for locating small bowel neoplasms, such as adenocarcinoma, gastrointestinal stromal tumor and lymphoma, were 94.4%, 100% and 100%, respectively. The positive biopsy rates for adenocarcinoma and lymphoma were 71.4% and 60%, respectively.

**CONCLUSION:** DBE is a useful diagnostic tool with high clinical practice value and should be considered the gold standard for the investigation of small bowel tumors.

**Key words:** Double-balloon enteroscopy; Small bowel tumors; Diagnosis; Capsule endoscopy; Endoscopic findings

**Core tip:** This was a single-center study with a large sample size of patients who underwent 440 consecutive double-balloon enteroscopy (DBE) examinations. The detection rates of various tumors, location of the

lesions, histological analyses and reasons for DBE were evaluated. Differences in the rates of detecting small bowel tumors between abdominal computed tomography, capsule endoscopy and DBE were compared. Based on the operation results, we analyzed the accuracy of DBE for locating neoplasms in addition to its positive biopsy rate. DBE's high clinical practice value indicated that it should be considered as the gold standard for small bowel tumors.

Double-balloon enteroscopy in small bowel tumors: A Chinese single-center study. *World J Gastroenterol* 2013; 19(23): 3665-3671 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i23/3665.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i23.3665>

## INTRODUCTION

Long considered to be a "black box" in the GI tract, the small bowel has been inaccessible to the endoscopist because of its anatomy, location and tortuosity. Small bowel tumors are relatively rare disorders and account for 3%-6% of all digestive neoplasms, most of which are malignant, and represent only 1.1%-2.4% of gastrointestinal malignancies<sup>[1]</sup>. This low incidence may be ascribed to its unique physiological features, which include an alkaline environment, fluidity, low bacterial count and a high level of IgA in the small intestine<sup>[2]</sup>. The diagnosis and management of small bowel tumors are formidable tasks for physicians.

The advent of capsule endoscopy (CE) and double-balloon enteroscopy (DBE) has completely changed our approach and launched a new era for small bowel diseases. DBE is a relatively noninvasive method, with a diagnostic yield of approximately 43%-80%<sup>[3,4]</sup>. Total enteroscopy can be achieved through antegrade and retrograde procedures. Compared with the use of CE in small bowel tumors, DBE has the particular advantage of biopsy and therapeutic potential, such as endoscopic stenting, balloon dilatation and localization before operation<sup>[5]</sup>. Additionally, DBE is not contraindicated in patients with stenosis of the intestine or an obstruction caused by neoplasms.

From January 2007 to April 2012, 440 examinations were performed in 400 patients, of whom 78 were diagnosed with small bowel tumors. However, little data involving large patient samples are available regarding the diagnostic value of DBE for small bowel tumors in China. In this context, our study was conducted to determine the characteristics of small bowel tumors in patients undergoing DBE and to evaluate the clinical value of DBE.

## MATERIALS AND METHODS

### Patients

A retrospective, descriptive study involving all patients

who were admitted to our hospital for DBE from January 2007 to April 2012 was conducted. Four hundred patients were enrolled in the present series (250 males and 150 females with a mean age of  $46.9 \pm 16.3$  years, range 14-86 years). The indications included the following: obscure gastrointestinal bleeding (OGIB) in 149 cases, abdominal pain in 123 cases, chronic diarrhea in 40 cases. The other 88 cases involved weight loss, abnormalities on computed tomography (CT) scan or CE, and anemia. The main characteristics of the patients are shown in Table 1. All the patients were suspected of having small bowel diseases, and other routine examinations, such as gastroscopy, colonoscopy, abdomen CT, and radiography, did not reveal an etiological diagnosis. The data collected included age, sex, the indication for DBE, the insertion length, the diagnosis and the results of the operation.

### DBE system and procedure

All DBE examinations were performed with a Fujinon enteroscope (EN450-P5/20, Fujinon, Inc, Saitama, Japan). The operating system consisted of a mainframe, an enteroscope, an overtube and an air pump. Two soft latex balloons, which could be inflated and deflated, were attached to the tip of the enteroscope and overtube. The balloons were connected to a pump that modulated the air automatically through an air channel in the endoscope, according to the different balloon pressures required. To reduce friction between the enteroscope and the overtube, olive oil and water were added as lubricants to the lacuna between them during the operation. When the procedure was performed as described by Yamamoto<sup>[6]</sup>, the endoscope achieved deep advancement into the small bowel using the overtube in coordination with the serial inflation and deflation of the balloons.

DBE was performed *via* the oral, anal or both approaches at the discretion of the endoscopist and according to the presumed location of the suspected lesions. When the location was uncertain, the oral approach was preferred.

### Preoperative preparation

For both the antegrade and retrograde approaches, preparation included overnight fasting and the consumption of three boxes of polyethylene glycol electrolyte (69.56 g  $\times$  3) diluted in 3000 mL of water 5-6 h before the examination.

DBE was carried out under conscious or deep sedation when required. Sedation was achieved with the help of an anesthesiologist. Conscious sedation required the intravenous injection of midazolam and meperidine. General anesthesia was indicated for select patients who were administered a combination of propofol and fentanyl. Patients who underwent DBE *via* the oral approach with deep sedation requested a tracheal cannula. The cardiovascular risk status of the patients was evaluated before the examination. During DBE, oxygen was administered along with electrocardiographic monitoring when necessary.

**Table 1 Patient characteristics *n* (%)**

| Characteristic          | <i>n</i> = 400      |
|-------------------------|---------------------|
| Age, yr, median (range) | 46.9 ± 16.3 (14-86) |
| Sex (male/female)       | 250/150             |
| Reasons for DBE         |                     |
| OGIB                    | 149 (37.3)          |
| Abdominal pain          | 123 (30.7)          |
| Chronic diarrhea        | 40 (10.0)           |
| Others                  | 88 (22.0)           |
| Tumors detected by DBE  | <i>n</i> = 78       |
| OGIB                    | 37 (47.4)           |
| Abdominal pain          | 19 (24.4)           |
| Intestinal obstruction  | 8 (10.3)            |
| Others                  | 14 (17.9)           |

DBE: Double-balloon enteroscopy; OGIB: Obscure gastrointestinal bleeding.

### Statistical analysis

The SPSS 16.0 software package was used for statistical analysis. Count data were expressed as a percentage, and measurement data were expressed as the mean ± SD. Differences were evaluated with the  $\chi^2$  test. We used Fisher's exact probability when the theoretical frequency was less than 5.  $P < 0.05$  (two sided) was considered to be statistically significant.

## RESULTS

In this study, 440 DBE procedures were performed in 400 patients (252 antegrade, 188 retrograde); 40 patients underwent both antegrade and retrograde procedures. Two patients completed the entire small intestine examination all at once *via* the oral approach. Seventy-eight cases of small bowel tumors were detected, giving a positive rate of 19.5% (78/400). Clinically positive DBE findings were observed in 67 patients.

All procedures were successfully performed, except for three patients who had a perforation after the examination. No hemorrhage, acute pancreatitis or other serious complications occurred. Uncomfortable feelings, such as nausea, abdominal distension and abdominal pain, occurred in some cases during the examination. However, these symptoms were transient and tolerable. The complication rate was 0.68% (3/440) in our study group.

### Tumors detected in our study

More than 10 types of tumors (Table 2) were found in our study. The majority of these tumors were adenocarcinoma, followed by gastrointestinal stromal tumor (GIST) and lymphoma. In contrast, some tumors had a low detection rate, such as lipoma, metastatic carcinoma and hamartoma. Some extremely rare cases, such as duodenal gangliocytic paraganglioma, jejunal mesangial fibrosarcoma, inflammatory myofibroblastic tumor and serosa fibromatosis, were also found in our group. The typical endoscopic images of the main tumors are shown in Figure 1.

In the 11 patients with negative DBE results, tumors

**Table 2 Tumors detected in the present study**

| Tumor                | DBE (positive/negative) | Detection rate | Benign/malignant | Duodenum/jejunum/ileum |
|----------------------|-------------------------|----------------|------------------|------------------------|
| Adenocarcinoma       | 23 (22/1)               | 29.50%         | 0/23             | 6/16/1                 |
| GIST                 | 19 (16/3)               | 24.40%         | 6/13             | 3/12/4                 |
| Lymphoma             | 12 (9/3)                | 15.40%         | 0/12             | 1/6/5                  |
| Lipoma               | 8 (7/1)                 | 10.30%         | 8/0              | 0/8/0                  |
| Metastatic carcinoma | 8 (8/0)                 | 10.30%         | 0/8              | 3/2/3                  |
| Hamartoma            | 2 (2/0)                 | 2.60%          | 2/0              | 1/0/1                  |
| Others <sup>1</sup>  | 6 (3/3)                 | 7.70%          | 4/2              | 2/3/1                  |
| Total                | 78 (67/11)              | 100%           | 20/58            | 16/47/15               |

<sup>1</sup>1 duodenal Brunner's adenoma, 1 ileal hemangioma, 1 duodenal gangliocytic paraganglioma, 1 jejunal mesangial fibrosarcoma, 1 jejunal inflammatory myofibroblastic tumor, 1 jejunal serosa fibromatosis. DBE: Double-balloon enteroscopy; GIST: Gastrointestinal stromal tumor.

were detected through surgery or capsule endoscopy and included three lymphomas, three GIST, one adenocarcinoma and one lipoma (Table 2). The reasons for the missed diagnoses were as follows: the depth of insertion was inadequate (five cases), the choice of insertion approach was not optimal and the tumors were located at the opposite end of the intestine (four cases), and the tumors were exophytic growths with normal intestinal mucosa (two cases).

### Delineation results

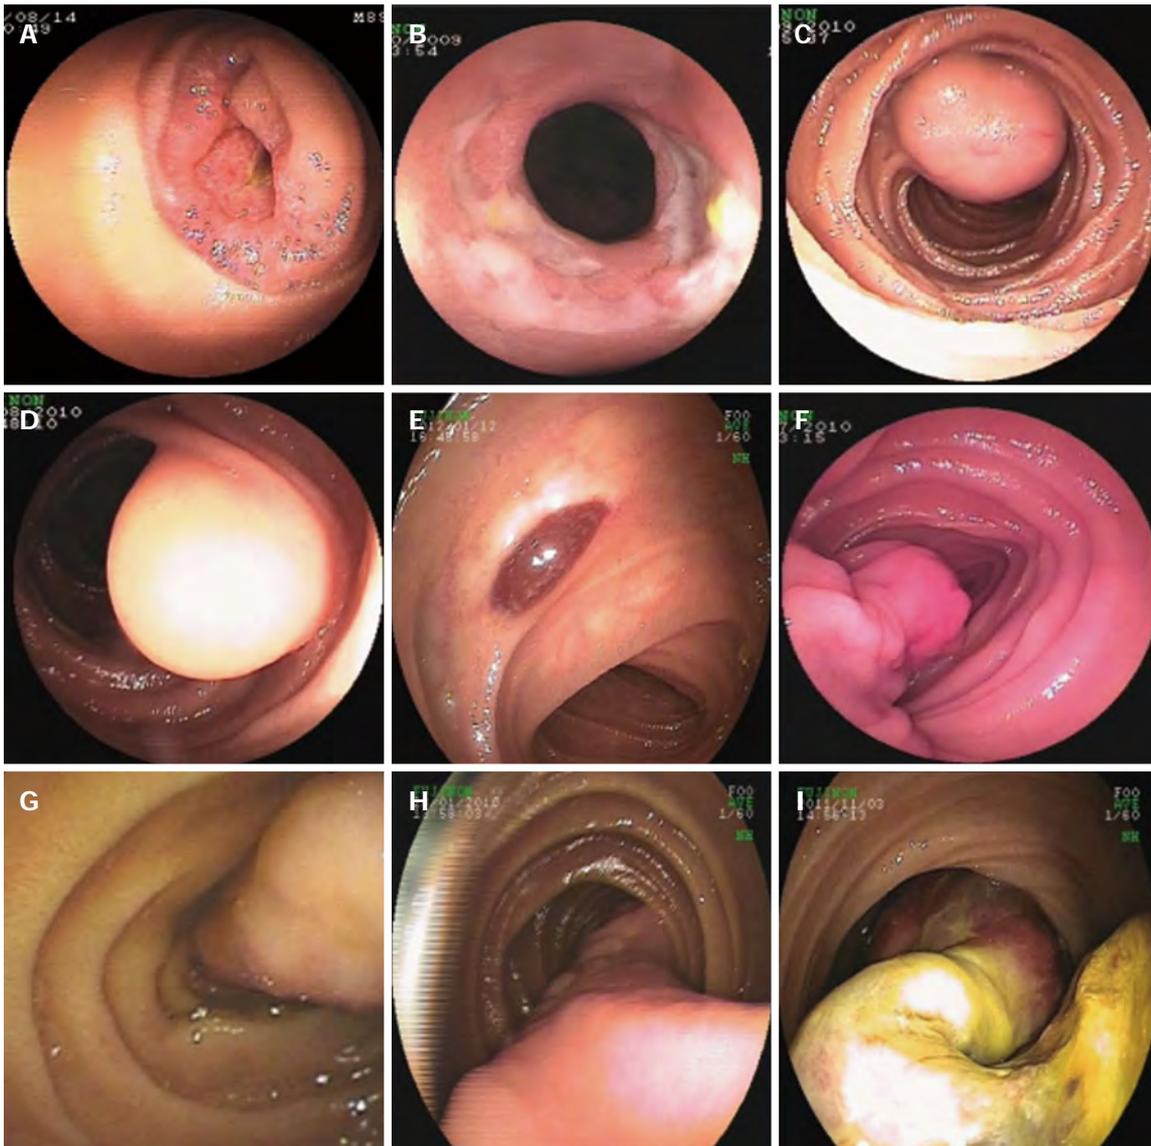

**Location of lesions:** In general, we determined the approximate location through the inserted depth of the endoscope, the size of the enteric cavity, and the shape of the mucosal fold and villi. Among the 78 tumors identified in the patients, those located in the jejunum had the highest detection rate (60.3%, 47/78). The detection rate of tumors in the duodenum was 20.5% (16/78), which was similar to that of tumors located in the ileum (19.2%). Most of the tumors, such as adenocarcinoma, lymphoma, GIST and lipoma, had a high incidence rate in the jejunum.

**Histological analysis:** Malignant tumors were found in 58 patients, with a detection rate of 74.4% (58/78). The distribution of tumors was as follows: 23 adenocarcinoma, 13 malignant GIST, 12 lymphoma, eight metastatic carcinoma and two others. In our study, compared with malignant tumors, benign tumors had lower detection rates (25.6%, 20/78); the primary benign tumors were eight lipomas and six GIST.

**Reasons for DBE:** Of the 78 patients with small bowel tumors, OGIB was the most common reason for DBE, followed by abdominal pain, intestinal obstruction and others, which included abdominal distention, vomiting, diarrhea and weight loss (Table 1).

### Comparisons between DBE and other imaging modalities

The positive detection rate for DBE in the 78 patients

**Figure 1 Typical gastrointestinal imaging.** A: Adenocarcinoma; B: Lymphoma; C: Gastrointestinal stromal tumor; D: Lipoma; E: Hemangioma; F: Gangliocytic paraganglioma; G: Brunner's adenoma; H and I: Hamartoma.

with small bowel tumors was 85.9% (67/78). Seventy of those 78 cases underwent an abdominal CT. If the CT showed a small mural mass, wall thickening with enhancement or luminal narrowing, then the results were considered positive. The positive rate for CT was 72.9% (51/70). CE was used to examine 27 cases, with a positive rate of 77.8% (21/27). Twenty-two patients underwent CE examinations before DBE; only five cases had the DBE examination first. We performed a statistical analysis of the detection rates for DBE, CE and abdominal CT. The results indicated that DBE had a higher detection rate compared with CT ( $P < 0.05$ ). There were no significant differences between DBE and CE or CE and CT ( $P > 0.05$ ).

**Operation results**

In general, we determined the types of tumors through the endoscopic features, imaging results and other aux-

iliary examinations performed before the operation. An endoscopic biopsy was carried out for some tumors. Fifty-three cases (68.0%) underwent an operation in this series of patients.

As a result of the operation, 18 cases were confirmed to have an adenocarcinoma, which was the most common tumor type in this group, followed by GIST (14 cases) and lymphoma (8 cases); the other 13 cases included metastatic carcinoma and hamartoma. Of the 53 patients who underwent an operation in our study, the positive rate of DBE in the 18 cases of adenocarcinoma was 100% (18/18), whereas the positive rate was 78.6% (11/14) for GIST and 62.5% (5/8) for lymphoma. The accuracy rates of DBE in locating small bowel neoplasms, such as adenocarcinoma, GIST and lymphoma, were 94.4%, 100% and 100%, respectively. The positive biopsy rates for adenocarcinoma and lymphoma were 71.4% and 60%, respectively.

## DISCUSSION

Although the small intestine comprises nearly 75% of the GI tract extension and nearly 90% of its mucosal surface, small bowel neoplasms are rare<sup>[7]</sup>. Recent epidemiological studies have indicated that the incidence of small bowel neoplasms has increased, particularly for malignant tumors, because of changes in diet and lifestyle<sup>[8]</sup>. Currently, the development of CE and DBE has made endoscopic examination of the entire small bowel practical. Although CE examination has revolutionized the standard small bowel evaluation<sup>[9]</sup>, some technical limitations hamper its potential usefulness and effectiveness, including its inability to sample tissue and perform therapeutic procedures. These drawbacks have been overcome with the introduction of DBE, which allows dynamic observation with the controlled movement of the endoscope, the collection of biopsies and many types of interventional procedures<sup>[10]</sup>. Under some circumstances, it can be assumed that most investigational laparotomies will be replaced by DBE.

Among the 400 patients who were submitted to examination with DBE, 67 of the 78 patients (78/400, 16.8%) who were eventually found to have small bowel tumors were detected with DBE. The results revealed that adenocarcinoma, GIST and lymphoma were the three most common tumors. In our study, adenocarcinoma had the highest incidence among the malignant neoplasms, while lipoma was the most common benign tumor. Some extremely rare tumors reported only in single cases<sup>[11,12]</sup>, including duodenal gangliocytic paraganglioma, jejunal mesangial fibrosarcoma, jejunal inflammatory myofibroblastic tumor and jejunal serosa fibromatosis, were also detected in our group. There are differences in reports regarding the incidence of small bowel tumors. In the United States, the most common small bowel tumors registered with the National Cancer Data Base are neuroendocrine (carcinoid) (44%), adenocarcinoma (33%) and lymphoma (17%)<sup>[13]</sup>. In contrast, in a Japanese multicenter study, small bowel tumors were identified in 144 of 1035 subjects (13.9%) who underwent DBE, of which lymphoma and GIST were the most frequent<sup>[14]</sup>. The hypothesis that adenocarcinoma is the most common tumor was corroborated by Safatle-Ribeiro *et al.*<sup>[15]</sup>. These differences may be ascribed to racial differences and geographical distribution.

To date, approximately 40 different histological types of small bowel tumors, of which approximately two-thirds are malignant, have been identified<sup>[16]</sup>. Of the 78 small bowel tumors of our study, the detection rate for malignancy was 74.4%. The majority of the lesions were located in the jejunum, followed by the duodenum and ileum, which is similar to the distribution reported in the literature<sup>[17]</sup>. Most of the small bowel tumors that have been reported occurred primarily in the proximal small bowel (duodenum and jejunum), except for lymphomas, sarcomas and carcinoids<sup>[18,19]</sup>. In our study, 95.7% of the adenocarcinoma (22/23) cases were found in the proximal small bowel, and only one case was located in the ileum. Among the GIST cases, 78.9% (15/19) were

detected in the proximal small bowel. In the 12 patients with lymphomas, the incidence in the jejunum was similar to that of the ileum. All of the lipomas were in the jejunum. Therefore, for patients with no clinical evidence indicating the tumor location, DBE *via* the oral approach is recommended in patients suspected of having tumors, especially adenocarcinoma, GIST and lipoma.

In large-sample studies, OGIB is the leading indication for DBE, and the diagnostic yield for OGIB is 43%-75%<sup>[20]</sup>. In our 400 patients, OGIB (37.3%, 149/400) was the main reason for DBE, which agreed with previously reported results, followed by abdominal pain (30.8%, 123/400) and chronic diarrhea (10%, 40/400). For small bowel tumors, early symptoms are often absent or nonspecific. The study by Talamonti MS indicated that obstruction, anemia and obscure bleeding were the most common symptoms of primary lesions<sup>[21]</sup>. In our group of 78 patients with small bowel tumors, the symptoms were not obviously different from those of the other patients; the top three causes for DBE were OGIB, abdominal pain and intestinal obstruction. Therefore, our research indicates that OGIB and abdominal pain were the most common reasons for DBE in both patients with small bowel tumors and patients with other diagnoses.

DBE and CE have diagnostic superiority over other routine procedures, such as push enteroscopy, abdominal CT and small bowel angiography, in detecting small bowel lesions<sup>[22]</sup>. In small bowel tumor patients, our study demonstrated that DBE had a higher detection rate than CT (85.90% *vs* 72.90%), whereas there was no difference between DBE and CE. Abdominal CT plays a pivotal role in the diagnosis, localization and staging of neoplasms and monitoring the treatment response<sup>[23]</sup>. At the same time, this examination is convenient and can determine the route of insertion for complementary DBE; therefore, it has become the initial screening method for tumors. However, it is not sufficient for the diagnosis of mucosal or small lesions of the small bowel. In the study of Cheung *et al.*<sup>[24]</sup>, tumors measuring less than 10 mm were missed with radiological techniques. CE examination has rapidly gained acceptance as the standard for small bowel evaluation. However, false-positive or false-negative results caused by the unique anatomical features of the small bowel are limitations of capsule endoscopy<sup>[25]</sup>. Imaoka *et al.*<sup>[26]</sup> reported that two-thirds of patients in whom small bowel tumors were identified had stenosis or ulceration; CE is an inappropriate modality for those who have stenosis. The capsule retention incidence ranges from 9.7%-25% in patients with small bowel tumors, which is higher than the retention incidence in all patients receiving CE and even higher than in patients with small bowel Crohn's disease<sup>[27]</sup>. DBE examination has no risk of obstruction and allows for the biopsy of tumors, which has high diagnostic value, especially for adenocarcinoma and lymphoma. In our group of 78 tumor patients, 53 cases who underwent an operation were compared regarding the DBE results, and the results indicated that the accuracy rate of DBE in locating small bowel tumors, such as adenocarcinoma, GIST and lymphoma, was very

high. The positive biopsy rates for adenocarcinomas and lymphomas were 71.4% and 60%, respectively. All of the above results indicate that DBE possesses a high value in the qualitative and localization diagnosis of small bowel tumors and provides marked reference values for surgery.

In summary, our study results indicate that DBE examination has high clinical practice value in the diagnosis of tumors and confirms it as a useful diagnostic and therapeutic tool for the investigation of small bowel diseases. DBE can obtain direct visualization and histological characterization of small bowel tumors. DBE should be considered the gold standard for the diagnosis of small bowel tumors because of its unique advantages compared with other procedures<sup>[28]</sup>.

## COMMENTS

### Background

Small bowel tumors are relatively rare, and the diagnosis of such tumors before surgery was difficult until the advent of double-balloon enteroscopy (DBE) and capsule endoscopy (CE). Compared with CE and other routine examinations used to identify small bowel tumors, DBE has particular advantages because of its diagnostic and therapeutic capabilities.

### Research frontiers

Studies are being performed to evaluate the diagnostic value of DBE in small bowel tumors.

### Innovations and breakthroughs

This study was a single-center experience in China with a large sample size involving 440 consecutive DBE examinations. The difference between abdominal computed tomography, CE and DBE in the positive rates of detecting small bowel tumors was evaluated. At the same time, the detection rates of various tumors, the location of the lesions, the histological analysis, the reasons for DBE, the accuracy rates for localization and the positive biopsy rates for DBE were also analyzed in detail.

### Applications

This study may encourage the use of DBE in the investigation of small bowel tumors. DBE has high diagnostic and therapeutic capabilities in clinical practice; therefore, should be considered as the gold standard for small bowel tumors. In the future, more therapies for small bowel tumors will be finished through DBE.

### Terminology

Double-balloon enteroscopy (DBE): a method of enteroscopy that can lead to the observation of the small intestine *via* the mouth or anus with the help of two balloons. One balloon is attached to the tip of the endoscope and the other balloon is attached to the distal end of a soft overtube.

### Peer review

This is an interesting paper with important results, which demonstrates the importance of DBE in the diagnosis of small bowel tumors and analyzes the clinical characteristics of 78 tumor patients who underwent DBE.

### Abstract

**AIM:** To compare short- and long-term outcomes of laparoscopy-assisted and open distal gastrectomy for gastric cancer.

**METHODS:** A retrospective study was performed by comparing the outcomes of 54 patients who underwent laparoscopy-assisted distal gastrectomy (LADG) with those of 54 patients who underwent open distal gastrectomy (ODG) between October 2004 and October 2007. The patients' demographic data (age and gender), date of surgery, extent of lymphadenectomy, and differentiation and tumor-node-metastasis stage of the tumor were examined. The operative time, intraoperative blood loss, postoperative recovery, complications, pathological findings, and follow-up data were compared between the two groups.

**RESULTS:** The mean operative time was significantly longer in the LADG group than in the ODG group ( $259.3 \pm 46.2$  min vs  $199.8 \pm 40.85$  min;  $P < 0.05$ ), whereas intraoperative blood loss and postoperative complications were significantly lower ( $160.2 \pm 85.9$  mL vs  $257.8 \pm 151.0$  mL; 13.0% vs 24.1%, respectively,  $P < 0.05$ ). In addition, the time to first flatus, time to initiate oral intake, and postoperative hospital stay were significantly shorter in the LADG group than in the ODG group ( $3.9 \pm 1.4$  d vs  $4.4 \pm 1.5$  d;  $4.6 \pm 1.2$  d vs  $5.6 \pm 2.1$  d; and  $9.5 \pm 2.7$  d vs  $11.1 \pm 4.1$  d, respectively;  $P < 0.05$ ). There was no significant difference between the LADG group and ODG group with regard to the number of harvested lymph nodes. The median follow-up was 60 mo (range, 5-97 mo). The 1-, 3-, and 5-year disease-free survival rates were 94.3%, 90.2%, and 76.7%, respectively, in the LADG group and 89.5%, 84.7%, and 82.3%, respectively, in the ODG group. The 1-, 3-, and 5-year overall survival rates were 98.0%, 91.9%, and 81.1%, respectively, in the LADG group and 91.5%, 86.9%, and 82.1%, respectively, in the ODG group. There was no significant difference between the two groups with regard to the survival rate.

**CONCLUSION:** LADG is suitable and minimally invasive for treating distal gastric cancer and can achieve similar long-term results to ODG.

**Key words:** Stomach neoplasms; Gastrectomy; Laparoscopy; Survival; Case matched study

**Core tip:** We retrospectively analyzed patients treated with laparoscopy-assisted distal gastrectomy (LADG) and compared the surgical and long-term outcomes of LADG and open distal gastrectomy for gastric cancer. Our analysis showed that LADG has the advantages of minimally invasive surgery, rapid recovery, and fewer complications. The effect of lymph node dissection and distance of excision margin were as good as those of

open gastrectomy. Long-term follow-up showed no obvious differences compared to open surgery. LADG can achieve a radical effect similar to that of open surgery.

Wang W, Chen K, Xu XW, Pan Y, Mou YP. Case-matched comparison of laparoscopy-assisted and open distal gastrectomy for gastric cancer. *World J Gastroenterol* 2013; 19(23): 3672-3677 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i23/3672.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i23.3672>

## INTRODUCTION

Since Kitano *et al*<sup>[1]</sup> described the first early gastric cancer treated by laparoscopy-assisted distal gastrectomy (LADG), this procedure has rapidly gained popularity in both international and domestic hospitals<sup>[2]</sup>. Although the minimally invasive effect of LADG is excellent, the therapeutic effects in adenocarcinoma still lack support from long-term follow-up studies. In this study, we performed a 1:1 case matched study to retrospectively analyze patients treated with LADG in our hospital and compared the surgical and long-term outcomes of LADG and open distal gastrectomy (ODG) for gastric cancer.

## MATERIALS AND METHODS

### Patients

A total of 108 (1:1 matched) consecutive patients who underwent LADG (54) or ODG (54) between October 2004 and October 2007 at the General Surgery Department of Sir Run Shaw Hospital were included in this study. The patients were matched for the following parameters: gender, age ( $\pm 5$  years), American Society of Anesthesiologists Physical Status score (ASA), time of operation ( $\pm 6$  mo), extent of lymph node resection (standard D<sub>2</sub>), and differentiation and tumor-node-metastasis (TNM) stage of tumor. Clinical and pathological staging was determined according to the American Joint Committee on Cancer (sixth edition) TNM classification scheme.

### Surgical technique for gastrectomy

The laparoscope was introduced through a 10-mm infra-umbilical trocar while the patient lay in the supine position, followed by placement of two 5-mm assistant ports in the bilateral anterior axillary line in the lower costal margin. The working port was placed to the right external rectus, 2 cm above the umbilicus through a 12-mm trocar, and another 5-mm assistant port was placed in the left corresponding position. These 5 operating trocars were placed in a V-shaped distribution. The surgeon and the second assistant (camera operator) stood on the patient's right and the first assistant stood on the patient's left. The procedure began with the division of the greater omentum and continued with the exposure of the right gastro-omental artery and vein along the gastroduodenal

artery and intermediate vein, dissecting at their roots and the infrapyloric lymph nodes. The root of the right gastric artery was exposed along the plane of the common and proper hepatic artery and the duodenohepatic ligament and suprapyloric lymph nodes were dissected. The duodenum was dissected and transected using the endoscopic gastrointestinal anastomosis (endo-GIA) stapler after thorough dissociation of the duodenal ampulla. After retracting the stomach specimen on the left, the lymph nodes along the proximal common hepatic artery, celiac axis, and the root of the splenic artery were dissected in the order described. The root of the left gastric artery was exposed and clipped. We then opened the right diaphragmatic crura and dissected the right cardiac nodes. The stomach specimen was extracted through a 6-cm vertical median incision at the epigastrium and a Billroth II gastrojejunostomy was performed after resection of the stomach specimen.

### Variables

The patients' surgical characteristics (operative time, extent of intraoperative hemorrhage, and amount of blood transfused), postoperative recovery (time to first flatus, time to initiate oral intake, complications, and length of postoperative hospital stay), and histopathologic indices (number of resected lymph nodes, surgical margins distance) were observed and compared between the two groups. Follow-up was conducted through an outpatient service, telephone call, or mail in order to determine whether recurrences, metastasis, or death occurred.

### Statistical analysis

All statistical analyses were performed using the Statistical Package for the Social Sciences (SPSS<sup>®</sup>) version 16.0 (SPSS, Inc. Chicago, IL, United States). The differences in the measurement data were compared using the Student's *t* test, and comparisons between groups were tested using the  $\chi^2$  test or the Fisher exact probability test. The survival data were estimated using the Kaplan-Meier method. *P* < 0.05 was considered statistically significant.

## RESULTS

### Preoperative characteristics and postoperative pathologic features

The preoperative characteristics and postoperative pathologic features of the LADG group and the ODG group are summarized in Table 1. There were no differences with respect to preoperative characteristics and postoperative pathologic features between the two groups.

### Comparison of surgical indices

Both surgical approaches were completed successfully with no conversion from LADG to open operation. Surgical indices are shown in Table 2. The operative time in the LADG group was longer than that in the ODG group (*P* < 0.01), whereas blood loss and blood infusion frequency were significantly lower (*P* < 0.01). There were no significant differences in the mean number of

retrieved lymph nodes between the two groups.

### Comparison of postoperative recovery

Postoperative recovery in the two groups is shown in Table 2. The time to first flatus, time to initiate oral intake, and postoperative hospital stay were significantly shorter in the LADG group than in the ODG group ( $P < 0.05$ ).

### Comparison of postoperative complications and mortality rate

Seven (13%) patients experienced postoperative complications after LADG. One patient developed short-term gastric emptying disorder and was discharged on the 16<sup>th</sup> postoperative day after treatment with gastrointestinal decompression, gastrointestinal prokinetic agents (GIPA), and total parenteral nutrition (TPN) support therapy. One patient developed chylous fistula and was discharged 14 d after surgery following treatment with short-term fasting and TPN support. Two patients developed pulmonary infections and both patients recovered after antibiotic treatment. Three patients developed abdominal cavity effusions with complicating inflammation, one was reversed after conservative therapy, the other two were treated with abscess needle puncture and drainage under computed tomographic (CT) guidance and were discharged 16, 22, and 24 d after surgery, respectively.

Sixteen (24.1%) patients in the ODG group developed postoperative complications. One patient developed an anastomotic leak and was discharged on the 36<sup>th</sup> postoperative day after undergoing re-operation. In two patients with intra-abdominal bleeding, one was reversed after conservative therapy, the other underwent re-operation, and they were discharged 12 and 13 d after surgery, respectively. Of four patients with abdominal cavity effusions with complicating infection, one underwent laparotomy, abdominal cavity flushing drainage and was discharged 40 d after surgery, and the others were treated with abscess needle puncture and drainage under CT guidance and were discharged 18, 20, and 21 d after surgery, respectively. Three patients had pulmonary infec-

ODG: Open distal gastrectomy; LADG: Laparoscopy-assisted distal gastrectomy.

tions and all recovered after antibiotic treatment. Two patients had short-term gastric emptying disorder and were discharged on the 20<sup>th</sup> and 26<sup>th</sup> postoperative day, respectively, after treatment with gastrointestinal decompression, GIPA and TPN support. Two patients developed chylous fistula and were discharged 15 and 16 d after surgery, respectively, following treatment with short-term fasting and TPN support. Two patients had wound infections which were reversed after the incision was opened and dressed. No preoperative deaths occurred in either group. Comparisons of postoperative complications and mortality rates are summarized in Table 3.

### Comparison of long-term results

Of the 108 identified patients, 96 (88.9%) were followed up and 12 were lost to follow-up. Follow-up data were available for 49 (90.1%) and 47 (87.0%) of patients treated with LADG and ODG, respectively. The mean follow-up was 60 mo (range, 5-97 mo).

In the LADG group, 11 (20.4%) patients experienced recurrence and 8 died due to the disease: one stage IA patient developed recurrence and he is still alive 64 mo after operation. Another stage I B patient died 51 mo after operation. Two stage II patients had recurrence, one is alive 57 mo after operation, and the other died. Five stage III A patients experienced recurrence, four of whom died during the follow-up period, and the remaining patient is alive 56 mo after operation. Two stage III B patients died of the disease 14 and 59 mo after operation, respectively.

In the ODG group, nine (16.7%) patients had recurrence and 8 patients died of metastatic disease: three stage IB patients died due to the disease 9, 11, 49 mo after operation, respectively; two stage II patients experienced recurrence, one of whom died, and the other is alive 79 mo after operation; another four stage III A patients also had recurrence, and they died 6, 11, 15, and 31 mo after operation, respectively.

The 1-, 3-, and 5-year disease-free survival rates were

ODG: Open distal gastrectomy; LADG: Laparoscopy-assisted distal gastrectomy.

94.3%, 90.2%, and 76.7%, respectively, in the LADG group and 89.5%, 84.7%, and 82.3%, respectively, in the ODG group. The 1-, 3-, and 5-year overall survival rates were 98.0%, 91.9%, and 81.1%, respectively, in the LADG group and 91.5%, 86.9%, and 82.1%, respectively, in the ODG group. There were no significant differences in these values between the two groups ( $P > 0.05$ ) (Figure 1).

## DISCUSSION

Since the first successful LADG by Kitano *et al*<sup>[1]</sup> for early gastric cancer in 1994, the use of LADG has significantly increased in both international and domestic hospitals. More and more studies, including some randomized controlled trials, have demonstrated the advantages of LADG in the treatment of early gastric cancer such as earlier recovery of ambulation and bowel movement, less pain, and a lower rate of complications. These studies confirmed that LADG is a safe and feasible surgical method<sup>[3-5]</sup>.

Kitano *et al*<sup>[6]</sup> reported the clinical findings of a multicenter trial which included 1491 cases of laparoscopy-assisted distal gastrectomy at 18 surgery centers, and found a complication rate of 12%, death rate of 0%, and recurrence rate of 0.4%. Prospective studies by Dulucq *et al*<sup>[7]</sup> revealed that postoperative complications and length of hospital stay in the LADG group were reduced compared with those in the ODG group. In the present study, complications, time to first flatus, time to initiate oral intake, and postoperative hospital stay were all significantly shorter in the LADG group than in the ODG group ( $P < 0.05$ ), showing the advantages of LADG during postoperative recovery. Several publications have reported that the rate of surgical complications following LAG are in the range of 3.8%-26.7%<sup>[8-11]</sup>, this rate was 13% in our study and was significantly lower than that in the ODG group. There was no preoperative death in our study; however, a recent survey showed that the mortality rate for open gastric cancer radical gastrectomy was 4%-6%<sup>[12]</sup>.

**Figure 1** Curves showing disease-free survival (A) and overall survival (B) after gastrectomy. ODG: Open distal gastrectomy; LADG: Laparoscopy-assisted distal gastrectomy.

Some studies have described the disadvantages of LADG compared to ODG, which include increased operative time similar to that in our study<sup>[13-16]</sup>. Operator experience, familiarity with instruments, and degree of assistant compliance are major factors influencing the operative time. During initial LADG procedures in our center, the operative time was often more than 300 min due to the above-mentioned reasons; these factors may be responsible for the significantly longer average operative time in the LADG group than in the ODG group. Other reports have also indicated that operative time with experienced surgeons was similar for LADG and ODG<sup>[17,18]</sup>.

Similar to most reports, the intraoperative blood loss in the LADG group was less than that in the ODG group<sup>[5,19]</sup>, as was blood transfusion, which reiterated the importance of careful laparoscopic manipulation during LADG. In addition, magnified vision also creates conditions for careful laparoscopic manipulation. Lack of blood is a common problem faced by many hospitals, especially in developing countries such as China; therefore, less invasive laparoscopic surgery can reduce the clinical requirement for blood and lower the rate of complications associated with blood transfusion such as virus infection and allergic reaction.

Radical resection of the tumor lymphatic drainage area should include complete resection and well incised

margins. Laparoscopic gastric cancer D<sub>2</sub> lymph node dissection is difficult and requires high technical expertise. Thus, whether laparoscopic techniques can be applied in the treatment of advanced gastric cancer is still controversial. However, the number of laparoscopically dissected lymph nodes is closely related to the surgical technique, and some studies have shown that there was no difference in the number of retrieved lymph nodes between LAG and OG<sup>[20,21]</sup>. Our analysis showed similar results in that D<sub>2</sub> lymph node dissection can be completed during laparoscopy. Park *et al.*<sup>[22]</sup> evaluated the long-term results of 239 patients who underwent LADG for the treatment of advanced gastric cancer. They found that the major recurrence was distant metastasis, whereas lymph node relapses were most frequent in para-aortic or distant lymph node metastasis; therefore, we believe that the dissection of lymph nodes around the stomach can be performed efficiently by LADG. In our study, the mean distance of the proximal and the distal margin in the LADG group was  $3.6 \pm 1.9$  cm and  $4.3 \pm 2.1$  cm, respectively, without residual cancer cells and no statistical difference compared with the OG group. We conclude that laparoscopy-assisted radical gastrectomy may help achieve results similar to those of abdominal opening on margin distance. Port-site metastasis caused by intraoperative pneumoperitoneum of LADG is another controversial issue. Port-site metastases were not reported in our study, similar to other studies, thus we conclude that pneumoperitoneum does not contribute to a higher risk of port-site metastasis.

Whether LADG can achieve effective radical cancer excision similar to that by ODG needs to be confirmed through long-term outcomes, however, large-volume long-term studies are still lacking. In a prospective trial conducted by Huscher *et al.*<sup>[11]</sup>, the long-term results of LAG and OG were similar, but the scope of lymph node dissection was identical. A retrospective analysis conducted by Hamabe *et al.*<sup>[23]</sup> revealed that the long-term results did not differ significantly between LAG and OG; however, because the application of LAG increased gradually, whereas the application of OG decreased gradually over the entire study period, the former had a short follow-up time. However, during the 10-year study, improvements in the chemotherapy program will certainly have an impact on the study results. Sato *et al.*<sup>[24]</sup> analyzed the difference between OG and LAG in relation to D<sub>1</sub>, D<sub>1+</sub>, or D<sub>2</sub> lymph node dissection using a hierarchical approach and found that the long-term results of LAG were comparable to those of OG; however, the pathological stage in the LAG group was significantly earlier than that in the OG group ( $P < 0.001$ ), which seriously affected the credibility of the analysis. Pak *et al.*<sup>[25]</sup> analyzed the follow-up of 714 patients who underwent LAG and calculated the 5-year survival rate of different TNM stages, however, their findings were not compared with those of open surgery over the same period. In addition, their follow-up duration was not long enough, as the median follow-up was less than 50 mo. Although postoperative recurrence after radical gastrectomy for cancer usually occurs within

36 mo, about 12% of cases with recurrence occur after 36 mo<sup>[26,27]</sup>. Therefore, prolonged follow-up can result in more reliable survival analysis data.

In our study, the follow-up duration was long enough as the median follow-up duration was 60 mo. In addition, we found no difference in the disease-free survival or overall survival rate between the two groups, after conducting a matched-pair design to eliminate the effects of confounding factors, including gender, age, operative period, ASA status, the extent of lymph node resection, and differentiation and TNM stage of the tumor. These results suggest that the LADG is as good as ODG with regard to long-term outcomes. The matched-pair design makes the results more credible. However, this study has several limitations, including its relatively small sample size, no survival analysis after stratification according to the TNM stage, and the use of matching research, which is a type of retrospective analysis that cannot replace prospective trials.

In conclusion, our analysis showed that LADG has the advantages of minimally invasive surgery, rapid recovery, and fewer complications. The effect of lymph node dissection and distance of excision margin were as good as those of open gastrectomy. Long-term follow-up of LADG patients showed no obvious differences compared to open surgery. We believe that LADG can achieve a radical effect similar to that of open surgery in patients with gastric cancer.

## COMMENTS

### Background

More and more studies, including some randomized controlled trials, have demonstrated the advantages of laparoscopy-assisted distal gastrectomy (LADG) in the treatment of early gastric cancer such as earlier recovery of ambulation and bowel movement, less pain, and a lower rate of complications. These studies have confirmed that LADG is a safe and feasible surgical method, but the therapeutic effects in adenocarcinoma still lack support from long-term follow-up studies.

### Research frontiers

Although the minimally invasive effect of LADG is excellent, the therapeutic effects in adenocarcinoma still lack support from long-term follow-up studies. Whether LADG can achieve effective radical cancer excision similar to that by open distal gastrectomy (ODG) requires to be confirmed through long-term outcomes, however, large-size long-term studies are still lacking.

### Innovations and breakthroughs

In this study, the authors performed a 1:1 case matched study to retrospectively analyze the patients treated by LADG and compared the surgical and long-term outcomes of LADG and ODG for gastric cancer. This study showed that LADG is suitable and minimally invasive for treating distal gastric cancer and can achieve similar long-term results to ODG.

### Applications

This study showed that LADG has the advantages of minimally invasive surgery, rapid recovery, and fewer complications. The effects of lymph node dissection and distance of the excision margin are as good as those of open gastrectomy. Long-term follow-up showed no obvious differences compared to open surgery. LADG can achieve a radical effect similar to that of open surgery in patients with gastric cancer. These findings are helpful in decision-making for the treatment of resectable gastric cancer.

### Peer review

This is a nice paper, which is worth reading and publication. The subject and findings are significant in clinical practice, especially in the field of laparoscopy-assisted surgery. Overall, the manuscript is well prepared.

**METHODS:** Only EUS studies confirmed by surgery or appropriate follow-up were selected. Articles were searched in Medline, Ovid journals, Medline nonindexed citations, and Cochrane Central Register of Controlled Trials and Database of Systematic Reviews. Pooling was conducted by both fixed and random effects model).

**RESULTS:** Initial search identified 2610 reference articles, of these 140 relevant articles were selected and reviewed. Data was extracted from 13 studies ( $n = 456$ ) which met the inclusion criteria. Pooled sensitivity of EUS in detecting a PNETs was 87.2% (95%CI: 82.2-91.2). EUS had a pooled specificity of 98.0% (95%CI: 94.3-99.6). The positive likelihood ratio of EUS was 11.1 (95%CI: 5.34-22.8) and negative likelihood ratio was 0.17 (95%CI: 0.13-0.24). The diagnostic odds ratio, the odds of having anatomic PNETs in positive as compared to negative EUS studies was 94.7 (95%CI: 37.9-236.1). Begg-Mazumdar bias indicator for publication bias gave a Kendall's tau value of 0.31 ( $P = 0.16$ ), indication no publication bias. The  $P$  for  $\chi^2$  heterogeneity for all the pooled accuracy estimates was  $> 0.10$ .

**CONCLUSION:** EUS has excellent sensitivity and specificity to detect PNETs. EUS should be strongly considered for evaluation of PNETs.

## INTRODUCTION

Neuroendocrine tumors of the gastrointestinal tract are rare, accounting for less than 1% of all malignancies with an estimated annual incidence of 1-4 per 100000; however, they may lead to significant morbidity and mortality<sup>[1,2]</sup>. These tumors are difficult to diagnosis, treat, and have a propensity for metastasis prior to their diagnosis given that many do not become clinically apparent until late in their course. These tumors may be found throughout the gastrointestinal tract; however, the pancreas is an area where neuroendocrine tumors are commonly discovered<sup>[3,4]</sup>.

Neuroendocrine tumors of the pancreas (PNETs) may be functional or non-functional and are mostly sporadic, although some are associated with other genetic diseases<sup>[1]</sup>. Functional PNETs often secrete active substances, such as insulin, somatostatin, gastrin, glucagon, or vasoactive intestinal peptide, which may allow them to be discovered earlier<sup>[1,5]</sup>. However, some of these PNETs are non-functional, secreting non-active substances, such as chromogranin A<sup>[1]</sup>. Serological tests have been used to determine levels of these compounds, leading to an enhanced ability to diagnosis PNET. However, these tumors tend to have metastasized by the time they are diagnosed, especially in non-functioning PNETs. Many imaging modalities have been utilized for PNETs, including trans-abdominal ultrasound (US), computed tomography (CT), and magnetic resonance imaging (MRI) with significant limitations. These imaging techniques are able to detect PNETs in 9%-48% with an estimated sensitivity of 29%-60%<sup>[6-8]</sup>. Given the need for improved imaging techniques, endoscopic ultrasound (EUS) has been evaluated as a possible diagnostic tool for PNETs.

Since its early introduction in the early 1990's, EUS has emerged as a safe and accurate technique for the diagnosis, stage, and treat a variety of lesions. A particularly useful aspect of EUS is the enhanced imaging of the pancreas. There are currently several reports of EUS in correctly detecting PNETs. However, the accuracy

of these results varies across centers. To the best of our knowledge, a meta-analysis summarizing these results has not been performed. The purpose of this investigation is to review the world literature regarding the accuracy of EUS in detecting PNET.

## MATERIALS AND METHODS

### Study selection criteria

Studies evaluating the use of EUS to characterize pancreatic neuroendocrine tumors with a gold standard (either confirmed by surgery or appropriate follow-up) were selected. From this pool, only studies from which a 2 × 2 table could be constructed for true positive, false negative, false positive and true negative values were included.

### Data collection and extraction

Articles were searched in MEDLINE (through PubMed, an electronic search engine for published articles and Ovid), PubMed, Ovid Journals, EMBASE, Cumulative Index for Nursing and Allied Health Literature, ACP Journal Club, DARE, International Pharmaceutical Abstracts, old Medline, Medline non-indexed citations, OVID Healthstar, and Cochrane Central Register of Controlled Trials and Database of Systematic Reviews (Central). The search was performed from January 1966 to January 2012. The terms used for search were endoscopic ultrasound, EUS, ultrasound, endosonography, pancreatic mass, neuroendocrine tumors, sensitivity, specificity, positive predictive value, and negative predictive value. Study authors were contacted when the required data could not be determined from the publications. Two by two tables were constructed with the data extracted from each study. Two authors (Puli SR, Bechtold ML) independently searched and extracted the data using an abstraction form. Any differences were resolved by mutual agreement. The agreement between reviewers for the collected data was quantified using the Cohen's  $\kappa$ <sup>[9]</sup>.

### Quality of studies

Clinical trials designed with control and treatment arms can be assessed for quality of the study. A number of criteria have been used to assess the quality of a study (*e.g.*, randomization, selection bias of the arms in the study, concealment of allocation, and blinding of outcome)<sup>[10,11]</sup>. There is no consensus on how to assess studies designed without a control arm. Hence, these criteria do not apply to studies without a control arm<sup>[11]</sup>. Therefore, for this meta-analysis and systematic review, studies were selected based on completeness of the data and inclusion criteria. Completeness was defined as data available for true positive, false negative, false positive and true negative values of the diagnostic test (EUS). Quality Assessment of Studies of Diagnostic Accuracy Included in Systematic Reviews (QUADAS) criteria has been proposed to evaluate quality of diagnostic studies<sup>[12,13]</sup>. This was used to evaluate the studies on 14 items described in the QUADAS criteria.

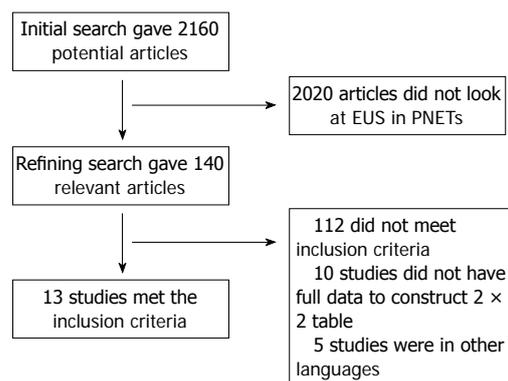

Figure 1 Search results. EUS: Endoscopic ultrasound; PNETs: Pancreatic neuroendocrine tumors.

### Statistical analysis

Meta-analysis for the accuracy of EUS in diagnosing PNETs was performed by calculating pooled estimates of sensitivity, specificity, likelihood ratios, and diagnostic odds ratios. Pooling was conducted using both Mantel-Haenszel Method (fixed effects model) and DerSimonian Laird Method (random effects model). The confidence intervals were calculated using the F distribution method<sup>[14]</sup>. Forrest plots were drawn to examine how the point estimates in each study related to the summary pooled estimate. For 0 value cells, a 0.5 was added as described by Cox<sup>[15]</sup>. The heterogeneity of the sensitivities and specificities were tested by applying the likelihood ratio test<sup>[16]</sup>. The heterogeneity of likelihood ratios and diagnostic odds ratios were tested using Cochran's  $Q$  test based upon inverse variance weights<sup>[17]</sup>. Heterogeneity among studies was also tested by using summary receiver operating characteristic (SROC) curves. SROC curves were used to calculate the area under the curve (AUC). The affect of publication and selection bias on the summary estimates was tested by Egger bias indicator<sup>[18]</sup>. Also, funnel plots were constructed to evaluate potential publication bias using the standard error and diagnostic odds ratio<sup>[19,20]</sup>.

## RESULTS

Initial search identified 2610 reference articles, of these 140 relevant articles were selected and reviewed. Data was extracted from 13 studies<sup>[21-33]</sup> ( $n = 456$ ) which met the inclusion criteria. Search results are shown in Figure 1. All the pooled estimates given are estimates calculated by the fixed effects model. The change adjusted agreement analysis between the reviewers for data collected separately gave a kappa value of 1.0. QUADAS criteria to evaluate the quality of studies demonstrated that all the studies fulfilled 4 to 5 out of 14 described criterion.

### Accuracy of EUS to detect PNETs

Pooled sensitivity of EUS in detecting PNETs was 87.2% (95%CI: 82.2-91.2). Forrest plot in Figure 2A shows the sensitivity of EUS in individual included studies. EUS had a pooled specificity of 98.0% (95%CI: 94.3-99.6). Figure 2B shows the specificity from various studies. The

positive likelihood ratio (+LR) of EUS was 11.1 (95%CI: 5.34-22.8) and negative likelihood ratio (-LR) was 0.17 (95%CI: 0.13-0.24). The diagnostic odds ratio (DOR), the odds of having anatomic PNETs in positive as compared to negative EUS studies was 94.7 (95%CI: 37.9-236.1). All the pooled estimates calculated by fixed and random effect models were similar. SROC curves showed an area under the curve of 0.94. Figure 3 shows SROC curve and the area under the curve. Egger bias indicator for publication bias gave a value of 1.39 (95%CI: -1.52-4.32,  $P = 0.31$ ), indication no publication bias. Funnel plot in Figure 4 also shows that there is no publication bias in the included studies. The  $P$  for chi-squared heterogeneity for all the pooled accuracy estimates was  $> 0.10$ .

Subgroup analysis was performed to see how EUS performs in detecting an Insulinoma or a Gastrinoma in the pancreas.

### Accuracy of EUS to detect an insulinoma in the pancreas

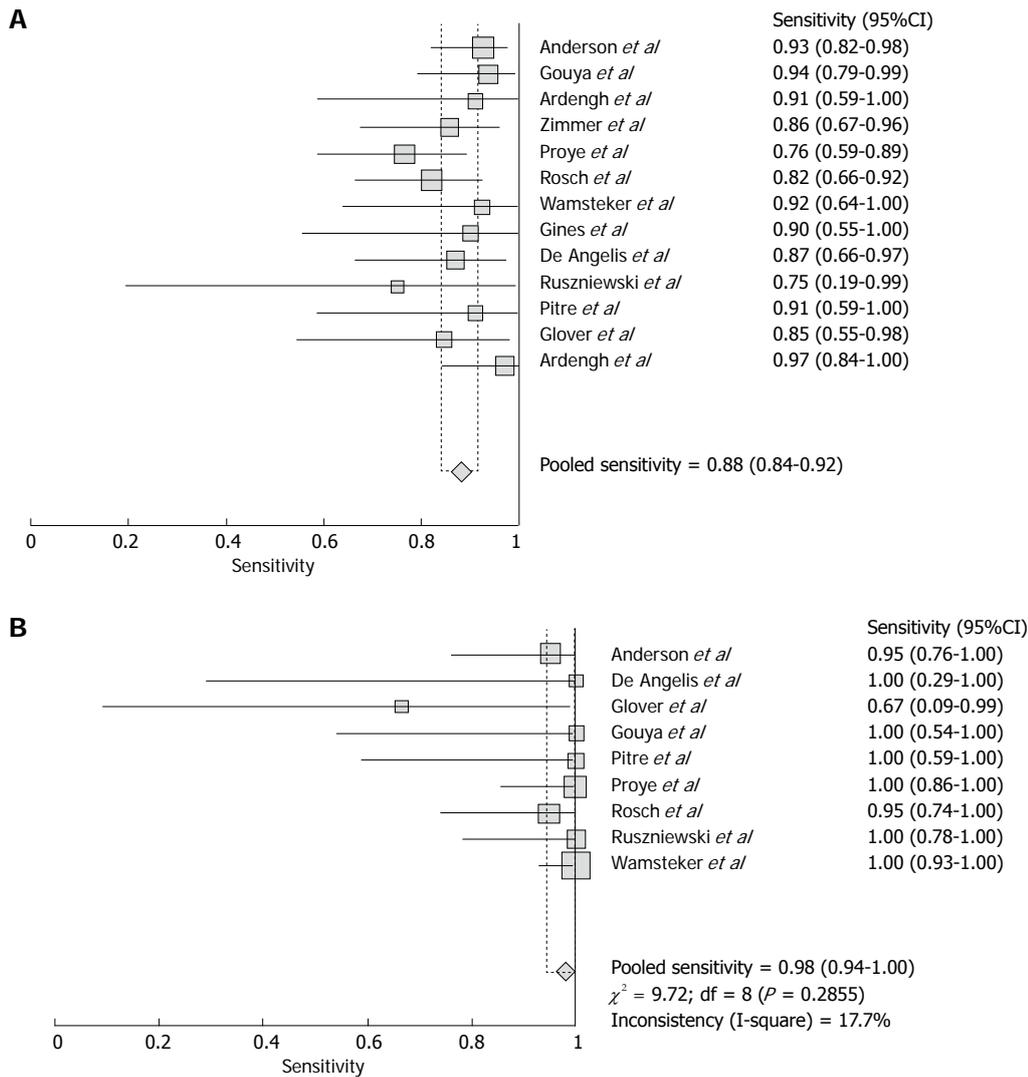

Data was extracted from 9 studies ( $n = 242$ ) which met the inclusion criteria. Pooled sensitivity of EUS in detecting a Pancreatic Insulinoma was 87.5% (95%CI: 81.2-92.3). EUS had a pooled specificity of 97.4% (95%CI: 90.8-99.7). The +LR of EUS was 8.2 (95%CI: 3.7-18.3) and -LR was 0.17 (95%CI: 0.12-0.26). The DOR, the odds of having anatomic Pancreatic Insulinoma in positive as compared to negative EUS studies was 67.6 (95%CI: 22.7-200.9). All the pooled estimates calculated by fixed and random effect models were similar. SROC curves showed an area under the curve of 0.94. Egger bias indicator for publication bias gave a value of -0.05 (95%CI: -4.13-4.04,  $P = 0.98$ ), indication no publication bias. The  $P$  for chi-squared heterogeneity for all the pooled accuracy estimates was  $> 0.10$ .

### Accuracy of EUS to detect gastrinoma in the pancreas

Five EUS studies ( $n = 122$ ) looked at detecting Gastrinomas in the pancreas. Pooled sensitivity of EUS in detecting a gastrinoma in the pancreas was 84.5% (95%CI: 72.6-92.7). EUS had a pooled specificity of 95.3% (95%CI: 86.9-99.0). The positive likelihood ratio of EUS was 10.5 (95%CI: 4.3-25.5) and negative likelihood ratio was 0.25 (95%CI: 0.13-0.47). The diagnostic odds ratio, the odds of having anatomic gastrinoma in positive as compared to negative EUS studies was 57.3 (95%CI: 15.1-217.2). All the pooled estimates calculated by fixed and random effect models were similar. SROC curves showed an area under the curve of 0.94. Egger bias indicator for publication bias gave a value of -0.74 (95%CI: -15.19-13.72,  $P = 0.88$ ), indication no publication bias. The  $P$  for  $\chi^2$  heterogeneity for all the pooled accuracy estimates was  $> 0.10$ .

## DISCUSSION

Localizing or detecting a neuroendocrine neoplasm in the pancreas helps not only with the planning of treatment but also when detected early might improve overall prog-

**Figure 2** Forrest plot. A: Forrest plot showing sensitivity of endoscopic ultrasound (EUS) to detect pancreatic neuroendocrine tumor; B: Forrest plot showing specificity of EUS to detect pancreatic neuroendocrine tumors.

nosis. Over the past sixteen years since the introduction of EUS, this minimally invasive technique has emerged as the premiere modality to confirm pancreatic neoplasms. In this meta-analysis we sought to pool and compare the findings of 13 high quality studies concerned with the performance of EUS in the evaluation of PNETs.

The strengths of this analysis are that the literature was reviewed and data was extracted independently by two independent reviewers. Comparison of their analyses indicates excellent agreement. This meta-analysis and systematic review was written in accordance with the proposal for reporting by the Quality of Reporting of Meta-analyses statement<sup>[34]</sup>. A standardized extraction algorithm was applied and only studies which fulfilled at least four of the QUADAS criterion were included. Additionally, extensive efforts were made to ensure that the true positive, false positive, true negative and false negative results for all studies were either gleaned from the literature or acquired via direct communication with the investigators. Egger bias estimates as well as funnel plots were performed and both methods suggest that there

was no significant publication bias. Since this manuscript looks at diagnostic accuracy of a test, the study design for this meta-analysis and systematic review followed the guidelines of Standards for Reporting of Diagnostic Accuracy initiative<sup>[35]</sup>.

A core finding of this meta-analysis is that in patients with symptomatic PNETs, EUS had high sensitivity (88%) and specificity (98%) in localizing the lesion to the pancreas. EUS as a diagnostic test has a very high DOR to detect PNETs (about 95 times). If EUS localizes the lesion to the pancreas, the odds of having the correct histological neuroendocrine tumor in the pancreas is 95 times.

Additional performance characteristics for EUS were assessed in this meta-analysis which demonstrate a high +LR and low -LR. The higher the positive likelihood ratio, the better the diagnostic test performs in correctly identifying the true disease state. On the flip side, negative likelihood ratio of a diagnostic test is a measure of how well the test correctly excludes a disease stage. The diagnostic tests ability to exclude a disease state is better

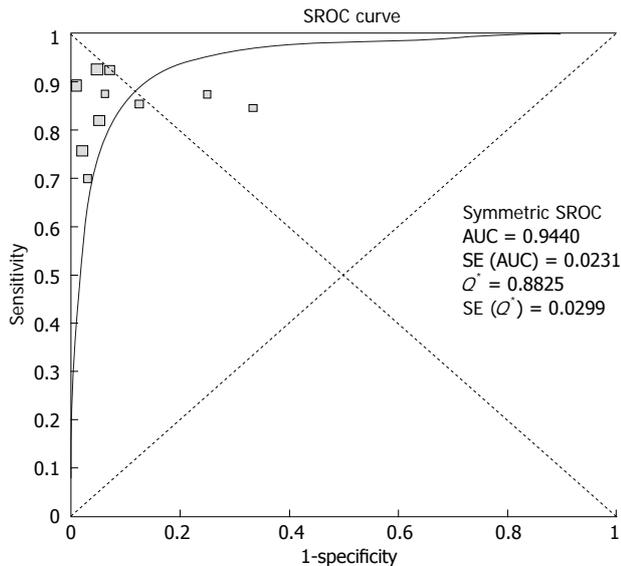

Figure 3 Summary receiver operating characteristic curves of endoscopic ultrasound to detect pancreatic neuroendocrine tumors. AUC: Area under the curve; SROC: Summary receiver operating characteristic.

if the negative likelihood ratio is lower. For PNETs, EUS has a high positive likelihood ratio and a low negative likelihood ratio. This indicates that EUS performs well in excluding as well as correctly localizing neuroendocrine tumor within the pancreas.

In a subgroup analysis to look at performance of EUS to correctly diagnose Insulinomas, EUS had high sensitivity (88%) and specificity (97%). Also, EUS had high sensitivity (85%) and specificity (95%) to detect Gastrinomas in pancreas.

A strength of this meta-analysis is that there was no heterogeneity among the studies included in this analysis. Heterogeneity among different studies was evaluated not only with test of heterogeneity but also by drawing SROC curves and finding the AUC. An AUC of 1 for any diagnostic test indicates that the test is excellent. SROC curves for EUS showed that the value of AUC was very close to 1, indicating that EUS is an excellent diagnostic test to detect PNETs.

One limitation of this meta-analysis is that none of the included studies were multicentre or randomized trials. The included studies were small in size indicating the low incidence of neuroendocrine tumors among general population. Studies on EUS with statistical significance tend to be published and cited leading to publication bias. Additionally smaller studies may show larger treatment effects due to fewer case-mix differences (*e.g.*, patients with only early localized *vs* late metastatic disease) than larger studies. This publication and selection bias may affect the summary estimates in any meta-analysis. This bias can be estimated by Egger bias indicators and construction of Funnel plots. In our meta-analysis and systematic review, bias calculations using Harbord-Egger bias indicator<sup>[18]</sup> showed no statistically significant bias. Furthermore, analysis using Funnel plots showed no significant publication bias among the studies included in

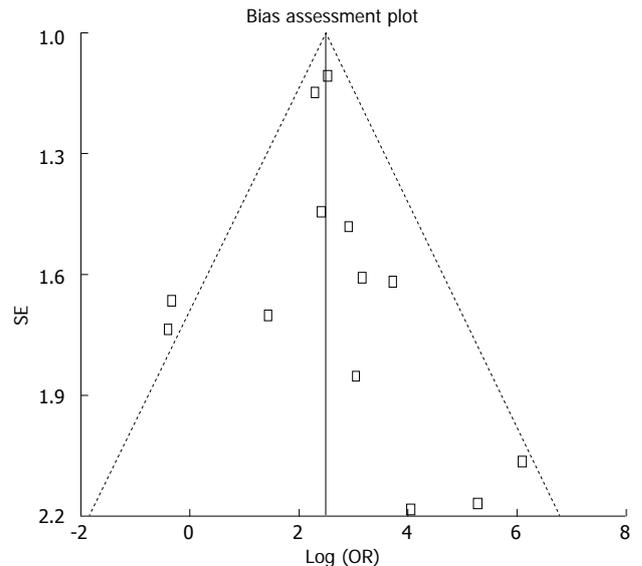

Figure 4 Funnel plot showing no publication bias in the studies included in this meta-analysis.

this analysis.

At this time the role of EUS to detect PNETs is as an adjunct to the imaging modalities such as CT scans. This is especially true when they are functional and when present in an early localized stage. More recently a single center study undertaken by Khashab *et al.*<sup>[36]</sup> showed the despite improvement in CT technology which has increased detection rates, they still missed PNETs that were smaller in size.

A subgroup analysis to see if FNA could improve the diagnostic accuracy could not be performed as there were only two studies<sup>[28,33]</sup> that included FNA data for PNETs. In a meta-analysis of 41 studies by Puli *et al.*<sup>[37]</sup>, the accuracy of EUS-FNA in the setting of solid pancreatic mass was analysed which showed a pooled sensitivity and specificity of 86.9% (95%CI: 85.5-87.9) and 95.8% (95%CI: 94.6-96.7) respectively. Given these findings it would make sense to probably conclude that EUS-FNA could replicate similar diagnostic characteristics in PNETs. In additional, Khashab *et al.*<sup>[36]</sup> also reported increased diagnostic accuracy of EUS in detected lesions to the pancreas when the were smaller in size. This was especially true for functional PNETs which tend to present early due to active peptides.

In conclusion, EUS has excellent sensitivity and specificity to localize PNETs approaching 100%. In a subgroup analysis, EUS had high sensitivity and specificity to detect Insulinoma or Gastrinoma in the pancreas. Though the studies in literature are small studies, EUS should be strongly considered for evaluation of PNETs.

## COMMENTS

### Background

Biochemically active neuroendocrine tumors often arise from the pancreas and are preceded by hormone related symptoms before metastasis. They are often small early on and could be missed on traditional imaging such as abdominal ultrasound, computed tomography (CT), and magnetic resonance imaging.

However, the performance characteristics of endoscopic ultrasound (EUS) from previously published studies have demonstrated varying results.

### Research frontiers

To our knowledge there is no published meta-analysis that has reported the diagnostic accuracy of EUS in neuroendocrine tumor of pancreas (PNETs). Several small studies have demonstrated varying results. This study is undertaken to assess pooled estimates on the diagnostic accuracy of EUS in early PNETs.

### Innovations and breakthroughs

EUS has excellent sensitivity and specificity in detecting PNETs both approaching close to 100%. A subgroup analysis is also performed for pancreatic functional PNETs *i.e.*, gastrinoma and insulinoma which showed high sensitivity and specificity. This gives additional diagnostic option in patients undergoing conventional imaging such as CT scan and scintigraphy with higher diagnostic accuracy compared to previously published data of the former tests.

### Applications

EUS can be used to identify pancreatic PNETs with high degree of diagnostic accuracy.

### Terminology

EUS has a very high sensitivity and specificity in PNETs especially in early stages aiding in early diagnosis and potential treatment.

### Peer review

The current paper of systematic review and meta-analysis investigates the diagnostic accuracy of EUS in diagnosis of PNETs. The statistical analysis performed in this study produced reliable results.

### Abstract

Walled-off pancreatic necrosis and a pancreatic abscess are the most severe complications of acute pancreatitis. Surgery in such critically ill patients is often associated with significant morbidity and mortality within the first few weeks after the onset of symptoms. Minimal invasive approaches with high success and low mortality rates are therefore of considerable interest. Endoscopic therapy has the potential to offer safe and effective alternative treatment. We report here on 3 consecutive patients with infected walled-off pancreatic necrosis and 1 patient with a pancreatic abscess who underwent direct endoscopic necrosectomy 19-21 d after the onset of acute pancreatitis. The infected pancreatic necrosis or abscess was punctured transluminally with a cystostome and, after balloon dilatation, a non-covered

self-expanding biliary metal stent was placed into the necrotic cavity. Following stent deployment, a nasobiliary pigtail catheter was placed into the cavity to ensure continuous irrigation. After 5-7 d, the metal stent was removed endoscopically and the necrotic cavity was entered with a therapeutic gastroscope. Endoscopic debridement was performed *via* the simultaneous application of a high-flow water-jet system; using a flush knife, a Dormia basket, and hot biopsy forceps. The transluminal endotherapy was repeated 2-5 times daily during the next 10 d. Supportive care included parenteral antibiotics and jejunal feeding. All patients improved dramatically and with resolution of their septic conditions; 3 patients were completely cured without any further complications or the need for surgery. One patient died from a complication of prolonged ventilation severe bilateral pneumonia, not related to the endoscopic procedure. No procedure related complications were observed. Transluminal endoscopic necrosectomy with temporary application of a self-expanding metal stent and a high-flow water-jet system shows promise for enhancing the potential of this endoscopic approach in patients with walled-off pancreatic necrosis and/or a pancreatic abscess.

**Key words:** Acute necrotizing pancreatitis; Walled off pancreatic necrosis; Endoscopic necrosectomy; Self-expanding metal stent; Water-jet system

**Core tip:** The endoscopic transluminal management of pancreatic necrosis and/or pancreatic abscess is associated with good initial and long-term clinical success, with acceptable morbidity and mortality rates. The advantages of endoscopic management are related to its minimal invasiveness. The combination of multiple endoscopic approaches is designed to achieve the goals of any treatment strategy.

## INTRODUCTION

Acute pancreatitis (AP) is a disease characterized by significant morbidity and mortality. Pancreatic necrosis (PN), occurring as diffuse or focal areas of non-viable pancreatic parenchyma as defined by the 1992 Atlanta classification, is a serious complication that can develop within a few days following the onset of AP<sup>[1]</sup>.

Acute necrotizing pancreatitis (ANP) complicates 15%-20% of all cases with AP and, in patients in whom the most severe infectious complication infected necrosis develops, the mortality can be as high as 25%-70%<sup>[2]</sup>.

“Organized” or “walled-off pancreatic necrosis” (WOPN), described as relatively well-circumscribed areas of PN, evolves during the several weeks after an episode of severe ANP. This process reflects the evolution from early diffuse PN to an encapsulated, loculated form<sup>[3]</sup>.

Similarly, a pancreatic abscess (PA), a serious complication of AP, can be defined as a circumscribed intra-abdominal collection of purulent material adjacent to the pancreas, containing little or no PN, but circumscribed within a well-defined wall<sup>[1]</sup>.

The conventional treatment of infected WOPN and PA necessitates open surgical debridement, together with sump drainage and continuous lavage. The key objectives of the surgical approach are the removal of all pancreatic- and peripancreatic necrotic tissue, the evacuation of purulent infected material, and the provision of continuous and adequate drainage to promote resolution of the inflammatory processes. The best current therapeutic approach comprises complete removal of the necrotic material, but preservation of all the viable pancreatic tissue, together with the best possible supportive care, preferably at an intensive care unit (ICU).

The recommended surgical procedure of open necrosectomy is associated with a high postoperative complication rate (95%)<sup>[4]</sup>, and the median mortality rate has been reported to be 25% (range 6%-56%)<sup>[5]</sup>.

Minimally invasive approaches with high success and lower mortality rates are therefore of considerable interest, and various percutaneous and endoscopic techniques for the management of PN and PAs have been described during the last decade.

Transluminal retroperitoneal endoscopy for the debridement of infected WOPN can be considered one of the first clinical applications of natural orifice transluminal endoscopic surgery. However, the history of endoscopic necrosectomy began with the endoscopic transmural drainage of pancreatic pseudocysts and ab-

scesses<sup>[3]</sup>.

Endoscopic interventions are typically performed under conscious sedation without the need for general anesthesia. Endoscopic therapy for PN may involve endoscopic retrograde cholangiopancreatography (ERCP) with sphincterotomy, stenting, and nasojejunal feeding tube placement, while a more aggressive and potent therapeutic approach is transmural (transgastric or transduodenal) endoscopic drainage<sup>[3]</sup>, with or without endoscopic ultrasonographic guidance<sup>[6,7]</sup>, followed by balloon dilation of the cystogastrostoma or cystoduodenostoma, and repeated direct endoscopic necrosectomies through the dilated fistulous tract using different accessories (*e.g.*, a polypectomy snare, Dormia basket, hot biopsy forceps, or tripod grasper)<sup>[8,9]</sup>, and stent and/or catheter placement into the necrotic cavity, followed by continuous lavage and irrigation<sup>[10]</sup> and, if required, repeated balloon dilations of the fistulous tract.

Two large, multicenter retrospective studies have demonstrated that the direct transluminal endoscopic management of PN is associated with good long-term maintenance of the high initial success rate<sup>[11,12]</sup>. Nevertheless, all of the current endoscopic techniques have obvious inherent limitations, such as the risk of air embolism, endoscopically uncontrollable bleeding, and inadequate drainage through multiple plastic stents, together with an early occlusion of the fistulous tract.

To overcome these difficulties, we demonstrate here a new and successful method of endoscopic transluminal necrosectomy (ETN); a combination of the temporary placement of a self-expanding metal stent (SEMS) into the fistulous tract and daily irrigations of the necrotic cavity with a high-flow water-jet system, using a flush knife.

## CASE REPORT

Direct endoscopic therapy was performed on 4 patients. The indication for the endoscopic transmural approach was infected PN in 3 cases and a PA in 1 case.

### Case 1

A 59-year-old female was admitted to our emergency sub-ICU with AP. At admission, she had severe upper abdominal pain that had started 24 h before. Abdominal ultrasonography revealed multiple small stones in the gallbladder, with concomitant dilation of the extrahepatic bile ducts. Laboratory tests demonstrated leukocytosis (26 g/L), and elevated blood glucose (13.4 mmol/L), liver function tests [aspartate aminotransferase (AST): 76 U/L, alanine aminotransferase (ALT): 106 U/L, gamma-glutamyl transferase (GGT): 389 U/L], and serum amylase (2262 U/L). The calculated Glasgow score was 7, which predicted a severe attack of pancreatitis. Emergency ERCP was performed, and after endoscopic sphincterotomy a small (5 mm in diameter) impacted gallstone was successfully removed from the common bile duct. Despite maximum conservative therapy, an abdominal

computed tomography (CT) scan 72 h later demonstrated severe APN with extensive necrosis and peripancreatic fluid accumulation was observed (Balthazar score: 6). After transmission to the ICU she received maximum supportive care, with mechanical ventilation, parenteral antibiotics (Imipenem and Metronidazole), parenteral volume replacement and nasojejunal feeding, epidural anesthesia and plasmapheresis. Despite the optimum therapy, her general condition was still deteriorating at the end of the third week, due to a high fever, sepsis, and multi-organ failure. Laboratory tests showed elevated C-reactive protein (CRP) and procalcitonin (PCT) levels (226 mg/L and 2.72 µg/L, respectively). A repeated CT scan demonstrated an approximately 14 cm × 11 cm × 12 cm volume of not clearly demarcated peripancreatic necrosis with accumulated fluid located between the stomach and the body of the pancreas; clinically, infection of the necrosis was assumed. After repeated surgical consultations, we decided to attempt ETN rather than open surgical necrosectomy in order to minimize the level of invasiveness in this critically-ill patient on day 21 after the onset of ANP.

### Case 2

A 62-year-old female patient was transferred from a secondary care hospital to our gastroenterological sub-ICU with upper abdominal pain and an elevated serum amylase level (4000 U/L). She had experienced the first attack of abdominal pain 2 wk earlier, though she then became asymptomatic, but the day before admission she again developed severe abdominal pain after a fatty food intake. At admission, the calculated Glasgow score was 8, indicating a severe attack of AP. On abdominal ultrasonography a large (2 cm in diameter) solitary gallbladder stone was detected. Laboratory tests demonstrated leukocytosis (21 G/L), elevated blood glucose (21 mmol/L), liver function tests (AST: 439 U/L, ALT: 339 U/L, GGT: 308 U/L), and serum amylase (1152 U/L). Emergency ERCP was performed, but, apart from the known gallbladder stone, no cholangiographic signs of biliary obstruction or gallstone pancreatitis were seen. Two days later, due to high fever and sepsis, she was transferred to the ICU. An abdominal CT scan on day 4 of hospitalization revealed ANP with extensive necrosis, duodenal compression, and an accumulation of peripancreatic fluid 45 mm in width at the bursa omentalis (Balthazar score: 7). Maximum supportive care at the ICU included parenteral antibiotics (Imipenem + Amikacin, followed by Tigecycline and Metronidazole), parenteral volume replacement, nasojejunal feeding, and epidural anesthesia; there was no need for long-term mechanical ventilation. A repeated CT scan demonstrated an 11 cm × 7 cm × 7.5 cm volume of peripancreatic necrosis with the extensive accumulation of fluid mainly between the posterior wall of the stomach and the pancreas. At the end of the third week, she still had high fever, and presented extremely high CRP (326 mg/L) and elevated PCT (2.67 µg/L) levels. From the clinical signs and laboratory results, infection of the PN was evident and therefore, after repeated surgical consul-

tations, we decided to perform ETN on day 20.

### Case 3

A 72-year-old female patient was admitted to our department with upper abdominal pain and vomiting that had persisted for 6 d before hospitalization. Her case history included hypertension and a vertebrobasilar stroke 7 years previously. At admission, laboratory tests revealed only mild leukocytosis (10.2 g/L), but high CRP (249.6 mg/L), elevated lactate dehydrogenase (741 U/L) and blood urea nitrogen (14.8 mmol/L), and mildly increased serum amylase (136 U/L). The liver function tests were normal, with the exception of mild GGT elevation (110 U/L). The clinical signs and abdominal ultrasonography (no gallstones or bile duct dilatation) led to a diagnosis of idiopathic AP. Despite maximum supportive care, with parenteral antibiotics (Ciprofloxacin and Metronidazole), parenteral volume replacement, nasojejunal feeding, and epidural anesthesia, an abdominal CT scan 3 wk later demonstrated severe ANP, with complete destruction of the pancreatic tissue, secondary antral and duodenal compression, and a 10 cm wide accumulation of peripancreatic fluid in the retrogastric region, from the liver hilum up to the spleen, but not clearly demarcated from the retroperitoneal tissue (Balthazar score: 9). After repeated surgical consultations, we decided on ETN rather than open surgical necrosectomy in order to minimize the invasiveness in this elderly patient with significant comorbidity, on day 31 after the onset of ANP.

### Case 4

A 52-year-old male patient was admitted to our department with upper abdominal pain and nausea. The symptoms had developed after a spicy and fatty food intake. The case history revealed two attacks of AP one year previously, with the consequent development of a pancreatic pseudocyst. At admission, laboratory tests indicated mild leukocytosis (12.2 g/L), CRP (15.2 mg/L), and mildly elevated blood glucose (6.5 mmol/L) levels. Liver function tests were normal, but the serum level of amylase was increased (653 U/L). On abdominal ultrasonography a large (11 cm × 4 cm) pancreatic pseudocyst was seen, without signs of bile duct dilation. A temporary improvement was achieved on supportive care, but on day 7 of hospitalization a sudden deterioration was observed and the patient was transferred to the ICU. An abdominal CT scan revealed a PA (8.5 cm × 5 cm). Despite maximum supportive care with mechanical ventilation, parenteral antibiotics (Imipenem and Metronidazole, followed by Amikacin), parenteral volume replacement, and nasojejunal feeding, no improvement was achieved. After repeated surgical consultations, we decided to perform ETN on day 13 after the onset of AP.

### Endoscopic treatment

All patients provided informed consent before each endoscopic intervention. The endoscopic procedures were performed with the patients under conscious sedation

with intravenous benzodiazepine and/or opioid administration. ERCP was carried out when indicated.

The feasibility of endoscopic drainage was assessed by endoscopic ultrasonography with the application of a linear echoendoscope (Fujinon EG-530UT). The optimum drainage site was selected, and vessel interposition was excluded by color-flow Doppler. After infiltration of the gastric wall with 20 mL of diluted adrenaline (1:10000 in saline), the cavity was punctured with a 22-gauge needle for sample collection (for microbiological analysis). Next, the gastric wall was perforated with a cystostome (Wilson-Cook, 60 W, forced coagulation) to access the necrotic cavity, followed by dilatation of the fistulous tract up to 12 F with the outer dilatation catheter of the same device. Contrast medium was then injected to assess the extent and borders of the cavity. After this, a 480 cm long, 0.035 inch diameter guidewire (Tracer Wire Guide; Wilson-Cook) was carefully advanced through the cystostome to form at least two loops inside the cavity, so as to facilitate safe catheter exchange. The puncture site was dilated with a wire-guided biliary balloon up to 10 mm and 1.5 psi (Olympus Endoscopy). Finally, a 6 cm long, 10 mm wide throughout, non-covered, biliary SEMS (Micro-Tech Europe) was positioned and opened inside the fistulous tract in order to make a permanent and wide connection between the necrotic cavity and the stomach. After opening of the SEMS, a large volume of purulent fluid and necrotic material emptied spontaneously into the stomach, and this was further facilitated with continuous flushing and suction *via* the endoscope. We finalized the first stage of the necrosectomy process with the placement of a 12 F nasobiliary pigtail catheter into the necrotic cavity through the SEMS. During the next 5 d, physiological saline was irrigated through this catheter at a flow rate of 100 mL/h to facilitate continuous lavage and optimum drainage of the necrotic material.

We entered the stomach with a double-channel therapeutic gastroscope (Fujinon EG-530D), and removed the SEMS from the necrotic cavity without any difficulty with standard foreign body forceps 5-7 d later. ETN was performed in the following steps: (1) the therapeutic gastroscope (Fujinon EG-530D) was inserted directly into the cavity; (2) with the application of a flush knife (Fujinon Flush Knife), the purulent debris was flushed from the inner cavity wall, using the high-flow water-jet system (Fujinon JW-2 Water Pump). For high-flow irrigation, we used Betadine solution (1:10 dilution in saline); continuous suction was achieved through the wide-channel therapeutic endoscope; (3) the necrotic remnant was removed by simultaneous application of the flush knife, a Dormia basket, and hot biopsy forceps; and (4) finally, placement of a 12 F nasobiliary catheter into the necrotic cavity and a suction drain into the stomach provided continuous lavage between the endoscopic sessions.

ETN and lavage were performed daily until complete evacuation of the necrotic and purulent material (Figures 1-3).

The puncture of the necrotic cavity and placement

of the SEMS into the fistulous tract, together with naso-pancreatic drainage, was successful in all patients. Access to the cavity was created by an endoscopic puncture into a clearly bulging lesion under endosonographic guidance in 3 cases, and by using a spontaneous perforation of the cyst to the gastrointestinal lumen in Case 4. Transgastric (Cases 1-3) or transduodenal access (Case 4) was chosen in 3 and 1 cases, respectively. After 5-7 days of lavage, the SEMSs were all safely removed. No SEMS-related complications were observed. After SEMS removal, the fistulous tract was sufficiently widely open (without any need for further balloon dilation) to be entered repeatedly with a double working channel therapeutic gastroscope; this allowed permanent access for transgastric necrosectomy during the next 2-3 wk. The average number of daily necrosectomies was 2.6 (range, 2-5). No endotherapy-related complications were observed. ERCP was performed in two patients. After endoscopic management, the Sequential Organ Failure Assessment score and the sepsis improved, the decreased level of consciousness ceased, CRP levels significantly decreased (Figure 4), and a CT scan showed no further evolution of peripancreatic fluid, necrosis, or abscess. All patients, except one (Case 2), were uneventfully and completely cured after endoscopic therapy and medical treatment. Following 6 wk of further basic supportive treatment and jejunal nutrition, they could leave the hospital. The average duration of hospitalization was 63 d (range 48-74 d). The artificial transluminal fistula spontaneously closed within 3 mo.

After a temporary improvement, one patient (Case 2) died 20 d after the first endoscopic intervention, on day 38 of ICU treatment. The autopsy revealed multifocal pulmonary abscesses and severe bilateral pneumonia (an obvious complication of prolonged ventilation), but no retroperitoneal abscess and only moderate inflammatory signs at the site of ETN.

## DISCUSSION

Despite receiving maximum ICU therapy, patients with ANP can succumb rapidly. In terms of the clinical disease course, severe AP is biphasic. During the first week after the onset, there is an early mortality peak, which is known to be mainly due to the systemic inflammatory response syndrome and early multiorgan failure evoked by the exaggerated pro-inflammatory response<sup>[13,14]</sup>. In contrast, 2-3 wk after the onset of the symptoms, at the time of the maximum anti-inflammatory response and consequent immunosuppression, there is a second peak of mortality, which is known to be mainly due to the infectious complications caused by bacterial translocation, followed by sepsis and late multiorgan failure<sup>[15,16]</sup>. At this point, even maximum ICU therapy may not be able to halt or reverse the disease progression in some patients.
