**ABOUT COVER** Editorial Board Member of *World Journal of Gastroenterology*, Terumi Kamisawa, MD, PhD, Department of Internal Medicine, Tokyo Metropolitan Komagome Hospital, 3-18-22 Honkomagome, Bunkyo-ku, Tokyo 113-8677, Japan

**AIMS AND SCOPE** *World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a peer-reviewed open access journal. *WJG* was established on October 1, 1995. It is published weekly on the 7<sup>th</sup>, 14<sup>th</sup>, 21<sup>st</sup>, and 28<sup>th</sup> each month. The *WJG* Editorial Board consists of 1352 experts in gastroenterology and hepatology from 64 countries.

The primary task of *WJG* is to rapidly publish high-quality original articles, reviews, and commentaries in the fields of gastroenterology, hepatology, gastrointestinal endoscopy, gastrointestinal surgery, hepatobiliary surgery, gastrointestinal oncology, gastrointestinal radiation oncology, gastrointestinal imaging, gastrointestinal interventional therapy, gastrointestinal infectious diseases, gastrointestinal pharmacology, gastrointestinal pathophysiology, gastrointestinal pathology, evidence-based medicine in gastroenterology, pancreatology, gastrointestinal laboratory medicine, gastrointestinal molecular biology, gastrointestinal immunology, gastrointestinal microbiology, gastrointestinal genetics, gastrointestinal translational medicine, gastrointestinal diagnostics, and gastrointestinal therapeutics. *WJG* is dedicated to become an influential and prestigious journal in gastroenterology and hepatology, to promote the development of above disciplines, and to improve the diagnostic and therapeutic skill and expertise of clinicians.

**INDEXING/ABSTRACTING** *World Journal of Gastroenterology* is now indexed in Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®), Journal Citation Reports®, Index Medicus, MEDLINE, PubMed, PubMed Central, Digital Object Identifier, and Directory of Open Access Journals. ISI, Journal Citation Reports®, Gastroenterology and Hepatology, 2012 Impact Factor: 2.547 (34/74); Total Cites: 19145 (6/74); Current Articles: 944 (1/74); and Eigenfactor® Score: 0.06035 (6/74).

### Abstract

Several factors influence the clinical course of hepatitis B virus (HBV) and hepatitis C virus (HCV) infection. The human leukocyte antigen (HLA) system, the major histocompatibility complex (MHC) in humans, has been considered one of the most important host factors with respect to outcomes. To date, conventional genotyping studies have shown that *HLA* class II loci are mainly associated with spontaneous clearance of HBV and HCV. However, the specific HLA locus associated with the outcomes of hepatitis virus infection remains unclear. A recent genome-wide association study (GWAS) using a comprehensive approach for human genotyping demonstrated single nucleotide polymorphisms (SNPs) associated with the outcomes of hepatitis virus infection. Examination of large numbers of cohorts revealed that several SNPs in both *HLA-DPA1* and *HLA-DPB1* loci are associated with persistent HBV infection in Asian populations. To date, however, few studies have focused on *HLA-DP* because polymorphisms of *HLA-DP* haplotype do not vary greatly as compared with other loci of *HLA*. There are not enough studies to reveal the function of *HLA-DP*. GWAS additionally detected candidate SNPs within HLA loci associated with chronic HBV or HCV hepatitis, hepatic fibrosis, and the development of hepatocellular carcinoma. The results

of one cohort were not always consistent with those of other cohorts. To solve several controversial issues, it is necessary to validate reported SNPs on *HLA* loci in global populations and to elucidate the *HLA*-allele-regulated molecular response to hepatitis virus infection.

**Key words:** Hepatitis B virus; Hepatitis C virus; Hepatocarcinogenesis; Human leukocyte antigen; Genome-wide association studies; Genotyping; Persistent infection

**Core tip:** Conventional genotyping studies have shown that human leukocyte antigen (*HLA*) typing was one of the most important host factors with respect to outcomes of hepatitis B and C virus infections. However, the specific HLA locus associated with the outcomes remains unclear. Recently a genome-wide association study for human genotyping demonstrated single nucleotide polymorphisms associated with the outcomes of hepatitis virus infection. Now it has been confirmed that several single nucleotide polymorphisms in both *HLA-DP* loci were associated with persistent hepatitis B virus infection in Asian populations.

Tamori A, Kawada N. HLA class II associated with outcomes of hepatitis B and C infections. *World J Gastroenterol* 2013; 19(33): 5395-5401 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i33/5395.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i33.5395>

### INTRODUCTION

The human leukocyte antigen (HLA) system, the major histocompatibility complex (MHC) in humans, has long been considered the most important region in the human genome with respect to infection, inflammation, autoimmunity, and transplantation medicine<sup>[1,2]</sup>. In humans, *HLA* complex consists of more than 200 genes located

close together on chromosome 6. Genes in this complex are categorized into three basic groups: class I (*HLA-A*, *-B*, and *-C*), class II (*HLA-DR*, *-DQ*, and *-DP*), and class III (some genes involved in inflammation and other immune-system activities). Interactions among HLA-restricted T lymphocytes, B lymphocytes, natural killer (NK) cells, and cytokines influence immune response to viral infection. *HLA* class I and II molecules are expressed as cell surface antigens that bind to peptide epitopes on CD8<sup>+</sup> T cells and CD4<sup>+</sup> T cells, respectively. Effective presentation of viral antigens by the HLA system induces good immune response.

It is well known that some patients infected with hepatitis B virus (HBV) or hepatitis C virus (HCV) spontaneously recover and can escape from persistent infection<sup>[3-5]</sup>. Progression of liver diseases by chronic viral infection also differs among patients. In addition, the response to HBV vaccination is different in each person. To identify immune systems against invaders in individual patients, *HLA* haplotypes related to persistent viral infection or providing protection against such infection have been examined. Singh *et al*<sup>[6]</sup> reported a detailed review about associations of *HLA* types with HBV and HCV infections among global populations. They speculated that there was a limited chance of detecting globally common *HLA* types related to outcomes or disease progression associated with hepatitis viral infection because *HLA* loci are diverse owing to racial admixture, environmental and selection pressure, and inherent polymorphic nature, leading to allelic variations among different ethnic groups.

Recent genome-wide association studies (GWAS) have demonstrated single nucleotide polymorphisms (SNPs) associated with the outcomes of hepatitis virus infection<sup>[7-14]</sup>. Imputation-based association analysis showed that some of the SNPs are located near *HLA* loci in chromosome 6p21<sup>[7,8,15]</sup>. Conventional genotyping and GWAS are different approaches for analysis. Conventional genotyping examines selected targeted genes, while GWAS can comprehensively examine hundreds of thousands of SNPs<sup>[16]</sup>. Although both approaches have suggested that *HLA* loci play important roles in the outcomes of viral hepatitis, the precise regions of *HLA* loci detected by each approach differed. In the present review, we summarize and compare the latest data obtained by GWAS with previous data obtained by conventional *HLA* typing.

## ASSOCIATION BETWEEN HEPATITIS VIRAL INFECTION AND *HLA* ALLELES IDENTIFIED BY GENOTYPING

Singh *et al*<sup>[6]</sup> suggested that an association of *HLA DR\*13* alleles in *HLA* Class II was protective in both HBV and HCV infections in several populations. *HLA DRB1\*11* and *HLA DQB1\*0301* were protective in HCV infection, but were associated with persistent HBV infection.

A recent meta-analysis showed that *HLA-DR\*03* and

*HLA-DR\*07* were associated with an increased risk of persistent HBV infection in 19 individual case-control studies including 9 Han Chinese cohorts, 3 Korean cohorts, 2 Iranian cohorts, and 1 cohort each of Caucasian, Gambian, Taiwanese, Thai, and Turkish subjects<sup>[17]</sup>. In contrast, *HLA-DR\*04* and *HLA-DR\*13* were associated with clearance of HBV infection. In Chinese Han populations, *HLA-DR\*01* was associated with clearance of HBV infection, while in other ethnic groups there was no association between *HLA-DR\*01* and HBV infection.

As for HCV infection, a study performed in patients from the United Kingdom and the United States reported that the inhibitory NK cell receptor KIR2DL3 and *HLA-C1* ligand, *HLA* class I interact directly to promote spontaneous viral clearance<sup>[18]</sup>. In global populations, *HLA* class II, especially several alleles in *HLA-DRB1*, has been linked to persistent HCV infection<sup>[19,20]</sup>. Interestingly, Spanish and American groups reported an association between *MICA* genotypes in *HLA* class III and clearance of HCV<sup>[21,22]</sup>.

## ASSOCIATION BETWEEN HEPATITIS VIRAL INFECTION AND SNPS IN *HLA* LOCUS IDENTIFIED BY GWAS

A recent GWAS discovered many SNP candidates associated with common diseases<sup>[16]</sup>. In research on viral hepatitis, several SNPs associated with outcomes, including the *HLA* coding region of chromosome 6p21.3, were detected by GWAS.

### *HBV* infection

Kamatani *et al*<sup>[7]</sup> reported the results of a case-control association study of HBV infection in 2009. They showed that rs3077 SNP near *HLA-DPA1* gene and rs9277535 SNP near *HLA-DPB1* were associated with persistent HBV infection in Japanese cohorts. In addition, *HLA* haplotype analysis showed that *HLA-DPA1\*0202-DPB1\*0501* and *HLA-DPA1\*0202-DPB1\*0301* were risk types for persistent HBV infection, and *HLA-DPA1\*0103-DPB1\*0402* and *HLA-DPA1\*0103-DPB1\*0401* were protective types for HBV infection. The same group performed a second GWAS analysis involving a larger number of cohorts<sup>[8]</sup>. The study validated that rs3077 SNP near *HLA-DPA1* gene and rs9277535 SNP near *HLA-DPB1* were strongly associated with persistent HBV infection. Other SNPs, rs2856718 and rs7453920 within the *HLA-DQ* locus, were also associated with persistent HBV infection. Moreover, HLA haplotype analysis indicated that *HLA-DQA1\*0102-DQB1\*0303* and *HLA-DQA1\*0301-DQB1\*0601* were risk types for persistent HBV infection, while *HLA-DQA1\*0102-DQB1\*0604* and *HLA-DQA1\*0101-DQB1\*0501* were protective types for HBV infection. GWAS of Han Chinese populations also showed that the *HLA-DPA1* and *HLA-DPB1* genes were related to persistent HBV infection. The first study from China indicated that 4 SNPs related to *HLA-*

HLA: Human leukocyte antigen; SNP: Single nucleotide polymorphism; HCC: Hepatocellular carcinoma.

*DPA1* gene, including rs3077, and 7 SNPs related to *HLA-DPB1*, including rs9277535, were associated with chronic HBV infection<sup>[9]</sup>. Another study showed that rs7453920 and rs2856718 SNPs near *HLA-DQ* were associated with persistent HBV infection in addition to the rs3077 and rs9277535 SNPs<sup>[10]</sup> (Table 1).

A recent report from another Japanese group showed that rs3077 SNP near *HLA-DPA1* gene and rs9277542 SNP near *HLA-DPB1* gene were associated with persistent HBV infection<sup>[12]</sup>. Studies using genotyping methods validated that the rs3077 and rs2395309 SNPs near *HLA-DPA1* gene and the rs9277542 SNP near *HLA-DPB1* were associated with HBV infection in Han Chinese populations<sup>[23-25]</sup>.

GWAS revealed three independent variants within the *HLA* complex that were related to a poor response

to HB vaccine in the Indonesian population. Specifically, rs3135363 SNP near *HLA-DR*, rs9277542 SNP near *HLA-DPB1*, and rs9267665 in *HLA* class III were associated with antibody titers after HB vaccination<sup>[10]</sup>.

A comparison between cohorts with and without hepatocellular carcinoma (HCC) showed that rs9272105 SNP near *HLA-DQA1/DRB1* and rs455804 SNP near *GRIK1* were significantly associated with HCC development in Chinese patients with HBV<sup>[11]</sup>. There was a partial association of the genotype of rs9272105 to *HLA-DRB1\*0405* and *\*0901*. Another study showed that rs2856718 SNP at *HLA-DQ* and rs3077 SNP at *HLA-DPA1* had a protective effect against HCC progression as compared with the dominant SNP of rs2856718 in Han Chinese populations<sup>[13]</sup>. In 2013, it was reported that rs9275319 at *HLA-DQ* and rs7574865 at *STAT4* were

**Table 2** Single nucleotide polymorphisms within human leukocyte antigen loci associated with outcomes of hepatitis C virus infection

Ethnic group	Outcome	No. of cohorts	HLA locus	SNP	Odds	95%CI	Haplotype	Odds	Ref.
Japanese	HCC	721 HCC <i>vs</i> 2890 HCV-negative controls	MICA	rs2596542	1.34	1.16-1.53			[30]
Japanese	Cirrhosis	682 cirrhosis <i>vs</i> 1045 Chronic hepatitis	C6orf10	rs910049	1.73	1.40-2.15			[31]
			No gene	rs3135363	1.58	1.32-1.90			
							DQA1*0601	2.80	
							DPB1*0405	1.45	

SNP: Single nucleotide polymorphism; HCC: Hepatocellular carcinoma; HLA: Human leukocyte antigen; HCV: Hepatitis C virus.

independently associated with the risk of HCC in Han Chinese populations<sup>[14]</sup>. There was a moderate association between the genotype of rs9275319 SNPs with *HLA-DQB1\*0401* and *HLA-DQA1\*0303*. On the other hand, there was no significant association between HCC development by HBV infection and *HLA* alleles in Korean or Japanese populations<sup>[26]</sup>. It thus remains unclear whether specific HLA loci play important roles in hepatocarcinogenesis in patients with HBV.

### HCV infection

It is globally recognized that interleukin-28B (IL-28B) gene polymorphisms originally detected by GWAS are associated with spontaneous clearance of HCV, as well as with the response to combination therapy with pegylated interferon and ribavirin in patients with HCV<sup>[27,28]</sup>. However, this SNP is not located in HLA loci. A recent study identified rs4273729 SNP near *HLA DQB1\*0301* as a candidate allele for spontaneous clearance of HCV in populations with European and African ancestry<sup>[29]</sup>. *HLA DQB1\*0301* and *IL28B* are independently associated with spontaneous resolution of HCV infection.

Comparisons between cohorts with and without HCC showed that rs2596542 SNP at the 5' flanking region of *MICA* in *HLA* class III was significantly associated with HCC development in Japanese patients with HCV<sup>[30]</sup>. Soluble MICA levels in serum were significantly lower in AA genotype of rs2596542 and were associated with a high risk of HCC progression. The same group identified 2 SNPs in the *MHC* region that were associated with progression from chronic hepatitis to cirrhosis. These SNPs were located at rs910049 and rs3135363 on chromosome 6p21.3<sup>[31]</sup>. Imputation-based association analysis showed that *HLA-DQA1\*0601* and *HLA-DPB1\*0405* were associated with progression of cirrhosis (Table 2).

### FUTURE DIRECTIONS

Ongoing association studies are evaluating the effects of genetic variations on the outcomes of hepatitis virus infection in large groups of patients. However, most SNPs identified by association studies did not link to phenotype, and many other SNPs remained untyped. Imputation-based association analysis exploits information on patterns of multi-marker correlation ("linkage disequilibrium") from publically available databases to estimate ("impute") patient genotypes associated with

identified SNPs and thereby assess the relations of such genotypes to phenotypes<sup>[32,33]</sup>. Owing to this method, the relations between SNPs and *HLA* haplotypes associated with the outcomes of HBV or HCV infection are becoming clearer.

In HBV infection, conventional genotyping showed that *HLA* class II, DR and DQ haplotypes were the most important regions of host genetic factors for outcomes. However, GWAS showed that rs3077 SNP near *HLA-DPA1* gene and rs9277535 SNP near *HLA-DPB1* gene were associated with persistent HBV infection in Asian populations<sup>[7,9,12,13]</sup>. *HLA-DPA1* and *DPB1* have also been associated with responsiveness to HB vaccination<sup>[10,34,35]</sup>. To date, however, few studies have focused on *HLA-DP* because polymorphisms of *HLA-DP* haplotype do not vary greatly as compared with other loci of *HLA*<sup>[36]</sup>. The structures of *HLA-DP* and *HLA-DP* molecules are similar to those of other *HLA* class II molecules. Therefore, similar to the functions of other *HLA* class II molecules, *HLA-DP* and *HLA-DP* molecules might affect the ability of *HLA* class II molecules to present antigens to CD4-positive helper T cells and result in immune response to HBV. Recently, *HLA-DPA1* and *HLA-DPB1* mRNA expressions in normal liver were respectively associated with SNP types rs3077 and rs9277535 in European populations. The mRNA expressions of *HLA-DPA1* and *HLA-DPB1* were low in genotypes rs3077-G and 9277535-G, which were associated with a high risk of persistent HBV infection<sup>[37]</sup>. However, another study in European- and African-Americans showed that rs9277534 of the *HLA-DPB1* allele (496-A/G) was a novel variant associated with persistent HBV infection<sup>[38]</sup>. In contrast to the former study, the 496-GG genotype was associated with both higher mRNA expression of *HLA-DP* and persistent HBV infection.

Inconsistent results have been obtained for the association between *HLA* alleles and HCC in patients with HBV infection. In Han Chinese populations, several SNPs in *HLA* class II have been associated with progression of HCC. However, no common SNP was confirmed by independent researchers. In addition, SNPs in chromosomes 1p36.22, 2q32.2, and 21q21.3, were also associated with HBV-related HCC<sup>[39]</sup>. Further examinations are definitely required to elucidate the role of *HLA* loci on the progression of HCC in patients with HBV.

GWAS indicated that *HLA* loci are related to important host factors involved in several aspects of HCV

infection. First, *HLA DQB1\*0301* was reported to be independently associated with spontaneous clearance of HCV infection. Previous HLA haplotype analysis showed that *HLA DQB1\*0301* was associated with HCV clearance in French females, African-Americans, and Italian populations<sup>[40-42]</sup>. Thus, GWAS confirmed the results of previous results. However, the mechanism by which such alleles affect HCV clearance remains undetermined.

In the Japanese population, rs4273729 SNP near *HLA DQB1\*0301* and *MICA* SNP in - *HLA* class III were respectively associated with progression of hepatitis to cirrhosis<sup>[31]</sup> and HCC<sup>[30]</sup> in patients with HCV. This is attractive information for the prediction of clinical course, but several issues remain to be defined. First, HCC most frequently develops in cirrhotic patients infected with HCV. It is not known why different SNPs are identified in continuous pathological conditions such as HCC and hepatic cirrhosis in patients with HCV. Next, an intronic SNP in the *DEPDC-5* gene, without an *HLA* locus, was also associated with HCC development in the Japanese population<sup>[43]</sup>. In European populations, several SNPs without *HLA* loci were associated with the progression of hepatic fibrosis<sup>[44]</sup>. The progression of chronic hepatitis C has been confirmed to depend on multiple factors, including age, gender, infection period, obesity, alcohol intake, and treatment<sup>[45]</sup>. It is suspected that the effects of *HLA* loci on fibrosis progression or the development of HCC (or both) differ in the each population studied.

In conclusion, genome association analysis of large numbers of cohorts indicated that *HLA* loci are one of the most important host determinants of the clinical characteristics of HBV and HCV infections, acting in conjunction with factors such as viral load, viral genotype, age, alcohol intake, and hepatic fibrosis. However, it is necessary to validate reported SNPs on *HLA* loci in global populations and to elucidate *HLA*-allele-regulated molecular responses to hepatitis virus infection.

### Abstract

Non-alcoholic fatty liver disease (NAFLD) and irritable bowel syndrome (IBS) are two very common diseases in the general population. To date, there are no studies that highlight a direct link between NAFLD and IBS, but some recent reports have found an interesting correlation between obesity and IBS. A systematic PubMed database search was conducted highlighting that common mechanisms are involved in many of the local and systemic manifestations of NAFLD, leading to an increased cardiovascular risk, and IBS, leading to microbial dysbiosis, impaired intestinal barrier and altered intestinal motility. It is not known when considering local and systemic inflammation/immune system activation, which one has greater importance in NAFLD and IBS pathogenesis. Also, the nervous system is implicated. In fact, inflammation participates in the development of mood disorders, such as anxiety and depression, characteristics of obesity and consequently of NAFLD and, on the other hand, in intestinal hypersensitivity and dysmotility.

**Key words:** Non-alcoholic fatty liver disease; Irritable bowel syndrome; Low grade chronic inflammation; Cytokines

**Core tip:** The link between non-alcoholic fatty liver disease (NAFLD) and irritable bowel syndrome (IBS) should be carefully evaluated in future research, representing an intriguing field of investigation. A better understanding of the role of systemic inflammation and activation of the immune system may be necessary to clarify obscure points of NAFLD and IBS pathogenesis, and therefore it can be helpful in the development of new therapies.

### INTRODUCTION

Fat accumulation in the liver in the absence of specific causes of hepatic steatosis, such as alcohol consumption, with or without liver inflammation and its consequences, is described as non-alcoholic fatty liver disease (NAFLD)<sup>[1]</sup>. To date, there are no studies that highlight the link between NAFLD and irritable bowel syndrome (IBS), but some recent reports have found an interesting correlation between obesity and IBS. A relationship between body mass index (BMI) and IBS-like symptoms seems to exist<sup>[2,3]</sup>. Moreover, in IBS subjects a high BMI is associated with significantly faster colonic and recto-sigmoid transit and high stool frequency<sup>[4]</sup>. Cremonini *et al*<sup>[5]</sup> have compared obese binge eaters and non binge eaters to healthy controls and have evidenced that obese subjects more frequently have constipation, diarrhea, straining and flatus regardless of the eating disorder, and that obese binge eaters are characterized by more recurrent upper

and lower gastrointestinal symptoms. Clements *et al*<sup>[6]</sup> have highlighted that obese patients experience more severe gastrointestinal symptoms than healthy controls, and that after laparoscopic Roux-en-Y gastric bypass they have increased abdominal pain, gastroesophageal reflux disease, sleep disturbance and IBS symptoms. The development of small intestinal bacterial overgrowth (SIBO) may explicate, perhaps partially, the incidence of IBS symptoms in obese subjects with previous abdominal surgery, and in this case the bacterial overgrowth may be the consequence of changes in the function and in the morphological structure of the gut<sup>[7]</sup>.

NAFLD pathogenesis is strictly allied to metabolic syndrome, insulin resistance and obesity<sup>[8,9]</sup> but inflammation plays an equally important role. Day *et al*<sup>[10]</sup> have developed in 1998 the classical “two-hit” theory: liver fat accumulation is the “first-hit”, linked to obesity, insulin resistance and metabolic syndrome, while the “second-hit” is activated by hepatic inflammation, together with oxidative stress and endotoxemia, which have a key role in the progression to non-alcoholic steatohepatitis (NASH) and, over time, to fibrosis, until the development of cirrhosis<sup>[11]</sup>.

Actually, this classic view has been revised, because a frank distinction between “first-hit” and “second-hit” is not easy to make, leading to the “multiple-hit theory”<sup>[12]</sup>. Recent studies have shown that, independently from fat accumulation in the liver, obesity systemically leads to activation of the immune system and low-chronic inflammation from the first stage of the disease<sup>[13]</sup>.

Obesity and hepatic fat accumulation are hypothetically implicated in IBS genesis or development. Moreover, an initial correlation between IBS and NAFLD can be suggested by some interesting data. In the pathogenesis of NAFLD and NASH, there is a strong involvement of the gastrointestinal system, as evidenced by many studies on the so-called “gut-liver axis”, aiming to comprehend the role of gut microbiota, SIBO and intestinal permeability dysfunction<sup>[14]</sup>. On the other hand, hepatic fat accumulation and hepatic inflammation in NAFLD subjects<sup>[15]</sup> and gastrointestinal symptoms in IBS subjects<sup>[16]</sup> both improve after therapy with probiotics.

IBS, one of the most common gastrointestinal disorders with an estimated prevalence of 7%-10% worldwide<sup>[17]</sup>, is characterized by abdominal pain/discomfort, changes in bowel habits and no association with organic cause. Despite the fact that in IBS subjects macroscopically evident pathological lesions at colonoscopy have not been found, molecular biology and in-depth histological investigations have revealed the activation of the immune system. A key piece of evidence is that the exposure of rodent<sup>[18-20]</sup> or human<sup>[21]</sup> tissues or cell cultures<sup>[22]</sup> to mucosal or luminal mediators from IBS subjects leads to impaired nervous stimulation or intestinal barrier damage. A proportion of patients develop IBS symptoms after infectious gastroenteritis, or in a remission state from microscopic colitis, Crohn's disease and ulcerative colitis, or on a gluten-free diet for celiac disease<sup>[23]</sup>.

Inflammation and immune system activation may be the mechanisms linking two apparently very different diseases, and the purpose of our review is to collect key evidence supporting their relationship and therefore to explain the pathophysiological link between the intestine and the liver, which is exquisitely firstly anatomical and consequently also functional.

## IMMUNITY IN NAFLD

A low-grade chronic inflammation underlies all NAFLD entities/stages and can develop and promote the liver damage<sup>[13]</sup>.

Innate and adaptive immune pathways are activated in obesity and many findings show that adipose tissue inflammation exacerbates hepatic steatosis and promotes non-alcoholic steatohepatitis (NASH). Obese individuals more frequently develop infectious diseases<sup>[24-26]</sup> as complications after surgery<sup>[27,28]</sup>, and an increased BMI is associated with enhanced risk of infections in institutionalized geriatric patients<sup>[29]</sup>.

The adipose tissue has an important role in regulating energy utilization, vascular functions and immune system homeostasis<sup>[30]</sup>. C-reactive protein (CRP)<sup>[8]</sup>, interleukin (IL)-6<sup>[31]</sup>, fibrinogen and plasminogen activator inhibitor-1<sup>[32]</sup> levels are higher in obese patients compared to healthy subjects. Stanton *et al*<sup>[33]</sup> have recently found that obese mice, after high fat and high cholesterol diets, express abnormal levels of macrophages and inflammation-associated genes in adipose tissue and in liver.

Obesity can influence liver metabolism directly, *via* circulating free fatty acids (FFA), and indirectly, *via* pro-inflammatory cytokine production. FFA and other lipids in hepatocytes are involved in production of reactive oxygen species, mitochondrial dysfunction and endoplasmic reticulum stress. They have proapoptotic capacity and can stimulate proinflammatory signaling pathways<sup>[30]</sup>. FFA from adipose tissue, food and intestinal bacteria can bind toll like receptors (TLR) expressed on immune cells systemically and also in the liver, and enhance the hepatic expression of TLR-4 and TLR-2<sup>[34]</sup>, these being receptors fundamental to the activity of immune system.

The presence of a dysregulation of the immune system in NAFLD has been firstly evidenced by the modification in immune cell populations in the liver. Natural killer (NK) cell circulating levels are reduced in obese rats<sup>[35]</sup>; meanwhile in the liver of NASH subjects their concentration is increased<sup>[36]</sup>. These cells have anti-fibrotic effects and produce apoptosis directly<sup>[37]</sup> and *via* interferon gamma (IFN $\gamma$ ) production<sup>[38]</sup> from hepatic stellate cells (HSC), which have a major role in liver fibrosis<sup>[39]</sup>. In the light of the strict resemblance between NASH and alcoholic hepatitis, Jeong *et al*<sup>[40]</sup> have detected that alcohol contributes to the anti-fibrotic effect of IFN $\gamma$  and NK cells in animals.

Another immune cell population, natural killer T (NKT) cells, which express NK cell markers and  $\alpha/\beta$  T cell receptors, are reduced in steatotic, obese mice<sup>[41,42]</sup>.

and in humans<sup>[43]</sup>. NKT cells are able to produce both T helper (Th) 1 and Th2 cytokines but their depletion in NAFLD has been associated with Th1 polarization of hepatic T cells in mice<sup>[44,45]</sup>.

Two T helper cell subsets were recently discovered and are strictly related to the innate immune response. Th17 cells on one side and Treg cells on the other balance tolerance and elicitation of immune responses<sup>[46]</sup>. Th17 cells produce IL-17, IL-21 and IL-22, and require transforming growth factor- $\beta$  (TGF- $\beta$ ) and IL-6 for their differentiation<sup>[47]</sup>, the same cytokines that inhibit Treg cells. A Chinese study group has recently discovered that oxidative stress induces Treg cell apoptosis in mice with fatty livers<sup>[48]</sup> and subsequently has found also that Th17 cells are increased in the liver of animal and human NASH models<sup>[49]</sup>.

Kupffer cells (KC) are liver macrophages involved in the response to such stressors as infections, ischemia and toxins<sup>[50]</sup> and they are also implicated in liver inflammation and NASH progression<sup>[51]</sup>.

Tumor necrosis factor (TNF) - $\alpha$ , a cytokine produced by KCs, hepatocytes, and abdominal fat, is associated with the development in rodents<sup>[52,53]</sup> and in humans<sup>[54-57]</sup> of insulin resistance, NAFLD and NASH. The role of TNF- $\alpha$  in NAFLD may be due to its capacity to induce hepatocyte apoptosis, insulin resistance and to regulate KC activation locally<sup>[58,59]</sup>. Moreover, TNF- $\alpha$  regulates hepatic lipid metabolism<sup>[60]</sup>.

In a NASH animal model involving choline-deficient diet fed rats it was found that there was an increase in serum and portal alanine aminotransferase levels and hepatic TNF- $\alpha$ , IFN $\gamma$  and TLR4. Higher TNF- $\alpha$  levels were detected in KCs and, most importantly, increased TNF- $\alpha$ , TLR4 expression, and macrophage/dendritic cell populations were found in ileal tissue specimens, demonstrating also the involvement of the gut in steatotic liver damage<sup>[61]</sup>.

To date, it is debatable whether circulating levels of TNF- $\alpha$  may discriminate the presence of NAFLD in obese subjects or in subjects with metabolic syndrome<sup>[62,63]</sup>, but they seem to be useful in the non-invasive diagnosis of hepatic fibrosis in NASH<sup>[64]</sup>.

IL-6 is a polyvalent cytokine with proinflammatory and prooncogenic activity, and it supports hematopoiesis<sup>[65]</sup> and is a predictive marker of insulin resistance and cardiovascular diseases<sup>[66]</sup>. In animal<sup>[67]</sup> and human<sup>[68,69]</sup> models respectively, hepatic and serum IL-6 levels are higher in NAFLD. Initially this cytokine was considered hepatoprotective because it reduces oxidative stress and prevents mitochondrial dysfunction in animal models<sup>[70,71]</sup>. Moreover, there are contrasting data on IL-6 production in the liver of NAFLD subjects<sup>[57,72]</sup>. IL-6, with TNF- $\alpha$ , suppresses adiponectin levels; meanwhile, TNF- $\alpha$  stimulates the production of leptin<sup>[73,74]</sup>. Adiponectin is an adipocytokine with anti-inflammatory properties and it decreases in subjects with increased liver fat concentration<sup>[75]</sup>. Leptin has opposite effects; it activates neutrophils and innate immune system<sup>[76]</sup>, is associated with obesity and may contribute to NAFLD progression<sup>[77]</sup>. IL-6 production is also enhanced by TNF- $\alpha$  and IL-1 and can act

with paracrine and endocrine mechanisms to activate IL-6 signaling systemically and peripherally in other organs such as liver and muscle<sup>[13]</sup>. FFA and IL-17 synergistically induce IL-6 production; on the other hand IL-6, with TGF- $\beta$ 1, enhances Th17 response in *in vitro* HepG2 cell models<sup>[49]</sup>. Tarantino *et al*<sup>[78]</sup> have also observed that, surprisingly, NAFLD subjects have increased TGF- $\beta$ 1 blood levels compared with those with chronic hepatitis C.

An anti-inflammatory cytokine, IL-10, is protective for hepatic steatosis, as seen in IL-10 deficient mice<sup>[79]</sup> as well as in NAFLD humans<sup>[80]</sup>, and the inhibition of IL-10 promotes hepatic steatosis, enhances the expression of proinflammatory cytokines and impairs insulin signal transduction<sup>[81]</sup>. Main data on the pathophysiological role of inflammatory cytokines in NAFLD are summarized in Table 1.

Brun *et al*<sup>[82]</sup> have observed that HSCs isolated from genetically obese and diabetic mice show more pronounced fibrogenic responses induced by lipopolysaccharide (LPS) than HSCs from lean animals. Thus, HSCs are more sensitive to bacterial endotoxins, because genetically obese mice have an impaired intestinal permeability leading to increased portal endotoxemia. To expand on the evidence that systemic inflammation is also related to intestinal inflammation, a recent study undertaken by Kant *et al*<sup>[83]</sup> has found that weight loss in obese subjects reduces fecal calprotectin levels. Precedent studies have pointed out that circulating calprotectin levels are related to increased BMI<sup>[84,85]</sup>. As detailed later, the intestine, and especially intestinal inflammation, is closely related to NAFLD pathogenesis.

## IMMUNITY IN IBS

In IBS subjects a low chronic inflammation is present and many other immune phenomena are also points of contact with hepatic steatosis.

The intestinal mucosa physiologically contains immune cells much more than other organs and tissues, and this is mainly due to its anatomical configuration and function as the first barrier of the organism<sup>[86]</sup>. In the "irritated" gut there is an increased population of immune cells in the small and large intestine, as reported in many studies<sup>[87,88]</sup>. Moreover, the inflammatory infiltrate is lower than in ulcerative colitis (UC) but is similar to that revealed in microscopic colitis<sup>[89]</sup>. These findings, with others discussed later, lead to the theory that IBS could be considered as an inflammatory disease.

The adaptive immune system is involved in the low grade inflammation of the gut, specifically, CD3<sup>+</sup>, CD4<sup>+</sup> and CD8<sup>+</sup> T cell count is increased<sup>[89-91]</sup> in the gut and in the peripheral blood of IBS subjects.

The innate immune response is also implicated in IBS pathogenesis. An increased number of mast cells are found in the small<sup>[92]</sup> and large<sup>[93]</sup> intestine. These cells are in close contact with enteric nerve endings<sup>[94]</sup> and this is an important factor in the neuronal stimulation that underlies the establishment of typical IBS symptoms<sup>[95]</sup>. Braak *et al*<sup>[96]</sup> are discordant on this point because they

**Table 1** Principal findings on inflammatory cytokines in non-alcoholic fatty liver disease in humans, and in *in vitro* and animal models

Principal findings
<p><b>TNF-<math>\alpha</math></b></p> <p><i>In vitro</i>: FFA induce <i>TNF-<math>\alpha</math></i> gene expression<sup>[60]</sup>. KC and hepatocytes from NAFLD produce <math>\uparrow</math> <i>TNF-<math>\alpha</math></i> and <math>\uparrow</math> lipid peroxidation and accumulation<sup>[59,61]</sup>. <i>TNF-<math>\alpha</math></i> induces hepatocyte apoptosis<sup>[59]</sup></p> <p>Animal: <i>TNF-<math>\alpha</math></i> regulates KC apoptosis<sup>[58]</sup>. Hepatic, portal blood and intestinal <i>TNF-<math>\alpha</math></i> is <math>\uparrow</math><sup>[52,53,61]</sup></p> <p>Human: Circulating levels are <math>\uparrow</math> in NAFLD and NASH<sup>[57,68]</sup>. Contrasting data on simple FL<sup>[55,62]</sup>. They correlate with activity and progression of NAFLD<sup>[64]</sup> But do not differentiate mild to severe NASH<sup>[60]</sup>. NASH subjects have also <math>\uparrow</math> PBMCs <i>TNF-<math>\alpha</math></i>, IL-6 and IL-8 production<sup>[68]</sup>. <i>TNF-<math>\alpha</math></i> mRNA expression is <math>\uparrow</math> in liver and fat of NASH compared with NAFLD<sup>[57]</sup>, but there are contrasting data<sup>[55,238]</sup> <i>TNF-<math>\alpha</math></i> polymorphism is most frequent in NAFLD and correlates also with IR<sup>[56]</sup></p>
<p><b>IL-6</b></p> <p><i>In vitro</i>: FFA induces IL-6 expression in hepatic cell cultures<sup>[72]</sup> and enhances Th17 response<sup>[49]</sup></p> <p>Animal: IL-6, <i>TNF-<math>\alpha</math></i>, IL-8 production is <math>\uparrow</math> in liver and muscle of NAFLD mice<sup>[64]</sup>. Possible hepatoprotective role<sup>[70,71]</sup></p> <p>Human: <math>\uparrow</math> IL-6 blood levels and other inflammatory and cytonecrosis indexes in NAFLD and NASH subjects compared to controls and obese<sup>[57,68,69]</sup>. IL-6 is an index of NASH activity and progression<sup>[72]</sup>. Normal levels of IL-6 and normal spleen longitudinal diameter may be useful in excluding NASH from NAFLD<sup>[34]</sup>. IL-6 tissue expression is controversial in liver of NAFLD<sup>[57,72]</sup></p>
<p><b>IL-8</b></p> <p><i>In vitro</i>: IL-8 with <i>TNF-<math>\alpha</math></i> are <math>\uparrow</math> in NAFLD and in NASH compared to FL<sup>[64]</sup>. FFA induces IL-8 expression<sup>[60]</sup></p> <p>Human: Blood levels of IL-8, IL-6 and <i>TNF-<math>\alpha</math></i> are <math>\uparrow</math> in NASH<sup>[68,69]</sup></p>
<p><b>IL-1<math>\beta</math></b></p> <p>Animal: NAFLD rats express similar IL-1<math>\beta</math>, <i>TNF-<math>\alpha</math></i> and IL-6 levels in liver and in muscle<sup>[64]</sup></p> <p>Human: <i>TNF-<math>\alpha</math></i>, IL-6 and IL-1<math>\beta</math> blood levels are <math>\uparrow</math> in NAFLD and NASH<sup>[68,69]</sup></p>
<p><b>TGF-<math>\beta</math>1</b></p> <p><i>In vitro</i>: IL-17 and FFA induce IL-6 in hepatocytes and IL-6, with TGF-<math>\beta</math>1, enhance Th17 response<sup>[49]</sup></p> <p>Human: TGF-<math>\beta</math>1 blood levels in NAFLD are <math>\uparrow</math> than CHC<sup>[78]</sup></p>
<p><b>IL-10</b></p> <p>Animal: After IL-10 inhibition, <i>TNF-<math>\alpha</math></i>, IL-6 and IL-1<math>\beta</math> levels increase in liver of HFD mice<sup>[81]</sup>. IL-10 knock-out mice have <math>\uparrow</math> FFA plasma levels and hepatic TG<sup>[79]</sup></p> <p>Human: In NAFLD and obese children, lower IL-10 blood levels correlate with markers of visceral and subcutaneous fat, insulin, HOMA-IR, ALT, AST and GGT<sup>[77]</sup></p>
<p><b>IL-17</b></p> <p><i>In vitro</i>: IL-17 and FFA induce IL-6 production<sup>[49]</sup></p> <p>Animal: LPS-induced liver injury ameliorated after IL-17 blockade in HFD rats<sup>[49]</sup></p> <p>Th2 cytokines (IL-4, IL-5, IL-13)</p> <p>Animal: Rats genetically oriented to a Th1 response develop steatosis and lobular inflammation more than others oriented to Th2 response<sup>[44,45]</sup></p>

TNF- $\alpha$ : Tumor necrosis factor- $\alpha$ ; FFA: Free fatty acids; KC: Kupffer cells; NAFLD: Non-alcoholic fatty liver disease; NASH: Non alcoholic steatohepatitis; FL: Fatty liver; PBMCs: Peripheral blood mononuclear cells; IL: Interleukin; IR: Insulin resistance; TGF-1 $\beta$ : Tumor growth factor 1  $\beta$ ; Th17: T helper 17; CHC: Chronic hepatitis C; HFD: High fat diet; TG: Triglycerides; HOMA-IR: Homeostasis model of assessment-insulin resistance; ALT: Alanine-aminotransferase; AST: Aspartate-aminotransferase; GGT:  $\gamma$ -Glutamyltransferase; LPS: Lipopolysaccharide; Th2: T helper 2; Th1: T helper 1.

have observed a decreased number of mast cells, macrophages and T cells in IBS subjects. Moreover, they do not find visceral hypersensitivity or abnormal stress response.

Few reports have examined other immune cells involved in the innate immune system in IBS. NK cells<sup>[97]</sup> and neutrophils<sup>[98]</sup> may be hyper-activated but, to determine their role in intestinal inflammation, more studies are needed.

Contrasting data are reported on the monocyte/macrophage population. These cells were reduced<sup>[99]</sup> or normal<sup>[90]</sup> in number in the gut of IBS patients compared to controls but they may be hyper-activated, as seen by increased calprotectin expression<sup>[90]</sup>. Calprotectin is a calcium-binding protein produced by phagocytes with pro-inflammatory activity, such as leukocyte recruitment<sup>[100]</sup>. Fecal calprotectin may be useful in the differential diagnosis between inflammatory bowel diseases (IBD) and IBS<sup>[101]</sup>. Moreover, other authors have observed that patients with IBD and IBS-like symptoms have significantly higher fecal calprotectin levels than those with IBD but without IBS symptoms<sup>[102]</sup>. Shulman *et al.*<sup>[103]</sup> have shown that fecal calprotectin concentration is greater in children with IBS and functional abdominal pain compared to

controls, and also in the same population there is an impaired permeability in the proximal and distal gut.

There are contrasting data on the role of Treg cells, a T cell subpopulation with regulatory functions in IBS: these cells seem to be normally or under-expressed in intestinal tissues and blood of IBS subjects<sup>[104,105]</sup>, even though previously Chadwick *et al.*<sup>[88]</sup> have observed increased CD25<sup>+</sup> T cell population in the lamina propria of IBS subjects. The role of Th17 cells in the pathophysiology of IBS is still unexplored but, recently, Andoh *et al.*<sup>[106]</sup> have summarized the main evidence on the role of this subpopulation in intestinal inflammation. It would be interesting to see if IBS might be involved in the dysregulation between Th17 and Treg cells as shown in NAFLD.

Studies on proinflammatory cytokine production in IBS have evidenced the activation of both the innate and adaptive immune systems. Indeed, different study methods were used to explore the systemic cytokine production and results were not always concordant<sup>[107]</sup>.

IL-6 and TNF $\alpha$  are the most studied inflammatory cytokines in IBS. In many reports blood levels of TNF $\alpha$  and IL-6 are increased<sup>[108-112]</sup>. Similar results are reported in cultured peripheral blood mononuclear

**Table 2 Principal findings on inflammatory cytokines in irritable bowel syndrome in humans, and in *in vitro* and animal models**

Principal findings
<p><b>TNF-<math>\alpha</math></b></p> <p>Animal: D-IBS supernatants have <math>\uparrow</math> levels of proinflammatory cytokines and they cause hypersensitivity in mouse colonic afferent endings<sup>[122]</sup></p> <p>Human: IBS has <math>\uparrow</math> circulating TNF-<math>\alpha</math> levels<sup>[109,112]</sup>, especially D-IBS<sup>[112]</sup> or in patients with comorbidities such as fibromyalgia, premenstrual dysmorphic disorder and chronic fatigue syndrome<sup>[109]</sup>. Baseline and LPS-stimulated levels in PBMCs of proinflammatory cytokines as TNF-<math>\alpha</math>, in IBD and D-IBS, are <math>\uparrow</math> and are related to symptom intensity<sup>[108]</sup>. TLR-2, TLR-4 and TLR-5 antagonists induce TNF-<math>\alpha</math> production<sup>[128]</sup>. No difference in TNF-<math>\alpha</math> and other proinflammatory cytokine production (IL-6 and IL-1<math>\beta</math>) in the gut of IBS subjects compared to controls<sup>[116]</sup></p>
<p><b>IL-6</b></p> <p><i>In vitro</i>: No differences in colonic production between IBS and controls 116. IL-6 have excitatory action on colonic cells from IBS rats producing neuronal activation and absorption/secretory responses<sup>[115]</sup></p> <p>Animal: IL-6 colonic secretion is <math>\uparrow</math> in IBS rats and activate submucosal neurons<sup>[127]</sup></p> <p>Human: IL-6 blood levels are <math>\uparrow</math> in all IBS subtypes<sup>[109-111]</sup>. IL-6 levels are related to ACTH response and <math>\Delta</math>ACTH/<math>\Delta</math>Cortisol ratio<sup>[110]</sup>. Baseline and LPS or TLR agonist-stimulated PBMC levels are <math>\uparrow</math> in IBS<sup>[108]</sup></p>
<p><b>IL-8</b></p> <p><i>In vitro</i>: Reduced expression of mRNA of IL-8 in <i>ex vivo</i> biopsy cultures<sup>[116]</sup></p> <p>Human: Circulating levels of IL-8 are <math>\uparrow</math> in IBS<sup>[109-111,119]</sup>. TLR-3 and TLR-7 agonists induce IL-8 production in PBMCs<sup>[128]</sup></p>
<p><b>IL-1<math>\beta</math></b></p> <p>Animal: In stressed rats with previous acute colitis IL-1<math>\beta</math> mRNA expression is <math>\downarrow</math><sup>[117]</sup></p> <p>Human: <math>\uparrow</math> IL-1<math>\beta</math> levels in IBS<sup>[108,128]</sup>, in C-IBS and in D-IBS<sup>[108]</sup>. With TNF-<math>\alpha</math>, IL-1<math>\beta</math> <math>\uparrow</math> levels are found in IBS subjects with fibromyalgia, premenstrual dysmorphic disorder and chronic fatigue syndrome<sup>[109]</sup>. IL-1<math>\beta</math> <math>\uparrow</math> production in PBMCs stimulated by antiCD3/CD28 antibody<sup>[91]</sup> and by TLR-4 and TLR-5 agonists<sup>[128]</sup>. Increased IL-1<math>\beta</math> expression in rectum of PI-IBS<sup>[121]</sup></p>
<p><b>TGF-1<math>\beta</math></b></p> <p>Animal: No different expression of TGF-<math>\beta</math>1 protein in colon of IBS rats<sup>[11]</sup></p> <p>Human: TGF-1<math>\beta</math> intermediate producers may be at risk of developing IBS<sup>[114]</sup></p>
<p><b>IL-10</b></p> <p>Human: IBS subjects have <math>\downarrow</math> circulating levels of IL-10<sup>[112]</sup>. Altered IL-10/IL-12 ratio in PBMCs with Th1 proinflammatory state<sup>[113]</sup>. IL-10 levels are <math>\downarrow</math> and IFN<math>\gamma</math> levels are <math>\uparrow</math> in colon of PI-IBS compared to non PI-IBS and controls<sup>[119]</sup>. IL-10 high producer genotype is protective against IBS<sup>[114]</sup></p>
<p><b>Th2 cytokines (IL-4, IL-5, IL-13)</b></p> <p>Animal: Th2 cytokines may have a role in intestinal hypercontractility<sup>[123]</sup></p> <p>Human: Stimulated PBMCs IL-5 and IL-13 levels are <math>\uparrow</math> in IBS<sup>[124]</sup></p>

TNF- $\alpha$ : Tumor necrosis factor  $\alpha$ ; D-IBS: Diarrhoea-predominant irritable bowel disease (IBS); IBD: Inflammatory bowel disease; LPS: Lipopolysaccharide; PBMCs: Peripheral blood mononuclear cells; TLR: Toll like receptor; IL: Interleukin; ACTH: Adrenocorticotrophic hormone; C-IBS: Constipation-predominant IBS; PI-IBS: Post-infectious IBS; TGF-1 $\beta$ : Tumor growth factor 1  $\beta$ ; IFN $\gamma$ : Interferon  $\gamma$ ; Th2: T-cell mediated helper response.

cells<sup>[108,111]</sup>. Studies on Peripheral blood mononuclear cells (PBMCs) have also noticed decreased levels of the anti-inflammatory IL-10<sup>[112,113]</sup>, in agreement with the systemic inflammatory state in IBS. Moreover, the IL-10 high producer genotype seems to be protective against IBS, whereas IL-10 low producer, and maybe even TGF-1 $\beta$  intermediate producer genotypes, are a risk factor for IBS development<sup>[114]</sup>. In IBS mice, IL-6 may enhance colonic cells neuronal activation and their absorption/secretory responses<sup>[115]</sup>. The intestinal cytokine production is poorly understood<sup>[116-119]</sup>, and, as described in a recent review by Ortiz-Lucas *et al.*<sup>[120]</sup>, only IL-1 $\beta$  expression is clearly increased in post-infectious IBS (PI-IBS)<sup>[121]</sup>. On the contrary, Hughes *et al.*<sup>[122]</sup> have observed increased cytokine expression in supernatants of mice with IBS and that visceral neurons express receptors for IL-6, TNF- $\beta$ , IL-1 $\beta$  and IL-10, confirming the role of these pro-inflammatory cytokines in gut homeostasis.

Th 2 cytokines were also considered in recent reports: in animals Th 2 cytokines enhance intestinal motility<sup>[123]</sup> and in IBS subjects stimulated PBMCs produce more IL-5 and IL-13 than controls<sup>[124]</sup>.

Cytokines have several roles in the development of IBS symptoms. For example, TNF- $\alpha$  can act on the peripheral nervous system as well as on the central nervous system (CNS) to develop a symptom burden of hyper-

sensitivity, nausea, emesis, gastric hypomotility, anorexia and fever<sup>[125,126]</sup>. IL-6 is able to stimulate submucosal neurons in IBS animal models<sup>[127]</sup>, most probably *via* a TLR-mediated mechanism<sup>[128]</sup>. TNF- $\alpha$  and IL-6 are also implicated in intestinal barrier integrity<sup>[129]</sup> (Table 2).

## NAFLD AND IBS MAY BE RELATED

The above-mentioned evidence suggests that innate immunity is a main pathogenetic component of both NAFLD and IBS. But, how does the immune system work in patients with both NAFLD and IBS? In other words, is the similar action of pro-inflammatory cytokines, such as IL-6 and TNF- $\alpha$ , the only one that can be found on the immune system side?

The metabolic syndrome, which often anticipates or is detected in conjunction with NAFLD, leads to a state of chronic inflammation, systemic or local (hepatic)<sup>[12]</sup>, but to date it is still unclear which one of the two types has a greater impact on these patients, even if a lot of evidence favors the former<sup>[13]</sup>. A very similar scenario, but with partly different participants, is possible in IBS. Although the disease has not been overtly related to an inflammatory systemic disease, as happens for the metabolic syndrome, nevertheless, IBS is characterized by hyper-activation of the immune system and general inflammation. Indeed, many

researchers have struggled to find a similar component at local level, studying the intestinal cytokine production, but they have not always had a favorable outcome<sup>[107,120]</sup>. In some subsets of IBS patients, such as diarrhoea-predominant IBS (D-IBS) and IBS developing following infective gastroenteritis (PI-IBS), there is often a frank intestinal inflammation<sup>[108,119]</sup>. On the contrary, in C-IBS a systemic inflammation is not always associated with a local counterpart or is less apparent than in D-IBS<sup>[122]</sup>.

NAFLD and IBS are classically defined as different diseases. NAFLD is related to the metabolic syndrome, obesity, diabetes and insulin resistance and IBS is a functional intestinal disease closest to psychological disorders such as depression and anxiety, certainly not to liver diseases. But, surprisingly, there are many points of contact, such as the dysfunction of the intestinal microbiota, the impaired intestinal barrier, intestinal dysmotility and brain-gut axis dysfunction, which are fundamental to their pathogenesis, being related to the immune activation and inflammation.

Thus, principal questions are: Can metabolic liver disease affect the functions of the gastrointestinal tract leading to syndromic manifestations typical of IBS? and may the bowel dysfunction lead or otherwise support the development of a chronic hepatic inflammatory state?

## GUT MICROBIOTA

The gut microbiota is a composite member of our body. Intestinal bacteria interact with the intestinal epithelial barrier and subsequently with extraintestinal organs performing physiological and pathological actions.

This close contact makes the microbiota important for the metabolism of nutrients and energy delivery<sup>[130]</sup>, the intestinal barrier function<sup>[131]</sup>, the natural tropism of the intestinal wall<sup>[132]</sup> and ensures the maturation of intestinal immune tolerance and the immune response<sup>[133]</sup>.

The dysregulation of the intestinal bacterial milieu is a component of NAFLD and IBS. Recent reports have also shown both in NAFLD and in IBS an important role for TLR. These are receptors that characterize the innate immunity and link specific molecules such as pathogen-associated molecular patterns, LPS, and danger-associated molecular patterns<sup>[134]</sup>. These receptors are able to elicit the innate immune response once activated (they induce the expression of proinflammatory chemokines, cytokines and adhesion molecules on immune cells)<sup>[135]</sup>. In NAFLD and in IBS this role is consistently related to the alteration of gut microbiota, impaired intestinal permeability and impaired intestinal motility<sup>[136,137]</sup>.

Changes in microbiota composition and simultaneous or subsequent dysregulation of intestinal permeability let PAMPs and TLRs be in strict contact in the deeper layers of the intestinal wall and thus lead to stimulation of the innate immune response<sup>[138]</sup>.

Despite the fact that the roles of TLRs in the liver of NAFLD and NASH are well established<sup>[137]</sup>, only recently have the activity of TLRs in IBS been studied. Ohman

*et al.*<sup>[139]</sup> have observed increased expression of TLR2 on circulating monocytes in IBS. A study from McKernan *et al.*<sup>[128]</sup> demonstrated that the TLR-induced cytokine release (IL-1 $\beta$ , IL-6, IL-8 and TNF- $\alpha$ ) was enhanced in blood from IBS subjects. The TLR mRNA production in the gut mucosa of mice with colonic visceral hypersensitivity was studied and significant increases were seen<sup>[140]</sup>. Similar results were found in humans<sup>[141]</sup>.

TLRs are fundamental in T-cell differentiation and activation, particularly for Th17 and Treg cells<sup>[142]</sup>. In the gut, bacterial products<sup>[143]</sup>, acute phase proteins<sup>[144]</sup> and proinflammatory cytokines such as IL-6 and TGF- $\beta$ <sup>[145]</sup> promote Th17 response, meanwhile IL-25 and IL-23<sup>[146]</sup> produced by epithelial cells inhibit it.

## Obesity and NAFLD

In the literature there are few reports on the intestinal microbiota composition in NAFLD. The role of intestinal dysbiosis in these patients may be assumed by reports on microbiota present in obese subjects or by indirect data on the action of bacterial products from the gut delivered to the liver in NAFLD.

Obese patients are characterized by low intestinal bacterial diversity. They have a reduced *Bacteroides* and increased *Firmicutes* population compared to controls, and this proportion improves with weight loss<sup>[147]</sup>. Studying the microbiome, the same group has found that obese patients exhibit impaired bacterial gene expression<sup>[148]</sup>.

Animal models have shown that the intestinal microbiota may have an important role in energy harvesting and fat storage. Germ-free mice seem to be protected from diet-induced weight gain<sup>[149]</sup> most probably because intestinal bacteria are involved in the fermentation of polysaccharides to monosaccharide and in the metabolism of short chain fatty acids<sup>[150]</sup>. The microbiota can also enhance the lipoprotein lipase activity because it reduces the expression of the fasting-induced adipocyte factor in the intestinal epithelium resulting in enhanced FFA storage in adipocytes<sup>[149]</sup>.

LPS produced by intestinal bacteria constitutes the outer membrane of Gram-negative bacteria and can elicit an immune response acting as an endotoxin. LPS may also have a role in the development of obesity, low-grade inflammation and insulin resistance<sup>[151]</sup>. An elegant study by Cani *et al.*<sup>[152]</sup> noticed that high-fat diet induces LPS production in mice and probably its abnormal absorption through the intestinal epithelium may be fat-dependent. The same study has evidenced that endotoxemia induces weight gain, intrahepatic triglyceride accumulation and hepatic insulin resistance, leading to increased expression of TLR4 and proinflammatory cytokines (TNF- $\alpha$ , IL-6, IL-1 and PAI1) in muscle, adipose tissue and liver.

The correlation between intestinal dysbiosis and lipid accumulation in the liver is evidenced by recent research by de Wit *et al.*<sup>[153]</sup>: in mice, a diet with high concentration of palm oil induces higher weight gain and liver triglyceride concentration, reduces microbial diversity and increases *Firmicutes/Bacteroidetes* ratio compared to one high in poly-

unsaturated fatty acids. The fecal microbiota of women following a choline-deficient diet, which induces steatosis, varies during choline depletion and correlates with changes in liver fat concentration, showing modifications in *Gammaproteobacteria* and *Erysipelotrichi* populations<sup>[154]</sup>.

## IBS

Intestinal dysbiosis is also involved in the development of IBS symptoms. The intestinal microbiota modulates intestinal motility and sensitivity<sup>[155]</sup>. An animal study has observed that oral antibiotic therapy perturbs the intestinal microbiota, reduces *Lactobacilli* and decreases *Bacteroides* and *Enterococci* populations, and affects pain perception and visceromotor responses in the gut. The myoelectrical activity in the gut is also altered in germ-free animals and it reversed after colonization<sup>[156]</sup>. The supernatant made from *Escherichia coli* Nissle 1917 stimulates smooth muscle cells and enhances colonic contractility<sup>[157]</sup>, and also *Lactobacillus rhamnosus* GG has a dose- and time-dependent effect on the acetylcholine-stimulated contraction of human colonic muscle cells<sup>[158]</sup>. *Lactobacillus rhamnosus* also has a protective role in pain prevention in animal models<sup>[159]</sup>.

The intestinal bacterial population inhabits a complex environment and its composition varies throughout the gut. It is necessary to distinguish at least three different types of microbiota evaluated in different studies: the luminal microbiota, within the intestinal lumen; the mucosal microbiota that adheres to the intestinal wall; and the fecal microbiota, excreted in feces. In IBS subjects, studies on fecal microbiota have found increased facultative and anaerobic bacteria (as *Escherichia coli* and *Clostridium*) and decreased *Lactobacilli* and *Bifidobacteria*<sup>[160,161]</sup>. Later studies used molecular techniques because most bacterial species in the gut are not cultivable; a recent report of the Rome foundation reviewed principal results<sup>[162]</sup>. The majority of reports have studied fecal microbiota while only a few are focused on the mucosal flora. Furthermore, different molecular techniques are carried out and other limitations may explain that data shown are often contradictory or inconsistent. Moreover, the evidence that SIBO is frequently found in IBS subjects<sup>[163]</sup>, especially in diarrhoea-predominant IBS (D-IBS)<sup>[164]</sup>, and that IBS can develop following infective gastroenteritis (PI-IBS)<sup>[165]</sup> confirms the role of gut dysbiosis in the IBS pathogenesis.

## INTESTINAL PERMEABILITY

A single layer of cells composes the intestinal epithelium, a selective filter and barrier for exogenous substances and water<sup>[129]</sup>. The ways to pass the epithelial layer are mainly two: transcellular and paracellular<sup>[166]</sup>.

The regulation of the paracellular pathway is mainly due to complex structures localized at the apical-lateral and along the lateral membrane between the cells of the intestinal epithelium: desmosomes, adherent junctions and tight junctions (TJs)<sup>[167]</sup>.

TJs regulate selective paracellular ionic solute transport, prevent the passage of luminal antigens, micro-

organisms and toxins, but also regulate the tropism of enterocytes<sup>[168]</sup>. TJs are so called “kissing points”, fusion points where there is no space between two enterocytes<sup>[166]</sup>, and are formed by different transmembrane proteins: tricellulin, occludin, claudins and junctional adhesion molecules, which seal together adjacent cells and cytoskeleton<sup>[169]</sup>.

Several stimuli can modulate the intestinal permeability, but bacterial toxins *inter alia* are able to modify the localization of TJ proteins directly<sup>[170]</sup> or *via* the release of proinflammatory cytokines such as TNF- $\alpha$ , IFN- $\gamma$ <sup>[171]</sup> and IL-6<sup>[172]</sup> that *per se* can reduce the expression of zonula occludens-1 (ZO-1), occludin and claudin.

## NAFLD and NASH

In a recent review, Ilan<sup>[151]</sup> have focused on the role of bacterial translocation in NASH. The bacterial translocation is intimately connected with liver damage from the first step of lipid accumulation in the liver to the development of steatohepatitis, passing through the activation of the innate immune system and mitochondrial dysfunction.

Many animal and human studies have focused on the microbial dysbiosis in NAFLD and to date the endotoxemia, subsequent to bacterial translocation from the gut to the liver through the venous portal system, is an important factor in the development of NASH<sup>[173]</sup>. The mechanisms that lead up to endotoxemia are bacterial overgrowth and impaired intestinal barrier. Sabat  *et al*<sup>[174]</sup>, and previously Wigg *et al*<sup>[175]</sup>, have pointed out that obese subjects have an increased prevalence of SIBO and this condition correlates with severe hepatic steatosis.

Obese mice have a modified distribution of occludin and ZO-1 in the intestinal mucosa in combination with a lower intestinal resistance and higher circulating levels of inflammatory cytokines and portal endotoxemia<sup>[82]</sup>. Similar results are found in mice with fructose-induced steatosis: treatment with metformin leads to a decrease in hepatic triglyceride accumulation and plasma alanine-aminotransferase levels and protection against the loss of the TJ proteins occludin and ZO-1 in the duodenum<sup>[176]</sup>.

In humans, an immunohistochemical analysis of duodenal expression of ZO-1 performed by Miele *et al*<sup>[177]</sup> has highlighted that subjects with biopsy-proven NAFLD have increased gut permeability and high prevalence of SIBO, and that both correlate with the severity of steatosis. Also, NASH subjects have a higher prevalence of SIBO, related to enhanced expression of TLR-4 and release of IL-8<sup>[178]</sup>. The presence of endotoxins in portal blood is found also in cirrhotic patients and is related to an impaired intestinal barrier function<sup>[179]</sup>. Non-cirrhotic NAFLD subjects have increased LPS<sup>[180]</sup> and LPS-binding protein serum levels<sup>[181]</sup>. Probiotic treatment of obese mice leads to a lower intestinal permeability and improved TJ function, a lower plasma LPS and cytokine concentration and a decreased hepatic expression of inflammatory and oxidative stress markers<sup>[182]</sup>. Recently, the association between metabolic syndrome, gut micro-

biota dysregulation and impaired intestinal barrier has been further confirmed in an animal model where dietary obese rats show reduced expression of ZO-1 in the gut and higher TNF- $\alpha$  levels in combination with reduced *Lactobacillus* and increased *Oscillibacter* fecal population. Moreover, TNF- $\alpha$  and IL-6 mRNA levels were higher in mesenteric fat<sup>[183]</sup>.

### IBS

The impaired intestinal permeability is not only a key factor in the development of NAFLD and NASH. Other inflammatory gastrointestinal diseases such as Crohn's disease, UC, bacterial infections caused by *Escherichia coli*, *Clostridium difficile* and *Vibrio cholera*, anti-inflammatory agents associated enteritis and IBS are involved. *In vivo* studies have observed that IBS patients have an impaired intestinal barrier function<sup>[87,90]</sup>. Nevertheless, it is likely that these findings are specific only to D-IBS and PI-IBS subjects and in other IBS subtypes similar results are not found<sup>[87,184]</sup>.

In IBS, intestinal dysbiosis is an important factor participating in damaging the intestinal barrier through the activation of the immune system<sup>[185]</sup> even though another possible cause of impaired intestinal barrier is the exposure to chronic stress. In healthy animals and humans, acute or chronic stress enhances the intestinal permeability to water and also to macromolecules, and IBS subjects are more sensitive to physical and mental stressors compared to healthy subjects<sup>[110]</sup>.

It has been explicated that in IBS subjects there is a low grade inflammation in the gut. Mast cells and T lymphocytes represent the majority of intestinal inflammatory infiltrate and mast cells are also involved in the regulation of motor and visceral responses in the intestine<sup>[19,21,88]</sup>.

The intestinal permeability is controlled by mast cells, *via* histamine, serotonin 5-hydroxytryptamine (5-HT) and protease production<sup>[21]</sup>. Proteases are markedly increased in the mucosa of IBS subjects<sup>[18,186]</sup> and supernatants rich in proteases from D-IBS subjects are able to evoke epithelial dysfunction and allodynia in healthy mice<sup>[20]</sup>. In addition, colonic soluble mediators in supernatants from IBS subjects are able to reproduce permeability alterations in Caco-2 cells and decrease ZO-1 expression<sup>[22]</sup>. A recent study by Martínez *et al.*<sup>[187]</sup> confirms this hypothesis because it has been demonstrated that activated mast cells induce the downregulation of ZO-1 in intestinal epithelium.

Another class of TJ proteins, claudins, is involved too; in fact, claudin-1 and claudin-4 levels are decreased in the small and large intestine of D-IBS patients, whereas claudin-1 and claudin-3 were elevated in constipation-predominant IBS (C-IBS) patients<sup>[188]</sup>.

## INTESTINAL MOTILITY

Intestinal motor and sensory functions are influenced by the immune system to activate a mechanism of defense from noxious agents in the intestinal lumen<sup>[189]</sup>.

Mice infected with *Trichinella spiralis* develop muscle

hyper-contractility in the gut<sup>[190]</sup> but these effects disappear in animal models of athymic and CD4<sup>+</sup> cell-deficient mice<sup>[191]</sup>, encouraging the hypothesis of a role for the immune system and inflammation in intestinal motor functions. Th2 cytokine production was associated with enhanced motor functions and appropriate helminthic elimination. On the other hand, the response with a reduced intestinal motility of Th1, but interestingly also of Th17 cells, seems to be involved in small intestine motor functions. In this setting, specifically IL-17 induces smooth muscle cell contraction<sup>[192]</sup>.

Among Th2 cytokines, IL-13 is secreted by CD4<sup>+</sup> cells and by many other immune cellular types of innate immunity, as the so called "innate helper cells", which can be found normally in the gut and in blood. IL-13 has, in low concentrations, regulatory effects, increasing IL-10 and decreasing IL-17 levels, but, when up-regulated, it leads to inflammatory modifications and hyper-contractility of smooth muscle in the gut<sup>[193]</sup>.

In agreement with these findings, the production of 5-HT, one of the most important neurotransmitters of intestinal motility<sup>[194]</sup>, is also influenced by immune response and cytokine production and its secretion seems to be enhanced by Th2 and reduced by Th1 response<sup>[195]</sup>. 5-HT is synthesized and secreted by enterochromaffin cells (EC) and acts on receptors located on the processes of intrinsic and extrinsic primary afferent neurons in the lamina propria of the gut to initiate peristaltic and secretory reflexes<sup>[196]</sup>. The 5-HT transporter (SERT) is the physiological inhibitor, it is expressed by enterocytes and removes 5-HT from the intestinal space by internalizing it<sup>[197]</sup>.

### Obesity and NAFLD

In high-fat diet fed mice a slower gastric emptying was found, as well as modified intestinal hormone production: higher plasma leptin and cholecystokinin (CCK) concentrations and lower plasma ghrelin levels were found<sup>[198]</sup>. Covasa *et al.*<sup>[199]</sup> have shown that in high-fat diet fed mice there is a reduction in CCK-induced and oleate-induced inhibition of gastric motility.

In obese rats, after Roux-en-Y gastric bypass, an increase in peptide YY and a decrease in ghrelin concentrations occurred. These hormonal modifications may contribute to weight loss by decreasing the food intake and slowing the gastric emptying and transit time<sup>[200]</sup>.

A recent study by Hyland *et al.*<sup>[201]</sup> confirms the presence of an impaired intestinal motility, a modified submucosal nerve function and a decreased electrogenic glucose transport in obese rats. The author hypothesizes that the loss of motor control may lead to an altered host defense and intestinal dysbiosis, and the adapted glucose transport may be a control mechanism in the restriction of nutrient absorption.

Obese subjects have an accelerated esophageal and gastric motility and impaired gastrointestinal hormone secretion<sup>[202,203]</sup>. Vazquez Roque *et al.*<sup>[204]</sup> have detected a lower postprandial gastric volume in obese subjects. A recent report disputes their data: in newborns, fasting

and postprandial gallbladder volumes and gastric emptying were similar between obese and lean subjects, but in obese pre-adolescents, and even more in adults, a larger fasting gallbladder volume with slower postprandial gastric emptying was found<sup>[205]</sup>.

Small and large intestinal motility are also involved, as reported by Xing *et al.*<sup>[206]</sup>. As we see above, SIBO is most frequently viewed in obese subjects and it has been associated with an altered pattern of migrating motor complexes (MMC) in the small intestine<sup>[207]</sup>.

The role of intestinal dysmotility in liver cirrhosis is confirmed by numerous data<sup>[208]</sup>. *Vice versa*, in NAFLD, only a few studies have focused on impaired intestinal motility, although obesity, which is one of the most important etiological factors of NAFLD, is strictly related to impaired intestinal motility. Initial studies have found that NAFLD<sup>[209]</sup> and non-alcoholic cirrhosis<sup>[210]</sup> subjects have a prolonged orocecal transit time.

Interestingly, an up-to-date study correlates 5-HT<sub>3</sub> antagonists to reduced endotoxin levels in the portal system, attenuated liver fat content, inflammation, and cell necrosis, improved TNF- $\alpha$  levels and increased TJ expression in the duodenum of obese, leptin-deficient mice<sup>[211]</sup>. The same group has confirmed these data and has found that SERT deficiency causes hepatic steatosis and impaired intestinal permeability<sup>[212]</sup>. These findings suggest that obesity, and consequently NAFLD, are affected by impaired gut motility and most probably the impaired intestinal barrier, the gut inflammation and also neuronal signaling are key points in their maintenance.

## IBS

IBS subjects frequently report upper gastrointestinal symptoms such as functional dyspepsia<sup>[213]</sup>. Impaired lower esophageal motility and delayed gastric emptying are frequently viewed<sup>[214]</sup> and should be related to small-bowel dysmotility<sup>[215]</sup>.

Many studies have focused attention on the small intestine and large intestine gut dysmotility in IBS subjects. As reviewed elsewhere, studies on MMCs and clustered activity as well as intestinal transit for the small intestine and on myoelectrical activity, intraluminal pressure recordings and transit for the large intestine confirm this hypothesis<sup>[216]</sup>.

In the small intestine of IBS subjects, alterations in the periodicity of MMCs are found<sup>[217]</sup>. Kellow *et al.*<sup>[218,219]</sup> have demonstrated that MMCs have a shorter periodicity in D-IBS, whereas in C-IBS this is longer.

EC cell numbers in the intestinal wall are increased<sup>[220,221]</sup> and postprandial 5-HT levels are increased in platelet-poor plasma<sup>[222]</sup> of IBS subjects, especially in PI-IBS. 5-HT signaling is involved in the pathogenesis of intestinal dysmotility and hypersensitivity; indeed 5-HT modulators are used in IBS therapy<sup>[223]</sup>. 5-HT<sub>4</sub> agonists accelerate colonic transit and are useful in constipation unresponsive to laxative treatment, while 5-HT<sub>3</sub> antagonists inhibit colonic secretion and motility, and visceral sensation, and for this reason are used in D-IBS.

Moses *et al.*<sup>[224]</sup> have found that SERT was less expressed in C-IBS and UC colonic biopsy specimens. Camilleri *et al.*<sup>[225]</sup> have shown that SERT polymorphisms may influence colonic motility in patients with D-IBS and may influence the response to a 5-HT<sub>3</sub> antagonist.

In the colon of IBS subjects activated mast cells in proximity to mucosal innervations may contribute to pain perception<sup>[93]</sup> and are correlated with 5-HT release by intestinal EC cells<sup>[226]</sup>. Interestingly, Mizutani *et al.*<sup>[123]</sup> have observed that in an animal model of IBS, muscle hyper-contraction is related to an increased Th2 cytokine profile (IL-4 and IL-13). Even if these data confirm the role of immune activation in gut motility alteration, it is mandatory to observe that in IBS, and especially in D-IBS and PI-IBS, there is an enhanced gut motor activity even though these IBS subtypes are often related to a Th1 cytokine profile, at least in peripheral blood or in PBMCs. However, there are no reports on the possible role of IL-17 and Th17 in IBS; meanwhile, IL-13 production by PBMCs is higher compared to controls<sup>[124]</sup>.

Recent studies have shown that bacterial products may regulate gastrointestinal motor functions<sup>[227,228]</sup>, but intestinal motility may also influence the gut microbiota composition<sup>[229]</sup>. Pimentel *et al.*<sup>[230]</sup> for the first time demonstrated that the impaired intestinal motility may be related to SIBO in IBS subjects, but subsequent contrasting data have questioned this theory<sup>[163]</sup>. Moreover, as has been described before, IBS and NAFLD are characterized by an intestinal dysbiosis and only a proportion of subjects meet diagnostic criteria for SIBO.

## CNS INVOLVEMENT

A recent review by Capuron *et al.*<sup>[231]</sup> has focused on how the immune system can affect the CNS and contribute to the development of neuropsychiatric disorders such as depression, with particular relevance to cytokine signaling. Cytokines are involved in production, function and reuptake of several neurotransmitters, such as 5-HT. They affect the hypothalamic-pituitary-adrenal (HPA) axis and can modify the neuronal architecture, neuronal plasticity and aging, and neuronal circuits in CNS.

As previously described, 5-HT is an important neurotransmitter of the enteric nervous system (ENS) but it is also fundamental to CNS functioning. 5-HT, produced from tryptophan, plays a major role in the modulation of brain-gut axis<sup>[232]</sup>. The brain-gut axis is constituted peripherally of ENS communicating with the gut wall and centrally with the CNS and HPA axis<sup>[233]</sup>. The gastrointestinal system and the brain communicate in bi-directional mode, both of them influencing each other (the so called top-down and bottom-up model developed in functional GI disorder studies)<sup>[234]</sup>. The HPA axis is composed of corticotropin-releasing hormone (CRH), produced in the hypothalamic para-ventricular nucleus, which stimulates adrenocorticotropin (ACTH) production in the anterior pituitary gland that in turn induces the adrenal cortex to produce cortisol in response to various stressors<sup>[235]</sup>.

In animal and human models the turnover of 5-HT in the brain is altered by acute and chronic exposure to pro-inflammatory cytokines<sup>[236,237]</sup>.

Cytokines stimulate CRH, ACTH and cortisol production and in chronic states influence the diurnal cortisol curve because they stimulate inflammatory signaling that reduces glucocorticoid receptor functions and expression leading to decreased responsiveness to glucocorticoids.

### Obesity and NAFLD

Recently, animal studies have shown that in the hippocampus and cortex of high-fat fed mice there is increased production of inflammatory products<sup>[238,239]</sup> and systemic inflammation is also related to cognitive dysfunctions<sup>[240,241]</sup>. Depression and depressed serotonergic state are strictly related to metabolic syndrome and obesity<sup>[242,243]</sup>. Tarantino *et al.*<sup>[244]</sup> have studied urinary 5-hydroxy-3-indoleacetic acid, a 5-HT metabolite, in depressed and obese/overweight subjects and have found that it negatively correlates with dysthymia and depression status.

Alteration in the HPA axis is well established in obese patients and chronic stress with hyper-alimentation is an important factor in its development<sup>[245]</sup>. Although there are contrasting data on urinary free cortisol (UFC) in obese subjects, a recent study has evidenced in NAFLD subjects increased UFC and cortisol serum concentrations after dexamethasone suppression, both correlated with hepatic inflammation and fibrosis stage<sup>[246]</sup>. Moreover, in a human model, cortisol clearance is increased in NAFLD subjects and is correlated with insulin sensitivity<sup>[247]</sup>. Peripherally, cytokines such as TNF- $\alpha$  and leptin stimulate 11 $\beta$ -HSD1, an enzyme required for the activation of cortisone to cortisol<sup>[248]</sup>. Also leptin and ghrelin increased levels are related to HPA axis dysregulation in obese subjects<sup>[245]</sup>.

Finally, early life stress predisposes to overweight and insulin resistance, at least in animal models<sup>[249]</sup>.

### IBS

Hypersensitivity and brain alterations, investigated with different study methods, have been found in the last 15 years in IBS subjects; and, despite often contradictory data, there is strong evidence of dysregulation in pain and other stimuli perception<sup>[250]</sup>. Moreover, mood disorders (depression, anxiety) and other psychiatric disorders (eating disorders, posttraumatic stress syndrome, panic attack, *etc.*) are frequent, evidencing the role of gut-brain dysfunction in these patients<sup>[107]</sup>.

As has been mentioned above, the majority of reports on 5-HT in IBS have studied its intestinal production; meanwhile, few are focused on its systemic production. Clarke *et al.*<sup>[251]</sup> have found that IBS subjects degrade tryptophan more *via* the kynurenine pathway, an alternative metabolic way producing neurotransmitters other than 5-HT. Subsequently, the same group has found that kinurein from blood of IBS subjects can influence TLR expression<sup>[252]</sup> in an *in vitro* model.

The main evidence on HPA dysregulation in IBS<sup>[250]</sup> is

the following: CRH and ACTH stimulate colonic secretion, intestinal motility, visceral sensitivity and anxiety. Principal brain regions influenced by HPA axis are the amygdala and hippocampus. In IBS there are increased HPA axis responses to stressors such as meals, hormonal stimuli, and mental stress compared to controls. Fatigue and depression are associated with increased mast cell counts in the colonic mucosa of IBS subjects, confirming the role of gut-brain dysfunction in IBS<sup>[253]</sup>. Indeed, a key question still unresolved is whether the SNC dysfunction is the *primum movens* of the gut inflammation and consequently the visceral hypersensitivity and dysmotility in IBS or whether the gut inflammation represents the main cause of subsequent SNC and systemic disorder.

## UNANSWERED QUESTIONS

Could weight loss ameliorate IBS symptoms by influencing intestinal microbiota? Is there a relationship between NAFLD severity and IBS symptoms? Could patients suffering from IBS be at major risk to develop NASH? Are circulating levels of inflammatory cytokines overlapping in IBS subjects and NAFLD? Could intestinal dysbiosis affect CVD risk *via* NAFLD<sup>[254]</sup>?

### Abstract

Recent advances in the treatment of achalasia include the use of high-resolution manometry to predict the outcome of patients and the introduction of peroral endoscopic myotomy (POEM). The first multicenter randomized, controlled, 2-year follow-up study conducted by the European Achalasia Trial group indicated that laparoscopic Heller myotomy (LHM) was not superior to

pneumatic dilations (PD). Publications on the long-term success of laparoscopic surgery continue to emerge. In addition, laparoscopic single-site surgery is applicable to advanced laparoscopic operations such as LHM and anterior fundoplication. The optimal treatment option is an ongoing matter of debate. In this review, we provide an update of the current progress in the treatment of esophageal achalasia. Unless new conclusive data prove otherwise, LHM is considered the most durable treatment for achalasia at the expense of increased reflux-associated complications. However, PD is the first choice for non-surgical treatment and is more cost-effective. Repeated PD according to an "on-demand" strategy based on symptom recurrence can achieve long-term remission. Decision making should be based on clinical evidence that identifies a subcategory of patients who would benefit from specific treatment options. POEM has shown promise but its long-term efficacy and safety need to be assessed further.

## INTRODUCTION

Achalasia is one of the primary motility dysfunctions of the esophagus that affects both sexes and all races equally<sup>[1,2]</sup>. The selective loss of inhibitory neurons of the myenteric plexus, which produces vasoactive intestinal polypeptide, nitric oxide (NO), and inflammatory infiltrate, is responsible for abnormal lower esophageal sphincter (LES) dysfunction. This results in unopposed excitation of the LES, and dysfunction or failure of the LES to relax in response to each swallow<sup>[3]</sup>. Dysphagia for both liquid and solid foods is the most common symptom. Food regurgitation is one of the main associated problems, causing pulmonary complications such as chronic cough and aspiration pneumonia. Gradual weight loss usually occurs as a result.

Achalasia is diagnosed on the basis of tests such as barium esophagography, esophageal manometry, and endoscopy. Pseudoachalasia has to be ruled out by performing endoscopic ultrasound, or computed tomography<sup>[4]</sup>. A classic “bird-beak” of the gastroesophageal junction, with atonia and a dilated esophageal body detected by barium ingestion and fluoroscopy, are the typical radiological signs. Manometry is still the standard diagnostic test for achalasia. Conventional manometry must at least meet the criteria of absent or abnormal swallowing relaxation of the LES, and the absence of peristalsis in the esophageal body. However, the sensitivities of these traditional studies have been challenged by the recent emergence of advanced techniques for the diagnosis of esophageal achalasia such as the use of high-resolution manometry (HRM) and the addition of pressure topography plotting<sup>[5]</sup>. Together, these technologies are also called high-resolution esophageal pressure topography<sup>[6]</sup>. HRM with pressure topography plotting is capable of identifying impaired esophagogastric junction relaxation and subcategorize achalasia into three clinically relevant subtypes based on the contractile function of the esophageal body according to the Chicago classification<sup>[6]</sup>. Type I (classic achalasia) refers to patients with no significant pressurization within the esophageal body and impaired LES relaxation (Figure 1A). Water swallows cause rapid pan-esophageal pressurization, which may exceed LES pressure, causing the esophagus to empty for Type II disease (achalasia with compression) (Figure 1B). Type III achalasia, also known as spastic achalasia, is usually associated with rapidly propagated pressurization attributable to an abnormal lumen obliterating contraction (Figure 1C).

Recent advances in the treatment of achalasia include the use of HRM to predict patient outcome, the

introduction of peroral endoscopic myotomy (POEM), and laparoendoscopic single-site Heller myotomy with anterior fundoplication. Contributing to the ongoing debate on the superiority of pneumatic dilation (PD) vs laparoscopic Heller myotomy (LHM), the first multicenter, randomized, controlled, 2-year follow-up study conducted by the European Achalasia Trial group indicated that LHM was not superior to PD<sup>[7]</sup>. Nevertheless, publications on the long-term success of laparoscopic surgery continue to emerge. This review seeks to address this issue and provide an update on the current progress in the treatment of achalasia. Current available treatment modalities include relaxing the LES and relieving the esophageal obstruction<sup>[2]</sup>. The durability of a successful treatment, complication rates, and cost-benefit are the primary concerns.

## TREATMENT OF ESOPHAGEAL ACHALASIA

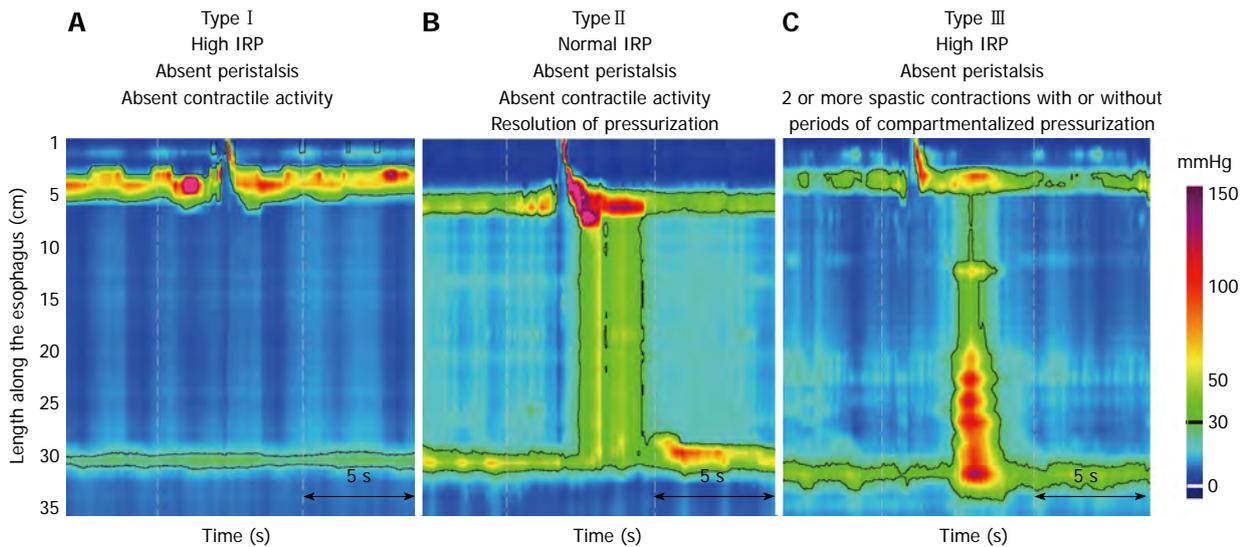

### *Pharmacological management*

Pharmacological management usually plays a minor role in the treatment of esophageal achalasia. Smooth muscle relaxation is partly effective for the reduction of LES pressure<sup>[8]</sup>. NO concentration in smooth muscle cells is increased by medication such as nitrates that increase cyclic GMP levels. Calcium antagonists block calcium entry and hence esophageal muscle contraction. When combined, these drugs can reduce LES pressure and ultimately relieve dysphagia but the efficacy is usually unsatisfactory and incomplete. Furthermore, side effects such as headache, dizziness, and pedal edema are important concerns, and they can be intolerable. These effects are similar to those with other drugs such as sildenafil<sup>[9]</sup>.

### *Endoscopic treatment*

Traditional endoscopic treatments for achalasia include injection of botulinum toxin and PD. Recently, a novel endoscopic technique, POEM, has been introduced and tested by gastroenterologists.

**Botulinum toxin injection:** Botulinum toxin is a biological toxin derived from *Clostridium botulinum* that causes paralysis of both voluntary and involuntary muscles<sup>[10]</sup>. It mainly acts at the terminal nerve endings of myoneural junctions by preventing the release of acetylcholine from vesicles, causing chemical denervation that can persist for several months. Botulinum toxin injection (BTI) is a treatment option for achalasia, and it is associated with a wide safety range and fewer complications<sup>[11]</sup>. Local injection of the toxin into the LES of patients with achalasia lowers sphincter tone, and the patient becomes asymptomatic. This treatment is reported to have excellent immediate responses (success rates > 90%)<sup>[11]</sup>. BTI is associated with a significant improvement in all objective tests of esophageal function, such as decreased LES pressure, increased esophageal diameter, and improvement of transit time by scintigraphy. Complications of BTI

**Figure 1** High-resolution manometry with pressure topography plotting classified achalasia into three subtypes. A: Type I (classic achalasia) refers to patients with absent of peristalsis, no pressurization within the esophageal body, high integrated relaxation pressure (IRP); B: Type II (achalasia with compression) refers to patients with absent of peristalsis, and contractile activity, panesophageal pressurization > 30 mmHg, and high IRP; C: Type III patient (spastic achalasia), associates with absent of peristalsis, and two or more spastic contractions with or without periods of compartmentalized pressurization and a high IRP.

therapy for achalasia are minor, with approximately 25% of patients presenting with transient chest pain and < 5% complaining of reflux symptoms. The dosage used is too small to induce serious adverse effects such as generalized paralysis. The main drawback of BTI is its short duration of effect, which lasts only 6-9 mo in most patients. Based on the number of injections required, the treatment costs are 50% higher than those of PD. Success rates have been reported to be highest among elderly patients and in patients with an LES pressure not exceeding the upper normal level prior to treatment<sup>[12]</sup>. Therefore, it is currently recommended to treat only elderly and high-risk patients with concomitant comorbid diseases.

**PD:** In this simple forceful bougie dilation method, considerable stretching strength is required for the dilation to result in an effective mechanical tear in the muscle fibers of the LES. The most commonly used dilator is the Rigiflex dilator with a fully inflated diameter that is usually  $\geq 3$  cm to achieve a satisfactory result, and is able to achieve maximal pressure. This procedure can be guided using fluoroscopy<sup>[13-15]</sup> or endoscopy<sup>[2,16,17]</sup>. The number of dilation sessions and the inflation time needed for a successful dilation vary and are operator dependent. A single dilation session with a bigger dilator may be used in patients presenting with relapse based on symptom scores<sup>[18]</sup>. Progressive PD methods, such as a series of dilations on successive days using a larger dilator, have been proposed<sup>[19]</sup>. Immediate and short-term results have reportedly been good in most series<sup>[20-25]</sup>. However, the first 5-10 years of published follow-up studies have shown that 20%-75% of patients needed a second or even more dilatations<sup>[26,27]</sup>. Large-scale, long-term follow-up investigations reported unfavorable recurrence in fluoroscopy-guided PD patients<sup>[13,27,28]</sup>. Repeat PD according to an

“on-demand” strategy based on symptom recurrence can achieve long-term remission<sup>[24]</sup>. Post-dilation radiographic findings in addition to the symptom-based scoring systems can reliably predict clinical remission and indicate the need for further treatment in patients with poor esophageal clearance after dilation to avoid progression to sigmoid type achalasia<sup>[29,30]</sup>.

Complications caused by PD are uncommon. The most severe complication is perforation with an incidence of 1%-2% as shown in Table 1. These perforations are usually minor but can be hazardous if undetected after PD<sup>[31]</sup>. Reflux symptoms after PD are usually minor and transient, and can be easily controlled with proton-pump inhibitors.

**Self-expanding metallic stents:** A study evaluating the utility of self-expanding, 30-mm metallic stents for achalasia at a single center over a 10-13-year period reported a long-term clinical success rate of > 80%<sup>[32,33]</sup>. No perforations or mortality associated with the treatment were reported, but stent migration occurred in 5% of patients, reflux in 20%, and chest pain in 38.7%. Overall, the authors claimed that self-expanding, 30-mm metallic stents were associated with a better long-term clinical efficacy in the treatment of patients with achalasia as compared with treatment with PD.

**POEM:** This novel endoscopic esophagomyotomy method for the treatment of achalasia was first reported by Pasricha *et al*<sup>[34]</sup> in porcine models and then by Inoue *et al*<sup>[35]</sup> in humans. POEM is performed by dissection and division of the inner circular muscle layer of the esophagus through a submucosal tunnel created endoscopically by a small proximal opening of the esophageal mucosa. When compared with surgical myotomy, POEM can accomplish a longer myotomy. Extending the length of the myotomy

to the thoracic esophagus is difficult for the surgeon, especially in patients with advanced disease and in those with severe fibrosis. Theoretically, the risk of injury to the vagus nerve should be lower with this approach.

Increasing numbers of reports on this technique have been published, and all of them showed good short-term results without serious complications; however, long term follow-up results are necessary<sup>[35-45]</sup>. A recently published prospective, international, multicenter study that aimed to determine the outcomes of 70 patients who underwent POEM at five centers in Europe and North America showed that the percentages of patients with symptom remission at 6 and 12 mo were 89% and 82%, respectively. Zhou *et al.*<sup>[45]</sup> reported that POEM was a promising new treatment for failed Heller myotomy, resulting in short-term symptom relief in > 90% of cases. Nevertheless, POEM can be a challenging and demanding technique even for experienced endoscopists. Although air leak such as that caused by pneumomediastinum, pneumoperitoneum, and air embolism can be prevented by carbon dioxide insufflation, it can be hazardous in cases of purulent mediastinitis. If it occurs, extensive surgical procedures such as esophagectomy may be necessary instead of revisional surgery because of the inflamed and scarred tissue of the plane between the submucosal and muscular layers after the endoluminal approach<sup>[35-41]</sup>.

**Surgical treatment**

Myotomy of the LES is the best treatment modality with satisfactory long-term results at the deleterious cost of a high incidence of postoperative reflux. Although controversy exists as to whether a concomitant antireflux procedure is necessary, minimally invasive LHM with a variety of fundoplication procedures has become the primary approach by many surgeons in the majority of patients with achalasia<sup>[46-49]</sup>. The overall success rates were between 77.0% and 97.2%<sup>[46-57]</sup> (Table 2). However, different surgeons have different opinions on the length of the myotomy. Generally, most surgeons choose a

LHM: Laparoscopic Heller myotomy.

myotomy length of 4-5 cm onto the esophagus and 2-3 cm onto the stomach<sup>[58]</sup>. Another controversial issue among surgeons is whether a concomitant antireflux procedure is necessary. Currently, most surgeons perform minimally invasive LHM with a variety of fundoplication procedures in the majority of patients with achalasia, and partial fundoplications are preferred because 360° fundoplications cause more dysphagia<sup>[46,47,59,60]</sup>. Randomized controlled trials have shown that the addition of an antireflux procedure to a myotomy substantially reduces the postsurgical incidence and severity of pathological reflux<sup>[61,62]</sup>. Recently, laparoendoscopic single-site surgery has proven to be an archetypal shift to more minimally invasive surgery, and is applicable to advanced laparoscopic operations such as LHM and anterior fundoplication<sup>[63]</sup>. Esophagectomy may be needed in patients with recurrent disabling symptoms or severe complications.

Overall, postsurgical complications are rare (< 4%)<sup>[64]</sup>. The major adverse event associated with surgery is severe reflux (3%-34%, Table 2). To minimize the reflux complications, it is generally accepted that a concomitant endoscopic examination during LHM to guide the myotomy and routine fundoplication is clinically necessary with either anterior fundoplication (Dor) or partial posterior fundoplication (Toupet)<sup>[65-67]</sup>. LMH is superior to thoracoscopic procedures because of the shorter operative time and hospital stay<sup>[68]</sup>.

The reported incidence of esophageal perforation in LHM is 5%-10%. However, robotically assisted Heller myotomy (RAHM) is safer than LHM because it decreases the incidence of esophageal perforation to 0%, even in patients who had undergone previous treatment<sup>[69,70]</sup>. RAHM with partial fundoplication using a robotic platform appears to be a more precise and safer operation than laparoscopic myotomy, with improved postoperative quality of

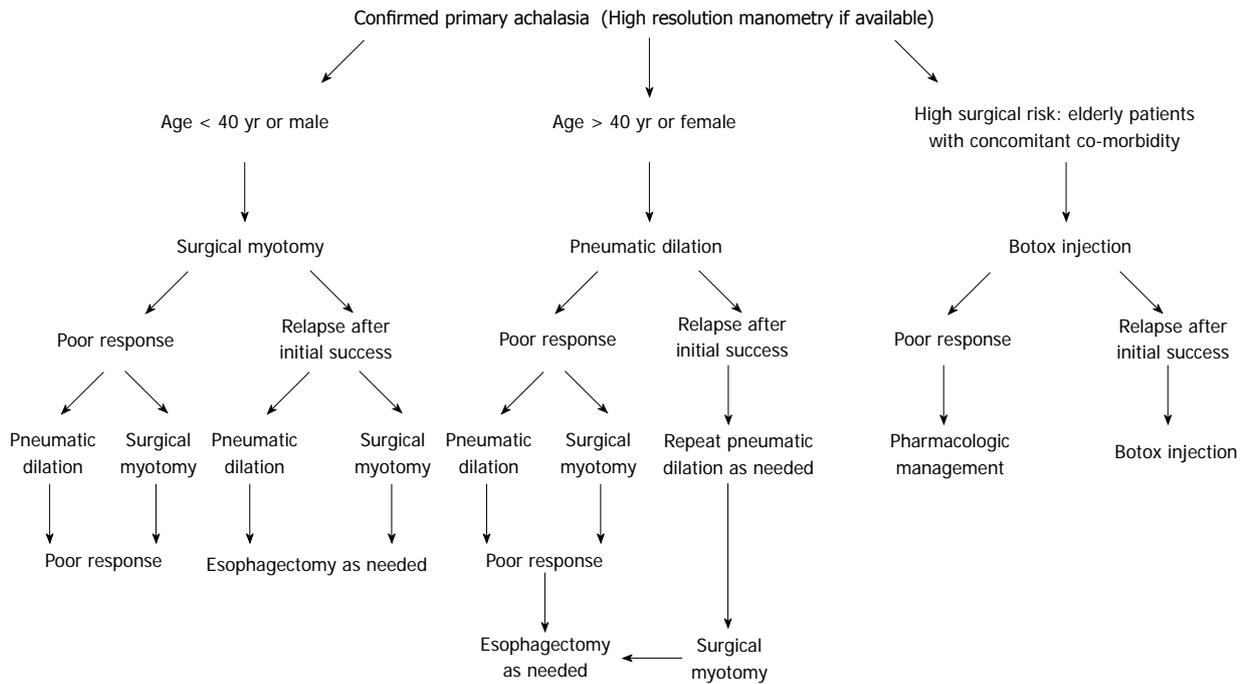

Figure 2 Proposed algorithm for the treatment of esophageal achalasia.

life. In addition, the outcomes of RAHM are slightly better than those of LHM, although the cost is higher<sup>[70]</sup>.

### DECISION MAKING: WHICH IS THE MOST APPROPRIATE TREATMENT?

A proposed algorithm for the selection of the optimal treatment modality for esophageal achalasia is summarized in Figure 2. LHM and PD remain the key treatment options. The short-term efficacy of BTI therapy is similar to that of PD, although it is less effective for sustained symptomatic relief in patients with achalasia in comparison to PD and LHM. BTI is also effective in patients with tortuous megaesophagus and previous failed pneumatic dilatations; however, a high rate of relapse during the first year of follow-up has been reported<sup>[71]</sup>. The selection of BTI should be made with caution in certain patients because some surgeons reported that it increased the risk and difficulty of subsequent LHM<sup>[72]</sup>. Therefore, taking into account the lower durability of BTI therapy, it is a suitable alternative only in the minority of high-risk patients with comorbidity<sup>[2,8]</sup>.

POEM can achieve favorable short-term results comparable to those of any of the above treatment modalities. Moreover, it enables the performance of a longer myotomy, especially in patients with advanced disease and those with severe fibrosis, with a lower risk of injury to the vagus nerve. Validation of the long-term durability and safety of this procedure could make POEM a breakthrough in the treatment of esophageal achalasia. Long-term follow-up of patients who undergo POEM is important to test the durability and safety of the procedure. After all, it is a very technically demanding procedure.

### Surgery vs PD

The choice of LHM as the primary treatment for achalasia or as second-line treatment following the failure of nonsurgical intervention remains a topic of controversy after many decades in clinical practice. Several studies have shown that repeated PD according to an on-demand strategy based on symptom recurrence can increase success rates to levels comparable with LHM<sup>[26,73,74]</sup>. This was supported by the first multicenter, randomized controlled, 2-year follow-up study conducted by the European Achalasia Trial group, which indicated that LHM was not superior to PD<sup>[7]</sup>, and it supports those who are in favor of PD, believing that PD and LHM are equally efficient. This is further supported by advantages of PD such as the fact that it is an outpatient procedure associated with minimal injury, and minimal reflux and bleeding. However, the follow-up duration of this study is not long enough to declare equality between the two procedures. In addition, another disadvantage of PD is that these patients usually require more than one treatment session. Nevertheless, publications on satisfactory long-term success of laparoscopic surgical outcome continue to emerge<sup>[75]</sup>, and patients usually require only one treatment session. Moreover, some surgeons believe that LHM can be more difficult technically following PD but others claim that PD does not hinder future myotomy procedures<sup>[76]</sup>.

Complications and cost-effectiveness, besides the durability of the procedure, are the main concerns for deciding on a treatment option. Perforation of the esophagus occurs in 1%-2% of patients during PD and can be hazardous if left undiscovered<sup>[51]</sup>. Mucosal tears occur in 12% of patients during LHM but can usually be repaired, and the patients recover. However, the main drawback of LHM is the incidence of acid reflux after surgery, which

**Table 3 Summary of the cumulative efficacies and complications of current treatment options of achalasia**

	PD	Surgical myotomy	BTI	POEM
No. of studies	12	12	9	11
No. of patients	1097	1860	315	210
Excellent/good symptom response (range)	28%-92.9%	77%-97.2%	At 1 mo: 79% (64%-93%) At 1 yr: 41% (10%-55%)	82%-100%
Follow up (yr)	0.5-15	2.6-10.9	18 (6-30)	0.1-1
Major complications (range)	1%-2% Perforation	3%-34% Acid reflux	-	0.03% Acid reflux

PD: Pneumatic dilations; BTI: Botulinium toxin injection; POEM: Peroral endoscopic myotomy.

could be long lasting despite partial fundoplication. Reflux can usually be treated with proton-pump inhibitors; however, long term complications of reflux such as stricture, Barrett’s esophagus, and adenocarcinoma, although rare, must be kept in mind. By contrast, symptoms of reflux in post-PD patients are usually mild and transient and can be easily controlled by prescribing proton-pump inhibitors. When considering the cost-effectiveness of treatment strategies for achalasia, LHM has a higher initial cost and PD is the most cost-effective treatment option for adults with achalasia<sup>[77]</sup>. However, LHM can be cost-effective if the durability is > 10 years<sup>[78]</sup>. A recent meta-analysis conducted by Weber *et al*<sup>[79]</sup> showed that both PD and LHM are effective treatment options, but LHM might be more durable.

The experience of the surgeons and gastroenterologist is also an important factor for treatment success. More importantly, the decision should be based on clinical evidence that identifies a subcategory of patients who may benefit from a specific treatment option. In general, unless new conclusive data prove otherwise, LHM is the more durable treatment for achalasia, but PD is the first nonsurgical choice and is more cost-effective. Practically, the correction of failed operations for esophageal achalasia is challenging; however, those operations are also performed at high-volume centers using laparoscopic procedures, and many patients prefer to avoid esophagectomy. However, some researchers have reported adverse effects of repeated dilations, especially the risk of perforations, and this must be considered in the decision making process. LMH is recommended for younger patients (< 40 years), male sex, and those showing pulmonary symptoms and failed response to one or two initial dilations<sup>[2,8,80]</sup>.

**PREDICTORS OF RISK FACTORS FOR RELAPSE AFTER TREATMENT FOR ACHALASIA**

To recognize the risk factors for relapse after treatment is an important issue. It is generally accepted that

young age (< 40 years), male sex, a single dilation session with a 3.0-cm balloon, immediate or 3-mo post-treatment LES pressure > 15 mmHg, poor esophageal emptying on timed barium swallow, and classic achalasia are considered the predicting risk factors for relapse after PD<sup>[2,8,20,21]</sup>. Therefore, both timed barium esophagography and manometry, especially HRM, should be performed at baseline and post-PD, and compared to predict the outcome of patients. The possible impact of the results of HRM on treatment outcome was highlighted in Pandolfino’s landmark study, which showed that Type II achalasia patients were significantly more likely to respond to any therapy [BTI (71%), PD (91%), or LMH (100%)] compared with Type I (56% overall) or Type III (29% overall) patients. Type II achalasia was a predictor of positive treatment response, whereas Type III and pretreatment esophageal dilatation were predictive of a negative treatment response<sup>[81]</sup>. This was confirmed in another study by Pratap *et al*<sup>[82]</sup>, which showed that patients with a Type II achalasia pattern (esophageal pressurization) on HRM were more likely to respond to all therapies such as PD, Heller myotomy, and BTI (70%-100% overall), as compared with Type I ( $\geq$  63.3% overall) and Type III approximately 30% overall) patients. More evidence with larger prospective studies and long-term follow-up results are necessary in the new era of HRM (Table 3).

**FUTURE PERSPECTIVES**

Most existing studies point toward autoimmune mechanisms affecting neurons possibly after an infectious event and an association with certain genetic factors as the possible etiology<sup>[83]</sup>. The identification of an immunomodulatory drug for the treatment of achalasia is a target to achieve in the future. Evidence indicates that transplanting neuronal stem cells could be “a dream come true” achievement in the future<sup>[84]</sup>. Theoretically, if this works, both LES function and peristalsis should recover.

**CONCLUSION**

The debate on PD and LHM is on-going. Unless new conclusive data prove otherwise, LHM is a more durable treatment option for achalasia at the expense of increased reflux complications. However, PD is the first nonsurgical choice and is more cost-effective. Repeated PD according to an on-demand strategy based on symptom recurrence can achieve long-term remission. It is recommended that the decision making should be based on clinical evidence that identifies a subcategory of patients who may benefit from a specific treatment option. POEM is a promising strategy, but more long-term efficacy and safety studies are necessary.

**ACKNOWLEDGMENTS**

The authors thank Dr. John Pandolfino for providing the figures of HMR and the interpretation.

the most frequent malignancies worldwide, with an increasing number of new cases and deaths every year. Traditional surgery is only suitable for a limited proportion of patients and imaging-guided percutaneous thermal ablation has achieved optimistic results for management of hepatic malignancy. This synopsis outlines the first clinical practice guidelines for ultrasound-guided percutaneous microwave ablation therapy for hepatic malignancy, which was created by a joint task force of the Society of Chinese Interventional Ultrasound. The guidelines aim at standardizing the microwave ablation procedure and therapeutic efficacy assessment, as well as proposing the criteria for the treatment candidates.

### Abstract

Primary liver cancer and liver metastases are among

## INTRODUCTION

Primary liver cancer is the sixth most commonly diagnosed cancer worldwide and hepatocellular carcinoma (HCC) accounts for 70%-90% of the total incidence. There were 748300 new liver cancer cases and 695900 cancer deaths worldwide in 2008 and half of the cases and deaths were estimated to occur in China as a result of the high prevalence of chronic viral hepatitis<sup>[1,2]</sup>. Metastases are another common hepatic malignancy. Colorectal liver metastasis is one of most common hepatic metastases. It has been reported that 14.5%-23.0% of colorectal cancer patients have synchronous liver metastases at the time of exploration for their primary tumor and 76.8% eventually develop liver metastases<sup>[3]</sup>. A number of different locoregional therapies for hepatic malignancy have been performed, including surgical resection, percutaneous ethanol injection, microwave ablation (MWA), radiofrequency ablation (RFA), high-intensity-focus ultrasound and transcatheter arterial chemoembolization (TACE). Traditionally, surgical resection is the reference standard for treatment of patients with hepatic malignancy, however, only a small proportion of them have the chance to be candidates because of disease progression, anatomical location, and poor liver function. As an alternative therapy, imaging-guided percutaneous ablation has been widely applied for management of hepatic malignancy, owing to its advantages of minimal invasion, favorable efficacy, and reproducibility<sup>[4-7]</sup>. Among thermoablative techniques, RFA is the most extensively used worldwide. MWA of liver cancer was first adopted in Japan by Saito *et al.*<sup>[8]</sup> and has been widely applied in China over the past two decades<sup>[5,6,9-15]</sup>. Several studies<sup>[16-19]</sup> showed that the local tumor control, complications and long-term survival were equivalent for RFA and MWA in treatment of hepatic malignancy. A recent multicenter study from China documented that 1007 patients with primary liver cancer treated by MWA achieved 1-, 3-, and 5-year survival rates of 91.2%, 72.5%, and 59.8%, respectively<sup>[20]</sup>. For liver metastases, MWA offers a mean 1-, 3- and 5-year survival rate of 73%, 30% and 16%, which represents an advantage over palliative chemotherapy even in patients with extrahepatic disease<sup>[17]</sup>.

## PURPOSE

The purpose of these guidelines is to establish basic clinical practice guidance to assist physicians with: (1) evaluating patients with hepatic malignancy, including primary liver cancer and liver metastases, who may be candidates undergoing percutaneous MWA under ultrasound (US) guidance; (2) providing relevant and updated technical information for performing this treatment; and (3) understanding the consequences of this treatment.

A working group including 44 experts from the Society of Chinese Interventional Ultrasound (SCIU) met in June 2011 to consider the evidence for developing the draft guidelines. Additional meetings were conducted *via*

teleconference. The guidelines were circulated in draft form to the full expert panel for review and approval. In addition, practitioner feedback was obtained from physicians in the province of interventional treatment, and their comments were incorporated into the guidelines. These recommendations represent the panel's attempt to extract practical guidelines from a combination of published evidence and expert opinion where the literature falls short.

## LITERATURE SEARCHES

The expert panel completed the review and analysis of data published since 1990. Computerized literature searches of MEDLINE, EMBASE and the Cochrane Collaboration Library were performed. The searches of the English-language literature from 1990 to June 2011 combined the terms "hepatic neoplasms" and "liver neoplasms", with the MeSH terms "microwaves" and "catheter ablation". The searches were limited to human-only studies and to specific study designs or publication types: randomized clinical trials, meta-analyses, systematic reviews, and major clinical trials in MWA of liver tumors.

## DESCRIPTION OF MWA

### *Mechanism*

MWA refers to all electromagnetic methods of inducing tumor destruction by using devices with frequencies  $\geq 900$  MHz<sup>[21]</sup>. The rotation of dipole molecules accounts for most of the heat generated during MWA<sup>[22,23]</sup>. Water molecules are dipoles with unequal electric charge distribution, and they attempt to reorient continuously at the same rate in the microwave oscillating electric field. Therefore, electromagnetic microwaves heat matter by agitating water molecules in the surrounding tissue, producing friction and heat, thus inducing cellular death *via* coagulation necrosis. Another mechanism responsible for heat generation is ionic polarization, which occurs when ions move in response to the applied electric field of microwaves. Displacement of ions causes collision with other ions, which converts kinetic energy into heat. However, it is a far less important mechanism than dipole rotation in living tissue. Currently, two kinds of frequencies: 915 and 2450 MHz are used for MWA. A frequency of 2450 MHz is more commonly adopted, which is also the frequency used in conventional microwave ovens given optimal heating profiles<sup>[23]</sup>. Microwaves of 915 MHz can penetrate more deeply than 2450 MHz microwaves<sup>[24]</sup>, therefore, the low frequency MWA may theoretically yield larger ablation zones.

### *Technical advantages*

MWA shows the following theoretical technique advantages over RFA. (1) active tissue heating of RFA is limited to a few millimeters surrounding the active electrode, with the remainder of ablation zone relying on the conduction of electricity into the tissue<sup>[22]</sup>. Microwaves use

electromagnetic energy with the much broader field of power density (up to 2 cm surrounding the antenna) to rotate rapidly adjacent polar water molecules to achieve primarily active heating, which can yield a much broader zone of active heating<sup>[21]</sup>; (2) RFA is limited by the increase in impedance with tissue boiling and charring<sup>[22]</sup>, because water vapor and char act as electrical insulators. MWA does not seem to be subject to this limitation. Therefore, temperature > 100 °C is readily achieved<sup>[25]</sup>; (3) Owing to the active heating ability, MWA can achieve higher intratumoral temperatures, larger ablation volumes, and shorter ablation times<sup>[25-28]</sup>. Because the cooling effect of blood flow is most pronounced within the zone of conductive rather than active heating, MWA is less affected by blood-vessel-mediated cooling (the heat-sink effect). These benefits have the potential to allow for a more uniform tumor kill in the ablation zone, both within the targeted zone and perivascular tissue<sup>[28,29]</sup>; (4) MWA allows for simultaneously multiple probe deployment to reduce the duration of therapy and increase the diameter of ablation zone<sup>[21,22,25]</sup>; and (5) MWA does not require the placement of grounding pads and the electrical energy is deployed in the target tissue only, which avoids applied energy loss and skin burns. Moreover, MWA is not contraindicated by the metallic materials like surgical clips or pacemaker.

However, as one of most recent advances in the field of thermoablative technology, MWA has a few limitations: (1) The higher thermal efficiency of MWA may become a double-edged sword to injury easily the adjacent critical tissues because of the tissue surrounding the antenna being rapidly ablated; and (2) Simultaneous deployment of multiple probes of microwave antennae can significantly increase the diameter of the ablation zone, whereas recession of the coagulation zone for the inter-antenna distance may not entirely cover the large tumor and result in incomplete ablation<sup>[30]</sup>.

Apart from theoretical comparison of technical characteristics, in limited comparative clinical trials between MWA and RFA, two ablation techniques achieved similar tumor necrosis effects and survival<sup>[18,19,31,32]</sup>. However, Japanese researchers thought RFA had a tumor control advantage in small liver lesions<sup>[33,34]</sup>. However, randomized controlled trials with large samples and long-term follow-up are lacking and are strongly recommended to provide evidence-based medicine.

### Equipment

All MWA systems are composed of three basic elements: microwave generator, low-loss flexible coaxial cable, and microwave antenna. Microwaves are generated by a magnetron in the generator. Antennae are connected *via* a low-loss coaxial cable to the generator and transmit microwaves from the magnetron into the tissue. Antennae can be classified as three types (dipole, slot, or monopole), based on their physical features and radiation properties<sup>[35]</sup>. Antenna shape includes straight, loop and triaxial. Design of the antenna is crucial to the therapeutic

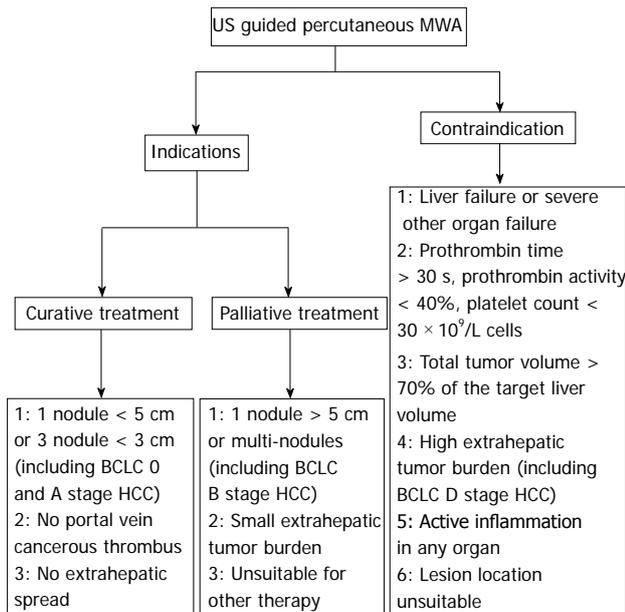

efficacy. Currently, the design has focused largely on needle-like, thin, coaxial-based interstitial antennae<sup>[35-37]</sup>, for the purpose of achieving larger ablation zones and being appropriate for percutaneous use. To prevent over-heating of the shaft, avoid skin injury, and permit further deposition of energy into tissue with low impedance during ablation, cooled-shaft antennae have been developed in recent years. The cooled-shaft antennae have facilitated remarkable progress in obtaining larger ablation zones<sup>[25,38]</sup>. The diameter of the antenna is from 1.6 to 2.8 mm (10-16 G), while the antenna with a diameter of 14-16 G is clinically commonly used.

Some types of commercially available radiofrequency devices contain a thermocouple in the nickel-titanium lateral tine of expandable electrode tip to allow temperature recording during the ablation procedure. The aim of temperature monitoring is to ensure that the maximum energy is applied by using the standard algorithm with the system<sup>[39]</sup>. The microwave machine can also be equipped with a thermal monitoring system that continuously measures temperature in real time during ablation. The thermal monitoring needles are usually classified into thermocouple and thermistor types, with a diameter of 0.7-0.9 mm (20-22 G). The thermal monitoring needle is inserted into the target area through a nonconducting needle trocar for real-time temperature monitoring during ablation under US guidance. The purposes of temperature monitoring include the following: (1) Therapeutic: the temperature monitoring needle is inserted about 5-10 mm away from the tumor margin. Total tumor necrosis is considered to be achieved when the temperature remains at 54 °C for at least 3 min or reaches 60 °C instantly; and (2) Protective: for high-risk localized tumors (< 5 mm from the vital tissues, such as bile duct, gastrointestinal tract, gallbladder, and blood vessels), the real-time temperature of the tumor margin is monitored to ensure that temperature does not reach damaging levels. The temperature cutting off of ablation therapy is set at 54 °C in the patients without a history of prior laparotomy, or 50 °C in patients with a history of laparotomy. The emission of microwaves is reactivated after the temperature decreases to 45 °C, and then in cycles until the entire tumor is completely encompassed by hyperchoic water vapor.

## DIAGNOSIS AND INDICATIONS

### Diagnosis

Pathological diagnosis is necessary for both HCC and metastatic cancer patients. The specific pathological result ensures that the tumor ablated is actually malignant, and tumor differentiation will also provide forceful surveillance guidance for the patients. Furthermore, the metastatic site can be confirmed to guide future chemotherapy and radiotherapy schedules. If the patients need to undergo biopsy to achieve pathological diagnosis, it is preferred to perform intraoperative tumor biopsy before ablation under US guidance. According to several

**Figure 1** Indications and contraindications of ultrasound-guided percutaneous microwave ablation. MWA: Microwave ablation; BCLC: Barcelona Clinic Liver Cancer; HCC: Hepatocellular carcinoma; US: Ultrasound.

reports with large-volume liver cancer patients treated by MWA, the neoplastic seeding as a complication of liver puncture is low risk with a rate of 0.4%-0.6%<sup>[10,40,41]</sup> and is considered generally acceptable. Ablation immediately after biopsy might decrease seeding rate after biopsy and the thermal effect can stop bleeding after biopsy.

If the patient has obtained a histopathological diagnosis during previous treatment, or the tumor location or the patient's condition is not appropriate for the biopsy procedure, a combination of contrast-enhanced US, contrast-enhanced computed tomography (CT) and/or magnetic resonance imaging (MRI) associated with a rising serum tumor marker level is recommended. Contrast-enhanced imaging should include early arterial phase enhancement and be performed to define better the extent and number of primary lesions, vascular anatomy, vessel involvement, tumor involvement, and extrahepatic disease<sup>[42-44]</sup>.

### Indications

Given the complexity of the hepatic malignancy, multi-disciplinary assessment of tumor stage, liver function, and physical status is required for proper therapeutic planning. In general, the indications for MWA are broad (Figure 1). One important application is to treat patients who are not considered surgical candidates. Included in this category are patients with inadequate liver remnant to tolerate resection, tumor multinodularity, unresectable lesions at difficult anatomical locations, or patients who decline resection. Previous MWA was limited to treat small liver tumors, but with the improvement of antennae and treatment strategies, lesions 5-8 cm can also be effectively ablated<sup>[10,45,46]</sup>.

For patients with very early stage and early stage HCC

[based on the Barcelona Clinic Liver Cancer (BCLC) Staging System<sup>[47]</sup>] and limited metastases, MWA should be considered as curative therapy. The inclusion criteria are: (1) a single nodule with a diameter < 5 cm or a maximum of three nodules with a diameter < 3 cm; (2) absence of portal vein cancerous thrombus; or (3) no extrahepatic spread to surrounding lymph nodes, lungs, abdominal organs, or bone.

Palliative treatment criteria for MWA include patients (1) with lesions > 5 cm in diameter or multiple lesions (including BCLC B stage HCC); (2) suffering from a small extrahepatic tumor burden (including part of BCLC C stage HCC); or (3) unsuitable for other modalities and capable of tolerating the MWA procedure.

### Contraindications

Contraindications include patients who have: (1) clinical evidence of liver failure, such as massive ascites or hepatic encephalopathy, or with a trance-like state; (2) severe blood coagulation dysfunction (prothrombin time > 30 s, prothrombin activity < 40%, and platelet count <  $30 \times 10^9/L$  cells); (3) high intrahepatic tumor burden (tumor volume > 70% of the target liver volume or multiple tumor nodules) or high extrahepatic tumor burden (including BCLC D stage HCC); (4) acute or active inflammatory and infectious lesions in any organ; (5) acute or severe chronic renal failure, pulmonary insufficiency or heart dysfunction; and (6) tumor proximity to diaphragm, gastrointestinal tract, gallbladder, pancreas, hepatic hilum and major bile duct or vessels. Successful treatment of the high-risk localized tumor may require adjunctive techniques (*e.g.*, artificial fluid infusion or percutaneous ethanol injection) to prevent off-target heating of adjacent structures during the ablation procedure.

## PATIENT PREPARATION AND DATA REQUIRED

Patients considered for MWA should be accurately evaluated through clinical history, physical examination, laboratory values and performance status. Pre-therapy evaluation of serum liver enzymes, cholinesterase, blood cell count, coagulation, creatinine, and tumor markers such as  $\alpha$ -fetoprotein/carcinoembryonic antigen should be monitored and known before the procedure. The impaired liver function and coagulation status need to be corrected to withstand the ablation procedures. A full pre-ablation imaging work-up (a combination of contrast-enhanced imaging including US, CT or MRI) should be performed to stage, locate the lesions and exclude portal venous thrombosis and metastases accurately (Table 1).

Patients should receive both written and verbal information about the procedure prior to therapy. Informed written consent must be obtained from the patient. Patients should be informed that this therapy is not likely to cure their disease and is a palliative treatment directed at their liver lesions. Patients must be informed of the potential side effects of therapy as well.

**Table 1** Indications and check list for microwave ablation of hepatic malignancy

Curative therapy	Palliative therapy	Check list
Single nodule with a diameter < 5 cm	Lesion > 5 cm in diameter	Histocytologic diagnosis
Maximum of 3 nodules with a diameter < 3 cm	Multiple lesions	US features of nodule (blood, location and size)
Absence of portal vein cancerous thrombus	Suffering from a small extrahepatic tumor burden	CEUS, CT or MRI of liver (lesion number, size, blood and location, portal venous thrombosis)
No extrahepatic spread	Unsuitable for other modalities	Laboratory tests (routine, coagulation function, serum biochemical item and tumor markers)

US: Ultrasound; CEUS: Contrast-enhanced ultrasonography; CT: Computed tomography; MRI: Magnetic resonance imaging.

## TECHNIQUES

Patients are laid in the supine or oblique position in the interventional US suite. Color Doppler and gray-scale US are performed to choose the safest intercostal or subcostal needle access. Local anesthesia and/or intravenous conscious analgesia-sedation is usually sufficient for the percutaneous approach. Local anesthesia is induced first with 1% lidocaine from the insertion point at the skin to the peritoneum along the US-guided puncture line before inserting the antennae. Then, the skin is pricked with a small lancet, and the antenna is introduced into the chosen area of the tumor. In the multiple-needles procedure two or three prefixed puncture lines are made. Two or three active needle antennae directly connected to the MW generator are inserted into the tumor in parallel 1-2.5 cm apart. After placing all the antennae (breathing cooperation is required from the patient to complete the insertion), venous conscious analgesia-sedation is induced with propofol and ketamine associated with standard hemodynamic monitoring. At each insertion, the tip of the needle is placed in the deepest part of the tumor. Multiple thermal lesions are created along the major axis of the needle antenna by simply withdrawing the needle from the preceding thermal lesion, and reactivating the MW generator. If necessary, due to tumor size, multiple overlapping ablations are usually needed to envelope the entire tumor with a safety margin. In general, the microwave energy application is set at 50-80 W for 5-10 min in a session.

Size of the ablation zone can be roughly judged by an expanding hyperechoic area arising during the procedure. For accurate assessment of the treatment efficacy, the thermal monitoring system attached to the MW generator can be used during MWA. One to three thermocouples are placed at different sites 5-10 mm outside the tumor. The thermocouple can be introduced into the parenchyma through an 18 G, 70-mm long, nonconducting needle trocar. If the measured temperature does not

reach 60 °C by the end of treatment and does not remain at 54 °C for at least 3 min, the treatment is prolonged until the desired temperature is reached. Overheating can also be avoided by thermal monitoring, thus decreasing the incidence of complications. In recent years, contrast-enhanced US has been used for immediate assessment of technical success which is performed 10-15 min after MWA<sup>[48]</sup>. If the foci of nodular enhancement in the treated tumor is observed, a new MWA session with an identical device is performed as part of another course of treatment. When withdrawing the antenna, the needle track is coagulated with the circulated distilled water in the shaft channel, which is stopped to prevent bleeding and tumor-cell seeding.

This ablation therapy often includes a 5-10-mm ablative margin of apparently healthy tissue adjacent to the lesion to eliminate microscopic foci of disease, and the uncertainty that often exists regarding the precise location of actual tumor margin. For patients with severe liver cirrhosis or the lesion adjacent to critical organs, an ablation margin of < 5 mm or conformal ablation based on tumor shape and contours is recommended to ensure safe and radical treatment; otherwise, a 5-10-mm surgical margin is preferred. Reducing the tumor bulk or conformal ablation is the strategy for patients undergoing palliative ablation treatment.

## CARE AFTER MWA

After the MWA procedure, the punctured site is covered with a sterile dressing under pressure. The patient then undergoes recovery for 4-6 h of bed rest. The patients are observed for 2-3 additional days and discharged from the hospital when they feel no severe pain or when their body temperature does not exceed 38 °C.

## COMBINED TREATMENT WITH OTHER MODALITIES

The therapeutic efficacy of MWA can be augmented by other therapies. Similar to other thermal ablation techniques, the coagulation area of MWA is also influenced by perfusion-mediated cooling. Interruption of hepatic blood flow can significantly increase the coagulation diameters<sup>[49]</sup>. TACE is an effective method for reducing the blood flow of liver tumor because of its artery-blocking effect. When combined with MWA, it may yield increased ablation volume. MWA can destroy the remaining viable part of the tumor after TACE, whereas TACE may possibly control microscopic intrahepatic metastasis that cannot be treated by MWA<sup>[50]</sup>. As the two modalities are complementary, the combination of them is preferred, especially for treating large and multiple tumors. The combination of TACE decreases the number of microwave antenna insertions and microwave irradiation time. The decision as to whether combined therapy with TACE, intermittent treatment, or sequential therapy is adopted should be based on the patient's general condi-

tion, liver function, local tumor size and number, tumor infiltration, tumor vascularization, and reaction of tumor to local treatment. Therefore, the principle of individual treatment must be advocated.

For patients with high-risk localized tumors, combination of multiple techniques to ensure favorable effects and few complications is also recommended. Hepatic tumor in high-risk sites refers to tumor adjacent to important organs and tissues including the diaphragm, gastrointestinal tract, hilum and major bile duct or vessels. The thermal energy may spread into surrounding structures, therefore, the major concern for MWA of such tumors lies in the increased opportunity of thermal injury in the important structures. However, combined with artificial ascites, artificial pleural effusion, intraductal saline perfusion, intermittent emission of microwave antennae, and temperature monitoring assisted with small-dose percutaneous ethanol injection<sup>[51-55]</sup>, MWA becomes feasible for the treatment of dangerous site tumors without sacrificing the therapeutic efficacy.

Although US guidance has the benefits of real-time visualization of applicator placement, portability of the technology, nearly universal availability and low cost, it has several limitations including occasional poor lesion visualization as a result of a lack of innate tissue conspicuity or overlying bone- or gas-containing structures. MWA assisted by a real-time virtual navigation system is a feasible and efficient treatment of patients with lesions undetectable by conventional US<sup>[56]</sup>. Recently, 3D US-guided MWA avoids the limitation of inaccurate needle placement and the skill requirement resulting from conventional US guidance. These new techniques provide an appealing alternative option, enabling the physician to perform consistent, accurate therapy with improved treatment effectiveness<sup>[57,58]</sup>.

## FOLLOW-UP AND THERAPEUTIC EFFICACY ASSESSMENT

The Working Group on Image-Guided Tumor Ablation proposed that postprocedural follow-up of patients to assess any treatment-emergent side effects and tumor response is conducted in the first week or, at the latest, no more than 4 wk after the last course of a defined ablation protocol<sup>[59]</sup>. Subsequent routine follow-ups are then recommended every 3-4 mo. Evaluation of therapeutic effects, including technique effectiveness, local tumor progression, and complications, is recommended. The Working Group also recognized the need for close surveillance and early reintervention to achieve optimal primary tumor ablation success.

Frequent imaging studies may be required for individual patients to assess the therapeutic efficacy and to detect the intrahepatic recurrent lesion. To ensure continuity of the follow-up, most of the studies are recommended to be performed serially at the institution where the ablation is performed. The imaging studies should consist of a high-quality, contrast-enhanced CT/MRI or

US, adhering to standard scanning protocols to facilitate comparisons. Intravenous contrast is critical because pathological studies have shown that the best correlation of necrotic tissue is defined by the zone of non enhancement on cross-sectional studies<sup>[60-62]</sup>. If any areas of the ablated mass are devoid of enhancement on follow-up enhanced imaging performed 1 mo after MWA, technique effectiveness, namely complete response, is achieved<sup>[59]</sup>. Then routine contrast-enhanced US, CT or MRI and serum tumor markers are repeated to detect the local treatment response and intrahepatic and extrahepatic metastases at 3-mo intervals after MWA. If irregular peripheral enhancement in scattered, nodular, or eccentric pattern occurs in the original sites that were previously considered to be completely ablated during follow-up, which represents local tumor progression, further ablation should be considered as soon as possible if the patient still meets the criteria for MWA. US scanning is the routine baseline examination method for the ablation zone. During follow-up, the treated lesions slowly diminish in size, becoming undetectable by US, or appearing only as small hyperechoic areas or isoechoic areas with a hypoechoic rim, or simply as heterogeneous areas. On contrast-enhanced imaging, the ablation zone presents as a non-enhancement area. Additionally, positron emission tomography may be helpful in identifying distant extrahepatic metastatic disease, and it can be considered as a part of the postoperative evaluation if necessary.

Major complications of MWA are events that lead to substantial morbidity and disability, increase the level of care, or result in hospital admission or substantially lengthen hospital stay. Major complications includes bile duct stenosis, uncontrollable bleeding, liver abscess, colon perforation, skin burn and tumor seeding (Table 2)<sup>[4,5,13,19,34,36,42,63,64]</sup>. These can be controlled by surgical operation, interventional approach, or medical therapy. Side effects are undesired consequences of the procedure that, although occurring frequently, rarely if ever result in substantial morbidity. Side effects include pain, post ablation syndrome, and asymptomatic pleural effusions, which are usually self-limited and do not require any further treatments. Low-grade fever and general malaise are common manifestations of post ablation syndrome. Careful patient selection, the most appropriate imaging modality, and the best puncture routine may also help prevent complications.

## DISCLAIMER

The SCIU has written and approved the guidelines to promote the cost effective use of high-quality MWA therapeutic procedures. Percutaneous MWA techniques are recommended for use by clinical or imaging doctors with at least 3 years experience with interventional procedures. These generic recommendations cannot be rigidly applied to all patients in all practice settings. The guidelines and technology assessments are not intended to supplant physician judgment with respect to particular patients or special clinical situations, and not be deemed

**Table 2 Procedure-related complications for microwave ablation of hepatic malignancies**

inclusive of all proper procedures or exclusive of other procedures reasonably directed towards obtaining the same results. Accordingly, SCIU considers adherence to this guideline assessment to be voluntary, with the ultimate determination regarding its application to be made by the physician in light of each patient's individual circumstances. At present, the guidelines have been put into practice in China by seven branches of the Chinese Medical Association, through holding standardized courses (3 finished), training and checking interventional physicians (> 300 physicians having obtained MWA licenses), and founding ablation demonstration bases (5 founded). MWA is undergoing rapid development and receiving keen interest in Europe and America, so access and training systems for MWA guidelines are expected to be recommend according to the situation in each country. The guidelines will be updated when data or publications might change a prior recommendation or when the panel feels clarifications are required for the oncology community.

### Abstract

Hepatocellular carcinoma (HCC) represents a major form of primary liver cancer in adults. MicroRNAs (miRs), small non-coding single-stranded RNAs of 19-24 nucleotides in length, negatively regulate the expression of many target genes at the post-transcriptional and/or translational levels and play a critical role in the initiation and progression of HCC. In this review we have summarized the information of aberrantly expressed miRs in HCC, their mechanism of action and relationship to cancer. The recent advances in HCC research reveal that miRs regulate expression of various oncogenes and tumor suppressor genes, thereby contributing to the modulation of diverse biological processes including proliferation, apoptosis, epithelial to mesenchymal transition and metastasis. From a clinical viewpoint, polymorphisms within miR-binding sites are associated with the risk of HCC. Polymorphisms in miR related genes have been shown to correlate with

survival or treatment outcome in patients. Furthermore, the review focuses on the potential role of miRs as novel biomarkers and their translational applications for diagnosis and therapy in HCC. With further insights into miR deregulation in HCC, it is expected that novel miR-based therapeutics will arise. Also, we orient the readers to other reviews that may provide better understanding of miR research in HCC.

**Key words:** MicroRNA; Cancer; Hepatocellular carcinoma; Biomarker; Polymorphism

**Core tip:** This review provides the relationship between microRNA (miR) and hepatocellular carcinoma and speculates on the progress that will be achieved through ongoing research. A research effort to identify genetic polymorphisms associated with cancer is emphasized. The review highlights that miR-based therapeutics, and diagnostic and prognostic systems should be used for patients.

### INTRODUCTION

Liver cancer is the second and sixth leading cause of cancer related-death in males and females respectively. Hepatocellular carcinoma (HCC) that accounts for most of the primary liver cancers is the fifth most frequently diagnosed cancer worldwide. Early detection of HCC is needed because the best indicator of prognosis is based on the stage of the disease. About 90% of HCC cases arise from cirrhosis and the disease is strongly associated with several risks factors, including hepatitis B and C

infections, alcohol abuse, primary biliary cirrhosis, autoimmune hepatitis and nonalcoholic steatohepatitis<sup>[1]</sup>. Epigenetic changes in microRNAs (miRs) and their target gene expression may provide tools and opportunities for detection and therapeutic intervention in HCC.

MiRs, a class of non-coding RNAs with lengths of 19- to 25 nucleotides (nt), act as post-transcriptional regulators by binding to 3'-untranslated region (3'UTR) of target messenger RNA (mRNA). MiRs function as endogenous suppressor of gene expression by inducing either mRNA degradation or translational repression. The promoters of *MiR* genes are regulated by transcription factors, co-activators, enhancers and suppressors similar to protein coding genes. Thus, proto-oncogene *c-myc*<sup>[2,3]</sup> and tumor suppressor *p53*<sup>[4]</sup> transactivate miRs in HCC. In a genomic cluster the individual miRs are often expressed at different times from the same pri-miR. Pri-miRs are transcribed in the nucleus into a 70-100 nt hairpin-shaped structure and the process is catalyzed by Droscha, which is associated with cofactor DGCR8 and other proteins. After translocation to the cytoplasm by Exportin5, miRs are cleaved into a 19-25 nt miR duplex by enzyme Dicer. One strand of the duplex is then incorporated into the RNA-induced silencing complex (RISC) for its mRNA targets. MiRs function as endogenous suppressor of gene expression by binding of RISC to the 3'UTR of target mRNAs and inducing either mRNA degradation or translational repression. The mRNA degradation is induced if miR binds completely or almost completely, however, if the binding is incomplete, miR represses translation of mRNA. Each step of the process is well regulated, and dysfunction at any level can result in inappropriate miR functions. Gene silencing is the most methodically studied role of miRs, however, they can up-regulate gene transcription during cell cycle arrest and, therefore, overexpression of miRs in human cancers hinted to probable oncogenic functions of miRs. As discussed earlier a direct binding of miR to 5'UTR or promoter of the target genes activate rather inhibit gene expression<sup>[5]</sup>.

Analogous to the protein-coding genes, epigenetic mechanisms, for example, CpG island hypermethylation<sup>[6-8]</sup> and histone modifications<sup>[9]</sup> also regulate miR expression in HCC. MiRs that are transcribed from CpG islands undergo DNA hypermethylation-coupled repression due to binding of the transcriptional repressor methyl CpG binding proteins. Epigenetic regulation of miRs might be more common than reported so far as approximately 16% of the annotated human miRs are located within 1000 bp of a CpG island. To date, more than 1000 human miRs have been identified and each miR control hundreds of genes. It has been suggested that miRs regulate the translation rate of more than 60% of protein coding genes.

## ABERRANT EXPRESSION OF MICRORNAS IN HCC

MiRs play a central role in basic biological processes such

as cellular differentiation, proliferation, apoptosis, migration and invasion. MiR expression profiles are different between normal tissue and derived tumors and between distinct tumor types. Protein coding genes of cell cycle, apoptosis, and metastasis are direct targets of miRs in HCC<sup>[10]</sup>. Microarray studies have identified a number of miRs that are either up-or down-regulated<sup>[11]</sup>. Down-regulation of subsets of miRs is a common finding in HCC, indicating that some of these miRs may act as putative tumor suppressor genes. Restoration of tumor suppressive miRs leads to cell cycle block, increased apoptosis and reduced tumor angiogenesis and metastasis by inhibiting migration and invasion. On the contrary, onco-miRs that are up-regulated in HCC potentially target many tumor suppressive genes. Experimental suppression of onco-miRs helps restoring expression of tumor suppressive genes that initiates apoptosis and inhibits cell proliferation, angiogenesis and metastasis in HCC. In general, to investigate the role of deregulated miRs in HCC, miR expression vectors and mature miR mimics or inhibitors (antagomirs) are transfected in HCC cell lines. Further, to confirm the target genes of respective miRs, 3'UTR luciferase vectors (empty luciferase vector or luciferase vector containing wild-type or mutant-type target gene 3' UTR) are utilized for reporter assays. Major down- and up-regulated miRs and their target genes in HCC are discussed in Table 1.

## CLINICAL SIGNIFICANCE AND TRANSLATIONAL APPLICATIONS OF MICRORNAS IN HCC

### *Single nucleotide polymorphism in miRs*

Single nucleotide polymorphisms (SNPs) in miRs and their targets have been associated with risk of various cancers. Due to the stringent recognition requirement needed by the miR and the binding region on its target gene, it is rather conceivable that SNPs could have functional implications on the post-transcriptional regulation of target genes. An SNP could either weaken a known miR target or create a sequence match to the miR that was not previously associated with the given mRNA. Changes in the expression pattern of a gene could therefore influence a person's risk of disease. Polymorphisms in miR-34b-c/rs4938723<sup>[12]</sup>, miR-101-1/rs7536540<sup>[13]</sup>, miR-101-2/rs-12375841<sup>[13]</sup>, miR-106b-25/rs99985<sup>[14]</sup> and miR-196a-2/rs11614913<sup>[15]</sup> are positively associated with HCC. On the contrary, miR-371-373/rs3859501<sup>[16]</sup> and miR-149c/rs2292832<sup>[17]</sup> are negatively associated with HCC risk. Also, a positive association of HCC risk has been demonstrated with polymorphisms in miR target genes IL-1/rs3783553 (miR-122 and miR-378)<sup>[18]</sup>, -TrCP/rs16405 (miR-920)<sup>[19]</sup>, IFNAR1/rs17875871 (miR-1231)<sup>[20]</sup>, ErbB4/rs6147150 (miR-let-7c)<sup>[21]</sup> and COL1A2/rs3917 (miR-let-7g)<sup>[22]</sup>.

### *miRs as biomarkers in HCC*

miRs are prognostic markers of HCC. Down-regulation

**Table 1** Down-regulated microRNA in hepatocellular carcinoma and their characteristics

miRs	Targets	Characteristics
Down-regulated		
miR-1	ET1	Proliferation <sup>[52]</sup>
miRs-7a, -7b, -7c, -7d, -7f-1, -7d	Caspase-3, HMGA2, C-myc, Bcl-xl	Proliferation, apoptosis <sup>[2,23,53-58]</sup>
miR-101	Mcl-1, SOX-9, EZH2, EED, DNMT3A	Proliferation, apoptosis <sup>[59-61]</sup>
miRs-122	Bcl-w, ADAM-1, Wnt-1	Angiogenesis, apoptosis, Metastasis <sup>[45,62-64]</sup>
miR-125a, -125b	MMP11, SIRT7, VEGF-A, LIN28B2, Bcl-2, Mcl-1, Bcl-w	Angiogenesis, apoptosis, metastasis, proliferation <sup>[65-70]</sup>
miR-139	c-Fos, Rho-kinase-2	Metastasis <sup>[30,71]</sup>
miR-145	IRS1-2, OCT4	Insulin-like growth factor pathway, Stem-like cells tumorigenicity <sup>[31,72]</sup>
miR-195	CDK6, E2F3, cyclinD1	Proliferation, apoptosis, tumorigenicity <sup>[73,74]</sup>
miR-199a-3p, -199-5p	c-Met, mTOR, PAK4, DDR1, caveolin-2	Proliferation, autophagy, metastasis <sup>[9,75-78]</sup>
miRs-214	HDGF, catenin	Proliferation, angiogenesis, metastasis <sup>[79-81]</sup>
Up-regulated		
miR-10a	EphA4, CADM1	EMT, metastasis <sup>[33,82]</sup>
miR-21	Pten, RhoB, PDCD4	Drug Resistance, metastasis <sup>[49,83-85]</sup>
miR-221	Bmf, DDIT4, Arnt, CDKN1B/p27, CDKN1C/p57	Angiogenesis, apoptosis, proliferation <sup>[86-89]</sup>
miRs-224	Yin Yang1/Raf-1 kinase, NFκB pathways, apoptosis inhibitor-5	Proliferation, apoptosis, metastasis <sup>[90-93]</sup>

miRs: MicroRNAs; EMT: Epithelial-mesenchymal transition.

of miR-let-7g<sup>[23]</sup>, -22<sup>[24]</sup>, -26<sup>[25]</sup>, -29<sup>[26]</sup>, -99a<sup>[27]</sup>, -122<sup>[28]</sup>, -124<sup>[29]</sup>, -139<sup>[30]</sup>, -145<sup>[31]</sup> and -199b<sup>[32]</sup> is associated with poor prognosis, increased risk of aggressive tumor recurrence and shorter disease free survival. Similarly, up-regulation of HCC associated miRs-10b<sup>[33]</sup>, -17-5p<sup>[34]</sup>, -21<sup>[35]</sup>, -135a<sup>[36]</sup>, -155<sup>[37]</sup>, -182<sup>[38]</sup>, -221<sup>[35]</sup>, and -222<sup>[35,39]</sup> is linked to poor prognosis. Studies have shown that miRs are protected from enzymatic cleavage by RNase in blood and therefore miR expression profile in serum or plasma could also be utilized as novel diagnostic markers. More than 20 miRs in serum and/or plasma have been associated with HCC detection. The expression profile of miRs-500, -92a, -25, -375 and let-7f could identify HCC cases from controls<sup>[40-43]</sup>. Furthermore, Zhou *et al*<sup>[44]</sup> demonstrated that miR-122, -192, -21, -223, -26a, -27a and -801a helped detecting early-stage HCC with high diagnostic accuracy.

### miRs as therapeutic targets in HCC

Tumor suppressive miRs that are expressed in normal liver, however, are down-regulated in tumor tissues during tumorigenesis and metastasis. For treatment, a good strategy would be to replenish such miRs systemically in HCC patients. Such miR replacement therapies have been demonstrated in the case of miRs -26a<sup>[3]</sup>, -122<sup>[45]</sup>, and -124<sup>[46]</sup> in mice models of HCC. Conversely, suppression of oncomir-221<sup>[47,48]</sup> by antagomirs resulted in prolonged survival and reduction of tumors. As targeted gene therapies are gaining interest in cancer treatment, miR as a therapeutic target would be more efficient since single miR can control multiple deranged genes in HCC. However, this hypothesis is yet to be tested in HCC patients. Further, chemotherapeutics kill normal cells and pose significant toxicities in cancer patients, a non-discriminatory behavior of chemotherapy drugs. In mice models, as discussed above, no such toxicity was observed when miRs were used to treat HCC. In this regard, miRs also influ-

ence sensitivity of tumors to anticancer drugs. Tumors with high expression of oncomir-21<sup>[49]</sup> and -181b<sup>[50]</sup> were resistant to IFN-5FU combination therapy and doxorubicin treatment respectively. A strategy to suppress these miRs by antagomirs might be useful in increasing drug efficacy. Similarly, studies have demonstrated that restoration of tumor suppressive miR-122<sup>[51]</sup> makes HCC cells more sensitive to Sorafenib treatment *via* down-regulation of multidrug resistance genes.

## CONCLUSION

miRs control expression of many target genes in HCC. miR profiling reveals molecular mechanisms of pathogenesis and hidden visions into early detection and treatment of HCC. Hundreds of miRs have been identified to date; however, computer models suggest there may be hundreds more. There are several online tools available for researchers and clinicians to identify and predict the targets of miRs. As research continues to verify *in silico* predictions, miR profiling will be a prominent tool for identification of differentially expressed miRs in HCC. More information from genome-wide association studies, assisted by high resolution SNP arrays and the next-generation sequencing technology, is anticipated to identify increasing number of polymorphisms in HCC specific miRs and their 3'UTR targets. For future studies, we should consider miRs and their regulatory networks in order to comprehend the complex processes underlying HCC transformation.

### Abstract

Hepatitis B virus (HBV) genotypes have distinct genetic and geographic diversity and may be associated with specific clinical characteristics, progression, severity of disease and antiviral response. Herein, we provide an updated overview of the endemicity of HBV genotypes H and G in Mexico. HBV genotype H is predominant among the Mexican population, but not in Central America. Its geographic distribution is related to a typical endemicity among the Mexicans which is characterized by a low hepatitis B surface antigen seroprevalence, apparently due to a rapid resolution of the infection, low viral loads and a high prevalence of occult B infection. During chronic infections, genotype H is detected in mixtures with other HBV genotypes and associated with other co-morbidities, such as obesity, alcoholism and co-infection with hepatitis C virus or human immunodeficiency virus. Hepatocellular carcinoma prevalence is low. Thus, antiviral therapy

may differ significantly from the standard guidelines established worldwide. The high prevalence of HBV genotype G in the Americas, especially among the Mexican population, raises new questions regarding its geographic origin that will require further investigation.

**Key words:** Hepatitis B virus genotypes; Hepatitis B virus genotype H; Hepatitis B virus genotype G; Molecular epidemiology; Mexico; Antiviral therapy; Severity of liver disease; Clinical outcome

**Core tip:** Molecular, clinical, geographical and ethnicity evidence are characteristics that define any hepatitis B virus (HBV) genotype. All of these features are there for HBV genotype H, which is most predominant in Mexico, but not in Central America. Likewise, HBV genotype G has unique molecular characteristics and a similar route of transmission among those infected with this viral genotype, but it lacks a geographic origin. To date, despite the high prevalence of HBV genotype G cases from the Americas, especially among Mexicans, the limited number of complete sequences hinders further investigation to establish a hypothesis of an Amerindian origin.

### INTRODUCTION

#### **Definition of hepatitis B virus genotypes and their association with human liver disease**

Hepatitis B virus (HBV) and humans share a close re-

relationship through the process of evolution and migration<sup>[1,2]</sup>. Numerous studies have demonstrated that most HBV genotypes are associated with a host population and geographical area of the world, while others tend to have a worldwide distribution, or still remain unknown<sup>[3,4]</sup>.

In 1988, Okamoto *et al.*<sup>[3]</sup> proposed the first genetic classification for HBV strains, defining a genotype as a viral sequence with an intertypic nucleotide divergence of more than 8% based on the entire genome. Later, a 4.2% nucleotide divergence using the S gene sequence was proposed by Norder *et al.*<sup>[5]</sup>. Throughout their discovery, each new genotype was defined by the same criterion and designated with letters in an alphabetical order, from A to J. However, given the wide diversity of HBV genomes worldwide, several authors have proposed over the years that precise criteria be fulfilled in order to identify and describe a specific genotype/subgenotype<sup>[6-9]</sup>. Recently, Kurbanov *et al.*<sup>[10]</sup> have endorsed and updated these recommendations which, in summary, are the following: use of whole genome sequences, divergence of  $\geq 7.5\%$  ( $> 4\%$  to  $< 7.5\%$  in the case of a subgenotype), strong independent clustering on molecular evolutionary analysis, avoidance of recombinants, as well as substantial epidemiological, virological and clinical evidence.

Regarding these latter points, in 2002, Chu *et al.*<sup>[11]</sup> raised key questions about the association of HBV genotypes with clinical practice: (1) “What is the predominant HBV genotype in each country or geographic region?” (2) “Is the geographic distribution of HBV genotypes related to the endemicity of HBV infection?” (3) “Is there a correlation between HBV genotype and HBV replication activity of liver disease, clinical outcome and treatment response?” and (4) “Is there a correlation between HBV genotype and risk of progression to chronic infection?”

Accordingly, the geographic distribution of HBV genotypes in regard to their regional host population and endemicity has been widely considered. In general, HBV genotypes B and C are associated with the populations of the Asian countries<sup>[3]</sup> while genotypes A and D are prevalent among European countries and the United States<sup>[3]</sup>; genotypes E and F are confined to countries of the African continent<sup>[12]</sup> and the Americas<sup>[12]</sup> (Central and South America), respectively. HBV genotype G (HBV/G) was originally reported in France<sup>[13]</sup> but has a global distribution, and HBV genotype H (HBV/H) was first revealed in Central America<sup>[14]</sup>. HBV genotypes I and J have been reported in dispersed regions of Asia and Japan, respectively<sup>[15,16]</sup>. Likewise, the genetic diversity, disease progression and response to antiviral therapy<sup>[17-20]</sup> of the European and Asian genotypes (A-D)<sup>[21-23]</sup> have received greater attention than those that are typically prevalent in the western hemisphere (E-H)<sup>[24-27]</sup>, while evidence about genotypes I and J is insufficient to respond to such arguments<sup>[10,28]</sup>.

### **Milestones in the discovery of HBV genotypes G and H worldwide and in Mexico**

HBV/G and HBV/H were revealed almost at the same time. Both discoveries represent the culminating results

of investigations carried out in the 1990s by many different laboratories worldwide. HBV/G was first described as an HBV variant<sup>[29,30]</sup> and formally reported by Stuyver *et al.*<sup>[13]</sup> in 2000. In our laboratory, HBV/G was detected in 2000, but not reported until 2002 by Sánchez *et al.*<sup>[31]</sup>. Further on, research studies focused on the development of molecular diagnostic methods<sup>[32]</sup> and the relationship between clinical and virological characteristics in comparison with the other known genotypes<sup>[26,33]</sup>. However, unlike the rest of them, the geographic origin of HBV/G is still unknown<sup>[34]</sup>.

As for HBV/H, Dr. Norder from Sweden and two other laboratories, Dr. Misokami from Japan and Dr. Panduro in Mexico, were studying the genetic variability of HBV that resulted in the identification of HBV/H in the last decade of the preceding century. However, the first HBV/H strains from Mexico were classified as HVB genotype F (HBV/F) by Sánchez *et al.*<sup>[31]</sup> since complete sequences of genotype H were not available for comparison. Later, after discussing our findings with Dr. Norder in Mexico, two strains from Nicaragua and one from the United States were made known as the new genotype H<sup>[14]</sup>. Since then, HBV/H has often been referred to as from Central America, because of the two original Nicaraguan strains. Further discussion regarding the validity of genotype H was provided by Kato *et al.*<sup>[35]</sup>, given that seven HBV isolates (doubtfully H) differed from a number of selected HBV/F strains by a genetic divergence of 7.3%-9.5%, thus proposing a new subtype (F2) of HBV/F.

Overall, in the last ten years, the knowledge on HBV/H regarding the relationship between virological-clinical characteristics and its geographical and host population prevalence has increased significantly, allowing us to have a better understanding of HBV-infected patients. Herein, we provide an updated overview of such evidence concerning the endemicity of HBV infection based on genotypes H and G in Mexico.

## **HBV GENOTYPE H**

### **Molecular characteristics of HBV genotype H**

In the study by Arauz-Ruiz *et al.*<sup>[14]</sup>, the three original samples (1853Nic, 2928Nic, LAS2523) designated as HBV/H diverged from selected genotype F strains by 7.2%-10.2%. In the polymerase region, the three strains had 16 unique conserved amino acid residues not present in genotype F strains. Additionally, HBV/H also differs from them by two distinct substitutions in the surface antigen protein, at Val<sup>44</sup> and Pro<sup>45</sup>, as well as at Ile<sup>57</sup>, Thr<sup>140</sup>, Phe<sup>158</sup> and Ala<sup>224</sup><sup>[4]</sup>. Furthermore, by “TreeOrder Scan” analysis, genotype H strains show evidence of recombination with genotype F within the small S gene (nucleotide 350-500)<sup>[1]</sup>.

As mentioned before, the limited number of sequences available at that time made it difficult to distinguish HBV/H as an independent genotype, due to its close phylogenetic relatedness with HBV/F<sup>[14,35]</sup>. Nevertheless, the amount of HBV/H sequences reported in GenBank

has increased; hence pair-wise analysis of complete sequences of HBV/F compared against the latest Mexican HBV/H strains result in a genetic distance of at least 0.08 (data not shown). Thus, the initial differences reported by the authors could have been related to the fact that the earlier isolates came from subjects with residence outside of Mexico<sup>[14,35]</sup>.

Additionally, the estimated maximum likelihood phylogeny of HBV/H and HBV/F genomes exhibits a distinct genetic divergence from a common ancestor while HBV/H sequences tend to cluster into multiple and nested clades<sup>[36]</sup>. Further phylogeographic studies based on coalescent models are necessary to provide fresh information regarding these evolutionary characteristics, and integrate them to the timeline of migrations of the prehispanic people from ancient Mexico towards South America.

### **Molecular epidemiology of HBV genotype H in Mexico**

During the last 10 years, the geographic origin of HBV/H was referred to as from Central America. Today, it is clearly evident that most HBV/H sequences deposited in GenBank are from Mexico, while those isolated worldwide come from individuals reporting sexual relationships with people from the Americas, and no further H strains have been reported from Central America<sup>[36]</sup>.

Epidemiological studies using only hepatitis B surface antigen (HBsAg) determinations have shown a steady prevalence rate of 0.3% since 1976 to date, ranking Mexico as a region of low endemicity<sup>[37]</sup>. However, by anti-HBc marker and molecular diagnosis of HBV genomes, high endemic areas of HBV infection have been detected in the native population<sup>[37-39]</sup>, similar to the indigenous populations of the Central and South American countries<sup>[40]</sup>.

It has been estimated that nearly 15 million Mexican adults have been infected by HBV during their lifetime, since the anti-HBc prevalence increases with age<sup>[41,42]</sup>. Additionally, estimates suggest that at least another 5 million native people could be at risk of acquiring infection<sup>[41]</sup>. HBV/H infection is acquired primarily during adulthood by horizontal transmission, through sexual relationships and contact with contaminated body fluids, which could explain why the majority of infected patients do not develop chronic liver disease<sup>[41]</sup>.

HBV/H is the predominant genotype in asymptomatic infected patients living in high endemic areas<sup>[36,38]</sup>, as well as in patients with acute and chronic liver disease<sup>[43,44]</sup>. Indeed, HBV/H is prevalent in more than 90% of the cases, followed by HBV/A, HBV/D and HBV/G, whereas other known HBV genotypes are rare<sup>[36]</sup>. Furthermore, the predominance of HBV/H in Mexico is historically related to the migrations of the prehispanic people, the settlement of the Aztecs in Mesoamerica before the Spanish conquest and the successive admixture of the population; hence, it is the predominant genotype detected in both Mexican native (Amerindian) and mestizo populations<sup>[36,38]</sup>.

### **Clinical presentation of HBV/H infected patients**

HBV/H infected patients usually are asymptomatic without clinical or laboratory manifestations of liver disease<sup>[38,43]</sup>; thus, the existence of liver damage is modest or undetectable, whereas occult B infection (OBI) is a common manifestation<sup>[38,45]</sup>. This situation may be attributed to a rapid resolution of the disease, associated with the genetic characteristics of either the virus or the host<sup>[46]</sup>.

HBV/H is often detected in patients with acute liver damage. This clinical symptom is observed in male patients, such as men who have sex with men, mainly during the acute phase, and then with viral clearance or OBI after acute infection and flares during immunosuppressive conditions<sup>[46]</sup>. In chronic patients, HBV/H is predominant also; however, OBI is common so that the association of the HBV/H with the progression and severity of liver disease is masked by the presence of other co-morbidities, such as alcoholism, obesity and co-infection with hepatitis C virus (HCV) or human immunodeficiency virus (HIV)<sup>[36]</sup>. HBV/H-infected patients tend to have low viral loads, usually < 4000 UI/L, that are easily detected as they increase, up to 100000 UI/L or above when patients are infected with mixtures of HBV genotypes<sup>[36]</sup>.

Lastly, the low prevalence of HBV infection among the Mexican population is associated with a low prevalence of hepatocellular carcinoma (HCC) from 1953 to date<sup>[47-49]</sup>. This is contrary to what occurs in the Asian countries, where acute and chronic HBV infection with genotypes B and C and HCC are highly prevalent. Thus, the predominance of HBV/H among the Mexican population is associated with low endemicity, low viral load, minimum cases of acute and chronic liver diseases due to HBV infection and a low prevalence of HCC.

This matter raises a word of caution regarding the strategy for antiviral therapy in Mexico since the main cause of liver disease may be attributed to co-morbidities, such as HCV or HIV infection, alcoholism or obesity, but not to HBV infection exclusively. Therefore, antiviral therapy for HBV/H-infected patients should be given with precaution until the usefulness of the conventional antivirals is fully demonstrated for this genotype, considering that the international guidelines for the treatment of chronic B infection have been designed for populations of other geographic regions that have different HBV genotypes, endemicity and progression of liver disease.

## **HBV GENOTYPE G**

### **Molecular characteristics of HBV genotype G**

The HBV/G genome has some unique characteristics. It contains a 36-nt/12 amino acid insertion with pleiotropic effects on core protein expression, genome replication and virion secretion, not found in any other HBV genotype<sup>[50]</sup>. It also has two stop codons in the preC region at position 2 and 28, which prohibits the translation of the hepatitis B e antigen (HBeAg)-precursor; thus, patients

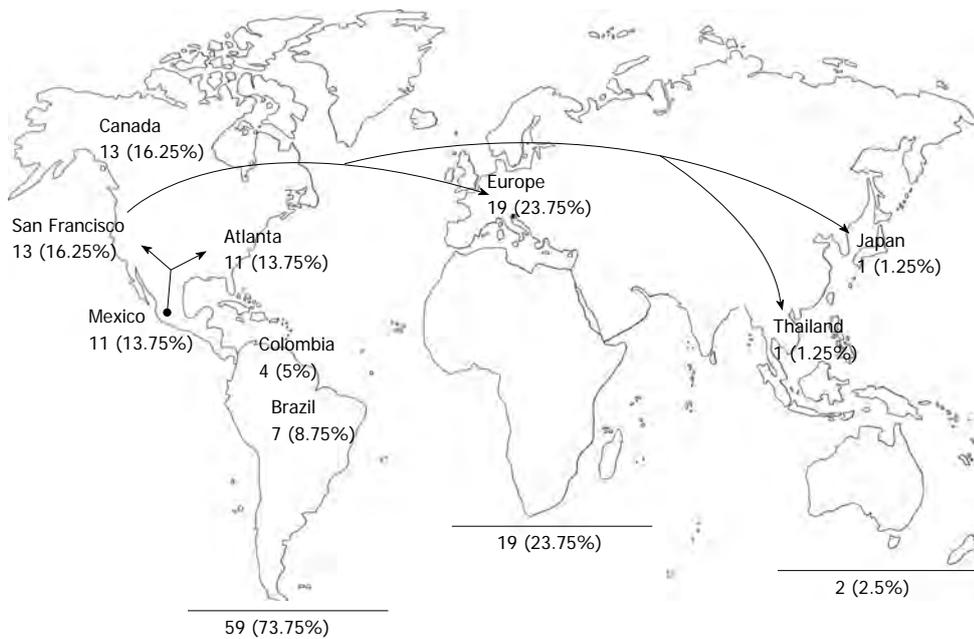

Figure 1 Geographic distribution of the worldwide epidemiology of the hepatitis B virus genotype G isolates. Fifty-nine genome sequences out of a total of 80 have been reported from the Americas (73.75%), whereas 23.75% are from Europe and 2.5% from Asia. The high prevalence of hepatitis B virus genotype G in America may be related to a common source of infection and transmission route.

who are mono-infected with HBV/G are negative for HBeAg<sup>[51]</sup>. Other molecular characteristics include two deletions, one at the carboxyl terminal region of HBcAg and another in the preS1 region<sup>[51]</sup>.

At the nucleotide level, the majority of the complete genome sequences of HBV/G strains share a remarkable sequence conservation of more than 99%<sup>[52]</sup>. Furthermore, there is a high nucleotide similarity within the S gene sequence (94.6%-97.5%), considered as evidence of recombination with genotype A (HBV/A) in the small S fragment (nucleotide 250-350)<sup>[11]</sup> and a 30 base pair fragment in the preS region that is almost identical to genotype E<sup>[34]</sup>.

### Molecular epidemiology of HBV/G in Mexico

Worldwide, a significant number of HBV/G strains have been detected in men who have sex with men<sup>[13,26,29,30,52-54]</sup>, suggesting that sexual genital-anal contact may play a significant role in the transmission of HBV infection<sup>[55]</sup>. However, parenteral transmission has been reported, mainly as mono-infection, such as in blood donors<sup>[56-58]</sup> and hemodialysis patients<sup>[59]</sup>.

In the past years, several publications continue to report that little is known about the geographical origin of HBV/G, and yet it is considered ubiquitous. Such statements have arisen due to earlier HBV/G cases reported from France<sup>[13]</sup>, Germany<sup>[54]</sup> and the cities of San Francisco, CA<sup>[26,29,52]</sup> and Atlanta, Georgia<sup>[13]</sup> in the United States. However, despite the limitations of using RFLPs or strip molecular methods for the detection of HBV/G, instead of complete genome sequences<sup>[10]</sup>, most of the cases of this genotype have been reported from the Americas (73.5%), including Mexico<sup>[31,38,46,55,60,61]</sup> and to a

lesser degree from Europe<sup>[30,50,56,62-65]</sup> (23.75%) and other regions of the world (2.5%)<sup>[66-68]</sup> (Figure 1).

As mentioned before, the geographic origin of HBV/G is still unknown, due to its low global prevalence combined with the lack of epidemiological and clinical data. The genomic characteristics of this genotype are puzzling. On one hand, HBV/G complete sequences share such a close similarity that a specific molecular epidemiological route of transmission among the international cases or a simple evolutionary history cannot be elaborated. On the other hand, the similarity of certain regions of the HBV/G genome with genotypes A<sup>[1]</sup> and E<sup>[34]</sup> suggest co-evolutionary processes among themselves<sup>[10]</sup>. These features have created considerable difficulties to pinpoint a distinct geographic origin for HBV/G.

A hypothesis on a plausible African geographic origin of HBV/G was proposed by Lindh<sup>[34]</sup> in 2005, based on its similarity with HBV/E which is prevalent in Africa and that the worldwide spread of HIV infection from Africa may have been the cause of the dispersion of HBV/G. Unfortunately, HBV/G African sequences have not been deposited in GenBank nor have G/E recombinants been associated with a host population to date. Furthermore, based on the low genetic diversity of HBV/E (1.67%) and its short evolutionary history<sup>[69]</sup>, it has been suggested that it was introduced into the African population after the Atlantic slave trade<sup>[69-71]</sup>. This is consistent with the fact that HBV/E is virtually absent in the Americas, despite the significant number of African slaves introduced into the United States and Latin America (including Mexico), both regions having a high presence of black population, the former of Afro origin and the latter mixed descendents of a large black popula-

tion forced into slavery. Thus, the worldwide spread of HBV/G appears to have not co-dispersed HBV/E, since G/E recombination or G-E co-infection is absent among the admixture populations. Interestingly, the similarity of the 150 base pair fragment between HBV/A and HBV/G could be related to the most common dual HBV G/A infection reported in the United States<sup>[26,52]</sup>, Canadian<sup>[53]</sup> and European cases<sup>[56]</sup>. Given that HBV/A is common in Europe, it may be speculated that genotype G could have reached the Americas by way of the Caucasian people. However, despite the fact that HBV/A is a minor strain in Mexico<sup>[36]</sup>, HBV G/H co-infection is more frequent than G/A<sup>[55]</sup>. Thus, G/H co-infection may be related to the plausibility that genotype G is endemic to Mexico, as well as genotype H. Furthermore, HBV/G has been detected in patients with chronic liver disease; pathogenesis of liver fibrosis has been documented in *in vitro* experiments<sup>[60,72]</sup> and corroborated in patients with co-infection with other HBV genotypes.

The relationship of HBV/G sequences with the Mexican population is based on the following observations: (1) the high prevalence of HBV/G sequences in the American continent (73.75%) (Figure 1); (2) 16 HBV/G cases were detected among 77 HIV/HBV co-infected individuals (21%)<sup>[61]</sup>; (3) 5 HBV/G cases out of 49 high risk individuals (10.2%)<sup>[27]</sup>; and (4) HBV/G sequences have been identified in an ongoing study cohort of young children with HBV infection in our laboratory. These findings lead us to ask ourselves: "Is HBV/G endemic to the Americas, including Mexico, Colombia, and Brazil or was it introduced into the continent?" The evidence that could support an Amerindian hypothesis requires that sequences from native and mestizo populations be analyzed. To date, 11 sequences from Mexico<sup>[31,38,55,60]</sup>, 7 from Brazil<sup>[73-75]</sup> and 4 from Colombia<sup>[58]</sup> have been retrieved from mestizo populations, except for one Mexican case belonging to a native from the Huichol community<sup>[38]</sup>. The presence of HBV/G in this community could be explained by the fact that native individuals engage in multi-partner sexual relationships and male-to-male sexual activity<sup>[38,76,77]</sup>. However, further phylogeographic studies are required in order to determine if these findings may be related to the transmission of HBV/G infection among distinct Amerindian communities before the global dissemination of blood-borne infectious diseases.

Nevertheless, Mexican and United States HBV/G strains share a close genetic homology<sup>[55]</sup>. This is consistent with the fluent migration events that have occurred for centuries across the United States-Mexican border, especially from the western states of Jalisco, Michoacan and Guanajuato, towards the large United States Hispanic communities, such as in Los Angeles, San Francisco and Atlanta, among others<sup>[78]</sup> (Figure 1). However, despite this feasible epidemiological association, further evidence is required to verify if the transmission of HBV/G infection may have occurred among same-sex couples/transgender individuals traveling to and from Mexico and the United States<sup>[79,80]</sup>.

## CONCLUSION

The predominance of HBV genotype H among the Mexican population is associated with a definite geographic region and historical context. The endemicity of HBV infection in Mexico manifests with a low HBsAg seroprevalence, due to a rapid response to the infection, low viral loads and a high prevalence of occult B infection. During chronic infections, HBV infection may be undetectable and associated with co-morbidities, such as obesity, alcoholism and co-infection with HCV or HIV. These manifestations correlate with the low prevalence of hepatocellular carcinoma. Based on these features, antiviral therapy may differ significantly from the international guidelines that have been established for patients within the regions of high endemicity. As for the high prevalence of HBV/G cases reported in Mexico, more detailed phylogenetic analysis of other HBV/G complete sequences will be required in order to elucidate its geographic origin.

### Abstract

**AIM:** To analyze phospholipid profiles in intrahepatic bile from patients with primary sclerosing cholangitis (PSC) and secondary sclerosing cholangitis (SSC).

**METHODS:** Intrahepatic bile specimens collected *via* endoscopic retrograde cholangiography from 41 patients were analyzed. Fourteen of these patients were diagnosed with PSC, 10 with SSC, 11 with choledocholithiasis or no identifiable biliary disease, and 6 with cholangiocellular carcinoma (CCC). Bile acid, cholesterol, and bilirubin contents as well as pancreas

lipase activity in bile were determined by biochemical methods. Phosphatidylcholine (PC) and lysophosphatidylcholine (LPC) species were quantified using nano-electrospray ionization tandem mass spectrometry.

**RESULTS:** Bile from all the examined patient groups showed a remarkably similar PC and LPC species composition, with only minor statistical differences. Total biliary PC concentrations were highest in controls ( $8030 \pm 1843 \mu\text{mol/L}$ ) and lowest in patients with CCC ( $1969 \pm 981 \mu\text{mol/L}$ ) ( $P = 0.005$ , controls *vs* SSC and CCC, respectively,  $P < 0.05$ ). LPC contents in bile were overall low ( $4.2\% \pm 1.8\%$ ). Biliary LPC/PC ratios and ratios of biliary PC to bilirubin, PC to cholesterol, PC to protein, and PC to bile acids showed no intergroup differences.

**CONCLUSION:** PC and LPC profiles being similar in patients with or without sclerosing cholangitis, these phospholipids are likely not of major pathogenetic importance in this disease group.

**Key words:** Primary sclerosing cholangitis; Secondary sclerosing cholangitis; Cholangiocellular carcinoma; Phosphatidylcholine; Lysophosphatidylcholine; Bile; Mass spectrometry

**Core tip:** Based on the idea that unfavorable alterations of biliary phospholipids might play a role in the pathogenesis of sclerosing cholangitis, phosphatidylcholine (PC) and lysophosphatidylcholine (LPC) species profiles were analyzed in endoscopically-acquired intrahepatic bile using nano-electrospray ionization tandem mass spectrometry. The examination of specimens from 14 patients with primary sclerosing cholangitis, 10 patients with secondary sclerosing cholangitis, 11 patients with choledocholithiasis/no biliary disease and 6 patients with cholangiocellular carcinoma revealed strikingly

similar PC and LPC species patterns, implicating at the most a minor role of biliary phospholipid changes in sclerosing cholangitis.

Biliary phosphatidylcholine and lysophosphatidylcholine profiles in sclerosing cholangitis. *World J Gastroenterol* 2013; 19(33): 5454-5463 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i33/5454.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i33.5454>

## INTRODUCTION

Primary sclerosing cholangitis (PSC) is a chronic cholestatic liver disease with fibrobliterative sclerosis of intra- and/or extrahepatic bile ducts, eventually leading to biliary cirrhosis<sup>[1,2]</sup>. The etiopathogenesis of the disease is not yet completely understood<sup>[3]</sup>.

Secondary sclerosing cholangitis (SSC) also belongs to the group of chronic sclerosing cholangitis. SSC is thought to develop as a consequence of known injuries or secondary to pathological processes of the biliary tree<sup>[4]</sup>. The mechanisms leading to cholangiopathy in critically ill patients are mostly unknown; however, the available clinical data indicate that ischemic injury to the intrahepatic biliary tree may be one of the earliest events responsible for the development of this severe form of sclerosing cholangitis. Therapeutic options for most forms of SSC are limited, and patients with SSC who do not undergo transplantation have significantly reduced survival compared to those with PSC. Sclerosing cholangitis in critically ill patients, in particular, is associated with rapid disease progression and poor outcome<sup>[4,5]</sup>. PSC and SSC can be treated successfully only by liver transplantation.

Genetic or chemical modifications of bile composition have been found to induce sclerosing cholangitis and liver fibrosis in a number of animal models, which gave rise to the “toxic bile” concept<sup>[6]</sup>. Bile contains various biochemical components whose alterations could lead to an imbalance between its protective and harmful effects, thus leading to chronic inflammation and, finally, to the destruction of small and large bile ducts. These alterations could be primary or secondary to inflammatory processes of different origins.

Phospholipids are an essential ingredient of bile. They represent one of its major lipid components besides cholesterol and bile salts. Among bile phospholipids, there are mostly mixed diacylphosphatidylcholines. They have a hydrophilic, zwitter-ionic phosphocholine head group and two hydrophobic fatty acid side chains<sup>[7]</sup>. Phospholipids are considered to potently emulsify hydrophobic molecules, such as certain bile acids, and thereby attenuate their toxicity<sup>[8]</sup>. If it can be shown that they are unfavorably altered in concentration or species composition, then

the “toxic bile” concept could be considered relevant in the pathogenesis of sclerosing cholangitis, especially the one of PSC.

To date, no reports have been published on the comparison of the biliary phospholipid composition in PSC patients, SSC patients, and controls. The present study was aimed at determining their potential differences, especially concerning the phosphatidylcholine (PC) species composition in bile, which could help obtain further insight into the pathogenesis of sclerosing cholangitis and might be useful as a diagnostic tool for easier differentiation between biliary diseases of various origins. The hypothesis that alterations in the phospholipid composition of bile are involved in the pathogenesis of sclerosing cholangitis is supported by the fact that mice with targeted disruption of the *Mdr2* (*Abcb4*) gene, which encodes canalicular phospholipid flippase, spontaneously develop cholangitis and typical onion-skin-type periductal fibrosis, which mirrors some of the key features of human PSC<sup>[9,10]</sup>. However, the composition of bile in PSC patients without elevated serum bilirubin has been shown to be normal<sup>[11]</sup>. Furthermore, the role of *MDR3* variants in the pathogenesis of PSC in humans is not yet clear<sup>[12]</sup>. Our group showed a reduced PC/bile acid ratio in bile from a patient suffering from inborn chronic cholestatic liver disease with fibrosis. He had a homozygous missense mutation of *Abcb4* encoding *MDR3*<sup>[13]</sup>. These findings still suggest that changes in biliary lipid composition and total concentrations could play an important role in the pathogenesis of PSC and maybe SSC, which seem to differ in etiological factors and pathogenesis, but have a similar phenotype, although the latter, being recently identified, has been scarcely described. Also to be mentioned in this context are previous publications dealing with potential protective effects of phospholipids, especially glycerophospholipids, in other liver diseases<sup>[14]</sup>. For example, it was shown that alcohol-induced hepatic fibrosis could be alleviated by polyunsaturated lecithin<sup>[14,15]</sup>.

In the light of the above-mentioned data and theories, we focused on a systematic electrospray mass spectrometric analysis of bile phospholipids in two types of sclerosing cholangitis and compared them to the data from specimens of patients with choledocholithiasis or malignant biliary disease. If the bile phospholipid composition was involved in the pathogenesis of sclerosing cholangitis, one would expect differences in phospholipid concentrations and/or species patterns between bile from patients with or without sclerosing cholangitis. The evaluation of the ratios of PC concentrations to bile acid as well as lysophosphatidylcholine (LPC) concentrations are particularly interesting in that respect, since certain bile acids and LPC are thought to have cytotoxic properties<sup>[16]</sup> which might be alleviated by PC.

## MATERIALS AND METHODS

Hepatic bile specimens were collected from the following four groups of patients: controls, PSC patients, SSC

**Table 1** Clinical characteristics of the four included patient groups

	Controls ( <i>n</i> = 11)	PSC ( <i>n</i> = 14)	SSC ( <i>n</i> = 10)	CCC ( <i>n</i> = 6) with PSC ( <i>n</i> = 2)	<i>P</i> value
Gender (M/F)	9/2	10/4	10/0	3/3	
Age at ERC (yr)	52.8 ± 6.6	41.1 ± 2.3	52.1 ± 4.0	64.5 ± 5.2	0.02; PSC <sup>a</sup>
Serum albumin level (g/L)	41.5 ± 1.5 (ND in 3)	39.2 ± 1.9	37.6 ± 3.1 (ND in 5)	34.5 ± 1.4	0.13
Serum AP level (U/L)	221.3 ± 99.9 (ND in 1)	271.5 ± 37.1	1004 ± 304 (ND in 3)	357 ± 62.4	0.003; controls <sup>d</sup>
Serum bilirubin level (mg/dL)	1.6 ± 0.5 (ND in 1)	2.7 ± 0.8	5.3 ± 2.3 (ND in 2)	4.9 ± 1.9	0.39
Sterile bile or scarce bacterial growth/moderate or abundant bacterial growth	6/5	9/5	5/5	4/1 (ND in 1)	
Intake of UDCA (yes/no)	0/11	13/1	6/2 (2 unknown)	3/3	
Dominant bile duct stenosis (yes/no)	0/11	4/10	1/9	6/0	
Cholelithiasis and/or sludge (yes/no)	9/2	0/14	2/8	0/6	
Diagnosis of inflammatory bowel disease (yes/no)	0/11	10/4	0/10	2/4	

M: Male; F: Female; PSC: Primary sclerosing cholangitis; AP: Alkaline phosphatase; ERC: Endoscopic retrograde cholangiography; UDCA: Ursodeoxycholic acid; ND: Not done. <sup>a</sup>*P* < 0.05 vs Cholangiocellular carcinoma (CCC); <sup>d</sup>*P* < 0.01 vs Secondary sclerosing cholangitis (SSC).

patients, and patients with cholangiocellular carcinoma (CCC). Clinical data originated from a data base predominantly set up for the collection of samples from PSC patients. As the sample collection is also used for other studies, only specimens with sufficient amounts of material left could be used. A maximum number of 14 patients per group was predefined. Fourteen PSC patients were randomly chosen from the sample bank by a technical assistant who was not involved in phospholipid measurements. For the other groups, less than 14 samples in every group were available. Clinical data were extracted from the database, which had been set up prospectively for a wide array of research projects. The clinical characteristics of the included patient groups are presented separately in Table 1. All procedures in this study were compliant with the Declaration of Helsinki and approved by the local ethics committee. All patients had provided written informed consent before their specimens and data were included in the database. Bile samples were collected during endoscopic retrograde cholangiography (ERC) at the Department of Endoscopy at the University Hospital Heidelberg between 2007 and 2012. For all groups, the serum albumin level, as a parameter of liver synthesis function, was within the normal range.

### Control group

The control group (11 patients in all; two women and nine men; aged 24 to 81 years) comprised nine patients with cholelithiasis without signs of relevant cholangitis when ERC was performed. The remaining two patients had undergone ERC for unexplained elevation of serum alkaline phosphatase (AP) levels; one of them had recurrent right side abdominal pain. ERC findings in both of these patients were completely normal.

### Patients with PSC

PSC was diagnosed on the basis of typical ERC findings. Of the 14 patients with PSC (four women, ten men; aged

25 to 55 years), four had no inflammatory bowel disease, nine had ulcerative colitis, and one suffered from Crohn's disease. The mean disease duration of PSC at sample acquisition was 8.9 ± 1.4 years. Four of the patients underwent endoscopic dilation for dominant stenosis of a major bile duct during the ERC. All the PSC patients received ursodeoxycholic acid (UDCA) at doses between 1000 and 1500 mg per day, except one patient who had to discontinue the drug due to adverse effects. More detailed information is provided in Table 1.

### Patients with SSC

Patients who had cholestatic liver disease with the ERC morphology of SSC without evidence of pre-existing hepatobiliary disease and who had previously required long-term treatment in an intensive care unit were included. Polytrauma and sepsis were the main reasons for long-term intensive care treatment among the patients. Ten patients (all male; aged 35 to 70 years) were included. The mean disease duration since first diagnosis of SSC was less than one year. None of these patients suffered from inflammatory bowel disease. Two of the patients did not take UDCA; six were on UDCA at daily doses between 500 and 1500 mg, and for two patients, the history of medication was unknown. Further clinical data are indicated in Table 1.

### Patients with CCC

All patients in this group were diagnosed with CCC on the basis of morphological and histological findings. They all had relevant stenosis of the common bile duct and had visited the hospital for a change in or the insertion of a bile duct endoprosthesis. Of the eight patients who were initially to be included, two had to be excluded since their bile was colorless and phospholipids were below the limit of detection. This could be explained by massive cholestasis in these two patients. Two of the six patients who were finally included had PSC-related CCC,

**Table 2** Phospholipids used as internal standards to determine phospholipid concentrations in bile

Fatty acid(s)		Molecular structure name	Provider
LPC standards			
482 Da	15:00	1-pentadecanoyl-2-hydroxy-sn-glycero-3-PC	Avanti (Alabaster, AL, United States)
552 Da	20:00	1-arachidoyl-2-hydroxy-sn-glycero-3-PC	Avanti (Alabaster, AL, United States)
PC standards			
622 Da	12:0/12:0	1, 2-didodecanoyl-sn-glycero-3-PC	Sigma (Deisenhofen, Germany)
678 Da	14:0/14:0	1, 2-tetradecanoyl-sn-glycero-3-PC	Sigma (Deisenhofen, Germany)
846 Da	20:0/20:0	1, 2-dieicosanoyl-sn-glycero-3-PC	Sigma (Deisenhofen, Germany)
902 Da	22:0/22:0	1, 2-didocosanoyl-sn-glycero-3-PC	Sigma (Deisenhofen, Germany)

PC: Phosphatidylcholine.

and four had CCC unrelated to PSC. All the patients with PSC-related CCC and one of the other patients were on UDCA at daily doses between 750 and 1500 mg (Table 1).

### Collection and storage of bile specimens

For endoscopic collection of bile specimens, the papilla of Vater was selectively cannulated. Bile samples were obtained by suction and, if possible, before injection of contrast medium and any therapeutic procedure. In patients with whom bile collection was not possible before injection of contrast medium into the bile duct, a volume equivalent to that of the contrast medium was first extracted by suction into a syringe to be discarded before the syringe for the actual bile specimen was attached. This was performed in order to minimize effects of dilution. All specimens were snap-frozen in liquid nitrogen and stored at  $-80^{\circ}\text{C}$  before further use. Bile specimens from 41 patients were included in this study (see above).

### Determination of levels of pancreas lipase activity, protein, cholesterol, bile acids, and bilirubin in bile

As an indicator of the amount of refluxing pancreatic juice in the bile specimens, pancreas lipase activity was determined photometrically by using the chromogenic lipase substrate DGGMR (1,2-O-dilauryl-rac-glycero-glutaric acid ester)<sup>[17]</sup>. Total protein concentrations in the bile were determined using the 2-D-Quant kit (Amersham Biosciences, Amersham, United Kingdom). Bile cholesterol levels were determined by the CHOD-PAP enzymatic photometric test ("Cholesterol FS\*", Diagnostic Systems International GmbH, Holzheim, Germany)<sup>[18]</sup>. Total bile salt concentrations were measured spectrophotometrically by using  $3\alpha$ -hydroxysteroid dehydrogenase<sup>[19]</sup>. Biliary bilirubin concentration was determined using the Jendrassik-Grof method<sup>[20]</sup>.

### Bacterial cultures

Aliquots of fresh bile specimens were sent to our Department of Microbiology directly after acquisition for

aerobic and anaerobic bacterial cultures. Bacterial growth was semiquantitatively described as non-existent, scarce, moderate, or abundant.

### Lipid extraction from bile specimens

Extraction of lipids from bile specimens was performed according to Folch<sup>[21]</sup>. One-microliter aliquots of bile were diluted in 75  $\mu\text{L}$  distilled water each. Four non-physiological PC and two non-physiological LPC standards were added before extraction. Both these phospholipid classes constitute more than 95% of biliary phospholipids<sup>[7]</sup>, and no additional phospholipid standards were used. Crude lipid extracts were completely dried. For mass spectrometry, each sample was redissolved in 50  $\mu\text{L}$  of methanol/chloroform 2:1 (v/v). Table 2 provides detailed information about the phospholipid standards used. It includes molecular weights (Da), numbers of carbon atoms and double bonds of fatty acids, names of the molecules as well as their structures and the companies where they were purchased.

### Nano-electrospray ionization tandem mass spectrometry

Mass spectrometry (MS) analyses were performed using a triple quadrupole instrument (Finnegan MAT, San Jose, CA, model TSQ 7000) with a nano-electrospray source operating at a typical flow rate of 20-50 nL/min. The electrospray capillary was positioned at a distance of 0.5-1 mm from the orifice of the heated transfer capillary ( $140^{\circ}\text{C}$ ). Argon was used as the collision gas (2 mTorr). Lipid extracts were infused into the heated capillary. The mass spectrometric resolution was set to the approximate nominal mass resolution for the scan range of an m/z of 400-1000. All specimens were analyzed in the precursor ion-scan mode for an m/z of 184. At least 100 consecutive scans of four seconds each were averaged for every measurement. After comparison of all spectra, the most abundant physiological PC and LPC species were identified. For the quantification of physiological phospholipid species, regression curves were determined from the non-physiological standards as per the method described by Brügger *et al.*<sup>[22]</sup>. A typical spectrum from a PSC patient is presented in Figure 1. Total amounts of PC and LPC were calculated by addition of all single species.

### Statistical analysis

The results have been expressed in terms of mean and standard error of the mean (SE) values. Due to small sample sizes, no assumptions of normality were made, and non-parametric tests (Kruskal-Wallis test and Dunn's post-test) were used to compare disease groups. *P* values of  $< 0.05$  were considered to be statistically significant. All statistical analyses were performed using GraphPad Prism 3.0 (GraphPad Inc., CA).

## RESULTS

### Clinical data

Statistical differences in the clinical data of the four pa-

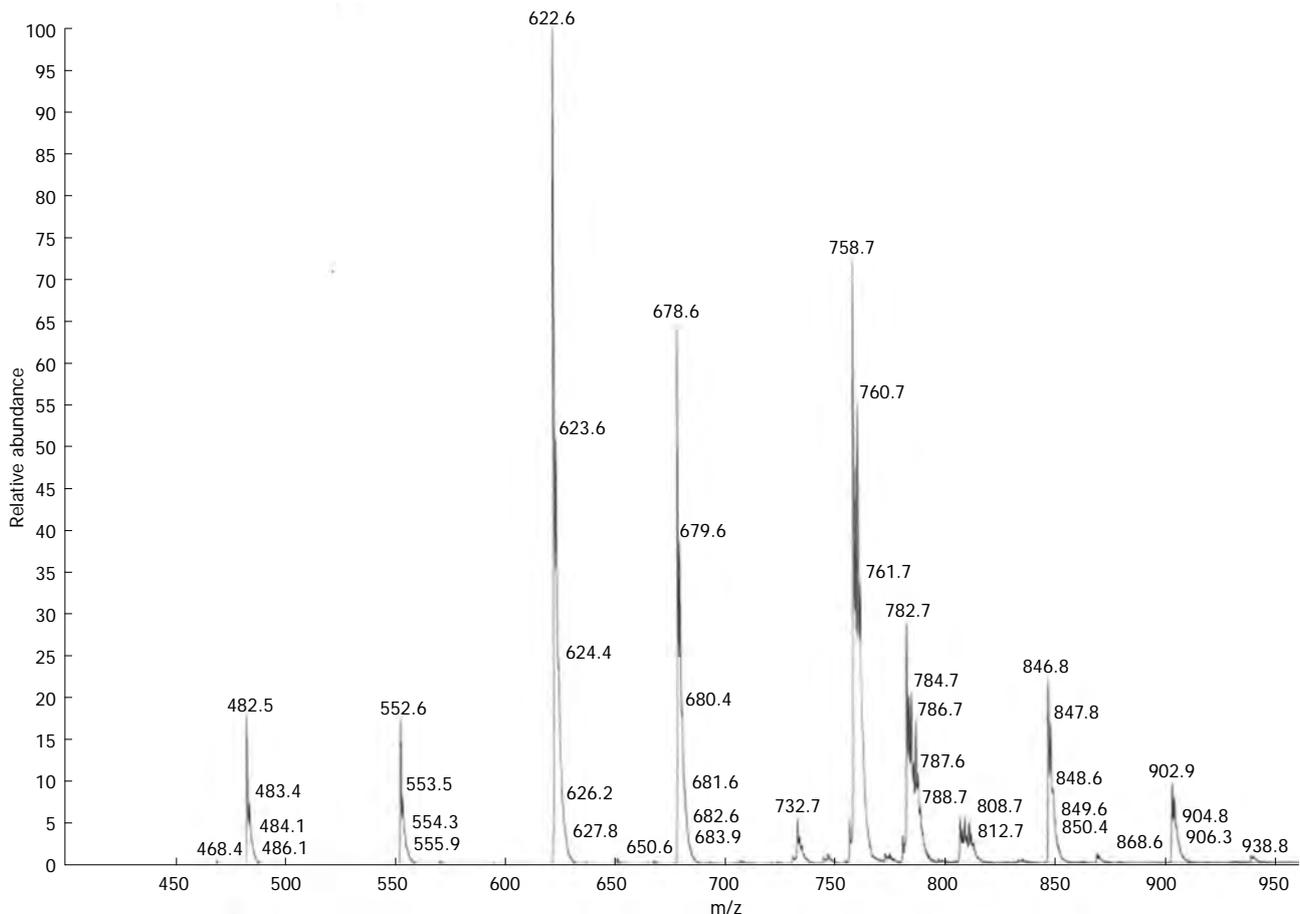

Figure 1 Electrospray mass spectrum of the total lipid extract from human bile of a patient with primary sclerosing cholangitis. For explanation of standards view Table 2.

tient groups were noted for serum AP levels at the time of ERC and for patient age (Table 1). Serum bilirubin concentrations, however, did not differ significantly between the groups.

### Biliary phospholipid analysis

The amounts of total phosphatidylcholine (PC) in relation to hepatic bile volume were compared between the four groups of patients (Table 3). They ranged between 47 and 22570  $\mu\text{mol/L}$  (median 2977  $\mu\text{mol/L}$ ). The highest biliary PC concentrations were noted in the controls (8030  $\pm$  1843  $\mu\text{mol/L}$ ), the lowest ones in SSC patients (2501  $\pm$  790  $\mu\text{mol/L}$ ) and CCC patients (1969  $\pm$  981  $\mu\text{mol/L}$ ) (overall  $P = 0.05$ , controls *vs* CCC and controls *vs* SSC,  $P < 0.05$ , respectively). In PSC patients, we found intermediate concentrations (6205  $\pm$  1465  $\mu\text{mol/L}$ ).

### Biliary PC species profiles

PC species in significant amounts were identified at molecular weights of 732, 734, 756, 758, 760, 782, 784, 786, 788, 804, 806, 808, and 810 Da. This corresponds to molecules with the following ratios of fatty acid (FA) carbon numbers to numbers of double bonds: 32:1, 32:0, 34:3, 34:2, 34:1, 36:4, 36:3, 36:2, 36:1, 38:7, 38:6, 38:5, and 38:4. Bile samples from the four patient groups showed a remarkably similar PC molecular species composi-

tion. Together constituting more than 50% of total PC, PC 34:1 and 34:2 represented in all cases the two most abundant PC species. DPPC (PC 34:0, 16:0-16:0) which is the most abundant PC species in pulmonary surfactant, represented only a very small percentage of biliary PC, ranging between 1.1% in controls and 3.6% in SSC patients (Table 4). Only minor intergroup differences were noted in biliary PC species patterns. These can be viewed in detail in Table 4 (for PC and LPC species, numbers of carbon atoms and double bonds of fatty acid side chains as well as molecular weights are indicated). Not even minor differences were found between PC species profiles in patients with PSC *vs* patients with SSC.

### LPC concentrations and LPC/PC ratios

Total LPC contents per bile volume ranged from 12.2  $\pm$  5.4  $\mu\text{mol/L}$  in CCC patients to 256  $\pm$  90  $\mu\text{mol/L}$  in the control group (overall,  $P = 0.02$ ; Dunn's post-test: no differences between single groups).

LPC species found in human hepatic bile had molecular weights of 496, 520, 522, and 524 Da, corresponding to 16:0, 18:3, 18:2, and 18:1, respectively. The distribution of different LPC species in the groups is shown in Table 4. Bile specimens obtained from patients with SSC contained relatively more LPC 496 (16:0) than those from patients with PSC and controls and relatively less LPC

520 (18:3) than those from patients with CCC and from controls.

Since the cytotoxic effect of LPC on the bile duct mucosa is likely to be alleviated by the presence of PC<sup>[23]</sup>, it was interesting to examine the LPC/PC ratios in bile. Except for two bile specimens obtained from PSC patients and one bile specimen from a SSC patient (LPC/PC ratios: 0.25, 0.64 and 10.5), the biliary LPC/PC ratios were remarkably low in the other patients, LPC accounting for 4.2% ± 1.8% of total PC (mean ± SE). LPC/PC ratios were not different between the four groups.

In order to determine the extent of potential reflux of pancreatic juice in the bile specimens, pancreatic lipase activity was quantified in the samples. In 31 of 41 specimens examined, pancreas lipase activity could be de-

termined. Its average in these specimens was 266 ± 95.3 U/L. Interestingly, no significant correlation was found between pancreas lipase activity in bile and LPC/PC ratios (*P* = 0.66, *r* = 0.08), suggesting that bile LPC in the examined patients originated more likely from a different source.

#### Ratios of phospholipids to other bile components

As shown in Table 3, PC or LPC/bilirubin, PC or LPC/protein, PC or LPC/cholesterol as well as PC or LPC/total bile salt ratios in hepatic bile did not differ between controls and patients with PSC, SSC, or CCC.

#### Bacterial cultures and biliary phospholipids

At certain concentrations, bacteria in hepatic bile are

known to lead to the degradation of protective biliary PC and subsequent increase in the amounts of potentially cytotoxic LPC<sup>[24]</sup>. Thereby, they might cause chronic irritation of the bile duct mucosa and subsequently fibrosis. The 41 patients included in this study were divided into two groups according to the amount of bacterial growth in their bile. Group 1 comprised patients with no or only scarce amounts of bacteria and/or *Candida* organisms, while group 2 comprised patients with at least moderate amounts of bacteria in their bile specimens. According to this classification, 24 of 40 patients (no microbiological results available in one of the CCC patients) belonged to group 1. Among the bacterial species identified were mainly *Enterococcus faecalis* and *Enterococcus faecium* as well as *Escherichia coli*. Other species identified were *Enterobacter cloacae*, *Klebsiella pneumoniae*, *Pseudomonas aeruginosa*, *Stenotrophomonas maltophilia*, and *Raoultella planticola*. Interestingly, biliary LPC/PC ratios did not differ significantly between the two groups.

## DISCUSSION

The main hypothesis of the present study was that, according to the “toxic bile” concept, alterations in biliary phospholipid concentrations and percentual distribution of species might play a role in the process of chronic inflammation and subsequent fibrosis in sclerosing cholangitis, such as PSC and SSC. Based on this hypothesis, we expected to find a biliary phospholipid imbalance with a lack of presumably cytoprotective PC and an abundance of presumably cytotoxic LPC in bile specimens from patients with sclerosing cholangitis.

To our knowledge, no data on MS of PC and LPC species patterns in human hepatic bile from patients with PSC and SSC have been published thus far. Most previous studies on biliary phospholipids have been performed using samples of gall bladder bile acquired during surgery in patients with gall stones<sup>[25-27]</sup>.

Compared to conventional methods of phospholipid analysis (*e.g.*, thin layer chromatography, derivatization, HPLC, and gas chromatography), electrospray-ionization (ESI)-tandem mass spectrometry (MS/MS) has several advantages since it has a high basic sensitivity for the detection of phospholipids (analyte concentrations between 0.1 and 50 pmol/ $\mu$ L), and since the specificity of MS/MS scan modes enables direct analysis of crude lipid extracts<sup>[28]</sup>. Thus, as little as 1  $\mu$ L of bile from every patient was sufficient for phospholipid analyses in the present study.

Further, for the analysis of bile in respect to potential secondary alterations of bile ducts, intrahepatic bile is more reliable than gall bladder bile. However, obtaining bile specimens during ERC has some drawbacks. Mostly, it is not justifiable from an ethical position to obtain specimens from completely healthy controls *via* ERC, since the procedure can cause complications, such as post-ERC pancreatitis, which is - of course - no different for patients in surgery. This is why we selected mainly

choledocholithiasis patients without signs of chronic inflammation as the controls in this study. However, lithogenic bile is known to show an imbalance between cholesterol, bile salts, and phospholipids. The primary pathophysiological defect in cholesterol gallstone disease is hypersecretion of hepatic cholesterol into bile with less frequent hyposecretion of bile salts and/or phospholipids<sup>[7]</sup>. For this reason, all the above-mentioned bile compounds were assessed in the present study.

The amount of total PC in relation to bile volume differed significantly between the controls and patients with SSC or CCC, with the latter two groups displaying lower concentrations (overall  $P = 0.005$ , controls *vs* SSC patients or CCC patients  $P < 0.05$ , respectively). The interpretation of this result is challenging since it cannot be ruled out that a few of the bile samples might have been diluted by contrast medium. However, the cases in which bile cannot be aspirated through the ERC-catheter before intervention are usually rare according to our experience, and we took care to first aspirate the contrast medium in such a case, and to discard it before obtaining the bile sample in a second syringe. Unfortunately, it was not indicated in the databank in which cases specimens were obtained without prior injection of contrast medium. Reduced biliary PC concentrations might be caused by lack or malfunction of biliary phospholipid transporters. Another reason for which the evaluation of total PC and LPC per bile volume might be hampered is that a high degree of cholestasis (with high serum levels of AP and bilirubin) can go along with low concentrations of bilirubin and the other analytes in bile. Bilirubin levels in serum from patients with SSC or CCC exceeded those of the other groups, albeit not significantly. AP levels in serum from patients with SSC were significantly higher than those in serum from controls. This is why we feel that - given the small sample sizes in the present study - the fact that we found lower levels of PC and LPC per bile volume should not be overrated. Yet we think that if our results can be confirmed in further studies with larger sample numbers and matched samples, a diagnostic tool might thereby be established. For such a future study, it would be helpful to take a note of the mode of bile acquisition in every included patient.

Importantly, the difference observed between the groups concerning total biliary PC per bile volume could not be reproduced when the groups were compared for the biliary PC/bile salt ratio, the reason for which might be dilution, as indicated above. The biliary PC/bile salt ratio was assumed to be of special pathophysiological importance since it may be indicative of a potential imbalance between factors protecting cholangiocytes and those harming cholangiocytes. Thus, before starting the study, we had hypothesized that PC-to-bile salt ratios in bile would be reduced in patients with sclerosing cholangitis *vs* controls. Our hypothesis was also due to recently published data showing that nonanastomotic strictures after liver transplantation were present more often in patients with low biliary phospholipids/bile salt ratios

than in patients with high biliary phospholipids/bile salt ratios<sup>[29]</sup>. When planning another study on this subject, it would be important to include more patients, and to not only focus on total bile salts as a reference parameter, but to also quantitate different bile salts with variable effects on cholangiocytes. Such an approach may also help to attenuate the intake of UDCA by many patients as a confounder.

Further, no major differences were noted in the biliary LPC/PC ratios and, most interestingly, in the LPC and PC species patterns in bile between the groups. As the distribution of biliary PC and LPC species was not relevantly changed in sclerosing cholangitis, we suggest that it plays no major role in the pathogenesis of the disease; based on our study, PC and LPC species patterns cannot be used as diagnostic tools to differentiate between PSC and SSC.

What is the role of LPC in bile? Remarkably, this study confirms that in normal bile, LPC is just a minor constituent. Analysis of the data for all 41 patients of the study together showed that total LPC accounted for less than 5% of total PC, after the exclusion of three patients with exceedingly high ratios, who were treated as outliers. In line with previous studies by other authors, our results revealed only traces of LPC in hepatic bile from “controls”<sup>[30]</sup>. LPC can be derived from PC by hydrolysis within the bile ducts. Nakano *et al.*<sup>[24]</sup> found that most bacterial strains isolated from bile possess both phospholipase A1 and A2 activity. Shimada *et al.*<sup>[27]</sup> showed in their study that patients with an anomalous pancreaticobiliary ductal junction have considerable amounts of LPC in their intrahepatic bile, which could not be correlated with concentrations of bacteria in bile, but with phospholipase A2 activity from refluxing pancreatic juice.

Although the four groups did not differ with respect to the biliary LPC/PC ratios in the present study, a few bile specimens displayed high biliary LPC/PC ratios. Retrospective analysis of these patients showed high lipase concentrations and/or abundant bacterial growth in some, but not in all, cases; some patients also showed abundant growth of bacteria in bile and/or high lipase concentrations with very low LPC/PC ratios. Again, the small numbers of subgroups might disguise potentially important differences here. Furthermore, most bile specimens with abundant bacterial growth contained predominantly gram-positive cocci. The latter have been previously shown to produce just minor amounts of phospholipases<sup>[24]</sup>. Considering all the data, it is still reasonable to suggest that recurrent bacterial cholangitis caused by certain bacterial strains in patients with a prior diagnosis of sclerosing cholangitis might lead to the aggravation of disease activity *via* increased LPC/PC ratios in bile, even though this could not be proven in the present study.

Data have recently been published on the lack of PC in the bile from patients with CCC<sup>[31]</sup>. Although total biliary PC contents per volume in the specimens from CCC patients in the present study were the lowest compared to the other groups, ratios of PC contents to any other

biliary compound did not differ between groups. Since the number of CCC patients was below ten in both the above-mentioned study and ours, further studies with larger sample numbers are necessary to determine whether patients with CCC indeed have lower biliary PC contents. This would be of major importance as there is still no diagnostic tool available for early diagnosis of CCC, especially in patients with known PSC.

PC and LPC species patterns in human bile were quite similar to those found in intestinal mucus in a previous study<sup>[32]</sup>. Unlike the case with pulmonary surfactant, biliary PC molecules with fatty acids containing at least one double bond clearly overweigh those with saturated fatty acid side chains. The fact that PC and LPC species patterns were remarkably similar between the groups supports the idea that biliary PC and LPC form a highly preserved system that cannot easily be changed by external influences. Previous reports indicating that bile of various animal species displayed a very similar phospholipid molecular species composition are also supportive of this notion<sup>[33]</sup>.

In conclusion, we showed that electrospray MS/MS is a very convenient method for bile phospholipid analysis in very low volume samples. Surprisingly, there were no major differences concerning the biliary PC and LPC species profiles between patients with PSC, SSC, CCC and controls. Yet our data can serve as an incentive and reference for further studies using the same methods for larger groups of patients or other disease conditions. Also, the lower total PC and LPC concentrations found in bile from patients with SSC and CCC compared to controls might be of diagnostic importance, if the results were certified in further studies with larger sample numbers and after exclusion of dilutional effects.

## COMMENTS

### Background

Primary sclerosing cholangitis (PSC) and secondary sclerosing cholangitis (SSC) are progressive diseases where chronic inflammation leads to scarring and strictures of the bile ducts. The process eventually results in liver cirrhosis and makes liver transplantation necessary. The two diseases have very similar features, but their pathogeneses seem to be different even though they are not yet fully known. In SSC, the afflictions of the bile ducts originate from a trigger in the patient's history, like *e.g.*, hypoxemia. SSC also progresses more rapidly than PSC. Biliary phospholipid transporter defects have been shown to lead to bile duct fibrosis in mice. Phosphatidylcholine (PC) is thought to have protective properties in bile. These facts led to the hypothesis that a deficiency of PC or an imbalance of its single species, or a relative abundance of potentially toxic lysophosphatidylcholine (LPC) could play a role in the pathogenesis of SSC and more significantly PSC. Such a finding could lead to the development of novel therapeutic options.

### Research frontiers

Due to its unfavorable disease course, lack of thorough understanding of the underlying pathophysiology, and absence of effective medical therapy, sclerosing cholangitis has become a subject of increasing scientific interest. In contrast to PSC, SSC has not been described at all until recently, so research in this field is breaking new ground. Research has been published on the relation between changes in biliary phospholipids and bile duct strictures after liver transplantation, but none on biliary PC and LPC species in PSC as well as SSC. The “toxic bile concept” - the theory which states that imbalances in the composition of bile could lead to chronic bile duct inflammation and destruction - remains relevant,

as a therapy would likely arise from the identification and regulation of these potential imbalances. Such a therapy would be effective regardless of whether these imbalances were primary or secondary factors of disease activity.

### Innovations and breakthroughs

Even though the data presented here have no direct implications for diagnosis or therapy, they can serve as motivation for future studies in the field using the very convenient and resource-economic method of nano-electrospray ionization mass spectrometry for bile phospholipid analysis. In this study, data on PC and LPC profiles in intrahepatic human bile in SSC are published for the first time.

### Applications

The method of nano-electrospray ionization mass spectrometry of bile phospholipids can be used for the examination of larger patient groups. Biliary phospholipid composition in cases of cholangiocellular carcinoma and after liver transplantation might be of special interest. As little as 1  $\mu$ L of bile is needed for analysis of all PC and LPC species.

### Terminology

PC is not only an essential component of biological membranes, but also of a wide array of functionally important body fluids like pulmonary surfactant, gastric and intestinal mucus, synovial fluid, peritoneal fluid and bile. It is a glycerophospholipid featuring a choline head group and two fatty acid side chains. The special biophysical qualities of these zwitter-ionic molecules depend on the composition of these fatty acid side chains. For example, PC in pulmonary surfactant has mostly saturated fatty acids, while in intestinal mucus - having to meet completely different functional challenges - PC almost always contains at least one unsaturated fatty acid side chain. This is why the exact composition of PC species of a fluid like bile is so important. LPC is produced from PC by partial hydrolysis, resulting in removal of one fatty acid side chain.

### Peer review

This manuscript is quite interesting, with a good methodology. There are not many patients, but due to ERC and rare etiologies, these could be enough. The authors took into account their limitations and made a clear discussion. This small study about the pathophysiology of sclerosing cholangitis is well designed and presented.

### Abstract

**AIM:** To investigate the effect of plasmapheresis *via* the portal vein for “small-for-size” syndrome (SFSS) aided by extracorporeal continuous portal diversion (ECPD).

**METHODS:** Extensive or total hepatectomy in the pig is usually adopted as a postoperative liver failure (PLF) or SFSS model. In this study, animals which underwent 85%-90% hepatectomy were randomized into either the Systemic group ( $n = 7$ ) or the Portal group ( $n = 7$ ). In the Systemic group, all pigs received temporal plasmapheresis (PP) *via* the extracorporeal catheter circuit (systemic to systemic circulation) from 24 to 30 h post-hepatectomy (PH); in the Portal group, all pigs received ECPD to divert partial portal vein flow (PVF) to the systemic circulation after hepatectomy, then converted to temporal PP from 24 to 30 h PH, and subsequently converted to ECPD again until 48 h PH. In the Portal group, the PVF was preserved at 3.0-3.3 times that of the baseline value, similar to that following 70% hepatectomy, which was regarded as the optimal PVF to the

hypertrophic liver remnant. At 48 h PH, all pigs were re-opened and the portal vein pressure (PVP), PVF, and HAF (hepatic artery flow) were measured, and then diversion of the portal venous flow was terminated. After 1 h the PVP, PVF, and HAF were re-measured. The portal hemodynamic changes, liver injury, liver regeneration and bacterial/lipopolysaccharide (LPS) translocation were evaluated in the two groups.

**RESULTS:** The PVP in the Portal group was significantly lower than that in the Systemic group during the time period from 2 to 49 h PH ( $P < 0.05$ ). Serum alanine aminotransferase (ALT), total bilirubin (TB) and ammonia were significantly reduced in the Portal group compared with the Systemic group from 24 to 48 h PH ( $P < 0.05$ ). The Portal group may have attenuated sinusoidal endothelial injury and decreased the level of HA compared with the Systemic group. In the Systemic group, there was significant sinusoidal dilation, hydropic changes in hepatocytes and hemorrhage into the hepatic parenchyma, and the sinusoidal endothelial lining was partially destroyed and detached into the sinusoidal space. CD<sub>31</sub> immunostaining revealed significant destruction of the endothelial lining. In the Portal group, there was no intraparenchymal hemorrhage and the sinusoidal endothelial cells and hepatocytes were well preserved. CD<sub>31</sub> immunostaining was mild which indicated less destruction of the endothelial lining. HA was significantly decreased in the Portal group compared with the Systemic group from 2 to 48 h PH. The rate of liver remnant regeneration was elevated, while apoptosis was attenuated in the Portal group compared with the Systemic group. Thymidine kinase activity was much higher in the Portal group than in the Systemic group at 48 h PH. The PCNA index was significantly increased and the apoptotic index was significantly decreased in the Portal group compared with the Systemic group. Bacterial translocation and endotoxin, as well as the inflammatory response, were significantly attenuated in the Portal group compared with the Systemic group. LPS, tumor necrosis factor- $\alpha$  and interleukin-6 levels were all significantly decreased in the Portal

group compared with the Systemic group from 24 to 48 h PH, while bacterial DNA level was significantly decreased from 2 to 48 h PH.

**CONCLUSION:** PP plus ECPD *via* the portal vein can attenuate toxic load and hyperperfusion injury, and should be undertaken instead of PP *via* the systemic circulation in SFSS or PLF.

**Key words:** Small-for-size syndrome; Postoperative liver failure; Extracorporeal portal diversion; Plasmapheresis; Hepatectomy

**Core tip:** Plasmapheresis (PP) and other artificial liver support (ALS) modalities have been used to treat postoperative liver failure (PLF) and “small-for-size” syndrome (SFSS). However, these modalities did not result in a significant improvement in survival. It is thought that these modalities cannot relieve portal hypertension, thus are inefficacious. This study demonstrated that ECPD plus temporal PP *via* the portal vein can not only dynamically turn the portal flow to the systematic circulation and attenuate portal overflow injury, but also reduces toxic load. This technique should be undertaken instead of PP or ALS *via* the systemic circulation in SFSS or PLF, and shows potential for clinical application.

Hou P, Chen C, Tu YL, Zhu ZM, Tan JW. Extracorporeal continuous portal diversion plus temporal plasmapheresis for “small-for-size” syndrome. *World J Gastroenterol* 2013; 19(33): 5464-5472 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i33/5464.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i33.5464>

## INTRODUCTION

Plasmapheresis (PP) and other plasma purification modalities have been used in the past to treat postoperative liver failure (PLF) and “small-for-size” syndrome (SFSS) following extensive liver resection and living donor liver transplantation (LDLT)<sup>[1-4]</sup>. However, none of these modalities has resulted in a significant improvement in survival. Currently, it is deemed that PP and other modalities *via* systemic circulation access adopted in clinical practice can decrease toxin load and improve serum biochemistry, but do not relieve portal hypertension or hyperperfusion, which results in significant harm to sinusoidal endothelial cells, liver function and intestinal barrier function and is regarded as the determining pathogenesis of PLF and SFSS following subtotal or critical hepatectomy<sup>[5-8]</sup>. This study aims to investigate the effects of temporal PP *via* portal vein access with the aid of extracorporeal continuous portal diversion (ECPD) in SFSS and PLF compared with temporal PP *via* systemic circulation access in a porcine model.

## MATERIALS AND METHODS

### Animal model of PLF and SFSS

Fourteen male Bama miniature pigs (15-20 kg) were obtained from the Pig and Poultry Production Institute (Guangxi Autonomous Region, China). The pigs were raised from a closed herd and kept under strict quarantine. All experiments were conducted according to the Guide for the Care and Use of Laboratory Animals prepared by the National Academy of Sciences and published by the National Institutes of Health (NIH). All animals in this study were treated humanely in accordance with institutional and national guidelines for the ethical treatment of animals.

All 14 animals, were anesthetized by initial sedation with a deep intramuscular injection of ketamine (15-20 mg/kg) and chlorpromazine (6-8 mg/kg) 15 min after the administration of atropine (0.01 mg/kg), then underwent 85%-90% hepatectomy (left tri-lobe and partial right posterior lobe resection) with less than 60 mL blood loss and no hepatic pedicle occlusion, according to a previously described protocol<sup>[6,9]</sup>. First, ultrasonic flow probes were connected to a flow meter (Transonic Systems INC. TS420, NY, United States) to measure hepatic artery flow (HAF) and portal vein flow (PVF). Second, two 11.5-Fr dual-lumen catheters (Hanahao, Tyco Healthcare, Tianjin, China) were introduced into the upper vena cava through the internal jugular vein and the portal vein before hepatectomy.

### Study protocol

Extensive or total hepatectomy in the pig is usually adopted as a model of acute liver failure<sup>[10]</sup>. All animals which underwent 85%-90% hepatectomy were randomized into either the Systemic group ( $n = 7$ ) or the Portal group ( $n = 7$ ). In the Systemic group, all pigs received temporal PP *via* the extracorporeal catheter circuit (systemic to systemic circulation) from 24 to 30 h post-hepatectomy (PH); in the Portal group, all pigs received ECPD to divert partial PVF to the systemic circulation after hepatectomy, then converted to temporal PP from 24 to 30 h PH, and subsequently converted to ECPD again until 48 h PH. In the Portal group, the PVF was preserved at 3.0-3.3 times that of the baseline value, similar to that following 70% hepatectomy, which was regarded as the optimal PVF to the hypertrophic liver remnant<sup>[5]</sup>. At 48 h PH, all pigs were re-opened and the portal vein pressure (PVP), PVF, and HAF were measured, then diversion of the portal venous flow was terminated. After 1 h, the PVP, PVF, and HAF were re-measured. The portal hemodynamic changes, liver injury, liver regeneration and bacterial/lipopolysaccharide (LPS) translocation were evaluated in the two groups.

### Postoperative management

At the end of surgery, one dose of 375 mg penicillin/streptomycin was given intramuscularly to all pigs. This dose was repeated daily every morning until the pigs were euthanized. Each pig was allowed access to food and water ad libitum in the postoperative phase, and they

were monitored postoperatively until euthanized at 49 h PH. The pigs’ systemic arterial pressure was monitored throughout the experiment. Food and water intake and serum glucose levels were evaluated at each postoperative assessment. The liver remnant was removed, weighed, and sampled, and the animals were euthanized.

### Plasma extraction

During each extraction, 200-300 mL plasma was obtained from 6 donor pigs *via* the internal jugular vein catheter and immediately frozen at -20 °C.

### PVF, HAF, and PVP measurement

PVF, HAF, and PVP were measured in both groups at several time points during the procedure: at laparotomy, at 1 h PH, 24 h PH, and 48 h PH. At 48 h PH, the pigs were re-opened, the ECPD was stopped, and the PVP, HAF and PVF were re-measured.

### Blood and serum analysis

Blood samples at pre-operation, 2, 24, 30, and 48 h PH were collected and analyzed. The serum levels of alanine aminotransferase (ALT), total bilirubin (TB) and ammonia were determined in these samples. Increased serum level of hyaluronic acid (HA), which is chiefly eliminated in the hepatic sinusoidal endothelium, indicated sinusoidal endothelial damage<sup>[11,12]</sup>. HA in serum samples was measured by radiometric assay using the Pharmacia HA test (Shanghai Hua Yi Scientific, Inc., Shanghai, China) at pre-operation, 2 h PH, 24 h PH and 48 h PH. Thymidine kinase (TK) activity is the index of hepatic regeneration. Serum TK activity was measured with the Liaison TK assay (DiaSorin, Inc., Stillwater, MN, United States) at pre-operation, 2 h PH, 24 h PH and 48 h PH<sup>[13,14]</sup>.

### Histological analysis

Hepatic tissue was sampled at 1 h PH. Each biopsy sample was divided into 2 specimens. The tissue specimens for electron microscopy were fixed in 2.5% glutaraldehyde and 2% paraformaldehyde in 0.1 mol/L sodium cacodylate buffer (pH 7.3). The other set of samples were preserved in 10% neutral buffered formalin, embedded in paraffin, and stained with hematoxylin and eosin. Then, 4- $\mu$ m-thick sections were immunostained with porcine anti-CD31 antibody (Serotec, Oxford, United Kingdom) to evaluate the microstructural integrity of the hepatic sinusoid<sup>[15,16]</sup>. The animals were sacrificed at 49-50 h PH. The liver was excised after laparotomy, then weighed and processed. The hepatic tissue was sampled again, preserved in 10% neutral-buffered formalin and embedded in paraffin for proliferating cell nuclear antigen (PCNA) immunostaining and *in situ* terminal deoxynucleotidyl transferase dUTP nick end labeling (TUNEL) examination.

The PCNA expression was detected by immunostaining using monoclonal anti-PCNA-antibody (DAKO) (Shanghai Hua Yi Scientific, Inc., Shanghai, China). The rate of increase of liver volume was evaluated by the following equation: The rate of increase = liver volume at sacrifice/

estimated remnant liver volume at operation  $\times$  100%.

Liver samples at 48 h PH were stained for PCNA. PCNA is a stable cell-cycle nuclear protein. The rate of DNA synthesis correlates with proliferation of the cells. Data were expressed as the percentage of hepatocytes stained with PCNA. The percent of PCNA-stained hepatocytes in the total cells per 10 high-power fields was calculated and compared between the two groups.

Three-micrometer-thick sections were stained with hematoxylin and eosin and analyzed by TUNEL using an *in situ* apoptosis-detection kit (Jiamei Biotech Co. Ltd., Shenzhen, China) following the manufacturer’s instructions. The percent of apoptotic cells in the total cells in each high-power field was measured and compared between the Portal group and the Systemic group. Ten consecutive high-power fields were calculated at  $\times$  400 magnification for each pig.

### Measurement of LPS levels

LPS levels in serum samples were measured by the quantitative chromogenic limulus amoebocyte lysate test (Yihua BioScience Ltd. Shanghai, China) according to the manufacturer’s instructions. All samples were tested in duplicate and read at 405 nm<sup>[17]</sup>.

### Bacterial translocation

Total bacterial quantification was accomplished by DNA isolation and real-time polymerase chain reaction (PCR). DNA was isolated from blood using the Fast DNA Spin Kit (Cat. 69506; Qiagen, United States) according to the manufacturer’s instructions. Subsequently, total bacterial quantification was performed with 16S rRNA gene-targeted primers. The sequences of the universal primers were as follows: 5’TTCCGGTTGATCCTGCCGGA3’ forward and 5’GGTTACCTTGTTACGACTT-3’ reverse<sup>[18,19]</sup>. The serially diluted genomic DNA of selected bacterial isolates was used as a real-time PCR positive control for total bacterial quantification. Bacterial counts are expressed as Log<sub>10</sub> cells per gram tissue (cells/g).

### Quantification of serum cytokine levels

Tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), interleukin-1 (IL-1) and IL-6 levels in serum were measured using enzyme-linked immunosorbent assays (ELISAs) following the manufacturer’s instructions (Jingmei Biotech Co. Ltd., Shenzhen, China). All samples were tested in triplicate and read at 490 nm in a thermomax microplate reader.

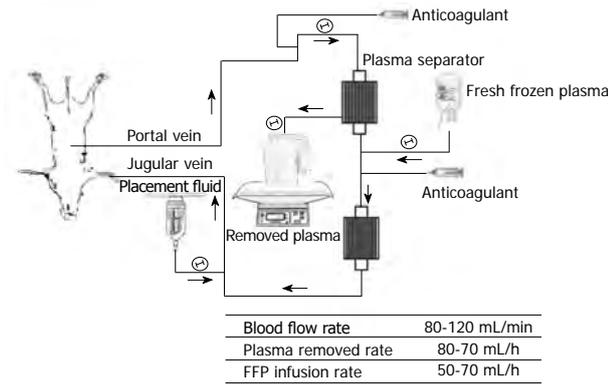

### Statistical analysis

All variables were expressed as mean  $\pm$  SD and compared with the Student’s *t* test using PASW Statistics 18 software (SPSS Inc., Chicago, IL, United States). *P* values of less than 0.05 were considered significant.

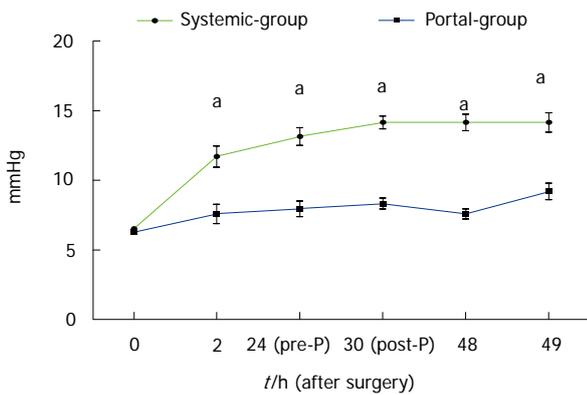

## RESULTS

### Arrangement of the experiment and the hemodynamic studies

Extracorporeal continuous portal diversion (ECPD) plus

**Figure 1** Flow diagram of the extracorporeal circuit indicating the plasmapheresis and conditions of slow plasma exchange. The portal venous blood was aspirated through the portal catheter and into tubing connected to a centrifugal pump immediately post-hepatectomy (PH), and then passed through plasma-separation cartridges with a blood flow of 90-110 mL/min. From 24 h PH these pigs were converted to plasma exchange for 6 h. After that the blood was returned to the pig through a double-lumen catheter inserted into the internal jugular or subclavian vein, and then continued on extracorporeal continuous portal diversion until 48 h PH. FFP: Fresh frozen plasma.

**Figure 2** Portal vein pressure was significantly reduced in the Portal group compared with the Systemic group. Portal vein pressure in the Portal group was significantly lower than that in the Systemic group from 2 to 49 h post-hepatectomy. <sup>a</sup>*P* < 0.05 indicates Portal group vs Systemic group.

temporal plasmapheresis (PP) by the extracorporeal catheter circuit was established (Figure 1). In the Portal group, portal venous blood was aspirated through the portal catheter and into tubing connected to a centrifugal pump immediately PH. The portal venous blood first passed through the centrifugal pump and then through plasma-separation cartridges with a blood flow of 90-110 mL/min to preserve the pigs’ PVF per unit volume range of 3.0-3.3 times that of the baseline. From 24 h PH, these pigs were converted to plasma exchange or PP for 6 h. After plasma exchange, the blood was returned to the pig through a double-lumen catheter inserted into the internal jugular or subclavian vein, and then continued on ECPD until 48 h PH. In the Systemic group, the extracorporeal catheter circuit was established with systemic circulation to systemic circulation at 24 h PH. The systemic circulation blood was aspirated through the systemic circulation catheter and into tubing connected to a centrifugal pump, and the same plasma exchange as the above group was performed for

All flow values are reported in mL/min per 100 g hepatic tissue. The data are expressed as mean ± SD. Estimated total liver weight = Weight of left trilobes × 100/80. ETL: Estimated total liver weight; WRL: Weight of resected liver; ERL: Estimated residual liver weight; PH: Post-hepatectomy; BAS: Baseline; EUT: Euthanasia; P/A: Portal-to-arterial flow ratio; PVF: Portal vein flow. <sup>1</sup>Extracorporeal continuous portal diversion was stopped for 1 h.

6 h in all pigs from 24 to 30 h PH, and then stopped after the blood was returned to the pig.

The infusion plasma volume was equal to 1.3 times the plasma volume that had been removed per hour in each pig. The total exchanged plasma volume was 4000-5000 mL each time. The adequacy of anticoagulation was monitored by activated clotting time (ACT), and heparin was administered as required to maintain ACT levels greater than 250 s. Standard monitoring (ECG and arterial line for blood pressure, and Foley catheter for urine output) was performed for all pigs.

The characteristics of the hemodynamic studies are shown in Table 1. The evolution of hemodynamic parameters was measured at baseline, immediately PH, 48 h PH, and euthanasia (49 h PH). All flow values are reported in mL/min per 100 g hepatic tissue. The results showed that hemodynamic parameters such as PVF, HAF and P/A gradually reduced with time in the Systemic group and the Portal group. These hemodynamic parameters were significantly decreased in the Portal group compared with the Systemic group.

**PVP was significantly reduced in the Portal group compared with the Systemic group**

The changes in PVP in both groups are shown in Figure 2. The results showed that PVP in the Portal group was significantly lower than that in the Systemic group during the time period from 2 to 49 h PH (*P* < 0.05). These results

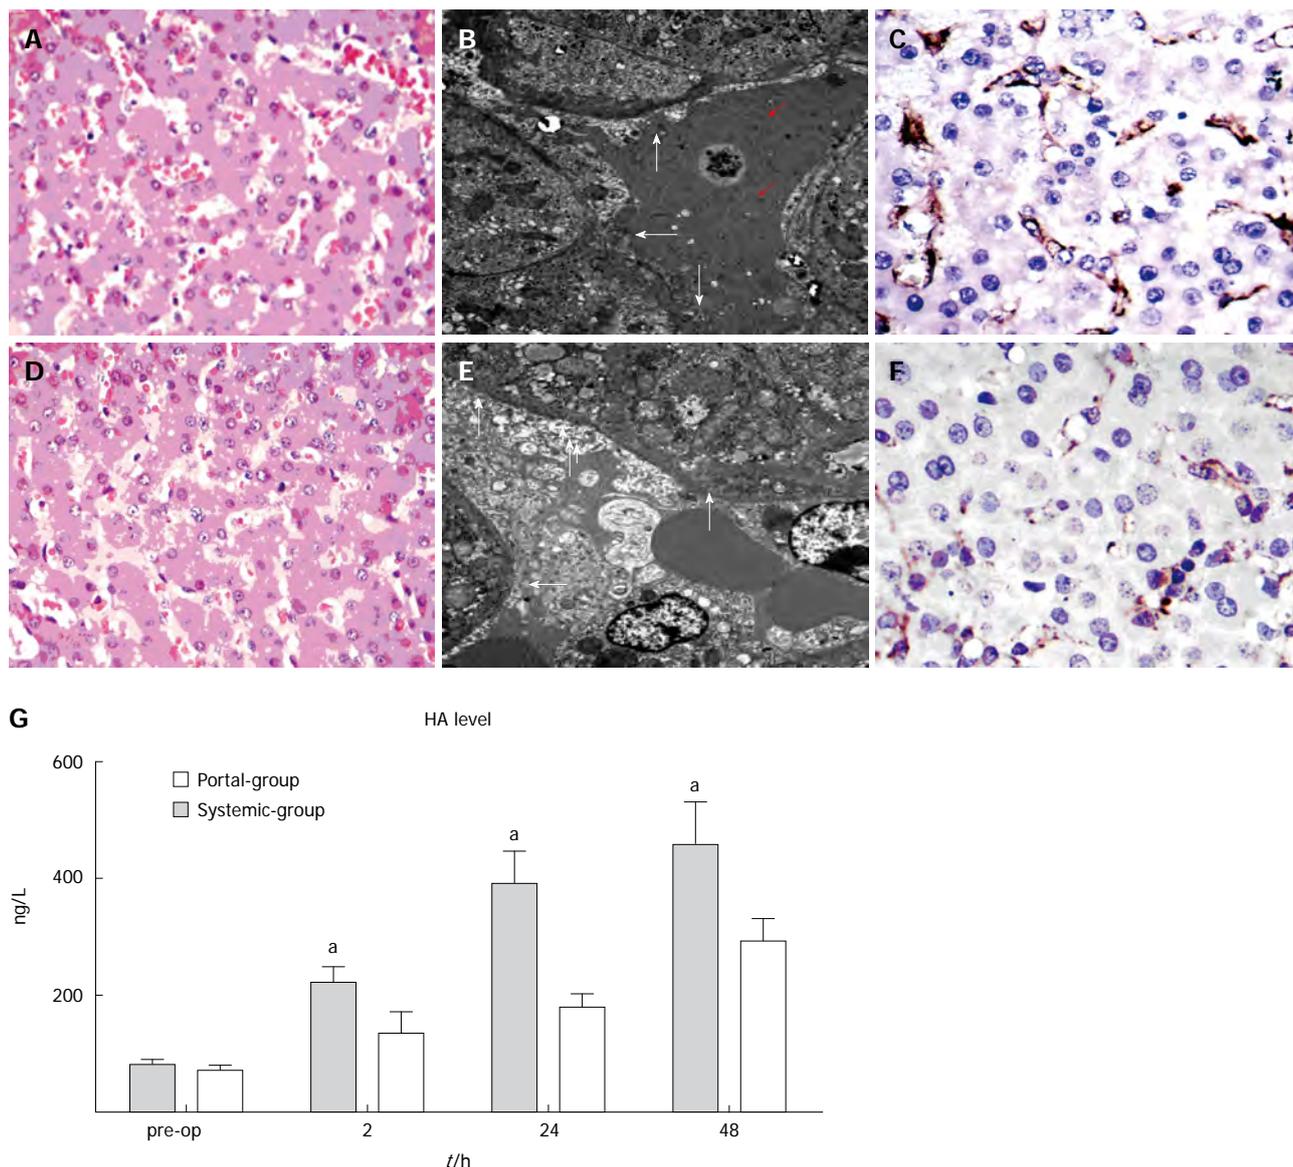

Figure 3 Portal group attenuated sinusoidal endothelial injury compared with the Systemic group. A, D: Hematoxylin and eosin staining ( $\times 400$  magnification) in the Systemic group and Portal group, respectively; B, E: Transmission electron microscopic (TEM) photographs ( $\times 6000$  magnification) in the Systemic group and Portal group, respectively; C, F: CD31 immunohistochemical staining of tissue samples ( $\times 400$  magnification) taken at 1 h post-hepatectomy (PH) in the Systemic group and Portal group, respectively; G: Serial changes in the level of hyaluronic acid (HA) in the two groups. <sup>a</sup> $P < 0.05$  indicates Portal group vs Systemic group.

suggested that PVP in the Portal group reduced much more than in the Systemic group. Thus, the Portal group had fewer complications in terms of portal hypertension compared with the Systemic group.

**Serum ALT, TB and ammonia were reduced in the Portal group compared with the Systemic group**

Levels of serum ammonia, ALT and TB collected serially during the follow-up period are shown in Table 2. The results showed that serum ALT, TB and ammonia were significantly reduced in the Portal group compared with the Systemic group from 24 to 48 h PH ( $P < 0.05$ ). In addition, serum ALT and ammonia in the Portal group were significantly improved, while TB remained the same after PP from 24 to 30 h PH ( $P < 0.05$ ). These results indicated that the Portal group may be better than the

Systemic group in improving liver function in PLF, and PP in the Portal group might enhance this protection of liver function.

**Portal group attenuated sinusoidal endothelial injury compared with the Systemic group**

In the Systemic group, there was significant sinusoidal dilation, hydropic changes in hepatocytes and hemorrhage into the hepatic parenchyma (Figure 3A). The sinusoidal endothelial lining was partially destroyed and detached into the sinusoidal space, accompanied by enlargement of the Disse’s spaces (red arrows) (Figure 3B). CD31 immunostaining revealed significant destruction of the endothelial lining (Figure 3C); whereas in the Portal group, no intraparenchymal hemorrhage was observed (Figure 3D), the sinusoidal endothelial cells and hepatocytes were

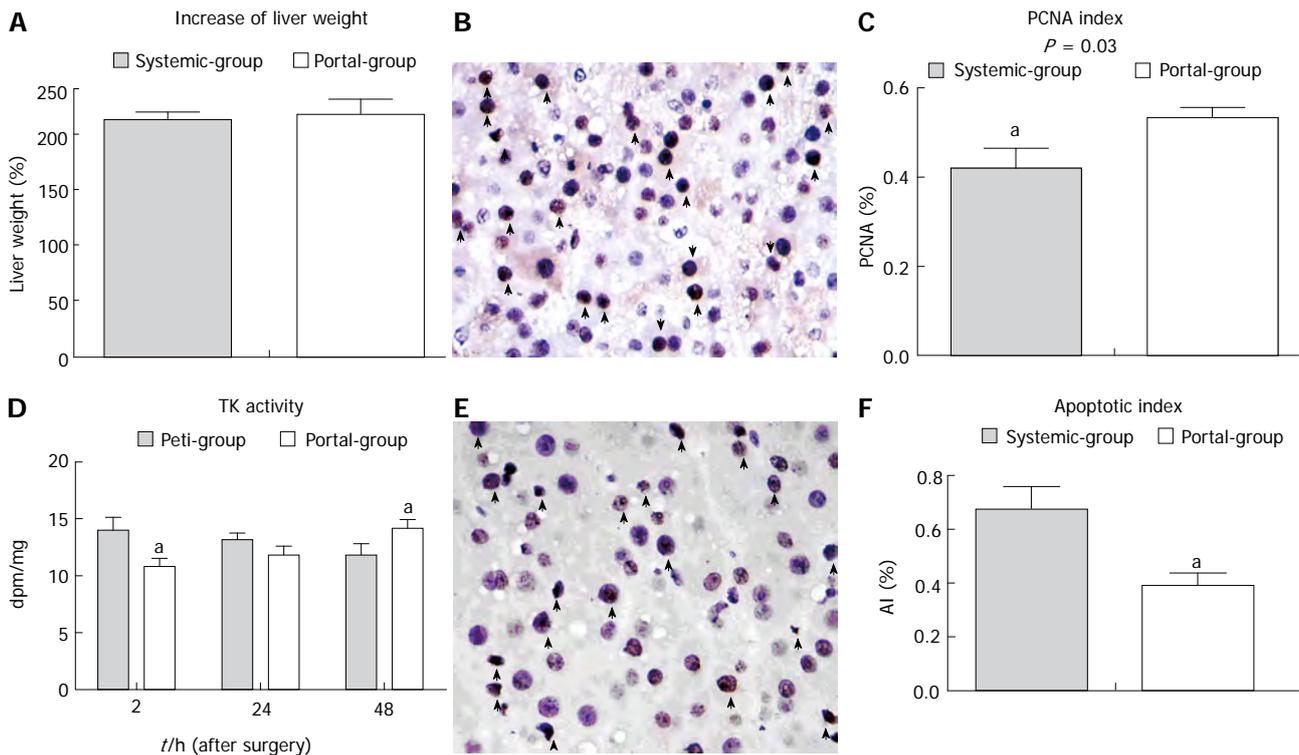

Figure 4 The rate of liver remnant regeneration was elevated and apoptosis was attenuated in the Portal group compared with the Systemic group. 	ALT (U/L)		TB (mmol/L)		Ammonia (μmol/L)	
	Systemic	Portal	Systemic	Portal	Systemic	Portal
Pre	45.2 ± 12.1	51.3 ± 15.5	17.3 ± 4.1	16.4 ± 5.5	158.4 ± 57.5	164.3 ± 46.2
2 h	67.2 ± 23.4	61.7 ± 26.1	19.5 ± 6.1	18.6 ± 6.3	239.6 ± 61.8	193.7 ± 47.0
24 h	129.7 ± 35.2	78.6 ± 24.5 <sup>1</sup>	45.9 ± 8.5	28.4 ± 5.7 <sup>1</sup>	345.2 ± 59.5	210.3 ± 67.7 <sup>1</sup>
30 h	101.5 ± 23.2	67.2 ± 16.4 <sup>1,2</sup>	36.4 ± 7.4	25.8 ± 5.1 <sup>1</sup>	217.4 ± 51.8	131.7 ± 37.4 <sup>1,2</sup>
48 h	118.6 ± 31.4	74 ± 29 <sup>1</sup>	58.4 ± 9.0	38.3 ± 7.1 <sup>1</sup>	254.3 ± 49.7	180.1 ± 54.5 <sup>1</sup>

<sup>1</sup>Indicates a significant difference between the two groups (*P* < 0.05); and <sup>2</sup>Indicates a significant difference in levels before and after Plasmapheresis (*P* < 0.05). ALT: Alanine aminotransferase; TB: Total bilirubin.

well preserved (arrow, Figure 3E), and CD31 immunostaining was mild which indicated less destruction of the endothelial lining (Figure 3F). Serial changes in the levels of HA in the two groups are shown in Figure 3G. HA was significantly decreased in the Portal group compared with the Systemic group from 2 to 48 h PH (*P* < 0.05). These results suggested that the Portal group may have attenuated sinusoidal endothelial injury and decreased HA level compared with the Systemic group.

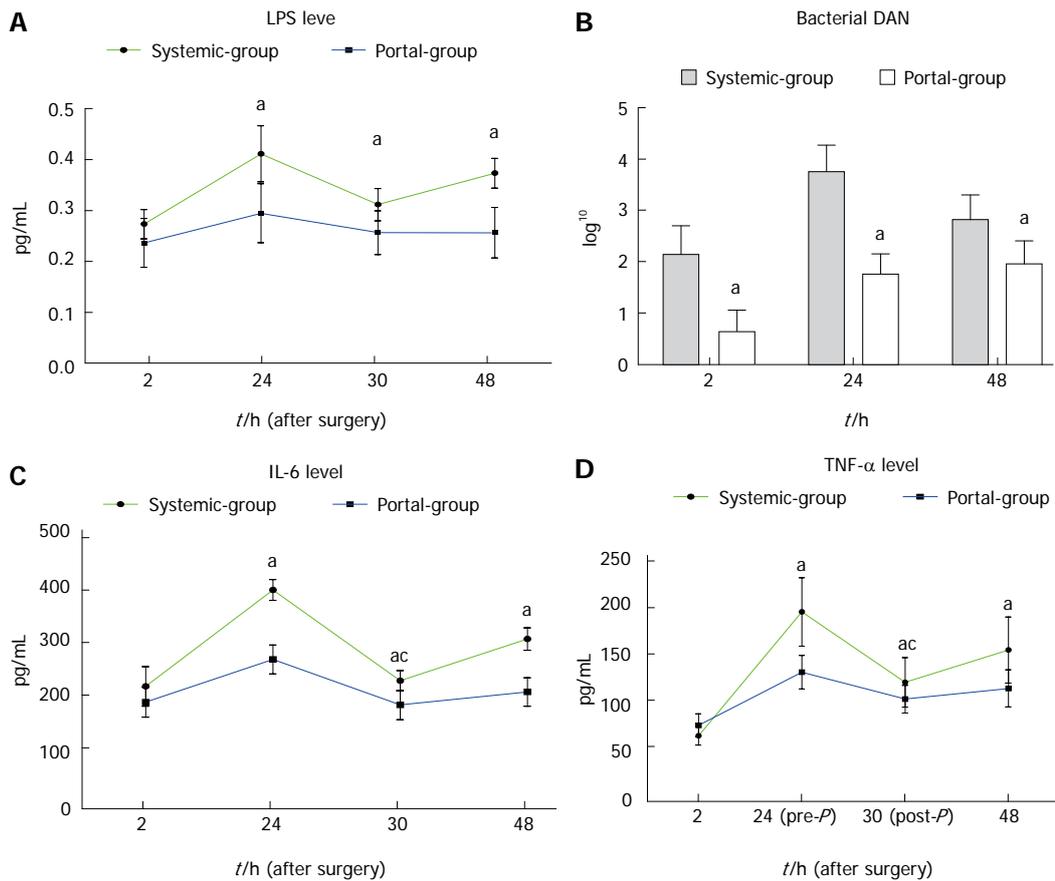

**Rate of liver remnant regeneration was elevated while apoptosis was attenuated in the Portal group compared with the Systemic group**

The rate of increase of liver volume in the Portal group was slightly increased compared with the Systemic group, although there was no statistical difference (*P* > 0.05)

(Figure 4A). Thymidine kinase activity was initially lower in the Portal group than the Systemic group immediately PH, and was subsequently higher at 48 h PH (Figure 4D). The PCNA index (PI) was significantly increased and the apoptotic index (AI) was significantly decreased in the Portal group compared with the Systemic group (Figure 4C, F). These results suggested that the rate of liver remnant regeneration was elevated, while the rate of apoptosis was attenuated in the Portal group compared with the Systemic group.

**Bacterial translocation and endotoxin as well as the inflammatory response were significantly attenuated in the Portal group compared with the Systemic group**

Serial changes in serum LPS levels, bacterial DNA levels, TNF-α and IL-6 levels in the Portal group compared

**Figure 5** Bacterial translocation and endotoxin, as well as the inflammatory response, were significantly attenuated in the Portal group compared with the Systemic group. A: Lipopolysaccharide (LPS) level was reduced in the Portal group compared with the Systemic group from 24 h post-hepatectomy (PH) until 48 h PH; B: Bacterial DNA level was reduced in the Portal group compared with the Systemic group from 2 h PH until 48 h PH; C: Interleukin (IL)-6 level was reduced in the Portal group compared with the Systemic group from 24 h PH until 48 h PH. D: tumor necrosis factor (TNF)-α level was reduced in the Portal group compared with the Systemic group from 24 h PH until 48 h PH. <sup>a</sup>*P* < 0.05 indicates Portal group vs Systemic group; <sup>c</sup>*P* < 0.05 indicates before plasma exchange vs after plasma

with the Systemic group are shown in Figure 5. The results showed that LPS, TNF-α and IL-6 levels were all significantly decreased in the Portal group compared with the Systemic group from 24 to 48 h PH, while bacterial DNA level was decreased from 2 to 48 h PH (Figure 5). In addition, LPS, bacterial DNA, TNF-α and IL-6 levels were all significantly decreased after plasma exchange from 24 to 30 h PH. These results suggested that bacterial translocation and endotoxin as well as the inflammatory response were significantly attenuated in the Portal group compared with the Systemic group.

## DISCUSSION

Following extensive hepatectomy when the remnant liver mass is low, it is unable to sustain synthetic, metabolic and detoxifying functions, and SFSS or PLF may ensue<sup>[5,6]</sup>. SFSS is a recognizable clinical syndrome, which is characterized by postoperative liver dysfunction with prolonged cholestasis, coagulopathy and portal hypertension. The mortality in severe SFSS or PLF after hepatectomy and LDLT is very high and ranges from 80% to 100%<sup>[5,20]</sup>.

PP or plasma exchange, a type of plasma purification, is usually performed in acute liver failure. During this process, the patient’s blood is introduced into the plasma

separator and the plasma is replaced. The harmful substances or protein-binding toxins are eliminated from the blood, and the blood cells and fresh frozen plasma are re-infused. PP can eliminate toxic soluble materials and small-molecule toxins, as well as coagulation factors, opsonins, and albumin among other factors<sup>[21]</sup>. In previous research<sup>[1,2,22,23]</sup>, it was demonstrated that these modalities can temporarily support the metabolic and excretory functions of the liver, and help to remove potentially hepatotoxic substances and maintain the patient’s clinical stability. The present study demonstrated that PP *via* both the systemic circulation and the portal vein can reduce toxic load and the inflammatory response and improve liver function, blood coagulation status, and LPS translocation. However, we were unable to find literature reports on the successful treatment of PLF<sup>[24-26]</sup>.

In SFSS or PLF following massive hepatectomy or LDLT, the toxic load is not “solely” pathogenic, as portal hypertension and splanchnic pooling have been reported to greatly contribute to the high postoperative morbidity and mortality of SFSS or PLF<sup>[6,24]</sup>. Severe damage to the sinusoidal endothelial cells (SECs) of the remnant liver is one of the main factors responsible for high mortality<sup>[5,16,27]</sup>. Sinusoidal overperfusion seems to be a significant factor impairing liver function following

liver resection. PP *via* systemic circulation access, which is currently universally adopted, did not improve survival rate and relieve portal hyperperfusion<sup>[2,25,28]</sup>. In the present study, the Portal group undergoing ECPD plus PP *via* the portal vein not only demonstrated removal of the toxic load, but also diversion of portal flow to the systemic circulation, thus relieving portal hypertension. This method attenuated sinusoidal endothelial injury and hepatocyte injury, and significantly decreased the serum endotoxin/bacterial DNA level, IL-6, and TNF- $\alpha$  level compared with the Systemic group without portal decompression. These results also indicated that portal hypertension not only damages the sinusoidal endothelium, but also aggravates endotoxin absorption/bacterial translocation<sup>[7,27,29]</sup>. Therefore, ECPD plus PP *via* the portal vein, which relieved both toxic load and portal hyperperfusion injury, has an advantage over PP *via* the systemic circulation. In a recent report, it was identified that PP combined with surgical modulation of the portal vein inflow was an effective treatment for SFSS after LDLT<sup>[26]</sup>.

Currently, the portacaval or mesocaval shunt is usually adopted to relieve portal hyperperfusion in both the clinic and in animal experiments. However, these techniques have many shortcomings, including surgical procedure-related complications and, long-lasting and excessive diversion of portal flow which could retard liver regeneration<sup>[16,30,31]</sup>. Fortunately, dynamic adjustment of the diverting flow between the portal and systemic circulation is characteristic of ECPD, which was able to halt the portal diversion, while the liver remnant underwent hypertrophy. This showed a potential advantage over the modalities presently adopted. In this study, the PVF per unit volume in the Portal group was preserved at more than 3 times the baseline value, and the increased rate of the liver remnant in the Portal group at 48 h PH was similar to that in the Systemic group with the presence of higher portal hyperperfusion. This indicated that PVF preserved at more than 3 times the baseline value was adequate and a good stimulus for liver regeneration. In addition, injury to the liver in the Portal group was milder and the AI was significantly lower than that in the Systemic group. To the best of our knowledge, this is the first study to investigate the feasibility and effectiveness of ECPD plus PP in relieving portal hyperperfusion in PLF or SFSS. As residual liver increases rapidly after major hepatectomy and within two days, portal hypertension will be relieved rapidly. Thus, ECPD is usually only needed for a short time. In this study, even when ECPD was stopped, the PVP only rose slightly compared with the baseline value, indicating that portal hypertension was relieved after a short time.

In general, ECPD plus temporal PP or plasma purification *via* the portal vein does not only dynamically turn the portal flow to the systemic circulation, attenuate portal overflow injury, and preserve the optimum portal flow for liver regeneration, but also reduces toxic load and improves biochemistry parameters. This technique should be undertaken instead of PP or ALS *via* the systemic circulation in SFSS or PLF.

## COMMENTS

### Background

Plasmapheresis (PP) and other plasma purification modalities have been used in the past to treat postoperative liver failure (PLF) and “small-for-size” syndrome (SFSS). However, these modalities have not resulted in a significant improvement in survival. It is thought that these modalities were unable to relieve portal hypertension, thus are inefficacious.

### Research frontiers

In SFSS or PLF after hepatectomy and living donor liver transplantation, the rationale for using PP or other plasma purification modalities is support for the patient, however, these modalities do not relieve portal hyperperfusion. The portacaval or mesocaval shunt (PCS/MCS) is usually adopted to relieve portal hyperperfusion, however, the long-lasting diversion of portal flow and the potential risk of excessive diversion of portal flow to the systemic circulation could retard liver regeneration.

### Innovations and breakthroughs

In SFSS and PLF, extracorporeal continuous portal diversion (ECPD) plus PP *via* the portal vein not only removes the toxic load, but continuously diverts the portal flow to the systemic circulation and relieves portal hypertension, attenuates sinusoidal endothelial injury and has an advantage over PP *via* the systemic circulation. In addition, ECPD *via* the portal vein can dynamically adjust the diverting flow to the “functional competition” between the portal and systemic circulation in the case of PCS/MCS, and is available to halt the portal diversion, while the remnant liver underwent hypertrophy. This showed a potential advantage of this technique over the modalities presently adopted.

### Applications

ECPD plus temporal PP *via* the portal vein does not only attenuate portal overflow injury, but also reduces toxic load and should be undertaken instead of PP or ALS *via* the systemic circulation in SFSS or PLF, and shows potential for application in the clinic.

### Peer review

It was supposed that PP and other artificial liver support (ALS) modalities did not relieve portal hypertension, resulting in inefficacious treatment. This study firstly demonstrated that the ECPD plus temporal PP *via* the portal vein can not only attenuate portal overflow injury, but also reduce toxic load, and should be undertaken instead of PP or ALS *via* the systemic circulation in SFSS or PLF.

### Abstract

**AIM:** To investigate the efficacy and potential mechanism of Xiaotan Tongfu granules (XTTF) in stress ulcers.

**METHODS:** One hundred sixty rats were randomly divided into 4 groups ( $n = 10$ ) as follows: the model group (MP group), the control group (CP group), the ranitidine group (RP group) and the XTTF granule group (XP group). Rats in the MP group received no drugs, rats in the CP group received 0.2 mL of a 0.9% sodium chloride solution *via* oral gavage, and rats in the RP and XP groups received the same volume of ranitidine (50 mg/kg) or XTTF granule (4.9 g/kg). The cold-restraint stress model was applied to induce stress ulcers after 7 consecutive days of drug administration. Afterwards, rats were sacrificed at 0, 3, 6 and 24 h. Gastric pH was measured by a precise pH meter;

gastric emptying rate (GER) was measured by using a methylcellulose test meal; myeloperoxidase activity (MPO), macrophage migration inhibitory factor (MIF), proliferating cell nuclear antigen (PCNA), and heat shock protein 70 (HSP70) were measured by immunohistochemical staining; and mucosal cell apoptosis was measured by transferase dUTP nick end labeling.

**RESULTS:** In the cold-restraint stress model, the development of stress ulcers peaked at 3 h and basically regressed after 24 h. Gastric lesions were significantly different in the RP and XP groups at each time point. Interestingly, although this index was much lower in the RP group than in the XP group immediately following stress induction (7.00  $\pm$  1.10 *vs* 10.00  $\pm$  1.79,  $P < 0.05$ ). Concerning gastric pH, between the RP and XP groups, we detected a statistically significant difference immediately after stress induction (0 h: 4.56  $\pm$  0.47 *vs* 3.34  $\pm$  0.28,  $P < 0.05$ ) but not at any of the subsequent time points. For GER, compared to the RP group, GER was remarkably elevated in the XP group because a statistically significant difference was detected (3 h: 46.84  $\pm$  2.70 *vs* 61.16  $\pm$  5.12,  $P < 0.05$ ; 6 h: 60.96  $\pm$  6.71 *vs* 73.41  $\pm$  6.16,  $P < 0.05$ ; 24 h: 77.47  $\pm$  3.17 *vs* 91.31  $\pm$  4.34,  $P < 0.05$ ). With respect to MPO and MIF, comparisons between the RP and XP groups revealed statistically significant differences at 3 h (MPO: 18.94  $\pm$  1.20 *vs* 13.51  $\pm$  0.89,  $P < 0.05$ ; MIF: 150.67  $\pm$  9.85 *vs* 122.17  $\pm$  5.67,  $P < 0.05$ ) and 6 h (MPO: 13.22  $\pm$  1.54 *vs* 8.83  $\pm$  0.65,  $P < 0.05$ ; MIF: 135.50  $\pm$  9.46 *vs* 109.83  $\pm$  6.40,  $P < 0.05$ ). With regard to HSP70, HSP70 expression was significantly increased in the RP and XP groups at 3 and 6 h compared to the MP and CP groups. In addition, comparing the RP and XP groups also showed statistically significant differences at 3 and 6 h. The expression of PCNA was higher in the RP and XP groups 3 h after stress induction. Between these two groups, small but statistically significant differences were observed at all of the time points (3 h: 69.50  $\pm$  21.52 *vs* 79.33  $\pm$  15.68,  $P < 0.05$ ;

6 h:  $107.83 \pm 4.40$  vs  $121.33 \pm 5.71$ ,  $P < 0.05$ ; 24 h:  $125.33 \pm 5.65$  vs  $128.50 \pm 14.49$ ,  $P < 0.05$ ) except 0 h. With regard to apoptosis, the apoptotic activity in the RP and XP groups was significantly different from that in the MP and CP groups. The XP group exhibited a higher inhibition of cell apoptosis than the RP group at 3 h ( $232.58 \pm 24.51$  vs  $174.46 \pm 10.35$ ,  $P < 0.05$ ) and 6 h ( $164.74 \pm 18.31$  vs  $117.71 \pm 12.08$ ,  $P < 0.05$ ).

**CONCLUSION:** The Xiaotan Tongfu granule was demonstrated to be similar to ranitidine in preventing stress ulcers. It exhibited multiple underlying mechanisms and deserves further study.

© 2013 Baishideng. All rights reserved.

**Key words:** Stress ulcer; Xiaotan Tongfu granule; Inflammation; Heat shock protein 70; Proliferation and apoptosis; Gastric emptying rate

**Core tip:** Although the underlying mechanism of stress ulcers is commonly believed to depend on the balance between known aggressive factors and mucosal defense mechanisms, most clinical strategies still aim to inhibit gastric acid. In this study, we demonstrated that the Xiaotan Tongfu granule was similar to ranitidine treatment in reducing gastric lesions in a cold-restraint stress model. The underlying mechanisms may include acceleration of the gastric emptying rate, inhibition of local inflammation, promotion of cell proliferation and suppression of apoptosis. Our study indicated that multiple manipulations of the factors involved in inducing stress ulcers could be as effective as simple acid inhibition.

## INTRODUCTION

Stress ulceration (SU) has been conventionally regarded as an inevitable complication of the gastrointestinal tract in people experiencing abnormally high physiological stress (*e.g.*, trauma, surgery, organ failure, sepsis, or burn)<sup>[1]</sup>. Gastrointestinal bleeding is a life-threatening complication of SU and was observed in 64% of patients with SU, compared to only 9% of patients without SU, in a previous study<sup>[2]</sup>. It is believed that clinically significant gastrointestinal bleeding in critically ill patients is associated with increased mortality rates, lengthened intensive care unit stays and additional costs<sup>[3-5]</sup>.

The development of stress ulcers is largely determined by the balance between known aggressive factors and defense mechanisms. The former usually include

gastric acid<sup>[6]</sup>, abnormal motility<sup>[7]</sup>, and *Helicobacter pylori* infection<sup>[8,9]</sup>, and the latter include heat shock protein<sup>[10]</sup>, cellular regeneration<sup>[11]</sup>, *etc.* SU prophylaxis (SUP) was thought to play a pivotal role in the care of critically ill patients, and it was reported that appropriate SUP could decrease mortality. At present, although multiple protocols are available for SUP, there are no universally accepted regimens<sup>[12]</sup>. Nevertheless, the evidence that the appropriate application of some pharmacologic agents, such as proton pump inhibitors, histamine-2 receptor antagonists, and sucralfate<sup>[13]</sup>, could decrease the risk of bleeding has been long established.

Traditional Chinese medicine (TCM) has been demonstrated to be effective in the management of stress-related gastrointestinal disorders, including irritable bowel syndrome<sup>[14,15]</sup>, and a number of studies have also indicated that TCM could exert measurable therapeutic effects on gastric ulcers in rats<sup>[16-18]</sup>. Based on these studies on TCM, the Xiaotan Tongfu (XTTF) granule (Table 1), which is primarily composed of a Xiao-cheng-qi decoction<sup>[19]</sup> and a Xiao-ban-xia decoction<sup>[20]</sup> (two ancient herbal formulas originating from the Treaty of Febrile and Miscellaneous written by Zhongjing Zhang in the years of 25-220 AD during the Eastern Han Dynasty), was used to treat gastrointestinal disorders in critically ill patients at our hospital. The rationale behind this treatment was that previous studies have indicated that the granule could improve the Acute Physical and Chronic Health Evaluation scores in patients experiencing gastrointestinal dysfunction (unpublished data). Considering this background, we speculated that the XTTF granule could be applied to the management of SU. In the present study, we investigated the efficacy of the XTTF granule in SU and the potential mechanisms involved.

## MATERIALS AND METHODS

### Animals

One hundred sixty male Sprague-Dawley rats weighing 200-220 g were purchased from Xipuier-Bikai Experimental Animal Co. LTD (Shanghai). The animals were housed in cages with wide mesh wire bottoms to prevent coprophagy, fed a standard laboratory diet and given free access to tap water. The cages were kept in a room with controlled temperature ( $22 \text{ }^\circ\text{C} \pm 1 \text{ }^\circ\text{C}$ ), relative humidity (65%-70%) and day/night cycle (12:12 light/dark). All of the rats were handled according to the recommendations of the National Institute of Health Guidelines for the Care and Use of Laboratory Animals. The protocol was approved by the Shanghai Medical Experimental Animal Care Commission.

### Drug administration

The XTTF granule was manufactured by Tian Jiang Pharmacy Co. Ltd (Jiangyin, China) and supervised by the Changzheng Hospital of the Second Military Medical University with the assigned batch number 1011370. We established the granule under the guidance of TCM

**Table 1** Ingredients and the corresponding percent of Xiaotan Tongfu granules

Chinese name	Common name	Latin name	Percent
Da Huang	Rhubarb	<i>Rhei Radix Et Rhizoma</i>	10%
Zhi Shi	Immature Bitter Orange	<i>Aurantii Fructus Immaturus</i>	10%
Ban Xia	Pinellia Tuber	<i>Pinelliae Rhizoma</i>	10%
Hou Pu	Magnolia Bark	<i>Magnoliae Officinalis Cortex</i>	6%
Bai Shao	White Peony Root	<i>Radix Paeoniae Alba</i>	10%
Xi Xin	Manchurian Wild Ginger	<i>Asari Radix Et Rhizoma</i>	4%
Huang Lian	Coptis Root	<i>Coptidis Rhizoma</i>	4%
Pu-Gong Yin	Dandelion	<i>Asari Radix Et Rhizoma</i>	10%
Bai-Hua-She-She Cao	Snake-needle Grass	<i>Hedyotis Diffusa</i>	10%
Fo Shou	Finger Citron	<i>Citri Sarcodactylis Fructus</i>	10%
Xiang Yuan	Citron Fruit	<i>Citri Fructus</i>	10%
Gan Cao	Licorice Root	<i>Glycyrrhizae Radix Et Rhizoma</i>	6%

related to stress ulcers<sup>[21]</sup>, and some of the components were previously shown to be effective in the management of stress-related symptoms. For example, the Xiao-ban-xia decoction could elevate gastric emptying<sup>[22]</sup>, which was delayed under stress conditions. In addition, the major component of the Xiao-cheng-qi decoction, *Rhei Radix Et Rhizoma*, was demonstrated to be effective in the prevention of stress ulcers *via* multiple mechanisms<sup>[23,24]</sup>. The rats were randomly divided into 4 groups ( $n = 10$ ) as follows: the model group (MP group), the control group (CP group), the ranitidine group (RP group) and the XTTF granule group (XP group). Rats in the MP group received no drugs; rats in the CP group received 0.2 mL of a 0.9% sodium chloride solution *via* oral gavage; and rats in the RP and XP groups received the same volume of ranitidine (50 mg/kg)<sup>[25-27]</sup> or XTTF granule (4.9 g/kg, corresponding to twice that of an adult human dose), respectively. The administration frequency was twice daily and sustained for 7 d. On the 8<sup>th</sup> day, rats were starved for 24 h (free of water) and prepared for the stress experiment.

### Induction of stress ulceration

The cold-restraint stress model used in the present study was originally devised by Senay *et al.*<sup>[28]</sup> and modified by Wong *et al.*<sup>[29]</sup>. Briefly, rats were restrained inside individual close-fitting tubular wire mesh cages and exposed to an ambient temperature of 4 °C for 3 h. Rats were anesthetized and sacrificed at 0, 3, 6 and 24 h after stress induction, and the stomachs were opened along the greater curvature. After measuring the mucosal lesions, sections of the tissues were fixed in 10% buffered formalin solution and stained for proliferating cell nuclear antigen (PCNA), heat shock protein 70 (HSP70), and macrophage migration inhibitory factor (MIF) *via* immunohistochemistry (IHC) and for apoptosis *via* transferase dUTP nick end labeling (TUNEL) staining.

### Measurement of gastric ulcer index, pH and emptying rate

The severity of the mucosal lesions was determined using a magnifier ( $\times 10$ ) and rated for gross pathology according to the scale of ulcer scores as described by Dekanski *et al.*<sup>[30]</sup> with a modification introduced by Martín *et al.*<sup>[31]</sup>. For every group, 4 rats were used in the precise measurement of gastric pH, and the test was performed by 3 independent investigators to determine the mean pH. Gastric emptying ( $n = 6$ , 2 rats were used as a control in each group) was measured using a methylcellulose test meal, as previously described<sup>[32,33]</sup>.

### Measurement of myeloperoxidase activity in the gastric mucosa

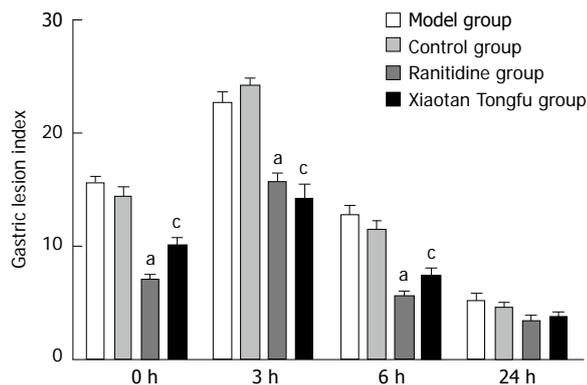

Myeloperoxidase (MPO) activity was determined by the method described by Bradley *et al.*<sup>[34]</sup> with some modifications<sup>[35]</sup>. The gastric mucosa was homogenized in a potassium phosphate buffer containing 0.5% hexadecyl trimethyl ammonium bromide, and the supernatant was assayed for MPO activity. The sample was mixed with hydrogen peroxide and *O*-Dianisidine prepared in a potassium phosphate buffer solution. The end point absorbance of the mixture was measured at 460 nm using a spectrophotometer with horseradish peroxidase as a standard. The protein assay was conducted using the method described by Lowry *et al.*<sup>[36]</sup>.

### Immunohistochemical staining for PCNA, HSP70 and MIF

Tissues were fixed in 10% formalin, embedded in paraffin, and processed by standard histological methods. From each paraffin block, 5- $\mu$ m serial sections were sliced. IHC studies were performed with kits utilizing the avidin-biotin-peroxidase complex according to the manufacturer's instructions (Invitrogen, United States). Primary antibodies [anti-PCNA (rabbit polyclonal, dilution 1:50, BD Biosciences) anti-HSP70 (rabbit polyclonal, dilution 1:50, BD Biosciences, United States), and anti-MIF (rabbit polyclonal, dilution 1:100, BD Biosciences, United States)] were incubated at room temperature overnight in a humidified chamber. The positive results were stained brown and counted by the Image Pro Express system (Olympus, Japan) at  $\times 400$  magnification (BX51, Olympus, Japan); the method of calculation was introduced by Soslow *et al.*<sup>[37]</sup>.

### Measurement of apoptotic cells in the gastric mucosa

Apoptosis measurement was detected by TUNEL staining according to the method of Gavrieli *et al.*<sup>[38]</sup>. After digestion with proteinase K, the tissues were treated with H<sub>2</sub>O<sub>2</sub> solution and washed with distilled water. The sections were then covered with TdT buffer containing TdT and biotinylated dUTP. The reaction was halted by washing the sections with a 3% H<sub>2</sub>O<sub>2</sub> methanol solution at room temperature. After blocking the non-specific binding with normal diluted serum, sections were incubated with peroxidase-labeled streptavidin and stained with

**Figure 1** Results of the gastric lesion index ( $n = 6$  for each group). At 0 h, ranitidine was demonstrated to be the most powerful agent in the inhibition of gastric lesions. The difference in the inhibition of gastric lesions between the ranitidine group and the Xiaotan Tongfu granule group was statistically significant ( $P < 0.05$ ). However, at the subsequent time points, this difference vanished. <sup>a</sup> $P < 0.05$  vs the model group; <sup>c</sup> $P < 0.05$  vs the control group.

diaminobenzidine-H<sub>2</sub>O<sub>2</sub>. Finally, the sections were counterstained with Mayer’s hematoxylin. Sections treated with DNase I in buffer solution served as the positive control, whereas the negative control was prepared by omitting the TdT from the buffer solution. The positive cells were counted by the Image Pro Express system (Olympus) at  $\times 400$  magnification (BX51, Olympus). The apoptotic index was defined as the average number from 10 to 25 glands of each mucosal section.

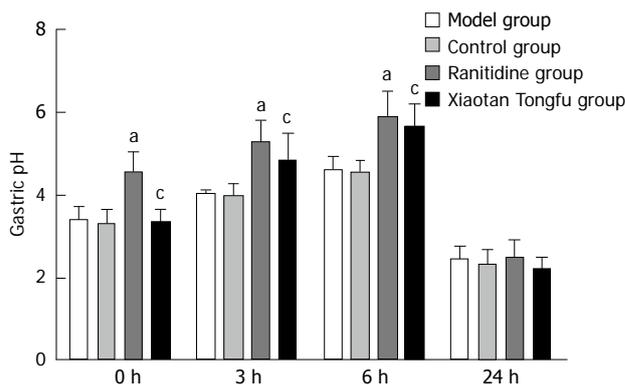

**Statistical analysis**

All data were processed by SPSS 18.0 and presented as the mean  $\pm$  SD. Comparisons between the different groups were evaluated by a one-way analysis of variance followed by the Bonferroni test. Values of  $P < 0.05$  were considered to be statistically significant. To avoid subjective bias of the parameters measured in this study, observers were blinded to the sample sources at the time of assessment.

**RESULTS**

**XTTF granule shows similar capabilities as ranitidine in reducing gastric lesions**

As shown in Figure 1, gastric lesions developed in a time-dependent manner and peaked at 3 h after stress induction; at 24 h after stress induction, these lesions had regressed. In the MP and CP groups, no statistically significant differences in this index were detected either overall or at each of the individual time points ( $P > 0.05$ ). In the RP and XP groups, gastric lesions were significantly different compared to the MP and CP groups at each time point ( $P < 0.05$ ), except at 24 h after stress induction ( $P > 0.05$ ). Interestingly, although this index was much lower in the RP group than in the XP group immediately after the stress ( $7.00 \pm 1.10$  vs  $10.00 \pm 1.79$ , respectively;  $P < 0.05$ ), this difference was eliminated at 3 h ( $15.67 \pm 1.97$  vs  $14.17 \pm 3.125$ , respectively;  $P > 0.05$ ), 6 h ( $5.50 \pm 1.05$  vs  $7.33 \pm 1.63$ , respectively;  $P > 0.05$ ) and 24 h ( $1.67$

**Figure 2** Results of gastric pH ( $n = 4$  in each group). At 0 h, ranitidine was demonstrated to be the most powerful agent in increasing the gastric pH, and the increase in the gastric pH was significantly different between the ranitidine group (RP group) and the Xiaotan Tongfu granule group (XP group) ( $P < 0.05$ ). In addition, there were no significant differences regarding the increase in the gastric pH among the XP, the model group (MP group), the control group (CP group) ( $P > 0.05$ ). At 3 h and 6 h after stress induction, there were no differences in the gastric pH between the RP and XP groups. <sup>a</sup> $P < 0.05$  vs the MP group; <sup>c</sup> $P < 0.05$  vs the CP group.

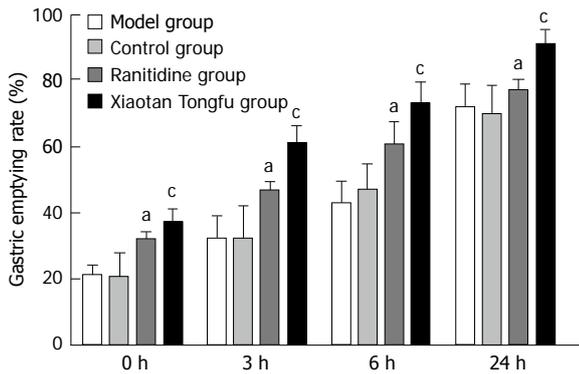

$\pm 0.52$  vs  $1.50 \pm 0.55$ , respectively;  $P > 0.05$ ) after stress induction.

**Gastric pH in the XP and RP groups is significantly lower than in the MP and CP groups**

As shown in Figure 2, the fluctuation of gastric pH was restricted to a limited range, except for 24 h after stress induction. There were no significant differences observed between the MP and CP groups ( $P > 0.05$ ). In the RP and XP groups, we detected a statistically significant difference immediately after stress induction ( $4.56 \pm 0.47$  vs  $3.34 \pm 0.28$ , respectively;  $P < 0.05$ ) but not at any of the subsequent time points ( $P > 0.05$ ). The gastric pH also recovered to normal levels 24 h after stress induction in these two groups, and no significant differences were observed among all of the groups ( $P > 0.05$ ).

**XTTF granule and ranitidine treatment accelerated the gastric emptying rate**

It has been established that stress could produce a marked delay of gastric emptying in both humans and animals<sup>[39,40]</sup>. As shown in Figure 3, the gastric emptying rate (GER) was remarkably suppressed very shortly after stress induction and was gradually restored over time. This effect was obvious in the MP and CP groups, and no significant differences were observed between these groups ( $P > 0.05$ ). Previous studies had shown that ranitidine could accelerate the GER in stress conditions<sup>[41,42]</sup>, and our study echoed this conclusion. In addition, we were intrigued by the greater improvement in GER for the XP group because a statistically significant difference was detected immediately after stress induction ( $46.84 \pm 2.70$  vs  $61.16 \pm 5.12$ , respectively;  $P < 0.05$ ), at 3 h ( $60.96 \pm 6.71$  vs  $73.41 \pm 6.16$ , respectively;  $P < 0.05$ ) and at 6 h ( $77.47 \pm 3.17$  vs  $91.31 \pm 4.34$ , respectively;  $P < 0.05$ ) compared to the RP group. This difference was sustained

**Figure 3** Results of the gastric emptying rate ( $n = 6$ , 2 rats were used as controls for each group). At 0 h, the Xiaotan Tongfu granule group (XP group) was superior in elevating the gastric emptying rate (GER); however, no significant difference was detected between the ranitidine group (RP group) and the XP group at this point ( $P > 0.05$ ). At 3, 6 and 24 h after stress induction, the GER in the XP group was sustained at a high value and was significantly different compared to the RP group ( $P < 0.05$ ). <sup>a</sup> $P < 0.05$  vs the model group; <sup>c</sup> $P < 0.05$  vs the control group.

at 24 h after stress induction ( $P < 0.05$  compared to all of the groups).

#### **XTTF granule and ranitidine inhibited local inflammation**

Tissue MPO levels were correlated with the neutrophil levels and served as a marker of neutrophil infiltration<sup>[43]</sup>. MIF, a 12.5-kDa cytokine, has increasingly been recognized for its proinflammatory properties in the inflammatory process in SU<sup>[43,44]</sup>. In our study, as shown in Figure 4, the variation of local inflammation (MPO and MIF) resembled the gastric pH. No significant differences were observed between the MP and CP groups, but comparisons between the RP and XP groups revealed statistically significant differences at 3 h ( $18.94 \pm 1.20$  vs  $13.51 \pm 0.89$ , respectively;  $P < 0.05$ ) and 6 h ( $13.22 \pm 1.54$  vs  $8.83 \pm 0.65$ , respectively;  $P < 0.05$ ) after stress induction.

#### **XTTF granule and ranitidine promoted the expression of HSP70**

Numerous studies have suggested that HSP70 could provide protection against gastric ulcers *via* multiple mechanisms<sup>[45]</sup>. As shown in Figure 5, there was a measurable expression of HSP70 3 h after stress induction, and this expression peaked at 6 h. No significant differences regarding HSP70 expression were observed between the MP and CP groups at any of the time points, but HSP70 expression was significantly higher in the RP and XP groups at 3 and 6 h compared to the MP and CP groups ( $P < 0.05$ ). In addition, comparison of the RP and XP groups also yielded statistically significant differences at 3 h ( $133.33 \pm 35.53$  vs  $176.17 \pm 9.37$ , respectively;  $P < 0.05$ ) and 6 h ( $182.83 \pm 38.78$  vs  $226.50 \pm 18.84$ , respectively;  $P < 0.05$ ) after stress induction.

#### **XTTF granule and ranitidine promote cell proliferation and inhibit gastric mucosal cell apoptosis**

As shown in Figure 6, cell proliferation varied in a time-

dependent manner and increased gradually after stress induction. No significant differences were observed between the MP and CP groups ( $P > 0.05$ ). In contrast with these groups, the expression of PCNA was higher in the RP and XP groups 3 h after stress induction ( $P < 0.05$ ), with small but significant differences observed at all of the time points except 0 h ( $37.50 \pm 10.91$  vs  $40.83 \pm 1.56$ , respectively;  $P > 0.05$ ) between these two groups. Peak apoptotic activity was observed at 3 h and returned to normal levels over time, as shown in Figure 6. There were no significant differences regarding apoptotic cells between the MP and CP groups, but the apoptotic activity in the RP and XP groups was significantly different from that in the MP and CP groups ( $P < 0.05$ ). Treatment in the XP group led to a higher inhibition of cell apoptosis than in the RP group at 3 h ( $232.58 \pm 24.51$  vs  $174.46 \pm 10.35$ , respectively;  $P < 0.05$ ) and 6 h ( $164.74 \pm 18.31$  vs  $117.71 \pm 12.08$ , respectively;  $P < 0.05$ ), but 24 h after stress induction, no significant differences could be detected between either of the groups.

## **DISCUSSION**

In the present study, the antiulcer effect of the Xiaotan Tongfu granule was established, and its efficacy was demonstrated to be similar to that of ranitidine. The cold-restraint stress model induced a series of pathological alterations and lesions in the stomach, which, when examined together with previous studies, suggested that SU is a process that results from multiple sources<sup>[46,47]</sup>. We concluded that although the XTTF granule was inferior to ranitidine in reducing gastric acid secretion immediately after stress induction, this did not impair its efficacy because the XTTF granule was superior in promoting a series of parameters, including inhibited local inflammation, increased GER, enhanced HSP70 expression, decreased cell apoptosis and elevated cell proliferation over time. The majority of these parameters have been demonstrated to contribute to ulcer prevention and healing<sup>[45]</sup>, which was confirmed by our observations of gastric lesions measured at the designated time points. Based on these results, we speculate that any agents that can interfere with the above parameters either individually or collectively would be useful to ameliorate any complications due to stomach ulcers.

The underlying mechanism of SU was previously not thoroughly understood and was commonly believed to depend on the balance between known aggressive factors and mucosal defense mechanisms<sup>[47]</sup>. Previous studies indicated that some components in our decoction, for example, the *Magnoliae Officinalis Cortex*, *Coptidis Rhizoma* and *Glycyrrhizae Radix Et Rhizoma*, were effective in inhibiting gastric acid secretion by a potential mechanism of regulating the activity of various postsynaptic gastric receptors such as histamine H2<sup>[48,49]</sup>. It was interesting that the XTTF granule was less efficacious in reducing gastric acid secretion immediately after stress induction and resulted in more serious gastric lesions compared to ra-

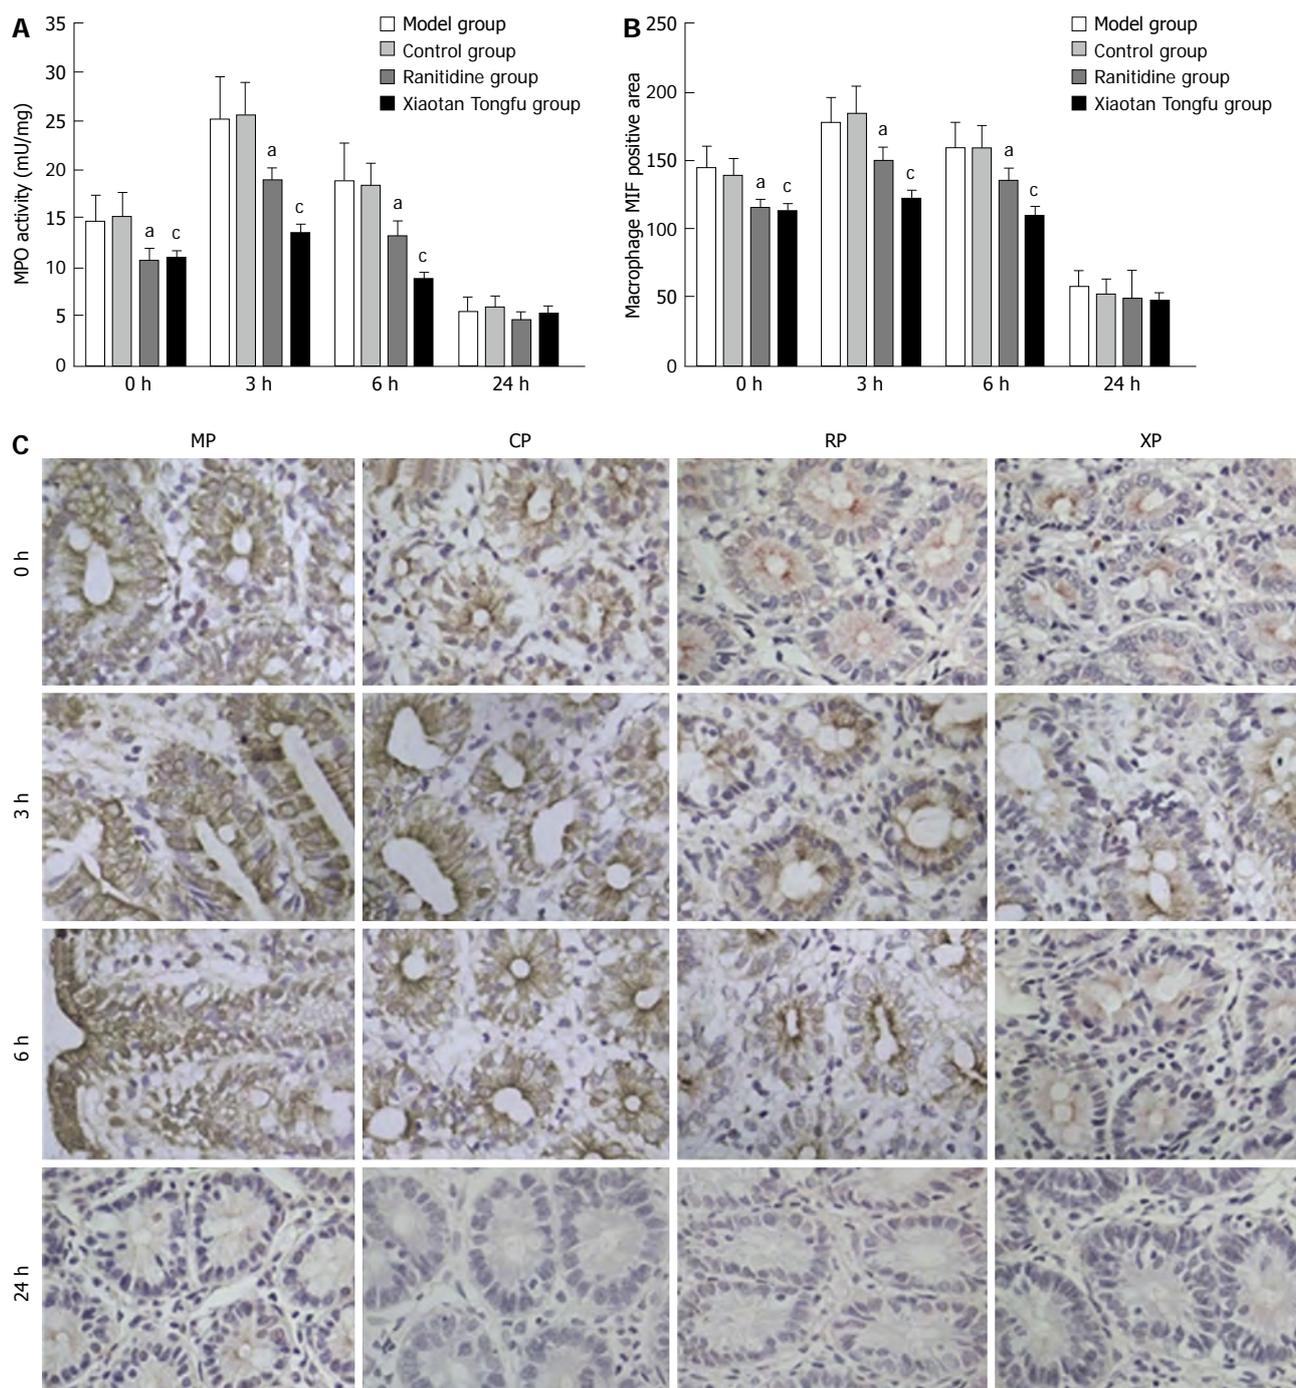

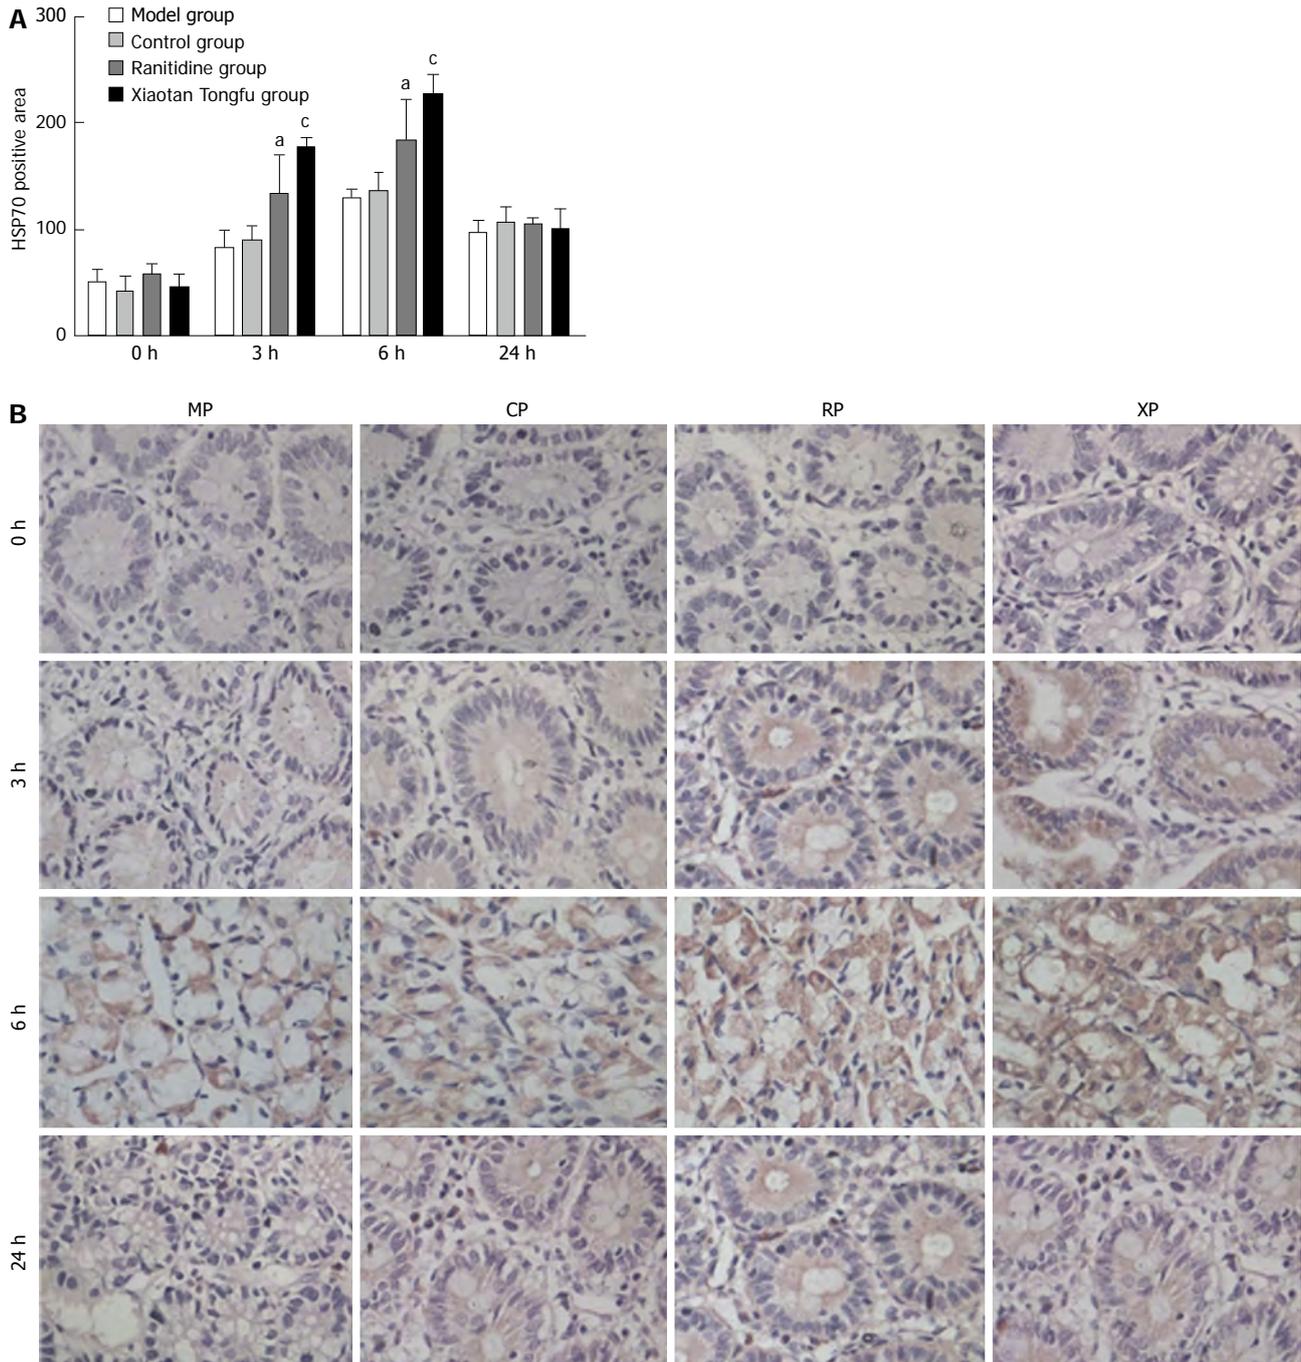

Figure 4 Measurement of myeloperoxidase activity and macrophage migration inhibitory factor ( $n = 6$  for each group). A, B: The variation of myeloperoxidase activity (MPO) activity and migration inhibitory factor (MIF) was similar. At 0 h, no significant difference was detected between the ranitidine group (RP group) and the Xiaotan Tongfu granule group (XP group) ( $P > 0.05$ ). However, 3 and 6 h after stress induction, these two indexes were inhibited in the XP group, which was a statistically significant difference compared to the RP group ( $P < 0.05$ ). <sup>a</sup> $P < 0.05$  vs the model group (MP group); <sup>c</sup> $P < 0.05$  vs the control group (CP group); C: The immunohistochemical staining results of MIF show that it was expressed in the cytoplasm of gastric epithelial cells and lamina propria cells. Original magnification  $\times 400$ .

nitidine. These results could be regarded as a footnote in that gastric acid is one of the most important factors in the formation of SU<sup>[50]</sup>. However, it should also be noted that not all clinically observed gastrointestinal bleeding can be prevented by manipulating the gastric pH<sup>[51]</sup>. The XTTF granule was shown to significantly promote GER, echoing the results in our previous study (unpublished observations) that concluded that the XTTF granule

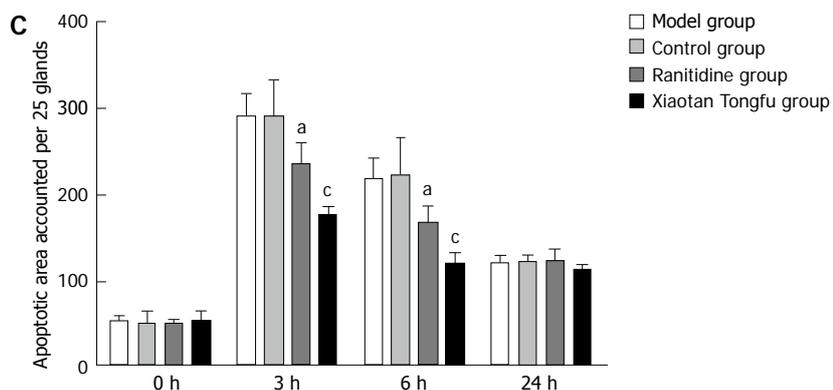

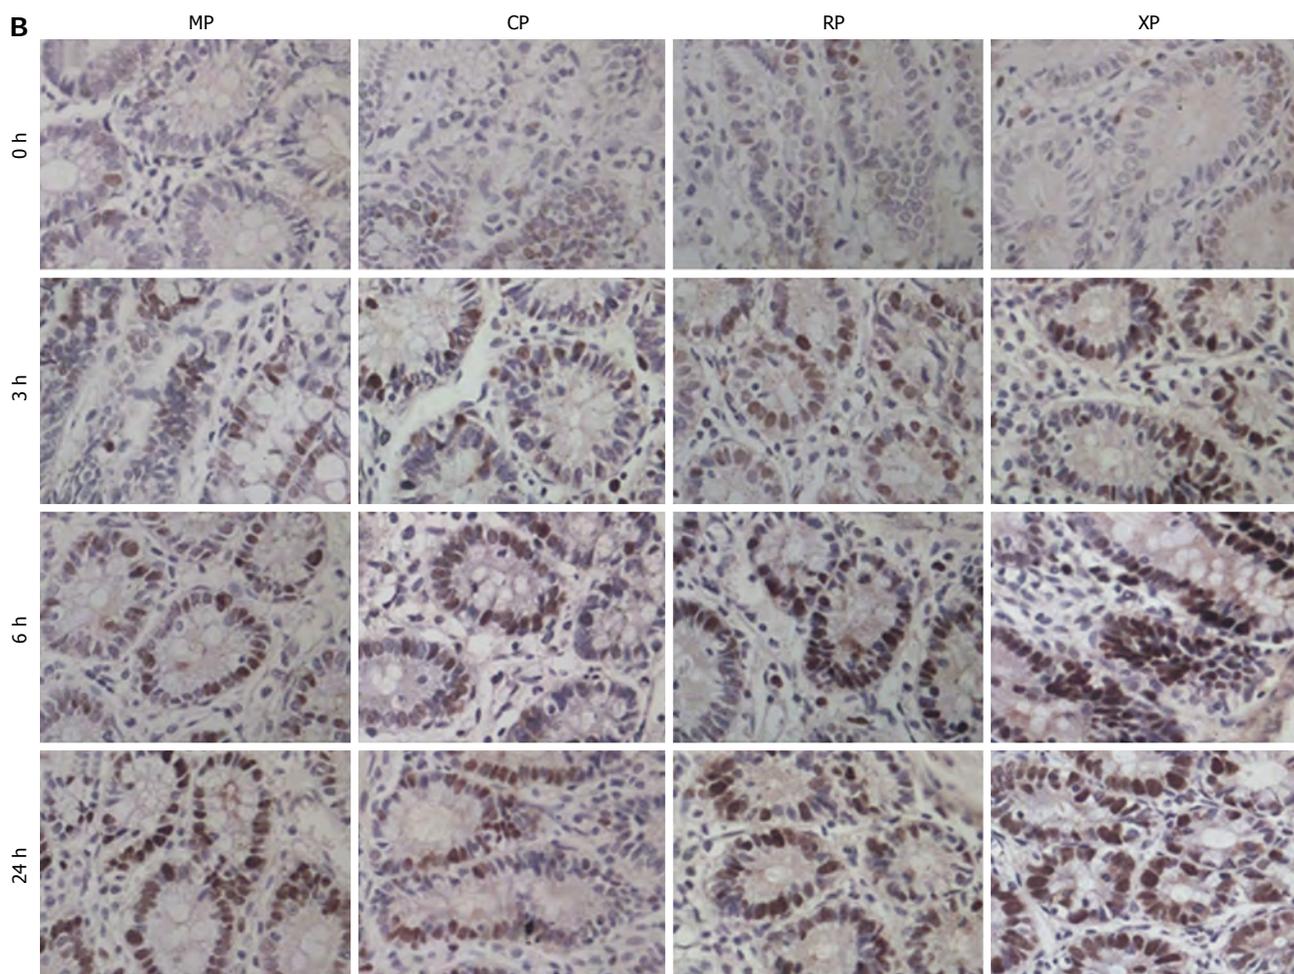

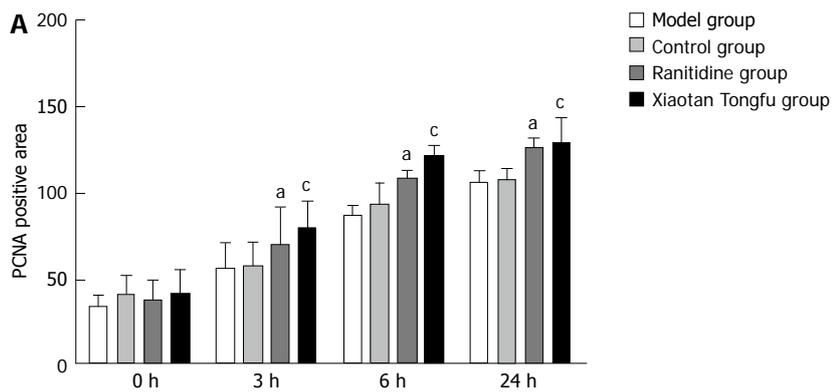

could enhance plasma motilin levels, which is important in gastric movement<sup>[52,53]</sup> in critically ill patients. Additionally, the Xiao-ban-xia decoction, which is an important component of the XTTF granule, has been demonstrated to be a regulative mediator of gastric motility<sup>[20]</sup>. An enhanced gastric emptying rate could remove acidic material and other irritants in the stomach<sup>[54]</sup>, which is beneficial for ulcer prevention. Additionally, it was notable that

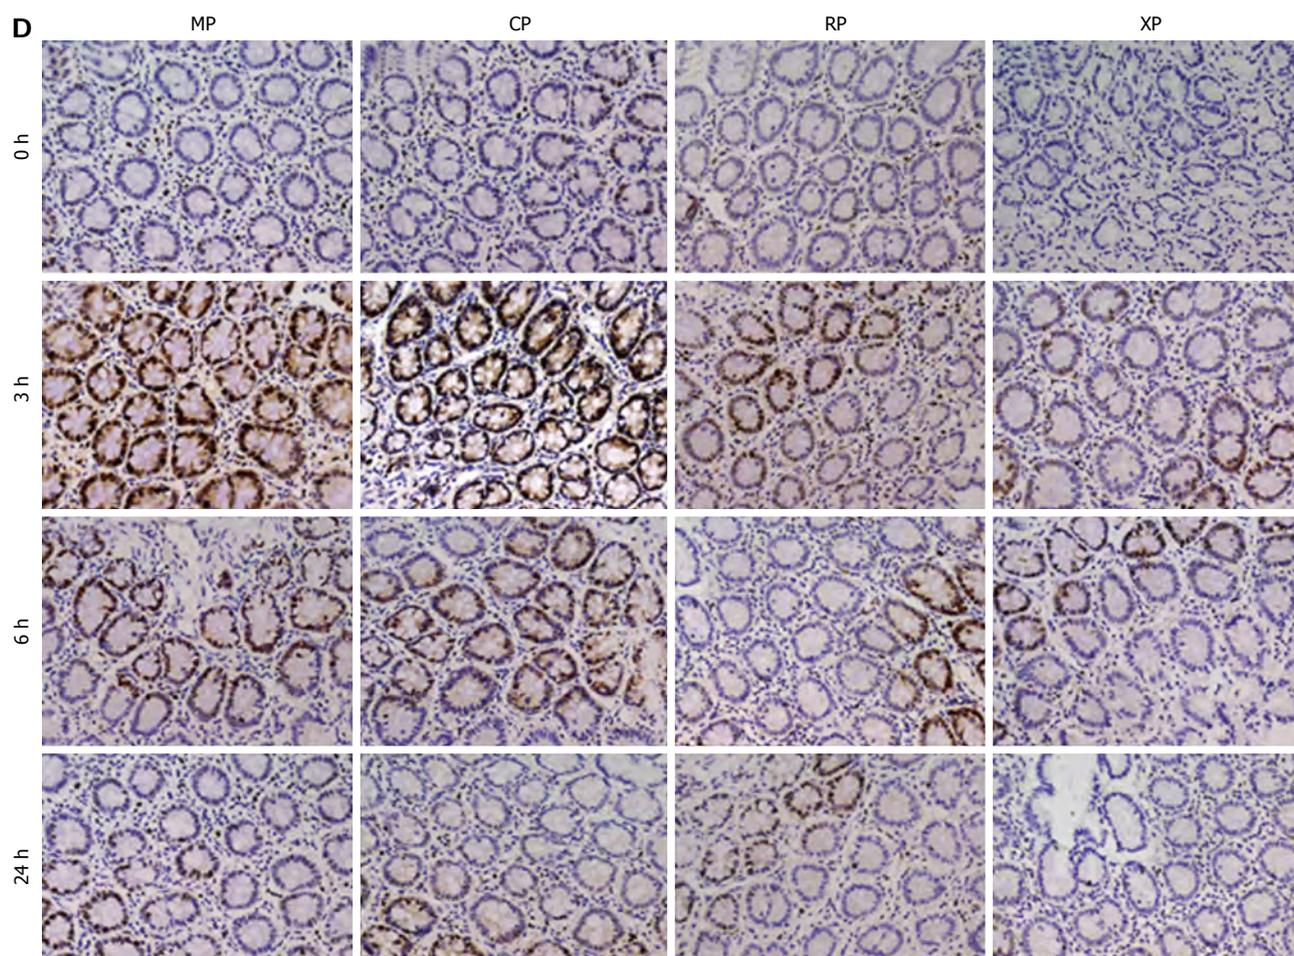

**Figure 5** Immunohistochemical staining results for heat shock protein 70 ( $n = 6$  for each group). **A:** There was a statistically significant difference in the protein expression levels between the ranitidine group (RP group) and the Xiaotan Tongfu granule group (XP group) groups at 3 and 6 h at the exact site of initial ulceration ( $P < 0.05$ ). <sup>a</sup> $P < 0.05$  vs the model group (MP group), <sup>c</sup> $P < 0.05$  vs the control group (CP group); **B:** Strong heat shock protein 70 (HSP70) immunoreactivity was observed in the gastric surface epithelium primarily in the nuclei, but protein was also observed in the cytoplasm. Original magnification  $\times 400$ .

some traditional Chinese herbal medicines were effective in preventing inflammation by various mechanisms, such as the inhibition of nuclear factor kappa B (NF- $\kappa$ B), tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), and interleukin-17<sup>[55,56]</sup>. Interestingly, in our study, the XTTF granule was able to alleviate local inflammation by decreasing MPO activity and restraining MIF expression. It is well known that neutrophil adherence within the gastric microcirculation and migration into the gastric tissue are major causes of gastric ulcers<sup>[54]</sup>. MIF has been suggested to play a pivotal

role in this process, and anti-MIF treatment could have therapeutic value in SU<sup>[57]</sup>. Although the data indicating that the XTTF granule could inhibit MIF are limited, *Rhei Radix Et Rhizoma* (a main herb in the Xiao-cheng-qi decoction<sup>[19]</sup>) was previously shown to inhibit gastrointestinal inflammation by acting on TNF- $\alpha$ <sup>[24]</sup>, a strong inducer of MIF secretion<sup>[58]</sup>. Furthermore, XTTF granule can also improve local microcirculation<sup>[22]</sup>, thereby reducing neutrophil concentrations<sup>[59]</sup>. Other components, such as *Coptidis Rhizoma*, could ameliorate acute inflammation by

**Figure 6** Measurement of cell proliferation and mucosal cell apoptosis ( $n = 6$  for each group). A: The cell proliferation was significantly different between the ranitidine (RP) and Xiaotan Tongfu granule (XP) groups ( $P < 0.05$ ) at 3 and 6 h; B: Proliferating cell nuclear antigen (PCNA) immunoreactivity was observed in the gastric surface epithelium, and this staining was focused in the nucleus; C, D: Strongly apoptotic cells were observed in the nucleus of the gastric surface epithelium. Similar to the cell proliferation, the cell apoptosis was significantly different between the RP and XP groups at 3 and 6 h ( $P < 0.05$ ). Original magnification  $\times 400$ . <sup>a</sup> $P < 0.05$  vs the model group (MP group); <sup>c</sup> $P < 0.05$  vs the control group (CP group).

inhibiting NF- $\kappa$ B-mediated nitric oxide and pro-inflammatory cytokine production<sup>[60]</sup>. Except these effects, the XTTF granule has also been shown to play a role in the manipulation of HSP70 expression, and although the data are still limited, the previous study did indicate that some herbal medicine constituents, such as *Glycyrrhizae Radix Et Rhizoma* (an herbal component in the Xiao-cheng-qi decoction<sup>[19]</sup>), could promote HSP expression<sup>[61]</sup>. Interestingly, *Glycyrrhizae Radix Et Rhizoma* was also demonstrated to be effective in protecting gastric mucosa *via* gastric mucin<sup>[62]</sup>. Finally, the XTTF granule also inhibited cell apoptosis and promoted cell proliferation, which is related to the mucosal protection of some components such as *Magnoliae Officinalis Cortex*<sup>[62]</sup> and *Aurantii Fructus Immaturus*<sup>[63]</sup>. We speculate that all of these actions may contribute to tissue regeneration and reconstruction in the stomach<sup>[64]</sup>.

It should be noted that the parameters manipulated by the XTTF granule in SU might not work individually, and these parameters could be connected in a complex relationship. For example, previous studies have shown that the aforementioned MIF inhibition effect of the

XTTF granule could result in the elevation of nitric oxide levels<sup>[57]</sup>, which are involved in HSP70 expression<sup>[65]</sup> and cell proliferation<sup>[66]</sup> during ulcer healing in the stomach. HSP70 could also exert its cytoprotective effect by interfering with the stress-induced apoptotic pathway<sup>[67,68]</sup>. Except that studies have indicated that ranitidine can inhibit gastric acid secretion<sup>[12]</sup>, accelerate GER<sup>[33,42]</sup>, and reduce apoptosis levels<sup>[69]</sup>, our study showed that the effect of ranitidine on parameters such as promoting cell proliferation may also be attributed to the comprehensive network of SU. The XTTF granule was shown to prevent ulcers and promote healing by attenuating aggressive factors and enhancing defensive factors. Future studies, such as randomized controlled trials, are necessary to further confirm its efficacy.

This study has several limitations. First, although we demonstrated that the XTTF granule exerts measurable preventative effects on SU, whether the XTTF granule acts in a dose-dependent manner remains unknown. Second, pretreatment with the XTTF granule in rats scheduled to undergo stress may not correspond to clinical practice because the majority of patients are administered

pharmacological agents for SUP after stress. Additional studies are necessary to measure the efficacy of the XTTF granule in this scenario.

## COMMENTS

### Background

Stress ulcer prophylaxis plays a pivotal role in the care of critically ill patients. Recent studies indicated that traditional Chinese medicine (TCM) could exert measurable therapeutic effects on gastric ulcers. The Xiaotan Tongfu (XTTF) granule has been used for a long time to treat gastrointestinal disorders in critically ill patients. However, whether it could be applied to stress ulcers remained unknown.

### Research frontiers

Emerging evidence suggests that TCM was effective in the management of stress-related gastrointestinal disorders, such as irritable bowel syndrome. In addition, a number of studies have also indicated that TCM could exert measurable therapeutic effects on gastric ulcers in rats. Stress ulceration was an inevitable complication of the gastrointestinal tract in animals experiencing abnormally high physiological stress. In this study, the authors demonstrated that a traditional Chinese herbal decoction could play an important role in the prevention of stress ulcers.

### Innovations and breakthroughs

Although the underlying mechanism of stress ulcers was commonly believed to depend on the balance between known aggressive factors and mucosal defense mechanisms, most of the clinical strategies are still aimed at inhibiting gastric acid. This study focused on demonstrating the efficacy of a traditional Chinese herbal medicine used to treat stress ulcers. The study indicated that traditional Chinese herbal medicine was effective in preventing stress ulcers and that inhibiting gastric acid would not be the only strategy.

### Applications

By confirming its efficacy and potential mechanisms in an animal study, the findings suggest that the XTTF granule could be regarded as a potential option for stress ulcer prophylaxis in the future.

### Terminology

Stress ulceration refers to an inevitable complication of the gastrointestinal tract in people experiencing abnormally high physiological stress, which usually leads to gastrointestinal bleeding. The underlying mechanism of stress ulcers was commonly believed to depend on the balance between known aggressive factors and mucosal defense mechanisms. Therefore, any agents that can interfere with the above factors, either individually or collectively, could be used as a stress ulcer prophylaxis.

### Peer review

The authors examined the efficacy and potential mechanisms of the XTTF granule in stress ulcers. This study revealed that the XTTF granule was similar to ranitidine treatment with regard to reducing gastric lesions in a cold-restraint stress model, and the underlying mechanisms may include acceleration of the gastric emptying rate, inhibition of local inflammation, promotion of cell proliferation and suppression of apoptosis. The results are interesting and may represent a potential option in the management of stress ulcers in the future.

### Abstract

**AIM:** To investigate the effect of propofol on human pancreatic cells and the molecular mechanism of propofol action.

**METHODS:** We used the human pancreatic cancer cell line MIAPaCa-2 for *in vitro* studies measuring growth inhibition and degree of apoptotic cell death induced by propofol alone, gemcitabine alone, or propofol followed by gemcitabine. All experiments were conducted in triplicate and carried out on three or more separate occasions. Data were means of the three or more independent experiments  $\pm$  SE. Statistically significant differences were determined by two-tailed unpaired Student's *t* test and defined as  $P < 0.05$ .

**RESULTS:** Pretreatment of cells with propofol for 24 h followed by gemcitabine resulted in 24%-75% growth inhibition compared with 6%-18% when gemcitabine was used alone. Overall growth inhibition was directly correlated with apoptotic cell death. We also showed that propofol potentiated gemcitabine-induced killing by downregulation of nuclear factor- $\kappa$ B (NF- $\kappa$ B). In con-

trast, NF- $\kappa$ B was upregulated when pancreatic cancer cells were exposed to gemcitabine alone, suggesting a potential mechanism of acquired chemoresistance.

**CONCLUSION:** Inactivation of the NF- $\kappa$ B signaling pathway by propofol might abrogate gemcitabine-induced activation of NF- $\kappa$ B, resulting in chemosensitization of pancreatic tumors to gemcitabine.

**Key words:** Pancreatic cancer; Propofol; Gemcitabine; Nuclear factor- $\kappa$ B; Apoptosis

**Core tip:** Pretreatment of cells with propofol for 24 h followed by gemcitabine resulted in significant growth inhibition compared with gemcitabine alone. Overall growth inhibition correlated directly with apoptotic cell death. Propofol potentiated gemcitabine-induced killing by downregulation of nuclear factor- $\kappa$ B (NF- $\kappa$ B). In contrast, NF- $\kappa$ B was upregulated when pancreatic cancer cells were exposed to gemcitabine alone. These results suggested that inactivation of the NF- $\kappa$ B signaling pathway by propofol abrogated gemcitabine-induced activation of NF- $\kappa$ B resulting in the chemosensitization of pancreatic tumors to gemcitabine.

Propofol induces apoptosis and increases gemcitabine sensitivity in pancreatic cancer cells *in vitro* by inhibition of nuclear factor- $\kappa$ B activity. *World J Gastroenterol* 2013; 19(33): 5485-5492 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i33/5485.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i33.5485>

### INTRODUCTION

Pancreatic cancer has the poorest prognosis of all major cancers, with an overall 5-year survival rate of around 5%<sup>[1]</sup>. The current clinical standard of care for advanced pancre-

atic cancer is gemcitabine, a cytotoxic nucleoside analog. Treatment with gemcitabine results in a tumor response rate of 12% and a median survival time of 5 mo<sup>[2]</sup>.

Drug resistance (both intrinsic and acquired) is thought to be a major reason for the limited benefit of most pancreatic cancer therapies<sup>[3]</sup>. Recent studies have indicated that targeted therapies in combination with gemcitabine can have statistically significant benefits<sup>[4]</sup>. However, the results to date remain insufficient, and new approaches to improving the effectiveness of gemcitabine are needed. One of the targets considered for combination therapy that has received wide attention is the transcription factor nuclear factor- $\kappa$ B (NF- $\kappa$ B)<sup>[5]</sup>. Pan *et al*<sup>[6]</sup> and Kong *et al*<sup>[7]</sup> reported that inhibition of NF- $\kappa$ B might be useful for pancreatic cancer therapy, as it increases gemcitabine sensitivity in pancreatic cancer cells. Recent studies also indicate that combination therapy with a targeted medicine that inhibits NF- $\kappa$ B activity potentiated the anti-tumor effects of gemcitabine in pancreatic cancer cells<sup>[8-10]</sup>.

Propofol is an intravenous anesthetic that is used to induce and maintain anesthesia, and to sedate and calm patients in intensive care. Increasing evidence suggests that propofol might be neuroprotective against ischemic neuronal injury in animal models of cerebral ischemia<sup>[11-13]</sup>. Xi *et al*<sup>[14]</sup> and Li *et al*<sup>[15]</sup> found that the neuroprotective effects of propofol against neuronal apoptosis might be a consequence of regulation of Bcl-2, caspase-3 and Bax. Propofol has protective effects against digestive injury. It inhibits HMGB1 expression and TLR4/MyD88/NF- $\kappa$ B-mediated inflammatory responses, and hampers apoptosis, which might contribute to its protective action against ethanol-induced gastric mucosal injury<sup>[16]</sup>. Propofol also has anticancer properties. Siddiqui *et al*<sup>[17]</sup> found that combinations of propofol and docosahexaenoate or propofol and eicosapentaenoate significantly induced apoptosis and inhibited cell adhesion and migration in breast cancer cells. Propofol inhibits MMP-2 and -9 expression, suppressing lung cancer cell invasion and migration<sup>[18]</sup>. Propofol induces proliferation and promotes invasion of gallbladder cancer cells through activation of Nrf2<sup>[19]</sup>. Li *et al*<sup>[20]</sup> showed that propofol reduced the level of MMP in breast cancer cells by inhibition of NF- $\kappa$ B pathways, significantly restraining migration and invasion of breast cancer cells. Propofol extensively counteracts the oxidative/nitrative and multiple apoptotic effects of doxorubicin in rat hearts<sup>[21]</sup>.

Most human pancreatic tumors show high levels of activated NF- $\kappa$ B, which mediates survival signaling and confers resistance to conventional therapeutics. Therefore, targeting NF- $\kappa$ B could be an effective therapeutic approach. The mechanism by which NF- $\kappa$ B stimulates cell survival is not fully understood; however, recent studies showed that activation of NF- $\kappa$ B leads to the activation of a series of survival factors, including bcl-2. This allows cancer cells to resist induction of apoptosis<sup>[7]</sup>. Many conventional cancer chemotherapeutic agents such as vinblastine, vincristine, daunomycin, doxorubicin, camptothecin, cisplatin, and etoposide activate NF- $\kappa$ B. This activation results in resistance to apoptosis, which results in poor clinical outcomes for pancreatic cancer patients.

Inactivating NF- $\kappa$ B activity induces apoptosis and abrogates *de novo* or acquired chemoresistance<sup>[22]</sup>. Based on these results, we hypothesized that propofol might block multiple intracellular signaling pathways that are known to confer a high degree of chemoresistance by pancreatic cancer cells, abrogating either *de novo* or acquired chemoresistance. Although the development of alternative gemcitabine schedules and chemotherapy combinations continues, we report our observations in support of our hypothesis that better pancreatic cancer cell killing is feasible by using propofol with gemcitabine. Our results are primarily due to inactivation of NF- $\kappa$ B signaling *in vitro*.

## MATERIALS AND METHODS

### Cell culture

The MIA-PaCa-2 human pancreatic cancer cell line was obtained from the American Type Culture Collection and cultured in Dulbecco modified Eagle's medium supplemented with 10% fetal calf serum, sodium pyruvate, nonessential amino acids, L-glutamine, penicillin/streptomycin antibiotics, and vitamins. Cells were maintained in a humidified incubator containing 10% carbon dioxide at 37 °C. Cells underwent serum starvation for 24 h before treatment with propofol or/and gemcitabine.

### Drug treatment

For single-agent treatment, MIA-PaCa-2 cells were treated with 10-100  $\mu$ mol/L propofol or 0.5 mmol/L Na<sub>2</sub>CO<sub>3</sub> (vehicle control) for 72 h; 100  $\mu$ mol/L per milliliter propofol for 24, 48, 72 h; or 10, 25, 50, 100  $\mu$ mol/L gemcitabine for 72 h. For combined treatment, MIA-PaCa-2 cells were treated with 50 or 100  $\mu$ mol/L per milliliter propofol for 24 h, then exposed to 10-100  $\mu$ mol/L gemcitabine for an additional 72 h.

### Growth inhibition by 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide assay

MIA-PaCa-2 cells were seeded at  $3 \times 10^3$  cells per well in 96-well microtiter culture plates. After overnight incubation, medium was replaced with fresh medium containing propofol 0-100  $\mu$ mol/L diluted from a 10 mmol/L stock. After 24-72 h incubation, 20  $\mu$ L 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) solution (5 mg/mL in PBS) was added to each well and incubated for 2 h. Supernatant was aspirated and the MTT formazan formed by metabolically viable cells was dissolved in 100  $\mu$ L isopropanol. Plates were mixed for 30 min on a shaker and absorbance was measured at 595 nm using a plate reader (TECAN, Durham, NC, United States). MIA-PaCa-2 cells were also treated with 25  $\mu$ mol/L propofol for 24 h and exposed to 0-100  $\mu$ mol/L gemcitabine for an additional 72 h before MTT assay.

### DNA ladder analysis for apoptosis

Cytoplasmic DNA was extracted from MIA-PaCa-2 cells treated with 100  $\mu$ mol/L propofol or 0.5 mmol/L Na<sub>2</sub>CO<sub>3</sub> (vehicle control) for 24-72 h; or 10-100  $\mu$ mol/L propo-

fol for 72 h using 10 mmol/L Tris (pH 8.0), 1 mmol/L EDTA, and 0.2% Triton X-100. MIA-PaCa-2 cells were also treated with 25  $\mu\text{mol/L}$  propofol for 24 h and exposed to 0-100  $\mu\text{mol/L}$  of gemcitabine for an additional 72 h before cytoplasmic DNA extraction. Lysate was centrifuged for 15 min at 13000 *g* to separate fragmented DNA (soluble) from intact chromatin (nuclear pellet). Supernatant from lysates was treated with RNase followed by SDS-Proteinase K digestion, phenol chloroform extraction, and isopropanol precipitation. DNA was separated by 1.5% agarose gels stained with ethidium bromide for DNA visualization by UV light.

#### **Terminal transferase dUTP nick-end labeling assay for apoptosis**

Apoptosis was evaluated by terminal transferase dUTP nick-end labeling (TUNEL) assay according to the manufacturer's instructions for MIA-PaCa-2 cells treated with 100  $\mu\text{mol/L}$  propofol or 0.5 mmol/L  $\text{Na}_2\text{CO}_3$  (vehicle control) for 24-72 h; or 10-100  $\mu\text{mol/L}$  propofol for 72 h; or 25  $\mu\text{mol/L}$  propofol for 24 h followed by 0-100  $\mu\text{mol/L}$  of gemcitabine for 72 h. TUNEL-positive cells were colored using diaminobenzidine as chromogen and counterstained with hematoxylin. The percentage of TUNEL-positive cells was assessed in five randomly selected fields per section. All assays were performed in quadruplicate.

#### **Quantification of apoptosis by enzyme-linked immunosorbent assay**

The Cell Apoptosis enzyme-linked immunosorbent assay (ELISA) Detection Kit (Chemicon International, Temecula, CA, United States) was used to detect apoptosis in MIA-PaCa-2 cells according to the manufacturer's protocol. MIA-PaCa-2 cells were treated with 10-100  $\mu\text{mol/L}$  propofol for 72 h or with 50  $\mu\text{mol/L}$  propofol for 24-72 h; or 50  $\mu\text{mol/L}$  propofol for 24 h followed by 0-100  $\mu\text{mol/L}$  gemcitabine for 72 h. After treatment, cytoplasmic histone DNA fragments from MIA-PaCa-2 cells were extracted and bound to immobilized anti-histone. Peroxidase-conjugated anti-DNA was used to detect immobilized histone DNA fragments. After addition of peroxidase substrate, spectrophotometric absorbance of samples was determined using an ULTRA Multifunctional Microplate Reader (TECAN) at 405 nm.

#### **Electrophoretic mobility shift assay**

Cell extracts were prepared using a commercially available nuclear extraction kit according to the manufacturer's protocol (Pierce, Rockford, IL, United States). Electrophoretic mobility shift assay (EMSA) was performed according to the provided protocol (Promega). Briefly, cells were washed with cold PBS and suspended in 0.15 mL lysis buffer (10 mmol/L HEPES pH 7.9, 10 mmol/L KCl, 0.1 mmol/L EDTA, 0.1 mmol/L EGTA, 1 mmol/L DTT, 1 mmol/L PMSF, 2  $\mu\text{g/mL}$  leupeptin, 2  $\mu\text{g/mL}$  aprotinin, and 0.5 mg/mL benzamidine). Cells were swelled on ice for 20 min and 4.8  $\mu\text{L}$  10% NP40 was added. Tubes

were vigorously mixed for a few seconds and microcentrifuged. The nuclear pellet was resuspended in 30  $\mu\text{L}$  ice-cold nuclear extraction buffer (20 mmol/L HEPES pH 7.9, 0.4 mol/L NaCl, 1 mmol/L EDTA, 1 mmol/L EGTA, 1 mmol/L DTT, 0.5 mmol/L PMSF, 2  $\mu\text{g/mL}$  leupeptin, 2  $\mu\text{g/mL}$  aprotinin, and 0.5 mg/mL benzamidine) and incubated on ice with intermittent mixing. Tubes were microcentrifuged for 5 min at 4  $^{\circ}\text{C}$ , and supernatant (nuclear extract) was collected in cold Eppendorf tubes and stored at -70  $^{\circ}\text{C}$ . Protein content was measured by bicinchoninic acid method. EMSA used 5  $\mu\text{g}$  of nuclear proteins incubated with IRDye-700-labeled NF- $\kappa\text{B}$  oligonucleotide. Incubation mixture was 2  $\mu\text{g}$  of poly (deoxyinosinic - deoxycytidylic acid) in binding buffer. DNA-protein complexes were separated from free oligonucleotides on 8.0% native polyacrylamide gels using buffer containing 50 mmol/L Tris, 200 mmol/L glycine (pH 8.5), and 1 mmol/L EDTA and visualized by an Odyssey Infrared Imaging System using Odyssey Software Release 1.1. Equal protein loading was ensured by immunoblotting 10  $\mu\text{g}$  of nuclear protein with anti-retinoblastoma.

#### **Statistical analysis**

All experiments were conducted in triplicate and carried out on three or more separate occasions. Data were means of the three or more independent experiments  $\pm$  SE. Statistically significant differences were determined by two-tailed unpaired Student's *t* test and defined as  $P < 0.05$ .

## **RESULTS**

#### **Effect of propofol on cell proliferation**

MIA-PaCa-2 cells were treated with 0-100  $\mu\text{mol/L}$  propofol over 72 h, and cell viability was determined by MTT assay. Treatment with 10, 25, 50, or 100  $\mu\text{mol/mL}$  of propofol for 72 h resulted in 95%, 87%, 64%, and 51% of cell growth relative to control, respectively (Figure 1A). Similar results were found with exposure to 100  $\mu\text{mol/mL}$  propofol for 24, 48, and 72 h (Figure 1B). Treatment of MIA-PaCa-2 cells with propofol resulted in dose- and time-dependent inhibition of cell proliferation, demonstrating that propofol applied as a single agent was an effective inhibitor of pancreatic cancer cell growth.

#### **Effect of propofol on apoptosis**

MIA-PaCa-2 cells were treated with 10-100  $\mu\text{mol/L}$  propofol for 72 h, or 100  $\mu\text{mol/L}$  propofol for 24-72 h. Apoptosis was determined by TUNEL, DNA ladder and ELISA assays. Treatment with 10, 25, 50, or 100  $\mu\text{mol/mL}$  propofol for 72 h resulted in 1.6%, 4.1%, 9.7%, or 13.8% apoptosis relative to controls (Figure 2A). Similar results were found with 100  $\mu\text{mol/mL}$  propofol for 24, 48, or 72 h (data not shown). Treatment of MIA-PaCa-2 cells with propofol resulted in dose- and time-dependent promotion of apoptosis, demonstrating that propofol used as a single agent was an effective promoter of pancreatic cancer cell death. DNA ladder (Figure 2B) and ELISA (Figure 2C)

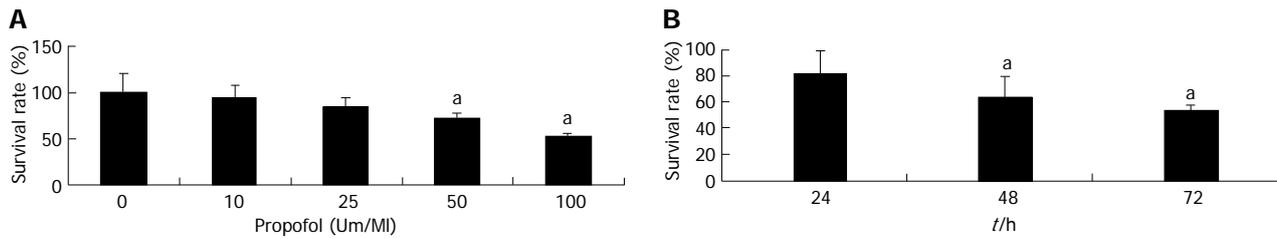

Figure 1 Evaluation by 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide assay of pancreatic cancer MIA-PaCa-2 cell viability after propofol pretreatment. A: Cells were either untreated or treated with 10-100  $\mu\text{mol/mL}$  propofol for 72 h; B: Cells treated with 100  $\mu\text{mol/mL}$  propofol for 24, 48, or 72 h. <sup>a</sup> $P < 0.05$  vs control group.

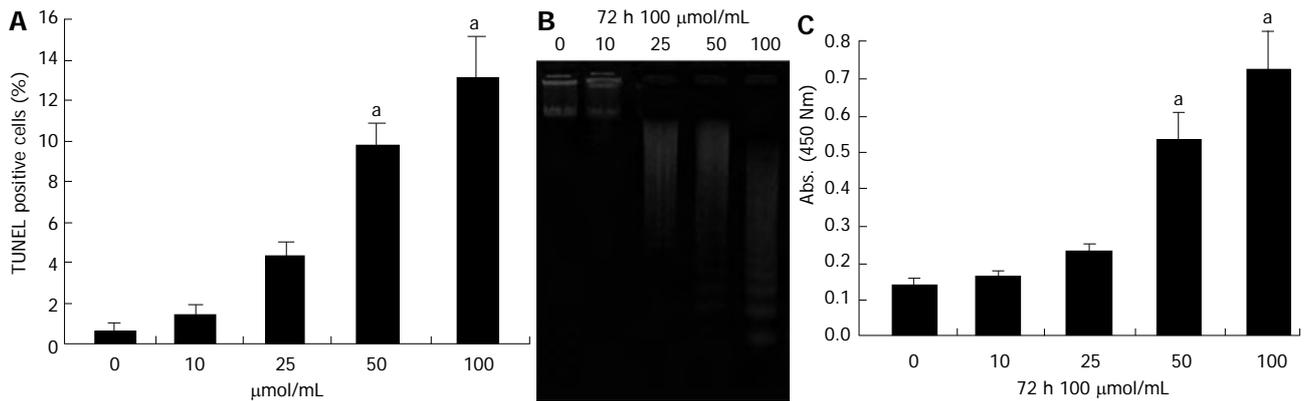

Figure 2 Evaluation of apoptosis of pancreatic cancer MIA-PaCa-2 cells after propofol treatment using terminal transferase dUTP nick-end labeling, DNA ladder and enzyme-linked immunosorbent assays. A: Propofol-induced apoptotic cell death by terminal transferase dUTP nick-end labeling (TUNEL) after 72 h of 10-100  $\mu\text{mol/L}$  propofol; B: DNA ladder indicative of apoptosis in pancreatic cancer cells treated with 10-100  $\mu\text{mol/mL}$  propofol for 72 h. C: Propofol-induced apoptosis measured by enzyme-linked immunosorbent assay after 72 h of 10-100  $\mu\text{mol/L}$  propofol. <sup>a</sup> $P < 0.05$  vs control group.

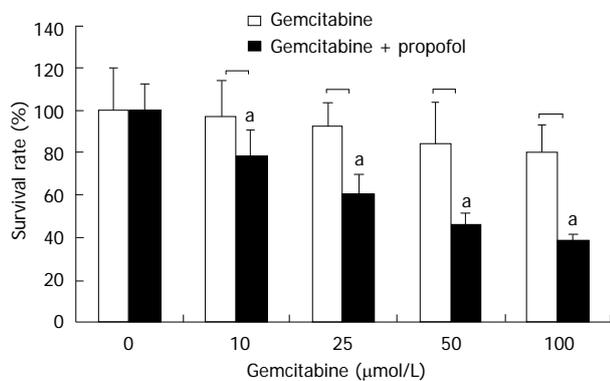

Figure 3 Cell viability by 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide assay of pancreatic cancer MIA-PaCa-2 cells after propofol pretreatment. MIA-PaCa-2 cells pretreated with propofol (50  $\mu\text{mol/mL}$ ) for 24 h followed by cocubation with gemcitabine (10, 25, 50 and 100  $\mu\text{mol/L}$ ) for 72 h were analyzed for viable cells by 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide. Viable cells were evaluated relative to gemcitabine-treated controls and interpreted as % viable cells. Data are averages of four to five independent experiments. <sup>a</sup> $P < 0.05$  vs control group.

assays gave the same results as TUNEL assays.

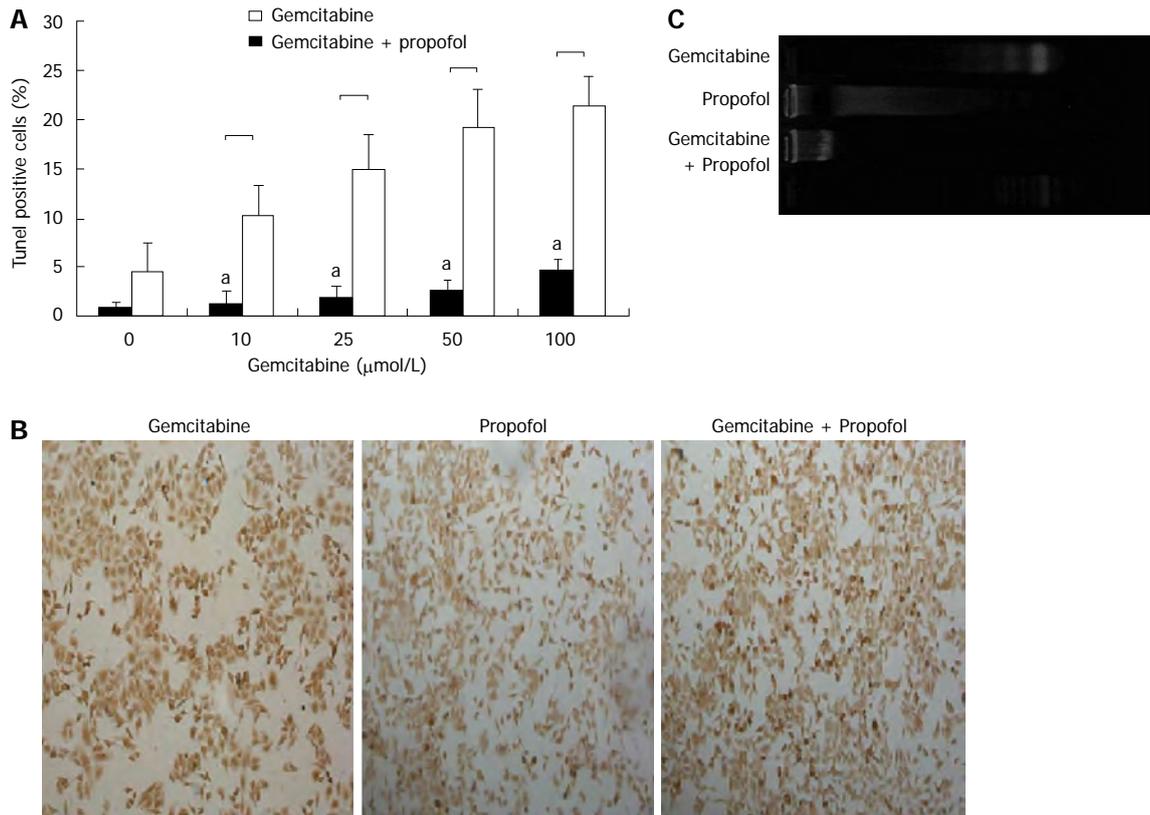

### Propofol potentiates growth inhibition by gemcitabine in MIA-PaCa-2 cells

MIA-PaCa-2 cells are resistant to gemcitabine treatment. We found that gemcitabine treatment did not result in

obvious MIA-PaCa-2 growth inhibition (Figure 3). We assessed the effect on cell viability of pretreatment and cotreatment of propofol and gemcitabine by MTT assay. Cells were pretreated with propofol (50  $\mu\text{mol/mL}$ ) alone or in combination with a single dose of gemcitabine (10, 25, 50 and 100  $\mu\text{mol/L}$ ), and viable cells were evaluated by MTT assay 72 h after treatment. Doses were chosen based upon a preliminary dose escalation study (data not shown). Treatment of MIA-PaCa-2 cells with a single dose of gemcitabine (10, 25, 50 and 100  $\mu\text{mol/L}$ ) for 72 h resulted in only 6% to 18% loss of viability. However, pretreatment with propofol for 24 h followed by treatment with gemcitabine resulted in 24% to 75% loss of viable MIA-PaCa-2 cells (Figure 3). These results suggested that the combination of propofol with low therapeutic doses of gemcitabine elicited significantly greater inhibition of cancer cell growth compared with either agent alone. This suggested that lower toxic side effects are likely to occur in normal cells. Inhibition of cell growth and viability as assessed by MTT assay might be due to the induction of apoptosis by propofol and gemcitabine. We therefore investigated whether gemcitabine in combination with propofol induced more apoptosis than either agent alone.

### Propofol sensitizes MIA-PaCa-2 cells to apoptosis induced by gemcitabine

By TUNEL analysis, treatment of MIA-PaCa-2 cells with

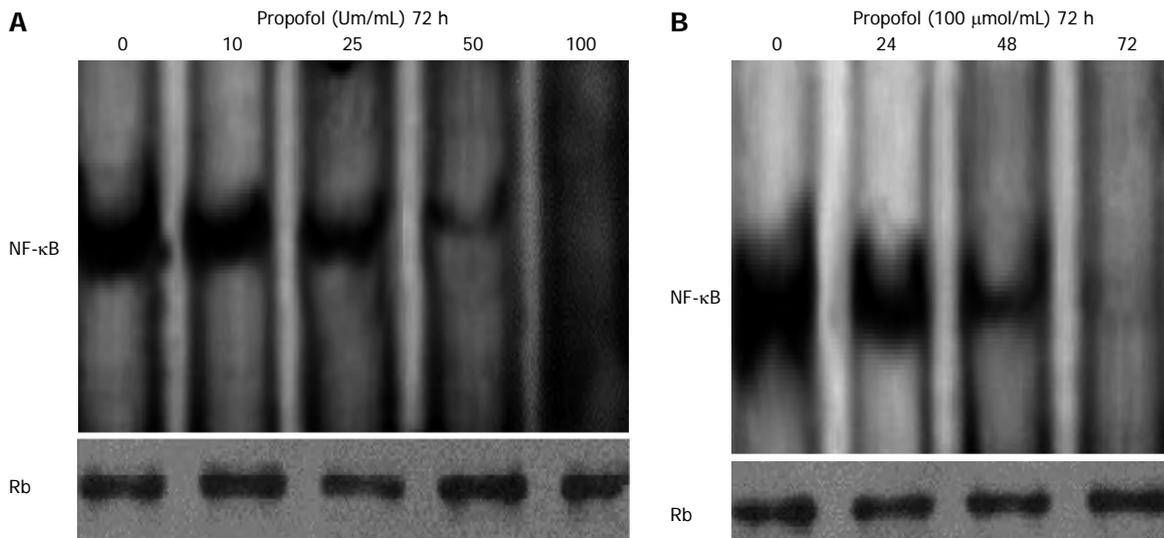

**Figure 4** Evaluation of apoptosis by terminal transferase dUTP nick-end labeling and DNA ladder assays in pancreatic cancer MIA-PaCa-2 cells after propofol pretreatment. **A:** Sensitization of pancreatic tumor MIA-PaCa-2 cells to propofol- and/or gemcitabine-induced apoptosis measured by terminal transferase dUTP nick-end labeling (TUNEL) assay after 24 h of pretreatment with propofol (50 μmol/mL), gemcitabine (0-100 μmol/L), or propofol and gemcitabine combined for 72 h. Increased apoptosis was evident in the combination treatment group relative to individual treatment groups. <sup>a</sup>*P* < 0.05 vs propofol and gemcitabine combined group; **B:** Representative TUNEL image of MIA-PaCa-2 cells pretreated with propofol (50 μmol/mL) for 24 h followed by coincubation with gemcitabine (50 μmol/L) for 72 h; **C:** Representative DNA ladder image of MIA-PaCa-2 cells pretreated with propofol (50 μmol/mL) for 24 h followed by coincubation with gemcitabine (50 μmol/L) for 72 h.

propofol (25 μmol/mL) for 72 h resulted in only 4.6% apoptosis (Figure 2 A), and treatment with 10, 25, 50 and 100 μmol/L gemcitabine) for 72 h resulted in 1.2% to 4.6% apoptosis (Figure 4A). Only low levels of apoptosis were detected with single-agent treatment. Figure 4B has representative TUNEL data of MIA-PaCa-2 cells pretreated with propofol (50 μmol/mL) for 24 h followed by coincubation with gemcitabine (25 μmol/L) for 72 h. Apoptosis measured by ELISA and DNA ladder assays gave the same results (data not shown). Figure 4C has Representative DNA ladder assay data of MIA-PaCa-2 cells pretreated with propofol (50 μmol/mL) for 24 h followed by coincubation with gemcitabine (25 μmol/L) for 72 h.

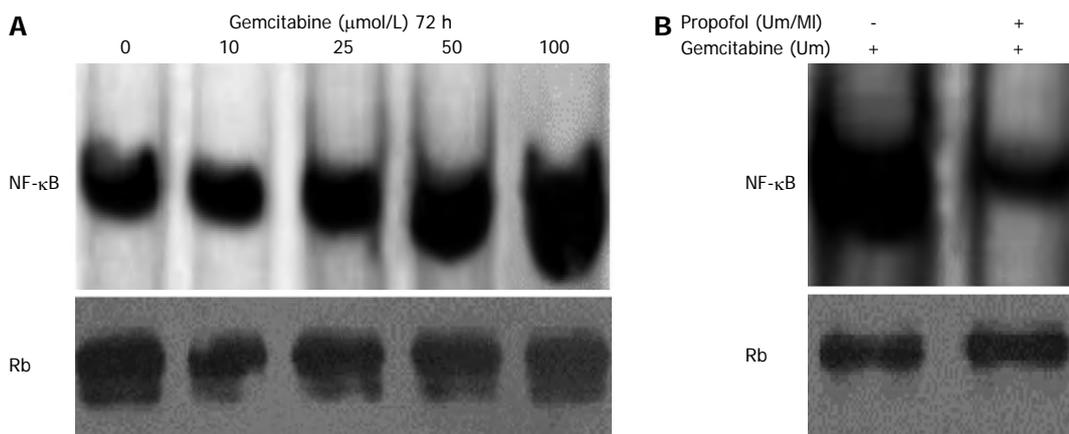

MIA-PaCa-2 cells pretreated with propofol (25 μmol/mL) for 24 h, followed by coincubation with gemcitabine (10, 25, 50 and 100 μmol/L) for 72 h, showed significant cell apoptosis by DNA ladder, TUNEL assay and ELISA assay. These results were consistent with the growth inhibition MTT assays, and suggested that loss of viable cells by propofol and gemcitabine was partly due to the induction of apoptosis.

#### Propofol inhibits NF-κB DNA-binding activity

Consistent with earlier reports, constitutively active NF-κB DNA-binding activity was found in nuclear extracts from MIA-PaCa-2 cells. Band specificity was confirmed by supershift. Based on reports indicating the potential of propofol to abrogate constitutive and inducible NF-κB in halothane-induced rat liver<sup>[23]</sup>, we analyzed whether propofol abrogated basal constitutive activation of NF-κB in MIA-PaCa-2 cells. To evaluate the effect of propofol in MIA-PaCa-2 cells, semiconfluent cells were treated with 0, 10, 25, 50 or 100 μmol/mL propofol for 72 h. As shown in Figure 5A, incubation with 50 μmol/mL propofol for 72 h resulted in a significant decrease in NF-κB DNA-binding activity in the MIA-PaCa-2 cells, and incubation with 100 μmol/mL propofol for 72 h resulted in complete disappearance of the activity. MIA-PaCa-2 cells treated with 100 μmol/L propofol for 24-72 h resulted in gradually reduced NF-κB DNA-binding activity (Figure 5B). These results clearly suggested that propofol was effective at downregulating NF-κB DNA-binding activity. We found no alterations in the nuclear protein content of retinoblastoma, which was used as protein loading control.

**Figure 5** Propofol inhibits constitutively active nuclear factor-κB in MIA-PaCa-2 cells. A: MIA-PaCa-2 cells were treated with 0, 10, 25, 50, or 100 μmol/mL propofol for 72 h and nuclear extracts were probed for nuclear factor-κB (NF-κB) binding to a DNA consensus sequence. Results of NF-κB DNA-binding activity by electrophoretic mobility shift assay (EMSA); B: MIA-PaCa-2 cells were treated with 100 μmol/mL propofol for 24, 48, or 72 h and nuclear extracts were probed for NF-κB binding to a DNA consensus sequence. Results of NF-κB DNA-binding activity by EMSA. Retinoblastoma protein in the nuclear extract was used as a loading control.

**Figure 6** Propofol abrogates gemcitabine-induced nuclear factor-κB in MIA-PaCa-2 cells. A: MIA-PaCa-2 cells were exposed to 10-100 μmol/L gemcitabine for 72 h. Nuclear extracts were analyzed by electrophoretic mobility shift assay (EMSA); B: Propofol abrogated gemcitabine induced nuclear factor-κB (NF-κB) in MIA-PaCa-2 cells exposed to 100 μmol/mL propofol for 24 h followed by incubation with 100 μmol/L gemcitabine. Nuclear extracts were harvested at 72 h and analyzed by EMSA. Propofol pretreatment downregulated gemcitabine-induced NF-κB with 100 μmol/L gemcitabine.

**Propofol abrogates NF-κB activation induced by gemcitabine**

Next, we analyzed whether gemcitabine induced NF-κB DNA-binding activity and whether inactivation of NF-κB by propofol abrogated the chemoresistant phenotype of MIA-PaCa-2 cells, resulting in more pronounced gemcitabine-induced apoptosis. First, we analyzed dose and time responses to gemcitabine by induction of NF-κB in MIA-PaCa-2 cells. Nuclear extracts were prepared from MIA-PaCa-2 cells treated with 10, 25, 50 or 100 μmol/L gemcitabine for up to 72 h and analyzed for NF-κB DNA-binding activity by EMSA. Our results showed dose escalation of gemcitabine, with significant upregulation of constitutive NF-κB DNA-binding activity after gemcitabine treatment (Figure 6A). Pretreatment of cells with 100 μmol/mL propofol for 24 h abrogated

gemcitabine-induced activation of NF-κB DNA-binding activity (Figure 6B). These results showed that propofol downregulates NF-κB DNA-binding activity in unstimulated conditions and inhibits gemcitabine-induced NF-κB activity. This might be the molecular mechanism of gemcitabine-induced cell death in propofol-pretreated cells.

**DISCUSSION**

Despite rapid advances in diagnostic and operative techniques, pancreatic cancer remains one of the most difficult human malignancies to treat. This is partly due to the advanced stage of the disease and *de novo* chemoresistant behavior towards cytotoxic chemotherapeutic agents and/or radiotherapy. In recent years, this problem has been addressed by a combinatorial approach. Several

randomized studies have shown a significant increase in patient response rates when different classes of chemotherapeutic agents are used in combination. However, a major problem is high treatment-associated toxicity with no added benefit in significant overall survival<sup>[24-26]</sup>. The FOLFIRINOX regimen (bolus and infusional 5-fluorouracil, leucovorin, irinotecan, and oxaliplatin) is a new option for patients with metastatic pancreatic cancer and has good performance. Compared with gemcitabine, FOLFIRINOX was associated with a survival advantage, but had increased toxicity<sup>[27]</sup>. These limitations could be overcome by rational chemotherapeutic combinations in which toxic agents are used in lower doses, and treatment efficacy is increased by use of a nontoxic agent with a different mechanism of action.

Propofol is a fairly new induction agent introduced in the 1980s. Animal studies have demonstrated the neuroprotective ability of propofol. Recent studies of propofol effects during global cerebral ischemia-reperfusion injury in rats (4-vessel occlusion) concluded that propofol inhibited neuronal death induced by brain ischemia<sup>[10,14,28]</sup>. Propofol is also a glutamate antagonist at the NMDA-receptor level and a calcium-channel antagonist<sup>[29]</sup>, has GABAergic activity and antioxidant properties<sup>[29]</sup>, and reduces excitotoxicity<sup>[30]</sup>. Increasing evidence suggests that propofol has anticancer properties<sup>[17-20]</sup>.

In this study, we used propofol in combination with a commonly used chemotherapeutic agent, gemcitabine, and tested its efficacy against the pancreatic cancer cell line MIA-PaCa-2. This preclinical study documented that sensitization of cancer cells was achieved by propofol during gemcitabine-induced killing, as shown by more pronounced cell death compared with single-agent treatment. We found that propofol pretreatment significantly enhanced tumor cell killing compared with either agent alone. This observation is important because 75% growth inhibition could be achieved using the same doses of gemcitabine that produced only 18% growth inhibition when gemcitabine was used alone. Consistent with the previously observed apoptotic effect of propofol, we showed that propofol alone not only significantly promoted pancreatic cancer MIA-PaCa-2 cell death and apoptosis, but also promoted gemcitabine-induced apoptosis as determined by MTT, ELISA, TUNEL staining and DNA ladder assays. In addition, we found for the first time that propofol inhibited the NF- $\kappa$ B activity in the MIA-PaCa-2 cells as demonstrated by EMSA assay. Together, these observations suggested that propofol strongly sensitized pancreatic cancer cells to gemcitabine-induced apoptosis.

Our results also showed that gemcitabine alone activated NF- $\kappa$ B, resulting in reduced apoptosis. This supported the model that NF- $\kappa$ B activation inhibits apoptosis. In addition, our *in vitro* results showed that propofol alone or propofol pretreatment followed by gemcitabine treatment abrogated NF- $\kappa$ B activation and increased the apoptotic index, suggesting that inhibition of NF- $\kappa$ B is mechanistically associated with sensitization of pancreatic cancer cells to apoptosis.

In conclusion, our findings are consistent with the hypothesis that chemosensitivity of pancreatic cancer cells is enhanced by pretreatment with propofol and that this effect is mediated by inactivation of NF- $\kappa$ B DNA-binding activity leading to apoptosis. Although in clinical practice the use of propofol in combination with gemcitabine might not result in this enhancement, our findings provide a new insight into propofol in cancer treatment. Our results suggest that propofol can be an anesthetic agent that reduces pain and might also be important in inhibiting the growth of pancreatic cancer cells in pancreatic cancer therapy.

## COMMENTS

### Background

Propofol is a popular agent for anesthesia and long-term sedation. Recently, propofol was found to be effective at inducing apoptosis and possibly contributing to anti-tumor activity.

### Research frontiers

Propofol was found to effectively induce apoptosis and possibly contribute to anti-tumor activity. Research is needed on whether propofol might inhibit growth, promote apoptosis, and increase gemcitabine sensitivity in pancreatic cancer cells.

### Innovations and breakthroughs

Propofol has anticancer properties. The combination of propofol and docosahexaenoate or propofol and eicosapentaenoate might significantly induce apoptosis and inhibit cell adhesion and migration in breast cancer cells. The results of this study show that pretreatment of cells with propofol for 24 h followed by gemcitabine resulted in 24%-75% growth inhibition compared with 6%-18% for gemcitabine used alone. Overall growth inhibition was directly correlated with apoptosis. The authors also showed that propofol potentiated gemcitabine-induced killing by downregulation of nuclear factor- $\kappa$ B (NF- $\kappa$ B). In contrast, NF- $\kappa$ B was upregulated when pancreatic cancer cells were exposed to gemcitabine alone, suggesting a potential mechanism of acquired chemoresistance.

### Applications

This study suggests that inactivation of the NF- $\kappa$ B signaling pathway by propofol could abrogate gemcitabine-induced activation of NF- $\kappa$ B, resulting in the chemosensitization of pancreatic tumors to gemcitabine.

### Terminology

Propofol is an intravenous anesthetic used to induce and maintain anesthesia, and to sedate and calm patients in intensive care units.

### Peer review

In this experimental study, the authors show that propofol induces apoptosis and increases *in vitro* gemcitabine sensitivity in pancreatic cancer cells by inhibition of NF- $\kappa$ B activity. The manuscript is interesting.

### Abstract

**AIM:** To compare the bowel cleansing efficacy, tolerability and acceptability of split 2-L polyethylene glycol (PEG)-citrate-simethicone (PEG-CS) plus bisacodyl (BIS) vs 4-L PEG for fecal occult blood test-positive screening colonoscopy.

**METHODS:** This was a randomised, observer-blind comparative study. Two hundred and sixty-four subjects underwent screening colonoscopy (mean age  $62.5 \pm 7.4$  years, male 61.7%). The primary objective of the study was to compare the bowel cleansing efficacy of the two preparations. Interventions: BIS plus PEG-CS: 3 tablets of 5-mg BIS at 16:00, PEG-CS 1-L at 19:00 and 1-L at 7:00, 4-L PEG: 3-L at 17:00, and 1-L at 7:00. Colonoscopy was carried out after 11:00, at least 3 h after the completion of bowel preparation. Bowel cleansing was evaluated using the Harefield Cleansing Scale.

**RESULTS:** Bowel preparation was successful for 92.8% of subjects in the PEG-CS group and for 92.1% of subjects in the 4-L PEG (RR = 1.01; 95%CI: 0.94-1.08). BIS + PEG-CS was better tolerated than 4-L PEG. A

greater rate of patients in the BIS + PEG-CS group had no difficulty and/or were willing to repeat the same preparation compared to split-dose 4-L PEG group. Subjects in the BIS + PEG-CS group rated the prep as good or satisfactory in 90.6% as compared to 77% in the 4-L PEG ( $P = 0.003$ ). Subjects receiving BIS + PEG-CS stated they fully adhered to instructions drinking all the 2-L solution in 97.1% compared with 87.3% in the 4-L PEG ( $P = 0.003$ ).

**CONCLUSION:** BIS plus split 2-L PEG-CS was as effective as but better tolerated and accepted than split 4-L PEG for screening colonoscopy. This new procedure may increase the positive attitude and participation to colorectal cancer screening colonoscopy.

**Key words:** Colonoscopy; Colon cleansing; Bowel preparations; Polyethylene glycol; Simethicone; Bisacodyl

**Core tip:** Colorectal cancer ranks as the most common newly-diagnosed cancer in Europe and the second most common cause of cancer death in Europe. A new colon cleansing procedure based on bisacodyl plus polyethylene glycol (PEG) with citrates and simethicone administered as split dose has the same efficacy but superior tolerability and acceptance to split conventional 4-L PEG. This new procedure may increase the positive attitude and participation to colorectal cancer screening colonoscopy.

Valiante F, Bellumat A, De Bona M, De Boni M. Bisacodyl plus split 2-L polyethylene glycol-citrate-simethicone improves quality of bowel preparation before screening colonoscopy. *World J Gastroenterol* 2013; 19(33): 5493-5499 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i33/5493.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i33.5493>

## INTRODUCTION

Colorectal cancer (CRC) ranks as the most common newly-diagnosed cancer in Europe and the second most common cause of cancer death in Europe<sup>[1]</sup>. Screening for early detection and removal of premalignant adenomas or localized cancer is crucial to reduce morbidity and mortality associated with CRC<sup>[2,3]</sup>. Colonoscopy is the current gold standard when non-invasive methods are positive (*i.e.*, faecal occult blood test, FOBT) in colorectal cancer population screening programs (> 50 years in Italy) and is also recommended and used as a primary screening modality<sup>[4,5]</sup>. The success of colonoscopy is largely dependent on the level of bowel cleansing<sup>[6]</sup>. Adequate visualization of the colonic mucosa requires a clean colon with no solid or residual brown liquid that could mask a potential lesion. It has been demonstrated that inadequate bowel preparation is associated with lower adenoma detection rates, incomplete colonoscopy or more technically difficult procedure<sup>[7-10]</sup>. A major concern is that detection of lesions in the right colon can be missed due to inadequate bowel preparation<sup>[11]</sup>. The quality of bowel preparation depends on the compliance of the patient, the type of bowel preparation and the timing of ingestion<sup>[12]</sup>.

Polyethylene glycol (PEG) solutions are widely used as they are safe and effective. However the large volume (4 L) to be taken may be a considerable burden for the patient. In clinical practice the reduced tolerability due to large volume and salty taste of PEG solutions may lead to low adherence to the instructions by patients, they drink less than the correct amount with the result of sub-optimal efficacy<sup>[13]</sup>.

Different low-volume formulations have been used such as sodium phosphate and magnesium citrates. They appear to be better tolerated but these solutions should be used with caution in frail patients or patients with renal failure as they can induce dehydration or electrolyte imbalance<sup>[11]</sup>. A more recent option is the addition of ascorbates to the PEG solution or the use of bisacodyl (BIS) for low-volume bowel preparation<sup>[14,15]</sup>.

Also timing and dose administration improve the overall performance and acceptance of bowel preparation<sup>[16,17]</sup>. A split dose regimen, in which the first half dose is taken on the day before and the second half dose on the day of procedure have been shown to be more effective for colon cleansing than single full dose administration on the day before. The split dosing rule appears to be valid for any type of bowel preparation<sup>[18-21]</sup>. A new iso-osmotic sulphate-free PEG electrolyte preparation with citrate and simethicone (PEG-CS) is commercially available to be used with BIS tablets to achieve optimal colon cleansing with threefold mechanism of action<sup>[22,23]</sup>. BIS has a stimulant effect on the colonic motility, while PEG and citrates act as osmotic agents and simethicone favors the foam coalescence improving mucosal visibility<sup>[24-27]</sup>. We therefore compared the efficacy, tolerability and compliance of the new low volume procedure with BIS plus PEG-CS solution versus standard 4-L PEG in

patients undergoing screening colonoscopy.

## MATERIALS AND METHODS

### Subjects selection

Eligible subjects were those referred to colonoscopy as a second level examination following positive FOBT or as a follow-up for adenomatous polyps in the CRC screening promoted by the Veneto region, from December 2009 to January 2011.

Subjects were excluded if they had a history of hypersensitivity to PEG or any other ingredient of products used in the study and other labeled contraindications of the commercially available products.

### Ethical considerations

This study was conducted according to the principles of the Declaration of Helsinki after obtaining approval from the Institutional Review Board. Written informed consent was obtained from each subject.

### Study preparations

All patients were instructed to follow a low-fiber diet for the three days preceding colonoscopy and to drink only clear fluids after starting the bowel preparation.

PEG-CS is an iso-osmotic low volume sulphate-free bowel preparation consisting of PEG 4000, citric acid, sodium citrate, sodium chloride, potassium chloride, simethicone and flavoring agents supplied in four 64.5 g sachets (Lovol-esse, Promefarm). The powder for oral solution must be dissolved in 500 mL of water. This product is combined with BIS 5-mg tablets (Lovoldyl, Promefarm) for full bowel preparation before colonoscopy. In this study, a split dose regimen was used: BIS 15 mg at 16:00 and PEG-CS 1 L at 19:00 the day before. On the day of colonoscopy, PEG-CS 1 L at 7:00 for colonoscopy after 11:00.

The reference preparation was standard PEG electrolyte solution (Isocolan, Bracco), given as split dosing, *i.e.*, 3 L at 17:00 and 1 L at 7:00 for colonoscopy after 11:00 (Table 1).

### Study design

This was a randomised comparative investigator-blind study including consecutive outpatients undergoing screening or follow-up colonoscopy at the Department of Gastroenterology and Digestive Endoscopy at Santa Maria del Prato Hospital in Feltre (Belluno, Italy).

At the time of registration, subjects were randomly allocated in a 1:1 ratio to receive PEG-CS plus BIS or the standard PEG 4-L. Randomization was computer-generated; eligible patients were sequentially numbered and received the corresponding preparation by a nurse in order to ensure adequate concealment.

Study medications were supplied to subjects using the commercially available preparations. Study investigators were kept blinded to study medications and subjects were asked not to reveal the preparation used.

**Table 1** Characteristics of the two polyethylene glycol bowel preparations

	PEG-CS	4-L PEG
Active ingredients	Bisacodyl, PEG, citrates, simethicone	PEG, sodium sulphate
Product description	4 sachets; each containing PEG 4000 60.7 g, sodium citrate 1.066 g, citric acid 1.25 g, simethicone 80 mg	8 sachets; each containing PEG 4000 29.5 g and sodium sulphate 2.843 g
Total volume	2-L	4-L
Electrolytes	Sodium chloride, potassium chloride	Sodium bicarbonate, sodium chloride, potassium chloride
Osmolality (mOsmol/kg)	293	288
Mixed with	Water	Water
Diet prior to colonoscopy	Clear liquid after starting solution intake	Clear liquid after starting solution intake
Timing of intake	1-L of solution at 19:00 the day prior to procedure 1-L of solution at 7:00 the day of the exam	3-L of solution at 17:00 the day prior to procedure 1-L of solution at 7:00 the day of the exam
Additional agents	15 mg bisacodyl (3 tablets) at 16.00 the day prior to procedure	

PEG: Polyethylene glycol; PEG-CS: PEG with citrates and simethicone.

Subjects visited the departments on 2 occasions: enrolment (randomization) and on the day of colonoscopy.

Medical history including concomitant medications, physical examination and vital signs were taken at baseline and on the day of colonoscopy. Subjects received oral and written instructions on the use of the bowel preparation including dietary advice consisting of a 3-d low-fibre diet followed by clear liquids on the day before colonoscopy.

Safety evaluation was based on reporting of adverse events and adverse drug reactions using a standard questionnaire during the visit before colonoscopy.

On the day of colonoscopy the patients were asked to fill a further questionnaire to provide information about whether or not they experienced gastrointestinal (GI) symptoms such as nausea, bloating, and abdominal discomfort, the amount of solution actually taken, difficulty to complete the preparation (3-point scale), taste (3-point scale), willingness to repeat the same preparation in the future (yes or no).

Bowel preparation was evaluated using a 5-point bowel cleansing rating scale for each colonic segment (caecum/ascending colon, transverse, descending and sigmoid colon, rectum)<sup>[12]</sup>. The overall quality of cleansing was based on the assessment of the individual segments using the grade A = all segment clean (*i.e.*, scores of 3 or 4 in all segments); B = brown liquid or removable semi-solid residue (*i.e.*, score of 2) in 1 or more segments; C = semi-solid only partially removable in at least one segment (*i.e.*, score of 1); D = presence of solid stool that can not be removed (*i.e.*, score of 0). In case of D the exam has to be repeated.

Although we used a validated rating scale, the degree

of cleansing remains a matter of personal judgment. In order to minimize this potential issue, four experienced endoscopists (> 5000 procedures in their career) participated in this study after training with the same rating scale by using a set of endophotographs of different segments with various degrees of cleansing.

In the primary analysis, successful bowel cleansing was considered as overall cleansing score equal to A or B. The primary objective of the study was to compare the degree of cleansing of the bowel preparations. It was also assumed that the low volume prep might improve tolerability and acceptability.

### Statistical analysis

The study was designed as a non-inferiority study and sample size was based on an expected rate of successful bowel cleansing of 80% for both groups. Based on practical considerations, the non-inferiority limit was specified as 15%. In order to reach a 80% statistical power with a significant level of 5%, and taking into account a drop-out rate of 10%, no less than 136 patients were needed in each arm.

## RESULTS

Overall, 280 patients were randomly allocated to receive BIS plus PEG-CS ( $n = 140$ ) or standard 4-L PEG ( $n = 140$ ). Colonoscopy data were not available for sixteen patients who did not show up and no information was available with regard to bowel preparation. Therefore 264 patients were included in the analysis of the primary outcome (138 in the PEG-CS and 126 in the 4-L PEG) (Figure 1).

Comparison of demographic characteristics at baseline show no significant differences between the two treatment groups [PEG-CS: male 59.4%; age  $63.6 \pm 7.1$  years; body mass index (BMI)  $27.3 \text{ kg/m}^2$ ; 4-L PEG: male 64.3%; age  $61.3 \pm 7.7$  years; BMI  $27.7 \pm 4.5 \text{ kg/m}^2$ ].

Bowel preparation was successful (grade A + B) for 92.8% of subjects in the PEG-CS group and for 92.1% of subjects in the 4-L PEG (RR = 1.01; 95%CI: 0.94-1.08) (Table 2). There was no statistical difference with regard to the primary outcome of the study also for the grade A alone between the two groups. Bowel cleansing scores according to colonic segment are shown in Table 3. The rates of excellent score were higher for 4-L PEG in the caecum/ascending colon ( $P < 0.02$ ) and in the sigmoid colon ( $P < 0.02$ ) compared with PEG-CS.

A numerically higher number of polyps was observed both in the right and left colon for PEG-CS than 4-L PEG though no statistical difference was found between groups. No adverse events were reported in the study.

The rate of patients with bloating or any GI volume-related symptoms was significantly lower following 2-L PEG-CS + BIS than 4-L PEG (Table 2).

A greater rate of patients in the PEG-CS + BIS had no difficulty and/or were willing to repeat the same preparation than split-dose 4-L PEG. Subjects in the PEG-CS group rated the prep as good or satisfactory in 90.6% as

**Table 2 Primary efficacy and other endpoints *n* (%)**

Outcome	BIS + 2-L PEG-CS ( <i>n</i> = 138)	4-L PEG ( <i>n</i> = 126)	<i>P</i> value
Bowel cleansing			
A (all segments as excellent or good)	107 (77.5)	105 (83.3)	NS
B (at least one segment as fair)	21 (15.2)	11 (8.7)	
C (at least one segment as poor)	7 (5.1)	8 (6.3)	
D (exam not completed)	3 (2.2)	2 (1.6)	
Successful (A + B)	128 (92.8)	116 (92.1)	NS
Unsuccessful (C + D)	10 (7.2)	10 (7.9)	
Tolerability			
Nausea	27 (19.6)	26 (20.6)	0.575
Bloating	11 (8.0)	33 (26.2)	< 0.001
Abdominal discomfort	13 (9.4)	5 (4.0)	0.079
Overall (any of previous ones)	45 (32.6)	57 (45.2)	0.035
Acceptance			
Good	70 (50.7)	30 (23.8)	< 0.001
Satisfactory	55 (39.9)	67 (53.2)	
Not acceptable	13 (9.4)	22 (23.0)	
Compliance			
100% of solution drunk	134 (97.1)	110 (87.3)	0.010
75% of solution drunk	4 (2.9)	15 (11.9)	
50% or less of solution drunk	0 (0.0)	1 (0.8)	

PEG: Polyethylene glycol; PEG-CS: PEG with citrates and simethicone; BIS: Bisacodyl.

compared to 77% in the 4-L PEG,  $P < 0.01$ ) (Table 2).

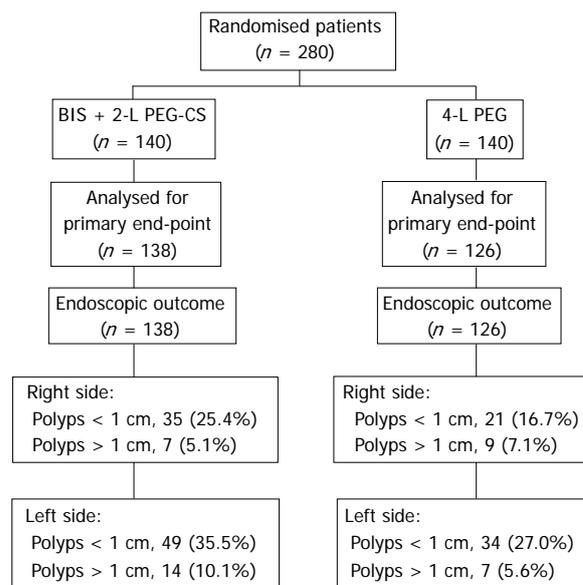

Subjects receiving PEG-CS stated they fully adhered to instructions drinking all the 2-L solution in 97.1% compared with 87.3% in the 4-L PEG ( $P < 0.01$ ) (Table 2).

## DISCUSSION

This study shows that a new isosmotic 2-L PEG formulation with citrate and simethicone plus BIS tablets was as effective as split 4-L PEG and electrolytes for bowel cleansing in subjects undergoing FOBT-positive screening colonoscopy. The low-volume formulation was associated with better tolerability, acceptability and compliance to instructions received for bowel preparation. Complete bowel preparation is an important component to ensure high quality in colonoscopy and minimize the risk of missing polyps and lesions<sup>[9,28]</sup>. Current PEG-based bowel preparations are safe but inadequate bowel preparation is common with about 25% of patients with inadequate colon cleansing and about 4%-5% of patients who have to repeat colonoscopy<sup>[7,8]</sup>. However the large volume of fluids, salty taste and difficulty to complete the preparation remain a deterrent for patients undergoing colonoscopy and to a greater extent for asymptomatic subjects invited to a screening CRC program.

Efforts have been made by the pharmaceutical industry to satisfy the need to reduce the burden and make PEG bowel preparation easier and more acceptable for patients without changing the level of efficacy and safety.

The new procedure based on BIS tablets and split PEG-CS appears to be a valuable option. In our study it provided a level of overall cleansing similar to split 4-L

**Figure 1** Enrolment, randomization and endoscopy outcome. PEG: Polyethylene glycol; PEG-CS: PEG with citrates and simethicone; BIS: Bisacodyl.

PEG. Previous studies have shown that BIS tablets plus 2-L PEG-CS given the day before is equally as effective and safe as 4-L PEG for bowel cleansing before colonoscopy<sup>[22,23]</sup>. There are important differences with earlier trials, regarding the PEG-formulation and the dose regimen.

First, the formulation of the low-volume PEG solution is different from the standard 4-L PEG. PEG-CS is sulphate-free, contains new active ingredients (citric acid, sodium citrate and simethicone) and a higher concentration of PEG per litre of reconstituted solution than the traditional PEG formulation. From our data, there is no clue to determine the relative contribution of BIS tablets or any other ingredient of the bowel preparation for bowel cleansing.

Second, this study compared the split dosing regimen for both the low-volume and reference bowel preparation. According to ACG guidelines, split dose bowel preparation enhances the quality of bowel preparation and therefore is now recommended for all patients undergoing screening or surveillance colonoscopy<sup>[2]</sup>. When a part of the bowel preparation is taken within 4-8 h of colonoscopy, there is a better cleansing of caecum and the ascending colon compared with traditional dosing schedule of the day before. With such regimen the long interval of > 12 h between bowel preparation and colonoscopy allows the flow of intestinal secretion across the ileo-caecum valve and yellow fluid cover mucosa of the right colon. For the full-dose, we have used an unequal split (PEG 3-L the day before and 1-L the day before the same day) which have been shown to be effective but more feasible as it allows to perform colonoscopy shortly in the morning<sup>[29]</sup>.

In our study BIS tablets were taken in the afternoon before, 1 L of PEG-CS was taken in the evening and

**Table 3** Quality of cleansing for each colonic segment

Score	Caecum/ascending colon		Transverse colon		Descending colon		Sigmoid colon		Rectum	
	BIS + 2-L PEG- CS (n = 138)	4-L PEG (n = 126)	BIS + 2-L PEG- CS (n = 138)	4-L PEG (n = 126)	BIS + 2-L PEG- CS (n = 138)	4-L PEG (n = 126)	BIS + 2-L PEG- CS (n = 138)	4-L PEG (n = 126)	BIS + 2-L PEG- CS (n = 138)	4-L PEG (n = 126)
Excellent	37.00%	52.40%	52.20%	57.90%	51.40%	59.50%	45.70%	60.30%	40.60%	51.60%
Good	50.70%	37.30%	38.40%	34.90%	37.00%	31.00%	39.90%	28.60%	43.50%	39.70%
Fair	7.20%	4.00%	5.10%	2.40%	6.50%	5.60%	9.40%	5.60%	12.30%	4.00%
Poor	2.90%	4.80%	2.20%	3.20%	5.10%	3.20%	5.10%	4.80%	3.60%	4.00%

PEG: Polyethylene glycol; PEG-CS: PEG with citrates and simethicone; BIS: Bisacodyl.

1 L in the morning about 4 h before colonoscopy. The important finding of this study is that for the first time a 2-L PEG preparation administered as a split-dose was shown to be as globally effective as 4-L PEG. Although this finding needs to be confirmed in future trials, a better cleansing in the right colon may favor the detection of small or flat lesions which are more likely to remain undetected compared to other sites of the colon<sup>9,10</sup>.

Any new low-volume bowel preparations should also be evaluated on the grounds of safety, tolerability, acceptance and compliance.

PEG-CS is an osmotically balanced PEG solution and therefore it is less likely to induce electrolyte imbalance as compared to bowel preparations based on sodium phosphate, magnesium phosphate or hyperosmotic PEG solutions. Based on vital signs, haemodynamic data and lack of extra-intestinal adverse events, no safety issue was identified in this study for both bowel preparations.

Similarly to standard 4-L PEG no issues of safety, in particular electrolyte imbalance and dehydration are associated with the new formulation.

The new formulation was significantly better tolerated and accepted by patients. A reduced rate of bloating and cumulative volume-related GI symptoms were observed in BIS plus PEG-CS than in the reference group. This is not surprising as a much lower amount of non-absorbable fluid must be taken for each session with PEG-CS (1-L only) than traditional PEG-formulation. The new formulation was also shown to be less difficult to complete, of pleasant taste and patients were more willing to repeat it for future examination. Although split-dosing itself may increase acceptance of bowel preparation, the features of this low-volume colon cleansing procedure improved acceptance, compliance and adherence to bowel preparation instructions.

This low-volume bowel preparation may be a first option for patients who poorly tolerated and accepted large volume bowel preparations for colonoscopy. Better tolerability, acceptance and compliance to bowel preparation may increase the attitude and uptake to screening colonoscopy. This requires a high level of quality as the objective of the examination is to detect even small but potentially dangerous lesions which may progress to cancer.

This single-centre study was carried out in a homogenous group of patients undergoing screening colonos-

copy. It should be noted that the high rate of adequate bowel cleansing in both groups is largely due to the fact the sample group was made of motivated subjects aged between 50 and 69 years who came for a second level examination after being found positive to occult blood. Our finding may have important implication for the general population or elderly people who may have lower levels of motivation to undergo colonoscopy also due to bowel preparation.

There are concerns about ischemic colitis related to BIS. To date, no reports of ischemic colitis were observed in the clinical trials reviewed and in the post-marketing pharmacovigilance according to the manufacturer. A causal relationship between use of BIS for colon cleansing and ischemic colitis remains to be established.

Over the last years the pharmaceutical industry has tried to offer bowel preparations which are better accepted without compromising efficacy and safety. Although further evidence is needed, it seems from our study that an important advance toward optimal and easy bowel preparation has been made.

In conclusion, this study evaluated a new low-volume bowel preparation for FOBt-positive screening colonoscopy. BIS plus PEG-CS was as effective but better tolerated and accepted than split 4-L PEG. Bowel preparation before colonoscopy has for a long time been an issue for our patients. Now progress has been made towards better tolerability, acceptance and compliance of bowel preparation. Reducing the burden for healthy subjects may improve their attitude and maximize the benefits of screening colonoscopy.

## ACKNOWLEDGMENTS

Promefarm provided supply of study medications.

## COMMENTS

### Background

Quality of bowel preparation is essential to identify lesions in the colon. The running time between the last dose of bowel preparation and the exam has been shown to play a key role toward the ideal bowel cleansing.

### Research frontiers

Split dose regimen with a fraction of bowel preparation taken the day of the exam may be an effective approach in clinical practice.

### Innovations and breakthroughs

A new colon cleansing procedure based on bisacodyl (BIS) plus polyethylene glycol (PEG) with citrates and simethicone (PEG-CS) administered as split dose has the same efficacy but superior tolerability and acceptance to split conventional 4-L PEG.

### Applications

The study results suggest that the split dose of the low volume PEG-CS after BIS increases the patient attitude and acceptance to colorectal cancer screening colonoscopy.

### Peer review

This is a well designed and written study that adds to the authors' understanding of optimal bowel preparation regimens.

### Abstract

**AIM:** To evaluate the protective effects of fucoidan on oxidative stress-induced barrier disruption in human intestinal epithelial cells.

**METHODS:** In Caco-2 cell monolayer models, the disruption of barrier function by oxidative stress is mediated by H<sub>2</sub>O<sub>2</sub>. The integrity of polarized Caco-2 cell monolayers was determined by measuring the transepithelial resistance (TER) and permeability was estimated by measuring the paracellular transport of FITC-labeled 4-kDa dextran (FD4). The protective effects of fucoidan on epithelial barrier functions on polarized Caco-2 cell monolayers were evaluated by TER and FD4 flux. The

expression of tight junction (TJ) proteins was assessed using reverse-transcription polymerase chain reaction (RT-PCR) and immunofluorescence staining.

**RESULTS:** Without H<sub>2</sub>O<sub>2</sub> treatment, fucoidan significantly increased the TER compared to control ( $P < 0.05$ ), indicating a direct enhancement of intestinal epithelial barrier function. Next, H<sub>2</sub>O<sub>2</sub> disrupted the epithelial barrier function in a time-dependent manner. Fucoidan prevented the H<sub>2</sub>O<sub>2</sub>-induced destruction in a dose-dependent manner. Fucoidan significantly decreased H<sub>2</sub>O<sub>2</sub>-induced FD4 flux ( $P < 0.01$ ), indicating the prevention of disruption in paracellular permeability. RT-PCR showed that Caco-2 cells endogenously expressed claudin-1 and -2, and occludin and that H<sub>2</sub>O<sub>2</sub> reduced the mRNA expression of these TJ proteins. Treatment with fucoidan attenuated the reduction in the expressions of claudin-1 and claudin-2 but not occludin. Immunofluorescence staining revealed that the expression of claudin-1 was intact and high on the cell surface. H<sub>2</sub>O<sub>2</sub> disrupted the integrity of claudin-1. Treatment with fucoidan dramatically attenuated the expression of claudin-1.

**CONCLUSION:** Fucoidan enhanced intestinal epithelial barrier function by upregulating the expression of claudin-1. Thus, fucoidan may be an appropriate therapy for the treatment of inflammatory bowel diseases.

**Key words:** Fucoidan; Tight junction; Intestinal epithelial cells; Oxidative stress; Inflammatory bowel diseases

**Core tip:** The oxidative stress-induced disruption of the intestinal epithelial cells and subsequent increased paracellular permeability are critically important in the pathogenesis of inflammatory bowel diseases (IBD). A growing body of experimental evidence indicates that fucoidan, a dietary substance of fucose-enriched

sulfated polysaccharides, display a wide variety of pharmacological anti-inflammatory activities. This study demonstrates that fucoidan protected the epithelial barrier function from oxidative injury of the tight junction as well as barrier disruption by upregulating the expression of claudin-1. Thus, fucoidan may be an appropriate therapy for the treatment of IBD.

## INTRODUCTION

Although the gastrointestinal (GI) tract is constantly exposed to bacterial microflora, an excess immune response against the bacterial microflora does not occur in the normal state, as a result of some type of immunological tolerance underlying the GI immune system. However, disruption of this immunological tolerance against intestinal microbial antigens may cause abnormal intestinal inflammation and the development of chronic inflammatory diseases, such as inflammatory bowel diseases (IBD)<sup>[1,2]</sup>. IBD can be classified into two distinct diseases, ulcerative colitis (UC) and Crohn's disease (CD). Although the precise etiology of these diseases remains unclear, several reports have indicated that intestinal microflora is responsible for the pathogenesis of both UC and CD<sup>[3,4]</sup>. Intestinal epithelial cells (IEC) play a role as the first line of defense and act as a functional barrier. IECs separate the host's internal milieu from the external environment. In addition to functioning as a barrier, it has become evident that IECs also play an important role in the maintenance of immune homeostasis<sup>[5]</sup>. IECs produce anti-microbial peptides, such as defensins, and protect the host from the attachment of luminal bacteria<sup>[6]</sup>. Not only do IECs function in a direct bacteriocidal role, but IEC-derived factors can also promote the differentiation of anti-inflammatory types of dendritic cells and macrophages to induce mucosal tolerance against luminal bacteria<sup>[7,8]</sup>. Furthermore, in intestinal inflammation, IECs can produce several chemokines and pro-inflammatory cytokines in response to luminal bacteria to induce the migration of granulocytes, lymphocytes, and dendritic cells, resulting in the induction of host immunity. Thus, IECs function as a defensive frontline of host mucosal immunity. Accordingly, direct epithelial cell damage, induced by mucosal irritants or cytotoxic agents, results in a marked loss of barrier function<sup>[9]</sup>. The epithelial barrier consists of several essential elements, including an intact epithelial monolayer and the tight junction (TJ). The TJ consists of four integral membrane proteins: occludins,

claudins, tricellulin and the junctional adhesion molecule. A large body of evidence indicates that disruption of the TJ and increased paracellular permeability are critically important in the pathogenesis of IBD<sup>[10]</sup>. The oxidative stress-induced opening of the TJ barrier is an important mechanism contributing to the TJ barrier defect present in IBD<sup>[11]</sup>.

Caco-2, a human intestinal epithelial cell line, is the most well studied cell line for investigations of *in vivo* intestinal epithelial barrier integrity and function<sup>[12]</sup>. Hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>), a highly toxic oxidizing agent, is constantly generated within intestinal epithelial cells and must quickly be detoxified by antioxidant enzymes<sup>[13]</sup>. It has been established that H<sub>2</sub>O<sub>2</sub> is involved in oxidative stress-induced cell injury and disrupts intestinal epithelial barrier function, thus leading to enhanced paracellular permeability and the promotion of marked changes in the expression and/or localization of a number of TJ proteins, including claudins and occludins. In Caco-2 cell monolayer models, the disruption of barrier function by oxidative stress is mediated by H<sub>2</sub>O<sub>2</sub><sup>[13]</sup>.

Fucoidan, a dietary substance, represents a class of fucose-enriched sulfated polysaccharides found in the extracellular matrix of brown algae. A growing body of experimental evidence indicates that fucoidans display a wide variety of pharmacological activities, including anti-inflammatory, anti-angiogenic, anti-coagulant, and anti-adhesive effects, in experimental models<sup>[14-16]</sup>. Thus, great interest has been generated in investigating the potential pharmacological effects of fucoidan on H<sub>2</sub>O<sub>2</sub>-induced TJ destruction in IECs.

In this study, we examined the protective effect of fucoidan on H<sub>2</sub>O<sub>2</sub>-induced TJ destruction in human IECs, which may provide a novel approach for the treatment of IBD.

## MATERIALS AND METHODS

### Materials

The brown algae *Cladosiphon okamuranus Tokida* was cultivated in Okinawa, Japan. Purified fucoidan derived from *C. o. Tokida* was provided by Uruma Bio Co. Ltd., (Okinawa, Japan). Fucoidan was dissolved in Dulbecco's Vogt modified Eagle's media (DMEM) (Sigma-Aldrich Co., St. Louis, MO).

### Cell culture

A human intestinal epithelial cell line, Caco-2 cells (RBRC-RCB0988 RIKEN Bio Resource Center, Ibaraki, Japan), were cultured in DMEM supplemented with 10% (v/v) heat-inactivated FBS (Nichirei Biosciences Inc., Tokyo, Japan), 100 U/mL penicillin, 100 µg/mL streptomycin (Life Technologies Gibco, France), and 10 ml GlutaMAX™ (100 ×) (Life Technologies Gibco, France). The cell cultures were incubated on collagen-coated tissue culture plates Transwell® (Corning, New York, NY) in a humidified atmosphere of 5% CO<sub>2</sub> at 37 °C.

### Measurement of transepithelial resistance

The integrity of polarized Caco-2 cell monolayers was determined by measuring the transepithelial resistance (TER), which reflects the tightness of the TJ between epithelial cells<sup>[17,18]</sup>. The TER was measured in  $\Omega\text{cm}^2$  using a Millicell ERS-2 Epithelial Volt-Ohm Meter (Millipore, Bedford, MA). Caco-2 cells were cultured on 24 mm Transwell<sup>®</sup> polycarbonate inserts (0.4  $\mu\text{mol/L}$  pore size) for 14 to 21 d. To examine the direct effect of fucoidan on well-polarized Caco-2 cell monolayers, confluent polarized Caco-2 cell monolayers were incubated in the presence or absence of fucoidan (2.5 mg/mL) in apical medium for 24 h. To evaluate the protective effects of fucoidan on epithelial cell injury, serial doses of fucoidan (0, 0.1, 1.0, or 2.5 mg/mL) were added to the apical medium 30 min prior to the administration of  $\text{H}_2\text{O}_2$  (500  $\mu\text{mol/L}$ ) to the basolateral side of the Transwell<sup>®</sup>. Changes in the TER during the experimental periods were calculated as the percentage of the corresponding basal values. TER of unseeded inserts was subtracted.

### Macromolecular permeability (FITC-dextran flux assay)

Permeability was estimated by measuring the paracellular transport of FITC-labeled 4-kDa dextran (FD4) (Molecular Probes, Netherland). Once the cells were grown to confluence ( $\text{TER} > 350 \Omega\text{cm}^2$ ), sterilized FD4 was added into the apical well at 1 mg/mL.  $\text{H}_2\text{O}_2$  (500  $\mu\text{mol/L}$ ) was administered to the basolateral side of the Transwell<sup>®</sup>. Fucoidan (2.5 mg/mL) was added to the apical medium 30 min prior to  $\text{H}_2\text{O}_2$  administration. After 6 h of incubation, the basolateral medium was collected, and the fluorescence was measured using a fluorescence spectrometer at an excitation of 485 nm and emission of 535 nm. The permeability was expressed as the percentage of fluorescence of the  $\text{H}_2\text{O}_2$ -treated group. Flux of unseeded inserts was subtracted.

### Analysis of tight junction protein mRNA expression using reverse-transcription polymerase chain reaction

Caco-2 cells were cultured for 14 to 21 d. Once grown to confluence ( $\text{TER} > 350 \Omega\text{cm}^2$ ),  $\text{H}_2\text{O}_2$  (500  $\mu\text{mol/L}$ ) was administered to the basolateral side of the Transwell<sup>®</sup>. Fucoidan (2.5 mg/mL) was added to the apical medium 30 min prior to  $\text{H}_2\text{O}_2$  administration. After 24 h of incubation, the cells were harvested, and total RNA was isolated using the RNeasy Mini kit (Qiagen, KJ Venlo, the Netherlands). Isolated RNA was treated with RNase-free DNase I (Qiagen) to prevent any carry-over of genomic DNA. The cDNA was synthesized from 2  $\mu\text{g}$  of total RNA with Quantitect reverse transcriptase (Qiagen). Reverse-transcription polymerase chain reaction (RT-PCR) was performed using a PCR master mix (Takara Biosystems, Foster City, CA). Primers were listed 5'-3' as follows: Claudin-1: F, GCG CGA TAT TTC TTC TTG CAG G; R, TTC GTA CCT GGC ATT GAC TGG. Claudin-2: F, CTC CCT GGC CTG CAT TAT CTC; R, ACC TGC TAC CGC CAC TCT GT. Occludin: F, TCA

GGG AAT ATC CAC CTA TCA CTT CAG; R, CAT CAG CAG CAG CCA TGT ACT CTT CAC.

### Immunofluorescence staining of TJ proteins

Caco-2 cells were cultured for 14 to 21 d on a Lab-Tek chamber plate (Corning).  $\text{H}_2\text{O}_2$  (500  $\mu\text{mol/L}$ ) was administered to the basolateral side of the Transwell<sup>®</sup>. Fucoidan (2.5 mg/mL) was added to the apical medium 30 min prior to  $\text{H}_2\text{O}_2$  treatment. After 6 h of incubation, the cells were washed twice with cold PBS and fixed with cold acetone (Wako Pure Chemical Industries, Osaka, Japan) for 10 min. The cells were then removed from the Transwell<sup>®</sup> and mounted on slides. Next, the cells were incubated with mouse anti-human claudin-1 (Zymed Laboratories, San Francisco, CA) at 4 °C overnight. After washing with PBS, the cells were incubated with Alexa Fluor 488-conjugated secondary antibody (Molecular Probes, Netherland) then subsequently washed in PBS. The immunofluorescence was examined and imaged using fluorescence microscopy (Nikon Eclipse 80i).

### Statistical analysis

Statistical analysis was performed using the GraphPad Prism software program, version 4.0 (GraphPad Software Inc., San Diego, CA). Differences with  $P < 0.05$  were considered significant. All of the data were expressed as the means  $\pm$  SEM.

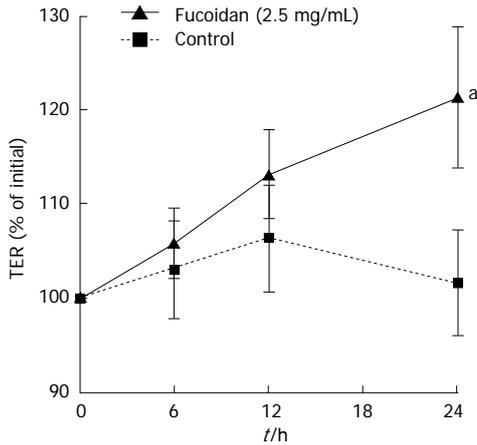

## RESULTS

### Fucoidan directly enhanced intestinal epithelial barrier function

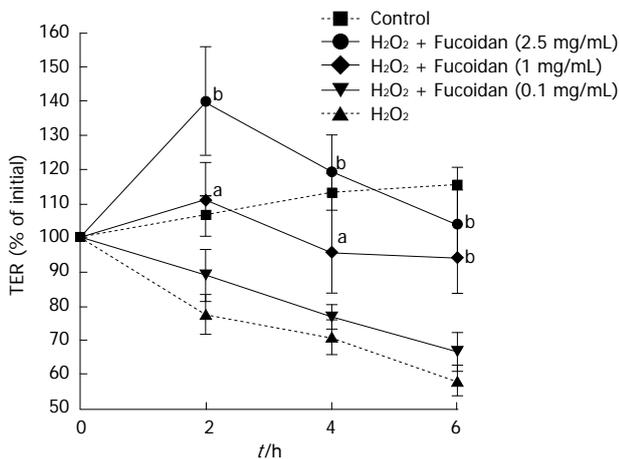

First, we determined the effect of fucoidan on the protective functions of Caco-2 cell monolayers. To determine whether fucoidan directly induced the increase in epithelial resistance or TER was upregulated by the promotion of epithelial cell proliferation, we examined the effect of fucoidan on well-polarized Caco-2 cell monolayers. Completely polarized Caco-2 cell monolayers showed approximately 600  $\Omega\text{cm}^2$  TER. Because polarized Caco-2 cells could not further proliferate, the direct effect of fucoidan on intestinal epithelial barrier functions could be examined. Interestingly, fucoidan significantly increased the TER ( $P < 0.05$  compared with control), indicating an enhancement of intestinal epithelial barrier function (Figure 1).

### Fucoidan prevented $\text{H}_2\text{O}_2$ -induced destruction of intestinal epithelial barrier function in a dose-dependent manner

Next, we focused on the preventive effects of fucoidan on epithelial cell injury. To assess the effect of fucoidan on intestinal epithelial barrier function, completely polarized Caco-2 cell monolayers were injured using  $\text{H}_2\text{O}_2$  (500  $\mu\text{mol/L}$ ).  $\text{H}_2\text{O}_2$  was added into the lower well of the Transwell<sup>®</sup> and changes in intestinal epithelial barrier function were monitored by measuring the TER. As shown in Figure 2,  $\text{H}_2\text{O}_2$  disrupted the epithelial barrier function

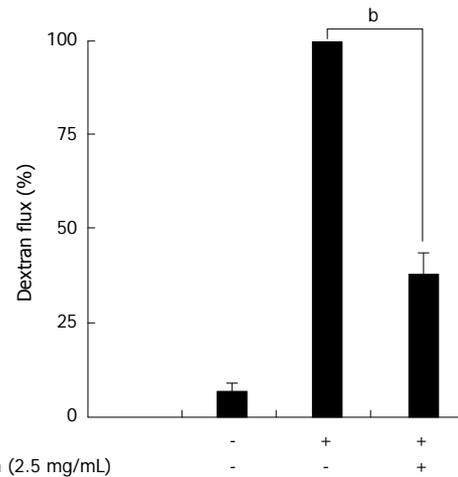

**Figure 1** Fucoidan directly enhanced intestinal epithelial barrier function. Polarized Caco-2 cell monolayers were incubated in the presence or absence of fucoidan (2.5 mg/mL) for 24 h. Changes in intestinal epithelial barrier function were monitored by measuring the trans-epithelial resistance (TER). The data are expressed as the means  $\pm$  SEM of 5 independent experiments. <sup>a</sup> $P < 0.05$  compared with control (Student's *t* test).

**Figure 2** Fucoidan prevented H<sub>2</sub>O<sub>2</sub>-induced destruction of intestinal epithelial barrier function in a dose-dependent manner. Polarized Caco-2 cell monolayers were injured by H<sub>2</sub>O<sub>2</sub> (500  $\mu$ mol/L) on the apical side of Caco-2 cell monolayers. Fucoidan was added into the basolateral side 30 min prior to H<sub>2</sub>O<sub>2</sub> stimulation and cultured for 6 h. Changes in intestinal epithelial barrier function were monitored by measuring the trans-epithelial resistance (TER). The data are expressed as the means  $\pm$  SEM of 5 independent experiments. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  compared with cells exposed to H<sub>2</sub>O<sub>2</sub> alone at respective time point (Tukey's multiple comparison test).

in a time-dependent manner. In contrast, treatment with fucoidan prevented H<sub>2</sub>O<sub>2</sub>-induced intestinal epithelial injury at an early time point ( $P < 0.05$ ,  $P < 0.01$  compared with cells exposed to H<sub>2</sub>O<sub>2</sub> alone at respective time point). However, low dose (0.1 mg/mL) of fucoidan did not protect the intestinal epithelium against H<sub>2</sub>O<sub>2</sub> injury after 4 h of exposure; however, high doses (1 and 2.5 mg/mL) of fucoidan prevented the disruption of the epithelial barrier to some extent even at the late phase. Thus, fucoidan prevented H<sub>2</sub>O<sub>2</sub>-induced destruction of the intestinal epithelial barrier in a dose-dependent manner.

**Figure 3** Fucoidan prevented H<sub>2</sub>O<sub>2</sub>-induced increases in paracellular permeability. First, 0.5 mg/mL 4-kDa FITC-labeled dextrans (FD4) were added into the apical well and cultured for 6 h with or without H<sub>2</sub>O<sub>2</sub> (500  $\mu$ mol/L) and/or fucoidan (2.5 mg/mL). After 6 h of incubation, the basal medium was collected, and the fluorescence was measured as fluxed-FD4. H<sub>2</sub>O<sub>2</sub>-induced FD4 flux was considered 100%. The data are expressed as the means  $\pm$  SEM of 5 independent experiments. <sup>b</sup> $P < 0.01$  (Student's *t* test).

### Fucoidan prevented H<sub>2</sub>O<sub>2</sub>-induced increases in paracellular permeability

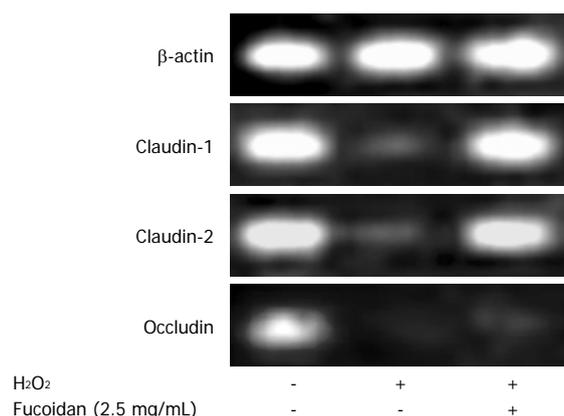

Next, we examined whether H<sub>2</sub>O<sub>2</sub> increased the paracellular permeability of Caco-2 cell monolayers following epithelial injury and whether fucoidan could prevent this effect. For this experiment, an FD4 flux assay was performed. H<sub>2</sub>O<sub>2</sub> markedly increased FD4 flux into the lower well (Figure 3). As expected, pretreatment with fucoidan 30 min prior to H<sub>2</sub>O<sub>2</sub> administration significantly suppressed the increase in FD4 flux into the lower well across the Caco-2 cell monolayers ( $P < 0.01$ ) (Figure 3). These results suggested that H<sub>2</sub>O<sub>2</sub> functionally injured the Caco-2 cell monolayers and that fucoidan prevented the disruption of intestinal epithelial barrier function.

### Fucoidan promoted intestinal epithelial barrier function via direct upregulation of tight junction proteins in IECs

To determine how fucoidan treatment promotes an increase in intestinal epithelial barrier function, we examined the effect of fucoidan on the mRNA expression of major TJ-associated proteins. As shown in Figure 4, Caco-2 cells endogenously expressed claudin-1 and -2, and occludin. H<sub>2</sub>O<sub>2</sub> reduced the mRNA expression of these proteins. In addition, pretreatment with fucoidan attenuated the reduction in the expressions of claudin-1 and claudin-2 mRNA but not occludin mRNA. These results suggested that fucoidan treatment strongly induced the expression of claudin-1 and -2 that promote intestinal epithelial barrier function.

### Fucoidan prevented H<sub>2</sub>O<sub>2</sub>-induced destruction of the tight junction protein claudin-1

We further examined the effect of fucoidan on the inter-

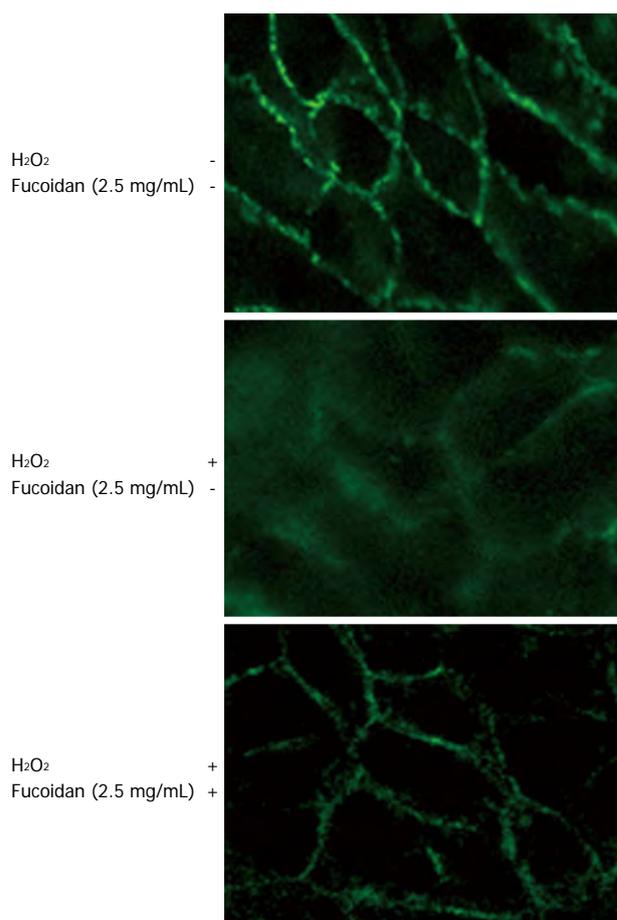

**Figure 4** Fucoidan promoted intestinal epithelial barrier function via direct upregulation of tight junction proteins in intestinal epithelial cells. Polarized Caco-2 cell monolayers injured by H<sub>2</sub>O<sub>2</sub> (500  $\mu$ mol/L) for 24 h with or without pretreatment of fucoidan (2.5 mg/mL) 30 min prior to H<sub>2</sub>O<sub>2</sub> administration. The expression of tight junction proteins, including claudin-1, claudin-2, and occludin, was examined using reverse-transcription polymerase chain reaction. The data shown are representative and are from 1 of the 3 independent experiments.

cellular localization of claudin-1 using immunofluorescence microscopy. We found that the expression of claudin-1 was intact and high on the cell surface in control cells. H<sub>2</sub>O<sub>2</sub> strongly disrupted the integrity of claudin-1, resulting in lower expression. Furthermore, pretreatment with fucoidan dramatically attenuated the H<sub>2</sub>O<sub>2</sub>-induced injury, restoring cell integrity and promoting the expression of claudin-1 (Figure 5).

## DISCUSSION

IBD is associated with an epithelial barrier defect characterized by impaired absorptive function and increased mucosal barrier defects, which are caused by impaired TJ complexity, particularly affecting claudins<sup>[19,21]</sup>. Whereas claudin-1, -3, -4, -5 and -8 demonstrate sealing functions, claudin-2, -10b and -15 act as paracellular channels and promote the charge-selective passage of small ions<sup>[10]</sup>. Recent studies have revealed that the expression of barrier-forming claudin-1 and -4 and occludin are downregulated in the intestinal epithelia of patients with UC<sup>[22]</sup>, and downregulation of claudin-3, -5 and occludin have been observed in CD<sup>[23]</sup>. However, the pore-forming protein claudin-2 is upregulated in both UC and CD, resulting in leaky TJ strands<sup>[22,23]</sup>. Amasheh *et al.*<sup>[24]</sup> recently established an experimental IBD model of native colon *in vitro*, which showed an impairment of epithelial barrier function via downregulation of claudin -1, -5, and -7 after exposure to tumor necrosis factor (TNF)- $\alpha$  and interferon gamma (IFN)- $\gamma$ . Because the present study showed the impaired expression of claudin-1 and occludin by oxidative stress, our model mimicked the intestinal inflammation observed in IBD.

Fucoidans represent an intriguing group of naturally occurring polysaccharides that might have promising therapeutic applications in various clinical situations. Algal

**Figure 5** Fucoidan prevented the H<sub>2</sub>O<sub>2</sub>-induced destruction of tight junction protein claudin-1. Caco-2 cells were grown on a Lab-Tek chamber plate. Polarized Caco-2 monolayers were injured by H<sub>2</sub>O<sub>2</sub> (500  $\mu$ mol/L) for 6 h with or without pretreatment of fucoidan (2.5 mg/mL). Immunofluorescence staining for claudin-1 was evaluated using confocal laser scanning microscopy. The data shown are representative and are from 1 of the 3 independent experiments.

fucoidans are characterized by a wide variety of biological functions and by a highly complex and heterogeneous structure, which varies within algal species. Fucoidans from various algal species might differentially affect inflammation. Although numerous biological activities of fucoidan have attracted attention, only a few studies have examined the pharmacological activity of fucoidan in intestinal inflammation<sup>[25]</sup>. Matsumoto *et al.*<sup>[26]</sup> have shown that the oral administration of fucoidan ameliorated murine chronic colitis by downregulating the synthesis of interleukin-6 (IL-6), a key pro-inflammatory cytokine in IBD, in colonic epithelial cells. They concluded that fucoidan derived from *C. o. Tokida* might be useful as a dietary substance for the treatment of IBD. In addition, Zhang *et al.*<sup>[27]</sup> revealed that intravenous administration of fucoidan reduced colonic mucosal damage and crypt destruction of dextran sodium sulfate-induced murine chronic colitis by reducing colonic myeloperoxidase activity and abolishing TNF- $\alpha$ -induced venular leukocyte rolling and extravascular recruitment. Moreover, Tanoue *et al.*<sup>[28]</sup> established an *in vitro* model of a co-culture system using intestinal epithelial Caco-2 cells and macrophage RAW264.7 cells

to treat intestinal inflammation by fucoidan. They clearly showed that fucoidan suppressed IL-8 gene expression in epithelial cells *via* reduction in TNF- $\alpha$  production from macrophages stimulated with lipopolysaccharide. For gastric inflammation, fucoidan has been found to protect against aspirin-induced gastric ulceration by inhibiting IL-6, TNF- $\alpha$ , and IFN- $\gamma$ <sup>[29,30]</sup>. However, to the best of our knowledge, our study is the first to report that fucoidan protects and strengthens epithelial barrier function, both under physiological and pathological conditions *via* induction of the expression of claudin-1 in human IECs. The mechanisms how fucoidan regulates the TJ proteins in this study are unknown. We next plan to investigate cytokine studies and signaling pathways which may regulate the expression of claudins and occludin by the treatment of fucoidan with a consistent time course experiments.

Pro-inflammatory cytokines, such as TNF- $\alpha$ , IFN- $\gamma$ , and IL-13, affect the expression of TJ proteins in IECs and induce epithelial cell apoptosis, resulting in the disruption of intestinal epithelial barrier function<sup>[22,31,32]</sup>. Because IECs function as a defensive frontline of host mucosal immunity in the intestine, disruption of barrier function of IECs causes an excessive immune response to intestinal bacteria<sup>[5]</sup>. Thus, dysfunction of IECs strongly contributes to the pathogenesis of bacteria-triggered chronic inflammation of the intestine in IBD. However, defects in TJ barrier function are insufficient to cause disease. Increased paracellular permeability can increase mucosal immune activity and enhance disease progression and severity. Thus, restoration of TJ barrier function might be effective, either alone or in combination with other agents, in preventing disease in at-risk individuals or maintaining remission in patients with IBD<sup>[9]</sup>. Although recent advances in anti-TNF- $\alpha$  antibody therapy can dramatically inhibit intestinal inflammation, strengthening the intestinal epithelial barrier is still challenging and has been eagerly investigated. It is well known that zinc, a trace element, assists with the maintenance of intestinal barrier integrity. Glutamine, an essential amino acid, supports recovery from a loss in TER. Moreover, the expression of claudin-1 and occludin proteins were decreased when Caco-2 cells were deprived of glutamine through inhibition of glutamine synthetase<sup>[33]</sup>. Furthermore, a direct influence on TJ protein expression has been observed from several plant components, including the flavonoid quercetin and the isoquinoline alkaloid berberine<sup>[34]</sup>. Quercetin, which is obtained from fruits, enhances barrier function by upregulating claudin-4 expression<sup>[35]</sup>, whereas berberine, a herbal agent, prevented the barrier impairment induced by TNF- $\alpha$  and IFN- $\gamma$ <sup>[36]</sup>. We have demonstrated that fucoidan directly induced the expression of some TJ proteins and might contribute to the enhancement of epithelial barrier functions. Thus, we believe that the activity of fucoidan, which increases the epithelial protective function and promotes epithelial regeneration, might serve as an appropriate therapy for the treatment of IBD.

Although dietary components may regulate TJ permeability by directly targeting the signal transduction

pathways involved in TJ regulation, specific dietary components have been identified that influence cytokine signaling, thereby modifying TJ permeability<sup>[34]</sup>. The intestinal barrier is a complex environment, and the regulation of barrier function cannot be elucidated using *in vitro* models alone. Interactions between dietary components and microbiota are also crucial in the regulation of barrier integrity<sup>[34]</sup>. It is important to consider the interactions between different components of the intestinal barrier when establishing strategies to enhance barrier integrity using dietary compounds. The present study may provide insight for the development of novel agents with low toxicity in the treatment of intestinal inflammation. Because the healing of intestinal inflammation is a complex process involving numerous factors, further work is required to elucidate the therapeutic effect of fucoidan.

## COMMENTS

### Background

The oxidative stress-induced disruption of the intestinal epithelial cells and subsequent increased paracellular permeability are critically important in the pathogenesis of inflammatory bowel diseases (IBD). Although recent advances in anti-tumor necrosis factor- $\alpha$  antibody therapy can dramatically inhibit intestinal inflammation, strengthening the intestinal epithelial barrier is still challenging and has been eagerly investigated.

### Research frontiers

Recent studies have revealed that some dietary components may regulate tight junction (TJ) permeability by directly targeting the signal transduction pathways involved in TJ regulation. A growing body of experimental evidence indicates that fucoidan, a dietary substance of fucose-enriched sulfated polysaccharides with low toxicity, display a wide variety of pharmacological anti-inflammatory activities. However, only a few studies have examined the protective effects of fucoidan for intestinal inflammation.

### Innovations and breakthroughs

The authors investigated the effect of fucoidan on oxidative stress-induced barrier disruption in a Caco-2 cell monolayer model, with an emphasis on the alterations of TJ proteins. This study demonstrates that fucoidan protected the epithelial barrier function from oxidative injury of the TJ as well as barrier disruption by upregulating the expression of claudin-1.

### Applications

Fucoidan may be an appropriate therapy to control the expression of claudin-1 for the treatment of IBD.

### Terminology

Tight junctions: TJ forms a network of close contacts between membranes of adjacent cells. TJ consists of four integral membrane proteins: claudins, occludins, tricellulin and the junctional adhesion molecule. A large body of evidence indicates that disruption of the TJ and increased paracellular permeability are critically important in the pathogenesis of IBD. Fucoidan: fucoidan is a dietary substance, which represents a class of fucose-enriched sulfated polysaccharides found in the extracellular matrix of brown algae. Numerous experimental evidences indicate that fucoidans display a wide variety of pharmacological activities, including anti-inflammatory, anti-angiogenic, anti-coagulant, and anti-adhesive effects.

### Peer review

The manuscript described that fucoidan is effective to improve intestinal epithelial barrier function. This is an interesting study that could be worth publishing.

### Abstract

**AIM:** To survey the antibiotic resistance pattern of *Helicobacter pylori* (*H. pylori*) strains isolated from Bhutanese population.

**METHODS:** We isolated 111 *H. pylori* strains from the gastric mucosa of *H. pylori*-infected patients in Bhutan in 2010. The Epsilometer test was used to determine the minimum inhibitory concentrations (MICs) of amoxicillin (AMX), clarithromycin (CLR), metronidazole (MNZ), levofloxacin (LVX), ciprofloxacin (CIP), and tetracycline (TET).

**RESULTS:** Nineteen of the isolated *H. pylori* strains were susceptible to all antibiotics tested. The isolated strains showed the highest rate of antibiotic resistance to MNZ (92/111, 82.9%). Among the 92 MNZ-resistant strains, 74 strains (80.4%) showed high-level resistance (MIC  $\geq$  256  $\mu$ g/mL). Three strains were resistance to LVX (2.7%). These strains were also resistance to CIP. None of the strains showed resistance to CLR, AMX and TET.

**CONCLUSION:** CLR-based triple therapy is a more effective treatment approach over MNZ-based triple therapy for *H. pylori* infection in Bhutan.

© 2013 Baishideng. All rights reserved.

**Key words:** *Helicobacter pylori*; Drug resistance; Bhutan

**Core tip:** In Bhutan, 82.9% of *Helicobacter pylori* isolates showed metronidazole resistance. Of these, 80.4% showed high-level resistance (minimum inhibitory concentration  $\geq$  256  $\mu$ g/mL). Only 2.7% strains showed levofloxacin, ciprofloxacin resistance. Intriguingly, none of them were resistance to clarithromycin, amoxicillin, and tetracycline.

## INTRODUCTION

*Helicobacter pylori* (*H. pylori*) is a spiral, Gram-negative bacterium that infects more than half of the world's population and is thought to be involved in the pathogenesis of chronic gastritis, peptic ulcer diseases, gastric cancer (GC), and mucosa-associated lymphoid tissue (MALT) lymphoma<sup>[1,2]</sup>. Eradication of *H. pylori* infection not only improves the healing of peptic ulcers, but it also prevents its recurrence and reduces the risk of developing GC<sup>[3-7]</sup>. Furthermore, other *H. pylori*-associated disorders such as MALT lymphoma, atrophic gastritis, and intestinal metaplasia have been shown to regress after treatment with antibiotics<sup>[8-10]</sup>.

Triple therapy regimens that include 1 proton pump inhibitor (PPI) and 2 antimicrobial agents such as amoxicillin (AMX), clarithromycin (CLR), metronidazole (MNZ), levofloxacin (LVX), ciprofloxacin (CIP), and tetracycline (TET) have been widely used to eradicate this bacterium<sup>[7,11,12]</sup>. Although the success of the treatment depends on several factors such as patient compliance and whether the patient is a smoker, antibiotic resistance is the most common factor causing treatment failure<sup>[13-15]</sup>. Prevalence of antibiotic resistance is now increasing worldwide and varies by the geographic area; it is generally higher in developing countries than in developed regions<sup>[16-18]</sup>. In addition, the antibiotic resistance rate often parallels the antibiotic consumption rate in the population<sup>[16,19-21]</sup>.

Bhutan is a small landlocked country in South Asia, located at the eastern end of the Himalayas, and shares its borders in the south, east, and west with the Republic of India and to the north with the People's Republic of China. In Bhutan, the incidence of GC is reported to be quite high (24.2 deaths/100000 population) compared to the neighboring areas<sup>[22]</sup>. Effective therapies to eradicate *H. pylori* can contribute to the decrease of GC incidence in Bhutan. However, information about the prevalence of drug-resistant *H. pylori* strains in Bhutan, which is essential for designing effective eradication therapies, is lacking.

In this study, we aimed to determine the antibiotic susceptibility of *H. pylori* strains isolated from Bhutanese population toward AMX, CLR, MNZ, LVX, CIP, and TET.

## MATERIALS AND METHODS

### Subjects and sample collection

*H. pylori* strains were obtained from the gastric mucosa of *H. pylori*-infected Bhutanese volunteers who under-

went endoscopy at 3 cities within the country (Thimpu, Punaka, and Wangdue) from December 6 to 9, 2010. Biopsy samples from the antrum were endoscopically obtained from each patient and used for culturing *H. pylori* by using standard methods. Cases of peptic ulcers and GC were identified by endoscopy, and GC was further confirmed by histopathology. Gastritis was defined as *H. pylori* infection-mediated gastritis in the absence of peptic ulcer or gastric malignancy. Written informed consent was obtained from all participants, and the protocol was approved by the Ethics Committee of Jigme Dorji Wangchuk National Referral Hospital, Bhutan.

### Drug sensitivity testing

Epsilon meter test (*E* test) was used to determine the minimum inhibitory concentrations (MICs) of AMX, CLR, MNZ, LVX, CIP, and TET. Mueller Hinton II Agar supplemented with 10% horse blood was used as the culture medium and the culture suspension was used to inoculate the agar plates. The *E* test strip of the corresponding antibiotic was placed on the plate and incubated for 3-5 d at 37 °C, under microaerophilic conditions. The MIC was defined by the point of intersection of the inhibition ellipse with the *E* test strip. Strains were considered "resistance" when the MIC values were  $\geq 1$   $\mu\text{g/mL}$  for AMX,  $\geq 1$   $\mu\text{g/mL}$  for CLR,  $\geq 1$   $\mu\text{g/mL}$  for LVX,  $\geq 8$   $\mu\text{g/mL}$  for MNZ, and  $\geq 4$   $\mu\text{g/mL}$  for TET<sup>[23]</sup>. In accordance with previous studies, strains were considered "resistance" to CIP when the MIC values were  $\geq 1$   $\mu\text{g/mL}$ <sup>[24,25]</sup>.

### Statistical analysis

All statistical analyses were performed by SPSS version 19 (SPSS Inc., Chicago, IL, United States). The univariate association between each group was quantified using the unpaired *t* test, Mann-Whitney *U* test, Fisher's exact test, and  $\chi^2$  test. A two-tailed *P* value of  $< 0.05$  was considered statistically significant.

## RESULTS

We isolated 111 strains of *H. pylori* from *H. pylori*-positive Bhutanese patients; the identity of these strains was microbiologically confirmed. The patient group included 51 men and 60 women, with an average age of  $36.8 \pm 13.9$  years. Seventy strains were isolated from patients with gastritis, 11 from patients with peptic ulcer, and 1 from a patient with GC. Nineteen strains were susceptible to all the antibiotics tested. The greatest proportion of isolated strains was resistance to MNZ (92/111, 82.9%, Table 1). The resistance rate was 84.2% (48/57) in the strains isolated from patients younger than 34 years of age, 82.4% (28/34) in the strains isolated from patients aged 35-49 years, 71.4% (10/14) in the strains isolated from patients aged 50-64 years, and 100% (6/6) in the strains isolated from patients above 65 years of age. There was no relationship between the age of the patient and the rate of resistance of the isolated strain to MNZ ( $P = 0.45$ ). Gender was not associated with MNZ resistance as well

**Table 1** Antibiotic susceptibility of 111 *Helicobacter pylori* strains isolated in Bhutan *n* (%)

Total	<i>n</i> = 111
Amoxicillin	0 (0.0)
Clarithromycin	0 (0.0)
Metronidazole	92 (82.9)
Levofloxacin	3 (2.7)
Ciprofloxacin	3 (2.7)
Tetracycline	0 (0.0)

( $P = 0.71$ ). All 11 strains of *H. pylori* from patients with peptic ulcer showed resistance to MNZ; however, it did not statistically differ from the resistance rates of strains isolated from gastritis patients ( $P = 0.11$ ). The distribution of MIC values for MNZ: among 92 MNZ-resistant strains, 74 strains (80.4%) showed high-level resistance (MIC  $\geq 256$   $\mu\text{g/mL}$ ). Three strains (2.7%), from patients with gastritis, were resistant to LVX. These strains were also resistance to CIP. The MIC values for LVX and CIP were 32 and 32  $\mu\text{g/mL}$ , respectively. These 3 strains were also resistance to MNZ. None of the strains showed resistance to CLR, AMX, and TET. Resistance to multiple antibiotics was observed in 3 strains (2.7%), where the bacteria were resistant to MNZ, LVX, and CIP. The strain isolated from the GC patient was susceptible to all the antibiotics tested.

## DISCUSSION

This is the first study exploring the antibiotic resistance pattern of *H. pylori* strains isolated from Bhutanese population. In Bhutan, no domestic guidelines are available for the treatment of *H. pylori* because of insufficient domestic data. At present, the European, Asia-Pacific, and American guidelines on the treatment of *H. pylori* infection recommend a combination of 1 PPI and 2 antibiotics, AMX plus CLR or MNZ, as the first-line therapy<sup>[7,11,12]</sup>. Although lack of patient compliance, inadequate length of therapy, or high bacterial burden are conditions that may contribute to loss of efficacy, antimicrobial resistance is regarded as the leading factor responsible for the failure of eradication of infection. This issue is of particular relevance with regard to CLR, where there can be up to 70% loss of antibiotic effectiveness, depending on macrolide susceptibility *in vitro*<sup>[16]</sup>. Meta-analysis showed that triple therapy consisting of PPI, AMX, and CLR in CLR-resistant infections decreased the treatment efficacy by 66%<sup>[26]</sup>. In fact, the Maastricht III guidelines on *H. pylori* infection management recommend that CLR should not be used when resistance to the antibiotic exceeds 15%-20%<sup>[7]</sup>. However, surprisingly, none of the strains isolated in Bhutan showed resistance to CLR, suggesting that CLR-based triple therapy can still be used to eradicate *H. pylori* in Bhutan. However, resistance to CLR is increasing worldwide with the increase in the use of CLR<sup>[27-29]</sup>, and it is imperative to examine the CLR resistance rate in the *H. pylori* strains in Bhutan.

Resistance to MNZ is extremely high in Bhutan. Recently, the rate of resistance to MNZ has been reported to increase; this can be considered a major factor leading to reduced efficacy of the standard triple therapy in most countries<sup>[11]</sup>. Most MNZ-resistant strains in this study showed a high MIC value ( $\geq 256$   $\mu\text{g/mL}$ ). Regimens including MNZ are not a preferred choice in populations with an MNZ resistance rate of  $> 40\%$ <sup>[19,30]</sup>. Therefore, if CLR resistance increases in future, MNZ cannot be used as a substitute for CLR in the first-line regimen in Bhutan.

MNZ is frequently used to treat not only *H. pylori* infections, but also other infections such as intestinal parasite infections and periodontal and gynecological diseases, which are common in developing countries<sup>[16,31]</sup>. National Statistics Bureau of Bhutan also showed that infectious diarrhea is one of the major causes of mortality in the country, which suggests that MNZ can be often used for its treatment (<http://www.nsb.gov.bt/>).

Recently, LVX has been prescribed as a rescue drug to eradicate infection in case of failure of the first-line therapy<sup>[32,33]</sup>. However, the prevalence of LVX resistance seems to be increasing worldwide and this may reduce the efficacy of treatment with LVX-based regimens<sup>[34-39]</sup>. Therefore, according to the European, Asia-Pacific, and American guidelines, LVX should be used in salvage therapy based on antibiotic susceptibility testing<sup>[7,11,12]</sup>. In Bhutan, LVX is rarely used for the treatment of other infectious diseases and LVX resistance was found only in 3 strains. These strains were also resistant to CIP, suggesting cross-resistance among the fluoroquinolone drugs. TET resistance was not noted in any of the strains tested, consistent with the findings of previous studies from other countries<sup>[25,40,41]</sup>. TET is not often used for the treatment of infectious diseases in Bhutan. Therefore, TET-based or quadruple therapy including TET can be a useful alternative to the first-line regimen, as recommended in the European and Asia-Pacific guidelines<sup>[7,11]</sup>. Likewise, all strains in this study were susceptible to AMX, which is consistent with previous findings<sup>[40,42,43]</sup>.

However, we should be cautious about implementing the eradication therapy in Bhutan. Despite the success of the *H. pylori* eradication therapy, the infection does frequently recur in patients in developing countries where there is a high prevalence of *H. pylori* infection<sup>[44]</sup>. Such repeat infection is either a recurrence of the original infection or reinfection with a new strain. Environmental factors, including poor living conditions, are related to high rates of *H. pylori* infection<sup>[45,46]</sup>. In rural areas of the country, river or pond water can be used as the source of drinking water (information from National Statistics Bureau, <http://www.nsb.gov.bt/>); furthermore, unsanitary pit latrines are widely used in this country. It is necessary to improve sanitary conditions to decrease the prevalence of *H. pylori*.

In conclusion, CLR-based triple therapy can still be used to eradicate *H. pylori* in Bhutan. However, because of high resistance rates, MNZ-based triple therapy is not useful as the first-line therapy. It is necessary to have

current and reliable information on the prevalence of antibiotic resistance to *H. pylori*, in particular, in Bhutan. Careful consideration is required for formulating national therapeutic guidelines for the first-line and second-line therapies for *H. pylori* infection, considering factors such as disease prevalence, access to health care centers, diagnostic facilities, and the burden of health care costs borne by the government.

## COMMENTS

### Background

Eradication of *Helicobacter pylori* (*H. pylori*) reduces the risk of developing gastric cancer (GC). Antibiotic resistance is the most common factor causing the failure of the treatment. Prevalence of antibiotic resistance is now increasing worldwide and varies in geographic area. The incidence of GC in Bhutan is reported to be quite high comparing with neighbor area. Therefore, effective eradication therapy can contribute to the decrease of incidence of GC in Bhutan. However, the prevalence of drug resistant *H. pylori* in Bhutan has not been elucidated.

### Research frontiers

Triple therapy regimens including one proton pump inhibitor and two antimicrobial agents such as amoxicillin (AMX), clarithromycin (CLR), metronidazole (MNZ), levofloxacin (LVX), ciprofloxacin (CIP), and tetracycline have been widely used to eradicate *H. pylori*. Prevalence of antibiotic resistance is now increasing worldwide and varies in geographic area. Although the success of the treatment depends on several factors such as smoking and patient compliance, antibiotic resistance is the most common factor causing the failure of the treatment. Therefore, it is necessary to examine the recent drug resistance rates to select the proper eradication regimens.

### Innovations and breakthroughs

Although the incidence of GC in Bhutan is quite high comparing with neighbor area, the prevalence of drug resistant *H. pylori* in Bhutan has not been elucidated. The author's findings can contribute to the decrease of incidence of GC in Bhutan.

### Applications

CLR-based triple therapy can be used to eradicate *H. pylori* whereas MNZ-based triple therapy is not suitable for *H. pylori* eradication in Bhutan.

### Peer review

The manuscript reports on the pattern of *H. pylori* resistance to antibiotics in Bhutan. The strains of *H. pylori*, cultured from antral mucosal biopsies 111 patients, were assessed for susceptibility to GC, clarithromycin, metronidazole, levofloxacin, ciprofloxacin, and tetracycline, using Epsilometer test. The results revealed the highest resistance rate (83%) to MNZ followed by LVX and CIP, both about 2.7%. This manuscript of limited importance, and of interest to those studying the health status of Bhutanese.

Published online: September 7, 2013

January 2010 and December 2011 to explore whether SEMS placement influenced the laparoscopic procedure or reduced long-term survival by influencing CRC oncological characteristics.

**RESULTS:** The characteristics of patients among these groups were comparable. The rate of conversion to open surgery was 12.5% in the stent-laparoscopy group. Bowel function recovery and postoperative hospital stay were significantly shorter ( $3.3 \pm 0.9$  d vs  $4.2 \pm 1.5$  d and  $6.7 \pm 1.1$  d vs  $9.5 \pm 6.7$  d,  $P = 0.016$  and  $P = 0.005$ ), and surgical time was significantly longer ( $152.1 \pm 44.4$  min vs  $127.4 \pm 38.4$  min,  $P = 0.045$ ) in the stent-laparoscopy group than in the stent-open group. Surgery-related complications and the rate of admission to the intensive care unit were lower in the stent-laparoscopy group. There were no significant differences in the interval between stenting and surgery, intraoperative blood loss, OS, and DFS between the two stent groups. Compared with those in the stent-laparoscopy group, all surgery-related parameters, complications, OS, and DFS in the control group were comparable.

**CONCLUSION:** The stent-laparoscopy approach is a feasible, rapid, and minimally invasive option for patients with ACO caused by left-sided CRC and can achieve a favorable long-term prognosis.

**Key words:** Self-expandable metallic stent; Colorectal cancer; Endoscopy; Laparoscopy; Efficiency; Safety

**Core tip:** Our study compared long-term survival between left-sided colorectal cancer (CRC) patients with acute colorectal obstruction (ACO) who had undergone self-expandable metallic stent (SEMS) placement followed by one-stage laparoscopic (stent-laparoscopy

### Abstract

**AIM:** To investigate the clinical advantages of the stent-laparoscopy approach to treat colorectal cancer (CRC) patients with acute colorectal obstruction (ACO).

**METHODS:** From April 2008 to April 2012, surgery-related parameters, complications, overall survival (OS), and disease-free survival (DFS) of 74 consecutive patients with left-sided CRC presented with ACO who underwent self-expandable metallic stent (SEMS) placement followed by one-stage open ( $n = 58$ ) or laparoscopic resection ( $n = 16$ ) were evaluated retrospectively. The stent-laparoscopy group was also compared with a control group of 96 CRC patients who underwent regular laparoscopy without ACO between

group) and open resection (stent-open group). Long-term survival in left-sided CRC patients without ACO who had undergone laparoscopic resection (control group) was compared with the stent-laparoscopy group. A stent-laparoscopy approach did not reduce long-term survival by influencing CRC oncological characteristics. Surgery-related parameters and postoperative complications in the stent-laparoscopy group were also compared with those of the other two groups; the results indicated that SEMS placement did not influence subsequent laparoscopic procedures.

Self-expandable metallic stent placement plus laparoscopy for acute malignant colorectal obstruction. *World J Gastroenterol* 2013; 19(33): 5513-5519 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i33/5513.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i33.5513>

## INTRODUCTION

Acute colorectal obstruction (ACO) is one of the common initial symptoms in patients with left-sided colorectal cancer (CRC). Emergent surgery is a conventional treatment, but it is usually associated with high morbidity, mortality, and stoma rate<sup>[1-3]</sup>. Since 1991, self-expanding metallic stent (SEMS) placement has been applied to relieve ACO caused by left-sided CRC and is effective in restoring colorectal transit, allowing sufficient preoperative preparation and tumor stage evaluation<sup>[4-6]</sup>. Compared with emergent surgery, preoperative stenting and elective surgery are safer and increase the probability of one-stage resection<sup>[7,8]</sup>. Open and laparoscopic colectomies are two recent approaches used as a subsequent elective surgery following successful SEMS placement. Laparoscopic colectomy has a lower postoperative complication rate and a shorter hospital stay<sup>[9]</sup>. The application of SEMS placement can increase the probability of performing laparoscopic colectomy and offers the advantages of two minimally invasive procedures<sup>[10]</sup>. The stent-laparoscopy approach was first introduced by Morino *et al*<sup>[11]</sup> in 2002, and its use has been reported in previous studies<sup>[12-18]</sup>. In Morino's study, preoperative SEMS placement was believed to make the laparoscopic procedure more difficult and the colonic segment more bulky and more technically difficult to remove through laparoscopy<sup>[10]</sup>, but this has not been confirmed. Similarly, the long-term survival of patients undergoing stent-laparoscopy is currently unknown. Therefore, the present study was designed to compare surgery-related parameters, including surgical time and intraoperative blood loss, postoperative complications, long-term overall survival (OS) and disease-free survival (DFS), of the stent-laparoscopy approach with the stent-open surgery approach in left-sided CRC patients with ACO and with regular laparoscopy in left-sided CRC patients without ACO to determine the clinical advantages and long-term prognoses of the stent-

laparoscopy approach and the influence of preoperative SEMS placement on the laparoscopic procedure.

## MATERIALS AND METHODS

### *Patients and follow-up*

From April 2008 to April 2012, 74 consecutive patients (47 males and 27 females, aged 34-84 years, median 60 years) with left-sided CRC and ACO, who had undergone SEMS placement followed by one-stage resection at Zhongshan Hospital, were reviewed retrospectively. The obstruction was diagnosed clinically and radiologically. Patient symptoms were abdominal pain and fullness, vomiting and constipation. Physical examination showed a distended and tympanic abdomen. Abdominal X-ray revealed a distended large bowel and an air-fluid level. All patients underwent endoscopic SEMS placement to release the obstruction. According to the particular subsequent resection approach selected by the attending surgeon, patients were allocated into the stent-laparoscopy group and the stent-open group. Additionally, from January 2010 to December 2011, 96 left-sided CRC patients without ACO who had undergone one-stage laparoscopic resection were enrolled consecutively as the control group. All patients were enrolled after informed consent. The Research Ethics Committee of Zhongshan Hospital approved the study.

After surgery, the follow-up procedures in the stent-surgery groups, including chest X-ray, abdominal ultrasound, computed tomography scan and blood tests, especially levels of cancer embryo antigen, were performed every 3 to 4 mo within 2 years, and continued every 4 to 6 mo for 3 to 4 years thereafter. Colonoscopy was performed every 6 mo in the first year and every year for 2 to 4 years. Tumor, node, metastasis (TNM) staging was performed according to the American Joint Committee on Cancer, 6<sup>th</sup> edition. OS was defined as the interval between SEMS placement and death or the last follow-up visit. DFS was defined as the interval between SEMS placement and recurrence or postoperative remote organ metastasis. If recurrence was not diagnosed, patients were censored on the date of death or last follow-up.

### *Endoscopic stenting procedure and laparoscopic resection*

Briefly, all SEMS placement procedures were performed by one of five experienced endoscopists using a colonoscope (CF-260I; Olympus, Tokyo, Japan) with fluoroscopic guidance. Water-soluble contrast material was injected through the catheter to visualize the stricture. The size of the SEMS was selected according to the length and caliber of the stricture (diameter, 26 mm; length, range 50-100 mm). The length of the SEMS was at least an additional 2 cm on each side of the stricture. A SEMS from MicroTech (MicroTech Co., Nanjing, China) or Boston Scientific (Boston Scientific, Natick, MA, United States) was used according to the endoscopist's preference. After deployment, the proper position and

TNM: Tumor, node, metastasis.

expansion of the SEMS was assessed using fluoroscopic visualization.

After complete remission of ACO, bowel preparation was performed with polyethylene glycol 24 h before surgery. Patients were placed in the Trendelenburg position, and slightly tilted to the right and downward. The target colorectum and its mesentery were mobilized laparoscopically, and the colon distal to the tumor was divided using endo linear staplers. A vertical periumbilical incision was made to remove the specimen and introduce the anvil of the circular stapler. An anastomosis was made in an end-to-end manner using the circular stapler or in a side-to-side manner using the double staples method to discriminate the size of the colorectal lumen.

### Statistical analysis

Values are expressed as the mean ± SD. An unpaired *t* test was used to compare quantitative variables. A Pearson's  $\chi^2$  test or Fisher's exact test was applied to compare qualitative variables. The patients' survival curve was plotted using the Kaplan-Meier method, and the log-rank test was used to determine the significant differences between groups. Analysis was performed using SPSS 16.0 for Windows (SPSS Inc., Chicago, IL, United States). A *P* value less than 0.05 was considered statistically significant. All images were edited using Photoshop CS5 extended (Adobe, San Jose, CA, United States).

## RESULTS

### Patient characteristics

Sixteen patients were in the stent-laparoscopy group and 58 patients were in the stent-open group. In the stent-laparoscopy group, two patients (12.5%) converted to open surgery for abdominal carcinomatosis and serious local intestinal adhesions; both conditions were unrelated to the stenting. In the control group, the rate of conversion to open surgery was 8.3% (8/96); three for serious local intestinal adhesions, four for extensive tissue invasion of the tumor and one for an inappropriate tumor site, which

**Table 2** Characteristics and outcomes

<sup>a</sup>*P* < 0.05 vs control group. ICU: Intensive care unit.

was not significantly different from the stent-laparoscopy group. These patients were excluded from the analyzed data. The patient characteristics were comparable among the three groups (Table 1).

### Comparison of clinical outcomes

The mean interval between stenting and surgery in the stent-open and stent-laparoscopy groups were 10.6 and 13.9 d, respectively (*P* = 0.397), and 8.8 and 10.2 d (*P* = 0.162), respectively, after the patients who received preoperative chemotherapy were excluded. No intraoperative morbidity was observed in either group. The mean surgical time in the stent-laparoscopy group was significantly longer than in the stent-open group (152.1 min vs 127.4 min, *P* = 0.045). However, intraoperative blood loss was not significantly different (*P* = 0.530). After surgery, mean bowel function recovery and postoperative hospital stay in the stent-laparoscopy group were significantly shorter than those in the stent-open group (3.3 d vs 4.2 d and 6.7 d vs 9.5 d, *P* = 0.016 and *P* = 0.005, respectively). In the stent-open group, 20.7% (12/58) of patients were admitted to the intensive care unit (ICU) after surgery, whereas none were admitted to the ICU in the laparoscopy group. No postoperative complications were observed in the stent-laparoscopy group, whereas seven patients (12.1%) with postoperative complications were observed in the stent-open group (Table 2).

Compared with the control group, surgery-related parameters, including surgical time, intraoperative blood loss, bowel function recovery, and postoperative hospital stay, were comparable in the stent-laparoscopy group. In the control group, eight patients (9.1%) were admitted to the ICU after surgery and postoperative complications occurred in two patients (2.3%) (Table 2).

### Comparison of long-term survival

The long-term survival of patients in the three groups was investigated. The follow-up period of patients in the stent-laparoscopy group was 28.2 ± 13.0 mo, which was not significantly different from that of the stent-

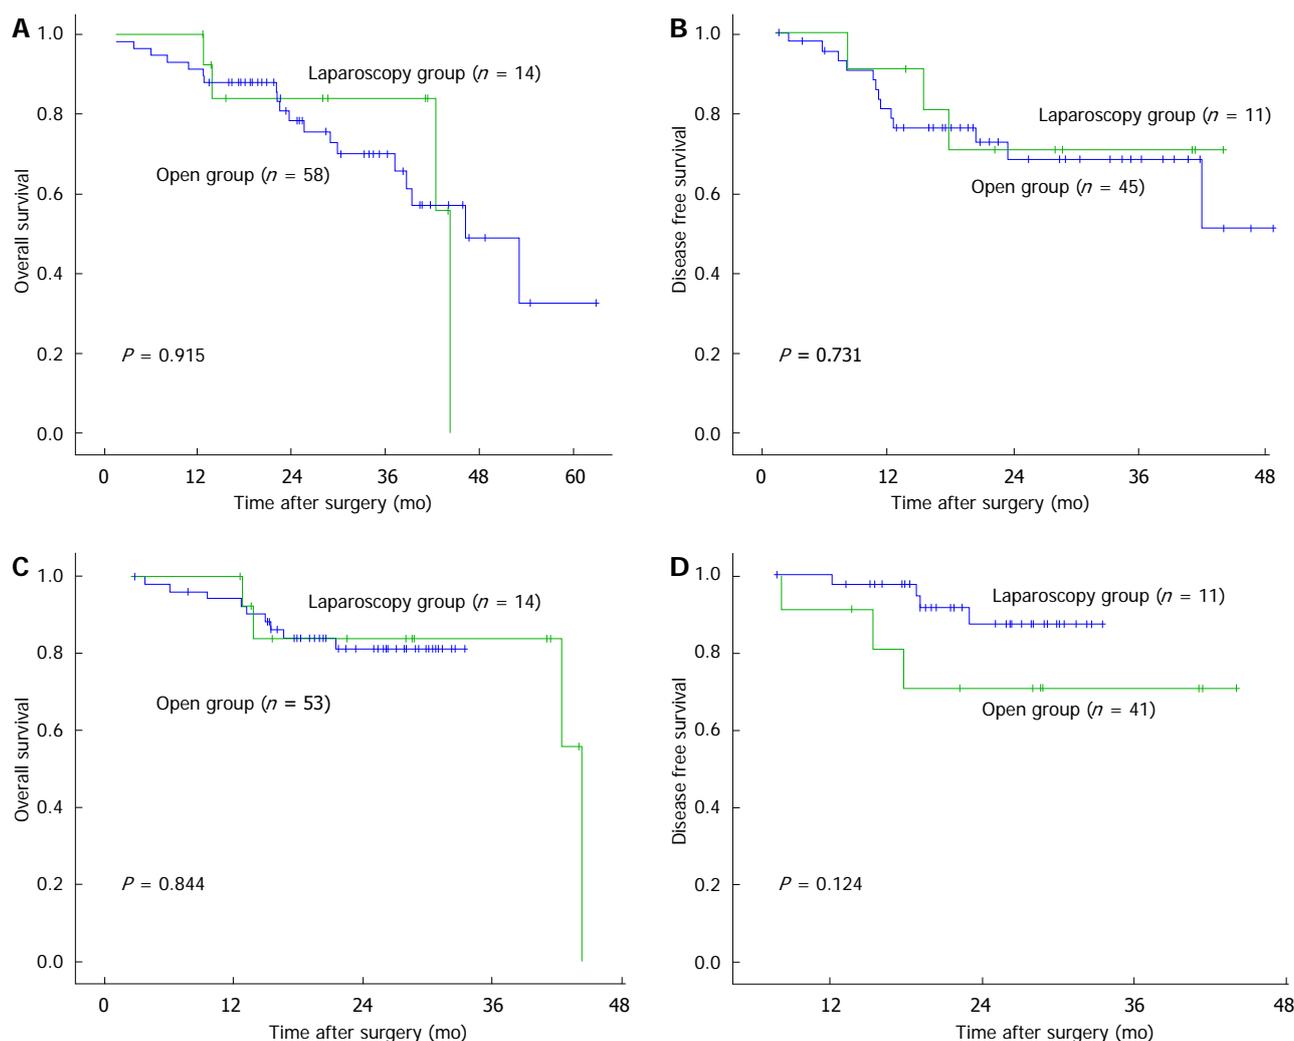

Figure 1 Kaplan-Meier analysis. A and B: In the stent-laparoscopy (green line) and stent-open (blue line) groups, there were no significant differences in overall survival and disease-free survival ( $P = 0.915$  and  $P = 0.731$ ); C and D: In the stent-laparoscopy (green line) and control (blue line) groups, there were also no significant differences in overall survival and disease-free survival ( $P = 0.844$  and  $P = 0.124$ ).

open group ( $28.9 \pm 13.8$  mo,  $P = 0.865$ ) and the control group ( $22.2 \pm 7.9$  mo,  $P = 0.118$ ), respectively. Patients with TNM stage IV were excluded from the DFS analysis. The 1-, 2-, 3-, and 4-year OS and DFS of patients in the stent-laparoscopy group were 100%, 83%, 83%, and 36%, and 91%, 71%, 71%, and 71%, respectively, which were not significantly different from those of the stent-open group (91%, 79%, 70%, and 50%; and 82%, 70%, 70%, and 57%, respectively,  $P = 0.915$  and  $P = 0.731$ ; Figure 1A and B). The 1-, 2-, and 3-year OS and DFS of patients in the control group were 94%, 80%, and 80%, and 100%, 88%, and 88%, respectively ( $P = 0.844$  and  $P = 0.124$ ; Figure 1C and D), which were also not significantly different from those of the stent-laparoscopy group. At the end of this study, 10 patients in the stent-laparoscopy group, 39 patients in the stent-open group, and 44 patients in control group remained alive. The details of recurrence, metastasis, and treatment are shown in Table 3 (Figure 2 shows a surgical specimen containing an SEMS).

## DISCUSSION

Malignant ACO was considered a relative contraindication of laparoscopy because of an unprepared fragile bowel and insufficient working space caused by the distended bowel, until SEMS placement was extended from a palliative treatment to a “bridge to surgery” treatment<sup>[19]</sup>. Meanwhile, the surgical approach to malignant ACO has changed extensively over time. The traditional three-stage operation was replaced gradually by a one-stage resection with primary anastomosis<sup>[11]</sup>. Preoperative SEMS placement also dramatically increases the probability of subsequent one-stage resection, using either an open or laparoscopic approach<sup>[7,20]</sup>. Morino *et al.*<sup>[11]</sup> first reported four left-sided CRC patients with ACO who were treated by a stent-laparoscopy approach. Although positive conclusions could be drawn, the lack of both an appropriate control group and long-term outcomes, as well as a limited number of patients made further study necessary. Likewise, other studies reported conflicting re-

<sup>1</sup>One patient's treatment was unknown; <sup>2</sup>Two patients' treatments were unknown.

sults. Thus, the present larger, long-term follow-up study aimed to report our experience and discuss the issues in previous studies by comparing the stent-laparoscopy approach with the stent-open approach and regular laparoscopy.

As the first step of the stent-laparoscopy approach, preoperative SEMS placement generally has a high success rate<sup>[8]</sup>. The technical and clinical success rates of SEMS placement are more than 96.7% and more than 90%, respectively. Moreover, no SEMS placement-associated morbidity or mortality was observed<sup>[11-17]</sup>. The technical and clinical success rates of patients in our center since 2005 were also similar to the data in these previous studies. A high success rate and low risk of preoperative SEMS placement guarantee the feasibility of the stent-laparoscopy approach.

For the laparoscopy procedure, several controversial issues have been reported in previous studies. Balagué *et al*<sup>[12]</sup> first suggested that the rigidity of the colonic segment containing the stent and the tumor made dissection more difficult than usual, prolonging the surgical time. In the same year, Law *et al*<sup>[13]</sup> reported that laparoscopic mobilization was not particularly difficult and the amount of blood loss was low. Following these studies, the results of study of Chung *et al*<sup>[17]</sup> partly supported Law's conclusions; the data from eight stent-open group patients were similar to those of the 17 stent-laparoscopy patients in terms of surgical time, estimated blood loss, and other surgery-related and postoperative parameters. In our study, intraoperative blood loss was not significantly different between the stent-laparoscopy and stent-open approaches, or regular laparoscopy, supporting Chung's conclusions and indicating the favorable safety of the stent-laparoscopy approach. However, the surgical times were not completely consistent with those reported in the above-mentioned studies. We found that compared with the stent-open approach, the stent-laparoscopy approach significantly prolonged the surgical time. When we compared the stent-laparoscopy approach with regular laparoscopy, no significant differences in the surgical times between these two groups were observed. Moreover, the rate of conver-

**Figure 2** Surgical specimen containing a preoperatively placed self-expandable metallic stent.

sion to open surgery in the stent-laparoscopy approach was 12.5%, which was similar to 8.3% in regular laparoscopy, and the two causes of conversion were related to the tumor or abdominal conditions (tumor invasion and intestinal adhesions), but unrelated to preoperative SEMS placement. Thus, we confirmed that the major influences on subsequent surgical procedures after stenting were the difficulties from the laparoscopy itself, and tumor or abdominal conditions, but not preoperative SEMS placement. Additionally, skilled surgeons performed all of the surgical procedures in our study, so a technical bias could be excluded.

Regarding postoperative recovery, bowel function recovery and postoperative hospital stays for the stent-laparoscopy group were significantly shorter than those for the stent-open group, and were similar to those of the regular laparoscopy group. Furthermore, no postoperative complications were observed for the stent-laparoscopy group, which was similar to that of the regular laparoscopy group, but fewer than the 12.1% in the stent-open group. Our results also indicated that using the stent-laparoscopy approach was associated with faster recovery and lower postoperative morbidity, which was similar to the results of previous studies<sup>[16,17,21-23]</sup>.

Long-term survival in these three groups was compared to estimate the curative effect of the stent-laparoscopy approach. Previously, Stipa *et al*<sup>[6]</sup> reported that their minimum follow-up period was 15 mo, and 17/22 (77%) surgically treated patients (six patients in the stent-open group and 16 in the stent-laparoscopy group) were alive at the end of their study. In Dulucq's study, neither recurrences nor port-site metastases were observed during a follow-up period of  $11 \pm 7$  mo<sup>[14]</sup>. Similarly, Olmi *et al*<sup>[15]</sup> reported that after a median 36-mo follow-up period, all 19 patients in the stent-laparoscopy group and four patients in the stent-open group were alive. The superiority of laparoscopic colectomy for treating malignancy over open surgery in terms of recurrence and cancer-related survival was demonstrated in a previous randomized trial<sup>[24]</sup>. In several recent, large-scale randomized control trials (RCTs), no significant differences in 3- or 5-year OS and DFS between laparoscopy and open surgery were ob-

served<sup>[21]</sup>. In the present study, 4-year OS and DFS were compared between laparoscopy and open surgery after SEMS placement, and no significant differences were observed, in accordance with the results of these RCTs. Thus, we suggest that different surgical approaches after stenting do not influence long-term clinical outcomes. On the other hand, no study had explored whether a preoperative SEMS influenced the curative effect of subsequent laparoscopy for exacerbating CRC oncological characteristics, such as promoting recurrence or metastasis. Therefore, we compared long-term OS and DFS between the stent-laparoscopy approach and regular laparoscopy, and no significant differences were observed. These results indicate that preoperative SEMS placement is completely safe for subsequent laparoscopy.

In conclusion, compared with the stent-open approach, the stent-laparoscopy approach was associated with a more difficult surgical procedure, but a faster postoperative recovery and lower morbidity. These two approaches show similar long-term survival, recurrence rates and metastasis rates. Furthermore, after comparison with regular laparoscopy, preoperative SEMS placement does not influence subsequent laparoscopic procedures and long-term survival could be assessed. Therefore, SEMS placement followed by one-stage laparoscopic surgery is a feasible and rapid recovery treatment option for patients with ACO caused by left-sided CRC, and provides a favorable long-term prognosis. Of course, this study is limited by the patients' conditions and the study method employed; thus, heterogeneity among the groups in our study cannot be excluded. A larger number of patients, a longer follow-up period and more homogeneous study groups should be included in a future study.

## COMMENTS

### Background

Acute colorectal obstruction (ACO) is a common initial symptom in patients with left-sided colorectal cancer (CRC). Placement of a self-expanding metallic stent (SEMS), followed by elective surgery, will gradually replace conventional treatment (emergent surgery), and become the predominant treatment. Meanwhile, the application of a SEMS enhances the need for laparoscopic colectomy, avoiding colostomy, and offers the advantages of two minimally invasive procedures.

### Research frontiers

SEMS placement followed by laparoscopy is an emerging and accepted treatment for left-sided CRC patients with ACO. However, preoperative SEMS placement is believed to make the laparoscopic procedure more difficult, because the SEMS make the colonic segment more bulky and more technically difficult to remove *via* laparoscopy. In addition, long-term clinical outcomes of the stent-laparoscopy approach are unknown.

### Innovations and breakthroughs

Authors compared surgery-related parameters, postoperative complications, and long-term survival using the stent-laparoscopy approach with those using the stent-open approach and regular laparoscopy in left-sided CRC patients without ACO. They first reported that preoperative SEMS placement did not influence any subsequent laparoscopic procedure. Furthermore, using a stent-laparoscopy approach could achieve a similar curative effect compared with the other two approaches and did not reduce long-term survival of patients by influencing CRC oncological characteristics.

### Applications

The results indicate that SEMS placement followed by one-stage laparoscopic surgery is a feasible treatment option for left-sided CRC patients with ACO,

and shows rapid recovery. Moreover, the treatment does not reduce long-term survival by influencing CRC oncological characteristics, which confirms the curative effect of the stent-laparoscopy approach and may allow it to be applied more widely.

### Terminology

SEMS placement: a SEMS is placed in the stricture of the ACO to drain the excrement.

### Peer review

This study details the clinical outcomes and long-term survival of patients undergoing preoperative SEMS placement and laparoscopy. The results show that the stent-laparoscopy approach is a feasible treatment for left-sided CRC patients with ACO, with rapid recovery and good long-term prognosis.

### Abstract

**AIM:** To evaluate the clinical value of diffusion-weighted magnetic resonance imaging (DW-MRI) in predicting the response of rectal cancer to neoadjuvant chemoradiation.

**METHODS:** This prospective study was approved by our institutional review board, and informed consent was obtained from each patient. Fifteen patients (median age 56 years) with locally advanced rectal cancer were treated in our hospital from June 2006 to December 2007. All patients were stage III B-C accord-

ing to the results of MRI and endorectal ultrasound examinations. All patients underwent pelvic irradiation with 45 Gy/25 fx per 35 days. The concurrent chemotherapy regimen consisted of capecitabine 625 mg/m<sup>2</sup>, *bid* (Monday-Friday), and oxaliplatin 50 mg/m<sup>2</sup>, weekly. The patients underwent surgery 5-8 wk after the completion of neoadjuvant therapy. T downstaging was defined as the downstaging of the tumor from cT3 to ypT0-2 or from cT4 to ypT0-3. Good regression was defined as TRG 3-4, and poor regression was defined as TRG 0-2. Diffusion-weighted magnetic resonance images were obtained prior to and weekly during the course of neoadjuvant chemoradiation, and the apparent diffusion coefficient (ADC) values were calculated from the acquired tumor images.

**RESULTS:** Comparison with the mean pretreatment tumor ADC revealed an increase in the mean tumor ADC during the course of neoadjuvant chemoradiation, especially at the 2<sup>nd</sup> week ( $P = 0.004$ ). We found a strong negative correlation between the mean pretreatment tumor ADC and tumor regression after neoadjuvant chemoradiation ( $P = 0.021$ ). In the T downstage and tumor regression groups, we found a significant increase in the mean ADC at the 2<sup>nd</sup> week of neoadjuvant therapy ( $P = 0.011$ ; 0.004).

**CONCLUSION:** DW-MRI might be a valuable clinical tool to help predict or assess the response of rectal cancer to neoadjuvant chemoradiation at an early time-point.

**Key words:** Locally advanced rectal cancer; Neoadjuvant chemoradiation; Diffusion-weighted magnetic resonance imaging; Apparent diffusion coefficient

**Core tip:** This original study prospectively evaluated the

clinical value of diffusion-weighted magnetic resonance imaging (DW-MRI) in predicting the response of rectal cancer to neoadjuvant chemoradiation. We found a strong negative correlation between the mean pretreatment tumor apparent diffusion coefficient (ADC) and tumor regression after neoadjuvant chemoradiation, as well as a significant increase in the mean ADC at the 2<sup>nd</sup> week in the T downstage and tumor regression groups. Therefore, DW-MRI might be a valuable clinical tool to help predict or assess the response of rectal cancer to neoadjuvant chemoradiation at an early timepoint.

Diffusion-weighted magnetic resonance imaging for predicting the response of rectal cancer to neoadjuvant concurrent chemoradiation. *World J Gastroenterol* 2013; 19(33): 5520-5527 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i33/5520.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i33.5520>

## INTRODUCTION

Neoadjuvant (chemo) radiation followed by total mesorectal excision has become the standard treatment for locally advanced rectal cancer (LARC)<sup>[1-3]</sup>. However, approximately 20%-30% of patients do not benefit from neoadjuvant treatment due to the radioresistance of the tumor<sup>[4]</sup>, and ineffective neoadjuvant treatment may result in unnecessary toxicity and expense as well as delays in receiving the proper treatment. Meanwhile, 10%-30% of patients with a pathological complete response (pCR) have a favorable long-term outcome<sup>[5]</sup>. Recently, data have even suggested that surgery is unnecessary for clinical complete responders<sup>[6]</sup>. To effectively guide patient-tailored treatments, reliable and early assessment of the treatment response is important.

Diffusion-weighted magnetic resonance imaging (DW-MRI) is a non-invasive functional MRI technique that is sensitive to the mobility of water protons in biological tissues, which is dependent on many factors, such as cell density, vascularity, the viscosity of the extracellular fluid, and cell membrane integrity<sup>[7-9]</sup>. The apparent diffusion coefficient (ADC) calculated from DW-MRI measurements can quantify and express these properties. However, published data on the value of DW-MRI as a predictive tool for anti-cancer treatment responses in patients with rectal cancer are scarce and conflicting. Most studies have found that the pretreatment ADC is negatively correlated with the response to treatment<sup>[10]</sup>. Furthermore, it is possible that necrotic areas with high pretreatment ADCs are less sensitive to radiation and chemotherapy, although several studies do not support this hypothesis, and others have obtained opposite results<sup>[11,12]</sup>. Therefore, we conducted this study to investigate the clinical value of DW-MRI as a predictor of the tumor response in patients receiving neoadjuvant chemoradiation therapy (CRT) for rectal cancer by measuring the tumor ADC.

## MATERIALS AND METHODS

Our institutional review board approved this prospective study, and informed consent was obtained from each patient.

### Patients and treatment

Fifteen patients (median age 56 years, range 32-69 years; 13 men and 2 women) with LARC were invited to participate in our study between June 2006 and December 2007. Each patient had histologically proven rectal adenocarcinoma of stage T3-T4 and was determined to be node-positive by endorectal ultrasound and pelvic MRI. Patients with a history of pelvic irradiation or chemotherapy, any other malignancy, or distant metastases were excluded (Table 1). The clinical and histopathological classification and stage according to the International Union Against Cancer TNM system<sup>[13]</sup> were recorded. Tumor regression grading was evaluated according to the criteria of Dworak *et al.*<sup>[14]</sup> (grade 0, no regression; grade 1, minor regression, dominant tumor mass with obvious fibrosis in 25% or less of the tumor mass; grade 2, moderate regression, 26%-50% of the tumor mass; grade 3, good regression, more than 50% tumor regression; and grade 4, total regression, no viable tumor cells, only fibrotic mass). A pCR was defined as the absence of viable tumor cells in the primary tumor and lymph nodes (ypT0N0). T downstaging was defined as the downstaging of the tumor from cT3 to ypT0-2 or from cT4 to ypT0-3. Good regression was defined as TRG 3-4, and poor regression was defined as TRG 0-2.

All patients received neoadjuvant concurrent CRT. Radiotherapy (RT) was delivered with a linear accelerator using 6- and 15-MV photons and a three-field technique (posterior-anterior and right and left laterals). Every patient underwent a planning computed tomography (CT) scan in the treatment position (prone position) using a belly board. Three-dimensional conformal RT was used for all patients based on the planning CT, with a total dose of 45 Gy at 1.8 Gy per fraction per day, Monday-Friday. Neoadjuvant chemotherapy was delivered concurrently with RT. Starting on day 1 of RT, patients received capecitabine 625 mg/m<sup>2</sup> orally, *bid* (Monday-Friday), and oxaliplatin 50 mg/m<sup>2</sup> weekly for five consecutive weeks. Surgical resection was scheduled for 5-8 wk after the completion of neoadjuvant treatment.

### DW-MRI

Each enrolled patient was examined by DW-MRI at six scheduled times. The initial DW-MRI scan was performed 7 d prior to the start of RT. DW-MRI scans were then taken once weekly during the course of neoadjuvant treatment.

DWI was performed on a 1.5 T magnetic resonance machine (1.5 T Signa Twin Speeder with Excite, GE, United States) using a phased-array body coil. Before DW-MRI, standard T2-weighted fast spin echo sequence and T1-weighted spin echo sequence images were used for clinical staging. DWI echo planar images were ac-

quired in the transverse plane using a GRE-EPI sequence (TR/TE 3000/min; field of view 22 cm<sup>2</sup>; matrix size 128 × 128; slice thickness 4 mm; intersection gap 1 mm). DW-MR images and ADC maps were obtained using *b* values of 0 and 1000 s/mm<sup>2</sup> applied in the *x*, *y*, and *z* directions. Patients did not undergo bowel preparation, receive anti-spasmodic medication, or undergo rectal distention before the MR examination. For the image analysis, the data were transferred to a Workstation (AW4.0, GE Medical Systems) and analyzed using the Functool dynamic analysis tool (GE Medical Systems). ADC values were calculated based on the ADC maps. The ADC map of the largest tumor extension in the transverse T2-weighted images was used for the analysis. Regions of interest (ROIs) were drawn manually along the edge of the tumor with a *b* value of 1000 s/mm<sup>2</sup> on the selected ADC maps by an experienced radiologist (Zhang S, with 10 years of experience in clinical MRI), who did not participate in the treatment of the patients or the evaluation of the therapeutic effect.

### Statistical analysis

Statistical analysis was performed using SPSS 12.0 statistical software. Paired comparisons were performed using the Wilcoxon test. Spearman's correlation was used to assess the significance of differences between groups. A *P* value < 0.05 was considered statistically significant.

## RESULTS

### Treatment characteristics

After neoadjuvant treatment, pCR was observed in 2 patients. Downstaging of the tumor was observed in eight patients. The tumor regression grades after neoadjuvant treatment were grade 0-2 in 6 patients and grade 3-4 in 9 patients.

### DW-MRI data

Diffusion data from 15 patients were obtained prior to

and at constant intervals once weekly during the course of neoadjuvant treatment. The observed ADC values are shown in Table 2. A total of 88 ADC values were obtained in our study, and 2 ADC values were excluded due to measurement errors. Sample T2-weighted and diffusion-weighted images prior to treatment are shown in Figure 1. Sample ADC maps from the images taken weekly during the course of neoadjuvant treatment are shown in Figure 2.

The mean tumor ADC value slightly increased from  $0.749 \times 10^{-3}$  mm<sup>2</sup>/s (95%CI:  $0.641 \times 10^{-3}$ - $0.858 \times 10^{-3}$  mm<sup>2</sup>/s) prior to treatment to  $0.772 \times 10^{-3}$  mm<sup>2</sup>/s (95%CI:  $0.627 \times 10^{-3}$ - $0.918 \times 10^{-3}$  mm<sup>2</sup>/s) after the 1<sup>st</sup> week of treatment. There was also a significant increase at the 2<sup>nd</sup> week to  $0.884 \times 10^{-3}$  mm<sup>2</sup>/s (95%CI:  $0.775 \times 10^{-3}$ - $0.994 \times 10^{-3}$  mm<sup>2</sup>/s). Subsequently, the mean ADC decreased to  $0.800 \times 10^{-3}$  mm<sup>2</sup>/s (95%CI:  $0.675 \times 10^{-3}$ - $0.925 \times 10^{-3}$  mm<sup>2</sup>/s) at the 3<sup>rd</sup> week and  $0.766 \times 10^{-3}$  mm<sup>2</sup>/s (95%CI:  $0.659 \times 10^{-3}$ - $0.872 \times 10^{-3}$  mm<sup>2</sup>/s) at the 4<sup>th</sup> week. ADC increased again at the 5<sup>th</sup> week to  $0.839 \times 10^{-3}$  mm<sup>2</sup>/s (95%CI:  $0.702 \times 10^{-3}$ - $0.976 \times 10^{-3}$  mm<sup>2</sup>/s). We also observed a significant increase in the mean ADC value at the 2<sup>nd</sup> (*P* = 0.004) and 5<sup>th</sup> week (*P* = 0.033) during treatment relative to the values prior to treatment. The mean observed ADC values and *P* values are shown in Table 3.

### Tumor ADC for the prediction of treatment response

We compared the tumor ADC values of the responder and non-responder groups to predict the treatment response based on T downstage and TRG criteria.

Downstaging of the tumor was observed for 8 of the 15 patients (53.3%). The ADC values at the 5<sup>th</sup> week during treatment increased for 6/8 patients with T downstaging and increased for 5/7 patients without T downstaging relative to the mean tumor ADC values before treatment. The mean observed ADC values for patients with and without T downstage are shown in Table 4. The difference between these two groups with respect to the mean ADC values measured at the six timepoints did not reach significance.

For the eight patients with tumor downstaging, there was a significant increase (*P* = 0.011) in the mean tumor ADC at the 2<sup>nd</sup> week of treatment relative to the ADC before treatment, whereas for the seven patients without tumor downstaging, there was no significant change in the ADC at any timepoint during treatment relative to the ADC values before treatment (Figure 3A, Table 3).

Good regression (TRG 3-4) was observed in 9 of the 15 patients (60%), and poor regression (TRG 0-2) was observed in 6 patients (40%). The ADC values at the 5<sup>th</sup> week during treatment were increased in 7/9 patients with good regression and 5/6 patients with poor regression relative to the mean tumor ADC values before treatment. The mean observed ADC values in patients with good regression and poor regression are shown in Table 4. Before treatment and at the 3<sup>rd</sup>, 4<sup>th</sup>, and 5<sup>th</sup> week during treatment, significant differences in the mean ADC values between the two groups were obtained.

For the nine patients with good regression, there

was a significant increase ( $P = 0.004$ ) in the mean tumor ADC value at the 2<sup>nd</sup> week of treatment relative to the ADC values before treatment, whereas for the six patients with poor regression, no significant change in ADC was observed at any timepoint during treatment (Figure

3B, Table 3). The two patients with pCR demonstrated lower ADC ( $0.659 \times 10^{-3} \text{ mm}^2/\text{s}$  and  $0.813 \times 10^{-3} \text{ mm}^2/\text{s}$ ) before treatment but significantly increased tumor ADC ( $0.825 \times 10^{-3} \text{ mm}^2/\text{s}$  and  $1.133 \times 10^{-3} \text{ mm}^2/\text{s}$ ) at the 2<sup>nd</sup> week of treatment.

## DISCUSSION

The recent trend toward patient-tailored treatment for LARC has highlighted the need for a reliable method for the early assessment of treatment response. DWI-MRI may be a promising functional imaging tool for the prediction of treatment response. In our study, DW-MRI was investigated as a potential clinical tool to predict or assess the response of rectal tumors to neoadjuvant concurrent CRT at an early timepoint.

Our results show that CRT induced a significant increase in mean tumor ADC in LARC. Because the ADC values obtained from DWI measurements reflect tumor cellularity and anti-tumor treatment decreases tumor cellularity, CRT should increase the ADC value. The administration of CRT results in cell swelling, necrosis, and apoptotic cell death. When CRT is initiated, the ADC may rapidly decrease over several hours due to cell swelling, followed by an increase over several days concurrent with cell death. Increased ADC values have also been

**Table 4 Mean tumor apparent diffusion coefficient values and *P* values for the comparisons between groups**

Group	Apparent diffusion coefficient values ( $\times 10^{-3} \text{ mm}^2/\text{s}$ )					
	Week 0	Week 1	Week 2	Week 3	Week 4	Week 5
T downstage ( $n = 8$ )	0.702	0.720	0.890	0.724	0.690	0.743
No T downstage ( $n = 7$ )	0.803	0.824	0.877	0.875	0.851	0.947
<i>P</i> value	0.339	0.463	0.909	0.202	0.108	0.114
Good regression ( $n = 9$ )	0.658	0.670	0.851	0.618	0.673	0.713
Poor regression ( $n = 6$ )	0.885	0.907	0.933	0.938	0.903	1.027
<i>P</i> value	0.021	0.081	0.452	0.032	0.016	0.010

correlated with tumor necrosis and reduced cell density<sup>[15]</sup>, and most studies have found an increase in ADC after CRT<sup>[12,16,17]</sup>. For example, Kim *et al.*<sup>[12]</sup> recently showed that neoadjuvant CRT caused a significant increase in the ADC values of 76 rectal cancer patients. In contrast, Hein *et al.*<sup>[18]</sup> reported a decrease in the ADC after CRT in all nine of their patients, and they attributed this result to intratumoral radiation-induced fibrosis and cytotoxic edema as well as to the method employed (ROI excluding apparent necrotic areas).

Our results indicate that the mean pre-CRT ADC was negatively correlated with tumor regression ( $P = 0.021$ ) but not with T downstaging ( $P = 0.339$ ). T downstaging and TRG criteria were used because these are common factors used for the evaluation of treatment responses<sup>[19,20]</sup>. The TRG was not completely concordant with T downstaging, and some studies have shown that the pretreatment ADC value is negatively correlated with treatment response in rectal cancer and other tumors<sup>[10,21-25]</sup>. Dzik-Jurasz *et al.*<sup>[10]</sup> found a strong negative correlation between the mean pretreatment tumor water ADC and the percent change in the size of the tumor after chemotherapy and chemoradiation in 2002. ADC values are generally higher for necrotic tumors than for solid or viable tumors<sup>[26]</sup>. Because necrotic areas in tumors are resistant to radiation, it may be hypothesized that tumors with necrotic areas, and thus high pretreatment ADC values, would have less favorable treatment responses. However, other studies have obtained different results; for example, several studies of rectal and other tumors found no correlation between the pretreatment ADC value and treatment response<sup>[11,27,28]</sup>, whereas another study found a positive correlation<sup>[12]</sup>. Several factors may explain these different correlations, such as small sample sizes, the use of different methods for calculating the ADC, and the use of different indicators for the evaluation of treatment response.

A substantial change in the mean ADC value at the 2<sup>nd</sup> week of CRT predicted the tumor response of LARC in our study. Most studies have assumed that CRT decreases tumor cellularity and results in a substantial change in the ADC value<sup>[18,26]</sup>. Although decreasing tumor cellularity will lead to a reduction in tumor size, this reduction is typically observed 3 wk or more after the start of CRT<sup>[29,30]</sup>. Thus, a more rapid evaluation or prediction of treatment response would be clinically useful. We

found a significant increase in the mean ADC at the 2<sup>nd</sup> week in the T downstage ( $P = 0.011$ ) and good regression ( $P = 0.004$ ) groups but not in the groups of patients without T downstaging and with poor regression. We believe that the significant increase in the mean ADC at the 2<sup>nd</sup> week of treatment was correlated with tumor necrosis and apoptosis, which reduce cell density, after the start of therapy. Similar results have been obtained in several other studies. For example, one study examined the ADC data of nine patients with LARC, and a significant change in the mean ADC starting at week 2 of CRT was observed<sup>[18]</sup>. In another study focused on the early detection of responses to CRT in cervical cancer, the changes in the ADC value after 2 wk of therapy were also significantly correlated with the treatment response<sup>[27]</sup>.

There are several limitations of our study. First, the study sample size was small. Second, the sample slice with the largest tumor extension was selected to determine the ADC value, and the use of this slice may not have adequately captured the heterogeneity of the tumor. Third, the ROIs were drawn manually, and this process may have influenced the ADC value and introduced subjectivity. The reason the ROIs were drawn manually by a single experienced radiologist was to obtain more uniform and stable ADC values.

Our study and several previous studies highlight the value of DW-MRI as a predictive tool for the response of rectal cancer to chemoradiation. However, there are some difficulties associated with incorporating DW-MRI into routine clinical practice. The reproducibility of DWI has been insufficiently investigated, and the cut-off values used to determine treatment response vary between treatments and ADC measurement techniques. Thus, a standardized guideline to predict or assess treatment response is needed before DWI can be implemented in clinical practice.

In this study, the tumor ADC values changed during the course of neoadjuvant chemoradiation. The pretreatment tumor ADC value was negatively correlated with tumor regression after chemoradiation for the treatment of LARC, and the ADC value at the 2<sup>nd</sup> week of therapy was significantly correlated with the tumor response. Our results indicate that DW-MRI may be a valuable clinical tool to help predict or assess the responses of rectal tumors to neoadjuvant concurrent chemoradiation at an early timepoint.

## COMMENTS

**Background**

Neoadjuvant (chemo)radiation followed by surgery has become the standard treatment for locally advanced rectal cancer (LARC). However, approximately 20%-30% of patients do not benefit from this neoadjuvant treatment due to radioresistance of the tumor. Functional non-invasive diffusion-weighted magnetic resonance imaging (DW-MRI) studies are increasingly used to predict response to cancer therapy, but definitive evidence is limited, especially for patients with rectal cancer treated with neoadjuvant chemoradiation therapy (CRT).

**Research frontiers**

DW-MRI is a non-invasive functional MRI technique. To date, published data on the value of DW-MRI as a predictive tool for assessing responses to anti-cancer treatment in patients with rectal cancer are scarce and conflicting.

**Innovations and breakthroughs**

The authors found that CRT induced a significant increase in the mean apparent diffusion coefficient (ADC) value of LARC. The pretreatment tumor ADC was negatively correlated with tumor regression after CRT for the treatment of LARC, and the ADC value at the 2<sup>nd</sup> week of therapy was significantly correlated with the tumor response.

**Applications**

The results of this study suggest that DW-MRI may be a valuable clinical tool to help predict or assess the responses of rectal tumors to neoadjuvant concurrent CRT at an early timepoint.

**Terminology**

DW-MRI is a non-invasive functional MRI technique that provides information by measuring water proton mobility in tissues. ADC values can be calculated from DWI measurements according to the impediment to free diffusion of water molecules in a single voxel due to restricting barriers such as membranes, macromolecules, and fibers inside different tissue compartments.

**Peer review**

This is an interesting study that investigates the use of DW-MRI as a predictor of the tumor response in 15 patients with rectal cancer undergoing CRT therapy by measuring the tumor ADC. This is an emerging field in which new knowledge is needed, and this study, despite its limits, provides novel information that may help to settle the current debate about the utility of DW-MRI as a predictive tool for the response to anti-cancer treatment.

### Abstract

**AIM:** To summarize our experience in the application of Crurasoft® for antireflux surgery and hiatal hernia (HH) repair and to introduce the work of Chinese doctors on this topic.

**METHODS:** Twenty-one patients underwent HH repair with Crurasoft® reinforcement. Gastroesophageal reflux disease (GERD) and HH-related symptoms including heartburn, regurgitation, chest pain, dysphagia, and abdominal pain were evaluated preoperatively and 6 mo postoperatively. A patient survey was conducted by phone by one of the authors. Patients were asked about "recurrent reflux or heartburn" and "dysphagia". An internet-based Chinese literature search in this field was also performed. Data extracted from each study included: number of patients treated, hernia size, hiatorrhaphy, antireflux surgery, follow-up period, recurrence rate, and complications (especially dysphagia).

**RESULTS:** There were 8 type I, 10 type II and 3 type III HHs in this group. Mean operative time was 119.29 min (range 80-175 min). Intraoperatively, length and width of the hiatal orifice were measured, ( $4.33 \pm 0.84$  and  $2.85 \pm 0.85$  cm, respectively). Thirteen and eight Nissen and Toupet funduplications were performed, respectively. The intraoperative complication rate was 9.52%. Despite dysphagia, GERD-related symptoms improved significantly compared with those before surgery. The recurrence rate was 0% during the 6-mo follow-up period, and long-term follow-up disclosed a recurrence rate of 4.76% with a mean period of 16.28 mo. Eight patients developed new-onset dysphagia. The Chinese literature review identified 12 papers with 213 patients. The overall recurrence rate was 1.88%. There was no esophageal erosion and the rate of dysphagia ranged from 0% to 24%.

**CONCLUSION:** The use of Crurasoft® mesh for HH repair results in satisfactory symptom control with a low recurrence rate. Postoperative dysphagia continues to be an issue, and requires more research to reduce its incidence.

**Key words:** Hiatal hernia; Gastroesophageal reflux disease; Anti-reflux surgery; Mesh; Prosthetic

**Core tip:** With a focus on the mesh fixation technique, the application of Crurasoft® for antireflux surgery and hiatal hernia repair achieved satisfactory outcome. The recurrence rate was 0% during the 6-mo follow-up period, and long-term follow-up disclosed a recurrence rate of 4.76% with a mean period of 16.28 mo. Eight patients developed new-onset dysphagia and this gradually resolved without difficulty in swallowing solid food in 6 patients. The Chinese literature review identified 12 papers with 213 patients. The overall recurrence rate was 1.88%. There was no esophageal erosion and

the rate of dysphagia ranged from 0% to 24%.

Zhang W, Tang W, Shan CX, Liu S, Jiang ZG, Jiang DZ, Zheng XM, Qiu M. Dual-sided composite mesh repair of hiatal hernia: Our experience and a review of the Chinese literature. *World J Gastroenterol* 2013; 19(33): 5528-5533 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i33/5528.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i33.5528>

## INTRODUCTION

Laparoscopic fundoplication is a safe and effective alternative to long-term medical treatment for patients with gastroesophageal reflux disease (GERD) and hiatal hernia (HH)<sup>[1]</sup>. Cryoplasty is considered to be an essential part of antireflux surgery<sup>[2]</sup>. Possible reasons for failed laparoscopic antireflux surgery and disruption of HH repair are lateral tension following simple hiatal closure, or poor character of the crural musculature. The use of a mesh, either by reducing tension or reinforcing the crural musculature, is associated with a significantly lower recurrence rate<sup>[1-5]</sup>.

Despite this, most concerns are focused on mesh-related complications (including intraluminal erosion, fibrosis, and esophageal stenosis)<sup>[3,6]</sup>. Although few mesh-related complications at the hiatus have been reported, anecdotal observations suggest that this complication may be more common<sup>[7]</sup>. Moreover, surgery to manage these complications is complex and may require esophagectomy or gastrectomy<sup>[3]</sup>. For these reasons, many surgeons avoid the use of synthetic mesh in HH repair<sup>[8]</sup>.

The ideal mesh generates adhesion to the diaphragmatic surface and not the visceral side<sup>[4]</sup>. "V" shaped composite polytetrafluoroethylene (PTFE) and expanded polytetrafluoroethylene (ePTFE) prostheses (dual-sided composite mesh, Crurasoft<sup>®</sup>) have some of these features. PTFE encourages ingrowth of host tissue from the underlying crura, producing local fibrosis and a more uniform mesh-tissue complex. ePTFE was thought to have a benign behavior as opposed to hollow viscera<sup>[9]</sup>, with encapsulation of the material and neomesothelialization of the exposed abdominal surface, thus becoming isolated from the esophagus and stomach<sup>[3]</sup>. That is, dual-sided mesh has the merits of prosthetic mesh and may avoid possible major complications. Chilintseva *et al*<sup>[10]</sup> reported the preliminary results of the use of this dual-sided prosthesis for large HH repairs, demonstrating satisfactory results. Although there was no erosion of the esophagus or stomach, severe periprosthetic fibrosis resulted in postoperative dysphagia in two patients, requiring reoperation. The authors proposed that positioning the mesh with care should be emphasized<sup>[10]</sup>.

To reduce postoperative dysphagia, some propose that space should be allowed between the esophagus and the mesh<sup>[11]</sup>. We summarize our experience in the ap-

plication of Crurasoft<sup>®</sup> for antireflux surgery and HH repair, focusing on whether a reduction in postoperative complications, especially erosion and dysphagia, can be achieved if technical attention to mesh fixation is applied. Moreover, Crurasoft<sup>®</sup> is the most commonly used prosthetic mesh in China. We also analyzed and introduced the work of Chinese doctors on this topic, as the Chinese language is still an obstacle for academic communication.

## MATERIALS AND METHODS

### Patients

From May 2010 to July 2012, 48 patients underwent surgery for pH-proven symptomatic GERD with HH in our institution. Of these, 21 patients (14 male, 7 female) underwent hiatal repair with an onlay Crurasoft<sup>®</sup> mesh reinforcement and were enrolled in this retrospective analysis. The indication for mesh implantation included a HH length longer than 3 cm, obesity, and weak hiatus tissue.

### Symptom evaluation

GERD and HH related symptoms including heartburn, regurgitation, chest pain, dysphagia, and abdominal pain were evaluated preoperatively and 6 mo postoperatively. The severity of symptoms was evaluated using a scaled 0-10 visual analog score, as previously described in the literature<sup>[12]</sup>.

### Preoperative work-up

Preoperative barium contrast swallowing or a computed tomography scan was used to evaluate the type and size of the HH. The presence and severity of esophagitis was confirmed by upper endoscopy. pH monitoring (24-h) and esophageal manometry were performed in all patients to evaluate lower esophageal sphincter function and esophageal motility.

### Surgical technique

Five trocars were used during laparoscopic surgery. The stomach was first reduced into the abdomen, followed by mobilization of the distal esophagus with at least 3 cm of intraabdominal esophagus restored to the abdominal cavity. All patients underwent primary closure of the hiatus with between 2 and 5 nonabsorbable sutures for posterior Cryoplasty, depending on the size of the hiatus defect (Figure 1). Additional anterior Cryoplasty was also performed if the defect was wide. A V-shaped dual-sided composite mesh (Crurasoft<sup>®</sup>, Composix mesh, CR Bard, Cranston, United States) was used to reinforce the primary repair, with the PTFE side facing the diaphragm (Figure 2). The lower of the two arms was positioned about 2-3 mm below the first stitch, and fixed with staples (EMS, Johnson and Johnson). Additional staples were applied to secure the mesh to the right and left crura and flatten it. The small ePTFE "tongue" was placed to protect the posterior esophageal wall from contacting the PTFE margin. After closing the hiatus, a fundoplication (Nissen/Toupet) was performed.

**Table 1** Classification of hiatal hernia

Type	Description
I	Sliding hernia with the GEJ above the diaphragm
II	Paraesophageal hiatus hernia. A part of the stomach herniates through the hiatus and lies beside the esophagus, without movement of the GEJ
III	Combined hernia. The combination of type I and II
IV	A large defect in the hiatus, allowing other organs to enter the hernia sac

GEJ: Gastroesophageal junction.

**Table 2** Baseline characteristics of the patients who underwent laparoscopic antireflux surgery

Item	Value
Age (yr)	53.81 ± 13.76 (21-75)
Body mass index (kg/m <sup>2</sup> )	28.95 ± 3.11 (21-35)
Hiatal hernia length (cm)	4.33 ± 0.84 (3.1-6.3)
Hiatal hernia width (cm)	2.85 ± 0.85 (1.8-5.4)
DeMeester score	50.30 ± 27.73 (12.7-112.7)
Surgery duration (min)	119.29 ± 23.84 (80-175)
Postoperative stay (d)	4.71 ± 0.85 (4-7)

Data are expressed as absolute mean ± SD (range).

### Intraoperative data

Operative duration and size of HH (length and width), were recorded.

### Phone questionnaire

In January 2013, a patient survey was conducted by phone by one of the authors. Patients were asked about “recurrent reflux or heartburn” and “dysphagia.” Dysphagia was defined as new-onset difficulty in swallowing; severity (mild/severe) and duration of symptoms (temporary/permanent, duration shorter than 6 mo was defined as temporary) were also surveyed. Patients were also asked about “whether you are satisfied with the outcome of surgery”.

### Data sources and study selection

An internet-based Chinese literature search was performed using the Chinese Medical Literature database (Chongqing VIP) between January 2000 and December 2012. The key words “hiatal hernia”, “GERD”, and “mesh” were used in all possible combinations to identify relevant articles. If data appeared appropriate for analysis, the abstract and full article were retrieved for in-depth review. All reference lists in the papers were manually searched for relevant articles. Inclusion criteria were: (1) antireflux surgery with HH repair using Crurasoft® composite mesh; (2) reports described surgical technique details; and (3) reports documented outcome of recurrence and follow-up data. The literature search, study selection, and data extraction were performed by two independent authors. Data extracted from each study included: number of patients treated, hernia size, hiatorrhaphy, antireflux surgery, follow-up period, recurrence rate, and

**Table 3** Symptom evaluation before and after surgery

	Before surgery	After surgery	P value
Heartburn	5.33 ± 1.65	2.14 ± 1.74	0
Regurgitation	5.00 ± 1.64	1.95 ± 1.16	0
Chest pain	3.62 ± 1.99	1.29 ± 1.15	0
Dysphagia	2.57 ± 1.66	1.62 ± 1.86	0.087
Abdominal pain	2.33 ± 1.28	1.38 ± 1.12	0.014

complications (especially dysphagia).

### Ethical approval of the study protocol

All patients were informed about the study protocol. Written consent for the investigation in accordance with the ethical guidelines of Changzheng Hospital was obtained.

### Statistical analysis

The student's *t* test and Pearson  $\chi^2$  test were used to compare means and categorical variables, respectively. A *P* value of less than 0.05 was considered statistically significant.

## RESULTS

### Perioperative data and 30-d complications

Classification of HH is listed in Table 1. There were 8 type I, 10 type II, and 3 type III HHs in this group. Mean operative time was 119.29 min (range 80-175 min). Intraoperatively, both the length and width of the hiatal orifice were measured, (4.33 ± 0.84 and 2.85 ± 0.85 cm, respectively; Table 2). Thirteen and 8 Nissen and Toupet funduplications were performed, respectively.

There was no mortality and no conversion to open surgery. The intraoperative complication rate was 9.52% (one spleen capsular laceration and 1 pneumothorax, all repaired laparoscopically without sequelae). Eight patients complained of new-onset dysphagia with difficulty eating solid food. No early reoperation or intervention (*e.g.*, endoscopic dilatation) was required. The median length of postoperative hospital stay was 5 (range 4-7) d.

### Symptomatic improvement

Preoperative and postoperative symptoms of GERD and HH were compared. As listed in Table 3, all relevant symptoms (except for dysphagia) improved significantly. 10 patients agreed to have a barium meal; no recurrence was demonstrated.

### Long-term complications

One patient was lost to follow-up. The mean follow-up period was 16.28 (6-32) mo. The overall satisfaction rate was 85.71% (18/21). One patient had a recurrence confirmed at the 8 mo postoperative visit, with the major complaint being dysphagia, different from her preoperative symptoms of heartburn. Barium meal examination showed a type II paraesophageal hernia. In a review of her history, she developed dysphagia at postoperative month 3, following an episode of severe vomiting. This

patient scored the outcome of surgery as dissatisfactory and was reluctant to undergo reoperation. The other two patients presented with recurrence of heartburn or regurgitation 4 and 7 mo following surgery, respectively. In these cases, barium swallowing failed to detect HH recurrence. Both patients underwent Nissen fundoplication without symptoms of dysphagia.

Of the 8 patients who complained of postoperative dysphagia, this gradually resolved without difficulty in swallowing solid food in 6 patients. The average period to resolution of dysphagia was 5.2 (range 4-7) mo. The remaining 2 patients complained of mild to moderate dysphagia, unabated even at the final phone call contact (11 and 19 mo postoperatively, respectively). One patient was confirmed to have a slight stricture at the level of the hiatus, for which dilatation achieved slight resolution. The other patient refused further workup and intervention.

### Chinese literature review

Our literature search identified 24 articles for review. Twelve papers fulfilled the inclusion criteria, with a total of 213 patients included in the final analysis. Reasons for exclusion were: no follow-up data ( $n = 8$ ), pediatric surgery ( $n = 1$ ), review ( $n = 1$ ), and overlapping study populations ( $n = 2$ ) (Table 4)<sup>[13-24]</sup>. All surgery involved hiatoplasty and fundoplication other than gastropexy. There were only 3 randomized controlled trials. Fei *et*

*al*<sup>[24]</sup> concluded that reinforcement of HH repair with Crurasoft<sup>®</sup> significantly improved HH-related symptoms. Zou *et al*<sup>[21]</sup> confirmed that the use of Crurasoft<sup>®</sup> significantly reduced recurrence from 36.4% with simple closure to 10%, with a follow-up period greater than 1 year. Yao *et al*<sup>[22]</sup> reported that there was 1 hernia recurrence following mesh placement in the 1-year follow-up period, compared with 3 cases in the simple Cryoplasty group. However, this difference was not statistically significant ( $P = 0.300$ ). Recurrence rates varied from 0% to 25%. This disparity might be due to differences in the definition of recurrence. Some authors define recurrence as symptoms, without radiological confirmation. The highest anatomic recurrence was reported by Zou *et al*<sup>[21]</sup> (10%), where all the HH in that cohort were larger than 6 cm. The overall anatomic recurrence rate was 1.88% (4/213). There were no cases of esophageal or stomach erosion. Postoperative dysphagia varied from 0% to 24% (median 6.67%).

### DISCUSSION

A survey on the use of mesh for HH repair by members of the Society of American Gastrointestinal and Endoscopic Surgeons (SAGES) showed that 33% preferred nonabsorbable to absorbable mesh<sup>[25]</sup>. This reflects the fact that prosthetic mesh has the advantage of reducing HH recurrence; biomaterial tends to be associated with

failure<sup>[9]</sup>. On the other hand, concerns still exist regarding mesh-related complications, including erosion, stricture, and fibrosis. Thus, there may be a trade-off in the choice of mesh repair for HH: permanent mesh risks erosion, while biologic mesh risks recurrence<sup>[9]</sup>.

Crurasoft<sup>®</sup> has the advantages of permanent mesh, while reducing mesh-related complications. Chilintseva *et al*<sup>[10]</sup> reported 38 cases who underwent HH repair using Crurasoft<sup>®</sup>, with no recurrences. Priego *et al*<sup>[26]</sup> concluded that Crurasoft<sup>®</sup>-reinforced hiatoplasty reduced HH recurrence in patients with large hiatal defects (larger than 5 cm), similar to that in patients with smaller hiatal defects (2% *vs* 2.1%). Granderath *et al*<sup>[27]</sup> selected a tailoring strategy for HH repair according to hiatal surface area (HAS). Those with HAS larger than 8 cm<sup>2</sup> underwent Crurasoft<sup>®</sup> placement in a tension-free, posterior onlay fashion. During a mean follow-up period of 6.3 mo, only 1 patient (1.8%) developed postoperative partial intrathoracic wrap migration. In the Chinese literature review, recurrence was between 0% and 10% (Table 3). The highest recurrence rate (2/20, 10%) was reported by Zou *et al*<sup>[21]</sup>, in whose series all HH were large, with orifices larger than 6 cm or herniation of more than half of the stomach. In our study cohort, we found a type II HH anatomic recurrence. Paraesophageal herniation is a complication that occurs in the immediate postoperative period following laparoscopic antireflux surgery, with an incidence of up to 7%. Vomiting in the early postoperative period, which occurred in this patient, has been identified as a risk factor for recurrence<sup>[3]</sup>. Violent diaphragmatic movements might also dislodge the mesh if fixation is inadequate<sup>[7]</sup>. Sufficient fixation of the mesh and avoidance of lifting or straining have been advocated to reduce this complication.

Two patients suffered symptomatic recurrence without any proof of anatomic recurrence. Both patients underwent Nissen fundoplication and the barium meal examination showed an intact wrap. A possible explanation for this could be poor correlation between postoperative symptoms and actual reflux<sup>[28]</sup>. Both patients presented with heartburn and acid regurgitation, the cardinal symptoms of GERD. However, these symptoms have a low specificity and sensitivity for the actual diagnosis of GERD. One patient agreed to resume manometry and pH monitoring, and all data indicated an improvement compared with that before surgery. As postoperative GERD symptoms actually indicate acid reflux in only 30% of patients and are not even accurate to rule out acid reflux in patients who are completely free of symptoms after surgery, Khajanchee *et al*<sup>[28]</sup> insisted that surgeons should explain the presence of symptomatic recurrence cautiously and that objective testing should be introduced to determine the actual cause.

In a collection of case reports pertaining to mesh complications after prosthetic hiatoplasty with special emphasis on mesh erosion, Stadlhuber *et al*<sup>[7]</sup> identified 17 cases of intraluminal erosion, involving not only different mesh material (polypropylene, PTFE, and biomaterial), but also different mesh configurations (keyhole, horse-

shoe and heart shaped). No apparent relationship between these parameters and mesh erosion was observed, thus the technique for mesh fixation was questioned. Fixation techniques such as the proximity of placement of the mesh at the esophagus are important factors in the development of postoperative complications. The edge of the mesh may “cheese wire” its way into the esophagus if it touches the esophagus or if shrinkage occurs. It is also possible that the mesh can migrate if fixation is insufficient, or traumatic events such as vomiting or repeated coughing may dislodge the mesh, causing it to be apposed to the esophageal wall, leading to erosion or stricture<sup>[7]</sup>. Use of Crurasoft<sup>®</sup> cannot completely eliminate this complication. In one case report, total migration of Crurasoft<sup>®</sup> into the stomach was detected by endoscopy 2 years after repeat fundoplication<sup>[29]</sup>. Both our series and a review of the Chinese literature failed to disclose any cases of this complication. However, a case of erosion was discussed at a conference without confirmation of its exact source and details (personal communication). Thus, the exact incidence of this complication may be underestimated<sup>[7,11]</sup>.

As opposed to erosion, esophageal stricture due to fibrosis associated with the prosthesis, may be a more common complication. Although ePTFE is less fibrogenic and is designed to prevent contact between the mesh and viscera, severe fibrosis enveloping the mesh can develop, leading to stricture refractory even to endoscopic dilatation<sup>[10]</sup>. Even though Wassenaar’s recommendations to maintain a 2-3 mm distance between the mesh and esophagus were followed, postoperative dysphagia cannot be completely eliminated (38.10% in our cohort). Only 2 patients had permanent symptoms, due to stricture at the hiatus and not the fundoplication itself (confirmed radiographically). Fortunately, most of these patients presented with mild dysphagia, which resolved within the first postoperative year, and did not require reoperation.

In conclusion, the use of Crurasoft<sup>®</sup> mesh for HH repair results in satisfactory symptom control with a low recurrence rate. Postoperative dysphagia continues to be an issue, and requires more research to reduce its incidence.

## COMMENTS

### Background

Cryoplasty is considered to be an essential part of antireflux surgery and use of a mesh, either by reducing tension or reinforcing the crural musculature, is associated with a significantly lower recurrence rate. Despite this, most concerns are focused on mesh-related complications.

### Research frontiers

Prosthetic mesh-related complications, including intraluminal erosion, fibrosis, and esophageal stenosis may be more common than reported. Moreover, surgery to manage these complications is complex and may require esophagectomy or gastrectomy. The ideal mesh generates adhesion to the diaphragmatic surface and not the visceral side.

### Innovations and breakthroughs

“V” shaped composite polytetrafluoroethylene (PTFE) and expanded polytetrafluoroethylene (ePTFE) prostheses (dual-sided composite mesh, Crurasoft<sup>®</sup>) might be an ideal mesh. PTFE encourages ingrowth of host tissue from the underlying crura, producing local fibrosis and a more uniform mesh-tissue complex. ePTFE was thought to have a benign behavior as opposed to hollow viscera,

with encapsulation of the material and neomesothelialization of the abdominal exposed surface, thus becoming isolated from the esophagus and stomach.

### Applications

Crurasoft® is the most commonly used prosthetic mesh in China. The authors summarize their experience in the application of Crurasoft® for antireflux surgery, focusing on whether reduction of postoperative complications, especially erosion and dysphagia, can be achieved if technical attention to mesh fixation is applied.

### Peer review

Clinical study and review by the authors demonstrate the benefit of the mesh Crurasoft in surgical therapy of hiatal hernia. The study is of clinical interest.

### Abstract

**AIM:** To propose an appropriate staging system for hepatocellular carcinoma (HCC) classification.

**METHODS:** Here, 288 in-patients with HCC were studied and divided into three groups: those with expansive growth, invasive growth (including satellite nodules, nodule fusions and direct tumor invasion of adjacent organs), or disseminative growth (including vascular involvement, regional lymph node metastasis and distant metastasis). A survival analysis was performed using a Kaplan-Meier analysis, and prognostic factors for overall survival were determined by the Cox proportional hazards regression model.

**RESULTS:** The overall survival (OS) of patients with invasive tumor growth was shorter than that of patients with expansive tumor growth ( $27.796 \pm 3.730$  and  $57.398 \pm 4.873$  mo, respectively,  $P < 0.001$ ). No significant difference in survival was observed between

patients with vascular involvement and patients with regional lymph node metastasis ( $21.667 \pm 4.773$  and  $14.619 \pm 2.456$  mo, respectively,  $P = 0.801$ ). The OS of patients with distant metastasis ( $6.417 \pm 1.395$  mo) was shorter than that of the other groups ( $P < 0.001$ ). No significant difference in survival was observed between patients with expansive tumor growth and vascular and/or regional lymph node involvement and patients with invasive tumor growth and no vascular and/or lymph node involvement ( $25.762 \pm 7.024$ ,  $21.200 \pm 7.794$  and  $39.533 \pm 5.840$  mo, respectively;  $P = 0.871$ ,  $0.307$  and  $0.563$ , respectively).

**CONCLUSION:** These data led to the proposal of a new staging system: the Expansive-Invasive-Disseminative growth staging classification.

© 2013 Baishideng. All rights reserved.

**Key words:** Hepatocellular carcinoma; Lymph node; Metastasis; Invasive growth; Staging system classification

**Core tip:** A number of staging systems were designed for all of hepatocellular carcinoma (HCC) patients based on some character of tumor, such as tumor size, vascular invasion, regional lymph node metastasis and extra-hepatic spread. But those systems failed to adequately stratify HCC patients with respect to prognosis. In our study, we explore an appropriate staging system for resectable patients with HCC based on tumor's growth characteristics, the Expansive-Invasive-Disseminative growth staging classification, which is a simple and efficacious prognostic model for postoperative patients with HCC.

## INTRODUCTION

A staging system has been widely used for malignant diseases to stratify patients into comparable groups to predict patients' long-term outcomes. The American Joint Committee on Cancer (AJCC) uses the tumor-node-metastasis (TNM) system as a staging system for many malignant diseases to predict prognosis. Nevertheless, the TNM system fails to adequately stratify hepatocellular carcinoma (HCC) patients with respect to prognosis. In fact, prognosis of patients with cirrhosis and HCC depends on both residual liver function and tumor characteristics. Staging systems that include liver function status were first proposed by Okuda *et al*<sup>[1]</sup>. In 1998, investigators from the Cancer of the Liver Italian Program (CLIP) proposed the CLIP score that is based on Child-Pugh stage, tumor morphology and extension, alpha-fetoprotein (AFP) level, and portal vein thrombosis<sup>[2,3]</sup>. Although the CLIP score has good prognostic value in HCC patients, this score has some limitations when applied to patients with resectable HCC<sup>[4]</sup>. The Chinese University Prognostic Index for HCC was identified in 2002<sup>[5]</sup>. It combines the conventional TNM system with liver function and AFP. In 2003, the Japan Integrated Staging score was proposed by Kudo *et al*<sup>[4]</sup>. It is based on new adapted TNM system and Child-Pugh grading.

Some of the tumor characteristics of HCC include the tumor size, tumor number, invasive growth, vascular invasion, regional lymph node metastasis, and extrahepatic spread<sup>[6-17]</sup>. The TNM staging system is based on tumor characteristics, such as tumor size, vascular invasion, regional lymph node metastasis and extrahepatic spread. In 1999, the Barcelona Clinic Liver Cancer (BCLC) staging classification for HCC was proposed by Llovet *et al*<sup>[18]</sup> based on certain tumor characteristics. Cammà *et al*<sup>[19]</sup> reported that the overall predictive ability of BCLC, CLIP and French classification staging systems was unsatisfactory for patients with both cirrhosis and HCC and did not have uniform predictive results for treated patients and untreated patients. None of the scoring systems provided confident prediction of survival in individual patients. However, because the liver function of the most resectable patients is either an A or B score by Child-Pugh analysis, the TNM staging system provides an effective means of assessing the prognosis of patients following curative resection of HCC<sup>[11]</sup>. Unfortunately, the TNM system fails to include comprehensive characteristics of the tumor, especially the tumor's growth pattern. Thus, it is crucial to design a system to evaluate the effects of tumor characteristics on the clinical outcome of resectable patients with HCC.

In this study, 288 postoperative patients with HCC were studied and followed until August 2012. Patients with a C score from the Child-Pugh analysis were ex-

cluded to eliminate the effect of poor liver function on the long-term outcome. The purpose of the study was to explore an appropriate staging system for resectable patients with HCC based on the patient's tumor growth characteristics.

## MATERIALS AND METHODS

### Patients

Two hundred and eighty-eight in-patients who were diagnosed with HCC and underwent curative resection of HCC at Tianjin Medical University Cancer Institute and Hospital from March 1999 to July 2007 were included in this study and were followed until August 2012. Pathological testing for all patients was performed to confirm HCC. Contrast-enhanced computed tomography (CT), magnetic resonance imaging or positron emission tomography-CT was performed to confirm patients without metastatic disease. The patients' medical records were reviewed, and demographic, clinical and histological variables were derived from the medical records. The pT and pN status were identified based on the 7<sup>th</sup> edition of AJCC TNM classification. This study was approved by our institutional research review board.

### Statistical analysis

Overall survival (OS) curves were plotted by the Kaplan-Meier method and compared using the Log-rank test. The prognostic factors which showed the potential associations with OS were analyzed using a univariate analysis. They Cox proportional hazard model was used to find independent characteristic factors for survival time for the multivariate analysis from the univariate analyses. Statistical calculations were performed using SPSS (Version: 16.0, Chicago, United States).

## RESULTS

### Characteristics of patients

All of the patients with HCC had an A and B score by Child-Pugh analysis. The patients and tumor characteristics are summarized in Table 1. The median age of patients in this study was 54 years. In total, 119 patients had stage I, 22 patients had stage II, 24 patients had stage IIIA, 25 patients had stage IIIB, 66 patients had stage IIIC, and 21 patients had stage IVA HCC. Although most patients with stage IVB HCC were excluded from tumor resection, 11 patients at Tianjin Medical University Cancer Institute and Hospital in stage IVB had a resected primary tumor from March 1999 to July 2007. The OS and median survival time were  $45.704 \pm 3.380$  and  $20.000 \pm 2.314$  mo, respectively, for postoperative patients with HCC. Tumor size, tumor status, regional lymph node metastasis, distant metastasis, Child-Pugh score, AFP and tumor growth pattern were the factors affecting survival (Table 2).

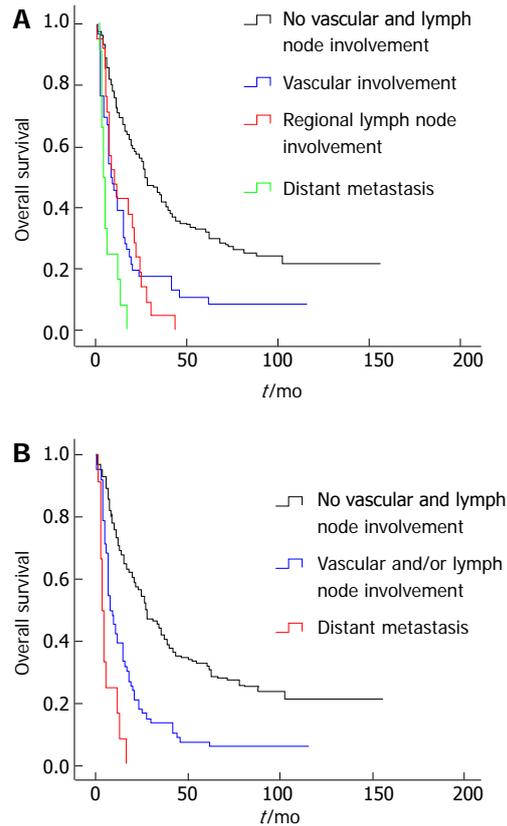

**Figure 2** Overall survival curves for patients with expansive tumor growth and invasive tumor growth. A: No significant difference in survival was observed between patients with a single tumor and patients with multiple tumors. Moreover, no significant difference in survival was observed among patients with satellite nodules, patients with nodule fusion and patients with tumor invasion of adjacent organs; B: Based on the data, patients were divided to two groups: expansive tumor growth (single tumor and multiple tumors) and invasive tumor growth (satellite nodules, nodule fusion and tumors with direct invasion of adjacent organs). The overall survival was  $57.398 \pm 4.873$  mo for patients with expansive tumor growth, while it was  $27.796 \pm 3.730$  mo for patients with invasive tumor growth ( $P < 0.001$ ).

observed among patients with satellite nodules, patients with nodule fusion or patients with tumor invasion of adjacent organs (Figure 2A). Based on the data, patients were divided into two groups: expansive tumor growth (single tumor and multiple tumors) and invasive tumor growth (satellite nodules, nodules fusion, and tumor with direct invasion of adjacent organs). The OS of patients with invasive tumor growth was shorter than that of patients with expansive tumor growth ( $P < 0.001$ , Figure 2B). The OS was  $57.398 \pm 4.873$  mo for patients with expansive tumor growth, while it was  $27.796 \pm 3.730$  mo for patients with invasive tumor growth. The median survival time of patients with expansive tumor growth and patients with invasive tumor growth were 30 and 13 mo, respectively.

**Survival analysis of disseminative growth**

Based on the extrahepatic metastatic tendency of tumor, the patients were divided to four groups: tumor without vascular and regional lymph node involvement; tumor

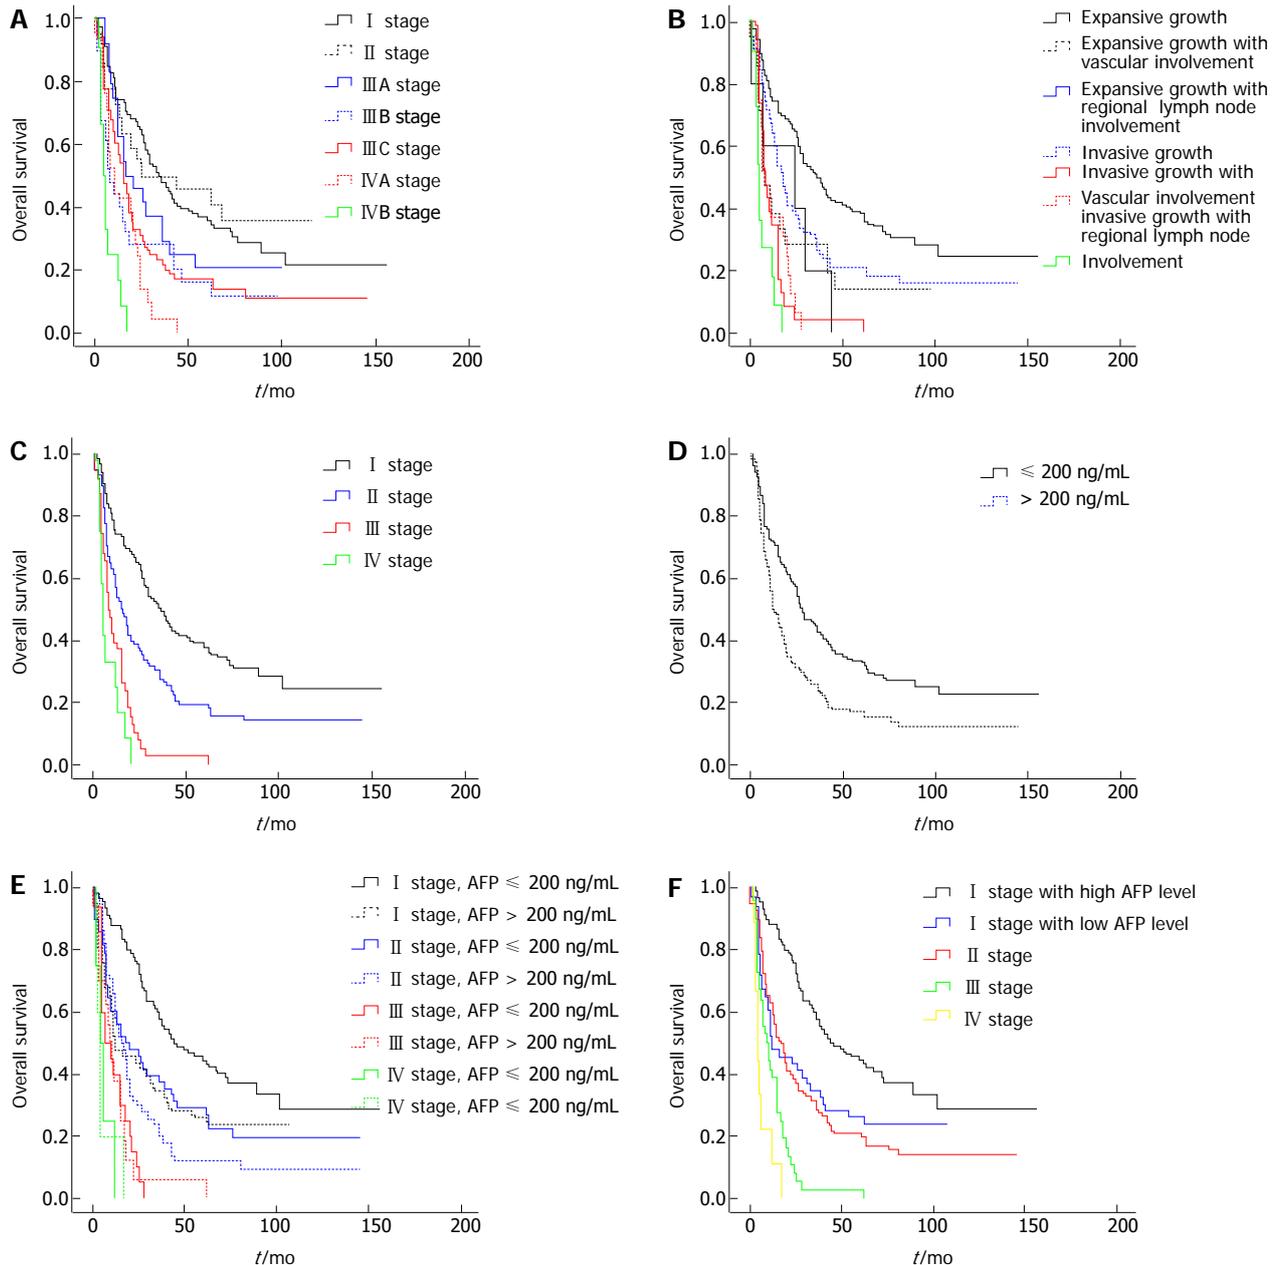

**Figure 3** Overall survival curves for patients with disseminative growth. A: No significant difference in survival was observed between patients with vascular involvement of tumor and patients with regional lymph node metastasis. The overall survival (OS) of patients with tumors that lacked vascular and regional lymph node involvement was longer than those of other groups, while the OS of patients with distant metastasis was shorter than those of other groups; B: Based on these data, patients were divided into three groups: tumors without vascular and regional lymph node involvement, tumors with vascular and/or regional lymph node involvement and distant metastasis.

with vascular involvement; regional lymph node metastasis; and distant metastasis. No significant differences in survival were observed between patients with vascular involvement of the tumor and patients with regional lymph node metastasis (Figure 3A). The OS of patients who lacked vascular and regional lymph node involvement was better than other groups, while the OS of patients with distant metastasis was shorter than those of other groups (Figure 3A). The OS of patients who lacked vascular and regional lymph node involvement was  $55.532 \pm 4.237$  mo, while the OS of patients with distant metastasis was  $6.417 \pm 1.395$  mo. The OS of patients with vascular and regional lymph node tumor involvement was  $21.667 \pm 4.773$  and  $14.619 \pm 2.456$  mo, respectively. The median survival times for each group were 28, 8, 10 and 4 mo, respectively. Based on these data, the patients were divided into three groups: tumor without vascular and regional lymph node involvement; tumor with vascular and/or regional lymph node involvement; and distant metastasis (Figure 3B).

**New classification of HCC**

According to the 7<sup>th</sup> edition TNM classification, no sig-

**Figure 4** New classification for hepatocellular carcinoma. A: Overall survival (OS) curves for patients based on tumor-node-metastasis system classification; B: OS curves for patients with expansive growth, invasive growth and disseminative growth; C: OS curves for patients based on Expansive-Invasive-Disseminative growth (EID) staging classification; D: OS curves for patients with different levels of alpha-fetoprotein (AFP); E: OS curves for patients based on EID staging classification and AFP; F: Overall survival curves for patients combined EID staging classification and AFP.

nificant difference in survival was observed between the groups with stage I or II HCC (Figure 4A). The OS of patients with stage I was  $59.460 \pm 5.806$  and  $55.585 \pm 10.289$  mo for patients with stage II. Moreover, no significant differences in survival were observed among the different stage III groups (Figure 4A). The OS of patients with stage IIIA, IIIB and IIIC were  $35.917 \pm 7.138$ ,  $24.760 \pm 6.250$  and  $31.996 \pm 5.457$  mo, respectively.

Patients were divided to seven groups based on the growth characteristics of the tumor: expansive growth, expansive growth with vascular involvement, expansive growth with regional lymph node involvement, invasive growth, invasive growth with vascular involvement, inva-

sive growth with regional lymph node involvement, and distant metastasis. The OS of each group was  $62.632 \pm 5.415$ ,  $25.762 \pm 7.024$ ,  $21.200 \pm 7.794$ ,  $39.533 \pm 5.840$ ,  $11.478 \pm 2.635$ ,  $12.653 \pm 2.076$  and  $6.727 \pm 1.490$  mo, respectively. There were significant differences in survival among patients with expansive tumor growth, invasive tumor growth and disseminative tumor growth. No significant difference in survival was observed between patients with expansive tumor growth along with vascular and/or regional lymph node involvement and patients with invasive tumor growth who lacked vascular and regional lymph node involvement (Figure 4B).

These data enable the proposal of a new staging sys-

**Table 3** Expansive-Invasive-Disseminative growth staging classification

Phase	Growth characteristics
I	Expansive tumor growth (single tumor and multiple tumors)
II	Expansive tumor growth along with vascular and/or regional lymph node involvement Invasive tumor growth (satellite nodules, nodule fusion and tumor direct invasion of adjacent organs)
III	Invasive tumor growth along with vascular/regional lymph node involvement
IV	Distant metastasis of tumor

tem: the Expansive-Invasive-Disseminative growth (EID) staging classification, which comprises four stages that select the best candidates for the best therapies currently available. Stage I includes patients with expansive tumor growth. Stage II has two subgroups: the first group consists of patients with expansive tumor growth along with vascular and/or regional lymph node involvement, and the second group includes patients with invasive tumor growth. Stage III includes patients with invasive tumor growth along with vascular/regional lymph node involvement. Stage IV includes patients with distant metastasis (Figure 4C). The OS values of patients at each stage were  $62.637 \pm 5.453$ ,  $36.880 \pm 7.779$ ,  $12.053 \pm 1.796$  and  $6.727 \pm 1.490$  mo, respectively. The overall median survival times of patients at each stage were 36, 16, 8 and 5 mo, respectively.

Table 2 showed the univariate analysis of the factors measured association with survival. The tumor characteristics that were statistically significant were tumor size, AFP, Child Pugh score, growth pattern, TNM stage and EID stage. Multivariate analyses identified EID stage and AFP as independent factors associated with OS ( $P < 0.001$ ,  $P = 0.008$ , respectively). There was no significant difference between the TNM stage and Child Pugh score. The OS of patients with high levels of AFP (AFP > 200 ng/mL;  $56.229 \pm 4.849$  mo) was shorter than that of patients with low levels of AFP ( $33.208 \pm 4.212$  mo;  $P < 0.001$ , Figure 4D). Moreover, the OS of stage I patients with high levels of AFP was shorter than that of patients with low levels of AFP ( $72.240 \pm 6.793$  mo,  $37.804 \pm 6.054$  mo, respectively,  $P < 0.001$ ). No significant difference in survival was observed between I stage patients with high levels of AFP and II stage patients. Dramatically, for stage II, III and IV patients, no significant difference in survival was observed between patients with high levels of AFP and patients with low levels of AFP (Figure 4E). Thus, AFP levels only affect the OS of stage I patients (Figure 4F).

## DISCUSSION

There are four main factors affecting the prognosis of HCC: (1) the stage, aggressiveness and growth rate of the tumor; (2) the general health of the patient; (3) the liver function of the patient; and (4) the specific intervention<sup>[20]</sup>. A number of staging systems have been devised for patients with HCC. Each staging system includes variables which evaluate one or more of the first 3 factors listed above. For example, the TNM staging system eval-

uates only the tumor characteristics, whereas the Child Pugh score provides information regarding liver function. Some of the characteristics of HCC tumors include the tumor size, tumor number, aggressiveness of growth, vascular involvement, regional lymph node metastasis, and extrahepatic spread. Although the TNM and BCLC staging classification for HCC were proposed based on certain tumor characteristics, no staging system systematically evaluates the effect of tumor growth patterns on the clinical outcome of patients with HCC.

In this study, 288 postoperative patients with HCC were studied, and the tumor growth patterns were divided into three types: (1) expansive growth (single tumor and multiple tumors without invasive and disseminative growth); (2) invasive growth (satellite nodules including perforation of the tumor encapsulation, nodule fusion including diffuse growth that lacks tumor encapsulation, and tumors with direct invasion of adjacent organs); and (3) disseminative growth (vascular involvement, regional lymph node metastasis and distant metastasis). Cheng *et al*<sup>[6]</sup> reported that the lack of tumor encapsulation was an independent factor for HCC. Other research showed that the presence of satellite nodules was an independent factor for the long-term survival of patients with HCC after curative resection<sup>[9,21]</sup>. The OS of patients with invasive tumor growth was shorter than that of patients with expansive tumor growth. No significant difference in survival was observed between patients with vascular involvement and patients with regional lymph node metastasis. The OS of patients with expansive tumor growth was longer than those of other groups, while the OS of patients with distant metastasis was shorter than those of other groups. No significant differences in survival were observed between patients with expansive tumor growth with vascular and/or regional lymph node involvement and patients with invasive tumor growth that lacked vascular and regional lymph node involvement.

These data enable the proposal of a new staging system to select the best candidates for the best therapies currently available: the four-stage EID staging classification (Table 3). Stage I includes patients with expansive tumor growths. Stage II has two subgroups: the first group contains patients with expansive tumor growth along with vascular and/or regional lymph node involvement, and the second group consists of patients with invasive tumor growth. Stage III includes patients with invasive tumor growth along with vascular/regional lymph node involvement. Stage IV comprises patients with distant tumor metastasis. The OS values of each stage

TNM stage				
I	117 (83.6)	2 (2.0)	0	0
II	12 (8.6)	10 (10.1)	0	0
III A	9 (6.4)	15 (15.2)	0	0
III B	0	20 (20.2)	5 (13.2)	0
III C	2 (1.4)	46 (44.5)	18 (47.4)	0
IV A	0	6 (6.1)	15 (39.5)	0
IV B	0	0	0	11 (100)
Tumor size (cm)				
≤ 5	71 (50.7)	27 (27.3)	5 (13.2)	2 (18.2)
5 < size ≤ 10	52 (37.1)	50 (50.5)	18 (47.4)	5 (45.5)
> 10	17 (12.1)	22 (22.2)	15 (39.5)	4 (36.4)
Child-Pugh score				
A	128 (91.4)	92 (92.9)	30 (78.9)	10 (90.9)
B	12 (8.6)	7 (7.1)	8 (21.1)	1 (9.1)
AFP (ng/mL)				
≤ 200	91 (66.4)	46 (47.4)	20 (55.6)	4 (44.4)
> 200	46 (33.6)	51 (52.6)	16 (44.4)	5 (55.6)

HBV: Hepatitis B virus; TNM: Tumor-node-metastasis; AFP: Alpha-fetoprotein.

were  $62.637 \pm 5.453$ ,  $36.880 \pm 7.779$ ,  $12.053 \pm 1.796$  and  $6.727 \pm 1.490$  mo, respectively. The median survival times of patients at each stage were 36, 16, 8 and 5 mo, respectively.

Univariate analysis showed that the statistically significant factors were EID staging classification and AFP (Table 4). There were no statistically significant correlative differences between OS and the Child-Pugh score. There is a substantial amount of research showing that the Child-Pugh score and AFP values > 200 ng/mL are independent factors for HCC<sup>[6-8,15,22]</sup>. In fact, patients with a C Child-Pugh score were excluded for this study to eliminate the effects of poor liver function on long-term outcome. The OS of stage I patients with high levels of AFP was shorter than that of patients with low levels of AFP. There is research showing that the Japan Integrated Staging Score and BCLC staging system combined with AFP levels may serve as a better staging system for early-stage HCC patients<sup>[22,23]</sup>. Dramatically, for patients in stages II, III and IV, no significant difference in survival was observed between patients with high levels of AFP and patients with low levels of AFP. Thus, AFP levels likely only affect the OS of stage I patients.

In conclusion, the EID staging classification is a simple and efficacious prognostic model for postoperative patients with HCC. Because the EID staging classification is easily obtained and objective, we propose it for widespread use in clinical practice as a staging system for postoperative patients with HCC.

## COMMENTS

### Background

The tumor-node-metastasis (TNM) system fails to include comprehensive characteristics of the tumor, especially the tumor's growth pattern. Thus, it is crucial to design a system to evaluate the effects of tumor characteristics on the clinical outcome of resectable patients with hepatocellular carcinoma (HCC).

### Research frontiers

The characteristics of HCC tumors include the tumor size, tumor number, aggressiveness of growth, vascular involvement, regional lymph node metastasis, and extrahepatic spread. Although the TNM and Barcelona Clinic Liver Cancer staging classification for HCC were proposed based on certain tumor characteristics, no staging system systematically evaluates the effect of tumor growth patterns on the clinical outcome of patients with HCC.

### Innovations and breakthroughs

These data enable the proposal of a new staging system to select the best candidates for the best therapies currently available: the four-stage Expansive-Invasive-Disseminative growth (EID) staging classification. Stage I includes patients with expansive tumor growths. Stage II has two subgroups: the first group contains patients with expansive tumor growth along with vascular and/or regional lymph node involvement, and the second group consists of patients with invasive tumor growth. Stage III includes patients with invasive tumor growth along with vascular/regional lymph node involvement.

### Applications

The EID staging classification is a simple and efficacious prognostic model for postoperative patients with HCC. Because the EID staging classification is obtained easily, authors propose it for postoperative patients with HCC.

### Terminology

Expansive growth includes single tumor and multiple tumors without invasive and disseminative growth; invasive growth consists of satellite nodules including perforation of the tumor encapsulation, nodule fusion including diffuse growth that lacks tumor encapsulation and tumors with direct invasion of adjacent organs; disseminative growth contains vascular involvement, regional lymph node metastasis and distant metastasis

### Peer review

The prognostic significance of the new staging method was confirmed by the detailed statistical analysis of 288 patients treated in a single facility, being compared with other staging systems previously proposed. This clinical study is interesting and novel. The author found a simply and efficacy prognostic model for postoperative patients with HCC.

### Abstract

**AIM:** To elucidate the potential impact of intraoperative blood loss (IBL) on long-term survival of gastric cancer patients after curative surgery.

**METHODS:** A total of 845 stage I-III gastric cancer patients who underwent curative gastrectomy between January 2003 and December 2007 in our center were enrolled in this study. Patients were divided into 3 groups according to the amount of IBL: group 1 (< 200 mL), group 2 (200-400 mL) and group 3 (> 400 mL). Clinicopathological features were compared among the three groups and potential prognostic factors were analyzed. The Log-rank test was used to assess statistical differences between the groups. Independent prognostic factors were identified by the Cox proportional haz-

ards regression model. Stratified analysis was used to investigate the impact of IBL on survival in each stage. Cancer-specific survival was also compared among the three groups by excluding deaths due to reasons other than gastric cancer. Finally, we explored the possible factors associated with IBL and identified the independent risk factors for IBL  $\geq$  200 mL.

**RESULTS:** Overall survival was significantly influenced by the amount of IBL. The 5-year overall survival rates were 51.2%, 39.4% and 23.4% for IBL less than 200 mL, 200 to 400 mL and more than 400 mL, respectively (< 200 mL vs 200-400 mL,  $P < 0.001$ ; 200-400 mL vs > 400 mL,  $P = 0.003$ ). Age, tumor size, Borrmann type, extranodal metastasis, tumour-node-metastasis (TNM) stage, chemotherapy, extent of lymphadenectomy, IBL and postoperative complications were found to be independent prognostic factors in multivariable analysis. Following stratified analysis, patients staged TNM I-II and those with IBL less than 200 mL tended to have better survival than those with IBL not less than 200 mL, while patients staged TNM III, whose IBL was less than 400 mL had better survival. Tumor location, tumor size, TNM stage, type of gastrectomy, combined organ resection, extent of lymphadenectomy and year of surgery were found to be factors associated with the amount of IBL, while tumor location, type of gastrectomy, combined organ resection and year of surgery were independently associated with IBL  $\geq$  200 mL.

**CONCLUSION:** IBL is an independent prognostic factor for gastric cancer after curative resection. Reducing IBL can improve the long-term outcome of gastric cancer patients following curative gastrectomy.

**Key words:** Gastric carcinoma; Intraoperative blood loss; Blood transfusion; Postoperative complication; Prognosis

**Core tip:** Intraoperative blood loss (IBL) has been shown to be associated with poor outcome in various types of malignancy. In this study, we found that the overall survival of gastric cancer patients was significantly affected by the amount of IBL, and IBL was an independent prognostic factor in multivariate analysis. We suggest that meticulous surgery and new surgical methods such as the application of an ultrasonic scalpel in lymph node dissection should be used to decrease the amount of IBL and improve the long-term outcome of gastric cancer patients following curative gastrectomy.

Impact of intraoperative blood loss on survival after curative resection for gastric cancer. *World J Gastroenterol* 2013; 19(33): 5542-5550 Available from: URL: <http://www.wjg-net.com/1007-9327/full/v19/i33/5542.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i33.5542>

## INTRODUCTION

Radical gastrectomy with regional lymph node dissection is the only possible curative treatment for gastric cancer<sup>[1]</sup>. Even after R0 resection, a significant number of patients suffer from recurrence, especially those with advanced gastric cancer<sup>[2-4]</sup>. Tumor depth and lymph node status are well-known prognostic factors, and patient age and performance status have also been reported to have an impact on the long-term outcome of patients<sup>[5-7]</sup>. Besides these factors, a number of potential prognostic factors have been reported in recent years, such as perioperative blood transfusion and intraoperative blood loss (IBL)<sup>[8-11]</sup>.

The impact of IBL on long-term outcome has previously been reported in patients with colorectal cancer, prostate cancer and pancreas cancer<sup>[12-14]</sup>. However, there are few reports assessing the relationship between IBL and long-term outcome in gastric cancer patients. Dhar *et al*<sup>[10]</sup> reported that more than 500 mL blood loss during surgery was an independent predictor of survival in gastric cancer patients with transmural depth invasion. Kamei *et al*<sup>[11]</sup> demonstrated that IBL was a crucial risk factor for peritoneal recurrence after curative resection for advanced gastric cancer. Unfortunately, the numbers of patients included in these aforementioned studies were small, and no further meticulous analysis was performed to explore the correlation between the prognosis of gastric cancer patients and the accurate amount of IBL.

The aim of the present study is to elucidate the potential impact of IBL on the long-term survival of gastric cancer patients after curative surgery in a single high-volume center in China.

## MATERIALS AND METHODS

### Patients

The surgical and pathological data of 845 patients with

gastric cancer who had undergone curative gastrectomy (R0 resection) with lymph node dissection and had been followed up between January 2003 and December 2007 at Tianjin Medical University Cancer Institute and Hospital were reviewed in this study. All the patients had been histologically diagnosed with adenocarcinoma of the stomach. Patients who previously underwent gastric surgery or received preoperative chemotherapy were excluded. Patients with distant metastasis were also excluded. The study population consisted of 845 patients, 607 males (71.8%) and 238 females (28.2%) with a median age of 62 years (range, 23-89 years).

### Surgical treatment and perioperative management

All the patients underwent gastrectomy with D1 or D2 lymph node dissection. The choice of surgical procedure for reconstruction was made by the surgeon. Resection margin was pathologically confirmed as negative. Postoperative adjuvant chemotherapy was administered according to tumor stage, physical condition and the patient's willingness. Chemotherapeutics consisted of 5-fluorouracil, leucovorin and oxaliplatin. Radiotherapy was not administered in the present study.

IBL was visually estimated according to the weight or volume of blood absorbed by gauze and suction pump by anesthesiologists immediately after surgery. We obtained this information from anesthesia records. IBL ranged from 50 to 1500 mL and the median IBL was 200 mL for the whole group. The patients were divided into 3 groups according to the amount of IBL: group 1 (< 200 mL), group 2 (200-400 mL) and group 3 (> 400 mL). The entire transfusion history during hospital stay for surgery was recorded. Patients whose perioperative hemoglobin was less than 70 g/L or who lost a lot of blood during surgery were routinely given a red blood cell transfusion. Of the 845 patients, 211 had a perioperative red blood cell transfusion, and the remaining 634 did not receive a transfusion. Postoperative complications during hospitalization only included these directly associated with surgery, such as hemorrhage, wound dehiscence, anastomotic leak, pancreatic fistula, lymphatic fistula and abdominal or wound infection.

### Evaluation of clinicopathological variables and survival

The clinicopathological features studied included gender, age, tumor location, tumor size, Borrmann type, histology, extranodal metastasis (EM), type of gastrectomy, combined organ resection, postoperative chemotherapy, tumour-node-metastasis (TNM) stage, extent of lymphadenectomy, postoperative complications, perioperative transfusion, and IBL. Clinicopathological features were first compared among the three groups and the impact of each factor on survival was evaluated to identify independent prognostic factors. We next determined whether IBL influenced cancer-specific survival by comparing overall survival among the three groups by excluding deaths due to reasons other than gastric cancer. Finally, we explored the possible factors associated with IBL and identified

IBL: Intraoperative blood loss; TNM: Tumour-node-metastasis.

the independent risk factors for IBL  $\geq$  200 mL. The tumors were staged according to the 7<sup>th</sup> edition Union for International Cancer Control TNM classification system, whereas lymphadenectomy and lymph node stations were defined according to the 3<sup>rd</sup> English Edition of the Japanese Classification of Gastric Carcinoma. Tumors were

classified into two groups based on histology: differentiated type including papillary, well or moderately differentiated adenocarcinoma; and undifferentiated type including poorly differentiated or undifferentiated adenocarcinoma, signet ring cell carcinoma and mucinous carcinoma.

### Follow-up

The patients were followed up every 3 mo up to 2 years after surgery, then every 6 mo up to 5 years, and then every year or until death. Physical examination, laboratory tests, imaging and endoscopy were performed at each visit. The median follow-up was 39 mo (range 1-103 mo), and the last follow-up date was December 20, 2012. The overall survival rate was calculated from the day of surgical resection until time of death or final follow-up.

### Statistical analysis

Categorical variables were analyzed by means of the  $\chi^2$  or Fisher's exact test. Overall survival curves were calculated using the Kaplan-Meier method based on the length of time between primary surgical treatment and final follow-up or death; the Log-rank test was used to assess statistical differences between the groups. Independent prognostic factors were identified by the Cox proportional hazards regression model. One-way analysis of variance (ANOVA) analysis or *t* test was used in univariate analysis to identify possible factors associated with IBL. Independent risk factors for IBL  $\geq$  200 mL were determined by logistic regression. *P* < 0.05 was considered statistically significant. The statistical analysis was performed using the statistical program SPSS 17.0 (SPSS, Chicago, IL, United States).

## RESULTS

### Clinicopathological features

Of the 845 patients, 397 (47.0%) patients underwent D2 or greater lymph node dissection, and the remaining 448 (53.0%) patients underwent D1 lymph node dissection. Sixty-seven patients underwent gastrectomy combined with other organ resections and 237 patients received postoperative adjuvant chemotherapy.

The patients were divided into three groups according to IBL (Table 1). The mean IBL was 99.4 mL in group 1, 223.2 mL in group 2 and 484.4 mL in group 3. There were no statistical differences in gender, age, Borrmann type, histology, EM and postoperative chemotherapy among the three groups. Tumors located in the upper one-third were more frequent in group 2 and group 3, while in group 1, 53.5% of tumors were located in the lower one-third. The incidence of postoperative complications and the ratios of tumors with a diameter  $\geq$  5 cm increased when the amount of IBL was high. Total gastrectomy and combined organ resection were more frequently performed in group 3 than in group 1 and group 2. Patients in group 2 and group 3 were more likely to have advanced tumor (T), node (N), and TNM stage than

OS: Overall survival; TNM: Tumour-node-metastasis.

patients in group 1.

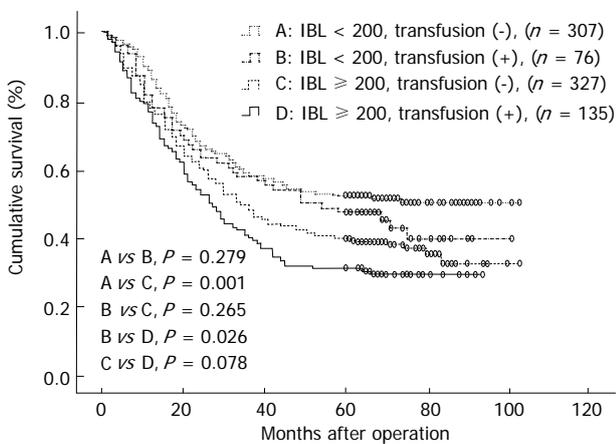

### Prognostic value of IBL in gastric cancer

Data from univariate and multivariate survival analyses are shown in Table 2. A total of 14 factors evaluated in the univariate analysis had a significant effect on survival: age (≤ 65 years *vs* > 65 years), tumor location, tumor size, Borrmann type (types I and II *vs* types III and IV), histology, EM, TNM stage, postoperative chemotherapy, type of gastrectomy, combined organ resection, extent of lymphadenectomy, IBL, perioperative transfusion and

postoperative complications. Gender did not influence survival. In multivariate analysis, age, tumor size, Borrmann type, EM, TNM stage, postoperative chemotherapy, extent of lymphadenectomy, postoperative complications and IBL were found to be independent prognostic factors for overall survival (OS). The 5-year OS rates were 51.2%, 39.4% and 23.4% for IBL < 200, 200-400, and > 400 mL, respectively, (< 200 mL *vs* 200-400 mL, *P* < 0.001; 200-400 mL *vs* > 400 mL, *P* = 0.001) (Figure 1A). When deaths due to factors other than gastric cancer were excluded, cancer-specific survival was still sig-

**Figure 1 Overall survival and cancer-specific curves for all patients grouped by intraoperative blood loss.** A: Overall survival curve; B: Cancer-specific survival curve. IBL: Intraoperative blood loss.

**Figure 2 Overall survival curves for all patients classified according to intraoperative blood loss and red blood cell transfusion.** IBL: Intraoperative blood loss.

nificantly influenced by IBL (Figure 1B). The 5-year OS rates for patients with red blood cell transfusion *vs* those without were 37.0% and 45.7% ( $P = 0.013$ ), respectively.

To assess the association between IBL and red blood cell transfusion, patients were categorized into 4 groups [IBL < 200 mL and transfusion (-); IBL < 200 mL, transfusion (+); IBL ≥ 200 mL, transfusion (-); IBL ≥ 200 mL, transfusion (+)], and OS was compared among these groups (Figure 2). As a blood loss of 200 mL was the median for the whole group, it was used for dichotomization in the statistical analysis. As a result, a IBL of 200 mL or more was a significant factor when excluding the influence of red blood cell transfusion ( $P = 0.001$ ;  $P = 0.026$ ). However, there was no significant difference in OS between patients with and without transfusion when the influence of IBL was excluded ( $P = 0.279$ ;  $P = 0.078$ ).

The results of the stratified analysis are shown in Table 3. In patients with TNM stage I, those with IBL less than 200 mL had significantly better survival than those with IBL 200-400 mL (Figure 3A). In the patients

**Table 3 Tumour-node-metastasis-stratified analysis of the overall survival**

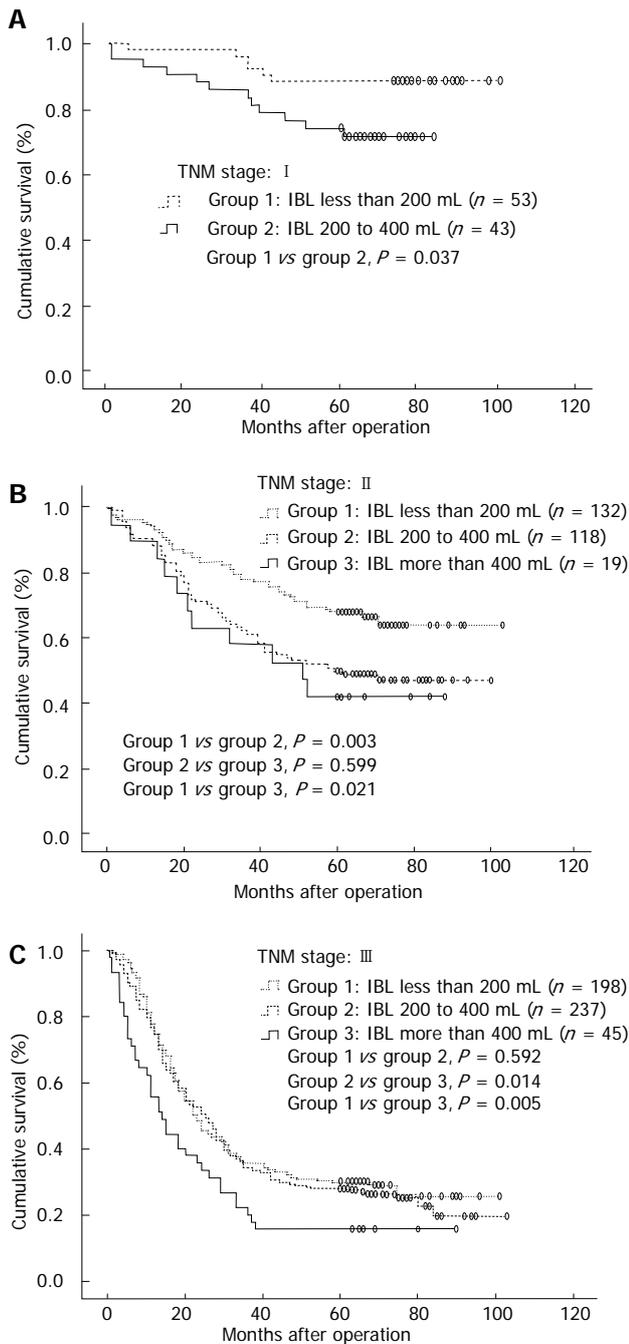

TNM	Group 1 <sup>1</sup>		Group 2 <sup>1</sup>		Group 3 <sup>1</sup>		$\chi^2$	P value
	n	5-yr OS	n	5-yr OS	n	5-yr OS		
I	53	88.7	43	74.4			4.538	0.037
II	132	68.2	118	50.0	19	42.1	10.763	0.005
III	198	29.8	237	27.8	45	15.6	8.035	0.018

<sup>1</sup>Group 1: IBL < 200 mL; Group 2: IBL 200-400 mL; Group 3: IBL > 400 mL. OS: Overall survival; TNM: Tumour-node-metastasis; IBL: Intraoperative blood loss.

staged with TNM II, those with IBL less than 200 mL had a significantly higher 5-year OS than those with IBL 200-400 mL or more than 400 mL, while there were no statistical differences in OS between those with IBL 200-400 mL and more than 400 mL (Figure 3B). For patients staged TNM III, OS did not differ significantly between those with IBL less than 200 mL and 200-400 mL, however, these patients had significantly higher 5-year OS than those with IBL more than 400 mL (Figure 3C).

**Risk factors associated with IBL**

Univariate analysis of factors associated with the amount of IBL is shown in Table 4. Following one-way ANOVA analysis or *t* test, tumor location, tumor size, TNM stage, type of gastrectomy, combined organ resection, extent of lymphadenectomy and year of surgery were found to be significant factors associated with the amount of IBL. Factors which had no influence on IBL were gender, age, Borrmann type, histology, and EM. As patients with IBL less than 200 mL had the best survival, we further identified the independent risk factors for IBL ≥ 200 mL. Factors significant in the univariate analysis were included in the multivariate analysis. Tumor location, type of gastrectomy, combined organ resection and year of surgery were found to be independent risk factors for IBL ≥ 200 mL in the multivariate analysis (Table 5).

**Figure 3 Overall survival curves.** A: 96 patients staged tumour-node-metastasis (TNM) I; B: 269 patients staged TNM II; C: 480 patients staged TNM III. IBL: Intraoperative blood loss.

## DISCUSSION

The prognosis of gastric cancer is mainly associated with tumor depth and lymph node status<sup>[15,6]</sup>. To improve the outcome of gastric cancer, standard surgery with D2 lymph node dissection is recommended<sup>[15,16]</sup>. However, even after curative gastrectomy with D2 dissection, the prognosis remains poor. In the present study, we evaluated the potential prognostic factors and found that IBL was significantly associated with the survival of patients

**Table 4 Association between clinicopathologic factors and the amount of intraoperative blood loss: univariate analysis**

Characteristics	n (%)	Amount of IBL (mL) (mean ± SD)	t/F	P value
Gender			1.770	0.077
Male	607 (71.8)	191.4 ± 128.6		
Female	238 (28.2)	175.2 ± 92.5		
Age (yr)			-1.128	0.260
≤ 65	489 (57.9)	182.9 ± 121.8		
> 65	356 (42.1)	192.3 ± 116.7

Year of surgery			-2.494	0.013
2003-2005	489 (57.9)	195.1 ± 133.6		
2006-2007	356 (42.1)	174.3 ± 97.6		

TNM: Tumour, node, metastasis; IBL: Intraoperative blood loss.

**Table 5 Multivariate analysis of risk factors for intraoperative blood loss ≥ 200 mL**

Feature	HR	95%CI	P value
Tumor location Upper 1/3 and 2/3 or more vs lower and middle 1/3	1.717	1.272-2.317	< 0.001
Tumor size ≥ 5 cm vs < 5 cm	1.129	0.833-1.513	0.434
TNM stage III vs I, II	1.174	0.872-1.580	0.290
Extent of gastrectomy D1 vs D2 and D2+	1.161	0.860-1.566	0.330
Type of gastrectomy Total vs subtotal	2.501	1.707-3.663	< 0.001
Combined organ resection Present vs absent	1.996	1.089-3.659	0.025
Year of surgery 2003-2005 vs 2006-2007	1.452	1.080-1.954	0.014

TNM: Tumour, node, metastasis.

with gastric cancer after curative resection.

IBL has been reported to be associated with the prognosis of many malignant tumors<sup>[12-14]</sup>. Mörner *et al*<sup>[12]</sup> reported that the degree of IBL in colon cancer influenced long-term survival. In their study, blood loss of 250 mL or more during surgery was a risk factor for overall mortality in both univariate and multivariate analyses. Nagai *et al*<sup>[13]</sup> demonstrated that IBL greater than 2000 mL was related to poor prognosis in patients with pancreatic cancer. These authors suggested that successful curative resection with limited blood loss can contribute to improved survival. With regard to gastric cancer, few studies have focused on IBL. Dhar *et al*<sup>[10]</sup> reported that IBL more than 500 mL was an independent prognostic factor. Kamei *et al*<sup>[11]</sup> demonstrated that the cumulative survival rate was significantly lower in patients with IBL  $\geq$  475 mL than in patients with IBL < 475 mL ( $P = 0.0038$ ), and IBL was a critical risk factor for peritoneal recurrence after curative resection of advanced gastric cancer. Our data are consistent with those results and strongly suggest that IBL, rather than transfusion, was an independent prognostic factor for gastric cancer after curative resection.

In previous studies, blood loss of 475 or 500 mL was proposed as a threshold for prognostic significance<sup>[10,11]</sup>. To date, no study has conducted a detailed statistical analysis by classifying patients into groups based on the level of IBL during resection for gastric cancer. When the thresholds were set at 200 and 400 mL, the OS was significantly affected based on a comparison between these 3 groups. The 5-year OS rates were 51.2%, 39.4% and 23.4% for IBL < 200 mL, 200-400 mL and > 400 mL, respectively (< 200 mL *vs* 200-400 mL,  $P < 0.001$ ; 200-400 mL *vs* > 400 mL,  $P = 0.003$ ; < 200 mL *vs* > 400 mL,  $P < 0.001$ ). Even when deaths due to factors other than gastric cancer were excluded, the differences in cancer-specific survival among the three groups were still significant. This clearly demonstrated the negative influence of IBL on survival after curative gastrectomy. Pathological stage is assumed to be the most important prognostic factor for gastric cancer following curative gastrectomy. Therefore, we stratified patients by TNM stage. Even after stratification, the same trend, *i.e.*, better outcomes in patients with a small amount of IBL, was still observed in each stage. Thus, reducing IBL in resectable gastric cancer may provide further improvements in survival. According to the results of the present study, for patients staged TNM I and II, IBL should be controlled within 200 mL to achieve a better outcome. In patients staged TNM III, IBL should be no more than 400 mL.

Blood transfusion is needed when performing complex surgery with a large amount of IBL. Although many studies<sup>[17-21]</sup> have confirmed that perioperative blood transfusion leads to poor outcome in gastric cancer, some studies<sup>[22-26]</sup> do not support this. In the present study, perioperative transfusion was a prognostic factor, but not an independent prognostic factor in the multivariate analysis. When the influence of IBL was excluded, OS did not dif-

fer significantly between patients with and without transfusion, although 5-year OS was higher in patients without transfusion than in patients with transfusion if the IBL was similar. However, when excluding the influence of transfusion, patients whose IBL was less than 200 mL had significantly better survival than those with IBL of 200 mL or more. The effect of IBL on survival was more pronounced than that of red blood transfusion.

It is still unclear why IBL affects the long-term outcome of patients. It is thought that excessive IBL reduces the body's immunity and thus its ability to fight cancer cells<sup>[10]</sup>. In a study conducted by Bruns *et al*<sup>[27]</sup>, IBL more than 700 mL following gastrointestinal surgery was associated with a significant decrease in natural killer cell activity, producing an unfavorable effect on patient survival. However, the degree of immune suppression was not assessed in this study. This should be examined in a future trial to clarify whether patients with excessive IBL have severe immune suppression resulting in a poor overall survival rate. Another possible explanation is that IBL is associated with peritoneal recurrence which leads to poor survival. It has been reported that operative blood loss is an independent risk factor for peritoneal recurrence of curatively resectable advanced gastric cancer<sup>[11]</sup>. In open abdominal surgery, most operative blood loss accumulates in the abdominal cavity, and thus, the peritoneal surface is considered to have direct contact with blood components. As extravascular blood cells, such as leukocytes and platelets, are activated, they may produce a number of soluble factors that may produce a favorable microenvironment for malignant cells. In fact, activated neutrophils, macrophages, and platelets are capable of producing a large amount of angiogenic factors, such as vascular endothelial growth factor, on the peritoneal surface, which is critical for the survival of isolated cancer cells<sup>[28,29]</sup>. Unfortunately, recurrence data was not obtained in our study.

IBL has been shown to be correlated with postoperative complications<sup>[30]</sup>. In the present study, the incidence of postoperative complications increased when the amount of IBL was high. Previous studies have affirmed the negative influence of postoperative complications on survival for many malignancies<sup>[31-35]</sup>. Sierzega *et al*<sup>[7]</sup> reported that anastomotic leakage was an independent prognostic factor for gastric adenocarcinoma following total gastrectomy. Tokunaga *et al*<sup>[35]</sup> found that postoperative intra-abdominal infectious complications had an adverse effect on 5-year OS and relapse-free survival rate. Our results were in accordance with those reports and showed that the presence of postoperative complications was an independent prognostic factor for OS. As a higher rate of complications was associated with a larger amount of IBL, we consider that the difference in the incidence of postoperative complications among the three groups was a possible contributing factor to the survival difference among the three groups.

As IBL is an independent prognostic factor and patients with IBL less than 200 mL had the best outcome,

it is necessary to explore the potential factors influencing IBL and to develop new surgical methods to reduce IBL. It is obvious that IBL could be affected by the type of gastrectomy and combined organ resection. Patients with tumors located in the upper 1/3 or more than 2/3 the area usually undergo a total gastrectomy or combined spleen resection, which may result in a larger amount of IBL. Lymph node dissection is considered to be a complex procedure and can easily lead to bleeding, especially dissection of the lymph nodes around the celiac trunk. We have used an ultrasonic scalpel for lymph node dissection of gastric cancer since 2006. Ultrasonic surgical devices have been reported to provide advantages in terms of operative time and blood loss<sup>[36,37]</sup>. A study conducted by Inoue K and colleagues showed that blood loss was significantly lower in patients using ultrasonic scalpel than in those not using the ultrasonic scalpel (median 351.0 mL *vs* 569.5 mL;  $P = 0.016$ )<sup>[38]</sup>. From this point of view, it is actually the application of the ultrasonic scalpel that leads to reduced IBL rather than the year, although year of surgery was found to be an independent risk factor for IBL in the present study.

In conclusion, IBL was found to be an independent prognostic factor for gastric cancer after curative resection. It can be used to stratify the risk for gastric cancer prognosis. Meticulous surgery is needed and new methods should be considered to decrease the amount of IBL and improve the long-term outcome of patients following curative gastrectomy.

## COMMENTS

### Background

Intraoperative blood loss (IBL) has been shown to be associated with poor outcome in various types of malignancy. However, the relationship between the amount of IBL and outcome of gastric cancer is still unclear.

### Research frontiers

IBL can not be avoided in surgery. Excessive blood loss may result in more postoperative complications and poorer prognosis. Research has shown the negative association between IBL and prognosis of many malignancies. Few researchers have focused on IBL during resection of gastric cancer. In this study, the authors demonstrated that IBL was an independent prognostic factor for gastric cancer after curative resection.

### Innovations and breakthroughs

Many studies have affirmed that perioperative blood transfusion leads to poor outcome in gastric cancer. However, when performing complex surgery, blood transfusion is required due to a large amount of IBL, which was also reported to have an adverse effect on survival. The impact of IBL on survival may be confused by blood transfusion. This study evaluated the prognostic value of both factors on survival in gastric cancer patients after curative resection and found that IBL influenced the prognosis of gastric cancer rather than blood transfusion.

### Applications

By understanding the negative association between the amount of IBL and prognosis of gastric cancer, this study may stimulate surgeons to pay attention to decreasing the amount of IBL during curative gastrectomy.

### Terminology

IBL is the amount of blood loss during surgery which is visually estimated by anesthesiologists immediately after surgery. Extranodal metastasis was defined as the presence of tumor cells in extramural soft tissue that was discontinuous with either the primary lesion or locoregional lymph nodes.

### Peer review

The IBL and perioperative transfusion have been the topics concerned by sur-

geons. And IBL has been shown to be associated with poor outcome in various types of malignancy. This study shows that IBL is an independent prognostic factor for gastric cancer patients after curative resection. This conclusion has some significance for guiding clinical work.

### Abstract

**AIM:** To investigate the effects of extended lymphadenectomy and postoperative chemotherapy on gastric cancer without lymph node metastasis.

**METHODS:** Clinical data of 311 node-negative gastric cancer patients who underwent potentially curative gastrectomy with more than 15 lymph nodes resected, from January 2002 to December 2006, were analyzed retrospectively. Patients with pT4 stage or distant metastasis were excluded. We analyzed the relationship between the D2 lymphadenectomy and the 5-year survival rate among different subgroups stratified by clinical features, such as age, tumor size, tumor location and depth of invasion. At the same time, the relationship between postoperative chemotherapy and the 5-year survival rate among different subgroups were also analyzed.

**RESULTS:** The overall 5-year survival rate of the entire

cohort was 63.7%. The 5-year survival rate was poor in those patients who were: (1) more than 65 years old; (2) with tumor size larger than 4 cm; (3) with tumor located in the upper portion of the stomach; and (4) with pT3 tumor. The survival rate was improved significantly by extended lymphadenectomy only in patients with pT3 tumor ( $P = 0.019$ ), but not in other subgroups. Moreover, there was no significant difference in survival rate between patients with and without postoperative chemotherapy among all of the subgroups ( $P > 0.05$ ).

**CONCLUSION:** For gastric cancer patients without lymph node metastasis, extended lymphadenectomy could improve the survival rate of those who have pT3-stage tumor. However, there was no evidence of a survival benefit from postoperative chemotherapy alone.

**Key words:** Gastric cancer; Lymph node negative metastasis; Extended lymphadenectomy; D2 lymphadenectomy; Chemotherapy

**Core tip:** Little information is available regarding the effects of D2 lymphadenectomy and postoperative chemotherapy in patients with node-negative early gastric cancer. Data of 311 gastric cancer patients without lymph node metastasis were analyzed retrospectively. Results showed that D2 lymphadenectomy could improve the survival rate of patients with pT3-stage tumor. However, there was no evidence of a survival benefit from postoperative chemotherapy. In conclusion, it is recommended that D2 lymphadenectomy with gastrectomy be applied for node-negative patients with pT3 gastric cancer whereas the effects of postoperative chemotherapy in patients with node-negative early gastric cancer need to be further studied.

on node-negative gastric cancer. *World J Gastroenterol* 2013; 19(33): 5551-5556 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i33/5551.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i33.5551>

## INTRODUCTION

Gastric cancer is one of the most common malignancies worldwide, with a high mortality rate<sup>[1]</sup>. Many studies indicate that, in gastric cancer, the presence or absence of lymph node metastasis is an important prognostic factor that could influence the prognosis of patients following curative gastrectomy<sup>[2-5]</sup>. It has been shown that an extended (D2) lymphadenectomy could bring benefits to the long-term survival rate of patients with node-positive gastric cancer<sup>[6,7]</sup>, and D2 lymphadenectomy has become a standard surgical procedure for curative treatment in South Korea and Japan<sup>[8]</sup>. However, recurrence and metastasis are also noted in node-negative gastric cancer after curative resection, and there are few studies on the effects of D2 lymphadenectomy in patients with node-negative gastric cancer. At the same time, postoperative chemotherapy is considered an effective treatment option for patients with advanced gastric cancer<sup>[9-11]</sup>, nevertheless, whether it could bring benefit to node-negative gastric cancer patients who received curative gastrectomy still needs to be further elucidated. Hence, the aim of this study was to investigate whether extended lymphadenectomy and postoperative chemotherapy could bring a survival benefit to patients with node-negative gastric cancer.

## MATERIALS AND METHODS

Between January 2002 and December 2006, 867 patients diagnosed with gastric adenocarcinoma were treated with curative gastrectomy (R0 resection) and with more than 15 lymph nodes resected at the Department of Gastric Cancer Surgery, Tianjin Medical University Cancer Hospital and City Key Laboratory of Cancer Prevention and Therapy, Tianjin, China. Of these patients, 311 had lymph node-negative metastasis. There were 230 males and 81 females with ages ranging from 21 to 82 years (60.0 ± 11.2 years). Patients with pT4 stage or distant metastasis were excluded. D2 lymphadenectomy was performed according to the guidelines of lymph node stations defined by the Japanese Gastric Cancer Association<sup>[12]</sup>.

Patients were stratified according to clinical features including age, sex, tumor size, location, Borrmann type, depth of invasion, and pathologic examination. Furthermore, patients with poor prognosis were stratified into subgroups according to the number of resected lymph nodes (LNs) and whether they received postoperative chemotherapy. According to the number of resected LNs, patients were divided into a 15-24 subgroup and a ≥ 25 subgroup. Patients were also divided into groups according to whether or not they received postoperative chemotherapy.

**Table 1 Clinicopathologic factors of patients with node-negative gastric cancer**

Characteristics	n	5-yr survival rate	χ <sup>2</sup>	P value
Gender			1.416	0.234
Male	230	67.40%		
Female	81	72.80%		
Age (yr)			4.979	0.026
< 65	156	75.20%		
≥ 65	155	62.40%		
Tumor size (cm)			5.930	0.015
≤ 4	166	73.80%		
> 4	145	63.00%		
Tumor location			8.721	0.033
Upper	103	58.70%		
Middle	45	67.90%		
Lower	150	76.50%		
Total	13	68.40%		
Borrmann type			3.834	0.280
I	60	71.60%		
II	129	74.20%		
III	108	62.80%		
IV	14	57.10%		
Depth of invasion			13.676	0.001
T1	22	100.00%		
T2	69	78.40%		
T3	220	62.20%		
Pathology			2.689	0.101
Differentiated	124	73.90%		
Undifferentiated	187	65.30%		

Patients received postoperative chemotherapy (FOLF-OX6): oxaliplatin (100 mg/m<sup>2</sup>) and leucovorin (400 mg/m<sup>2</sup>), followed by 5-FU (400 mg/m<sup>2</sup>) bolus, then a 46 h continuous infusion of 5-FU (3000 mg/m<sup>2</sup>). The regimen was repeated every 2 wk for 6-8 cycles and follow-up was conducted until November 2011 or until death. Data collection was based on review of clinical charts and on telephone interviews with discharged patients.

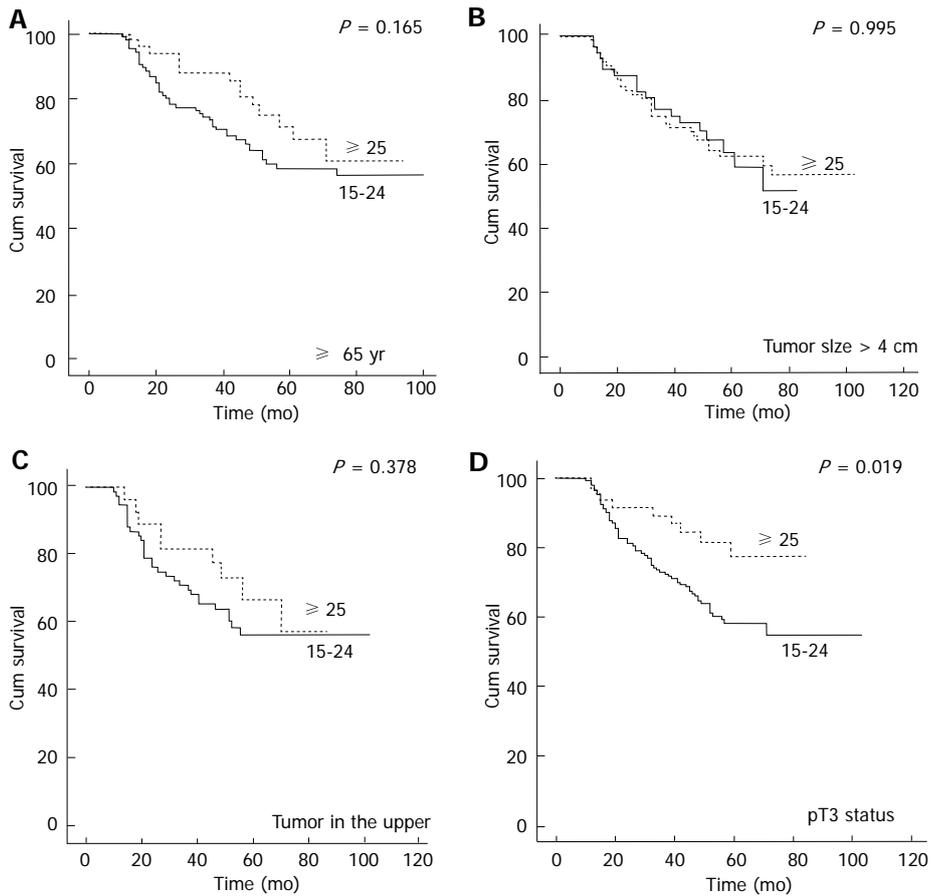

### Statistical analysis

The analysis was performed using the Statistical Package for Social Science (SPSS), version 13.0 for Windows. Actuarial survival rate was determined *via* the Kaplan-Meier method, and univariate comparisons of survival between different groups were performed using the log rank test. Significance of differences was accepted at P value < 0.05.

## RESULTS

The overall 5-year survival rate (5-YSR) of the entire cohort was 63.7%. Factors influencing the 5-YSR were as follows: age (P = 0.026), tumor size (P = 0.015), tumor location (P = 0.033) and depth of invasion (P < 0.001). The survival rate was lower in patients who were more than 65 years old, with tumor size larger than 4 cm, with tumor located in the upper portion of the stomach, or with pT3 status. Gender (P = 0.234), Borrmann type (P = 0.280) and pathological types (P = 0.101) had no significant influence on the survival rate. The clinicopathological variables tested in the univariate analysis are shown in Table 1.

The survival rate of different groups divided by the

**Figure 1** Five-year survival curve for patients with N0 gastric cancer according to the number of resected lymph nodes. A: In  $\geq 65$  years group, survival curve for 155 patients with N0 gastric cancer according to the number of resected lymph nodes (15-24 and  $\geq 25$ ); B: In tumor size  $> 4$  cm group, survival curve for 145 patients with N0 gastric cancer according to the number of resected lymph nodes (15-24 and  $\geq 25$ ); C: In the upper location group, survival curve for 103 patients with N0 gastric cancer according to the number of resected lymph nodes (15-24 and  $\geq 25$ ); D: In pT3 group, survival curve for 220 patients with N0 gastric cancer according to the number of resected lymph nodes (15-24 and  $\geq 25$ ).

**Table 2** Major postoperative complications observed in the study

Type of complications	15-24 LNs removed (n = 189)	Above 25 LNs removed (n = 122)	$\chi^2$	P value
Pulmonary	16	13		
Abdominal abscess	15	9		
Pancreatic fistula	5	3		
Anastomotic leak	2	2		
Lymphorrhhea	4	3		
Paralytic ileus	2	2		
Others	3	2		
Total	47	34	0.347	0.556

LNs: Lymph nodes.

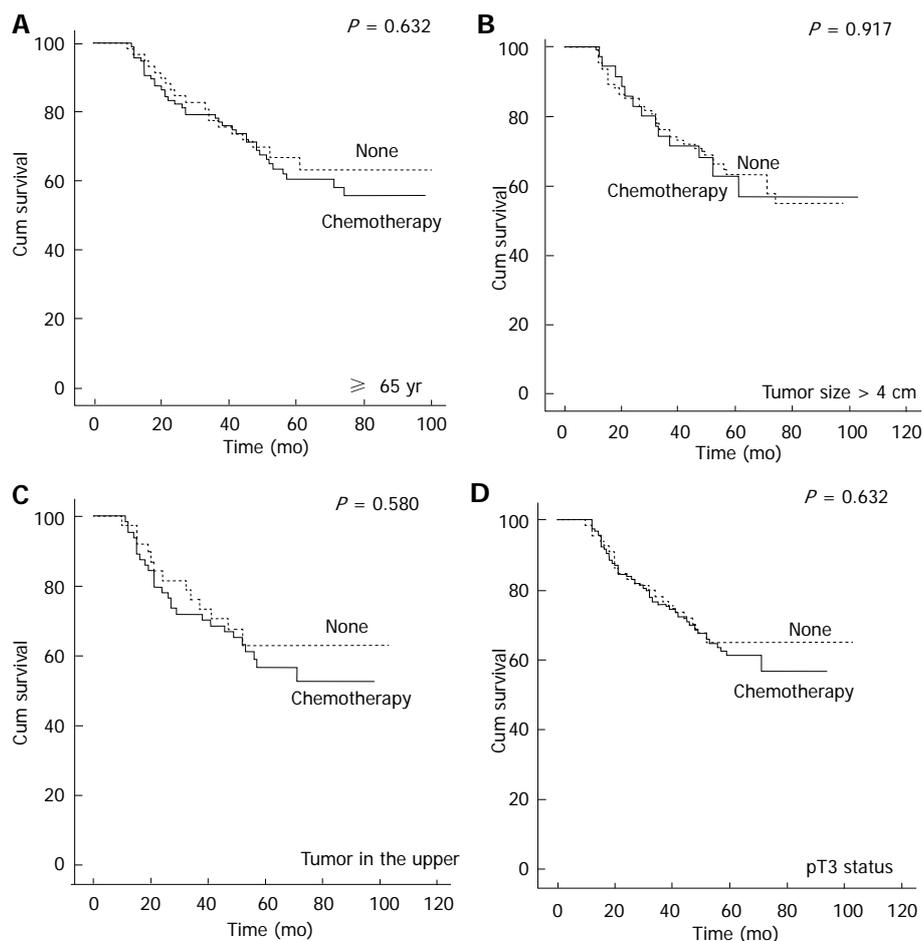

number of resected LNs and whether patients received post-operative chemotherapy were compared between groups stratified by age, tumor size, tumor location and pT status. In patients who were more than 65 years old, with tumor size larger than 4 cm, with tumor located in the upper portion of the stomach, the survival rate was not significantly different between the two subgroups of patients with 15-24 and  $\geq 25$  LNs dissected ( $P = 0.165, 0.995, 0.378$ , respectively). However, for patients with pT3 cancer, the survival rate in patients with  $\geq 25$  LNs dissected was significantly higher than that of patients with 15-24 LNs dissected ( $P = 0.019$ ). The survival curves are presented in Figure 1.

There was no significant difference in survival rates between patients with or without postoperative chemotherapy in all 4 groups, divided according to whether patients were more than 65 years old, with tumor size larger than 4 cm, with tumor located in the upper portion of the stomach or in pT3 status ( $P = 0.632, 0.917, 0.580, 0.632$ , respectively). The survival curves are shown in Figure 2.

Eighty-one of the 311 patients developed postoperative general and surgical complications (morbidity: 26.0%), such as pulmonary affections, abdominal abscess, pancreatic fistula, anastomotic leak, lymphorrhhea, paralytic ileus, and no patients died during the perioperative period. Forty-seven patients with complications were in the patient group with 15-24 LNs dissected, and thirty-four were in the group with  $\geq 25$  LNs dissected. There was no significant difference in the post-operative complication rate between these two groups ( $P = 0.556$ ). Table 2 lists the type of complications and their frequency.

## DISCUSSION

Nowadays, due to the significant improvements in diagnosing techniques as well as the popularization of health screening, gastric cancers tend to be detected in their early stages. Of all the patients with gastric cancer treated in our hospital, 35.9% were in the early period. It is commonly considered that lymph node metastases is one of the most important prognostic factors for patients with gastric cancer after curative surgery<sup>[13]</sup>. What's more, re-

**Figure 2** Five-year survival curve for patients with N0 gastric cancer according to whether patients received postoperative chemotherapy. A: In  $\geq 65$  years group, survival curve for 155 patients with N0 gastric cancer according to whether patients received postoperative chemotherapy; B: In tumor size  $> 4$  cm group, survival curve for 145 patients with N0 gastric cancer according to whether patients received postoperative chemotherapy; C: In the upper location group, survival curve for 103 patients with N0 gastric cancer according to whether patients received postoperative chemotherapy; D: In pT3 group, survival curve for 220 patients with N0 gastric cancer according to whether patients received postoperative chemotherapy.

currence and metastasis were also noted in gastric cancer without lymph node metastasis after curative resection. The recurrence rate of early gastric cancer (EGC) was reported as 1.7%-3.4%<sup>[14-17]</sup>. In previous studies<sup>[18-20]</sup>, it was reported that some variables such as pT status, tumor size, tumor location, Lauren type and the number of resected LNs were associated with survival in pN0 gastric cancer. According to our study, the survival rate was lower in patients whose age was more than 65 years old, tumor size was larger than 4 cm, tumor location was in the upper portion of the stomach, or tumor stage was pT3.

Studies have shown that D2 lymphadenectomy could improve the overall survival of patients with advanced node-positive gastric cancer<sup>[21,22]</sup>. D2 lymphadenectomy for pN0 gastric cancer patients who received gastrectomy has been a topic of much discussion. Some recent studies reported that D2 lymphadenectomy with gastrectomy could prolong the survival rate of patients with node-negative advanced gastric cancer<sup>[23-25]</sup>. Consistently, in this study we found that the survival rate of node-negative patients with pT3 gastric cancer could be improved by D2 lymphadenectomy ( $P = 0.019$ ). One possible reason is that the node and tissue with micrometastasis were removed by D2 lymphadenectomy. In one recent study<sup>[26]</sup> it is reported that lymph node micro-metastasis was detectable in 10% of node-negative EGC patients, and occurred more frequently in cases with larger tumor,

lymphatic invasion, or venous invasion. Based on these results, it is recommended that, for node-negative patients diagnosed with pT3 gastric cancer by endoscopic ultrasound preoperatively or at operation, the D2 lymphadenectomy should be performed even without clinically detectable node metastases. However, for other patients with poor survival rate, the effect of D2 lymphadenectomy is inconspicuous.

Previously, it was claimed that the postoperative morbidity and mortality may be increased by D2 lymphadenectomy<sup>[27,28]</sup>. However, with the improvement of surgical techniques, this situation has been changed. As reported in one study<sup>[29]</sup>, there was no difference in the incidence of four major complications (anastomotic leak, pancreatic fistula, abdominal abscess, pneumonia) between the D2 group and D2 plus group. In this study, we also found that the mortality of postoperative general complications was not significantly different between two groups with and without D2 lymphadenectomy (24.9% *vs* 27.9%,  $P = 0.556$ ).

To date, it has been recommended that postoperative chemotherapy should be used in advanced gastric cancer<sup>[9-11,30,31]</sup>. The efficacy and safety of FOXFOL6 regimen for advanced gastric cancer has been demonstrated by a phase II study<sup>[32]</sup>. However, the therapeutic value of chemotherapy for pN0 gastric cancer is still unclear and scarcely reported. Inconsistent with results

from advanced gastric cancer, we found that the survival rate of pN0 gastric cancer patients with postoperative chemotherapy was not significantly different from that of patients without chemotherapy, regardless of whether patients were more than 65 years old ( $P = 0.632$ ), with tumor size larger than 4 cm ( $P = 0.917$ ), with tumor located in the upper portion of the stomach ( $P = 0.580$ ) or in pT3 status ( $P = 0.632$ ).

There were several limitations to the current study. First, in this study, the overall survival is evaluated as an endpoint, while disease-free or recurrence-free survival was not investigated, which are also important for patients with gastric cancer. Second, the extent of lymphadenectomy was variable according to the decisions made by different surgeons, which may affect the results of this study. Finally, as this is a retrospective study, the regimen and dose of chemotherapy might be multifarious, which may affect the accuracy of the comparison of groups.

In conclusion, it is recommended that D2 lymphadenectomy with gastrectomy be applied for node-negative patients with pT3 gastric cancer. However, the effect of postoperative chemotherapy in pN0 gastric cancer patients still need to be further studied.

## COMMENTS

### Background

Many studies have shown that D2 lymphadenectomy could bring benefits to the long-term survival rate of patients with node-positive gastric cancer, however, little information is available regarding its effects in patients with node-negative gastric cancer. At the same time, although the efficacy and safety of FOXFOL6 regimen for advanced gastric cancer has been validated by many studies, the effects of postoperative chemotherapy for pN0 gastric cancer are still unclear and scarcely reported.

### Research frontiers

Some recent studies reported that D2 lymphadenectomy with gastrectomy could prolong the survival rate of patients with node-negative gastric cancer, whereas the impact of postoperative chemotherapy on the survival is scarcely reported.

### Innovations and breakthroughs

The authors retrospectively reviewed 311 patients with node-negative gastric cancer, who were treated with curative gastrectomy and with more than 15 lymph nodes resected at a hospital in Tianjin between 2002 and 2006, to assess whether D2 lymphadenectomy and postoperative chemotherapy may affect their survival rate.

### Applications

The authors suggest that, for node-negative patients diagnosed with pT3 gastric cancer, D2 lymphadenectomy be performed even without clinically detectable node metastases. However, for other patients with poor survival rate, the effect of D2 lymphadenectomy is less obvious.

### Peer review

This article demonstrated the necessity of extended lymphadenectomy for gastric cancer patients without lymph node metastasis. In this study, the authors found that the survival rate of node-negative patients with pT3 gastric cancer could be improved by D2 lymphadenectomy.

### Abstract

**AIM:** To examine transforming growth factor- $\beta 1$  (*TGF-β1*) promoter methylation in gastric cancer and to determine if *Helicobacter pylori* (*H. pylori*) or interleukin (IL)-1 $\beta$  could induce *TGF-β1* hypermethylation *in vitro*.

**METHODS:** We examined the frequency and extent of *TGF-β1* promoter methylation using methylation-specific PCR in the gastric tissues from 47 gastric cancer patients and 39 non-gastric cancer subjects. *H. pylori* infection was confirmed by a positive result from either a serological test, histological analysis or C<sup>13</sup> urea breath test. GES-1 and MKN-45 cells co-cultured with *H. pylori* or treated with IL-1 $\beta$  for 12, 24 and 48 h *in vitro* tested the effects of *H. pylori* or IL-1 $\beta$  on *TGF-β1*.

**RESULTS:** Twenty-four/forty-seven (51%) cases of gastric cancer (GC) tissues showed *TGF-β1* promoter methylation, 15/47 (31.9%) cases of matched non-cancerous gastric mucosa tissues from the GC patients, and 11/39 (28%) case of the normal gastric mucosa tissues from non-GC subjects showed *TGF-β1* promoter methylation (51% vs 28%,  $P < 0.05$ ). Significantly higher levels of methylation of *TGF-β1* were found in the tumor tissues than in non-tumor tissues from GC patients ( $0.24 \pm 0.06$  vs  $0.17 \pm 0.04$ ,  $P < 0.05$ ) and normal gastric tissues from non-GC subjects ( $0.24 \pm 0.06$  vs  $0.15 \pm 0.03$ ,  $P < 0.05$ ). *TGF-β1* methylation was found in 48.3% of *H. pylori*-positive gastric mucosal tissues whereas only 23.1% of *H. pylori*-negative gastric mucosal tissues showed *TGF-β1* methylation (48.3% vs 23.1%,  $P < 0.05$ ). IL-1 $\beta$  appeared to induce a dose-dependent methylation of *TGF-β1* and the strongest methylation was observed in GES-1 cells treated with 2.5 ng/mL of IL-1 $\beta$  for 48 h. Further studies showed that pre-treatment of GES-1 cells with 20 ng/mL IL-1RA for 1 h could partially abolish the effect of IL-1 $\beta$  on *TGF-β1* methylation. Infection of GES-1 cells by *H. pylori* was not found to induce significant *TGF-β1* promoter methylation.

**CONCLUSION:** Our data revealed that *TGF-β1* promoter is methylated in GC patients. IL-1 $\beta$  may be an important mediator for *H. pylori* induced gene methylation during GC development.

**Key words:** Transforming growth factor- $\beta$ 1; Interleukin-1 $\beta$ ; Methylation; *Helicobacter pylori*; Gastric cancer

**Core tip:** *In vitro* studies showed that GES-1 cells exposed to *Helicobacter pylori* (*H. pylori*) did not show significant transforming growth factor- $\beta$ 1 (*TGF- $\beta$ 1*) methylation. However, treatment of the GES-1 cells with interleukin (IL)-1 $\beta$  led to a dose-dependent methylation of *TGF- $\beta$ 1*, which was partially abolished by IL-1RA. The high levels of *TGF- $\beta$ 1* promoter methylation in *H. pylori* positive patients was likely the result of *H. pylori*-induced inflammation rather than *H. pylori* itself. IL-1 $\beta$  may be an important mediator for *H. pylori*-induced gene methylation during gastric cancer development.

## INTRODUCTION

Genetic and epigenetic alterations in tumor suppressor genes or oncogenes are implicated in cancer formation. DNA methylation is the major form of epigenetic change in eukaryotic genomes. It involves the addition of a methyl group to the carbon 5 position of the cytosine ring within the CpG dinucleotide. CpG islands (CGIs) are regions of the genome that contain a large number of CpG dinucleotide repeats. In mammalian genomes, CGIs usually extend for 300-3000 base pairs. They are located within, and close to, sites of about 40% of gene promoters. It is estimated that in mammalian genomes, about 80% of CpG dinucleotides are methylated. However, CpG dinucleotides in regions abundant in GC pairs, such as CGIs, are normally protected from DNA methylation, and this is an important controlling mechanism for gene promoters and gene expression<sup>[1]</sup>. Although most CGIs linked to promoters are non-methylated, recent studies have revealed that promoter CpG hypermethylation, associated with transcriptional inactivation, may play a pivotal role in tumorigenesis<sup>[2]</sup>.

Gastric cancer (GC) remains a major health threat because of its high incidence, poor prognosis and limited treatment options. Multiple epigenetic and genetic alterations have been identified in GC patients. High levels of aberrant CpG island methylation and DNA methylation in the gastric mucosae correlate with increased GC risk, and as such, they are increasingly recognized as candidate markers for GC<sup>[3]</sup>.

Clinical and epidemiological studies have demonstrated that *Helicobacter pylori* (*H. pylori*) infection is correlated strongly with aberrant methylation in GC, whereas eradication of *H. pylori* significantly reduces gene methylation<sup>[4,5]</sup>.

Clearly, *H. Pylori*-induced aberrant methylation plays a role in GC formation. However, the precise molecular mechanisms of how *H. Pylori* might induce aberrant CpG island methylation remain elusive.

Chronic inflammation is a well-known promoting factor for many cancers. Approximately 15%-20% of all human cancers are related to chronic inflammation<sup>[6]</sup>. GC is a typical inflammation-related malignancy, being closely linked to *H. Pylori*-induced chronic inflammation in gastric mucosa. Chronic inflammation in the esophagus and colon may precipitate aberrant methylation, but whether *H. pylori* itself or the chronic inflammation caused by *H. pylori* infection induces methylation in CGIs remains controversial<sup>[7,8]</sup>.

*H. pylori* infection is characterized by infiltration of inflammatory cells, such as neutrophils and lymphocytes, into the gastric mucosa, as well as increased production of inflammatory cytokines<sup>[9,10]</sup>. Interleukin (IL)-1 $\beta$  is a pro-inflammatory cytokine primarily secreted by activated monocytes/macrophages in response to bacterial infection. IL-1 $\beta$  mediates many pathophysiological events during host-environment interactions. Recent studies have demonstrated that the levels of several inflammatory cytokines including IL-1 $\beta$ , IL-6, IL-8 and tumor necrosis factor  $\alpha$  (TNF- $\alpha$ ) are significantly higher in the gastric mucosal tissues from *H. pylori*-positive patients than those from *H. pylori*-negative patients<sup>[11-13]</sup>. It was further demonstrated that IL-1 $\beta$  could directly induce promoter methylation of *E-cadherin*, an important extracellular matrix component involved in the maintenance of epithelial stability: *H. pylori*-induced methylation of *E-cadherin* promoter was mediated through IL-1 $\beta$ <sup>[14]</sup>.

Transforming growth factor- $\beta$ 1 (*TGF- $\beta$ 1*) is an anti-inflammatory cytokine with multiple, and perhaps even opposite, biological effects in many tissues. TGF- $\beta$ 1 was shown to inhibit the growth of epithelial cells, but stimulates the proliferation of mesenchymal cells<sup>[15,16]</sup>. Many studies have shown that TGF- $\beta$ 1 is overexpressed in epithelial cancers and exerts its transforming potential through several mechanisms, such as stimulating the progression of stromal cells, promoting angiogenesis and suppressing immune surveillance<sup>[17]</sup>. However, TGF- $\beta$ 1 was reported to function as a tumor suppressor, because it could inhibit potently the proliferation of many types of cancer cells derived from breast, prostate, lung, colon and liver<sup>[18,19]</sup>. Furthermore, methylation-induced silencing of *TGF- $\beta$ 1* has been implicated in the development of several solid tumors, and silencing of *TGF- $\beta$ 1* signaling through methylation of the gene encoding its receptor have been reported<sup>[20,21]</sup>.

It has been reported that the expression level of host TGF- $\beta$ 1 in gastric mucosa was an important determinant for the pathogenesis of *H. pylori*-associated gastric diseases<sup>[22-24]</sup>. The gastric mucosa of *TGF- $\beta$ 1* null mice exhibit similar changes to those observed in *H. pylori*-associated gastritis, and these mice were found to progressively develop inflammatory diseases and die within 3-4 wk of birth<sup>[25]</sup>. However, the role of *TGF- $\beta$ 1* methylation in the development of *H. pylori*-related GC remains largely unknown.

In this study, we aimed investigate if *H. pylori* could induce promoter methylation of TGF- $\beta$ 1 in GC and whether IL-1 $\beta$  plays a role in this process.

## MATERIALS AND METHODS

### Patients and specimens

This study involved 47 consecutive GC patients (35 males and 12 females, mean age 56.2 years) who underwent gastrectomy and 39 consecutive non-GC subjects (28 males and 11 females, mean age 52.1 years) who underwent upper gastroduodenoscopy. *H. pylori* infection was confirmed by a positive result from either one of the following diagnostic approaches: serological test, histological analysis or C<sup>15</sup> urea breath test. No patients received prior *H. pylori* eradication therapy. Ninety-four gastric specimens (two from each patient, from tumor and non-tumor gastric mucosa) from GC patients and 39 gastric mucosa tissues from non-GC subjects were collected. The tissues were snap-frozen in liquid nitrogen and subsequently stored at -80 °C for the studies described below. Patients who received eradication therapy for *H. pylori* before the study and those with severe systemic diseases (such as major organ failure, server infection, autoimmune disease, organ transplantation and immunosuppressive therapy) were excluded.

### Cell culture

Human gastric epithelium cell line GES-1 was kindly provided by Professor Bingdong Zhu (School of Basic Medical Sciences, Lanzhou University). Cells were cultured in DMEM medium containing 10% FBS supplemented with 100 IU/mL penicillin, 100 IU/mL streptomycin and maintained at 37 °C in a humidified atmosphere with 5% CO<sub>2</sub>.

### Bacterial strain and conditions

NCTC11637, a *CagA*-positive strain of *H. pylori*, was purchased from the American Type Cell Culture (ATCC) (Rockville, MI, United States). *H. pylori* were cultured on 4.2% Columbia Blood A gar (Youkang Foundation of Biological Science and Technology Beijing Co. Ltd. Beijing, China) containing 7.5% normal sheep blood and 0.5% antibiotics (vancomycin, 10 mg/mL; polymyxin, 0.025 mg/mL; and amphotericin B, 10 mg/mL) under micro-aerophilic conditions for 72 h. Bacteria were harvested and re-suspended in sterile phosphate buffered saline (PBS) and counted by absorbance at 660 nm (1 OD<sub>660</sub> = 1 × 10<sup>8</sup> colony forming units/mL).

### Infection of gastric epithelial cells by *H. pylori*

To establish an *in vitro* model of *H. pylori* infected gastric mucosa, GES-1 cells were grown to 80% confluence under the above-mentioned conditions. Cells were infected with live *H. pylori* at *H. pylori*/cell ratios of 5:1, 10:1, 50:1, and 100:1. To determine the involvement of IL-1 $\beta$  in *H. pylori*-induced pathology, GES-1 cells were pre-treated with human interleukin-1 receptor antagonist (IL-1RA) (Peptotech, Rocky Hill, NJ, United States) for 1 h before

*H. pylori* infection. IL-1RA was used at various concentrations (10, 20, 50 and 100 ng/mL) to select the concentration at which it can effectively block the IL-1 $\beta$  signaling. 20 ng/mL for 48 h was found to be an effective dose. All cells were cultured in 6-well plates at 37 °C in a humidified atmosphere for 12, 24 and 48 h.

### Treatment of GES-1 cells with IL-1 $\beta$

GES-1 cells were pre-treated with or without various concentrations of IL-1RA (10, 20, 50 and 100 ng/mL) for 1 h, followed by treatment with different concentrations IL-1 $\beta$  (Peptotech, Rocky Hill, NJ, United States) (0.1, 0.25, 1.0 and 2.5 ng/mL) for 12, 24, and 48 h in fresh serum-free DMEM medium.

### Methylation-specific polymerase chain reaction

Genomic DNA was extracted from each sample using the TIANamp Genomic DNA Kit (Tiangen Biotech Beijing Co. Ltd, Beijing, China), according to the manufacturer's instructions. The extracted DNA was treated with sodium bisulfite using the EZ DNA Methylation-Gold™ Kit (Zymo Research, Los Angeles, CA, United States), according to the manufacturer's instructions. After bisulfite treatment, DNA was purified using a Zymo-Spin™ IC Column (Zymo Research, Los Angeles, CA, United States) and resuspended in 10  $\mu$ L of dilution buffer (M-Elution Buffer, Zymo Research, Los Angeles, CA, United States). DNA methylation of the TGF- $\beta$ 1 promoter was analyzed by methylation-specific polymerase chain reaction (MSPCR), using Zymo Taq™ PreMix (Zymo Research), according to the manufacturer's instructions. Briefly, the bisulfite-modified DNA (2  $\mu$ L) was amplified using specific primers for methylated and unmethylated sequences of TGF- $\beta$ 1. The primer sequences used in the study were as follows. For methylated TGF- $\beta$ 1, forward: TATATCGTTCGTAAAGTTATAGCGT, reverse: AACATAAAAAAACTAAACCACCGTC. For unmethylated TGF- $\beta$ 1, forward: ATTTATATTGTTTGTAAAGTTATAGTGT, and reverse: AACATAAAAAAACTAAACCACCATC. PCR was performed in a 50- $\mu$ L reaction system, which contains Zymo Taq™ PreMix (25  $\mu$ L), forward primer (10  $\mu$ mol/L) 4  $\mu$ L, reverse primer (10  $\mu$ mol/L) 4  $\mu$ L, DNA template (2  $\mu$ L), and double distilled water (15  $\mu$ L). The reactions were hot-started at 97 °C for 10 min, followed by 40 cycles of reactions (15 s at 95 °C, 35 s for annealing, and 30 s at 72 °C) and a final 7-min extension in a Thermal Cycler (Veriti, ABI Co., Foster, CA, United States). For positive controls, we used CpGenome Universal Methylated DNA (Intergen, New York, NY, United States). Five microliters of PCR products were separated by electrophoresis on 2% agarose gel stained with ethidium bromide, and imaged using a VersaDoc Imaging System (Bio-Rad Laboratories Co., Ltd. Hercules, CA, United States).

### Densitometric analysis of TGF- $\beta$ 1 methylation Levels

Quantity One software v4.62 (Bio-Rad Laboratories Co., Ltd. Hercules, CA, United States) was used to perform

densitometric analyses of methylated and un-methylated bands of *TGF-β1*, and the results were presented as the mean of three independent experiments. The methylation levels were calculated as the ratio of the value of methylated band to methylated plus unmethylated bands.

**Statistical analysis**

The frequencies of promoter methylation were compared between the two groups by two-sided Fisher’s exact test or Pearson  $\chi^2$  test. Differences in methylation levels of *TGF-β1*

between two groups were examined by Student’s *t* test. A *P* value of < 0.05 was considered statistically significant.

**RESULTS**

**Methylation frequency and levels of TGF-β1 in GC and non-GC subjects**

As shown in Table 1, 24/47 (51%) cases of GC tissues showed *TGF-β1* promoter methylation, 15/47 (31.9%) cases of matched non-cancerous gastric mucosa tissues from the GC patients, and 11/39 (28%) cases of the normal gastric mucosa tissues from non-GC subjects showed *TGF-β1* promoter methylation (51% vs 28%, *P* = 0.032).

To evaluate the levels of *TGF-β1* methylation, we analyzed quantitatively the MSPCR product bands by their fluorescence intensities. Typical MSPCR bands are shown in Figure 1A, and the quantitative data for the methylation levels of *TGF-β1* in gastric tissues are shown in Figure 1B. Significantly higher levels of methylation of *TGF-β1* were found in the tumor tissues (0.24 ± 0.06) than in non-tumor tissues from GC patients (0.17 ± 0.04) (*P* = 0.001) and normal gastric tissues from non-GC subjects (0.15 ± 0.03) (*P* = 0.001).

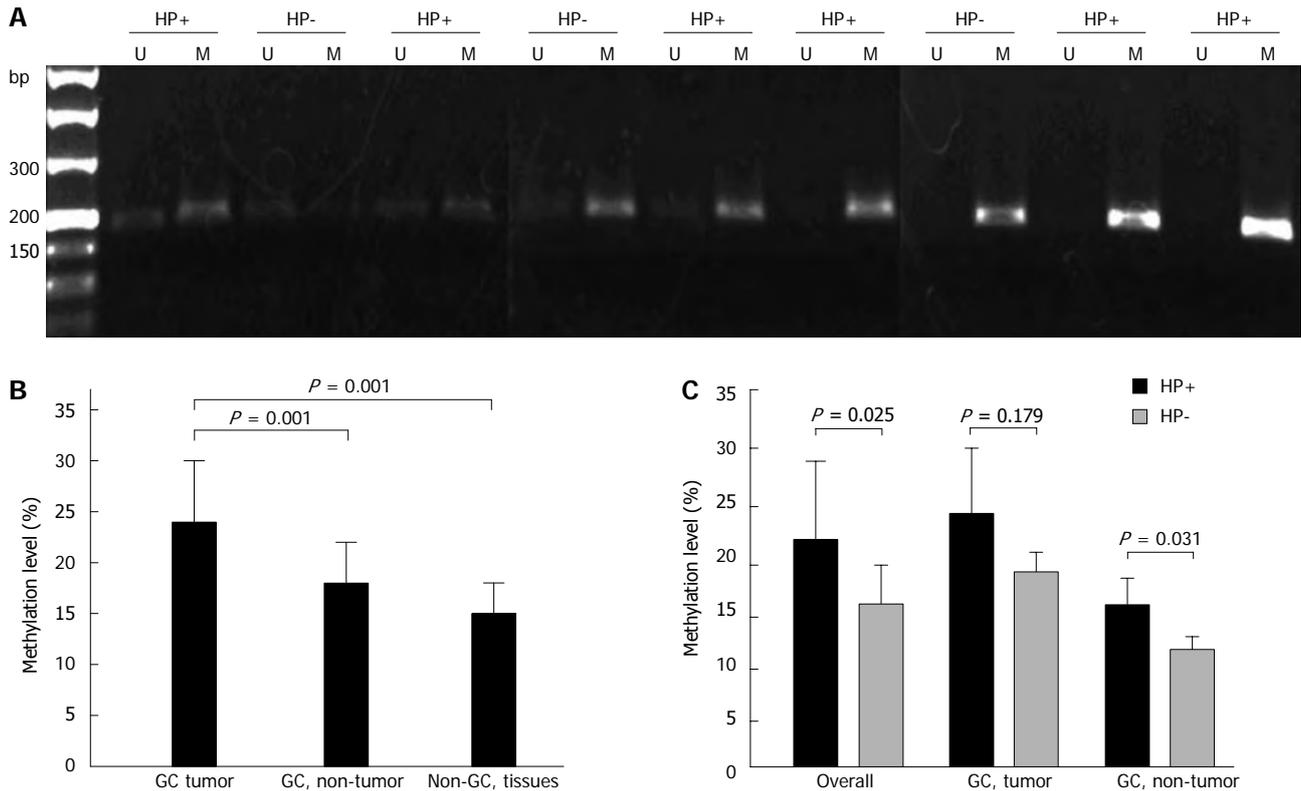

**Methylation frequency and levels of TGF-β1 in H. pylori-positive and H. pylori-negative subjects**

To examine the impact of *H. pylori* on the methylation of *TGF-β1*, we compared the methylation frequency of *TGF-β1* in *H. pylori*-positive and *H. pylori*-negative GC tissues and non-cancerous gastric tissues. As shown in Table 1 and best shown in Table 2, 21/38 (55.3%) cases of *H. pylori*-positive GC tissues showed *TGF-β1* methylation, whereas only 3/9 (33.3%) cases of *H. pylori*-negative GC tissues showed *TGF-β1* methylation. In non-cancerous gastric tissues obtained from GC patients, the frequency of *TGF-β1* methylation appeared to be similar between *H. pylori*-positive and *H. pylori*-negative gastric tissues (31.6% vs 33%, *P* = 0.919). In normal gastric mucosa from non-GC patients, *H. pylori*-positive tissues exhibited more frequent *TGF-β1* methylation than the *H. pylori*-negative gastric tissues (36.4% vs 17.6%, *P* = 0.288). Overall, *TGF-β1* methylation was found in 48.3% of *H. pylori*-positive gastric mucosal tissues, whereas only 23.1% of *H. pylori*-negative gastric mucosal tissues showed *TGF-β1* methylation (48.3% vs 23.1%, *P* = 0.029).

Further densitometric analysis showed that *H. pylori*-positive GC tumor tissues exhibited much higher levels of *TGF-β1* methylation than *H. pylori*-negative GC tumor tissues (Figure 1A and C). Furthermore, higher levels of *TGF-β1* methylation were also found in *H. pylori* positive non-GC mucosal tissues (Figure 1C). Overall, more *TGF-β1* methylation was present in *H. pylori* positive gastric mucosa than in *H. pylori*-negative gastric tissues (0.23 ± 0.06 vs 0.16 ± 0.03, *P* = 0.025) (Figure 1C).

**Effect of IL-1β signaling on TGF-β1 promoter methylation**

To examine the mechanisms of *TGF-β1* methylation, GES-1 cells were incubated in the presence or absence

**Figure 1** Detection of transforming growth factor-β1 promoter methylation by methylation-specific polymerase chain reaction. Genomic DNA was extracted from human gastric tissues. A: Representative methylation-specific polymerase chain reaction results from gastric cancer (GC) tissues with or without *Helicobacter pylori* (*H. pylori*) infection are shown; B: Levels of transforming growth factor-β1 (*TGF-β1*) promoter methylation in GC tissues, non-cancerous gastric mucosa from the GC patients (GC, non-tumor) and normal gastric mucosa from non-GC subjects (Non-GC tissues); C: Impact of *H. pylori* status on the levels of *TGF-β1* promoter methylation in GC tissues (GC, tumor), non-cancerous gastric mucosa from the GC patients (GC, non-tumor) and combined samples (overall). HP+: *H. pylori*-positive; HP-: *H. pylori*-negative; U: Unmethylated; M: Methylated.

**Table 2** Impact of *Helicobacter pylori* on the frequency of transforming growth factor-β1 methylation in gastric tissues

	<i>TGF-β1</i> methylation in GC patients		<i>TGF-β1</i> methylation in Non-GC patients	Total <sup>1</sup>
	Tumor	Non-tumor	Normal gastric mucosa	
<i>H. pylori</i> (+)	21/38 (55.3%)	12/38 (31.6%)	8/22 (36.4%)	41/98 (41.8%)
<i>H. pylori</i> (-)	3/9 (33%)	3/9 (33%)	3/17 (17.6%)	9/35 (25.7%)

<sup>1</sup>Combined tumor and non-tumor tissue. GC: Gastric cancer; TGF-β1: Transforming growth factor-β1; *H. pylori*: *Helicobacter pylori*.

of different concentrations of IL-1β (0.1, 0.25, 1.0 and 2.5 ng/mL) for 12, 24 and 48 h, and *TGF-β1* promoter methylation was then measured by MSPCR. As shown in Figure 2A, IL-1β appeared to induce a dose-dependent methylation of *TGF-β1*, with the strongest methylation being observed in GES-1 cells treated with 2.5 ng/mL of IL-1β for 48 h. Further studies showed that pre-treatment of GES-1 cells with 20 ng/mL of IL-1RA for 1 h could partially abolish the effect of IL-1β on *TGF-β1* methylation (Figure 2B).

***H. pylori* alone dose not induce TGF-β1 methylation in vitro**

Infection of GES-1 cells by *H. pylori* did not induce significant *TGF-β1* promoter methylation (data not shown).

**DISCUSSION**

Promoter hypermethylation leading to epigenetic inactivation of tumor suppressor genes plays a pivotal role in tumorigenesis. Aging, chronic inflammation, and viral and bacterial infections promote methylation of promoter CpG islands and may represent the “environmental” triggers of carcinogenesis. The stomach is one of the organs that constantly undergoes DNA methylation of CpG islands in its epithelial cells. The oncogenic role of *H. pylori* for gastric malignancies, mainly gastric carcinoma and MALT lymphoma, has been well documented, and as such, *H. pylori* has been designated a Class I carcinogen. However, the mechanism by which *H. pylori* induces GC remained poorly defined.

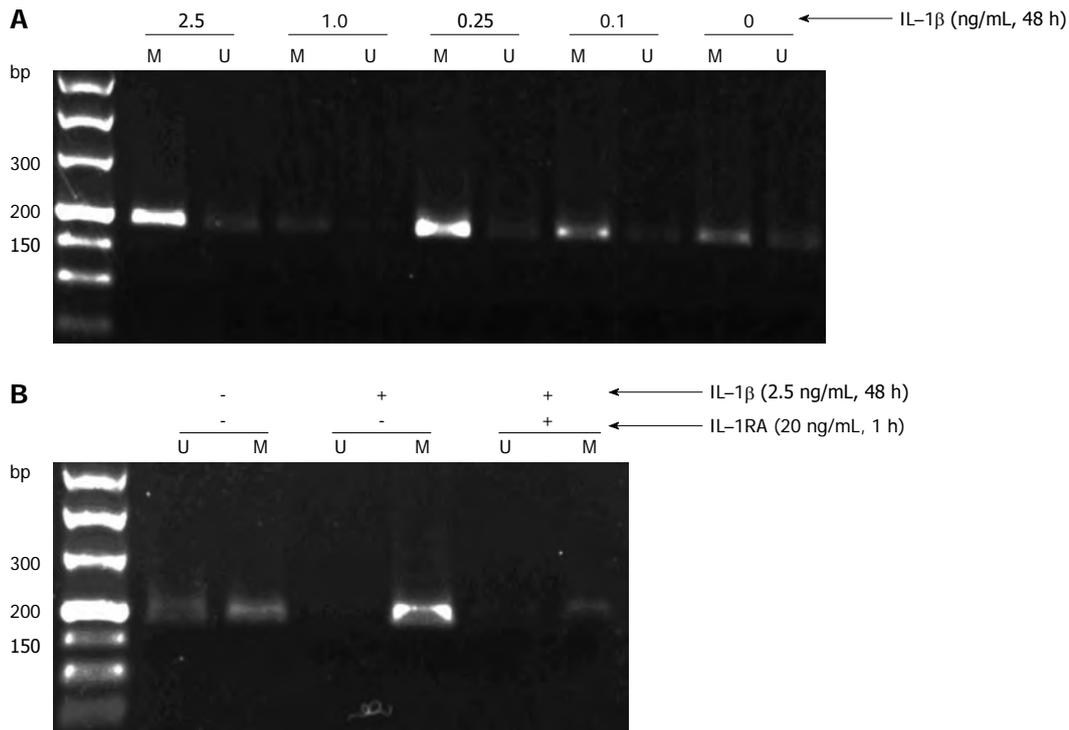

Figure 2 Induction of transforming growth factor- $\beta$ 1 methylation by interleukin-1 $\beta$  in GES-1 cells. A: Treatment of GES-1 cells by interleukin (IL)-1 $\beta$  led to a dose-dependent methylation of transforming growth factor (TGF)- $\beta$ 1; B: IL-1 $\beta$ -induced TGF- $\beta$ 1 methylation in GES-1 cells was partially abolished by IL-1RA. U: Unmethylated; M: Methylated; *H. pylori*: *Helicobacter pylori*.

In the present study, we have revealed, for the first time, that significantly more frequent and higher levels of TGF- $\beta$ 1 promoter methylation are present in GC patients than in non-cancerous controls. Although aging is a recognized risk factor for DNA methylation, from the current study, the impact of age (and sex) on TGF- $\beta$ 1 DNA methylation could be excluded, because our study populations in each group were well-balanced in their distribution of age and sex.

TGF- $\beta$ 1 shows biphasic effects in tumorigenesis<sup>[26]</sup>. In the initial stage, it may function as a tumor suppressor by inhibiting cell growth. This was demonstrated in breast cancer in which constitutive activation of the TGF- $\beta$ 1 pathway prolonged the latency of tumorigenesis or resulted in smaller tumor formation in mice<sup>[27,28]</sup>. However, in the later stage of tumorigenesis (*i.e.*, when the tumors are well established), activation of the TGF- $\beta$ 1 signaling can strongly promote tumor progression<sup>[29]</sup>.

Chronic inflammation-induced methylation of promoter CGIs has been closely linked to the development of human cancers<sup>[30,31]</sup>. In gastric cancer, whether the gene hypermethylation observed in *H. pylori*-infected individuals is caused directly by *H. pylori*, or the gene hypermethylation results from *H. pylori*-induced gastric inflammation remains a topic of debate. In our study, we first examined if *H. pylori* could directly cause methylation of TGF- $\beta$ 1. We made use of a gastric epithelial cell line GES-1, and co-cultured this cell line with *H. pylori*. Contrary to our initial hypothesis, *H. pylori* did not induce apparent promoter methylation of TGF- $\beta$ 1. However, treatment of GES-1 cells with IL-1 $\beta$  led to a marked

methylation of the TGF- $\beta$ 1 promoter, and this was partially reversed by antagonizing IL-1 $\beta$  signaling using its receptor blocker IL-1RA. IL-1 $\beta$  is an important pro-inflammatory cytokine that initiates and amplifies the inflammatory responses to *H. pylori* infection. IL-1 $\beta$  is closely linked to DNA methylation of gastric epithelial cells, particularly in *H. pylori* infected individuals. We think that IL-1 $\beta$  may be an important mediator in *H. pylori*-induced TGF- $\beta$ 1 methylation<sup>[32,33]</sup>.

Our *in vitro* data did not correlate with the *in vivo* data, which showed that *H. pylori* infected individuals, particularly *H. pylori*-positive GC tissues, showed more frequent and higher levels of TGF- $\beta$ 1 methylation. This inconsistency may be explained in several ways. Firstly, the acute infection of GES-1 cells by *H. pylori* may not be a valid model for studying the impact of *H. pylori* on gastric mucosa. It was reported that chronic, rather than acute, *H. pylori* infection was responsible for methylation induction. Secondly, *H. pylori* may not directly induce hypermethylation, but rather it induces inflammation and the production of pro-inflammatory cytokines, such as IL-1 $\beta$ , is likely a contributing factor for TGF- $\beta$ 1 methylation. Our data support this view. Lastly, inflammatory cytokines or molecules may also be involved in *H. pylori*-induced methylation. For example, nitric oxide may be involved in *H. pylori* infection-related DNA methylation<sup>[34]</sup>.

## COMMENTS

### Background

Hypermethylation of promoter CpG islands (CGIs) leads to functional silenc-

ing of some tumor suppressor genes and is thus involved in carcinogenesis. Chronic inflammation is closely associated with cancer formation. Inflammation-induced gene methylation is an important mechanism for inflammation-associated cancers, of which gastric cancer is a classical example. During gastric cancer formation, frequent aberrant CpG methylation has been reported and the role of *Helicobacter pylori* (*H. pylori*) infection during this process is controversial. Inactivation of transforming growth factor- $\beta$ 1 (TGF- $\beta$ 1) by promoter methylation has been implicated as an important mechanism for the development of several malignancies, such lung and prostate cancers; however, the role of TGF- $\beta$ 1 methylation in gastric cancer remains unknown.

### Research frontiers

Multiple epigenetic and genetic alterations have been identified in gastric cancer (GC) patients. High level of aberrant CpG island methylation in the gastric mucosae is correlated with increased GC risk, and as such, they are increasingly recognized as candidate markers for GC. Clinical and epidemiological studies have demonstrated that *H. pylori* infection is strongly correlated with aberrant methylation in GC. However, the precise molecular mechanism by which *H. pylori* might induce aberrant CpG island methylation remain elusive. GC is a typical inflammation-related malignancy, being closely linked to *H. pylori* induced chronic inflammation in the gastric mucosa. Whether *H. pylori* itself or the chronic inflammation caused by *H. pylori* infection can induce methylation in CpGs remains controversial.

### Innovations and breakthroughs

TGF- $\beta$ 1 is an anti-inflammatory cytokine with multiple effects in many tissues. Many studies have shown that TGF- $\beta$ 1 is overexpressed in epithelial cancers and exerts its transforming potential through several mechanisms, such as stimulating the progression of stromal cells, promoting angiogenesis and suppressing immune surveillance. In the present study, the authors have revealed, for the first time, that significantly more frequent and higher levels of TGF- $\beta$ 1 promoter methylation is present in GC patients with *H. pylori* infection than in non-cancerous controls. *In vitro* studies showed that normal gastric epithelial cell line GES-1 cells exposed to *H. pylori* did not show significant TGF- $\beta$ 1 methylation. However, treatment of the GES-1 cells with IL-1 $\beta$  led to a dose-dependent methylation of TGF- $\beta$ 1. The data show that *H. pylori* may not directly induce hypermethylation, but rather this bacteria induced inflammation and the production of pro-inflammatory cytokines, such IL-1 $\beta$ , is likely a contributing factor for TGF- $\beta$ 1 methylation.

### Applications

High levels of TGF- $\beta$ 1 methylation in the gastric cancer tissue suggest that TGF- $\beta$ 1 functions as a tumor suppressor in *H. pylori* related gastric cancer.

### Terminology

CpG island: CpG islands are DNA segments, at least 0.5 kb in size, that are rich in G:C and CpG content, and are often located in the promoter or 50-exon sequences of genes. Promoter CpG islands have traditionally been thought to be unmethylated in normal cells, with the exception of those on the inactive X chromosome and those associated with imprinted genes. DNA methylation: DNA methylation is the major epigenetic phenomenon of eukaryotic genomes, and involves the addition of a methyl group to the carbon 5 position of the cytosine ring within the CpG dinucleotide. DNA methylation is required for the normal development of cells, whereas aberrant methylation of CpG islands confers a selective growth advantage that results in cancerous growth.

### Peer review

The manuscript by Wang *et al* demonstrates that high levels of TGF- $\beta$ 1 promoter methylation in *H. pylori* positive patients was the result of *H. pylori*-induced inflammation rather than by *H. pylori* itself, and that IL-1 $\beta$  may be an important mediator for *H. pylori*-induced gene methylation during gastric cancer development. The overall goal of the paper is relevant. The data presented are solid and credible. The results are interesting, clinically important and worthy of publication in World Journal of Gastroenterology.

### Abstract

**AIM:** To perform a meta-analysis of palliative stent placement *vs* palliative surgical decompression for management of incurable malignant colorectal obstructions.

**METHODS:** The databases of Medline, Web of Science, Embase, and the Cochrane Central Register of Controlled Trials were searched from their inception to July 2012 for studies (prospective, retrospective, randomized controlled trials, and case-control trials) designed as comparative analyses of patients with incurable malignant colorectal obstructions treated by self-expanding metallic stents (SEMS) or palliative surgery. No language restrictions were imposed. The main outcome measures were hospital stay, intensive care unit admission, clinical success rate, 30-d mortality, stoma formation, complications, and overall survival time. The data extraction was conducted by two investigators

working independently and using a standardized form. The Mantel-Haenszel  $\chi^2$  method was used to estimate the pooled risk ratios with 95%CI under a fixed-effects model; when statistical heterogeneity existed in the pooled data (as evaluated by  $Q$  test and  $I^2$  statistics, where  $P < 0.10$  and  $I^2 < 25\%$  indicated heterogeneity), a random-effects model was used.

**RESULTS:** Thirteen relevant articles, representing 837 patients (SEMS group,  $n = 404$ ; surgery group,  $n = 433$ ), were selected for analysis. Compared to the surgery group, the SEMS group showed lower clinical success (99.8% *vs* 93.1%,  $P = 0.0009$ ) but shorter durations of hospital stay (18.84 d *vs* 9.55 d,  $P < 0.00001$ ) and time to initiation of chemotherapy (33.36 d *vs* 15.53 d,  $P < 0.00001$ ), and lower rate of stoma formation (54.0% *vs* 12.7%,  $P < 0.00001$ ). Additionally, the SEMS group experienced a significantly lower rate of 30-d mortality (4.2% *vs* 10.5%,  $P = 0.01$ ). Stent-related complications were not uncommon and included perforation (10.1%), migration (9.2%), and occlusion (18.3%). Surgery-related complications were slightly less common and included wound infection (5.0%) and anastomotic leak (4.7%). The rate of total complications was similar between these two groups (SEMS: 34.0% *vs* surgery: 38.1%,  $P = 0.60$ ), but the surgery-related complications occurred earlier than stent-related complications (rate of early complications: 33.7% *vs* 13.7%,  $P = 0.03$ ; rate of late complications: 32.3% *vs* 12.7%,  $P < 0.0001$ ). The overall survival time of SEMS- and surgery-treated patients was not significantly different (7.64 mo *vs* 7.88 mo).

**CONCLUSION:** SEMS is less effective than surgery for palliation of incurable malignant colorectal obstructions, but is associated with a shorter time to chemotherapy and lower 30-d mortality.

© 2013 Baishideng. All rights reserved.

**Key words:** Self-expandable metal stents; Palliative sur-

gery; Incurable malignant colorectal obstruction; Large-bowel obstruction; Treatment outcomes

**Core tip:** This meta-analysis demonstrates the advantages of self-expandable metal stent (SEMS) placement as palliative therapy for incurable malignant colorectal obstructions. Specifically, when compared to the outcomes of surgical treatment, the SEMS treatment is associated with shorter hospital stay and interval to chemotherapy initiation, as well as lower early morbidity and 30-d mortality rates. These advantageous features may surmount the overall lower rate of palliative efficacy when considering treatment options for cases with extensive metastatic disease or severe comorbid medical illness that disqualify a patient from operative candidacy; regardless, SEMS application should be performed as an alternative to surgery with caution.

Zhao XD, Cai BB, Cao RS, Shi RH. Palliative treatment for incurable malignant colorectal obstructions: A meta-analysis. *World J Gastroenterol* 2013; 19(33): 5565-5574 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i33/5565.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i33.5565>

## INTRODUCTION

Malignant colorectal obstruction, a type of large bowel obstruction (LBO), is a frequent and serious complication of advanced cancers, including colorectal cancer or those with near organ (*e.g.*, ovary, vagina, and prostate) or distant metastases<sup>[1]</sup>. LBO initially manifests non-specific gastrointestinal symptoms, such as vomiting, abdominal distention and abdominal pain; however, if left untreated, the condition may progress to a life-threatening status, as the weak necrotic areas of the bowel become more susceptible to tears and a risk for rapid onset infection and septicemia.

The traditional therapeutic approach for LBO is surgical, and the Hartmann's pouch procedure and loop colostomy are the most widely applied surgical methods used for treating obstruction of incurable advanced cancer. Unfortunately, these procedures are associated with substantial drawbacks, including high mortality and morbidity<sup>[2-4]</sup>, as well as detrimental impacts on a patient's quality of life when irreversible ostomies necessitate a colostomy bag<sup>[1,5,6]</sup>. The alternative method of colonic stent insertion was introduced by Dohmoto<sup>[7]</sup> to overcome the risks associated with open surgery. Since then, self-expanding metallic stents (SEMS) have been widely applied to patients with incurable malignant obstructions as palliative treatment or as a bridge to elective primary resection and anastomosis.

SEMS placement is achieved by feeding the metal tube in a collapsed state to the site of obstruction by using a guidewire and visualization by fluoroscopy and/or endoscopy. The inserted stents then undergo passive expansion to create a strong, passable space and relieve

the obstruction. Numerous stents of various lengths and maximal expanded diameter have been designed specifically for treating lower gastrointestinal obstructions, so that the appropriate stent can be chosen for each patient based on location and length of the lesion and severity of the obstruction.

Despite the widespread availability and application of SEMS, its efficacy and safety for treating incurable malignant colorectal obstruction, as compared to that of the traditional surgical approach, has been addressed in relatively few studies with small populations. Thus, this meta-analysis was designed to provide stronger evidence of the outcomes, benefits, and risks of these two palliative treatments through the increased statistical power afforded by pooling data of the previously studied patient populations.

## MATERIALS AND METHODS

### Literature search strategy and data extraction

Two investigators (Zhao XD and Cai BB) performed independent searches of the Medline, Web of Science, Embase, and Cochran Central Register of Controlled Trials databases. These literature collections were queried from inception to July 2012 using the following keywords and medical subject heading terms: stents, colonic stent, colorectal stent, Hartmann's procedures, Hartmann's, colostomy, palliative surgery, intestinal obstruction, large bowel obstruction, colorectal obstruction, comparative study, treatment outcomes, and human. The search strategy was widened or narrowed by applying Boolean operators (NOT, AND, and OR), and no language restriction was applied. All potentially relevant abstracts, studies, and citations were retrieved for review, and the references cited in each were further searched to identify any additional potentially relevant publications.

The two investigators also performed the data extraction (inclusion and exclusion criteria described below), working independently and using pre-determined forms to record first author, year of publication, study design including inclusion and exclusion criteria, and study population characteristics. The extracted datasets were compared and any disagreements were resolved by discussion and consensus.

### Inclusion criteria

Potentially relevant studies were selected for inclusion in the meta-analysis according to the following criteria: (1) comparative analysis of palliative SEMS and palliative surgery for treating malignant colorectal obstructions that were unresectable and had negative margins; (2) patients lacked signs of peritonitis and perforation; (3) reporting of at least one of the outcomes measures listed below; (4) designed as randomized controlled trials (RCTs) or other case-control study; and (5) performed with human patients.

### Exclusion criteria

Studies were excluded from the meta-analysis according to the following criteria: (1) evaluation of SEMS as

**Table 1 Study characteristics of included nonrandomized controlled studies *n* (%)**

Study design is randomized controlled trial (RCT); diagnosis is colorectal cancer (a) or ovarian cancer (b); matching for age (1), sex (2), tumor site (4), tumor stage (5), or the publication made no comment (NC) on the matching status; all studies were classified as high-quality according to the modified Jadad score between 4 and 7. SEMS: Self-expanding metallic stents.

a bridge to surgery (SBTS) or as a treatment for benign strictures, or comprehensive studies in which the data could not be clearly separated for exclusion; and (2) missing or unclear data for the outcomes of interest.

**Assessment of methodology quality**

The Newcastle-Ottawa scale<sup>[8]</sup> was employed to assess the quality of non-randomized studies, with scores of ≥ 5 indicating high quality. The modified Jadad score<sup>[9]</sup> was employed to assess the quality of randomized studies, with the cumulative scores of 4 to 7 indicating high quality.

**Statistical analysis**

The meta-analysis was performed by the RevMan 5.0.25 software (The Cochran Collaboration, Oxford, England) and the statistical analysis was carried out by the Stata 12.0 software (StataCorp, College Station, TX, United States). The risk ratios (RRs, with 95%CI) of dichotomous data were estimated by the Mantel-Haenszel  $\chi^2$  method; *P* values of < 0.05 were considered to indicate statistically significant differences between groups. Between-study heterogeneity was evaluated by the *Q* test and *I*<sup>2</sup> statistic, for which *P* values > 0.10 and *I*<sup>2</sup> < 25% indicated a lack of heterogeneity, respectively. In order to broaden the effect estimate in the presence of heterogeneity, the random-effects model was applied for evaluation of the pooled data. Finally, publication bias was estimated by Egger’s and Begg’s funnel plots, for which *P* values > 0.05 indicated a lack of publication bias.

**RESULTS**

**Characteristics of selected studies**

Thirteen studies, including 10 nonrandomized controlled studies<sup>[10-19]</sup> and three RCTs<sup>[20-22]</sup>, met the criteria for inclusion in the meta-analysis. The studies’ characteristics and quality assessment scores are presented in Tables 1 and 2, respectively. Eleven (84.62%) of the studies were categorized as high-quality. The total number of included patients was 837, of which 404 were treated by SEMS (48.3%) and 433 (51.7%) by palliative surgery. Eleven of the studies<sup>[10-12,14-19,21,22]</sup> focused solely on cases with colorectal cancer etiology, and the remaining two studies<sup>[13,20]</sup> also included etiologies of ovarian cancer and disseminated upper gastrointestinal malignancy. The studies also used different definitions of palliative surgery, with four of the studies<sup>[12,13,20,21]</sup> specifically reporting the colostomy procedure and the others reporting primary resection with anastomosis, primary resection without anastomosis, bypass, or Hartmann’s procedure, as well. Complications reported for the total case population were categorized as early (occurring ≤ 30 d post-treatment) or late (occurring > 30 d post-treatment).

**Features of clinical management**

**Length of hospital stay:** The mean length of hospital stay for the pooled SEMS group was significantly lower than that of the pooled surgery group (9.6 d *vs* 18.8 d, *P* < 0.00001).

**Intensive care unit admission:** Three studies<sup>[10,12,18]</sup> reported cases requiring intensive care unit (ICU) admission after treatment. Analysis of the 241 patients, including 119 treated with SEMS and 122 treated with surgery, indicated that the rate of ICU usage was significantly lower in the SEMS group than in the surgery group (0.8% *vs* 18.0%,  $P = 0.001$ ; Figure 1A).

**Time to chemotherapy initiation:** Three studies<sup>[17-19]</sup> reported cases receiving chemotherapy after treatment. Analysis of the 330 patients, including 152 treated with SEMS and 178 treated with surgery, indicated that the mean time to chemotherapy initiation following treatment was significantly lower in the SEMS group than in the surgery group (15.5 d *vs* 33.4 d).

### Short-term outcomes and complications

**Clinical relief of obstructions:** Data of treatment efficacy were available for all cases from all 13 studies. The surgery-treated patients showed a significantly higher rate of clinical relief of obstructions than the SEMS-treated patients (93.1% *vs* 99.8%,  $P = 0.0009$ ; Figure 1B).

**30-d mortality or in-hospital mortality:** Two studies<sup>[19,21]</sup> reported zero mortalities during both the in-hospital stay period and the 30-d follow-up. Meta-analysis of the 688 patients in the remaining ten studies, including 334 treated with SEMS and 354 treated with surgery, indicated that the SEMS group experienced fewer overall deaths than the surgery group (4.2% *vs* 10.5%,  $P = 0.01$ ; Figure 1C).

**Overall, early- and late-onset complications:** Data of treatment-related complications were available for all cases from all 13 studies. Although a slightly lower percentage of the SEMS-treated patients experienced complications, the amount was not significantly different from that in the surgery-treated patients (34.0% *vs* 38.1%,  $P = 0.60$ ; Figure 1D). Nine of the studies<sup>[10,14-18,20-22]</sup> reported data sub-categorized as early complications; while five studies<sup>[15-18,22]</sup> reported data as late complications. Compared to the surgery group ( $n = 326$ ), the SEMS-treated patients ( $n = 300$ ) experienced significantly less early complications (13.7% *vs* 33.7%,  $P = 0.03$ ; Figure 1E) but significantly more late complications (32.3% *vs* 12.7%,  $P < 0.0001$ ; Figure 1F).

### Stent-related complications

Eleven studies<sup>[10-19,22]</sup> reported stent-related complications. The overall rate of perforation was 10.1% (for 367 patients), of stent migration was 9.2% (for 361 patients), of stent obstruction was 18.3% (for 331 patients).

**Surgery-related complications:** Seven studies<sup>[10,11,15-19]</sup> reported surgery-related complications. Six of those studies<sup>[10,15-19]</sup> reported wound infection, and the rate was 5.0% (for 15 patients). Three of those studies<sup>[11,17,19]</sup> reported anastomotic leak, and the rate was 4.7% (for 95 patients).

### Long-term outcomes

**Overall survive time:** Data of survival time were available for all cases from all 13 studies. The overall survival time was similar between the SEMS-treated and surgery-treated patients (7.6 mo *vs* 7.9 mo;  $P > 0.05$ ).

**Stoma formation:** Ten studies<sup>[10-13,15,17-21]</sup> reported stoma formation. Among the 299 patients for whom colonic stent insertion was attempted, 12.7% ( $n = 38$ ) ultimately required a stoma. Among the 315 surgery-treated patients, 54.0% ( $n = 170$ ) required stoma formation. The amount of patients with stoma formation was significantly lower in the SEMS group (*vs* surgery group,  $P < 0.00001$ ; Figure 1G).

### Sensitivity analysis

#### Therapeutic efficacy and outcomes of SEMS and surgery for colorectal cancer-related obstructions:

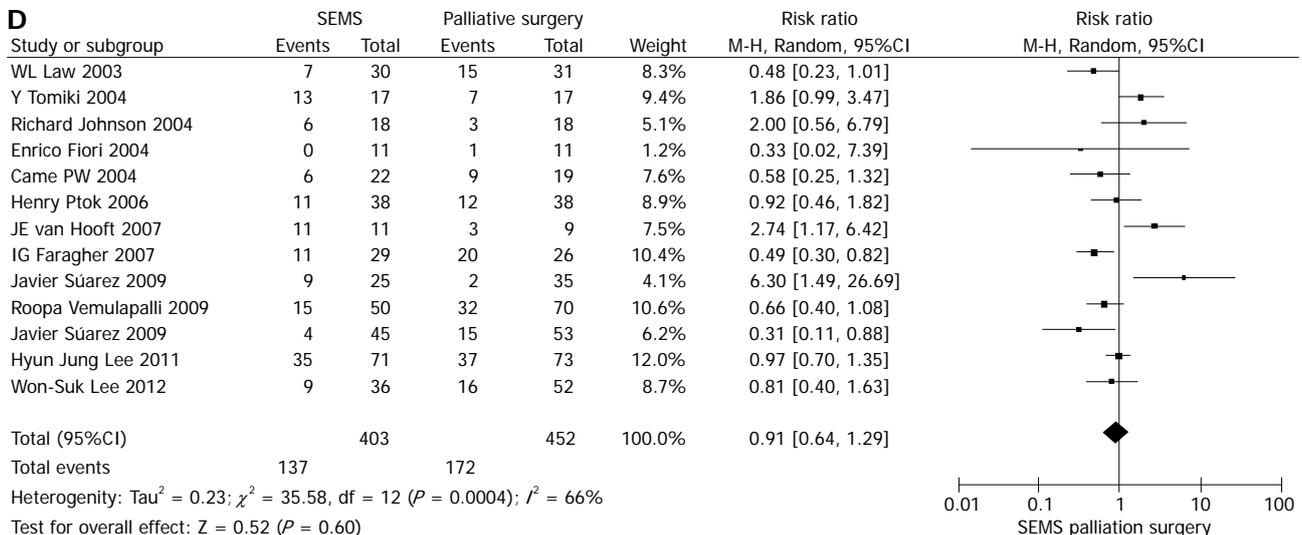

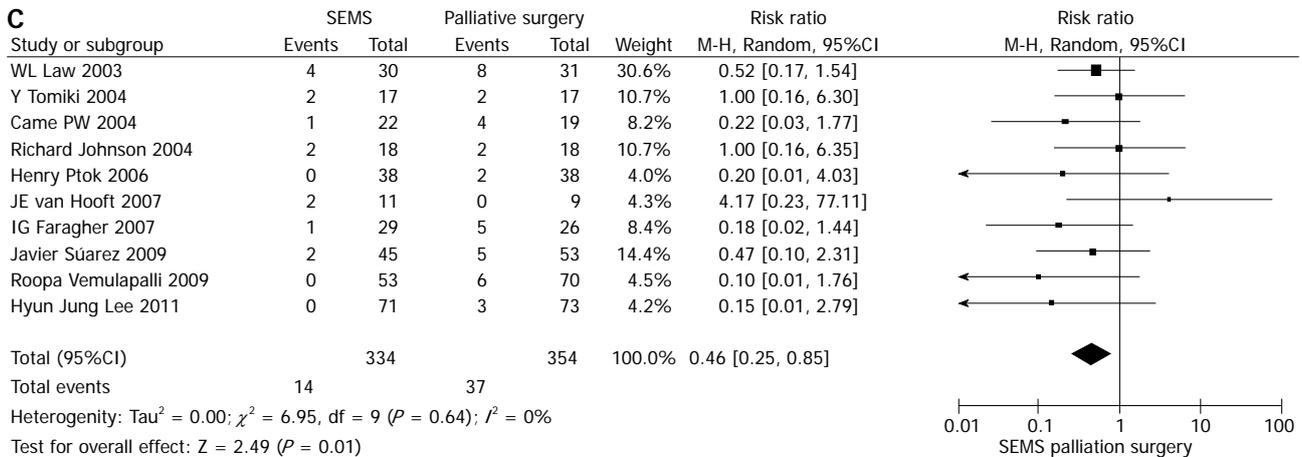

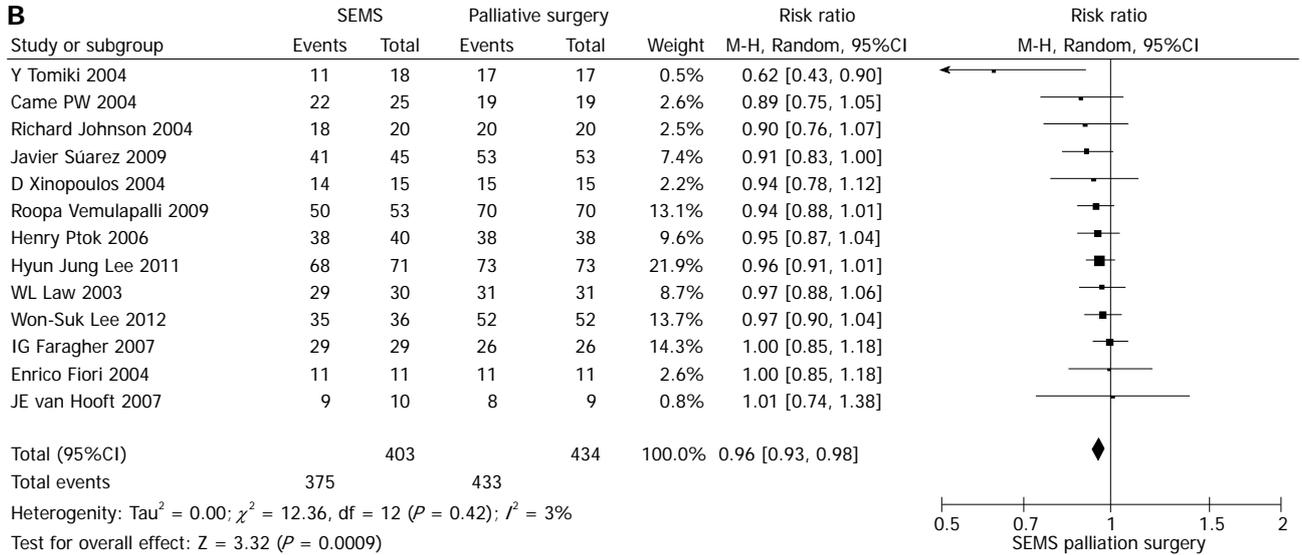

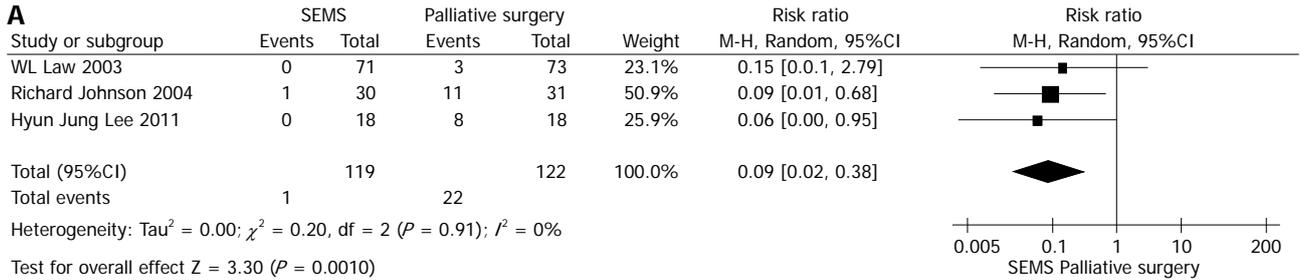

Comparative analysis of the therapeutic efficacies of SEMS and surgery for resolving colorectal cancer-related obstructions<sup>[10-12,14-19,21]</sup> and obstructions caused by other advanced cancers<sup>[13,20]</sup> revealed no differences between the two treatment approaches. However, among the subset of patients with colorectal cancer-related obstructions ( $n = 772$ ), the SEMS-treated patients ( $n = 370$ ) showed significantly lower rates of 30-d mortality (3.79% *vs* surgery-treated patients: 10.4%,  $P = 0.008$ ), early complications (11.2% *vs* 34.7%,  $P = 0.0002$ ), and stoma formation (12.0% *vs* 48.8%,  $P < 0.00001$ ). Unfortunately, these SEMS-treated patients also showed a significantly lower rate of clinical relief of the colorectal cancer-related obstructions (94.6% *vs* 99.8%,  $P = 0.002$ ). No significant difference was observed between the two treatments for total complications (SEMS: 32.1% *vs* surgery: 37.9%,  $P = 0.34$ ) (Table 3).

#### Therapeutic efficacy and outcomes of SEMS *vs* the colostomy surgical treatment:

Four studies<sup>[12,13,20,21]</sup> compared outcomes of SEMS against the colostomy surgical approach. In contrast to the results of SEMS compared to all types of surgeries for treating incurable malignant colorectal obstructions, there was no significant difference found between clinical relief attained by SEMS and colostomy (84.4% *vs* 100%,  $P = 0.18$ ). The SEMS-treated patients, however, did require significantly less stoma formation than the colostomy-treated patients (12.7% *vs* 100%,  $P < 0.00001$ ), and experienced significantly less total complications (23.9% *vs* 41.3%,  $P = 0.04$ ). The rates of 30-d mortality and early complications were not significantly different between the SEMS-treated group and the colostomy-treated group ( $P = 1.00$  and  $P = 0.64$ , respectively) (Table 3).

### Publication bias

As shown in Figure 2, three comparisons showed potential bias: clinical relief of incurable malignant LBO (Egger's test  $P = 0.04$  and Begg's test,  $P = 0.12$ ) and stoma formation (incurable malignant LBO: Egger's test,  $P = 0.001$

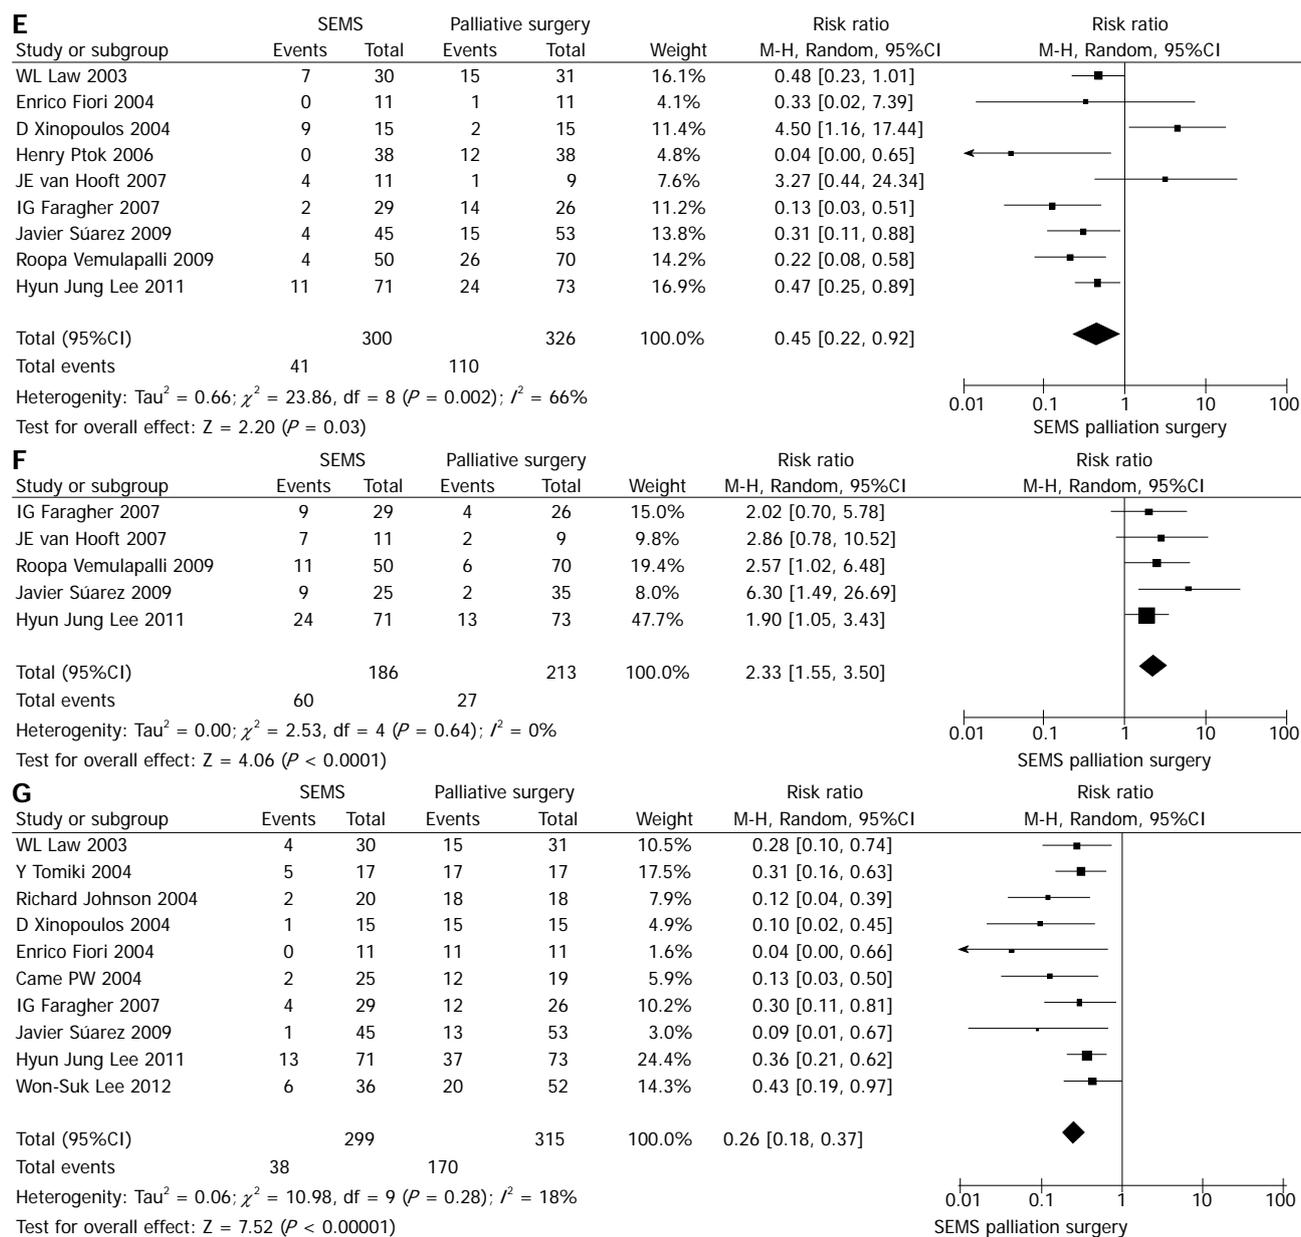

Figure 1 Forest plot. A: Intensive care unit admissions; B: Overall clinical success rates; C: Overall 30-d mortality rates; D: Total complications; E: Complications with early-onset ( $\leq 30$  d post-treatment); F: Complications with late-onset ( $> 30$  d post-treatment); G: Stoma formation. SEMS: Self-expanding metallic stents.

and Begg's test,  $P = 0.03$ ; incurable malignant colorectal cancer-related obstructions: Egger's test,  $P = 0.005$  and Begg's test,  $P = 0.04$ ). However, the statistical analysis revealed no evidence of publication bias among any of these comparisons.

## DISCUSSION

Previous studies have demonstrated the risks associated with the traditional surgical approach for treating malignant LBO, namely high rates of morbidity, mortality, and stoma formation<sup>[23,24]</sup>. The less invasive alternative approach of colonic stent insertion, particularly of SEMS, promised to overcome the high hospitalization costs and poor quality of life related to these outcomes. While subsequent meta-analyses have been conducted to investigate

the benefit and risk of endoscopic SBTS<sup>[25-28]</sup>, no study to date had performed a focused comparison of palliative SEMS and palliative surgery for treating incurable malignant LBO-as is described herein.

In the current meta-analysis, palliative surgery was found to be superior to SEMS for decompressing incurable malignant LBO; while this finding is contrary to the majority of individual studies of this subject<sup>[29,32]</sup>, it is consistent with the investigations by Cirocchi *et al.*<sup>[28]</sup> and Sagar<sup>[33]</sup>. An important distinguishing feature among these collective studies is the variable definitions of palliative surgery that were used as the basis of analysis; in addition, these studies have yet to address whether and to what extent primary tumor resection affects the mean survival time of those patients suffering from advanced cancer<sup>[34,35]</sup>. In our meta-analysis of eleven studies, the

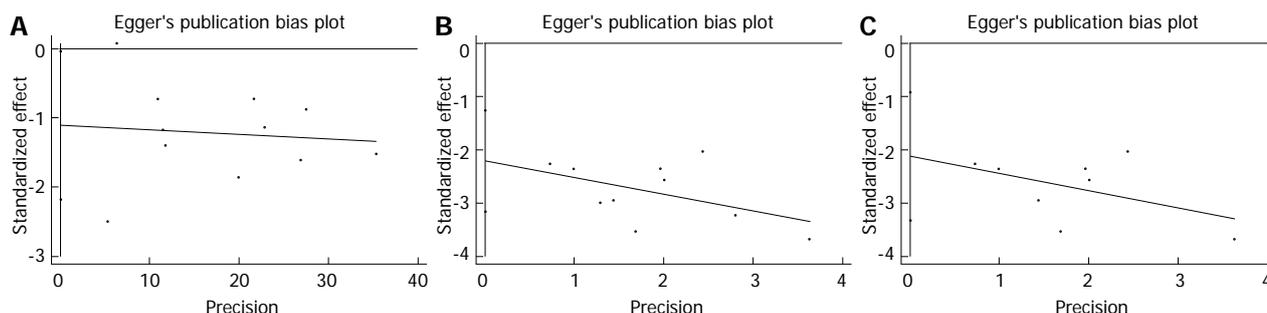

Figure 2 Egger's and Begg's plots of publication bias among the included trials. A: Clinical relief of incurable malignant large bowel obstruction (LBO); B: Stoma formation of incurable malignant LBO; C: Stoma formation of incurable colorectal cancer obstruction.

**Table 3 Sensitivity analysis of the included studies**

	Studies (n)	Patients (n)	RR (95%CI)	P value
Studies including colorectal cancer only				
Clinical success rate	11	772	0.96 (0.93, 0.98)	0.002
30-d mortality	9	654	0.42 (0.22, 0.80)	0.008
Total complications	12	821	0.84 (0.59, 1.20)	0.340
Early complications	8	596	0.35 (0.20, 0.60)	0.0002
Stoma formation	8	550	0.26 (0.17, 0.39)	< 0.00001
Studies including colostomy only				
Clinical success rate	4	127	0.89 (0.76, 1.05)	0.18
30-d mortality	2	70	1.00 (0.27, 3.68)	1.00
Total complications	3	92	1.79 (1.03, 3.09)	0.04
Early complications	2	52	1.80 (0.16, 20.79)	0.64
Stoma formation	4	124	0.16 (0.07, 0.38)	< 0.00001

overall clinical success rate of SEMS treatment ranged from 70%-95%. A previous multicenter study<sup>[36]</sup> of SEMS with long-term follow-up revealed that the clinical success rate increased gradually over time (87.8% at 30 d, 89.7% at 3 mo, 92.8% at 6 mo, and 96% at 12 mo). The follow-up period in our included studies are different but all within 12 mo and the clinical success rate was approximately similar. In addition, our meta-analysis revealed that obstructions caused by colorectal cancer benefited more from the surgical approach. Fernández-Esparrach *et al.*<sup>[37]</sup> have reported a similar finding and hypothesized that the severe complications associated with the SEMS procedure, such as migration, obstruction and perforation, limited its long-term clinical efficacy. Moreover, the authors advised that adjunct palliative chemotherapy may help to promote the life expectancy of SEMS-treated patients. A retrospective study conducted in Korean patients advanced gastric cancer<sup>[38]</sup> also indicated that SEMS insertion was less effective than emergency surgery for the palliative treatment for colorectal obstructions. In light of these previous findings, and in agreement with the opinions expressed by other interested groups in this field<sup>[39,40]</sup>, it is possible that the clinical stent success rate observed in our current meta-analysis had nothing to do with the stent placement or the etiology of the obstructions. Indeed, Sebastian *et al.*<sup>[31]</sup> suggested that the clinical success rate of stenting is mainly associated with the site and extent of the obstruction.

Our meta-analysis also indicated that SEMS treatment is associated with shorter lengths of hospital stay,

reduced ICU admissions, fewer stoma formation, and shorter time to initiation of adjunct chemotherapy; These findings are consistent with results from other relevant studies<sup>[30,32,33,41]</sup> and suggest that the less trauma endured produced by the SEMS approach eliminates delay of post-procedure chemotherapy, thereby promoting beneficial patient outcome. It was unfortunate that the current meta-analysis was limited by a lack of comparative data concerning quality of life outcome and cost-effectiveness between these two palliative treatments; analysis of such data will be necessary for comprehensively assessing the feasibility of these palliative management approaches for advanced disease. Only one of the studies included in the meta-analysis, a RCT<sup>[20]</sup> comprised of 30 patients, attempted to address the monetary expense of stent placement, as compared to colostomy treatment; however, the analysis was abandoned due to the high rate of colonic perforation that occurred in the nonsurgical arm. However, some studies<sup>[32,42]</sup> that did not meet the criteria for inclusion in our meta-analysis have suggested that SEMS may be less costly than the conventional surgical approach for treating colonic cancer obstructions; but, we cannot comment on the quality or appropriateness of these data or the implications related to our findings.

The safety of stent placement was also evaluated in the current meta-analysis. Although SEMS insertion is considered a less invasive method than surgery, and advanced procedure-related devices, such as hydrophilic elastic guidewires and stent delivery systems, have improved the ease and successful application of this method, complications still occur. Fortunately, the majority of complications are minor, such as low fever and abdominal discomfort, and resolved easily by medication. While less frequent, the major complications of the stent procedure, such as bleeding, colonic perforation, stent migration and stent occlusion, can be life-threatening<sup>[43]</sup>. In a systematic review<sup>[30]</sup> of 88 articles reporting on stent-related complications in cases of LBO, the median rates of stent migration, perforation, and reconstruction were reported as 11%, 4.5% and 12%, respectively. In the current meta-analysis, the rates of perforation and reconstruction were slightly higher; we believe this finding reflects the fact that data on perforations caused by tumor infiltration were included in the analysis and that the data on reconstructions included not only the etiologies of tu-

mor ingrowth/overgrowth and stent migration, but also of fecal implant.

The contributing factors to complications of stent insertion have been extensively studied. Factors related to stent type have been particularly well studied, and it is believed that covered stents provide the optimal resistance to tumor ingrowth, thereby helping to reduce reconstruction events, while uncovered stents are believed to minimize stent migration<sup>[30,39,44]</sup>. The type of stent, however, does not appear to be related to perforation events<sup>[30]</sup>, nor to have a significant effect on the safety of stent placement<sup>[45]</sup>. Furthermore, a retrospective analysis of uncovered SEMS for treating primary colorectal cancer *vs* non-colorectal extrinsic cancer found no significant difference in migration or occlusion events<sup>[46]</sup>. That study also suggested that insufficient stent expansion (< 70%) at 48 h after insertion may be a predictor of subsequent stent occlusion. Another retrospective analysis of 168 SEMS-treated LBO patients<sup>[47]</sup> identified five risk factors of therapeutic inefficacy, including male sex, complete obstruction, stent diameter  $\leq$  22 cm, premature dilation of the stent, and operators' experience. In addition, subsequent chemotherapy, especially Bevacizumab therapy, was demonstrated to nearly triple the risk of perforation. This latter finding was not supported by the study by Kim *et al*<sup>[39]</sup>, who demonstrated that chemotherapy had no affect on migration or reconstruction and that stent length had no relationship with complications, but showed that stent diameter < 24 cm had negative impact on palliative SEMS migration. In another study, stent migration was shown to occur more frequently in the distal colon<sup>[51]</sup>.

Despite significant improvements in the surgical procedures used for managing incurable malignant colorectal obstructions, the perioperative morbidity and mortality rates have remained high. Similarly, the patients treated with surgery in the current meta-analysis experienced appreciable levels of anastomotic dehiscence, wound infection, and death. The former two complications may have a negative influence on tumor recurrence, metastasis, and long-term survival. In the current meta-analysis, a greater number of surgery-treated patients died within 30 d after treatment, as compared to those treated with SEMS. While this result is contrary to those obtained with other similar patient series<sup>[30,33]</sup> and meta-analyses comparing SBTS<sup>[25-28]</sup>, it may be explained by the lower amount of total complications that were experienced by the overall SEMS-treated group. Another study also found significantly lower complications in a stent-treated group, but we cannot comment on the related implications for our findings as the previous data had significant heterogeneity<sup>[25]</sup>. In an attempt to address this issue, we performed sub-group analysis of the complications, independently assessing the early- and late-onset complications; the results indicated that surgery had a higher risk of early complications, while SEMS insertion had a higher risk of late complications. Future studies should further investigate the roles of early and late complications in therapeutic efficacy and overall survival.

Two of the studies<sup>[13,20]</sup> included in the overall meta-analysis were excluded from the focused comparison of SEMS and surgery outcomes for incurable colorectal-related obstructions. The results were not impacted by their removal and were in accordance with the findings reported by Kim *et al*<sup>[40]</sup>. Then, we investigated the comparison between SEMS and colostomy for incurable malignant LBO (using four studies). Unlike the previous results, these results suggested that, compared to colostomy, SEMS could be an effective palliative treatment for incurable malignant LBO; no significant difference was found for the clinical success rates between groups with fewer stoma, but the 30-d mortality and the complications should be taken into account. Unfortunately, the current meta-analysis was underpowered to investigate the differences in overall survival time between these two groups.

Other limitations of our meta-analysis design may have impacted our results and their interpretation. First, only three of the 13 included studies are RCTs. Second, the pooled sample size was still relatively small and the data from the included studies was not uniform for the outcome measures. Third, publication bias existed among four of the studies; indeed, a general limitation of all meta-analyses is publication bias introduced by the fact that positive results are more likely to be published. To overcome these limitations, long-term RCTs should be conducted with large numbers of patients to achieve a sufficient level of statistical power for accurately estimating the optimal palliative treatment for incurable malignant LBO.

In summary, palliative SEMS does not appear to have a significant advantage over palliative surgery for decompressing incurable malignant colorectal obstructions, regardless of etiology; however, the use of colonic stents is safe. The shorter interval to chemotherapy and significantly lower rates of 30-d mortality and short-term complications suggest that SEMS may be a reasonable alternative for treating patients with extensive metastatic disease or who are poor operative candidates due to severe comorbid medical illnesses.

## COMMENTS

### Background

Malignant colorectal obstruction is a common and serious complication of advanced cancer. The traditional treatment approach, surgery, is associated with high risks of morbidity and mortality. The more recently developed approach of stent insertion is less invasive and has been widely applied, especially using self-expanding metallic stents (SEMS), but its risks and benefits in patients with incurable malignant large bowel obstruction (LBO) remain to be definitively established.

### Research frontiers

The current meta-analysis was carried out to comparatively assess the outcomes of palliative surgery and palliative SEMS insertion in patients with incurable malignant LBO; the main outcome measure included length of hospital stay, intensive care unit admission, clinical success rate, 30-d mortality, complications, stoma formation, and overall survival time.

### Innovations and breakthroughs

The current meta-analysis demonstrated the advantages of SEMS as a pal-

liative therapy for incurable malignant LBO, in terms of shortened durations of hospital stay and time to chemotherapy initiation, and decreased rates of 30-d mortality and early-onset complications. However, SEMS failed to show a greater efficacy than palliative surgery for resolving obstructions.

### Applications

The results from this meta-analysis suggests that colonic stent insertion may be a safe and feasible alternative palliative treatment for patients who are otherwise poor candidates for the traditional surgical treatment, such as those with extensive metastatic disease or severe comorbid medical illnesses. SEMS is not absolutely recommended, however, since it is associated with significant late-onset complications and mortality. Until further randomized controlled trials, with large patient populations, are carried out, application should be considered on a case-by-case basis.

### Terminology

SEMS: expandable metal tubes that are placed in the collapsed state at the site of obstruction by means of a guidewire and fluoroscopy and/or endoscopy visualization; gradual, automatic expansion to the maximum diameter of the stent serves to relieve the obstruction and create a strong and passable space. Meta-analysis: the collection, combination, and analysis of data from multiple previously completed studies on a particular topic of interest that is carried out with the aim of increasing statistical power to draw stronger conclusions about a controversial subject.

### Peer review

The current meta-analysis was designed to evaluate the risks and benefits of SEMS treatment for incurable malignant colorectal obstructions, as compared to surgical treatment. The analysis included a total of 13 studies, nine of which scored high upon established quality assessment systems. The research design is solid, and its results have clinical relevancy as they demonstrate that, in patients with incurable malignant colorectal obstruction, stent placement improves treatment outcome, specifically by shortening the time to chemotherapy initiation and lowering the 30-d mortality rate.

### Abstract

All oral nucleoside analogues against hepatitis B virus, with an exception of telbivudine, have been reported causing lactic acidosis (LA). Here we report the first case of chronic hepatitis B developing severe refractory LA during telbivudine monotherapy. A 36-year-old man of Chinese origin received telbivudine antiviral treatment for chronic hepatitis B. After 11 mo of therapy, he developed anorexia, nausea, and vomiting with mild muscle weakness. The patient was found with elevated serum creatine phosphokinase up to 3683 U/L (upper limit of normal 170 U/L) and marked LA. LA did not resolve immediately following discontinuation of telbivudine. His condition began to improve after he-

modialysis treatment for 16 times and usage of glucocorticosteroid. The patient fully recovered after 16 wk of treatment. This is the first documented case with severe LA caused by telbivudine monotherapy. Besides serum creatine phosphokinase, blood lactate level should also be closely monitored in patients receiving telbivudine.

**Key words:** Lactic acidosis/hyperlactatemia; Telbivudine; Hepatitis B virus; Nucleoside analogue; Adverse effects

**Core tip:** Myopathy is the most common side effect resulting from telbivudine. Lactic acidosis (LA) is rare but fatal, and LA caused by telbivudine has never been reported. Here, we report the first case of chronic hepatitis B developing severe refractory LA during telbivudine monotherapy. This case shows that telbivudine may cause muscle damage and even lead to fatal LA in chronic hepatitis B patients. Patients under telbivudine treatment should be closely monitored for muscular, blood lactate and other mitochondrial toxicity associated side effects.

Lactic acidosis during telbivudine treatment for HBV: A case report and literature review. *World J Gastroenterol* 2013; 19(33): 5575-5580 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i33/5575.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i33.5575>

### INTRODUCTION

Suppression of hepatitis B virus (HBV) DNA is a principal goal in treating chronic hepatitis B because this was shown to significantly improve liver histology as well as

to decrease rates of hepatic complications and hepatocellular carcinoma. Current treatment options are pegylated interferon alpha and nucleoside analogues including lamivudine, telbivudine, entecavir, adefovir dipivoxil and tenofovir disoproxil. These agents have relatively fewer side effects than interferon alpha, and generally well tolerated<sup>[1]</sup>. Infrequent but serious adverse events have been reported in clinical trials and post-marketing surveillance in individual cases. Lactic acidosis (LA) is one of the severe adverse events and has been reported in the patients treated by all the other four nucleoside analogues except for telbivudine.

All of the five approved oral antiviral agents for HBV treatment can inhibit the polymerase activity of HBV, leading to a reduction in viral replication and serum HBV DNA levels. At the same time, some of these agents have a low level of activity against the human mitochondrial DNA (mtDNA) polymerase gamma and can lead to impaired mitochondrial replication with mitochondrial loss or dysfunction<sup>[1]</sup>. Clinical manifestations of mitochondrial toxicity vary based on the affected tissues, but may include myopathy, neuropathy, hepatic steatosis, pancreatitis, macrocytosis, nephrotoxicity, hyperlactatemia and LA. All nucleoside analogues have a “black box” warning regarding potential mitochondrial toxicity in their product labeling.

Telbivudine is a potent oral nucleoside analogue approved for the treatment of chronic hepatitis B in 2006 at a dose of 600 mg/d. A significantly higher incidence of grade 3-4 serum creatine phosphokinase (CPK) elevation (*i.e.*, > 7 times upper limit of normal) was reported in a large, multinational registration clinical trial<sup>[2]</sup>. However, to date, there has been no published report of LA caused by telbivudine monotherapy. Here, we report a case of LA during telbivudine treatment, discuss the pathophysiology, clinical features and potential treatment of LA.

## CASE REPORT

The patient is a 36-year-old, HIV-negative young male farmer. He was admitted to our hospital because of nausea and vomiting repeatedly for 40 d.

He had suffered from chronic hepatitis B for 13 years. His liver function test (LFT) revealed an intermittent elevation of alanine aminotransferase (ALT) levels between 1999 and 2011, and recovered to normal level after some symptomatic treatment. In September 2011, his LFT became abnormal again, the ALT was 704 U/L and HBV DNA was  $7.0 \times 10^7$  copies/mL, HBV markers showed HBsAg, HBeAg and HBcAb were positive. Subsequently, he began to take telbivudine 600 mg/d regularly (Figure 1). In early September 2012 (47 d before admission), he began to develop anorexia, nausea and vomiting without apparent causes. There were no other concurrent symptoms, such as fever, headache, abdominal pain and altered level of consciousness. But he had mild muscle pain and weakness. The diagnostic workup including gastroscopie, cranial CT and abdominal plain

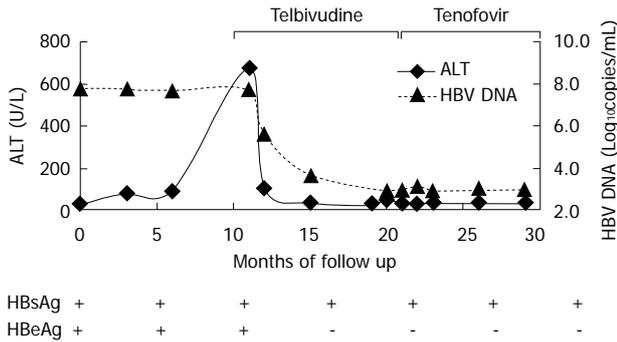

film revealed bilateral multiple renal calculi. CPK was significantly elevated at 3683 U/L (normal range: 25-170 U/L) 20 d before admission (Figure 2). The arterial blood gas analysis at that time showed pH 7.41, carbon dioxide partial pressure 37.2 mmHg, oxygen partial pressure 87.1 mmHg, actual bicarbonate 23.2 mmol/L, standard bicarbonate 23.6 mmol/L, base excess -1.4 mmol/L, and blood lactate level 4.4 mmol/L (upper limit of normal 2.5 mmol/L). It was considered that hyperlactatemia was caused by telbivudine at a local clinic. Subsequently telbivudine was discontinued.

However, the patient's condition continued to deteriorate despite alkalization treatment. Two weeks before admission, his CPK level decreased to 1183 U/L, but the arterial blood gas analysis demonstrated a worsening of metabolic acidosis: pH 7.2, actual bicarbonate 10.6 mmol/L, base excess 15.8 mmol/L, and blood lactate level elevated to 10.7 mmol/L (Figure 3). The clinical symptoms included persisting nausea and vomiting. The blood lactate level rose further to more than 12 mmol/L (the upper limit can be detected in the laboratory) (Figure 3). A week before admission, the patient received eight times of hemodialysis treatment at a local clinic. His blood lactate returned to a normal level each time after hemodialysis, however, it would rebound the next day. The patient was eventually transferred to our hospital because of refractory LA. On the day of admission, the blood lactate was 7.93 mmol/L, ALT was 42 U/L, aspartate aminotransferase was 66 U/L, LDH was 349 U/L and CPK was 632 U/L. Physical examination on admission revealed waddling gait and proximal muscular weakness in both lower limbs, quantitative value was 4 grade.

The patient was noticed to have a history of hypokalemic periodic paralysis for more than 10 years after a serious inquiry. His first attack was the most severe one, with paralysis affecting both of his legs but recovered after potassium supplement. There was no further event in the recent years.

The examination after admission also revealed hypothyroidism: TSH 12.39 mIU/L, T4 110.1 nmol/L, T3 1.31 nmol/L, and FT4 14.42 pmol/L. B-mode ultrasonography showed diffuse enlargement of thyroid. Endocrinologist consultation considered a subclinical hypothyroidism, and 25 µg euthyrox was prescribed daily.

Electromyography revealed mild myopathic changes. Prolonged exercise test was normal. Muscle biopsy on left biceps revealed moderate variation in fiber size as well as increased muscle nucleus (Figure 4). A substantial number of degenerative muscle fibers occurred. Regeneration of muscle fiber could be seen, with no inflammatory cells infiltration. Mitochondrial damage was identified by modified Gomori trichrome stain and other histopathological studies. Modified Gomori trichrome staining revealed many ragged red fibers (RRF); reduced form of nicotinamide-adenine dinucleotide (NADH) and succinic dehydrogenase (SDH) staining showed disorganized enzyme activity in the fibers with RRF. ATP staining showed mosaic arrangement of type I and type

**Figure 1** Progression of serum hepatitis B virus DNA and aminotransferase. Telbivudine was introduced when alanine aminotransferase (ALT) and hepatitis B virus (HBV) DNA level was both high. The indication was clear and sufficient, and lactic acidosis happened after 11 mo of antiviral treatment when liver function was controlled well. HBV DNA continued to be normal after telbivudine was stopped and changed to tenofovir soon after.

II fibers. Oil Red O staining showed that several muscle fibers were filled with increased lipid droplets. Histo-Immunochemical tests were Rod-Dystrophin (+), C-Dystrophin (+), N-Dystrophin (+), Dysferlin (+), Merosin (+),  $\alpha$ -Sarcoglycan (+),  $\beta$ -Sarcoglycan (+), and  $\gamma$ -Sarcoglycan (+). The patient was diagnosed with LA (type B2), HBeAg negative chronic hepatitis B and drug-induced myopathy.

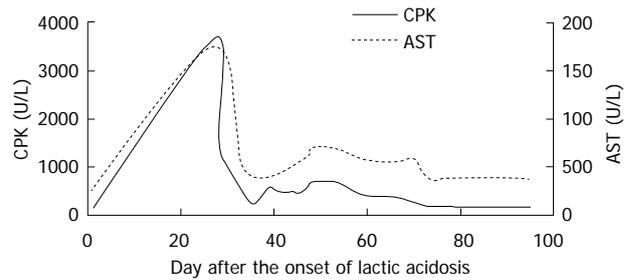

He was given hemodialysis for more than eight times after admission. The blood lactate level reduced to normal range (less than 2.5 mmol/L) after hemodialysis but slightly elevated the following day. The symptoms of nausea and vomiting completely recovered, so the hemodialysis was discontinued. He was given hydration, alkalization and supplementation with Coenzyme Q 10 and Levocarnitine. Two weeks after hemodialysis, the blood lactate level still fluctuated between 5 and 7 mmol/L. As a result, methylprednisolone tablets (24 mg/d) was given. Meanwhile, HBV DNA was rechecked and showed a slight rebound at  $1.59 \times 10^3$  copies/mL, consequently tenofovir (300 mg/d) was given to suppress the HBV.

In the following two weeks, his blood lactate level returned to a normal range, and the HBV DNA was undetectable (less than 1000 copies/mL), so methylprednisolone was tapered off within a ten-week period. The patient has remained very well and followed up regularly to date.

## DISCUSSION

Our patient had marked LA without evidence of infection or organ hypoperfusion. It is very likely that his acidosis was secondary to the nucleoside analogue, telbivudine, during treatment of HBV.

In basic terms, lactic acid is the normal endpoint of the anaerobic breakdown of glucose in the tissues. In the setting of decreased tissue oxygenation, lactic acid is produced as the anaerobic cycle is utilized for energy production. The normal blood lactate concentration in unstressed patients is 0.5-1 mmol/L. Lactate concentration

**Figure 2** Progression of serum creatine kinase level. Creatine kinase (CPK) elevated at the very beginning of lactic acidosis and returned to normal range quickly. AST: Aspartate aminotransferase.

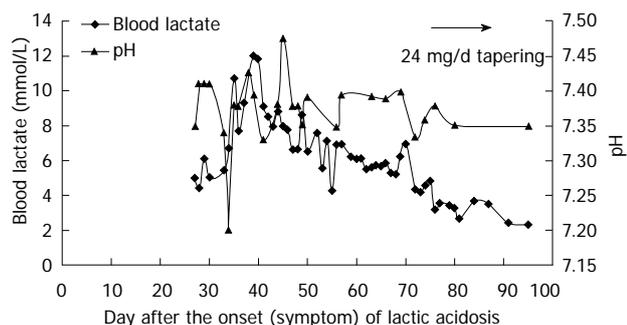

of less than 2 mmol/L can be considered to be normal in patients with critical illness. Hyperlactatemia is defined as a persistent, mild to moderate (2-4 mmol/L) increase in blood lactate concentration without metabolic acidosis; whereas LA is characterized by constant increased in blood lactate levels (usually > 5 mmol/L) in association with metabolic acidosis (usually present as pH < 7.3 and serum bicarbonate < 10 mmol/L)<sup>[1]</sup>.

The LA syndrome linked to nucleoside analogue is associated with steatosis, abnormal mitochondrial appearance and function, pancreatitis, neuropathy, and myopathy. The onset may be abrupt or insidious, it generally begins with nausea, vomiting, and abdominal pain. It will progress to tachypnea, shortness of breath, and hypoxia. Patients with severe LA may subsequently develop renal failure, liver failure, coagulopathy, seizures, arrhythmias, and even death. The patient reported here was a severe LA case with a lactate level of more than 12 mmol/L and pH value of 7.2. His blood lactate level did not recover to normal even after hemodialysis treatment for 16 times.

The Food and Drug Administration approved oral nucleoside analogues for HBV treatment, including lamivudine, adefovir, telbivudine, entecavir, and tenofovir, are well tolerated. However, these still carry the “black box” warning for the potential development of mitochondrial damage with resultant LA based on the data from the human immunodeficiency virus (HIV) treatment literature<sup>[3-7]</sup> and the experience using fialuridine (FIAU) in HBV treatment<sup>[8]</sup>.

Lamivudine<sup>[4,5]</sup> and tenofovir<sup>[3,7]</sup> associated LA was reported only in HIV patients treated with combination regimens (Table 1), while their mitochondrial toxicity is far less than those antiretroviral nucleoside analogues. The risk of LA with entecavir treatment in chronic hepatitis B patients remain controversial. However, it was reported to occur more often in patients with impaired liver function<sup>[1,9,10]</sup>, especially in those with high MELD (model for end stage liver diseases) scores and multi-organ failure (Table 1). Report of LA caused by adefovir is rare, and all reported cases were present in a combination regimens<sup>[9]</sup>.

Telbivudine, as with all the other approved nucleoside analogues, has a potential of mitochondrial toxicity which will lead to LA in theory. However, no single case has been reported to date. This will be the first documented case of type B LA in a chronic hepatitis B patient who

**Figure 3** A refractory lactic acidosis case and the fluctuation of blood lactate level. Symptoms lasted more than 3 mo and recovered slowly after 16 times of hemodialysis and small dosage of glucocorticoid helped to resolve the persistent serum lactate elevation.

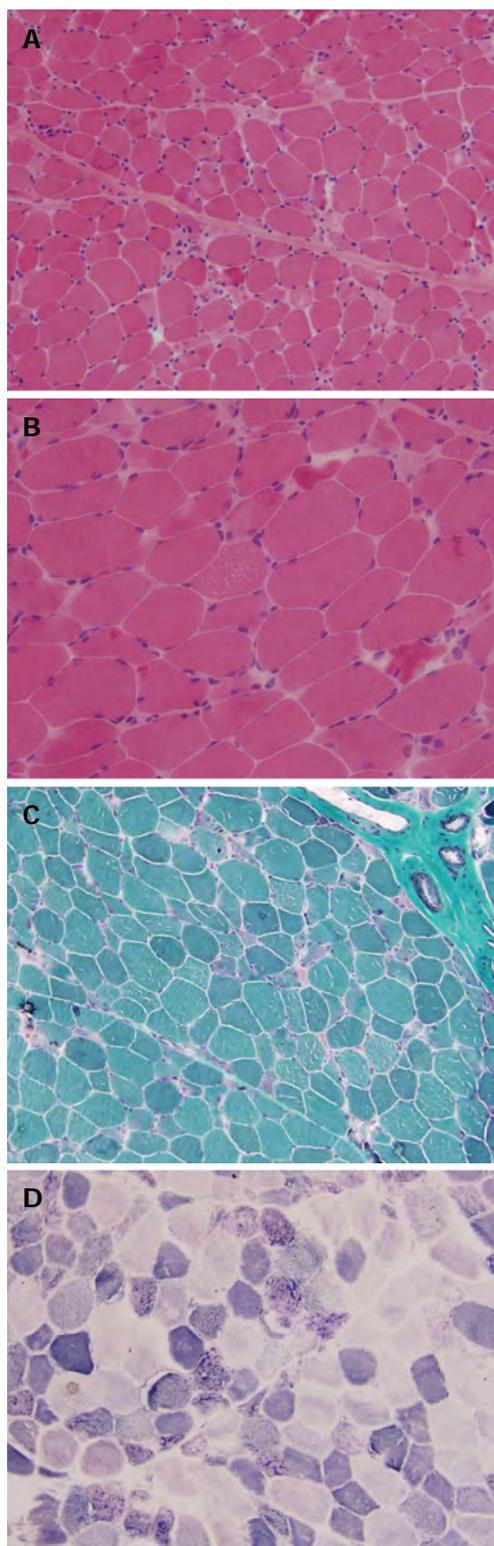

received telbivudine monotherapy.

Among the five nucleoside analogues approved for the use in hepatitis B, the inhibitory strength of mtDNA polymerase gamma in an *in vitro* test system is actually far less than that seen in antiretroviral agents. In the registration trial of telbivudine for HBV, the side-effect profile of telbivudine was generally favorable<sup>[2]</sup> and similar to comparator arm of lamivudine throughout 2 years of treatment. There was no LA case reported, however, a significantly higher incidence of grade 3 to 4 serum CPK elevations (*i.e.*, 7 times upper limit of normal) was noted in telbivudine-treated compared to lamivudine-treated patients at 2 years (12.9% *vs* 4.1%).

We noticed that our patient had a history of hypokalemic periodic paralysis. Hypokalemic periodic paralysis is an autosomal-dominant disorder characterized by episodic attacks of muscle weakness with hypokalemia. Whether there was pre-existence of myopathy in our patient prior to telbivudine treatment is uncertain, only transient CPK elevation was observed and most of time the CPK value was normal before LA occurred. The reason that LA and CPK elevation does not co-exist in most cases during monotherapy of nucleoside analogues in chronic hepatitis B patients is unclear. Interestingly, our case is a rare incident where CPK elevation and LA occurred simultaneously (Table 1). This case has suggested that besides CPK, serum lactate level should also be monitored closely during the treatment of telbivudine.

LA can be divided into 2 categories, type A and type B. Type A is LA occurring in association with clinical evidence of poor tissue perfusion or oxygenation of blood (*e.g.*, hypotension, cyanosis, cool and mottled extremities). Type B is LA occurring when no clinical evidence of poor tissue perfusion or oxygenation exists. Type B can be divided into 3 subtypes based on underlying etiology. Type B1 occurs in relation to systemic disease, such as renal and hepatic failure, diabetes and malignancy. Type B3 is due to inborn errors of metabolism. Type B2 is caused by several classes of drugs and toxins, including biguanides, alcohols, iron, isoniazid, zidovudine, and salicylates.

Our patient had marked LA without evidence of in-

**Figure 4** Histopathology of muscle biopsy specimens showed mitochondrial toxicity. A: Many regenerating and necrotic muscle fibers, mild nuclear proliferation and necrosis around muscle fibers (HE, magnification × 200); B: Part of muscle fibers filled with fatty droplets (HE, magnification × 400); C: Ragged red fibers under envelope of shrinking muscle cells (modified Gomori trichrome stain, magnification × 200); D: The figure revealed the structural disorders of mitochondria. The myocytes different in size; Type I and Type II muscle fibers showed mosaic arrangement (nicotinamide-adenine dinucleotid, magnification × 200).

fection or organ hypoperfusion. In view of the fact that no other underlying causes were identified, his acidosis may be due to telbivudine (Type B2 LA). The patient also had mild muscle pain and proximal muscle weakness consistent with a myopathy, as shown on the electromyography. It is likely LA and myopathy arise from the same pathological origin, *i.e.*, mitochondrial dysfunction. Indeed, subsequent muscle biopsy showed RRF, lipid storage and mitochondrial dysfunction, which indicated the mitochondrial toxicity.

Management options for type B LA may include treatment for primary diseases, renal replacement therapy, bicarbonate alkalization and supplementation with thiamine, L-acetylcarnitine as well as Coenzyme Q 10<sup>[10]</sup>. In term of nucleoside analogues, discontinuation should be instantaneously. Most of the LA cases can resolve rapidly after discontinuation of the causative drug. Majority of the patients who developed LA secondary to nucleoside analogues had a good outcome. The recovery progression for our patient was slow with a total period of more than three months. The symptoms improved after hemodialysis therapy for 16 times, and blood lactate level normalized to the upper limit of normal, but halted for a period of time. No plausible reasons can be found for this phenomenon, but small dosage of glucocorticoid seems to be effective. The use of low-dose glucocorticoid for a short period of time may have an unusual effect. However, a larger controlled clinical trial is required for further clarification. It should be applied cautiously by an experienced clinical hepatologist.

This case shows that telbivudine may cause muscle damage and even lead to fatal LA in telbivudine-treated chronic hepatitis B patients. Thus patients receiving tel-

bivudine should be closely monitored for muscular abnormalities, blood lactate level and other mitochondrial toxicity associated side effects.

### Abstract

This study explored the clinical value of endoscopic ligation for the treatment of upper gastrointestinal (GI) protuberant lesions in children. According to the appearance and size of lesions, we used different ligation techniques for the treatment of the lesions. Endoscopic ultrasonography was used for preliminary characterization of the lesions. One case diagnosed with Peutz-Jeghers syndrome was successfully treated by a detachable snare. Two cases with semi-pedunculated or broad-base lesions originating from the submucosal layer of the upper GI were treated with endoscopic variceal ligation; endoscopic examination showed that one case had complete healing 11 wk after ligation, while an ulcer scar was observed at the ligation site after 6 wk in the other case. All lesions were successfully ligated at the first attempt. No significant complications occurred either during or after the procedure. Selective endoscopic ligation of upper GI lesions is an effective and safe treatment for upper GI protuberant lesions in

children.

**Key words:** Endoscopy; Ligation; Endoscopic ultrasonography; Protuberant lesion; Children

**Core tip:** Endoscopic ligation is an effective method in the management of protuberant lesions. It is less invasive and less expensive than surgical interventions. However, there are few studies of this technique in the treatment of upper gastrointestinal (GI) lesions in children. This paper reports selective endoscopic ligation for the treatment of different upper GI protuberant lesions in children. Endoscopic ultrasonography was used to determine the depth of invasion and provided a preliminary characterization of the lesions.

Selective endoscopic ligation for treatment of upper gastrointestinal protuberant lesions. *World J Gastroenterol* 2013; 19(33): 5581-5585 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i33/5581.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i33.5581>

### INTRODUCTION

Protuberant lesions in the gastrointestinal (GI) tract may cause clinical symptoms (e.g., abdominal pain, bleeding, intussusception, obstruction) and have malignant potential. In addition, the presence of the lesion is a source of psychological distress. With the development of endoscopic techniques and devices, endoscopic treatment has become an effective method for protuberant lesions in the gastrointestinal tract. It is less invasive than surgical interventions.

Endoscopic ligation has been widely used in the management of post polypectomy bleeding, bleeding of esophageal and gastric varices, and angiodysplasias<sup>[1]</sup>. In

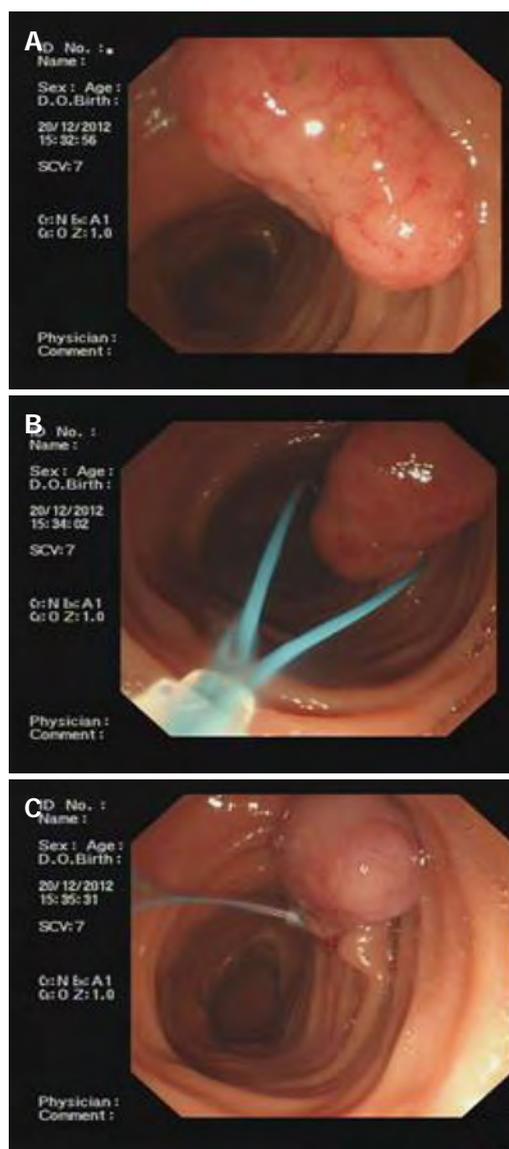

Figure 1 Imaging in case 1. A: Endoscopic view of the large pedunculated polyp in the descending part of duodenum; B: Endoscopic ligation with a detachable snare; C: Endoscopic view of the ligated polyp, with the endoloop placed around the stalk.

2004, Sun *et al.*<sup>[2]</sup> first reported endoscopic band ligation without electrosurgery was an effective and safe treatment for resection of small upper GI leiomyoma. They found most leiomyomas could slough spontaneously within 3.6 to 4.5 wk. Complications related to use of electrosurgery were avoided. There was a case report about colonoscopic polypectomy with a detachable snare to remove a large juvenile polyp in 1-year-old girl<sup>[3]</sup>. However, there are few published reports regarding endoscopic ligation to treat upper GI protuberant lesions in children. Here, we report three patients with upper GI protuberant lesions who received endoscopic treatment with ligation.

## CASE REPORT

### Case 1

A 4-year-old girl presented with abdominal pain for 6 mo.

She was diagnosed with Peutz-Jeghers syndrome. Under general anesthesia, conventional upper GI endoscopic examination (GIF-XQ260, Olympus, Japan) revealed multiple polyps. A large, 25 mm × 15 mm, pedunculated polyp with a hyperemic and edematous surface was found in the descending part of the duodenum (Figure 1). Another polyp with a thick stalk, 16 mm × 10 mm in size, also appeared in the opposite side of the duodenal papilla. To remove the two large polyps safely, we performed endoscopic ligation with detachable snares (MAJ339, Olympus, Japan). The device was composed of an elliptically shaped nylon loop and a silicone-rubber stopper which maintained the tightness of the loop. The nylon loop was placed at the base of the stalk, tightened around the stalk, then the stopper was detached from the device. We observed the color change in the target lesion to ensure proper tightening, when the ligated lesion changed to dark red because of congestion. A smaller lesion, 3 mm × 3 mm, was found in the gastric body. It was removed using the electrocoagulation technique. No complications occurred during or after the procedure using the detachable snare.

### Case 2

A 10-year-old boy with nausea and belching for 2 mo underwent upper gastrointestinal endoscopy (GIF-XQ260, Olympus, Japan) in our hospital. The result revealed a protuberant lesion located in the gastric antrum. Endoscopic ultrasonography (EUS) was performed using a radial echoendoscope with a 20 MHz catheter probe (UM-DP12-25R, Olympus, Japan), and showed a 6.5 mm × 5.0 mm hypoechoic, homogeneous lesion originating from the submucosal layer. The lesion did not involve the muscularis propria. Endoscopic ligation was performed using an attached endoscopic variceal ligation (EVL) device (Six Shooter Saeed Multiband Ligator, Wilson-Cook Medical, Winston-Salem, NC, United States), which aspirated the lesion into the ligator cap, and then an elastic rubber band was released then tightened around the base of the lesion (Figure 2). The goal of ligation was to create a polypoid form with a pseudo stalk. For complete ligation, suction should be maintained for at least 1 min before releasing the rubber band. There were no significant procedure-related complications. The lesion completely healed within 11 wk after the ligation.

### Case 3

A 10-year-old boy with an episode of recurrent abdominal pain was referred to our hospital for gastrointestinal endoscopy (GIF-XQ260, Olympus, Japan). Under general anesthesia, EUS examination showed a hypoechoic homogeneous mass, 13.6 mm × 9.2 mm in size, originating from the submucosal layer of the duodenal bulb (Figure 3). It did not extend to the muscularis propria. The ligation of this lesion was carried out with the EVL device. The lesion was sucked sufficiently into the ligator cap and the band was tightened to ligate the base of the tissue. No complications were reported during the proce-

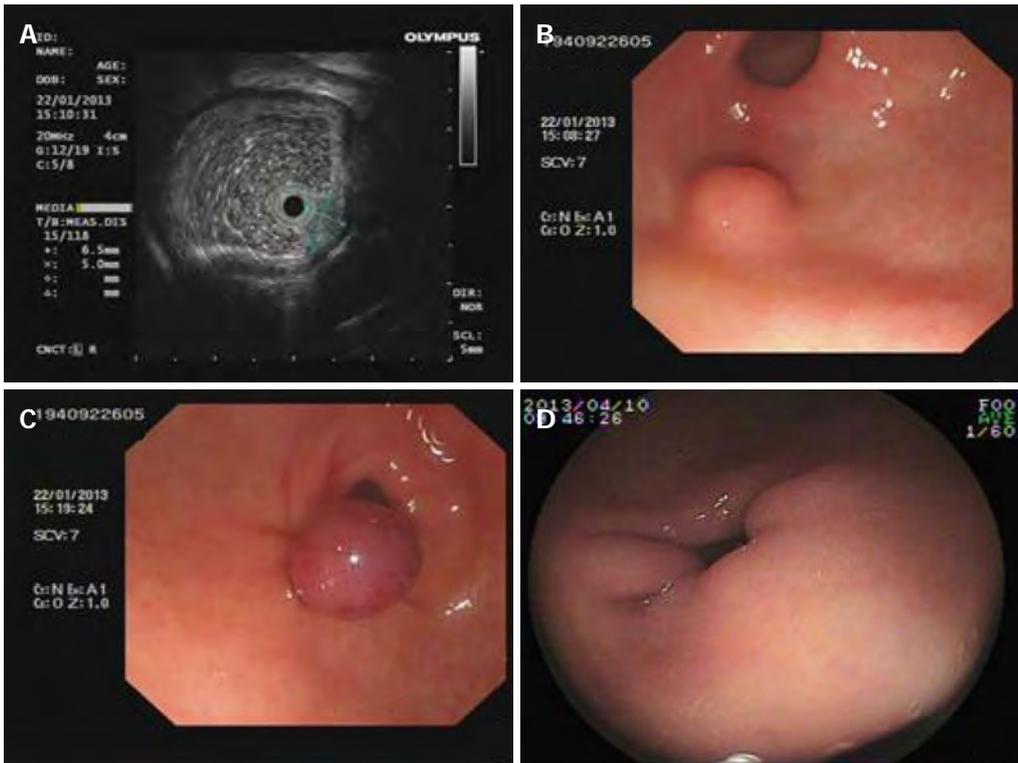

Figure 2 Imaging in case 2. A: Endoscopic ultrasonography image of the submucosal lesion; B: Endoscopic view of the lesion in gastric antrum; C: Endoscopic view showing the ligated lesion; D: Endoscopic image at 11 wk after ligation, showing healing at the ligation site.

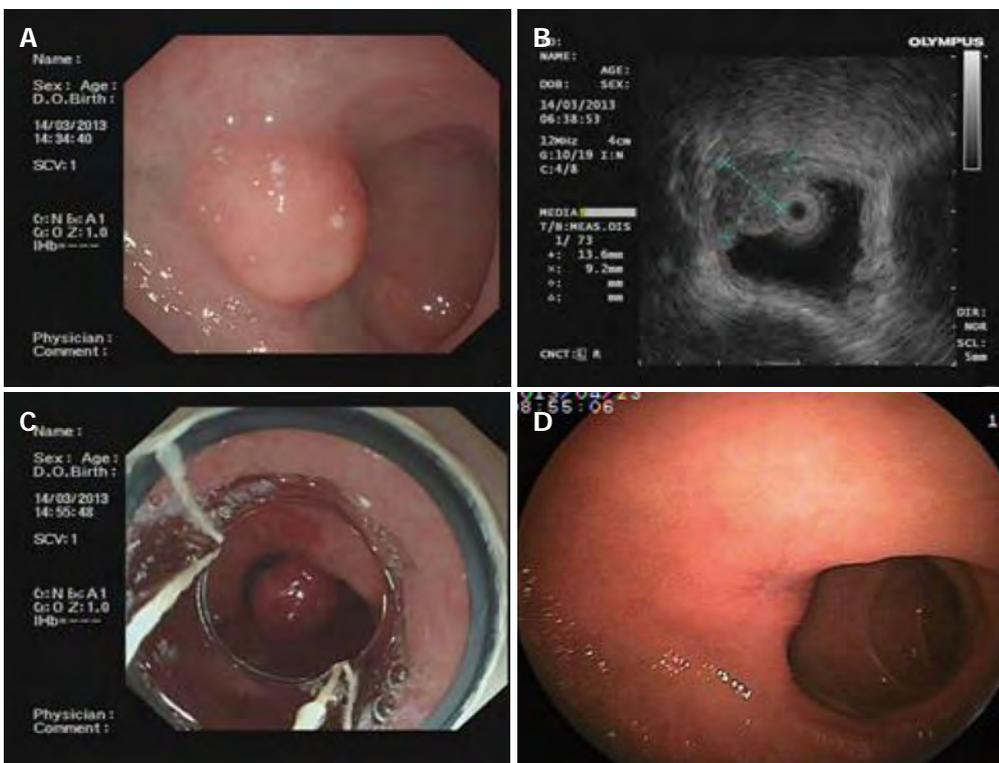

Figure 3 Imaging in case 3. A: Endoscopic view of the protuberant lesion in the duodenal bulb; B: Endoscopic ultrasonography image of the size of the lesion; C: Endoscopic view of the ligated lesion using the endoscopic variceal ligation device; D: Endoscopic view of an ulcer scar at the ligation site after 6 wk.

ture. Four days later, GI endoscopy showed sloughing of the raised lesion, and an ulcer could be observed. A scar

was seen at the ligation site on a follow-up examination of 6 wk later.

## DISCUSSION

There has been remarkable progress in the use of endoscopic treatment for gastrointestinal diseases. A detachable snare for endoscopic use was first developed by Hachisu<sup>[4]</sup>. Large polyps or other raised lesions have been successfully removed by detachable snares. In a randomized trial, Iishi *et al.*<sup>[5]</sup> used endoscopic ligation with a detachable snare for the stalk of a large pedunculated polyp and evaluated the safety and effectiveness of the procedure in comparison with conventional endoscopic snare polypectomy. Results showed that no bleeding occurred in 47 patients assigned to colonoscopic polypectomy with a detachable snare, but bleeding occurred in five of 42 patients who received conventional colonoscopic polypectomy. Moreover, the use of a detachable snare reduced the duration of hospitalization after polypectomy. In 2005, Raju *et al.*<sup>[6]</sup> first described a new technique for successful removal of a large pedunculated, 4 cm wide, broad-based colonic lipoma using endoloops without the need for cautery. Lee *et al.*<sup>[7]</sup> reported that nine cases diagnosed with large pedunculated GI submucosal tumors were successfully treated by endoloop ligation in 2008, and the tumors were removed within 4 wk. Recently, a trial was published to evaluate the clinical impact of selective ligation using a detachable snare for small intestinal polyps in three adult patients with Peutz-Jeghers syndrome<sup>[8]</sup>. The technique of endoscopic ligation is safer than conventional snare polypectomy or endoscopic mucosal resection. It could reduce the risk of bleeding and injury of the deeper tissue layers. However, to our knowledge, the effect of endoscopic ligation for upper GI protuberant lesions in children has not been reported.

According to our experience, there are two aspects to be considered in endoscopic treatment. One is the appearance of elevated lesions. A study described some instances where the use of a detachable snare was ineffective for colonoscopic polypectomy of large polyps with thin stalks or for lesions that were semi-pedunculated<sup>[9]</sup>. It is difficult to tighten the lesion sufficiently in semi-pedunculated or broad-based lesions, as the loop is more likely to slip off. A target lesion positioned at the 5 o'clock to 7 o'clock position is easier to remove by an endoloop<sup>[1]</sup>. Huang *et al.*<sup>[10]</sup> reported the methodology for different lesions using an EVL device or endoloop. Small GI stromal tumors ( $\leq 12$  mm) were treated by endoscopic band ligation with an EVL device. Large pedunculated tumors ( $> 12$  mm) could be managed by endoscopic ligation with a detachable endoloop, while ligation of large sessile tumors was carried out with a large-sized transparent cap plus an endoloop. In our cases, we used a detachable snare for large pedunculated lesions. If the lesion was semi-pedunculated or sessile, endoscopic ligation was carried out with an attached band ligator device. In one of the two cases using an EVL device, the lesion was larger than 12 mm in diameter. For smaller lesions (3 mm  $\times$  3 mm), conventional electrocoagulation was performed. Thus, selective ligation is essential to avoid complications.

The second consideration is that endoscopic band li-

gation is associated with a risk of perforation. It is necessary to be careful to avoid aspirating excessive tissue into the cap. Perforations were reported in two studies after endoscopic band ligation<sup>[11,12]</sup>; two cases were GI stromal tumors in the gastric fundus, and one was a gastric submucosal tumor partly connecting with the muscularis propria. The reason might be that all the layers of the gastric wall were ligated. It seems that the risk of perforation is greater with deeper layer tumors. Determination of the origin of the lesion and appropriate suction force are essential factors that should be considered.

Endoscopic ligation allows the lesion to slough spontaneously. The main limitation of this technique is the difficulty in retrieving the tissue specimen. Histopathologic diagnoses could not be made. However, protuberant lesions in children are mostly considered as benign and to have very low potential for malignant transformation. Sun *et al.*<sup>[13,14]</sup> reported that EUS-assisted band ligation with systematic follow-up by EUS was an effective treatment for small upper GI stromal tumors. EUS was used to determine the histologic layer of origin and evaluate whether the mass was confined completely by the band. It has significant value in the diagnosis of submucosal lesions. In the present study, EUS examination was used to identify the depth of invasion. It provided preliminary identification of the property of the lesion. We recommend that our patients should have close follow-up in order to detect any recurrence early.

In conclusion, endoscopic ligation appears to be a feasible method for removal of upper GI lesions in children. According to the characteristics and volume of the lesions, selecting the correct application of ligation and controlling the suction force can reduce the risk of related complications, such as hemorrhage and perforation. In addition, combining endoscopic ligation with EUS examination may be a useful technique for submucosal tumors in children. Pediatric experience with this endoscopic technique remains limited. Thus, studies involving more subjects and longer follow-up are needed to further define the clinical role of endoscopic ligation in children.

### Abstract

Gallstone ileus (GI) is characterized by occlusion of the intestinal lumen as a result of one or more gallstones. GI is a rare complication of gallstones that occurs in 1%-4% of all cases of bowel obstruction. The mortality associated with GI ranges between 12% and 27%. Classical findings on plain abdominal radiography include: (1) pneumobilia; (2) intestinal obstruction; (3) an aberrantly located gallstone; and (4) change of location of a previously observed stone. The optimal management of acute GI is controversial and can be: (1) enterotomy with stone extraction alone; (2) enterotomy, stone extraction, cholecystectomy and fistula closure; (3) bowel resection alone; and (4) bowel resection with fistula closure. We describe a case to highlight some of the pertinent issues involved in GI management, and propose a scheme to minimize recurrent disease and postoperative complications. We conclude that GI is a rare condition affecting mainly the older

population with a female predominance. The advent of computed tomography and magnetic resonance imaging has made it easier to diagnose GI. Enterotomy with stone extraction alone remains the most common surgical method because of its low incidence of complications.

**Key words:** Gallstone ileus; Fistula closure; Intestinal obstruction; Bowel obstruction; Enterolithotomy

**Core tip:** We present the case of a 56-year-old female who presented at our institution with symptoms of bowel obstruction. Abdominal computed tomography (CT) and exploratory laparotomy revealed a large gallstone in the terminal ileus. She underwent enterolithotomy and had an uneventful postoperative course. The literature suggests that gallstone ileus (GI) is a rare condition affecting mainly the older population and has a female predominance. CT and magnetic resonance imaging have made it easier to diagnose GI. Enterotomy with stone extraction alone remains the most common surgical method because of its low incidence of complications.

### INTRODUCTION

Gallstone ileus (GI) is characterized by occlusion of the intestinal lumen as a result of one or more gallstones<sup>[1,2]</sup>. According to reports from the 1990s, GI is a rare complication of gallstones that occurs in 1%-4% of all cases of bowel obstruction and in  $\leq 25\%$  of cases of non-strangulated small-bowel obstruction in patients aged  $> 65$  years. The mortality associated with GI ranges between

Figure 1 Abdominal radiographs were normal.

12% and 27%<sup>[3]</sup>. GI accounts for only 0.095% of cases of mechanical bowel obstruction in the United States<sup>[4]</sup>. The optimal management of acute GI is controversial<sup>[3,4]</sup>. We describe a case here to highlight some of the pertinent issues involved in GI management, and propose a scheme to minimize recurrent disease and postoperative complications.

## CASE REPORT

A 56-year-old female presented with intermittent vomiting and abdominal pain for 7 d. This patient had cholecystolithiasis for 10 years and had been treated with antibiotics. She had been treated in another hospital with intravenous fluids and antibiotics. She had undergone gastrointestinal decompression and regulation of water and electrolytes for approximately 1 wk, but the symptoms had not abated.

One week after the latest attack, she was referred to our hospital for nausea, vomiting, constipation and abdominal pain. Upon examination, her abdomen was moderately distended, and tympanic and high-pitched bowel sounds were audible. Rectal examination was normal. Blood tests revealed an elevated total leukocyte count ( $14.4 \times 10^9$  cells/L) and unremarkable liver function test values. Plain radiographs of the abdomen were normal (Figure 1). She was treated with intravenous fluids and antibiotics. However, 2 d after hospital admission, clinical deterioration was investigated with computed tomography (CT). CT demonstrated a small-bowel obstruction due to a 50-mm calculus within an ileal loop. CT showed air in the gallbladder and adhesions between the thickened gallbladder wall and duodenal wall. A severe air-fluid level was also seen (Figure 2). We therefore made a diagnosis of GI.

The patient underwent an exploratory laparotomy, during which a wide fistula from the gallbladder to the second part of the duodenum was found. Abdominal adhesions around the gallbladder were very severe. Exploration revealed massively dilated loops of the small bowel proximal to the distal ileum. An obstruction was seen 100 cm from the terminal ileum, where an enterotomy was made to reveal a large gallstone (5 cm  $\times$  3 cm  $\times$  4 cm).

The gallstone was removed and the enterotomy repaired in two layers (Figure 3). The patient had an uneventful postoperative course and was discharged home on postoperative day 10.

## DISCUSSION

GI is more common in women, and the ratio of females to males is 3.5 to 1<sup>[4]</sup>. The gallstone may enter the intestine through a fistula and it can impact anywhere in the gastrointestinal tract<sup>[5]</sup>. The gallstone must be  $\geq 2$ -2.5 cm in diameter to cause obstruction<sup>[6-9]</sup>. As shown by Reisner and Cohen, impaction of the stone can occur in any part of the bowel, *i.e.*, the ileum (60.5% of cases), jejunum (16.1%), stomach (14.2%), colon (4.1%), and duodenum (3.5%). It can also be passed spontaneously (1.3%)<sup>[3,10]</sup>. It occurs most frequently in the terminal ileum and the ileocecal valve because of their narrow lumen and potentially less active peristalsis<sup>[10]</sup>.

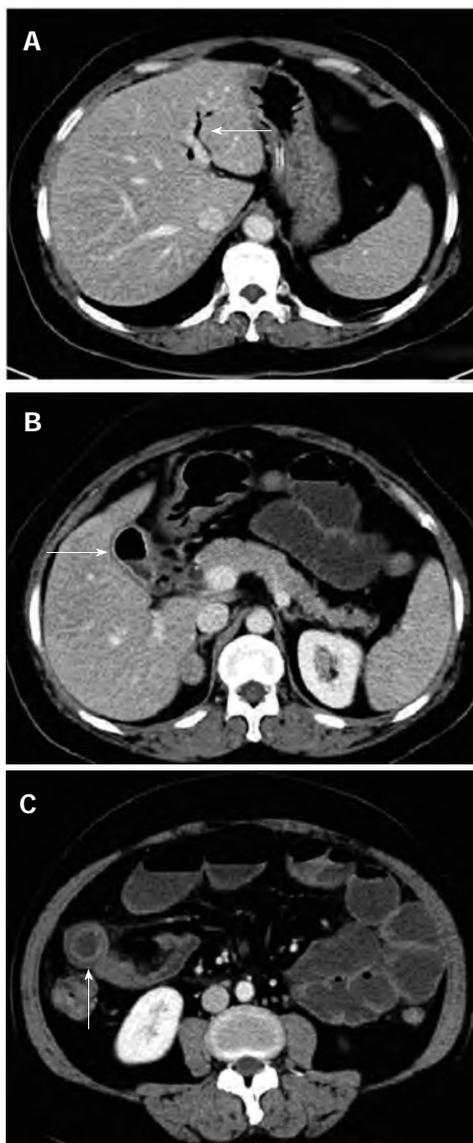

If GI occurs in elderly patients with comorbidities, the often vague, intermittent symptoms may delay the diagnosis by days<sup>[3]</sup>. Presentation is typically non-specific, and often with intermittent symptoms of nausea, vomiting, abdominal distension and pain. We should pay more attention to those patients who have the history of cholecystolithiasis and with symptoms such as nausea, vomiting, abdominal distension and pain. In the past, confirming the diagnosis was difficult, but the advent of CT and magnetic resonance imaging (MRI) has made it easier to diagnose GI<sup>[10,11]</sup>.

Classical findings on plain abdominal radiography include: (1) pneumobilia; (2) intestinal obstruction; (3) an aberrantly located gallstone; and (4) a change in location of a previously observed stone<sup>[9,11-14]</sup>. The widespread use of CT with an overall sensitivity, specificity, and diagnostic accuracy of 93%, 100% and 99%, respectively, has aided diagnosis<sup>[14]</sup>. Interestingly, no aerobilia which can be easily detected by transabdominal ultrasound may be one reason for the delayed diagnosis. Additionally, the absence of significant calcification of the stone reduces the chance of an early diagnosis. In 50% of cases, the diagnosis is often only made at laparotomy<sup>[3]</sup>.

GI is a mechanical intestinal obstruction caused by impaction of gallstones within the lumen of the bowel. Most reports indicate that stones smaller than 2.5 cm usually pass through spontaneously, so conservative treatment (decompression by nasogastric drainage) is conducted before a decision is made to remove the impacted stone by surgical means<sup>[6,8]</sup>.

Management of GI is controversial and includes: (1) enterotomy with stone extraction alone; (2) enterotomy, stone extraction, cholecystectomy and fistula closure; (3) bowel resection alone; and (4) bowel resection with fistula closure<sup>[4,6,15]</sup>.

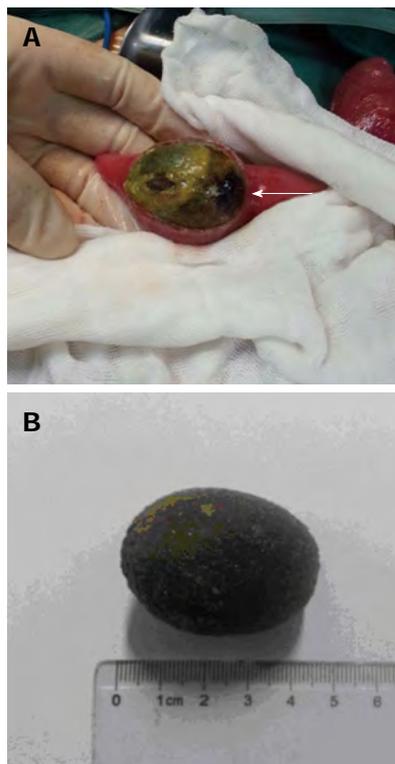

Enterotomy with stone extraction alone remains the most common surgical method because of its low incidence of complications<sup>[4]</sup>. Spontaneous closure of the fistulous tract is observed in  $> 50\%$  of cases<sup>[12]</sup>. Small-

**Figure 2 Severe air-fluid level.** A: Axial view of the upper abdomen demonstrates air in an intrahepatic bile duct (arrow); B: Axial view of the upper abdomen demonstrates an air in the gallbladder (arrow); C: Computed tomography demonstrating gallstones of approximately 5 cm in diameter (arrow) within the small bowel.

bowel obstruction requires enterolithotomy with a longitudinal incision placed on the anti-mesenteric border proximal to the site of impaction. Careful closure of the enterolithotomy is needed to avoid narrowing of the intestinal lumen, and we usually employ a transverse closure for this reason. The choice of surgical procedure is determined largely by clinical status. GI patients are usually elderly and have comorbidities so enterotomy with stone extraction alone appears to more suitable than more invasive techniques<sup>[4,16]</sup>.

However, 5% of patients who undergo enterolithotomy alone go on to develop biliary symptoms, and 10% require an unplanned reoperation. In the presence of residual stones, the estimated prevalence of recurrence ranged from 5% to 17%, and more than half of these recurrences occur within 6 mo of the index presentation.

**Figure 3** The gallstone was removed and the enterotomy repaired in two layers. A: Impacted stone (arrow) removed from the intestine; B: Gallstone measuring 3 cm × 4 cm × 5 cm.

Retrospective cohort and literature reviews of GI reveal a prevalence of biliary malignancy of 2%-6%<sup>[4,17]</sup>.

We noted that fistula closure, if conducted urgently or as an emergency during the initial procedure, was independently associated with a higher prevalence of mortality than enterotomy and stone extraction alone. The reason may be that elderly patients have multiple comorbidities and an edematous surrounding area. Bowel resection is sometimes necessary, particularly in the presence of a perforation.

Laparoscopy-assisted methods have been reported by Sarli *et al*<sup>[18]</sup>, who successfully treated three women with GI. Their patients made uneventful recoveries. However, laparoscopy is somewhat more challenging in cases of dilated and an edematous bowel<sup>[18,19]</sup>.

Some special types of GI, such as Bouveret's syndrome (stones impacting in the duodenum causing gastric outlet obstruction), and stones in the stomach or the colon are suitable for non-surgical therapeutic options in around 20% of the patients. For example laserlithotripsy in Bouveret's syndrome<sup>[20]</sup> or extracorporeal shock wave lithotripsy<sup>[21]</sup> or even only endoscopic extraction<sup>[22]</sup> may be a promising and fast therapeutic alternative.

Historically, wound infections and dehiscence have been cited as being the most common complications after surgery in 25% to 50% of GI cases. In contrast to what has been published so far, the most common post-operative complication is acute renal failure followed by urinary tract infection and wound infections. Gastrointes-

tinal complications related to anastomotic leaks and intra-abdominal abscesses are highest in patients undergoing enterotomy with fistula closure<sup>[3,4,12]</sup>.

If the gallbladder is preserved at the initial procedure, delayed cholecystectomy must be addressed. This is because 5% of patients who have undergone enterolithotomy alone go on to develop biliary symptoms, and the risk of patent fistula reflux and resulting biliary malignancy<sup>[3,4,12]</sup>. In conclusion, GI is a rare condition affecting mainly the older population with a female predominance. If GI occurs in elderly patients with comorbidities, the often vague, intermittent symptoms may delay the diagnosis by days. The advent of CT and MRI has made it easier to diagnose GI. Enterotomy with stone extraction alone remains the most common surgical method because of its low incidence of complications.

High-grade dysplasia; Choledochoscope

**Core tip:** Due to significant surgical trauma and a low risk of canceration, surgeons face a dilemma regarding the decision to perform pancreaticoduodenectomy for high-grade dysplasia of the distal bile duct. This report is the first to describe the successful treatment of high-grade dysplasia of the distal bile duct using photodynamic therapy *via* a choledochoscope. This clinical case demonstrated that photodynamic therapy *via* a trans-T-tube choledochoscope may be an effective and promising protocol for carcinoma *in situ* or high-grade dysplasia of the distal common bile duct.

Zhou JJ, Xiong L, Li QL, Gu Y, Wen Y, Deng XF, Miao XY. Photodynamic therapy for high-grade dysplasia of bile duct *via* a choledochoscope. *World J Gastroenterol* 2013; 19(33): 5590-5592 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i33/5590.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i33.5590>

### Abstract

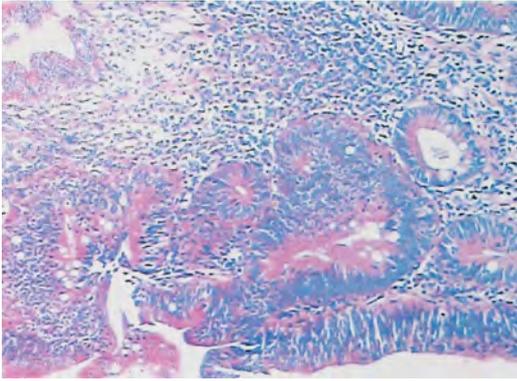

When a distal common bile duct neoplasm is at the stage of carcinoma *in situ* or high-grade dysplasia, it is difficult for the surgeon to decide whether to perform pancreaticoduodenectomy. Here we describe a patient with a progressive dysplastic lesion in the common bile duct, which developed from moderate-high to high-grade dysplasia in approximately 2 mo. The patient refused major surgery. Therefore, endoscopic-assisted photodynamic therapy was performed. The result at follow-up using a trans-T-tube choledochoscope showed that the lesion was completely necrotic. This report is the first to describe the successful treatment of high-grade dysplasia of the distal bile duct using photodynamic therapy *via* a choledochoscope.

### INTRODUCTION

Endoscopic treatment is an alternative treatment option with low morbidity. Premalignant lesions such as high-grade dysplasia are being treated increasingly *via* endoscopy. Furthermore, as a promising clinical protocol, endoscopic-assisted photodynamic therapy may result in a more precise effect due to its selective damage to tumor cells. Saleem *et al*<sup>[1]</sup> reported successful photodynamic treatment (PDT) *via* endoscopic retrograde cholangiopancreatography (ERCP) for a villous adenoma with high-grade dysplasia. Here we report a unique case of progressive dysplasia in the distal common bile duct, which developed from moderate-high to high-grade dysplasia in approximately 2 mo, and was successfully treated by PDT *via* a choledochoscope.

**Figure 1** Pathological findings showed moderate-high grade dysplasia of the distal common bile duct lesion (hematoxylin/eosin staining,  $\times 100$ ).

## CASE REPORT

A 47-year-old man with previous common bile duct exploration and T-tube drainage for obstructive jaundice and poor general condition was admitted for follow-up examination. The patient had undergone surgery approximately 2 mo previously, which revealed an easily bleeding lesion of 3 cm in diameter occupying the distal common bile duct, and the pathological findings showed moderate-high grade dysplasia (Figure 1).

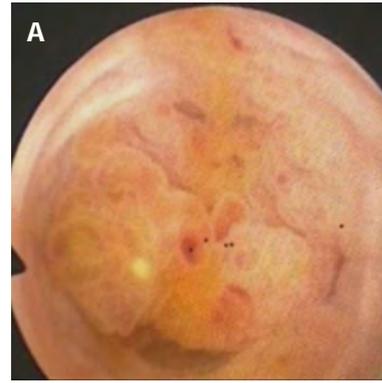

Choledochoscopy showed the same easily bleeding lesion as before (Figure 2A), and a second endoscopic biopsy revealed villous adenoma-like epithelia with moderate-high dysplasia and focal high-grade dysplasia. A trans-T-tube cholangiogram was performed, which demonstrated a dilated biliary tree with an irregular filling defect in the distal common bile duct (Figure 3).

The patient refused major surgery. Therefore, endoscopic-assisted PDT was performed. Informed consent was obtained from the patient prior to PDT. Hematoporphyrin (5 mg/kg) was administered intravenously 48 h before PDT. According to the surgical record and a previous computer tomography (CT) scan, we performed PDT through the T-tube sinus tract using a 4-cm long, cylindrical light diffuser at a power output of 250 mW/cm<sup>2</sup> in one application for a total dose of 70 J/cm<sup>2</sup>. This covered the whole distal common bile duct area. We noticed that the lesion became purple soon after light irradiation (Figure 2B). The patient felt well after the procedure and was discharged the next day.

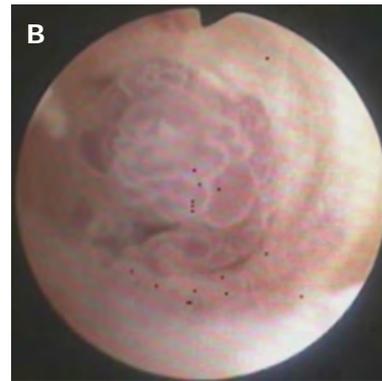

Two weeks later, trans-T-tube choledochoscopy showed that the lesion was completely necrotic (Figure 2C). The patient remained symptom-free, and at repeat choledochoscopy 3 mo later, no intraductal lesion was seen (Figure 2D). Furthermore, the video showed a functional duodenal papilla. The latest follow-up by choledochoscopy showed that the distal common bile duct was patent and the patient was asymptomatic and in good condition in March 2013.

## DISCUSSION

Tumors of the distal common bile duct present a serious

2012/8/1 Choledochoscopy finding: easily bleeding tumor in the lower extreme of common bile duct.

2012/8/13 Choledochoscopy view: the tumor 10 min after PDT.

2012/8/27 Two weeks after PDT: necrosis of the tumor.

A new bile duct with function observed 3 mo after PDT.

**Figure 2** Images taken *via* the trans-T-tube choledochoscope. A: Before photodynamic treatment (PDT); B: Ten minutes after PDT; C: Two weeks after PDT; D: Three months after PDT.

surgical problem because they necessitate a complicated and extensive resection. Pancreaticoduodenectomy (the Whipple procedure) is one of the most difficult procedures in general surgery, but should only be considered if the tumor is locally contained when identified. However, these small lesions tend to present late in the disease

**Figure 3 Trans-T-tube cholangiogram.** This image shows the dilated common bile duct and intrahepatic bile duct with an irregular filling defect in the distal common bile duct.

course, and many are unresectable<sup>[2]</sup>. Unfortunately, these lesions are not sensitive to chemotherapy or radiotherapy. In addition, studies have shown that intrahepatic bile duct hyperplasia is a potent precursor of cholangiocellular carcinoma. Livers with cholangiocellular carcinoma are closely associated with atypical hyperplasia and carcinoma *in situ*<sup>[3]</sup>. Therefore, when they are at the stage of carcinoma *in situ* or high-grade dysplasia, a new set of management dilemmas occur with regard to major surgery.

With more attention being paid to earlier detection and more careful pathological assessment, these previously overlooked histological features are attracting more interest not only in the diagnosis but also in the treatment.

Endoscopic surgery is an alternative treatment option with low morbidity in many cases<sup>[4]</sup>. Endoscopic-assisted photodynamic therapy is a promising method for lesions in the biliary tree due to the thickness of the bile duct wall being within the penetration depth of the light. PDT can be regarded as a standard palliative therapy for

unresectable cholangiocarcinoma as reported in previous studies<sup>[5]</sup>. In our case, it demonstrated high selectivity for the dysplastic lesion, and did not damage the duodenal papilla. This indicates the potential for endoscope-assisted PDT to provide precise ablation of intraductal lesions with progressive dysplasia. This protocol may serve as a standard modality for patients who are not candidates for surgery, and the T-tube sinus provides a good tract for both treatment and follow-up.

## ACKNOWLEDGMENTS

We want to thank our colleagues from the Department of Digestive Endoscopy for providing the pictures taken *via* a choledochoscope.

## GENERAL INFORMATION

*World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a peer-reviewed open access (OA) journal. *WJG* was established on October 1, 1995. It is published weekly on the 7<sup>th</sup>, 14<sup>th</sup>, 21<sup>st</sup>, and 28<sup>th</sup> each month. The *WJG* Editorial Board consists of 1352 experts in gastroenterology and hepatology from 64 countries.

### Aims and scope

The primary task of *WJG* is to rapidly publish high-quality original articles, reviews, and commentaries in the fields of gastroenterology, hepatology, gastrointestinal endoscopy, gastrointestinal surgery, hepatobiliary surgery, gastrointestinal oncology, gastrointestinal radiation oncology, gastrointestinal imaging, gastrointestinal interventional therapy, gastrointestinal infectious diseases, gastrointestinal pharmacology, gastrointestinal pathophysiology, gastrointestinal pathology, evidence-based medicine in gastroenterology, pancreatology, gastrointestinal laboratory medicine, gastrointestinal molecular biology, gastrointestinal immunology, gastrointestinal microbiology, gastrointestinal genetics, gastrointestinal translational medicine, gastrointestinal diagnostics, and gastrointestinal therapeutics. *WJG* is dedicated to become an influential and prestigious journal in gastroenterology and hepatology, to promote the development of above disciplines, and to improve the diagnostic and therapeutic skill and expertise of clinicians.

*WJG* is published by Baishideng Publishing Group (BPG) in both electronic and online forms. All *WJG* articles are published in *WJG* website and PubMed Central. The major advantages of OA journals are faster release and delivery, no page or graph restrictions, and increased visibility, usage and impact. Full-text PDF articles and electronic/online versions are freely available to global readers. After the paper is published, the author(s) can obtain high-quality PDF files, which contain the journal cover, a list of editorial board members, table of contents, text, and back cover of the journal. BPG has a strong professional editorial team composed of editorial board members, editors-in-chief, science editors, language editors, and electronic editors. BPG currently publishes 42 OA clinical medical journals, including 41 in English, has a total of 15471 editorial board members or peer reviewers, and is a world first-class publisher.

### Columns

The columns in the issues of *WJG* will include: (1) Editorial: The editorial board members are invited to make comments on an important topic in their field in terms of its current research status and future directions to lead the development of this discipline; (2) Frontier: The editorial board members are invited to select a highly cited cutting-edge original paper of his/her own to summarize major findings, the problems that have been resolved and remain to be resolved, and future re-

search directions to help readers understand his/her important academic point of view and future research directions in the field; (3) Diagnostic Advances: The editorial board members are invited to write high-quality diagnostic advances in their field to improve the diagnostic skills of readers. The topic covers general clinical diagnosis, differential diagnosis, pathological diagnosis, laboratory diagnosis, imaging diagnosis, endoscopic diagnosis, biotechnological diagnosis, functional diagnosis, and physical diagnosis; (4) Therapeutics Advances: The editorial board members are invited to write high-quality therapeutic advances in their field to help improve the therapeutic skills of readers. The topic covers medication therapy, psychotherapy, physical therapy, replacement therapy, interventional therapy, minimally invasive therapy, endoscopic therapy, transplantation therapy, and surgical therapy; (5) Field of Vision: The editorial board members are invited to write commentaries on classic articles, hot topic articles, or latest articles to keep readers at the forefront of research and increase their levels of clinical research. Classic articles refer to papers that are included in Web of Knowledge and have received a large number of citations (ranking in the top 1%) after being published for more than years, reflecting the quality and impact of papers. Hot topic articles refer to papers that are included in Web of Knowledge and have received a large number of citations after being published for no more than 2 years, reflecting cutting-edge trends in scientific research. Latest articles refer to the latest published high-quality papers that are included in PubMed, reflecting the latest research trends. These commentary articles should focus on the status quo of research, the most important research topics, the problems that have now been resolved and remain to be resolved, and future research directions. Basic information about the article to be commented (including authors, article title, journal name, year, volume, and inclusive page numbers); (6) Minireviews: The editorial board members are invited to write short reviews on recent advances and trends in research of molecular biology, genomics, and related cutting-edge technologies to provide readers with the latest knowledge and help improve their diagnostic and therapeutic skills; (7) Review: To make a systematic review to focus on the status quo of research, the most important research topics, the problems that have now been resolved and remain to be resolved, and future research directions; (8) Topic Highlight: The editorial board members are invited to write a series of articles (7-10 articles) to comment and discuss a hot topic to help improve the diagnostic and therapeutic skills of readers; (9) Medical Ethics: The editorial board members are invited to write articles about medical ethics to increase readers' knowledge of medical ethics. The topic covers international ethics guidelines, animal studies, clinical trials, organ transplantation, etc.; (10) Clinical Case Conference or Clinicopathological Conference: The editorial board members are invited to contribute high-quality clinical case conference; (11) Original Articles: To report innovative and original findings in gastroenterology and hepatology; (12) Brief Articles: To briefly report the novel

## Instructions to authors

and innovative findings in gastroenterology and hepatology; (13) Meta-Analysis: Covers the systematic review, mixed treatment comparison, meta-regression, and overview of reviews, in order to summarize a given quantitative effect, *e.g.*, the clinical effectiveness and safety of clinical treatments by combining data from two or more randomized controlled trials, thereby providing more precise and externally valid estimates than those which would stem from each individual dataset if analyzed separately from the others; (14) Case Report: To report a rare or typical case; (15) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (16) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (17) Autobiography: The editorial board members are invited to write their autobiography to provide readers with stories of success or failure in their scientific research career. The topic covers their basic personal information and information about when they started doing research work, where and how they did research work, what they have achieved, and their lessons from success or failure.

### Name of journal

*World Journal of Gastroenterology*

### ISSN

ISSN 1007-9327 (print)

ISSN 2219-2840 (online)

### Launch date

October 1, 1995

### Frequency

Weekly

### Editors-in-chief

**Ferruccio Bonino, MD, PhD, Professor** of Gastroenterology, Director of Liver and Digestive Disease Division, Department of Internal Medicine, University of Pisa, Director of General Medicine 2 Unit University Hospital of Pisa, Via Roma 67, 56124 Pisa, Italy

**Myung-Hwan Kim, MD, PhD, Professor, Head**, Department of Gastroenterology, Director, Center for Biliary Diseases, University of Ulsan College of Medicine, Asan Medical Center, 388-1 Pungnap-2dong, Songpa-gu, Seoul 138-736, South Korea

**Kjell Öberg, MD, PhD, Professor**, Department of Endocrine Oncology, Uppsala University Hospital, SE-751 85 Uppsala, Sweden

**Matt D Rutter, MBBS, MD, FRCP**, Consultant Gastroenterologist, Senior Lecturer, Director, Tees Bowel Cancer Screening Centre, University Hospital of North Tees, Durham University, Stockton-on-Tees, Cleveland TS19 8PE, United Kingdom

**Andrzej S Tarnawski, MD, PhD, DSc (Med), Professor of Medicine, Chief** Gastroenterology, VA Long Beach Health Care System, University of California, Irvine, CA, 5901 E. Seventh Str., Long Beach, CA 90822, United States

### Instructions to authors

Full instructions are available online at [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315215714.htm](http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm)

### Indexed and abstracted in

Current Contents<sup>®</sup>/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch<sup>®</sup>), Journal Citation Reports<sup>®</sup>, Index Medicus, MEDLINE, PubMed, PubMed Central, Digital Object Identifier, and Directory of Open Access Journals. ISI, Thomson Reuters, 2011 Impact Factor: 2.471 (32/74 Gastroenterology and Hepatology).

### SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

### Biostatistical editing

Statistical review is performed after peer review. We invite an expert in Biomedical Statistics to evaluate the statistical method used in the paper, including *t* test (group or paired comparisons), chi-squared test, ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc.* The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word “significantly” should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

### Conflict-of-interest statement

In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read “Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest” from International Committee of Medical Journal Editors (ICMJE), which is available at: [http://www.icmje.org/ethical\\_4conflicts.html](http://www.icmje.org/ethical_4conflicts.html).

### Statement of informed consent

Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

### Statement of human and animal rights

When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

## SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manu-

scripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/esps/>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS ([http://www.wjgnet.com/1007-9327/g\\_info\\_20100315215714.htm](http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm)) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [wjg@wjgnet.com](mailto:wjg@wjgnet.com), or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

## MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Viscer-

## Instructions to authors

al, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039 Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision on acceptance is made only when at least two experts recommend publication of an article. All peer-reviewers are acknowledged on Express Submission and Peer-review System website.

### Abstract

There are unstructured abstracts (no less than 200 words) and structured abstracts. The specific requirements for structured abstracts are as follows:

An informative, structured abstract should accompany each manuscript. Abstracts of original contributions should be structured into the following sections: AIM (no more than 20 words; Only the purpose of the study should be included. Please write the Aim in the form of “To investigate/study/...”), METHODS (no less than 140 words for Original Articles; and no less than 80 words for Brief Articles), RESULTS (no less than 150 words for Original Articles and no less than 120 words for Brief Articles; You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.,  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ), and CONCLUSION (no more than 26 words).

### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

### Core tip

Please write a summary of less than 100 words to outline the most innovative and important arguments and core contents in your paper to attract readers.

### Text

For articles of these sections, original articles and brief articles,

the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both.

### Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: ...*etc.* It is our principle to publish high resolution-figures for the E-versions.

### Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  should be noted ( $P > 0.05$  should not be noted). If there are other series of *P* values, <sup>c</sup> $P < 0.05$  and <sup>d</sup> $P < 0.01$  are used. A third series of *P* values can be expressed as <sup>e</sup> $P < 0.05$  and <sup>f</sup> $P < 0.01$ . Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, “Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]”</sup>. If references are cited directly in the text, they should be put together within the text, for example, “From references<sup>[19,22-24]</sup>, we know that...”.

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

**PMID and DOI**

Please provide PubMed citation numbers to the reference list, e.g., PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

**Style for journal references**

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

**Style for book references**

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

**Statistical data**

Write as mean  $\pm$  SD or mean  $\pm$  SE.

**Statistical expression**

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as *v* (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

**Units**

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4  $\pm$  2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6

## Instructions to authors

24.5 µg/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23243641.

The format for how to accurately write common units and quantum numbers can be found at: [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315223018.htm](http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm).

### Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

### Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gypA*, *arg 1*, *c myc*, *c fos*, *etc.*

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kbo I*, *Kpn I*, *etc.*

Biology: *H. pylori*, *E. coli*, *etc.*

### Examples for paper writing

All types of articles' writing style and requirement will be found in the link: <http://www.wjgnet.com/esps/Navigation-Info.aspx?id=15>.

## RESUBMISSION OF THE REVISED MANUSCRIPTS

Authors must revise their manuscript carefully according to the revision policies of Baishideng Publishing Group Co., Limited. The revised version, along with the signed copyright transfer agreement, responses to the reviewers, and English language Grade A certificate (for non-native speakers of English), should be submitted to the online system *via* the link contained in the e-mail sent by the editor. If you have any questions about the revision, please send e-mail to [esps@wjgnet.com](mailto:esps@wjgnet.com).

### Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A.

### Copyright assignment form

Please download a Copyright assignment form from [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315222818.htm](http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm).

### Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315222607.htm](http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm)

### Proof of financial support

For papers supported by a foundation, authors should provide a copy of the approval document and serial number of the foundation.

## STATEMENT ABOUT ANONYMOUS PUBLICATION OF THE PEER REVIEWERS' COMMENTS

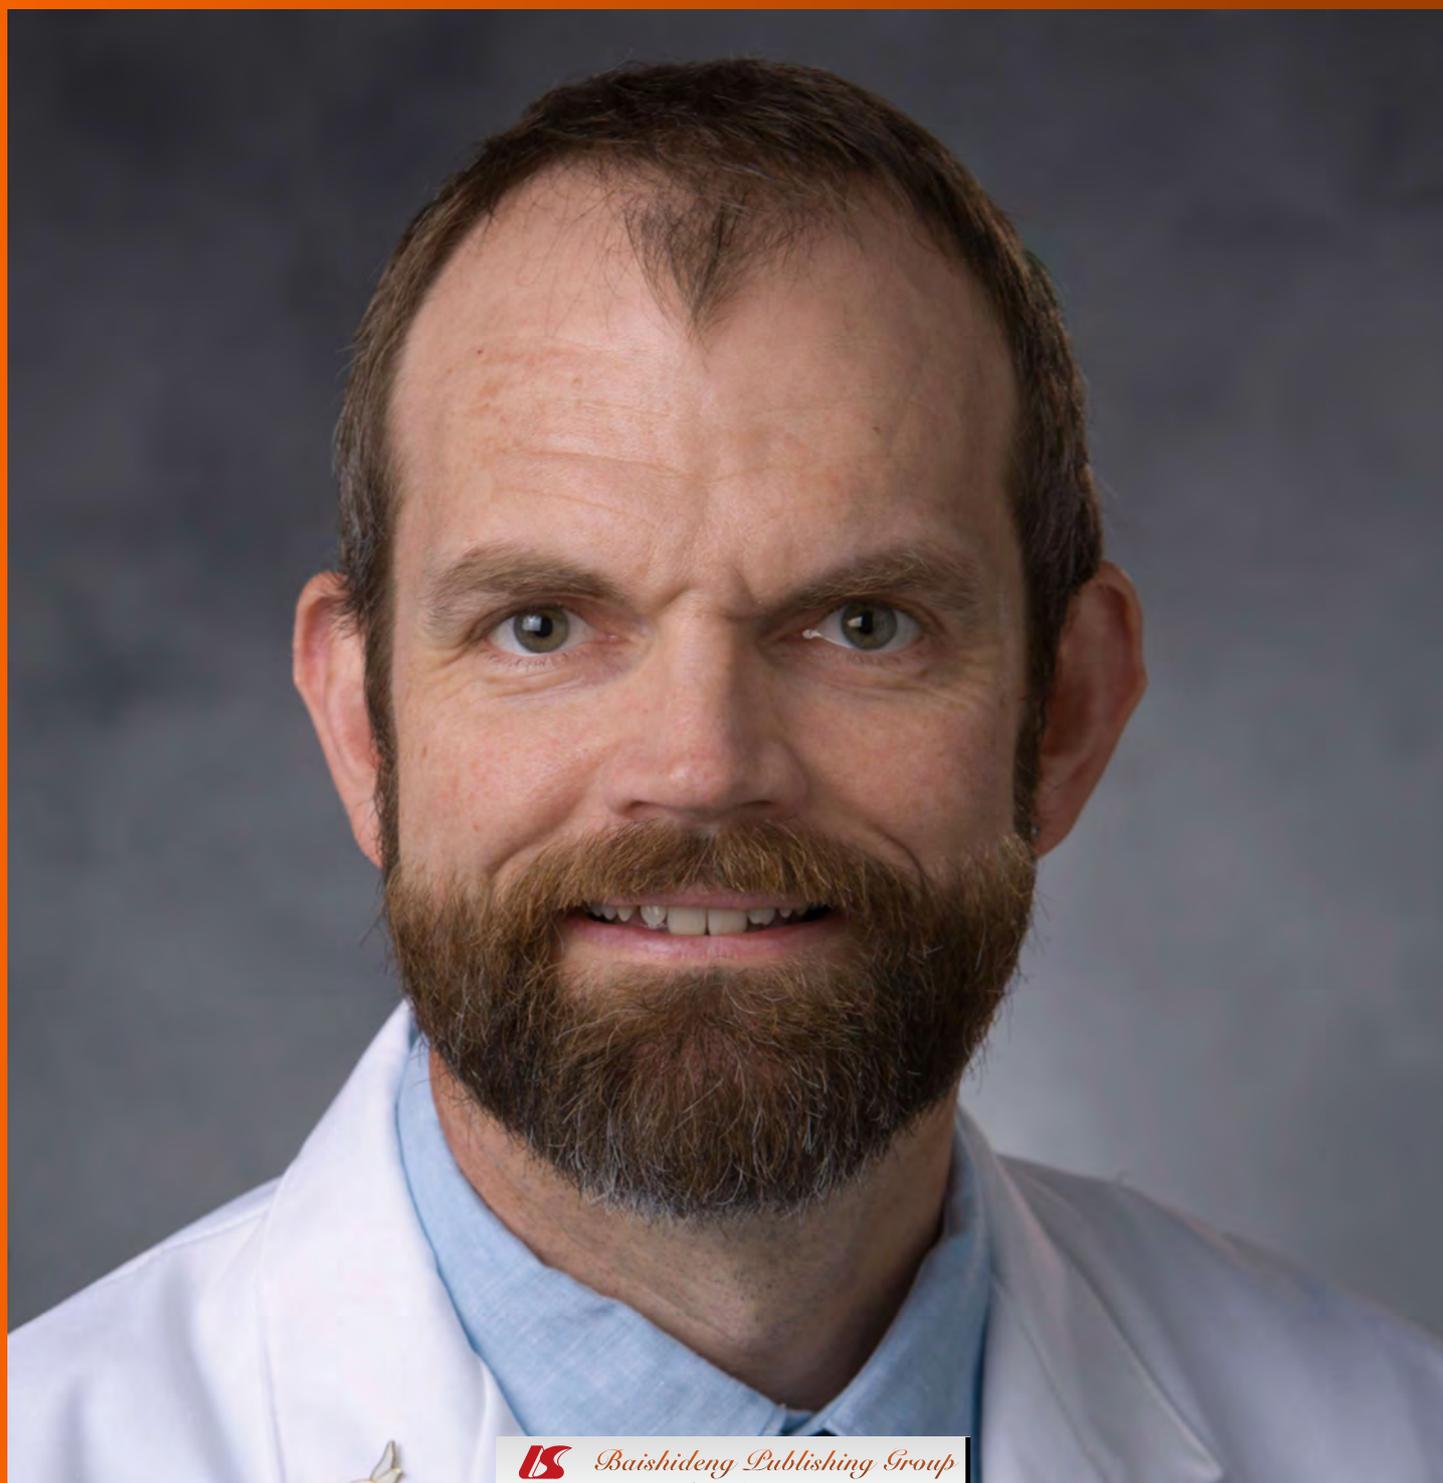

In order to increase the quality of peer review, push authors to carefully revise their manuscripts based on the peer reviewers' comments, and promote academic interactions among peer reviewers, authors and readers, we decide to anonymously publish the reviewers' comments and author's responses at the same time the manuscript is published online.

## PUBLICATION FEE

*WJG* is an international, peer-reviewed, open access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non-commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. Publication fee: 1365 USD per article. All invited articles are published free of charge.

### Dysplasia

**Core tip:** This paper reviews the current data on the clinical application of confocal laser endomicroscopy (CLE) in the study of colonic mucosa in patients with inflammatory bowel diseases (ulcerative colitis and Chron's disease). Moreover, the use of CLE has in diagnosing a biliary dysplasia/neoplasia in patients with primary sclerosing cholangitis, is evidenced.

De Palma GD, Rispo A. Confocal laser endomicroscopy in inflammatory bowel diseases: Dream or reality? *World J Gastroenterol* 2013; 19(34): 5593-5597 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i34/5593.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i34.5593>

### Abstract

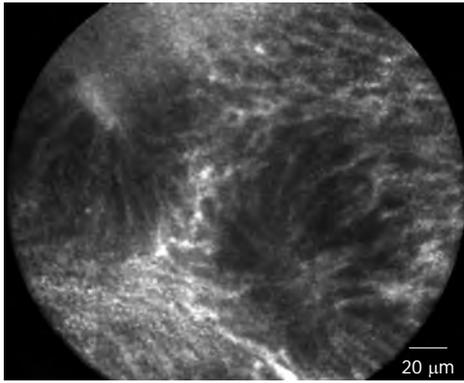

Confocal laser endomicroscopy (CLE) is a newly introduced procedure that provide real-time, high-resolution imaging of the gastrointestinal mucosa during endoscopy, allowing the visualization of the pathology of the mucosal epithelium with its cellular and subcellular structures. Recently, the use of CLE was reported in the study of colonic mucosa in patients with inflammatory bowel diseases and in particular in patients affected by ulcerative colitis. CLE has the potential to have an important role in management of inflammatory bowel diseases (IBD) patients as it can be used to assess the grading of colitis and in detection of microscopic colitis in endoscopically silent segments. Moreover, CLE can be used in surveillance programs especially in high-risk patients. Finally, CLE has been effectively used in diagnosing a biliary dysplasia/neoplasia in patients with primary sclerosing cholangitis, a pathological condition frequently associated with IBD, with a coexisting bile duct stricture.

### CONFOCAL LASER ENDOMICROSCOPY

Confocal laser endomicroscopy (CLE) is a newly introduced procedure which allows to capture the images of "virtual histology" of the gastrointestinal mucosa during endoscopy<sup>[1,2]</sup>, so offering the opportunity to get the "real time" visualization of the pathology of the mucosal epithelium with its cellular and subcellular structures<sup>[3,4]</sup>. At present, CLE can be performed with 2 devices: one integrated into an endoscope (Pentax, Tokio, Japan, herein termed e-CLE) and one as a mini-probe through the scope (p-CLE; Cellvizio, Mauna Kea Technologies, Paris, France). Confocal microscopy consists of focusing a laser ray onto the mucosal surface and filtering the returned light by means of a small pinhole which rejects out-of-focus light. The illumination and detection systems are in the same focal plane and are termed "confocal". After passing the pinhole, the fluorescent light is detected by a photo-detection, transforming the light signal into an electrical one that is recorded by a computer. All detected signals from the illuminated spot are captured and measured. As the laser scans over the plane of interest, a whole

**Figure 1** Rectal mucosa of patient in remission from ulcerative colitis. Irregular alignment of crypt, crypt distortion and fusion with reduced amount of goblet cells.

image is obtained pixel-by-pixel and line-by-line, whereas the brightness of a resulting image pixel corresponds to the relative intensity of detected fluorescent light. The gray-scale image created is an optical section representing one focal plane within the examined specimen. Real-time confocal laser scanning microscopy-sequences (duration 1 min are recorded and stored digitally for later evaluation. CLE evaluation and its relative high-quality images have shown high agreement with the real histology of the tissue, so opening a wide spectrum of potential applications, all focused on the possibility of reducing and/or targeting the biopsies during endoscopy<sup>[5,6]</sup>. The current potential indications for CLE imaging are broad and include almost all the cases in which endoscopic biopsy is needed.

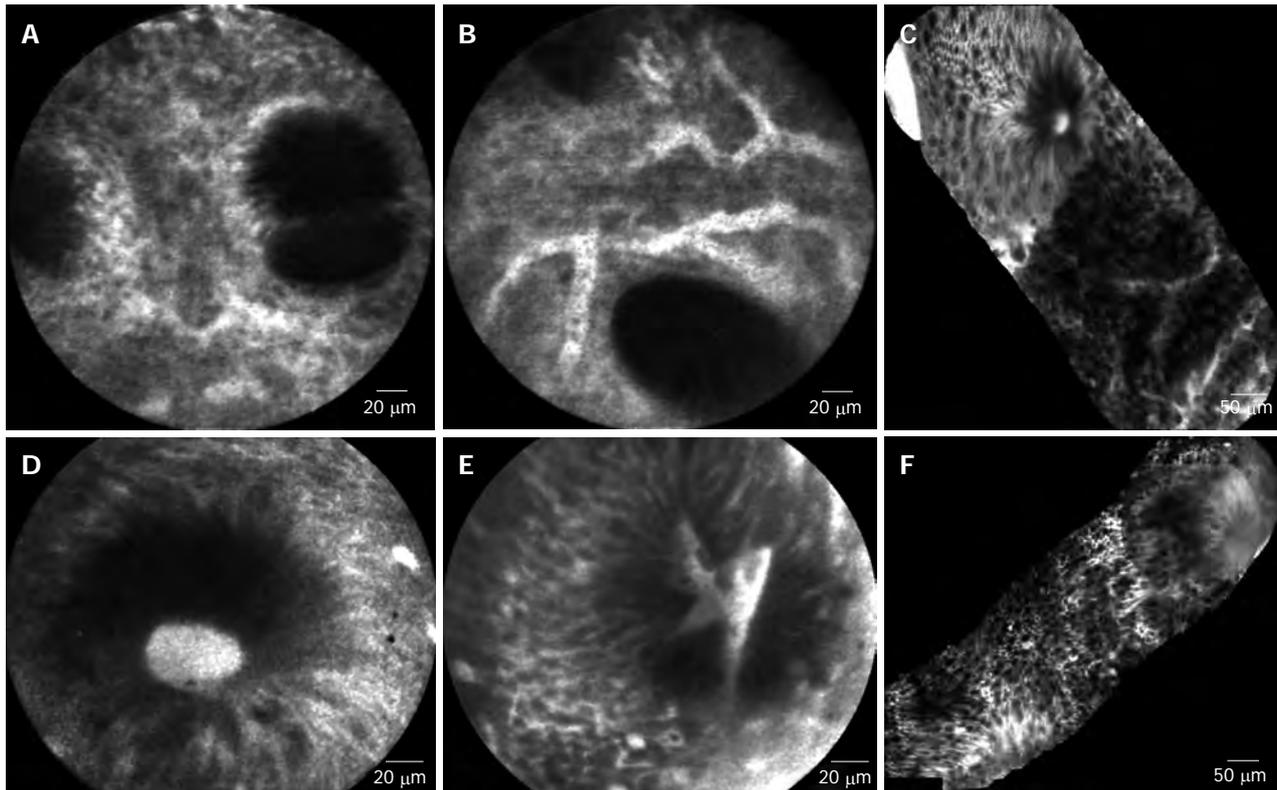

At now, various studies have addressed the potential usefulness of CLE in diagnostic work-up of inflammatory bowel disease (IBD), with particular interest to ulcerative colitis (UC)<sup>[7-9]</sup>. In effect, all the studies concerning the application of CLE in the UC context have shown that this technique can have a potential role in assessing the extension and the activity of disease and in targeting biopsies, reducing the number of useless biopsies and improving the early detection of dysplasia<sup>[10-13]</sup>. In the field of UC, the most frequent alterations in crypt architecture are represented by dilation of crypt openings, more irregular arrangement of crypts, enlarged spaces between crypt, crypt destruction and/or crypt fusion, and crypt abscess with fluorescein leaks into the crypt lumen (therefore making the lumen brighter than the surrounding epithelium). Microvascular alterations are mainly represented by dilated, prominent branching vessels (Figures 1 and 2). The study by Watanabe *et al*<sup>[14]</sup>, including 17 patients with active UC compared with 14 controls, showed that CLE images provided equivalent information to histopathology with respect to definition of the main histological outcomes (crypt architecture, capillaries and inflammatory cells). On these bases, a new classification of inflammatory activity in UC using CLE has been proposed<sup>[15]</sup>, which comprises the assessment of crypt architecture, microvascular alterations and fluores-

cein leakage.

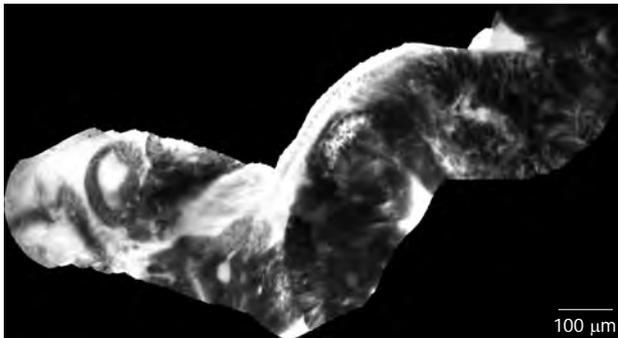

One of the most important diagnostic goals in the management of patients with UC, especially of those who present risk factors for cancer development, should be the “real-time” endoscopic identification and diagnosis of dysplasia/neoplasia, as this would reduce the number of unnecessary biopsies with their associated time and costs<sup>[16,17]</sup>. Starting from these assumptions, Kiesslich *et al*<sup>[18]</sup> have shown for the first time that the diagnosis of dysplasia/neoplasia in UC could be maximized by using both pan-chromoendoscopy (CE) and targeted CLE, with high values of diagnostic accuracy (sensitivity 94%, specificity 98%). This result has been recently confirmed, although with less remarkable diagnostic values, by van den Broek *et al*<sup>[19]</sup>, who reported a diagnostic accuracy of 81% when comparing CLE with narrow-band imaging plus high-definition endoscopy (diagnostic accuracy 92%). In accordance with these reports, a recent paper produced by our group, exploring the efficacy of the combined application of CE and targeted p-CLE in diagnosing dysplasia in longstanding UC in the “real-life”, has underlined the high diagnostic accuracy of such a procedure compared to standard histology (sensitivity 100%, specificity 90%, positive predictive value 83% and negative predictive value 100%)<sup>[20]</sup> (Figure 3). Giving value to all the above-mentioned contributions, the combination of CE and CLE corresponds to a diagnostic gain of 3- to 5-fold for detecting dysplasia/neoplasia than conventional colonoscopy<sup>[21]</sup>. The diagnostic gain is mainly due to CE application which could dramatically decreased (about of 10 times) the number of biopsies when just circumscribed suspicious lesions on CE would have been targeted; if only CLE-suspected neoplastic lesions had undergone biopsy after CE, the mean number of biopsies would be further reduced.

More recently, Neumann *et al*<sup>[22]</sup> have explored the clinical utility of CLE also in 76 patients affected by Crohn’s disease (CD), particularly determining whether the disease activity can be graded by using CLE. In effect, a relevant percentage of patients with active CD presented an increased colonic crypt tortuosity, enlarged crypt lumen, microerosions, augmented vascularization and increased cellular infiltrates. Starting from these considerations, these authors proposed a CLE score for assessing CD activity *in vitro*, with such a score having of potential utility for predicting the course of CD and the response to medical therapy.

CLE application in IBD has been evaluated even under a prognostic view. A nice work by Kiesslich *et al*<sup>[23]</sup> have shown that “cell shedding” and “barrier loss” detected by CLE are able to predict relapse of IBD and have potential role as diagnostic tool for the management of the disease. In this paper, the sensitivity, specificity and accuracy for the “CLE grading system” to predict a flare were 62.5%, 91.2% and 79%, respectively. Interestingly, a recent paper by Turcotte *et al*<sup>[24]</sup> confirmed the high prognostic power of CLE in predicting the course for other relevant clinical end-points for patients affected by IBD.

**Figure 2** Colonic mucosa. A: Patient in remission from ulcerative colitis. Crypt distortion and fusion and many capillaries visible in the lamina propria; B: Patient in remission from ulcerative colitis. Enlarged spaces between crypts and dilated prominent branching vessels; C: In patient with active ulcerative colitis (distal colitis). Image of colonic mucosa showing the switch from normal mucosa (top of the figure) to inflamed mucosa. Inflamed mucosa showing irregular arrangement of crypts, crypt fusion and capillaries alterations; D: In patient with active ulcerative colitis. Dilated and bright crypt lumen (fluorescein leakage) with intact epithelium; E: In patient with active ulcerative colitis. Dilated, irregular and bright crypt lumen (fluorescein leakage) with partially intact epithelium; F: In patient with highly active ulcerative colitis (Mayo CU3). Crypts distortion and destruction, crypt abscess and crypts replacement by diffuse necrosis.

**Figure 3** Dysplasia-associated lesional mass in long-standing ulcerative colitis. Image of colonic mucosa evidencing the switch from the inflamed mucosa, to the neoplastic mucosa. Inflamed mucosa is characterized by crypts fusion and distortion, dilation of crypt openings, enlarged spaces between crypts, and microvascular alterations with fluorescein leaks into the crypt lumen. Dysplastic mucosa (right corner) is characterized by "dark" cells, irregular architectural patterns with villiform structures and a "dark" epithelial border.

In particular, increased epithelial gaps in the small intestine as determined by CLE were a predictive factor for future hospitalization or surgery in IBD patients.

Going to another potential indication of this procedure in diagnostic work-up of IBD patients, CLE has been effectively used in diagnosing a biliary dysplasia/neoplasia in patients with primary sclerosing cholangitis

(PSC), a pathological condition frequently associated with IBD, with a coexisting bile duct stricture<sup>[25]</sup>. In effect, Heif *et al*<sup>[25]</sup> showed a high diagnostic accuracy in detecting the presence of a bile duct neoplasia in 15 PSC patients with 21 dominant stenoses (sensitivity 100%; specificity 61%; positive predictive value 22%; negative predictive value 100%). This paper has opened the doors to a further potential application of CLE in IBD.

Unfortunately, some relevant limitations reduced the current application of CLE in general practice: the need for a learning curve, the cost of the equipment, the need for an extra-time (about 30 min) to enhanced colonoscopy and, not less important, a number of medical-legal issues. Furthermore, the promising results in the literature derived from a little number of trials and still from a few experienced centers and, as a consequence, these cannot be generalized easily.

In our mind, among these limitations, the need for an adequate learning curve represents the less relevant topic. In effect, as shown in previous papers, the operator's endoscopic expertise and learning curve represent the crucial issues and main limitation for the routine application of this endoscopic technique. However, a recent report has highlighted that the ability to accurately interpret CLE images for predicting neoplastic lesions can be learned rapidly by a range of GI specialists<sup>[26]</sup>; similarly,

the ability to acquire high-quality CLE images can also be learned quickly.

About medical-legal issues, mainly regarding the application of CLE for surveillance endoscopy in UC, the principal matter is represented by the fact that endoscopists would make a histological diagnosis without the confirmation by a pathologist and would decide during the endoscopy if performing or not multiple biopsies. At now, this kind of diagnostic approach is not reported by the current guidelines<sup>[27]</sup> and should be applied only within a controlled trial formally approved by an ethical committee.

Concluding, new multicenter studies are needed to assess the real cost-effectiveness of CLE technique for IBD. In our opinion, when balancing the interesting diagnostic advantage of CLE in clinical practice with its important realistic limitation, the wide application of this procedure in the current endoscopic practice still appears to be more a dream than a reality.

### Abstract

Esophageal cancer (EsC) is one of the least studied and deadliest cancers worldwide because of its extremely aggressive nature and poor survival rate. It ranks sixth among all cancers in mortality. In retrospective studies of EsC, smoking, hot tea drinking, red meat consumption, poor oral health, low intake of fresh fruit and vegetables, and low socioeconomic status have been associated with a higher risk of esophageal squamous cell carcinoma. Barrett's esophagus is clearly recognized as a risk factor for EsC, and dysplasia remains the only factor useful for identifying patients at increased risk, for the development of esophageal adenocarcinoma in clinical practice. Here, we investigated the epidemiologic patterns and causes of EsC. Using population based cancer data from the Surveillance, Epidemiology and End Results Program of the United States; we generated the most up-to-date stage distribution and 5-year relative survival by stage at diagnosis for 1998-2009. Special note should be given to the fact that esophageal cancer, mainly adenocarcinoma, is one of the very few cancers that is contributing to increasing death rates (20%) among males in the United States. To further explore the mechanism of development of EsC will hopefully decrease the incidence of EsC and improve outcomes.

### INTRODUCTION

Esophageal cancer (EsC) including squamous cell carcinoma (SCC) and adenocarcinoma is considered as a serious malignancy with respect to prognosis and a fatal outcome in the great majority of cases<sup>[1,2]</sup>. Esophageal carcinoma affects more than 450000 people worldwide and the incidence is rapidly increasing<sup>[3]</sup>. Currently, EsC is the eighth most common incident cancer in the world because of its extremely aggressive nature and poor survival rate<sup>[4,5]</sup>.

EsC exhibits an epidemiologic pattern distinct from all other cancers<sup>[6,7]</sup>. The incidence of esophageal adenocarcinoma has increased sharply over the past few decades, both by period and birth cohort. Etiological studies are required to explain the rapid increase of this lethal cancer<sup>[8]</sup>. Understanding the epidemiology of EsC will be the key to elucidating the causes and risk factors for esophageal cancer and thus the cornerstone of developing any prevention strategies.

### PATHOLOGY AND ANATOMY

Cancer of the esophagus typically occurs in one of two

forms, SCCs arising from the stratified squamous epithelial lining of the organ, and adenocarcinomas affecting columnar glandular cells that replace the squamous epithelium<sup>[9]</sup>. Sarcomas and small cell carcinomas generally represent less than 1%-2% of all esophageal cancers<sup>[10,11]</sup>. On rare occasions, other carcinomas, melanomas, leiomyosarcomas, carcinoids, and lymphomas may develop in the esophagus as well<sup>[5]</sup>.

SCC is the predominant histologic type of esophageal cancer worldwide<sup>[12]</sup>. The incidence of squamous cell cancer of the esophagus increases with age as well and peaks in the seventh decade of life. The incidence of squamous cell esophageal cancer is three times higher in blacks than in whites, whereas adenocarcinomas are more common in white men.

The natural histories of SCCs and adenocarcinomas of esophagus appear to differ substantially. For squamous cell cancers, transition models have described squamous epithelium undergoing inflammatory changes that progress to dysplasia and in situ malignant change<sup>[13,14]</sup>.

Most adenocarcinomas, however, tend to arise in the distal esophagus from columnar-lined metaplastic epithelium, commonly known as Barrett's esophagus<sup>[15,16]</sup>, which replaces the squamous epithelium during the healing reflux esophagitis and may progress to dysplasia. Gastroesophageal reflux disease (GERD), or just reflux<sup>[17-19]</sup> can damage the lining of esophagus which causes Barrett's esophagus<sup>[17]</sup>, characterized by abnormal "tongues" of salmon-colored mucosa extending proximally from the gastroesophageal junction into the normal pale esophageal mucosa, develops in approximately 5 to 8 percent of patients with gastroesophageal reflux disease.

Cancers that start at the area where the esophagus joins the stomach (the GE junction), which includes about the first 2 inches of the stomach (called the cardia), tend to behave like esophagus cancers (and are treated like them, as well), so they are grouped with esophagus cancers. Approximately three quarters of all adenocarcinomas are found in the distal esophagus, whereas SCCs are more evenly distributed between the middle and lower third. The cervical esophagus is an uncommon site of disease. Nowadays the terminology used for the definition of adenocarcinomas at the GE junction is "cardiac carcinoma", which can be easily misunderstood. This definition of adenocarcinomas of the GE junction does not allow correct comparison of diagnosis (endoscopic, radiological and pathologic), epidemiology and surgical therapy in national and international aspects, because different tumor can develop in the same area, and all called cardia tumors<sup>[20]</sup>. Siewert and Stein recommended a classification to solve this problem<sup>[21]</sup>. The classification of the tumors is morphological/topographical<sup>[21,22]</sup>. Type I is adenocarcinoma of the distal part of the esophagus. Type II is adenocarcinoma of the real cardia and type III is subcardial gastric adenocarcinoma. The importance of this classification is it enables unified pre-operative assessment and it can also help to decide the type of the surgical intervention<sup>[20,23-27]</sup>.

## INCIDENCE

Cancers arising from the esophagus, including the GE junction, are relatively uncommon in the United States<sup>[28,29]</sup>. The rate of cancer of the distal esophagus is about equal to that of the more proximal two-thirds<sup>[30]</sup>. SCC is the predominant histologic type of esophageal cancer worldwide. The incidence of SCC increases with age as well and peaks in the seventh decade of life, which is three times higher in blacks than in whites, whereas adenocarcinomas are more common in white men.

The most important precancerous disease is Barrett's esophagus<sup>[31-34]</sup>. Patients with Barrett's esophagus have a 50 to 100 times increase in their risk of developing cancer compared to the general population. People with Barrett's esophagus are much more likely to develop cancer of the esophagus. These people require close medical follow-up in order to find cancer early. Still, although they have a higher risk, most people with Barrett's esophagus do not go on to develop cancer of the esophagus. In their population-based cohort study, Hvid-Jensen *et al*<sup>[35]</sup> reported an annual risk of esophageal adenocarcinoma of 0.12% among patients with Barrett's esophagus.

For different types of esophageal cancer, the risk increases with age, with a mean age at diagnosis of 67 years. Esophageal cancer age-adjusted incidence of blacks was about twice that of whites (8.63/100000 *vs* 4.39/100000,  $P < 0.05$ )<sup>[36]</sup>. Squamous cell carcinoma was more commonly diagnosed in blacks and white females, whereas adenocarcinoma was more common among white males.

Although the disease is relatively uncommon in the United States, it is a major global health threat<sup>[37]</sup>. Esophageal cancer is four times more common and slightly more lethal in men than in women. According to the National Cancer Institute (Cancer.gov) in 2012, it is estimated that 17460 persons (13950 men and 3510 women) will be diagnosed with and 15070 persons will die of cancer of the esophagus in 2012.

Esophageal cancer occurs at a rate 20 to 30 times higher in China than in the United States. An esophageal "cancer belt," primarily squamous cell cancers, extends from northeast China to the Middle East<sup>[38-40]</sup>. Evidence of an association between environment and diet and esophageal cancer comes from the profound differences in incidence observed in various parts of the world. The majority of the factors so far implicated in cancer of the esophagus appear to act directly on the esophagus rather than systemically. Nutritional deficiencies can develop by chronic alcohol use as well as by poverty and lack of an adequate food supply, but diet does not explain the whole picture. External carcinogens are necessary to affect the end result. The association between nutrition and esophagitis may suggest methods of primary prevention of esophageal cancer and provide a chance of lowering the incidence of this deadly disease<sup>[31]</sup>.

From 1996-2009, the annual percentage change was increased by 0.5% in all races and 0.4% in white. How-

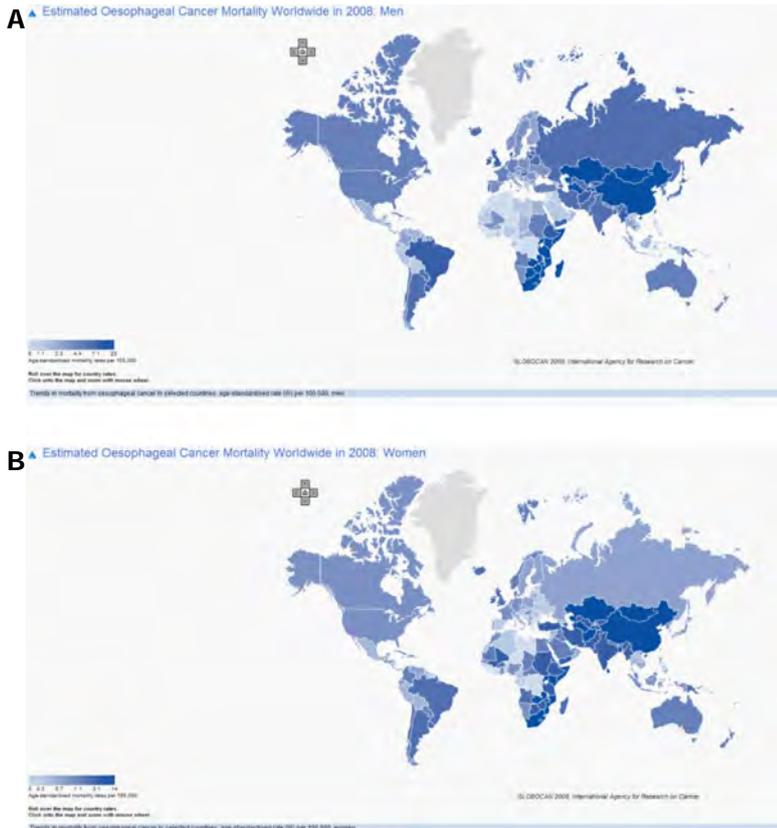

Figure 1 Estimated esophageal cancer mortality worldwide in 2008 (GLOBOCAN 2008). A: Men; B: Women.

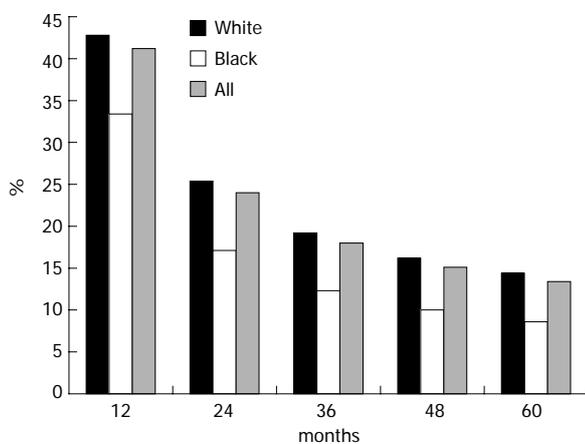

Figure 2 Relative survivals for esophageal cancer for all races.

ever, the increase of incidence is because of the increase incidence in men. Actually, the incidence in woman dropped by 0.4% (Surveillance, Epidemiology and End Results, SEER).

## MORTALITY

Figure 1 shows the age-adjusted esophageal cancer mortality. It is in line with the incidence rate in the world but there is no difference between men and women. Age-adjusted mortality for blacks, although showing a declining trend, was nearly twice that of whites (7.79 vs 3.96,  $P < 0.05$ ). Squamous cell carcinoma was more commonly diagnosed in blacks and white females, whereas adeno-

carcinoma was more common among white males ( $P < 0.001$ )<sup>[41]</sup>. The reasons are economic status, diet, and poor eating habits, *etc.*

## SURVIVAL

Survival varied widely according to cancer site. The differences in survival related to histology were also expected<sup>[42]</sup>. Although survival was poor for all groups, it was significantly poorer in blacks than in whites (Figure 2). The overall 5-year relative survival for 2002-2008 from 18 SEER geographic areas was 16.9%. Five-year relative survival by race and sex was: 18.1% for white men; 17.0% for white women; 10.4% for black men; 12.6% for black women.

The overall relative 5-year survival rates over time increase gradually in white and black, man and women. For example, the rate was below 2% in 1995 to over 10% in 2008 in black men (SEER).

Although the overall outlook for patients diagnosed with esophageal cancer has improved in the past 30 years, most patients still present with advanced disease, and their survival remains poor<sup>[43]</sup>. One-third to one-half of patients treated with either chemoradiation therapy or chemoradiation therapy plus surgery are alive at 2 years, without recurrence of esophageal cancer.

The reason is because esophageal cancer is diagnosed at rather late stage. Overall, more than 30 percent of patients have metastatic disease at the time of presentation (32.15% in white and 31.83% in black). None was found that has in situ cancer, due to the fact that it can be diffi-

**Table 1** Stage distribution and 5-year relative survival by stage at diagnosis for 1998-2009, all races, both sexes

Stage at diagnosis	Stage distribution	5-year relative survival
Localized (confined to primary site)	22%	37.80%
Regional (spread to regional lymphnodes)	30%	19.80%
Distant (cancer has metastasized)	35%	3.40%
Unknown (unstaged)	13%	10.50%

cult to diagnose esophageal cancer early. Among patients who are undergoing primary surgery, 22 percent have localized disease, 30 percent have regional cancer (Table 1).

## RISK FACTORS

The patterns of esophageal cancer are dramatically changing in the United States. However, the mechanisms of esophageal tumorigenesis are not fully understood<sup>[5]</sup>. Three decades ago the large majority of these cancers were SCCs, but the incidence of esophageal adenocarcinoma has been steadily increasing<sup>[44]</sup>. Tobacco and alcohol consumption are the primary causes of SCCs of the esophagus<sup>[45]</sup>. One of the strongest emerging risk factors, however, is obesity. Increases in the prevalence of obesity and the incidence of esophageal adenocarcinoma are parallel, and several epidemiologic studies have shown upwards of threefold excess risks among overweight individuals. Further research into the causes of these usually fatal cancers may help identify other potential determinants and provide needed information to help stem their increase.

Cigarettes, red meat, alcohol and hookah smoking<sup>[4]</sup>, nass use (a chewing tobacco product), opium consumption, hot tea drinking, poor oral health, low intake of fresh fruit and vegetables, and low socioeconomic status have been associated with a higher risk of esophageal SCC (Table 2). Barrett's esophagus is clearly recognized as a risk factor for EsC, and dysplasia remains the only factor useful for identifying patients at increased risk, for the development of esophageal adenocarcinoma in clinical practice.

### Smoking increases risk of SCC and adenocarcinoma of the esophagus

Moderate to heavy smokers face an increased risk of both SCC and adenocarcinoma of the esophagus. Research suggests that when a smoker ingests tobacco condensates, it causes tobacco carcinogens, particularly nitrosamines, to come in contact with the esophageal mucosa. There is a direct correlation between the number of cigarettes a smoker smokes per day; the length of time the smoker spends smoking, and the risk of esophageal cancer<sup>[2]</sup>.

### The effects of chronic irritation and inflammation on SCC

The incidence of SCC of the esophagus has been found to dramatically increase in the presence of any factor that causes chronic irritation and inflammation, such as exces-

**Table 2** Esophageal cancer risk factors<sup>[5,80-87]</sup>

Risk factor	Squamous-cell carcinoma	Adenocarcinoma
First or second hand smoke	+++	++

TERT A279T polymorphism	+	+

--: No effect; +: Suspicious effect; ++: Positive effect; +++, ++++: Strong positive effect.

sive alcohol intake, especially in combination with smoking<sup>[46,47]</sup>. This does not hold true for adenocarcinoma. This may account for more than 90 percent of all cases of SCC of the esophagus in developed countries<sup>[48]</sup>.

Chronic esophageal irritation also occurs when food is retained and decomposed by bacteria, releasing various chemical irritants. Frequent consumption of hot beverages also appears to increase the incidence of SCC<sup>[49]</sup>.

### Obesity

Esophageal squamous cell carcinoma (ESCC) is clearly linked to a low socioeconomic status. The increasing prevalence of obesity in the Western world is thought to add to the rising incidence of esophageal adenocarcinoma. More specifically, it has been postulated that obesity increases intraabdominal pressure and gastroesophageal reflux by a specific mechanism, although some studies provided contradictory results. On the other hand, adipose tissue itself influences tumor development<sup>[50-54]</sup>. Adipocytes and inflammatory cells secrete adipokines and cytokines which are known to promote tumor development. The abundant availability of lipids from adipocytes in the tumor microenvironment, supports tumor progression and uncontrolled growth. Given that adipocytes are a major source of adipokines and energy for the cancer cell, understanding the mechanisms of metabolic symbiosis between cancer cells and adipocytes, should reveal new therapeutic possibilities.

### Genetic changes

The genetic and molecular changes underlying the development of EsC remain poorly understood. Genetic analysis of these cancers reveals frequent chromosomal losses (4q, 5q, 9p, and 18q), chromosomal gains (8q, 17q, and 20q), and occasional gene amplifications (7, 8, and 17q)<sup>[5]</sup>.

In the past decade, efforts have been made to use can-

didate gene approaches to identify genetic susceptibility factors for ESCC. The genome-wide association studies (GWAS) has emerged as a powerful and successful tool to identify common disease alleles by using high-throughput genotyping technology to interrogate a large number of tagging single nucleotide polymorphisms (SNPs) that serve as surrogates for untested common SNPs across the genome. So far, GWAS of esophageal cancers including ESCC in individuals of European and Japanese ancestry, have shown that variants in *ADH* genes and/or *ALDH2* are associated with risk of ESCC<sup>[55-58]</sup>. More recently, Wu *et al* further reported that nine new ESCC susceptibility loci, of which seven, at chromosomes 4q23, 16q12.1, 17q21, 22q12, 3q27, 17p13 and 18p11, had a significant marginal effect ( $P = 1.78 \times 10^{-39}$  to  $P = 2.49 \times 10^{-11}$ ) and two of which, at 2q22 and 13q33, had a significant association only in the gene-alcohol drinking interaction [gene-environment interaction  $P (P_{G \times E}) = 4.39 \times 10^{-11}$  and  $P_{G \times E} = 4.80 \times 10^{-8}$ , respectively]. Variants at the 4q23 locus, which includes the *ADH* cluster, each had a significant interaction with alcohol drinking in their association with ESCC risk ( $P_{G \times E} = 2.54 \times 10^{-7}$  to  $3.23 \times 10^{-3}$ ). They confirmed the known association of the *ALDH2* locus on 12q24 to ESCC, and a joint analysis showed that drinkers with both of the *ADH1B* and *ALDH2* risk alleles had a fourfold increased risk for ESCC compared to drinkers without these risk alleles. Their results underscore the direct genetic contribution to ESCC risk, as well as the genetic contribution to ESCC through interaction with alcohol consumption<sup>[55]</sup>.

There are also some studies on polymorphism on other locations for esophageal adenocarcinoma with smaller samples. Cyclin D1 (*CCND1*) *G870A* polymorphism has been known to be a risk factor in multiple cancers<sup>[59-63]</sup>. However, investigations concerning the association of *CCND1 G870A* polymorphism with esophageal cancer risk have generated conflicting results<sup>[64-69]</sup>. The overall data suggest that *CCND1 G870A* variations might have an association with increased esophageal cancer susceptibility. The earliest findings, published in 2005, reported that *CCND1 G870A* was a risk factor for esophageal adenocarcinoma<sup>[67]</sup>. A study conducted by Liu's group, drew the exact opposite conclusion: *CCND1 G870A* was not associated with susceptibility to esophageal adenocarcinoma<sup>[70]</sup>. Liu's group explained the discrepancy by noting that all previous studies were based on small samplings.

Since the definition of *G870A* is the same for both groups, the significant difference lies in the methods that they used. Casson's group did polymerase chain reaction (PCR) followed by enzyme digestion, and visualized the result by running the products in a 15% acrylamide gel, and is referred to as "PCR-restriction fragment length polymorphism (RFLP)," which was widely used ten years ago. Liu's group genotyped by the 5'-nuclease assay (Taq-Man), using the ABI Prism 7900HT Sequence Detection System (Applied Biosystems, Foster City, CA, United States). This is currently considered the gold standard in genotyping. Casson's group included patients with

GERD. Since GERD is rather common in the general population, they selected strictly asymptomatic individuals for their control groups. Liu's group chose instead to use healthy visitors as their control group. And those healthy controls might have had some undiagnosed diseases related to GERD, such as Barrett's esophagus.

One source of bias between the two groups may lie in the different controls that were used. This may explain why the rate of G/G is different between the two groups. The second reason may be due to the detection method used. Usually, sequencing is viewed as the gold standard, but it is not always correct<sup>[71]</sup>. To detect polymorphism, the PCR-RFLP that Casson's group used, might have been a better choice because PCR-RFLP tests detect the correct genotype. Direct sequencing of the PCR products, obtained with one of the primers located adjacent to a mutated nucleotide, may cause unequal amplification of alleles in heterozygous samples. This effect is even stronger when mismatched primers are used. Therefore, there is a potential pitfall in DNA sequencing, indicating that sequencing may not always be the gold standard. The third reason may be due to the inherent differences between the two groups. As we know, the minor allele frequency (maf) of a SNP is different among different populations. Since it is ethnicity related, more information is needed to know the demographic information of the patient and the control group.

Although Li argues that others may be drawing different conclusions than his group, due to smaller samplings, it cannot be ruled out that other factors are involved, such as how the different control groups were recruited. Zhuo *et al*<sup>[64]</sup> reported that homozygous AA alleles might elevate esophageal cancer risk among Asians, but not Caucasians. This might partially explain why the two groups drew different conclusions.

*CCND1 G870A* polymorphism might be a low-penetrant risk factor for esophageal carcinoma, particularly among Asians. More information is needed to study large samples in relationship to pertinent demographic data.

## PREVENTIVE FACTORS

The keys to prevention of esophageal cancer vary by cell type. For SCC, reduction or elimination of tobacco and alcohol consumption provide the best means to reduce the incidence of this cancer. However, no one particular risk factor is responsible for the rising incidence of esophageal adenocarcinoma. Several preventive strategies are under investigation using such agents as nonsteroidal anti-inflammatory drugs, selenium, alpha-difluoromethylornithine, and retinoids<sup>[72]</sup>. Vegetable intake, and fruit intake is considered to be a preventive role. Carotene, vitamin C, and vitamin E are protective, most likely in combination with each other and other micronutrients. The role of vitamin A is not clear because of conflicting findings in the studies reviewed<sup>[73]</sup>. When intake of raw vegetables and cooked vegetables was analyzed separately, raw vegetables were found to be more protective.

Because fruits are relatively expensive in most places, increased consumption may reflect higher socioeconomic status.

Since obesity is closely related to the incidence of the esophageal cancer, it would be interesting to follow up those patients with precancerous lesion to monitor their weight.

In patients with high-grade dysplasia, the options for preventive approaches include surveillance, endoscopic therapies, and surgical resection, but the optimum approach is debated<sup>[5]</sup>. In an analysis of more than 15 studies, the mean incidence of occult adenocarcinoma in patients with a preoperative diagnosis of high-grade dysplasia treated with esophagectomy was 41%. This high incidence provides a rationale for use of esophagectomy, but there is concern about the risk of morbidity. Use of endoscopic treatments for high-grade dysplasia has been supported in two randomised trials. In one trial of photodynamic therapy plus proton-pump inhibitors compared with proton-pump inhibitors alone, progression to cancer was significantly decreased in the photodynamic-therapy group (13% *vs* 28%). In the other, which assessed endoscopic radiofrequency ablation in patients with Barrett's esophagus and high-grade dysplasia, radio frequency ablation was more effective in eradication of high-grade dysplasia than a proton-pump inhibitor alone, and the progression to cancer was lower (4% *vs* 22%) during short-term follow-up<sup>[74-77]</sup>.

## SCREENING AND EARLY DETECTION

Although several potential preventive measures exist, none has been proven to decrease the risk of esophageal carcinoma in prospective well-designed trials<sup>[5]</sup>. The relatively low incidence of esophageal cancer, the absence of early symptoms, and the rarity of a hereditary form of the disease make population-based screening untenable except in certain high-risk areas of the world<sup>[5]</sup>.

Patients who are found to have Barrett's esophagus, however, may be candidates for regular endoscopic surveillance, since the incidence of low-grade dysplasia, high-grade dysplasia, and cancer is approximately 4 percent, 1 percent, and 0.5 percent per year, respectively, among such patients<sup>[5]</sup>. Whether endoscopic screening programs to detect Barrett's esophagus in patients with chronic reflux disease symptoms are useful has been debated. Critics point out the high number of people in the general population who have reflux symptoms and the fact that at least 40% of patients with Barrett's esophagus do not have reflux symptoms, and question the cost-effectiveness of screening. Proponents of screening for Barrett's esophagus point to the clear associations between reflux, Barrett's esophagus, and esophageal adenocarcinoma, and suggest that the rising incidence of esophageal adenocarcinoma justifies screening. No definitive data are available on whether endoscopic screening for Barrett's esophagus is associated with a reduction in cancer-related mortality and, therefore, screening is

not routinely recommended.

However, some experts have recommended that endoscopy be performed every three to five years in patients who have Barrett's esophagus in the absence of epithelial dysplasia and more frequently if they are found to have low-grade dysplasia. Diagnostic endoscopy for early detection can be conducted in 2 steps: at first detection of an abnormal area through changes in relief, in color or in the course of superficial capillaries; then characterization of the morphology of the lesion. Then treatment decision offers 3 options according to histologic prediction: abstention, endoscopic resection, surgery. The rigorous quality control of endoscopy will reduce the miss rate of lesions and the occurrence of interval cancer<sup>[78]</sup>.

## CONCLUSION

The precise causes of EsC have not been identified. Despite uncertainties in our understanding of the causes of mechanistic pathways of esophageal cancer, there is sufficient evidence to take effective steps to prevent the majority of SCC in western countries, while more information is needed to curb the epidemic increase in adenocarcinoma<sup>[7,79]</sup>.

### Abstract

Advances in understanding the interaction between the human immune system and the microbiome have led to an improved understanding of the function of the vermiform appendix as a safe-house for beneficial bacteria in the colon. These advances have been made despite long standing clinical observations that the appendectomy is a safe and effective procedure. However, more recent clinical data show that an appendectomy puts patients at increased risk for recurrent *Clostridium difficile* (*C. difficile*)-associated colitis, and probably other diseases associated with an altered microbiome. At the same time, appendectomy does not apparently put patients at risk for an initial onset of *C. difficile*-associated colitis. These clinical observations point toward the idea that the vermiform appendix might not effectively protect the microbiome in the face of broad spectrum antibiotics, the use of which precedes the initial onset of *C. difficile*-associated colitis. Further, these observations point to the idea that historically important threats to the microbiome such as infectious gastrointestinal pathogens have been supplanted by other threats, particularly the use of broad spectrum antibiotics.

**Key words:** Appendectomy; *Clostridium difficile*; Colitis; Diarrheal illness; Vermiform appendix

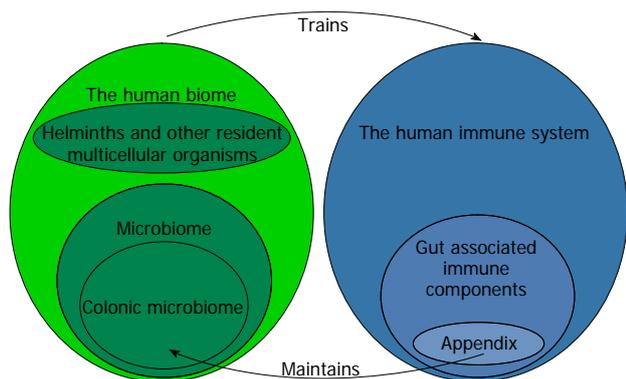

**Core tip:** Although the function of the appendix has remained an enigma for centuries, recently emerging advances in the fields of immunology and gut microbiology have merged with observations made in the clinic to form a coherent picture. Although the appendix is apparently a safe-house for beneficial bacteria, it seems likely that this safe-house does not satisfactorily protect the microbiome from broad spectrum antibiotics. In this view, selection pressures which threatened the microbiome and likely drove the evolution of the appendix have been supplanted in post-industrial society by new threats to the microbiome that the human body is not adapted for.

### INTRODUCTION

#### *Is appendectomy the removal of a functional organ?*

Appendectomy, like a wide variety of other surgical procedures, is extremely common in industrialized society. However, unlike common surgical procedures that include sterilizations for contraception, Cesarean sections, and inguinal hernia repairs, appendectomies are frequently performed as a prophylaxis for disease. The lifetime risk for appendicitis is only 8.6% for males and 6.7% for females, contrasting to the 12% and 23% lifetime rate of appendectomies performed, respectively<sup>[1]</sup>. These numbers indicate that approximately half of all appendectomies, including more than 60% in females, are

**Figure 1** Interactions between the human biome (left Venn diagram) and the human immune system (right Venn diagram). In this view, all living organisms associated with the human body, either as permanent residents or through transient interactions, are part of the human biome. Two subsets of the biome, helminths and the microbiome, are shown as being part of the human biome. The colonic microbiome, in turn, is shown as being a subset of the microbiome in the Venn diagram of the human biome. Similarly, the appendix is shown as being a subset of the gut associated immune components, which in turn are a subset of the entire human immune system. The idea that the biome “trains” the immune system, equivalent to the view that the immune system is dependent on the biome for proper development, is illustrated. In this model, profound alterations in the biome as a result of post-industrial societies lead to aberrant immune system development, resulting in a variety of immune related pathologies, including appendicitis. The view that the appendix assists in maintaining of the colonic microbiome is also shown. Alterations in the biome that affect immune system training in post-industrial societies predominantly involve compartments of the biome other than the microbiome (*e.g.*, loss of helminths), so the processes leading to appendicitis are generally distinct from processes involved in support of the microbiome by the appendix.

incidental procedures, aimed at averting future episodes of appendicitis. This approach is generally successful, but 36 incidental appendectomies are required to prevent one case of appendicitis<sup>[1]</sup>. Given the large number of appendectomies currently performed, many of them elective, recently emerging evidence regarding the apparent function of the vermiform appendix has justifiably garnered much interest.

The idea that the vermiform appendix is a vestige of evolution was developed more than 150 years ago by Darwin<sup>[2]</sup>. The proposal was simple and made sense in the light of available data: the appendix and small cecum present in humans and some primates is the remainder of a larger cecum used for fermentation in a human ancestor with a diet much higher in fiber<sup>[2]</sup>. However, recent studies using current methods employed in the field that Darwin<sup>[2]</sup> founded have disproved that idea. In summary, a modern cladistics-based approach demonstrates that the appendix has evolved repeatedly in a wide range of animals, that some clades have a propensity to evolve an appendix, and that the evolution of the appendix is usually not associated with a decrease in the size of the cecum. In fact, a recent analysis of 361 mammalian species found a significant direct correlation between appendix and cecum size<sup>[3]</sup>. In other words, the appendix tends to be associated with a large cecum, not a smaller one. At present, many questions regarding the evolution of the appendix remain unanswered: it is not even

known whether the first appendix evolved before or after the first cecum<sup>[4]</sup>, or how often which precedes the other in evolution (given the rise of the appendix more than once during evolution). Although the absolute disproof of Darwin’s views of the appendix is recent, the idea that the appendix is a vestige of evolution has been disputed effectively for more than a century. For example, Berry<sup>[5]</sup> concluded in 1900 that, based on anatomical and phylogenetic data, “The vermiform appendix of man is not, therefore, a vestigial structure. On the contrary, it is a specialized part of the alimentary canal”. Keith<sup>[6]</sup> supported Berry’s views and argued further that that the appendix, rather than being a flawed structure which gives rise to appendicitis, is a victim of changes in the environment due to industrialization: “When we come to realize how slowly evolutionary processes have affected man’s body in past times, we can hardly expect our internal digestive system to adapt itself to the rapid pace demanded by the ever-accumulating resources of civilization”.

When Keith<sup>[6]</sup> recorded his views in 1912, the incidence of appendicitis had profoundly increased in the lifetime of many practicing physicians, and it was therefore correctly surmised that something environmental was causing the disease. The opinion of the day was that changing diet following industrialization was in some way responsible for appendicitis. Although the view that appendicitis was due to an environmental factor or factors in industrial and post-industrial environments was solidified by numerous epidemiologic studies<sup>[7-11]</sup>, it was not until the 1980s that Barker *et al.*<sup>[12-14]</sup> determined that factors associated with indoor plumbing were somehow responsible for appendicitis<sup>[14]</sup>. These intriguing findings by Barker as well as additional work by Strachan on allergic disease<sup>[15]</sup> eventually gave rise to the currently held view that factors within post-industrial culture, including sanitation practices (*e.g.*, toilets and water treatment facilities) and modern medicine, lead to depletion of species normally associated with the ecosystem of the human body, or the “human biome” (not to be confused with the “microbiome”, Figure 1). The resulting state, termed “biome depletion” is associated with a profoundly over-reactive immune system that is prone to a variety of immune related diseases, including appendicitis. Barker’s personal view is that the introduction of running hot water into a home might be the single most telling factor associated with an increased incidence of appendicitis (personal communication to Parker W). Since hot water is necessary for the effective use of soap, and given the effectiveness of soap in biological decontamination, this view makes sense. Here it should be noted that approaches which deal with the consequences of biome depletion are expected to one-day make appendicitis a rare disease. These approaches involve reconstitution of the human biome without abandoning the modern technology, including soap, water treatment facilities and medicine, which so effectively prevents the spread of water-borne disease<sup>[16-18]</sup>.

Despite proof that the appendix is not a vestige of

evolution and that appendicitis is not the result of a faulty structure, the idea that the appendix is a vestige seems attractive simply because removal of the appendix does not, to the practicing physician or to the patients concerned, seem to have deleterious effects. This observation, apparent to everyone, presents a quandary: how can the appendix have some function, but yet appendectomy has no negative side effects? The answer to this quandary is readily apparent if one considers that actual function of the appendix.

In 2003 it was observed that the immune system apparently supports growth of mutualistic biofilms in the mammalian gut<sup>[19]</sup>. This view, although surprising at the time due to prevailing views in the field of immunology, now seems rather obvious in hindsight based on current knowledge regarding microbial ecology and host-microbe relationships<sup>[20-22]</sup>. This new view led to the evaluation of biofilm distribution in the human gut, and biofilms were indeed found to be most abundant in the appendix, where immune tissue had long been known to be the most abundant within the gut. This biofilm distribution in the gut set the stage for a deductive proof regarding the function of the appendix: Since the appendix is a structure harboring microbial biofilms, and since biofilms are protective of bacteria (a long standing observation in the field of microbiology), the appendix is, in essence, a safe house for bacteria (Figure 1). Given the shape and location of the appendix, it would indeed be difficult to imagine how the appendix might not be protective of bacteria.

Given the apparent function of the appendix, it has been proposed that an evolutionary driving force for the emergence of the appendix may be as an aid in the recovery from diarrheal illness associated with gastrointestinal (GI) infection. In this view, fragments of biofilms routinely shed from the appendix would serve as “seeds” for inoculation of the colon with a normal microbial flora following a diarrheal purge<sup>[23]</sup>. This explanation makes sense in light of (1) the relative seclusion of the apex of the appendix from the fecal stream, which presumably affords some protection from pathogenic organisms that might temporarily infect the GI tract; and (2) the pronounced role of diarrheal illness in human survival. Indeed, water-borne diseases followed by dysentery are frequently the leading cause of death during war and natural disasters<sup>[24-27]</sup>, have affected both the rich and the poor<sup>[28]</sup> and are still one of the leading causes of death in developing cultures<sup>[29,30]</sup>. These observations are consistent with the view that that rapid reconstitution of the microbiome and restoration of a normal bowel following diarrheal illness might be adaptive in many circumstances. In fact, the relatively low mortality rate associated with diarrheal illness, less than one percent<sup>[31]</sup>, is possibly a testament to the effectiveness of natural recovery mechanisms such as those that might involve the appendix. Adding further weight to this view, a very recent study by

Guanine *et al*<sup>[32]</sup> found that “the human appendix contains a wealth of microbes, including members of 15 phyla”. Species identified included members of phyla which constitute more than 98% of the normal colonic microbiome (*Firmicutes*, *Proteobacteria*, *Bacteroidetes*, *Actinobacteria*, and *Fusobacteria*), indicating that the appendix possesses a microbial diversity sufficient to reconstitute the microbiome of the colon.

If this inductive rationale is correct, the paradoxical removal of the functional appendix without immediate and substantial harm is readily explained: Although water-borne disease is one of the leading causes of death in developing countries, the use of modern water treatment facilities and sanitation prevents widespread outbreaks of pathogens which might deplete the normal flora from a substantial portion of the population. Further, the absence of starvation and the presence of modern medicine in developed countries minimize the effects of diarrheal illness on the population.

### Causes of appendicitis

Approximately 50% of cases of appendicitis are generally considered to be enigmatic in origin, with the remainder being attributed to a blockage of the appendix. However, work from David Barker during the 1980’s first identified clues which eventually pointed toward the underlying cause of appendicitis. Barker noticed that epidemics of appendicitis followed the introduction of indoor plumbing into various communities. This observation was followed by epidemiologic studies showing that appendicitis is associated with developed but not with developing countries. Almost at the same time, another epidemiologist, Strachan<sup>[15]</sup>, found that a hyper-active immune system is a consequence of the hygienic environment following the industrial revolution<sup>[15]</sup>. Strachan’s observations point toward the idea that appendicitis, like many other allergic, autoimmune, and inflammatory diseases, is a result of biome depletion, a consequence of industrialization<sup>[16-18]</sup>. This culture-related basis for appendicitis explains why the appendix was not selected against during the course of evolution. Many components of the immune system, such as the appendix, are made obsolete by post-industrialized society, and these have also not been selected against during evolutionary history. Not only are these components now obsolete, but these components often become overly sensitive due to an absence of stimulation and cause detrimental health effects, such as ulcerative colitis that is exacerbated by the appendix<sup>[33]</sup>. Another example of a maladapted immune component is the immune compartment that produces immunoglobulin E (IgE). High levels of IgE lead to allergies and other destructive side effects in industrialized societies, but levels significantly higher than those found in industrialized countries are present in developing countries as a result of productive (beneficial) responses to parasitic infections<sup>[34-36]</sup>.

## THE EFFECT OF APPENDECTOMY IN LIGHT OF THE FUNCTION OF THE APPENDIX

Although an appendectomy is a relatively simple surgical procedure, the effects of removing the appendix are not necessarily straightforward. The appendix is associated with the highest concentration of gut associated lymphoid tissue (GALT) in the gut, and the function of the GALT is vastly complex and incompletely understood. Thus, an appendectomy is expected to profoundly alter the immune system with its hundreds or possibly thousands of interconnected components. Numerous functions have been attributed to the GALT, and it remains unknown how appendectomy alters many of those functions. However, some effects are established. First, appendectomy does have a moderating effect on pathogenic inflammatory immune responses of the gut. The observation that patients without an appendix tend to be at less risk for ulcerative colitis is more than 10 years old<sup>[33]</sup>. More recently, Bolin *et al.*<sup>[37]</sup> used appendectomy as a treatment for ulcerative proctitis, a form of colitis, and showed an improvement of symptoms in 90% of patients, with complete remission in 40% of patients<sup>[37]</sup>. Possibly the most straight-forward explanation for this result is that removal of a substantial amount of GALT from the intestinal tract led to decreased immune reactivity in the gut. Whether the “safe-house” function of the appendix had anything to do with the result seems more speculative.

### **The appendix and the initial onset of *Clostridium difficile* colitis**

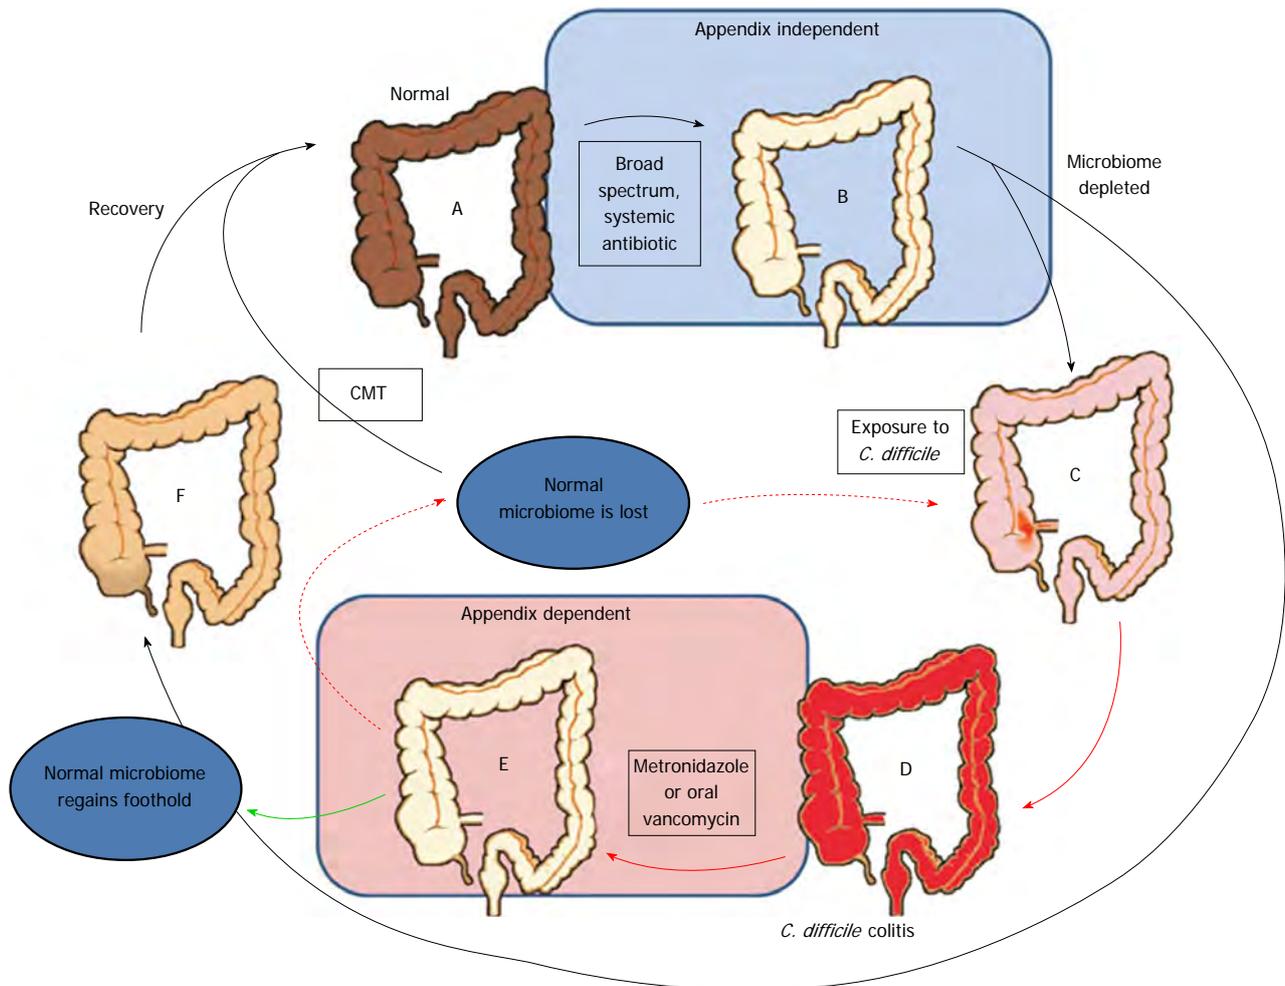

Perhaps the most intriguing effects of appendectomy involve its effects on the incidence of *Clostridium difficile* (*C. difficile*) colitis. *C. difficile* colitis is a pathogenic state associated with overgrowth of the bacterium *C. difficile*, a gram-positive, spore-forming, anaerobic bacillus<sup>[38,39]</sup>, and is generally not seen in individuals with a normal microbiome. However, alteration of the normal flora (generally by antibiotic use) can lead to overgrowth of *C. difficile* and subsequent disease. Recurrent *C. difficile* colitis is not a minor problem in modern medical practice, with one study showing nosocomial *C. difficile* diarrhea present in 3.4 to 8.4 cases per 1000 hospital admissions<sup>[40]</sup>, and an increase in in-hospital mortality from 2.4% to 13.5%<sup>[41]</sup>.

It might at first glance be expected that the appendix, if present, would be protective against *C. difficile* overgrowth. There is, however, at least one central problem with this supposition: it remains unknown if the appendix can effectively protect mutualistic bacteria against the modern antibiotics which generally precede *C. difficile* colitis. It seems reasonable that the appendix has evolved in the presence of enteric pathogens and thus that it may be effective in helping the body to recover from infectious disease. However, the use of high dose antibiotics is a very recent development in human history, and thus it is not reasonable to assume that the appendix may be

protective under these conditions. To our knowledge, no studies have addressed this issue. Our laboratory has assessed the protection from antibiotics afforded by immune-mediated biofilms *in vitro*, and found that immune mediated biofilms formed by one species (*Escherichia coli*) are poorly protected from antibiotics. However, much additional work needs to be done in this field using a wide range of microbial species as well as whole animal models before any sort of answer which might have clinical implications can be obtained.

The supposition that the appendix, if indeed it is a safe-house for bacteria, should be protective against *C. difficile* colitis has a second potential flaw: If indeed the appendix does not protect mutualistic bacteria from antibiotic use, the appendix could hypothetically protect those organisms which are resistant to antibiotics, such as *C. difficile*, from a diarrheal purge. Thus, if the appendix performs its function perfectly, it could hypothetically increase the incidence of *C. difficile* colitis in the face of antibiotic use. Fortunately, this does not appear to be the case. At present, clinical data point toward the idea that the presence or absence of an appendix does not strongly affect the propensity for the initial onset of *C. difficile* colitis. In a study by Im *et al.*<sup>[42]</sup>, 80% of their patients with *C. difficile* colitis (203 out of 253) had an appendix, which is only slightly lower than the percentage found in the total population<sup>[1]</sup>. Another study, by Merchant *et al.*<sup>[41]</sup>, obtained essentially identical results, with 80% of their patients with *C. difficile* colitis (109 out of 136) having an appendix. Merchant *et al.*<sup>[41]</sup> found that 82% of “normal” individuals (in their study, patients without GI complaints) had an appendix, as would be expected based on larger studies<sup>[1]</sup>. However, these observations do not directly address the actual effect of the appendix on the propensity for *C. difficile* colitis following antibiotic use, since they do not address the effect of appendectomy on the use of antibiotics. In other words, the data indicate that appendectomy does not affect the risk for *C. difficile* colitis, but it does not indicate whether an appendectomy might affect the risk for *C. difficile* colitis following antibiotic treatment. Since Merchant *et al.*<sup>[41]</sup> did not control for antibiotic treatment, increased antibiotic use in those with an appendix, if it exists, would have confounded the study. Nevertheless, the observations do clearly indicate that the loss of an appendix is not associated with a dramatically increased risk for an initial onset of *C. difficile* colitis.

As stated above, it is possible that a perfectly functional appendix, if indeed it did not protect the normal flora from antibiotics, might selectively protect antibiotic resistant organisms such as *C. difficile* from a diarrheal purge. This possibility has been previously proposed by Merchant *et al.*<sup>[41]</sup>. However, since the relative number of patients with and without an appendix in patient groups with *C. difficile* colitis is essentially the same as that in the normal population, the possibility that the appendix preferentially protects *C. difficile* seems extremely unlikely. Further, appendectomy itself affords a much lower risk of *C. difficile* colitis (0.2%) compared to colectomy (1.11%)

**Figure 2** The cycle of microbiome depletion with antibiotics, the occurrence of *Clostridium difficile* colitis, and recovery of the microbiome. The cycle is initiated when the normal colon (A) is depleted of its microbiota using broad spectrum antibiotics (B). Although the microbiota often recovers spontaneously from such treatment, the patient is at risk of *Clostridium difficile* (*C. difficile*) colitis (C and D) in a fashion that is independent of the presence of an appendix. Although *C. difficile* colitis is often effectively treated with metronidazole or vancomycin (E), the microbiome can fail to normalize, leading to recurrent *C. difficile* colitis. This cycle of treatment followed by recurrence is indicated by the red arrows. The presence of a vermiform appendix enhances recovery (A and F) of a normal microbiome following *C. difficile* colitis (green arrow), thus averting the cycle of recurrent *C. difficile* colitis. Colonic microbiota transplants (CMT) are also effective at restoring the normal flora and interrupting the cycle of recurrent *C. difficile* colitis.

small-bowel resection (1.17%) and gastric resection (1.02%)<sup>[41]</sup>, further suggesting that the appendix may be relatively uninvolved in the initial onset of *C. difficile* colitis. In addition, the fact that an intact appendix protects against recurrent (as opposed to the initial onset of) *C. difficile* colitis (see below) argues strongly against this view. However, again, it is not known to what extent the presence or absence of an appendix might affect antibiotic use, the major trigger for *C. difficile* colitis. This factor probably needs to be examined before any firm conclusions can be drawn.

**The appendix and recurrent *C. difficile* colitis**

Strong evidence from Im *et al*<sup>[42]</sup> study indicates that the appendix may play a protective role in recurrent *C. difficile* colitis. Im *et al* found a 2.5-fold increased risk of recurrent *C. difficile* colitis in patients without an appendix compared to those with an appendix. Figure 2 illustrates a possible scenario that potentially explains the connection

between the appendix, the initial onset of *C. difficile* colitis, and recurrent *C. difficile* colitis. The central issue revolves around the use of broad spectrum antibiotics which initiate the initial *C. difficile* colitis, and the more limited antibiotic treatments used after the first *C. difficile* infection. The standard of care for recurrent and severe *C. difficile* colitis is oral vancomycin, a treatment that is limited to the lumen of the bowel. Given the position of the appendix out of the main flow of the bowel, it seems likely that it may indeed be effective at protecting the normal flora from oral vancomycin, just as it putatively protects the normal flora from contamination by pathogens in the main fecal stream.

Consistent with the idea that the connection between recurrent *C. difficile* colitis and the appendix involves the bacterial safe-house function of the appendix, recurrent *C. difficile* colitis can be rapidly resolved using fecal microbiome transplants<sup>[43-45]</sup>. This observation indicates that *C. difficile* colitis is indeed an issue involving a depleted gut

microbiome, thus adding support to the idea that an appendix might help restore the gut microbiome in times of stress. Indeed, proof of a depleted biome in recurrent *C. difficile* colitis patients has been provided by phylogenetic analyses of stool samples in patients with recurrent *C. difficile* colitis: decreased bacterial diversity<sup>[46]</sup> as well as a deficiency of Firmicutes and Bacteroidetes<sup>[47]</sup> have been demonstrated in those patients.

Although the function of the appendix as a safe-house for the colonic microbiome explains the clinical observations illustrated in Figure 2, an alternative, although not mutually exclusive, explanation also exists: as noted above, appendectomy probably lowers the immunoreactivity of the gut, and thus may lower the ability of the gut to respond to *C. difficile*. Thus, the loss of the appendix may, hypothetically, reduce the ability of the immune system to mount an immune response to *C. difficile*, which is known to be important in the resolution of the colitis. Thus, a second explanation for the connection between appendectomy and recurrent *C. difficile* colitis shown in Figure 2 may be that the immunosuppressive effect of appendectomy impedes the immune response to *C. difficile*, thus putting the patient at risk for recurrent *C. difficile* colitis. Consistent with this view, Im's data also indicated that increasing age (> 60 years), which is associated with reduced immune function, was also a risk factor for recurrent *C. difficile* colitis<sup>[42]</sup>. In this view, the lack of a connection between the initial onset of *C. difficile* colitis and appendectomy may be due to the lack of time necessary to mount an immune response that would be dependent on the immune tissue of the appendix.

### **The appendix and gastrointestinal pathology unrelated to *Clostridium difficile***

A potentially alarming observation was made in the study by Merchant *et al*<sup>[41]</sup>: 31 percent (39 out of 121) of their patients which were tested for *C. difficile* colitis but which were found negative for *C. difficile* colitis had a previous appendectomy. This number is very significantly greater than is expected if the presence or absence of an appendix was not related in some way: The probability (binomial test) of observing 38 out of 121 patients with an appendectomy is < 0.0001 given a null hypothesis of 0.18 (a population-wide rate of 18% appendectomy). If this observation is confirmed by additional studies, it would indicate an association between appendectomy and complications which resemble *C. difficile* colitis (and thus induce clinicians to order a test for *C. difficile*), but which are in fact not associated with *C. difficile*. This idea deserves further attention before any firm conclusions can be drawn, but the observations made by Merchant *et al*<sup>[41]</sup> nevertheless have great potential importance, and certainly raise a sense of urgency for further study of this topic.

The strongest connection between appendectomy and inflammatory diseases unrelated to *C. difficile* colitis of the bowel is provided by the Merchant *et al* study<sup>[41]</sup>. However, additional indirect evidence for this connection

is provided by the effectiveness of colonic microbiota transplants in treating some patients whose disease has resisted other therapeutic options<sup>[43,44]</sup>. The effectiveness of microbiota transplants in some patients strongly indicates that a loss of the normal microbiome is at the root of the symptoms experienced by these patients. Thus, to the extent that the appendix assists in maintenance of the microbiome, the lack of an appendix may influence the incidence of these idiopathic cases. At the same time, it is recognized that loss of the microbiome by a wide range of modern medical interventions (*e.g.*, sterile birth practices, broad spectrum antibiotics) may circumvent any protective role of the appendix, and direct assessment of the rate of appendectomy in patients with an altered microbiome should be undertaken.

### **Alternatives to appendectomy**

Acute appendicitis is the widely recognized indication for appendectomy, although alternatives involving medical treatment are being considered. Medical treatment alone has the substantial disadvantages that (1) heavy use of antibiotics must be employed, which is not without its own side effects; and (2) recurrence of appendicitis following antibiotic use is possible. A controlled study by Eriksson *et al*<sup>[48]</sup> compared the outcomes of patients treated with a 10 d antibiotic regimen (cefotaxime and tinidazole in the hospital for two days followed by eight days of oral antibiotics) versus patients who underwent appendectomy. They found that patients on the antibiotic regimen used significantly less morphine, had lower white blood cell counts, and had less pain at follow up. Two surgical patients underwent post-operative antibiotic therapy for complications, and there was an appendicitis recurrence rate of 35% in the antibiotic group. Another study by Styruud *et al*<sup>[49]</sup> saw an 86% success rate with antibiotics with only a 14% recurrence rate within one year. The complication rate in the surgical group was 14%. These studies suggest that acute non-perforated appendicitis can be treated conservatively with an antibiotic regimen; however, the risk of recurrence should be compared to the risk of surgical complication in the patient.

Antibiotics have also proven effective at delaying appendectomy. Nine sailors who were diagnosed with appendicitis while serving at sea received various antibiotic regimens until the men could be taken to a hospital, and all achieved positive outcomes<sup>[50]</sup>. A study of 695 children showed that an antibiotic regimen in children allowed the appendectomy to be delayed up to 18 h after admission without an increase in complications<sup>[51]</sup>.

## **CONCLUSION**

It seems highly likely that the appendix, evolved in a time before sewer systems and water treatment facilities existed, is somewhat out of place in post-industrial society. Removal of the appendix and its associated GALT does afford some degree of immune suppression, which can be advantageous in a post-industrial environ-

ment rampant with inflammatory diseases of the bowel. However, removal of the appendix may also impede the ability of the body to replenish helpful bacteria, and/or appendectomy might hinder helpful immune responses, such as those directed at *C. difficile*. Whatever the cause, appendectomy appears to be associated with an increased risk for recurrent *C. difficile* colitis, which is not a minor problem in modern medical practice. Indeed, one study found nosocomial *C. difficile* diarrhea present in 3.4 to 8.4 cases per 1000 hospital admissions<sup>[40]</sup>, and an increase in in-hospital mortality from 2.4% to 13.5%<sup>[41]</sup>. With this in mind, further studies aimed at biome reconstitution, which are predicted to eliminate the vast majority of appendicitis cases, and thus the need for most appendectomies, are warranted. Further, studies regarding the long term effects of incidental appendectomies should be carefully considered.

**Key words:** Colorectal cancer; MicroRNA; Diagnosis; Treatment; Chemotherapy

**Core tip:** We summarize the latest study findings about microRNA-21 in colorectal cancer through a systematic review of literature. We recommend microRNA-21 as one of the most important microRNAs, which is rapidly emerging as a novel biomarker, with good potential as a diagnostic and therapeutic target.

### Abstract

Colorectal cancer (CRC) is one of the most common malignant diseases worldwide and the prognosis is still poor although much progress has been achieved in recent years. In order to reduce CRC-related deaths, many studies are aimed at identifying novel screening- and prognosis-related biomarkers. MicroRNAs (miRNAs) are a class of 18-27-nucleotide single-stranded RNA molecules that regulate gene expression at the post-transcriptional level. It has been demonstrated that miRNAs regulate a variety of physiological functions, including development, cell differentiation, proliferation, and apoptosis. They play important roles in various physiologic and developmental processes and in the initiation and progression of various human cancers. It has been shown that miRNAs can critically regulate tumor cell gene expression, and evidence suggests that they may function as both oncogenes and tumor suppressor genes. In CRC, miRNAs-21 is one of the most important miRNAs and is rapidly emerging as a novel biomarker in CRC, with good potential as a diagnostic and therapeutic target. In this review, we summarize the latest research findings of the clinicopathological relevance of miRNAs-21 in CRC initiation, development, and progress, highlighting its potential diagnostic, prognostic, and therapeutic application, as well as discuss-

Li T, Leong MH, Harms B, Kennedy G, Chen L. MicroRNA-21 as a potential colon and rectal cancer biomarker. *World J Gastroenterol* 2013; 19(34): 5615-5621 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i34/5615.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i34.5615>

### INTRODUCTION

Colorectal cancer (CRC) is the third most common cancer and the second leading cause of death in the United States. It was estimated that there were about 142570 new cases diagnosed and 51370 deaths in 2010<sup>[1]</sup>. Progress in diagnosis and treatment has had a positive effect in improving overall survival, with more patients being diagnosed in the early stage of the disease, but the outcomes of patients diagnosed with advanced stage disease remains quite poor<sup>[2]</sup>. Long-term survival and better prognosis of patients depend on the stage of the tumor at the time of detection. Fecal occult blood testing and tumor markers (*e.g.*, carcinoembryonic antigen) are used as the primary screening tools, with colonoscopy reserved for patients testing positive. However, they are generally considered to lack the desired convenience, sensitivity and specificity<sup>[3]</sup>. There are currently no tests or biomark-

ers that precisely predict the presence of early tumors, recurrence, sensitivity to chemotherapy and long-term survival. It is clear that improvements in early detection of primary and recurrent disease are required.

MicroRNAs (miRNAs) are a family of small, non-coding RNAs (19-22 nucleotides) which post-transcriptionally regulate gene expression. In general, miRNAs are transcribed as a group called the pri-miRNA complex, which is cleaved in the nucleus to form the pre-miRNA which is then translocated to the cytoplasm where they undergo final maturation into a functional miRNA<sup>[4]</sup>. Once in the cytoplasm, the miRNAs regulate gene expression by binding to the 5'-untranslated region of their target mRNA resulting in degradation of the double-stranded mRNA mediated by the Dicer complex. More than 700 miRNAs have thus far been identified in plants, viruses, animals and humans, and this number continues to increase (www.mirbase.org). Studies have shown that about 30% of human genes are regulated by miRNAs<sup>[5]</sup>. This wide regulation has implications in many important cellular functions including development, differentiation, proliferation, and programmed cell death<sup>[6-8]</sup>. Given the critical regulatory roles miRNAs serve, it is no surprise that they have been shown to be associated with many cancers<sup>[9]</sup>. CRC is a complex genetic disease characterized by uncontrolled proliferation, migration, invasion, and failure of apoptotic cell death, due to oncogene activation and tumor suppressor gene defects<sup>[10]</sup>. Many miRNAs which mediate cell growth and tumor progression have been found to be upregulated in CRC including miR-20, miR-21, miR-17-5p, miR-15b, miR-181b, miR-191 and miR-200c<sup>[9,11-14]</sup>. While lower levels of mature miRNAs such as miR-34a, miR-126, miR-143, miR-145 and miR-342 are also found, suggesting that they act as tumor suppressor miRNAs<sup>[15-18]</sup>. This deregulation of various miRNAs has been associated with tumor diagnosis and prognosis indicating that they might be potential biomarker in clinical application<sup>[3,19-21]</sup>. Multiple studies have identified that miR-21 plays a significant role in cancer biology, diagnostics and prognosis. In this article, we review the literature demonstrating the importance of miR-21 in CRC, summarize the association of miR-21 expression level with CRC diagnosis and prognosis, and discuss the potential therapeutic implications for the future.

## MIR21 IN COLORECTAL CANCER

Human miR-21 (hsa-miR-21) was cloned from HeLa cell total RNA and is highly conserved among species including human, rat, mouse, fish and frog<sup>[22]</sup>. It is located on chromosome 17q23-1 overlapping with the TMEM49 gene, a human homologue of rat vacuole membrane protein-1. MiR-21 encodes a single hairpin and is regulated by its own promoter containing binding sites for AP-1 and PU.1 transcription factors<sup>[23]</sup>. Experimental data has shown that miR-21 functions in many cell types as an anti-apoptotic and pro-survival factor and plays a significant role in cancer biology and prognosis<sup>[24-26]</sup>. Asangani *et al.*<sup>[26]</sup> transfected Colo206f cells with miR-21 and found

**Table 1 Current screening methods and guidelines for colorectal cancer**

Method	Sensitivity	Interval	Society
Fecal tests			
FOBT		Yearly	USPSTF, ASGE, USMSTF
FIT	65.8% <sup>[32,33]</sup>	Yearly	
Fecal DNA	50%-60% <sup>[34]</sup>	Unspecified	USMSTF
Serum markers			
CEA	30% <sup>[35]</sup>		
CA19-9			
Imaging tests			
DCBE	85%-97% <sup>[36]</sup>	Every 5 years	USMSTF
CTC	55%-94% <sup>[37]</sup>	Every 5 years	USMSTF
Optical tests			
FS		Every 5 years Every 10 years	USPSTF, ASGE, USMSTF
FC			USPSTF, ASGE, USMSTF

FOBT: Fecal occult blood test; FIT: Fecal immunochemical based stool tests; CEA: Carcinoembryonic antigen; DCBE: Double-contrast barium enema; CTC: Computed tomography colonography; FS: Flexible sigmoidoscopy; FC: Flexible colonoscopy; USPSTF: United States Preventive Services Task Force; ASGE: American Society for Gastrointestinal Endoscopy; USMSTF: Multi-Society Task Force on Colorectal Cancer.

significant suppression of PDCD4 proteins *in vitro*. Resected normal and tumor tissues of 22 CRC patients demonstrated that miR-21 expression has a direct correlation with tumor invasion and metastasis.

### miR-21 in adenomas

It is clear that the majority of CRCs begin as benign adenomas, and through a series of accumulated genetic events, end up as invasive tumors. However, not all polyps will progress to invasive carcinomas. In fact, it is estimated that up to 20% of benign, subcentimeter adenomas will ultimately regress<sup>[27,28]</sup>. Therefore, it seems that the key to preventing polyps from progressing to malignant carcinomas is being able to determine which ones have the potential to progress and removing them at the benign stage. Interestingly, increased expression of several miRNAs such as miR-21, miR-31, miR-96, miR-221, miR-191, miR-19a, and miR-135b has been shown to correlate with the presence of adenomas<sup>[29,30]</sup>. In fact, Yamamichi *et al.*<sup>[31]</sup> analyzed miR-21 expression patterns in different stages of CRC development using *in situ* hybridization, and found higher miR-21 expression in precancerous adenomas but not in non tumorigenic polyps. Furthermore, the frequency and extent of miR-21 expression increased during the transition from precancerous colorectal adenoma to advanced carcinoma. This demonstrates that expression of miR21 in benign colon adenomas may represent an early event in the progression to carcinoma.

### Expression of miR-21 as a screening test for colorectal cancer

Current recommendations for CRC screening are found in Table 1<sup>[32-37]</sup>. Fecal occult blood testing is a widely used test but its low specificity and sensitivity limits its clinical

use, particularly for early detection. Newer screening tests are taking advantage of the presence of stem cells from human exfoliated deciduous teeth cells in the stool and are using various molecular tests to examine these cells for genetic events consistent with malignant changes. Expression levels of miRNAs offer attractive new potential biomarkers as they are uniquely stable and may represent some of the earliest changes in adenomas. Ng *et al.*<sup>[38]</sup> reported high expression levels of miRNAs in colorectal tumors and plasma. Of the panel of 95 miRNAs analyzed by real-time polymerase chain reaction (PCR), five were upregulated in both plasma and tissue. The results were again validated using the plasma of 25 patients with CRC and 20 healthy controls. In these studies, the miRNAs 21, 17-3p, and 92 were elevated in patients with CRC ( $P < 0.0005$ ). The authors further demonstrated that the plasma levels of these markers were significantly reduced after surgery in 10 patients with CRC ( $P < 0.05$ ) suggesting that the high levels specifically indicate the presence of a carcinoma. Kristina *et al.* tested the levels of 15 miRNAs in stool and colorectal tissue samples from 15 patients with CRC and five healthy individuals<sup>[39]</sup>. Although, variability was more pronounced among the stool samples than the tissue samples, the authors concluded that specific miRNA expression profiles could be defined, suggesting that stool is yet another biological material in which miRNAs are preserved and are amenable for early diagnosis of CRC. A stage-independent, sensitive, and specific marker for CRC in plasma or stool would be clinically important, and clearly these promising results support further assessment of miRNAs as potential biomarkers both in adenoma and extracellular fluids.

### **miR-21 expression levels and prognosis**

The prognosis of patients with CRC is associated with tumor stage and phenotypic characteristics of resected cancer specimens such as tumor grade, positive lymph nodes, and angiolymphatic invasion<sup>[40]</sup>. Unfortunately, recently identified genomic and proteomic biomarkers, tumor cell mutations, and microsatellite instability cannot be recommended for routine clinical use because of insufficiently available data<sup>[41]</sup>. However, markers of prognosis are needed to help stratify patients into high risk thereby identifying patients who are likely to benefit from further therapy. Many studies on tumor biomarkers have been undertaken<sup>[42]</sup>. However, no study has identified a new marker that has been validated in clinical trials. The miRNAs represent particularly attractive markers as they seem to be micromanagers of cellular gene expression and may represent the earliest events responsible for carcinogenesis. In fact, studies have shown that the expression levels of different miRNAs, such as miR-21, miR-320, miR-498, miR-106a and miR-200c, correlate with disease-free and overall survival<sup>[43]</sup>.

miR-21 may be a particularly attractive target as it has been shown to regulate the expression of many genes thought to be important in carcinogenesis. Target validation studies on putative miR-21 targets in breast cancer samples and CRC cells have demonstrated a link between

miR-21 expression levels and the p53 tumor suppressor, and also demonstrated that the tumor suppressors PDCD4 and maspin are targets of miR-21<sup>[44]</sup>. Consistent with the importance in the process of carcinogenesis, Staby *et al.*<sup>[45]</sup> demonstrated that higher miR-21 expression levels were correlated with advanced cancer stages, worse outcome, poor response to therapy, and shorter disease-free survival. Additionally, they found that miR-21 levels were positively correlated with cancer stage, lymph node involvement, and development of distant metastasis.

The most comprehensive analysis of miRNA expression in CRC performed to date tested two cohorts of 197 colon cancer patients by utilizing microarrays containing 389 miRNAs probes<sup>[46]</sup>. This analysis revealed 37 miRNAs which were differentially expressed in stage II colonic adenocarcinoma compared with adjacent normal tissue using a test set and two validation cohorts. In one of the cohorts, miR-20a, miR-21, miR-106a, miR-181b, and miR-203 were found to be overexpressed in tumor tissues with high tumor to normal ratios, as well as being associated with poor overall survival. However, the prognostic relevance could be confirmed in the validation set for only one of the candidates, miR-21, and the clinical and biological implications of differential expression of the remaining miRNAs were unclear. Similar conclusions were drawn from a study of 29 tumor samples, in which miR-21 expression was associated with poor survival and therapeutic outcome in stage II and III CRC<sup>[46]</sup>. Nielsen *et al.*<sup>[47]</sup> reported the expression of miRNA-21 in 130 colon and 67 rectal stage II cancer specimens using high-affinity locked nucleic acid (LNA) probes. High levels of miR-21 correlated with shorter disease-free survival (hazard ratio: 1.28; 95% confidence interval: 1.06-1.55;  $P = 0.004$ ) in the stage II colon cancer patient group, whereas no significant correlation with disease-free survival was observed in the stage II rectal cancer group.

### **miR-21 expression and implications for treatment**

**miR-21 and response to chemotherapy:** The current treatment for CRC involves a multidisciplinary approach including surgery supplemented with chemotherapy and radiation therapy in certain instances. In general, patients with node-positive disease benefit from chemotherapy. However, there may be a subgroup of patients with node-positive disease who are at low risk of recurrence, as nearly 40% of patients randomized to a no-treatment arm in chemotherapy trials did not develop a recurrence<sup>[48]</sup>. In addition, it is clear that some patients with node-negative disease who have advanced T-stage tumors are at high risk of developing recurrences<sup>[49]</sup>. A test that would allow for the accurate stratification of patients with stage II and III disease into low and high risk would be very clinically useful. Recently, the role of miRNAs in predicting the response to 5-fluorouracil (5-FU)-based chemotherapy in CRC treatment has been explored. A significant focus has been placed on the value of miR-21 expression levels and their abilities to predict both response to and need for chemotherapy<sup>[50]</sup>.

Rossi *et al.*<sup>[51]</sup> utilized two subclones from the human

**Table 2** MicroRNA-21 expression in colorectal cancer

Ref.	Regulation	Biological material tested	Detection method	Clinical relevance	Comment
Tumor development Fassan <i>et al</i> <sup>[60]</sup>	Up	300 polypoid lesions of the colon mucosa	RT-PCR ISH	Significant miR-21 upregulation in preneoplastic/neoplastic samples	High miR-21 expression is consistent with PDCD4 downregulation
Yantiss <i>et al</i> <sup>[61]</sup>	Up	24 patients < 40 years 45 patients ≥ 40 years	RT-PCR	Significantly higher expression	
Tumor diagnosis Link <i>et al</i> <sup>[62]</sup>	Up	Stool samples	RT-PCR	Higher expression in patients with adenomas and CRCs	May be an excellent candidate of a noninvasive screening test for colorectal neoplasms
Tumor prognosis Chang <i>et al</i> <sup>[63]</sup>	Up	48 colorectal tumors, 61 normal tissues, 7 polyps	RT-PCR	Disease recurrence	miR-21 post-transcriptionally modulates PDCD4 <i>via</i> mRNA degradation
Nielsen <i>et al</i> <sup>[47]</sup>	Up	130 stage II colon and 67 stage II rectal cancer specimens	ISH	Shorter disease-free survival in colon cancer, but not in rectal cancer	
Kulda <i>et al</i> <sup>[64]</sup>	Up	46 paired tissue samples 30 tissue samples with live metastasis	RT-PCR	Disease-free interval	
Schetter <i>et al</i> <sup>[46]</sup>	Up	196 paired tissues	RT-PCR	Association with cancer-specific mortality, including stage II patients alone	miR-21 expression are independent predictors of colon cancer prognosis and may provide a clinically useful tool to identify high-risk patients
Schetter <i>et al</i> <sup>[46]</sup>	Up	US cohort: 84 patients; Hong Kong cohort: 113 patients	MicroRNA microarray, RT-PCR	Poor survival and poor therapeutic outcome	

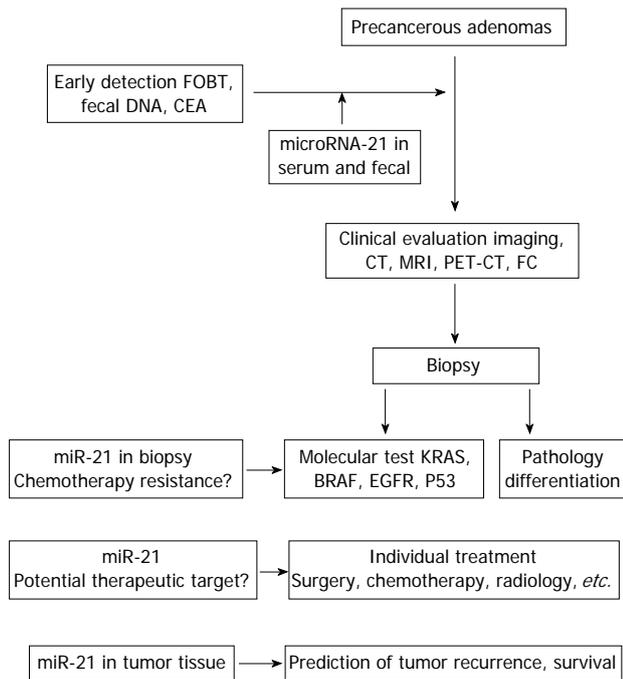

RT-PCR: Reverse transcription-polymerase chain reaction; ISH: *In situ* hybridization; PDCD4: Programmed cell death protein 4.

CRC cell lines HT29 and HCT116 to investigate the effect of 5-FU on miRNA expression and also to determine patterns of expression that correlated with response to therapy. Quantitative real-time PCR revealed that 5-FU upregulated 19 and downregulated three miRNAs. While some changes in miRNA expression were consistent with the antitumor effects of the drug, others were not, such as upregulation of miR-21 and the polycistronic miR-17-92 cluster (which include miR-19a and miR-20). In fact, a number of miRNAs that are already overexpressed in neoplastic tissues, including miR-21, have been shown to be upregulated in colon cancer cell lines treated with 5-FU<sup>[51]</sup>. Tomimaru *et al*<sup>[52]</sup> found that hepatocellular carcinoma cells transfected with pre-miR-21 were significantly resistant to 5-FU, while the 5-FU sensitivity of transfected anti-miR-21 was weakened by transfection with siRNAs of the target molecules, PTEN and PDCD4. This finding may be a cell-specific defense mechanism to survive 5-FU treatment. Svoboda *et al*<sup>[53]</sup> found significant changes in miRNA expression in 35 patients with rectal carcinoma undergoing preoperative capecitabine chemoradiation therapy. Tumor biopsies were taken before starting therapy and after 2 wk of therapy. The extent of the tumor response to the therapy was investigated microscopically by an experienced pathologist according to Mandard's tumor regression criteria. In addition, the levels of miRNAs were evaluated using real-time PCR. The authors found dramatic changes in the expression levels of many miRNAs including miR-21,

miR-10a, miR-145, miR-212, miR-339, miR-361. However, only two miRNAs, miR-125b and miR-137, were found to be significantly increased after 2 wk of therapy and these miRNA expression levels had a positive correlation with a poorer tumor regression response<sup>[53]</sup>. These types of studies highlight the potential for using miRNA expression profiles to predict the response to chemotherapy. However, verification of the targets in adequately designed clinical panels is the important next step that has yet to be taken.

**miR-21 maybe a potential therapeutic target in colorectal cancer treatment:** miRNAs are important regulators of gene expression and may present potentially interesting therapeutic targets in cancer. The synthesis, maturation and activity of miRNAs can be manipulated with various oligonucleotides that encode the sequences complementary to mature miRNAs. By influencing particular miRNAs, a cascade of pathways could be modified to inhibit tumor growth.

Wong *et al*<sup>[54]</sup> reported the application of 20-O-methyl-and/or DNA/LNA-mixed oligonucleotides to specifically inhibit miR-21 in cultured glioblastoma and breast cancer cells suppressed cell growth *in vitro* in association with increased caspase-mediated apoptosis<sup>[55]</sup>. Suppression of miR-21 also significantly reduced invasion and lung metastasis in MDA-MB-231 metastatic breast cancer<sup>[56]</sup>. Although there are at present no clinical reports describing therapy targeting miR-21 in CRC treatment,

**Figure 1** miR-21 as a potential biomarker in colon and rectal cancer. CT: Computed tomography; MRI: Magnetic resonance imaging; PET-CT: Positron emission tomography-computed tomography; FC: Fiber colonoscopy; FOBT: Fecal occult blood test; CEA: Carcinoembryonic antigen.

most seem to have optimistic views on the future utility of miR-21 as therapeutic targets but further studies are clearly needed<sup>[57-59]</sup>. Expression of microRNA-21 and the clinical relevance in CRC are summarized in Table 2.

## FUTURE PERSPECTIVES

The role of miRNAs in CRC presents potentially exciting new opportunities for future investigations to determine the use of miRNAs as potential biomarkers for prognosis at the time of diagnosis as well as to determine their ability to predict the response to chemotherapy. In addition, the potential for miRNAs to serve as targets for new chemotherapeutic treatments has yet to be realized. Among the many miRNAs that have been associated with clinical outcomes, miR-21 has been consistently shown to be dysregulated in CRC. Many of the early studies relating miR-21 to CRC have been performed *in vitro* on established cell lines. In addition, studies using human tumor tissue have been performed in a retrospective fashion, which limits the conclusions because of inherent study bias. If these micromanagers of cell processes are to be useful tools in the diagnosis or treatment of colon cancer, we will have to study them in well-designed prospective trials. It remains to be discovered if these types of molecular expression profiles will be used in clinical practice (Figure 1).

### Abstract

**AIM:** To assess the possible effect of two different types of preoperative transcatheter arterial chemoembolization (TACE) on recurrence-free survival after liver transplantation (LT) in patients with hepatocellular carcinoma (HCC) and to analyze the effects of TACE on tumor histology.

**METHODS:** We retrospectively analyzed the histological features of 130 HCC nodules in 63 native livers removed at transplantation. Patients who received any other type of treatment such as radiofrequency tumor ablation, percutaneous ethanol ablation or who were not treated at all were excluded. All patients in the present study were within the Milan Criteria at the last imaging findings before transplantation. Doxorubicin-eluting bead TACE (DEB-TACE) was performed in 22 patients (38 nodules), and conventional TACE (c-TACE) in 16 (25 nodules). Patients' and tumors' characteristics were retrospectively reviewed. We performed a per-nodule analysis of the explanted livers to establish the mean percentage of necrosis of any nodule treated by TACE (conventional or DEB) and a per-patient analysis to establish the percentage of necrosis in the cumulative tumor area, including 21 nodules not reached by TACE. Inflammatory and fibrotic changes in the tissue surrounding the tumor nodule were analyzed and categorized as poor/absent, moderate and enhanced reaction. Uni- and multivariate analysis of risk factors for HCC-recurrence were performed.

**RESULTS:** The number and diameter of the nodules, the time spent on the waiting list and the number of treatments were similar in the two groups. A trend towards higher appropriate response rates (necrosis  $\geq$

90%) was observed in the DEB-TACE group (44.7% vs 32.0%,  $P = 0.2834$ ). The mean percentage of necrosis in the cumulative tumor area was  $58.8\% \pm 36.6\%$  in the DEB-TACE group and  $50.2\% \pm 38.1\%$  in the c-TACE group ( $P = 0.4856$ ). Fibrotic and inflammatory reactions surrounding the tumor nodule were markedly more common in the DEB-TACE group ( $P < 0.0001$ , for both the parameters). The three-year recurrence-free survival was higher in DEB-TACE-treated patients than in conventionally treated patients (87.4% vs 61.5%,  $P = 0.0493$ ). Other factors affecting recurrence-free survival included viable tumor beyond Milan Criteria on histopathological examination, the percentage of necrosis on CTA  $\leq 50\%$  and a pre-transplant serum  $\alpha$ -fetoprotein level greater than 70 ng/mL. On multivariate analysis, the lack of treatment with DEB-TACE, high levels of  $\alpha$ -fetoprotein and viable tumor beyond Milan Criteria at histology examination were identified as independent predictors of tumor recurrence.

**CONCLUSION:** DEB-TACE can effectively promote tumor necrosis and improves recurrence-free survival after LT in HCC.

**Key words:** Liver transplantation; Hepatocellular carcinoma; Transcatheter arterial chemoembolization; Doxorubicin-eluting bead; Tumor histology; Recurrence-free survival; Locoregional therapies

**Core tip:** The manuscript reports the experience with a newer technique of transcatheter arterial chemoembolization (TACE) that uses doxorubicin-eluting beads (DEB) for the treatment of hepatocellular carcinoma in liver transplant candidates. The results of DEB-TACE were compared to those of conventional TACE, and remarkably, a significantly higher recurrence-free survival after liver transplantation was observed in patients who were treated with DEB-TACE. The histological pattern observed in the area surrounding the tumor nodules of DEB-TACE patients was characterized by an intense inflammatory and fibrotic reaction, which could play a role in limiting tumor spread during waiting list time.

## INTRODUCTION

Hepatocellular carcinoma (HCC) accounts for approximately 5% of all cancers, with more than 500000 new cases diagnosed each year<sup>[1]</sup>. The link between liver cir-

rhosis and HCC is well known; more than 90% of HCCs develop in cirrhotic livers, and 3%-8% of cirrhotic patients are diagnosed as HCC carriers each year<sup>[2]</sup>. Ideally, liver transplantation (LT) is the best treatment option for HCC, as it removes both the tumor and the underlying chronic condition<sup>[3]</sup>.

Milan Criteria (MC) of LT candidates with HCC, based on the number and size of the tumor nodules, has led to 5-year survival rates well above 70% and recurrence rates below 15%<sup>[4]</sup>. Currently, more than 30% of LT recipients in the United States are HCC carriers<sup>[5]</sup>.

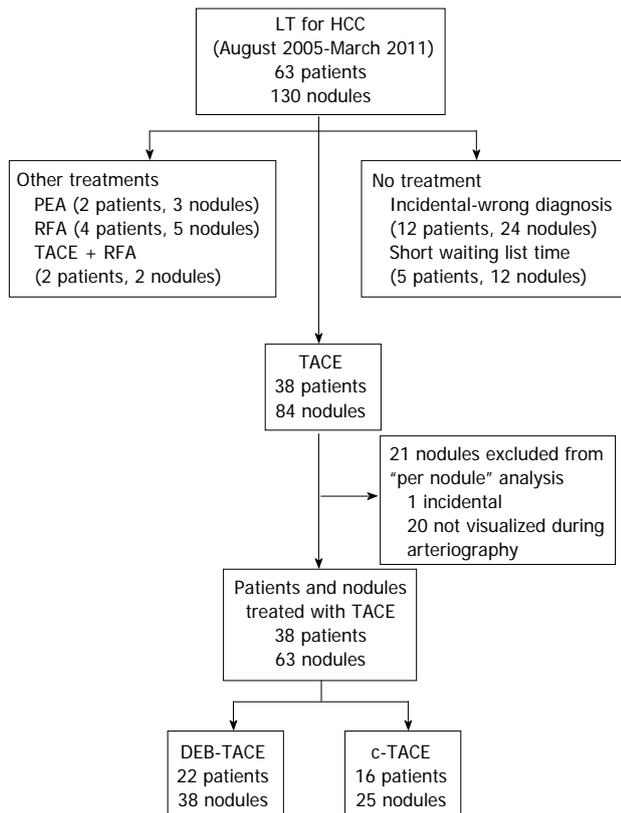

In an intent-to-treat purpose, one of the major limitations of LT in HCC carriers is the time spent on the waiting list; the risk of tumor progression increases with time, resulting in a cumulative probability of dropout from the waiting list of 7.2% for a 6-mo waiting time, which rises to 37.8% and 55.1% for 12 and 18 mo of waiting time, respectively<sup>[6]</sup>.

To attempt to cure to a larger number of HCC carriers, two strategies have been outlined. The first is to downstage those tumors that exceed the Milan Criteria at the time of the first observation, thereby allowing transplantation. The second strategy is to delay the tumor growth using locoregional treatments while the patient is on the waiting list to reduce the dropout rate. The response to locoregional treatment is related to patient prognosis and seems to denote favorable tumor biology<sup>[7-10]</sup>.

Transcatheter arterial chemoembolization (TACE) is the most frequently used treatment of HCC in LT candidates<sup>[11]</sup>. TACE is usually performed by administering a mixture of epirubicin and Lipiodol to concentrate the drug within the tumor. This is followed by a gelatin sponge (conventional TACE, c-TACE) to obtain occlusion of the feeding arteries of the tumor, with the aim of producing infarction and necrosis of the tumor tissue. Recently, a novel doxorubicin-eluting bead (DEB) has been developed to bind, deliver and elute chemotherapeutic drugs in the tumor area during TACE. Pre-clinical and clinical studies have demonstrated that DEB-TACE produces a higher drug concentration within the tumor than c-TACE while maintaining a lower systemic concentration<sup>[12-14]</sup>.

The assessment of the tumor response after TACE remains a critical issue; the Response Evaluation Criteria in Solid Tumors (RECIST), based on the sum of the largest diameter of target lesions on computed tomography (CT) or magnetic resonance (MR) before and during treatment, can be misleading when assessing the treatment-related tumor necrosis, which is not necessarily associated with a reduction in tumor diameter<sup>[15,16]</sup>. In 2001, a panel of experts concluded that an estimation of the reduction of viable tumor (recognized as the non-enhancing areas on a CT scan) should be considered the optimal method to assess local response (modified-RECIST)<sup>[17]</sup>.

However, CT findings often underestimate the residual tumor extent, which can be accurately determined only at histology<sup>[18]</sup>; in this regard, LT represents a unique set-

**Figure 1** Flow chart of the patients included in the study. TACE: Transcatheter arterial chemoembolization; DEB: Doxorubicin-eluting bead; HCC: Hepatocellular carcinoma; LT: Liver transplantation; PEA: Percutaneous ethanol ablation; RFA: Radiofrequency tumor ablation; c-TACE: Conventional TACE.

ting to correctly assess tumor necrosis induced by TACE, as the whole native liver becomes available for histological examination.

Although excellent tumor necrosis rates induced by TACE are reported in LT recipients<sup>[19]</sup>, the impact of TACE on recurrence-free survival remains to be established<sup>[20-22]</sup>.

The aim of this study was to compare DEB-TACE with c-TACE by assessing the histological features of the tumor nodules in native livers removed at transplantation, focusing on the degree of necrosis, as well as to assess the recurrence-free survival of HCC recipients after LT.

## MATERIALS AND METHODS

From August 2005 to March 2011, 63 liver transplants were performed in patients with HCC on cirrhosis in our center. We retrospectively analyzed the histological features of 130 HCC nodules in 63 native livers removed at transplantation (2.06 nodules per patient). Patients who received any other type of treatment, including radiofrequency tumor ablation (RFA) or percutaneous ethanol ablation (PEA), or those who were not treated at all were excluded from the present analysis, as described in Figure 1. Thirty-eight patients who received one or more TACEs as the only neoadjuvant therapy before LT represent the study population.

The policy of our center for TACE is to downstage those tumors that are initially beyond the MC. In the present study, only those patients who were successfully downstaged within the MC and therefore underwent LT are considered; TACE was also performed in those patients who fulfilled the MC and entered the waiting list with an expected waiting time longer than 2 mo. Based on the imaging findings, all the patients in the present study were within the Milan Criteria at the time of transplantation.

As the initial endpoint of our study was to confirm the safety of DEB-TACE and to assess its efficacy in achieving tumor necrosis in comparison with c-TACE, we performed a per nodule analysis of the explanted livers to establish the mean percentage of necrosis of any nodule treated by TACE (conventional or DEB). Twenty-one nodules were not reached by the treatment due to the failure to visualize the tumor’s feeding arteries during arteriography (20 cases) or failure to visualize the tumor itself in the pre-LT imaging (1 case); these 21 nodules were not included in the “per nodule” analysis to assess the mean percentage of necrosis produced by TACE. However, these nodules were taken into account in the “per patient analysis” and in the “survival analysis” to precisely quantify the neoplastic burden of each patient, which could influence the prognosis.

Demographics (age, sex), etiology of cirrhosis, the Child-Pugh and the Model for End Stage Liver Disease (MELD score), radiological and pathological tumor classification according to MC, laboratory tests, imaging studies and pathology reports were recorded for each patient. Factors related to tumor biology, such as serum alpha-fetoprotein, microvascular invasion (MVI) and grading, that play a key role in determining tumor recurrence<sup>[23-26]</sup> were compared between the 2 groups. The waiting time for LT and the interval between the last TACE and LT were also calculated. Computed tomography scans were performed one month after TACE and every 3 mo thereafter; candidates who were initially beyond MC at imaging were reassessed by two interventional radiologist according to the European Association for the Study of the Liver guidelines<sup>[17]</sup> to define the amount of tumor necrosis after TACE. When radiologic findings demonstrated viable tumor beyond MC, chemoembolization was repeated.

In addition to the type of TACE, the impact of the following risk factors on recurrence-free survival was also assessed: adherence to MC at pathology (considering only the viable portion of each nodule), tumor grading (G3-G4), the presence of MVI, the presence of multiple nodules at pathology, a percent necrosis in the cumulative tumor area (CTA) less than or equal to 50%, high levels of  $\alpha$ -fetoprotein (> 70 ng/mL) and the need to repeat TACE before LT.

### Transcatheter arterial chemoembolization

All patients underwent baseline celiac and superior mesenteric arteriography *via* a femoral artery approach. Prior to embolization, liver vascular anatomy was identified

to check the patency of the portal vein and visualize the arterial feeders of the tumor(s). The procedure was defined as “superselective” when the tip of a highly flexible coaxial microcatheter (2.7 Fr; Progreat; Terumo) was successfully placed in the branches supplying the tumor. When nodules were fed by multiple tiny arteries or when multinodular disease was present, TACE was performed with segmental or lobar (only for c-TACE group) catheterization (non-superselective TACE). Conventional TACE was performed by administering a mixture of 50 mg of epirubicin (Pfizer, New York, NY, United States) in an emulsion with lipiodol (Guebert, Aulnay-sous-Bois, France), followed by embolization with gelatin sponge particles (SPONGOSTAN; Johnson and Johnson, Gargrave, United Kingdom). DC beads (Biocompatibles, Farnham, Surrey, United Kingdom) became available at our institution beginning in June 2007; thereafter, patients were randomly assigned to one of the two techniques. The caliber of beads was chosen based on the type of catheterization, the vascularity of the lesion, and the tumor diameter. DEB-TACE was performed using 100- to 300- $\mu\text{m}$  beads for single lesions < 50 mm without arteriovenous shunts, whereas in larger tumors, multiloculated lesions or suspected satellites, one vial of 100- to 300- $\mu\text{m}$  beads and one vial of 300- to 500- $\mu\text{m}$  beads were injected. DC beads were impregnated with 75 mg of doxorubicin in each vial to a maximum of 150 mg of doxorubicin loaded in two vials of DC beads (4 mL total).

### Histopathology

After LT, a dedicated liver pathologist performed the analysis of all the explanted livers, which were serially cut into sections of approximately 0.5 cm in thickness. The presence of cirrhosis was confirmed in all cases. Every lesion suspected to be HCC was completely paraffin-embedded, and multiple histological sections were made. Tumor grade according to the Edmonson and Steiner<sup>[27]</sup> classification and the presence of MVI were also assessed, except when complete necrosis of the tumor was achieved. The necrosis rate of each nodule was expressed as the percentage of necrotic tissue within the whole area of the nodule; necrosis was categorized as complete (100%), appropriate (90% or greater), partial (between 51% and 89%), or inadequate (50% or lower) as described previously<sup>[28,29]</sup>. The sum of the tumor diameters, CTA, and the cumulative necrotic and viable areas (including not-treated nodules) were measured in each patient to calculate the percentage of tumor necrosis within the cumulative tumor area (% necrosis on CTA). Adherence to MC was assessed during the pathological examination using only the viable portion of each nodule. Inflammatory and fibrotic changes in the tissue surrounding the tumor nodule were analyzed and categorized as poor/absent, moderate or enhanced reaction. The localization of microspheres with respect to the 38 HCC nodules treated with DEB-TACE was assessed and defined as intratumoral (exclusively within the tumor capsule), peritumoral (outside the nodule but within 5 mm

of the tumor capsule), intra- and peritumoral or intratumoral (microspheres found in the cirrhotic parenchyma beyond 5 mm from the tumor capsule).

### Statistical analysis

Continuous variables were reported as the mean and standard deviation or as median and range and were compared using Student's *t* test or Mann-Whitney *U* test when appropriate. Categorical variables were reported as numbers and percentages and compared using Fisher's exact test. Recurrence-free survival was calculated from the day of surgery to the first follow-up visit at which tumor recurrence was diagnosed or, in patients without recurrence, to the most recent follow-up visit. Follow-up of those patients who died without evidence of recurrence was censored at the time of death. The impact of each individual variable in determining HCC recurrence-free survival was assessed using the Kaplan-Meier method and compared using the log-rank test. Continuous variables, including pre-LT serum alpha-fetoprotein levels and the percentage of necrosis on CTA, were dichotomized; cutoff values were defined according to receiver operating characteristic curve analysis<sup>[30]</sup>. To identify factors independently related to HCC recurrence, the multivariate Cox proportional-hazard regression analysis was applied, taking in account only the variables that proved significant in the univariate analysis. A two-sided *P* value of less than 0.05 was considered statistically significant in all cases.

## RESULTS

Twenty-two patients underwent DEB-TACE, and 16 underwent c-TACE. Age at LT, gender, etiology and severity of cirrhosis were comparable in the two treatment arms (Table 1).

No major complications were observed after TACE. The post-embolization syndrome (transient fever, abdominal pain, nausea) was the most common complication following chemoembolization in both groups; all side effects were successfully treated with medical therapy. The median time spent on the waiting list was similar in the two groups (3.3 mo in the c-TACE, *vs* 2.9 mo in the DEB-TACE group, respectively, *P* = 0.5844).

DEB-TACE and c-TACE were repeated in 12 (54.5%) and 8 (50%) patients, respectively; the maximum number of treatments per patient was 3. The post-LT mean follow-up time was  $34.9 \pm 19.0$  and  $46.8 \pm 25.6$  mo for the DEB-TACE and c-TACE groups, respectively (*P* = 0.1065). No patients were lost at follow-up.

### Nodule analysis according to the type of TACE

The size and focality of the tumors were comparable in the two groups at explant examination. The mean tumor necrosis was  $55.7\% \pm 41.9\%$  and  $52.2\% \pm 40.9\%$  in DEB- and c-TACE groups, respectively (*P* = 0.7420). A trend towards a higher probability of an appropriate response was observed in the DEB-TACE group (17/38,

<sup>1</sup> Serum α-fetoprotein > 70 ng/mL	8/33 (24.2)	3/18 (16.7)	5/15 (33.3)	0.4811
Post-LT follow-up (mo)	39.9 ± 22.5	34.9 ± 19.0	46.8 ± 25.6	0.1065

Continuous variables are reported as the mean and standard deviation or median and range and compared using Student's *t* test or the Mann-Whitney *U* test as appropriate. Categorical variables are reported as numbers and percentages. <sup>1</sup>Value of serum α-fetoprotein was not available for 5 patients. TACE: Transcatheter arterial chemoembolization; DEB: Doxorubicin-eluting bead; MC: Milan Criteria; LT: Liver transplantation; HCV: Hepatitis C virus; HBV: Hepatitis B virus; MELD: Model for End Stage Liver Disease; c-TACE: Conventional TACE; BCLC: Barcelona Clinic Liver Cancer.

44.7% of nodules) in comparison with the c-TACE group (8/25, 32.0% of nodules), although this difference was not statistically significant ( $P = 0.2834$ ). No difference in necrosis was found comparing the superselective procedures performed with DEB-TACE or c-TACE ( $76.2\% \pm 33.8\%$  vs  $69.1\% \pm 36.5\%$ ,  $P = 0.5803$ ). However, independent of the type of TACE (DEB or conventional), superselective procedures resulted in a higher percentage of necrosis than did non-superselective procedures ( $73.9\% \pm 34.3\%$  vs  $31.3\% \pm 37.0\%$ ,  $P = 0.0018$ ) (Table 2).

Microscopically, tumor necrosis was mixed, colliquative and coagulative in all cases. In the DEB-TACE group only, a "foreign body reaction" with granulomatosis giant cells was observed in the tissue surrounding the tumor in 20 out of 22 patients (90.1%). As described in Figure 2, the nonspecific acute inflammatory infiltrate, containing foamy histiocytes and lymphocytes, was more enhanced at the tumor periphery of DEB-TACE-treated nodules in comparison with the c-TACE-treated ones. In most cases, DEB-TACE-treated nodules were surrounded by thick walls of tissue made of degenerated collagen fibers, inflamed granulation tissue, and hyalinization. The peritumor fibrous tissue of the nodules treated with c-TACE was thinner and apparently less affected by the secondary changes induced by DEB-TACE. These features were not dependent on the time between last treatment and LT; patients with nodules surrounded by an enhanced or mild fibrotic reaction were transplanted  $4.2 \pm 4.0$  mo

after TACE, whereas patients with poor-absent fibrosis were transplanted  $6.0 \pm 4.1$  mo after TACE ( $P = 0.2024$ ).

The distribution of microspheres with respect to the 38 nodules treated by DEB-TACE was intratumoral (11/38, 28.9%), intra- and peritumoral (14/38, 36.8%), peritumoral (10/38, 26.3%) and intratumoral (3/38, 7.9%). Nodules' necrosis differed with respect to the distribution of beads (85.9%, 57.0%, 34.5% and 10.0% for intratumoral, intra- and peritumoral, peritumoral and intratumoral distribution, respectively,  $P = 0.0041$ ).

#### Patient analysis according to the type of TACE

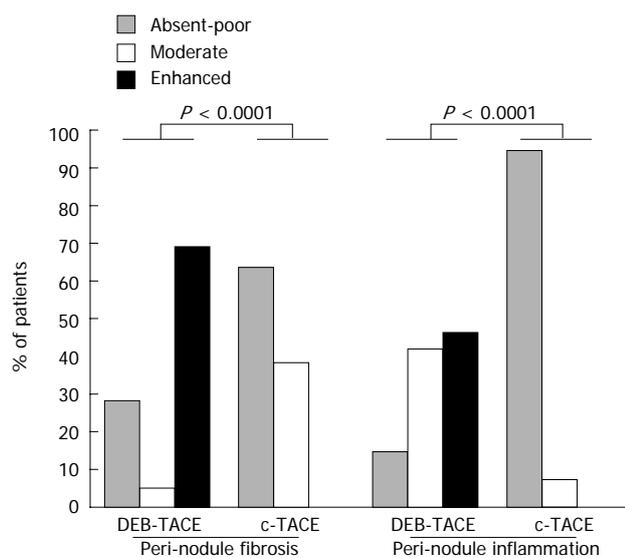

Ten of 17 patients were successfully downstaged within the MC; the effectiveness of DEB-TACE and c-TACE was similar to this regard. Seven out of 17 patients who were beyond MC at the imaging performed before TACE (8 patients in DEB-TACE and 9 in c-TACE group) remained outside the MC at pathology; the failure to accurately stage the tumor during the imaging performed before the LT was related to the misdiagnosis of complete necrosis (Table 3).

The number of nodules that were not reached by TACE (21/84, 25%) was similar in the 2 groups (13/51, 25.4% in DEB-TACE and 8/33, 24.2% in c-TACE group,  $P = 0.8934$ ). The mean diameter of the missed nodules was  $1.1 \pm 0.5$  cm, and 10 out of these 21 nodules (47.6%) were equal or inferior to 1 centimeter in size. The number of HCC nodules, the sum of the tumor diameters and the CTA (also including untreated nodules)

**Table 2** Analysis of the treated nodules according to the type of transcatheter arterial chemoembolization (per nodule analysis) *n* (%)

Variable	All treated nodules 63 in 38 patients	Type of TACE		P value
		DEB-TACE 38 in 22 patients	c-TACE 25 in 16 patients

Analysis performed considering nodules reached by transarterial treatment (targeted lesions). Continuous variables are reported as median and range or mean and standard deviation and compared using the Student's *t* test or Mann-Whitney *U* test as appropriate. TACE: Transcatheter arterial chemoembolization; DEB: Doxorubicin-eluting bead; c-TACE: Conventional TACE.

**Figure 2** Inflammatory and fibrotic changes in the tissue surrounding the tumor nodules. TACE: Transcatheter arterial chemoembolization; DEB: Doxorubicin-eluting bead.

were similar in the two groups. The mean percentage of necrosis on CTA was 58.8% and 50.2% in the DEB- and c-TACE group, respectively ( $P = 0.4856$ ); no difference in terms of response to treatment in various subcategories was observed. Risk factors for recurrence, such as a pre-transplant serum  $\alpha$ -fetoprotein greater than 70 ng/mL (Table 1), tumor grading and microvascular invasion were similarly distributed in the two treatment arms.

### Recurrence and survival after LT

Overall 3-year survival after LT was 73.9% and 58.7% in the DEB-TACE and c-TACE groups, respectively ( $P$

$= 0.7511$ ). Seven (18.4%) patients experienced tumor recurrence after LT; the main site of recurrence was the liver (5 patients), the spinal cord and the liver concurrently (1 patient) and the adrenal gland (1 patient). The mean time to recurrence was  $17.0 \pm 5.5$  mo; three out of seven patients were alive with recurrence at the time of publication.

The three-year recurrence-free survival was significantly higher in patients who were treated preoperatively with DEB-TACE than with c-TACE (87.4% *vs* 61.5%,  $P = 0.0493$ , Figure 3A).

Other factors affecting recurrence-free survival included Milan Criteria unfulfilled at pathology, percentage of necrosis on CTA lower than 50% and pre-transplant serum  $\alpha$ -fetoprotein levels greater than 70 ng/mL (Figure 3B-D). On multivariate analysis, a lack of treatment with DEB-TACE, serum  $\alpha$ -fetoprotein levels exceeding 70 ng/mL and Milan Criteria unfulfilled at pathology were independent predictors of tumor recurrence (Table 4).

## DISCUSSION

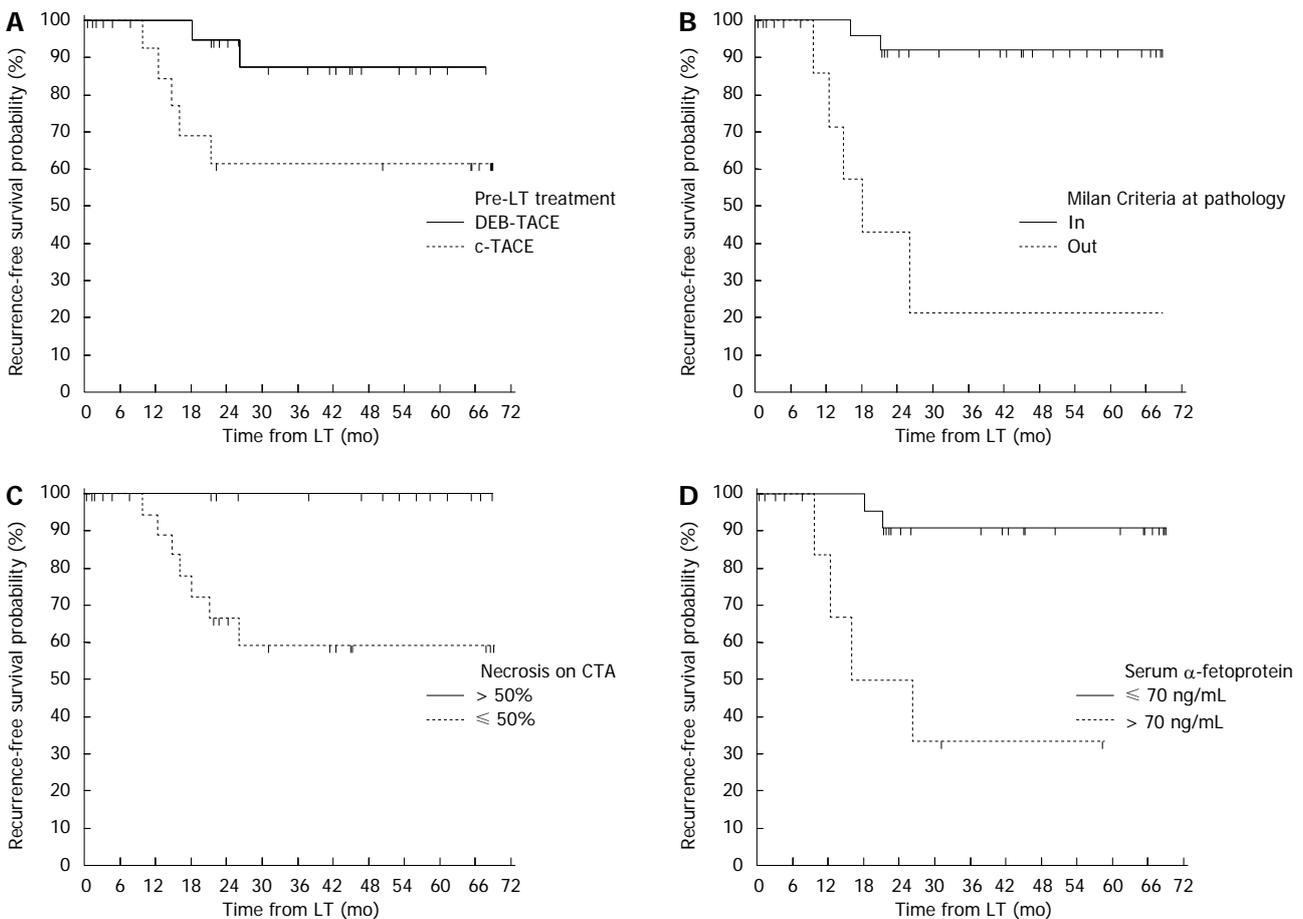

Among patients with HCC awaiting LT, TACE is the most commonly used neo-adjuvant therapy<sup>[11]</sup>. Although TACE can successfully downstage 24% to 63% of HCCs, pre-LT treatment is not clearly associated with any survival benefit<sup>[22,31-33]</sup>; in a large multicenter study, the 5-year recurrence-free survival was 67% in patients treated with TACE prior to LT and 64% in those not treated<sup>[20]</sup>.

Unlike conventional TACE, which is the most commonly used technique, DEB-TACE is based on calibrated microspheres made of non-degradable polymers that produce permanent vascular embolization and

$\alpha$ -fetoprotein > 70 ng/mL ( <i>vs</i> $\leq$ 70 ng/mL)	33.3% <i>vs</i> 90.9%	10.31 (4.749-370.242)	0.0008	15.31 (1.766-132.614)	0.0137

<sup>1</sup>Heart rate calculation and the inclusion of the covariate in the multivariate analysis was not applicable due to the lack of hepatocellular carcinoma recurrence events in necrosis on the cumulative tumor area (CTA) > 50% group. TACE: Transcatheter arterial chemoembolization; DEB: Doxorubicin-eluting bead; MC: Milan Criteria; NA: Not available.

increase intra-tumor drug delivery. There are 3 substantial pharmacokinetic advantages associated with DEB-TACE: a continuous elution of the drug for prolonged time, a higher concentration locally into the tumor and a lower systemic exposure to the drug in comparison with c-TACE<sup>[12]</sup>. In a preclinical study, Hong *et al* demonstrated that the peak of doxorubicin within the tumor is registered after three days, and drug levels remain high up to fourteen days after treatment<sup>[14]</sup>.

Several clinical studies have compared DEB and conventional TACE in non-transplant settings. A recent randomized study including 212 patients failed to demonstrate a significant difference in the overall radiological response, although a better safety profile and a trend toward a better response rate was observed for DEB-TACE<sup>[13]</sup>. Malagari *et al*<sup>[34]</sup> demonstrated that DEB-TACE was able to stabilize disease in a higher percentage of patients when compared with bland embolization (embolic agents without drug), but the survival rate at 12 mo did not differ in the two groups. In another prospective study, complete and partial response rates, tumor recurrence and overall survival were similar with DEB-TACE and conventional TACE<sup>[35]</sup>. Although a retrospective study recently suggested a higher 2-year survival rate in DEB-TACE patients<sup>[36]</sup>, the superiority of this technique remains to be further investigated.

Liver transplant candidates exhibit completely different characteristics than those patients considered in the above-mentioned studies. First, HCC in LT candidates is not advanced. Furthermore, the response to TACE in terms of tumor necrosis has clinical relevance only in those patients who require downstaging, whereas in the others, the goal is to halt tumor progression. Last, recurrence-free survival, measured following LT, is a realistic endpoint, as in the non-transplant setting, TACE is not intended to be curative<sup>[37]</sup>.

Few reports are available about the results of DEB-TACE in LT candidates. A small study from Milan reported a higher complete histological necrosis rate (77%) in patients treated with DEB-TACE. However, only 8 patients had been treated with DEB-TACE in that study,

while the 8 patients of the control group received bland embolization (non-loaded microspheres), with very low complete necrosis rates (27.2%)<sup>[38]</sup>. Unlike from the present study, Farris *et al*<sup>[39]</sup> recently reported a significantly higher necrosis rate after c-TACE in comparison with DEB-TACE (66.4% *vs* 46.1%). However, no mention of the HCC recurrence-free survival of the patients was made in these studies.

In our series, histopathological examination of the native livers did not indicate a significant difference between DEB-TACE and conventional TACE with regard to the effectiveness of the two different procedures in inducing histological necrosis and achieving tumor downstaging. However, a peculiar histological pattern was associated with DEB-TACE; DEB-TACE was characterized by an intense inflammatory and fibrotic reaction in the area surrounding the tumor tissue that was not observed in those patients treated with conventional TACE. Remarkably, a lower tumor recurrence rate after LT was associated with DEB-TACE. Furthermore, DEB-TACE was identified as an independent predictor of recurrence-free survival in the multivariate analysis. The others independent prognostic determinants found in the present study, serum alpha-fetoprotein levels and adherence to MC at histopathological examination, have been previously identified by others to be strictly linked with HCC recurrence after LT<sup>[3]</sup>.

Pretransplant ablative treatments have the potential to decrease the release and growth of HCC metastases. As the release of tumor cells can be intermittent, the continuous elution of doxorubicin and the distribution of loaded beads in the vessels around the nodule might maintain a prolonged antineoplastic effect and explain the lower recurrence rate observed in the DEB-TACE group. The biological significance of the intense tissue reaction that surrounds the tumor treated with DEB-TACE must to be further investigated. However, one might speculate that the tissue reaction could play a role in limiting tumor spread.

The difference in the chemotherapeutic agent employed in the two different TACE techniques (epirubicin

in c-TACE and doxorubicin in DEB-TACE) is unlikely to have influenced the results; in a large randomized controlled trial that compared c-TACE made using a lipiodol emulsion containing epirubicin or doxorubicin, no difference in the incidence of adverse reactions, changes in alpha-fetoprotein, extent of tumor reduction or the survival rates between the two drugs was reported<sup>[40]</sup>.

Although further confirmation of our findings with randomized controlled trials is warranted, our report seems to indicate that the use of DEB-TACE in LT recipients with HCC can increase recurrence-free survival after liver transplantation.

## COMMENTS

### Background

Transcatheter arterial chemoembolization (TACE) is the most common locoregional treatment in cirrhotic patients with hepatocellular carcinoma (HCC) awaiting liver transplantation (LT), and the main objective of TACE is to prevent tumor progression in HCC patients who have already met the Criteria for transplantation or to downstage tumors initially outside Milan Criteria to allow LT. In addition to conventional TACE (c-TACE), based on mixtures of anticancer drugs, lipiodol and a gelatin sponge, a procedure with calibrated doxorubicin-loaded microspheres has been recently developed (DEB-TACE). In pre-LT setting, only a few reports have compared the impact of different TACE regimens on tumor histology and recurrence-free survival after transplantation.

### Research frontiers

Pre-clinical and clinical studies have demonstrated that DEB-TACE produces a higher drug concentration within the tumor than does c-TACE in presence of a lower systemic concentration, but its superiority in inducing tumor necrosis and increasing recurrence-free survival remains to be further investigated. As the whole native liver becomes available for histological examination, LT represents a unique setting to correctly assess necrosis and histological changes in tumor nodules of patients treated by TACE. This approach can be useful in developing new strategies to decrease the release of HCC metastases in patients awaiting LT.

### Innovations and breakthroughs

A lower tumor recurrence rate after LT was observed in patients who were treated preoperatively with DEB-TACE. Although no significant differences were observed in terms of tumor necrosis between DEB and c-TACE, a peculiar histological pattern was associated with DEB-TACE, characterized by an intense inflammatory and fibrotic reaction in the area surrounding the tumor tissue. This finding, in addition to the prolonged antineoplastic effect of loaded beads in the vessels around the nodule, could limit tumor spread during time on the waiting list and could explain the lower postoperative recurrence rate observed in the DEB-TACE group.

### Applications

According to the results of this study, DEB-TACE is an effective locoregional tool for the management of HCC patients awaiting liver transplantation and can increase recurrence-free survival after LT.

### Terminology

TACE indicates transcatheter arterial chemoembolization. DEB-TACE indicates TACE with calibrated, doxorubicin-loaded microspheres used to bind, deliver and elute chemotherapeutic drugs in the tumor area. c-TACE indicates the conventional TACE procedure, performed by administering a mixture of epirubicin in an emulsion with lipiodol followed by a gelatin sponge to obtain occlusion of the feeding arteries of the tumor. HCC indicates hepatocellular carcinoma. LT indicates liver transplantation.

### Peer review

The authors present an interesting retrospective single-center study that clearly addresses pre-LT treatment of HCC. The authors highlight an important locoregional therapeutic tool, DEB-TACE, which has become increasingly utilized and can improve the outcomes of LT for HCC. The explanted livers underwent very close pathological scrutiny to judge the effects of the 2 different therapies; data analysis is well done. The paper is well written, and the manuscript improves significantly on the knowledge of the role of DEB-TACE in the management of HCC.

### Abstract

**AIM:** To evaluate the ameliorative effect of naringenin (NG) during ulcerative colitis (UC) in rats.

**METHODS:** Rats were treated with three different doses (25, 50 and 100 mg/kg per day) of NG and a single dose of mesalazine (MES, 300 mg/kg per day) for seven days prior to ulcerative colitis induction by 4% acetic acid (AA). Twenty four hours after AA rectal administration, animals were scarified and the colonic tissues were dissected. Colonic mucus content was estimated using Alcian blue dye binding technique. In colon tissues, levels of total glutathione sulphadryls (T-

GSH), non-protein sulphadryls (NP-SH) and thiobarbituric acid reactive substances (TBARS) were evaluated. The activities of the antioxidant enzymes, catalase (CAT) and superoxide dismutase (SOD) were measured. Concentrations of nucleic acids (DNA and RNA) and total protein were also estimated in colon tissues. Colonic levels of tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), interleukin-1 $\beta$  (IL-1 $\beta$ ), interleukin-6 (IL-6), prostaglandin E<sub>2</sub> (PGE<sub>2</sub>) and nitric oxide (NO) were estimated. In cross section of colitis tissue the histopathological changes were observed.

**RESULTS:** Colonic mucus content was decreased in AA compared to controls ( $587.09 \pm 65.59$  mg/kg *vs*  $941.78 \pm 68.41$  mg/kg,  $P < 0.001$ ). AA administration markedly reduced T-GSH ( $5.25 \pm 0.37$  nmol/L *vs*  $3.04 \pm 0.24$  nmol/L,  $P < 0.01$ ), NP-SH ( $3.16 \pm 0.04$  nmol/L *vs*  $2.16 \pm 0.30$  nmol/L,  $P < 0.01$ ), CAT ( $6.77 \pm 0.40$  U/mg *vs*  $3.04 \pm 0.2$  U/mg,  $P < 0.01$ ) and SOD ( $3.10 \pm 0.11$  U/mg *vs*  $1.77 \pm 0.18$  U/mg,  $P < 0.01$ ) while TBARS, TNF- $\alpha$ , IL-1 $\beta$ , IL-6, PGE<sub>2</sub> and NO levels ( $15.09 \pm 3.84$  nmol/L *vs*  $59.90 \pm 16.34$  nmol/L,  $P < 0.01$ ;  $113.56 \pm 1.91$  pg/mg *vs*  $134.24 \pm 4.77$  pg/mg,  $P < 0.01$ ;  $209.20 \pm 36.38$  pg/mg *vs*  $422.19 \pm 31.47$  pg/mg,  $P < 0.01$ ;  $250.83 \pm 25.09$  pg/mg *vs*  $638.58 \pm 115.9$  pg/mg,  $P < 0.01$ ;  $248.19 \pm 36.98$  pg/mg *vs*  $541.74 \pm 58.34$  pg/mg,  $P < 0.01$  and  $81.26 \pm 2.98$  mmol/g *vs*  $101.90 \pm 10.73$  mmol/g,  $P < 0.001$ ) were increased in colon of rats with UC compared controls respectively. Naringenin supplementation, significantly and dose dependently increased the colonic mucus content. The elevated TBARS levels were significantly decreased ( $39.35 \pm 5.86$  nmol/L,  $P < 0.05$ ;  $26.74 \pm 3.17$  nmol/L,  $P < 0.01$  nmol/L and  $17.74 \pm 2.69$  nmol/L,  $P < 0.01$ ) compared to AA ( $59.90 \pm 16.34$  nmol/L) group while the decreased levels of T-GSH and NP-SH and activities of CAT and SOD found increased by NG treatments in dose dependent manner. The decreased values of nucleic acids and total protein in AA group were also significantly ( $P < 0.01$ ) increased in all three NG supplemented groups

respectively. NG pretreatment inhibited the TNF- $\alpha$  levels ( $123.76 \pm 3.76$  pg/mg,  $122.62 \pm 3.41$  pg/mg and  $121.51 \pm 2.61$  pg/mg *vs*  $134.24 \pm 4.78$  pg/mg,  $P < 0.05$ ) compared to AA group, respectively. Interleukins, IL-1 $\beta$  and IL-6 levels were also decreased in NG50 + AA ( $314.37 \pm 16.31$  pg/mg and  $292.58 \pm 23.68$  pg/mg,  $P < 0.05$ ) and NG100 + AA ( $416.72 \pm 49.62$  pg/mg and  $407.96 \pm 43.87$  pg/mg,  $P < 0.05$ ) when compared to AA ( $352.46 \pm 8.58$  pg/mg and  $638.58 \pm 115.98$  pg/mg) group. Similar decrease ( $P < 0.05$ ) was seen in PGE<sub>2</sub> and NO values when compared to AA group. The group pretreated with MES, as a reference drug, showed significant ( $P < 0.01$ ) protection against the changes induced in colon tissue by AA administration respectively.

**CONCLUSION:** In present study, NG produced antioxidant and anti-inflammatory effects demonstrating protective effect in inflammatory bowel disease.

© 2013 Baishideng. All rights reserved.

**Key words:** Naringenin; Ulcerative colitis; Inflammatory bowel disease; Oxidative stress

**Core tip:** Inflammatory bowel disease (IBD), consisting of Crohn's disease (CD) and ulcerative colitis (UC), results in substantial morbidity and is difficult to treat. New strategies for adjunct therapies are needed. Systemic corticosteroids are highly effective at inducing clinical remission in cases of acute exacerbation of CD and UC; however, their use is limited by their frequent and sometimes severe side effects. Results of present study revealed that, naringenin has protective effects against acetic acid-induced UC by inhibiting inflammatory and oxidative bio-markers. Thus, it may pose promising outcomes for future clinical usage as a natural non-toxic effective supplement in IBD.

Protective effect of naringenin on acetic acid-induced ulcerative colitis in rats. *World J Gastroenterol* 2013; 19(34): 5633-5644 Available from: URL: <http://www.wjg-net.com/1007-9327/full/v19/i34/5633.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i34.5633>

## INTRODUCTION

Inflammatory bowel disease (IBD) is a common chronic inflammatory disease of the gastrointestinal tract. Several etiological factors, such as genetic, immunological, and environmental have been linked with the pathophysiology of the disease<sup>[1]</sup>. There are two main subtypes of IBD; Crohn's disease (CD) and ulcerative colitis (UC) having a combined prevalence of 150-250/100000 population<sup>[2,3]</sup>. Moreover, the prevalence of hospitalization due to CD and UC is estimated to be 50.1 and 50.6 per 100000 population, respectively<sup>[4]</sup>. UC involves only the colon and rectum. Al-

though the etiology of UC is not completely understood, it has been commonly associated with reduced antioxidant capacity as well as increased free radical production such as reactive oxygen species (ROS)<sup>[5]</sup>. Over production of ROS leads to lipid peroxidation (LPO), which can inhibit cellular antioxidant capability finally resulting in prominent colonic inflammation<sup>[6]</sup>. Clinically, colitis patients were found to overproduce ROS and nitrogen species leading to LPO of membranes and attack on tissue proteins and DNA<sup>[7,8]</sup>. Endogenous antioxidant defenses against ROS production even in low concentrations influence on two main types: (1) enzymatic such as superoxide dismutase (SOD), glutathione peroxidase (GPx) and catalase (CAT); and (2) non-enzymatic such as glutathione (GSH) and ascorbic acid (vitamin C). It is suggested that inflammatory response amplification can induce inflammatory cells chemotaxis resulting in release of ROS and inflammatory cytokines such as tumor necrosis factor (TNF)- $\alpha$ , interleukin (IL)-6 and IL-1 $\beta$ , which triggers the pathological responses and symptoms during IBD<sup>[9]</sup>. Elevated levels of pro-inflammatory cytokines in both the IBD forms reported to have a vital role of such mediators, which also play in determining the severity of the disease<sup>[10]</sup>. Medications that have ability to inhibit the production of these inflammatory mediators are shown to be clinically effective, which indicate their contribution to IBD and other chronic inflammatory conditions aggravation<sup>[11]</sup>.

Some natural products, such as flavonoids, are getting more attention as novel agents for therapeutically usage. Flavonoids are one of the most abundant natural antioxidants present in plants and the human diets. Naringenin (4,5,7-trihydroxy flavanone) a flavonoid, widely distributed in citrus fruits, tomatoes, cherries, and cocoa<sup>[12]</sup>. Several pharmacological studies revealed its effects including antidiabetic<sup>[13]</sup>, antiatherogenic<sup>[14]</sup>, antidepressant<sup>[15]</sup>, immunomodulatory<sup>[14]</sup>, antitumor<sup>[16]</sup>, DNA protective<sup>[17]</sup>, hypolipidemic<sup>[18]</sup> and peroxisome proliferator-activated receptors activator<sup>[19]</sup>. It has also been shown to have prominent antioxidant<sup>[20]</sup> and anti-inflammatory<sup>[21]</sup> potentials. Inês Amaro *et al.*<sup>[22]</sup> reported that, naringenin (NG) has reducing effect on intestinal edema-induced by dextran sodium sulphate in mice.

In several studies, pathogenesis of UC disease has demonstrated that excessive inflammation and oxidative stress play a significant role<sup>[23,24]</sup>. Amelioration of LPO as well as free radicals scavenging would provide a useful, protective and therapeutic treatment for UC. With respect to the high antioxidant capacity and anti-inflammatory activity, NG would be expected to reduce injury and/or improve tissue healing following injury from ulcerative colitis. In the present study we had evaluated the protective effect of NG during experimental ulcerative colitis and the possible mechanism of action.

## MATERIALS AND METHODS

### *Animals and ethical approval*

Eight weeks old male Wister albino rats weighting 250-280 g were received from Experimental Animal

Care Center, College of Pharmacy, King Saud University, Riyadh, Saudi Arabia. Animals were housed under controlled environmental conditions (25 °C and a 12 h light/dark cycle). Animals had free access to Purina rat chow (Manufactured by Grain Silos and Flour Mills Organization, Riyadh, Saudi Arabia) and tap water. All experimental procedures and protocols in this study including euthanasia were conducted in accordance with the National Institute of Health Guide for the Care and Use of Laboratory Animals, Institute for Laboratory Animal Research (NIH Publications No. 80-23; 1996) as well as the Ethical Guidelines of the Experimental Animal Care Center, College of Pharmacy, King Saud University, Riyadh, Saudi Arabia.

### Induction of ulcerative colitis

Experimental ulceration in colon tissue was done according to the method described by Mousavizadeh *et al.*<sup>[25]</sup> with slight modification. In brief, under light ether anesthesia rats were administered 2 mL of 4% acetic acid solution (v/v; Merck, Darmstadt, Germany) by transrectally using a (2.7 mm) soft pediatric catheter. After AA administration, rats were holed horizontally for 2 min to prevent AA leakage. Control animals underwent the same procedure using equal volume of normal saline instead of AA solution.

### Experimental design

Forty two rats were divided into seven groups (six animals in each) as follows: (1) Control (Cont); (2) NG 100 mg/kg per day (NG100); (3) AA treated rats (AA); (4) NG 25 mg/kg per day + acetic acid (NG25 + AA); (5) NG 50 mg/kg per day + AA (NG50 + AA); (6) NG 100 mg/kg per day + AA (NG100 + AA); and (7) MES 300 mg/kg per day + AA (MES + AA). Naringenin (Sigma Aldrich, United States) and MES treatments were continued for 7 consecutive days by gavage<sup>[26]</sup>. At end of the treatment, ulcerative colitis was induced in all AA groups. Twenty four hours after the colitis induction, animals were sacrificed under deep anesthesia<sup>[27]</sup>. The colon (5-6 cm) specimens were dissected, washed with saline solution, imaged, weighted and small cross section was fixed in 10% formaldehyde solution for histopathological evaluation. The remaining tissues were stored at -75 °C (Ultra-low freezer, Environmental Equipment, Cincinnati, Ohio, United States) till analysis.

### Evaluation of the adherent colonic mucus

The modified procedure of Popov *et al.*<sup>[28]</sup> was used to determine adherent colonic mucus concentration. Briefly, a small portion of colon tissue was excised, weighted then transferred immediately to 1% Alcian blue solution (in 0.16 mol/L sucrose solution buffered with sodium acetate, pH 5) for 24 h. The excess dye was removed by rinsing with sucrose solution. The dye complexed with the gastric wall mucus was extracted using 10 mL of 0.5 mol/L MgCl<sub>2</sub> solution. A 4 mL aliquot of blue extract was then shaken with an equal volume of diethyl ether. The resulting emulsion was centrifuged at 4000 rpm and the absorbance of the aqueous layer was recorded at 580

nm by using spectrophotometer (LKB-Pharmacia, Mark II, Ireland). The quantity of Alcian blue extracted (µg) per grams of wet colonic tissue was then calculated.

### Histopathological investigations

Colon sections were fixed 10% neutral buffered formalin then put for 24 h in decal. Samples were then cut into several sections and embedded into paraffin wax blocks. Tissues were stained with haematoxylin and eosin and were mounted and observed microscopically for histopathological changes by a pathologist in blinded fashion.

### Estimations of total glutathione sulphadryls and non-protein sulphadryls concentrations in colon

In colon tissues, total glutathione sulphadryls (T-GSH) and non-protein sulphadryls (NP-SH) levels were estimated according to the method described by Sedlak *et al.*<sup>[29]</sup>. Tissues were homogenated in ice-cold 0.02 mol/L ethylenediamine tetra-acetic acid. An aliquots of 0.5 mL of tissue homogenate was mixed with 0.2 mol/L Tris buffer, pH 8.2 and 0.1 mL of 0.01 mol/L Ellman's reagent, [5,5'-dithiobis-(2-nitr-benzoic acid)] (DTNB). Each sample tube was centrifuged at 3000 rpm at room temperature for 15 min the absorbance of the clear supernatant was measured using spectrophotometer (LKB-Pharmacia, Mark II, Ireland) at 412 nm. For NP-SH estimation, homogenate was diluted with distilled H<sub>2</sub>O and mixed with 1 mL of 50% trichloroacetic acid (TCA). The tubes were shaken intermittently for 10-15 min and centrifuged for 15 min at approximately 3000 g. Two milliliter of supernatant was then added to 4 mL of 0.4 mol/L Tris buffer (pH 8.9) then 0.1 mL DTNB added. The absorbance was read within 5 min of the addition of DTNB at 412 nm against a reagent blank.

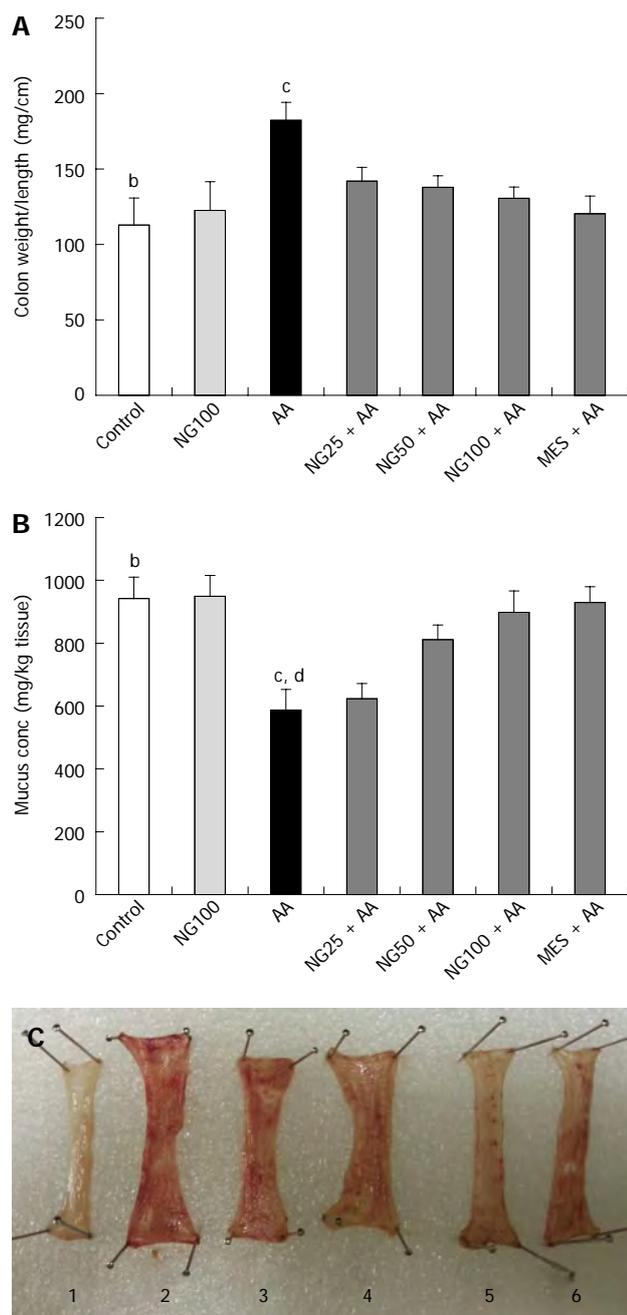

### Estimation of thiobarbituric acid reactive substances levels in colon

A thiobarbituric acid reactive substances (TBARS) assay kit (ZeptoMetrix, United States) was used to measure the LPO products, malondialdehyde (MDA) equivalents. Briefly, one hundred microliters of colon homogenate was added to 2.5 mL reaction buffer (provided by the kit) and heated at 95 °C for 60 min. After the mixture cooling, supernatant absorbance was measured at 532 nm using a spectrophotometer (LKB-Pharmacia, Mark II, Ireland). The LPO products are expressed in terms of nmoles MDA/mg protein.

### Estimation of CAT and SOD activities in colon

Catalase activity in colon tissues was estimated by the method described by Aebi<sup>[30]</sup>. In brief, aliquot of 0.5 mL post-mitochondrial supernatant was mixed with 2.5 mL of 50 mmol/L phosphate buffer (pH 7.0) and 20 mmol/L H<sub>2</sub>O<sub>2</sub>. CAT activity was estimated spectrophotometrically following the decrease in absorbance at 240 nm and expressed in terms of units/mg protein as compared to a standard curve.

The SOD activity in colon tissue was measured by using the method described by Kono<sup>[31]</sup>. The principle of this method was that superoxide anions generated by the

**Figure 1** Effect of naringenin on colon weight/length (A), mucus concentration (B) and induction of ulceration and its protection by treatments in colonic tissue of rats with acetic acid-induced ulcerative colitis (C) ( $n = 6$ ). Values in (A) and (B) are expressed as mean  $\pm$  SE and analyzed using one way analysis of variance followed by Newman-Keuls *post hoc* test. <sup>b</sup> $P < 0.01$  control vs acetic acid (AA); <sup>c</sup> $P < 0.05$ , <sup>d</sup> $P < 0.01$  AA vs naringenin (NG) 25 + AA, NG50 + AA, NG100 + AA or mesalazine (MES) + AA groups. Groups in (C) are arranged as follows: control (1), AA (2), NG25 + AA (3), NG50 + AA (4), NG100 + AA (5) and MES + AA (6).

oxidation of hydroxylamine hydrochloride can mediate the reduction of nitrobluetetrazolium to blue formazon. The color was then measured at 560 nm under aerobic conditions. Addition of superoxide dismutase inhibited nitrobluetetrazolium reduction and the extent of this inhibition was taken as a measure of enzymatic activity. The SOD activity was expressed as units/mg protein.

### Determination of nucleic acids and total protein levels in colon

The method described by Bregman<sup>[32]</sup> was used to determine the levels of nucleic acids (DNA and RNA) in colon. In brief, colon tissues were homogenized in 4 mL ice-cold distilled water and 2 mL homogenate was suspended in 5 mL of 10% ice-cold trichloroacetic acid (TCA). After centrifugation, the pellet was extracted twice with 95% ethanol. Finally, the nucleic acids were extracted in 5% TCA. DNA was determined by treating the nucleic acid extract with diphenylamine reagent and measuring the intensity of blue color at 600 nm. For quantification of RNA, the nucleic acid extract was treated with orcinol reagent and the green color was read at 660 nm. Standard curves were used to determine the amounts of nucleic acids present. Total protein in colon was estimated by Lowry *et al.*<sup>[33]</sup> method using Bovine plasma albumin as a standard.

### Determination of inflammatory cytokines, PGE<sub>2</sub> and NO levels in colon

In colon, TNF- $\alpha$ , IL-1 $\beta$ , IL-6 and PGE<sub>2</sub> levels were assessed and quantified according to the method of Mousavizadeh *et al.*<sup>[25]</sup> using enzyme-linked immunosorbent assay ELISA (R and D systems, United States). The results were expressed as pg/mg tissue. Levels of colonic nitric oxide were assayed by Griess reaction method using commercial kit (R and D systems, United States).

### Statistical analysis

Data were expressed as mean  $\pm$  SE. Statistical analysis was carried out using one-way ANOVA followed by Newman-Keuls *post hoc* test.  $P$  value of  $\leq 0.05$  was considered statistically significant. All statistics tests were conducted using Graph Pad Prism (version 5) software.

## RESULTS

Acetic acid significantly ( $P < 0.01$ ) increased the colonic weight as compared to control group. Pretreatment with NG following three doses and MES for 7 d, showed significant ( $P < 0.05$ ) inhibition in weight increase while compared to AA group (Figure 1A). Mucus concentration was significantly ( $P < 0.01$ ) reduced in AA administered group when compared to control animals. Pretreatment with higher doses (50 and 100 mg/kg) of NG and MES significantly elevated the reduced colonic mucus concentration ( $P < 0.05$ ,  $P < 0.01$  and  $P < 0.05$ , respectively) as compared to AA group (Figure 1B). The colon images were clearly showed the induction of ulceration and its protection by the treatments (Figure 1C).

Histopathological changes with their intensity are presented in Figure 2. Slide from control group, showing benign mucosal epithelium of tall columnar epithelial cells with goblet cells (Table 1 and Figure 2A). In the AA group, the slide revealed diffused active colitis with widely eroded mucosa with ulcerations and necrosis associated with edema, goblet cell hyperplasia, lymphoid follicular

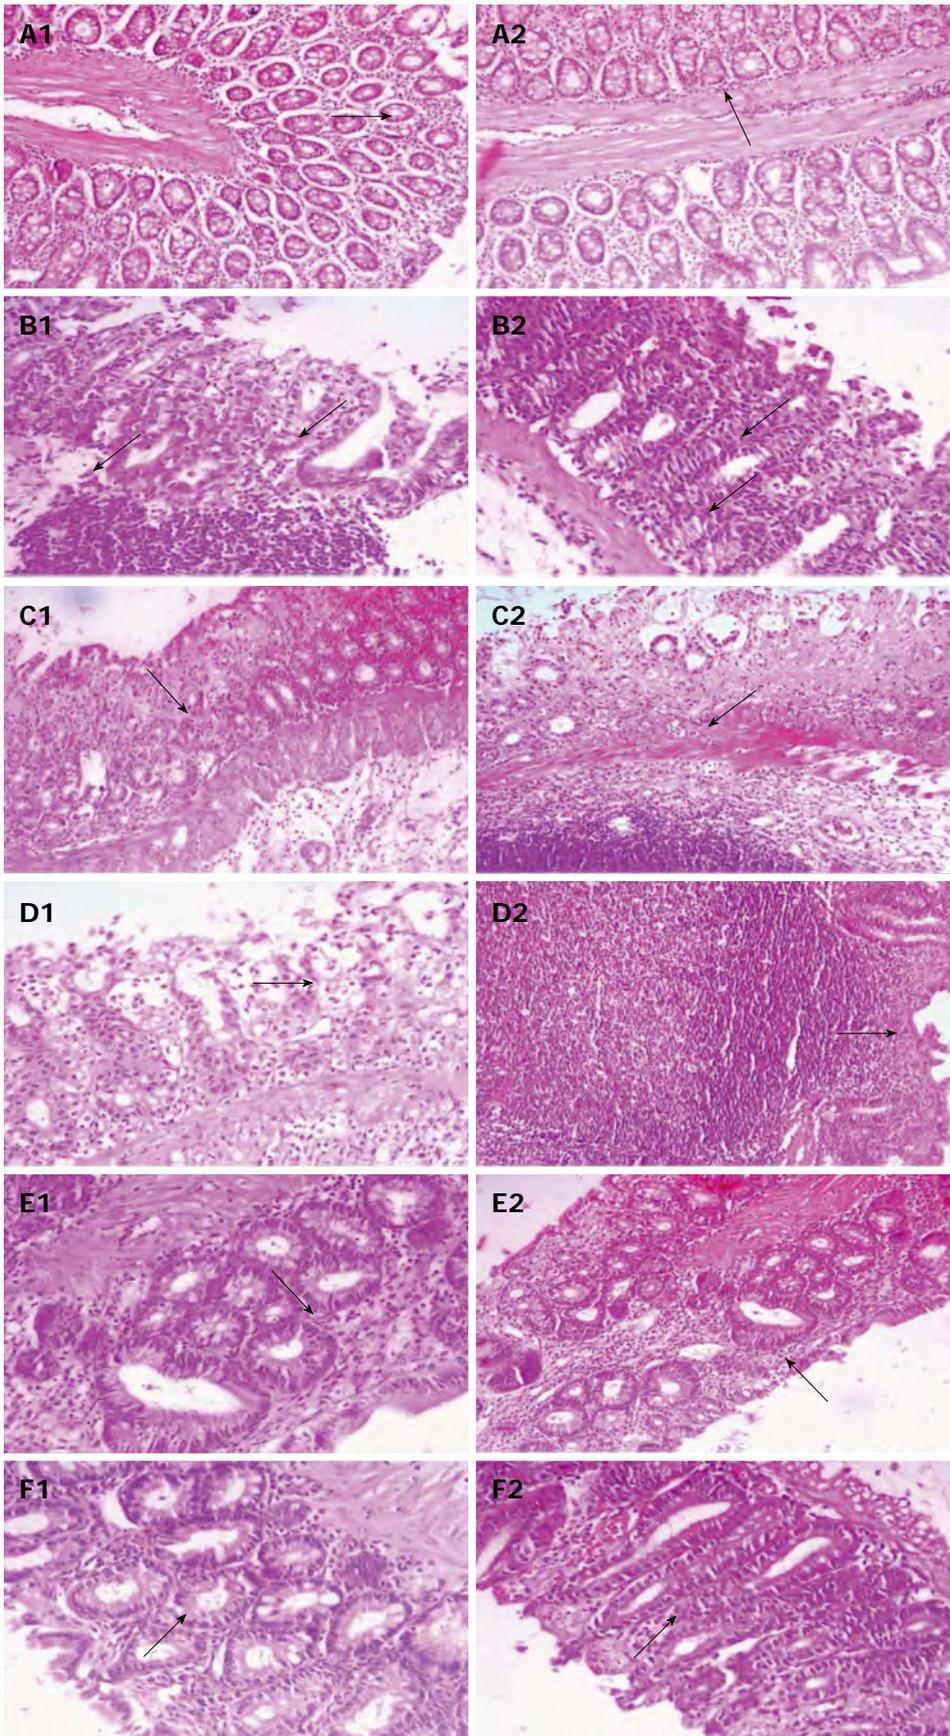

Figure 2 Histopathological changes with their intensity are presented. A-1 and 2: Histopathological colonic sections showing normal benign looking mucosa; B-1 and 2: Diffused active colitis with superficial erosions, stromal edema, dense acute and chronic inflammatory cells infiltrate with widely ulcerating mucosa; C-1 and 2: Reparative epithelial changes with little ulcer healing and inflammatory cells infiltrate; D-1 and 2: Reparative epithelial changes and healing ulcer with lymphoid follicle form; E-1 and 2: Healing ulcer and reparative epithelial changes; F-1 and 2: Attenuated cell damage with complete ulcer healing. A1-F1 ( $\times 400$ ), A2-F2 ( $\times 200$ ).

MES: Mesalazine; AA: Acetic acid; NG: Naringenin; NG25: NG 25 mg/kg per day; NG50: 50 mg/kg per day; NG100: 100 mg/kg per day; 0: Normal; +: Mild; ++: Moderate; +++: Sever; ++++: Very sever.

hyperplasia and transmural lymphoplasmacytic infiltrate with few intraepithelial neutrophilic cells within stromal (Table 1 and Figure 2B). In NG25 + AA group, slight healing epithelial cells with scattered superficial ulcers lined by colonic glands with reparative epithelial changes with hyperchromatic nuclei and infrequent mitosis and less goblet cells surrounded by transmucosal fewer lymphoplasmacytic infiltrate within stromal edemas was seen (Table 1 and Figure 2C). Slide from NG50 + AA group showed intestinal rat lined by healing epithelial cells with tall columnar epithelium, with superficial shredded epithelial cells, less eroded surface surrounded by few inflammatory edema and less necrosis with colonic gland showed reparative epithelial changes (Table 1 and Figure 2D). In higher dose of NG treatment (NG100 + AA) group, superficial tiny eroded mucosa with mucosal, hemorrhage, edema and scattered acute and chronic inflammatory cells infiltrate surrounding colonic glands with reparative epithelial changes and few goblet cells were seen (Table 1 and Figure 2E). Slide from MES + AA group revealed intestinal section with more better healed and improvement of intestinal mucosa compared to positive controlled sections with few mucosal lymphoplasmacytic infiltrate within stromal edema (Table 1 and Figure 2F).

Acetic acid administration resulted in a significant ( $P < 0.01$ ) decrease in colon levels of both T-GSH and NP-SH when compared to control animals. Pretreatment with NG with higher doses (50 mg/kg and 100 mg/kg) significantly ( $P < 0.01$ ) attenuated T-GSH and NP-SH ( $P < 0.05$ ) the reduced levels as compared to AA group. Pretreatment with MES significantly inhibited the decreased levels of T-GSH and NP-SH ( $P < 0.001$  and  $P < 0.05$ , respectively) (Figure 3A and B). Concentration of TBARS in the colons of AA treated rats were significantly ( $P < 0.01$ ) increased compared to control animals. A significantly lower concentrations of TBARS values were found in NG25 + AA ( $P < 0.05$ ), NG50 + AA ( $P < 0.01$ ), NG100 + AA ( $P < 0.01$ ) and MES + AA ( $P < 0.01$ ) groups as compared to AA group (Figure 3C). CAT activity was significantly ( $P < 0.01$ ) decreased in colon tissues of AA administered rats compared to control animals. Pretreatment with 50 mg/kg per day and 100 mg/kg per day of NG, significantly ( $P < 0.05$ ) inhibited the decrease CAT activity in colon as compared to AA group (Figure 3D). SOD activity was significantly ( $P < 0.01$ ) reduced in the colons of AA treated animals as compared to control rats. Group

of rats pretreated with 100 mg/kg per day of NG for 7 d showed a significant ( $P < 0.05$ ) increase in colon SOD activity while compared to AA treated animals (Figure 3E). Pretreatment with MES also markedly ( $P < 0.05$  and  $P < 0.01$ , respectively) enhanced the CAT and SOD activities as compared to AA group (Figure 3D and E).

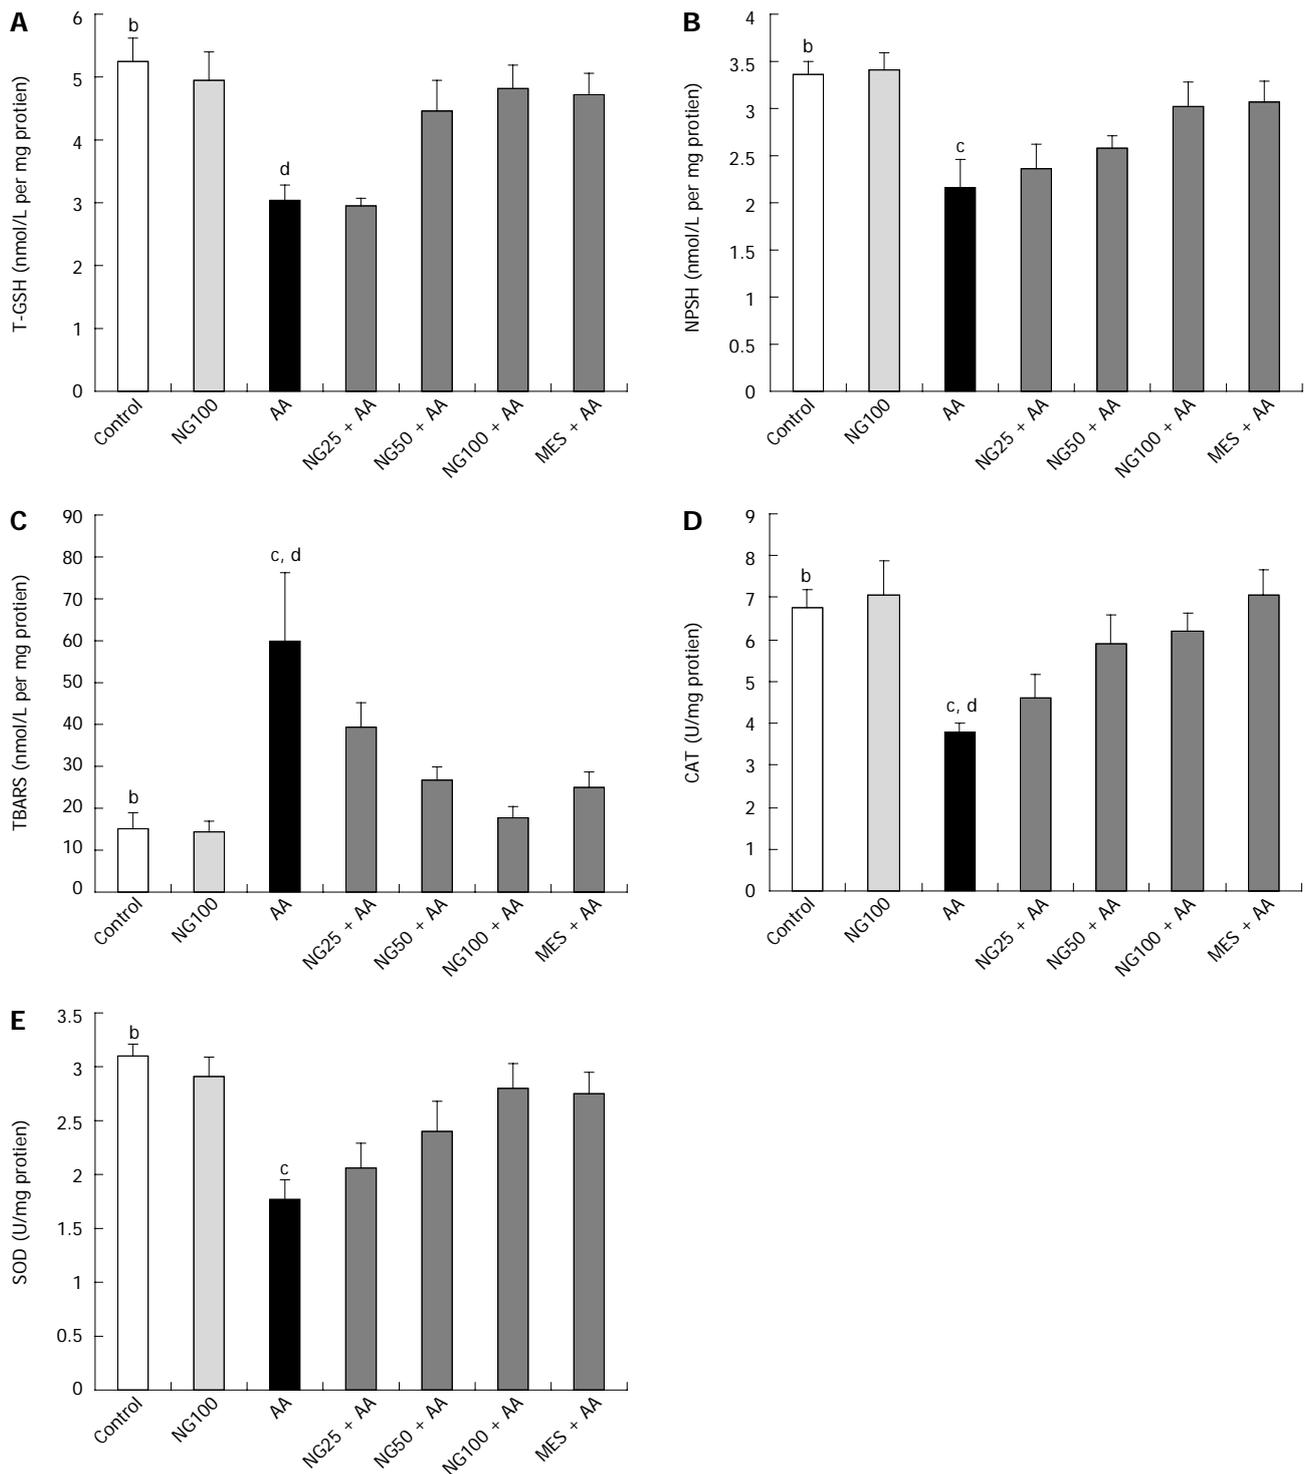

There was a significant ( $P < 0.001$ ) decrease in colon levels of DNA, RNA and total protein in AA administered group as compared to control animals. Pretreatment with NG (100 mg/kg per day) or MES (300 mg/kg per day) significantly ( $P < 0.01$ ) increased the DNA content in colon tissue compared to AA group. The RNA levels in NG higher doses and MES groups found significant ( $P < 0.01$ ) elevation compared to AA group. Total protein levels were also significantly ( $P < 0.05$ ) increased in NG50 + AA, NG100 + AA and MES + AA groups compared to AA group (Table 2).

Pro-inflammatory cytokines including TNF- $\alpha$ , IL-1 $\beta$  and IL-6 levels produced significant ( $P < 0.01$ ) increase in AA-induced ulcerative colitis and levels found significantly ( $P < 0.05$  and  $P < 0.01$ ) diminished in NG higher doses and MES pretreated groups as compared to AA group, respectively (Figure 4A-C). Similar changes in PGE<sub>2</sub> levels were seen in colon tissue of rats (Figure 4D). In colon tissue, NO levels were significantly ( $P < 0.01$ ) increased AA group compared to controls. The elevated NO levels were markedly ( $P < 0.05$ ) reduced in NG and MES treated group compared AA group respectively (Figure 4E).

## DISCUSSION

Present investigation outlines the anti-ulcerogenic effect of NG against experimentally induced UC in rats as a model for IBD. The preventative effect of NG was confirmed by histological evaluation and also using MES as a standard drug. Seven days pretreatment with NG significantly reduced the AA-induced colonic mucus content and prevented oxidative and inflammatory response in dose dependent manner.

Ulcerative colitis is characterized by mucosal inflammation and ulcerations with a variable extent and severity<sup>[34]</sup>. Rectal administration of 4% AA to experimental rodents to induce UC is a well-established animal model, which phenotypically resembles human colon inflammation<sup>[35]</sup>. It also causes colonic epithelial lesions and

**Figure 3** Effect of naringenin on total glutathione sulphadryls (A), non-protein sulphadryls (B) and thiobarbituric acid reactive substances levels (C) as well as catalase (D) and superoxide dismutase activities (E) in colonic tissue of rats with acetic acid-induced ulcerative colitis ( $n = 6$ ). Values are expressed as mean  $\pm$  SE and analyzed using one way analysis of variance followed by Newman-Keuls *post hoc* test. <sup>b</sup> $P < 0.01$  control vs AA; <sup>c</sup> $P < 0.05$ , <sup>d</sup> $P < 0.01$  AA vs NG25 + AA, NG50 + AA, NG100 + AA or MES + AA groups. T-GSH: Total glutathione sulphadryls; NP-SH: Non-protein sulphadryls; TBARS: Thiobarbituric acid reactive substances; CAT: Catalase; SOD: Superoxide dismutase; AA: Acetic acid; UC: Ulcerative colitis; MES: Mesalazine; NG: Naringenin.

necrosis associated with neutrophils and macrophages infiltration to the damaged colon indicating inflammatory conditions<sup>[28,35]</sup>. In present study, the 4% AA administration resulted a significant increase in colonic weight and induced sever ulceration and tissue necrosis associated with inflammatory infiltrate and goblet cell hyperplasia

as indicated in the results of the histopathological estimations. Similar pathological impairments were reported in earlier studies using the same animal model<sup>[26,36]</sup>. Application of AA in the present study disturbed the colonic mucus, which is in agreement with Popov *et al*<sup>[28]</sup>. Colonic mucus plays an important protective role against

**Table 2** Effect of naringenin on DNA, RNA and total protein levels in colonic tissue of rats with acetic acid-induced ulcerative colitis

Groups	DNA ( $\mu\text{g}/100$ mg wet tissue)	RNA ( $\mu\text{g}/100$ mg wet tissue)	Total protein (mg/100 mg wet tissue)
Control	652.05 $\pm$ 17.12 <sup>b</sup>	378.51 $\pm$ 38.44 <sup>b</sup>	3.0 $\pm$ 0.19 <sup>b</sup>
NG100	688.84 $\pm$ 47.69	380.24 $\pm$ 48.96	2.43 $\pm$ 0.31

MES + AA	425.04 $\pm$ 38.23	307.44 $\pm$ 18.31	2.14 $\pm$ 0.26

Values are expressed as mean  $\pm$  SE ( $n = 6$ ) and analyzed using one way ANOVA followed by Newman-Keuls *post hoc* test. <sup>b</sup> $P < 0.01$  control *vs* acetic acid (AA); <sup>c</sup> $P < 0.05$ , <sup>d</sup> $P < 0.01$  AA *vs* Naringenin (NG) 25 + AA, NG50 + AA, NG100 + AA or mesalazine (MES) + AA groups.

chemically induced ulceration which may also facilitate the repair of the damaged epithelium<sup>[37]</sup>. Although, numerous pharmacotherapies have been suggested for UC treatment, the side effects or toxicity of these medications are a major clinical problem<sup>[38]</sup>. That is why naturally occurring products such as flavonoids are now suggested as an alternative option beside the conventional therapies<sup>[39]</sup>. Indeed, earlier experimental studies demonstrated flavonoids such as quercitrin, kushenin, kaempferol and baicalin to promote UC healing<sup>[40-43]</sup>.

Previous studies demonstrated that NG administration effectively protected the experimentally induced gastric lesions and ulcers<sup>[44,45]</sup>. Protection against experimental UC induced by NG was accompanied by restoration of the increased colon thickening in AA group, which is an indirect assessment of colon inflammation. Microscopic scoring of the histopathological sections confirmed the protective action of NG as it decreased colonic tissue ulceration, necrosis and inflammation in dose dependent manner. Motilva *et al.*<sup>[45]</sup> reported that NG treatment increased the gastric mucus levels in rats induced gastric lesions by absolute ethanol. In the present study, NG was also found to inhibit the depletion of colonic mucus caused by AA treatment. This protective activity could be attributed to its antioxidant and anti-inflammatory properties.

Oxidative stress is known to play an important role in IBD initiation and progression<sup>[46]</sup>. Experimentally induced colitis in animals is characterized by oxidative damage and an imbalance between oxidant and antioxidant substances<sup>[47]</sup>. The AA-induced colitis model is known to cause vascular dilatation and white blood cells accumulation, as well as an increase in blood flow, leading to increased production of oxygen and hence the excessive generation of free radical and ROS<sup>[35,48]</sup>. Several studies have indicated the vital role that free radicals play in the pathogenesis of mucosal injuries<sup>[49,50]</sup>. Moreover, free radicals and ROS were reported in colorectal specimens of ulcerative colitis<sup>[51,52]</sup>. The first line of oxidative defense system against free radicals is the sulphadryls groups in peptide namely GSH or NP-SH. It is widely distributed in all biological

tissues and work as a non-enzymatic antioxidant. GSH inhibits ROS oxidative injuries directly *via* its sulfhydryl group and indirectly as a cofactor or a coenzyme in ROS enzymatic detoxification process<sup>[53,54]</sup>. Another line in oxidative defense system is the enzymatic antioxidants. Examples for important antioxidant enzymes are SOD, CAT, and GPx<sup>[55]</sup>. In present study, levels and activities of non-enzymatic and enzymatic defense systems were severely decreased in the colon of AA administered animals indicating oxidative cellular injury. Furthermore, free radicals are known to attack lipid contents of cellular membranes leading to activation of LPO process and cellular damage. Therefore, the concentrations of LPO specific products such as TBARS were elevated, while the critical cellular macro- and micro-molecules such as nucleic acids and total proteins levels were decreased in the present work indicating cellular oxidative injury and cytotoxicity. These results, which are in agreement with previous findings, suggest the harmful effects of AA on cellular macromolecules and its ability to impair the epithelial cell integrity and hinder mucosal recovery<sup>[23,36]</sup>.

In present study, NG was able to attenuate AA induced oxidative damage and injury of colon tissues confirming its strong antioxidant and anti-inflammatory properties. It has seen in earlier studies that NG markedly increased the antioxidant markers such as GSH, NP-SH levels and SOD, and CAT activities<sup>[12,56,57]</sup>. Han *et al.*<sup>[56]</sup> found that NG pretreatment can increase the activity of antioxidant enzyme GPx, which suggest the ability of NG to attenuate oxidative stress by decreasing the lipid peroxide level and to inhibit accumulation of free radicals generation during LPO process<sup>[57]</sup>. In the current study, NG treatment significantly corrected the impaired levels of nucleic acids and total protein in colon tissue suggesting the cytoprotective properties of the naturally occurring flavonoids. The antioxidant activity of NG depends mainly on the presence of B-ring catechol group, which can stabilize a radical species by donating hydrogen ( $\text{H}^+$ )<sup>[12]</sup>.

Inflammatory cytokines are known to play a crucial role in modulating mucosal immune system where the neutrophils and macrophages are responsible for disrupting epithelial integrity and causing colon injury<sup>[58]</sup>. The pathogenesis of UC is characterized by migration of granulocytes and other leukocytes to the inflamed mucosa and superficial ulcers leading to increased levels of pro-inflammatory cytokines such as TNF- $\alpha$ , IL-6 and IL-1 $\beta$ <sup>[59,60]</sup>. In present study, the elevated colon level of TNF- $\alpha$ , IL-6 and IL-1 $\beta$  in AA administered group is an evidence for epithelial cell necrosis, edema, and neutrophil infiltration, which is also supported by the histopathological results. These results are in accordance with earlier experimental and clinical studies<sup>[6,28,36,61]</sup>. The reported increased levels of colonic PGE<sub>2</sub> in AA group of animals is in agreement with Otani *et al.*<sup>[62]</sup>, where the enhanced level of PGE<sub>2</sub> was attributed to its overproduction rather than decreased metabolism, both of which are mediated by pro-inflammatory cytokines. Naringenin was found in the current

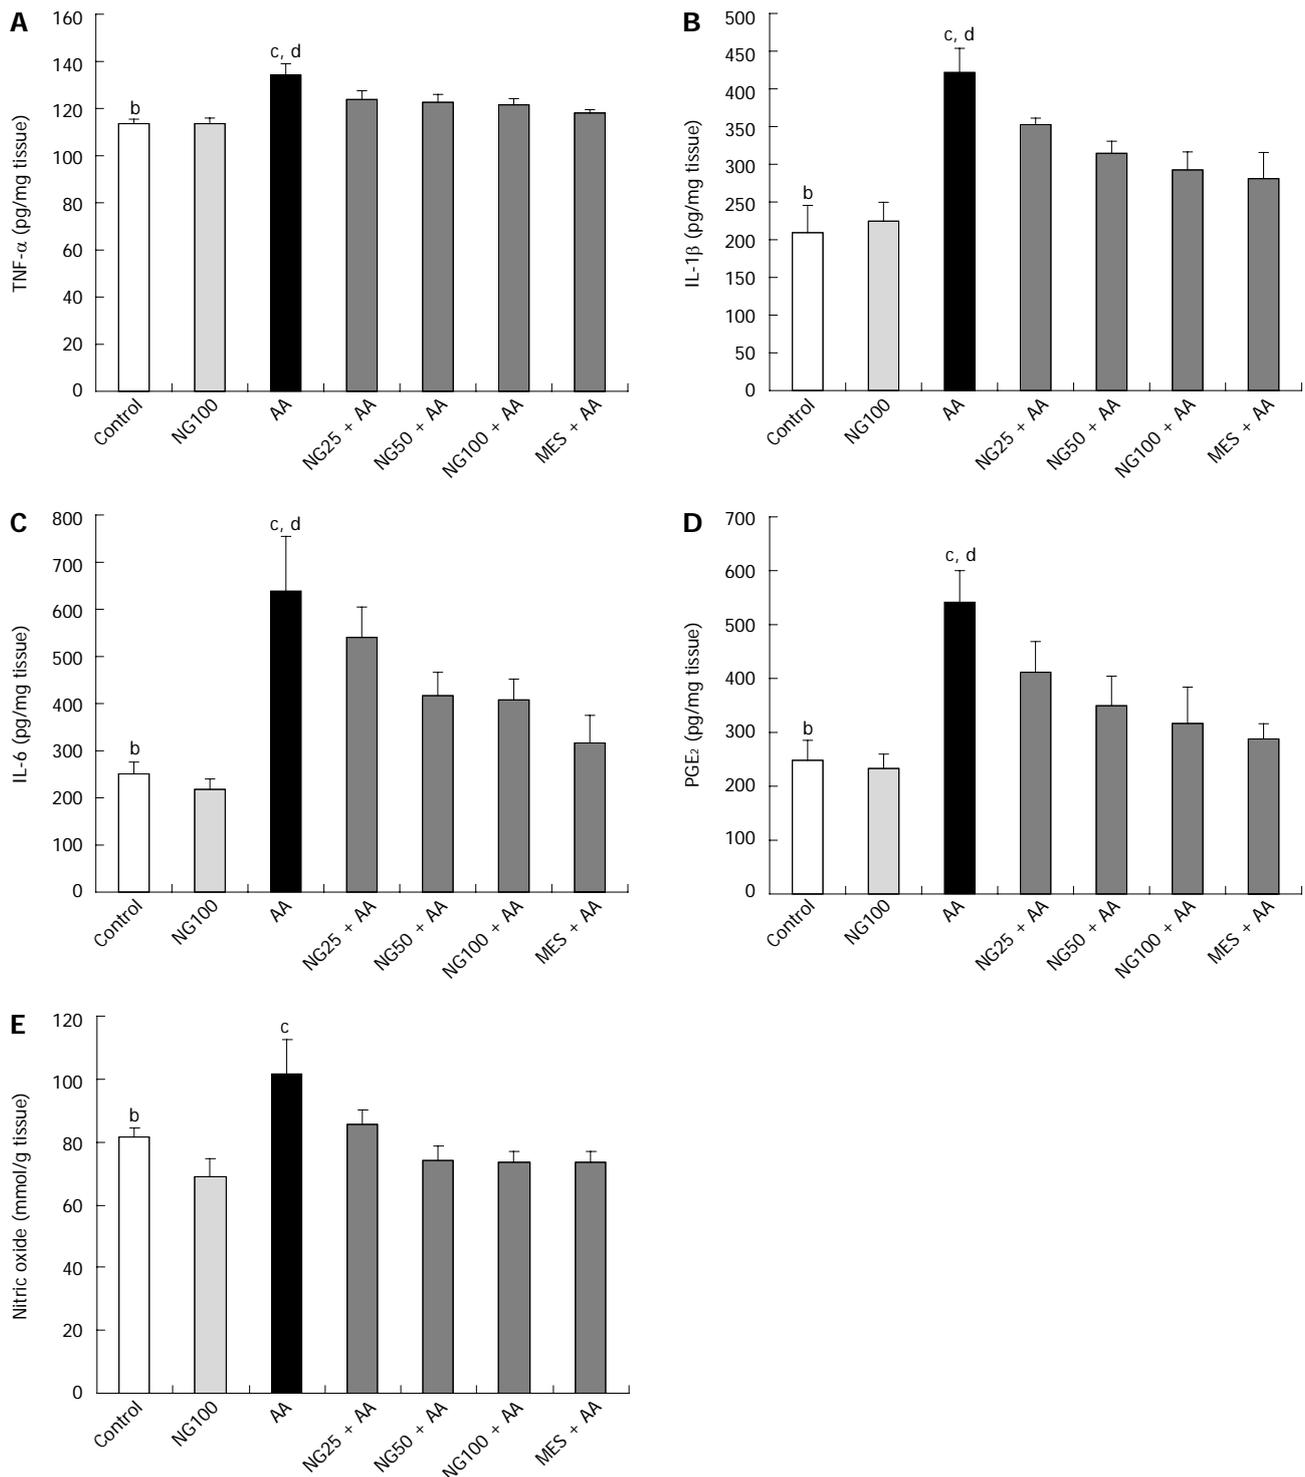

Figure 4 Effect of naringenin on tumor necrosis factor- $\alpha$  (A), interleukin-1 $\beta$  (B), interleukin-6 (C), prostaglandin E $_2$  (D) and nitric oxide (E) levels in colonic tissue of rats with acetic acid-induced ulcerative colitis ( $n = 6$ ). Values are expressed as mean  $\pm$  SE and analyzed using one way analysis of variance followed by Newman-Keuls *post hoc* test. <sup>b</sup> $P < 0.01$  control vs AA; <sup>c</sup> $P < 0.05$ , <sup>d</sup> $P < 0.01$  AA vs NG25 + AA, NG50 + AA, NG100 + AA or MES + AA groups. TNF- $\alpha$ : Tumor necrosis factor- $\alpha$ ; IL-1 $\beta$ : Interleukin-1 $\beta$ ; IL-6: Interleukin-6; PGE $_2$ : Prostaglandin E $_2$ ; AA: Acetic acid; NG: Naringenin; MES: Mesalazine.

and earlier studies to inhibit the level of inflammatory cytokines including TNF- $\alpha$ , IL-6 and IL-1 $\beta$ <sup>[63]</sup>. The anti-inflammatory properties of naringenin were suggested to be through several mechanisms including increased phosphorylation of ERK 5 and P38 MAPK and inhibition of NF- $\kappa$ B and activator protein-1 signaling<sup>[64,65]</sup>. Additionally, naringenin, which present in high concentrations in cit-

rus fruits, was found to block NF- $\kappa$ B activation resulting in down regulation of the downstream target genes of NF- $\kappa$ B such as iNOS and COX-2 expression<sup>[66]</sup>. These enzymes catalyze oxidative stress-induced production of NO and prostaglandins respectively, which are known as an important inflammatory mediators in the pathogenesis of colitis<sup>[63,67]</sup>. These findings are in agreement with our

results where pretreatment with naringenin significantly ameliorated AA induced elevation of the level of PGE<sub>2</sub> and NO in rats' colon.

In conclusion, the present study revealed that NG-protects the AA-induced ulcerative colitis by inhibiting inflammatory and oxidative bio-markers. Finally, our results may pose promising outcomes for future clinical usage of NG as a natural non-toxic effective supplement in IBD.

## COMMENTS

### Background

The pathogenesis of inflammatory bowel disease (IBD) such as ulcerative colitis (UC) is usually associated with reduced antioxidant capacity. Generation of free radicals like reactive oxygen species (ROS) leads to lipid peroxidation, which inhibits cellular antioxidant capability, resulting in prominent colonic inflammation. There is a great need to search for safe and tolerable compounds for the management of IBD to reduce patient compliance as well as the adverse effects of conventional treatments. Naringenin (NG) is a naturally occurring flavonoid that can be extracted from citrus fruits, tomatoes, cherries, grapefruit, and cocoa. Like most of the flavonoids, NG was experimentally found to have several pharmacological potentials, including antioxidant, antitumor and anti-inflammatory because of NG has properties to produce sufficient hydroxyl (-OH) substitutions, which give it the capability to scavenge ROS. Thus, it has considered that NG may diminish and/or improve pathological conditions where oxidation or inflammation is deemed to play a vital role, like in case of IBD.

### Research frontiers

In the present study, NG was orally (gavage) treated with three doses (25, 50 and 100 mg/kg per day body weight) for 7 consecutive days, 24 h later UC was induced by 4% acetic acid. In colitis tissue, Alcian blue, pro-oxidative and inflammatory biomarkers were estimated. The biochemical alterations were further justified with histopathological changes.

### Innovations and breakthroughs

NG pretreatment clearly revealed the protection against acetic acid-induced UC in animal model. Antioxidant and anti-inflammatory properties of NG are suggested to be the key for these effects as NG significantly reduced oxidative stress and inflammatory biomarkers in a dose dependent manner.

### Applications

The present data shows that NG has a promising protective effect against experimentally-induced UC in animal model. Thus, NG could be recommended for its use as potential alternative and complementary therapy for IBD after confirmation of the obtained findings by clinical trials.

### Peer review

The preclinical preventative properties of NG against UC are outlined in present study. Also the possible pharmacological mechanisms of action responsible for these effects are evaluated. Overall, this study proofed that NG is an effective and safe compound that worth to be investigated in future clinical trials for its colonic anti-ulcerogenic properties.

### Abstract

**AIM:** To investigate the quality of topical 2% diltiazem formulations extemporaneously compounded by retail pharmacies openly offering drug-compounding services.

**METHODS:** A participating healthcare professional wrote 12 prescriptions for compounded 2% diltiazem cream, with 2 refills allowed per prescription. The 12 sets of prescriptions were filled, at intervals of 1-2 wk between refills, at 12 different independent retail pharmacies that openly offer drug-compounding services in a major metropolitan region. The 36 resultant preparations, provided as jars or tubes, were shipped, as soon as each was filled, at ambient temperature to the study core laboratory for high-performance liquid chromatography (HPLC) analysis, within 10 d of receipt. For the HPLC analysis, 8 different samples of the topical diltiazem, each approximately 1 g in weight, were taken from prespecified locations within each container. To initiate the HPLC analysis, each sample was transferred

to a 100 mL volumetric flask, to which methanol was added. The HPLC analysis was conducted in accordance with the laboratory-validated method for diltiazem in cream, ointment, and gel formulations. The main outcome measures were potency (percentage of label claim) and content uniformity of the compounded topical 2% diltiazem formulations.

**RESULTS:** Of the 36 prescriptions filled, 30 were packaged in jars and 6 were packaged as tubes. The prescriptions were specifically for cream formulations, but 6 of the 12 pharmacies compounded 2% diltiazem as an ointment; for another pharmacy, which had inadequate labeling, the dosage form was unknown. The United States Pharmacopoeia (USP) standard for potency is 90%-115% of label claim. Of the 36 preparations, 5 (13.89%) were suprapotent and 13 (36.11%) were subpotent. The suprapotent prescriptions ranged in potency from 117.2% to 128.5% of label claim, and the subpotent prescriptions ranged in potency from 34.8% to 89.8% of label claim. Fourteen (38.9%) preparations lacked content uniformity according to the USP standard of 90%-110% potency and < 6% relative standard deviation. Of the 30 formulations packaged in jars, 12 (40%) lacked content uniformity, while of the 6 formulations packaged in tubes, 2 (33.3%) lacked content uniformity. Nine of the 12 pharmacies (75%) failed USP potency or content-uniformity specifications for at least 1 of the 3 prescription fills. For 5 of the 12 pharmacies (41.7%), the mean potency across all three prescription fills was < 90% of label claim.

**CONCLUSION:** Patients prescribed topical 2% diltiazem for treatment of anal fissure frequently receive compounded formulations that are misbranded with respect to potency and that lack content uniformity.

**Key words:** Anal fissure; Pharmacy compounding; Topical diltiazem; Formulation potency; Content uniformity

**Core tip:** The use of topical 2% diltiazem hydrochloride for treating anal fissures is supported by multiple clinical trials and is recommended in published practice parameters. As no commercially manufactured formulation of topical 2% diltiazem has been approved yet by the Food and Drug Administration for the treatment of anal fissure, prescriptions for the medication need to be extemporaneously compounded by retail pharmacies. Employing high-performance liquid chromatography analysis of topical 2% diltiazem formulations compounded by a sampling of pharmacies, we found a notable trend toward lack of content uniformity and misbranding of potency, suggesting that many patients might not receive the anticipated relief of anal-fissure pain.

Quality of compounded topical 2% diltiazem hydrochloride formulations for anal fissure. *World J Gastroenterol* 2013; 19(34): 5645-5650 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i34/5645.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i34.5645>

## INTRODUCTION

The use of topical 2% diltiazem hydrochloride for treating anal fissures by lowering anal sphincter pressure has been explored in multiple clinical trials since 2000<sup>[1-5]</sup>. Diltiazem hydrochloride, a calcium channel blocker, is well known as an oral treatment for hypertension and angina<sup>[6]</sup>. In 2010, the Standard Practice Task Force of the American Society of Colon and Rectal Surgeons (ASCRS) published revised practice parameters for managing anal fissure, assigning to each practice parameter a grade of recommendation and a class of evidence<sup>[7]</sup>. Noting that conservative (nonsurgical) therapy is safe and should be the first step for managing anal fissure<sup>[8-10]</sup>, the ASCRS task force stated that topical formulations of calcium channel blockers may be appropriately used to treat anal fissure and that these drugs seemed to have a lower incidence of adverse effects than topical nitrates, such as nitroglycerin. This practice parameter was accorded the highest grade of recommendation and the second highest class of evidence by the task force<sup>[7]</sup>.

No commercially manufactured formulation of topical 2% diltiazem has been approved by the United States Food and Drug Administration (FDA) for the treatment of anal fissure. Consequently, colon and rectal surgeons, gastroenterologists, and other physicians who want to follow ASCRS practice parameters and prescribe a topical calcium channel blocker for treatment of anal fissure have to write prescriptions for a product that will be extemporaneously compounded by retail pharmacies. Directions for compounding 2% diltiazem as a topical formulation are readily available in published literature. For example, propylene glycol, hydroxyethyl cellulose, and heated purified water are mixed with diltiazem, and

the resulting formulation is packaged in a tight, light-resistant container, usually a tube or jar<sup>[11]</sup>. A few pharmacies that specialize in compounding services advertise the availability of compounded topical 2% diltiazem on the internet. However, many nonspecialized retail pharmacies also fulfill prescriptions by compounding the product.

In 2006, the FDA investigated the quality of compounded products, collecting active pharmaceutical ingredients (API) and finished compounded drug samples during unannounced visits to compounding pharmacies throughout the country. All API samples passed analysis, but a third of the 36 compounded samples that were collected failed analysis by being either subpotent or suprapotent or by lacking content uniformity. The United States Pharmacopoeia (USP) standard for potency is 90%-115% of label claim<sup>[12]</sup>. Because the API samples passed analysis, the FDA observed that the failures of the samples in the analysis were directly related to faulty compounding processes at the pharmacies, including the lack of proper in-process controls and end-product testing<sup>[13]</sup>.

To examine the quality of compounded formulations of topical 2% diltiazem, we undertook a high-performance liquid chromatography (HPLC) analysis of preparations gathered from retail pharmacies in a major metropolitan region.

## MATERIALS AND METHODS

### Data source

A healthcare professional was asked to write prescriptions for extemporaneously compounded 2% diltiazem cream for fulfillment by retail pharmacies in the greater New York metropolitan region. The selection criteria, intended to locate retail pharmacies that might have experienced pharmacists on staff with competency at compounding, included stipulations that the pharmacies be independent, not parts of retail pharmacy chains, and that they openly offer drug-compounding services by means of online or other advertising. A total of 12 qualifying retail pharmacies were selected from different parts of the metropolitan region.

The participating healthcare professional wrote 12 prescriptions, with 2 refills allowed per prescription, so that 3 prescriptions could be filled at each of the 12 pharmacies (36 total fills) for compounded 2% diltiazem cream. The prescriptions were filled at each of the 12 pharmacies during May 2012 and June 2012, at intervals of 1-2 wk in between refills. As soon as any prescription was filled by a retail pharmacy, it was collected and shipped at ambient temperature in a prepared bubble-wrap mailer to DermPathe Pharmaceuticals (Branchberg, NJ, United States), the laboratory engaged for the HPLC analysis. The compounded formulations of topical 2% diltiazem were provided by the retail pharmacies as either jars or tubes.

Upon receipt of each package, DermPathe logged the time and date and stored the compounded formulation at ambient temperature. HPLC analysis was conducted

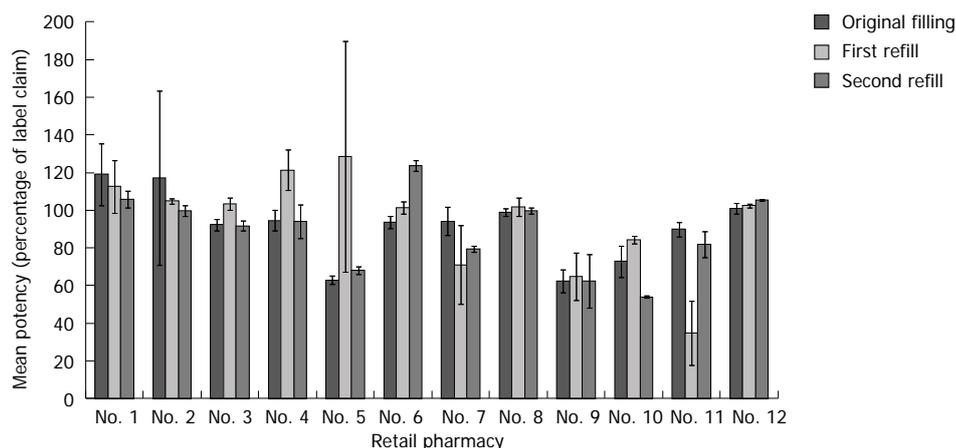

Figure 1 Mean potency of diltiazem content in each of the 3 samples from each of the 12 different retail pharmacies (mean  $\pm$  SD).

in accordance with the DermPathe-validated method for diltiazem in cream, ointment, and gel formulations. The analysis included an assessment of potency (percentage of label claim) and content uniformity for each of the compounded formulations. For the analysis of each formulation, 8 different samples of the topical diltiazem, each approximately 1 g in weight, were taken from pre-specified locations within the compounded formulation container. If the compounded formulation was provided in a jar, 4 samples were taken from the top of the jar: 1 at the top front, 1 at the top center, 1 at the top right back corner, and 1 at the top left back corner. In the middle layer of the jar, 1 sample was taken from the center and 1 from the middle right corner. At the bottom of the jar, 1 sample was taken from the center and 1 from the bottom left corner. If the compounded formulation was provided in a tube, the tube was sectioned horizontally and opened up. Then 2 samples were drawn from the top left and top right of the tube, 2 more from the middle left and middle right of the tube, 2 from the bottom left and bottom right of the tube, and the final 2 randomly on the left and on the right between the middle and the bottom of the tube.

Each sample was transferred to a 100 mL volumetric flask, to which methanol was added to fill approximately 80% of the flask volume. The solution was sonicated for 1 h, and the flask was then filled to volume with methanol and mixed thoroughly by shaking. Filtered through a 0.45-micron filter, the solution was then transferred into HPLC vials for analysis using a Waters 2695 HPLC system with a 2487 dual wavelength detector (Waters Corporation, Milford, MA, United States). A Luna C8 150 mm  $\times$  4.6 mm, 5 mm column with a C8 Security Guard column (Phenomenex, Torrance, CA, United States) was used as the stationary phase. The mobile phase consisted of an acetate buffer, acetonitrile, and methanol, in a 50:25:25 ratio. The acetate buffer contained 8.2 g of anhydrous sodium acetate and 1.16 g of *D*-10-camphorsulphonic acid in 1000 mL of water, with pH adjusted to 6.2 with 1 mol/L sodium hydroxide. The flow rate was set at 2 mL per minute, the detector wavelength was set at 240 nm, and the column temperature was set to 30 °C.

### Statistical analysis

Descriptive statistics were used in this study. For categorical variables, frequencies and percentages are reported. For continuous variables, the number of observations, mean  $\pm$  SD, and relative standard deviation are reported. Statistical analyses were performed using Excel 2010 (Microsoft, Redmond, WA, United States).

## RESULTS

Thirty-six prescriptions for compounded topical 2% diltiazem were written, filled, and shipped to DermPathe for analysis. Of these preparations, 30 were packaged in jars and 6 were packaged as tubes (only 2 of the 12 retail pharmacies used tubes for packing). One of the 12 retail pharmacies failed to label each of the 3 filled prescriptions of topical 2% diltiazem with the drug name; the label on each of the 3 formulations from this pharmacy simply read “compound.”

The prescriptions were specifically for cream formulations. Five of the 12 pharmacies compounded 2% diltiazem as a cream, using lipoderm, but 6 of the 12 pharmacies compounded 2% diltiazem as an ointment, using petrolatum. For 1 pharmacy, the same that had the inadequate labeling, the dosage form was unknown.

The preparations were analyzed by DermPathe within 10 d of receipt. Prior to being analyzed, the products were stored at room temperature. In the published directions for preparing topical 2% diltiazem, the shelf life of the preparation is given as 30 d when stored at room temperature<sup>[11]</sup>. At the time of HPLC analysis, there were no visible signs of product degradation in any of the jars or tubes.

### Potency results

Of the 36 prescriptions, 18 (50.0%) were misbranded for potency according to the USP standard. Five (13.9%) of the prescriptions were suprapotent (that is, the measured drug activity was  $>$  115% of label claim) (Figure 1). The suprapotent prescriptions ranged in potency from 117.2% to 128.5% of label claim. No retail pharmacy produced more than 1 suprapotent formulation. Thirteen

<sup>1</sup>Jars: 1: Top front; 2: Top left back corner; 3: Top right back corner; 4: Top center; 5: Center of jar; 6: Middle right corner; 7: Bottom left corner; 8: Bottom center. Tubes: 1: Top left; 2: Top right; 3: Middle left; 4: Middle right; 5: Random left; 6: Random right; 7: Bottom left; 8: Bottom right.

(36.1%) of the prescriptions were subpotent (that is, the measured drug activity was < 90% of label claim) (Figure 1). The subpotent prescriptions ranged in potency from 34.8% to 89.8% of label claim. Only 3 of the 12 pharmacies compounded each of the 3 prescriptions they filled without misbranding potency. For 3 of the 12 pharmacies, all 3 of the filled prescriptions were subpotent.

### Content uniformity results

Of the 36 preparations, 14 (38.9%) lacked content uniformity according to the USP requirement of 90% to 110% potency and < 6% relative standard deviation<sup>[12]</sup>. Table 1 shows the potency variations at the different sample locations of these 14 preparations. Of the 30 formulations packaged in jars, 12 (40%) lacked content uniformity; of the 6 formulations packaged in tubes, 2 (33.3%) lacked content uniformity. In some of the jars the potency varied by more than 100%. In batch 4, provided as a jar, the potency at the top center of the jar was 99.8% while the potency at the bottom center of the jar was 231.7%. In batch 14, also provided as a jar, the potency at the top center of the jar was 72.4% while the potency at the bottom of the jar was 220.8%. Batch 32, provided as a tube, was overall subpotent and also lacked content uniformity: at the middle left of the tube, potency was 16.8%; at the bottom left of the tube, potency was 42.0%.

### Pharmacy performance

Nine of the 12 pharmacies failed USP potency or content-uniformity specifications for at least 1 of their 3 prescriptions. Three of the 12 pharmacies failed USP potency or content-uniformity specifications for all 3 of their prescriptions. When the potencies of the 3 time-separated prescriptions were averaged together for each of the 12 pharmacies, the mean potency was < 90% of label claim for 5 of the 12 pharmacies (Table 2).

## DISCUSSION

In this HPLC analysis of 36 preparations of compounded topical 2% diltiazem from 12 retail pharmacies, half

of the preparations did not meet USP specifications for potency and almost 40% of the preparations did not meet USP specifications for content uniformity. Of the 12 retail pharmacies, only three were able to fill all three of the time-separated prescriptions consistently within USP specifications.

When compounded preparations of topical 2% diltiazem fall outside USP specifications for potency, they are more likely to be subpotent (36.1% of the prescriptions) than suprapotent (13.9% of prescriptions). With more than a third of the prescriptions of compounded 2% diltiazem being subpotent, such prescriptions might not routinely relieve anal fissure pain to the extent or with the speed established in clinical trials of topical 2% diltiazem<sup>[1,4,14-16]</sup>. In one of those trials, Carapeti *et al*<sup>[1]</sup> compared different diltiazem gel concentrations (0.1%, 0.5%, 1%, 2%, 5%, and 10% weight per volume) and found a dose-dependent effect on maximum resting anal sphincter pressure (MRP), with the maximal effect (28% reduction compared with pretreatment,  $P < 0.0001$ ) achieved with the 2% formulation. The MRP was not lowered as effectively with the 1% concentration, while concentrations higher than the 2% produced no additional effect.

The potency of the 5 suprapotent preparations of topical 2% diltiazem did not exceed 128.5% of label claim. However, owing to a lack of content uniformity in some preparations, especially when packaged in jars, compounded diltiazem could be more than twice as potent as the label claim in some sections of a container. The level of suprapotency in these sections, as high as 231.7% of label claim in a section of one jar, could put patients at potential risk for drug-related side effects. Because diltiazem is also used as a hypertensive agent, the largest risk associated with suprapotent topical 2% diltiazem might be dizziness or postural hypotension. In studies that have evaluated topical 2% diltiazem for treatment of anal fissure, the side effect profile has been mild, and the most frequent side effects have been headache or anal pruritus<sup>[5,17-20]</sup>. However, there have been reports of postural hypotension associated with the use of topical diltiazem<sup>[21]</sup>.

Azarnoff *et al*<sup>[12]</sup> conducted a similar HPLC analysis

**Table 2 Mean potency as percentage of label claim for 3 prescriptions of compounded topical 2% diltiazem filled by 12 retail pharmacies**

Pharmacy No.	Label claim (mean $\pm$ SD)	Relative SD
1	95.9% $\pm$ 9.8%	8.7
2	107.3% $\pm$ 16.5%	15.4
3	95.9% $\pm$ 2.2%	2.2
4	103.3% $\pm$ 5.1%	4.9
5	86.5% $\pm$ 20.1%	23.2
6	106.2% $\pm$ 1.8%	1.7
7	81.6% $\pm$ 6.5%	8.0
8	100.1% $\pm$ 2.0%	1.9
9	63.2% $\pm$ 3.8%	6.0
10	70.4% $\pm$ 3.2%	4.5
11	68.8% $\pm$ 6.5%	9.4
12	102.9% $\pm$ 0.8%	0.8

of compounded formulations of topical 0.3% nitroglycerin ointment for anal fissure. The investigators acquired 24 filled compounded prescriptions from 24 retail pharmacies across different geographic regions. They found that 7 (29.2%) of the 24 compounded formulations were subpotent and that 1 (4.8%) was suprapotent. Moreover, 5 (20.8%) of the 24 samples lacked content uniformity. In comparison, in the current study, in which 36 compounded preparations were acquired from 12 different pharmacies, 13 (36.11%) of the preparations were subpotent, 5 (13.9%) were suprapotent, and 14 (38.9%) lacked content uniformity. The relatively worse analytic performance of compounded topical 2% diltiazem formulations in the current study might be an artifact of study design. Another explanation might be that it is more difficult to prepare compounded diltiazem formulations rather than compounded nitroglycerin formulations in accordance with USP standards, although it is unclear why this might be the case.

In October 2012, an FDA report of an outbreak of fungal meningitis related to contaminated products produced by the New England Compounding Center (Framingham, MA, United States) brought to public awareness the practice and business of pharmacy compounding<sup>[22,23]</sup>. There are legitimate reasons for physicians to prescribe extemporaneously compounded drugs: for example, to provide patients with products like topical 2% diltiazem, currently recommended in the ASCR practice parameters for anal fissure but not approved by the FDA, or to create unique medications for specific patients, such as those who have documented allergies to certain drug ingredients or who require dosage forms different from those of FDA-approved drugs<sup>[24-26]</sup>. However, not only have both branded and generic drugs undergone FDA approval for safety and efficacy, they are also required by law to be produced under federal Good Manufacturing Practice (GMP) regulations in order to ensure their identity, quantity, potency, and purity<sup>[24]</sup>. In contrast, although extemporaneously compounded drugs might be formulated under professional pharmacy standards, these standards are inherently less rigorous than federal GMP quality standards. Because there is no federal surveillance

of compounded drugs, the extent of quality and safety problems with compound drugs is unknown<sup>[24]</sup>. Clearly, a topical 2% diltiazem cream produced under GMP regulations is needed to avoid the large percentage of substandard compounded formulations of a drug specifically recommended by the practice parameters of a medical society.

There were limitations to this study. The sample size was small, and the collection of samples was restricted to a single major metropolitan area. None of the compounded formulations were analyzed for microbiologic content when received by the laboratory. Upon routine inspection of the formulations after 8 mo of refrigerated storage at 5 °C, the laboratory discovered mold on some of them, and all samples were discarded. A future study of compounded formulations of topical 2% diltiazem will need to include analyses of microbiologic content, of possible drug degradation, and of the release of diltiazem from the formulations.

In conclusion, this study shows that when patients are prescribed topical 2% diltiazem cream for treatment of anal fissure in a major metropolitan region, they receive compounded formulations from retail pharmacies that are misbranded in respect to potency approximately 50% of the time and that lack content uniformity approximately 40% of the time. Because approximately one third of the compounded preparations were subpotent, patients treated with compounded formulations of topical 2% diltiazem might not receive the anticipated relief of pain associated with anal fissure.

## COMMENTS

### Background

The use of topical 2% diltiazem hydrochloride for treating anal fissures is supported by multiple clinical trials and is recommended in published medical society practice parameters. In countries where no commercially manufactured formulation of topical 2% diltiazem is available, prescriptions for the medication need to be extemporaneously compounded by retail pharmacies. Up to now, the quality of these compounded diltiazem formulations has not been evaluated.

### Research frontiers

High-performance liquid chromatography analysis was undertaken with 36 preparations of compounded 2% topical diltiazem that were gathered from 12 different independent retail pharmacies in a major metropolitan area.

### Innovations and breakthroughs

This is the first study to show that when patients are prescribed topical 2% diltiazem cream for treatment of anal fissure, they receive compounded formulations from retail pharmacies that are misbranded in respect to potency approximately 50% of the time and that lack content uniformity approximately 40% of the time. Because over one third of the compounded preparations were subpotent, patients treated with compounded formulations of topical 2% diltiazem might not receive the anticipated relief of anal-fissure pain.

### Applications

By demonstrating that a sample of retail pharmacies compound a large percentage of substandard formulations of topical 2% diltiazem, the study underscores that this drug, recommended for use by medical society practice parameters, should be produced under Good Manufacturing Practice regulations to ensure its identity, quantity, potency, and purity.

### Peer review

Local absorption of diltiazem depends on skin thickness and local inflammation. It is also proportional to the medication amount. This study is similar to a 2007 study concerning compounded formulations of nitroglycerin ointment for anal

fissure. The authors noticed a problem that is presumably unknown to gastroenterologists and surgeons: that compounded formulations of topical 2% diltiazem, recommended by the American Society of Colon and Rectal Surgeons for anal fissure therapy but not approved by the United States Food and Drug Administration, may be subpotent or suprapotent. Of 36 compounded preparations examined in the study, 38.9% lacked content uniformity, and 50% did not meet United States Pharmacopoeia specifications for potency.

### Abstract

**AIM:** To investigate the epidemiological characteristics of colorectal cancer (CRC) in patients under 50 years of age across two institutions.

**METHODS:** Records of patients under age 50 years of age who had CRC surgery over a 16 year period were assessed at two institutions. The following documents where reviewed: admission notes, operative notes, and discharge summaries. The main study variables included: age, presenting symptoms, family history, tumor location, operation, stage/differentiation of disease, and post operative complications. Stage of disease was classified according to the American Joint Committee on Cancer TNM staging system: tumor depth; node status; and metastases.

**RESULTS:** CRC was found in 180 patients under age 50 years (87 females, 93 males; mean age  $41.4 \pm 6.2$  years). Young patients accounted for 11.2% of cases during a 6 year period for which the full data set was

available. Eight percent had a 1<sup>st</sup> degree and 12% a 2<sup>nd</sup> degree family CRC history. Almost all patients (94%) were symptomatic at diagnosis; common symptoms included: bleeding (59%), obstruction (9%), and abdominal/rectal pain (35%). Evaluation was often delayed and bleeding frequently attributed to hemorrhoids. Advanced stage CRC (Stage 3 or 4) was noted in 53% of patients. Most tumors were distal to the splenic flexure (77%) and 39% involved the rectum. Most patients (95%) had segmental resections; 6 patients had subtotal/total colectomy. Poorly differentiated tumors were noted in 12% and mucinous lesions in 19% of patients of which most had Stage 3 or 4 disease. Twenty-two patients (13%) developed recurrence and/or progression of disease to date. Three patients (ages 42, 42 and 49 years) went on to develop metachronous primary colon cancers within 3 to 4 years of their initial resection.

**CONCLUSION:** CRC was common in young patients with no family history. Young patients with symptoms merit a timely evaluation to avoid presentation with late stage CRC.

© 2013 Baishideng. All rights reserved.

**Key words:** Colorectal cancer; Colorectal cancer screening; Sporadic colorectal cancer; Early-age onset colorectal cancer; Sigmoidoscopy

**Core tip:** Colorectal cancer (CRC) is rising among patients under age 50 years. In our study, the majority of patients did not have a family history of CRC and presented with advanced disease stages. In America, many physicians wrongly believe that CRC in patients under age 50 years is uncommon and mostly found in patients with a 1<sup>st</sup> degree family history of CRC. This misconception delays time to diagnosis, contributing to a more advanced disease stage on presentation. The authors hope, after reading this article, doctors will recommend timely and complete colon evaluations for

patients under age 50 years who present with rectal bleeding.

Colorectal cancer in patients under 50 years of age: A retrospective analysis of two institutions' experience. *World J Gastroenterol* 2013; 19(34): 5651-5657 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i34/5651.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i34.5651>

## INTRODUCTION

Colorectal cancer (CRC) remains a notable source of morbidity and mortality worldwide<sup>[1]</sup>. CRC is consistently the third most commonly diagnosed cancer in the United States. The American Cancer Society estimated that there would be 103170 new cases of colon and 40290 new cases of rectal cancer in 2012; in addition, 51690 deaths were predicted<sup>[2]</sup>. Although common, the overall incidence of CRC in the general population declined by 2.9% in men and 2.2% per year in women between 1998 and 2009<sup>[3]</sup>. An increase in the proportion of the population undergoing screening colonoscopy and the removal of benign precancerous polyps is thought to account for, at least, part of this decrease.

Patients with a first degree family history of CRC are advised to begin screening colonoscopy at age 40 or 10 years prior to the youngest age at which a family member with CRC was diagnosed. In addition, screening programs for CRC are now widely implemented for "average risk" patients, defined as those without a first degree family history of CRC or other risk factors, other than age. Universally, it is advised that screening begin at age 50 years for "average risk" patients. Asymptomatic patients under 50 years of age without a family history are excluded from almost all screening programs. Perhaps, in part, because of the age 50 years cut off many patients and doctors have a low index of suspicion for CRC in young patients without family history who present with bleeding or other symptoms. It is also the impression of many doctors and patients that the majority of young patients who develop CRC have a positive family history. Although less common than in older patients, sporadic CRC accounts for the majority of cases in patients under age 50 years.

The National Cancer Database Report on CRC noted that individuals under 50 years of age accounted for roughly 7% of all CRC in a 1990 study population of over 38000 patients<sup>[4]</sup>. As per the Surveillance Epidemiology and End Results (SEER) Program data from 1993 to 1997, patients younger than 55 accounted for roughly 12% of all CRC cases<sup>[5]</sup>. A recent study that examined data from the SEER Program cancer registries between 1992-2009 reported that the overall incidence of CRC per 100000 people (20-49 years age category) increased 1.6% and 1.7% per year in men and women, respectively,

over this time period<sup>[3]</sup>. A review of SEER Program data from 2005-2009 provides more detailed information regarding CRC in younger patients; in patients under 20 years the incidence was about 0.1%, in those 20-34 years of age it was 1.1%, in the 35-44 years sub-group the incidence was 4.0% whereas in the 45-54 years group it was 13.4%<sup>[2]</sup>. The data suggests that the incidence in younger patients is increasing<sup>[3]</sup>.

A number of reports regarding young patients with CRC have been published over the last few decades (Table 1); however, these reviews typically span many years, often include patients with familial syndromes and/or ulcerative colitis, and do not adequately comment on the relevant family history of the study patients<sup>[6-15]</sup>. This focused review regarding two institutions' experiences with patients under 50 years of age with CRC that came to surgery over a 16 year interval was conducted to determine: the volume of CRC operations for young patients, the proportion with a family history of CRC, the stage at presentation, the specific cancer location, and the presenting symptoms, if any.

## MATERIALS AND METHODS

### Patient population

Hospital records of patients under the age of 50 years who underwent CRC operations between July 1996 and May 2012 at two institutions were reviewed (New York Presbyterian Hospital, Columbia University Campus and St. Luke's Roosevelt Hospital, NY, United States). Specifically, the following documents were reviewed; admission notes, operative notes, discharge summaries, endoscopy records, and pathology reports. A subset of this data was also obtained from an IRB approved prospective data base of patients undergoing colorectal resection maintained by the senior author from 2006 to June 30, 2009 at New York Presbyterian Hospital and from July 1, 2009 until May 2012 at St. Luke's Roosevelt Hospital. This prospective database also provided the information regarding CRC patients over 50 years of age ( $n = 392$ ) used in this study. Additional information for this retrospective review was obtained from office charts and from telephone interviews.

### Study endpoints

The main study variables included: demographics, presenting symptoms leading to diagnosis, family history of CRC, tumor location, type of surgical resection, stage and differentiation of disease, and post operative complications. Patients with inflammatory bowel disease or known polyposis syndromes such as familial adenomatous polyposis syndrome, Gardner's syndrome and the like were excluded from the study.

Disease stage was reported according to the TNM Classification System used by the American Joint Committee on Cancer<sup>[16,17]</sup>. "T" refers to the size or direct extent of invasion of the primary tumor; "N" refers to the degree of spread to regional lymph nodes, if any; and "M"

### Statistical analysis

Statistical methods for comparing stage and tumor distribution between the under age 50 years and the 50 and over years groups included a 2-proportion Z test.

## RESULTS

### Patient demographics

One hundred eighty patients under 50 years of age (87 females, 93 males; range 17-49 years; mean 41.4 ± 6.2 years) underwent a CRC operation between July 1996 and May 2012 at the two institutions. In regards to the total number of patients (regardless of age) that underwent a CRC operation, complete data is only available for the period between July 2006 and May 2012; during this time period 437 CRC operations on adults were carried out of which 49 (11.2%) involved patients less than 50 years of age. When the total population of 180 patients under age 50 is considered, the distribution of CRC within age categories is as follows: under age 30 years, 8 patients (4%); age 30-39 years, 46 patients (26%); age 40-49 years, 126 (70%). Of note, 30% of the patients were younger than

**Table 3** Location of cancers *n* (%)

Anatomic location of cancer <sup>2</sup>	Cancers
Right colon <sup>1</sup>	31 (17.2)
Transverse colon	13 (7.2)
Descending colon	17 (9.4)
Descending and sigmoid colon junction	2 (1.1)
Sigmoid colon	29 (16.1)
Rectosigmoid colon	19 (10.6)
Rectum	71 (39.4)

<sup>1</sup>Right colon includes cecum, ascending, hepatic flexure; <sup>2</sup>Two patients had synchronous cancers.

40 years of age. One hundred and seventy patients (94%) reported symptoms upon presentation (Table 2).

### Family history of CRC

Family history data was available for 167 patients; 13 patients (7.8%) did not know their family history. Regarding the 167 patients with family history data, 14 patients (8.4%) had a first degree family history of CRC, 20 patients (12.0%) had a second degree history, and 6 patients (3.6%) had both a first and second degree family history of CRC. Thus, a total of 12% of patients had, at least, a first degree family history of CRC. Seventy six percent were sporadic CRC cases. One patient (age 42 years) presented with synchronous primary cancers of the cecum and splenic flexure and had a family history notable for 3 first and 1 second degree relatives with CRC. The Amsterdam criteria for hereditary non-polyposis colorectal cancer (HNPCC) were met in this patient<sup>[14]</sup>. Unfortunately, none of the patients in this series were evaluated for gene mutations associated with HNPCC (*i.e.*, *hMLH1*, *hMSH2*, *etc.*)<sup>[18]</sup>.

### Distribution of tumor location and colorectal resection

The majority of tumors (77%) were located distal to the splenic flexure, with 39% involving the rectum (Table 3). Proximal (right and transverse colon) cancers were noted in only 24% of patients. In comparison, a cohort of 392 CRC patients 50 years of age and older who underwent an operation between 2006 and 2012 at the same institutions by the same surgeons, presented with more proximal tumors (age < 50 years, 24% *vs* age ≥ 50 years, 43%; *P* < 0.0001) and fewer rectal tumors (age < 50 years, 39% *vs* age ≥ 50 years, 27%; *P* = 0.002) using 2-proportion Z-test (Table 4).

A formal colorectal resection was done in the majority of patients (95%), a transanal excision of a rectal cancer in 1 patient, colocolonic bypass for unresectable Stage 4 disease in 1 patient, and proximal diversion in 6 patients with obstructing, locally invasive cancers (Table 5). Twenty three abdominoperineal resections and 3 low anterior resections with mucosectomy and subsequent coloanal anastomosis were performed. A Hartmann's procedure was done in 4 patients with sigmoid or rectal lesions. Two patients (ages 34 and 42 years) had synchronous primary colon cancers and underwent subtotal colectomy. Twenty-

**Table 4** Colorectal cancer staging *n* (%)

Present series	Value	SEER <sup>2</sup>	Value
Age < 50 yr			
Stage 1 <sup>1</sup>	37 (21)	Localized	30%
Stage 2	47 (26)	Regional	40%
Stage 3	70 (39)	Distant	27%
Stage 4	26 (14)	Unstaged	3%
Age ≥ 50 yr			
Stage 1	88 (22)	Localized	38%
Stage 2	143 (36)	Regional	37%
Stage 3	135 (34)	Distant	19%
Stage 4	26 (7)	Unstaged	6%

<sup>1</sup>Two patients had Stage 0 disease and one patient had Tis disease following polypectomy; <sup>2</sup>Surveillance Epidemiology and End Results (SEER) 18, 2000-2009 stage distribution. Localized (confined to primary site), regional (spread to regional lymph nodes), distant (cancer has metastasized).

four distal resection patients were temporarily diverted (16% of all patients with anastomoses). Regarding the surgical methods used in the 172 patients who underwent bowel resection, the breakdown is as follows: laparoscopic-assisted, 78 patients (45.3%); hand-assisted or hybrid laparoscopic/open technique, 29 patients (16.9%); and open methods, 65 patients (37.8%).

### Staging distribution

According to the TNM system for cancer staging by the American Joint Committee on Cancer<sup>16,17</sup>, 37 patients (21%) had Stage 1 disease, 47 patients (26%) had Stage 2 disease, 70 patients (39%) had Stage 3 disease, and 26 patients (14%) had Stage 4 disease (Table 4). Three patients who underwent neoadjuvant chemoradiation for T3 rectal lesions based on preoperative endorectal ultrasound imaging had no residual disease on final pathology at the time of colorectal resection and were considered as Stage 2 lesions. Likewise, 3 patients who had sessile polyp cancers removed colonoscopically (invasion into submucosa noted on pathology) who underwent formal resection that revealed no residual cancer or involved lymph nodes on pathologic evaluation were classified as having Stage 1 cancers. Twenty patients with Stage 4 disease had known hepatic involvement and 3 patients had peritoneal carcinomatosis diagnosed at laparotomy.

Thirty-five patients (19%) underwent neoadjuvant chemoradiation, 3 patients (1.7%) underwent neoadjuvant chemotherapy alone, 10 patients (5.6%) underwent adjuvant chemoradiation, 56 patients (31%) underwent adjuvant chemotherapy, and 1 patient underwent adjuvant radiation alone for bony metastases. Of note, compared to the cohort of 392 CRC patients 50 years of age or older who underwent an operation between 2006 and 2012, patients under age 50 more often presented with Stages 3 and 4 disease (age < 50 years, 53% *vs* age ≥ 50 years, 41%; *P* = 0.003 using 2-proportion *Z*-test) (Table 4).

### Histopathological evaluation

Moderately or well differentiated cancers were noted in

**Table 5** Type of colon resection *n* (%)

Operation	Patients	Laparoscopic
Right colectomy	34 (19.8)	17 (50)
Transverse colectomy	2 (1.2)	2 (100)
Left colectomy	20 (11.6)	10 (50)
Descending and sigmoid colectomy	1 (0.6)	1 (100)
Sigmoid colectomy	22 (12.8)	15 (7)
Rectosigmoidectomy	24 (13.9)	21 (88)
Low anterior resection	40 (23.2)	26 (65)
Abdominoperineal resection	23 (13.4)	11 (48)
Subtotal/total colectomy	6 (3.5)	4 (67)
Total resections	172 (95.0)	107 (62)

124 patients (69%) whereas poorly differentiated cancers were found in 22 patients (12%). Of those with poorly differentiated histology, 67 percent presented with advanced Stage CRC (Stage 3 or 4). Thirty-four patients (19% of total) had mucinous adenocarcinomas of which 62% had advanced stage CRC.

### Postoperative complications and short-term outcomes

Regarding postoperative complications, there was 1 anastomotic leak and 4 intra abdominal/pelvic abscesses (reoperation in 1 patient, percutaneous drainage in 3 patients). Other postoperative complications included: ileus, 6 patients; small bowel obstruction, 6 patients (all required reoperation); wound infection, 7 patients; wound dehiscence, 2 patients (reoperation × 2); urinary retention, 3 patients; portal vein thrombosis, 1 patient; *C. difficile* colitis, 1 patient (treated with antibiotics); and incisional hernia, 1 patient (surgically repaired). There were no deaths perioperatively. Twenty-two patients (13%) developed recurrence and/or progression of disease to date. Three patients (ages 42, 42, and 49 years) went on to develop metachronous primary colon cancers within 3-4 years of their initial resection.

## DISCUSSION

It is well established that the incidence of CRC increases significantly beyond the 5<sup>th</sup> decade of life and continues to rise thereafter with increasing age. More recent reviews have shown that the percentage of CRC patients under 50 years of age has increased to approximately 12 percent<sup>15</sup>. Our data corroborates these findings as 11.2% of CRC patients in our study were younger than age 50 years.

Many people, lay and physician alike, falsely believe that the majority of patients under 50 years of age who develop CRC have a significant family history and are genetically predisposed to developing CRC. Interestingly, only 12% of patients in our study had a first degree relative with CRC and only 1 patient (age 42 years) met the Amsterdam criteria for HNPCC based on family history. A literature search revealed several reports regarding young patients with CRC that showed family history data<sup>16-15</sup> similar to that of our study findings. In the general population of CRC patients (all ages), an estimated 15%-20% of patients have a family history of colorectal

neoplasia<sup>[19]</sup>. Therefore, regardless of age at diagnosis, the vast majority of patients with CRC have sporadic disease and are “average risk” patients without a family or personal history of colorectal neoplasm, inflammatory bowel disease, polyposis syndromes, or other risk factors.

Are CRCs in the under 50 population different from tumors that occur in older patients? In the absence of detailed genetic analyses of the tumors we must use clinical and basic pathologic data to address this question. The stage breakdown data may be helpful in this regard, although it is influenced by factors other than the tumors’ biologic aggressiveness (*i.e.*, the timeliness of diagnosis). Similarly, the differentiation profile of the tumors in the younger and older CRC populations permits comparison of the 2 groups.

SEER stage distribution data from 2000-2009 for individuals with CRC under 50 years of age noted that 30% had localized disease (confined to primary site), 40% had regional disease (spread to mesenteric lymph nodes), and 27% had distant disease (metastatic) at the time of diagnosis; thus, 67% had Stage 3 or 4 disease. In contrast, in the over 50 age group, 39% of patients had localized disease, 37% had regional disease and 19% had distant disease at diagnosis; thus, 56% had Stage 3 or 4 disease<sup>[2]</sup>. Our study results, as well as other investigators<sup>[8,10,11,13]</sup>, support the notion that advanced Stage (Stage 3 or 4) at presentation is more common among young patients compared to older patients (50 years and older). Taken together, the available data suggests that younger patients with CRC more often present with advanced disease when compared to the general population<sup>[8,10,11,13]</sup>.

Regarding tumor differentiation, previous studies report a greater percentage of poorly differentiated (19%-49% of total) and mucinous tumors (9%-49%) in younger CRC populations<sup>[3,8,20,21]</sup>, whereas, in the current study, only 12% of patients had poorly differentiated adenocarcinomas and 20% had mucinous histology. Data concerning the general CRC population from two previously published studies suggests that about 15% of colorectal adenocarcinomas are poorly differentiated and 17% demonstrate mucinous histology<sup>[22,23]</sup>. The relatively low percentage of poor prognosis histologies in our study may be related, in part, to the small number of HNPCC patients in the study population since HNPCC is associated with a higher incidence of poorly differentiated and mucin producing tumors. Regardless, the histology data does not provide an explanation for the high incidence of advanced stage tumors seen in the current study population. As mentioned earlier, there may be factors other than unfavorable histology and aggressive tumor biology contributing to the high rate of advanced stage tumors seen in younger CRC patients.

It has been suggested that delays in diagnosis may account, in part, for the advanced Stage at presentation noted in many CRC patients under 50 years of age<sup>[14,24]</sup>. Young symptomatic patients may delay presentation to a physician out of ignorance, fear, or denial. Furthermore, when confronted with young, average risk patients, clini-

cians may attribute their symptoms to any number of common benign anorectal disorders. The already mentioned fixation on 50 years as the age after which CRC occurs likely figures into the practitioner’s thinking as well. Consequently, a full colorectal evaluation may not be carried out for months to years following the onset of symptoms. For example, in the current study multiple patients reported a history of intermittent rectal bleeding and were treated for “hemorrhoids” for a year or longer before referral for diagnostic endoscopy. In one patient with an 18 mo history of diarrhea and occasional bleeding with mucus, a corresponding note from a gastroenterologist stated that the change in bowel habits likely represented irritable bowel syndrome with hemorrhoids. This patient ultimately underwent a colonoscopy and was found to have a sigmoid cancer. Another patient who reported postpartum rectal bleeding was told by her family practitioner that the cause was most likely hemorrhoids. This patient was eventually referred for a colonoscopy two years later after developing abdominal pain at which time she had a palpable rectal mass; she proved to have a Stage 3 lesion.

The ramifications of delayed diagnosis, specifically presentation with a more advanced CRC stage with its attendant increased mortality, justify, in the authors’ opinion, prompt and complete large bowel evaluation in all patients under 50 years of age who present with suspicious colorectal symptoms in order to “rule out” an occult neoplasm. Signs and symptoms that may prompt such an evaluation include: bleeding, heme-positive stool, anemia, changes in stool caliber or bowel habits, and abdominal pain or persistent distension of unclear etiology.

### **Current screening and surveillance guidelines**

There are currently no screening guidelines in place by the American Society of Colon and Rectal Surgeons (ASCRS) or the American Cancer Society (ACS) pertaining specifically to young patients who present with symptoms that could signify an underlying neoplasm. The ASCRS<sup>[25]</sup> does recommend, in general, that anyone “with symptoms or signs that suggest the presence of CRC or polyps who fall outside the domain of screening should be offered an appropriate diagnostic evaluation.” However, it appears that in the United States too few practitioners are following this recommendation when confronted with young patients who report bleeding or other symptoms.

Questions regarding cancer surveillance and screening for patients and their families commonly arise when caring for young CRC patients. The following guidelines from the ASCRS and the ACS have evolved over the last 3 decades; although there are some minor differences they are quite similar. People with a first-degree relative (parent, sibling, or child) who has had CRC or adenomatous polyp(s) are advised to have screening colonoscopy starting at age 40 or ten years younger than the age, at diagnosis, of the youngest family member with CRC (whichever comes first) with repeated evaluation every

5 years. Individuals with two second degree relatives (grandparent, aunt, or uncle) with CRC or polyps are advised to be screened as average risk patients (see below), but beginning at age 40 years. Individuals with a single second or third degree relative (cousin, great-grandparent) with CRC or polyp(s) are advised to follow average risk screening guidelines. Individuals in HNPCC kindreds are advised to begin colonoscopic evaluation starting at 20-25 years of age or 10 years before the age of diagnosis in the youngest CRC patient in the immediate family, whichever comes first<sup>[25]</sup>.

In average risk patients the ASCRS<sup>[25]</sup> recommends that routine screening commence at age 50 years. As per the ASCRS, acceptable screening strategies for average risk patients include: (1) flexible sigmoidoscopy every 5 years; (2) a double contrast barium enema every 5-10 years; or (3) a colonoscopy every 10 years. The ACS recommendations are almost identical to those of the ASCRS except that they include virtual colonoscopy every 5 years as an acceptable screening option. In regards to average risk patients under age 50 years without family history, the ASCRS<sup>[25]</sup> advises that they commence annual digital rectal examination and fecal occult blood testing at age 40 years; the ACS makes no recommendations for this group.

### Future directions

Is endoscopic screening indicated for asymptomatic patients under 50 years of age? The rising incidence of CRC in this group and the tendency towards advanced Stage at presentation would argue in favor of such programs. Yet, the cost of screening colonoscopy programs would be very high and given the current economic climate and the fact that the incidence of CRC is still considerably lower in this group (*vs* the over age 50 population) the initiation of such programs is highly unlikely. However, perhaps a case can be made for a single screening sigmoidoscopy at age 40. In the present series a screening sigmoidoscopy would most likely have revealed a significant number of the neoplasms. As per the ACS, sigmoidoscopy identifies 70%-80% of individuals with advanced lesions and is associated with a 60%-80% reduction in CRC mortality for the area of the colon within its reach. Furthermore, in a recent multi-center randomized trial a single screening sigmoidoscopy carried out between the ages of 55 and 64 reduced CRC incidence by 33% and mortality by 43%<sup>[26]</sup>. Sigmoidoscopy, although invasive, is a safe procedure with a very low rate of perforation that is well tolerated without sedation. Although the chances for successful initiation of a flexible sigmoidoscopy screening program for young patients are small, the authors believe that our current dismal record with young CRC patients justifies the effort.

### Study limitations

The lack of genetic testing for HNPCC in this study population is a clear weakness of this study. Similarly, the lack of long term cancer recurrence and survival results is

also a major shortcoming. Ideally, genetic categorization of the tumors *via* microarray would be done which would permit a detailed analysis and comparisons.

In conclusion, this review corroborates recent national data regarding the rising incidence of CRC in the under age 50 population and the fact that a greater percentage of younger patients present with Stages 3 and 4 disease when compared to the entire CRC population. The vast majority of the young patients in this study had sporadic CRC; only 12% had a first degree family history of CRC and only 1 patient met the clinical criteria for HNPCC. The histologic breakdown of the tumors was similar to that reported in the general population of CRC patients.

Although it is impossible to confirm, it is the impression of the authors that in many patients there was a delay, either by the patient, physician, or both, in carrying out the appropriate diagnostic evaluation. The widely held belief that CRC occurs in patients age 50 and older likely contributes to this mind set. Clearly, at the very least, young symptomatic patients with rectal bleeding, a change in bowel habits, or abdominal pain should be promptly evaluated, preferably with a full colonoscopy. Finally, the medical and surgical community need to consider the concept of some type of screening program for young patients, perhaps flexible sigmoidoscopy, beginning at age 40 years. The goal is to diagnose CRC in this population at an earlier stage so that the recurrence rates and mortality can be reduced. The medical community and the public must be made aware of the fact that CRC occurs in patients under age 50 years with regularity and that thorough evaluation is indicated for symptomatic patients regardless of their age.

## COMMENTS

### Background

While the incidence of colorectal cancer (CRC) is declining in the overall population, it is on the rise among individuals under 50 years of age. Many patients and practitioners, alike, believe most cases of early-age onset CRC are attributed to a family history of CRC; however, a growing number of small studies now show that the majority of these young patients have no family history.

### Research frontiers

A growing number of small studies are being published that examine the rising incidence of CRC among patients under age 50 years. It is becoming increasingly evident that the majority of these patients do not have a family history of CRC; however, it is unclear what predisposition these patients have to develop CRC at an earlier age. The research hotspot may be to perform genetic categorization of these tumors *via* microarray analysis to determine how they differ from sporadic CRC in older patients.

### Innovations and breakthroughs

Previous studies in the literature that have examined the incidence of early-age onset CRC often include patients with hereditary, familial, and sporadic CRCs (see below). In the study, the authors excluded patients with a known genetic CRC predisposition or history of inflammatory bowel disease. The vast majority of patients under age 50 years in the study had no reported family history of CRC and did not meet criteria by family history for hereditary nonpolyposis colorectal cancer (HNPCC). Therefore, the authors believe the majority of patients in the study had early-age onset "sporadic" CRC similar to the general population.

### Applications

The study corroborates the findings of several other studies evaluating early-age onset CRC in that the majority of patients have no family history of CRC and most tumors were found in the distal colon and rectum. This contradicts the

believe of many practitioners that early-age onset CRC's are more often located in the proximal colon and are attributable to inherited predispositions (*i.e.*, hereditary non-polyposis colorectal cancer). The next logical step is to investigate what triggers the development of a "sporadic" CRC at a younger age of onset among some individuals.

### Terminology

Familial CRC is defined as CRC that presents 10-20 years earlier than the general population with no clear inheritance pattern. It is presumed that lower-penetrance susceptibility genes may play a role. Hereditary CRC accounts for approximately 5%-10% of patients diagnosed with CRC. Examples include familial adenomatous polyposis syndrome and HNPCC (Lynch Syndrome), which show autosomal dominant inherited germline mutations. Tumors are often located in the proximal colon and can be synchronous or metachronous in nature. Sporadic CRC occurs in patients without identifiable genetic predispositions or a reported family history of CRC.

### Peer review

This is a descriptive study in which the authors investigate the incidence of early-age onset CRC among two institutions. The results corroborate a growing body of literature that now suggests that most CRC's, regardless of age of onset, occur without a particular genetic or familial predisposition.

### Abstract

**AIM:** To describe the cardiovascular disease (CVD) risk factors in a population of children with celiac disease (CD) on a gluten-free diet (GFD).

**METHODS:** This cross-sectional multicenter study was performed at Schneider Children's Medical Center of Israel (Petach Tikva, Israel), and San Paolo Hospital (Milan, Italy). We enrolled 114 CD children in serologic remission, who were on a GFD for at least one year. At enrollment, anthropometric measurements, blood lipids and glucose were assessed, and compared to values at diagnosis. The homeostasis model assessment-estimated insulin resistance was calculated as a measure of insulin resistance.

**RESULTS:** Three or more concomitant CVD risk factors [body mass index, waist circumference, low density lipoprotein (LDL) cholesterol, triglycerides, blood pressure and insulin resistance] were identified in 14% of CD subjects on a GFD. The most common CVD risk factors were high fasting triglycerides (34.8%), elevated blood pressure (29.4%), and high concentrations of calculated LDL cholesterol (24.1%). On a GFD, four children (3.5%) had insulin resistance. Fasting insulin and HOMA-IR were significantly higher in the Italian cohort compared to the Israeli cohort ( $P < 0.001$ ). Children on a GFD had an increased prevalence of borderline LDL cholesterol (24%) when compared to values (10%) at diagnosis ( $P = 0.090$ ). Trends towards increases in overweight (from 8.8% to 11.5%) and obesity (from 5.3% to 8.8%) were seen on a GFD.

**CONCLUSION:** This report of insulin resistance and CVD risk factors in celiac children highlights the importance of CVD screening, and the need for dietary counseling targeting CVD prevention.

**Key words:** Celiac disease; Cardiovascular disease risk factors; Gluten-free diet; Insulin resistance; Children; Hyperlipidemia; Cholesterol

**Core tip:** In our study we demonstrate a relatively high proportion of children with celiac disease (CD) adherent to a gluten-free diet (GFD) with one or more cardiovascular disease (CVD) risk factors. Furthermore, this is the first report of insulin resistance in celiac patients either in adults or children. These findings suggest that screening for CVD risk factors in celiac children both at diagnosis and during follow-up is important. Furthermore, dietary counseling over time, targeting obesity and CVD risk factors in addition to monitoring adherence to a GFD in children and adolescents diagnosed with CD, may be warranted.

Cardiovascular disease risk factor profiles in children with celiac disease on gluten-free diets. *World J Gastroenterol* 2013; 19(34): 5658-5664 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i34/5658.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i34.5658>

## INTRODUCTION

Celiac disease (CD) is a common gastrointestinal autoimmune disorder characterized by inflammation of the small bowel mucosa triggered and sustained by ingestion of gluten in genetically predisposed individuals<sup>[1]</sup>. The prevalence of CD worldwide ranges between 0.5% and 3% of the general population<sup>[2-4]</sup>. Although CD has traditionally been considered a malabsorptive disorder associated with diarrhea and weight loss, these symptoms are now seen less frequently<sup>[5]</sup>. Several recent studies have reported that only a minority of newly diagnosed patients were underweight. Instead, many patients, both children and adults were overweight or even obese<sup>[6,7]</sup>.

A definitive diagnosis of CD is currently made using IgA anti-tissue transglutaminase (tTG) antibody screening followed, in most cases, by confirmatory biopsies of the small intestine with compatible histopathological findings<sup>[8]</sup>. Currently, the only treatment for CD is a strict, life-long gluten-free diet (GFD) which leads to rapid clinical improvement, especially in children. The normalization of serological tests usually occurs 6 to 12 mo after initiation of a GFD<sup>[2]</sup>.

Deranged adiposity, blood lipid profile abnormalities and other risk factors for cardiovascular disease (CVD) in CD patients are still debated, and clear conclusions have yet to be reached<sup>[9]</sup>. Several studies have demonstrated that CVD risk factors, namely obesity, abnormal blood lipid profile, hypertension and insulin resistance have their roots in childhood and tend to track into adulthood<sup>[10-12]</sup>. The primary aim of this study was to describe CVD risk factors in a population of celiac children adherent to a GFD for at least one year, in two Mediterranean countries.

## MATERIALS AND METHODS

This cross-sectional multicenter study was performed at Schneider Children's Medical Center of Israel (Petach Tiqva, Israel), and San Paolo Hospital (Milan, Italy) between June 2010 and December 2011.

The study population included individuals less than 18 years old, previously diagnosed with CD, without known co-morbidities, who were referred for follow-up to the pediatric gastroenterology clinics of the participating centers. Patients were included if they had a definitive diagnosis of CD, ascertained by both positive serology and confirmed by compatible duodenal biopsies, and who had been on a GFD for at least one year with complete normalization of their CD serology (tTG antibodies) at

the time of enrollment.

At enrollment, all patients underwent physical examination including measurement of weight using a digital scale, and height using a stadiometer. Measurement of waist circumference was performed with a tape measured to the nearest 0.5 cm at the midpoint between the bottom of the rib cage and the top of the iliac crest. Blood pressure was measured in the sitting position using an appropriately sized cuff. Body mass index (BMI) was calculated as weight in kilograms divided by height in meters squared. To evaluate BMI values across different age and gender groups we used the BMI standard deviation score percentiles that were calculated according to the Center of Disease Control and Prevention growth charts of 2000<sup>[13]</sup>. Children with BMI values lower than the 5<sup>th</sup> percentile for age and gender were classified as "underweight", those in the 5<sup>th</sup> to 85<sup>th</sup> percentile were classified as "normal weight", those in the 85<sup>th</sup> and 95<sup>th</sup> percentile were classified as "overweight" and those greater than the 95<sup>th</sup> percentile were classified as "obese"<sup>[13]</sup>. Pre-hypertension was defined as an average systolic or diastolic blood pressure between the 90<sup>th</sup> and 95<sup>th</sup> percentile for sex, age, and height-percentile-specific, and hypertension if the values were above the 95<sup>th</sup> percentile<sup>[14]</sup>. The same pediatrician performed the Tanner stage of puberty.

After an overnight fast of at least 8 h, blood samples were drawn for fasting glucose and insulin, triglycerides, total cholesterol, high density lipoprotein (HDL) cholesterol and tTG antibodies. The samples were analyzed in local laboratories. tTG antibody levels were quantified by enzyme linked immunosorbent assay. Serum glucose level was measured by the enzymatic UV test method using an automated analyzer and total cholesterol, triglycerides, and HDL cholesterol concentrations were measured by an enzymatic colorimetric method on an automated analyzer. LDL cholesterol was calculated using the Friedewald equation: LDL cholesterol = total cholesterol - [HDL cholesterol + (triglyceride/5)]. Serum insulin concentrations were measured by an immunometric assay with the Immulite 2000 Analyzer. According to the American Academy of Pediatrics (AAP) criteria, borderline levels of cholesterol were defined by values between the 75<sup>th</sup> and 95<sup>th</sup> percentile of LDL cholesterol, while values greater than the 95<sup>th</sup> percentile were considered elevated<sup>[15]</sup>. Insulin resistance was estimated by the homeostatic model assessment (HOMA-IR), as follows: HOMA-IR = [fasting insulin ( $\mu$ U/mL)  $\times$  fasting glucose (mmol/L)/22.5]. Although the hyperinsulinemic euglycemic clamp is the only validated method to evaluate insulin sensitivity in the pediatric population, HOMA has been widely used to estimate insulin resistance in the screening of large populations of euglycemic children<sup>[16]</sup>. In this study, insulin resistance was defined as HOMA > 3.16 according to the most recent cut-off for the pediatric population<sup>[17]</sup>. Based on the Bogalosa Heart Study<sup>[11]</sup>, we analyzed six risk factors for CVD. The CVD risk factors considered were BMI Z-scores greater than the 85<sup>th</sup> percentile, waist circumference over the 90<sup>th</sup> percentile<sup>[18]</sup>, fasting LDL cholesterol or triglycerides higher than the 75<sup>th</sup> percentile,

systolic or diastolic blood pressure greater than the 90<sup>th</sup> percentile and the state of insulin resistance<sup>[19]</sup>.

In addition, we retrieved all the available data on anthropometry, blood lipids and glucose profiles at the time of diagnosis of CD from patient files.

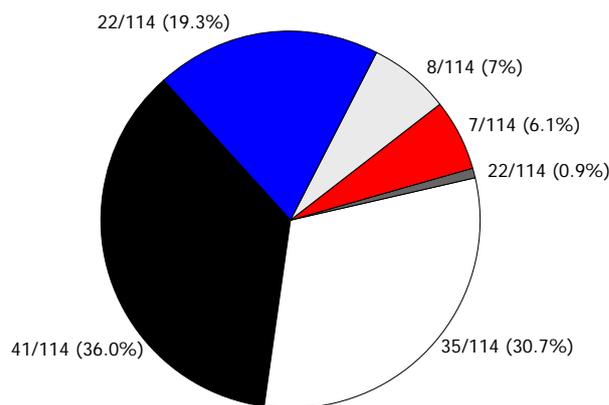

This study was approved by the institutional review boards at each of the participating centers. Signed informed consent was provided by a legal guardian of each participant.

### Statistical analysis

Descriptive data are shown as mean ± SD or number of observations (percentage). Symmetry of distribution of the variables was tested by the Kolmogorov-Smirnov test (*P* > 0.05). Triglycerides were not symmetrically distributed and were therefore log-transformed for analysis. Comparisons between the groups for continuous variables were performed by the *t* test for unpaired data or the Wilcoxon-Mann-Whitney test as appropriate. The  $\chi^2$  test for unpaired discrete variables and the Wilcoxon-Mann-Whitney test for paired discrete variables were used in this study. Additionally, a multiple logistic regression analysis was performed to assess the independent association of the center with HOMA-IR, adjusted for age, gender, BMI Z-score, Tanner stage and duration of diet. All *P*-values less than 0.05 were considered to indicate statistical significance (two tailed test). The SPSS software, version 18.0 (SPSS Inc, Chicago, IL, United States) was used for the statistical analysis.

## RESULTS

During the study period, 114 children with a mean age of 10.4 (± 4.1) years (70 from Israel and 44 from Italy) were enrolled. The two populations of children had comparable demographic data and anthropometry both at diagnosis and after at least 1 year of a GFD (Table 1). The only significant difference was a longer follow-up period in the Italian children. Complete fasting lipid profiles prior to

**Figure 1** Risk factors for cardiovascular disease in pediatric patients with celiac disease in serological remission on gluten-free diets. White: 0 risk factor; Black: 1 risk factor; Blue: 2 risk factors; Light gray: 3 risk factors; Red: 4 risk factors; Dark gray: 5-6 risk factors. Risk factors sought included BMI Z-scores greater than the 85<sup>th</sup> percentile, waist circumference over the 90<sup>th</sup> percentile<sup>[18]</sup>, fasting low density lipoprotein cholesterol or triglycerides higher than the 75<sup>th</sup> percentile, blood pressure systolic or diastolic greater than the 90<sup>th</sup> percentile and insulin resistance<sup>[19]</sup>.

initiation of the GFD were available for 52/114 children, 36/70 from Israel and 16/44 from Italy, and insulin levels were not available from CD diagnosis as prior to our study the screening of lipid and glucose profiles was not routinely performed in patients with suspected CD.

### CVD risk factors

Overall, 14% of the cohort had 3 or more concomitant risk factors (Figure 1). Only 30.7% of the cohort did not have any risk factors (Figure 1). No significant difference was seen in the prevalence of CVD risk factors between the two countries in the cohort. The most common CVD risk factors were high fasting triglycerides (34.8%), elevated blood pressure (29.4%), and high concentrations of calculated LDL cholesterol (24.1%).

### Anthropometry

We did not find any significant difference in the anthropometrics data between the Israeli and Italian CD children (Table 1). Anthropometrics in the whole cohort prior to and following the introduction of a GFD revealed significant increases in both height and weight Z-scores with an increase in BMI Z-scores which did not reach significance (Table 2). When scores were pooled into the CDC BMI categories, we found that both the prevalence of overweight and obesity increased from 8.8% and 5.3%, respectively, at the time of diagnosis to 11.4% and 8.8%, respectively, after the introduction of a GFD. This trend did not attain statistical significance (*P* = 0.105).

### Lipid profile

There were no significant differences in the lipid profiles between the Israeli and Italian cohorts, except for higher levels of HDL cholesterol in the Italian patients. According to AAP criteria, 63% of the patients in our cohort had normal LDL cholesterol, 30% had borderline and

**Table 2** Changes in height, weight, and body mass index at diagnosis (T0) and recruitment (T1) *n* (%)

Variable	T0	T1	P-value
Z-score height	-0.447 ± 1.1	-0.238 ± 1.1	0.001 <sup>1</sup>
Z-score weight	-0.567 ± 1.3	-0.198 ± 1.2	< 0.001 <sup>1</sup>
BMI Z-score	-0.207 ± 1.1	-0.078 ± 1.2	0.103
BMI categories <sup>2</sup>			
Underweight	11/114 (9.6)	12/114 (10.5)	
Normal weight	87/114 (76.3)	79/114 (69.3)	
Overweight	10/114 (8.8)	13/114 (11.4)	
Obese	6/114 (5.3)	10/114 (8.8)	0.105

<sup>1</sup>Statistically significant; <sup>2</sup>Classification<sup>[13]</sup>. Values are mean ± SD or number of subjects (percentage). BMI: Body mass index.

7% had hypercholesterolemia after at least one year of a GFD (Table 2). Although data on the lipid profile before CD diagnosis were available only in 50% of enrolled patients, we found significant increases in both total cholesterol and HDL cholesterol in patients on a GFD. The categorization of the LDL cholesterol values highlighted an increase in the prevalence of borderline cholesterol levels (from 9.6% to 23.1%), which did not reach statistical significance ( $P = 0.090$ ).

### Insulin resistance

The Italian children were found to have both higher fasting insulin and HOMA-IR levels while on a GFD when compared to the Israeli cohort (Table 3). Four patients (3.5%) were identified with frank insulin resistance, three from Italy, and one from Israel (Table 3). Two of these had normal weight and the remaining patients were overweight.

## DISCUSSION

This cross-sectional study is the first to describe the profile of CVD risk factors in a cohort of children with CD in serologic remission on a GFD. Furthermore, this is the first report of insulin resistance in children with CD on a GFD.

Less than one third of our cohort did not have any CVD risk factors, while 14% had three or more risk factors. This finding suggests that CVD screening may be important in pediatric CD patients both at diagnosis and during follow-up. Studies have demonstrated that an earlier onset and greater number of CVD risk factors increase the chance of atheromatous plaque formation<sup>[10,11]</sup>.

Our study design, which did not include a healthy control group, did not intend to determine whether children with CD have a higher risk than the general population for the development of CVD. Further prospective studies are needed to evaluate if changes in lifestyle and environment are responsible for a higher cardiovascular risk in celiac patients compared with the normal population. Nevertheless, although this study is limited by the lack of data prior to initiation of a GFD, it may suggest that the clinical and dietary follow-up should target adiposity, lipid profile and other CVD risk factors in addition to the common practice of dietary monitoring of

**Table 3** Lipidic, glycemic and insulinemic profile at enrollment in the two populations *n* (%)

Variable	Israel	Italy	P-value
Total cholesterol (mg/dL)	158.3 ± 27.6	162.5 ± 24.9	0.570
Cholesterol LDL (mg/dL)	95.4 ± 21	89.9 ± 22.3	0.116
Cholesterol HDL (mg/dL)	49.9 ± 10.6	59.4 ± 12.4	< 0.001 <sup>1,3</sup>
Triglycerides (mg/dL)	71.1 ± 25.2	62.7 ± 20.9	0.055
LDL cholesterol classes <sup>2</sup>

HOMA-IR > 3.16	1/70 (1.4)	3/44 (6.8)	0.108

<sup>1</sup>Statistically significant; <sup>2</sup>AAP classification<sup>[15]</sup>; <sup>3</sup>P-values are adjusted for age, gender, body mass index (BMI) Z-score, Tanner stage and duration of diet. Values are mean ± SD or number of subjects (percentage). HOMA-IR: Homeostasis model assessment-estimated insulin resistance; LDL: Low density lipoprotein.

adherence to a GFD.

The introduction of a GFD in CD patients increases the intestinal absorption of both macro and micro-nutrients. This leads to improved weight and height in celiac children presenting with malabsorption (weight loss, failure to thrive, poor weight gain)<sup>[20]</sup>. In our cohort, the majority of patients were of normal weight at the time of diagnosis and the percentage of overweight or obese patients was higher than those who were underweight. This drift in clinical presentation is concordant with previous reports<sup>[7]</sup> and may be attributed to increased awareness and early diagnosis. Alternatively, it may be explained by the radical change in diet and lifestyle in developed countries in recent decades, in line with the increasing prevalence of overweight and obesity in the general population. The increased prevalence of overweight and obesity after the introduction of a GFD in this study, although not significant ( $P = 0.10$ ), may suggest the potential of a GFD to increase weight even in children presenting as normal or overweight at the time of CD diagnosis. The influence of a GFD on BMI remains unclear both in adults and children<sup>[9]</sup>. In adults, the debate is mainly based on two discordant theories. Dickey *et al.*<sup>[21]</sup> demonstrated further weight gain in patients already overweight at the time of CD diagnosis after the introduction of a GFD, while Cheng *et al.*<sup>[22]</sup> showed a positive effect of a GFD by demonstrating weight gain in previously underweight patients and weight loss in those previously overweight. Furthermore a recent study<sup>[23]</sup> recruiting a very large cohort of adult patients found that strict GFD adherence could increase the prevalence of overweight and obesity in CD patients. Contrasting studies have also recently appeared in the pediatric literature. Valletta *et al.*<sup>[24]</sup> reported an increase in the fraction of overweight children following the introduction of a GFD, while Brambilla *et al.*<sup>[25]</sup> demonstrated a beneficial effect of GFD on BMI in the

majority of CD children. Reilly *et al.*<sup>[26]</sup> found a beneficial effect of GFD on the BMI of overweight celiac children. Our data, demonstrating that a GFD increases the prevalence of overweight and obesity in children with CD, is in agreement with studies reporting increased weight as a potential adverse effect of GFD.

The data concerning LDL cholesterol after at least one year of a GFD suggests an important role for cholesterol as a CVD risk factor in our cohort. In this study, LDL cholesterol was the third most prevalent CVD risk factor in celiac children on a GFD.

The increase in total and HDL cholesterol after GFD introduction in comparison to levels prior to initiation of a GFD (available from a subset of patients), is concordant with some studies which theorized that derangement of intestinal absorption, chylomicron production and lipoprotein metabolism may underlie the finding of lower levels of total and HDL cholesterol in untreated CD, which can revert to normal after treatment<sup>[27-30]</sup>. In contrast, we found that the rate of borderline LDL cholesterol concentrations more than doubled (from 9.6% to 23.1%) following adherence to a GFD. This may be the result of a tendency in adult and adolescent patients to consume gluten-free products with high fat contents<sup>[31-33]</sup> in order to compensate for the withdrawal of common gluten-containing carbohydrates from the diet.

Our data seem to suggest that although the increase in the rate of borderline LDL cholesterol could raise the cardiovascular risk, the concomitant increase in HDL may be cardioprotective, and thus future studies looking at surrogate markers of atherosclerosis are needed to determine whether a GFD is harmful in this regard.

Four children (3.5%) on a GFD had insulin resistance. As far as we are aware, the only studies reporting HOMA-IR in CD were performed in patients with concomitant insulin-dependent diabetes mellitus (IDDM) 1<sup>[34]</sup>. It is not known whether insulin resistance was present on CD diagnosis. As such, this is the first description of the presence of insulin resistance in CD children.

Due to the lack of insulin levels before CD diagnosis, we were unable to assess whether such insulin resistance is directly related to the introduction of a GFD. Previous publications have reported that available gluten-free products (*e.g.*, gluten-free bread, pasta, pizza *etc.*) have much higher glycemic indices than their gluten-containing equivalents, ingestion of which may lead to increased secretion of insulin<sup>[35-37]</sup>. Our findings, along with the previously mentioned change in the pattern of CD presentation, may suggest that future assessment of fasting glucose and insulin in children diagnosed with CD before and during the introduction of GFD should be performed. This is especially true in light of the role of insulin resistance as a CVD risk factor, and a predisposing condition for the development of type 2 diabetes<sup>[19]</sup>. The significantly higher fasting insulin levels and HOMA-IR in our Italian cohort may be explained by genetic and dietary differences between the two groups<sup>[37]</sup>. Our findings suggest that despite the classical consideration of CD as a malabsorptive condition, metabolic derangements, gen-

erally not attributed to this condition, should be actively sought even in patients who are non-obese. Although our data may hint to insulin resistance as a new complication of CD, a word of caution is due, as this study was performed on a cohort of CD patients and data is lacking in the literature regarding the prevalence of glucose intolerance in the healthy, non-overweight/obese children and adolescents.

This study has a number of limitations such as the relatively small number of patients, the cross-sectional design which did not allow for pre-GFD levels of all measured parameters, and the lack of familial history for CVD risk factors which may have further impacted our findings. However, despite these limitations, we have described the presence of insulin resistance in pediatric CD for the first time, and specifically addressed other CVD risk factors in the pediatric CD population on a GFD in serological remission.

Prior to initiation of the study, the relationship between CD and CVD risk factors was not clear, and therefore screening of lipid and glucose profiles was not routinely performed in patients with suspected CD. Additionally, the similarity in most findings between patients from two different countries, suggest that these findings are neither geographically nor ethnically specific. Prospective studies are needed to delineate the role of the GFD in the development of CVD risk factors in celiac children.

In conclusion, this cross-sectional study demonstrates a relatively high proportion of children with CD adherent to a GFD with one or more CVD risk factors including insulin resistance. These findings suggest the importance of screening for CVD risk factors in celiac children both at diagnosis and during follow-up. Furthermore, dietary counseling over time, targeting obesity and CVD risk factors in addition to monitoring adherence to a GFD in children and adolescents diagnosed with CD, may be warranted.

## COMMENTS

### Background

Celiac disease has traditionally been considered a malabsorptive disorder associated with diarrhea and weight loss, however, these symptoms are now seen less frequently. Several recent studies have reported that only a minority of newly diagnosed patients were underweight. Instead, many patients, both children and adults were overweight or even obese.

### Research frontiers

Several studies have demonstrated that cardiovascular disease (CVD) risk factors, namely obesity, abnormal blood lipid profile, hypertension and insulin resistance have their roots in childhood and tend to track into adulthood.

### Innovations and breakthroughs

Deranged adiposity, blood lipid profile and other risk factors for CVD in celiac disease (CD) are still debated, and clear conclusions have yet to be reached. The authors' study aimed to describe CVD risk factors in a population of celiac children adhering to a gluten-free diet (GFD) for at least one year, in two Mediterranean countries.

### Applications

The authors' results suggest the importance of screening for CVD risk factors in celiac children both at diagnosis and during follow-up. Furthermore, they highlight that dietary counseling over time should target obesity and CVD risk factors in addition to monitoring adherence to a GFD in children and adolescents

diagnosed with CD.

### Terminology

The homeostatic model assessment is a method used to quantify insulin resistance and beta-cell function. This model correlated well with estimates using the euglycemic clamp method ( $r = 0.88$ ).

### Peer review

The present study is an appreciable work in the sense that it explores a concept that was not given attention before. With changing lifestyle and environment are celiac children more exposed to cardiovascular risk factors than normal population it needs to be validated in further prospective studies. The results of study convince for metabolic screening in celiac disease children in follow up visits and hence initiate early intervention to prevent cardiovascular morbidity.

### Abstract

**AIM:** To compare the mucosal concentrations of 5-aminosalicylic acid (5-ASA) resulting from different pharmaceutical formulations and analyse the influence of inflammation on the mucosal concentrations.

**METHODS:** The study included 130 inflammatory bowel disease (IBD) patients receiving 5-ASA as pH-dependent-release formulations (73 patients), time-dependent-release formulations (11 patients), or pro-drugs (18 patients). In addition, 28 patients were receiving topical treatment (2-4 g/d) with pH-dependent-release formulations. Endoscopic biopsies were obtained from the sigmoid region during the colonoscopy. The 5-ASA concentrations (ng/mg) were measured in tissue homogenates

using high-pressure liquid chromatography with electrochemical detection. The *t* test and Mann-Whitney test, when appropriate, were used for statistical analysis.

**RESULTS:** Patients receiving pH-dependent-release formulations showed significantly higher mucosal concentrations of 5-ASA ( $51.75 \pm 5.72$  ng/mg) compared with patients receiving pro-drugs ( $33.35 \pm 5.78$  ng/mg,  $P = 0.01$ ) or time-dependent-release formulations ( $38.24 \pm 5.53$  ng/mg,  $P = 0.04$ ). Patients with endoscopic remission had significantly higher mucosal concentrations of 5-ASA than patients with active disease ( $60.14 \pm 7.95$  ng/mg vs  $35.66 \pm 5.68$  ng/mg,  $P = 0.02$ ). Similar results were obtained when we compared patients with the histological appearance of remission and patients with active histological inflammation ( $67.53 \pm 9.22$  ng/mg vs  $35.53 \pm 5.63$  ng/mg,  $P < 0.001$ ). Significantly higher mucosal concentrations of 5-ASA were detected in patients treated with both oral and topical treatments in combination compared with patients who received oral treatment with pH-dependent-release formulations alone ( $72.33 \pm 11.23$  ng/mg vs  $51.75 \pm 5.72$  ng/mg,  $P = 0.03$ ).

**CONCLUSION:** IBD patients showed significant variability in mucosal 5-ASA concentrations depending on the type of formulation, and the highest mean concentration was achieved using pH-dependent-release formulations.

**Key words:** 5-aminosalicylic acid; Inflammatory bowel diseases; Mucosal concentration

**Core tip:** We report on the concentrations of 5-aminosalicylic acid in the colonic mucosa of ulcerative colitis patients. Significant variations in concentration were observed that were dependent on the type of pharmaceutical formulation and the presence of active disease. Combined oral and topical therapy yielded higher tissue mesalamine concentrations. These differences should

be taken into account in treatment strategies, especially in view of the fact that mesalamine can induce mucosal healing in ulcerative colitis.

## INTRODUCTION

Mesalamine[5-aminosalicylic acid (5-ASA)]-containing formulations represent the first-line therapy for the treatment of mild to moderate active ulcerative colitis and the prevention of recurrence<sup>[1]</sup>. When 5-ASA is administered and is absorbed by the colonic epithelium, *N*-acetyltransferase 1 metabolises a large amount of the 5-ASA to *N*-Ac-5-ASA, an inactive metabolite that is secreted back into the intestinal lumen and excreted in the faeces<sup>[2]</sup>. Sulphasalazine (Salazopyrin EN) is a pro-drug composed of sulphapyridine and 5-ASA connected by an azo-bond. Salazopyrin is metabolised to sulphapyridine and 5-ASA by the bacterial azoreductases of the intestinal microbiota. Sulphapyridine is excreted in the urine after most of it is absorbed from the colon, acetylated in the liver, and conjugated with glucuronic acid. The main action of sulphapyridine is to carry the 5-ASA moiety to the colon while preventing its proximal absorption. Absorption through the colon is necessary for the efficacy of 5-ASA<sup>[3]</sup>. Side effects, such as nausea, heartburn, headache, anaemia, skin rashes, reversible abnormalities of sperm number and morphology, and, rarely, hepatitis and nephritis, occur primarily due to high plasma sulphapyridine concentrations, which can generally be detected in patients taking higher doses of sulphasalazine or in genetically predisposed individuals (slow acetylators)<sup>[4]</sup>. Alternative preparations include modified-release formulations (which are supplied with pharmacological coatings that dissolve at a given pH or in a time-dependent manner) and pro-drugs. In pro-drugs such as sulphasalazine, an azo-bond links 5-ASA molecules to a carrier molecule. Similar compounds include olsalazine and balsalazide. Olsalazine was the first formulation, and it contains two 5-ASA molecules linked by an azo-bond. Approximately 12%-16% of patients being treated with olsalazine may suffer from secretory diarrhoea<sup>[5-7]</sup>. Balsalazide consists of 5-ASA linked *via* an azo-bond to an internal carrier (4-aminobenzoyl- $\beta$ -alanine). This formulation is not systemically absorbed. Modified-release formulations include delayed-release formulations (which release 5-ASA along a pH gradient) and sustained-release formulations (which release 5-ASA over a specified time interval) that are targeted to release 5-ASA in the lower small intestine and right colon. The pH-sensitive acrylic resin coat of Eudragit dissolves when the luminal pH rises above a critical

value. Pentasa is a sustained-release formulation that is gradually released based on a time-controlled mechanism. It consists of ethylcellulose-coated microgranules from which mesalazine is released into the small and large intestine. Its ethylcellulose coating is a semi-permeable membrane that dissolves when hydrated<sup>[8]</sup>. Combination therapy with oral and topical mesalazine administration can achieve higher mucosal concentrations than oral treatment alone<sup>[9]</sup>. Several *in vitro* studies have established a direct dose-effect relationship between 5-ASA and most of its immuno-inflammatory targets<sup>[10]</sup>. Furthermore, *in vivo* studies have demonstrated that there are inverse relationships between mucosal 5-ASA concentrations and the endoscopic and histological scores and mucosal levels of sIL-2R (a marker of mucosal inflammation). Higher drug mucosal concentrations lead to lower disease activity<sup>[11]</sup>. It follows that inadequate mucosal concentrations will result in inadequate disease management, particularly in patients with Crohn's disease and especially for the prevention of post-operative recurrence<sup>[12]</sup>. As a result, we can state that the therapeutic efficacy of 5-ASA is directly related to its mucosal concentration. Nevertheless, a large degree of individual variability in mucosal mesalamine concentrations exists, which is possibly due to differences in intestinal behaviour, dosage, route of administration, and the severity of the colonic inflammation<sup>[13-16]</sup>.

In this study, we focused on different pharmaceutical formulations of 5-ASA.

## MATERIALS AND METHODS

### *Patients and endoscopic procedures*

The study included 130 consecutive ulcerative colitis patients (mean age 47.76 years, range 23-84 years; 81 men and 49 women) who were referred to the Department of Surgical, Oncological and Gastroenterological Sciences, Gastroenterology Unit on continuous oral 5-ASA treatment. The general characteristics of the patients are shown in Table 1. All of the patients were receiving treatment with oral 5-ASA three times per day in one of three different pharmaceutical formulations: pH-dependent delayed-release formulations (73 patients at a dose of 2.4 g daily; Asacol Giuliani-Bracco Italy, Pentacol Sofar Italy), mesalamine pro-drug (18 patients at a dose of 3 g daily; Salazopyrin EN, Pfizer, Italy), and time-dependent sustained-release formulations (11 patients at a dose of 3 g daily; Pentasa, Ferring, Italy). There were 28 patients who received both oral and topical (2-4 g/d by enema) pH-dependent-release formulations. The patients receiving combined treatment (mean age 46.5 years, range 23-79 years; 64.2% male) were comparable with respect to age and gender distribution to patients receiving oral therapy alone (mean age 47.24 years, range 25-84 years; 67.1% male). No concomitant immunological, renal, or hepatic disorders were reported by any of the patients. Moreover, none of the patients were taking steroids, immunosuppressive agents, antibiotics, H<sub>2</sub>-receptor antagonists, or proton pump inhibitors. Colonoscopy was performed for surveillance or to detect symptom re-exacerbation. Bowel

**Table 1** Demographic and clinical characteristics of patients

Characteristics	pH-dependent delayed release ( <i>n</i> = 73)	Pro-drugs ( <i>n</i> = 18)	Time-dependent sustained release ( <i>n</i> = 11)
Age (mean ± SE) (yr)	47.24 ± 1.61	51.38 ± 2.39	47.54 ± 4.97
Gender (M/F)	49/24	8/10	6/5

Age at diagnosis (mean ± SE)	34.88 ± 1.61	32.72 ± 2.30	31.09 ± 3.30
Duration of disease (yr)	11.56 ± 0.81	17.22 ± 4.21	15.00 ± 2.62
Time since last 5-ASA administration (h)	21.43 ± 1.22	23.88 ± 4.21	20.63 ± 2.52

M: Male; F: Female; 5-ASA: 5-aminosalicylic acid.

cleansing was achieved using a polyethylene glycol oral solution, 3-5 L, on the day before the colonoscopy. After the patients provided their informed consent, the time at which they took their last pill/enema was recorded, and two biopsies were taken from the sigmoid region at 25 cm from the anal verge. The observation of inflammatory changes in the colonic mucosa on endoscopy was considered endoscopic activity following the Baron classification, while the absence of mucosal inflammatory changes was considered endoscopic remission<sup>[17,18]</sup>. The histological activity of the disease was examined according to a semi-quantitative score that took into consideration the extent of lymphocytic and polymorphonuclear leukocyte infiltration, mucus depletion, crypt distortion, the presence of crypt abscesses, and lymphoid follicle activation. Histological remission was defined as the absence of inflammatory changes in the mucosa<sup>[19]</sup>.

### Chemicals and reagents

Purified 5-ASA was obtained from Acros (NJ, United States). Purified water and methanol were used for the high-pressure liquid chromatography (HPLC) analysis. The use of these products was important to reduce background current and noise within the HPLC-electrochemical detection system.

A stock solution of 5-ASA was prepared at 1 mg/mL in 0.2 mol/L protocatechuic acid (PCA), 100 μmol/L ethylenediaminetetraacetic acid (EDTA), and 100 μmol/L sodium metabisulfite and stored at 4 °C.

### Tissue preparation

The specimens were homogenised in 0.2 mol/L PCA, 100 μmol/L EDTA, and 100 μmol/L sodium metabisulfite at 4 °C and then centrifuged (1800 *g*) for 10 min. The supernatants were collected and filtered with 0.2-μm cellulose acetate filters and stored at -80 °C. A sample volume of 20 μL was used throughout this study.

### Quantification of 5-ASA

A sensitive HPLC method capable of measuring the mucosal 5-ASA concentrations was used. Briefly, analyses were performed on a chromatographic apparatus (Alliance Waters, United States) that consisted of a model 2695 solvent-delivery system and an electrochemical detector, Coulochem (ESA, United States) Model 5100A,

that was integrated with Empower Software (Waters, United States).

Separation of the analytes was achieved using a reversed-phase DHBA-250 column (5 μm, 250 × 3.0 mm), and the analytes were detected on a high-sensitivity analytical cell model 5011, with the oxidation potentials of electrodes 1 and 2 adjusted to +750 mV to oxidise the 5-ASA.

The mobile phase consisted of 50 mmol/L sodium acetate, 50 mmol/L sodium citrate, 8% methanol, and 2% 2-propanol. The pH of the mobile phase was adjusted to 2.5 with phosphoric acid after the addition of the organic modifiers. The mobile phase was passed through the system at 0.5 mL/min.

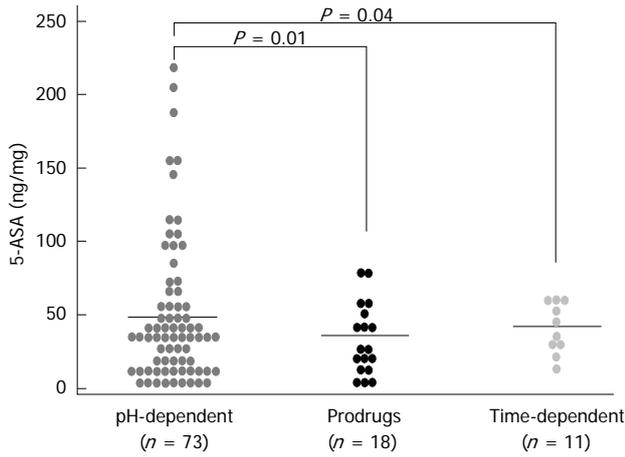

The standard curve for 5-ASA was linear in the selected range ( $r^2 = 0.99$ ) with an inter-assay coefficient of variation < 4%.

### Statistical analysis

The mucosal 5-ASA concentrations in patients being treated with any pharmaceutical 5-ASA formulation and in patients with different endoscopic and histological degrees of activity were compared using an unpaired Student's *t* test and the Mann-Whitney test where appropriate. A *P* value of 0.05 or less was considered significant. The data are presented as the mean ± SE. The 5-ASA concentrations are expressed as ng/mg tissue. The statistical analyses were performed using the statistical software package SPSS for Windows, version 13.0 (SPSS, Chicago, IL, United States).

## RESULTS

The demographic and clinical characteristics of the patients being treated with different pharmaceutical formulations were similar (Table 1). Figure 1 shows the distribution of the mucosal concentrations of mesalamine in the sigmoid region for the three groups studied. The mean mucosal mesalamine concentration was significantly higher in patients being treated with pH dependent-release formulations than in patients being treated with pro-drugs (51.75 ± 5.72 ng/mg *vs* 33.35 ± 5.78 ng/mg, *P* = 0.01). Similarly, the concentration of mesalamine was significantly higher in patients being treated with pH-dependent-release formulations than in patients being

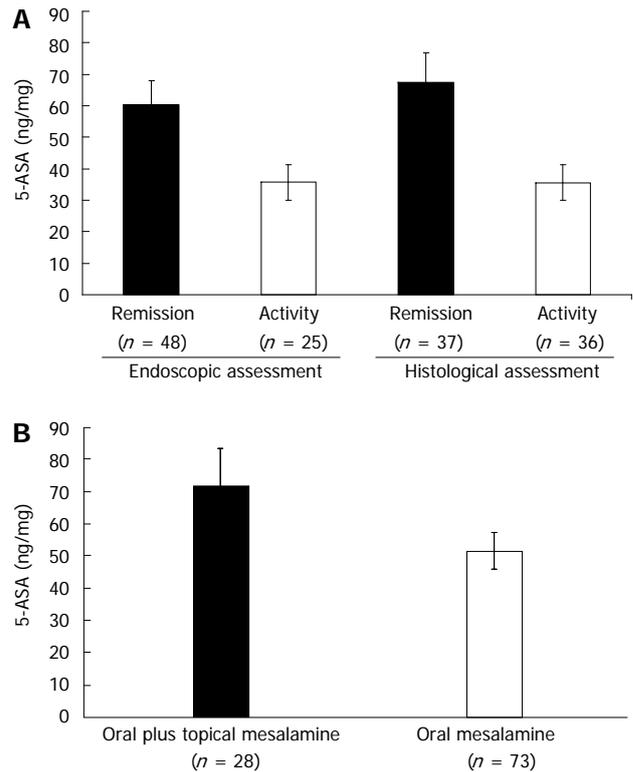

**Figure 1** Distribution of 5-aminosalicylic acid mucosal concentrations in the sigmoid colon in patients receiving oral 5-aminosalicylic acid either pH-dependent release formulations, time-dependent release formulations or prodrugs. 5-ASA: 5-aminosalicylic acid.

treated with time-dependent-release formulations ( $51.75 \pm 5.72$  ng/mg *vs*  $38.24 \pm 5.53$  ng/mg,  $P = 0.04$ ). Furthermore, the absolute mucosal 5-ASA concentrations were significantly higher in patients being treated with pH-dependent-release formulations; specifically, 28% of the patients were found to have mucosal 5-ASA concentrations above 70 ng/mg of tissue, which was the highest concentration achieved with any of the other formulations. Figure 2A shows the distribution of the mucosal mesalamine concentrations in patients receiving pH-dependent-release formulations according to endoscopic and histological activity or disease remission.

Twenty-five patients showed active disease in the sigmoid colon, while the remaining 48 patients presented an endoscopic appearance of remission or a normal assessment. The histological grade of the mucosal inflammation in the sigmoid colon was “active” in 36 patients, while the remaining 37 patients presented a “normal” histological assessment or the appearance of remission. Patients with a normal endoscopic assessment or an endoscopic appearance of remission showed significantly higher concentrations of mucosal 5-ASA than patients with active endoscopic inflammation ( $60.14 \pm 7.95$  ng/mg *vs*  $35.66 \pm 5.68$  ng/mg,  $P = 0.02$ ). Similarly, significant differences were found in the mucosal 5-ASA concentrations between patients with a normal histological assessment or the histological appearance of remission and patients with active histological inflammation ( $67.53 \pm 9.22$  ng/mg *vs*  $35.53 \pm 5.63$  ng/mg,  $P < 0.001$ ).

Twenty-eight patients received both pH-dependent mesalamine orally at a dose of 2.4 g/d and rectal mesalamine at a dose of 4 g/d. Figure 2B shows the distribution of mucosal 5-ASA concentrations in patients receiving combination treatment compared with those in patients receiving oral treatment alone. The mean mucosal 5-ASA concentration was significantly higher in patients receiving combined oral and topical treatment than in patients taking oral mesalamine only ( $72.33 \pm 11.23$  ng/mg *vs*

**Figure 2** 5-aminosalicylic acid mucosal concentrations in the sigmoid colon. A: In patients receiving oral 5-aminosalicylic acid (5-ASA) pH-dependent release formulations according to endoscopic and histological grading of disease; B: In patients receiving 5-ASA pH-dependent release formulations on oral plus topical treatment or oral therapy alone.

$51.75 \pm 5.72$  ng/mg,  $P = 0.03$ ).

## DISCUSSION

IBD patients usually receive chronic treatment with 5-ASA to both control the active disease and reduce the frequency and severity of clinical relapses. Although this drug has been used for the last 50 years, the precise mechanism of action of 5-ASA, with the exception of its topical efficacy, is unknown<sup>[20]</sup>. However, its topical activity implies the necessity of its delivery to the inflamed tissue. Therefore, appropriate dosages and targeted delivery of the drug are needed. Many studies have demonstrated marked variability in 5-ASA metabolism and distribution following oral dosing<sup>[14,15]</sup>. Thus, the clinical course of the disease, which encompasses periods of prolonged remission and frequent episodes of relapse, could derive from variable availability of the drug. We know from several *in vitro* studies that there is a direct relationship between the 5-ASA concentration and its therapeutic efficacy<sup>[21,22]</sup>. Previous *in vivo* studies have reported that the therapeutic efficacy is dose-dependent. In fact, high mucosal mesalamine concentrations have been shown to be associated with endoscopic and histological scores of disease remission or mild activity rather than moderate or severe disease in ulcerative colitis. They have also been shown to be associated with a reduced risk of severe post-operative recurrences in Crohn’s disease<sup>[11,12]</sup>. However, the appro-

priate mucosal concentration is unknown, and it is therefore not easy to provide guidance. There is wide inter-individual variability in mucosal concentrations, and the factors governing tissue drug concentrations are largely unknown because increased mucosal concentrations do not always derive from increased oral doses<sup>[23]</sup>.

Adherence to therapy may be another important factor that influences mucosal concentrations. We did not test adherence specifically; however, samples were obtained only from patients who reported that they had taken their last pill within 24 h of endoscopy. Moreover, the 5-ASA concentration can be variable along the entire length of the colon. Oral administration of 5-ASA ensures a higher drug concentration in the right colon than in the rectum, where the amount often becomes negligible; however, the rectum is the preferential site of the disease and is almost invariably affected. Because the oral dose is not strictly related to the 5-ASA concentration, the tissue absorption, drug metabolism and excretion, and pharmaceutical variables, such as the route of administration and formulation type, need to be investigated. Several clinical studies have confirmed that the highest therapeutic efficacy is reached when patients are treated with oral and topical treatments<sup>[24,25]</sup>. Patients with active distal disease in whom oral treatment is frequently inadequate respond to mesalazine enemas<sup>[9]</sup>. Rectal formulations are also successful in maintaining remission in patients suffering from frequent relapses. According to Frieri *et al.*<sup>[26]</sup>, patients being treated with oral and topical treatments show similar mucosal mesalamine concentrations in the rectum and in the descending colon, while oral treatment alone results in a higher drug concentration in the descending colon than in the rectum. Indeed, we found higher mucosal concentrations in the sigmoid mucosa in patients receiving both topical and oral 5-ASA than in patients receiving oral mesalamine alone. It is possible that the level of adherence may have been higher in patients experiencing active disease who therefore were receiving combined therapy.

To date, few and discordant reports have investigated the relationship between the colonic mucosal concentration of 5-ASA and its different pharmaceutical formulations<sup>[27,28]</sup>. We demonstrated that the sigmoid mucosal concentration of 5-ASA was significantly higher in IBD patients receiving pH-dependent delayed-release formulations compared with patients receiving preparations dependent on bacterial degradation (pro-drugs). Similarly, the mucosal concentration of 5-ASA in the sigmoid mucosa of the pH-dependent delayed-release formulations group was higher than that of the time-dependent sustained-release formulations. Moreover, we found that the absolute mucosal 5-ASA concentrations were significantly higher in patients being treated with pH-dependent-release formulations than in patients being treated with pro-drugs. In fact, in 28% of the patients receiving pH-dependent-release formulations, the mucosal 5-ASA concentration was above 70 ng/mg of tissue, which was the highest value achieved from any of the formulations. Because of the dose-related anti-inflammatory effect

of 5-ASA, we should expect the highest efficacy when the highest mucosal tissue concentration of 5-ASA is achieved. As reported by Hussain *et al.*<sup>[23]</sup>, rectal mucosal concentrations of aminosaliclates are lower during relapses. As previously demonstrated by Frieri *et al.*<sup>[11]</sup>, we confirmed that the colonic mucosal concentrations of 5-ASA were inversely related to disease activity as measured by both endoscopic and histological evaluation. Oedema occurring during the active phase of the disease may account for a possible dilution effect on the biopsy specimens. Alternatively, the faster rate of tissue renewal in the presence of inflammation could produce a wash-out effect on the drug and contribute to a reduced mucosal mesalamine concentration.

In conclusion, because we have reinforced the relationship between tissue mesalamine levels and disease activity, additional studies are needed to determine how to reach optimal mucosal concentrations of 5-ASA. We have demonstrated that different pharmaceutical preparations achieve different mucosal concentrations and that disease activity lowers the drug mucosal concentration. Higher dosages could therefore be justified during active disease to obtain better clinical results.

## COMMENTS

### Background

The use of mesalamine represents the first-line treatment strategy in patients with ulcerative colitis. Many formulations are available, and they are often used interchangeably because it is assumed that they are all equally effective.

### Research frontiers

The mucosal concentration of 5-aminosalicylic acid (5-ASA) was measured in the colon of ulcerative colitis patients and at the anastomotic site of Crohn's disease patients in the post-operative setting. In this study, the authors demonstrated that tissue concentrations could be measured by high-pressure liquid chromatography and that the type of 5-ASA formulation influenced the mucosal concentration.

### Innovations and breakthroughs

Mesalamine is poorly absorbed; therefore, blood monitoring is not helpful. The tissue concentration may represent a better tool for tailoring therapy in ulcerative colitis patients.

### Applications

The response to treatment with mesalamine in ulcerative colitis patients can be optimised by administering the proper formulation of the drug at the right dose to the patient.

### Peer review

The authors examined the colonic mucosal concentrations of mesalamine in patients with ulcerative colitis who were being treated with different formulations of mesalamine. The results are interesting and may guide clinicians in tailoring therapies to their patients.

### Abstract

**AIM:** To evaluate if 3 mo oral supplementation with Eviendep<sup>®</sup> was able to reduce the number of duodenal polyps in familial adenomatous polyposis (FAP) patients with ileal pouch-anal anastomosis (IPAA).

**METHODS:** Eleven FAP patients with IPAA and duodenal polyps were enrolled. They underwent upper gastrointestinal (GI) endoscopy at the baseline and after 3 mo of treatment. Each patient received 5 mg Eviendep twice a day, at breakfast and dinner time, for 3 mo. Two endoscopists evaluated in a blinded manner the number and size of duodenal polyps. Upper GI endoscopies with biopsies were performed at the baseline

(T0) with the assessment of the Spigelman score. Polyps > 10 mm were removed during endoscopy and at the end of the procedure a new Spigelman score was determined (T1). The procedure was repeated 3 mo after the baseline (T2). Four photographs were examined for each patient, at T1 and T2. The examined area was divided into 3 segments: duodenal bulb, second and third portion duodenum. Biopsy specimens were taken from all polyps > 10 mm and from all suspicious ones, defined by the presence of a central depression, irregular surface, or irregular vascular pattern. Histology was classified according to the updated Vienna criteria.

**RESULTS:** At baseline the mean number of duodenal detected polyps was 27.7 and mean sizes were 15.8 mm; the mean Spigelman score was 7.1. After polypectomy the mean number of duodenal detected polyps was 25.7 and mean sizes were 7.6 mm; the mean Spigelman score was 6.4. After 3 mo of Eviendep *bid*, all patients showed a reduction of number and size of duodenal polyps. The mean number of duodenal polyps was 8 ( $P = 0.021$ ) and mean size was 4.4 mm; the mean Spigelman score was 6.6. Interrater agreement was measured. Lesions > 1 cm found a very good degree of concordance ( $\kappa$  0.851) and a good concordance was as well encountered for smaller lesions ( $\kappa$  0.641).

**CONCLUSION:** Our study demonstrated that short-term (90 d) supplementation with Eviendep<sup>®</sup> in FAP patients with IPAA and with recurrent adenomas in the duodenal mucosa, resulted effective in reducing polyps number of 32% and size of 51%.

**Key words:** Familial adenomatous polyposis; Ileal pouch-anal anastomosis; Duodenal polyps; Eviendep

**Core tip:** Our open study demonstrated for the first time that short-term (90 d) supplementation with Eviendep® in familial adenomatous polyposis patients with ileal pouch-anal anastomosis and with recurrent adenomas in the duodenal mucosa, resulted effective in reducing polyps number of 32% and size of 51%. Eviendep® was easy to manage and its daily use was well tolerated by the patients. Its safety was guaranteed by its composition. Each ingredient is blended into the composition in a lower dose than the one otherwise needed for the single component to similarly exert the desired effect, thus leading to synergistic and/or potentiating effect, with the added advantage of higher safety, even over long-term exposure.

Calabrese C, Praticò C, Calafiore A, Coscia M, Gentilini L, Poggioli G, Gionchetti P, Campieri M, Rizzello F. Eviendep® reduces number and size of duodenal polyps in familial adenomatous polyposis patients with ileal pouch-anal anastomosis. *World J Gastroenterol* 2013; 19(34): 5671-5677 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i34/5671.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i34.5671>

## INTRODUCTION

Familial adenomatous polyposis (FAP) is a disease with autosomal dominant inheritance. It is caused by an alteration of the *FAP* gene that is located on chromosome 5q21, affecting roughly 1 in 15000 live births in the Northern European population. FAP shares its phenotype with biallelic Homolog Gene Mutation Carriers, characterized by the early onset of hundreds to thousands of adenomas throughout the colon, with a nearly 100% progression to colorectal cancer by the age of 35-45 years in untreated subjects<sup>[1-3]</sup>. Patients with FAP have a cumulative lifetime risk of over 80% of developing duodenal adenomas, the precancerous lesions of duodenal adenocarcinoma. Consequently, these patients have a 4% lifetime risk of peri-ampullary or duodenal adenocarcinoma<sup>[4,5]</sup>.

Early prophylactic colorectal surgery changed the prognosis of patients with FAP, and nowadays desmoids and peri-ampullary duodenal cancers are the most common causes of death in these patients<sup>[6,7]</sup>.

Nearly 100% of FAP patients will develop duodenal adenomatosis<sup>[5-11]</sup> with an estimated lifetime risk of progression to duodenal carcinoma of 5%-10%<sup>[5-12]</sup>. The severity of duodenal adenomatosis is graded according to the Spigelman classification<sup>[10]</sup>, which ranges from grade 0 to IV and is based on the number, size and histopathological features of the duodenal adenomas. Patients with advanced Spigelman stages are most at risk of developing duodenal carcinoma<sup>[5,10]</sup>. Current guidelines recommend frequent endoscopic surveillance in these patients, which improved the prognosis through earlier detection of duodenal malignancy<sup>[13]</sup>.

A new recent line of intervention focuses on the role of the estrogen receptors (ERs) in intestinal carcinogenesis<sup>[14-16]</sup>. A pivotal role of ER-β has been suggested in preventing malignant transformation of colon epithelial cells in humans<sup>[16]</sup>. Data confirm the involvement of ERs-β in colorectal carcinogenesis and suggest a possible explanation for the protective effect of estrogens in cancer development<sup>[17-19]</sup>. They also provided further support of the role of vegetable-rich diets in the prevention of bowel cancer, thanks to their high content of phytoestrogens. Phytoestrogens include a variety of vegetable derived compounds with estrogen-like chemical structure and differential selectivity to the two ERs, ERα and ERβ. Particularly the dietary flavonolignan silymarin and the lignans have been reported to exert selective agonism to the ERβ the former, and preferential selectivity the latter. Since the promotion and progression of carcinogenesis are susceptible to nutritional interventions<sup>[5]</sup>, the aim of this study was to evaluate if 3 mo oral supplementation with a patented blend of phytoestrogens and indigestible and insoluble fibres (Eviendep®, CM&D Pharma Limited, United Kingdom) was able to reduce the number of duodenal polyps in FAP patients with ileal pouch-anal anastomosis (IPAA).

## MATERIALS AND METHODS

### Population

This study was conducted in FAP patients with IPAA. The patients were ongoing the surveillance program at our department by screening upper gastrointestinal (GI) endoscopies for the follow-up of duodenal adenoma (polyp) recurrence and progression to adenocarcinoma. Cardiovascular diseases and inadequate organ function were study exclusion criteria. All patients gave their informed consent.

### Endoscopic and histological procedures

Endoscopies were performed after an overnight fast; patients were prepared by a light sedation (*iv* midazolam coupled with 20 mg of scopolamine N-butyl bromide) and were examined with an upper GI endoscopy (Olympus GIF 165) until the third portion of the duodenum.

The severity of duodenal polyposis was classically assessed using the Spigelman classification<sup>[10]</sup>. This classification system describes five stages in duodenal polyposis development. Points are accumulated for number, size and histology of adenomatous polyps. Spigelman stage I (1-4 points) indicates mild disease, whereas stage III-IV (> 6 points) implies severe duodenal polyposis. The traditional Spigelman classification classified adenomas into mild, moderate and severe dysplasia, whereas the updated classification distinguishes low- and high-grade dysplasia.

Upper GI endoscopies with biopsies were performed by the first operator (Calabrese C) at the baseline (T0) with the assessment of the Spigelman score. Polyps > 10 mm were removed during endoscopy and at the end

of the procedure a new Spigelman score was determined (T1). The procedure was repeated 3 mo after the baseline (T2), which also coincided with the 3 mo oral supplementation of Eviendep.

The first operator together with another experienced endoscopist (Rizzello F) re-evaluated all the endoscopy videos and photos. They evaluated images in a blinded manner and scored the images separately. Each expert first evaluated them individually and then in case of disagreement, a consensus was reached afterward by discussion.

Four photograms were examined for each patient, at T1 and T2. The examined area (photogram) was divided into 3 segments: duodenal bulb, second and third portion duodenum. For each segment the two operators were asked to assess the total number of polyps observed and their sizes by using an open biopsy forceps (8 mm).

Lastly, biopsy specimens were taken from all polyps > 10 mm and from all suspicious ones, defined by the presence of a central depression, irregular surface, or irregular vascular pattern.

Histologic samples were processed by using standard procedures and evaluated by gastroenterology specialized pathologists. Histology was classified according to the epithelium type (tubular, tubulovillous, or villous adenoma) and the degree of dysplasia (none, low grade, high grade, or cancer according to the updated Vienna criteria).

### Treatment procedures

Eviendep<sup>®</sup> was chosen for its specifically high content of phytoestrogens and fibres. It comprises the selective ER $\beta$ -targeted flavonolignan silymarin (qualified for a 30% content in silibinin) and lignans (qualified for at least 40% of secoisolariciresinol diglucoside), in combination with non-starch, insoluble and indigestible fibres (qualified for or less than 5% lignin content). Each patient received 5 mg Eviendep twice a day, at breakfast and dinner time, for 3 mo.

### Statistical analysis

Statistical significance was determined using Student's *t*-tests for paired and unpaired samples. Treatment results were compared by  $\chi^2$  test for comparison of proportion with a 95% confidence interval (CI). All statistical analyses were 2-tailed, and significance was accepted at a *P* value < 0.05. To test the reproducibility of these findings, interrater agreement was calculated with kappa analysis. A score of < 0.20 was considered poor, 0.21 to 0.40 fair, 0.41 to 0.60 moderate, 0.61 to 0.80 good, and 0.81 to 1.00 very good. We performed all the statistical analyses using a statistical software package (SPSS Inc, Chicago, IL, United States).

## RESULTS

Eleven patients (M/F 5/6; mean age 40.7 years, SD  $\pm$

**Table 1 Findings at baseline and patients characteristics in 11 jejunal polyposis patients**

Patient No.	Age, yr (gender)	Age at colectomy (yr)	No. of duodenal polyps	Max size of duodenal polyps (mm)	Spigelman score
1	32 (F)	18	53	12	8
2	57 (M)	31	32	21	8
3	43 (F)	21	21	22	8
4	31 (F)	16	20	5	7
5	23 (M)	22	30	12	7
6	29 (M)	18	12	5	6
7	62 (M)	32	19	23	7
8	31 (F)	17	22	19	7
9	45 (M)	28	19	12	6
10	35 (F)	19	54	21	7
11	60 (F)	31	23	22	7

F: Female; M: Male.

13.6 years) met the inclusion criteria and were enrolled; they were followed prospectively between November 2012 and January 2013 at our department outpatients' clinic. The mean age at colectomy was  $23 \pm 6.2$  years and mean age of IPAA was  $17.7 \pm 8.5$  years. Table 1 shows the demographic, clinical characteristics and polyps' histological features.

At baseline (T0) the mean number of duodenal detected polyps was  $27.7 \pm 13.8$  (range 12-54) and mean sizes were  $15.8 \pm 6.8$  mm (range 5-23 mm); the mean Spigelman score was  $7.1 \pm 0.7$  (range 6-8). Histology confirmed tubular adenomatous tissue with low-grade dysplasia.

After polypectomy (T1) the mean number of duodenal detected polyps was  $25.7 \pm 13.4$  (range 10-51) and mean sizes were  $7.6 \pm 1.9$  mm (range 5-10 mm); the mean Spigelman score was  $6.4 \pm 0.5$  (range 6-7). After 3 mo of Eviendep *bid* (T2), all patients showed a reduction of number and size of duodenal polyps. The mean number of duodenal polyps was  $8 \pm 6.2$  (range 2-19) ( $\chi^2 = 28.42$ , *P* = 0.021) and mean size was  $4.4 \pm 2.1$  mm (range 2-9 mm); the mean Spigelman score was  $6.6 \pm 0.7$  (range 4-6) (Table 2, Figure 1).

Interrater agreement was measured. Lesions > 1 cm found a very good degree of concordance (kappa value 0.851) and a good concordance was as well encountered for smaller lesions (kappa value 0.641).

All the eleven patients completed the study. Compliance was excellent; only one patient reported mild intestinal bloating, and the therapy was not discontinued.

## DISCUSSION

Colonic surveillance programs and proctocolectomy with IPAA have improved the prognosis of patients with FAP. Current leading disease-related causes of death are desmoids tumours and duodenal adenocarcinomas. Duodenal cancer is nowadays the most important cause of death in FAP patients<sup>[13]</sup>. With respect to the duodenal manifestation of this disease, surveillance and prophylactic treatment strategies will hopefully further improve

**Table 2 Findings at baseline after polypectomies and after 3 mo of treatment**

prognosis. The secondary chemoprevention of duodenal cancer identifies three different lines of intervention.

**First chemopreventive strategy**

Pharmacological intervention studies have been primarily focused on targeting the inflammatory pathway of cyclooxygenase-2 (COX-2), an enzyme with increased expression in experimental and human intestinal neoplasia. Most of these studies tested the efficacy of nonsteroidal anti-inflammatory drugs (NSAIDs) and acetylsalicylic acid on either adenoma regression or new polyps prevention<sup>[20]</sup>. Randomized placebo-controlled trials have demonstrated that the NSAIDs sulindac and the selective COX-2 inhibitors celecoxib and rofecoxib have chemopreventive efficacy in FAP, with a significant regression of polyps<sup>[21-23]</sup>.

However, evaluations of the safety of the COX-2 inhibitors and NSAIDs showed an elevated risk of serious cardiac disorders, selected renal and hypertension events and a rebound effect on adenomas after the discontinuation of the treatments<sup>[24]</sup>.

**Second chemopreventive strategy**

Dietary interventions are the second chemopreventive treatment line. The studies on these interventions are based on potential chemopreventive properties of several dietary components and on the evidence of epigenetic mutations of tumour suppressor genes in the intestinal

mucosa after an unbalanced diet<sup>[25,26]</sup>. These studies forecasted an increase in servings/day of either fruit, vegetables, wholegrain and fibres in populations at risk of colorectal carcinoma, as well as the supplementation of specific nutrient blends.

**Third chemopreventive strategy**

The third new line of intervention focuses on the role of the ERs<sup>[27]</sup>. Since the discovery of ERs in the colonic tumour cells<sup>[28,29]</sup>, several epidemiological and clinical studies have supported the idea that estrogens play a protective role in the pathogenesis of colorectal neoplastic lesions, suggesting their potential use in the prevention of colorectal cancer<sup>[16,30-33]</sup>. There is evidence of estrogens proliferative modulation not only on the usual estrogens responsive tissues<sup>[34]</sup> but also on other apparatuses<sup>[35]</sup>.

Estrogens bind two types of receptors: estrogen receptor-alpha (ER- $\alpha$ ), prevalent in the breast, bone, cardiovascular tissue, urogenital tract and central nervous system, and estrogen receptor-beta (ER- $\beta$ ), prevalent in the gut<sup>[36,37]</sup>.

ER- $\beta$  expression is significantly lower in colonic adenocarcinoma cells than in normal colonic epithelial cells and this reduction is directly correlated with the degree of tumour dedifferentiation<sup>[15]</sup>. Although ER expression has been widely investigated in colorectal cancer cells (CRCs)<sup>[15,38,39]</sup>, few data are available about colorectal pre-

cancerous lesions.

Recently data confirm the involvement of ERs- $\beta$  in colorectal carcinogenesis and suggest a possible explanation for the protective effect of oestrogens on cancer development<sup>[17-19]</sup>. They also further support the role of vegetable-rich diets in the prevention of bowel cancer, thanks to their high content of phytoestrogens<sup>[5]</sup>.

In particular milk thistle, traditionally used as an antioxidant and antifibrotic agent in chronic liver disease<sup>[14]</sup>, is the source of silymarin, an ER- $\beta$  selective-agonist<sup>[15]</sup>. Silymarin has been documented to be an effective chemopreventive in the intestinal tumour progression<sup>[15,16,39]</sup>. The lignans, non-soluble dietary fibres has been reported to be similarly effective in the chemoprevention of CRC<sup>[17,40]</sup> most likely for their ability to absorb potential carcinogens in the intestinal lumen<sup>[17-18]</sup>. Barone *et al*<sup>[41]</sup> demonstrated with animal studies that ER- $\beta$  expression is amenable to dietary modulation to regress and/or oppose the progression of the adenoma-adenocarcinoma sequence. In a randomized, double-blind and placebo controlled study in patients undergoing surveillance colonoscopy because of recurrent sporadic adenomatous polyposis, a two months supplementation of Eviendep<sup>®</sup> (5 g *bid*) was able to specifically induce the expression of the ER $\beta$  in the colon mucosa, with optimal tolerability and safety<sup>[42]</sup>. The same group recently demonstrated that the oral supplementation of Eviendep to patients undergoing surveillance colonoscopy because of recurrent sporadic adenomatous polyposis was able to significantly increase the expression of ER- $\beta$  in the colon mucosa, with optimal tolerability and safety<sup>[42]</sup>.

At the same time, Yamada *et al*<sup>[43]</sup> performed a study with capsule endoscopy and found that patients with duodenal polyps had a larger number of polyps in the small intestine than those without duodenal polyps. In our experiences 8 of the 11 patients enrolled were previously investigated by capsule endoscopy. In our subset of patients there was no evidence of polyps in the small intestine.

In conclusion, our study demonstrated for the first time that short-term (90 d) supplementation with Eviendep<sup>®</sup> in FAP patients with IPAA and with recurrent adenomas in the duodenal mucosa, resulted effective in reducing polyps number by 32% and size by 51%. Eviendep<sup>®</sup> was easy to manage and its daily use was well tolerated by the patients. Its safety was guaranteed by its composition. Each ingredient is blended into the composition in a lower dose than the one otherwise needed for the single component to similarly exert the desired effect, thus leading to synergistic and/or potentiating effect, with the added advantage of higher safety, even over long-term exposure. Further molecular studies are needed to better confirm the role of estrogens in the duodenal mucosa, but we do believe that they also play a central role in duodenal carcinogenesis in the colon.

## COMMENTS

### Background

Familial adenomatous polyposis (FAP) is a disease with autosomal dominant

inheritance. Early prophylactic colorectal surgery changed the prognosis of patients with FAP, and duodenal cancer is nowadays the most important cause of death in FAP patients.

### Research frontiers

The recent discover of the involvement of estrogen receptors (ERs)- $\beta$  in colorectal carcinogenesis suggests a possible explanation for the protective effect of estrogens in cancer development. This also provided further support of the role of vegetable-rich diets in the prevention of bowel cancer, thanks to their high content of phytoestrogens (ER- $\beta$  selective agonists).

### Innovations and breakthroughs

Several epidemiological and clinical studies have supported the idea that estrogens play a protective role in the pathogenesis of colorectal neoplastic lesions, suggesting their potential use in the prevention of colorectal cancer. The aim of this study was to evaluate if dietary supplementation with phytoestrogens, selective agonists of the estrogen receptor, was able to prevent as well the progression of carcinogenesis in duodenal polyps.

### Applications

Their study demonstrated that short-term supplementation with phytoestrogens in FAP patients with ileal pouch-anal anastomosis (IPAA) is effective in reducing duodenal polyps number and size.

### Peer review

The authors investigated the effects of short-term (90 d) supplementation with Eviendep on the reduction of the number and size of duodenal polyps in FAP patients who had undergone IPAA.

### Abstract

**AIM:** To evaluate changes in the fatty acid composition of erythrocyte membrane phospholipids during severe and mild acute pancreatitis (AP) of alcoholic and nonalcoholic etiology.

**METHODS:** All consecutive patients with a diagnosis of AP and onset of the disease within the last 72 h admitted to the Hospital of Lithuanian University of Health Sciences between June and December 2007 were included. According to the Acute Physiology and Chronic

Health Evaluation (APACHE II) scale, the patients were subdivided into the mild (APACHE II score < 7,  $n = 22$ ) and severe (APACHE II score  $\geq 7$ ,  $n = 17$ ) AP groups. Healthy individuals ( $n = 26$ ) were enrolled as controls. Blood samples were collected from patients on admission to the hospital. Fatty acids (FAs) were extracted from erythrocyte phospholipids and expressed as percentages of the total FAs present in the chromatogram. The concentrations of superoxide dismutase and glutathione peroxidase were measured in erythrocytes.

**RESULTS:** We found an increase in the percentages of saturated and monounsaturated FAs, a decrease in the percentages of total polyunsaturated FAs (PUFAs) and  $n-3$  PUFAs in erythrocyte membrane phospholipids of AP patients compared with healthy controls. Palmitic (C16:0), palmitoleic (C16:1n7cis), arachidonic (C20:4n6), docosahexaenoic (DHA, C22:6n3), and docosapentaenoic (DPA, C22:5n3) acids were the major contributing factors. A decrease in the peroxidation and unsaturation indexes in AP patients as well as the severe and mild AP groups as compared with controls was observed. The concentrations of antioxidant enzymes in the mild AP group were lower than in the control group. In severe AP of nonalcoholic etiology, the percentages of arachidic (C20:0) and arachidonic (C20:4n6) acids were decreased as compared with the control group. The patients with mild AP of nonalcoholic etiology had the increased percentages of total saturated FAs and gamma linoleic acid (C18:3n6) and the decreased percentages of elaidic (C18:1n9t), eicosapentaenoic acid (EPA, C20:5n3), DPA (C22:5n3), DHA (C22:6n3) as well as total and  $n-3$  PUFAs in erythrocyte membrane phospholipids.

**CONCLUSION:** The composition of FAs in erythrocyte membranes is altered during AP. These changes are likely to be associated with alcohol consumption, inflammatory processes, and oxidative stress.

© 2013 Baishideng. All rights reserved.

**Key words:** Acute pancreatitis; Alcohol; Fatty acids; Oxidative stress; Systemic inflammatory response syndrome

**Core tip:** The manuscript by Kuliaviene *et al.* elucidates the changes of fatty acids in erythrocyte membrane phospholipids during acute pancreatitis. Alcohol may influence the increased percentage of saturated and monounsaturated fatty acids of erythrocyte membrane. Fatty acids that are linked with inflammatory processes change differently during severe and mild nonalcoholic acute pancreatitis. The decrease of pro-inflammatory acids is seen in severe acute pancreatitis while anti-inflammatory players decrease during mild acute pancreatitis. The antioxidant enzymes of erythrocytes change in mild but not severe pancreatitis group. Thus the erythrocyte membranes can reflect the inflammatory and oxidative processes of acute pancreatitis.

## INTRODUCTION

Acute pancreatitis (AP) is a sudden inflammation of pancreas. About 20%-30% of patients develop severe forms of the disease manifesting with local and systemic complications. Acute pancreatitis carries an overall mortality rate of 10%-15%<sup>[1,2]</sup>. The main causes of death are associated with multiple organ failure and pancreatic infection<sup>[3,4]</sup>. The initial process of inflammation starts in the pancreas, but no strict correlation between pancreatic necrosis and organ failure has been reported<sup>[5]</sup>. Systemic inflammatory response is responsible for multiple organ failure and has the most considerable impact on the severity of acute pancreatitis and mortality from this disease<sup>[6]</sup>.

The role of fatty acids (FAs) in the pathogenesis of AP is important but far from being clear. An increase the total serum free FA level is observed during AP<sup>[7]</sup>. Unsaturated FAs, especially polyunsaturated FAs (PUFAs), are liberated from pancreatic necrotic tissues and are responsible for the disturbance of FA profile in the serum of patients with AP<sup>[7,8]</sup>. The increased amount of unsaturated FAs in the necrotic pancreatic tissue and serum during AP is associated with multisystem organ failure and worse outcomes of patients<sup>[9]</sup>. Moreover, alcohol, an important etiological factor for pancreatitis, has an impact on the FA composition of serum and erythrocyte membranes<sup>[10-13]</sup>. Surprisingly, during alcohol-induced pancreatitis, the percentage of PUFAs is decreased in the serum FA profile in mild and moderate AP as well as chronic pancreatitis<sup>[14,15]</sup>. These data suggest that alcohol

could play a specific role in the pathogenesis of pancreatitis.

FAs of cell membranes are precursors for lipid mediators and play an important role in the process of inflammation and oxidant status<sup>[16]</sup>. Experimental findings show that n-3 PUFAs may be beneficial in the prevention of oxidative stress-induced inflammation in pancreatitis<sup>[17]</sup>. Moreover, it influences the histological severity of AP<sup>[18-21]</sup>. Human studies also indicate likely clinical benefits of enteral feeding rich in n-3 PUFAs in patients with AP<sup>[22]</sup>.

The aim of our study was to evaluate changes in the FA profile of erythrocyte membrane phospholipids and antioxidant enzymes of erythrocytes in patients with severe and mild AP, also of nonalcoholic etiology separately, in comparison with healthy individuals. We believe that erythrocyte membrane phospholipids can better reflect systemic changes caused by oxidative stress and inflammatory response in patients with AP comparing with FAs in serum, which are greatly influenced by necrotic changes in the pancreas and peripancreatic tissues. To our knowledge, no studies examining the FA composition of erythrocyte membrane phospholipids during AP have been carried out.

## MATERIALS AND METHODS

### Patients

All consecutive patients with a diagnosis of AP and onset of the disease within the last 72 h admitted to the Departments of Surgery and Gastroenterology at the Hospital of Lithuanian University of Health Sciences between June and December 2007 were included in this study. The diagnosis was established based on acute abdominal pain, at least 3-fold elevated levels of serum amylase, and typical radiological findings. According to the Acute Physiology and Chronic Health Evaluation (APACHE II) scale, the patients were subdivided into the mild (APACHE II score < 7,  $n = 22$ ) and severe (APACHE II score  $\geq 7$ ,  $n = 17$ ) AP groups. Healthy subjects ( $n = 26$ ) without a past history of pancreatic diseases were enrolled as controls.

### Fatty acid and antioxidant analysis

Peripheral blood samples were drawn from patients on admission to the hospital. Plasma and leukocytes were removed after centrifugation. Erythrocytes were washed and centrifuged twice. The samples were stored at -80 °C until analysis. The blood samples of the control group were subjected to the same procedure.

FA analysis was performed in the Laboratory for Health Protection Research, National Institute for Public Health and the Environment (The Netherlands), as described previously<sup>[23]</sup>. Briefly, 200  $\mu$ L of erythrocytes was taken, and phospholipids were washed with distilled water and extracted with chloroform/methanol (1:1). The chloroform layer was evaporated, and the phospholipids were hydrolyzed and methylated simultaneously

**Table 1** Demographic and clinical data of patients and controls

with BF<sub>3</sub>/MeOH for 60 min at 100 °C. After extraction with hexane, the methylated FAs (FAME) were separated on a fused silica capillary column using a GC-3900 gas chromatograph with FID detection (Varian Assoc). The baseline separation of more than 50 FAME peaks was accomplished using FAME standards (Sigma) within 57 min. Individual FAs were expressed as percentages of the total FAs present in the chromatogram.

The concentrations of superoxide dismutase (SOD) and glutathione peroxidase (GPx) were measured in erythrocytes on an auto analyzer (LX-20 Pro, Beckman-Coulter, Woerden, Netherlands) with kits from Randox (Ransod and Ransel, Crumlin, United Kingdom).

### Peroxidation and unsaturation index

The indexes were calculated according to the formulas used by Viviani *et al.*<sup>24</sup>. The peroxidation index (PI) was determined from the percentages of monoenoic, dienoic, trienoic, tetraenoic, pentaenoic and hexanoic FAs according to the following formula: PI = [(%monoenoic × 0.025) + (%dienoic × 1) + (%trienoic × 2) + (%tetraenoic × 4) + (%pentaenoic × 6) + (%hexanoic × 8)].

The unsaturation index (UI) is also known as the index of hydrogen deficiency. It was calculated from the number of unsaturated double bonds of each FA: UI = [(%monoenoic × 1) + (%dienoic × 2) + (%trienoic × 3) + (%tetraenoic × 4) + (%pentaenoic × 5) + (%hexanoic × 6)].

### Ethics

The study was approved by Kaunas Regional Ethics Committee for Biomedical Research (BE-2-47). All patients and healthy subjects provided written informed consent.

### Statistical analysis

Statistical analysis was performed using SPSS® for Windows release 14.0 (SPSS, Chicago, IL, United States). The data are presented as mean ± SD. The Mann-Whitney test and one-way and two-way ANOVA tests were applied for analysis of variables. All statistical tests were two sided, and *P* < 0.05 was considered statistically significant.

## RESULTS

The demographic characteristics of patients and controls

Results are presented as mean ± SD. Percentages of saturated, monounsaturated and polyunsaturated fatty acids (PUFA) in erythrocyte membrane phospholipids in patients with acute pancreatitis (AP) of alcoholic and nonalcoholic etiology. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 vs control group.

are presented in Table 1. There was no difference in the FA composition of membrane phospholipids between men and women in the control group (data not shown).

As shown in Table 2, the percentage of saturated FAs in erythrocyte membrane phospholipids was greater in the patients with AP than the control group. Palmitic acid (C16:0) had a major impact on the increase. The percentages of monounsaturated FAs were also increased, and *cis*-isomers, especially palmitoleic (C16:1n7*cis*) and erucic (C22:1n9*cis*) acids, mostly contributed to the change. We found a decreased percentage of some *trans* monounsaturated FAs in erythrocyte membrane phospholipids. Those were elaidic (C8:1n9*trans*) and vaccenic (C18:1n7*trans*) acids (Table 2).

The percentages of total and n-3 PUFAs were decreased in erythrocyte membrane phospholipids of AP

**Figure 1** Peroxidation and unsaturation indexes of fatty acids of erythrocyte membrane phospholipids in the acute pancreatitis, severe acute pancreatitis, mild acute pancreatitis, and control groups. A significant decrease of peroxidation index and unsaturation index in acute pancreatitis (AP) patients compared with controls was observed. Bars represent mean values with standard deviation. The extent of change in the indexes in mild AP was greater than in severe AP patients comparing with controls (<sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs control group).

patients. This was particularly caused by the decreased percentages of docosahexaenoic (DHA C22:6n3) and docosapentaenoic (DPA C22:5n3) acids. The percentage of arachidonic acid (AA, C20:4n6) was decreased in the patients with AP comparing with the controls, though the percentages of gamma-linoleic (C18:3n6) and dihomo gamma linoleic (C20:3n6) acids were increased (Table 2).

A decrease of PI and UI in AP patients as well as the severe and mild AP groups compared with the controls was observed. The extent of change in the indexes in the mild AP group was greater than in the severe AP group compared with controls (Figure 1). The concentrations of SOD and GPx in the mild AP group were lower comparing with the control group ( $321.55 \pm 75.19 \mu\text{mol}/\text{mL}$  and  $10059.21 \pm 2666.96 \text{ U}/\text{L}$  vs  $384.88 \pm 42.21 \mu\text{mol}/\text{mL}$  and  $11649.09 \pm 1844.75 \text{ U}/\text{L}$ ,  $P < 0.001$  and  $P < 0.05$ , respectively). To rule out the impact of alcohol in the changes of FAs in erythrocyte membrane phospholipids of AP patients, we analyzed AP of non-alcoholic etiology (Table 3). In the severe AP group, the percentages of arachidic acid (C20:0) and AA (C20:4n6) were decreased as compared with the control group. In the mild AP group, an increase in the percentages of total saturated FAs and gamma linoleic acid (C18:3n6) and a decrease in the percentages of elaidic (C18:1n9t), EPA (C20:5n3), DPA (C22:5n3), DHA (C22:6n3), total PUFAs, and omega 3 PUFAs in erythrocyte membrane phospholipids were recorded. The change in the concentrations of antioxidant enzymes showed the same pattern: they were decreased in patients with mild AP and showed no change in the severe AP group. The changes in the PI and the UI appeared to be greater in the mild AP than severe AP group as compared with the control group.

## DISCUSSION

This study has analyzed the impact of systemic inflam-

matory response and oxidative stress on the FA composition of erythrocyte membranes and the concentrations of enzymes in patients with AP. The initial generation of ROS and inflammatory events occur in the pancreas, but systemic changes have a crucial impact on the severity and fatal outcomes of AP<sup>[6]</sup>. A better understanding of these systemic processes occurring during AP could help identifying new therapeutic treatment options and escaping undesirable complications or fatal outcomes.

In our study, we found that the FA composition of erythrocyte membrane phospholipids was significantly altered during AP compared with controls mainly because of the increased percentages of saturated and monounsaturated acids, namely palmitic and palmitoleic, and a decreased percentage of PUFAs. Contrary, Sztéfko *et al*<sup>[7]</sup> found that the proportion of saturated and monounsaturated acids was decreased and the proportion of PUFAs was increased in the serum levels of free FAs in patients with AP. An increase in the percentage of PUFAs in the necrotic pancreatic tissue has also been reported<sup>[8]</sup>. On the other hand, in severe sepsis, a similar pathology with systemic inflammatory response syndrome, the lower proportions of PUFAs and the greater proportions of monounsaturated FAs in erythrocyte phospholipids have been documented<sup>[25]</sup>. These findings suggest that the FA composition of erythrocyte membrane phospholipids may reflect not only the direct events in the pancreas, but also the systemic response syndrome during AP.

Alcohol consumption can be associated with the higher percentages of saturated and monounsaturated FAs, such as palmitic and oleic acids, and the lower percentages of PUFAs, especially DHAs and arachidonic acid, in serum and membranes<sup>[10-13]</sup>. Alcoholics have also been shown to have a disturbed oxidant status of plasma and erythrocyte enzymes<sup>[26-28]</sup>. In the study by Khan *et al*<sup>[14]</sup>, the authors showed the increased percentages of saturated palmitic and monounsaturated FAs as well as the decreased percentages of some PUFAs in serum of patients with alcohol-induced AP comparing with alcoholic controls. Moreover, Gabianelli *et al*<sup>[29]</sup> reported that ethanol can have a direct toxic effect on erythrocyte membranes and antioxidant systems of the cells. These findings indicate that alcohol may have an impact on the FA composition of erythrocyte membrane phospholipids. Thus, the increased percentages of saturated and monounsaturated FAs in our study could partly be explained by etiological factors, most probably alcohol.

To rule out the impact of alcohol and to study the influence of inflammatory and oxidative processes during AP on the phospholipid composition of erythrocyte membranes, we analyzed patients with AP of nonalcoholic etiology. The PUFAs of cell membranes are precursors for prostaglandins and other lipid mediators of inflammatory process<sup>[16]</sup>. Arachidonic acid is the main proinflammatory actor. Meanwhile, EPA, DHA, and possibly DPA are precursors for products with anti-inflammatory and proresolving functions<sup>[30,31]</sup>. We found that in the severe AP group, the percentage of proinflammatory arachidonic acid was significantly decreased, and

Results are presented as mean ± SD. Percentages of fatty acids in erythrocyte membrane phospholipids, peroxidation and unsaturation indexes, and concentrations of superoxide dismutase (SOD,  $\mu\text{mol}/\text{mL}$ ) and glutathione peroxidase (GPx, U/L) in patients with acute pancreatitis (AP) of nonalcoholic etiology. <sup>a</sup> $P < 0.05$  comparing mild and severe AP; <sup>c</sup> $P < 0.05$ , <sup>d</sup> $P < 0.01$  vs control group. PUFA: Polyunsaturated fatty acids; SFA: Saturated fatty acids.

in the mild AP group, a decrease in the percentages of anti-inflammatory players (EPA, DHA, and DPA) was seen as compared with controls. It is now thought that saturated FAs could also be involved in the inflammatory process<sup>[32,33]</sup>. We also found a significant increase in the percentage of total saturated FAs in the mild but not severe AP group. Erythrocytes are not usually considered to be active players in the inflammatory process, but our study showed that the changes in the percentage of FAs in erythrocyte membrane phospholipids were different during mild and severe AP, therefore, we hypothesize that the composition of erythrocyte membrane phospholipids may reflect the inflammatory processes and the severity of the disease.

Oxidative stress plays a central role in the development of pancreatic inflammation and extra pancreatic complications<sup>[34-36]</sup>. The changes of the FA composition of erythrocyte membrane phospholipids could be affected from “the outside” as PUFAs of erythrocyte membrane phospholipids are extremely sensitive to oxidation<sup>[37]</sup>. SOD and GPx are important components of enzymatic antioxidant defense<sup>[37]</sup>. We found that the levels of antioxidant enzymes in erythrocytes were also altered significantly in the mild but not severe AP group comparing with controls. There were significant differences in the PI and the UI mainly because of the different percentage of PUFAs in erythrocyte membrane phospholipids in the severe and mild AP groups comparing with controls. Moreover, there was a significant difference between the severe and mild AP groups. This suggests that oxidative stress might be involved in the changes of the FA composition of erythrocyte membrane phospholipids and systemic inflammatory response.

It was unexpected to find the changes of PI and UI to be more apparent in the mild AP than severe AP group comparing with controls. It is known that systemic response followed by organ failure influences the severity

and outcome of AP more than the events in the pancreas itself<sup>[5]</sup>. The similar phenomenon was also noticed in cytokine expression during mild and severe AP<sup>[38]</sup>. We hypothesize that these findings could reflect the disproportion of pro- and anti-inflammatory processes during severe AP possibly associated with oxidative stress. The mechanisms of these processes are still not clear and remain to be elucidated.

The composition of FAs in erythrocyte membranes is altered during AP. These changes are likely to be associated with alcohol intake as an etiological factor for AP, and systemic inflammatory processes and oxidative stress after the onset of the disease could influence the changes.

## COMMENTS

### Background

Acute pancreatitis carries an overall mortality rate of 10%-15%. Systemic inflammatory response has the most considerable impact on the severity of acute pancreatitis and mortality from this disease. Fatty acids of cell membranes are precursors for lipid mediators and play an important role in the process of inflammation and oxidant status. Erythrocyte membrane phospholipids can reflect systemic changes caused by oxidative stress and inflammatory response in patients with acute pancreatitis.

### Research frontiers

The role of fatty acids in the pathogenesis of acute pancreatitis is important but far from being clear. Fatty acids are the components of membrane phospholipids. They are responsible for inflammatory and oxidative processes. Free fatty acids in serum are associated with necrotic lesions in the pancreas and peripancreatic tissues. Moreover, alcohol, an important etiological factor for pancreatitis, has an impact on the fatty acid composition of serum and erythrocyte membranes.

### Innovations and breakthroughs

The earlier studies of alterations in the fatty acid composition during acute pancreatitis mainly investigated the fatty acid composition in serum that is greatly influenced by necrotic changes in the pancreas and peripancreatic tissues. Authors believe that erythrocyte membrane phospholipids can better reflect systemic changes caused by oxidative stress and inflammatory response as well as alcohol impact in patients with acute pancreatitis. To the knowledge, no studies examining the fatty acid composition of membranes during acute pan-

creatitis have been carried out.

### Applications

This study elucidates the pathogenesis of acute pancreatitis, especially the systemic and oxidative processes that are of high importance in the severity of acute pancreatitis and mortality from this disease.

### Terminology

Fatty acids are the components of phospholipids that form the lipid bilayers of cell membranes. Fatty acids of membranes are precursors for lipid mediators of inflammatory response syndrome. Oxidative stress is a disturbance of the pro-oxidant-antioxidant balance in favor of the former, leading to potential damage, and is associated with many chronic and acute inflammatory conditions.

### Peer review

This study evaluates changes in fatty acids of erythrocyte membrane phospholipids during mild and severe acute pancreatitis, of alcohol and non-alcohol etiology. The study is a prospective one and Acute Physiology and Chronic Health Evaluation II score was used to classify patients into mild ( $n = 22$  patients) and severe ( $n = 17$  patients). Some 26 healthy individuals were enrolled as control. This is a well conducted prospective study, and to my knowledge this is the first study that examines the fatty acid profile of the erythrocyte membrane in acute pancreatitis.

### Abstract

**AIM:** To investigate the diversity of *Helicobacter pylori* (*H. pylori*) genotypes and correlations with disease outcomes in an Iranian population with different gastroduodenal disorders.

**METHODS:** Isolates of *H. pylori* from patients with different gastroduodenal disorders were analyzed after culture and identification by phenotypic and genotypic methods. Genomic DNA was extracted with the QIAamp DNA mini kit (Qiagen, Germany). After DNA extraction, genotyping was done for *cagA*, *vacA* (s and m regions), *iceA* (*iceA*<sub>1</sub>, *iceA*<sub>2</sub>) and *babA* with specific primers for each allele using polymerase chain reaction (PCR). All patients' pathologic and clinical data and their relation with known genotypes were analyzed by using SPSS version 19.0 software.  $\chi^2$  test and Fisher's exact test were used to assess relationships between categorical variables. The level of statistical significance was set at  $P < 0.05$ .

**RESULTS:** A total of 71 isolates from 177 patients with different gastroduodenal disorders were obtained. Based on analysis of the *cagA* gene (positive or negative), *vacA* s-region (*s*<sub>1</sub> or *s*<sub>2</sub>), *vacA* m-region (*m*<sub>1</sub> or *m*<sub>2</sub>), *iceA* allelic type (*iceA*<sub>1</sub> and *iceA*<sub>2</sub>) and *babA* gene (positive or negative), twenty different genotypic combinations were recognized. The prevalence of *cagA*, *vacA* *s*<sub>1</sub>, *vacA* *s*<sub>2</sub>, *vacA* *m*<sub>1</sub>, *vacA* *m*<sub>2</sub>, *iceA*<sub>1</sub>, *iceA*<sub>2</sub>, *iceA*<sub>1</sub>+*iceA*<sub>2</sub> and *babA* were 62%, 78.9%, 19.7%, 21.1%, 78.9%, 15.5%, 22.5%, 40.8% and 95.8%, respectively. Interestingly, evaluation of PCR results for *cagA* in 6 patients showed simultaneous existence of *cagA* variants according to their size diversities that proposed mixed infection in these patients. The most prevalent genotype in *cagA*-positive isolates was *cagA*<sup>+</sup>/*vacA*<sub>s1</sub>/*m*<sub>2</sub>/*iceA*<sub>1</sub>+*A*<sub>2</sub>/*babA*<sup>+</sup> and in *cagA*-negative isolates was *cagA*<sup>-</sup>/*vacA*<sub>s1</sub>/*m*<sub>2</sub>/*iceA*<sub>1</sub>-/*babA*<sup>+</sup>. There were no relationships between the studied genes and histo-

pathological findings (*H. pylori* density, neutrophil activity, lymphoid aggregation in lamina propria and glandular atrophy). The strains which carry *cagA*, *vacAs1/m1*, *iceA2* and *babA* genes showed significant associations with severe active chronic gastritis ( $P = 0.011$ ,  $0.025$ ,  $0.020$  and  $0.031$ , respectively). The *vacAs1* genotype had significant correlation with the presence of the *cagA* gene ( $P = 0.013$ ). Also, *babA* genotype showed associations with *cagA* ( $P = 0.024$ ). In the combined genotypes, only *cagA*<sup>+</sup>/*vacAs1/m1/iceA2/babA*<sup>+</sup> genotype showed correlation with severe active chronic gastritis ( $P = 0.025$ ).

**CONCLUSION:** This genotyping panel can be a useful tool for detection of virulent *H. pylori* isolates and can provide valuable guidance for prediction of the clinical outcomes.

Diversity of *Helicobacter pylori* genotypes in Iranian patients with different gastroduodenal disorders. *World J Gastroenterol* 2013; 19(34): 5685-5692 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i34/5685.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i34.5685>

## INTRODUCTION

Infection with *Helicobacter pylori* (*H. pylori*) causes different clinical disorders such as persistent gastritis, peptic ulcers and mucosa associated lymphoid tissue (MALT) lymphoma. Current studies suggest that *H. pylori* infection may be a crucial risk factor in the development of gastric cancer<sup>[1,2]</sup>. In this regard, this pathogen has been categorized as a group I carcinogen by the International Agency for Research on Cancer<sup>[3]</sup>. The detailed reasons for these different clinical outcomes are unknown, but they may be related to host genetic factors, exposure to environmental factors (*e.g.*, diet, drug usage, acidity of the stomach and smoking) and to the bacterial genotypes<sup>[4]</sup>. *H. pylori* shows extensive genetic diversity and this variability has a crucial role in pathogenesis of this bacterium<sup>[5]</sup>. Several *H. pylori* virulence factor genes related to the risk of gastroduodenal disorders, including *cagA*, *vacA*, *babA* and *iceA*, have been proposed<sup>[6]</sup>. A tremendous number of studies have proved that CagA and VacA producing strains are related to severe clinical outcomes<sup>[7]</sup>. In addition to *cagA* and *vacA*, the other *H. pylori* virulence factors, such as *iceA* and *babA*, also showed such associations in some studies<sup>[8,9]</sup>. Beyond the role of these factors in progression of the disease, there are several papers which reported a relationship between failure of *H. pylori* eradication therapy and the strains' virulence factor genotypes<sup>[10]</sup>. Analysis of genetic structure of virulence factors among the isolates from different geographic regions will provide new insights regarding the pathogenesis and treatment of *H.*

*pylori* infection. *H. pylori* genotyping may have multiple roles including impact on the cure rates of eradication therapy<sup>[10]</sup>, determination of clinical outcomes<sup>[11]</sup>, tracking human migration<sup>[12,13]</sup> and recently, the prediction of progression of gastric preneoplastic lesions<sup>[14]</sup>. The distribution pattern of *H. pylori* genotypes and its correlation with disease outcome shows geographic differences. The aim of this study was to assess the diversity of *H. pylori* genotypes in an Iranian population to determine genotypically the *H. pylori* isolates more associated with different gastroduodenal disorders.

## MATERIALS AND METHODS

### Clinical specimens

Three gastric biopsies (two were used for histological examination and one for culture) were obtained from 177 adult patients undergoing routine diagnostic endoscopy referred to the Endoscopy Centre of Taleghani Hospital of Tehran, Iran, after obtaining informed consent. All subjects answered questionnaires related to age, sex, gastric or duodenal peptic ulcer diseases upon endoscopy.

### Culture

Antral or body biopsy specimens from each patient were kept in transport medium consisting of thioglycolate with 1.3 g/L agar (Merck) and 3% yeast extract (Oxoid). The endoscopic biopsy specimens were cut into small pieces, homogenized with a sterile scalpel and were smeared on the surface of Brucella agar plates supplemented with 7% horse blood and Campylobacter selective supplement (vancomycin 2.0 mg, polymyxin 0.05 mg, trimethoprim 1.0 mg) and amphotericin B (2.5 mg/L). Incubation was performed in microaerophilic conditions at 37 °C for 5-7 d. Identification of *H. pylori* isolates was performed by analyzing colony morphology, Gram staining, oxidase, catalase and urease activities and *H. pylori*-specific polymerase chain reaction (PCR) (*glmM*). The isolates were preserved in BHI broth containing 20% glycerol and 10% fetal calf serum and stored at -70 °C.

### DNA extraction

Genomic DNA was extracted with the QIAamp DNA mini kit (Qiagen, Germany) according to the manufacturer's instructions. The DNA was stored at -20 °C until used for molecular studies.

### *H. pylori* genotyping

After DNA extraction, polymerase chain reactions (PCR) were performed in a volume of 25 µL containing 1 × PCR buffer, 1 µmol/L of each primer, 1 µL of genomic DNA (approximately 150 ng), 200 µmol/L of dNTPs mix, 2 mmol/L of MgCl<sub>2</sub>, and 0.05 U/µL Taq DNA polymerase. PCR amplifications were performed in an automated thermal cycler (AG 22331; Eppendorf, Hamburg, Germany) under the following conditions: for *vacA s/m*: 33 cycles of 1 min at 94 °C, 33 s at 55 °C, and 1 min at 72 °C; for *cagA*: 33 cycles of 1 min at 94 °C, 1 min at

59 °C, and 1 min at 72 °C; for *iceA*<sub>1</sub>/*A*<sub>2</sub>: 33 cycles of 1 min at 94 °C, 40 s at 58 °C, and 1 min at 72 °C, and for *babA*: 35 cycles of 1 min at 94 °C, 40 s at 58 °C and 1 min at 72 °C. The amplified genes were detected by electrophoresis in a 1.2% agarose gel with ethidium bromide. Table 1 summarizes the primer sequences, annealing temperatures and the expected size of the PCR products.

### Histopathological evaluation

Sections were stained with hematoxylin and eosin for analysis of *H. pylori*-related histology by an expert pathologist. Then the grade of gastritis was scored based on the updated Sydney System.

### Statistical analysis

Data were analyzed by using SPSS version 19.0.0 software (IBM, IL, United States).  $\chi^2$  test and Fisher's exact test were used to assess relationships between categorical variables. The level of statistical significance was set at  $P < 0.05$ .

## RESULTS

### Infection rates and clinical disorders

A total of 71 isolates from 177 patients (parenthesis approximately 40%) with different gastroduodenal disorders were obtained. The *H. pylori*-positive patients consisted of 24 males and 47 females, with their ages ranging between 19 and 85 years (mean age, 66 years). All of the isolates showed positive results for the common identification test and *H. pylori*-specific PCR (*glmM*). Most of the infected patients suffered from chronic gastritis (84.6%), while the others showed duodenitis (9.8%), intestinal metaplasia (2.8%), hyperplasia (1.4%) and gastric cancer diseases (1.4%) (Table 2).

### Allelic diversities in main putative virulence markers

***cagA* genotyping:** The 400-bp PCR product indicating the presence of the *cagA* gene was obtained in 44 isolates (62%) and 27 (38%) were negative. Interestingly, evaluation of PCR results for *cagA* in 6 patients showed simultaneous existence of *cagA* variants according to their size

diversities.

***vacA* genotyping:** The frequency of *vacA* s<sub>1</sub>, *vacA* s<sub>2</sub>, *vacA* m<sub>1</sub> and *vacA* m<sub>2</sub> were 78.9%, 19.7%, 21.1% and 78.9%, respectively. Only one isolate was *vacA* som2 (with no PCR product for s region).

***iceA* genotyping:** Sole existence of *iceA*<sub>1</sub> genotype was detected in 15.5% and *iceA*<sub>2</sub> genotype in 22.5% of the colonized patients. Interestingly, out of the total studied samples, 40.8% were infected with both *iceA*<sub>1</sub> and *iceA*<sub>2</sub> genotypes and 21.1% were negative for these genes.

***babA* genotyping:** *babA* was found in 68 of the patients (95.8%); however, three patients (4.2%) did not show this allelic variant (Figure 1).

### Correlation of *H. pylori* genotypes with pathological data, patients' age and clinical outcome

**Combination of genotypes:** Based on the analysis of the *cagA* gene (positive or negative), *vacA* s-region (s<sub>1</sub> or s<sub>2</sub>), *vacA* m-region (m<sub>1</sub> or m<sub>2</sub>), *iceA* allelic types (*iceA*<sub>1</sub> and *iceA*<sub>2</sub>) and *babA* (positive or negative), twenty different genotypic combinations were recognized. The most prevalent genotype in *cagA* positive isolates was *cagA*<sup>+</sup>/*vacA*s<sub>1</sub>m<sub>2</sub>/*iceA*<sub>1</sub>+*A*<sub>2</sub>+/*babA*+ and in *cagA* negative isolates was *cagA*<sup>-</sup>/*vacA*s<sub>1</sub>m<sub>2</sub>/*iceA*-/*babA*+ (Figure 2).

***Helicobacter pylori* density, neutrophil activity, lymphoid aggregation in lamina propria and glandular atrophy:** There was no significant relationship between *cagA* positivity and *H. pylori* density, neutrophil activity, lymphoid aggregation in lamina propria and glandular atrophy in the biopsies. Also no relationships were found between other genes and these histopathological findings.

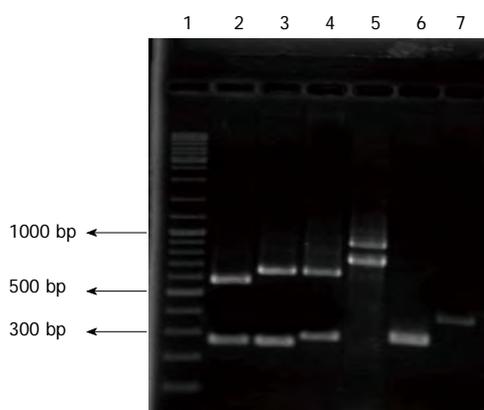

**Patients' age:** There was no significant relationship between the genotypes, clinical and pathological data and patients' age.

**Chronic gastritis:** The gastritis was scored as severe ac-

**Table 2 Association of combined genotypes with pathological conditions in *Helicobacter pylori* isolates**

<sup>1</sup>Only  $P < 0.05$  are indicated; <sup>2</sup>This  $P$  value is related to severe active chronic gastritis (SACG). SCG: Severe chronic gastritis; MACG: Moderate active chronic gastritis; MiACG: Mild active chronic gastritis; MCG: Moderate chronic gastritis; H: Hyperplasia; M: Metaplasia; GC: Gastric cancer; D: Duodenitis.

**Figure 1** Polymerase chain reaction products of the main putative virulence markers. Lane 1: DNA ladder mix; Lane 2: *vacAs1m1* genotype; Lane 3: *vacAs1m2* genotype; Lane 4: *vacAs2m2* genotype; Lane 5: *iceA1+iceA2* genotype; Lane 6: *babA* genotype; Lane 7: *cagA* genotype

tive chronic gastritis, moderate active chronic gastritis, mild active chronic gastritis, severe chronic gastritis and moderate chronic gastritis. The strains which carried the *cagA* gene showed significant associations with severe active chronic gastritis ( $P = 0.011$ ). Also, the strains which carried the *vacA* *s1/m1* gene showed significant associations with severe active chronic gastritis ( $P = 0.025$ ). *babA* ( $P = 0.031$ ) and *iceA2* ( $P = 0.020$ ) also had significant correlation with severe active chronic gastritis. In the combined genotypes this association was observed for *cagA*<sup>+</sup>/*vacAs1m1*/*iceA2*/*babA*<sup>+</sup> genotype in the case of severe active chronic gastritis ( $P = 0.025$ ).

**Genotype correlation:** Interestingly, the *vacA* *s1* geno-

type had significant correlation with the presence of the *cagA* gene ( $P = 0.013$ ). Also *babA* genotype showed this association in *cagA* positive isolates ( $P = 0.024$ ).

## DISCUSSION

*H. pylori* infection is usually present in 60%-80% of gastric and 95% of duodenal ulcers. However, some conditions affect infection rate of this bacterium in different geographic and socioeconomic regions. The prevalence of infection is typically higher in developing countries (greater than 80%) and lower in the developed ones (typically less than 40%)<sup>[20]</sup>. It has been demonstrated that the prevalence of *H. pylori* infection in developing countries with low socioeconomic status and poor management of drinking water is much higher (> 80%) than that in developed countries (< 60%)<sup>[21]</sup>. In our study the recovery rate of *H. pylori* was 40% which shows the improvement in the living conditions and hygiene in Iran that has also been reported recently<sup>[22]</sup>.

*H. pylori* can be divided into *cagA*-positive and *cagA*-negative strains, and there is increasing evidence that infection with *cagA*-positive isolates is associated with a greater risk of adverse clinical outcomes than infections with strains lacking this gene. In the current study, the strains which carried the *cagA* gene showed significant associations with severe active chronic gastritis. Interestingly, the prevalence of the *cagA*-positive strain differs among different countries, and more than 90% of *H. pylori* strains are *cagA*-positive in East Asian countries, irrespective of clinical presentation<sup>[23]</sup>. Sasaki *et al*<sup>[24]</sup> showed that among *H. pylori* DNA-positive samples, *cagA* was detected in 45.9% from Ecuador and 20.0% from Panama.

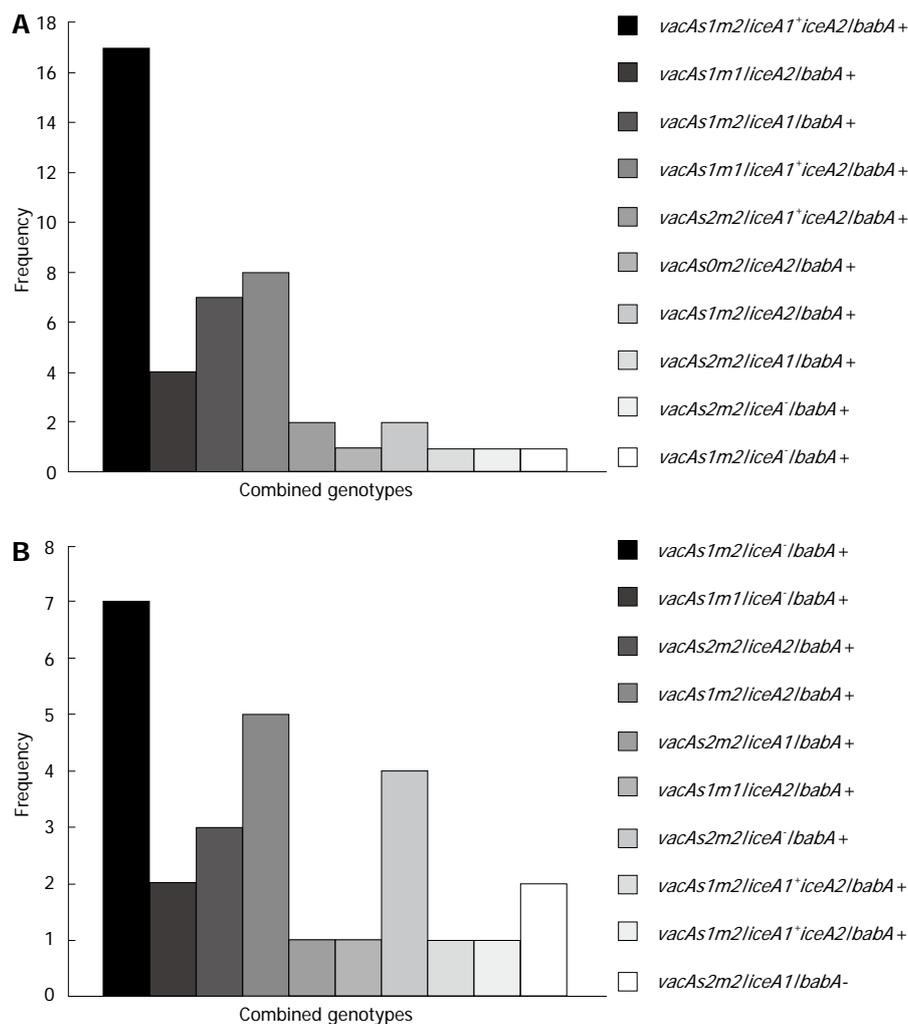

Figure 2 The frequency of combined genotypes. A: Combined *vacA*, *iceA* and *babA* genotypes in 44 *cagA* positive isolate; B: Combined *vacA*, *iceA* and *babA* genotypes in 27 *cagA* negative isolates.

In our study the prevalence of *cagA*-positive isolates is 62% which is less than other Asian countries and more than other countries (e.g., Ecuador, Panama). According to Watada *et al.*<sup>[25]</sup> study, the prevalence of *cagA* was 65.5% in Colombia and 100% in Japan, which showed that the prevalence of this gene in our study is similar to the Colombian isolates. In another study conducted in Bulgaria, the prevalence of *cagA* was 84.9% which is more than our results<sup>[26]</sup>. Interestingly, we had 6 isolates which had two different sizes of *cagA* simultaneously, showing the occurrence of mixed infection in these patients.

Variations of *vacA* are associated with different risks of gastrointestinal disorders. In general, *vacA* *s1* and *m1* genotypes produce a large amount of toxin, whereas *s2* and *m2* genotypes show little or no toxin production<sup>[27]</sup>. Recently, a third polymorphic determinant of vacuolating activity has been described as located between the s-region and m-region, an intermediate (i) region<sup>[28]</sup>. The frequency of the *vacA* *s1* and *vacA* *m1* genotypes in the Middle Eastern countries was found to be 71.5% and 32.8%, respectively<sup>[11]</sup>, which is in concordance with our study. We did not detect any *vacA* *s2m1* genotypes in our isolates which

has been reported to be rare<sup>[23]</sup>. The *vacA* *s1* and *m1* genotypes have been reported to be associated with *H. pylori*-related diseases; however *vacA* *s2* and *m2* strains are rarely associated with peptic ulcer and gastric cancer because of their low or non-vacuolating activities<sup>[23]</sup>. Genotyping of *vacA* will be useful in screening individuals for risk factors associated with gastric cancer and peptic ulcer development. Asrat *et al.*<sup>[29]</sup> showed that *vacAs1m1* genotype was the most common genotype in Ethiopian adult dyspeptic patients, and also *vacA*- and *cagA*-positive *H. pylori* strains were detected to a higher degree in patients with chronic active gastritis. Interestingly, similar to our results, correlation of the *vacA* *s1* genotype with the presence of the *cagA* gene was reported by Atherton<sup>[30]</sup>. The *vacAs1m2* genotype is more common in our Iranian patients, as previously described in Iran<sup>[31]</sup>. As reviewed by Suzuki *et al.*<sup>[32]</sup>, the predominant *vacA* genotypes in Asia, Europe and Africa are *vacAs1m1* and their subtypes, which is in contrast to our genotypes in Iranian isolates.

In spite of the low frequency of *vacAs1m1* genotypes in our study, isolates which carried the *vacAs1m1* gene showed significant associations with severe active chronic

gastritis. In a review by Hosseini *et al*<sup>[33]</sup>, they concluded that in contrast to *vacA*, there is no correlation between *cagA* genotype and disease status in the majority of studies conducted in Iran; but results of our study, however, proposed both of these genetic markers as useful indicators for predicting clinical outcomes in the studied population.

The meta-analysis by Shiota *et al*<sup>[8]</sup> confirmed the importance of the presence of *iceA* gene for peptic ulcer, although the significance was controversial. Such different results between the *iceA* allelic types and clinical disorders could be explained by the difference in geographic regions. In our study we found a significant relationship between *iceA*<sub>2</sub> genotype and clinical outcomes (severe active chronic gastritis), which was also observed by Caner *et al*<sup>[34]</sup> in Turkey. As Shiota *et al*<sup>[8]</sup> summarized in their meta-analysis, most of the studies showed no association between *iceA*<sub>1</sub> and *cagA* status, which is in concordance with our study. Interestingly, the prevalence of mixed genotype *iceA*<sub>1</sub> + *iceA*<sub>2</sub> (40.8%) in our study was higher than other studies which had detected this mixed genotype<sup>[35-37]</sup>. So this high prevalence with mixed genotypes makes it difficult to analyze potential relationships between the presence of each *iceA* allelic variant and clinical outcomes. *babA* genotype was frequently found in *H. pylori* strains in our study (95.8%); this was associated with severe active chronic gastritis. Although this genotype showed significant correlation with the existence of *cagA*, no significant correlation was observed with other virulence factors such as *vacA* *s*<sub>1</sub>/*s*<sub>2</sub>, *vacA* *m*<sub>1</sub>/*m*<sub>2</sub> and *iceA*<sub>1</sub>/*iceA*<sub>2</sub>. Chomvarin *et al*<sup>[38]</sup> detected the *babA* gene in 92% (103/112) of Thai patients, which is almost similar to our results; while in another study conducted in Cuba the prevalence of *babA* gene was lower (82.3%)<sup>[39]</sup>. It is important to mention that this PCR based method for *babA* genotyping must be confirmed by immunoblotting. Actually isolates were scored as *babA*-gene positive if the PCR and/or Southern blot analysis yielded a positive result<sup>[9]</sup>.

Regarding the combination of genotypes, we observed twenty different genotypes which showed vast diversities in the *H. pylori* isolates in our study. Interestingly there was not any significant association between these combined genotypes and clinical outcomes, except for *cagA*<sup>+</sup>/*vacA*<sub>1</sub>*m*<sub>1</sub>/*iceA*<sub>2</sub>/*babA*<sup>+</sup> genotype which showed significant association with severe active chronic gastritis.

Genotypes of *H. pylori*, especially *cagA* and *vacA*, are reported to be crucial factors determining the cure rates. So to select an *H. pylori* eradication regimen, we need to consider *H. pylori* genotypes<sup>[10]</sup>. *H. pylori* genotype distributions and their correlations with disease outcomes have shown geographical differences. In this regard, Yamaoka *et al*<sup>[7]</sup> reviewed that within East Asia, where the incidence of gastric cancer is high, that *vacA* *m*<sub>1</sub> genotype is dominant; whereas in southern parts where the gastric cancer incidence is low, the *m*<sub>2</sub> genotype, which we observed in our study, is predominant. Dabiri *et al*<sup>[31]</sup> showed that there was statistically no association between the *vacA*,

*cagA* and *cagE* status and clinical outcomes in Iranian patients, and recommended that other different markers may be more useful for this analysis. In comparison, in the current study, genotyping on the basis of *cagA*, *babA*, *vacA* and *iceA* was considered as a useful tool for predicting the clinical outcomes. Therefore, analyzing the multiple virulence factors of *H. pylori* (*cagA*, *vacA*, *iceA* and *babA*) might enable us to predict the patient's clinical outcome among Iranian patients. This prediction could be more accurate when accompanied by the impacts of environmental factors and host genetic polymorphisms such as interleukin-1 receptor antagonist gene polymorphism<sup>[37]</sup>. Nowadays, concurrent genotyping of *H. pylori* virulence markers and host factors is becoming increasingly crucial in the prediction of the diseases outcomes<sup>[40]</sup>.

In conclusion, our results show that most of the *H. pylori* isolates were highly virulent on the basis of the main clinically allelic variants in three or four virulence factors they carried. The Iranian isolates predominantly possessed different genotypes which showed vast diversities. Significant association of the noted genotypes with severe active chronic gastritis suggests that this genotyping panel is a suitable tool for detection of virulent *H. pylori* isolates that could provide valuable guidance for prediction of the clinical outcomes.

## ACKNOWLEDGMENTS

## COMMENTS

### Background

Infection with *Helicobacter pylori* (*H. pylori*) causes diverse clinical outcomes such as persistent gastritis, peptic ulcers, mucosa associated lymphoid tissue lymphoma and gastric cancer. One of the reasons for these different clinical outcomes is genetic diversity of *H. pylori*; therefore determination of the pattern of *H. pylori* genotypes and its correlation with disease outcome, which shows geographic differences, is crucial.

### Research frontiers

The *H. pylori* genotyping may have multiple roles including prediction of clinical outcomes, impact on the *H. pylori* infection therapy, tracking human migration, and recently, the prediction of progression of gastric preneoplastic lesions. Therefore genotyping of *H. pylori* can be a valuable and multifunctional tool in the clinical field.

### Innovations and breakthroughs

In the majority of previous studies, the researchers were not able to detect any significant relationship between their genotyping panels and clinical outcomes for *H. pylori* infections. Most of these studies had used few genetic markers. In order to overcome this disadvantage, the authors have chosen greater numbers of *H. pylori* genetic markers for studying this association.

### Applications

The genotyping panel which contains eight important genetic markers can serve as a useful tool for typing of *H. pylori* isolates and, to some extent, predict clinical outcomes.

### Peer review

This is an epidemiological paper with statistical analysis, dealing with the important question of association between certain *H. pylori* genotypes and specific

pathologies, and with the problem of predictive value of *H. pylori* infection genotyping. In the submitted manuscript this issue is dissected in fine detail and uses quite extensive clinical material, thus providing novel and more reliable data.

## Polymorphism in the interleukin-17A promoter contributes to gastric cancer

### Abstract

**AIM:** To evaluate the contribution of the *G-197A* polymorphism in the interleukin-17 (IL-17) promoter region to gastric cancer risk in an Iranian population.

**METHODS:** We performed a case control study using samples from 161 individuals with gastric cancer and 171 healthy controls. For each individual, the *G-197A* genotype was determined by restriction fragment length polymorphism analysis of polymerase chain reaction-amplified fragments. Statistical analyses were performed to determine whether any demographic or behavioral factors, infection with *Helicobacter pylori* (*H. pylori*), or a particular *G-197A* genotype was associated with gastric cancer risk.

**RESULTS:** We found that the *G-197A* genotype was

significantly associated with increased gastric cancer risk ( $P = 0.001$ ). Patients who were homozygous (AA) at position -197 were 2.9 times more likely to develop disease (95%CI: 1.56-5.4;  $P = 0.001$ ). Furthermore, logistic regression analysis revealed that the presence of a single A allele increased the risk of gastric cancer up to 1.7-fold (95%CI: 1.26-2.369;  $P = 0.001$ ). This association was observed for early stage gastric adenocarcinomas only, and was not linked to *H. pylori* infection.

**CONCLUSION:** These results suggest that carrying one or more *G-197A* polymorphisms at position -197 in the IL-17 promoter region significantly increases gastric cancer risk in this patient population.

**Key words:** Gastric cancer; Interleukin-17A; Cancer; *Helicobacter pylori*

**Core tip:** There is currently a need for genetic markers to identify individuals at risk for developing gastric cancer. In this study, we describe one such marker, a *G-197A* polymorphism in the interleukin-17A (IL-17A) promoter. Within our study population, individuals who carry the *G-197A* polymorphism in the IL-17A promoter region may be at a significantly greater risk of developing gastric cancer. Importantly, the presence of this polymorphism alone was sufficient to increase risk of gastric cancer development.

## INTRODUCTION

Gastric cancer is one of the most common causes of cancer-related deaths worldwide. Despite an overall decrease in gastric cancer incidence in recent years, this disease is still responsible for over 700000 deaths per year<sup>[1,2]</sup>, and represents a significant medical burden in many countries. In Northern Iran, gastric cancer has a major impact on public health due to the high morbidity and mortality associated with this disease. Indeed, several Iranian provinces, including Manzaradan, Semnan, Golestan, and the greater Tehran area, report age-standardized incidence rates for gastric cancer ranging from 25.4-49.1<sup>[3]</sup>. While these high incidence rates may be partially explained by the fact that a significant proportion of this population is also colonized by the carcinogenic bacterium *Helicobacter pylori* (*H. pylori*)<sup>[3,4]</sup>, the fact that this region maintains a high rate of gastric cancer despite an intensive *H. pylori* eradication program suggests that there are other host genetic and environmental factors involved in gastric cancer development.

Over the last several years, many studies have identified a variety of environmental, behavioral, and host genetic factors that play a role in gastric carcinogenesis across many patient populations. Among these behavioral factors are smoking and a high salt diet<sup>[5-8]</sup>, which have been shown to be particularly important for disease development in Northern Iran<sup>[6]</sup>. However, there is currently a lack of information regarding which host genetic factors may play a role in carcinogenesis in the Iranian patient population. Previous reports have identified a group of host immune factors that, when aberrantly expressed, can influence the development of gastric disease. Among these factors are the interleukin-1 (IL-1), IL-8, IL-10, and tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) genes, where specific polymorphisms have been associated with gastric cancer risk<sup>[9,10]</sup>. Additionally, in some instances, this effect can be compounded when the polymorphism exists in an *H. pylori* colonized individual. It is hypothesized that these polymorphisms result in a pro-inflammatory gastric environment, which may prime the tissue for cancer development.

Another, more recently described, pro-inflammatory cytokine is IL-17A (IL-17). This cytokine is one of a larger group of IL-17 family ligands and is primarily produced from a subset of CD4<sup>+</sup> effector cells known as Th17 cells<sup>[11-13]</sup>. IL-17 is involved in both innate and adaptive immunity and can act on a variety of cell types<sup>[11,12]</sup>. Recently, reports have indicated that certain *IL-17* polymorphisms are associated with autoimmune disease such as rheumatoid arthritis, graft *vs* host disease<sup>[14]</sup>, and inflammatory diseases such as ulcerative colitis<sup>[15]</sup>, suggesting that aberrant expression of this cytokine may polarize the body toward a variety of disease states. In addition, a recent study indicated that *H. pylori*-mediated induction of IL-17 may impact disease progression<sup>[16]</sup>; collectively, these studies highlight the importance of levels of IL-17 in a variety of diseases.

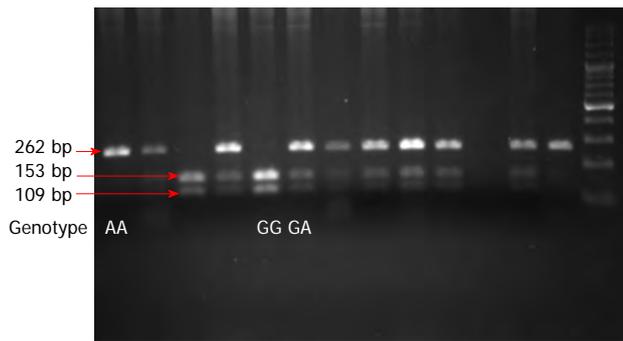

One particular *IL-17* polymorphism (G-197A or rs22759133) has also been associated with certain types of gastric cancer in both Japanese and Chinese populations<sup>[17,18]</sup>. The guanine to adenine substitution at position -197 within the *IL-17* promoter region is located in close proximity to 2 nuclear factors activated T cell binding motifs<sup>[19]</sup>. Because this region was shown to be required for *IL-17* expression<sup>[19]</sup>, it is believed that cells that harbor this mutation produce higher levels of *IL-17*, which in turn upregulates *IL-17*-mediated immune responses. This hypothesis is supported by the fact that various types of tumors express increased levels of *IL-17*<sup>[12]</sup>, and patients with gastric cancer have a greater number of circulating *IL-17*-producing Th17 cells than healthy controls<sup>[20]</sup>. Taken together, these findings highlight the potential role of *IL-17* in gastric cancer development.

Herein, we describe an epidemiologic study in which we investigate the role of the *IL-17* G-197A promoter polymorphism in gastric cancer risk among individuals from Northern Iran, which is traditionally a poorly studied population. We found that within this patient population the *G-197A* polymorphism was significantly more frequent in gastric cancer patients compared with controls. This association was independent of *H. pylori* colonization status. These data indicate that the *IL-17* G-197A polymorphism may be a good indicator for susceptibility to gastric cancer development in this patient population.

## MATERIALS AND METHODS

### Study participants

All aspects of the current study were approved by the Medical Research Ethics Committee at the Mandazaran University of Medical Sciences and conformed to the ethical guidelines set forth in the Declaration of Helsinki. Prior to enrollment, all patients were given an explanation of the nature of the study, and written informed consent was obtained from all individuals. Enrollees from the Mandazaran province of Iran were accepted after seeking treatment at Imam Teaching Hospital or Touba Polyclinic between April 2008 and November 2011. The diagnosis of gastric cancer cases were made based on gastric endoscopy, and cases were defined using the International Classification of Diseases for Oncology IX, Protocol 151 and Lauren criteria<sup>[21]</sup>. In order to simplify TNM staging<sup>[22]</sup>, Stages I A and I B were grouped into "Stage I", and Stages III A and III B were similarly combined into "Stage III". We enrolled a total of 161 patients with gastric cancer (89 male, 72 female), with a mean age of  $62.6 \pm 12.4$  years. One hundred seventy-one healthy controls (84 male and 87 female) were also enrolled, with a mean age of  $60.8 \pm 12.8$  years. Subjects within the control group were matched to the case group with respect to age, sex, ethnic background, and geographic origin. Demographics and behavioral and epidemiological risk factors were self-reported by study participants using a written questionnaire. Cigarette smokers were defined

**Figure 1 Interleukin-17 genotyping.** A representative image of the results of an interleukin-17 (IL-17) genotyping assay is shown. The IL-17 promoters were amplified by polymerase chain reaction and the resulting products were digested with Xag I. Products were then separated by sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE). The *IL-17* GG genotype was evident as 153 and 109 bp fragments, GA as 262, 153 and 109 bp fragments, and AA as a single 262 bp fragment.

as those participants who reported smoking at least one cigarette per day for 12 mo. Consumption of salted fish, pickles, and fast food was defined as eating these items at least once a week for 6 mo.

#### *H. pylori* detection

All patients were tested for *H. pylori* infection using *H. pylori* specific IgG by ELISA (Diagnostic Automation, CA, United States) and by the urea breath test. Individuals that tested positive by either of these methods were considered as positive for *H. pylori*.

#### *IL-17* genotyping

Venous blood collected from all study participants was used to isolate genomic DNA restriction fragment length polymorphism analysis of polymerase chain reaction-amplified fragments (PCR-RFLP) as previously described<sup>[18]</sup>. Briefly, each PCR amplification was performed using 1  $\mu\text{mol/L}$  each of the forward (5'-ACAAGTA-AGAATGAAAAGAGGACATGGT-3') and reverse (5'-CCCCAATGAGGTCATAGAAGAATC-3') primers, 200  $\mu\text{mol/L}$  of each dNTP, 2 mmol/L MgCl<sub>2</sub>, 0.4 U of Hot Start Taq polymerase (Takara), 1X Takara Hot Start Taq PCR buffer, and 100 ng of genomic DNA in a final volume of 25  $\mu\text{L}$ . Each reaction was initially denatured at 95 °C for 4 min, followed by 35 cycles of denaturation at 95 °C for 40 s, primer annealing at 60 °C for 35 s, and extension at 72 °C for 30 s, followed by a final extension at 72 °C for 4 min. Amplified PCR products were subjected to enzymatic digestion with XagI (Fermentas) for 12 h at 60 °C and visualized after separation by 3% sodium dodecyl sulfate polyacrylamide gel electrophoresis and staining with ethidium bromide. This procedure allowed us to clearly differentiate between the homozygous GG, heterozygous GA, and homozygous AA genotypes: the resulting restriction digest products from individuals with a homozygous (GG) genotype were 153 bp and 109 bp; digestion products from individuals who were heterozygous (GA) were 262 bp, 153 bp, and 109

**Table 1 Demographic data of the gastric cancer patients and healthy controls**

	Gastric cancer ( <i>n</i> = 161)	Control ( <i>n</i> = 171)	<i>P</i> -value <sup>1</sup>
Age (yr)	62.56 ± 12.44	60.81 ± 12.76	0.21
Sex (M/F)	89/72	84/87	0.16
Marital status			
Single	8 (5)	3 (1.8)	
Married	149 (92.5)	166 (97.1)	0.002
Divorced	4 (2.5)	2 (1.2)	
Occupation			
Unemployed	4 (2.5)	1 (0.6)	0.003
Employed	24 (14.9)	35 (20.5)	
Housewife	48 (29.8)	75 (43.9)	
Other	85 (52.8)	60 (35.1)	
Education 12 yr	53 (32.9)	85 (49.7)	0.003

<sup>1</sup>Significance of categorical variables was assessed using the  $\chi^2$  test; Differences in age were evaluated using the Student *t*-test. Percentages are shown in parentheses. "Other" is defined as an occupation that does not fall into one of the defined groups.

bp; a single 262 bp product was produced from individuals with a homozygous (AA) genotype (Figure 1).

#### Statistical analysis

After determining that all quantitative data were normally distributed (*via* Kolmogorov-Smirnov test), differences between patient populations were evaluated using the Student *t*-test. Qualitative differences between groups were assessed by the  $\chi^2$  test as indicated. The association between *IL-17* genotype and gastric cancer risk was determined using logistic regression analysis and an odds ratio (OR) with 95%CI. *P*-values  $\leq 0.05$  were considered significant for all tests.

## RESULTS

#### Patient demographics and epidemiology

The demographic data of gastric cancer patients and healthy controls are summarized in Table 1. Ages of study participants across the control group (*n* = 171) ranged from 24 to 87 years, and in the gastric cancer group (*n* = 161) from 28 to 86 years. The age difference between these 2 groups of participants was not statistically significant (*P* = 0.21). Similarly, the distribution of males and females in the study was also not significantly different between the gastric cancer group and the healthy controls (*P* = 0.16,  $\chi^2$  test). We did note a statistically significant difference in the distribution of married individuals in the cancer group and the healthy controls, where individuals in the gastric cancer group were more likely to be single or divorced (*P* = 0.002,  $\chi^2$  test). Similarly, we also noted that individuals within the gastric cancer group were more likely to be unemployed than those in the control group (*P* = 0.003,  $\chi^2$  test). Finally, we also detected a difference in the level of education between patients in the 2 groups; a significantly higher number of the healthy controls had > 12 years of education compared with the gastric cancer patients (*P* = 0.003,  $\chi^2$  test).

**Table 2** Frequency of the distribution of the *G-197A* (rs2275913) polymorphism of the interleukin-17A gene in gastric cancer patients and healthy controls *n* (%)

Genotype	Cancer ( <i>n</i> = 161)	Controls ( <i>n</i> = 171)	OR	CI	<i>P</i> -value <sup>1</sup>
GG	56 (34.8)	78 (45.6)	1.00 <sup>2</sup>		
GA	61 (37.9)	72 (42.1)	1.2	0.73-1.91	0.53
AA	44 (27.3)	21 (12.3)	2.92	1.56-5.4	0.001
G allele	173 (53.7)	228 (66.7)	1.00 <sup>2</sup>		
A allele	149 (46.3)	114 (33.3)	1.72	1.26-2.36	0.001
A allele carriage (AA + GA vs GG)	105 (64.2)	93 (54.4)	1.57	1.01-2.45	0.04

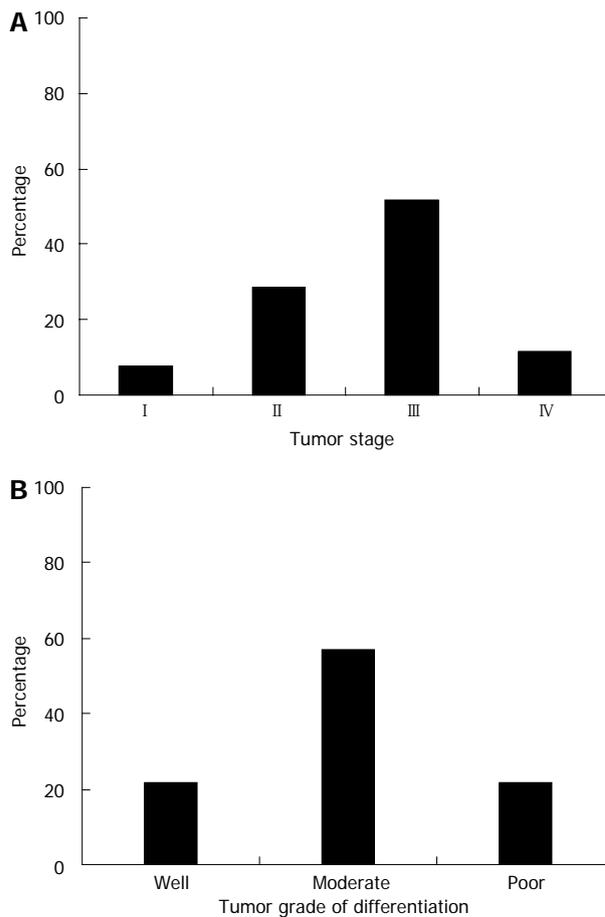

Genotype frequencies are indicated in absolute values, with the percentage in parentheses. G allele and A allele indicates the total number of each individual allele within each group. <sup>1</sup>Two-sided  $\chi^2$ -test; <sup>2</sup>The first allele or genotype is considered as the reference for this analysis. OR: Odds ratio.

**Frequency and distribution of IL-17 genotypes and gastric cancer risk**

We next evaluated the distribution of the IL-17-197 alleles between the 2 study groups essentially as previously described<sup>[17,18]</sup>. The genotype frequencies of this polymorphism in controls were within the Hardy-Weinberg equilibrium (*P* = 0.49). As shown in Table 2, the predominant genotype found in gastric cancer patients was the heterozygous GA allele (38%), followed by the homozygous alleles GG (35%) and AA (27%). In contrast, within the healthy control group, the most common genotype was the wildtype GG allele (45.6%) followed by the heterozygous GA allele (42%) and the homozygous AA allele (12%). While the difference in the distribution of the GG and GA genotypes between the gastric cancer and control groups was not statistically significant, the finding that a larger number of cancer patients carried the AA allele was significant (*P* = 0.001,  $\chi^2$  test). There was also a significant difference in the frequency of the A allele between the 2 groups; this allele was present in 46% of gastric cancer patients compared with only 33% of healthy controls (*P* = 0.001,  $\chi^2$  test). We next performed a multivariate regression analysis to determine the predictive value of the *G-197A* polymorphism for gastric cancer development. After correcting for covariates such as age, sex, and *H. pylori* infection, this analysis indicated that the presence of the A allele increased gastric cancer risk by 1.7-fold (95%CI: 1.26-2.36; *P* = 0.001). The presence of the AA mutant genotype increased the odds of developing gastric cancer up to 2.9-fold (95%CI: 1.56-5.4; *P* = 0.001), indicating that the presence of the AA genotype at this locus is significantly associated with increased gastric cancer risk. Additionally, harboring the allele (AA + GA) enhanced the risk of gastric cancer up to 1.6-fold (95%CI: 1.01-2.45; *P* = 0.04).

**Effect of G-197A polymorphism and cancer progression**

In order to determine whether the presence of the -197A allele was associated with disease progression within the gastric cancer group, we stratified a subset of the patients from this group based on TNM staging, extent of tumor

**Figure 2** Tumor, node, metastasis staging, and cellular differentiation in the gastric cancer population. A: Breakdown of tumor staging among a subset of the gastric cancer population. Staging was categorized as described in the Materials and Methods section. For simplicity, individuals that were categorized as Stage I A or I B were grouped into Stage I. Similarly, patients with Stage III A or III B tumors were grouped into Stage III; B: The degree of cellular differentiation seen in patient tumors was graded as well, moderate, or poor as described in the Materials and Methods.

cell differentiation, and the presence or absence of the mutant A allele (AA + GA vs GG); TNM information for 77 of the 161 patients enrolled in the gastric cancer group was available. A breakdown on tumor staging and degree of cellular differentiation are shown in Figure 2A and B, respectively. We placed individuals with lower grade malignancies (Stage I or II) in one group (*n* = 28), and those with Stage III or IV malignancies into a second group (*n* = 49) (Table 3). Within the group with Stage I or II malignancies, 22 patients had at least one A allele (GA or AA genotype), while only 6 patients had the GG genotype. This difference in Stage I / II patients was statistically significant (*P* = 0.001,  $\chi^2$  test). Furthermore, the presence of the 197A allele increased the risk of gastric cancer development at the early stages of tumorigenesis by 6.3-fold (95%CI: 2.2-18.56; *P* = 0.001). In contrast, this association was not observed in patients with Stage III/Stage IV malignancies or when we grouped the cancer patients by age, sex, *H. pylori* status, or tumor cell differentiation (Table 3). These data suggest

**Table 3** Effect of *G-197A* polymorphism on gastric cancer development *n* (%)

	GA + AA	GG	OR	95%CI	P-value <sup>2</sup>
Age					
< 50 yr	18 (17.1)	4 (7.1)	2.7	0.8-8.4	0.09
≥ 50 yr	87 (82.9)	52 (92.9)			
Gender					
Male	51 (48.6)	21 (37.5)	1.6	0.8-3.05	0.19
Female	54 (51.4)	35 (62.5)			
<i>H. pylori</i> +	65 (61.9)	33 (58.9)	0.88	0.45-1.71	0.74
<i>H. pylori</i> -	40 (38.1)	23 (41.1)			
TNM stage <sup>1</sup>					
I - II	22 (55)	6 (16.2)	6.3	2.2-18.5	0.001
III-IV	18 (45)	31 (83.8)			
Tumor differentiation					
Well	25 (23.8)	9 (16.1)	1.00 <sup>3</sup>		
Moderate	57 (54.3)	35 (62.5)	0.56	0.24-1.34	0.19
Poor	23 (21.9)	12 (21.4)	0.66	0.23-1.86	0.43

<sup>1</sup>Data presented for 77 patients; <sup>2</sup>All comparisons between categorical variables were made using a two-sided  $\chi^2$  test; <sup>3</sup>Used as reference for tumor differentiation analyses. Values in parentheses indicate the percentage. *H. pylori*: *Helicobacter pylori*; TNM: Tumor, node, metastasis.

that while the presence of a mutant A allele at this locus increased the risk of developing a low grade (Stage I or II) malignancy, it was not a risk factor for progression to later stage cancer (Stage III or IV).

## DISCUSSION

Gastric cancer remains a significant source of morbidity and mortality worldwide. As such, being able to identify which patients or patient populations are most at risk for developing this severe disease is of the utmost importance. This fact is particularly true for geographical regions such as Iran that have exceptionally high disease rates<sup>[23]</sup>. Indeed, despite the alarmingly high rates of gastric cancer in this region, few studies have focused on the identification of host factors or mutations in these factors that may predispose members of this population to gastric cancer development. Once identified, these factors or mutations could then be exploited to aid in the diagnosis of high-risk patients.

Numerous studies have attempted to unravel the complex nature of gastric cancer development. From these studies it has become clear that carcinogenesis is a multi-factorial process that involves a combination of environmental/behavioral, and genetic factors. For many populations/geographic areas, including the focus of the current study, major environmental/behavioral risk factors for gastric cancer development have been identified<sup>[2,5-8]</sup>. Additionally, there have been many studies that have identified potential genetic markers or polymorphisms that are associated with gastric cancer risk. Several of these factors play a role in maintaining proper immune homeostasis, including the pro-inflammatory cytokines IL-1 $\beta$ , inducible nitric oxide synthase, TNF- $\alpha$ , IL-8, IL-10<sup>[9,10,24]</sup>, and more recently IL-17<sup>[17,18]</sup>. However, since many of these factors have only been studied in

limited patient populations, it remains unclear whether or not the prognostic value of these markers applies equally to all groups. In fact, as more studies are performed across a variety of patient populations, it has become evident that the degree to which these factors impact on disease development is often dependent upon the group being studied<sup>[19,25-28]</sup>. As a result, there is a need to examine the role of these factors in additional populations.

Here, we described a case-control study that examined the association of the *G-197A* IL-17 promoter mutation with gastric cancer development in an Iranian population. This particular polymorphism has been previously associated with an increased risk of gastric mucosal atrophy and gastric cancer in a Japanese population<sup>[17]</sup>, as well as gastric cancer risk in a Chinese population<sup>[18]</sup>. In accordance with those studies, we found that the *G-197A* polymorphism is significantly associated with an increase in gastric cancer risk (Table 2). Specifically, harboring 2 copies of the mutant allele (AA) at this locus increased a patient's likelihood of developing cancer by a factor of 2.8 (Table 2). Furthermore, harboring only a single copy of this polymorphism (a heterozygous GA genotype) increased gastric cancer risk by 1.5 fold; this finding suggests that the effect of this polymorphism follows a dose-response. These data are consistent with the previous finding that the effect of the *G-197A* polymorphism on inflammation follows a similar dose-response pattern<sup>[17]</sup>.

In healthy individuals, IL-17 is involved in both innate and adaptive arms of the immune system. Specifically, IL-17 is involved in induction of other pro-inflammatory cytokines as well as the recruitment and activation of inflammatory cells such as neutrophils and macrophages<sup>[11,29]</sup>. As the receptor for this cytokine is widely distributed on intestinal epithelial cells<sup>[12]</sup> and other tissue types<sup>[29]</sup>, changes in the levels of IL-17 expression may have far reaching effects. This fact is illustrated by several studies, which have implicated increased IL-17 production with a variety of pathologic processes. Indeed, increased IL-17 transcript levels have been detected in patients with coronary artery disease<sup>[30]</sup>, and inflammatory bowel disease<sup>[31]</sup>, and specific *IL-17* polymorphisms have been associated with ulcerative colitis<sup>[15]</sup>, rheumatoid arthritis<sup>[32]</sup>, and graft *vs* host disease<sup>[14]</sup>. While these conditions may present quite differently from gastric cancer, the underlying commonality among these diseases is their inflammatory origin.

While the precise mechanistic role of the *G-197A* polymorphisms in gastric cancer development remains unclear, a plausible hypothesis is that increased/constitutive expression of IL-17 may skew the gastric environment to become pro-inflammatory. As chronic inflammation is a known precursor for gastric cancer development<sup>[33]</sup>, this IL-17-mediated inflammatory environment may result in an increase in carcinogenic cellular damage, which predisposes an individual to develop disease. Once these initial steps have begun, the cancer may progress in an IL-17 dependent or independent manner. In the current study, we found that the -197A allele was

only significantly associated with the development of lower grade malignancies (Stage I or II) (Table 3). Similarly, a previous study linked the -197A polymorphism to an increased risk of poorly differentiated TNM Stage I / II cancer<sup>[18]</sup>. These data perhaps suggest that progression to more severe disease (Stages III or IV) occurs at least partially in an IL-17-independent manner. However, as 18 of the 49 TNM Stage III or IV cancer patients (Table 3) carried at least one mutant allele, we cannot completely rule out the possibility that this *IL-17* polymorphism impacts on disease progression to some extent.

Gastric cancer remains a global health problem. As diagnosis of this disease often occurs only after the progression to more severe stages, there is a serious need for diagnostic markers that could help preemptively screen patients in high-risk populations and identify those who are most at risk of developing disease. Because the *G-197A* polymorphism in the *IL-17* promoter region is consistently linked to gastric cancer development in multiple populations, it may be a good global candidate marker to identify gastric cancer risk.

## COMMENTS

### Background

Individuals who carry specific genetic polymorphisms can be prone to cancer development. As a result, these polymorphisms may be used to identify these at risk individuals. However, before a particular polymorphism can be reliably used as a marker for cancer risk, the link between the polymorphism and disease propensity must be verified in a multiple populations of people with diverse genetic backgrounds.

### Research frontiers

Interleukin-17 (IL-17) is an important pro-inflammatory cytokine that is involved in both the innate and adaptive arms of the human immune system. One of the research hotspots in the field of IL-17 research is determining how increased or decreased levels of this cytokine effect human physiology and disease development.

### Innovations and breakthroughs

Previous studies have identified the *G-197A IL-17* polymorphism as a potential genetic marker for gastric cancer risk. However, those studies were performed on a limited population that had a similar genetic background. The current study verified the *G-197A* polymorphism as a potential genetic marker for gastric cancer risk in a genetically distinct population. Their results reinforce the possibility of using this *IL-17* polymorphism as a marker for disease risk in many diverse populations.

### Applications

The study highlights the possibility that the *IL-17 G-197A* polymorphism could be used as a marker for gastric cancer risk across diverse populations.

### Terminology

A polymorphism is where multiple forms of a DNA sequence may be present at a single genetic site.

### Peer review

The manuscript is quite well written. The results justify the conclusions drawn.

non-obstructed lobe, there were no significant differences within each group. The duration of PV occlusion did not seem to be strong enough to introduce liver weight increase. Stimulation of liver regeneration was brought about in the non-occluded lobe by 12-h occlusion, and was sustained even at 48 h after reperfusion. The obstructed lobe atrophied with the passage of time in the obstructed state. However, the proliferating-cell nuclear antigen labeling index also increased at 48 h after reperfusion, and a repair mechanism was observed.

**CONCLUSION:** Temporary blood flow obstruction of the portal vein may become a significant trigger for liver regeneration, even with an obstruction of 12 h.

### Abstract

**AIM:** To investigate time-dependent changes caused by temporal portal vein obstruction and subsequent reperfusion in the lobe with or without an occluded portal vein.

**METHODS:** The portal vein (PV) of the anterior lobe of the liver of a male Wistar rat (8 wk-old) was obstructed (70%) for 12, 24, 36 and 48 h, respectively, and models were sacrificed at 48 h after reperfusion (each group:  $n = 10$ ). The histological changes and the status of liver regeneration were compared between a liver biopsy performed on each lobe after temporary obstruction of the portal vein in the same rat liver, and the liver extracted at the time of sacrifice (48 h after reperfusion).

**RESULTS:** With regard to the obstructed lobe, the liver weight/body weight ratio significantly decreased according to obstruction time. On the other hand, in the

**Core tip:** This paper describes the chronological effects of temporary portal venous branch ligation on liver regeneration in rats. These results imply that, in the future, it might be possible to control liver regeneration. In the clinical setting, we have just completely occluded the portal venous branch irreversibly.

Chronological changes in the liver after temporary partial portal venous occlusion. *World J Gastroenterol* 2013; 19(34): 5700-5705 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i34/5700.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i34.5700>

### INTRODUCTION

Permanent obstruction of the portal vein, as clinically

applied in portal branch ligation (PBL) or percutaneous transhepatic portal venous embolization, evokes liver regeneration<sup>[1-4]</sup>. This technique enables relatively major hepatic resection for malignancy in an occluded liver lobe<sup>[5-9]</sup>. In addition, PBL has been used to induce a regenerative stimulus for transplanted hepatocytes or pancreatic islet cells for cell therapy<sup>[10,11]</sup>.

Although short term temporary occlusion can induce some degree of liver regeneration, an investigation of liver regeneration caused by temporary portal vein obstruction, as well as time-dependent changes resulting from reperfusion, has not yet been performed<sup>[12]</sup>. Therefore, the current study aimed to examine time-dependent changes in a lobe with a portal vein occlusion of an unobstructed portal vein caused by temporary portal vein obstruction and reperfusion as the central focus.

## MATERIALS AND METHODS

### Animals

Male Wistar rats (200-240 g, Japan SLC Inc., Shizuoka, Japan) were used for the experiments. All animals were maintained at 24 °C with a 12-h light-dark cycle and given free access to tap water and standard laboratory chow. The animals were treated in accordance with the guidelines stated in the University of Nagasaki Research Animal Resources during all experimental procedures.

### Experimental design

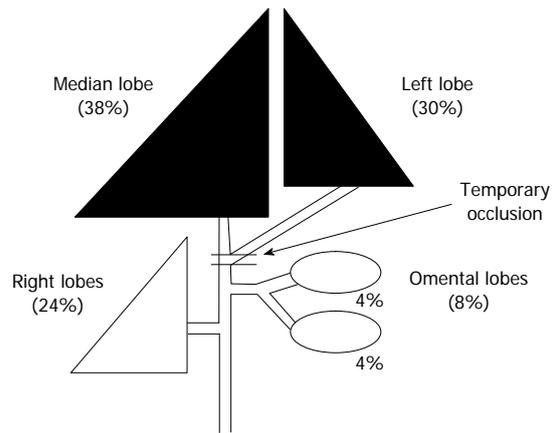

The portal vein of the anterior lobe (medial and left lobes) of the liver of a male Wistar rat (8 wk old) was occluded (70%) for 12, 24, 36 and 48 h, respectively (Figure 1). Rats to be sacrificed were prepared at 48 h after each reperfusion (models for each group:  $n = 10$ , Figure 2). The histological changes over time and the status of liver regeneration were compared between liver biopsies performed from each lobe after temporary obstruction of the portal vein in the same rat liver, and the liver extracted at the time of sacrifice (48 h after reperfusion).

### Liver to body weight ratio

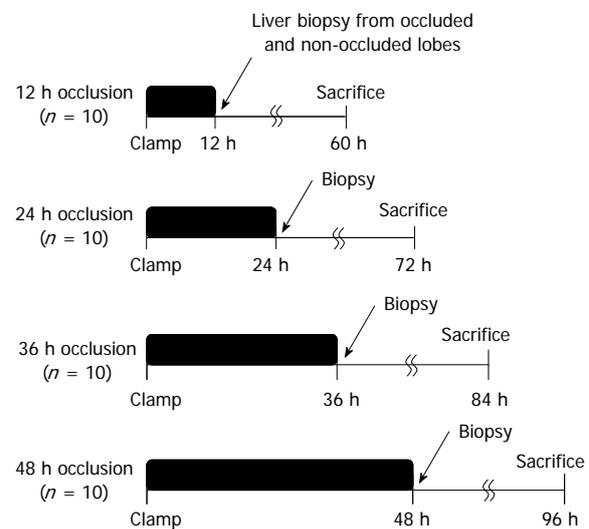

The body weights and liver weights were recorded following the sacrifice of the rats to compare the rate of liver regeneration. The liver weight was expressed as a percentage of the body weight (%) and used as an index.

### Histology and immunohistochemistry

Formalin-fixed paraffin embedded (4  $\mu\text{m}$ ) sections were used for hematoxylin-eosin (HE) staining. Proliferating-cell nuclear antigen (PCNA) immunostaining was performed to examine hepatocyte proliferation using a mouse monoclonal antibody against PCNA (clone-PC 10; Dako, Kyoto, Japan)<sup>[13]</sup>. Briefly, liver tissue specimens were fixed in 10% buffered formalin, embedded in paraffin and then cut into 5  $\mu\text{m}$  sections. The deparaffinized sections were heated in a microwave three times in phosphate-buffered saline (PBS) for 5 min each and were then washed three times with PBS for 5 min each. After blocking endogenous peroxidase activity, the specimens

**Figure 1** Schematic drawing of the rat model. The portal vein of the anterior lobe (black area) of the liver was occluded (68%) for various durations, while the arteries remained open.

**Figure 2** Experimental protocol. The portal vein of the anterior lobe (median and left liver lobes) of the liver of a male Wistar rat was occluded (70%) for 12, 24, 36 and 48 h. Rats to be sacrificed were prepared at 48 h after each reperfusion (models for each group:  $n = 10$ ).

were washed three times with PBS for 5 min each. The sections were incubated with an antibody against PCNA overnight at 4 °C. After washing several times with PBS, biotin-labeled secondary antibody was added for 1 h at room temperature. After washing several times with PBS, the tissue peroxidase activity was visualized using diaminobenzidine.

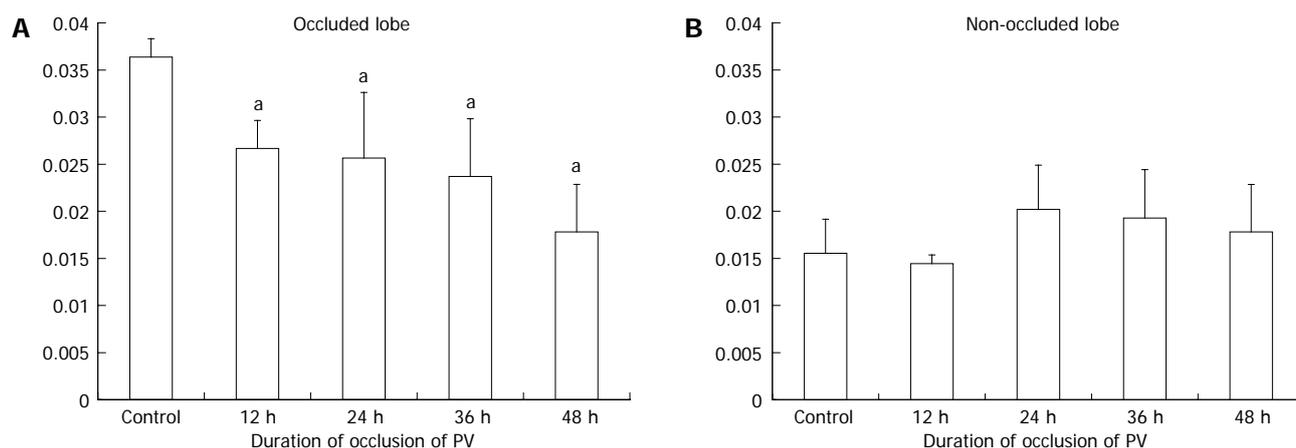

The PCNA labeling index (PCNA LI) was then determined as the number of PCNA-positive cells among 1000 counted cells.

### Statistical analysis

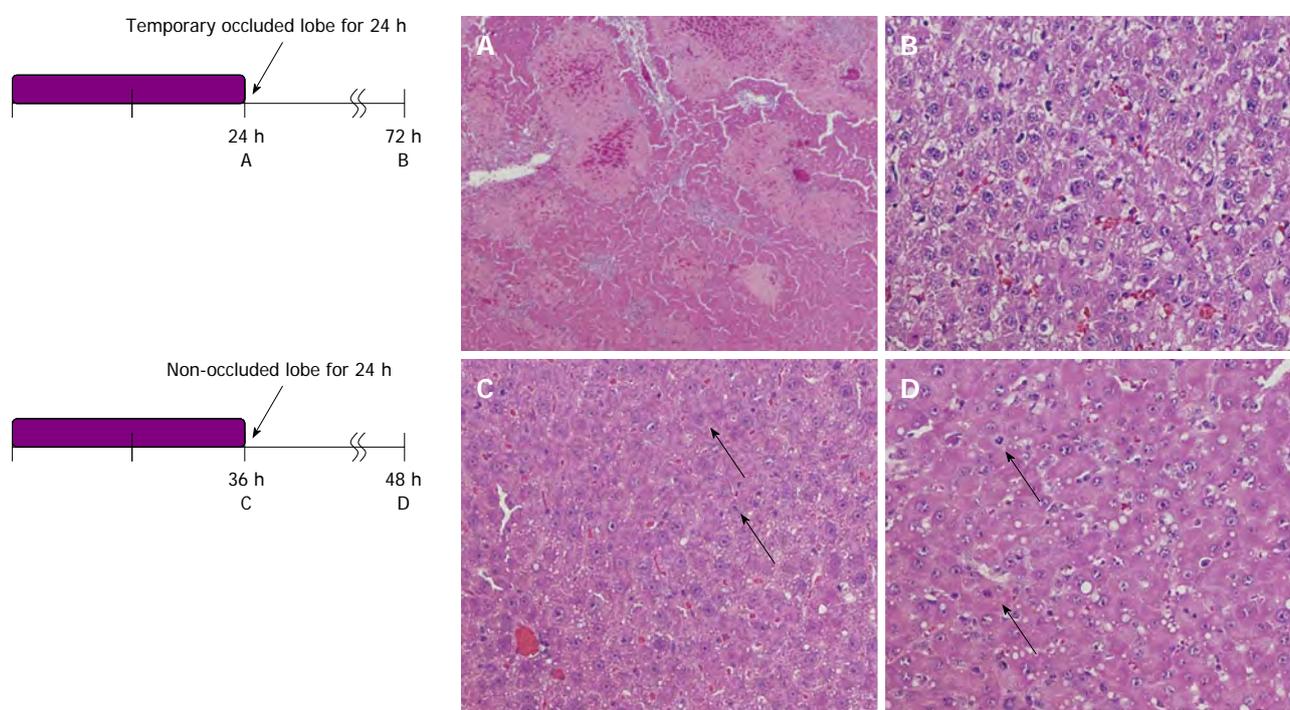

All of the data were expressed as the mean  $\pm$  SD. The Mann-Whitney *U*-test was used for data analysis. A level of  $P < 0.05$  was considered statistically significant.

## RESULTS

With regard to the obstructed lobe, the liver weight/body

**Figure 3 Liver weight/body weight.** A: The liver weight/body weight ratio was decreased by temporary occlusion of the occluded anterior lobes; B: There were no significant differences within each group in non-occluded lobe. <sup>a</sup> $P < 0.05$  vs control group.

**Figure 4 Changes in hepatic histology.** Histology in temporary occluded lobes. A: 24 h occlusion,  $\times 100$ ; B: 36 h occlusion,  $\times 400$ ; C: In non-occluded lobes 24 h occlusion,  $\times 100$ ; D: 48 h occlusion,  $\times 400$  is shown by HE staining. In the occluded liver lobe, before reperfusion, coagulative necrosis may be observed around the central vein in proportion to the occlusion time. However, the above-mentioned necrotic area decreased at 48 h after portal vein reperfusion. In the non-occluded liver lobe, hepatocytes became hypertrophic, and some mitoses could be observed (arrows).

weight ratio significantly decreased with increasing obstruction time (Figure 3). On the other hand, in the non-obstructed lobe, there were no significant differences within each group. The duration of PV occlusion did not seem to be strong enough to induce an increased in liver weight.

Liver histology was investigated under HE staining (Figure 4). In the occluded liver lobe, before reperfusion, coagulative necrosis was observed around the central vein in proportion to the occlusion time. However, after 48 h of reperfusion, the above-mentioned necrotic area

decreased. On the other hand, in the non-occluded liver lobe, hepatocytes became hypertrophic, and some mitoses were observed.

In the non-obstructed lobe, there were no significant differences in the PCNA LI within each group (Figure 5). LI seemed to peak at 36 h of biopsy (non-obstructed models at 12, 24, 36 and 48 h = 24%, 32%, 36% and 31%, Figure 5C). In the non-occluded lobe at 48 h after reperfusion (models for each group = 33%, 32%, 36% and 32%), the PCNA LI was still significantly increased at all points compared with the control (Figure 5D).

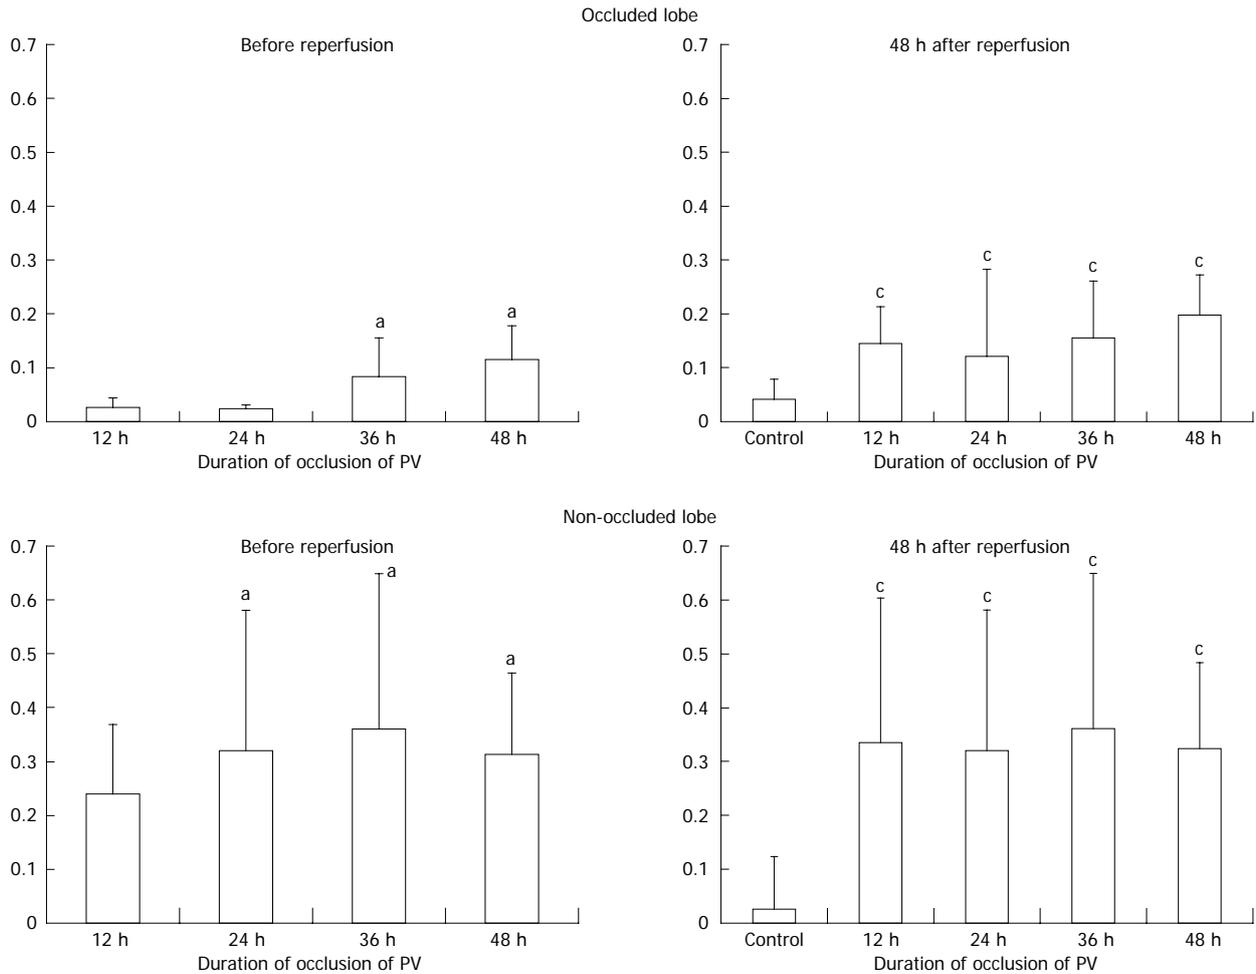

Figure 5 Proliferating-cell nuclear antigen labeling index. Proliferating-cell nuclear antigen (PCNA) labeling index in each lobe at the time before reperfusion and 48 h after reperfusion. <sup>a</sup>*P* < 0.05 vs 12 h group; <sup>c</sup>*P* < 0.05 vs 24 h group. PV: Portal vein.

On the other hand, hardly any positive cells were observed in a biopsy of the obstructed lobe (obstructed models at 12, 24, 36 and 48 h = 2%, 2%, 8% and 10%). However, at 48 h after reperfusion, an increase in LI was observed (models for each group = 14%, 12%, 15% and 19%).

## DISCUSSION

Portal venous branch ligation or embolization (PBL or PBE) can induce atrophy of the ligated lobe, while inducing hypertrophy of a non-ligated lobe, which enables extended hepatectomy for a malignant tumor in a ligated lobe<sup>[14-16]</sup>. In addition, PBL has been used as a regenerative stimulator to induce transplanted cell proliferation in animal models for hepatocyte-based cell therapy<sup>[17-23]</sup>. The length of time of occlusion needed to induce remnant liver regeneration, *i.e.*, temporary portal venous occlusion, remains unknown. In the present study, the stimulation of liver regeneration brought about in the non-occluded liver lobe was sustained, even after 48 h from reperfusion. Thus, temporary blood flow obstruction of the portal vein may be a significant trigger of liver regeneration, with an obstruction of at least 12 h. However, the

duration of PV occlusion in this study did not seem to be long enough to induce an increase in liver weight.

Interestingly, there was no significant difference in PCNA LI in the non-occluded lobe according to the duration of portal vein occlusion up to 48 h. Therefore, in the clinical setting, the same extent of liver hypertrophy may be induced with temporary balloon occlusion in as short as 12 h, to minimize an invasive procedure, although there might be difference among species.

As a cell therapy, many investigator have used liver for the engraftment of many cell types<sup>[10-12,14-16]</sup>. In fact, transplanted cells (hepatocytes, pancreatic islet cells or genetically engineered cells) could be induced to proliferate using temporary portal venous occlusion. Although there must be some differences between humans and rodents in terms of liver regenerative activity, our results provide a new insight into temporary stimulation of liver regeneration for subsequent treatment procedures<sup>[24-26]</sup>.

On the other hand, the PCNA labeling index of the obstructed lobe was also increased 48 h after portal venous reperfusion. This could be a repair mechanism for portal vein ischemia in the occluded lobe, although PCNA LI was lower compared to that in the non-occluded lobe that undergoes liver regeneration<sup>[14]</sup>. Although it

was not observed up to 48 h, this result of the temporary occlusion of the lobe provided an interesting phenomena; however, the lack of temporal portal venous flow could become atrophic if portal venous ischemia had lasted longer. The duration for the “point of no return” should be investigated in further research.

In conclusion, a temporary blood flow obstruction of the portal vein may be a significant trigger for liver regeneration, even with an obstruction of 12 h. The histological changes in the unobstructed lobe and obstructed lobe in cases of temporary blood flow obstruction of the portal vein and at 48 h after reperfusion were described.

## COMMENTS

### Background

Permanent obstruction of the portal vein, as clinically applied in portal branch ligation (PBL) or percutaneous transhepatic portal venous embolization, evokes liver regeneration. This technique enables relatively major hepatic resection for malignancy in an occluded liver lobe. In addition, PBL has been used to induce a regenerative stimulus for transplanted hepatocytes or pancreatic islet cells for cell therapy.

### Research frontiers

Portal venous branch ligation or embolization can induce atrophy of the ligated lobe, while inducing hypertrophy of a non-ligated lobe, which enables extended hepatectomy for a malignant tumor in a ligated lobe. In addition, PBL has been used as a regenerative stimulator to induce transplanted cell proliferation in animal models of hepatocyte based cell therapy. The length of time of occlusion required to induce remnant liver regeneration, *i.e.*, temporary portal venous occlusion, remains unknown.

### Innovations and breakthroughs

The histological changes and the status of liver regeneration were compared between a liver biopsy performed on each lobe after temporary obstruction of the portal vein in the same rat liver, and the liver extracted at the time of sacrifice (48 h after reperfusion).

### Peer review

This research is very important because it shows that a temporary obstruction of the portal vein as a trigger of liver regeneration. Recently, it has been used as a regenerative stimulator to induce transplanted cell proliferation. Thus, the manuscript approached an interesting subject from the surgical and scientific points of view; however, several aspects should be better evaluated.

### Abstract

**AIM:** To prospectively compare the healing rates of endoscopic submucosal dissection (ESD)-induced ulcers treated with either a proton-pump inhibitor (PPI) or rebamipide.

**METHODS:** We examined 90 patients with early gastric cancer who had undergone ESD. All patients were administered an intravenous infusion of the PPI lansoprazole (20 mg) every 12 h for 2 d, followed by oral administration of lansoprazole (30 mg/d, 5 d). After 7-d treatment, the patients were randomly assigned to 2 groups and received either lansoprazole (30 mg/d orally,  $n = 45$ ; PPI group) or rebamipide (300 mg orally, three times a day;  $n = 45$ ; rebamipide group). At 4 and 8 wk after ESD, the ulcer outcomes in the 2 groups were compared.

**RESULTS:** No significant differences were noted in patient age, underlying disease, tumor location, *Helicobacter pylori* infection rate, or ESD-induced ulcer

size between the 2 groups. At both 4 and 8 wk, the healing rates of ESD-induced ulcers were similar in the PPI-treated and the rebamipide-treated patients (4 wk: PPI, 27.2%; rebamipide, 33.3%;  $P = 0.5341$ ; 8 wk: PPI, 90.9%; rebamipide, 93.3%;  $P = 0.6710$ ). At 8 wk, the rates of granulation lesions following ulcer healing were significantly higher in the PPI-treated group (13.6%) than in the rebamipide-treated group (0.0%;  $P = 0.0103$ ). Ulcer-related symptoms were similar in the 2 treatment groups at 8 wk. The medication cost of 8-wk treatment with the PPI was 10945 yen *vs* 4889 yen for rebamipide. No ulcer bleeding or complications due to the drugs were observed in either treatment group.

**CONCLUSION:** The healing rate of ESD-induced ulcers was similar with rebamipide or PPI treatment; however, rebamipide treatment is more cost-effective and prevents granulation lesions following ulcer healing.

**Key words:** Early gastric cancer; Rebamipide; Endoscopic submucosal dissection; Gastric ulcer; Proton-pump inhibitor

**Core tip:** In this prospective randomized, parallel-controlled study, we demonstrated that rebamipide monotherapy was as effective as proton-pump inhibitor (PPI) in the healing of endoscopic submucosal dissection-induced ulcers, regardless of the location of the resected cancer, the degree of atrophic gastritis, or the presence of *Helicobacter pylori* infection. In addition, rebamipide treatment is more cost-effective and results in a better quality of ulcer healing compared with the PPI lansoprazole.

## INTRODUCTION

Endoscopic mucosal resection (EMR) is a well-established curative treatment for gastric neoplasms, such as early gastric cancer confined to the mucosa. However, EMR, performed using conventional techniques such as strip biopsy or cap EMR, does not always achieve *en bloc* resection. Thus, endoscopic submucosal dissection (ESD) has become the preferred treatment method. Compared with EMR, ESD facilitates the collection of larger specimens, regardless of lesion size or location, resulting in a higher rate of *en bloc* and histologically complete resection. Moreover, the rate of local recurrence of tumors after ESD may be lower than that after conventional EMR<sup>[1]</sup>. However, the iatrogenic ulcer that develops as a result of ESD is large, and requires a considerably longer healing time compared to that resulting from conventional EMR.

Proton-pump inhibitors (PPIs) are the most effective medications for the treatment of ESD-induced ulcers. However, studies have shown that PPI monotherapy does not heal the ESD-induced ulcers sufficiently within 4 wk<sup>[2-6]</sup>. Increased understanding of the mucosal defense system has prompted the development of mucoprotective agents for clinical use in Japan. The efficacy of combination treatment involving PPIs and the mucoprotective agent rebamipide in the early treatment of ESD-induced ulcers and in the prevention of relapse of such disorders has been clearly indicated<sup>[2-5]</sup>.

Rebamipide [2-(4-chlorobenzoylamino)-3-[2-(1H)-quinolinon-4-yl]-propionic acid], a novel mucosal-protective and ulcer-healing drug, is widely prescribed in East Asia. Previous studies have indicated that rebamipide is effective in the treatment of gastric ulcers as well as decreasing the recurrence rate, without affecting the *Helicobacter pylori* infection status of the patients<sup>[7-12]</sup>. In addition, previous randomized-controlled studies have also found that rebamipide can prevent the formation of peptic ulcers induced by the administration of nonsteroidal anti-inflammatory drugs (NSAIDs) and can suppress the mucosal inflammation associated with chronic erosive gastritis<sup>[13,14]</sup>. However, to our knowledge, no reports on the use of rebamipide for the treatment of ESD-induced ulcers have been published.

In the present study, we have prospectively evaluated the efficacy of rebamipide monotherapy in comparison to PPI monotherapy for the treatment of iatrogenic ulcers resulting from ESD for early gastric cancers.

## MATERIALS AND METHODS

### Patients

We examined 90 consecutive patients with early gastric cancer who had been treated with ESD at Kinki University Hospital between February 2011 and January 2013.

The study protocol was approved by the Kinki University Ethics Committee, and all participants provided written informed consent before undergoing ESD. In addition, the study was registered at the University Hospital Medical Information Network 000005134. All patients with early gastric cancer, including well-differentiated or moderately differentiated adenocarcinoma, were included in the study. The exclusion criteria were as follows: (1) current use of other anti-ulcer drugs, aspirin, NSAIDs, or prednisolone; (2) treatment with anti-coagulative agents; or (3) previous endoscopic treatment or surgery.

### ESD procedure

ESD was performed with an insulation-tipped knife (KD-610L; Olympus Medical Systems, Tokyo, Japan) and a flush knife (BTDK2618JB; Fujifilm Medical System, Tokyo, Japan). The electrosurgical unit used was A VIO-300D (ERBE). The injection solutions contained glycerin with 1% indigo carmine dye and, depending on the tumor location, hyaluronic acid sodium (0.4%) was also added. The ulcers that developed after ESD were carefully examined endoscopically, and any visible vessels were heat-coagulated by using hot biopsy forceps (KD-410LR; Olympus Medical Systems). Thereafter, the resected specimens were stretched, pinned flat on a rubber plate, and measured.

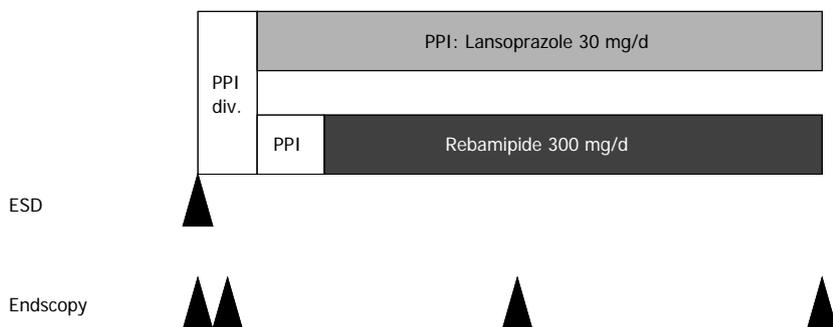

### Study design

The design of this single-center, open-label, prospective, randomized, parallel-controlled study is illustrated in Figure 1.

After ESD, all patients were administered an intravenous infusion of lansoprazole (20 mg; Takepron; Takeda Pharmaceutical, Osaka, Japan) every 12 h for 2 d, and received oral lansoprazole (30 mg/d) for 5 d. On post-operative day 7, the patients were randomly assigned to 2 groups and received either lansoprazole at a dose of 30 mg/d orally (PPI group;  $n = 45$ ), or rebamipide (Mucosta; Otsuka Pharmaceutical Co., Tokyo, Japan) at a dose of 300 mg orally, 3 times a day ( $n = 45$ ) for 8 wk. The primary endpoint was endoscopically documented ulcer healing; complete healing was defined as regression to the S-stage on the Sakita and Miwa scale<sup>[23]</sup>. Moreover, we evaluated the healing rates of atrophic gastritis based on the Kimura and Takemoto classification<sup>[24]</sup>, in the presence or absence of *Helicobacter pylori* (*H. pylori*) infection. We also compared the response of ulcers in relation to their locations in the stomach (lower, middle, or upper).

The secondary endpoint was the ulcer reduction ratio, which was compared according to the ulcer location. For calculation of the ratio, we determined the maximum diameters of the ulcers and the diameters perpendicular to the maximum diameters, which were measured using a bendable endoscopic measuring device (M2-3; Olympus Corp., Tokyo, Japan). Moreover, we determined the ulcer size (maximal diameter  $\times$  diameter perpendicular to the maximal diameter). At 4 and 8 wk after ESD, the healing and reduction rates for the ulcers were compared between the 2 groups. In addition, at 8 wk after ESD, we

were compared using Pearson’s  $\chi^2$  test or Student’s *t*-test. Pearson’s  $\chi^2$  test was also used to compare the healing rates of the ESD-induced ulcers and for the evaluation of the scar status of the ESD-induced ulcers according to the QOUH. Statistical significance was defined as  $P < 0.05$ .

**RESULTS**

Table 1 shows the patient characteristics of the 2 treatment groups. No significant differences were noted between the groups with regard to age; gender; tumor location; tumor size; histologic classification; ESD-induced ulcer size; glandular atrophy; history of disease; and the rates of *H. pylori* infection, smoking, drinking alcohol, or the presence of complicated disease or intestinal metaplasia. One patient was excluded from the PPI group because histologic examination of the resected specimen

**Figure 3** Rates of healing in both groups. A: The rates of healing to S stage in both groups; B: The rates of healing to S stage in both groups according to resected location. L: Low stomach, M: Middle stomach; U: Upper stomach. C: The rates of healing to S stage in both groups. <sup>1</sup>*Helicobacter pylori* (*H. pylori*) positive <sup>2</sup>*H. pylori* negative. D: The rates of healing to S stage in both groups in atrophic gastritis. <sup>3</sup>Closed type; <sup>4</sup>Open type. RM: Rebamipide.

indicated deep submucosal invasion (depth ≥ 500 μm; SM2 invasion). Hence, 44 patients in the PPI group and 45 in the rebamipide group constituted the final study cohort (Figure 2).

**Ulcer responses**

The rates of ulcer healing (regression to S-stage) were not significantly different between the PPI group (27.2%) and the rebamipide group (33.3%) at 4 wk ( $P = 0.5341$ ) or at 8 wk (90.9% for the PPI group and 93.3% for the rebamipide group;  $P = 0.6710$ ) (Figure 3A). Moreover, at 4 and 8 wk, the healing rates were not significantly different between the treatment groups with regard to ulcer location (low, middle, or upper stomach; Figure 3B) or with regard to the presence of absence of *H. pylori* infection (Figure 3C). In addition, at 4 and 8 wk, the healing rates of atrophic gastritis (closed or open type) were similar in the 2 treatment groups (Figure 3D).

**Reduction ratios of ESD-induced ulcers**

The reduction ratios of ESD-induced ulcers were similar at 4 and 8 wk in the rebamipide group (98.0% and 99.9%,

respectively) and in the PPI group (97.2% and 99.9%, respectively) (Figure 4). These ratios were not influenced by the locations of the ulcers in the stomach (low, middle, and upper).

**Quality of ulcer healing and adverse events**

Six patients in the PPI group developed unusual gastric lesions, which comprised an overgrowth of granulation tissue at the ulcer site. At 8 wk, the proportion of patients who developed a flat scar in the rebamipide group (100%) was found to be significantly higher than that in the PPI group (86.3%;  $P = 0.0103$ ) (Figure 5). No ulcer bleeding or complications related to the drugs used after ESD were observed in any of the study subjects.

**DISCUSSION**

Some authors have reported that the combination therapy involving PPI and rebamipide is superior to PPI monotherapy in the healing of ESD-induced ulcers<sup>[2-5]</sup>; however, to our knowledge, no reports on the efficacy of rebamipide for the treatment of ESD-induced ulcers

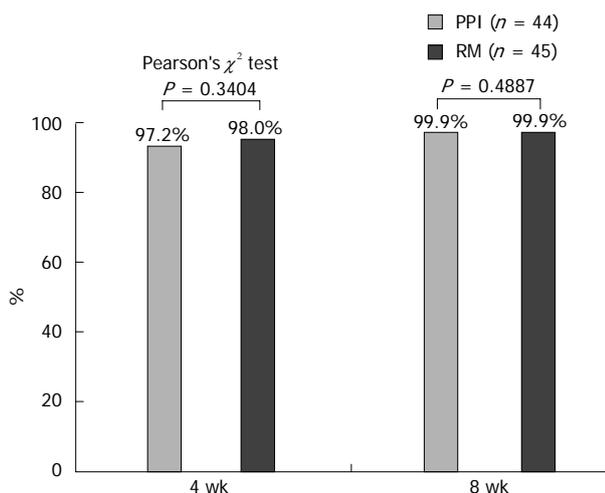

Figure 4 Reduction ratio of the endoscopic submucosal dissection-induced ulcers in both groups. PPI: Proton-pump inhibitor; RM: Rebamipide.

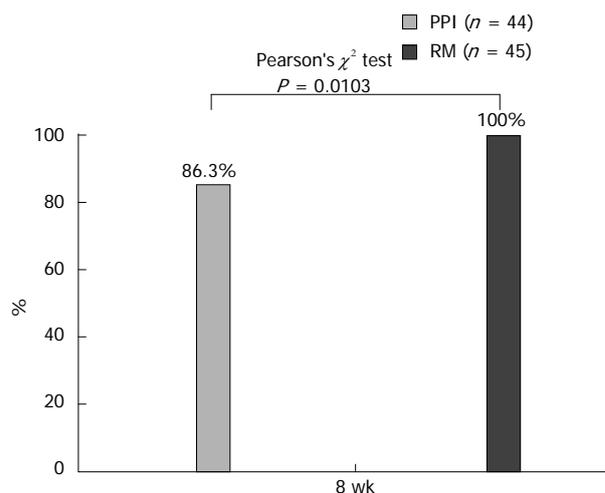

Figure 5 Proportion of patients who developed a flat scar after ulcer healing in both groups. PPI: Proton-pump inhibitor; RM: Rebamipide.

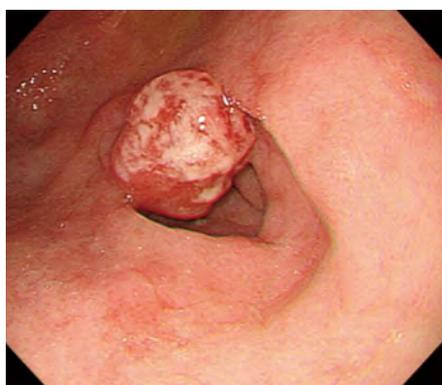

Figure 6 At 8 wk, granulation lesions following ulcer healing in the proton-pump inhibitors treated group.

have been published. In this prospective randomized, parallel-controlled study, we demonstrated that rebamipide monotherapy was as effective as PPI in the healing of ESD-induced ulcers, regardless of the location of the resected cancer, the degree of atrophic gastritis, or the presence of *H. pylori* infection.

Although the response of post-ESD ulcers to PPIs and rebamipide may be similar, the mechanisms of action of these drugs are different. PPIs decrease gastric acid production, whereas rebamipide stimulates the production of prostaglandins<sup>[19]</sup>, epidermal growth factor<sup>[12,20]</sup>, and nitric oxide<sup>[21]</sup>, and decreases the level of oxygen-free radicals<sup>[22]</sup>. These mucosal protective actions of rebamipide appear to promote ulcer healing. Fujiwara *et al*<sup>[3]</sup> showed that 8 wk of PPI and rebamipide treatment was particularly effective for patients with severe atrophic gastritis, classified as O-3. Severe atrophic gastritis may result in the formation of a low-acid environment in the stomach; therefore, acid-suppressive agents such as PPI alone may have a limited effect. However, rebamipide can be effective in this environment because of its different mechanism of action. We believe that this is a contributing factor to the similar efficacies ob-

served between PPIs and rebamipide regardless of the degree of atrophic gastritis.

Previous studies have reported that various mechanisms are involved in the effects of rebamipide on *H. pylori*-positive atrophic gastritis; these include prevention of adhesion of the bacteria to gastric epithelial cells, and inhibition of *H. pylori*-induced secretion of prostaglandin E2 from neutrophils and interleukin-8 expression in gastric epithelial cells<sup>[25-28]</sup>. Terano *et al*<sup>[15]</sup> indicated that the treatment of gastric ulcers with rebamipide promotes ulcer healing regardless of the success or failure of *H. pylori* eradication therapy, and Higuchi *et al* showed that rebamipide prevents the recurrence of gastric ulcers without affecting the *H. pylori* infection status<sup>[10]</sup>. In the present study, PPI and rebamipide appeared to aid in ulcer healing without affecting the *H. pylori* infection status.

Moreover, we noted that the proportion of patients who developed a flat scar at the ulcer site was significantly higher in the rebamipide group than in the PPI group. Thus, rebamipide appears to be more effective than PPIs in improving the QOUH. In animal studies, rebamipide was found to improve the QOUH by increasing the level of prostaglandin E2 and decreasing the levels of malondialdehyde and interleukin-8 in the gastric mucosa<sup>[16]</sup>. In the present study, the unusual elevated gastric lesions that were observed following ulcer healing could not be easily characterized as benign granulation tissue or a malignant recurrence without performing a biopsy (Figure 6). Therefore, we believe that improvement in QOUH is essential for preventing the occurrence of mucosal protrusion due to the growth of granulation tissue.

The most frequent complication that occurs after endoscopic therapy is bleeding, and the rate of intraoperative bleeding is significantly higher with ESD than with EMR. Jeong *et al*<sup>[17]</sup> reported that PPIs may be more effective than histamine H<sub>2</sub> inhibitors in preventing bleeding after ESD by promoting a more rapid healing of these large iatrogenic ulcers<sup>[17]</sup>. Moreover, Uedo *et al*<sup>[18]</sup> indicated that therapy with PPI was more effective than treatment

with histamine H<sub>2</sub> inhibitors in preventing delayed bleeding from ulcers induced by ESD. However, in the present study, no post-ESD bleeding or complications related to the drugs used were noted in the patients receiving rebamipide or PPI treatment; moreover, the ratio of ulcer reduction was at least 90% in both groups at 8 wk after initiation of therapy. Thus, our findings indicated that the rate of intraoperative bleeding was not significantly different between both the groups.

In addition, in the present study, we found that treatment with rebamipide was more cost-effective than treatment with the PPI lansoprazole. The cost of the 56-d treatment course was 4889 yen for rebamipide and 10945 yen for lansoprazole, which is a difference of 44.7%. This high difference in cost may be a factor in determining which medication to prescribe in the treatment of ESD-induced ulcers.

In conclusion, rebamipide monotherapy was equivalent to treatment with a PPI (lansoprazole) in the healing of ulcers induced by ESD for early gastric cancer. The similarity in the treatment efficacy was observed irrespective of the presence of *H. pylori* infection, the severity of atrophic gastritis, or the locations of the ulcers in the stomach. However, rebamipide therapy also resulted in a more favorable QOUL compared with that obtained by PPI treatment. Moreover, the treatment involving rebamipide was more cost-effective compared to the treatment with the PPI lansoprazole for the treatment of ESD-induced ulcers.

## COMMENTS

### Background

Endoscopic submucosal dissection (ESD) is useful for treating early gastric cancer. The artificial ulcer that is generated after ESD is large, and needs a considerably longer healing time compared with conventional endoscopic mucosal resection (EMR). Rebamipide is one of the mucoprotective antiulcer drug, and is widely employed treatment of gastric ulcer in Japan.

### Research frontiers

Previous studies have shown that the combination therapy involving proton pump inhibitor (PPI) and rebamipide is superior to PPI monotherapy in the healing of ESD-induced ulcers; however, to people knowledge, no reports on the efficacy of rebamipide for the treatment of ESD-induced ulcers have been published. Therefore, the authors prospectively investigated differences in healing of ESD-induced ulcers according to treatment with PPI or rebamipide only.

### Innovations and breakthroughs

In this prospective randomized, parallel-controlled study, the authors demonstrated that rebamipide monotherapy was as effective as PPI in the healing of endoscopic submucosal dissection-induced ulcers. In addition, rebamipide treatment was more cost-effective and resulted in a better quality of ulcer healing compared to the PPI lansoprazole treatment.

### Applications

This article suggests that the healing rate of ESD-induced ulcers was similar with rebamipide or PPI treatment; however, rebamipide treatment is more cost-effective and prevents granulation lesions following ulcer healing. However, it is a small study, therefore, a prospective multicenter study with a large sample size should be performed to assess the efficacy of treatment with rebamipide

for endoscopic submucosal dissection-induced ulcers.

## Terminology

ESD is a well-established curative treatment for early gastric cancer. ESD facilitates the collection of larger specimens, regardless of lesion size or location, resulting in a higher rate of en bloc and histologically complete resection. However, the iatrogenic ulcer that develops as a result of ESD is large, and requires a considerably longer healing time compared to that resulting from conventional EMR. Rebamipide is a novel mucosal-protective and ulcer-healing drug that has been widely prescribed in East Asia. Rebamipide stimulates the production of prostaglandins, epidermal growth factor, and nitric oxide, and decreases the level of oxygen-free radicals. These mucosal protective actions of rebamipide appear to promote ulcer healing.

## Peer review

This paper is well written. The clinical results are appropriately described. The authors present the Efficacy of treatment with rebamipide for endoscopic submucosal dissection-induced ulcers. The data indicate the healing rate of ESD-induced ulcers was similar with rebamipide or PPI treatment; however, rebamipide treatment is more cost-effective and prevents granulation lesions following ulcer healing.

### Abstract

**AIM:** To distinguish acinar cell carcinoma (ACC) from pancreatic adenocarcinoma (AC) by comparing their computed tomography findings.

**METHODS:** Patients with ACC and AC were identified on the basis of results obtained using surgically resected pancreatotomy specimens. The preoperative computer tomographic images of 6 acinar cell carcinoma patients and 67 pancreatic adenocarcinoma patients in 4 phases (non-contrast, arterial, portal venous, and delayed phase) were compared. The scan delay times were 40, 70, and 120 s for each contrast-enhanced phase. The visual pattern, tomographic attenuation value, and time attenuation curve were assessed and compared between AC and ACC cases using the  $\chi^2$  test, Wilcoxon signed-rank test, and Mann Whitney *U* test.

**RESULTS:** The adenocarcinomas tended to be hypodense in all 4 phases. The acinar cell carcinomas also tended to be hypodense in the 3 contrast-enhanced

phases, although their computed tomographic attenuation values were higher. Further, 5 of the 6 acinar cell carcinomas (83%) were isodense in the non-contrast phase. The time attenuation curve of the adenocarcinomas showed a gradual increase through the 4 phases, and all adenocarcinomas showed peak enhancement during the delayed phase. The time attenuation curve of the acinar cell carcinomas showed peak enhancement during the portal venous phase in 4 cases and during the arterial phase in 2 cases. None of the 6 acinar cell carcinomas showed peak enhancement during the delayed phase.

**CONCLUSION:** The tumor density in the non-contrast phase and time attenuation curve pattern clearly differ between acinar cell carcinomas and adenocarcinomas, and multidetector-row computed tomography can thus distinguish these tumors.

## INTRODUCTION

Acinar cell carcinoma (ACC) is a rare malignant epithelial neoplasm that exhibits exocrine enzyme production, and it accounts for approximately 1% of all pancreatic neoplasms<sup>[1]</sup>. ACCs have been reported to be bulky tumors that mainly occur in the pancreatic head<sup>[2]</sup>, and recent reports have shown that ACCs are often accompanied by intratumoral necrosis and have various specific extraparenchymal progression patterns, such as intraductal tumor growth (ITG) and venous tumor thrombus (VTT)<sup>[3-9]</sup>. Several reports have described the computed tomography (CT) findings of ACC: it is typically solitary and is accompanied by an intratumoral hypodense area when large. In terms of the visual pattern, although a few hyperdense ACCs have been reported, most ACCs have been reported to be hypodense on contrast-enhanced CT<sup>[10,11]</sup>. Despite these previous reports on imaging findings, the correct preoperative diagnosis of ACC remains difficult, and ACC is often misdiagnosed as another hypodense pancreatic tumor, namely, adenocarcinoma (AC)<sup>[11]</sup>.

ACCs had been previously considered equally aggressive as ACs<sup>[12,13]</sup>, and pretreatment differentiation between ACC and AC was not considered important. However, in recent years, increasing evidence has shown that ACCs are characterized by less aggressive growth and that ACC shows significantly better long-term survival than AC<sup>[12]</sup>. Further, although no consensus has been reached on surgery for metastatic ACCs, a few reports have described a good prognosis after resection of limited metastatic disease. Because the malignant potential of ACC and AC is significantly different, correct pretreatment distinction between these two tumors is very important.

This study aims to elucidate the characteristic CT findings of ACC to allow accurate diagnosis of even small ACCs. The visual pattern, CT attenuation value, and time attenuation curve (TAC) pattern of ACCs on 4-phase multidetector-row computed tomography (MDCT) were retrospectively reviewed, and the results were compared with those of ACs.

## MATERIALS AND METHODS

### Patients

The study design was approved by the institutional review board. Informed consent was not required because the review of the patients' data was anonymous. After a thorough search of the computerized database of the Hepatobiliary Pancreatic Surgery Division from April 2006 to March 2011, 6 patients with ACC and 88 patients with AC were identified on the basis of results obtained using surgically resected pancreatotomy specimens. Twenty-one AC patients were excluded because CT attenuation values for these tumors could not be measured accurately for the following reasons: halation of indwelling biliary drainage tube (11 ACs), small size and unclear tumor margin (9 ACs), and allergy to contrast media (1 AC). MDCT images of the 6 ACC patients and the remaining

67 AC patients were comparatively reviewed.

### MDCT examination

All MDCT studies were performed using a scanner with 16 rows of detectors (Aquilion 16; Toshiba Medical Systems, Tokyo, Japan). CT images, both unenhanced and contrast enhanced, were routinely obtained with the patient in the supine position during full inspiration. For contrast-enhanced imaging, 100 mL of nonionic contrast material with iodine was administered at a rate of 3.2 cc/s using a mechanical power injector through a 20-gauge angiographic catheter inserted into a forearm vein. The scan delay time was 40 s for the arterial phase, 70 s for the portal venous phase, and 120 s for the delayed phase. Four-phase images (1 unenhanced image and 3 contrast-enhanced images) were routinely obtained. The scanning parameters for each phase were 1-mm collimation, 3-mm slice thickness, 3-mm reconstruction interval, 120 kV, and auto mA.

### Imaging analysis

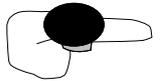

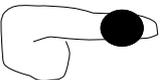

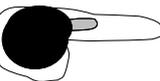

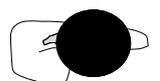

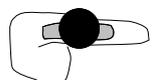

MDCT images were available from the picture archiving and communication system (PACS), and all images were reviewed on the PACS monitor. All CT images were evaluated retrospectively by 2 experienced hepatobiliary and pancreatic surgeons with 13 and 24 years of experience, respectively. CT images were assessed for the visual pattern and CT attenuation value of the ACs and ACCs. The visual pattern of each lesion was classified as hyperdense, isodense, or hypodense, compared to the surrounding normal pancreatic parenchyma in each phase. The CT attenuation value in Hounsfield units was obtained using region of interest (ROI) analysis. To reduce the effect of tumor heterogeneity, one ROI of the largest possible area was identified within the tumor at the level of maximum tumor diameter. The ROI value was calculated as the CT attenuation value of the tumor. Three ROIs of diameter 1 cm were also identified in the normal parenchyma adjacent to the tumor, and the mean of the 3 ROI values was calculated as the CT attenuation value of the surrounding parenchyma. While defining ROIs, special attention was paid to exclude cystic areas, calcification, the pancreatic duct, and the surrounding vessels. TAC patterns were drawn on the basis of each CT attenuation value, and they were compared between the ACCs and ACs.

### Pathological examination and analysis

All the ACCs and ACs in this study were surgically resected, and 2 pathologists reviewed the gross appearance of the tumor specimens and hematoxylin-eosin-stained specimens on microscopic slides. For the ACCs, immunohistochemical analysis was performed for chromogranin and synaptophysin to exclude mixed acinar-endocrine carcinomas (MAEs).

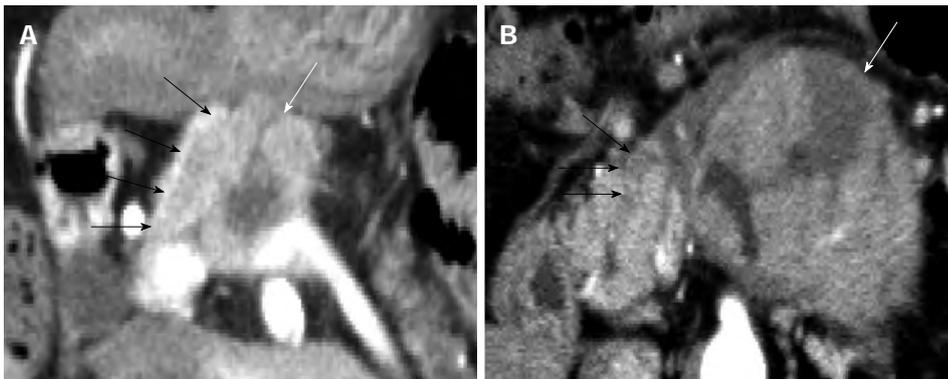

### Statistical analysis

The visual patterns of the ACCs and the ACs were compared using the  $\chi^2$  test. The CT attenuation values were

No.	Age, sex	Pre diag	Scheme	Location/size/surgery	Intra-tumoral necrosis	Intraductal tumor growth	Venous tumor thrombus

compared between each phase by using the Wilcoxon signed-rank test. The CT attenuation values of the ACCs and the ACs were compared by using the Mann-Whitney *U* test. Data were analyzed using IBM SPSS Statics 19, and *P* values less than 0.05 were considered statistically significant.

## RESULTS

### Clinicopathological findings

Each pancreatic tumor had been preoperatively diagnosed on the basis of blood examination, CT images and endoscopic findings at weekly hepatobiliary pancreatic conferences involving radiologists, gastroenterologists, and surgeons. Of the ACC cases, 5 tumors had been diagnosed as AC, and only 1 tumor (case 6) had been correctly diagnosed as ACC (Figure 1). In all 6 ACC cases, the patients

were male (mean age, 69 years; range, 52-89 years). Two patients underwent pancreaticoduodenectomy, and the other 4 patients underwent distal pancreatectomy. The maximum diameter of the tumors ranged from 31 to 87 mm, and the mean maximum diameter was 46.8 mm. Five tumors showed intratumoral necrosis. Extraparenchymal tumor extension as ITG and VTT was observed in 3 patients and 1 patient, respectively (Figures 1 and 2). All ACCs were characterized by extensive cellularity and minimal stroma, and the tumor cells showed basophilic cytoplasm and frequently contained eosinophilic granules in the cytoplasm. The tumor cells were arranged in an acinar pattern in 3 ACCs and in a solid pattern in 3 ACCs. Immunohistochemical analysis showed negative reactions for chromogranin and synaptophysin in all cases. Re-examination of the morphological characteristics, cell structure, and immunohistochemical reactions of all resected

**Figure 3** Visual patterns of the adenocarcinoma and the acinar cell carcinoma in the 4 phases. A-D: Adenocarcinoma in the pancreatic tail (circle); The tumor was hypodense in all 4 phases (A: Non-contrast phase; B: Arterial phase; C: Portal venous phase; D: delayed phase). It showed a gradual enhancement pattern across the phases; E-H: Case 1, Acinar cell carcinoma in the pancreatic head (circle); The tumor was isodense and undetectable in the non-contrast phase, although calcification was identified (arrow) (E); It was hypodense in all 3 contrast-enhanced phases (F: Arterial phase; G: Portal venous phase; H: Delayed phase); Contrast enhancement was the strongest in the portal venous phase (G).

tumors excluded neuroendocrine tumors and MAEs. All tumors were diagnosed as pure ACCs. Among 67 AC patients, 34 AC patients were male and 33 were female (mean age, 71.4 years; range, 34-87 years). The maximum diameter of the tumors ranged from 12 to 105 mm, and the mean maximum diameter was 35 mm. All tumors were whitish, solid, and associated with dense fibrotic stroma. None of the tumors was accompanied by significant intratumoral necrosis. All tumors were diagnosed as tubular adenocarcinoma; adenocarcinoma variants such as adenosquamous carcinoma, colloid carcinoma, and undifferentiated carcinoma were not observed.

### MDCT findings

**Visual pattern:** Fifty-three ACs (79%) were hypodense while 14 (21%) were isodense in the non-contrast phase

(Figure 3, Table 1). All ACs were hypodense in the arterial and portal venous phases. Forty-six ACs (69%), 13 ACs (19%), and 8 ACs (12%) were hypo-, iso-, and hyperdense in the delayed phase, respectively.

One ACC (17%) was hypodense and 5 (83%) were isodense in the non-contrast phase (Figure 3, Table 1). All ACCs were hypodense in all 3 contrast-enhanced phases, except for 1 tumor, which was isodense in the delayed phase. Thus, the visual pattern was clearly different between ACCs and ACs in the non-contrast phase ( $P < 0.01$ ) (Table 1).

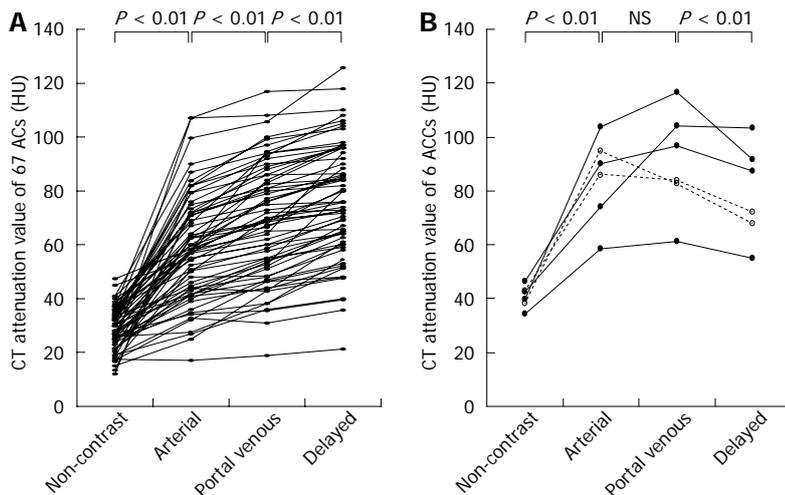

**CT attenuation value and TAC pattern:** The CT attenuation values of the ACs showed a gradually increasing pattern (non-contrast *vs* arterial,  $P < 0.01$ ; arterial *vs* portal venous,  $P < 0.01$ ; portal venous *vs* delayed,  $P < 0.01$ ) (Figure 4). The TAC of all 67 ACs showed peak enhancement during the delayed phase.

The TAC of 4 ACCs showed peak enhancement during the portal venous phase. That of the remaining 2 ACCs showed peak enhancement during the arterial phase, followed by a gradual decline. Unlike the ACs, the ACCs showed significantly higher CT attenuation values in the portal venous phase than in the delayed phase ( $P < 0.01$ ) (Figure 4).

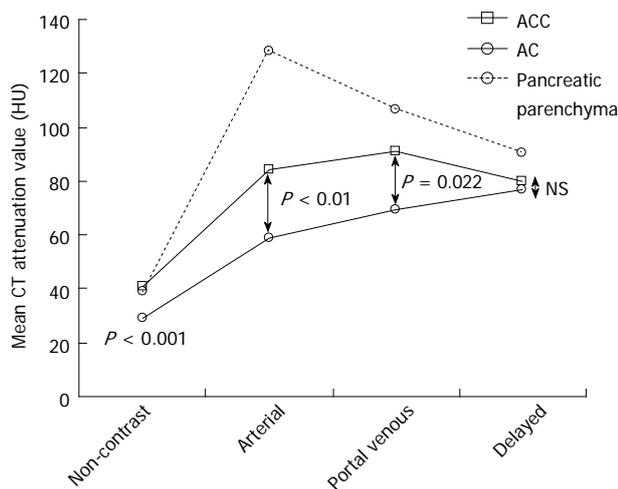

In all 3 phases (non-contrast, arterial, and portal venous), the CT attenuation values of the ACCs were significantly higher than those of the ACs, although the visual patterns of the 2 tumors were clearly different only in the non-contrast phase (Figure 5, Table 1).

## DISCUSSION

Previously, ACCs were considered equally aggressive

**Figure 4** Time attenuation curve of the 67 adenocarcinomas (A) and 6 acinar cell carcinomas (B). Peak enhancement is seen during the delayed phase for all 67 acinar cell carcinomas. Meanwhile, peak enhancement is seen during the portal venous phase for 4 acinar cell carcinomas (ACCs) and during the arterial phase for 2 ACCs. None of the 6 ACCs show peak enhancement during the delayed phase. AC: Adenocarcinomas; CT: Computed tomography; NS: Not significant.

**Figure 5** Mean computed tomography attenuation values of the tumors and the surrounding pancreatic parenchyma in the 4 phases. In 3 phases (non-contrast, arterial, and portal venous phase), the computed tomography (CT) attenuation values of the acinar cell carcinomas (ACCs) were significantly higher than those of the adenocarcinomas (ACs). NS: Not significant.

cancers as ACs<sup>[12,13]</sup>. Therefore, the treatment strategy for both tumors was essentially the same, and preoperative differentiation between ACC and AC was not considered important. However, in recent years, increasing evidence has shown that ACCs exhibit less aggressive growth and significantly better long-term survival than ACs<sup>[12]</sup>. Two recent large population-based studies proved the better prognosis of ACC<sup>[14,15]</sup>. Schmidt *et al.*<sup>[14]</sup> reported the largest ACC series of 865 patients from the National Cancer Database, and they described the 5-year survival rates to be 36.2% and 10.4% for the resected and non-resected cases, respectively. The stage-specific 5-year survival was significantly better for resected ACC than AC (stage I: 52.4% *vs* 28.4%; II: 40.2% *vs* 9.8%; III: 22.8% *vs* 6.8%; IV: 17.2% *vs* 2.8%). These findings suggest that the survival rate is better for ACC than for AC, and even in advanced

ACC cases, survival can be improved by resection. Further, although no consensus has been reached on surgery for metastatic ACCs, a few reports have described a good prognosis after resection of limited metastatic disease. Hartwig *et al.*<sup>[12]</sup> reported that the overall survival did not differ between 9 patients who underwent metastatic disease resection and 6 patients who underwent nonmetastatic disease resection. Suzuki *et al.*<sup>[16]</sup> reported the case of a long-term survivor of metastatic ACC who was successfully treated with repetitive surgery. Because surgery might result in longer survival for ACC patients, even those with metastatic disease, the malignant potential of ACC and AC is thought to be significantly different, and accurate diagnosis of ACC is very important.

Recent reports on CT have shown that ACCs are typically solitary, and they are homogeneously enhanced when the lesion is small but may contain hypodense areas because of necrosis if the lesion is large<sup>[11,17]</sup>. In terms of the visual pattern in contrast-enhanced phases, although a few reports described ACC to be a hyperdense tumor in the arterial phase<sup>[18]</sup>, some reported that it tended to be enhanced less than the adjacent normal pancreatic parenchyma<sup>[10,11]</sup>. Chiou *et al.*<sup>[17]</sup> reported on the CT manifestations of 8 ACCs, of which 6 were hypodense and 2 were isodense in the early arterial and portal venous phases. As shown in previous reports, ACCs tended to be hypodense in all 3 contrast-enhanced phases in the current study, and hypervascular pancreatic tumors, such as neuroendocrine tumor or metastatic renal cell carcinoma, were not included among the preoperative differential diagnoses. Although several such valid imaging findings of ACCs are available, accurate preoperative imaging-based diagnosis of ACCs, especially small ACCs, remains difficult<sup>[19]</sup>. In the current study, ACC was correctly diagnosed on the basis of recognizable widespread ITG on CT images in only 1 case (Figure 2A). Although the characteristic progression patterns of ITG or VTT were observed in 3 other cases (cases 2, 4, and 5), ACC was not preop-

eratively diagnosed in these cases. Because the ITG or VIT lesions were small and continuous with the primary tumor in these cases, they could not be considered to be the tumor that had progressed into the pancreatic duct or splenic vein, and they were regarded as part of the primary tumor (Figure 2B). To identify novel indicators for the accurate diagnosis of ACC, the CT attenuation values of ACC were compared with those of AC, which was the most frequently suspected disease in the preoperative diagnosis in our ACC cases, and we found that ACCs had a unique TAC pattern. The TAC of the ACCs showed the peak enhancement during the portal venous phase in the 4 ACCs, and during the arterial phase in the 2 ACCs. None of the 6 ACCs showed the peak enhancement during the delayed phase. This TAC pattern of ACC was clearly different from that of AC. Several studies have reported the CT findings of pancreatic AC, and it is well known that AC with fibrous stroma appears hypodense with delayed enhancement on dynamic CT<sup>[20-22]</sup>. The ACs in the current study also showed the gradual enhancement pattern, and all 67 ACs showed the peak enhancement during the delayed phase. Although the reasons for the different TAC pattern of ACs and ACCs have not been elucidated, we speculate that the degree of intratumoral fibrosis is one. Hattori *et al.*<sup>[23]</sup> reported that the CT attenuation value of ACs correlated negatively with the extent of intratumoral fibrosis in 3 contrast-enhanced phases. The scanty fibrous stroma in the ACCs might have led to their higher CT attenuation values compared with those of the ACs. The isodensity of most ACCs in the non-contrast phase, which is clearly different from the hypodensity of most ACs, is also thought to reflect the degree of fibrosis. In this study, 3 relatively small ACCs (31, 32, and 35 mm in diameter) also showed the specific TAC pattern. Thus, this TAC pattern might be useful to distinguish ACCs from ACs, especially when they are small and have no distinguishing morphological features. Further, in the future, it may be possible to apply these different patterns of enhancement on MDCT to echoendoscopy.

Echoendoscopy has been reported to be superior to any other modality with respect to spatial resolution, and it can accurately detect small pancreatic lesions<sup>[24-26]</sup>. Contrast-enhanced endoscopic ultrasonography (CE-EUS) has emerged as a recent technological development, and this modality can be used to evaluate the degree of enhancement in pancreatic lesions<sup>[25,26]</sup>. Kitano *et al.*<sup>[26]</sup> reported that CE-EUS was useful for characterizing pancreatic lesions and that it was superior to MDCT for diagnosing small lesions. Although, to our knowledge, no study has compared the enhancement pattern between ACs and ACCs using echoendoscopy, this modality may prove useful for distinguishing these 2 pancreatic tumors.

Despite the novel findings of this study, it does have some limitations. Firstly, the number of ACC cases included is small, and it is not clear whether or not every ACC definitely shows the unique TAC pattern. Another limitation is that the actual effectiveness of this TAC pat-

tern is unclear, because of the retrospective nature of this study. Further investigation is necessary to prove that the TAC pattern is specific to ACCs and that it is actually useful in distinguishing ACCs from other pancreatic tumors.

In conclusion, the tumor density in the non-contrast phase and TAC pattern are clearly different between ACCs and ACs, although both tumors tend to be hypodense in the contrast-enhanced phases.

## COMMENTS

### Background

Acinar cell carcinoma (ACC) is a rare malignant epithelial neoplasm that exhibits exocrine enzyme production, and it accounts for approximately 1% of all pancreatic neoplasms. ACCs have been reported to be bulky tumors that mainly occur in the pancreatic head, and recent reports have shown that ACCs are often accompanied by intratumoral necrosis and have various specific extraparenchymal progression patterns, such as intraductal tumor growth and venous tumor thrombus. Several reports have described the computed tomography (CT) findings of ACC: it is typically solitary and is accompanied by an intratumoral hypodense area when large. In terms of the visual pattern, although a few hyperdense ACCs have been reported, most ACCs have been reported to be hypodense on contrast-enhanced CT.

### Research frontiers

ACCs had been previously considered equally aggressive as ACs, and pretreatment differentiation between ACC and AC was not considered important. However, in recent years, increasing evidence has shown that ACCs are characterized by less aggressive growth and that ACC shows significantly better long-term survival than AC. Further, although no consensus has been reached on surgery for metastatic ACCs, a few reports have described a good prognosis after resection of limited metastatic disease. Because the malignant potential of ACC and AC is significantly different, correct pretreatment distinction between these two tumors is very important.

### Innovations and breakthroughs

The tumor density in the non-contrast phase and time attenuation curve pattern clearly differ between acinar cell carcinomas and adenocarcinomas, and multidetector-row computed tomography can distinguish these tumors.

### Applications

Each pancreatic tumor had been preoperatively diagnosed on the basis of blood examination, CT images and endoscopic findings at weekly hepatobiliary pancreatic conferences involving radiologists, gastroenterologists, and surgeons.

### Peer review

This is an interesting paper. The number of acinar carcinomas is relatively small but still there are some interesting results. Suggest authors edit the paper before publication if they have more cases in hand.

### Abstract

**AIM:** To assess the feasibility, safety, and advantages of minimally invasive laparoscopic-endoscopic cooperative surgery (LECS) for gastric submucosal tumors (SMT).

**METHODS:** We retrospectively analyzed 101 consecutive patients, who had undergone partial, proximal, or distal gastrectomy using LECS for gastric SMT at Peking Union Medical College Hospital from June 2006 to April 2013. All patients were followed up by visit or telephone. Clinical data, surgical approach, pathological features such as the size, location, and pathological type of each tumor; and follow-up results were analyzed. The feasibility, safety and effectiveness of LECS for gastric SMT were evaluated, especially for patients with tumors located near the cardia or pylorus.

**RESULTS:** The 101 patients included 43 (42.6%) men

and 58 (57.4%) women, with mean age of  $51.2 \pm 13.1$  years (range, 14-76 years). The most common symptom was belching. Almost all ( $n = 97$ ) patients underwent surgery with preservation of the cardia and pylorus, with the other four patients undergoing proximal or distal gastrectomy. The mean distance from the lesion to the cardia or pylorus was  $3.4 \pm 1.3$  cm, and the minimum distance from the tumor edge to the cardia was 1.5 cm. Tumor pathology included gastrointestinal stromal tumor in 78 patients, leiomyoma in 13, carcinoid tumors in three, ectopic pancreas in three, lipoma in two, glomus tumor in one, and inflammatory pseudotumor in one. Tumor size ranged from 1 to 8.2 cm, with 65 (64.4%) lesions  $< 2$  cm, 32 (31.7%)  $> 2$  cm, and four  $> 5$  cm. Sixty-six lesions (65.3%) were located in the fundus, 21 (20.8%) in the body, 10 (9.9%) in the antrum, three (3.0%) in the cardia, and one (1.0%) in the pylorus. During a median follow-up of 28 mo (range, 1-69 mo), none of these patients experienced recurrence or metastasis. The three patients who underwent proximal gastrectomy experienced symptoms of regurgitation and belching.

**CONCLUSION:** Laparoscopic-endoscopic cooperative surgery is feasible and safe for patients with gastric submucosal tumor. Endoscopic intraoperative localization and support can help preserve the cardia and pylorus during surgery.

**Key words:** Laparoscopic-endoscopic cooperative surgery; Gastric submucosal tumor; Minimally invasive surgery; Laparoscopy; Endoscopy

**Core tip:** We retrospectively analyzed 101 consecutive patients who had undergone partial, proximal or distal gastrectomy using laparoscopic-endoscopic cooperative surgery (LECS) for gastric submucosal tumor (SMT) at Peking Union Medical College Hospital from June 2006 to April 2013. Ninety-seven patients underwent surgery with preservation of the cardia and

pylorus, with the other four patients undergoing proximal or distal gastrectomy. LECS is feasible and safe for gastric SMT, especially for patients with tumors near the cardia or pylorus. Intraoperative localization and support by endoscopy can help preserve the cardia and pylorus during surgery.

## INTRODUCTION

Since the first gastrectomy was performed in 1880, surgical methods have developed rapidly due to improvement in anastomosis techniques, surgical staplers, and gastrointestinal tube application<sup>[1]</sup>. Moreover, since the first cholecystectomy by electronic laparoscopy was performed in 1987, minimally invasive laparoscopic surgery has become more popular for its lower postoperative morbidity rates and faster postoperative recovery<sup>[2-5]</sup>. Minimally invasive surgery is suitable for benign gastric lesions, especially for gastrointestinal stromal tumors (GISTs). Although GISTs are potentially malignant, nodal metastasis is rare. Therefore, excision of the tumor with negative margins but without lymphadenectomy has become a standard approach, while GISTs are indicated for minimally invasive partial gastrectomy<sup>[6-9]</sup>.

Although gastric small mucosal tumors (SMT) have been resected laparoscopically, this type of surgery is associated with two potential problems. Laparoscopy may be unable to determine the location of gastric SMTs, because of their small size or intraluminal growth pattern. In addition, complications may arise during the laparoscopic removal of SMTs located near the cardia or pylorus; these complications can include stenosis or damage to the cardia or pylorus. We have therefore developed a technique, called minimally invasive laparoscopic-endoscopic cooperative surgery (LECS), for removal of SMTs. This paper represents our analysis of findings in 101 patients who successfully underwent LECS for gastric SMT at the Department of General Surgery, Peking Union Medical College Hospital, from June 2006 to April 2013.

## MATERIALS AND METHODS

### Clinical data

From June 2006 to April 2013, 101 patients successfully underwent LECS for gastric SMT at the Department of General Surgery, Peking Union Medical College Hospital; the cardia and pylorus were preserved in 97 of these patients. In addition to routine preoperative tests, all patients underwent upper gastrointestinal endoscopy with

endoscopic ultrasound (EUS) and a computed tomography (CT) scan with three-dimensional gastric display. Demographic and clinicopathological characteristics were analyzed retrospectively. Demographic features assessed included patient sex and age, the length of the operation, estimated blood loss, and rate of conversion to open surgery. Postoperative data included time to bowel function recovery (normal passage of gas), surgical complications (*e.g.*, leakage, stenosis, and bleeding), and length of postoperative hospital stay. The clinicopathological characteristics of the SMTs included their size, location, and pathological type.

### Surgical procedures

LECS was performed with the patient under general anesthesia in the reverse Trendelenburg position. The surgeon stood between the patient's legs, the first assistant was to the right or the left of the patient's body, the laparoscopist to the right of the patient's legs, and the gastroscopist to the left of the patient's head.

### Setup for laparoscopic surgery

A camera port was inserted into the inferior (1 cm) umbilical incision (10 mm port) using an open technique. Three additional ports (two 5 mm and one 12 mm in diameter) were inserted into the left upper and right upper quadrants and the inferior xiphoid process (on the right or left side according to the location of the SMT), respectively, under a pneumoperitoneum of 1.60-1.86 kPa, with a laparoscopic view (30° angle range).

### Endoscopic procedures

With the patient anesthetized, the endoscope was inserted through the oropharynx. The mucosae of the esophagus and stomach were viewed, taking care not to infuse too much air into the stomach. The location of the SMT was confirmed, all liquids and gas were withdrawn, and the endoscope was withdrawn through the cardia to remain in the esophagus<sup>[10]</sup>.

### Operative approaches

**Tumors within the anterior wall of the stomach:** The omentum was detached and a little air was allowed to fill the stomach endoscopically. Using both the laparoscope and the endoscope, the location of the SMT was confirmed by the method of touch and marked by one or two suture lines. The gastric wall, including the SMT, was elevated with two seromuscular sutures placed opposite each other and 2-4 cm from the lesion. The tumors, as well as some normal gastric tissues, were removed with a linear endoscopic gastrointestinal stapler (*e.g.*, EC60). If the tumor was located near the esophagogastric junction or pyloric ring, the endoscope was placed distally into the stomach or duodenum to protect the normal gastric tissues from stenosis or damage. After the lesion was resected, direct intraluminal visualization was performed to ensure that the tumor was totally removed and that there was no bleeding or leakage. The amount of air in

**Table 1 Demographic and clinical characteristics of the 101 patients who underwent laparoscopic and endoscopic cooperative surgery for gastric submucosal tumors *n* (%)**

Parameters	Statistics
No. of patients	101
Age (yr)	51.2 ± 13.1 (range 14-76)
Sex	
Male	43 (42.6)
Female	58 (57.4)
Chief complaint	
Dyspepsia (regurgitation, eructation, belching, epigastralgia, and epigastric discomfort)	69 (68.3)
Physical examination (asymptomatic)	27 (26.7)
Melena	5 (5.0)
Tumor location	
Cardia	3 (3.0)
Gastric fundus	66 (65.3)
Gastric body	21 (20.8)

Distance between the tumor and cardia or pylorus (cm)	3.4 ± 1.3 (minimum 1.5)

Data are presented as mean ± SD.

the stomach and peritoneum was balanced, resulting in a good visual field.

#### Tumors within the posterior wall of the stomach:

The proximate curvature was detached to expose the tumor, using, for example, the Ligasure vascular sealing system. The posterior wall was rotated, and the tumor was resected using a technique similar to that described for anterior lesions.

#### Tumors within the lesser curvature (anterior and posterior gastric wall borderline) of the stomach:

The small omentum was detached to expose the tumor, followed by tumor resection using the technique described above. For larger tumors, the left gastric vessels were cut off to prevent both operative and postoperative bleeding. Endoscopic support was especially important for tumors located near the esophagogastric junction<sup>[11]</sup>.

The resected tumor was placed in a specimen retrieval bag located outside the left upper quadrant port. The tumor was cut open along the suture lines, and any ruptures in tumor integrity were assessed. The tumor was measured, immersed in 10% formalin solution, and sectioned. The sections were routinely stained with hematoxylin and eosin, and the number of mitotic figures per 50 high powered fields (HPF) was counted. Risk classifications for GIST were those described by the National Institutes of Health (NIH) in 2008. Gastric GIST was confirmed by immunohistochemistry, using antibodies to identify CD-117 (c-kit), CD-34, and DOG-1.

#### Follow-up

All patients were followed up by visit or telephone after 1, 3, 6, 9, 12, 24, 36, 48, and 60 mo. Each follow-up included a medical history review of any reports of abdominal

discomfort, as well as CT scans and upper gastrointestinal endoscopy to exclude tumor recurrence or metastasis.

#### Statistical analysis

Data are expressed as mean ± SD. All analyses were performed using SPSS 12.0 software (SPSS, Chicago, IL, United States).

## RESULTS

Surgery was successful in all 101 patients. The demographic and clinical characteristics of the 101 patients are depicted in Table 1. Three patients each had two GISTs.

Of the 101 patients, four underwent proximal or distal gastrectomy, including three with tumors located at the cardia, and one with a tumor located at the pylorus. The remaining 97 patients had preservation of the cardia and pylorus. During surgery, tumor location could not be confirmed by laparoscopy alone in 92 patients.

The mean operation time was 113 ± 36 min, and none of these patients required conversion to open surgery. Mean estimated blood loss was 36 ± 18 mL. The postoperative course of all patients was uneventful, with no anastomosis leakage. One patient who underwent proximal gastrectomy had an anastomotic stenosis because of scar physique. This patient was successfully treated by balloon dilatation under X-ray fluoroscopy. One patient experienced anastomotic bleeding and was successfully treated by conservative methods (drug hemostasis and blood transfusion). The average time to first gas passage was 2.9 ± 0.9 d, the average time for nasogastric tube placement was 1.9 ± 0.5 d, and the average postoperative hospital stay was 4.2 ± 1.1 d (Table 2). Seven patients underwent simultaneous laparoscopic cholecystectomy for gallstones, and two underwent simultaneous endoscopic polypus dissection.

All the resected tumors were cut open along the suture lines, with none showing evidence of rupture.

The clinicopathological characteristics of the submucosal stomach tumors, including their location, are shown in Table 3. Of the 101 tumors, 78 (77.2%) were GISTs, with 53 located in the gastric fundus, 14 in the gastric body, seven in the antrum, three in the cardia, and one in the pylorus. The remaining tumors included 13 (12.9%) leiomyomas, 11 in the gastric fundus and two in the gastric body; three (3.0%) ectopic pancreases, two in the gastric fundus and one in the antrum; three (3.0%) carcinoids, two in the gastric body and one in the antrum; two (2.0%) lipomas, one each in the gastric body and antrum; one (1.0%) glomus tumor in the gastric body; and one (1.0%) inflammatory pseudotumor in the gastric body. Maximum tumor size ranged from 1 to 8.2 cm, with 65 (64.4%) lesions < 2 cm in size, 32 (31.7%) > 2 cm, and four > 5 cm.

Gastric GIST was confirmed by immunohistochemistry in 78 patients, with 68 (87.2%) positive for CD117, 65 (82.9%) positive for CD34, and 65 (82.9%) positive for DOG1. Using the NIH biological risk classification for GIST<sup>[12]</sup>, we found that 54 (69.2%) tumors were of

very low risk, including 41 in the gastric fundus, seven in the gastric body, four in the antrum, and two in the cardia; and 16 (23.5%) were of low risk, including eight in the gastric fundus, four in the gastric body, two in the antrum, one in the cardia, and one in the pylorus. Six tumors (7.7%), of mean size  $5.4 \pm 1.3$  cm, were of moderate risk, including three in the gastric fundus, two in the gastric body, and one in the antrum. Two tumors (2.6%) were of high risk, one located in the gastric fundus was 8.2 cm in size; and the second, located in the gastric body, showed 13 mitotic figures/50 HPF. The first patient was treated with imatinib for 2 mo before the surgery, which decreased the tumor size from 8.8 to 8.2 cm in diameter. The eight patients in the moderate- and high-risk classes were treated with adjuvant imatinib for 1-2 years.

All the patients were followed up after LECS, for a mean time of 28 mo (range, 1-69 mo). The three patients who underwent proximal gastrectomy developed symptoms of regurgitation, eructation, and belching. None of the 101 patients who underwent LECS showed evidence of tumor recurrence, metastasis, nutritional disturbances (*e.g.*, weight loss, vitamin deficiency, deficiency of trace elements), or decreased quality of life. One patient developed primary liver cancer 2 years and 4 mo after LECS, but this patient remains alive. In addition, none of the patients with preserved cardia and pylorus experienced any symptoms of epigastric discomfort.

## DISCUSSION

We have shown here that LECS is feasible, yielding satisfactory surgical results, in patients with gastric SMT. Usually, gastric SMTs are resected by open surgery, either distal or proximal gastrectomy<sup>[13]</sup>. Operation time and postoperative hospital stay are longer, and many patients develop gastroesophageal reflux disease (GERD). Quality of life may decrease, and the risk of remnant gastric cancer or esophageal carcinoma may increase. In contrast, LECS requires a relatively small resection of the healthy gastric wall, with very low rates of postoperative morbidity and mortality. Of our 101 patients, only two experienced postoperative complications, one with anastomotic

stenosis and one with anastomotic bleeding. Although tumors with an extragastric growth pattern can be easily treated using conventional laparoscopic wedge resection, laparoscopic methods alone have some limitations for the resection of gastric SMTs. Laparoscopy has been found to be less efficient than open surgery in removing small tumors and tumors located in the posterior gastric wall and lesser curvature of the stomach. In addition, the removal of large tumors and those located near the cardia or pylorus can result in post-operative complications, such as stenosis or damage to the cardia or pylorus.

All of our patients routinely underwent two important preoperative tests, upper gastrointestinal endoscopy with EUS and CT scan with a three-dimensional gastric display, both of which are very important for this surgery. EUS was used to assess depth of tumor invasion, lesion location, tumor size, and growth pattern<sup>[14-18]</sup>. The diagnostic accuracy of EUS, however, may be affected by technical problems or skills or the subjective view of the operator, whereas the diagnostic accuracy of CT scanning was less subjective. CT three-dimensional imaging was helpful in assessing tumor size, the distance between the tumor and local tissues (cardia and pylorus), and the diagnosis and staging of SMTs. Use of these two tests could therefore determine whether localized gastric SMTs can be resected.

Endoscopic submucosal dissection (ESD) performed by experienced endoscopists has been used to remove gastric SMTs<sup>[19,22]</sup>. We found that 78 of our 101 (77.2%) SMTs were GISTs. GISTs are a type of mesenchymal neoplasm, originating from Cajal cells; are located in the submucous, muscularis propria, or subserous layer; and have an intraluminal or extrinsic growth pattern. ESD resection of tumors in the muscularis propria, while preserving the integrity of the serous layer, is very difficult. ESD alone may result in high rates of resection failure, intraoperative bleeding, and perforation. In addition, this procedure cannot easily differentiate between benign and malignant tumors. Since GISTs are regarded as potentially malignant and in need of complete resection, ESD alone should not be used to remove gastric SMTs.

The development of the LECS procedure has expanded the range of minimally invasive surgery. The endoscopic assistant cut the exact edges from the gastric

lumen, followed by tumor resection aided by endoscopy. Endoscopic support could reduce complications, such as stenosis or damage to the cardia or pylorus, especially when the tumor is located in the gastric fundus or antrum. Moreover, direct intraluminal visualization can confirm that the tumor has been totally removed, that there is no bleeding from the suture lines, and that there are no perforations. When observing through the endoscope, the pneumoperitoneum should be at lower pressure and the laparoscope should be removed for a better view. All gas and liquid should be removed endoscopically for better laparoscopic procedures. Laparoscopy may be sufficient, however, for large tumors, for tumors located near the cardia and pylorus, and for tumors with an extrinsic growth pattern. Even in these situations, however, endoscopic support is important for protecting the cardia and/or pylorus from damage during resection, even if the endoscope is not need to confirm tumor location. LECS can therefore improve the success rates and outcomes of minimally invasive surgery without postoperative morbidity or mortality.

The sphincter muscles in the cardia and pylorus are important anatomical structures for preserving regurgitation. Although 59.1% of SMTs were reported located at the fundus<sup>[11]</sup>, we found that the percentage was higher, 67.9%. Resection of the cardia can cause symptoms like heartburn due to gastric acid regurgitation. These patients may have to take medicines like proton pump inhibitors for a long time, reducing patient quality of life, and may develop GERD or esophageal carcinoma. Of our 101 patients, only three underwent proximal gastrectomy, with all three developing symptoms of regurgitation, eructation, and belching. Similar findings would be observed after resection of the pylorus, since duodenal juice would regurgitate into the remnant stomach, causing inflammation at the suture lines and corresponding symptoms and ultimately leading to remnant gastric cancer<sup>[21,22]</sup>. Therefore, it is very important to preserve these important anatomical structures. LECS can decrease the risk to resect the cardia and pylorus. We found that the minimum distance from the edge of the tumor to the cardia was 1.5 cm. The importance of endoscopic support was inversely correlated with the distance between the tumor edge and the cardia or pylorus<sup>[23]</sup>. In addition, GISTs are supplied by many blood vessels. When resecting larger tumors within the lesser curvature, the left gastric vessels should be cut off to prevent postoperative bleeding. In this study, one 76-year-old patient experienced anastomotic bleeding, because of atherosclerosis. After 2 d of conservative therapy, consisting of blood transfusions, he got better and was discharged.

All 101 of our patients underwent minimally invasive surgery, with LECS in 97 resulting in the preservation of the cardia and pylorus. None of these patients required conversion to open surgery. Intraoperative bleeding was limited and recovery of bowel function was rapid, with a low postoperative morbidity (except for one patient each with anastomotic stenosis and bleeding), and no

postoperative mortality. Postoperative hospital stay was much shorter than in several previous studies. Except for the three patients who underwent proximal gastrectomy, none developed symptoms like GERD and their quality of life did not decrease over a relatively long-term follow-up, suggesting the importance of preserving the anatomical structure and physical function of the cardia and pylorus. None of our 78 patients with gastric GIST developed tumor recurrence or metastasis after LECS, regardless of risk classification, indicating that total resection of SMTs, including potentially malignant GISTs, by the LECS techniques yields satisfactory surgical outcomes. We found that 50% of tumors classified as moderate or high risk, and most with more than five mitoses per 50 HPFs, were located at the gastric fundus. Patients in moderate- and high-risk categories required adjuvant imatinib<sup>[24]</sup>. We found that two patients had tumors < 5 cm, but more than 10 mitotic figures per 50 HPFs.

LECS can be used for two types of partial gastrectomy. The first consists of laparoscopic wedge resection of gastric SMTs and distal or proximal gastrectomy under endoscopic guidance; and the second consists of laparoscopic cutting of the anterior wall of the stomach, to expose SMTs in the posterior gastric wall, followed by partial resection of the posterior gastric wall. All 101 of our patients with SMTs underwent complete resection, even if the tumors were located in the posterior, the lesser curvature of the stomach or near the cardia or pylorus. The greater curvature of the stomach was detached, the stomach was turned axially, and wedge resection was performed. A good view during this procedure requires that the amount of air in the stomach and peritoneum should be balanced.

LECS is indicated for the removal of SMTs (*e.g.*, leiomyomas, lipomas, and schwannomas), polyps with broad stalks, gastric epithelial tumor degeneration (moderate or severe atypical hyperplasia), lesions with low potential for malignancy (*e.g.*, carcinoid tumors and GISTs), and early-stage, localized gastric carcinomas<sup>[25]</sup>. Because GISTs may easily rupture during laparoscopic surgery, resulting in peritoneal seeding, the integrity of a resected GIST is regarded as a significant prognostic factor. Before 2007, the guidelines of the National Comprehensive Cancer Network did not recommend laparoscopic surgery for GIST resection, except for tumors < 2 cm in diameter and with a low risk of rupture. Although almost one-third of the tumors in this study were > 2 cm in diameter, LECS was successful for all tumors, regardless of tumor size. These findings indicate that the performance of laparoscopic and endoscopic techniques by skilled operators, non-contact with the tumor during surgery, and the use of a specimen retrieval bag are key factors for good surgical results. Tumors > 5 cm in diameter require resection of a relatively large portion of healthy stomach to ensure tumor integrity without rupture<sup>[26]</sup>.

This study had several limitations, including its retrospective design and lack of comparisons with open or laparoscopic surgery. Prospective, multicenter, compara-

tive studies are needed to evaluate the role of LECS for gastric SMT.

In conclusion, we have shown here that LECS is a safe, easy, and beneficial procedure for gastric SMTs. Endoscopy functions to locate the tumor and to support the gastric lumen. The LECS technique, therefore, provides an alternative gastric wedge resection procedure with minimal transformation of the stomach.

## COMMENTS

### Background

Although gastric small mucosal tumors (SMT) have been resected laparoscopically, this type of surgery is associated with two potential problems. Laparoscopy may be unable to determine the location of gastric SMTs, because of their small size or intraluminal growth pattern. In addition, complications may arise during the laparoscopic removal of SMTs located near the cardia or pylorus; these complications can include stenosis or damage to the cardia or pylorus.

### Research frontiers

Laparoscopic-endoscopic cooperative surgery (LECS) is indicated for the removal of SMTs (*e.g.*, leiomyomas, lipomas, and schwannomas), polyps with broad stalks, gastric epithelial tumor degeneration (moderate or severe atypical hyperplasia), lesions with low potential for malignancy (*e.g.*, carcinoid tumors and gastrointestinal stromal tumors), and early-stage, localized gastric carcinomas.

### Innovations and breakthroughs

The authors have developed a technique, called minimally invasive LECS, for removal of SMTs. This paper represents the analysis of findings in 101 patients who successfully underwent LECS for gastric SMT at the Department of General Surgery, Peking Union Medical College Hospital, from June 2006 to April 2013.

### Applications

The study results suggest that the LECS is feasible and safe for patients with gastric SMT. Endoscopic intraoperative localization and support can help preserve the cardia and pylorus during surgery.

### Terminology

LECS represents a technique, called minimally invasive laparoscopic-endoscopic cooperative surgery for removal of gastric small mucosal tumors.

### Peer review

This is a very interesting paper about laparoscopic-endoscopic surgery for gastric submucosal tumor. In this manuscript, the authors analyzed 101 patients who underwent laparoscopic-endoscopic surgery for gastric submucosal tumor. The authors discussed the safety and advantages of minimally invasive laparoscopic-endoscopic cooperative surgery for gastric submucosal tumor. The clinical data was well collected, and the surgical procedures of the patients were well described. The references are updating.

### Abstract

**AIM:** To study the diagnostic value of immunoglobulin heavy chain (IgH) and T-cell receptor  $\gamma$  (*TCR- $\gamma$* ) gene monoclonal rearrangements in primary gastric lymphoma (PGL).

**METHODS:** A total of 48 patients with suspected PGL at our hospital were prospectively enrolled in this study from January 2009 to December 2011. The patients were divided into three groups (a PGL group, a gastric linitis plastica group, and a benign gastric ulcer group) based on the pathological results (gastric mucosal specimens obtained by endoscopy or surgery) and follow-up. Endoscopic ultrasonography (EUS) and EUS-guided biopsy were performed in all the patients. The tissue specimens were used for histopathological examination and for *IgH* and *TCR- $\gamma$*  gene rearrangement polymerase chain reaction analyses.

**RESULTS:** EUS and EUS-guided biopsy were successfully performed in all 48 patients. In the PGL group ( $n = 21$ ), monoclonal IgH gene rearrangements were detected in 14 (66.7%) patients. A positive result for each set of primers was found in 12 (57.1%), 8 (38.1%), and 4 (19.0%) cases using FR1/JH, FR2/JH, and FR3/JH primers, respectively. Overall, 12 (75%) patients with mucosal-associated lymphoid tissue lymphoma ( $n = 16$ ) and 2 (40%) patients with diffuse large B-cell lymphoma ( $n = 5$ ) were positive for monoclonal IgH gene rearrangements. No patients in the gastric linitis plastica group ( $n = 17$ ) and only one (10%) patient in the benign gastric ulcer group ( $n = 10$ ) were positive for a monoclonal *IgH* gene rearrangement. No *TCR- $\gamma$*  gene monoclonal rearrangements were detected. The sensitivity of monoclonal IgH gene rearrangements was 66.7% for a PGL diagnosis, and the specificity was 96.4%. In the PGL group, 8 (100%) patients with stage IIE PGL ( $n = 8$ ) and 6 (46.1%) patients with stage IE PGL ( $n = 13$ ) were positive for monoclonal *IgH* gene rearrangements.

**CONCLUSION:** *IgH* gene rearrangements may be associated with PGL staging and may be useful for the diagnosis of PGL and for differentiating between PGL and gastric linitis plastica.

**Key words:** Immunoglobulin heavy chain; T-cell receptor  $\gamma$ ; Gene rearrangement; Primary gastric lymphoma; Endoscopic biopsy specimen

**Core tip:** In 2003, a new primer system was successfully developed and standardized for the detection of clonally rearranged immunoglobulin (Ig) and T-cell receptor (*TCR*) genes. This study was a prospective analysis of Ig heavy chain (*IgH*) and *TCR- $\gamma$*  gene rearrangements using the new primer system and endoscopic biopsy specimens from patients with suspected primary gastric lymphoma (PGL). Our study revealed that the detec-

tion of monoclonal *IgH* gene rearrangements is useful for the diagnosis of PGL and for differentiating between PGL and gastric linitis plastica. Monoclonal *IgH* gene rearrangements may be associated with PGL staging. The sensitivity and the specificity of *IgH* gene rearrangements for the diagnosis of PGL were 66.7% and 96.4%, respectively.

Clonal immunoglobulin heavy chain and T-cell receptor  $\gamma$  gene rearrangements in primary gastric lymphoma. *World J Gastroenterol* 2013; 19(34): 5727-5731 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i34/5727.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i34.5727>

## INTRODUCTION

Primary gastric lymphoma (PGL) is a relatively rare tumor type that accounts for 5% of all gastric tumors<sup>[1]</sup>. Gastroscopy and biopsy are the primary methods for diagnosis. However, most PGLs arise in the submucosa, and the diagnosis of PGL by gastroscopy and biopsy is often difficult. An endoscopic presentation of polypoid lesions, flat lesions, enlarged gastric folds, ulcers, erosions, and negative or inconclusive histology may lead clinicians to suspect gastric lymphoma<sup>[2-8]</sup>. It is recommended that biopsy specimens undergo histomorphological, immunohistochemical, and immunophenotypic analyses for a diagnosis of gastric lymphoma. However, these methods may not lead to a diagnosis, especially in the early stages of the disease.

Immunoglobulin (Ig) and T cell receptors (TCRs) are the molecules responsible for B- and T-cell immune responses. The analysis of antigen receptor gene rearrangements by polymerase chain reaction (PCR) is a routine diagnostic tool for lymphoproliferative disorders<sup>[9]</sup>.

Previous studies have demonstrated that Ig gene rearrangements in endoscopic biopsy samples were an additional tool for the diagnosis of gastric mucosal-associated lymphoid tissue (MALT) lymphoma<sup>[10-15]</sup>. In previous studies, the primers and PCR conditions were not standardized. Multiplex PCR assays have been available since 2003, and these assays have been standardized for the detection of clonally rearranged *Ig* and *TCR* genes<sup>[16]</sup>. However, multiplex PCR assays for the detection of Ig heavy chain (*IgH*) and *TCR- $\gamma$*  gene rearrangements in PGL have not been previously reported. The aim of this study was to investigate the detection rate and the diagnostic value of *IgH* and *TCR- $\gamma$*  gene monoclonal rearrangements in PGL endoscopic biopsy specimens.

## MATERIALS AND METHODS

### Patients

A total of 48 patients with suspected PGL at our hospital were prospectively enrolled in this study from January 2009 to December 2011. The patients were divided into three groups based on the pathological results (gastric

mucosal specimens obtained by endoscopy or surgery) and follow-up. The PGL group consisted of 21 patients (14 males, 7 females, a mean age of 51 years, range 20-81 years). The gastric linitis plastica group consisted of 17 patients (11 males, 6 females, a mean age of 53 years, range 17-79 years). The benign gastric ulcer group consisted of 10 patients (7 males, 3 females, a mean age of 47 years, range 22-76 years).

### Methods

Patients who met the criteria for suspected gastric lymphoma (an endoscopic presentation of polypoid lesions, flat lesions, enlarged gastric folds, ulcers, erosions, and negative or inconclusive histology) were included in the study. Patients with palpable superficial lymphadenopathy, obvious mediastinal lymphadenopathy, abnormal total and differential white blood cell counts, and the involvement of other organs in the abdomen were excluded from the study.

Informed consent was obtained from all the patients and this study was approved by the hospital before endoscopic ultrasonography (EUS) and the medical records analysis. EUS and EUS-guided biopsy were performed in all the patients. Overall, 8-10 biopsies were obtained from each patient. The specimens were submitted for histopathological examination. A portion of each specimen was stored at -80 °C for the gene rearrangement analysis by PCR.

DNA was isolated from frozen tissue by cell lysis, phenol extraction, and ethanol precipitation according to standard procedures. Alternatively, reactive DNAzol (Songon Biotech, Shanghai, China) was used according to the manufacturer's specifications. In each experiment, polyclonal DNA (reactive lymphoid tissue) and negative (sterile water) and positive controls were systematically included. To analyze the *IgH* gene, three sets of VH primers and one JH consensus primer were combined in three multiplex tubes. To analyze the *TCR- $\gamma$*  gene, four V $\gamma$  primers and two J $\gamma$  primers were divided into two tubes (Table 1).

The PCR conditions were  $\times$  1 PCR buffer [50 mmol/L KCl, 10 mmol/L Tris (pH, 8.3), 1.5 mmol/L MgCl<sub>2</sub>], 200  $\mu$ mol/L of each deoxynucleotide, 10 pmol of each primer, and 2 U of Taq polymerase (Songon Biotech, Shanghai, China). The total PCR reaction volume was 50  $\mu$ L. The thermal cycling conditions were pre-activation for 7 min at 95 °C, followed by annealing at 60 °C. Each reaction consisted of 35 cycles. The cycles were preceded by an initial denaturation step for 45 s, followed by a terminal extension for 10 min.

Patients with PGL were staged at baseline using computed tomography scans of the neck, the thorax, and the abdomen, followed by EUS and bone marrow biopsy. EUS staging was performed according to the Ann Arbor staging system<sup>[10]</sup>.

## RESULTS

EUS and EUS-guided biopsy were successfully performed in all 48 patients. In the PGL group, monoclonal

The detection of immunoglobulin heavy chain (*IgH*) gene rearrangement using three sets of VH primers and one JH consensus primer combined in three multiplex tubes. The detection of T-cell receptor  $\gamma$  (*TCR- $\gamma$* ) gene rearrangement using four V $\gamma$  primers and two J $\gamma$  primers, which were divided into two tubes.

*IgH* gene rearrangements were detected in 14 (66.7%) patients. Positive results for each set of primers were obtained in 12 (57.1%), 8 (38.1%), and 4 (19.0%) cases using FR1/JH, FR2/JH, and FR3/JH primers, respectively (Figure 1). No patients in the gastric linitis plastica group were positive for a monoclonal *IgH* gene rearrangement. In the benign gastric ulcer group, a monoclonal *IgH* gene rearrangement was detected in one (10%) patient. Overall, no *TCR- $\gamma$*  gene monoclonal rearrangements were detected. For the diagnosis of primary gastric lymphomas, the sensitivity of the monoclonal *IgH* gene rearrangements was 66.7% and the specificity was 96.4%.

In the PGL group, the clinical stage distribution was as follows: IE in 13 patients and IIE in 8 patients. All 8 (100%) patients with stage IIE PGL were positive for monoclonal *IgH* gene rearrangements. Additionally, 6 (46.1%) patients with stage IE PGL were positive for monoclonal *IgH* gene rearrangements. The PGL group consisted of 16 patients with MALT lymphoma and 5

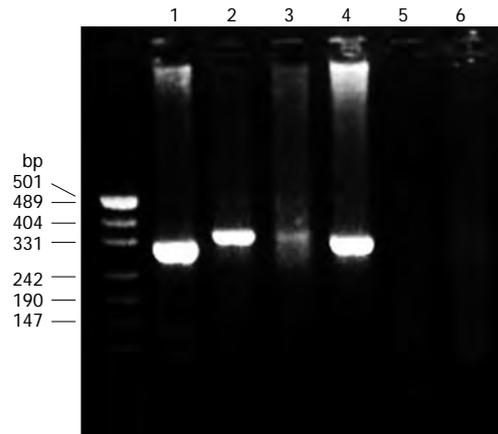

Figure 1 The results of immunoglobulin heavy chain gene rearrangement using FR1/JH primers. Lanes 1, 5, and 6 indicate a positive B-cell gastric lymphoma cell line, a negative control (sterile water), and a polyclonal control, respectively. Lanes 2, 3, and 4 show the presence of a monoclonal rearranged band that is within the expected range of size (242-331 bp).

patients with diffuse large B-cell lymphoma (DLBCL). In the patients with MALT lymphomas, 12 (75%) were positive for monoclonal *IgH* gene rearrangements. In the patients with DLBCL, 2 (40%) were positive for monoclonal *IgH* gene rearrangements.

In the benign gastric ulcer group, patients were treated with a proton-pump inhibitor (esomeprazole 20 mg daily) for 8-16 wk. Repeated endoscopies revealed that the gastric ulcers were completely healed in all the patients. All the patients were followed up for 12-18 mo, and no malignant gastric lesions were found.

## DISCUSSION

Antigen receptor gene rearrangement in lymphocytes is a physiological process. Tumor cells that originate from lymphocytes often carry the same *Ig* and *TCR* gene rearrangements (monoclonal), whereas T and B cells have a unique type of rearrangement in benign lymphoid disorders (polyclonal). Antigen receptor gene rearrangement analysis is useful in differentiating between malignant lymphoproliferative disorders and non-neoplastic lymphoid disorders. There are several PCR targets for the detection of *Ig* and *TCR* rearrangements. Three multiplex PCR assays are available for the detection of clonal *IgH* (VH-JH) rearrangements, and these assays can reliably identify clonal B-cell proliferation and *TCR- $\gamma$*  gene monoclonal rearrangements that occur in most T-cell lymphoid neoplasms<sup>[10]</sup>. *IgH* (VH-JH) and *TCR- $\gamma$*  are the most common PCR targets for detecting *Ig* and *TCR* rearrangements.

In the PGL group, the positive rate of monoclonal *IgH* gene rearrangement in patients with stage IIE PGL was 100% but only 46.1% in patients with stage IE PGL. Previous studies have demonstrated that the positive rate of monoclonal *IgH* gene rearrangements was associated with histological grading (the histological grading of lymphoid infiltrates in the stomach according to the Wother-

spoon-Isaacson histological scoring system). Aiello *et al*<sup>[10]</sup> reported that monoclonal *IgH* gene rearrangements were detected in 64.2%, 41.6%, and 3.1% of samples with histological grading scores of 5, 4, and 0-3, respectively. Additionally, the results of this study suggest that the positive rate of monoclonal *IgH* gene rearrangements may be associated with PGL staging.

In the PGL group, 75% (12/16) of MALT lymphoma patients were positive for monoclonal *IgH* gene rearrangements. However, only 40% (2/5) of DLBCL patients were positive for monoclonal *IgH* gene rearrangements. A previous study reported that the positive rate of monoclonal *IgH* gene rearrangements in MALT lymphoma patients ranged from 62.5%-98.5%<sup>[10-13]</sup>. In the series in this study, a similar rate was observed for monoclonal *IgH* gene rearrangements in MALT lymphoma patients. Thériault *et al*<sup>[17]</sup> reported that the positive rate of monoclonal *IgH* gene rearrangements in DLBCL patients was 78.9% (30/38). However, the specimens in the study included lymph nodes, tonsils, spleens, bone marrow, skin biopsies, and gastrointestinal tract samples. In this study, the positive rate for DLBCL patients was lower than that in the previous study. In addition, recent studies have demonstrated that the detection rate of monoclonal *IgH* gene rearrangement was closely associated with the cell origin of lymphomas<sup>[9]</sup>.

The differential diagnosis between gastric linitis plastica and PGL is not easy for a physician to determine. PGL and gastric linitis plastica usually result in low rates of positive endoscopic biopsies<sup>[18]</sup>. In this series, the first endoscopic biopsies from PGL and gastric linitis plastica patients were all negative. The distinction between PGL and gastric linitis plastica is important because of the different prognoses of these diseases. In this study, 14 (66.7%) patients in the PGL group were positive for a monoclonal *IgH* gene rearrangement; however, no *IgH* gene rearrangements were detected in the patients in the gastric linitis plastica group. One case of gastric cancer was positive for a monoclonal *IgH* gene rearrangement. The patient was diagnosed with carcinoma accompanied by lymphoma<sup>[12]</sup>. This result suggests that the detection of *IgH* gene rearrangements may be helpful in differentiating between PGL and gastric linitis plastica.

According to previous studies, monoclonal rearrangements involving *IgH* genes were detected in 3% of lymphoid disorders that were benign based on clinical and immunohistological evaluations, which is consistent with the findings of this study<sup>[19]</sup>. The majority of these patients suffered from autoimmune diseases, including rheumatoid arthritis, systemic lupus erythematosus, and Sjögren's syndrome. These diseases are characterized by polyclonal B-cell activation and autoantibodies<sup>[20]</sup>. In the series in this study, a monoclonal *IgH* gene rearrangement was detected in one patient who was suffering from a benign gastric ulcer. Additionally, this patient had suffered from Sjögren's syndrome for several years.

Gene rearrangement studies can be informative; however, false-positive and false-negative PCR results are problematic. According to previous studies, there are two

main problems with PCR techniques: improper primer annealing and difficulties in discriminating between monoclonal and polyclonal *Ig/TCR* gene rearrangements<sup>[16,21,22]</sup>. Single-strand conformation polymorphism analysis, denaturing gradient gel electrophoresis, heteroduplex analysis, or gene scanning may be performed to reduce false-positive and false-negative rates<sup>[16,23-26]</sup>.

In this study, there was one patient with false-negative results in the PGL group. The three endoscopic biopsies for this patient were negative, but the PCR results for a monoclonal *IgH* gene rearrangement were always positive. Autoimmune diseases were excluded. The patient was followed up for 7 mo and was diagnosed with PGL based on the fourth endoscopic biopsy. In addition, Fend *et al*<sup>[14]</sup> reported that the detection of clonal rearrangements in the biopsy specimens from two patients preceded the histological diagnosis of lymphoma by several mo. Because the detection of clonal rearrangements can precede a histological diagnosis, we suggest that patients with suspected PGL and positive results for *IgH* rearrangements need close follow-up.

In conclusion, the presence of an *IgH* gene rearrangement is useful for the diagnosis of PGL and for differentiating between PGL and gastric linitis plastica. Additionally, *IgH* gene rearrangements may be associated with PGL staging.

## COMMENTS

### Background

Primary gastric lymphoma (PGL) is a relatively rare tumor type. The diagnosis of PGL by gastroscopy and biopsy is often difficult. The analysis of antigen receptor gene rearrangements by polymerase chain reaction is a routine diagnostic tool for lymphoproliferative disorders. Previous studies have demonstrated that the positive rate of gene rearrangement was relatively high in PGL patients; however, no prospective studies of gene rearrangement in PGL patients have been reported.

### Research frontiers

Studies are being performed to assess the diagnostic value of immunoglobulin heavy chain (*IgH*) and T-cell receptor  $\gamma$  (*TCR-\gamma*) gene monoclonal rearrangements in PGL patients.

### Innovations and breakthroughs

This study was a prospective analysis of *IgH* and *TCR-\gamma* gene rearrangements in endoscopic biopsy specimens from patients with suspected PGL. According to the pathological results, 48 patients with suspected PGL were divided into three groups, including a PGL group, a gastric linitis plastica group, and a benign gastric ulcer group. The study revealed that the detection of monoclonal *IgH* gene rearrangements is useful for the diagnosis of PGL and for differentiating between PGL and gastric linitis plastica. Additionally, these gene rearrangements may be associated with PGL staging.

### Applications

The results of this study may encourage the detection of *IgH* gene rearrangements for a diagnosis of PGL and for differentiating between PGL and gastric linitis plastica.

### Terminology

Antigen receptor gene rearrangement is a physiological process. Tumor cells that originate from lymphocytes often carry the same *IgH* and *TCR* gene rearrangements (monoclonal), whereas T and B cells have a unique type of rearrangement in benign lymphoid disorders (polyclonal). Antigen receptor gene rearrangement analysis is useful in differentiating between malignant lymphoproliferative disorders and non-neoplastic lymphoid disorders.

### Peer review

This paper includes interesting results and presents an acceptable case for publication because few reports have been published on this subject in China.

Then, the findings were compared with the postoperative pathological results.

**RESULTS:** Among 605 lymph nodes, 358 were confirmed as metastatic, accounting for 59.2%. A total of 535 lymph nodes were detected in original axis images combined with multiplanar reconstruction images of MSCT. The metastatic lymph nodes had specific signs in computed tomography. This study showed that the long diameter of lymph nodes  $\geq 8$  mm indicated metastasis; the sensitivity and specificity were 79.6% and 78.8%, respectively. The difference of the mean value of lymph node enhancement density  $\geq 80$  Hu indicated metastasis; the sensitivity and specificity were 81.6% and 75.6%, respectively. The ratio of short diameter to long diameter of lymph nodes  $\geq 0.7$  indicated metastasis; the sensitivity and specificity were 85.6% and 71.8%, respectively.

**CONCLUSION:** MSCT is a non-invasive and reliable method for preoperative examination of gastric cancer. Sensitivity and specificity for prediction of lymph node metastasis are high.

### Abstract

**AIM:** To evaluate the application value of multi-slice spiral computed tomography (MSCT) for imaging determination of metastatic lymph nodes of gastric cancer and to explore reasonable diagnostic criteria.

**METHODS:** Sixty patients with gastric cancer underwent 64 MSCT scans before operation. Gastric cancer samples and perigastric lymph nodes were obtained after operation, formalin fixation and haematoxylin-eosin staining. The metastatic conditions of gastric cancer and perigastric lymph nodes were determined under a light microscope. A total of 605 lymph nodes were grouped and assessed according to distribution, size, shape and degree of lymph node enhancement.

**Core tip:** Gastric cancer is one of the most common malignant tumours of the digestive system. In recent years, individualised surgical therapy has been applied for gastric cancer. This study plan explored the distribution, size, shape and enhancement characteristics of metastatic lymph nodes. It also provided a basis for determining lymph node metastasis before surgery by retrospectively analyzing multi-slice spiral computed tomography manifestations of lymph nodes of patients with gastric cancer after surgery in the hospital. The

findings were compared with the pathological results.

Dai CL, Yang ZG, Xue LP, Li YM. Application value of multi-slice spiral computed tomography for imaging determination of metastatic lymph nodes of gastric cancer. *World J Gastroenterol* 2013; 19(34): 5732-5737 Available from: URL: <http://www.wjg-net.com/1007-9327/full/v19/i34/5732.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i34.5732>

## INTRODUCTION

Gastric cancer is one of the most common malignant tumours of the digestive system. In recent years, individualised surgical therapy has been applied for gastric cancer. The choice of reasonable surgical methods for different stages of gastric cancer depends on accurate preoperative diagnosis. The traditional diagnostic methods of gastric cancer include gastrofiberscope and barium meal of the upper gastrointestinal tract. However, these two methods have certain limitations in the diagnosis of gastric cancer. They cannot clearly display the gastric wall structure, and their ability to determine the presence or absence of adjacent organ invasion, distant metastasis and lymph node metastasis is limited. Multi-slice spiral computed tomography (MSCT) has been used to conduct TM preoperative staging among many patients with gastric cancer in recent years. Original axial images combined with multiplanar reconstruction (MPR) reorganised images are used to carry out preoperative assessment. The assessment includes the location, extent, depth of invasion of gastric cancer, relationship with adjacent organs and metastasis of abdominal organs. Satisfactory results have been achieved. Research on lymph node metastasis of gastric cancer before surgery has shown that a unified standard for determining lymph node metastasis by MSCT is not available worldwide. Lymph node metastasis is a major metastatic mechanism of gastric cancer. Seto *et al*<sup>[1]</sup> reported that the rate of lymph node metastasis of early gastric cancer is 5.7%-29.0%, and the rates are 0.0%-6.4% and 9.7%-24.3% for early gastric intramucosal carcinoma and gastric submucosal carcinoma, respectively. Yasuda *et al*<sup>[2]</sup> showed that the rate of lymph node metastasis of early gastric cancer is 8.9%, and the rates are 2.5% and 17.6% for early gastric intramucosal carcinoma and gastric submucosal carcinoma, respectively. Okusa *et al*<sup>[3]</sup> proposed the concept of metastatic lymph node ratio (MLR). The results of numerous studies worldwide<sup>[4,5]</sup> have shown that MLR is one of the independent prognostic factors of survival of patients with gastric cancer, which is closely correlated with the five-year survival rate of patients with gastric cancer. Both the Union for International Cancer Control (UICC) and the Japanese General Rules for Gastric Cancer Study consider that lymph node metastasis is an independent and important factor for predicting the prognosis of patients with gastric cancer<sup>[6,7]</sup>. To date, radical gastrectomy of

gastric cancer with radical lymph node excision adjacent to the stomach has achieved better therapeutic effects in the surgical therapy of gastric cancer<sup>[8]</sup>. The presence or absence of lymph node metastasis, as well as the degree and extent of metastasis, is directly correlated with the choice of therapeutic methods and prognostic evaluation of patients with gastric cancer, which are primary indices for surgical approach selection. Radical excision of metastatic lymph nodes has important clinical significance and prognostic value in patients with gastric cancer. Radical excision of metastatic lymph nodes may affect the immune function in patients and lead to increased surgical trauma, which cannot improve curative effect. Therefore, confirming the presence or absence of lymph node metastasis of gastric cancer before surgery is important for preoperative staging, formulation of clinical therapeutic schedule and prognosis evaluation<sup>[9]</sup>. MSCT has the advantages of rapid scanning speed, high resolution ratio and convenient image reconstruction, which can estimate lymph nodes by thin-layer scanning and reconstruction technique and direct clinical staging<sup>[10-12]</sup>. The standard for determining metastasis of lymph nodes by enhancement characteristics and lymph node size displayed by MSCT is the focus of studies and controversies among many researchers. Too high or too low MSCT staging may appear during clinical application because of different standards of size and morphology of lymph nodes and different sizes of lymph nodes in different positions<sup>[13]</sup>. Thus, this study plan explored the distribution, size, shape and enhancement characteristics of metastatic lymph nodes. It also provided a basis for determining lymph node metastasis before surgery by retrospectively analyzing MSCT manifestations of lymph nodes of patients with gastric cancer after surgery in the hospital. The findings were compared with the pathological results.

## MATERIALS AND METHODS

### Objectives

Sixty patients with gastric cancer who were hospitalised in the First Affiliated Hospital of Jilin University and underwent MSCT scanning before operation from February 2010 to October 2011 were included the study. The patients comprised 48 male and 12 female with a mean age of 59.5 years (36-78 years). A total of 51 patients were confirmed to have metastatic lymph nodes of gastric cancer after operation, whereas no metastatic lymph nodes were observed in nine patients. The histopathological types included poorly differentiated adenocarcinoma (39 patients), moderately differentiated tubular adenocarcinoma (17 patients) and signet-ring cell carcinoma (4 patients).

### Methods

All the patients were asked to fast for 6-8 h before scanning. They were treated with intramuscular injection of 654-2 (20 mg) and oral administration of warm water 10 min before scanning. The patients were scanned in

supine position using 64-MSCT (Siemens, Germany). Scanning parameters were as follows: spiral collimation,  $64 \times 0.625$ ; thickness of every layer, 5 mm; interval thickness of every layer, 5 mm; speed of bed movement, 12 mm/s; tube voltage, 120 kV and tube current, 260-320 mAs. During plain, arterial and venous scanning phases, the extent of scanning was from the lower oesophagus to the level of inferior pole of kidney, including the whole gastric area. During equilibrium phase, the extent of scanning was from the diaphragmatic dome to the pelvic cavity. Each scan was performed during a breath hold at the end of inspiration. Anconal venous transfusion of non-ionic contrast medium (OmniPaque 300 or Ultravist 300; 80-100 mL) with high pressure injector was used during the enhanced scanning. The rate of injection was 3.0 mL/s, and the starting times of arterial scanning, venous scanning and equilibrium phases were 25, 35 and 60 s after the beginning of injection. After scanning, the original data were treated with thin-slice reconstruction (1 mm; the interval between two adjacent slices was 1 mm). The images of all patients underwent MPR.

### Image analysis

Two doctors with years of experience on abdominal image diagnosis analysed and treated the images. According to anatomic sites, original axis images combined with MPR were applied to observe various indices of lymph nodes, including distribution, number, size, shape and degree of lymph node enhancement.

### Evaluation of results

Evaluation criteria of CT signs: The lymph nodes were divided into three groups according to the long diameter:  $\geq 5$  mm group,  $\geq 8$  mm group and  $\geq 10$  mm group. Ten points of non-cystic area in each detected lymph node were randomly selected in MSCT. The mean difference of CT value during venous scanning phase and plain scanning was measured. Then, the lymph nodes were divided into three groups according to the degree of enhancement: the difference of mean value of enhancement density  $\geq 100$  Hu group,  $\geq 80$  Hu group and  $\geq 40$  Hu group. The lymph nodes were divided into two groups according to the ratio of short diameter to long diameter:  $\geq 0.5$  group and  $\geq 0.7$  group.

### Pathological criteria

Gastric cancer samples and perigastric lymph nodes were obtained after operation, formalin fixation and haematoxylin-eosin staining. The metastatic conditions of gastric cancer and perigastric lymph nodes were determined under a light microscope.

### Statistical analysis

All the data were analysed using SPSS17.0 software. *K* test was used to evaluate the consistency of metastatic lymph nodes of gastric cancer between MSCT and postoperative pathological diagnosis. Kappa coefficient within 0.71-1.00, 0.41-0.70 and  $\leq 0.4$  indicated strong, general

and weak consistencies, respectively.

## RESULTS

Comparison of different long diameters of lymph nodes displayed by MSCT and postoperative pathological results for determination of lymph node metastasis.

A total of 605 lymph nodes were cleaned up in the operation, among which 358 were diagnosed as metastatic by postoperative pathological examination, accounting for 59.2%. Original axis images combined with MPR images found 535 lymph nodes. The lymph nodes could be analysed and determined with a group of lymph nodes as a unit in MSCT images because the lymph nodes were excised with a group as a unit instead of surgically operated, according to the images. A single lymph node could not be specifically studied. Thus, the ability of MSCT to determine the specificity and sensitivity of lymph nodes could be improved as a whole in the study. The data from the different groups were compared with the pathological results. The consistency of lymph node diameter  $\geq 5$  mm and the postoperative pathological results was general ( $K = 0.464$ ). The consistency of lymph node diameter  $\geq 8$  mm and the postoperative pathological results was strong ( $K = 0.831$ ). The consistency of lymph node diameter  $\geq 10$  mm and the postoperative pathological results was weak ( $K = 0.232$ ) (Table 1).

Comparison of different degrees of lymph node enhancement displayed by MSCT and postoperative pathological results for determination of lymph node metastasis.

The consistency of the difference of the mean value of enhancement density  $\geq 80$  Hu and the postoperative pathological results was strong ( $K = 0.849$ ). The consistency of the difference of the mean value of enhancement density  $\geq 100$  Hu and the postoperative pathological results was weak. The consistency of the difference of the mean value of enhancement density  $\geq 40$  Hu and the postoperative pathological results was weak ( $K < 0.40$ ) (Table 1).

Comparison of different ratios of short diameter to long diameter of lymph nodes displayed by MSCT and postoperative pathological results for determination of lymph node metastasis.

The consistency of the ratio of short diameter to long diameter of lymph nodes  $\geq 0.7$  and the postoperative pathological results was strong ( $K = 0.873$ ). The consistency of the ratio of short diameter to long diameter of lymph nodes  $> 0.5$  and the postoperative pathological results was general ( $K = 0.513$ ) (Table 1).

The diagnostic criteria of metastatic lymph nodes in MSCT for patients with gastric cancer included long diameter of lymph nodes  $\geq 8$  mm, the ratio of short diameter to long diameter of lymph nodes  $\geq 0.7$  and the difference of the mean value of enhancement density  $\geq 80$  Hu. Compared with the postoperative pathological results, the sensitivities and specificities of MSCT for detection of lymph nodes adjacent to the celiac artery and lesser curvature were 89.4% and 90.3%, respectively. The

**Table 1 Comparison of different long diameters of lymph nodes displayed, degrees of lymph node enhancement displayed and ratios of short diameter to long diameter of lymph nodes displayed by multi-slice spiral computed tomography and postoperative pathological results for determination of lymph node metastasis**

		Number of lymph nodes detected by MSCT	K value	Sensitivity	Specificity
Diameter of lymph nodes	≥ 5 mm	470	0.464	88.5%	60.1%
	≥ 8 mm	317	0.831	79.6%	78.8%
	≥ 10 mm	128	0.232	48.6%	93.5%
Difference of enhancement of lymph nodes	≥ 40 Hu	495	0.397	89.3%	65.5%
	≥ 80 Hu	379	0.849	81.6%	75.6%
	≥ 100 Hu	197	0.335	53.8%	95.5%
Ratio of short diameter to long diameter of lymph nodes	≥ 0.5	447	0.513	94.3%	57.3%
	≥ 0.7	375	0.873	85.6%	71.8%

MSCT: Multi-slice spiral computed tomography.

**Table 2 Comparison of sensitivities and specificities of metastatic lymph nodes in different groups displayed by multi-slice spiral computed tomography**

Positions of lymph nodes	Specificity	Sensitivity
Right area of cardiac orifice	79.2%	57.8%
Left area of cardiac orifice	81.3%	73.5%
Lesser curvature	79.6%	90.3%
Greater curvature	87.5%	45.0%
Superior area of pylorus	88.1%	76.7%
Inferior area of pylorus	78.0%	81.9%
Adjacent to left gastric artery, common hepatic artery, and arteria coeliaca	83.2%	89.4%

detection rates of lymph nodes in the right area of the cardiac orifice and adjacent to the greater curvature were 57.8% and 45.0%, respectively (Table 2).

## DISCUSSION

Tumour-node-metastasis staging system is one of the most commonly used staging systems, and is accepted and maintained by the UICC and the American Joint Committee on Cancer<sup>[14]</sup>. Lymph node metastasis is a major metastatic pathway of gastric cancer. The metastatic rates of lymph nodes in gastric cancer at early and progressive stages are 10% and 74.8%, respectively<sup>[15]</sup>. The lymph node size determines the lymph node metastasis. Lymph node diameter > 10 mm is used as one of the criteria to diagnose lymph node metastasis of gastric cancer by MSCT. Some researchers have suggested that the lymph node diameter > 5 mm can be used as a criterion of lymph node metastasis of gastric cancer<sup>[16,17]</sup>. Dux proposed that all the lymph nodes detected by MSCT could be considered as lymph node metastasis. Some researchers have considered that the short diameter of perigastric lymph nodes > 6 mm or the short diameter of lymph nodes adjacent to the stomach > 8 mm should be regarded as metastasis<sup>[18]</sup>. Moreover, other researchers believe that determining lymph node metastasis by imaging is not sufficient because the sensitivity of revealing small lymph nodes by imaging is low. This study selected 5, 8 and 10 mm (long diameter of lymph nodes) as threshold values of lymph node metastasis, and then a comparative

study was performed. The long lymph node diameter of 8 mm was determined as the threshold value of lymph node metastasis after statistical analysis. Compared with the postoperative pathological results, the sensitivity and specificity were more reasonable.

The degree of lymph node enhancement is an important index to determine lymph node metastasis. The perigastric lymph nodes have a specific blood supply, and this blood supply is abundant when metastasis of lymph nodes occurs. After MSCT enhancement, obvious lymph node enhancement is displayed, but the non-metastatic lymph nodes exhibit absence of enhancement or mild enhancement. Fukuya *et al.*<sup>[9]</sup> posited that high density or peripheral high density and central low density of metastatic lymph nodes of gastric cancer show moderate or obvious enhancement, but non-metastatic lymph nodes show no enhancement or mild enhancement. Some researchers believe that CT value ≥ 25 Hu during plain scanning phase, CT value ≥ 70 Hu during arterial scanning phase or CT value ≥ 80 Hu during venous scanning phase is a criterion of positive lymph nodes, which can significantly improve the diagnostic rate of lymph node metastasis<sup>[20,21]</sup>. In this study, the consistency of the difference of the mean value of enhancement density ≥ 80 Hu and the postoperative pathological results was strong ( $K = 0.849$ ). The sensitivity and specificity were 81.6% and 75.6%, respectively. Selecting 80 Hu is recommended to determine the threshold value of metastatic lymph nodes of gastric cancer.

The morphology of lymph nodes displayed by MSCT is also an important index to determine lymph node metastasis. Certain exogenous and expansible growth characteristics are shown in lymph nodes when lymph node metastasis occurs. These characteristics contribute to the round or oval morphology of lymph nodes, and the expansible growth of lymph nodes is not balanced so the margin of metastatic lymph nodes is irregular and appears blurred. Thus, the morphology of lymph nodes is one of the references in determining lymph node metastasis by imaging. Fukuya *et al.*<sup>[9]</sup> posited that the ratio of short diameter to long diameter of lymph node metastasis of gastric cancer was  $(0.81 \pm 0.15)$ , but the ratio of short diameter to long diameter of lymph node metastasis of gastric cancer was  $(0.57 \pm 0.15)$ . This study showed

that the consistency of the ratio of short diameter to long diameter of lymph nodes  $\geq 0.7$  and the postoperative pathological results was strong ( $K = 0.873$ ). When the ratio of short diameter to long diameter of lymph node metastasis of gastric cancer  $\geq 0.7$  was selected as a criterion, the sensitivity and specificity were 85.6% and 71.8%, respectively. This result showed that the ratio of short diameter to long diameter of lymph node metastasis of gastric cancer  $\geq 0.7$  in MSCT is more reasonable as a criterion.

The detection rate of lymph nodes in MSCT is correlated with the location of lymph nodes. Some studies have reported that the detection rates of MSCT for mesenteric lymph nodes and lymph nodes adjacent to the aorta were the highest, followed by the lymph nodes adjacent to the lesser curvature and celiac artery. The detection rates of MSCT for lymph nodes adjacent to the ligamentum hepatoduodenale and common hepatic artery were relatively low, and the detection rate of MSCT for lymph nodes adjacent to the nidi was low<sup>[6]</sup>. The statistical results of the study showed that the sensitivities of MSCT for lymph nodes adjacent to the celiac artery and lesser curvature were 89.4% and 90.3%, respectively. However, the detection rates of MSCT for lymph nodes adjacent to the right area of cardiac orifice and greater curvature were relatively low, especially the lymph nodes adjacent to the greater curvature (45.0%). These results were attributed to the lymph nodes adjacent to the lesser curvature, which were near the stomach wall. The lymph nodes showed soft tissue density; after filling the stomach with water, the lymph nodes were easily foiled. The lymph nodes adjacent to the celiac artery were near the vessels, and lymph node enhancement and vascular enhancement were not significantly co-gradient. They were easily distinguished according to density; thus, the sensitivity of lymph nodes adjacent to the celiac artery was high. The perigastric fat content is one of the important factors affecting the detection rate of lymph nodes by MSCT. In this study, the stomachs of the patients were filled after drinking water, thereby reducing the fat adjacent to the greater curvature and surrounding organs. This phenomenon caused the surrounding lymph nodes not to be displayed, which was one of the main reasons for the low detection rate of lymph nodes adjacent to the greater curvature. In addition, the resolution ratio of MSCT for lymph nodes adjacent to the pancreas was relatively low because most of the patients with gastric cancer were elderly. Their pancreas atrophied, showing nodositas. The densities of lymph nodes adjacent to the pancreas during plain scanning and enhancement scanning were similar to the density of pancreatic substance. The lymph nodes were easily diagnosed as swelling lymph nodes, so determining swelling lymph nodes adjacent to the pancreas by MSCT has a certain limitation.

In conclusion, conducting MSCT examination before operation among patients with gastric cancer, as well as observing and measuring the size, degree of enhancement and morphology of lymph nodes, is helpful in

determining lymph node metastasis before operation. The results will provide references for staging of gastric cancer before operation and for choosing a therapeutic schedule.

## COMMENTS

### Background

Lymph node metastasis is the most important metastatic methods of gastric cancer; it is also one of the important factors affecting the prognosis of patients. The presence or absence of lymph node metastasis, as well as the degree and extent of metastasis, is directly correlated with the choice of therapeutic methods and prognostic evaluation of gastric cancer. Considerable studies exist on predicting lymph node metastasis of gastric cancer before surgery by multi-slice spiral computed tomography (MSCT). A number of predictive criteria are available, including distribution, size and enhancement of lymph nodes, but they are not unified and acknowledged diagnostic criteria.

### Research frontiers

MSCT is widely used for diagnosis of preoperative staging of gastric cancer, especially 64-row MSCT or above. This method significantly improves the resolution ratio of images, achieves complete accordance of resolution ratios on axial view, coronal view, sagittal view, inclined plane and curved surface, and provides valuable information for displaying metastatic lymph nodes.

### Innovations and breakthroughs

This study investigated the enhancement characteristics of metastatic lymph nodes displayed by MSCT and the relationship between the size of lymph nodes and metastasis. This research also determined the effects of different positions of lymph nodes on the detection rate of MSCT and the relationship between morphology of lymph nodes and metastasis. Preoperative MSCT scanning is one of the important tools used to evaluate the prognosis of patients with gastric cancer.

### Applications

N-stage and prognostic evaluation of gastric cancer were performed and applied in the First Affiliated Hospital of Jilin University according to the diagnostic criteria of lymph node metastasis of gastric cancer before surgery designed in this study. The accurate rate of preoperative MSCT for evaluation of lymph node metastasis of gastric cancer was high based on the pathological results of more than 60 patients with gastric cancer after surgery.

### Peer review

Application value of multi-slice spiral computed tomography for imaging determination of metastatic lymph nodes of gastric cancer. In this article, authors try to evaluate the application value of multi-slice spiral computed tomography for imaging determination of metastatic lymph nodes of gastric cancer and to explore reasonable diagnostic criteria. As is known, MSCT has been used to conduct TM preoperative staging among many patients with gastric cancer in recent years.

### Abstract

**AIM:** To evaluate the efficacy and tolerability of herbal medicines in inflammatory bowel disease (IBD) by conducting a meta-analysis.

**METHODS:** Electronic databases were searched for studies investigating efficacy and/or tolerability of herbal medicines in the management of different types of IBD. The search terms were: "herb" or "plant" or "herbal" and "inflammatory bowel disease". Data were collected from 1966 to 2013 (up to Feb). The "clinical response", "clinical remission", "endoscopic response", "endoscopic remission", "histological response", "histological remission", "relapse", "any adverse events", and "serious

adverse events" were the key outcomes of interest. We used the Mantel-Haenszel, Rothman-Boice method for fixed effects and DerSimonian-Laird method for random-effects. For subgroup analyses, we separated the studies by type of IBD and type of herbal medicine to determine confounding factors and reliability.

**RESULTS:** Seven placebo controlled clinical trials met our criteria and were included (474 patients). Comparison of herbal medicine with placebo yielded a significant RR of 2.07 (95%CI: 1.41-3.03,  $P = 0.0002$ ) for clinical remission; a significant RR of 2.59 (95%CI: 1.24-5.42,  $P = 0.01$ ) for clinical response; a non-significant RR of 1.33 (95%CI: 0.93-1.9,  $P = 0.12$ ) for endoscopic remission; a non-significant RR of 1.69 (95%CI: 0.69-5.04) for endoscopic response; a non-significant RR of 0.64 (95%CI: 0.25-1.81) for histological remission; a non-significant RR of 0.86 (95%CI: 0.55-1.55) for histological response; a non-significant RR of 0.95 (95%CI: 0.52-1.73) for relapse; a non-significant RR of 0.89 (95%CI: 0.75-1.06,  $P = 0.2$ ) for any adverse events; and a non-significant RR of 0.97 (95%CI: 0.37-2.56,  $P = 0.96$ ) for serious adverse events.

**CONCLUSION:** The results showed that herbal medicines may safely induce clinical response and remission in patients with IBD without significant effects on endoscopic and histological outcomes, but the number of studies is limited to make a strong conclusion.

© 2013 Baishideng. All rights reserved.

**Key words:** Herbal medicine; Inflammatory bowel disease; Efficacy; Relapse; Adverse events; Meta-analysis

**Core tip:** Meta-analysis of seven controlled trials involving 474 patients demonstrated that herbal medicines may safely induce clinical response and remission in patients with inflammatory bowel disease without significant effects on endoscopic and histological outcomes. The results of sub-analyses based on plant

type demonstrated that induction of clinical remission was obtained only by *Artemisia absinthium* and *Boswellia serrata* and induction of clinical response was gained by only *Aloe vera* and *Triticum Aestivum*. *Boswellia serrata* in one study evaluating recurrence rate did not cause prevention of relapse. Induction of adverse events by none of the plants was significant compared to that of placebo.

Rahimi R, Nikfar S, Abdollahi M. Induction of clinical response and remission of inflammatory bowel disease by use of herbal medicines: A meta-analysis. *World J Gastroenterol* 2013; 19(34): 5738-5749 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i34/5738.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i34.5738>

## INTRODUCTION

Inflammatory bowel disease (IBD) is a group of inflammatory conditions of gastrointestinal tract with two major types including ulcerative colitis (UC) and Crohn's disease (CD) and some atypical forms like collagenous colitis and intractable colitis. Many etiological factors have been implicated to play role in IBD; the most important one is immunological disturbances. Different drug categories are used for the management of IBD like aminosalicylates<sup>[1]</sup>, corticosteroids<sup>[2]</sup>, anti-tumor necrosis factor alpha drugs<sup>[3,4]</sup>, antibiotics<sup>[5,6]</sup>, probiotics<sup>[7,8]</sup>, and immunosuppressants<sup>[9]</sup>. Because of lack of desirable efficacy and poor tolerability of these drugs, approach toward complementary and alternative medicines especially herbal medicines for the management of IBD are increasing<sup>[10,11]</sup>. Besides many *in vivo* studies<sup>[12-14]</sup>, the efficacy and tolerability of herbal medicines in IBD have been investigated through several clinical trials. In this paper, all of these clinical trials were retrieved and a meta-analysis was performed to obtain conclusive results about efficacy and tolerability of herbal medicines for the management of IBD.

## MATERIALS AND METHODS

### Methods

The procedures performed in this meta-analysis are in accordance with recent guidelines for the reporting of meta-analysis (PRISMA guidelines).

### Data sources and searches

PubMed, Scopus, Web of Science, and Cochrane Central Register of Controlled Trials were searched for studies evaluating efficacy and/or tolerability of herbal medicines in any types of IBD. Data were collected from 1966 to 2013 (up to Feb). The search terms were: "herb" or "plant" or "herbal" and "inflammatory bowel disease". There was no language restriction. The reference list from retrieved articles was also reviewed for additional

applicable studies.

### Study selection

Controlled trials evaluating the efficacy and/or tolerability of herbal medicines in patients with any types of IBD were considered. The "clinical response", "clinical remission", "endoscopic response", "endoscopic remission", "histological response", "histological remission", "relapse", "any adverse events", and "serious adverse events" were the key outcomes of interest. All published studies as well as abstracts presented at meetings were evaluated. Two reviewers independently examined the title and abstract of each article to eliminate duplicates, reviews, case studies, and uncontrolled trials.

The reviewers independently extracted data on patients' characteristics, therapeutic regimens, dosage, trial duration, and outcome measures. There was no disagreement between reviewers.

### Quality assessment

Jadad score, which indicates the quality of the studies based on their description of randomization, blinding, and dropouts (withdrawals) was used to assess the methodological quality of trials<sup>[15]</sup>. The quality scale ranges from 0 to 5 points with a low quality report of score 2 or less and a high quality report of score at least 3.

### Statistical analysis

Data from selected studies were extracted in the form of 2 × 2 tables by study characteristics. Included studies were weighted and pooled. Data were analyzed using StatsDirect software version 2.7.9. RR and 95%CI were calculated using Mantel-Haenszel, Rothman-Boice (for fixed effects) or Der Simonian-Laird (for random effects) methods. The Cochran *Q* test was used to test heterogeneity and *P* < 0.05 considered significant. In case of heterogeneity or few included studies, the random effects model was used. Funnel plot was used as publication bias indicator.

## RESULTS

The electronic searches yielded 1224 items; 698 from PubMed, 5 from Cochrane Central, 35 from Web of Science, and 355 from Scopus. Of those, 41 trials were scrutinized in full text.

Thirty four reports were considered ineligible. Thus, 7 trials were included in the analysis represented 474 patients (Figure 1)<sup>[16-22]</sup>. From these 7 studies, 5 obtained Jadad score of 4 or more<sup>[16,17,20-22]</sup> and remaining two gained Jadad score of 2<sup>[18,19]</sup> (Table 1). Among studies included, 3 investigated the efficacy and/or tolerability of herbal medicines in CD<sup>[18-20]</sup>, 3 in UC<sup>[16,17,22]</sup> and 1 in collagenous colitis<sup>[21]</sup>. Five plants were investigated in 7 included studies: *Aloe vera*<sup>[16]</sup>, *Andrographis paniculata*<sup>[17]</sup>, *Artemisia absinthium*<sup>[18,19]</sup>, and *Boswellia serrata*<sup>[20,21]</sup>, and *Triticum aestivum*<sup>[22]</sup>. Induction of treatment was investigated in six studies and duration of these studies is between 4

Table 1 Characteristics of studies included in the meta-analysis

Study	Scientific name of plant(s)	Study design	Method of randomization	Blindness	Withdrawal Jadad score	Inclusion criteria	Exclusion criteria	Interventions	Concomitant medications	Duration	Outcomes
Sandborn <i>et al.</i> <sup>[17]</sup>	<i>Andrographis paniculata</i>	Randomized, placebo-controlled, double-blind	Block randomization schedule	Double-blind	4	Patients with at least 18 yr of age and confirmed diagnosis of mildly to moderately active UC (Mayo Score of 4-10 points and endoscopic subscore of at least 1) while receiving either oral mesalamine (or equivalent sulfasalazine, medications balsalazide, and olsalazine) for at least 4 wk or no medical therapy	Patients with CD or indeterminate colitis, severe UC (Mayo Score of 11 or 12 points, toxic mega-colon, toxic colitis), previous colonic surgery or probable requirement for intestinal surgery within 12 wk, enteric infection within 2 wk, a history of tuberculosis, a positive chest X-ray or tuberculin protein-purified derivative skin test, active infection with hepatitis B or any infection with hepatitis C, infection with human immunodeficiency virus, cancer within 5 yr, inadequate bone marrow, hepatic, or renal function, a history of alcohol or drug abuse that would interfere with the study, significant concurrent medical diseases, allergy to plants in the Acanthaceae family, women who were pregnant or breastfeeding, receiving oral or rectal steroids within 1 mo, rectal mesalamine within 1 wk, azathioprine, anti-tumor necrosis factor agents, or immunosuppressive therapy within 6 wk	Group 1: Capsules containing 1200 or 1800 mg <i>Andrographis paniculata</i> ethanol (male/female: 81/68); 1 cap <i>tds</i> Group 2: The same capsules without herbal extract. [ <i>n</i> = 149 (male/female: 41/34)]; 1 cap <i>tds</i>	Mesalazine	8 wk	(1) Clinical response (a decrease from baseline in the total Mayo Score by at least 3 points and at least 30% with an accompanying decrease in rectal bleeding subscore of at least 1 point or an absolute rectal bleeding subscore of 0 or 1 point); (2) Clinical remission (a total Mayo Score of 2 points or lower, with no individual subscore exceeding 1 point); (3) Mucosal healing (a decrease from baseline in the endoscopy subscore by at least 1 point and an absolute endoscopy subscore of 0 or 1 point)
Holtmeier <i>et al.</i> <sup>[20]</sup>	<i>Boswellia serrata</i>	Randomized, placebo-controlled, double-blind	A computer generated randomization scheme: In blocks of four	Double-blind	4	Outpatients between 18 and 75 yr with a history of CD currently in remission with at least two documented relapses during the last 4 yr, one within the last 18 mo, or a recent resection (fibrotic strictures without inflammation were not considered a relapse); CDAI < 150 and no symptoms suspicious of activity for the previous 28 d	CDAI of > 150 at screening and at baseline visit ( $\geq 28$ d apart); severe fistulizing CD; abscesses; symptomatic stenoses; any condition that places the patient at an undue risk; surgical bowel resections within 3 mo, short bowel syndrome; total proctocolectomy; serious infections, nutritionally compromised patients requiring enteral or parenteral therapy; severe hypertension, chronic liver disorder; impaired renal function; myocardial infarction < 3 mo, cerebral blood flow disturbances or cerebral infarction < 6 mo; any history of malignancy within the past 5 yr (except for squamous or basal cell carcinoma of the skin); subjects with severe psychiatric illnesses, inability to give informed consent; and history of severe alcoholism and drug abuse; taken monoclonal antibody therapy (e.g., infliximab) within 12 mo, immunosuppressives (azathioprine/6-mercaptopurine, cyclosporine, methotrexate) within 4 mo, or corticosteroids, mesalamine/sulfasalazine, or <i>Boswellia serrata</i> within 6 wk prior to randomization	Group 1: Capsules containing 400 mg 8% ethanol extract of <i>Boswellia serrata</i> resin. [ <i>n</i> = 42 (male/female: 13/29)]. 2 caps <i>tds</i> Group 2: The same capsules without herbal extract. [ <i>n</i> = 40 (male/female: 15/25)]. 2 caps <i>tds</i>	ND	52 wk	(1) Maintenance of remission (maintenance of CDAI < 150 throughout study); (2) Relapse (relapse was defined as both a CDAI score > 150 points and an increase in the CDAI score of $\geq 70$ points)

Krebs <i>et al</i> <sup>[18]</sup>	<i>Artemisia absinthium</i>	Randomized, open label	ND	Unblinded	Not any	2	Patients between 18 and 80 yr with CDAI $\geq$ 200 at least for 3 mo receiving CD treatments with 5-aminosalicylates stable dose for at least 4 wk, azathioprine stable dose for 8 wk, methotrexate stable dose for 6 wk or steroids with stable dose in the range of 20-30 mg (equivalent to dexamethasone)	Treatment with TNF- $\alpha$ inhibitors such as infliximab; Patients with serious pathological findings in ECG, liver, kidney and heart functions, or coexisting organic diseases such as a history of cancer, asthma or other autoimmune disease, or pregnancy; opinion placed the patient at undue risk by participating in the study; parasites in the patient's stools, positive <i>Clostridium difficile</i> toxin test and active fungal or viral infection	Group 1: Capsules containing 250 mg leave and stem powder of <i>Artemisia absinthium</i> . [n = 10 (male/female: 6/4)]. 3 caps <i>tids</i> Group 2: No medication. [n = 10 (male/female: 3/7)]	Azathioprine, mesalazine	6 wk	Response: a decrease in the CDAI score of at least 70 points from the qualifying score, or a decrease in 30% of CDAI score from the baseline score
Madsch <i>et al</i> <sup>[20]</sup>	<i>Boswellia serrata</i>	Randomized, placebo-controlled, double-blind	Groups of four patients according to a central computer-generated randomization list	Double-blind	5 patients in <i>Boswellia</i> group	5	Patients, aged between 18 and 80 yr were eligible for the study if they had at least five liquid or soft stools per day on average per week, a complete colonoscopy performed within the last 4 wk before randomization, and a histologically confirmed diagnosis of collagenous colitis	Treatment with budesonide, salicylates, steroids, prokinetics, antibiotics, ketoconazole, or non-steroidal anti-inflammatory drugs within 4 wk before randomization, other endoscopically or histologically verified causes for diarrhea, infectious diarrhea, pregnancy or lactation, previous colonic surgery, and known intolerance to <i>Boswellia</i> extract	Group 1: 400 mg capsules containing <i>Boswellia serrata</i> extract standardized to 80% boswellic acids, 1 capsule <i>tid</i> Group 2: Identical placebo capsules, 1 capsule <i>tid</i>	Loperamide was allowed for the first 3 wk but was not allowed for the last 3 wk of the study. Patients were allowed to use butylscopolamine in case of abdominal pain	6 wk	Clinical remission (stool frequency equal to or less than three soft or solid stools per day on average during the last week of treatment)
Omer <i>et al</i> <sup>[9]</sup>	<i>Artemisia absinthium</i>	Double-blind, placebo-controlled	ND	Double-blind	ND	2	Patients between 18 and 80 yr with CDAI $\geq$ 200 at least for 3 mo receiving CD treatments with 5-aminosalicylates stable dose for at least 4 wk, azathioprine stable dose for 8 wk, methotrexate stable dose for 6 wk or corticosteroids (prednisolone, prednisone or budesonide) at the equivalent of 40 mg/d of prednisone or Less stable dose for 3 wk	Treatment with infliximab; patients with serious pathological findings in ECG, liver, kidney and heart functions, or coexisting organic diseases such as a history of cancer, asthma or other autoimmune disease, or pregnancy; any condition that in the investigators opinion placed the patient at undue risk by participating in the study; parasites in the patient's stools, positive <i>Clostridium difficile</i> toxin test and active fungal or viral infection	Group 1: Capsules containing 250 mg leave and stem powder of <i>Artemisia absinthium</i> . [n = 20 (male/female: 12/8)]. 3 caps <i>bid</i> Group 2: The same capsules without <i>Artemisia absinthium</i> . [n = 20 (male/female: 11/9)]. 3 caps <i>bid</i>	Glucocorticoids, 5-aminosalicylates, azathioprine, methotrexate	10 wk	A decrease in the CDAI score of at least 70 points from the qualifying score, or a decrease in 30% of CDAI score from the baseline score

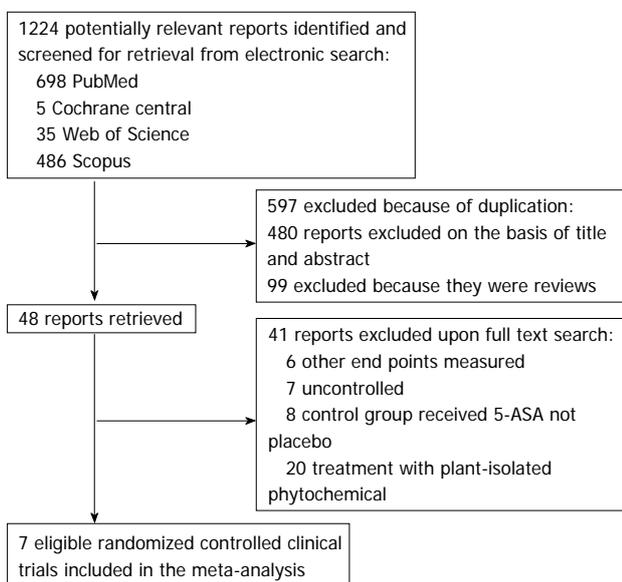

Langmead <i>Aloe vera</i> <i>et al.</i> <sup>[6]</sup>	Randomized, double-blind, placebo-controlled in 2:1 ratio. Computer-generated, block-design.	Double-blind	6 patients in aloë group and 3 in the placebo group	4	Age of 18-80 yr. mildly to moderately active UC (as defined by a modified SCCAI $\geq 3$ ) and no recent changes in conventional prophylactic therapy	Acute severe UC requiring hospital admission (SCCAI > 12); inactive disease (SCCAI < 3); positive stool examination for pathogens; CD or indeterminate colitis; use of antibiotics, warfarin, cholestyramine, sucralfate, anti-diarrhoeal drugs (loperamide, codeine phosphate, diphenoxylate), non-steroidal anti-inflammatory drugs, aspirin > 75 mg/d, aloë vera or other herbal remedies; alcohol or drug abuse; pregnancy or breast feeding; female of child-bearing age not taking adequate contraception; participation in another drug trial in the previous 3 mo; and serious liver, renal, cardiac, respiratory, endocrine, neurological or psychiatric illness, alteration in their dosage of aminosaliculates in the previous 4 wk, had taken > 10 mg/d or had altered oral prednisolone dosage in the previous 4 wk, changed their dose of azathioprine or 6-mercaptopurine in the previous 3 mo, or had used more than five corticosteroid or aminosaliculate enemas in the previous 2 wk	Group 1: <i>Aloe vera</i> gel. [n = 30 (male/female: 16/14)]. 100 mL <i>bid</i> Group 2: The same lipiquid product without <i>Aloe vera</i> gel. [n = 14 (male/female: 6/8)]	5-ASA, prednisolone, azathioprine, topical 5-ASA, topical steroid	4 wk	(1) Clinical remission (SCCAI $\leq 2$ ); (2) Sigmoidoscopic remission [Baron score of zero (normal-looking mucosa) or one (mucosal oedema as indicated by loss of the normal vascular pattern)]; (3) Histological remission (Savery-muttu score of $\leq 1$ , <i>i.e.</i> , no loss of colonocytes, absence of crypt inflammation, and normal lamina propria content of mononuclear cells and neutrophils); (4) Clinical improvement (a reduction in SCCAI of $\geq 3$ points); (5) Clinical response (remission or improvement); (6) Sigmoidoscopic improvement (decrease in Baron score of $\geq 2$ points; and (7) Histological improvement (decrease in Savery-muttu score of $\geq 3$ points)
Ben-Arye <i>Triticum aestivum</i> <i>et al.</i> <sup>[23]</sup>	Randomized, double-blind, placebo-controlled	Double blind; both the true juice and the placebo were packaged in coded, identical, sealed, opaque containers. A driver, blinded to the allocation scheme and given only the addresses for each package, then distributed all the packages	2 patients in triticum group and 1 in the placebo group	4	Age > 18 yr; sigmoidoscopic finding of active UC that involves the left colon; clinical activity comparable with UC; no change in drug treatment (type and dosage) in the month prior to entry; lack of serious systemic involvement-fever > 38 °C, erythema nodosum, arthritis; blood hemoglobin > 11 g%; negative stool culture and test for ova and parasites	ND	Group 1: 100 mL of <i>Triticum aestivum</i> seed juice. [n = 11 (male/female: 6/5)] Group 2: 100 mL of matching placebo. [n = 12 (male/female: 9/3)]	-	1 mo	Improvement (larger than 0.4 in an analog scale where -3 designates the lowest score of aggravation, 0 no change, and +3 highest score of improvement)

CD: Crohn's disease; CDAI: Crohn's disease activity index; ND: Not determined; SCCAI: Simple clinical colitis activity index; ASA: Aminosalicic acid. ECC: Electrocardiography; TNF: Tumor necrosis factor.

and 10 wk<sup>[16-19,21,22]</sup>. Maintenance of remission was evaluated in one study and duration of this study was 52 wk<sup>[20]</sup>. Scientific name of plant(s) used in herbal medicine, study design, inclusion and exclusion criteria, interventions, concomitant medications, patients’ characteristics, duration of study and definition of outcomes investigated in each included study have been shown in Table 1. Results of investigated outcomes for each included study have been demonstrated in Table 2.

**Efficacy**

**Clinical remission:** The summary for RR of clinical remission in IBD patients for four included trials comparing herbal medicines to placebo<sup>[16,17,19,21]</sup> was 2.07 with 95%CI: 1.41-3.03 ( $P = 0.0002$ , Figure 2A). The Cochrane  $Q$  test for heterogeneity indicated that the studies are not

heterogeneous ( $P = 0.08$ , Figure 2B) and could be combined, thus fixed effects for individual and summary of RR was applied. Regression of normalized effect *vs* precision for all included studies for clinical remission in IBD patients among herbal medicines *vs* placebo therapy was 2.02 (95%CI: 0.37-3.67,  $P = 0.03$  and Kendall’s tau = 1,  $P = 0.08$  (Figure 2C).

The RR of clinical remission in patients with CD<sup>[19]</sup> was 27 with 95%CI: 3.23-260.81, a significant RR.

The summary for RR of clinical remission in UC patients for two included trials comparing herbal medicines to placebo<sup>[16,17]</sup> was 1.59 with 95%CI: 0.8-3.15 ( $P = 0.18$ , Figure 3A). The Cochrane  $Q$  test for heterogeneity indicated that the studies are not heterogeneous ( $P = 0.28$ , Figure 3B) and could be combined but because of few included studies random effects for individual and summary of RR was applied. Regression of normalized effect *vs* precision for all included studies for clinical remission in UC patients could not be calculated because of too few strata.

Based on plant type, RR of clinical remission was significant for *Artemisia absinthium* (27.00; 95%CI: 3.23-260.81) and *Boswellia serrata* (2.34; 95%CI: 1.02-6.07) and non-significant for *Aloe vera* and *Andrographis paniculata* (Table 3).

**Clinical response:** The summary for RR of clinical response in IBD patients for five included trials comparing herbal medicines to placebo<sup>[16-19,22]</sup> was 2.59 with 95%CI: 1.24-5.42 ( $P = 0.01$ , Figure 4A). The Cochrane  $Q$  test for heterogeneity indicated that the studies are heterogeneous ( $P = 0.08$ , Figure 4B) and could not be combined, thus the random effects for individual and summary of RR was applied. Regression of normalized effect *vs* precision for all included studies for clinical response in IBD patients was 2.33 (95%CI: 1.55-3.11,  $P = 0.003$ ) and Kendall’s tau = 0.8,  $P = 0.08$  (Figure 4C).

The summary for RR of clinical response in CD patients for two included trials<sup>[18,19]</sup> was 9.61 with 95%CI:

**Table 3 Results obtained from sub-analyses based on plant type**

Plant	IBD type	Study	Patients reported AE		Clinical efficacy		Endoscopic efficacy		Histological efficacy		Recurrence relapse
			Any AE	Serious AE	Clinical remission	Clinical response	Endoscopic remission	Endoscopic response	Histological remission	Histological response	
<i>Aloe vera</i>	UC	16	0.70 (0.25-2.08)	-	4.20 (0.84-24.84)	3.27 (1.06-12.13)	1.48 (0.44-5.84)	1.69 (0.69-5.04)	0.64 (0.25-1.81)	0.86 (0.55-1.55)	-
<i>Andrographis paniculata</i>	UC	17	0.94 (0.75-1.20)	1.01 (0.22-4.65)	1.41 (0.92-2.23)	1.32 (0.98-1.84)	1.32 (0.93-1.93)	-	-	-	-
<i>Artemisia absinthium</i>	CD	18	-	1.00 (0.06-16.69)	-	9.61 (0.73-126.15), <i>P</i> = 0.09	-	-	-	-	-
<i>Boswellia serrata</i>	CD	19	-	-	27.00 (3.23-260.81)	-	-	-	-	-	-
	CD	20	0.82 (0.66-1.04), <i>P</i> = 0.11	0.95 (0.27-3.31), <i>P</i> = 0.94	-	-	-	-	-	-	0.95 (0.52-1.73)
	Collage-nous colitis	21	-	-	2.34 (1.02-6.07)	-	-	-	-	-	-
<i>Triticum aestivum</i>	UC	22	-	-	-	2.18 (1.19-4.78)	-	-	-	-	-

Results are expressed as relative risk (95%CI). AE: Adverse event; CD: Crohn’s disease; UC: Ulcerative colitis; IBD: Inflammatory bowel disease.

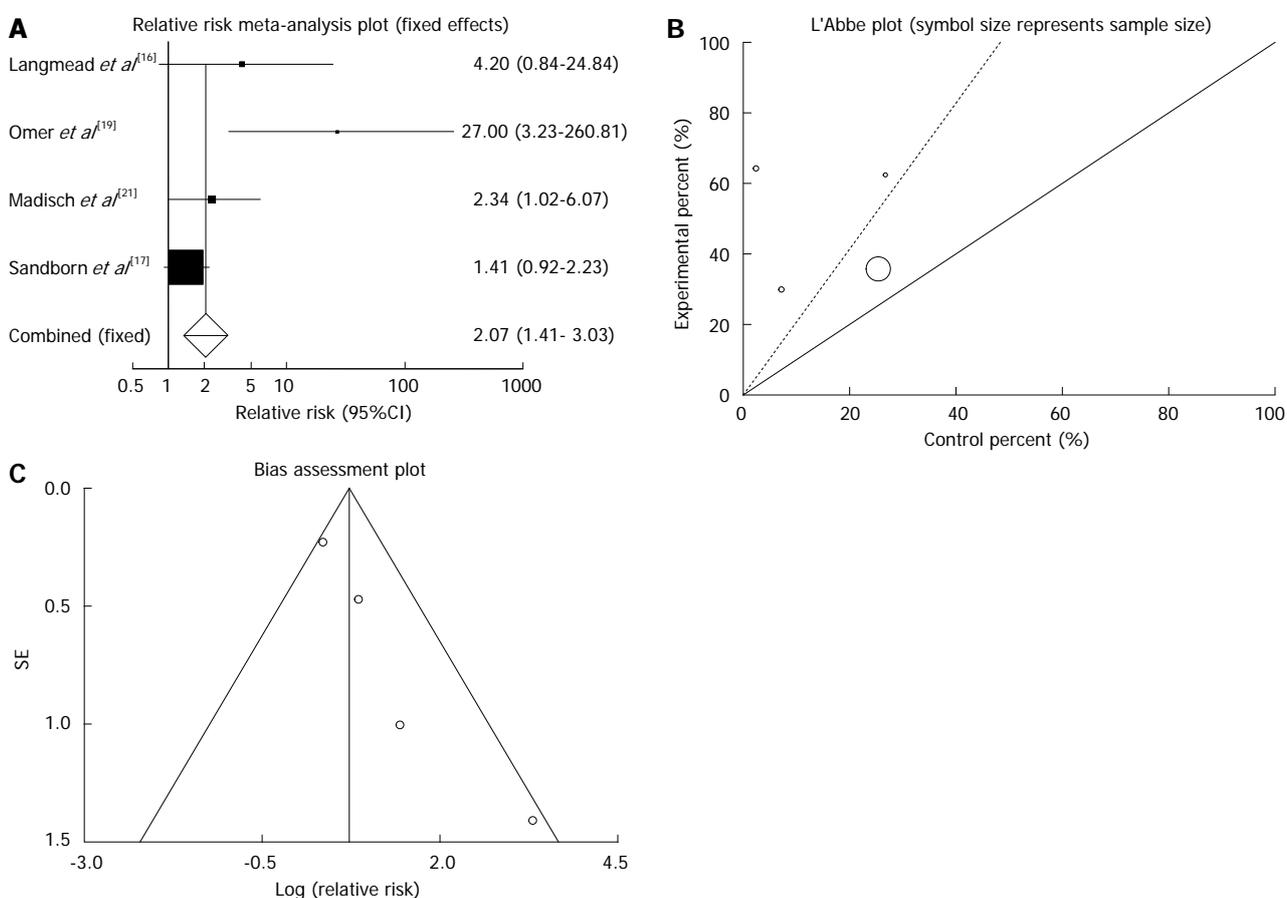

Figure 2 Individual and pooled relative risk (A), heterogeneity indicators (B) and publication bias indicators (C) for the outcome of “clinical remission” in the studies considering herbal medicines comparing to placebo therapy in inflammatory bowel disease patients.

0.73-126.15 (*P* = 0.09, Figure 5A). The Cochrane *Q* test for heterogeneity indicated that the studies are not heterogeneous (*P* = 0.08, Figure 5B) and could be combined but because of few included studies the random effects for individual and summary of RR was applied. Regression of normalized effect *vs* precision for all included studies for clinical response in CD patients could not be calculated because of too few strata.

The summary for RR of clinical response in UC

patients for three included trials comparing herbal medicines to placebo<sup>[16,17,22]</sup> was 1.67 with 95%CI: 1.06-2.65 (*P* = 0.03, Figure 6A). The Cochrane *Q* test for heterogeneity indicated that the studies are not heterogeneous (*P* = 0.22, Figure 6B) and could be combined but because of few included studies the random effects for individual and summary of RR was applied. Regression of normalized effect *vs* precision for all included studies for clinical response in UC patients among herbal medicines *vs* pla-

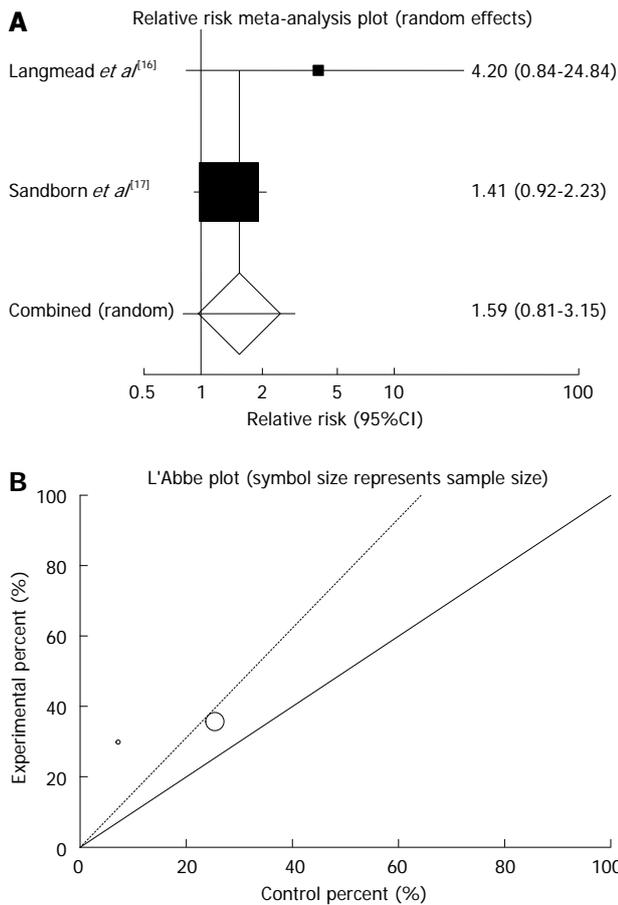

Figure 3 Individual and pooled relative risk (A) and heterogeneity indicators (B) for the outcome of “clinical remission” in the studies considering herbal medicines comparing to placebo therapy in ulcerative colitis patients.

cebo therapy could not be calculated because of too few strata.

Based on plant type, RR of clinical response was significant for *Aloe vera* (3.27; 95%CI: 1.06-12.13) and *Triticum aestivum* (2.18; 95%CI: 1.19-4.78) and non-significant for *Andrographis paniculata* and *Artemisia absinthium* (Table 3).

**Endoscopic remission:** The summary for RR of endoscopic remission in IBD patients for two included trials (all of the patients in these studies had UC) comparing herbal medicines to placebo<sup>[16,17]</sup> was 1.33 with 95%CI: 0.93-1.9 ( $P = 0.12$ , Figure 7A). The Cochrane  $Q$  test for heterogeneity indicated that the studies are not heterogeneous ( $P = 0.87$ , Figure 7B) and could be combined but because of few included studies random effects for individual and summary of RR was applied. Regression of normalized effect *vs* precision for all included studies for endoscopic remission in IBD (UC) patients could not be calculated because of too few strata.

Based on plant type, RR of endoscopic remission was non-significant for *Aloe vera* (1.48; 95%CI: 0.44-5.84) and *Andrographis paniculata* (1.32; 95%CI: 0.93-1.93) (Table 3).

**Endoscopic response:** The RR of endoscopic response in UC patients comparing herbal medicines with pla-

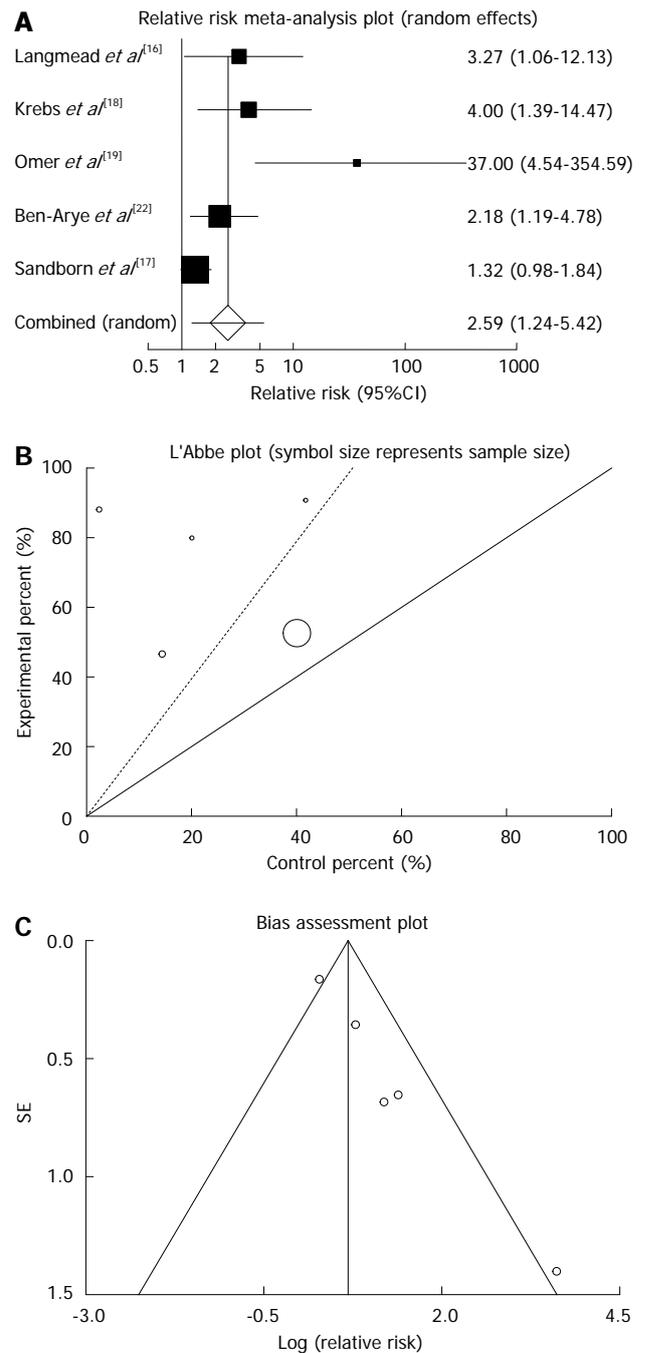

Figure 4 Individual and pooled relative risk (A), heterogeneity indicators (B) and publication bias indicators (C) for the outcome of “clinical response” in the studies considering herbal medicines comparing to placebo therapy in inflammatory bowel disease patients.

cebo<sup>[16]</sup> was 1.69 with 95%CI: 0.69-5.04, a non-significant RR.

**Histological remission:** The RR of histological remission in IBD (UC) patients comparing herbal medicines with placebo<sup>[16]</sup> was 0.64 with 95%CI: 0.25-1.81, a non-significant RR.

**Histological response:** The RR of histological response in UC patients comparing herbal medicines with placebo<sup>[16]</sup> was 0.86 with 95%CI: 0.55-1.55, a non-significant RR.

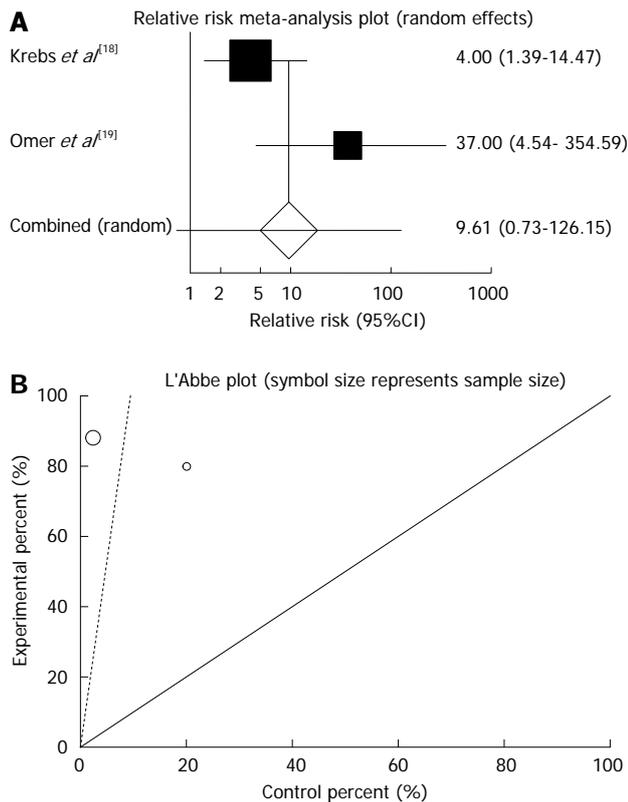

Figure 5 Individual and pooled relative risk (A) and heterogeneity indicators (B) for the outcome of “clinical response” in the studies considering herbal medicines comparing to placebo therapy in Crohn’s disease patients.

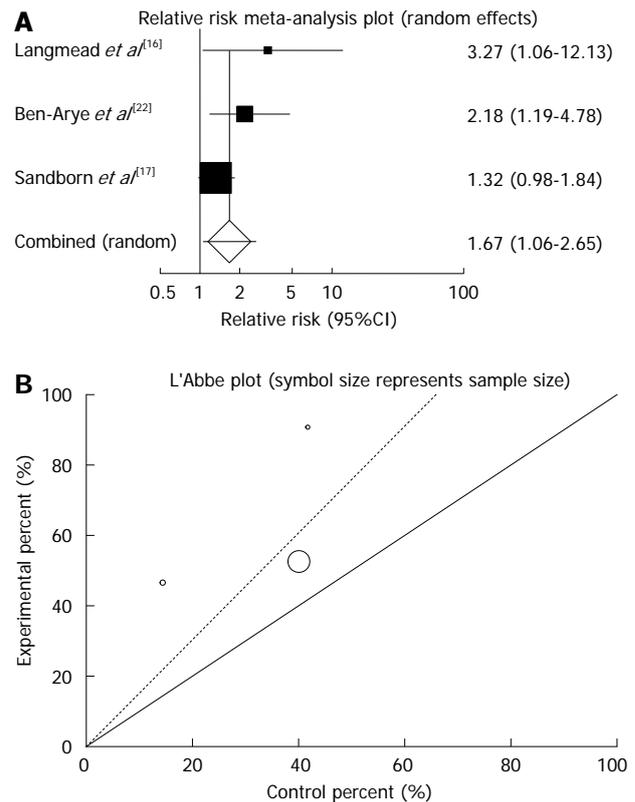

Figure 6 Individual and pooled relative risk (A) and heterogeneity indicators (B) for the outcome of “clinical response” in the studies considering herbal medicines comparing to placebo therapy in ulcerative colitis patients.

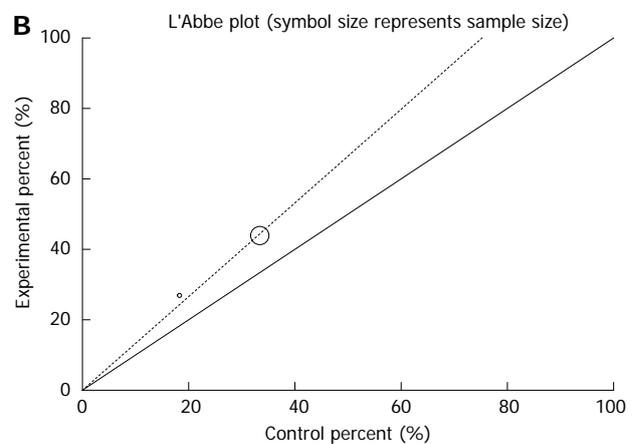

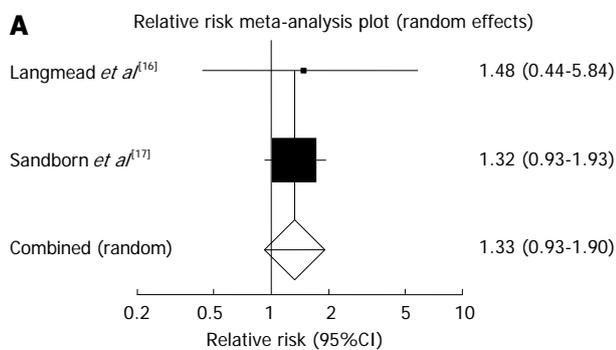

Figure 7 Individual and pooled relative risk (A) and heterogeneity indicators (B) for the outcome of “endoscopic remission” in the studies considering herbal medicines comparing to placebo therapy in inflammatory bowel disease (ulcerative colitis) patients.

**Relapse:** The RR of relapse in CD patients comparing herbal medicines with placebo<sup>[20]</sup> was 0.95 with 95%CI: 0.52-1.73, a non-significant RR.

**Tolerability**

**Any adverse events:** The summary for relative risk (RR) of any adverse events in IBD patients for four included trials comparing herbal medicines to placebo<sup>[16,17,20,21]</sup> was 0.89 with 95%CI: 0.75-1.06 ( $P = 0.2$ , Figure 8A). The Cochrane Q test for heterogeneity indicated that the studies

are not heterogeneous ( $P = 0.71$ , Figure 8B) and could be combined, thus fixed effects for individual and summary of RR was applied. Regression of normalized effect *vs* precision for all included studies for any adverse events in IBD patients was 0.18 (95%CI: -2.73-3.09,  $P = 0.81$ ) and Kendall’s tau = 0,  $P = 0.75$  (Figure 8C).

**Serious adverse events:** The summary for RR of serious adverse events in IBD patients for four included trials comparing herbal medicines to placebo<sup>[17,18,20,21]</sup> was

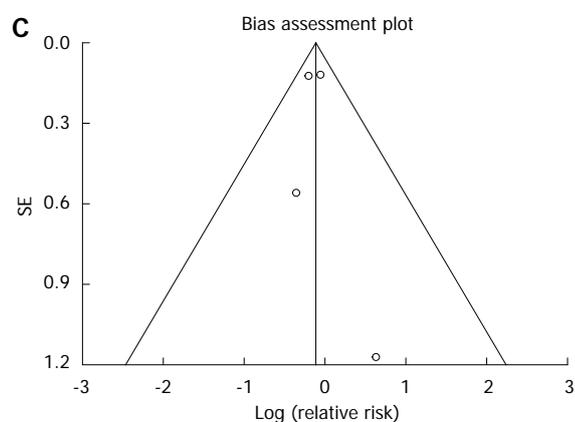

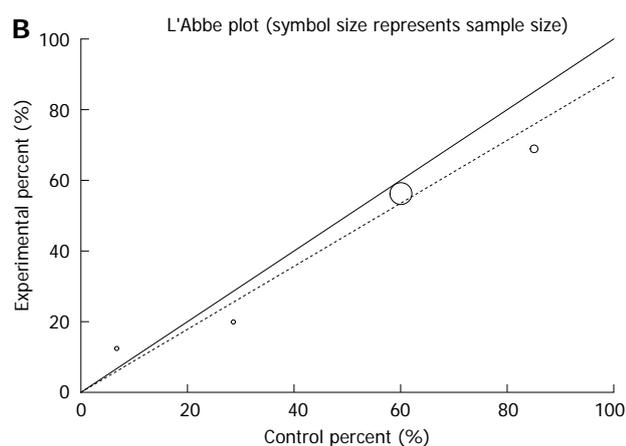

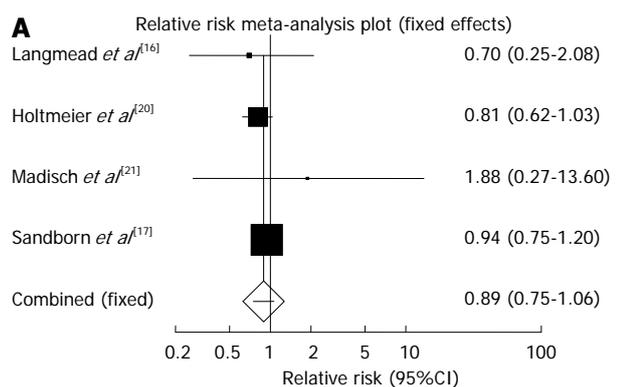

Figure 8 Individual and pooled relative risk (A), heterogeneity indicators (B) and publication bias indicators (C) for the outcome of “any adverse events” in the studies considering herbal medicines comparing to placebo therapy in inflammatory bowel disease patients.

0.97 with 95%CI: 0.37-2.56 ( $P = 0.96$ , Figure 9A). The Cochrane  $Q$  test for heterogeneity indicated that the studies are not heterogeneous ( $P > 0.99$ , Figure 9B) and could be combined, thus fixed effects for individual and summary of RR was applied. Regression of normalized effect  $\nu$ s precision for all included studies for serious adverse events in IBD patients was 0.01 (95%CI: -0.19-0.21,  $P = 0.83$ ) and Kendall's tau = 0,  $P = 0.75$  (Figure 9C).

## DISCUSSION

In the current meta-analysis, the efficacy and tolerability

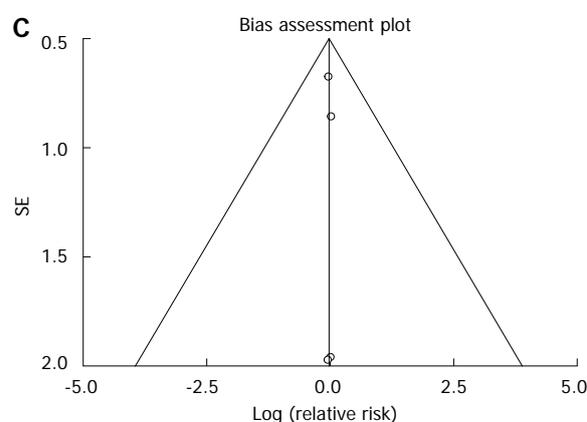

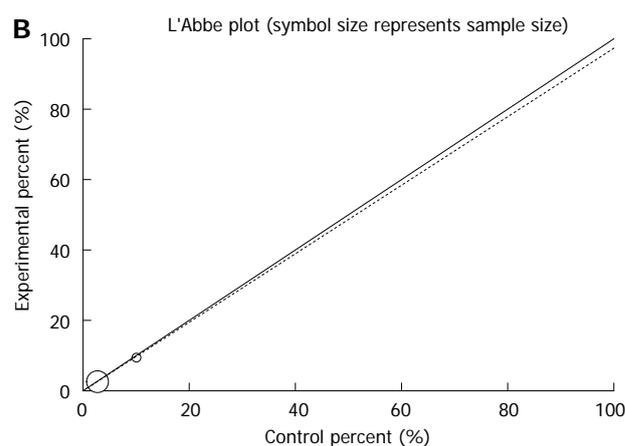

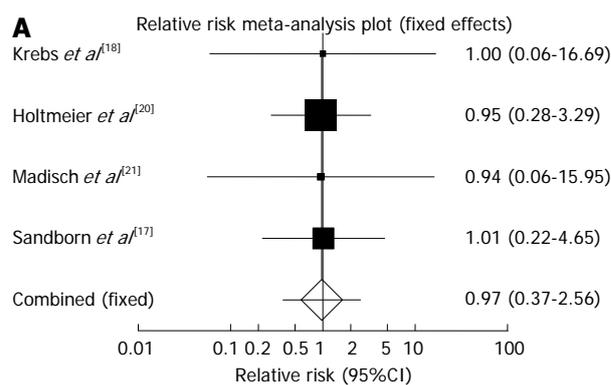

Figure 9 Individual and pooled relative risk (A), Heterogeneity indicators (B) and publication bias indicators (C) for the outcome of “serious adverse events” in the studies considering herbal medicines comparing to placebo therapy in inflammatory bowel disease patients.

of herbal medicines in the management all forms of IBD were compared with placebo. The results showed that herbal medicines may induce clinical remission and clinical response in patients with IBD. Endoscopic efficacy was investigated in two studies, both on patient with UC. Herbal medicines did not demonstrate significant effect on induction of endoscopic remission and endoscopic response. Histopathological efficacy was also evaluated in two studies both on patients with UC and the results were the same as endoscopic efficacy. This may be due to short duration of studies and possible slow action of herbal medicines. Moreover, the scoring system used to

assess the mucosal appearance macroscopically is prone to inter-observer variability resulting in non-detecting a significant improvement<sup>[23]</sup>.

The efficacy of herbal medicines in prevention of relapse was investigated in only one study and showed no priority of these products compared to placebo. The number of patients showed any adverse events or serious adverse events were not significantly different between herbal medicines and placebo and this confirmed safety and tolerability of these products.

The present meta-analysis may have been limited by small sample sizes of studies and heterogeneity. Since the included trials involved herbal medicines contained different plants administered to patients with various subtypes of IBD, the trials were disaggregated. Thus, sub-analyses based on type of IBD and plant type was performed. The results of sub-analysis based on IBD type showed that herbal medicines significantly induce clinical remission in patients with CD and clinical response in patients with UC; however the induction of clinical remission in patients with UC and induction of clinical response in patients with CD by herbal medicines were not significant. The results of sub-analyses based on plant type demonstrated that induction of clinical remission was obtained only by *Artemisia absinthium* and *Boswellia serrata* and induction of clinical response was gained by only *Aloe vera* and *Triticum Aestivum*. None of the plants caused induction of endoscopic or histological efficacy. *Boswellia serrata* in one study evaluating recurrence rate did not cause prevention of relapse. Induction of adverse events by none of the plants was significant in comparison to that of placebo.

Overall, the results show that herbal medicines may induce clinical efficacy in patients with IBD, but the evidence is too limited to make any confident conclusions. Meta-analysis of clinical trials that have compared efficacy of herbal medicines with that of conventional drugs such as amino-salicylates can be helpful that is being carried out by authors of this paper. Further high quality, large controlled trials using standardized preparation are warranted to better elucidate the effects of these herbs in IBD.

## COMMENTS

### Background

Inflammatory bowel disease (IBD) is a group of inflammatory conditions of gastrointestinal tract. Due to lack of desired efficacy and poor tolerability of conventional drugs, approach toward complementary and alternative medicines especially herbal medicines for the management of IBD are growing. Besides many experimental studies, the efficacy and tolerability of herbal medicines in IBD have been investigated through several clinical trials.

### Research frontiers

Although the efficacy and tolerability of herbal medicines for the management of IBD were evaluated through several clinical trials in comparison to placebo, no meta-analysis has been conducted to reach a convincing conclusion.

## Innovations and breakthroughs

Based on this meta-analysis, herbal medicines may safely induce clinical response and remission in patients with IBD without significant effects on endoscopic and histological outcomes, but the number of studies is yet limited to make a strong conclusion.

## Applications

Regarding desirable effects of herbal medicine in induction of clinical response and remission in IBD and their low adverse events, it would not be surprising to introduce good medicines to clinic if proper standardization and dose adjustments are done.

## Peer review

The aim of the study was to evaluate the efficacy and tolerability of herbal medicines in IBD by conducting a meta-analysis. This paper is good for IBD community.

(US) showed a solid mass of approximately 7 cm × 5.5 cm on the pancreas head. Abdominal computerized tomography showed dilation of the biliary tract, an enlarged pancreas (up to 4.5 in the head region), with dilation of the major pancreatic duct. The patient underwent exploratory laparotomy, and the surgical description consisted of a tumor, measuring 7 to 8 cm with a poorly-defined margin, adhering to posterior planes and mesenteric vessels, showing an enlarged bile duct. External drainage of the biliary tract, Roux-en-Y gastroenteroanastomosis, lymph node excision, and biopsies were performed, but malignant neoplasia was not found. Microscopic analysis showed chronic pancreatitis and a granulomatous chronic inflammatory process in the choledochal lymph node. Acid-alcohol resistant bacillus and fungus screening were negative. Fine-needle aspiration of the pancreas was performed under US guidance. The smear was compatible with infection by *Paracoccidioides brasiliensis*. We report a rare case of paracoccidioidomycosis simulating a malignant neoplasia in the pancreas head.

### Abstract

Paracoccidioidomycosis is a systemic granulomatous disease caused by fungus, and must be considered in the differential diagnosis of intra-abdominal tumors in endemic areas. We report a rare case of paracoccidioidomycosis in the pancreas. A 45-year-old man was referred to our institution with a 2-mo history of epigastric abdominal pain that was not diet-related, with night sweating, inappetence, weight loss, jaundice, pruritus, choluria, and acholic feces, without signs of sepsis or palpable tumors. Abdominal ultrasonography

**Core tip:** This is a report of a rare case of pancreatic paracoccidioidomycosis, which shows its importance in the differential diagnosis of intra-abdominal tumors in endemic areas. This is apparently the first such report written in English. The patient had a pancreatic mass adhering to vessels and deep planes, with enlargement of satellite lymph nodes; but malignant neoplasia was not found. The ultrasonography-guided pancreas fine-needle aspiration defined the diagnosis and successfully directed the therapy. Remarkably, although the patient had abdominal lymph node enlargement, he did not present peripheral lymphadenopathy, which is usually

the major complaint in patients with the juvenile form of paracoccidioidomycosis.

Pancreatic paracoccidioidomycosis simulating malignant neoplasia: Case report. *World J Gastroenterol* 2013; 19(34): 5750-5753 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i34/5750.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i34.5750>

## INTRODUCTION

Paracoccidioidomycosis (also known as Pb mycosis or South American blastomycosis) is a systemic granulomatous disease caused by the fungus *Paracoccidioides brasiliensis*<sup>[1]</sup>, which is autochthonous in Latin America. It was described by Lutz<sup>[2]</sup>, and its incidence ranges from 3 to 4 cases per million, up to 1 to 3 cases per one hundred thousand inhabitants per year in endemic areas, with an annual mortality of 1.45 per million inhabitants, which is the highest rate observed among systemic mycoses<sup>[1]</sup>. It affects 10 to 15 adult males per one female case, mostly between the 3<sup>rd</sup> and 6<sup>th</sup> decades of life, and has two main forms: the juvenile form, constituting 3%-5% of cases, which compromises the reticuloendothelial system, and the somewhat more common chronic form that comprises 90% of cases, mainly affecting the skin and the lungs<sup>[1]</sup>. Paracoccidioidomycosis can mimic neoplasias, such as periampullary<sup>[3]</sup> or colon<sup>[4]</sup> cancer. Therefore, it must be considered in the differential diagnosis of intra-abdominal tumors in endemic areas<sup>[5]</sup>. This case illustrates a rare case of paracoccidioidomycosis simulating a malignant neoplasia in the pancreas head.

## CASE REPORT

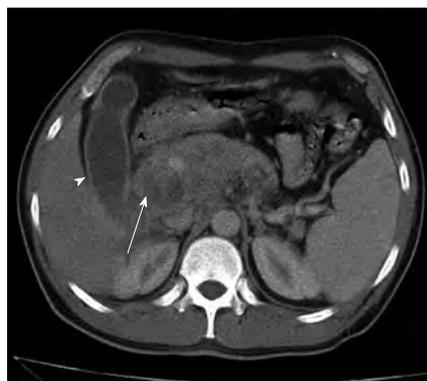

A 45-year-old white adult male from São Paulo state was referred to our institution with a 2-mo history of epigastric pain that was not diet-related. It was intermittent, of strong intensity, with radiation to the back and relieved by the use of omeprazole. Additionally, the patient had night sweating and a weight loss of 13 kg in 45 d, and lacked vomiting, diarrhea, or fever. Twenty days before admission, the patient reported jaundice, pruritus over the whole body, choloria, and acholic feces. The patient was a current smoker and alcohol user, while his physical examination revealed jaundice and pain after deep abdominal palpation, without signs of sepsis or palpable tumors. Pulmonary auscultation showed no alterations, and laboratory exams confirmed cholestatic syndrome (Table 1).

Abdominal ultrasonography (US) showed a solid mass of approximately 7 cm × 5.5 cm on the pancreas head, with a small tumor of 1 to 2 cm juxtaposed with the mass, suggesting local metastases. Abdominal com-

**Figure 1** Contrast enhanced abdominal computed tomography. Head, body, and tail of pancreas with enlarged dimensions and a poorly-defined margin, with two hypodense areas without significant enhancement after intravenous contrast (white arrow). The same image shows a hypodense gallbladder (arrow head) and mild splenomegaly.

puterized tomography (CT) showed dilation of the biliary tract, an enlarged pancreas (up to 4.5 in the region of the head) with a poorly-defined margin and two hypodense areas without significant enhancement after intravenous contrast, leading to dilation of the major pancreatic duct, but without retroperitoneal lymphadenopathy (Figure 1). Due to the momentary unavailability of the necessary equipment at our institution to perform a puncture guided by CT or US, the patient underwent exploratory laparotomy. The surgical description consisted of a pancreatic tumor measuring 7 to 8 cm with a poorly-defined margin, adhering to posterior planes and to mesenteric vessels, and showing an enlarged bile duct. Transcystic cholangiography showed obstruction of the passage of contrast through the distal bile duct, which was compatible with extrinsic compression. External drainage of the biliary tract, Roux-en-Y gastroenteroanastomosis, lymph node excision, and biopsies were performed. Malignant

**Figure 2** Pathological findings (hematoxylin/eosin  $\times$  200 magnification). A: Epithelioid granuloma in a lymph node near the ductus choledochus, with absence of necrosis, fungi, or bacteria; B: Fine-needle aspiration smear showing rounded yeast forms with a birefringent wall and multiple sporulation compatible with *Paracoccidioides brasiliensis* (black arrows).

neoplasia was not found at the intraoperative frozen section analysis. Microscopic analysis showed chronic pancreatitis and a granulomatous chronic inflammatory process in the choledochal lymph node. The presence of granulomas without caseous necrosis in the lymph node would suggest a diagnosis of sarcoidosis; however, at that time it was not possible to definitively discard the diagnosis of tuberculosis (Figure 2A). Acid-alcohol resistant bacillus and fungus screening by Ziehl-Neelsen, PAS, and Gömöri staining were negative. The biopsies were reviewed, and a cohesive granuloma without caseous necrosis was found attached to peripancreatic fat. The abdominal pain and the jaundice worsened, and the patient developed fever, leukocytosis, and drainage of purulent secretion by a surgical drain located near the pancreas. Upper digestive endoscopy showed esophageal varices. Plain chest X-ray and thoracic CT scan were normal. Metronidazole and ciprofloxacin were prescribed due to the hypothesis of bacterial cholangitis, and clinical improvement was observed. Fine-needle aspiration (FNA) of the pancreas was performed with US guidance. The obtained smear was compatible with infection by *Paracoccidioides brasiliensis* (Figure 2B). Enzyme-linked immunosorbent assay tests, employed for the detection of anti-*Paracoccidioides brasiliensis* antibodies, produced positive results (titers of 1/8 and 1/16). Intravenous sulfamethoxazole-trimethoprim (800/160 mg two times per day) was introduced, after which the patient showed

clinical and laboratory improvement (Table 1).

## DISCUSSION

Pancreatic paracoccidioidomycosis simulating pancreatic neoplasia has been infrequently reported in the literature<sup>[6]</sup>. Clinical findings include weight loss, weakness, dizziness, repletion, pruritus, jaundice, choluria, and fecal acholia, as in the reported case. Signs of cholestatic disease are the most reported abnormalities, with an increase in alkaline phosphatase and gamma-glutamyl transferase. Jaundice is usually observed in the late stage of the disease, and is associated with differential diagnoses of greater severity<sup>[7]</sup>, such as malignant pancreatic neoplasia. The findings of pancreatic tumor adhering to vessels and deep planes, as well as satellite nodules and obstruction of the biliary tract with secondary portal hypertension (diagnosed through the esophageal varices), suggested a diagnosis of metastatic pancreatic cancer. As shown in this report, abdominal lymphatic compromise may give rise to such clinical conditions as abdominal tension and pain, which may even simulate acute abdomen affections<sup>[8]</sup>. The granulomatous involvement of lymph nodes initially led to the hypothesis of sarcoidosis, which may affect multiple organs, particularly the lungs (90%) and lymph nodes (75%)<sup>[9]</sup>. But sarcoidosis rarely affects the pancreas<sup>[10,11]</sup>, and when it does, it is usually asymptomatic<sup>[12]</sup>. The type of granuloma found in the lymph node, characteristically epithelioid, without necrosis or bacilli, favored this diagnosis. On the other hand, immunosuppression with corticoids, which would be recommended in a case of sarcoidosis, may be harmful if the patient has had an infectious disease. At that time, the second pancreatic tissue sample obtained by FNA defined the paracoccidioidomycosis diagnosis and successfully directed the therapy. Interestingly, although the patient had had an abdominal lymph node enlargement, he did not have peripheral lymphadenopathy, which is usually the major complaint in patients with the juvenile form of paracoccidioidomycosis. Additionally, there were none of the pulmonary manifestations that occur in 90% of patients with the chronic form<sup>[1]</sup>. Although it is rare, pancreatic paracoccidioidomycosis must be considered in the differential diagnosis of intra-abdominal tumors in endemic areas, even without peripheral lymphadenopathy.

### Abstract

We devised an extended 72-wk peginterferon- $\alpha$ -2a/ribavirin therapy regimen for the retreatment of highly intractable cases, *i.e.*, 48-wk peginterferon- $\alpha$ -2b/ribavirin therapy-intractable cases. Although 2 cases achieved a rapid virological response to 72-wk peginterferon- $\alpha$ -2a/ribavirin therapy, 1 case failed to achieve a sustained virological response. Although the reason for this difference in the effectiveness of 72-wk peginterferon- $\alpha$ -2a/ribavirin therapy between the cases was unclear, the rebound phenomenon of serum transaminase after 48-wk peginterferon- $\alpha$ -2b/ribavirin therapy and the resultant lower viral load compared to that before 48-wk peginterferon- $\alpha$ -2b/ribavirin therapy might have influenced the treatment outcome. Thus, it may be beneficial to consider the rebound phenomenon of serum transaminase and the changes in viral load resulting from previous interferon-based therapy and then cau-

tiously determine the indication and the timing of the administration of 72-wk peginterferon- $\alpha$ -2a/ribavirin in highly intractable cases. Further studies should be performed to confirm this strategy.

**Key words:** Hepatitis C; Genotype 2 and high viral loads; Interferon-based therapy; Highly intractable case; Extended therapy duration

**Core tip:** The optimal therapy for 48-wk peginterferon- $\alpha$ -2b/ribavirin therapy-intractable hepatitis C patients with genotype 2 and high viral loads remains unknown. Our cases are notable in that 72-wk peginterferon- $\alpha$ -2a/ribavirin therapy may have been effective for these highly intractable cases. Additionally, the rebound phenomenon of serum transaminase after the 48-wk peginterferon- $\alpha$ -2b/ribavirin therapy and the resultant lower viral load compared to that before the 48-wk peginterferon- $\alpha$ -2b/ribavirin therapy might have influenced the treatment outcome. Thus, our cases highlight the importance of the results of the previous 48-wk peginterferon- $\alpha$ -2b/ribavirin therapy in the indication and timing of the administration of 72-wk peginterferon- $\alpha$ -2a/ribavirin in highly intractable cases.

### INTRODUCTION

The American Association for the Study of Liver Diseases Practice Guidelines recommend treatment with

peginterferon/ribavirin for 24 wk using a ribavirin dose of 800 mg for interferon-based therapy-naïve patients with hepatitis C virus (HCV) genotype 2<sup>[1]</sup>. However, retreatment with peginterferon/ribavirin in patients who do not achieve a sustained virological response (SVR) after a full course of peginterferon/ribavirin is not recommended, even if a different type of peginterferon is administered<sup>[1]</sup>. However, some patients who have previously completed peginterferon- $\alpha$ -2b [PegIntron; Merck Sharp & Dohme (MSD), Tokyo, Japan]/ribavirin (Rebetol; MSD) therapy but failed to achieve an SVR can be treated with a 24- to 48-wk course of peginterferon/ribavirin<sup>[2-4]</sup>. Oze *et al*<sup>[2]</sup> suggested that the SVR rate was similar between 24-wk and 48-wk peginterferon/ribavirin therapy in patients with genotype 2 who achieved a rapid virological response (RVR) upon retreatment. We previously demonstrated the superiority of 48-wk therapy over 24-wk therapy for patients with genotype 2 and high viral loads  $\geq 10^5$  international units (IU)/mL; 5 logIU/mL as determined using the quantitative reverse transcription polymerase chain reaction-based Cobas TaqMan HCV Test (Roche Diagnostics, Tokyo, Japan) who demonstrated serum HCV RNA levels [measured using the Cobas Amplicor Monitor HCV ver. 2.0 Assay (Roche Diagnostics)]  $\geq 50$  IU/mL at week 4 of therapy regardless of the history of interferon-based therapy<sup>[5]</sup>. The Japan Society of Hepatology also recommends a 24- to 48-wk course of peginterferon/ribavirin retreatment following peginterferon/ribavirin treatment in patients with HCV genotype 2 and high viral loads<sup>[6]</sup>. However, the effectiveness of retreatment in highly intractable cases, *i.e.*, 48-wk peginterferon- $\alpha$ -2b/ribavirin therapy-intractable cases, remains unknown. Therefore, we devised a 72-wk peginterferon/ribavirin therapy regimen for the retreatment of highly intractable cases, regardless of the time of disappearance of serum HCV RNA.

As for the type of peginterferon, the superiority of peginterferon- $\alpha$ -2a therapy over peginterferon- $\alpha$ -2b therapy for chronic hepatitis C has not been determined. However, given that peginterferon- $\alpha$ -2a therapy is significantly superior or has a tendency to increase the efficacy of treatment in patients with HCV genotype 2 compared to peginterferon- $\alpha$ -2b therapy according to randomized controlled trials<sup>[7,8]</sup> and a meta-analysis of randomized controlled trials<sup>[9]</sup>, we selected peginterferon- $\alpha$ -2a (Pegasys; Chugai Pharmaceutical Co., Ltd., Tokyo, Japan)/ribavirin (Copegus; Chugai Pharmaceutical Co., Ltd.) for the retreatment of 48-wk peginterferon  $\alpha$ -2b/ribavirin therapy-intractable cases.

The submitted case reports comply with the Declaration of Helsinki. Informed consent was obtained from the patients.

## CASE REPORT

### Case 1

A 55-year-old male was referred to our hospital because

of chronic HCV infection and abnormal transaminase levels. His medical history included an operation for the treatment of appendicitis at 8 years of age and acute hepatitis with jaundice at 23 years of age after he had acquired a tattoo and abused drugs at 25 years of age. He had neither a history of blood transfusion nor a family history of liver diseases. The transmission of hepatitis C in this case could have been mediated by either the tattoo or drug abuse. His complete blood counts appeared normal, although blood tests showed elevated levels of serum alanine aminotransferase (ALT) (44 IU/mL). The quantitative detection of HCV RNA [real-time polymerase chain reaction (PCR), COBAS TaqMan Test] revealed a level of 6.5 logIU/mL; the HCV genotype was 2b. The interleukin-28B (IL28B) locus single nucleotide polymorphisms (SNPs) previously reported to be associated with therapy outcome, including rs8099917, rs11881222 and rs8103142<sup>[10]</sup>, were all major homozygous. The inosine triphosphatase (ITPA) locus SNP previously reported to be associated with ribavirin-induced hemolytic anemia<sup>[11]</sup> and interferon-induced thrombocytopenia<sup>[12]</sup> in Japanese chronic hepatitis C patients under peginterferon- $\alpha$ /ribavirin therapy (rs1127354) was major homozygous. A liver biopsy obtained prior to interferon-based therapy was graded F1/A2 according to the New Inuyama classification.

We initiated treatment with peginterferon- $\alpha$ -2b (100  $\mu$ g once weekly, subcutaneously) and ribavirin (800 mg per day) based on the patient's body weight. Serum HCV RNA was not detectable at wk 8 of therapy. Thus, we extended the duration of therapy from the standard 24-wk regimen to a 48-wk regimen based on our prospective study<sup>[5]</sup>. The patient's adherence to peginterferon- $\alpha$ -2b/ribavirin was 100%, although his serum HCV RNA level became positive 4 wk after the completion of therapy. Notably, the rebound phenomenon of serum transaminase after completion of the 48-wk therapy occurred, and the viral load decreased below the pre-treatment level. He was retreated with peginterferon- $\alpha$ -2a (180  $\mu$ g once weekly, subcutaneously) and ribavirin (800 mg per day) based on his body weight. Because the 48-wk therapy with peginterferon- $\alpha$ -2b and ribavirin resulted in viral relapse, we extended the duration of therapy from the recommended 24-48 wk to 72 wk, although the serum level of HCV RNA became undetectable after 4 wk of therapy. Although the patient's adherence to ribavirin was 74% due to anemia, he achieved an SVR. The laboratory findings, treatments and outcomes for case 1 are shown in Table 1.

### Case 2

A 55-year-old male was referred to our hospital because of chronic HCV infection. His previous medical history included an operation due to appendicitis at 14 years of age and euthyroid sick syndrome, the onset of which was unclear. He had neither a history of blood transfusion nor a family history of liver disease. Thus, the transmission source of hepatitis C in this case could not be

HCV: Hepatitis C virus; IL28B: Interleukin-28B; SNPs: Single nucleotide polymorphisms; IITPA: Inosine triphosphatase; first therapy: 48-wk peginterferon  $\alpha$ -2b/ribavirin; second therapy: 72-wk peginterferon  $\alpha$ -2a/ribavirin; BMI: Body mass index; ALT: Alanine aminotransferase; AST: Aspartate aminotransferase; WBC: White blood cell; RBV: Ribavirin; SVR: Sustained virological response.

identified. A complete blood count showed slight anemia, and blood tests showed a slightly high serum ALT level (32 IU/mL). The quantitative detection of HCV RNA (real-time PCR, COBAS TaqMan Test) revealed a level of 7.2 logIU/mL; the HCV genotype was 2b. The IL28B locus SNPs, including rs8099917, rs11881222 and rs8103142, were all major homozygous. The IITPA locus SNP rs1127354 was major homozygous. A liver biopsy obtained prior to interferon-based therapy was graded F1/A2 according to the New Inuyama classification.

We initiated treatment with peginterferon- $\alpha$ -2b (100  $\mu$ g once weekly, subcutaneously) and ribavirin (800 mg per day) based on the patient's body weight. Serum HCV RNA disappeared at week 16 of therapy. Thus, we extended the therapy duration from the standard 24-wk regimen to a 48-wk regimen based on our prospective study<sup>[5]</sup>. Although the patient's adherence to peginterferon- $\alpha$ -2b/ribavirin was 100%, his serum HCV RNA level became positive 4 wk after the completion of therapy. In contrast to case 1, no obvious rebound phenomenon of serum transaminase was observed after completion of the 48-wk therapy, and the viral load returned to the pre-treatment level. He was retreated with peginterferon- $\alpha$ -2a (180  $\mu$ g once weekly, subcutaneously) and ribavirin (800 mg per day) based on his body weight. Because the 48-wk therapy with peginterferon- $\alpha$ -

2b and ribavirin resulted in viral relapse, we extended the duration of therapy from the recommended 24-48 wk to 72 wk, and his serum HCV RNA level became negative at wk 4 of therapy. Although the patient's adherence to both drugs was 100%, his serum HCV RNA level became positive again at 4 wk after the completion of therapy, and he therefore could not achieve an SVR. The laboratory findings, treatments and outcomes of case 2 are shown in Table 1.

## DISCUSSION

The major findings from these case reports are twofold: 72-wk peginterferon- $\alpha$ -2a/ribavirin therapy may represent an effective therapy for 48-wk peginterferon- $\alpha$ -2b/ribavirin therapy-intractable cases, and by contrast, even 72-wk peginterferon- $\alpha$ -2a/ribavirin therapy-intractable HCV infection can occur in patients with genotype 2 and high viral loads. Although the difference in the effectiveness of 72-wk therapy between the 2 cases was not clear, the rebound phenomenon of serum transaminase after the 48-wk therapy and the resultant lower viral load compared to that before the 48-wk therapy might be possible contributing factors that could influence the treatment outcome, based on these case reports and our previous study<sup>[5]</sup>. Case 1 was consistent with a previous

report indicating that patients who showed biochemical relapse after initial interferon therapy had a significantly lower serum HCV RNA level at recovery after ALT relapse compared to before the initial interferon therapy<sup>[13]</sup>. Moreover, our cases showed that an RVR was not sufficient for predicting an SVR, even for 72-wk interferon-based therapy. Because both of our cases carried major homozygous IL28B SNPs, our findings support a limited role for *IL28B* genotypes regarding the virological responses achieved in chronic hepatitis C patients with genotype 2 and high viral loads<sup>[5]</sup>. However, because the number of our highly intractable cases was small, further studies are needed to test this hypothesis.

One possible solution for the treatment of highly intractable cases is telaprevir in combination with peginterferon- $\alpha$ -2b/ribavirin therapy. In fact, this therapy achieved an SVR in a 48-wk peginterferon- $\alpha$ -2b/ribavirin therapy-intractable female patient with genotype 2 and a high viral load in a phase III clinical trial (unpublished data). In addition, direct-acting anti-viral (DAA) combination therapy may overcome this difficulty in highly intractable cases in the near future. However, for cases in which it is difficult to use DAA due to the risk of drug interactions between DAA and medicines administered to treat complications or for patients who are discouraged from waiting for antiviral therapy, such as those who developed hepatocellular carcinoma, 72-wk peginterferon- $\alpha$ -2a/ribavirin therapy may be one strategy for curing highly intractable patients with genotype 2 and high viral loads. For case 1 presented here, 24- to 48-wk peginterferon- $\alpha$ -2a/ribavirin therapy for retreatment may have been effective, although we selected 72-wk therapy to improve the likelihood of an SVR. However, 72-wk therapy is not always sufficient, as demonstrated in case 2 (although he did achieve an RVR). In case 1, the viral load after 48-wk peginterferon- $\alpha$ -2b/ribavirin therapy decreased significantly in comparison to the level prior to treatment, whereas the viral load returned to the pre-treatment level in case 2. We were able to initiate the 72-wk therapy under the condition that the viral load had become lower than that before the 48-wk therapy in case 1. This indicates that it may be a good strategy to consider the rebound phenomenon of serum transaminase and the changes in viral load as a result of previous interferon-based therapy and then cautiously determine the indication and timing of administration of the 72-wk peginterferon- $\alpha$ -2a/ribavirin in highly intractable cases. However, a therapy duration of less than 72 wk should also be considered as a second therapy if the pre-treatment viral load before the second therapy is low (less than 5 logIU/mL) because chronic hepatitis C patients with low viral loads are likely to achieve an SVR in short-term therapy. Further studies should be examined to confirm the strategy of extended therapy duration.

### Abstract

Variceal bleeding is the most serious complication of portal hypertension, and it accounts for approximately one fifth to one third of all deaths in liver cirrhosis patients. Currently, endoscopic treatment remains the predominant method for the prevention and treatment of variceal bleeding. Endoscopic treatments include band ligation and injection sclerotherapy. Injection sclerotherapy with *N*-butyl-2-cyanoacrylate has been successfully used to treat variceal bleeding. Although injection sclerotherapy with *N*-butyl-2-cyanoacrylate provides effective treatment for variceal bleeding, injection of *N*-butyl-2-cyanoacrylate is associated with a variety of complications, including systemic embolization. Herein, we report a case of cerebral and splenic infarctions after the injection of *N*-butyl-2-cyanoacrylate to treat esophageal variceal bleeding.

### INTRODUCTION

Variceal bleeding is a catastrophic complication of liver cirrhosis. Although the short-term mortality of variceal bleeding has improved due to recent advances in treatment, the long-term outcomes remain guarded.

Currently, endoscopic treatment remains the predominant method for prevention and treatment of variceal bleeding. Endoscopic treatments include band ligation and injection sclerotherapy. Injection sclerotherapy with *N*-butyl-2-cyanoacrylate (Histoacryl, B-Braun Surgical GmbH, Melsungen, Germany) has been successfully used for variceal bleeding, but Histoacryl injection is associated with a variety of complications, some of which can be disastrous<sup>[1]</sup>.

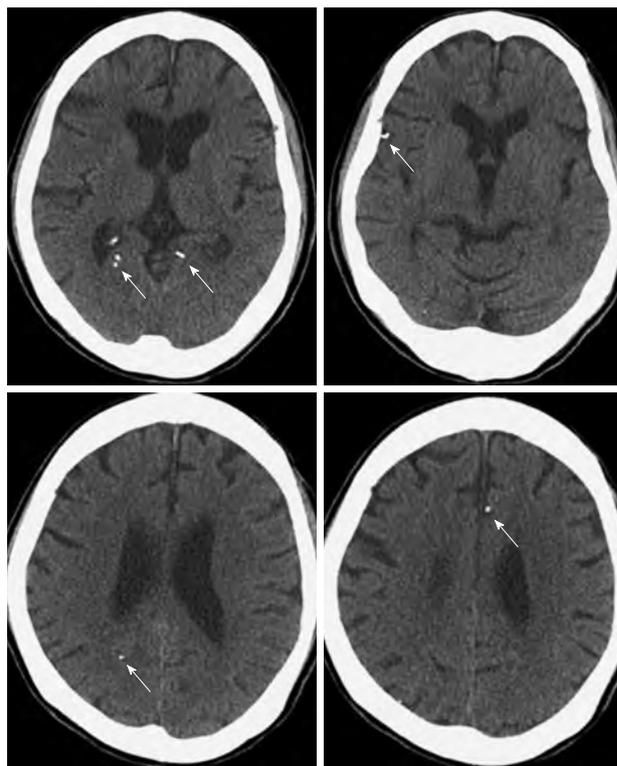

**Figure 1** Endoscopy showing a large esophageal varix. The varix occupies more than half of the esophageal lumen. The adherent, whitish fibrin plug on top of the varix is considered a site of recent hemorrhage.

Systemic embolization including the cerebrum, lung, spleen, and portal vein is a rare and serious complication of Histoacryl injection that has been principally described in the treatment of gastric variceal bleeding<sup>[2,3]</sup>. However, this complication following the esophageal variceal injection of Histoacryl is extremely rare. To date, few cases of this complication at one site have been reported in the English literature.

To our knowledge, this is the first report of a case of multiple embolizations including the cerebrum and spleen after Histoacryl injection in esophageal variceal bleeding.

## CASE REPORT

A 55-year-old woman with alcohol-induced liver cirrhosis of Child-Pugh class B was admitted to Chonnam National University Hwasun Hospital (Jeonnam, South Korea) with a 1-d history of hematemesis. She denied prior gastrointestinal bleeding, peptic ulcer diseases, and use of ulcerogenic medications. On admission, she had a pulse of 90 beats/min, a blood pressure of 80/50 mmHg, and a respiratory rate of 30 breaths/min. The head and neck examination was normal, except for anemic conjunctiva. She had florid spider angiomas. The abdomen was non-tender with ascites, and the spleen tip was slightly palpable. Rectal examination demonstrated the presence of maroon-colored, liquid stool. Laboratory studies revealed the following: hemoglobin, 8.2 g/dL (normal range, 12-18 g/dL); hematocrit, 24.8% (37%-52%); white blood cell count, 9300/mm<sup>3</sup> (4000-10800/mm<sup>3</sup>); platelet count, 100000/mm<sup>3</sup> (130000-450000/mm<sup>3</sup>); total protein, 5.1 g/dL (5.8-8.1 g/dL); albumin, 2.3 g/dL (3.1-5.2 g/dL); total bilirubin, 1.4 mg/dL (0.3-1.3 mg/dL); aspartate aminotransferase, 90 U/L (7-38 U/L); and alanine aminotransferase, 8 U/L (6-42 U/L). Her coagulation profiles were prothrombin time 19.6 s (11-14.9 s) and activated partial thromboplastin time 34.5 s (28-40 s). Endoscopy showed a large esophageal varix with a fibrin plug (Figure 1). Because the bleeding esophageal varix was too large to apply band ligation, we performed injection sclerotherapy

**Figure 2** Non-contrast brain computed tomography showing multiple high attenuation lesions (arrows). The multiple high attenuation lesions are emboli of the Histoacryl-Lipiodol mixture. The high attenuation lesions were seen in the frontal lobe and the parieto-occipital lobe.

with a mixture of Histoacryl and Lipiodol (Laboratoire Guerbet, Aulnay-Sous-Bois, France). The mixture was injected intra-variceally using a 21-gauge needle injector (Injector Force, NM-200L-0821, Olympus Optical Co., Ltd., Tokyo, Japan). The mixture consisted of 0.5 mL of Histoacryl and 0.5 mL of Lipiodol. Because variceal bleeding was not controlled after the first injection, a second injection was performed in the same manner. After the second injection, variceal bleeding was controlled. The total injected volume was 2 mL. However, she developed dysarthria and right motor weakness (grade III/V) 1 h after the injection. Brain computed tomography (CT) showed multiple hyperdense foci in the frontal lobe and the parieto-occipital lobe (Figure 2). Magnetic resonance imaging of the brain showed acute multifocal cortical infarctions. Abdominal CT revealed several wedge-shaped, low attenuation lesions in the spleen, indicating infarction (Figure 3). To evaluate the cause of the newly developed cerebral and splenic infarctions, a transcranial Doppler (TCD) bubble test was performed. The TCD bubble test is used to detect a right-to-left shunt. We used 2 MHz M-mode TCD (ST3, Spencer Technologies, Seattle, Washington, United States; SONARA, Viasys Healthcare, Conshohocken, Pennsylvania, United States) to detect microbubbles in the middle cerebral artery. TCD demonstrated the presence of a microbubble on the M-mode displays in the middle cerebral artery. TCD using Spencer Logarithmic Scale Grades was indicative of grade III during resting and grade IV during the Valsalva maneuver

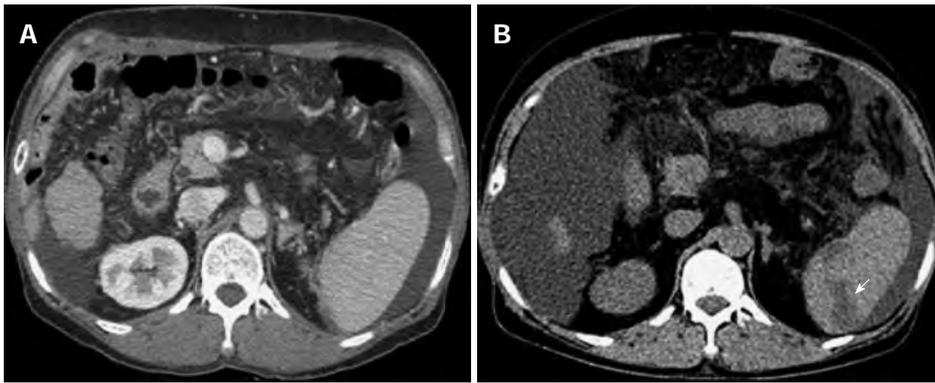

Figure 3 Abdominal computed tomography reveals several wedge-shaped, low attenuation lesions in the spleen, indicating infarction (arrow). A: Computed tomography (CT) before endoscopic treatment; B: CT after endoscopic treatment.

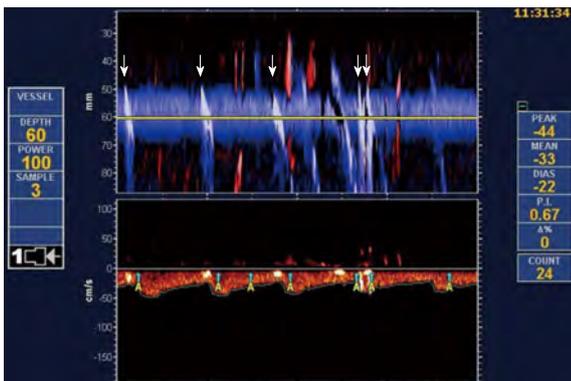

Figure 4 Transcranial Doppler bubble test showing the Doppler flow through the middle cerebral artery. The embolus is clearly represented in the power M-mode (upper panel) as a whitish sloping track. The whitish sloping track means that microemboli disrupt the ultrasonic signal (arrows).

(Figure 4). In the Spencer Logarithmic Scale Grades, grade I and II are considered negative for patent foramen ovale, and grades III through V are considered positive. These findings indicate that the patient had a patent foramen ovale. Therefore, cerebral and splenic infarctions may develop due to emboli cause by a right-to-left shunt. At the follow-up examination, her neurologic symptoms were improved, but neurologic sequelae remained.

## DISCUSSION

Endoscopic treatments, such as band ligation and injection sclerotherapy, became the cornerstone of the management of variceal bleeding. Endoscopic band ligation is the preferred form of endoscopic treatment for esophageal variceal bleeding, but its application in actively bleeding patients is still challenging because the bands at the endoscope tip limit the operator's field of vision. Injection sclerotherapy with various sclerosants is recommended in patients in whom endoscopic band ligation is not technically feasible. Several sclerosants are available, including 5% sodium morrhuate, 1%-3% sodium tetradecyl sulfate, 5% ethanolamine oleate, and 0.5%-1% polidocanol<sup>[2]</sup>. Adhesives such as Histoacryl have been used successfully for the treatment of variceal bleeding.

Injection sclerotherapy provides effective treatment for variceal bleeding, but it has been associated with a

variety of complications. Minor complications including chest pain, dysphagia, fever, and esophageal ulcer are common, although not typically serious. Uncommon and serious complications include bacteremia, esophageal perforation, mediastinitis, and brain abscess. Rarely, systemic embolic complications have followed injection sclerotherapy, and these can be disastrous<sup>[4]</sup>. Systemic embolic complications following Histoacryl injection have been reported, and the common sites of embolic complications were the lung, spleen, cerebrum, and portal vein. Additionally, this complication has been principally described in the treatment of gastric variceal bleeding. Because most gastric varices are associated with a gastrorenal and splenorenal shunts<sup>[5]</sup>, blood flow is abundant, and Histoacryl injection is likely to cause systemic embolization due to the migration of the agent through a shunt<sup>[6]</sup>. In contrast to gastric variceal injection, systemic embolic complications arising from esophageal variceal injection sclerotherapy are extremely rare; to date, only three cases of cerebral embolic complications following esophageal variceal injection sclerotherapy have been documented in the literature<sup>[7,8]</sup>.

Because the bleeding esophageal varix was too large to apply band ligation, we performed injection sclerotherapy with Histoacryl. Cerebral and splenic infarctions followed the bleeding esophageal variceal injection sclerotherapy. Ours is an additional case of cerebral infarction caused by the esophageal variceal injection of Histoacryl, although it is the first report of a case of multiple embolizations including the cerebrum and spleen after the esophageal variceal injection of Histoacryl. The possible explanation for the development of systemic emboli may be the transient patent foramen ovale caused by the episodes of coughing, which induced a temporary right-to-left shunt.

Clearly, transesophageal echocardiography (TEE) is considered the gold standard for right-to-left shunt diagnosis, but it is poorly tolerated by patients and sometimes requires sedation. Additionally, TEE limits the patient's ability to perform a Valsalva maneuver<sup>[9]</sup>. Because our case had a large esophageal varix, we performed a TCD bubble test rather than TEE. The TCD bubble test has proven to be a trustworthy and less invasive method for diagnosing a right-to-left shunt<sup>[10]</sup>. In our case, the ultrasound waves were reflected by microbubbles on the TCD bubble

test, indicating the patent foramen ovale. Additionally, the TCD bubble test was grade III during resting and grade IV during the Valsalva maneuver, according to the Spencer Logarithmic Scale<sup>[8]</sup>. Therefore, the cerebral and splenic infarctions in our case may have been caused by emboli via the patent foramen ovale.

Factors that increase embolization risk include the size of varices, the presence of a collateral vessel, excessive dilution, rapid polymerization, large volume (> 1 mL/injection) and rapid Histoacryl injection. Our case had the three possible embolic risk factors including the large size of the varices, the large volume (> 1 mL) of the mixture injected, and rapid injection<sup>[6]</sup>. Because most embolization risks associated with Histoacryl, as described above, are preventable, proper injection technique may help minimize the risk of serious complications and improve the long-term outcome.

Taken together, although injection sclerotherapy with Histoacryl is a relatively safe and efficacious procedure for the treatment of variceal bleeding, serious complications such as systemic embolization can occur. Ours is the first report of a case of multiple embolizations including the cerebrum and spleen after Histoacryl injection to treat esophageal variceal bleeding. Systemic embolization, despite its rarity, should be considered among the serious complications of Histoacryl injection for the treatment of esophageal variceal bleeding.

### Abstract

Budd-Chiari syndrome (BCS) is defined as hepatic venous outflow obstruction at any level from the small hepatic veins to the junction of the inferior vena cava (IVC) and the right atrium, regardless of the cause of obstruction. We present two cases of acute iatrogenic BCS and our clinical management of these cases. The first case was a 43-year-old woman who developed acute BCS following the implantation of an IVC stent for the correction of stenosis in the IVC after hepatectomy for hepatolithiasis. The second case was a 61-year-old woman with complete obstruction of the outflow of hepatic veins during bilateral hepatectomy for hepatolithiasis. Acute iatrogenic BCS should be con-

### INTRODUCTION

Budd-Chiari syndrome (BCS) is characterized by hepatic venous outflow obstruction at the level of the hepatic venules, the large hepatic veins (HV), the inferior vena cava (IVC), or the right atrium<sup>[1]</sup>. Obstruction of the hepatic venous outflow tract, which leads to hepatic congestion as blood flows into, but not out of the liver, results in damage to the hepatic parenchymal cells and the cells lining the hepatic sinusoids. BCS can cause liver dysfunction and even lead to liver failure.

There are multiple known causes of BCS, including both heritable and acquired hypercoagulable states, compression or invasion of the IVC, as well as other less common miscellaneous causes<sup>[2-4]</sup>. BCS can also be idiopathic. Here, we report two cases of acute BCS with an uncommon cause and present our clinical experience in managing these cases.

## CASE REPORT

### Case 1

A 43-year-old woman developed acute BCS following the implantation of an IVC stent for correction of stenosis in the IVC after hepatectomy for hepatolithiasis. The patient was admitted with recurrent cholangitis. Magnetic resonance cholangiopancreatography showed lithiasis in the intra- and extra-hepatic bile duct, dilatation of the biliary tract and enlargement of the gallbladder. In addition, computed tomography (CT) (Figure 1) demonstrated right lobe, caudate lobe and segment II (Counauid's classification) atrophy of the liver. After biliary decompression by endoscopic retrograde cholangio-pancreatography and control of infection, the following procedures were performed: right hemi-hepatectomy, segment II resection, caudate lobectomy, cholecystectomy, choledochotomy, and choledochojejunostomy. During right hepatectomy, the IVC was accidentally wedge resected due to the obscure boundary between the IVC and the right lobe of the liver, which was immediately sutured.

After surgery, the patient developed congestive hepatopathy, manifested as rapidly progressive abdominal distention, and severe pitting edema of the lower back and lower limbs. Magnetic resonance venography 3 d after operation (Figure 2) showed obvious stenosis near the entrance of the three HVs into the IVC, at the same location where the wedge was resected and repaired. Emergent balloon dilation was performed using a balloon catheter and a metallic stent (30 mm × 75 mm), guided by digital subtraction angiography (Figure 3). However, after this procedure, the patient's liver function deteriorated (Table 1). Contrast enhanced CT confirmed hepatic congestion and revealed that the proximal end of the stent was directly at the entrance of the HV into the IVC. Doppler ultrasonography showed reduced blood flow velocity in the HVs, the maximum velocity in the middle HV was 14 cm/s. There was turbulence in the left HV and backflow in the portal vein. Based on these findings, the patient was diagnosed with acute BCS, caused by the improper position of the stent which blocked the entrance of the HV into the IVC.

Following this diagnosis, the patient was immediately scheduled for surgery to remove the metallic stent. The stenosis of the IVC was 5 cm long and the diameter of the lumen was only 1 cm. The stenosis was repaired using a BalMedic (Beijing Balance Medical Co. Ltd, China) pericardial patch (2 cm × 5 cm) under cardiopulmonary bypass and deep hypothermic circulatory arrest (Figure 4). After surgery, the clinical manifestations of BCS

were alleviated, liver function improved, and the patient recovered without further complications (Table 1). Anticoagulation therapy with low molecular weight heparin (LMWH) for 3 d followed by Warfarin for 3 mo was administered. At one year follow-up, the patient had no recurrent cholangitis, no symptoms related to BCS, and normal liver function. CT angiography showed no obvious stenosis in the IVC (Figure 2).

**Case 2**

A 61-year-old woman experienced complete obstruction of the outflow of HVs during bilateral hepatectomy for hepatolithiasis. She underwent an open cholecystectomy and choledocholithotomy with T-tube drainage 15 years previously for cholelithiasis. In recent years, she suffered from recurrent cholangitis. Imaging findings (Figure 5) showed bilateral hepatolithiasis, dilation of the biliary

**Figure 5 Preoperative imaging findings.** A: Magnetic resonance imaging shows bilateral hepatolithiasis with infection at the posterior right lobe of the liver; B: Major hepatic vein on computed tomography.

tract, common bile duct stones, and a hypodense area on CT in the posterior lobe of the right liver, suggesting infection.

During surgery, the liver was found to be distorted with marked atrophy of the right posterior hepatic lobe and left half of the liver. In addition, the right anterior hepatic lobe (segment V and VIII), and the right caudate lobe showed significant hyperplasia. No neoplasms were found in the wall of the bile duct during choledochoscopy. The liver was then freed to begin resection of the left part of the liver, the right posterior lobe and the right caudate lobe. The left half was resected first. Then, the right HV was revealed and divided using a 45-mm endoscopic linear stapler (Echelon 45 ENDOPATH Stapler, Ethicon ENDO-Surgery, Cincinnati, Ohio, United States). Immediately after ligation, there was sudden and significant congestion of the liver, and hepatic outflow blockage was suspected. The liver was examined and stenosis was found in the middle HV, which was thought to be the left HV. Thus, we set out to repair the middle HV and the right HV.

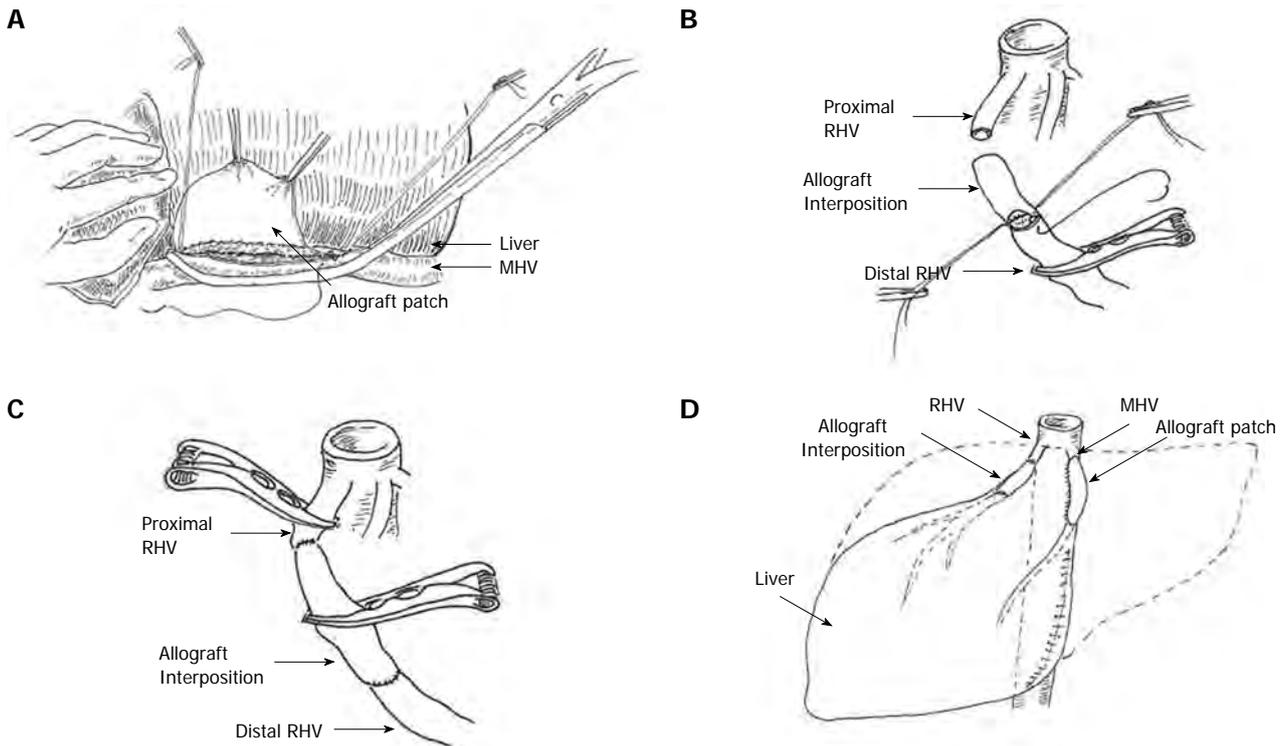

The stenosed middle HV was opened and cryopreserved (-80 °C). A common iliac artery allogeneic graft about 3 cm was prepared. The lumen of the artery was opened and anastomosed to the MHV forming a patch to broaden the stenosed middle HV. Liver swelling was observed to subside after middle HV reconstruction. Both ends of the right HV were then clamped using vascular clamps to control bleeding, and a 1-2 cm allogeneic iliac vein graft was used to repair the right HV (Figure 6). The outflow of blood from the liver was then assessed; no thrombosis or air embolism was found and the liver swelling subsided. It should be noted that the hepatic blood inflow of the porta hepatis was blocked several times during this procedure. The longest blockage time was 40 min with a total length of 60 min. During the procedure, the liver was cold conditioned using ice to attenuate warm ischemic injury. A T-tube was placed in the common bile duct for drainage and to improve accessibility for the future removal of residual stones in the biliary tract. Due to the episode of HV obstruction, a right posterior lobectomy was not performed.

Postoperatively, peak liver enzymes aspartate aminotransferase 380 U/L and alanine aminotransferase 407 U/L were detected, with normal total bilirubin at postoperative day 2. Liver enzymes decreased to the normal range within one week. Postoperative recovery was uneventful. Anticoagulation therapy with LMWH for 3 d followed by Warfarin for 3 mo was administered. Postoperative CT scan (Figure 7) showed no obstruction or thrombosis in the right or middle HV.

## DISCUSSION

BCS is a rare clinical condition characterized by hepatic venous outflow obstruction due to various causes<sup>[1]</sup>. The most common causes of BCS are hypercoagulable states, other uncommon causes have been identified such as tumor invasion, otherwise its origins are idiopathic<sup>[5]</sup>. There are also sporadic reports of BCS as a surgical complication after liver transplantation<sup>[5]</sup>, and right hepatectomy resulting from torsion of the remnant liver<sup>[6]</sup>. In this study, we report two cases of acute BCS following hepatectomy for hepatolithiasis.

Hepatolithiasis is a common disease in Asian countries<sup>[7]</sup>. A multimodal approach has been advocated in the management of this condition, including endoscopic, percutaneous, or open surgery. Hepatectomy is considered the most effective treatment and is indicated in some cases, especially those with recurrent bacterial cholangitis and irreversible atrophy of parts of the liver<sup>[8-10]</sup>. Despite the efficacy of this approach, higher morbidity and mortality is associated with hepatectomy for hepatolithiasis<sup>[9]</sup>. As observed in the two reported cases, performing a partial hepatectomy for hepatolithiasis is a particularly difficult and challenging procedure because of the dense perihepatic adhesions (due to recurrent cholangitis or previous surgery), and abnormal intrahepatic anatomy (due to the atrophy-hypertrophy complex)<sup>[11]</sup>. These challenges require detailed preoperative evaluation to avoid venous injury, including high resolution imaging to identify the intrahepatic anatomy, as well as the relationship between the liver and the IVC. In addition, due to co-existing atrophy and regeneration of the liver, the func-

tion of the HV is frequently abnormal, thus it is crucial to ligate the major HV for testability before continuing with the procedure. Based on our experience with hepatic outflow obstruction, we believe that awareness of possible complications and timely management are critical for attenuating liver congestion and salvaging the liver.

The treatment of BCS is based on its cause, consisting of anticoagulation therapy, thrombolytic therapy, radiological procedures (*i.e.*, angioplasty, stenting or transjugular intrahepatic portosystemic shunts), surgical decompression, surgical shunts, and surgical correction of the lesion. Rarely, liver transplantation may be necessary if the liver is irreparably damaged<sup>[12,13]</sup>. Of note, balloon angioplasty and stent placement has been increasingly favored and the effectiveness of these procedures has been documented<sup>[1,14]</sup>. However, in the first case presented
