In conclusion, it can be stated that ERC using single balloon enteroscopy in patients with Roux-en-Y HJA is more difficult than standard ERCP, due to altered post-operative anatomy, and considerable endoscopic skill and experience is needed in order to perform ERC successfully. CRE requires a lot of time for individual procedures and the presence of an anesthesiologist is essential. The cannulation success rate reached in our group of patients was 80% (12 of 15 patients). Endoscopic treatment was successful in 90% (9 of 10 patients). Most ERC procedures in our group of patients were therapeutic (10 of 12 patients - *i.e.*, 83%). There were no complications in our patients. This method is highly demanding but, at the same time, effective and safe, significantly widening the possibilities of resolving biliary tract diseases.

## COMMENTS

### Background

Single balloon enteroscopy (SBE) was originally and still is used for endoscopic diagnosis and treatment of diseases of the small intestine. It was also intro-

duced in endoscopic retrograde cholangiography (ERC) in patients with Roux-en-Y hepaticojejunostomosis (HJA), especially in cases in which standard ERC (by lateroscopy) was unsuccessful, because it was impossible to reach the area of the HJA.

### Research frontiers

The need to continue developing and possibly improving equipment (both endoscopes and endoscopic accessories) is still present. They should be better adjusted to the needs of the ERC procedures in patients with Roux-en-Y HJA (enteroscopes with sideways or oblique optics with an elevator, shorter enteroscopes with wider channels specially designed for these procedures, and development of endoscopic accessories of greater length).

### Innovations and breakthroughs

When surgically altered gastrointestinal or pancreatobiliary anatomy is present, endoscopic retrograde cholangiopancreatography becomes even more demanding than in a normal anatomical situation. In spite of that, we managed to achieve a comparatively high success in diagnostic (80%) and therapeutic (90%) ERC using single balloon enteroscopy in our cohort of 15 patients with Roux-en-Y HJA, and there were no complications after ERC.

### Applications

ERC using single balloon enteroscopy in patients with Roux-en-Y HJA is time consuming and technically demanding. Nevertheless, it is also an effective and safe method that widens the possibilities of resolving biliary tract diseases. Previously, the only possibility of resolution was using percutaneous transhepatic cholangiography or a surgical approach.

### Peer review

The study reported high-quality results of diagnostic and therapeutic ERC using single balloon enteroscopy in patients with Roux-en-Y HJA. The study retrospectively evaluated 15 patients with Roux-en-Y HJA with signs of biliary obstruction. Altogether, 23 ERC procedures were performed without any complications.

### Abstract

**AIM:** To evaluate the potential use of colonoscopy and endoluminal ultrasonic biomicroscopy (eUBM) to track the progression of mouse colonic lesions.

**METHODS:** Ten mice were treated with a single azoxy-

methane intraperitoneal injection (week 1) followed by seven days of a dextran sulfate sodium treatment in their drinking water (week 2) to induce inflammation-associated colon tumors. eUBM was performed simultaneously with colonoscopy at weeks 13, 17-20 and 21. A 3.6-F diameter 40 MHz mini-probe catheter was used for eUBM imaging. The ultrasound mini-probe catheter was inserted into the accessory channel of a pediatric flexible bronchofiberscope, allowing simultaneous acquisition of colonoscopic and eUBM images. During image acquisition, the mice were anesthetized with isoflurane and kept in a supine position over a stainless steel heated surgical waterbed at 37 °C. Both eUBM and colonoscopic images were captured and stored when a lesion was detected by colonoscopy or when the eUBM image revealed a modified colon wall anatomy. During the procedure, the colon was irrigated with water that was injected through a flush port on the mini-probe catheter and that acted as the ultrasound coupling medium between the transducer and the colon wall. Once the acquisition of the last eUBM/colonoscopy section for each animal was completed, the colons were fixed, paraffin-embedded, and stained with hematoxylin and eosin. Colon images acquired at the first time-point for each mouse were compared with subsequent eUBM/colonoscopic images of the same sites obtained in the following acquisitions to evaluate lesion progression.

**RESULTS:** All 10 mice had eUBM and colonoscopic images acquired at week 13 (the first time-point). Two animals died immediately after the first imaging acquisition and, consequently, only 8 mice were subjected to the second eUBM/colonoscopy imaging acquisition (at the second time-point). Due to the advanced stage of colonic tumorigenesis, 5 animals died after the second time-point image acquisition, and thus, only three were subjected to the third eUBM/colonoscopy imaging acquisition (the third time-point). eUBM was able to detect the four layers in healthy segments of

colon: the mucosa (the first hyperechoic layer moving away from the mini-probe axis), followed by the muscularis mucosae (hypoechoic), the submucosa (the second hyperechoic layer) and the muscularis externa (the second hypoechoic layer). Hypoechoic regions between the mucosa and the muscularis externa layers represented lymphoid infiltrates, as confirmed by the corresponding histological images. Pedunculated tumors were represented by hyperechoic masses in the mucosa layer. Among the lesions that decreased in size between the first and third time-points, one of the lesions changed from a mucosal hyperplasia with ulceration at the top to a mucosal hyperplasia with lymphoid infiltrate and, finally, to small signs of mucosal hyperplasia and lymphoid infiltrate. In this case, while lesion regression and modification were observable in the eUBM images, colonoscopy was only able to detect the lesion at the first and second time-points, without the capacity to demonstrate the presence of lymphoid infiltrate. Regarding the lesions that increased in size, one of them started as a small elevation in the mucosa layer and progressed to a pedunculated tumor. In this case, while eUBM imaging revealed the lesion at the first time-point, colonoscopy was only able to detect it at the second time-point. All colonic lesions (tumors, lymphoid infiltrate and mucosal thickening) were identified by eUBM, while colonoscopy identified just 76% of them. Colonoscopy identified all of the colonic tumors but failed to diagnose lymphoid infiltrates and increased mucosal thickness and failed to differentiate lymphoid infiltrates from small adenomas. During the observation period, most of the lesions (approximately 67%) increased in size, approximately 14% remained unchanged, and 19% regressed.

**CONCLUSION:** Combining eUBM with colonoscopy improves the diagnosis and the follow-up of mouse colonic lesions, adding transmural assessment of the bowel wall.

**Key words:** Ultrasound biomicroscopy; Animal model; Diagnostic imaging; Colonic neoplasm; Longitudinal study

**Core tip:** This paper employed imaging methods, endoluminal ultrasonic biomicroscopy (eUBM) associated to colonoscopy, in a longitudinal study to evaluate the progression of chemically-induced colonic lesions in mice, during a period of two months. The eUBM method complemented colonoscopy and enhanced the study, once the ultrasonic images allowed the detection of lesions underneath the epithelium. Potential future application of eUBM combined with colonoscopy could be in the monitoring of therapeutic efficacy of chemotherapeutic drugs *in vivo*.

## INTRODUCTION

Colorectal cancer (CRC) has a high incidence in the world as it is the third most common cancer in men and women in developed countries<sup>[1]</sup>. It is estimated that more than 142000 people in the United States will be diagnosed with CRC in 2013<sup>[2]</sup>. In Europe, CRC is detected in approximately 413000 people each year, half of whom die during the course of the disease. Despite its high incidence and mortality rates, the majority of CRC-related deaths could be prevented through the implementation of powerful tools for CRC early detection and staging.

Currently, colonoscopy is the recommended screening method for CRC screening and follow-up, but it has some limitations. Studies have demonstrated that the detection of adenomas, serrated polyps and sessile serrated adenomas differs significantly among endoscopists<sup>[3]</sup>. Furthermore, colorectal neoplasms of a diminutive size (smaller than 10 mm) or nonpolypoid shape may be more easily overlooked during a routine colonoscopy<sup>[4-6]</sup>. The miss rate for CRC lesions may explain the high proportion (3.3%-12.4%) of proximal CRC that is diagnosed shortly after a clearing colonoscopy<sup>[7,8]</sup>. Therefore, the efforts of some research groups are focused on the development of other imaging methods that complement the results of a colonoscopy.

High frequency endoscopic ultrasonography (EUS) is a relatively new technique in which an ultrasonography probe is inserted into the accessory channel of a regular endoscope. EUS has the capacity to look deep below the lining of the colon and is a useful modality for transmural assessment of the bowel wall<sup>[9,10]</sup>. Usually, the ultrasound transducers used in EUS instrumentations operate at low frequencies (7.5-12 MHz), but higher ultrasound frequencies are also employed by using a mini-probe<sup>[11-13]</sup>. Higher ultrasound frequencies increase EUS resolution, allowing for the staging of colon tumors and the visualization of small colonic lesions. The use of high frequency mini-probe ultrasound for the diagnosis of mucosal and submucosal colorectal lesions and for the guidance of lesion resection has already been proposed as a safe and effective technique<sup>[13,14]</sup>. However, the role for high frequency mini-probe ultrasound in the routine diagnosis of colonic lesions has not been fully established<sup>[15-18]</sup>.

Animal models of diseases can be used to develop and evaluate new diagnostic tools before they are applied clinically. The development of non-invasive experimental imaging modalities allows for the study of the same ani-

Soletti RC, Alves KZ, de Britto MAP, de Matos DG, Soldan

mal over time, enabling the investigation of disease development and therapeutic interventions. Mouse models of chemically induced CRC are highly reproducible, can be tested on animals with different genetic backgrounds and recapitulate human CRC. The use of an effective and valuable mouse model of chemically induced CRC can help investigators understand colonic tumorigenesis and to probe novel diagnostic platforms for use in clinical practice<sup>[19]</sup>.

Our group has previously used ultrasonic biomicroscopic (UBM) instrumentation, operating at 45 MHz, for *in vitro* imaging of chemically induced mouse CRC<sup>[20]</sup> to demonstrate that UBM is a feasible tool to identify the layers of mouse colon with adequate contrast between them and with sufficient resolution. Afterwards, endoluminal UBM (eUBM), operating at 40 MHz, was performed along with a colonoscopy, and simultaneous eUBM and colonoscopic images were generated *in vivo*<sup>[21]</sup>.

Recently, studies have verified the efficacy of UBM as a tool for longitudinal studies in mice: Harmon and co-workers<sup>[22]</sup> validated the use of 40 MHz extracorporeal UBM for carotid plaque development in mice; Tiwari *et al*<sup>[23]</sup> used a 40 MHz UBM for longitudinal monitoring of infliximab treatment efficacy in a mouse model of pancreatic cancer; Fernández-Domínguez *et al*<sup>[24]</sup> also used a 40 MHz UBM in a longitudinal study to evaluate the progression of fatty liver disease in mice; and Campos-Junior *et al*<sup>[25]</sup> analyzed the efficacy of UBM in the evaluation of induced ovarian follicular growth and ovulation in mice. Despite growing evidence confirming the efficacy of high frequency ultrasound in the monitoring of lesion progression, the ability of eUBM to diagnose colonic tumoral development in animal models has not yet been studied.

The present work comprises the use of eUBM instrumentation associated with colonoscopy in a longitudinal study to evaluate the progression of chemically induced colonic lesions in mice.

## MATERIALS AND METHODS

### Animals

Ten mice [*Mus musculus* (Linnaeus, 1758)] of both genders, with an average age of 7 wk, an average weight of 25 g, and  $p53^{+/+}$  and  $p53^{+/-}$  (heterozygous for tumor suppressor gene *Trp53*), were used. The mice were originally purchased from The Jackson Laboratory (Bar Harbor, ME, United States) and kept in the 129/SvJ background. We used the  $p53^{+/-}$  mice because *Trp53* mutations accelerate tumorigenesis in several tissues, including the colon<sup>[26]</sup>.

The animals were maintained at room temperature with the appropriate circadian cycle and diet. The Guide for Care and Use of Laboratory Animals (National Institutes of Health) was also considered.

Colon tumors were induced using a protocol (DAHE-ICB 042) approved by the Animal Care and Use Commit-

tee of the Biological Science Institute/Federal University of Rio de Janeiro. The studies involving colon imaging, such as eUBM combined with colonoscopy, were conducted under a protocol (71/08) approved by the Ethical Committee for Laboratory Animal Research/Federal University of Rio de Janeiro.

### Azoxymethane and dextran sulfate sodium carcinogenesis protocol

Inflammation-related colon tumors were induced using azoxymethane (AOM) and dextran sulfate sodium (DSS)<sup>[27-29]</sup>. AOM is a colon-specific carcinogen that can be combined with DSS, a mucosal-irritant agent, to mimic inflammation-associated colon carcinogenesis<sup>[29,30]</sup>. The animals were subjected to a single intraperitoneal (*ip*) injection of AOM (A5486; Sigma Aldrich, St. Louis, MO, United States) with a concentration of 12.5 mg/kg. One week after AOM administration, the mice were fed with water containing 3% DSS salt, 36000-50000 Da (02160110; MP Biomedicals, Santa Ana, CA, United States), for 1 wk. All of the mice received solid food and water *ad libitum*, with regular water given after the week of DSS intake.

### Endoluminal ultrasonic biomicroscopy system

Briefly, images were generated by employing a 3.6-F diameter 40 MHz mini-probe catheter (Atlantis® SR Pro Coronary Imaging Catheter; Boston Scientific Corporation, Natick, MA, United States) mechanically driven by a motordrive unit (MD5; Boston Scientific Corporation, Natick, MA, United States). The ultrasonic transducer rotates 360° around its axis, providing cross-sectional ultrasound images of the colon wall. More details concerning the eUBM instrumentation are described in Alves *et al*<sup>[21]</sup>.

### Simultaneous eUBM and colonoscopic image acquisition

Colonoscopy was used simultaneously with eUBM and served to guide the mini-probe through the colon. The ultrasound mini-probe catheter was inserted into the accessory channel of a pediatric flexible bronchofiberscope (FB120P; Fujinon, Tokyo, Japan), allowing simultaneous acquisition of colonoscopy and eUBM images. The bronchofiberscope has a total length of 920 mm and outer diameters of 2.8 and 2.7 mm for the flexible and distal-end portions, respectively.

To ensure that the colonoscopy and eUBM techniques acquired simultaneous images from the same region, the ultrasonic transducer, at the mini-probe imaging core tip, was positioned outside of the distal end accessory channel extremity, while still as close as possible to the bronchofiberscope extremity. The mini-probe telescoping shaft section was used to advance and retract the imaging core, placing it in the correct position.

During image acquisition, the mice were anesthetized with isoflurane (Cristália; São Paulo, Brazil) at 1.5% in 1.5 L/min oxygen, using a laboratory animal anesthe-

**Figure 1** Schematic overview of the azoxymethane and dextran sulfate sodium model and subsequent image acquisition. A single azoxymethane (AOM) *ip* injection was given to 6-wk-old mice (week 1). One week later (week 2), 3% dextran sulfate sodium (DSS) administration was given in the drinking water for 7 d, followed by regular water. The first endoluminal ultrasonic biomicroscopy (eUBM) and colonoscopic images were acquired at week 13, the second acquisition was from weeks 17-20, and the third acquisition was at week 21.

sia system (EZ-7000; Euthanex, Palmer, PA, United States). The animals were kept in a supine position over a stainless steel heated surgical waterbed at 37 °C using the T/Pump System (Gaymar, Orchard Park, NY, United States). Before the examination, an enema was performed with 1 mL of water to remove feces. Subsequently, the flexible bronchofiberscope containing the ultrasound mini-probe catheter was introduced into the descending colon. Both eUBM and colonoscopy images were captured simultaneously and stored when a lesion was detected by colonoscopy or when the eUBM image revealed a modified colon wall anatomy. During the procedure, the colon was irrigated with water that was injected through a flush port of the mini-probe catheter and that acted as the ultrasound coupling medium between the transducer and the colon wall.

### Study design

The sequential evaluation of colonic lesions by simultaneous *in vivo* eUBM and colonoscopic imaging started at 13 wk after AOM administration and was performed at three different time-points, according to Figure 1: the first one at week 13, the second one between weeks 17 and 20 and the last one at week 21.

Colon lesion images acquired at the first time-point for each mouse were compared with subsequent eUBM/colonoscopic images of the same sites obtained in the following acquisitions. After the last eUBM examination, the images of each lesion were separated for subsequent comparison with histopathology.

### Histological analysis

Once the acquisition of the last image for each animal was completed, each anesthetized mouse was euthanized by cervical dislocation. The distal colon was excised, cleaned and fixed in 4% formaldehyde for 16 h before paraffin embedding. The paraffin-embedded tissues were cross-sectioned (5 µm) stepwise transversally to the colon longitudinal axis and stained with hematoxylin and eosin. All stained sections were analyzed by light microscopy and compared with the ultrasonic images, whose frames were obtained from the same lesions observed with the eUBM and/or colonoscopy.

**Table 1** Simultaneous endoluminal ultrasonic biomicroscopy and colonoscopy image acquisition on colon tumor-bearing mice

eUBM: Endoluminal ultrasonic biomicroscopy; AOM: Azoxymethane.

## RESULTS

The time-points for image acquisition of each animal are presented in Table 1. All 10 mice had eUBM and colonoscopic images acquired at week 13. Two animals died immediately after the first imaging acquisition and, consequently, only eight mice were subjected to the second eUBM/colonoscopy imaging acquisition. Due to the advanced stage of colonic tumorigenesis, five animals died after the second time-point image acquisition, and thus, only three were subjected to the third eUBM/colonoscopy imaging acquisition.

An example of interrelated eUBM and histological images of a healthy section from the mouse colon is presented in Figure 2A. The mucosal layer is seen as a hyperechoic circular layer (the first hyperechoic layer moving away from the mini-probe axis), followed by a hypoechoic layer representing the muscularis mucosae. The submucosa corresponds to a hyperechoic layer, followed by the muscularis externa, the second hypoechoic layer. At the center of the lumen is the ultrasound mini-probe, represented by a gray circle. An eUBM image of a colonic lymphoid infiltrate, represented by a hypoechoic region between the mucosa and muscularis externa layers, is presented in Figure 2B with the corresponding histological image.

An example of an eUBM image of a pedunculated tumor, whose size increased during the 6 wk between the first and second time-points, is presented in Figure 3A. At the first eUBM exam, a small elevation in the mucosa layer is seen, indicating an early adenoma. At this time, colonoscopy was unable to visualize the lesion. Six weeks later, eUBM showed that the adenoma had increased in size, and the lesion was then observed in the colonoscopic image. Figure 3B presents an eUBM image of a pedunculated adenoma, whose size remained virtually unchanged between the first and third image acquisitions. The adenoma was also visualized in all of the colonoscopy sections. Finally, a sequence of three eUBM images of a lesion that decreased in size during the observation period is depicted in Figure 3C. This lesion was identified at the first eUBM exam (Figure

**Figure 2** Correlation between endoluminal ultrasonic biomicroscopy and histological images. A: Endoluminal ultrasonic biomicroscopy (eUBM) (right) and the corresponding hematoxylin and eosin-stained histological section (left,  $\times 40$  magnification) obtained from a healthy region of a mouse colon. The eUBM image displays two hyperechoic layers: mucosa (Mu) and submucosa (Sm) and two hypoechoic layers: muscularis mucosae (Mm) and muscularis externa (Me). The ultrasound catheter mini-probe (Mp) is at the center of the lumen; B: eUBM (right) and the corresponding hematoxylin and eosin-stained histological section (left,  $\times 40$  magnification) obtained from a mouse colon containing a lymphoid infiltrate in the colonic wall. The eUBM image displays the mucosa (Mu), muscularis mucosae (Mm) and submucosa layer (Sm). The lymphoid infiltrate (LI) lesion is seen as a hypoechoic region underneath the mucosa. The ultrasound catheter mini-probe (Mp) is at the center. All layers identified in the ultrasound images are well correlated with the histological images from the same site.

3C-a) as a mucosal hyperplasia with ulceration at the top. The ulceration was also visualized by colonoscopy. Four weeks later, at the second eUBM exam (Figure 3C-b), the mucosal hyperplasia had decreased, and a hypoechoic area underneath the mucosa was observed, indicating the emergence of an inflammatory infiltrate. At this point, colonoscopy showed no alterations in this colonic section. At the last eUBM exam (Figure 3C-c), both the mucosal hyperplasia and lymphoid infiltrate had almost completely disappeared. Histological analysis of the same section confirmed the presence of the remaining diminutive lymphoid infiltrate section (Figure 3C-d).

Colonic lesions detected by either the last eUBM or colonoscopy, and confirmed by *post mortem* histology, are indicated in Table 2. Altogether, eUBM identified all of the lesions (tumors, lymphoid infiltrate and mucosal thickening), while colonoscopy identified just 76% of them. Colonoscopy identified all colonic tumors but failed to diagnose lymphoid infiltrates and increased mucosal thickness and failed to differentiate lymphoid infiltrates from small adenomas.

Additionally, the lesion progression outcomes, based on eUBM image analysis, are presented in Table 2. During the observation period, most of the lesions (approximately 67%) increased in size, approximately 14% remained unchanged and 19% regressed.

## DISCUSSION

This report describes the use of a eUBM imaging system for the detection and follow-up of mouse colonic lesions. The simultaneous use of eUBM with colonoscopy was able to detect, diagnose and analyze the progression of tumoral and non-tumoral lesions in a CRC mouse model. Our group has previously demonstrated that two UBM systems, one operating at 45 MHz and the other at 40 MHz, could diagnose mouse colonic lesions *in vitro*<sup>[20]</sup> and *in vivo*<sup>[21]</sup>, respectively. Here, we have demonstrated that a variety of colon lesions can be detected by eUBM in a minimally invasive way. In contrast to histopathological analysis, eUBM can be employed to make repeated measures on the same animal, facilitating the investigation of pathological processes and therapies.

Similar to the previous work, the ultrasound images obtained with eUBM also allowed for the visualization of normal colonic layers: the mucosa, muscularis mucosae, submucosa and muscularis externa (Figure 2A), as well as colon alterations, such as lymphoid infiltrates, ulcerations and tumors (Figure 2B and Figure 3). Confirming our previous findings, lymphoid infiltrates appear as hypoechoic regions underneath a hyperechoic layer representing the mucosa. Colon tumors appear as hyperechoic masses above the mucosa layer. This characteriza-

**Figure 3** Endoluminal ultrasonic biomicroscopy images. **A:** Show increase in tumor volume. Endoluminal ultrasonic biomicroscopy (eUBM) colon images acquired at the first (left) and second (right) time-points from azoxymethane (AOM)-dextran sulfate sodium (DSS)-treated mice. The volume of the pedunculated adenoma (Ad) increased between the first and second eUBM examinations; **B:** Show no alteration in tumor volume. eUBM colon images acquired at the first (left), second (middle) and third (right) time-points from AOM-DSS-treated mice. The lesion observed is a pedunculated tumor. Images show that the tumor volume is unchanged during the observation period; **C:** Show reduction in lesion size. eUBM colon images acquired at the first (a), second (b) and third (c) time-points from AOM-DSS-treated mice. The lesion observed at the first eUBM image is a mucosa hyperplasia (MH) with ulceration at the top. In the subsequent eUBM image, the MH has decreased, and a lymphoid infiltrate (LI) has appeared in the submucosa layer. In the third and last eUBM image, MH and LI have almost completely disappeared, which is confirmed by histological analysis (d,  $\times 40$  magnification). Mu: Mucosa; Sm: Submucosa.

tion is of great importance because it could be used to distinguish small adenomatous polyps from lymphoid

hyperplasias, both seen by colonoscopy as mucosal elevations.

The correct detection and diagnosis of colonic neoplasias during a colonoscopy is essential for CRC prevention. The ranges for adenoma detection rates during a routine colonoscopy could vary up to 37% among endoscopists<sup>[3]</sup>, increasing the chances to misdiagnose CRC. Most postcolonoscopy cancers have a small macroscopic appearance<sup>[31,32]</sup> and in these cases, the simultaneous use of eUBM with colonoscopy could aid in accurately detecting submucosal invasion in colonic lesions.

The small elevation in the mucosa layer observed with eUBM and registered in Figure 3A was not detected by colonoscopy. Perhaps, this fact was due to the poor bronchofiberscope image quality and could be overcome with high-resolution scopes designed specifically for work with rat and mouse models of colonic diseases<sup>[33]</sup>. These high-resolution scopes are usually rigid telescopes and a working channel is formed in a space between an operating sheath and the telescope external wall. Although the bronchofiberscope used in the present work is unable to produce high-resolution images, it has the advantage of being flexible. According to the authors' experience, this facility of the bronchofiberscope is important to position the eUBM mini-probe tip close to a lesion, which improves the lesion visualization, or at the center of the colon lumen in order to generate circular eUBM images of the colon.

According to the results obtained with this longitudinal evaluation of inflammation-associated colon tumor

progression, most of the lesions increased in size, mimicking human cancer development. All tumoral lesions were diagnosed at the first analysis (13 wk after AOM administration), even when the size was very diminutive. The diameter of the smallest detected tumoral lesion was 0.45 mm, and eUBM was able to identify even smaller structures, such as mucosal elevations with a height of 0.1 mm. Of all the lesions detected by eUBM, approximately 15% of them (four lesions) showed a reduction in size. Of these lesions, two were lymphoid infiltrates, whose size reduction indicated inflammation resolution; one was an increase in mucosal thickness that regressed; and the last one was a small adenoma whose tumoral mass decreased. Besides pedunculated and depressed lesions, we have also detected flat lesions in animal models of CRC and current work is being conducted using *p53* knockout mice, which develop flat lesions with a higher incidence than wild type mice<sup>[34]</sup>, to evaluate the eUBM sensitivity.

The data presented here suggest that the use of high-resolution endoluminal ultrasound is a valuable tool to evaluate the progression of colonic lesions. eUBM detected alterations in mouse colonic lesion morphology and in adenoma volume throughout the examination period. Longitudinal high-resolution ultrasound measurements could be helpful in the monitoring of therapeutic efficacy of chemotherapeutic drugs *in vivo*. Additionally, this technique allows for the study of lesion progression in animal models, providing detailed insights into the biology of tumor development.

The potential of the eUBM technique to differentiate malignant from non-malignant lesions is yet to be implemented. Nowadays, the technique of narrow band imaging (NBI) has the capacity to diagnose colon lesion malignancy in real time based in mucosal and superficial vascular structures imaging enhancement<sup>[35]</sup>. However, eUBM has the potential to detect lesion penetration depth through submucosal layers. Both methodologies have their advantages and limitations and could be performed simultaneously to complement each other.

Another advantage of longitudinal eUBM imaging is the possibility to use ultrasound contrast agents to target specific molecules involved in tumor development, such as the angiogenic promoter vascular endothelial growth factor, providing a minimally invasive tool for molecular diagnosis. This new modality of molecular imaging is now being tested in preclinical models with successful results in the characterization of tumor response to anti-angiogenic treatment<sup>[36-38]</sup>.

In summary, the simultaneous use of eUBM with colonoscopy enhances the ability to correctly diagnose and follow-up colonic lesions, offering rapid imaging acquisition and distinct advantages because high-resolution transmural imaging of the bowel wall improves lesion detection and cost-effectiveness.

## COMMENTS

### Background

Colonoscopy is the recommended screening method for colorectal cancer screening and follow-up, but it fails to detect some small or nonpolypoid lesions. Therefore, the development of other imaging methods that complement the results of colonoscopy is extremely important. The authors have previously show that endoluminal ultrasonic biomicroscopy (eUBM) associated to colonoscopy improves the detection and diagnose of inflammatory and tumoral colonic lesions in animal models. Here the authors analyze the capacity of eUBM to evaluate the progression of chemically-induced colonic lesions in mice.

### Research frontiers

The use of eUBM to diagnose mucosal and submucosal colorectal lesions and to guide lesion resection has already been proposed as a safe and effective clinical technique. However, its significant role in the routine diagnosis of colonic lesions has not yet been established. The use of animal models contributes in the development and evaluation of new diagnostic tools before they are completely clinically applied.

### Innovations and breakthroughs

A step forward of previous work done by our group, which now includes the longitudinal study of lesion progression.

### Applications

The current results suggest that the use of eUBM simultaneously to colonoscopy enhances the ability to correctly diagnose and follow up colonic lesions. In addition to its potential clinical application, eUBM can aid investigators to study colonic tumorigenesis processes and to evaluate novel therapeutic agents for colorectal cancer.

### Terminology

eUBM, also known as high frequency endoscopic ultrasonography is a relatively new technique in which an ultrasound probe is inserted into the accessory channel of a regular endoscope. eUBM is an useful modality for transmural assessment of the bowel wall.

### Peer review

The authors describe the evaluation of the potential use of colonoscopy and eUBM to track the progression of mouse colonic lesions. This is a clinically very interesting study.

### Abstract

**AIM:** To evaluate the effects of disease severity and necrosis on organ dysfunctions in acute pancreatitis (AP).

**METHODS:** One hundred and nine patients treated as AP between March 2003 and September 2007 with at least 6 mo follow-up were included. Patients were classified according to severity of the disease, necrosis ratio and localization. Subjective clinical evaluation and fecal pancreatic elastase- I (FPE- I) were used for exocrine dysfunction evaluation, and oral glucose tolerance test was completed for endocrine dysfunction. The correlation of disease severity, necrosis ratio and localization with exocrine and endocrine dysfunction were investigated.

**RESULTS:** There were 58 male and 51 female patients, and mean age was  $56.5 \pm 15.7$ . Of the patients, 35.8% had severe AP (SAP) and 27.5% had pancreatic necrosis. Exocrine dysfunction was identified in 13.7% of the patients [17.9% were in SAP, 11.4% were in mild AP (MAP)] and 34.7% of all of the patients had endocrine dysfunction (56.4% in SAP and 23.2% in MAP). In patients with SAP and necrotizing AP (NAP),

FPE- I levels were lower than the others ( $P < 0.05$  and  $0.001$  respectively) and in patients having pancreatic head necrosis or near total necrosis, FPE-1 levels were lower than  $200 \mu\text{g/g}$  stool. Forty percent of the patients who had undergone necrosectomy developed exocrine dysfunction. Endocrine dysfunction was more significant in patients with SAP and NAP ( $P < 0.001$ ). All of the patients in the necrosectomy group had endocrine dysfunction.

**CONCLUSION:** Patients with SAP, NAP, pancreatic head necrosis and necrosectomy should be followed for pancreatic functions.

**Key words:** Acute pancreatitis; Exocrine dysfunction; Endocrine dysfunction; Pancreas function test; Pancreatic necrosis

**Core tip:** The aim of this study was to evaluate the effects of disease severity and necrosis on organ dysfunctions in acute pancreatitis (AP). Exocrine and endocrine dysfunctions were investigated according to disease severity and necrosis ratio after acute pancreatitis. Exocrine dysfunction was identified in 13.7% of the patients [17.9% were in severe AP (SAP), 11.4% were in mild AP (MAP) and 34.7% of all of the patients had endocrine dysfunction (56.4% in SAP and 23.2% in MAP)]. Forty percent of the patients who had undergone necrosectomy developed exocrine dysfunction. Endocrine dysfunction was more significant in patients with SAP and NAP. All of the patients in the necrosectomy group had endocrine dysfunction. Patients with SAP, NAP, pancreatic head necrosis and necrosectomy should be followed for pancreatic functions.

## INTRODUCTION

Eighty percent of the pancreatic mass is devoted to exocrine function, and the remaining part is responsible for endocrine function, which is crucial to the maintenance of homeostasis of the body<sup>[1]</sup>. Clinically, the severity of acute pancreatitis (AP) varies significantly. Some patients experience a mild form (mild AP, MAP) of the disease (80%-90% of all cases), which is a self-limiting condition with patients recovering within 3-4 d after onset of the disease. Serious insult occurs in 20%-30% of the cases in the first week after AP attack and mortality can be 30% in the severe form. Pancreatic necrosis develops in 20% of all cases<sup>[2,3]</sup>. Both the presence and extent of the necrosis affects the clinical course of the disease. Necrosis larger than 50% of the pancreatic mass significantly increases the local and systemic complication rates<sup>[4]</sup>. There are contradictory results from evaluations of exocrine and endocrine dysfunction in mild and severe cases<sup>[5,6]</sup>. In 1984 at the Marseille symposium, it was accepted that pancreatic injury is temporary and endocrine and exocrine functions recover during the following month<sup>[7]</sup>. But there are some contradictory reports claiming that pancreatic injury is persistent<sup>[8-10]</sup>. Currently, it is accepted that pancreatic function recovers in the absence of pancreatic necrosis and if necrosectomy is not performed<sup>[11]</sup>.

Previous studies have demonstrated that severity of AP, extent of the pancreatic necrosis and the cause of pancreatitis are closely related to the magnitude of pancreatic dysfunction<sup>[12,13]</sup>. After severe acute pancreatitis (SAP), Bozkurt *et al*<sup>[14]</sup> and Boreham *et al*<sup>[15]</sup> reported 85% and 86% pancreatic exocrine dysfunction, respectively. Boreham also reported 13% pancreatic exocrine dysfunction after mild cases. The etiologic factor is also correlated with the level of pancreatic injury; acute pancreatitis due to alcohol consumption may cause pancreatic dysfunction<sup>[9]</sup>. While it is mostly  $\beta$  cell injury that induces endocrine dysfunction, insulin resistance may also contribute to glucose intolerance<sup>[16-18]</sup>. Endocrine dysfunction is reported in 15%-35% of the cases<sup>[12,14,18]</sup>.

There is no consensus about the frequency and severity of endocrine and exocrine dysfunction due to acute pancreatitis. Also, experts do not agree on the necessity of enzyme supplementation following the discharge of these patients<sup>[15]</sup>. Our study aimed to clarify the relationship between pancreatic dysfunction, the severity of the disease and the extent of the pancreatic necrosis.

## MATERIALS AND METHODS

This study was undertaken in the Uludag University Department of Surgery-Bursa, Turkey. From March 2003 to October 2007, 216 consecutive patients with AP were evaluated in our center. This study was approved by the

Institutional Review Board of Uludag University (September 11<sup>th</sup> 2007, No: 2007-14/64). Patients who died ( $n = 16$ ) or with less than 6 mo of follow-up after onset of the disease ( $n = 11$ ) were excluded. All of the patients were invited to the hospital to participate the study by phone or mail. Fifty-five patients could not be contacted due to change of address and 25 patients declined to participate. The remaining 109 patients were included the study, and written informed consent was obtained from each subject.

The data of the patients who were treated for AP were recorded prospectively in previously prepared forms. Diagnosis of AP and determination of its etiology were based on clinical evaluation, serum and urine amylase (higher than three times the upper level of normal was considered diagnostic), liver function tests, serum triglycerides, calcium, alkaline phosphatase and abdominal ultrasound (US) at the admission. Within 72 h following admission, contrast enhanced abdominal computed tomography (CECT) was performed. Patients with gallstones on US were assumed to be cases of biliary pancreatitis; patients consuming large amounts of alcohol (but not having chronic pancreatitis) were considered as having alcoholic pancreatitis. In patients with high levels of serum fat (triglyceride level more than 1000 mg/dL), hyperlipidemia was accepted as the etiological factor. Patients with undetermined etiology were considered to be idiopathic cases. For prognostic evaluation and classification of the severity of the disease, the Acute and Physiology and Chronic Health Evaluation II scoring system (APACHE II) was used. Patients with APACHE II  $\geq 8$  were accepted as severe AP (SAP). While patients who had  $< 8$  score were accepted as mild AP (MAP) and treated conservatively (fluid resuscitation only), patients who had SAP were treated with aggressive fluid resuscitation, nutritional support (enteral or parenteral) and antibiotic prophylaxis. If the patient's clinical status deteriorated and CECT findings revealed infected necrosis or if fine needle aspiration cytology demonstrated infection, they were treated surgically. The Beger procedure (open necrosectomy and closed continuous lavage) plus feeding jejunostomy was our treatment of choice. In some of the cases, more conservative procedures (*i.e.*, percutaneous drainage) had to be undertaken due to the patient's condition.

Following designation of the participating patients and receiving informed consent, specific questions were asked of the patients to evaluate the clinical findings of the pancreatic exocrine insufficiency. The findings were recorded on the Subjective Clinical Evaluation (SCE) form (Table 1). If a patient answered "yes" to even only one of the questions on the SCE form, the test was accepted as positive. Exocrine pancreatic function was also evaluated using the fecal pancreatic elastaz-1 (FPE-1) test in a random stool sample. Patients who were having pancreatic enzyme supplements were instructed to taper their enzyme supplementation 1 mo before the FPE-1 test. Stool samples were collected from the patients and

**Table 1 Subjective clinical evaluation test**

Age/sex:
- Did DM develop after AP?
(a) yes (b) no
- Any abdominal pain, discomfort, steatorrhea, weakness, weight loss, lack of appetite after AP?
(a) yes (b) no
- Did you use pancreatic enzyme supplementation? If so, how long time did you use it?
(a) yes (b) no

AP: Acute pancreatitis; DM: Diabetes mellitus.

stored at -20 °C. FPE-1 level was measured by a commercially available Enzyme-Linked Immunosorbent Assay kit (Bioserv Diagnostics, BS-86-01, Rostock, Germany 2007) according to manufacturer's instructions. Stool elastase 1 concentration higher than 200 µg/g stool indicated normal pancreatic function, whereas concentration of 100 to 200 µg/g stool indicated mild to moderate pancreatic insufficiency, and concentrations below 100 µg/g stool were qualified as pointing to severe pancreatic insufficiency<sup>[12]</sup>.

In all of the patients without diagnosed insulin-dependent diabetes mellitus (DM), endocrine pancreatic function was assessed by oral glucose tolerance test (OGTT). Measurement of glucose concentration was made on patients who had fasted overnight and discontinued drugs and food that could have affected the results. After taking blood samples for fasting blood glucose measurement during the OGTT, the patients drank 75 g glucose dissolved in 300 mL, and their blood glucose concentration was measured at 30, 60, 90 and 120 min. Basal blood glucose levels < 120 mg/dL and between 126-200 mg/dL at 120 min were accepted as impaired glucose tolerance. Basal glucose levels > 126 mg/dL and > 200 mg/dL at 120 min were accepted as DM.

The association between pancreatic dysfunction (either SCE or FPE-1 level) and disease severity and necrosis was investigated.

### Statistical analysis

Statistical analysis was performed using SPSS 13.0 for Windows (Chicago, IL). Non-parametric tests were used to analyze the data. When comparing more than 3 groups, the Kruskal-Wallis test was used. Comparison between 2 groups was made with Mann-Whitney *U* test. The  $\chi^2$  test was used to compare categorical variables. A *P* value of < 0.05 was considered significant.

## RESULTS

### Patient demographics

A total of 109 patients with a mean follow-up of 32 mo (range: 6-48 mo) was included in this study. Fifty-eight of the subjects were male (53.2%), and 51 were female (46.8%). The mean age of the patients was  $56.5 \pm 15.7$  (range: 19-89) years. The etiologies were biliary (66%),

**Figure 1 Disease severity and fecal pancreatic elastase- I level.** Fecal pancreatic elastase- I (FPE-1) level was lower in severe acute pancreatitis (SAP) than mild acute pancreatitis (MAP) ( $P < 0.05$ ). FPE levels are  $330.9 \pm 170.6$  µg/g and  $475.2 \pm 223$  µg/g stool in SAP and MAP, respectively.

idiopathic (15.5%), alcohol (8.2%), hyperlipidemia (4.6%), endoscopic retrograde cholangio-pancreatography related (2.7%) and drug-related (2.7%). According to the APACHE II scoring system, 35.8% of the patients were SAP, and the remaining were MAP. Necrosis was found in 27.5% of the patients, and there was only pancreatic edema in 49.6% of the patients on CECT examination. Almost 23% of the CECT findings were noted to be normal. While necrosis was found in 59% of the SAP cases, it was found in 10% of MAP. On the other hand, of the patients who had necrosis according to CECT findings, 76.6% had SAP, and the remaining had MAP according to APACHE II criteria. Twenty-six percent of the patients who had pancreatic edema on CECT scan had SAP.

Five patients were operated on due to infected pancreatic necrosis, and a Beger procedure plus feeding jejunostomy was performed. Cystoenterostomy was performed in 17 cases due to a pancreatic pseudocyst. Percutaneous drainage was performed in 7 cases for pancreatic and peripancreatic abscesses. The remaining patients were treated medically. Before starting the study, 50.4% of the patients were taken pancreatic enzyme supplementation.

### Exocrine dysfunction after acute pancreatitis

Exocrine dysfunction was detected in 13.7% of the patients according to both subjective clinical evaluation and the FPE-1 test. It was found in 17.9% with SAP and in 11.4% with MAP. Four patients in the SAP group had severe exocrine dysfunction according to FPE-1 measurement, and 11 patients had moderate exocrine dysfunction (7 of them in the MAP and 4 in the SAP group). Disease severity and necrosis were not associated with subjective clinical evaluation (Table 2). FPE-1 was lower in the SAP than MAP group and was lower in patients with necrotizing AP (NAP) than those without necrosis (Figures 1 and 2). FPE-1 was lower in cases with pancreatic head or near total necrosis than patients with necrosis at other localizations (Figure 3). This was under the critical level of FPE-1 (200 mg/g stool). There was no significant correlation between FPE- I level and subjective clinical evaluation.

**Figure 2** Fecal pancreatic elastase- I levels and contrast enhanced abdominal computed tomography findings. Fecal pancreatic elastase- I (FPE-1) level was significantly lower in necrotizing acute pancreatitis (NAP) than the patients without pancreatic necrosis ( $^bP < 0.001$ ). FPE- I levels as follows;  $292.43 \pm 178.78$ ,  $487 \pm 226.21$ , and  $443.91 \pm 167.83$  µg/g stool in NAP, edematous acute pancreatitis (EAP) and normal contrast enhanced abdominal computed tomography (CT) groups, respectively.

**Table 2** The association between disease severity and contrast enhanced computed tomography findings and exocrine dysfunction *n* (%)

Disease severity and CT findings	Exocrine dysfunction	P value
SAP	7/39 (17.9)	NS
MAP	8/70 (11.4)	NS
NAP	8/30 (26.6)	NS
EAP	5/54 (9.2)	NS
Normal CT	2/25 (8.0)	

CT: Computed tomography; SAP: Severe acute pancreatitis; MAP: Mild acute pancreatitis; NAP: Necrotizing acute pancreatitis; EAP: Edematous acute pancreatitis; NS: Not significant.

### Endocrine dysfunction after acute pancreatitis

DM was detected in 11.9% of the cases before the AP attack. DM and impaired glucose tolerance were detected in 30.2% and 4.5% of the remaining cases, respectively, according to the OGTT test. Therefore, endocrine dysfunction was noted to be present in 34.7% of the cases (56.4% with SAP and 23.2% with MAP). According to CECT findings, patients with necrosis had more severe endocrine dysfunction than patients without necrosis (endocrine dysfunction rate was 66.6% in NAP, 27.8% in Edematous AP (EAP) and 12% in normal CECT) (Figure 4).

## DISCUSSION

AP is a mediator disease caused by proinflammatory cytokine release and has a clinical picture ranging from mild disease to multiorgan failure and sepsis. The clinical picture is serious in 15%-20% of patients; complications can develop and mortality can be seen in these patients. Pancreatic necrosis develops in 20%-30% of the patients<sup>[3]</sup>. In this series, SAP was diagnosed in 35.8% and NAP was determined in 27.5% of the AP cases. The fact that SAP and NAP rates in our series are higher than those in the literature might be due to our hospital being the tertiary

**Figure 3** Necrosis localization and fecal pancreatic elastase- I levels. Fecal pancreatic elastase- I (FPE-1) level was lower in head and near total necrosis of the pancreas than body or tail necrosis ( $^aP < 0.05$ ). FPE-1 levels as follows;  $189.18 \pm 82.7$ ,  $324.86 \pm 194$ ,  $258.06 \pm 134.63$  and  $181.12 \pm 134.25$  µg/g stool in head, body, tail and near total necrosis groups, respectively.

care referral center.

Currently, there is no consensus on whether or not pancreatic functions recover and to what extent after an AP attack. Full pancreatic functional recovery has been reported in some studies<sup>[6,19,20]</sup>, whereas others have reported that both endocrine and exocrine insufficiency might develop<sup>[8-10]</sup>. The research is not conclusive or sufficient to answer the question. The results of previous studies remain conflicting because of very small patient numbers and non-homogenous etiologies that affect pancreatic functions. Using ineffective and non-standardized tests can also lead to some mistakes and controversies<sup>[11]</sup>. In the current study, we used subjective clinical evaluation and the FPE-1 test, which has a relatively high sensitivity for exocrine function. Pancreatic elastase is a specific protease of humans and it undergoes minimal breakdown during intestinal transit. Strong parallelism between stool FPE-1 and amylase, lipase and trypsin in pancreatic juice has been reported<sup>[21,22]</sup>. The sensitivity of the FPE- I test is 90% in SAP and 60%-70% in mild disease<sup>[23]</sup>. Although the test is easy and used widely in many reference laboratories, it is not an ideal test. But, FPE-1 test is more reliable than the direct tests which are more expensive, invasive and time-consuming.

Long term results after AP, in terms of pancreatic functions are heterogeneous. The pancreatic dysfunction rate after AP ranges between 11%-85% in SAP and 13%-55% in MAP<sup>[12,15,16,24]</sup>. Bozkurt *et al*<sup>[14]</sup> reported the results of their relatively small series. They observed mild-moderate exocrine dysfunction rates of 74% and 81% at 1 and 18 mo follow-up, respectively. Severe exocrine dysfunction following AP was noted in 26% at 1 mo and 6% at 18 mo. On the other hand, Ibars *et al*<sup>[11]</sup> observed normal pancreatic exocrine function after AP in their study of the same size. In our study, the exocrine dysfunction rate was found to be 13.7% among the patients. This rate was higher in the NAP group and lower in edematous cases and among patients with normal CECT findings. The duration between the AP attack and FPE-1 test of patients having exocrine dysfunction was relatively long (most of them longer than 24 mo). The relation between pancreatic exocrine dysfunction and pancreatic necrosis and its localization is not clear. Although no relation was found between necrosis and subjective clinical evalua-

**Figure 4 Acute pancreatitis and endocrine dysfunction.** Endocrine dysfunction was much higher in severe acute pancreatitis than mild acute pancreatitis (A) and also much higher in necrotizing acute pancreatitis than without necrosis (B) ( $P < 0.001$ ). SAP: Severe acute pancreatitis; MAP: Mild acute pancreatitis; NAP: Necrotizing acute Pancreatitis; EAP: Edematous acute pancreatitis.

tion, the FPE-1 level was low in SAP, NAP and patients with pancreatic head necrosis. FPE-1 was noted to be under the critical threshold ( $< 200 \mu\text{g/g}$  stool) in patients having head necrosis. Kemppainen *et al.*<sup>[25]</sup> reported that in patients with pancreatic head and body necrosis, the complication rate was much higher than the others and they attributed this to proximal obstruction.

As seen in some of our cases, the occurrence of exocrine dysfunction or enzyme insufficiency after AP may be independent of organ necrosis and severity of disease. We can only speculate about the cause of this finding. It is not ethical to biopsy the pancreas after AP. On the other hand, measuring tissue microcirculation and organ perfusion is not practical. We can speculate that fibrosis and the loss of functional units might occur during the healing period under cytokine cascade after AP attack. It has been reported that pancreatic exocrine dysfunction is relatively more common in the long term, especially after NAP, and in patients with necrosectomy<sup>[15,26]</sup>. Exocrine dysfunction was observed in 26.6% of NAP cases and 40% of patients who had necrosectomy in our study. We did not analyze the FPE-1 level in different time periods. Therefore, from our data, we cannot draw conclusions about the course of enzyme insufficiency over the long term.

We have very limited data about pancreatic enzyme supplementation and its dosage and duration after AP. Approximately 50% of our cases were on enzyme supplementation before starting the study. Interestingly, only 12.8% of these patients had exocrine dysfunction after one month tapering of enzyme supplementation. On the other hand, only 3 of 15 patients with exocrine dysfunction had been taking enzyme supplementation. Therefore these results showed that enzyme supplementation regimes should be questioned.

The reported rate of endocrine dysfunction after AP is 15%-35%<sup>[18,27]</sup>. The rate in the present study was relatively high (34.7%). In previous studies, endocrine dysfunction has been reported to occur in up to 50%-70% of cases of necrosis or necrosectomy<sup>[5,17,28]</sup>. In our study, endocrine dysfunction was related to disease severity and presence of necrosis but was not related to the necrosis ratio and localization. This finding can be also explained with pancreatic fibrosis occurring as a result of inflam-

mation, leading to exocrine dysfunction. In addition to beta cell loss, increased insulin resistance is thought to be another causal factor for endocrine dysfunction after AP<sup>[17]</sup>. This factor was demonstrated in an experimental study<sup>[29]</sup>. In contrast to exocrine dysfunction, endocrine dysfunction was not related to pancreatic head necrosis. This also can be explained by the fact that islet cells are disseminated homogenously through the organ. Therefore islet cells localized in uninjured regions of the organ can compensate. Endocrine dysfunction can occur without necrosis if the whole pancreas is affected by fibrosis.

Necrosis is a risk factor for pancreatic dysfunction; however, pancreatic dysfunction can occur without necrosis over the long term. It is not easy to detect pancreatic dysfunction, especially exocrine dysfunction. Reasons for this include: (1) There is no ideal test to detect exocrine dysfunction; (2) Pancreatic dysfunction can be explained by apoptosis in patients who did not have necrosis; (3) Ultrastructural changes and fibrosis due to the healing process in the ductal system can cause dysfunction; and (4) Recurrent attacks might be a source of morphologic changes and dysfunction.

In conclusion, long-term quality of life after AP should be evaluated in SAP, NAP, patients having necrosectomy and patients with pancreatic head necrosis.

## COMMENTS

### Background

Eighty percent of the pancreatic mass is devoted to exocrine function, and the remaining part is responsible for endocrine function, which is crucial to the maintenance of homeostasis of the body. This study aimed to clarify the relationship between pancreatic dysfunction, the severity of the disease and the extent of the pancreatic necrosis.

### Research frontiers

To evaluate the effects of disease severity and necrosis on organ dysfunctions in acute pancreatitis.

### Innovations and breakthroughs

Necrosis is a risk factor for pancreatic dysfunction; however, pancreatic dysfunction can occur without necrosis over the long term. It is not easy to detect pancreatic dysfunction, especially exocrine dysfunction.

### Peer review

In this study the authors evaluate the effects of disease severity and necrosis on organ dysfunction in acute pancreatitis. Fecal pancreatic Elastaz-1 and oral glucose tolerance test are used to measure exocrine and endocrine insufficiency. This is an interesting manuscript dealing with an area of investigation

poorly explored in the past.

### Abstract

**AIM:** To evaluate the therapeutic effect of Shugan-decoction (SGD) on visceral hyperalgesia and colon gene expressions using a rat model.

**METHODS:** Ninety-six adult male Wistar rats were randomized into six equal groups for assessment of SGD effects on psychological stress-induced changes using the classic water avoidance stress (WAS) test. Untreated model rats were exposed to chronic (1 h/d for 10 d consecutive) WAS conditions; experimental treatment model rats were administered with intragastric SGD at 1 h before WAS on consecutive days 4-10 (low-dose: 0.1 g/mL; mid-dose: 0.2 g/mL; high-dose: 0.4 g/mL); control treatment model rats were similarly administered

with the irritable bowel syndrome drug, dicetel (0.0042 g/mL); untreated normal control rats received no drug and were not subjected to the WAS test. At the end of the 10-d WAS testing period, a semi-quantitative measurement of visceral sensitivity was made by assessing the abdominal withdrawal reflex (AWR) to colorectal balloon-induced distension (at 5 mmHg increments) to determine the pain pressure threshold (PPT, evidenced by pain behavior). Subsequently, the animals were sacrificed and colonic tissues collected for assessment of changes in expressions of proteins related to visceral hypersensitivity (transient receptor potential vanilloid 1, TRPV1) and sustained visceral hyperalgesia (substance P, SP) by immunohistochemistry and real-time polymerase chain reaction. Inter-group differences were assessed by paired *t* test or repeated measures analysis of variance.

**RESULTS:** The WAS test successfully induced visceral hypersensitivity, as evidenced by a significantly reduced AWR pressure in the untreated model group as compared to the untreated normal control group ( $190.4 \pm 3.48$  mmHg *vs*  $224.0 \pm 4.99$  mmHg,  $P < 0.001$ ). SGD treatments at mid-dose and high-dose and the dicetel treatment significantly increased the WAS-reduced PPT ( $212.5 \pm 2.54$ ,  $216.5 \pm 3.50$  and  $217.7 \pm 2.83$  mmHg respectively, all  $P < 0.001$ ); however, the low-dose SGD treatment produced no significant effect on the WAS-reduced PPT ( $198.3 \pm 1.78$  mmHg,  $P > 0.05$ ). These trends corresponded to the differential expressions observed for both TRPV1 protein (mid-dose:  $1.64 \pm 0.08$  and high-dose:  $1.69 \pm 0.12$  *vs* untreated model:  $3.65 \pm 0.32$ ,  $P < 0.001$ ) and mRNA ( $0.44 \pm 0.16$  and  $0.15 \pm 0.03$  *vs*  $1.39 \pm 0.15$ ,  $P < 0.001$ ) and SP protein ( $0.99 \pm 0.20$  and  $1.03 \pm 0.23$  *vs*  $2.03 \pm 0.12$ ,  $P < 0.01$ ) and mRNA ( $1.64 \pm 0.19$  and  $1.32 \pm 0.14$  *vs*  $2.60 \pm 0.33$ ,  $P < 0.05$ ). These differential expressions of TRPV1 and SP related to mid- and high-dose SGD treatments were statistically similar to the changes induced by dicetel treatment. No signs of overt damage to the rat system were observed for any of the SGD dosages.

**CONCLUSION:** Shugan-decoction can reduce chronic stress-induced visceral hypersensitivity in rats, and the regulatory mechanism may involve mediating the expressions of TRPV1 and SP in colon tissues.

**Key words:** Shugan-decoction; Visceral hypersensitivity; Sustained visceral hyperalgesia; Water avoidance stress; Transient receptor potential vanilloid 1; Substance P

**Core tip:** The classical rat model of chronic stress induction *via* water avoidance stress (WAS) test was used to investigate the therapeutic effect of the Shugan-decoction (SGD) on visceral hypersensitivity of the gastrointestinal tract and its underlying molecular mechanisms. The study design reflected the therapeutic potential of SGD for treating the stress-related gut aspects of irritable bowel syndrome (IBS) in humans. Mid- and high-dose SGD treatments significantly increased the WAS-reduced pressure thresholds, similarly to those induced by the IBS drug dicetel. The SGD treatments also restored WAS-related changes in transient receptor potential vanilloid 1 and substance P expression in the colon.

Shugan-decoction relieves visceral hyperalgesia and reduces TRPV1 and SP colon expression. *World J Gastroenterol* 2013; 19(44): 8071-8077 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i44/8071.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i44.8071>

## INTRODUCTION

In recent decades, irritable bowel syndrome (IBS) has emerged as a highly prevalent functional gastrointestinal disorder that is strongly associated with high levels of stress in daily life. The spectrum of IBS symptoms, ranging from discomfort associated with altered bowel habits to recurrent abdominal pain, is non-life threatening, but can severely impact an individual's general wellbeing and severely disrupt daily life. Despite the extensive laboratory- and clinical-based investigations that have been carried out to determine the underlying etiology and pathogenesis of IBS, no precise causative factors have been identified for the onset and progression of this disease. Patients present with an absence of IBS-specific structural and biochemical abnormalities<sup>[1,2]</sup>, but have higher incidences of psychological stress (both acute and chronic), visceral sensory abnormalities, gastrointestinal motility disorders, and gastrointestinal infections.

The theory of increased visceral sensitivity as a feature of IBS has been addressed by numerous studies. Indeed, IBS patients have been reported to show an enhanced sensitivity to colon and rectal balloon dilatation<sup>[3]</sup>. The mechanisms underlying such visceral hypersensitivity

remain unknown, but are likely multifactorial and complex<sup>[4,5]</sup>. Under normal physiological conditions, visceral sensitivity is mediated by a variety of neuron-localized ion channels, such as the transient receptor potential (TRP) non-selective cation channels, that also function in the formation and regulation of hyperalgesia.

The transient receptor potential vanilloid 1 (TRPV1) TRP family member plays a key role in modulation of the sensation of pain and thermal hyperalgesia<sup>[6]</sup> and is widely expressed throughout the gastrointestinal tract<sup>[7]</sup>. In the colon, substance P (SP)-mediated phosphorylation activates TRPV1, thereby enhancing the probability of channel gating promoting development of visceral hypersensitivity<sup>[8]</sup>. In this manner, SP itself acts as an important regulator of sustained visceral hyperalgesia, and has been characterized as an etiological factor of the repeated stress rat model system<sup>[9]</sup>.

Clinical observations of IBS patients have indicated that remarkably aggravated disease symptoms occur during times of increased emotional and mental stress<sup>[10]</sup>. In traditional Chinese medicine (TCM), these disrupted states correspond to liver-depression and spleen-deficiency. Thus, therapies that soothe the liver and strengthen the spleen are applied to IBS patients. One such therapy is the TCM compound Shugan-decoction (SGD), which, when administered orally, has been shown to significantly improve the clinical symptoms of IBS<sup>[11]</sup>. In this study, a rat model of stress-induced visceral hypersensitivity was employed to investigate the efficacy profile and therapeutic mechanism of SGD in IBS-like conditions.

## MATERIALS AND METHODS

### Animals

Ninety-six Wistar rats (150 ± 20 g adult males) were obtained from the Experimental Animal Center of Shanghai University of TCM (China) for analysis. The animals were housed under a 12/12 light cycle, with standard temperature (21-23 °C) and humidity (50% ± 5%) and *ad libitum* access to standard rat chow and tap water. All consecutive daily experimental procedures were conducted between 8:00-11:00 AM to minimize confounding due to diurnal variations.

The study was designed according to the guidelines of ethical treatment in research published by the Committee of International Association for the Study of Pain and approved by the Committee on the Use of Human and Animal Subjects in Teaching and Research at the Shanghai University of TCM. All protocols were carried out with the aim of minimizing or eliminating discomfort to the animals.

### Experimental compounds

The constituent ingredients of SGD (white atractylodes rhizome, white peony root, dried old orange peel, Ledebouriella root and *Radix bupleuri*) were purchased as crude herbs from the Yanghetang Pharmacy (Shanghai, China). The aqueous extract of SGD was made by the Herbal Chemistry Lab at the Shanghai University of TCM, using

the following steps: decoction of the crude herbs twice, combination of the two filtrate samples, decompression recovery to obtain the final aqueous extract product. The standard IBS pharmaceutical drug dicetel (pinaverium bromide; 50 mg tablets) was obtained from Solvay Pharma (Suresnes, France).

### **Water avoidance stress test**

Repeated water avoidance stress (WAS) was conducted as previously described to induce chronic psychological stress with gastric disruption<sup>[12]</sup>. Briefly, rats were placed on a clear glass platform (10 × 8 × 8 cm) in the middle of a plexiglass tank (45 × 25 × 25 cm) filled with water at 25 °C (to fill the tank up to 1 cm below the top of the platform), and remained on the platform for 1 h. The WAS procedure was repeated once daily for 10 consecutive days.

### **Treatment and control groups**

Untreated model rats ( $n = 16$ ) were exposed to chronic (1 h/d for 10 d consecutive) WAS conditions. Experimental treatment model rats ( $n = 16$  each dosage group) were administered with intragastric SGD at 1 h before WAS on consecutive days 4–10 (low-dose: 0.1 g/mL; mid-dose: 0.2 g/mL; high-dose: 0.4 g/mL). Control treatment model rats ( $n = 16$ ) were similarly administered the IBS drug, dicetel (0.0042 g/mL). Untreated normal control rats ( $n = 16$ ) received no drug and were not subjected to the WAS test.

### **Measurement of fecal pellet output**

To estimate distal colonic motility, fecal pellet output was measured as previously described<sup>[9]</sup>. Briefly, fecal pellets found in the WAS tank were counted at the end of each 1 h WAS test. For the untreated normal control rats, the amount of fecal pellets left in the home cage were counted over a 60 min period of time. Data are presented as mean ± SE ( $n = 16$ ).

### **Colorectal distension and semi-quantitative measurement of pressure pain threshold**

At the end of the 10-d WAS testing period, a semi-quantitative measurement of visceral sensitivity was made in each group ( $n = 8$  each group) by assessing the abdominal withdrawal reflex to colorectal balloon-induced distension to determine the pressure threshold (evidenced by pain behavior)<sup>[10]</sup>. Briefly, rats were lightly sedated with halothane and a deflated latex balloon (4–5 cm diameter at full inflation) was inserted intra-anally with its end 1 cm proximal to the anus into the descending colon and rectum. Animals were then placed into a small lucite cubicle (20 × 8 × 8 cm) and allowed to wake up and adapt for 30 min prior to initiation of colorectal distension (CRD). The CRD was performed by progressive inflation of the colorectally-inserted balloon at 5 mmHg increments, and stopped when the animal exhibited pain behavior. The pressure pain threshold (PPT) value was recorded as the mmHg pressure that evoked contraction of the animal's abdominal muscles following

balloon-mediated CRD delivered for 30 s duration at 4 min intervals. All the measurements were observed by two investigators (Shi HL and Qian W) working independently and blinded to the animals' grouping.

### **Sacrifice and colon tissue collection**

All rats were sacrificed by cervical dislocation immediately after visceral sensitivity measurements were completed so that the descending colon (2 cm above the anus, which had not undergone CRD) could be removed by dissection. The tissue sample was then divided into two parts: one was fixed with 10% formalin [for subsequent immunohistochemical (IHC) analysis] and the other was snap-frozen and stored at -80 °C [for subsequent real-time polymerase chain reaction (PCR) analysis].

### **IHC analysis**

The IHC analysis of TRPV1 and SP protein expression in colon tissues was performed using the EnVision + System two-step horseradish peroxidase staining technique (Dako-Cytomation, Glostrup, Denmark) with targeted polyclonal rabbit anti-human primary antibodies (1:100 dilutions; Santa Cruz Biotechnology, Inc., Santa Cruz, CA, United States). Negative controls were run with the primary antibodies omitted from the procedure. Positive detection was indicated by visualization of a brown stain in the cytoplasm. Three randomly selected × 200 magnification fields were evaluated using a BH2 microscope (Olympus, Tokyo, Japan) equipped with a Nikon 4500 digital camera (Tokyo, Japan). The computer-aided image analysis system by Qiu Wei Inc. (Shanghai, China) assessed the area and optical density (OD) of TRPV1 and SP-positive cells in each field. The IHC index was calculated as the average integral optical density: [(positive area × OD)/total area]. Data are presented as mean ± SE ( $n = 6$ ).

### **Real-time PCR**

Total RNA was extracted from the thawed colon tissue samples using the TRIzol Reagent (Invitrogen Life Technologies, Carlsbad, CA, United States) and reverse transcribed to cDNA by using the Prime-Script™ Reagent Kit (Takara, Tokyo, Japan), according to the manufacturers' instructions. The following primer sets (forward and reverse, respectively) were used for gene-specific amplifications: TRPV1 (GenBank accession No. NM\_031982): 5'-CCACACAAGTGCCGGGGGTC-3' and 5'-CCAGGTCGCCCATGCCGATG-3'; SP (GenBank accession No. NM\_053844): 5'-CTTCCTGGACGCGATGGGCTG-3' and 5'-TGGAATCCTGGCAGGCCCTT-3'; GAPDH (normalizing control; primers were synthesized by Dawei Biotechnology Co., Shijiazhuang, China): 5'-GCCACAGCACTCCATCGAC-3' and 5'-GTCTCCGATCTGGAAAACGC-3'. The real-time PCR was carried out with Synergy Brands Green I dye (Qiagen GmbH, Hilden, Germany) using a Prism 7500 System (Applied Biosystems Inc., Foster City, CA, United States) under the following conditions: 40 cycles of 94 °C for 30 s, 57 °C for 30 s and 72 °C for 30 s, followed by a single final extension cycle of 72 °C for 7 min.

Samples were run in triplicate and the normalized values were averaged. Data are presented as mean  $\pm$  SE ( $n = 6$ ).

### Statistical analysis

All statistical analyses were carried out with the GraphPad Prism v5.0 software (GraphPad Software Inc, La Jolla, CA, United States). Inter-group differences were assessed by a paired  $t$  test or repeated measures analysis of variance. A  $P$  value of  $< 0.05$  was set as the threshold for statistical significance.

## RESULTS

### WAS-induced visceral hypersensitivity and hyperalgesia are relieved by SGD

The WAS test successfully induced visceral hypersensitivity, as evidenced by a sustained significant increase in fecal pellet output (distal colonic motility) from the untreated model group as compared with the untreated normal control group not subject to the WAS test (day 3:  $8.69 \pm 0.60$  *vs*  $2.31 \pm 0.66$  and day 10:  $8.56 \pm 0.63$  *vs*  $0.56 \pm 0.29$ , both  $P < 0.001$ ). After 7 d of SGD treatment, significant relief of the WAS-stimulated increase in fecal output was achieved by the mid-dose (day 3:  $8.38 \pm 0.77$  *vs* day 10:  $4.31 \pm 0.42$ ,  $P < 0.001$ ) and high-dose (day 3:  $8.19 \pm 0.62$  *vs* day 10:  $3.63 \pm 0.39$ ,  $P < 0.001$ ). Although the extent of relief in these groups was similar to that achieved with the dicetel control treatment (day 3:  $8.75 \pm 0.53$  *vs* day 10:  $4.00 \pm 0.35$ ,  $P < 0.001$  for all *vs* corresponding mid- and high-dose SGD values), none of the treatments reduced fecal output to untreated normal control group levels by day 10. The low-dose SGD treatment produced no significant effect on WAS-stimulated fecal output increase (day 3:  $8.94 \pm 0.84$  and day 10:  $6.88 \pm 0.51$ ; both  $P < 0.001$  *vs* untreated normal control group;  $P > 0.05$  for day 3 *vs* day 10).

The same WAS-induced and SGD-relieved trends were seen for visceral hyperalgesia. The untreated model group showed significantly lower PPT than the untreated normal control group ( $190.40 \pm 3.48$  mmHg *vs*  $224.00 \pm 4.99$  mmHg,  $P < 0.001$ ), which was relieved by the mid- and high-dose SGD treatments ( $212.50 \pm 2.54$  mmHg and  $216.50 \pm 3.50$  mmHg) to a similar extent achieved with dicetel control treatment ( $217.70 \pm 2.83$  mmHg) (all  $P < 0.001$  *vs* untreated model group). Again, the low-dose SGD treatment produced no significant effect on the WAS-reduced pressure threshold ( $198.30 \pm 1.78$  mmHg,  $P > 0.05$  *vs* untreated normal control group and  $P < 0.001$  *vs* untreated model group).

### WAS-reduced expression of colon-expressed genes related to visceral hypersensitivity (TRPV1) and hyperalgesia (SP) was relieved by SGD treatment

IHC detection of TRPV1 and SP in colon tissues of untreated normal control rats showed that their expressions were mainly localized to the mucosa and submucosa (Figure 1). The untreated model group showed significantly higher AOID levels than the untreated normal

controls for both TRPV1 ( $3.65 \pm 0.32$  *vs*  $0.86 \pm 0.11$ ,  $P < 0.001$ ) and SP ( $2.03 \pm 0.12$  *vs*  $0.64 \pm 0.11$ ,  $P < 0.001$ ). These WAS-stimulated increases in protein levels were significantly reduced by the SGD treatments at mid-dose (TRPV1:  $1.64 \pm 0.08$  and SP:  $0.99 \pm 0.20$ ) and high-dose (TRPV1:  $1.69 \pm 0.12$  and SP:  $1.03 \pm 0.23$ ) compared with the untreated model group (TRPV1:  $P < 0.001$  and SP:  $P < 0.01$ ). Furthermore, the extent of reduction was similar to that achieved with dicetel control treatment (TRPV1:  $1.46 \pm 1.60$  and SP:  $0.76 \pm 0.11$ ; both  $P < 0.001$  *vs* untreated model group). The low-dose SGD treatment produced no significant effect on the WAS-stimulated increases in TRPV1 ( $3.48 \pm 0.33$ ,  $P < 0.001$  *vs* untreated model group) or SP ( $1.69 \pm 0.22$ ,  $P < 0.01$  *vs* untreated model group).

The same WAS-induced and SGD-relieved trends were seen for the gene expressions of TRPV1 and SP. The untreated model group showed significantly higher relative expressions of both genes compared with the untreated normal control group (TRPV1:  $1.39 \pm 0.15$  *vs*  $0.14 \pm 0.03$  and SP:  $2.60 \pm 0.33$  *vs*  $0.70 \pm 0.12$ , both  $P < 0.001$ ). The mid- and high-dose SGD treatments significantly reduced the WAS-increased mRNA expression of TRPV1 ( $0.44 \pm 0.16$  and  $0.15 \pm 0.03$ , both  $P < 0.001$  *vs* untreated model group) and SP ( $1.64 \pm 0.19$  and  $1.32 \pm 0.14$ , both  $P < 0.05$  *vs* untreated model group), with the SP levels being uniquely reduced by mid-dose SGD to levels similar to those of the untreated normal controls ( $P < 0.05$ ). Furthermore, the trends in SGD-mediated relief were similar to those observed with the dicetel control treatment (TRPV1:  $0.22 \pm 0.02$ ,  $P < 0.001$  *vs* untreated model group and SP:  $1.35 \pm 0.13$ ,  $P < 0.01$  *vs* untreated model group). Again, the low-dose SGD treatment produced no significant effect on the WAS-stimulated increase in mRNA expression of TRPV1 ( $0.99 \pm 0.16$ ) and SP ( $2.34 \pm 0.19$ ) (both  $P < 0.001$  *vs* untreated normal control group).

## DISCUSSION

In the present study, the well-established animal model of chronic water avoidance stress was used to stimulate the gastrointestinal tract hypersensitivity that is characteristic of human IBS. The WAS-induced physical manifestations (*i.e.*, increased fecal output and lower PPT) were accompanied by differential expression patterns of genes/proteins related to visceral hypersensitivity (TRPV1) and hyperalgesia (SP) in colon tissues. In addition, the model was used to evaluate the therapeutic efficacy of SGD, as a TCM alternative to dicetel, the pharmacologic agent most commonly used to treat IBS in humans. The findings indicated SGD was able to relieve the WAS-induced visceral hypersensitivity and hyperalgesia, as well as restore the perturbed TRPV1 and SP expressions.

Visceral pain, related to CRD and visceral hypersensitivity, is a hallmark feature of IBS and is often the factor precipitating a patient's presentation to the clinic<sup>[13-16]</sup>. However, the underlying molecular mechanisms of the

**Figure 1** Reductions in the expressions of substance P and transient receptor potential vanilloid 1 protein by water avoidance stress in the colon are relieved by SGJGD treatment. A-F: Substance P protein; G-L: Transient receptor potential vanilloid 1. IHC-detected colon tissues ( $\times 200$ ) from: untreated normal group (A, G); untreated model group (B, H); high-dose Shugan-decoction (SGD) model group (C, I); mid-dose SGD model group (D, J); low-dose SGD model group (E, K); dicetel control model group (F, L).

IBS pain response are poorly understood, which has inhibited development of effective pain management strategies<sup>[17,18]</sup>. The demonstration of TRPV1 as a contributor to WAS-induced colonic hypersensitivity, suggests its potential as a target of molecular therapies that may not only reduce the overactive distal colonic motility, but also relieve the associated lower PPT. Indeed, when TRPV1 was knocked-out in mice, the visceral sensitivity to CRD was significantly reduced<sup>[19]</sup>, and enhanced TRPV1 expression has been observed in a variety of gastrointestinal diseases<sup>[20,21]</sup>, including human cases of IBS<sup>[22]</sup>.

An increased amount of TRPV1-expressing nerve fibers have been reported in IBS-affected tissues from

human patients<sup>[22]</sup>, and may represent a physiological link between increased TRPV1 transcription and the pain response in IBS<sup>[23,24]</sup>. In addition, inflammatory factors are known agonists of TRPV1 channels<sup>[25]</sup> and might explain the common feature of low-grade inflammation in IBS. Considering a previous finding that development of fecal urgency and rectal hypersensitivity correlated with increased immunoreactivity to TRPV1 within the gastrointestinal tract<sup>[20]</sup>, it is possible that therapeutic antagonism of TRPV1 channels may result in antihyperalgesic effects without hypoalgesic activity, and might be beneficial in the treatment of IBS visceral pain<sup>[26]</sup>.

The current study's finding of chronic WAS-induced

changes in SP colon expression agree with other recent studies using the same model system that have implicated this neuropeptide in the maintenance of visceral hyperalgesia<sup>[9,27]</sup>. As a critical neurotransmitter of injurious signals, SP effectively links the gut nervous system to the immune system, stimulating a wide range of effector cells in the stomach and intestine to facilitate proper gastrointestinal motility, sensibility, secretion and absorption. The mechanism by which SP mediates visceral hypersensitivity may involve a myriad of cellular processes and signaling cascades, including promotion of the mast cell degranulation response, the release of histamines, leukotrienes, prostaglandins and bradykinin, all of which can cause inflammatory reactions leading to neuropathic pain<sup>[28]</sup>.

The clinical observations of increased SP expression in the intestinal mucosa of IBS patients<sup>[29,30]</sup>, coupled with the previous demonstration of SP's ability to activate TRPV1 *via* phosphorylation, thereby enhancing the probability of channel gating<sup>[9]</sup>, suggested that SP might be a vital mediator of chronic stress-induced visceral hyperalgesia through the modulation of TRPV1 channels. When TRPV1 channels are activated, a large Ca<sup>2+</sup> influx can lead to cellular depolarization<sup>[31]</sup>, with neurons releasing an array of neurotransmitters to trigger the downstream response of visceral hypersensitivity.

Dicetel is the most commonly applied pharmacotherapy of IBS, yet it is associated with a wide range of side effects, such as itching, rash, nausea and dry mouth. In addition, its widespread adoption in clinical practices worldwide has been hampered by its high monetary cost. In the current study, SGD treatment led to decreased expression of the WAS-stimulated TRPV1 and SP proteins and mRNAs in the hypersensitive colon, and increased the pain threshold of the rats. Thus, SGD appears to be an effective alternative to the pharmacologic agent dicetel for treating IBS by affecting the transcription and translation (and presumably secretion) of TRPV1 and SP in the colon.

In conclusion, the TCM SGD is an effective agent for reducing WAS-induced expressions of TRPV1 and SP in rat colons, thereby reducing visceral hypersensitivity and hyperalgesia. However, the chronic WAS testing (10 consecutive days) used in this study caused no overt damage to the colon's histological structure (data not shown), which may be a limitation in the study's findings, because human IBS is accompanied by significant structural changes (likely associated with the inflammatory component of IBS). Nonetheless, the present findings indicate an underlying mechanism of stress-induced disruption of distal colon motility and pain, which may represent useful targets for molecular based therapies to treat the pain and sensitivity symptoms of abdominal diseases, such as IBS.

## COMMENTS

### Background

Visceral hypersensitivity has been proposed as a significant contributor to the pathophysiology of irritable bowel syndrome (IBS). Activation of the transient

receptor potential vanilloid 1 (TRPV1) channel on neurons, by such effector molecules as the neurotransmitter substance P (SP), increases the probability of channel gating and promotes the formation of visceral hypersensitivity. Therefore, SP-mediated activation of TRPV1 might play a role in the visceral hypersensitivity and hyperalgesia induced by chronic stress conditions, as in IBS. The traditional Chinese medicine (TCM) compound Shugan-decoction (SGD) has been shown to significantly improve the clinical symptoms of IBS patients; however, the therapeutic mechanism of SGD remains unknown.

### Research frontiers

The molecular mechanisms underlying IBS remain to be fully elucidated, and may represent useful targets of therapies to relieve not only the symptoms associated with visceral hypersensitivity (increased distal colonic motility), but also those related to visceral hyperalgesia (abdominal pain, possibly related to an overactive inflammatory response). In this study, the classical rat model of chronic stress inducement *via* the water avoidance stress (WAS) test was used to investigate the underlying molecular mechanisms of visceral hypersensitivity and hyperalgesia in the gastrointestinal tract and to evaluate the related therapeutic effect of SGD for treating the stress-related gut aspects of IBS in humans. Mid- and high-dose SGD treatments significantly increased the WAS-reduced pressure thresholds and restored WAS-related changes in TRPV-1 and SP expression in the colon, suggesting this TCM compound as a feasible alternative to the pharmacological agent dicetel.

### Innovations and breakthroughs

This study provided novel insights into the molecular mechanisms underlying the observations of SGD-mediated improvements in the clinical symptoms of IBS. Specifically, SGD was demonstrated to reduce WAS-induced perturbations in TRPV1 and SP expressions in the colon that accompany visceral hypersensitivity and hyperalgesia.

### Applications

The finding that SGD may reduce WAS-induced visceral hypersensitivity and hyperalgesia through regulation of the colonic expressions of TRPV1 and SP confirm this TCM compound as a useful prescription for the treatment of abdominal pain in IBS.

### Terminology

Shugan-decoction is made according to the classic Tongxieyao Fang recipe and is reported to soothe the liver soothing and strengthen the spleen. Irritable bowel syndrome is a functional gastrointestinal disorder that is associated with high levels of stress in daily life, and manifests as altered bowel habits and recurrent abdominal pain. The water avoidance stress test is a well-established technique for inducing chronic psychological stress with gastric disruption in a rat model system. TRPV1 is widely expressed on neurons throughout the gastrointestinal tract and modulates visceral sensitivity and hyperalgesia. SP is a neurotransmitter that activates TRPV1 and regulates visceral hyperalgesia.

### Peer review

The authors investigated the therapeutic potential and underlying molecular mechanisms of the TCM compound SGD, in comparison to the common IBS pharmacologic agent dicetel, to relieve stress-induced visceral hypersensitivity and hyperalgesia. This is an interesting manuscript, and the general design is acceptable.

### Abstract

**AIM:** To explore the clinical characteristics and prognosis of young patients with colorectal cancer patients in Eastern China.

**METHODS:** A total of 1335 patients with colorectal cancer treated from December 1985 to December 2005 at the Second Affiliated Hospital of Zhejiang University School of Medicine were studied retrospectively. The patients were divided into two groups, a younger group (aged  $\leq 30$  years) and an older group (aged  $> 30$

years), and comparison was made in the clinical characteristics and prognosis between the two groups. Chi-square test was used for data analysis of all categorical variables, and overall survival (OS) was calculated by the Kaplan-Meier method. A multivariate analysis was performed using the Cox model.

**RESULTS:** There were 42 (3.1%) and 1293 (96.9%) cases in the younger group and older group, respectively. Univariate analysis showed that the 5- and 10-year OS in the younger group were 33.9% and 26.1%, respectively, and those in the older group were 60.1% and 52.2%, respectively. Younger group had poor survival ( $\chi^2 = 14.146$ ,  $P = 0.000$ ). Multivariate analysis revealed that age was not a dependent factor for prognosis (OR = 0.866, 95%CI: 0.592-1.269,  $P = 0.461$ ). Stratified analysis indicated that in stage III and IV disease, the 5- and 10-year OS were 24.6% and 14.8% in the younger group, and 40.4% and 33.3% in the older group, respectively, with a significant difference between the two groups ( $\chi^2 = 5.101$ ,  $P = 0.024$ ). In the subgroup of radical surgery, the 5- and 10-year OS were 44.3% and 34.2% in the younger group, and 69.6% and 60.5% in the older group, with a difference being significant between the two groups ( $\chi^2 = 7.830$ ,  $P = 0.005$ ).

**CONCLUSION:** Compared with older patients, the younger patients have lower survival, especially in the subgroups of stage III and IV disease and radical surgery.

**Key words:** Colorectal cancer; Young; Clinicopathologic feature; Prognosis; Radical surgery

**Core tip:** We firstly described the clinical characteristics and prognosis of young patients with colorectal cancer in Eastern China. The incidence rate of colorectal

cancer in young patients was higher than that in other reports. Younger patients with colorectal cancer had more poorly differentiated and advanced tumors, and worse prognosis, especially patients with stage III and IV disease.

Clinical characteristics and prognosis of young patients with colorectal cancer in Eastern China. *World J Gastroenterol* 2013; 19(44): 8078-8084 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i44/8078.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i44.8078>

## INTRODUCTION

As a kind of common cancer, colorectal cancer severely threatens the health of people. Colorectal cancer is the fourth common cancer and the second leading cause of cancer death in the world<sup>[1]</sup>. The majority of patients are affected in their 50s to 70s, but the age at diagnosis is getting younger<sup>[2]</sup>. The annual percentage of colorectal cancer in young people is increasing<sup>[2]</sup>. There has been an increasing number of reports about young colorectal cancer patients in recent years. The outcomes of young colorectal cancer patients varied widely among different regions<sup>[2-4]</sup>. The incidence rate of colorectal cancer in young patients has also been increasing in recent years in China<sup>[5]</sup>. Nearly all reports showed that young colorectal cancer patients had specific clinicopathologic characteristics, including poor histological feature, and more mucinous tumors, signet ring cell tumors, and advanced tumors<sup>[6-8]</sup>. However, the relationship between the age and survival was not confirmed. Some reports documented that young colorectal cancer patients had worse survival compared with the older counterparts<sup>[2,7-9]</sup>. But the others indicated opposite results<sup>[10-15]</sup>. There are still controversies about the definition of the age of young population. This study was to retrospectively analyze the data of patients with colorectal cancer who received surgery at our center over the past 30 years. Based on the distribution of the age, the population with colorectal cancer aged < 30 years was considered as a special subgroup in our center. Therefore, the young population was defined as those aged ≤ 30 years in our study. This study was designed to explore the clinicopathologic characteristics and prognosis of young colorectal cancer patients in Eastern China.

## MATERIALS AND METHODS

A total of 1335 consecutive patients with colorectal cancer (aged 19-92 years, mean 58 ± 13.3 years) treated from December 1985 to December 2005 at the Second Affiliated Hospital of Zhejiang University School of Medicine, located in Eastern China, were studied retrospectively. The patients were divided into two groups, a younger

group (42 cases, aged ≤ 30 years, average age, 26.0 ± 3.5 years) and an older group (1293 cases, aged > 30 years, average age 58.0 ± 12.3 years). The criteria for inclusion were as follows: (1) patients with pathologically confirmed colorectal cancer; and (2) patients who underwent operations, including palliative surgeries. Patients with anal cancer or non-adenomas were excluded. Following the approval by the ethics committee of the hospital, the data including age, gender, tumor location, histological grade, approach of surgery, tumor infiltration, number of metastatic lymph nodes, distant metastasis and survival were obtained. Follow-up was made every 3 mo for 2 years, 6 mo for 5 years, then every one year. The follow-up proceeded through telephone calls or mail correspondence. The events of relapse and death in all patients were recorded.

The deadline of follow-up was November 2011. The follow-up lasted 0-302 mo (median, 57.0 ± 68.1 mo). Finally, 1335 patients who had complete data were analyzed; 267 patients (20.0%) were lost to follow-up, with 5 patients (11.9%) in the younger group and 262 patients (20.3%) in the older group. There was no significant difference in the percentage of lost patients between two groups ( $P = 0.183$ ). The lost patients were taken as censors when the survival was analyzed. Twenty-nine patients died of colorectal cancer in the younger group and 604 patients died in the older group, including 51 patients who died due to other causes. They were considered as censors when cancer-related survival was calculated. All 1335 cases were included when we analyzed the clinicopathologic difference between the two groups.

The tumor was staged according to the 7<sup>th</sup> pathologic TNM staging system of AJCC<sup>[16]</sup>. Tumor location was described in detail as the cecum, ascending colon, liver flexure colon, transverse colon, descending colon, sigmoid, sigmoidectal junction and rectum. Overall survival was calculated from the time of operation to death. Cancer-related survival was from the time of operation to the date of death because of the colorectal cancer. Causes of non-special cancer-related death included benign disease, accident, and secondary cancer. Radical surgery was classified as a procedure for no residual tumor left behind microscopically at resection margins. Palliative surgery was defined as a procedure for the residual tumor left macroscopically, which also included bypass or ileostomy. All palliative surgeries were considered as non-radical surgery.

### Statistical analysis

Data of all categorical variables are summarized using frequencies and percentages. The data were analyzed with  $\chi^2$  test. Overall survival was calculated according to the Kaplan-Meier method. Survival rates were compared by the log-rank test. A multivariate analysis was performed using the Cox model. When a  $P$ -value was less than 0.05, the difference was considered significant. SPSS 16.0 statistical software was used for data analysis.

## RESULTS

### Clinicopathologic characteristics

The patient age ranged from 19 to 92 years, with a median of  $58 \pm 13.3$  years. There were 42 (3.1%) and 1293 (96.9%) cases in the younger group and older group, respectively. The ratio of male to female was 1.3:1 in both groups.

The rectum was the frequent location in colorectal cancer, with a slightly higher rate in the younger group than in the older group (59.5% *vs* 49.3%,  $P > 0.05$ ). Compared with the older group, significantly more patients in the younger group had mucinous tumor (33.3% *vs* 13.8%,  $P = 0.000$ ), signet ring cell cancer (7.1% *vs* 1.7%,  $P = 0.010$ ) and poorly differentiated tumor (59.5% *vs* 15.7%,  $P = 0.000$ ).

As for tumor infiltration, no tumor *in situ* (Tis) was found in the younger group, but 17 (13.1%) patients in older group were diagnosed with tumor *in situ* (Tis). Interestingly, there was no significant difference between the two groups in the tumor infiltration ( $P = 0.264$ ). The percentages of patients with lymph node metastasis ( $\geq 4$  lymph nodes), distance metastasis, stage IV and stage I disease and radical surgery were 35.7%, 28.6%, 31.0%, 2.4% and 66.7%, respectively, in the younger group, and 14.2%, 15.4%, 15.5%, 30.2% and 83.7%, respectively, in the older group, with significant differences between the two groups ( $P = 0.021, 0.021, 0.007, 0.008$  and  $0.008$ , respectively) (Table 1).

### Overall survival

Univariate analysis showed that there was a significant difference in total overall survival between the two groups ( $\chi^2 = 14.146$ ,  $P = 0.000$ ) (Figure 1, Table 2). Multivariate analysis revealed that age was not an independent factor for the prognosis of colorectal cancer (OR = 0.866, 95%CI: 0.592-1.269,  $P = 0.461$ ). TNM stage III/IV, the approach of palliative surgery, rectal cancer, mucinous cancer and poorly differentiated tumor were independent factors for worse prognosis (Table 2).

As for stage I and II disease, the 10-year overall survival and median survival time had not reached until the deadline in the younger group, which might be due to the small sample size of the study. There was no significant difference in the 10-year overall survival and median survival time between the two groups ( $\chi^2 = 0.016$ ,  $P = 0.899$ ) (Figure 2A, Table 3). Fifty-one patients died of other diseases in the older group. In order to diminish the influence of the non-cancer death, the cases in the subgroup of stage I and II disease were analyzed; as a result, there was also no difference in cancer-related survival between the two groups ( $\chi^2 = 0.356$ ,  $P = 0.551$ ) (Figure 2B). For stage III and IV disease, the outcome was worse in the younger group than in the older group ( $\chi^2 = 5.101$ ,  $P = 0.024$ ) (Figure 3, Table 3). For the subgroup of radical surgery, in the older group, the median survival time had not reached until the deadline. There was a significant difference in median survival time between the two groups ( $\chi^2 = 7.830$ ,  $P = 0.005$ ) (Figure 4A, Table 3). In the non-

radical surgery subgroup, there was no significant difference in median survival time between the two groups ( $\chi^2 = 0.112$ ,  $P = 0.737$ ) (Figure 4B, Table 3).

## DISCUSSION

A total of 1335 patients with colorectal cancer were ana-

Figure 1 Overall survival of patients in the younger group ( $\leq 30$  years) and older group ( $> 30$  years). The younger group had worse prognosis than the older group ( $P = 0.000$ ).

**Table 2 Multivariate analysis (Cox proportional hazard model) of prognostic factors for 1335 patients with colorectal cancer**

Variable	OR	95%CI	P value
Stage (III + IV / I + II)	2.196	1.827-2.639	0.000
Approach of surgery (non-radical/radical)	4.496	3.718-5.437	0.000
Age ( $> 30$ yr/ $\leq 30$ yr)	0.866	0.592-1.269	0.461
Gender (male/female)	0.997	0.852-1.167	0.970
Tumor location (rectum/colon)	1.270	1.084-1.488	0.003
Differentiation (moderate + well/low)	0.802	0.650-0.990	0.041
Histology (others/mucinous)	0.791	0.632-0.990	0.041

lyzed retrospectively in this study, including 42 (3.1%) patients in the younger group (aged  $\leq 30$  years). In other studies, the incidence rate was less than 1% and 3% if young patients with colorectal cancer were defined as those aged  $\leq 30$  years<sup>[17-19]</sup> and  $\leq 40$  years<sup>[4,15]</sup>, respectively. The incidence rate in this study was higher than in other regions, suggesting an obvious regional difference. In this study, Eastern China refers to Yangtze River delta region where people enjoy a similar lifestyle and economic status. Consequently, the epidemiological characteristics of colorectal cancer in this region are similar. Therefore, data from our center could represent the features of this tumor in Eastern China. There might be statistical biases about the incidence rate of colorectal cancer in young patients because the data were collected retrospectively by a single medical center.

### Gender

There was no significant difference in gender ratio between the two groups. The percentage of female patients is becoming higher with the trend of younger age in gastric cancer. This phenomenon was not seen in colorectal cancer. Estrogen was considered to be related with gastric cancer in younger patients<sup>[20]</sup>. It is not clear whether estrogen was related to the occurrence of colorectal cancer in young people<sup>[21,22]</sup>. On the other hand, this study indicated that female patients with colorectal cancer had bet-

Figure 2 Overall survival of younger patients ( $\leq 30$  years) and older patients ( $> 30$  years) in stage I and II tumor subgroup. A: Overall survival was totally similar between the two groups ( $P = 0.899$ ); B: Cancer-related survival was similar between the two groups ( $P = 0.551$ ).

ter outcome than male patients, but with no significant difference (OR = 0.969,  $P = 0.708$ ) in survival as shown by the multivariate analysis.

### Tumor location

In this study, the rectum and sigmoid were common sites of the tumor in both groups. The proportion of rectal cancer was higher in the younger group (59.5%) than in older group (49.3%), but without significant difference ( $P = 0.191$ ). Some reports indicated that the rate of rectal cancer in younger population was higher than in older one<sup>[2]</sup>. That might be related to the epidemics of colorectal cancer that rectal cancer is more common than colonic cancer in China. Eating habit and lifestyle might contribute more to the occurrence of colorectal cancer than age.

### Pathological characteristics

In this study, mucinous tumor and signet ring cell cancer were more common in the younger group than in the older group. A majority of patients in the younger group had poor histologic grade compared with the older group. Studies on gastric cancer also indicated that there were more poorly differentiated cancers in younger

**Table 3** Survival of subgroup patients by stratified analysis with stage and approach of surgery

	Age (yr)	n	5-yr OS	10-yr OS	Median survival time (mo, 95%CI)
Total <sup>1</sup>	≤ 30	42	33.90%	26.10%	29.0 (18.0-40.0)
	> 30	1293	60.10%	52.20%	140.0 (111.6-168.4)
Stage I and II	≤ 30	10	68.60%	/ <sup>4</sup>	/ <sup>4</sup>
	> 30	665	78.60%	69.80%	264.0 (203.5-324.5)
Stage III and IV <sup>2</sup>	≤ 30	32	24.60%	14.80%	22 (2.6-41.4)
	> 30	628	40.40%	33.30%	35 (27.9-42.1)
Radical surgery <sup>3</sup>	≤ 30	28	44.30%	34.20%	40.0 (10.1-69.9)
	> 30	1082	69.60%	60.50%	/ <sup>5</sup>
Non-radical surgery	≤ 30	14	14.30%	0%	6 (2.3-9.7)
	> 30	211	11.80%	0%	11 (9.2-12.8)

<sup>1</sup> $\chi^2 = 14.146$ ,  $P = 0.000$ ; <sup>2</sup> $\chi^2 = 5.101$ ,  $P = 0.024$ ; <sup>3</sup> $\chi^2 = 7.830$ ,  $P = 0.005$ ; <sup>4</sup>The sample was too small to analyze; <sup>5</sup>The median survival time was not reached.

population than in older population, especially signet ring cell cancer<sup>[23]</sup>. It was not clear about the age impact on the occurrence of gastrointestinal cancer.

### Stage

Compared with the older population, the percentage of patients with stage IV disease increased and that of patients with stage I disease decreased in the younger group. As for the infiltration of tumor and nodal metastasis, the patients in the younger group presented with more aggressive findings. Some studies found that 66.0% of younger patients with colorectal cancer were diagnosed with stage III or IV disease, which was obviously lower (32.0%) in the older patients<sup>[24]</sup>. This may result from the poor differentiation and high aggressiveness of tumors which were often diagnosed in younger patients with colorectal cancer. Besides, younger patients with colorectal cancer often had delayed diagnosis, but the older ones would be diagnosed earlier through screening program.

### Overall survival

Univariate analysis revealed that the patients in the younger group had poorer survival than those in the older group. The impact of young age on the prognosis of colorectal cancer is not confirmed. Some studies showed that young patients with colorectal cancer had more mucinous cancer and signet ring cancer, poorer histologic grade, later stage and worse prognosis<sup>[2,7-9]</sup>. But results were contradictory from other studies which indicated that young age had no impact on the prognosis<sup>[10-15]</sup>. In our study, young colorectal cancer patients had worse prognosis, while multivariate analysis indicated that age was not an independent factor for prognosis. Furthermore, multivariate analysis also showed that disease stage and approach of surgery were strongly related to the prognosis. Worse prognosis might result from stage III and IV disease and non-radical surgery. Therefore, stratified analyses with these two factors were carried out.

The result of stratified analysis with stage indicated that younger patients had poor prognosis, and univariate analysis showed that younger patients presented with mainly stage III and IV disease. The reasons might be that young patients had more poorly differentiated tumor, and

mucinous carcinoma and signet ring cell cancer, which were more aggressive in the same stage. As for patients with stage I and II disease, age exerted no effect on the survival. In this study, there were more patients in the older group who did not die of colorectal cancer. In order to exclude the influence of the non-cancer special death, the cancer-related survival in patients with stage I and II disease was analyzed. The result showed no significant difference in cancer-related survival in stage I and II tumor between the two groups. The study of Quah *et al.*<sup>[25]</sup> considered that patients with an earlier stage disease had better survival in younger group than older group; young patients were more tolerable to surgery and aggressive adjuvant chemotherapy and radiotherapy<sup>[26]</sup>. And the study of McMillan *et al.*<sup>[27]</sup> indicated that in the older group, non-special cancer factors were major causes of death.

The stratified analysis with approach of surgery revealed that patients had poorer prognosis in the younger group than in the older group with radical surgery, but there was no significant difference between the two groups without radical surgery. In stratified analysis with stage, patients with stage I and II disease had similar prognosis between the two groups. Stage I and II tumors were often considered to be resectable. For patients with resectable stage III and stage IV tumors, younger age strongly contributed to poor survival. For patients who received operation without adjuvant chemotherapy in the 1980s and 1990s, the value of postoperative adjuvant therapy should be highlighted for patients with resectable stage III or more advanced colorectal cancer<sup>[28]</sup>.

The current study had some limitations. The clinical data did not include the signs and symptoms of colorectal cancer patients. It was impossible to identify the alarming symptoms for younger patients. Family histories were not described, which were routinely detected in young population as the other studies<sup>[29]</sup>. The percentage of lost patients was 20%, which might influence the result of survival. In China, there are several medical centers owning elaborate clinical data, but few centers carried out the systemic follow-up. The data of 10-year follow-up are rare.

In summary, compared with older patients, the younger ones have specific clinicopathologic characteristics that

Figure 3 Overall survival of younger patients ( $\leq 30$  years) and older patients ( $> 30$  years) in stage III and IV tumor subgroup. The younger group had worse prognosis than the older group ( $P = 0.024$ ).

are worthy to be explored and managed differentially. Younger patients with colorectal cancer tend to be diagnosed at later stage. For younger patients who have poor survival, especially those with stage III and IV disease and treated by radical surgery, more aggressive adjuvant therapies are recommended.

## COMMENTS

### Background

The incidence rate of colorectal cancer has been increasing in recent years. The onset age of colorectal cancer is getting younger. Should the young colorectal cancer patients be treated as a heterogeneous group? It is important to explore the phenotype of young patients with colorectal cancer.

### Research frontiers

Age is an independent prognostic factor for many cancers such as breast cancer, thyroid cancer and gastric cancer. Young patients have more triple negative breast cancers and worse prognosis. Lymph node-positive thyroid cancers are commonly diagnosed in adolescent patients, who have satisfactory prognoses. Young patients with gastric cancer in early stage have better prognosis than old ones, while their prognoses are worse in advanced gastric cancer. It is unknown about the age impact on the prognosis of colorectal cancer. Some studies showed that young patients with colorectal cancer had more mucinous cancer and signet ring cancer, poorer histologic grade, later stage and worse prognosis. But results were contradictory in other studies which indicated that the young age had no impact on prognosis.

### Innovations and breakthroughs

The authors described systematically for the first time the clinical characteristics and prognosis of young colorectal cancer patients in Eastern China. The incidence rate of young colorectal cancer was higher than in other reports. Colorectal cancer in younger patients was characterized by poorer differentiation and advanced stage. Young colorectal cancer patients had worse prognosis, especially those with stage III and IV disease, rather than stage I and II disease.

### Applications

Relapse risk of postoperative stage II colonic cancer is a crucial factor for decision-making in postoperative treatment. This study showed that age was not an independent risk factor for stage II colorectal cancer. On the other hand, young colorectal cancer patients with stage III and IV disease had worse prognosis, and more aggressive adjuvant therapy is recommended for these patients.

### Terminology

Young patients with colorectal cancer: Onset age of colorectal cancer was less than or equal to 30 years. Eastern China refers to Yangtze River delta region where people have similar lifestyle and economic conditions. Epidemiologi-

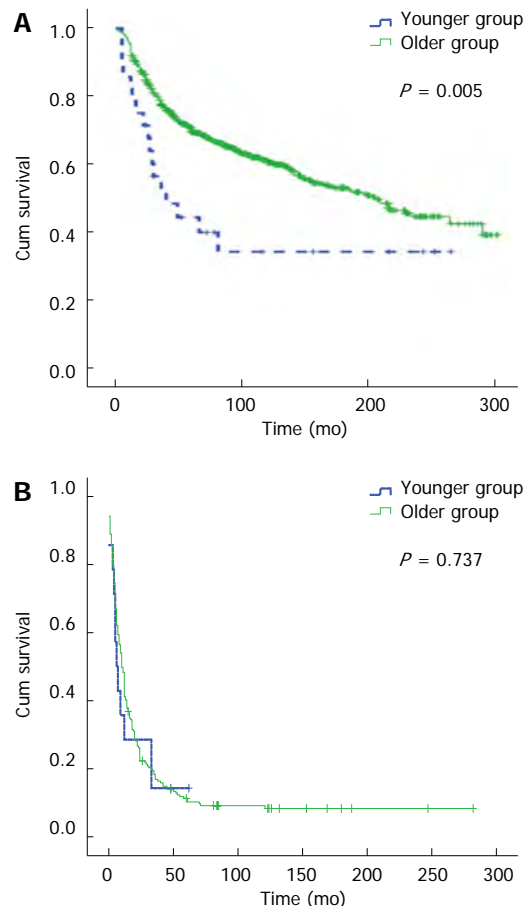

Figure 4 Overall survival of younger patients ( $\leq 30$  years) and older patients ( $> 30$  years) based on approach of surgery. A: The younger group had worse prognosis than the older group ( $P = 0.005$ ) undergoing radical surgery; B: There was no difference between the two groups ( $P = 0.737$ ) treated by non-radical surgery.

cal characteristics of colorectal cancer in this region are also similar.

### Peer review

The study described the detailed clinicopathologic characteristics of 1335 cases of colorectal cancer in Eastern China and analyzed the significance of prognosis by many statistical methods. The major goal of authors was to analyze the difference between younger patients ( $\leq 30$  year-old) and older patients ( $> 30$  year-old). The information enclosed in this manuscript is very plentiful and clear, and the authors applied many different statistical methods to perform the analysis. Although the results are not novel and methodology was orthodox, it is worth reporting the present results.

### Abstract

**AIM:** To determine the clinical effects and complications of transjugular intrahepatic portosystemic shunt (TIPS) for portal hypertension due to cirrhosis.

**METHODS:** Two hundred and eighty patients with portal hypertension due to cirrhosis who underwent TIPS were retrospectively evaluated. Portal trunk pressure was measured before and after surgery. The changes in hemodynamics and the condition of the stent were assessed by ultrasound and the esophageal and fundic veins observed endoscopically.

**RESULTS:** The success rate of TIPS was 99.3%. The portal trunk pressure was  $26.8 \pm 3.6$  cmH<sub>2</sub>O after surgery and  $46.5 \pm 3.4$  cmH<sub>2</sub>O before surgery ( $P < 0.01$ ).

The velocity of blood flow in the portal vein increased. The internal diameters of the portal and splenic veins were reduced. The short-term hemostasis rate was 100%. Esophageal varices disappeared completely in 68% of patients and were obviously reduced in 32%. Varices of the stomach fundus disappeared completely in 80% and were obviously reduced in 20% of patients. Ascites disappeared in 62%, were markedly reduced in 24%, but were still apparent in 14% of patients. The total effective rate of ascites reduction was 86%. Hydrothorax completely disappeared in 100% of patients. The incidence of post-operative stent stenosis was 24% at 12 mo and 34% at 24 mo. The incidence of post-operative hepatic encephalopathy was 12% at 3 mo, 17% at 6 mo and 19% at 12 mo. The incidence of post-operative recurrent hemorrhage was 9% at 12 mo, 19% at 24 mo and 35% at 36 mo. The cumulative survival rate was 86% at 12 mo, 81% at 24 mo, 75% at 36 mo, 57% at 48 mo and 45% at 60 mo.

**CONCLUSION:** TIPS can effectively lower portal hypertension due to cirrhosis. It is significantly effective for hemorrhage of the digestive tract due to rupture of esophageal and fundic veins and for ascites and hydrothorax caused by portal hypertension.

**Key words:** Transjugular intrahepatic portosystemic shunt; Cirrhosis; Portal hypertension; Therapeutic effect; Complication

**Core tip:** This study identified the clinical effects and complications of transjugular intrahepatic portosystemic shunt (TIPS) for portal hypertension due to cirrhosis in 280 patients who underwent this procedure at our centre between January 2005 and December 2009. TIPS can effectively lower portal hypertension due to cirrhosis. It is significantly effective for hemorrhage of the

digestive tract due to rupture of esophageal and fundic veins and for ascites and hydrothorax caused by portal hypertension.

Qin JP, Jiang MD, Tang W, Wu XL, Yao X, Zeng WZ, Xu H, He QW, Gu M. Clinical effects and complications of TIPS for portal hypertension due to cirrhosis: A single center. *World J Gastroenterol* 2013; 19(44): 8085-8092 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i44/8085.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i44.8085>

## INTRODUCTION

Transjugular intrahepatic portosystemic shunt (TIPS) is an effective procedure for portal hypertension due to cirrhosis and related complications. At the end of the 1980s, Rösch *et al*<sup>[1]</sup> and Rössle *et al*<sup>[2]</sup> first reported the use of Palmaz, a self-expanding stent. Since then Palmaz had been gradually applied and disseminated in clinical practice. In our centre, TIPS was used, in the initial stage, mainly for the treatment of patients intolerant of surgery, patients with recurrent hemorrhage despite medication and in patients with refractory ascites. As this procedure was developed and improved, it was also used in the treatment of recurrent hemorrhage of the digestive tract due to cirrhosis, hemorrhage after endoscopic ligation and sclerosing therapy, hemorrhage after surgery, portal thrombosis, ascites and hydrothorax due to portal hypertension, hepatorenal syndrome, and emergency hemorrhage. In this study, the significant clinical effects and complications of TIPS are discussed in 280 patients who underwent this procedure at our centre between January 2005 and December 2009.

## MATERIALS AND METHODS

### Patients

The clinical data on the outcome of TIPS in 280 patients between January 2005 and December 2009 were retrospectively analyzed. These 280 patients with portal hypertension due to cirrhosis met the criteria of the American Hepatological Association<sup>[3,4]</sup> for the clinical application of TIPS.

### TIPS procedure

Patients with cirrhotic portal hypertension underwent routine abdominal enhanced computed tomography (CT) scanning and hepatic portal vein CT three-dimensional reconstruction prior to TIPS. During TIPS, after paracentesis from the right hepatic vein or hepatic segment of the inferior vena cava to the branch of the portal vein, direct portography was carried out, then balloon dilatation, followed by stent placement. Portal venous pressure was measured before and after stent placement. Spring wire loops, a gelatine sponge and sclerosing agent were used for blockage of the collateral circulation of esophageal and fundic varices. The stents used were Zilver stents.

Specifications of the stents: ZIV 6-80-8 or 10-8.0 (Cook Corporation, Bloomington, IN). Specifications of the balloon: ATB 5-35-8-6.0 or 4.0 (Cook Corporation). Specifications of the spring wire loop: MWCE-35-3-3, 4, 5, 8, 10 (Cook Corporation). Generally, the puncture path was dilated with a balloon of 8 mm inside diameter, and a stent of 8 or 10 mm inside diameter was then positioned.

### Postoperative management

Anticoagulant therapy was administered in addition to routine expectant treatment. Heparin sodium 12500 IU was administered by intravenous drip 24-h for 7 d 24 h after surgery, and then oral sodium warfarin tablets for 1 year. Prothrombin time (PT) was maintained for 17-20 s.

### Follow-up

All patients were followed up 1 wk and 1 mo after surgery, followed by every 3 mo for 12 mo and then every 6 mo after 12 mo. Each follow-up visit included ultrasonography, liver and renal function tests, blood ammonia, routine blood examination and blood coagulation tests, and symptoms and signs of portal hypertension. Gastroscopy was performed in each patient from the month 1 to the month 3 after surgery and direct portography from the month 9 to the month 12.

### Statistical analysis

All measurement data are presented as mean  $\pm$  SD. The data before and after surgery were analyzed using the *t* test. *P* values  $< 0.05$  were considered statistically significant. Stent stenosis, hepatic encephalopathy, recurrent hemorrhage and survival were analyzed by the Kaplan-Meier method.

## RESULTS

### Clinical data

All 280 patients had portal hypertension. Of these patients, 220 had severe esophageal varices, 60 had severe esophageal and moderate-severe fundic varices, 42 had a large amount of ascites, 31 had a moderate amount of ascites and 40 had intractable ascites which was complicated by a large right hydrothorax in 4. Table 1 shows the patients' sex, causes of portal hypertension and Child-Pugh grading. Differences between the patients' sex, age, causes and Child-Pugh grading and their survival rate, incidence of rebleeding, incidence of hepatic encephalopathy and incidence of stent stenosis were not statistically significant ( $P > 0.05$ ).

### TIPS procedure

All 280 patients underwent puncture of the right internal jugular vein. Of these patients, 200 underwent puncture of the right hepatic vein, 80 puncture of the inferior vena cava near the liver, 198 underwent puncture of the right branch of the portal vein and 80 puncture of the left branch and 2 had severe hemorrhage in the abdominal cavity during this procedure (1 died, and the other

All parameters shown in Table 1 were significantly different before and after surgery ( $P < 0.01$ ).

survived after emergency treatment). The success rate of surgery was 99.3% and the incidence of lethal complications was 0.7%. Embolism caused a collateral circulation in esophageal and fundal varices.

### Influence of TIPS on liver hemodynamics

Following the establishment of a portosystemic shunt pathway, liver hemodynamics changed. Portal pressure decreased after surgery, the internal diameters of the portal and splenic veins decreased and the blood velocity in the trunk of the portal vein increased (Table 2).

### Liver function before and after TIPS

Liver function was slightly altered after TIPS. No marked changes in alanine aminotransferase (ALT), total bilirubin,

**Table 3 Changes in liver function and prothrombin time before and after transjugular intrahepatic portosystemic shunt ( $n = 278$ , mean  $\pm$  SD)**

TIPS	ALT (IU/L)	TBIL ( $\mu$ mol/L)	Alb (g/L)	PT (s)

and albumin (Alb) before and after surgery were observed. Routine anticoagulant therapy was given postoperatively. PT increased significantly after surgery (Table 3).

### Clinical effects of TIPS

The short-term hemostasis rate was 100% when TIPS was used in the treatment of emergency hemorrhage and recurrent hemorrhage unresponsive to medication, endoscopy or surgery. Ascites disappeared completely in 62% of patients, decreased obviously in 24% and remained in 14%. The total effective rate was 86%. Hydrothorax completely disappeared in 100% of patients. Fifteen patients who had hepatorenal syndrome became responsive to diuretic therapy. Ascites completely disappeared in 7 patients and was obviously reduced in 8 after 7-14 d of observation.

### Complications of TIPS

Complications occurred during surgery and both short- and long-term postoperative complications were observed (Table 4). The most serious complication was abdominal cavity hemorrhage, which frequently endangered the patient's life. Short-term severe complications after surgery were hepatic failure, septicemia and abdominal cavity hemorrhage. Intermediate and long-term complications were stent stenosis and hepatic encephalopathy.

### Follow-up

All the 278 patients who underwent TIPS were followed up. Hemorrhage, stent function, hepatic encephalopathy and survival were observed during the follow-up. The incidence of recurring hemorrhage was 9% in 12 mo, 19% in 24 mo and 35% in 36 mo (Figure 1A). The incidence of stent stenosis was 24% in 12 mo and 34% in 24 mo postoperatively (Figure 1B). The incidence of hepatic encephalopathy was 14% in 3 mo, 17% in 6 mo and 19% in 12 mo (Figure 1C). The cumulative survival rate was 86% in 12 mo, 81% in 24 mo, 75% in 36 mo, 57% in 48 mo and 45% in 60 mo (Figure 2). In our center, 3 patients died 1 mo after TIPS, of whom 2 died of hepatic failure and 1 of septicemia.

## DISCUSSION

TIPS is an effective method of treating portal hyperten-

TIPS: Transjugular intrahepatic portosystemic shunt.

sion due to cirrhosis and its complications. Because it is characterized as safe, micro-traumatic, effective and easily repetitive, it has been used more and more widely in clinical practice. Hepatic transplantation has not yet been popularized in China, therefore TIPS is effective for treating portal hypertension due to cirrhosis and its complications, particularly hemorrhage of the digestive tract, and is effective for treating refractory ascites and hydrothorax caused by portal hypertension. It is used mainly in the treatment of approximately 15%-20% of patients with refractory ascites and hemorrhage due to varices that are not responsive to medication or endoscopy. TIPS is used for 99% of cases with these two conditions<sup>[5,6]</sup>. In addition, TIPS is used for the treatment of hepatic hydrothorax, hepatorenal syndrome, hepatopulmonary syndrome and Budd-Chiari syndrome<sup>[7]</sup>. In our study, TIPS was also successfully adopted in emergency and portal thrombosis.

In our study, the success rate of TIPS was 99.3%. Once the shunt pathway was established, the portal vein pressure fell from  $46.5 \pm 3.4$  cmH<sub>2</sub>O before surgery ( $P < 0.01$ ) to  $26.8 \pm 3.6$  cmH<sub>2</sub>O after surgery. The instant rate of hemostasis was 100%. These results are consistent with literature reports<sup>[8-10]</sup> which show that the short-term effective rate of TIPS is 90%-97.4% and the rate of emergency hemorrhage control is 90%-100%. In the present study, the total effective rate of TIPS for ascites was 86% and the rate of elimination of hydrothorax was

**Figure 1** Incidence of recurring hemorrhage (A), stent stenosis (B) and hepatic encephalopathy (C) after transjugular intrahepatic portosystemic shunt.

**Figure 2** Cumulative survival rate after transjugular intrahepatic portosystemic shunt.

100%. These findings are similar to the reported<sup>[9]</sup> effective rate of 50%-92% for refractory ascites and elimination of ascites in 70%-75% of patients. According to the literature reports<sup>[11]</sup>: 82% of patients who underwent TIPS had significantly reduced hydrothorax and in 71% hydrothorax was eliminated, however, patients over 60 did not respond well to TIPS. In our study, hydrotho-

rax was eliminated in 4 cases. However, the number of cases was small and the therapeutic effects remain to be determined. Fifteen patients with hepatorenal syndrome became responsive to diuretic therapy after TIPS and their renal functions were obviously improved. Ascites was eliminated in 7 of these patients and was improved in 8. Eight patients were alive after a one-year of follow-up (53%). According to the literature reports<sup>[12]</sup>, renal function was remarkably improved by TIPS in patients with hepatorenal syndrome and the survival rate was 48% after a one-year follow-up, however, only 10% of the patients who did not undergo TIPS lived for three months. These findings suggest that TIPS is an effective method of treating hepatorenal syndrome.

Of the 280 patients in the present study, 2 had abdominal cavity hemorrhage after TIPS. One patient died and the other survived after portal vein repair. Hemorrhage was due to dilation of the sacculus near the bifurcation of the portal vein. The incidence of this severe complication was 0.7%. It is the most severe complication of TIPS in that a patient immediately suffers from hemorrhagic shock and dies. Therefore, the operator should pay close attention to this complication. As reported<sup>[13]</sup>, the incidence of lethal complications related to the procedure was 0.6%-4.2%. The most critical complications after TIPS were worsening of liver function and hepatic encephalopathy. Both were related to a decrease in blood perfusion in the liver due to the establishment of the shunt pathway<sup>[14]</sup>. In our study, various degrees of hepatic injury occurred in all 280 patients after TIPS, however liver function was gradually restored after approximately 1 mo in most patients. The changes in bilirubin, ALT and Alb were not significantly different. This may be related to our patients having mainly Child-Pugh B and A liver function, few patients with Child-Pugh C liver function (36 patients) and dilation of the path using a balloon of 8 mm inside diameter. The incidence of hepatic failure 1 mo postoperatively was 7.2% (20/278) in our patients, which occurred mainly in emergency and Child-Pugh C TIPS patients. This may be related to poor liver reserve function in some patients and hypoperfusion of the liver due to the artificial shunt and the short supply of hepatic nutrients.

In order to reduce and avoid severe complications of TIPS, the operator is required to be familiar with the anatomy of the portal system. As reported<sup>[15,16]</sup>, the bifurcation of the portal vein is in the liver in about 25.8% of patients, outside the liver in about 48.4% and in the hepatic capsule in about 25.8%. In patients with cirrhosis, the cleavage of the liver is widened and the right trunk and the left horizontal trunk are outside the parenchyma of the liver with bare inferior walls, suggesting that puncture of the bifurcation and peri-bifurcation region is very dangerous. Therefore, the puncture point should be located 2 cm above the bifurcation of the portal vein to reduce or avoid the risk of hemorrhage due to portal vein rupture. In addition, the blood coagulation mechanism is poor in some patients, especially if they have ascites.

Hemorrhage will occur if the hepatic capsule is ruptured, and is not easy to stop. Of our patients, 2 (0.7%) had postoperative abdominal cavity hemorrhage and 7 (2.5%) bloody ascites. The bleeding stopped after management.

The intermediate and long-term complications of TIPS are stent abnormality and hepatic encephalopathy. It is reported<sup>[10,17]</sup> that the rate of stent abnormality (inclusive of stenosis and obstruction) is 17%-50% 6 mo after TIPS and 23%-87% 12 mo after TIPS. The application of a Viatorr stent has improved the condition.

The current criteria<sup>[18-20]</sup> for the evaluation of stent abnormalities (mainly stenosis) are: (1) the velocity of blood flow is over 200 cm/s or less than 50 cm/s in the shunt path, or the diameter of the shunt path is less than 50%; (2) the velocity of blood flow is less than 20 cm/s in the portal vein; (3) the portosystemic pressure gradient is more than or equal to 16 cmH<sub>2</sub>O; (4) portal hypertension recurs, *i.e.*, esophagofundic hemorrhage due to varicose vein or ascites not responsive to low salt diet therapy and routine diuretic therapy. Once the stent abnormality is detected by ultrasound, direct portography and repair should be carried out.

The cumulative rate of stent stenosis is 24% in 12 mo and 34% in 24 mo. The currently used Viatorr stent-graft was first adopted in Europe at the end of 1999 and granted approval by the FDA in 2004. The technical success rate is 100%. The first and second patency rates in one year were 76%-84% and 98%-100%<sup>[21-23]</sup>, respectively. In our study, the patency rate in one year was 76%, which was similar to the first patency rate in the report. Explanations for this rate are as follows: puncture was through the inferior vena cava near the liver (80 cases), avoiding stenosis induced by puncture of the liver vein; the shunt was straight and short apart from the left portal branch; attention was paid to the appliance of the puncture path and care was taken care to avoid angulating the stent; and anticoagulant therapy was given after the procedure, which lasted 1 year. PT was maintained for 17-20 s. It is now accepted that stent stenosis<sup>[24,25]</sup> is related to pseudo-endometrial hyperplasia, the mechanism of which is still unclear but leads to active proliferation of myofibroblasts and the accumulation of extracellular matrix containing collagen. The Viatorr stent-graft has not yet been extensively used, therefore, the prevention of stent stenosis is very important. In our centre a pathological study is now being carried out.

Hepatic encephalopathy is another complication of TIPS. In our study, the incidence of hepatic encephalopathy was 14% in 3 mo and 18% in 6 mo after TIPS. According to the literature<sup>[8,10,21,23,26]</sup>, the incidence of hepatic encephalopathy was 33%-55% after TIPS and 13%-26% after therapeutic endoscopy. International reports<sup>[27,28]</sup> showed that there was no significant difference in the occurrence of hepatic encephalopathy between the bare and Viatorr stents 10 mm in diameter, and the incidence was 20%-30%. The incidence of hepatic encephalopathy was 5%-10% when Viatorr stents of 8 mm in diameter were used, which supported shunting without hepatic

encephalopathy. In our study, the incidence of hepatic encephalopathy was lower than that reported and similar to that of the Viatorr stent and endoscope, which may be related to the selection of patients, puncture paths, stent diameters, etiological treatment and postoperative management. Of the 280 patients, most were graded as Child-Pugh A and B (244/280) with better liver function potential. Cirrhosis was induced mainly by HBV (238/280) and antiviral therapy was given before and after surgery. The patients' general physical condition was improved before surgery as far as possible. A stent with an appropriate diameter was carefully selected to avoid over shunting. Generally, we chose a balloon of 8 mm inside diameter and a stent of 8 mm or 10 mm inside diameter. For all patients, protein intake was limited 1 wk after surgery, bowel movement was regulated and enema with vinegar ordered to prevent intestinal infection. The mechanism of hepatic encephalopathy<sup>[29]</sup> involves multiple factors, but is mainly related to a decrease in blood flow and enhancement of the biological availability of enteric toxins.

The rate of recurrent hemorrhage was 9% in 1 year and 19% in 2 years after TIPS in our study. From previous reports<sup>[10,17,21,30]</sup> the rate was 15% in 1 year and 21% in 2 years after TIPS; and was 48% in 1 year and 52% in 2 years after gastroscopic treatment; and was less than 10% with the Viatorr stent. It was believed that the rate of recurrent hemorrhage was higher in the gastroscope group than in the TIPS group; and was lower in the Viatorr stent group than in the bare stent group. In our study, the rate of recurrent hemorrhage was similar to that of the Viatorr stent. Recurrent hemorrhage was related to stent abnormality. Any cause of stent stenosis or obstruction could lead to portal hypertension again, and the obstructed collateral circulation might reopen or a new collateral circulation could appear, resulting in hemorrhage from esophageal or fundic varices. Once the varicose vein ruptures, recurrent hemorrhage occurs. The maintenance of stent function is important in avoiding this situation. In our research, the rate of stent stenosis was low and the rate of recurrent hemorrhage was also low. In addition, the collateral vein with esophageal and fundic varices due to intraoperative embolism could significantly reduce or delay the occurrence of rebleeding.

Gastroscopy was performed in our patients. The results showed that 68% of patients had complete relief of esophageal varices and 32% had obvious relief. Approximately 80% of patients had complete relief of stomach fundic varices and 20% had obvious relief. This confirmed the effectiveness of TIPS and was an important procedure for recurrent hemorrhage. In our patients, hyperglycemia, puffiness of the face and other rare complications occurred in addition to the complications reported. Hyperglycemia may be explained by the metabolic disorder of glucose in the liver and insulin injection is indicated. The cause of puffiness of the face is unclear, but it gradually disappeared following diuretic therapy.

The cumulative survival rate was 86% at 1 year and 81% at 2 years after TIPS in our patients, which was simi-

lar to previously published reports<sup>[8,9]</sup> that is 64%-87% at 1 year and 56%-71% at 2 years after TIPS. Survival is related to liver function reserve. The survival rate was lower in patients graded as Child-Pugh C than in patients graded as A and B. Our patients were mainly Child-Pugh B, and few patients had Child-Pugh A and B. Statistical analysis showed that the survival rate of the patients was not significantly correlated with their Child-Pugh grading of liver function, which requires further study. There were 15 patients with hepatorenal syndrome in our study, with a death rate of 47% 1 year after TIPS. Three patients died 1 mo postoperatively, of whom 2 died of hepatic failure and 1 of hematosepsis. Our patients mainly developed cirrhosis after hepatitis B virus infection. The etiological treatment is critical in that we found that antiviral therapy and moderate shunting prolonged the survival of patients, especially of those graded as Child-Pugh A and B. These findings remain to be confirmed by future multicenter, randomized and controlled trials.

TIPS is characterized by its effectiveness and few complications. However, stent stenosis and hepatic encephalopathy are still leading factors affecting the intermediate and long-term therapeutic effects. Even though these problems can be solved to a considerable degree by the use of the Viatorr stent, this procedure is not popular in China, and the mechanism of stent stenosis remains to be studied further. Therefore the determination of the therapeutic effects and the association of the shunt pathway with encephalopathy requires further research.

## COMMENTS

### Background

Esophageal and fundic varicose hemorrhage is a critical complication of portal hypertension due to cirrhosis, and often endangers the patient's life. The clinical effects of routine treatment on hepatic thoracoabdominal ascites and hepatorenal syndrome are not good. Transjugular intrahepatic portosystemic shunt (TIPS) is an ideal method of treating these complications.

### Research frontiers

TIPS is one of the most difficult operations in vascular interventional therapy at the present time. A shunt path must be established between the branches of the hepatic veins and portal vein, and at the same time a collateral circulation by embolization in esophageal and fundic varices is necessary to achieve a partial shunt and cutout. TIPS has progressively become the method of choice for treating portal hypertension due to cirrhosis and its complications.

### Innovations and breakthroughs

By comparison with the results in the literature, in this study, TIPS improved patient outcome. Portal vein puncture was guided by replacing routine trans-superior mesenteric indirect portal venography with hepatic enhanced computed tomography (CT) scanning and hepatic portal vein CT three-dimensional graphic reconstruction. More cases were treated as the technique was developed. The patients were followed up over a long period, and satisfactory clinical effects were achieved.

### Applications

As the authors were unable to carry out hepatic transplantation, the complications of cirrhosis were mainly managed clinically, especially varicose hemorrhage and intractable thoracoabdominal ascites. The effects of the presently used drugs, endoscopes and surgical management are not ideal, however, treatment by TIPS has achieved satisfactory results. With the constant expansion of indications, TIPS will be used more extensively.

### Terminology

TIPS involves the establishment of a shunt path in the liver parenchyma between the two puncture points after paracentesis from the right hepatic vein or

hepatic segment of inferior vena cava to the branch of the portal vein, shunting of the portal venous blood flow and lower portal venous pressure, and at the same time causes a collateral circulation by embolization of esophageal and fundic varices and blockage of hemorrhagic blood vessels.

### Peer review

This study comprehensively and systematically evaluated the clinical effects and complications of TIPS for portal hypertension due to cirrhosis, and described how to improve the therapeutic effects of TIPS and the experience in reducing its complications. The improved TIPS is of great clinical significance and favors clinical dissemination.

### Abstract

**AIM:** To validate the “Metroticket” predictor using a large cohort of liver transplantation (LT) patients with hepatocellular carcinoma (HCC) in China.

**METHODS:** In total, 230 cases of LT for HCC treatment at our center, from July 2000 to August 2008, were included in the present study. The predicted 1-, 3- and 5-year post-LT survival rates were calculated using the Metroticket model (<http://89.96.76.14/metroticket/calculator/>). The predicted and observed long-term survival rates were then compared and analyzed.

**RESULTS:** The predicted survival rates for all 230 cases, as calculated by the Metroticket model, were 64.7% and 56.2% at 3 and 5 years, respectively, and the observed survival rates for these patients were 71.3% and 57.8%, respectively. For the 23 cases with macrovascular invasion, the predicted 5-year survival rate was 43.5%, whereas the observed 5-year survival rate was only 8.7%. For the 42 cases with microvascular invasion but an absence of macrovascular invasion,

the predicted 5-year survival rate was 44.9%, and the observed 5-year survival rate was 50%. For the remaining 165 patients without any vascular invasion, the predicted 5-year survival rate was 65.8%, and the observed 5-year survival rate was 66.7%.

**CONCLUSION:** The Metroticket model can be used to accurately predict survival in HCC-related LT cases with an absence of macrovascular invasion.

**Key words:** Metroticket; Model; Survival; Hepatocellular carcinoma; Liver transplantation

**Core tip:** The aim of our study was to validate the “Metroticket” predictor using a large cohort of liver transplantation (LT) patients with hepatocellular carcinoma (HCC). The predicted survival rates for all 230 cases, as calculated by the Metroticket model, were 64.7% and 56.2% at 3 and 5 years, respectively, and the observed survival rates for these patients were 71.3% and 62.2%, respectively. For the 23 cases with macrovascular invasion, the predicted 5-year survival rate was 43.5%, whereas the observed 5-year survival rate was only 8.7%. The Metroticket model can be used to accurately predict survival in HCC-related LT cases with an absence of macrovascular invasion.

## INTRODUCTION

Hepatocellular carcinoma (HCC) is the fifth most common cancer globally<sup>[1]</sup>, and this burden is heavier in China, which accounts for nearly 55% of all cases worldwide<sup>[2]</sup>. Despite the prevalence of using the hepatitis B vaccine in recent years, HCC is also the fifth most common malignancy in males and the sixth most common in females in China<sup>[3]</sup>. Liver transplantation (LT), resection and radiofrequency ablation (RFA) were once the only three potential curative treatments for early HCC<sup>[4]</sup>. LT was theoretically the best therapeutic option for HCC patients due to the procedure's overall eradication of the remnant liver with cirrhosis compared with resection and RFA<sup>[5,6]</sup>. Despite its thoroughness, LT was not suitable for all HCC cases: in that time, the very low survival rate after LT in HCC patients was mainly due to advanced HCC<sup>[7]</sup>. The Milan criteria, which were proposed in 1996 by Mazzaferro *et al.*<sup>[8]</sup>, resulted in excellent survival, with a 5-year survival rate of 61.1% compared with the previously observed 5-year survival rate of 25.3% in 1987. Thereafter, dozens of inclusion criteria were introduced for HCC-related LT<sup>[9-13]</sup>. However, these criteria were only inclusion criteria and could not be used to predict the results of LT, and especially the survival and recurrence rates.

In recent years, many groups have found certain risk factors that predict survival and recurrence after LT in HCC patients<sup>[14-18]</sup>. However, only few researchers have found risk factors for HCC recurrence after LT and built predictive models, such as the Metroticket<sup>[19]</sup>, Alpha-feto-protein (AFP)<sup>[20]</sup> and Markov<sup>[21]</sup> models. Derived from the largest collection of pathological data from patients with HCC (1556 overall and 1112 exceeding the Milan criteria), the Metroticket model offers individualized survival predictions based on a continuum of tumor size and number, whereby each patient is assigned an individual prognosis for 3- and 5-year survival<sup>[22]</sup>. The Metroticket model has been validated in several studies<sup>[6,21,22]</sup>. However, no analysis has been performed on the effectiveness of this predictive model using data from China with a large cohort of HCC cases, where nearly 55% of all cases worldwide<sup>[2]</sup> occurred and 24801 cases of LT were performed. Thus, in the present study, we aimed to prove the prognostic accuracy of the Metroticket model using single-center data from mainland China.

## MATERIALS AND METHODS

Our study used data from a retrospective database on LT in HCC patients that was developed at our center between August 2000 and August 2008 (230 consecutive patients). All of the data from these patients, including baseline demographic data, preoperative laboratory and radiological data, intraoperative data, postoperative recovery data and long-term outcomes, were retrospectively analyzed. All of these data were collected from the China Liver Transplant Registry System. Demographic data in-

cluded age, gender, height, weight and body mass index (BMI). Preoperative liver function data included underlying liver disease and liver function (Child score and MELD score). Tumor characteristics included the tumor number, diameter and differentiation. Intraoperative data included the graft type (DDLT/LDLT), operative time, blood loss and rate of transfusion. Postoperative data included mortality, complications (classified using the Clavien system), hospital stay days and overall cost. Long-term outcomes were mainly the overall survival rate.

The diagnosis of HCC was confirmed preoperatively in all patients if the patient simultaneously fulfilled the following three criteria: radiological evidence of HCC (helical triple-phase computed tomography or magnetic resonance imaging scans in arterial, portal venous and delayed venous phases; blush with washout; and a pseudo-capsule), serology positive for hepatitis B or C and levels of AFP > 400 ng/mL. If the patient lacked one of these features, biopsy (histology or cytology) was performed to prove HCC. For each patient in the present study, a "Metroticket"-predicted survival score was calculated using the online calculator (<http://89.96.76.14/metroticket/calculator/>). All of the imaging data were based on pre-transplant radiological measurements obtained within 15 d pre-LT. The Metroticket calculator only incorporates tumors greater than 10 mm in diameter and no more than 10 nodules. We also divided all of the patients into subgroups according to the presence of micro- and macrovascular invasion. Thus, the main analysis was a comparison between the Metroticket model-predicted and observed survival rates, and the subgroup analysis also compared the Metroticket model-predicted and observed survival rates in the presence and absence of macrovascular invasion.

All of the deceased donors were brain-dead donors at our hospital, and no prisoners served as donors at our center. All of the liver donations were voluntary and altruistic. Written consent was given by the donors or their families. For all of these procedures, authorization was obtained from the donors' families, the ethics committee and the Red Cross Society of China. The surgical procedure and postoperative antiviral and immunosuppression protocols have been previously reported<sup>[23-25]</sup>.

Descriptive statistics are expressed as proportion for categorical variables, and mean  $\pm$  SD or median and range were used for continuous variables. The predicted survival rates at 3 and 5 years were calculated using the Metroticket online calculator for each patient, and the mean sum of the individual scores was calculated and compared with our observed survival rates at 3 and 5 years. Overall survival was defined as the time interval between LT and death from any cause. Survival rates were estimated using the Kaplan-Meier method, whereas statistical significance between survival curves was tested by the log-rank test. Statistical tests were considered to be significant when the corresponding *P*-value was less than 5%. Statistical analyses were performed using the SPSS package (SPSS 17.0, Inc., Chicago, IL).

**Table 1** Complications of recipients, as classified by the Clavien system *n* (%)

	LT to treat HCC <i>n</i> = 230
Grade I: Treated conservatively without any drugs	22 (9.6)
Pleural effusion	8
Wound infection	8
Bile leak	6
Grade II: Treated with medication	14 (6.1)

Grade IIIb: Intervention using general anesthesia	17 (7.4)
Intra-abdominal Bleeding	6
Biliary obstruction	3
Intra-abdominal abscess	4
Portal venous thrombosis	2
Hepatic artery thrombosis	2
Grade IVa: Single-organ dysfunction	6 (2.6)
Small-for-size syndrome	2
Renal dysfunction	2
Respiratory failure	2
Grade IVb: Multi-organ dysfunction	2 (0.9)
Grade V: Death	22 (9.6)
Respiratory failure	3
Graft-vs-host disease	1
Cardiopulmonary arrest	2
Liver failure	4
Septic shock	3
Bleeding	3
Rejection	5

LT: Liver transplantation; HCC: Hepatocellular carcinoma.

## RESULTS

The baseline demographics of all patients showed that there were many more male patients (210 cases) than female ones (20 cases). The patients' mean age was  $46.1 \pm 10.3$  years, mean height was  $165.2 \pm 9.1$  cm, mean weight was  $67.3 \pm 8.8$  kg and mean BMI was  $23.2 \pm 2.2$  kg/m<sup>2</sup>. Underlying liver disease showed that most of these patients (215 cases) were diagnosed with HBV infection. Two patients had HCV, and 13 patients did not have hepatitis B or C. There were 100 patients who were HBV-DNA positive ( $> 1.00E + 03$  copies/mL). The preoperative liver function reflected by the MELD score of these patients was  $11.1 \pm 5.5$  and 129 patients had Child-Pugh A, 66 patients had Child-Pugh B, and 36 patients had Child-Pugh C.

The preoperative imaging scan indicated that the mean diameter of all targets was  $8.6 \pm 5.0$  cm and that the mean target number was  $3.1 \pm 2.9$  for these HCC patients. In total, 26 new tumor targets were found in the explanted liver in 14 patients, and the diameter of these new targets ranged from 0.6 to 2.4 cm. The mean

preoperative AFP level was 1838.2 ng/mL:  $< 400$  ng/mL in 97 patients, 400-800 ng/mL in 12 patients, 800-1200 ng/mL in 19 patients, and  $> 1200$  ng/mL in 102 patients. Explanted tumor histopathologic grading indicated 78 patients with good differentiation, 78 patients with moderate differentiation and 74 patients with poor differentiation.

The intraoperative and postoperative data showed that 177 patients had accepted whole-graft LT and that 53 cases had accepted living-donor LT at our center. The mean graft to recipient weight ratio was 0.81 for the 53 DDLT cases. The mean operative time was  $7.8 \pm 2.1$  h, mean blood loss was  $874.5 \pm 422.5$  mL, and mean length of hospital stay was  $33.2 \pm 12.3$  d. Table 1 shows the postoperative complications for all cases. All of these postoperative complications were classified using the Clavien system. The overall complication rate was 47%, the serious (more than grade III) complication rate was 22.5%, and the mortality rate was 9.6% in the hospital.

For all 230 patients, the predicted survival rates calculated by the Metroticket model based on preoperative imaging data were 64.7% and 56.2% at 3 and 5 years, respectively, and the observed survival rates for these patients were 71.3% and 57.8%, respectively. The actuarial 3- and 5-year survival rates were 71.7% (95%CI: 62.3%-77.0%) and 64.8% (53.5%-68.4%), respectively. The Metroticket predictions of the 3- and 5-year survival rates both fell within the 95%CI of the actuarial survival. For the subgroup patients (23 cases) with macrovascular invasion, the predicted 5-year survival rate was 43.5%, whereas the observed 5-year survival rate was only 8.7%. For the subgroup patients (42 cases) with microvascular invasion but an absence of macrovascular invasion (as proven by pathological examination), the predicted 5-year survival rate was 44.9%, and the observed 5-year survival rate was 50%. For the patients (165 cases) without macro- or microvascular invasion, the predicted 5-year survival rate was 65.8%, and the observed 5-year survival rate was 66.7%. The most common recurrence site was the liver (78.6%), followed by intra-abdominal metastasis (22.1%), lung metastasis (20.2%), bone metastasis (13.2%) and brain metastasis (4.6%).

## DISCUSSION

For HCC patients, LT is one of the most effective treatments. However, there are still continual pressure on limited donor resources, especially in China, and debate about what should be considered as an acceptable minimum survival outcome<sup>[22]</sup>. Since the first introduction of the Milan criteria for HCC-related LT in 1996, proposed by Mazzaferro *et al*<sup>[8]</sup>, more than one decade of excellent outcomes of LT for HCC treatment was achieved with these restrictive selection criteria. However, many groups worldwide have suggested expanding the Milan criteria due to comparable survival and recurrence outcomes<sup>[9-13]</sup>. Groups everywhere have suggested adding different types of risk factors for recurrence to the inclusion criteria: for example, Toso *et al*<sup>[26]</sup> proposed a total volume

of 115 cm<sup>[3,11]</sup>, and Zheng *et al.*<sup>[27]</sup> proposed the AFP level and histological grade. However, most of the criteria only considered the tumor diameter or number alone<sup>[10]</sup>. The Metroticket calculator was the first to combine the tumor number with the size of the largest nodule and is a model designed to predict 3- and 5-year overall survival after transplantation on the basis of the characteristics of the HCC (the size of the largest nodule, the number of nodules and the presence or absence of vascular invasion) in a given patient. This model changes the paradigm from "one size fits all" to an individual prognosis for each patient<sup>[22]</sup>. Our key finding is that the Metroticket calculator is an accurate predictor of post-transplant survival for patients with an absence of macrovascular or microvascular invasion, but not for patients with macrovascular invasion.

The Metroticket model was built in 2009 based on data from Europe. These HCC cases were caused by alcoholic or hepatitis C virus-related liver cirrhosis. Raj *et al.*<sup>[22]</sup> tried to evaluate the veracity of this model, but the study cohort was relatively small (82 cases), as mentioned as a weakness in the report, and only 40 cases included HBV. Compared with the small sample size and low rate of HBV cases in Raj's study, our study included 230 cases of HCC-related LT, and nearly all of our cases (93.5%, 215 cases) were HBV cases. Thus, our study may be more reliable and convincing. The Metroticket calculator was derived from explants' pathological data, but many reports<sup>[21,22,28]</sup> have proven the model's validity based on pre-transplant radiological criteria. Therefore, this model can be applied prospectively to patient selection.

Compared with other inclusion criteria, such as the Milan, Up-to-Seven and UCSF criteria, the Metroticket model provides a continuous range of survival probabilities rather than a dichotomous "in or out" basis for patient selection<sup>[22]</sup>. The upper limit of the tumor number is 10, and there is no upper limit for tumor diameter; the calculated tumor diameter is the largest one. Most importantly, the model also considers the presence of vascular invasion, which is a very strong risk factor for HCC recurrence after LT. This model considered all of these risk factors when it was built and thus may provide a reliable prediction of outcome for a patient who plans to accept LT for HCC treatment. However, there are certain limitations, as mentioned in Raj's study<sup>[22]</sup>. The diagnosis of microvascular invasion requires biopsy, with a risk of needle-tract seeding<sup>[29]</sup> and bleeding and false negatives<sup>[30,31]</sup>. Several other risk factors are AFP levels<sup>[32,33]</sup>, the neutrophil-to-lymphocyte ratio<sup>[15,34]</sup> and the serum C-reactive protein<sup>[35]</sup> and gene<sup>[36]</sup>, and all of these reported risk factors and biomarkers are available before transplantation and can be routinely used to predict recurrence and survival after HCC-related LT.

In the present study, we first examined the effectiveness of the Metroticket model in a subgroup of patients with macrovascular invasion. Our results showed that in subgroup patients with macrovascular invasion, the observed 5-year survival rate was only 8.7%, which was

much lower than the predicted 5-year survival rate of 43.5%. It is known that vascular invasion is an independent risk factor for HCC recurrence after LT, especially in the presence of macrovascular invasion<sup>[16]</sup>. However, there are still certain differences between the effects of macro- and microvascular invasion on HCC recurrence. As mentioned in other studies, macrovascular but not microvascular invasion is a risk factor for HCC recurrence<sup>[37,38]</sup>. In the present study, we found that the Metroticket model can be used to predict the outcome of microvascular invasion cases but not macrovascular invasion cases. However, the Metroticket calculator website does not make a distinction between micro and macrovascular invasion. Based on our results, we believe that the Metroticket calculator needs revision on the topic of vascular invasion.

Certain potential limitations of this study are related to our single-center data analysis. The need for a 5-year follow-up limited the size of our study, as we could only include patients (230 cases) who received transplants before 2009. The retrospective nature of our study also limited the reliability. In future work, multiple-center, randomized control trials and a larger number of studies may be needed.

In conclusion, with accurately predicted 3- and 5-year survival rates, the Metroticket model should be introduced as a useful tool for selecting HCC patients for LT based on preoperative imaging examinations. However, macrovascular invasion should be considered as a contraindication to use of the Metroticket model.

The authors thanks for the data from the Chinese Liver Transplant Registry (<http://www.cltr.org>).

## COMMENTS

### Background

Liver transplantation was theoretically the best therapeutic option for hepatocellular carcinoma (HCC) patients due to the procedure's overall eradication of the remnant liver with cirrhosis compared with resection and radiofrequency ablation. Dozens of inclusion criteria were introduced for HCC-related liver transplantation (LT). However, these criteria were only inclusion criteria and could not be used to predict the results of LT, and especially the survival and recurrence rates. Recent years, many groups have found certain risk factors that predict survival and recurrence after LT in HCC patients. However, only few researchers have found risk factors for HCC recurrence after LT and built predictive models, such as the Metroticket. The Metroticket model offers individualized survival predictions based on a continuum of tumor size and number.

### Research frontiers

The Metroticket model has been validated in several studies. However, no analysis has been performed on the effectiveness of this predictive model using data from China. Thus, in the present study, this study aimed to prove the prognostic accuracy of the Metroticket model using single-center data from mainland China.

### Innovations and breakthroughs

The Metroticket model was introduced several years ago, but there is still no consensus about its effectiveness. 230 cases of LT for HCC treatment at our center were included in the present study. The predicted 1-, 3- and 5-year post-LT survival rates were calculated using the Metroticket model (<http://89.96.76.14/metroticket/calculator/>). The predicted and observed long-term survival rates

were then compared and analyzed. Due to the similar predicted and observed long-term survival rates, the Metroticket model can be used to accurately predict survival in HCC-related LT cases with an absence of macrovascular invasion.

### Applications

The Metroticket model can be used to accurately predict survival in HCC-related LT cases with an absence of macrovascular invasion.

### Terminology

Liver transplantation is a surgical method to cure end-stage liver disease, removing the liver with disease and implanting one or part of new liver from the donor.

### Peer review

This is an interesting study to evaluate the effectiveness of the Metroticket model.

detect the differential levels of uH2B, H3K4-2me and H3K4-3me modifications in GC specimens from chemo/radiotherapy-naïve patients who underwent potentially curative surgical resection ( $n = 159$ ) and in a random sampling of non-tumor gastric epithelium specimens (normal controls,  $n = 20$ ). The immunohistochemistry (IHC)-detected modifications were classified as negative, low-level, or high-level using a dual-rated (staining intensity and percentage of positively-stained cells) semi-quantitative method. The relationships between uH2B modification levels and clinicopathological parameters of GC were assessed by a Wilcoxon rank sum test (pairwise comparisons) and the Kruskal-Wallis H test (multiple comparisons). The correlation between uH2B modification and survival was estimated by Kaplan-Meier analysis, and the role of uH2B as an independent prognostic factor for survival was assessed by multivariate Cox regression analysis.

**RESULTS:** The presence and level of H3K4-2me and H3K4-3me IHC staining was similar between the normal controls and GC specimens. In contrast, the level of uH2B was significantly lower in the malignant gastric tissues (*vs* normal control tissues) and decreased along with increases in dedifferentiation (well differentiated > moderately differentiated > poorly differentiated). The level of uH2B correlated with tumor differentiation ( $P < 0.001$ ), Lauren's diffuse- and intestinal-type classification ( $P < 0.001$ ), lymph node metastasis ( $P = 0.049$ ) and tumor-node-metastasis stage ( $P = 0.005$ ). Patients with uH2B+ staining had higher 5-year survival rates than patients with uH2B-staining ( $52.692 \pm 2.452$  *vs*  $23.739 \pm 5.207$ ,  $P < 0.001$ ). The uH2B level was an independent prognostic factor for cancer-specific survival (95%CI: 0.237-0.677,  $P = 0.001$ ).

**CONCLUSION:** uH2B displays differential IHC staining patterns corresponding to progressive stages of GC. uH2B may contribute to tumorigenesis and could be a potential therapeutic target.

### Abstract

**AIM:** To investigate H2B monoubiquitination (uH2B) and H3K4 di- and tri-methylation (H3K4-2me, H3K4-3me) levels and their clinical significance in gastric cancer (GC).

**METHODS:** Immunohistochemistry (IGC) was used to

© 2013 Baishideng Publishing Group Co., Limited. All rights

reserved.

**Key words:** Gastric cancer; Epigenetics; Histone modification; H2B monoubiquitination; Nuclear immunostaining

**Core tip:** The abundant H2B monoubiquitination (uH2B) modification detected by immunohistochemistry (IHC) in normal human gastric epithelium is decreased in malignant gastric cancer specimens, and the decreasing trend is correlated with decreased tumor differentiation, Lauren's classification intestinal-type, presence of lymph node metastasis, and TNM stage. Positive uH2B staining is associated with higher 5-year survival. Multivariate analysis identified uH2B modification level as an independent prognostic factor for gastric cancer-specific survival. Collectively, these findings indicate the clinical significance of IHC-detected uH2B differential staining patterns as a potential prognostic biomarker in early stage gastric cancer.

Decreased histone H2B monoubiquitination in malignant gastric carcinoma. *World J Gastroenterol* 2013; 19(44): 8099-8107 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i44/8099.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i44.8099>

## INTRODUCTION

Focused public health efforts to increase awareness of gastric cancer (GC) and implementation of screening programs to detect malignancy in asymptomatic patients have led to a decline in the overall mortality of this disease worldwide. Asian countries continue to report the highest incidence rates of GC and these cases have worse prognosis. The low overall 5-year survival rate of GC cases in China (about 40%)<sup>[1,2]</sup> highlights the particular burden facing these nations' healthcare systems and the impact on the overall social and economic well-being of their citizens.

The aggressive nature of GC remains a particular challenge to clinical management of this malignancy, and surgical resection of the affected tissues is the only effective treatment, with chemo/radiotherapy providing some benefit as adjuvant treatment. However, the efficacy of GC surgery is reliant upon the disease stage at which it is applied. Delays associated with incorrect or mis-diagnosis of the generally non-specific clinical symptoms in early stage GC (when the tumor is localized and has low risk of metastasis) can completely preclude surgery. Indeed, it has been reported that > 30% of GC patients in China are diagnosed at malignancy stages that are too far advanced for resection to be a feasible (benefit: risk) option<sup>[3]</sup>.

One way to improve timely diagnosis in GC patients is to develop more accurate and sensitive methods of screening. Biomarkers, such as epigenetic modifications,

are good candidates for such tests as they are detectable in serum samples and may reflect not only the presence of disease, but also its prognosis (when differential levels correspond to progressive stages of tumor pathology). In addition, diagnostic and prognostic biomarkers represent putative molecular targets of therapeutic strategies and may be exploited to develop more effective, less invasive and more individualized therapies against these aggressive tumors.

Several forms of epigenetic modifications exist, and their various alterations to the chromatin structure affect gene expression and have been implicated in pathological processes underlying a multitude of disease conditions, including tumorigenesis<sup>[4,5]</sup>. In particular, the post-translational modifications (PTMs) of histones, including acetylation, methylation, phosphorylation and ubiquitination, function as regulators of DNA-associated signaling networks required for normal physiological processes<sup>[6]</sup>, such as cell growth, cycling, and movement - all important features of human cancer<sup>[6-9]</sup>.

Compared to the other histone modifications, ubiquitination is less well studied and its specific roles in many types of tumors remain to be precisely defined. Focused research efforts involving monoubiquitination of lysine 120 on histone H2B (uH2B), however, have begun to elucidate its regulatory mechanism and its downstream effects under normal physiological conditions. Upon catalyzation by ubiquitin-conjugating enzyme (Rad6) and ubiquitin-protein ligase (RNF20)<sup>[10,11]</sup>, uH2B acts to promote or suppress gene transcription<sup>[12,13]</sup>. Intriguingly, recruitment of RNF20 to gene promoter regions, mediated by transactivators such as Gal4 or p53, has been shown to be required for full induction of transcription of genes related to cancer, such as p21 and MDM2. Furthermore, de-regulation of uH2B has been suggested as an etiology of cancer development<sup>[14,15]</sup>.

The current study was designed to investigate the potential roles of three forms of histone modification, uHB and di- and tri-methylation at H3 lysine 4 (H3K4-2me and H3K4-3me, respectively), in gastric carcinoma and in relation to its clinicopathological features. Detecting cancer type- and stage-specific differential immunohistochemistry (IHC)-staining patterns of histone modifications may represent a useful biomarker-based prognostic method and provide novel insights into potentially manipulable targets of anti-GC molecular therapies.

## MATERIALS AND METHODS

### Clinical samples

One-hundred-and-fifty-nine formalin-fixed, paraffin-embedded GC tissue specimens obtained from gastrectomy or upper-gastrointestinal endoscopy performed at the Department of Gastrointestinal Surgery and Digestive Endoscopy Center of West China Hospital between January 2006 to January 2007 were selected for analysis. The GC specimens included 23 well-differentiated, 55

moderately-differentiated and 81 poorly-differentiated tumors. According to the Lauren classification system, 60 were intestinal-type and 59 were diffuse-type GC. According to staging by the tumor-node-metastasis (TNM) system, 15 were at stage I, 20 were at stage II, 99 were at stage III and 25 were at stage IV.

According to the medical records, all GC specimens were obtained during potentially curative surgical resection, and none of the patients had received preoperative chemotherapy or radiotherapy. Follow-up data was available for all patients until December 2012 or until death.

In addition, 20 non-tumor gastric mucosa specimens, including sections from normal and inflammatory epithelium, were randomly selected for use as normal controls.

### ***IHC staining of uH2B, H3K4-2me, and H3K4-3me***

The GC and normal control specimens (5  $\mu$ m) were deparaffinized and incubated with 0.3% hydrogen peroxide in 28% methanol for 30 min to quench the endogenous peroxidase activity. Following EDTA/high-pressure antigen retrieval, the sections were exposed to 1% bovine serum albumin for 20 min to block non-specific binding sites and then to primary antibodies against uH2B, H3K4-2me and H3K4-3me (Cat. No. 05-1312, 05-1338, and 05-1339 respectively; Millipore, Billerica, MA, United States) for 30 min. An additional 15 min post-antibody blocking step was carried out before exposure to the PowerVision+ poly-horseradish peroxidase (HRP)-anti-mouse/rabbit IgG secondary antibodies (Leica Biosystems, Newcastle, United Kingdom) for 30 min and HRP antibody (VECTASTAIN<sup>®</sup>; Vector Laboratories Inc., Burlingame, CA, United States) for 30 min. Immunoreactivity was visualized upon exposure to the DAB chromogen. The processed tissue sections were then counterstained with hematoxylin, dehydrated and mounted.

### ***Dual-rated semiquantitative analysis of IHC staining levels***

The degree of uH2B, H3K4-2me and H3K4-3me immunostaining in each specimen was assessed by two investigators (Yang JL and Wang YP) working independently, as described below. The two sets of results were compared and in the case of disagreement, the section was re-examined by both investigators simultaneously with discussion to achieve a consensus score.

For each processed specimen, three high-power ( $\times 200$ ) magnification fields encompassing an average of 1000 cells (range: 800-1200) were selected (BX51 microscope; Olympus, Tokyo, Japan) and image obtained (FAST 1394 camera with accompanying QCapture suite software; QImaging, Surrey, BC, Canada) to capture an overall representation of different staining densities. An immunoreactivity score (IRS) for each of the three modifications detected was calculated as the product of staining intensity (SI) multiplied by percentage of positively-stained cells (PP)<sup>[16]</sup>. SI was defined according to a four-point gradient scale, where no staining = 0, weak-coloring (light yellow) = 1, moderate-coloring (bright yellow) = 2,

and strong-coloring (brown) = 3. PP was defined according to a four-point positive/negative scale, where 0-9% positive cells = 0, 10%-25% positive cells = 1, 26%-50% positive cells = 2, 51%-75% positive cells = 3, and > 75% positive cells = 4.

The triplicate IRS scores for each of the three detected modifications were averaged for each specimen and used to classify the degree of uH2B, H3K4-2me and H3K4-3me immunostaining as follows: no modification: 0; low-level modification; 1-5; high-level modification:  $\geq 6$ .

### ***Statistical analysis***

All statistical analyses were performed by the SPSS software suite, version 13.0 (SPSS Inc., Chicago, IL, United States). The relationships between uH2B modification levels and clinicopathological parameters of GC were examined by a Wilcoxon rank sum test (for pairwise comparisons) and the Kruskal-Wallis *H* test (for multiple comparisons). The correlation between uH2B modification and survival was estimated by Kaplan-Meier analysis. The role of uH2B as an independent prognostic factor for survival was assessed by multivariate Cox regression analysis. The threshold for statistical significance was set as  $P < 0.05$ .

## **RESULTS**

### ***uH2B, and not H3K4-2me or H3K4-3me, shows differential IHC staining in GC associated with extent of tumor differentiation***

The IHC staining patterns of H3K4-2me and H3K4-3me were similar between the GC and normal control tissues, with the nuclear staining distributed evenly, regardless cancer status or tumor differentiation (Figure 1). In contrast, the uH2B staining patterns and IRS scores were remarkably different between the GC and the normal control tissues, as well as between the different classes of tumor differentiation (Figure 2). All 20 non-tumor mucosa specimens showed high-level uH2B modification ( $\geq 6$  IRS). The amount of GC specimens with high-level uH2B modification decreased in conjunction with increasing level of tumor dedifferentiation, with IRS scores  $\geq 6$  seen in 65.2% (15/23) of well-differentiated GC tumors, 47.2% (26/55) of moderately-differentiated GC tumors, and 2.4% (2/81) of poorly-differentiated GC tumors. Moreover, this trend of decreased uH2B with increased degree of differentiation was statistically significant ( $P < 0.001$ , Table 1), suggesting that uH2B may play a role in maintenance of tumor differentiation.

### ***Differential uH2B IHC staining correlates with Lauren classification of the histological type of tumor***

When the GC specimens were divided by the Lauren classification, significantly more of the intestinal-type samples showed positive uH2B staining than the diffuse-type samples [90.0% (54/60) *vs* 71.2% (42/59),  $P <$

Figure 1 Immunohistochemical nuclear staining of H3K4-2me and H3K4-3me. H3K4-2me (A-D) and H3K4-3me (E-H) in normal gastric mucosa (A, E), well-differentiated gastric cancer (GC) tumor (B, F), moderately-differentiated GC tumor (C, G), and poorly-differentiated GC tumor (D, H). Regardless of the GC differentiation status, H3K4-2me and H3K4-3me displayed high-level nuclear signals, as visualized by immunohistochemistry. Magnification: × 200.

Figure 2 Immunohistochemical detection of staining patterns of uH2B in gastric cancer at various stages of differentiation. A: Normal gastric mucosa shows high-level staining (brown); B: Well-differentiated gastric cancer (GC) shows high-level staining; C: Moderately-differentiated GC shows low-level staining; D: Poorly-differentiated GC shows negative staining. Magnification: × 200.

0.05; Figure 3]. In addition, significantly more of the intestinal-type tumors showed high-level modification

**Figure 3** Level of nuclear staining of uH2B according to Lauren classification of tumor type. A, B: Intestinal-type tumors showing (A) high-level staining (brown) of well-differentiated tumors and (B) fewer uH2B<sup>+</sup> cells and moderate staining (yellow) of moderately-differentiated tumors; C, D: Diffuse-type tumors showing (C) low-level staining (light yellow) and few uH2B<sup>+</sup> cells of poorly-differentiated tumors and (D) negative staining in poorly-differentiated tumors. Magnification:  $\times 200$ .

**Figure 4** Immunohistochemical detection of uH2B staining at different TNM stages. A: Stage I (well-differentiated) gastric cancer (GC) tumor shows high-level staining; B: Stage II (moderately-differentiated) GC tumor shows fewer uH2B<sup>+</sup> cells and moderate staining (yellow); C: Stage III (poorly-differentiated) GC tumor shows few uH2B<sup>+</sup> cells and low-level staining; D: Stage IV (dedifferentiated) GC tumor shows no uH2B<sup>+</sup> cells and negative staining. Magnification:  $\times 200$ .

[55.0% (33/60) *vs* low-level modification: 35.0% (21/60),  $P < 0.05$ ; Figure 3], and this pattern was significantly dif-

**Figure 5** Kaplan-Meier curves of cancer-specific survival for gastric cancer patients based on uH2B<sup>+</sup> and uH2B<sup>-</sup> status, as detected by immunohistochemistry. The 5-year survival rate of patients with positive uH2B staining ( $n = 130$ ) was significantly higher than that of patients with negative uH2B staining ( $n = 23$ ).

**Table 1** Immunohistochemical detection of uH2B modification levels and gastric cancer clinicopathological parameters

Parameter	n	IHC Staining Level			u/H <sup>1</sup>	P value
		Negative	Low	High		
Age (yr)					3059.000	0.969
< 60	93	10	62	21		
≥ 60	66	15	29	22		
Sex					2728.000	0.373
Male	100	13	59	28		
Female	59	12	32	15		
Tumor differentiation					40.376	< 0.001
Well	23	1	7	15		
Moderate	55	7	22	26		
Poor	81	17	62	2		
Lauren classification					933.000	< 0.001
Intestinal	60	6	21	33		
Diffuse	59	17	35	7		
Lymph node metastasis					2330.000	0.049
Absent	53	2	35	16		
Present	106	23	56	27		
TNM stage					12.896	0.005
I	15	1	6	8		
II	20	2	15	3		
III	99	14	55	30		
IV	25	8	15	2		

<sup>1</sup>u represents the test statistic of the Kruskal-Wallis H test and H represents the Wilcoxon ranks sum test. IHC: Immunohistochemistry.

ferent from that seen in the diffuse-type tumors [*vs* high-level modification in diffuse-type: 11.9% (7/59),  $P < 0.001$ ; Table 1].

#### Differential uH2B IHC staining correlates with TNM stage and lymph node metastasis

When the GC specimens were divided by TNM stages, a statistically significant trend in differential uH2B modification level was observed. As shown in Figure 4, the frequency of high-level uH2B modification was 53.3% (8/15) in stage I tumors, 15.0% (3/20) in stage II tumors, 30.3% (30/99) in stage III tumors, and 8.0% (2/25)

**Table 2** Multivariate analysis for prognostic factors in gastric cancer-specific survival of patients

Variable	Comparison	RR	95% CI	P value
Age (yr)	< 60 <i>vs</i> ≥ 60	0.761	0.493-1.174	0.217
Sex	male <i>vs</i> female	0.961	0.618-1.494	0.858
Tumor differentiation	Well <i>vs</i> moderate, poor	0.497	0.301-0.819	0.006
Lymph node metastasis	Present <i>vs</i> absent	3.274	1.728-6.201	< 0.001
TNM stage	I <i>vs</i> II, III, IV	1.695	1.112-2.583	0.014
uH2B modification	IHC stain positive <i>vs</i> negative	0.400	0.237-0.677	0.001

in stage IV tumors. The difference in frequency of high-level uH2B modification detected in stage I and stage IV tumors reached statistical significance ( $P = 0.005$ ; Table 1).

In addition, GC cases with lymph node metastasis showed a significantly lower frequency of high-level uH2B modification [25.4% (27/106) *vs* no lymph node metastasis: 30.2% (16/53),  $P = 0.049$ ; Table 1].

#### Prognostic significance of uH2B modification in GC

Of the 159 GC patients treated with surgical resection, 96 (60.4%) died from GC-related causes during the follow-up period and six died from non-GC causes. When the overall patient population was divided by presence of uH2B staining, GC-related deaths were found to have occurred in a significantly higher proportion of patients with negative uH2B staining than those with positive uH2B staining [88.0% (22/25) *vs* 55.2% (74/134),  $P < 0.05$ ]. The cumulative 5-year cancer-specific survival rate was 43.4%. Moreover, the 5-year survival rate of patients with positive uH2B staining was significantly higher than that of patients with negative uH2B staining ( $52.69 \pm 2.45$  *vs*  $23.74 \pm 5.21$ ,  $P < 0.001$ ; Figure 5).

According to Cox multivariate regression, uH2B modification level is an independent prognostic factor for cancer-specific survival of GC patients. The risk of death in patients with negative uH2B staining was 2.5-times (1:0.4) that of patients with positive uH2B modification (RR = 0.40, 95%CI: 0.237-0.677,  $P = 0.001$ ; Table 2).

## DISCUSSION

In this study, immunohistochemical detection of human GC samples was performed as a semi-quantitative approach to measure the H2B monoubiquitination at lysine 121 and investigate its potential clinical significance with regards to diagnosis (GC *vs* control tissues) and prognosis (progressive stages of GC tumorigenesis). To the best of our knowledge, this study provides the first evidence of correlation between uH2B modification level and clinicopathological and prognostic features of human GC, including tumor differentiation, Lauren's classification, lymph node metastasis, and TNM stage but not with sex or age (data not shown).

The modification of H2B at lysine 121, shown by

the percentage of positivity and intensity of immunohistochemical detection, was significantly less robust in tumors of lower differentiation level. The degree of differentiation is considered to be strongly associated with the malignancy of cancer; therefore, this result indicates that reduced uH2B may be correlated with a worse prognosis. The more frequent and intense staining of uH2B observed in intestinal-type tumors in the current study, compared to the diffuse-type tumors, suggests that loss of uH2B may contribute to GC tumor progression. From a histological perspective, the composition of intestinal-type GC tumors includes a remarkable amount of ductal structures, displaying a better differentiation than the diffuse-type GC tumors that may be related to the better prognosis of the former tumor type<sup>[17,18]</sup>. Finally, the current observation of lower uH2B modification level in higher grade TNM stages, which tend to be more aggressive and invasive towards the inner tissues and more metastatic, suggest that this modification may be a useful predictive biomarker of the invasive potential of a GC specimen.

The collected results of the current study indicate that the progressive stages of GC are accompanied by differential uH2B modification levels that are detectable by IHC. Prenzel *et al.*<sup>[19]</sup> reported a similar finding for human specimens of breast cancer. Specifically, the abundant uH2B signals detected by IHC in normal mammary epithelium and benign breast tumors were absent in most malignant and metastatic breast tumors. Urasaki *et al.*<sup>[20]</sup> also demonstrated drastically reduced uH2B modification levels in breast, colon and lung cancer cells, as compared to the abundant expression in matched normal control tissues. Thus, loss of uH2B may lead to progression and metastasis of tumors, in general.

The mechanisms underlying tumor-related decreases in uH2B remain unknown. Besides the known Rad6 and RNF20 regulatory enzymes<sup>[10,11]</sup>, other de/ubiquitinating enzymes are likely to be involved in the dynamic process of uH2B promotion of tumorigenesis. For example, the ubiquitin-specific protease 22 (USP22), a member of the recently identified polycomb/cancer stem cell signature<sup>[21]</sup>, has been shown to deubiquitinate H2Aub1 or H2Bub1 *in vitro*, suggesting functions in epigenetic regulation, cancer progression and transcription activation<sup>[22,23]</sup>. If USP22 plays a role in the cancer-related differential uH2B modifications, then corresponding changes in USP22 expression may be detected.

In fact, studies of USP22 expression level in cancer have demonstrated significant upregulation in malignant tumors (compared to the normal low or moderate levels in non-cancerous skeletal, heart, muscle, liver and lung tissues)<sup>[24]</sup> and significant correlations to tumor relapse, invasion depth, pathological stage and lymph node metastasis<sup>[25]</sup>. Moreover, a study of primary GC showed that upregulated USP22 protein expression was related to lymph node metastasis<sup>[26]</sup>. Future investigations may elucidate a role for USP22 in the de-regulation of uH2B, particularly in GC.

Another potential regulator of tumor-related decreases in uH2B is the ubiquitin-specific peptidase 49 (USP49) complex, which specifically deubiquitinates histone H2B *in vivo* to enhance the stability of a nucleosome spanning the affected exons<sup>[27]</sup>. Again, further research is required to determine whether USP49 acts as a histone H2B-specific deubiquitinase to promote tumorigenesis.

While the current study provided clear evidence of decreased uH2B in malignant and poorly-differentiated human GC specimens, the physiological significance of the loss of this histone code remains unclear. The critical roles of H3K4-2me and H3K4-3me modifications in gene expression and cellular viability are well established; however, the requirement for uH2B in these processes remains controversial. Genome-wide studies have shown that uH2B is associated mostly with actively transcribed genes in mammals, suggesting that H2B is universally required for gene transcription. However, loss of the H2B-specific RNF20/40 enzyme produced only moderate effects on a fraction of the transcriptome and no overall effects on cell viability<sup>[28]</sup>. This apparent differential function of H3K4 modifications and the uH2B modification is in line with the observations of the current study of GC tissues, whereby the uH2B level showed a unique gradual decrease from the benign to malignant stages.

In conclusion, the compelling evidence of uH2B not being required for viability of malignant cells in gastric carcinoma provided by the current study indicates that the decrease of uH2B might be an early event in GC and could be a counteracting factor against carcinogenesis of GC.

## COMMENTS

### Background

Gastric cancer (GC) remains a significant healthcare burden worldwide, with high mortality rates in countries with the highest incidences, such as China. Surgery is currently the only effective treatment, but must be applied in the early stages when the tumor is less aggressive. Unfortunately, the asymptomatic nature of early stage GC leads to missed diagnosis and precludes early surgical management. There is an urgent need to identify sensitive biomarkers that accurately diagnose GC at the early stage, as well as indicate prognosis for a particular patient. Such factors may also represent novel targets of molecular therapies, helping to overcome the limitations and risks associated with surgical resection.

### Research frontiers

The physiological and pathological roles of monoubiquitination on lysine 120 of histone H2B (uH2B) remain to be fully elucidated. As a general transcriptional regulator, de-regulation of uH2B may contribute to tumorigenesis and cancer progression by promoting expression of cancer-associated genes or suppressing expression of anti-tumor genes. Investigating the differential level of uH2B in specific cancer types, such as GC, will provide insights into its clinicopathological and prognostic significance.

### Innovations and breakthroughs

In this study, immunohistochemical (IHC) analysis of human GC specimens was used to detect the tumor-related levels of uH2B modification. Application of a dual-rated semi-quantitative method to score the IHC results allowed for statistical correlation analysis of uH2B modification level and tumor-related features. The GC-related decrease in uH2B modification level was positively correlated with extent of tumor dedifferentiation, intestinal-type tumors, occurrence of lymph node metastasis, worse TNM stage and lower 5-year survival rate. IHC-detected differential uH2B

modification may be developed as clinically useful prognostic biomarker in early GC.

### Applications

The uH2B differential staining pattern detected by IHC that accompanies progressive stages of GC not only indicated a potentially important role for this histone modification in carcinogenesis, but also suggested its potential as a target of molecular therapy.

### Terminology

uH2B, the monoubiquitination on lysine 120 of histone H2B, is a general transcriptional regulator, and its deregulation has been implicated in various cancers. IHC is a well-established laboratory detection method that exploits the antibody-antigen binding reaction to identify and visualize the location and level of a target protein in tissues or individual cells.

### Peer review

This paper is an interesting article regarding the role of histone modification events in the development of GC. The results of the paper show that decrease of uH2B might be an early event in GC, which could be a counteracting factor against carcinogenesis of gastric cancer. Furthermore, histone modification plays important roles in understanding the pathogenesis of gastric carcinoma, and could be a potential therapeutic target in the future

### Abstract

**AIM:** To determine the effects of RNAi-mediated inhibition of the growth hormone receptor (*GHR*) gene on tumors and colon cancer cells *in vivo*.

**METHODS:** Construction of a eukaryotic vector for human *GHR* expression, the pcDNA<sup>TM</sup>6.2-GW/EmGFP-small interfering RNAs (siRNAs)-*GHR* plasmid, was used to inhibit *GHR* expression. Thirty-six BALB/c nude mice were randomly divided into groups and treated with normal saline (NS), recombinant plasmid (*G<sub>2</sub>*), growth hormone (GH), 5-fluorouracil (FU), *G<sub>2</sub>*+FU or *G<sub>2</sub>*+FU+GH. Each nude mouse was subcutaneously inoculated with  $1 \times 10^7$  human colon cancer SW480 cells; the nude mice were weighed before inoculation and on the 2<sup>nd</sup>, 5<sup>th</sup>, 8<sup>th</sup>, 11<sup>th</sup>, 14<sup>th</sup> and 17<sup>th</sup> day after inoculation. All nude mice were sacrificed after 17 d. Each subcutaneous tumor was removed and studied. Tumor volume was measured on the 5<sup>th</sup>, 8<sup>th</sup>, 11<sup>th</sup>, 14<sup>th</sup> and 17<sup>th</sup> day after inoculation. The expression of *GHR* protein in the tumor tissue was detected by Western blotting analy-

sis, and the differences in *GHR* mRNA expression in the tumor tissue were detected by real-time quantitative reverse transcription-polymerase chain reaction.

**RESULTS:** Compared to the control group, the weights of the inoculated nude mice on the 17<sup>th</sup> day after inoculation were: *G<sub>2</sub>*:  $21.60 \pm 0.71$  g, GH:  $21.64 \pm 0.45$  g, FU:  $18.94 \pm 0.47$  g, FU+*G<sub>2</sub>*:  $19.40 \pm 0.60$  g, *G<sub>2</sub>*+FU+GH:  $21.04 \pm 0.78$  g *vs* NS:  $20.68 \pm 0.66$  g,  $P < 0.05$ ; the tumor volumes after the subcutaneous inoculation were: *G<sub>2</sub>*:  $9.71 \pm 3.82$  mm<sup>3</sup>, FU:  $11.54 \pm 2.42$  mm<sup>3</sup>, FU+*G<sub>2</sub>*:  $11.42 \pm 1.11$  mm<sup>3</sup>, *G<sub>2</sub>*+FU+GH:  $10.47 \pm 1.02$  mm<sup>3</sup> *vs* NS:  $116.81 \pm 10.61$  mm<sup>3</sup>,  $P < 0.05$ . Compared to the GH group, the tumor volumes were significantly decreased in the experimental groups. The *GHR* protein expression (*G<sub>2</sub>*:  $0.39 \pm 0.02$ , FU:  $0.40 \pm 0.02$ , FU+*G<sub>2</sub>*:  $0.38 \pm 0.01$ , *G<sub>2</sub>*+FU+GH:  $0.39 \pm 0.01$  *vs* NS:  $0.94 \pm 0.02$ ,  $P < 0.05$ ) and the *GHR* mRNA expression (*G<sub>2</sub>*:  $14.12 \pm 0.10$ , FU:  $15.15 \pm 0.44$ , FU+*G<sub>2</sub>*:  $16.46 \pm 0.27$ , *G<sub>2</sub>*+FU+GH:  $15.37 \pm 0.57$  *vs* NS:  $12.63 \pm 0.14$ ,  $P < 0.05$ ) were significantly decreased and increased, respectively, in the experimental groups.

**CONCLUSION:** Inhibition of *GHR* in human colon cancer SW480 cells resulted in anti-tumor effects in nude mice.

**Key words:** Growth hormone receptor; Small interfering RNAs; Colon cancer; Gene therapy; Signaling pathway

**Core tip:** Human growth hormone receptor (*GHR*) is highly expressed in colon cancer tissues. GH/*GHR* plays an important role in colon cancer emergence and development. After specific binding of GH to *GHR* in tumor tissues, the JAK-STAT signaling pathway is activated, resulting in improved cell growth and proliferation. small interfering RNAs (siRNAs)-targeted inhibition of the human *GHR* gene was used to investigate

its impact on the emergence and development of colon cancer and to determine how human colon cancer cells respond to GHR suppression. The siRNA-containing plasmid could suppress GHR expression in colon cancer cells and exhibited anti-tumor effects in nude mice.

Zhou D, Yang J, Huang WD, Wang J, Zhang Q. siRNA-targeted inhibition of growth hormone receptor in human colon cancer SW480 cells. *World J Gastroenterol* 2013; 19(44): 8108-8113 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i44/8108.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i44.8108>

## INTRODUCTION

As shown previously by our team, human growth hormone receptor (GHR) is highly expressed in colon cancer tissues. Additionally, less differentiated tumor tissues have higher levels of GHR expression. During tumor development, the expression of GHR demonstrates an upward tendency<sup>[1,2]</sup>. Some researchers<sup>[3-6]</sup> believe that the expression of GHR in tumor tissue is linked with the vegetative state of the tumor and that GH and GHR play important roles in the emergence and development of colon cancer. After specific binding of GH to GHR in tumor tissues, the JAK-STAT signal transduction pathway is activated, resulting in improved cell growth and proliferation<sup>[7-10]</sup>. Signal transduction therapy is a commonly used chemotherapy strategy, and currently, treatment often involves the use of small interfering RNAs (siRNAs) that target different signal transduction pathways<sup>[11-13]</sup>.

In this study, siRNA targeting the human *GHR* gene was used to investigate the impact that GHR has on the emergence and development of colon cancer and to determine how human colon cancer cells respond to the suppression of GHR expression.

## MATERIALS AND METHODS

### Experimental animals and cell lines

Thirty-six 8-wk old, female BALB/c nude mice, weighing between 20 and 22 g, were purchased from Vital River Laboratories (VRL) with license No. SCXK (Jing) 2006-0009. The mice were kept in the SPF environment of the animal experiment center in Kunming Medical University. The human colon cancer cell line SW480 was obtained from the Cell Resource Center of Shanghai Institutes for Biological Sciences, Chinese Academy of Science.

### Laboratory reagents

The HQ high purity plasmid extraction kit was purchased from Invitrogen (Invitrogen, Carlsbad city, California, United States). The BCA protein concentration kit (Tiangen Biology and Chemistry) and the molecular mass albumin standard were purchased from Tiangen Biology and Chemistry (Fermentas Company). The mouse monoclonal anti-human GHR antibody was obtained

from R and D Company (MAB1210), and the goat secondary anti-mouse IgG-HRP antibody was purchased from Abmart Company. RNase H was obtained from Invitrogen, and the Golden Taq PCR kit was purchased from Tiangen Biology and Chemistry. SYBR Green-Real Master Mix was purchased from Tiangen Biology and Chemistry, and all primers used in the study were obtained from Invitrogen.

### Preparation of cell suspension

Colon cancer SW480 cells were cultivated in RPMI 1640 nutrient solution supplemented with 10% fetal calf serum (FCS),  $10.0 \times 10^3$  U/L penicillin, and 100 mg/L streptomycin in a 37 °C incubator with 50 mL/L CO<sub>2</sub>. This is an adherent cell line. Cells in the exponential growth phase were harvested using 0.25% trypsin, and the cells were resuspended using a machine. The cells were then centrifuged at 2000 rpm for 5 min. Then, the supernatant was removed, and the cells were resuspended in physiological saline at a concentration of  $1 \times 10^7$  cells/mL. Trypan blue staining was used to ensure that cell viability was above 95%; after resuspension the cells were stored in an ice bath.

### Construction of siRNA and eukaryotic expression vectors

siRNA oligonucleotides were designed against the mRNA sequence of human *GHR* found in GenBank, which had a total length of 4414 bp (Accession No.: X06562, GI: 31737). We used the RNAi Designer website (<http://bio-info.clontech.com/rnaidesigner>) to design the siRNA that targeted the hGHR mRNA (527-547: GTCAGTTTA-ACTGGGATTCAT). Using the BLAST search program (<http://blast.ncbi.nlm.nih.gov/Blast.cgi>) to search the EST database, we found that the siRNA was not homologous to another gene and would be an effective siRNA sequence. The complementary single strand primer was incubated at 94 °C in annealing buffer solution for 3 min, and the oligonucleotides were annealed at 37 °C for 1 h. The annealed oligonucleotides were then phosphorylated at 37 °C for 30 min with T4 DNA-PNK. The oligonucleotides were then ligated into the linearized (BamHI/HindIII) pcDNA<sup>TM</sup> 6.2-GW/EmGFP-GHR-siRNA plasmid using T4 DNA ligase. The final product was transformed in competent *E. coli* DH5 $\alpha$  cells, and the transformants were spread on transformation plates containing 50  $\mu$ g/mL spectinomycin dihydrochloride (Sigma, Catalog No. S4014). The plates were kept in a 37 °C incubator overnight, and three co-nobium clones were picked from each plate and subcultured. The plasmids were extracted using plasmid extraction kits, and the plasmids were confirmed by restriction enzyme digestion with *Eco*R I, *Sac* I and *Sal* I. The transformation liquid was also sequenced to ensure that recombination had not occurred in the insert fragments during the cloning process. Finally, the pcDNA<sup>TM</sup>6.2-GW/EmGFP-GHR-siRNA plasmids were constructed successfully and are referred to as G2 throughout the paper. Additionally, the plasmids were extracted and diluted in

DMEM as a precaution.

### Groups and method of drug distribution

We subcutaneously injected  $1 \times 10^7$  human colon cancer SW480 cells into BALB/c nude mice. On the first day after the injection, the mice were divided into six groups and administered the indicated drug and dose. (1) Normal saline (NS): 10  $\mu$ L of NS was injected into the abdominal cavity of each mouse; (2) Plasmid (G<sub>2</sub>): 10  $\mu$ g of the G<sub>2</sub> eukaryotic expression plasmid was injected subcutaneously into each mouse; (3) Growth hormone (GH): 2 IU/kg rhGH, a physiological dose of GH, was hypodermically injected into each mouse; (4) 5-fluorouracil (FU): 20 mg/kg 5-FU was injected into the abdominal cavity of each mouse; (5) 5-FU+plasmid (FU+G<sub>2</sub>): 20 mg/kg 5-FU and 10  $\mu$ g of the G<sub>2</sub> plasmid were injected into the abdominal cavity of each mouse; (6) 5-FU+GH+plasmid (FU+GH+G<sub>2</sub>): 20 mg/kg 5-FU, 10  $\mu$ g of the G<sub>2</sub> plasmid, and 2 IU/kg rhGH were injected into the abdominal cavity of each mouse; and (7) Each of the above groups was treated every 5 d for three rounds of treatment.

### Observation index

**Observation of weight and tumor volume of nude mice:** The weight of the nude mice was recorded before injection of the SW480 cells and on the 2<sup>nd</sup>, 5<sup>th</sup>, 8<sup>th</sup>, 11<sup>th</sup>, 14<sup>th</sup> and 17<sup>th</sup> day after injection. The length and the minimum diameter of the tumors were recorded, and the tumor volume was calculated on the 5<sup>th</sup>, 8<sup>th</sup>, 11<sup>th</sup>, 14<sup>th</sup> and 17<sup>th</sup> day after hypodermic injection of human colon cancer SW480 cells. The following equation was used to calculate the tumor volume:  $V = (A \times B^2)/2$ , where A represents the major diameter and B represents the minimum diameter.

### Expression of GHR in tumor tissues as detected by Western blotting analysis

A sample of each tumor was removed from the nude mice and cut into pieces. Cleanser lysate solution containing PMSF (400  $\mu$ L) was added to the tumor sample in a homogenizer. After the cells were lysed for 30 min, the homogenate was centrifuged at 12000 rpm for 5 min at 4 °C. The supernatant was removed, placed in 0.5 mL centrifuge tubes, and stored at -20 °C. Then, 20  $\mu$ L of the lysate sample was separated and analyzed using SDS-PAGE; the proteins were electrotransferred onto nitrocellulose membranes and detected using a chemiluminescent detection system. Beta-actin was used as a loading control. The images were analyzed using the BandScan5.0 program. The ratio of GHR expression to beta-actin expression was analyzed using the integral optical density value (RV) of the band in the same sample. The results are shown as the expression of GHR relative to beta-actin, and the results were measured as, mean  $\pm$  SD.

### Expression of GHR mRNA in tumor tissue was detected by quantitative reverse transcription-polymerase chain reaction

Twenty microliters of the lysate sample was centrifuged

at 5000 rpm for 10 min. Prechilled PBS was used to wash the cells, and total RNA was extracted using the Trizol reagent in a one-step method. For first strand synthesis, 1  $\mu$ g of total RNA was combined with 1  $\mu$ L of 0.5  $\mu$ g/ $\mu$ L oligo primer and 12  $\mu$ L of deionized water. The mixture was then incubated at 70 °C for 5 min. Then, the samples were quenched in a bath of ice water and centrifuged at 5000 rpm for 4 s. Next, 4  $\mu$ L of 5  $\times$  reaction buffer, 1  $\mu$ L of 20 U/ $\mu$ L ribonuclease, and 2  $\mu$ L of 10  $\mu$ mol/ $\mu$ L dNTPs were added, and the mixture was incubated at 37 °C for 5 min. Then, 1  $\mu$ L of 200 U/ $\mu$ L reverse transcriptase was added, and the reaction was incubated at 42 °C for 60 min, followed by a 10 min incubation at 70 °C. After the reaction, the cDNA was incubated at 0 °C and was stored at -20 °C. Real time PCR with the SYBR-Green fluorochrome was used to detect the expression of GHR mRNA. For this reaction, 10  $\mu$ L of cDNA, 2  $\mu$ L of both forward and reverse primers, 10  $\mu$ L of buffer solution, 4  $\mu$ L of ddH<sub>2</sub>O, and 1  $\mu$ L of the ROX fluorochrome were incubated at 95 °C for 10 min, followed by 35 cycles of 94 °C for 10 s, 56 °C for 30 s, and 72 °C for 30 s; a final extension time of 5 min at 72 °C ended the reaction. GAPDH was used as a negative control. The following primers were used in this experiment: GHR forward: GCAGCTATCCTTAGCAGAGCAC; GHR reverse: AAGTCTCTCGCTCAGGTGAACG; GAPDH forward: GGTCTCCTCTGACTTCAACA; and GAPDH reverse: GAGGGTCTCTCTTCTTCT. The levels of GHR mRNA in the transfection group and the control group were determined by quantitative PCR, and the  $\Delta$ CT value of the GHR mRNA was determined between the two groups. It was demonstrated that a higher  $\Delta$ CT value represented a larger inhibition of GHR mRNA.

### Statistical analysis

Data were expressed as the mean  $\pm$  SD. Univariate or multivariate data were analyzed using variance analysis and pairwise comparison *t* test by SPSS 18.0 statistical software package. Statistical significance was considered at  $P \leq 0.05$ .

## RESULTS

### Weight changes in the tumor-bearing mice

At the end of the experiment, all 36 tumor-bearing mice survived from inoculation 2 to 17 d, except for the NS group. After injection, there was a statistically significant difference ( $P < 0.05$ ) in the weight of the mice compared with their weight before injection. The weight of the GH group increased after inoculation with SW480 cells, while the other groups decreased in weight ( $P < 0.05$ ). The weight of the G<sub>2</sub>, FU, and G<sub>2</sub>+FU groups noticeably decreased ( $P < 0.05$ ) compared with the NS group. The weight of the FU and G<sub>2</sub>+FU groups decreased compared with the G<sub>2</sub> group; however, this change was not significant. After the addition of GH, the weight of the G<sub>2</sub>+GH+FU group increased compared with the FU group in the same period ( $P < 0.05$ ; Table 1).

**Table 1** Weight changes of tumor-bearing mice ( $n = 6$ ; mean  $\pm$  SD)

### Changes in tumor volume in the tumor-bearing mice of all groups

By the end of the experiment, the tumor volume of the mice in all groups increased compared to the fifth day after inoculation. The tumor volume of the GH group had the most dramatic increase, followed by the NS group. The tumor volumes of the G<sub>2</sub>, FU, G<sub>2</sub>+FU, and G<sub>2</sub>+GH+FU groups only slightly increased. Compared with the NS group in the same period, the tumor volume of the experimental group obviously decreased, whereas that of the GH group significantly increased ( $P < 0.05$ ). Compared with the G<sub>2</sub> group, the G<sub>2</sub>+FU group had a more pronounced tumor inhibition ( $P < 0.05$ ). There was no obvious difference in the tumor volume of the G<sub>2</sub>+GH+FU group compared with the G<sub>2</sub>, FU, and G<sub>2</sub>+FU groups in the same period (Table 2).

### GHR protein expression in the subcutaneous tumors of tumor-bearing mice in all groups

The expression levels of GHR protein in the tumors of the GH (0.94  $\pm$  0.02) and NS (0.94  $\pm$  0.02) mice were significantly higher than the GHR levels in the G<sub>2</sub> (0.39  $\pm$  0.021), FU (0.40  $\pm$  0.02), G<sub>2</sub>+FU (0.38  $\pm$  0.01) and G<sub>2</sub>+FU+GH (0.39  $\pm$  0.01) mice. However, there was no significant difference between the G<sub>2</sub> group and the FU, G<sub>2</sub>+FU, and G<sub>2</sub>+FU+GH groups ( $P > 0.05$ ).

### GHR mRNA expression in the subcutaneous tumors of tumor-bearing mice

Compared with the NS group and the control group that did not have a plasmid, the  $\Delta$ CT value of the G<sub>2</sub>, FU, G<sub>2</sub>+FU, and G<sub>2</sub>+FU+GH groups significantly increased

( $P < 0.05$ ). In the experimental groups, the inhibition ratios of the FU+G<sub>2</sub> and FU+G<sub>2</sub>+GH groups against GHR mRNA were higher than that of the G<sub>2</sub> group ( $P < 0.05$ ; Table 3).

## DISCUSSION

Colon cancer is one of the most common malignant tumors<sup>[14-16]</sup>. Currently, the treatment for colon cancer is surgery combined with radiotherapy and chemotherapy. However, most patients cannot undergo operation or do not respond to chemotherapeutics, leading to the failure of the therapy. Determining the appropriate tumor target spot related to gene and specific therapy has become a hotspot of research in tumor therapy<sup>[17]</sup>. Due to its action as an anabolic agent and mitogen, GH has a wide range of functions in substance metabolism and body fluid equilibrium, which can accelerate the use of nitrogen and improve the synthesis of liver and muscle proteins. The nutritional effect of GH has already been shown in cachexia<sup>[18]</sup>. Because GH can increase the brittleness of chromosomes, which, in turn, can cause malignant transformation of cells, and can increase tumor growth, GH has been excluded as a therapy option for the treatment of tumors<sup>[19,20]</sup>. It has been demonstrated by many epidemiological researchers that patients who receive long term treatment with growth hormone have an increased risk of colon cancer<sup>[3,21]</sup>, and GHR expression in the colon might relate to the occurrence, development and metastasis of these tumors<sup>[1,22]</sup>. The presence of GHR in the local tissue is a prerequisite for GH to play its role, which means that when determining

**Table 3**  $\Delta$ CT value of growth hormone receptor mRNA expression detected by real-time reverse transcription-polymerase chain reaction in all groups

	NS	LP	Negative	GH	G <sub>2</sub>	FU	FU+G <sub>2</sub>	G <sub>2</sub> +FU+GH
$\Delta$ CT	12.63 $\pm$ 0.14	12.63 $\pm$ 0.43	12.67 $\pm$ 0.21	12.71 $\pm$ 0.39	14.12 $\pm$ 0.10 <sup>1</sup>	15.15 $\pm$ 0.44 <sup>1</sup>	16.46 $\pm$ 0.27 <sup>1,2</sup>	15.37 $\pm$ 0.57 <sup>1,2</sup>

<sup>1</sup>Compared with NS group,  $P < 0.05$ ; <sup>2</sup>Compared with G<sub>2</sub> group,  $P < 0.05$ . NS: Normal saline; G<sub>2</sub>: Recombinant plasmid; GH: Growth hormone; FU: 5-fluorouracil.

whether to use GH as a therapy, it is important to know the expression and distribution of GHR in a specific tumor cell. GHR is highly expressed in colon cancer tissues<sup>[1,2]</sup>, and high GHR expression has been correlated with poor patient prognosis<sup>[23]</sup>.

RNAi refers to complementary double-stranded RNAs (dsRNAs) that bind to specific endogenous mRNAs, resulting in the degradation of those mRNAs and the silencing of gene expression. Aiming at the relevant signal of the auxanodifferentiation of tumor cells for transduction and targeting the interference of the expression of crucial proteins in transduction pathways of cell signaling can inhibit the growth of a tumor specifically and highly efficiently<sup>[24,25]</sup>.

In this research, we constructed plasmids containing siRNAs that targeted the expression of GHR in colon cancer cells, thereby decreasing the expression of GHR in the colon cancer tissues and blocking the GHR-induced signal transduction that promotes tumor cell growth. The results demonstrated that, compared to the control group, the tumor volume and the mRNA and protein expression of GHR in the tumor tissue significantly decreased. Additionally, the combination of GHR silencing and 5-FU treatment had an anti-tumor effect. After the siRNA blocked the expression of GHR in the tumor tissue, the addition of GH could bind to the GHR in the normal tissue. As a result, the weight and nutrition of the nude mice may improve, and GH treatment increases the nude mouse tolerance towards chemotherapy and increases the chemosensitivity of the tumor cells<sup>[9]</sup>. Compared with the other experimental groups, the FU+G<sub>2</sub>+GH group had no significant difference in its reduced tumor volume or decreased expression of GHR protein and mRNA.

Our research showed that the siRNA-containing plasmid influenced the expression of GHR in the colon cancer cells and played an anti-tumor role in the nude mice.

## COMMENTS

### Background

Human growth hormone receptor (GHR) is highly expressed in colon cancer tissues. In addition, less differentiated tumor tissues have higher levels of GHR expression. During tumor development, the expression of GHR increases. Some researchers believe that the expression of GHR in tumor tissue is linked with the vegetative state of the tumor, and GH/GHR plays an important role in the emergence and development of colon cancer. After specific binding between GH and GHR in tumor tissue, the JAK-STAT signal transduction pathway is activated, leading to improved cell growth and proliferation.

### Research frontiers

Signal transduction therapy is a commonly used chemotherapy strategy, and currently, treatment often involves the use of small interfering RNAs (siRNAs) that target different signal transduction pathways. RNAi refers to complemen-

tary double-stranded RNAs that bind endogenous mRNAs, resulting in the specific degradation of that mRNA, which leads to decreased expression of that gene. Aiming at the relevant signal of the auxanodifferentiation of tumor cells and targeting the interference of the expression of crucial proteins in transduction pathways of cell signaling can inhibit the growth of tumor specifically and highly efficiently.

### Innovations and breakthroughs

In this study, siRNA-targeted inhibition of the *GHR* gene was used to investigate GHR's impact on the emergence and development of colon cancer and to determine how human colon cancer cells respond to the suppression of *GHR* gene expression.

### Applications

The results showed that the siRNA-containing plasmid influenced the expression of GHR in the colon cancer cells and played an anti-tumor role in the nude mice.

### Peer review

The manuscript is well designed and had appropriate methodology.

### Abstract

**AIM:** To conduct a meta-analysis comparing laparoscopic total gastrectomy (LTG) with open total gastrectomy (OTG) for the treatment of gastric cancer.

**METHODS:** Major databases such as Medline (PubMed), Embase, Academic Search Premier (EBSCO), Science Citation Index Expanded and the Cochrane Central Register of Controlled Trials (CENTRAL) in The Cochrane Library were searched for studies comparing LTG and OTG from January 1994 to May 2013. Evaluated endpoints were operative, postoperative and on-

cological outcomes. Operative outcomes included operative time and intraoperative blood loss. Postoperative recovery included time to first flatus, time to first oral intake, hospital stay and analgesics use. Postoperative complications comprised morbidity, anastomotic leakage, anastomotic stenosis, ileus, bleeding, abdominal abscess, wound problems and mortality. Oncological outcomes included positive resection margins, number of retrieved lymph nodes, and proximal and distal resection margins. The pooled effect was calculated using either a fixed effects or a random effects model.

**RESULTS:** Fifteen non-randomized comparative studies with 2022 patients were included (LTG - 811, OTG - 1211). Both groups had similar short-term oncological outcomes, analgesic use (WMD -0.09; 95%CI: -2.39-2.20;  $P = 0.94$ ) and mortality (OR = 0.74; 95%CI: 0.24-2.31;  $P = 0.61$ ). However, LTG was associated with a lower intraoperative blood loss (WMD -201.19 mL; 95%CI: -296.50--105.87 mL;  $P < 0.0001$ ) and overall complication rate (OR = 0.73; 95%CI: 0.57-0.92;  $P = 0.009$ ); fewer wound-related complications (OR = 0.39; 95%CI: 0.21-0.72;  $P = 0.002$ ); a quicker recovery of gastrointestinal motility with shorter time to first flatus (WMD -0.82; 95%CI: -1.18--0.45;  $P < 0.0001$ ) and oral intake (WMD -1.30; 95%CI: -1.84--0.75;  $P < 0.00001$ ); and a shorter hospital stay (WMD -3.55; 95%CI: -5.13--1.96;  $P < 0.0001$ ), albeit with a longer operation time (WMD 48.25 min; 95%CI: 31.15-65.35;  $P < 0.00001$ ), as compared with OTG.

**CONCLUSION:** LTG is safe and effective, and may offer some advantages over OTG in the treatment of gastric cancer.

**Key words:** Gastric cancer; Laparoscopic total gastrectomy; Laparoscopic assisted total gastrectomy; Open

total gastrectomy; Meta-analysis

**Core tip:** Currently, surgical resection is the mainstay treatment for gastric cancer. With technical advances and improved instrumentation, laparoscopic total gastrectomy (LTG) is being used increasingly to treat this malignant disease. However, compared with conventional open total gastrectomy (OTG), the safety and technical feasibility of LTG have not been adequately evaluated. This study clarified that, compared with OTG, LTG has similar short-term oncological outcomes, analgesic use and mortality. Furthermore, LTG was associated with lower intraoperative blood loss and overall complication rate, fewer wound-related complications, quicker recovery of gastrointestinal motility and a shorter hospital stay, albeit with a longer operation time.

## INTRODUCTION

Gastric cancer is one of the most common cancers worldwide and is a leading cause of cancer death<sup>[1]</sup>. Despite improvements in diagnosis and systemic therapy, surgery, in the form of gastrectomy with lymph node dissection, still forms the mainstay of treatment<sup>[2]</sup>. Since it was first described in 1994<sup>[3]</sup>, laparoscopic surgery, and more specifically laparoscopic distal gastrectomy, has been used widely in the far East to treat early gastric cancers and is associated with many advantages over open surgery<sup>[4-7]</sup>. On the other hand, laparoscopic total gastrectomy (LTG) with lymph node dissection, which was reported in 1999<sup>[8]</sup>, is practiced less widely and is more challenging to perform<sup>[9]</sup>. The procedure is associated with a high risk of bleeding and a technically demanding anastomosis, all within a narrow operating field<sup>[9,10]</sup>. However, with technical advances and improved instrumentation, LTG is now being used increasingly to treat gastric cancer<sup>[11-14]</sup>.

A number of studies comparing the short-term or long-term outcomes, of LTG vs conventional open total gastrectomy (OTG) for early and advanced gastric carcinoma have shown it to be feasible, oncologically effective and safe in experienced hands<sup>[14-17]</sup>. LTG offers the potential advantage of being less invasive, causing less surgical trauma with less postoperative pain and a quicker recovery<sup>[18,19]</sup>. However, most studies were too small to adequately evaluate the surgical outcomes of LTG. The aim of the current study was to inform future surgical practice by comparing the technical feasibility, effectiveness, and safety of LTG and OTG in the treatment of

early and advanced gastric cancer, through a systematic review and meta-analysis of published comparative studies.

## MATERIALS AND METHODS

### Literature search

A comprehensive literature search in Medline (PubMed), Embase, Academic Search Premier (EBSCO), Science Citation Index Expanded and the Cochrane Central Register of Controlled Trials (CENTRAL) in The Cochrane Library was carried out for relevant studies, between January 1994 and May 2013, comparing OTG and LTG in the treatment of gastric cancer. The following search terms were used: “gastric cancer; laparoscopic total gastrectomy; laparoscopic assisted total gastrectomy; minimally invasive surgery; open total gastrectomy” along with their synonyms or abbreviations. Reference lists of selected articles were also examined to identify relevant studies that were not identified in the database searches. Investigators and experts in the field of laparoscopic surgery were contacted to ensure that all relevant studies were identified. Only comparative clinical trials with full-text descriptions were included. Final inclusion of articles was determined by consensus; when this failed, a third author adjudicated.

### Inclusion criteria

Studies included: (1) English language articles published in peer-reviewed journals; (2) human studies; (3) studies with at least one of the outcomes mentioned; (4) clear documentation of the operative techniques as “open” or “laparoscopic” or “laparoscopic-assisted”; and (5) where multiple studies came from the same institute and/or authors, either the higher quality study or the more recent publication was included in the analysis.

### Exclusion criteria

Excluded studies: (1) abstracts, letters, editorials, expert opinions, case reports, reviews and studies lacking control groups; (2) studies for benign lesions and gastrointestinal stromal tumor (GIST); (3) studies comparing two laparoscopic surgical approaches or comparing laparoscopic and robot-assisted gastrectomy; (4) studies including only subgroup analyses comparing LTG with OTG; and (5) repeated reports between authors, centers, and the patient community.

### Outcomes of interests

Operative outcomes included operation time and intraoperative blood loss. Oncological outcomes included positive resection margins, number of retrieved lymph nodes, and proximal and distal resection margins. Postoperative recovery outcomes included time to first flatus, time to first oral intake, analgesic use and hospital stay. Outcomes for postoperative complications included overall complication rate, anastomotic leakage, anastomotic stenosis, ileus, bleeding, abdominal abscess, wound-related prob-

lems and mortality.

### Data extraction and quality assessment

Two independent observers using standardized forms extracted the data. The recorded data included study characteristics, quality assessment and perioperative outcomes. The quality of the studies was assessed using the modified Newcastle-Ottawa Scale, with changes made to reflect the needs of this study<sup>[20,21]</sup>. The maximum number of stars in the selection, comparability, and outcome categories were 3, 4, and 2, respectively. Studies achieving 6 or more stars were considered high quality<sup>[22]</sup>.

### Statistical analysis

Meta-analysis was performed using Review Manager Version 5.0 software (The Cochrane Collaboration, Oxford, United Kingdom). For continuous variables, treatment effects were expressed as weighted mean difference (WMD) with corresponding 95% confidence interval (CI). For categorical variables, treatment effects were expressed as odds ratio (OR) with corresponding 95%CI. Heterogeneity was evaluated using the  $\chi^2$  test, and a  $P$  value  $< 0.1$  was considered significant;  $I^2$  values were used for the evaluation of statistical heterogeneity<sup>[23]</sup>. A fixed-effects model was initially calculated for all outcomes<sup>[24]</sup>, but if the test rejected the assumption of homogeneity of the studies, then a random-effects analysis was performed<sup>[25]</sup>. Sensitivity analyses were performed by removing individual studies from the data set and analyzing the effect on the overall results, to identify sources of significant heterogeneity. Subgroup analyses were also undertaken by including only high quality studies to present cumulative evidence. Funnel plots based on the operation time were constructed to evaluate potential publication bias<sup>[26]</sup>.

## RESULTS

### Description of trials included in the meta-analysis

The search strategy generated 91 relevant clinical studies, among which 19 full text articles<sup>[9,10,14-18,27-38]</sup> were identified for further investigation. Of these, four studies<sup>[18,31,35,36]</sup> were excluded for various reasons: 1 study<sup>[36]</sup>, based on an administrative database, was used to assess hospital practice performance with regard to the quantity of medical care items and diet provided during hospitalization; another study<sup>[35]</sup> only compared LTG with OTG in a subgroup analysis; and two studies were repeated reports<sup>[18,31]</sup>. Finally, 15 studies<sup>[9,10,14-17,27-30,32-34,37,38]</sup> were identified for inclusion, of which two were prospective non-randomized comparative studies<sup>[14,28]</sup>, the rest being retrospective comparative studies. Figure 1 shows the study selection process in our meta-analysis.

### Study and patient characteristics

Two thousand and twenty-two patients, 811 patients from the LTG group and 1211 patients from the OTG group, were included in the study. Eleven stud-

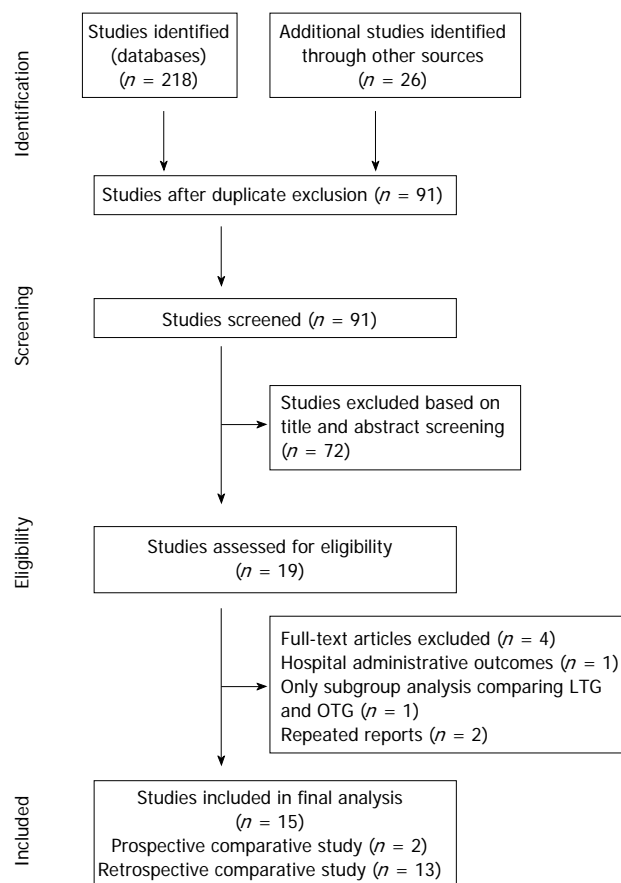

Figure 1 Flow diagram outlining the study selection process according to PRISMA guidelines. OTG: Open total gastrectomy; LTG: Laparoscopic total gastrectomy.

ies<sup>[9,10,14,16,17,28,29,32,34,37,38]</sup> included patients with both early and advanced gastric cancer, while three studies<sup>[15,30,33]</sup> only included patients with early gastric cancer; one study<sup>[27]</sup> only included patients with advanced gastric cancer. In seven studies<sup>[14,17,27,30,32,33,37]</sup>, D2 lymph node dissection was exclusively performed, while D1+ $\beta$  was completed in three studies<sup>[9,15,28]</sup>. The remaining studies<sup>[10,16,29,34,38]</sup> reported D1+ $\alpha/\beta$  and D2 dissections. All the studies were conducted in Asia and Europe, and were published between 2009 and 2013. The sample size ranged from 19 to 448 patients. From the nine studies<sup>[9,15,17,27,28,30,32,37,38]</sup> that reported data on conversion to an open procedure; LTG was converted to an open procedure in five patients in two studies<sup>[17,37]</sup>. The study characteristics (Table 1), quality assessment scoring (Table 2), perioperative outcomes of the included studies (Table 3) and the results of the meta-analysis (Table 4) have been summarized appropriately.

### Operative outcomes

“Operation time” was reported in all studies. The analysis showed that the LTG group had a significantly longer operation time compared with the OTG group (WMD 48.25 min, 95%CI: 31.15-65.35,  $P < 0.00001$ ), albeit with a significant heterogeneity ( $I^2 = 93\%$ ). Data from 12 studies<sup>[9,14-17,27-29,31,33,37,38]</sup> were pooled together to obtain the

mean intraoperative blood loss in the two groups. LTG was associated with a significantly lower intraoperative blood loss compared with OTG (WMD -201.19 mL, 95%CI: -296.50--105.87 mL,  $P < 0.0001$ ), with a significant heterogeneity ( $I^2 = 98\%$ ). Forest plots for operative outcomes are shown in Figure 2.

### Postoperative recovery

Twelve studies<sup>[9,16,17,27-30,32-34,37,38]</sup> reported the time to first flatus and eight studies<sup>[9,16,17,27,29,32,33,37]</sup> reported data on oral intake post-surgery. Our analyses showed that patients undergoing LTG had a quicker recovery of intestinal motility compared with the OTG group. The time to first flatus (WMD -0.82, 95%CI: -1.18--0.45,  $P < 0.0001$ ) and the time to first oral intake (WMD -1.30, 95%CI: -1.84--0.75,  $P < 0.0001$ ) were significantly shorter in the LTG group compared with the OTG group. Analysis of the 13 studies<sup>[9,10,15-17,28-30,32-34,37,38]</sup> that reported the duration of hospital stay indicated that LTG was associated with a significantly shorter postoperative hospital stay compared with OTG (WMD -3.55, 95%CI: -5.13--1.96,  $P < 0.0001$ ). However, there was no statistically significant difference between the two groups in the use of analgesics post-surgery (WMD -0.09, 95%CI: -2.39-2.20,  $P = 0.94$ ). Forest plots for postoperative recovery outcomes are shown in Figure 3.

### Postoperative complications

A pooled analysis of 14 studies<sup>[10,14-17,27-30,32-34,37,38]</sup> indicated that the overall complication rate was significantly lower in the LTG group compared with the OTG group (OR = 0.73, 95%CI: 0.57-0.92,  $P = 0.009$ ). Also, the analysis of 13 studies<sup>[10,15-17,27-30,32-34,37,38]</sup> suggested that patients in the LTG group had significantly fewer wound-related complications compared with the OTG group (OR = 0.39, 95%CI: 0.21-0.72,  $P = 0.002$ ). However, there were no significant differences in the rate of anastomotic leak (OR = 1.6, 95%CI: 0.88-2.91,  $P = 0.12$ ), anastomotic stenosis (OR = 1.22, 95%CI: 0.68-2.21,  $P = 0.50$ ), ileus (OR 1.26, 95%CI: 0.69-2.30;  $P = 0.46$ ), bleeding (OR = 1.42, 95%CI: 0.70-2.87;  $P = 0.33$ ), abdominal abscess (OR = 0.53, 95%CI: 0.28-1.03,  $P = 0.06$ ) or mortality (OR = 0.74, 95%CI: 0.24-2.31,  $P = 0.61$ ) between the two groups. Forest plots for postoperative outcomes are shown in Figure 4.

### Oncological outcomes

All included studies reported data on the number of lymph nodes retrieved; there was no significant difference between the two groups (WMD -2.49, 95%CI: -5.18-0.21,  $P = 0.07$ ), albeit with a significant heterogeneity in the result ( $I^2 = 74\%$ ). Five studies<sup>[14,17,27,28,32]</sup> reported

ported data on long-term survival following the two procedures<sup>[10,15,16,27,28,37,38]</sup>. Lee *et al*<sup>[37]</sup> reported no significant difference in the disease-specific survival rate between the LTG and OTG groups at a median follow-up of 50 months; there were also no significant differences reported in the disease-free survival rate (100% vs 90.9%,  $P = 0.5$ ) and the cumulative survival rate (91.5% vs 95.2%,  $P = 0.618$ ) in patients with stage I cancer (TNM) between the LTG and OTG groups. Eom *et al*<sup>[10]</sup> reported no significant difference in the disease-free survival rates between the LTG and OTG groups, after adjustment for five variables (age, tumor size, Lauren classification, depth of invasion and lymph node metastasis). Mochiki *et al*<sup>[15]</sup> reported no significant difference in the cumulative 5-year or disease-specific survival rates between the LTG and OTG groups, while Siani *et al*<sup>[38]</sup> reported 5-year overall and disease free survival rates of 55.7% and 54.2% in the LTG group and 52.9% and 52.1% in the OTG group respectively, with no statistically significant differences. However, as the duration of follow-up varied between studies, it was difficult to compare the survival rates. Forest plots for oncological outcomes are shown in Figure 5.

### Sensitivity and subgroup analysis

Sensitivity analyses were performed by removing individual studies from the data and analyzing the effect on the overall results to identify sources of significant heterogeneity. These exclusions did not alter the results obtained from the cumulative analyses. Subgroup analyses were undertaken for all outcome measures by including only high quality studies. Analysis of the high-quality studies showed that there were no significant differences for any of the outcomes. These are shown in Figure 6.

### Publication bias

The funnel plot based on the operation time is shown in

Figure 7. There was no broad evidence of publication bias, as none of the studies lay outside the 95%CI limits.

## DISCUSSION

Laparoscopic surgery is being used increasingly to treat gastric cancer, and has been shown to have many advantages over open surgery. However, LTG is less widely practiced compared with laparoscopic distal gastrectomy because of the technical challenges it poses and the absence of compelling evidence to substantiate its use<sup>[9]</sup>. Technical advances, better instrumentation and increasing surgical experience in the procedure are aiding its increasing application to treat of early and advanced gastric cancer. The aim of the current study was to inform future surgical practice by comparing the technical feasibility, effectiveness, and safety of LTG with OTG in the treatment of early and advanced gastric cancer, using a systematic review and meta-analysis of published comparative studies.

Our analyses indicated that the operation time was significantly longer in the LTG group than in the OTG group. This may be because LTG is more technically demanding than OTG and may result from the learning curve associated with the procedure<sup>[9,10,35]</sup>. While adequate training in laparoscopic techniques is necessary, it was concluded that an experienced laparoscopic surgeon would not require any more time to perform LTG compared with OTG<sup>[15]</sup>. In one study, the operation time for LTG in the later period was significantly shorter than in the early period; this related to the experience gained by the surgeon over the period of the study<sup>[34]</sup>. Further development in surgical techniques, especially for anastomosis and new instruments, may further decrease the operation time for LTG<sup>[10]</sup>. In our study, LTG was associated with a significantly lower intraoperative blood

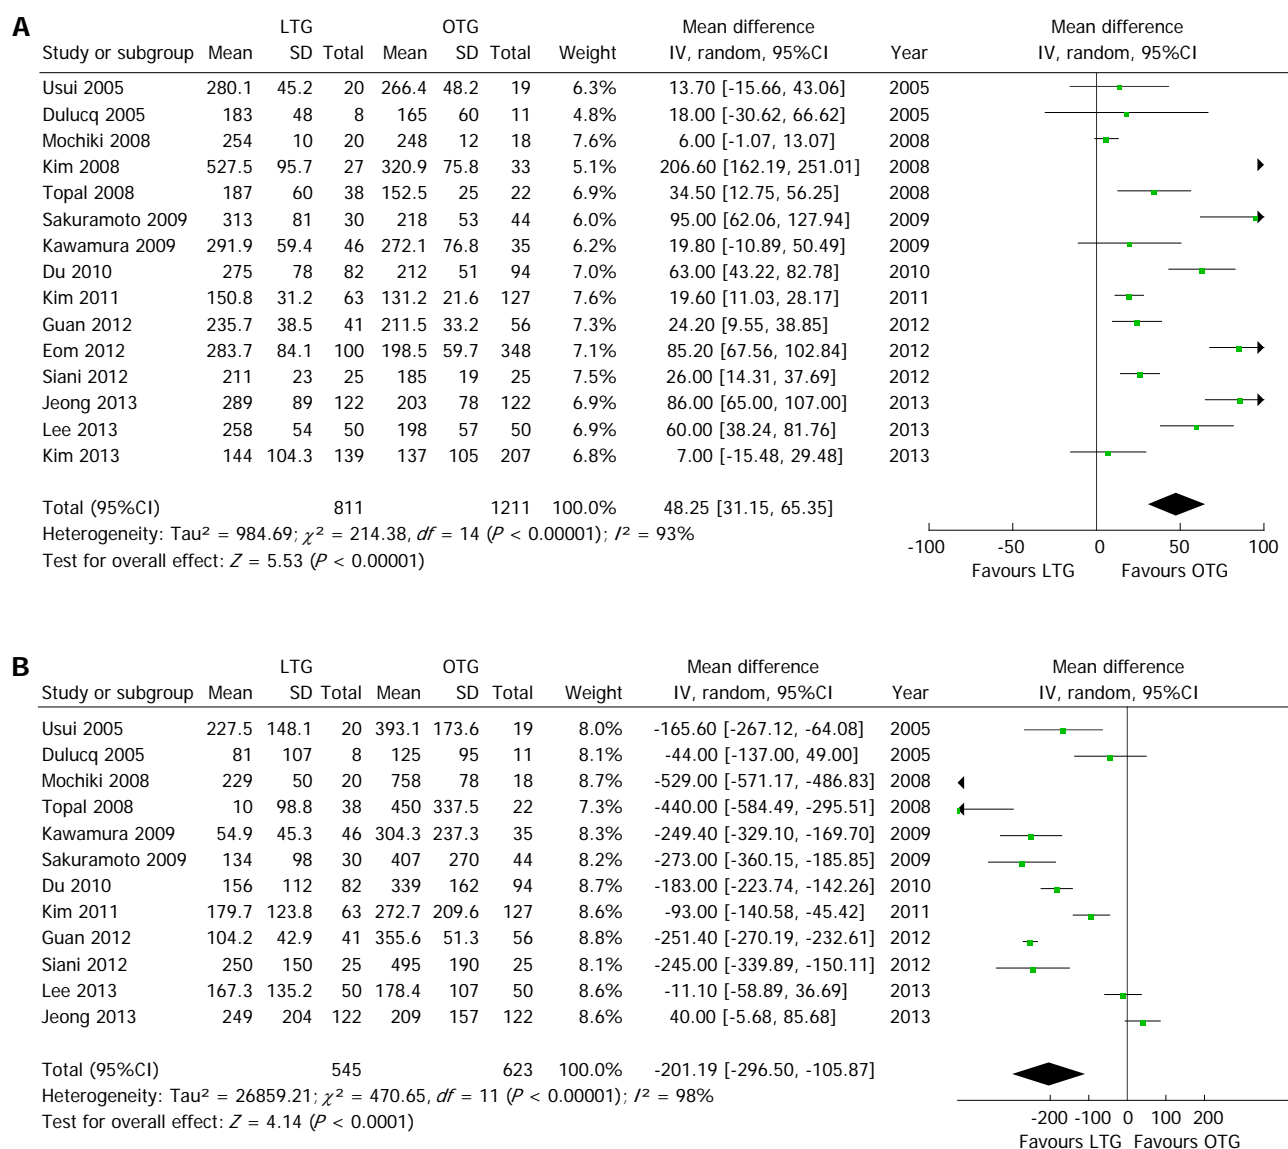

Figure 2 Forest plots illustrating results of operative outcomes in the form of a meta-analysis comparing laparoscopic total gastrectomy vs open total gastrectomy for gastric cancer. Pooled weighted mean difference (WMD) with 95%CI was calculated using the random effects model. A: Operation time; B: Intraoperative blood loss. LTG: Laparoscopic total gastrectomy; OTG: Open total gastrectomy.

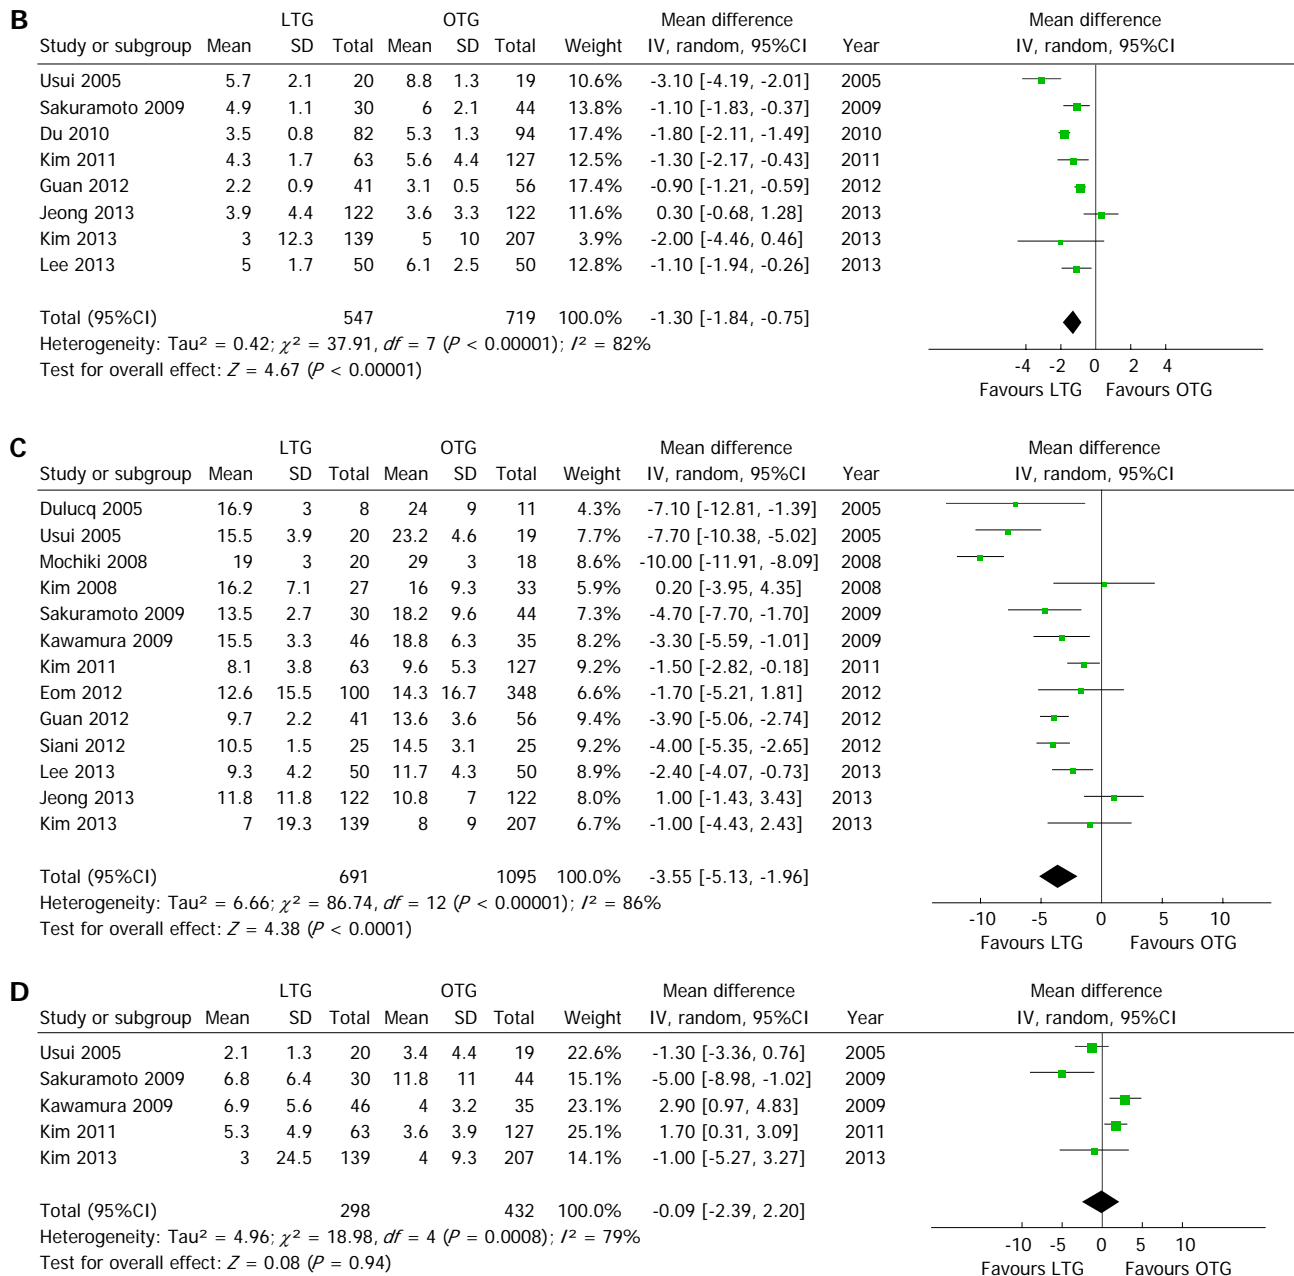

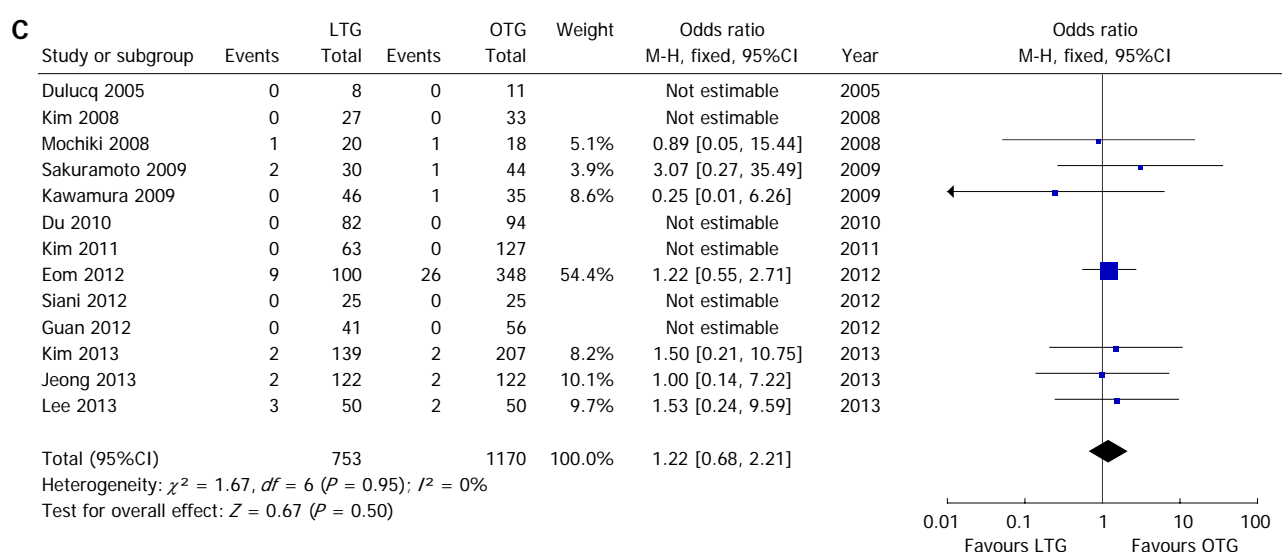

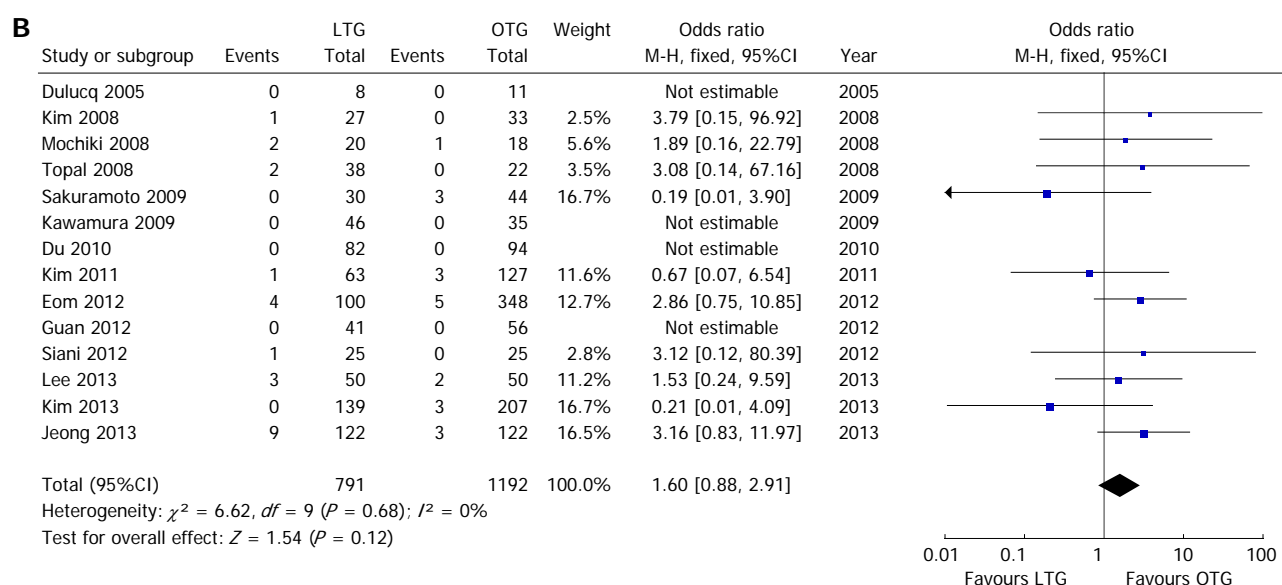

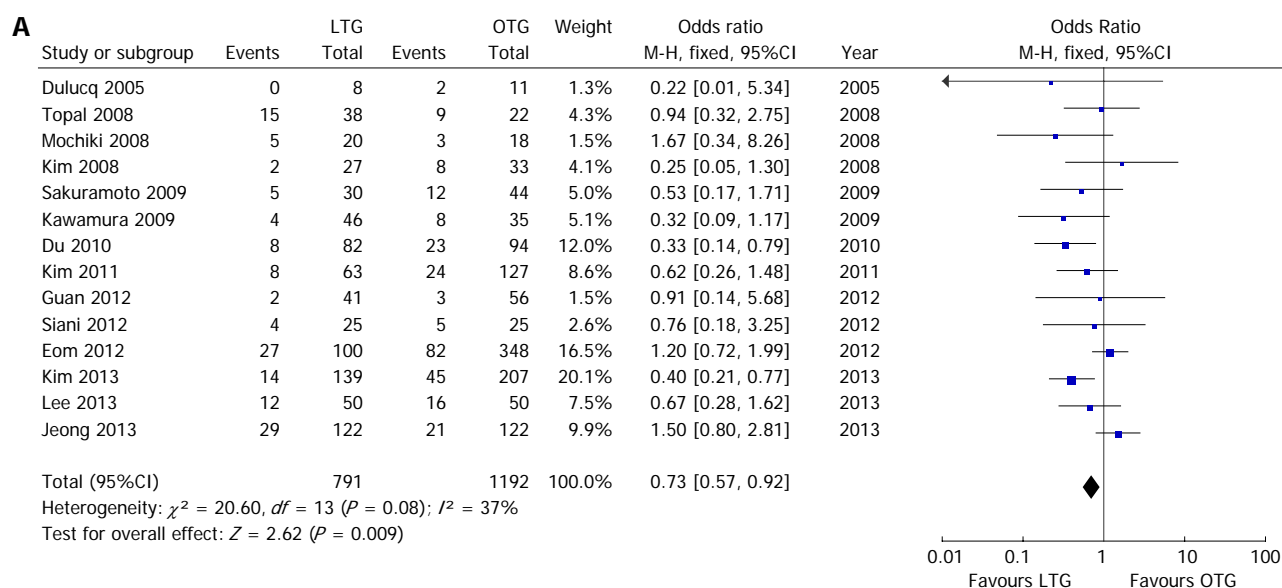

Figure 3 Forest plots illustrating results of postoperative recovery in the form of a meta-analysis comparing laparoscopic total gastrectomy vs open total gastrectomy for gastric cancer. Pooled weighted mean difference (WMD) with 95%CI was calculated using the random-effects model. A: Time to first flatus; B Time to first oral intake; C: Hospital stay; D: Analgesic use. LTG: Laparoscopic total gastrectomy; OTG: Open total gastrectomy.

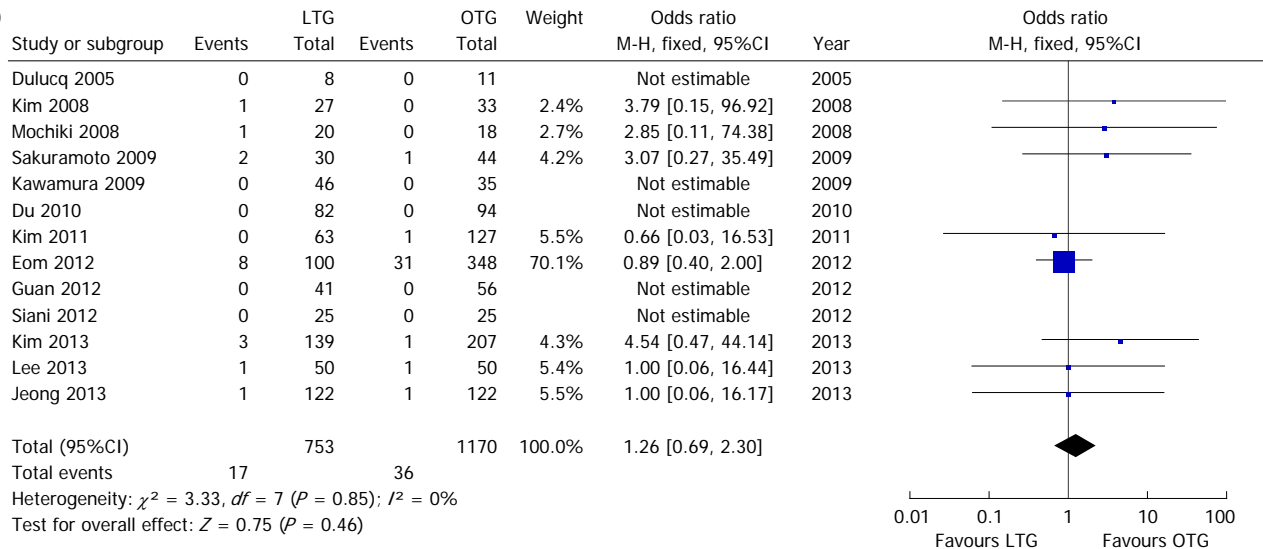

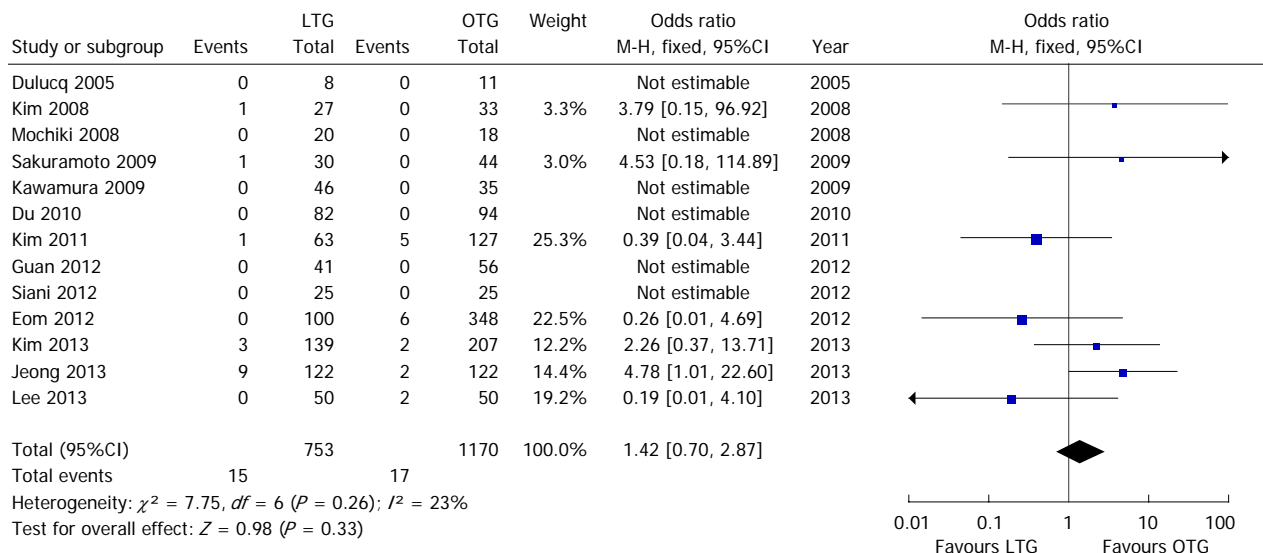

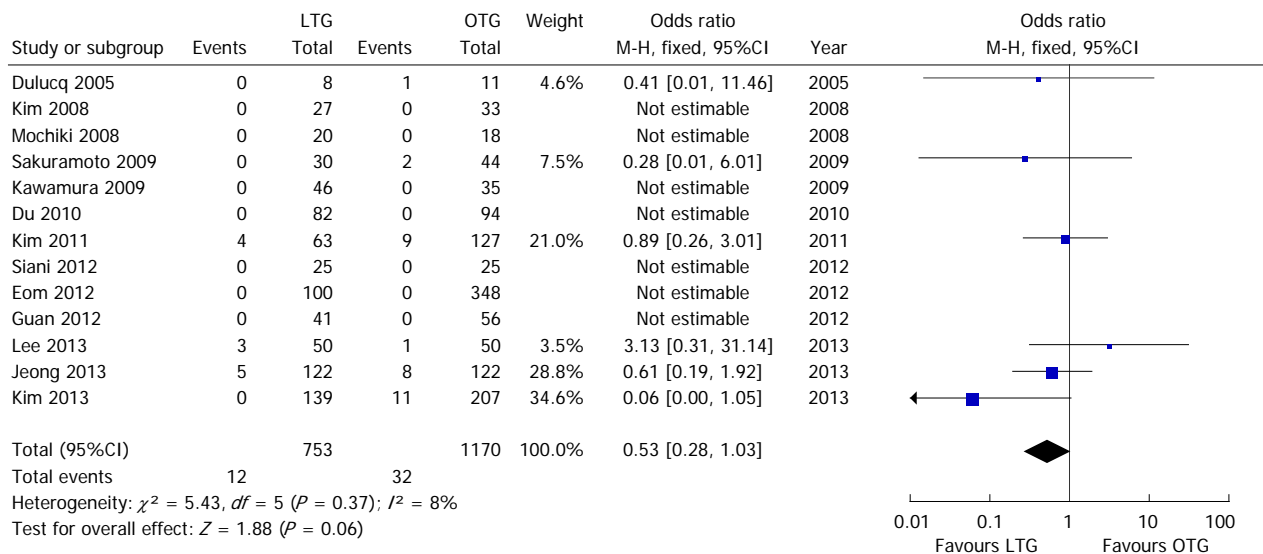

loss, which depends considerably on a surgeon's skill and experience<sup>[34]</sup>.

The times to first flatus and to first oral intake were significantly shorter in the LTG group compared with the OTG group, which suggests that intestinal motility recovered more quickly in the LTG group. Also, the period of hospital stay was significantly shorter in the LTG group. LTG is a less invasive procedure and is associated with less surgical trauma. This results in a reduced inflammatory response and better glucose tolerance, which may aid a quicker recovery<sup>[19,30]</sup>. Pain following LTG subsides earlier when compared to OTG<sup>[18]</sup>. However, our study showed no significant difference in the postoperative use of analgesics between the two groups.

A quicker recovery and shorter hospital stay have important cost and quality of life implications for the wider use of LTG in the treatment of gastric cancer.

Total gastrectomy has often been described as high-risk<sup>[39,40]</sup> and LTG is technically demanding<sup>[9,10]</sup>. Common postoperative complications associated with LTG include anastomotic leak, anastomotic stenosis and luminal bleeding<sup>[37]</sup>. The anastomotic complications could be caused by excessive traction applied on the esophagus and jejunal limb mobilization<sup>[10]</sup> or may reflect the learning curve associated with LTG<sup>[37]</sup>. In our study, the overall complication rate was significantly lower in the LTG group compared with the OTG group. Also, there were significantly fewer wound-related complications in the LTG

Pooled weighted mean difference (WMD) or odds ratio (OR) with 95%CI were calculated using the fixed or random-effects model. A: Operation time; B: Intraoperative blood loss; C: Time to first flatus; D: Time to first oral intake; E: Hospital stay; F: Analgesics use; G: Postoperative complications; H: No. of resected lymph nodes; I: Proximal resection margin; J: Distal resection margin; K: Positive resection margins; L: Anastomotic leakage; M: Anastomotic Stenosis; N: Ileus; O: Bleeding; P: Abdominal abscess; Q: Wound-related complications; R: Mortality. LTG: Laparoscopic total gastrectomy; OTG: Open total gastrectomy.

group. However, there were no significant differences in rate of anastomotic leak, anastomotic stenosis, bleeding, abdominal abscess and postoperative mortality in the two groups. These results indicate that LTG is a safe procedure.

While lymph node metastasis is associated with a poor prognosis in gastric cancer, the extent of lymph node dissection required is open to debate. Many surgeons believe that D1+ $\alpha$  or  $\beta$  dissection is adequate for early gastric cancer, and D2 dissection is optimal for advanced gastric cancer, although this remains controversial<sup>[41,42]</sup>. Surgical removal of at least 15 lymph nodes is advocated in gastric cancer<sup>[43]</sup>. The mean number of harvested lymph nodes in all included studies was more than 15. The surgical approach did not appear to influence the lymph node yield; however, LTG with extended lymph node dissection may require further refinement of the operative technique and improved instrumentation, and should be performed with caution by surgeons with adequate experience in laparoscopic gastrectomy<sup>[29]</sup>. Another major concern of laparoscopic resection for gastric cancer is obtaining clear

proximal esophageal and distal duodenal margins<sup>[17]</sup>. Five included studies reported tumor margins, but only one study reported positive resection margins in one patient each in LTG and OTG, respectively; there was no statistically significant difference between the two groups. Our analyses also showed that there was no significant difference in the lengths of the proximal and distal resection margins between the two groups. Seven studies reported data on long-term survival following the two procedures. However, as the duration of follow-up varied between studies, it was difficult to compare them.

Our study has some limitations. Firstly, all the studies included were non-randomized, because of a lack of randomized controlled trials. Secondly, there was significant heterogeneity in the studies with respect to the extent of lymph node dissection, tumor staging and surgical anastomosis techniques. Also, there were differences in the number of patients in the two groups and between studies.

In conclusion, compared with OTG, LTG with regional lymph node dissection for early and advanced gas-

Figure 7 Funnel plot of operation time of all included studies.

tric cancer is safe and effective; with comparable short-term oncological outcomes; lower intraoperative blood loss and overall complication rates; fewer wound-related complications; quicker recovery of gastrointestinal motility and a shorter hospital stay, albeit with a longer operating time. However, there is a need to develop well-designed, adequately powered, prospective, multicenter, randomized controlled trials, investigating LTG with adequate long-term follow-up, before recommending its wider use in surgical practice.

## COMMENTS

### Background

Since laparoscopic total gastrectomy (LTG) was first reported in 1999, it has been used increasingly to treat gastric cancer as result of technical advances and improved instrumentation. However, compared with conventional open total gastrectomy (OTG), the safety and efficacy of LTG is not known.

### Research frontiers

To conduct a meta-analysis comparing the safety and effectiveness of LTG with OTG in patients with gastric cancer; the available perioperative and oncological outcomes were included in this study.

### Innovations and breakthroughs

Based on this meta-analysis, when compared with OTG, LTG for early and advanced gastric cancer is safe and effective; with comparable short-term oncological outcomes; lower intraoperative blood loss and overall complication rates; fewer wound-related complications; quicker recovery of gastrointestinal motility and a shorter hospital stay, albeit with a longer operating time.

### Applications

LTG is safe, effective and offers some advantages over OTG in the treatment of early and advanced gastric cancer. However, well-designed prospective multicenter, randomized controlled trials investigating the advantage of LTG with adequate long-term follow-up need to be performed before recommending its wider use in surgical practice.

### Peer review

In the future, LTG will be rapidly developed in the field of abdominal minimally invasive surgery. This is a well-written study that clarifies some advantages of LTG in the treatment of patients with early and advanced gastric cancer. This study may be interesting for gastrointestinal surgeons worldwide.

### Abstract

**AIM:** To investigate the clinical usefulness of interferon-gamma release assays (IGRAs) in the differential diagnosis of intestinal tuberculosis (ITB) from Crohn's disease (CD) by meta-analysis.

**METHODS:** A systematic search of English language studies was performed. We searched the following databases: Medline, Embase, Web of Science and the Cochrane Library. The Standards for Reporting Diagnostic Accuracy initiative and Quality Assessment for Studies of Diagnostic Accuracy tool were used to assess the methodological quality of the studies. Sensitivity, specificity, and other measures of the accuracy of IGRAs in the differential diagnosis of ITB from CD were pooled

and analyzed using random-effects models. Receiver operating characteristic curves were applied to summarize overall test performance. Two reviewers independently judged study eligibility while screening the citations.

**RESULTS:** Five studies met the inclusion criteria. The average inter-rater agreement between the two reviewers for items in the quality checklist was 0.95. Analysis of IGRAs for the differential diagnosis of ITB from CD produced summary estimates as follows: sensitivity, 0.74 (95%CI: 0.68-0.80); specificity, 0.87 (95%CI: 0.82-0.90); positive likelihood ratio, 5.98 (95%CI: 3.79-9.43); negative likelihood ratio, 0.28 (95%CI: 0.18-0.43); and diagnostic odds ratio, 26.21 (95%CI: 14.15-48.57). The area under the curve was 0.92. The evaluation of publication bias was not significant ( $P = 0.235$ ).

**CONCLUSION:** Although IGRAs are not sensitive enough, they provide good specificity for the accurate diagnosis of ITB, which may be helpful in the differential diagnosis of ITB from CD.

© 2013 Baishideng Publishing Group Co., Limited. All rights reserved.

**Key words:** Intestinal tuberculosis; Crohn's disease; Interferon-gamma; Meta-analysis

**Core tip:** The misdiagnosis rate between Crohn's disease (CD) and intestinal tuberculosis (ITB) is 50%-70%. Interferon-gamma release assays (IGRAs) have been used mainly to identify latent tuberculosis infection in patients in several areas and countries. However, the clinical usefulness of IGRAs in the differential diagnosis of ITB from CD is unknown. This is the first study to investigate the clinical usefulness of IGRAs in the differential diagnosis of ITB from CD by meta-analysis. IGRAs provided good specificity for ITB,

and should be helpful in the differential diagnosis of ITB from CD.

## INTRODUCTION

Tuberculosis (TB) is a major worldwide cause of morbidity and mortality<sup>[1,2]</sup>. The geography of TB is changing and expanding due to immigration, human immune deficiency virus, immune suppressants, and the development of multidrug-resistant strains of TB<sup>[1-5]</sup>, especially in privileged areas of the world. Intestinal tuberculosis (ITB) is an important extra-pulmonary TB that primarily affects the ileum and colon, causing gastrointestinal symptoms such as diarrhea or abdominal pain. Along with the increased incidence of TB, the incidence of ITB has also increased. Recently, with the emergence of Crohn's disease (CD) in Asian countries<sup>[3,6,7]</sup>, differentiating between ITB and CD is more important than ever. Unfortunately, it is difficult to differentiate ITB from CD due to similar symptoms, and pathologic, radiologic, and endoscopic findings<sup>[4,8]</sup>.

ITB and CD are both chronic granulomatous inflammatory disorders of the intestine<sup>[9,10]</sup>, but have a different pathophysiology, clinical course, and treatment options. ITB could be completely cured if diagnosed early and treated appropriately. CD is not curable and recurs easily. Although several endoscopic and histologic parameters to differentiate these two diseases have been suggested<sup>[11,12]</sup>, a large number of ITB cases are diagnosed by assessing the outcomes of empirical anti-tuberculosis therapy. Moreover, in South Korea, 42%-45% of patients with CD received empirical anti-tuberculosis therapy before they were finally diagnosed with CD<sup>[13,14]</sup>.

A delayed diagnosis of ITB and CD may result in a delay in initiating effective therapy, resulting in a negative economic impact and increased morbidity and mortality. Furthermore, the use of steroids, immune suppressants and biological agents after a presumptive diagnosis of CD, can result in severe and sometimes fatal complications such as systemic dissemination of TB. In recent years, T-cell based interferon-gamma (IFN- $\gamma$ ) release assays (IGRAs) have increasingly been used to replace the traditional tuberculin skin test (TST) as a diagnostic tool for TB. IGRAs have been shown to have superior sensitivity and specificity<sup>[15,16]</sup>. There are two commercially available methods for IGRAs: the QuantiFERON-TB Gold In-Tube (QFT-G-IT) method and the T-SPOT-TB method. QFT-G-IT uses an enzyme-linked immunosorbent assay to measure antigen-specific production

of IFN- $\gamma$  by circulating T-cells in whole blood being challenged with *Mycobacterium tuberculosis* (MTB)-specific antigens. T-SPOT-TB test is a blood IFN- $\gamma$  assay measuring the number of activated T-cells by identifying IFN- $\gamma$  release when stimulated by MTB-specific antigens, including early secretory antigenic target 6 (ESAT-6) and culture filtrate protein 10 (CFP-10). However, whether IGRAs contribute to the differential diagnosis of ITB from CD remains controversial. In the present study, we systematically analyzed and assessed the clinical utility of IGRAs in distinguishing ITB from CD *via* meta-analysis techniques.

## MATERIALS AND METHODS

### Search strategy and study selection

We searched the following databases: Medline (1980-2013), Embase (1980-2013), Web of Science (1990-2013) and the Cochrane Library. An updated search was carried out in March 2013. The following search terms were used: "intestinal tuberculosis", "Crohn's disease", "interferon-gamma/IFN- $\gamma$ ", "sensitivity", "specificity" and "accuracy". We contacted experts in the specialty and searched the reference lists of primary and review articles. Although no language restrictions were imposed initially, our resources only permitted the review of articles published in the English language for the full text review and final analysis. Conference abstracts and letters were excluded due to unavailable data.

A study was included if it provided both sensitivity (true-positive rate) and specificity (false-positive rate) of IGRAs for the differential diagnosis of ITB from CD, or provided IGRAs values in a dot-plot form which allowed the results to be extracted for individual study subjects. Patients of any age diagnosed with ITB underwent smear or culture of MTB and/or histologic observation of ileum and/or colon tissue, as well as clinical diagnosis, such as response to anti-TB therapy. All patients were diagnosed with CD according to the Japanese diagnostic criteria<sup>[17]</sup> or the World Health Organization diagnostic criteria<sup>[18]</sup> based on clinical, endoscopic, radiological and pathological features. In addition, we selected studies which included at least 10 ITB/CD specimens eligible for inclusion in order to reduce selection bias due to a small number of participants. Two reviewers (Chen W and Fan JH) independently judged study eligibility while screening the citations. Disagreements were resolved by consensus.

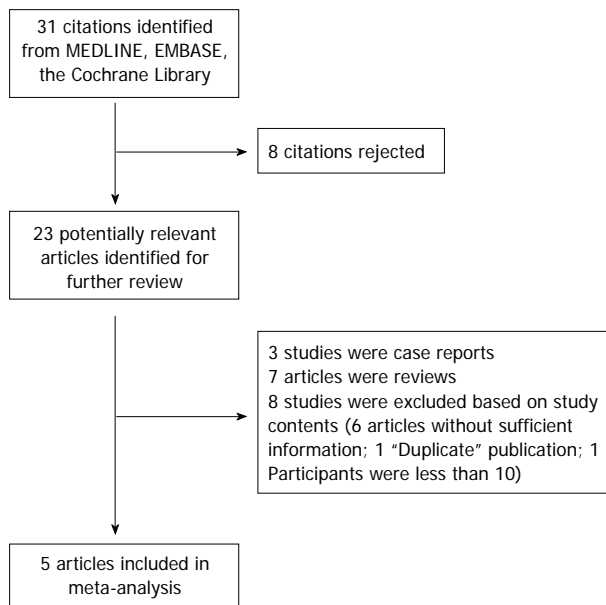

### Data extraction and quality assessment

Two reviewers (Chen W and Fan JH) checked and extracted data independently. The reviewers were blinded to publication details, and disagreements were resolved by consensus. Data retrieved from the reports included participant characteristics, assay methods, sensitivity and specificity data, cutoff values, year of publication, and methodological quality. The value of IGRAs provided in dot plots were measured by placing scalar grids over

**Table 1** Summary of the included studies

Study	Country/Area	Patients (n)	Assay method	Cutoff	Test results				Quality score	
					TP	FP	FN	TN	STARD	QUADAS
Lee <i>et al</i> <sup>[28]</sup>	South Korea	60	T-SPOT-TB	-	12	8	0	40	16	11
Lei <i>et al</i> <sup>[29]</sup>	China	191	T-SPOT-TB	-	36	5	6	62	18	13
Kim <i>et al</i> <sup>[30]</sup>	South Korea	128	QFT-G-IT	0.35 IU/mL	43	6	21	58	17	12
Li <i>et al</i> <sup>[31]</sup>	China	84	T-SPOT-TB	-	16	16	3	49	17	12

T-SPOT-TB: An enzyme-linked immunosorbent spot assay; QFT-G-IT: Quanti-FERON-TB Gold In-Tube; TP: True-positive; FP: False-positive; FN: False-negative; TN: True-negative; STARD: Standards for reporting diagnostic accuracy; QUADAS: Quality assessment for studies of diagnostic accuracy.

**Figure 1** Flowchart of study selection.

the plots, and analyzed using a receiver operating characteristic (ROC) curve for each study (SPSS; Chicago, IL, United States). A summary of each study, including the numbers of true-positive, false-positive, false-negative and true-negative results, is shown in Table 1.

We assessed the methodological quality of studies using guidelines established by the standards for reporting diagnostic accuracy (STARD)<sup>[19]</sup> initiative and the quality assessment for studies of diagnostic accuracy (QUADAS) tool<sup>[20]</sup>. In addition, the following study design characteristics were retrieved: (1) cross-sectional design (*vs* case-control design); (2) consecutive or random sampling of patients; (3) blind (single or double) interpretation of determination and reference standard results; and (4) prospective data collection. If primary studies did not show data that met the above criteria, we requested the data from the authors. The “unknown” items were treated as “no” if we did not receive a response from the authors.

### Statistical analysis

We used standard methods recommended for meta-analyses of diagnostic test evaluations<sup>[21]</sup>. Analyses were performed using two professional statistical software

programs (STATA, version 11; Stata Corporation, College Station, TX, United States and Meta-DiSc for Windows; XI Cochrane Colloquium; Barcelona, Spain). The following measures of test accuracy were analyzed for each study: sensitivity, specificity, positive likelihood ratio (PLR), negative likelihood ratio (NLR), positive predictive value (PPV), negative predictive value (NPV) and diagnostic odds ratio (DOR).

The analysis was based on a summary ROC (SROC) curve<sup>[21]</sup>. Sensitivity and specificity as a single test threshold identified for each study were used to plot an SROC curve<sup>[22]</sup>. A random-effects model was adopted to calculate the average sensitivity, specificity, and other measures across studies<sup>[23,24]</sup>.

The term heterogeneity refers to the degree of variability in results across studies, which was used in relation to meta-analyses. We detected statistically significant heterogeneity with the  $\chi^2$  test. To assess the effects of STARD and QUADAS scores on the diagnostic ability of IGRAs, we included them as covariates in the univariate meta-regression analysis (inverse variance weighted). We also analyzed the effects of other covariates on DOR, such as cross-sectional design, consecutive or random sampling of patients, single or double interpretation of determination, reference standard results, and prospective data collection. The relative DOR (RDOR) was calculated according to standard methods to analyze the change in diagnostic precision in the study per unit increase in the covariate<sup>[25,26]</sup>. Since publication bias is of concern for meta-analyses of diagnostic studies, we tested for the potential presence of this bias with funnel plots and the Egger test<sup>[27]</sup>.

## RESULTS

### Selection and summary of studies

Five out of 31 publications reporting IFN- $\gamma$  for the differential diagnosis of ITB from CD were considered to be eligible for inclusion in the analysis<sup>[28-32]</sup>. Of these 31 publications, 8 citations were rejected, 3 studies were case reports, 7 papers were reviews, and 8 studies were excluded based on study contents (Figure 1). A total of 5 studies including 616 patients were available for analysis, and the clinical characteristics of these studies, along with STARD and QUADAS scores, are outlined in Table 1.

**Table 2** Characteristics of the included studies

Ref.	ITB/CD patients (n)	Reference standard	Cross-sectional design	Consecutive or random	Blinded design	Prospective
Lee <i>et al</i> <sup>[28]</sup>	12/44	Bac/His or Clin	Unknown	Yes	Unknown	Yes
Lei <i>et al</i> <sup>[29]</sup>	88/103	Bac/His	Unknown	Yes	No	Yes
Kim <i>et al</i> <sup>[30]</sup>	64/64	Bac/His	No	Yes	No	Yes
Li <i>et al</i> <sup>[31]</sup>	19/65	Bac/His or Clin	Yes	Yes	No	Yes
Kim <i>et al</i> <sup>[32]</sup>	75/72	Bac/His or Clin	No	Yes	No	Yes

ITB: Intestinal tuberculosis; CD: Crohn's disease; Bac: Bacteriology; His: Histology; Clin: Clinical course.

**Figure 2** Forest plot of estimates of sensitivity and specificity for interferon-gamma release assays in the differential diagnosis of intestinal tuberculosis from Crohn's disease. Forest plot shows sensitivity and specificity of interferon-gamma release assays for intestinal tuberculosis diagnosis. The point estimates of sensitivity and specificity from each study are shown as solid circles. Error bars indicated 95%CI. Numbers indicate the studies included in the meta-analysis, as cited in the reference list. Pooled estimates for interferon-gamma release assays were as follows: sensitivity, 0.74 (95%CI: 0.68-0.80) and specificity, 0.87 (95%CI: 0.82-0.90).

### Quality of reporting and study characteristics

The average inter-rater agreement between the two reviewers for items in the quality checklist was 0.95. All studies were collected from consecutive patients. The average sample size was 112 (range, 60-191) in the included studies. All studies reported that the study design was prospective (Table 2). None of the studies reported blinded interpretation of the IGRAs independent of the reference standard.

### Diagnostic accuracy

The sensitivity and specificity of IGRAs in the 5 studies for the differential diagnosis of ITB from CD are shown in the forest plot (Figure 2). Sensitivity of IGRAs for ITB diagnosis ranged from 0.54 to 1.00 (mean, 0.74; 95%CI: 0.68-0.80), while specificity ranged from 0.63 to 0.98 (mean, 0.87; 95%CI: 0.82-0.90). We also noted that PLR was 5.98 (95%CI: 3.79-9.43), NLR was 0.28 (95%CI: 0.18-0.43) and DOR was 26.21 (95%CI: 14.15-48.57). The Chi-square values of sensitivity, specificity, PLR, NLR and DOR were 15.22 ( $P = 0.0043$ ), 10.55 ( $P = 0.0322$ ), 9.28 ( $P = 0.0544$ ), 9.74 ( $P = 0.0504$ ) and 4.99 ( $P = 0.2882$ ), respectively, indicating heterogeneity for sensitivity and specificity between studies.

Two methods of IGRAs were used in the included studies in this meta-analysis. One was the T-SPOT-TB test, in which mononuclear cells from blood are used and the number of IFN- $\gamma$  producing cells responding

to antigens such as the ESAT-6 and CFP-10 is reported. The other method of IGRAs was QuantiFERON-TB Gold In-Tube (QFT-G-IT), which measures T-cell INF- $\gamma$  production (expressed as pg/mL or IU/mL) in blood in response to a cocktail of ESAT-6, CFP-10 and TB 7.7. The  $P$  value following a comparison of overall diagnostic values from T-SPOT-TB and QFT-G-IT was 0.3073. It could not be concluded that the overall accuracy of T-SPOT-TB for the differential diagnosis of ITB from CD was superior or inferior to that of QFT-G-IT.

The SROC plot is different from the traditional ROC plot that explores the effect of varying thresholds on sensitivity and specificity in a single study. In a SROC plot, any of the data points represent a separate study. The SROC curve presents a global summary of test performance and shows the tradeoff between sensitivity and specificity. A graph of the SROC curve for IGRA determination showing true-positive rates and false-positive rates from individual studies is shown in Figure 3. As a global measure of test efficacy we used the  $Q$ -value, the intersection point of the SROC curve with a diagonal line from the left upper corner to the right lower corner of the ROC space, which corresponds to the highest common value of sensitivity and specificity for the test. This point represents an overall measure of the discriminatory power of a test. Our data showed that the SROC curve was positioned near the upper left corner and that the maximum joint sensitivity and specificity was 0.87.

**Figure 3** Summary receiver operating characteristic curves for interferon-gamma release assays. Solid circles represent each study included in the meta-analysis. The size of each study is indicated by the size of the solid circle. Summary receiver operating characteristic (SROC) curves summarize the overall diagnostic accuracy.

The area under the curve (AUC) was 0.92. These data indicated that the overall accuracy of IGRAs was not as high as expected.

### Multiple regression analysis

By using the STARD guidelines<sup>[19]</sup>, a quality score for each study was compiled on the basis of title and introduction, methods, results and discussion (Table 1). Quality scoring was also carried out using QUADAS<sup>[20]</sup>, in which a score of 1 indicated a fulfilled criterion, 0 if an unclear criterion, and -1 if the criterion was not achieved. These scores were used in the meta-regression analysis to assess the effect of study quality on the RDOR of IGRAs in the differential diagnosis of ITB from CD. All studies were of high quality (STARD score,  $\geq 13$ ; QUADAS score,  $\geq 10$ ) in this review. The differences in the studies with or without blinding, cross-sectional, consecutive/random and prospective designs did not reach statistical significance ( $P = 0.218$ ), indicating that the study design did not substantially affect the diagnostic accuracy.

### Publication bias

Although the Egger test is widely used to evaluate publication bias, it is not useful if less than 10 studies are included. Based on this meta-analysis, which included five articles, we would consider that there was potential for publication bias.

## DISCUSSION

The misdiagnosis rate between CD and ITB is 50%-70%<sup>[4,5,33,34]</sup>. It is important to differentiate between ITB and CD in order to provide effective and prompt therapies due to the increasing incidence of CD and widespread drug-resistant TB<sup>[8]</sup>. In recent years, methods including TST, MTB culture and acid fast bacilli staining have been used for the detection of TB infection. However, the low sensitivity and specificity and complicated processing of

samples has limited the use of these methods<sup>[35,36]</sup>. New techniques, such as CT enteroclysis, capsule endoscopy, single and double balloon enteroscopy, polymerase chain reaction (PCR) and immunological assays for MTB, have also been used in clinical practice. PCR was associated with high sensitivity, but low specificity<sup>[37,38]</sup>. Endoscopic and histopathological examinations are also conducted to differentiate between the two disorders<sup>[39]</sup>, but specific and precise criteria are lacking. The T-SPOT-TB test, an IGRA, has mainly been used to identify latent tuberculosis infection in patients in several areas and countries including the United States, Europe and Japan. However, the clinical usefulness of IGRAs for the differential diagnosis of ITB from CD is unknown.

In recent studies, the most popular biomarkers proposed for the diagnosis of TB-related disease were adenosine deaminase and  $\text{INF-}\gamma$ <sup>[40,41]</sup>. The levels of both biomarkers were significantly higher in tuberculous peritonitis than in non-tuberculous peritonitis patients. Both showed relatively high sensitivity and specificity in diagnosing tuberculous peritonitis<sup>[42-47]</sup>. However, for distinguishing ITB from CD, the present meta-analysis has shown that the mean sensitivity of IGRAs was 0.74, while the mean specificity was 0.87. The maximum joint sensitivity and specificity was 0.85, while the AUC was 0.92, indicating that overall accuracy was relatively high, but not as high as expected.

The DOR is a single indicator of test accuracy that combines the sensitivity and specificity data into a single number<sup>[48]</sup>. The DOR of a test is the ratio of the odds of positive test results in the patient with disease relative to the odds of positive test results in the patient without disease. The value of DOR ranges from 0 to infinity, and higher values indicate better discriminatory test performance (higher accuracy). A DOR of 1.0 indicates that a test did not discriminate between patients with and those without disease. In the present meta-analysis, the mean DOR was 26.21, indicating that IGRAs may be helpful in the differential diagnosis of ITB from CD.

Since the SROC curve and the DOR are not easy to interpret and use in clinical practice<sup>[49]</sup>, the likelihood ratios are considered to be more clinically meaningful<sup>[49]</sup>. We also determined both PLR and NLR as measures of diagnostic accuracy. Likelihood ratios of  $> 10$  or  $< 0.1$  generate large and often conclusive shifts from pretest to posttest probability (indicating high accuracy). A PLR value of 5.98 suggests that patients with ITB have an approximately six-fold higher chance of being  $\text{INF-}\gamma$  assay-positive compared with CD patients. This six-fold high probability would be considered not high enough to begin or to continue anti-TB treatment in ITB patients, especially in the absence of any malignant evidence (for clinical purposes). On the other hand, NLR was found to be 0.28 in the present meta-analysis. If the  $\text{INF-}\gamma$  assay result was negative, the probability that this patient has ITB is approximately 28%, which is not low enough to rule out ITB from CD. These data suggest that a negative  $\text{INF-}\gamma$  assay result should not be used alone as a justification to deny or to discontinue anti-TB therapy. The

choice of therapeutic strategy should be based on the results of culture of MTB, morphological observation of capsule endoscopy or single/double balloon enteroscopy, and/or histologic observation of peritoneal tissue, as well as other clinical data, such as response to anti-TB therapy.

The PPV is the proportion of patients with positive test results who are correctly diagnosed, while the NPV is the proportion of patients with negative test results who are correctly diagnosed. The pooled results showed that the PPV for IGRAs was 0.74, suggesting that 26% of positive results would actually be false positives. On the other hand, the NPV for IGRAs was 0.87, indicating a false negative rate of 13%. The relatively high NPV suggests that IGRAs would be acceptable for clinical purposes.

An exploration of the reasons for heterogeneity rather than computation of a single summary measure is an important goal of meta-analysis<sup>[50]</sup>. In our meta-analysis, both STARD and QUADAS scores were used in the meta-regression analysis to assess the effect of study quality on RDOR. All the studies were of high quality (STARD score of  $\geq 13$  or QUADAS score of  $\geq 10$ ). We found that there was no statistical heterogeneity for sensitivity, specificity, PLR, NLR, and DOR among the studies, which indicated that the differences in the studies with or without blinding, cross-sectional, consecutive/random and prospective designs did not reach statistical significance, and the study design did not substantially affect diagnostic accuracy.

Our meta-analysis has several limitations. Firstly, the exclusion of conference abstracts, letters to the editors, and non-English-language studies might have led to publication bias. Secondly, misclassification bias may have occurred. ITB is not always diagnosed by either histologic or microbiological examination. Some patients were diagnosed with ITB based on the clinical course. This issue regarding accuracy of diagnosis could cause nonrandom misclassification, leading to biased results. Thirdly, all the articles were from Asia, and this may also have led to publication bias. Finally, the number of studies that met the inclusion criteria was not large enough. Multi-center and large blinded randomized controlled trials using IGRAs for ITB diagnosis should be performed.

In conclusion, evidence from the present meta-analysis showed that although IGRAs are not sensitive enough, they did show good specificity for the diagnosis of ITB, which may be helpful in the differential diagnosis of ITB from CD. IFN- $\gamma$  may be a clinical diagnostic marker for the differential diagnosis of ITB from CD. Currently, the literature focusing on the use of IGRAs in ITB is limited; thus, further large multicenter studies are necessary to substantiate the diagnostic accuracy of IGRAs in patients with ITB or CD.

## COMMENTS

### Background

The differential diagnosis of intestinal tuberculosis (ITB) from Crohn's disease (CD) is challenging. The misdiagnosis rate between CD and ITB is 50%-70%. T-cell based interferon-gamma release assays (IGRAs) have increasingly been used as a diagnostic tool in the differential diagnosis of ITB from CD. However, whether IGRAs contribute to accurate ITB diagnosis remains controversial.

### Research frontiers

IGRAs have mainly been used to identify latent tuberculosis infection in patients in several areas and countries including the United States, Europe and Japan. However, the clinical usefulness of IGRAs for the differential diagnosis of ITB from CD is unknown.

### Innovations and breakthroughs

This is the first time that the clinical usefulness of IGRAs for the differential diagnosis of ITB from CD has been investigated by meta-analysis.

### Applications

IGRAs provided good specificity for ITB, and should be helpful in the differential diagnosis of ITB from CD. Interferon-gamma may be a clinical diagnostic marker for the differential diagnosis of ITB from CD.

### Terminology

IGRAs: T-cell based interferon-gamma release assays have increasingly been used to replace the traditional tuberculin skin test as a diagnostic tool for tuberculosis. IGRAs have been shown to have superior sensitivity and specificity. ITB: Intestinal tuberculosis is an important extra-pulmonary tuberculosis that primarily affects the ileum and colon, causing gastrointestinal symptoms such as diarrhea or abdominal pain. Standards for reporting diagnostic accuracy and quality assessment for studies of diagnostic accuracy scores: these scores are used in the meta-regression analysis to assess the effect of study quality on relative diagnostic odds ratio.

### Peer review

This study is an interesting meta-analysis comment. It provides a new evidence of IGRAs helping differential diagnosis ITB from CD.

**Key words:** Early gastric cancer; Synchronous; Metastasis; Lymph node; Endoscopy

**Core tip:** Early gastric cancer is often found synchronously in 2 to 3 lesions. However, this case reports on an unprecedented case of 7 lesions of early gastric cancer. Furthermore, this case deserves more attention because 28 out of 48 lymph nodes showed post-operative metastasis, even though there was only 1 invasion to the 1/3 of the submucosal layer and the remaining 6 invading only up to the mucosal layer. This report speaks to the necessity of extra caution in diagnosing multiple synchronous lesions of early gastric cancer with esophagogastro-duodenoscopy.

### Abstract

An 85 year male patient complaining epigastric discomfort was admitted. From the esophagogastroduodenoscopy, three early gastric cancer (EGCa) lesions had been identified and these were diagnosed as adenocarcinoma with poorly differentiated cell type. The patient underwent operation. From the post-operative mapping, however, additional 4 EGCa lesions were found, and the patient was diagnosed with 7 synchronous EGCa. Out of the 7 EGCa lesions, 6 had shown invasion only to the mucosal layer and one had shown invasion into the 1/3 layer of submucosa. In spite of such superficial invasions, 28 of 48 lymph nodes had been identified as metastases. The multiple lesions of EGCa do not increase

Seong H, Kim JI, Lee HJ, Kim HJ, Cho HJ, Kim HK, Cheung DY, Kim DJ, Kim W, Kim TJ. Seven synchronous early gastric cancer with 28 lymph nodes metastasis. *World J Gastroenterol* 2013; 19(44): 8141-8145 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i44/8141.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i44.8141>

### INTRODUCTION

Owing to the recent development of diagnostic technology through esophagogastroduodenoscopy (EGD), the prevalence of early gastric cancer (EGCa) is increasing. Also, reports of multiple synchronous EGCa lesions

are increasing as well. The prevalence of multiple EGCa does not differ between advanced gastric cancer patients as 6%-14%<sup>[1]</sup> and EGCa patients as 8.3%-17%<sup>[2]</sup>. Multiple EGCa show a high level of prevalence in elder patients or in male patients, and also when the cancer is well differentiated or invasion is limited to the mucosal layer<sup>[3]</sup>. And most accessory lesions have been known to occur adjacent to the main lesion with same or even better differentiation<sup>[4]</sup>. It was found that there was no difference in lymph node metastasis when comparing multiple EGCa with single EGCa in general, but if the invasion depth was deep, the possibility of lymph node metastasis was even higher<sup>[3]</sup>. If the indications of endoscopic treatment are expanded, since even the surgical treatment tends to orient towards less invasive methods to preserve the normal part of stomach as much as possible, accurate pretreatment diagnosis is important for the multiple lesions of EGCa. In our case, 7 EGCa had been found in an 85 year old male patient and there were multiple lymph node metastases identified post-operatively even though the cancer had shown invasion into the upper portion of the submucosal layer.

## CASE REPORT

An 85-year-old male patient complaining of epigastric pain for 3 mo was admitted to our hospital. He had no special medical, family and social history, not to mention cancer, and was found nonspecific in his physical examination and initial laboratory finding. From the results of his physical examination, we found that his blood pressure was 135/87 mmHg, pulse rate was 70 times/min, respiratory rate was 20 times/min and body temperature was 36.5 °C. The conjunctivae were not pale and no jaundice was observed from the sclerae. There were no palpable lymph nodes from the neck examination, and the auscultation had a normal respiratory sound from the thorax. There was no palpable mass, no tenderness or no rebound tenderness found from the abdominal examination.

From the complete blood count of the laboratory findings, hemoglobin was 12.4 g/dL, white blood cell count was 5670/mm<sup>3</sup> and the platelet count was 212000/mm<sup>3</sup>, whereas biochemistry examination revealed, fasting blood glucose as 93 mg/dL, urea nitrogen as 14.5 mg/dL, creatinine as 1.19 mg/dL, aspartate aminotransferase as 30 IU/L and alanine aminotransferase as 22 IU/L, total bilirubin was 0.66 mg/dL, direct bilirubin was 0.22 mg/dL, total protein was 6.7 g/dL and albumin 3.56 g/dL, presenting that all the results were in the normal range. Also, tumor markers such as carcinoembryonic antigen and cancer antigen 19-9 were within normal limit as 2.59 ng/mL and 11.13 U/mL.

From the EGD, the whole stomach had atrophic mucosal change from antrum to cardia, open type III atrophic gastritis and had no *Helicobacter pylori* infection in Warthin-Starry silver stain. There were findings of a well demarcated erythematous depressed erosion in the sized

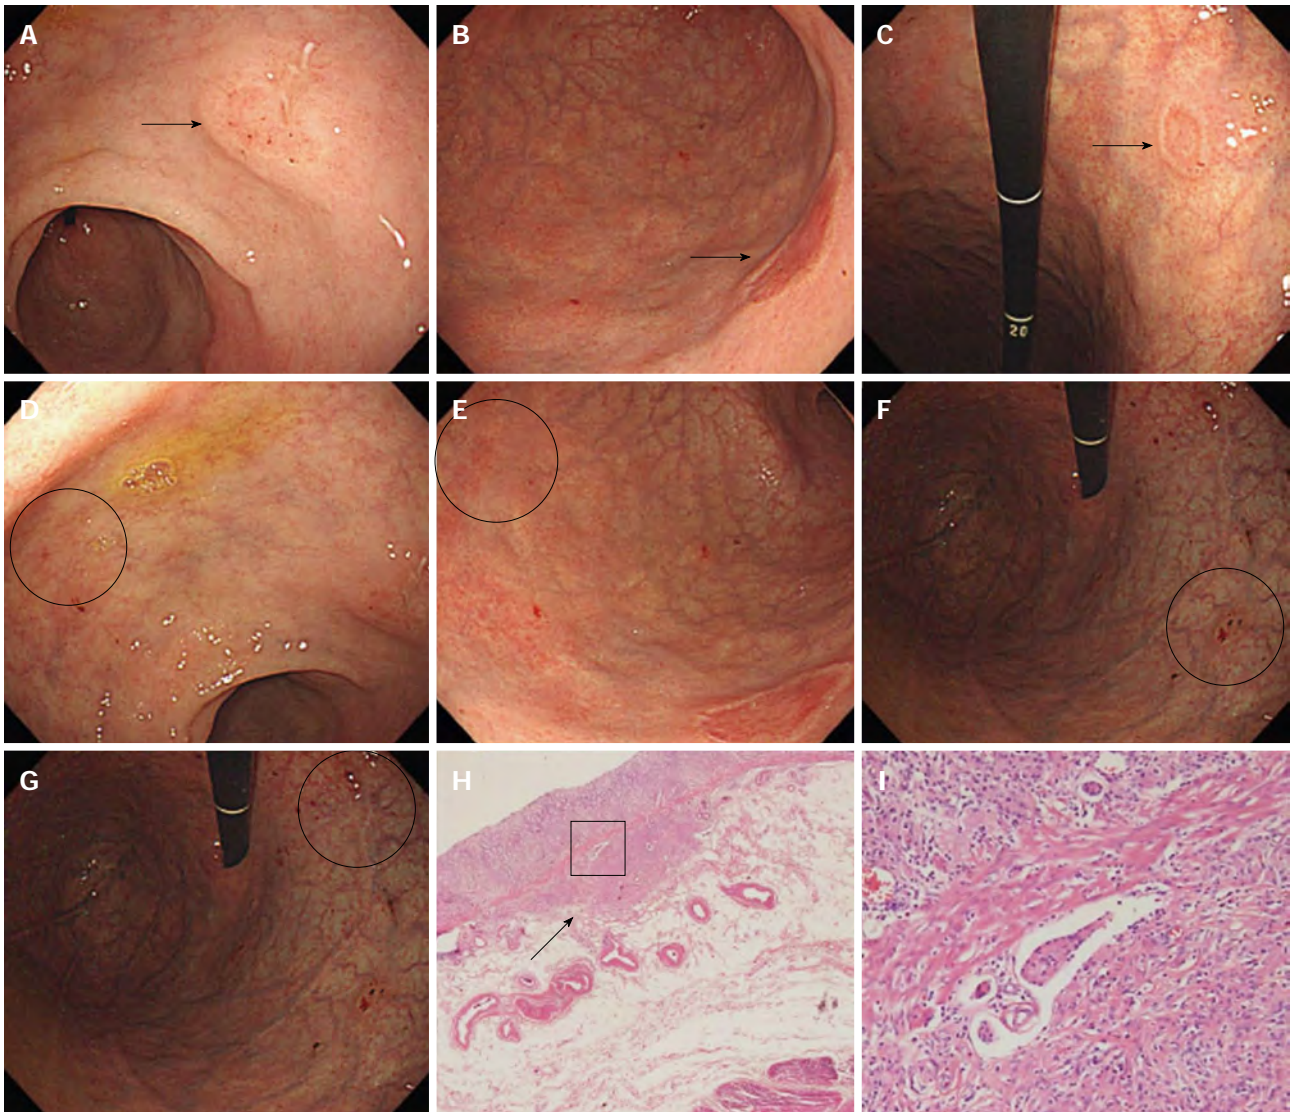

of 8 mm on the posterior wall of proximal antrum (Figure 1A) and a depressed mucosal lesion with a red colored center, pale boundary and clear margin in the size of 15 mm on the posterior wall of lower body (Figure 1B), as well as a depressed erosion in the sized of 7 mm on the posterior wall of lower body (Figure 1C). The lesions were diagnosed as EGCa IIc and the biopsy revealed an adenocarcinoma, poorly differentiated cell type. Although the lesions occurred in multiple regions showing reddish depression with surrounding white rim, the main lesion was very small and in its early stage, suggesting that they are multiple EGCa rather than metastasis. From the abdominal computerized tomography, the locations of lesions could not be identified. Furthermore there was neither any finding of metastasis to neighboring organs such as the liver or pancreas nor any finding of lymph node enlargement in the neighboring areas.

As the patient had shown three lesions of EGCa, poorly differentiated cell type cell type, we did not perform endoscopic submucosal dissection but instead performed subtotal gastrectomy. After the surgery, we also performed a mapping of the subtotal gastrectomy specimen and were able to diagnose additional lesions (Figure 2). The lesions were flat erosions 6 mm in diameter on the anterior wall of proximal antrum (Figure 1D), depressed mucosal lesion 10 mm in diameter on the anterior wall of lower body (Figure 1E), depressed mucosal lesion 7 mm in diameter on the anterior wall of mid body (Figure 1F) and squamous mucosal lesion in the sized 2 mm on the lesser curvature of mid body (Figure 1G). We had reviewed pictures taken during EGD, but could not find any definite lesion and there were no ulcer findings of each lesions (Figure 1).

In histopathological findings, each lesion was identified as adenocarcinoma, poorly differentiated cell type which was the diffuse type and the growth pattern was infiltrative type in accordance with Lauren's classification. All lesions were composed of poorly differentiated adenocarcinoma. There were no lesions with well or moderate differentiated cancer component and the back ground was atrophic gastritis, marked grade (Figure 3). On the invasion depth, the lesion (Figure 3A, C-G) had invaded into the mucosal layer, while the lesion (Figure 3B), which was the largest, had shown invasion into 1/3 of the submucosal layer, SM1, 1000 µm (Figure 1H and I) (Table 1). There was no perineural invasion but vascular and lymphatic invasion were found from the subtotal gastrectomy specimen. The grade of lymphatic invasion was marked (Figure 1I) and out of the 48 resected lymph nodes, 28 lymph nodes had shown metastasis (Figure 3H). Lymph node metastasis was as follow: 1 (4/4), 3 (4/6), 4 (3/10), 5 (5/6), 6 (12/15), 8a (0/7). According to American Joint Committee on Cancer TNM staging classification for gastric cancer, the final pathologic stage was T1bN3bM0.

## DISCUSSION

The diagnosis of EGCa is increasing as the performance

**Figure 1 Endoscopic and histologic findings.** Multiple early gastric cancer lesions were as follow: A: Raised lesion on the posterior wall of the proximal antrum; B: Erythematous depressive lesion; C: Depressed lesion on the posterior wall of the low body; D: III demarcated flat lesion on the anterior wall of the proximal antrum; E, F: III demarcated depressed lesion on the anterior wall of the low body (E), on the anterior wall of the mid body (F); G: III demarcated flat lesion on the lesser curvature of mid body; H: Adenocarcinoma in lesion B showed invasion into 1/3 of the submucosal layer (arrow) ( $\times 40$ ); I: Lymphatic invasion magnified in quadrangle in H ( $\times 100$ ).

**Figure 2 Gross specimen.** Three lesions (D-F) are located on the anterior wall, and the other three lesions (A-C) are on the posterior wall. One lesion (G) shows flat early gastric cancer type IIb configuration and is centered at the body, lesser curvature.

of upper endoscopy-related equipments advances and as pathological diagnosis techniques became more developed in recent days. In South Korea, health screening EGD is performed biannually to the entire public nationwide and this led to increase in diagnosis of early stage stomach cancer, thereby leading to increase in diagnosis of multiple EGCa. However, in spite of much effort to find multiple EGCa lesions, the rate of lesions unidentified prior to surgical intervention are as high as 20% to 25%<sup>[4]</sup>.

In the past, gastrectomy was the major treatment of gastric cancer even if multiple gastric cancers were not identified, but because the multiple gastric cancers were included in the resected portion of stomach there was no significant difference in prognosis in some cases. However, in recent days, as endoscopic submucosal dissection is being used as treatment of EGCa, the finding of multiple EGCa is considered important. Moreover, as more

non-invasive procedures are preferred for elderly patients for the treatment of EGCa, the importance of finding multiple lesions became more significant.

According to Moertel *et al.*<sup>[5]</sup>, diagnosis of multiple EGCa requires evidence of pathological malignancy for each lesion, which should be present at independent locations without the possibility of metastasis from the other organs. Multiple EGCa are more prevalent in male or older patients. In many cases, the area of occurrence is located at middle third portion and lower third portion of the stomach, whereas most accessory lesions incur at adjacent locations to the main lesion, usually the distal part<sup>[3,4]</sup>. Most multiple EGCa have shapes of the elevated type or flat type rather than the depressed type, and most

are associated with well differentiated lesions rather than poorly differentiated lesion, and majority of them show invasion only to the mucosal layer<sup>[3,4]</sup>. In addition, when there is adenoma or atrophic gastritis, and when the patient has a family history of stomach cancer, multiple EGCa is more likely to be prevalent<sup>[1,6]</sup>.

The prognosis and 5 year survival rate of multiple EGCa as well as single EGCa are both similarly over 90%<sup>[7]</sup>. The recurrence rate is also similarly 11.2% in both types, and a substantial number of them are considered to be caused by multiple synchronous EGCa which had been overlooked during prior EGD<sup>[8]</sup>. Therefore, it is important to keep in mind the possible existence of synchronous lesion when establishing plans for examination and treatment.

There are arguments that total gastrectomy should be performed for the treatment of multiple EGCa due to the risk of recurrence but subtotal gastrectomy can also be performed as the treatment of multiple EGCa as they mainly occur at the distal part and not much different in prognosis. In consideration of the post-operative quality of life, even if subtotal gastrectomy is performed when possible with accurate diagnosis, the results are not different from the cases performed with total gastrectomy.

Recently, endoscopic submucosal dissection is increasing trend as the treatment method of EGCa, and lymph node metastasis becomes an important factor in deciding endoscopic therapy over surgical treatment. Other important factors for prediction of lymph node metastasis include presence/absence of ulcer lesion, tumor size, and invasion depth. Due to the increased accuracy of pre-operative CT scan and endoscopic ultrasonography, it is easier to find lymph node metastasis, therefore the identification of depth of invasion as major risk factors of lymph node metastasis becomes important<sup>[9]</sup>. In our case, although the depth of invasion is limited to the mucosal layer or the 1/3 part of the submucosa layer, numerous lymph node metastasis had occurred. Such outcomes were considered to be caused not from the presence of multiple lesions but from the lympho-vascular invasion.

This case was finally diagnosed as a very rare case of EGCa with 7 multiple synchronous EGCa in a male patient of old age. In addition, the patient had shown metastasis of 28 lymph nodes out of 48 resected lymph nodes although its depth of invasion was limited to the mucosal and the 1/3 part of the submucosal layer. Thereby, we report this very rare case with literature review in order to inform the importance of accurate diagnosis on multiple EGCa.

dice; Liver mass; Bile duct mass; Neuroendocrine tumor

**Core tip:** We report a rare case of small cell carcinoma of the liver and biliary tract. Despite its rarity, liver and bile duct small cell carcinoma should be considered in the differential diagnosis of atypical chest pain because this symptom might indicate the presence of abdominal malignancy. We also explain why previous studies have reported inconsistent immunohistochemical findings in tissues obtained from extrapulmonary small cell carcinomas.

Jo JM, Cho YK, Hyun CL, Han KH, Rhee JY, Kwon JM, Kim WK, Han SH. Small cell carcinoma of the liver and biliary tract without jaundice. *World J Gastroenterol* 2013; 19(44): 8146-8150 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i44/8146.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i44.8146>

### Abstract

An 80-year-old woman presenting with chest pain was found to have a large, lobulated soft tissue mass in the liver and nearby tissues on abdominal computed tomography (CT). The tumor had invaded the common hepatic artery and main portal vein. Jaundice developed 4 wk later, at which point, a pancreas and biliary CT scan revealed a large mass in the right lobe of the liver and a hilar duct obstruction, which was found to be a small cell carcinoma. Despite its rarity, liver and bile duct small cell carcinoma should be considered in the differential diagnosis of atypical chest pain without jaundice.

**Key words:** Extrapulmonary small cell carcinoma; Jaun-

### INTRODUCTION

Most small cell carcinomas occur in the lung, and extrapulmonary small cell carcinoma comprises only 2.5%-4% of all small cell carcinoma cases<sup>[1,2]</sup>. These malignancies are now considered to be distinct clinicopathological entities from small cell lung cancer, and there is little consensus regarding the optimal treatment strategy in such cases. Extrapulmonary small cell carcinomas are rarely found in the trachea, larynx, thymus, esophagus, stomach, small intestine, colon, prostate, gallbladder, skin, breast, and uterine cervix, and they are even rarer in the liver or biliary tract<sup>[3]</sup>. To the best of our knowledge, only 10 cases of primary small cell carcinomas of the liver have been reported in the English literature<sup>[4-10]</sup>.

Here, we report the case of a patient with small cell carcinoma of the liver and biliary tract initially presenting with atypical chest pain without jaundice.

**Figure 1** Findings of initial abdominal computed tomography. Computed tomography showed a large mass located in the liver, common hepatic duct, and common bile duct.

## CASE REPORT

An 80-year-old woman was admitted to our hospital with a 7-d history of anorexia and chest pain. On admission, she was afebrile, her blood pressure and pulse rate were normal, and she appeared well nourished despite the recent anorexia. During the work-up for chest pain, an electrocardiogram showed a normal sinus rhythm and an echocardiogram showed no significant functional abnormality. The scleras were not icteric. The abdomen was mildly distended, with tenderness in the right upper quadrant. Laboratory studies revealed a white blood cell count of  $4500/\text{mm}^3$  (normal range,  $6000\text{--}10000/\text{mm}^3$ ); hemoglobin,  $12.1\text{ g/dL}$  (normal range,  $12\text{--}16\text{ g/dL}$ ); platelet count,  $199000/\text{mm}^3$  (normal range,  $130000\text{--}450000/\text{mm}^3$ ); serum albumin,  $3.8\text{ g/dL}$  (normal range,  $3.0\text{--}5.0\text{ g/dL}$ ); aspartate aminotransferase (AST),  $101\text{ U/L}$  (normal range,  $5\text{--}37\text{ U/L}$ ); alanine aminotransferase (ALT),  $64\text{ U/L}$  (normal range,  $5\text{--}40\text{ U/L}$ ); alkaline phosphatase,  $720\text{ U/L}$  (normal range,  $39\text{--}117\text{ U/L}$ ); gamma-guanosine-5'-triphosphate,  $215\text{ U/L}$  (normal range,  $7\text{--}49\text{ U/L}$ ); total bilirubin,  $0.4\text{ mg/dL}$  (normal range,  $0.2\text{--}1.2\text{ mg/dL}$ ); and proBNP,  $170.6\text{ pg/mL}$  (normal range,  $0\text{--}125\text{ pg/mL}$ ). Coagulation profiles were within normal limits. After confirming the absence of a significant cardiac problem, we performed esophagogastrosocopy and colonoscopy; however, these investigations also yielded no significant findings, except for that of chronic atrophic gastritis. Abdominal computed tomography (CT) revealed a lobulated soft tissue mass measuring  $10.1\text{ cm}$  and located in the liver, common hepatic duct, common bile duct, gall bladder, and hepatoduodenal ligament. The intrahepatic duct was dilated, and the tumor had invaded both the common hepatic artery and main portal vein (Figure 1); multiple enlarged lymph nodes were present near the celiac and common hepatic arteries and in the left gastric and aortocaval spaces. Additional laboratory studies showed that CA19-9 concentration was  $12.57\text{ U/mL}$  (normal range,  $0\text{--}37\text{ U/mL}$ ) and  $\alpha$ -fetoprotein (AFP) concentration was  $2.19\text{ ng/mL}$  (normal range,  $0\text{--}10.9\text{ ng/mL}$ ). Concentrations of carcino-embryonic antigen (CEA) and PIVKAI were not assessed.

These findings led to clinical suspicion of cholangio-

carcinoma, but the patient refused to undergo a biopsy and was discharged. However, four weeks later, the patient visited the hospital with jaundice. At this second visit, laboratory analysis of the patient's blood provided the following results: AST,  $566\text{ U/L}$ ; ALT,  $261\text{ U/L}$ ; alkaline phosphatase,  $6783\text{ U/L}$ ; gamma-GTP,  $476\text{ U/L}$ ; total bilirubin,  $25.8\text{ mg/dL}$ ; and direct bilirubin,  $19.8\text{ mg/dL}$ . A CT scan of the pancreas and biliary duct revealed a large mass in the right lobe of the liver as well as an obstruction of the hilar duct (Figure 2). An ultrasonography-guided gun biopsy was performed, and pathological analysis of the biopsy specimen revealed a tumor consisting of tightly packed nests and diffuse irregularly shaped sheets of cells with areas of necrosis (Figure 3). The tumor cells were of small-to-intermediate size with hyperchromatic, round-to-oval nuclei and scanty, poorly defined cytoplasm. The nuclear chromatin was finely granular, and nucleoli were absent or inconspicuous. Very few cell borders were visible, and there was frequent nuclear molding (Figure 3). The tumor cells were immunoreactive for synaptophysin and CD 56, but negative for hepatocyte-specific antigen (HSA) and thyroid transcription factor (TTF)-1. The Ki-67 index was high (more than 80%), and approximately 5 mitotic cells/10 HPF were observed. Taken together, these findings led us to diagnose small cell carcinoma (Figure 4). On the basis of the World Health Organization 2010 classification for neuroendocrine tumors (NETs)/neuroendocrine carcinomas (NECs), we identified the carcinoma as a grade 3 (G3) NEC (small cell type).

The tumor was unresectable; therefore, palliative chemotherapy was considered to be the best treatment option. However, the patient refused chemotherapy because of her advanced age and poor health. Hence, only supportive care, including percutaneous transhepatic biliary drainage, was provided, and the patient died 8 wk after the diagnosis was confirmed.

## DISCUSSION

Extrapulmonary small cell carcinomas represent only 0.1%–0.4% of all cancer cases<sup>[11,12]</sup>. Most small cell carcinomas arise in the lung or bronchial trees as small cell lung cancers (SCLCs). However, cases of extrapulmonary

Figure 2 Computed tomography scan obtained before biopsy. One month after the first visit, a computed tomography scan of the pancreas and biliary duct revealed that the large mass in the right lobe of the liver had grown and that there was an obstruction of the hilar duct.

Figure 3 Tumor consisted of tightly packed nests and diffuse, irregularly shaped sheets of cells with necrotic areas. A: The tumor cells were of small-to-intermediate size with hyperchromatic, round-to-oval nuclei and scanty, poorly defined cytoplasm (HE,  $\times 100$ ); B: The nuclear chromatin was finely granular, and nucleoli were absent or inconspicuous. Cell borders were rarely seen, and nuclear molding was common (HE,  $\times 400$ ).

Figure 4 Immunohistochemical findings ( $\times 200$ ). The tumor cells were immunoreactive for synaptophysin (A) and negative for hepatocyte-specific antigen (B).

small cell carcinomas are gradually becoming more common, and there have been reports of small cell carcinomas in both the gall bladder<sup>[13]</sup> and pancreas<sup>[14]</sup>. A few studies have reported small cell NEC of the ampulla of Vater<sup>[15,16]</sup>. However, reports of small cell carcinoma of the liver or common bile duct, as in the present case, are extremely rare.

Differential diagnosis is important to exclude pulmonary small cell carcinoma. In most cases, a finding of occult extrapulmonary small cell carcinoma is subsequently

found to be a distant metastasis from an undetected small cell lung cancer. To exclude this possibility, chest radiography and CT, and/or bronchoscopic examination with appropriate biopsies and sputum cytology are required. In addition, growing evidence suggests that positron emission tomography (PET) is also sufficiently sensitive to rule out SCLC<sup>[17-19]</sup>. In the present case, results of sputum cytology were negative for malignancy, and there was no evidence of lung cancer on chest CT, making bronchoscopy unnecessary.

Extrapulmonary small cell carcinomas shows structural features of both primitive epithelial and neuroendocrine differentiation<sup>[17]</sup>. Neuroendocrine carcinoma arises from embryonic neural crest cells, which migrate to the bronchopulmonary system and gastrointestinal tracts during development. However, these cells do not usually migrate to the liver and bile duct; this may be the reason for the rare occurrence of neuroendocrine tumors of the liver and bile duct<sup>[1,20]</sup>.

Small cell carcinoma can be distinguished from other carcinomas or lymphomas that have cells of a similar size. Under light microscopy, the diameter of small cell carcinoma cells is generally 2 or 3 times greater than that of a small lymphocyte. In addition, small cell carcinoma cells are spindle-like, have a fusiform or polygonal shape, and tend to grow in sheets or ribbon- or rosette-like patterns. Extensive necrosis and high mitotic rates are also typical features that differentiate small cell carcinoma from atypical carcinoid tumors<sup>[5]</sup>.

Furthermore, several distinct immunohistochemical features associated with extrapulmonary small cell carcinoma are potentially important in distinguishing it from hepatic metastasis of small cell lung carcinoma<sup>[21-24]</sup>; unfortunately, the results of previous studies are somewhat inconsistent in this respect. Ryu *et al.*<sup>[4]</sup> reported an 8 cm-sized small cell carcinoma of the liver that was positive for CD56/C-kit/synaptophysin and negative for TTF-1. Zanconati *et al.*<sup>[7]</sup> studied 3 cases and found that all of the tumors were positive for AE1/AE3, CK8, CK18, CK19, and NSE and negative for S-100/CEA, and that 2 of them were AFP positive. Frazier *et al.*<sup>[25]</sup> reported a case of small cell carcinoma of the liver in which the patient underwent hepatic segmentectomy and adjuvant etoposide/cisplatin therapy. The tumor in this case was positive for CD56/NSE/c-kit/synaptophysin/mixed CK/EMA and negative for CK7, CK8, CK19, CK20, AFP, CEA, vimentin, and desmin/TTF-1/AFP. In the present case, the tumor was positive for both CK and synaptophysin, weakly positive for CD56, and negative for HSA. These tumor cells originate from multipotent stem cells that can differentiate into various cell types; this may explain the frequent coexistence of mixed tumors with various immunohistochemical features.

Small cell carcinoma frequently shows distant metastasis and consequently has a poor prognosis. Correspondingly, patients with small cell lung cancer generally have poor long-term survival. However, some cases of good long-term survival have been reported in patients with extrapulmonary small cell carcinoma. Little is known about the survival of patients with small cell carcinoma of the liver; generally, the clinical course of this condition is not well described, and reports of patient survival vary. Zanconati *et al.*<sup>[7]</sup> reported two cases in which the patients died soon after diagnosis, and treatment could not be initiated. In contrast, Sengoz *et al.*<sup>[6]</sup> reported two cases of extrapulmonary small-cell carcinoma of the liver, in which one patient survived for 13 mo after chemotherapy and the other survived 67 mo after receiving right hemihepatectomy. Choi *et al.*<sup>[10]</sup> reported the case of a patient

who survived more than 18 mo after receiving treatment with oral etoposide alone.

It is often not possible to effectively treat small cell carcinoma of the biliary system with surgical resection alone. As an alternative, Hazama *et al.*<sup>[26]</sup> performed surgical resection after neoadjuvant chemotherapy for small cell carcinoma of the common bile duct, and Okamura *et al.*<sup>[27]</sup> suggested that multimodality treatment including neoadjuvant chemotherapy, surgical resection, and adjuvant chemotherapy improves survival of patients with small cell carcinoma of the biliary system. The generally accepted optimal treatment for extrapulmonary small cell carcinoma is appropriate surgical resection followed by adjuvant chemotherapy. However, Levenson asserted that there is no survival benefit from using surgery to treat either small cell lung cancer or extrapulmonary small cell carcinoma. This may be because the most important prognostic factor is the extent of disease at diagnosis, when most patients with extrapulmonary small cell carcinoma already have occult metastasis<sup>[1]</sup>.

In the present case, we could not administer palliative chemotherapy because of the patient's advanced age and very poor performance status. Although there is no established standard treatment for extrapulmonary small cell carcinoma, chemotherapy should be tried if the patient can tolerate it, because this malignancy is often chemosensitive<sup>[28]</sup>. The recommended chemotherapy regimen for extrapulmonary small cell carcinoma is the same as that for small cell lung cancer<sup>[10]</sup>. Furthermore, for patients who are able to undergo surgical resection, platinum-based adjuvant chemotherapy is also advisable, because it can reduce the chance of systemic recurrence<sup>[29-31]</sup>.

In previous reports of primary small cell carcinoma of the liver or bile duct, patients usually presented with jaundice, a palpable mass, or abdominal discomfort as their first symptom. Despite its rarity, liver and bile duct small cell carcinoma should be considered in the differential diagnosis of atypical chest pain as this symptom might indicate the presence of an abdominal malignancy.

### Abstract

Paragangliomas typically develop in the extra-adrenal sites along the sympathetic and/or the parasympathetic chain. Occasionally, the tumors may arise in some exotic sites, including the head and neck region and the urogenital tract. Paraganglioma presenting as a primary rectal neoplasm has not been well described in the literature. Here, we report the first case of malignant paraganglioma arising in the rectum of a 37-year-old male. He presented to the clinic because of hematochezia with tenesmus. The anorectal digital examination and colonoscopic examination revealed a polypoid mass of the rectum, measuring approximately 4 cm in diameter. The overall morphology and immunophenotype were consistent with a typical paraganglioma. However, the tumor exhibited features suggestive of malignant potential, including local extension into adjacent adipose tissue, nuclear pleomorphism, confluent tumor necrosis, vascular invasion and metastases to regional lymph nodes. In conclusion, we present the first case of rectal malignant paraganglioma. Due to the unexpected occurrence in this region, malignant paraganglioma may be misdiagnosed as other tumors with overlapping features; in particular, a neuroendocrine tumor of epithelial origin. Because of the differences in

treatment, separating paraganglioma from its mimics is imperative. Combination of morphology with judicious immunohistochemical study is helpful in obtaining the correct diagnosis.

### INTRODUCTION

Paragangliomas are rare but well-described non-epithelial neuroendocrine tumors that typically develop in the extra-adrenal sites along the sympathetic and/or the parasympathetic chain<sup>[1]</sup>. Occasionally, the tumors may arise in some exotic sites where normal paraganglia are not well documented. The majority of these unusual tumors have been described preferentially in the head and neck region and the urogenital tract<sup>[2]</sup>. With the exception of gangliocytic paraganglioma, paraganglioma is extremely rare in the gastrointestinal tract. Of note, the hitherto reported gas-

trointestinal paragangliomas are exclusively limited to the stomach<sup>[3-7]</sup>. To the best of our knowledge, paraganglioma has not been well described in the rectum. Due to the unexpected occurrence in this region, rectal paraganglioma may be misdiagnosed as other common types of rectal tumors with morphological overlap. Because the treatments vary, separation of rectal paraganglioma from its mimics, in particular neuroendocrine tumors of epithelial origin, is imperative. In this study, we report a case of malignant paraganglioma presenting as a primary rectal neoplasm to broaden the clinical and morphological spectrum.

## CASE REPORT

A 37-year-old male presented to the clinic because of hematochezia. The symptom had lasted for 8 mo and was accompanied intermittently with tenesmus. On anorectal digital examination, a round firm mass was identified on the posterior wall of the rectum. Colonoscopic examination revealed a polypoid mass, measuring approximately 4 cm in diameter. Clinically, the mass was suspected to be a rectal carcinoma. A biopsy was performed and was interpreted as a low-grade neuroendocrine tumor. After the admission, laparoscopic radical rectectomy was performed. The postoperative course was uneventful. The patient received no adjunctive therapy after surgery and is well at 9-mo follow-up.

### Pathologic studies and findings

Hematoxylin and eosin-stained sections were reviewed. Immunohistochemical study was performed on 4-mm thick unstained sections of formalin-fixed paraffin-embedded tissue using the standard EnVision technique. The primary antibodies used in the study included antibodies against Chromogranin A (dilution 1:200), synaptophysin (dilution 1:100), neuron-specific enolase (dilution 1:100), CD56 (dilution 1:50), S100 protein (dilution 1:300), pancytokeratin (dilution 1:100), cytokeratin 8/18 (dilution 1:50), epithelial membrane antigen (dilution 1:200), CD34 (dilution 1:50), Human Melanoma Black 45 (dilution 1:60), alpha smooth muscle actin (dilution 1:400), desmin (dilution 1:500), CD117 (dilution 1:100), and discovered on GIST-1 (DOG1) (dilution 1:100). Heat-induced epitope retrieval was performed using a pressure cooker. Appropriate positive controls were run simultaneously throughout the process.

The resected specimen consisted of a segment of rectum measuring 11 cm in length. A polypoid mass was observed protruding into the intestinal cavity, measuring 4.0 cm × 4.0 cm × 1.5 cm in size. On the cut section, the tumor was red-brownish in color and fleshy in consistency, involving the full thickness of the intestinal wall with local extension into the adjacent adipose tissue.

Histologically, the tumor was composed of sheets or organoid nests of large polygonal cells surrounded by a rich network of delicate arborizing vasculature, generating a characteristic “zellballen” (Figure 1A and B). The polygonal cells contained copious eosinophilic

to amphiphilic granular cytoplasm, with round to oval nuclei and prominent nucleoli. Although focal nuclear pleomorphism was present (Figure 1C), mitotic activity was relatively low (1-2/50 high power fields). Confluent tumor necrosis and vascular invasion were observed (Figure 1D and E). In addition, the tumor cells metastasized to regional lymph nodes (Figure 1F).

Immunohistochemically, the large polygonal cells exhibited diffuse and strong expression of chromogranin A (Figure 2A), synaptophysin, CD56, neuron-specific enolase and vimentin. In areas with distinct organoid structure, the staining of S100 protein highlighted the presence of slender sustentacular cells located at the periphery of the tumor nests (Figure 2B). However, in areas with more diffuse architecture, the sustentacular cells were difficult to identify. The tumor cells were negative for all of the epithelial, melanocytic, myogenic and Cajal cell markers tested in this study. The Ki67 index was approximately 20% (Figure 2C). The endothelial markers of CD34 and CD31 outlined the rich vascular network (Figure 2D).

## DISCUSSION

Paragangliomas have been rarely reported in the gastrointestinal tract. Approximately 12 tumors have been described in this region, most of which were located in the stomach, with only one tumor occurring in the rectum<sup>[3-8]</sup>. Of note, the only reported rectal paraganglioma was included in a study focusing on a statistical analysis and was only quoted as an anatomic location. Insufficient data were provided in that case, either clinically or pathologically.

In the current study, we present the clinical and pathological features of a malignant paraganglioma occurring in a 37-year-old male who presented with non-specific symptoms. Clinically, the lesion was suspected as a rectal carcinoma based on anorectal digital findings and rectoscopy examination. Due to the striking organoid structure and strong positivity for neuroendocrine markers, the biopsy specimen was initially interpreted as a low-grade neuroendocrine tumor of epithelial origin, formerly known as a carcinoid tumor. The final diagnosis of paraganglioma was established on the postoperative specimen, which provided enough sections for comprehensive review. The negativity for epithelial marker and presence of slender sustentacular cells allowed the distinction from an epithelial neuroendocrine neoplasm. Other tumors that may enter into the differential diagnosis include neoplasms with perivascular epithelioid cell differentiation (PEComas), alveolar soft part sarcoma (ASPS) and, rarely, gastrointestinal stromal tumor (GIST) of epithelioid subtype. Like paragangliomas, both PEComas and ASPS may exhibit an organoid or nesting pattern surrounded by thin-walled vessels. By immunohistochemistry, PEComas typically express melanocytic and sometimes express myogenic markers, whereas ASPS is characterized by nuclear staining of TFE3 with no expression of neuroendocrine antibodies. The application

**Figure 1** Histological features. A-B: The tumor was composed of sheets or organoid nests of large polygonal cells surrounded by a rich network of delicate arborizing vasculature, generating a characteristic "zellballen" (A: HE, × 100; B: HE, × 400); C: Focal nuclear pleomorphism (HE, × 400); D: Confluent tumor necrosis (HE, × 100); E: Vascular invasion (HE, × 400); F: Metastases of lymph nodes (HE, × 100).

**Figure 2** Immunohistochemistry. A: The tumor cells exhibited diffuse and strong expression of chromogranin A; B: S100 protein highlighted the presence of slender sustentacular cells located at the periphery of the tumor nests; C: The Ki67 index was approximately 20%; D: CD34 outlined the rich vascular network.

of Cajal cell markers, namely CD117 and DOG1, will facilitate the distinction from an epithelioid GIST.

Malignant paraganglioma accounts for 14%-50% of

all paragangliomas in some large series<sup>[9,10]</sup>. Only three cases of primary malignant paraganglioma have been reported in the gastrointestinal tract, all of which occurred

in the stomach<sup>[4,6]</sup>. To the best of our knowledge, rectal malignant paraganglioma has not been described thus far. The current case represents the first case of malignant paraganglioma arising in the rectum.

The diagnosis of malignancy in a paraganglioma is based principally on the aggressive behavior of the tumor. According to the World Health Organization classification of tumors of the endocrine system, the reliable diagnostic criteria of malignant paraganglioma refer to the presence of metastasis or tumor spread in sites normally devoid of chromaffin tissue<sup>[11]</sup>. Although not considered definitive, several morphological features are believed to be correlated with malignant potential. These features include large size of the tumor (> 5 cm), prominent nuclear pleomorphism, increased mitotic activity, presence of confluent tumor necrosis, diffuse growth pattern with a lack of sustentacular cells, extension to adjacent tissues or structures, vascular invasion and high Ki67 index<sup>[11,12]</sup>. It is worth noting that none of these features are able to identify a malignant tumor alone. As an alternative approach, some scoring systems have been proposed in the evaluation of malignant potential. One of the most utilized scoring systems is the "Pheochromocytoma of the Adrenal gland Scales Score (PASS)"<sup>[13]</sup>. A PASS score > 6 is highly suggestive of potential aggressive biological behavior. The current case exhibited local extension into the adjacent adipose tissue, focal nuclear atypia, confluent tumor necrosis, vascular invasion, high Ki67 index and metastases to regional lymph nodes, justifying a diagnosis of malignant paraganglioma.

Recently, an increasing number of studies have focused on identifying molecular markers or biomarkers that can reliably predict malignant potential of the paraganglioma. Several markers, including telomerase, telomerase associated protein, heat shock protein 90, SNAIL and miR-483-5p, also have been found to be closely related to the malignant potential of paraganglioma<sup>[10,14]</sup>. On the other hand, molecular genetic detection is only gradually being applied to paraganglioma. It has been demonstrated that malignant paraganglioma is strongly associated with SDHB mutations<sup>[15]</sup>. Despite these recent advances, it remains difficult to reliably predict the outcome of any given patient.

With regard to the prognosis, the 5-year survival rate in malignant paraganglioma is approximately 30%-50%<sup>[10]</sup>. The majority metastasize to regional lymph nodes, followed by bone, liver and lung<sup>[11,14]</sup>. At present, there is no optimal therapy for malignant paraganglioma. For the past few years, molecular targeted therapy has been increasingly applied in the therapeutic protocol of malignant paraganglioma. Some targeted agents, such as hypoxia inducible factor-1 inhibitors, mammalian target of rapamycin inhibitors (everolimus), and receptor tyrosine kinase inhibitors (sunitinib), have been attempted with promising effectiveness<sup>[14]</sup>. Nevertheless, more clinical trials are needed. The patient in the current study received no adjunctive chemotherapy or radiotherapy. He remains well 9 mo after the surgery and continues to be closely monitored.

In summary, we present the first case of rectal malignant paraganglioma. Because of its rarity in the rectum, malignant paraganglioma may be misdiagnosed as other tumors with overlapping features. Because of the differences in treatment, separation of malignant paraganglioma from its mimics, in particular from neuroendocrine carcinoma, is imperative. Combination of morphology with judicious immunohistochemical study is helpful in obtaining the correct diagnosis.

### Abstract

Ileal conduit stomal varices are rare, and may result in bleeding. The standard treatment modality for management of this type of hemorrhage has not been established. We present the case of a 70-year-old woman with progressive ileal conduit stomal variceal bleeding which was successfully managed by endovascular embolization *via* the transjugular transhepatic approach. In conclusion, transjugular transhepatic endovascular embolization is a good choice in patients with ileal conduit stomal variceal bleeding who have failed conservative therapy.

### INTRODUCTION

Varices are a common complication of liver cirrhosis with portal hypertension. Typically, they are found in the gastro-esophageal region. Ectopic varices are rare, and can arise along the entire gastrointestinal tract, including the duodenum, jejunum, ileum, colon and rectum, but seldom at the umbilicus, in the peritoneum and stomas<sup>[1,2]</sup>. Ectopic varices can present with hemorrhage, accounting for up to 5% of all variceal bleeding<sup>[1]</sup>. However, due to the difficulty in their diagnosis and treatment, the mortality secondary to their initial bleeding is up to 40%<sup>[3]</sup>. Currently, reports on ectopic variceal bleeding are mostly located in the gut, especially in the duodenum and rectum. Variceal bleeding from a stoma, especially from an ileal conduit stoma, has rarely been reported<sup>[4]</sup>. Here, we present a case of ectopic variceal bleeding from an ileal conduit stoma (Figure 1) which was successfully managed by endovascular embolization *via* the transjugular transhepatic approach.

### CASE REPORT

A 70-year-old woman, who had undergone cystectomy and an ileal conduit due to interstitial cystitis two years before, presented with chronic bleeding from the ileal

Figure 1 The bluish ectopic varices at the ileal conduit stoma (black arrow).

Figure 2 Three-dimensional reconstruction showed the ectopic varices (black arrow) at the ileal conduit stoma fed by the superior mesenteric vein (white arrow) and communicated to the paraumbilical vein (white arrow) and femoral vein (white arrow).

conduit stoma after the operation. The patient also had drug-induced liver cirrhosis and a history of two episodes of hepatic encephalopathy. The bleeding was first considered to be wound bleeding and was treated with homeostatic drugs. However, the hemorrhage persisted, and an enhanced multislice computed tomography (CT) scan and 3-dimensional (3D) reconstruction imaging showed ectopic varices fed by the superior mesenteric vein (SMV) and communicated to the paraumbilical vein and femoral vein at the ileal conduit ostomy (Figure 2). The hemorrhage could be paused by local compression. Two weeks previously, with the bleeding worsening, local compression and vasoactive therapy (Octreotide 50 mg/h) failed to achieve hemostasis. A wound resuture was then performed, however, the result was disappointing. Three days before, massive hemorrhage had occurred and the patient developed hemorrhagic shock (systolic blood pressure 88 mmHg, heart rate 103/min) and became severely anemia (hemoglobin 57 g/L, red blood cell  $2.14 \times 10^{12}/L$ ). The platelets, prothrombin time and international normalized ratio were  $78 \times 10^9/L$ , 18.6 s, and 1.18, respectively. Considering her hepatic function [Child-Pugh B (9 score)], abundant ascites and her history of recurrent hepatic encephalopathy,

Figure 3 Opacification showed the varices fed by the superior mesenteric vein (black arrow) and communicated to the paraumbilical vein and femoral vein (white arrows).

Figure 4 Opacification showed disappearance of the ileal conduit stoma varices and colic (black arrow) in the ectopic varices.

an emergency transjugular transhepatic embolization was planned. Portal venography and peripheral superior mesenteric venography demonstrated varices arising from the SMV with retrograde flow toward the stoma and communicated to the paraumbilical vein and femoral vein (Figure 3). The portal-pressure gradient measured during surgery was 18 cmH<sub>2</sub>O. Ectopic varices embolization with a stainless steel coil was then performed. The portal-pressure gradient measured after the operation was 19 cmH<sub>2</sub>O, and postoperative opacification showed that the varices had disappeared (Figure 4). The patient had no complications following the procedure and received conservative medical therapy with Propranolol after the operation. Follow-up at 4 mo showed no focal bleeding.

## DISCUSSION

Reports on the hemorrhage of ectopic varices are limited, and most are of digestive tract bleeding or umbilical vein bleeding<sup>[5-9]</sup>. Abdominal intestinal ostomy may result in the formation of collateral vessels at the stoma, such as the development of ileostomy stomal varices after ileal conduit ostomy and ileostomy in several case

reports<sup>[4,10,11]</sup>. The patient in this study developed ileal conduit stomal variceal bleeding. Due to persistent hemorrhage, a contrast enhanced multislice CT scan and 3D reconstruction imaging were performed which revealed ectopic varices fed by the SMV and communicated to the paraumbilical vein and femoral vein at the stoma. The correct diagnosis of variceal bleeding with portal hypertension was made.

The standard therapy for ectopic variceal bleeding has not yet been determined, and a recent review<sup>[12]</sup> recommended that management should include medical conservative therapy, endoscopic therapy, interventional therapy, surgical shunt or liver transplantation. Similar to variceal bleeding from the esophageal-gastric region, sclerotherapy or band ligation of the varices are theoretically feasible. However, because of potential necrosis and perforation following sclerotherapy, and a high risk of massive hemorrhage following sloughing of the occluded varices after band ligation, and persistence of portal hypertension, the results of this treatment modality were disappointing<sup>[13]</sup>, especially in stomal variceal bleeding<sup>[11]</sup>. Our patient was treated with ectopic varices suture ligation, however, bleeding did not stop. As transjugular intrahepatic porto-systemic shunt (TIPS) alone or in combination with variceal embolization has demonstrated effectiveness for the hemostasis of ectopic variceal bleeding in patients with portal hypertension in some studies<sup>[14,15]</sup>, it seemed appropriate that our patient should be treated with this modality. However, the current common understanding of TIPS shunt creation for hemostasis is that it increases the incidence of hepatic encephalopathy and damages liver function. Our patient had a history of recurrent hepatic encephalopathy, thus, the TIPS shunt was not applicable in this patient. Surgical shunts have been shown to be effective in preventing hemorrhage recurrence, but are associated with mortality ranging from 1% to 50%, and many patients are not healthy enough to endure the operation<sup>[11]</sup>. Our patient had hemorrhagic shock, therefore it was clearly unwise to choose this treatment modality. Thus, embolization of the ectopic varices was the best choice for this patient. Usually, varices embolization can be managed *via* the percutaneous transhepatic<sup>[16-18]</sup> or transjugular transhepatic route<sup>[4]</sup>. Hemoperitoneum is the most common complication of percutaneous transhepatic embolization<sup>[18]</sup>, other complications include bile leak, liver trauma, and portal thrombosis<sup>[17]</sup>. As the patient had abundant ascites and we had successfully performed thousands of TIPS procedures, endovascular embolization of the stomal varices *via* the transjugular transhepatic route for hemostasis was the appropriate therapy in this case. The varices were occluded after the procedure and no complications occurred during the procedure. No focal bleeding was observed after four months of follow-up.

In conclusion, although rare, when a patient with ileal conduit stoma presents with persistent stomal bleeding, ectopic variceal bleeding from the ileal conduit should be considered. Endovascular embolization *via* the tran-

sjugular transhepatic approach is a reasonable choice in patients with stomal variceal bleeding which failed conservative therapy and local resuture, especially in an emergency situation.

### Abstract

Garcinia cambogia extract (GC) with its active component consisting of hydroxycitric acid (HCA) is widely utilized for weight loss. Various HCA salts are available, including calcium, magnesium, potassium and mixtures of these. Experimentally, these salts exhibit different properties with some, but not all, improving glucose tolerance and blood pressure. Recently, obesity-prone C57BL/6J mice were fed a high-fat diet (HFD, 45 kcal% fat) with or without GC (1%, w/w) for 16 wk. The active arm reduced visceral fat, adipocyte size and serum glucose, yet purportedly also exhibited hepatic collagen accumulation, lipid peroxidation and increased mRNA levels of genes related to oxidative stress. The latter findings are at odds with a large body of animal and human studies that have been conducted on the safety and efficacy of HCA. This literature shows HCA to be protective against the liver toxicity associated with ethanol and dexamethasone administration, and to maintain serum aspartate aminotransferase, alanine aminotransferase and alkaline phosphatase at near normal levels. In both animal and clinical literature, elevated intakes of HCA *per se* have not led to signs of inflammation or hepatotoxicity. The compound has

been found to reduce markers of inflammation in brain, intestines, kidney and serum.

**Key words:** Garcinia cambogia; Hepatic collagen; Hepatic inflammation; Hepatic oxidative stress; Hydroxycitric acid; Metabolic syndrome; Tumor necrosis factor- $\alpha$ ; Weight loss

**Core tip:** The preponderance of animal and human studies of Garcinia cambogia extract have found it to reduce markers of inflammation in brain, intestines, kidney and serum and to be either protective or neutral in terms of liver health. The limited reports of toxicities thus far have been linked to improperly manufactured materials and/or to peculiarities with the animal models used. The available data indicate that Garcinia cambogia extract/hydroxycitric acid does not cause liver toxicity.

Clouatre DL, Preuss HG. Hydroxycitric acid does not promote inflammation or liver toxicity. *World J Gastroenterol* 2013; 19(44): 8160-8162 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i44/8160.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i44.8160>

### TO THE EDITOR

Kim *et al*<sup>[1]</sup> recently reported that a Garcinia cambogia extract (GC, 1%, w/w) fed to C57BL/6J mice in conjunction with a high-fat diet (HFD, 45 kcal% fat) for 16 wk protected against “HFD-induced obesity by modulating adipose fatty acid synthesis and  $\beta$ -oxidation but induces hepatic fibrosis, inflammation and oxidative stress<sup>[1]</sup>.” A review of this article in light of other published research on (-)-hydroxycitric acid (HCA), the active component in GC, raises a number of questions. The most significant

are these: what was the form of HCA used (not indicated) and is the toxicity reported induced by HCA *per se* or, instead, was it caused by the source of HCA/GC tested? These issues are particularly acute inasmuch as the results of Kim *et al*<sup>[1]</sup> are at variance with numerous published studies involving both animals and humans, several of which indicate that HCA actually exerts a protective effect upon the liver.

Differences among various sources of HCA can be quite significant, yet against copious evidence, it too often is assumed that all sources of HCA are the same in terms of physiology. In the study in question, the tested compound is not fully identified. The only information provided is that the tested compound provided “1%, w/w, 60% hydroxyl citric acid” and was provided by Newtree Inc. of the United States (although Newtree appears to be a South Korean company). Whether this material was stabilized with calcium, potassium, sodium, *etc.* or some mixture of these is not revealed. Similarly, no information is provided on the free acid or lactone content, whether the extraction process is novel or established, the amount of residual toxins, such as chloride ion, left in the extract, and so forth and so on. For instance, some HCA calcium salts contain up to approximately six percent halogenated compounds due to improper processing of starting materials that had been dried with the help of sodium chloride—is the material used by Kim *et al*<sup>[1]</sup> one of these?

That the nature of the HCA-containing source is important was made clear years ago in a critical analysis of another study that purported to demonstrate toxicity, in that particular case, testicular toxicity, at high dosages. This was a study by Saito *et al*<sup>[2]</sup>. When examined closely by Burdock *et al*<sup>[3]</sup>, it was determined that the HCA salt tested was very unusual in that it contained a high lactone content and that the weight loss results were not typical of literature on HCA. In this case, the particular animal model also turned out to have been inappropriately chosen. Hence, in an instance of supposed testicular toxicity, there were unacceptable levels of uncertainty about the compound being tested. Moreover, various aspects of the study design and its assumptions proved to be questionable.

Kim *et al*<sup>[1]</sup> remind the reader of the “potential for hepatotoxicity of hydroxycut, a formulation that contains GC among other ingredients<sup>[1]</sup>.” Not mentioned is the fact that after almost two decades of free sale of HCA products, there appear to be no reports of human liver toxicity aside from those involving Hydroxycut and only 8 out of 14 of the Hydroxycut formulas associated with liver toxicity even contained HCA/GC! The safety, including liver safety, of HCA as relates to Hydroxycut and other products was evaluated at length by Stohs *et al*<sup>[4]</sup> and no evidence of toxicity was found. In retrospect, the common denominator in these cases appears to be green tea extracts. Animal models have established the hepatotoxicity of high oral doses of (-)-epigallocatechin-3-gallate<sup>[5]</sup>. Reviews of human usage strongly suggest a causal association, albeit an idiosyncratic one, between green tea consumption and liver damage<sup>[6]</sup>. In contrast, quite a number of reviews

have affirmed that HCA is extremely safe. These include Chuah *et al*<sup>[7]</sup>, Márquez *et al*<sup>[8]</sup> and Stohs *et al*<sup>[9]</sup>.

Published studies involving both animal models and humans indicate that HCA *per se* is either neutral with regard to the liver or actively protective. For instance, GC in a rat model has been tested against toxic challenge to the liver by both ethanol and dexamethasone. Mahendran and Devi<sup>[10]</sup> demonstrated that GC supplementation was sufficient to prevent undesirable changes in the lipid profile on dexamethasone administration and also to protect normal liver phospholipid levels. Likewise, when rats were challenged with ethanol to induce peroxidation damage to the liver, Devi and Mahendran<sup>[11]</sup> found “co-treatment of the rats with *Garcinia cambogia* significantly inhibited the rise in lipid levels and also the peroxidative damage caused by ethanol, which is evident from the improved antioxidant status. The levels of serum aspartate aminotransferase (AST), alanine aminotransferase (ALT) and alkaline phosphatase were maintained at near normalcy in *Garcinia cambogia* treated rats”. Similar protection was provided by GC with regard to liver superoxide dismutase, catalase and various glutathione compounds.

The study of Clouatre and Preuss, which lasted eight weeks and involved high-fat/high-sugar diets in rats, found results that are in line with those of Mahendran and Devi<sup>[10-12]</sup>. In healthy and relatively young animals, HCA treatment compared with control led to strong trends towards reduced CRP and tumor necrosis factor- $\alpha$  without exerting significant effects on ALT and AST. These results are similar to those found in a formal safety assessment of a commercial potassium-calcium hydroxycitrate salt (60% HCA) by Soni *et al*<sup>[13]</sup>, which was designed, in part, specifically to look for potential hepatotoxicity. The gavage administration of this salt at doses up to 2500 mg/kg per day for a period of 90 d did not lead to any significant adverse effects, including in the histological examinations of the livers of the test and control arms. Given the high dosage of HCA and the time frame comparable to that of Kim *et al*<sup>[1]</sup>, the results of the study by Soni *et al*<sup>[13]</sup> in the rat rodent model clearly are at variance with the findings in the mouse model and in line with other research reports of HCA's safety. The human equivalent dosage of HCA in the Soni study is approximately 30 g in a 60 kg individual.

There have been at least four published studies of the safety of HCA in humans and these trials reached the same conclusion confirming the safety of the oral consumption of HCA salts. The studies are those of Hayamizu *et al*<sup>[14]</sup>, Hayamizu *et al*<sup>[15]</sup>, Ishii *et al*<sup>[16]</sup> and Hayamizu *et al*<sup>[17]</sup>. None of these studies found any significant adverse effects on the liver. Hayamizu *et al*<sup>[14]</sup> in a study lasting three months, but involving only 1000 mg HCA per day (*i.e.*, 1666 mg of a 60% salt) found no significant change in any liver parameter. Hayamizu *et al*<sup>[16]</sup> found no observed adverse effects 4000 mg HCA per day for ten days and Hayamizu *et al*<sup>[17]</sup> found no adverse effects at 3000 mg HCA for 30 d.

Finally, the issue of GC and inflammation needs to be

addressed more generally. Clouatre *et al*<sup>[18]</sup> were the first researchers to discover that HCA consumption relieves a number of markers of inflammation and this information was confirmed in Clouatre *et al*<sup>[12]</sup>. A number of recent studies now have established these findings regarding HCA and inflammation. A study using rats performed by dos Reis *et al*<sup>[19]</sup> found that the “antiinflammatory effects provided by the *Garcinia cambogia* extract result in an improvement of several parameters analysed (sic) in experimental colitis and could provide a source for the search for new antiinflammatory compounds useful in inflammatory bowel disease treatment.” Similar protective effects have been found by Amin *et al*<sup>[20]</sup> in relation to a high fat diet, metabolic disturbances and brain oxidative dysfunction and by Amin *et al*<sup>[21]</sup> in relation to renal oxidative stress on a high fat and high sucrose diet.

found in industrialized countries. At present only a minority of CRCs are characterized by a strong genotype-to-phenotype relation. This is due to several additional factors determining phenotype expression. In conclusion, molecular characterization (genotype) is essential to interpret the histological findings (phenotype) and to identify prognostic groups as well as patients for targeted therapy.

Kaemmerer E, Klaus C, Jeon MK, Gassler N. Molecular classification of colorectal carcinomas: The genotype-to-phenotype relation. *World J Gastroenterol* 2013; 19(45): 8163-8167 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i45/8163.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i45.8163>

### Abstract

Colorectal carcinomas (CRCs) are frequently found in industrialized countries and lead to a high incidence of malignancy-related mortality. Defined by histomorphological features, CRCs and their pre-invasive lesions are quite heterogeneous. The underlying molecular mechanisms include genomic instability, genomic mutation of tumor suppressor genes or oncogenes, epigenetic changes, and the microRNA network. The molecular mechanisms are guided by repeated clonal selections. The genotype-to-phenotype relation is assumed to be the great challenge of cancer research and the development of effective targeted therapies. At present a strong genotype-to-phenotype relation is characterized only for a minority of CRCs. Consequently, the molecular characterization of CRCs is essential to interpret histological patterns and to identify prognostic groups as well as patients for targeted therapy.

**Core tip:** Colorectal carcinomas (CRCs) are frequently

### INTRODUCTION

Colorectal carcinoma (CRC) is frequently found in industrialized countries and is a leading cause of cancer-related death<sup>[1]</sup>. It is suggested by several studies that the genotype-to-phenotype relation remains the great challenge of basic cancer research<sup>[2,3]</sup>. The important development of DNA sequencing technologies enables clinicians and scientists to perform assessment through to full mutation analysis of CRCs. This approach makes it clear that the number of genetic aberrations in tumor cells is highly variable, including tumors with more than 80 mutations as well as carcinomas harboring fewer than 10 mutations<sup>[4,5]</sup>. However, in addition to cancer-related mutations, several other genetic and epigenetic mechanisms contribute to CRC heterogeneity. This point of view implies that the genotype-to-phenotype relation is more complex than previously assumed and is not only founded by mutations. The basic molecular events determining and guiding development of histologically defined CRC phenotypes (adenocarcinomas and non-glandular variants classified by the World Health Organization) are not elucidated. At present, several histomorphological tu-

mor variants can be distinguished, but specific molecular characteristics reflecting the histotype only exist in small subgroups. For example, microsatellite instability (MSI) is frequently found in mucinous adenocarcinomas and some signet ring cell carcinomas, but not in all tumors of these classes. In addition, microsatellite stability and cytosine-phosphate-guanine (CpG) island hypermethylation are usually, but not always, found in intestinal cribriform comedo-type adenocarcinomas. Because of the molecular heterogeneity of CRCs, identification of basic principles of carcinogenesis has been studied in hereditary CRCs where distinct molecular events were characterized. Familial adenomatous polyposis and hereditary non-polyposis colon cancer (HNPCC) are the most important syndromes that account for the vast majority of hereditary CRCs.

At present, the combination of multiple genetic alterations and clonal selections modified by lifestyle and environmental factors is recognized as the driving force in colorectal carcinogenesis<sup>[6]</sup>. The imbalance between mutation development and cell-cycle control further contributes to tumor development. In the review, major classes of molecular events targeting colorectal carcinogenesis are detailed concerning the genotype-to-phenotype relation.

## GENOMIC INSTABILITY

Genomic instability (GIN) is determined by separate molecular phenomena and describes loss of mutation control by the cell-cycle<sup>[1]</sup>. The important molecular events/pathways of GIN are chromosomal instability (CIN), CpG island methylator phenotype (CIMP), and MSI. In the following, these main pathways are further detailed.

### CIN

The molecular mechanisms underlying CIN, the most common type of GIN, include chromosome rearrangements, sequence changes, chromosomal number alterations, and chromosomal segregation defects. Loss of 18q with the deletion of genes such as *SMAD2*, *SMAD4*, or *DCC*, which is found in up to 70% of primary CRCs, is a common molecular finding in CIN-related tumors<sup>[7]</sup>. The carcinomas almost always have a mutation in the *APC*, while *KRAS* mutations occur in about 50%. CIN-related molecular lesions are found in dysplastic crypt foci. However, it has not been clear up to now whether CIN is a cause or a consequence of malignant cell growth<sup>[1,7]</sup>. It is suggested that CIN acts as a molecular founder and promoter of neoplastic growth.

CIN-related CRCs demonstrate no characteristic histomorphological pattern. They differ in tumor grading, occurrence of necrosis, and accumulation of extracellular mucin. The putative molecular founder event/mutation for the intestinal phenotype of CRCs has not been characterized up to now.

### MSI

MSI is found in up to 15% of so-called sporadic CRCs

and in almost all HNPCC (Lynch syndrome) associated CRCs due to either somatic inactivation of both alleles or an inherited germline mutation to one allele with additional somatic inactivation of the other<sup>[8]</sup>. A mismatch repair function usually corrects deletion/insertion errors during DNA replication. In MSI, sequence corrections resulting in alleles of varying length are not performed. The differences in length are diagnostic in PCR-based strategies using consensus primer panels. In standardized panels for MSI testing, two mononucleotides (BAT25 and BAT26) and three dinucleotide microsatellites (D5S346, D2S123, D17S250) were used<sup>[9]</sup>. MSI CRCs are not usually associated with mutations in *KRAS* or *TP53*. However, genes containing simple repeats such as *EGFR*, *BAX*, and *TGFβRII* are often mutated in these tumors. The *BRAF* status is another variable in MSI CRCs and a prognostic factor. Disease-free survival and overall survival are significantly improved in patients with MSI and non-mutated *BRAF*<sup>[10]</sup>. MSI CRCs do not have chromosomal abnormalities.

On microscopic examination, MSI CRCs are often poorly differentiated, containing mucinous components, have intratumoral lymphocytes, displaying Crohn's like inflammatory response near to the tumor edge, and are plump infiltrative. These morphological features are variably expressed and sometimes absent in MSI CRCs.

### CIMP

The CIMP was originally grouped together with MSI tumors. The islands are CpG rich regions within the genome and especially found in promoter sequences. In carcinogenesis, methylation of CpG islands (so-called type C methylation) leads to transcriptional silencing of genes involved in tumor suppression, apoptosis, DNA repair, and cell-cycle control<sup>[11]</sup>. Genes that are frequently affected by this non-covalent epigenetic modification are *p16*, *MGMT*, and *bMLH1*. The age-related methylation of genes is designated as type A methylation. Based on molecular data, different subgroups of CIMP CRCs are defined. CIMP1 includes carcinomas with frequent MSI and *BRAF* mutation, whereas CIMP2 refers to microsatellite stable carcinomas with a high frequency of *KRAS* mutations. Microsatellite stable carcinomas with frequent *TP53* mutations are commonly CIMP negative<sup>[12]</sup>.

Clinically, CIMP CRCs are commonly found in a proximal location and often have methylation of the *bMLH1* mismatch repair gene. However, over 50% of the CIMP CRCs are microsatellite stable. In general, CIMP CRCs have a poor prognosis and are associated with mutations in *KRAS* and/or *BRAF*. The histological phenotype of CIMP CRCs is not well characterized or defined. In these carcinomas a poor degree of histomorphological differentiation is frequently found reflecting some aspects of MSI. However, despite methylation of the *bMLH1* mismatch repair gene, histomorphological MSI-related histological features are not fully expressed in CIMP CRCs.

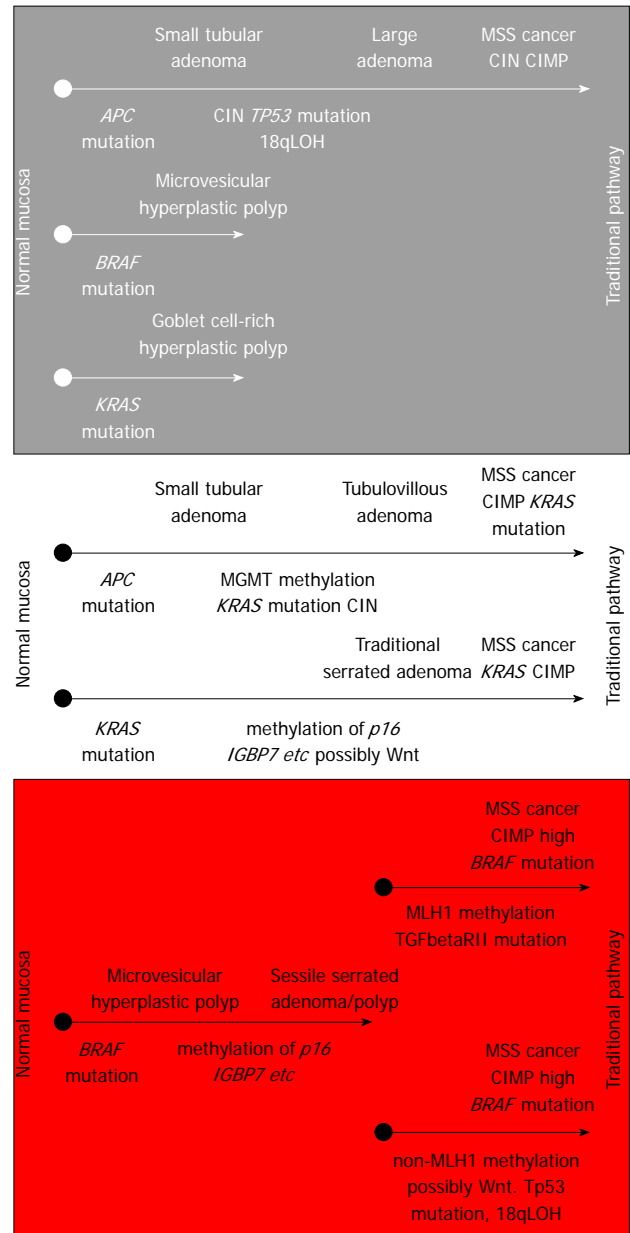

## SERRATED NEOPLASTIC PATHWAY

It has been recognized that about 20% of CRCs arise from a distinct pathway including special molecular and histomorphological features<sup>[1]</sup>. The so-called serrated pathway is associated with a sequence of genetic and epigenetic alterations. Activating mutations of the *BRAF* gene, coding a pro-proliferative, anti-apoptotic serine-threonine kinase, are an early event. The anti-apoptotic *BRAF* function and probably additional failures in the apoptotic pathway of enterocytes are assumed to be crucial in the establishment of serration, where an accumulation of cells is found. The *BRAF* associated proliferative burst is probably followed by up-regulation of *p16INK4a*, acting as a tumor suppressor, and increased secretion of an insulin-like, growth-factor-binding protein 7 (IGFBP7). Silencing of either *p16INK4a* or *IGFBP7* CIMP sensible cells *via* methylation is proposed as essential in the progression to sessile serrated adenoma/polyp (SSA/P)<sup>[13]</sup>.

The phenotypes of serrated polyps vary considerably and the entity mixed polyp reflects the considerable overlap among these lesions<sup>[14]</sup>. SSA/P constitutes about 20% of all serrated polyps and is morphologically defined by the elongation of serrated crypts and distortion of the proliferative zone<sup>[15]</sup>. Several crypts display a dilated, L-shaped, inverted T-shaped or anchor-shaped morphology with excess serration at the crypt base. Progression of SSA/P is associated with the occurrence of cytological dysplasia and development of invasive adenocarcinoma. SSA/P and related adenocarcinomas are preferentially found in the right hemicolon.

Traditional serrated adenomas (TSA) are morphological variants of serrated adenomas and show considerable differences from SSA/P concerning mutation (*KRAS* mutation in about 25%), localization (left-sided), and methylation status (increased methylation, but not methylation of *MLH1*)<sup>[16]</sup>. In terms of histomorphology, TSAs display an overall complex, often filiform configuration with tall columnar cells, eosinophilic cytoplasm, a centrally placed, elongated, hyperchromatic nucleus, and the formation of so-called ectopic crypts (the relationship of crypts with the adjacent muscularis mucosae is not preserved). The filiform serrated adenoma may represent a TSA subset. Conventional adenomas with serrated architecture are defined as an additional subgroup in the alternative serrated neoplastic pathway<sup>[1]</sup>. These morphologically defined entities are reflected by molecular findings and the model of an alternate pathway in colorectal carcinogenesis<sup>[13]</sup>. Important pathways in colorectal carcinogenesis are summarized in Figure 1.

Given the malignant potential of serrated polyps, two important serrated pathways of colorectal carcinogenesis were characterized: (1) sessile serrated pathway; and (2) traditional serrated pathway. The resulting serrated adenocarcinoma has architectural similarity to a SSA/P that may be accompanied by additional morphological features including trabecular and mucinous areas. However, these CRCs can have *MSI-L* or *MSI-H*, *BRAF*- or *KRAS*-

**Figure 1** Three important molecular pathways in colorectal carcinogenesis are characterized at present. In these models only a basal genotype-to-phenotype relation is given. CIN: Chromosomal instability; CIMP: Cytosine-phosphate-guanine island methylator phenotype.

mutations, and CIMP<sup>[13,14]</sup>. Given the molecular heterogeneity of serrated adenocarcinomas, a strong genotype-to-phenotype relation is not well established at present.

## ADDITIVE MOLECULAR PATHWAYS

In addition to the molecular mechanisms and pathways in colorectal carcinogenesis detailed above, several other molecular events have been characterized<sup>[1]</sup>. These molecular lesions include mutational inactivation of tumor suppressor genes such as *APC*, *TP53*, and *TGF-beta*, activation of oncogene pathways driven by the RAS-RAF-MAPK or the PI3K-Akt signaling, injury of the miRNA network (common changes in CRCs are: up-regulation

of miR-31, miR-183, and miR-17-5; down-regulation of miR-143, and miR-145), and epigenetic changes such as histone modification<sup>[1,17-19]</sup>. Experimental data describing and characterizing the molecular network behind colorectal carcinogenesis are continuously growing and should give more insight into the genotype-to-phenotype relation.

## CONCLUSION

CRC is a heterogeneous disease and a leading cause of cancer-related mortality. At present, a strong genotype-to-phenotype relation, which is assumed to be the great challenge of cancer research and the development of effective targeted therapies, is only defined in a small number of CRC variants. Nevertheless, the molecular understanding of key events and modifying pathways in colorectal carcinogenesis has been essentially improved through CRC classification and therapeutic regimes in molecular terms. However, the scientific progress in the molecular understanding of CRCs calls the paradigm of a strong genotype-to-phenotype relation into question. Factors that govern the expression of pathogenic mutations include genomic aberration in a heterozygote background, the network of products from mutant and wild type genes, and environmental factors. In summary, the molecular characterization of CRCs is essential to interpret histological patterns and to identify prognostic groups as well as patients for targeted therapy.

## ACKNOWLEDGMENTS

We would like to thank Akens P for her help in typing and proofreading the manuscript.

some regimens are limited by their use in very small geographic districts. Moreover, not all therapeutic trials have considered bacterial and host factors affecting the therapeutic outcome. The additional use of probiotics may help to reduce adverse events, but their therapeutic impact is doubtful. In conclusion, the "ideal therapy", paradoxically, appears to be a "utopia", despite the unprecedented volume of studies in the field and the real breakthrough in medical practice made by the discovery and treatment of *H. pylori*. The ample discrepancies observed in the different areas do not encourage the development of therapeutic guidelines that could be valid worldwide. On these bases, one of the main challenges for the future might be identifying a successful solution to overcome antibiotic resistances. In this context, geography must be considered a relevant matter.

**Key words:** *Helicobacter pylori*; Antibiotic resistance; Geography; Therapeutic regimens; Therapeutic outcome

**Core tip:** The present topic outlines the main data regarding antibiotic resistances, paying particular attention to the discrepant results obtained in different geographic areas worldwide, and even in the same districts. Discordances between *in vitro* and *in vivo* studies are detailed and the possible factors explaining this phenomenon are analyzed. Finally, the challenge for the future of devising a successful solution to overcome antibiotic resistances is highlighted, and geography is suggested as a relevant matter.

## Abstract

Therapeutic management of *Helicobacter pylori* (*H. pylori*) remains an unsolved issue. Indeed, no therapeutic regimen is able to cure the infection in all treated patients, and in many the infection persists despite the administration of several consecutive standard therapies. Although antibiotic resistance reports describe alarming results, the outcome of therapeutic regimens does not seem to parallel this scenario in most cases, since a successful performance is often reached in more than 80% of cases. However, the phenomenon of increasing antibiotic resistance is being closely studied, and the results show controversial aspects even in the same geographic area. For the continents of Europe, America, Asia, Africa, and Oceania, minimal and maximal values of resistance to the main antibiotics (clarithromycin, amoxicillin, metronidazole, and levofloxacin) feature wide ranges in different countries. The real enigma is therefore linked to the several different therapeutic regimens, which show results that often do not parallel the *in vitro* findings even in the same areas. A first aspect to be emphasized is that

Ierardi E, Giorgio F, Losurdo G, Di Leo A, Principi M. How antibiotic resistances could change *Helicobacter pylori* treatment: A matter of geography? *World J Gastroenterol* 2013;

## INTRODUCTION

*Helicobacter pylori* (*H. pylori*) eradication has undoubted benefits. The bacterium's diffusion worldwide, even if it is decreasing, especially in developed countries, still dictates the treatment of all infected subjects, and the possible legal implications that denial of treatment could have must also be considered. In Table 1, epidemiological studies of the last five years from five continents of the world (Europe, America, Asia, Africa, and Oceania) are reported<sup>[1-14]</sup>. Different infection rates depend on the type of study population (pediatric, adult, or geriatric patients), since increasing age, as well as poor hygienic environmental factors, are well known to have a strong influence. Arresting the bacterium's diffusion still has not been achieved.

Treatment of the infection nowadays is both a simple and, at the same time, complex problem. Alongside the conventional first-line regimen (triple therapy), others have been proposed (sequential, concomitant, quadruple, and miscellaneous) to face the growing problem of antibiotic resistance. For no other infection have so large a number of therapeutic proposals been reported by different working groups. The results, however, often appear conflicting and the same regimen may be extremely effective in one geographic area and deliver disappointing results in another. Finally, although many experts believe that there is no such thing as untreatable *H. pylori*, only ill-treated *H. pylori*, no clinical trial has yielded a successful 100% eradication. We must therefore conclude that "the infallible therapy" does not exist at present. Therefore, the aim of this review is to analyze the different results of therapeutic schemes in different geographic regions, as well as their relationship with the diffusion of antibiotic resistances in the same areas.

## ANTIBIOTIC RESISTANCES

*H. pylori* antibiotic resistances are defined as primary (no previous treatment for bacterium eradication) and secondary (a susceptible strain acquires resistance during a treatment)<sup>[15]</sup>. The main reason for this phenomenon is point mutations of *H. pylori* DNA, often associated with inappropriate antibiotic use<sup>[15]</sup>. Heteroresistance is a condition characterized by the coexistence of susceptible and resistant strains in the same patient. Resistances are currently detected by culture-based and molecular methods. Different tests for both techniques have been described. The main culture-based techniques are the agar dilution method, *E*-test, breakpoint susceptibility test, and modified disk diffusion method. Molecular techniques include polymerase chain reaction (PCR), restriction fragment length polymorphism, allele-specific

PCR, sequencing, real-time PCR, and fluorescent *in situ* hybridization<sup>[16-22]</sup>. Although these tests require sophisticated tools, their performance before starting a treatment for *H. pylori* will undoubtedly significantly improve the therapeutic outcome. However, this strategy is hard to apply in clinical practice owing to the long period necessary before obtaining results, as well as the high costs of routine performance of such methods.

## GEOGRAPHIC DIFFERENCES IN ANTIBIOTIC RESISTANCES

A large number of reports from different geographic areas are available in the literature, showing heterogeneous results. Firstly, we will consider the geographic rates of resistance to each antibiotic, thus underlining differences and consequent clinical implications.

### Clarithromycin

Clarithromycin is a drug that belongs to the macrolide family, and its mechanism of action is the inhibition of protein synthesis by binding and slowing down the activity of the bacterial ribosomal unit<sup>[23]</sup>. The mutations that may cause resistances are point mutations in the 23S rRNA component of ribosomes<sup>[24]</sup>: the three most frequent mutations that may occur are A2143G, A2142G, and A2142C, which are responsible for 90% of cases of primary clarithromycin resistance in *H. pylori* strains isolated in Western countries<sup>[25,26]</sup>. In particular, the A2143G mutation has a much stronger impact on conferring resistance than the other two<sup>[27]</sup>. In Eastern countries (*e.g.*, South Korea) additional mutations, such as T2183C and A2223G, have been frequently found to justify the observed clarithromycin resistance, while A2143G accounted only for 23% of resistant strains<sup>[26]</sup>. This finding, if confirmed in other Asian countries, suggests that point mutations inducing clarithromycin resistance might differ in this continent as compared to those in Europe and North America. In conclusion, resistance to clarithromycin is considered as the cause of most eradication regimen failures<sup>[28]</sup>, as its prevalence is continuously increasing. Moreover, new point mutations have also emerged in South America<sup>[29]</sup>. However, isolated reports may not reflect the real scenario; therefore, it would be more useful to consider epidemiological data about resistance region by region.

In Eastern Asian countries, very high clarithromycin resistances have been recorded. The highest rate of resistance was found in Japan (86.4%) in a study on the efficacy of this antibiotic in a third line regimen<sup>[30]</sup>. Interestingly, in the same country, a lower percentage of 15.2% was detected in another study of first line therapy<sup>[31]</sup>. In any case, in every region of the Far East, the rates of resistance were at least 15%, a percentage that often determines the failure of clarithromycin-based therapy. In another two Japanese studies the rates were 32.4%<sup>[32]</sup> and 18.9%<sup>[33]</sup>, respectively. In China, resistances ranged between 21.5% and 23.8%<sup>[34,35]</sup>, while in Viet-

Oceania				
Australia	Pandeya <i>et al</i> <sup>[13]</sup> , 2011	15.5%	Serology	Combined data
New Zealand	Fawcett <i>et al</i> <sup>[14]</sup> , 2005	6.2%	Serology	Children, adolescents

nam they were considerably higher (33%)<sup>[36]</sup>. A South Korean study revealed, in a pediatric population, tripled resistance rates within 20 years. Surprisingly, a Malaysian study carried out on 90 gastric samples did not show any strain resistant to clarithromycin: this is the only discordant value in this geographical area<sup>[37]</sup>.

A similar pattern is observed in the Near East, where the percentages range between 14.3% (Iran)<sup>[38]</sup> and 37% (Pakistan)<sup>[39]</sup>. Interestingly, it is noticeable that in the same area, another study found a much lower resistance (17.1%)<sup>[40]</sup>, emphasizing that even in the same geographical region, relevant differences may occur.

In Southern America, the most recent studies report a resistance rate that ranges between 13.6% and 19.5%, illustrating a more homogeneous distribution of resistant strains<sup>[41,42]</sup>. In the United States the continuous migration flows from Mexico and other Latin American countries are causing rapid changes in local *H. pylori* strains, as witnessed by the need for new regimens<sup>[43]</sup>. If we consider that in a 2011 randomized study the success rate of a therapy including levofloxacin, amoxicillin, and clarithromycin was only 73.3%<sup>[44]</sup>, whereas in 1995 a clarithromycin-based therapy achieved eradication in more than 90%<sup>[45]</sup>, this is a remarkable difference.

In Europe, there are ample variations between Northern Europe and Mediterranean countries, where the resistances to clarithromycin are considerably more widespread. Finland and Sweden recorded a rate of 2% and 1.5%<sup>[46,47]</sup>, respectively, whilst in Germany and Norway the rates were 7.5% and 5.9%, respectively<sup>[48,49]</sup>.

Resistance is higher in Central/Eastern Europe [9.3% (95%CI: 0-22)], and is at its highest in Southern Europe [18% (95%CI: 2.1-34.8)]<sup>[50]</sup>. In Italy, the trend is continually on the increase; while in the year 2000 the percentages ranged between 1.8% and 14%<sup>[51-53]</sup>, a few years later resistance had increased up to 24.1%, and will likely have

doubled within 15 years<sup>[54,55]</sup>. As in all of Europe, primary clarithromycin resistance in Italy is highly variable in different geographic areas: 0%-6% in the north, 7%-15% in central areas, and 10%-25% in the south<sup>[56]</sup>. Other Mediterranean countries with high rates of clarithromycin resistance are Greece (40%), Spain (15%-20%), France (17.5%), and Portugal (34.7%)<sup>[57-60]</sup>. In Eastern Europe, the situation is similar to that in Southern Europe; several Bulgarian studies have reported a resistance rate of 18.4%-23.4%<sup>[13,61,62]</sup>. An isolated phenomenon has been observed in Poland; in 2013, resistance is around 22%, with a trend toward a perceptible decrease (it was 34% in 2008)<sup>[63]</sup>. Another strong diffusion of resistant strains has been shown in Lithuania (24.7%)<sup>[64]</sup>.

In Oceania, resistance rates range between 8.7%<sup>[65]</sup> and 15.7%<sup>[66]</sup>, suggesting that there is still a fair option for the use of the antibiotic in those areas.

Finally, the main data about the prevalence of resistance to clarithromycin in Africa show very low values in Gambia and Senegal (0% and 1%, respectively)<sup>[67,68]</sup>, but not in South Africa (15.3%)<sup>[69]</sup>.

### Metronidazole

Metronidazole is a nitroimidazole antibiotic used particularly against anaerobic bacteria and protozoa. It works as a pro-drug: it is non-enzymatically reduced by reacting with reduced ferredoxin, which is generated by pyruvate oxidoreductase, and then the reduced molecule is taken up into bacterial DNA and forms unstable molecules that cause the death of the organism<sup>[70]</sup>. The resistance mechanism to metronidazole is not entirely straightforward<sup>[71,72]</sup>. Clearly, alterations of the *rdxA* gene are of primary relevance, but it has not been possible to identify a clear panel of point mutations which could explain the phenomenon. Moreover, other genes such as *frxA* seem to be involved<sup>[73]</sup>.

Eastern Asian countries are the geographical area where it is possible to detect the highest percentages of resistance: 56.6%-95.4% in China<sup>[34,35]</sup>, 57% in Japan<sup>[30]</sup>, 27.3%-52.9% in South Korea<sup>[74,75]</sup>, 69.9% in Vietnam<sup>[36]</sup>, and 75.5% in Malaysia<sup>[37]</sup>. A very similar pattern has been detected in Africa, where the rates vary between 68.8% and 85%<sup>[67,68]</sup>. Indeed, it is well known that the prevalence is much higher in developing countries (50%-80%) like Mexico (76.3%)<sup>[76]</sup>, Colombia (75.5%)<sup>[41]</sup>, and Brazil (40%)<sup>[42]</sup>. In the Near East, a 69.5% resistance was reported in Saudi Arabia<sup>[77]</sup>, 64.5% in Pakistan<sup>[40]</sup>, and 76.8% in Iran<sup>[38]</sup>.

The scenario appears to be slightly different in Europe, where in a multicenter study the global resistance rate to metronidazole was 33.1% (95%CI: 7.5-58.9), with no significant difference between the north [33% (95%CI: 7.1-69.2)] and south [40.8% (95%CI: 27.3-54.3)], but with a significantly lower prevalence in central and eastern areas [29.2% (95%CI: 17.9-41.5)]<sup>[78]</sup>. However, this report was dated 2001, and in the last ten years the situation appears to have changed surprisingly, featuring a decreasing rate of resistance in northern countries (22.5% in Norway<sup>[49]</sup>, 1.1% in Lithuania<sup>[63]</sup>, 19.9% in the Netherlands<sup>[79]</sup>, and 13% in the United Kingdom<sup>[51]</sup>). In Southern and Central-Eastern Europe however, rates of resistance are much higher (34.9% in France<sup>[59]</sup>, 63.6% in Croatia<sup>[80]</sup>, 37.2% in Germany<sup>[48]</sup>, and 23.3% in Bulgaria<sup>[15]</sup>).

Several Italian studies<sup>[81]</sup> have described a resistance rate of 20%-23.9%<sup>[82-84]</sup>, but the resistant strain could be undergoing a dizzying growth, if we consider that only five years later a single group reported a more than doubled rate (59.3%)<sup>[85]</sup>.

In Oceania, three recent studies reported values of 20%<sup>[86]</sup>, 36%<sup>[87]</sup>, and 43.5%<sup>[65]</sup>, suggesting an overall high rate of resistances.

### Amoxicillin

Amoxicillin is a  $\beta$ -lactam antibiotic included in all current therapeutic regimens for *H. pylori* eradication<sup>[88]</sup>. Amoxicillin acts by interfering with peptidoglycan synthesis, in particular by blocking transporters named penicillin binding proteins<sup>[16]</sup>. This drug was the first antibiotic used for *H. pylori* therapy due to a presumed absence of resistance<sup>[89]</sup>. In almost all studies, percentages of resistance are quite low, and these data seem homogeneous worldwide. No resistances have been detected in Croatia, France, Germany, the Netherlands, Portugal, Spain, or Sweden<sup>[90-96]</sup>. In Italy, resistances range from 0% to 0.2%<sup>[97]</sup>, while in the United Kingdom they range from 0% to 0.4%<sup>[98,99]</sup>. Almost negligible resistances have also been reported in America and Oceania. Data in contrast with this trend have been described in Iran and Japan, with a resistance prevalence of 28.6%<sup>[38]</sup> and 8.2%-15.2%<sup>[30,33]</sup>, respectively. Surprisingly, an extremely high resistance rate (85.6%) has been observed in Cameroon<sup>[81]</sup>.

### Levofloxacin

Levofloxacin is a broad spectrum antibiotic of the

fluoroquinolone drug class which is active against both Gram-positive and Gram-negative bacteria<sup>[100,101]</sup>. It acts by inhibiting DNA gyrase, type II topoisomerase, and topoisomerase IV, an enzyme which is necessary to separate replicated DNA and block cell division<sup>[102]</sup>. Resistance of *H. pylori* to fluoroquinolones is due to point mutations in the quinolone resistance determining regions of gyrA<sup>[103]</sup>.

Levofloxacin has recently appeared in therapeutic regimens for *H. pylori* eradication: in the Maastricht-Florence IV consensus for *H. pylori* treatment, a levofloxacin-containing regimen was proposed as second-line treatment when classical first-line therapy containing clarithromycin failed<sup>[88]</sup>. However, in the last three years, resistant strains are increasing, because of plasmid-mediated horizontally transferable genes encoding quinolone resistance<sup>[104]</sup>, so that more and more levofloxacin-based treatments will likely be ineffective in the future.

An example of this unfavorable trend is evident in Asian countries, where the rates of resistance exceed 10%: 18.4% in Vietnam<sup>[36]</sup>, 20.6% in China<sup>[34]</sup>, and are as high as 63.3% in Pakistan<sup>[39]</sup>. Only Malaysia registered 0%<sup>[37]</sup>, although Japan was also low at 8.2%<sup>[30]</sup>.

In Europe, the overall resistance to levofloxacin, detected in a recent multicentric epidemiologic study, is 14.1%<sup>[105]</sup>, with values ranging between 11.7% in Ireland<sup>[106]</sup> and 29.1% in Germany<sup>[107]</sup>: these last percentages must set the clinician on guard, if we consider that only a few years before, in 2003, a resistance rate of 3.3% was detected in France<sup>[108]</sup>. In Italy, a single study found resistance in 10.6% of strains<sup>[81]</sup>, data confirmed by a recent overview that noted a rate of 11.8% in already treated patients<sup>[109]</sup>. In Africa, resistant strains are also not very widespread: 15% in Senegal and 10.2% in South Africa<sup>[68,69]</sup>.

In America, a rate of 19% was found in Alaska<sup>[110]</sup>, while in South America percentages are higher (23% in Brazil, where a clarithromycin resistance of only 8% means that this last drug is still a good therapeutic option)<sup>[111]</sup>. Surprisingly, no report about levofloxacin resistance in Oceania has yet been made, to the best of our knowledge.

### Other antibiotics

Resistance to tetracycline is very low, or even absent, in most countries. Very low rates have been reported in Spain (0.7%<sup>[95]</sup>), the United Kingdom (0.5%<sup>[98]</sup>), and Hong Kong (0.5%<sup>[112]</sup>). Values lower than 5% are recorded in Germany<sup>[48]</sup> and Lithuania<sup>[64]</sup>. The highest prevalence rates are found in Korea (5.3%<sup>[113]</sup>), Iran<sup>[38]</sup> (18.7%), and Vietnam<sup>[36]</sup> (5.8%). The resistance mechanism has been described as a change in three contiguous nucleotides in the 16S rRNA gene (AGA 926-928RTTC)<sup>[114,115]</sup>.

Rifabutin is a bactericidal antibiotic drug primarily used in the treatment of tuberculosis, and its effect on bacteria is based on DNA-dependent RNA polymerase blockage<sup>[116]</sup>. When it was firstly used in the late '90s, the prevalence of *H. pylori* resistance to this group of antibiotics was extremely low, as these drugs were used

Figure 1 Comparison of the minimal (A) and maximal (B) resistance rates reported in five world continents (Europe, America, Asia, Africa, and Oceania) for the main antibiotics used for *Helicobacter pylori* eradication (clarithromycin, amoxicillin, metronidazole, and levofloxacin).

only in a limited number of patients to treat mycobacterial infections. For example, Heep *et al.*<sup>[117]</sup> did not find a single resistant strain among 81 German patients tested in 1999, nor did Fujimura *et al.*<sup>[118]</sup> among 52 strains in Japan. Even today in some regions such as Brazil, Ireland, and Senegal, no resistant strain has been detected<sup>[42,68,106]</sup>, but data from Malaysia<sup>[37]</sup>, Germany<sup>[48]</sup>, and Iran<sup>[38]</sup> report a resistance rate of 2.2%, less than 5%, and 28.6%, respectively. Resistance is due to point mutations in the *rpoB* gene, as for other bacteria, and occurs in all rifamycin drugs, suggesting a potential risk of cross-resistances between antibiotics of the same family<sup>[119,120]</sup>.

Furazolidone is a nitrofurantoin antibiotic. As a veterinary medicine, it is used to treat salmonids for *Myxobolus cerebralis* infections. In the past, it has been used in humans to treat diarrhea and enteritis caused by bacteria or protozoan infections, but since 1991 it has been recognized by the FDA as a carcinogenic agent and so is no longer used, except in a few developing countries that allow its use for human diseases<sup>[121]</sup>. It was previously used to treat traveler's diarrhea, cholera, and bacteremic salmonellosis. Its use to treat *H. pylori* infections was also proposed<sup>[122]</sup>. Primary furazolidone resistance is rare. In Spain<sup>[123]</sup>, the rates were less than 2%, and in Bulgaria 1.8%<sup>[124]</sup>. Lower values have been described in China<sup>[34]</sup> (0.1%) and Brazil<sup>[42]</sup> (no resistant strains detected). A higher furazolidone resistance rate (9%) was found in Iranian children<sup>[125]</sup>. As the high cost of some drugs,

such as clarithromycin and quinolones, prevents their use in developing countries, where a high prevalence of primary metronidazole resistance is also present, to overcome these limitations, furazolidone-based treatments have been suggested. On the other hand, the low rate of primary *H. pylori* resistance to furazolidone in developed countries may make the use of this drug attractive. In this case, however, it is imperative to consider that furazolidone-based first-line therapy achieves *H. pylori* eradication rates of 75.7% and 79.6%<sup>[126]</sup>, and its use cannot ignore obvious ethical considerations in view of the carcinogenic evidence.

## ANTIBIOTIC RESISTANCES: A COMMENT ON THE DATA IN THE LITERATURE

Figure 1 illustrates the simultaneous minimal and maximal resistance rates in five world continents (Europe, America, Asia, Africa, and Oceania). It is evident that clarithromycin shows a good prospect of success in Africa, Oceania, and few Northern European countries (*e.g.*, Norway), whilst in Southern Europe (*e.g.*, Italy, Spain, Portugal, and Greece) and even South Africa, the risk of failure is high. Metronidazole might be very effective in Lithuania, but its use should be strongly discouraged in Italy and Croatia as well as most American, Asian, and African countries. Amoxicillin appears to be a reliable option in many countries, but it is almost ineffective in Iran and Cameroon. Finally, levofloxacin, which has been proposed as an alternative to clarithromycin in the areas where this last key antibiotic shows a high resistance rate, has been shown to be moderately ineffective worldwide, aside from Oceania, thus confirming the rapid trend toward therapeutic failure. Therefore, proposals for wider use could induce a counterproductive effect.

Among the other antibiotics, tetracycline and rifabutin appear to have low resistance rates, even if the use of the latter drug is limited by the regulations of many countries, where it is not indicated in *H. pylori* infection care, even apart from its high cost. Finally, furazolidone, despite its effectiveness, has been forbidden in many countries.

An obvious point is that, in each country, an ideal specific therapy should be identified. Nevertheless, all the studies on resistances *in vitro* might lack positive feedback *in vivo*. In fact, therapy failure may depend on several factors, of both bacterial and host origin. Not infrequently, different factors act simultaneously in reducing antibiotic therapy efficacy in the same patient. Indeed, a poor compliance to the *H. pylori* eradication regimen is inversely associated with the probability of therapeutic success. Unfortunately, the approved eradication regimens require the combination of 3-4 different drugs in multiple daily doses. Therapy regimen complexity and the onset of side effects are associated with reduced patient compliance. The *in vitro* activity of various antibiotics is greatly reduced or eliminated *in vivo* by the very low pH values encountered in gastric juices. This explains

the need to include a proton pump inhibitor in *H. pylori* eradication regimens. However, a significant variability in gastric acid secretion among different subjects has been reported. A small proportion of subjects show a higher basal acid output in association with normal gastrin values. These hyper-secretor subjects probably have a large parietal cell mass and a low eradication rate<sup>[127]</sup>.

These considerations may partially account for the wide discrepancies demonstrated between studies on resistances *in vitro* and the results of clinical trials *in vivo*. A final factor which might limit the reliability of *in vitro* resistance studies is the different methods used for detection. The methods are complex, expensive, and may often fail even in expert hands, and for this reason, their use is predominantly confined to research purposes.

## MAIN THERAPEUTIC REGIMEN EFFECTIVENESS

Triple therapy is one of the oldest schemes for *H. pylori* eradication. In Europe, it was used successfully in the United Kingdom until 5 years ago<sup>[128]</sup>, achieving an eradication rate of 92%. However, it is characterized by an enormous variability, if we consider the poor rate of 50% calculated in a German study in 2011<sup>[129]</sup>. The possibility of failure was very high in a Turkish study<sup>[130]</sup>, where only 32.7% of eradication occurred. In Asia, a high percentage of eradication was seen in India (82.9%)<sup>[131]</sup>, with a lower percentage in Korea (67.7%)<sup>[132]</sup>. In the American continent, eradication rates range from 78% to 97%<sup>[133,134]</sup>. Data from Africa are more homogeneous, but the weight of resistances affects the possibility of the eradication achieved in 71%-78.2% of cases, in a multicentric and in a Moroccan study, respectively<sup>[135,136]</sup>. The only recent available data from Oceania derive from two trials in which rifampicin was used instead of clarithromycin as second-line regimen, which achieved eradication rates of 95% and 96.6%, respectively<sup>[137,138]</sup>.

Quadruple therapy appears to be more effective than triple therapy, if we consider that in United States, Laine *et al.*<sup>[139]</sup> reported a success rate of 87.7%, and a lower value was seen only in a Canadian study<sup>[140]</sup> (70.8%). However, in Europe, failures are more frequent: quadruple therapy was effective only in 64.8% of cases in a Greek study<sup>[141]</sup>, despite a success rate of 91% in a British trial<sup>[128]</sup>. In Asian countries, the rates seem to be even more discouraging, ranging between 47.1% and 89.5% in Turkey<sup>[130]</sup> and China<sup>[142]</sup>, respectively. No data are available from Africa to the best of our knowledge. Only one Australian study investigated the effectiveness of quadruple therapy, but using a novel combination of a proton pump inhibitor, bismuth subcitrate, rifabutin, and ciprofloxacin as a first-line regimen for patients allergic to penicillin, and achieving an eradication rate of 94.2%<sup>[143]</sup>.

Concomitant therapy is a combination of antibiotics including amoxicillin, metronidazole, clarithromycin, and

a proton pump inhibitor (PPI) for a period of five or seven days. It has proven very effective in Japan, where an eradication rate of 98.1%<sup>[144]</sup> was achieved, but in South Korea the percentage was much lower (63.2%)<sup>[145]</sup>. In two different European studies, the same author reported the minimal and the maximal eradication rates of concomitant therapy as 85.5% and 95.5%, respectively<sup>[146,147]</sup>. In a multicentric Southern American study, this therapy achieved only 78.7% eradication<sup>[148]</sup>. We did not find any results from Africa for this regimen. No further data are available from Oceania.

Sequential therapy is a ten-day therapy that consists of a PPI plus amoxicillin in the first 5 d and a PPI, clarithromycin, and metronidazole in the following 5 d. In Italy it has proven to be very useful compared to other combinations<sup>[149]</sup>; it achieved eradication rates that range between 97.3% in a pediatric population<sup>[150]</sup>, 97% in an elderly population<sup>[151]</sup>, and 89% in a multicentric study involving more than 1000 patients<sup>[83]</sup>. The data from other European countries, however, are very poor. A good performance of this therapy was demonstrated in Africa, with a positive outcome ranging between 89.9% and 94.2%<sup>[136,152]</sup>. However, in South America this scheme appears to be less effective, if we consider the Peruvian percentage of success of 73%<sup>[153]</sup> and overall rate of 81.1%<sup>[148]</sup>. In Asia, a good result was achieved in South Korea<sup>[154]</sup> (92.6% maximum), whilst in China<sup>[155]</sup> only 78.3% eradicated the bacterium. No data are available from Oceania.

Miscellaneous therapy has been recently introduced and includes sequences of different combinations of antibiotics. The main four studies are from the four continents that show promising results: Colombia 94%<sup>[156]</sup>, Italy 85.7%<sup>[157]</sup>, Iran 92.9%<sup>[158]</sup>, and Taiwan 97.4%<sup>[159]</sup>. This regimen requires further confirmation of these excellent results, as well as an accurate evaluation of patient compliance owing to the risk of a large number of side effects and consequent drop-outs.

## THERAPEUTIC REGIMEN EFFECTIVENESS: A COMMENT ON THE DATA IN THE LITERATURE

Although resistance reports describe alarming results, the outcomes of therapeutic schemes do not seem to parallel this scenario in most cases, since a success of more than 80% is often reached. Despite some of the factors that may explain this discrepancy between *in vitro* and *in vivo* results that have been mentioned previously, it is possible that other factors may elucidate this controversial point: (1) most studies are performed in single centers and include populations selected from geographic areas of irrelevant dimensions. This may be an important handicap for the reproducibility of the therapeutic regimen in other areas; (2) the selection of patients is limited to bacterial positivity, often based on non-invasive tests, and does not take into account some bacterial

factors such as the intra-gastric load<sup>[160]</sup>, the possibility of primary resistances (which may even be different in the body and antrum of the same subject)<sup>[161]</sup>, heteroresistance status, and CagA status<sup>[162,163]</sup>. Finally, the presence of coccoid forms<sup>[164]</sup> in the stomach may have clinical relevance, due to the potential reactivation of *H. pylori* in its spiral form following therapy; (3) the results of therapeutic studies may be affected by host factors such as PPI metabolism<sup>[165]</sup>, parietal cell mass<sup>[166]</sup>, and related gastric pH, which is strictly related to antibiotic MIC values, the mucus layer (which affects bacterium/antibiotic contact), the frequent patchy distribution of *H. pylori* in the stomach, and even its persistence in small areas (*e.g.*, cardiac) after apparently successful eradication; and (4) the already outlined technical problems related to resistance detections *in vitro*.

## PROBIOTICS: HAVE THEY A ROLE IN *H. PYLORI* TREATMENT?

The possibility of probiotics interfering with *H. pylori* gastric colonization has been postulated by many authors and, therefore, many studies are available in the literature about the treatment of infected patients with beneficial bacteria supplementation. However, conflicting data have been obtained.

A review of available data showed that clinical trials can be divided into two groups: those using probiotics in association with antibiotic therapy and those using probiotics alone. In the first group, the efficacy of a single strain of probiotics associated with antibiotic triple or quadruple therapy generally resulted in a decrease of side effects such as diarrhea, bloating, nausea, and taste disturbances during treatment<sup>[167,168]</sup>, as well as an improvement of the eradication rate. Some studies have tested the association of a multi-strain probiotic mixture associated with antibiotic therapy. Two of these<sup>[169,170]</sup> showed a reduction in the side effects of antibiotic therapy and a higher eradication rate than that obtained with a single strain, whilst the third study<sup>[171]</sup> did not obtain any significant result.

Among the second group of clinical trials (only probiotics) we found that most studies tested a single probiotic strain, especially *Lactobacillus* species, obtaining a *H. pylori* load reduction as expressed by the urea breath test delta value. Experience by our group confirmed this finding after oral administration of *Lactobacillus reuteri* ATC 55730, not only with a delta value reduction, but also with a semiquantitative fecal antigen decrease<sup>[172]</sup>.

Recently, Szajewska *et al.*<sup>[173]</sup> reported a very interesting meta-analysis of the effects of *Saccharomyces boulardii* supplementation in standard triple therapy, showing a significant effect in both increasing the eradication rate and reducing side effects, in a total of 1307 patients from five randomized controlled trials.

## CONCLUSION

Therapeutic management of *H. pylori* remains an un-

solved issue. Indeed, no therapy regimen is able to cure the infection in all treated patients, and a definite number remain infected despite several consecutive standard therapies. This therapeutic failure is often considered to be the consequence of incorrect treatment rather than treatment limitation, since this appears unacceptable in the antibiotic era. However, no clinical trial has reported an eradication rate of 100% to the best of our knowledge.

Therapeutic failures are attributed to increasing antibiotic resistance. However, this phenomenon has been widely studied and the results show controversial findings even in the same geographic area. For each world continent, minimal and maximal values of resistance to different antibiotics have been reported for different countries, although some regimens appear to be almost unknown in some areas.

Another enigma is the outcomes of several different therapeutic schemes, which often do not parallel *in vitro* findings even in the same areas. Moreover, some schemes are limited by their use in very small geographic districts. Finally, not all therapeutic trials have considered bacterial and host factors affecting the therapeutic outcome.

In conclusion, the “ideal therapy”, paradoxically, appears to be a “utopia”, despite the unprecedented volume of studies in the field and the real breakthrough in medical practice made by the discovery and the treatment of *H. pylori*. A key point could be the possibility, in the near future, to group *in vivo* and *in vitro* studies by geographic areas in order to identify the best therapy, which is certainly related to the local habitat. Indeed, the ample discrepancies observed in the different areas do not encourage the development of therapeutic guidelines that could be valid worldwide. The main challenge for the future might be identifying a successful solution for overcoming antibiotic resistances and, in this context, geography must be considered a relevant matter.

## Abstract

Recent progress in the research regarding the molecular pathogenesis and management of gastric mucosa-associated lymphoid tissue (MALT) lymphoma is reviewed. In approximately 90% of cases, *Helicobacter pylori* (*H. pylori*) infection plays the causative role in the pathogenesis, and *H. pylori* eradication is nowadays the first-line treatment for this disease, which leads to complete disease remission in 50%-90% of cases. In *H. pylori*-dependent cases, microbe-generated immune responses, including interaction between B and T cells involving CD40 and CD40L co-stimulatory molecules, are considered to induce the development of MALT lymphoma. In *H. pylori*-independent cases, activation of the nuclear factor- $\kappa$ B pathway by oncogenic products of specific chromosomal translocations such as t(11;18)/API2-MALT1, or inactivation of tumor necrosis

factor alpha-induced protein 3 (A20) are considered to contribute to the lymphomagenesis. Recently, a large-scale Japanese multicenter study confirmed that the long-term clinical outcome of gastric MALT lymphoma after *H. pylori* eradication is excellent. Treatment modalities for patients not responding to *H. pylori* eradication include a "watch and wait" strategy, radiotherapy, chemotherapy, rituximab immunotherapy, and a combination of these. Because of the indolent behavior of MALT lymphoma, second-line treatment should be tailored in consideration of the clinical stage and extent of the disease in each patient.

## INTRODUCTION

Extranodal marginal zone lymphoma of mucosa-associated lymphoid tissue (MALT) lymphoma is an indolent non-Hodgkin lymphoma derived from marginal zone B-cells, which occurs in a number of extranodal organs, including the gastrointestinal tract, lung, salivary gland, thyroid, ocular adnexa, liver or skin<sup>[1]</sup>. Among these, the stomach is the most frequent site for MALT lymphoma. Gastric MALT lymphoma comprises 40%-50% of primary gastric lymphomas, 20%-40% of all extranodal lymphomas, 4%-9% of all non-Hodgkin lymphomas, and 1%-6% of all gastric malignancies<sup>[2-5]</sup>. *Helicobacter pylori* (*H. pylori*) plays a causative role in the development of gastric MALT lymphoma, and the eradication of *H. pylori* leads to a complete disease remission (CR) in 50%-90% of cases<sup>[6,7]</sup>.

In the present paper, we review the current knowledge on the etiology, diagnosis and optimal management strategies for patients with gastric MALT lymphoma, with special reference to its association with *H. pylori* infection and efficacy of the eradication therapy.

## PATHOGENESIS OF GASTRIC MALT LYMPHOMA

### *H. pylori*

A link of *H. pylori* with gastric MALT lymphoma was first suggested in 1991 by identification of the bacteria in the vast majority of patients<sup>[8]</sup>. This association was supported by subsequent epidemiological and histopathological studies<sup>[9,10]</sup>. Approximately 90% of patients with gastric MALT lymphoma are infected with *H. pylori*<sup>[7,11,12]</sup>, and about 70% of the cases respond to *H. pylori* eradication<sup>[6,7]</sup>. In such responders, survival of the lymphoma cells depends critically upon the microbe-generated immune responses<sup>[13]</sup>. Laboratory studies demonstrated that the growth of neoplastic B cells is stimulated by tumor-infiltrating *H. pylori*-specific T-cells, which require interaction between B and T cells involving CD40 and CD40L co-stimulatory molecules<sup>[14-19]</sup>. Thus, the genesis of *H. pylori*-dependent gastric MALT lymphoma is now considered as follows: an *H. pylori* infection results in T cell-dependent responses through the classic germinal center reaction, and thus generates reactive B and T cells. The *H. pylori*-specific T cells raised in the reactive component then migrate to the marginal zone/tumor area and provide non-cognate help to autoreactive neoplastic B cells, which may involve stimulation of CD40 and other surface receptors by soluble ligands and cytokines<sup>[13,19]</sup>.

Recently, Munari *et al.*<sup>[20]</sup> reported that high levels of a proliferation-inducing ligand (APRIL) were produced

exclusively by tumor-infiltrating macrophages in *H. pylori*-dependent gastric MALT lymphoma cases, and that macrophages produced APRIL on direct stimulation with both *H. pylori* and *H. pylori*-specific T cells. APRIL is a tumor necrosis factor (TNF) superfamily member known to be important for B-cell development, maturation and survival. It should be noted that APRIL-producing macrophages were dramatically reduced on lymphoma regression induced by *H. pylori* eradication<sup>[20]</sup>. These findings suggest that APRIL may also play some important role in the *H. pylori*-dependent lymphomagenesis.

### Genetic abnormalities

Genetic abnormalities are common in gastric MALT lymphomas. To date, a number of chromosomal translocations have been described in MALT lymphomas. Among these, t(11;18) (q21;q21)/*API2-MALT1*, t(1;14) (p22;q32)/*BCL10-IGH*, t(14;18) (q32;q21)/*IGH-MALT1* and t(3;14) (p13;q32)/*FOXP1-IGH* are replicable<sup>[11,13,21]</sup>. MALT1 and BCL10 proteins are involved in surface immune receptor-mediated activation of the nuclear factor kappa B (NF- $\kappa$ B) transcription factor; the chromosomal translocations involving these genes are believed to exert their oncogenic activities through constitutive activation of the NF- $\kappa$ B pathway, leading to expression of a number of genes important for cell survival and proliferation<sup>[21]</sup>.

In gastric MALT lymphoma, t(11;18)/*API2-MALT1* is the most frequent translocation, which is detected in 15%-24% of cases. The translocation fuses the N-terminal region of *API2* to the C-terminal region of *MALT1* and generates a functional chimeric fusion, which gains the ability to activate the NF- $\kappa$ B pathway<sup>[13,21]</sup>. Clinically, t(11;18) is more frequently associated with absence of *H. pylori* infection, and the majority of the translocation-positive cases do not respond to *H. pylori* eradication therapy<sup>[7,11,21,22]</sup>. Interestingly, t(11;18)-positive cases rarely transform to diffuse large B-cell lymphoma (DLBCL)<sup>[23]</sup>.

Recently, the TNF- $\alpha$ -induced protein 3 gene (*TNFAIP3*, *A20*), a negative regulator of NF- $\kappa$ B, was identified as the target of 6q23 deletion in many cases of MALT lymphoma<sup>[13,24,25]</sup>. *A20* mutation and deletion, which lead to A20 inactivation, are preferentially found in MALT lymphoma of the ocular adnexa, salivary glands, thyroid and liver. It is considered that A20-mediated oncogenic activities in MALT lymphoma depend on the NF- $\kappa$ B activation triggered by TNF or other unidentified molecules<sup>[13]</sup>. In gastric MALT lymphomas, however, *A20* deletion was detected only in 2 of 29 (7%) cases examined<sup>[25]</sup>. Thus, further investigations are needed to determine to what extent A20 inactivation contributes to the genesis of gastric MALT lymphoma.

## DIAGNOSIS OF GASTRIC MALT LYMPHOMA

### Histopathological diagnosis

The diagnosis of gastric MALT lymphoma should be

**Figure 1** Endoscopic images of gastric mucosa-associated lymphoid tissue lymphoma, superficial type. A, B: Pretreatment images; a superficially depressed lesion with multiple erosions and small ulcers with reddish granular mucosa can be seen on the posterior wall of the angularis; C: Follow-up image 6 mo after *H. pylori* eradication showing regression of the initial lesion.

**Table 1** Lugano staging system for gastrointestinal lymphomas

Stage	Definition	Description
Stage I	Tumor confined to gastrointestinal tract	Single primary site or multiple, non contiguous lesions
Stage II	Tumor extending into abdomen from primary gastrointestinal site	
	Nodal involvement	
	II <sub>1</sub> local	Paragastric (gastric cases) or paraintestinal (intestinal cases) nodal involvement
	II <sub>2</sub> distant	Mesenteric, paraaortic, paracaval, pelvic or inguinal nodal involvement
Stage II E	Penetration of serosa to involve adjacent organs or tissues	Gastrointestinal lesion extending to involve adjacent organs, <i>i.e.</i> , penetration, direct invasion, perforation or peritonitis by lymphoma
Stage IV	Disseminated extranodal involvement, or supra-diaphragmatic nodal involvement	Cases with Ann-Arbor stage III disease should be included

Rohatiner *et al.*<sup>[31]</sup> with modification.

based on the histopathological criteria according to the World Health Organization classification, using tissue specimens appropriately obtained by biopsy or surgery<sup>[1,5,26]</sup>. Histologically, the small to medium-sized neoplastic lymphoid cells (centrocyte-like cells) infiltrate around reactive follicles showing marginal zone growth pattern, which often infiltrate into gastric glands causing destruction of the epithelial cells (lymphoepithelial lesions)<sup>[1,26]</sup>. Immunohistochemically, the neoplastic cells of MALT lymphoma are usually CD20<sup>+</sup>, CD79a<sup>+</sup>, CD5<sup>+</sup>, CD10<sup>+</sup>, CD23<sup>+</sup>, CD43<sup>+</sup>, cyclin D1<sup>+</sup>. Staining for Ki-67 may help in identifying components of DLBCL. Cytogenetic analyses using G-banding, reverse transcription-polymerase chain reaction and/or fluorescence *in situ* hybridization for t(11;18)/*API2-MALT1* or other chromosomal translocations are also useful for confirming the diagnosis<sup>[1,21,26]</sup>.

### Macroscopic diagnosis

The standard macroscopic classifications for gastric lymphomas have not been established. In Western countries, gastric B-cell lymphomas have been endoscopically classified either as ulcerative (34%-69%), mass/polypoid (26%-35%), diffusely infiltrating (15%-40%), or other types<sup>[27-29]</sup>. We previously reported that 197 Japanese cases of primary gastric B-cell lymphoma (MALT lymphomas

and DLBCLs) were macroscopically classified as superficial-spreading (46%), mass-forming (41%), diffuse-infiltrating (6%), or other types (8%)<sup>[30]</sup>. Importantly, the most frequent macroscopic type in gastric MALT lymphomas is superficial type (Figure 1), while that in gastric DLBCLs is mass/polypoid type<sup>[29,30]</sup>.

### Clinical staging

An appropriate clinical staging is mandatory in order to determine the optimal management for malignant lymphomas. For the staging classification in patients with gastric MALT lymphoma, the Ann Arbor staging system with its modifications by Musschoff and Radaszkiewicz (I<sub>1</sub>E, I<sub>2</sub>E, II<sub>1</sub>E, II<sub>2</sub>E, III E, or IV) was recommended in the consensus report of the EGILS (European Gastro-Intestinal Lymphoma Study) group<sup>[26]</sup>. To date, however, the Lugano International Conference (Blackledge) classification (I, II<sub>1</sub>, II<sub>2</sub>, II E, or IV) has been widely applied for the clinical staging in gastrointestinal lymphomas (Table 1)<sup>[31]</sup>. In addition to esophagogastroduodenoscopy, the following are recommended for the initial staging workup: physical examination (including peripheral lymph nodes and Waldeyer's ring), complete hematological biochemical examinations (including LDH and  $\beta$ 2-microglobulin), computerized tomography of abdomen and pelvis, and endoscopic ultrasonography<sup>[26]</sup>.

**Table 2** Groupe d'Etude des Lymphomes de l'Adulte histological grading system for post-treatment evaluation of gastric mucosa-associated lymphoid tissue lymphoma

Score	Lymphoid infiltrate	LEL	Stromal changes	Clinical significance
CR	Absent or scattered plasma cells and small lymphoid cells in the LP	Absent	Normal or empty LP and/or fibrosis	Complete remission
pMRP	Aggregates of lymphoid cells or lymphoid nodules in LP/MM and/or SM	Absent	Empty LP and/or fibrosis	Complete remission
rRD	Dense, diffuse or nodular extending around glands in the LP	Focal LEL or absent	Focal empty LP and/or fibrosis	Partial remission
NC	Dense, diffuse or nodular	Present, "may be absent"	No changes	Stable disease or progressive disease

Copie-Bergman *et al.*<sup>[34]</sup> with modification<sup>[26]</sup>. LEL: Lymphoepithelial lesions; LP: Lamina propria; MM: Muscularis propria; SM: Submucosa; CR: Complete histological response; pMRP: Probable minimal residual disease; rRD: Responding residual disease; NC: No change.

In our opinion, however, ileocolonoscopy, bone marrow aspiration or biopsy, and fluorine-18 fluorodeoxyglucose positron emission tomography should also be included. In addition, endoscopic examinations of the small bowel (balloon-assisted endoscopy or capsule endoscopy) can be considered<sup>[32]</sup>.

## TREATMENT FOR GASTRIC MALT LYMPHOMA

### *H. pylori* eradication

The first-line treatment of all gastric MALT lymphomas is *H. pylori* eradication therapy<sup>[1,26,33]</sup>. In patients with stage I / II<sub>1</sub> disease, CR is achieved in 50%-90% of cases only by *H. pylori* eradication<sup>[6,7]</sup>. Histological evaluation of post-treatment biopsies should be performed according to the Groupe d'Etude des Lymphomes de l'Adulte (GELA) grading system (Table 2)<sup>[26,34]</sup>. Various predictive factors for resistance to *H. pylori* eradication therapy have been described, including absence of *H. pylori* infection, advanced stage, proximal location in the stomach, endoscopic non-superficial type, deep tumor invasion in the gastric wall, and t(11;18)/*API2-MALT1* translocation<sup>[6,7,21,22,26]</sup>.

In a systematic review of the data from 32 published studies that included 1408 patients with gastric MALT lymphoma, the CR rate after *H. pylori* eradication was 78%<sup>[6]</sup>. Recently, we confirmed excellent long-term outcomes of the disease after *H. pylori* eradication by a large-scale multicenter study of 420 Japanese patients with gastric MALT lymphoma<sup>[7]</sup>. In the study, CR was achieved by *H. pylori* eradication in 77% of patients. During the follow-up periods of up to 14.6 years (mean 6.5 years, median 6.04 years), treatment failure was observed in 9% of patients (37 patients; 10 relapse, 27 progression). Probabilities of freedom from treatment failure, overall survival and event-free survival after 10 years were 90%, 95% and 86%, respectively. Table 3 summarizes 28 previously published studies that included more than 20 patients initially treated by *H. pylori* eradication<sup>[7]</sup>. In the 28 studies, CR was achieved in 1361 of 1877 patients (73%), Progressive disease (PD) was observed in 17 of 1576 patients (1.1%), relapse was recorded in 60 of 1203 CR

patients (4.9%), and treatment failure (PD or relapse) was found in 118 of all 1877 patients (6.3%). These data are almost similar to those in our multicenter study<sup>[7]</sup>, except for PD rate (1.1% *vs* 6.4%).

As for the regimen for *H. pylori* eradication therapy, proton pump inhibitor (PPI) + clarithromycin-based triple therapy composed of a double dose of a PPI plus clarithromycin and amoxicillin or metronidazole for 7 or 14 d is recommended<sup>[26,35]</sup>. In the areas where the clarithromycin resistance rate exceeds 15%, use of this drug should be avoided without prior susceptibility testing<sup>[35]</sup>. A pooled data analysis in 1271 patients with gastric MALT lymphoma from 34 studies showed a successful eradication was achieved in 91% of cases after the first-line treatment, and the eradication rate was extended to 98% after the second-line treatment or more attempts<sup>[36]</sup>.

Several studies have demonstrated that *H. pylori* eradication therapy is also effective even in cases with gastric DLBCL<sup>[37,38]</sup>. In those reports, 27%-60% of *H. pylori*-positive patients with DLBCL in stage I / II<sub>1</sub> achieved CR after *H. pylori* eradication. Not only cases with MALT lymphoma component, but also cases without any evidence of MALT lymphoma responded to eradication therapy<sup>[37,38]</sup>. Therefore, *H. pylori* eradication should be tried in *H. pylori*-positive patients with gastric DLBCL.

### Treatments for patients not responding to *H. pylori* eradication

The management strategy for the patient with gastric MALT lymphoma who does not respond to *H. pylori* eradication still remains to be elucidated. While patients with PD or clinically evident relapse should undergo oncological treatment, for patients with persistent histological lymphoma without PD (responding residual disease or no change), a "watch and wait" strategy was recommended up to 24 mo after *H. pylori* eradication in the EGILS consensus report<sup>[26]</sup>.

As for the second-line oncological treatment, radiotherapy is highly effective in localized cases (stage I / II<sub>1</sub>)<sup>[7,26,33]</sup>. While chemotherapy and immunotherapy with rituximab are also effective, these systemic treatments are suitable for cases with an advanced stage<sup>[26,33]</sup>. Recently, the combination of rituximab and chlorambucil<sup>[39]</sup> or fluda-

rabine<sup>[40]</sup> provided excellent responses in patients with MALT lymphoma of variable organs, including gastric cases. Surgical resection is nowadays restricted to the management of cases with perforation or bleeding that cannot be controlled endoscopically<sup>[26]</sup>.

## CONCLUSION

While a large amount of clinical evidence has confirmed the validity of *H. pylori* eradication as the first-line treatment for gastric MALT lymphoma, there are many choices for the second-line treatments. Because of the indolent behavior of MALT lymphoma, the strategy for patients not responding to *H. pylori* eradication should be tailored in consideration of the clinical stage and extent of the disease. Despite the recent advances in our understanding of the pathogenesis of gastric MALT lymphoma, there still exist many questions to be answered. Further basic and clinical research is needed to clarify the molecular mechanisms in the development of the disease.

## Abstract

Stool antigen tests (SATs) are noninvasive diagnostic modules for *Helicobacter pylori* (*H. pylori*) infection. Two types of SATs exist for the diagnosis of *H. pylori* infection, one based on enzyme immunoassay (EIA) and another on immunochromatography (ICA). SATs do not require expensive chemical agents or specified equipment; hence, they are less expensive compared with the urea breath test. Both European and Japanese guidelines have shown that EIA-based SATs using monoclonal antibodies are useful for primary diagnosis as well as for the assessment of eradication therapy. ICA-based tests do not require particular equipment and are therefore useful in developing countries. SATs are also useful for the diagnosis of *H. pylori* infection in children and post gastric surgery patients. SATs performed via EIA can assess *H. pylori* infection in a large number of subjects, almost as well as serology. Thus, SATs would be useful or detecting current infection in such a survey to identify and eradicate *H. pylori* infection. The accuracy of SATs is lower when the stool samples are unformed or watery, because *H. pylori*-specific antigens in the stool samples are diluted. Temperature and the interval between stool sample collection and measurement also affect the results of SATs.

The choice of test kit depends on the sensitivity and specificity in each region and the circumstances of each patient.

**Key words:** *Helicobacter pylori*; Stool antigen test; Diagnosis; Enzyme immunoassay; Immunochromatography

**Core tip:** Stool antigen tests (SATs) are relatively inexpensive noninvasive tests. Several guidelines on *Helicobacter pylori* (*H. pylori*) infection from around the world indicate that SATs using monoclonal antibodies are useful for primary diagnosis as well as for assessing the results of eradication therapy. SATs are also useful for diagnosing *H. pylori* infection in children and post gastric surgery patients. The choice of test kit depends on the accuracy in each population and the circumstances of each patient.

## INTRODUCTION

Infection by *Helicobacter pylori* (*H. pylori*) has been implicated in the pathogenesis of gastro-duodenal diseases. Several guidelines on *H. pylori* infection from around the world indicate that eradication of *H. pylori* would result in a reduction of the incidence of gastroduodenal diseases, including gastric cancer, and would decrease new infections in future generations<sup>[1,2]</sup>. Following the recommendation of the Japanese guidelines for the management

of *H. pylori* infection (2009 revised edition), in 2013, the Japanese health insurance system approved the coverage of the diagnosis and eradication of *H. pylori* in all infected patients<sup>[3]</sup>. Consequently, an expansion in the role of *H. pylori* diagnostic tests will accompany the increased number of patients undergoing *H. pylori* testing and eradication.

Stool antigen tests (SATs) are noninvasive diagnostic modules for *H. pylori* infection and were introduced after the urea breath test (UBT). Early SATs used an enzyme immunoassay (EIA) based on polyclonal antibodies. While they provided reliable results in the diagnosis of *H. pylori* infection, controversial results were sometimes observed in the post-eradication assessment because of false-positives<sup>[4,5]</sup>. Monoclonal antibody-based techniques generally have higher specificity. SATs based on monoclonal antibodies have been developed, and have been found to be more accurate than those using polyclonal antibodies<sup>[6,7]</sup>. A meta-analysis also showed that the specificity of SATs based on monoclonal antibodies was 0.97 (95%CI: 0.96-0.98)<sup>[8]</sup>. Both European and Japanese guidelines have indicated that SATs using monoclonal antibodies are useful for primary diagnosis as well as for the assessment of eradication therapy<sup>[1,3]</sup>.

Two types of SATs exist for the diagnosis of *H. pylori* infection, one based on EIA and another on immunochromatography (ICA). Although both types of tests are highly sensitivity and specificity, a recent study showed that currently available ICA-based tests provide less reliable results than EIA-based tests<sup>[9]</sup>. However, ICA-based tests are easy to perform and are useful for in-office rapid diagnoses of *H. pylori* infection<sup>[10]</sup>. ICA-based tests do not require specialized equipment; therefore, they would be useful in developing countries.

## DIAGNOSIS

### Comparison with UBT

Among non-invasive diagnostic tests, SAT and UBT have higher accuracy than serological or urinary antibody-based tests<sup>[1,3]</sup>. The American Gastroenterological Association recommends both SAT and UBT for the diagnosis of *H. pylori* infection in patients with dyspepsia<sup>[4]</sup>. While UBT has been considered the most reliable noninvasive test for the diagnosis of *H. pylori* infection, it has several limitations. The cost of UBT is still relatively high because of the price of <sup>13</sup>C-urea (approximately 30.3 USD) and the cost of measuring <sup>13</sup>CO<sub>2</sub>. By contrast, SATs do not require expensive chemical agents and special equipment and hence are less expensive (1400 JPY; approximately 14.2 USD). In addition, patients are required to fast before UBT testing, but not before a SAT. Furthermore, proton pump inhibitor (PPI) administration modulates gastric pH, resulting in lower urease activity of *H. pylori* in the stomach. UBT detects gastric mucosal urease activity; therefore, false-negative results are noted in patients who have been taking PPIs<sup>[11]</sup>. It is therefore generally recommended that PPI administra-

tion be discontinued 2 wk before UBT testing<sup>[11]</sup>. PPIs can similarly influence SAT<sup>[12,13]</sup> results, but some monoclonal antibody-based SATs that are currently available are not affected by PPIs<sup>[14]</sup>. Such SATs, which do not require PPI discontinuation, are useful for the management of *H. pylori* infection in patients with gastroesophageal reflux diseases or those taking nonsteroidal anti-inflammatory drugs.

### Diagnosis in children and post gastric surgery patients

A systematic review and meta-analysis showed that SATs using a monoclonal antibody-based EIA are useful for the diagnosis of *H. pylori* infection in children<sup>[15]</sup>. UBT is also highly accurate in children older than 6 years, while studies from developed countries showed that its specificity was less than 90% in very young children<sup>[16,17]</sup>. By contrast, both monoclonal SAT and UBT were reliable in young children aged 6-30 mo in South American developing countries<sup>[18]</sup>. These results indicate that monoclonal antibody-based SATs are the most effective tests for children in populations with both high and low prevalences of *H. pylori* infection<sup>[18,19]</sup>.

In patients who received distal gastrectomy, the accuracy of UBT was lower than that of a biopsy urease test<sup>[20]</sup>. However, in Japanese patients who underwent distal gastrectomy, the specificity of SAT was 90.5% while that of UBT was only 59.1%<sup>[21]</sup>.

### Mass survey and screening

In mass surveys, with regard to technique and cost, serology has generally been used despite its lower specificity<sup>[3]</sup>. SATs performed *via* EIA can assess *H. pylori* infection in a large number of subjects, almost as well as serology. In 994 healthy Japanese adults who participated in a mass survey, concordance of the results of SAT and serology was over 90%<sup>[22]</sup>. However, in that study, the positivity of SATs was significantly lower than that of serology in 303 subjects with severe atrophic gastritis. In the gastric mucosa of patients with severe atrophic gastritis and intestinal metaplasia, colonization by *H. pylori* is decreased or non-existent. Therefore, in the setting of a mass survey, serology is useful for the detection of both current and past infection. SATs should be used to detect current infection in such a survey to identify and eradicate *H. pylori* infection for the prevention of gastric malignancies.

## ASSESSMENT OF ERADICATION

To date, many studies have demonstrated the usefulness of SATs in the evaluation of the results of eradication therapy. Recent guidelines of the European Helicobacter Study Group (EHSG) recommend both UBT and laboratory-based monoclonal SAT<sup>[1]</sup>. After eradication therapy, the amount of *H. pylori* colonization in the stomach would be reduced, even when eradication therapy was unsuccessful. Therefore, SATs should be performed to detect the reduced number of bacteria. Among laboratory-based monoclonal SATs, the Premier Platinum

HpSA Plus (HpSA ELISA II; Meridian Diagnostics, Inc., Cincinnati, OH, United States), which uses multiple murine monoclonal antibodies, seems to be accurate. We previously demonstrated the significantly higher sensitivity of HpSA ELISA II to that of the Testmate Pylori Antigen EIA (TPAg EIA; Wakamoto Pharmaceutical Co. Ltd., and Kyowa Medex, Tokyo, Japan), which uses a single monoclonal antibody<sup>[23]</sup>. HpSA ELISA II produced a higher positive predictive value, although the TPAg EIA provided efficient results<sup>[24]</sup>.

In the guidelines of the EHSG, laboratory-based tests, but not in-office tests, are recommended for the evaluation of treatment results<sup>[1]</sup>. However, recent observations indicate that some in-office monoclonal antibody-based tests can accurately evaluate the results of eradication treatment<sup>[9,25]</sup>. In-office tests allow physicians to evaluate the results of eradication therapy in a single visit and the next eradication therapy can be started on the same day in non-eradicated patients. In-office tests do not require specialized equipment; therefore, they would be suitable in institutes that cannot measure <sup>13</sup>CO<sub>2</sub>.

PPI administration should be discontinued 2 wk before evaluating treatment results by UBT or SAT<sup>[1]</sup>. However, as described above, the results of certain SATs are not affected by PPIs<sup>[13]</sup>. Actually, in a small series of 22 Japanese patients, we showed that the results of eradication therapy assessed by TPAg EIA during PPI administration were the same those determined by UBT 4 wk after discontinuing PPI in 21 patients<sup>[26]</sup>.

In several guidelines, evaluation of the results of eradication therapy by SATs should be performed at least 4 wk after finishing the treatment<sup>[1,3]</sup>. However, relapse after eradication is considered to be mainly recurrence of the same infection rather than reinfection. Therefore, proposals have been made to extend the timing to 6 or 8 wk after finishing treatment. A monoclonal antibody-based EIA test could determine the treatment results at 6 wk after finishing the treatment as well as 8 wk<sup>[26]</sup>.

## TO BE MENTIONED WHEN PERFORMING SATS

Several factors influence the results of SATs. The accuracy of SATs is lower when the stool samples are unformed or watery, because *H. pylori*-specific antigens in the stool samples are diluted. Therefore, watery stools should not be used, particularly in the determination of the results of eradication therapy. The sensitivity of SATs is also lower in patients with upper gastrointestinal bleeding<sup>[27]</sup>.

Temperature and the interval between stool sample collection and measurement also affect the results of SATs. Such information is available for two kits. Querioz *et al*<sup>[18]</sup> examined the results of HpSA ELISA II and showed a remarkable reduction of the OD value when stool samples were maintained at 37 °C for 48 h. They also retested a stool sample with an OD value of 0.183 after 6 h of incubation at 37 °C and found that the OD value fell below the cutoff (0.120). In samples tested by TPAg EIA

we found that the OD values of initially negative stool samples increased and were almost similar to the cutoff level if the samples were maintained at 40 °C<sup>[9]</sup>. However, OD values were unchanged for up to 7 d at -5 °C-25 °C when stool sample suspensions were stored in their particular collection devices. Therefore, stool samples should be stored at a low temperature and be tested over a short period if the collection devices are not available. To maintain the antigenicity over a longer term, stool samples should be stored at -80 °C.

Differences in the antigenicity of *H. pylori* strains sometimes affect the accuracy of SATs in different populations<sup>[28]</sup>. Therefore, sensitivity and specificity of SATs should be tested in each population before use in the management of *H. pylori* infection.

## CONCLUSION

In summary, SATs are relatively inexpensive noninvasive tests. SATs using monoclonal antibodies are useful for primary diagnosis as well as for the assessment of eradication therapy. SATs are also useful in the management of *H. pylori* infection in children and post gastric surgery patients. In the future, SATs should be used in mass surveys to identify and eradicate *H. pylori* infection for the prevention of gastric malignancies. The choice of test kit depends on the sensitivity and specificity in each region and the circumstances of each patient.

**Key words:** *Helicobacter pylori*; Interleukin-8; Signals; Gastric cancer; Therapeutics

**Core tip:** There is a close association between gastric cancer and *Helicobacter pylori* (*H. pylori*) infection. *H. pylori* upregulates interleukin-8 (IL-8) gene expression in gastric epithelial cells and the levels of IL-8 may be indicative of poor prognosis. We propose that IL-8 overexpression induced by *H. pylori* plays a major role in gastric cancer development and progression, and that targeting IL-8 may be a promising strategy for gastric cancer treatment.

## Abstract

*Helicobacter pylori* (*H. pylori*) is a major etiological factor in the development of gastric cancer. Large-scale epidemiological studies have confirmed the strong association between *H. pylori* infection and both cancer development and progression. Interleukin-8 (IL-8) is overexpressed in gastric mucosa exposed to *H. pylori*. The expression of IL-8 directly correlates with a poor prognosis in gastric cancer. IL-8 is multifunctional. In addition to its potent chemotactic activity, it can induce proliferation and migration of cancer cells. In this review, we focus on recent insights into the mechanisms of IL-8 signaling associated with gastric cancer. The relationship between IL-8 and *H. pylori* is discussed. We also summarize the current therapeutics against IL-8 in gastric cancer.

## INTRODUCTION

Gastric cancer has affected humans for millennia. The risk of gastric cancer appears to evolve over a lifetime as a possible result of changes in diet and lifestyle. In 1984, Marshall and Warren were first to describe the association between peptic ulcer disease and *Helicobacter pylori* (*H. pylori*)<sup>[1]</sup>. *H. pylori* was subsequently causally linked with the development of gastric cancer.

Despite the improved prognosis of gastric cancer resulting from the early diagnosis and development of adjuvant therapy, overall 5-year survival rates for patients with gastric cancer remain disappointing, with a mortality rate of 20% in Western countries and up to 60% in Asian countries<sup>[2]</sup>. Although current combinatory chemotherapeutic regimes result in a median overall survival of up to

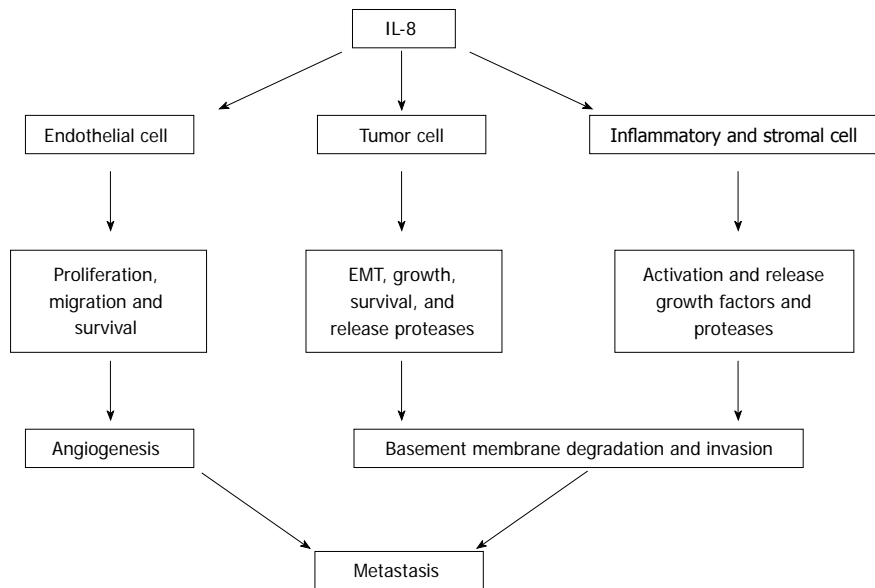

Figure 1 Roles for interleukin-8 in tumor progression and metastasis. EMT: Epithelial-mesenchymal transition; IL-8: Interleukin-8.

11 mo, toxicity is increased<sup>[3,4]</sup>. To overcome the adverse effects, novel chemotherapeutic concepts have focused on the development of targeted therapies for gastric cancer. An understanding of the detailed mechanisms of invasion and metastasis in gastric cancer would be helpful in improving the treatment outcome.

*H. pylori* infection is usually asymptomatic in most hosts, as virtually all carriers develop superficial chronic active gastritis, whereas only about 10% suffer gastric or duodenal ulceration and 0.5%-2.0% develop gastric adenocarcinoma or B cell lymphoma of mucosa-associated lymphoid tissue<sup>[5]</sup>. *H. pylori* colonize the gastric mucosa of 35%-70% of people worldwide and infection with *H. pylori* is the main etiologic factor for development of chronic active gastritis and peptic ulcers<sup>[6,7]</sup>. Epidemiologic data indicate that gastric cancer occurs more frequently in populations with higher rates of *H. pylori* infection, and the World Health Organization has classified this bacterium as a class 1 carcinogen for gastric cancer<sup>[8]</sup>. Animal models have also demonstrated the importance of *H. pylori* in gastric carcinogenesis<sup>[9]</sup>. *H. pylori* infection is important in the process of tissue remodeling, angiogenesis, tumor invasion and metastasis<sup>[10]</sup>, and induces a number of genes in host cells that are potential determinants of inflammation, angiogenesis, and metastasis including interleukin-8 (IL-8), cyclooxygenase-2<sup>[11]</sup>, monocyte chemoattractant protein-1<sup>[12]</sup>, vascular endothelial growth factor<sup>[13]</sup>, and matrix metalloproteinase (MMP)-9<sup>[14]</sup>. However, it remains unclear how *H. pylori* infection activates specific transcription factors and induces gene expression.

IL-8 seems to have significant potential as a prognostic and predictive cancer biomarker. IL-8 was originally identified as a chemoattractant for neutrophils that release angiogenic growth factors, stimulating angiogenesis as a part of cancer progression. As shown in Figure 1, IL-8 increases the proliferation, migration and survival of

endothelial cells, potentiates the epithelial-mesenchymal transition and survival of cancer cells, and activates macrophage and immune responses at the tumor site<sup>[15]</sup>. IL-8 enhances the production and secretion of MMP-2 and MMP-9<sup>[16,17]</sup>, suggesting that it can modulate invasiveness and/or extracellular matrix remodeling in normal physiological conditions and in cancer progression.

An understanding of the basic principles and underlying signals by which *H. pylori* regulates IL-8 may lead to the development of new therapeutic strategies in gastric cancer. With this in mind, we present a brief review.

## A ROLE FOR IL-8 IN GASTRIC CANCER

A significant correlation between high expression levels of IL-8 in gastric mucosa and risk of gastric cancer has been reported<sup>[18]</sup>. Macri *et al.*<sup>[19]</sup> reported that the serum levels of IL-8 act as markers of gastric cancer. Increased expression of IL-8 mRNA in tissue extracts from gastric cancer patients has been associated with some clinicopathological aspects of the disease, including poor prognosis<sup>[20]</sup>. In IL-8 transgenic mice, where expression of human IL-8 is controlled by its own regulatory elements, expression of IL-8 increased tumorigenesis, suggesting that IL-8 might have a crucial role in gastrointestinal cancers<sup>[21]</sup>. These observations indicate that high levels of IL-8 may be associated with poor prognosis as judged by stage and histology, and that IL-8 may be indicative of more aggressive gastric cancers.

The roles for IL-8 in the angiogenesis of gastric cancer have drawn much interest. Since invasion and angiogenesis are all involved in the metastatic process, IL-8 expression in gastric cancer can influence their metastatic capabilities. Upregulation of IL-8 in human gastric carcinomas correlates closely with their angiogenesis<sup>[22]</sup>. Kitadai *et al.*<sup>[23]</sup> reported that the expression of IL-8 directly

correlated with the vascularity of human gastric carcinomas and that IL-8-transfected cells produced rapidly growing, highly vascular neoplasms, compared to control cells. In contrast, inhibition of IL-8 decreases angiogenesis in gastric cancer. Wang *et al.*<sup>[24]</sup> reported that CHIP, a protein that interacts with the carboxy terminus of Hsc70, also interacted with nuclear factor-kappa B (NF- $\kappa$ B), terminating NF- $\kappa$ B activity and inhibiting IL-8-induced angiogenesis. IL-8 stimulates vascular endothelial growth factor (VEGF) expression in endothelial cells *via* CXCR-2 and thereby promotes the activation of VEGF receptors in an autocrine fashion<sup>[25]</sup>. IL-8 has a direct role in angiogenesis by enhancing endothelial cell proliferation and survival in CXCR1- and CXCR2-expressing endothelial cells<sup>[26]</sup>. IL-8 stimulates both endothelial proliferation and capillary tube formation *in vitro*, and both of these effects can be blocked by monoclonal anti-bodies to IL-8. *H. pylori*-derived heat shock protein 60 (HpHSP60) enhances angiogenesis by a CXCR2-mediated signaling pathway<sup>[27]</sup>. Use of an angiogenic array showed that HpHSP60 markedly induced IL-8 and that inhibition of CXCR2, the receptor for IL-8, significantly abolished HpHSP60-induced tube formation. IL-8 has also been linked with cell adhesion and migration in gastric cancer<sup>[23]</sup>. IL-8 activates NF- $\kappa$ B and Akt signals, and induces adhesion molecules including intercellular adhesion molecule-1 (ICAM-1), vascular cell adhesion molecule-1 and CD44 expression in gastric cancer cells<sup>[28]</sup>. Inhibition of IL-8 with small interfering RNA reportedly decreased the adhesion, migration and invasion functions in cancer cells<sup>[23]</sup>.

IL-8 polymorphisms may increase the risk of gastric cancer. Taguchi *et al.*<sup>[29]</sup> reported the association of the *IL-8-251 A/T* polymorphism with higher expression of IL-8 protein, severe neutrophil infiltration and increased risk of atrophic gastritis and gastric cancer. *IL-8-251 T/A* and *IL-8-251 A/A* polymorphisms may be associated with angiogenesis in gastric carcinogenesis in *H. pylori*-infected Koreans<sup>[30]</sup>. In the study, there were significant correlations between MMP-9, angiopoietin-1 concentrations and disease progression in *IL-8-251 A/A* and *IL-8-251 A/T* genotypes. Felipe *et al.*<sup>[31]</sup> reported that patients with the heterozygous *IL-8-251 A/T* genotype, high fat intake and smokers or ex-smokers presented an increased risk of gastric cancer in a Brazilian population. However, the association of IL-8 polymorphisms and gastric cancer is controversial. The IL-8 polymorphism was not consistently associated with gastric cancer risk in a Polish population<sup>[32]</sup>. Furthermore, a meta-analysis of epidemiological studies revealed an overall lack of association between *IL-8-251* gene polymorphisms and risk of gastric cancer; any association is likely to be variable depending on histological type, tumor location, *H. pylori* infection, and ethnicity/country<sup>[33]</sup>.

The downstream signals of IL-8 produced by *H. pylori* have been intensively studied. All biological effects of IL-8 are mediated by two receptors designated CXCR1 and CXCR2. IL-8 binds with high specificity

to CXCR1<sup>[34]</sup> and with less specificity to CXCR2<sup>[35]</sup> expressed on stromal, endothelial and tumor cells. CXCR1, a cell-surface G-protein-coupled receptor, has been associated with tumorigenesis, development and progression of some tumors. Hu *et al.*<sup>[36]</sup> documented that CXCR1 overexpression is associated with late-stage gastric cancer. They reported that knockdown of CXCR1 could inhibit cell proliferation *in vitro* and *in vivo*. Lin *et al.*<sup>[37]</sup> reported that enforced expression of the cysteine-rich 61 (*Cyr61*) gene or treatment with recombinant Cyr61 protein enhanced expression of CXCR1 and CXCR2 in gastric cancer cells. The upregulated functionality of CXCR1 and CXCR2 could facilitate their chemotactic migration toward IL-8 and contribute to transendothelial migration, as well as intravasation. The interaction between IL-8 and epidermal growth factor receptor (EGFR) promotes cell proliferation through transactivation of the receptor by activation of a disintegrin and metalloproteinase<sup>[38]</sup>. IL-8 could induce EGFR phosphorylation, while anti-IL-8 and anti-IL-8 receptor antibodies suppressed EGFR phosphorylation, indicating that *H. pylori*-stimulated IL-8 accelerates the processing of EGFR ligands, and that cleaved EGFR ligands bind and stimulate EGFR in paracrine and autocrine manners to induce cell proliferation.

## SIGNALS INVOLVED IN

### *H. PYLORI*-INDUCED IL-8 IN GASTRIC CANCER

A whole genome analysis of the epithelial response to *H. pylori* exposure revealed *IL-8* as the most markedly up-regulated gene<sup>[39]</sup>. IL-8 appears to play a paramount role in the epithelial cell response to *H. pylori* infection and in the pathological processes leading to gastric disease. IL-8, a CXC chemokine specific for neutrophil granulocyte chemotaxis, has been correlated with the histological severity of gastritis<sup>[40]</sup>. The majority of gastric cancers are end products of an inflammatory process. A chronic *H. pylori* infection is characterized by an inflammation of the gastric mucosa and is accepted as the major cause of chronic gastritis.

IL-8 induction in gastric epithelial cells has been clearly correlated with a functional *cagA* gene<sup>[41]</sup>. In *H. pylori* strains that express *cagA*, cytokine expression has been linked with an elevated inflammatory response *in vivo*<sup>[42]</sup>. *H. pylori* strains are classified as *cagA*-positive or *cagA*-negative according to the presence or absence of *cagA*, respectively<sup>[43]</sup>. *CagA* protein is a major virulence factor of *H. pylori* that has attracted clinical interest as a marker of *H. pylori*-associated disease, having been shown to confer increased gastric cancer risk<sup>[6,44]</sup>. The *cagA* gene is located at one end of the *cag* pathogenicity island (*cagPAI*). The island contains two segments: an upstream *cag* II region and a downstream *cag* I region<sup>[45]</sup>. *PAI* comprises a gene cluster of 40 kbps that encodes a type IV secretion system (T4SS) that functions to translocate *cagA* from epithelium-adherent bacteria into gastric epithelial

cells<sup>[45]</sup>. Once inside the cells, *cagA* is phosphorylated by host cellular kinases, Src<sup>[46,47]</sup> and Abl<sup>[48]</sup>, on a repeating glutamic acid proline-isoleucine-tyrosine-alanine tyrosine phosphorylation motif located at the carboxyl terminus of the protein. *In vitro* examinations of *H. pylori* infection of gastric epithelial cells revealed the requirement of proteins encoded by the *cagPAI*, with the exception of *cagA*, for IL-8 secretion, and the regulation of IL-8 induction by the NF- $\kappa$ B pathway<sup>[44,49]</sup>. However, *H. pylori*-induced pro-inflammatory responses remain controversial<sup>[50-52]</sup>. Ando *et al*<sup>[51]</sup> observed upregulated IL-8 expression in gastric epithelial cells infected with *H. pylori* containing an inactivated *cagA* gene, while Peng *et al*<sup>[52]</sup> reported up-regulation of IL-8 expression in gastric epithelial cells in response to treatment with extracts of *cagA*-positive and *cagA*-negative strains. Bacterial *cagA* expression may not be essential for the upregulation of IL-8 expression in *H. pylori*-infected gastric epithelial cells.

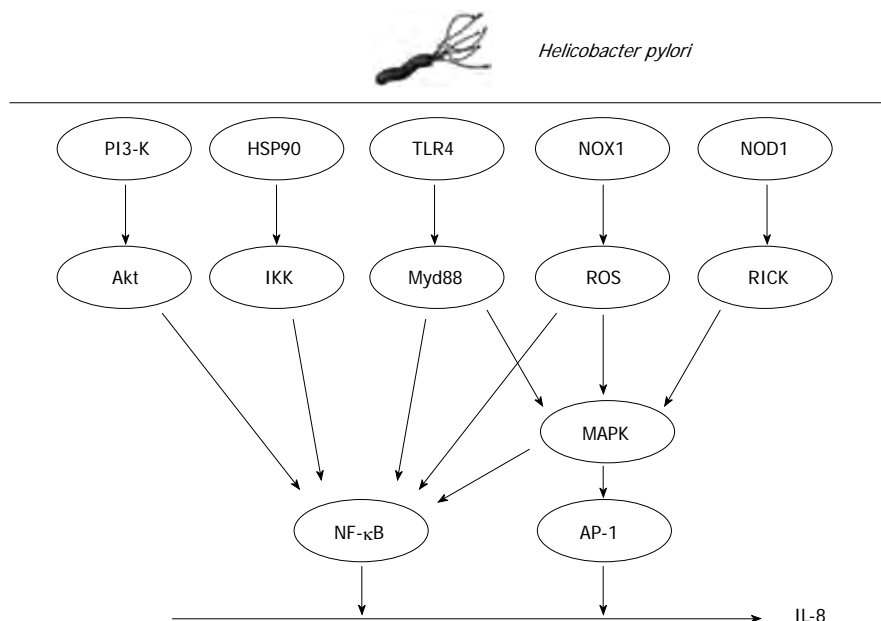

Although it is well known that *H. pylori* upregulates IL-8 expression in gastric cancer cells, the underlying molecular mechanism is not fully understood. Analyses of the genomic structure of IL-8 have revealed many potential targets for regulation at both the transcriptional and post-transcriptional levels. Within its 3'-flanking region, the IL-8 gene contains a repetitive ATTTA motif, which is responsible for destabilization of various cytokine mRNAs<sup>[53]</sup>. Within the 5'-flanking region, the gene contains multiple *cis* elements including a CCAAT box, steroid-responsive element, hepatocyte nuclear factor-1 element, two interferon regulatory factor-1 elements and binding sites for activator protein-1 (AP-1), CCAAT/enhancer binding protein and NF- $\kappa$ B, all of which have been implicated in the induction of IL-8 gene transcription by the aforementioned stimuli<sup>[54]</sup>. As demonstrated by mutation and deletion analyses, these promoter elements are regulated in cell type-specific manners<sup>[55]</sup>. A myriad of intracellular signals have been suggested to mediate the effects of *H. pylori* including production of reactive oxygen species (ROS), and activation of transcription factor NF- $\kappa$ B, AP-1 and mitogen-activated protein kinase (MAPK).

ROS are involved in the pathogenesis of *H. pylori*-associated gastric diseases that include gastric cancer<sup>[56,57]</sup>. Park *et al*<sup>[57]</sup> reported that ROS are produced by NADPH oxidase (NOX1) and induce apoptotic cell death of *H. pylori*-infected gastric epithelial cells. NOX1 induced by *H. pylori* in gastric disease functions in the constitutive production of superoxide anion and hydrogen peroxide<sup>[58]</sup>. Increased expression of NOX1 mRNA moderately increases the generation of superoxide anion, which leads to a reduction in aconitase activity, making NOX1 a good marker of oxidative stress. ROS induced by *H. pylori* stimulate MAPKs, such as extracellular signal-related kinases (ERKs), c-Jun NH<sub>2</sub>-terminal kinases (JNKs) and p38 MAPK, and upregulate transcription of NF- $\kappa$ B<sup>[59]</sup>. Interestingly, IL-8 contributes to the generation of copious quantities of ROS, and can elicit the induction of IL-1 $\beta$ , IL-6, IL-8, IL-12, tumor necrosis factor- $\alpha$ <sup>[60,61]</sup>, and

interferon- $\gamma$ <sup>[60]</sup>. IL-8 activates the CD11b/CD18 dimer, which forms a complex with neutrophils. The complex activates ICAM-1 on the vascular endothelial cell membrane. The resulting tetramer (CD11b/CD18/neutrophil/ICAM-1) infiltrates gastric epithelial cells and facilitates the copious release of ROS through neutrophil NADPH oxidase, resulting in an oxidative burst<sup>[62,63]</sup>. The ROS released from gastric epithelial cells may mediate the chemotactic action of neutrophils and monocytes in *H. pylori*-infected gastric tissues<sup>[56]</sup>.

Co-culture of *H. pylori* with cells can induce IL-8 through the activation of the oxidant-sensitive transcriptional factor NF- $\kappa$ B. ROS are important in this process in *H. pylori*-infected cancer cells<sup>[64]</sup>. NF- $\kappa$ B exists in a latent form in the cytoplasm, bound to the inhibitory protein, I $\kappa$ B. I $\kappa$ B kinase (IKK) directly phosphorylates I $\kappa$ B molecules, leading to the ubiquitin-mediated proteolysis of I $\kappa$ B. The NF- $\kappa$ B dimer that is released from I $\kappa$ B translocates to the nucleus where it activates target genes by binding to the promoter/enhancer region. In addition to ROS, several mechanisms for NF- $\kappa$ B activation by *H. pylori* have been proposed. *H. pylori* induces the phosphorylation of heat shock protein 90 (Hsp90) in gastric epithelial cells<sup>[65,66]</sup>. Hsp90 associates stoichiometrically with the IKK complex, which contributes to the stabilization, activation and shuttling of IKKs to the plasma membrane, because Hsp90 regulates the stability and function of a unique complement of signaling molecules<sup>[67]</sup>. Given that Hsp90 is associated with IKK- $\alpha$  and IKK- $\gamma$  in *H. pylori*-infected gastric epithelial cells<sup>[65]</sup>, the Hsp90-IKK complex may be a target for the pharmacological inhibition of the *H. pylori*-mediated activation of NF- $\kappa$ B signaling. Takeshima *et al*<sup>[68]</sup> reported that NF- $\kappa$ B activation by *H. pylori* requires Akt-mediated phosphorylation of p65. Phosphorylated Akt is detected in epithelial cells of *H. pylori* positive gastric tissues. The application of phosphoinositol-3-kinase inhibitor, dominant-negative Akt and small interfering RNA for Akt suppresses *H. pylori*-induced p65 phosphorylation as well as IL-8 expression, suggesting that Akt signals are involved in *H. pylori*-induced NF- $\kappa$ B activation.

*H. pylori* also activates the transcription factor AP-1 in a *cagPAI*-dependent manner<sup>[69,70]</sup>. The AP-1 complex activated during *H. pylori* infection is composed primarily of c-jun and c-fos heterodimers<sup>[71]</sup>. AP-1 is activated by MAPK and is capable of inducing a strong pro-inflammatory response, often in concert with NF- $\kappa$ B<sup>[71]</sup>. *H. pylori* rapidly activate MAPKs upon contact with gastric epithelial cells<sup>[72]</sup>. MAPK cascades are well characterized pathways that transduce signals from the cell surface to the nucleus. The family includes distinct subgroups: ERKs, JNKs and p38 MAPK. A number of bacterial factors have been implicated in MAPK activation including *vacA*<sup>[73]</sup> and *cagA*<sup>[72]</sup>. The signaling events leading to rapid MAPK phosphorylation during *H. pylori* infection are not well understood, although T4SS is required for ERK phosphorylation of p38 MAPK and JNK<sup>[67]</sup>. *CagA* is capable of activating ERK<sup>[73]</sup>, though ERK can also be

**Figure 2** Scheme of signaling of *Helicobacter pylori*-induced interleukin-8 in gastric cancer cells. PI3-K: Phosphoinositide 3-kinase; HSP: Heat shock protein; TLR: Toll-like receptor; NOX: NADPH oxidase; NOD: Nucleotide binding and oligomerization domain; IKK: IκB kinase; ROS: Reactive oxygen species; RICK: Receptor-interacting protein serine-threonine kinase; MAPK: Mitogen-activated protein kinase; NF-κB: Nuclear factor kappa B; AP-1: Activator protein-1.

activated by *cagA*-independent mechanisms<sup>[74]</sup>, suggesting that *cagA* has an additive role in transcription factor activation. JNK activation during *H. pylori* infection also requires a functional T4SS<sup>[72]</sup>. *H. pylori* peptidoglycan is delivered to the host cell *via* the T4SS, where it is recognized by cytosolic nucleotide binding and oligomerization domain 1 (NOD1)<sup>[75]</sup>. Upon stimulation with purified agonist, NOD1 associates with the receptor-interacting protein serine-threonine kinase 2, triggering a pro-inflammatory response that is characterized by NF-κB activation and IL-8 production<sup>[76]</sup>. In addition to activation of the classical NF-κB pathway, NOD1 is reported to be required for MAPK activation in response to bacterial pathogens. This NOD1-dependent p38 MAPK activation induces IL-8 production<sup>[77]</sup>. Allison *et al*<sup>[77]</sup> observed that NOD1 was necessary for MAPK activation in the early stages of infection and that NOD1 was essential for the activation of both NF-κB and AP-1, as well as the release of IL-8 in response to *H. pylori*. These observations support previous findings that *cagA* induces IL-8 induction *via* the Ras→Raf→Mek→ERK→NF-κB signaling pathway<sup>[78]</sup> and that *cagA* can activate the Ras→ERK pathway<sup>[79]</sup>. Understanding the signals involved in IL-8 expression by *H. pylori* may be beneficial to develop new therapeutics in gastric cancer (Figure 2).

## IL-8 AS A THERAPEUTIC TARGET IN GASTRIC CANCER

Gastric cancer features increased IL-8 expression, suggesting that IL-8 might be a promising therapeutic targeting to prevent cancer progression. Many inhibitors that prevent *H. pylori*-induced IL-8 expression and regulate the

IL-8 downstream signals have been proposed (Table 1).

Polyphenols derived from natural products that include resveratrol, apigenin and anthocyanins inhibit IL-8 induced by *H. pylori*. Resveratrol suppresses the secretion of IL-8 from *H. pylori*-infected gastric epithelial cells. IL-8 secretion is usually regulated by the transcription factor NF-κB and *H. pylori* can induce IL-8 expression by activating a NF-κB pathway in gastric epithelial cells<sup>[80,81]</sup>. Since resveratrol inhibits NF-κB<sup>[82]</sup>, its suppressive effect on IL-8 secretion may correlate with its NF-κB inhibitory activity. Inhibition of IL-8 expression by resveratrol may also be due to modulation of regulatory enzymes like MAPK<sup>[83]</sup>. Anti-oxidant anthocyanins from black soybean may inhibit IL-8 production<sup>[84]</sup>. Cyanidin-3-glucoside, which is abundant in anthocyanins, is reportedly an effective anti-oxidant that inactivates NF-κB by inhibiting phosphorylation of IκB<sup>[85,86]</sup>. Anthocyanins have anti-oxidant effects and the ability to downregulate ROS generation, and decrease the activation of MAPKs induced by *H. pylori*. Apigenin, one of the most common flavonoids, increases IκBα expression, and thus inhibits NF-κB activation and decreases IL-8 expression<sup>[87]</sup>. Apigenin's anti-inflammatory activity has been characterized *in vitro* and *in vivo*<sup>[88,89]</sup>.

Phenyl-thiophenyl propenone RK-I-123 is a small molecule that reportedly reduces the level of ROS and suppresses the activation of NF-κB and AP-1, and the expression of IL-8 in *H. pylori*-infected gastric epithelial cells<sup>[90]</sup>. RK-I-123 was synthesized as a novel propenone compound in an attempt to develop a dual inhibitor of COX-2 and 5-LOX<sup>[91]</sup>. 7-Carboxymethoxy-3',4',5-trimethoxy flavone, abbreviated as DA-6034, is a synthetic derivative of eupatilin that also inhibits IL-8 induced by *H. pylori*<sup>[92]</sup>. DA-6034 promotes the dissociation of the

**Table 1** Inhibitors targeting interleukin-8 in cancer progression

Inhibitors	Mechanisms	Ref.
Resveratrol	Reduces ROS, inhibits MAPK, AP-1 and NF- $\kappa$ B	[82,83]
Anthocyanin	Reduces ROS, inhibits MAPK, AP-1 and NF- $\kappa$ B	[84-86]
Apigenin	Increases the I $\kappa$ B $\alpha$ and thus inhibits NF- $\kappa$ B	[88,89]
RK-I-123	Reduces ROS and inhibits AP-1 and NF- $\kappa$ B	[91]
DA-6034	Dissociates IKK/HSP90 complex and inhibits NF- $\kappa$ B	[92,93]
Rebamipide	Prevents PLD expression <i>via</i> NF- $\kappa$ B	[94,95]
Gefitinib [Iressa <sup>TM</sup> ]	Inhibits EGFR	[98,99]
<i>L. bulgaricus</i>	Inhibits TLR4	[101]
<i>L. acidophilus</i>	Dissociates IKK/Hsp90 complex and inhibits NF- $\kappa$ B	[65,103]
NRF peptide	Disrupts interaction of NRF and NF- $\kappa$ B	[105]
miR-146	Negatively regulates IL-8	[110,111]
miR-155	Inhibits MyD88 <i>via</i> NF- $\kappa$ B	[112,115]
G31P	Synthetic derivative of IL-8	[117]
SCH-527123	CXCR2 inhibitor	[118]

I $\kappa$ B $\alpha$ : Inhibitor of kappa B alpha; RK-I-123: Phenyl-thiophenyl propenone; DA-6034: 7-Carboxymethoxy-3',4',5-trimethoxy flavone; HSP: Heat shock Protein; PLD: Phospholipase D; EGFR: Epidermal growth factor receptor; NRF: NF- $\kappa$ B repressing factor; IL-8: Interleukin-8; miR: MicroRNAs; MAPK: Mitogen-activated protein kinase; IKK: I $\kappa$ B kinase; AP-1: Activator protein-1; ROS: Reactive oxygen species; TLR4: Toll-like receptor 4.

IKK-HspP90 complex and suppresses NF- $\kappa$ B signaling, leading to the inhibition of IL-8 expression in *H. pylori*-infected cells. DA-6034 also inhibits ERK in such cells<sup>[93]</sup>.

Rebamipide [2-[4-chlorobenzoylamino]-3-[2[1H]quinolinon-4-yl] propionic acid; OPC-12759], a mucosal-protective anti-ulcer agent, was reported to inhibit IL-8 in gastric cancer by the regulation of phospholipase D (PLD) expression. Gastric cancer cells infected with *H. pylori* display significant induction of PLD1 expression *via* activation of NF- $\kappa$ B<sup>[94]</sup>. The level of PLD1 protein and I $\kappa$ B $\alpha$  phosphorylation is aberrantly upregulated in *H. pylori*-infected human gastric tissues. Rebamipide is a gastroprotective agent used in the treatment of gastritis and gastric ulcers<sup>[95]</sup>. It protects against gastric mucosa inflammation induced by *H. pylori* by inhibiting neutrophil function<sup>[96]</sup>. Moreover, rebamipide inhibits the growth of gastric cancer cells<sup>[97]</sup>. PLD and IL-8 might be novel targets of rebamipide in *H. pylori*-associated gastric cancer.

Gefitinib (Iressa<sup>TM</sup>, ZD1839) reportedly inhibits epidermal growth factor (EGF) signals and IL-8 production in gastric cancer cells<sup>[98]</sup>. Gefitinib is an orally active, quinazoline-derived agent that inhibits EGF receptor (EGFR)-tyrosine kinase<sup>[99]</sup>. Previous studies have shown that EGFR-mediated signals contribute to the expression of IL-8 and that IL-8 may be involved, at least in part, in EGF/EGFR-induced cancer progression<sup>[100]</sup>. Kishida *et al.*<sup>[98]</sup> employed SN38 (an active metabolite of CPT-11) for activation of EGFR-tyrosine kinase. SN38 activates the EGF/EGFR autocrine loop and induces IL-8 in gastric cancer cells. SN38 induces binding activities in both NF-

$\kappa$ B and AP-1, critical transcription factors for the expression of IL-8, and this reaction is inhibited by gefitinib.

Interestingly, Zhou *et al.*<sup>[101]</sup> suggested that the probiotic application of lactobacilli may inhibit IL-8 production induced by *H. pylori*-activated Toll-like receptor 4 (TLR4). *Lactobacillus bulgaricus* (LBG), a bacterium used in the production of yogurt, is one of the best-studied probiotic microbes. Probiotics are living microorganisms with no or low pathogenicity, which exert beneficial effects on the host. *H. pylori* induces mucosal inflammation including IL-8 production *via* TLR4 signaling<sup>[102]</sup>. Conjugated linoleic acids (CLA) produced by *Lactobacillus acidophilus* (LBA) also decreases the activation of NF- $\kappa$ B and IL-8 expression in *H. pylori*-infected gastric epithelial cells<sup>[103]</sup>. Kim *et al.*<sup>[65]</sup> demonstrated that CLA-containing conditioned medium produced by LBA has anti-inflammatory effects on *H. pylori* infection. In their study, conditioned medium produced by LBA significantly inhibited the activation of the core inflammatory gene signal NF- $\kappa$ B in gastric epithelial cells by dissociation of the complex between Hsp90 and the I $\kappa$ B kinase-subunit. CLA-containing conditioned medium also inhibited the expression of IL-8<sup>[65]</sup>. There is increasing evidence<sup>[104]</sup> that *Lactobacillus* has therapeutic effects on *H. pylori*-related diseases, including enhanced eradication of *H. pylori*, amelioration of resistance to antibiotics, downregulated side effects of antibiotic-based therapy, decreased recurrence of *H. pylori* infection, and inhibition of *H. pylori*-induced apoptosis.

Bartel *et al.*<sup>[105]</sup> suggested that a peptide capable of disrupting the interaction between NF- $\kappa$ B and NF- $\kappa$ B repressing factor (NRF) inhibits *H. pylori*-induced IL-8 expression. In *IL-8* gene expression, exclusively, NRF had two functions. It repressed the basal transcription of *IL-8* gene in unstimulated cells<sup>[106]</sup>, but, following cell stimulation, it was required for the transcriptional activation of the *IL-8* gene. A synthetic peptide corresponding to amino acid 223-238 of NRF interfered with the binding of endogenous NF- $\kappa$ B to NRF interaction, which significantly decreased endogenous *IL-8* gene transcription in response to *H. pylori* infection.

Several microRNAs (miR) are reported to regulate *IL-8* gene expression<sup>[107]</sup>. miRNAs are central regulators of various physiologic processes and their disruption is associated with human diseases<sup>[108]</sup>. Recently, Liu *et al.*<sup>[109]</sup> reported that miR-146a negatively regulated *H. pylori*-induced IL-8 *via* reduced NF- $\kappa$ B activity. miR-146a reportedly suppresses NF- $\kappa$ B activity through the reduction of metastatic potential in cancer cells<sup>[110]</sup>. The authors also reported that miR-146a is the negative regulator of NF- $\kappa$ B activity through the downregulation of IRAK1 and TRAF6 in cancer cells. Perry *et al.*<sup>[111]</sup> found that miR-146a was able to negatively regulate the release of IL-1 $\beta$ -induced IL-8, independent of IRAK1 and TRAF6 signals. miR-155 was also suggested to regulate IL-8 in *H. pylori*-infected gastric epithelial cells. Overexpression of miR-155 reportedly reduced the *H. pylori*-induced IL-8 expression<sup>[112]</sup>. miR-155 has been indicated to play a key role in the regulation of normal immunity or inflammation

response<sup>[113,114]</sup>. Among a number of targets of miR-155, MyD88 is suggested for IL-8 regulation<sup>[115]</sup>. miR-155 may downregulate the protein MyD88 through inhibition of translation. Most TLRs activate MyD88 leading to the nuclear translocation of transcription factors, such as NF- $\kappa$ B and AP-1, and thus transcriptionally regulate IL-8<sup>[116]</sup>. The function of miRNAs during *H. pylori* infection is complex and miR-155 may cooperate with other *H. pylori*-induced miRNAs including miR-146a in response to *H. pylori*. There may be crosstalk between miR-146a and miR-155 in the signal pathways leading to the downregulation of *H. pylori*-induced IL-8 in gastric cancer.

Small molecule inhibitors targeting IL-8 receptors (CXCR1 and CXCR2) have been developed to suppress prostate and colon cancers<sup>[117,118]</sup>. Inhibition of these receptors reduces cell migration and invasion, while increasing apoptosis in cancer cells<sup>[119]</sup>. Liu *et al.*<sup>[117]</sup> synthesized a derivative of the human cytokine IL-8, G31P, with high-affinity for human CXCR1 and CXCR2. G31P treatment significantly reduced prostate cancer cell viability, adhesion and migration capacity. Additionally, G31P inhibited tumor tissue vascularization, which was associated with the decreased expression of vascular endothelial growth factor and NF- $\kappa$ B in orthotopic xenograft tissues. Another small molecule inhibitor targeting CXCR2 is SCH-527123<sup>[118]</sup>. SCH-527123 is able to suppress CXCR2-mediated signal transduction as shown through decreased phosphorylation of the NF- $\kappa$ B, MAPK and Akt pathways in colon cancer cells. The anti-tumor activity of SCH-527123 resulted from inhibition of cancer cell growth, motility, and angiogenesis. In addition to having a direct anti-angiogenic and anti-tumor effect, targeting IL-8 or CXCR2 may also increase chemosensitivity to chemotherapeutics. Wilson *et al.*<sup>[120]</sup> also showed that IL-8/CXCR2 signaling confers resistance to chemotherapeutics (oxaliplatin) through NF- $\kappa$ B activity, which is an important determinant of cancer cell sensitivity to chemotherapeutics.

## CONCLUSION

There is a close association between *H. pylori* infection and gastric cancer. IL-8 is overexpressed in gastric epithelial cells exposed to *H. pylori*. IL-8 is significantly upregulated in both the tumor and its microenvironment, and acts as a key regulator of proliferation, angiogenesis and metastasis. IL-8 expression also contributes to the resistance of gastric cancer to chemotherapeutics. Although anti-IL-8 therapeutic agents are yet to enter preclinical and clinical trials, a large body of published evidence suggests that targeting IL-8 in gastric cancer could have broad-spectrum anti-tumor effects. Many advances have been made since the discovery that IL-8 regulates cell signaling in cancer development and progression independently of chemotaxis during the inflammatory process. Thus, we propose that IL-8 induced by *H. pylori* plays a major role in gastric cancer and that targeting IL-8 may be a promising strategy for the treatment of cancer.

## Abstract

*Helicobacter pylori* (*H. pylori*) produce an enzyme known as  $\gamma$ -glutamyl transpeptidase (HpGGT) that is highly conserved and common to all strains. HpGGT has been gaining increasing attention as an important virulence factor of the bacterium, having been demonstrated to be an important colonization factor in several animal models and has also recently been strongly associated with the development of peptic ulcer disease. From the results of various independent researcher groups, it is clear that HpGGT acts through several pathways to damage gastric epithelial cells including the induction of apoptosis and cell cycle arrest, production of reactive oxygen species leading to DNA damage, promotion of inflammation by increasing cyclooxygenase-2 and interleukin-8 expression, and upregulation of heparin-binding epidermal growth factor-like growth

factor resulting in cell survival and proliferation. In addition, the potential role of HpGGT in promoting gastric carcinogenesis will also be discussed in this review. Apart from affecting the gastric epithelium, HpGGT also has immunomodulatory actions on host immune cells where it displays an antiproliferative effect on T cells by inducing cell cycle arrest and also works with other *H. pylori* virulence factors to skew dendritic cells towards a tolerogenic phenotype, possibly contributing to the persistence of the pathogen in the gastric mucosa.

## INTRODUCTION

*Helicobacter pylori* (*H. pylori*) is a Gram-negative, spiral-shaped bacterium that selectively colonizes the human gastric mucosa. It has been reported to chronically infect at least half of the world's population<sup>[1,2]</sup> and may persist for life in the absence of appropriate treatment. *H. pylori* is a major etiological factor of a range of gastroduodenal diseases including chronic gastritis<sup>[3]</sup> and peptic ulcer disease<sup>[4]</sup>, and has been closely associated with the development of mucosa-associated lymphoid tissue lymphoma<sup>[5]</sup> and even gastric cancer<sup>[6]</sup>.

Since the first isolation of *H. pylori* in 1983<sup>[7]</sup>, numerous virulence factors of the pathogen have been identified including the extensively studied cytotoxin-associated gene A (CagA)<sup>[8]</sup> and vacuolating cytotoxin (VacA)<sup>[9]</sup>. In western countries, strains harbouring CagA and VacA (with s1/mL alleles) have been strongly associated with peptic ulcer disease and gastric cancer<sup>[10,11]</sup>. However, their relevance in East Asia remains unclear as such correlations were not apparent<sup>[12,13]</sup>. From these observations, it can be inferred that CagA and VacA are probably not the only factors contributing to *H. pylori* pathogenesis. There is thus a constant search for other pathogenic factors that could aid in the virulence of the bacterium. One such factor is *H. pylori*  $\gamma$ -glutamyl transpeptidase (HpGGT) which has been gaining increasing attention in recent years and will be the main focus of this review.

## PROPERTIES AND FUNCTIONS OF HpGGT

Similar to mammalian GGTs, HpGGT catalyzes reactions in which a  $\gamma$ -glutamyl moiety is transferred from  $\gamma$ -glutamyl compounds, such as glutathione, to amino acids (transpeptidation) or water (hydrolysis)<sup>[14]</sup>. HpGGT is first translated in a single-chain precursor form which is inactive. The proenzyme then undergoes intramolecular autocatalytic cleavage, resulting in a catalytically active heterodimer comprising a large (40 kDa) and small (20 kDa) subunit. Interestingly, the amino acid sequence of HpGGT is considerably different from the GGTs of other bacterial species, sharing only 52.5%, 47.7% and 38% amino acid sequence identities with *Escherichia coli*, *Pseudomonas aeruginosa* and *Bacillus subtilis* GGTs, respectively<sup>[15]</sup>. Among different *H. pylori* strains however, HpGGT is highly conserved with > 97% sequence homology between isolates<sup>[16]</sup>. Notably, HpGGT is also constitutively expressed and is commonly found in all *H. pylori* strains<sup>[15]</sup>, suggesting its importance in the physiology of the bacterium. In further support of this, a subsequent study by Gong and Ho<sup>[17]</sup> demonstrated the importance of HpGGT in the growth of *H. pylori* where strains with higher GGT activity exhibited more profuse growth compared to those having lower GGT activity. Indeed, it was later found that one of the main physiological functions of HpGGT is to metabolize extracellular glutathione and glutamine (substrates that it is unable to uptake directly) as a source of glutamate which is then taken up by the bacterium and subsequently incorporated into the

tricarboxylic acid cycle<sup>[18]</sup>.

## HpGGT and colonization

Although not essential for *in vitro* survival, two pioneer studies on HpGGT had earlier demonstrated the enzyme to be an important virulence factor of the gastric pathogen<sup>[15,19]</sup>. Using the Swiss specific pathogen-free murine model, Chevalier *et al.*<sup>[15]</sup> first described HpGGT to be essential for colonization as *H. pylori* SS1 GGT-deficient mutants could not be recovered from the mice stomachs from 3–60 d post-infection. Interestingly, McGovern *et al.*<sup>[19]</sup> later showed using two different animal models, namely gnotobiotic piglets and C57BL/6 mice, that although the *H. pylori* HpM5 *ggt*-isogenic mutants were still able to colonize the animals, the bacterial load was significantly reduced compared to the parental strain. The differences in animal models and *H. pylori* strains used by both groups could have contributed to the variations observed but nevertheless, both studies had consistently shown that the presence of HpGGT provides an advantage to the bacterium in colonization.

## Association between HpGGT and peptic ulcer disease

The clinical importance of HpGGT was reported by our group in 2010 where *H. pylori* isolates from patients with peptic ulcer disease ( $n = 54$ ) were found to have significantly higher GGT activity ( $P < 0.001$ ) compared to those cultured from patients with non-ulcer dyspepsia ( $n = 44$ )<sup>[16]</sup>. Furthermore, no correlation was observed between HpGGT and other known virulence genes such as *cagA*, *vacA*, *iceA* and *babA*, suggesting a causal link between HpGGT and gastroduodenal diseases. The exact mechanisms detailing how the presence of HpGGT leads to disease development have not been fully elucidated. However, several pathways involving both gastric epithelial cells as well as immune cells have been put forward by various groups and these will be discussed in this review.

## EFFECTS OF HpGGT ON GASTRIC EPITHELIAL CELLS

### HpGGT induces apoptosis

*H. pylori*-induced apoptosis of gastric epithelial cells both *in vitro* and *in vivo* had earlier been described by many researchers<sup>[20–22]</sup>, however the bacterial factor(s) responsible were not clearly defined. By analyzing various *H. pylori* membrane fractions capable of inducing apoptotic cell death in AGS cells, HpGGT was later found to be one of the leading factors involved in the induction of apoptosis by *H. pylori*<sup>[23]</sup>. The pathway by which this occurs is mitochondria-mediated as evident from the accompanying activation of caspases 9 and 3, upregulation of proapoptotic Bax and downregulation of antiapoptotic Bcl-2 and Bcl-xL as well as the release of cytochrome *c* from the mitochondria into the cytosolic space<sup>[24]</sup>. In addition, it has also been shown by Kim *et al.*<sup>[25]</sup> that HpGGT inhibits cell cycle progression at the G<sub>1</sub>-S phase transition and the authors have suggested that this dysregulation

results in the enhancement of apoptosis.

The underlying mechanism as to how HpGGT triggers apoptosis was not addressed in these earlier studies. Interestingly, we had recently reported that exposure of gastric cells to purified native HpGGT resulted in the formation of reactive oxygen species (ROS), in particularly  $H_2O_2$ <sup>[16]</sup> which is a known inducer of apoptosis<sup>[26-28]</sup>. Accordingly, we and others have shown that pro-oxidant products generated by HpGGT through glutathione degradation triggered apoptosis in gastric epithelial cells<sup>[16,29]</sup>, hence providing the link between HpGGT and its ability to induce apoptotic cell death. This model also corroborates with earlier observations whereby *H. pylori* infection was found to be associated with excessive ROS levels<sup>[30,31]</sup> and diminished glutathione levels in the infected gastric mucosa<sup>[32]</sup>.

Intriguingly, apart from gastric cells, HpGGT has also recently been shown to be capable of inducing mitochondria-mediated apoptosis in a human cholangiocarcinoma cell line<sup>[33]</sup>. This suggests that HpGGT-induced apoptosis is not only restricted to gastric epithelial cells and may possibly occur via a common pathway across different cell types. Hence, future studies investigating the effects of HpGGT on other cell lines may be of particular interest.

### **HpGGT is pro-inflammatory**

*H. pylori*-infected subjects develop an inflammatory and immune response towards the pathogen characterized by infiltration of the mucosa by polymorphonuclear and mononuclear leukocytes as well as neutrophils<sup>[34]</sup>. However, this response is ineffective in clearing the bacteria, thereby resulting in chronic gastric inflammation<sup>[35]</sup>. With regard to the role of HpGGT in inflammation, Busiello *et al.*<sup>[36]</sup> showed by using the MKN28 gastric cell line that HpGGT upregulates cyclooxygenase-2 (COX-2) expression and its enzymatic product prostaglandin  $E_2$ , whose role in inflammation has been well established<sup>[37]</sup>. Notably, COX-2 has been found to be overexpressed in various types of cancer including gastric carcinoma<sup>[38-40]</sup> and has roles in promoting cell proliferation, angiogenesis and metastasis<sup>[41-43]</sup>.

In addition, our group had also previously reported that purified native HpGGT stimulated the activation of the transcription factor NF- $\kappa$ B, leading to increased expression and secretion of the pro-inflammatory chemokine interleukin-8 (IL-8) from both AGS and primary gastric epithelial cells<sup>[16]</sup>. HpGGT-induced IL-8 production in gastric cells may thus contribute to the recruitment of immune cells to the sites of infection and the maintenance of chronic inflammation in the gastric mucosa. Importantly, *H. pylori* infection has been associated with elevated levels of gastric IL-8<sup>[44,45]</sup>, a potent neutrophil recruitment factor thought to play a pivotal role in the immunopathogenesis of *H. pylori* infections<sup>[46]</sup>. Collectively, these results strongly support the contributory

role of HpGGT in pro-inflammatory processes.

### **Increase in epidermal growth factor-related peptide expression**

HpGGT upregulates the expression of heparin-binding epidermal growth factor-like growth factor (HB-EGF), a member of the EGF-like growth factor family of proteins and a ligand of epidermal growth factor receptor (EGFR)<sup>[36]</sup>. HB-EGF is first synthesized as a membrane-anchored precursor which is subsequently cleaved at the cell surface, yielding the mature, soluble form<sup>[47]</sup>. Binding of soluble HB-EGF to EGFR activates the Raf/Ras/MEK/Erk and phosphoinositide-3-kinase (PI3K)/Akt pathways which promote cell survival and proliferation<sup>[48,49]</sup>. Importantly, expression of HB-EGF has been reported to be increased in various cancer types including hepatic<sup>[50]</sup>, breast<sup>[51]</sup>, ovarian<sup>[52]</sup> and gastric cancer<sup>[53]</sup>. Furthermore, both expression and protein shedding of HB-EGF have been found to be increased in *H. pylori* infections<sup>[54]</sup> and this has been suggested to contribute to gastric cancer progression by promoting epithelial-mesenchymal transition<sup>[55]</sup>. Till date, the definitive role of HpGGT-induced HB-EGF expression in gastric cells has not been clearly elucidated but its potential role in carcinogenesis would certainly be an area worth investigating in future studies.

### **Disturbing the balance between cell survival and cell death: Link to carcinogenesis?**

It seems contradictory for HpGGT to have both apoptosis- and survival-promoting properties. However, both effects may play different roles during the various events of carcinogenesis. HpGGT-induced apoptosis has been suggested to be important particularly in the early events of carcinogenesis<sup>[23]</sup>. This is because an increase in the rate of apoptosis in a subpopulation of cells could induce a secondary hyperproliferative response where the gastric mucosa attempts to maintain its cell mass<sup>[56]</sup>. Hyperproliferation, coupled with DNA damage induced by HpGGT<sup>[16]</sup>, could then potentially lead to an increase in the mutation rates of important tumor suppressor genes in these cells, resulting in their transformation to a malignant phenotype. In tumor cells that have become apoptosis-resistant, it is then possible that HpGGT-induced COX-2 upregulation in these cells contribute to their continuous survival and proliferation. This postulation is partially supported by the finding that HpGGT-dependent induction of COX-2 mRNA is higher in MKN28 cells compared to AGS cells as observed by Busiello *et al.*<sup>[36]</sup>. Although AGS and MKN28 cells are both carcinoma cells lines, MKN28 cells have a mutation in p53, an important tumor suppressor involved in the control of cell cycle progression and apoptosis<sup>[57]</sup>. Thus, it is plausible that COX-2-induced cell proliferation affects apoptosis-resistant tumor cells to a greater extent, leading to the survival and proliferation of these cancerous cells.

Figure 1 Schematic diagram highlighting important effects of *Helicobacter pylori*  $\gamma$ -glutamyl transpeptidase on both gastric epithelial and immune cells and their implications on carcinogenesis and persistence of *Helicobacter pylori* in the gastric mucosa. COX-2: Cyclooxygenase-2; HpGGT: *Helicobacter pylori* (*H. pylori*)  $\gamma$ -glutamyl transpeptidase; GSH: Glutathione; HB-EGF: Heparin-binding epidermal growth factor-like growth factor; IL-8: Interleukin-8; LPS: Lipopolysaccharide; miR-155: microRNA-155; NF- $\kappa$ B: Nuclear factor-kappa B; ROS: Reactive oxygen species; VacA: Vacuolating cytotoxin. Red arrows indicate upregulation of the respective molecules.

## HpGGT MODULATES THE IMMUNE SYSTEM

Apart from directly influencing gastric epithelial cells, an increasing body of evidence pointing to the role of HpGGT in modulating the immune response is emerging. Being a secreted bacterial protein<sup>[58]</sup>, the possibility of HpGGT interacting with other non-gastric cells is highly possible especially since *H. pylori* is capable of disrupting gastric epithelial barrier function<sup>[59]</sup>. Interestingly, the effects of HpGGT on immune cells have been investigated in various studies and have yielded important results and implications.

### Effects on T cells

In one of the earlier studies investigating the effects of HpGGT on immune effector cells, Schmees *et al.*<sup>[60]</sup> found that HpGGT was capable of abrogating the proliferation of both primary and immortalized human T cells. A corresponding cell cycle arrest at the G<sub>1</sub> phase was observed in these cells which possibly occurred due to disruption of a Ras-dependent signalling pathway. Intriguingly, inhibition of T cell proliferation by HpGGT was found in the same study to be mediated by an apoptosis-indepen-

dent mechanism which is different from that observed in gastric epithelial cells, suggesting that separate mechanisms exist in both cell types. HpGGT-induced inhibition of T cell proliferation has been proposed to have immunosuppressive effects which contribute to the persistence of *H. pylori* infections<sup>[60]</sup>. Interestingly, in a separate study by Beigier-Bompadre *et al.*<sup>[61]</sup>, HpGGT-dependent antiproliferative effect on T cells was found to be modulated by bacterial cholesterol/cholesterol  $\alpha$ -glucoside content, suggesting that HpGGT works with other *H. pylori* factors to shape the immune response during an infection.

Working together with *H. pylori* lipopolysaccharide and vacuolating cytotoxin (VacA), HpGGT was recently reported to upregulate microRNA-155 (miR-155) expression in CCRF-CEM cells, the first study to investigate the regulation of miRNAs by *H. pylori* in T cells<sup>[62]</sup>. Clinically, miR-155 has been shown to be induced upon *H. pylori* infection<sup>[63]</sup> and has also been associated with the development of diffuse large B-cell lymphoma<sup>[64,65]</sup>. In addition, HpGGT-induced miR-155 expression in both CCRF-CEM cells and primary human peripheral blood mononuclear cells was found to be dependent on forkhead box P3 (Foxp3) and requires activation of the cyclic adenosine monophosphate cascade<sup>[62]</sup>. Foxp3 is a tran-

**Table 1** Summary of the effects of *Helicobacter pylori*  $\gamma$ -glutamyl transpeptidase on the host and the possible underlying mechanisms involved

Ref.	Study description	Main findings
Peptic ulcer disease Gong <i>et al</i> <sup>[16]</sup> (2010)	Comparison of GGT activity between <i>H. pylori</i> isolates from PUD ( <i>n</i> = 54) <i>vs</i> NUD ( <i>n</i> = 44) patients.	HpGGT is associated with PUD as strains isolated from PUD patients had significantly higher HpGGT activity compared to those from NUD patients ( <i>P</i> < 0.001).
Gastric epithelium damage by apoptosis Shibayama <i>et al</i> <sup>[23]</sup> (2003)	Identification of apoptosis-inducing factors from <i>H. pylori</i> by testing different purified membrane fractions of the bacteria on AGS cells.	HpGGT is a leading factor in <i>H. pylori</i> -mediated apoptosis induction.
Kim <i>et al</i> <sup>[24]</sup> (2007)	Determination of the pathway involved in HpGGT-induced apoptosis by analyzing levels of caspase-9, -3, Bax, Bcl-2, Bcl-xL and cytochrome c release in AGS cells upon treatment with recombinant HpGGT.	HpGGT induces apoptosis <i>via</i> a mitochondria-mediated pathway.
Kim <i>et al</i> <sup>[25]</sup> (2010)	Examination of the effects of recombinant HpGGT on cell cycle progression in AGS cells.	HpGGT induces cell cycle arrest at the G <sub>1</sub> -S phase transition. (The authors propose this dysregulation enhances apoptosis induction)
Gong <i>et al</i> <sup>[16]</sup> (2010)	Investigation of the effects of HpGGT-induced H <sub>2</sub> O <sub>2</sub> production on apoptosis. AGS cells were incubated with purified native HpGGT and NAC (H <sub>2</sub> O <sub>2</sub> inhibitor) and the activities of caspase-3, -8 and -9 were measured.	HpGGT-mediated oxidative stress is required for HpGGT-associated apoptosis.
Promotion of inflammation Busiello <i>et al</i> <sup>[36]</sup> (2004)	Purification and identification of secreted <i>H. pylori</i> factors involved in the upregulation of COX-2 expression in MKN28 cells.	HpGGT is able to upregulate COX-2 expression and its enzymatic product, prostaglandin E <sub>2</sub> .
Gong <i>et al</i> <sup>[16]</sup> (2010)	Determination of the ability of HpGGT to induce IL-8 production in AGS and primary gastric epithelial cells.	Purified native HpGGT activates NF- $\kappa$ B and upregulates IL-8 production in gastric epithelial cells.
Upregulation of heparin-binding epidermal growth factor-like growth factor Busiello <i>et al</i> <sup>[36]</sup> (2004)	Investigation of the ability of HpGGT to upregulate HB-EGF expression in MKN28 cells and elucidating the underlying host cellular pathways involved using specific pathway inhibitors.	HpGGT upregulates HB-EGF expression <i>via</i> activation of a phosphatidylinositol-3 kinase and p38 kinase-dependent signalling transduction pathway. Increase in HB-EGF promotes cell survival and proliferation.
Modulation of host immune response Schmees <i>et al</i> <sup>[60]</sup> (2007)	Purification and identification of <i>H. pylori</i> factors responsible for inhibition of T cell proliferation.	HpGGT inhibits T cell proliferation by inducing cell cycle arrest in the G <sub>1</sub> phase, possibly through the disruption of a Ras-dependent signalling pathway.
Beigier-Bompadre <i>et al</i> <sup>[61]</sup> (2011)	Characterization of the interdependent effects of VacA, HpGGT and bacterial cholesterol on T cell proliferation using <i>H. pylori</i> and relevant mutants.	HpGGT antiproliferative activity on T cells is modulated by the bacterial cholesterol/cholesterol $\alpha$ -glucoside content.
Fassi Fehri <i>et al</i> <sup>[62]</sup> (2010)	Identification of <i>H. pylori</i> factors involved in the regulation of miRNAs in T cells using miRNA profiling.	HpGGT works with <i>H. pylori</i> VacA and lipopolysaccharide to upregulate miRNA-155 expression in CCRF-CEM cells. This was dependent on Foxp3 transcription factor and requires activation of the cAMP cascade.
Oertli <i>et al</i> <sup>[68]</sup> (2013)	Determination of the role of HpGGT and VacA in dendritic cell reprogramming and development of immune tolerance using <i>in vitro</i> and <i>in vivo</i> models.	Both HpGGT and VacA independently interfere with dendritic cell maturation, possibly contributing to dendritic cell tolerization and hence promoting the persistence of <i>H. pylori</i> infection.

cAMP: Cyclic adenosine monophosphate; COX-2: Cyclooxygenase-2; EGFR: Epidermal growth factor receptor; Foxp3: Forkhead box P3; *H. pylori*: *Helicobacter pylori*; HB-EGF: Heparin-binding epidermal growth factor-like growth factor; HpGGT: *H. pylori*  $\gamma$ -glutamyl transpeptidase; IL-8: Interleukin-8; miRNA: microRNA; NAC: N-acetylcysteine; NF- $\kappa$ B: Nuclear factor-kappa B; NUD: Non-ulcer dyspepsia; PUD: Peptic ulcer disease; VacA: Vacuolating cytotoxin.

scription factor thought to be the master regulator in the development of regulatory T cells (Treg)<sup>[66]</sup>, a subset of T cells with a suppressive activity on immune responses<sup>[67]</sup>. In support of this, mice infected with *ggt*-isogenic mutants were found to have lower Treg counts compared to wild type-infected mice<sup>[68]</sup>. Hence, it was suggested that HpGGT may play an important role in the modulation of the immune system<sup>[62]</sup>.

### HpGGT affects dendritic cells

The ability of *H. pylori* to reprogram dendritic cells (DCs) towards a tolerogenic phenotype has been implicated in

the development of immune tolerance and favors persistence of the bacteria in the gastric mucosa<sup>[69]</sup>. Recently, it has been reported that both VacA and HpGGT play critical roles in DC reprogramming by interfering with their maturation and that this occurred in a manner independent of their suppressive effects on T cells<sup>[68]</sup>. The underlying mechanisms dictating how both factors prevent DC maturation and promote tolerization were not clearly elucidated in the study but it is known that they act via non-redundant pathways since neither of the respective isogenic mutants was capable of rescuing the effect of the other.

## CONCLUSION

*H. pylori* produces a potent virulence factor, HpGGT, which causes injury to host cells through multiple ways (illustrated in Figure 1 and summarized in Table 1), many of which have been implicated in carcinogenesis. To gastric epithelial cells, it induces mitochondrial-dependent apoptosis, cell cycle arrest and production of the pro-inflammatory IL-8. To T cells, it inhibits their proliferation and upregulates miR-155 expression while to DCs, it skews them towards a tolerogenic phenotype. Taken together, it is clear that HpGGT plays an important role in the pathogenesis of *H. pylori* by directly damaging gastric epithelial cells and also in modulating the immune response towards the bacterium, resulting in persistent colonization by the organism. Despite the relatively numerous reports on its effects on the host, much of the underlying mechanisms of how such effects are brought about by HpGGT remain ill-defined. Future studies on the molecular mechanisms responsible for the actions of HpGGT will be required to better understand the role of HpGGT in the pathogenesis of *H. pylori*. This will be particularly important in the consideration of HpGGT as a viable anti-*H. pylori* target. In addition, it could also be worthwhile to evaluate the efficacy of HpGGT as a potential vaccine candidate against *H. pylori* infections especially since the protein is present in all *H. pylori* strains.

### Abstract

*Helicobacter pylori* (*H. pylori*) is a common human pathogen responsible for various gastric diseases. This bacterium relies on the production of urease and hydrogenase to inhabit the acidic environment of the stomach. Nickel is an essential cofactor for urease and hydrogenase. *H. pylori* has to uptake sufficient nickel ions for the maturation of urease, and on the other way, to prevent the toxic effects of excessive nickel ions. Therefore, *H. pylori* has to strike a delicate balance between the import of nickel ions, its efficient intracellular storage, and delivery to nickel-dependent metalloenzymes when required. The assembly and maturation of the urease enzyme is a complex and timely ordered process, requiring various regulatory, uptake, chaperone and accessory proteins. In this review, we focus on several nickel trafficking proteins involved in urease maturation: NikR, NixA, HypAB, UreEFGH, HspA, Hpn and HpnI. The work will deepen our understanding of how this pathogenic bacterium adapts to severe habitat environments in the host.

### INTRODUCTION

*Helicobacter pylori* (*H. pylori*), a micro-aerophilic Gram-negative spirobacterium, infects around half of the people worldwide and is responsible for gastric diseases

**Figure 1** Structure of *Helicobacter pylori* urease. A: The urease enzyme subunit UreAB (UreA, blue; UreB, cyan; PDB code: 1E9Z); B: The active sites of *H. pylori* urease with the side chains of the enzyme involved in the chelation of the catalytic di-nickel center shown (Ni, green; O, red; N, blue; C, pink). *H. pylori*: *Helicobacter pylori*.

such as chronic gastritis, peptic ulcer and gastric cancer<sup>[1]</sup>. The bacterium is widely present in the mucus layer of the stomach, the mucus glands in the stomach cavity and the surface of gastric epithelial cells as well as within the cells. Due to the wide presence in the differential parts of the stomach, it is difficult to completely eradicate the pathogen during gastric disease therapy<sup>[2]</sup>. The commonly used treatment for *H. pylori* related diseases is the so-called triple therapy, which consists of two antibiotics and either a proton pump inhibitor (PPI) or one kind of bismuth-based colloidal drug<sup>[3,4]</sup>. In some countries, standard triple therapy combining one PPI, amoxicillin and clarithromycin is the best option. However, in countries where clarithromycin resistance rate is over 20%, bismuth-containing quadruple therapy, or non-bismuth sequential or concomitant therapies are the preferred option. The medical and social impact of the discovery of *H. pylori* was acknowledged by the award of the 2005 Noble Prize in Physiology and Medicine to Marshall and Warren.

Around 80% of *H. pylori* cells inhabit the moderately acidic gastric mucus. Once entry into the stomach, the first hurdle for *H. pylori* is to be quickly transmitted through the extremely acidic gastric lumen, exhibiting a median pH of approximately 1.4<sup>[5]</sup>. *H. pylori* multiplies in an environmental pH from 6.0 to 8.0<sup>[6]</sup>, and cannot survive when the pH < 4.0 or > 8.2<sup>[7]</sup>. In order to live in the gastric environment, *H. pylori* has developed various acid-resistant mechanisms. Time-independent acid resistance depends on the high isoelectric points of the inner and outer membrane proteins to reduce proton permeability<sup>[8]</sup>. Acute acid resistance depends on the constitutive synthesis of urease that catalyzes the hydrolysis of urea to ammonia and carbamate, the latter of which is further degraded to ammonia and carbonic acid. The end products are in an equilibrium between their protonated and de-protonated forms, leading to an elevation of the surrounding pH from absolutely acidic to approximately neutral<sup>[9]</sup>. Urease is an oligomeric Ni<sup>2+</sup>-containing heterodimer of UreA and UreB subunits and is essential for *H. pylori* to infect in all animal models so far examined<sup>[10-12]</sup>. The substrate gastric juice urea is able to rapidly

access intrabacterial urease through a pH-gating urea channel, UreI<sup>[13]</sup>, when the periplasmic pH falls < 6.2.

*H. pylori* urease is produced in a high level, accounting for up to 10% of total cellular proteins<sup>[14]</sup>. Expression of urease protein is constitutive<sup>[15]</sup>, primarily due to the housekeeping  $\sigma^{80}$ -dependent promoters for the transcription of both *ureAB* and *ureEFGHI*<sup>[16,17]</sup>. Under *in vitro* growth conditions without additionally added Ni<sup>2+</sup>, only 2% of the active sites were filled with Ni<sup>2+</sup><sup>[18,19]</sup>. Urease produces NH<sub>3</sub> from gastric juice urea with maximal efficiency at millimolar concentrations<sup>[14,20]</sup>, 10<sup>14</sup> times faster than uncatalyzed reactions. The enzymatic hydrolysis of urea causes an abrupt overall pH increase, resulting in negative side effects for human and positive effects in the buffering of the periplasm and maintenance of a proton motive force adequate for ATP synthesis of the bacterium<sup>[21]</sup>. *H. pylori* urease was shown to be a giant 1.1 MDa complex containing 12 subunits of UreA and UreB (Figure 1), with two Ni<sup>2+</sup> needed for enzyme activity<sup>[6,22]</sup>. The assembly of the urease enzyme is a complex, timely ordered process, and the UreEFGH accessory proteins are absolutely necessary<sup>[23,24]</sup>. UreH stabilizes the apoprotein<sup>[23]</sup>; UreF facilitates carbamylation of the Ni<sup>2+</sup>-bridging lysine residue and blocks premature Ni<sup>2+</sup> binding to the active site<sup>[26]</sup>; UreG provides energy during urease assembly<sup>[27]</sup>, and UreE facilitates Ni<sup>2+</sup> incorporation into the active center<sup>[28]</sup>. The hydrogenase accessory proteins HypA and HypB are also necessary to maintain the urease activity, indicating that the bacterium utilizes both maturation systems for the activation of its urease<sup>[18]</sup>. This present review intends to cover the reports and discoveries in the field of nickel trafficking system in urease maturation of *H. pylori*, which may deepen our understanding of how this pathogenic bacterium adapts to severe habitat environments in the host.

## NICKEL REGULATORY PROTEIN NIKR

Bacteria have developed sophisticated mechanisms to regulate levels of intracellular nickel ions, to ensure sufficient nickel for enzyme processes in one way and to

prevent excessive toxic free ions in the other way<sup>[29]</sup>. NikRs, a novel class of ribbon-helix-helix nickel regulatory proteins, are homotetrameric transcription factors that repress and/or activate specific genes in response to nickel availability. *H. pylori* NikR, a tetrameric protein made of two dimeric N-terminal DNA-binding domains (DBD) and C-terminal domains for tetramerization and metal binding (MBD), binds stoichiometric nickel with picomolar affinities<sup>[30,31]</sup>, comparable to NikRs from other species<sup>[32-34]</sup>. The DBD and MBD are connected by a flexible linker, allowing for differential conformations (open, trans and cis) of NikR. In *E. coli* and *Pyrococcus horikoshii*, the apo-NikRs adopt an open conformation, whereas the apo-NikR shows an unusual closed *trans*-conformation and asymmetrical quaternary arrangement, where the DBDs are on the opposite sides of the transmembrane domain<sup>[35]</sup>. Computational and NMR studies suggest that NikR is interconverting among the open, trans and cis forms in solution and nickel binding facilitates the interconversion<sup>[36]</sup>.

At non-physiologically low pH (4.6-5.6), NikR had three types of nickel-binding sites: the final high affinity site (F) with square-planar geometry, the intermediate site (I) involving residues belonging either to the F or external site, and the external sites (X) with an octahedral geometry<sup>[35,37]</sup>. Whereas in physiological conditions (pH 5.6-7.5), NikR binds four low-spin Ni<sup>2+</sup> at the protein tetramerization interface, although differential nickel coordination modes are proposed. Michel's group suggests that two nickels are bound at 4-coordinate square-planar sites with His<sub>3</sub>Cys ligands (*i.e.*, 4-sites) and the other two are coordinated by His<sub>3</sub>(H<sub>2</sub>O)<sub>2-3</sub> in square pyramidal or octahedral geometries (*i.e.*, 5/6 sites)<sup>[37]</sup>. Ciurli's group reports a structure with all four nickel ions bound to 4 sites<sup>[38]</sup>, and the four binding sites are classified into two sets (2/2), with binding affinities differing by one order of magnitude<sup>[39]</sup>. The findings may suggest that an equilibrium exists between the two nickel-bound forms of the protein.

The biological role of NikR is to regulate the transcription of multiple genes as a function of nickel availability<sup>[40,41]</sup>: up-regulated genes in nickel metabolism (*nikABCDE*, *nixA*, *ureA*, *ureB*, *hpn* and *hpn-like*); down-regulated genes in iron uptake and storage (*pfr*, *fur* and *exbB/exbD*), motility (*cheV*, *flaA* and *flaB*), and stress responses to outer membrane proteins (*omp11*, *omp31* and *omp32*)<sup>[40]</sup>. The nickel-responsive binding of NikR to target promoters *pUreA*, *pNikR*, *pexbB* and *pFur* have been characterized by the *in vitro* gel shift and DNase I footprinting studies. Michel's<sup>[42]</sup> group proposed a mechanism for nickel-mediated DNA recognition by NikR. NikR prefers binding Ni at 5/6 sites. Upon addition of two Ni, the ligands are rearranged to two 4-sites. Addition of two more Ni results in mixed coordination geometry (two 4-sites and two 5/6-sites) and makes the protein binding to target DNA. The binding to DNA changes the orientation of the DBD from trans to cis, an orientation that is stabilized at the MBD/DBD interface<sup>[42]</sup>.

Controversial opinions exist for the roles of NikR

in urease activation as a function of pH. One opinion goes that under acidic conditions, the greater availability of Ni<sup>2+</sup> leads to the formation of Ni<sup>2+</sup>-NikR complexes which further increase the expression of urease, Ni<sup>2+</sup> transporter NixA and iron regulator Fur<sup>[43,44]</sup>. Whereas, Pflock *et al.*<sup>[45]</sup> found that a two-component system ArsRS (acid responsive signaling) regulated urease expression in response to low pH, and further proposed that urease expression is mediated by two distinct mechanisms: one in response to increasing Ni<sup>2+</sup> concentration (NikR) and one in response to decreasing pH (ArsR).

## NICKEL UPTAKE

Due to the essential stasis of Ni<sup>2+</sup>-containing urease for the host colonization and infection of *H. pylori*, a constant supply of Ni<sup>2+</sup> into *H. pylori* is required. The concentration of nickel ions in the environment is relatively low: around 30 nM in seawater and 5 nM in freshwater, a condition requiring highly specific importers of Ni<sup>2+</sup> ions for *H. pylori*<sup>[46]</sup>. Thus far, two types of nickel uptake strategies have been identified in *H. pylori*<sup>[46]</sup>: (1) NixA<sup>[47]</sup>, a member of the nickel-cobalt transporter family (Ni-CoT)<sup>[48]</sup>; and (2) the multiple-component ATP-binding protein cassette (ABC)-transporters, which are believed to be a four-gene operon designated as *abcABCD*<sup>[49]</sup>.

NixA is required for effective *H. pylori* colonization, as disruption of the gene led to reduced colonization<sup>[50]</sup>. NixA is predicted to have eight transmembrane-spanning helices, and transports Ni<sup>2+</sup> with a V<sub>max</sub> of 1750 pmol Ni<sup>2+</sup>/min per 10<sup>8</sup> cells and a K<sub>m</sub> of 11.3 nmol<sup>[51,52]</sup>, thus enabling *H. pylori* to efficiently scavenge nickel ions in the range of 2-11 nmol from the human body<sup>[53]</sup>. NixA transcription was shown to be repressed by NikR in a nickel-dependent manner to prevent excess toxic *in vivo* nickel<sup>[44,54]</sup>.

NixA deletion mutants still retained urease activity in some levels (up to 50% in some strains)<sup>[50,55]</sup>, indicating the existence of an alternative nickel transporter. Further analysis identified the *abcABCD* genes, a component of the ATP-dependent nickel transport system to be potentially involved in NixA-independent nickel uptake, as mutations in *abcCD* decreased urease activity<sup>[49]</sup>. Another work identified FrpB4 to be a potential outer membrane nickel uptake protein as energized by the TonB/ExbB/ExbD machinery<sup>[56]</sup>, indicating that the established iron uptake machinery may be involved in nickel uptake. However, further work is needed to confirm their role and mechanism in nickel transport.

## CHAPERONES

Similar to other bacteria, *H. pylori* has to maintain a delicate balance between the import of nickel ions, its efficient intracellular storage, and delivery to nickel-dependent metalloenzymes when required. Metals, such as nickel, pose problems for the cell because they are required for the growth, whereas they inhibit growth and

**Figure 2** Amino acid sequence of Hpn (A) and the apparent rate of nickel release vs concentrations of ethylenediaminetetraacetic acid at pH 6.8 and 7.4 and the best nonlinear fit of the data (B). EDTA: Ethylenediaminetetraacetic acid.

exhibit toxic effects when present in excess. In this section, we would like to discuss the proteins involved in metallocenter assembly in urease.

### HypA and HypB

HypA and HypB are named to emphasize their roles in the maturation and activation of NiFe hydrogenase (*hyp*, hydrogenase pleiotropic). However HypA and HypB are also found to be accessory proteins for urease<sup>[57]</sup>, as reflected by the reduced urease activity (40-200 folds) upon *hypA* or *hypB* disruption<sup>[18]</sup> and the competition between HypA and UreG for UreE (see below) recognition<sup>[58]</sup>. HypA binds nickel and zinc ions and HypB is a P-loop GTPase to provide energy during nickel insertion in hydrogenase. HypA and HypB exist as homodimers in solution and form heterodimers with each other<sup>[59,60]</sup> with a low affinity ( $K_d$  of  $52.2 \pm 8.8 \mu\text{mol}$ )<sup>[61]</sup>. HypA and HypB also make heterodimers with UreE<sup>[62]</sup> and SlyD<sup>[63]</sup>, respectively in solution. The NMR structure of zinc-bound HypA monomer indicates that the nickel binding site is located at the N-terminus and nickel is bound to four nitrogens in a square planar geometry<sup>[64]</sup>. A thermodynamic study indicates that the zinc binding site has a much higher affinity to zinc than nickel and zinc binding induces a great change in the secondary structure of HypA to exert its structural role in the metalloprotein<sup>[65]</sup>. Further study with XAS showed that HypA dimer has a unique structural flexibility of the zinc site and has roles in sensing nickel binding and pH<sup>[66,67]</sup>: a decrease of pH from 7.2 to 6.3 induces a change of the zinc binding ligands from Cys<sub>4</sub> to Cys<sub>2</sub>His<sub>2</sub> and results in a change of the nickel binding stoichiometry from one Ni per monomer to one Ni per dimer<sup>[66]</sup>. Cys106 and His107 of HypB are required for nickel binding and metal-dependent dimerization<sup>[68]</sup>. Nickel binding of HypB is possibly facilitated by SlyD *via* its IF (insert-in-flap) domain<sup>[63]</sup>. Zinc binding significantly inhibits the GTPase activity of

HypB<sup>[68]</sup>. Nickel binding is reported to either slightly<sup>[68]</sup> or highly<sup>[61]</sup> stimulate the activity of HypB, with reasons for these discrepancies yet unknown. The regulation of HypB activities by metal binding may contribute to the maturation of the hydrogenase and urease.

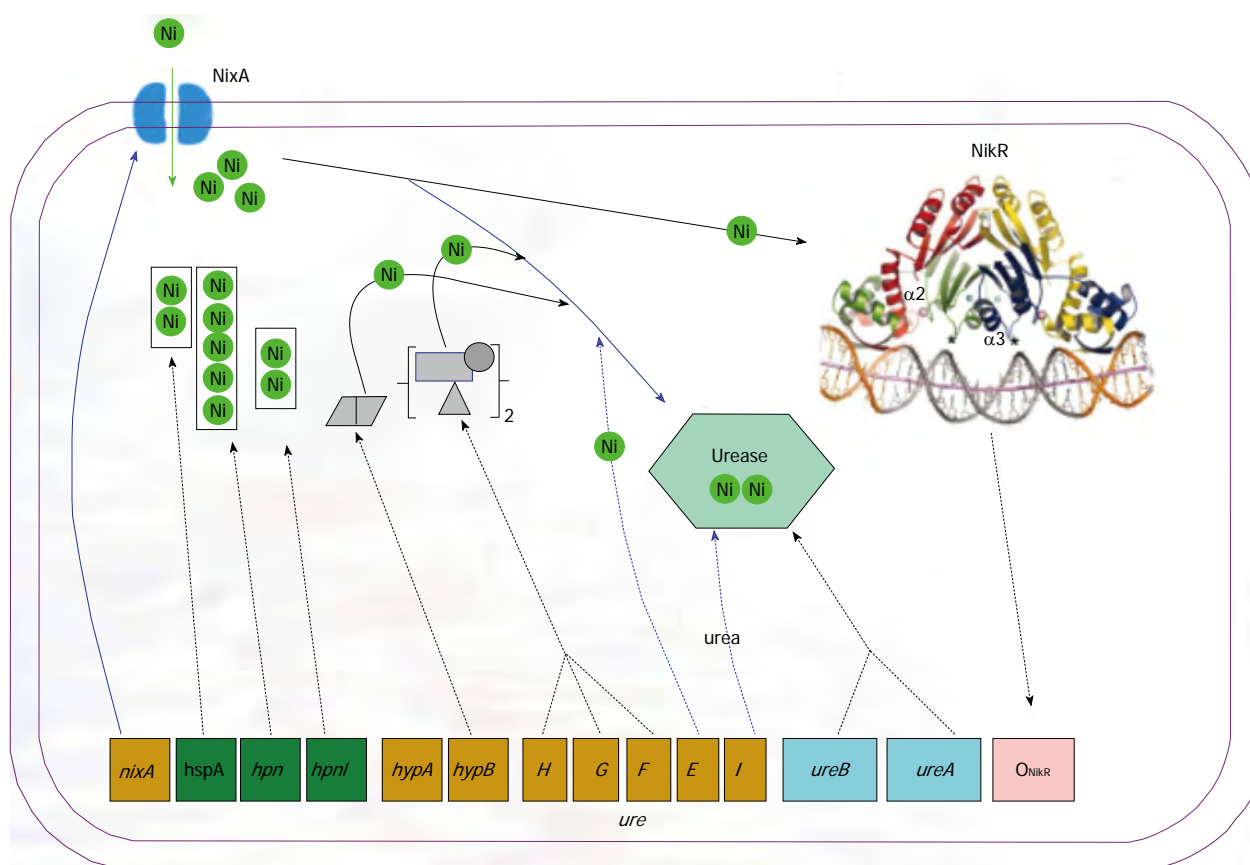

### UreEFGH

UreEFGH is a group of accessory proteins involved in the synthesis of the urease active site<sup>[41]</sup>, which has been excellently covered recently in a review by Farrugia *et al.*<sup>[69]</sup>. This review will only briefly discuss their respective roles. The information about UreH is quite limited primarily due to its insolubility in solution, although it is believed to be the first protein to bind to apo-urease<sup>[70]</sup>. UreE is the chaperone to deliver nickel to urease and UreF activates the GTPase activity of UreG<sup>[29,41]</sup>. UreE is capable of binding Ni and Zn ( $K_d$  of 0.15 and 0.49  $\mu\text{mol}$ , respectively) in a stoichiometry of one per dimer<sup>[71,72]</sup>. Apo-UreE is a dimer and the metal-bound protein is a tetramer (dimer of dimer) formed by the coordination of the metal ion by His104 from each subunit<sup>[73]</sup>. A second UreE crystal structure indicates that Ni is six-coordinate (His102 from one monomer, His102, His152, Glu4 from the other, a water molecule and one unidentified ligand)<sup>[74]</sup>. His152 is disordered in the crystal and could be replaced by UreG residues, thus leading to the transfer of nickel from UreE to UreG. In the calculated structure of UreDEFG through computational modeling, the convex surface of the UreG dimer is in direct contact only with the shallow crevice at the interface of the two UreF monomers through weak van der Waals and polar interactions<sup>[75]</sup>. UreF and UreH can form dimer or heterodimers in solution with concomitant conformational changes in two distinctive regions of UreF<sup>[76]</sup>: (1) the flexible C-terminus becomes ordered to form an extra helix  $\alpha_{10}$  and a loop stabilized by hydrogen bonds involving Arg250; and (2) the first turn of helix  $\alpha_2$  uncoils to expose a conserved residue Tyr48. Both Arg250 and Tyr48 are critical for the heterotrimeric formation of UreG-UreF-UreH and urease maturation<sup>[76]</sup>. One crystal structure of UreGFH indicates that UreFH facilitates UreG dimerization and assembles its metal binding sites by juxtaposing two Cys66-Pro67-His68 motifs at the interface to form the (UreGFH)<sub>2</sub> complex<sup>[77]</sup>.

### HspA, Hpn and Hpn-like

HspA, Hpn and Hpn-like (HpnI) proteins in *H. pylori* are histidine-rich in full or in part. HspA is a bacterial GroES homologue with a unique cysteine- and histidine-rich C-terminal domain<sup>[78]</sup>. HspA binds 2 Ni per monomer with a dissociation constant of 1.1  $\mu\text{mol}$  *in vitro*<sup>[79]</sup>. The *in vivo* work showed that HspA is involved in intracellular nickel sequestration and detoxification, and plays a role as a specific nickel chaperone in the maturation of hydrogenase, while not for urease<sup>[80]</sup>. Hpn (Figure 2A) is a histidine rich protein (accounting for around half of its amino acids) and highly abundant in the cell cytoplasm (approximately 2% of all protein synthesized)<sup>[81]</sup>.

**Figure 3** Complex network controlling urease synthesis and activity in *Helicobacter pylori*. The different levels of control comprise (1) expression of the UreAB structural subunits fine-tuned by acidity and the nickel-dependent transcriptional regulator NikR; (2) nickel uptake into cells via NixA importer; (3) nickel storage in histidine-rich proteins such as Hpn, HpnI and HspA; (4) nickel incorporation into urease as mediated by accessory proteins UreEFGH and HypAB; and (5) urea substrate entry via UreI. *H. pylori*. *Helicobacter pylori*.

The majority of histidines are located within the central part of the protein and include two separated stretches of 6 and 7 consecutive histidine residues. There are two internal short repeats of Glu-Glu-Gly-Cys-Cys, four sets of paired histidine residues and an X-X-His motif at the N-terminus. All these sequence features indicate that this protein would strongly bind metal ions. Mutated strains of *H. pylori* lacking the *hpn* gene are four times more sensitive to ranitidine bismuth citrate, a metal-containing drug widely used to treat *H. pylori* infections, than the wild type<sup>[3,82,83]</sup>. Hpn exists in solution as a range of multimeric forms with the 20-mer to be potentially physiologically relevant<sup>[84]</sup>. The protein can bind nickel in a stoichiometry of five Ni per monomer with a  $K_d$  of 7.1  $\mu\text{mol}$ . Therefore it is possible that nickel may be transferred from Hpn to stronger nickel binding proteins, such as HypA ( $K_d$  of 1.3  $\mu\text{mol}$ ) and HspA ( $K_d$  of 1.8  $\mu\text{mol}$ ). Nickel can be released from Hpn by decreasing pH ( $\text{pH}_{1/2}$  of 6.3) or by adding nickel chelating agent EDTA<sup>[84,85]</sup>, which indicates that Hpn could provide stored nickel ions to the relevant chaperone proteins for the subsequent urease maturation upon intracellular pH decrease. The nickel release from Hpn by EDTA is a two-step process consisting of a rapidly established equilibrium (formation of Hpn-Ni•EDTA,  $K$ ) followed by a rate-determining step (dissociation of Hpn-Ni•EDTA to Ni-EDTA and apo-Hpn,

$k_2$ )<sup>[85]</sup>. The data was fitted in Figure 2B which suggests that lower pH favors both the formation of the Hpn-Ni•EDTA intermediate and its decomposition to the Ni-exchanged products<sup>[85]</sup>. Later work by our group showed that this His-rich protein can form amyloid-like structures and exhibit some cytotoxic effects to gastric epithelia cells<sup>[86]</sup>, indicating that Hpn may be involved in the pathological roles of *H. pylori* other than the nickel storage role in the maturation of nickel specific enzymes<sup>[87]</sup>. HpnI is a histidine- and glutamine-rich protein in *H. pylori*, the N-terminus (46 residues) of which shows 56% identity to Hpn. HpnI binds two nickel ions per monomer in the histidine-rich domain with a dissociation constant of 3.8  $\mu\text{mol}$ <sup>[88]</sup>. Nickel release experiments established that HpnI is similar to Hpn, as nickel can be release from HpnI at acidic pH ( $\text{pH}_{1/2}$  of 4.6) and in the presence of EDTA. One *in vivo* study by Maier's group indicated *H. pylori* can utilize stored nickel ions *via* Hpn and HpnI to aid colonization of the host<sup>[89]</sup>.

## CONCLUSION

*H. pylori* is an established agent causing various gastric diseases. The nickel containing urease and hydrogenase are essential for the successful infections of *H. pylori* in the stomach. Nickel is an essential cofactor for urease

and hydrogenase. Various nickel-binding proteins play key roles in microbial nickel homeostasis by shuttling nickel within the cells. In this review we discussed the regulatory, uptake, chaperone and accessory proteins involved in the maturation of urease, especially the proteins NikR, NixA, HypAB, UreEFGH, HspA, Hpn and HpnI. The proteins function in a coordinated way to mature the urease in an efficient way for the successful inhabitation of the bacterium in the stomach (Figure 3). The work will deepen our understanding of how this pathogenic bacterium adapts to severe habitat environments in the host.

## Abstract

*Helicobacter pylori* (*H. pylori*) infection might initiate and contribute to the progression of lymphoma from gastric mucosa-associated lymphoid tissue (MALT). Increasing evidence shows that eradication of *H. pylori* with antibiotic therapy can lead to regression of gastric MALT lymphoma and can result in a 10-year sustained remission. The eradication of *H. pylori* is the standard care for patients with gastric MALT lymphoma. Cytotoxin-associated gene A (CagA) protein, one of the most extensively studied *H. pylori* virulence factors, is strongly associated with the gastric MALT lymphoma. CagA possesses polymorphisms according to its C-terminal structure and displays different functions among areas and races. After being translocated into B lymphocytes *via* type IV secretion system, CagA deregulates intracellular signaling pathways in both tyrosine

phosphorylation-dependent and -independent manners and/or some other pathways, and thereby promotes lymphomagenesis. A variety of proteins including p53 and protein tyrosine phosphatases-2 are involved in the malignant transformation induced by CagA. Mucosal inflammation is the foundational mechanism underlying the occurrence and development of gastric MALT lymphoma.

**Key words:** *Helicobacter pylori*; Cytotoxin-associated gene A; Gastric mucosa-associated lymphoid tissue lymphoma; Lymphomagenesis; Molecular mechanism

**Core tip:** Cytotoxin-associated gene A (CagA) protein encoded by *cag* pathogenicity island of *Helicobacter pylori* is a bacterium-derived oncoprotein and is strongly associated with the gastric mucosa-associated lymphoid tissue (MALT) lymphoma. After being translocated into B cells *via* type IV secretion system in ATP-dependent manner, CagA deregulates several pathways in both tyrosine phosphorylation-dependent and -independent manners, and thereby promotes lymphomagenesis. Two important proteins, p53 and protein tyrosine phosphatases-2, are involved in the malignant transformation induced by CagA. In addition, mucosal inflammation is the foundational mechanism underlying the occurrence and development of gastric MALT lymphoma. However, the exact mechanism by which CagA promotes onco-genesis needs further clarification.

Wang HP, Zhu YL, Shao W. Role of *Helicobacter pylori* virulence factor cytotoxin-associated gene A in gastric mucosa-associated lymphoid tissue lymphoma. *World J Gastroenterol* 2013; 19(45): 8219-8226 Available from: URL: <http://www.wjgnet.com>

## INTRODUCTION

*Helicobacter pylori* (*H. pylori*), a spiral-shaped, microaerophilic, Gram-negative bacterium, infects approximately 50% of humans worldwide. *H. pylori* is associated with chronic active gastritis and peptic ulcers, is a risk factor for gastric cancer<sup>[1]</sup> and has been ranked as a class I carcinogen by the International Agency for Research on Cancer since 1994<sup>[2,3]</sup>. *H. pylori* infection might initiate and contribute to the progression of lymphoma from gastric mucosa-associated lymphoid tissue<sup>[4,5]</sup>. Clinical observations have shown that the eradication of *H. pylori* with antibiotic therapy can lead to regression of gastric mucosa-associated lymphoid tissue (MALT) lymphoma in 77.5%-94.0% of patients<sup>[6-9]</sup> and can result in a 10-year sustained remission in up to 64% of cases<sup>[10]</sup>. The eradication of *H. pylori* is the standard care for patients with gastric MALT. The results of a population-based study showed that the incidence of *H. pylori*-positive gastric MALT lymphoma had reduced sharply in the era of anti-*H. pylori* intervention<sup>[11]</sup>. This review summarizes the role of *H. pylori* cytotoxin-associated gene A (CagA) in the development and/or maintenance of gastric MALT lymphoma.

## H. PYLORI CAGA IS CLOSELY RELATED TO THE DEVELOPMENT AND/OR MAINTENANCE OF GASTRIC MALT LYMPHOMA

The CagA protein, encoded by the cytotoxin-associated gene (*cag*) pathogenicity island, is one of the most important *H. pylori* virulence factors<sup>[12,13]</sup> and is causally linked to gastric MALT lymphoma. Fischbach *et al*<sup>[14]</sup> and Eck *et al*<sup>[15]</sup> determined that seropositivity of CagA was present in 89.0%-95.5% of patients with gastric MALT lymphoma, as tested by enzyme-linked immunosorbent assay and Western blot. The seroprevalence rate exceeded the prevalence of chronic active gastritis in the German population. The serological discovery of *cagA*-positive *H. pylori* isolates does not necessarily reflect the current colonization of the gastric mucosa because the immunoglobulin (Ig)A/IgG represents a past immune response. Mucosal-derived antibodies play an important part in the mucosal immune response. CagA-specific mucosal IgA and IgG antibodies occur in almost all patients with *H. pylori*-associated gastric MALT lymphoma<sup>[16,17]</sup>. Sumida *et al*<sup>[18]</sup> showed that in t(11;18)(q21;q21)-negative gastric MALT lymphoma patients, concentrations of anti-CagA IgG were significantly higher in the *H. pylori*-dependent cases than in the *H. pylori*-independent cases, and the *H. pylori*-dependent cases had a better therapeutic effect. The CagA protein can be detected in B lymphocytes in people

infected with *cagA*-positive *H. pylori* strains<sup>[19]</sup>. Kuo further explored that CagA can be detected in the malignant B cells of *H. pylori*-associated gastric MALT lymphoma. The expression of CagA was evaluated using immunohistochemistry and confirmed using immunoblot analyses<sup>[20]</sup>. These findings suggest that gastric MALT lymphoma is associated with *H. pylori* strains expressing the CagA protein. Ohnishi and colleagues transfected C57BL/6 mice with a *cagA*<sup>Hs</sup> (humanized *cagA* gene) expression vector throughout the body or predominantly in the stomach to generate transgenic mice<sup>[21]</sup>. They performed immunoprecipitation, immunoblotting, histological examinations and other analyses of the gastric mucosa from 72-wk-old *cagA*<sup>Hs</sup> mice and determined that CagA induced abnormal proliferation of the gastric epithelial cells and hematopoietic cells, which was followed by the development of gastrointestinal carcinomas and lymphomas of B-cell origin. These results indicate that CagA is involved in the development of gastric MALT lymphoma, which provide the first direct evidence that CagA functions as a bacterium-derived oncoprotein in mammals<sup>[21]</sup>.

## MOLECULAR MECHANISM OF CAGA INVOLVEMENT IN GASTRIC MALT LYMPHOMA

### The pathogenesis of lymphoma

Lymphomas are malignant tumors that originate in the lymphatic system. Lymphocytes proliferate in response to the stimulation of persistent antigens and repeated infections in patients with immune deficiencies. The deregulation of the cell cycle and apoptosis is important in the pathogenesis of lymphoma. Lymphocytes that lack self-control divide faster than normal cells or survive longer than they should, proliferating in response to antigenic stimulation, which leads to the occurrence of unlimited proliferation and eventual lymphoma. Lymphocytes and lymphoid tissues do not normally exist in the stomach<sup>[22]</sup>. The onset of gastric MALT lymphoma is preceded by the acquisition of MALTs as a result of sustained *H. pylori* infection, which initiates the inflammatory lymphoproliferation<sup>[23,24]</sup>. The persistence of bacterial colonization, acting as immunologic stimuli, results in the recruitment of immune lymphocytes that migrate to and infiltrate the site of *H. pylori* infection in the stomach, which induce and sustain an actively proliferating B-cell population. Eventually, the formation of acquired lymphoid follicles and mucosal associated lymphoid tissues develop<sup>[25-27]</sup> (Figure 1). Much attention has been focused on the role of CagA in malignant transformation of the B cells. CagA may deregulate the host intracellular signaling transduction and lower the threshold for neoplastic transformation<sup>[28]</sup>.

### Structure of the CagA protein

CagA is encoded by the *cagA* gene within the *cag* pathogenicity island, a chromosomal region that simultaneously

**Figure 1** Oncoprotein cytotoxin-associated gene A is involved in the gastric mucosa-associated lymphoid tissue lymphoma development. *H. pylori*: *Helicobacter pylori*; CagA: Cytotoxin-associated gene A; NF-κB: Nuclear factor kappa-light-chain-enhancer of activated B cells; Erk1/2: Extracellular signal-regulated kinase1/2.

encodes a type IV secretion system (T4SS) specializing in the transfer of CagA from bacteria to the target cells in an ATP-dependent manner<sup>[29,30]</sup>. CagA is the only known effector protein that is translocated by a T4SS<sup>[31-33]</sup>. Analyses of the DNA sequence and molecular phylogenetic trees show that the CagA protein comprises a solid structured N-terminal region<sup>[31,34]</sup> and a variable, intrinsically disordered C-terminal region that is different among strains and exhibits scaffold/hub functions that are responsible for the morphogenetic activity of CagA<sup>[35]</sup>. The C-terminal domain contains repeated tandem five-amino-acid motifs of glutamic acid-proline-isoleucine-tyrosine-alanine (EPIYA). Within the variable region of CagA, there are different intervening sequences between the EPIYA motifs. One copy of EPIYA plus an intervening sequence is identified as an EPIYA segment. The tyrosine residues on the EPIYA (Y) motifs undergo tyrosine phosphorylation. Both the number and type of the EPIYA motifs determine the outcomes of cellular and gastric lesions<sup>[36,37]</sup>. Four unique types of EPIYA motifs (A, B, C and D) have been described based on their flanking amino acid sequences, which contribute to the CagA sequence polymorphism and geographical difference among strains. Almost all CagA contains both EPIYA-A and EPIYA-B motifs. The EPIYA-C motif is usually present in one to three repeats forming the typical Western CagA configuration of ABC, ABCC and ABCCC subtypes. In contrast, the EPIYA-D motif rarely repeats and thus prevalent East Asian CagA strains are ABD combinations<sup>[38]</sup>. The EPIYA-C and EPIYA-D motifs act as phosphorylation sites<sup>[39]</sup>. It is reported that increased number of EPIYA-C could enhance the binding ability to protein-tyrosine phosphatase-2 (SHP-2)<sup>[40]</sup>. Compared with EPIYA-C, EPIYA-D experiences a greater degree of tyrosine phosphorylation and stronger SHP-2-binding affinity, which leads to increased oncogenic potential<sup>[41,42]</sup>. Epidemiological data identified that the incidence rate of gastric MALT lymphoma is higher in East Asia than in Western countries<sup>[11,43-45]</sup>. East Asian might be prone

to gastric MALT lymphoma at least partly, if not all, because most *H. pylori* strains are *cagA*-positive and nearly 90% of CagA carry EPIYA-D motif, 83.6% of which are of EPIYA-ABD genotype<sup>[46]</sup>.

#### ***CagA deregulates intracellular signaling pathways in tyrosine phosphorylation-dependent and -independent manners to initiate pathogenesis.***

**Tyrosine phosphorylation-dependent pathway:** CagA was directly injected from bacteria into attached gastric epithelial cells by a T4SS. Lin *et al.*<sup>[19]</sup> further showed that the translocation of the CagA protein into human B lymphocytes could occur through the T4SS. The delivered CagA activates and stimulates the B lymphocytes, initiating the first step of the B-cell malignant stimulation. In host cells, CagA undergoes tyrosine phosphorylation by c-src/Lyn kinase on specific tyrosine residues of the EPIYA motifs<sup>[19,47]</sup>. The phosphorylated CagA deregulates the intracellular signaling pathways and initiates the malignant transformation of B lymphocytes. CagA specifically binds to intracellular target molecules, including the SHP-2 [Src homology 2 (SH2) domain containing phosphotyrosine phosphatase 2]<sup>[39,41,48,49]</sup>. SHP-2, encoded by *PTPN11*, is a protein tyrosine phosphatase (PTP) and plays a vital role in normal hematopoiesis. SHP2 has two tandem SH2 domains, a PTP domain and a carboxyl-terminal tail which contains multiple tyrosine phosphorylation sites and is rich in proline motifs. In the inactive state, the N-terminal SH2 domain binds the PTP domain and hampers access of potential substrates to the active site. Thus, SHP-2 is auto-inhibited. In contrast, the N-terminal SH2 domain is free from the PTP domain by binding to target phospho-tyrosyl residues, catalytically activating the enzyme by relieving this auto-inhibition<sup>[50]</sup>. Mutation in *PTPN11*, an identified cellular proto-oncogene<sup>[51]</sup>, or aberrant SHP-2 expression/activity positively correlates with the hyperproliferation of leukemic hematopoiesis<sup>[50,52]</sup>. SHP-2 functions as a vital adaptor protein in CagA signaling pathway<sup>[48,49]</sup>. However, *PTPN11*/

SHP-2 has dual roles in different cell types and its oncogenic role is tissue specific<sup>[53]</sup>. Most recent experimental data suggest *PTPN11*/SHP-2 as a tumor suppressor in hepatocarcinogenesis<sup>[54]</sup>. The above pathway depends on tyrosine phosphorylation of CagA.

Zhu *et al.*<sup>[47]</sup> transiently transfected a recombinant retrovirus encoding an inserted *cagA* into conditionally immortalized B lymphocytes. The expressed and phosphorylated CagA was detected in the transfected B cells by Western blot and co-immunoprecipitation analyses, and CagA/SHP-2 complex was detected. The transfection of B lymphocytes with *cagA* significantly increased extracellular signal-regulated kinase1/2 (Erk1/2) phosphorylation, which is negatively regulated by MKP-1 and MKP-6, resulting in the phosphorylation of Bad at Serine 112 of CagA. Erk1/2, activated by CagA, can hamper apoptosis of B lymphocytes by inducing phosphorylation of Bad at Ser-112. *cagA* transfection did not alter the levels of the pro-apoptotic Bcl-2 and Bax. Immunofluorescence staining analysis displayed that CagA-activated Erk1/2 could translocate simultaneously to the cytoplasm and the nucleus, whereas serum-stimulated activated Erk1/2 was located only in the cytoplasm. The evidence indicates that the CagA-activated Erk1/2 can block apoptosis by activating the downstream target molecules, promoting the development of lymphoma. Lin *et al.*<sup>[19]</sup> suggested that CagA translocation, following the phosphorylation of CagA which subsequently binds to and activates endogenous SHP-2, induces the activation of Erk1/2 and mitogen activated protein kinase and the up-regulation of the anti-apoptotic proteins Bcl-2 and Bcl-X<sub>L</sub> in human B lymphocytes. The step prevents human B lymphocytes from apoptosis, allowing the lymphocytes to acquire survival ability, which contributes to the pathogenesis of lymphoma.

#### Tyrosine phosphorylation-independent pathway:

Umehara *et al.*<sup>[55]</sup> determined that CagA may block the cell cycle progression in the Ba/F3 and gastric epithelial cancer AGS cells, and inhibit the B lymphocyte apoptosis by impairing the p53 and JAK/STAT pathway. The enforced expression of CagA in the interleukin (IL)-3-dependent B-lymphoid cells functions as a G1 inhibitor, suppressing cell proliferation through the inhibition of JAK-STAT pathway and resulting in significant retardation of the G1- to S-phase cell-cycle transition. The IL-3 signal is mainly transmitted by the sequential activations of JAK and STAT. CagA offsets hydroxyurea-induced B-cell apoptosis by disturbing the tumor suppressor p53 accumulation. CagA inhibits the expression of p53 at the level of transcription. Meanwhile, *cagA*-positive *H. pylori* may be involved in the initial stage of gastric MALT lymphoma development, whereas it might not be necessary in the maintenance stage of lymphoma cell proliferation. CagA blocks apoptosis, promoting the accumulation of genetically abnormal cells that should otherwise be removed from the tissue. In IL-3-dependent B cells including BaF3, inhibitors of deoxyribonucleotide

synthesis such as hydroxyurea induce apoptosis in a p53-dependent manner, whereas, DNA-damaging agents such as X-irradiation and cisplatin induce cell death in a p53-independent manner<sup>[56]</sup>. Interestingly, oxidative stress has been reported to be contributed to a variety of gastric disorders such as gastritis and ulcer diseases, especially gastric cancer<sup>[57,58]</sup>. Upon *H. pylori* infection and colonization, CagA might stimulate the response of gastric epithelial cells to oxidative stress and produce, mainly from neutrophils, reactive oxygen species (ROS) and/or reactive nitrogen species (RNS). Excessive ROS/RNS causes dysfunction of antioxidant defense mechanism in gastric mucosal, leading to DNA damage, accelerating cell death including apoptosis and subsequent cell proliferation, and resulting in the pathogenesis of gastric disorders as well as carcinogenesis<sup>[58]</sup>. Meanwhile, additional ROS and RNS may decline the expression of Runt domain transcription factor 3 (RUNX3), a marker of oxidative stress, which could restore after *H. pylori* eradication<sup>[58]</sup>. Therefore, RUNX3 acts as a tumor suppressor and is involved in *H. pylori* CagA-dependent gastric carcinogenesis. Moreover, some other molecules have been reported to be correlated with CagA-induced gastric carcinogenesis. Murine double minute 2 (MDM2) might promote pathogenesis of gastric cancer through inactivating the apoptotic and cell cycle arrest function of p53<sup>[59]</sup>. Yet, the role of RUNX3, MDM2 as well as oxidative stress production in CagA-induced gastric MALT lymphoma has been unclear and should be elucidated by further exploration. The malignant transformation from *cagA*<sup>+</sup> *H. pylori* infection into gastric MALT lymphoma should involve multiple steps. CagA has phosphorylation-dependent and -independent activities, and the biological effects of CagA in mammals depend on the cellular context. An imbalance between apoptosis and proliferation is involved in the pathogenesis and development of *H. pylori*-dependent gastric MALT lymphoma<sup>[60]</sup>. CagA inhibits apoptosis and impairs survival in the B cells, resulting in the transformation of MALT lymphoma<sup>[20]</sup> (Figure 2).

## CONCLUSION

Mucosal inflammation is the basic mechanism underlying the occurrence and development of gastric MALT lymphoma. Infection with *H. pylori* induces inflammatory and immune responses in the gastric mucosa. The incapability of the host immune response to clear the bacterial pathogen results in a persistent infection and the subsequent development of chronic gastric inflammation<sup>[61]</sup>. The T-helper 17 (Th17) cells, whose hallmark cytokine is IL-17A, are important for the clearance of extracellular bacteria<sup>[62]</sup>, and they play a role in infection control and precarcinogenesis. IL-17A may contribute to inflammation-associated carcinogenesis<sup>[62,63]</sup>. B7-H2 is among the newer members of the B7 family and is known to have a co-stimulatory function on T cell activity<sup>[64]</sup>. Recent *in vitro* and *in vivo* studies showed that *H. pylori* down-regulates B7-H2 (the positive co-stimulators required for an effi-

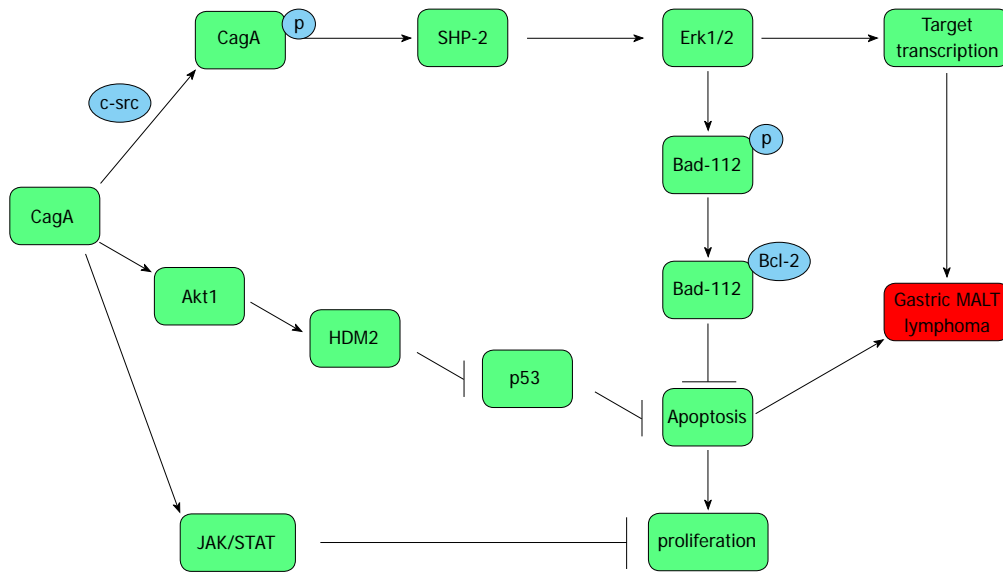

Figure 2 Cytotoxin-associated gene A deregulates intracellular signaling pathways in tyrosine phosphorylation-dependent and -independent manners to initiate lymphomagenesis. cient effector T cell response) in a CagA-dependent manner in gastric epithelial cells (GECs). CagA-dependent B7-H2 down-regulation in GECs suppresses the Th17-mediated immune response, contributing to outcomes of chronic gastric inflammation and persistent *H. pylori* colonization<sup>[63]</sup>. This process may be involved in gastric carcinogenesis, but the relationship with the development of gastric MALT lymphoma remains unclear. The activation of nuclear factor kappa-light-chain-enhancer of activated B cells and the up-regulation of IL-8 induced by *H. pylori* infections in B lymphocytes lead to the malignant transformation of B cells in a SHP-2-dependent and CagA-independent mechanism<sup>[66-68]</sup>. There is no direct evidence associating CagA, inflammation and gastric MALT lymphoma.

In recent years, microRNAs (miRNAs), a class of small non-coding RNAs that can modulate gene expression at the post-transcriptional level, have been implicated in *H. pylori*-dependent gastric carcinogenesis<sup>[69,70]</sup>. Much data suggest that miRNAs are important in fundamental cellular processes such as proliferation and apoptosis, and miRNAs can function as tumor promoters or suppressors<sup>[71]</sup>; the role of the miRNAs in the association between CagA and gastric MALT lymphoma remains unclear. Gastric MALT lymphoma is considered one of the best models of how infectious pathogens and genetic events lead to oncogenesis<sup>[72,73]</sup>. CagA functions as a typical bacterium-derived oncoprotein in gastric MALT lymphoma pathogenesis, but the molecular mechanism of CagA underlying the development of gastric MALT lymphoma should be further elucidated.

### Abstract

Antiviral therapy consisting of interferon-alpha and ribavirin for chronic hepatitis C infection is associated with multi-system side-effects. Ophthalmologic complications are common and can be classified into two groups: interferon-associated retinopathy and atypical adverse events. Interferon-associated retinopathy has been investigated by multiple observational studies that have found widely divergent results. The clinical importance of this complication is, consequently, controversial. This review examines the literature with the specific goal of identifying the most important ophthalmologic issues facing the hepatologist prescribing antiviral therapy. Accordingly, it assesses the incidence of interferon-associated retinopathy, as well as its risk factors, pathogenesis, clinical manifestations and

options for management using data from the observational studies. The likely benefit of a screening program, especially one targeting patients with the highest risk of developing interferon-associated retinopathy, is analysed. Atypical ophthalmologic adverse events occur less frequently than interferon-associated retinopathy during antiviral therapy for chronic hepatitis C infection. They often, however, lead to irreversible vision loss. We examine the reports of these adverse events - in individual case reports or case series and in the observational studies investigating interferon-associated retinopathy - to describe the spectrum of these adverse events, the likely outcome for patients and to highlight the most important areas of future clinical research.

**Key words:** Interferon; Hepatitis C; Ocular complications; Retinopathy

**Core tip:** Interferon-associated retinopathy is usually a benign, transient phenomenon with no lasting impact on visual function. It occurs in approximately 30% of patients receiving antiviral therapy for chronic hepatitis C infection. The main risk factors for its development appear to be hypertension and diabetes. Unless a clear benefit to patients can be shown, a screening program for the development of interferon-associated retinopathy is not justified. No conclusive evidence exists for a causal link between it and the atypical adverse events of antiviral therapy, which tend to cause irreversible vision loss.

## INTRODUCTION

With 160 to 170 million infected people worldwide, hepatitis C virus (HCV) presents a major health care problem<sup>[1,2]</sup>. Current standard of care treatment consists of pegylated interferon alpha (PEG-IFN $\alpha$ ) and ribavirin (RBV) for genotypes 2 to 6<sup>[3,4]</sup>. Boceprevir or telaprevir may be added to these for genotype 1 infections<sup>[5]</sup>. Standard of care therapy is associated with side effects in many organs, the majority of which are attributed to interferon. Ophthalmologic complications can be classified into two groups: interferon-associated retinopathy and atypical adverse events.

## BACKGROUND

HCV, first identified in 1989, is a major cause of chronic liver disease<sup>[6,7]</sup>. It is the most common indication for liver transplantation in the Western world<sup>[8]</sup>. The natural course of HCV infection results in chronic disease in approximately 70% of patients, with the remaining 30% clearing the infection spontaneously<sup>[9]</sup>. Patients with chronic hepatitis C (CHC) infection can transmit HCV and are at risk of progression to liver cirrhosis and/or hepatocellular carcinoma<sup>[10]</sup>.

The treatment of chronic hepatitis C infection has evolved over the past 20 years. Interferon alpha (IFN $\alpha$ ) monotherapy was the first drug regimen found to induce viral clearance<sup>[11]</sup>. The combination of IFN $\alpha$  with oral RBV, a synthetic guanosine nucleoside, was subsequently found to increase the rate of viral clearance by 2-3 times<sup>[12,13]</sup>. Pegylation, the process of attaching IFN $\alpha$  to a polyethylene glycol moiety, both increased viral clearance and decreased the frequency of dosing of interferon to once weekly injections<sup>[14,15]</sup>. Most recently, treatment for HCV genotype 1 infection has been amended to include a third drug, either boceprevir or telaprevir, both of which are direct-acting antivirals<sup>[5]</sup>.

## INTERFERON-ASSOCIATED RETINOPATHY

Interferon-associated retinopathy was first described by Ikebe *et al*<sup>[16]</sup> in 1990. It has been widely investigated since then. Our literature review identified 22 English-language reports of observational studies assessing its incidence and clinical features<sup>[17-38]</sup>. These studies all performed ophthalmological examinations during a course of antiviral therapy for chronic hepatitis C monitoring for interferon-associated retinopathy and atypical adverse events. They are summarised in Tables 1 and 2. Table 1 presents studies where more than half of the patients were treated with IFN $\alpha$  based regimens ( $n = 10$ ), whereas Table 2 presents studies with majority PEG-IFN $\alpha$  treated patients ( $n = 12$ ).

### *What are the clinical manifestations of interferon-associated retinopathy?*

Interferon-associated retinopathy can be unilateral or bilateral and typical findings on slit lamp biomicroscopy or fundus photography are cotton wool spots and/or retinal hemorrhages (Figure 1). These lesions usually occur at the posterior pole within 2 disc diameters from the optic disc<sup>[20,39]</sup>. Most commonly, it has a benign course with no impact on vision (Tables 1 and 2). It usually self-resolves during a course of antiviral therapy, or shortly thereafter, without requiring a reduction in dose (Tables 1 and 2).

### *How common is interferon-associated retinopathy?*

The observational studies have found a wide range of incidence of interferon-associated retinopathy during antiviral treatment for chronic hepatitis C infection, from under 4% to over 60% (Tables 1 and 2). Different protocols of ophthalmologic follow up and differences in patient populations are the most obvious causes of these divergent results. Other potential contributors to be considered are RBV combination therapy versus interferon monotherapy and whether different forms and doses of interferon- $\alpha$  are more likely to develop interferon-associated retinopathy.

Observational studies that had infrequent or symptom-initiated ophthalmologic examinations were more likely to find a lower incidence of interferon-associated retinopathy than those with more rigorous ophthalmologic follow up (Tables 1 and 2). Interferon-associated retinopathy most commonly develops between 2 and 12 wk after the initiation of antiviral therapy<sup>[17,22,32,36]</sup>. It is a transient phenomenon lasting from a few weeks to years<sup>[30,32,36]</sup>. Study protocols that did not examine patients multiple times within the first 6 mo of starting treatment were predisposed to underreport rates of interferon-associated retinopathy<sup>[34,38]</sup>. Similarly, most patients who develop interferon-associated retinopathy have no visual symptoms (Tables 1 and 2). Thus, protocols that initiated ophthalmologic review only once a patient became symptomatic would, therefore, also result in underreporting<sup>[33,35]</sup>. Four of the five studies reporting the lowest incidences of interferon-associated retinopathy displayed at least one of these two factors<sup>[33-35,38]</sup>.

Inclusion of patients with retinopathy at baseline skewed studies towards over-reporting of the incidence of interferon-associated retinopathy. No study has specifically assessed the clinical course of patients who have retinopathy from other causes prior to starting antiviral therapy, such as diabetes or hypertension. It is logical, however, that these patients would be at higher risk of having retinopathy during treatment than eyes without retinopathy at baseline. In the 22 observational studies considered in this review, 22 patients were identified as having retinopathy at baseline and 17 (77%) of these had progression of retinopathy<sup>[26,29,31]</sup>. In one trial, half

**Table 1 Incidence of interferon-associated retinopathy in observational studies during which more than half of the patients are treated with interferon- $\alpha$  based regimens for chronic hepatitis C**

Study	IAR incidence	Country	Timing of examinations	Comment
Nagaoka <i>et al</i> <sup>[17]</sup>	22 of 36 (61%)	Japan	Baseline, 2, 4, 8, 16 and 24 wk	IAR: no reduced VA in eyes that developed IAR. No dose reduction for management of IAR. Age was a risk factor for the development of IAR. HTN and DM were not. Atypical adverse events: nil reported.
d'Alteroche <i>et al</i> <sup>[18]</sup>	36 of 144 (25%) <sup>1</sup>	France	Baseline and then 3 monthly	IAR: No reduced VA in eyes that developed IAR. No dose reduction for management of IAR. HTN (9 of 11), receiving PEG-IFN $\alpha$ and older age were more likely to develop retinopathy. Insufficient numbers with DM ( $n = 1$ ). Atypical adverse events: nil reported.
Okuse <i>et al</i> <sup>[19]</sup>	14 of 73 (19%)	Japan	Baseline, 2, 4, 12 and 24 wk	IAR: no reduced VA in eyes that developed IAR. No dose reduction for management of IAR. HTN significantly associated with development of IAR (5 of 15), T2DM not (1 of 2). Atypical adverse events: nil reported.
Schulman <i>et al</i> <sup>[20]</sup>	27 of 42 (64%)	United States	Baseline and then 2-3 monthly for 4-20 mo	IAR: therapy discontinued in two patients with multiple CWS, one with mild decrease in VA. All other patients with IAR continued with treatment. High doses of interferon used, up to 5MIU/d. HTN was not predictive of the development of IAR. Insufficient eyes for analysis of DM as risk factor ( $n = 2$ ). Atypical adverse events: permanent peripheral monocular scotoma in 1 patient. Disc edema in 1 patient with a background of rheumatoid arthritis; no long term vision loss.
Jain <i>et al</i> <sup>[21]</sup>	8 of 19 (42%)	Canada	Baseline and then monthly	IAR: no change in VA in any patient with retinopathy. IAR resolved during study period in all but one patient. No dose reduction for management of IAR. Atypical adverse events: nil reported.
Saito <i>et al</i> <sup>[22]</sup>	28 of 81 (35%)	Japan	Baseline and then 2 weekly	IAR: no reduced VA in eyes that developed IAR. No dose reduction for management of IAR. IAR was more likely in older patients and those with DM and/or HTN. Atypical adverse events: nil reported.
Kadayifcilar <i>et al</i> <sup>[23]</sup>	7 of 20 (35%) <sup>2</sup>	Turkey	Baseline, monthly during treatment and 1 yr after completing treatment.	IAR: one of 7 with CWS at the macular had dose reduction by 1/2 for decreased VA. Full resolution in 4 wk. Otherwise no dose reduction for IAR. 16 of 20 patients had backgrounds of chronic renal failure. Atypical adverse events: unilateral BRVO in 1 patient with a background of CRF resulting in normal visual acuity at 12 mo but residual upper quadrantanopia.
Sugano <i>et al</i> <sup>[24]</sup>	6 of 25 (24%)	Japan	Baseline and then 4 weekly	IAR: not available. Atypical adverse events: not available.
Kawano <i>et al</i> <sup>[25]</sup>	36 of 63 (57%)	Japan	Baseline, 1, 2 and 4 wk and then 4 weekly until 6 mo after completing treatment	IAR: no dose reduction for 35 of 36 patients with IAR. Significantly higher incidence of retinopathy in patients with diabetes (11 of 12) and HTN (4 of 5). Atypical adverse events: severe RH in 1 patient with a background of DM; no long term vision loss.
Hayasaka <i>et al</i> <sup>[26]</sup>	14 of 40 (35%) <sup>3</sup>	Japan	1 mo prior to starting treatment and 2 weekly during treatment.	IAR: no reduced VA in eyes that developed IAR Not clear, but seems that interferon was ceased if developed IAR. Three patients with retinopathy at baseline all showed progression. Atypical adverse events: nil reported.

<sup>1</sup>Twelve patients treated for chronic hepatitis B infection were excluded from the incidence data shown; <sup>2</sup>Sixteen patients treated for chronic hepatitis B infection were excluded from the incidence data shown; <sup>3</sup>Three patients that had baseline diabetic retinopathy were excluded from the incidence data shown. BRVO: Branch retinal vein occlusion; CRF: Chronic renal failure; CWS: Cotton wool spots; DM: Diabetes; HTN: Hypertension; IAR: Interferon-associated retinopathy; MIU: Million international units; PEG: Pegylated; IFN: Interferon; RBV: Ribavirin; RH: Retinal hemorrhage; VA: Visual acuity; VEGF: Vascular endothelial growth factor.

of the patients with retinopathy at baseline had resolution of retinopathy during treatment<sup>[31]</sup>. In the other trials that identified patients with retinopathy, all eyes with baseline retinopathy had progression during the course of treatment.

When patients with baseline retinopathy and studies with suboptimal ophthalmologic follow up are excluded, 313 of 1007 (31%) patients developed interferon-associ-

ated retinopathy with a range of 8%-64% (Tables 1 and 2). The size of this corrected range implies that these factors do not fully explain the wide range of incidence of interferon-associated retinopathy.

Differences in the dose and type of interferon used in the observational studies have been proposed as key reasons for the wide range of incidence of interferon-associated retinopathy found. Early studies of IFN $\alpha$  for

**Table 2** Incidence of interferon-associated retinopathy in observational studies during which more than half of the patients were treated with pegylated interferon- $\alpha$  based regimens for chronic hepatitis C

Study	IAR incidence	Country	Timing of examinations	Comments
Mousa <i>et al</i> <sup>[27]</sup>	8 of 98 (8%)	Egypt	Baseline, 2, 4, 8, 12 and 24 wk then every 3 mo	IAR: seven of 8 patients with IAR had no reduction in VA. No dose reduction for management of IAR. Combined DM and HTN gave relative risk of 6.5 of developing IAR. Atypical adverse events: vitreous hemorrhage from retinal tears with retinal detachment requiring vitrectomy in 1 patient, final visual outcomes were not described.
Fouad <i>et al</i> <sup>[28]</sup>	22 of 84 (26%)	Egypt	Baseline, 12, 24 and 48 wk and 1 mo after completing treatment	IAR: no reduced VA in eyes that developed IAR. Three patients with IAR developed retinal hemorrhages and treatment was ceased. Logistic regression found HTN (9 of 12) and DM (13 of 16) to be predictors of developing IAR. Atypical adverse events: NAION in 2 patients and optic neuritis in 1 patient, final visual outcomes for these patients were not described.
Vujosevic <i>et al</i> <sup>[29]</sup>	21 of 97 (22%) <sup>1</sup>	Canada	Baseline, 3 and 6 mo and 3 mo after completing treatment	IAR: all patients with pre-existing retinopathy, 9 patients, had worsening of retinopathy during treatment. Factors associated with developing IAR were age, metabolic syndrome, HTN, cryoglobulinemia and pre-existing intraocular lesions. Using multivariate analysis only HTN was a significant predictor of developing IAR. Insufficient number of patients with DM ( $n = 5$ ). Atypical adverse events: bilateral BRVO in one patient with a background of HTN resulting in irreversible vision loss in the left eye only.
Lim <i>et al</i> <sup>[30]</sup>	5 of 10 (50%) <sup>2</sup>	Korea	Baseline and then 3 weekly for 6 mo	IAR: no reduced VA in eyes that developed IAR. No dose reduction for management of IAR. Atypical adverse events: unilateral CRVO in 1 patient with a background of DM resulting in irreversible vision loss.
Mehta <i>et al</i> <sup>[31]</sup>	18 of 64 (28%) <sup>3</sup>	United States	Baseline, 3 and 6 mo	IAR: no reduced VA in eyes that developed IAR. 1 of 88 ceased treatment for asymptomatic IAR. Male only cohort. HTN and DM not significant predictor of developing IAR. Poor follow up rates - 69% had an eye exam within the first 12 weeks of starting treatment. Atypical adverse events: nil reported.
Kim <i>et al</i> <sup>[32]</sup>	11 of 32 (34%)	Korea	Baseline, 4, 8, 12, 16, 24, 36 wk	IAR: no reduced VA in eyes that developed IAR alone. No dose reduction for management of IAR. All retinal lesions spontaneously resolved. 91% of retinopathy developed within 2 mo, but 1 occurred at 4 mo. HTN significantly associated with development of IAR (6 of 10), T2DM not (1 of 2). Atypical adverse events: unilateral BRVO in 1 patient with background of HTN resulting in irreversible vision loss.
Panetta <i>et al</i> <sup>[33]</sup>	7 of 183 (4%)	United States	Baseline and repeat examination when visually symptomatic	IAR: three patients ceased treatment. Two with visual symptoms associated with IAR. 46% of patients had HTN and 16% had DM - neither predictive of developing IAR. Atypical adverse events: nil reported.
Malik <i>et al</i> <sup>[34]</sup>	3 or 38 (8%)	United Kingdom	Baseline, 3 and 6 mo. Low follow up rates	IAR: no reduced VA in eyes that developed IAR. No dose reduction for management of IAR. Atypical adverse events: nil reported.
Andrade <i>et al</i> <sup>[35]</sup>	5 of 34 (15%)	Spain	Baseline, at cessation of treatment and when visually symptomatic	IAR: no reduced VA in eyes that developed IAR. No dose reduction for management of IAR. Higher serum VEGF in patients with retinopathy and/or subconjunctival hemorrhage. Atypical adverse events: cystoid macular edema in 1 patient, final visual outcomes were not described.
Ogata <i>et al</i> <sup>[36]</sup>	25 of 69 (36%)	Japan	Baseline and then regularly for 6 months	IAR: no reduced VA in eyes that developed IAR. No dose reduction for management of IAR. 46% (13 of 28) treated with IFN $\alpha$ developed IAR compared to 29% (12 of 41) treated with PEG-IFN $\alpha$ . Atypical adverse events: no details.
Chisholm <i>et al</i> <sup>[37]</sup>	5 of 10 (50%)	United Kingdom	Baseline, 2, 4, 8, 12 and 24 wk and 12 wk after completing treatment	IAR: no dose reduction for management of IAR. Atypical adverse events: nil reported.
Cuthbertson <i>et al</i> <sup>[38]</sup>	4 of 25 (16%)	United Kingdom	3 mo after starting treatment or when visually symptomatic	IAR: no reduced VA in eyes that developed IAR. No dose reduction for management of IAR. Atypical adverse events: nil reported.

<sup>1</sup>Nine patients that had baseline retinopathy were excluded from the incidence data shown. All 9 had progression of retinopathy; <sup>2</sup>Thirty-six of the 46 patients treated for chronic hepatitis B infection were excluded from the incidence data shown; <sup>3</sup>Ten patients that had baseline diabetic retinopathy were excluded from the incidence data shown. Five of these had resolution of retinopathy on subsequent eye exams. BRVO: Branch retinal vein occlusion; CRVO: Central retinal vein occlusion; DM: Diabetes; HTN: Hypertension; IAR: Interferon-associated retinopathy; NAION: Non-arteritic anterior ischemic optic neuropathy; PEG: Pegylated; IFN: Interferon; RBV: Ribavirin; VA: Visual acuity; VEGF: Vascular endothelial growth factor.

**Figure 1** Fundus photographs of a 60-year-old male treated with high dose interferon- $\alpha$  for renal cell carcinoma. These images show bilateral, typical interferon-associated retinopathy consisting of cotton wool spots and retinal hemorrhages surround the optic disc.

age-related macular degeneration found that the incidence of interferon-associated retinopathy was dose-dependent<sup>[40]</sup>. Consistent with this, the study with the highest incidence analysed in this review used the highest dose of interferon: 3-10 million units IFN $\alpha$  subcutaneous injection daily<sup>[20]</sup>. It has also been proposed that PEG-IFN $\alpha$ , which has a ten-fold longer serum-half life than conventional IFN $\alpha$ , may cause interferon-associated retinopathy more readily<sup>[36]</sup>. This would contrast with the systemic side effect profile of PEG-IFN $\alpha$ , which appears to be similar to conventional IFN $\alpha$ <sup>[14,15]</sup>. One large study found a significantly higher incidence of interferon-associated retinopathy in patients treated with PEG-IFN $\alpha$  than patients treated with IFN $\alpha$  of 45% *vs* 19%<sup>[18]</sup>. Two other smaller trials have found contradicting non-significant trends<sup>[32,36]</sup>. Ultimately, the significance of this issue is questionable since it is unlikely that small differences in the incidence of interferon-associated retinopathy, which is largely benign, will alter these use of PEG-IFN $\alpha$  over IFN $\alpha$  or the dose used to treat chronic hepatitis C infection.

The effect of ribavirin on the incidence of interferon-associated retinopathy is unclear due to conflicting results found by the observational studies that addressed this issue. It is used for its synergistic effect with interferon therapy, but does not result in HCV eradication as a monotherapy<sup>[12,13]</sup>. Conjunctivitis is the only ophthalmologic adverse event regularly associated with RBV<sup>[41]</sup>. It has, however, been suggested that combination therapy with RBV may increase the risk of interferon-associated retinopathy as compared to interferon monotherapy<sup>[21,30]</sup>. Lim *et al*<sup>[30]</sup> found a significantly higher rate of interferon-associated retinopathy in patients with chronic hepatitis C infection treated with PEG-IFN $\alpha$  and RBV combination therapy than patients with chronic hepatitis B infection treated with PEG-IFN $\alpha$  monotherapy, that is 50% *vs* 14%. These results are difficult to interpret as chronic hepatitis C infection is associated with a hypercoagulable state, which itself may confer an increased risk of developing interferon-associated retinopathy<sup>[42]</sup>. Further studies are required to determine the impact of RBV on the development of interferon-associated retinopathy.

### **Why does interferon-associated retinopathy occur?**

The pathogenesis of interferon-associated retinopathy is yet to be fully elucidated. Its clinical manifestations, cotton wool spots and retinal hemorrhages suggest an ischemic mechanism. These changes are most commonly associated with diabetes or hypertension<sup>[43,44]</sup>. It has been proposed that endothelial dysfunction, as evidenced by the failure of dilatation of retinal arterioles in response to wall shear stress in eyes that subsequently developed interferon-associated retinopathy, is the central process leading to retinal ischemia<sup>[17]</sup>. Endothelial dysfunction, it is proposed, causes platelet aggregation and leukocyte adherence to vascular endothelium<sup>[17]</sup>. These “immune complexes” act as microthrombi and cause focal retinal infarction<sup>[39]</sup>. This hypothesis is supported by data suggesting IFN $\alpha$  may promote pro-thrombotic autoantibody production mediated by T cell activation<sup>[45]</sup>. Further, IFN $\alpha$  may increase production of the highly potent intravascular aggregator of platelets, plasma-activated complement 5<sup>[24]</sup>. Moreover, IFN $\alpha$  increases leukocyte adherence to the vascular endothelium resulting in leukocyte trapping in the retinal microcirculation<sup>[46]</sup>.

### **Does interferon-associated retinopathy causes vision loss?**

Cotton wool spots and retinal hemorrhages are not usually associated with vision loss. They would if they occurred at the central macula, but the *fovea centralis* is avascular. Nevertheless, there are at least two reported cases of irreversible visual disturbance after interferon-associated retinopathy that consisted of cotton wool spots and/or retinal hemorrhages only, i.e. that were not associated with an atypical adverse event<sup>[20,47]</sup>. One patient developed a permanent peripheral monocular scotoma in the same eye due to interferon-associated retinopathy consisting of cotton wool spots and retinal hemorrhages only<sup>[20]</sup>. The other patient developed permanent bilateral reduced visual acuity and visual field defects after isolated interferon-associated retinopathy<sup>[47]</sup>. Such cases, however, are rare; in most patients isolated interferon-associated retinopathy causes no impact on visual func-

tion (Tables 1 and 2). Indeed, in the 1289 patients, only 1 had interferon-associated retinopathy that caused vision impairment<sup>[20]</sup> (Table 1). Importantly, vision loss that occurs whilst taking antiviral therapy is usually due to the development of an atypical adverse event.

### ***Are there any groups that are at greater risk for developing interferon-associated retinopathy?***

Hypertension and diabetes mellitus appear to be risk factors for the development of interferon-associated retinopathy; however, this has not been established unequivocally. Such a finding would be theoretically consistent with the proposed pathogenesis of interferon-associated retinopathy. The same methodological problems that resulted in the diversity in the incidence of interferon-associated retinopathy found by the observational studies described above also apply to this issue. Compounding this, the numbers of patients with diabetes or hypertension that developed interferon-associated retinopathy in most studies were too small to enable meaningful statistical analysis (Tables 1 and 2).

Observational studies of standard of care therapy for chronic hepatitis C infection during which at least 10 patients developed interferon-associated retinopathy identified diabetes and hypertension as its main risk factors<sup>[28,29,31,32]</sup> (Table 2). Fouad *et al*<sup>[28]</sup> performed a comprehensive study of 84 patients treated with standard of care therapy in Egypt with extensive ophthalmologic follow up. Their study, which included a number of patients with hypertension and diabetes, 12 and 16 respectively, found that both predicted the development of interferon-associated retinopathy using logistic regression analysis. By contrast, Mehta *et al*<sup>[31]</sup> found higher rates of interferon-associated retinopathy in patients with hypertension and diabetes, but the differences were not statistically significant. Their study had sufficient numbers of patients with these conditions - 13 patients with diabetes mellitus and 31 with hypertension - however, ophthalmologic follow up was poor with less than 70% of patients receiving an eye exam within 12 weeks of starting standard of care therapy. Both Vujosevic *et al*<sup>[29]</sup> and Kim *et al*<sup>[32]</sup> performed observational studies with good numbers and adequate ophthalmologic follow up. They both found hypertension to be a significant predictor of the development of interferon-associated retinopathy using univariate and multivariate analysis. Diabetes mellitus was not found to be a significant predictor of the development of interferon-associated retinopathy using multivariate analyses in either, but the cohorts only had 5 and 2 patients with diabetes mellitus, respectively. In Vujosevic *et al*<sup>[29]</sup>, a higher percentage of patients with diabetes mellitus developed interferon-associated retinopathy on univariate analysis. There were insufficient numbers of patients with diabetes mellitus in earlier studies involving IFN $\alpha$  to assess its effect<sup>[18-20]</sup>. Studies with adequate numbers of patients with diabetes mellitus tended to find it as a risk factor for the development of interferon-associated retinopathy.

No other patient characteristics that have been assessed have been found to predict the development of interferon-associated retinopathy (Tables 1 and 2). Older age has been suggested to represent a greater risk for its development, but this has not been a consistent finding<sup>[17,19,22,29]</sup>. The larger studies that assessed risk factors identified above did not implicate age, with the exception of Fouad *et al*<sup>[28]</sup>, Vujosevic *et al*<sup>[29]</sup>, Mehta *et al*<sup>[31]</sup> and Kim *et al*<sup>[32]</sup>. An association of age with the development of interferon-associated retinopathy may be because it is also associated with a higher risk of diabetes and hypertension.

### ***If a patient develops interferon-associated retinopathy, what should be done?***

There is a growing body of clinical experience that it is safe to continue standard of care therapy with no dose reduction in patients who develop interferon-associated retinopathy so long as they do not have reduced visual acuity or other visual symptoms which would suggest the development of an atypical adverse event (Tables 1 and 2). Various dose reduction and cessation regimens aiming to minimise the impact of interferon-associated retinopathy have been used. One study described the dose reduction regimens used by two clinicians in their management of 38 patients with interferon-associated retinopathy over 10 years<sup>[18]</sup>. This study did not compare outcomes between the groups. In fact, no formal comparator studies have assessed different strategies of managing standard of care dosing in patients who develop interferon-associated retinopathy. There is, therefore, no good evidence to guide whether interferon therapy should be modified or discontinued when interferon-associated retinopathy has been diagnosed. It is, however, well established that dose reduction of interferon increases the risk of treatment failure. Thus, dose reduction should be considered carefully.

### ***Should we screen for interferon-associated retinopathy?***

No consensus has been reached regarding the need to screen for interferon-associated retinopathy. Cuthbertson *et al*<sup>[38]</sup> argue that due to the low incidence of interferon-associated retinopathy and its generally benign course there is no need for routine screening. By contrast, Vujosevic *et al*<sup>[29]</sup> support a screening program targeting hypertensive patients, who they found to be at greater risk of developing interferon-associated retinopathy. Mousa *et al*<sup>[27]</sup> propose that screening should only be for patients with both diabetes and hypertension, but not those with either in isolation. On the other end of the spectrum, Schulman *et al*<sup>[20]</sup> considered close ophthalmological follow up for all patients as appropriate.

We propose that screening for interferon-associated retinopathy should only be performed if it meets the following criteria: (1) it can be used to predict the patients at risk for developing pathology that causes irreversible visual impairment; and (2) early treatment of these patients will reduce the chance of the development of that pathology. As discussed above, interferon-associated

retinopathy, with a few exceptions, has a generally benign course. Screening for interferon-associated retinopathy may be justified if it can be proved that eyes that develop it are more likely to develop an atypical adverse event, which in turn causes poor visual outcomes. Evidence of such a relationship does not exist to date. In addition, it would need to be established that early detection would enable an intervention that reduces the severity of that atypical adverse event. For example, it would need to be shown that strict risk factor control after the diagnosis of interferon-associated retinopathy prevents the development of an atypical adverse event<sup>[48]</sup>. With the current state of the evidence, a screening program for interferon-associated retinopathy, even one including only those patients at high risk of developing it, does not appear to be justified.

## ATYPICAL ADVERSE EVENTS

Many atypical ophthalmologic adverse events have been encountered during antiviral therapy for chronic hepatitis C infection. The most common of these are retinal vein occlusion (RVO)<sup>[21,29,30,32,49-55]</sup>, and non-arteritic anterior ischemic optic neuropathy (NAION)<sup>[28,49,56-59]</sup>. Other atypical adverse events that have been reported include ocular myasthenia<sup>[60,61]</sup>, optic neuritis<sup>[62]</sup>, Vogt-Koyanagi-Harada disease<sup>[49,63-67]</sup>, ocular sarcoidosis<sup>[68,69]</sup>, ocular toxocariasis<sup>[70]</sup>, neurovascular glaucoma<sup>[71]</sup>, conjunctival hemorrhage<sup>[20,26,35]</sup>, macular edema<sup>[72-74]</sup>, oculomotor nerve palsy<sup>[75]</sup>, trichomegaly<sup>[23]</sup> and retinal detachment<sup>[76]</sup>.

The mechanisms that cause an atypical adverse event may be distinct from the ischemic mechanism thought to be responsible for interferon-associated retinopathy. For example, there is growing evidence that interferon is directly toxic to the optic nerve<sup>[62,77,78]</sup>. Chisholm *et al*<sup>[37]</sup> found high levels of subclinical retinal toxicity, measured as aberration on multifocal electro-retinogram, in patients treated with IFN $\alpha$  and ribavirin. The electro-retinogram changes were not correlated with clinical signs of interferon-associated retinopathy, cotton wool spots and retinal hemorrhages<sup>[37]</sup>.

Atypical complications of antiviral therapy often result in dramatic, irreversible vision loss. In an exhaustive review of NAION that occurred during interferon therapy, half of the 36 documented cases of this complication suffered from permanent visual dysfunction<sup>[56]</sup>. Similarly, in a recent review of RVO during interferon- $\alpha$  therapy, only 4 of 14 cases had full recovery of vision<sup>[53]</sup>. Other atypical complications also lead to long-term visual impairment. In particular, inflammatory complications of antiviral therapy, such as Vogt-Koyanagi-Harada disease, also tend to have poor visual outcomes<sup>[49,67]</sup>. In the 22 observational studies identified by our literature review involving 1287 patients treated with antiviral therapy for chronic hepatitis C infection, 12 (0.93%) patients developed an atypical adverse event. Five (0.39%) of these led to documented irreversible vision loss and 4 (0.31%) did not describe final visual outcomes (Tables 1 and 2).

The relationship between interferon-associated retinopathy and the atypical complications of antiviral therapy is unclear. Indeed, there is limited evidence that atypical adverse events are caused by interferon treatment and not merely due to chance<sup>[56]</sup>. The most common complications, AION and RVO, are both vascular in nature. It has been suggested that there may be common elements between the pathogenesis of these complications and interferon-associated retinopathy<sup>[49,56]</sup>. Certainly, there are many cases in the literature where AION and RVO are concomitant with interferon-associated retinopathy<sup>[51,55,79]</sup>. As the atypical complications are the key causes of vision loss during antiviral therapy and interferon-associated retinopathy is common and well-described, any relationship between them should be explored in depth.

## THE FUTURE

The standard of care regimen is in the process of a major re-evaluation after two major breakthroughs. Firstly, multiple HCV-specific direct-acting antivirals are at various stages of development and two of these have been approved for the treatment of genotype 1 HCV infection<sup>[80-83]</sup>. Secondly, a host genetic polymorphism near the interleukin-28B (IL28B) gene on chromosome 19 that strongly predicts spontaneous and standard of care-induced recovery from infection was identified by four groups in 2009 and 2010<sup>[84-87]</sup>.

Despite the advent of direct-acting antivirals, it is likely that PEG-IFN $\alpha$  will remain an integral part to HCV treatment regimens for the foreseeable future<sup>[5]</sup>. When used as monotherapy, rapid virological resistance develops *in vivo* to the first generation direct-acting antivirals - telaprevir and boceprevir - inhibiting antiviral response<sup>[88]</sup>. Moreover, the antiviral activity of these first generation direct-acting antivirals, the only approved by the FDA, appears genotype specific<sup>[89]</sup>. Accordingly, they are presently recommended for use in genotype 1 chronic HCV only<sup>[5]</sup>. Investigations of second generation direct-acting antivirals are currently under way, so eventually we very likely will have interferon free-regimens<sup>[90,91]</sup>. RBV, however, remains a core component of most of these regimens.

A controversial issue at present is whether patients, particularly those with IL-28B non-responder genotypes, should defer treatment for chronic hepatitis C infection until new, more effective regimens become available<sup>[92]</sup>. Considering that the most common interferon-associated retinopathy seems to be largely benign in most patients, we do not feel that there is enough evidence for the potential risk for ophthalmologic complications to significantly impact this discussion as the most common is largely benign and there is no obvious, established link between interferon and the rarer, more severe adverse events.

## CONCLUSION

In summary, the most common complication of antiviral

therapy for chronic hepatitis C infection is interferon-associated retinopathy. This is usually a benign, self-limiting phenomenon with no lasting impact on visual function. It occurs in approximately 30% of patients undergoing standard of care therapy, however, there is significant variability in its incidence in observational studies. Hypertension and diabetes mellitus appear to be the most important risk factors for its development. The rarer, atypical adverse events of antiviral therapy often cause irreversible vision loss. The most common of these are RVO and NAION. To date, no definitive pathogenic link has been proven between antiviral therapy or interferon-associated retinopathy and any of the various atypical adverse events. If such a relationship can be found, screening for interferon-associated retinopathy may be justified as a means to prevent the development of an atypical adverse event. Newer direct-acting antivirals are likely to outpace further study into this area, making interferon-free antiviral therapy likely in the next 5 years.

**Key words:** Thyroid hormone; Thyroid hormone receptor; Nonalcoholic fatty liver disease; Obesity

**Core tip:** The clinical findings that nonalcoholic fatty liver disease (NAFLD) patients have more prevalence of subclinical hypothyroidism and patients with hypothyroidism may develop fatty liver give the evidence that dyslipidemia and fatty liver have some relationship with thyroid dysfunction, and thyroid hormone and its receptor may be a therapeutic target for NAFLD. We review here that thyroid hormone and TR are a potential target for pharmacologic treatments that can benefit NAFLD patients a lot.

Huang YY, Gusdon AM, Qu S. Cross-talk between the thyroid and liver: A new target for nonalcoholic fatty liver disease treatment. *World J Gastroenterol* 2013; 19(45): 8238-8246 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i45/8238.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i45.8238>

### Abstract

Nonalcoholic fatty liver disease (NAFLD) has been recognized as the most common liver metabolic disease, and it is also a burgeoning health problem that affects one-third of adults and is associated with obesity and insulin resistance now. Thyroid hormone (TH) and its receptors play a fundamental role in lipid metabolism and lipid accumulation in the liver. It is found that thyroid receptor and its isoforms exhibit tissue-specific expression with a variety of functions. TR $\beta$ 1 is predominantly expressed in the brain and adipose tissue and TR $\beta$ 2 is the major isoform in the liver, kidney and fat. They have different functions and play important roles in lipid metabolism. Recently, there are many studies on the treatment of NAFLD with TH and its analogues. We review here that thyroid hormone and TR are a potential target for pharmacologic treatments. Lipid metabolism and lipid accumulation can be regulated and reversed by TH and its analogues.

### INTRODUCTION

Nonalcoholic fatty liver disease (NAFLD) is a burgeoning health problem that affects one-third of adults and is associated with obesity and insulin resistance. Its pathogenesis remains poorly understood, and therapeutic options are limited. Here, we discuss recent treatment insights into NAFLD that focus primarily on its relationship with thyroid function.

### THYROID HORMONE AND ITS RECEPTORS

Thyroid hormone (TH) regulates cellular and tissue me-

tabolism throughout the body. The active form of TH, 3,3',5-triiodo-L-thyronine (T3), controls gene expression in target tissues by binding to its cognate nuclear receptors (TRs), which are ligand-inducible transcription factors. In the presence of T3, TRs activate transcription by binding to T3-response elements (TREs) of the target genes and forming coactivator complexes containing histone acetyltransferase activity<sup>[1]</sup>. In the absence of T3, TRs recruit corepressors, such as nuclear receptor co-repressor (NCoR) and silencing mediator of retinoid and thyroid receptors, which form a complex with transducin  $\beta$ -like protein 1 and histone deacetylase 3 that has histone deacetylase activity on the promoters of target genes that repress basal transcription<sup>[2]</sup>.

Two TR isoforms, TR $\alpha$  and TR $\beta$ , have been identified. They share high sequence homology in the functional DNA and T3-binding domains, but differ greatly in the lengths and sequences of the amino-terminal A/B domains. Studies of mice deficient in either of these two TR genes or both TR genes indicate that TR isoforms have both redundant roles and specific functions<sup>[3]</sup>. TR $\alpha$ 1, TR $\beta$ 1, and TR $\beta$ 2 isoforms bind T3; however, TR $\alpha$ 2 does not. TR $\alpha$ 2 functions, at least *in vitro*, as a TR $\alpha$ 1 and TR $\beta$ 1 antagonist<sup>[4]</sup>. Activation of TRs affects a multitude of physiological processes ranging from embryonic development to maintenance of energy homeostasis in adults. Excess TH can result in some therapeutically desirable effects, such as increased metabolic rate, increased lipolysis, lowered cholesterol levels, improved heart contractility, and suppressed thyroid-stimulating hormone (TSH) levels. At the same time, systemic thyrotoxicosis can lead to undesirable effects, including tachycardia, arrhythmia, muscle wasting, nervousness, fatigue, and loss of bone mass<sup>[5]</sup>. A series of studies in mice with inactivation or mutation of different TR isoforms<sup>[6-12]</sup>, as well as studies in patients with resistance to TH, suggest that TR isoforms selectively mediate tissue-specific TH responses<sup>[13]</sup>.

There is a tissue-specific expression pattern for TRs. TR $\beta$ 2 is the major isoform in the liver, kidney, and thyroid, and TR $\beta$ 1 is predominantly expressed in the brain and adipose tissue<sup>[14-17]</sup>. There is also a general consensus that TR $\alpha$  mediates the effects of TH on the heart, whereas TR $\beta$  mediates its effects on plasma cholesterol and TSH secretion. Therefore, the development of T3 analogues with preferential binding to TR $\beta$  may induce the beneficial effects of T3 while avoiding undesirable side effects.

## EFFECTS OF TH ON HEPATIC LIPID METABOLISM

TH maintains lipid homeostasis *via* its effects on gene expression in target organs, including the liver and adipose tissues. T3 has profound and diverse effects on lipid metabolism and lipid accumulation in the liver. In the liver, TR $\beta$  is responsible for mediating the majority of the actions of T3, whereas in other tissues, such as the heart

and brown adipose tissue (BAT), TR $\alpha$  is the main mediator of TH effects<sup>[18,19]</sup>.

T3 exerts strong effects on hepatic carbohydrate and lipid metabolism in both anabolic and catabolic states. Elevated levels of T3 in hyperthyroidism are associated with increased lipolysis and lower body weight. In contrast, lower levels of T3 in hypothyroidism are associated with cold intolerance, weight gain, reduced lipolysis, and cholesterol clearance. Mice devoid of all TR isoforms exhibit decreased body temperature and basal metabolic rate, growth retardation, and an increased amount of fat tissue<sup>[20,21]</sup>. T3 increases the expression of several genes involved in hepatic lipogenesis by increasing the expression of lipogenic genes such as fatty acid synthase (FAS), Thrsp (Spot14), acetyl-CoA carboxylase (ACC1)<sup>[22]</sup>, acyl-CoA synthetase 5, fatty acid transporter protein, malic enzyme, and glucose-6-P dehydrogenase. It also induces the expression of genes involved in fatty acid oxidation, such as fatty acid transporter (Fat), fatty acid-binding protein, lipoprotein lipase (LPL)<sup>[23]</sup>, and carnitine palmitoyltransferase-1 alpha (Cpt-1 $\alpha$ )<sup>[24]</sup>. Cpt-1 $\alpha$  is a key rate-limiting enzyme in mitochondrial fatty acid oxidation. Many of these metabolic genes (*e.g.*, malic enzyme, Fas, and Cpt-1 $\alpha$ ) in the liver are directly regulated by the interaction between T3 and TR, as TREs have been identified in promoters of these genes<sup>[25]</sup>. However, the regulation of lipid homeostasis by T3 is complex and tissue dependent, as it involves the coordinated regulation of several target tissues, mainly adipose tissue and the liver. The tissue-dependent manner of lipid regulation *via* TH was uncovered using knockin mice harboring identical mutations in the TR $\alpha$  (TR $\alpha$ 1PV mouse) and TR $\beta$  (TR $\beta$ PV mouse) genes. TR $\alpha$  gene mutations dramatically decrease the mass of both the liver and white adipose tissue (WAT). In contrast, TR $\beta$  gene mutations markedly increase liver mass with an excess deposition of lipids, but no significant abnormality is observed in WAT. Molecular studies showed that the expression of lipogenic genes was decreased in WAT of TR $\alpha$ 1PV mice, but not in TR $\beta$ PV mice. Markedly increased lipogenic enzyme expression and decreased fatty acid  $\beta$ -oxidation activity contribute to adipogenic steatosis and lipid accumulation in the liver of TR $\beta$ PV mice. In contrast, reduced expression of genes critical for lipogenesis mediates decreased liver mass with lipid scarcity in TR $\alpha$ 1PV mice.

TH action is mediated by a complex interaction between TRs and other nuclear receptors, including the PPARs and the liver X receptor (LXR), which respond to circulating metabolite levels<sup>[26,27]</sup>. Cross-talk between TH signaling and these nutrient-responsive factors occurs through a variety of mechanisms, including but not limited to competition for retinoid X receptor (RXR), transcriptional co-factors, DNA-binding sites, or transcriptional cofactors.

Studies in several animal models, including the PPAR $\alpha$  KO mouse, have demonstrated that hepatic steatosis occurs when nuclear receptors involved in metabolic control are inactivated. In both humans and animal

models, obesity is associated with lipid deposition in the liver, which can lead to fibrosis and even cirrhosis<sup>[28,29]</sup>. In both human and murine microarray studies, the greatest change in liver gene expression as a consequence of hepatic lipid accumulation is the downregulation of a set of T3-responsive genes, including genes involved in energy metabolism<sup>[19,30]</sup>.

Autophagy of lipid droplets, termed “lipophagy,” is a major pathway of lipid mobilization in hepatocytes<sup>[31-33]</sup>, and its inhibition has been linked to the development of fatty liver and insulin resistance<sup>[34-36]</sup>. TH is a well-known metabolic regulator of energy expenditure that activates fatty acid  $\beta$ -oxidation in mammals<sup>[37]</sup>. However, the precise mechanism of this effect has not yet been revealed. During periods of starvation, autophagy degrades cytoplasmic materials, producing amino acids and fatty acids that can be used to synthesize new proteins or generate ATP for cell survival<sup>[38]</sup>. Derangement of the autophagic response has been implicated in several pathological hepatic conditions, such as ischemia, reperfusion, viral infections, acute injury,  $\alpha$ 1-antitrypsin deficiency, hepatocellular carcinoma, alcoholic liver disease, and NAFLD<sup>[36,39,40]</sup>.

“Lipophagy”<sup>[31]</sup> leads to the degradation of intracellular lipid droplets, and this process is believed to provide fatty acid substrates for  $\beta$ -oxidation<sup>[41]</sup>. Such lipophagy is coupled to the effects of T3 stimulation in altering the levels of a broad array of hepatic lipid-related metabolites, which is consistent with a key role for T3 as an important regulator of fatty acid delivery to mitochondria and mitochondrial metabolism. Autophagy is a stress-induced catabolic process, conserved in all eukaryotes, involving fusion of autophagosomes with lysosomes and resulting in degradation of cytoplasmic cargo. T3 induces lipophagy in cultured liver cell lines, and it induces hepatic autophagy *in vivo* coupled with ketogenesis, resulting in a lipolytic-metabolomic profile. Moreover, TH stimulation of autophagy and lipid metabolism is TR dependent and modulated by NCoR corepressor activity. These findings suggest that T3 plays an important role in the regulation of hepatic autophagy, which is a critical step for the amelioration of NAFLD.

## THYROID MALFUNCTION IN DYSLIPIDEMIA AND NAFLD PATIENTS

The most frequent metabolic syndrome disorders are dyslipidemia and NAFLD. The pathogenesis of NAFLD is a complex, multifactorial process characterized by insulin resistance and other endocrine disorders. TH can stimulate the expression of uncoupling proteins in the mitochondria of adipocytes and skeletal muscle and modulate adrenergic receptor numbers by enhancing responsiveness to catecholamines<sup>[42]</sup>, thus controlling metabolic and energy homeostasis. TH influences body weight, thermogenesis, lipolysis, and metabolism of cholesterol and bile acids. Thyroid dysfunction is associated with hepatic lipid peroxidation and oxidative stress

in experimental models<sup>[43,44]</sup>, raising the question of the role of hypothyroidism in NAFLD patients. The prevalence of hypothyroidism in patients with NASH is twice as high as in controls<sup>[45]</sup>. NASH is twice as common in postmenopausal compared with premenopausal women, and hormonal replacement therapy decreases the risk of steatosis. This association seems plausible, taking into consideration that thyroid dysfunction can lead to hyperlipidemia, obesity, and insulin resistance<sup>[46]</sup>, all of which are major components of metabolic syndrome<sup>[47,48]</sup> and are implicated in the pathogenesis of NAFLD.

The mechanism of hypothyroidism-induced hyperlipidemia has been shown to be due to a decrease in cholesterol excretion and a marked increase in apoB lipoproteins due to decreased catabolism and turnover secondary to a reduced number of low-density lipoprotein (LDL) receptors on the liver cell surface<sup>[49]</sup>. Thus, common findings in patients with hypothyroid are increased levels of total and LDL cholesterol. In hypothyroidism, a reduced removal rate of triglycerides from plasma and an accumulation of intermediate LDL (IDL) have also been reported. Thus, NAFLD can develop in hypothyroid patients due to increased LDL and deposition of triglycerides in the liver.

In addition to hyperlipidemia and obesity, hypothyroidism has been associated with insulin resistance<sup>[50]</sup>. There is a strong link between insulin resistance and excessive deposition of triglycerides in hepatocytes. A recent study investigated the frequency of metabolic syndrome in hypothyroid patients. These authors studied 100 patients with overt hypothyroidism, 100 patients with subclinical hypothyroid, and 200 healthy controls. The authors found that the HOMA index was higher in the hypothyroid group than in the control ( $P = 0.008$ ) and subclinical hypothyroid groups ( $P = 0.014$ ). Metabolic syndrome prevalence was 44% in the hypothyroid group and 33% in the control group ( $P = 0.016$ )<sup>[51]</sup>.

Thyroid dysfunction commonly occurs in the elderly population, and overt thyroid dysfunction is associated with some liver abnormalities. Xu *et al.*<sup>[52]</sup> performed a cross-sectional study among 878 euthyroid elderly Chinese, in which 227 (25.85%) subjects fulfilled the diagnostic criteria for NAFLD. Patients with NAFLD had significantly lower levels of serum-free thyroxine (FT4) than control patients ( $11.12 \pm 1.43$  pmol/L *vs*  $11.58 \pm 1.47$  pmol/L;  $P < 0.001$ ). The prevalence of NAFLD decreased in proportion to progressively higher serum FT4 levels ( $P < 0.001$ ). Age-, gender-, and smoking status-adjusted correlation analysis showed that serum FT4 levels were negatively correlated with body mass index, waist circumference, and triglyceride and serum uric acid levels (all with  $P < 0.05$ ). Stepwise logistic regression analysis showed that serum FT4 level was significantly associated with the risk for NAFLD. These results suggest that thyroid function, even within the reference range, is associated with NAFLD in elderly people.

TH may interfere with the regulation of lipid and carbohydrate metabolism, and correlate with the severity

of NAFLD; however, these results are still under debate. Mazo *et al.*<sup>[53]</sup> performed a retrospective evaluation of clinical and metabolic correlations between hypothyroidism and NAFLD. Clinical, biochemical, and histological investigations of 103 NAFLD patients exhibiting drug-treated hypothyroidism were conducted. Steatosis was present in 32.0% of the population and nonalcoholic steatohepatitis was present in 68.0%. Females were the majority in both groups. A link was identified between hypothyroidism and markers of glucose and lipid homeostasis, but not with severity of NAFLD.

Hepatic steatosis can progress to hepatocyte injury, inflammation, and fibrosis in the presence of potential synergistic factors such as oxidative stress from  $\beta$ -oxidation, increased expression of inflammatory cytokines by NF- $\kappa$ B-dependent pathways, and adipocytokines<sup>[54-56]</sup>. This is called the “multi-hit hypothesis” and has been used to describe the pathogenesis of NAFLD<sup>[57]</sup>. Lipid peroxidation and oxidative stress are both believed to play important roles in the progression of disease from steatosis to NASH<sup>[56,58]</sup>. Previous experimental data regarding thyroid dysfunction and hepatic lipid peroxidation have shown that, in a state of hyperthyroidism, TH elevation stimulates the metabolic rate, possibly leading to reactive oxygen species generation, lipid peroxidation, and liver cell damage<sup>[43,44]</sup>. On the other hand, reduced levels of oxidative stress accompanying hypothyroidism might be responsible for the experimental results indicating that hypothyroidism protects from hepatic fibrosis<sup>[59]</sup>. This concept correlates with the absence of an association between hypothyroidism and steatosis or NASH. In some studies, mainly with obese NAFLD patients, hypothyroidism appears to contribute to the major components of metabolic syndrome, leading primarily to the accumulation of fat. However during progression to NASH, additional results are needed, with emphases on the role of oxidative stress and lipid peroxidation.

## POTENTIAL PHARMACOLOGIC TREATMENT WITH TH IN BASIC RESEARCH AND CLINICAL PRACTICE

The current pharmacologic treatment for NAFLD is limited, relying mostly on weight loss<sup>[60-62]</sup>. Insulin-sensitizing agents, such as thiazolidinediones, have been shown to decrease hepatic steatosis by promoting fat redistribution to the liver.

### TH

T3 treatment in rats stimulates thermogenesis from fatty acid  $\beta$ -oxidation as a result of lipolysis and increased caloric intake<sup>[63]</sup>. Lipogenesis is also stimulated by T3. However, this effect occurs to a much lesser extent and is mainly seen in the context of restoration of depleted fat stores after a period of energy deficit<sup>[64]</sup>. Previous studies have shown that treatment with T3 itself, or with selec-

tive agonists of TR $\beta$ , may improve the metabolic status of diet-induced obese rodents<sup>[13,65,66]</sup>.

Recently, mice treated with T3 showed a dose-dependent increase in hepatic *FGF21* expression with significant induction at doses as low as 100  $\mu$ g/kg. *FGF21* expression is downstream of the nuclear receptor peroxisome proliferator-activated receptor  $\alpha$  (PPAR $\alpha$ ). PPAR $\alpha$  knockout mice treated with T3 did not have an increase in *FGF21* expression, indicating that hepatic regulation of *FGF21* by T3 in the liver is *via* a PPAR $\alpha$ -dependent mechanism. In contrast, in WAT, *FGF21* expression was suppressed by T3 treatment, with other T3 targets being unaffected. In cell culture studies with an *FGF21* reporter construct, three transcription factors were required for the induction of *FGF21* expression: TR $\beta$ , RXR, and PPAR $\alpha$ . These findings indicate a novel regulatory pathway whereby T3 positively regulates hepatic *FGF21* expression, presenting a novel therapeutic target for diseases such as NAFLD.

In addition, prolonged T3 treatment promotes the catabolism of fatty acids by increasing the expression and activity of Cpt-1 $\alpha$ , a rate-limiting enzyme for transport and  $\beta$ -oxidation of fatty acids in the mitochondria<sup>[25]</sup>. Thus, the catabolism of fatty acids is a cardinal metabolic feature of prolonged hyperthyroidism<sup>[63]</sup>. T3 stimulates the shuttling of free fatty acids (FFAs) for delivery into mitochondria<sup>[67]</sup>. While this process is well described, the T3-regulated cellular pathways that lead to the generation of FFAs from stored lipid droplets in the liver are not very well understood. In that way, T3 treatment is beneficial to patients with high TSH and high FFA levels.

### TR $\alpha$ inhibition

TR $\alpha$  or TR $\beta$  gene knockout mouse models display a range of defects in lipogenesis, lipolysis, cholesterol metabolism, and fatty acid oxidation. Francois<sup>[68]</sup> reported that TR $\alpha$  gene knockout mice are protected from diet-induced hepatic insulin resistance. With the goal of examining whether TR $\alpha$  would be a potential therapeutic target to prevent diet-induced NAFLD and insulin resistance, they assessed insulin action in high-fat diet fed TR $\alpha$  gene knockout (Thra-0/0) and wild-type mice using hyperinsulinemic-euglycemic clamps combined with <sup>3</sup>H/<sup>14</sup>C-labeled glucose to assess basal and insulin-stimulated rates of glucose and fat metabolism. Body composition was assessed by <sup>1</sup>H magnetic resonance spectroscopy, and energy expenditure was measured using indirect calorimetry. Thra-0/0 mice were lighter, leaner, and manifested greater whole-body insulin sensitivity than wild-type mice during the clamp, and these results could be attributed to increased insulin sensitivity both in the liver and peripheral tissues. Increased hepatic insulin sensitivity could be attributed to decreased hepatic diacylglycerol content, resulting in decreased activation of protein kinase C and increased insulin signaling. Therefore, TR $\alpha$  inhibition represents a novel pharmacologic target for the treatment of NAFLD, obesity, and type 2 diabetes.

### TR $\beta$ agonists

The use of TR agonists for the treatment of NAFLD has not been considered viable because TH increases FFA flux from the periphery to the liver, induces hepatic lipogenesis, and therefore could potentially contribute to steatosis. However, specifically targeting TR $\beta$  could provide therapeutic benefit while avoiding the potential of non-selective TR agonists to increase hepatic FFA accumulation. MB07811 is an orally active liver-targeted TR $\beta$  agonist. Cable<sup>[29]</sup> reported a reduction of hepatic steatosis in rats and mice after treatment with MB07811. The purpose of these studies was to assess the effects of MB07811 on whole body and liver lipid metabolism of normal rodents and rodent models of hepatic steatosis. Animal studies showed that MB07811 markedly reduced hepatic steatosis as well as plasma FFA and triglyceride levels. In contrast to MB07811, treatment with T3 induced adipocyte lipolysis *in vitro* and *in vivo*, but had a diminished ability to decrease hepatic steatosis. This finding suggests the influx of FFA from the periphery to the liver may partially counteract the antisteatotic activity of T3. Clearance of liver lipids by MB07811 results from accelerated hepatic fatty acid oxidation, a known consequence of hepatic TR activation, as reflected by increased hepatic mitochondrial respiration rates, changes in hepatic gene expression, and increased plasma acyl-carnitine levels. Transaminase levels remained unchanged or reduced, and no evidence of liver fibrosis or other histological liver damage was observed after treatment with MB07811 for up to 10 wk. Additionally, MB07811, unlike T3, did not increase heart rate or decrease pituitary TSH $\beta$  expression. Therefore, MB07811 represents a novel class of liver-targeted TR agonists with beneficial LDL cholesterol-lowering properties that may provide additional therapeutic benefit to hyperlipidemic patients with concomitant NAFLD.

### LXR activator

TH action is mediated by interactions between TRs and nuclear receptors such as LXR, and Thrsp is known to be regulated by a variety of transcription factors, including TR, PXR, and CAR. Thrsp has been reported to be a lipogenic gene in cultured hepatocytes, suggesting an important role for Thrsp in the pathogenesis of NAFLD. Hepatic overexpression of Thrsp increases triglyceride accumulation with enhanced lipogenesis in the liver of C57Bl/6 mice, whereas hepatic Thrsp gene silencing attenuates the fatty liver phenotype in db/db mice. It has been reported that the LXR activator TO901317 induces Thrsp expression in the liver of wild-type and LXR $\beta$  gene-deficient mice, but not in LXR $\alpha$  or LXR $\alpha/\beta$  double knockout mice. Emerging *in vitro* evidence also points to a critical role for LXR in regulating Thrsp transcription in hepatocytes. New evidence<sup>[69]</sup> also shows that Thrsp is upregulated in the liver of db/db mice and high-fat diet-fed mice, two models of murine NAFLD. The expression of Thrsp depends on LXR $\alpha$  *via* an SREBP1c-dependent mechanism. TO901317 treatment significantly enhances hepatic SREBP1c expression and activity in

wild-type mice but fails to induce Thrsp expression in SREBP-1c gene-deficient mice. TO901317 treatment and LXR $\alpha$  overexpression fail to induce, whereas overexpression of SREBP1c significantly increases, Thrsp promoter activity. Moreover, deletion of the SRE site completely abolishes SREBP1c-induced Thrsp transcription. These findings demonstrate that Thrsp is a lipogenic liver gene that is induced by the LXR agonist through an LXR $\alpha$ -mediated, SREBP1c-dependent mechanism. Thrsp may therefore represent a potential therapeutic target for the treatment of NAFLD.

### TR $\beta$ -specific agonist GC-1

GC-1 is a synthetic TH analogue that is relatively selective for both the binding and activation functions<sup>[13]</sup> of TR $\beta$ 1 over TR $\alpha$ 1. GC-1 has several structural differences with respect to the natural hormone T3, including replacement of the three iodine residues with methyl and isopropyl groups, replacement of the biaryl ether linkage with a methylene linkage, and replacement of the amino acid side chain with an oxyacetic acid side chain<sup>[70]</sup>. GC-1 binds TR $\beta$ 1 with the same affinity as T3 does, but GC-1 binds TR $\alpha$ 1 with an affinity approximately 10 times lower than that of T3, both *in vitro* and *in vivo*<sup>[71]</sup>. The differential effects of GC-1, compared with those of T3, on the thermogenesis by BAT<sup>[72]</sup>, tadpole metamorphosis<sup>[73]</sup>, and the development of bone and central nervous system<sup>[74-76]</sup> may be the result of GC-1 selectivity for TR $\beta$ <sup>[77]</sup>. On the other hand, the selective effects of GC-1 may also be related to the body distribution of the TR isoforms. In agreement with studies in which the TR $\beta$  gene was disrupted<sup>[78]</sup>, GC-1 has almost no effect on the heart, which expresses mainly TR $\alpha$ 1, but does lower serum levels of cholesterol and triglycerides, in agreement with the predominant expression of TR $\beta$ 1 in the liver. Other studies also suggest that the selective actions of GC-1 might be explained by differential tissue uptake, since GC-1 presents a clear tissue-specific accumulation<sup>[79]</sup>. It has been shown, for example, that GC-1 accumulates selectively in the liver as compared in the heart. The tissue/plasma ratio was similar for GC-1 and T3 in the liver but was 30-times lower in the heart<sup>[71]</sup>. It is well known that thyrotoxicosis affects body composition, reducing both fat and lean mass<sup>[80,81]</sup>. In primates, treatment with GC-1 increases oxygen consumption and reduces body weight, but its effects on body composition have not yet been determined. Treatment with GC-1 increases the metabolic rate, has no effect on food intake, and decreases fat mass while sparing lean mass in rats. These data illustrate the potential of GC-1 for the selective activation of TR $\beta$  in rats to induce UCP1 gene expression, while only minimally mediating synergism between TH and the sympathetic nervous system. The use of GC-1 or other TR $\beta$ -selective agonists in rodents and primates has recently been shown to increase energy expenditure and decrease fat mass and plasma levels of cholesterol<sup>[82]</sup>, while sparing the heart<sup>[71]</sup> and skeletal system<sup>[83]</sup>. The TR $\beta$ -specific agonist GC-1 increases energy expenditure and prevents fat

mass accumulation in rats.

The effect of GC-1 on biological processes has not yet been demonstrated. The effects of 6-wk treatment with T3 (daily injections of 3 or 6 µg/100 g body weight) or GC-1 (equimolar doses) on different metabolic parameters in adult female rats were investigated by Villicev<sup>[13]</sup>. Whereas all animals gained weight (17-25 g) equally with T3 or GC-1 treatment, only T3 treatment increased food intake (50%-70%). Oxygen consumption was significantly and equally increased (50%-70%) by T3 and GC-1. Analysis of body composition by dual-energy X-ray absorptiometry (DEXA) revealed that whereas control animals gained about 80% of fat mass, T3- or GC-1-treated animals lost 70%-90% and 20%, respectively. Analysis of the carcasses showed that T3 treatment resulted in a 14%-74% decrease in fat content, whereas GC-1 treatment resulted in only a 15%-23% reduction. The gain in lean mass by DEXA and carcass protein content were unaffected by either T3 or GC-1 treatment. However, the masses of individual skeletal muscles were negatively affected by T3, but only marginally by GC-1. These findings highlight the potential use of GC-1 for the treatment of obesity and metabolic syndrome.

## GC-24

BAT is a tissue specialized in adaptive thermogenesis with the expression of mitochondrial uncoupling protein 1 (UCP1) in response to cold induction. In contrast to WAT, the main function of BAT is to dissipate energy, not to store it. Therefore, the conversion of WAT to BAT is sought as a possible strategy to treat obesity. In rats fed a high-calorie diet, GC-24 confers resistance to diet-induced obesity through the promotion of energy expenditure<sup>[84]</sup>. In addition, a recent case report<sup>[85]</sup> indicates that in a diabetic patient with extreme insulin resistance due to a mutation in the insulin receptor gene, TH induces BAT and ameliorates diabetes.

Overall, TH or TR dysfunction can serve as another mechanism that is related to fatty liver and obesity. Evidence based on animal models and clinical phonemes can lead us to further explore the pathway between thyroid and fatty tissues or the liver. With an understanding of a functional thyroid, we believe that TH analogues and receptor agonists will be potential pharmacologic targets in patients with NAFLD in the near future.

**Key words:** Constipation; Prucalopride; Linaclotide

**Core tip:** When standard laxatives fail in the management of constipation, licensed medication linaclotide and prucalopride show useful efficacy in clinical trials.

### Abstract

Constipation is a common medical problem and when standard laxatives fail it can be difficult to treat. Different aetiologies require tailored therapeutic approaches. Simple constipation may only require dietary manipulation while severe neurological or slow transit constipation may need pharmacologic intervention. Recently new drug therapies have been introduced. PubMed and Ovid were searched for reviews, systematic reviews and meta-analysis published since 2003 using the terms: constipation, Prucalopride, Linaclotide and Lubiprostone. This review summarizes potential novel therapies identified as effective in the management of chronic constipation. Prucalopride is a selective 5-hydroxytryptamine receptor agonist. The prucalopride study was in patients, largely women with idiopathic constipation showed improved spontaneous complete bowel movement (SCBM) at a dose of 2 mg a day with few adverse events reported. Linaclotide is a 14-amino acid peptide guanylate cyclase-C agonist. The linaclotide study was carried out in patients with irritable bowel syndrome, constipation group (IBS-C). There was significant improvement of bowel evacuation and symptom resolution in patients on the active treatment arm. Lubiprostone activates type-2 chloride channels, increasing intestinal fluid secretion. In the trials of this drug, the lubiprostone arms had a greater mean number of SCBM. The novel therapies, prucalopride, lubi-

### INTRODUCTION

Constipation is a common complaint reported to General practitioners and Gastroenterologists. A systematic review by Peppas *et al*<sup>[1]</sup> found that the mean value of constipation rates in Europe is 17.1% and 15.3% in Oceania. Constipation is a symptom complex. A thorough history and physical examination is paramount in the evaluation of a patient presenting with constipation. The physician should seek to understand the patient's perception of their current bowel habit, compared to the past and should include stool frequency, form and the ease of passage of stool<sup>[2]</sup>. The use of the Bristol Stool Chart may aid the patient in their description of the stool form (Table 1)<sup>[2,3]</sup>.

The presence of alarm features such as unintentional weight loss and rectal bleeding should be excluded during the history taking. The drug history should include the type of laxatives and the dose and duration previously tried. Physical examination should include both an abdominal examination for palpation of any masses or

**Table 1 Bristol stool chart**

Type	Description
1	Separate hard lumps
2	Sausage shaped but lumpy
3	Like a sausage but with cracks on its surface
4	Like a sausage or snake, smooth and soft
5	Soft blobs with clear cut edges
6	Fluffy pieces with ragged edges, a mushy stool
7	Watery, no solid pieces, entirely liquid

palpable stool and a rectal examination, which may reveal evidence of strictures or fissures.

Various definitions of constipation have been used, ranging from a self-reported sense of constipation to the formal criteria used in clinical trials. A practical definition would be a reduced frequency or ease of stool passage that is different to the individual's normal pattern. Constipation can be acute and chronic, with chronic constipation defined as duration of greater than three months<sup>[2]</sup>.

The Rome III criterion for chronic constipation includes the presence of two or more of six symptoms for at least twelve weeks in the preceding six months (Table 2)<sup>[2-4]</sup>. Constipation leads to a reduction in quality of life. A recent systematic review by Belsey *et al.*<sup>[5]</sup> has shown that this reduction is predominant in the mental health domain and is equivalent to chronic conditions such as diabetes.

Constipation can be a primarily functional disorder or secondary to medications, and systemic diseases. Constipation can be classified as normal transit, slow transit, or due to obstructed defaecation<sup>[6]</sup>. A study conducted in Thailand found that 13% of patients had slow transit, 29% had obstructed defaecation, 11% of patients had a mixture of slow transit and obstructed defaecation, with the remaining 47% having normal transit<sup>[7]</sup>.

### Obstructed defaecation

Functional outlet obstruction can occur because of dysfunction of the anal sphincter, pelvic floor muscle dyssynergia or structural abnormalities like obstructing rectoceles<sup>[6]</sup>.

### Slow transit constipation

Patients with slow transit constipation have a reduction in the frequency of high amplitude colonic contractions<sup>[6]</sup>. Scintigraphic measurements indicate that slow transit is more common in the left colon than in the transverse and ascending colon<sup>[8]</sup>. A loss of co-ordination between contractile activity in the rectum and sigmoid colon and a reduced rectal sensory threshold has been implicated in slow transit constipation<sup>[6-10]</sup>.

### Normal transit constipation

In this subgroup the colonic transit time is normal and there is no evidence of functional outlet obstruction on testing. It is the cohort of patients with constipation pre-

**Table 2 Rome III criteria**

- 1 Straining at defaecation on at least 1/4 of occasions.
- 2 Stools that are lumpy/hard on at least 1/4 of occasions.
- 3 Sensation of incomplete evacuation on at least 1/4 of occasions.
- 4 Manual manoeuvres to facilitate at least 25% of defaecations.
- 5 Sensation of anorectal obstruction/blockage at least 25% of defaecations.
- 6 Fewer than 3 bowel movements a week.

dominant irritable bowel syndrome that typically fall into this subgroup<sup>[6]</sup>.

Health professionals have traditionally advised patients presenting with constipation to increase fibre and fluid intake and to exercise. However, the evidence behind this is inconsistent<sup>[11]</sup>. Current guidelines don't make any firm recommendations to support the use of laxatives in chronic constipation<sup>[12-14]</sup>.

In recent years new pharmacological agents have appeared on the market. This review article serves to address the following novel therapies available for the management of primary constipation: Prucalopride, Lubiprostone and Linaclotide.

## PRUCALOPRIDE

Prucalopride is a selective, high affinity 5-hydroxytryptamine receptor agonist, used in patients with severe chronic constipation. There have been 3 pivotal studies of the use of Prucalopride in the management of chronic constipation-Camilleri 2008<sup>[15]</sup>, Tack 2009<sup>[16]</sup> and Quigley 2009<sup>[17]</sup>. They enrolled both men and women, however over 85% of the evaluated patients were female. This has led to the drug being restricted to women only. This is not to say that it is not effective in men, it merely hasn't been adequately tested in them. The recommended dose of Prucalopride is 2 mg as a dose response effect was not obvious between the 2 mg and 4 mg dose tested in the 3 studies. The use of Prucalopride is approved for chronic constipation in women in whom laxatives have failed to provide adequate relief<sup>[18]</sup>.

The study by Camilleri *et al.*<sup>[15]</sup> was a multicentre, randomized, placebo-controlled, trial in 620 patients with severe chronic constipation (< 2 spontaneous, complete bowel movements per week). They found that the proportion of patients with 3 or more spontaneous, complete bowel movements per week was 30.9% of those receiving 2 mg of Prucalopride and 28.4% of those receiving 4 mg of Prucalopride, compared to 12.0% in the placebo group ( $P < 0.001$  for both comparisons). The most frequently reported side effects of the drug have been headache, nausea, and diarrhoea<sup>[15]</sup>.

In the 12 wk study 713 patients recruited patients were given either 2 or 4 mg Prucalopride daily versus placebo. The number of patients achieving > 3 SCBMs/wk was 19.5%;  $P < 0.01$  on 2 mg prucalopride and 23.6;  $P < 0.001$  on 4 mg prucalopride *vs* 9.6% for placebo<sup>[16]</sup>.

Quigley *et al.*<sup>[17]</sup> also demonstrated a similar efficacy

of Prucalopride in 641 patients compared to placebo in chronic constipation. In this 12 wk study 641 patients received either 2 or 4 mg of prucalopride *vs* placebo. In the 2 mg prucalopride group 23.9% had > 3 SCBM per week. In the 4 mg group 23.5% had > 3 SCBM per week ( $P < 0.01$ , in both cases) *vs* 12.1% with placebo<sup>[18]</sup>.

A study from the Asia-Pacific region evaluated the efficacy and safety of the 2 mg dose of prucalopride compared to placebo in patients with chronic constipation. This study found that prucalopride greatly improved bowel function, and patient satisfaction in individuals suffering from chronic constipation over a 12-wk treatment period. It found that prucalopride was safe and was well tolerated by patients<sup>[19]</sup>.

Prucalopride has not been found to have a significant interaction with the hERG potassium channel which was assumed to have been responsible for the development of adverse cardiovascular effects seen with Cisapride<sup>[18,20]</sup>. The three pivotal clinical trials of prucalopride did not demonstrate any relevant electrocardiographic changes<sup>[15-17]</sup>. A recent meta-analysis of seven RCT's of prucalopride found that the number needed to treat (NNT) was 6<sup>[21,22]</sup>.

### Lubiprostone

Chloride channels play a vital role in the transport of fluid and maintaining cell volume and pH in cells and tissues, particularly intestinal epithelial cells. The CIC-2 channel when activated promotes the secretion of intestinal fluid. Lubiprostone activates type-2 chloride channels, increasing intestinal fluid secretion. This may facilitate intestinal transit, thereby increasing the passage of stool<sup>[23]</sup>.

In a multicentre 4 wk trial, Johanson *et al* demonstrated that the use of Lubiprostone in chronic constipation produced a bowel motion within 24-48 h of initial dosing and improved frequency of bowel motions with short term treatment. This double-blinded trial recruited 242 patients with constipation. The patients were randomized to receive either 24 mcg oral Lubiprostone or placebo twice daily for 4 wk. One hundred and twenty patients received Lubiprostone and 122 received placebo. The Lubiprostone arm reported a greater mean number of spontaneous bowel movements at week 1 compared with the placebo arm (5.69 *vs* 3.46,  $P = 0.0001$ ), with an increased frequency of spontaneous bowel movements reported at weeks 2, 3 and 4 ( $P \leq 0.002$ ). Twenty-four hours after the first dose 56.7% of the Lubiprostone group reported a SCBM compared with 36.9% in the placebo group ( $P = 0.0024$ ); within 48 h, 80% and 60.7% of these patients reported a SCBM ( $P = 0.0013$ ), respectively. The two most common treatment-related adverse events were nausea (31.7%) and headache (11.7%)<sup>[24]</sup>.

Barish *et al*<sup>[25]</sup> showed a similar outcome in their multicentre, double-blinded study. A total of 237 patients with chronic constipation were randomized to 4 wk of 24 mcg oral Lubiprostone or placebo twice daily. The Lubipro-

stone arm again had a greater mean number of SCBM at week 1 compared to placebo (5.89 *vs* 3.99,  $P = 0.0001$ ), with a higher proportion having SCBM's in the first 24 h of the initial dose (61.3% *vs* 31.4%,  $P < 0.0001$ )<sup>[25]</sup>.

### Linaclotide

Linaclotide is a 14-amino acid peptide guanylate cyclase-C agonist. It binds to and activates GC-C on the luminal surface of the intestinal epithelium. Activation of GC-C leads to increased cGMP (cyclic guanosine monophosphate) which triggers a signal transduction cascade activating the cystic fibrosis transmembrane conductance regulator. This causes an increase in the secretion of chloride and bicarbonate into the intestinal lumen, resulting in increased luminal fluid secretion and an acceleration of intestinal transit.

A recent 26 wk, randomized, double-blinded trial was done across 102 centres across the United States. The objective of this phase 3 clinical trial was to assess the safety and efficacy of Linaclotide at a daily dosage of 290 mcg *vs* placebo to patients with IBS-C. Based on the recommendations for IBS-C trial design and in the FDA guidance for IBS clinical trials, a responder was defined as a patient who reported: (1) An improvement of > 30% from baseline in average daily worst abdominal pain score; and (2) Increase of > 1 complete spontaneous bowel movement from baseline, both in the same week for > 6/12 wk and 3 other primary end points, based on improvements in abdominal pain and CSBMs for 9/12 wk<sup>[26,27]</sup>.

After the initial screening, 804 patients were recruited. 33.7% of the Linaclotide arm were FDA end point responders *vs* 13.9% of the placebo arm ( $P < 0.0001$ ). The NNT was 5.1, (95%CI: 3.9-7.1). The pain responder criterion of the FDA end point was met by 48.9% of Linaclotide treated patients *vs* 34.5% of placebo-treated patients (NNT = 7.0, 95%CI: 4.7-13.1) and the CSBM responder criterion was met by 47.6% of Linaclotide-treated patients, *vs* 22.6% of placebo patients (NNT = 4.0, 95%CI: 3.2-5.4)<sup>[26]</sup>.

Another 12 wk trial by Rao *et al*<sup>[28]</sup> recruited 800 patients to a double-blinded, parallel group, placebo controlled trial to placebo *vs* 290 mcg linaclotide once daily, followed by a 4 wk randomized withdrawal period. Percent of thirty three point six of the linaclotide-treated patients met the FDA end point compared with 21% of placebo treated patients ( $P < 0.0001$ ) (NNT = 8, 95%CI: 5.4-15.5). Throughout the randomized withdrawal period, patients remaining on linaclotide showed a sustained improvement. The patients that were re-randomized from linaclotide to placebo showed a return of symptoms without any worsening of symptoms relative to baseline<sup>[28]</sup>. The most common adverse effects were GI-related, of which diarrhoea had the highest incidence<sup>[29]</sup>.

## CONCLUSION

Novel therapies such as Prucalopride, Lubiprostone, and

Linaclotide have been shown to be efficacious and safe in the treatment dose for constipation. They have different mechanisms of action influencing and activating colonic motility, secretions and transit time leading to improvement in frequency and consistency of stool and bowel symptoms with greater satisfaction in chronic constipation. Overall, all these new treatment options have been shown to have a good safety profile.

### Abstract

Portopulmonary hypertension (PPHTN) is a known complication of cirrhosis. Moderate-to-severe PPHTN implies an extremely poor prognosis. It occurs in 5%-10% of patients referred for liver transplantation (LT), and probably with an higher incidence in patients with large portosystemic shunts. Patients with moderate-to-severe pulmonary hypertension have been previously excluded from LT because of the extremely high surgical risk and since the post-transplant outcome reported was poor. Recently, new perspectives in the management of patients with portopulmonary hypertension are emerging. In fact, some pulmonary vasoactive drugs have become routine in the treatment of patients with idiopathic pulmonary hypertension. These drugs, particularly epoprostenol, have been recently introduced in the treatment of patients with PPHTN, and have been shown to be effective in reducing pulmonary artery pressure as well as pulmonary vascular resistances.

Furthermore, recent studies seem to demonstrate that treatment with pulmonary vasoactive drugs could allow liver transplantation with acceptable surgical risks and excellent survival. Although there are not large series nor prospective studies addressing this topic, the clinical scenario of patients with PPHTN seems to be positively changing.

### INTRODUCTION

Portopulmonary hypertension (PPHTN) is a known and uncommon severe complication of cirrhosis, since moderate-to-severe forms have grave prognostic significance with

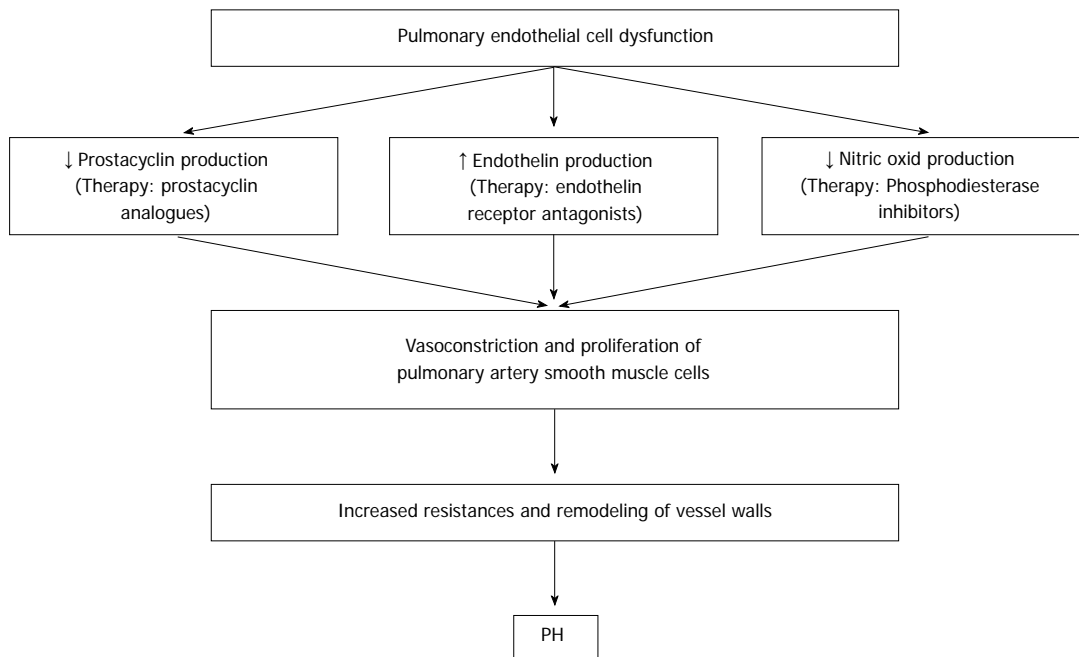

Figure 1 Pathophysiology of pulmonary hypertension and possible drug targets.

the majority of patients succumbing within 2 years<sup>[1-4]</sup>.

PPHTN affects 1%-2% of patients with portal hypertension or cirrhosis and 5%-10% of patients being evaluated for liver transplantation<sup>[5]</sup>.

Diagnosis is suggested by either elevation of the right ventricular systolic pressure or right ventricular dysfunction on echocardiography, but requires confirmation by right heart catheterization<sup>[6-8]</sup>.

## DEFINITION OF PORTOPULMONARY HYPERTENSION

PPHTN definition has evolved over time, specifically with regard to the cutoff for pulmonary vascular resistances (PVR). Initial studies used  $PVR > 120$  dynes  $s\ cm^{-5}$  as abnormal. Subsequent studies and the Consensus Report of the European Respiratory Task Force on pulmonary vascular diseases associated with liver diseases have recommended  $PVR > 240$  dynes  $s\ cm^{-5}$  as the “gold standard”.

Therefore the current consensus diagnostic criteria for PPHTN include mean pulmonary artery pressure (MPAP)  $> 25$  mmHg,  $PVR > 240$  dynes  $s\ cm^{-5}$ , and pulmonary artery occlusion pressure (PAOP)  $< 15$  mmHg<sup>[1,6,7]</sup>.

Since it has been shown that some patients with  $PAOP > 15$  mmHg and  $PVR > 240$  dynes  $s\ cm^{-5}$  may present a trans-pulmonary gradient (TPG) strongly suggestive of obstruction to pulmonary arterial flow, recently new criteria have been proposed by authors from Mayo Clinic<sup>[8]</sup>. These are the following: (1) Portal Hypertension and/or liver disease (clinical diagnosis-ascites/varices/splenomegaly); (2)  $MPAP > 25$  mmHg at rest; and (3)  $PVR > 240$  dynes  $s\ cm^{-5}$ ; and (4)  $PAOP < 15$  mmHg or  $TPG > 12$  mmHg, where  $TPG = MPAP - PAOP$ .

In fact, many patients managed as pulmonary hypertension have elevated left-sided filling pressure, probably due to ventricular interaction. Then, it has been recently proposed that only values of PAOP higher than 18 mmHg exclude the diagnosis of PPHTN<sup>[9-12]</sup>.

## PATHOPHYSIOLOGY AND PATHOGENESIS

PPHTN involves endothelial and smooth muscle proliferation, and have the same features of plexogenic arteriopathy of Idiopathic Pulmonary Hypertension (Figure 1). There is not a clear link between portal hypertension and the development of PPHTN. Because only 5%-10% of patients with portal hypertension develop PPHTN, factors other than portal hypertension must be involved in its development. Moreover, the link between liver dysfunction and PPHTN is not obvious, because PPHTN may develop in cases of portal vein thrombosis or idiopathic hypertension, in absence of any liver dysfunction. Data of a recent retrospective study by Talwalkar *et al*<sup>[13]</sup>, suggest a strong association between large portosystemic shunts, hepatofugal portal blood flow, and PPHTN. These data may support the hypothesis that vasoactive factors from the splanchnic circulation may be pathogenic for PPHTN development. The fact that the most occurring shunt observed in this study was spleno-renal might suggest that the blood flow coming from the spleen, which is involved in the destruction of platelets and prostaglandins delivery, might be of primary importance in the PPHTN pathogenesis. Moreover, presence of large portosystemic shunts, such as those reported in this study, seems to be associated with lack of response to vasoactive treatment.

## PROGNOSIS OF PPHTN AND LIVER TRANSPLANTATION

Moderate-to-severe PPHTN (MPAP  $\geq 35$  mmHg) that is present in up to 5%-10% of patients referred for liver transplantation (LT)<sup>[4,5]</sup>, excludes patients from LT in most of the centers, since post-transplant outcome is poor and because of the high surgical risk<sup>[11-13]</sup>.

A multicenter transplant database has shown that 36% of PPHTN patients died during the immediate post-transparent period due to progressive right ventricular failure, acute respiratory distress syndrome and cardiovascular collapse<sup>[11]</sup>. Moreover, Krowka *et al.*<sup>[14]</sup> reported that only 29% of transplanted patients with untreated PPHTN survived 3 years.

## VASODILATION TREATMENT IN PPHTN

Several vasomodulating and vasodilating drugs have been introduced for the treatment of idiopathic pulmonary hypertension. More recently, vasomodulating and vasodilating drugs, available for the treatment of idiopathic pulmonary hypertension, have also been shown to significantly improve pulmonary hemodynamics in some patients with PPHTN<sup>[5-16]</sup>.

Current medications target three pulmonary hypertension pathways. The first agent, the endothelin receptor antagonists, target the vasoconstrictive endothelin pathway. The second agent targets the prostacyclin pathway, resulting in vasodilation, antiplatelet effect, and vascular remodelling. The third one involves nitric oxide-mediated vasodilation through cyclic guanosine monophosphatase and the inhibition of the phosphodiesterase type 5 enzyme. Therefore, some drugs have a vasodilation effect, while others have remodeling and antiplatelet effects.

Since we do not yet know which is the predominant mechanism which determines pulmonary hypertension in patients with portal hypertension<sup>[4]</sup>, different drugs have been used in the treatment of patients with PPHTN.

The drugs that have been mostly used for the treatment of patients with PPHTN are the prostacyclin analogues, such as Epoprostenol, inhaled Iloprost and Treprostinol. Epoprostenol is a potent pulmonary and systemic vasodilator, that also reduces platelet aggregation<sup>[16-18]</sup>. In PPHTN it has been shown to improve hemodynamics acutely, because of its vasodilator effects<sup>[15]</sup>. Furthermore, in two studies prolonged use of the drug has shown additional improvement<sup>[5,15]</sup>. A recent paper by Awdish *et al.*<sup>[19]</sup> reports the long-term effects of treatment with and without epoprostenol on pulmonary hemodynamics, liver function and survival, in a large retrospective cohort of patients with moderate to severe PPHTN. They showed significant improvements in mean pulmonary artery pressure, pulmonary vascular resistances and cardiac output with epoprostenol after a median of 15.4 mo, and no significant change of liver biochemistry. However, survival seemed not to differ between treatment groups. These studies argue against the hypothesis by Krowka

that epoprostenol might worsen portal hypertension by increasing splenic blood flow and portal system congestion<sup>[15]</sup>. In fact, it is possible to hypothesize that by improving pulmonary hemodynamics and right heart function, epoprostenol could potentially improve liver function<sup>[20]</sup>.

A recent prospective observation study has stressed the utility of early initiation of parenteral prostacyclin therapy in PPHTN patients, so improving 5-year survival, as compared with data of the REVEAL Registry<sup>[20]</sup>.

There are scarce studies concerning the treatment with Treprostinil<sup>[21]</sup>, and inhaled Iloprost<sup>[22]</sup>, sometimes used together with other vasoactive drugs<sup>[23,24]</sup> in patients with PPHTN.

Concerning the endothelin receptor antagonists, such as Bosentan, there are some recent studies that seem to demonstrate a possible hemodynamic improvement and safety of these drugs<sup>[23,25-29]</sup>. Moreover, Bosentan has been administered together with different drugs in some studies: inhaled Iloprost<sup>[23,24,29]</sup>, or with Sildenafil and Iloprost<sup>[24]</sup>.

Phosphodiesterase inhibitor Sildenafil has the advantage of being an oral compound with pulmonary vasoselective action but no hepatotoxicity<sup>[27]</sup>. Few recent retrospective studies, performed in a small number of patients with PPHTN<sup>[30-33]</sup>, seem to show that sildenafil might be effective in monotherapy, and in combination with inhaled prostanoids, leading to hemodynamic improvement. These data have also been confirmed by a recent paper by Krowka<sup>[34]</sup> reporting favourable follow up in seven patients with moderate or severe PPHTN treated with oral combination therapy.

## LIVER TRANSPLANTATION FOLLOWING MEDICAL MANAGEMENT

PPHTN survival in the absence of transplantation has been reported in 38% at 3 years<sup>[1]</sup> and 28% at 5 years<sup>[35]</sup>. Furthermore, it has been demonstrated that PPHTN prognosis is worse than that of idiopathic pulmonary hypertension<sup>[1]</sup>.

PPHTN is a serious problem in the context of liver transplantation. Mild PPHTN (MPAP  $< 35$  mmHg) has scarce perioperative risks<sup>[36,37]</sup>, but moderate disease (MPAP 35-45 mmHg, PVR  $> 250$  dyne scm<sup>-5</sup>) has been associated with a perioperative mortality of 50%-80%<sup>[8,38]</sup>, and a MPAP  $> 50$  mmHg is universally fatal<sup>[14,36,37]</sup>.

Recently numerous studies have demonstrated the possibility of reducing MPAP and PVR, at least in some patients affected by PPHTN, leading to a decrease of perioperative risk due to liver transplantation. Moreover, some studies have shown that PPHTN may resolve following transplantation, presumably by removing the root cause of the problem<sup>[39-41]</sup>.

As a consequence of recent improved knowledge of PPHTN management, a potential therapeutic opportunity arises: PPHTN might initially be controlled with vasodilator therapy and subsequently cured with liver transplantation. Several studies have been performed to examine the feasibility of this hypothesis<sup>[31-42]</sup>. Moreover,

in the last years some retrospective studies have been published reporting patients with PPHTN in whom liver transplantation was successfully performed after treatment with pulmonary vasoactive drugs<sup>[22,43,44]</sup>. In the study by Ashfaq *et al.*<sup>[43]</sup>, 16 of 20 patients with moderate-to-severe pulmonary hypertension (MPAP  $\geq$  35 mmHg) were otherwise considered suitable liver transplant candidates and were treated with vasoactive pulmonary drugs (epoprostenol in 13, bosentan + epoprostenol in 1, sequential; bosentan + diltiazem + epoprostenol, sequential in 1, diltiazem in 1). In these patients MPAP fell to less than 35 mmHg in 12 (75%), and 11 of them underwent liver transplantation. One-year survival was 91%, and 5-year survival was 67%. Nine of 11 patients were off vasodilator therapy after a median of 9.2 mo after transplantation. In patients who failed vasodilator therapy median survival was 8 mo. The Authors conclude that effective pharmacologic control of PPHTN before transplantation is associated with posttransplant survival that is similar to patients transplanted for other indications.

In the study by Sussman *et al.*<sup>[44]</sup>, 8 cirrhotic patients with MPAP  $\geq$  35 mmHg, were treated with continuous intravenous epoprostenol (2-8 ng/kg per minute). In these patients liver transplant was considered if MPAP was lowered to < 35 mmHg. In seven patients the treatment improved hemodynamics within 6.5 mo therapy: mean vascular resistances declined from 410 to 192 dyne s cm<sup>-5</sup>, and cardiac output increased from 6.6 to 10 L/min. Six of the seven responders were listed for transplantation; two died on the waiting list; four were transplanted and remained alive and well after 9 to 18 mo post LT. Epoprostenol was continued throughout surgery and into the post-transplant period. In two of the patients it was possible to stop the vasodilator therapy, whereas in two patients oral medication with bosentan was continued.

In the study by Swanson *et al.*<sup>[41]</sup>, a retrospective screening-right heart catheterization-survival analysis of patients with PPHTN was performed. Patients were categorized in three subgroups: (1) no vasoactive therapy and no transplantation; (2) therapy for pulmonary hypertension alone; and (3) therapy for pulmonary hypertension followed by liver transplantation. Even though it is a relatively small study, it seems to demonstrate that the survival of untreated patients was poor, whereas subgroups of patients selected to medical treatment with or without liver transplantation had better long-term survival. The best survival was in the subgroup of patients in whom liver transplantation was performed following effective medical therapy for pulmonary hypertension. However, it is to stress that this study is retrospective and reports a small number of patients. Moreover, 4 of 5 deaths in the LT group occurred in patients with PAOP  $\leq$  10 mmHg, while only two out of seven LT survivors had PAOP  $\leq$  10 mmHg. The authors hypothesize that lower values of PAOP may be correlated to lower cardiac outputs, and this might contribute to the poor prognosis. In the assessment of patients with PPHTN that are candidate to liver transplantation it is very important to perform an accurate evaluation of right ventricular function, because

the success of undertaking liver transplantation will be determined by the ability of the right ventricle to sustain the increase of cardiac output and of pulmonary vascular resistance that acutely occur at the time of reperfusion that may cause acute right heart failure<sup>[45]</sup>. Therefore, pre-transplant evaluation of right ventricular function by means of right heart catheterization and stress echocardiography is essential. Continuous intraoperative transoesophageal echocardiography has also been recommended for following right ventricular function<sup>[46]</sup>.

## MODEL FOR END-STAGE LIVER DISEASE AND PPHTN

Results of recent studies concerning LT following medical treatment in patients with PPHTN, as discussed above, probably change the clinical scenarios of patients with moderate or even severe pulmonary hypertension and portal hypertension.

Outcome of these patients, traditionally excluded from LT, could benefit from LT if a response to vasoactive therapy is evident. In fact, there is increasing evidence that many patients with PPHTN have important decrease of MPAP and PVR after therapy, so that they have excellent survival following liver transplantation. Furthermore, in some of these patients, vasoactive therapy may be stopped a few months after LT. Moreover, there is not any doubt that many patients who positively respond to medical therapy die on the waiting list for transplantation. Finally, another reason could support early transplant of these patients. In fact, long-term intravenous epoprostenol, probably the most effective drug, is expensive, labor-intensive, requires hospitalization and is difficult to tolerate. These are the reasons why in some studies patients with PPHTN on intravenous therapy are given a MELD exception of 25 points in Region 4<sup>[43]</sup>.

In a recent paper, Krowka *et al.*<sup>[47]</sup> discuss this topic suggesting MELD exception (Meld score = 26 points) when the acceptable candidates satisfy the following criteria: (1) POPH exists with severity characterized by MPAP > 35 mmHg; and (2) a minimum of 12 wk of United States Food and Drug Administration-approved pulmonary arterial hypertension therapy results in the following hemodynamic profile: (1) MPAP < 35 mmHg and PVR < 400 dynes scm<sup>-5</sup>; and (2) satisfactory right ventricular function exists.

## LIVER AND LUNG TRANSPLANTATION

Combined lung and liver transplantation is a therapeutic option for selected patients with coexisting lung and liver diseases such as cystic fibrosis and  $\alpha$ 1-proteinase inhibitor deficiency, and has also been performed in few cases of patients with PPHTN<sup>[48-53]</sup>. Recently, a report concerning 13 consecutive patients who underwent combined lung and liver transplantation has been published. In the whole cohort of patients, 5 with PPHTN and 8 with other severe hepatic and pulmonary diseases (sarcoidosis, cystic

fibrosis, alfa 1-proteinase inhibitor deficiency), patient and graft survival rates, after combined transplantation, were 69% after 1, 62% after 3, and 49% after 5 years<sup>[54]</sup>. However, further studies are needed to confirm the efficacy, as well as the indications of this surgical approach in the management of patients with PPHN.

### Abstract

Radiologists first described the removal of bile duct stones using balloon dilation in the early 1980s. Recently, there has been renewed interest in endoscopic balloon dilation with a small balloon to avoid the complications of endoscopic sphincterotomy (EST) in young patients undergoing laparoscopic cholecystectomy. However, there is a disparity in using endoscopic balloon papillary dilation (EPBD) between the East and the West, depending on the origin of the studies. In the early 2000s, EST followed by endoscopic balloon dilation with a large balloon was introduced to treat large or difficult biliary stones. Endoscopic balloon dilation with a large balloon has generally been recognized as an effective and safe method, unlike EPBD. However, fatal complications have occurred in patients with endoscopic papillary large balloon dilation (EPLBD). The safety of endoscopic balloon dilation is still a debatable issue. Moreover, guidelines of indications and tech-

niques have not been established in performing endoscopic balloon dilation with a small balloon or a large balloon. In this article, we discuss the issue of conventional and large balloon endoscopic dilation. We also suggest the indications and optimal techniques of EPBD and EPLBD.

**Key words:** Endoscopic papillary balloon dilation; Endoscopic papillary large balloon dilation; Common bile duct stone; Endoscopic sphincterotomy; Mechanical lithotripsy

**Core tip:** Endoscopic papillary dilation with a dilating balloon is technically simple and effective. However, there is still debate regarding safety, and there is no guideline or consensus of detailed techniques. Because the procedure is performed to treat a common benign condition, it is important to ensure that there are no lethal procedure-related complications. It, however, can lead to potential morbidity and even death. As the foremost priority is patient safety, it should be performed with appropriate techniques in selected patients. Therefore, we suggest the optimal indications and tips for avoiding severe complications of endoscopic papillary balloon dilation with a small balloon or a large balloon.

### INTRODUCTION

A common bile duct (CBD) stone is one of the most

common indications of endoscopic retrograde cholangiopancreatography (ERCP). In 1974, endoscopic sphincterotomy (EST) was introduced to remove CBD stones<sup>[1]</sup>. It has since become established as the standard treatment for widening the biliary orifice. Although the success rate of ERCP with EST is more than 90%, EST accounts for a major portion of the morbidity and mortality associated with ERCP<sup>[2,3]</sup>.

To avoid complications of EST, endoscopic papillary balloon dilation with a small balloon (EPBD) was introduced as an alternative to EST. Before the development of EPBD, interventional radiologists originally introduced the transpapillary elimination of CBD stones through dilation of the sphincter with a 6 mm balloon in 1981<sup>[4]</sup>. In 1983, Staritz *et al*<sup>[5]</sup> applied this technique to endoscopy during an ERCP procedure. However, EPBD had not been routinely used for the removal of CBD stones in those days because of frequent complications, mainly acute pancreatitis (in patients with sphincter of Oddi dysfunction)<sup>[6]</sup>. Nevertheless, there was renewed interest in EPBD to preserve the function of the biliary sphincter.

As time passed on, various studies reported on the safety, effectiveness, and advantages of EPBD in the East. In contrast, Western studies showed more frequent lethal complications of EPBD compared with EST<sup>[7,8]</sup>. This disparity has led to the different current practices between East and West. Balloon dilation of the intact papilla is rarely used in most Western countries whereas this technique is popularly used in Eastern countries.

Recently, EST followed by endoscopic papillary balloon dilation with a large balloon (EPLBD) was introduced<sup>[9]</sup>. This review discusses conventional EPBD and EPLBD separately, because the concept, potential advantage, indication, and main purpose of EPBD may differ from those of EPLBD, which utilizes a larger balloon. EPBD may be technically simple and easy to use, but there is still debate regarding safety. The aim of this review is to address the concept, outcomes, safety, techniques and advantages of EPBD and EPLBD. In addition, we suggest indications and technical tips for EPBD and EPLBD individually.

## DEFINITIONS AND CONCEPTS

EPBD involves the dilation of the biliary sphincter with a dilating balloon, and is usually performed without EST by using a small-diameter dilating balloon ( $\leq 10$  mm) (Figure 1). The potential advantages of the EPBD over EST are to avoid short-term complications of bleeding and perforation, to preserve the biliary sphincter, and possibly to reduce long-term sequelae of EST<sup>[8,10,11]</sup>. EPLBD is usually defined as the use of a dilating balloon with a diameter of 12 mm or larger in order to remove large stones that require a larger opening of the CBD<sup>[12,13]</sup>. The potential advantages of EPLBD are to reduce the use of mechanical lithotripsy (ML) and to reduce the complications related to full EST in removing large or difficult

CBD stones<sup>[14]</sup>.

In EPLBD, EST is generally recommended before balloon dilation, because the preceding EST may shift the expansile force toward the CBD rather than the pancreatic orifice. When this combined approach is used, a large endoscopic sphincterotomy is not required. As a result, EPLBD can enlarge the biliary orifice to a greater extent than a standard full EST and create a large biliary orifice (Figure 2). EPLBD may have the advantages of a lower risk of bleeding and perforation over a routine full EST<sup>[14]</sup>. Although EST is generally used at the start of the EPLBD procedure, the safety of large balloon dilation alone without a preceding EST is reported in some studies<sup>[15,16]</sup>. In contrast to EPLBD, the biliary orifice after EPBD is usually less wide than after a full EST. The target stones of EPBD are small- to moderate-sized in minimally dilated CBDs, whereas those of EPLBD are large stones in considerably dilated CBDs (Table 1).

## OUTCOMES

### *Outcome of EPBD compared with that of EST for extraction of bile duct stones*

In a Japanese randomized controlled trial (RCT), EPBD and EST had similar outcomes in the successful removal of bile duct stones (99.3% *vs* 100%) and overall complications (14.5% *vs* 11.8%)<sup>[2]</sup>. In contrast, RCTs from Western countries did not show the same results. In a German RCT, EPBD was inferior to EST in terms of stone removal during the first attempt (77% *vs* 100%)<sup>[7]</sup>. The overall complication rate of EPBD was also higher than that of EST (30.0% *vs* 5.0%). Although the bleeding rate was lower in the EPBD group, cholangitis and pancreatitis developed more frequently than in the EST group. Severe pancreatitis with pancreatic necrosis occurred only in the EPBD group (6.7%). This study was terminated early due to this complication in the EPBD group. Another well-known RCT from the United States reported 2 deaths due to severe pancreatitis developing after EPBD<sup>[8]</sup>. This study was also terminated at the first interim analysis.

Two meta-analyses evaluating the outcome of EPBD compared with EST are available by Baron *et al*<sup>[3]</sup> (8 studies analyzed) and Weinberg *et al*<sup>[17]</sup> (15 studies analyzed). Baron *et al*<sup>[3]</sup> showed that EST and EPBD had comparable overall success rates of stone removal (94.3% *vs* 96.5%). However, in the first attempt without EST, the initial success rate of stone removal was lower in the EPBD group than in the EST group (70.0% *vs* 79.8%). Furthermore, the use of ML was also more prevalent in the EPBD group than in the EST group (20.9% *vs* 14.8%). Overall complication rates were similar in both the EPBD and EST groups (10.5% *vs* 10.3%). However, the rate of pancreatitis was significantly higher in the EPBD group than in the EST group (7.4% *vs* 4.3%) while the rate of bleeding was lower in the EPBD group than in the EST group (0% *vs* 2.0%). Rates of cholangitis and perforation were similar in both groups.

**Figure 1** Endoscopic papillary balloon dilation with a small dilating balloon. A: Huge periampullary diverticulos were noted near the ampulla; B: The 8 mm sized small balloon is gradually inflated with diluted contrast material; inflation is maintained for 30 s; C: Fluoroscopy during balloon dilation shows complete disappearance of the sphincter waist; D: A common bile duct stone was removed by basket through the enlarged biliary orifice.

**Figure 2** Endoscopic papillary large balloon dilation with minor sphincterotomy. A: A minor incision of up to one-third of the papilla was performed over a guidewire; B: The 15 mm sized large balloon is gradually inflated with diluted contrast material; inflation is maintained for 30 s; C: Fluoroscopy during balloon dilation shows complete disappearance of the sphincter waist; D: A large biliary orifice can be seen after balloon dilation.

Weinberg *et al*<sup>[17]</sup> reported that EPBD was statistically less successful for extraction of the stone at the first attempt than EST (73.5% *vs* 80.9%), and the overall success rate of EPBD was slightly lower than that of EST (90.1% *vs* 95.3%). There was no significant difference in short-term complications between the EPBD and EST groups (12.1% *vs* 12.7%). Incidences of bleeding and short-term

infections were significantly lower in the EPBD group than in the EST group. The incidence of perforation was not different between the 2 groups. While many of the complications were similar or lower in the EPBD group than in the EST group, this meta-analysis showed that the incidence of pancreatitis was significantly higher in the EPBD group than in the EST group (8.6% *vs* 4.3%).

**Table 1 Comparison of endoscopic balloon dilation methods according to balloon diameter**

	Small-balloon EPBD	Large-balloon EPBD
Balloon diameter used	≤ 10 mm (6–10 mm)	≥ 12 mm (12–20 mm)
Target stone	Small to moderate sized stones in no or minimally dilated CBD	Large stones in considerably dilated CBD
Endoscopic biliary sphincterotomy	Not performed	Mostly, in conjunction with a small EST <sup>1</sup>

<sup>1</sup>Preceding small-endoscopic biliary sphincterotomy (EST) use may shift the expansile force more toward the common bile duct (CBD) rather than the pancreatic orifice. EPBD: Endoscopic papillary balloon dilation.

Furthermore, in the subgroup analysis, the risk of pancreatitis was higher in younger patients of the EPBD group. These meta-analyses consistently showed that, while EPBD and EST had similar overall success rates for stone removal, acute pancreatitis occurred more frequently in the EPBD group than in the EST group.

### Outcomes of EPLBD

**EPLBD with EST:** In the first introduction of EPLBD by Ersoz *et al.*<sup>[9]</sup>, stone clearance was successful without using ML in patients with large stones (> 15 mm). After this retrospective study, many studies showed that EPLBD could be a useful alternative technique in patients with large CBD stones that were difficult to remove with standard EST.

Recent studies showed that complete stone removal in the first session of EPLBD was accomplished in 89.3% of procedures, and ML was required in 9.5% of patients (including 6 retrospective and 1 prospective trials involving 496 patients)<sup>[14,18–23]</sup>. Overall success of stone removal was 97.6%. Only 8.5% of patients had documented complications, such as bleeding and perforation. Pancreatitis developed in 1.6% of patients. Severe pancreatitis was not reported, contrary to that seen with EPBD.

In a retrospective comparison of EPLBD (with EST) and EST alone (2 studies involving 250 patients)<sup>[24,25]</sup>, EPLBD showed similar outcomes to EST in overall successful stone removal (98.4% *vs* 96.0%) and complications (4% *vs* 6%). However, ML was required significantly more often in the EST group than in the EPLBD group (21.6% *vs* 7.2%). Total procedure time was shorter in the EPLBD group due to less use of ML (13 min *vs* 22 min)<sup>[24]</sup>. Moreover, EPLBD was an effective and safe method for removal of CBD stones in patients with Billroth II gastrectomy, prior biliary sphincterotomy, and periampullary diverticulum<sup>[14,26,27]</sup>.

In prospective randomized comparison studies (2 studies involving 255 patients)<sup>[28,29]</sup>, EPLBD showed similar outcomes to EST for overall success rate of bile duct stones (97.0% *vs* 98.0%) and stone removal at the first attempt (83.5% *vs* 85.9%). Overall use of ML was not different in the EPLBD group and in the EST group (13.4% *vs* 14.1%). The prevalence of overall complications was similar in the EPLBD and EST groups (7.1%

*vs* 7.0%). Moreover, no significant difference was seen in the frequency of pancreatitis, perforation, hemorrhage or cholangitis. In another prospective randomized comparison of EPLBD with EST and ML with EST (involving 90 patients), EPLBD had a similar success rate of stone removal as ML with EST (97.7% *vs* 91.1%), whereas the complication rate was lower in the EPLBD group than in the ML with EST group (4.4% *vs* 20.0%)<sup>[30]</sup>. Cholangitis was less frequent in the EPLBD group than in the ML with EST group (0% *vs* 13.3%). Rates of pancreatitis were similar between the 2 groups.

**EPLBD without a preceding EST:** Although EST is generally used at the start of the EPLBD procedure, only large balloon dilation without a preceding EST is performed for removal of large CBD stones in some studies. In a retrospective study, the overall success rate of EPLBD without a preceding EST was 97.4%, and complete duct clearance with EPLBD alone was performed in 76.3% of patients<sup>[16]</sup>. ML was used in 21.1% of patients. Procedure-related pancreatitis was observed in only one patient (2.6%) and there were no other complications, such as bleeding, perforation, or cholangitis. This study suggested that EPLBD without a preceding EST might be as simple, effective, and safe in patients with large bile duct stones, as EPLBD with a preceding EST. However, the study had a limitation in that there was no comparison of EPLBD without a preceding EST and EPLBD with a preceding EST. Therefore, EPLBD without a preceding EST was not regarded as a routine technique for the removal of large bile duct stones, though it could be an alternative treatment.

## POTENTIAL ADVANTAGES OF EPBD

### Avoidance of bleeding

An important advantage of EPBD over EST is the avoidance of sphincterotomy-induced bleeding. Patients with coagulopathy and those who take anticoagulation medication have a higher risk of EST-induced bleeding<sup>[31,32]</sup>. Several RCTs showed that EPBD might significantly reduce the risk of bleeding compared with EST<sup>[2,8,33]</sup>. In a comparison of bleeding risk in patients with liver cirrhosis and coagulopathy, it was reported that the rate of EST-related hemorrhaging was 30%, whereas the hemorrhagic rate of EPBD was 0%<sup>[34]</sup>. Moreover, a meta-analysis commented that the occurrence of major bleeding was significantly lower in patients treated with EPBD than those treated with EST<sup>[17]</sup>. EPBD is currently regarded as an alternative method to EST in patients with coagulopathy to avoid sphincterotomy-induced bleeding.

### EPLBD

The rate of bleeding after EPLBD was reported as various rates, approximately 0%–8.3%<sup>[23,29,35]</sup>. According to a recent report, severe bleeding occurred less frequently in patients with EPLBD than with EST, though minor bleeding and bleeding in patients with coagulopathy were

excluded<sup>[36]</sup>. However, the rate of bleeding was not significantly different between EPLBD and EST in comparison studies<sup>[28,30]</sup>. Moreover, several reports mentioned that serious massive bleeding had occurred after EPLBD<sup>[37,38]</sup>. Severe bleeding may be caused by the large balloon, and it may lead to surgical intervention or even mortality. These results suggest that EPLBD is not superior to EST with regard to ERCP-related bleeding, unlike EPBD.

### **Preservation of sphincter of Oddi function**

Until now, EST has been widely accepted as an effective and standard technique for the removal of CBD stones; however, EST causes permanent loss of sphincter of Oddi (SO) function. Pneumobilia and duodenal biliary reflux were observed in approximately 50% of patients after EST and almost 100% of patients developed bactericholia and chronic inflammation of the biliary system<sup>[39,40]</sup>. Because laparoscopic cholecystectomy (LC) has been widely performed, preservation of the SO function is needed to avoid complications in young patients undergoing LC<sup>[41]</sup>.

Since EST disrupts the SO function for a long period of time, it is hoped that EPBD reduces damage to SO function compared with EST. Based on an anatomic study in pigs, EPBD showed no rupture of SO smooth muscle, and it was expected to preserve papillary smooth muscle integrity in humans<sup>[42]</sup>. In a manometric study of the SO function<sup>[43]</sup>, EPBD seemed to depress SO function for at least 1 wk. However, 1 mo after EPBD, SO peak pressure and frequency of SO contraction increased significantly, and SO basal and CBD pressure tended to increase compared with the first week's values. These results suggested at least partial recovery of SO function in 1 month after EPBD. In another manometric comparison study of SO function between EPBD with EST, SO basal and peak pressures partially recovered at 1 year, although these values still remained lower than those before EPBD<sup>[44]</sup>. The risk of long-term complications and pneumobilia were also lower in the EPBD group than in the EST group. This study suggested that SO function was preserved to a greater degree than after EST. However, there were studies with different results of preservation of the SO function after EST or EPBD.

In a comparison study, SO function was estimated by measurement of pancreatic enzyme activity in bile aspirated from the CBD<sup>[45]</sup>. According to this study, there were no significant differences in pancreatic enzyme levels from before the procedure *vs* 1 year after the procedure in both EPBD and EST groups. In another prospective study, bacterial cultures of bile were used to evaluate bacterial contamination of the biliary tract after EPBD or EST<sup>[46]</sup>. There was no significant difference in the bacterial cultures at 6 mo or 2 years after the procedures between the EPBD and EST groups. As a result, it is not clear whether the preservation of SO function with EPBD was superior to that of EST, although several studies showed that damaged SO function after EPBD was substantially recovered over time.

Although the preservation of SO function is in-

complete, EPBD is still an attractive method, especially in younger patients, to avoid long-term complications. However, young age is an important risk factor for acute pancreatitis, and acute pancreatitis is more frequent after EPBD. Furthermore, a meta-analysis showed that the pancreatitis risk was higher in younger patients than in older patients in the EPBD group<sup>[17]</sup>. Although EPBD was performed to preserve SO function in younger patients, it is ironic that post-EPBD pancreatitis was more evident in the younger patients.

### **EPLBD**

The preservation of SO function after EPLBD is not clear. Because the acquirement of the large CBD opening after ballooning was the aim of EPLBD, preservation of SO function was not regarded as an important factor in EPLBD. Theoretically, SO function is permanently ablated after EPLBD. From our experience, it is found that SO function does not recover after EPLBD regardless of EST.

## **POTENTIAL ADVANTAGES OF EPLBD**

### **ML**

ML has been commonly used for the management of large CBD stones. EPLBD was developed to reduce the complications related to full EST and to avoid the use of ML for removal of large bile duct stones. In a prospective study of 60 patients, only 3 patients (5%) required adjuvant ML for stone extraction after EPLBD<sup>[23]</sup>. In another RCT, ML was required significantly more often in the EST group than in EPLBD group (25% *vs* 6%)<sup>[24]</sup>. Contrary to previous reports, EPLBD compared with EST alone resulted in similar outcomes in terms of overall successful large CBD stone removal (94.4% *vs* 96.7%) and the use of ML (8.0% *vs* 9.0%) in another RCT<sup>[28]</sup>. Furthermore, there was no difference in the use of ML for large-sized CBD stones in a recent meta-analysis<sup>[47]</sup>, although the overall rate of ML use for various sized stones was less frequent in the EPLBD group than in the EST group. A few discrepancies in the use of ML for removal of large CBD stones have been seen, although many studies report that ML has been used less often in the EPLBD group compared with the EST group. Because the outcomes of the use of ML were not consistent, the choice of EPLBD only to reduce the use of ML in the removal of large CBD stones should be carefully considered.

### **EPBD**

A reduction in the use of ML is not the main purpose of EPBD, unlike EPLBD. Most studies, including 2 meta-analyses, reported that the use of ML was more prevalent in EPBD groups than in EST groups<sup>[3,17,48]</sup>.

## **SAFETY ISSUES**

EPBD and EPLBD are technically simple and effective, but safety is still a debatable issue. As the procedures are performed to treat a common benign condition, it is important to ensure that there are no lethal procedure-

EPBD: Endoscopic papillary balloon dilation

related complications. Although adequate procedural techniques may reduce complications, optimal techniques do not always prevent all complications.

Acute pancreatitis is the most common severe complication of EPBD. In a United States RCT, 2 patients with post-EPBD pancreatitis died<sup>[6]</sup>. Another study reported that one patient died of retroperitoneal perforation after EPBD<sup>[49]</sup>, although perforations are usually rare in EPBD. EPLBD has been regarded as a safe and effective method, regardless of a preceding EST. However, massive bleeding and perforation were occasionally reported in some studies. Life-threatening hemorrhage following EPLBD with a preceding EST was reported, and it was treated with angiographic embolization<sup>[57]</sup>. Four patients died due to EPLBD-related complications in a Korean and Japanese multicenter study<sup>[50]</sup>. Of these 4 patients, 3 died as a result of perforation, and the other died due to delayed massive bleeding. Perforation was a more frequent severe complication of EPLBD, although some patients died due to both bleeding and perforation.

For EPBD, serious pancreatitis has been reported in several studies, although it was showed that discrepancy of complications between East and West. Therefore, the choice of EPBD (in the young patients with CBD stone) only to preserve SO function should be carefully considered. The reason is that the long-term effect from the preservation of SO functions has not proven, until now. For EPLBD, although EPLBD is reported as an effective method in many studies, several reports showed procedure-related deaths due to perforation and delayed bleeding. Therefore, the choice of EPLBD only to reduce the use of ML should be carefully considered. In terms of safety issue, to avoid serious complications, strict selection of patients is of utmost importance in both EPBD and EPLBD.

## TECHNICAL ISSUES

### EPBD

It is not clear why small balloon EPBD has been shown to have a high risk compared with EST in the United States while it is relatively safe in South Korea and Japan. A recent study showed that post-EPBD pancreatitis was more frequent in an EPBD group than in a group with percutaneous transhepatic papillary balloon dilation<sup>[25]</sup>. This suggests that post-EPBD pancreatitis may be associated with detailed procedure protocols, rather than balloon dilation itself. Differences in the detailed methodology might lead to differences in outcome, although there are several possible reasons for the differences in outcome. The EPBD techniques in various RCTs are summarized along with procedure-related complications in Table 2. Technical factors that may be related to the outcomes include balloon diameter, dilation pressure, and dilation time.

Among these technical factors, selection of the optimal balloon diameter is important. Generally, a balloon smaller than the diameter of the CBD is recommended to reduce the damage to the SO and pancreatic orifice<sup>[51]</sup>. If a large CBD stone exceeding the diameter of the papillary orifice remains after EPBD, additional treatment, such as

Table 3 Techniques and outcomes of endoscopic papillary large balloon dilation in various studies

ML: Mechanical lithotripsy; EPBD: Endoscopic papillary balloon dilation; EST: Endoscopic biliary sphincterotomy.

EST or ML, is often needed.

Other techniques, such as balloon inflation and duration of balloon dilation, were also analyzed in several studies. Techniques of balloon inflation were divided into 2 categories in a recent study<sup>[52]</sup>. In the ungraded inflation method, the balloon was gradually inflated to the target pressure during a fixed time (approximately 30-60 s). In the graded inflation method, the balloon was slowly inflated until the disappearance of the balloon's waist, and then the pressure was maintained for 15 s. In the graded inflation group, the incidence of post-EPBD pancreatitis was significantly lower than in the ungraded inflation group. The result suggested that lower pressure and shorter duration was less traumatic to the papilla, resulting in fewer complications.

Until recently, the optimal duration of balloon dilation had not been established. In most studies and during actual practice, the dilation of EPBD was performed for a short duration of 1 min or less. However, some studies examined a longer duration of balloon dilation and the results showed adequate outcomes with no post-EPBD pancreatitis<sup>[43,53]</sup>. A 5-min EPBD improved the efficacy of stone removal and reduced the risk of post-EPBD pancreatitis, compared with a 1-min EPBD<sup>[54]</sup>. In addition, the duration of EPBD was inversely associated with pancreatitis risk in a meta-analysis, with less than 1-min dilations actually increasing acute pancreatitis<sup>[55]</sup>. Another 2 studies explained that a long duration of balloon dilation served to loosen the SO sufficiently and to resolve compartment syndrome, which involved intramucosal hemorrhaging and edema at the papilla. They suggested that an inadequately loosened SO surrounding the common channel may cause a compartment phenomenon that compresses pancreatic flow and increases the risk of post-EPBD pancreatitis<sup>[3,42]</sup>. Therefore, a long duration (5 min) of EPBD might be preferred over a short duration (less than 1 min) to reduce the risk of post-EPBD pancreatitis.

EPLBD

There are not many analyses of EPLBD technique, although EPLBD has been accepted to be an effective and safe method for large CBD stone removal. The EPLBD techniques of several studies are summarized with procedure-related complications in Table 3. In contrast to EPBD, the important complications of EPLBD are not post-EPBD pancreatitis, but perforation and bleeding. Therefore, the techniques of concern are different from that of EPBD.

Regarding the techniques related to EPLBD, the extent of EST, diameter of the balloon, and the method of balloon inflation are considered the most important. The size

**Table 4** Indications for endoscopic balloon dilation according to balloon diameter

	Small-balloon EPBD	Large-balloon EPBD
Absolute indication	Patients with coagulopathy and need for anticoagulation to avoid sphincterotomy-induced bleeding	No indication
Relative indication	Patients with anatomical abnormalities including gastric bypass surgery (Billroth II gastrectomy) or perampullary diverticulum	Patients with altered anatomy, such as gastric bypass surgery (Billroth II gastrectomy), perampullary diverticulum and prior biliary sphincterotomy
Possible indication	To preserve SO functions	To reduce the use of ML for removal of large CBD stones To avoid full EST-induced bleeding

SO: Sphincter of Oddi; EPBD: Endoscopic papillary balloon dilation; CBD: Common bile duct.

of the CBD stone and diameter of the dilated CBD are significant factors for the selection of balloon size. Among these factors, the diameter of the CBD is regarded more important, because excessive balloon dilation over the CBD diameter might increase the risk of perforation. Therefore, the maximal inflated diameter of balloon should not exceed the diameter of the proximally dilated CBD. Generally, a small EST is recommended to reduce the risk of bleeding, because full EST increases the damage of the large vessel at the papillary roof. A small EST also lowers the risk of perforation, because direct observation of ampullary tearing is possible during balloon dilation.

In a South Korean study, the techniques of larger balloon dilation were recommended to avoid severe complications, such as perforation and massive bleeding<sup>[56]</sup>. If the balloon waist remained at 80% of the maximum inflation capacity, it meant that significant stricture existed in the distal CBD. Excessive inflation for distal CBD stricture could cause a perforation. Therefore, the balloon should be inflated gradually to avoid perforation, with observation of disappearance of the balloon waist at the distal CBD. Unlike EPBD, the duration of ballooning was regarded to be of no importance in the EPLBD, because the small EST might prevent acute pancreatitis<sup>[15]</sup>. In EPLBD, bleeding is not uncommon; however, the bleeding site could be invisible endoscopically. If hemostasis could not be completed by local therapy, the insertion of a fully covered biliary metal stent should be considered for a tamponade effect<sup>[57]</sup>.

## CONCLUSION

Endoscopic papillary dilation with a dilating balloon is an old technique. However, it seems that there is no guideline or consensus on detailed techniques. According to various studies, EPBD and EPLBD for the removal of CBD stones are useful and effective methods. To clini-

**Table 5** Tips for avoiding severe complications of endoscopic papillary balloon dilation

EPBD	EPLBD
1. A balloon smaller than the diameter of the CBD is recommended to reduce damage to the SO and pancreatic orifice.	1. Maximal inflated diameter of balloon should not exceed the CBD diameter.
2. Graded balloon inflation may significantly reduce the incidence of post-EPBD pancreatitis.	2. A small extent of EST followed by large balloon dilation may be recommended, rather than large balloon dilation without EST.
3. If the balloon's waist remains after 2–3 s at maximal balloon inflation, balloon dilation must be stopped immediately.	3. The balloon should be inflated gradually to avoid perforation and bleeding.
	4. If the balloon's waist remains at 80% of the maximum inflation capacity, balloon dilation must be stopped immediately and change to alternative procedures, such as EST and ML.
	5. Close monitoring must be necessary after EPLBD to detect the delayed complications, such as perforation and delayed bleeding.

SO: Sphincter of Oddi; EPBD: Endoscopic papillary balloon dilation; CBD: Common bile duct; EST: Endoscopic biliary sphincterotomy; ML: Mechanical lithotripsy; EPLBD: Endoscopic papillary large balloon dilation.

cians, these methods are very attractive because they are very easy to perform, technically simple, and have a short learning curve. Although EPBD and EPLBD are generally safe, clinicians must remain aware that they can lead to potential morbidity and even death. The foremost priority is the patient's safety, so these methods should not be use indiscriminately, but be performed carefully in selected patients. In addition, doctors should be prepared to use EST or ML if the initial treatment fails. When EPBD and EPLBD are used for the correct indications (Table 4), according to the technical guideline (Table 5), an effective and safe outcome should be expected.

### Abstract

**AIM:** To investigate the level of mucosal expression and the involvement of the receptor for the advanced glycation end products (RAGE) in delayed apoptosis and tumor necrosis factor (TNF)- $\alpha$  production in Crohn's disease (CD).

**METHODS:** Surgical and endoscopic specimens from both inflamed and non-inflamed areas of the ileum and/or colon were collected from 20 and 14 adult CD patients, respectively, and used for the assessment of RAGE expression by means of immunohistochemistry and western blotting analysis. Normal tissues from 21

control subjects were used for comparison. The same polyclonal anti-human RAGE antibody (R and D System) was used in all experimental conditions. RAGE staining was quantized by a score including both the amount of positive cells and intensity of immunoreactivity; cellular pattern was also described. The effects of RAGE blocking on apoptotic rate and TNF- $\alpha$  production were investigated on immune cells freshly isolated from CD mucosa and incubated both with and without the muramyl dipeptide used as antigenic stimulus. Statistical analysis was performed *via* the test for trend, with regression models to account for intra-patient correlations. A 2-sided  $P < 0.05$  was considered significant.

**RESULTS:** In inflamed areas, RAGE expression in both the epithelial and lamina propria compartments was higher than control tissues ( $P = 0.001$  and  $0.021$ , respectively), and a cluster of positive cells were usually found in proximity of ulcerative lesions. Similar results were obtained in the lamina propria compartment of non-inflamed areas ( $P = 0.025$ ). The pattern of staining was membranous and granular cytosolic at the epithelial level, while in the lamina propria it was diffuse cytosolic. When evaluating the amount of protein expression by immunoblotting, a significant increase of both surface area and band intensity ( $P < 0.0001$  for both) was observed in CD inflamed areas compared to control tissue, while in non-inflamed areas a significant increase was found only for band intensity ( $P < 0.005$ ). Moreover, a significantly lower expression in non-inflamed areas in comparison with inflamed areas was found for both surface area and band intensity ( $P < 0.0006$  for both). Finally, RAGE blocking largely affects both the apoptotic rate of mucosal cells (towards an increase in both non-inflamed and inflamed areas of  $P < 0.001$  and  $< 0.0001$ , respectively) and TNF- $\alpha$  secretion (towards a decrease in both non-inflamed and inflamed areas of  $P < 0.05$  and  $< 0.01$ , respectively), mainly in the presence of antigenic stimulation.

**CONCLUSION:** RAGE is up-regulated in CD, especially in inflamed areas, and it appears to play a role in the mechanisms involved in chronic inflammation.

**Key words:** Apoptosis; Crohn's disease; Chronic inflammation; Immunohistochemistry; Receptor for advanced glycation end products; Tumor necrosis factor- $\alpha$

**Core tip:** Receptor for the advanced glycation end products (RAGE) is a multiligand transmembrane receptor whose activation sustains chronic inflammation. The inhibition of RAGE-ligand interaction has proved successful in an experimental model of Crohn's disease (CD). Our work shows an up-regulation of RAGE expression in both inflamed and non-inflamed mucosa of CD patients in comparison to healthy tissue from control subjects. Moreover, RAGE blocking significantly affects both the apoptotic rate and tumor necrosis factor- $\alpha$  secre-

tion of mucosal immune cells, which are considered to be leading mechanisms in the chronic inflammation of CD. These findings pave the way for a possible use of RAGE blocking agents as a new therapeutic tool in this disabling condition.

## INTRODUCTION

Dysregulation of immune tolerance towards components of the intestinal microbiota plays a crucial role in the pathogenesis of Crohn's disease (CD)<sup>[1]</sup>. Recently, the receptor for the advanced glycation end products (RAGE) has received a great deal of attention as a key molecule involved in tissue damage occurring in diabetes<sup>[2]</sup>, atherosclerosis<sup>[3]</sup>, neurodegeneration<sup>[4]</sup>, cancer, and inflammation<sup>[5]</sup>. It belongs to the immunoglobulin superfamily and is expressed at low levels by a wide range of differentiated adult cells, including immune cells, but at high levels when activated by its ligands<sup>[6]</sup>. Remarkably, thanks to its ability to recognize a three-dimensional structure rather than a specific amino acid sequence, it binds a broad repertoire of molecules<sup>[6]</sup>; other than the advanced glycation end products, it is also engaged by amyloid- $\beta$  peptides, high-mobility group (HMG) B1 proteins, and S100/calgranulins<sup>[6]</sup>. Since the latter act as damage-associated molecular pattern molecules<sup>[7]</sup>, RAGE is now considered a pattern-recognition receptor<sup>[8]</sup>. It seems very likely that the interaction of RAGE with both S100/calgranulins and HMGB1-proteins plays a proximal role in the inflammatory cascade by triggering the intracellular synthesis of nuclear factor (NF)- $\kappa$ B which, in turn, promotes the transcription of several pro-inflammatory and pro-fibrotic cytokines, such as tumor necrosis factor (TNF)- $\alpha$  and transforming growth factor- $\beta$ , respectively<sup>[9]</sup>. Most importantly, RAGE is also able to bind the  $\beta$ 2-integrin Mac-1, thus determining the recruitment and migration of leucocytes to the site of inflammation<sup>[10,11]</sup>.

As far as CD is concerned, an up-regulation of both RAGE ligands and its mediators has already been found<sup>[12,13]</sup>, with a prominent role played by TNF- $\alpha$ , since blocking with monoclonal antibodies results in both induction and maintenance of remission<sup>[14]</sup>. In addition, the inhibition of the RAGE/HMGB1 pathway in experimental models of colitis led to a significant improvement in both clinical and histological features, with a parallel reduction of the levels of pro-inflammatory cytokines<sup>[15]</sup>. The lack of definitive information about a possible role

of this receptor in human inflammatory bowel disease has prompted us to study RAGE expression in the intestine of CD patients through both immunohistochemistry and western blotting assays, and to investigate its functional role in affecting the apoptotic rate and TNF- $\alpha$  production of mucosal immune cells, which are key mechanisms in causing chronic inflammation and tissue damage<sup>[16]</sup>.

## MATERIALS AND METHODS

### Immunohistochemistry

The immunohistochemical study was performed on archival material from the Pathology Department of the Luigi Sacco Hospital (Milan, Italy), obtained from 20 patients who had undergone surgical procedures of small and/or large bowel resection and/or stricturoplasty for CD (indicated hereafter as A series). Their demographic and clinical features, including body mass index (BMI), disease duration, location, and phenotype according to Montreal classification<sup>[17]</sup>, the CD activity index (CDAI)<sup>[18]</sup>, and the drug therapy followed, all determined at the time of surgery, are shown in Table 1. In all patients, the diagnosis of CD had been established according to widely accepted criteria<sup>[19]</sup> and confirmed at pathology. Specimens from both macroscopically diseased and non-diseased areas were obtained from each patient. Specifically, in order to prevent confounding results due to the proximity to diseased areas, the samples from normal tissue were collected from non-diseased zones at least 50 cm away from the resected area. In addition, surgical specimens from 9 subjects (M/F: 4/5, median age: 65  $\pm$  8.32 years, range: 63-86 years; BMI: 21.8  $\pm$  1.2 kg/m<sup>2</sup>, range: 18.1-24.8 kg/m<sup>2</sup>) who underwent right hemicolectomy for neoplasms, were selected from macroscopically healthy mucosa of both ileum and colon at more than 20 cm from the lesion, and used as controls. Each patient and control signed the informed consent, and all tissues were studied in an anonymous manner in accordance with the recommendations of the local Bio-Ethics Committee.

After tissue sampling during surgery to avoid autolysis artifacts, all specimens were immediately fixed in 40 g/L formaldehyde and embedded in paraffin. Serial 4- $\mu$ m-thick sections were cut from the blocks, mounted on electrostatically charged slides (DIAPATH Super Frost Plus<sup>®</sup>, Menzel-Gläser, Braunschweig, Germany) and dried overnight. After dewaxing and rehydration, the sections were processed for both traditional histology and immunohistochemistry. In addition, samples from both colonic adenomatous polyps<sup>[20]</sup> and normal lung tissue<sup>[21]</sup> were used as positive controls to test both the appropriate pre-treatment and primary antibody dilution. After 0.88 mol/L hydrogen peroxide was applied for 5 min, sections were treated with Tris/EDTA buffer (Target Retrieval Solution, DAKO, Carpinteria, CA, United States) at 1:10 dilution and pH 9.0, and then incubated in a microwave oven in citrate buffer (10 mmol/L, pH 7.0) for three cycles of 5 min each at 650 W, to unmask the antigen. Afterwards,

<sup>1</sup>Montreal classification<sup>[17]</sup>. BMI: Body mass index; CDAI: Crohn's disease activity index; IS: Immunosuppressors.

the slides were incubated with CAS-Block solution (Invitrogen Corporation, Carlsbad, CA, United States) for 10 min, as this treatment had been already proved successful in avoiding unspecific ligands<sup>[22]</sup>. The primary antibody we used was the polyclonal anti-human RAGE antibody (R and D System, Minneapolis, MN, United States) at 1:1000 dilution overnight at 4 °C<sup>[22,23]</sup>. Finally, sections were soaked in a stop-wash buffer, rinsed in phosphate-buffered saline, and then incubated with the *Avidin Biotin Complex* (LSAB2 System, HRP, DAKO), followed by the usual reactions to allow color development (Liquid DAB+ Substrate Chromogen System, DAKO) and counterstaining with Harris hematoxylin (Sigma-Aldrich, St. Louis, MO, United States). For the negative control, a goat anti-human IgG1 isotype (R and D System) was used as a primary antibody<sup>[23]</sup>, while in order to determine the origin of lamina propria RAGE<sup>+</sup> cells, seriate sections were processed with the following monoclonal antibodies: anti-CD3 (clone PSI, Novocastra Laboratories, Newcastle, United Kingdom), -CD20 (clone L26, DAKO), -CD138 (Clone B-A38, IQ Products, Houston, TX, United States), -CD68 (clone PG-M1, DAKO), and smooth muscle actin (clone 1A4, DAKO), according to the manufacturers' instructions, whilst neutrophils were identified

through morphology. Finally, in order to quantize RAGE expression, the analysis was split into two compartments, epithelial layer and lamina propria, and all sections were examined by two blinded pathologists under high-power field microscopes (HPFs) (*Nikon ECLIPSE E800*) at constant magnification ( $\times 400$ ). As regards the epithelial layer, the number of positive cells was calculated by using a differential count of at least 500 cells and the results were expressed as a percentage, while the intensity of the staining was estimated by applying an ordinal scale (0-3), where "3" indicated strong staining, "2" moderate staining, "1" weak staining, and "0" no staining. Thereafter, both results were combined together in a score as follows: grade I when less than 10% of epithelial cells were positive and/or had weak immunoreactivity, grade II when 10%-50% of epithelial cells were positive and/or had moderate immunoreactivity, and grade III when more than 50% of epithelial cells were positive and/or had strong immunoreactivity. In the lamina propria compartment, the quantization was performed by applying differential counts of positive cells on 10 HPF per slide, and the results were displayed as the mean number of positive cells. The same ordinal scale and grading score of the epithelial compartment (see above) for quantization of staining intensity and whole expression, respectively, were used. Finally, the pattern of cellular staining was reported as cytosolic (granular or diffuse) and/or membranous.

### Western blot analysis

Two snap-frozen perendoscopic specimens from both macroscopically diseased and non-diseased areas of the colonic mucosa were collected from 14 CD outpatients (indicated hereafter as B series), whose demographic and clinical features are shown in Table 1, and 12 control patients suffering from irritable bowel syndrome (M/F: 3/9; median age: 49 years, range: 21-72 years; BMI: 23.35 kg/m<sup>2</sup>, range: 18.6-25.6 kg/m<sup>2</sup>), all admitted to the Center for the Study and Cure of Inflammatory Bowel Disease at the Fondazione IRCCS Policlinico (Pavia, Italy). The CD patients were taking mesalazine, steroids, azathioprine, or biologics, as single or combined therapy (Table 1), whilst the control patients were drug-free. Each patient gave written informed consent, and approval from the Bio-Ethics Committee was obtained (protocol number: 20110002492).

Mucosal samples were lysed in 200  $\mu$ L ice-cold lysis buffer (53.8  $\mu$ L HEPES pH 7.9 0.93 mol/L, 10  $\mu$ L EDTA pH 8.0 0.5 mol/L, 300  $\mu$ L KCl 1 mol/L, 100  $\mu$ L Nonidet P-40, 4385  $\mu$ L distilled water, 50  $\mu$ L DTT 0.1 mol/L, 50  $\mu$ L PMSF 0.1 mol, 20  $\mu$ L aprotinin, 10  $\mu$ L leupeptin, 50  $\mu$ L NaVO<sub>4</sub> 0.1 mol/L, 10  $\mu$ L NaF 0.5 mol/L), sonicated (Sonifier 150, BRANSON, St. Louis, MO, United States), and incubated for 90 min in the dark. After centrifugation, the supernatants were harvested and the protein concentration was determined using the *Bio-Rad Protein Assay* (BIORAD, Hercules, CA, United States). A total of 50  $\mu$ g of protein from each sample, plus the loading buffer, were boiled and then

loaded onto 0.347 mol/L sodium dodecyl sulfate-polyacrylamide gel electrophoresis (Invitrogen-Life Technologies, Carlsbad, CA, United States) and run for 90 min. Proteins were then transferred to nitrocellulose sheets by means of the *PowerEase® 500* electrophoresis instrument (Invitrogen), and non-specific binding was blocked with 50 g/L non-fat milk powder in TBS 100 mL/L solution. Afterwards, the membranes were incubated with the primary antibody (polyclonal anti-RAGE immunoglobulin G 1:2000 dilution, R and D System) overnight on a rocker (Stuart SSL4, Fisher Scientific, Illkirch Cedex, France). After washing, the secondary antibody (polyclonal rabbit anti-goat immunoglobulin G-HRP 1:2000 dilution, DAKO) was applied, and the reaction was developed using a chemiluminescence kit (ECL Plus, GE Healthcare, Buc Cedex, France). Finally, the membranes were aligned with the film (GE Healthcare) in the developing liquid (Kodak, Rochester, New York, NY, United States). Negative control blots were obtained by omitting the primary antibody. Finally, blots were stripped and analyzed for  $\beta$ -actin as an internal control, using a rabbit anti-human polyclonal anti- $\beta$ -actin antibody 1:5000 dilution (Abcam, Cambridge, United Kingdom). Films were acquired using VersaDoc 3000 (BIORAD), and the bands measured in terms of both surface area and intensity by the QuantityOne software (BIORAD) and normalized for  $\beta$ -actin values.

### Functional assay

Six fresh additional perendoscopic mucosal biopsies from both macroscopically diseased and non-diseased colonic areas and peripheral blood samples were collected from seven out of the 14 CD outpatients. After digestion with collagenase A 1 mg/mL (Sigma-Aldrich) in complete medium (X-VIVO-15 plus 50 mL/LHS, penicillin/streptomycin 10000 U/10 mg/mL, gentamicin 2.5 mL/L, amphotericin B 4 mL/L, all by Lonza Group Ltd, Basel, CH) for 90 min, the cellular suspension was passed through a cell filter strainer, 40  $\mu$ m (BD Falcon™, Franklin Lakes, NJ, United States), centrifuged, and washed twice. The lamina propria mononuclear cells (LPMC) thus obtained were plated overnight in 48-well flat bottom tissue culture plates (Sarstedt, Newton, NC, United States) at  $1.0 \times 10^6$  cells/well in complete culture medium plus interleukin-2 40 U/mL (Chiron, Emeryville, CA, United States). After washing,  $0.5 \times 10^6$  LPMC for each well were incubated in the presence of the anti-RAGE antibody or IgG1 isotype antibody (R and D System) as a negative control, at 50 and 100  $\mu$ g/mL for 4 h, and then stimulated overnight in the presence or absence of muramyl dipeptide (MDP) (10  $\mu$ g/mL, Sigma-Aldrich, St. Louis, MO, United States) plus  $1.5 \times 10^6$  autologous irradiated (3000 rads) peripheral blood mononuclear cells used as feeding cells. Finally, the supernatants were collected and stored at -80 °C for evaluation of TNF- $\alpha$  levels by enzyme-linked immunosorbent assay (R and D System), while LPMC were harvested for the detection of the apoptotic rate by flow cytometry (BD FACSCanto, FACS Diva software, BD

Biosciences, San Jose, CA, United States) by using the Annexin V/Propidium Iodide kit (*APOTEST™-FITC*, DAKO).

### Statistical analysis

Continuous variables were described as median and 25<sup>th</sup>-75<sup>th</sup> percentiles, while categorical variables were expressed as counts and percentages. Comparison between data from CD patients and control subjects was performed by using the test for trend and the Mann-Whitney *U* test, as appropriate. Data among CD patients were compared using a general linear or a general ordinal logistic model (according to the type of data), with calculation of the Huber-White robust SE for intra-patient correlation. The Spearman rank correlation test was applied to measure the association between continuous variables. A 2-sided *P* value ≤ 0.05 was considered to be statistically significant. Stata 12.1 (StataCorp LP, College Station, TX, United States) was used for computation.

## RESULTS

### RAGE expression in diseased areas

In both the epithelial and lamina propria compartments, the grading of RAGE expression in CD was significantly higher than in control tissues (test for trend: *P* = 0.001 and 0.021, respectively; Table 2, Figure 1A and B). When splitting the analysis for the two variables considered, there appeared to be no difference in intensity between the groups in either compartment (Table 2, Figure 1C and D), whilst the amount of positive cells, either at epithelial (Figure 2) or lamina propria level (Figure 3), was significantly higher in CD than in control tissues (test for trend: *P* = 0.008 and 0.030, respectively; Table 2, Figure 1E and F). Remarkably, in CD specimens, most of the strongly

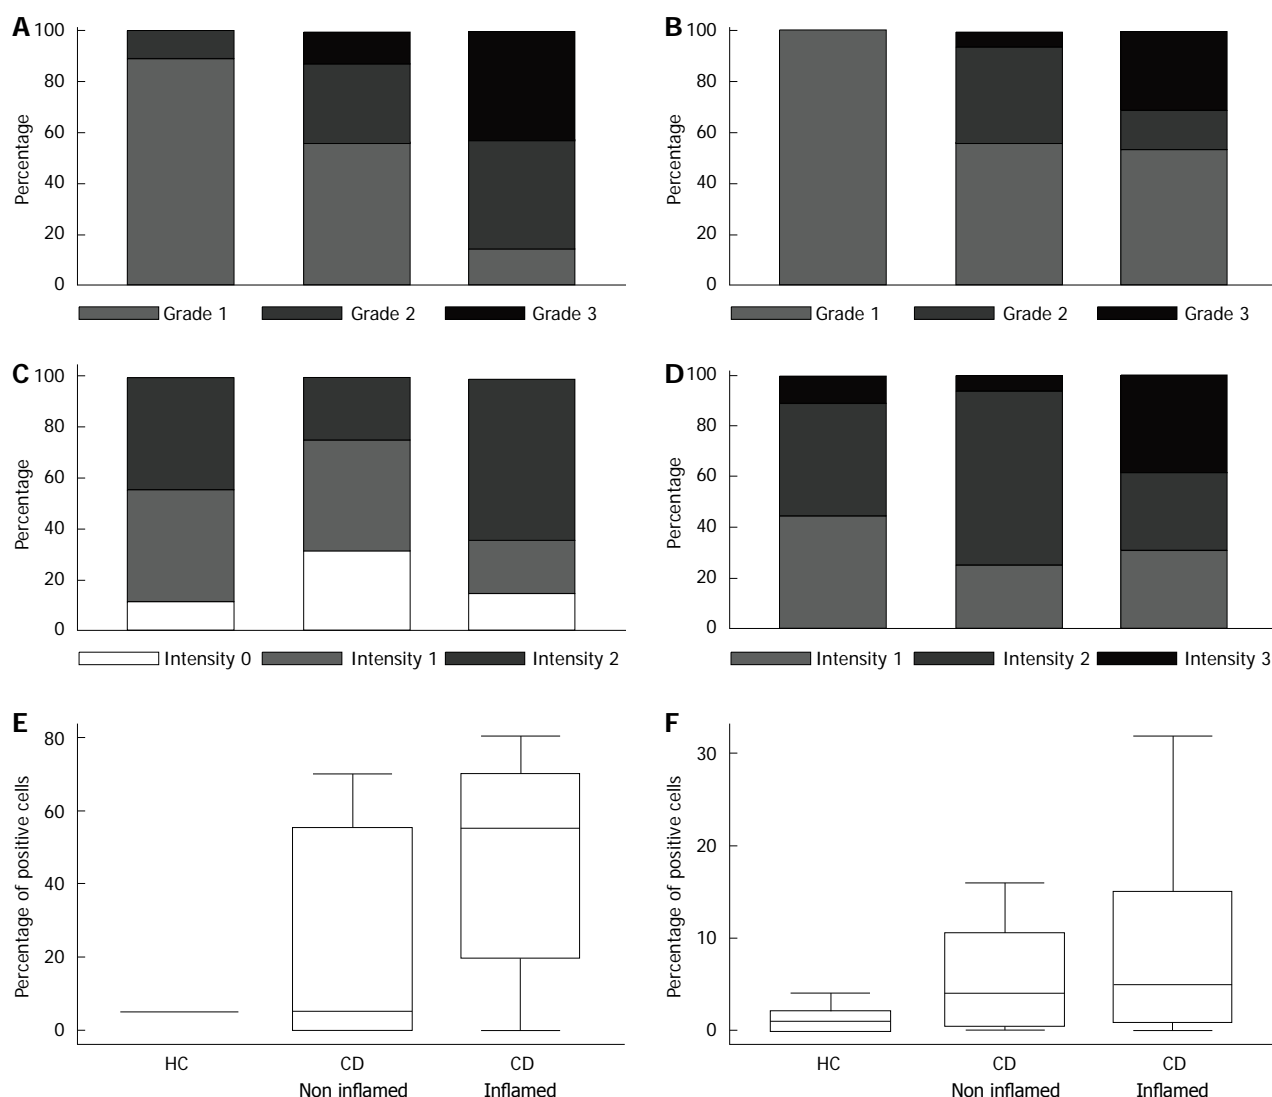

positive cells were found in close proximity to ulcers at epithelial level (Figure 4), while in the lamina propria they were sparsely distributed (Figure 3A and B). Moreover, in all CD samples, the pattern of RAGE expression at epithelial level was both membranous and granular cytosolic (Figure 2B, thin and thick red arrows, respectively), while in the lamina propria it was diffuse cytosolic (Figure 3A and B, black arrows). As regards the type of lamina propria positive cells, the vast majority were plasma cells (median 3, 25<sup>th</sup>-75<sup>th</sup>: 1-10) (Figure 5A) and monocytes/macrophages (median 3, 25<sup>th</sup>-75<sup>th</sup>: 2-12) (Figure 5B), with only a few scattered T lymphocytes and subepithelial myofibroblasts being stained, whilst neutrophils did not display RAGE expression (data not shown). When evaluating the amount of protein expression at mucosal level by immunoblotting, a significant increase of RAGE expression for both surface area and band intensity (*P* < 0.0001 for both) was observed in CD diseased areas with respect to control tissue (Figure 6). Finally, as regards the clinical features, no correlation was found between the grading of RAGE expression with BMI, CDAI score, or the duration, localization, or behavior of the disease, nor with the drug therapy followed (data not shown).

### RAGE expression in non-diseased areas

In both the epithelium and lamina propria compartments, the grading of RAGE expression in CD tissues was generally higher than in control tissues (Figure 1), though statistical significance was achieved only in the lamina propria compartment (test for trend: *P* = 0.025, Table 3). Similarly, no difference between these two groups was found either in intensity (Figure 1) or in the number of positive cells (Figure 1 and Table 3). Within the CD patient group, both grading and amount of RAGE<sup>+</sup> cells tended to be higher in the diseased areas, though significant variations were never reached (Figure 1 and Table 4). As far as the level of RAGE expression was concerned, a significant increase in non-diseased areas of CD patients in comparison with control tissues was observed only for band intensity at Western blot analysis (*P* < 0.005, Figure 6). Moreover, a significantly lower expression in non-diseased areas in comparison with diseased areas was found for both surface area and band intensity (*P* < 0.0006 for both, Figure 6). Finally, a positive correlation between the grading of RAGE expression at epithelial level and BMI was found in the CD group (median 25.5 ± 3.2, range: 20-30, *P* = 0.0116, *r* = 0.55, Figure 7), whilst no correlation was found with the CDAI score, behavior, localization, duration of the disease, nor with current therapies (data not shown).

### Functional assay

In order to investigate whether RAGE blocking has the ability to favor LPMC apoptosis and to reduce the production of the pro-inflammatory cytokine TNF-α, LPMC from both diseased and non-diseased areas of CD patients were incubated with the RAGE blocking antibody and stimulated with MDP, a component of the bacterial cell-wall peptidoglycan, which is present in most

**Figure 1** Receptor for the advanced glycation end products expression. The percentage of samples in each category of both grading (A and B) and intensity (C and D) staining, and the number of positive cells (E and F) are reported. The average values of receptor for the advanced glycation end products (RAGE) immunoreactivity detected at the epithelial (A and C) and the lamina propria (B and D) compartments of patients suffering from Crohn's disease (CD) and the control subjects (HC) are given. In CD patients, the averages of assessments between the areas of diseased mucosa and the areas of non-diseased mucosa were also compared. Moreover, the number of positive cells in the epithelial compartment (E) was calculated by a differential count of at least 500 cells and the results expressed as a percentage, while in the lamina propria (F) compartment, it was performed by differential counts of positive cells on 10 high-power microscopic fields per slide ( $n/10$  HPF), and the results displayed as the mean number of positive cells. A higher, but not statistically significant, number of RAGE+ cells were observed in both diseased and non-diseased areas of CD patients in comparison with normal tissue of HC. The box-plots in panels E and F show median, 25<sup>th</sup>, and 75<sup>th</sup> percentile and extremes.

species of the gut microbiota, and whose ligation with the intracellular receptor NOD2 triggers inflammatory cascade in CD<sup>[24]</sup>. As expected, the apoptotic rate of the cell population obtained from non-diseased areas was higher than that found in cells isolated from diseased mucosa, both in the presence and absence of the antigenic stimulus ( $P < 0.001$  for both, Figure 8A and B). When incubating the LPMC from non-diseased areas with the lower concentration of the RAGE-blocking antibody, a significant increase in the apoptotic rate in comparison with the basal values was observed both in the absence ( $P < 0.01$ ) and presence of MDP ( $P < 0.001$ ), while the higher dose only slightly increased the percentages of cell death in both cases (Figure 8A and B). Similar effects

were observed on cells from diseased areas only when applying the higher dose of the RAGE blocking agent ( $P < 0.0001$  for both), since the lower dose was effective only in the presence of MDP stimulus ( $P < 0.005$ , Figure 8A and B). As far as TNF- $\alpha$  secretion is concerned, in the absence of antigenic stimulation, a higher basal level was observed in cultures with cells from diseased mucosa ( $P < 0.0002$ ), and this was consistently reduced by the higher dose of the anti-RAGE agent ( $P < 0.01$ , Figure 8C). Upon antigenic stimulation, both doses of the blocking antibody appeared capable of lowering the level of TNF- $\alpha$  production, both when using cells from diseased ( $P < 0.01$  and  $< 0.005$ , respectively) and non-diseased areas ( $P < 0.05$  and  $< 0.01$ , respectively, Figure 8D).

**Figure 2** Receptor for the advanced glycation end products staining in Crohn's disease and healthy mucosa. A: Almost all cells of the epithelial compartment at both crypt and surface levels showed positive immunostaining (brown cells) in a representative case of Crohn's disease affected areas, with only a few scattered positive cells in the lamina propria (black arrows); B: The pattern of the cellular staining in the crypt zone of a representative case of Crohn's disease affected area is shown, indicating both membranous and cytosolic distribution; C: A representative case of control mucosa is shown, with weak staining of the epithelial cells and only a few scattered positive cells in the lamina propria (receptor for the advanced glycation end products, immunoperoxidase-hematoxylin; original magnification,  $\times 200$ ).

**Figure 3** Receptor for the advanced glycation end products staining in Crohn's disease and healthy mucosa lamina propria. A: Many lamina propria mononuclear cells proved receptor for the advanced glycation end products (RAGE)-positive (the brown cells) in a representative case of Crohn's disease affected areas; B: A cluster of RAGE-positive lamina propria mononuclear cells next to an ulceration (red arrow) in a representative case of Crohn's disease affected area showing a cytosolic distribution; C: A representative case of control mucosa is shown, with weak staining of a few lamina propria mononuclear cells (black arrow) (RAGE immunoperoxidase-hematoxylin; original magnification,  $\times 200$ ).

## DISCUSSION

Originally identified in diabetic tissues<sup>[25]</sup>, RAGE was subsequently found to be up-regulated in many pathological conditions<sup>[6]</sup> and, in recent years, it also seems to be involved in the pathogenesis of chronic inflammatory diseases<sup>[26]</sup>, such as rheumatoid arthritis<sup>[27]</sup>, systemic lupus erythematosus<sup>[28]</sup>, and multiple sclerosis<sup>[29]</sup>. As regards the gastrointestinal tract, RAGE has been found to play a role in chronic gastritis due to *Helicobacter pylori* by favor-

ing its adhesiveness to epithelial cells<sup>[30]</sup>, as well as in CD, where an increased expression was found in phagocytes infiltrating inflamed areas<sup>[31]</sup>. Moreover, the administration of HMGB1 blocking agent has proved to be of benefit in experimental models of Crohn's colitis, through a decrease in the expression of RAGE and related pro-inflammatory cytokines<sup>[15]</sup>. On this basis, we first of all investigated RAGE expression by immunohistochemistry on surgical specimens from CD patients where samples of healthy tissue at a certain distance from the workpiece

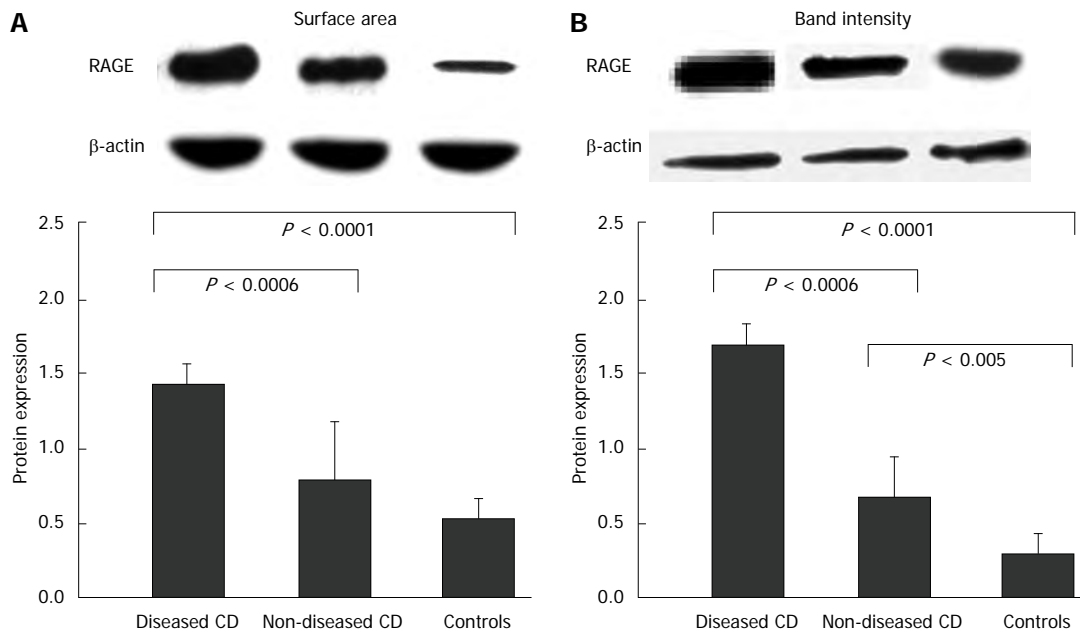

**Figure 4** Receptor for the advanced glycation end products staining in Crohn's disease ulcerative areas. A: Almost all cells of the epithelial compartment in close proximity to an ulceration (red arrows) proved receptor for the advanced glycation end products (RAGE)-positive (the brown cells), with the ulcer-associated cell lineage showing the highest immunoreactivity (black arrows); B and C: A detail of the epithelial cells in the crypt compartment at level of an ulceration (red arrows) showing moderate to strong RAGE-positive staining (black arrows); D: A detail of the epithelial cells of the surface compartment next to an ulceration (red arrow) showing strong RAGE immunoreactivity (black arrows) (RAGE immunoperoxidase-hematoxylin; original magnification,  $\times 200$ ).

**Figure 5** Type of receptor for the advanced glycation end products (+) immune cells. Representative seriate sections of Crohn's disease lamina propria with heavy inflammatory infiltrate, in which the correspondence between the positivity for both CD138 (panel A) indicating the plasma cells, and CD68 (panel B) showing the macrophages, with receptor for the advanced glycation end products (+) cells given (Immunoperoxidase-hematoxylin; original magnification,  $\times 200$ ). The same cellular elements indicated by the black arrows are shown in the boxes at higher magnification (Immunoperoxidase-hematoxylin; original magnification,  $\times 400$ ). RAGE: Receptor for the advanced glycation end products.

**Figure 6** Receptor for the advanced glycation end products expression at mucosal level. Immunoblotting of mucosal samples from both diseased and non-diseased areas of Crohn's disease (CD) patients and from normal areas of control patients with the polyclonal anti-receptor for the advanced glycation end products (RAGE) antibody. The protein levels were measured by scanning densitometry as band area (A) and band intensity (B), expressed as arbitrary units, and normalized towards β-actin levels. In the upper part of both panels, representative cases of band area and intensity with respect to those of β-actin are shown. Specifically, the values for RAGE expression in diseased areas for both band area and band intensity were significantly higher ( $1.48 \pm 0.16$  and  $1.64 \pm 0.14$ , respectively) than those found in non-diseased areas ( $0.71 \pm 0.40$  and  $0.66 \pm 0.23$ , respectively) and healthy mucosa ( $0.44 \pm 0.17$  and  $0.27 \pm 0.15$ , respectively).

of intestine were also available. This is why we set out to determine whether the activation of the RAGE pathway occurs only within an inflamed *milieu*, or if it represents a predisposing condition which involves the entire length of the intestine in CD. Our results clearly show an increased grade of RAGE expression, in comparison with control tissues, in the entire bowel of CD patients, albeit predominately in macroscopically damaged areas.

Specifically, the vast majority of epithelial cells in the diseased areas, both on the surface and in crypt regions, express RAGE with a whole cellular staining, compared to control tissues where only a few cells were positive. It is worth noting that the highest numbers of positive cells were found close to ulcerative lesions. In the non-diseased tissue, a trend towards up-regulation was evident, but does not reach the statistical significance. Also

**Figure 7** Correlation between receptor for the advanced glycation end products expression and body mass index. A positive correlation between the grading of receptor for the advanced glycation end products (RAGE) expression in the epithelial compartment of non-diseased Crohn's mucosa and body mass index (BMI) was clearly evident.

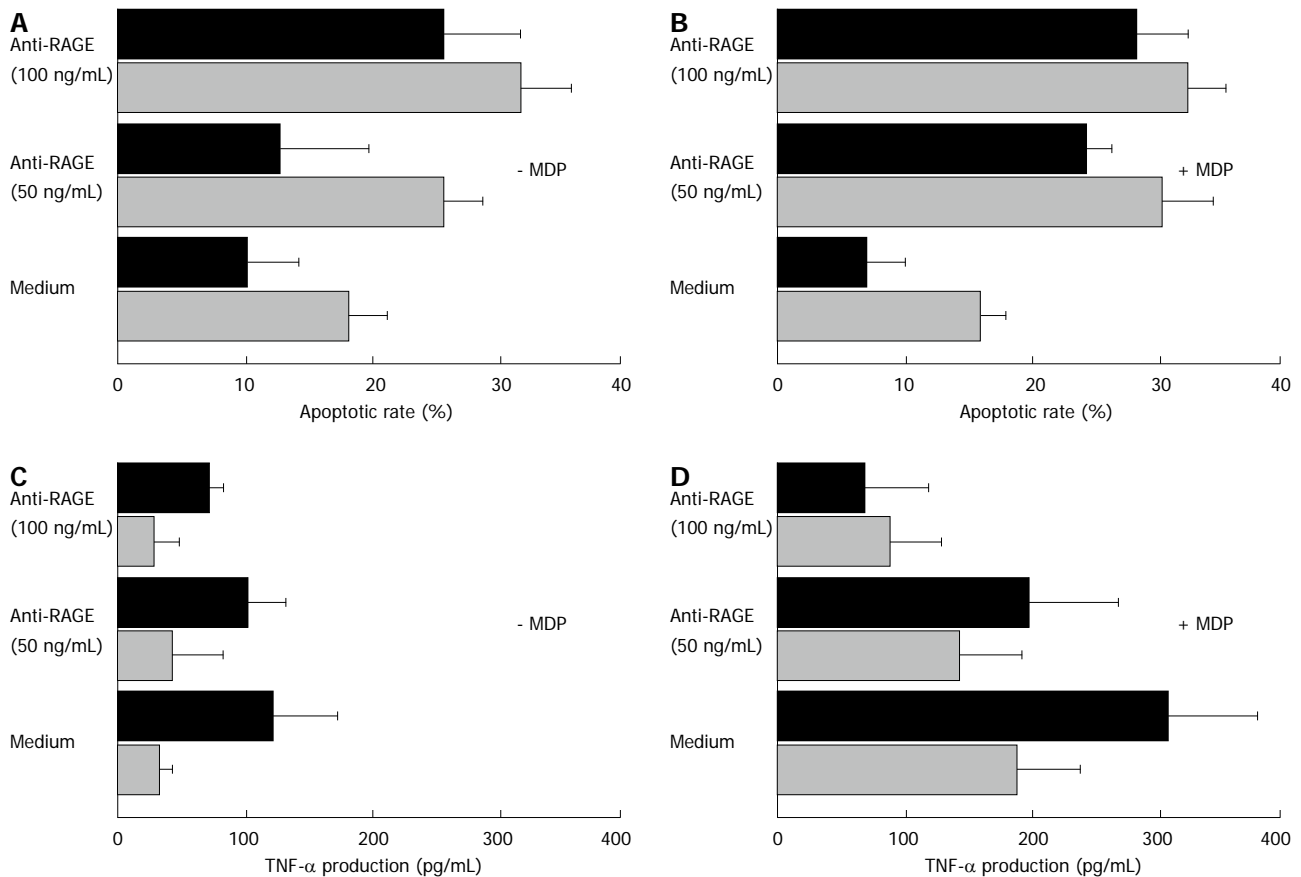

in the lamina propria, the grade of RAGE<sup>+</sup> cells was higher in CD diseased areas compared to healthy tissues, although their distribution did not seem to be associated with ulcerative lesions and the pattern of expression was cytosolic. These differences in both distribution and cellular pattern between epithelial and lamina propria cells seem to indicate a separate role of RAGE, with that in the epithelial cells possibly being a response to external injury, while that in the lamina propria cells mostly being involved in magnification of inflammation. Here, the diffuse cytoplasmic staining may be a consequence of the activated status, whereas the granular cytosolic and membranous staining in the epithelial compartment may represent a secretory pathway<sup>[32]</sup>. Remarkably, the up-regulation of RAGE in epithelial cells under inflammatory stimuli has been shown to mediate the trans-epithelial migration of neutrophils through its binding with the specific  $\beta_2$  integrin CD11b/CD18<sup>[33]</sup>. It is worth noting that we did not find any extracellular positivity in the stromal area, indicating that there is no storage of RAGE in the extracellular matrix. Furthermore, when splitting the results between the two variables included in the grading system, *i.e.*, the intensity of the staining and the number of positive cells, we found that a significant difference was still evident only for the latter. In the non-diseased tissue of CD patients, a significantly higher grade of RAGE expression was found in the lamina propria compartment compared to control tissue. The reason may lie in the small number of samples and the high variability found mainly in the CD group. The results found at immunohistochemistry were confirmed by the analysis of RAGE expression at protein level by immunoblotting on mucosal samples, where an increase in both diseased and non-diseased areas of CD patients in comparison with healthy tissues from irritable bowel syndrome patients was observed. Moreover, the up-regulation of RAGE expression even in non-inflamed areas suggests that in CD, an unbalanced activation of the RAGE pathway may take place along the entire length of the intestine, reaching the

highest levels in inflamed areas where the concentration of its ligands is higher. In this regard, an up-regulation of both S100A12 and HMGB1 in inflammatory bowel disease has been already shown<sup>[12,13]</sup>. In addition, it is recognized that the activation of the RAGE pathway plays a crucial role in regulating apoptosis and autophagy<sup>[34]</sup>, and in favoring the differentiation of T cells towards a T helper-1 phenotype<sup>[35]</sup>, both being leading mechanisms in generating tissue damage in CD<sup>[1,36,37]</sup>. Therefore, we explored RAGE blocking's ability to affect the delayed apoptosis and TNF- $\alpha$  production of LPMC isolated from diseased and non-diseased mucosa of CD patients, and found that pre-treatment with the anti-RAGE antibody induces a dose-dependent increase of the apoptotic rate, with the effect clearly evident also at a lower dose in the presence of MDP. The latter represents the main bacterial wall component which is recognized by NOD2, an intracellular pattern recognition receptor whose variants are associated with CD<sup>[38]</sup>. The binding of MDP to mutated NOD2 is followed by activation of pro-inflammatory pathways mainly regulated by nuclear factor- $\kappa$ B<sup>[39]</sup>. It is interesting to note that the latter molecule is also the transducer of the RAGE pathway upon activation by S100/calgranulins and HMGB1 proteins<sup>[9]</sup>. Our further evidence of a significant and dose-dependent decrease of TNF- $\alpha$  production, mainly in those cells from inflamed mucosa following RAGE blocking, fits perfectly into this context. It seems likely, therefore, that a progressive accumulation of RAGE ligands in those tissues primed by genetic and/or environmental factors leads to an increased expression which, in turn, causes magnification rather than dampening of the inflammation<sup>[26,39]</sup>.

Finally, as far as clinical features are concerned, at variance with the epithelial compartment of the non-diseased areas, where a positive correlation between the grading of RAGE expression and BMI was clearly evident, no correlation was found in diseased areas, probably by virtue of the high concentration of ligands, which *per se* leads to an increased expression that overcomes any systemic regulation<sup>[40]</sup>. Also, no correlation with the duration, localization, behavior, activity of the disease, or current therapies was observed in any condition. Notably, in the diseased areas, we did not find any correspondence between the zones of high RAGE<sup>+</sup> cells density in the epithelial compartment and those in the lamina propria. It is conceivable, therefore, that this might depend on different timing or mechanisms of activation of the RAGE pathway in the two compartments, which deserves further investigation. Also, the limited size of our sample groups, dictated by the need to obtain surgical specimens from macroscopically healthy tissue at a certain distance from the workpiece of intestine, implies that larger studies are needed in order to confirm our evidence.

In conclusion, the evidence we obtained of an increased expression of RAGE on both epithelial and lamina propria cells in CD, mainly in macroscopically injured areas, represents a further step up in the understanding of its pathogenesis, thus paving the way for future thera-

**Figure 8 Functional assays.** The *in vitro* apoptotic rates of lamina propria mononuclear cells (LPMC) incubated in the absence or presence of two different concentrations of the anti-receptor for the advanced glycation end products (RAGE) blocking antibody, and with or without the muramyl dipeptide (MDP) used as antigenic stimulation are given in panels A and B. The analysis was carried out by flow cytometry, and the mean percentage values  $\pm$  SD of at least three experiments for each condition were the following: in the absence of MDP (A), LPMC from non-diseased mucosa (grey bars) showed a spontaneous apoptotic rate of  $18.4 \pm 3.1$ , and a value of  $26.9 \pm 2.8$  and  $32.7 \pm 4.6$  in the presence of 50 and 100 ng/mL concentration of the anti-RAGE blocking antibody, respectively; when using LPMC from diseased mucosa (black bars), a value of spontaneous apoptotic rate of  $10.1 \pm 4.2$  was found, while when incubating with 50 and 100 ng/mL concentration of the anti-RAGE blocking antibody, values of  $13.0 \pm 6.2$  and  $26.1 \pm 5.5$  were found, respectively. In the presence of MDP (B), LPMC from non-diseased mucosa showed a spontaneous apoptotic rate of  $15.6 \pm 2.1$ , and values of  $31.9 \pm 3.8$  and  $33.3 \pm 2.9$  in the presence of 50 and 100 ng/mL concentration of the anti-RAGE blocking antibody, respectively; when using LPMC from diseased mucosa, a value of spontaneous apoptotic rate of  $7.8 \pm 2.6$  was found, while when incubating with 50 and 100 ng/mL concentration of the anti-RAGE blocking antibody, values of  $24.1 \pm 2.2$  and  $28.0 \pm 4.1$ , respectively, were found. The tumor necrosis factor (TNF)- $\alpha$  production of LPMC cultured *in vitro* in the absence or presence of two different concentrations of the anti-RAGE blocking antibody, and with or without the MDP as antigenic stimulation are given in the panels C and D. The analysis was carried out by ELISA assay on culture supernatants, and the mean values  $\pm$  SD were as follows: in the absence of MDP (C), the cytokine level was  $32 \pm 14$  pg/mL in the cultures with LPMC from non-diseased areas, and  $124 \pm 48$  pg/mL in those with LPMC from diseased areas; when incubating with 50 and 100 ng/mL of the anti-RAGE blocking antibody, values of  $41 \pm 38$  and  $27 \pm 21$  pg/mL for LPMC from non-diseased areas, and of  $102 \pm 29$  and  $67 \pm 11$  pg/mL for LPMC from diseased areas, respectively, were observed. In the presence of MDP (D), the TNF- $\alpha$  level was  $184 \pm 49$  pg/mL in the cultures with LPMC from non-diseased areas, and  $307 \pm 68$  pg/mL in those with LPMC from diseased areas; when incubating with 50 and 100 ng/mL of the anti-RAGE blocking antibody, values of  $138 \pm 50$  and  $87 \pm 41$  pg/mL for LPMC from non-diseased areas, and of  $198 \pm 68$  and  $71 \pm 47$  pg/mL for LPMC from diseased areas, respectively, were observed.

peutic use of RAGE blocking agents. Although it does not seem to be the primary cause, once set in motion, the RAGE pathway may be considered to contribute significantly to chronic inflammation.

## ACKNOWLEDGMENTS

The authors are grateful to Prof. Enrico Solcia, MD (Department of Human Pathology, Fondazione IRCCS Policlinico San Matteo, University of Pavia, Italy) for his support in the new control experiments and critical revision of the manuscript; to Ms. Sheila McVeigh for her thorough revision of the English text, and to Doctor Alessandra Pasini, BSc, (Department of Internal Medicine,

Fondazione IRCCS Policlinico San Matteo, Pavia, Italy) for her technical help in the western blotting analysis.

## COMMENTS

### Background

Crohn's disease (CD) is a disabling, lifelong, inflammatory disease which affects the gastrointestinal tract in a discontinuous manner, and whose lesions depend on a dysregulated immune response towards antigens of the gut microbiota. The receptor for the advanced glycation end products (RAGE) is a multiligand transmembrane receptor, whose activation sustains chronic inflammation.

### Research frontiers

The inhibition of RAGE-ligand interaction was proved successful in an experimental model of CD. However, the information available on the role of RAGE in human inflammatory bowel disease is scanty.

## Innovations and breakthroughs

In this study, the authors show an up-regulation of RAGE expression in the entire bowel of Crohn's patients, although prevalently in macroscopically affected areas, compared to healthy tissue of control subjects, as evaluated by both immunohistochemistry and Western blot analysis. Moreover, RAGE blocking significantly affects both the apoptotic rate and tumor necrosis factor- $\alpha$  secretion of mucosal immune cells, which are the key mechanisms involved in chronic inflammation and tissue damage.

## Applications

This study contributes to their understanding of the pathogenesis of CD and provides a scientific basis for future therapeutic use of RAGE blocking agents.

## Terminology

RAGE is a multiligand receptor which belongs to the immunoglobulin superfamily, and is natively present on the surface of monocyte/macrophage lineage cells and vascular cells. It is constitutively expressed during embryonic development, but progressively down-regulated in adulthood, where it is present at low levels in most normal tissues. The exceptions are the skin and lungs, where expression remains high throughout life. An increased expression of RAGE was found in a number of different pathological conditions, including chronic inflammatory diseases, neurodegenerative disorders, ageing, and cancer.

## Peer review

The authors investigated the involvement of RAGE in CD and found an enhanced expression in both the macroscopically diseased and non-diseased intestine, together with an attenuated inflammatory response of mucosal immune cells following RAGE blocking. The study is well designed and conducted, and the results are clearly presented. This is an excellent study whose only limitation is the relatively small sample size.

### Abstract

**AIM:** To investigate whether miRNA-155 (miR-155) dysregulates apical junctional complex (AJC) protein expression in experimental severe acute pancreatitis (SAP).

**METHODS:** Twenty-four male BALB/c mice were randomly assigned to two groups: the SAP group ( $n = 12$ ) receiving sequential intraperitoneal injection of 50  $\mu$ g/kg caerulein and 10 mg/kg lipopolysaccharide over 6 h, and the control group ( $n = 12$ ) receiving intraperitoneal injection of normal saline. Animals were sacrificed 3 h following the last injection for collection of blood samples and pancreas and distal ileal segment specimens. Routine pancreas and intestine histology was used to assess SAP pathology and intestinal epithelial barrier damage. Levels of serum amylase, diamine oxidase (DAO), and tumor necrosis factor (TNF)- $\alpha$  were determined using commercial kits. Total RNA samples

were isolated from intestinal epithelial specimens and reversely transcribed into cDNA. miR-155 and RhoA mRNA expression profiles were determined using quantitative real-time polymerase chain reaction. Target genes for miR-155 were predicted using the miRTarBase database, RNA22 and PicTar computational methods. Western blotting was performed to quantitate the protein expression levels of the target gene RhoA, as well as zonula occludens (ZO)-1 and E-cadherin, two AJC component proteins.

**RESULTS:** Intraperitoneal injection of caerulein and lipopolysaccharide successfully induced experimental acute pancreatic damage (SAP *vs* control,  $10.0 \pm 2.0$  *vs*  $3.2 \pm 1.2$ ,  $P < 0.01$ ) and intestinal epithelial barrier damage ( $3.2 \pm 0.7$  *vs*  $1.4 \pm 0.7$ ,  $P < 0.01$ ). Levels of serum amylase ( $21.6 \pm 5.1$  U/mL *vs*  $14.3 \pm 4.2$  U/mL,  $P < 0.01$ ), DAO ( $21.4 \pm 4.1$  mg/mL *vs*  $2.6 \pm 0.8$  mg/mL,  $P < 0.01$ ), and TNF- $\alpha$  ( $61.0 \pm 15.1$  ng/mL *vs*  $42.9 \pm 13.9$  ng/mL,  $P < 0.01$ ) increased significantly in SAP mice compared to those in control mice. miR-155 was significantly overexpressed in SAP intestinal epithelia ( $1.94 \pm 0.50$  fold *vs*  $1.03 \pm 0.23$  fold,  $P < 0.01$ ), and RhoA gene containing three miR-155-specific binding sites in the three prime untranslated regions was one of the target genes for miR-155. RhoA ( $22.7 \pm 5.8$  folds *vs*  $59.6 \pm 11.6$  folds,  $P < 0.01$ ), ZO-1 ( $46 \pm 18$  folds *vs*  $68 \pm 19$  folds,  $P < 0.01$ ), and E-cadherin proteins ( $48 \pm 15$  folds *vs*  $77 \pm 18$  folds,  $P < 0.01$ ) were underexpressed in SAP intestinal epithelia although RhoA mRNA expression was not significantly changed in SAP ( $0.97 \pm 0.18$  folds *vs*  $1.01 \pm 0.17$  folds,  $P > 0.05$ ).

**CONCLUSION:** TNF- $\alpha$ -regulated miR-155 overexpression inhibits AJC component protein syntheses of ZO-1, and E-cadherin by downregulating post-transcriptional RhoA expression, and disrupts intestinal epithelial barrier in experimental SAP.

**Key words:** miRNA-155; Severe acute pancreatitis; Intestinal barrier dysfunction; Apical junctional complex

**Core tip:** Apical junction complex (AJC) damage leads to intestinal barrier dysfunction and disease progression in severe acute pancreatitis (SAP) by an unknown mechanism. We reported for the first time that miRNA (miR)-155, a major mediator regulating early-stage inflammatory process, was overexpressed in experimental SAP intestinal epithelia as induced by circulating tumor necrosis factor (TNF)- $\alpha$ . RhoA gene, a predicted targeted gene for miR-155, was underexpressed at the post-transcriptional level, accompanied by downregulation of ZO-1 and E-cadherin expression; two key component proteins of AJC. Our study demonstrated that the TNF- $\alpha$ /miR-155/RhoA/ZO-1/E-cadherin signaling pathway contributed to intestinal barrier dysfunction in complicated SAP.

Overexpressed miRNA-155 dysregulates intestinal epithelial apical junctional complex in severe acute pancreatitis. *World J Gastroenterol* 2013; 19(45): 8282-8291 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i45/8282.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i45.8282>

## INTRODUCTION

Severe acute pancreatitis (SAP) is a serious medical condition with a high mortality rate. Intestinal barrier dysfunction in SAP patients leads to endotoxemia and multiple organ failure, and contributes to disease progression<sup>[1-3]</sup>. It is helpful to elucidate the pathogenetic mechanisms underlying intestinal barrier damage in SAP for successful treatment of patients who are critically ill in the great majority of cases.

Intestinal mucosal barrier is composed of a layer of crosslinked, highly differentiated epithelial cells located at the apical junction complex (AJC). A tight AJC maintains epithelial cell polarity, reduces the gap between epithelial cells, and decreases epithelial permeability. Therefore, the AJC can prevent intestinal toxins, pathogens and other exogenous substances from entering into the submucosal tissues and the circulation through the epithelial layer. The AJC is believed to be the mainstay structure that maintains the intestinal barrier and prevents enteric endotoxemia, and damage can lead to intestinal barrier dysfunction<sup>[4-8]</sup>.

The mechanisms underlying AJC damage in SAP remain elusive. The structure and function of AJC depend on the regulation of its component proteins. miRNA is a newly established protein regulator<sup>[9-11]</sup> and is critically involved in maintaining epithelial junctions and polarity, as well as cytoskeletal remodeling in tumors<sup>[12-14]</sup>. Tang *et al*<sup>[15]</sup> reported that the expression of zonula occludens (ZO)-1 protein, a major AJC component, was downregulated

by miRNA (miR)-212 in Caco-2 cells and patients with alcoholic liver disease and intestinal barrier dysfunction. Ye *et al*<sup>[16]</sup> reported that downregulated expression of occludin, the component protein of AJC, was regulated by miR-122 in mouse and Caco-2 cells and resulted in intestinal barrier dysfunction. Aside from their critical role in maintaining intestinal epithelial junctions and regulating AJC proteins, miRNAs, especially miR-155, are also implicated in inflammatory processes<sup>[17,18]</sup>, which normally occur at the early stage of SAP. It has been also reported that miR-155 is a major inflammatory mediator<sup>[17-21]</sup> and regulates the inflammatory response and carcinogenesis<sup>[22]</sup>. However, it is yet to be investigated how miR-155 regulates AJC protein expression in intestinal epithelial cells.

The objectives of this study were to investigate how miR-155 regulates AJC protein expression, to predict target genes for miR-155, and to identify the possible miR-155 regulatory pathways in SAP.

## MATERIALS AND METHODS

### Laboratory animals and experimental protocols

The animal experimentation protocol was approved by the Animal Research Committee at First People's Hospital, Shanghai Jiaotong University. Twenty-four male BALB/c mice weighing 25 g were purchased from Shanghai Laboratory Animal Center and housed at room temperature (25 °C) with a 12-h light/dark cycle. All animals were given free access to rodent chow and tap water *ad libitum* and acclimated for  $\geq 3$  d prior to the experiment.

Following 12 h fasting, all experimental mice were randomly divided into two groups, the SAP group ( $n = 12$ ) and the control group ( $n = 12$ ). An experimental SAP mouse model was established as previously reported<sup>[23]</sup>. In the SAP group, intraperitoneal injection of 50  $\mu$ g/kg caerulein dissolved in normal saline (Bachem, Bubendorf, Switzerland) was repeated at hourly intervals for 6 h followed by intraperitoneal injection of 10 mg/kg *Escherichia coli* lipopolysaccharide (LPS) dissolved in normal saline (Sigma-Aldrich, St Louis, MO, United States). In the control group, the same volume of normal saline in place of caerulein and LPS was injected at hourly intervals for 6 h.

All animals were euthanized by injecting 3% intraperitoneal pentobarbital (0.1 mL/100 g; Dongchang Chemical, Shanghai, China) at 3 h after the last injection. Blood samples and pancreas and distal ileal segment specimens were collected. Blood samples were centrifuged at 3000 rpm for 8 min at 4 °C within 2 h after collection, and the supernatants were collected and stored at -80 °C for further experiments. Pancreas and intestine specimens were immediately fixed in 10% buffered formaldehyde (Dongchang Chemical) for further histological examination. Mucosal tissues of the distal ileal segment, 3-5 cm long, were stripped, snap frozen in liquid nitrogen, and stored at -80 °C for further experiments.

### Histological examination

Paraffin-embedded pancreatic and intestinal tissues were cut into 5- $\mu$ m sections. Sections were stained with hematoxylin and eosin (Sigma-Aldrich) and examined using a light microscope (Olympus, Tokyo, Japan). Acute pancreatic damage, including pancreatic edema, acinar cell necrosis, adipose necrosis and hemorrhage, parenchymal inflammation, and extravascular infiltration, was evaluated according to Schmidt's criteria<sup>[24]</sup>, with a maximum score of 16. Intestinal epithelial barrier damage, including changes in mucosal cells, mucosal structure, parenchymal hemorrhage, and inflammatory cell infiltration, was semiquantitatively evaluated using the following scale: (0) no injury; (1) local atrophy and necrosis of mucosal cells; (2) patchy shedding of mucosal cells, hemorrhage, inflammatory cell infiltration, and intact mucosal structure; (3) large areas of shedding and necrosis of mucosal cells, inflammatory cell infiltration, and destroyed mucosal structure; and (4) extensive necrosis of mucosal cells, inflammatory cell infiltration, loss of mucosal structure, and patchy hemorrhage. All experiments were performed in duplicate.

### Serum amylase, diamine oxidase, and tumor necrosis factor- $\alpha$ assays

Serum amylase (a biomarker of acute pancreatic damage) concentration was measured using a commercially available biochemical kit (Kehua, Shanghai, China) as instructed by the manufacturer; serum diamine oxidase (DAO) (a biomarker of intestinal barrier dysfunction) concentration was determined using ultraviolet UV spectrophotometer; and serum tumor necrosis factor (TNF)- $\alpha$  (a biomarker of systemic inflammation and acute phase reaction) level was determined using an ELSIA kit (R and D Systems, Minneapolis, MN, United States). All experiments were performed in duplicate.

### Western blotting assay of ZO-1 and E-cadherin

Intestinal epithelial specimens were homogenized in ice-cold lysis buffer (Sigma-Aldrich). The soluble lysate was mixed with the loading buffer containing 40% glycerol (Sigma-Aldrich), 200 mmol/L dithiothreitol (Sigma-Aldrich) and 0.04% bromophenol blue (Kehua, Shanghai, China), and boiled for 5 min. SDS-PAGE (Sigma-Aldrich) was used to separate the proteins, and the electroblotting technique was used to transfer the proteins to a polyvinylidene fluoride membrane. The blots were blocked with 5% bovine serum albumin (Beyotime, Jiangsu, China) at room temperature for 1 h and incubated with primary antibodies against ZO-1 (1:200, polyclonal; Santa Cruz Biotechnology, Santa Cruz, CA, United States) and E-cadherin (1:1000, polyclonal; Cell Signaling Technology, Danvers, MA, United States) at 4 °C overnight. The blots were further incubated with horseradish-peroxidase-conjugated secondary antibodies (Abcam, Cambridge, United Kingdom) for 1 h. The Fujifilm chemiluminescence detection system (Fuji, Tokyo, Japan) was used to detect and visualize the immunoblot bands. The band

density of the target protein was quantified using Image J software (<http://rsbweb.nih.gov/ij/>) and normalized to that of  $\beta$ -actin (internal control). All experiments were performed in duplicate.

### miR-155 real-time reverse transcriptase polymerase chain reaction

Total RNA samples were isolated from mouse intestinal epithelial specimens using the mirVana miRNA isolation kit (Ambion, Austin, TX, United States). RNA was reversely transcribed into cDNA using the TaqMan miRNA reverse transcription kit (Applied Biosystems, Foster City, CA, United States). miR-155 was detected using stem-loop reverse transcription primers, and U6 served as an internal control. Quantitative reverse transcriptase polymerase chain reaction (qRT-PCR) was performed using the TaqMan miRNA assay kit (Applied Biosystems) and quantitated using the 7900HT sequence detection system (Applied Biosystems). The thermal cycling was set as follows: denaturation at 95 °C for 15 s, annealing at 60 °C for 1 min, and extension at 60 °C for 1 min, for a total of 40 cycles. Threshold cycle (Ct) was defined as the fractional cycle number of fluorescence that passed through a given threshold. The  $2^{-\Delta\Delta C_t}$  method was used to determine the relative miR-155 expression level<sup>[25]</sup>. All experiments were performed in duplicate.

### miRNA target gene prediction

Possible target genes for miR-155 were predicted using the miRTarBase database (<http://mirtarbase.mbc.nctu.edu.tw/>), a database curating experimentally validated miRNA-target interactions, and two computational methods, namely, RNA22 (<http://cbcsrv.watson.ibm.com/rna22.html>) and PicTar (<http://pictar.mdc-berlin.de/>). The structural analyses were conducted to confirm the AJC-associated target genes for miR-155. The expression of the possible target gene was validated at the transcriptional and post-transcriptional levels.

### Real-time RT-PCR and Western blotting of Ras homolog gene family, member A

Ras homolog gene family, member A (RhoA) mRNA samples were extracted from intestinal epithelial specimens using the TRIzol reagent (Invitrogen, San Diego, CA, United States) and reverse transcribed into cDNA with the high-capacity cDNA reverse transcription kit (Applied Biosystems). cDNA was determined by qRT-PCR using the SYBR Green PCR Master Mix kit (Applied Biosystems). PCR amplification was performed using the 7900HT sequence detection system (Applied Biosystems), and the thermal cycling was set as follows: denaturation at 95 °C for 1 min, annealing at 60 °C for 1 min, and extension at 75 °C for 1 min, for a total of 40 cycles. All primers were designed using the Primer Premier software (PREMIER Biosoft, Palo Alto, CA, United States) and synthesized by Sangon (Shanghai, China). The sequences of primers were as follows: for RhoA, sense, AGCTTGTGGTAAGACATGCTTG, antisense,

**Figure 1** Pancreas histology and serum amylase level in severe acute pancreatitis and control mice. A: Representative photomicrographs of the pancreas in severe acute pancreatitis (SAP) (left panel) and control (right panel) mice (hematoxylin-eosin,  $\times 100$ ); B: Schmidt's acute pancreatic damage scores in SAP and control mice,  $P < 0.01$  vs control; C: Serum amylase levels in SAP and control mice,  $P < 0.01$  vs control.

GTGTCCCATAAAGCCAACTCTAC; for  $\beta$ -actin (internal control), sense, CCAGGCACCAGGGCGTGATG, antisense, CGGCCAGCCAGGTCCAGACG. The  $2^{-\Delta\Delta Ct}$  method was also used to determine the relative RhoA expression level<sup>[25]</sup>. All experiments were performed in duplicate.

RhoA western blotting assay was performed as mentioned above and using a primary antibody against RhoA (1:2000, polyclonal; Abcam) with  $\beta$ -actin as the internal control.

### Statistical analysis

Statistical analysis was performed using the PASW Statistics version 18.0 software (SPSS Inc., Hong Kong, China). All data were expressed as mean  $\pm$  SD. The means were compared using the two independent samples Student's *t* test, one-way analysis of variance.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Sequential intraperitoneal injection of caerulein and LPS induces experimental SAP

The control group showed no obvious abnormality in the pancreatic tissue on gross and microscopic examination (Figure 1A, right panel). In contrast, the SAP group exhibited patchy hemorrhage and necrosis of the pancreas (Figure 1A, left panel). Moreover, scattered saponification spots on macroscopic examination corresponded to

inflammatory cell infiltration with swollen acinar cells and intercellular space widening on microscopy in the SAP group. The Schmidt's acute pancreatic damage score was significantly higher in the SAP than the control group ( $10.0 \pm 2.0$  vs  $3.2 \pm 1.2$ ,  $P < 0.01$ ; Figure 1B). Serum amylase level was also significantly higher in the SAP than control group ( $21.6 \pm 5.1$  U/mL vs  $14.3 \pm 4.2$  U/mL,  $P < 0.01$ ; Figure 1C). These results showed that sequential intraperitoneal injection of caerulein and LPS successfully induced experimental SAP in mice, manifesting as pancreatic hemorrhage, necrosis, and inflammatory cell infiltration, as well as hyperamylasemia.

### Caerulein and LPS induces intestinal barrier dysfunction in experimental SAP

Histological examination in the control group showed mild intestinal mucosal congestion and shedding (Figure 2A, right panel), while the SAP group exhibited marked intestinal mucosal congestion and hemorrhage, inflammatory cell infiltration, glandular atrophy, and necrosis and shedding of epithelial cells (Figure 2A). The intestinal epithelial barrier damage score was significantly higher in the SAP than control group ( $3.2 \pm 0.7$  vs  $1.4 \pm 0.7$ ,  $P < 0.01$ ; Figure 2B), and serum DAO level was also significantly higher in the SAP group ( $21.4 \pm 4.1$  mg/mL vs  $2.6 \pm 0.8$  mg/mL,  $P < 0.01$ ; Figure 2C). These results showed that sequential intraperitoneal injection of caerulein and LPS also induced intestinal barrier damage in experimental SAP mice.

**Figure 2** Intestine histology and serum diamine oxidase levels in severe acute pancreatitis and control mice. A: Representative photomicrographs of the intestine in severe acute pancreatitis (SAP) (left panel) and control (right panel) mice (hematoxylin-eosin,  $\times 100$ ); B: Intestinal barrier damage scores in SAP and control mice,  $P < 0.01$  vs control; C: serum diamine oxidase (DAO) levels in SAP and control mice,  $P < 0.01$  vs control.

**Figure 3** Serum tumor necrosis factor- $\alpha$  levels in severe acute pancreatitis and control mice. Serum tumor necrosis factor- $\alpha$  level was measured using ELISA;  $P < 0.01$  vs control. SAP: Severe acute pancreatitis.

### Massive TNF- $\alpha$ release in experimental SAP

Serum TNF- $\alpha$  concentration in the SAP group was significantly higher than in the control group ( $61.0 \pm 15.1$  ng/mL *vs*  $42.9 \pm 13.9$  ng/mL,  $P < 0.01$ ; Figure 3). This showed that a systemic inflammatory response occurred in experimental SAP and resulted in massive release of TNF- $\alpha$ , a major proinflammatory cytokine.

### ZO-1 and E-cadherin are underexpressed in experimental SAP intestinal epithelia

Western blotting analysis showed that the expressions of ZO-1 ( $46 \pm 18$  fold *vs*  $68 \pm 19$  fold,  $P < 0.01$ ; Figure 4A and B) and E-cadherin ( $48 \pm 15$  fold *vs*  $77 \pm 18$  fold,  $P < 0.01$ ; Figure 4C and D) were significantly downregulated in experimental SAP intestinal epithelia as compared to the control group. These results showed that ZO-1 and E-cadherin, two major component proteins of the AJC, were damaged in experimental SAP with intestinal barrier dysfunction.

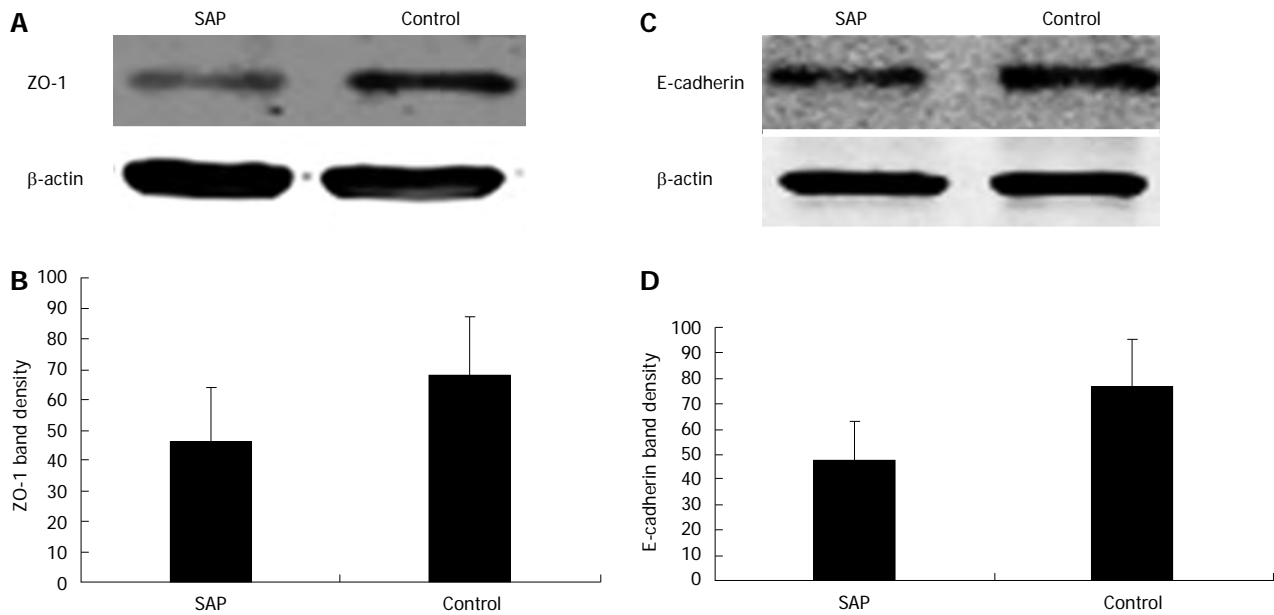

### miR-155 is overexpressed in experimental SAP intestinal epithelia

As shown in Figure 5, miR-155 was significantly overexpressed in intestinal epithelia in the SAP group as compared to the control group ( $1.94 \pm 0.50$  fold *vs*  $1.03 \pm 0.23$  fold,  $P < 0.01$ ). This result showed that miR-155 overexpression might dysregulate AJC protein expression and contribute to intestinal barrier dysfunction in experimental SAP mice.

### RhoA is a target gene for miR-155

miRNA regulates its target mRNA by binding to its specific binding site in the 3'-untranslated region (UTR). Prediction with miRTarBase, RNA22, and PicTar ana-

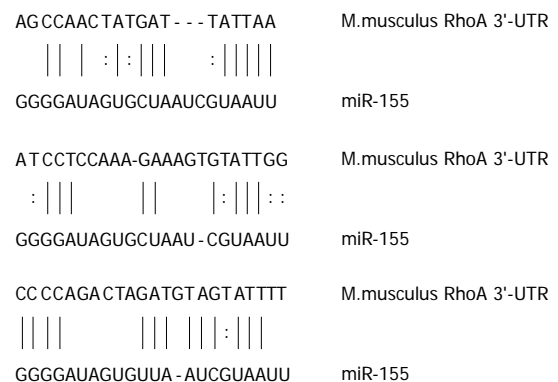

**Figure 4** Expressions of zonula occludens-1 and E-cadherin in the intestinal epithelia of severe acute pancreatitis and control mice. SAP: Severe acute pancreatitis.

**Figure 5** TaqMan miRNA real-time reverse transcriptase polymerase chain reaction for miRNA-155 expression in severe acute pancreatitis and control mice. Quantification of miRNA (miR)-155 expression level was normalized to that of U6 expression;  $P < 0.01$  vs control. SAP: Severe acute pancreatitis.

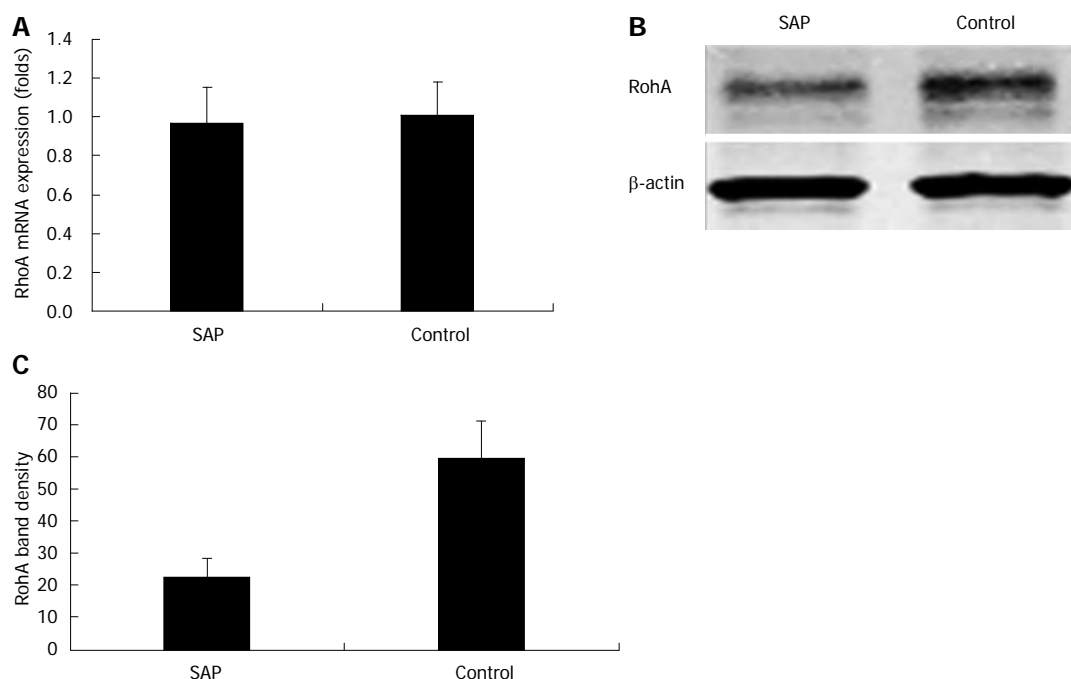

lytical and computational tools showed that RhoA gene encoding a small GTPase protein known to regulate the actin cytoskeleton in the formation of stress fibers and cell division was one of the possible target genes for miR-155. Moreover, structural analysis of miR-155 and RhoA mRNA confirmed that the latter contained three miR-155-specific binding sites in the 3'-UTR (Figure 6). This result showed that miR-155 overexpression might dysregulate AJC protein expression through the RhoA signaling pathway in experimental SAP with intestinal barrier dysfunction.

**Figure 6** Sequence of miRNA-155 and 3'-untranslated region of Ras homolog gene family, member A gene. Ras homolog gene family, member A (RhoA) mRNA contains three miR-155 specific binding sites in the 3'-untranslated region (UTR). Vertical lines and columns indicate the Watson-Crick and wobble base pairing, respectively.

### RhoA is underexpressed in experimental SAP intestinal epithelia

RhoA mRNA expression was not significantly upregulated or downregulated in SAP intestinal epithelia as compared to the control group ( $0.97 \pm 0.18$  fold *vs*  $1.01 \pm 0.17$  fold,  $P > 0.05$ ; Figure 7A). However, western blotting analysis showed that RhoA protein expression was significantly underexpressed in experimental SAP intestinal epithelia ( $22.7 \pm 5.8$  fold *vs*  $59.6 \pm 11.6$  fold,  $P < 0.01$ ; Figure 7B and C). This result suggested that miR-155 overexpression negatively regulated the target gene RhoA expression at the post-transcriptional level, and post-transcriptional RhoA underexpression was implicated in AJC

**Figure 7** Expressions of Ras homolog gene family, member A mRNA and protein in the intestinal epithelia of severe acute pancreatitis and control mice. **A:** Real-time reverse transcriptase polymerase chain reaction showing the relative level of Ras homolog gene family, member A (RhoA) mRNA expression normalized to that of  $\beta$ -actin,  $P > 0.05$  vs control; **B:** Representative western blots showing RhoA protein expression downregulation in severe acute pancreatitis (SAP) mice, with  $\beta$ -actin as an internal control; **C:** Quantification of RhoA protein expression in SAP and control mice,  $P < 0.01$  vs control.

protein dysregulation in experimental SAP with intestinal barrier dysfunction.

## DISCUSSION

Intestinal barrier dysfunction is closely associated with poor prognosis in SAP patients, and is believed to be the primary cause of SAP progression<sup>[26-28]</sup>. It has remained unknown until now how intestinal barrier dysfunction occurs in SAP. To the best of our knowledge, the present work was the first study to report the implication of miR-155 dysregulation in SAP with intestinal barrier dysfunction. Our results showed that a systemic inflammatory response occurred in experimental SAP, as indicated by massive TNF- $\alpha$  release, and miR-155 overexpression was seen in SAP intestinal epithelia with barrier dysfunction. These pathogenetic processes were accompanied with significant underexpression of RhoA, a target gene for miR-155, as well as ZO-1 and E-cadherin, two major component proteins of AJC; all of which contributed to intestinal barrier dysfunction in experimental SAP.

Serum DAO level is regulated by the intestinal mucosal permeability, and is believed to be a reliable biomarker of intestinal barrier function<sup>[29,30]</sup>. Our results showed that serum DAO level increased significantly in experimental SAP. Intestinal barrier dysfunction manifested histologically as necrosis and shedding of epithelial cells in the intestinal mucosal layer as observed in experimental SAP mice. All this biochemical and pathological evidence confirmed that intestinal barrier damage occurred in experimental SAP.

TJs and adherens junctions (AJs) are among the key protein complexes of the AJC<sup>[7,31]</sup>. ZO-1 and E-cadherin

are the major component proteins in TJs and AJs, respectively<sup>[15]</sup>. In TJs, as a cytoskeletal protein, ZO members, including ZO-1, ZO-2, and ZO-3, are linked to the transmembrane protein through its intracellular domains and connected with adjacent epithelial cells *via* its extracellular domains<sup>[32]</sup>. E-cadherin, a transmembrane protein, is connected to adjacent cells *via* its extracellular domains and linked with the cytoskeleton by binding to  $\beta$ -catenin *via* its intracellular domains. These two AJC proteins tightly crosslink epithelial cells in the intestinal mucosa, and maintain the intestinal barrier<sup>[8]</sup>. The AJC is the key structure for maintenance of intestinal barrier function<sup>[4-8]</sup>. The underexpression of ZO-1 and E-cadherin in experimental SAP could result in AJC disruption and consequently compromise intestinal barrier dysfunction.

Our study results showed that miR-155 was significantly overexpressed in experimental SAP intestinal epithelia. miRNA is an endogenous non-coding RNA, at a length of 21-25 nucleotides, which plays a crucial role in the post-transcriptional regulation of gene expression. Moreover, miRNA, especially miR-155, is known to be implicated in regulating the systemic inflammatory response<sup>[33]</sup>, which normally occurs at the early stage of SAP<sup>[17-21]</sup>. Multiple biological functions of miR-155 have been identified, including induction of Toll-like receptor (TLR) activation in monocytes/macrophages, regulation of LPS-induced non-specific immunity, and feedback modulation of the TLR signaling pathway<sup>[22,34]</sup>. More importantly, miR-155 expression can be induced by inflammatory cytokines, such as TNF- $\alpha$  and interferons<sup>[17,22,34-37]</sup>. TNF- $\alpha$ , one of the most important early proinflammatory mediators, is the first factor that is mas-

sively released into the circulation and plays a key role in systemic inflammatory response syndrome<sup>[38,39]</sup>. TNF- $\alpha$  is also destructive for the AJC in other inflammatory diseases. Sasaki *et al*<sup>[40]</sup> reported that the increase in serum TNF- $\alpha$  in inflammatory bowel disease induced by enteric bacteria downregulated expression of ZO-1 protein and E-cadherin and disrupted the AJC. Fries<sup>[41]</sup> found that excessive TNF- $\alpha$  release decreased the protein synthesis of TJs in inflammatory bowel disease, which could be treated with anti-TNF- $\alpha$  therapy by improving TJ protein synthesis. Ma *et al*<sup>[42]</sup> demonstrated that increased serum TNF- $\alpha$  inhibited ZO-1 protein synthesis in Crohn's disease intestinal epithelial cells and consequently resulted in AJC damage. TNF- $\alpha$  release increased in response to systemic inflammation in SAP, which was accompanied by significant overexpression of miR-155 in SAP intestinal epithelia. These results suggested that excessive TNF- $\alpha$  release caused AJC damage by dysregulating miR-155 expression in SAP epithelial cells.

miRNA exerts a regulatory effect by acting on target genes. miRNA binds to argonaute proteins to form the RNA-induced silencing complex, inhibits the transcription of the target genes by acting on its specific binding site in the 3'-UTR<sup>[43]</sup>, and leads to reduced protein synthesis of the target genes<sup>[44]</sup>. The presence of a specific structural pairing between miRNA and its target gene allows for structural analysis to predict the target genes for miRNA. In this study, RhoA was determined to be one of the possible target genes for miR-155. RhoA mRNA contains three miR-155-specific binding sites in the 3'-UTR, which are highly conserved among multiple species, including rats, mice and humans. RhoA, a small GTPase belonging to the Rho family<sup>[45]</sup>, is the major regulator of AJC expression<sup>[46-48]</sup>. RhoA promotes the formation and maintenance of the AJC, and RhoA underexpression leads to disrupted AJC<sup>[49-51]</sup> by blocking protein synthesis of TJs<sup>[52,53]</sup> and AJs<sup>[54]</sup>. Our results showed that RhoA protein rather than mRNA was significantly underexpressed in SAP intestinal epithelia. This indicates that miR-155 overexpression in SAP intestinal epithelia dysregulates RhoA gene expression at the post-transcriptional instead of transcriptional level.

In conclusion, miR-155 plays a crucial role in the structural and functional regulation of the AJC in the intestinal epithelial cells. In SAP, excessive inflammatory response leads to excessive release of inflammatory cytokines, such as TNF- $\alpha$ , and induces miR-155 overexpression in the intestinal epithelia. miR-155 overexpression inhibits RhoA protein synthesis by dysregulating RhoA gene expression at the post-transcriptional level, and consequently downregulates expressions of ZO-1 and E-cadherin; two major component proteins of the AJC. This pathogenetic process eventually results in intestinal barrier dysfunction in SAP.

## COMMENTS

### Background

Intestinal barrier dysfunction is believed to result in endotoxemia and multiple

organ failure, complicating severe acute pancreatitis (SAP). The apical junction complex (AJC) is the mainstay structure that maintains the intestinal barrier and prevents enteric endotoxemia, while AJC damage can lead to intestinal barrier dysfunction. However, the mechanisms underlying AJC damage complicating SAP remain unknown.

### Research frontiers

miRNA (miR) is known to maintain epithelial junctions and polarity, as well as cytoskeletal remodeling, by regulating protein synthesis. miR-dysregulation-induced proinflammatory factors are reported to contribute to AJC disruption in inflammatory bowel disease via an unknown signaling pathway. miR-155 is a major inflammatory mediator emerging at the early stage of the inflammatory process. There is a knowledge gap in the current literature as to whether miR-155 dysregulation is implicated in intestinal barrier dysfunction complicating SAP, and through which signaling pathway dysregulated miR-155 expression interrupts AJC component protein synthesis.

### Innovations and breakthroughs

This successfully created an experimental SAP mouse model with complicating intestinal barrier dysfunction by inducing intraperitoneal inflammatory response, which was validated histologically and biochemically. This study reported for the first time that miR-155 was overexpressed in experimental SAP intestinal epithelia as induced by excess circulating tumor necrosis factor (TNF)- $\alpha$ . RhoA, a small GTPase belonging to the Rho family, is the major regulator of AJC component protein expression. Their target gene prediction test showed that RhoA gene was one of the target genes for miR-155 and was underexpressed in experimental SAP intestinal epithelia at the post-transcriptional level. Downregulated RhoA expression was also accompanied by underexpression of zonula occludens (ZO)-1 and E-cadherin, which are component proteins of tight junctions and adherens junctions - two major constituents of the AJC. Release of proinflammatory factors, such as TNF- $\alpha$ , dysregulates miR-155 expression in intestinal epithelia and consequently disrupts protein synthesis of AJC components, possibly via the TNF- $\alpha$ /miR-155/RhoA/ZO-1/E-cadherin signaling pathway.

### Applications

The results suggest that miR-155 is a key mediator implicated in intestinal barrier dysfunction complicating SAP and other inflammatory gastrointestinal diseases. Inhibitor targeting of the miR-155 signaling pathway may be an effective alternative for treating inflammatory gastrointestinal diseases by repairing intestinal epithelial barrier.

### Terminology

The AJC is a functional unit located at the cell apex and connects the epithelial cells, which is composed of tight junctions and zonula adherens, and desmosomes, and functions to regulate cell polarity, tissue integrity, and intercellular adhesion and permeability. miR-155 is encoded by miR-155 host gene and plays a critical role in regulating inflammatory responses implicated in inflammatory, infectious, and neoplastic disorders. miRTarBase is a computational bioinformatics database accumulating > 3000 miR-target interactions, which are collected by manual survey of pertinent literature through data mining of the text and systematically filtering miR functional studies, and miR-target interactions are normally validated by experimental reporter genes, Western blotting, and microarray and gene sequencing analyses.

### Peer review

The authors demonstrated evidence of SAP. miR-155 expression increased compared to the controls and was associated with a decrease in ZO-1, E-cadherin, and RhoA expression. The authors conclude that these results suggest that SAP decreases intestinal barrier function by decreasing synthesis of key junctional complex proteins via miR-155 signaling.

### Abstract

**AIM:** To investigate the inhibitory effects of sinomenine (SIN) combined with 5-fluorouracil (5-FU) on esophageal carcinoma *in vitro* and *in vivo*.

**METHODS:** Esophageal carcinoma (Eca-109) cells were cultured in DMEM. The single or combined growth inhibition effects of SIN and 5-FU on the Eca-109 cells were examined by measuring the absorbance of CCK-8 dye in living cells. Hoechst 33258 staining and an Annexin V/PI apoptosis kit were used to detect the percentage of cells undergoing apoptosis. Western blotting was used to investigate the essential mechanism underlying SIN and 5-FU-induced apoptosis. SIN at 25 mg/kg and 5-FU at 12 mg/kg every 3 d, either combined or alone, was injected into nude mice and tumor growth inhibition and side effects of the drug treatment were observed.

**RESULTS:** SIN and 5-FU, both in combination and individually, significantly inhibited the proliferation of

Eca-109 cells and induced obvious apoptosis. Furthermore, the combined effects were greater than those of the individual agents ( $P < 0.05$ ). Annexin V/PI staining and Hoechst 33258 staining both indicated that the percentage of apoptotic cells induced by SIN and 5-FU combined or alone were significantly different from the control ( $P < 0.05$ ). The up-regulation of Bax and down-regulation of Bcl-2 showed that the essential mechanism of apoptosis induced by SIN and 5-FU occurs *via* the mitochondrial pathway. SIN and 5-FU alone significantly inhibited the growth of tumor xenografts *in vivo*, and the combined inhibition rate was even higher ( $P < 0.05$ ). During the course of chemotherapy, no obvious side effects were observed in the liver or kidneys.

**CONCLUSION:** The combined effects of SIN and 5-FU on esophageal carcinoma were superior to those of the individual compounds, and the drug combination did not increase the side effects of chemotherapy.

**Key words:** Esophageal carcinoma; Chemotherapy; Sinomenine; 5-Fluorouracil

**Core tip:** The cooperative inhibitory effects of sinomenine (SIN) and 5-fluorouracil (5-FU) on esophageal carcinoma *in vitro* and *in vivo* were investigated. SIN and 5-FU alone or in combination significantly inhibited the proliferation and induced apoptosis of esophageal carcinoma cells in a dose-dependent manner. The essential mechanism underlying SIN and 5-FU-induced apoptosis, as investigated by Western blotting, involved the mitochondrial pathway. No obvious side effects were observed in the liver and kidneys of nude mice. These results indicated that the combined effects of SIN and 5-FU on esophageal carcinoma were superior to the effects of the individual compounds, without an increase in side effects.

Cooperative inhibitory effect of sinomenine combined with 5-fluorouracil on esophageal carcinoma. *World J Gastroenterol* 2013; 19(45): 8292-8300 Available from: URL: <http://www.wjg-net.com/1007-9327/full/v19/i45/8292.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i45.8292>

## INTRODUCTION

Esophageal carcinoma is one of the most refractory and common malignant diseases worldwide and is associated with poor disease outcomes<sup>[1,2]</sup>. An estimated 482300 new esophageal cancer cases and 406800 deaths occurred globally in 2008<sup>[2]</sup>. Generally, the primary tumor of most patients can be cured with surgical resection, however, due to early distant metastases, the remainder of patients will eventually succumb to the disease. Despite the advances in surgical methods combined with perioperative treatment that have led to improved prognoses, the overall mortality rate remains low due to early distant metastases<sup>[3-5]</sup>. Systemic chemotherapy is regarded as one of the most effective treatments to improve survival. Although chemotherapy forms an important part of the multidisciplinary treatment approach for metastatic disease, the toxicity of the agents to normal tissues has been the main obstacle to successful treatment. Therefore, to enhance efficacy and reduce toxicity, combined treatments of several chemotherapy regimens are often used.

5-Fluorouracil (5-FU) is universally used as an anti-cancer agent in esophageal carcinoma. Cisplatin and fluorouracil combination therapy has been a standard choice for treating esophageal cancer, for which the median survival time is 9.2 mo for responders and 5.3 mo for non-responders, with a resulting 1-year survival rate of approximately 27.8%-37.6%<sup>[6-8]</sup>. To improve the prognosis of patients with esophageal cancer, more effective novel regimens with high therapeutic effect are urgently needed.

Sinomenine (SIN) is an immunosuppressive compound extracted from the Chinese medicinal plant *Sinomenium acutum* which has been successfully used in Chinese folk medicine to treat various autoimmune diseases for centuries<sup>[9]</sup>. Previous studies have indicated that SIN exhibits a wide range of significant pharmacological activities, including anti-inflammatory, anti-rheumatic, anti-arrhythmic, anti-angiogenesis, analgesic and immunosuppressive effects<sup>[10-12]</sup>. Lu *et al.*<sup>[13]</sup> observed that SIN can promote cell cycle arrest in the G1 phase, which was associated with increased p21/WAP/Cip expression. Additionally, SIN induces caspase-dependent apoptosis, which is involved in the disruption of mitochondrial membrane potential. SIN can also significantly inhibit basic fibroblast growth factor (bFGF)-induced angiogenesis, an effect that may render the compound a prime candidate for possible anti-cancer agents<sup>[12]</sup>.

The aim of this study was to evaluate the effects of SIN combined with 5-FU in terms of their activity

against esophageal carcinoma *in vitro* and *in vivo*.

## MATERIALS AND METHODS

### Chemicals and cell culture

SIN (C<sub>19</sub>H<sub>23</sub>NO<sub>4</sub> · 0.3 CHCl<sub>3</sub>) and 5-FU (C<sub>4</sub>H<sub>3</sub>FN<sub>2</sub>O<sub>2</sub>) were purchased from Sigma (Sigma-Aldrich, St. Louis, MO, United States) and dissolved at 100 mmol/L in dimethylsulfoxide (DMSO) for storage at -20 °C. The esophageal carcinoma cell line Eca-109 was obtained from China Center for Type Culture Collection. The growth medium consisted of DMEM (Gibco BRL Gaithersburg, MD, United States) containing 10% fetal bovine serum. Cell cultures were maintained at 37 °C in a 95% humidified atmosphere of 5% CO<sub>2</sub> in air.

### Cell proliferation assay

Cell proliferation *in vitro* was determined using the WST-8 Cell Counting Kit-8 (Beyotime Biotechnology, Jiangsu, China) as previously described<sup>[14]</sup>. Generally, cells were seeded in 96-well micro plates at a density of  $5 \times 10^3$ /well in 0.1 mL growth medium. After exposure to different concentrations of SIN (40, 80, 160, 320, 640 μmol/L), 5-FU (40, 80, 160, 320, 640 μmol/L) or SIN + 5-FU for 48 h, 10 μL CCK-8 solution was added to each well. The plates were then incubated for an additional 2 h at 37 °C. The optical density at 450 nm was measured by a microplate reader (BIO-RAD iMark). The procedure was performed in triplicate.

### Annexin V/PI staining for apoptosis

The amount of phosphatidylserine exposed on the extracellular membrane of the apoptotic cells was quantified by the Annexin V-FITC kit. Following incubation with SIN (160 μmol/L) and 5-FU (160 μmol/L) alone or combined for 48 h, adherent cells were harvested by mild trypsinization, washed twice with cold PBS and resuspended in 500 μL binding buffer. After adding 5 μL Annexin V-FITC conjugate and 10 μL Propidium Iodide (PI), the cells were incubated for 15 min at room temperature in the dark. Flow cytometric analysis was performed immediately with FACSCalibur using the CellQuest software.

### Hoechst 33258 assay for apoptosis

The morphological features of apoptotic cells were detected by Hoechst 33258 staining following the manufacturer's protocol (Beyotime Biotechnology, Jiangsu, China). Cells were seeded on sterile cover glasses placed in the 6-well plates. After exposure to SIN (160 μmol/L), 5-FU (160 μmol/L) alone or combined for 48 h, the cells were fixed, washed and stained with 0.5 mL Hoechst 33258 staining solution for 5 min at room temperature in the dark. Then washed twice with PBS and stained nuclei were scored and categorized according to the condensation and staining characteristics of chromatin under a fluorescence microscope (Olympus, Shinjuku-ku, Tokyo, Japan). Ten random fields per dish were observed and

**Figure 1** The individual and combined effects of sinomenine and 5-Fluorouracil on the proliferation of esophageal carcinoma cells. The proliferation of Esophageal carcinoma (Eca-109) cells was inhibited by SIN and 5-FU in a dose dependent manner ( $P < 0.05$ ). SIN and 5-FU had significant synergistic effects on inhibiting the proliferation of Eca-109 cells especially at lower concentrations. SIN: Sinomenine; 5-FU: 5-Fluorouracil.

counted.

### Western blot analysis

Whole protein extracts were prepared and analyzed by western blotting using a wet transfer system (Bio-Rad, Hercules, CA, United States). Protein samples (20 μg) were resolved by electrophoresis of SDS-polyacrylamide gels and electro-transferred to nitrocellulose membranes. Transfer efficiency and homogeneous loading was assessed by Ponceau stain. Membranes were blocked for 1 h in 10% non-fat milk, incubated with titrated primary antibody overnight at 4 °C and then labeled with the horseradish peroxidase conjugated secondary antibody for 2 h at ambient temperature. The following antibodies were used: Bax, Bcl-2, GAPDH (Santa Cruz Biotechnology, CA, United States) 1:1000. Antibody reaction was revealed using an enhanced chemiluminescence system (Millipore, Bedford, MA, United States) and then exposed with Kodak X-ray film. Protein band intensity was determined using the CMIASWIN video imaging system (Bio-Rad, Hercules, CA, United States).

### Xenograft tumor model

Animal experiments, which complied with the NIH Guide for the Care and Use of Laboratory Animals, were approved by the committee on Animal Experiment of Wuhan University. Esophageal carcinoma tumors were established in male BALB/c nude mice (4-6 wk, Laboratory Animal Central of Wuhan University) by serial subcutaneous transplantation of Eca-109 cells ( $1 \times 10^7$  cells/mouse). Eighteen mice bearing xenografted tumors were obtained and a further six mice inoculated with saline acted as controls. When the tumors reached approximately 100 mm<sup>3</sup> in size, the mice were divided into four groups ( $P < 0.05$ ): SIN group (25 mg/kg), 5-FU group (12 mg/kg), combination group, and saline control group. Treatment was ad-

ministered *via* intratumoral injection every 3 d. Tumor size was measured 2-3 times per week in two dimensions by calipers, and the volumes were calculated using the following formula: volume (mm<sup>3</sup>) = [length × (width)<sup>2</sup> × π/6].

### Hematoxylin and eosin staining and TUNEL assay

For histologic analysis, tumor tissues were prepared according to a standard protocol, and the paraffin-embedded tumor tissue sections were subsequently stained with hematoxylin and eosin (HE). For TUNEL assay, an in situ apoptosis detection kit (Roche, Branchburg, NJ, United States) was used to detect apoptotic cells in tumor tissue sections. The apoptotic cells were identified, counted (nine random fields per slide), and analyzed under light microscopy (Olympus, Japan).

### Evaluation of side effects

Blood samples were collected by cardiac puncture. The biomarkers of liver and renal injury, such as the activity of alanine aminotransferase (ALT), aspartate aminotransferase (AST), blood urea nitrogen (BUN) and serum creatinine (Cr), were detected using an OLYMPUS AU5400 analyzer (OLYMPUS, Japan).

### Statistical analysis

All data were expressed as the mean ± SE of the mean, and then subjected to the unpaired Student's *t* test. Statistical significance was defined as a value of  $P < 0.05$ .

## RESULTS

### Inhibition of Eca-109 cell proliferation by SIN and 5-FU

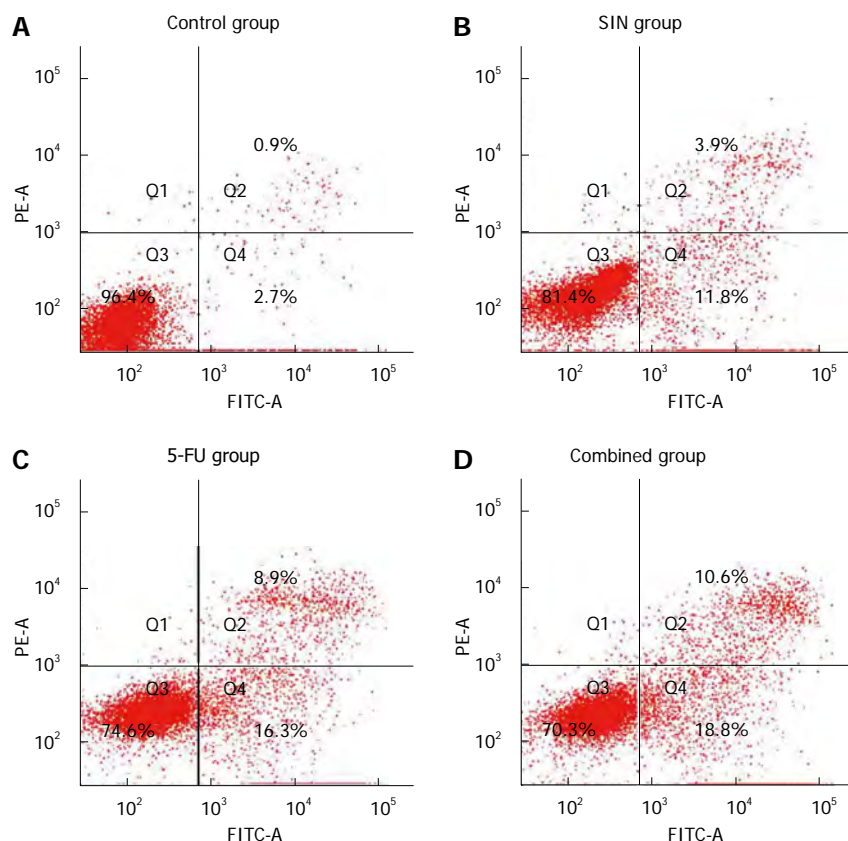

The inhibition of Eca-109 cell proliferation by SIN and 5-FU was assessed by the WSK-8 cell viability assay after 48 h of drug exposure, following 24 h culture in a drug-free medium. As shown in Figure 1, the growth of Eca-109 cells was significantly inhibited in a dose-dependent manner ( $P < 0.05$ ). Significant differences were observed for each concentration of the combined treatment (SIN:5-FU ratio was 1:1) compared to SIN or 5-FU given individually ( $P < 0.05$ ), especially at lower concentrations.

### Apoptosis induced by SIN and 5-FU

Apoptosis induced by SIN and 5-FU was confirmed by Annexin V/PI staining to quantify the amount of phosphatidylserine exposed on the apoptotic cellular membrane. As shown in Figure 2, the percentage of Annexin V-positive/PI-negative cells increased progressively in Eca-109 cells incubated at low concentrations of SIN (160 μmol/L) and 5-FU (160 μmol/L) for 48 h. SIN and 5-FU alone significantly induced apoptosis, as compared with the control group ( $P < 0.05$ ); furthermore, the combined treatment effect was stronger than that of SIN and 5-FU given individually ( $P < 0.05$ , Figure 2).

The morphological features of apoptotic cells were detected by Hoechst 33258 staining. The apoptotic nuclei were assessed by changes revealed by Hoechst staining and were identified by condensed chromatin as well as

**Figure 2** Quantitative flow cytometric measurements of G<sub>2</sub>/M arrest and apoptosis in esophageal carcinoma cells treated with sinomenine and 5-Fluorouracil alone or in combination. The density plots illustrate four cell populations (live, apoptotic, necrotic, and late apoptotic/dead) defined by their fluorescence profiles. SIN and 5-FU alone significantly induced apoptosis compared with the group control ( $P < 0.05$ ), and the combined effects were stronger than those of SIN or 5-FU alone ( $P < 0.05$ ). SIN: Sinomenine; 5-FU: 5-Fluorouracil.

nuclear fragmentation with formation of apoptotic bodies. Ten random fields per dish were observed and counted under a fluorescence microscope. The mean values are expressed as the percentage of apoptotic nuclei per field. Significant changes were detected in the number of apoptotic cells, and the percentage of apoptotic cells induced by SIN and 5-FU combined or alone were significant when compared with the group control ( $P < 0.05$ , Figure 3); furthermore, the apoptotic rate of the combined treatment was greater than those of the individual treatments ( $P < 0.05$ , Figure 3).

#### **SIN and 5-FU induce apoptosis through activation of the mitochondrial pathway**

To further investigate the essential mechanism underlying SIN- and 5-FU-induced apoptosis, their effects on the mitochondrial pathway were examined. As shown in Figure 4, SIN (160  $\mu\text{mol/L}$ ) and 5-FU (160  $\mu\text{mol/L}$ ) treatment combined or alone caused an increase in Bax/GAPDH protein levels and a decrease in Bcl-2/GAPDH levels in Eca-109 cells, which led to a decrease in the antiapoptotic/proapoptotic (Bcl-2/Bax) protein ratio. The apoptotic effect in the combined treatment group was significantly greater than that of the individual treatment groups.

#### **Effect of SIN and 5-FU on tumor development in nude mice**

The effects of SIN and 5-FU on the growth of primary tumor xenografts in nude mice were examined. None of the mice died during the course of the experiment, and all 24 mice successfully grew tumor xenografts. After 14 d growth, the tumor xenografts reached a mean size of 100  $\text{mm}^3$ . The mice were then randomly divided into four treatment groups, and no significant differences were observed in tumor size in the different groups at the start of the study. The results demonstrated that the tumor volumes and weights in the treatment groups were both significantly reduced compared with the saline control group ( $P < 0.05$ , Tables 1 and 2), while the extent of tumor reduction differed for each group. The combination treatment induced greater tumor growth suppression than did SIN or 5-FU alone ( $P < 0.05$ , Table 1), and a difference in tumor weight was also observed between groups ( $P < 0.05$ , Table 2). When compared with the control group, the tumor volume inhibition rate for the combination group was 91.22%, whereas the inhibition rates for the SIN and 5-FU groups were 64.68% and 71.68%, respectively (Table 1). When compared with the control group, the tumor weight inhibition rate for the combination group was 83.38%, whereas the inhibition

**Figure 3** Apoptosis of esophageal carcinoma induced by sinomenine and 5-Fluorouracil alone or in combination. A: Control group; B: SIN group; C: 5-FU group; D: Combined group; apoptotic features were assessed by observing chromatin condensation and fragment staining. SIN: Sinomenine; 5-FU: 5-Fluorouracil.

**Figure 4** Sinomenine and 5-Fluorouracil alone or in combination induced apoptosis in esophageal carcinoma cells through the mitochondrial pathway. Western blotting analysis results of Bcl-2 and Bax protein after SIN (160  $\mu\text{mol/L}$ ) and 5-FU (160  $\mu\text{mol/L}$ ) treatment. GAPDH was used as a loading control. SIN: Sinomenine; 5-FU: 5-Fluorouracil; GAPDH: Glyceraldehyde 3-phosphate dehydrogenase.

rates for the SIN and 5-FU groups were 63.10% and 61.97%, respectively (Table 2). The results suggest that SIN combined with 5-FU exhibits significant anti-tumor potential *in vivo*.

HE staining and TUNEL analysis of the subcutaneous primary tumor sections indicated that SIN and 5-FU individually or in combination induced significant apoptosis of Eca-109 cells *in vivo*, as compared with the saline control group ( $P < 0.05$ , Figure 5), although the degree of apoptosis differed for each group; the apoptotic rate in the combination treatment group was greater than that in the SIN alone and 5-FU alone groups.

The above data indicated that the effects of SIN combined with 5-FU against esophageal carcinoma *in vivo* were superior to that of SIN and 5-FU used individually.

#### Evaluation of side effects

At the end of the experiment, the nude mice were sacrificed and necropsied. No obvious metastasis, hemorrhage, or injury of the liver and kidneys was observed by visual examination.

Blood samples collected by cardiac puncture were used to monitor hepatic and renal toxicity. As biomarkers of liver and renal injury, the activity of ALT and AST,

**Figure 5** Detection of apoptotic cells in xenograft tumor tissue by the terminal deoxynucleotidyl transferase dUTP nick end labeling assay. A: Control group; B: SIN group; C: 5-FU group; D: Combined group; SIN and 5-FU induced significant apoptosis of esophageal carcinoma cells *in vivo* compared with the saline control group ( $P < 0.05$ ), and the apoptotic rate of the combination treatment group was more significant than that of the SIN alone and 5-FU alone groups. SIN: Sinomenine; 5-FU: 5-Fluorouracil.

SIN	6	0.218 (0.061) <sup>bd</sup>	63.10
5-FU	6	0.225 (0.088) <sup>bd</sup>	61.97
SIN + 5-FU	6	0.098 (0.066) <sup>d</sup>	83.38
Control	6	0.593 (0.070)	

Data presented as mean (SD) and are expressed as inhibition rate (%) = (1 - mean of tumor weight of tests/mean of tumor weight of control) × 100%. There were 6 mice per group. <sup>b</sup> $P < 0.05$ , significantly different from SIN + 5-FU group; <sup>d</sup> $P < 0.05$ , significantly different from control group. SIN: Sinomenine; 5-FU: 5-Fluorouracil.

as well as the urea and Cr values, were determined to evaluate potential toxicity. The hepatic and renal toxicity induced by SIN and 5-FU alone or in combination is shown in Table 3. Compared to the control group, there were no significant increases in the values of ALT, AST, urea, and Cr ( $P > 0.05$ , Table 3), and no significant differences were observed between the SIN alone, 5-FU alone and combination treatment groups ( $P > 0.05$ , Table 3). At necropsy, the livers and kidneys of the mice from the different treatment groups appeared smooth and normal in color. There was no significant difference in the liver and renal volume or weight between the treated groups and the control group, and the histological pathology examination showed no obvious lesions.

## DISCUSSION

Esophageal carcinoma is one of the most aggressive malignancies and remains a major public health threat globally. In 2008, the number of new esophageal cancer cases was estimated to be 482300 which accounts for 3.8% of all cancers, while the number of deaths was 406800 which accounts for approximately 5.4% of global cancer mortalities<sup>[2]</sup>. More effective treatments, as well as methods for earlier diagnosis, have led to improved survival over recent decades. However, patients with esophageal cancer still exhibit rapid progression and poor prognosis, with a natural disease history of 6-8 mo and a 5-year survival rate of 5%-7%<sup>[15]</sup>, owing to extensive local inva-

**Table 3** Effect of sinomenine combined with 5-Fluorouracil or alone on hepatic and renal function

Group	ALT (U/L)	AST (U/L)	Urea ( $\mu$ mol/L)	Cr ( $\mu$ mol/L)
SIN	45.50 (7.37)	143.67 (28.82)	8.18 (2.04)	16.63 (3.41)
5-FU	45.33 (6.02)	145.33 (18.53)	8.04 (1.20)	15.73 (4.30)
SIN + 5-FU	46.17 (7.17)	146.83 (19.55)	8.28 (1.44)	16.68 (2.68)
Tumor control	45.83 (3.76)	144.67 (17.32)	7.98 (0.70)	16.74 (4.46)
Normal control	46.00 (5.00)	145.17 (11.27)	8.09 (1.03)	16.29 (4.51)

Data presented as mean (SD), with  $n = 6$  mice/group. Groups were treated as follows: SIN (25 mg/kg); 5-FU (12 mg/kg); SIN (25 mg/kg) + 5-FU (12 mg/kg); Tumor control (saline of equal volume); Normal control. No differences were observed in ALT, AST, Urea, and Cr among the groups ( $P > 0.05$ ). SIN: Sinomenine; 5-FU: 5-Fluorouracil; ALT: Alanine aminotransferase; AST: Aspartate aminotransferase; Cr: Serum creatinine.

sion, lymph node involvement and distant metastases at the time of diagnosis<sup>[16]</sup>. Consequently, more effective chemotherapies have become an important means of extending the survival of esophageal cancer patients.

5-FU is widely used in chemotherapeutic regimens, including those for cancers of the gastrointestinal tract and breast. Although 5-FU-based chemotherapy improves the overall survival of patients with esophageal carcinoma, the response rate is extremely low, and even the combination of 5-FU with newer chemotherapies such as cisplatin and doxorubicin only generates response rates of 25%-35%, with 1-year survival rates of 27%-37%<sup>[6,7]</sup>. To improve the prognosis of patients with esophageal cancer, researchers have undertaken the investigation of novel drugs and combinations of chemotherapeutics.

Over the last few years, interest in exploring the use of traditional medicines for the prevention or treatment of tumors has increased. SIN is an alkaloid derived from the stem of the Chinese medical plant *Sinomenium acutum*, which has been used in traditional Chinese medicine for over 2000 years to treat various rheumatoid diseases with minimal side effects<sup>[17,18]</sup>. The chemical structure of SIN has been clarified, and its potential value in treating rheumatoid arthritis has been recognized by Western medicine. Many studies have indicated that SIN has a wide range of significant pharmacological actions, such as anti-inflammatory, anti-arrhythmic, anti-angiogenesis and immunosuppressive effects. Previous studies have demonstrated that inflammation can affect the angiogenesis and invasion of various types of tumors<sup>[19,20]</sup>. Kok *et al.*<sup>[12]</sup> found out that SIN possesses anti-angiogenic activity in several systems both *in vitro* and *in vivo*. Similarly, in a recent study, SIN was demonstrated to induce apoptosis by modulating NF- $\kappa$ B expression and activity<sup>[21]</sup>, and was able to significantly inhibit NF- $\kappa$ B activity even at  $> 10$  ng/mL<sup>[13]</sup>. Based on these results, SIN was hypothesized to enhance the sensitivity of various cancers to anti-cancer drugs.

In the present study, we investigated the inhibitory effects of SIN combined with 5-FU treatment on esophageal carcinoma *in vitro* and *in vivo*. We found that SIN and 5-FU alone can significantly inhibit the proliferation of

Eca-109 cells in a dose-dependent manner ( $P < 0.05$ ). In addition, the combined effect of SIN and 5-FU on the proliferation of human esophageal carcinoma was superior to that of SIN or 5-FU alone *in vitro* and *in vivo*. We also examined the apoptotic effect induced by SIN combined with 5-FU or administered individually. The results indicated that SIN and 5-FU alone significantly induced apoptosis compared with the control, and that the combined treatment effects were stronger than the individual effects of SIN and 5-FU.

SIN, as a typical anti-arrhythmic drug, has also been reported to inhibit the proliferation and induce apoptosis in various tumors<sup>[22]</sup>. However, the exact mechanisms underlying this apoptotic effect are poorly understood. Apoptosis is a tightly controlled type of cell death, with characteristic effects such as cell shrinkage, membrane blebbing and DNA fragmentation. The signals for apoptosis can be either initiated extrinsically through the death receptor pathway or intrinsically through the mitochondrial pathway<sup>[23,24]</sup>. Mitochondria are considered to play a pivotal role in apoptosis. The mitochondrial pathway has been shown to be an important signaling pathway for apoptosis, and SIN has been proven to utilize this pathway to induce the apoptosis of cancer cells<sup>[25-27]</sup>. 5-FU is well known to inhibit the thymic pyrimidine nucleotidase of tumor cells and affect DNA stability<sup>[28]</sup>. Moreover, 5-FU has been demonstrated to induce the apoptosis of various cancer cells such as breast and colon cancer, with resulting changes in p53<sup>[29]</sup>, caspase-3<sup>[30]</sup> and caspase-8<sup>[31]</sup>. In this study, we confirm that SIN combined with 5-FU treatment can induce apoptosis through the mitochondrial pathway.

A mouse tumor xenograft model was established, and the animals were administered chemotherapy consisting of SIN (25 mg/kg) and 5-FU (12 mg/kg) every 3 d. Similar effects on the proliferation and apoptosis of esophageal cancer cells induced by SIN and 5-FU were also observed *in vivo*. No adverse effects such as gastroenterol disturbance, hemorrhage or kidney dysfunction were observed. The model was also used to evaluate the potential histological pathology and hepatic and renal toxicity resulting from treatment, with no significant differences found between the treatment and control groups. Thus, we conclude that SIN combined with 5-FU demonstrates an anti-cancer effect with no increase in side effects *in vivo*.

In conclusion, SIN combined with 5-FU exhibited a significantly superior anti-cancer effect in comparison to SIN or 5-FU alone. In addition, this study demonstrated that SIN and 5-FU did not increase toxicity *in vivo* when used in combination. Above all, the present study indicates the potential for the combined use of SIN and 5-FU in clinical treatment.

## ACKNOWLEDGMENTS

We are very grateful to Mr. Hong Xia from the Key Laboratory of Hubei Province for Digestive System Disease

for assistance in data collection.

## COMMENTS

### Background

Esophageal carcinoma is one of the most refractory and common malignant diseases and is associated with poor outcome. To enhance the effect of systemic chemotherapy and reduce the toxicity, combined treatments with several regimens are often used. 5-Fluorouracil (5-FU) is universally used as an anti-cancer agent in esophageal carcinoma. Sinomenine (SIN) is an immunosuppressive compound extracted from the Chinese medicinal plant *Sinomenium acutum*; this compound has a wide range of significant pharmacological actions and has been hypothesized to enhance the sensitivity of various cancers to anti-cancer drugs.

### Research frontiers

As an alkaloid derived from a medical plant, SIN has been used in traditional Chinese medicine for over 2000 years. In the area of SIN treatment for cancer, the crucial areas of research are to confirm its effects, investigate the agent's mechanism of action and identify combined systemic chemotherapy regimens to prevent the growth of cancer.

### Innovations and breakthroughs

Few studies have described the anti-inflammatory, anti-rheumatic, anti-cancer, and anti-angiogenesis effects of SIN. The results of this study suggest that the combined effects of SIN and 5-FU on the growth of esophageal carcinoma are superior, with no observed increase in side effects. The essential mechanism underlying SIN- and 5-FU-induced apoptosis, as investigated by Western blotting, involved the mitochondrial pathway.

### Applications

In this study, the combined effects of SIN and 5-FU, as well as their essential mechanism were investigated in esophageal carcinoma. The combined use of these two medicines generated a superior anti-cancer effect without increased side effects. This finding may help to provide novel combined systemic chemotherapy in the treatment of esophageal carcinoma.

### Terminology

SIN: SIN is an alkaloid derived from the stem of the Chinese medical plant *Sinomenium acutum*, which has been used in traditional Chinese medicine for over 2000 years to treat various rheumatoid diseases. The chemical structure of SIN has been clarified, and its potential value in the treatment of immunological and other diseases is recognized by Western medicine.

### Peer review

This is a valuable original study in which the authors examine the inhibitory effects of SIN combined with 5-FU on esophageal carcinoma Eca-109 cells *in vitro* and *in vivo*. The results are exciting and suggest that the combined use of SIN and 5-FU is superior to the effects of the individual agents. This study is important for enhancing the efficacy and reducing the toxicity of chemotherapy regimens for patients with esophageal cancer.

### Abstract

**AIM:** To explore associations between nonalcoholic fatty liver disease (NAFLD) and benign gastrointestinal and pancreato-biliary disorders.

**METHODS:** Patient demographics, diagnoses, and hospital outcomes from the 2010 Nationwide Inpatient Sample were analyzed. Chronic liver diseases were identified using International Classification of Diseases, the 9<sup>th</sup> Revision, Clinical Modification codes. Patients with NAFLD were compared to those with other chronic liver diseases for the endpoints of total hospital charges, disease severity, and hospital mortality. Multivariable stepwise logistic regression analyses to assess for the independent association of demographic, comorbidity, and diagnosis variables with the event of NAFLD (vs

other chronic liver diseases) were also performed.

**RESULTS:** Of 7800441 discharge records, 32347 (0.4%) and 271049 (3.5%) included diagnoses of NAFLD and other chronic liver diseases, respectively. NAFLD patients were younger (average 52.3 years vs 55.3 years), more often female (58.8% vs 41.6%), less often black (9.6% vs 18.6%), and were from higher income areas (23.7% vs 17.7%) compared to counterparts with other chronic liver diseases (all  $P < 0.0001$ ). Diabetes mellitus (43.4% vs 28.9%), hypertension (56.9% vs 47.6%), morbid obesity (36.9% vs 8.0%), dyslipidemia (37.9% vs 15.6%), and the metabolic syndrome (28.75% vs 8.8%) were all more common among NAFLD patients (all  $P < 0.0001$ ). The average total hospital charge (\$39607 vs \$51665), disease severity scores, and intra-hospital mortality (0.9% vs 6.0%) were lower among NAFLD patients compared to those with other chronic liver diseases (all  $P < 0.0001$ ). Compared with other chronic liver diseases, NAFLD was significantly associated with diverticular disorders [OR = 4.26 (3.89-4.67)], inflammatory bowel diseases [OR = 3.64 (3.10-4.28)], gallstone related diseases [OR = 3.59 (3.40-3.79)], and benign pancreatitis [OR = 2.95 (2.79-3.12)] on multivariable logistic regression (all  $P < 0.0001$ ) when the latter disorders were the principal diagnoses on hospital discharge. Similar relationships were observed when the latter disorders were associated diagnoses on hospital discharge.

**CONCLUSION:** NAFLD is associated with diverticular, inflammatory bowel, gallstone, and benign pancreatitis disorders. Compared with other liver diseases, patients with NAFLD have lower hospital charges and mortality.

**Key words:** Nationwide inpatient sample; Nonalcoholic fatty liver disease; Chronic liver disease; Diverticular disease; Pancreatitis; Gallstones; Inflammatory

bowel disease

**Core tip:** This study analyzed the 2010 Nationwide Inpatient Sample to compare outcomes and associations between patients with nonalcoholic fatty liver disease (NAFLD) and other chronic liver diseases. Compared with other liver diseases, NAFLD is associated with diverticular, inflammatory bowel, gallstone, and benign pancreatitis disorders when these latter disorders are considered as either the principal or associated diagnoses on discharge. These associations suggest shared mechanisms of pathology between NAFLD and these benign gastrointestinal disorders. Furthermore, patients with NAFLD have lower hospital mortality and consume fewer healthcare resources compared to patients with other chronic liver diseases.

Reddy SK, Zhan M, Alexander HR, El-Kamary SS. Nonalcoholic fatty liver disease is associated with benign gastrointestinal disorders. *World J Gastroenterol* 2013; 19(45): 8301-8311 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i45/8301.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i45.8301>

## INTRODUCTION

Nonalcoholic fatty liver disease (NAFLD) is the most common chronic liver disease in the United States<sup>[1]</sup>. Outpatient primary care and specialist cohort series report prevalence proportions of 25%-46%<sup>[2-4]</sup>. Yet the proportion of hospitalized patients diagnosed with NAFLD is unknown. The prevalence of NAFLD in hospitalized patients maybe similar to outpatient cohorts given the associations between NAFLD and disorders common among hospitalized patients--including diabetes, cardiovascular disease, venous thromboembolism, colorectal cancer, and inflammatory bowel disease<sup>[5-13]</sup>. Conversely, NAFLD may comprise a small percentage of chronic liver disease among hospitalized patients because hepatic complications (such as ascites, variceal bleeding, and hepatocellular carcinoma) are less common with NAFLD compared to hepatitis B, hepatitis C, and alcohol associated liver diseases<sup>[10,14-19]</sup>. Finally, it is unclear if NAFLD is widely recognized by health care providers. This knowledge gap is important given recent small, single institutional studies suggesting relationships between NAFLD and benign digestive and pancreato-biliary disorders including diverticular disease, gallstone disorders, and inflammatory bowel disease<sup>[20-23]</sup>. Recognition of associations between NAFLD and these conditions may reveal insights into the pathologic mechanisms of all disorders.

The objectives of this study were to estimate the prevalence of the diagnosis of NAFLD among hospitalized patients in the United States and to explore associations between NAFLD and benign gastrointestinal and pancreato-biliary disorders.

## MATERIALS AND METHODS

### Database

Data were abstracted from the 2010 Nationwide Inpatient Sample (NIS), Healthcare Cost and Utilization Project, Agency for Healthcare Research and Quality (AHRQ). The 2010 NIS contains discharge information from 1051 non-Federal, short-term, general, and specialty hospitals located in 45 states; approximating a 20% stratified sample of United States community hospitals<sup>[24]</sup>. This study was deemed exempt by the Institutional Review Board at the University of Maryland School of Medicine.

### Sample identification

This study comprised patients with a diagnosis of chronic liver disease and compared patients with NAFLD *vs* any other chronic liver disease. All 25 diagnoses listed in each record were searched in creating each subsample in this study. The International Classification of Diseases, the 9<sup>th</sup> Revision, Clinical Modification (ICD-9-CM) diagnosis code of 571.8 ("other chronic nonalcoholic liver disease") was used to identify the NAFLD subsample. The "other chronic liver disease" subsample was identified using diagnosis codes describing other recognized etiologies of chronic liver disease, chronic liver disease of unknown etiology, and viral infections and errors in mineral metabolism which may lead to chronic liver disease (Table 1). Patient discharge records with diagnoses representing other liver diseases were eliminated from the NAFLD subsample. To eliminate records with possible alcoholic liver disease from the NAFLD subsample, records which included diagnoses pertaining to ethanol abuse, dependence, and/or overdose (Table 1) were removed from the NAFLD subsample. Similarly, records with an ICD-9-CM diagnosis code of 571.8 were eliminated from the "other chronic liver disease" subsample. Nationwide prevalence estimates were calculated using both unweighted and discharge weights, which account for the number of calendar quarters for which each hospital contributed discharges to the NIS<sup>[24,25]</sup>.

### Demographics and diagnoses

The location of patient's residence included central counties of greater than one million population, fringe counties of metropolitan areas of greater than one million population, counties in metropolitan areas of 250000-999999 population, counties in metropolitan areas of 50000-249999 population, and micropolitan counties in areas of less than 50000 population. The reported median income is the median income for the population in the zip code from which the patient pertaining to that particular discharge record resides<sup>[25]</sup>.

All diagnoses were searched to determine the presence of obesity (ICD-9-CM codes 278, 278.0, 278.00, 278.01, 278.02, or 278.03) and dyslipidemia (ICD-9-CM codes 272, 272.0, 272.1, 272.2, 272.3, 272.4, 272.5, 272.8, or 272.9). The presence of associated diagnoses (principal or secondary) were determined using the clinical classification

148	Peritonitis and intestinal abscess
149	Benign biliary tract disease
152	Benign pancreatic disorders excluding diabetes mellitus
153	Gastrointestinal hemorrhage
154	Noninfectious gastroenteritis

CCS: Clinical classification software categories; ICD-9-CM: International classification of diseases, 9<sup>th</sup> revision, clinical modification.

cation software provided by the AHRQ<sup>[26]</sup> (Table 2). Criteria for the metabolic syndrome include the presence of any three of obesity, diabetes mellitus, hypertension, and dyslipidemia<sup>[27,28]</sup>. Principal discharge diagnoses were also identified by the Disease Staging<sup>®</sup> (Thomson Reuters) classification system<sup>[29]</sup> (Table 3). The all patient refined diagnosis related group (APR-DRG<sup>®</sup> 3M) assesses severity of illness and mortality risk of the DRG pertaining to each patient discharge record<sup>[30]</sup>.

### Statistical analysis

Discrete and continuous variables were compared using  $\chi^2$  and Student's *t* tests with two-sided *P* values. Multivariable stepwise logistic regression analyses to assess for the independent association of each variable with the event of NAFLD were performed. The *P* value for variable entry and stay was 0.05. OR point estimates with 95% Wald confidence limits are reported. Results for those variables that did not stay in each model were not reported. Two

**Table 3 Disease Staging<sup>®</sup> (Thomson Reuters) classification system used to identify principal discharge diagnoses**

Discharge category	Description
GIS03, GIS04, GIS18	Benign anal-rectal disorders
GIS05	Appendicitis
GIS09 or GIS37	Inflammatory bowel disease
GIS10	Diverticular disease
GIS17 or GIS84	Gastroduodenitis
GIS19	Hernia
GIS20	Esophagitis
GIS25-30, HEP11, GIS82-83	Upper gastrointestinal cancers
GIS31	Gastroduodenal ulcer
HEP01 or HEP 84	Gallstone related disorders
HEP12 or HEP85	Non-malignant pancreatitis
HEP81 or HEP82	Hepatobiliary malignancies

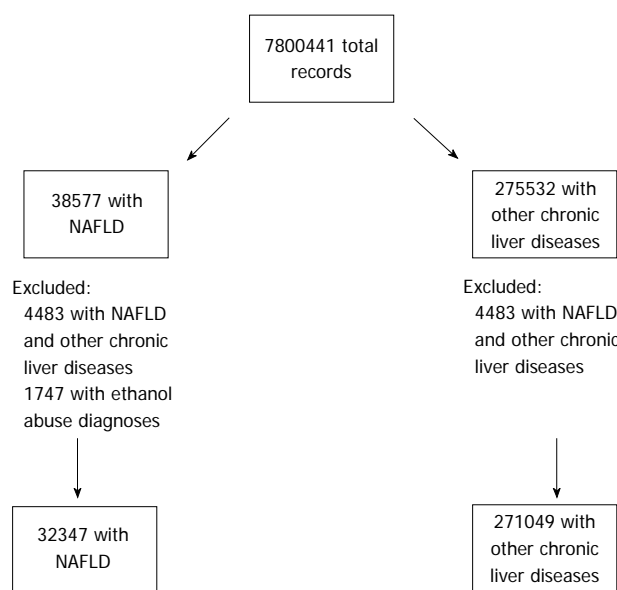

multivariable analyses were performed-one using associated diagnoses and another using principal diagnoses. SAS<sup>®</sup> Version 9.2 (SAS Institute, Inc., Cary, NC, United States) was used to perform all analyses.

## RESULTS

### Patient demographics and comorbidities

Of the 7800441 discharge records in the 2010 NIS, 314109 (4.0%) included a diagnosis describing any chronic liver disease (Figure 1). After excluding patients with diagnoses describing ethanol abuse, dependence, and/or overdose and those with other chronic liver diseases in addition to NAFLD, 32347 (0.4%) records contained the NAFLD diagnosis. Similarly, 271049 (3.5%) records included diagnosis codes describing other chronic liver diseases and did not include NAFLD. When using discharge weighted analyses, 3.9% of all discharge records included a principal or secondary diagnosis describing any chronic liver disease. 0.4% and 3.4% records included diagnoses describing NAFLD and other chronic liver diseases excluding NAFLD, respectively.

NAFLD patients were younger, more often female, and less often black compared to counterparts with other chronic liver diseases (Table 4). Diabetes mellitus, hypertension, obesity, and dyslipidemia were all more common

**Figure 1** Identification of nonalcoholic fatty liver disease and “other chronic liver diseases” subsamples from the Nationwide Inpatient Sample. NAFLD: Nonalcoholic fatty liver disease.

among NAFLD patients. Nearly 29% of the patients in the NAFLD subsample had the metabolic syndrome. NAFLD patients were from higher income areas and more often had private health insurance. The average total hospital charge and length of hospital stay were significantly shorter than among patients with other chronic liver diseases. Rates of NAFLD intra-hospital mortality and advanced APRDRG mortality and disease severity scores were all significantly lower than among patients with other chronic liver diseases.

### Associated gastrointestinal and pancreato-biliary disorders

As a *principal* or *secondary* (e.g., associated) diagnoses, abdominal hernia, appendiceal disorders, benign biliary and pancreatic disorders, diverticular disease, non-variceal esophageal disorders, gastritis/duodenitis, gastroduodenal ulcer, inflammatory bowel disease, and intestinal infection were all significantly more common among NAFLD patients (Table 5). Conversely, gastrointestinal and hepatobiliary malignancies, gastrointestinal hemorrhage, and peritonitis/intra-abdominal abscess were all more common among patients with other chronic liver diseases. NAFLD patients were more likely to have a *principal* diagnosis on discharge of appendicitis, benign pancreatitis, diverticular disease, esophagitis, gallstone disorders, gastroduodenitis, and inflammatory bowel disease. In contrast, benign ano-rectal disorders, gastroduodenal ulcers, and hepatobiliary cancers were more common among patients with other chronic liver diseases.

All variables with statistically significant differences ( $P < 0.05$ ) on univariable analysis (Table 4) were included in multivariable logistic regression models. When considering each gastrointestinal, hepatic, or pancreato-biliary diagnosis as an associated diagnosis, the patterns

of association observed on univariable comparisons were maintained on multivariable logistic regression (Table 5). When considering each disorder as the *principal* diagnosis, appendicitis, benign pancreatitis, diverticular disease, esophagitis, gallstone disorders, Gastroduodenitis, and hernia were all associated with NAFLD on multivariable logistic regression (Table 6). Hepatobiliary cancers were independently associated with other liver diseases. In both analyses, female gender, younger patient age, diabetes mellitus, obesity, dyslipidemia, higher income, and private health insurance were independently associated with NAFLD.

### Subgroup analysis for selected disorders

We performed subgroup analyses of records with a principal discharge diagnosis of diverticular disease, gallstone related disorders or benign pancreatitis. We chose these disorders because of their high prevalence in our sample. When stratified by type of background liver disease, similar differences in ethnicity, gender, comorbidities, health insurance payer, age, hospital charges, and income existed for each subgroup as in the overall sample (Table 7). As in the overall sample, total hospital charges, length of hospital stay, discharge disposition, rates of hospital death and APRDRG mortality and disease severity scores were all greater among patients with other chronic liver diseases in each subgroup.

## DISCUSSION

The diagnosis of NAFLD among hospitalized patients is much less common compared to that noted in outpatient cohort studies<sup>[2-4]</sup>. Our findings that patients with NAFLD were more likely to be female, obese, and non-Black and more likely have diabetes mellitus, hypertension, dyslipidemia, and the metabolic syndrome compared to patients with other chronic liver diseases is in agreement with other studies<sup>[10,14-19]</sup>—suggesting that our methods to identify these patients were accurate. Similarly, patients with other liver diseases were more frequently from low-income regions and less likely to have private insurance as the primary health care payer; reflecting the higher prevalence of hepatitis C viral infections and alcohol abuse in low-income areas. The discrepancy in prevalence of NAFLD in outpatient series compared with hospitalized patients shows that NAFLD is under-recognized in hospital patients and that the impact of NAFLD on clinical outcomes and health care resource utilization is unrecognized.

NAFLD is associated with several benign gastrointestinal and pancreato-biliary disorders. The exceptions were gastrointestinal hemorrhage and peritonitis, which are expected to occur in patients with decompensated liver disease and thus are less likely in NAFLD patients compared to those with other chronic liver diseases<sup>[10,14-19]</sup>. Several studies have established the role of bacterial translocation in nonalcoholic steatohepatitis and severe steatosis<sup>[20,21,31-33]</sup>. This could be a potential mechanism

NAFLD: Nonalcoholic fatty liver disease; OLD: Other liver diseases; AMA: American medical association.

fewer health care resources compared to patients with other chronic liver diseases (Table 4). These relationships occurred despite the fact that more NAFLD patients underwent major operations, and were maintained in

subgroup analysis of diverticular disease, gallstone disease, and benign pancreatitis (Table 7). Given that hepatic related morbidity more often occurs with other chronic liver diseases (such as hepatitis C and alcoholic liver dis-

ease) compared to NAFLD<sup>[10,14-19]</sup>, these findings suggest that the type and severity of background liver disease plays a vital role in determining overall patient outcomes and health care resource utilization.

There are several limitations to this study. It is unknown how background liver disease diagnoses were derived. Thus, the accuracy of NAFLD in this sample cannot be verified—especially when discharge abstracts used to construct this database were intended for reimbursement and not clinical research purposes. Similar problems regarding the accuracy of entered codes may exist when using ICD-9 diagnosis codes for elements of the metabolic syndrome, gastrointestinal disorders, and pancreato-biliary diseases. Distinctions between simple hepatic steatosis, steatohepatitis, and degrees of fibrosis cannot be made in the NIS. Because medications were not included in the NIS, we were not able to account for drug induced fatty liver disease. This limitation has minimal influence on our conclusions since less than 2% of steatohepatitis is drug induced<sup>[9]</sup>. We attempted to homogenize the NAFLD subsample by using only one ICD-9-DM identifier and eliminating any records listing any other major potential etiology of background liver disease. We focused on patients with any diagnosis of chronic liver disease and postulated that these patients are the most likely to have undergone evaluation for NAFLD. NAFLD may coexist with other chronic liver diseases in a minority of patients<sup>[35-37]</sup>. It is therefore possible that we may have included patients with undiagnosed NAFLD in the “other liver disease” sample. The NIS is a discharge level database where each entry represents a hospital admission and not an individual patient—thus multiple readmissions for a single patient may have biased our results.

In conclusion, NAFLD is widely under diagnosed among hospitalized patients in the United States. NAFLD is associated with diverticular, gallstone, and benign pancreatic disorders. The type of background liver disease is a key factor in hospital outcomes and healthcare resource utilization among hospitalized patients.

## COMMENTS

### Background

Nonalcoholic fatty liver disease (NAFLD) is the most common chronic liver disease in the developed world. While prevalence proportions among outpatient series are well described, the proportion of hospitalized patients diagnosed with NAFLD is unknown. Moreover, associations of NAFLD to other gastrointestinal disorders are not well established.

### Research frontiers

The important research hotspots related to this article include (1) the prevalence of NAFLD diagnosis among hospitalized patients; (2) outcomes among hospitalized patients with NAFLD; and (3) relationships between NAFLD and other gastrointestinal disorders.

### Innovations and breakthroughs

Most prior reports examining the prevalence of NAFLD are based on outpatient or cohort registry studies—data regarding the prevalence of NAFLD among hospitalized patients are sparse. Few studies have examined hospital outcomes among patients with NAFLD—most focus on long-term survival related to hepatic or cardiovascular complications. Previous studies looking at associations between NAFLD and other gastrointestinal disorders are small, single institution

based, and often biased by patient selection and particular care settings. To overcome these obstacles, the authors used a large database that provides an accurate estimate of the prevalence of NAFLD diagnosis among hospitalized patients across the United States. Analyses of these data show that patients with NAFLD have a lower frequency of hospital mortality and consume fewer healthcare resources compared to those with other chronic liver diseases. Finally, authors' study demonstrates that NAFLD is associated with diverticular, inflammatory bowel, gallstone, and benign pancreatitis disorders independent of demographics or other comorbidities.

### Applications

The study results suggest that suggest that the type of background liver disease plays a vital role in determining overall patient outcomes and health care resource utilization among hospitalized patients. The results also suggest shared mechanisms of disease pathology between NAFLD and diverticular, inflammatory bowel, gallstone, and benign pancreatitis disorders.

### Terminology

A principal diagnosis is the one diagnosis describing the main indication for admission and/or the condition which was the central focus of management during hospitalization. Associated diagnoses include the principal diagnosis, comorbid conditions, and disorders previously managed but not the focus of the particular hospitalization.

### Peer review

The authors mentioned the prevalence of NAFLD and the associations between NAFLD and other common gastrointestinal and pancreato-biliary disorders among hospitalized patients. The authors also discussed the impact of NAFLD on healthcare resource utilization.

to have an ectopic gastrinoma located in the biliary tree.

**RESULTS:** Seventeen MEN1 patients affected with ZES were analyzed. The mean age was 40 years. Fifteen patients underwent DP and two TP. On histopathological examination, duodeno pancreatic endocrine tumors were found in all 17 patients. Eighty-one gastrinomas were detected in the first three portions of the duodenum. Only one gastrinoma was found in the pancreas. The mean number of gastrinomas per patient was 5 (range 1-16). Malignancy was established in 12 patients (70.5%) after lymph node, liver and omental metastases were found. Three patients exhibited biliary tree gastrinomas as well as duodenal gastrinoma(s). In two cases, the ectopic gastrinoma was removed at the same time as pancreatic surgery, while in the third case, the biliary tree gastrinoma was resected one year after DP because of recurrence of ZES.

**CONCLUSION:** These findings suggest the importance of checking for the presence of ectopic gastrinomas in the biliary tree in MEN1 patients undergoing ZES surgery.

### Abstract

**AIM:** To describe our patients affected with ectopic biliary tree gastrinoma and review the literature on this topic.

**METHODS:** Between January 1992 and June 2012, 28 patients affected by duodenopancreatic endocrine tumors in multiple endocrine neoplasia type 1 (MEN1) syndrome underwent surgery at our institution. This retrospective review article analyzes our experience regarding seventeen of these patients subjected to duodenopancreatic surgery for Zollinger-Ellison syndrome (ZES). Surgical treatment consisted of duodenopancreatectomy (DP) or total pancreatectomy (TP). Regional lymphadenectomy was always performed. Any hepatic tumoral lesions found were removed during surgery. In MEN1 patients, removal of duodenal lesions can sometimes lead to persistence or recurrence of hypergastrinemia. One possible explanation for this unfavorable outcome could be unrecognized ectopic localization of gastrin-secreting tumors. This study described three cases among the seventeen patients who were found

**Core tip:** Enteropancreatic endocrine neoplasms affect up to 90% of multiple endocrine neoplasia type 1 (MEN1) patients. Gastrinomas are the most common functional enteropancreatic neuroendocrine tumors and were thought to be located almost exclusively in the duodenum in MEN1 patients. This study describes our experience regarding ectopic biliary tree gastrinomas in MEN1 syndrome. Our data doubles the number of cases reported in literature on this topic. Furthermore, the present study brings to light important issues that could

help to establish the best biochemical and oncological cure for such cases, of which clinicians should be aware to improve the management of MEN1 patients.

## INTRODUCTION

Multiple endocrine neoplasia type 1 (MEN1) is a familial syndrome characterized by tumors of the parathyroids, the anterior pituitary and the enteropancreatic endocrine system. Enteropancreatic endocrine neoplasms affect up to 90% of MEN1 patients, the incidence increasing with age<sup>[1-3]</sup>. In MEN1, the most common functional enteropancreatic neuroendocrine tumors are gastrinomas, located almost exclusively in the duodenum. According to recent literature, pancreatic localization is extremely rare<sup>[4-6]</sup>. Zollinger-Ellison syndrome (ZES) and/or increased basal or stimulated plasma gastrin levels<sup>[5]</sup> often persist after surgical treatment. This could be caused by either metastatic disease or potentially unrecognized localization of gastrin-secreting tumors.

Interestingly, primary sporadic gastrinomas may arise not only in the pancreas and duodenum, but also in other organs, such as the stomach, ovary, omentum, kidney, jejunum, esophagus, extra-hepatic biliary tree or liver<sup>[7-13]</sup>. All these sites have usually been considered atypical in MEN1 syndrome, or until now, never described. Recently, the extra-hepatic biliary tree and liver were indicated as the sites of primary gastrinomas in three MEN1 patients from two different centers<sup>[14,15]</sup>. Our experience includes a further three MEN1 patients with an ectopic gastrinoma in the biliary tree, thus doubling the number of cases recognized in the international literature. The implications of this phenotype are important in the clinical management of MEN1 ZES.

## MATERIALS AND METHODS

Between January 1992 and June 2012, 28 MEN1 patients affected with duodenopancreatic endocrine tumors were observed and operated on at our institution, following a protocol approved by the Tuscany Region. MEN1 diagnosis was confirmed after genetic testing on germline DNA obtained from peripheral blood leukocytes. Serum gastrin, chromogranin A, pancreatic polypeptide (PP), somatostatin, glucagon and vasoactive intestinal peptide levels were assessed. A preoperative secretin stimulation test (bolus 2 µg/kg, Secrelux®, SANOCHEMIA Pharmazeutika AG) were carried out in all patients and taken as positive where gastrin increased to > 120 pg/dL 2-5 min after secretin infusion. Indications for surgery were

established by the presence of hypergastrinemia, insulinoma or pancreatic nodule(s) over 1 cm in diameter. Abdominal ultrasonography (US), computed tomography (CT) and/or magnetic resonance imaging (MRI), somatostatin receptor scintigraphy (SSRS-Octreoscan), endoscopic ultrasonography (EUS) or selective pancreatic angiography with hepatic venous sampling after selective arterial secretin injection (SASI) test were performed in the majority of patients. Surgical intervention included: (1) complete duodenopancreatic mobilization, and colo-epiploic detachment; (2) inspection and palpation of the pancreas, duodenum, first jejunal loops and gallbladder; (3) abdominal intraoperative US (IOUS); (4) transillumination of the duodenum; and (5) intraoperative serum gastrin measurement by rapid immunoradiometric assay at the induction of anesthesia (basal value), 15, 30 and 45 min after pancreatic surgery. Further postoperative samples were taken after 3, 4 and 24 h. Gastrin values were measured using the rapid radioimmunoassay for serum gastrin, using specific antibodies (100% cross-reactivity) for small gastrin (G-17).

Surgery consisted of duodenopancreatectomy (DP) or total pancreatectomy (TP). Regional lymphadenectomy was performed in all patients and included pancreaticoduodenal, splenic and celiac nodes. Any hepatic tumoral lesions were removed during surgery.

All specimens were available for analysis and were confirmed as being gastrinomas by immunohistochemistry. In accordance with the World Health Organization's criteria for endocrine tumors, we distinguished between microadenomas (< 5 mm) and macromors (> 5 mm). Tumor size, proliferation index, immunohistochemical phenotype, angioinvasion, and evidence of metastatic spread were assessed. The diagnosis of each tumor as a gastrinoma was based on the presence of over 90% of cells displaying positive immunoreaction to gastrin.

During follow-up, fasting serum gastrin, additional entero-hormone levels and secretin provocative tests were performed 3 and 6 mo postoperatively, and yearly thereafter. Cure of hyperestrinism was defined as a normal serum gastrin concentration and a negative secretin test. Abdominal US and/or EUS, CT or MRI were carried out once every two years, or, if necessary, when hormonal levels increased.

## RESULTS

Seventeen of the 28 operated patients (60.7%) were affected with gastrinomas, ten patients with insulinoma and one patient with vipoma. All the patients also had non-functioning tumors in the pancreas. The mean age of patients affected by ZES was 40 years (range 24-63 years): 15 patients underwent DP and two TP. On histological examination, duodenopancreatic endocrine tumors were found in all 17 patients. Immunohistochemical evaluation revealed a total of 81 gastrinomas in the first three portions of the duodenum. In our series, only one gastrinoma was located in the pancreas. The mean number

Table 1 Characteristics, surgical treatment and follow-up of multiple endocrine neoplasia type 1 patients with biliary gastrinomas in our series									
Pt	Sex/age (yr)	MEN1 mutation	Basal gastrinemia (NV < 108 pg/mL)	Previous surgical treatment	Surgical treatment	Postoperative complications	Latest complications and adverse events	Basal serum gastrin postoperative (pg/mL)	Secretin provocative test (at follow-up)
1	F/46	Missense, Leu413Pro exon 9	213.2	Total PTX	TP and removal of a bile duct gastrinoma		Insulin-dependent diabetes mellitus Cholangitis	39.9	NEG
2	F/55	Frameshift, 843del GA, exon 6	87.1	Left nephrectomy for hydronephrosis, total PTX with autotransplantation	WDP	Pancreatojejunal dehiscence for acute pancreatitis→TP with splenectomy	Abdominal abscess	24.8	NEG

PTX: Parathyroidectomy; TP: Total pancreatectomy; WDP: Whipple’s duodenopancreatectomy; PPDP: Pylorus preserving duodenopancreatectomy; MEN1: Multiple endocrine neoplasia type 1.

of gastrinomas per patient was 5 (range 1-16). The largest gastrinoma was 1.8 cm in diameter (mean diameter 0.54 cm), the smallest less than 1 mm in diameter. One apparently primary gastrinoma was detected in a peri-pancreatic lymph node. Overall, malignancy was established in 12 patients (70.5%) after finding lymph node, liver and omental metastases. Two cases, believed to be liver metastases intraoperatively, turned out to be focal nodular hyperplasia on pathological examination.

During follow-up, the secretin stimulation test was positive in only two patients after a mean of 84.8 mo. One (case 3) is discussed below, the other developed nodal recurrence of gastrinoma.

Out of the 17 patients with gastrinoma, three were found to be located in the biliary tree, either at surgery, on histological examination of the surgical specimen or during follow-up. These three cases are detailed below.

Case 1

The first case concerns a 46-year-old woman whose father had suffered from gastric ulcer and died of a myocardial infarction at the age of 61 years. Her mother had colorectal cancer at the age of 78 years. Our patient had had kidney stones since 1992, with recurrent renal colic episodes. She was also affected by type II mellitus diabetes and monoclinal gammopathy. In 1999, she experienced epigastralgia; esophago-gastro-duodenoscopy (EGDS) showed ulceration of the first and second portions of the duodenum. Genetic testing for MEN1 gene mutation was positive (Table 1). Complete biochemical assessment showed elevated levels of calcium, parathyroid hormone (PTH) and gastrin (213.2 pg/mL; VR < 108). Abdominal US revealed multiple nodules over 2 cm in diameter in the head, body and tail of the pancreas. Abdominal CT confirmed the pancreatic lesions, displaying additional smaller nodules. In December 2000, she underwent total parathyroidectomy with eight parathyroid fragments autografted in the non-dominant forearm. After surgery, she was normocalcemic and the PTH serum level was within the normal range.

Serological and radiological examination and a secretin provocative test were performed on follow-up, showing increased gastrin values after stimulation. In 2001, the patient was subjected to TP with gastroduodenal resection and splenectomy (Table 1). During surgery, a nodule was noted in the bile duct and resected. IOUS did not show any hepatic lesions. Gastrin progressively decreased, reaching 42 pg/mL at the end of the surgical procedure. Pathological examination revealed 16 non-functioning neuroendocrine tumors in the pancreas (maximum diameter 3.4 cm in the pancreatic tail) and two neuroendocrine gastrin-positive tumors reaching 1 cm, one in the duodenum and one in the bile duct. The Ki-67 index was less than 1% for all lesions. There was no evidence of lymph node metastasis (Table 2). The patient was discharged after 12 d and is currently on MEN1 follow up.

**Table 2** Pathological findings in multiple endocrine neoplasia type 1 patients with biliary gastrinomas

Pt	Gastrinomas (n)	Size of largest duodenal gastrinoma (cm)	Size of largest biliary gastrinoma (cm)	Other pancreatic endocrine neoplasms (n)	Size of largest NF PEN (cm)	Total tumors (n)	Hepatic findings	Gastrinoma metastases

2	4 (3D, 1G)	0.2	0.2	32 NF	1.6	32	Negative	Negative
3	3 (2D, 1BD)	0.3	1.5	37 NF	2.0	40	Negative	Positive (N)

D: Duodenal; BD: Biliary duct; G: Gallbladder; N: Lymph node; PEN: Pancreatic endocrine neoplasms; NF: Non-functioning.

## Case 2

The second case concerns a 55-year-old woman. Her mother had died of chronic renal failure at the age of 86 and her father at 67 of a carcinoid of the small bowel, her sister had died at the age of 46 from neurologic complications of a pituitary prolactinoma.

Our patient's clinical history began at the age of 24 when she developed kidney stones with recurrent renal colic. In 1994, she underwent left nephrectomy for hydronephrosis and hysterectomy for uterine leiomyomatosis. In 1999, she suffered episodes of epigastric pain and EGDS showed the presence of a duodenal ulcer. In 2001, the patient was clinically diagnosed with MEN1 and was referred to our department for a complete serum biochemical assessment, which showed elevated levels of PTH and calcium. A genetic diagnosis of MEN1 was made (Table 1), and in 2002, she underwent total parathyroidectomy, with a parathyroid autograft in the non-dominant forearm. After surgery, she was normocalcemic with normal PTH serum levels.

On follow-up, a secretin provocative test showed an increase in gastrin values after stimulation. CT revealed the presence of nodules in the pancreatic head. SSRS confirmed the presence of pathological neuroendocrine tissue in the first and second portions of the duodenum, and in the head of the pancreas. In October 2003, she underwent Whipple's duodenopancreatectomy with regional lymphadenectomy and cholecystectomy (Table 1). Intraoperative US showed no residual pancreatic or hepatic lesions, and gastrin levels decreased to 25 pg/mL at the end of the surgical procedure. Pathological examination revealed 28 non-functioning neuroendocrine tumors of the pancreas (maximum diameter 1.6 cm) and four gastrin-secreting tumors (maximum diameter 0.2 cm), three in the duodenum and one in the gallbladder fundus. The Ki-67 index was less than 1%. There was no evidence of lymph node involvement (Table 2). The postoperative course was complicated by acute pancreatitis and consequent pancreato-jejunal anastomotic dehiscence, thus requiring TP with splenectomy. The patient was discharged after 38 d and is still on follow-up for MEN1.

## Case 3

The third case concerns a 36-year-old woman, whose father had died of myocardial infarction at the age of 52, while her mother and two sisters were in good health. In 2004, she was subjected to left inferior parathyroidectomy for primary hyperparathyroidism, which recurred 4 mo

later. The right superior parathyroid gland was removed, and partial thymectomy was carried out. Intraoperative PTH decreased from 1050 pg/mL at baseline to 150 pg/mL, 20 min after parathyroidectomy. On suspicion of MEN1, the patient was referred to our institution for a genetic test, which revealed mutation of the *MEN1* gene (Table 1). She underwent complete biochemical and radiological examination with CT, but no neuroendocrine lesions of the pancreas were found. MRI was negative for pituitary lesions.

In 2010, she was admitted to our surgical unit for heartburn, abdominal pain and diarrhea. An increase in basal gastrin serum levels (184 pg/mL; NV < 108) and a secretin provocative test confirmed hypergastrinemia (9783 pg/mL). EGDS showed esophagitis and gastroduodenitis with peptic ulcers. The clinical diagnosis of ZES in MEN1 was put forward, and the patient started proton pump inhibitor (PPI) therapy. Abdominal EUS showed a 7-mm nodule in the pancreatic head, together with small submucosal lesions of the first and second parts of the duodenum. In October 2010, she underwent pylorus-preserving duodenopancreatectomy extended to the pancreatic body, with removal of the regional lymph nodes and the gallbladder (Table 1). End-to-side Wirsung-jejunal anastomosis, and common bile duct-jejunal and duodeno-jejunal anastomoses through transmesocolic Roux-en-Y loop were then performed. The IOUS showed no hepatic lesions. Gastrin serum levels progressively decreased, reaching 20 pg/mL at the end of the surgical procedure. Pathology revealed 37 neuroendocrine tumors of the pancreas (maximum diameter 2 cm) and three gastrin positive tumors of the duodenum (maximum diameter 2 mm). Of the 31 lymph nodes examined, two had neuroendocrine tumor tissue positive for gastrin. The postoperative course was uneventful and the patient was discharged 17 d later on PPI therapy (Omeprazole 40 mg × 2/die). One month after surgery, she had abdominal pain and vomiting, and was readmitted to our ward. An upper gastro-intestinal tract X-ray showed slow transit at the level of the anastomotic jejunal loop. Laparotomy was carried out with dissection of adhesions between the small bowel and the great omentum, and the mesocolic defect was closed, suturing it to the stomach. The day after surgery, gastrin levels were measured, revealing a significant increase in serum values (173 pg/mL). Five days later the patient was discharged and given PPI drugs and somatostatin analogs. After two mo, a 12 mm hepatic lesion, posterior to the V-VIII seg-

**Figure 1** Computed tomography scan. A: The tumor (arrow) near the glissonian capsule of the right portal triad sheet; B: The lesion was positive at somatostatin receptor scintigraphy; C: Intraoperative picture: the tumor is close to the hepatic hilum, as indicated by the surgical forceps; D: Surgical resection of the V-VIII hepatic segments: the nodule is shown by the surgical forceps; E: Overview of the neuroendocrine tumor found inside the glissonian capsule of the right portal triad sheet; F: Tumor displaying distinct trabecular pattern; G: Massive gastrin production by the majority of neoplastic cells is shown by immunophenotyping.

ment portal vein branch, was detected by CT and confirmed at US. MRI was subsequently performed to better define the hepatic lesion, which showed a 15 mm nodule in the V segment, immediately below the right portal bifurcation. SSRS confirmed the presence of the hepatic nodule with a high density of SST2 receptor (Figure 1).

Basal gastrin serum levels were within the normal range (45.6 pg/mL), but a secretin stimulation test displayed an increase to 482 pg/mL. In January 2012, the patient was readmitted to our department with epigastric pain, heart-burn and anemia (Hb 7.1) associated with a syncopal episode. An EGDS and a colonoscopy gave negative results.

A SASI test was carried out, producing two gastrin peaks at 1541 and 1217 pg/mL 40 s after stimulation in the hepatic and superior mesenteric arteries, respectively. EUS identified three pancreatic lesions of approximately 0.5 cm in diameter. In February 2012, the patient underwent hepatic resection of the V-VIII segments to remove the lesion, which was found inside the glissonian sheet of the anterior sectional pedicle and not in the liver parenchyma (Figure 1 and Table 1). A 0.7 cm lesion of the residual pancreatic body was also enucleated (Table 2). Intraoperative gastrin levels decreased below the normal range to 32 pg/mL. A gastrin-secreting tumor in the biliary tree and a pancreatic neuroendocrine lesion were found at histology (Figure 1). Both lesions had a Ki-67 index lower than 1%. The patient developed a biliary fistula, which was then treated conservatively. She was discharged after 15 d and is still on follow-up for MEN1.

## DISCUSSION

Primary gastrinomas are classified as duodenal, pancreatic and extraintestinal-extrapancreatic. The pancreas and duodenum are the most frequent sites of sporadic gastrinomas, while the duodenum is almost exclusively the localization of gastrinomas in MEN1 patients<sup>[4-6]</sup>. MEN1-associated gastrinomas occur predominantly in the first three parts of the duodenum, are usually multiple and measure less than 5 mm in diameter<sup>[3-6,16]</sup>. In some cases, duodenal gastrinomas are only found on microscopic examination. From 34% to 85% of duodenal gastrinomas are metastatic at the time of surgery, but tumor spread is usually restricted to the regional lymph nodes<sup>[4-6]</sup>. Pancreatic localization is rare in MEN1 syndrome, sometimes being associated with a more aggressive behavior of the tumor, which may metastasize to the liver<sup>[17]</sup>.

Extraduodenal-extrapancreatic gastrinomas in MEN1 syndrome are rare, while they account for 22% of sporadic gastrinomas according to Norton *et al.*<sup>[18]</sup>. The improved ability to identify gastrinomas in the duodenal wall, either preoperatively or intraoperatively, has resulted in an apparent increase in the incidence of duodenal gastrinomas and decrease in the incidence of occult lesions and primary peripancreatic lymph node gastrinomas. Wu *et al.*<sup>[19]</sup> found extrapancreatic and extraduodenal gastrinomas in only 8 (5%) of 142 patients with ZES, none of whom had MEN1. The sites of these gastrinomas were the ovary, omentum, stomach, jejunum, kidney, biliary tract, and, in 2 cases, the liver<sup>[19]</sup>.

To the best of our knowledge, only twenty cases of hormonally active gastrin-producing or immunostaining gastrin positive neuroendocrine tumors of the extrahepatic biliary tree have been published in literature, 18 in the sporadic setting and two in MEN1<sup>[14]</sup>. The majority of these patients were female and under 50 years of age. The most common symptom was jaundice and, more rarely, peptic ulceration or frank ZES. Generally, basal gastrin serum levels were high and the secretin test was positive. These gastrinomas mainly occurred in the com-

mon bile duct or common hepatic duct, less frequently at the confluence of the hepatic duct. Tumor size varied from a few millimeters to over 2 centimeters. Lymph node or liver metastases were detected in almost 50% of these cases. All these gastrinomas were resectable, and in most cases radical surgery was carried out with no evidence of disease recurrence at either short or long term follow-up.

Primary hepatic gastrinomas are even less frequent than those occurring in the extrahepatic biliary tree, with fewer than 20 cases reported in the literature and only one case described in MEN1<sup>[15,20]</sup>. These gastrinomas are generally single nodules, 1-7 cm in diameter, with high radiotracer uptake at octreoscan. Liver resection resulted in prompt normalization of gastrin serum levels with no evidence of recurrence, suggesting these tumors are primary rather than metastases of occult extrahepatic microgastrinomas. Therefore, only three MEN1 ectopic gastrinomas have been described before the present study: two in the extrahepatic biliary tree and one in the liver<sup>[14,15]</sup>. The clinicopathological characteristics of these primary ectopic gastrinomas are summarized in Table 3. All the patients were young females, with associated hyperparathyroidism, pituitary adenoma, and pancreatic functioning or non-functioning tumors. In all cases, the basal gastrin values were high and the ectopic gastrinoma was single, varying from 6 to 15 mm. The two extrahepatic biliary duct cases were detected intraoperatively, while the hepatic gastrinoma was diagnosed preoperatively at CT and SSRS. Lymph nodes displayed neuroendocrine tumor tissue positivity for gastrin in only one patient. In another, a suspected hepatic metastasis was ablated with radiofrequency and alcoholization. In all but one patient, excision of these ectopic gastrinomas was carried out during DP to remove concomitant duodenal or pancreatic neuroendocrine tumors. These patients were eugastrinemic immediately after surgery and at follow-up.

Our experience regarding MEN1 ectopic gastrinomas is similar to that in the literature: gastrinomas were found incidentally during DP in two patients, and detected in the liver in another after recurrence of ZES. The most likely hypothesis explaining the development of gastrinomas in the biliary tree is the presence of stem cells with the capacity to differentiate into specific endocrine cells. Endocrine cells are widely distributed in the epithelial layer of organs that originate from the primitive gut. Argrophil and somatostatin cells have been identified in the glandular epithelium of both the extrahepatic and intrahepatic bile ducts in adult and infant normal livers<sup>[21,22]</sup>. These cells may increase in number, and many kinds of other endocrine cells appear anew and even proliferate in hepatocytes<sup>[22]</sup>. Endocrine cells also occur in the gallbladder, where metaplastic changes of the mucosa can be induced by lithiasis. Similarly, primary gastrinomas developing in the hepatic parenchyma may originate from endocrine cells within the small peripheral intrahepatic biliary tree. In our third case, the gastrinoma was not localized in the hepatic parenchyma, but along the vascular

Price <i>et al</i> <sup>[14]</sup>	F/55	CD (CBD junction)/6 mm	4500/NR	IOUS, discovered at surgery	pHPT, PA, NF-PETs (n°21/1-6 mm)	Distal splenopancreatectomy; RFA hepatic excision BC	Liver, (solitary)	780 (2 yr)
Price <i>et al</i> <sup>[14]</sup>	F/43	CBD/15 × 12 × 1	580/4300	IOUS, discovered at surgery	pHPT, PA, NF-PET (4), DG (3/1-4 mm); GC, lipoma	PPDP; enucleation; gastric excision	Lymph nodes (CBD HA)	86 (2 yr)
Lee <i>et al</i> <sup>[15]</sup>	F/39	Liver (II-III seg)/16 × 15 × 0.9	447/NR	CCT, SSRS, IOUS	pHPT, PA, insuli- noma	WDP; II-III liver segmentec- tomy	-	34 (po)

pHPT: Primary hyperparathyroidism; PA: Pituitary adenoma; DG: Duodenal gastrinoma; GC: Gastric carcinoid; WDP: Whipple's duodenopancreatectomy; PPDP: Pylorus preserving duodenopancreatectomy; D: Duodenal; CBD: Common bile duct; CD: Cystic duct; G: Gallbladder; N: Lymph node; F: Female.

pedicle, suggesting a possible origin from cells arranged along the bile duct.

Histological findings of gastrinomas almost invariably correspond to well-differentiated neuroendocrine tumors, according to the WHO 2010 classification<sup>[23]</sup>. Immunohistochemically, gastrin can be detected in all tumors: many duodenal gastrinomas are multihormonal, and contain single somatostatin or serotonin expressing cells. Approximately 50% of gastrinomas contain PP, glucagon and/or insulin, as well as gastrin. There is a high risk of gastrinomas behaving malignantly, irrespective of size, with frequent lymph node and liver metastases; pancreatic tumors tend to be worse than duodenal lesions. Malignancy cannot be predicted histologically, except on evidence of angioinvasion or infiltration of surrounding tissues. The proliferation fraction can be taken as an indicator of malignancy and a Ki-67 index greater than 10% is invariably associated with development of metastases<sup>[23]</sup>.

Distinguishing ectopic primary gastrinomas from metastatic gastrinomas is not easy. MEN1 gastrinomas of the duodenum or pancreas can metastasize to the liver and be mistaken for ectopics if the primary tumor goes undetected. Several factors in our MEN1 patients helped to exclude the biliary gastrinomas as being metastatic rather than ectopic. First, segmentary biliary ducts and gallbladder are unusual sites for metastasis. Second, the gastrinomas in all the patients were single lesions and with no disease progression, as commonly occurs in metastatic neuroendocrine tumors. No liver or lymph node metastases were found in two cases, while in the third, diagnosed with duodenal gastrinomas metastatic to the regional lymph nodes, gastrin values normalized rapidly at the end of the first operation, but increased one month later.

Surgical treatment of MEN1 gastrinomas is a matter of debate. Some authors suggest simple enucleation of the duodenal mucosa or limited full-thickness duodenal resection, while others recommend DP<sup>[24,25]</sup>. The majority of patients after duodenal resection, are not cured definitively, and hypergastrinemia, as well as metastatic disease, can occur<sup>[26,27]</sup>. According to Thompson<sup>[28]</sup>, the secretin stimulation test proved negative in only one third

of patients submitted to this procedure, in spite of the fact that most of them (68%) remained eugastrinemic for a long postoperative period. DP has been claimed to promote higher curability rates<sup>[27,33]</sup>. In our experience, surgery is curative after resection of affected pancreatic tissue and enucleation of macroscopic nodules in the residual pancreas. On reviewing the literature, the curability rate of DP with regional lymphadenectomy in MEN1 gastrinomas is more than 85%<sup>[27,31,34-36]</sup>. Indeed, resection of the so-called "gastrinoma triangle", achieved with DP, also allows the removal of lesions located in the common bile duct, the cystic duct or the gallbladder. The frequent relapse in MEN1 gastrinoma patients after duodenal excision, could be caused by residual ectopic gastrinomas that were not removed through conservative surgery, rather than to duodenal recurrence.

The possibility of primary gastrinomas arising in the biliary tree in MEN1 syndrome must always be taken into consideration to ensure that appropriate therapy is used, as this ectopic localization can explain surgical failure in MEN1 ZES. Intraoperative palpation, transillumination and IIOUS of the biliary tree could be useful to locate ectopic gastrinomas. The clinical community should be made aware of these findings to improve the management of MEN1 patients.

## COMMENTS

### Background

Surgical removal of duodenal multiple endocrine neoplasia type1 (MEN1) gastrinomas can lead to persistence or recurrence of hypergastrinemia. A possible explanation for this unfavorable outcome could be unrecognized ectopic localization of gastrin-secreting tumors.

### Research frontiers

Primary gastrinomas arising in the biliary tree can explain surgical failure in the treatment of Zollinger-Ellison syndrome in MEN1 syndrome.

### Innovations and breakthroughs

Only twenty cases of hormonally active gastrin-producing or immunostaining gastrin positive neuroendocrine tumors of the extrahepatic biliary tree have been published in the literature, 18 in the sporadic setting and two cases in MEN1. Primary hepatic gastrinomas are even more infrequent than those of the extrahepatic biliary tree, with fewer than 20 cases reported in the literature to date and only one case described in MEN1.

### Applications

Three out of 17 MEN1 patients were found to be affected by an ectopic gastri-

noma located in the biliary tree. These findings suggest that in MEN1 patients, the presence of ectopic biliary tree gastrinoma is not rare, occurring in 17.6% of cases.

### Terminology

MEN1 is a familial syndrome characterized by tumors of the parathyroids, the anterior pituitary and the enteropancreatic endocrine system. Enteropancreatic endocrine neoplasms affect up to 90% of MEN1 patients. Gastrinomas are the most common functional enteropancreatic neuroendocrine tumor and, according to recent literature, are located almost exclusively in the duodenum in MEN1 patients.

### Peer review

These results lead to doubling of the number of cases described in the literature regarding ectopic biliary tree gastrinomas in MEN1 patients. These findings should be made available to the clinical community to improve the management of MEN1 patients.

### Abstract

**AIM:** To evaluate the use of the Roux loop on the postoperative course in patients submitted for gastroenteroanastomosis (GE).

**METHODS:** Non-jaundiced patients ( $n = 41$ ) operated on in the Department of General and Transplant Surgery in Lodz, between January 2010 and December 2011 were enrolled. The tumor was considered unresectable when liver metastases or major vascular involvement were confirmed. Patients were randomized to receive Roux ( $n = 21$ ) or conventional GE ( $n = 20$ ) on a prophylactic basis.

**RESULTS:** The mean time to nasogastric tube withdrawal in Roux GE group was shorter ( $1.4 \pm 0.75$  vs  $2.8 \pm 1.1$ ,  $P < 0.001$ ). Time to starting oral liquids, soft diet and regular diet were decreased ( $2.3 \pm 0.86$  vs  $3.45 \pm 1.19$ ;  $P < 0.001$ ;  $3.3 \pm 0.73$  vs  $4.4 \pm 1.23$ ,  $P < 0.001$  and  $4.5 \pm 0.76$  vs  $5.6 \pm 1.42$ ,  $P = 0.002$ ; respectively). The Roux GE group had a lower use of prokinetics (10 mg thrice daily for  $2.2 \pm 1.8$  d vs  $3.7 \pm 2.6$  d,  $P = 0.044$ ;

total  $62 \pm 49$  mg vs  $111 \pm 79$  mg,  $P = 0.025$ ). The mean hospitalization time following Roux GE was shorter ( $7.7$  d vs  $9.6$  d,  $P = 0.006$ ). Delayed gastric emptying (DGE) was confirmed in 20% after conventional GE but in none of the patients following Roux GE.

**CONCLUSION:** Roux gastrojejunostomy during open abdomen exploration in patients with unresectable pancreatic cancer is easy to perform, decreases the incidence of DGE and lowers hospitalization time.

© 2013 Baishideng Publishing Group Co., Limited. All rights reserved.

**Key words:** Unresectable pancreatic cancer; Roux and conventional gastroenteroanastomosis; Gastroenteroanastomosis; Delayed gastric emptying; Hospital length of stay

**Core tip:** The lower rate of delayed gastric emptying, which determines lower use of prokinetics after Roux compared to conventional antegastric gastroenterostomy (GE) suggested that prophylactic Roux GE should be performed during surgical exploration of patients with unresectable pancreatic head tumors. The length of hospital stay is shorter following palliative Roux GE, thus the treatment costs of these patients are likely to be smaller. Further research is needed on the cost-effectiveness of prophylactic Roux GE in unresectable pancreatic cancer.

## INTRODUCTION

Adenocarcinoma of the pancreas is a serious public health problem. It accounts only for 2% of new cancer diagnoses in both men and women, but it ranks as the fourth leading cause of cancer-related deaths in the United States<sup>[1]</sup>. Despite recent developments in new imaging techniques and improved staging studies, the incidence rate of early pancreatic cancer has changed little over the last decades. Nonetheless, the surgical treatment of pancreatic cancer is palliative in more than 80%, with median overall survival of 6 mo when diagnosed at the metastatic stage<sup>[2]</sup>.

Nowadays, with increasing incidence of pancreatic cancer, annual costs for therapy have risen rapidly<sup>[3-6]</sup>. The average monthly cost of treatment of a patient with pancreatic cancer is almost \$7000; in patients with terminal disease this can rise to as much as \$6555<sup>[7]</sup>. New anti-cancer agents are the largest expenditure, although the greater part of the costs comes from palliative surgical procedures and postoperative hospitalization care<sup>[8]</sup>. Pancreatic surgeries in high-volume centers are associated with low mortality, but high morbidity<sup>[9-12]</sup>. Postoperative complications increase the duration of the hospital stay and treatment costs.

Limited survival benefit and unfavorable cost-effectiveness make surgery for later stages of pancreatic cancer controversial. From this perspective, the optimal method of palliation is uncertain when tumor unresectability is determined at exploration. Shortening of the length of postoperative hospital stay and associated direct costs is an important part of the development of the new palliative procedures.

The aim of our study was to evaluate the influence of two different surgical techniques for creating gastroenterostomy on the postoperative delayed gastric emptying (DGE) rate and the length of hospital stay in non-jaundiced patients with unresectable pancreatic head cancer.

## MATERIALS AND METHODS

This prospective, randomized study comprised non-jaundiced patients with unresectable pancreatic head tumor ( $n = 41$ ), hospitalized in the Department of General and Transplant Surgery of Medical University in Lodz, who received solitary gastroenterostomy on a prophylactic basis from January 2010 to December 2011. Patients were randomized to receive either antecolic Roux ( $n = 21$ ), or conventional antegastric hand-sewn side-to-side gastroenterostomy ( $n = 20$ ). Before surgery, each patient was allotted a code (Roux or conventional group). Blinded investigators performed all postoperative assessments.

All patients gave signed, written, informed consent for the study. Most of the patients ( $n = 37$ ) originally presented with jaundice in the endoscopic units, where the biliary stents have been inserted. As endoscopic retrograde cholangiopancreatography in Roux-en-Y gastric bypass patients is challenging, anastomoses was performed without the stomach being transected or divided.

Therefore, blockage of the biliary stents causing recurrent jaundice could easily have been managed with stent replacement, without the need of percutaneous drainage. The risk of occlusion of stents increased in our group after 3 mo, thus elective stent exchange at 3-6 mo was performed using the standard technique. Changing a stent was available for the Roux and conventional GE group.

The tumor was considered unresectable when the presence of distant metastases or major vascular involvement was confirmed. Conventional GE was performed in a standard side-to-side antecolic fashion, 20 cm from the ligament of Treitz. Roux GE was constructed as follows. A Roux-en-Y intestinal loop, 60 cm long, was prepared by transecting the jejunum 20 cm from the ligament of Treitz, which was then anastomosed to the stomach in an antecolic fashion to construct a latero-lateral gastro-jejunosomy. The intestinal continuity was restored by a jejuno-jejunal, hand-sewn anastomosis. In all cases, the Tru-cut biopsy of the tumor was obtained. All patients without microscopic diagnosis of the cancer were excluded from the study. Eventually, 21 patients with pancreatic cancer confirmed by pathological report received Roux gastroenterostomy and 20 received the conventional GE. Experienced pancreatic surgeons performed all surgeries. All patients provided written informed consent for the study.

The postoperative course of every patient was documented retrospectively, with special regard to the length of hospital stay as a primary endpoint, as well as prokinetic therapy duration, the number of days of nasogastric tube decompression (NGT), the start of oral fluids, soft diet and solid diet (secondary endpoints). According to recent studies<sup>[13]</sup>, DGE was defined as (1) the nasogastric decompression lasting more than 3 postoperative days (POD) or the need for reinsertion of NGT for persistent nausea and vomiting after POD 3; (2) the inability to tolerate a solid diet by POD 7; or (3) the need for prokinetic agents after POD 10. All data were shown in the text and tables as means  $\pm$  SD.

### Statistical analysis

All statistical calculations were performed using Sigma-Plot version 12.0 (Systat Software Inc., San Jose, CA, United States) with the level of statistical significance set at  $P < 0.05$ . To compare the differences in mean length of hospital stay, time to the postoperative nasogastric tube withdrawal, liquids, liquid diet and full regular diet following Roux and conventional GE, we applied the parametric *t* test and non-parametric Mann-Whitney test. In the *t*-test, equal variance tests were performed to demonstrate differences in the use of prokinetics. All data were shown in the text and tables as means or medians  $\pm$  SD.

## RESULTS

Figure 1 is a flow chart of patient enrollment, randomization and progress through the study. The demographics of the patients from both groups are summarized in Ta-

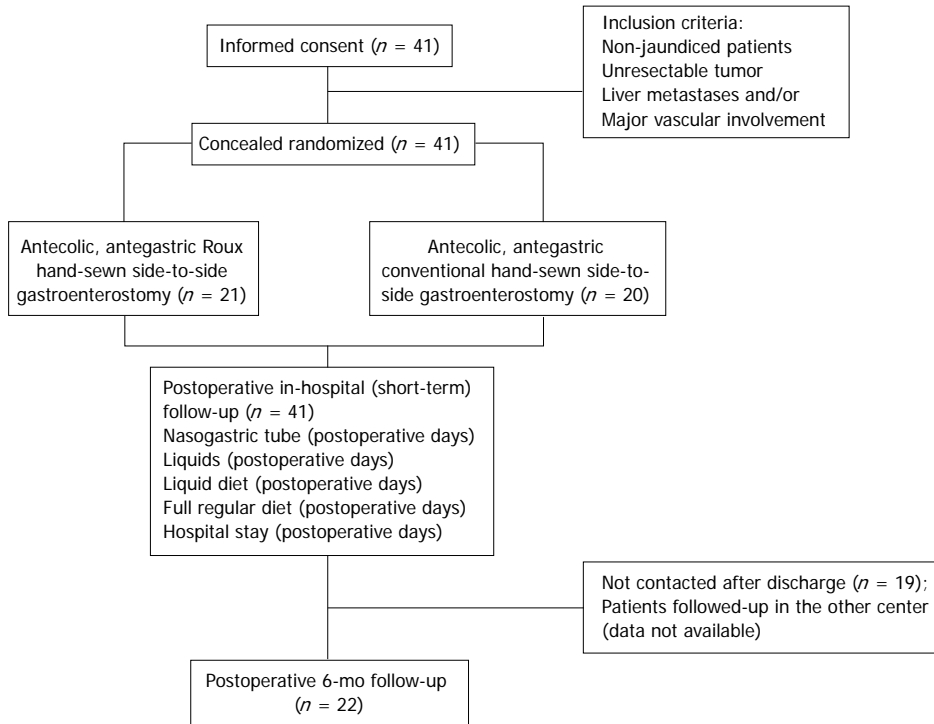

Figure 1 Flow chart of patient enrollment, randomization and progress through the study.

**Table 1 Characteristics and demographics of patients with pancreatic cancer undergoing Roux and conventional gastroenteroanastomosis**

Patients characteristics and demographics	Roux GE	Conventional GE
Age (yr)	60.2 ± 10.6	61.6 ± 8.5
Gender		
Female	10 (50)	8 (40)
Male	10 (50)	12 (60)
Reason for unresectability		
Local	15 (75)	14 (70)
Liver metastases	5 (25)	6 (30)
Indication	Prophylactic	Prophylactic
Reconstruction	Antecolic	Antecolic
Position	Antegastric	Antegastric

Data are expressed as absolute numbers (percentage) or mean ± SD. GE: Gastroenteroanastomosis.

ble 1. The mean operative time of Roux GE was  $55 \pm 25$  min *vs*  $48 \pm 36$  min for conventional GE. Shorter mean time to the postoperative nasogastric tube withdrawal (by 50%,  $P < 0.001$ ), liquids (by 33.3%,  $P < 0.001$ ), liquid diet (by 25%,  $P < 0.001$ ) and full regular diet (by 19.6%,  $P = 0.002$ ) following Roux in contrast to conventional GE was demonstrated (Table 2). No patients required reinsertion of the nasogastric tube. Delayed gastric emptying did not occur after Roux GE, whereas it was confirmed in four cases after conventional GE (20%). The Roux GE group had a lower use of prokinetics compared with conventional GE (10 mg of metoclopramide iv thrice daily for  $2.2 \pm 1.8$  d *vs*  $3.7 \pm 2.6$  d,  $P = 0.044$ ; total  $62 \pm 49$  mg *vs*  $111 \pm 79$  mg,  $P = 0.025$ ; respectively). The mean length of hospital stay was shorter following pallia-

tive Roux GE (7.7 d *vs* 9.6 d;  $P = 0.006$ ). The recurrence of jaundice and cholangitis (23% of patients) and mean survival were comparable in both groups during 6-mo follow-up.

## DISCUSSION

The palliative treatment of patients with unresectable pancreatic cancer is a significant economic burden to public healthcare. As limited survival is expected and the total costs of treatment per incident case are high, there are general concerns about the necessity of palliative procedures, which most frequently surgical in patients with pancreatic cancer. Biliary stents or biliary bypass in patients with jaundice have a definite role because they decrease morbidity; however, performing prophylactic gastroenterostomy is still a matter of debate for several reasons. First, it is difficult to predict the number of patients who will develop duodenal obstruction. Second, delayed gastric emptying is a frequent complication after gastroenterostomy. It is usually not a life-threatening condition and can be treated conservatively, although it compromises quality of life, prolongs the hospital stay and adds to hospital costs in patients with a very limited life expectancy. Recent reports have proved that prophylactic gastroenterostomy should be constructed in patients that are found to have unresectable pancreatic cancer at exploration<sup>[14]</sup>; therefore, it is necessary to decrease the incidence of DGE.

The occurrence of DGE after gastroenterostomy varies from 9% to 26%<sup>[15]</sup>. These differences may reflect considerable variations in DGE definition in previous

**Table 2** Postoperative course following Roux and conventional gastroenteroanastomosis

Postoperative course	Roux GE		Conventional GE		Differences in the Roux and conventional GE ( <i>P</i> value)	Power analysis <sup>1</sup>
	mean $\pm$ SD	Median	mean $\pm$ SD	Median		
Nasogastric tube (postoperative days)	1.4 $\pm$ 0.75	1	2.8 $\pm$ 1.1	3	< 0.001	0.962
Liquids (postoperative days)	2.3 $\pm$ 0.86	2	3.45 $\pm$ 1.19	3	< 0.001	0.86
Liquid diet (postoperative days)	3.3 $\pm$ 0.73	3	4.4 $\pm$ 1.23	4	< 0.001	0.853
Full regular diet (postoperative days)	4.5 $\pm$ 0.76	4	5.6 $\pm$ 1.42	5	0.002	0.784
Hospital stay (postoperative days)	7.7 $\pm$ 3.01	7	9.6 $\pm$ 2.79	10	0.006	0.499

<sup>1</sup>Power *t*-test analysis was performed to justify the sample size. DGE: Delayed gastric emptying; GE: Gastroenteroanastomosis.

studies. However, we used the strict definition of DGE suggested by the International Study Group of Pancreatic Cancer<sup>[13]</sup>.

DGE is a multifactorial problem, which has been linked to tumor involvement of the coeliac axis and interruption of splanchnic innervations, as well as the technique of gastroenterostomy<sup>[15-20]</sup>. Our study confirmed that construction of a gastrojejunal anastomosis with an isolated Roux loop was beneficial (Table 2). The incidence of postoperative DGE was reduced. The procedure was technically simple and convalescence was rapid. Success may depend on already known parameters. Roux anastomosis remains mechanically efficient; however, postoperative gastric motility is temporarily impaired.

The development of laparoscopic surgical methods offers further reduction in costs associated treatment of unresectable pancreatic cancer. Laparoscopic gastric bypass is an effective and safe procedure for patients with gastric outlet obstruction. The hospital stay is shorter than after open surgery and recovery is more rapid<sup>[21]</sup>. It is technically feasible<sup>[22]</sup> for Roux gastrojejunostomy to be utilized for laparoscopic approach<sup>[23-26]</sup>. Thus, it may reveal new perspectives in prophylactic gastrojejunostomy in patients with unresectable pancreatic cancer. If curative resection is not possible, the response to chemotherapy is expected. Minimally invasive laparoscopic Roux GE may enable the patient to receive postoperative chemotherapy earlier. However, until now, the laparoscopic approach in pancreatic cancer has remained limited.

In conclusion, Roux gastroenterostomy should be performed routinely during open abdomen exploration in patients with unresectable pancreatic head carcinoma, because it is easy to perform, is free of specific complications, decreases incidence of DGE, and reduces the length of hospital stay and associated health care costs.

## COMMENTS

### Background

The surgical palliation is an important component of the treatment of pancreatic head cancer. However, the optimal method of palliation is uncertain when tumor unresectability is determined at exploration.

### Research frontiers

Prophylactic gastroenterostomy should be constructed in patients who are found to have unresectable pancreatic cancer at exploration. Nevertheless, delayed gastric emptying is a frequent complication after gastroenterostomy. This research evaluated the use of different surgical techniques for creating gastroenterostomy on the postoperative delayed gastric emptying (DGE) rate and the

hospital length of stay in non-jaundiced patients with unresectable pancreatic head cancer.

### Innovations and breakthroughs

This is the first paper to precisely describe differences in the postoperative course between antecolic Roux and conventional antegastric hand-sewn side-to-side *gastroenterostomy* in patients with unresectable pancreatic head cancer.

### Applications

The study results suggest that Roux instead of conventional antegastric gastroenterostomy should be performed routinely during open abdomen exploration in patients with unresectable pancreatic head carcinoma, because it is easy to perform, is free of specific complications, decreases incidence of DGE, and reduces the length of hospital stay and associated health care costs.

### Peer review

The results evaluate the influence of two different surgical techniques of creating gastroenterostomy on the postoperative delayed gastric emptying rate and the length of stay hospital in non-jaundiced patients with unresectable pancreatic head cancer. This is an interesting randomized study, though it suffers from many vulnerabilities.

of ESD, as well as complications were registered. In patients, their clinical, endoscopic and histologic evolution was additionally added.

**RESULTS:** Thirty *en bloc* ESDs were carried out in animal models. The mean  $\pm$  SD size of the pieces was of  $28.4 \pm 1.2$  mm, and the time of ESD was  $41.7 \pm 2.4$  min. The time of ESD in the first 15 procedures was  $43.0 \pm 3.0$  min whereas in the next 15 procedures, the time was  $40.3 \pm 3.9$  min,  $P = 0.588$ . The speed in the first 15 ESDs was  $1.25 \pm 0.11$  cm<sup>2</sup>/min vs  $2.12 \pm 0.36$  cm<sup>2</sup>/min in the remaining 15,  $P = 0.028$ . There were no complications. In patients, 5 lesions were resected *en bloc*. The size of the pieces was  $25.2 \pm 5.1$  mm and the time was  $85.0 \pm 25.6$  min. Endoscopic and histological controls did not show evidence of residual neoplastic tissue.

**CONCLUSION:** A sequential ESD training program of a unique endoscopist, based on the practice in porcine models, contributed to learning ESD for its subsequent application in humans, yielding good results in efficacy and safety.

### Abstract

**AIM:** To assess whether the use of porcine models is useful for learning endoscopic submucosal dissection (ESD), thus contributing to its subsequent application in human patients.

**METHODS:** This study/learning process was carried out in 3 phases: Phase I : *Ex vivo* animal; Phase II : *In vivo* animal; Phase III: Humans. One endoscopist performed 30 gastric ESDs in porcine models, and later 5 gastric ESDs in 5 patients. The ESD was done following the method practiced at the National Cancer Center in Tokyo, Japan. Technical aspects, size, time and speed

**Key words:** Endoscopic submucosal dissection; Porcine models; Animal models; Training

**Core tip:** This study was conducted with the purpose of determining in a prospective manner the results, the efficacy and safety of learning endoscopic submucosal dissection (ESD), in porcine models and assessing whether this practice contributes to subsequent application of this technique in patients. The present study shows interesting findings in this regards. The authors have demonstrated the value of a sequential ESD program and believe that it can contribute to disseminate this technique and encourage its learning mostly in western countries where it is still not a common prac-

tice for different reasons.

Gastric endoscopic submucosal dissection: From animal model to patient. *World J Gastroenterol* 2013; 19(45): 8326-8334 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i45/8326.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i45.8326>

## INTRODUCTION

Endoscopic submucosal dissection (ESD) is a technique for resection of early neoplastic gastric lesions. It is applied to extirpate large lesions (greater than 15 mm), removing in one bloc more healthy adjacent tissue (horizontal oncologic border) and more submucosal tissue (vertical oncologic border), thus obtaining more complete resections than with the standard mucosectomy and decreasing the probability of relapses<sup>[1-5]</sup>. The ESD was developed in 1999 in Japan, initially for resection of gastric tumors, and later of esophageal, colonic and rectal lesions<sup>[1,2]</sup>. Although it is an effective, safe and widely accepted<sup>[3,4]</sup> technique in experienced hands, its application in Western countries has not yet been extensive due to several reasons. One of them is that the main indication of ESD in Japan is early gastric cancer, which has a high prevalence in that country but is less frequent in the Western world, which makes learning this technique a difficult task<sup>[5]</sup>.

To learn the ESD technique, Japanese authors have suggested a structured and progressive training program, with the recommendation of being initially applied in porcine models. First *ex vivo* and then *in vivo* in order to acquire the necessary technical skill and experience before moving on to practice ESD in patients, mainly when it cannot be performed under the direct supervision of experts<sup>[6]</sup>.

Despite these recommendations, there are not many publications on gastric ESD results in porcine models as part of the training for the practice of this technique<sup>[7-10]</sup>.

### Aims

To prospectively determine the results, efficacy and safety of ESD in porcine models during the training period. To assess whether the practice in porcine models contributes to its subsequent application in patients.

## MATERIALS AND METHODS

One endoscopist with experience in ESD (Parra-Blanco A) trained a younger one (González N), in that technique. This one had previous experience in diagnostic and emergency gastroscopy and therapeutic colonoscopy and in performing endoscopic mucosal resection. During this training period, González N observed 6 ESD procedures, of which 5 were conducted in *ex vivo* models and one in

Figure 1 Plastic box with cadaveric model.

the stomach of a live porcine. He additionally performed two gastric dissections in cadaveric models and one dissection of a gastric lesion in an *in vivo* model.

The training was further supplemented with the reading of articles related to ESD, in order to internalize theoretical concepts along with the visualization of videos showing how this technique was applied by Japanese experts.

He finally carried out a study/learning process in 3 phases: Phase I : *Ex vivo* animals; Phase II : *In vivo* animals; Phase III: Humans.

### Animal model

**Ex vivo model:** For the cadaveric stomach models a plastic box (45 cm × 30 cm × 20 cm) that had a plastic tube (overtube) to which the esophagus was connected, was designed (Figure 1). On some occasions, a cut-out 10 mL plastic syringe was used as a connecting device with a 14 mm diameter to connect the esophaguses of small pigs.

Twenty cadaveric stomachs of pigs ranging between 20 and 150 kg were used. In some stomachs 2 dissections were performed. The stomachs, which were stored in the freezer at a temperature of -16 degrees Celsius, were collected 12 h prior to the procedure and were left at room temperature for their subsequent use, in order to preserve the wall elasticity at the moment of performing the procedure. In most cases, the stomachs were opened on the greater curvature so that profuse washing with water and soap could be carried out. This allowed us to perform a thorough cleaning of the mucosa with a brush and later drying it with gauze, thus achieving adequate cleaning without the inconvenience of persistent mucus which is hard to eliminate. Later the stomachs were sutured with coated vicryl suture or prolene suture 3-0 without any insufflation inconvenience whatsoever in any of the cases (Figure 2).

In those cases where the stomachs were closed, a 10 cm long incision was performed with a scalpel on the greater curvature. Another advantage that an open stomach offers is the possibility of carrying out one or more artificial lesions of different diameters and in different topographies through tattooing with Chinese ink or

**Figure 2** The stomachs were sutured with coated vicryl suture or prolene suture 3-0 without any insufflation inconvenience whatsoever in any of the cases. A: Open porcine stomach greater curvature; B: Porcine stomach sutured with vicryl.

**Figure 3** Tattooing artificial lesion with methylene blue.

methylene blue (Figure 3).

To adhere the esophagus to the overtube, plastic clamps were used to prevent the air from coming out and slipping with the movements of the endoscope.

To conduct the study, an Olympus gastroscope (GIF-CV-160: 9.2 mm, diameter/2.8 mm, therapeutic channel) was used and then intended for use in models.

***In vivo* model:** Two domestic female pigs (*Sus scrofa domestica*) of about 30-40 kg underwent ESD. For 48 h they were given a liquid diet and experienced an 8 h-long total fast prior to the procedure. The general anesthesia was administered and controlled by 2 expert veterinarians, who were in charge of monitoring the vital signs and control to prevent complications.

As premedication, 15 mg/kg + 2 ketamine and 1.1 mg/kg intramuscular xylazine were used. For anesthetic induction 5 mg/kg + 0.5 mg/kg (*iv*) midazolam was administered, and for maintenance sedation a dilution of similar amounts of 5% ketamine and 5% midazolam (*iv*), administering approximately 2 mL every 10 min as needed and according to breathing frequency.

Once the procedures were over, a liquid diet was administered for 24 h and then a hypercaloric diet. Omeprazole 20 mg was administered orally every 12 h until the pigs were sacrificed by veterinarians as regulations indicate, following quality standards and required

controls in this type of study. Animal handling was carried out by 2 veterinarians in compliance with the current regulations<sup>[11]</sup>.

### ***Endoscopic submucosal dissection in patients***

After performing 30 ESDs, number recommended by Japanese experts<sup>[11]</sup>, 28 in the cadaveric animal model and 2 ESDs in *in vivo* animal models, 5 gastric dissection procedures were carried out in 5 patients, previous consultation of each case with one of the authors (Parra-Blanco A). The patients were told to discontinue NSAIDs and/or anticoagulants 15 d prior to the procedure, having to present at the moment of the appointment the coagulation test done the day before. The studies were done with an Olympus gastroscope (GIF-CV-160).

The first two cases were carried out in a surgical room and were treated under general anesthesia. A surgical team was present at the operating room in the event that some complications might occur. The other 3 cases were performed in a therapeutic endoscopy room with general anaesthesia. The hospital emergency surgery team was well aware of the procedure.

All the patients were informed of the benefits and of the possible serious complications that might arise with the use of this technique, and signed an informed consent.

An endoscopic control was carried out monthly until the fourth month, with conventional endoscopic vision, chromoendoscopy with FICE using filter number 4 and magnification. A photographic register was made and biopsies were taken of the scar area and of suspicious areas 2 or 3 mo after the procedures.

### ***Technique used for ESD***

The ESD was done in a similar way than the one generally carried out at the National Cancer Center in Japan<sup>[7]</sup>: (1) artificial lesion marking using a coagulation current with needle knife (NK: Needle Knife, Boston, Scientifics, Natick, Massachusetts) or dual knife (Olympus KD-650L); (2) a mixture solution (including 100 mL of normal saline, 1 mL of methylene blue, 1 mL of epinephrine or hyaluronic acid alone), was injected into the submucosa; (3) circumferential incision of 5 mm was made out-

side of the artificial lesion. The incision was performed with NK, dual knife or insulated tip needle knife (IT Knife 2 o, Olympus KD-611L) as single instruments or combined (NK-IT Knife 2 or dual Knife-IT Knife 2). In cases where IT Knife 2 was used, 2 cuts were made with needle knife (hours 6 and 12) to facilitate the incision; on some occasions, it was necessary to perform 1 or 2 more incisions (hours 11 and 2); and (4) the submucosal dissection was performed in all the cases with IT Knife 2, and at times with NK. In the majority of the cases, a transparent cap (Olympus D-201-12704, Tokyo, Japan) was attached to the tip of the gastroscope to provide direct views of the submucosal layer.

For the purpose of facilitating dissection through a better visualization of the plane separation between the submucosa and the muscular layer, in 3 cases ESD was carried out with the clip technique (Resolution Clip. Boston Scientifics R) and an elastic band<sup>[12]</sup>.

The Erbotom ICC 200 ERBE system was used (ERBE, Elektromedizin GmbH, Tübingen, Germany), effect 3, endocut mode with a potency of 120-60 W was used for the circumferential incision; 80-40 W for the submucosal incision, and soft coagulation (40 W) for the haemostasis.

For bleeding control, a coagulation tweezer (Coag-rasper, FD-41OLR) with soft coagulation was used. All the resected pieces were stacked on cork with pins and their measurements were calculated in millimeters and photographically registered. All the procedures were recorded on DVD.

For the prospective analysis of the results obtained, the following variables were registered: (1) lesion topography; (2) size of the resected lesion; (3) total dissection time (circumferential cut and submucosal dissection); (4) surgical instruments and technique used; (5) type of resection (*en bloc* resection or fragmented resection); (6) complications (perforation, bleeding); (7) weight of pig whose stomach was used; and (8) condition of the stomach; fresh (cadaveric but not frozen), thawed (after preservation in freezer) or *in vivo* porcine. In the case of the patients the following variables were registered: whether the ESD was complete (resection with a tumor-free margin in which both the lateral and basal margins were free of tumor cells) or partial (resection in which the tumor extended into the lateral or basal margin, or the margins were indeterminate because of artificial burn effects) and the clinical, endoscopic and histologic evolution.

### Statistical analysis

For the statistical analysis, the description with mean values (standard deviation) for quantitative variables and frequencies for qualitative variables is presented. The Student's *t* test was used (statistical significance threshold of  $\alpha = 0.05$ ) after assumption of normal distribution, to verify differences in terms of qualitative variables. The statistical software used was SPSS 17.0.

## RESULTS

### In animal model

In a period of 5 mo and 13 d, 30 ESDs were performed with an average of 1.4 ESD per week (Table 1). Eighty percent of these ESDs ( $n = 24$ ) were done in frozen stomachs, 13.3% ( $n = 4$ ) in fresh stomachs, and 6.7% (2) in *in vivo* stomachs. Concerning the topography, 90% ( $n = 27$ ) of ESDs were performed in the gastric body, 6.7% (2) in antrum and 3.3% (1), in cardias. In the two *in vivo* models, the regions were antrum and body. In the four fresh stomachs, 3 were in the body and 1 in the antrum. In the 24 thawed stomachs, 23 were in the body and the remaining one in the cardias. The mean  $\pm$  SD size of the pieces was of  $28.4 \pm 1.2$  mm (range: 20-45 mm).

Keeping in mind the condition of the stomach, the mean  $\pm$  SD size for the thawed stomachs was of  $28.8 \pm 1.4$  mm (range: 22.0-45.0 mm). For the fresh stomachs, the mean  $\pm$  SD size was of  $24.5 \pm 0.9$  mm (range: 22.0-26.0 mm). In the cases of *in vivo* stomachs, the mean  $\pm$  SD size was of  $32.5.6 \pm 2.5$  mm (range: 30-35 mm).

According to the topography where the procedure was performed, the following was observed in relation to the size: for the region of the antrum the mean  $\pm$  SD size was of  $28.5 \pm 6.5$  mm (range: 22-35 mm). For the region of the body, the mean  $\pm$  SD size was of  $28.6 \pm 1.2$  mm (range: 20.0-45.0 mm). In the case of the cardias, the size was of 25.0 mm.

The total mean  $\pm$  SD time of the procedure was  $41.7 \pm 2.4$  min (range: 18-70 min). If a cutoff value of 30 mm for the size of the resected piece is established, the dissection time for those lesser than 30 mm was of  $38.0 \pm 2.3$  min, whereas for sizes greater or equal than 30 mm, was  $45.9 \pm 4.0$  min. The difference in dissection time was of 8 min between both size categories with a cutoff value of 30 mm difference which is not significant,  $P = 0.104$ . The mean  $\pm$  SD weight of the pigs where the pieces were obtained from was  $41.7 \pm 6.1$  kg (range: 20-150 kg).

The total mean  $\pm$  SD time of ESD (circumferential cut and submucosal dissection) in the first 15 procedures was  $43.0 \pm 3.0$  min (range: 22-70 min). In the next 15 procedures, the mean  $\pm$  SD time dropped to  $40.3 \pm 3.9$  min (range: 18-70 min), having found no significant differences for the dissection time between the first and the second 15 procedures ( $P = 0.588$ ). The mean  $\pm$  SD size of the pieces in the first 15 procedures was of  $26.1 \pm 1.4$  mm and for the second 15 procedures the mean  $\pm$  SD size increased significantly to  $30 \pm 1.7$  mm ( $P = 0.039$ ). In order to assess if there was any progress in learning, the ESD speed in the second 15 procedures was also calculated and this was compared to the ESD speed in the first 15 procedures. For this purpose, the area of the resected pieces was calculated by using the formula for calculating the area of a circle: ( $\text{Area} = \text{Pi} \times \text{radius}^2$ ) ESD speed was calculated by dividing the area of the resected piece in relation to the total dissection time ( $\text{speed} =$

**Figure 4** Endoscopic dissection speed (cm<sup>2</sup>/min) according endoscopic submucosal dissection group. Shows that the median rate in the first 15 dissections were placed in 1.28 cm<sup>2</sup>/min and in the second group was 1.89 cm<sup>2</sup>/min, showing an increase in the speed of dissection in the second group,  $P = 0.028$ .

area/time).

In the first 15 dissections, the mean  $\pm$  SD speed was  $1.25 \pm 0.11$  cm<sup>2</sup>/min (95%CI: 1.02-1.48). In the case of the second 15 dissections, the mean  $\pm$  SD speed was of  $2.12 \pm 0.36$  cm<sup>2</sup>/min (95%CI: 1.35-2.90) (Figure 4).

Through a Student's *t* test for independent samples, it can be shown that there are statistically significant differences in the speed of both dissection groups ( $P = 0.028$ ).

Due to a possible variation related to the state of the stomach (thawed, fresh, *in vivo*), additionally, only the time of the resections carried out in pre-frozen stomachs in the first 15 ESDs and in the group of the second 15 were analyzed. In the first 15 ESD, 11 resections were performed in thawed stomachs with a mean dissection time of 43.6 min *vs* 13 dissections in thawed stomachs in the second group with a mean time of 38.4 min, these differences were not significant ( $P = 0.386$ ).

In the 30 dissection cases the ESDs were completed achieving the resection of the pieces in one single bloc on all occasions. There were no complications (perforation) in this group, as there was no bleeding in the *in vivo* models.

### In patients

Five surgical procedures in 5 patients with neoplastic lesions (intramucosal carcinoma, 2 adenomatous lesions with low grade dysplasia, and 2 adenomatous lesions with high grade dysplasia) were performed in a period of 6 mo. The endoscopic (Paris classification<sup>[13]</sup>), and histologic characteristics and results are shown in Table 2. The mean  $\pm$  SD size of the lesions was of  $25.2 \pm 5.1$  mm

**Table 2** Endoscopic submucosal dissection results in humans

Topography	Size (mm)	Lesion type <sup>1</sup>	Total time ESD (min)	<i>En bloc</i> resection	Complications	Histology	Complete ESD <sup>2</sup>
Incisura angularis	25	0- II a	65	Yes	No	Adenoma LGD	Yes
Antrum	20	0- II a	60	Yes	No	Intramucosal carcinoma	Yes
Antrum	18	0- II a	30	Yes	No	Adenoma HGD	Yes
Body	18	0- II a	90	Yes	No	Adenoma LGD	Yes
Subcarinal	45	0- II a	180	Yes	Bleeding	Adenoma HGD	Yes

<sup>1</sup>Paris Endoscopic Classification; <sup>2</sup>Anatomopathological study: resection *en bloc*, lateral and vertical margins free of neoplastic tissue. LGD: Low grade dysplasia; HGD: High degree dysplasia; ESD: Endoscopic submucosal dissection.

(range: 18.0–45.0 mm).

In all the cases, the medical instrument used for the dissection was IT-Knife 2. The mean  $\pm$  SD dissection time was  $85.0 \pm 25.6$  min (range: 30–180 min).

In 3 of the procedures in the incisura angularis and in the antrum, the dissection time did not exceed 65 min, reaching 90 min in the high body region and 180 min in the subcarinal area. The piece of lesser size (18.0 mm) was done in 30 min, while the larger lesion (45.0 mm.) lasted 180 min. In one of the procedures some bleeding occurred, which was controlled satisfactorily with a coagulation tweezer.

The five lesions were resected *en bloc*. The pathology study of the pieces reported that the dissections were complete and curative, since no submucosal invasion or vascular or lymphatic involvement was found, nor were detected cell nests of the undifferentiated type in none of the cases (*en bloc* R0 resection).

After the procedures were completed, all the patients went into a surgical room; per oral was discontinued for 24 h; 1000cc *iv* glucophysiological serum was administered plus 2 g of potassium chloride every 12 h, and Omeprazole 40 mg *iv* every 12 h for 72 h. When discharged from hospital, they all received proton pump inhibitors in simple dosage every 12 h until complete scar formation was confirmed by endoscopy.

All of the patients had a good short (immediate post-procedure) and long-term (4 mo post-procedure) clinical evolution without abdominal pain or evidence of digestive bleeding. In the endoscopic controls conducted with conventional vision, intelligent chromoendoscopy with FICE (Filter 4) and magnification, there was no evidence of residual neoplastic tissue. The biopsies conducted in the scar areas, taken 2 or 3 mo after each procedure tested negative for residual neoplastic tissue.

## DISCUSSION

The endoscopic submucosal dissection is a complex and difficult procedure to learn, being conducted mostly in Asian countries, where a large number of superficial gastrointestinal lesions are diagnosed and treated by this technique.

The difficulties inherent to this procedure, the long process of training required to perform it, and the low frequency of superficial gastric lesions diagnosed in Western countries are some of the causes that explain

why very few medical centers outside Japan perform this procedure. Furthermore, access to learning and application of this technique is limited due to lack of Japanese experts in most Western countries. Although outstanding scientific evidence has been published on its applications and results, the publications related to its teaching are scarce, not existing to date a universally accepted standardized learning program on porcine models for subsequent application of this technique in patients.

Gotoda *et al.*<sup>[6]</sup>, have developed training programs on ESD in porcine models. They suggest that these models are a way of rapid rise into the learning curve of this technique in a relatively short period of time and thus may favor its learning in Western countries. They also state that at least 30 submucosal dissections of gastric lesions should be performed to achieve a certain degree of mastery, since at the beginning of the learning curve it is estimated that the perforation rate may reach 20%<sup>[6]</sup>.

In Uruguay, the standardization of ESD teaching does not yet exist and the lack of experts on this technique hampers its dissemination. Due to this inconvenience, as it was formerly pointed out, the practice of ESD in institutions where experts are not available may be developed through the combination of training in animal models before performing endoscopic procedures of this nature in humans. Some authors have described their teaching experience in the acquisition of technical skills using porcine models for the training of ESD for gastric lesions.

Vázquez-Sequeiros *et al.*<sup>[8]</sup>, have described a sequential training program on ESD with the aim of identifying a cheap, safe, efficient and reproducible method for the learning and dissemination of this technique in Spain. According to these authors, such training can be conducted in 4 phases: (1) theoretical phase based on the acquisition of basic knowledge on ESD and in the review of scientific literature; (2) training in an *ex vivo* animal model; (3) training in an *in vivo* animal supervised by an expert; and (4) application of the ESD technique in patients. In this study, 4 endoscopists performed a total of 12 gastric ESDs in porcine models (6 in *ex vivo* model and 6 in *in vivo* model) and later a gastric ESD supervised by an expert in one patient.

Tanimoto *et al.*<sup>[14]</sup> assessed the usefulness of an *in vivo* canine model for ESD practice. They performed 5 esophageal dissections and 5 stomach dissections, completing all the procedures without any complications.

Even though the number and size of the resected pieces were small, the authors recommend the use of this model, which being an *in vivo* model, has the advantage of serving for a more real context and closer to dissections conducted in animals.

Parra-Blanco *et al*<sup>[7]</sup>, have proposed an ESD learning strategy based on an *ex vivo* gastric porcine model and in an *in vivo* porcine model. After an initial ESD learning period conducted in isolated animal stomachs and supervised by an expert, one endoscopist performed a training procedure in esophagus and stomach in an *in vivo* porcine model, dividing the learning period in 2 phases, conducting in each phase 11 ESDs. As the learning process progressed, it was noticed that without existing differences in the size of the resected pieces, only if the gastric resections were considered, the time spent on the dissection phase and the total time were lesser in the second phase as compared to the first one, which suggested the acquisition of a certain skill in ESD performance. However according to the authors, one of the restrictions of this study was the fact that there was no assessment of the impact of previous training on *ex vivo* animal model under supervision, which does not prove if this initial step is necessary to undertake self-learning in animal model. The subsequent impact of animal training in the ESD performance in humans was not evaluated either.

In the present study, the impact of training on the animal model was evaluated early in human patients; therefore, there is a description of the results when the same endoscopist applies the technique in patients after the training program in animal models, thus yielding good results in terms of efficacy and safety.

In relation to the state of the stomachs at the moment of performing the procedures, in most cases, ESDs were performed in pre-frozen porcine stomachs because of its usefulness. However, the authors recommend, if possible, using fresh stomachs due to the fact that the walls are frequently more rigid in pre-frozen organs and, especially, submucosal injection may prove more difficult.

Another important element to be keep in mind is the right size of the organs. Large pigs (greater than 70 kg) have larger stomachs which allow for the performance of multiple resections in different places. In this study, porcine organs ranging from 20 to 150 kg were used. The organs of smaller animals have thinner walls with a greater risk of perforation, and the movements in the stomach are limited due to their reduced size. The use of small stomachs might have the potential benefit of requiring greater skill and therefore the endoscopist will have a greater degree of difficulty. Consequently, the authors recommend the use of small stomachs after an initial practice in large organs in order to acquire greater skill.

Concerning the type of animal model, the *in vivo* porcine model has proven to be more adequate for endoscopic formation in the upper digestive tract<sup>[15-17]</sup>. It is important and recommendable to perform ESD in *in vivo* porcine model as a prior step to the application of

this technique in humans, since this type of model offers several advantages. The principal advantage of the *in vivo* model, as compared to the *ex vivo* model is that the former is more realistic, with presence of peristaltic, intraluminal secretions, and hemorrhage is a possible complication. However, in an initial stage, the basic movements and the ESD strategy may and should be first learned in *ex vivo* models, and probably there is no justifications for using *in vivo* pigs initially, which are more expensive, require more preparation and technical assistance, and it would not be ethically correct<sup>[18]</sup>.

As an objective variable for measuring skill acquisition and learning progress, the following markers of technical skill in ESD have been proposed: decrease in time employed in the procedure, greater speed in the dissection process and/or achieving a greater complete resection rate without need of help from the supervising endoscopist.

Based on the above mentioned, the results of this study suggest that there was progress in the learning curve in animal models. As it can be seen in the results, the time required for the dissection was reduced in the second 15 procedures performed in porcine models. Even though this difference was not significant when compared to the first 15 procedures in animal model, this could be due to the fact that the size of the pieces in the second 15 procedures increased in a significant way. Likewise, it can also be noticed that there was an increase in the dissection speed in the second ESDs, this being the sign of greater acquisition of skill in the technique and therefore progress in its learning.

Distension and elasticity of the stomach walls in different samples (fresh, thawed or *in vivo*) may vary and thus interfere in the dissection time. As it is increased in the frozen models because of lesser distension and elasticity of the tissues, only the times of the dissections performed in frozen stomachs in the first 15 and in the second 15 procedures were compared. In the analysis of the results it was observed that in the second group the procedures were also performed in shorter time, although this difference was not significant. Therefore, the reduction in time cannot be attributed to the state of the stomachs.

One of the restrictions of this study is the fact that very few cases were performed in human patients. Furthermore, it is the experience of just one center and one single endoscopist. The ability and experience of each endoscopist is different, not homogeneous, so this result does not assure its reproducibility.

With respect to the pattern of lesions, usually, the pattern of early gastric cancer is detected as 0-I, II-C or 0-III types in Japan and most of the world. However, in the present study, the most common early gastric cancer was the type II a.

In this article we have discussed the learning curve for ESD, but it is very important to mention that these techniques are useful only after acquiring proficiency in an accurate diagnosis of the early gastrointestinal cancer lesions with the adequate technology and knowledge of

early gastrointestinal cancer classifications (*i.e.*, Vienna and Paris Classifications; Chromoendoscopy and Magnification).

Therefore, before starting the practice of this technique, it is necessary and more important that the endoscopist knows how to thoroughly examine the neoplastic lesion to achieve the identification of endoscopic characteristics that predict the existence of deep invasion, an increased risk of lymph node metastasis and to demarcate the line between the area with cancer and without cancer. This step, prior to the ESD, is very important, because it may avoid unnecessary surgical resection or endoscopy. Furthermore, it is important that before starting to develop this technique, the endoscopist acquires ample experience in therapeutic endoscopy, since he must be able to deal with and solve possible complications during the ESD process, such as bleeding or perforation.

It is worth mentioning that even though the training in ESD in porcine models is safe and accessible, it is recommendable to carry out all of the steps suggested before performing this technique in humans. Besides, it is important to highlight that to define the learning curve only in terms of time, dissection speed or number of procedures conducted is not appropriate since this may vary according to the conditions of each center, and mostly according to the skills of each endoscopist. This is the reason why it is very important to be self-critical, know each one's limitations and to receive permanent feedback, so that the ESD practice can be carried out in a safe and efficient way. When the time comes to move on to performing ESD in humans, it is recommendable that this practice be progressive, starting with resection of lesions in areas with lesser technical difficulty (antrum, incisura angularis) and later ESD in lesions with greater difficulty (lesser curvature, subcardinal region).

Due to the scarce number of patients that can be benefited of the application of ESD in Western countries (mostly due to the low prevalence of early gastric neoplasia), the interval between dissection procedures in humans can be too long. This can be the reason why in this period the technical skills and acquired confidence can decrease. To overcome this situation, the authors recommend that before the performance of this technique in humans, it is necessary to previously perform it in animal model.

In Latin America, the standardization of ESD teaching does not exist and there is shortage of experts in this technique, thus hampering its dissemination. For this reason, it is important to train endoscopy teams to perform ESD so that they can share the knowledge developed on the basis of the experience acquired during the learning curve and to form multicenter endoscopy teams who can do research work, develop this technique in-depth and design structured training programs suited to the needs and resources available.

In conclusion, according to the analysis of the results obtained, the authors conclude that in Uruguay an ESD sequential training program of a unique endoscopist,

initially based on practice in porcine model (performing the number of dissections recommended by Japanese experts), conducted in the absence of experts to supervise the procedures, contributed to the learning of the ESD technique, and yielded promising results in efficacy and safety for its subsequent application in humans, even though the sample is small.

## ACKNOWLEDGMENTS

The authors wish to express their sincere thanks to veterinary doctors, Dr. Diego Fernández and Dr. Lorena López for their invaluable cooperation in the preparation, handling and administration of the anaesthesia in the *in vivo* animal models, Mrs. Elizabeth Silva and Mr. Evaristo González for supplying the cadaveric stomachs and the *in vivo* models. We would also like to extend our appreciation to Assistant Endoscopists, Sandra Mellán, Adrián Duarte, Dardo Debenedetti, to Administrative Staff Member, Karina Balmelly, and to Mr. Juan Carlos Márquez, for their support and participation during the training in models. Our sincere gratitude also goes to the surgical team (Quirúrgica "B", Professor Dr. César Canessa) for his support in the event complications might arise during the procedures in humans.

## COMMENTS

### Background

Endoscopic submucosal dissection (ESD) is a technique for resection of early neoplastic lesions of the gastrointestinal tract, thus obtaining more complete resections than with the standard mucosectomy and decreasing the probability of relapses. However, it is associated with a high rate of complications, but it is an effective and safe technique in experienced hands, and widely accepted. In the absence of experts in western countries, practicing with animal models may be helpful to overcome the learning curve.

### Research frontiers

ESD is an effective and safe technique in experienced hands, and widely accepted. In the present study, the authors demonstrated the feasibility of using porcine models as a learning resource to teach the ESD technique. The results of multicenter studies of ESD in humans after previous training with animal models have to be explored further.

### Innovations and breakthroughs

In Latin American countries there are few training centers at which an endoscopy fellow can be trained in the ESD technique. More ESD training centers in Latin America are needed to offer our patients this technique with good results.

### Applications

ESD has been considered technically difficult. The potential implications of starting such a complex technique in an animal model rather than in human cases are evident. A formal training program is still necessary to teach this technique in western countries and Latin America. For this reason, animal models are an invaluable learning resource. It would be justified to start training with animal models instead of with real patients, if experts are not available to supervise the procedures.

### Terminology

ESD is an endoscopic method for complete *en bloc* resection of early gastrointestinal neoplasms with minimal risk of deeper wall-layer involvement or lymph node metastases. In selected cases, ESD may replace surgery and provide clean margins for accurate histological diagnosis of the lesion borders and complete curative treatment.

### Peer review

This is an interesting investigation that presents the feasibility of using porcine models for ESD training. It provides an alternative way to learn ESD in Western

countries.

### Abstract

**AIM:** To investigate the association of procalcitonin (PCT) with ulcerative colitis (UC) activity.

**METHODS:** Serum PCT levels, C-reactive protein (CRP) levels, the erythrocyte sedimentation rate, and the white blood cell count were analyzed in 18 patients with UC and 11 healthy volunteers. Serum PCT levels were analyzed by an electrochemiluminescence immunoassay. Severity assessments were based on Truelove and Witts' severity index. Correlation of serum PCT and CRP levels with UC activity was examined. Moreover, we assessed serum PCT and CRP levels in patients with a Mayo endoscopic subscore.

**RESULTS:** Serum PCT levels in severe UC patients ( $n = 7$ ) ( $0.096 \pm 0.034$  ng/mL) were significantly higher

than in mild-to-moderate UC patients ( $n = 11$ ) ( $0.033 \pm 0.012$  ng/mL) and healthy volunteers ( $n = 11$ ) ( $0.035 \pm 0.005$  ng/mL) ( $P = 0.0005$  and  $P < 0.0001$ , respectively). In addition, there was no difference in serum PCT levels between mild-to-moderate UC patients and healthy volunteers. Interestingly, patients with a Mayo endoscopic subscore of 3 points displayed significantly increased levels of serum PCT ( $0.075 \pm 0.043$  ng/mL) compared with patients with a subscore of 2 points ( $0.03 \pm 0.011$  ng/mL) ( $P = 0.0302$ ). Moreover, CRP levels in patients with severe UC or a Mayo endoscopic subscore of 3 points were not significantly higher than in patients with mild-to-moderate UC or a Mayo endoscopic subscore of 3 points.

**CONCLUSION:** Serum PCT levels were significantly correlated with UC activity.

**Key words:** C-reactive protein; Disease activity; Procalcitonin; Severity; Ulcerative colitis

**Core tip:** To investigate the association of procalcitonin (PCT) with ulcerative colitis (UC) activity, we analyzed 18 UC patients (7 with severe and 11 with mild-to-moderate UC) and 11 healthy volunteers. Serum PCT levels in severe UC patients were significantly higher than in mild-to-moderate UC patients and healthy volunteers. Moreover, patients with a Mayo endoscopic subscore of 3 points displayed significantly increased serum PCT levels compared with patients with a subscore of 2 points. However, serum C-reactive protein was not associated with disease activity or the Mayo endoscopic score. Thus, serum PCT may be a good biomarker for assessing UC activity.

Clinical significance of serum procalcitonin in patients with ulcerative colitis. *World J Gastroenterol* 2013; 19(45): 8335-8341 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i45/8335.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i45.8335>

## INTRODUCTION

Ulcerative colitis (UC) and Crohn's disease (CD) are idiopathic inflammatory bowel diseases that are generally complicated by systemic or local infection. Clinical, endoscopic, histological, and radiological investigations are typically necessary to make an accurate diagnosis and assessment of disease activity<sup>[1]</sup>; however, disease activity in UC is difficult to assess objectively because clinical disease activity indices depend on several subjective components. Biological markers have also been investigated in the United States for diagnostic purposes, for the assessment of disease activity and the prediction of relapse, and for monitoring the effect of therapy<sup>[2]</sup>. However, traditional markers, such as C-reactive protein (CRP), the erythrocyte sedimentation rate (ESR), and the white blood cell (WBC) count, are still the most common markers used in clinical practice<sup>[3]</sup>. Among these biological markers, CRP is a protein produced by the liver in response to various acute and chronic inflammatory conditions and has been shown to be a good marker for predicting the course and outcome of several diseases<sup>[4]</sup>. Importantly, heterogeneity exists among individuals' immune responses, and elevations in CRP levels are more common in CD than in UC due to differences in acute-phase responses in CD and UC<sup>[5]</sup>. Indeed, only 51% of UC patients with active disease based on colonoscopy have elevated CRP levels<sup>[6]</sup>. This finding suggests that CRP levels add to clinical assessment's ability to predict active mucosal inflammation in UC patients. Thus, the UC biomarkers currently used in clinical practice are of low sensitivity and often do not reliably assess clinical activity<sup>[2]</sup>.

Procalcitonin (PCT), a prohormone composed of 116 amino acids, is the precursor of the calcium homeostasis hormone calcitonin, which is found in thyroid C cells and pulmonary endocrine cells<sup>[7]</sup>. Clinically relevant levels of PCT influence the immunologic responses that contribute to systemic inflammatory responses and septic shock<sup>[8]</sup>. Many studies have indicated that PCT is an excellent marker of bacterial infection in patients with sepsis and its related conditions<sup>[9,10]</sup>. As a marker of disease activity, PCT has also been evaluated in chronic inflammatory and autoimmune conditions, such as pulmonary Wegener's granulomatosis<sup>[11]</sup> and systemic lupus erythematosus/systemic antineutrophil cytoplasmic antibody-associated vasculitis<sup>[12]</sup>; therefore, serum PCT levels may be helpful for predicting the disease activity of UC.

This prospective study aimed to assess the correlation of serum PCT levels with UC activity. Moreover, we

compared PCT levels, CRP levels, the ESR, and the WBC count and evaluated the additional diagnostic benefit of measuring serum PCT levels along with CRP levels in the assessment of disease activity in UC.

## MATERIALS AND METHODS

### Study subjects

This study was conducted prospectively from March 2011 to May 2013 in a single-center cohort. The study protocol was reviewed and approved by the ethics committee of the Jikei Institutional Review Board, Jikei University School of Medicine, and the clinical study committee of Jikei University Kashiwa Hospital. All of the subjects provided written informed consent. The diagnosis of UC was confirmed by a typical history combined with appropriate endoscopic, histopathological, and radiologic findings. The eligibility criteria for study participation were mild-to-severe UC<sup>[13]</sup> with an endoscopy score of at least 1 (erythema, a decreased vascular pattern, and mild friability) on a scale of 0 (normal or inactive) to 3 (spontaneous bleeding and ulceration)<sup>[14]</sup> and/or watery diarrhea at least 5 times/d with visible blood in the stools. Severity assessments were based on Truelove and Witts' severity index<sup>[13]</sup>. After total colonoscopy, the endoscopic findings were evaluated according to the Mayo system, with scores of 0-3<sup>[14]</sup>. Patients with toxic megacolon or concomitant diseases, including diabetes, hematological disorders, any malignancies, obvious infection or sepsis, chronic liver disorder, or any liver or renal diseases were excluded. Subjects who were recruited had venous blood samples drawn to assess PCT levels, CRP levels, the WBC count, and the ESR. Where clinically indicated, stool cultures were performed to exclude infective etiology for diarrhea symptoms.

### Study design

When patients had an established diagnosis of UC, serum PCT levels, CRP levels, the WBC count, and the ESR were examined. Serum PCT levels were analyzed by an electrochemiluminescence immunoassay (ECLIA) at the SRL (Tokyo, Japan), with a lower detection limit of 0.02 ng/mL. The normal value for PCT levels was defined as < 0.05 ng/mL, with a cut-off of  $\geq 0.5$  ng/mL being indicative of bacterial sepsis at the SRL. Based on our laboratory reference, the normal limits for the other inflammatory variables were a CRP level of 0.0-0.3 mg/dL, a WBC count of 3300-8600 count/ $\mu$ L, and an ESR of 2-19 mm/h.

### Statistical analysis

Values are expressed as the mean  $\pm$  SD. The statistical analysis was performed using the Mann-Whitney test and the Kruskal-Wallis one-way analysis of variance on ranks. Proportions were compared using Fisher's exact test and Cramer's  $V$  post-test. The statistical analysis was performed with STAT VIEW software, version J 5.1 (SAS Institute, Inc., Cary, NC, United States), which was used

There was no difference in the extent of disease and concomitant medication use between mild-to-moderate and severe UC. ASA: 5-aminosalicylic acid.

for all analyses.  $P < 0.05$  was considered significant.

## RESULTS

### Baseline characteristics

Eighteen UC patients (mean age:  $39.6 \pm 15.2$  years; 13 male, 5 female) were included in the study. The distribution of age and sex was not significantly different between mild-to-moderate UC (mean age:  $39.3 \pm 12.5$  years; 6 male, 5 female), severe UC (mean age:  $40.0 \pm 19.7$  years; 7 male, 0 female), and the control healthy volunteers (mean age  $40.2 \pm 9.92$  years, 10 male, 1 female) (Table 1). In patients with UC, mild-to-moderate activity was observed in 11 patients (61.1%), and severe activity was observed in 7 (38.9%). Moreover, there was no difference in the extent of disease and concomitant medication use between mild-to-moderate and severe UC (Table 1).

### Biomarkers in severe UC

In this study, serum PCT levels were analyzed by ECLIA at the SRL, with a lower detection limit of 0.02 ng/mL. The normal value for PCT levels has been defined as  $< 0.05$  ng/mL, with a cut-off of  $\geq 0.5$  ng/mL being indicative of bacterial sepsis at the SRL. There was no significant difference in serum PCT levels between patients with mild-to-moderate UC ( $0.033 \pm 0.012$  ng/mL) and healthy volunteers ( $0.035 \pm 0.005$  ng/mL) ( $P = 0.3108$ ) (Figure 1A). Interestingly, patients with severe UC displayed significantly increased levels of serum PCT ( $0.096 \pm 0.034$  ng/mL) compared with patients with mild-to-moderate UC and healthy volunteers ( $P = 0.0005$  and  $P < 0.0001$ , respectively, Figure 1A). Moreover, CRP levels, the ESR, and the WBC count in severe UC were not significantly higher than in mild-to-moderate UC ( $P =$

> 4.050	71.43%	29.04-96.33	90.91%	58.72-99.77
> 4.700	71.43%	29.04-96.33	100%	71.51-100.0
> 7.100	57.14%	18.41-90.10	100%	71.51-100.0
> 9.850	42.86%	9.899-81.59	100%	71.51-100.0
> 10.75	28.57%	3.669-70.96	100%	71.51-100.0
> 11.35	14.29%	0.3610-57.87	100%	71.51-100.0
> 11.35	14.29%	0.3610-57.87	100%	76.84-100.0

A procalcitonin cut-off value of 0.055 ng/mL had good diagnostic accuracy for detecting severe ulcerative colitis, as demonstrated by the sensitivity (100%; 95%CI: 59.04-100.0) and specificity (100%; 95%CI: 71.51-100.0) (Table 2). Moreover, at a cut-off level of C-reactive protein  $> 3.6$  mg/dL, the sensitivity for detecting severe ulcerative colitis was 85.71% (95%CI: 42.13-99.64), and the specificity was 90.91% (95%CI: 58.72-99.77).

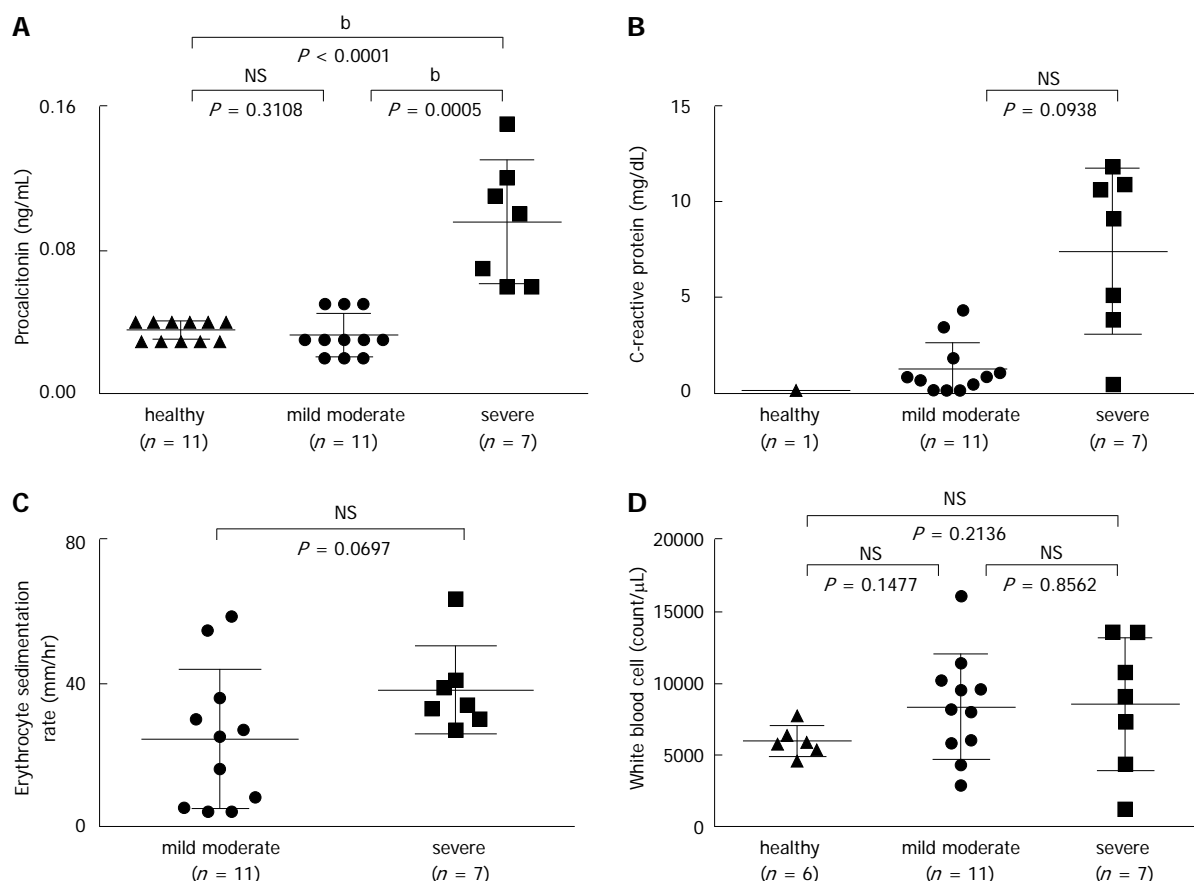

0.0938, 0.0697, and 0.8562, respectively) (Figure 1B-D).

### Correlation of serum PCT and CRP levels with UC activity

Among mild-to-moderate UC patients, 3 displayed 0.05 ng/mL serum PCT, which was above normal; however, another 8 exhibited normal levels. Interestingly, serum PCT levels were  $> 0.06$  ng/mL in all 7 patients with severe UC. In addition, the levels in all healthy volunteers were  $< 0.04$  ng/mL, which was defined as normal at the SRL. A PCT cut-off value of 0.055 ng/mL had good diagnostic accuracy for detecting severe UC, as demonstrated by the sensitivity (100%; 95%CI: 59.04-100.0) and specificity (100%; 95%CI: 71.51-100.0) (Table 2). Moreover, at a cut-off level of CRP  $> 3.6$  mg/dL, the sensitivity for detecting severe UC was 85.71% (95%CI: 42.13-99.64), and the specificity was 90.91% (95%CI: 58.72-99.77) (Table 2). In addition, there was a significant correlation between PCT and CRP levels ( $r = 0.2776$ ,  $P = 0.0247$ ) (Figure 2). Taken together, these results suggest that serum PCT is superior as a detection marker of severe UC compared with CRP.

### Serum PCT and CRP levels in patients with Mayo endoscopic subscore of 2 or 3 points

Regarding Truelove and Witts' scoring, it could be diffi-

**Figure 1** Scatter dot plot of biological markers in mild-to-moderate and severe ulcerative colitis patients. A: Procalcitonin (PCT) levels; B: C-reactive protein levels (CRP); C: The erythrocyte sedimentation rate (ESR); D: The total white blood cell (WBC) count were examined in healthy volunteers or mild-to-moderate and severe ulcerative colitis patients. Serum PCT levels in healthy volunteers were used as a control. Based on our laboratory reference, the normal limits for the other inflammatory variables were a CRP level of 0.0-0.3 mg/dL, a WBC count of 3300-8600 count/ $\mu$ L, and an ESR of 2-19 mm/h. The results are expressed as the mean  $\pm$  SD. <sup>b</sup> $P < 0.01$  vs healthy or mild-to-moderate group. NS: Not significant.

**Figure 2** Correlation of serum procalcitonin levels with C-reactive protein levels in patients with ulcerative colitis. The two curves represent the 95%CI for the regression line. This interval includes the true regression line, with a 95% probability. There was a significant correlation between procalcitonin (ng/mL) and C-reactive protein (mg/dL) levels ( $r = 0.2776$ ,  $P = 0.0247$ ).

cult to use a scale of 1-3. Therefore, 14 patients with UC were also examined for their Mayo endoscopic score and serum PCT and CRP levels after total colonoscopy in this study. As only 1 patient had an endoscopic subscore

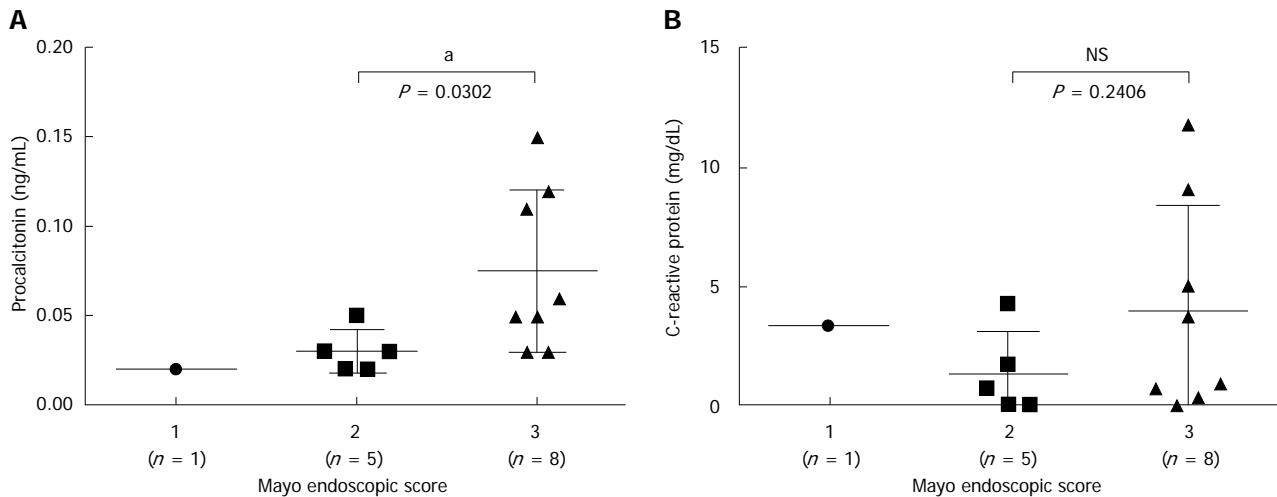

of 1 point, we assessed serum PCT and CRP levels in patients with a subscore of 2 ( $n = 5$ ) or 3 ( $n = 8$ ) points. There was no significant difference in serum CRP levels between patients with a subscore of 2 or 3 points ( $P = 0.2406$ ), whereas patients with a subscore of 3 points displayed significantly increased levels of serum PCT ( $0.075 \pm 0.043$  ng/mL) compared with patients with a subscore of 2 points ( $0.03 \pm 0.011$  ng/mL) ( $P = 0.0302$ ) (Figure 3).

## DISCUSSION

This study demonstrates that serum PCT levels are correlated with clinical, biological, or endoscopic disease activity in patients with UC. Moreover, serum PCT levels have superior diagnostic accuracy for detecting severe UC in comparison with CRP levels, the ESR, and the WBC count.

The assessment of disease activity in patients with UC has been performed using clinical and endoscopic indices. Biological markers are a noninvasive way of objectively measuring inflammation and can play an adjunctive or primary role in the assessment of disease activity. The currently used UC biomarkers, such as CRP, the ESR, and WBC and platelet counts, have low sensitivity and

**Figure 3** Serum procalcitonin and C-reactive protein levels in patients with Mayo endoscopic subscore of 2 or 3 points. A: Procalcitonin; B: C-reactive protein levels were examined in patients with a Mayo endoscopic subscore of 1 ( $n = 1$ ), 2 ( $n = 5$ ), or 3 ( $n = 8$ ) points. The results are expressed as the mean  $\pm$  SD. <sup>a</sup> $P < 0.05$  vs score 2 group. NS: Not significant.

often do not reliably assess clinical activity<sup>[2,15]</sup>. It has been reported that although both PCT and CRP are acute-phase reactant proteins, PCT is a more specific marker of bacterial infections<sup>[16]</sup>. Moreover, PCT is an excellent marker of bacterial infection in patients with sepsis and its related conditions<sup>[9,10]</sup>. There is growing evidence that colonic luminal bacteria contribute to clinical activity in UC<sup>[17]</sup>, suggesting that serum PCT levels may be an important biomarker for detecting active UC; however, little is known about whether serum PCT is a reliable marker for the diagnosis of active UC. To date, four studies have evaluated PCT levels in adult patients with UC<sup>[18-21]</sup>. Among the four studies, only one<sup>[21]</sup> evaluated the correlation between serum PCT levels and Truelove and Witts' severity index or a simple clinical colitis activity index (SCCAI)  $> 5$ <sup>[22]</sup>; however, this report demonstrated conflicting results when evaluating serum PCT as a biological marker of UC activity. Our present study is the first to show that serum PCT levels in patients with UC are significantly correlated with Truelove and Witts' severity index and a Mayo endoscopic subscore. Importantly, serum PCT levels in patients with a Mayo endoscopic subscore of 3 points are significantly higher than in patients with a subscore of 2 points. PCT levels have been evaluated in chronic inflammatory and autoimmune conditions, such as pulmonary Wegener's granulomatosis<sup>[11]</sup> and systemic lupus erythematosus/systemic antineutrophil cytoplasmic antibody-associated vasculitis<sup>[12]</sup>. Moreover, PCT levels have been associated with bacterial infection<sup>[9,10]</sup>. Severe UC patients are characterized by bacterial invasion due to a defensive deficiency of the mucosa; thus, it is possible that PCT levels are correlated with disease activity in UC. In our study, serum PCT levels were analyzed by ECLIA, which showed good reproducibility, linearity, and functional sensitivity compared with previously reported immunofluorescent assays<sup>[23]</sup>. The superior detection of serum PCT in our study may be explained, at least in part, by differences in methodology. In contrast, serum

CRP levels in severe UC and in patients with a Mayo endoscopic subscore of 3 points were not significantly higher than in mild-to-moderate UC or in patients with a subscore of 2 points, respectively. It has been reported that local and systemic administration of steroids has the potential to decrease CRP levels<sup>[24-27]</sup>, whereas PCT levels appear to be unaltered<sup>[24,25]</sup>. In the current study, there was no significant difference in concomitant medication use, such as steroid use, between mild-to-moderate and severe UC. Therefore, it is suggested that PCT levels are correlated with disease activity in UC.

In conclusion, our results suggest that serum PCT levels are useful in clinical practice to assess disease activity in patients with UC. The limitation of our study is the relatively small sample size that was evaluated. Thus, further studies are needed to evaluate the clinical significance of serum PCT in a large sample of UC patients. Moreover, a definitive approach is needed to assess serum PCT levels as a marker for managing severe UC patients after treatment.

## COMMENTS

### Background

Biological markers have been investigated in the United States for the assessment of disease activity. Among traditional biological markers, C-reactive protein (CRP) has been shown to be a good marker for predicting the course and outcome of several diseases. However, only 51% of ulcerative colitis (UC) patients with active disease based on colonoscopy have elevated CRP levels, suggesting that CRP levels add to clinical assessment's ability to predict active mucosal inflammation in UC patients.

### Research frontiers

Traditional biological markers, such as CRP, often do not reliably assess clinical activity in UC patients. In the assessment of clinical activity in UC, the research hotspot is the identification of excellent biomarkers.

### Innovations and breakthroughs

It has been reported that although procalcitonin (PCT) is an excellent specific marker of bacterial infections in patients with sepsis and its related conditions. Moreover, colonic luminal bacteria contribute to clinical activity in UC. Thus, serum PCT levels may be an important biomarker for detecting active UC. This

prospective study aimed to assess the correlation of serum PCT levels with UC activity. Authors showed that serum PCT levels in patients with UC were significantly correlated with Truelove and Witts' severity index and the Mayo endoscopic subscore.

### Applications

The study's results suggest that serum PCT is an excellent biological marker for assessing the activity of UC.

### Terminology

UC and Crohn's disease are idiopathic inflammatory bowel diseases that are generally complicated by systemic or local infection. Clinical UC activity is difficult to assess objectively because of several subjective components. PCT is the precursor of the calcium homeostasis hormone calcitonin, which is found in thyroid C cells and pulmonary endocrine cells.

### Peer review

The strength of this study is a well-executed study. The statistics are appropriate, and the manuscript is well written. This study demonstrates that serum PCT levels are useful in clinical practice to assess disease activity in patients with UC. However, the limitation of the study is the relatively small sample size evaluated. The study recommends a future study on the results of treatment based on PCT levels in a large sample.

### Abstract

**AIM:** To assess the safety and utility of capsule endoscopy (CE) for children who are unable to swallow the capsule endoscope.

**METHODS:** The medical records of all of the children who underwent CE between 2010 and 2012 were retrospectively reviewed. The patients were divided into 2 groups: group A included patients who were unable to swallow the capsule endoscope, and group B included patients who were able to swallow it. For the patients who were unable to swallow the capsule endoscope, it was placed in the duodenum endoscopically. The small bowel transit time, endoscopic diagnosis and complications of the 2 groups were compared.

**RESULTS:** During the study period, 28 CE procedures

were performed in 26 patients. Group A included 11 patients with a median age of 2 years (range 10 mo-9 years), and group B included 15 patients with a median age of 12 years (range 8 years-16 years). The lightest child in the study weighed 7.9 kg. The detection rates did not differ between the 2 groups. The median small bowel transit time was 401 min (range 264-734 min) in group A and 227 min (range 56-512 min) in group B ( $P = 0.0078$ ). No serious complications, including capsule retention, occurred. No significant mucosal trauma occurred in the pharynx, esophagus, stomach or duodenum when the capsule was introduced using an endoscope.

**CONCLUSION:** CE is a safe and useful procedure for infants and young children who are unable to swallow the capsule endoscope.

**Key words:** Capsule endoscopy; Retention; Infants; Children; Small bowel transit time; Complications

**Core tip:** We retrospectively reviewed the medical records of all children who underwent capsule endoscopy (CE) and compared the results of the patients who were unable to swallow the capsule (group A) with those of the patients who were able to swallow the capsule (group B). Although the mean small bowel transit time was significantly longer in group A, there were no significant differences between the 2 groups in the frequency of lesion detection or in the occurrence of adverse events. Capsule retention was not observed in either group. Thus, CE is a safe and useful procedure for infants and young children.

endoscopy for infants and young children. *World J Gastroenterol* 2013; 19(45): 8342-8348 Available from: URL: <http://www.wjg-net.com/1007-9327/full/v19/i45/8342.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i45.8342>

## INTRODUCTION

The United States Food and Drug Administration (FDA) approved the use of capsule endoscopy (CE) for the evaluation of small bowel diseases in adults in 2001 and in patients 10 to 18 years of age in January 2004. In September 2009, CE was approved by the FDA for use in children 2 years of age and older<sup>[1]</sup>.

CE provides a unique opportunity to visualize the entire small bowel, not only in adults but also in children. When the patient cannot swallow the endoscopic capsule, it can be safely introduced into the duodenum using various techniques or an introducing device<sup>[2-4]</sup>. Based on recent reports, the use of CE in the pediatric population is increasing<sup>[5-7]</sup>. However, its use in infants and young children who are unable to swallow the endoscopic capsule remains limited<sup>[8-12]</sup>, and the safety and utility of CE in this age group are relatively unknown. The aim of this study was to clarify the safety and utility of CE in infants and young children who were unable to swallow the capsule endoscope, including patients younger than 1 year of age.

## MATERIALS AND METHODS

All of the CE procedures performed at the Children's Center for Health and Development at Saiseikai Yokohama City Tobu Hospital from August 2010 through March 2012 were retrospectively reviewed. Informed consent was obtained from the guardians of the children who underwent CE. The patients were divided into 2 groups: group A included patients who were unable to swallow the endoscopic capsule, and group B included patients who were able to swallow the capsule. We compared the 2 groups in terms of small bowel transit time, complications and endoscopic findings and diagnosis. The small bowel transit time was calculated from the first duodenal image to the first image of the cecum. Capsule retention was defined as a capsule endoscope remaining in the digestive tract for a minimum of 2 wk or requiring directed intervention or therapy to aid its passage<sup>[13]</sup>.

Prior to the CE procedures, patients who were suspected of having a small bowel stricture were screened by small bowel X-ray in an attempt to decrease the risk of capsule retention. A standard PillCam<sup>®</sup> 2 (Given Imaging, Ltd., Yokneam, Israel) was used to perform all of the CE procedures. The PillCam<sup>®</sup> SB2 capsule is 11 mm × 26 mm in size and weighs 2.9 g. Its battery allows more than 8 h of work (usually approximately 13 h), during which the capsule photographs 2 images per second. All of the patients fasted overnight for at least 8 h prior to the delivery of the capsule. The patients were allowed to drink clear liquids 2 h after the procedure and to consume a

**Figure 1** A capsule endoscope in a net device for foreign body extraction; B: A capsule endoscope in a net device for foreign body extraction; the device has been retracted and is seated firmly against a clear plastic hood attached to the tip of the upper gastrointestinal endoscope.

light meal 4 h after the procedure.

If a patient was unable to swallow the capsule, it was placed into the duodenum endoscopically. These patients were anesthetized intravenously with midazolam and ketamine. A plastic hood was attached to the tip of a gastrointestinal endoscope (XQ260, Olympus, Tokyo, Japan). A net device for foreign body extraction was then introduced into the operative channel, and the capsule was placed into the net, pulled into the plastic hood and fixed. To avoid posterior pharyngeal damage during the introduction of the endoscope, a slight angle was created between the long axis of the capsule endoscope and that of the plastic hood (Figure 1). The pediatric endoscopist introduced the capsule into the stomach while observing both the real-time viewer of the endoscopic capsule and the video monitor of the endoscope. The endoscopic capsule was released into the stomach, caught with a polypectomy snare and delivered into the proximal portion of the duodenum (Figure 2).

## Statistical analysis

The results are reported as percentages or, in the case of continuous variables, as medians and ranges. The Mann-Whitney *U* test was used to evaluate differences in continuous variables between the 2 groups, and the chi-square test was used for dichotomous variables. A *P* value of less than 0.05 was considered statistically significant.

## RESULTS

Twenty-eight CE procedures were performed in pediatric patients during the study period, August 2010 to March 2012. Thirteen males and 13 females underwent CE; the median age of the patients was 9.5 years (range 10 mo-16 years).

Group A included 11 patients (median age 2 years, range 10 mo-9 years), and group B included 15 patients (median age 12 years, range 8 years-16 years) (Table 1). The age distribution of the patients in each group is shown in Table 2. The lightest child, a group A patient,

	Group A ( <i>n</i> = 11)	Group B ( <i>n</i> = 15)	<i>P</i> value
Median age (yr)	2 (0.8-9)	12 (8-16)	0.0006
Male:female	5:6	8:7	NS
Median weight (kg)	14 (7.9-24.1)	41.8 (21.8-52.9)	0.0003
Median gastric transit time (min)	10 (1-313)	32 (4-446)	0.0169
Median small bowel transit time (min)	401 (264-734)	227 (56-512)	0.0078
Number of retentions	0	0	NS
Number of complications	0	0	NS

The numbers in parentheses represent ranges. NS: Not significant.

weighed 7.9 kg. Ten of the 11 procedures performed in group A used endoscopy to place the capsule endoscope into the duodenum. For a 9-year-old boy in group A, a net device for foreign body extraction was used to pass the capsule through the pharynx and into the stomach without endoscopy.

Of the 28 CE procedures, 26 were completed (92.9%) and 2 were not completed (7.1%). In one case, it took 9 h for a capsule endoscope placed in the stomach of a 2-year-old girl to pass through the stomach; the battery's power became depleted before the entire small bowel could be observed. Therefore, the next day, we delivered the capsule into the duodenum using an endoscopic guide and successfully observed the entire small bowel without any problems. In another case, we misidentified the location of the capsule and terminated the examination before the capsule reached the cecum. The procedure was not repeated in the latter patient.

**Table 2** Age distribution of the patients

Age at examination, yr	Cases ( <i>n</i> )	
	Group A	Group B
< 1	2	0
1	2	0
2	2	0
3	1	0
4	0	0
5	1	0

7	1	0
8	0	1
9	1	2
10	0	1
11	0	3
12	0	1
13	0	0
14	0	5
15	0	1
16	0	1

The median gastric transit time in group B was 32 min (range 4-446 min). The median small bowel transit time in group A (401 min, range 264-734 min) was significantly longer than that in group B (227 min, range 56-512 min) (Table 1).

The indications and findings of CE are summarized in Table 3. The CE examinations were performed for the following reasons: anemia or obscure gastrointestinal bleeding (OGIB) (*n* = 2), small bowel polyps with juvenile polyposis (*n* = 1), chronic or recurrent abdominal pain of unknown etiology (*n* = 8), evaluation of small bowel lesions associated with intractable Henoch-Schönlein purpura (HSP) (*n* = 3), recurrent vomiting (*n* = 1),

Figure 3 Three-year-old girl with Henoch-Schonlein purpura. A: Extended ulcer; B, C and D: Multiple erosions and ulcers.

Figure 4 Ten-month-old girl with allergic gastroenteropathy (A and B) caused by the ingestion of cow's milk.

diarrhea or steatorrhea ( $n = 3$ ), ulcerative colitis ( $n = 4$ ) and suspicion of Crohn's disease ( $n = 4$ ). Three patients with ulcerative colitis underwent CE to rule out Crohn's disease, and 1 underwent CE to evaluate small bowel lesions caused by ulcerative colitis and portal hypertension due to primary sclerosing cholangitis. The most common indication in group B was abdominal pain (7 patients, 53.8%); among the patients in group A, the indications were more diverse.

Seven of the 26 capsule procedures (26.9%) were interpreted as normal. CE resulted in a new diagnosis for 6 patients (23.1%): 3 in group A (27.3%) and 3 in group B (20.0%). The CE small bowel findings were not sufficiently specific to permit a diagnosis in 12 patients (46.2%), 5 of in group A (45.5%) and 7 in group B (46.7%). The CE findings resulted in a change in therapy

for 1 patient (6.6%) in group B. There was no significant difference in the incidence of abnormal findings between the 2 groups.

Of the 2 cases in which OGIB or anemia was investigated, CE identified angiodysplasia in both. The patient with juvenile polyposis was found to have no abnormal lesions in the small intestine. Of the 8 procedures performed to investigate abdominal pain, CE identified erosion in 1, duodenal ulcers in 1 and petechiae suggestive of HSP in 2. In a 3-year-old girl with intractable steroid-dependent HSP, CE revealed multiple erosions, extended ulcers and bleeding (Figure 3). In the child examined for recurrent vomiting, CE identified ulcers and aphthae (Figure 4). Of the 3 procedures in which diarrhea or steatorrhea were investigated, CE identified ulcers and erosion in 1. Of the 4 children with ulcerative colitis, 1

**Table 3** Capsule endoscopy findings and outcomes *n* (%)

	<i>n</i>	Normal	New diagnosis	Suggestive of specific small bowel findings	Nonspecific small bowel findings	Change in therapy
Group A	11	4 (36.4)	3 (27.3)	5 (45.5)	2 (18.2)	0 (0.0)
Group B	15	3 (20.0)	3 (20.0)	7 (46.7)	5 (33.3)	1 (6.6)

exhibited erosion and mucosal redness; 1 had a longitudinal ulcer and round ulcers; and 2 had mucosal edema. Of the 4 procedures undertaken for suspicion of Crohn's disease, 1 revealed a linear ulcer; 1 showed a round region of redness; 1 revealed erosions with hematin; and 1 demonstrated white villi and erosion.

No significant mucosal trauma to the pharynx, esophagus, stomach or duodenum occurred when the capsule was introduced using an endoscope. No further complications were noted; specifically, no capsule retention occurred.

## DISCUSSION

CE is an endoscopic technique that offers an extremely safe approach for investigating small bowel pathology in adults. Although the US FDA has approved the use of CE in children 2 years of age and older, Japan's Ministry of Health, Labor and Welfare has not officially approved CE for infants or young children who cannot swallow the capsule endoscope. Several techniques and devices for introducing the capsule endoscope into the duodenum have been described<sup>[2-4,14,15]</sup>, and reports of the use of CE in children who are unable to swallow the capsule have been increasing<sup>[2,3,11,12]</sup>. Fritscher-Ravens *et al*<sup>[8]</sup> conducted a multicenter study to evaluate the feasibility and proper technique for using CE to identify small intestinal pathology in children < 8 years of age. No instances of severe complications or capsule retention occurred in the 85 examinations in that study, in which the smallest child weighed merely 10 kg. To our knowledge, the smallest child (an 8-mo-old) in whom the use of this technique has been reported weighed 9 kg<sup>[12]</sup>.

In this study, we used a net device for foreign body extraction to introduce the capsule and a plastic hood adaptor to hold and stabilize the alignment of the capsule during its passage through the pharynx into the esophagus. It proved difficult to pass the capsule into the duodenum using a net device according to the method described by Barth *et al*<sup>[21]</sup>; therefore, we used a polypectomy snare to pass the capsule beyond the pylorus. Using this technique, we successfully performed CE in children who were unable to swallow the capsule. These children included 4 infants weighing < 10 kg, the lightest of whom weighed 7.9 kg and the youngest of whom was 10 mo old. The smallest child in group A weighed 7.9 kg; to our knowledge, this child is the smallest patient to be included in a study of CE.

Aparicio *et al*<sup>[16]</sup> reported that the patient's age, sex, diabetes mellitus and body position after swallowing the capsule endoscope did not influence the gastric transit

time or small intestinal transit time. In contrast, Fireman *et al*<sup>[17]</sup> reported age- and pathology-related effects on the small bowel transit time of the capsule endoscope. It has been unclear what factors influence small bowel transit time in children. We compared the small bowel transit time between group A, children who could not swallow the endoscopic capsule, and group B, children who could swallow the capsule, and found a significant difference between the 2 groups. This is the first report to compare small bowel transit times between 2 such groups. Small bowel transit time is thought to be influenced by the sphincter of the ileocecal valve, the length and luminal diameter of the small bowel and digestive peristalsis. Post-mortem studies have revealed that the capsule endoscope can traverse the pylorus and ileocecal valve in infants 1 year of age<sup>[8]</sup>, suggesting that the size of the ileocecal valve may not be the primary factor influencing small bowel transit time during CE in children 1 year of age and older. Growth in intestinal length continues during early postnatal life; from approximately 1 year of age (75 cm body length) onward, this growth slows but continues to progress linearly with age until adulthood<sup>[18]</sup>. A study employing the lactulose hydrogen breath test showed that there was no correlation between age and transit time<sup>[19]</sup>, although a test using solids might produce different results. We examined the relationships between small bowel transit time and age and body weight and found no significant relationships between these parameters. We demonstrated that small bowel transit time was significantly longer in group A than in group B. We hypothesize that the depression of digestive peristalsis caused by the anesthetic agents used during the placement of the capsule may have influenced the small bowel transit time.

CE is generally considered more sensitive than radiological and standard endoscopic modalities for the detection of small bowel lesions in children, especially for the distribution of Crohn's disease lesions<sup>[20,21]</sup>, the source of OGIB and the presence of polyps<sup>[8,22,23]</sup>. In our study, the source of bleeding was identified in all of the patients who underwent CE for OGIB or anemia. However, there was a low detection rate among the patients with juvenile polyposis or abdominal pain.

A major concern of both investigators and ethics review boards is the possibility of respiratory complications and/or CE retention in infants and young children. General endotracheal anesthesia was not required for the endoscopic placement of the capsule endoscope in any of the patients in group A, and no respiratory complications occurred in this group. There may be a risk of airway obstruction by the capsule or the endoscope during capsule introduction without general endotracheal anesthesia in infants and young children. The patient's blood oxygen saturation, blood pressure, heart rate, electrocardiogram and respiratory rate must be monitored, and oxygen should be supplied via nasal cannula during capsule introduction in all cases. Our technique considerably reduces the risk of airway obstruction because it allows the accurate determination of the location of the CE: the

use of the clear plastic hood permits the observation of both the real-time viewer of the capsule endoscope and the monitor of the endoscope.

A systematic review of CE studies, primarily in adults, reported retention rates of 1.4%, 1.2%, 2.6% and 2.1% for overall, OGIB, Crohn's disease and neoplastic lesions, respectively<sup>[13]</sup>. A meta-analysis indicated that the CE retention rate in the pediatric population was 2.6% (stomach, 0.5%; small bowel, 1.9%), and pediatric patients showed similar risks of retention in OGIB, Crohn's disease and polyp cases, with rates of 1.6% ( $n = 2/125$ ), 2.5% ( $n = 9/359$ ) and 1.3% ( $n = 1/75$ ), respectively<sup>[24]</sup>. In a European multicenter study, Fritscher-Ravens *et al*<sup>[8]</sup> reported that no capsule retention was observed in 83 children younger than 8 years of age. These reports suggest that the retention rate is related to the indication for the procedure rather than to the age of the patient and that capsule retention is relatively uncommon in both adults and children. Atay *et al*<sup>[25]</sup> reported that the "red flags" for potential capsule retention included inflammatory bowel disease (IBD) (5.2% retention risk), previous small bowel follow-through demonstrating small bowel Crohn's disease (37.5% retention risk) and body mass index < 5th percentile with known IBD (43% retention risk). To reduce the risk of capsule retention, small bowel follow-through should be performed prior to CE in all cases of suspected Crohn's disease, especially in cases of growth failure. In our study, all of the patients with suspicion of Crohn's disease underwent small bowel follow-through before CE, and no capsule retention occurred. If capsule retention were to occur, we would attempt to remove the capsule by double balloon endoscopy or by surgery if double balloon endoscopy could not be performed. Although the use of patency capsules in children has been reported<sup>[26]</sup>, we did not use patency capsules prior to CE because such capsules are unavailable in Japan. Furthermore, the number of patients in this study was small, and any comparison of 2 groups with significant differences in age and weight would likely be of questionable validity. Because the number of pediatric patients who undergo endoscopy is far smaller than the number of adult patients who undergo this procedure, there are few data regarding the safety and utility of CE in infants and young children. We believe that our findings will encourage pediatric endoscopists to perform CE more frequently in infants and young children who cannot swallow capsules.

In conclusion, CE examinations of infants and young children who were unable to swallow the endoscopic capsule were performed without adverse events. In infants and young children, as in adults, CE is a useful and safe diagnostic method, especially in cases of gastrointestinal bleeding or anemia.

## COMMENTS

### Background

The United States Food and Drug Administration (FDA) approved capsule endoscopy (CE) for the evaluation of small-bowel diseases in adults in 2001 and

for patients 10 to 18 years of age in January 2004. In September 2009, CE was approved by the FDA for use in children 2 years of age and older. However, the safety and utility of the use of CE in infants and young children who cannot swallow the capsule are unclear.

### Research frontiers

The smallest child (an 8-mo-old) in whom the use of CE was previously reported weighed 9 kg. In this report, authors used a net device for foreign body extraction and a plastic hood adaptor to hold the capsule and stabilize its alignment during its passage through the pharynx into the esophagus. Using this technique, authors successfully performed CE in children who were unable to swallow the capsule, including an infant weighing 7.9 kg.

### Innovations and breakthroughs

Authors compared the small bowel transit time between group A, consisting of children who could not swallow the endoscopic capsule, and group B, consisting of children who could swallow the capsule, revealing a significant difference between the 2 groups. This is the first report to compare the small bowel transit times in 2 such groups.

### Applications

The capsule was endoscopically placed into the duodena of the patients who were unable to swallow the capsule. Thus, CE is a safe and useful procedure for infants and younger children who are unable to swallow the capsule endoscope.

### Peer review

This is a valuable retrospective observational study. The study is very well thought out and should be useful to the readers in the Pediatric Group. If the retention of the capsule were to occur, what intervention or action would be undertaken by the clinician?

VAT and subcutaneous adipose tissue area as a reference group.

**RESULTS:** The body mass index (BMI), total cholesterol, fasting glucose and VAT areas were significantly different among normal, adenoma and CRC groups. The VAT area was  $120.6 \pm 49.0 \text{ cm}^2$  in normal controls,  $130.6 \pm 58.4 \text{ cm}^2$  in adenoma group and  $117.6 \pm 51.6 \text{ cm}^2$  in CRC group ( $P = 0.002$ ). In univariate analysis, increased BMI was a risk factor for CRC compared to control ( $P = 0.025$ ). However, VAT area was not a risk factor for CRC compared to control. In multivariate analysis that adjusted for smoking, alcohol consumption and subcutaneous adipose tissue area, VAT area was inversely related to CRC, compared to the adenoma (OR = 0.53, 95%CI: 0.31-0.92, highest quartile vs lowest quartile).

**CONCLUSION:** Our study shows that visceral obesity is not a risk factor for early CRC. Visceral obesity might influence the normal-adenoma sequence but not the adenoma-early carcinoma sequence.

### Abstract

**AIM:** To examine whether visceral adipose tissue (VAT) serves as a risk factor for colorectal adenoma-early colorectal cancer (CRC) sequence.

**METHODS:** A retrospective case-control study was conducted with 153 patients with stage I CRC, age/sex-matched 554 patients with colorectal adenoma and 557 normal controls. All subjects underwent various laboratory tests, abdominal fat computed tomography (CT), and colonoscopy. VAT was defined as an intra-abdominal adipose tissue area measured by CT scan. Adipose tissue area was measured at the level of the umbilicus from CT scan. We used the lowest quartile of

**Key words:** Adipose tissue; Visceral fat; Obesity; Colorectal cancer; Colorectal adenoma; Abdominal computed tomography

**Core tip:** This study showed that visceral obesity is not a risk factor for early colorectal cancer, although it is an independent risk factor for colorectal adenoma in previous studies. Therefore, these data suggest that visceral obesity might influence the normal-adenoma sequence but not the adenoma-early carcinoma sequence.

## INTRODUCTION

The prevalence of obesity has increased over the past few decades<sup>[1]</sup>, and the prevalence of colorectal neoplasia has also increased in Asian countries, particularly in South Korea<sup>[2]</sup>. There is mounting evidence linking obesity to colorectal neoplasia<sup>[3]</sup>. Data from recent studies, including our previous research, have suggested that among the diverse methods that are used to define obesity, the visceral adipose tissue (VAT) area is a strong indicator of obesity as a risk factor for developing colorectal adenoma<sup>[4-7]</sup>. The natural course of adenoma is well known as the “adenoma-carcinoma sequence”<sup>[8]</sup>. Therefore, the role of VAT in developing colorectal cancer (CRC) should be interpreted at each step of this sequence. Several studies have assessed the association between the VAT area and CRC. For example, in a Japanese study<sup>[9]</sup>, VAT was positively associated with developing early stage CRC but not adenoma. However, in this study, the number of CRC patients was small, and the control subjects were selected from the subjects with negative screening results but without colonoscopic exams, which may have resulted in including patients with colorectal adenomas. In a Turkish study<sup>[10]</sup>, the VAT area did not differ between the CRC patients and controls. This study involved also a small number of cases, and the controls were consecutively collected, which means that they were not matched by age or gender.

The relationship between VAT and the colorectal adenoma-cancer sequence has not yet been completely documented. The aim of this study was to examine whether VAT serves as a risk factor for the colorectal adenoma-early CRC sequence.

## MATERIALS AND METHODS

### Study population

A retrospective case-controlled study was conducted to compare stage I, early CRC patients with an age- and sex-matched colorectal adenoma group and normal controls. From October 2004 to December 2008, 1206 CRC patients underwent colectomy at Seoul National University Hospital by an identical main operator. For preoperative evaluation, all patients had colonoscopic examination and abdominal computed tomography (CT) scan. To minimize the wasting effect of cancer itself, we included only the stage I CRC patients in our study. The cancer stage was determined using the American Joint Committee on Cancer criteria<sup>[11]</sup>. Stage I CRC includes the T1N0 and T2N0 on tumor node metastasis stages. There were 153 eligible patients after the following exclusion criteria were applied: preoperative neoadjuvant chemoradiation therapy, a history of colonic disease such as CRC, inflammatory bowel disease and a family history of CRC.

The colon adenoma patients and normal controls were recruited at Seoul National University Hospital Healthcare System Gangnam Center during a routine health check-up over a similar time period. The inclusion criteria were those who underwent abdominal fat CT scan and colonoscopy on the same day. Patients with colorectal adenoma and normal controls (subjects with normal colonoscopic findings) followed the study design as previously described<sup>[4]</sup>. The following exclusion criteria were applied to the colorectal adenoma and normal control groups: a history of colonic disease, such as colorectal adenomatous polyps, cancer, inflammatory bowel disease, and bowel resection; a colonic examination including sigmoidoscopy, colonoscopy, or barium enema in the previous 10 years, a family history of CRC.

To adjust for age and sex, which are considered important confounders in CRC and adenoma studies, we formed three age- and sex-matched groups: the early CRC group, the adenoma group and the control group.

### Ethics statement

The Institutional Review Board of Seoul National University Hospital approved the study protocol (IRB number H-1208-001-420), and the study was conducted in accord with the Helsinki Declaration. Informed consent was waived by the board.

### Clinical and laboratory evaluations

All subjects were questioned regarding smoking, alcohol consumption, diabetes mellitus, hypertension, and medication histories. Height, weight and blood pressure were measured by trained nurses using a standardized protocol. Venous samples were drawn after an overnight 12-h fast to check serum total cholesterol and fasting glucose. All biochemical tests were performed using an automatic analyzer within the Department of Laboratory Medicine at Seoul National University Hospital.

### Definitions and exposure measurements

Current smoking was defined as smoking at least one cigarette per day for the previous 12 mo, and alcohol consumption was defined as drinking over 140 g of alcohol per week. Hypertension was defined as a blood pressure of > 140/90 mmHg or taking an anti-hypertensive medication. Diabetes mellitus was defined as a fasting glucose of > 126 mg/dL or taking a diabetes mellitus medication. Body mass index (BMI) was calculated from the measured weight and height.

### Measurement of adipose tissue areas by CT

All of the CRC patients had preoperative abdominal CT for staging work-up. The adipose tissue area was measured at the level of the umbilicus using a 16-detector row CT scanner (Somatom Sensation 16, Siemens medical Solutions, Forchheim, Germany), as previously described<sup>[12]</sup>. We defined VAT as an intra-abdominal adipose tissue area confined by the parietal peritoneum, excluding the paraspinal muscles and the vertebral column. Subcutaneous

**Table 1** Comparison of the baseline characteristics of the colorectal cancer, adenoma, and control groups *n* (%)

Characteristics	Control ( <i>n</i> = 557)	Adenoma ( <i>n</i> = 554)	Cancer ( <i>n</i> = 153)	<i>P</i> value

Results are expressed as mean ± SD.

adipose tissue (SAT) areas were defined as adipose tissue areas external to the abdomen and the back muscles<sup>[4]</sup>. As there are no standard values for the definition of a normal amount of abdominal adipose tissue, we used the lowest quartile of SAT and VAT area in this study as a reference group. Same method was applied to the normal and adenoma groups from their abdominal fat CT. To minimize interpersonal variation, all measurements were performed by one experienced nurse who was blinded to the clinical and laboratory details of subject.

#### Colonoscopy and the detection of colorectal adenoma

The colonoscopies were performed by experienced gastroenterologists. The colonoscopists were blinded to the clinical findings and adipose tissue amounts. The bowel preparations were performed using four liters of colon-lyte solution. Histopathologically, colorectal carcinoma was defined as colorectal adenocarcinoma, regardless of amount of the mucinous component or differentiation. Colorectal adenoma was defined as a colorectal adenoma, regardless of the grading and the amount of villous component.

#### Statistical analysis

The continuous variables are expressed as the mean ± SD. The  $\chi^2$  test or Student's *t* test and an analysis of variance (ANOVA) for independent samples were used to assess the differences in risk factors among the groups. The effect of obesity, as measured by SAT or VAT area, were estimated by calculating an OR and a 95%CI using conditional logistic regression analysis. In addition to the risk factors that were determined to be significant in a univariate analysis, we included additional variables that are known or reportedly have an association with CRC, such as smoking and alcohol consumption, for the multiple conditional logistic regression model to identify independent risk factors for CRC. All of the statistical analyses were performed using SPSS 19.0 (SPSS, Chi-

cago, IL, United States) and SAS 9.2 (SAS institute, Cary, NC, United States). *P* < 0.05 was considered statistically significant.

## RESULTS

#### Characteristics of participants

Of 1206 colorectal patients who had colectomies, 153 stage I patients met the inclusion criteria and were enrolled in the final analysis. The patients were matched by age and sex to produce 554 adenoma group members and 557 normal controls. The mean age of all 1264 subjects was 59.2 ± 8.5 years, and the male to female ratio was 842:422. The BMI, total cholesterol and fasting glucose levels, total adipose tissue, VAT and SAT areas were significantly different among the three groups. The VAT area was 120.6 ± 49.0 cm<sup>2</sup> in normal controls, 130.6 ± 58.4 cm<sup>2</sup> in the adenoma group, and 117.6 ± 51.6 cm<sup>2</sup> in the early CRC group (*P* = 0.002). There were no differences in age, gender, smoking history, alcohol consumption, hypertension or diabetes (Table 1). The VAT areas in colorectal carcinoma patients were significantly lower than in the adenoma patients (*P* = 0.02), but not significantly lower than in the control group (*P* = 0.51). The VAT areas in colorectal adenoma patients were significantly higher than in the control group (*P* = 0.005) (Figure 1).

#### Adiposity in stage I CRC vs normal group

In a prior paper from our research group, the VAT area was an independent risk factor for colorectal adenoma compared to normal controls<sup>[4]</sup>. In this study, according to a univariate analysis, the VAT and SAT area were not risk factors for early CRC. However, BMI was found to be significantly associated with the presence of CRC (*P* = 0.021). Conditional logistic regression models adjusting for smoking and alcohol consumption showed that CRC was not associated with VAT area. Including the SAT

**Figure 1** Comparison of visceral adipose tissue area (cm<sup>2</sup>) among patients with colorectal carcinoma, those with colorectal adenoma, and controls. Visceral adipose tissue (VAT) area in colorectal carcinoma patients was significantly lower than in adenoma patients ( $P = 0.018$ ), but it was not significantly lower than in control group ( $P = 0.513$ ).

area in the multivariate analysis provided the same result. Increased BMI, as a surrogate marker for general obesity, was an independent risk factor for CRC ( $P$  for trend = 0.025) (Table 2).

#### Adiposity in stage I CRC vs adenoma group

In the univariate analysis, VAT area, SAT area and BMI were not risk factors for early CRC compared to colorectal adenoma. The conditional logistic regression models (adjusted for smoking and alcohol consumption) showed that overall obesity, which is indicated by BMI, was not different between the adenoma and CRC groups. Contrary to expectations, an inverse relationship of the VAT area to early CRC was observed, compared with colorectal adenoma (OR = 0.53, 95%CI: 0.31-0.92,  $P = 0.02$ , highest quartile *vs* lowest quartile of the VAT area) (Table 3).

## DISCUSSION

In this study of 153 stage I CRC patients, age- and sex-matched 554 colorectal adenoma patients and 557 normal controls, we found that visceral obesity was not a risk factor for early CRC. Overall obesity (measured by BMI) was a significant risk factor for CRC compared with normal controls. This was consistent with previous findings<sup>[13]</sup>.

Recently, the prevalence of obesity has increased rapidly and is becoming a major public health problem. At present, more than 300 million people worldwide are obese<sup>[14]</sup>. There is mounting evidence relating obesity to colorectal neoplasia. However, the relationship between obesity and colorectal neoplasia differs depending on the methodology used to measure obesity. Whole body fat area is distributed into two main compartments with different metabolic characteristics: SAT and VAT<sup>[15]</sup>. BMI and body weight reflects the whole body fat amount.

Waist circumference (WC) and waist to hip ratio (WHR) implies the visceral fat area. Visceral obesity is also referred to as abdominal or central obesity. In several reports, BMI and body weight were not consistently related to the development of colorectal neoplasia, an association which is strongly influenced by gender<sup>[6,10,16-18]</sup>. WC and WHR have shown a stronger positive relationship<sup>[18-21]</sup>; however, several studies of WC and WHR suggested a greater risk for CRC in men than women, thus providing inconclusive results regarding their relationship<sup>[22,23]</sup>. The visceral fat area can be assessed most objectively by CT scanning at the umbilical level<sup>[12]</sup>. Therefore, our study assessed the relationship of visceral obesity with colorectal adenoma and cancer based on CT analysis instead of WC and WHR. The technique we used for visceral adipose tissue area measurements in CT scan has been standardized and validated in previous studies<sup>[24-28]</sup>. Note that many studies have related visceral obesity to colorectal adenoma<sup>[7,17,19,29,30]</sup>. Our institute reported a similar result<sup>[4]</sup>. Results assessing the relationship between abdominal obesity and colorectal neoplasia are inconclusive. Studies have proven positive<sup>[9]</sup>, negative<sup>[10]</sup> or no association<sup>[31]</sup>. In the paper showing a positive relationship, the number of case subjects with CRC was small, and the authors did not confirm with colonoscopy that the control groups were polyp-free<sup>[31]</sup>. In the study showing an inverse relationship, the number of cases was small, and the authors included overall CRC stages, which resulted in the weight loss over the course of cancer development influencing the result. Studies that evaluate the effect of abdominal obesity in a large number CRC cases and define the control and adenoma groups clearly by colonoscopic examination are sparse. Colorectal neoplasia follows the “adenoma-carcinoma sequence”<sup>[8]</sup>, which is characterized by the progression from precancerous adenoma to carcinoma. Because adenomatous polyps are common and only a small portion progress to cancer<sup>[32]</sup>, the association of visceral obesity with colorectal neoplasia should be explored at each step. However, studies assessing their association with cancer (separately) are sparse. In our study, we assessed the effect of visceral obesity on the “normal to cancer” and “adenoma to cancer” progression. Contrary to the effect of visceral obesity on the “normal to colorectal adenoma sequence”, visceral obesity was not a risk factor for developing CRC. Every step of the “adenoma-carcinoma sequence” is affected by multiple factors<sup>[33-37]</sup>, such as genetic instability, cell cycle, apoptosis and other environmental factors, including inflammatory cells and dietary carcinogens. Therefore, the association between visceral fat and these multiple factors may be step-specific over the progression of this sequence. The role of visceral fat in the progression of the “adenoma-carcinoma sequence” is complex and has not been thoroughly explored. From the previous research and our paper, it appears that visceral obesity is a risk factor for colorectal adenoma formation but does not have an additional effect on its further progress to colorectal carcinoma.

<sup>1</sup>Multivariate model 1 was adjusted for current smoking status, and alcohol consumption; <sup>2</sup>Multivariate model 2 was adjusted for subcutaneous adipose tissue (SAT) and visceral adipose tissue (VAT), in addition. Since body mass index (BMI) showed co-linearity to adipose tissue amount, it was not included in the analysis; <sup>3</sup>P value for test of trend of odds.

Contrary to Western population, carcinogenesis is different in the Asian population, which develops CRC more often directly in normal colonic mucosa without adenoma stage. Our results might be compatible to this *de novo* pathway hypothesis. Further studies were needed to prove this hypothesis<sup>[38]</sup>.

Diabetes, one of the factors comprising metabolic syndrome, is also considered a risk factor for CRC. Some studies have shown positive<sup>[39-41]</sup> association between diabetes and CRC while others have shown inconclusive<sup>[39,41,42]</sup>. There are reports that the association is affected by ethnicity, gender and the duration of treatment<sup>[43,44]</sup>. In our study, diabetes showed no relationship with CRC. Recent study demonstrated that colon cancer risk is increased in diabetic men before diabetes onset<sup>[45]</sup>. Diabetes did not alter colon cancer risk in men or women after

clinical diabetes onset<sup>[45]</sup>. Because we only included patients with early CRC, we thought abnormal glucose metabolism, including impaired fasting glucose and diabetes all together, was a risk factor for early CRC. Multivariable analysis showed impaired fasting glucose/diabetes is an independent risk factor of early colon cancer (data was not shown). Future studies with objective measurement of diabetes (insulin level, C-peptide) and incorporating ethnicity, gender and medication difference might help elucidate the risk of CRC in diabetes.

Our study has some superiority over previous studies. Although several studies have assessed the effect of visceral obesity on colorectal neoplasia using CT scanning, few studies that analyzed its respective effect on the normal to adenoma and the adenoma to carcinoma sequences<sup>[7,9,10,19,31,46]</sup>. In our study, we included only the

stage I CRC patients to minimize the wasting characteristics of the cancer itself. Because we perform more than 500 cases CRC surgery in a year, the total number of early CRC cases that were included was sufficiently larger. In our study, we benefited from utilizing a control group that was selected by performing a complete; therefore, definite comparisons among the control, adenoma and CRC groups were feasible.

Several limitations of the study also warrant mentioning. First, because this study had a cross-sectional design, we could not evaluate the effect of the duration of visceral obesity and could not consider recent weight changes. Second, we did not adjust healthcare, socioeconomic status, dietary factors or physical activity factors, which affect the visceral fat amount and the CRC development. Third, as the control and adenoma groups were selected from the health screening population, there might be a socioeconomic difference in the CRC groups. However, several variables such as diabetes, hypertension, smoking, and alcohol consumption were not different from three groups. Fourth, information of previous adenoma before surgery was not available, which might affect the development of CRC. Fifth, since we did not analyze the genetic data in each group, *de novo* pathway, which is comprise some portion for CRC development<sup>[47]</sup>, was not taken into consideration to explain CRC development. Sixth, volumetric measure of VAT was more accurate than visceral adipose tissue area measurement<sup>[48,49]</sup>. However, the technique we used for VAT area measurements has been standardized and validated in previous studies<sup>[24-28]</sup>. Finally, since our study was designed retrospectively, we could not take into consideration in the relationship of metabolic syndromes for analysis because data such as triglyceride, high-density lipoprotein-cholesterol and insulin level, were not available. In addition, we did not have data such as WC or WHR in patients with CRC due to our retrospective study design.

In conclusion, although visceral obesity is an independent risk factor for colorectal adenoma in previous studies, it is not a risk factor for early CRC. Visceral obesity might not influence the adenoma-early carcinoma sequence, but it does influence the normal-adenoma sequence. In addition, role of visceral obesity which might be explained *de novo* pathway for CRC development in Asian population need to be studied in future.

## COMMENTS

### Background

Recently, several studies have addressed the association between colorectal adenoma and visceral adipose tissue (VAT) area as measured by abdominal computed tomography (CT). In addition, it has been well documented that most colorectal cancers (CRC) stem from colorectal adenoma in a process referred to as the adenoma-carcinoma sequence. However, the relationship between VAT and early CRC has not been thoroughly documented.

### Research frontiers

Although several studies have assessed the effect of visceral obesity on colorectal neoplasia using CT scanning, few studies that analyzed its respective effect on the normal to adenoma and the adenoma to carcinoma sequences. The authors investigated the role of VAT in developing CRC at each step of this sequence

## Innovations and breakthroughs

This study showed that visceral obesity is not a risk factor for early CRC, although it is an independent risk factor for colorectal adenoma in previous studies. Therefore, these data suggest that visceral obesity might influence the normal-adenoma sequence but not the adenoma-early carcinoma sequence. All of these observations are original and provide new information between visceral obesity and colorectal neoplasia above and beyond CT-measured visceral adiposity.

## Applications

The role of visceral fat in the progression of the "adenoma-carcinoma sequence" is complex and has not been thoroughly explored. From the previous research and our paper, it appears that visceral obesity is a risk factor for colorectal adenoma formation but does not have an additional effect on its further progress to colorectal carcinoma. These findings will be valuable data to understand the role of adipose tissue in the progression of "adenoma-carcinoma sequence".

## Terminology

VAT is defined as an intra-abdominal adipose tissue area confined by the peritoneum, excluding the paraspinal muscles and the vertebral column. Subcutaneous adipose tissue areas were defined as adipose tissue areas external to the abdomen and the back muscles.

## Peer review

Although there are some limitations due to its retrospective study design, this article is a nice and well written case controlled study showing the role of adipose tissue in the progression of colorectal adenoma-carcinoma sequence.

### Abstract

**AIM:** To determine the added value of hepatobiliary phase (HBP) gadoxetic acid-enhanced magnetic resonance imaging (MRI) in evaluating hepatic nodules in high-risk patients.

**METHODS:** The institutional review board approved this retrospective study and waived the requirement for informed consent. This study included 100 patients at high risk for hepatocellular carcinoma (HCC) and 105 hepatic nodules that were larger than 1 cm. A blind review of two MR image sets was performed in a random order: set 1, unenhanced (T1- and T2-weighted) and dynamic images; and set 2, unenhanced, dynamic 20-min and HBP images. The diagnostic accuracy, sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were compared for the two image sets. Univariate and multivariate analyses were performed on the MR characteristics utilized to diagnose HCC.

**RESULTS:** A total of 105 hepatic nodules were identified in 100 patients. Fifty-nine nodules were confirmed to be HCC. The diameter of the 59 HCCs ranged from 1 to 12 cm (mean: 1.9 cm). The remaining 46 nodules were benign (28 were of hepatocyte origin, nine were hepatic cysts, seven were hemangiomas, one was chronic inflammation, and one was focal fat infiltration). The diagnostic accuracy significantly increased with the addition of HBP images, from 88.7% in set 1 to 95.5% in set 2 ( $P = 0.002$ ). In set 1 *vs* set 2, the sensitivity and NPV increased from 79.7% to 93.2% and from 78.9% to 91.8%, respectively, whereas the specificity and PPV were not significantly different. The hypointensity on the HBP images was the most sensitive (93.2%), and typical arterial enhancement followed by washout was the most specific (97.8%). The multivariate analysis revealed that typical arterial enhancement followed by washout, hyperintensity on T2-weighted images, and hypointensity on HBP images were statistically significant MRI findings that could diagnose HCC ( $P < 0.05$ ).

**CONCLUSION:** The addition of HBP gadoxetic acid-enhanced MRI statistically improved the diagnostic accuracy in HCCs larger than 1 cm. Typical arterial enhancement followed by washout and hypointensity on HBP images are useful for diagnosing HCC.

**Key words:** Magnetic resonance imaging; Liver; Gadaxetic acid; Hepatobiliary phase; Hepatocellular carcinoma

**Core tip:** This study demonstrated the added value of hepatobiliary phase gadoxetic acid-enhanced magnetic resonance imaging (MRI) for diagnosing hepatocellular carcinoma, based on the changes in contrast uptake

on hepatobiliary phase images during hepatocarcinogenesis. The pitfalls of interpreting hepatobiliary phase MRI are important to recognize in obtaining the most accurate results.

Added value of hepatobiliary phase gadoxetic acid-enhanced MRI for diagnosing hepatocellular carcinoma in high-risk patients. *World J Gastroenterol* 2013; 19(45): 8357-8365 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i45/8357.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i45.8357>

## INTRODUCTION

Liver cancer is the second most frequent cause of death in men and the sixth leading cause of death in women worldwide. Southeast Asia is one of the regions with the greatest incidences of liver cancer, and hepatocellular carcinoma (HCC), associated with the hepatitis B virus, accounts for the majority of the cases<sup>[1,2]</sup>.

The therapeutic approach for HCC depends on the accurate diagnosis and identification of HCC lesions, *i.e.*, the number, size, and location of the lesions. In practice, the high prevalence of benign lesions in cirrhotic livers and the variability in HCC imaging characteristics, which depend on differentiation of the state of the disease, render the detection of HCC difficult. Magnetic resonance imaging (MRI), particularly contrast-enhanced dynamic MRI, plays an important role in accurately diagnosing HCC<sup>[3]</sup>. A study by Forner *et al.*<sup>[4]</sup> reported that the sensitivity and specificity were as high as 62% and 97%, respectively, for detecting HCC with conventional contrast-enhanced dynamic MRI. Nevertheless, undetectable HCC lesions pose a serious issue.

A recent molecular study reported that organic anion transporting polypeptide 8 (OATP8) is expressed in hepatocytes and that OATP8 expression significantly decreases during the multistep process of hepatocarcinogenesis<sup>[5]</sup>. A newly developed liver-specific contrast agent, gadoxetic acid, is taken up by hepatocytes *via* OATP8 in an *in vitro* study<sup>[6]</sup>. Therefore, the use of liver-specific contrast-enhanced MRI might provide superior detection and characterization of HCC<sup>[7-9]</sup>.

Gadoxetic acid, or gadolinium ethoxybenzyl diethylenetriamine pentaacetic acid (Gd-EOB-DTPA), has the properties of being both an extracellular gadolinium chelate and a hepatobiliary agent, thus enabling dynamic perfusion imaging, delayed hepatocyte uptake, and biliary excretion. A recent study demonstrated that, compared with conventional contrast-enhanced dynamic and T2-weighted MRI, Gd-EOB-DTPA-enhanced hepatobiliary phase MRI improved HCC detection<sup>[3]</sup>. However, there are no supportive data for such a benefit in the Thai population, which has a high prevalence of HCC with different risk factors. Because of differences in the population and the nature of the disease, we performed a study to determine the added value of Gd-EOB-DTPA-enhanced

**Table 1** Demographic characteristics of the study population (*n* = 100) *n* (%)

hepatobiliary phase MRI for diagnosing HCC in high-risk patients.

## MATERIALS AND METHODS

### Patient selection and reference standards

This retrospective study was approved by our institutional review board, which waived the informed consent requirement. Between January 2010 and July 2010, 100 consecutive patients (mean age: 59.5 years old; range: 27-89 years), consisting of 71 men (mean age: 59.4 years; range: 27-89 years) and 29 women (mean age: 59.6 years old; range: 36-81 years), were registered as high-risk patients with HCC and underwent Gd-EOB-DTPA-enhanced MRI. The high-risk patients included those with chronic viral hepatitis infections (HBV or HCV infection), liver cirrhosis, or elevated serum alpha-fetoprotein (AFP) levels. Among the 100 patients, 76 had liver cirrhosis. Forty-five patients had hepatitis B-related cirrhosis, 16 had hepatitis C-related cirrhosis, nine had alcoholic cirrhosis, six had nonalcoholic steatohepatitis, 22 had a chronic hepatitis infection (20 with chronic hepatitis B and two with chronic hepatitis C), and the remaining two patients only presented with abnormal serum AFP. The Child-Pugh score was calculated for all of the patients within 60 d of the MRI scan (Table 1).

The reference standard for diagnosing HCC was classified as follows: based on pathologically proven HCC (by surgical specimen or percutaneous biopsy); by lipiodol staining after transhepatic arterial chemoembolization (TACE); or on the basis of progression of the disease on follow-up computed tomography (CT) or MRI performed at least 6 mo after the initial imaging.

### MRI methods

All of the MRI studies were performed with a 1.5-T system (Signa HDxt; GE Healthcare, Milwaukee, Wisconsin, United States) and a 3.0-T system (Intera Achieva; Philips Medical Systems, Best, The Netherlands) with phased-array coils. All of the images were obtained on the axial plane. The field of view (32-40 cm × 32-40 cm) was adjusted for each patient. The MR protocol consisted of a double-echo T1-weighted gradient-echo sequence (in-phase and opposed-phase), a respiratory-triggered fast-spin T2-weighted sequence, and a contrast-enhanced dynamic sequence. The parameters for all of the sequences are presented in Table 2. For the contrast-enhanced dynamic MR images, Gd-EOB-DTPA was administered at 0.025 mmol per kilogram of body weight at 2 mL per second, followed by a 10-mL saline flush. After administering the contrast, early arterial phase (25-30 s), late arterial phase (45-50 s), portal venous phase (65-70 s), equilibrium phase (5 min), and additional hepatobiliary phase (after 20 min) images were obtained.

### MR image analysis

Two sets of MR images were reviewed by an experienced gastrointestinal radiologist (S.P.) in a random order. The observer was blinded to the patient history, the findings from other imaging modalities, treatments, outcomes, and the final diagnoses. Set 1 of the MR images contained unenhanced (pre-contrast T1- and T2-weighted images) and Gd-EOB-DTPA-enhanced dynamic images (arterial, portal venous, and 5-min equilibrium phases); set 2 consisted of unenhanced, Gd-EOB-DTPA-enhanced dynamic, and 20-min hepatobiliary phase images. The MR images in set 2 were obtained at least 1 mo after finishing the reviews of all of the MR images in set 1. A diagnosis of HCC met at least one of the following criteria: (1) a liver nodule 1 cm or larger, with increased enhancement on arterial phase images and washout on portal venous or equilibrium phase images<sup>[10]</sup>; or (2) a hypervascular liver nodule 1 cm or larger, with no uptake on 20-min hepatobiliary phase Gd-EOB-DTPA-enhanced MR images<sup>[11]</sup>.

The observer recorded the possibility of HCC for each dominant lesion (defined as 1 cm or larger) using a four-point confidence rating scale: (1) unlikely to be HCC; (2) a concerning nodule; (3) probably HCC; and (4) definitely HCC. A score of 0 was recorded when the observer did not find any dominant lesions. Lesions

that received a score of 3 or 4 were classified as positive for HCC in later analyses. The size and location of each lesion were clearly documented using liver segmental anatomy, defined by Couinaud classification and MR characteristics (in-phase, opposed-phase, T2-weighted, arterial phase, portal venous phase, 5-min equilibrium phase, and 20-min hepatobiliary phase images, which were only obtained in set 2). All of the MR images were reviewed with Picture Archiving and Communications System (PACS) and Digital Imaging and Communications in Medicine Conformance (Synapse, version 3.2.0, FUJIFILM Medical Systems United States's Synapse® PACS system, Stamford, Connecticut, United States).

### Statistical analysis

Statistical analyses were performed using statistical software (SPSS, version 17.0.1, SPSS, Chicago, Illinois, United States). Descriptive statistics were calculated for all of the clinical variables and for those evaluated on the MR images. For continuous data (age, AFP level, total bilirubin level, and lesion size), the means, SDs, and ranges were calculated. Descriptive statistics, such as raw numbers and percentages, were determined for categorical data. An alternative free-response receiver operating characteristic analysis was performed on the confidence rating scale of the observer. The area under the alternative free-response receiver operating characteristic curve ( $A_z$ ) was utilized to determine the diagnostic accuracy of detecting HCC in each image set and according to lesion size (1-2 cm or larger than 2 cm). Sensitivity, specificity, positive predictive values (PPVs), and negative predictive values (NPVs) were calculated for the two MR image sets.

The relationships between each MRI variable and the presence of an HCC lesion were tested *via* univariate analysis. Significant variables identified by the univariate analysis were integrated into the logistic regression model for the multivariate analysis. The MRI variables with significant associations in the multivariate analysis were regarded as significant predictors of the presence of HCC. All of the statistical tests were two-tailed, and a *P* value of < 0.05 indicated statistical significance.

## RESULTS

A total of 105 hepatic nodules were identified in 100 patients. Fifty-nine nodules were confirmed to be HCC by

Figure 1 Magnetic resonance images from a 77-year-old woman with hepatitis B virus cirrhosis. A liver nodule at segment VII was surgically confirmed as hepatocellular carcinoma. Gadolinium ethoxybenzyl diethylenetriaminepentaacetic -enhanced magnetic resonance (MR) arterial phase images depicting a 1.9-cm arterial enhanced nodule (A) with rapid washout on the equilibrium phase image (B). C: Hyperintensity on a T2-weighted MR image; D: Hypointensity on a 20-min hepatobiliary phase image.

Table 3 Diagnostic accuracy of diagnosing hepatocellular carcinoma using conventional dynamic magnetic resonance imaging or conventional dynamic magnetic resonance imaging with hepatobiliary phase images			
	Conventional dynamic MRI	Conventional dynamic MRI+ HBP	P value
All lesions	88.7%	95.5%	0.002
Lesions 1-2 cm	86.7%	94.0%	0.008
Lesions > 2 cm	94.4%	100%	0.145

MRI: Magnetic resonance imaging; HBP: Hepatobiliary phase.

Table 4 Sensitivity, specificity, and positive and negative predictive values for diagnosing hepatocellular carcinoma using conventional dynamic magnetic resonance imaging or conventional dynamic magnetic resonance imaging with hepatobiliary phase images				
	Conventional dynamic MRI	95%CI	Conventional dynamic MRI+ HBP	95%CI
Sensitivity	79.7%	67.2-89.0	93.2%	83.5-98.1
Specificity	97.8%	85.5-99.9	97.8%	88.5-99.9
Positive predictive value	97.9%	88.9-99.9	98.2%	90.4-100.0
Negative predictive value	78.9%	66.1-88.6	91.8%	80.4-97.7

MRI: Magnetic resonance imaging; HBP: Hepatobiliary phase.

pathologic examination of surgical resection or percutaneous biopsy specimens ( $n = 23$ ), by lipiodol staining after TACE ( $n = 30$ ), or on the basis of disease progression on follow-up CT or MRI at least 6 mo after the initial imaging ( $n = 6$ ; mean: 11.9 mo). The diameter of the 59 HCCs ranged from 1 to 12 cm (mean: 1.9 cm). The remaining 46 nodules were benign (28 were of hepatocyte origin, nine were hepatic cysts, seven were hemangiomas, one was chronic inflammation, and one was focal fat infiltration). Four of the 46 nodules were pathologically confirmed as benign lesions (two were regenerative nodules, one was a cirrhotic nodule, and one was a hemangioma), and 42 nodules were considered benign because they decreased or remained unchanged in size on the last follow-up CT, or MRI (mean: 22.1 mo).

The diagnostic accuracy of diagnosing HCC in the two image sets is presented in Table 3. The diagnostic accuracy of the combination of unenhanced, Gd-EOB-DTPA-enhanced dynamic, and 20-min hepatobiliary phase images (set 2, 95.5%) was significantly greater than

that of the unenhanced and Gd-EOB-DTPA-enhanced dynamic images (set 1, 88.7%) ( $P = 0.002$ ; Figure 1). For 1- to 2-cm lesions, the diagnostic accuracy significantly improved from 86.7% in set 1 to 94.0% in set 2 ( $P = 0.008$ ), whereas there was no statistical improvement for lesions > 2 cm (94.4% in set 1 and 100% in set 2;  $P = 0.145$ ).

The sensitivity, specificity, PPVs, and NPVs for the two image sets are presented in Table 4. The addition of 20-min hepatobiliary phase images increased the sensitivity from 79.7% (95%CI: 67.2-89) to 93.2% (95%CI: 83.5-98.1). The specificity of both sets was 97.8% (95%CI: 85.5-99.9). The addition of 20-min hepatobiliary phase images increased the positive and NPVs from 97.9% (95%CI: 88.9-99.9) to 98.2% (95%CI: 90.4-100) and from 78.9% (95%CI: 66.1-88.6) to 91.8% (95%CI: 80.4-97.7), respectively.

The sensitivity, specificity, PPVs, and NPVs of each MRI characteristic utilized to diagnose HCC were as follows: (1) fat metamorphosis: 16.9% (95%CI: 8.4-29), 95.7% (95%CI: 85.2-99.5), 83.3% (95%CI: 51.6-97.9),

**Table 5** Sensitivity, specificity, and positive and negative predictive values for diagnosing hepatocellular carcinoma based on magnetic resonance imaging findings after excluding cysts and hemangiomas ( $n = 89$ )

MRI findings	Sensitivity (%)	Specificity (%)	Positive predictive value (%)	Negative predictive value (%)
Fat metamorphosis	16.9 (8.4-29.0)	93.3 (77.9-99.2)	83.3 (51.6-97.9)	36.4 (25.7-48.1)
Hyperintensity on T2-weighted images	66.1 (52.6-77.9)	93.3 (77.9-99.2)	95.1 (83.5-99.4)	58.3 (43.2-72.4)
Arterial enhancement	88.1 (77.1-95.1)	70.0 (50.6-85.3)	85.2 (73.8-93.0)	75.0 (55.1-89.3)
Arterial enhancement and washout on venous or equilibrium phase	79.7 (67.2-89.0)	96.7 (82.8-99.9)	97.9 (88.9-99.9)	70.7 (54.5-83.9)
Hypointensity on 20-min hepatobiliary phase	93.2 (83.5-98.1)	53.3 (34.3-71.7)	79.7 (68.3-88.4)	80.0 (56.3-94.3)
Arterial enhancement and no/partial uptake on 20-min hepatobiliary phase	83.1 (71.0-91.6)	93.3 (77.9-99.2)	96.1 (86.5-99.5)	73.7 (56.9-86.6)

and 47.3% (95%CI: 36.9-57.9); (2) hyperintensity on T2-weighted images: 66.1% (52.6-77.9), 60.9% (45.4-74.9), 68.4% (54.8-80.1), and 58.3% (43.2-72.4); (3) arterial enhancement: 88.1% (77.1-95.1), 67.4% (52.0-80.5), 77.6% (65.8-86.9), and 81.6% (65.7-92.3); (4) arterial enhancement and washout on venous or equilibrium phase images: 79.7% (67.2-89.0), 97.8% (88.5-99.9), 97.9% (88.9-99.9), and 78.9% (66.1-88.6); (5) hypointensity on 20-min hepatobiliary phase images: 93.2% (83.5-98.1), 34.8% (21.4-50.2), 64.7% (53.6-74.8), and 80% (56.3-94.3); and (6) arterial enhancement and no or partial uptake on 20-min hepatobiliary phase images: 83.1% (71.0-91.6), 82.6% (68.6-92.2), 86% (74.2-93.7), and 79.2% (65.0-89.5). The MRI finding with the greatest sensitivity (93.2%) for detecting HCC was hypointensity on the 20-min hepatobiliary phase images, and the greatest specificity (97.8%) for detecting HCC occurred with typical arterial enhancement and washout on venous or

equilibrium phase images. Excluding cysts and hemangiomas, the specificity of diagnosing HCC was greater for hyperintense T2-weighted images and for hypointensities on hepatobiliary phase images (Table 5).

Table 6 summarizes the results of the univariate analysis of the ability of the MRI findings in the two groups to diagnose HCC, as well as the results after excluding cysts and hemangiomas. Although almost all of the MRI features were statistically significant in the univariate analysis, the multivariate analysis revealed that only the arterial enhancement and washout on venous or equilibrium phase images were statistically significant MRI findings ( $P < 0.001$ ; OR = 102.0; 95%CI: 10.3-1012.4; Table 7). Furthermore, typical arterial enhancement followed by washout on venous or equilibrium phases, hyperintensity on T2-weighted images, and hypointensity on 20-min hepatobiliary phase images were statistically significant MRI findings, after excluding cysts and hemangiomas.

**Figure 2** Magnetic resonance images from a 59-year-old woman with hepatocellular carcinoma at hepatic segment VI. This patient underwent transhepatic arterial chemoembolization, and the 6-wk follow-up computerized tomography scan revealed lipiodol staining in the lesion. A and B: Arterial phase and portal venous phase images; C: T2-weighted magnetic resonance image with no definite focal lesion; D: The hepatobiliary phase image revealed a 1.0-cm discrete nodule that was not visible on the dynamic or T2-weighted images.

## DISCUSSION

Our study demonstrated that adding hepatobiliary phase Gd-EOB-DTPA-enhanced MRI significantly improved the accuracy of diagnosing HCC. The significant improvement was particularly apparent for small lesions (1–2 cm in diameter). No significant differences were observed for lesions larger than 2 cm in diameter. This finding could be explained by most large HCCs being unequivocally diagnosed based on clearly enhanced characteristics using conventional dynamic MRI. Smaller HCCs sometimes exhibit atypical enhancement characteristics. Therefore, the inclusion of the hepatobiliary phase provided more information for including or excluding the diagnosis of HCC for small nodules. However, other important information for diagnosing HCC was still based on conventional dynamic MRI.

Sensitivity increased with the addition of hepatobiliary phase images, whereas specificity did not change. The inclusion of hepatobiliary phase images allowed subtle abnormalities present in other sequences to be visualized more clearly. The results of our study agreed with those of recent reports in terms of the improvement of diagnostic performance, the characterization of HCC, and the dismissal of pseudolesions<sup>[3,10,12–14]</sup>. In our study, adding the hepatobiliary phase images increased lesion detection by eight HCCs (13.5%), compared with conventional dynamic MRI (Figure 2).

Our study also highlighted other characteristic MRI findings that were involved in diagnosing HCC. Fat metamorphosis, which can be seen with chemical shift GRE imaging, was present in 10 of 59 HCCs (16.9%) with high specificity (93.3%). Two of the 46 benign lesions (4.3%) with fat components were histologically confirmed to be regenerative nodules in the background of cirrhosis and focal fat infiltration in normal livers. The results were similar to those in the study by Martín *et al.*<sup>[15]</sup>. The presence of various fat alterations might be a significant morphological marker for malignant transformation from adenomatous hyperplasia to HCC, although it occurs rarely and can be present in benign hepatic nodules

in cirrhotic patients<sup>[15,16]</sup>.

A recent study demonstrated that T2-weighted images did not provide additional diagnostic value in detecting and characterizing focal lesions. The heterogeneity and hyperintense fibrotic septa and bridges in cirrhotic liver parenchyma can obscure moderately hyperintense HCCs on T2-weighted images, and 42%–53% of HCCs can also be isointense to hypointense on T2-weighted images<sup>[17]</sup>. In this study, however, the specificity improved with the addition of T2-weighted images after excluding cysts and hemangiomas, and T2-weighted images had the greatest sensitivity among all of the tests, with an odds ratio statistically different from 1 for differentiating HCC from benign lesions larger than 1 cm; these results were similar to those of previous reports<sup>[18,19]</sup>.

In 2010, the American Association for the Study of Liver Diseases guidelines for 1- to 2-cm HCCs were changed to require the visualization of a typical enhancement pattern using only one contrast-enhanced imaging technique<sup>[10]</sup>. In our series, a typical enhancement pattern was observed in 47 of 59 HCC lesions (79.7%) and in one of 30 benign lesions (3.3%); this benign lesion was determined by tissue biopsy to be a regenerating nodule. In our study, 12 of 59 HCC lesions (20.3%) had no typical arterial enhancement or washout on portal venous or equilibrium phase images, and these lesions were classified as well-differentiated HCCs (Figure 3); one had a motion artifact that resulted in a technical error. A recent study by Witjes *et al.*<sup>[20]</sup> demonstrated a strong association between the presence of washout on dynamic MRI and moderately to poorly differentiated HCC.

The majority of the HCCs in our study (55 lesions, 93.2%) had no uptake or partial uptake on the hepatobiliary phase images. Only four HCC lesions (6.8%) were iso- or hyperintense on the hepatobiliary phase images. Fortunately, three-quarters were scored as probably HCC based on the presence of a hypointense capsule, even without the typical enhancement pattern (Figure 3). Two lesions were histologically confirmed to be well-differentiated HCCs. The diminished obviousness of these well-differentiated lesions on hepatobiliary phase

**Figure 3** Magnetic resonance images from a 54-year-old man with a 1.4-cm hepatocellular carcinoma with liver-specific contrast uptake at segment VII. This nodule was confirmed by tissue biopsy to be a well-differentiated hepatocellular carcinoma. Arterial enhanced nodule (A) without washout on the portal venous (B) phase images; C: A slightly hyperintense nodule with a hypointense capsule on a T2-weighted magnetic resonance image; D: Hepatobiliary phase image illustrating the hyperintense nodule.

images might have been related to residual hepatocyte activity within the lesions, enabling the delayed uptake of the contrast material<sup>[3]</sup>. Another possible cause of diminished obviousness on the hepatobiliary phase images was impaired hepatic function or hyperbilirubinemia, which can affect the hepatocyte uptake of the contrast agent in the liver parenchyma<sup>[21]</sup>. However, all of the false-negative cases in our study that demonstrated iso- or hyperintensity on the hepatobiliary phase images had normal bilirubin levels. A recent study by Kim *et al*<sup>[22]</sup> reported that 10% of HCCs were hyperintense on hepatobiliary phase images, and most of the hyperintense HCCs were either well differentiated or moderately differentiated.

A variety of benign hepatic lesions can appear hypointense on hepatobiliary-phase MRI because of the following causes: (1) a lack of functional hepatocytes in the lesion; (2) damage to the functional hepatocytes from infection or inflammation; and (3) impairment of the biliary function of the lesion<sup>[23]</sup>. In this study, hepatic cysts and hemangiomas accounted for most of the benign hypointense lesions on hepatobiliary phase images. To reduce false-positive findings, hepatobiliary phase imaging should be considered an adjunct method, rather than the sole method, for diagnosing HCC. By excluding benign hepatic cysts and hemangiomas, the arterial enhancement with hypointensity on hepatobiliary phase images had high diagnostic accuracy, comparable to the typical enhancement pattern for HCC (sensitivity: 83.1% *vs* 79.7%; specificity: 93.3% *vs* 96.7%). However, false-positive cases accounted for one (3.3%) typical enhancement pattern and two (6.7%) arterial enhancement patterns with hypointensity on hepatobiliary phase images. These cases were hypothesized to be dysplastic nodules that had stable appearances on imaging.

Several limitations of this study should be addressed. First, the retrospective nature introduced the possibility of selection bias, although we attempted to avoid bias by recruiting consecutively registered patients who met the inclusion criteria. Second, not all of the lesions were confirmed pathologically, which could have introduced verification bias. Histopathology was obtained for 23 of 59

(39%) HCC lesions and four of 46 (8.7%) benign lesions. However, we attempted to avoid this factor by extending the follow-up period to confirm the benign diagnoses (mean: 22.2 mo). Additionally, lesions smaller than 1 cm in diameter were not included in the study. Third, because we had only one observer scoring the images, testing inter-observer reliability was not feasible, and observer bias could have occurred. Finally, our findings might not reflect a direct comparison between imaging with an extracellular contrast agent and a liver-specific hepatobiliary agent. Hepatobiliary enhancement can begin as early as the first pass (the portal venous phase); therefore, it can be difficult to define clearly which phase is the most important for diagnosing HCC: the contrast-enhanced dynamic images or the hepatobiliary phase images.

In a conclusions, The addition of hepatobiliary phase imaging after the intravenous injection of Gd-EOB-DTPA significantly improved diagnostic accuracy in detecting HCC in high-risk patients. Typical arterial enhancement followed by washout, hyperintensity on T2-weighted images, and hypointensity on 20-min hepatobiliary phase images were useful for diagnosing HCCs larger than 1 cm.

## COMMENTS

### Background

Dynamic imaging plays an important role in diagnosis of hepatocellular carcinoma (HCC), which is based on typical enhancement characteristics. For years, rapid arterial enhancement and rapid washout pattern in dynamic contrast study is accepted as one of diagnostic criteria without tissue pathology. However, there are still limitations in term of sensitivity and specificity, particular in small lesions or during early phase of hepatocarcinogenesis. The newly developed hepatocyte-specific contrast [gadolinium ethoxybenzyl diethylenetriaminepentaacetic (Gd-EOB-DTPA)] that has ability to evaluate both enhancement characteristics and hepatocyte function could have a potential in improving diagnostic accuracy.

### Research frontiers

The change of organic anion transporting polypeptide 8 expression in hepatocytes during the multistep process of hepatocarcinogenesis could be imaged by a newly developed hepatocyte-specific contrast agent, gadoxetic acid, on dynamic magnetic resonance imaging (MRI). The use of hepatocyte-specific contrast-enhanced MRI provides superior detection and characterization of HCC.

### Innovations and breakthroughs

Adding hepatobiliary phase Gd-EOB-DTPA-enhanced MRI significantly improved the accuracy of diagnosing HCC. The significant improvement is apparent for small lesions (1-2 cm in diameter), for including or excluding the diagnosis of HCC, particular when the nodules exhibit atypical enhancement characteristics. The specificity can be improved with the addition of T2-weighted images after excluding cysts and hemangiomas during interpretation.

### Applications

A typical enhancement pattern on dynamic imaging for diagnosing HCC has limited sensitivity, particular for small lesions. Therefore, the addition of hepatobiliary phase imaging after the intravenous injection of Gd-EOB-DTPA will improve diagnostic accuracy in detecting HCC. However, a variety of benign hepatic lesions can appear hypointense on hepatobiliary-phase MRI. To get the best diagnostic accuracy, the hepatobiliary phase imaging should be interpreted in together with early dynamic phases and T2-weighted images.

### Peer review

Gadoxetic acid (Gd-EOB-DTPA)-enhanced MRI of the liver has certain advantages over other imaging modalities in the detection and characterization of HCC in the high-risk liver. Hepatobiliary phase images obtained after Gd-EOB-DTPA-enhanced MRI imaging may improve diagnosis of HCC and assist in surgical planning. This study aims to the added value of hepatobiliary phase Gadoxetic acid-enhanced MRI for diagnosis of HCC by the fact that there would be the changes of hepatocyte-specific contrast uptake on hepatobiliary phase during hepatocarcinogenesis and the interpretation's pitfalls of hepatobiliary phase MRI is also important to know for getting the most accurate result.

### Abstract

**AIM:** To determine the role of the fecal immunochemical test (FIT), used to evaluate fecal hemoglobin concentration, in the prediction of histological grade and risk of colorectal tumors.

**METHODS:** We enrolled 17881 individuals who attended the two-step colorectal cancer screening program in a single hospital between January 2010 and October 2011. Colonoscopy was recommended to the participants with an FIT of  $\geq 12$  ngHb/mL buffer. We classified colorectal lesions as cancer (C), advanced adenoma (AA), adenoma (A), and others (O) by their

colonoscopic and histological findings. Multiple linear regression analysis adjusted for age and gender was used to determine the association between the FIT results and colorectal tumor grade. The risk of adenomatous neoplasia was estimated by calculating the positive predictive values for different FIT concentrations.

**RESULTS:** The positive rate of the FIT was 10.9% (1948/17881). The attendance rate for colonoscopy was 63.1% (1229/1948). The number of false positive results was 23. Of these 1229 cases, the numbers of O, A, AA, and C were 759, 221, 201, and 48, respectively. Regression analysis revealed a positive association between histological grade and FIT concentration ( $\beta = 0.088$ ,  $P < 0.01$ ). A significant log-linear relationship was found between the concentration and positive predictive value of the FIT for predicting colorectal tumors ( $R^2 > 0.95$ ,  $P < 0.001$ ).

**CONCLUSION:** Higher FIT concentrations are associated with more advanced histological grades. Risk prediction for colorectal neoplasia based on individual FIT concentrations is significant and may help to improve the performance of screening programs.

**Key words:** Colorectal cancer; Fecal immunochemical test; Screening; Risk prediction; Performance

**Core tip:** The fecal immunochemical test (FIT) for hemoglobin is specific for detecting colorectal lesions. With adjustment for age and gender of 17 881 attendees at a colorectal cancer screening program in a single hospital, we demonstrated that higher FIT concentrations were associated with more advanced histological grades ( $\beta = 0.088$ ,  $P < 0.01$ ). A significant log-linear relationship was found between the FIT concentration and positive predictive value of the FIT for predicting

colorectal tumors ( $R^2 > 0.95$ ,  $P < 0.001$ ). Risk stratification for colorectal neoplasia based on individual FIT concentration may help to improve the performance of screening programs.

## INTRODUCTION

Colorectal cancer (CRC) accounts for the highest number of newly diagnosed cancer cases in Taiwan<sup>[1]</sup>. Most CRC develops *via* the well-known adenoma-carcinoma sequence that averages 10-15 years for progression and enables clinicians to detect neoplasms at the precancerous or early stages through adequate screening of the average-risk population<sup>[2]</sup>.

Several population-based studies suggest that screening for colorectal neoplasms using the fecal occult blood test can reduce mortality<sup>[3,4]</sup>. Occult blood may be measured using either the guaiac fecal occult blood test or the fecal immunochemical test (FIT). The FIT has several advantages. For example, the FIT can provide a measurable value of the fecal hemoglobin concentration and can predict colorectal bleeding more specifically<sup>[5-7]</sup>. Notably, the quantitative FIT value may be converted using a defined cut-off value into a “negative” or “positive” qualitative result, which facilitates subsequent management. Despite its widespread use, little is known about the clinical significance and application of the quantitative value of the FIT. Recently, Omata *et al.*<sup>[8]</sup> reported that the performance of the FIT for detecting CRC could be promising by choosing an optimal cut-off value of the quantitative FIT concentration<sup>[8]</sup>. Chen *et al.*<sup>[9]</sup> investigated the association between baseline fecal hemoglobin concentration and the risk of incident colorectal neoplasia using a cut-off fecal hemoglobin concentration of 100 ng/mL to classify attendees as negative or positive. In subjects with a negative FIT, the adjusted hazard ratios (HRs) increased from 1.43 for a baseline fecal hemoglobin concentration of 20-39 ng/mL, to 3.41 for a baseline concentration of 80-99 ng/mL (*t* test  $P < 0.0001$ ), relative to 1-19 ng/mL. They concluded that quantitative fecal hemoglobin concentration at baseline could predict subsequent risk of incident colorectal neoplasia<sup>[9]</sup>. These important findings suggest that quantitative FIT could be applied more widely in clinical practice.

The Taiwan Bureau of National Health Insurance began population-based CRC detection programs in 2006 for average-risk individuals aged between 50 and 69 years. A two-step approach was applied: a biennial 1-d FIT was

used as a screening tool; subjects with a “positive” FIT underwent follow-up endoscopy to detect asymptomatic CRC. The effectiveness of the program appeared encouraging as a significant number of CRCs were detected in the early stages. However, a substantial portion of the participants did not adhere to the screening protocol because they were asymptomatic and/or worried about the discomfort and risk associated with colonoscopy. In addition, some physicians and health providers were less inclined to recommend feces-based CRC screening to patients. These factors may limit the outcomes of the project<sup>[10-12]</sup>. To improve the performance of CRC screening, a more personalized approach on the basis of risk stratification may be helpful<sup>[13]</sup>. Here, we evaluated the quality of colonoscopy in the screening program and determined the association between the FIT and colorectal neoplasia with the aim of determining whether the risk of CRC could be deduced from the quantitative value of the FIT.

## MATERIALS AND METHODS

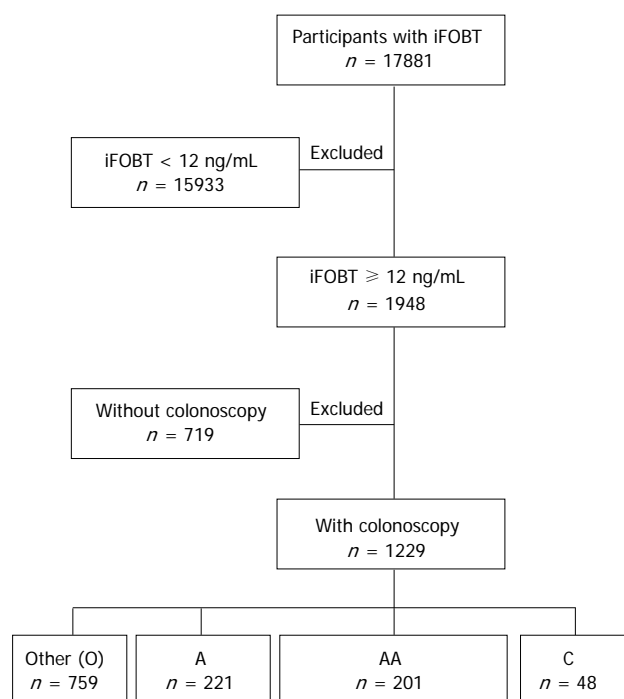

### Subjects and feces analysis

We enrolled individuals who attended the national colorectal cancer screening program in a single medical center from January 2010 through October 2011. The participants were interviewed by a cancer screening specialist nurse during a face-to-face meeting to explain the purpose of CRC screening, the procedure for feces collection, and to sign the consent form. They were asked to provide one sample of feces in a stool container (Kyowa, Tokyo, Japan) to enable an accurate and quantitative evaluation by decreasing the variations in feces sampling levels. Storage of the samples was suggested at 4 °C and they were to be returned to the hospital within 3 d. Feces specimens were analyzed on a fully automated analyzer. The reagents, calibrators and controls for the samples were prepared according to the manufacturer's guidance (Kyowa, Tokyo, Japan). The FIT measurements were converted to the proposed standardized reporting units:  $2.5 \text{ (ngHb/mL buffer)} = 1 \text{ (}\mu\text{gHb/g feces)}$ <sup>[14,15]</sup>.

Colonoscopy within 2 months was recommended to the subjects if their FIT was  $\geq 12 \text{ ngHb/mL buffer}$ . If a polyp with a diameter  $> 0.5 \text{ cm}$  was observed, polypectomy or biopsy was performed to obtain histological results. The Hospital Ethics Committee approved this study.

### Quality indicators

Several quality indicators were chosen according to the National Health Service bowel cancer screening program guideline to investigate the performance of the screening program<sup>[16]</sup>. The colonoscopic attendance rate was determined as: No. of colonoscopies/No. of positive FITs. Cecal intubation rate was defined as: No. of photographic documentations of the cecal landmark/No. of colonoscopies. The adenoma detection rate was calculated as: no. of cases with adenomatous tumors/No. of colonos-

**Figure 1** Flowchart of study participants recruited from the two-step colorectal cancer screening program. O: Other; A: Adenoma; AA: Advanced adenoma; C: Cancer.

copies. The cancer detection rate was calculated as: no. of cases with cancer/No. of colonoscopies. The incidence of complications was calculated as: No. of cases with major bleeding or perforation/No. of colonoscopies).

### Cancer stage

The cancer stage was recorded according to the American Joint Committee on Cancer 7<sup>th</sup> edition. To determine whether cancer detected by screening (CS) was at an earlier stage compared with the hospital cancer registry (CR), the stage migration was calculated as the difference in the proportion of tumors at each stage between CS and CR.

### Classifications used in the study

The colorectal findings were classified as cancer (C), advanced adenoma (AA), adenoma (A), and other (O) on the basis of their endoscopic and histological findings. Advanced adenoma was defined by the presence of any of the following characteristics: adenoma with a villous component, high-grade dysplasia, and polyp size  $\geq 1.0$  cm. If more than two lesions were found in one examination, we grouped the cases according to the most advanced findings.

The FIT data of all participants with colonoscopies were recorded. We transformed the continuous *F* value (ngHb/mL buffer) into ordinal scales: 12.1-25.0, 25.1-50.0, 50.1-100.0, 100.1-200.0, 200.1-400.0, 400.1-800.0, and  $> 800.0$ . To determine the associations between age, gender, FIT concentration and tumor grade, these non-normally distributed data were compared among the groups using the Kruskal-Wallis test. Subsequently, a multiple linear regression analysis adjusted for

**Table 1** Quality measures of the colorectal cancer screening program in this study

Quality indicator	Outcomes	<sup>1</sup> Standard	Quality
Colonoscopy attendance rate	63.10%	$\geq 85\%$	Inadequate
Cecum intubation rate	98.10%	$\geq 90\%$	Adequate
Polyp detection rate	57.20%	-	-
Adenoma detection rate	35.70%	$\geq 35\%$	Adequate
Cancer detection rate	2.7‰ screened by FIT 3.9‰ screening colonoscopies	$\geq 2\%$ screened by fecal occult blood test $\geq 11\%$ screening colonoscopies	Auditable outcome
Major bleeding	0.24%	$< 1\%$	Adequate
Perforation	0	$< 1\%$	Adequate

<sup>1</sup>NHS BCSP quality assurance guidelines for colonoscopy 2011. NHS: National Health Service; BCSP: bowel cancer screening program.

age and gender was used to determine whether the FIT concentration was independently associated with the histologic grade of colorectal tumors.

### Statistical analysis

To determine the risk of colorectal neoplasia with regard to the FIT concentration, we evaluated the positive predictive value (PPV) of the FIT concentration (ngHb/mL buffer) at different cut-off concentrations (12, 25, 50, 100, 200, 400, 800 and 1000) for detecting A + AA + C, AA + C, and C. After log(2) transformation of the FIT results, a simple linear regression analysis was performed to determine the relationship. All statistical analyses were conducted using the software SPSS 19.0 to compare the differences among groups.

## RESULTS

### Baseline characteristics and performance of the CRC screening program

A flowchart of the study participants is shown in Figure 1. A total of 17881 participants underwent the FIT for colorectal cancer screening. The positive rate of the FIT was 10.9% (1948/17881). The number of false positive results was 23. The indicators for the quality of colonoscopy are listed in Table 1. The attendance rate for colonoscopy was 63.1% (1229/1948). The cecum-reaching rate was 98.1% (1206/1229). The polyp detection rate was 57.2% (703/1229). The adenoma detection rate was 35.7% (422/1181). The cancer detection rate was 3.9% (48/1229). The incidence of complications was 0.24% (3 cases of bleeding requiring hemostasis intervention and no perforations). The other endoscopic findings included normal, hemorrhoids, colitis, ulcers, diverticulum, and submucosal lesions.

### Cancer stage migration

The stage migration of colorectal cancer is shown in Figure 2. Of the 48 malignancies, 1 was a lymphoma and 47

**Figure 2** Cancer stage difference between the colorectal cancer screening program and cancer registry database. The cancer stage (X-axis) and proportion (Y-axis) of screening-detected cancers (CS) and the hospital cancer registry (CR) database. The stage migration was calculated as the difference in cancer proportions between the two databases (CS-CR).

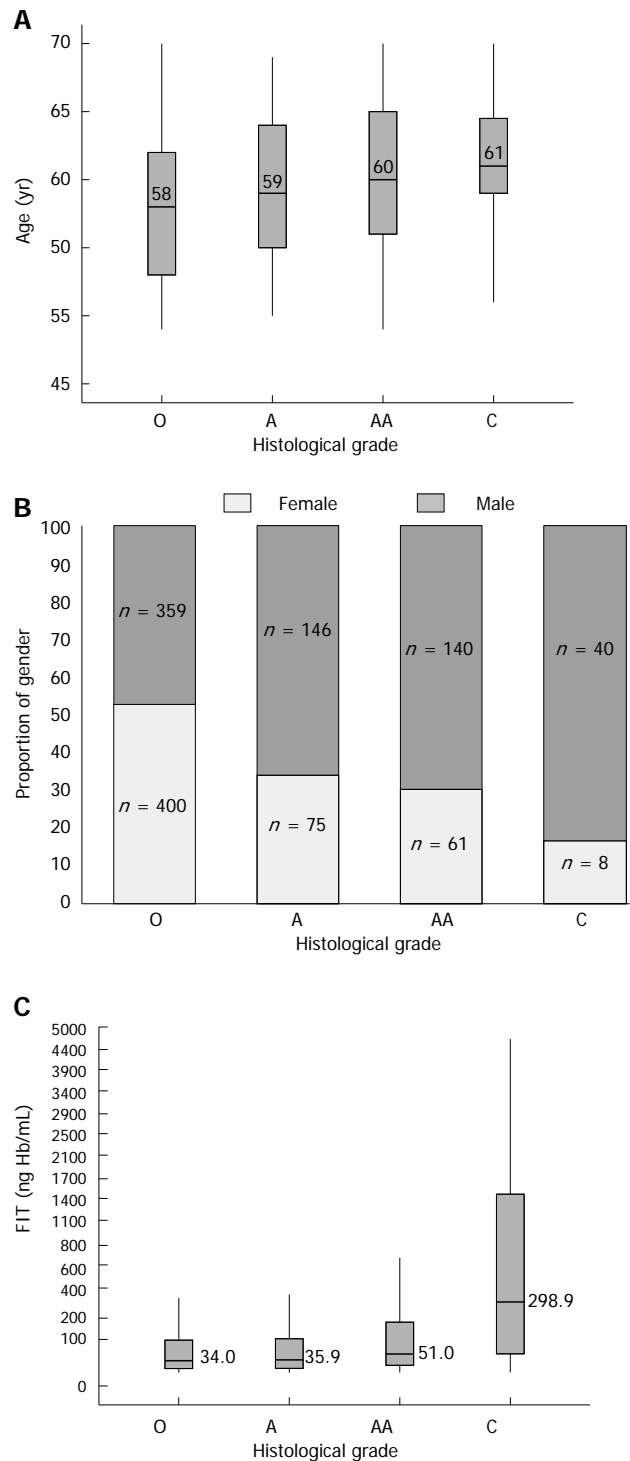

were adenocarcinomas. Of the 47 cases, the proportions of stages 0, I, II, III, and IV were 25.5%, 31.9%, 6.4%, 25.5%, and 10.6%, respectively. In the hospital cancer registration database, the proportions of stages 0, I, II, III, and IV were 14.1%, 18.1%, 22.8%, 30.9%, and 14.1%, respectively. Therefore, the corresponding differences for stages 0, I, II, III, and IV were 11.4%, 13.9%, -16.4%, -5.4%, and -3.5%, respectively, indicating that cancers tended to be detected at an earlier stage by screening.

#### Age, gender, and FIT in association with histologic grade of colorectal tumors

The patient numbers in the 4 groups O, A, AA, and C were 759, 221, 201, and 48, respectively. Figure 3 shows the differences in age, gender, and FIT concentrations in these groups. The median age of the 1229 patients was 59 years. The median ages of patients with O, A, AA, and C were 58, 59, 60 and 61 years, respectively. Male patients accounted for 55.7% of the 1229 patients. The percentages of men with O, A, AA, and C were 47.3%, 66.1%, 69.7% and 83.3%, respectively. The median FIT concentration (ngHb/mL buffer) in the 1229 cases was 37.5. The median FIT values in patients with O, A, AA, and C were 34.0, 35.9, 51.0 and 298.9, respectively. Comparing the distributions of age, gender, and FIT concentration among the groups, the histological grade of the colorectal tumors increased with increased age, FIT level and male gender (Kruskal-Wallis test, all  $P < 0.001$ ). Subsequent multiple linear regression analysis revealed a significant association between ordinal scales of the FIT and histological grade of colorectal tumors after adjusting for age and gender ( $\beta = 0.088$ ,  $P < 0.001$ ) (Table 2).

#### Risk prediction for colorectal tumors based on the FIT

The PPVs for detecting A + AA + C, AA + C, and C were elevated from 38.2%-58.7%, 20.3%-42.7% and 4.0%-21.3%, respectively, as the FIT concentration (ngHb/mL buffer) increased from 12 to 1000. After log(2) transformation of the FIT values, a linear relation-

**Figure 3** Age, gender, and fecal immunochemical test concentration in association with histological grade of colorectal tumor. A: Age; B: gender; C: FIT. The differences in age, gender, and FIT concentrations (Y-axis) in the different histological groups (X-axis). (Kruskal-Wallis test, all  $P < 0.001$ ). FIT: fecal immunochemical test; O: Other; A: Adenoma; AA: Advanced adenoma; C: Cancer.

ship between quantitative level and PPV of the FIT for predicting colorectal adenomatous polyps and malignancies was observed (all  $R^2 > 0.95$ ,  $P < 0.001$ ). The linear relationship reached a plateau when the FIT concentration was  $> 800$  (Figure 4).

**Table 2** Age, gender, and fecal immunochemical test concentration in association with histological grade of colorectal tumor: multiple linear regression analysis

<sup>1</sup> Multiple linear regression model		Beta (95%CI)	P value
Age (yr)	50-69	0.021 (0.012-0.030)	< 0.001
Gender	Female: 0, Male: 1	0.342 (0.245-0.44)	< 0.001
<sup>2</sup> FIT (ngHb/mL)	Scale 1: 12.1-25	0.088 (0.062-0.114)	< 0.001
	Scale 2: 25.1-50		
	Scale 3: 50.1-100		
	Scale 4: 100.1-200		
	Scale 5: 200.1-400		
	Scale 6: 400.1-800		
	Scale 7: > 800		

<sup>1</sup>The model revealed a significant association between histological grade of colorectal tumors and three independent variables: age, gender and FIT concentrations; <sup>2</sup>We converted the continuous FIT value into an ordinal variable after a log(2) transformation of the FIT concentrations. FIT: Fecal immunochemical test.

## DISCUSSION

According to these results, the performance of the two-step CRC screening strategy in our study appeared satisfactory as most of the quality indicators were adequate<sup>[16]</sup>, and a stage migration phenomenon of the detected cancer was observed in the screening population. However, the following issues remain to be clarified: (1) whether colonoscopy should be recommended in asymptomatic subjects only on the basis of a “positive” feces test; (2) whether subjects with “positive” feces tests, but different FIT concentrations have the same risk of significant tumors; and (3) how to improve the performance of the CRC screening program.

Compared with the hospital cancer registry, we observed a stage migration phenomenon in detected cancer in the screening program. The transition zone was between stages I and II reflecting early cancer detection (Figure 2). This result was similar to several cohort studies which showed that feces-based screening programs may offer better prognosis and a reduced CRC mortality rate due to early diagnosis<sup>[17,18]</sup>. Whether early detection translates to improved overall survival may be disputed. CRC occurs predominantly in elderly patients, who may have comorbid conditions. CRC screening mainly identifies slower-growing lesions, and as most symptomatic populations have more advanced stages, they will not attend the screening program. Therefore, the lead-time bias and length bias cannot be neglected in the migration phenomenon<sup>[19-21]</sup>. Even so, the CRC screening program was still effective in detecting precancerous lesions and preventing tumor progression to more advanced stages. Taking these advantages together, colonoscopy should be recommended in individuals in the screening population with a positive feces test.

Consistent with previous reports, our research showed that the FIT concentration increases as disease becomes more serious, from non-significant findings to non-advanced adenomas to advanced adenomas to cancer<sup>[6,22,23]</sup>. This trend is independent after adjustment for age and

**Figure 4** Fecal immunochemical test concentration in the prediction of colorectal neoplasia: linear regression analysis. The association between FIT concentration with log(2) transformation (X-axis) and PPV (Y-axis). (all  $R^2 > 0.95$ ,  $P < 0.001$ ). FIT: Fecal immunochemical test; O: Other; A: Adenoma; AA: Advanced adenoma; C: Cancer; PPV: Positive predictive value.

gender which are important influencing factors<sup>[24]</sup>. The biological explanation for this association is complex. In summary, a more advanced tumor may be larger and more friable, may have increased vascularity in the stroma, and may have significant inflammation in the surrounding tissues<sup>[25,26]</sup>. These changes in the characteristics and environment of the tumor may result in significant occult bleeding and an increased FIT concentration. These interesting findings suggest that interpretation of the FIT should be extended beyond “negative” or “positive” and should be tailored according to concentration.

Colonoscopy compliance in participants who were positive for the FIT was 63.1% in this study. This inadequate performance has been frequently reported in other studies. The reasons for non-adherence to the protocol may be due to lack of awareness in the patient or inadequate recommendation by the physicians<sup>[27]</sup>. The present study demonstrated a dose-dependent relationship between the FIT level and the risk of colorectal tumors. This relationship between the FIT level and colorectal neoplasia could be used to offer more personalized care in risk stratification and management<sup>[7,8,28]</sup>. As we increased the FIT cut-off values, the trend in predicting advanced colorectal neoplasia increased from 20.3% to 42.7% (Figure 4). These data allow both participants and physicians to be aware of the possibility of occult tumors at each FIT concentration. Accordingly, patients may be more willing to undergo colonoscopy if they are aware of the risk of advanced neoplasia according to the FIT concentration.

There are some limitations in this study. First, the study design was retrospective. Second, the lifestyles, BMI, and family history of colorectal cancer patients, which could be weighted risk factors for colorectal tumors, were incomplete and not included in the present study due to recall bias and missing records. Subsequent prospective studies will be needed to determine the validity of risk prediction for advanced colorectal neoplasia

based on the FIT.

In summary, the adenoma detection rate and cancer stage migration support the effectiveness of the FIT as the first step in the current screening strategy. In addition, higher FIT concentrations were associated with more advanced colorectal neoplasia in the average-risk population. Risk prediction for colorectal neoplasia based on the FIT was significant and may help to improve the performance of the colorectal cancer screening program.

## COMMENTS

### Background

The fecal immunochemical test (FIT) for hemoglobin is specific for detecting colorectal lesions. Screening for colorectal neoplasms using the fecal occult blood test can reduce mortality.

### Research frontiers

Despite its widespread use, little is known about the clinical significance and application of the quantitative value of the FIT.

### Innovations and breakthroughs

This study used a linear regression model to determine the associations between key variables (age, gender and FIT concentration) and the pathology of colorectal neoplasia. The result demonstrated a dose-dependent relationship between the FIT level and the risk of colorectal tumors.

### Applications

FIT concentrations are associated with histological grades and can improve risk prediction for colorectal neoplasia in screening programs.

### Peer review

The paper contains interesting results. Authors reported a linear relationship between quantitative level and positive predictive value of FIT for predicting colorectal adenomatous polyps and cancers. Furthermore, this study includes a very large cohort of individuals and it is therefore possible to assume that the results actually reflect the trend of the general population.

### Abstract

**AIM:** To study the clinical outcome of antiviral therapy in hepatitis B-related decompensated cirrhotic patients.

**METHODS:** Three hundred and twelve patients with decompensated hepatitis B cirrhosis were evaluated in a prospective cohort. With two years of follow-up, 198 patients in the group receiving antiviral therapy with nucleos(t)ide analogues and 39 patients in the control

group without antiviral treatment were analysed.

**RESULTS:** Among the antiviral treatment patients, 162 had a complete virological response (CVR), and 36 were drug-resistant (DR). The two-year cumulative incidence of hepatocellular carcinoma (HCC) in the DR patients (30.6%) was significantly higher than that in both the CVR patients (4.3%) and the control group (10.3%) ( $P < 0.001$ ). Among the DR patients in particular, the incidence of HCC was 55.6% (5/9) in those who failed rescue therapy, which was extremely high. The rtA181T mutation was closely associated with rescue therapy failure ( $P = 0.006$ ). The Child-Pugh scores of the CVR group were significantly decreased compared with the baseline ( $8.9 \pm 2.3$  vs  $6.0 \pm 1.3$ ,  $P = 0.043$ ).

**CONCLUSION:** This study showed that antiviral drug resistance increased the risk of HCC in decompensated hepatitis B-related cirrhotic patients, especially in those who failed rescue therapy.

**Key words:** Hepatitis B; Decompensated cirrhosis; Nucleos(t)ide analogues; Hepatocellular carcinoma; Drug resistance

**Core tip:** This study was performed to analyse the clinical data of 312 patients with decompensated hepatitis B cirrhosis in a prospective cohort. These data showed that complete virological response could improve the clinical outcome in decompensated hepatitis B cirrhotic patients. However, clinicians should be aware of the high risk of hepatocellular carcinoma and liver failure in antiviral drug-resistant patients.

DX, Ding HG. Antiviral drug resistance increases hepatocellular carcinoma: A prospective decompensated cirrhosis cohort study. *World J Gastroenterol* 2013; 19(45): 8373-8381 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i45/8373.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i45.8373>

## INTRODUCTION

Chronic hepatitis B virus (HBV) infection, the main aetiology of liver cirrhosis and hepatocellular carcinoma (HCC), remains a major public health problem worldwide, especially in China<sup>[1-3]</sup>. Among these patients, the annual incidence of HCC is 2%-5%<sup>[3-5]</sup>. The most effective method to prevent HCC is to control HBV infection through vaccination<sup>[5,6]</sup>. In patients already infected with HBV, antiviral therapy remains the best strategy to prevent liver cirrhosis and HCC<sup>[6-9]</sup>. Major progress in the treatment of chronic hepatitis B has recently been made during the last decade with the development of antiviral drugs, especially nucleos(t)ide analogues (NUCs)<sup>[10-12]</sup>. Some data supporting the benefit of antiviral therapy on the prevention of HCC in chronic hepatitis B patients have been reported in several randomised controlled trials<sup>[12-15]</sup>. Nonetheless, antiviral drug resistance is important in determining the success of long-term therapy for chronic hepatitis B patients<sup>[16,17]</sup>. Based on recent clinical data, the development of resistance to NUCs is associated with an exacerbation of liver disease, including the development of cirrhosis and HCC<sup>[16]</sup>. In addition, the risk of HCC remains high in HBV-related cirrhosis patients who are treatment-naïve for NUCs<sup>[17]</sup>. Decompensated cirrhosis is the end stage of the disease and is characterised by high mortality and an extremely high risk of HCC. In HBV-related decompensated cirrhotic patients (DCPs), antiviral therapy using NUCs is recommended according to the 2005 global guidelines<sup>[18-20]</sup>. However, clinical data regarding the incidence of HCC in HBV-related DCPs with NUC antiviral therapies are limited. Therefore, the aim of the current study was to evaluate the two year outcomes in HBV-related decompensated cirrhotic, treatment-naïve patients using NUCs in a real life practical prospective cohort.

## MATERIALS AND METHODS

### Patients

The patients were enrolled due to HBV-related decompensated cirrhosis in a clinical practice between January 2008 and July 2012 at the Beijing Youan Hospital Affiliated Capital Medical University. Four hundred and seventy-six patients with hepatitis B-related decompensated cirrhosis were screened. Three hundred and twelve patients fulfilled the inclusion criteria and were prospectively enrolled in this study. The study protocol was approved by the Ethical Committee at Beijing Youan Hospital of Capital Medical University. All the patients provided written informed consent before being included in the study.

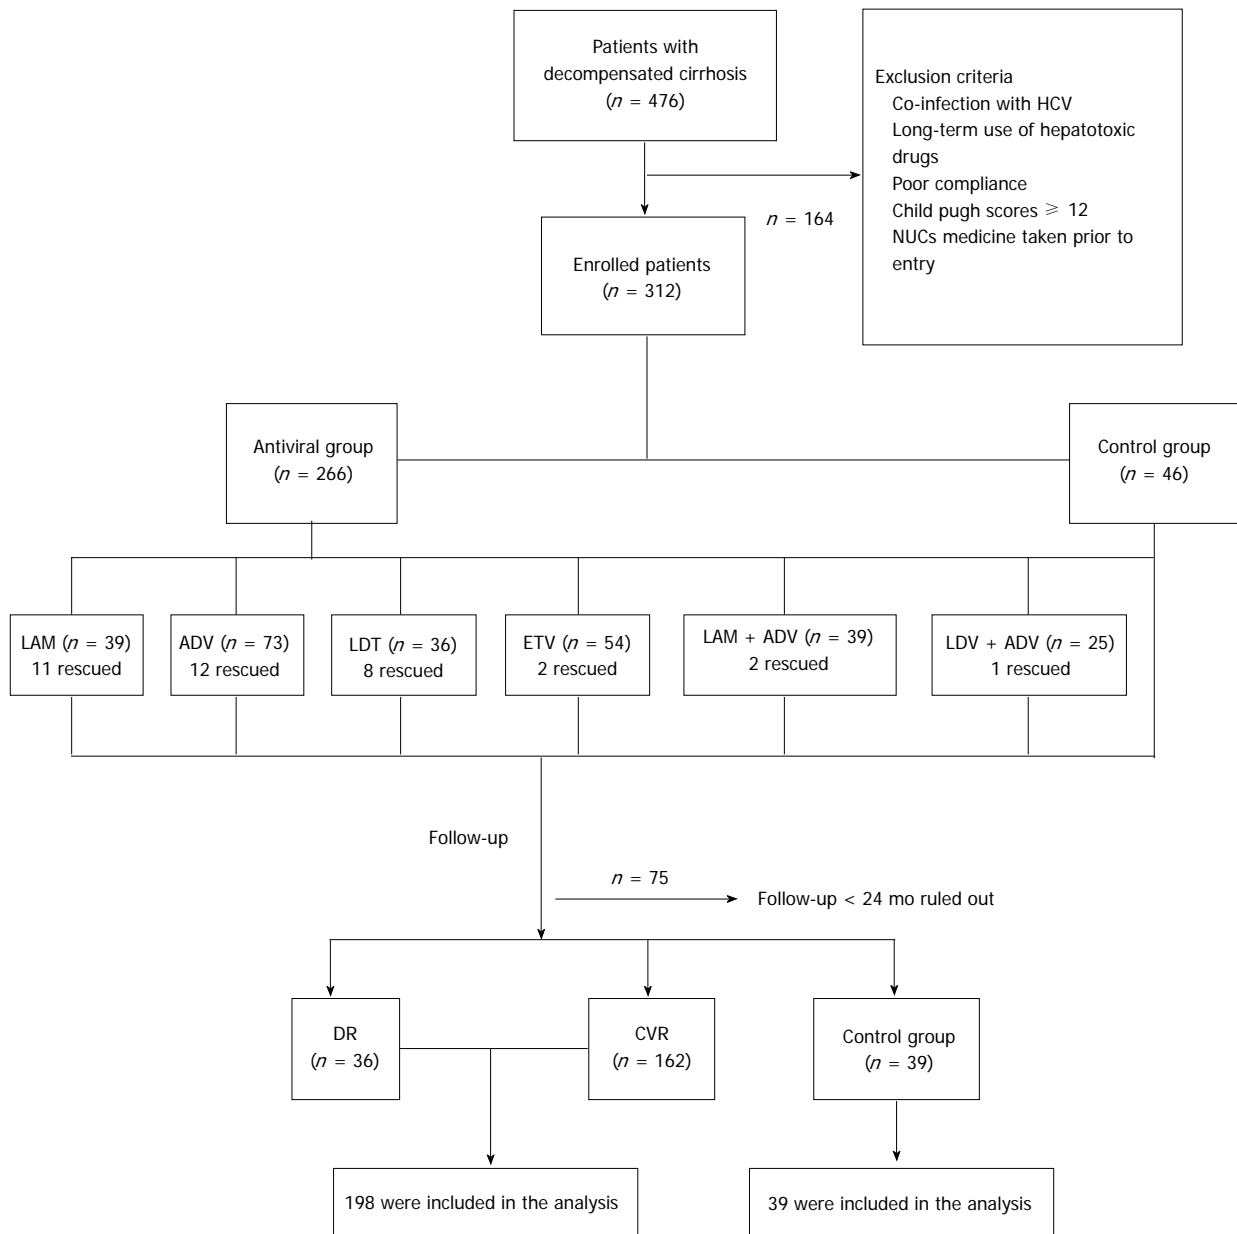

Clinical parameters (gender, age, family history of hepatitis B, alcohol abuse, Child-Pugh scores, HBeAg positive, HBV DNA load, renal function, and presence of ascites, encephalopathy, or variceal bleeding) were recorded. A diagnostic work-up for decompensated liver cirrhosis was performed, including clinical manifestations, physical examination, and laboratory tests, according to the criteria suggested by the Chinese Medical Association in 2005 for liver diseases<sup>[18]</sup>. The inclusion criteria were as follows: (1) chronic hepatitis B history and/or signs; (2) abnormal liver function accompanied by portal hypertension, such as ascites, encephalopathy, and esophageal or gastric variceal bleeding; (3) B-ultrasound scanning (LOGIQ9; GE Company, Fairfield, United States) and computerised tomography (CT; GE HISPEED DXI; GE Company) results consistent with the signs of liver cirrhosis without images of liver cancer; and (4) no NUC medications taken prior to entry. The exclusion criteria were as follows: (1) co-infection with HAV, HCV, HDV, HEV, and HIV as determined by an electrochemical luminescence method for the detection of the HAV and HCV antibodies and by an enzyme-linked immunosorbent assay for the HDV, HEV, and HIV antibodies; CMV and EBV IgM-positive patients as determined by an enzyme-linked immunosorbent assay for the detection of CMV and EBV IgM; (2) use of hepatotoxic drugs, including long-term analgesics and antipyretics, antibiotics, anti-lipidemic drugs, hypoglycaemic drugs, and herbal medicines; (3) HCC or metastatic liver cancer; (4) poor compliance and uncontrolled serious cardiovascular, respiratory, digestive, and nervous system diseases; (5) pregnant or lactating; and (6) Child-Pugh score  $\geq 12$ . Alcohol abuse was defined in this study as follows: (1) alcohol abuse  $> 5$  years, (2) drinking the ethanol equivalent of  $> 40$  g/d for men or 20 g/d for women, or (3) heavy drinking in the most recent 2 wk equivalent to ethanol  $> 80$  g/d.

In addition, 10 mL of venous blood was collected and centrifuged at 4 °C. All serum samples were stored at -80 °C in the Medical Bioinformation Research Center Biobank (Beijing, China).

### Antiviral therapy

In the HBV-related DCPs in this cohort, the antiviral therapy included lamivudine (LAM; 100 mg/d;  $n = 39$ ), adefovir (ADV; 10 mg/d;  $n = 73$ ), telbivudine (LDT; 600 mg/d;  $n = 36$ ), and entecavir (ETV; 0.5 mg/d;  $n = 54$ ) monotherapies or combinations of LAM (100 mg/d) and ADV (10 mg/d; LAM + ADV;  $n = 39$ ) or of LDT (600 mg/d) and ADV (10 mg/d; LDT + ADV;  $n = 25$ ) according to clinical real-life practices. The control group consisted of patients who declined antiviral therapy ( $n = 46$ ). All patients were followed every 3 mo, and their virologic, biochemical, and clinical parameters were obtained. Among these patients, 75 were excluded because they had follow-up  $< 24$  mo or were lost to follow-up; thus, 198 patients in the antiviral therapy group and 39 in the control group were included in the analysis. The antiviral therapy patients were subdivided into a drug-resistant

**Figure 1** Flow chart of enrolled patients. NUCs: Nucleos(t)ide analogues; HCC: Hepatocellular carcinoma; DR: Drug-resistant; CVR: Complete virologic response; LAM: Lamivudine; ADV: Adefovir; LDT: Telbivudine; ETV: Entecavir; HCV: Hepatitis C virus.

(DR) group ( $n = 36$ ) and a complete virologic response (CVR) group ( $n = 162$ ) based on whether they showed drug resistance before HCC was diagnosed (Figure 1). Rescue therapy for the drug-resistant patients was performed according to the guidelines for hepatitis B treatment<sup>[2]</sup> (Table 1).

#### Detection of HBV

Serum hepatitis B markers were detected by an electrochemiluminescence immunoassay using a Roche E170 modular immunoassay analyser (Roche Diagnostics, Mannheim, Germany) following the manufacturer's protocol. The serum HBV-DNA was quantified using a real-time polymerase chain reaction (PCR, FQ-PCR Kit; DaAn Gene Co., ShenZhen, China) and a GeneAmp 5700 Sequence Detection System (PE Applied Biosys-

tems, Boston, United States). The lower limit of HBV DNA detection was 500 copies/mL. CVR was defined as HBV-DNA being undetectable and persistently negative during the antiviral therapy for two years. Successful rescue therapy was defined as undetectable HBV-DNA 12 wk after changing antiviral drugs.

#### DR mutation detection by HBV polymerase

DR was defined as the conversion of HBV DNA to positive (virologic rebound) or the detection by sequence analysis of mutations known to be related to drug resistance during the NUC treatment. Serum HBV DNA was extracted according to the instructions of a commercial kit (Qiagen Blood Kit, Dusseldorf, Germany), using Platinum Taq DNA polymerase high fidelity (Invitrogen, CA, United States) for nested PCR amplification.

**Table 1** Rescue therapy strategies in drug resistance patients

DR patients	Rescue therapy prescriptions	HBN DNA after rescue therapy 12 w	
		< 500 copies/mL (n)	> 500 copies/mL (n)
LAM (n = 11)	+ ADV (n = 6) → ETV + ADV (n = 5)	4 3	2 2
ADV (n = 12)	+ ETV (n = 5) + LAM (n = 7)	4 6	1 1
LDT (n = 8)	+ ADV (n = 6) → ETV + ADV (n = 2)	4 2	2 0
ETV (n = 2)	+ ADV (n = 2)	2	0
LAM+ADV (n = 2)	→ ETV + ADV (n = 2)	1	1
LDT+ADV (n = 1)	→ ETV + ADV (n = 1)	1	0

+: Add-on; →: Altered drug. DR: Drug resistance; LAM: Lamivudine; ADV: Adefovir; LDT: Telbivudine; ETV: Entecavir; HBV: Hepatitis B virus.

The first-round primer sequences were as follows: P54, 5'-TYCCTGCTGGTGGCT CCAGTTC-3' (nt54-75) and P1287, 5'-CATACTGCGGAATCCTAGCG-3' (nt1267-1287). The second-round primer sequences were as follows: P253, 5'-CTCGTGGTGGACTTCTCTC-3' (nt253-271) and P1000, 5'-GCAAANCCCM AAA GRC-CCAC-3' (nt1000-1019). The primers were synthesised by the Yingjun Biotechnology Company (Shanghai, China). The PCR products were sequenced with an ABI 3730XL sequencer using the bi-directional method. The sequencing results were spliced and corrected by Contig Express and Bioedit software. The spliced and corrected results of the sequencing were submitted to the Stanford University webpage for antiviral resistance and genotypic resistance location analysis (<http://www.hiv-grade.de/hbvgrade/deployed/>).

### Assessment of liver and renal functions

The parameters of the liver and renal biochemical profiles, such as alanine aminotransferase, aspartate aminotransferase, total bilirubin, albumin, blood urea nitrogen, and creatinine (Cr) levels, were tested with an Olympus automatic biochemical analyser (Olympus AU640, Tokyo, Japan). The prothrombin time (PT) was measured using a blood coagulation analyser (AcL Top; Beckman Coulter, CA, United States). The Child-Pugh scores were calculated according to the parameters.

### HCC screening

The incidence of HCC was monitored by serum alpha fetoprotein (AFP) and liver ultrasonography every 3 mo in the HBV-related DCPs. HCC was diagnosed according to the criteria suggested by the Chinese Anticancer Association in 2001<sup>[21]</sup>. In brief, the diagnostic criteria for HCC were as follows: (1) AFP > 400 ng/mL and posi-

**Table 2** Clinical characterizations of the enrolled patients at baseline *n* (%)

tive B-ultrasound and CT findings or (2) serum AFP < 400 ng/mL, positive B-ultrasound and CT findings, and pathological findings for HCC in a liver biopsy specimen. The serum AFP levels were tested by electrochemiluminescence (Abbott Ltd, IL, United States).

### Study endpoints

The study endpoints were considered to be patient death, liver transplantation, or diagnosis with HCC.

### Statistical analysis

Parametric data were expressed as the mean with SD when a normal distribution was assumed. The statistical analysis was conducted using SPSS (version 16.0; SPSS, Inc., Chicago, IL, United States). Logistic regression analysis was performed to evaluate the association of variables with liver failure, death, and HCC. The Kaplan-Meier method was used to estimate the cumulative incidence of HCC, liver failure, and cumulative survival and compared with the log-rank test. Categorical variables were analysed using the Fisher test. Differences between paired and unpaired samples were determined with the non-parametric Wilcoxon paired sample test, the Mann-Whitney *U* test, or the Kruskal-Wallis test. All tests were two-sided, and a *P* value < 0.05 was considered statistically significant.

## RESULTS

### Clinical characteristics

No differences in the gender, age, family history of hepatitis B or HCC, alcohol abuse, Child-Pugh score, HBeAg positivity, HBV DNA load, renal function, or the presence of ascites, encephalopathy, or variceal bleeding existed among each group at baseline (*P* > 0.05; Table 2). The Child-Pugh score of the CVR group was significantly decreased at 2 years, compared with the baseline ( $8.9 \pm 2.3$  vs  $6.0 \pm 1.3$ , *P* = 0.043). In the control group and

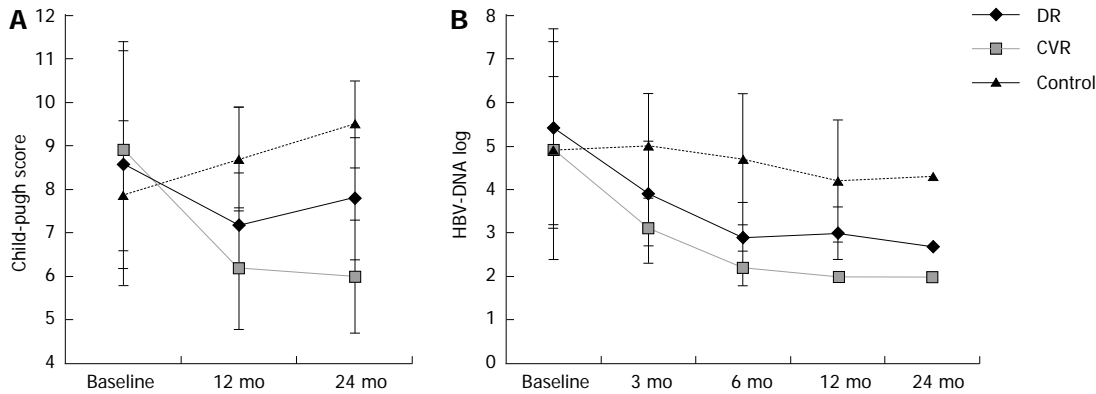

Figure 2 Child-Pugh score (A) and sequential change of serum hepatitis B virus DNA level (B) in the course of antiviral therapy over 2 years.

DR patients, however, the Child-Pugh score showed an increasing trend at 2 years without significance ( $P > 0.05$ ). Compared with the DR and control groups, the serum HBV DNA level during the course of antiviral therapy over 2 years in the CVR group declined sharply and was maintained at an undetectable level (Figure 2).

### Incidence of HCC

The two-year cumulative incidence of HCC in the DR patients (30.6%) was significantly higher than that in both the CVR patients (4.3%) and control group (10.3%) ( $P < 0.001$ ). Among these DR patients, the incidence of HCC was 55.6% (5/9) in those who failed rescue therapy, which was extremely high. The Kaplan-Meier curves representing the incidence of HCC in the DR, CVR, and control groups are shown in Figure 3A and B. The 2-year cumulative incidence of HCC in the DR group was higher than in the CVR (RR = 7.1; 95%CI: 2.2-16.1;  $P < 0.001$ ) and control groups (RR = 3.0; 95%CI: 1.3-9.5;  $P = 0.042$ ). However, there was no difference in the two-year cumulative HCC incidence between the patients who received antiviral therapy and the controls ( $P = 0.805$ ). The mutations associated with HBV polymerase-related antiviral drug resistance are shown in Table 3. The rtA181T mutation was closely associated with rescue therapy failure ( $P = 0.006$ ). The mutation combination rate in the subgroup of failed rescue therapy was markedly higher than that in the subgroup of successful rescue therapy (66.7% *vs* 11.1%,  $P = 0.004$ ).

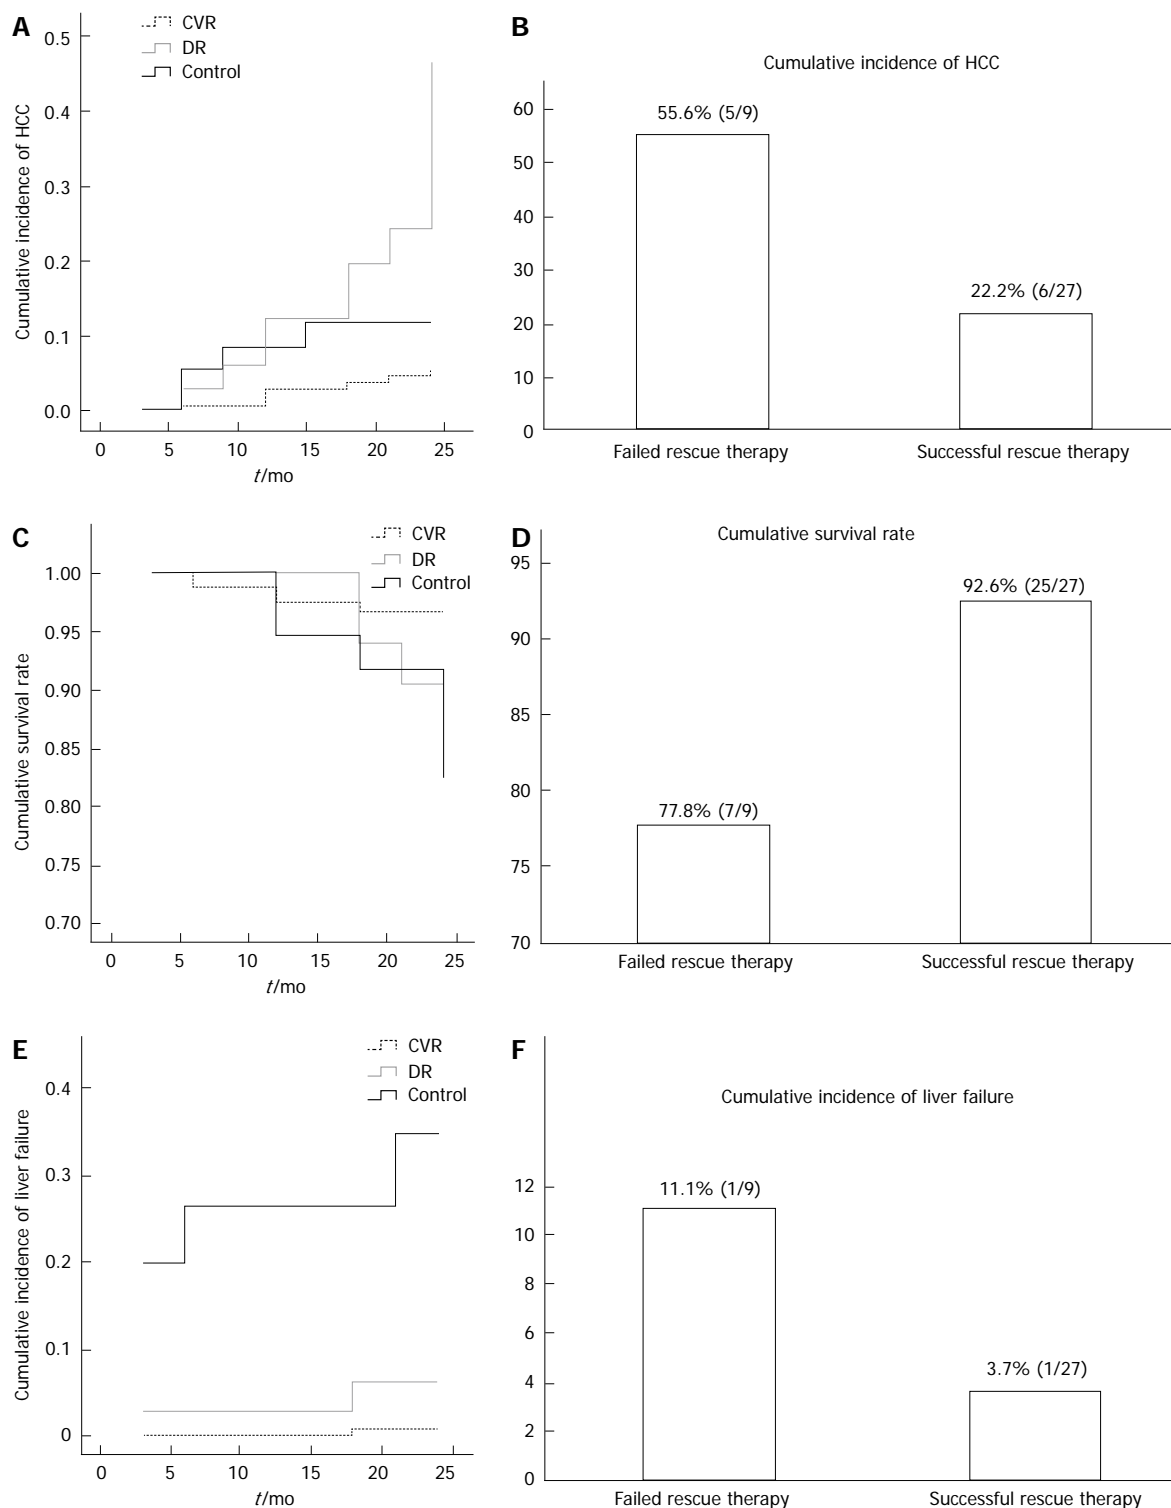

### Prognosis

The cumulative survival rates in the DR, CVR and control groups were 88.9% (32/36), 96.9% (157/162), and 84.6% (33/39), respectively. No significant difference was observed in the two year cumulative survival between the DR and CVR groups ( $P = 0.059$ ) (Figure 3C). There was no significant difference between the subgroups of failed rescue therapy and successful rescue therapy (77.8% *vs* 92.6%,  $P = 0.221$ ) (Figure 3D). The cumulative incidence of liver failure in the DR, CVR and control groups was 5.6% (2/36), 0.6% (1/162), and 28.2% (11/39), respectively. The two-year cumulative incidence of liver failure in the CVR group was significantly lower than those in

the DR (RR = 9.0, 95%CI: 2.8-34.5,  $P < 0.001$ ) and control (RR = 45.69, 95%CI: 13.8-96.4,  $P < 0.001$ ) groups (Figure 3E). However, there was no significant differences between the subgroups of failed rescue therapy and successful rescue therapy (11.1% *vs* 3.7%,  $P = 0.401$ ) (Figure 3F). These results suggested that the CVR patients had a good prognosis.

## DISCUSSION

HBV infection remains a global public health problem. The geographic distribution of the rates of chronic HBV infection and HCC are strikingly parallel. The incidence and mortality of HBV-related cirrhosis and HCC, however, have increased significantly<sup>[1-3]</sup>. The clinical evidence clearly shows that the differences in clinical outcomes after HBV infection might be related to the HBV DNA level, antiviral treatment response, and immune activation<sup>[22-24]</sup>. All guidelines for the prevention and treatment of chronic hepatitis B in China and in other countries state that the main aim of the treatment for chronic hepatitis B is to reduce the incidence and death rate of cirrhosis and liver cancer, to prolong life, and to improve the quality of life<sup>[15,25]</sup>. For patients with liver cirrhosis, especially those in the decompensation period, the clinical outcomes after antiviral therapy with nucleoside analogues are unclear<sup>[8,26,27]</sup>. NUCs are effective drugs for the suppression of HBV reproduction, and compliance is good amongst most chronic hepatitis B patients, especially in those with HBV-related cirrhosis. Failure of the antiviral treatment and drug resistance are serious factors for liver disease progression and for increases in the incidence of liver cancer<sup>[16,28]</sup>. Bae *et al*<sup>[24]</sup> reported that 58.2% of patients showed complete antiviral responses using LAM in decompensated HBV-related cirrhosis, which can improve the clinical prognosis. A single randomised double-blind controlled trial of LAM in patients with HBeAg and/or high serum HBV DNA levels showed that antiviral therapy prevented disease progression and reduced the incidence of HCC<sup>[29]</sup>. Several studies have shown that the failure of the antiviral treatment of chronic hepatitis B or drug resistance increases the risk of liver cirrhosis and liver cancer and also causes the progression of

**Figure 3** Kaplan-Meier curve. Kaplan-Meier curve for incidence of hepatocellular carcinoma (HCC) in drug resistance (DR), complete virologic response (CVR) and control group was shown (A). The two-year cumulative incidence of HCC was extremely higher in rescue therapy failure group (B). However, no significant difference was seen in two years cumulative survival between DR group and CVR group as well as between the subgroup of failed rescue therapy and successful rescue therapy (C and D). The cumulative incidence of liver failure was higher in the control group than in the DR, CVR (E). However, there was no significant difference between failed rescue therapy and successful rescue therapy subgroups (F).

liver disease<sup>[30-33]</sup>. Recently, a beneficial effect of antiviral therapy on the risk of HCC was also shown in cohort studies and meta-analyses, particularly among responders. A greater effect was observed in patients who achieved a sustained virologic response, whereas the benefit in non-

responders was unclear<sup>[12,17,22]</sup>. In this study, we found that antiviral therapy patients with a CVR response may show significantly improved liver function. The Child-Pugh score in the CVR group was significantly decreased over 2 years. In the drug-resistance group, however, the

+: DR mutations positive; -: DR mutations negative; DR: Drug resistance.

Child-Pugh score increased. Interestingly, the incidence of HCC was high at 30.6% in the DR patients, especially in the failed rescue therapy patients, whereas the incidence of HCC was 4.3% in the CVR group and 10.3% in the control group. Therefore, the rescue therapies were very important for the DR patients. Kim *et al*<sup>[34]</sup> and Ha *et al*<sup>[35]</sup> recently reported that the adefovir add-on treatment in patients with LAM-resistant CHB suppressed HBV replication more effectively than ETV or ADV monotherapy. Therefore, NUC combination therapy as a rescue therapy could be a better prescription for NUC-

resistant HBV patients in this cohort study. In this study, the rtA181T mutation was found to be closely associated with rescue therapy failure, which may be related to the high incidence of HCC in patients with antiviral drug-resistance. Yeh *et al*<sup>[16]</sup> reported that the emergence of the rtA181T/sW172 mutation in the LAM-resistant patients increased the risk of HCC development during the subsequent courses of antiviral therapy. In this cohort study, we also found that the 2-year cumulative incidence of HCC was 22.2% in the successful rescue therapy group and 55.6% in the failed rescue therapy group among the DR patients. Therefore, we conclude that effective antiviral therapies might have benefits and a good prognosis for decompensated HBV-related cirrhosis. However, we observed an increased incidence of HCC in the patients with antiviral drug-resistance. The aetiology for carcinogenesis is still being studied.

Therefore, the maintenance of virologically persistent remission is important for the reduction of HCC risk in DCPs. More effective and more affordable antiviral therapies are needed for patients with HBV-related decompensated cirrhosis to ensure that more patients could benefit from the treatment and more HCCs could be prevented, which might have a major impact on the global incidence of HCC.

In conclusion, a complete virological response should reduce the incidence of HCC and improve the clinical outcomes in decompensated hepatitis B cirrhotic patients. However, clinicians should be aware of the extremely high risk of HCC and liver failure in antiviral drug-resistant patients or in those not treated with antiviral therapy.

## COMMENTS

### Background

The decompensated cirrhosis is the end stage of the disease and is characterised by high mortality and an extremely high risk of hepatocellular carcinoma (HCC). In HBV-related decompensated cirrhotic patients (DCPs), antiviral therapy using nucleos(t)ide analogues (NUCs) is recommended according to the 2005 global guidelines. The antiviral therapy remains the best strategy to prevent liver cirrhosis and HCC in chronic hepatitis B patients. However, clinical data regarding the incidence of HCC in HBV-related DCPs with NUCs antiviral therapies are limited.

### Research frontiers

Some cohort studies and meta-analyses have shown a beneficial effect of antiviral therapy on the risk of HCC, particularly among responders. A greater effect was observed in patients who achieved a sustained virologic response, whereas the benefit in non-responders is unclear, especially in those DCPs.

### Innovations and breakthroughs

This study revealed that, in decompensated cirrhotic patients, a complete virologic response (CVR) should reduce the incidence of hepatocellular carcinoma and improve the clinical outcomes in decompensated hepatitis B cirrhotic patients. However, in those with antiviral drug resistance the risk of HCC increased, especially in those who failed rescue therapy.

### Applications

From this study, it is suggested that the maintenance of virologically persistent remission is important for the reduction of HCC risk in DCPs. The clinicians should be aware of the extremely high risk of HCC and liver failure in antiviral drug-resistant patients. Therefore, more effective and more affordable antiviral therapies are needed for patients with HBV-related decompensated cirrhosis to ensure that more patients could benefit from the treatment and more HCC could be prevented.

## Terminology

A CVR was defined as HBV-DNA being undetectable and persistently negative during the antiviral therapy for two years.

## Peer review

This is a large single centre prospective cohort study based on real life clinical practice aimed to evaluate the relationship between drug-resistance and the development of HCC in hepatitis B related decompensated cirrhotic patients. This study gave interesting and partially innovative results for the clinician.

### Abstract

**AIM:** To investigate the clinical characteristics, diagnosis, treatment, and prognosis of primary adenosquamous carcinoma (ASC) of the esophagus.

**METHODS:** A total of 4015 patients with esophageal carcinoma underwent surgical resection between January 1995 and June 2012 at the Cancer Hospital of Shantou University Medical College. In 37 cases, the histological diagnosis was primary ASC. Clinical data were retrospectively analyzed from these 37 patients, who underwent transthoracic esophagectomy with lymphadenectomy. The  $\chi^2$  or Fisher's exact test was used to compare the clinicopathological features between patients with ASC and those with squamous cell carcinoma (SCC). The Kaplan-Meier and Log-Rank methods were used to estimate and compare survival

rates. A Cox proportional hazard regression model was used to identify independent prognostic factors.

**RESULTS:** Primary esophageal ASC accounted for 0.92% of all primary esophageal carcinoma cases (37/4015). The clinical manifestations were identical to those of other types of esophageal cancer. All of the 24 patients who underwent preoperative endoscopic biopsy were misdiagnosed with SCC. The median survival time (MST) was 21.0 mo (95%CI: 12.6-29.4), and the 1-, 3-, and 5-year overall survival rates were 67.5%, 29.4%, and 22.9%, respectively. In multivariate analysis, only adjuvant radiotherapy (HR = 0.317, 95%CI: 0.114-0.885,  $P = 0.028$ ) was found to be an independent prognostic factor. The MST for ASC patients was significantly lower than that for SCC patients [21.0 mo (95%CI: 12.6-29.4) vs 46.0 mo (95%CI: 40.8-51.2),  $P = 0.001$ ]. In subgroup analyses, the MST for ASC patients was similar to that for poorly differentiated SCC patients.

**CONCLUSION:** Primary esophageal ASC is a rare disease that is prone to be misdiagnosed by endoscopic biopsy. The prognosis is poorer than esophageal SCC but similar to that for poorly differentiated SCC patients.

**Key words:** Adenosquamous carcinoma; Diagnosis; Esophagus; Prognosis; Treatment

**Core tip:** Primary adenosquamous carcinoma (ASC) of the esophagus is an uncommon malignant esophageal neoplasm containing coexisting elements of infiltrating squamous cell carcinoma and adenocarcinoma. The biological behavior and response to therapies of this disease have not been well studied. In the current study, we reported the largest ever single-center patient cohort undergoing surgical resection for pri-

mary esophageal ASC, and we investigated the clinical characteristics, diagnosis, treatment, and prognosis in these patients. These data will give us a better understanding of this disease and help select the proper strategy for therapy.

## INTRODUCTION

Primary adenosquamous carcinoma (ASC) of the esophagus is an uncommon malignant esophageal neoplasm containing coexisting elements of infiltrating squamous cell carcinoma (SCC) and adenocarcinoma (AC)<sup>[1]</sup>. To our knowledge, no more than 40 cases of primary esophageal ASC have been published in the English literature over the past 20 years<sup>[1-11]</sup>. Most of the previous studies concerning esophageal ASC were case reports, while only one series of 18 cases was previously reported by Yachida *et al*<sup>[1]</sup>. The biological behavior and response to therapies of this disease have not been well studied. In the current study, we present data of 37 patients with primary esophageal ASC who underwent surgical resection with systematic lymphadenectomy from a single cancer center. We investigate the clinical characteristics, diagnosis, treatment, and prognosis in these patients, and we further analyze the factors that are associated with survival.

## MATERIALS AND METHODS

This study was undertaken at the Cancer Hospital of Shantou University Medical College and was approved by the Ethics Committee of that hospital. A total of 4015 patients with esophageal carcinoma underwent surgical resection between January 1995 and June 2012. In 37 cases (0.92%, 37/4015), the histological diagnosis was primary ASC. The clinical records of these 37 patients were analyzed retrospectively.

### Patient selection

The medical history was obtained from all patients, who then underwent a physical examination. A chest radiograph, barium meal, contrast-enhanced computed tomography scan of the chest and abdomen, complete blood count, blood biochemistry analyses, and liver and renal function evaluations were also performed. Twenty-four patients underwent esophagoscopy biopsy before surgery. The remaining 13 patients from the early period of the study did not undergo an endoscopic biopsy when typical features of esophageal cancer were confirmed by clinical manifestations, esophagographic examinations and computed tomography scan of the chest. All histological

specimens were re-examined by expert pathologists.

### Histopathology

All resection specimens, including the lymph nodes, were assessed by two expert pathologists (Wu MY and Tian DP). Specimen analysis was performed in a standardized fashion with prospective documentation of all of the assessed parameters. Tumors were classified as ASC when the features of SCC and AC could be identified by light microscopy, with each accounting for at least 20% of the area in the sections of the deepest portion of tumor penetration. Patients with mucoepidermoid carcinomas were not included in this series.

### Follow-up

Follow-up was performed every 3 mo for the first year, every 6 mo for the second year and every 6-12 mo thereafter. During each follow-up visit, the patients received a clinical evaluation, blood biochemistry examination, including that of tumor markers (SCC antigen, carcinoembryonic antigen), ultrasonography, and X-ray examination. Computed tomography was performed every year. Endoscopic examinations were performed when necessary. Follow-up was continued up to January 2013 or until death, if this occurred earlier. The mean follow-up was 33.5 mo (range: 1-158 mo). One patient was lost to follow-up (2.7%).

Local and regional recurrences were defined, respectively, as recurrence at the anastomosis or at any site within the operative field. Distant metastases were defined as tumor growth outside the operative field. A diagnosis of recurrent disease was made when pathologically or radiologically confirmed.

### Statistical analysis

Statistical analysis was performed using SPSS 13.0 software (SPSS Inc., Chicago, IL). The  $\chi^2$  or Fisher's exact test was used to compare the clinicopathological features between patients with ASC and SCC. Overall survival time was calculated from the date of operation to the date of death or the most recent follow-up. Univariate analysis of survival was performed using the Kaplan-Meier method to estimate survival probabilities in patient subgroups, with the entry factors of gender, age ( $\leq 60$  years *vs*  $> 60$  years), location, length of the primary lesion ( $\leq 4$  cm *vs*  $> 4$  cm), macroscopic tumor type, pT category, pN category, operation (radical/palliative), and radiotherapy (yes/no). The log-rank test was used to assess differences in survival between groups. Factors identified at a significance level of  $P < 0.2$  in the univariate analysis were selected for inclusion in a multivariate Cox proportional hazard regression model. All of the performed statistical tests were two-sided, and a  $P$  value less than 0.05 was considered to be statistically significant. The treatment results in this group of patients were compared with those in patients with different histological grades of SCC who were treated during the same period.

## RESULTS

### Patient characteristics

The clinicopathological features of the 37 primary esophageal ASC patients are shown in Table 1. This study group contained 31 men and 6 women, ranging in age from 40 to 78 years (median: 60 years). The primary lesions were most often found in the middle third of the thoracic esophagus and had a median length of 4.0 cm (2.0-10.0 cm). The clinical manifestations were identical to those of other types of esophageal cancer, with dysphagia, retrosternal pain, and loss of body weight being the main presenting symptoms.

None of the 37 patients underwent chemotherapy or radiotherapy before surgery, and none had prior malignant disease or distant metastases on routine examination before surgery.

### Treatment

All 37 patients underwent transthoracic esophagectomy

with two-field lymphadenectomy (the mediastinal and perigastric lymph nodes), including 34 cases of radical resection and three cases of palliative resection. A total of 480 lymph nodes were removed, and 69 had metastases. Twenty of the 37 patients (54.1%) proved postoperatively to have histologically confirmed lymph node metastases. According to the seventh edition of the American Joint Committee on Cancer staging system for esophageal cancer, there were fourteen stage pN1 cases, three stage pN2 cases, and three stage pN3 cases. Postoperative complications included pneumonia, pneumothorax, and esophagogastric anastomotic leak in each of two cases. No patients died during treatment in hospital and 30 d after surgery.

Adjuvant therapies were routinely recommended to patients with a locally advanced tumor or mediastinal lymph node metastases. However, not all patients complied with this recommendation. Twenty-four patients who underwent a radical operation were treated by surgery alone, and ten patients who underwent a radi-

Figure 1 Adenosquamous carcinoma of the esophagus. Adenocarcinoma and squamous cell carcinoma could be intermingled (A: Hematoxylin and eosin staining,  $\times 200$  magnification) or have a fairly clear boundary (B: Hematoxylin and eosin staining,  $\times 100$  magnification).

cal operation were treated by surgery plus postoperative radiotherapy. None of the 34 patients who underwent a radical operation received adjuvant chemotherapy. One of the 3 patients who underwent a palliative operation received adjuvant chemotherapy (Cisplatin plus 5-Fu for two cycles) and died 5 mo after surgery. One palliatively operated patient died 2 mo after surgery and did not receive adjuvant therapy. The other palliatively operated patient did not receive adjuvant therapy for economic reasons and survived for 20 mo. Therapeutic radiation was delivered using 6 or 8 MV photons. A total dose of 50 Gy was delivered in 2 Gy fractions 5 d/wk.

### Pathology

Grossly, ASC was indistinguishable from pure SCC. The macroscopic tumor was classified as intraluminal type in one case, polyploid type in two cases, ulcerative type in two cases, sclerotic type in three cases, and medullary type in 29 cases. Microscopically, ASC was characterized by a mixture of AC and SCC features (Figure 1). SCC could have different stages of squamous differentiation with or without intercellular bridges, individual cell keratinization, and cancer pearls. AC contained tubular or glandular structures with focal to abundant intracellular or extracellular mucin. The AC and SCC could be intermingled or have a fairly clear boundary. No intermediate cells such as the type observed in mucoepidermoid carcinoma were evident in ASC. In most tumors, SCC dominated in the mucosa, while AC was identified in the deeper portion of the tumor.

Twenty-four patients underwent esophagoscopy biopsy before surgery, and all of them were misdiagnosed with SCC.

### Survival and prognostic factors

By January 2013, with a mean follow-up of 33.5 mo (range: 1–158 mo), 29 patients had died, seven were still alive, and one was lost to follow-up.

The median survival time (MST) of the 37 patients was 21.0 mo (95%CI: 12.6–29.4), and the 1-, 3-, and 5-year overall survival rates were 67.5%, 29.4%, and 22.9%, re-

spectively. One patient died of myocardial infarction 140 mo after the surgery.

Univariate analysis and multivariate analysis were performed to assess the relationship between the clinicopathological features and the prognosis of ASC patients. The variables related to survival in univariate analysis are shown in Table 2. Only location, macroscopic tumor type, pN category, and operation (radical/palliative) affected the overall survival ( $P < 0.05$ ). Although the MST at 32.0 mo for the patients who received adjuvant radiotherapy was longer than that at 19.0 mo for the patients who did not, the difference was not significant ( $P = 0.066$ ). In multivariate analysis, adjuvant radiotherapy ( $P = 0.028$ ) was found to be an independent factor for the prediction of prognosis (Table 3). Patients who received adjuvant radiotherapy had a relatively better survival.

Finally, we assessed the prognosis between esophageal ASC and different histological grades of SCC. Three thousand seven hundred eighty five of 4015 esophageal carcinoma patients were histologically diagnosed with SCC. Of these patients, 3439 did not receive neoadjuvant therapy, including 1011 cases of well-differentiated SCC, 2007 cases of moderately differentiated SCC, and 421 cases of poorly differentiated SCC. All patients underwent transthoracic esophagectomy with two-field lymphadenectomy (the mediastinal and perigastric lymph nodes). One hundred twenty patients were lost to follow-up (3.5%). The clinicopathological features of patients with ASC or different histological grades of SCC are shown in Table 4. All of the factors were balanced between patients with ASC and SCC. The MST at 21.0 mo for ASC patients was significantly lower than that at 46.0 mo for SCC patients ( $P = 0.001$ ) (Figure 2). We further sub-classified SCC into different histological grades and compared the prognosis with esophageal ASC. The MSTs for well-differentiated SCC, moderately differentiated SCC, and poorly differentiated SCC were 148.0, 39.0, and 22.0 mo, respectively (Table 5). The MST for ASC patients was significantly lower than that for well- ( $P < 0.001$ ) and moderately differentiated SCC patients ( $P = 0.004$ ), but there was no significant difference in the MST

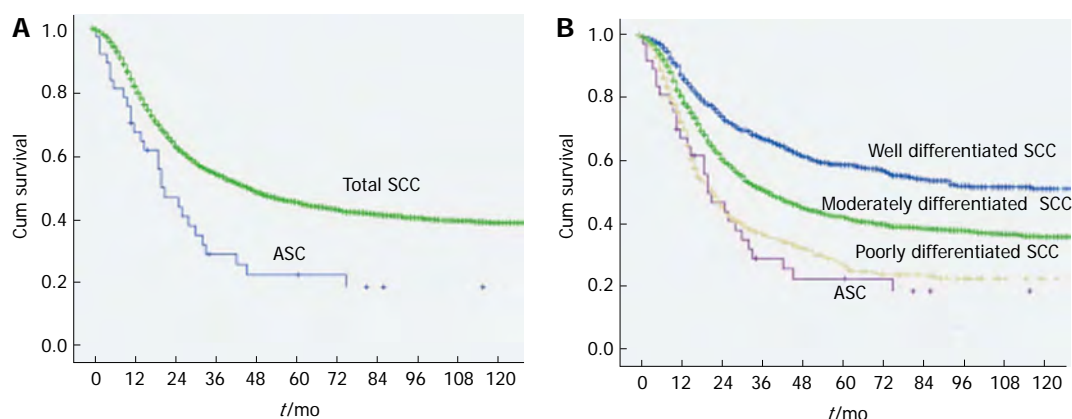

Figure 2 Comparison of Kaplan-Meier curves for patients with esophageal adenosquamous carcinoma and those with squamous cell carcinoma. A: Kaplan-Meier curves for esophageal adenosquamous carcinoma (ASC) patients and total esophageal squamous cell carcinoma (SCC) patients. The survival difference was significant ( $P = 0.001$ ); B: Kaplan-Meier curves for patients with esophageal ASC and those with different histological grades of SCC (between ASC and well-differentiated SCC,  $P < 0.001$ ; between ASC and moderately differentiated SCC,  $P = 0.004$ ; between ASC and poorly differentiated SCC,  $P = 0.536$ ).

**Table 2** Univariate analysis of the prognosis of the 37 patients with esophageal adenosquamous carcinoma

	Number of patients	Survival rate			MST (mo, 95%CI)	P value

## DISCUSSION

ASC is a malignant tumor that has granular and squa-

mous histological components. According to the guidelines for clinical and pathological studies of carcinomas of the esophagus established by the Japan Esophageal Society, ASC of the esophagus is defined as having at least 20% of the SCC and AC features on routine microscopic examination using hematoxylin and eosin staining<sup>[12]</sup>. Primary esophageal ASC was relatively uncommon, and in our study, it accounted for only 0.92% of all cases of primary esophageal carcinoma. Due to the low incidence of esophageal ASC, the biological behavior and response to therapies of this disease have not been well studied.

We report the largest ever single-center patient cohort undergoing surgical resection for primary esophageal ASC, having investigated the clinical characteristics, diagnosis, treatment, and prognosis in these patients. Most of the patients were male with a median age of 60 years. The primary lesions were most often found in the middle third of the thoracic esophagus, and progressive dysphagia, retrosternal pain, and loss of body weight were the main presenting symptoms, which were identical to those of other types of esophageal carcinoma.

The origin of primary esophageal ASC remains obscure. It has been suggested that both components of an ASC originate from the same clone<sup>[11]</sup>. Some authors believe that this type of tumor arises from esophageal gland cells or ductal cells<sup>[10]</sup>. However, it has also been speculated that ASC first develops as SCC and that glandular differentiation subsequently occurs in the tumor cell populations<sup>[1,8]</sup>. In our study group, most of the tumors exhibited carcinoma *in situ* differentiating in the mucosa adjacent to the tumors, while no cellular atypia or transition to tumor cells was found in the underlying esophageal glands or their ducts. These features indicated that esophageal ASC could originate from the covering squamous epithelium.

Because the clinical features of primary esophageal ASC are basically identical to those of other types of esophageal cancer, the diagnosis of this disease is dependent on histopathological examination. Esophagoscopy biopsy is the most frequently used method for diagnosis before treatment. However, in our study, all 24 patients who underwent esophagoscopy biopsy before surgery were misdiagnosed with SCC. In the postoperative pathological examinations, we found that SCC dominated in the mucosa in most tumors, while AC was identified in the deeper portion of the tumor. This difference could have contributed to the high misdiagnosis rate of esophageal ASC due to the small volume of the biopsy specimen. Deeper biopsies that include a greater tissue volume and are performed under an endoscope could help improve the diagnostic accuracy.

No standard treatment for esophageal ASC has been established because its incidence is low. Few studies have addressed the treatment of esophageal ASC. At present, the treatment for this condition is similar to that for other types of esophageal carcinoma because of the difficulty in establishing the definitive diagnosis preop-

eratively. Surgical resection is still an important method for resectable esophageal carcinoma with neoadjuvant chemoradiotherapy for a locally advanced disease<sup>[13-16]</sup>. In the current study, none of the 37 patients received neoadjuvant therapy, while 10 patients were treated by surgery plus postoperative radiotherapy. We found that adjuvant radiotherapy was an independent prognostic factor in multivariate analysis ( $P = 0.028$ ). Patients who received adjuvant radiotherapy had a relatively better survival. The role of postoperative radiotherapy is still debated in esophageal cancer, and most previous studies have revealed no survival benefit with postoperative radiotherapy for esophageal SCC and AC<sup>[17,18]</sup>. In our study, although postoperative radiotherapy was found to be predictive of survival in the multivariate analysis, because the number of patients in this study was small, we think that more data should be collected to confirm this finding. Recently, neoadjuvant chemoradiotherapy had been increasingly used for the treatment of esophageal cancer patients, and it has shown a significant survival benefit<sup>[13-16]</sup>. It is suggested that further research should be conducted to establish the value of this new therapeutic approach for patients with esophageal ASC.

ASC has been confirmed to be more aggressive than “pure” AC and SCC in many other tumors, with frequent lymph node metastasis and poor prognosis<sup>[19-27]</sup>. Some case reports of esophageal ASC have also indicated that it has a highly aggressive biological behavior<sup>[5,7]</sup>. Another study of 18 cases reported by Yachida *et al.*<sup>[1]</sup> found that esophageal ASC had a better prognosis than conventional SCC and AC, but their finding is likely due to the smaller size and lower stage of the tumors in that study. In our study, although the 54.1% rate of lymph node metastases was higher than that of esophageal SCC (46.3%, 1591/3439), no significant difference was observed ( $P > 0.05$ ). Regarding the prognosis, the MST at 21.0 mo for ASC patients was significantly lower than that at 46.0 mo for the SCC patients in our study ( $P = 0.001$ ). In the subgroup analyses, the MST for ASC patients was significantly lower than that for well- and moderately differentiated SCC patients ( $P < 0.001$ ) but was similar to that for poorly differentiated SCC patients ( $P = 0.536$ ). The poor prognosis of esophageal ASC could be caused by its aggressive biological behavior.

In summary, primary esophageal ASC is a rare disease that is prone to be misdiagnosed by endoscopic biopsy. The prognosis for patients undergoing surgical resection is poorer than that for most esophageal SCC patients but similar to that for poorly differentiated SCC patients. Further investigations are required to determine the biological behavior of this tumor and develop new therapeutic modalities to achieve further improvements in the clinical outcome.

## ACKNOWLEDGMENTS

We thank Dr. Ming-Yao Wu and Dr. Dong-Ping Tian from the Pathologic Department of Shantou University Medical College for their sincere help in this study.

## COMMENTS

## Background

Primary adenosquamous carcinoma (ASC) of the esophagus is an uncommon malignant esophageal neoplasm containing coexisting elements of infiltrating squamous cell carcinoma (SCC) and adenocarcinoma (AC). The biological behavior and response to therapies of this disease have not been well-studied due to its low incidence.

## Research frontiers

No more than 40 cases of primary esophageal ASC have been published in the English literature over the past 20 years. Most of the previous studies concerning esophageal ASC were case reports. The authors reported the largest ever single-center patient cohort of 37 cases undergoing surgical resection for primary esophageal ASC, and investigated the clinical characteristics, diagnosis, treatment, and prognosis.

## Innovations and breakthroughs

This study was the largest that was conducted by a single institution to report the clinical characteristics, diagnosis, treatment, and prognosis of esophageal ASC. For the first time, the authors determined that esophageal ASC was prone to be misdiagnosed by endoscopic biopsy and that the prognosis for patients undergoing surgical resection is poorer than that for most esophageal SCC patients but similar to that for poorly differentiated SCC patients.

## Applications

This is the largest study of primary esophageal ASC, and it will give the authors a better understanding of this disease and help the selection of the proper therapy strategy.

## Terminology

Esophageal ASC is an uncommon malignant esophageal neoplasm containing coexisting elements of infiltrating SCC and AC. According to the guidelines for clinical and pathological studies of carcinomas of the esophagus that were established by the Japan Esophageal Society, ASC of the esophagus is defined as having at least 20% each of the SCC and AC elements on routine microscopic examination using hematoxylin and eosin staining.

## Peer review

This is a well written and thorough coverage of this important topic. The authors investigated the clinical characteristics, diagnosis, treatment, and prognosis of 37 cases of ASC of the esophagus from 4015 esophageal carcinoma patients who received surgical resection between January 1995 and June 2012. They concluded that the prognosis of esophageal ASC is poorer than SCC. The paper is of interest for gastroenterologists.

### Abstract

**AIM:** To investigate the relationships among subtypes of gastroesophageal reflux disease (GERD) using narrow band imaging (NBI) magnifying endoscopy.

**METHODS:** A reflux disease questionnaire was used to screen 120 patients representing the three subtypes of GERD ( $n = 40$  for each subtypes): nonerosive reflux disease (NERD), reflux esophagitis (RE) and Barrett's esophagus (BE). NBI magnifying endoscopic procedure was performed on the patients as well as on 40 healthy controls. The demographic and clinical characteristics,

and NBI magnifying endoscopic features, were recorded and compared among the groups. Targeted biopsy and histopathological examination were conducted if there were any abnormalities. SPSS 18.0 software was used for all statistical analysis.

**RESULTS:** Compared with healthy controls, a significantly higher proportion of GERD patients had increased number of intrapapillary capillary loops (IPCLs) (78.3% vs 20%,  $P < 0.05$ ), presence of microerosions (41.7% vs 0%,  $P < 0.05$ ), and a non-round pit pattern below the squamocolumnar junction (88.3% vs 30%,  $P < 0.05$ ). The maximum ( $228 \pm 4.8$  vs  $144 \pm 4.7$ ,  $P < 0.05$ ), minimum ( $171 \pm 3.8$  vs  $103 \pm 4.4$ ,  $P < 0.05$ ), and average ( $199 \pm 3.9$  vs  $119 \pm 3.9$ ,  $P < 0.05$ ) numbers of IPCLs/field were also significantly greater in GERD patients. However, comparison among groups of the three subtypes showed no significant differences or any linear trend, except that microerosions were present in 60% of the RE patients, but in only 35% and 30% of the NERD and BE patients, respectively ( $P < 0.05$ ).

**CONCLUSION:** Patients with GERD, irrespective of subtype, have similar micro changes in the distal esophagus. The three forms of the disease are probably independent of each other.

**Key words:** Gastroesophageal reflux; Gastroesophageal reflux disease; Intrapapillary capillary loops; Magnifying endoscopy; Narrow band imaging

**Core tip:** Gastroesophageal reflux disease (GERD) has been diagnosed with conventional endoscopy and 24-h esophageal pH monitoring. There are three forms of GERD: nonerosive reflux disease (NERD), reflux esophagitis (RE) and Barrett's esophagus (BE). However,

whether GERD is a spectrum of diseases or a “tripartite” disease remains unclear. Using narrow band imaging magnifying endoscopy, we observed no significant differences in the lower esophagus among patients with the three forms of GERD. There was also no increasing trend from NERD, RE to BE, indicating that these subtypes might be independent of each other. Thus, GERD is a “tripartite” disease, rather than a spectrum of diseases.

Investigation of relationships among gastroesophageal reflux disease subtypes using narrow band imaging magnifying endoscopy. *World J Gastroenterol* 2013; 19(45): 8391-8397 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i45/8391.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i45.8391>

## INTRODUCTION

The montreal definition<sup>[1]</sup>, an evidence-based global consensus definition, has demonstrated that gastroesophageal reflux disease (GERD) is a common chronic disorder that develops when the reflux of stomach contents causes troublesome symptoms and/or complications. The prevalence of GERD has been reported to range from 10% to 48% in Asia, slightly lower than that in Western countries<sup>[2-4]</sup>, and is increasing year by year<sup>[5-8]</sup>. GERD affects seriously patients' quality of life and poses heavy economic burdens on individuals as well as society because the lack of effective treatment. Unfortunately, the natural history of GERD has not been fully illustrated. Based on the findings of conventional endoscopy and histopathological examination, GERD is generally categorized into three progressive stages: nonerosive reflux disease (NERD), reflux esophagitis (RE), and Barrett's esophagus (BE). Patients with GERD, according to the current model of GERD as a spectrum disease, could potentially progress from mild NERD toward RE, BE, and then neoplasia<sup>[9]</sup>. This concept may in fact help the planning of diagnostic and therapeutic approaches, as well as the allocation of financial resources. Nevertheless, some researchers disagree, and propose that GERD is a “tripartite” disease. By dividing GERD into the three unique subtypes, physicians or surgeons may concentrate on the specific mechanisms that lead to the development of a subtype of GERD, leading to improvements in the specific therapeutic modalities that benefit the patients with a particular subtype.

Narrow band imaging (NBI) can better capture the microstructures of the superficial mucosa. Recent studies have shown that NBI can reveal subtle changes of esophageal superficial mucosa in GERD patients<sup>[10-15]</sup>. However, NBI endoscopy has not yet been used to study the microvascular differences among patients with NERD, RE and BE.

The present study aimed to explore the relationships among the three subtypes of GERD by observing the

subtle vascular changes detected with NBI magnifying endoscopy. Our study might provide a basis for further diagnosis and treatment of GERD.

## MATERIALS AND METHODS

### Subjects

Patients with reflux-associated symptoms, who were treated in our hospital between June 2010 and May 2012, were recruited in this study. All the patients were required to fulfill the reflux disease questionnaire (RDQ) concerning their reflux-associated symptoms to decide whether or not NBI magnifying endoscopy would be performed. The inclusion criteria were: aged between 18 and 70 years; ability to provide written informed consent; RDQ score of no less than 12; reflux-related symptom duration of no less than 3 mo; and effective treatment with proton pump inhibitors (PPIs). The exclusion criteria included: evidence of cancer or mass lesion in the upper alimentary tract, such as esophageal varices and gastric lesion; severe gastroparesis; history of drug use 4 wk before the study, including PPIs, nonsteroidal anti-inflammatory drugs, aspirin, antibiotics, antacid, mucosal protective agents, calcium channel blocks and acetylcholine or histamine receptor antagonists; and prior history of upper alimentary surgery, hemorrhage or severe uncontrolled systematic dysfunction. The healthy control group comprised subjects without any gastroesophageal reflux (GER) symptoms and with no positive findings confirmed by conventional endoscopy.

Written informed consent was obtained from all the subjects before endoscopy. The study protocol form was prepared according to the Declaration of Helsinki and approved by the Ethical Institutional Board of the hospital (No. 2010091).

### Research facility

The NBI magnifying endoscope (Olympus EVLS LU-CERA CV-260SL GIF-H260Z) used in this study was purchased from Olympus Medical Systems Corp. (Tokyo, Japan), and permitted a magnification of alimentary mucosa up to 80-fold by zoom and was compatible with an NBI light source in addition to the conventional white light source.

### Endoscopic procedure

After oral administration of 20 mL (1.0%) dimethicone and 10 mL (0.1 g) oropharyngeal anesthesia agent of dyclonine hydrochloride mucilage, all subjects underwent endoscopic procedure by the same experienced endoscopist who was blind to the GER symptoms. A complete evaluation of the upper alimentary tract was performed under the conventional mode. Then, the distal 5 cm of the esophagus, the squamocolumnar junction (SCJ) and cardia were reexamined carefully with the NBI light source under the maximum magnification of 80-fold. The key point was observation of the superficial vasculature. Images with the microstructure features in these locations were collected during the endoscopy, together

**Figure 1** Evaluation indicators of narrow band imaging magnifying mode ( $\times 80$ ). A: Normal intrapapillary capillary loops (IPCLs); B: Increment of IPCLs; C: Prolongation of IPCLs; D: Dilation of IPCLs; E: Tortuosity of IPCLs; F: Microerosion (indicated by arrows); G: Round pit pattern; H: Non-round pit pattern.

with the standardized four-quadrant images from the distal esophagus above the SCJ. An experienced investigator blinded to the GER symptoms evaluated the images.

#### Diagnostic criteria

The diagnostic criteria of NERD were: one or more of the typical reflux-associated symptoms of heartburn, regurgitation and retrosternal pain as chief complaints<sup>[1]</sup>; absence of mucosal breaks at conventional endoscopy; and effective treatment response to PPIs.

Diagnosis of RE followed the Los Angeles classification<sup>[16]</sup>.

BE was diagnosed when conversion of normal esophageal squamous epithelium to specialized intestinal metaplastic epithelium was confirmed by histopathological examination<sup>[1]</sup>.

Criteria of healthy controls included: no symptoms, no prior history of GERD, RDQ score of 0, and no visible mucosal breaks at conventional endoscopy. If microerosions were detected during the NBI magnifying endoscopy, 24-h pH monitoring was used to exclude asymptomatic GERD.

#### Evaluation indicators of NBI magnifying mode

Intrapapillary capillary loops (IPCLs) arise from the sub-mucosal drainage vein and go into the esophageal papillary. Assessment of IPCLs is important in the diagnosis of esophageal disorders. Histopathological examination has revealed that normal IPCLs exist in the esophageal submucosa, and are usually shown as dot-like structures with regular intervals of about 100  $\mu\text{m}$ . The IPCLs in the esophageal mucosa can be readily identified with the help of NBI magnifying endoscopy, under which their morphology is seen to be dynamic and can be affected by neoplasia and inflammation. The morphological changes of IPCLs were defined as follows: (1) Normal IPCLs (Figure 1A): hairpin-like structures with small diameters; (2) Increment (Figure 1B): an increase in the number of

IPCLs in individual fields; (3) Prolongation (Figure 1C): a change in the pattern characterized by increased lengths of individual IPCLs; (4) Dilation (Figure 1D): a change in the pattern characterized by increased sizes or calibers of individual IPCLs; (5) Tortuosity (Figure 1E): presence of corkscrewing or the twisted nature of individual IPCLs; (6) Another indicator was microerosion (Figure 1F): mucosal breaks not visible under conventional endoscopy but visible under NBI magnifying endoscopy; (7) Mucosal pit pattern under SCJ was the third indicator. Taking the Endo Classification Criteria as a reference<sup>[17]</sup>, the pit pattern was classified into two categories: round (Figure 1G) and non-round (including straight, oval, tubular and villous pit patterns) (Figure 1H); and (8) Photoshop software (Photoshop CS5 v 8.0; Adobe Inc., United States) was used to edit the image files.

#### Histopathological examination

Targeted biopsy was conducted when there was any mucosal lesion, such as erosion. Biopsy samples above and below the SCJ in four quadrants were also taken from all subjects. If esophageal metaplasia was suspected, biopsy sampling was performed in a systematic manner, *i.e.*, four-quadrant biopsies were obtained every 2 cm throughout the affected segment<sup>[18]</sup>. Histopathological examination was then performed on all the biopsy tissues.

#### Statistical analysis

The statistical software SPSS (SPSS PASW Statistics v18 Multilingual-EQUiNOX; SPSS Inc., United States) was used for all statistical analyses. The two-sample *t* test and analysis of variance (ANOVA) were performed on appropriate continuous quantitative variables that were normally distributed to determine whether significant differences existed among groups. Continuous quantitative variables that were not normally distributed were tested using the Wilcoxon test. Categorical variables were analyzed by the  $\chi^2$  test. Whenever the validity of  $\chi^2$  was

called in question, Fisher's exact test was used instead. The probability of error (alpha) (*P*) was set at 0.05. *P* < 0.05 was considered statistically significant.

## RESULTS

### Characteristics of the subjects

A total of 157 patients were screened, of whom 145 were eligible for inclusion (40 NERD, 54 RE and 51 BE). To keep a balance among the groups, we selected 40 RE and 40 BE patients randomly. Altogether, we had 120 (66 male, 54 female) patients and 40 healthy controls (16 male, 24 female) included in the final analysis. Among these 120 GERD patients, there were 40 NERD, 40 RE and 40 BE patients. There were no significant differences between healthy controls and GERD patients in terms of gender, age, body mass index (BMI), prevalence of hiatus hernia, and prevalence of bile regurgitation. As for inter-subtype comparison, NERD patients were more likely to be female (*P* < 0.05), while most of the RE patients were male (*P* < 0.05). Patients with BE were less likely to demonstrate bile regurgitation (*P* < 0.05). In addition, the differences were not significant with respect to age, BMI, course, scores of RDQ and prevalence of hiatus hernia. The demographic and clinical characteristics, and conventional observations of the subjects are shown in Table 1.

### Evaluation indicators with NBI magnifying endoscopy mode

The majority of GERD patients presented abnormalities

under NBI magnifying endoscopy. Increment of IPCLs appeared in a significantly higher proportion of GERD patients than in healthy controls (*P* < 0.05). Microerosion above and non-round pit pattern below the SCJ were also seen more frequently in patients with GERD (*P* < 0.05). However, there was no significant difference in the presence of prolonged, dilated, or tortuous IPCLs between patients and controls. The comparison among groups of different GERD subtypes revealed no evident difference in the number of patients presenting with abnormalities. No statistical differences were found in the increased, prolonged, dilated or tortuous IPCLs in the distal esophagus, as well as in the distributions of the mucosal pit patterns below the SCJ. As expected, RE patients were more likely to demonstrate microerosions. The NBI magnifying endoscopic features are shown in Table 2.

Qualitative analysis of the IPCLs increment was also performed. The numbers of IPCLs/field in the standardized four-quadrant images from the distal esophagus were counted manually in each subject. The results showed that the maximum, minimum and average numbers of IPCLs/field were significantly higher in GERD patients than in healthy controls (*P* < 0.05). There was no significant difference among the three subtype groups. More importantly, there was no linear increasing trend from NERD to RE to BE. The quantitative data are presented in Table 3.

Receiver operating characteristic curves were plotted for the maximum, minimum and average numbers

**Figure 2** Receiver operating characteristic curves analysis. Receiver operating characteristic (ROC) curves were drawn based on the maximum, minimum and average numbers of IPCLs/field in gastroesophageal reflux disease patients and healthy controls. IPCLs: Intrapapillary capillary loops.

of IPCLs/field in GERD patients to obtain the cut-off values with the best sensitivity and specificity for diagnosis, namely, diagnostic threshold. The best sensitivity and specificity for GERD were 81.7% and 95.0% at a maximum IPCLs/field count of 185, 80% and 95% at a minimum IPCLs/field count of 135, and 80% and 95% at an average IPCLs/field count of 162 (Figure 2). The areas under the curves were 0.900, 0.902 and 0.925, respectively.

## DISCUSSION

GERD is considered to result from a long period of GER that causes troublesome symptoms and/or complications<sup>[1]</sup>. It has traditionally been approached as a spectrum of diseases with the same pathophysiological mechanisms. Based on conventional endoscopy and histopathological examination, GERD is generally categorized into three progressive stages: NERD, RE and BE. This understanding of GERD has a profound impact on its treatment, which focuses on esophageal mucosal injury<sup>[19]</sup>. Nevertheless, some researchers believe that GERD is a “tripartite” disease, rather than the model above. They take the three forms of GERD as being independent of each other, which may have their own mechanisms and should be approached with specific therapeutic modalities.

NBI, based upon the optical phenomenon that the depth of light penetrating into tissues depends on its wavelength, can capture the more detailed microstructure of the superficial mucosa. Some researchers have already used NBI magnifying endoscopy to observe the superficial mucosal changes in NERD patients, which cannot be observed under conventional endoscopy. For patients with RE and BE, micro changes have also been revealed

**Table 3** Intrapapillary capillary loops/field in gastroesophageal reflux disease patients and healthy controls

IPCLs/field	HC	GERD			
		GERD	NERD	RE	BE
Maximum (SD)	144 ± 4.7	228 ± 4.8	229 ± 7.8	233 ± 8.2	220 ± 9.3
Minimum (SD)	103 ± 4.4	171 ± 3.8	162 ± 5.6	178 ± 6.7	174 ± 7.1
Average (SD)	119 ± 3.9	199 ± 3.9	193 ± 5.7	208 ± 6.8	195 ± 7.7

GERD: Gastroesophageal reflux disease; RE: Reflux esophagitis; BE: Barrett's esophagus; NERD: Nonerosive reflux disease; HC: Healthy controls; IPCLs: Intrapapillary capillary loops.

with NBI magnifying endoscopy, in addition to the macro changes visualized by conventional endoscopy.

The microscopic IPCLs in the esophageal mucosa can be readily identified with the help of NBI magnifying endoscopy. A pilot feasibility trial conducted by Sharma *et al.*<sup>[11]</sup> illustrated the clinical utility of NBI magnifying endoscopy, which presents a significant improvement over standard endoscopy in the diagnosis of GERD. Their results indicated that increased number and dilatation of IPCLs may be the best predictors for the diagnosis of GERD. Normal IPCLs appear to be hairpin-shaped and small in diameter, while there are evident changes in the morphology and arrangement of IPCLs in GERD patients<sup>[10,12-15]</sup>. However, the micro vascular differences among NERD, RE and BE patients have not been investigated before.

The demographic and clinical characteristics of the subjects in our study are consistent with former epidemiological data in China. The increased number of IPCLs identified in the GERD patients would be helpful for the diagnosis of the disease. There were no remarkable differences in the micro structural changes among patients with the three subtypes of GERD. Additionally, there is no trend of development from NERD to RE and then BE. As pointed out by some researchers, the micro changes of esophageal mucosa, such as increment of IPCLs and microerosion, could truly represent the regurgitation-induced damage, and the assessment of differences in micro mucosal structure and vascular architecture could provide useful information for predicting histopathological findings<sup>[11,20-22]</sup>. Therefore, our statistics imply that GERD may be a “tripartite” disease resulting from GER, rather than a spectrum of diseases.

NERD, RE and BE, as three independent forms of GERD, may have their respective pathogenesis, clinical manifestations and complications. As Fass *et al.*<sup>[19]</sup> and Fass<sup>[23]</sup> have proposed, genetic factors may play a role in determining the phenotypes of GERD. Correspondingly, the diseases may require different therapeutic approaches and will have different prognoses and natural histories. There has already been clinical evidence for the independence of the three GERD forms. RE can be diagnosed with endoscopy and BE with endoscopy together with biopsy. However, conventional endoscopy is merely an exclusive examination for NERD. As to the 24 h pH monitoring, the symptomatic severity and frequency

between NERD and RE are not significantly different, and they affect the patients' quality of life similarly. Martinez *et al*<sup>[24]</sup> noted that the esophageal acid exposure of patients with NERD, RE and BE were different, and the reflux characteristics and symptom patterns suggested heterogeneity among their patients. In addition, the therapeutic efficacy in patients with different forms of GERD is different. A systematic review showed that a higher proportion of RE patients, compared with patients with NERD, achieved sufficient heartburn relief after the use of PPIs, and the therapeutic efficacy of NERD was poorer than that of RE<sup>[25]</sup>. The reason for the difference between NERD and RE patients in response to PPIs is still unclear. Limited data has indicated that NERD rarely moves on to RE with the prolonged course, relapse in cured RE patients after drug withdrawal often displays esophageal mucosal erosion, and BE is usually discovered during the first endoscopy examination instead of being developed from NERD or RE<sup>[19,26]</sup>. However, there have not been adequate follow-up studies to show the natural history of GERD.

It remains controversial whether GERD is a spectrum of diseases or not, and the relationships among the three forms of GERD has not yet been clarified. The montreal definition<sup>[1]</sup>, which takes RE as an esophageal complication of GERD, has shifted the attention from esophageal mucosal lesion to reflux symptoms, and may influence the cognition of the subtypes of GERD. More epidemiological investigation, prospective follow-up research and clinical observation are needed to clarify this issue.

Despite the value of our study, some limitations exist. This is a single-center investigation with a limited number of patients. A multicenter study with a larger sample size will be more reliable. In addition, NBI magnifying endoscopy has not yet been widely used. The inspection area under the magnifying mode is very small, which makes it time-consuming to examine the entire distal esophagus.

If the view that NERD, RE and BE are relatively independent forms of GERD is confirmed, the therapeutic strategy for each form could be adjusted according to the specific mechanism of that form, increasing efficacy. Therefore, determination of the internal relationships among NERD, RE and BE has profound significance in clinical practice.

## COMMENTS

### Background

Gastroesophageal reflux diseases (GERD), with the subtypes of nonerosive reflux disease (NERD), reflux esophagitis (RE) and Barrett's esophagus (BE), has been studied for many years. Conventional endoscopy and 24-h esophageal pH monitoring are common diagnostic approaches for GERD. However, it has not been clarified whether GERD is a spectrum of diseases or a "tripartite" disease.

### Research frontiers

Narrow band imaging (NBI) can capture the more detailed microstructure of the superficial mucosa. Some recent studies have shown that NBI magnifying endoscopy can reveal subtle changes of esophageal superficial mucosa in GERD patients. However, the microvascular differences among NERD, RE and BE

patients have not been investigated before using this new technology.

### Innovations and breakthroughs

It has been reported that patients with GERD could potentially progress from mild NERD toward RE, then BE, and finally neoplasia, which indicates that GERD may be a spectrum of diseases. However, some researchers disagree. They regard GERD a "tripartite" disease. The relationships among the three forms of GERD have not been fully investigated. The present study aimed to explore the relationships among the three subtypes of GERD by observing the subtle vascular changes detected by NBI magnifying endoscopy. The authors study might provide a basis for further diagnosis and treatment of GERD.

### Applications

By dividing GERD into three unique subtypes, physicians or surgeons may concentrate on the specific mechanisms leading to the development of a subtype of GERD and improve the specific therapeutic modalities that benefit the patients with subtype of disease.

### Terminology

Normal intrapapillary capillary loops (IPCLs) exist in the esophageal submucosa, and are dot-like structures, arranged at regular intervals of about 100  $\mu\text{m}$ . The microscopic IPCLs in the esophageal mucosa can be readily identified with the help of NBI magnifying endoscopy. Under magnifying endoscopy, they appear hairpin-shaped and small in diameter. Their morphology is dynamic and could be affected by neoplasia and inflammation.

### Peer review

In this study, the authors conducted research on the relationships among the three common forms of GERD using NBI magnifying endoscopy to observe the micro changes in the patients. All efforts to establish classifications in this very frequent disease are welcome. NBI facilitates diagnosis and includes new imaging areas. The results demonstrated that the GERD patients had similar micro changes in the distal esophagus, and they indicated that the disease might be a model of "tripartite" disease, rather than a spectrum of diseases.

### Abstract

**AIM:** To determine whether an elevated neutrophil-lymphocyte ratio (NLR) is negatively associated with tumor recurrence in patients with hepatitis B virus (HBV)-related hepatocellular carcinoma (HCC) after liver transplantation (LT), and to determine the optimal predictive NLR cut-off value.

**METHODS:** The data of HCC patients who had undergone LT came from the China Liver Transplant Registry database. We collected data from 326 liver cancer patients who had undergone LT at our medical center. We divided the patients into groups based on their NLRs (3, 4 or 5). We then compared the clinicopathological data and long-time survival between these groups. Meanwhile, we used receiver operating characteristic analy-

sis to determine the optimal NLR cut-off.

**RESULTS:** Of 280 HCC patients included in this study, 263 were HBV positive. Patients with an NLR < 3 and patients with an NLR  $\geq$  3 but < 4 showed no significant differences in overall survival (OS) ( $P = 0.212$ ) or disease-free survival (DFS) ( $P = 0.601$ ). Patients with an NLR  $\geq$  4 but < 5 and patients with an NLR  $\geq$  5 also showed no significant differences in OS ( $P = 0.208$ ) or DFS ( $P = 0.618$ ). The 1-, 3- and 5-year OS rates of patients with an NLR < 4 vs an NLR  $\geq$  4 were 87.8%, 63.8% and 61.5% vs 73.9%, 36.7% and 30.3%, respectively ( $P < 0.001$ ). The 1-, 3- and 5-year DFS rates of patients with an NLR < 4 vs NLR  $\geq$  4 were 83.9%, 62.9% and 60.7% vs 64.9%, 30.1% and 30.1%, respectively ( $P < 0.001$ ). Univariate and multivariate analyses demonstrated that three factors, including NLR  $\geq$  4 ( $P = 0.002$ ), were significant predictors of tumor recurrence in HCC patients after LT.

**CONCLUSION:** A preoperative elevated NLR significantly increased the risk for tumor recurrence in HCC patients after LT.

**Key words:** Hepatocellular carcinoma; Liver transplantation; Inflammatory reaction; Neutrophil-lymphocyte ratio; Hepatitis B virus

**Core tip:** Inflammation has been linked to the biological characteristics of tumors. The neutrophil-lymphocyte ratio (NLR) is a simple biomarker of inflammation. Several studies have reported that a preoperative elevated NLR (in peripheral blood) is negatively associated with the prognosis of patients with hepatocellular carcinoma (HCC) after liver transplantation (LT). However, the ideal cut-off value is controversial, with studies citing both

3 and 5 as the appropriate cut-off NLR. In this study, we report 326 HCC patients who had undergone LT at our center. We identify NLR = 4 as the cut-off point for predicting the prognosis of HCC patients after LT.

Xiao GQ, Liu C, Liu DL, Yang JY, Yan LN. Neutrophil-lymphocyte ratio predicts prognosis of patients with hepatocellular carcinoma after liver transplantation. *World J Gastroenterol* 2013; 19(45): 8398-8407 Available from: URL: <http://www.wjg-net.com/1007-9327/full/v19/i45/8398.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i45.8398>

## INTRODUCTION

Hepatocellular carcinoma (HCC) is the fifth most common cancer in the world and is the third leading cause of cancer-related death. Every year, more than 500000 people are diagnosed with HCC, and most of these patients are in developing countries<sup>[1]</sup>. Liver transplantation (LT) is the ideal choice for HCC patients<sup>[2]</sup> because it completely removes tumors in the liver and also improves hepatic function. However, the outcome of HCC patients after LT was unsatisfactory, owing to a high tumor recurrence, until Mazzaferro *et al*<sup>[3]</sup> proposed the Milan criteria. Since the Milan criteria were adopted, the outcome of HCC after LT has significantly improved. Several LT centers have confirmed the satisfactory outcome of HCC patients within the Milan criteria after LT<sup>[4-7]</sup>. However, a large proportion of patients fall outside the Milan criteria when they are diagnosed with liver cancer. Thus, the LT criteria for HCC should be revised so that more people can become candidates for LT. Over the past 10 years, many centers have attempted to establish more suitable criteria for selecting HCC patients<sup>[8-12]</sup>. Yao *et al*<sup>[8]</sup> presented the University of California San Francisco (UCSF) criteria in 2001. The Milan and UCSF criteria are based on tumor number, tumor size and macro-vascular invasion, which are estimated by preoperative imaging.

However, preoperative radiological imaging is inaccurate, especially for patients with liver cirrhosis. Micro-vascular invasion and histological grade cannot be detected by imaging, and these two important factors greatly influence the recurrence of HCC after LT. Some studies have reported a recurrence rate of HCC after LT of nearly 15%-20% in patients who were within Milan or UCSF criteria<sup>[13,14]</sup>. This condition prompted us to identify better predictors of the recurrence of HCC after LT.

Several studies have investigated the effect of inflammation on carcinogenesis because the cytokines and mediators released by inflammatory cells can promote angiogenesis and tumor cell metastasis<sup>[15-17]</sup>. Several inflammatory markers, such as C reactive protein, have been suggested as surrogates for biological characteristics in some types of tumors<sup>[18,19]</sup>. The neutrophil-lymphocyte ratio (NLR) is a simple biomarker of inflammation, and an elevated NLR has been linked to several malignan-

cies<sup>[20-22]</sup>. Halazun *et al*<sup>[23]</sup> reported that patients with colorectal liver metastases with an elevated NLR had higher rates of recurrence after partial hepatic resection than patients with normal NLRs. Furthermore, studies have also shown that an elevated NLR has a negative impact on the prognosis of HCC patients after LT. However, these different studies have employed NLRs of 3, 4 and 5 as the cut-offs<sup>[24-28]</sup>, and the NLR cut-offs are not unified. Our study aimed to calculate the optimal preoperative cut-off NLR for predicting the prognosis of HCC patients after LT.

## MATERIALS AND METHODS

### *Patient selection and intra- and post-operative treatment*

The data of HCC patients who had undergone LT came from the China Liver Transplant Registry database. We collected data from 326 liver cancer patients who had undergone LT at our medical center from August 2000 to January 2011. Preoperative demographic, clinical and laboratory data were recorded for these patients. A systemic plain/enhanced computed tomography (CT) scan or a magnetic resonance imaging scan was employed within one week before the surgery. Pathology was considered as the definite diagnosis for HCC. Pathological data were considered as the standard for tumor characteristics. Moreover, micro-vascular invasion and tumor differentiation were also assessed by pathology.

Blood cell testing is part of the routine work-up for HCC patients who have undergone LT. The absolute value of white blood cells and the differential counts were recorded within one week before surgery. The NLR was calculated by dividing the neutrophil count by the lymphocyte count. Patients with missing blood records; patients who had preoperative sepsis, hypersplenism, massive alimentary tract bleeding, hepatitis C virus (HCV) infection, cholangiocarcinoma or other neoplasms; and pediatric patients were excluded from this study.

The patients received LT at least one month after they had received preoperative adjuvant therapy when their blood test became normal. LT was performed using standard techniques without the use of veno-venous bypass, and a "piggy back" was used when necessary. After surgery, an immune-suppression regimen, including corticosteroids, cyclosporine or tacrolimus with or without azathioprine and mycophenolate, was administered. The steroids were withdrawn after 3-6 mo of post-operative treatment<sup>[29]</sup>. The e antigen status and HBV-DNA of several patients were positive, and the HBV-positive patients received anti-viral drugs, such as lamivudine, adefovir, telbivudine and entecavir, prior to and after transplantation<sup>[30]</sup>.

### *Follow-up*

After surgery, the patients underwent follow-up procedures. Plain/enhanced CT scans and  $\alpha$ -fetoprotein (AFP) tests were performed every month for the first 6 mo. The above examinations were performed every 2 mo for the second 6 mo. In the following years, the patients received

examinations every 3-6 mo or when necessary. Suspicious lesions in the liver or lung were biopsied. Bone pain and progression of growth were observed. The date of tumor recurrence was regarded as the time that the AFP level began to rise once tumor recurrence had been confirmed.

### Ethics

This study was approved by the Institutional Review Board of West China Hospital of Sichuan University in Sichuan Province. Written informed consent was obtained according to the Declaration of Helsinki of the World Medical Association.

### Statistical analysis

SPSS v17.0 and MedCalc v11.3.0.0 were used to analyze the data. Receiver operating characteristic (ROC) analysis was used to determine the NLR cut-off value. Independent sample *t* test, Pearson's  $\chi^2$  test and Fisher's exact test were used to analyze the differences among HCC patients classified by different NLR values. Kaplan-Meier survival analysis was used to analyze overall survival (OS) and disease-free survival (DFS). Univariate analysis was performed to estimate the hazard ratio of the clinicopathological factors for the risk of tumor recurrence. The factors that had a significant impact on the outcome of HCC patients after LT were selected into multivariate Cox proportional hazards regression analysis to assess the hazard ratio for the risk of tumor recurrence in HCC patients after LT. The confidence interval quoted area was 95%, and significant differences were defined as *P* < 0.05.

## RESULTS

### Patient demographics and outcomes

Of 326 HCC patients who had undergone LT at our

medical center from August 2000 to January 2011, 46 were excluded from the study: 10 for missing blood records, 2 pediatric patients, 3 for preoperative sepsis, 10 for hypersplenism, 2 for massive alimentary tract bleeding, 1 HCV-positive patient and 18 for the diagnosis of cholangiocarcinoma or other neoplasms by pathology. Thus, 280 patients were included in this study. Of these patients, 263 (93.9%) were HBV positive. The carcinogenic factor of 17 HCC patients may have been alcohol because they had a history of alcohol abuse. Among 280 patients, there were 31 (11.1%) women and 249 (88.9%) men. The mean age of the patients who had received LT was 46.5 years (range: 20.5-69.1 years, SD: 9.6 years). The median waiting times for living donor and deceased donor LT were 0.9 and 1.6 mo, respectively. The mean follow-up time was 2.63 years (range: 1.1-12.0 years). A total of 120 people died during follow-up. The 1-, 3- and 5-year OS rates of the patients in our study were 82.2%, 52.6% and 48.5%, respectively, and the 1-, 3- and 5-year DFS rates were 76.1%, 50.3% and 47.8%, respectively.

### Comparison of variables between patients with different NLRs

Several studies have considered NLRs of 3, 4 and 5 as the cut-off points to predict the prognosis of HCC patients after LT<sup>[24-28]</sup>. Thus, we divided the HCC patients who had received LT at our hospital based on these three NLR cut-offs. There were 105 patients with an NLR < 3, 61 patients with NLRs between 3 and 4, 56 patients with NLRs between 4 and 5 and 58 patients with an NLR ≥ 5. We compared the demographic and clinicopathological data of HCC patients after LT. HCC patients classified based on their NLRs showed significant differences in tumor number > 3 (*P* = 0.036) and macro-vascular invasion (*P* = 0.028). There were no significant differences in the other variables among the groups with different NLRs (Table 1).

<sup>1</sup>Significant P value. NLR: Neutrophil-lymphocyte ratios; AFP:  $\alpha$ -fetoprotein; HBV: Hepatitis B virus.

### Outcome of different HCC categories divided by NLRs

Of the 105 patients with an NLR  $< 3$ , 12 died and 15 had tumor recurrence within 1 year. For these patients, the 1-, 3- and 5-year OS rates were 88.6%, 65.8% and 65.8%, respectively, and the 1-, 3- and 5-year DFS rates were 85.4%, 63.7% and 62.0%, respectively. For the 61 patients with NLRs between 3 and 4, their OS and DFS were not significantly different compared with patients having an NLR  $< 3$  ( $P = 0.212$  and  $P = 0.601$ , respectively). There were 56 patients with an NLR  $\geq 4$  but  $< 5$  and 58 patients with an NLR  $\geq 5$ . The outcome of these two categories was not significantly different, as shown in Figure 1. However, the outcome of patients with an NLR  $\geq 3$  but  $< 4$  and an NLR  $\geq 4$  but  $< 5$  revealed significant differences: the 1-, 3- and 5-year OS rates of patients with an NLR  $\geq 3$  but  $< 4$  *vs* an NLR  $\geq 4$  but  $< 5$  were 86.4%, 57.3% and 54.3% *vs* 79.7%, 35.5% and 31.1%, respectively ( $P = 0.026$ ). The 1-, 3- and 5-year DFS rates of patients with an NLR  $\geq 3$  but  $< 4$  *vs* an NLR  $\geq 4$  but  $< 5$  were 81.2%, 61.6% and 58.6% *vs* 68.9%, 31.2% and 31.2%, respectively ( $P = 0.005$ ) (Figure 1).

In addition, we used ROC curve analysis to determine the optimal NLR cut-off for HCC patients who received LT. The area under the ROC curve was 0.670 (Figure 2). When the NLR was 4.0634, the sensitivity was 56.3%, the specificity was 75.0%, and the sensitivity and specificity were highest. Therefore, we considered NLR = 4 as the cut-off. Patients with an NLR less than 3 and patients with an NLR  $\geq 3$  but  $< 4$  were combined into one cat-

egory, while the patients with an NLR  $\geq 4$  were considered as one category. We then compared the outcome of these two categories. As shown in Figure 3, the OS and DFS of these two categories were significantly different.

### Predictors of prognosis of HCC patients after LT

The lists in Table 2 show 8 significant factors that affects the DFS of HCC patients after LT by univariate analysis: age  $\geq 60$  years, AFP  $\geq 400$  g/L, NLR  $\geq 4$ , tumor number  $> 3$ , largest tumor size more than 5 cm, total tumor size more than 9 cm, macro-vascular invasion and micro-vascular invasion. The significant predictors were then utilized for a multivariate proportional hazard regression analysis. The result revealed that NLR  $\geq 4$  ( $P = 0.002$ , HR = 1.758, 95%CI: 1.222-2.527), total tumor size  $> 9$  cm ( $P < 0.001$ , HR = 2.725, 95%CI: 1.691-3.393) and macro-vascular invasion ( $P < 0.001$ , HR = 2.013, 95%CI: 1.336-3.035) were independent predictors of DFS of HCC patients after LT (Table 3). We also performed univariate analysis and multivariate proportional hazard regression analysis to analyze the factors that affect the OS of HCC patients who underwent LT. The results showed that NLR  $\geq 4$  ( $P = 0.006$ , HR = 1.695, 95%CI: 1.164-2.466), total tumor size  $> 9$  cm ( $P < 0.001$ , HR = 4.114, 95%CI: 2.438-6.940) and macro-vascular invasion ( $P < 0.001$ , HR = 2.049, 95%CI: 1.364-3.078) were independent predictors of OS of HCC patients after LT.

## DISCUSSION

Since the Milan criteria were proposed by Mazzaferro *et al.*<sup>[3]</sup> in 1996, many liver transplantation centers worldwide have reported excellent results after LT for patients with HCC who fall within the Milan criteria<sup>[6,29,31]</sup>. However, most HCC patients are outside the Milan criteria. To let those people receive corresponding treatment, revised LT criteria for HCC patients need to be established. Therefore, Yao *et al.*<sup>[8]</sup> presented revised criteria and demonstrated that the outcomes of patients with HCC after LT outside the Milan criteria but within UCSF had no significant difference compared with the outcomes of patients within the Milan criteria. This result has been confirmed

by many LT centers<sup>[9,32]</sup>. With the revision of the LT criteria for HCC, another issue arises: organ shortages. Therefore, it is necessary to judge the biological characteristics of the tumor to exclude patients with negative tumor behavior. These patients will likely respond poorly to LT despite being within the Milan or UCSF criteria. Tumor size and number, as assessed by preoperative radiology, are used as surrogate markers of tumor biology. Some studies have reported that tumor size is related to the risk of recurrence and vascular invasion<sup>[13,33]</sup>. However, we found tumor number > 3 and largest tumor size > 5 cm were not independent predictors of the OS and DFS of patients with HCC after LT. Nevertheless, total tumor size > 9 cm was an independent factor that predicted OS and DFS (Table 2). In view of the inaccuracy of preoperative tumor assessments and the inconsistency of the effect of tumor number and size on the prognosis of HCC patients after LT, new non-invasive surrogates are needed to predict the outcome of HCC patients after partial hepatic resection or LT.

Several studies have reported that inflammation plays an important role in the development of malignant disease<sup>[15,17]</sup>. NLR was first linked to liver malignancy by Halazun *et al*<sup>[23]</sup>. NLR is a simple marker of inflammation and can be obtained easily by routine blood testing. However, the cut-off values of NLR are not unified. We found that the outcomes of patients with an NLR < 3 and patients with an NLR ≥ 3 but < 4 were not significantly different, nor were the outcomes of patients with an NLR ≥ 4 but < 5 and patients with an NLR ≥ 5. In

our study, ROC analysis demonstrated that the sensitivity and specificity were highest when the NLR was 4.0634. Therefore, we considered patients with an NLR < 4 as one group and patients with an NLR ≥ 4 as another group. We then compared the outcomes of these two groups. We observed a marked and significant difference between these two groups in OS and DFS. Therefore, we consider NLR ≥ 4 as an elevated ratio. NLR ≥ 4 was also recognized as elevated by Shimada *et al*<sup>[21]</sup> in patients with gastric cancer. Halazun *et al*<sup>[25]</sup> considered NLR ≥ 5 to be elevated, and they reported the 1-, 3- and 5-year DFS of patients with an elevated NLR *vs* a normal NLR as 62%, 28% and 28% *vs* 88%, 74% and 64%, respectively ( $P = 0.001$ ).

Although HCC patients with an elevated NLR have a poor prognosis, the mechanism through which the NLR affects tumor recurrence remains undefined. There are several hypotheses regarding the link between elevated NLR and tumor recurrence. First, neutrophils are the major source of vascular endothelial growth factor (VEGF), which promotes tumor angiogenesis and metastasis<sup>[34-37]</sup>. High levels of VEGF expression have been correlated with tumor recurrence in HCC<sup>[38]</sup>. Furthermore, some studies have reported that patients with elevated VEGF expression have increased vascular density in their tumor nodules<sup>[34,39]</sup>. Generally, the white blood cell counts of these patients were within the normal range, so patients with a higher NLR had higher neutrophil counts and higher VEGF expression. Second, the human immune system mostly depends on lymphocytes. However, lymphocyte counts are greatly reduced in patients with elevated NLRs, who are left unable to defend against the tumor malignancy. Several studies have demonstrated that patients with few lymphocytes infiltrating into the tumor margin have poor outcomes after treatment<sup>[39,40]</sup>. Patients with elevated NLRs have relative neutrophilia and lymphocytopenia, leading to an imbalance in the inflammatory cascade and immune response to malignant tumors. In this type of micro-environment, tumors proliferate and metastasize more easily. It remains unclear whether neutrophils or lymphocytes play a more important role in tumor recurrence of HCC after LT, and the mechanism has not been explored clearly. It is necessary to perform more clinical and basic studies.

Although univariate analysis of this study demonstrated that age ≥ 60 years, AFP ≥ 400 g/L, tumor number > 3, largest tumor size > 5 cm and micro-vascular invasion were preoperative predictors of DFS, none of these variables were independent factors for predicting tumor recurrence of HCC after LT. Some studies have reported tumor nodules > 3 as an independent predictor of tumor recurrence<sup>[9,24,41]</sup>. However, our results showed that the long-term survival of HCC patients with tumor nodules < 3 and those with tumor nodules > 3 was unchanged after LT, and our result is in agreement with the results of several other studies<sup>[25,42]</sup>. In this study, NLR ≥ 4 ( $P = 0.002$ , HR = 1.758, 95%CI: 1.222-2.527), total tumor size > 9 cm ( $P < 0.001$ , HR = 2.725, 95%CI: 1.691-3.393) and

**Figure 3** Kaplan-Meier survival analysis curve. A: The overall survival for patients with hepatocellular carcinoma undergoing liver transplantation classified by the cut-off neutrophil-lymphocyte ratio (NLR) of 4; B: The disease-free survival for patients with hepatocellular carcinoma undergoing liver transplantation by the cut-off NLR of 4.

macro-vascular invasion ( $P < 0.001$ , HR = 2.013, 95%CI: 1.336-3.035) were independent factors that predict the prognosis of HCC patients after LT. HCC patients with a higher preoperative NLR had a higher tumor recurrence rate than those with a normal NLR after LT.

There are many limitations to this study. First, we know that the preoperative NLR is affected by many factors, such as unidentified sepsis, weight loss, massive hemorrhage and instrumental error, which make the NLR inaccurate. In addition, the majority of patients enrolled in our study had HBV infection, which may bias the result because hepatitis C is the most common cause of HCC in developed countries. Moreover, this is a retrospective study, and the number of patients included in our study is relatively small. More multi-center and prospective studies are needed to confirm and update the findings demonstrated in this study.

In summary, we have found that HCC patients with an elevated preoperative NLR have poorer OS and DFS after LT. This biomarker allows us to preoperatively identify patients with a high NLR, who have a poor prognosis and adverse tumor biology.

## ACKNOWLEDGMENTS

The authors thank Yang Jian for his help with the data analysis and design of this study and Wang Qiao for his assistance with patient follow-up.

## COMMENTS

### Background

Several studies have investigated the effect of inflammation on carcinogenesis because cytokines and mediators released by inflammatory cells can promote angiogenesis and tumor cell metastasis. Several inflammatory markers, such as C reactive protein, have been suggested as surrogates for biological characteristics in some types of tumors. The neutrophil-lymphocyte ratio (NLR) is a simple biomarker of inflammation, and an elevated NLR has been linked to several malignancies.

### Research frontiers

Halazun *et al* reported that patients with colorectal liver metastases with an elevated NLR had higher rates of recurrence after partial hepatic resection than patients with normal NLRs. Furthermore, studies have also shown that an elevated NLR has a negative impact on the prognosis of hepatocellular carcinoma (HCC) patients after liver transplantation (LT).

### Innovations and breakthroughs

Several studies have employed NLRs of 3, 4 and 5 as the cut-offs, and the NLR cut-offs are not unified. The study aims to calculate the optimal preoperative NLR cut-off for predicting the prognosis of HCC patients after LT.

### Applications

A preoperative elevated NLR significantly increased the risk for tumor recurrence in HCC patients after LT. This biomarker allows them to preoperatively identify patients with a high NLR, who have a poor prognosis and adverse tumor biology.

### Terminology

The NLR was calculated by dividing the neutrophil count by the lymphocyte count in peripheral blood.

### Peer review

This is a very interesting paper on a prognostic factor for liver cancer recurrence after transplantation. The authors stated that NLR is a strong prognostic factor for outcome of liver transplantation for HCC from their experience. This manuscript is easy to understand and well organized.

### Abstract

**AIM:** To evaluate the efficacy, safety and influential factors of proton pump inhibitor (PPI) treatment for non-erosive reflux disease (NERD).

**METHODS:** PubMed, MEDLINE, EMBASE and the Cochrane Library were searched up to April 2013 to identify eligible randomized controlled trials (RCTs) that probed into the efficacy, safety and influential factors of PPI treatment for NERD. The rates of symptomatic relief and adverse events were measured as the outcomes. After RCT selection, assessment and data collection, the pooled RRs and 95%CI were calculated. This meta-analysis was performed using the Stata 12.0 software (Stata Corporation, College Station, Texas, United States). The level of evidence was estimated by the Grading of Recommendations Assessment, Development and Evaluation system.

**RESULTS:** Seventeen RCTs including 6072 patients

met the inclusion criteria. The results of the meta-analysis showed that PPI treatment was significantly superior to H<sub>2</sub> receptor antagonists (H<sub>2</sub>RA) treatment (RR = 1.629, 95%CI: 1.422-1.867,  $P = 0.000$ ) and placebo (RR = 1.903, 95%CI: 1.573-2.302,  $P = 0.000$ ) for the symptomatic relief of NERD. However, there were no obvious differences between PPI and H<sub>2</sub>RA (RR = 0.928, 95%CI: 0.776-1.110,  $P = 0.414$ ) or PPI and the placebo (RR = 1.000, 95%CI: 0.896-1.116,  $P = 0.997$ ) regarding the rate of adverse events. The overall rate of symptomatic relief of PPI against NERD was 51.4% (95%CI: 0.433-0.595,  $P = 0.000$ ), and relief was influenced by hiatal hernia ( $P = 0.030$ ). The adverse rate of PPI against NERD was 21.0% (95%CI: 0.152-0.208,  $P = 0.000$ ), and was affected by hiatal hernia ( $P = 0.081$ ) and drinking ( $P = 0.053$ ).

**CONCLUSION:** PPI overmatched H<sub>2</sub>RA on symptomatic relief rate but not on adverse rate for NERD. Its relief rate and adverse rate were influenced by hiatal hernia and drinking.

**Key words:** Proton pump inhibitor; Non-erosive reflux disease; Symptomatic relief; Adverse event; Meta-analysis

**Core tip:** As a kind of powerful and effective acid-suppressive drugs, proton pump inhibitor (PPI) has been used for patients with non-erosive reflux disease (NERD), but its efficacy, safety and their influential factors are inconclusive. We performed this systematic review and meta-analysis of randomized controlled trials to assess its efficacy, safety and influential factors. Based on the results of the meta-analysis, we conclude that PPI has a higher symptomatic relief rate and roughly the same adverse rate for NERD. Hiatal hernia and drinking could influence symptomatic relief rate and adverse rate of PPI on NERD.

Proton pump inhibitor for non-erosive reflux disease: A meta-analysis. *World J Gastroenterol* 2013; 19(45): 8408-8419 Available from: URL: <http://www.wjg-net.com/1007-9327/full/v19/i45/8408.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i45.8408>

## INTRODUCTION

Non-erosive reflux disease (NERD) is a heterogeneous group of disorders, which present with the typical gastroesophageal reflux symptoms of heartburn, regurgitation or both in the absence of visible esophageal injury upon endoscopy<sup>[1-3]</sup>. Patients with NERD are more likely to be female, young, thin, and without hiatal hernias<sup>[4-6]</sup>, and over time, the regurgitation of gastric juice associated with NERD can have significant and comparable negative effects on their quality of life that correlate with heartburn severity<sup>[7-9]</sup>. To improve these patients' quality of life, provide a rapid relief of symptoms and reduce the severity and number of recurrent episodes<sup>[10-12]</sup>, acid-suppressive drugs have been used to combat NERD.

Proton pump inhibitors (PPI) are a type of acid-suppressive drugs that inhibit the secretion of gastric acid by restraining the exchange of  $H^+-K^+$ <sup>[13,14]</sup>. Due to their powerful inhibition of the secretion of gastric acid, PPIs have been widely used to treat gastroesophageal diseases that result from too much acid, including gastroesophageal reflux disease, gastritis and gastric and duodenal ulcers<sup>[15-18]</sup>. However, the efficacy, safety and influential factors of PPI use remain inconclusive, especially for NERD<sup>[19,20]</sup>.

Although two papers<sup>[21,22]</sup> have previously discussed the efficacy and influential factors of PPI use against NERD, neither paper used randomized controlled trials (RCTs) as the source of their data or used  $H_2$  receptor antagonists ( $H_2RA$ ) or placebos as control groups. Meanwhile, the clinical safety of PPIs was not addressed by the authors of these two papers. In view of the importance of understanding their clinical implications, we determined that the quality of the previous two papers was insufficient and performed the present meta-analysis.

## MATERIALS AND METHODS

### Search strategy

We conducted a computer-aided search for RCTs which probed into the efficacy, safety and influential factors of PPI for NERD. Source databases were PubMed (1966 to April 2013), the Cochrane Library (1997 to April 2013), MEDLINE (1966 to April 2013) and EMBASE (1985 to April 2013). The medical subject headings which were used in retrieving citation were: non-erosive reflux disease or NERD, proton pump inhibitors or PPI or esomeprazole or pantoprazole or omeprazole or rabeprazole or lansoprazole. We also searched the references in retrieved articles manually in order to prevent missing relevant

publications.

### Study selection

The titles and abstracts were independently screened by two reviewers (Zhang JX and Song J), and studies were chosen for the meta-analysis if they fit the following criteria: (1) randomized controlled trials; (2) comparing PPI with other acid-suppressive drugs or placebo; and (3) probing into the efficacy, safety and influential factors of PPI on the symptomatic relief of NERD. We did not consider the restriction on language of publication. Exclusion criteria were: (1) no human subjects in the study; (2) without control group; (3) comparing a PPI with another one; (4) incomplete outcome data; (5) selective reporting; and (6) duplicate publication.

### Data extraction and quality assessment

Independently, three reviewers (Qiu S, Ai MH and Wang J) extracted data including the following items: first author, year of publication, country, type of publication, study duration, age, gender, medication duration, drug dose, follow-up time, methods of treatment, *H. pylori* infection and primary outcomes. Based on the adequate sequence generation, allocation concealment, blinding, incomplete outcome data addressed, free of selective reporting, free from baseline imbalance, sample size calculation and free from sources of funding bias, the risk of bias was evaluated in detail. Each quality component was judged as high, unclear, or low. On the basis of each separate component, the quality of the trials was assessed. When difference appeared, a forth reviewer (Lei HB) joined in the discussion.

### Statistical analysis

We treated the rates of symptomatic relief of PPI *vs* placebo and PPI *vs*  $H_2RA$  as the primary endpoints and the rates of adverse events as the secondary endpoints. Meanwhile, factors influencing rates of symptomatic relief and adverse events of PPI against NERD were analyzed. The RRs, to summary statistics in meta-analysis, were strongly recommended for dichotomous data. So we used Stata12.0 to calculate RR for the rates of symptomatic relief and the rates of adverse events in this meta-analysis. When the *P* value was less than 0.05, it was considered significant. The data was pooled according to the Mantel-Haenszel fixed-effects model and the DerSimonian and Laird random-effects model. The differences were shown as pooled RRs and 95%CI between different groups. The statistical heterogeneity among trials was assessed by the  $\chi^2$  test and  $I^2$  test. The percentage of the variability in the estimates of effect, caused by heterogeneity but not chance, was described by  $I^2$  test. When the values were greater than 50%, it was considered having substantial heterogeneity. If there was no statistically significant heterogeneity, the fixed-effects model was chosen. According to the drug dose and therapeutic duration, subgroup analysis was performed.

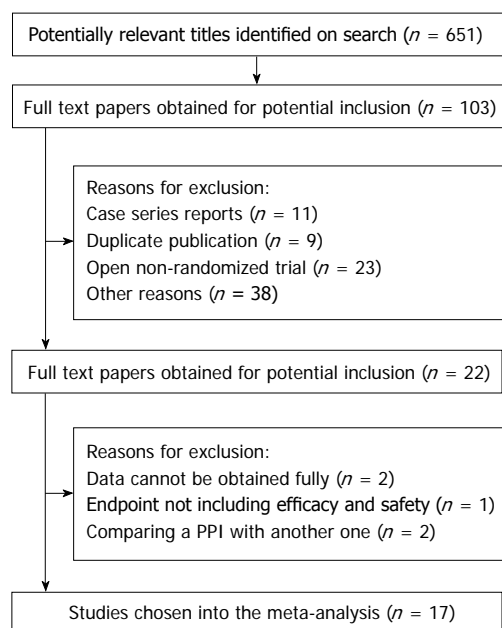

Figure 1 Screening process of studies. PPI: Proton pump inhibitor.

### Risk of bias and publication bias

We assessed the risks of bias according to assessment of study quality in Cochrane Handbook 4.2.2. Egger's test and Begg's test were used to check the publication bias, and  $P < 0.05$  indicated that there was a risk of bias.

### Sensitivity analysis

Sensitivity analysis was performed to identify the studies which influence the result obviously.

### Meta-regression analysis

Meta-regression analysis was performed to study the relationship between covariates and the outcomes and to find the source of heterogeneity.

### Assessment of quality evidence

Grade system was applied to assess the quality of these outcomes.

## RESULTS

### Study identification and selection

Following the searching strategy, we initially acquired 651 studies. Having discarded the studies of repetitive publication and that did not meet the criteria apparently, and after reading the titles and abstracts, there were 51 studies left. To search and read the full text, 34 studies which were not RCTs or without control groups were abandoned and 17 RCTs<sup>[23-39]</sup> were left finally. The screening process of studies is shown in Figure 1.

### Study characteristics

For the 17 RCTs, 5 were single-center studies and 12 were multi-center studies. In the RCTs, there were 6072 patients with 3937 patients in the combination group and

the 2135 patients in PPI alone group. The details of these studies are listed in Table 1.

### PPI vs H<sub>2</sub>RA on the rate of symptomatic relief

Seven studies<sup>[24,26,29,30,32,34,39]</sup>, which involved 1882 patients, compared PPI with H<sub>2</sub>RA on the rate of symptomatic relief of NERD. There are 935 patients who received PPI and 947 patients who received H<sub>2</sub>RA. Heterogeneity analysis showed that there was obviously statistical heterogeneity among these studies ( $I^2 = 42.4\%$ ,  $P = 0.096$ ). Sensitivity analysis indicated that one study<sup>[32]</sup> influenced the result apparently, and after excluding this study, the heterogeneity disappeared ( $I^2 = 0.1\%$ ,  $P = 0.422$ ). The result showed that PPI was significantly superior to H<sub>2</sub>RA on the rate of symptomatic relief of NERD (RR = 1.629, 95%CI: 1.422-1.867,  $P = 0.000$ ), (Figure 2A).

In the subgroup analysis of short duration (PPI 158/372, placebo 112/384,  $I^2 = 0\%$ ,  $P = 0.640$ ), PPI advanced over H<sub>2</sub>RA (RR = 1.521, 95%CI: 1.303-1.775,  $P = 0.000$ ). In the subgroup analysis of long duration (PPI 90/186, placebo 43/184,  $I^2 = 0\%$ ,  $P = 0.737$ ), similar result was found (RR = 2.063, 95%CI: 1.544-2.756,  $P = 0.000$ ).

In the subgroup analysis of low dose (PPI 130/308, placebo 78/307,  $I^2 = 0\%$ ,  $P = 0.422$ ), PPI significantly overmatched H<sub>2</sub>RA (RR = 1.656, 95%CI: 1.320-2.078,  $P = 0.000$ ). In the subgroup analysis of high dose (PPI 220/526, placebo 141/537,  $I^2 = 23.5\%$ ,  $P = 0.365$ ), PPI was also superior to H<sub>2</sub>RA (RR = 1.614, 95%CI: 1.361-1.914,  $P = 0.000$ ).

In the subgroup analysis of lansoprazole (PPI 227/585, placebo 141/584,  $I^2 = 0\%$ ,  $P = 0.603$ ), PPI advanced over H<sub>2</sub>RA (RR = 1.866, 95%CI: 1.435-2.448,  $P = 0.000$ ). But compared with groups of omeprazole (PPI 41/67, placebo 31/64,  $I^2 = 0\%$ ,  $P = 0.434$ ), there were no statistical differences ( $P = 0.149$ ).

### PPI vs placebo on the rate of symptomatic relief

There were 11 studies<sup>[23,25,27,28,31,33-38]</sup> which compared PPI with placebo on the rate of symptomatic relief of NERD. In the 5416 patients of the 11 trials, there are 3287 patients who received PPI and 2129 patients received placebo. Heterogeneity analysis showed that there was obviously statistical heterogeneity among these studies ( $I^2 = 84.3\%$ ,  $P = 0.000$ ). Sensitivity analysis did not find studies that influenced the result obviously. The result showed that PPI was significantly superior to placebo on the rate of symptomatic relief of NERD (RR = 1.903, 95%CI: 1.573-2.302,  $P = 0.000$ ), (Figure 2B).

In the subgroup analysis of long duration (PPI 407/855, placebo 114/315,  $I^2 = 65.4\%$ ,  $P = 0.034$ ), PPI advanced over placebo (RR = 1.442, 95%CI: 1.034-2.010,  $P = 0.031$ ). In short duration (PPI 1139/2432, placebo 459/1241,  $I^2 = 78.6\%$ ,  $P = 0.000$ ), similar result was also found (RR = 2.029, 95%CI: 1.665-2.473,  $P = 0.000$ ).

In the subgroup analysis of high dose (PPI 486/1098, placebo 131/718,  $I^2 = 0\%$ ,  $P = 0.506$ ), PPI significantly overmatched placebo (RR = 2.664, 95%CI: 2.251-3.154,

**D** Study**E** Study

**Figure 2 Forest plot.** A: Comparison of proton pump inhibitor (PPI) vs H<sub>2</sub> receptor antagonists (H<sub>2</sub>RA) on the rate of symptomatic relief; B: Comparison of PPI vs placebo on the rate of symptomatic relief; C: Comparison of PPI vs H<sub>2</sub>RA on the rate of adverse events; D: Comparison of PPI vs placebo on the rate of adverse events; E: Overall efficacy of PPI against non-erosive reflux disease (NERD); F: Adverse rate of PPI against NERD.

$P = 0.000$ ). In low dose (PPI 1060/2189, placebo 442/1411,  $I^2 = 75.1\%$ ,  $P = 0.000$ ), PPI was significantly superior to placebo (RR = 1.726; 95%CI: 1.451-2.054,  $P = 0.000$ ).

In the subgroup analysis of lansoprazole (PPI 505/1136, placebo 128/714,  $I^2 = 0\%$ ,  $P = 0.879$ ), pantoprazole (PPI 252/649, placebo 88/320,  $I^2 = 0\%$ ,  $P = 0.844$ ), omeprazole (PPI 427/874, placebo 210/680,  $I^2 = 81.4\%$ ,  $P = 0.000$ ) and rabeprazole (PPI 317/478, placebo 130/336,  $I^2 = 81.3\%$ ,  $P = 0.001$ ), PPI advanced over placebo ( $P = 0.000$ ).

#### PPI vs H<sub>2</sub>RA on the rate of adverse events

Three studies<sup>[24,32,39]</sup>, which involved 565 patients, compared PPI with H<sub>2</sub>RA on the rate of adverse events of NERD. There were 287 patients who received PPI and 278 patients who received H<sub>2</sub>RA. Because there was no obviously statistical heterogeneity among these studies ( $I^2 = 25.1\%$ ,  $P = 0.263$ ), fixed-effects model was chosen to perform the meta-analysis. The result showed that there was no significantly difference between PPI and H<sub>2</sub>RA on the rate of adverse events of NERD (RR = 0.928; 95%CI: 0.776-1.110,  $P = 0.414$ , Figure 2C).

#### PPI vs placebo on the rate of adverse events

There were eight studies<sup>[23,25,27,28,31,36]</sup> which compared PPI

with placebo on the rate of adverse events of NERD. Among the 4150 patients, 2494 patients received PPI and 1656 patients received placebo. Because there was no obviously statistical heterogeneity among these studies ( $I^2 = 27.9\%$ ,  $P = 0.156$ ), fixed-effects model was chosen to perform the meta-analysis. The result showed that there was no significant difference between PPI and placebo on the rate of adverse events of NERD (RR = 1.000; 95%CI: 0.896-1.116,  $P = 0.997$ ), (Figure 2D).

In the subgroup analysis of long duration (PPI 184/892, placebo 72/360,  $I^2 = 8.5\%$ ,  $P = 0.364$ ), there was no significant difference between PPI and placebo (RR = 0.921, 95%CI: 0.812-1.046,  $P = 0.206$ ). In short duration (PPI 346/1602, placebo 332/1296,  $I^2 = 0\%$ ,  $P = 0.565$ ), PPI was significantly superior to placebo (RR = 1.290, 95%CI: 1.032-1.613,  $P = 0.025$ ).

In the subgroup analysis of high dose (PPI 316/1661, placebo 252/1068,  $I^2 = 45.6\%$ ,  $P = 0.075$ ), there was no obvious difference between PPI and placebo (RR = 0.999, 95%CI: 0.868-1.150,  $P = 0.988$ ). In low dose (PPI 214/833, placebo 152/588,  $I^2 = 2.9\%$ ,  $P = 0.398$ ), no significant difference was found either (OR = 1.002, 95%CI: 0.841-1.195,  $P = 0.979$ ).

In the subgroup analysis of lansoprazole (PPI 308/962, placebo 233/719,  $I^2 = 75.4\%$ ,  $P = 0.017$ ), pantoprazole (PPI 80/668, placebo 68/224,  $I^2 = 0\%$ ,  $P =$

**Table 2 Results of univariate meta-regression analysis exploring factors influencing efficacy and adverse rate of proton pump inhibitor for non-erosive reflux disease**

0.981), omeprazole (PPI 51/593, placebo 48/398,  $I^2 = 23.5\%$ ,  $P = 0.270$ ) and rabeprazole (PPI 31/131, placebo 34/136,  $I^2 = 0\%$ ,  $P = 0.732$ ), the significant difference was also not found ( $P > 0.05$ ).

#### Overall efficacy of PPI against NERD and its influential factors

All the 17 studies<sup>[23-39]</sup> provided the data of the efficacy of PPI against NERD and its influential factors. Heterogeneity analysis showed that there was obviously statistical heterogeneity among these studies ( $I^2 = 96.8\%$ ,  $P = 0.000$ ). The result showed that the overall rate of symptomatic relief of PPI against NERD was 51.4% (95%CI: 0.433-0.595,  $P = 0.000$ ), (Figure 2E).

In the subgroup analysis of long duration, the effective rate of PPI against NERD was 51.4% (95%CI: 0.433-0.595,  $P = 0.000$ ). In short duration, the rate was 51.5% (95%CI: 0.432-0.598,  $P = 0.000$ ).

In the subgroup analysis of high dose, the effective rate of PPI against NERD was 48.4% (95%CI: 0.404-0.564,  $P = 0.000$ ). In low dose, the rate was 56.3% (95%CI: 0.395-0.732,  $P = 0.000$ ).

In the subgroup analysis of lansoprazole, the effective rate of PPI against NERD was 52.1% (95%CI: 0.392-0.650,  $P = 0.000$ ). In that of pantoprazole, omeprazole and rabeprazole, the effective rate were 44.7% (95%CI: 0.369-0.526,  $P = 0.000$ ), 52.1% (95%CI: 0.355-0.688,  $P = 0.000$ ) and 60.8% (95%CI: 0.367-0.849,  $P = 0.000$ ), respectively.

Univariate meta-regression analysis found that the rate of hiatal hernia ( $P = 0.030$ ) was associated with the rate of symptomatic relief of PPI against NERD, but not with others.

#### Overall safety of PPI against NERD and its influential factors

Twelve studies<sup>[23-25,27,28,31,32,34,37-39]</sup> provided the data of the rate of adverse events of PPI against NERD and its influential factors. Heterogeneity analysis showed that there

was obviously statistical heterogeneity among these studies ( $I^2 = 97.5\%$ ,  $P = 0.000$ ). Sensitivity analysis indicated that no study influenced the result apparently. The result showed that the adverse rate of PPI against NERD was 21.0% (95%CI: 0.152-0.208,  $P = 0.000$ ), (Figure 2F).

In the subgroup analysis of long duration, the adverse rate of PPI against NERD was 18.0% (95%CI: 0.094-0.265,  $P = 0.000$ ). In short duration, the rate was 23.3% (95%CI: 0.145-0.322,  $P = 0.000$ ).

In the subgroup analysis of high dose, the adverse rate of PPI against NERD was 21.1% (95%CI: 0.152-0.268,  $P = 0.000$ ). In low dose, the rate was 20.8% (95%CI: 0.100-0.317,  $P = 0.000$ ).

In the subgroup analysis of lansoprazole, the adverse rate of PPI against NERD was 21.5% (95%CI: 0.121-0.309,  $P = 0.000$ ). In that of pantoprazole, omeprazole and rabeprazole, the effective rate respectively were 26.2% (95%CI: 0.150-0.375,  $P = 0.000$ ), 9.8% (95%CI: 0.036-0.161,  $P = 0.002$ ) and 29.5% (95%CI: 0.165-0.426,  $P = 0.000$ ).

Univariate meta-regression analysis found that the rate of hiatal hernia ( $P = 0.081$ ) and drinking ( $P = 0.053$ ) were associated with the rate of adverse events of PPI against NERD, but not with the other factors (Table 2).

#### Sensitivity analysis

In the analysis of PPI *vs* H<sub>2</sub>RA on the rate of symptomatic relief, sensitivity analysis indicated that one study<sup>[32]</sup> influenced the result apparently, and after excluding the this study, the heterogeneity disappeared ( $I^2 = 0.1\%$ ,  $P = 0.422$ ). And in other analysis, there was no study which influenced the results.

#### Risk of bias and publication bias

Three studies<sup>[26,28,32]</sup> performed adequate sequence generation with the others unclear. No study carried out allocation concealment. Two studies<sup>[24,26]</sup> were open-label trials without blinding of participants and personnel and 11 studies<sup>[23,25,27,28,31-36,39]</sup> mentioned blinding of participants and personnel. All the studies had complete data, without selective reporting and other bias. According to the Egger's test and Begg's test, we did not find obvious publication bias in the outcome of PPI *vs* H<sub>2</sub>RA on the rate of symptomatic relief (Egger's test:  $P = 0.711$  and Begg's test:  $P = 0.646$ ), PPI *vs* H<sub>2</sub>RA on the rate of adverse events (Egger's test:  $P = 1.000$  and Begg's test:  $P = 0.374$ ) and PPI *vs* placebo on the rate of adverse events (Egger's test:  $P = 0.125$  and Begg's test:  $P = 0.552$ ). But in the outcome of PPI *vs* placebo on the rate of symptomatic relief, the potential publication bias may exist (Egger's test:  $P = 0.010$  and Begg's test:  $P = 0.013$ ). A language bias, inflated estimates by a flawed methodologic design in smaller studies, and/or a lack of publication of small trials with opposite results may be the causes.

#### Quality of evidence

Following the classification of the Grading of Recommendations Assessment, Development and Evaluation,

**Table 3** Quality of outcomes according to Grade system

Outcome	Study design	Risk of bias	Inconsistency	Indirectness	Imprecision	Publication bias	Quality of evidence
PPI vs H <sub>2</sub> RA on the rate of symptomatic relief	RCT	Serious <sup>1</sup>	No	No	No	Serious <sup>4</sup>	Low
Long-duration subgroup	RCT	Serious <sup>2</sup>	No	No	No	Serious <sup>4</sup>	Low
Short-duration subgroup	RCT	Serious <sup>2</sup>	No	No	No	Serious <sup>4</sup>	Low

<sup>1</sup>Allocation concealment and blind method were not offered which resulted in very serious bias; <sup>2</sup>Allocation concealment and blind method were not offered which resulted in very serious bias mild bias; <sup>3</sup>The assessing standard of outcomes maybe contribute to the heterogeneity; <sup>4</sup>Publication bias may be existed. RCT: Randomized controlled trials; NERD: Non-erosive reflux disease; PPI: Proton pump inhibitor; H<sub>2</sub>RA: H<sub>2</sub> receptor antagonists.

the quality of evidences and their causes are shown in Table 3.

## DISCUSSION

PPIs have been widely used to treat NERD, but their efficacy, safety and influential factors are unclear. Our meta-analysis, including 17 well-designed randomized controlled trials, 12 of which were multi-center and 5 of which were single-center, had systematically and comprehensively evaluated the evidence concerning the efficacy, safety and influential factors of PPIs against NERD.

The first major finding revealed by this comprehensive approach was that the activity of PPIs is obviously superior to that of H<sub>2</sub>RA in its efficacy and safety against NERD. Because heartburn, the main symptom of patients with NERD, results from erosion due to gastric acid reflux into the esophagus, acid-suppressive drugs, including PPI and H<sub>2</sub>RA, have been deemed effective treatments for NERD<sup>[40,41]</sup>. After a meal, gastrin secretion stimulates the release of histamine by enterochromaffin-like cells, which binds to histamine H<sub>2</sub> receptors, leading to acid release via the hydrogen potassium ATPase (H<sup>+</sup>-K<sup>+</sup>-ATPase) pump<sup>[42]</sup>. Compared to the mechanism of H<sub>2</sub>RA, which acts against one of the three histamine-H<sub>2</sub>

receptors, PPI acts against the H<sup>+</sup>-K<sup>+</sup>-ATPase<sup>[43]</sup>. To control for the influences of different dose and therapeutic duration, we performed a subgroup analysis. This analysis showed that PPI treatment against NERD was superior to H<sub>2</sub>RA and placebo regardless of the dose or duration. However, only after short durations was PPI treatment safer than placebo.

The second major finding of this meta-analysis was that the overall rate of symptomatic relief of PPI against NERD was 51.4%; this value was influenced by the presence of a hiatal hernia. Compared with the approximate 50% symptomatic relief rate of PPI against ERD<sup>[44,45]</sup>, the 51.4% rate of PPI against NERD is fairly high. PPIs with a high dose, long duration and from a new generation should be more effective than those with a low dose, short duration and from an older generation; however, according to our subgroup analysis, there were no obvious differences among different doses, durations and PPI types. PPI enacts its role by binding to the binding sites of the saturable enzyme H<sup>+</sup>-K<sup>+</sup>-ATPase; therefore, an excessively high blood concentration of PPI is not only unable to increase but even decreases the acid suppression effect of the enzyme. Univariate meta-regression analysis found that the rate of hiatal hernia was associated with the rate of the symptomatic relief of PPI use

against NERD. One role of the gastroesophageal junction is to minimize gastroesophageal reflux; hiatal hernias, which are protrusions (or herniations) of the upper part of the stomach into the thorax through a tear or weakness in the diaphragm, can cause reflux and reduce the clear effects of the esophagus<sup>[46]</sup>. Due to their effects on gastroesophageal reflux and the normal function of the esophagus, the presence of hiatal hernias may influence the symptomatic relief rate of PPIs against NERD.

The third major finding of this meta-analysis was that the adverse rate of PPI treatment against NERD was 21.0%; this value was affected by hiatal hernia and drinking. PPI use was not, however, without shortcomings. Primary adverse events, typically in the order of 1%-5%, included headache, diarrhea, constipation, nausea, and rash<sup>[47]</sup>. Long-term PPI use was able to cause diminished acid secretion and reduced somatostatin release, resulting in enterochromaffin-like cell hyperplasia and hypergastrinemia<sup>[48,49]</sup>. As indicated by univariate meta-regression analysis, the adverse rate of PPI use for NERD was influenced by hiatal hernia and drinking. The mechanism through which hiatal hernia influences the adverse rate of PPI for NERD is uncertain, but the reason might be that hiatal hernias cause reflux, stimulating the nausea-inducing receptors in the esophageal and throat, as well as other adverse events. In addition, the metabolism of PPI generates two different CYP isoforms in the liver, which are responsible for the majority of their biotransformation due to their susceptibility to ethyl alcohol (CYP2C19 and CYP3A4)<sup>[50-52]</sup>. Thus, as drinking increases the blood concentration of ethyl alcohol, adverse events due to the reduced biotransformation of CYP2C19 and CYP3A4 and an increased blood concentration of PPI may arise.

There are a few shortcomings in our meta-analysis that should be mentioned. First, the analytical results are influenced by the reviewers, although we attempted to overcome this drawback. Second, a few differences may exist due to the various assessments of the efficacy and safety of PPI against NERD. Third, the evaluation index resulted from subjective feelings, which may influence the authenticity of these studies.

In conclusion, our meta-analysis showed that PPI is more effective than H<sub>2</sub>RA or placebo for the treatment of NERD. However, there was no significant difference between the safeties of PPI and H<sub>2</sub>RA or placebo. In addition, the effective rate of PPI for NERD was associated with hiatal hernia, while the adverse rate was associated with hiatal hernia and drinking. In the clinic, it is necessary to choose a PPI with a suitable dose, therapeutic duration and type for different NERD patients. More multi-center, high-quality randomized controlled trials with larger samples and longer term of follow-up visits are desirable.

## COMMENTS

### Background

Patients with non-erosive reflux disease (NERD) suffer from heartburn due to gastric acid in the reflux content. Acid-suppressive drugs, especially proton

pump inhibitor (PPI), have been used widely to manage NERD.

### Research frontiers

Though PPI has been used for patients with NERD for years, however, sufficient and convictive evidences concerning its efficacy and safety are lacking and whether its efficacy and safety are influenced by other factors remains unclear.

### Innovations and breakthroughs

The meta-analysis and systematic review was conducted according to Cochrane Handbook. The rates of symptomatic relief of PPI vs placebo and PPI vs H<sub>2</sub> receptor antagonists (H<sub>2</sub>RA) were treated as the primary endpoint and the rates of adverse events as the secondary endpoint. Meanwhile, factors influencing rates of symptomatic relief and adverse events of PPI against NERD are analyzed.

### Applications

This meta-analysis indicated that PPI overmatched H<sub>2</sub>RA on symptomatic relief rate but not on adverse rate for NERD. The rate of symptomatic relief of PPI against NERD was influenced by hiatal hernia and the adverse rate was affected by hiatal hernia and drinking.

### Peer review

This is a well written, sufficiently interesting original article in which the authors reviewed the efficacy, safety and their influential factors of PPI against NERD.

### Abstract

**AIM:** To assess systematically the safety and efficacy of bile leakage test in liver resection.

**METHODS :** Randomized controlled trials and controlled clinical trials involving the bile leakage test were included in a systematic literature search. Two authors independently assessed the studies for inclusion and extracted the data. A meta-analysis was conducted to estimate postoperative bile leakage, intraoperative positive bile leakage, and complications. We used either the fixed-effects or random-effects model.

**RESULTS:** Eight studies involving a total of 1253 patients were included and they all involved the bile leakage test in liver resection. The bile leakage test group was associated with a significant reduction in bile leakage compared with the non-bile leakage test group (RR = 0.39, 95%CI: 0.23-0.67;  $I^2 = 3\%$ ). The white test had superiority for detection of intraoperative bile leakage compared with the saline solution test (RR =

2.38, 95%CI: 1.24-4.56,  $P = 0.009$ ). No significant intergroup differences were observed in total number of complications, ileus, liver failure, intraperitoneal hemorrhage, pulmonary disorder, abdominal infection, and wound infection.

**CONCLUSION:** The bile leakage test reduced postoperative bile leakage and did not increase incidence of complications. Fat emulsion is the best choice of solution for the test.

**Key words:** Bile leakage test; Bile leakage; Liver resection; Postoperative complications; Meta-analysis

**Core tip:** Bile leakage is a common complication after hepatic resection and seriously affects postoperative quality of life. The bile leakage test was introduced to prevent bile leakage after liver resection. Many studies have evaluated the feasibility, safety and efficacy of the bile leakage test, however, the clinical significance of this technique remains inconsistent. We conducted a systematic review and showed that the bile leakage test reduced the incidence of postoperative bile leakage and did not increase the incidence of complications. In addition, fat emulsion may be the best choice of solution for the bile leakage test.

### INTRODUCTION

With the refinement of surgical techniques and periop-

erative care in liver surgery, the postoperative morbidity and mortality have markedly decreased. However, the incidence of bile leakage has not changed over the past few decades, ranging from 4.0% to 9.8% in recent studies<sup>[1-7]</sup>. Biliary complications remain a common cause of major morbidity after hepatic resection<sup>[1]</sup>. The presence of bile in the peritoneal cavity may impair the normal host defense mechanisms and predispose to the development of sepsis, liver failure and mortality<sup>[2,3]</sup>. Therefore, many methods have been introduced to prevent bile leakage after liver transection, including intraoperative cholangiography<sup>[8]</sup>, spreading fibrin glue on the transected liver surface<sup>[9]</sup>, assessing bile duct patency by injecting air under ultrasonographic monitoring<sup>[10]</sup>, and the bile leakage test. The latter is a common approach to reduce postoperative bile leakage<sup>[11]</sup>. With this technique, after cholecystectomy and liver parenchymatous division, a catheter is inserted through the cystic duct into the common bile duct and the distal common bile duct is occluded. A solution, such as isotonic sodium, fat emulsion, indocyanine green or methylene blue, is slowly injected into the biliary tree and a clinical judgment is then made as to whether a bile leak is present on the transected surface of the liver. If so, the bile leakage site will be closed steadily beforehand<sup>[11]</sup>. Using this technique, some studies<sup>[2,11-14]</sup> have identified intraoperatively additional potential bile leakage points in 19.7%-80.8% of the patients. The bile leakage test proved to be useful for preventing postoperative bile leakage in several studies, however, other studies suggested no advantage in using the bile leakage test. Moreover, the additional operation associated with the test may also result in a risk of postoperative complications. Some studies have suggested excessive bile duct pressure from the bile leakage test could cause cholangiovenous reflux and cholangitis<sup>[15,16]</sup>.

Many randomized controlled trials (RCTs) and controlled clinical trials have evaluated the feasibility, safety and efficacy of the bile leakage test, however, the clinical significance of this technique remains inconsistent. To date, we have been unable to identify any meta-analysis that assessed the role of the bile leakage test. We conducted a systematic review and meta-analysis to evaluate the safety and efficacy of the test in liver resection.

## MATERIALS AND METHODS

We conducted the meta-analysis and systematic review according to the Cochrane Handbook for Systematic Reviews of Interventions<sup>[17]</sup> and preferred reporting items for systematic reviews and meta-analysis<sup>[18]</sup>.

### Systematic literature search

A systematic literature search was independently conducted by two authors. We systematically searched the Cochrane Central Register of Controlled Trials, Embase, Science Citation Index (Web of Knowledge), PubMed and Chinese Biomedical Literature Database up to June 7, 2013. The search strategies were as follows: (biliary leakage OR bile leakage OR bile fistula OR biliary fistula

OR bile leakage test OR biliary complication) AND (hepatic resection OR hepatectomy (MeSH terms) OR liver resection). The literature search was performed with restriction in language to English or Chinese and RCTs or controlled clinical trials. After completing all searches, we merged the search results using Endnote X3 (reference management software) and removed duplicated records. Two independent authors scanned the title and abstract of every record identified by the searches for inclusion. If compliance with inclusion criteria was not clear from the abstract, we retrieved full texts for further assessment.

### Inclusion and exclusion criteria

**Types of studies:** RCTs and controlled clinical trials were considered for this review.

**Types of participants:** Patients who were about to undergo selective liver resection for any disease were included in our study, irrespective of age, sex, tumor size and nodule numbers. Trials in which patients required living donor liver transplantation were excluded. Trials in which patients required the bile leakage test without liver resection were excluded.

**Types of interventions:** We included trials comparing patients with and without the bile leakage test undergoing hepatectomy, or trials comparing bile leakage with different methods.

**Types of outcome measures:** Primary outcomes: postoperative bile leakage, and intraoperative positive bile leakage; secondary outcomes: operation time, blood loss, postoperative complications, postoperative hospital stay, and duration of drainage.

### Data collection and analysis

**Selection of studies:** Any disagreement during study selection and data extraction was resolved by discussion and referral to a third author for adjudication.

**Data extraction:** Two authors extracted data on a standard form that included population characteristics, intraoperative parameters, and information about the outcome measures in each trial. In the case of missing data, we contacted the original investigators to request further information.

**Quality assessment:** Two authors assessed the methodological quality of the trials independently. The Jadad score<sup>[19,20]</sup> was used to assess the quality of RCTs, with a cumulative score of  $> 3$  indicating high quality. The Newcastle-Ottawa scale<sup>[21,22]</sup> was used to assess the quality of non-randomized studies, with a score  $\geq 5$  indicating high quality.

### Statistical analysis

We pooled the synchronized extraction results as estimates of overall treatment effects in a meta-analysis

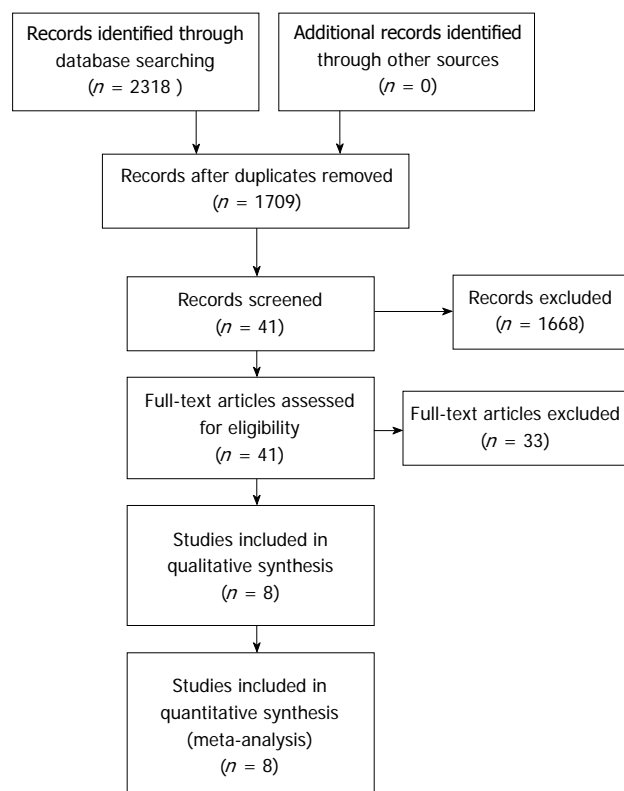

Figure 1 Flow diagram of the study selection process.

using Review Manager for Windows version 5.0. The estimated effect measures were RR for dichotomous data and weighted mean difference (WMD) for continuous data; both reported with 95%CI. We checked all results for clinical and statistical heterogeneity. Clinical heterogeneity was evaluated by assessing study populations and interventions, definition of outcome measures, concomitant treatment, and perioperative management. Heterogeneity was explored by  $\chi^2$  test with significance setting at  $P = 0.10$ , and  $I^2$  statistics were used for the evaluation of statistical heterogeneity ( $I^2 \geq 50\%$  indicating presence of heterogeneity)<sup>[23]</sup>. We used a fixed-effects model to synthesize data when heterogeneity was absent, otherwise a random-effects model was used for synthesizing data. Data are presented as forest plots and the funnel plot was used to assess publication bias.

## RESULTS

### Description of the included studies

A total of 2318 articles were retrieved through the search strategy. Eight studies<sup>[2,11-13,24-27]</sup> including 1253 patients matched the inclusion criteria (Figure 1). Details on the included studies are shown in Table 1. Five studies<sup>[2,11-13,24]</sup> compared patients with and without the bile leakage test, including 1032 patients (505 in the bile leakage test group and 527 in the control group). Two trials<sup>[25,27]</sup> compared a bile leakage test using indocyanine green solution with fluorescent imaging (ICGF Test)

Figure 2 Funnel plot of studies included in the meta-analysis of bile leakage test group vs non-bile leakage test group.

with a bile leakage test without fluorescent imaging (N-ICGF Test), including 161 patients (79 in the trial group and 82 in the control group). One study<sup>[26]</sup> compared a bile leakage test using fat emulsion (white test; injecting a fat emulsion solution through the cystic duct) with a test using saline solution, including 60 patients (30 in the white test group and 30 in the saline solution test group). These studies were published between 2000 and 2012. One trial<sup>[24]</sup> only enrolled liver donor patients and another<sup>[13]</sup> enrolled patients with tumor or hepatolithiasis; all remaining trials enrolled patients with a tumor. The quality assessment of RCTs and controlled clinical trials is displayed in Tables 2 and 3.

### Bile leakage test group vs non-bile leakage test group

**Bile leakage:** Information on postoperative bile leakage was available for all five trials<sup>[2,11-13,24]</sup>. Funnel plot (Figure 2) did not demonstrate strong asymmetry. Meta-analysis indicated that the bile leakage test group had less postoperative bile leakage than the non-bile leakage test group (Figure 3) (RR = 0.39, 95%CI: 0.23-0.67,  $P = 0.39$ ,  $I^2 = 3\%$ ). Clinical heterogeneity analysis found that one study<sup>[2]</sup> including a large sample of 616 patients was a retrospective study and the others were prospective. Meta-analysis of the other four trials also showed higher incidence of bile leakage in the non-bile leakage test group (RR = 0.32, 95%CI: 0.15-0.70,  $P = 0.29$ ,  $I^2 = 20\%$ ).

**Other complications:** Four trials<sup>[11-13,24]</sup> reported the incidence of total complications, however, only data from three trials<sup>[11-13]</sup> could be used for analysis, and one trial<sup>[24]</sup> did not provide sufficient information on complications. There was no significant difference in the incidence of total complications (RR = 0.84, 95%CI: 0.63-1.13,  $P = 0.37$ ,  $I^2 = 0\%$ ). No significant heterogeneity was observed. Other complications such as wound infection, ileus, liver insufficiency, intraperitoneal hemorrhage, pulmonary disorder, and hepatic failure were reported and analyzed. Wound infection (RR = 1.83, 95%CI: 0.58-5.78,  $P = 0.94$ ,  $I^2 = 0\%$ ), pulmonary disorder (RR = 1.03, 95%CI: 0.54-1.96,  $P = 0.87$ ,  $I^2 = 0\%$ ), and abdominal infection (RR = 1.47, 95%CI: 0.61-3.55,  $P = 0.56$ ,  $I^2 = 0\%$ ) were reported in three studies<sup>[11-13]</sup>

Table 2 Quality assessment of the included randomized controlled trials based on the Jadad scoring system

Study	Randomized	Appropriate randomization	Appropriately double blinded	Description of withdrawals	Jadad score	Study quality
Ijichi <i>et al</i> <sup>[11]</sup> , (2000)	Yes	Yes	No	Yes	3	High
Liu <i>et al</i> <sup>[13]</sup> , (2012)	Yes	Yes	No	Yes	3	High
Kaibori <i>et al</i> <sup>[25]</sup> , (2011)	Yes	No	No	Yes	2	Low

Table 3 Quality assessment of the included non-randomized controlled trials based on the Newcastle-Ottawa scale

Study	Selection star	Comparability star	Outcome star	Total star	Study quality
Li <i>et al</i> <sup>[12]</sup> , (2009)	4	2	3	9	High
Suehiro <i>et al</i> <sup>[24]</sup> , (2005)	3	2	3	8	High
Lam <i>et al</i> <sup>[21]</sup> , (2001)	3	1	3	7	High
Leelawat <i>et al</i> <sup>[26]</sup> , (2012)	4	2	3	9	High
Sakaguchi <i>et al</i> <sup>[27]</sup> , (2010)	3	1	3	7	High

and no significant difference was observed between the bile leakage test group and non-bile leakage test group. Two studies<sup>[11,12]</sup> reported ileus (RR = 1.86, 95%CI: 0.24-14.24,  $P = 0.68$ ,  $I^2 = 0\%$ ) and liver insufficiency (RR = 1.18, 95%CI: 0.17-8.29,  $P = 0.21$ ,  $I^2 = 37\%$ ), and no significant difference was observed between the bile leakage test group and non-bile leakage test group. Intraperitoneal hemorrhage was reported in two

studies<sup>[11,13]</sup> and there was no significant difference between the bile leakage test group and non-bile leakage test group (RR = 1.01, 95%CI: 0.18-5.71,  $P = 0.37$ ,  $I^2 = 0\%$ ). Two trials<sup>[12,13]</sup> reported liver failure, and meta-analysis showed that there was no significant difference between the bile leakage test group and non-bile leakage test group (RR = 1.47, 95%CI: 0.41-5.29,  $P = 0.76$ ,  $I^2 = 0\%$ ).

ENBD: Endoscopic nasobiliary drainage.

### ICGF test vs N-ICGF test

**Bile leakage:** Both of the studies<sup>[25,27]</sup> provided data on postoperative bile leakage. Meta-analysis of the two studies revealed that there was no significant difference between the ICGF test group and N-ICGF test group (RR = 0.13, 95%CI: 0.02-1.00,  $P = 0.64$ ,  $I^2 = 0\%$ ).

**Other complications:** There was no significant difference in total complications (RR = 0.48, 95%CI: 0.21-1.07;  $P = 0.21$ ,  $I^2 = 36\%$ ) between the ICGF test group and N-ICGF test group<sup>[25,27]</sup>, nor in pleural effusion (RR = 1.78, 95%CI: 0.49-6.44,  $P = 0.73$ ,  $I^2 = 0\%$ ) or wound infection (RR = 0.42, 95%CI: 0.09-2.09,  $P = 0.71$ ,  $I^2 = 0\%$ ).

### White test vs saline solution test

Only one self-controlled study<sup>[26]</sup> compared the white test with the saline solution test. Only data on intraoperative bile leakage were provided and meta-analysis revealed that the white test had a higher rate of bile leakage points (RR = 2.38, 95%CI: 1.24-4.56,  $P = 0.009$ ).

**Other outcomes:** These studies did not provide enough data on operation time, blood loss, postoperative hospital stay, or duration of drainage for analysis. The bile leakage test showed intraoperative bile leakage points on the hepatic resection plane in an average of 39.3% patients (range, 19.7%-80.8%). The postoperative bile leakage rate was 0%-5.9% after suturing. Among the bile leakage patients, 25 (41.0%) were treated conservatively; 12 (19.8%) underwent puncture drainage; 11 (18.0%) underwent endoscopic nasobiliary drainage; and 13 (21.2%) required reoperation (Table 4).

## DISCUSSION

Bile leakage is a common complication after hepatic resection and seriously affects postoperative quality of life, and also causes intra-abdominal infection and liver failure<sup>[13]</sup>. During the operation, it is difficult for surgeons to identify bile leakage by traditional methods such as the gauze test. Technical diligence in liver resection is required intraoperatively to minimize bile leakage. The bile leakage test is considered to be an effective method to prevent intraoperative bile leakage. The aim of the

bile leakage test is to detect insufficiently closed stumps of bile ducts on the transected liver surface by elevating biliary pressure<sup>[24]</sup> and then the leakage site is sutured.

We conducted a systematic review and meta-analysis and eight trials including three aspects of the bile leakage test were included. In the bile leakage test group vs non-bile leakage test group, studies involving the bile leakage test drew different conclusions. Three studies<sup>[2,12,13]</sup> showed that the bile leakage test decreased postoperative bile leakage, whereas two studies<sup>[11,24]</sup> showed no significant difference. Our meta-analysis showed that the bile leakage test group had a lower incidence of bile leakage than the non-bile leakage test group. Moreover, there was no significant difference in complications between the two groups. This suggests an effective and safe method for prevention of postoperative bile leakage. In the ICGF test group, ICG was injected into the biliary duct and then bound with proteins in bile<sup>[28]</sup>. The ICG-bile mixture can evoke fluorescent images that are obtained using an infrared camera system. Bile leakage can be easily detected by the extra-biliary fluorescent signal<sup>[25,27]</sup>. Meta-analysis found no difference in bile leakage rate and postoperative complications. Only one self-controlled study<sup>[26]</sup> compared the white test with the saline solution test and only positive rate of the intraoperative bile leakage test could be used for analysis. Meta-analysis found that the white test was superior for the detection of bile leakage compared with the saline solution test. However, the limitations of the number of trials (only one) may have affected our results and interpretation. Therefore, our results showed that the bile leakage test reduced postoperative biliary leakage, and considering the solution used in the test, fat emulsion may be more effective than saline solution.

To perform the bile leakage test, incidental cholecystectomy and cystic duct exploration are always necessary. One meta-analysis<sup>[29]</sup> reported increased morbidity in patients undergoing incidental cholecystectomy. However, in our meta-analysis, total complications, wound infection, ileus, liver insufficiency, intraperitoneal hemorrhage, pulmonary disorder, and hepatic failure showed no significant difference. The detection of bile leakage depends on elevated pressure by injecting solution into the biliary tract, however, excessive bile duct pressure

could lead to regurgitation of bacteria and induce cholangitis and abdominal infection<sup>[15,16]</sup>. Although abdominal infection did occur in some trials, our meta-analysis showed that the bile leakage test did not increase the risk of abdominal infection. Therefore, the bile leakage test is a safe technique and does not cause additional complications.

In all the included studies, the bile leakage test detected leakage in an average of 39.3% patients (range, 19.7%-80.8%). After prophylactic closure of the leaking bile duct stump, bile leakage occurred in only an average of 3.42% of patients, which was significantly lower than before. This suggests that the bile leakage test can reduce bile leakage in liver resection, but it does not completely eliminate it. Several reasons could explain this. First, we need to consider the lack of refinement of surgical techniques. For example, the pressure on the bile duct was not high enough so that bile leakage was not observed during the operation. Inadequate suturing of the defect<sup>[2]</sup> also could lead to bile leakage. Second, minor bile ducts in the wound surface of the liver were obstructed by microliths, and the bile leakage was formed when the microliths dropped off after the operation<sup>[13]</sup>. Third, there were defects in the technique of the bile leakage test. Parts of the leaky bile ducts were not in communication with the biliary tree, therefore, the leakage sites could not be identified through the use of an intraoperative bile leakage test<sup>[13]</sup>. Moreover, solutions such as ICG and methylene blue have the drawback of staining surrounding tissues, and saline solution has poor sensitivity. These drawbacks make precise localization or identification of multiple sites of leakage difficult<sup>[12]</sup>. However, the white fat emulsion can be easily washed out from the bile ducts<sup>[26]</sup> and it does not contaminate the surface of the wound, and it can be used repeatedly in tests. This may be the reason why the white test can decrease bile leakage more than the saline solution test can.

However, some patients without the bile leakage test did not develop bile leakage, for the following reasons. First, partial minor leakage points can be closed spontaneously. Second, bile leakage from small biliary stumps with some communication to the main biliary tree would usually close spontaneously, with the restoration of peristalsis and papillary function<sup>[11]</sup>. Thus, the bile leakage test could not completely eliminate bile leakage, but just decrease it.

This review had some limitations. The first concerns the small number of RCTs included, and we also included non-randomized trials. Second, incomplete reporting of important methodological issues, such as randomization process and blinding assessment of trial quality, raises doubts about the adequate power of these studies. Third, the heterogeneity of the patients in the included trials may have influenced the conclusions because some trials included liver tumor patients and only one study included living donors. To overcome these limitations, more RCTs should be conducted with large numbers of patients to achieve a sufficient level of statistical power for accurate evaluation of the bile leakage test.

In conclusion, this review provides the best available evidence for the safety and efficacy of the bile leakage test. On the basis of this evidence, the bile leakage test appears to reduce the incidence of postoperative bile leakage and does not increase the incidence of other complications. In addition, fat emulsion may be the best choice of solution for use in the bile leakage test. Further trials are required to assess the role of the bile leakage test in liver resection patients.

## COMMENTS

### Background

Liver resection is an important treatment method for liver diseases, especially for liver cancer. Bile leakage is a common complication after hepatic resection and seriously affects patients' postoperative quality of life. Therefore, it is important to prevent bile leakage in liver resection. Many methods have been introduced to prevent bile leakage after liver transection and the bile leakage test is a common approach.

### Research frontiers

Several trials have evaluated the safety and efficacy of the bile leakage test; however, the results of this technique remain inconsistent. The authors conducted a systematic review and meta-analysis to evaluate the safety and efficacy of the bile leakage test in liver resection.

### Innovations and breakthroughs

The authors have provided the best available evidence for the safety and efficacy of the bile leakage test. This meta-analysis found that the bile leakage test lowered the incidence of postoperative bile leakage and could not increase the incidence of other complications. In addition, fat emulsion may be the best choice of solution for use in the bile leakage test.

### Applications

The study results suggest that the bile leakage test is an effective and safe method that could be used in preventing bile leakage after liver resection.

### Terminology

The bile leakage test is a common approach to reduce postoperative bile leakage. With this technique, after cholecystectomy and liver resection, a catheter is inserted through the cystic duct into the common bile duct and the distal common bile duct is occluded. Solution is slowly injected into the biliary tree and a clinical judgment is then made as to whether a bile leak is present on the transected surface of the liver. If so, the bile leak site will be closed steadily beforehand to avoid bile leakage.

### Peer review

The authors present a meta-analysis of the literature describing feasibility, safety and efficacy of a method to avoid complications after hepatic surgery, the so-called bile leakage test. The topic of the article is important for researchers and the literature analysis reported is interesting.

### Abstract

**AIM:** To establish the role of magnetic resonance cholangiography (MRC) in diagnosis of biliary anatomy in living-donor liver transplantation (LDLT) donors.

**METHODS:** A systematic review was performed by searching electronic bibliographic databases prior to March 2013. Studies with diagnostic results and fulfilled inclusion criteria were included. The methodological quality of the studies was assessed. Sensitivity, specificity and other measures of the accuracy of MRC for diagnosis of biliary anatomy in LDLT donors were summarized using a random-effects model or a fixed-effects model. Summary receiver operating characteristic (SROC) curves were used to summarize overall test performance. Publication bias was assessed using Deek's funnel plot asymmetry test. Sensitivity analysis was ad-

opted to explore the potential sources of heterogeneity.

**RESULTS:** Twelve studies involving 869 subjects were eligible to the analysis. The scores of Quality Assessment of Diagnostic Accuracy Studies for the included studies ranged from 11 to 14. The summary estimates of sensitivity, specificity, positive likelihood ratio, negative likelihood ratio, diagnostic OR of MRC in diagnosis of biliary anatomy in LDLT donor were 0.88 (95%CI: 0.84-0.92), 0.95 (95%CI: 0.93-0.97), 15.33 (95%CI: 10.70-21.95), 0.15 (95%CI: 0.11-0.20) and 130.77 (95%CI: 75.91-225.27), respectively. No significant heterogeneity was detected in all the above four measures. Area under SROC curve was 0.971. Little publication bias was noted across the studies ( $P = 0.557$ ). Sensitivity analysis excluding a study with possible heterogeneity got a similar overall result, which suggested the little influence of this study on the overall results.

**CONCLUSION:** Our results suggest that MRC is a high specificity but moderate sensitivity technique in diagnosis of biliary anatomy in LDLT donors.

**Key words:** Magnetic resonance imaging; Cholangiography; Biliary; Anatomy; Living donors

**Core tip:** The current findings on the value of magnetic resonance cholangiography (MRC) in diagnosis of biliary anatomy in living-donor liver transplantation (LDLT) donors are conflicting. This meta-analysis including 12 studies with 869 patients suggested that MRC has a high specificity in diagnosis of biliary anatomy in LDLT donors, but the sensitivity is moderate. This is the first meta-analysis to investigate the diagnostic accuracy of MRC in the detection of biliary anatomy in LDLT donors; and these results will provide valuable information to the doctors when they make a decision for the living liver donors.

Magnetic resonance cholangiography in assessing biliary anatomy in living donors: A meta-analysis. *World J Gastroenterol* 2013; 19(45): 8427-8434 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i45/8427.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i45.8427>

## INTRODUCTION

Adult living-donor liver transplantation (LDLT) is an alternative therapeutic option for patients with end-stage liver disease. Some transplantation centers have reported high rates of biliary complications following LDLT<sup>[1-3]</sup>. Biliary complications after LDLT are closely related to the complex anatomy of the donor's biliary tree. Therefore, preoperative knowledge of the donor's aberrant biliary anatomy can minimize postoperative morbidity in the recipient and maximize safety for the donor. Several techniques are currently being used in this setting; however, they all have some limitations. For example, endoscopic retrograde cholangiography (ERC) and intraoperative cholangiography (IOC) are both invasive techniques that can result in serious complications<sup>[4,5]</sup>, while the non-invasive multidetector computed tomography (MDCT) technique exposes the potential donor to ionizing radiation and the risks associated with nephrotoxic contrast agents<sup>[6]</sup>.

Magnetic resonance cholangiography (MRC) is a non-invasive imaging technique and has shown promise in the preoperative evaluation of the biliary anatomy of LDLT donors. Previously, two studies<sup>[7,8]</sup> reported meta-analyses on the value of MRC in the diagnosis of biliary complications after liver transplantation. However, neither evaluated the role of MRC in evaluating the biliary anatomy of LDLT donors. In addition, although some studies<sup>[9-12]</sup> reported a high diagnostic accuracy for MRC in the diagnosis of biliary anatomy, the sample sizes were small; thus, the results remained inconclusive. Given the importance of a preoperative evaluation of biliary anatomy and the uncertainty regarding the diagnostic accuracy of MRC, we performed a meta-analysis to determine the overall diagnostic accuracy of MRC in the evaluation of the biliary anatomy of LDLT donors.

## MATERIALS AND METHODS

### Search strategy and study selection

We systematically searched the Cochrane clinical trials database, MEDLINE/PubMed, and Embase to identify suitable studies prior to March 1, 2013. No starting date limit was applied. Articles were also identified using the related articles function in PubMed. References within the identified articles were also searched manually. The search terms included "magnetic resonance cholangiography" or "MRC," "biliary anatomy," and "donors."

The searches were limited to human studies. Potentially relevant articles were then screened by at least two independent reviewers. Disagreements were resolved by discussion or upon consensus from a third reviewer.

### Inclusion and exclusion criteria

A study was included in the meta-analysis when it provided data on both the sensitivity and specificity of MRC for the diagnosis of the biliary anatomy of living donors, or when it provided values in a scatterplot form, allowing test results for individual study subjects to be extracted. Studies were excluded if they were review articles, case reports, or animal studies. In order to obtain a more reliable estimation of the accuracy of MRC, we only included studies that fulfilled at least nine items of the Quality Assessment of Diagnostic Accuracy Studies (QUADAS) criteria. Two reviewers independently judged the eligibility of the studies. Disagreements between reviewers were resolved by consensus. The authors of some publications were contacted for clarifications and additional information.

### Data extraction and quality assessment

The final set of articles was assessed independently by two reviewers. The data retrieved included the authors, publication year, the country where the study was conducted, the number of patients and their mean age, the reference standard (gold standard), true-positive, false-negative, false-positive, and true-negative values, and the quality of the methodology. The methodological quality of the studies was assessed using QUADAS, an evidence-based quality assessment tool developed for use in systematic reviews of studies of diagnostic accuracy and fully described by Whiting *et al.*<sup>[13]</sup>, with a maximum score of 14.

### Statistical analysis

Standard methods recommended for the meta-analysis of diagnostic test evaluations were used<sup>[14]</sup>. The following measurements of test accuracy were computed for each study: sensitivity, specificity, positive likelihood ratio (PLR), negative likelihood ratio (NLR), and diagnostic odds ratio (DOR). The analysis was based on a summary receiver operating characteristic curve (SROC); the results are described as the area under the curve (AUC) of the SROC, with its Q-point representing the maximal joint sensitivity and specificity<sup>[15,16]</sup>. The summary sensitivity, specificity, and other measures across MRC studies were calculated using a random-effects model and a fixed-effects model, respectively. A  $\chi^2$  test and an inconsistency index ( $I^2$ ) were used to detect statistically significant heterogeneity across studies. Publication bias was assessed using Deeks' Funnel Plot Asymmetry Test<sup>[17]</sup>. Analyses were performed using Meta-DiSc version 1.4 (Unit of Clinical Biostatistics, the Ramón y Cajal Hospital, Madrid, Spain) and Stata 11.2 (Stata Corporation, College Station, TX, United States) software.

## RESULTS

### Study selection

The primary literature search retrieved 25 studies that were considered eligible for the analysis. After a detailed evaluation, 13 studies were excluded, as six were laboratory studies, three were reviews, three provided insufficient data for calculations<sup>[1,10,18]</sup>, and one was irrelevant to the current analysis. Consequently, 12 studies<sup>[9,11,12,19-27]</sup> involving 869 subjects were finally included in the present meta-analysis.

### Characteristics of the studies and quality assessment

All included studies adequately described the MRC techniques used and the types of conventional and aberrant biliary anatomy; however, the screening techniques were different across the studies. All but one study were using IOC as the reference standard. Additional patient demographics from each of the included studies are listed in Table 1. The QUADAS scores for the included studies ranged from 11 to 14 (Table 2).

### Meta-analysis

The overall analysis of the 12 studies showed that the summary sensitivity, specificity, PLR, NLR, and DOR were 0.88 (95%CI: 0.84-0.92), 0.95 (95%CI: 0.93-0.97), 15.33 (95%CI: 10.70-21.95), 0.15 (95%CI: 0.11-0.20), and 130.77 (95%CI: 75.91-225.27), respectively; no significant heterogeneity was detected in any of the above four measures (all  $P > 0.05$ ). The AUC of the SROC was 0.971, suggesting a high diagnostic accuracy (Figures 1 and 2). The moderate sensitivity indicates that 12% of the cases with aberrant biliary anatomy could be missed, and the high specificity indicates a small probability of the pres-

ence of aberrant biliary anatomy when the MRC diagnosis is normal. A PLR of 15.33 suggests that patients with aberrant biliary anatomy have about a 15-fold higher chance of a positive test than those without. An NLR of 0.15 suggests that if the MRC result is negative, the probability of the patient having aberrant biliary anatomy is 15%.

### Sensitivity analysis

Because one of the studies<sup>[27]</sup> used surgery as the reference, we excluded it from the sensitivity analysis. The results were similar to the overall results; the summary sensitivity, specificity, PLR, NLR, DOR, and AUC of the SROC were 0.88 (95%CI: 0.84-0.92), 0.96 (95%CI: 0.93-0.97), 15.41 (95%CI: 10.69-22.22), 0.148 (95%CI: 0.11-0.20), 132.19 (95%CI: 75.72-230.76), and 0.972, respectively, which suggested that the excluded study had little influence on the overall results.

### Publication bias

Deeks' Funnel Plot Asymmetry Test for the overall analysis showed that no significant publication bias was found ( $P = 0.557$ ; Figure 3).

## DISCUSSION

Generally, ERC, IOC, MRC, and MDCT cholangiography have been used to evaluate the biliary anatomy of liver donors. However, these techniques all have their inherent strengths and weaknesses. Although ERC is an accurate method to identify biliary anatomy, the high incidence of serious complications caused by the invasiveness of the procedure makes it excessively risky to perform on healthy donors. IOC is considered the gold standard for

the imaging of the biliary anatomy; however, because it does not allow a three-dimensional (3D) view, this technique may not be helpful in obtaining a single bile duct orifice in some cases with anatomical variations. MDCT or MDCT cholangiography are both non-invasive techniques, and they have shown promise in delineating biliary anatomy in potential right lobe living donors<sup>[26,29]</sup>. However, compared with MRC, the obvious disadvantages of CT are the exposure to ionizing radiation and nephrotoxic contrast agents; especially, the intravenous contrast agent iodipamide meglumine is associated with poor patient tolerance and adverse reactions<sup>[6]</sup>. Several studies showed that MRC has a strong correlation with IOC in delineating the intrahepatic biliary anatomy. In addition to biliary anatomy imaging, MRC is also able to assess other aspects of a potential donor's liver anatomy. It can perform an assessment of the vascular and biliary anatomy and provide an assessment of iron and fat depositions in the liver in a single examination<sup>[23]</sup>.

One of the obvious advantages of the MRC technique is the elimination of the need for an invasive procedure, thus considerably reducing the cost and associated complications. However, this technique also has limitations. For example, MRC is more limited in temporal and spatial resolution than direct digital subtraction angiography and IOC. In addition, the conventional MRC technique (half-Fourier acquisition) provides a depiction of the biliary anatomy with limited detail, especially of non-dilated ducts. However, recent progress in MRC techniques seems to have overcome some of these limitations. Mangafodipir trisodium-enhanced 3D T1-weighted MRC is reported to provide an increased signal-to-noise ratio and a greater visualization rate of the ductal anatomy compared with T2-weighted MRC or two-dimensional (2D) gradient-echo images<sup>[30,31]</sup>. Gadobenate dimeglumine-enhanced T1-weighted MRC can provide information about the differentiation of cystic structures near bile ducts and the bile duct lumen<sup>[12]</sup>. In addition, gadobenate dimeglumine is easier to use and less expensive than mangafodipir trisodium.

The present meta-analysis suggests that MRC has a high diagnostic specificity and moderate sensitivity for biliary anatomy in LDLT donors. Likelihood ratios  $> 10$  or  $< 0.1$  generate large and often conclusive shifts from the pre-test to post-test probability<sup>[32,33]</sup>. DOR is a single indicator of test accuracy that combines the sensitivity and specificity data into a single number<sup>[34]</sup>. The SROC curve presents a global summary of test performance and shows the tradeoff between sensitivity and specificity<sup>[35]</sup>. The summary DOR and the AUC of the SROC were 130.77 and 0.971, respectively, indicating that the overall accuracy was as high as expected, and that MRC is helpful in the diagnosis of aberrant biliary anatomy.

To our knowledge, this is the first meta-analysis exploring the value of MRC in the detection of biliary anatomy of LDLT donors. Our study included more published articles with more subjects, which can provide a more reliable statistical power. In addition, the quality of the selected studies was higher, as all had QUADAS scores over 10. Furthermore, the negligible heterogeneity and publication bias suggest the robustness of the results. In the present study, although several MRC techniques were used and the diagnostic accuracy varied across the studies (the sensitivity ranged from 0.71 to 1.00), the screening techniques were not a significant factor contributing to differences in diag-

Figure 1 Forest plot of summary results of magnetic resonance cholangiography in the diagnosis of biliary anatomy in living-donor liver transplantation. A: Sensitivity; B: Specificity; C: Positive likelihood ratio; D: Negative likelihood ratio.

nosis. Even though both were using a conventional MRC technique, Limanond *et al*<sup>[11]</sup> reported the lowest sensitivity of 0.71, while Song *et al*<sup>[26]</sup> reported a higher sensitivity of 0.95. Likewise, Kim *et al*<sup>[23]</sup> and Chiang *et al*<sup>[20]</sup> both used GD-DTPA MRC techniques, and their diagnostic sensitivities were not similar, reporting 0.92 and 0.86, respectively. These differences suggest that there were other factors, such as sample size, imaging treatment technique (2D, 3D, or maximum intensity projection), or the variability among different imaging readers. These factors may have led to the differing levels of diagnostic accuracy.

There were several limitations to the present meta-analysis. First, the MRC screening techniques were heterogeneous across the studies, although the techniques

Figure 3 Deek's funnel plot asymmetry test for identifying publication bias in the diagnosis of biliary anatomy in living-donor liver transplantation.

are all considered good enough to make a correct diagnosis by our contributing radiologists (Min ZG and Zeng ZY). However, the heterogeneity of the MRC techniques across the studies may have led to a differential verification bias and could have falsely elevated the reported sensitivities. Second, five of the included studies<sup>[9,19,23,26,27]</sup> did not specifically state that the readers were blinded to the results of the MRC, thus, it might raise the possibility of a review bias. Third, five of the included studies<sup>[11,20-22,25]</sup> were retrospective in design; thus, the biases of retrospective design studies, such as selection bias and recall bias<sup>[36]</sup>, should not be neglected. Fourth, although there were 12 studies included, the number of subjects was rel-

atively small; a larger sample size of subjects is warranted to obtain more reliable results. Fifth, the eligible studies for the present study were all English publications, which may have led to the observed publication bias. Sixth, although all the included studies stated that the results of the MRC were evaluated by experienced radiologists, a reviewer bias caused by inter-observer variability among different readers should not be neglected.

In summary, this meta-analysis demonstrates that MRC is a diagnostic technique with high specificity, but moderate sensitivity, in the diagnosis of biliary anatomy in LDLT donors. Therefore, other techniques such as MDCT may be complementary methods to enhance the sensitivity of the evaluation.

## COMMENTS

### Background

Magnetic resonance cholangiography (MRC) is a non-invasive procedure in diagnosis of the biliary anatomy. The current findings on the value of MRC in diagnosis of biliary anatomy in living-donor liver transplantation (LDLT) donors are conflicting.

### Research frontiers

This study suggests that MRC has a high specificity in diagnosis of biliary anatomy in LDLT donors, but the sensitivity is moderate.

### Innovations and breakthroughs

This is the first meta-analysis to investigate the diagnostic accuracy of MRC in the detection of biliary anatomy in LDLT donors.

### Applications

The results will provide valuable information to the doctors when they make a decision for the living liver donors.

### Peer review

In LDLT, preoperative assessment of biliary duct is so important, especially in a case of posterior graft. Authors reported MRC is a high specificity but moderate sensitivity technique in diagnosis of biliary anatomy in LDLT donors. Other inspection of biliary duct is maybe invasive, and therefore MRC is a good tool for the first survey of the biliary tree. This report is informative for transplant surgeons, even though the sensitivity is moderate.

### Abstract

Erosive hemorrhage due to pseudoaneurysm is one of the most life-threatening complications after pancreatectomy. Here, we report an extremely rare case of rupture of a pseudoaneurysm of the common hepatic artery (CHA) stump that developed after distal pancreatectomy with en block celiac axis resection (DP-CAR), and was successfully treated through covered stent placement. The patient is a 66-year-old woman who underwent DP-CAR after adjuvant chemoradiotherapy for locally advanced pancreatic body cancer. She developed an intra-abdominal abscess around the remnant pancreas head 31 d after the surgery, and computed tomography (CT) showed an occluded portal vein due to the spreading inflammation around the abscess. Her general condition improved after CT-guided drain-

age of the abscess. However, 19 d later, she presented with melena, and CT showed a pseudoaneurysm arising from the CHA stump. Because the CHA had been resected during the DP-CAR, this artery could not be used as the access route for endovascular treatment, and instead, we placed a covered stent *via* the inferior pancreaticoduodenal artery originating from the superior mesenteric artery. After stent placement, cessation of bleeding and antegrade hepatic artery flow were confirmed, and the patient recovered well without any further complications. CT angiography at the 6-mo follow-up indicated the patency of the covered stent with sustained hepatic artery flow. To our knowledge, this is the first reported case of endovascular repair of a pseudoaneurysm that developed after DP-CAR.

Endovascular pseudoaneurysm repair after distal pancreatectomy with celiac axis resection. *World J Gastroenterol* 2013; 19(45): 8435-8439 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i45/8435.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i45.8435>

## INTRODUCTION

Erosive hemorrhage due to pseudoaneurysm, concomitant to a pancreatic fistula and intra-abdominal abscess, is one of the most serious complications after pancreatectomy<sup>[1]</sup>. Several recent reports have described the successful endovascular treatment of pseudoaneurysms that may develop after pancreaticoduodenectomy<sup>[1,2]</sup>. However, there has been no published report of endovascular repair of pseudoaneurysms that develop after distal pancreatectomy with en block celiac axis resection (DP-CAR) because of the difficulty of the endovascular approach associated with resection of the common hepatic artery (CHA) in this procedure. Here, we report an extremely rare case of a successfully treated pseudoaneurysm of the CHA stump that developed after DP-CAR by covered stent placement *via* the inferior pancreaticoduodenal artery (IPDA). To our knowledge, no similar case has been reported.

## CASE REPORT

A 66-year-old woman presented with intractable back pain. Laboratory test results showed a high level of carbohydrate antigen 19-9 (CA19-9; 936 U/mL) and contrast-enhanced computed tomography (CT) indicated the presence of a 4.3 cm low-density pancreatic body tumor that involved the CHA, splenic artery (SpA), celiac axis (CeA), and superior mesenteric artery (SMA) (Figure 1A). No distant metastasis was detected. We determined that the tumor was unresectable at that time, and initiated conversion chemoradiation therapy with gemcitabine (1000 mg/body per 2 weeks) and 50 Gy external beam radiation. After the first chemoradiation treatment, the patient received additional gemcitabine chemotherapy (1600 mg/body per 2 weeks) at the discretion of the medical oncologist. After 5 mo of this chemoradiation therapy, the CA 19-9 level had declined to the normal range (14.1 U/mL) and contrast-enhanced CT revealed that the maximum tumor diameter had decreased to 3.0 cm (Figure 1B). Furthermore, although the tumor still involved the CeA, SpA, and CHA, the invasion around the SMA was remarkably diminished. At this point, we determined that the tumor could be completely removed by DP-CAR, and the surgery was planned. At laparotomy, the SMA and the gastroduodenal artery (GDA) were free of tumor invasion. The resectability was confirmed, and the DP-CAR procedure with concomitant portal vein resection was performed. Histopathological examination showed a mucinous carcinoma with lymph node metastasis. Portal venous invasion and extrapancreatic perineural invasion were also confirmed; however, the resection margin of the specimen indicated a negative result for cancer (R0). According to the UICC-TNM classification system, the pancreatic tumor was classified as Stage III (T3N1M0). The patient's intractable back pain disappeared immediately after the surgery, and the postoperative course was uneventful. The patient was discharged on postoperative

**Figure 1** Computed tomography images before and after chemoradiation therapy. day 13. One week after discharge, she was re-admitted because of appetite loss and oral feeding difficulty. Contrast-enhanced CT at 31 d after surgery showed formation of an intra-abdominal abscess around the remnant pancreas head as well as portal vein occlusion due to the spreading inflammation around the abscess (Figure 2A). CT-guided abscess drainage was performed, and the patient's general condition improved. However, 19 d after drainage of the abscess, the patient presented with melena, and contrast-enhanced CT showed a pseudoaneurysm arising from the CHA stump (Figure 2B). Emergent angiography also showed the pseudoaneurysm arising from the CHA stump (Figure 2C). Because the CHA had been resected during the distal pancreatectomy, the artery could not be used as the access route for endovascular treatment. Therefore, we performed covered stent placement *via* the inferior pancreaticoduodenal artery (IPDA) originating from the SMA (Figures 2D and 3) using a Jostent GraftMaster 3.0 mm × 16 mm stent (Abbott Vascular, Chicago, United States). After stent placement, cessation of bleeding and anterograde hepatic artery flow were confirmed. Although the portal vein remained occluded, the maximum values of GOT and GPT only reached 119 U/L and 70 U/L, respectively, on day 5 after stent placement, and the patient recovered well without any further complications. CT angiography at the 6-mo follow-up indicated the patency of the covered stent with

sustained hepatic artery flow (Figure 2E). Further, there was no sign of recurrence by 8 mo after DP-CAR.

## DISCUSSION

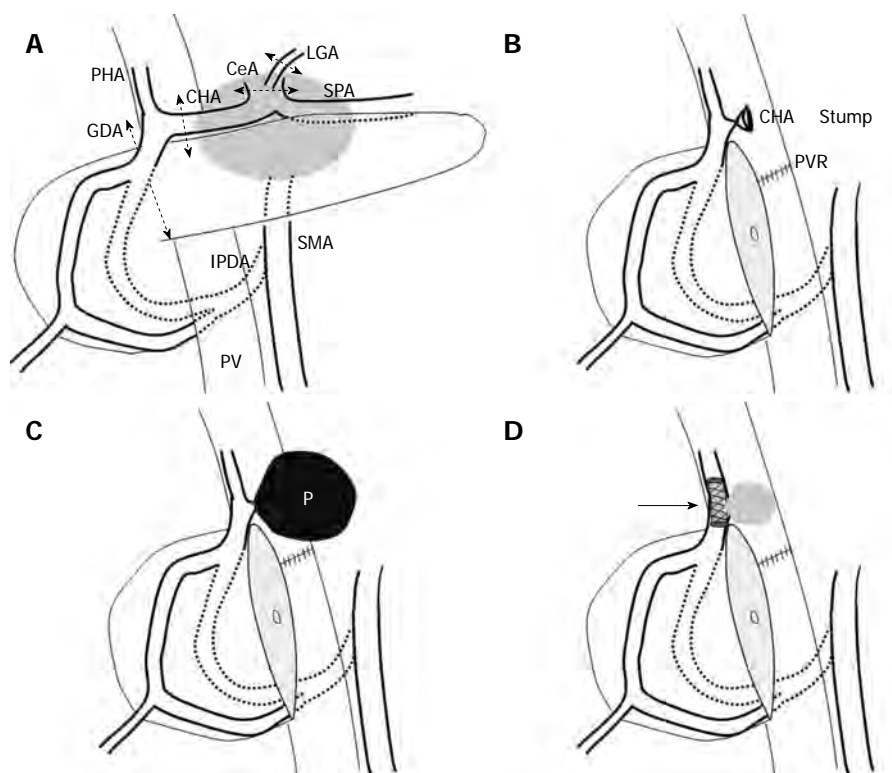

Perineural invasion of pancreatic body cancer can spread towards the celiac plexus and ganglia directly or *via* the nerve plexus surrounding the SpA and CHA<sup>[3]</sup>. Therefore, locally advanced pancreatic body cancer often involves the CHA and/or the celiac axis, and it was often regarded as an unresectable disease. DP-CAR is an operative method that can be adopted in such cases of locally advanced pancreatic body cancer<sup>[3,4]</sup>. The procedure includes distal pancreatectomy and en block resection of the CHA and the CeA with the surrounding neuroplexus. A drawback of this procedure is that, sufficient blood supply from the IPDA to the liver and stomach can not always be ensured. Angiography is routinely performed before DP-CAR in our institution in order to prevent ischemia-related complications in these organs after the surgery. After balloon occlusion of both the CHA and the left gastric artery (LGA), a superior mesenteric angiogram is obtained. If the angiogram indicates insufficient blood flow of the proper hepatic artery and the right gastroepiploic artery, subsequent coil embolization of both the CHA and the LGA is performed to increase the blood flow in the IPDA and prevent ischemia-related

complication after DP-CAR.

With DP-CAR, locally advanced pancreatic body cancers can be resected completely, and some authors have reported prolonged postoperative survival times<sup>[3,4]</sup>. Hirano *et al*<sup>[3]</sup> reported on 23 patients who underwent DP-CAR and described a high R0 resectability rate of 91% with a postoperative mortality rate of 0%. The estimated overall 1- and 5-year survival rates were 71% and 42%, respectively, and the median survival time was 21.0 mo. Baumgartner *et al*<sup>[4]</sup> reported on 11 patients who underwent DP-CAR after neoadjuvant therapy. These authors also described an R0 resectability rate of 91%, with a median overall survival of 26 mo.

Although DP-CAR can offer survival benefit and can potentially achieve complete local control in selected patients, the morbidity rate remains very high, ranging from 25% to 80%<sup>[5,6]</sup>. One of the most serious life-threatening morbidities after pancreatectomy is erosive hemorrhage due to pseudoaneurysm, concomitant to a pancreatic fistula and intra-abdominal abscess<sup>[1]</sup>. This requires emergent treatment, and the mortality rate of patients who develop intra-abdominal arterial hemorrhage after pancreaticoduodenectomy (PD) is reportedly 20%-50%<sup>[7-10]</sup>. Takahashi *et al*<sup>[11]</sup> successfully treated a case of pseudoaneurysm that developed after DP-CAR using relaparotomy. In their case, as in the current case, the pseudoaneurysm emerged on the stump of the CHA,

**Figure 3** Schema of the treatment course. A: The range of tumor invasion after the chemoradiation therapy (gray circle) and the resection line of the distal pancreatotomy with en-bloc celiac axis resection (DP-CAR) (double-headed arrow); B: After DP-CAR: Remnant pancreas head and the arcade of the pancreaticoduodenal artery; C: The pseudoaneurysm (P) at the CHA stump; D: Covered stent delivered *via* the IPDA (arrow). LGA: Left gastric artery; SpA: Splenic artery; CeA: Celiac axis; CHA: Common hepatic artery; SMA: Superior mesenteric artery; PV: Portal vein; PHA: Proper hepatic artery; GDA: Gastroduodenal artery; IPDA: Inferior pancreaticoduodenal artery; PVR: Portal vein resection.

and resection of the pseudoaneurysm with ligation of the GDA were performed.

In recent years, successful endovascular treatment for pseudoaneurysms that develop after PD has been described, and it is presently believed that endovascular treatment should be a first choice for hemorrhage resulting from the pseudoaneurysm<sup>[1,2]</sup>. Lee *et al*<sup>[2]</sup> reported on 27 patients who developed ruptured pseudoaneurysm after PD. Angiographic procedures for initial hemostasis were technically successful in 25 of the 26 patients who underwent angiography. The procedures for hemostasis included transarterial embolization (TAE) using a microcoil in 21 patients and stent graft in 4 patients. There was no recurrent bleeding in any patient in the group, and the selective microcoil embolization or stent graft procedures were effective for controlling the pseudoaneurysmal bleeding.

Among these endovascular treatments, TAE has been recommended as a first-line treatment, because it has been associated with 83%-100% success rates<sup>[2]</sup>. However, despite the dual blood supply from the hepatic artery and portal vein, there is a risk of the major complication of liver infarction or abscess after TAE for pseudoaneurysms arising from the hepatic arteries. In the present case, the portal vein was already occluded, and maintaining hepatic artery flow was indispensable in order to avoid hepatonecrosis and concomitant liver failure. Thus, we decided to use a covered stent to maintain hepatic ar-

tery flow, and the patient remained free of liver infarction and liver abscess after stent placement. We had to use the arcade of the pancreaticoduodenal artery as the access route for covered stent placement because the CHA had already been resected during the distal pancreatectomy. Although the diameter of the IPDA differs among patients and it is uncertain that the stent can always be successfully delivered *via* this route, we believe the method is worth attempting after DP-CAR in critical situations such as the one described herein.

### Abstract

Intestinal lymphangiectasia is a rare disease characterized by focal or diffuse dilated enteric lymphatics with impaired lymph drainage. It causes protein-losing enteropathy and may lead to gastrointestinal bleeding. Commonly, lymphangiectasia presents as whitish spots or specks. To our knowledge, small bowel bleeding resulting from polypoid intestinal lymphangiectasia has not been reported. Here, we report a rare case of active bleeding from the small bowel caused by polypoid lymphangiectasia with a review of the relevant literature. An 80-year-old woman was hospitalized for melena. Esophagogastroduodenoscopy could not identify the source of bleeding. Subsequent colonoscopy showed fresh bloody material gushing from the small bowel. An abdominal-pelvic contrast-enhanced computed tomography scan did not reveal any abnormal findings. Video capsule endoscopy showed evidence of active and recent bleeding in the ileum. To localize the bleeding site, we performed double balloon enteros-

copy by the anal approach. A small, bleeding, polypoid lesion was found in the distal ileum and was successfully removed using endoscopic snare electrocautery.

### INTRODUCTION

Nonpathologic lymphangiectasias are commonly detected throughout the gastrointestinal (GI) tract<sup>[1]</sup>. Lymphangiectasias can be pathologic, thus leading to GI symptoms including abdominal pain, steatorrhea, ascites, and, rarely, mid-gastrointestinal bleeding<sup>[2-4]</sup>. Small bowel infections such as tuberculosis or parasitic infections that cause impaired lymph flow might lead to diffuse lymphangiectasia resulting in protein-losing enteropathy<sup>[5]</sup>. Other infectious diseases can also cause focal

**Figure 1** Colonoscopy and video capsule endoscopy findings. A-C: Colonoscopy shows fresh blood material that gushed from the small bowel; D: Subsequent video capsule endoscopy shows evidence of active and recent bleeding in the ileum.

lymphangiectasia and obscure gastrointestinal bleeding. Lymphangiectasia presents either as whitish spots or specks, or yellowish, well-circumscribed, raised mucosal or submucosal lesions on endoscopy<sup>[6,7]</sup>. The polypoid form is extremely rare in patients with gastrointestinal vascular and lymphatic malformation. A few cases of small bowel bleeding resulting from lymphangiectasia have been reported. In this report, we present a case of ileal lymphangiectasia that was detected and treated by double balloon enteroscopy (DBE).

## CASE REPORT

An 80-year-old woman was referred to our department for investigation of gastrointestinal bleeding that she experienced for 7 d. She had chronic kidney disease and atrial fibrillation. She had been receiving hemodialysis twice a week for approximately 1 year prior to this episode, and had been taking warfarin for approximately 2 years. She had no history of habitual drinking or smoking and no specific family history of other diseases. On admission, her blood pressure was 120/80 mmHg, heart

rate was 66 bpm, body temperature was 36.1 °C, and respiratory rate was 22 breaths/min. On physical examination, the patient was alert and pale, and digital rectal examination revealed melena. Laboratory studies showed the following values: hemoglobin (Hb), 8.1 g/dL; hematocrit, 23.6%; white blood cells, 11300/ $\mu$ L (neutrophils, 79.1%; lymphocytes, 13.9%; eosinophils, 2.5%); platelets, 209/ $\mu$ L; prothrombin time, 27.3 s (International Normalized Ratio, 2.53); activated partial thromboplastin time; 28.8 s, protein, 8.2 g/dL; albumin, 4.5 g/dL; aspartate aminotransferase/alanine aminotransferase, 19/11 IU/L; alkaline phosphatase/gamma-glutamyl transpeptidase, 64/14 IU/L; total bilirubin, 0.43 mg/dL; and direct bilirubin, 0.15 mg/dL. We stopped warfarin on admission. We measured her Hb level every 4 h and administered packed red blood cell (RBC) transfusion when her Hb level was < 8.0 g/dL. Consequently, she received 4 pints of packed RBC by transfusion during hospitalization. An emergency esophagogastroduodenoscopy revealed atrophic mucosal changes and several raised erosions in the antrum; however, no active bleeding was found. A subsequent colonoscopy showed fresh

**Figure 2 Double balloon enteroscopy findings.** A: Double balloon enteroscopy shows a small, whitish polypoid lesion with active bleeding in the distal ileum; B, C: After submucosal injection of a saline-epinephrine mixture, polypectomy was performed; D: After the procedure, argon plasma coagulation was performed on the post-polypectomy ulcer to achieve hemostasis.

bloody material gushing from the small bowel (Figure 1A-C). An abdominal-pelvic contrast-enhanced computed tomography scan did not reveal any abnormal findings. Video capsule endoscopy (IntroMedic, Seoul, South Korea) showed evidence of active and recent bleeding in the ileum but could not localize the bleeding site (Figure 1D). To localize the bleeding site, we performed DBE. Retrograde DBE (EN450T5, Fujinon, Saitama, Japan) showed a small bleeding polyp in the distal ileum (Figure 2A). The ileal polyp was removed using an endoscopic snare (SD-9L-1; Olympus Optical Co., Ltd., Tokyo, Japan). Thereafter, electrocautery was performed after submucosal injection of a hypertonic saline-epinephrine solution (Figure 2B and C). After the procedure, argon plasma coagulation was performed for an ulcer caused by polypectomy to attain hemostasis (Figure 2D). The entire procedure lasted for approximately 150 min. The results of the histological examination were consistent with a diagnosis of lymphangiectasia characterized by dilated lymphatic channels in the lamina propria (Figure 3A and B). We administered warfarin 3 d after the procedure. After removal of the ileal polyp, the patient was discharged with no gastrointestinal bleeding. The patient has been followed up for 1 year and has shown no sign of recurrence.

## DISCUSSION

Intestinal lymphangiectasia is a rare disease characterized by dilated intestinal lacteals causing loss of lymph into the lumen of the small intestine resulting in hypoproteinemia, hypogammaglobulinemia, hypoalbuminemia, and lymphopenia<sup>[8]</sup>. The most commonly affected site in the intestine is the duodenum<sup>[9,10]</sup>.

Gastrointestinal symptoms range from mild to severe presentations such as diarrhea, steatorrhea, abdominal mass, and mechanical ileus. Chronic occult blood loss may occur in some cases, and non-specific small bowel ulceration has been reported in others<sup>[9,11,12]</sup>. Rarely, massive bleeding has also been recorded<sup>[13,14]</sup>. The patient in our case had chronic kidney disease and was receiving treatment with warfarin for atrial fibrillation. Although we could not find any report on whether anticoagulation or hemodialysis increased the risk of bleeding in patients with lymphangiectasia, we consider that she had a bleeding diathesis and hence, had bleeding from the ileal polyp.

Several mechanisms have been suggested to interpret the pathophysiology of bleeding lymphangiectasias. Obstruction of the normal flow of chyle from the small intestine may increase intraluminal pressure sufficiently to open latent lymphatic-venous connections<sup>[15]</sup>. Conse-

**Figure 3** Histopathologic findings of intestinal lymphangiectasia. A, B: Microscopic examination shows dilated lymphatic channels in the lamina propria (hematoxylin and eosin,  $\times 40$ ). Protein-rich fluid can escape from these channels into the extracellular space of the lamina propria and ultimately into the gut lumen (hematoxylin and eosin,  $\times 200$ ).

quently, this pressure gradient opens latent lymphatic-arterial (rather than venous) connections<sup>[16]</sup>. Such openings into another closed system of higher pressure would allow the retrograde flow of blood into the lymphatics and as a result, bursting of blood-filled dilated lymphatics may lead to intestinal bleeding. However, we could find neither the pathologic lymphatic-blood vessel connection nor obstruction of lymphatic channel in the pathological sections of the biopsy specimen.

Intestinal lymphangiectasia was confirmed by the endoscopic findings and intestinal biopsy results. Marked dilation of the lymphatics was seen in the mucosa, sometimes extending into the submucosa. The overlying intestinal epithelium usually appears normal, but occasionally creamy yellow villi may be seen<sup>[17]</sup>. In recent years, the development of newer endoscopic methods, particularly video capsule endoscopy and DBE has simplified diagnosis and treatment of small bowel lesions. In our case, although small bowel bleeding was detected by video capsule endoscopy, the definite location and etiology of bleeding could not be confirmed. As the bleeding lesion was found to be limited to the ileum in video capsule endoscopy, DBE was performed by the anal approach. The oral approach was not used subsequently because there were no signs of bleeding after polypectomy and coagulation. We diagnosed and treated ileal polypoid intestinal lymphangiectasia using DBE.

To our knowledge, this is the first case to report small bowel bleeding from a solitary ileal polypoid intestinal lymphangiectasia. This case represents the successful detection and treatment of bleeding resulting from rare, solitary, ileal polypoid intestinal lymphangiectasia using DBE.

### Abstract

Gastric duplication cyst is a very rare gastrointestinal tract malformation that accounts for 2%-4% of alimentary tract duplications. Most cases are diagnosed within the first year of life, following presentation of abdominal pain, vomiting, and weight loss and clinical discovery of an abdominal palpable mass. This case report describes a very uncommon symptomatic gastric duplication cyst diagnosed for the first time in adulthood. Only a few other case reports of similar condition exist, and all were identified by endosonography. The current case involves a 52-year-old male who presented with a one-month history of progressive iron deficiency anemia without overt gastrointestinal bleeding. The patient underwent esophagogastroduodenoscopy, which revealed a 2.0 cm pinkish subepithelial lesion, suspected to be a gastrointestinal stromal tumor (GIST) and source of gastrointestinal bleeding. The endosonography showed

inhomogeneous hypoechoic lesions with focal anechoic areas arising from a second and third layer of the gastric wall. Differential diagnoses of GIST, neuroendocrine tumor, or pancreatic heterotopia were made. The lesion was removed using an endoscopic submucosal resection technique. Histopathology revealed an erosive gastric mass composed of a complex structure of dilated gastric glands surrounded by fibro-muscular tissue, fibroblasts, and smooth muscle bundles, which led to the diagnosis of gastric duplication.

**Core tip:** Gastric duplication cyst is a very rare gastrointestinal malformation and most of the cases are diagnosed within the first year of life following clinical investigations of abdominal symptoms including pain, vomiting, and palpable mass. Gastrointestinal hemorrhage is a rare clinical manifestation. Here, we report a 52-year-old man who presented with a one-month history of progressive iron deficiency anemia without overt gastrointestinal bleeding. Esophagogastroduodenoscopy revealed general gastrointestinal bleeding and a 2.0 cm subepithelial tumor originating from the third layer of gastric wall. After complete removal by endoscopic mucosal resection, histopathological findings indicated a diagnosis of gastric duplication cyst with erosion.

## INTRODUCTION

Gastric duplication cyst is a rare congenital malformation of the upper gastrointestinal tract, accounting for 2%-4% of all duplications of the alimentary tract<sup>[1]</sup>. Most cases are diagnosed in the first year of life, following presentation of abdominal pain, vomiting, and weight loss and clinical discovery of an abdominal palpable mass or upon clinical investigation of gastrointestinal obstruction and/or perforation<sup>[1-3]</sup>. Bleeding was a very rare clinical manifestation of this condition, and very few cases of gastric duplication cysts have been diagnosed in adulthood<sup>[2-6]</sup>. Some of the adult cases have been incidentally detected during upper endoscopy [endoscopic ultrasound (EUS) technology] or abdominal imaging studies for other reasons<sup>[3,5,6]</sup>. Yet, the reported radiographic and endosonographic findings from these limited cases have not revealed any characteristic profile useful for diagnosis.

Herein we describe an unusual case of gastric duplication cyst which was identified in an adult male following endosonographic investigations of subacute anemia and discovery of upper gastrointestinal bleeding.

## CASE REPORT

A 52-year-old man presented with a one-month history of progressive iron deficiency anemia without overt gastrointestinal bleeding. Laboratory tests indicated remarkably low hemoglobin level (9.0 mg/dL; reference range: 13.0-17.0 mg/dL) and slightly low ferritin level (18.0 ng/mL; reference range: 12-200 ng/mL). Esophagogastroduodenoscopy was performed and revealed a 2.0 cm pinkish umbilicated subepithelial lesion located at antrum and accompanied by evidence of ulceration and blood clotting (Figure 1A). Gastrointestinal stromal tumor (GIST) was suspected, and subsequent endosonographic evaluation was ordered.

In the endoscopic suite, the patient underwent total intravenous anesthesia using propofol with full anesthetic monitoring. A curvilinear echoscope (EG-3870UTK; Pentax, Miyaki, Japan) was used and revealed a 1.8 cm hypoechoic mass arising from the second and third layer of the gastric wall, with a centralized anechoic area lacking vascular flow (Figure 1B). The findings suggested small GIST with cystic change. An endoscopic submucosal resection (EMR) technique was applied with an 8.8 mm gastroscope (GIF-Q180; Olympus, Tokyo, Japan) and creation of a submucosal cushion by injecting a 4 mL mixture of adrenaline (1 mg), Indigo carmine (0.4% solution) and Gelofucine<sup>®</sup> (500 mL) using a 23 gauge needle [Heyinovo<sup>™</sup>; Wilson Instruments Co., Ltd., Shanghai, China]. The lesion was removed in an *en-bloc* fashion by an electrical snare (Figure 2).

Histopathological analysis of the resected tissue revealed an erosive gastric mass that was composed of a complex structure characterized by dilated gastric glands surrounded by fibromuscular tissue, fibroblasts, and smooth muscle bundles. Immunohistochemistry analysis

showed negativity for CD117, DOG-1, and S-100, but focal positivity for smooth muscle actin. Although these pathology findings suggested a differential diagnosis of pancreatic heterotopia, no evidence was found for this diagnosis (Figure 3) and the diagnosis of gastric duplication was made.

## DISCUSSION

Gastric duplication cysts are rare congenital malformations with frequent localization in the alimentary tract that follows the incidence hierarchy of ileum > esophagus > jejunum > colon > stomach > appendix<sup>[2-4]</sup>. Yet, the etiopathogenetic origin of gastric duplication cysts remains undefined. These duplications, however, are usually found to be distributed dorsally to the primitive gut during development, so that most gastric duplication cysts appear along the greater curvature of the stomach, adjacent to the gastric wall (only 5.5% are found in the lesser curvature<sup>[3]</sup>). The stomach is lined by typical gastric mucosa, which is often accompanied by patches of ectopic intestinal epithelium; in addition, a smooth muscle coat fuses with the muscularis propria of the stomach, making it contiguous with the wall of the stomach, and shares a common blood supply. The cyst in the current case was located at the greater curvature of the antral area.

The rarity of the current case was furthered by the manifestation of symptoms and diagnosis having occurred in later adulthood. Furthermore, gastric duplication cysts are usually asymptomatic in adult patients, yet this case presented with anemia from upper gastrointestinal bleeding. Based upon the pathological findings, we speculate that acid erosion of the gastric lining near the cyst led to the hemorrhage, as well as the observed ulceration.

Throughout the case management course, various differential diagnoses were suggested and rejected. In particular, the endoscopic and EUS findings of small subepithelial lesions with umbilication suggested potential diagnoses of GIST, neuroendocrine tumor, or pancreatic heterotopia. The endosonographic characteristics of this patient are very distinctive from those reported for previous cases, even though all cases involved cystic lesions at greater curvature sites of the stomach. The cysts of previous cases have ranged in diameter from 5 to 7 cm, and were located adjacent to the fourth layer of the gastric wall. In addition, most of these cysts showed an inhomogeneous echoic pattern, which was suspected to reflect secretions from the gastric gland composed of both mucous and serous material<sup>[3,5,6]</sup>. We hypothesized the atypical endosonographic findings of the current case corresponded to the smaller cyst size and low fluid volume, which caused the lesion to appear more like a solid mass with cystic degeneration than a cystic lesion. Therefore, the final diagnosis was gastric duplication cyst. Finally, even though fine needle aspiration cytology may have been able to achieve the differential diagnosis<sup>[4]</sup>, we felt that complete removal of the lesion was justified by

**Core tip:** Intussusception is a common cause of bowel obstruction in pediatric patients. Primary diffuse large B cell non-Hodgkin's lymphoma of the small intestine is rare. Intussusception due to primary diffuse large B cell non-Hodgkin's lymphoma in the small intestine is even rarer in adults and is often difficult to diagnose. This article describes the diagnosis and management of this rare disease.

Xu XQ, Hong T, Li BL, Liu W. Ileo-ileal intussusception caused by diffuse large B-cell lymphoma of the ileum. *World J Gastroenterol* 2013; 19(45): 8449-8452 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i45/8449.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i45.8449>

### Abstract

The occurrence of adult intussusception from small intestinal lymphoma is quite rare. We present an 82-year-old man with a two-month history of intermittent abdominal pain, nausea and fatigue. Clinical symptoms included moderate abdominal tenderness in the right lower abdomen. Computed tomography scan of the abdomen revealed a mass in the terminal ileum with the sign of "bowel within bowel" which was suspicious of ileo-ileum intussusception. The patient underwent laparoscopic segmental ileal resection. Pathologic evaluation revealed a diffuse large B cell non-Hodgkin's lymphoma of the ileum. The postoperative course was uneventful.

### INTRODUCTION

Intussusception is most often seen in infants and children and only 5% of all cases occur in adults. It accounts for about 1% of all cases of adult bowel obstruction. Adult intussusception is rare and about 40% are related to malignant lesions<sup>[1]</sup>. In general, most lesions in the small intestine are benign. Malignant lesions account for up to 30% of all cases of intussusception in the small intestine. Intussusception occurring in the large bowel is more likely to be related to malignant lesions in 63%-68% of cases<sup>[2]</sup>. Primary malignant tumors of the small intestine are very rare, accounting for less than 2% of all gastrointestinal malignancies. Malignant lesions resulting in intussusception in the small intestine include primary adenocarcinoma, gastrointestinal stromal tumors (GISTs), lymphoma and carcinoid tumors<sup>[3]</sup>.

The gastrointestinal tract is the most common site of primary extranodal non-Hodgkin's lymphoma (NHL), accounting for 20%-40% of all extranodal disease<sup>[4]</sup>. The stomach (50%-60%) is the most frequently affected site, followed by the small bowel (20%-30%), whereas 85%

Figure 2 Positron emission tomography and computed tomography showing high metabolism in the right ileum (arrow) and multiple lymph nodes with high metabolism in the mesentery root of the small intestine, in which malignant lesions in the terminal ileum were suspected.

Figure 3 Endoscopic findings showing a mass approximately 50 cm away from the ileocecal valve, which almost filled the ileal cavity.

of primary gastrointestinal lymphomas and 60%-80% of intestinal lymphomas are B-cell type followed by T-cell NHL and Hodgkin's lymphoma<sup>[5]</sup>. The ileum is the most common site of small intestine lymphoma. Intussusception is very rarely seen in intestinal NHL and the most common type of lymphoma causing intussusception is diffuse B-cell NHL<sup>[5]</sup>.

We herein describe a case of adult ileal intussuscep-

tion caused by diffuse large B-cell lymphoma of the small bowel in an 82-year-old male patient.

## CASE REPORT

An 82-year-old male was admitted with a two-month history of intermittent abdominal pain, nausea and fatigue. He also complained of marked weight loss (8 kg) during the last two months. He was diagnosed with incomplete intestinal obstruction and was supported with parenteral nutrition in the community hospital. His past medical history was hypertension for 20 years. Physical examination revealed moderate abdominal tenderness in the right lower abdomen.

Blood tests revealed a white blood cell count of  $4.1 \times 10^9/L$  with 63% neutrophils and a hemoglobin level of 96 g/L with a hematocrit of 29%. His liver and kidney function test results and tumor marker (CEA, CA19-9, CA242 and CA724) levels were all normal. The fecal occult blood test was positive. Plain abdominal radiography was unremarkable. Contrast-enhanced computed tomography (CT) showed multiple lymphadenoma in the mesentery root of the small intestine and posterior peritoneum, a mass in the terminal ileum with the sign of “bowel within bowel” was suspicious of ileo-ileum intussusception (Figure 1). Positron emission tomography and computed tomography (PET-CT) showed high metabolism in the terminal ileum and multiple lymph nodes with high metabolism in the mesentery root of the small intestine, in which malignant lesions in the terminal ileum were considered (Figure 2). Therefore, balloon-assisted enteroscopy was performed. A mass, approximately 50 cm away from the ileocecal valve, almost filled the ileal cavity (Figure 3) and did not allow the enteroscope to pass. A biopsy was taken from this lesion and the pathology result showed a diffuse large B cell NHL of the ileum (Figure 4). Laparoscopic exploration was performed due to low hemoglobin, weight loss and the mass with suspected intussusception on CT. A tumor mass of  $5.0 \text{ cm} \times 3.0 \text{ cm}$  was revealed with ileo-ileum intussusception which was 40 cm distal to the ileum with multiple lymphadenoma in the mesentery root

**Figure 4** Histological and immunohistological examination of the endoscopic and surgical specimens showing diffuse large B-cell non-Hodgkin's lymphoma. A:  $\times 400$ , HE staining; B:  $\times 400$ , CD5 (-); C:  $\times 400$ , CD10 (-); D:  $\times 400$ , CD20 (+); E:  $\times 400$ , CD23 (-); F:  $\times 400$ , MUM-1 (+); G:  $\times 400$ , Bcl-6 (-); H:  $\times 400$ , Cyclin D1 (-).

of the small intestine. A segmental ileal resection was performed laparoscopically. After opening the specimen, a mass of approximately 3 cm was found in the ileum wall almost filling the ileal cavity. The histopathological findings were suggestive of a diffuse large B cell NHL of the ileum (Figure 4), which was consistent with the preoperative pathological results of endoscopic biopsy. Tumor infiltration was detected in 2 of 16 lymph nodes. The postoperative course was uneventful. Bone marrow biopsies showed a normal marrow without infiltration. Cervical and chest PET-CT scans were unremarkable. Postoperative chemotherapy with cyclophosphamide, doxorubicin, vincristine, and prednisolone combined with the monoclonal antibody, rituximab, was administered. At the 6-mo follow up, there was no evidence of tumor activity.

## DISCUSSION

Intussusception is rare in adults ( $< 5\%$ ), but it is the most common cause of intestinal obstruction in infants aged 6-18 mo<sup>[1]</sup>. The characteristic pediatric presentation triad of abdominal pain, palpable abdominal mass and bloody stool is rarely seen in adult cases. An abdominal mass is palpated in 12%-30% of cases, whereas 6%-25% of cases present with complications of the disease such as obstruction, hemorrhage, perforation, or intussusception<sup>[5]</sup>. Most patients present with subacute (24.4%) or chronic (51.2%) symptoms of abdominal pain, nausea, vomiting and constipation. The non-specific clinical

presentation makes the preoperative diagnosis difficult<sup>[6]</sup>. CT scan is one of the most useful preoperative diagnostic modalities for intussusception as it can show the thickened segment of bowel with an eccentrically placed crescent-like fatty area (bowel within bowel)<sup>[5]</sup>. If the patient does not have a complete intestinal obstruction, colonoscopy is helpful for the clinical and pathological diagnosis of intussusception. PET-CT is useful for detecting the primary benign or malignant lesion sites and the distal regions which may be involved in lymphoma, although it is not often routinely used<sup>[7]</sup>.

About 52%-55% of adult intussusceptions occur in the small intestine<sup>[8]</sup>. Sixty-three percent of adult small intestinal intussusception cases were associated with benign lesions, 23% cases were idiopathic, and 14% cases were associated with malignant lesions<sup>[9]</sup>. The incidence of primary lymphomas in the small intestine accounts for less than 2% of all gastrointestinal malignancies and 10%-20% of small intestine malignancies<sup>[1]</sup>.

The management of small intestine intussusception caused by NHL is mandatory surgical intervention for adult intussusception due to the high incidence of underlying malignancy in intussusceptions and the inability to differentiate non-operatively benign from malignant causes in enteric intussusceptions<sup>[5]</sup>. For adult small intestinal intussusception caused by NHL, primary surgical resection of the localized intestinal lesions with NHL is the treatment modality of choice, especially in patients who have complications of intussusception.

In conclusion, we describe the diagnosis of adult

ileal intussusception with detailed images of this specific case. Adult intussusception must be considered in the differential diagnosis of patients with abdominal pain and vomiting. The work-up must include X-ray, ultrasound and CT scan of the abdomen and PET-CT in special cases. Surgical intervention is required and warranted once the diagnosis of intussusception is made, due to the high risk of malignancy and bowel obstruction.

## COMMENTS

### Clinical diagnosis

Ileo-ileal intussusception caused by diffuse large B-cell lymphoma of the ileum.

### Differential diagnosis

Adult intussusception must be considered in the differential diagnosis of patients with abdominal pain and vomiting.

### Imaging diagnosis

Diagnostic imaging must include X-ray, ultrasound and computed tomography scan of the abdomen which can show the sign of "bowel within bowel".

### Treatment

Surgical intervention is required and warranted once the diagnosis of intussusception is made, due to the high risk of malignancy and bowel obstruction.

### Peer review

This is an interesting case report, which shows a rare case of ileo-ileal intussusception caused by diffuse large B-cell lymphoma of the ileum.

### Abstract

During the past decade, laparoscopic distal pancreatectomy (LDP) has gained increasing acceptance in the surgical community as a viable treatment option for distal pancreatic lesions. However, the possible complication of post-LDP pancreatic leakage remains a challenge, because it may lead to a series of events resulting in intraperitoneal abscess formation, sepsis, pseudoaneurysm formation, and occasional fatal hemorrhage. Dealing with these complications is extremely difficult and not much experience has been reported to date. We report a case involving the aforementioned post-LDP complications successfully managed by interventional radiological techniques while avoiding reop-

eration. We conclude that these management options are attractive, safe and minimally invasive alternatives to standard protocols.

**Key words:** Interventional radiology; Pancreatectomy; Laparoscopy; Postoperative complications

**Core tip:** A 48-year-old man who suffered from a series of complications of pancreatic leakage and resultant abscess formation, sepsis, and intra-abdominal hemorrhage after laparoscopic distal pancreatectomy (LDP), was treated successfully by interventional radiology, with avoidance of reoperation. These interventional radiological approaches seem to be attractive, safe and minimally invasive options for treatment of post-LDP complications.

Successful interventional radiological management of postoperative complications of laparoscopic distal pancreatectomy. *World J Gastroenterol* 2013; 19(45): 8453-8458 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i45/8453.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i45.8453>

### INTRODUCTION

Laparoscopic pancreatectomy was first reported in the early 1990s. Since then, a variety of procedures have been introduced, such as staging of pancreatic malignancy, debridement for acute necrotizing pancreatitis, cystoenterostomy for pancreatic pseudocysts, pancreatic tumor enucleation, and pancreaticoduodenectomy<sup>[1-4]</sup>. Laparoscopic distal pancreatectomy (LDP) is widely accepted by the surgical community due to its advantages

**Figure 1** Computed tomography. A: Distal pancreatic tumor; B: Hydrops adjacent to the pancreatic stump; C: A pigtail catheter (percutaneous catheter drainage tube 1) was placed into the left anterior pararenal space under computed tomography (CT) guidance; D: Abdominal contrast-enhanced CT revealed extravasation of contrast medium adjacent to the pancreatic stump.

of decreased postoperative pain, earlier normalization of bowel function, and shorter length of hospitalization compared to open surgery<sup>[5-8]</sup>. However, the complication of pancreatic leakage after LDP remains a challenge because it may lead to a series of events including intraperitoneal abscess, subsequent sepsis, pseudoaneurysm formation, and occasional fatal hemorrhage<sup>[9]</sup>. Dealing with these complications by reoperation is particularly difficult due to adhesion formation and the generally fragile postoperative condition of the patient.

## CASE REPORT

A 48-year-old man was admitted because of the incidental discovery of a pancreatic mass during a routine medical check-up. Abdominal computed tomography (CT) showed a low-density lesion of 1.5 cm × 1.3 cm with arterial enhancement in the pancreatic tail (Figure 1A). The patient underwent spleen-preserving LDP in April 2009. During the procedure, the splenic artery and vein were meticulously dissected from the pancreatic tissue and preserved. Branches from these two vessels to the pancreatic parenchyma were either severed by a harmonic scalpel or carefully ligated and separated. The pancreas was transected by an endoscopic linear stapler and the stump continuously sutured. A Jackson-Pratt drainage tube was placed in close proximity to the pancreatic stump. The procedure which lasted for 160 min was smooth. Postoperative pathological examination diagnosed a pancreatic insulinoma.

The patient complained of abdominal fullness at 4 d after the operation, with physical examination revealing fever (up to 38.8 °C), tachycardia, and left abdominal tenderness. Amylase-rich abdominal fluid (4389 IU/L) draining from the Jackson-Pratt tube was detected. An effusion was demonstrated on both abdominal ultrasonography and CT beside the pancreatic stump (Figure 1B). Pancreatic leakage from the stump was therefore diagnosed according to International Study Group for Pancreatic Fistula criteria<sup>[10]</sup>. It was also noted that the patient's sclera and skin were yellow in hue. Laboratory

findings showed obvious elevation of serum bilirubin (total/direct bilirubin: 6.7/3.4 mg/dL) without evidence of biliary obstruction on imaging studies.

CT-guided percutaneous catheter drainage (PCD) was performed using Seldinger's method: A 12-Fr locking pigtail catheter (Angiotech, Stenlose, Denmark) was placed into the left anterior pararenal space (Figure 1C). Thick brown amylase-rich (19000 IU/L) fluid of about 50 mL in volume was drained out daily; drainage continued for 6 d after which the daily drainage decreased to < 10 mL. The patient's body temperature returned to normal 2 d after the PCD procedure. His white blood cell count and serum bilirubin level declined to the normal range in subsequent laboratory examinations. The patient was discharged with two drainage tubes in place on postoperative day 15.

Six days later, the patient was readmitted due to persistent epigastric pain. On readmission, his vital signs were stable. There was tenderness and rebound pain at the upper quadrant of his abdomen with moderate muscle guarding. Sentinel bleeding was suspected because bloody fluid was observed in the PCD tube. The patient underwent an emergency abdominal CT scan that showed extravasation of contrast medium beside the pancreatic stump (Figure 1D). Follow-up arteriography revealed a splenic arterial wall irregularity at the proximal portion 3 cm from the celiac trunk, suggesting a pseudoaneurysm (Figure 2A). Under interventional radiology, the pseudoaneurysm was occluded at both proximal and distal sites with microcoils (Figure 2B). There was no continuous intra-abdominal bleeding after embolization, however, leakage of pancreatic juice and bacterial infection did not cease despite administration of octreotide and antibiotics. On postoperative day 25, the patient complained of epigastric pain and fever again, whereas his abdominal drainage decreased to < 5 mL/d. Enhanced abdominal CT revealed a peripancreatic effusion of considerable size (Figure 3A) and multiple low-density splenic shadows (Figure 3B). A second PCD was subsequently performed for drainage of the peripancreatic fluid collection (Figure 3C). Dark brown turbid fluid of a total volume

**Figure 2** Celiac trunk angiography. A: Celiac trunk angiography revealed pseudoaneurysm of the splenic artery; B: Celiac trunk angiography revealed no extravasation of contrast medium after embolization of the splenic artery with microcoils.

**Figure 3** Examination. of 200 mL/d was drained out by the two PCD catheters (PCD tube 1: 20 mL/d, PCD tube 2: 180 mL/d) and the patient's symptoms were alleviated promptly. After 10 d, drainage from the two catheters began to decrease gradually and re-examination by CT showed apparent absorption of the peripancreatic effusion (Figure 3D). The second PCD tube was removed on postoperative day 40.

One week later, the patient suffered another episode of epigastric pain, fever, and leukocytosis despite cessation of drainage from PCD 1. Abdominal CT revealed

an encapsulated fluid collection in front of the pancreatic stump (Figure 4) and the third PCD was inserted under CT guidance (Figure 5). Continuous intra-abdominal lavage was established between the two drainage catheters (PCD tube 1 and PCD tube 3) afterwards. As a result, the encapsulated peripancreatic fluid collection was absorbed within 1 mo after the third PCD was inserted and the two catheters were eventually removed. The patient was discharged on postoperative day 80. The patient was well on subsequent follow-up and remained so until April 2013.

## DISCUSSION

LDP has been increasingly utilized as management for various lesions of the distal pancreas (*e.g.*, neuroendocrine tumors and cystic lesions) since development of the procedure towards the turn of the century. For benign lesions of the left pancreas, spleen-preserving LDP (SPLDP) has been proposed in order to reduce risks associated with splenectomy<sup>[11,12]</sup>. In SPLDP, the blood supply to the spleen can be maintained by either preserving the splenic artery and vein<sup>[13]</sup> or preserving collaterals of short gastric and left gastroepiploic arteries and veins while severing the splenic vessels (the Warshaw's method)<sup>[14]</sup>. The pancreatic lesion of the presented case, which was visualized as a hypodense mass on arterial enhance-

**Figure 5** A pigtail catheter (percutaneous catheter drainage tube 3) was placed anterior to the pancreatic stump to drain the effusion. A: Percutaneous catheter drainage (PCD) tube 3; B: PCD tubes 1 and 3.

ment of preoperative CT, was diagnosed as a neuroendocrine tumor. Tumor margins were clear with no apparent involvement of the splenic artery and vein, therefore, SPLDP was performed as surgical treatment.

The most common and clinically relevant complication of LDP is pancreatic leakage, which may lead to a series of sequelae including intra-abdominal abscess formation, sepsis, and even fatal bleeding. Although the incidence of pancreatic leakage after distal pancreatectomy has declined in the past decade, various high-volume centers have reported an occurrence rate of 5%-30% in recent studies<sup>[15-17]</sup>. A literature review revealed no significant variation in the incidence of pancreatic leakage after LDP and SPLDP<sup>[18-20]</sup>. Various techniques have been used to prevent pancreatic leakage, such as transecting the pancreatic parenchyma with endo-GI, or endo-GI closure with subsequent suturing, wound sealing with either fibrin-glue or an omental plug, and postoperative administration of octreotide. However, none of these aforementioned methods produced results of efficacious superiority.

On postoperative day 4, the patient complained of marked abdominal fullness. Physical examination revealed fever, tachycardia, and left abdominal tenderness. Amylase-rich fluid meeting the criteria for pancreatic leakage was detected from the Jackson-Pratt tube<sup>[10]</sup>. Fluid effusion was revealed adjacent to the pancreatic stump on ultrasonography and abdominal CT. The patient was noted to have jaundice on both physical and laboratory

examinations. Given that there was no evidence of biliary obstruction, sepsis associated with pancreatic leakage was determined to be a likely etiology.

Percutaneous catheter drainage has proven effective in evacuating intra-abdominal abscesses in the past decade, with a reported resolution rate of 50%-80%<sup>[21-24]</sup>. In the present case, the left anterior pararenal space was considered an ideal route for percutaneous drainage, and PCD was performed with resultant rapid mitigation of fever, leukocytosis, and jaundice.

Pseudoaneurysm formation and bleeding, as a fatal complication following pancreatic surgery, occurs in 2%-4% of patients with pancreatic leakage<sup>[25]</sup>. Such bleeding usually presents as a sudden or intermittent event in the late postoperative stage. According to the literature, most patients with pseudoaneurysm hemorrhage develop some form of sentinel bleeding prior to major onset<sup>[26]</sup>. Immediate diagnostic intervention of sentinel bleeding is essential to save patients from a foreseeable massive hemorrhage. Angiography has been established as the management of choice for sentinel bleeding, because it can simultaneously determine the origin of the hemorrhage and provide selective embolization<sup>[9]</sup>. In the present patient, the cause of pseudoaneurysm formation was considered to be exposure of underlying parenchymal vasculature to the leaked pancreatic juice, with subsequent regional infection. Furthermore, we speculate that there may have been several weak points on the trunk of the splenic artery postoperatively, particularly the origins of small branches from the splenic artery to the pancreatic parenchyma, which were severed via harmonic scalpel without ligation. These points might have been sensitive to erosion by pancreatic juice and thus were particularly prone to pseudoaneurysm formation. Therefore, we recommend that every visible branch between the splenic artery and pancreatic parenchyma should be ligated and severed. It is also questionable whether this patient's intra-abdominal bleeding was related to postoperative drainage catheter retention. However, iatrogenic etiology involving a pigtail catheter was deemed unlikely due to its coiled tip, which reduces friction between the catheter and surrounding tissue.

Based on the fact that radiological intervention has been widely recommended for pseudoaneurysm occlusion with a high success rate (67%-100%)<sup>[9,27-29]</sup>, transcatheter microcoil embolization of the splenic artery was performed in our patient. Both the distal and proximal portions of the pseudoaneurysm were blocked and hemorrhage was effectively controlled. Occlusion of the splenic artery, the main arterial blood supply of the spleen, might have led to splenic infarction and secondary infection. Post-embolization CT revealed multiple patchy ischemic changes in the spleen, without obvious progression of splenic infarction on subsequent CT. Delayed follow-up at 2 years postoperatively indicated that perfusion of the spleen recovered, apparently compensated for by adequate circulatory collateralization. It is therefore reasonable to assume that the short gastric and

gastroepiploic arteries are selectively preserved during SPLDP even when the splenic vessels are preserved.

The patient's hemorrhage ceased after splenic artery embolization. However, pancreatic leakage and sepsis continued and resulted in recurrence of abdominal abscess formation. According to Gervais *et al*<sup>[22]</sup>, repeated percutaneous drainage had a success rate of 91% in evacuating recurrent abdominal abscesses and was effective in obviating surgery in 56% of patients. In our case, two peripancreatic drainage catheters were inserted under interventional radiological guidance and peritoneal lavage was performed between the two tubes. Eventually, the pancreatic leakage ceased and the infection was controlled without further episodes of intra-abdominal bleeding.

In conclusion, apart from surgery, interventional radiological approaches are viable treatment options for post-LDP pancreatic leakage and ensuing secondary complications with safety and less invasiveness.

## APPENDIX I-VI Instructions to authors

## ABOUT COVER

Editorial Board Member of *World Journal of Gastroenterology*, Yeun-Jun Chung, MD, PhD, Professor, Director, Department of Microbiology, Integrated Research Center for Genome Polymorphism, The Catholic University Medical College, 505 Banpo-dong, Socho-gu, Seoul 137-701, South Korea

## AIMS AND SCOPE

*World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a peer-reviewed open access journal. *WJG* was established on October 1, 1995. It is published weekly on the 7<sup>th</sup>, 14<sup>th</sup>, 21<sup>st</sup>, and 28<sup>th</sup> each month. The *WJG* Editorial Board consists of 1352 experts in gastroenterology and hepatology from 64 countries.

The primary task of *WJG* is to rapidly publish high-quality original articles, reviews, and commentaries in the fields of gastroenterology, hepatology, gastrointestinal endoscopy, gastrointestinal surgery, hepatobiliary surgery, gastrointestinal oncology, gastrointestinal radiation oncology, gastrointestinal imaging, gastrointestinal interventional therapy, gastrointestinal infectious diseases, gastrointestinal pharmacology, gastrointestinal pathophysiology, gastrointestinal pathology, evidence-based medicine in gastroenterology, pancreatology, gastrointestinal laboratory medicine, gastrointestinal molecular biology, gastrointestinal immunology, gastrointestinal microbiology, gastrointestinal genetics, gastrointestinal translational medicine, gastrointestinal diagnostics, and gastrointestinal therapeutics. *WJG* is dedicated to become an influential and prestigious journal in gastroenterology and hepatology, to promote the development of above disciplines, and to improve the diagnostic and therapeutic skill and expertise of clinicians.

## INDEXING/ABSTRACTING

*World Journal of Gastroenterology* is now indexed in Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®), Journal Citation Reports®, Index Medicus, MEDLINE, PubMed, PubMed Central, Digital Object Identifier, and Directory of Open Access Journals. ISI, Journal Citation Reports®, Gastroenterology and Hepatology, 2012 Impact Factor: 2.547 (34/74); Total Cites: 19145 (6/74); Current Articles: 944 (1/74); and Eigenfactor® Score: 0.06035 (6/74).

### Abstract

The liver experiences various changes with aging that could affect clinical characteristics and outcomes in patients with liver diseases. Both liver volume and blood flow decrease significantly with age. These changes and decreased cytochrome P450 activity can affect drug metabolism, increasing susceptibility to drug-induced liver injury. Immune responses against pathogens or neoplastic cells are lower in the elderly, although these individuals may be predisposed to autoimmunity through impairment of dendritic cell maturation and reduction of regulatory T cells. These changes in immune functions could alter the pathogenesis of viral hepatitis and autoimmune liver diseases, as well as the development of hepatocellular carcinoma. Moreover, elderly patients have significantly decreased reserve functions of various organs, reducing their tolerability to treatments for liver diseases. Collectively, aged patients show various changes of the liver and other organs that could affect the clinical characteristics and management of liver diseases in these patients.

**Key words:** Liver disease; Aging; Physiology; Immunology

**Core tip:** The morphology and physiology of the liver changes with aging and an understanding of those changes is important for the management of liver diseases. We first summarized the various changes in the liver with aging. We then reviewed the reported characteristics of liver diseases found in the elderly. This kind of information could be increasingly important in the near future, because the proportion of the world's population over 60 years old is increasing, especially in developed countries.

Tajiri K, Shimizu Y. Liver physiology and liver diseases in the elderly. *World J Gastroenterol* 2013; 19(46): 8459-8467 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i46/8459.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i46.8459>

### INTRODUCTION

The proportion of the world's population over 60 years old is increasing, especially in developed countries. Morphology and functions of the liver as well as other organs change with aging. Understanding these changes is important for the management of liver diseases in the elderly. In addition, the pathogenesis of many liver diseases is immune-mediated, and immune systems also change with aging, affecting the clinical picture of liver diseases.

### CHANGES IN LIVER MORPHOLOGY AND FUNCTIONS WITH AGING

#### *Morphology of the aged liver and microscopic or molecular characteristics of senescent hepatocytes*

In general, liver volume is reduced by 20%-40% in the elderly, with these reductions more marked in women (up to 44% decline) than in men<sup>[1]</sup>. Microscopically, elderly subjects have elevated numbers of hepatocytes with increased ploidy. Hepatocytes show decreased numbers of

mitochondria but increased volume of individual mitochondria, although functional impairment of mitochondria has not been demonstrated. Hepatocytes in elderly subjects contain denser body compartments, such as secondary lysosomes and lipofuscin, than do hepatocytes in younger subjects<sup>[2]</sup>. Lipofuscin accumulation has been associated with chronic oxidative stress and a failure to degrade damaged and denatured proteins<sup>[3]</sup>. Moreover, accumulating evidence suggests that lipofuscin interferes with cellular pathways due to its ability to trap metallic cations and facilitate further free radical formation<sup>[4]</sup>.

Vacuolation of hepatocyte nuclei has been associated with diabetes mellitus and non-alcoholic fatty liver disease. However, vacuolated hepatocyte nuclei were recently shown to be more abundant in senescent hepatocytes expressing p21 or  $\gamma$ H(2)AX<sup>[5]</sup>, suggesting they are a marker of hepatocyte senescence. Moreover, increased size of hepatocyte nuclei in nonalcoholic fatty liver disease (NAFLD) has been associated with telomere shortening and p21 upregulation<sup>[6]</sup>, suggesting that increased nuclear size is also a marker of hepatocyte senescence.

Cellular senescence is associated with aberrant activation of oncogenes, and senescent pre-malignant hepatocytes have been found to secrete cytokines and chemokines through interactions with their environment, resulting in immune-mediated clearance of these cells. Impairment of immune surveillance has been associated with the development of hepatocellular carcinoma (HCC)<sup>[7]</sup>. This scenario could account for the preferential development of HCC in aged patients with chronic liver diseases, irrespective of the etiology of these diseases<sup>[8]</sup>.

Recently, resistin, an adipokine that inhibits phosphorylation of AMP-activated protein kinase and modulates insulin resistance, has been shown to induce senescence-associated  $\beta$ -galactosidase in mouse hepatocytes<sup>[9]</sup>. Resistin has been shown to act by inhibiting the function of sirtuin 1, one of the 7 members of the sirtuin family of histone deacetylases shown to act as crucial negative regulators during the aging process<sup>[9]</sup>.

Molecular changes during hepatocyte senescence should be clarified in more detail in the near future. The identification of senescence-causing factors may be beneficial in preventing senescence-associated liver diseases.

### Blood flow

Liver blood flow is estimated to be decreased by 35%-50% in the elderly, and may be responsible for age-related reductions in liver volume<sup>[10]</sup>.

### Hepatic function

**Liver function tests:** Although interindividual differences have been observed, liver functions are relatively well preserved in elderly individuals. Hepatic enzymes and high-density lipoprotein cholesterol are well maintained, while bilirubin levels may decline with age due to reductions in muscle mass and hemoglobin concentrations<sup>[11]</sup>. Moreover, age was reported to be associated with modest decreases in albumin and  $\gamma$ -glutamyl transpeptidase con-

centrations, and increases in bilirubin concentration, after adjustments for sex, alcohol use, and components of the metabolic syndrome, suggesting that liver function may be decreased in these individuals<sup>[12]</sup>.

Alanine aminotransferase (ALT) concentrations have been reported to decrease with age in both men and women, independent of components of the metabolic syndrome. These findings suggest the need to identify an optimal cut-off point for normal ALT in elderly patients<sup>[12]</sup>.

### Drug metabolism

Phase I hepatic metabolism (first-pass hepatic uptake) of drugs has been reported to be decreased in the elderly, possibly due to reduced liver volume and hepatic blood flow, leading to a decline in hepatic drug metabolism. Metabolism of drugs with low phase I hepatic metabolism is likely to be impaired mainly by liver volume reduction.

A previous report suggested that drug metabolism is reduced by up to 30% after 70 years of age, and that a reduction in liver cytochrome P450 may also contribute to decreased drug metabolism. Cytochrome P450 activity was shown to be 32% lower in subjects > 70 years than in subjects aged 20-29 years<sup>[13]</sup>.

### Liver regeneration

Liver regeneration capacity has been reported to decline with age<sup>[14,15]</sup>. The mechanisms underlying the reductions in regeneration capability are complex. One of these mechanisms involves a decrease in the concentrations of circulating epidermal growth factor (EGF), with the response of hepatocytes to EGF also reduced due to age-associated loss of EGF receptors or deficits in signaling after EGF binds to its receptor<sup>[16]</sup>. Another mechanism underlying reduced hepatocyte proliferation capacity may be the inhibition of cyclin-dependent kinases by interaction with the chromatin remodeling protein Bim, which is expressed in aged hepatocytes<sup>[17]</sup>. Along with reductions in regenerative capacity, telomere length has been reported reduced in aged livers, especially in patients with liver diseases<sup>[18]</sup>.

### Immune system

Many liver diseases are mediated by the host immune response. Therefore, changes in immune functions may affect the clinical picture of various liver diseases. Several changes in the immune system have been observed in elderly individuals.

**Innate immunity:** Most of the immune cells involved in innate immunity, such as monocytes/macrophages and natural killer (NK) cells, show decreased function with aging<sup>[19]</sup>. Although the percentage and number of CD56<sup>bright</sup> NK cells gradually decline with age, the percentage and number of CD56<sup>dim</sup> NK cells progressively increase<sup>[20]</sup>.

In addition, dendritic cells (DCs), which are the most potent antigen-presenting cells, show significant function-

al changes with aging. DCs play pivotal roles in the onset and regulation of adaptive immune responses and control the state of tolerance to self-antigens<sup>[21]</sup>. Immature DCs promote tolerance through induction of regulatory T cells (Treg), whereas mature DCs stimulate effector T cells. DCs in the elderly show inappropriate maturation induced by infections or tissue injury, which may lead to alterations in the balance between the tolerogenic and immunogenic functions of DCs and instigate the development of autoimmune diseases<sup>[22]</sup>.

**Adoptive immunity:** T cell number and diversity of repertoire are decreased and T cell expansion, differentiation, and signaling intensity are impaired with aging. The numbers of CD4<sup>+</sup> T cells are decreased, while the numbers of CD8<sup>+</sup> T cells are increased. The expression of the costimulatory molecule CD28 is decreased on T cells, impairing their ability to proliferate and secrete interleukin-2<sup>[23]</sup>. Treg function is decreased after age 50 years, which may be associated with the increases in autoimmunity<sup>[24]</sup>.

The numbers of B cell precursors in the bone marrow (pre-B cells), as well as peripheral B cells, decrease with age<sup>[25]</sup>. In contrast, immunoglobulin concentrations may increase with age<sup>[26]</sup>, but the quantities of specific antibodies and the diversity of the B cell repertoire decrease<sup>[27]</sup>.

In summary, immune responses against foreign antigens and malignant cells seem to be impaired with age because of the reductions in number and functions of most immunocompetent cells. In contrast, the decrease in Tregs and the impairment of DC maturation may result in a predisposition to autoimmunity.

## LIVER DISEASES IN THE ELDERLY

The prevalence of some liver diseases increases with aging, and advanced liver disease is observed more often in older than in younger patients. Moreover, various physiological changes associated with aging may affect the pathogenesis of liver diseases. In addition, the decreased reserve capacity of most organs in elderly individuals may impair their ability to manage liver diseases.

### Viral hepatitis

**Hepatitis A:** Acute hepatitis A virus (HAV) infection is usually self-limiting. However, elderly patients with acute HAV infection experience hepatocellular dysfunction with frequent jaundice and coagulopathy, as well as an increased incidence of complications, such as prolonged cholestasis, pancreatitis, and ascites<sup>[28]</sup>. Higher hospitalization and mortality rates have been reported in elderly patients with HAV. For example, during an outbreak of HAV infection in the United States, 42% of patients aged 70 years or older required hospitalization compared with 3%-20% of adults aged 40-49 years<sup>[29]</sup>. Age-related differences in outcomes were also reported, with death rates of 0.004% in individuals aged 5-14 years and 2.7%

in those older than 49 years<sup>[30]</sup>. More recent data from the Centers for Disease Control and Prevention (CDC, 2009 Surveillance) also indicate that mortality due to HAV increases with age, with no fatalities reported in patients younger than 34 years of age. The mortality rates have been estimated to be 0.05 per 100000 patients aged 45-54 years, and 0.11 per 100000 patients older than 75 years. Vaccination for hepatitis A should, therefore, be considered for people, especially the elderly, who plan to travel to endemic areas<sup>[30]</sup>.

**Hepatitis B:** Acute hepatitis B virus (HBV) infection is uncommon in the elderly because the opportunities for HBV infection are estimated to be low in this population. However, hepatitis B and hepatitis C infections have been reported in aged residents of nursing homes<sup>[31,32]</sup>. Risk factors include sharing bath brushes, non-disposable syringes, and shaving blades, as well as sexual contact. Clinical manifestations of acute HBV infection are similar to those in younger adults. During an outbreak of acute HBV in elderly nursing home residents, most infected patients were asymptomatic, and no patient died or required hospitalization during the outbreak<sup>[31]</sup>. However, the rate of progression to chronic hepatitis B is higher in elderly than in younger patients. A report on an outbreak of acute HBV infection in a nursing home showed that 59% of patients older than 65 years of age developed chronic infection<sup>[31]</sup>. This may be due to a decreased immune response to the pathogens.

In chronic HBV infection, the prevalence rates of HBeAg and HBsAg are inversely related to patient age during the natural course of HBV infection. The prevalence rates of HBsAg in Taiwanese men and of HBeAg among HBsAg-positive men older than 60 years of age were reported to be 12.5% and 5.5%, respectively, while prevalence rates in patients aged 30-39 years were 23.8% and 23.3%, respectively<sup>[33]</sup>. Serum HBV DNA levels were found to vary by country and to be associated with HBeAg or HBV genotype<sup>[34]</sup>. Older age and male sex, in addition to serum HBV DNA levels, are regarded as risk factors not only for progression to cirrhosis<sup>[35]</sup>, but the development of HCC<sup>[36]</sup>.

Nucleos(t)ide analogs are effective in treating HBV infected patients, with similar efficacy in the elderly as in younger patients<sup>[37]</sup>. Although interferon-based therapy may also be effective for the treatment of chronic HBV infection, its therapeutic effects are inferior in elderly patients<sup>[38]</sup>.

**Hepatitis C:** The prevalence of hepatitis C virus (HCV) infection varies by age because HCV infection is transmitted by blood contact, such as blood transfusion (especially before 1992), military service, intravenous drug use, tattoos, hemodialysis, and health care work. In the United States, the prevalence of HCV infection is highest in patients aged 40-49 years (4.3%), whereas those aged 60-69 years and 70 years or older have lower prevalence rates of 0.9% and 1%, respectively<sup>[39,40]</sup>. A European

study showed that the prevalence of genotype 1 HCV increases with age, being 57% in patients aged < 65 years, 72% in those aged 65–80 years, and 84% in patients older than 80 years of age<sup>[41]</sup>. Older age at the time of infection, but not duration of infection, has been associated with fibrotic progression<sup>[41]</sup> and hepatocarcinogenesis<sup>[42]</sup>. Normal ALT levels are more likely observed in elderly than in younger HCV-infected patients (46% *vs* 10.6%, respectively)<sup>[43]</sup>. However, older patients often show more fibrosis regardless of serum ALT levels<sup>[41]</sup>. Moreover, the incidence of hepatocellular carcinoma increases with aging both in hepatitis C<sup>[42]</sup> and hepatitis B<sup>[44]</sup> infected patients. Therefore, progression of fibrosis and development of hepatocellular carcinoma should be considered, especially in elderly patients with chronic viral hepatitis.

Powerful regimens have been established for the treatment of chronic HCV infection, including pegylated interferon and ribavirin, have been established. However, adverse effects are observed more often in older patients<sup>[45]</sup>. The sustained viral response rate has been shown lower in elderly than in younger patients (46% *vs* 69.7%, respectively), perhaps due to the high proportion of elderly patients who stop antiviral therapy due to side effects<sup>[46]</sup>.

**Hepatitis E:** The prevalence of hepatitis E virus (HEV) infection differs markedly in endemic and non-endemic areas. However, recent reports suggested that exposure to HEV occurs frequently in Western countries. In the United States, 16% of blood donors younger than 60 years of age were positive for anti-HEV IgG, compared with 25.5% of those older than 60 years<sup>[47]</sup>. Furthermore, 3% of patients with acute liver injury suspected of being drug-induced liver injury were seropositive for anti-HEV IgM. Most patients with serology consistent with acute HEV infection were older than 60 years of age<sup>[48]</sup>.

### Autoimmune liver disease

The prevalence rates of autoimmune liver diseases, including autoimmune hepatitis (AIH) and primary biliary cirrhosis (PBC), are relatively high in older patients, whereas primary sclerosing cholangitis is more common in those in the third or fourth decade of life<sup>[49–51]</sup>. However, the results of laboratory tests associated with these autoimmune liver diseases are not associated with age, and treatment strategies are usually identical in older and younger patients.

**AIH:** Almost 20% of patients develop AIH after 60 years of age, and the disease is frequently progressive and unexpected because ascites and cirrhosis are common manifestations at presentation with few other symptoms<sup>[49,52,53]</sup>. Most elderly patients respond well to corticosteroid therapy<sup>[52]</sup>. Rates of treatment failure are lower in older than in younger patients (5% *vs* 24%), and elderly patients have lower rates of fatality from liver failure or need for liver transplantation (5% *vs* 21%)<sup>[52,53]</sup>. Notably,

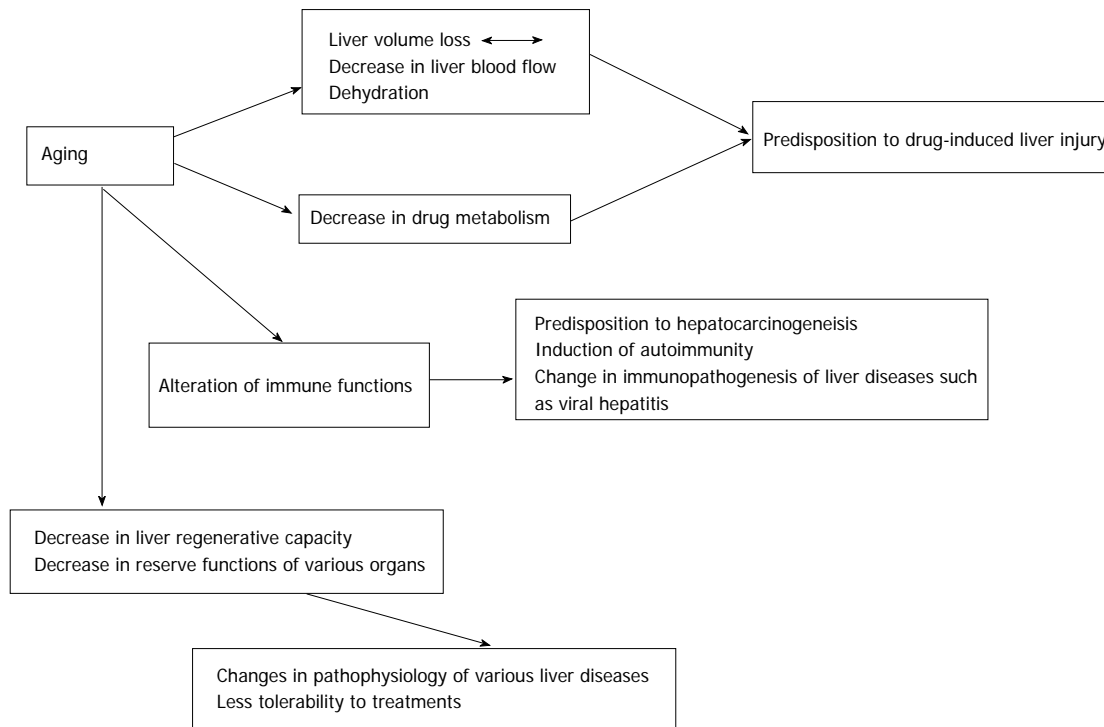

elderly patients are at risk of treatment-related complications, especially osteopenia and compression fracture<sup>[54]</sup>. Furthermore, they may have other comorbidities and medication requirements that complicate their management.
