## APPENDIX I-VI Instructions to authors

**ABOUT COVER** Editorial Board Member of *World Journal of Gastroenterology*, Alessandro Grasso, MD, Gastroenterology Unit, Department of Internal Medicine, San Paolo Hospital, Via Genova 38, 17100 Savona, Italy

**AIMS AND SCOPE** *World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a peer-reviewed open access journal. *WJG* was established on October 1, 1995. It is published weekly on the 7<sup>th</sup>, 14<sup>th</sup>, 21<sup>st</sup>, and 28<sup>th</sup> each month. The *WJG* Editorial Board consists of 1352 experts in gastroenterology and hepatology from 64 countries.

The primary task of *WJG* is to rapidly publish high-quality original articles, reviews, and commentaries in the fields of gastroenterology, hepatology, gastrointestinal endoscopy, gastrointestinal surgery, hepatobiliary surgery, gastrointestinal oncology, gastrointestinal radiation oncology, gastrointestinal imaging, gastrointestinal interventional therapy, gastrointestinal infectious diseases, gastrointestinal pharmacology, gastrointestinal pathophysiology, gastrointestinal pathology, evidence-based medicine in gastroenterology, pancreatology, gastrointestinal laboratory medicine, gastrointestinal molecular biology, gastrointestinal immunology, gastrointestinal microbiology, gastrointestinal genetics, gastrointestinal translational medicine, gastrointestinal diagnostics, and gastrointestinal therapeutics. *WJG* is dedicated to become an influential and prestigious journal in gastroenterology and hepatology, to promote the development of above disciplines, and to improve the diagnostic and therapeutic skill and expertise of clinicians.

**INDEXING/ABSTRACTING** *World Journal of Gastroenterology* is now indexed in Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®), Journal Citation Reports®, Index Medicus, MEDLINE, PubMed, PubMed Central, Digital Object Identifier, and Directory of Open Access Journals. ISI, Journal Citation Reports®, Gastroenterology and Hepatology, 2012 Impact Factor: 2.547 (34/74); Total Cites: 19145 (6/74); Current Articles: 944 (1/74); and Eigenfactor® Score: 0.06035 (6/74).

### Abstract

The high rate of sustained viral response (SVR) to boceprevir or telaprevir-based triple therapy in hepatitis C (HCV)-related, non-cirrhotic naïve patients or relapsers to previous antiviral treatment leads clinicians to believe that the impact of metabolic host factors on SVR is minimal when triple therapy is used, unlike what is observed with the peginterferon and ribavirin schedules. This concept is strongly expressed by some opinion leaders on the basis of the data derived from sub-analyses of registrative trials as well as from a post-hoc analysis of the phase II C208 clinical trial. The perception of unrestrainable therapeutic success with the use of newer, more powerful antivirals is now reinforced by the brilliant results obtained with sofosbuvir, an HCV NS5B polymerase inhibitor, as well as by the data from the phase II and III studies on the various combinations of second-generation NS3/4A inhibitors and NS5A and/or NS5B inhibitors. However, a great deal of concern has emerged from the real world scenario in which patients are often older and have more comorbidities than patients in the "world of trials". Furthermore, many of them have advanced fibrosis and previous failure with peginterferon and ribavirin treatment. Some

data from the recent literature suggest that the host metabolic factors may play a minor but non-negligible role in these difficult-to-treat patients, an issue that will hopefully be investigated in further studies. This editorial aims to provide a detailed analysis of the role that host metabolic factors played in the past and what role they may play in the era of direct antiviral agents.

© 2013 Baishideng Publishing Group Co., Limited. All rights reserved.

**Key words:** Metabolic factors; Insulin resistance; Direct antiviral agents; Chronic hepatitis C

**Core tip:** This editorial explores the past and present role of metabolic factors by analyzing the data that has emerged from the post hoc analysis of registrative trials of direct antiviral-based treatment. Low-density lipoprotein-cholesterol and statin use proved to be predictors of sustained viral response (SVR) in both boceprevir and telaprevir-treated patients, respectively. Furthermore, HOMA-IR negatively influenced SVR in prior partial and null responders treated with telaprevir-based schedules. By transferring these data to the real world scenario in which patients have comorbidities, advanced fibrosis and prior failure to antiviral treatment, we believe that metabolic factors might play a non-negligible role in influencing antiviral response, even in triple therapy.

Grasso A, Malfatti F, Testa R. Are metabolic factors still important in the era of direct antiviral agents in patients with chronic hepatitis C? *World J Gastroenterol* 2013; 19(41): 6947-6956 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i41/6947.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i41.6947>

### INTRODUCTION

More than 170 million people are chronically infected

with the hepatitis C virus (HCV) worldwide<sup>[1]</sup>, thus HCV has become the main cause of chronic liver disease leading to death from liver failure or hepatocellular carcinoma (HCC) in many Western countries and in Japan<sup>[2]</sup>. Viral eradication resulting from antiviral treatment has led to a decrease in these complications. However, treatment with pegylated interferon and ribavirin, which has been the standard-of-care therapy for chronic hepatitis C for the last decade, has been able to cure only about 40%-50% of patients with hepatitis C genotype 1, the main strain in Europe and the United States<sup>[3-6]</sup>.

Genotype 1 is the main viral-related variable associated with treatment failure<sup>[3,4]</sup>. However, a number of other pretreatment variables related to the virus (high viral load) and to the host (interleukin 28b polymorphism, age, overweight, metabolic factors), as well as on-treatment variables (4-wk negativization of viral load) have been shown to affect the response to anti-viral dual therapy<sup>[7-10]</sup>.

## HCV INFECTION AND METABOLIC SEQUELAE: WHAT WE LEARNED FROM THE PAST

### Insulin resistance

Epidemiological data suggest that HCV interferes with glucose and lipid metabolism. Patients with diabetes show a greater prevalence of HCV as compared to the non-diabetic population<sup>[11]</sup>. Moreover, the prevalence of diabetes is significantly higher in chronic hepatitis C patients than in those with chronic liver disease other than HCV<sup>[12]</sup>. Furthermore, it is well known that HCV infection is an independent risk factor for developing diabetes<sup>[13]</sup>. These data suggest that HCV, rather than liver disease *per se*, predisposes patients to diabetes. The link between HCV and diabetes is the development of insulin resistance (IR), a metabolic prerogative of HCV (*i.e.*, IR is more than six fold higher in HCV patients than in those with HBV)<sup>[14]</sup>. IR, hepatic steatosis and body mass index (BMI) are related in a genotype-dependent fashion. In fact, HCV genotype 3 exerts a direct cytopathic and steatogenic effect on hepatocytes, thus resulting in a higher prevalence of steatosis and a lower prevalence of IR compared with HCV genotype 1, which very quickly induces IR and some steatosis<sup>[15-17]</sup>. IR occurs very early in transgenic mice expressing the HCV core protein and may even precede the occurrence of hepatic steatosis, thus indicating that IR is not a consequence of hepatic steatosis<sup>[18]</sup>, similarly to what is observed in humans<sup>[17]</sup>. Furthermore, IR is a pro fibro genetic stimulus<sup>[17]</sup>, thus patients with high IR show more advanced liver fibrosis than patients with low IR<sup>[19]</sup>. Finally, the association between IR and high HCV RNA levels<sup>[14]</sup> suggests a complex interplay between viral replication and insulin action. HCV may induce over-expression of the suppressor of the cytokine signaling-3 (SOCS3) gene in liver tissue. This gene is involved in the interferon signaling pathway and

is associated with poorer treatment outcome<sup>[20,21]</sup>. HCV core-induced SOCS3 may promote proteosomal degradation of the insulin receptor substrates 1 and 2 (IRS1/2), thus inducing severe hepatic IR<sup>[22,23]</sup>. Both SOCS3 over-expression and hepatic steatosis promote intra-hepatic and systemic lipid oxidation, thus leading to an imbalance of total glucose disposal in the muscles and resulting in peripheral (and not only hepatic) IR<sup>[24]</sup>.

Direct involvement of HCV in glucose metabolism has also been demonstrated "*in vivo*". In fact, there is robust evidence showing that IR improved significantly in patients with HCV genotype 1 who achieved SVR compared with patients who did not obtain viral clearance after treatment<sup>[25,26]</sup>. Furthermore, achieving viral clearance is demonstrated to significantly reduce the risk of both type 2 diabetes in retrospective cohorts<sup>[27]</sup> and of de novo IR in non-diabetic HCV patients<sup>[28]</sup>.

### Lipids

Hepatic steatosis is also related, in a genotype-specific manner<sup>[29]</sup>, to a decrease in serum levels of total cholesterol, low-density lipoprotein cholesterol (LDL-C) and apolipoprotein B (apoB), thus demonstrating the close link between HCV and lipids. A variable fraction of HCV in the serum circulates in lipo viro particles (LVP), with very-low-density-lipoprotein (VLDL) containing apoB and apoE. LVP reach the highest levels in the post prandial phase, suggesting that their formation is a dynamic process<sup>[30]</sup>. Very recently, a strong correlation between the maximum amount of LVP *in vivo* and both IR and metabolic syndrome was reported, suggesting that lipids may play a role in HCV-induced IR<sup>[31]</sup>. ApoE is considered the central component of the HCV-host lipid interaction, mediating HCV infectivity *via* lipoprotein receptors<sup>[32]</sup>. Lipoproteins (LP) are easily endocytosed, thus supporting the hypothesis that HCV can use this association with LP to adhere to the cell and subsequently enter the host cell by endocytosis<sup>[33]</sup>. Various cell surface receptors, including tetraspanin CD814, scavenger receptor class B member I, tight-junction proteins claudin-1 and occludin, and clathrin-mediated endocytosis have been proposed as entry factors for HCV, but the role each of them plays remains controversial. Recently, the Niemann-Pick type C1-like 1 (NPC1L1) gene receptor has come to the attention of researchers in the view of a potentially new therapeutic antiviral strategy since it is the possible target of the receptor-blocker drug ezetimibe<sup>[34,35]</sup>.

Few and inconsistent data have been reported on serum lipid level modifications during interferon therapy. Increased total cholesterol and triglyceride levels have been observed with interferon treatment, with a subsequent drop to pretreatment levels of both after discontinuing therapy, but with different trends depending on the HCV genotype<sup>[36,37]</sup>. In a small population of patients with genotype 2 and 3, viral clearance induced serum level modifications of lanosterol, a cholesterol precursor, suggesting a direct viral interference with the enzymes of sterol synthesis<sup>[29]</sup>.

### ***The effects of IR on antiviral response to dual treatment***

Patients with high IR show a slower decay of HCV viral load than patients with low IR, even in the very early phase of treatment (first 24 h), suggesting that hyperinsulinemia reduces the cellular response to pegylated-interferon<sup>[38]</sup>. Furthermore, high IR has been associated with a low rate of rapid viral response (RVR) in genotypes 1<sup>[39]</sup>, 3<sup>[40]</sup> and 4<sup>[41]</sup>.

Whether or not IR influences SVR rate has been a question of debate since 2005<sup>[9]</sup>. Two meta-analyses assessing the impact of IR on treatment outcome, both of which included fourteen studies with more than 2700 patients, were published in 2011<sup>[42,43]</sup>. However, among the studies which failed to find an association between IR and SVR, the main baseline HOMA value, an indirect measurement of IR<sup>[44,45]</sup>, was < 3 and the prevalence of advanced fibrosis or cirrhosis was also low or even absent<sup>[42]</sup>. This observation supports the hypothesis that the HOMA value is predictive of response to antiviral treatment mainly in patients with advanced disease stage. Liver fibrosis is an event which may occur as a consequence of HCV-related chronic necroinflammatory activity or via HCV related IR, or probably both. However, non-HCV related IR (genetic, or related to true metabolic syndrome) may also occur since almost 25% of the general population has the metabolic syndrome stigmata<sup>[46]</sup>. On the basis of these data, we can assume that a proportion of patients with prevalent virus-related IR (likely those with lower fibrosis as well as a lower incidence of cardio-metabolic comorbidities) have lower HOMA values and a higher likelihood of SVR after antiviral treatment, whereas other HCV patients with prevalent metabolic IR (likely those with the phenotype of metabolic syndrome) have a higher probability of advanced fibrosis as well as higher HOMA levels and a lower probability of achieving SVR<sup>[28,42,47]</sup>.

### ***The effects of obesity and lipids on antiviral response to dual treatment***

Obesity is another important metabolic cofactor that can affect antiviral response. It may induce IR and hepatic steatosis, both of which are associated with poor antiviral response either directly or by ultimately promoting liver fibrosis. However, it has been demonstrated that obesity is an independent negative predictor of response to antiviral treatment regardless of genotype and cirrhosis<sup>[7]</sup>.

Obesity is now considered an inflammatory condition, resulting in an abnormal immune response to therapy. Adipose tissue secretes many proteins, including adipokines, which regulate hepatic and peripheral glucose and lipid metabolism. One of the adipokines secreted by adipose cells is leptin, whose expression is regulated by interleukin-1 (IL-1), tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) and insulin. Although leptin secretion from adipocytes provides antiobesity signals, obese patients have elevated levels of leptin. This suggests an intrinsic leptin resistance in the obese, a complex phenomenon involving increased levels of SOCS3, which impairs post-receptor signaling

and leads to reduced adenosine monophosphate-activated protein kinase (AMPK) activation<sup>[48,49]</sup>.

Increased SOCS3 expression, which is associated with nonresponse to antiviral treatment<sup>[20]</sup>, has been demonstrated to be independently associated with obesity in patients with chronic HCV viral genotype 1<sup>[50]</sup>.

Regarding the role of circulating lipid levels on the efficacy of antiviral treatment, there are few, but concordant, data. Higher pretreatment total cholesterol and LDL-C<sup>[51,52]</sup>, as well as lower triglyceride levels are independent variables associated with higher SVR rates<sup>[53]</sup>.

### ***The interplay of Interleukin 28b polymorphisms and metabolic variables***

The relationship between IL28b polymorphisms and metabolic variables has been reported in several studies, thus emerging as a new and challenging issue. There is a close association between IL28b and lipid levels. In HCV genotype 1 patients, low apoE levels and higher LDL-C were associated with IL28b rs12979860 CC rather than CT/TT<sup>[54,55]</sup>. Both IL28CC and LDL-C were good predictors of SVR, but the predictive power of IL28CC was higher. Thus, the LDL-C level was found to be a significant predictor of SVR, mainly for IL28 heterozygous CT patients<sup>[56]</sup>.

Furthermore, lower steatosis<sup>[57]</sup> as well as lower IR<sup>[58]</sup> have been seen in genotype 1 patients with IL28b rs12979860 CC. In a recent, large cohort of genotype 1 patients from Italy, IL28b rs12979860 CC was associated with higher levels of total and LDL-C, lower levels of triglycerides, lower prevalence of IR and moderate-to-severe steatosis. However, only IR and steatosis were associated with IL28b rs12979860 CC after correcting for BMI and lipid profile, suggesting an indirect role of LDL-C status on IL28b polymorphism<sup>[58]</sup>. IR was found to have a predictive power for SVR which is independent of IL28 genotype<sup>[59]</sup>, although the likelihood of achieving SVR progressively increases from the lowest probability in patients carrying both negative predictors (IR and rs12979860 TT/TC; SVR = 20.7%) to the highest probability in patients with no IR and rs12979860 CC (SVR = 78.4%)<sup>[58]</sup>. These data give rise once again to the thorny question concerning the intimate pathogenetic interplay between metabolic and genetic host factors.

### ***Can pretreatment correction of the metabolic co-factor improve SVR to dual treatment?***

One of the most intriguing and challenging tasks was to transfer the information regarding the predictive power of a metabolic variable for SVR to a practical ground. This gave rise to a series of studies aimed at improving SVR by correcting the metabolic factors before or during antiviral treatment.

Some studies with very small cohorts have explored the effect of a lifestyle intervention in obese and insulin-resistant subjects with chronic hepatitis C. BMI, HOMA values and leptin levels, but not TNF- $\alpha$  and IL-6, decreased significantly after aerobic exercise<sup>[60]</sup>. A more

structured intervention based on 24-wk dietary and physical activity regimens significantly reduced BMI and HOMA values<sup>[61]</sup> and could be an interesting baseline strategy in difficult-to-treat chronic hepatitis C patients who are obese and insulin-resistant prior to starting peginterferon and ribavirin. However, to date, no studies have demonstrated the efficacy of this strategy. Tarantino *et al.*<sup>[62]</sup> demonstrated that a low-calorie diet for 3 mo before starting antiviral therapy in patients with genotype 1-chronic hepatitis C resulted in a significant improvement in IR as well as a 60% “end-of-treatment” response rate in the low-calorie diet group as compared to the control group (17.6%).

More data have been reported on insulin sensitizing agents used in combination with peginterferon and ribavirin. The randomized, double-blind TRIC-1 trial by Romero-Gómez *et al.*<sup>[63]</sup> analyzed 125 naive genotype 1 patients treated with peginterferon alpha-2a and ribavirin plus metformin or placebo on an intention-to-treat basis. Their final results showed that there was a significant decrease in both HOMA value and viral load during the first 12 wk, as well as an improvement in SVR rate in the metformin group as compared with the placebo group, but only in females<sup>[63]</sup>. While metformin failed to improve overall SVR, conflicting results have been obtained with other insulin sensitizing agents, mainly pioglitazone. Although comforting results have been obtained in genotype 4<sup>[64]</sup>, no improvement in SVR was observed by adding pioglitazone (30 mg/d) to peginterferon and ribavirin as compared with the standard of care of dual therapy<sup>[65,66]</sup>. Similar negative results have been shown by Harrison *et al.*<sup>[67]</sup> in a randomized controlled trial which compared pioglitazone plus standard of care *vs* standard of care alone. This study definitively demonstrated that even when pioglitazone was administered at an appropriate dose (45 mg/d), it failed to improve SVR, regardless of administration timing (*i.e.*, prior to starting the standard of care or during the peginterferon and ribavirin course)<sup>[67]</sup>.

## ADVENT OF DIRECT ANTIVIRAL AGENTS AND THE NEW SCENARIO

In recent years, several antiviral drugs that directly target HCV have been developed. These new drugs, known as direct-acting antiviral agents (DAAs), are designed to interfere directly with the HCV life cycle by inhibiting enzymes such as HCV NS3/4A protease and HCV NS5B polymerase, or other proteins such as NS5A. Two NS3/4A protease inhibitors, boceprevir and telaprevir, have become the first new drugs approved for the treatment of patients with genotype 1 HCV who have either not previously received treatment or who failed to achieve SVR with previous therapy<sup>[68]</sup>. These new drugs, however, must be given with peginterferon and ribavirin because of their low barrier to viral resistance when they are used as monotherapy, and this may limit efficacy. A further limitation is due to overall side effects resulting in

higher discontinuation rates. However, when candidates for this treatment are carefully selected, the overall SVR rates can almost double in naive and even triple in relapsers to previous double therapy<sup>[69-75]</sup>. Thus, triple therapy is the new standard treatment for HCV genotype 1 chronic liver disease.

One of the questions under debate is whether the predictors of treatment failure that are observed when using dual therapy in HCV genotype 1 also exert a negative influence in triple therapy.

### What we know about metabolic factors and triple therapy

Among the variables which have shown predictive power for SVR in dual therapy, some of them, such as IL28b polymorphism, fibrosis and the 4-wk viral response in both naive or previously treated patients, have also been highlighted in triple therapy on the basis of data emerging from registrative trials. Metabolic factors seem to play either no role at all, or only a minor one in influencing SVR in the context of triple treatment. However, some considerations have to be made when looking carefully at the post-hoc analysis of landmark phase-III trials.

In the boceprevir-based SPRINT-2 trial, two metabolic variables were associated with SVR, but only statin use proved to be an independent predictor of SVR (OR = 3.4; 95%CI: 1.1-10.7; *P* = 0.04), whereas BMI was not retained in the multivariate model after adjustment for other variables<sup>[72]</sup>.

In RESPOND-2, a boceprevir-based trial focusing on previously treated patients, both the response-guided treatment (RGT) group and the 48-wk triple treatment group had a significantly higher SVR rate compared with dual treatment. However, in obese patients (BMI ≥ 30), a 10% lower SVR rate was observed in the RGT group compared with the 48-wk triple treatment group (56% *vs* 65%)<sup>[73]</sup>.

A sub-analysis of baseline predictors in the SPRINT-2 and RESPOND-2 trials showed that a BMI ≤ 30 was significantly associated with SVR and with a ≥ 1 log10 HCV-RNA decline at week 4 in untreated patients but not in patients previously treated with peginterferon and ribavirin<sup>[76]</sup>.

In the two telaprevir-based studies carried out on untreated patients, both ADVANCE<sup>[77]</sup> and ILLUMINATE<sup>[75]</sup> showed a higher SVR rate in the RGT arms compared with the double treatment arm, regardless of diabetes and obesity. In the ADVANCE study, although a 30% greater improvement in the SVR rate of patients receiving telaprevir for 12 wk was achieved in all 3 BMI groups (< 25, 25-30 and > 30) as compared to the control group, a 12%-16% lower SVR rate was observed in overweight and obese patients compared to normal weight patients.

An important contribution was provided by Serfaty *et al.*<sup>[78]</sup> in their post-hoc analysis of the phase II C208 clinical trial<sup>[79]</sup>. In this study, which is the first to focus on the influence of baseline metabolic variables on SVR

in patients treated with triple therapy, only LDL-C was associated with SVR (even in multivariate analysis), thus confirming its predictive role for SVR even in the telaprevir-based triple regimen and not only in dual therapy. However, this is not the case for baseline IR measured by the HOMA index, which did not show any relationship with SVR. Furthermore, the HOMA index did not influence the 4-wk HCV RNA decline, nor were the rates of HCV RNA undetectability at week 4 found to differ among patients with or without IR. However, this is not surprising since baseline HOMA values were not found to be associated with SVR in many European studies in which the study population had a low prevalence of advanced fibrosis and a relatively low BMI<sup>[39,40,80,81]</sup>. This may suggest that a higher prevalence of “viral” IR, which can easily be counteracted by antivirals, actually does exist in this population of patients. The significant association between HCV RNA and HOMA values in the study of Serfaty *et al.*<sup>[78]</sup>, as well as the improvement of HOMA in patients who achieved SVR compared with those who did not, further confirm the direct “*in vivo*” involvement of HCV in IR pathways. On the other hand, a powerful, combined effect on suppressing HCV viremia and rapidly lowering IR was previously observed using a 14-d course of danoprevir monotherapy, *i.e.*, another powerful, selective inhibitor of NS3/4A HCV serine protease. Interestingly, overweight patients had a greater decrease in HOMA values than patients with normal BMI, despite a similar decrease in serum HCV RNA, suggesting a complex interplay between these two variables. The authors hypothesize an anti-inflammatory or insulin sensitizing effect of danoprevir<sup>[82]</sup>.

Other important data concerning IR were obtained from a post-hoc analysis of the REALIZE phase III study which was carried out to assess the impact of IR on virological response to a telaprevir-based regimen in previously treated patients. Baseline HOMA values were found to be associated with SVR at univariate analysis (TVR: OR = 0.76; 95%CI: 0.60-0.96) but not after adjustment for other baseline prognostic factors (TVR: OR = 0.95; 95%CI: 0.71-1.29)<sup>[83]</sup>. SVR decreased as HOMA values increased, both in the control group and in the pooled T12-PR48 group where, however, this trend was observed only in prior partial and null responders, but not in prior relapsers.

In summary, on the basis of all these data we can say that LDL-C and statin use proved to be predictors of SVR in telaprevir and boceprevir-treated patients, respectively. Obesity may negatively influence rapid virologic decline as well as SVR in previously naive patients treated with a boceprevir-based regimen. To the best of our knowledge, no sub-analysis regarding the impact of obesity on SVR has ever been carried out for telaprevir. No data on HOMA are available for boceprevir. HOMA values were reported as being univariately associated with SVR in a telaprevir-based trial on previously treated patients. In naive patients treated with a telaprevir-based regimen, the HOMA value

was not a predictor of SVR, nor was it found to be associated with rapid virological response.

However, some comments have to be made. First, we have no data on the real weight of baseline metabolic factors in patients with less favorable probability of response, such as those with advanced fibrosis and/or non-CC IL28b. It is reasonable to suppose that in patients with advanced fibrosis or cirrhosis, as well as in prior partial or null responders to dual therapy and in whom non-CC IL28b is highly prevalent, metabolic IR, metabolic syndrome and obesity may be significant cofactors of nonresponse to triple therapy. Hopefully, this will be an issue for further studies. Secondly, in a real world setting we have to face a change in the epidemiology of candidates to triple therapy compared with the “world of trials”. In the “real world scenario” we have to expect a higher prevalence of patients over 65 years of age who have often previously been treated with dual therapy and have a higher prevalence of comorbidities, including hypertension, dyslipidemia and diabetes. In this context, many patients might experience either a worsening in the sensitivity to interferon as well as a higher probability of side effects when a protease-inhibitor is added to therapy.

These points seem to have been taken into consideration by United Kingdom consensus guidelines for the use of protease inhibitors in the treatment of HCV genotype 1 infected patients. These guidelines recommend evaluating the presence of factors predictive of poor response to therapy, such as BMI and type 2 diabetes among others<sup>[84]</sup>.

Currently, an enormous effort is being made by researchers and companies to provide physicians with new and more powerful drugs with a high genetic barrier and able to work on several HCV genotypes. Recently, phase II and III studies on sofosbuvir, a new nucleotide analogue HCV NS5B polymerase inhibitor used in combination with peginterferon and ribavirin in genotypes 1, 4, 5 and 6 or in combination with ribavirin in genotypes 2 and 3, showed a high rate of SVR, up to 90% in untreated genotype 1 patients after a 12-wk regimen, with no additional side effects to those occurring with peginterferon and ribavirin<sup>[85-87]</sup>.

New combinations of drugs with interferon-free schedules are under evaluation in phase II or III studies<sup>[88-91]</sup>. Hopefully, by the end of the decade the holy grail of a pangenotypic oral association of highly powerful drugs will be able to cure virtually all patients. In this scenario, the role of predictors of SVR will rapidly fade, but we have to keep in mind that in the short amount of time that separates us from the availability of new and more powerful treatment schedules, many patients will have to be treated with boceprevir and telaprevir-based triple therapy. Furthermore, many patients around the world have no, or only limited access to DAAs. With this in mind, SVR predictors remain important tools that are available to us in order to assign patients to the best treatment schedules.

## CONCLUSION

Baseline metabolic factors seem to have a minor, though likely not negligible, role in influencing antiviral response to direct antiviral agent-based treatment in patients with genotype 1 chronic hepatitis C. Further studies aimed at clarifying their role in a subpopulation of unfavorable candidates to this treatment, such as patients with advanced fibrosis or prior partial or null responders to peginterferon and ribavirin, are needed.

## Abstract

It has been suggested that hepatitis C virus (HCV) is selectively transmitted to a new host as an infectious clone from multiple HCV variants (quasispecies) in the donor. Most individuals with HCV infection develop chronic hepatitis, but approximately 15%-40% of them clear the virus spontaneously and the hepatitis is resolved in a self-limiting manner in the acute phase of infection. This difference in the outcome of acute hepatitis C is attributable to both viral characteristics and genetic regulation of infection. In particular, the evolutionary dynamics of the infecting virus and host genetic polymorphisms pertaining mainly to the immune system, including polymorphisms in the region of the Interleukin 28B gene encoding interferon- $\lambda$ -3, are associated with susceptibility to HCV infection.

**Core tip:** Most individuals with hepatitis C virus (HCV)

infection develop chronic hepatitis, but in some the hepatitis is resolved in a self-limiting manner in the acute phase of infection. What factors are responsible for this difference in the outcome of hepatitis C? The evolutionary dynamics of the infecting virus and host genetic polymorphisms pertaining mainly to the immune system, including the Interleukin 28B gene, as well as susceptibility to HCV infection, are important in determining the outcome of infection.

## INTRODUCTION

Hepatitis C virus (HCV) infection is a major threat to public health, and about 170 million people are estimated to be infected worldwide with a potential risk of progression to cirrhosis and hepatocellular carcinoma<sup>[1,2]</sup>. This review summarizes the two current topics of HCV study: the transmission mode of HCV with multiple variants (quasispecies) and the factors associated with susceptibility to HCV infection, with special reference to viral characteristics and host genetic variation.

## MODE OF HCV TRANSMISSION: HOW IS HCV WITH MULTIPLE VARIANTS TRANSMITTED?

HCV shows significant genetic heterogeneity among isolates, and the degree of variability is unevenly distributed throughout the viral genome: some regions are conserved and some are highly variable<sup>[3]</sup>. In particular, the hyper-

variable region 1 (HVR1) of the *HCV* E2 gene encoding a putative envelope glycoprotein mutates at a high rate, resulting in a wide spectrum of mutants referred to as “quasispecies” during infection<sup>[4,5]</sup>. Some virions may contain defective RNA genomes, which also affect the infectivity and replicability of the virus<sup>[6]</sup>. The mixture of clones present determines the biological and immunological properties of the virus.

How is HCV with multiple variants (quasispecies) transmitted to the new host? Does the status of transmitted HCV consist of multiple clones or a selected single clone? The transmission mode of HCV has been investigated by sequencing of the recovered viral genome from both donor and recipient<sup>[7,8]</sup>. HCV infection in human communities has occurred sporadically because no effective neutralizing vaccine against HCV has been developed. In particular, HCV infection in health-care workers through exposure to patient's blood due to a needle stick accident or accidental droplet transmission is a serious problem<sup>[9-12]</sup>. We previously reported a case of HCV infection resulting from a needle stick accident, and had an opportunity to investigate how HCV variants from the donor are transmitted to the recipient by comparing the HCV HVR1 genome encoding the envelope E2 protein recovered from the serum of both the donor and recipient<sup>[7]</sup>. In this case, we had observed the recipient before the onset of hepatitis and collected serum samples after obtaining informed consent. Thus, we were able to compare the HCV HVR1 genome between the donor's HCV at inoculation and the recipient's HCV just after onset of viremia. Interestingly, a minor subset of the donor's HCV clones was selectively transmitted to the recipient, and this selection determined the predominant clone in the new host. Several clones that appeared to stem from the recipient's predominant clone had one amino acid change within the HVR1 region during this short period. This particular case progressed to chronic hepatitis, and the same phenomenon has been demonstrated in the case of acute, self-limiting hepatitis<sup>[8]</sup>. These data suggest that a minor clone of the donor's HCV is transmitted and adapts to the new host. The precise mechanism of this viral selection in the initial phase of transmission has not been elucidated.

The simplicity of the transmitted viral strain in the initial phase of infection may explain some of the important clinical manifestations. Anti-viral therapy using interferon elicits a favorable response in the acute phase of HCV infection<sup>[13-16]</sup>. In addition, if a single strain is transmitted selectively in the initial phase of infection, this specific strain may be one of the factors determining disease activity. In fact, a study using a model of HCV transmission has demonstrated that a specific HCV strain recovered from a patient with fulminant hepatitis caused unusually severe hepatitis in a chimpanzee to which it was transmitted<sup>[17]</sup>. At present, the specific strain of HCV responsible for progressive liver disease cannot be discriminated from viral quasispecies in contaminated blood. Further investigation would be useful for clarifying the

specific viral strain responsible for the disease, and such efforts would be important for planning future strategies for the development of an effective therapeutic vaccine.

## SELF-LIMITING HEPATITIS OR CHRONIC HEPATITIS? HOW IS SUSCEPTIBILITY TO HCV DETERMINED?

### *The spontaneous clearance rate of HCV in the acute phase of infection*

Most individuals with HCV infection fail to clear the virus and develop chronic hepatitis with a risk of progression to cirrhosis and hepatocellular carcinoma. However, a small proportion of individuals are known to show resolution of the infection in a self-limiting manner. The rate of spontaneous viral clearance in acute HCV infection is reported to be approximately 15%-40% of all HCV-infected individuals<sup>[18-20]</sup>. Although differences in study populations such as race may influence the clearance rate in each cohort, a systematic review of 31 studies has estimated this rate to be 26%<sup>[20]</sup>. We have previously reported a Japanese population-based cohort study of the natural history of HCV infection in an area where community-acquired acute hepatitis C is endemic; here, the spontaneous viral clearance rate was estimated to be approximately 20%<sup>[21,22]</sup>. What is the difference between self-limiting resolution of hepatitis and progression to chronic hepatitis? Comparative studies of this issue have focused on both viral characteristics and genetic regulation.

### *Viral characteristics influencing the outcome of acute hepatitis C*

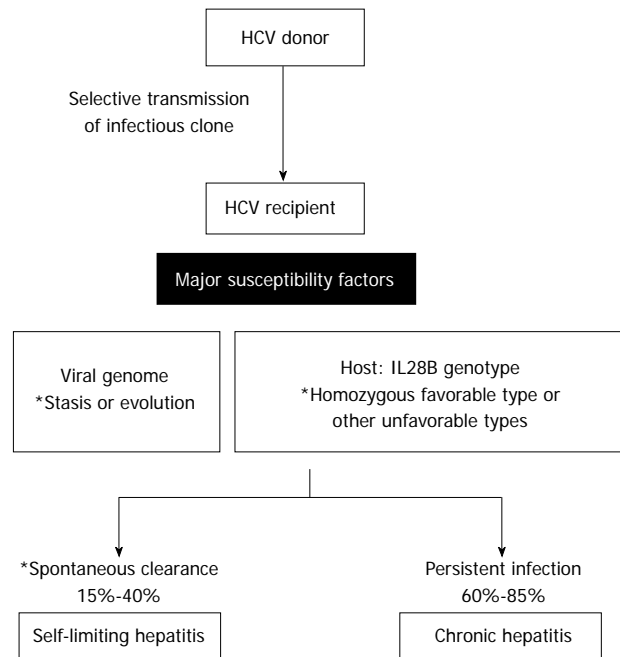

After the establishment of HCV infection, the viral genome mutates at a high rate, especially in the HVR1 of the HCV E2 region. The evolutionary dynamics of the infected virus are associated with the outcome of acute hepatitis C; genetic stasis and a high rate of evolution of HCV HVR1 are associated with resolution of infection in self-limiting hepatitis and progression to chronic infection, respectively<sup>[23]</sup>. The case we experienced progressed to chronic infection and 8 of 30 homogeneously predominant HCV HVR1 clones recovered from the recipient developed one amino acid mutation within this region during a short period of only 6 wk after infection<sup>[7]</sup>. As for the relationship between the viral load at the time of infection and the outcome of acute HCV infection, a recent study has shown that a high viral load in the initial phase of infection is associated with spontaneous viral clearance, leading to self-limiting resolution of hepatitis<sup>[24]</sup>. A high viral load may trigger strong innate immunity in the acute phase. However, it has also been reported that viral clearance may occur after a low infectious dose of HCV has been transmitted<sup>[25]</sup>. In addition, spontaneous viral clearance rarely occurs in the chronic phase of HCV infection where a low viral load is associated with spontaneous clearance<sup>[26]</sup>. The spontaneous clearance of HCV may thus depend on the immune system of indi-

viduals rather than the viral load. Further studies using a greater number of cohorts are needed to clarify the relationship between spontaneous viral clearance and the initial viral load, as well as the degree of induction of the innate immune response.

### Genetic regulation of HCV infection

HCV-specific humoral and cellular immune responses are detectable in infected individuals, and a strong immune response against HCV favors viral clearance<sup>[18,27]</sup>. Genetic variation in host genes involved in immune response is likely to account for the difference in outcome. In particular, induction of natural killer (NK) cells in the innate immune response during the acute phase of infection plays a crucial role in resolving HCV infection. We have previously reported differences in genetic variations between HCV-infected individuals with and without viremia in the Japanese population<sup>[22]</sup>, where a single nucleotide polymorphism (SNP) of transforming growth factor (TGF)- $\beta$ 1, which suppresses the proliferation and cytotoxicity of NK cells (the -509CC genotype or -509C allele), was associated with high HCV clearance rates and low transcriptional activity of TGF- $\beta$ 1<sup>[28]</sup>. The killer cell immunoglobulin-like receptor (KIR) and its human leukocyte antigen (HLA) have been reported to influence the outcome of HCV infection. Combinations of genotypes involving genes encoding the inhibitory NK cell receptor KIR2DL3 and HLA-C1 ligand directly influence HCV clearance in Caucasians and African Americans with an expected low infectious dose of HCV<sup>[25]</sup>. These data suggest that a diminished inhibitory effect of NK cells resulting from such gene regulation confers protection against HCV.

In a recent genome-wide association study, SNPs in the region of the Interleukin 28B (*IL28B*) gene encoding interferon- $\lambda$ -3 were shown to be closely associated with the virologic response of HCV to antiviral therapy<sup>[29-31]</sup>. Patients carrying an *IL28B* homozygote for the major alleles of rs12979860 (CC genotype)<sup>[29]</sup> or rs8099917 (TT genotype)<sup>[30]</sup> show a greater propensity to achieve a sustained virologic response to pegylated interferon- $\alpha$  and ribavirin therapy than those carrying an *IL28B* heterozygote or homozygote for its minor allele. This SNP (rs12979860) also influences the outcome of HCV infection in the context of natural history; the CC genotype enhances resolution of HCV infection with spontaneous clearance among individuals of European and African ancestry<sup>[32]</sup>. This CC genotype has also been reported to be associated with a higher rate of spontaneous clearance in Asian populations<sup>[33]</sup>. In addition, a recent study has demonstrated that SNPs in the region of *IL28B* (rs12979860) and HLA class II (rs4273729) are independently associated with spontaneous resolution of HCV infection in individuals of European and African ancestry<sup>[34]</sup>. A prospective follow-up study of patients who developed acute hepatitis C also revealed a strong correlation between the *IL28B* C allele at rs12979860 and clearance<sup>[24]</sup>. Taken together, the SNP of *IL28B* (rs12979860) can be a marker

**Figure 1** Transmission of hepatitis C virus, and the significance of viral and host factors for predicting the outcome of infection. HCV: Hepatitis C virus; IL28B: Interleukin 28B.

for indicating whether immediate antiviral treatment needs to be started in patients with acute hepatitis C<sup>[35]</sup>. Recently, upstream of the *IL28B* gene, a dinucleotide variant ss469415590 (TT or AG), in which ss469415590 (AG) activates the *IFNL4* gene encoding interferon- $\lambda$ -4 protein through a genome frameshift, has been reported to be more strongly associated with HCV clearance in individuals of African ancestry than the SNP of *IL28B* (rs12979860), but comparable to that in Europeans and Asians<sup>[36]</sup>. This variant is in high linkage disequilibrium with rs12979860, and further investigations are expected to elucidate the functional role of ss469415590 (AG) that activates the *IFNL4* gene in association with the innate immune response to HCV.

## CONCLUSION

Both the viral characteristics of an infecting clone and genetic regulation of infection by the host determine differences in the outcome of acute HCV infection (Figure 1). The evolutionary dynamics of the virus and genetic polymorphisms in the host pertaining mainly to the immune system influence susceptibility to HCV. In particular, the discovery of SNPs in the region of the *IL28B* gene has led to the characterization of a novel genetic marker of hepatitis C that is able to predict self-limiting viral clearance in the acute phase of infection as well as the response to antiviral therapy.

## Abstract

The technique of endoscopic submucosal dissection (ESD), which was developed for *en bloc* resection of large lesions in the stomach, has been widely accepted for the treatment of the entire gastrointestinal tract. Many minimally invasive endoscopic therapies based on ESD have been developed recently. Endoscopic submucosal excavation, submucosal tunneling endoscopic resection and laparoscopic-endoscopic cooperative surgery have been used to remove submucosal tumors, especially tumors which originate from the muscularis propria of the digestive tract. Peroral endoscopic myotomy has recently been described as a scarless and less invasive surgical myotomy option for the treatment of achalasia. Patients benefit from minimally invasive endoscopic therapy. This article, in the highlight topic series, provides detailed information on the indications and treatments for esophageal diseases.

## INTRODUCTION

Endoscopic submucosal dissection (ESD) was originally developed in Japan as a method of endoscopic “*en bloc*” resection of superficial gastric cancers. Today, ESD is increasingly used for superficial esophageal cancers and esophageal submucosal tumors (SMTs)<sup>[1,2]</sup>. With improved ESD technology, it has been used not only for tumors, but also for functional disorders, and has produced good therapeutic effects. In this review, an outline of the current status of minimally invasive endoscopic therapy based on ESD for esophageal diseases is described.

## ESD

As with candidates suffering from other gastrointestinal tract diseases, patients scheduled for esophageal ESD are assessed using two factors: a small likelihood of lymph node metastasis and technical resectability<sup>[3,4]</sup>. ESD for lesions in esophageal squamous epithelium is performed as outlined in Figure 1. The lesion is dyed with 2% Lugol's solution to obtain a clear margin, and

**Figure 1** Process of endoscopic submucosal dissection. A: The lesion is dyed with 2% Lugol's solution; B: Marking of the lesion by argon plasma coagulation probes; C: Submucosal injection; D: The mucosa is incised outside the marker dots, and then the submucosal tissue underneath the lesion is gradually dissected; E: The wound after resection; F: The lesion.

several marker dots are made approximately 5-10 mm from the margin of the lesion using argon plasma coagulation (APC). After injection of several milliliters of injection solution into the submucosal layer, the mucosa is incised outside the marker dots with an electric knife (IT knife, hook knife, or HybridKnife). The submucosal tissue underneath the lesion is then gradually dissected with the electric knife. The solution is injected repeatedly, when necessary, during the dissection. Exposed vessels on the artificial ulcer are coagulated with APC or coagulation forceps to prevent delayed bleeding, and metallic clips are always used to close the deeply dissected areas. Although numerous injection solutions have been proposed and tested, saline is the most commonly used in the clinic due to its low cost and ease of use. Indigo carmine is added to obtain a clear layer and epinephrine is used to reduce bleeding. Hyaluronic acid is also used to improve submucosal lift durations<sup>[5-7]</sup>.

## ENDOSCOPIC SUBMUCOSAL EXCAVATION

With improved ESD technology, ESD is not only used for mucous layer tumors, but also for muscularis propria tumors of the digestive tract. During this process, ESD is used to remove the submucosa muscularis propria of the tumor and to peel the tumor from the muscularis propria. We consider this application a new technology and named it endoscopic submucosal excavation (ESE). ESE is performed as outlined in Figure 2: (1) Marker

dots are made approximately 5 mm away from the lesion; (2) Using a 23-gauge disposable needle, several milliliters of submucosal injection solution are injected around the lesion to lift it off the muscularis propria layer, but only the mucosa is lifted, not the tumor. This step shows that the tumor has originated from the muscularis propria layer; (3) The mucosa is then incised outside the marker dots using the electric knife; (4) The submucosal connective tissue beneath the lesion is gradually dissected from the muscularis propria layer with the electric knife to show the lesion; and (5) The electric knife is used to peel the muscularis propria layer along the edge of the lesion. Finally, the lesion is resected completely from the muscularis propria layer using the electric knife<sup>[8,9]</sup>.

## SUBMUCOSAL TUNNELING ENDOSCOPIC RESECTION

ESE was developed to allow *en bloc* resection of SMTs which originated from the muscularis propria layer under direct vision. However, the surgical area in the esophagus is limited and the esophageal adventitia is very thin. If perforation occurs and the mucosal defect cannot be completely closed, serious complications such as esophageal fistula will occur. We performed a new endoscopic technique for the treatment of SMTs, called submucosal tunneling endoscopic resection (STER), which can reduce the risk of postoperative GI tract leakage and secondary infection. The procedure for STER is as follows: (1) Submucosal injection of diluted indigo carmine or methylene

Figure 2 Process of endoscopic submucosal excavation. A: A round-shaped submucosal tumor; B: Removal of the mucosa; C: Dissecting the tumor from the muscular layer; D: The wound after resection; E: Sealing the wound with metallic clips; F: The lesion.

Figure 3 Process of submucosal tunneling endoscopic resection. blue is needed to locate SMTs in the cardia when they are difficult to identify; (2) A submucosal tunnel is created to expose the tumor. A fluid cushion is obtained using an injection needle 5 cm proximal to the SMT. A 2-cm, lon-

gitudinal mucosal incision is made using the electric knife at the esophageal mucosa as the entry point. A submucosal longitudinal tunnel is created with the electric knife between the submucosal and muscular layers. Tunneling

**Figure 4** Process of peroral endoscopic myotomy. A: The esophagogastric junction (EGJ) before surgery; B: Submucosal injection and an initial mucosal incision; C-D: A submucosal tunnel was created; E: The muscle was incised; F-G: The mucosal incision site was closed with clips; H: EGJ after surgery.

ends 1-2 cm distal to the tumor to ensure a satisfactory endoscopic view of the SMT and enough working space for resection; (3) Resection of the SMT is performed under direct endoscopic visualization. During the procedure, safe and complete resection of the tumor, without interruption of the tumor capsule, is the highest priority;

and (4) Closure of the mucosal incision site. After tumor resection and hemostasis with APC or hot biopsy forceps in the tunnel, the gastroscope is withdrawn through the natural orifice. Most commonly, the mucosal incision site is closed with 4 to 6 hemostatic clips<sup>[10,11]</sup> (Figure 3).

**Figure 5** Process of thoracoscope-assisted tunnel endoscopic resection. A: Thoracoscopic exploration of the tumor; B: Endoscopic exploration of the tumor; C-D: A submucosal tunnel was created to expose the tumor under endoscopy, which was the same as the submucosal tunneling endoscopic resection procedure; E: The thoracoscopic electric hook was used to separate the esophagus and open the muscular layer over the tumor by blunt dissection, we removed the large tumor from the chest; F: Use of metallic clips to close the mucosal entry; G: Use of thoracoscopy to suture the pleura mediastinalis; H: The lesions.

## PERORAL ENDOSCOPIC MYOTOMY

Peroral endoscopic myotomy has recently been described as a scarless and less invasive surgical myotomy option for

the treatment of achalasia<sup>[12,13]</sup>. Briefly, submucosal injection and an initial mucosal incision are first performed at the 5- to 6-o'clock position on the posterior esophagus, approximately 10 cm proximal to the esophagogastric

junction (EGJ). A submucosal tunnel is created passing over the EGJ and approximately 3 cm into the proximal stomach. The myotomy is initiated 2 cm distal to the mucosal entry point, approximately 6-8 cm above the EGJ, and is extended for a distance of 2-3 cm toward the stomach. After careful hemostasis, the mucosal incision site is closed with 4 to 6 hemostatic clips<sup>[14-16]</sup> (Figure 4).

## THORACOSCOPE-ASSISTED TUNNEL ENDOSCOPIC RESECTION

With the development of ESD technology, endoscopy is used to treat large esophageal SMTs. Thus, endoscopic treatment is risky and of limited value in patients with huge esophageal or extraluminal SMTs. Minimally invasive thoracoscopic treatment also has its advantages, however, for esophageal SMTs larger than 3 cm, use of the thoracoscope involves a risk of tearing the mucosa when separating tumors, causing serious complications such as GI leakage. Laparoscopic-endoscopic cooperative surgery has been introduced<sup>[17,18]</sup>. Recently, we developed combined thoracoscopic and endoscopic therapy to treat esophageal SMTs originating from the muscularis propria. The indications for thoracoscope-assisted tunnel endoscopic resection are: (1) Tumors larger than 5 cm; and (2) U-shaped tumors larger than 3 cm and which extend to more than 1/2 of the esophagus circumference. This type of tumor is difficult to treat by endoscopic or thoracoscopic treatment alone. The detailed steps of this procedure are as follows: The patient lies in the left lateral position, the thoracoscope is introduced and any adhesion or pleural effusion in the pleural cavity is checked; (1) Thoracoscopic exploration of the tumor; (2) Submucosal injection is administered and a submucosal tunnel is created to expose the tumor using the ESD technique under endoscopy, which is the same as the STER procedure; (3) If the tumor is so large that it can not be removed from the tunnel by endoscopy, the thoracoscopic electric hook is used to separate the esophagus and open the muscular layer over the tumor by blunt dissection. In addition, the submucosal "tunnel" is under surveillance by endoscopy to avoid esophageal mucosa injury; (4) Under endoscopic surveillance in the submucosal tunnel, the esophageal muscular layer is sutured by thoracoscopy, and insufflation in the tunnel is performed to observe whether there is any leakage in the thoracic cavity. The endoscope is withdrawn from the submucosal tunnel after hemostasis and metallic clips are used to close the mucosal entry; (5) Endoscopy is used to identify mucosal rupture. The esophagus is insufflated to observe any leakage in the thoracic cavity and then thoracoscopy is used to suture the pleura mediastinalis; and (6) A drainage tube is placed in the chest cavity if there is no obvious bleeding<sup>[19]</sup> (Figure 5).

The main complications consist of bleeding, perforation and esophageal stricture, most of which were treated by endoscopy and surgery was not required<sup>[20-22]</sup>. With the development of endoscopic techniques and the improvement in people's health consciousness, the model of the

diagnosis and treatment of some esophageal diseases is changing. Patients benefit from minimally invasive endoscopic therapy based on ESD, which results in reduced pain, rapid resumption of normal activity, and shorter hospital stay.

### Abstract

The 148 Isoleucine to Methionine protein variant (I148M) of patatin-like phospholipase domain-containing 3 (PNPLA3), a protein is expressed in the liver and is involved in lipid metabolism, has recently been identified as a major determinant of liver fat content. Several studies confirmed that the I148M variant predisposes towards the full spectrum of liver damage associated with fatty liver: from simple steatosis to steatohepatitis and progressive fibrosis. Furthermore, the I148M variant represents a major determinant of progression of alcohol related steatohepatitis to cirrhosis, and to influence fibrogenesis and related clinical

cal outcomes in chronic hepatitis C virus hepatitis, and possibly chronic hepatitis B virus hepatitis, hereditary hemochromatosis and primary sclerosing cholangitis. All in all, studies suggest that the I148M polymorphism may represent a general modifier of fibrogenesis in liver diseases. Remarkably, the effect of the I148M variant on fibrosis was independent of that on hepatic steatosis and inflammation, suggesting that it may affect both the quantity and quality of hepatic lipids and the biology of non-parenchymal liver cells besides hepatocytes, directly promoting fibrogenesis. Therefore, PNPLA3 is a key player in liver disease progression. Assessment of the I148M polymorphism will possibly inform clinical practice in the future, whereas the determination of the effect of the 148M variant will reveal mechanisms involved in hepatic fibrogenesis.

**Core tip:** The 148 Isoleucine to Methionine protein variant (I148M) of patatin-like phospholipase domain-containing 3 (PNPLA3) has recently been identified as a major determinant of liver fat content. Several studies conducted in different ethnicities confirmed that I148M influences the full spectrum of liver damage: from simple steatosis to nonalcoholic steatohepatitis and progressive fibrosis to hepatocellular carcinoma. Furthermore, I148M turned out to represent a major determinant of progression of alcohol related steatohepatitis, and to influence fibrosis progression and related clinical outcomes in chronic hepatitis C virus hepatitis, as well as other in liver diseases. All in all, studies suggest that the PNPLA3 I148M polymorphism may represent a general modifier of fibrogenesis in liver diseases.

## INTRODUCTION

The clinical evolution of chronic liver diseases is highly variable, and genetic factors plays a key role in determining the inter-individual susceptibility towards end-stage liver disease and hepatocellular carcinoma. It is now established that all common diseases, including type 2 diabetes, atherosclerosis, and nonalcoholic fatty liver disease (NAFLD) among liver diseases<sup>[1]</sup>, exhibit a heritable component of susceptibility accounting for 30%-50% of risk. Indeed, also liver diseases can be considered complex traits that result from environmental exposures, *e.g.*, diet and physical inactivity for NAFLD, excessive alcohol intake for alcoholic liver disease (ALD), or infection for chronic viral hepatitis, acting on a susceptible polygenic background comprising multiple independent modifiers<sup>[2]</sup>. These are generally represented by common genetic variants with a mild effect or rare variants associated with a more marked phenotype<sup>[3]</sup>.

Despite initial hypothesis-driven, case-control studies identified some genetic loci associated with the progression of liver damage, the genetic determinants of NAFLD remained obscure until recently<sup>[1]</sup>. By 2008, the first genomewide association studies in the field of hepatic steatosis allowed to identify the rs738409 variant, by an hypothesis free drive approach, as the single major genetic determinant of hepatic fat content<sup>[4,5]</sup>. This sequence variation is a C > G single nucleotide change, encoding for the 148 Isoleucine to Methionine protein variant (I148M) of Patatin-like phospholipase domain-containing 3 (PNPLA3). The main purpose of this review is to provide an overview of the current knowledge of the PNPLA3 I148M polymorphism role in the progression of liver disease.

## NONALCOHOLIC FATTY LIVER

Ectopic fat accumulation in the liver related to systemic insulin resistance represents the prototypical manifestation of NAFLD<sup>[6]</sup>. With a prevalence of 20%-34% and rising, NAFLD is now the most frequent liver disease in industrialized countries<sup>[7,8]</sup>. In a minority of susceptible individuals, steatosis, that is excessive fat accumulation in the liver (> 5%), is associated with oxidative hepatocellular damage, inflammation and activation of fibrogenesis, *i.e.* nonalcoholic steatohepatitis (NASH)<sup>[9,10]</sup>, which can progress to cirrhosis and hepatocellular carcinoma<sup>[11,12]</sup>.

NAFLD is epidemiologically associated with obesity and metabolic syndrome. The pathogenesis is related to adipose tissue insulin resistance<sup>[13]</sup>, leading to an increased flux of free fatty acids to the liver<sup>[14]</sup>, increased lipogen-

esis induced by hyperinsulinemia, abnormal intra-hepatic lipid metabolism and dietary factors. Hepatic fat accumulation, in turn, worsens insulin resistance and liver damage, determining an increased risk of both cardiovascular and liver related mortality<sup>[15-17]</sup>.

Besides hepatocytes, two cell types play a key role in the pathogenesis of NASH. Kupffer cells are the hepatic macrophages that under basal conditions are involved in the maintenance of immune homeostasis, but during NASH become activated by intestinal bacterial products and oxidized lipids *via* Toll-like receptor-4 and secrete reactive oxygen species, chemokines and several cytokines, thereby orchestrating inflammation<sup>[18]</sup>. Hepatic stellate cells are hepatic pericytes localized between sinusoidal endothelial cells and the hepatocytes, which in quiescent conditions store lipids and retinoids, secrete extracellular matrix, and regulate blood flow. Upon activation in NASH, stellate cells release retinoids, undergo myofibroblast transition, secrete type 1 collagen and a variety of fibrogenic mediators thereby initiating the process of fibrogenesis<sup>[19,20]</sup>.

## GENETIC PREDISPOSITION TO FATTY LIVER

The risk of NAFLD is highly variable even in individuals with obesity and type 2 diabetes. Furthermore, even if the majority of obese subjects with metabolic syndrome develop simple steatosis, only about one third has NASH, and a minority progresses to more severe forms of the disease.

Epidemiological, familial and twin studies provide evidence for a component of heritability of liver fat content and NAFLD<sup>[21,22]</sup>. Indeed, NAFLD is more prevalent in Hispanics compared to Europeans, and less common in African-Americans, and this difference is not explained by diabetes and obesity<sup>[22,23]</sup>. Family studies demonstrated a strong heritability of NASH<sup>[21,24,25]</sup>. Accordingly, twin studies shown that, in subjects without viral hepatitis and alcohol abuse, alanine aminotransferases (ALT) levels and liver fat content are strongly heritable traits, with genetic factors explaining up to 60% of variability<sup>[26,27]</sup>. Overall, evidences indicate that about half of steatosis variability, determined by biochemical indices or noninvasive assessment of liver fat, is inherited<sup>[1]</sup>. Therefore, several hypothesis-driven studies tried to evaluate the role of candidate genetic variants in the susceptibility to NAFLD and progressive NASH, with the goal of identifying disease markers or potential drug targets, but with inconsistent results<sup>[1]</sup>.

## PNPLA3 I148M IS A MAJOR DETERMINANT OF FATTY LIVER

In 2008, two independent genome-wide association studies linked the common rs738409 polymorphism of PNPLA3 (I148M) with hepatic fat content and ALT levels<sup>[4,5]</sup>. In particular, a genomewide scan of the associa-

**Figure 1** Hypothetical mechanism of hepatic fat accumulation associated with the 148 Isoleucine to Methionine protein variant patatin-like phospholipase domain-containing 3 polymorphism. ER: Endoplasmic reticulum; LPA: Lyso-phosphatidic acid; PA: Phosphatidic acid; Tg: Triglycerides; ?: To be confirmed; PNPLA3: Patatin-like phospholipase domain-containing 3.

tion of non-synonymous sequence variations in the Dallas Heart Study revealed a very strong association of increased fat content with a single missense variant, I148M, in PNPLA3<sup>[4]</sup>.

Remarkably, the association between PNPLA3 I148M and liver fat was independent of major differences in body composition, diabetes and serum lipoprotein levels. Furthermore, the 148M at risk allele was more prevalent in Hispanics [minor allele frequency (MAF): 0.49] than in Europeans (MAF: 0.23), and less common in Afro-Americans (MAF: 0.17) explaining a consistent fraction of the inter-ethnic variability in NAFLD susceptibility<sup>[4,28]</sup>.

Since then, several studies and a recent meta-analysis have replicated the association between the I148M polymorphism and NAFLD in all ethnic groups, both in adults and in the developmental age<sup>[28-41]</sup>. The association of the I148M variant with hepatic lipid content is exposed in the presence of other risk factors, such as severe obesity<sup>[32]</sup>, visceral adiposity<sup>[42]</sup>, increased intake of sugars<sup>[43]</sup> or omega-6 poly-unsaturated fatty acids<sup>[44]</sup>, and other genetic factors<sup>[45,46]</sup>. Vice versa, weight loss results in a rapid decrease of intra-hepatic fat and of indices of liver damage in subjects homozygous for the 148M variant<sup>[47]</sup>. All in all, these data suggest that the 148M variant becomes a critical factor determining hepatocellular fat accumulation when stressing factors such as increased flux of free fatty acids related to adipose tissue insulin resistance in visceral obesity, increased lipogenesis stimulated by hyperinsulinemia and carbohydrates, or altered lipid metabolism intervene.

## FUNCTION OF WILD-TYPE AND MUTANT PNPLA3

PNPLA3, also called adiponutrin, encodes a 481 amino

acid protein with a molecular mass of approximately 53 kDa that in humans is mainly expressed in intracellular membrane fractions in hepatocytes<sup>[48]</sup>, and is induced in the liver after feeding and during insulin resistance by the master regulator of lipogenesis Steroid Regulatory Element Binding Protein-1c<sup>[49]</sup>.

Wild-type (148I) *PNPLA3* has lipolytic activity towards triglycerides<sup>[48,50]</sup>. The 148M mutation determines a critical aminoacidic substitution next to the catalytic domain, likely reducing the access of substrates and reducing the PNPLA3 enzymatic activity towards glycerolipids, thereby leading to the development of macrovesicular steatosis<sup>[48,50]</sup>. However, other reported a gain of lipogenic function associated with the 148M variant, which would acquire the ability to synthesize phosphatidic acid from lysophosphatidic acid<sup>[51]</sup>. In addition, results deriving from murine models gave contradictory results<sup>[52-55]</sup>. The issue of the functional consequences of the I148M polymorphism is therefore still intensively debated, and it may be hypothesized that PNPLA3 has additional physiological substrates. Human studies have also suggested a possible direct or indirect influence of *PNPLA3* genotype on adipose tissue biology<sup>[56,57]</sup>, which however awaits replication.

A model depicting hypothetical mechanisms of hepatic fat accumulation associated with the I148M *PNPLA3* polymorphism is shown in Figure 1.

## ASSOCIATION OF PNPLA3 I148M WITH PROGRESSIVE FIBROSIS IN STEATOHEPATITIS

Even if steatosis severity is a risk factor for NASH and progressive disease in NAFLD<sup>[58]</sup>, the association is not invariable, and hepatocellular fat is believed to represent

**Table 1** Studies evaluating the association between the 148M polymorphism of patatin-like phospholipase domain-containing 3 and liver fibrosis in patients affected by chronic hepatitis C virus infection, a leading cause of liver related mortality in Western countries

Study	Design	Patients	Outcome	OR	95%CI
Valenti <i>et al.</i> <sup>[75]</sup>	Cross-sectional	819	Cirrhosis	1.5	1.2-1.9
Müller <i>et al.</i> <sup>[76]</sup>	Cross-sectional	605	Cirrhosis	2.8	1.2-6.2
Trépo <i>et al.</i> <sup>[77]</sup>	Cross sectional prospective	537	Fibrosis stage	3.1	1.5-6.5
			Fibrosis progression	2.6	1.2-5.7

more a epiphenomenon of insulin resistance and altered lipid metabolism than the key driver underpinning liver damage progression. Indeed, accumulation of neutral lipids in cytoplasmic droplets is now retained to represent a protective response towards the increased burden of hepatotoxic free fatty acids and other lipids<sup>[14]</sup>. Therefore, the first question arising after the discovery of *PNPLA3* genotype as the major determinant of hepatic fat content, was whether the *I148M* polymorphism decreased liver damage favoring accumulation of fatty acids in lipid droplets or conversely increased the susceptibility to develop progressive NASH and fibrogenesis.

The answer came soon, as the *148M* allele was linked with NASH<sup>[30]</sup>, and our group first reported that homozygosity for the *148M* allele was associated with an 3.3-fold increased risk of both NASH and liver fibrosis in two independent cohorts of European subjects with histological NAFLD<sup>[31]</sup>. The association between *PNPLA3* *I148M* and the severity of fibrosis in NAFLD was almost contemporarily replicated by independent groups in adults<sup>[34,35]</sup> and in the pediatric population<sup>[59]</sup>, and confirmed by a recent meta-analysis<sup>[36]</sup>.

ALD shares many pathophysiological features with NAFLD<sup>[18]</sup>, most notably steatohepatitis being the key driver of fibrogenesis and liver damage progression. Indeed, candidate gene studies demonstrated that the *I148M* polymorphism is also strongly associated with the risk of developing ALD and with the susceptibility towards cirrhosis in alcohol abusers of different ethnic groups<sup>[60-62]</sup>. In one study in German subjects, the *I148M* polymorphism alone explained as much as 26% of cirrhosis variability in alcohol abusers<sup>[61]</sup>. Furthermore, the earlier the age of the increase at risk alcohol intake the stronger the effect of the *PNPLA3* *148M* mutation has on the cirrhosis susceptibility<sup>[63]</sup>.

## PNPLA3 *I148M* AND CHRONIC HCV HEPATITIS

The next natural question was clearly whether *PNPLA3* genotype represents a modifier of progression of other liver diseases in which steatosis plays a key role in the pathogenesis. Chronic hepatitis C virus (CHC), a leading cause of end stage liver disease and hepatocellular carcinoma in many Western countries<sup>[64]</sup>, is frequently characterized by steatosis, occurring in more than half of

patients. The presence of steatosis has been associated with more aggressive histological features, faster progression of fibrosis, and poorer response to therapy<sup>[65-68]</sup>. Hepatic steatosis favors hepatitis C virus (HCV) life-cycle<sup>[69]</sup>, and both viral and host factors are believed to contribute to its pathogenesis<sup>[67,70-73]</sup>. It became soon clear that the *I148M* polymorphism is a major determinant of the susceptibility to steatosis in also CHC, in particular in patients not infected by genotype 3 strains that *per se* strongly induces steatosis by altering very low density lipoproteins export<sup>[74-77]</sup>. This model is also consistent with the recent finding of a nonsense mutation of *APOB* in humans causing hypo-beta-alipoproteinemia and a massive history of severe steatosis associated with development of hepatocellular carcinoma in carriers of this mutation<sup>[78]</sup>.

Studies that specifically evaluated the association between the *I148M* *PNPLA3* variant and fibrosis progression in CHC are reported in Table 1. As in NAFLD and ALD, the effect of the *148M* mutation was not limited to predisposition to steatosis, but extended towards progressive fibrosis and cirrhosis development<sup>[75-77,79]</sup>. Interestingly, the size effect of the association of the *I148M* polymorphism with fibrosis appeared larger in subjects with at risk alcohol intake (> 30 g/d in males/females)<sup>[76,80]</sup>, suggesting the existence of an interaction between different triggering factors and *PNPLA3* genotype in fibrogenesis. Furthermore, genetic factors influencing immunological response towards HCV, *i.e.*, *IL28B* region polymorphisms, may influence the association between *PNPLA3* and steatosis<sup>[81]</sup>.

We could speculate that when steatosis inducing stressors such as obesity and insulin resistance, excess alcohol intake, and HCV infection stress the liver, in the presence of the “normal” *148I* *PNPLA3* allele the damage will result in simple uncomplicated steatosis, whereas the *148M* “at risk” allele will favor steatohepatitis and fibrogenesis, with progression towards cirrhosis and its complication in susceptible individuals<sup>[82]</sup>.

Finally, some studies indicate that during treatment with peg-interferon plus ribavirin the *I148M* polymorphism may affect sustained virological response (*i.e.*, cure rate)<sup>[75]</sup> and viral kinetics<sup>[83]</sup>, especially in difficult to cure CHC patients with advanced fibrosis<sup>[79]</sup>. However, the clinical impact of *PNPLA3* on the response to therapy will likely be modest in the new era of direct antiviral agents<sup>[79]</sup>.

## PNPLA3 *I148M* IN OTHER LIVER DISEASES

Having established that the *I148M* polymorphism is a modifier of the natural history of liver diseases associated with steatosis, *i.e.*, NAFLD, ALD and CHC, the possible role of *I148M* in determining the susceptibility to steatohepatitis and progressive liver damage in other liver diseases is becoming the subject of investigation.

As it affects more than 350 million people worldwide

**Figure 2** Hypothetical mechanisms linking the 148 Isoleucine to Methionine protein variant of patatin-like phospholipase domain-containing 3 polymorphism with hepatic fibrogenesis in the presence of triggering factors for steatosis (Obesity and insulin resistance, excessive alcohol intake and chronic hepatitis C virus infection). A: Direct effect of mutant 148 Isoleucine to Methionine protein variant patatin-like phospholipase domain-containing 3 (148M PNPLA3) on inflammation, oxidative stress, and cellular damage (ballooning) in hepatocytes with secondary activation of non-parenchymal cells, including Kupffer cells (KC) and hepatic stellate cells (HSC). Hepatocytes are shown in brown, KC in light green, neutrophils in dark green, HSC in blue. Nuclei are shown in darker shades of the cell color, whereas lipid droplets and steatosis in yellow, and ballooning (endoplasmic reticulum swelling) in white; B: Direct effect of the mutant 148M PNPLA3 on the activation of non-parenchymal cells. Mutant PNPLA3 (148M) is shown as a red box.

and is a leading causes of liver-related mortality<sup>[84]</sup>, chronic hepatitis B virus (CHB) infection represented the next disease in which the role of *PNPLA3* genotype had to be understood. Steatosis is indeed commonly observed also in CHB, and overall evidence suggests that it contributes to fibrosis progression<sup>[85-88]</sup>. Recent data from our group obtained in a relatively large cohort of European CHB patients with histological evaluation of liver damage indicate that the 148M variant predisposes to steatosis<sup>[89]</sup>. In patients with overweight or a positive history of alcohol intake, the I148M polymorphism predisposes also to severe steatosis, which in this population was associated with more severe fibrosis<sup>[89]</sup>. Additional studies will be required to test the interaction between the I148M genetic variant and acquired risk factors in the pathogenesis of progressive fibrosis and on related clinical outcomes also in CHB infection.

Hereditary hemochromatosis represents another interesting disease model. In fact, in a homogeneous genetic background in subjects homozygous for the C282Y mutation of the *HFE* gene, activation of fibrogenesis is caused by progressive hepatocellular iron overload *via* generation of oxidative stress<sup>[90,91]</sup> in the presence of precipitating factors, among which steatosis has a major role<sup>[92]</sup>. In a large series of Italian *HFE* C282Y homozygous patients with hemochromatosis, we showed that the I148M polymorphism is a strong predictor of the presence of steatosis and higher liver enzymes levels, and it is

also associated with the severity of fibrosis<sup>[93]</sup>. A possible interaction with other genetic forms of liver disease (*i.e.*, Wilson disease) may also be hypothesized and studies on this topic would help understanding the whole picture of *PNPLA3* gene interaction with liver stressors.

Finally, it has been reported that in primary sclerosing cholangitis, an autoimmune cholestatic liver disease characterized by inflammatory changes of major bile ducts, the 148M PNPLA3 variant is associated with increased mortality<sup>[94]</sup>. The effect of *PNPLA3* genotype was evident in the subgroup of patients with severe disease, *i.e.*, males with stenosis of the main duct, but unfortunately it could not be determined whether the association was mediated by steatosis and faster progression of fibrosis.

Although much work has clearly yet to be done in these and many other forms of liver damage, collectively these initial studies suggest that *PNPLA3* I148M is a promising candidate general modifier of fibrogenesis in liver diseases.

## ROLE OF PNPLA3 IN FIBROGENESIS

Intriguingly, the association between the I148M polymorphism and NASH appears to be independent of the severity of steatosis<sup>[31]</sup>, thus suggesting that this genetic variant not only influences the overall amount of hepatocellular fat, but by impacting on the concentration or subcellular localization of specific lipid species directly

modulates inflammation. It should not be forgotten that several lipids behave as inflammatory mediators acting through specific receptors<sup>[9]</sup>. Alternatively, if the *148M* mutation slows down triglycerides kinetics between cell compartments, it could be speculated that renders them more susceptible to lipoperoxidation, leading to oxidative stress, and in turn to hepatocellular damage and inflammation<sup>[9]</sup>. These hypothetical mechanisms linking the *PNPLA3 148M* mutation with hepatic fibrogenesis are shown in Figure 2. In the aforementioned scenario, shown in panel A, hepatocellular damage and the release of inflammatory mediators would lead to secondary activation of Kupffer cells amplifying the inflammatory cascade and cell death, and of hepatic stellate cells with initiation of fibrogenesis.

Even more striking is though the observation that patients the *I148M* polymorphism is associated in NAFLD with advanced fibrosis independently of NASH<sup>[31]</sup>, and in CHC with cirrhosis independently of steatosis, ALT levels, and hepatic necroinflammatory activity<sup>[75]</sup>. It could therefore be envisioned that the *148M* mutation also directly influences the activation of non-parenchymal hepatic cells in response to hepatotoxic insults, as shown in Figure 2B. This hypothesis needs to be addressed and the potential mechanisms investigated by experimental studies.

## PNPLA3 I148M AND HEPATOCELLULAR CARCINOMA

Last but not least, evidence is also accumulating that the *I148M* polymorphism predisposes to hepatocellular carcinoma, a common complication of cirrhosis and the fifth cause of cancer worldwide, with a clinically significant increment in risk, thereby representing a potentially useful biomarker<sup>[75,95-97]</sup>. We have recently reviewed elsewhere the clinical studies supporting such an association and the potential mechanisms involved<sup>[3]</sup>. To summarize, data indicate that the *148M PNPLA3* mutation favors hepatic carcinogenesis in steatohepatitis as well as in other liver diseases, and the mechanism is partly independent of the predisposition towards fibrogenesis and cirrhosis.

## CONCLUSION

In conclusion, *PNPLA3* is a novel key player in liver disease progression. Assessment of the *I148M* polymorphism will possibly inform clinical practice in the future, whereas the determination of the physiological role of wild-type *PNPLA3* and the *148M* variant will reveal mechanisms involved in hepatic fibrogenesis and carcinogenesis and hopefully identify novel therapeutic targets.

### Abstract

Several gastrointestinal and gynecological malignancies have the potential to disseminate and grow in the peritoneal cavity. The occurrence of peritoneal carcinomatosis (PC) has been shown to significantly decrease overall survival in patients with liver and/or extraperitoneal metastases from gastrointestinal cancer. During the last three decades, the understanding of the biology and pathways of dissemination of tumors with intraperitoneal spread, and the understanding of the protective function of the peritoneal barrier against tumoral seeding, has prompted the concept that PC is a loco-regional disease: in absence of other systemic metastases, multimodal approaches combining aggressive cytoreductive surgery, intraperitoneal hyperthermic

chemotherapy and systemic chemotherapy have been proposed and are actually considered promising methods to improve loco-regional control of the disease, and ultimately to increase survival. The aim of this review article is to present the evidence on treatment of PC in different tumors, in order to provide patients with a proper surgical and multidisciplinary treatment focused on optimal control of their locoregional disease.

### INTRODUCTION

Several gastrointestinal and gynecological malignancies have the potential to disseminate and grow in the peritoneal cavity. This condition is often associated with disease progression and poor prognosis. The occurrence of peritoneal carcinomatosis (PC) has been shown to significantly decrease overall survival in patients with liver and/or extraperitoneal metastases from gastrointestinal cancer. Moreover, overall survival in patients with

PC is generally only slightly influenced by systemic chemotherapy, so that the occurrence of PC is traditionally regarded by the surgeon as a terminal condition.

In 10%-35% of patients with recurrent colorectal cancer (CRC) and in up to 50% of patients with recurrent gastric cancer (GC), tumor recurrence is confined to the peritoneal cavity: those patients have been shown to ultimately die from complications of locoregional tumoral widespread, in most cases without occurrence of metastases in other sites. This natural unfavorable evolution of recurrence is commonly observed in epithelial ovarian cancer (EOC) too, a condition always associated with PC and in which locoregional widespread of the tumor is the most common cause of death. However, while in EOC there is general agreement that complete removal of peritoneal seedings is associated with longer survival, in CRC and GC complete removal of peritoneal carcinomatosis is usually followed by short-term recurrence, so that patients are usually treated with limited palliative resection or gastrointestinal bypass without the intent for complete cytoreduction.

On the other hand, almost 15% of patients with colorectal cancer and almost 40% of patients with stage II-III gastric cancer present with PC at abdominal exploration: in these cases there are no standardized indications for surgery, and operations vary from simple exploration and biopsy to palliative resection of the primary tumor, the latter procedure being associated with wide interruption of the peritoneal integrity and further seeding of neoplastic cells.

Preoperative diagnosis of PC could be very difficult. Imaging techniques (mainly based upon computed tomography-scan and magnetic resonance imaging), could assist in planning cytoreduction but also in preventing unwarranted laparotomy in patients with unresectable disease. However, they are limited in their ability to visualize localized PC, having low sensitivity for small-volume disease. The gold standard in diagnosing PC continues to be the direct peritoneal visualization, either by laparotomy or laparoscopy.

During the last three decades, the understanding of the biology and pathways of dissemination of tumors with intraperitoneal spread, and the understanding of the protective function of the peritoneal barrier against tumoral seeding, has prompted the concept that PC is a loco-regional disease: in absence of other systemic metastases, multimodal approaches combining aggressive cytoreductive surgery (CRS), intraperitoneal hyperthermic chemotherapy (HIPEC) and systemic chemotherapy have been proposed and are actually considered as promising methods to improve loco-regional control of the disease and ultimately to increase survival. Even if evidence of efficacy of these multimodal approaches comes from several phase-II studies, a few phase-III studies have been published for CRC and GC, and other are ongoing for EOC. HIPEC privileges consist in increasing loco-regional drugs concentration limiting their systemic diffusion and consequentially their tox-

icities and adverse events. The role of peritoneal plasma barrier in promoting a loco-regional high-dose effect is very important. Indeed, peritoneum has the capability to limit the systemic drugs diffusion in the peritoneal space. Moreover, the hyperthermia enhances the efficacy and the penetration of many of the drugs employed.

The renewed interest on treatment of PC is going to change the attitude of the surgeon towards tumors with peritoneal seeding, thus new paradigms are focusing on the proper behavior that the surgeon should adopt when PC is encountered during operation. Consideration should be given to the different proposed approaches facing different degrees of peritoneal cancer dissemination, but, above all, the question should be: what should be done if PC is encountered? In presence of PC, therapeutic algorithms should be addressed, taking into account the different pathologies and the risk-benefit balance.

The aim of this review article is to present the evidence on treatment of PC in different tumors and to give indications to surgeons who deal with patients with PC, in order to provide patients with a proper surgical and multidisciplinary treatment focused on optimal control of their locoregional disease.

## ROLE OF CYTOREDUCTIVE SURGERY AND HIPEC IN THE TREATMENT OF ABDOMINAL CARCINOMATOSIS FROM DIFFERENT PRIMARY MALIGNANCIES

Biological research has identified three pattern of peritoneal cancer spread: (1) random proximal distribution (RPD), in which early peritoneal implantation is due to the presence of adherence molecules on cancer cell surface, even when ascites is present; this is typical of moderate-grade and high-grade cancers, such as adenocarcinoma and carcinoid of the appendix, non-mucinous colorectal cancer, gastric cancer and serous ovarian cancer; (2) complete redistribution (CRD), in which there is no adhesion to the peritoneal surface close to the primary tumor, due to the low biologic aggressiveness of tumor cells; this distribution is typical of pseudomyxoma peritonei and diffuse malignant mesothelioma; and (3) widespread cancer distribution (WCD), in which there is presence of adherence molecules on the surface of cancer cells that produce a great amount of mucus, interfering with cell adherence: this biological behavior is found in aggressive and undifferentiated tumors such as G2-G3 cistadenocarcinoma of the appendix, mucinous colorectal cancer and mucinous ovarian cancer.

Information about patterns of spread are very important to plan the best surgical treatment. In fact, while RPD should be treated by a selective parietal peritonectomy of the macroscopically involved regions, for CRD and WCD a complete peritonectomy and an extended cytoreduction are needed<sup>[1]</sup>.

## PERITONEAL MESOTHELIOMA

Malignant mesothelioma is an uncommon tumor arising from the serosal layer of pleura, peritoneum, pericardium and tunica vaginalis testis.

The incidence of this disease has been rising worldwide since 1970, due to widespread exposure to asbestos during previous decades, and it is not expected to decrease before the next 20 years. In the United States, approximately 2500 new cases of mesothelioma are registered each year. Diffuse malignant peritoneal mesothelioma accounts for 10% to 30% of all mesotheliomas.

Despite the absence of randomized studies, which are obviously difficult in a rare disease, clinical results obtained with the combination of CRS and HIPEC support the adoption of this procedure as a treatment of choice for peritoneal mesothelioma.

In historical series, standard therapy with palliative surgery and systemic chemotherapy is associated with a median survival of about one year, ranging from 9 to 15 mo. With such a classical approach, the disease tends to remain within the abdominal cavity throughout its clinical course; an autopsy study demonstrated that 78% of patients had died because of complications directly related to local-regional progression.

On the contrary, Yan *et al*<sup>[2]</sup> in a recent multi-institutional study examined 407 patients affected by peritoneal mesothelioma treated with CRS and HIPEC in 7 different surgical centers. The mean age of the patients was 50 years, 89% of the cases were epithelial mesothelioma while 11% were sarcomatoid or bifasic. CC0-CC1 rates was achieved in 46% of cases, lymph nodes metastases were found in 6% and distant metastases in 3% of the patients. After a mean follow up of 30 mo, the median survival was 53 mo. A multivariate analysis showed as independent prognostic factor the histological type of the mesothelioma, the level of cytoreduction achieved, lymph node metastases, and the possibility to perform HIPEC.

## PRIMARY PERITONEAL CARCINOMA

Primary peritoneal carcinoma (PPC), was described for the first time by Swerdlow<sup>[3]</sup>. Its pathogenesis has been controversial. Some Authors believe that PPC develops from a malignant transformation of embryonic germ cell nests cells<sup>[4]</sup>, other from the celomic epithelium lining the abdominal cavity (peritoneum) and the ovaries (germinal epithelium), manifesting a common response to an oncogenic stimulus<sup>[5]</sup>. A multifocal origin have been suggested by Muto *et al*<sup>[6]</sup> with clonality studies, while other authors suggest a unifocal origin<sup>[7]</sup>.

Even if from an histological and a clinically point of view PPC is similar to advanced epithelial ovarian cancer, it diffusely involves the peritoneum by papillary carcinoma in the absence of an obvious primary site and grossly normal ovaries<sup>[8]</sup>. It accounts for 10% of all pelvic serous carcinomas. Most reported cases of PPC have been described in women, usually elderly; however,

rare cases have been reported in children and males. Histologically most reported PPC cases are primary peritoneal serous papillary carcinoma, while rarely are they described as peritoneal mixed epithelial carcinoma and malignant mixed Mullerian tumor.

The prognosis of PPC is poor, the median survival time ranging between 7 and 27.8 mo; 5-year survival rates range from 0% to 26.5%<sup>[9]</sup>.

PPC diagnosis cannot be easily made preoperatively, being typically made by exclusion after both operative assessment and pathological study. In fact if ovaries seem normal with widespread disease elsewhere in the abdomen, PPC may be considered as a diagnostic possibility. However, because surface involvement of the ovaries is present in approximately 96% of the cases, the distinction between extra ovarian primary peritoneal cancer and epithelial ovarian carcinoma may only be made after histological examination to evaluate the extent of ovarian invasion by tumor<sup>[10]</sup>.

Therefore, surgery remains critically important for both diagnosis and therapy of PPC. Once the diagnosis has been established and the extent of disease documented, maximal cytoreduction becomes the primary goal of the procedure. Excision of all visible implants is the hallmark of cytoreductive efforts. To the best of our knowledge, no study has been conducted assessing the efficacy of CRS with HIPEC for this kind of carcinomatosis, even if it is reasonable that this approach should be taken in consideration in the context of clinical studies.

## PSEUDOMYXOMA PERITONEI

Pseudomyxoma peritonei (PMP), a syndrome firstly described by Rokitansky in 1842, is an enigmatic, often fatal intra-abdominal disease characterized by gelatinous ascites and multifocal peritoneal epithelial implants secreting copious globules of extracellular mucin. This condition is almost always due to a perforated epithelial appendix cancer. Three pathologic variants of PMP are known: disseminated peritoneal adenomucinosis (DPAM), peritoneal mucinous carcinomatosis (PMCA), and peritoneal mucinous carcinomatosis with intermediate or discordant features.

The natural history of this disease has been drastically changed by the introduction of CRS combined with HIPEC. Ronnett *et al*<sup>[11]</sup> found a significant difference in the prognosis of patients affected by this three different forms of PMP. The most important prognostic variable affecting 10 years survival rates are the possibility to achieve CC0-CC1 (the more the complete cytoreduction, the longer the survival) and the pathological feature of PMP. Deraco *et al*<sup>[12]</sup> reported an overall 10 years survival rate of 78.9% in patients affected by PMP and treated with CC0-CC1 CRS, while no patient with CC2-CC3 CRS survived 10 years. Patients affected by DPAM had a 10 years survival of 67% while those affected by PMCA had no more than 40.7% 10 years survival rate. Baratti *et al*<sup>[13]</sup> recently published a study on prognostic

value of serum tumor markers in patients with PMP undergoing CRS and HIPEC. It is clear that pre-operative normal values of C385 were statistically related to the ability to perform an adequate cytoreduction and that elevated pre-operative values of C17.9 were associated with reduced progression-free survival. CEA has also been shown to have good sensitivity in case of progression. Chua *et al.*<sup>[14]</sup> published the results of a retrospective multi-institutional study. The purpose of this study was to evaluate outcome and long-term survival after CRS and HIPEC in PMP patients. The registry included 2296 patients from 16 centers with a mean PCI of 20, CCR0/1 was achieved in 83%, mortality was 2% and major morbidity was 24%. Median survival was 196 mo, disease free median survival was 98 mo, and 10 and 15 years survival was respectively 63% and 59%. Multivariate analysis have identified as negative prognostic factor for overall survival: previous chemotherapy courses, PMCA histological type, major postoperative complication, CCR 2/3, older age, while negative prognostic factor for progression free survival were all the above plus high peritoneal cancer index and not using HIPEC.

## PERITONEAL CARCINOMATOSIS FROM GASTRIC CANCER

Penetration of the gastric serosa and lymphatic spread are the two most important factors affecting prognosis in gastric cancer (GC)<sup>[15-17]</sup>. When the gastric serosa is infiltrated by tumor, PC becomes praverly frequent<sup>[18]</sup>. Subsequently, up to half of the patients with advanced gastric cancer (AGC) will develop a peritoneal carcinomatosis in spite a radical surgery<sup>[19-22]</sup>, and PC is quite common in gastric cancer, being already present in 5%-20% of patients explored for potentially curative resection<sup>[18,23]</sup>. There are several methods for detecting the presence of free peritoneal tumor cells (FPTC) with different sensitivity<sup>[24-26]</sup>. FPTC in the washing could be identified in up to 24% of stage IB and up to 40% of stage II or III GC patients<sup>[27]</sup>. Moreover, after radical resection, the peritoneum is the only site of recurrence in 10%-34% of cases, and one of the recurrences sites in 29%-44% of cases<sup>[28-32]</sup>.

The five-year survival rate in patients with peritoneal carcinosis from GC (PCGC) is lower than 3%<sup>[33]</sup>, with an overall mean and median survival of 6.5 and 3.1 mo, respectively<sup>[34]</sup>. Among the non-gynecologic malignancies, PCGC has a better prognosis than PC from pancreatic cancer but worse than PC from CRC<sup>[34]</sup>. Saito *et al.*<sup>[35]</sup> reported a 5-year survival rate of advanced GC with FPTC of 15.3%, similar to that of patients having macroscopical peritoneal metastasis (14.8%). As a counterpart, there are no 5-year survivors among patients with distant peritoneal metastases.

Systemic chemotherapy may improve median survival up to 12 mo in advanced/metastatic GC<sup>[36-39]</sup>, but a similart survival benefit has not been reported in macroscopic PC<sup>[40-43]</sup>. One possible explanation seems to be

that systemic chemotherapy inadequately reaches the abdominal cavity<sup>[44]</sup>. Yonemura *et al.*<sup>[45]</sup> demonstrated a survival benefit by treating patients with PFTC with radical resection followed by adjuvant systemic chemotherapy. Patients treated with adjuvant chemotherapy survived significantly longer than patients in control group: the 1 and 2-year survival rates were 88% and 44%, and 53% and 9%, in adjuvant group and control group, respectively. The mean overall survival was 21.1 and 9.1 mo for adjuvant and control group ( $P < 0.05$ ). The ineffectiveness of systemic chemotherapy in PC may be related to a number of factors, such as the peritoneal-plasma barrier, the intraperitoneal poor blood supply and oxygenation of cancer cells, and the low apoptotic potential of such hypoxic tumor cells<sup>[37,46-48]</sup>. Neoadjuvant chemotherapy (NACT) has been described to decrease the load of macroscopic PCGC<sup>[37,49]</sup>. Yano *et al.*<sup>[50]</sup> reported a small series of 4 out of 26 (15.4%) patients affected by PCGC with complete remission of peritoneal metastasis with after NACT. All these patients subsequently underwent curative resection. Inokuchi *et al.*<sup>[51]</sup> reported a partial response in 9 out of 13 patients (69%). However, one further study suggests that after NACT the detection of FPTC can change from positive to negative and vice versa. This change is not linked to the response to the systemic chemotherapy. Ten out of 42 (24%) patients with negative peritoneal cytology shifted into positive for FPTC during NACT, while 7 out of 19 (37%) with FPTC positive cytology at staging laparoscopy turned negative<sup>[52]</sup>.

GC peritoneal spread remains a major problem, and some Authors finally suggest that there is no role for surgery in PCGC<sup>[53]</sup>. Since the 80s, Japanese surgeons combined CRS, regional hyperthermia and intraperitoneal chemotherapy in a multimodal approach<sup>[54]</sup>. As for other types of PC, in GC HIPEC after CRS is accomplished to eliminate FPTC and to prevent or delay PC<sup>[53,55]</sup>. A number of studies have been conducted, with the aim to demonstrate a significant reduction in the rate of subsequent PC and an increase in survival of patients with AGC when radical surgery was combined with HIPEC<sup>[20,56-61]</sup>. Yonemura *et al.*<sup>[62]</sup> demonstrated that HIPEC could improve significantly the median survival from 15 to 48 mo and the 5-years survival rate from 12% to 42% in patients with PFTC. On the other hand, the combined CRS and HIPEC treatment of PCGC seems to be the one with less encouraging results in terms of survival and of morbidity and mortality when compared to other types of PC<sup>[63,64]</sup>. A French retrospective, multi-center study published in 2010 evaluated toxicity and significant prognostic factors after CRS and HIPEC (and/or early postoperative intraperitoneal chemotherapy, EPIC) for PC from nongynecologic neoplasms<sup>[65]</sup>. The study involved 1290 patients from 25 French institutions who underwent 1344 CRS procedures between 1989 and 2007. HIPEC was made in 1154 cases (86.4%). The principal origin of PC was CRC ( $n = 523$ , 40.5%), and no more than 159 GC cases were present in this series

(12.3%). The whole group overall 3- and 5-year survival rates were 49% and 37% respectively. The PCGC group showed the worse outcome with a 3- and 5-year survival rates of 18% and 13%, respectively. The overall median survival of the whole group and of the PCGC group were 34 and 9 mo respectively. Li *et al*<sup>[66]</sup> from China reported in 2010 a series of 128 patients with PCGC. Fifty-four (42.2%) underwent gastrectomy, and 10 underwent resection with HIPEC. The other 74 (57.8%) received non-resection surgery. The median survival in the unresected group was 6 mo compared to 11.8 mo of the resected patients. Moreover, they observed a significantly improved survival in the patients treated with surgery and HIPEC compared to those treated with surgery alone<sup>[67]</sup>. Post-operative complications were more frequent in the HIPEC than in the resection alone group (20.0% *vs* 13.2%,  $P = 0.34$ ). Yang *et al*<sup>[68]</sup> published the final results of a phase III randomized trial, performed in China in order to evaluate the efficacy and safety of CRS plus HIPEC for the treatment of PCGC. The median overall survival was 6.5 mo in CRS alone group and 11 mo in the CRS + HIPEC group ( $P = 0.046$ ). This outcome was even more significant in patients with synchronous PCGC ( $n = 51$ ), being the median overall survival 12 mo in CRS + HIPEC group ( $n = 24$ ) and 6.5 mo in the CRS group ( $n = 27$ ,  $P = 0.029$ ). The 1-, 2-, and 3-year survival rates were 29.4%, 5.9% and 0% for CRS group, and 41.2%, 14.7% and 5.9% for CRS + HIPEC group, respectively. The CC-score has been demonstrated to influence survival, but HIPEC obtained a significant advantage both in CC 0-1 and CC 2-3 patients. In the CRS + HIPEC patients, the median overall survival in CC 0-1 ( $n = 20$ ) and in CC 2-3 subgroups ( $n = 14$ ) was 12 and 8.2 mo respectively. In CRS patients, the median overall survival in CC 0-1 ( $n = 20$ ) and in CC 2-3 subgroup ( $n = 14$ ) was 11 and 4 mo respectively. Serious adverse events arose in 9 patients, 4 in the CRS group (11.7%) and 5 in the CRS + HIPEC group (14.7%) ( $P = 0.839$ ). Multivariate analysis recognized CRS + HIPEC, synchronous PC, CC 0-1, systemic chemotherapy and no serious adverse events as major independent predictors for better survival. HIPEC was about 2.6 times likely to increase survival.

Gill *et al*<sup>[67]</sup> published a systematic review analyzing survival, mortality and morbidity in the treatment of PCGC with CRS and HIPEC. Ten studies were included. Overall median survival was 7.9 mo. In the subgroup of patients with residual nodules after CRS, less than 0.25 cm in size, the median survival raised up to 15 mo. The 1- and 5-year survival were 43% and 13%. The treatment-related mortality rate was 4.8% and the morbidity was 21.5%.

Recently, Yonemura *et al*<sup>[61]</sup>, proposed a multimodal strategy which associates neoadjuvant intraperitoneal and systemic chemotherapy (NIPS), CRS + HIPEC and early postoperative intraperitoneal chemotherapy (EPIC). The rationale of this method is to reduce tumor burden before surgery with NIPS, a bidirectional chemotherapy that attacks PC from both sides of peritoneum (from the

peritoneal cavity and from sub-peritoneal blood vessels), and reducing macroscopic and microscopic PC with CRS + HIPEC. At the end, the use of EPIC is proposed to eradicate residual intraperitoneal cancer cells before fibrin and adhesion development. Authors recommend two cycles of NIPS to achieve a negative cytology status. Severe complication post-NIPS have been reported in 4 out of 79 patients. This strategy allowed to obtain a change in washing cytology from positive to negative in 41 out of 79 patients (63%).

Three recent meta-analysis of randomized trials analyzing patients with advanced GC (with or without PC) demonstrated the survival benefit offered by HIPEC<sup>[69-71]</sup>.

In the last ten years, a new drug for intraperitoneal treatment of GC has been developed in Germany. Catumaxomab (trade name Removab<sup>®</sup>) is a rat-mouse hybrid monoclonal antibody that is made up of one "half" (one heavy chain and one light chain) of an anti-Epithelial cell adhesion molecule (EpCAM) antibody and one half of an anti-CD3 antibody, thus finally binding both EpCAM and CD3. EpCAM is an epithelial differentiation antigen that is expressed on normal epithelial cells and on almost all carcinomas (especially gastrointestinal and ovarian carcinomas) and functions as cell adhesion molecule<sup>[72]</sup>. In addition, the Fc-region can bind to an Fc receptor on accessory cells like other antibodies, which has led to calling the drug a trifunctional antibody. Actually Catumaxomab is used to treat malignant ascites, because of the intraperitoneal application of this anti-EpCAM antibody has shown significant benefits in puncture-free survival (survival without repeated paracentesis) for patients with malignant ascites in a phase III randomized trial<sup>[73]</sup>. This study demonstrated no statistically significant increases in median overall survival for other cancers, while in patients with GC a small survival increase was associated with the use of Catumaxomab<sup>[73]</sup>. Progression-free survival has been analyzed in a phase II study with the use of intraperitoneal catumaxomab in gastrointestinal EpCAM<sup>+</sup> tumors<sup>[74]</sup>. Furthermore two phase 2 studies are ongoing (follow-up phase), evaluating resectable advanced GC patients treated with adjuvant intraperitoneal Catumaxomab.

In conclusion, in PCGC CRS and HIPEC proved with good evidence to improve survival with acceptable morbi-mortality. It is very important to obtain the diagnosis and the diffusion grade of PCGC before the CRS and HIPEC with the use of staging laparoscopy. The role of surgery is fundamental, complete cytoreduction demonstrated to be strictly related to an improvement in survival. In patients with PCGC, multimodal treatment should be mandatory, leaving a pivotal role to HIPEC after CRS.

## PERITONEAL CARCINOMATOSIS FROM OVARIAN CANCER

Nowadays, the treatment diagram for advanced EOC

has been universally accepted as a combination of maximal CRS and adjuvant chemotherapy, including cases with grossly peritoneal diffuse disease. Grade III C and IV are no longer considered as “lost”. Different studies demonstrated that a progressively more aggressive surgical effort is associated with improvements in disease-free and overall survival rates. It is suggested that aggressive surgery should be performed in dedicated centers with high volume of cases, offering in-hospital mortality significantly lower than low volume ones<sup>[75]</sup>. The more the surgeon became radical and increases his/her surgical volume, the more he/she prolongs the disease-free and overall survival and reduces the in-hospital mortality. As a counterpart, the tumor biology and the initial disease diffusion have been suggested as the most important factors in survival benefit of surgery<sup>[76-79]</sup>. It's still undefined how the intrinsic features of the tumor make intra-abdominal implants easier to remove<sup>[80]</sup>. In general, upper abdominal tumor implants are suggestive of an aggressive tumor biology<sup>[81]</sup>. Covens and Berman criticized the role of CRS in advanced EOC. They proposed that both survival and surgical resectability are mostly determined by tumor biology instead of the operative effort by the surgeon<sup>[82,83]</sup>. The retrospective review of data from the Scottish Randomized Trial in Ovarian Cancer revealed in a population of 889 patients with disease stage ranging from IC to IV that the benefit of optimal debulking surgery seems to depend from the extent of disease before surgery<sup>[79]</sup>. Hager *et al.*<sup>[84]</sup> analyzing 456 women with advanced stage III/IV ovarian cancer, demonstrated no correlation between nodal status and survival. Moreover in advanced EOC nodal status was not a prognostic factor for patients undergone to optimal cytoreduction.

Complete cytoreduction is reached when no visible tumor remains after the surgical procedure. Starting from this classification a number of prospective and retrospective studies have been conducted to investigate the feasibility and the impact on survival of CRS in advanced EOC.

Up to now, the majority of available series report cases treated with the standard systemic platinum-taxanes chemotherapy and CRS. Only one study analyzed cases treated also with intraperitoneal chemotherapy<sup>[85]</sup>.

Between 2003 and 2010, 15 studies have been published analyzing patients treated with CRS and systemic chemotherapy for advanced EOC. The overall survival (OS) ranges between 46.5 and 106 mo for patients with complete CRS (no residual disease) and between 12 and 39 mo for incomplete CRS (residual disease of more than 1 cm)<sup>[85-92]</sup>. All these papers demonstrated that CRS plays a central role in advanced EOC treatment. The necessity of adjuvant chemotherapy has already been demonstrated. Surgical effort must be absolute.

Between 2000 and 2010, 20 observational studies have been published about CRS + HIPEC in treating PC from advanced and recurrent EOC. The first was published by Cavaliere *et al.*<sup>[93]</sup> reporting about 20 patients with recurrent EOC. They reported a median OS of 25

mo with a 3-year survival of 50%.

De Bree *et al.*<sup>[94]</sup> and Chatzigeorgiou *et al.*<sup>[95]</sup> reported about 19 and 20 patients respectively with recurrent ovarian cancer. They found median DFS of 26 and 21 mo, respectively. De Bree reported a median OS of 54 mo and Chatzigeorgiou a median OS for optimally cytoreduced patients (considered as residual disease of < 1.5 cm) of 29 mo. De Bree found a 3 and 5 year survival of 63% and 42%. Both studies reported a perioperative mortality rate of about 10%.

Four studies have been published in 2004<sup>[96-98]</sup>. Zanon *et al.*<sup>[96]</sup> described a cohort of 19 patients with recurrent EOC. They reported a median DFS of 17 mo with a median OS and OS in optimally cytoreduced patients (residual disease < 0.25 cm) of 28 and 38 mo respectively. Three and 5-year survival were 35% and 12% respectively. Perioperative mortality rate was 3 % with grade 1 or 2 morbidity rate of 27% and 3% respectively and with grade 3 and 4 morbidity of 7%.

Piso *et al.*<sup>[97]</sup> reported a series of 19 patients with peritoneal carcinomatosis due to primary or recurrent EOC. The median DFS was 18 mo, with mean OS and OS in optimally cytoreduced patients (residual disease < 0.25 cm) of 33 and 44 mo respectively and a 5-year survival rate of 15%. Perioperative mortality rate was 3%, grade 1-2 morbidity rate was 10% and grade 3-4 morbidity of 10% and 15% respectively<sup>[97]</sup>.

Ryu *et al.*<sup>[98]</sup> reported a series of 57 patients with advanced EOC. The median DFS was 26 mo. Median OS in optimally cytoreduced patients (residual disease < 1 cm) was 41 mo. The OS at 5-year was 54%. The survival advantage has been found to be more pronounced in stage 3 disease. Multivariate analysis showed HIPEC as an independent prognostic factor. Perioperative mortality was 4 % with grade 1, 2 and 4 morbidity rate of 14%, 5% and 4%, respectively.

Gori *et al.*<sup>[99]</sup> and Reichman *et al.*<sup>[100]</sup> reported about 29 and 13 patients respectively with advanced EOC. Median DFS were 15 and 11 mo respectively, with a median OS in Gori's paper of 64 mo and a 3-year survival rate in Reichman's study of 55%. None of these two studies reported morbidity nor mortality.

Raspagliesi *et al.*<sup>[101]</sup> and Rufán *et al.*<sup>[102]</sup> published two reports with 40 and 33 patients respectively, with advanced and recurrent EOC. Median DFS and OS in the first paper were 11 and 32 mo, and median OS and OS in optimally cytoreduced patients (residual disease < 1 cm) were 48 and 66 mo respectively. Five-year survival in Raspagliesi's series was 15%; 3 and 5-year survival rate in Rufian study were 46% and 37%, respectively. Reported mortality for both papers was 0%. Raspagliesi reported 20% of grade 1 morbidity. Rufian reported grade 1 and 2 morbidity rate of 12% and 10% and grade 3 and 4 morbidity of 10% and 6% respectively.

Helm *et al.*<sup>[103]</sup>, Cotte *et al.*<sup>[104]</sup> and Bae *et al.*<sup>[105]</sup> published series of 18, 81 and 67 patients with recurrent (Helm and Cotte) and advanced EOC (Bae). Helm *et al.*<sup>[103]</sup> reported a median DFS of 10 mo and median OS and OS

in optimally cytoreduced patients (residual disease < 0.5 cm) was 31 and 31 mo respectively. Perioperative mortality was 6% and grade 1, 2, 3 and 4 complications have been reported in 11%, 50%, 40% and 13% of patients respectively.

Cotte *et al*<sup>[104]</sup> described a median DFS of 19 mo and an OS and OS in optimally cytoreduced patients (residual disease < 0.25 cm) of 28 and 55 mo respectively. Perioperative mortality was 3% and grade 1, 2, 3 and 4 complications have been reported in 6%, 1%, 5% and 2% of patients respectively.

Bae *et al*<sup>[105]</sup> reported a 5-year survival rate of 66%, with a 0% perioperative mortality and grade 1, 2, 3 and 4 morbidity rate of 14%, 13%, 0% and 0%, respectively.

Di Giorgio *et al*<sup>[106]</sup> published data about 47 patients with advanced and recurrent EOC. They reported a median DFS of 20 mo with an OS and OS in optimally cytoreduced patients (residual disease < 0.25 cm) of 24 and 26 mo respectively. Five-year survival rate was 17% and perioperative mortality 4%. Grade 2, 3 and 4 complication rate were 21%, 9% and 13% respectively.

Bereder *et al*<sup>[87]</sup>, Guardiola *et al*<sup>[107]</sup>, Fagotti *et al*<sup>[108]</sup>, Pavlov *et al*<sup>[109]</sup> described results of CRS + HIPEC in advanced and recurrent EOC and in recurrent EOC.

Guardiola *et al*<sup>[107]</sup> published a series of 47 patients with a median DFS of 14 mo and a 5-year survival of 63%. Perioperative mortality rate was 0% and grade 4 complication rate was 13%. Fagotti *et al*<sup>[108]</sup> reported a median DFS of 10 mo, with 0% perioperative mortality and grade 2, 3 and 4 complication rate 36%, 8% and 8% respectively. Pavlov *et al*<sup>[109]</sup> described 56 patients with a median DFS and OS of 26 and 38 mo respectively. Perioperative mortality was 2% and grade 1, 2 and 4 complication rate were 5%, 11% and 2% respectively. Bereder *et al*<sup>[87]</sup> published the widest series reporting about 246 patients with advanced and recurrent EOC. Median DFS was 13 mo, median OS and OS in optimally cytoreduced patients (residual disease < 0 cm) were 49 and 56 mo respectively. Three and 5-year survival were 60% and 35%. Reported intraoperative mortality was 0.4% and grade 3 morbidity 12%.

Lastly, Deraco *et al*<sup>[110]</sup> published a multi-institutional phase 2 study evaluating the impact of CRS + HIPEC as upfront treatment on PFS and OS in 26 women with stage 3-4 advanced EOC. All enrolled patients underwent CRS, followed by HIPEC. Patients were then treated with adjuvant systemic chemotherapy. Macroscopically complete cytoreduction was achieved in 57% of patients, with minimal residual disease ( $\leq 2.5$  mm) remaining in the other 43%. Five-year OS was 60.7% and 5-year DFS 15.2%. Excluding operative death, all the patients underwent a median of 6 cycles of systemic chemotherapy at a median of 46 d from combined treatment. Four patients experienced  $\geq$  grade 3 morbidity, with one post-operative death due to sepsis.

Globally, 7 randomized controlled trials evaluating the effectiveness of HIPEC in advanced and recurrent EOC have been proposed: five are already ongoing<sup>[111-115]</sup>

and two have been only proposed<sup>[116]</sup>.

Ansaloni *et al*<sup>[117]</sup> reported about 39 patients with advanced and recurrent EOC. The mean DFS was 14 mo. Grade 1-3 post-operative complications occurred in 18% of patients. Perioperative mortality was 0.3%.

In conclusion, despite the lack of high evidence data that will be brought from the ongoing randomized trials, HIPEC associated to complete CRS seems to give survival results comparable to the standard treatment. Data are still heterogeneous due to the different meaning given to the completeness of cytoreduction, as showed in all the aforementioned studies. Some centers consider cytoreduction complete when there is no macroscopic residual disease, others follow more permissive limits. Moreover, confusion exists about “optimal” and “complete” cytoreduction. However, data clearly show as in patients with no macroscopic residual disease CRS + HIPEC increases the survival rates. These results could be overcome in terms of surgical effort and morbidity rate reduction by the use of NACT.

## PERITONEAL CARCINOMATOSIS FROM COLO-RECTAL CANCER

The multi-disciplinary treatment of CRC is actually standardized up to stage III C<sup>[118-120]</sup>, while it is unclear and not supported by strong evidences for stages IVa and IVb. American guidelines from NCI recently consider liver resection as available treatment for IVa stage, but they don't mention nowadays HIPEC as treatment option for IVb CRC, including the peritoneal carcinomatosis (PCCRC).

Another way to assess the actual relationship between HIPEC for PCCRC and Evidence Based Medicine is to measure the percentage of ongoing trials from the NCI database: worldwide, among 239 active registered trials on IVb stage CRC, only eight include HIPEC as keyword (2 phase III, 4 phase II and 2 phase I trials: from www.cancer.gov, consulted 26<sup>th</sup> of June 2013). The only concluded randomised clinical trial comparing systemic chemotherapy with cytoreduction plus HIPEC is the Dutch trial published in 2003<sup>[121]</sup>: 105 patients with PCCRC without evidence of hematogenous metastases enrolled between 1998 and 2001 were randomly allocated to receive 5-fluorouracil and leucovorin with or without palliative surgery or “aggressive” cytoreduction plus HIPEC followed by the same chemotherapy regimen. They demonstrated a median overall survival of 22.3 mo for the HIPEC arm against 12.6 mo for the standard therapy, with a significant difference ( $P = 0.032$ ). Unfortunately, the value of this RCT is limited by several factors: it was based on a chemotherapy scheme that is not the actual gold standard (not including *i.e.*, Irinotecan and Oxaliplatin); appendiceal ( $n = 18$ ) and rectal ( $n = 12$ ) tumors were not balanced in the two groups; the HIPEC protocol was based only on mitomycin C in the perfusate; the role of surgery in the control arm was unclear and impossible to determine on available data. Another randomized trial was designed by Elias to com-

pare early postoperative intraperitoneal chemotherapy plus systemic chemotherapy with chemotherapy alone after complete cytoreductive surgery for the PCCRC treatment. In 2000, after 4 years and only 35 patients enrolled, the study was stopped and the partial results analysis did not demonstrate any advantage in term of survival<sup>[122]</sup>.

Another attempt to design a RCT comparing standard systemic therapy with CRS + HIPEC + chemotherapy is the USMCI8214/ACOSOG Z6091 trial<sup>[123]</sup>, a well designed study, trying to overcome the Dutch trial limitations, with a specific target population (peritoneal carcinomatosis only, colon cancer) and using advanced/state-of-the-art chemotherapy. This trial recently closed, failing to meet accrual and amplifying the concerning from Elias *et al*<sup>[122]</sup> about the feasibility of this kind of studies: basically, even if few trials are active nowadays (in particular the last could be the PRODIGE 7 French trial<sup>[124]</sup>, with 150/280 patients enrolled at January 2012), the idea to get a level of evidence I a/ I b in support of HIPEC for PCCRC is near to be abandoned.

Anyway, the Dutch study was the base for several other trials more adequate and focusing on singular aspect, but without the same level of evidence: in particular three case control studies (evidence IIIa) have been published between 2009 and 2011. Elias *et al*<sup>[125]</sup> had the merit to include the oxaliplatin at 460 mg/m<sup>2</sup> dose in the perfusate, plus Irinotecan in 18/48 patients, comparing the HIPEC group with a standard therapy based on 5-fluorouracile (5-FU), folinic acid and systemic postoperative oxaliplatin (OX) or Irinotecan (IRI). They reached the impressive median survival of 63 mo, with a 5-year survival rate of 51% for the HIPEC group patients with a complete CRS. Franko *et al*<sup>[126]</sup> compared 67 patients treated with mitomycin C-based HIPEC with 38 controls and all the 105 patients received 5-FU, IRI, OX and bevacizumab/cetuximab. Unfortunately they included patients with liver metastases and the use of OX and target therapies was greater in the HIPEC group (78% *vs* 18% and 59% *vs* 18% respectively). Chua *et al*<sup>[127]</sup> included 294 patients, comparing supportive care and palliation with postoperative systemic chemotherapy based on 5-FU, IRI, OX, Capecitabine and monoclonal antibodies, with or without HIPEC (low-dose mitomycin C) and EPIC (high dose 5-FU). The difference between curative or palliative therapy was based on preoperative assessment of the Peritoneal Surface Disease Severity Score.

Among not randomized, retrospective multi-institutional studies, the largest published series comes from the French registry, including 523 patients with PCCRC treated from 1990 to 2007 with CRS and HIPEC<sup>[128]</sup>. Even if a 16% of incomplete CRS, with macroscopic residual (CCR-1) makes it difficult to extrapolate data about survival and the great number of participants centres adds variability (relating in particular to learning curve and surgical standardization), the reported 30-d mortality was only 3%, absolutely lower than in the Dutch trial (8%).

The peritoneal cancer index (PCI) is a semi-quantitative powerful tool, easily reproducible and validated by several studies and expert consensus<sup>[129-132]</sup>, which aims at defining and measuring the peritoneal involvement. However, using PCI to select PCCRC patients and to guide the therapeutic strategy need some comments: a threshold value to get a formal contraindication to CRS + HIPEC is not available today; a PCI greater than 20 is associated with a worse prognosis, even if in a small series (24 patients). Elias *et al*<sup>[133]</sup> described a significant advantage in survival even when PCI was over 24; for PCI < 10, there is agreement about the usefulness of CRS + HIPEC, and the median survival for these patients ranges from 31 to 48 mo<sup>[128,134-136]</sup>; similar data are provided by Gilly *et al*<sup>[137]</sup>; in currently active trials a high PCI value is generally not an exclusion criteria; different studies from the same center stressed the difference between the PCI declared at the beginning and at the end of surgery, suggesting to systematically add 2 point at the preoperative score<sup>[138]</sup>; Sugarbaker *et al*<sup>[139]</sup> suggest to correlate PCI with patients demographic when deciding to add or not HIPEC to their therapeutic scheme.

Pioneering studies about chemotherapeutic agent penetration in the tumor were available since early 90s<sup>[140,141]</sup> and have recently been confirmed<sup>[142]</sup>, showing, for example, a diffusion depth of about 1-2 mm for Mitomycin C<sup>[143]</sup>. Nevertheless, even if the rationale is something more than the common principle of resect as more tumor as possible, the attitude to consider useful HIPEC only after an adequate CRS is a recent acquisition. Moreover, there is no accordance on the dimensional cut-off (1, 2.5 or 5 mm) and in different series the impact of CCR on survival varies enormously<sup>[129,131,136,144]</sup>. In particular, if the role of macroscopic residual (CCR-2) nodules seems clear and formally contraindicate HIPEC, it is unclear the difference between nothing (CCR-0) and very small nodules (up to 2.5 mm, CCR-1 in some series). Indeed, even in CCR-1 cases, CRS + HIPEC was reported to be related to a better prognosis<sup>[134,145-147]</sup>.

Surprisingly, the tumor progression during neo-adjuvant chemotherapy is not demonstrated to be an independent prognostic factor as for gastric cancer with PC and actually is not a formal contraindication to CRS + HIPEC<sup>[148,149]</sup>.

As for other organs and pathologies, in the treatment of PCCRC the acronym HIPEC correlate to a wide spectrum of possible variation in temperature, molecules, concentration and contact time<sup>[129,131,134,145,146,150,151]</sup>. The associated systemic chemotherapy is highly variable too. This great number of parameters makes a standardization difficult: the statement from Elias *et al*<sup>[124]</sup> on the necessity to follow the most experienced centers protocols is acceptable and functional, though not methodologically correct. Finally, the lack of evidence suggests the enrollment of as many patients as possible into well designed randomized trials.

Among the most significant HIPEC protocols, those based on Oxaliplatin in the perfusate have to be report-

ed. From first demonstrations of the rationale<sup>[152]</sup> and the pharmacokinetic<sup>[153]</sup> during hyperthermic application, few phase II trials included OXt in their protocols<sup>[145,154]</sup>. In particular, Elias *et al.*<sup>[133]</sup> published a series of 24 patients treated with Oxaliplatin in the perfusate at 460 mg/m<sup>2</sup> in 2 L/m<sup>2</sup>, during 30 min at 43 °C and later a revised protocol including 106 consecutive patients treated with lower dose of oxaliplatin (360 mg/m<sup>2</sup>) combined with irinotecan (360 mg/m<sup>2</sup>) in 2 L/m<sup>2</sup> of 5% dextrose, for the same time at 43 °C. The usefulness of the Irinotecan association is controversial and may be the cause of an increased toxicity<sup>[155]</sup>.

Starting from 1995, several attempts were done to clarify the relationship between the primary tumor pathology and the outcome of PCCRC: tumor site (appendix, colon and rectum), grading, nodal and liver metastases were analyzed<sup>[130,131,146,150,156-158]</sup>. Following the substantial failure of this search (no strong correlation at several multivariate analysis), researchers lost their attention on tumor demographic in more recent publication, maintaining some interest only for tumor size<sup>[159]</sup>. Moreover, earlier reports on HIPEC suffered from the very small number of included patients, making any stratification impossible. However, beside their role as independent prognostic factors, tumor characteristics are mandatory to get a better stratification, given that the only outcome parameter used is the overall survival, whereas only few studies considered quality of life and PC-free survival<sup>[160-162]</sup>.

The combined treatment of synchronous liver metastases in patient with PCCRC is beyond the scope of this review, but this topic is strongly related to HIPEC: a variable percentage of patients included in retrospective studies underwent at the same time liver resection and CRS<sup>[128-130,145,163,164]</sup>; the report of a different impact of liver metastasis in patient accordingly to the CCR (with a significant prognostic negative value only for CCR-0 patients) underlines the possible different meaning of these two types of tumor spread ("local" *vs* "systemic"); even if a liver metastasis is not considered an absolute but only a relative contraindication to HIPEC, it seems logical that all the randomized recently designed study on HIPEC should exclude cases with liver involvement.

Currently, the main research effort is forwarded to RCTs evaluating mandatory second-look surgery with CRS + HIPEC in patients at high risk of developing PCCRC versus standard of care (control arms)<sup>[165]</sup>. Background for this new field of interest mainly are: increasing importance assigned to metachronous PC in the natural history of the tumor; definition of parameters to estimate the risk of secondary PC<sup>[166]</sup>, including synchronous completely resected PC, ovarian metastases, perforated primary tumor and in some experiences pT<sub>4</sub> tumor, colon occlusion and positive peritoneal cytology<sup>[124,167]</sup>; a great percentage of asymptomatic and work up negative high risk patients were diagnosed to harbor macroscopic PC during second look laparotomy at one year<sup>[168]</sup>. As expression of the two main groups working on HIPEC

for CRC (American and French), two different RCTs are enrolling patients to demonstrate the usefulness of an early second look treatment for high risk patients to detect and treat (with CRS + HIPEC) metachronous PC, with acceptable morbidity and mortality<sup>[165]</sup>.

In summary, to date there is no level I or II evidence that HIPEC increases the survival of patients with PC-CRC when added to modern perioperative chemotherapy protocols. The role of a complete cytoreduction, even if well recognized as beneficial and mandatory to allow a rational use of HIPEC, is not supported by RCTs.

In this lack of evidence, there are two opposite attitudes: the NCI does not even mention HIPEC among the treatment options, while the French guidelines recommended it in the treatment of patients with PC from CRC.

Beside its role as prognostic factor, the PCI is a fundamental tool to guide toward a tailored therapy, shifting from the idea of a threshold value to a parameter integrating with every tumor biology data and the clinical status of the single patient.

The next goal will be the demonstration of the usefulness of the "second-look strategy" for high risk patients in terms of overall survival and PC-free survival.

## CONCLUSION

Peritoneal carcinomatosis is a real challenge for oncologists and surgeons, which treatment is very difficult. Many surgeons and oncologists are still use to raise the white flag in discovering them. The loco-regionality of PC and the real characteristic and barrier ability of peritoneum with its proper lymphatic system have not still sufficiently investigated.

Substantial differences exist in treating the different form of PC from different diseases among different centers and countries. Consequently different evidences in results still remain and are undoubtedly discussed. For this reason the chemosurgery (association of chemotherapy and surgery as one entity) is not yet considered as a definitive valid option.

The different forms of PC from different diseases should not continue to be treated in unique centers. Advanced diseases should be centralized in all countries, and centers performing chemosurgery should not continue to treat all diseases, but disease-specialized centers should start to apply chemosurgery to the different forms of PC. The major risk is to lose the link between the PC and the primary tumor: waiting for a better understanding of the peritoneal diffusion pathophysiology and trying to redefine its prognostic role, it would be prudent to mention the pathological classification of the primitive tumor, that is frequently missed.

Lastly, to increase knowledge and overcome the actual limits, we all need a big effort toward a multidisciplinary approach, selection and discussion of the different cases with a reciprocal knowledge increase. More importance and credit should be given to translational medicine.

**Key words:** Hepatitis B virus; Next generation sequencing; Quasispecies; Linkage analysis; Gene overlapping

**Core tip:** We provide an update of hepatitis B virus (HBV) virology, focusing on its complex replication cycle which generates high genetic variability, which led HBV infection to evolve as viral quasispecies, complex distributions of variant populations that are closely related but not identical. We also discuss the clinical and virological implications of this population structure and the application of different next-generation sequencing approaches, which enable analysis of thousands of clonally amplified regions, to study these heterogeneous viral populations.

### Abstract

Hepatitis B virus (HBV) is a DNA virus with complex replication, and high replication and mutation rates, leading to a heterogeneous viral population. The population is comprised of genomes that are closely related, but not identical; hence, HBV is considered a viral quasispecies. Quasispecies variability may be somewhat limited by the high degree of overlapping between the HBV coding regions, which is especially important in the P and S gene overlapping regions, but is less significant in the X and preCore/Core genes. Despite this restriction, several clinically and pathologically relevant variants have been characterized along the viral genome. Next-generation sequencing (NGS) approaches enable high-throughput analysis of thousands of clonally amplified regions and are powerful tools for characterizing genetic diversity in

### HEPATITIS B VIRUS INFECTION HAS SINGULAR VIROLOGY: IS IT A “PSEUDORETROVIRUS”?

Human hepatitis B virus (HBV; Hepadnaviridae family) causes acute and chronic infection in humans and chimpanzees. HBV infection is distributed throughout the world, and it is estimated that around 2000 million

people worldwide have been in contact with this pathogenic agent. Despite successful vaccination programs and effective antiviral therapies, there are over 350 million carriers of HBV surface antigen (HBsAg). Some 150 million of them have active infection and a high risk of progression to cirrhosis or hepatocellular carcinoma (HCC). HBV-infected individuals have a 30-fold higher risk of developing HCC than the remainder of the population, and it is estimated that 53% of liver cancers worldwide are associated with HBV<sup>[1]</sup>.

HBV consists of a spherical particle with a diameter of 42 nm. The outer envelope is comprised of a phospholipid/protein layer and the inner shell contains core antigen (HBcAg) with the viral genome. Based on differences in the nucleotide sequence of its genome, HBV virus is currently classified into 10 genotypes (A-J) and multiple subgenotypes, with characteristic ethnic/geographic distributions<sup>[2-4]</sup>. The viral genome is 3.2 kb in length, and within the double-shelled particle, the genome adopts the conformation of a circular, partially double-stranded DNA molecule (rcDNA), with a complete non-covalently closed minus strand and an incomplete plus strand.

The HBV genome has four highly overlapping open reading frames (ORFs) - S, P, C and X - that encode seven proteins. The S ORF encodes three different-sized surface antigens whose common region contains the main antigenic loop, the "a" epitope (amino acids 124-147). The a epitope is one of the main targets for neutralizing anti-HBs antibodies. The S ORF is completely overlapped by the P ORF, which encodes a polyprotein with different domains: the reverse transcriptase (RT), the polymerase, RNase H, and the terminal protein (TP). The catalytic center of RT is located at the C domain and is defined by four amino acids mapped at positions 203-206: tyrosine, methionine, aspartate, and aspartate (203YMDD206). The YMDD motif is highly conserved among viral polymerases/reverse transcriptases. The 3' region of C ORF is overlapped by P ORF and contains two start (ATG) codons. The region between these codons is called the preCore region, while the remaining region from the second ATG is known as the Core gene. The two proteins translated from these two ATG start codons are the viral capsid (HBcAg) and the e antigen (HBeAg); the latter is a soluble antigen that acts as an immunomodulator. Finally, the 5' end of the X ORF is overlapped by the P ORF, and the 3' end is overlapped by part of the preCore. The X ORF encodes the x antigen (HBxAg), which is a multifunctional transactivator protein. Furthermore, the HBV genome contains various elements that regulate replication. One important element is enhancer II (ENH II), located in the X gene sequence, which modulates the promoters of transcription of viral mRNA.

#### ***Viral cycle: a DNA virus with a retrotranscription step, similar to a retrovirus***

The HBV population is highly heterogeneous and is comprised of genomes that are closely related, but not identical; hence, it is considered a viral quaspecies, a term commonly associated with RNA viruses. The com-

plex viral replication cycle of HBV may be the cause of this quaspecies nature.

HBV replication occurs exclusively in hepatocytes, but the specific and highly effective viral determinants that direct HBV into hepatocytes are still unknown. It has been hypothesized that HBV hepatotropism is mediated through specific binding of the myristoylated N-terminal preS1 domain of the large HBV surface protein to a hepatocyte-specific receptor that has not been completely defined<sup>[5]</sup>. After interacting with the cellular receptor, HBV particles enter the liver cell<sup>[6]</sup> and release the outer envelope. HBcAg from the inner shell directs the particle to the nucleus, where the rcDNA genome is repaired by host and viral polymerases to a fully double-stranded covalently closed circular genome (cccDNA). This molecule remains in the nucleus of the infected hepatocyte as a minichromosome until the cell dies<sup>[7]</sup>. cccDNA also acts as a template for synthesis of five different viral mRNAs: preCore mRNA, pre-S2 mRNA, X mRNA, S1 mRNA, and the pregenomic RNA (pgRNA). The largest of these, pgRNA, is 3.5 kb in length and contains a redundant fragment of the preCore region at both ends. pgRNA yields the polymerase and core transcripts. In addition, the 5' and 3' ends of pgRNA adopt a hairpin stem-loop structure, named epsilon. The epsilon signal at the 5' end directly interacts with the polymerase and constitutes the first step in initiation of reverse transcription. The interaction induces recruitment of HBcAg monomers around the polymerase/pgRNA complex. These particles can be considered true previrions, with the HBV genome in RNA conformation. Within these particles, pgRNA serves as a template for reverse transcription to the minus strand of HBV DNA, which acts as a template for synthesis of the HBV DNA plus strand by the HBV polymerase. The plus strand is incomplete and yields a new particle with a new rcDNA genome<sup>[8]</sup>.

Thus, the HBV viral cycle includes a transcription and translation step, but also a reverse transcription step similar to what occurs in retroviruses, mediated by the different activities of HBV polymerase<sup>[2,3]</sup>. One potential explanation for the quaspecies nature of the virus occurs at the retrotranscription step: the viral enzyme lacks proofreading activity and the new genomes are highly prone to accumulate errors<sup>[9]</sup>. This fact, in addition to the extremely high viral replication rate results in a remarkably heterogeneous viral population, referred to as a quaspecies<sup>[10]</sup>. In the section *Variability only due to poor fidelity of the viral polymerase?* we discuss further potential sources of the virus quaspecies formation.

Nonetheless, quaspecies variability may be somewhat limited by the high degree of overlap between the HBV coding regions (67%)<sup>[11]</sup>. This restriction would not be very important in the Core region because it is not overlapped and contains variable epitopic domains that play a central role in the immune response against the virus<sup>[12,13]</sup>. In contrast, the viral reverse transcriptase is highly conserved, due to its important functions and overlapping with the S ORF<sup>[3]</sup>. Positions at or near the

initiation site for synthesis of the first viral strand are also highly conserved, and are homologous over 67 nucleotides to the U5 region; a region comparable to retroviral long terminal repeats<sup>[14]</sup>.

The Core is the most suitable region to study the natural evolution of the viral genome, keeping in mind that the immune system is the main driver of evolutionary pressure<sup>[15]</sup>. Certain specific mutations observed in viral variants may have implications in the pathogenesis of viral disease. For example a G to A substitution at nucleotide 1896 yields a *de novo* stop codon in the preCore region that is associated with HBeAg seroconversion and a high risk of fulminant hepatic failure in acute infection<sup>[16]</sup>. In conclusion, depending on the HBV region analyzed, different features of the quasiespecies will be examined.

### ***Singular HBV virology: viral genome integration and nuclear reinfection of nascent viral capsids***

One peculiarity of hepadnaviruses is that their genome is often found to be inserted in the hepatocyte genome<sup>[17-19]</sup>, a fact that could indicate a possible common origin with retroviruses. These integrations can induce chromosome changes, genome instability, or changes in the expression of human genes<sup>[20]</sup> and have been found throughout the different chromosomal sites in the host genome [*e.g.*, near the telomerase reverse transcriptase gene (*tert*) and fibronectin gene (*fn1*)<sup>[19,21-24]</sup>]. Integrated HBV DNA sequences and episomal HBV genomes have been found in 85%-90% of HBV-related cases of HCC<sup>[19,21]</sup>. Recent studies using various genetic approaches and microarray technology have reported that HBV-related HCC displays higher rates of chromosomal abnormalities than HCC due to other risk factors, and even generates chimeric oncogenic proteins<sup>[25,26]</sup>. Ding *et al.*<sup>[19]</sup> analyzed 286 unique integration sites from 40 pairs of HBV-related HCC and tumor-adjacent tissues by massive sequencing on the Illumina platform [see next-generation sequencing (NGS) methods in later sections], and seven HBV integrations per individual were detected. However, the relationship between HBV integration and HCC has not been completely elucidated.

Another peculiarity of viral replication is nuclear reinfection. The nascent capsids have the same structure and conformation as those that originally infected the hepatocytes and released the outer envelope, and this similarity enables nuclear reinfection. In this way, the new capsids can increase the amount and diversity of nuclear cccDNA during viral replication<sup>[27]</sup>. This leads to an increase in the intracellular and intranuclear viral quasiespecies.

Based on its singular virology, HBV can be considered a non-enveloped RNA virus at the intracellular level and an enveloped DNA virus at the extracellular level. In addition, it has “pseudoretroviral” behavior consisting of an ability to integrate into the host cell genome, and a highly variable genome that leads to a quasiespecies nature. In the next sections, the variability of the HBV genome will be discussed in the light of data obtained by recently developed massive sequencing technologies.

## **TOOLS FOR VIRAL QUASIESPECIES**

### **STUDY: NGS TECHNOLOGIES AS A NEW STRATEGY FOR A DEEP ANALYSIS**

Study of HBV quasiespecies evolution together with disease progression is important to clarify the pathogenesis of this condition and improve the available treatment strategies<sup>[28]</sup>. This type of study can be performed by standard methods or by new, more powerful approaches.

#### ***Standard approaches to describe genomic variability***

For the past 40 years, the most widely used method for sequencing DNA has been Sanger sequencing, which is based on a single sequencing reaction with fluorescent dideoxynucleotides, which act as chain terminators<sup>[29-31]</sup>. This produces a mixture of DNA fragments of different sizes, all ending with one of four terminators, each of which is marked with a different fluorochrome that can be detected when the fragments are separated by size in capillary electrophoresis-based sequencers. To obtain the maximum amount of product to be analyzed, polymerase chain reaction (PCR) is performed to amplify the region of interest. Analysis of a complex genomic sample (*e.g.*, a viral quasiespecies) by Sanger sequencing yields the most common nucleotide present in the quasiespecies, known as the consensus sequence, but individual sequences are not obtained. Thus, analysis of the HBV RT domain C (putative active center) covering codons 202 to 206 can yield positions with different nucleotides (A/GGC<sub>202</sub> TAT<sub>203</sub> A/GTG<sub>204</sub> GAT<sub>205</sub> GAT<sub>206</sub>), but it is uncertain whether the changes are present in the same sequence or in two different sequences, for example GGC<sub>202</sub>.TAT<sub>203</sub>.ATG<sub>204</sub>.GAT<sub>205</sub>.GAT<sub>206</sub> or AGC<sub>202</sub>.TAT<sub>203</sub>.GTG<sub>204</sub>.GAT<sub>205</sub>.GAT<sub>206</sub>. Minor nucleotide changes in the same position can only be detected as “inner small peaks” when their frequency is higher than 20% (*e.g.*, a clear G peak with a small A peak inside in codon 202). Therefore, Sanger sequencing of a complex genomic mixture presents two main limitations: low sensitivity for minor variant detection and inability to perform haplotype analysis.

In addition to such direct sequencing methods, some indirect molecular techniques, mainly focussed on detection of specific variants, have also been extensively used. The most common is reverse hybridization in Line Probe Assays format that can detect specific variants present as at least 5% of the viral quasiespecies<sup>[32,33]</sup>. Other, less commonly used methods for detecting specific variants include restriction fragment length polymorphism (RFLP) analysis<sup>[34-36]</sup>, 5'-nuclease assays<sup>[35]</sup>, melting point analysis<sup>[37]</sup>, mass spectrometry<sup>[38]</sup>, DNA chip technology<sup>[39]</sup> and real-time PCR using mutation-specific primers<sup>[40]</sup>. Although these methods can differentiate between population mixtures<sup>[41]</sup>, they do not allow simultaneous detection of different substitutions in the same viral genome. Therefore, complex variants with two or more amino acid changes, such as those related to entecavir resistance or those causing a fitness increase during lamivudine

treatment, cannot be properly studied by these indirect methods. Furthermore, they cannot be used to properly describe the composition of a quasispecies.

The traditional method used to analyze a heterogeneous genomic population, such as a viral quasispecies, is cloning and sequencing. This is a costly, labor-intensive process that requires multiple, complex experimental steps, and provides limited resolution regarding the mutation spectrum and frequencies. Analysis of a quasispecies by cloning requires a large number of clones (> 100) which significantly hampers its use.

## NGS

The genome sequencing scenario is now changing, mainly because of the development of NGS techniques<sup>[42]</sup>. NGS approaches enable high-throughput analysis of thousands of clonally amplified regions and are powerful tools for characterizing genetic diversity in viral strains<sup>[43]</sup>.

The most widespread platforms available are the 454 FLX (Roche)<sup>[44]</sup>, the Solexa genome analyzer (Illumina)<sup>[45,46]</sup>, the SOLiD system (Applied Biosystems)<sup>[47]</sup>, and recently, the Ion Torrent system (Life Technologies)<sup>[48]</sup>. These platforms apply different experimental strategies (enzymological, chemical) and complex engineering (high-resolution optics, hardware, and software), and provide significant time saving and a minimal requirement for associated equipment in comparison to cloning. NGS technologies seek amplification of single strands of DNA with specific sequences (added by chemical binding or by specific PCR primers) and perform sequencing reactions on the amplified strands. The presence of specific sequences enables selection of PCR-amplified fragments without requiring a bacterial cloning step. The yield of sequence reads and total bases per instrument run is significantly higher than that produced in a capillary sequencer run: from several hundred thousand reads (454 FLX and Ion Torrent) to tens of millions of reads (Illumina and SOLiD)<sup>[44]</sup>.

**FLX-454 pyrosequencing platform (Roche):** The 454 technology is based on ultra-deep pyrosequencing (UDPS), a DNA sequencing method that relies on chemiluminescent detection of pyrophosphate release during polymerase-mediated dNTPS incorporation. The pyrophosphate is converted into ATP, which allows generation of light by the enzyme luciferase in amounts proportional to the amount of ATP. UDPS is a fast method that can detect and quantify small viral subpopulations (present in < 5%)<sup>[43,49]</sup>; specifically, a recent study reported detection of HBV subpopulations accounting for 2% of the total viral population<sup>[50]</sup>.

The 454 Sequencing System supports analysis of samples from a wide variety of starting materials, including genomic DNA, PCR products, artificial bacterial chromosomes, and cDNA. The system relies on fixing nebulized and adapter-ligated DNA fragments to small DNA-capture beads in a water-in-oil emulsion. The emulsion is prepared to achieve oil drops with a diameter that

accommodates only one bead and a single DNA molecule. The oil drops act as microreactors for clonal PCR amplification. DNA-bound beads are placed on a PicoTiter-Plate (PTP), together with a fiber optic chip and a mix of enzymes such as DNA polymerase, ATP sulfurylase, and luciferase. The PTP is then placed in the GS FLX system for sequencing. The sequencing process is monitored by the light flashes released once a nucleotide is incorporated. However, the calibrated base calling cannot properly interpret long stretches (> 6) of the same nucleotide and for this reason, homopolymeric regions (defined as repeats of  $\geq 4$  identical bases) are prone to artifactual base insertions and deletions. In contrast, as each incorporation step is nucleotide-specific, substitution errors are rarely encountered in Roche/454 sequence reads.

The raw reads are processed by the 454 analytical software and then screened by various quality filters to remove poor-quality sequences. Fragments > 400 nucleotides can be sequenced (currently around 700 nucleotides), allowing haplotypic analysis that would theoretically be useful even for phylogenetic studies. UDPS is currently the only platform for quantitative analysis of long clonal sequences that allows detection of particular mutations as well as combinations of mutations in the same sequence. It is, therefore, highly useful as a high-throughput, massive sequencing method to describe quasispecies.

**Solexa (Illumina):** The single molecule amplification step of the Illumina Genome Analyzer starts with an Illumina-specific adapter library. This step automatically takes place on the oligo-derivatized surface of a flow cell, which is an eight-channel sealed glass microfabricated device that allows a special process, “bridge amplification”, of fragments on its surface. This process uses DNA polymerase to produce multiple DNA clusters, each representing the single molecule that initiated the cluster amplification. Bridge amplification generates multiple copies of a specific DNA molecule on an “oligo-decorated” solid support. Each cluster contains approximately 1 million copies of the original fragment.

The Illumina system utilizes a sequencing-by-synthesis approach in which all four nucleotides and the DNA polymerase are simultaneously added to flow cell channels for incorporation into the oligo-primed cluster fragments<sup>[46]</sup>. The nucleotides carry a unique base fluorescent label in which the 3'-OH group is chemically blocked. The DNA chains are then extended by one nucleotide, and an image is taken. Subsequently, the 3' blocking group is chemically removed to prepare each strand for the next incorporation by DNA polymerase. This series of steps continues for a specific number of cycles, permitting discrete read lengths of 50-250 nucleotides. However, this approach is not suitable for haplotypic analysis or quasispecies studies.

**SOLiD (Applied Biosystems/Life Technologies):** The SOLiD platform, which is similar to that of other NGS methods, uses an adapter-ligated fragment library

and an emulsion PCR (similar to 454 technology)<sup>[47]</sup>. However, it is based on the principle of “two-base encoding” and uses a DNA ligase as the enzyme. The system has random 8-mer fluorescent probes with all 16 combinations of di-bases at the 3' ends. Once one of these fluorescent probes hybridizes over the sequence, the probe is linked to the region of interest by ligase. Each ligation step is followed by fluorescence detection and removal of the ligated 8-mer. This method sequences short fragments of 35-50 nucleotides and does not allow haplotypic studies.

**Ion torrent: ion semiconductor sequencing (Life Technologies):** This platform is similar to the FLX 454 method, but has a semiconductor-based detection system<sup>[48]</sup>. The sequencing system is based on detection of hydrogen ions (protons) released during DNA polymerization, instead of the image capture used in other sequencing systems. A microwell containing a DNA template is flooded with a single type of nucleotide. If the nucleotide introduced is complementary to the leading template nucleotide, it will be incorporated into the growing complementary strand. This phenomenon releases a hydrogen ion that triggers a hypersensitive ion sensor, whose signal indicates that a reaction has occurred. If homopolymer repeats are present in the template sequence, multiple nucleotides will be incorporated in a single cycle. This leads to a corresponding number of released hydrogen molecules and a proportionately higher electronic signal. In this sense, this method can be considered more accurate than FLX-454 for homopolymeric sequences. Currently, fragments up 200 nt can be sequenced, with an approximation to haplotypic analysis. However, the sequence length is too short for phylogenetic studies, and the method is not useful to describe quasispecies.

### NGS applications and limitations

NGS techniques have been used to study some quasispecies, such as human immunodeficiency virus (HIV)<sup>[51,52]</sup>, HBV<sup>[53-59]</sup>, and hepatitis C virus (HCV)<sup>[46,60]</sup>. The 454 platform has been successful in analysis of HIV quasispecies, exhibiting high sensitivity for detecting treatment-resistant variants<sup>[51,61-63]</sup>, in describing HCV heterogeneity<sup>[46,60]</sup>, and more recently, in HBV quasispecies studies<sup>[53-59]</sup>. UDPS has been used in studies to quantify HBV minority variants carrying resistant mutations<sup>[55,58]</sup>, and to detect defective variants<sup>[53-58]</sup>. In addition, the UDPS NGS approach has enabled dynamic study of clonal evolution in cancer cells, detecting somatic mutations in rare sub-clones at a rate of 1 in 5000 copies<sup>[49]</sup>.

Several factors should be remembered in relation to NGS reads. First, the length of an NGS sequence read is shorter than that of Sanger sequencing, and second, each NGS platform has a unique error model that differs from the error model established for capillary sequence reads. In consequence, complex, accurate computational algorithms are required to process the raw data from massive parallel sequencing (background subtraction, base calling,

and quality assessment), and they should be specific for each platform. Bioinformatic filtering has been the main method developed to validate variants carrying substitutions, but it has not been completely optimized for variants with insertions and deletions, which are common in HBV, especially in the X ORF and basic Core promoter, mapped at the preCore region<sup>[64-68]</sup>. Therefore, study of insertion and deletion variants still requires classical cloning analysis, and that is why they have been little investigated.

In addition, UDPS is associated with sequencing errors in homopolymeric regions, although some of the variants identified have been true variants previously reported by cloning<sup>[69,70]</sup>. Currently, it is uncertain how natural insertion/deletion variants can be differentiated from variants resulting from errors in UDPS processing; therefore, the computational analysis of UDPS reads must be improved. One possible approach could include systematic analysis of forward and reverse reads in duplicate by NGS and in parallel with cloning. Another strategy could be targeted searching for sequences with known deletions and insertions, previously detected by classical clonal analysis<sup>[70]</sup>, or selection of insertions or deletions that cause relevant changes, such as *de novo* stop codons<sup>[69,70]</sup>.

The importance of investigating insertions and deletions in the HBV quasispecies is underscored with the G2091 deletion, described by Schories *et al.*<sup>[69]</sup> and recently detected by Ramírez *et al.*<sup>[70]</sup>. This deletion produces three *de novo* stop codons: (wild type, 2086TGG.GGG.GAA.TTG.ATG.ACT.CTA.GCT, and the deleted variant, 2086TGG.GGG.AAT.TGA.TGA.CTC.TAG.CT), resulting in an HBV “capsid-defective genome”. The presence of potentially defective genomes in the HBV quasispecies has been recently reported in the S ORF<sup>[56,58]</sup>, in the HBcAg start codon, and even in the HBxAg stop codon in studies using massive UDPS<sup>[56]</sup>.

Another factor that must be taken into account in NGS data analysis is the possibility of recombination events occurring during PCR amplification<sup>[71]</sup> by different mechanisms; for example, short incomplete amplicons can act as primers for different sequences present in the quasispecies, or crossing of amplified sequences can occur, similar to chromosome recombination events. These phenomena may be a potential limitation of UDPS, but they can also occur in classical cloning and any other technique that includes a PCR amplification step. This confounding factor questions the reliability of haplotype analysis of the quasispecies, which requires minimization of recombination events. Thus, the true impact of these events should be carefully evaluated in the future by UDPS analysis of *in vitro* mixtures from different clonal sequences. It would be particularly interesting to know the impact of recombination in order to derive conclusions from linkage analysis of different relevant nucleotide substitutions reported in the HBV polymerase and preCore region by classical cloning<sup>[72]</sup> and UDPS<sup>[56-58]</sup>.

Lastly, the limit of detection of the UDPS approach has not been established, and differences between studies

from different groups must be taken into account when viewing the results.

## QUASISPECIES NATURE OF HBV

The term quaspecies was coined to refer to RNA viruses that genetically evolve as complex distributions of variants that are closely related, but not identical<sup>[73]</sup>. In quaspecies infection, the genome is not precisely defined, and an average of different variants is used as the consensus genome. Study of quaspecies dynamics is important to understand the adaptability, pathogenic power, and persistence of viruses, and to design strategies to prevent and treat the diseases they cause. A viral quaspecies is seen as a swarm of variants in a host, among which variants carrying a biological advantage during replication are selected. When changes occur in the environmental conditions of the virus, the quaspecies structure responds by rebalancing its composition. The predominant sequence (master sequence) may even shift by selection of a variant that is better adapted to the new environment, in the classic Darwinian process of survival of the fittest<sup>[57]</sup>.

### *Variability only due to poor fidelity of the viral polymerase?*

The hepadnavirus family replicates by a reverse transcriptase that lacks proofreading activity, and this fact seems to justify their high mutation rate ( $3.2 \times 10^{-5}$  -  $7.9 \times 10^{-5}$  nucleotide substitutions/replicative cycle); 100 times higher than other DNA viruses<sup>[74]</sup>. The high mutation rate, intense replicative activity ( $10^{12}$  viral particles/d), and small genome size of HBV, results in approximately  $10^{10-11}$  point mutations being produced per day in individuals with active replication.

In addition, certain host factors are reported to be associated with hypermutational activity. One example is the innate antiviral defense mechanism that mediates host enzymes belonging to the APOBEC3 cytidine deaminase family, which cause extensive deamination of cytidine (C) to uridine (U) bases in negative-stranded DNA<sup>[75]</sup>. This activity results in a guanine (G) to adenine (A) hypermutation in positive-stranded DNA<sup>[76]</sup>. APOBEC-mediated G to A hypermutation was initially reported in HIV, but it has also been described in HBV<sup>[77-79]</sup>, other retroviruses, and retrotransposons<sup>[76]</sup>. In fact, several clinically relevant HBV variants result from G to A mutations, such as rtA181T (GCN to ACN) and rtM204I (ATG to ATA), interpreted as RT resistance mutations, and the G1896A and G1899A main preCore variants (see next sections).

Thus, viral and host factors yield an HBV quaspecies provided with plasticity and rapid adaptation to the changing environmental conditions caused by the immune response or antiviral treatments<sup>[80,81]</sup>. In this line, nascent HBV capsids can contain new mutations produced during reverse transcription or APOBEC activity; therefore, the genomes may differ from those that previously infected the nucleus. This reinfection process

generates a kind of intracellular quaspecies, in addition to the circulating one, thereby increasing the complexity of HBV. Another factor potentially responsible for causing variability is the fact that the same liver cell can be infected by multiple virions simultaneously or sequentially during its lifetime.

The versatility of the quaspecies structure may include mechanisms to tolerate variants with changes involving long fragments of the HBV genome, such as deletions reported by genome splicing<sup>[73,82,83]</sup>. This tolerance might yield defective genomes that can be maintained by transcomplementation mechanisms. For instance, HBsAg-defective variants might be enveloped by functional surface proteins encoded by other variants present in the quaspecies<sup>[58,84]</sup> (see next sections). For this reason, viral genomes that cannot self-replicate sufficiently may be detected in the viral quaspecies population<sup>[56,58,85]</sup>. Such defective genomes have been isolated from liver tissue of infected patients<sup>[86]</sup>, and the proteins they encode, which are known as hepatitis B spliced proteins, appear to contribute to persistent replication in patients with HCC<sup>[86]</sup>. This suggests that defective genomes may have modulatory roles and provides evidence of regulatory mechanisms directly associated with the HBV quaspecies structure.

These data seem to indicate that the quaspecies nature of HBV can further increase the encoding capacity of the virus, which is somewhat limited by the high overlapping of its genome. ORF overlapping represents a strategy to restrict the viral genome size and maximize its coding capacity<sup>[3,87-89]</sup>. An indication of gene overlapping may be the presence of unusually strong constraints at third codon positions<sup>[90-92]</sup>. Hepadnaviruses are representative of this situation, and overlapping must be systematically taken into account when HBV viral infection is investigated at the virological and clinical level.

As was discussed above, it is generally assumed that the main source of quaspecies variability is the viral polymerase lack of error correction. However, certain characteristics of the target sequences themselves, such as the presence of homopolymeric regions, may be associated with an increased risk of errors by polymerase “sliding”. This phenomenon would result in errors by deletion or insertion, giving rise to altered reading frame variants and resulting in potentially deficient genomes<sup>[69,70]</sup>. The presence of these variants in the circulating viral quaspecies would provide evidence of complementary mechanisms whose effect on infection is unknown.

In this line, it cannot be excluded that truncated proteins encoded by these variants may have some type of regulatory function. For example, lengthening the life of infected cells by changing cell apoptosis (carcinogenesis) has been reported in association with truncated HBx proteins<sup>[93-96]</sup>. To explain the existence of these truncated versions of HBx, it has been hypothesized that transcomplementation could be achieved by using functional protein encoded by competent variants. This process would potentially modulate viral encapsidation and replication, with direct effects on the clinical evolution of the infection.

**Table 1** Main amino acid variants described in the hepatitis B virus genome and its effect

ORF	Amino acid variant	Effect
P	A181T and M204 I/V (compensatory: L80I/V, T128N, R153Q, V173L, L180M, A200V <sup>1</sup> , V207I <sup>1</sup> ) N236T (compensatory: A181 T/V/S. Low sensitivity: V84M, S85A, L217R, I233V) I169T, T184S, S202C/I/G, M250I A194T <sup>1</sup>	LMV resistance ADV resistance ETV resistance <sup>2</sup> TDF resistance
S	G145R W156Stop, W163Stop, W172Stop, W196Stop D144A, P142S, K141E, Q129H, I/T126N, T131I, M133L	Immune therapy failure HBsAg structural alterations

<sup>1</sup>Antiviral treatment resistances not completely defined<sup>[58]</sup>; <sup>2</sup>Linked to lamivudine (LMV) signature (L180M + M204V). ORF: Open reading frames; ADV: Ad-efovir; ETV: Entecavir; TDF: Tenofovir; HBsAg: Hepatitis B virus (HBV) surface antigen; HBeAg: HBV e antigen; HCC: Hepatocellular carcinoma.

*et al.*<sup>[98]</sup> analyzed a group of entecavir-treated patients and found that responders presented a less complex quaspecies than the group of partial responders, whereas partial and non-responders showed similar patterns of complexity. A recent report based on a cloning method has shown that viral diversity after lamivudine treatment was higher in HBeAg-seroconverters than in non-seroconverters<sup>[72]</sup>. Nonetheless, these studies have the limitation of a low number of clones analyzed.

Nishijima *et al.*<sup>[59]</sup> applied UDPS to study quaspecies complexity in a group of chronic hepatitis B patients, comparing the viral genome sequences determined in liver tissue with those in serum. Although the results cannot be compared with those of the cloning studies, the authors found no significant differences in the viral population between liver and serum from the same individual. In addition, they found no significant differences in viral complexity at the HBV DNA level, or according to age or degree of fibrosis. Nishijima *et al.*<sup>[59]</sup> did not compare quaspecies diversity in relation to nucleos(t)ide analog (NUC) response or HBeAg seroconversion, but they observed similar complexity between naïve and NUC-treated cases. A preliminary study by our group using UDPS and Shannon entropy calculation indicated a decrease in quaspecies complexity at the HBV preCore/Core region after NUC treatment failure, likely due to selection of specific NUC-resistant variants. In contrast, diversity mainly increased during the natural evolution of the virus, probably because of immune system evolutive pressure. In this sense, it should be remembered that the main HBV epitopic regions are located in the preCore/Core region<sup>[99]</sup>.

## CLINICALLY SIGNIFICANT HBV GENOMIC VARIANTS: MASSIVE SEQUENCING FOR A DETAILED DEPICTION OF THE SITUATION

Several clinically and pathologically relevant variants have

been characterized along the viral genome, despite the restriction resulting from the high degree of HBV genome overlapping. This restriction is especially important in the P and S gene overlapping regions, but is less significant in the regions corresponding to the X and preCore/Core genes. Therefore, the X and preCore/Core genes may be the most suitable for studying quaspecies variability, even though they contain the major enhancer of the viral genome (ENH II). The following sections will discuss the major variants of each of the HBV genome regions (P, S, X, preCore and Core) and their clinical and pathological implications, which are summarized in Table 1. Most of the reported data were obtained by direct sequencing or short clonal studies, which means that the variants were present in significant percentages. However, recent results obtained by massive sequencing are also included to provide a more detailed picture.

### P gene variability and its implications in antiviral treatment

The polymerase gene (P ORF, nucleotides 2307-1623), the largest HBV gene, encodes the 90-kDa viral polymerase protein, a multifunctional enzyme involved in DNA synthesis and pgRNA retrotranscription (RT domain), with additional priming [TP domain and RNase (RH) domain] functions. The main genomic variants of this region have been reported in the proper viral polymerase RT domain, which has both DNA polymerase and retrotranscriptase activities (retrotranscribes pgRNA to the minus DNA strand and synthesizes the incomplete plus strand). RT activity is located between the non-functional spacer region (Spc) and the RH domain. The TP domain, which acts as a primer for synthesis of the negative DNA strand is located at the N-terminal of the P ORF. The Spc region, located next to TP, is dispensable for enzyme function and therefore, easily tolerates mutations. The Spc region overlaps the preS region of the envelope gene and accumulates important mutations, such as long deletions<sup>[3,100,101]</sup>. The crystal structure of

HBV polymerase has not yet been reported, but the 3D structure of HBV RT has been modeled, based on the crystal structure of HIV-1 RT<sup>[2,102]</sup>. The model shows the common right-handed configuration of both polymerases and identifies seven different domains (A-G). The catalytic center of RT activity (nucleotides 736-747) corresponds to the YMDD sequence, identical to what is observed in HIV-1<sup>[103]</sup>. The YMDD motif contains two of the three essential D (aspartate) residues of the polymerase. Attending to the specific nomenclature of the RT region, position 348 of the polymerase gene corresponds to the first amino acid of RT; hence, the catalytic motif is located at positions 203-206 (Y<sub>203</sub>M<sub>204</sub>D<sub>205</sub>D<sub>206</sub>)<sup>[32]</sup>. The RT region is highly conserved among retroviruses and hepadnaviruses<sup>[14]</sup>. In this putative structure, the YMDD main catalytic motif is identified in the C domain, located in the palm region of the right-handed RT structure<sup>[104,105]</sup>.

As in HIV, therapy for HBV infection is currently based on the use of NUCs [lamivudine (LMV), adefovir (ADV), emtricitabin (EMT), telbivudin (LdT), entecavir (ETV), and tenofovir (TDF)], which are HBV RT inhibitors. Among them ETV and TDF are usually recommended as the first-line treatment option because of their high potency and low resistance rates. NUCs and host nucleotides, the natural polymerase substrates, bind at the YMDD motif. NUCs act as competitive inhibitors by blocking elongation of new HBV DNA strand. The central role of HBV polymerase in the viral replication cycle seems to justify the stability of its AA sequence relative to the remaining HBV protein products. However, non-synonymous nucleotide changes that result in amino acid substitutions have been reported in relation to resistance to NUC therapies. The presence of these drugs induces selection of HBV variants carrying amino acid substitutions in the RT domain. These mutations may cause structural changes in the polymerase, resulting in a decrease of drug affinity and antiviral activity. Thus, NUCs efficiently inhibit wild-type HBV variants present in the viral quasiespecies, whereas variants carrying resistant mutations can maintain their replicative activity. Under NUC treatment, the percentage of resistant variants in the quasiespecies may increase and ultimately be selected as the major variant, thereby causing treatment failure, manifested as viral breakthrough (VBK).

Because they can confer resistance to oral antiviral treatment, mutated strains are of great interest clinically. The intensity of viral resistance is related to the type of drug and the viral variant. The most commonly reported variants, rtM204V and rtM204I, are changes in the YMDD motif to YVDD or YIDD (located in RT domain C and analogous to the M184V/I LMV resistance mutation of the HIV-1 RT) (Table 1). Both these variants show low affinity for LMV, making them highly resistant to the drug and easily selected during treatment (70% of patients show resistance after 5 years of LMV therapy). These variants are also resistant to other nucleoside therapies such ETV and LdT, but with lower resistance rates than

with LMV (*e.g.*, 17% after 2 years of LdT treatment)<sup>[106]</sup>.

The fitness of viruses with rtM204V and rtM204I variants is markedly reduced in comparison to wild-type<sup>[107]</sup>, but they alone can replicate under LMV therapy<sup>[108,109]</sup>. Long-term LMV therapy increases the probability of new variants emerging, which will restore the replication capacity of the mutant and worsen the outcome of infection<sup>[110]</sup>. The most common of these additional, potentially compensatory mutations is rtL180M<sup>[107]</sup>, which is often detected together with rtM204V and less often with rtM204I. Other mutations, such as rtV173L and rtL80I/V, do not alter the sensitivity of HBV to LMV, but instead, enhance its replication efficiency<sup>[111]</sup>. The rtL80I/V mutation (located in the RT A domain) is associated with severe disease in HBV genotype C patients<sup>[112]</sup>. rtV173L (combined with rtL180M and rtM204V) is the second most commonly detected compensatory mutant (19% of cases showing LMV resistance)<sup>[109]</sup>. Selection of compensatory mutants also occurs with the rtA200V/rtM204I combination<sup>[113]</sup> and with the variants rtT128N or rtR153Q in combination with the rtL180M/M204V polymerase mutations<sup>[114]</sup> (Table 1).

The compensatory effect of additional variants has been explained by molecular interactions between the various substitutions that provide HBV polymerase with a more efficient catalytic structure<sup>[102]</sup>. The rtA181T variant has been associated with LMV resistance in less than 1% of cases and has also shown resistance to ADV treatment<sup>[84]</sup>. The rare rtA181S mutation, which is similar to rtA181T, presents cross-resistance to LMV and ADV treatment in combination with M204I<sup>[115]</sup>. Emergence of resistance to ETV is uncommon in treatment-naïve patients (< 1% over 6 years), but in those with previous LMV failure, it increases dramatically to 40% after 4 years<sup>[106,116]</sup>. In fact, ETV resistance seems to be associated with the concomitant presence of LMV resistant variants and mutations in other RT codons (169, 184, 202 or 250, with at least four different substitutions in the same sequence), which confer decreased susceptibility to both LMV and ETV<sup>[117]</sup> *in vitro*, explaining the high genetic barrier of ETV.

The NUC ADV is active against HBV wild-type virus and variants resistant to LMV, EMT, and LdT. Emergence of ADV-resistant variants is less frequent than with LMV therapy (29% at 5 years)<sup>[118]</sup>. ADV resistance has been associated with the A181T/V and rtN236T variants, and less frequently, with rtI233V<sup>[119-121]</sup>. Interestingly, variant A181T has also shown LMV resistance according to *in vivo* and *in vitro* evidence; thus, rtA181T is cross resistant to LMV and ADV<sup>[84]</sup>. Other amino acid changes have been occasionally linked to resistance or low sensitivity to ADV, such as rtV84M and rtS85A in the A domain and rtL217R; a natural polymorphism in the D domain observed in subgenotype A2 HBV strains<sup>[2,120,122]</sup>. In addition to the main resistant variant, other minor variants are selected after LMV or ADV failure<sup>[123]</sup>, and some of them seem to be associated with the viral genotype (*e.g.*, rtS85F, rtL91I, and C2456G associated with LMV resistance

in HBV genotype D, or rtI53V, rtW153R and rtF221Y associated with ADV resistance in HBV genotype A). Of note, it seems that the main LMV resistant variants, M204V and M204I, are also associated with viral genotype (rtM204I is not often detected in genotype A)<sup>[123]</sup>.

TDF treatment, which is extensively used in HIV-1 infection, is also highly active against wild-type and LMV-resistant HBV polymerase variants<sup>[122,124,125]</sup>. TDF is associated with high sustained viral response (SVR) rates and a low rate of resistances: 0% after 6 years of therapy<sup>[106]</sup>. However, the rtA194T variant observed in some HIV/HBV coinfecting patients has been related with TDF resistance, and shows a reduced *in vitro* replication rate in combination with the rtL180M and rtM204V LMV variants<sup>[110]</sup>. Use of LMV, ETV, LdT, and ADV has been largely replaced by the new potent NUCs, ETV and TDF<sup>[106]</sup>. However, extensive application of LMV and the use of ADV as rescue therapy for LMV failure over many years has resulted in a considerable percentage of chronic HBV patients in whom resistance to these NUCs has developed, and a quaspecies enriched in LMV-resistant variants can be expected. These variants can limit the response to new-generation NUCs. This is the case of the rtL180M + rtM204V combination (known as the LMV signature) in ETV therapy and rtN236T in TDF treatment.

For all these reasons, early detection of RT resistant variants by highly sensitive methods, even minor components of the HBV quaspecies in treatment-naïve patients, could be highly useful for therapy purposes. Detection of minor variants can easily be performed by conventional techniques (reverse hybridization or clonal sequencing) or by NGS methods<sup>[53-58]</sup>. An essential consideration to bear in mind is the S and P gene overlapping, which can lead to reciprocal consequences when there is a nucleotide substitution in either ORF. For example, the rtA181T and rtM204I polymerase variants also produce a stop codon in the S gene (sW172stop and sW196stop, respectively) (Figure 1). Therefore, antiviral treatment pressure may cause selection of viral genomes that are potentially defective for envelope proteins<sup>[58,84]</sup>. Another relevant variant in this regard is rtW153Q, which leads to the sG145R variant in the S ORF, associated with failure of immunotherapy.

Complex variants with two or more amino acid changes, such as those conferring ETV resistance or causing a fitness increase during LMV treatment, cannot be properly studied by indirect methods (LiPa, RFLP, 5'-nuclease assays, melting points, mass spectrometry, DNA chip technology, or real-time PCR), because they do not allow simultaneous detection of different substitutions in the same viral genome. Identification of these substitutions requires clonal techniques, such as classical clonal sequencing or the recent NGS methods. Specifically, UDPS enables simultaneous analysis of thousand of clonally amplified long fragments (700 nucleotides), and deeper and more sensitive detection of minor populations in complex mixtures; therefore, it may be the most

suitable method for viral quaspecies studies.

As was mentioned above, the limit of detection of UDPS remains to be resolved. To date, different studies have achieved mixed results. Ijaz *et al.*<sup>[126]</sup> reported a lower quantitation limit of 2% for minor HBV populations. More recently, Mello *et al.*<sup>[50]</sup> reported values of 4%-17% for LMV-resistant variants<sup>[50]</sup>. Our group recently reported a cut-off value of 0.03% that enabled detection of extremely low percentages (0.04%-0.09%) of RT variants in treatment-naïve patients. In another recent UDPS study we detected RT variants in treatment-naïve samples at values of 0.1%-0.55%<sup>[56]</sup>. In the study by Nishijima *et al.*<sup>[59]</sup>, in which drug-resistant mutants were investigated in chronic-naïve cases by Illumina, frequencies of 0.3%-30% were reported. These three recent studies<sup>[56,58,59]</sup> as well as the previously reported ones<sup>[53,54]</sup> have all shown that resistant RT variants are present at baseline in treatment-naïve chronically HBV-infected individuals. This suggests that a reservoir of RT variants may exist, which would be prone to selection by the effect of antiviral therapies. Furthermore, LMV-resistant variants (LMV signature) linked to specific mutations responsible for ETV resistance have been simultaneously detected with 454 UDPS<sup>[58,127]</sup> (Figure 2). Moreover, Margeridon-Thermet *et al.*<sup>[55]</sup> reported low-level persistence of LMV-resistant variants even 1 year after LMV treatment discontinuation using UDPS with a sensitivity level of 0.5%.

Nevertheless, the clinical significance of these minor drug-resistant mutations remains uncertain. Nishijima *et al.*<sup>[59]</sup> concluded that pre-existing drug-resistant mutants (at naïve status), such as low-abundance mutant clones, may provide the opportunity to develop drug resistance against NUCs through selection of dominant mutations. However, a predictive cut-off value for baseline percentages to define preferential selection after NUC treatment has not been reported. Along this line, we found<sup>[56,58]</sup> that after VBK on LMV treatment, the variants selected were not the ones most frequently detected at baseline, suggesting that the low percentages observed at baseline ( $\leq 1\%$ ) do not determine the variant selected at VBK. Interestingly, we detected a small population of ETV-resistant variants<sup>[58]</sup> after LMV treatment in a patient who developed ETV resistance. See examples of UDPS haplotypic study in Figure 2. Additional sequential studies with a larger number of cases must be performed to define a cut-off value for the baseline percentage of resistant RT variants that can predict drug resistance. Hence, massive sequencing has opened the door to a more profound knowledge of the dynamic behavior of the HBV quaspecies that may clarify the role of minor variants in the HBV RT region on the outcome of infection<sup>[55,58]</sup>.

### ***S gene variability and its implications in immunoprophylaxis***

As was discussed in the HBV virology section, the surface ORF (nucleotides 2848-835) is completely overlapped by the P gene (Figure 1). S ORF has three in-frame start codons encoding the three types of surface antigens pres-

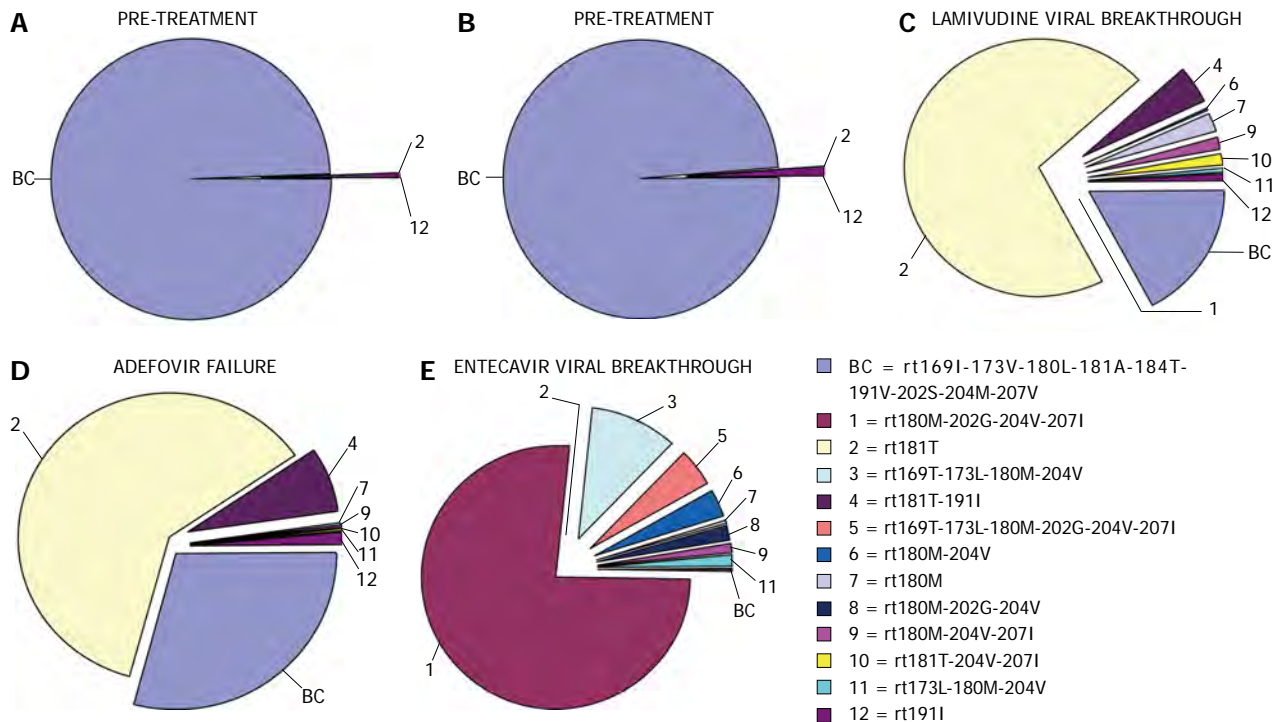

Figure 2 Changes in percentages of reverse transcriptase variants during follow-up of a patient included in one of our studies. Reproduced from Rodriguez-Frias *et al*<sup>[80]</sup>. BC: Baseline combination.

ent on the outer envelope: small (SHBS), middle (MHBS), and large (LHBs, 39 kDa). SHBS, which is common to all three, contains the main antigenic loop, also called the “a” determinant (codons 124-147 within the major hydrophilic region, which covers codons 100-170).

The antigenic loop activates the primary response of the neutralizing antibodies in HBV infection. In the so-called preS region, located in front of the SHBS start (positions 2950 and 3125 of the HBV genome), there is a highly variable sequence that is used to distinguish four major HBV serotypes (adr, adw, ayr, and ayw). HBsAg can self-assemble without containing the HBV genome, and adopt non-infective structural spheres or filamentous forms, which represent nearly the entire population of HBV-related particles (> 99.9%)<sup>[128]</sup>. The preS region overlaps the dispensable spacer domain of the P protein, which allows high heterogeneity. In contrast, the SHBS region (shared by all S-derived proteins) overlaps the essential RT domain of the P protein, which strongly restricts its variability. Deletions are the most relevant variants in the preS region<sup>[129]</sup>, being the main cause of the different genome lengths of the HBV genotypes and affecting the balance between the various types of HBsAg proteins<sup>[130]</sup>. Thus, it can be speculated that a partial or complete HBsAg defect may decrease virion assembly and secretion and lead to a parallel increase in the amount of cccDNA by enhancement of the capsid recycling pathway. An increase in preS deletions has been reported in HBeAg-positive chronic cases (35% in the sixth decade of infection), and has been related to a poor outcome (detected in 60% of HCC patients)<sup>[130,131]</sup>. The study of Kao *et al*<sup>[100]</sup> has reported a significantly higher rate of

preS deletions in HCC patients than in chronic carriers, mainly clustered (> 70%) in the C-terminal preS1 and N-terminal pre-S2 sequences. Interestingly, all these deletions encompassed T and B cell epitopes, and functional mapping showed that they affect the viral secretion site.

In addition, preS deletions can induce oxidative DNA damage and genomic instability; upregulation of certain genes, such as cyclooxygenase-2 and cyclin A, induces cell cycle progression and hepatocyte proliferation - a phenomenon linked to a high risk of developing HCC<sup>[130]</sup>. It must be kept in mind that the S region encoding HBsAg is completely overlapped with the HBV RT region. A mutation in RT codon 153, selected as compensatory after lengthy LMV therapy, causes an sG145R change in the S region (Figure 1), which is strongly associated with immunotherapy failure<sup>[111]</sup> (Table 1). Other relevant examples are the rtA181T or rtM204I RT variants, which result in stop codons in envelope proteins (sW172stop and sW196stop, Figure 1). In the shared S/P region, the main variants have been described in the antigenic determinant “a” (located the major hydrophilic region, amino acids 100-170). These variants (mainly sG145R) were first reported in an Italian boy, son of an HBsAg/HBeAg-positive mother, who had HBsAg and anti-HBs in serum despite receiving both active (vaccine) and passive [hepatitis B immune globulin (HBIG)] immunization<sup>[132]</sup>. The variant was not detected in his mother<sup>[129,132]</sup>, which suggests that sR145 presumably arose by immune selection pressure in the infant after HBV vaccination (vaccine escape variant), selected from a very small population in the mother’s HBV quasispecies. Most hepatitis B vaccines contain the major surface protein, SHBS, which induces

an immune response against the “a” determinant and constitutes an evolutive factor for variant selection.

Other minor substitutions in the S gene include sG145R (again, a G to A mutation in nucleotide 587), followed by sD144A, sP142S, sK141E, sQ129H, sI/T126N/A, sT131I, and sM133L (Table 1), all of which strongly affect the HBsAg structure<sup>[114,133,134]</sup>. The sR145 main variant seems to alter the projecting loop (aa 139-147) of the “a” determinant, inhibiting recognition of induced neutralizing antibody<sup>[135]</sup>. This variant can horizontally infect<sup>[136]</sup> and replicate for several years<sup>[137]</sup>, but at lower rate than the wild-type sG145 variant, probably because of a decrease in virion stability<sup>[138]</sup>. However, the presence of anti-HBs (hepatitis B immunoglobulin prophylaxis or vaccine-induced), which would block the sG145 strain, may allow selection of sR145 when it is present in the quaspecies as a minor variant. This mechanism would ultimately establish infection with the predominant presence of this variant in a clear manifestation of the adaptation capability of quaspecies structures. Such immune selection from the quaspecies would explain the strong association of this and other “a” determinant variants with HBV vaccination failure.

Variants observed in low percentages under immunoprophylaxis escape are detected in low prevalence in practically all the clinical stages of HBV infection<sup>[133,139]</sup>. Longitudinal studies have reported their accumulation during the course of chronic infection<sup>[140,141]</sup> as the major cause (70% of cases) of the paradoxical coexistence of HBsAg and anti-HBs<sup>[142]</sup>. Variant sG145R in conjunction with other S mutations located in the HLA I T cell epitope have been observed in fulminant HBV cases<sup>[143]</sup>. However, unlike sG145R, other variants appearing after vaccination often rapidly revert to the strain seen in the mother<sup>[144]</sup>.

Vaccination at birth is an ideal situation for escape variant selection, similar to administration of high-titer anti-HBs preparations to prevent graft infection in liver transplantation<sup>[145-147]</sup>. A screening program for school-age children in Taiwan found a 0.7% prevalence of “a” determinant mutants<sup>[148]</sup>. Interestingly, the percentage of HBsAg mutants increased from 8% to 25% over 10 years after introduction of a universal vaccination program from 1984 to 1994, but remained stable (23%) in 1999. This study clearly suggests a role for HBV vaccine in selecting HBsAg mutations. In a study in the United States, only 0.8% of vaccinated children born to HBsAg-positive mothers were infected with sG145R<sup>[149]</sup>. The prevalence of this variant in North Americans and in Europeans seems to be low<sup>[150]</sup>. However, some recent studies have reported relevant new data about this type of variant. Perinatal transmission of HBV has not been fully controlled despite adequate immunoprophylaxis in infants in Thailand, with escape mutants in the “a” determinant region (residues 144 and 145) being observed in 14% of infected infants<sup>[151]</sup>. Shahmoradi *et al.*<sup>[152]</sup> reported HBV-DNA activity in 28% of children born to HBsAg-positive mothers, and 62% of these cases carried enve-

lope variants, mainly (77%) the sG145R variant. In fact, these variants seem to be present as minor populations in 9% of HBV carriers who have not been exposed to HBV vaccination or HBIG prophylaxis<sup>[153]</sup>.

HBIG therapy is used to prevent recurrent HBV infection after liver transplantation (LT) for end-stage HBV liver disease. However, in some LT patients who become HBsAg<sup>+</sup> and HBV DNA-positive on HBIG therapy, emergence of mutations in putative neutralizing epitopes such as sG145R, similar to what occurs in vaccine failure, has been described<sup>[154-156]</sup>. A recent report found that 50% of reinfected LT recipients had mutations in the “a” determinant region and flanking sequences; a fact suggesting that quaspecies formation contributes to HBV reinfection following LT<sup>[156]</sup>. Therefore, HBIG-associated variants, like HBV vaccine-related variants, would arise from a pre-existing, but extremely minor population. Confirmation of this hypothesis would require application of ultrasensitive NGS massive sequencing methods, as has been used for other HBV regions<sup>[53-59]</sup>.

The longer the duration of HBIG therapy, the greater likelihood that “a” determinant variants will arise. Discontinuation of HBIG often leads to reversion to the pretransplant sequence<sup>[140,155]</sup>, thus providing further evidence of HBV quaspecies dynamics and reinforcing the idea that these variants are less replication-efficient than the wild-type strain. HBIG-treated liver transplant patients infected with “a” determinant escape variants in positions 144 or 145 showed a poorer clinical outcome than those infected with other variants or wild-type viruses<sup>[157]</sup>. In order to decrease selection of these variants, HBIG plus LMV combination therapy is used. This strategy has drastically reduced recurrence rates from 35% to less than 10%<sup>[158]</sup>. However, it should be remembered that there is a relationship between these variants and those in the overlapping polymerase region that arise during NUC therapy; especially the polymerase variant rtR153Q, which partially restores the replication efficiency of LMV-resistant variants such as rtM204V, and is associated with the main “a” determinant sG145R variant<sup>[114]</sup>. Therefore, patients with pre-LT polymerase variants may have a high risk of reinfection despite HBIG therapy<sup>[159]</sup>, and patients with “a” determinant variants due to HBIG therapy may develop polymerase variants, associated with high viral replication and a poor outcome<sup>[160]</sup>.

Currently, there are no available studies in which the S ORF is analyzed by NGS techniques. However, because of the complete overlapping between the S and P ORFs, some NGS studies mainly focussing on P ORF variability have reported interesting findings about the HBV quaspecies in S ORF<sup>[53,58]</sup>. Our group performed massive UDPS sequencing of samples from patients sequentially treated with LMV and ADV (Figure 2), and found a high frequency of rtA181T<sup>[58]</sup>, the substitution that causes the sW172stop stop codon in S ORF. The consequence of this change is that two-thirds of all HBV particles lacked 50 amino acids in HBsAg (in all types of envelope proteins) including several essential codons (hot spots

sS174 and sL175, sV177, sQ181, sW191, sL192, and sI195 placed in the Core-Surface interphase and residues sV184, sL186, sS187, and sW190 from the S-S interaction interphase<sup>[161]</sup>. Therefore, it is suggested that HBsAg carrying this stop codon may not be completely functional. Moreover, despite this drastic alteration, samples with a high prevalence of this defective variant showed considerable replication, which suggests that the quaspecies has some type of recourse to compensate for this theoretical handicap. That mechanism could be trans-complementation of the defective S protein genomes for enveloping with complete S proteins encoded by other quaspecies members. As has been suggested by Villet *et al.*<sup>[84]</sup>, existence of such a mechanism may be a requirement for emergence and maintenance of this incomplete variant. Hence, this may be an example of cooperation within the quaspecies<sup>[162]</sup>, as a relevant property that fits in with the idea that this population structure has remarkable plasticity. In our UDPS study<sup>[58]</sup>, other surface positions showed *de novo* stop codons at frequencies of 0.13% to 0.17% (sW156stop, sW163stop, sW165stop, and sW191stop); of note, sW156 is involved in HBV infectivity<sup>[163]</sup>. These *de novo* stop codons accounted for around 1.5% of the viral population in our study<sup>[58]</sup> and between 1% and 2.8% in the study of Solmone *et al.*<sup>[53]</sup>; both using UDPS. Therefore, UDPS has brought to light what seems to be a systematic phenomenon in the HBV quaspecies: the presence of defective genomes that participate in HBV virology. The pathological consequence of this phenomenon must be defined in further studies.

### ***X gene variability and its implications in HCC***

The X gene (nucleotides 1374-1838) encodes the HBV X protein (HBx). HBxAg is a 154-amino-acid protein with an N-terminal negative regulatory domain and a C-terminal transactivation/coactivation domain that plays a key role in control of cell proliferation, viability, and transformation<sup>[164-166]</sup>. This protein has been detected in both the cytoplasm and nuclei of infected hepatocytes<sup>[167-169]</sup>. HBx is a regulatory protein that is not packaged in virions during assembly, but is expressed in the new host cell to allow epigenetic control of HBV transcription from cccDNA<sup>[7,170]</sup>. In contrast to the other HBV genes, but similar to retroviral oncogenes, Miller *et al.*<sup>[14]</sup> reported that HBx shows codon usage preference (third nucleotide in degenerated codons), which is more related to the behavior of eukaryotic genes than viral genes and suggests that HBxAg is of eukaryotic origin. However, the X ORF lacks homology to host protein<sup>[167]</sup>.

The high conservation of X gene in mammalian hepadnavirus genomes strongly suggests that HBx is essential to the viral life cycle. It has been reported that HBx is required to initiate and maintain HBV replication, making HBx the key regulator of the natural infection process<sup>[170]</sup>. It is believed that HBx contributes to HBV oncogenicity<sup>[96,167,171-173]</sup> and it is reported to transform SV40-immortalized murine hepatocytes, induce cell cycle progression within the regenerating liver, and cause or

accelerate liver cancer in transgenic mouse models<sup>[174-177]</sup>. HBx expression affects several cellular functions in transfected cells, such as cytoplasmic calcium regulation, cell signaling, transcription, cell proliferation, DNA repair and apoptosis<sup>[169,177-180]</sup>.

To develop its functions, HBx interacts with many cellular partners, such as nuclear proteins involved in regulation of transcription and transcription factors<sup>[167,179]</sup>. Furthermore, HBx interacts and cooperates with cAMP response element binding (CREB)-binding protein/p300 to modify chromatin dynamics of target genes and to synergistically enhance CREB activity<sup>[181]</sup>.

HBx stimulates HBV replication 5-10-fold; likely by enhancing transcription of pgRNA<sup>[167]</sup> by activating the proteasome<sup>[182]</sup>. In this sense, HBx regions 61-69 and 105-140 seem to be essential for viral replication and expression. Paradoxically to its antiapoptotic capacity related to inhibition of tumor suppressor genes, the HBx 68-104 region is associated with mitochondrial membrane alterations that promote cell death<sup>[172]</sup>. Multiple evidence has related HBV infection with inhibition of the innate antiviral immune response, such as inhibition of the Toll-like receptor response<sup>[183]</sup>. HBx directly binds to interferon promoter stimulator-1 factor and inhibits activation of interferon  $\beta$ <sup>[184]</sup>, thereby inhibiting the innate antiviral immune response; a pathway in common with other viruses, and even inhibiting signals through the mitochondrial proteins<sup>[185]</sup>. These and other data clearly indicate that HBx protein has a key role in HBV infection.

In liver tumor tissue, the X gene is often integrated into the genome of infected hepatocytes while retaining its functionality, especially antiapoptotic capability, mediated by inhibition of p53 transcriptional activation<sup>[96,186]</sup> or adenosylmethionine<sup>[187]</sup>. HBx stimulates methyltransferases leading to hypermethylation, which is associated with chromosomal instability<sup>[96]</sup>. HBx also activates cell proliferation by repression of tumor suppressor genes, such as melanoma inhibitory activity 2<sup>[188]</sup>, or by increasing  $\beta$ -catenin expression<sup>[189]</sup>. HBx activity over nuclear factor  $\kappa$ B has been associated with antitumor therapy failure<sup>[187,190-192]</sup>. HBx does not directly bind to DNA; it acts through the activation process of various transduction signal cascades *in cis*<sup>[172]</sup>. It seems that HBx binds to the cccDNA HBV minichromosome histone-like transcriptional complex, thus modifying epigenetic regulation of this essential structure<sup>[7]</sup>.

The multiple functions of HBx may indicate that nucleotide substitutions in the X gene would have important consequences in HBV infection. Several specific substitutions have been reported in the region where X and ENH II overlap (T1485, C1479, A1613, T1653, T1689, A1753, T1766, A1768, and A1776)<sup>[82,193-195]</sup> and some of them seem to be related with the viral genotype<sup>[196]</sup>. These variants, which are found alone or in combination, can change the regulatory function of basal core promotor (BCP) motifs, thereby decreasing HBeAg expression and facilitating HBeAg seroconversion<sup>[197-199]</sup>. Furthermore, some of these variants, particularly the T1762/A1764 double muta-

tion, are strongly associated with cirrhosis and HCC<sup>[200,201]</sup>. Other variants, such as those detected in preCore region, may also show this relationship and there may even be a link with HBeAg status<sup>[202,203]</sup>. In one study, 40% of HCC patients presented six or more of these mutations, while they were present in only 2.7% of non-HCC patients, indicating a predictive value of these variants for HCC similar to that of  $\alpha$ -fetoprotein<sup>[201]</sup>. In another, more recent study performed in India, the A1753 mutation was detected in 35% of cases of HBV-related liver cirrhosis<sup>[204]</sup>.

Multiple X gene variants directly affect the HBx amino acid sequence; these include xI130M, xV131I, and xF132Y, which are associated with the main BCP variants (Table 1). Mutations in amino acids 5, 130, and 131 may contribute to HCC development and could be useful to predict clinical outcome in patients with chronic HBV infection<sup>[205]</sup>. Some HBx amino acid variants are typically located in the region between TATA boxes TA2 and TA3 of the BCP sequence (overlapping with the X gene). Our group observed that the most common variants are 8-nucleotide deletions-some of these (unpublished) deletions in the quasiespecies, obtained by UDPS are shown in Figure 3 - which result in frame shifting and often create a *de novo* stop codon at position 134, resulting in a 20-amino-acid truncation of the C terminus of the HBx protein<sup>[56]</sup>. This could cause a huge change in the proapoptotic functionality of this region<sup>[96]</sup> or in its transactivator role<sup>[206]</sup>. X gene deletions are commonly found in DNA integrated in liver tumor tissue<sup>[192]</sup> and are strongly associated with the development of HCC by multiple mechanisms, such as deregulation of the centromeric protein A<sup>[93]</sup>, regulation of miRNA<sup>[94]</sup>, and loss of the proapoptotic effect<sup>[96]</sup>.

It is likely that the highly complex scenario of the quasiespecies in this extremely relevant region of the HBV genome can be clarified by applying massive sequencing. However, no UDPS studies in this line have been reported to date, probably because of the technical difficulties associated with the presence of deletions. In a recent UDPS study by our group<sup>[56]</sup>, mainly focused on the preCore region but including the last eight HBx codons (positions 1814-1838), we found that around 3% of sequences carried the TAG amber stop codon instead of the major TAA codon. Even more interesting was the significant percentage of sequences (0.2%) in which a T1836C substitution changed the ochre stop codon TAA to CAA (Q). After this substitution, the HBx protein would be translated to the next in-frame stop codon TAG at position 1992, inducing expression of 51 additional amino acids at the C terminus, which could potentially alter HBx functionality. Thus, this preliminary UDPS study revealed a minor HBV population with highly relevant HBx changes (AA deletions or insertions) whose significance in the HBV quasiespecies and in the outcome of infection requires a more systematic and extensive UDPS study of this region.

### Variability in the preCore/Core regions

The Core gene (positions 1814-2548) has two in-frame

start codons encoding two proteins: the component of the viral capsid or Core (HBc, start codon at 1901), and the preCore protein, the precursor of HBeAg (start codon at position 1814). HBeAg protein is secreted by infected hepatocytes and seems to have an immunomodulatory function, establishing immune tolerance and predisposing infants of HBV-infected mothers to develop persistent infection. HBeAg promotes a Th2 response that leads to suppression of the host immune response against the virus, preventing clearance and allowing viral persistence<sup>[207]</sup>. HBeAg-mediated IL-1 activation may also increase hepatocyte proliferation, inducing anti-apoptotic genes and promoting hepatocarcinogenesis<sup>[207]</sup>.

In clinical practice, HBeAg expression differentiates between chronic HBV carriers as HBeAg-positive and HBeAg-negative; the latter are usually positive for the corresponding antibody (anti-HBe). The anti-HBe seroconversion event is a crucial turning point in the natural history of chronic hepatitis B. Anti-HBe seroconversion is considered a favorable prognostic factor in the disease, and sustained virological response in HBeAg-positive cases is a treatment endpoint<sup>[106]</sup>. The factors involved in HBeAg seroconversion have been extensively studied. However, seroconversion is not always followed by establishment of HBV inactive carrier status. Some patients show elevated transaminases and active viral replication after seroconversion to anti-HBe, indicating that the disease continues to be active in the absence of HBeAg<sup>[208]</sup>. In addition, significant differences in treatment response have been seen between HBeAg-positive and -negative status. In particular, HBeAg-negative patients present response rates 10%-20% higher than HBeAg-positive ones; even with the last generation antivirals ETV and TDF<sup>[106]</sup>. This phenomenon may be associated with different levels of viral replication between patients positive and negative to HBeAg<sup>[106]</sup>. However, other mechanisms associated with viral characteristics may also be implicated in response rates, such as baseline quasiespecies composition<sup>[72,98]</sup> and differing sensitivities to antivirals of certain HBV variants<sup>[57,59]</sup>. In fact, as described below, certain preCore and BCP variants that prevent or significantly decrease HBeAg expression (HBeAg-negative variants) may promote the process of HBeAg seroconversion. In many HBV cases from the Mediterranean area, the disease remains active after seroconversion, and HBeAg-negative preCore or BCP variants have been detected in these patients<sup>[209,210]</sup>. Once these variants become detectable, they perpetuate the infection beyond seroconversion<sup>[211]</sup>. Nonetheless, recent evidence seems to suggest that some HBeAg-negative variants may be more sensitive to antivirals<sup>[56,57,59]</sup>.

Variants in the preCore region (between start codons 1814 and 1901) are clinically important because they abolish HBeAg expression. The most common is G1896A (interestingly another G to A substitution), which leads to premature termination of the preCore protein (the HBeAg precursor) and creates a *de novo* in-frame stop codon at codon 28 (TGG to TAG) in the pre-

Figure 3. Quasispecies of the X gene obtained by unpublished result. The four TA-like boxes are highlighted in red and the eight nucleotides detected are indicated in green.

Core region (pcW28stop, Table 1). This change is located in a region of four G residues that are prone to G to A mutations<sup>[129]</sup>. G1896A abrogates HBeAg synthesis, does not disturb HBeAg production<sup>[212]</sup>, and has been detected in virtually all clinical stages of HBV infection, from extremely severe to the most benign forms<sup>[210-214]</sup>. Although G1896A-containing strains are independently transmissible<sup>[214]</sup>, HBeAg-negative HBV carriers do not develop chronic infection, but acute or fulminant hepatitis can occur<sup>[204,215,216]</sup>. This mutation shows a strong association with viral genotype, and is commonly found in Mediterranean and oriental anti-HBe-positive chronic HBV patients who show a high prevalence of genotypes D and B, respectively.

In contrast, the mutation is notably less prevalent in chronic HBV patients from Western Europe or North America, where genotype A is more prevalent<sup>[217]</sup>. This genotype association is clearly related to the overlapping of the preCore and the encapsidation signal sequences of  $\epsilon$ . In this essential pgRNA secondary structure, positions 1896 and 1858 are paired in the lower stem of the  $\epsilon$  stem loop secondary structure<sup>[218,219]</sup> (Figure 4). The G1896A substitution results in stabilization of the  $\epsilon$  structure in genotypes B, D, E, G and H, and in C strains in which there is a T in the paired position, 1858. In contrast, in genotype A and F strains, there is a C in position 1858, and the G1896A substitution would result in a loss of thermodynamic stability of  $\epsilon$ , producing a decrease in encapsidation and viral replication<sup>[209,220,221]</sup>. This observation explains the frequent detection of G1896A in genotype D strains, but rarely in genotype A strains<sup>[222]</sup>. The G1899A substitution (again, G to A) produces a pcG29D change, is frequently associated with liver cirrhosis, and is usually detected together with G1896A<sup>[222]</sup>.

A lack of HBeAg expression can also be the result of mutations in any of the three nucleotides of the preCore start codon. Although they are less common than G1896A, these mutations represent a large percentage of preCore defective variants<sup>[210]</sup>. Mutations in the preCore start codon do not disturb the encapsidation process, because they are located outside of the canonical  $\epsilon$  signal sequence<sup>[219]</sup> and are not restricted by genotype. preCore frameshift mutations due to insertions or deletions are uncommon events occurring outside essential regions, such as  $\epsilon$  or DR1 (*e.g.*, deletion in nt 1836-9)<sup>[129]</sup>. In contrast, the rare G1862T variant (pcV17F) affects the  $\epsilon$  structure bulge and disrupts viral replication, but not HBeAg expression.

The G1862T variant is found in the African A1 sub-genotype, is associated with lower viremia than European A1<sup>[223]</sup>, and is more common in HBeAg-positive than -negative patients (37% *vs* 11%)<sup>[224]</sup>. In addition to the G1896A change, three other preCore stop codons have been observed (positions 1817, 1874 and 1897), all of which disrupt the secondary pgRNA structure (as deduced by the secondary structure predicted by magnetic resonance study)<sup>[219]</sup>. The 1817, 1874 and 1897 changes need compensatory changes to stabilize the pgRNA structure, a

fact that seems justify their low-frequency detection.

In HBeAg-positive patients (immunotolerance phase), defective preCore variants are rarely found as minority populations by conventional direct Sanger sequencing or even by clonal analysis. However, these variants emerge following activation of hepatitis, often associated with anti-HBe seroconversion. In fact, the G1896A preCore mutation and the double A1762T/G1764A BCP mutation are associated with HBeAg seroconversion<sup>[197,225]</sup>. These variants accumulate along seroconversion and are the predominant viral population in anti-HBe-positive patients<sup>[226]</sup>. Whether HBeAg-defective preCore variants are selected from the viral quaspecies in persistent infection is still uncertain. However, the host immune system seems to be the main cause of emergence of preCore variants.

Hypermutations in the B and T epitopes of the HBcAg sequence have been observed in the presence of preCore mutations (HBeAg-negative)<sup>[209]</sup>, allowing escape of these variants. Some preCore variants, such as G1899A, have been clearly associated with HCC progression in HBeAg-positive patients, while G1896A plays a similar role in HBeAg-negative cases<sup>[202]</sup>. Therefore, early detection of preCore variants seems to have predictive value for spontaneous or interferon-induced seroconversion<sup>[220,227]</sup>.

Our group investigated the variability of the preCore region and its relationship with  $\epsilon$  structure functionality using UDPS at a sensitivity of 0.03%<sup>[56]</sup>. Minor populations of G1896A, G1899A variants, and preCore start codon variants were observed, but these mutations showed thermodynamic and structural restrictions in the encapsidation signal. Minor percentages of preCore variants were also seen in HBeAg-positive patients, but not in HBeAg-negative cases<sup>[56]</sup>. The study included a small number of patients, however, and did not explain the presence of a minor population of preCore variants in the HBV quaspecies. Hence, NGS studies including a large number of patients are needed to elucidate the significance of these findings.

The C gene also encodes HBcAg, which forms the HBV nucleocapsid. This protein is highly immunogenic, whereas the envelope proteins have low immunogenicity. Thus, HBV-infected individuals develop an early, intense anti-HBc humoral response that remains after clinical recovery. Multiple epitopic regions in nearly the entire HBc sequence have been described in relation with B cell and T helper epitope response<sup>[228,229]</sup>. Among them, the region flanked by codons 74 to 84 (B74-84) located at the tip of the spike structures of the capsid and included in the so-called major immunodominant region should be highlighted. This epitope is shared by HBc and HBeAg, hence it constitutes the major epitope for B cells<sup>[13,230]</sup>. Other regions stimulate CD4<sup>+</sup> Th cells, the best known being the immunodominant epitope flanked by amino acids 50 and 69 (TH50-69). Variability in these two regions has been related with immune response escape, disease persistence, and interferon therapy failure<sup>[57,231]</sup>. Furthermore, amino acid variants in the C gene, specifically cE83D and

and G1899A (pcG29D), and certain C variants (Table 1), such as cP5H/L/T, cD32N/H, cC/E43K, cP50A/H/Y, cE83D, cI97F/L, cL100I, cA131G/N/P, cS181H/P and cC/Q182K/stop. In a recent study performed in India, single nucleotide substitutions such as C1914G were found in 32% of HCC cases<sup>[204]</sup>.

In addition to amino acid substitutions, deletions leading to truncated HBc proteins have been described, such as the single G deletion in position 2090 in a group of six Gs<sup>[69,70]</sup>. It has been reported that these C-defective genomes are unable to replicate, but they are always present in the HBV quasiespecies, regardless of the region studied (S or C)<sup>[69,70]</sup>. Hence, their presence might indicate that there are active transcomplementation mechanisms in HBV infection that tolerate them. The natural tendency to maintain these defective particles may be because they confer a benefit for viral evolution<sup>[69,70]</sup>, although they seem to be poorly represented in the baseline HBV quasiespecies, making them difficult to detect by conventional sequencing technologies, even clonal analysis. In contrast to what was previously thought, UDPS study has brought to light the fact that these defective variants can replicate and form minor populations in the HBV quasiespecies<sup>[56,58]</sup>. Study of these variants by massive sequencing may help to establish whether their presence is only occasional and a mere side effect of the quasiespecies structure, or whether they are more prevalent and have functions affecting the outcome of infection.

Significant changes in the immunodominant epitopes of the viral capsid have been observed by direct Sanger sequencing, mainly under the effect of antiviral treatment with the immunomodulator interferon and even with NUCs<sup>[231]</sup>. Similar results were obtained in a preliminary study using massive sequencing<sup>[57]</sup>. However, it should be noted that HBeAg shares many epitopes of the HBc protein, and an association between the presence of preCore HBeAg-negative variants and mutations in Core epitopes has been reported<sup>[209]</sup>. This relationship shows that in the absence of HBeAg, immune pressure stimulates selection of some Core variants and provides further evidence that the immune system is an evolutionary factor acting on the HBV quasiespecies<sup>[57,209]</sup>.

The baseline presence of HBV RT variants resistant to antiviral therapy has been reported in multiple studies by conventional direct sequencing and cloning<sup>[233]</sup>, and recently by NGS methods<sup>[53-56,58,234]</sup>. However, study of the preCore region, which could help to understand the phenomenon of anti-HBe seroconversion and its association with SVR rates, has only been reported by our group<sup>[56,57]</sup>. Highly sensitive methods are required to detect minor variants in certain environmental situations, and evaluate the evolution of these variants within the quasiespecies. We found strong selection of a minor member of the quasiespecies (around 1%) in the absence of antiviral therapy in an HBeAg-negative case; possibly as a result of immune pressure. In this case, variants carrying amino acid substitutions were found in a motif commonly recognized by T helper cells (D<sub>64</sub>VTN<sub>67</sub> instead of E<sub>64</sub>LMT<sub>67</sub>,

located in the main TH 50-69 epitope). To date, only one preliminary study has analyzed epitope variability in the C region of the viral capsid by massive sequencing<sup>[99]</sup>. The results seem to confirm the dynamics of variant selection in the major epitopes of the C region in the absence of treatment, as well as some degree of simplification or decreased quasiespecies diversity after antiviral treatment, as evaluated by Shannon entropy<sup>[70]</sup>. Study of the variability of immunodominant epitopes might permit a redefinition of these epitopic motifs (*e.g.*, the B74-84 epitope could include positions 71, 72 and 87 or putative new immune-stimulating positions, such as 40, 41, 92 and 93).

The BCP region in preCore/Core controls expression of the preCore mRNA (precursor of HBeAg) and pre-genomic RNA. BCP is located between positions 1742 and 1842 and overlaps with the 3' end of the X gene and the 5' end of precore/Core. BCP contains 4 TATA boxes (TA1-TA4) and includes a fragment of the 3' terminal region of ENH II, which is involved in controlling S and X gene expression<sup>[210]</sup>. Despite its essential nature, clinically relevant BCP variants have been detected. The most common of these changes is the double mutation A1762T/G1764A associated with significant decreases in HBeAg levels and in viral activity<sup>[64,235-241]</sup>, and with severe liver disease<sup>[199-201,205]</sup>.

The liver-specific activity of ENH II is regulated by multiple liver-enriched transcription factors, specifically nuclear receptor hepatocyte nuclear factor (HNF) 4 or 1, which span the TATA box-like sequence of the pre-C promoter. A functional synergism between some nuclear receptors (including HNF4) upregulates the liver-specific activity of ENH II<sup>[242]</sup>. The effect of BCP variants at ENH II is associated with modification of specific sites recognized by hepatic factors. For example, the HNF1-binding site created by the A1762T/G1764A double mutation is imperfect for a response to HNF1, which results in suppression of preCore mRNA synthesis and increases in pregenomic RNA. Both these actions seem to explain the decrease in HBeAg (promoting seroconversion) and the increase in viral activity in the presence of the A1762T/G1764A mutation. In addition, this double mutation is associated with HBx substitutions in amino acids 130 and 131, which may contribute to HCC development<sup>[205]</sup>. Other minor mutations in the BCP region, such as C1740, C1753, and T/A1768, have been associated with severe liver damage<sup>[200,210,243-245]</sup> and even fulminant hepatitis<sup>[85,246]</sup>. The presence of BCP mutations in inactive carriers is significantly lower than in patients with active chronic infection and those with persistently elevated ALT levels<sup>[210]</sup>. Both BCP and preCore mutations (*e.g.*, A1762T/G1764A and G1896A stop codon) are present in most cases of HBV reactivation in immunosuppressed anti-HBc-positive individuals<sup>[247,248]</sup>. Early, sensitive detection of BCP and/or preCore mutant populations in the HBV quasiespecies could reveal potential predictors of seroconversion to anti-HBe or of evolution of the disease<sup>[82,190,211,232]</sup>. Fortunately, quantification of HBV variants is currently possible by massive sequencing

techniques<sup>[70]</sup>.

Due to the overlapping of BCP and X, BCP changes can also cause changes in the 3' region of the X gene<sup>[205]</sup>. Some such changes have been reported in the region immediately preceding the precore start codon (positions -5, -3 and -2 from 1814, the preCore start). This region corresponds to Kozak sequences, and associated nucleotide changes have been found with effects similar to those related to BCP mutations<sup>[249]</sup>. BCP variants between positions 1763 and 1779, which cause X gene deletions and decrease HBeAg expression have been associated with reactivation after chemotherapy and with disease severity<sup>[64,65]</sup>. However the effect of these variants on viral replication varies depending on the specific deletion (*e.g.*, deletion affecting TA3 1768-1775 causes a decrease in pregenomic and preCore RNA with a concomitant decrease in viral activity)<sup>[66-68]</sup>. Many BCP deletions produce a frame shift that results in a 20-amino-acid truncation of the HBx protein (amino acid 154 passes to 134) and partial loss of the C-terminal region, which contains the HBx transactivating activity. All these mutations have enormous clinical-pathological interest and have been related to interferon failure<sup>[250]</sup>.

## TREATMENT RESPONSE: VIRAL VARIANTS AND GENOTYPE

### BCP and precore variants

As was discussed above, HBeAg-negative variants result from changes in the preCore and/or BCP regions, and are observed in all clinical forms of HBV infection (from asymptomatic to severe) and in all the viral genotypes. However, their distribution and prevalence show important differences<sup>[210,246]</sup>. PreCore mutations are more common in genotype D<sup>[209,251]</sup> and BCP mutations are more frequent in genotype A<sup>[210]</sup>. In Asia, where HBV infection is widespread, genotype C is associated with a higher prevalence of BCP mutations, whereas genotype B shows more preCore mutations<sup>[252,253]</sup>. The poorer prognosis of genotype C is probably associated with the prevalence of BCP mutations<sup>[68,240,254]</sup>. During seroconversion in genotype C, BCP variants are selected before preCore variants, whereas in genotype B the opposite occurs<sup>[253]</sup>. BCP and preCore mutations are more prevalent in severe forms of infection<sup>[68,240,240,255]</sup>, in which BCP deletions are particularly important<sup>[254]</sup>. Although the impact of HBV genomic features during seroconversion is unknown, the viral quaspecies structure and its qualitative and quantitative composition is likely associated with this essential phenomenon in natural infection<sup>[28]</sup> and in the response to antiviral therapy<sup>[98]</sup>. In this sense, it has been reported that the evolutionary pattern of the viral reverse transcriptase region differs between responders and partial responders during the initial phase of ETV treatment<sup>[98]</sup>.

### Treatment of chronic HBV infection and its relationship with variability: is the RT region the only one involved?

Chronic HBV infection is now primarily treated with

NUCs, and these treatments are associated with a risk of selecting resistant RT variants that cause treatment failure. Currently, ETV or TDF are universally recommended as first-line therapy<sup>[106]</sup>. Both treatments present a small risk of resistance development (< 1% for ETV and 0% for TDF after 6 years of treatment). In contrast, LMV has been associated with a high risk of emerging resistance (> 80% at 5 years of treatment). LMV has been widely used, and a large number of LMV-treated patients have developed treatment-resistant variants. The percentage of RT variants increases after LMV relative to their baseline proportion. We looked into this situation by UDPS study and found the following: the LMV resistant variant L180M + M204V was undetectable in pre-LMV samples, was selected during LMV therapy, remained in significant percentages after ADV treatment, and was re-selected after ETV treatment<sup>[58]</sup>. A recent UDPS study by Margeridon-Thermet *et al*<sup>[55]</sup> also reported a high percentage of resistant RT variants after LMV treatment.

In general, HBeAg-negative patients (with preCore variants) showing viral activity after seroconversion present higher rates of SVR to NUCs than HBeAg-positive patients<sup>[106]</sup>. However, the response rates to interferon treatment differ: HBeAg-negative patients present lower response rates than HBeAg-positive ones<sup>[256,257]</sup>. These differences seem to be related to viral genotype, because significantly higher SVR rates have been found for genotype A, in which preCore variants are strongly restricted<sup>[258]</sup>, than for the remaining genotypes, especially genotype D. The reason for this genotype-dependent response is not clear, but the diversity of the viral quaspecies may play a role, as has been described for HBeAg seroconversion and treatment response<sup>[98]</sup>.

In chronic LMV-treated HBV patients, major defective precore mutations occasionally revert to wild-type forms, with reappearance of HBeAg<sup>[238,259]</sup>. This seems to suggest that HBeAg-negative variants are more sensitive to antiviral treatment than HBeAg-positive ones<sup>[238,260]</sup>. *In vitro* studies indicate that defective preCore mutations restore the replication efficacy of LMV-resistant mutants<sup>[261]</sup>. In one UDPS study, we found that the percentage of HBeAg-negative G1896A preCore variants in the quaspecies of HBeAg-positive cases (present as minor populations and undetectable by conventional sequencing) decreased after a period of treatment with LMV<sup>[56,57]</sup>. This was also seen in BCP variants associated with low HBeAg expression in a preliminary study<sup>[99]</sup>. These data suggest that these variants are more sensitive to LMV treatment than HBeAg-positive variants, and could explain the seroreversion phenomenon. In a recent study using quantitative real-time PCR, Nishijima *et al*<sup>[59]</sup> reported that liver tissue of NUC-treated HBeAg-negative cases showed low levels of the G1896A preCore mutant (0.0%-1.1%). The authors also reported a significant reduction in the percentage of this mutant following treatment in 13 of 14 cases (92.9%). These results reinforce the hypothesis that the G1896A preCore mutant is highly sensitive to NUCs. A decline in the percentage of HBeAg-negative variants (preCore and/or BCP muta-

tions) and selection of HBeAg-positive variants (without preCore or BCP mutations) after antiviral treatment<sup>[56,57,99]</sup> seems to agree with the lower SVR rates in the presence of HBeAg than in the absence of this antigen<sup>[106]</sup>.

Interestingly, preCore mutations reappear after prolonged therapy, with return to HBeAg-negative status (seroconversion)<sup>[238]</sup>. It has also been reported that HBeAg-negative preCore and BCP variants compensate for the decreased replicative capacity of resistant RT variants<sup>[261]</sup>. This observation, and the reappearance of HBeAg-negative variants after therapy continuation seem to be contradictory and suggest that additional factors such quasispecies complexity or adaptation to the host immune system would be involved. The application of NGS to analyze quasispecies dynamics in cases with seroreversion after anti-HBe loss might elucidate this phenomenon.

## CONCLUSION

In conclusion, HBV infection remains a major health problem worldwide, despite the continuing advances in treatment and development of effective vaccines. The high incidence of HBV infection is mainly due to the virological characteristics of this pathogen. HBV shows high variability that characterizes it as a quasispecies in a manner similar to other infectious agents such as HCV and HIV, but with a much higher prevalence than these. Detailed study of the viral population structure is essential to combat these infections successfully, and this type of study is now possible with NGS methods. These techniques have contributed important data over recent years, and they are expected to undergo spectacular development in the medium term. NGS promises to be a powerful resource that will help the scientific community in the management of HBV and other infections, as well as other key problems related to human health, such as genetic and oncologic disease.

### Abstract

Accumulating evidence has implicated *Helicobacter pylori* (*H. pylori*) infection in extragastrointestinal diseases, including obesity, type 2 diabetes mellitus, cardiovascular disease, and liver disease. Recently, there has been a special focus on *H. pylori* infection as a risk factor for the development of nonalcoholic fatty liver disease (NAFLD). NAFLD is currently considered to be the most common liver disorder in western countries, and is rapidly becoming a serious threat to public health. The mechanisms of pathogenesis underlying NAFLD remain unclear at present and therapeutic options are limited. The growing awareness of the role of *H. pylori* in NAFLD is thus important to aid the development of novel intervention and prevention strategies, because the eradication of *H. pylori* is easy and much less expensive than long-term treatment of the other risk factors. *H. pylori* infection is involved in the pathogenesis of insulin resistance (IR), which is closely linked with NAFLD. It provides a new insight into the pathogenesis of NAFLD. This review probes the possible relationship between *H.*

*pylori* and NAFLD, from the perspective of the potential mechanism of how *H. pylori* infection brings about IR and other aspects concerning this correlation.

**Key words:** *Helicobacter pylori*; Nonalcoholic fatty liver disease; Insulin resistance; Inflammation; Cytokines

**Core tip:** A growing body of evidence suggests that *Helicobacter pylori* (*H. pylori*) infection is linked with nonalcoholic fatty liver disease (NAFLD). There are some potential pathogenic mediators and mechanisms involved in this progress, including fetuin-A, tumor necrosis factor- $\alpha$  and adiponectin. Long-term *H. pylori* infection may cause insulin resistance and inflammation, contributing to NAFLD. *H. pylori* toxins in the portal circulation arising from the gastroduodenal area may be another intriguing point, which might be related to the increased intestinal permeability in patients with NAFLD. It is hoped that eradication of *H. pylori* will provide a new treatment strategy for NAFLD.

### INTRODUCTION

*Helicobacter pylori* (*H. pylori*) is a Gram-negative and micro-aerophilic bacterium<sup>[1]</sup>. The incidence of *H. pylori* infection in adults is particularly high in developing countries compared with developed countries<sup>[2]</sup>.

*H. pylori* colonizes the stomach in childhood and persists throughout life, causing diseases mainly in adults,

including chronic gastritis, peptic ulcer disease, gastric mucosa-associated lymphoid tissue lymphoma, and gastric cancer<sup>[3,4]</sup>. This persistent infection elicits a chronic inflammatory and immune response<sup>[5]</sup>, inducing both local and remote lesions. The interaction of the host with *H. pylori* can have profound systemic effects<sup>[6]</sup>. A growing body of evidence has implicated *H. pylori* infection in extragastrintestinal diseases such as cardiovascular, liver and biliary diseases<sup>[7-9]</sup>. The possible causative role of *H. pylori* infection in these diseases is intriguing. The contribution of *H. pylori* to the development of hepatic encephalopathy and hyperammonemia has been revealed<sup>[10]</sup>, and the possible correlation of *H. pylori* with other liver diseases has attracted a lot of attention<sup>[8,11]</sup>. Recent reports have emerged on the relationship between *H. pylori* infection and nonalcoholic fatty liver disease (NAFLD).

In recent years, there has been increased appreciation of the significance of NAFLD, which is currently considered to be the most common liver disorder in western countries, affecting up to 25%-30% of individuals<sup>[12-14]</sup>. NAFLD encompasses a range of related disorders<sup>[15]</sup>. The earliest stage is simple steatosis. It can progress to nonalcoholic steatohepatitis (NASH) with the cardinal features including hepatocyte injury, and inflammation with or without fibrosis<sup>[16-18]</sup>. NASH, in turn, may progress to cirrhosis and ultimately liver cancer in some patients<sup>[19]</sup>. Consequently, NAFLD is rapidly becoming a serious threat to public health. However, the mechanisms of the pathogenesis underlying NAFLD are complex and remain unknown at present<sup>[20,21]</sup>.

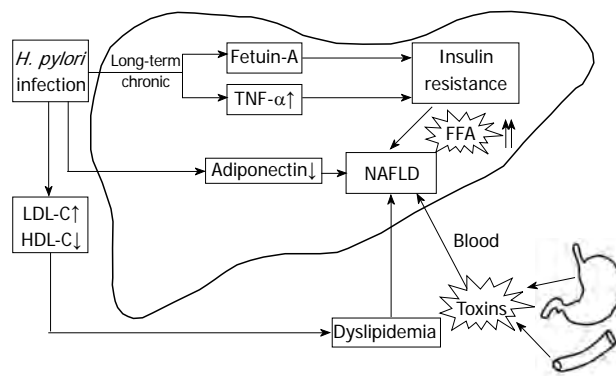

NAFLD is now regarded as the liver manifestation of the metabolic syndrome (MetS)<sup>[22]</sup>. It is strongly associated with obesity, diabetes, cardiovascular disease (CVD) and dyslipidemia<sup>[23]</sup>, because they spring from a "common soil", namely, insulin resistance (IR)<sup>[24]</sup>. A growing body of experimental evidence suggests that NAFLD and IR are closely related<sup>[25,26]</sup>.

*H. pylori* infection is implicated in the pathogenesis of IR<sup>[27]</sup>, which is important in the development of NAFLD, therefore, investigating the impact of *H. pylori* infection as a risk factor for IR might have implications in understanding its effect on NAFLD. It is hoped that the eradication of *H. pylori* can provide a novel strategy for the treatment of NAFLD. This review focuses on the possible relationship between *H. pylori* and NAFLD; mainly from the perspective of the potential mechanism of how *H. pylori* infection brings about IR and other aspects concerning this correlation (Figure 1).

## EXPERIMENTAL EVIDENCE LINKING

### *H. PYLORI* WITH NAFLD

A novel finding in the study of Cindoruk *et al.*<sup>[28]</sup> was the presence of 16S rDNA of *H. pylori* in the liver sample of a 44-year-old woman with NASH. They used polymerase chain reaction-based techniques to amplify 16S rDNA sequences of *H. pylori*. In that study, 27 of 75 patients with suspected liver disease were diagnosed with NASH. It

**Figure 1** Potential mechanism of how *Helicobacter pylori* contribute to nonalcoholic fatty liver disease. Insulin resistance (IR) may be an important link between *Helicobacter pylori* (*H. pylori*) infection and nonalcoholic fatty liver disease (NAFLD). IR favors accumulation of free fatty acids (FFAs) in the liver. *H. pylori*-induced IR may be mediated through fetuin-A. Tumor necrosis factor (TNF)- $\alpha$  plays a central role in the response to inflammation elicited by long-term *H. pylori* infection. The decrease in adiponectin is implicated in *H. pylori*-induced NAFLD. *H. pylori* toxins arising from the gastrointestinal area may cause liver damage. *H. pylori* may be associated with the altered lipid profile, leading to dyslipidemia, which is involved in the pathogenesis of NAFLD.

turned out in one sample that 16S rDNA of *H. pylori* was detected. This observation suggested that *H. pylori* play a role in NAFLD.

*H. pylori* is mainly identified by 16S rDNA sequencing<sup>[8]</sup>. In bacteria, there are three types of rDNA that are readily identifiable by size: the 120-nucleotide (nt) 5S rDNA, the 1600-nt 16S rDNA, and the 3000-nt 23S rDNA<sup>[29]</sup>. Researchers have recently tended to use genetic criteria including virulence gene and 16S rDNA sequencing for distinguishing it from other curved Gram-negative rods<sup>[30]</sup>.

In 2009 another study added credence to this finding, in which Pirouz *et al.*<sup>[31]</sup> noticed that patients with various chronic liver diseases (CLDs) had a greater probability of positive *H. pylori* 16S rDNA compared with the control group. In the 46 liver biopsies from patients with CLD, they detected *H. pylori* DNA in five of 11 samples from patients who were diagnosed with NAFLD.

## CLINICAL EVIDENCE LINKING *H. PYLORI* WITH NAFLD

Polyzos *et al.*<sup>[32]</sup> showed that NAFLD patients had significantly higher anti-*H. pylori* IgG, insulin, homeostatic model of assessment insulin resistance (HOMA-IR), and tumor necrosis factor (TNF)- $\alpha$ , but less total and high-molecular-weight adiponectin compared to the control group. However, there were no significant differences in steatosis grade, fibrosis stage, lobular or portal inflammation, or ballooning, when NAFLD patients were divided into subgroups according to *H. pylori* IgG seropositivity or <sup>13</sup>C-urea breath test positivity. This might be a clue that *H. pylori* infection is strongly linked to the pathogenesis of early-stage NAFLD, which is described as simple steatosis. Yet at the same time, it indicates that *H. pylori* infection may not contribute to the progression of NASH.

A randomized controlled single-blind study from

Doğan *et al*<sup>[33]</sup> showed that fatty liver was significantly more frequent in *H. pylori*-positive patients. The severity of the fatty appearance assessed by ultrasonography was also higher in the *H. pylori*-positive group. A study conducted in Japan demonstrated that *H. pylori* infection was one of the independent risk factors for the development of NAFLD<sup>[7]</sup>. These studies had some limitations and further research is warranted with larger, longer-term studies to confirm their findings. It is hard to determine if *H. pylori* is responsible for the natural course of NAFLD, or if it is merely an incidental finding. If this association is confirmed, eradicating *H. pylori* infection may have certain therapeutic perspectives in NAFLD.

## POTENTIAL PATHOGENETIC MEDIATORS AND MECHANISMS

### *IR: a possible bond linking H. pylori with NAFLD*

IR is a key pathogenic factor in NASH<sup>[34]</sup>. It leads to hyperinsulinemia and favors accumulation of free fatty acids (FFAs) in the liver because of decreased mitochondrial  $\beta$ -oxidation, on account that insulin inhibits hepatic mitochondrial  $\beta$ -oxidation of fatty acids<sup>[35]</sup>. Moreover, IR predisposes the liver to oxidative stress by stimulating microsomal lipid peroxidases<sup>[23]</sup>.

*H. pylori* infection is involved in diverse biological processes<sup>[36]</sup>, comprising inflammation, metabolism and oncogenic transformation<sup>[31,37]</sup>. In view of its effect on metabolic variables, *H. pylori* is associated with IR.

*H. pylori* infection is implicated in the pathogenesis of obesity<sup>[38]</sup> and type 2 diabetes mellitus (T2DM)<sup>[39-41]</sup>, which are closely related to MetS. IR is thought to be the underlying mechanism for MetS. However, so far, only limited clinical data directly suggest that *H. pylori* infection is involved in the development of NAFLD. Polyzos *et al*<sup>[32]</sup> showed that the contribution of *H. pylori* to NAFLD might be achieved indirectly through increasing IR, or directly, given that it can predict NAFLD independently from IR. Inspired by this hypothesis, studies investigating the relationship between *H. pylori* infection and IR would be of importance to infer the mechanism of how *H. pylori* induce NAFLD. A few studies have explored the possible link between *H. pylori* infection and IR. Besides, research on the influence of eradication therapy on IR and other metabolic parameters has been conducted. However, results are controversial, and whether *H. pylori* infection plays a role in IR remains to be determined. Assessed by HOMA-IR, existing data indicate a potential association between *H. pylori* infection and IR. HOMA-IR, which derives from fasting insulin and glucose levels<sup>[42]</sup>, is the most common method for assessment of IR in clinical practice and epidemiological studies<sup>[43]</sup>. Using this method, a high HOMA-IR score denotes low insulin sensitivity. In 2011, Polyzos *et al*<sup>[27]</sup> performed a systematic review<sup>[27]</sup>, summarizing the evidence for the association between *H. pylori* infection and quantitative indexes of IR. Summary data indicate a potential association between *H. pylori* infection and IR.

Eshraghian *et al*<sup>[44]</sup> showed that HOMA-IR score was significantly higher in the *H. pylori*-positive group compared with the negative group. They suggest that *H. pylori* infection is a risk factor for IR. However, Naja *et al*<sup>[45]</sup> have suggested no association of *H. pylori* infection with IR or MetS. They take the view that eradication of *H. pylori* infection to prevent IR or MetS is not warranted.

We must take into consideration that most of the studies that investigated the association between *H. pylori* and IR or MetS were small and did not adjust for potential confounders. Many of them did not control for the bacterial strain type or the host genetic factors. Due to the limited quantity and quality of these studies, more high-quality, multicenter, large-scale randomized controlled trials are required to clarify the association between *H. pylori* infection and IR development. A positive link between *H. pylori* infection and IR could have certain therapeutic prospects.

**A peculiar intermediary: fetuin-A:** *H. pylori* infection has been proposed in an attempt to elucidate the multifaceted aspects of the pathogenesis of IR. However, the pathogenetic link between *H. pylori* infection and IR is not fully understood as yet.

Among the various factors capable of inducing IR and subsequent IR syndrome, fetuin-A is peculiar because it is a glycoprotein that is produced exclusively in the liver and then secreted into the circulation in high concentrations<sup>[46]</sup>. Previous studies have shown that fetuin-A is closely related to IR<sup>[47-49]</sup>, and it has been linked with impaired insulin sensitivity, glucose metabolism, and the onset of diabetes mellitus<sup>[50,51]</sup>.

Recent studies have investigated whether the *H. pylori*-induced IR is mediated through fetuin-A. In the study of Kebapcilar *et al*<sup>[52]</sup>, fetuin-A level significantly decreases in *H. pylori*-infected patients when compared to control subjects. Moreover, *H. pylori* eradication reduces the levels of proinflammatory cytokines such as migration inhibitory factor and high-sensitivity C-reactive protein (CRP), with a significant increase in fetuin-A. They regarded fetuin-A as a potential anti-inflammatory cytokine<sup>[53]</sup>, on the basis of the theory that anti-inflammatory cytokines produced during inflammation tend to modulate the inflammatory reaction.

However, the findings of Manolakis *et al*<sup>[54]</sup> were the opposite. They noted that *H. pylori*-infected individuals showed higher levels of fetuin-A, insulin and HOMA-IR than controls. In addition, there was a positive correlation between fetuin-A and HOMA-IR. This has interesting therapeutic implications because it suggests that *H. pylori* eradication might decrease IR. This observation coincides with the results of Ou *et al*<sup>[55]</sup>, who showed that fetuin-A is considered to be a key proinflammatory mediator that plays a pivotal role in inflammatory and immune diseases. They suggest that elevated fetuin-A level has clinical implications in NAFLD and impaired glucose tolerance, which are features of IR<sup>[55]</sup>.

Fetuin-A is an endogenous inhibitor of insulin receptor tyrosine kinase in the liver and skeletal muscle<sup>[48]</sup>. Srin-

vas *et al*<sup>[48]</sup> have revealed that fetuin-A specifically inhibits insulin-stimulated insulin receptor autophosphorylation *in vitro* and *in vivo*, as well as exogenous substrate tyrosine phosphorylation. Moreover, they have demonstrated that fetuin-A influences insulin signaling by inhibiting insulin-induced tyrosine phosphorylation of insulin receptor substrate (IRS)-1<sup>[56]</sup> and insulin-dependent mitogenesis. The glucoregulatory effects derived from insulin are predominantly exerted in three tissues consisting of liver, muscle and fat<sup>[57]</sup>. Thus, when IR occurs, the liver can be the point of attack. Based on the theory that fetuin-A inhibits insulin signaling in hepatocytes, it is reasonable to assume that the elevated fetuin-A in patients with NAFLD may contribute to the deteriorated hepatic IR.

Although the mechanism underlying fetuin-A-mediated IR remains elusive, it is a novel concept that fetuin-A may represent a promising index for assessing the *H. pylori*-related contributions to IR and MetS. If this particular association is confirmed, fetuin-A could be a potential target for therapy of IR and IR-related disorders, including T2DM, CVD and NAFLD.

### Chronic inflammation, cytokines and adipokines:

*Helicobacter* spp. are strong inducers of proinflammatory cytokines<sup>[58]</sup>. Long-standing *H. pylori* infection induces inflammation by stimulating excessive release of proinflammatory cytokines and vasoactive substances, such as interleukin (IL)-6, IL-8, IL-1 $\beta$  and TNF- $\alpha$ <sup>[59-61]</sup>. *H. pylori*-positive individuals exhibit elevated levels of these proinflammatory cytokines<sup>[62]</sup>.

A growing body of evidence supports that inflammation is involved in the pathogenesis of IR and IR-related disorders<sup>[63]</sup>. Festa *et al*<sup>[64]</sup> have suggested that low-grade inflammation is a risk factor for the development of T2DM<sup>[64]</sup>. Several studies indicate that chronic subclinical inflammation is associated with CVD<sup>[65]</sup>.

Hotamisligil *et al*<sup>[66]</sup> and Feinstein *et al*<sup>[67]</sup> have demonstrated that TNF- $\alpha$  is able to induce IR. Therefore, we reckon that TNF- $\alpha$  may be a key mediator of both direct and indirect effects of *H. pylori* infection on NAFLD.

TNF- $\alpha$  interferes with insulin signaling, thereby favoring steatosis, and may play a proinflammatory role in the pathogenesis of NASH<sup>[68,69]</sup>. On the one hand, TNF- $\alpha$  promotes Ser phosphorylation of IRS-1<sup>[70]</sup>, resulting in a net decrease in insulin-receptor-mediated signaling. On the other hand, TNF- $\alpha$  can inhibit the autophosphorylation of insulin receptor or tyrosyl phosphorylation of IRS-1<sup>[67]</sup>. In addition, TNF- $\alpha$  downregulates the expression of key genes in adipose cells such as GLUT4<sup>[71]</sup>, resulting in decreased glucose transport<sup>[72]</sup>. Besides, TNF- $\alpha$  is capable of accelerating lipolysis, leading to an increase in FFAs, which can cause detrimental effects in hepatocytes, including oxidative stress<sup>[73]</sup>, induction of endoplasmic reticulum stress<sup>[74]</sup> and subsequent expression of proinflammatory cytokines. TNF- $\alpha$  promotes and is activated by IR *via* activation of IKK- $\beta$ <sup>[17]</sup>, which is a central coordinator of inflammatory responses through activation of nuclear factor (NF- $\kappa$ B)<sup>[75]</sup>. NF-

$\kappa$ B is a proinflammatory “master switch” that regulates inflammatory mediators including CRP, plasminogen activator inhibitor, TNF- $\alpha$ , IL-6 and IL-1 $\beta$ <sup>[76]</sup>.

Lower adiponectin level was observed in *H. pylori*-positive patients with NAFLD in the study of Polyzos *et al*<sup>[32]</sup>. This finding gives us a new clue that adiponectin may play a part in the process of *H. pylori*-induced NAFLD. Adiponectin, the adipocyte-derived hormone, is implicated in the pathogenesis of IR and NASH. Low serum adiponectin levels in NAFLD patients are suggestive of advanced hepatic fibrosis<sup>[77]</sup>. Adiponectin exerts several anti-inflammatory effects<sup>[78]</sup>, including inhibition of NF- $\kappa$ B activation<sup>[79]</sup> and suppression of macrophage function. Adiponectin and TNF- $\alpha$  are mutually antagonizing adipokines<sup>[80]</sup>. In contrast to TNF- $\alpha$ , adiponectin has an antilipogenic effect<sup>[81]</sup>. Thus, when adiponectin is decreased, its effects of controlling FFA entry and oxidation in the mitochondria are subsequently weakened, allowing FFAs to accumulate in the cytoplasm<sup>[82]</sup>.

### Lipid metabolism

Inflammation, IR and aberrant lipid metabolism may be interlinked components of the MetS<sup>[83,84]</sup>. Abnormalities of serum lipid concentrations are common in patients with NASH<sup>[23]</sup>. It is acknowledged that hypertriglyceridemia is involved in the pathogenesis of NASH. Each of the steps involved in hepatic lipid accumulation is altered in NAFLD, although to a different extent<sup>[85]</sup>. Satoh *et al*<sup>[86]</sup> have shown that *H. pylori* infection is a significant and independent risk factor for a modified lipid profile, including high low-density lipoprotein cholesterol (LDL-C) and low high-density lipoprotein cholesterol (HDL-C) in Japanese men, whereas these associations are not significant in women. Kebapcilar *et al*<sup>[52]</sup> demonstrated that *H. pylori* infection is significantly associated with lower HDL-C<sup>[52]</sup>, but they showed that eradication of *H. pylori* had no effect on the lipid profile. Akbas *et al*<sup>[87]</sup> reported that there was no significant difference in serum HDL-C, LDL-C, or total cholesterol between *H. pylori*-seropositive and *H. pylori*-seronegative individuals, whereas serum triglyceride level was higher in the *H. pylori*-positive group.

### Increased intestinal permeability, *H. pylori* toxins and cross-reactive antibody response

*H. pylori* is thought to have deleterious consequences on the hepatobiliary tract because the biliary epithelium can easily be colonized by bacteria from the duodenum<sup>[88]</sup>. The human gastrointestinal tract is an ecosystem integrated by microbiota. The mucosal epithelium of the small intestine is the barrier between the microbiota and gut lumen<sup>[89]</sup>. It is reported that increased intestinal permeability and small intestinal bacterial overgrowth (SIBO), may reflect qualitative and quantitative changes in the microbiota, leading to disruption of the intestinal barrier, subsequent bacterial translocation, and development of portal endotoxemia<sup>[90]</sup>. As a result, lipopolysaccharide, which is produced by Gram-negative bacteria, is increased in the portal circulation and accompanied by increased levels of

endotoxin-mediated cytokines in the liver. Bacterial translocation occurs due to impaired barrier function<sup>[91]</sup>, and bacterial constituents enhance hepatic inflammation and fibrosis<sup>[92]</sup>. Miele *et al.*<sup>[93]</sup> found that in NAFLD patients, increased gut permeability and the prevalence of SIBO correlated with the severity of steatosis but not with the presence of NASH.

In light of the above considerations, we speculate that the liver may be damaged by *H. pylori* toxins and constituents circulating in the blood coming out from the gastroduodenal area. And it is probably linked with the increased intestinal permeability in patients with NAFLD. Abenavoli *et al.*<sup>[94]</sup> reported a case of a 36-year-old woman with diagnosis of celiac disease (CD), primary biliary cirrhosis (PBC) and *H. pylori* infection. They found that strict adherence to a gluten-free diet, associated with ursodeoxycholic acid administration and eradication of *H. pylori* infection, led to a marked histological and serological improvement of PBC. *Helicobacter* spp. are implicated in the pathogenesis of PBC, because microbial DNA is found in liver tissue and bacterial antibodies in the serum of patients with PBC<sup>[95,96]</sup>, which is characterized by the presence of antimitochondrial antibodies directed predominantly against the E2 subunit of the pyruvate dehydrogenase complex<sup>[97]</sup>. They indicated that increased permeability to intraluminal antigens could induce an immune response against antigens sharing common epitopes to self-liver proteins and/or against cryptic antigens unmasked by the reaction with gliadin. Their study supports the pathogenetic role of increased intestinal permeability in the course of CD and *H. pylori* infection to induce PBC. However, this concept remains obscure. More studies are needed to clarify the reality of this association.

## CONCLUSION AND OUTLOOK

NAFLD affects both adults and children who present with particular risk factors, including obesity, sedentary lifestyle and/or a predisposing genetic background<sup>[98]</sup>. In some individuals it can progress to cirrhosis, or even hepatocellular carcinoma. Treatment strategies ranging from simple lifestyle modifications to pharmacological agents and even invasive surgical procedures<sup>[99]</sup> have been investigated as potential treatments for NAFLD. However, at present, it is regrettable that there is no one ideal therapy suitable for all patients<sup>[100]</sup>. Thus, new treatment strategies are important to halt the progression of NAFLD.

IR assumes importance in the pathogenesis of NAFLD progression<sup>[101]</sup>. Recent studies, largely on the possible contribution of *H. pylori* to IR, provide new insights into the link between *H. pylori* and NAFLD. Eradication of *H. pylori* is easy and relatively inexpensive, therefore, the interest in exploring its involvement in extragastric diseases is of importance for public health. Thus, understanding the pathogenetic role of *H. pylori* in NAFLD is important for devising new specific management strategies.

The clinical data regarding *H. pylori* infection in

NAFLD are limited, thus, it is premature to advocate intervention measures in patients with NAFLD. However, once this particular association is confirmed, it could drastically change our understanding of pathophysiology and treatment of NAFLD. Therefore, further studies are warranted to verify such associations before the strategy can be recommended in routine clinical practice.

### Abstract

Except for the most organized mature hepatocytes, liver stem/progenitor cells (LSPCs) can differentiate into many other types of cells in the liver including cholangiocytes. In addition, LSPCs are demonstrated to be able to give birth to other kinds of extra-hepatic cell types such as insulin-producing cells. Even more, under some bad conditions, these LSPCs could generate liver cancer stem like cells (LCSCs) through malignant transformation. In this review, we mainly concentrate on the molecular mechanisms for controlling cell fates of LSPCs, especially differentiation of cholangiocytes, insulin-producing cells and LCSCs. First of all, to certificate the cell fates of LSPCs, the following three features need to be taken into account to perform accurate phenotyping: (1) morphological properties; (2) specific markers; and (3) functional assessment including *in vivo* transplantation. Secondly, to promote LSPCs differentiation, systematical attention should be paid to inductive materials (such as growth factors and chemical stimulators), progressive materials including intracellular and extracellular signaling pathways, and implementary materials (such as liver enriched transcriptive factors). Accordingly, some recommendations were proposed to standardize, optimize, and enrich the

effective production of cholangiocyte-like cells out of LSPCs. At the end, the potential regulating mechanisms for generation of cholangiocytes by LSPCs were carefully analyzed. The differentiation of LSPCs is a gradually progressing process, which consists of three main steps: initiation, progression and accomplishment. It's the unbalanced distribution of affecting materials in each step decides the cell fates of LSPCs.

**Key words:** Liver stem/progenitor cells; Cholangiocytes; Biliary differentiation; Unbalanced distribution of materials; Cell therapy

**Core tip:** After liver stem/progenitor cells (LSPCs) are isolated by different groups from both fetal and adult livers, it is urgent to decide the cell fates of LSPCs. Especially, it is found that the core issue for LSPCs application lies in their accurate differentiation. Because there are lots of literatures concentrating on self-renewal and hepatic differentiation of LSPCs, in this review, we mainly summarize the molecular mechanisms for controlling other cell fates of LSPCs, especially differentiation into cholangiocytes. For biliary differentiation, we propose that it is a gradually progressing process consisting of three main steps: initiation, progression and accomplishment.

### INTRODUCTION

Liver stem/progenitor cells (LSPCs) possess high pro-

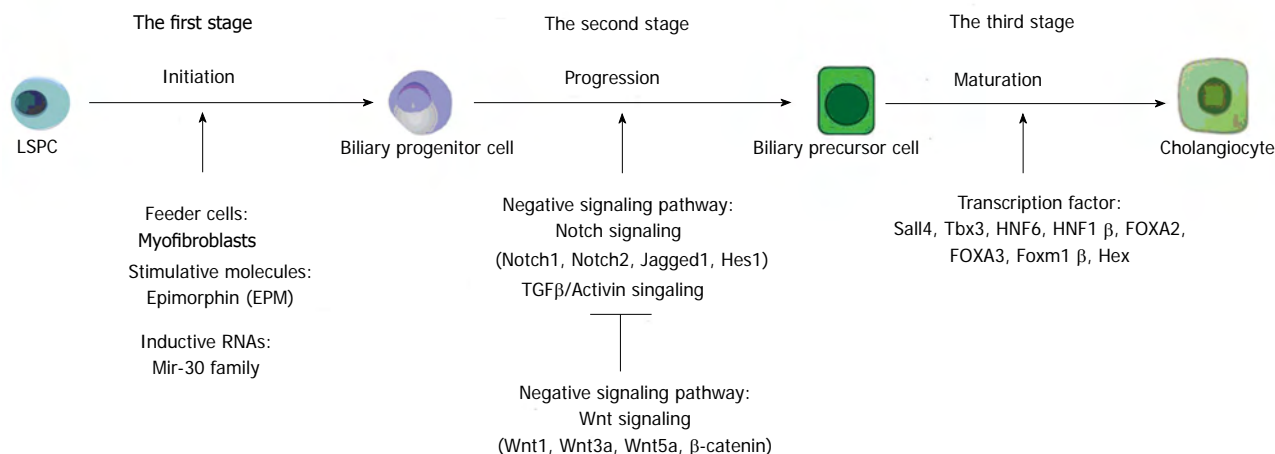

**Figure 1** The different cell fates of liver stem/progenitor cells under distinct situations. Under special stem microenvironment, LSPCs would probably self renew to keep stem properties. In the contrary, under differentiating stimuli, LSPCs could give birth to two kinds of fundamental mature cells in the liver, hepatocytes and cholangiocytes. This is very important for liver development and liver regeneration. Except for the traditional differentiation directions, LSPCs have the capacity to trans-differentiate into insulin producing cells, which is promising for treating diabetes. While in some bad situations, LSPCs may carry out malignant transformation to become liver cancer cells, even liver cancer stem cells, as a result, these cancer cells replicate themselves to cause liver cancer. This is a different way from mutation of hepatocytes for liver carcinogenesis. LSPC: Liver stem/progenitor cell.

liferative capacity and low immunogenicity and are robust in the face of cryopreservation or ischemic injury: properties that could enhance their engraftment within a recipient liver. Because of this, these LSPCs are very promising for the treatment of end-stage liver disease<sup>[1]</sup>. A series of animal models transplanted with LSPCs have been established, and several clinical trials have been reported. In one animal model, transplanted rat embryonic day (ED) 14 fetal liver stem/progenitor cells (FLSPCs) differentiated into the two mature epithelial cell phenotypes in the liver, *i.e.*, hepatocytes and cholangiocytes, and long-term, *in vivo* functional reconstitution of the liver tissue was achieved (Figure 1)<sup>[2,3]</sup>. The important recent progress is the use of human FLSPCs engrafted into naturally derived scaffolds to create a liver-like tissue *in vitro*<sup>[4]</sup>. However promising LSPCs are for cell therapy or tissue engineering, the fundamental purpose lies in generating mature, functional cells<sup>[5,6]</sup>.

LSPCs constitute approximately 0.5%-2.5% of liver parenchyma at all donor ages. The self-renewal capacity of LSPCs is demonstrated by their phenotypic stability after expansion for > 150 population doublings in a serum-free, defined medium, with a doubling time of approximately 36 h<sup>[7]</sup>. In fetal liver, LSPCs are commonly called hepatoblasts<sup>[2,3]</sup>. In some studies, some groups have used other terms than hepatoblasts to represent the cell populations with stem properties in fetal liver, such as embryonic hepatic stem cells or fetal liver stem-like epithelia. Thus, it would be more appropriate to denote these

cells as the “FLSPCs”, and we will adopt this description in this review. In adult liver, LSPCs are generally referred to as oval cells (OCs), with scant, lightly basophilic cytoplasm and pale blue-staining nuclei<sup>[8]</sup>. The appearance of OCs has been reported in rat livers treated with hepatotoxins, such as 2-acetylaminofluorene, combined with partial hepatectomy (PHx) and D-galactosamine<sup>[9,10]</sup>. However, in addition to OCs, small hepatocytes (SHs) are also well known in adult liver, and they are better suited to the appellation “progenitor” cells. As it is not an easy task to distinguish stem cells from progenitors because of the difficulty of proving the unlimited self-renewal activity of stem cells in many situations, we use the term “adult liver stem/progenitor cells (ALSPCs)” to describe such cells, including both OCs and SHs in this review article. In the field of liver biology, the definitions of “LSPCs” include the following: (1) cells responsible for normal tissue turnover; (2) cells that regenerate liver after PHx; (3) cells responsible for progenitor-dependent regeneration; (4) transplantable liver repopulating cells; and (5) cells that adopt hepatocyte and bile duct phenotypes *in vitro*.

Currently, researchers are working hard to characterize, localize and isolate LSPCs, though this has been difficult because of the lack of specific markers<sup>[11]</sup>. To avoid the restriction of lacking specific markers, Liu *et al.*<sup>[12,13]</sup> have tried other strategies for isolating LSPCs. Based on the concept that stem cells have specific physical and morphological properties, Liu *et al.*<sup>[12]</sup> isolated FLSPCs by a percoll continuous gradient centrifugation-centered

**Figure 2** The molecular mechanisms in each step of biliary differentiation of liver stem/progenitor cells. The biliary differentiation of LSPCs can be divided into three main stages comprising of initiation, progression and maturation. Some important jacent or feeder cells and specific molecules are proposed to be responsible for initiating the first stage of biliary differentiation. When the biliary differentiation goes on, several key signaling pathways including Notch and TGFβ have essential impacts on guarantee of the second stage. After some transcription factors activated, the third stage of biliary differentiation could be accomplished and LSPCs could be matured into cholangiocytes. LSPCs: Liver stem/progenitor cells; TGFβ: Transforming growth factor β.

three-step method. Because stem cells have specific functional characteristics, such as excluding biological vital dyes such as Hoechst 33342, Liu *et al.*<sup>[13]</sup> obtained ALSPCs by side population (SP) enrichment. Although many groups have isolated LSPCs using various strategies, LSPCs for disease application remain far off. The core issue is how to manipulate LSPC differentiation, which is essential for both cell therapy and liver regeneration<sup>[14,15]</sup>. Thus, to guarantee the efficiency and security of LSPC-based therapy for liver diseases, it is important to clarify the strategies and related mechanisms for proper differentiation of LSPCs.

In recent years, many studies have shed light on the tangle of regulatory mechanisms that govern the complex process of LSPC differentiation, but an overall understanding remains a challenge. Here, we review the current understanding of the exact mechanisms related to the differentiation of LSPCs, especially toward cholangiocyte differentiation. We divided the process of LSPC differentiation into three stages (Figure 2). The first stage is the onset of differentiation, when LSPCs are induced to mature into certain cell types. In this stage, the lineage-specific cytokines/growth factors (GFs), their (relative) doses and order of application are crucial for directing the lineage specification of the LSPCs<sup>[16]</sup>. The second stage is the acceleration of differentiation, when LSPCs are quickly progressing through the process. Many developmental regulatory signaling pathways, including the Wnt, Notch, bone morphogenetic protein and fibroblast growth factor pathways, may play a role in directing the cell fates of LSPCs<sup>[17]</sup>. The third stage is to guarantee the accomplishment of differentiation. In this stage, transcription factors are vital to make cells express lineage-specific markers<sup>[5]</sup>.

## IDENTIFICATION OF CHOLANGIOCYTES GENERATED FROM LSPCs

LSPCs can differentiate into a wide range of cell types, including hepatocytes, cholangiocytes, pancreatic cells and intestinal epithelial cells (Figure 1)<sup>[18]</sup>. However, in this review, we focus on cholangiocyte specification from LSPCs. To ascertain the cell fates of LSPCs, the following three features inherent to LSPC transitions must be taken into account for accurate phenotyping: (1) the differentiation of LSPCs toward a specific lineage often involves uncontrolled processes, resulting in a heterogeneous cell population; (2) the differentiation into mature cells is a steady process; and (3) the ultimate proof of functional cell behavior is *in vivo* transplantation of *ex vivo* generated LSPC-based mature cells into immunodeficient animal models with liver injury<sup>[19,20]</sup>.

As LSPCs differentiate into cholangiocytes, the cells grow in size to > 12 μm and display a keystone morphology with cholangiocyte-type epithelial polarity. These cells are concentrically layered to form a cyclic structure or arranged in lines to form ductal plates. Under the electron microscope, these cells acquired the classic cholangiocyte features of small numbers of organelles and many primary cilia on their surface.

Aside from morphological identification, the analytical work is limited to the elucidation of (1) cholangiocyte RNA transcripts *via* (quantitative) reverse transcriptase polymerase chain reaction and (2) cholangiocyte proteins by immunofluorescence. During the process of LSPC differentiation into cholangiocytes, cells transition from the expression of early biliary markers (such as Sox9, which is a representative transcriptional factor expressed in biliary precursor cells), to the expression of mid-stage

biliary markers (such as the cytokine CK19 and E-cadherin), and then mature biliary markers (such as CK7)<sup>[21]</sup>. In addition, gamma-glutamyl transpeptidase (GGT), a major enzyme of glutathione homeostasis, is often used as a biliary marker to follow the differentiation of LSPCs<sup>[22]</sup>. Furthermore, multidrug resistance-associated protein 3<sup>[23]</sup> and secretin receptors<sup>[24]</sup> are also found to be expressed in cholangiocytes.

Although the induced differentiation of cholangiocytes has been performed, the functional examination of LSPC-derived cholangiocytes is very scarce. Thus, the *in vivo* identification of induced cholangiocytes is essential, and to some extent it can be considered the “gold standard” of certifying the cell fates of LSPCs<sup>[25]</sup>. LSPC-derived cholangiocytes *in vivo* should be able to replace injured cholangiocytes or lost bile duct cells.

## STRATEGIES FOR CHOLANGIOCYTIC DIFFERENTIATION OF LSPCs

The components of the stem-cell microenvironment regulating differentiation include distinct cell-cell interactions and paracrine signals, which comprise both soluble and extracellular matrix factors, as well as the three-dimensional architecture, which shapes and dictates the delivery of these cues. It is reported that mature stellate cells and/or myofibroblasts resulted in differentiation of LSPCs into cholangiocytes<sup>[26]</sup>. These feeder cells control the cell fates of LSPCs through either paracrine signaling pathways or cell-cell interaction<sup>[27-30]</sup>. Thus, if the paracrine signals produced by the feeders are replaced with similar components, the same induced differentiation of LSPCs could be achieved. There are feeder-free conditions that yield equivalent results, consisting of the embedding of LSPCs into hydrogels containing type I collagen (60%) and Matrigel (40%) with modified Kubota's medium for cholangiocytes. It is also demonstrated that the murine FLSPC cell line, hepatoblast cell line-3, can be induced to differentiate toward cholangiocyte by plating in Matrigel<sup>[31]</sup>. Furthermore, Matrigel-coated films are also widely used for manipulating LSPCs. Although PLL-terminal t-(poly-L-lysine/poly-L-glutamic acid) (PLL/PLGA) films are less favorable for stem cell cultures than PLGA-terminal t-(PLL/PLGA) films, the cell fates of LSPCs are correlated with the film thickness on both types of film, with differentiation favored on the thinner films<sup>[32]</sup>.

Recent evidence has shown that expression of miRNAs can regulate the divergent differentiation pathways of stem cells<sup>[33]</sup>. Therefore, Liu *et al.*<sup>[33]</sup> reasoned that miRNAs could be responsible for regulating cell fate decisions in LSPCs by regulating the cells' responses to ubiquitous GFs. It was found that the miR-23b cluster, including miR-23b, miR-27b, and miR-24-1 and miR-10a, miR-26a and miR-30a, was highly expressed in LSPCs<sup>[34]</sup>. MiR-23b cluster repressed bile duct gene expression in LSPCs while promoting their growth; low levels of the miR-23b miRNAs were needed in cholangiocytic differentiation and bile duct formation<sup>[34]</sup>.

## MOLECULAR MECHANISMS OF CHOLANGIOCYTIC DIFFERENTIATION FROM LSPCs

The process of intrahepatic bile duct (IHBD) formation from LSPCs involves cholangiocyte differentiation (lineage specification) and morphogenesis of ductal structures<sup>[21]</sup>. Understanding how LSPCs can generate differentiated bile ducts is crucial for studies on epithelial morphogenesis and for development of cell therapies for hepatobiliary diseases. Many groups<sup>[35-37]</sup> have demonstrated that, during *in vivo* liver development and *in vitro* differentiation, LSPCs located around the portal vein first develop as biliary precursor cells and then generate cholangiocytes. Nevertheless, the molecular mechanisms behind these events have yet to be fully elucidated. It is shown that Wnt and Notch signaling are active in the adult human liver to drive proliferation and differentiation of LSPCs into the hepatocyte or cholangiocyte lineages<sup>[38]</sup>. The Notch pathway is triggered by expression of the Notch ligand Jagged1 by myofibroblasts, thereby promoting biliary differentiation of LSPCs, and the enhancement of Wnt3a expression in macrophages after uptake of hepatocyte debris and paracrine activation of Wnt signaling in neighboring LSPCs specifies hepatocytic differentiation<sup>[39,40]</sup>. The opposing roles of Wnt and Notch signals in cholangiocyte fate determination in the LSPCs are described below. The molecules responsible for differentiation of LSPCs into cholangiocytes are also discussed in this section (Figure 2).

## INITIATION OF CHOLANGIOCYTIC DIFFERENTIATION

When the LSPCs are cultured in Matrigel, they are likely to differentiate into cholangiocytes. Recently, the key stimulator has been found. Epimorphin/syntaxin 2 (EPM) is a highly conserved and very abundant protein involved in epithelial morphogenesis in various epithelial organs<sup>[41]</sup>, and in the liver, it is exclusively expressed on the surface of hepatic stellate cells and myofibroblasts<sup>[42]</sup>. Biliary differentiation markers elevated by EPM include Yp, Cx43, aquaporin-1, CK19 and GGT<sup>[41]</sup>. Moreover, the signaling pathway of EPM was analyzed by focal adhesion kinase (FAK), extracellular regulated kinase 1/2 (ERK1/2) and RhoA. Most importantly, RhoA was found to be necessary for EPM-induced activation of FAK and ERK1/2 and bile duct formation. In addition, EPM regulated GGT IV and GGT V expression differentially, and this was possibly mediated by C/EBP $\beta$ . Taken together, these data demonstrated that EPM regulates biliary differentiation of LSPCs through effects on RhoA and C/EBP $\beta$ , implicating a dual aspect of this morphoregulator in bile duct epithelial morphogenesis. In another study, it was reported that EPM selectively induced bile duct formation through upregulation of CK19 expression and suppression of hepatocyte nuclear factor

(HNF) 3 $\alpha$  and HNF6<sup>[43]</sup>. These results demonstrate a new biophysical action of EPM in bile duct formation, during which the determination of LSPCs play a crucial role. MiRNAs could also initiate biliary differentiation of LSPCs. In the previous section, we described the requirement for miR-23b miRNAs in growing hepatocytes to repress bile duct genes and repress tumor growth factor (TGF)  $\beta$  signaling. There has also been another report providing evidence that miR-30 family miRNAs were required for complete bile duct formation to repress hepatocyte genes<sup>[44]</sup>.

## PROGRESSION OF CHOLANGIOCYTIC DIFFERENTIATION

Bile ducts are formed only around the portal side, suggesting that region-specific signals induce cholangiocytes from LSPCs. Two signaling pathways, TGF $\beta$ /Activin<sup>[21,45]</sup> and Notch<sup>[46,47]</sup>, are specifically activated in LSPCs near the portal vein. Although differentiation of LSPCs to cholangiocytes by TGF $\beta$  and Notch signaling occurs in mid-gestation, surprisingly, LSPCs can be induced to differentiate into cholangiocytes and form ectopic duct structures in the parenchyma upon Notch activation after birth<sup>[48]</sup>. That is, the Notch pathway plays an essential role in the morphogenesis of bile duct structures<sup>[49]</sup>. Indeed, conditional knockout of Recombination signal binding protein J $\kappa$ , an essential downstream signal component of the Notch receptor, results in a reduced number of cholangiocytes at ED 16.5, confirming a role for this signaling pathway in cholangiocyte cell fate specification<sup>[48]</sup>. In general, Notch signaling is likely to play the most important role in controlling biliary differentiation of LSPCs.

A study using an *in vitro* culture of FLSPCs has shown that activation of the Notch signaling pathway promotes LSPC differentiation into the cholangiocyte lineage by coordinating a network of LETFs including HNF1 $\alpha$ / $\beta$ , HNF4 $\alpha$  and C/EBP $\alpha$ <sup>[46]</sup>. Among multiple Notch signaling components, Notch1, Notch2 and Jagged1, Hes1 are widely accepted as essential for promoting bile duct differentiation<sup>[49-51]</sup>, while Notch3 and Jagged2 play key roles in hepatic differentiation<sup>[52]</sup>. Lacking Hes1, a target of the Notch signaling, ductal plate formation occurs normally, but the subsequent remodeling and tubular structure formation is completely blocked<sup>[53]</sup>. In humans, mutations in Jagged1, a ligand for the Notch receptors, are associated with Alagille syndrome, an autosomal dominant disorder characterized by multiple developmental defects including neonatal cholestasis caused by a paucity of IHBD<sup>[54-56]</sup>. In addition, another form of Alagille syndrome has been found to be caused by mutations in the *Notch2* gene<sup>[57]</sup>.

TGF $\beta$  is necessary for the formation of bile ducts<sup>[58]</sup>. The inhibition of TGF $\beta$  signaling allows LSPCs to undergo normal hepatocyte differentiation<sup>[45]</sup>. Wnt signaling is also involved in regulating biliary epithelial cell fate. The addition of Wnt3a in *ex vivo* culture experiments supports biliary epithelial cell differentiation of FLSPCs<sup>[59]</sup>. However, as to Wnt5a, a non-canonical Wnt ligand, *in*

*vitro* differentiation assays showed that Wnt5a-mediated signaling in FLSPCs suppresses biliary differentiation through the activation of phosphorylated Calcium/calmodulin-dependent protein kinase II<sup>[60]</sup>. Similarly, in the absence of Wnt1 signaling, LSPCs failed to differentiate into hepatocytes and underwent atypical ductular hyperplasia, exhibiting epithelial metaplasia and mucin production<sup>[61,62]</sup>. Furthermore, the inhibition of  $\beta$ -catenin, a core component of canonical Wnt signaling, prevents LSPCs from expressing biliary markers<sup>[63]</sup>.

In brief, Notch signaling promotes LSPCs differentiation into the biliary epithelial lineage and concurrently inhibits hepatic differentiation by reducing the expression of hepatic genes. In contrast, Wnt signaling is more likely to aid in promoting hepatic differentiation and repressing biliary differentiation. The unbalanced activation of Wnt and Notch signaling pathways influences the cell fates of LSPCs.

## ACCOMPLISHMENT OF CHOLANGIOCYTIC DIFFERENTIATION

With regard to the molecular mechanisms involved in cholangiocyte differentiation, several transcription factors have been implicated, including Sal-like 4 (Sall4), T-box transcription factor 3 (Tbx3), the Onecut transcription factor HNF6 and HNF1 $\beta$ , HES1, FOXA2, FOXA3, forkhead Box (Fox) m1 $\beta$  (Foxm1 $\beta$ ), and Hex<sup>[36,37,64-68]</sup>. Sall4 is expressed in LSPCs but not in mature liver cells. The expression level of Sall4 gradually falls during liver development. Sall4 has been shown to play a role in regulating the lineage commitment of LSPCs by inhibiting their differentiation into hepatocytes while driving differentiation toward cholangiocytes<sup>[36]</sup>. When bile duct-like structures were induced by collagen gel-embedded culture conditions, overexpression of Sall4 markedly augmented the size and number of CK19<sup>+</sup> branching structures. These results suggest that Sall4 plays a crucial role in controlling the lineage commitment of LSPCs not only by inhibiting their differentiation into hepatocytes but also by driving their differentiation toward cholangiocytes<sup>[36]</sup>. Tbx3 also contributes to the hepato-biliary lineage decision<sup>[37,69]</sup>. Tbx3 functions to maintain expression of the hepatocyte transcription factors HNF4 $\alpha$  and C/EBP $\alpha$  while suppressing expression of the cholangiocyte transcription factors HNF6 and HNF1 $\beta$ <sup>[69]</sup>. In addition, as a direct and critical target of HNF6, HNF1 $\beta$  shows a decisive effect in bile duct development<sup>[65]</sup>.

## DIFFERENTIATION OF LSPCs INTO INSULIN-POSITIVE CELLS

Although organ-specific stem cells possess plasticity that permits differentiation along new lineages, production of endocrine pancreas and insulin-secreting beta cells from stem cells has not been fully demonstrated. The liver and pancreas share a common developmental origin, and a

bipotential precursor cell population for these organs has been identified within the embryonic endoderm<sup>[70]</sup>. Consistent with these facts, many studies have demonstrated that LSPCs can be converted to insulin-producing cells by stable expression of pancreatic duodenal homeobox 1 (Pdx1) or its super-active form (Pdx1-VP16) or to functional pancreatic beta-cell-like cells, and/or islet-like cell clusters containing other pancreatic lineages under certain other conditions<sup>[71-74]</sup>. The most common condition under which LSPCs are induced to differentiate into insulin-producing cells is a high-glucose environment<sup>[75]</sup>. In addition, there are studies indicating an efficient chemical protocol for differentiating LSPCs into functional insulin-producing cells using small molecules, and they represent a promising LSPC-based treatment for diabetes mellitus. When ALSPCs were incubated with a combination of 5 mmol/L sodium butyrate and 1 nmol/L betacellulin, most of the cells were converted into morphologically beta cell-like cells. An immunoreactive pancreatic polypeptide, somatostatin, and insulin were detected in sodium butyrate and betacellulin-treated ALSPCs<sup>[72]</sup>. Based on induction by a combination of 5-aza-2'-deoxycytidine, trichostatin A, retinoic acid and a mix of insulin, transferrin and selenite, LSPCs could also trans-differentiate into beta-like cells<sup>[76]</sup>. Furthermore, transduction of pancreatic transcription factors, such as Pdx1, Neurogenin3, NeuroD and MafA, can induce the formation of ectopic islet-like cells and the production of insulin in ALSPCs<sup>[77,78]</sup>. Stepwise differentiation from LSPCs into functional insulin-secreting cells will identify key steps in beta-cell development and may yet prove useful for transplantation therapy for diabetic patients<sup>[79]</sup>.

## MALIGNANT TRANSFORMATION OF LSPCs INTO LIVER CANCER STEM LIKE CELLS

Stem cells have potential for therapy of liver diseases, but they may also be involved in the formation of cancer<sup>[80]</sup>. At present, it is widely accepted that cancer arises from the malignant transformation of stem cells<sup>[81,82]</sup> because these are the only cells that persist sufficiently long to acquire the required number of genetic changes. Specifically, LSPCs are hypothesized to be the precursors for a subset of liver cancer<sup>[83,84]</sup>. Presently, accumulating evidence supports the above notion as follows<sup>[85]</sup>: (1) similar signaling pathways may regulate self-renewal in LSPCs and liver cancer cells; and (2) liver cancer contains rare cells with stem cell-like properties, which may derive from malignant transformation of LSPCs. Herein, we propose that liver cancer stem like cells (LCSCs) might arise from LSPCs it would facilitate our understanding of stem-cell origin of liver cancer. It has been demonstrated that deletion of p53 from LSPCs is sufficient to induce tumor formation<sup>[86]</sup>. Recently, through loss expression of Tg737, You *et al.*<sup>[87]</sup> successfully induced FLSPCs to malignantly transform into LCSCs. These LCSCs from LSPCs could

generate liver cancer after transplantation into immunodeficient mice. In addition to gene manipulation, dysregulated miRNAs may also initiate malignant transformation. To find the possible target miRNAs, Liu *et al.*<sup>[13]</sup> compared the miRNA profiles between LSPCs and LCSCs. As a result, Liu *et al.*<sup>[13]</sup> found 78 miRNAs were dysregulated, including miR-200a (the most down-regulated miRNA in LCSCs) and miR-181 (the most greatly upregulated miRNA in LCSCs)<sup>[13]</sup>. After inhibition of miR-200a in LSPCs, Liu *et al.*<sup>[13]</sup> found that cells displayed malignant properties such as unlimited proliferation and strong metastasis. A novel regulatory link between miR-181 and LCSCs was proven by a study from another group<sup>[88]</sup>. They found that miR-181 could induce LSPCs' malignant transformation by directly targeting hepatic transcriptional regulators of differentiation (for example, caudal type homeobox transcription factor 2 and GATA binding protein 6) and an inhibitor of Wnt/beta-catenin signaling (nemo-like kinase).

## CONCLUSIONS AND FUTURE DIRECTIONS

Despite uncertainty surrounding the mechanism underlying the role of LSPCs in liver regeneration<sup>[89]</sup>, there is great hope for the use of these cells in liver-based therapies<sup>[90]</sup>. First, LSPCs can be used for the treatment of inherited end-stage liver disease. Second, they can also serve as a source of cells for cell transplantation in acquired liver diseases such as acute failure due to toxic or viral injury. Third, because LSPCs can be expanded *in vitro* to a desired extent, they can be used to populate liver assist devices or artificial livers based on bioengineered matrices. Lastly, they can be used as targets for gene therapies in primary liver diseases or diseases where extra-hepatic manifestations arise from abnormal gene expression or defective protein production in the liver. Considering the strong proliferative potential and amenability for *in vitro* manipulation, LSPCs may be attractive candidates for liver disease treatment. In addition, LSPCs may be useful for cell therapy to treat diabetic patients, given their potential to be effectively reprogrammed toward pancreatic lineages<sup>[91]</sup>. Furthermore, the development of such protocols would reduce the likelihood of malignant transformation upon transplantation.

Although LSPCs are promising for the future use in many fields, the accurate control of cell fates of LSPCs is far from accomplishment. Thus, it is necessary to clear the mechanisms for LSPCs differentiation and build standardisation of the production of functional cholangiocytes from LSPCs. Here, we want to list several directions that may help to guide future research of LSPCs differentiation: (1) The knowledge of biliary development and liver regeneration can best provide detailed information for *in vitro* cholangiocyte differentiation of LSPCs. It is a good choice to thoroughly investigate the molecular basis of biliary development during the period from fetal liver to adult liver; (2) LSPCs react differently to stimulative

materials at different stages. The dosage, timing, and combinations of materials should thus be fine-tuned according to the differentiated stage LSPCs located. Hence, it is important to figure out what state LSPCs are presented; (3) The molecular mechanism in each step of cholangiocytic differentiation from LSPCs is essential for cell-based therapies. Both positive and negative factors responsible for the initiation, progression and maturation of cholangiocytic differentiation should be specially considered; and (4) Although we divide the process of cholangiocytic differentiation into three stages, it is actually a continuous evolving process. That is to say, it should be kept in mind that many key factors may not only take effect in some stage of cholangiocytic differentiation from LSPCs.

### Abstract

Pharmaceutical companies that produce gastrointestinal (GI) medications often utilize phthalates for their ability to localize medication release. Commonly prescribed GI medications that may utilize phthalates are 5-Aminosalicylates, proton pump inhibitors, and pancreatic enzymes. Our understanding of the cumulative health effects of phthalates from medications remains unclear, and there is increasing evidence that phthalates are not harmless. Experimental studies in animals have shown that phthalates, specifically dibutyl phthalate and Di-(2-ethyl-hexyl) phthalate, have the potential to alter and/or inhibit reproductive biology and in utero development. Despite the lack of definitive human data, many cohort and cross-sectional studies demonstrate concerning associations between phthalates and poor health status, specifically developmental problems. Longitudinal studies and studies with larger sample sizes are required to determine whether phthalates actually cause negative health consequences. It is also important that physicians regularly review and discuss with patients the medicinal ingredients in their medications and supplements, specifically in pregnant woman with

inflammatory bowel disease.

**Key words:** Phthalates; Dibutyl phthalate; 5-Aminosalicylates; Medications; Development; Pregnancy

**Core tip:** Phthalates are widely used as excipients in medications used to treat gastrointestinal disease. Research into the adverse effects associated with certain phthalates continues to produce uncertainty regarding the safety of their use in medications. Gastroenterologists should be aware of the potential harm of specific phthalates so that they can make informed decisions of whether the benefits of the medication outweigh the potential risks. Additional studies using human populations will help elucidate if regulatory bodies should mandate the use of alternative excipients.

### INTRODUCTION

Phthalates are plasticizers with widespread industrial use. Their unique chemical structure allows them to make plastic more flexible and durable<sup>[1]</sup>. Phthalates are commonly used as softeners, solvents and additives, and are employed as excipients in gastrointestinal (GI) medications<sup>[2-4]</sup>. Pharmaceutical companies that produce GI medications often utilize phthalates for their ability to localize medication release. More specifically, low molecular weight (LMW) phthalates are found in oral medications that require both controlled time release and location

sensitive release at certain points along the GI tract<sup>[5]</sup>. Our understanding of the cumulative health effects of phthalates from medications remains unclear, and there is increasing evidence that phthalates are not harmless. This paper will review phthalate utilization in GI medications and summarize the evidence for the possible hidden danger of these common additives.

## CHEMICAL STRUCTURE

Phthalates are diesters of 1,2-benzendicarboxylic acid (phthalic acid) and are present in both industrial and commercial synthetic products<sup>[5]</sup>. Phthalate esters are prepared by the esterification of two moles of monohydric alcohol with one mole of phthalic anhydride<sup>[6]</sup>. When used as an additive to industrial products, phthalates are often combined with polyvinyl chloride (PVC) because they are cheap and are able to provide important properties to plastics such as flexibility and durability. As a result, phthalates are found in more than 80% of the global plasticizer market<sup>[6]</sup>. LMW phthalate subgroups have fewer than eight carbon atoms and include diethyl phthalate (DEP) and dibutyl phthalate (DBP), while high molecular weight (HMW) phthalates have eight or more carbon atoms in an alkyl chain<sup>[7]</sup>. The commonly used HMW phthalate, Di-(2-ethyl-hexyl) phthalate (DEHP), is found in many products containing PVC<sup>[7]</sup>. Most phthalates used as plasticizers have between 4 and 13 carbon atoms. These specific carbon lengths are used since fewer than four carbons can make compounds too volatile and more than 13 carbons are less effective at combining with PVC molecules<sup>[6]</sup>.

## BIOABSORPTION

Since phthalates are the most widely used additives in plastics, their absorption in the body has been extensively studied. Phthalates do not bio-accumulate in the body. However, their widespread use translates into a large exposure in the general population<sup>[8]</sup>. Phthalates are quickly metabolized to mono-alkyl metabolites and glucuronides and are excreted in both urine and feces<sup>[9-12]</sup>. The urine content of phthalates and their metabolites have been shown to be sensitive biomarkers of phthalate intake. Therefore, urine screening has been used in many studies to assess phthalates levels in the population<sup>[2,13,14]</sup>. Specifically, United States and German population data have shown widespread exposure to phthalates in urine samples<sup>[5,14,15]</sup>. A United States study using data from the National Health and Nutrition Examination Survey found that over 75% of urinary samples contained some form of a phthalate metabolite, and it has been speculated that urine studies may underestimate phthalate levels in humans, as metabolites may be metabolized into undetectable byproducts<sup>[2,14]</sup>.

## GI MEDICATIONS AND PHTHALATES

Scientists utilize various techniques to permit the release

of medication at specific parts of the luminal GI tract. For instance, using the prodrug technique, an inert drug is transformed into its active form at various pH levels. As an alternative method, the pharmaceutical industry has relied heavily on phthalates to assist with delivery of GI medications to precise areas of the luminal GI tract.

Compared to HMLW phthalates, LMW phthalates are more commonly used in pharmaceutical products. Phthalates used as excipients include cellulose acetate phthalate, DBP, DEP, dimethyl phthalate, hypromellose phthalate, and PVC<sup>[16]</sup>. Excipients are defined as inactive ingredients found in medications that aid in the manufacturing, administration or absorption of the drug<sup>[17]</sup>. They usually possess no active pharmacological ingredients and are regarded as inert. For example, LMW excipients such as DBP and DEP are listed in the FDA Inactive Ingredients Database for use in oral capsules, delayed action, enteric coated and controlled release tablets<sup>[18]</sup>. Phthalates can also be combined with different polymers to maintain medication flexibility<sup>[19]</sup>. This can assist with the localization of active ingredients through the delayed release of the inner components of solid drugs<sup>[19,20]</sup>.

An extensive review of pharmaceutical literature revealed that many GI medications contain phthalates as both excipients and inactive ingredients<sup>[17]</sup>. For instance, this review found that mesalamine, pancreatic lipase, sulfasalazine, ranitidine and omeprazole are prescription drugs marketed in either Canada or the United States with labels that identified an ortho-phthalate as an inactive ingredient. The phthalate DBP, which has been shown to have potentially harmful adverse effects, is found in nonprescription medications such as bisacodyl and many probiotic supplements used frequently by gastroenterologists<sup>[17]</sup>. Omeprazole and ranitidine contain the phthalate DEP, of which there is no evidence of potential harm.

The extensive use of phthalates in GI medications has prompted research into the cumulative effects of phthalates on those taking these drugs for prolonged periods of time. GI medications utilize phthalates more than most medications and are, therefore, more likely to result in high exposure to phthalates. Studies have shown that among patients prescribed, some of the aforementioned GI medications, specifically mesalamine and omeprazole, urine concentrations of phthalates have been documented at levels 100 times higher than the general population<sup>[5]</sup>. It has also been shown that DBP and DEP, commonly used as excipients, can be found at concentrations of 9000 micrograms per capsule in some GI medications<sup>[11]</sup>. These concentrations are concerning, as it has been shown that only 3600 micrograms per capsule can result in DBP metabolites in urine that are above the recommended tolerable daily intake<sup>[11]</sup>. Well-designed retrospective studies are needed to determine the long-term effects of using GI medications with high levels of phthalates.

## HARMFUL EFFECTS OF PHTHALATES

Experimental studies in animals have shown that phthal-

ates, specifically DBP and DEHP, have the potential to alter and/or inhibit reproductive biology and in utero development<sup>[5]</sup>. One study demonstrated that mice exposed to 190 times the recommended amount of Asacol, a 5-ASA drug that contains DBP, were at risk for developing skeletal malformations and reproductive adverse effects<sup>[21]</sup>. These concerns prompted additional studies which revealed that phthalates can act as anti-androgens and subsequently have toxic interactions with androgen receptors<sup>[22,23]</sup>. Nonetheless, little data exists to help determine whether phthalates act as endocrine hormones at high levels in humans. Whether phthalates have meaningful interactions with proteins at the cellular level also remains unclear<sup>[24,25]</sup>.

Despite the lack of definitive human data, many cohort and cross-sectional studies demonstrate concerning associations between phthalates and poor health status, specifically developmental problems. For instance, a study in the United States found positive associations between LMW phthalate metabolites and several developmental indicators, including gestational age and head circumference. These results demonstrate that phthalates may potentially alter childhood development from birth<sup>[26]</sup>. Research from Denmark showed a potentially detrimental correlation between phthalate monoesters and hormones essential for normal in utero development<sup>[26,27]</sup>. Multi-center cohort studies from the United States and Mexico studying male children demonstrated that prenatal urinary phthalate concentration is negatively correlated with genital development, including anogenital distance, an index of demasculinization of the male reproductive tract, and penile width<sup>[23,28,29]</sup>. Cross-sectional data from the United States, China, and Sweden comparing phthalates levels with semen concentration and semen quality have raised concern about deleterious interactions<sup>[30-34]</sup>. By measuring phthalate metabolites in urine, dose-response relations have been found between some phthalate metabolites and sperm concentration, motility, and morphology<sup>[30,32]</sup>. Despite the associations between phthalates and semen indices, this data has not been reproduced in the general population.

Additionally, phthalates have been associated with stunted neurodevelopment<sup>[35,36]</sup>. A cross-sectional study from South Korea displayed a negative relationship between urinary concentration of phthalate metabolites and performance on various IQ tests<sup>[35]</sup>. Moreover, United States cohort data indicated a positive association between maternal urine concentration of certain phthalates and increased negative behavior on validated behavior reporting tools<sup>[36]</sup>. One cohort study from Denmark showed a negative association between phthalate metabolites in urine and normal serum levels of thyroid hormone<sup>[37]</sup>. Interestingly, a cohort study from South Korea showed an association between phthalate metabolites in the urine, specifically DEHP, and increased attention deficit hyperactivity disorder symptoms<sup>[38]</sup>. Recent research has provided conflicting data on the association of phthalates with the early onset of puberty and its associ-

ated symptoms<sup>[22,39]</sup>. A case-control study from Turkey demonstrated an association between plasma levels of certain phthalates and gynecomastia, while a multicenter cohort study performed in the United States showed no association between phthalates concentration in the urine and precocious puberty<sup>[22,39]</sup>. Finally, cross-sectional and cohort studies out of Sweden, Russia and Finland have implicated respiratory complications such as rhinitis and asthma with phthalates<sup>[40-43]</sup>. However, the evidence for the association between phthalates and these clinical manifestations remains weak as most of these studies used PVC exposure as a proxy to phthalate exposure.

## 5-AMINOSALICYLATES

5-Aminosalicylates (5-ASAs) are used as first line therapy in treatment for mild to moderate ulcerative colitis (UC). Initial research in phthalate exposure and GI medications has focused on 5-ASAs users. Specifically, absorption data shows concerning levels of phthalates in the urine of chronic users of mesalamine, a 5-ASA drug. United States data demonstrated that six individuals taking mesalamine had metabolites of DBP 50-fold higher than those not using mesalamine<sup>[10]</sup>. Similarly, one third of patients taking mesalamine had urine levels of phthalates that exceeded FDA recommended levels<sup>[5,10]</sup>. While no equivocal evidence exists, gastroenterologists treating UC should consider prescribing 5-ASAs without DBP. This consideration should be especially taken in women of child-bearing age, as DBP may have deleterious effects during pregnancy based on animal studies.

Studies of pregnant and lactating women have shown that phthalates appear in maternal and umbilical blood, amniotic fluid and breast milk<sup>[27,44-46]</sup>. As a result, women taking 5-ASA formulations have been evaluated for potential adverse effects during pregnancy<sup>[47-50]</sup>. While no randomized control studies exist, a meta-analysis using 7 cohort studies did not indicate that woman taking 5-ASA during pregnancy have significantly higher rates of congenital abnormalities compared to control groups using no medication<sup>[51]</sup>. Pooled odd ratios from these studies demonstrated 1.16, 2.38, 1.14, 1.35 and 0.93 fold increase in congenital malformations, still births, spontaneous abortions, preterm deliver and low birth weight, respectively<sup>[51]</sup>. Based on this data, the 5-ASA formulation under the brand name of Asacol has been classified by the FDA as a pregnancy class C, which reflects adverse effects in animal but not human studies<sup>[21]</sup>. As such, it is important that women taking 5-ASA drugs are informed about the potential risk of drugs containing DBP, especially when there are alternative 5-ASA formulations that do not contain DBP. Nonetheless, it must be emphasized that the risks of not taking 5-ASA while in remission far outweigh the benefits of avoiding phthalates. In addition, clinicians should consider 5-ASA formulations that release predominantly into the colon and do not contain phthalates. For example, Mezavant is a 5-ASA drug that uses an Multi Matrix system delayed release mechanism,

which allows release to be primarily in the colon where it can be most effective at treating ulcerative colitis. It has been shown to be equally efficacious at achieving IBD remission and does not contain phthalates in its coating<sup>[52]</sup>. Salofalk is another alternative 5-ASA formulation available in Canada and utilizes pH-dependent release. Its Eudagrit-L coating, contains the DEP rather than DBP. Unlike the latter, DEP has not been shown to be harmful in animal studies.

## REGULATION OF PHTHALATES

Throughout the previous decade, much of the media attention covering phthalates has targeted the presence of these plasticizers in children toys. Multiple agencies throughout the world have regulated phthalates in non-medical products including toys, cosmetics, environmental chemicals and health related products<sup>[53-57]</sup>.

Only recently has more attention been focused on phthalates in medications. In December 2012, the Center for Drug Evaluation and Research, a group affiliated with the FDA, recommended against the use of DBP and DEHP as excipients in prescription and nonprescription medications, and encouraged the use of alternative phthalates when possible<sup>[20]</sup>.

The FDA has likely limited their advice to recommendations since clinical and nonclinical research has only demonstrated an association between exposure to these phthalates and developmental problems, and there remains no evidence that medications with phthalates cause phenotypic physiologic abnormalities. These studies have been strictly correlational in nature, and thus a cause-effect relationship cannot be proven.

Accumulating pressure on pharmaceutical companies has encouraged the development of alternatives to phthalates. Pharmaceutical companies have developed excipients that do not contain phthalates. As mentioned, Salofalk and Mezavant are alternative 5-ASA formulations that contain alternative phthalates other than DBP or DEHP or a delayed release mechanism that does not incorporate phthalates<sup>[52,58]</sup>.

## FUTURE DIRECTIONS FOR PHTHALATES

It is currently challenging to identify which medications contain phthalates, along with the specific dosage of phthalates included. Levels of phthalates for many medications are not openly displayed, due to proprietary formulations<sup>[17]</sup>. Current standards do not require that inactive components are included on the package labeling of dietary supplements<sup>[59]</sup>. It is the authors' opinion that government regulators should continue to advocate for the display of all components on drug packaging. It is also important that physicians regularly review and discuss with patients the medicinal ingredients in their medications and supplements. Patients should also be encouraged to use their pharmacists as a resource. Specifically, pregnant woman should review their medications

with pharmacists and discuss the potential presence of phthalates and possible alternatives. Of course, all these decisions should be made in conjunction with the advice of a physician.

Based on the empirical evidence available to date, government regulators and physicians must take caution against phthalates. Recommendations from government regulators should be followed if feasible and will hopefully facilitate the development and utilization of alternatives to phthalates. In order to further explore preliminary concerns, additional research with robust methodology should be conducted. Longitudinal studies capable of demonstrating causation are required to determine whether phthalates actually cause negative health consequences. Studies with larger sample sizes will also help quantify how much DBP and DEHP is being absorbed through specific medications. These studies might help with comparative quantification of bioabsorption between medication and environment (non-medical) exposures, which will help direct policy. Such research will permit government regulatory bodies, drug companies and doctors to respond appropriately.

mechanism. Neuromodulation is a minimally invasive procedure with a low rate of adverse events and apparently favorable cost-efficacy profile. This review is intended to expand knowledge about this effective intervention among the non-surgically skilled community who deals with this disabled group of patients.

© 2013 Baishideng Publishing Group Co., Limited. All rights reserved.

**Key words:** Fecal incontinence; Neuromodulation; Sacral nerve stimulation; Biofeedback; Anal sphincter

**Core tip:** This review summarizes the evidence for neuromodulation of fecal incontinence. Neuromodulation is effective for some patients with fecal incontinence of different etiology unknown mechanism; when analyzed by intent to treat analysis, the median responder rate is 59%. The most common serious adverse event is infection at the site of implant which occurs in about 3% of patients. Cost of treatment is high relative to conservative treatment and biofeedback but seems to be cost-effective when offset by gains in quality-adjusted years. Randomized controlled trials comparing neuromodulation with biofeedback therapy in fecal incontinence are advisable to tailor patients' management.

### Abstract

Fecal incontinence is a disabling symptom with medical and social implications, including fear, embarrassment, isolation and even depression. Most patients live in seclusion and have to plan their life around the symptom, with secondary impairment of their quality of life. Conservative management and biofeedback therapy are reported to benefit a good percentage of those affected. However, surgery must be considered in the non-responder population. Recently, sacral nerve electrostimulation, lately named neuromodulation, has been reported to benefit patients with fecal incontinence in randomized controlled trials more than placebo stimulation and conservative management, by some unknown

Chiarioni G, Palsson OS, Asteria CR, Whitehead WE. Neuromodulation for fecal incontinence: An effective surgical intervention. *World J Gastroenterol* 2013; 19(41): 7048-7054 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i41/7048.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i41.7048>

### INTRODUCTION

Fecal incontinence (FI) is defined as the accidental loss of solid or liquid stools and is a common disabling condition that is often under-reported at medical consultation

because of fear and embarrassment. In a recent study of > 1500 primary care patients, FI was self-reported by 36.2% of patients, but only 2.7% of them had a medical diagnosis of FI<sup>[1]</sup>. FI has a significant impact on quality of life (QOL) and health expenditure and may facilitate the placement of older patients in nursing home facilities<sup>[2]</sup>. Therefore, increased medical screening of FI is needed because both conservative and interventional treatments are available. Biofeedback therapy to increase rectal awareness of stools and ameliorate anal sphincter response improved continence in about two-thirds of patients in open and randomized controlled trials (RCTs)<sup>[3,4]</sup>. However, patients with severe impairment of rectal sensation and/or previous anal trauma do poorly with biofeedback, and alternative options are desirable in selected patients<sup>[5]</sup>. In the past a number of surgical procedures has been proposed to treat FI. Major drawbacks were the small sample sizes and potential worsening of incontinence<sup>[6]</sup>. Sacral nerve electrostimulation, later also called neuromodulation (NRM), was first applied in 1995 by Matzel *et al*<sup>[7]</sup> with encouraging results in a small group of patients with FI without evidence of anal sphincter defects. The technique was attractive because of its limited side effects and for being minimally invasive. Since then, the effectiveness of NRM in improving FI has been proven in a number of studies, although its mechanism of action remains ill defined<sup>[8]</sup>. However, physicians involved in the treatment of disordered anal continence should consider NRM among potential treatment options, and this review is intended to be a primer for the non-surgical community.

### Search methods

Search terms were fecal incontinence OR anal incontinence and sacral nerve stimulation OR neuromodulation. These searches were limited to human subjects, adults, and studies published in full in the English language between January 1995 and December 2012. Case reports, preliminary studies, and small sample series investigating < 15 patients were not considered. Databases searched were PubMed, Web of Science, Cochrane Reviews, and Embase. The bibliographies of identified studies were also searched for additional references. To address NRM effectiveness, special consideration was given to RCTs and adequately powered prospective trials.

## TECHNIQUE, SAFETY AND MECHANISM OF ACTION OF NRM

### Technique

NRM is a minimally invasive surgical intervention consisting of: (1) a testing evaluation interval; and (2) a second stage with permanent stimulator implantation, provided the testing interval results are clinically successful. The first stage, also termed percutaneous nerve evaluation (PNE), is of most relevance to determine the feasibility of electrode implantation into the sacral foramina, and to demonstrate clinical benefits worth pursuing

with permanent NRM<sup>[9]</sup>. Two technical options are available for PNE: a temporary, percutaneously placed, unipolar stimulation lead to be later removed, or the surgical placement of a quadripolar lead next to a target nerve<sup>[9]</sup>. Both types of leads are then connected to an external pulse generator to be substituted by a permanent pulse generator implanted subcutaneously in case of positive outcome. The permanent implant sized a quarter dollar or 2 euro coin (diameter 24.26 mm, thickness 1.75 mm) is commonly placed in the gluteal area and can be managed by a small handheld device<sup>[9]</sup>. A small retrospective study evaluated outcome and complications of the two PNE techniques<sup>[10]</sup>. No difference in outcome was shown, but the infection rate was slightly higher in patients undergoing surgical placement.

### Safety

The commonest adverse events are implant site pain and paresthesia, which is seen in up to 28% of patients in some large series with careful reporting about safety<sup>[11,12]</sup>. Pain is usually managed conservatively and explant of the device is rarely needed. However, a recent meta-analysis concluded that incidence of implant site pain may be as low as 6%<sup>[8]</sup>. The most serious complication is infection at the implant site, which was seen in up to 10.8% in the largest series of > 100 patients<sup>[11,12]</sup>. The control of site infection may require device explant in approximately half of those affected<sup>[12]</sup>. The meta-analysis by Tan *et al*<sup>[8]</sup> supports diverse evidence indicating that the typical infection rate is 3%, with the proportion requiring the device to be removed for refractory infection being about 3% of those infected. Additional side effects reported in < 8% of patients are urinary incontinence, diarrhea, and extremity pain, which always resolve spontaneously or are effectively managed by medication<sup>[8]</sup>. In older series, broken or displaced electrodes occurred in about 4% of cases<sup>[8]</sup>, and sometimes required device explantation. However, this problem is becoming less frequent since the electrodes were redesigned. Battery replacement is usually required after a median of 7 years<sup>[13]</sup>.

### Mechanism of action

In 1999, Vaizey *et al*<sup>[14]</sup> first reported the effect of NRM on anorectal physiology measured by 24-h solid state catheter manometry in a small group of 10 patients with FI. Resting anal pressure did not change significantly and some evidence of modification of rectal sensitivity and tone was observed. The authors speculated that NRM worked via complex neuromodulation of sacral reflexes to regulate rectal sensitivity and anorectal motility<sup>[14]</sup>. Since then, several studies focused on modifications of anorectal physiology associated with NRM in FI, with conflicting results. In their meta-analysis, Tan *et al*<sup>[8]</sup> concluded that NRM is associated with improvement in anal canal pressure at rest and with voluntary squeezing, and a decrease in the maximum tolerable rectal volume. However, subsequent studies had inconsistent results, with RCTs and long-term studies failing to show a rel-

evant influence of NRM on anal pressure<sup>[15,16]</sup>. When there are significant improvements in anal canal pressure, the size of the effect is small and the final resting and squeeze pressures appear to be below the normal range for healthy controls<sup>[8]</sup>. This is not commensurate with the large clinical effects seen for FI and suggests that the mechanism by which NRM improves continence is not primarily an improvement in anal canal pressure. This issue was addressed in a recent review by Gourcerol *et al*<sup>[17]</sup>, which specifically focused on defining the potential mechanism of action of NRM. The authors speculated on three potential mechanisms: (1) somatovisceral reflex; (2) modulation of the perception of afferent information; and (3) increase in external anal sphincter activity<sup>[17]</sup>. However, no definitive evidence could be found to support any of these and a multifactorial component was further speculated to justify the efficacy of NRM. The authors concluded that NRM is effective almost certainly *via* modulation of spinal and/or supraspinal afferent inputs, but many gaps remain in the understanding of the mechanism of action of NRM<sup>[17]</sup>.

## EFFECTIVENESS

### RCTs

After the early report of Matzel *et al*<sup>[7]</sup>, a number of trials were developed to evaluate the efficacy of NRM in FI<sup>[7,8]</sup>. A major drawback to assessing this literature is the huge variance in inclusion and outcome criteria and follow-up intervals<sup>[8]</sup>. Additional limitations are small sample size (often < 20 patients) and lack of adequate control groups<sup>[8]</sup>. However, the majority of uncontrolled trials reported a favorable outcome in more than two-thirds of patients with limited side-effects. Researchers were unable to identify any clinical and/or functional variable that could predict outcome<sup>[8]</sup>. In earlier reports, patients were selected on findings of either no or marginal evidence of anal sphincter defects. However, this limitation was later dropped because of the unclear definition of the mechanism of action of the treatment<sup>[8]</sup>. In 2005, Leroi *et al*<sup>[18]</sup> reported on the first randomized, controlled, double blind, multicenter study testing the efficacy of NRM in FI and/or severe urgency of any etiology. Patients with an ultrasound diagnosis of sphincter defect were included, provided the defect was not considered to be the main determinant of incontinence<sup>[18]</sup>. After implantation, 27 of 34 patients with FI were randomized in a double-blind crossover manner to NRM active treatment (electrostimulator ON) *vs* placebo (electrostimulator OFF) for a 1-mo period with the device *in situ*. A final interval of 3 mo was also included in the evaluation with patients still blinded, potentially choosing either the ON or the OFF modality<sup>[18]</sup>. Twenty-four patients completed the trial, making the sample underpowered. However, patients reported a significant improvement in both symptoms and QOL scores, and anal physiology when in active treatment compared to placebo, providing evidence that a placebo effect was not the main determi-

nant of NRM outcome<sup>[18]</sup>. However, until recently, NRM was not compared to conservative management (diet, lifestyle modification, constipating drugs, and biofeedback), which is cheaper, commonly available, and often associated with benefits in at least 50% of patients with FI<sup>[3]</sup>. Tjandra *et al*<sup>[15]</sup> randomized 120 patients with FI to either supervised optimal medical therapy or NRM. Conservative treatment included bulking agents, pelvic floor exercises, or lifestyle and dietary manipulations, but it did not include biofeedback<sup>[15]</sup>. NRM was significantly more effective in improving frequency of incontinence with 25 patients regaining perfect continence<sup>[15]</sup>. Cleveland Clinic Continence Score and QOL score were both significantly improved as well<sup>[15]</sup>.

### Open label trials and meta-analysis

In a recent prospective, open label, multicenter trial, Wexner *et al*<sup>[11]</sup> confirmed the effectiveness of NRM in improving FI in a large sample of 120 patients with 112 of them undergoing permanent implantation. The vast majority of patients (83%) reported significant improvement of FI according to the outcome measurement selected, including 41% gaining complete anal continence, after a mean follow-up of 28 mo<sup>[11]</sup>. FI is a chronic disorder, therefore, Mellgren *et al*<sup>[12]</sup> reported on the same cohort after a mean follow-up of 3.1 years (range: 0.2-6.1 years) with at least a partial data set available in 64% of the patients. A significant decrease in episodes of incontinence was still reported by 86% of available patients with 41% regaining continence. A stable improvement in QOL score was also reported by patients<sup>[12]</sup>. To deepen the analysis, a carried forward observation at 3 years was performed showing a 78% success rate. However, the success rate dropped to 59% at 3 years when considering all missing data as failures<sup>[12]</sup>. Historically, anal sphincter disruption has been considered a contraindication to perform NRM, which was not even considered in the presence of a relevant morphological alteration<sup>[7-9]</sup>. However, Chan *et al*<sup>[19]</sup> provided sound evidence against this assumption in a comparative cohort study. The effectiveness of NRM in improving FI and QOL at 1 year was not significantly different in 21 patients with a disrupted external anal sphincter (81% persisting after previous sphincter repair) when compared to the outcome of 32 patients with FI and an intact anal sphincter<sup>[19]</sup>. These data were confirmed by an RCT comparing NRM with conservative treatment in which many patients with defects in both the internal and external sphincters were included, showing that NRM was equally effective in those with or without sphincter disruption<sup>[15]</sup>. The therapeutic potential of NRM compared to conservative treatment in FI has also been reported in several, mostly small studies including patients with distinct pathological conditions, including rectal resection and pelvic irradiation<sup>[8,20,21]</sup>. In these distinct conditions dealt with in the following section, FI response rates may be lower, with about 50% of patients responding to temporary stimulation<sup>[20,21]</sup>. A recent meta-analysis by Tan *et al*<sup>[8]</sup> reported on a total of

Table 1 Effectiveness of neuromodulation in fecal incontinence

Ref.	Sample	Study design	Major findings	Adverse events	Comments
Tjandra <i>et al</i> <sup>[9]</sup>	120 patients with severe FI (solid or liquid FI > 1/ wk) were randomized to 2 groups. Of 60 randomized to test stimulation, 53 received permanent implants. Average age 63 yr; > 90% female. Sphincter defect or scar in 47% of both groups	Single site RCT comparing NRM to optimal medical management	71% of permanently implanted patients (63% of randomized patients - ITT analysis) reported > 50% reduction in FI episodes/wk at 12 mo. FI episodes/wk decreased from 9.5 to 3.1 in SNS group, and not at all in controls. All 4 QOL domains significantly improved in SNS. Anal squeeze pressure was unchanged. SNS significantly different from control on all outcomes	Pain in 6%, seroma in 2%, and excessive tingling in vaginal region in 9%, but no septic complications	Low complication rate and excellent outcomes may be related to this being a single-site study
Wexner <i>et al</i> <sup>[11]</sup>	Multicenter study. 133 received test stimulation; 120 (90.2%) qualified for permanent implant. Average age 60.5 yr; 92% females. Inclusion required > 2 solid or liquid accidents/wk for > 6 mo and > 12 mo postpartum	Multicenter cohort study in United States, Canada, and Australia. Hypothesis was that > 50% would report > 50% reduction in FI frequency at 12 mo compared to baseline. QOL and safety were secondary endpoints	73% of permanently implanted patients (66% of all undergoing test stimulation - ITT analysis) showed > 50% reduction in FI episodes/wk at 12 mo. FI episodes/wk decreased from 9.4 at baseline to 1.9 at 12 mo. All 4 domains of the FI QOL improved significantly. An IAS defect predicted poorer outcome	Pain in 25.8%, paresthesia in 12.5%, infection in 10.8%	
Mellgren <i>et al</i> <sup>[12]</sup>	See Wexner (2010). 77 patients completed the 36 mo FU assessment	This reports the 36 mo outcomes for the Wexner (2010) study	At 36 mo, 86% of 77 patients available for assessment, but only 55% of 120 enrolled patients, reported > 50% reduction in FI	Pain in 28%, paresthesia in 15%, infection in 10%. 5/120 required device explant and 2 required device replacement	ITT analysis under-estimates efficacy because some patients were lost to FU for reasons unrelated to efficacy
Michelsen <i>et al</i> <sup>[16]</sup>	177 patients at single Danish hospital. Average age 60. 142 (80%) had positive PNE and 126 received NRM	Uncontrolled case series	In 107 of 111 who still had stimulator in place at 12 mo, Wexner score decreased in 87 (median decrease of 7) and was unchanged or worse in 20. No significant change in anorectal manometry	15 of 126 with permanent implant had device explanted. There were 2 infections requiring explant	ITT analysis was not possible. Many patients were lost to FU
Hollingshead <i>et al</i> <sup>[13]</sup>	118 patients received PNE, 91 (77%) qualified for NRM; and 86 received NRM	Uncontrolled case series	For all 86, median FI episodes/wk decreased from 8.5 to 1.3 and Wexner score decreased from 15 to 9. In 16% of patients reporting 50% reduction initially, efficacy was lost at median of 11.5 mo	Broken leads in 2. Battery replacement in 7 at mean of 81 mo. No other AEs reported	ITT analysis not possible
Altomare <i>et al</i> <sup>[23]</sup>	94 patients from 6 hospitals underwent PNE, and 60 qualified for and underwent NRM. Average age 58 yr, 83% female	Uncontrolled case series	Of 60 implanted, 2 died (unrelated) and 6 had devices explanted, leaving 52 for 5 year FU. At 5 yr, 37 (39% by ITT) had > 50% decrease in FI frequency. Squeeze and resting pressures increased, maximum tolerated volume decreased	AEs in 8 patients: electrode displacement in 8; pain in 3, allergic reaction in 1; myocardial infarct in 1; unrelated death in 2	ITT success rate at 5 yr was 40% after adjustment for 2 unrelated deaths
Muñoz-Duyos <i>et al</i> <sup>[24]</sup>	Spanish study of 47 patients who received PNE, of whom 29 (62%) received NRM. PNE was ineffective in 16 and 3 had technical failures	Uncontrolled case series with median 3 yr FU. Cost analysis was primary focus	At last FU, 14 were continent and 11 had > 50% reductions in FI frequency. QOL significantly improved. Total direct costs for NRM were €371 434, estimated to be €16 181 per quality adjusted life year. No improvement in anal canal pressures	8 patients experienced pain but none required explantation	ITT response rate was 53.2%
Dudding <i>et al</i> <sup>[22]</sup>	British study of 70 patients who received PNE, of whom 61 had > 50% reduction. At analysis, 51 had received permanent implants, and FU was available for 48. These patients may also be included in the Hollingshead (2011) report	Uncontrolled case series with median 24 mo FU. Primary focus was cost-effectiveness. Direct and indirect costs were estimated by theoretical model of services required rather than on actual costs	At 2 yr FU, 41 of 48 with long-term FU (85.4%) had >50% reduction. Direct costs were estimated at £9795 for SNS compared to £2529 for conservative treatment. The estimated incremental cost-effectiveness ratio was £25 070, which is convenient, being within £30 000 recommended by United Kingdom national guidelines	10/48 had complications including 2 wound infections, 1 lead migration, 5 pain, 2 device failures	ITT response rate was 58.6%. Cost analysis was based on theoretical/ imputed data rather than real costs

Chan <i>et al</i> <sup>[19]</sup>	60 consecutive patients underwent PNE and 53 received NRM. These were separated into 21 with EAS defect vs 32 with intact EAS. One surgeon did all surgeries	Prospective cohort study comparing those with EAS defect to those with intact sphincter	There was a trend for patients with EAS defect to have worse incontinence and poorer squeeze pressures at baseline and FU, but not significant. Outcomes were similar: At 12 mo FU 68.8% with sphincter disruption vs 72.0% with intact sphincter had > 50% reduction in FI. No differences in anal manometry or QOL outcomes	Seroma in 1/53; pain in 3/53. No AEs required explant	Strong support for hypothesis that NRM is equally effective in patients with EAS defects. ITT responder rate for combined group was 63%
Michelsen <i>et al</i> <sup>[28]</sup>	20 patients randomized; 19 had complete data	Randomized prospective crossover comparing NRM continuously for 3 wk to NRM on only during waking hours for 3 wk	Wexner and St Mark's incontinence scores and frequency of soiling were significantly worse during device off period. However, FI frequency was not significantly different between conditions	AEs were not reported	Not directly relevant to efficacy of NRM
Leroi <i>et al</i> <sup>[8]</sup>	34 consecutive FI patients (31 females) considered, 27 eventually studied, 24 completed the trial	Randomized, double-blind, crossover, controlled trial. All 27 patients underwent NRM then randomized in a double-blind crossover design to stimulator ON vs stimulator OFF for 1-mo interval. Patients while blinded choose to meet the final period of 3 mo ON or OFF	Cleveland Clinic Continence score, frequency of FI and urgency, delay in postponing defecation, subjective feeling of improvement, anal physiology, QOL score all significantly improved in the ON interval compared to the OFF interval	10 out of initial 34 reported AE, 4 device explantations; 3 for pain and 1 for infection	First RCT to show effectiveness of NRM compared to placebo; underpowered sample

AE: Adverse event; EAS: External anal sphincter; FU: Follow-up; IAS: Internal anal sphincter.

994 patients undergoing NRM with 665 permanently implanted, confirming significant improvement in symptoms and QOL in patients with FI. A disrupted anus was not the main determinant of outcome<sup>[8]</sup>. However, some criticisms of NRM outcome reports should be considered (Table 1). Outcomes for NRM are often expressed as the proportion of patients receiving a permanent implant who continue to have at follow-up assessment a > 50% reduction in FI relative to baseline<sup>[8,11,12]</sup>. However, this likely overestimates the efficacy of NRM compared to other treatments (e.g., biofeedback therapy), where it is conventional to report effectiveness in terms of an intention-to-treat (ITT) analysis<sup>[13]</sup>. To calculate the ITT response rate, one must include in the denominator all patients who received test stimulation (PNE). When this is done (Table 1), the responder rate ranges from 40% to 66%, with a median of 59%, compared to a median of 85% when only those who received a permanent implant were included in the denominator<sup>[11,22,23]</sup>. In addition, some large studies did not provide the data to calculate the ITT responder rate<sup>[13,14]</sup>. The response to PNE ranges from 64% to 96.7%, with a median of 87%, and 10 reporting at least a 50% reduction in FI from baseline<sup>[8,22-24]</sup>. In a recent Danish study, a questionnaire was mailed to 127 patients with FI and ongoing NRM, to assess subjective patient satisfaction and frequency of incontinence, and 85% responded<sup>[25]</sup>. A total of 57.3% of the responders reported positively about NRM treatment<sup>[25]</sup>, a percentage close to the calculated ITT response rate. In addition, satisfaction with treatment was closely related to pretreatment frequency of incontinence; namely, the more incontinent the patient, the more likely to report treatment dissatisfaction<sup>[25]</sup>. Finally, the effects of NRM are well sustained with 75% of those treated still reporting > 50% symptom reduction at about 7 years<sup>[26]</sup>. In a separate study, Uludağ *et al*<sup>[27]</sup> reported that 84% were still reporting > 50% reduction in FI at 7 years. Switching off the sacral nerve stimulator at night might reduce the device-associated cost, but it is likely associated with a poor long-term outcome<sup>[28]</sup>.

Distinct and rare conditions

The efficacy of NRM has also been investigated under several distinct and rare conditions associated with FI, including: (1) double incontinence; (2) rectal resection; (3) pelvic radiotherapy; (4) anal sphincter atrophy; and (5) spinal lesions. In these conditions, FI is commonly deemed unresponsive to conservative treatment and poorly amenable to surgical intervention<sup>[2-3]</sup>. These conditions have mostly been studied in case reports and small case series of NRM of FI with encouraging results, but no adequately powered RCTs<sup>[9]</sup>. Notwithstanding that NRM to treat FI was developed by sporadic observations of symptom benefit in urinary urge incontinence, few studies have addressed the bene-

fit of NRM in double incontinence<sup>[9]</sup>. Caremel *et al*<sup>[29]</sup> first reported on clinical questionnaires sent to 57 patients with double incontinence treated by permanent implantation, with FI as the main indication for NRM in 60% of them. About two-thirds of patients responded, with 49% reporting an improvement in both fecal and urinary incontinence. Patients implanted for urinary incontinence as the main indication were more likely to report full amelioration of both types of incontinence<sup>[29]</sup>. Recently, Faucheron *et al*<sup>[30]</sup> reported a single-center study of 57 patients (54 women) who underwent PNE and permanent implantation for double incontinence of multiple etiology, with a median follow-up of 62.8 mo. Improvement in both fecal and urinary incontinence was evaluated by dedicated scores, with about 50% of patients reporting amelioration of both symptoms<sup>[30]</sup>. Surprisingly, bladder-related clinical improvement scored slightly lower than bowel-related improvement. Re-intervention rate (29%) and complication rate (12%) were both relatively high<sup>[30]</sup>. Rectal resection for cancer and pelvic radiotherapy are conditions commonly associated with secondary severe alterations in bowel compliance<sup>[3]</sup>. Incontinence is predominant at night and mostly deemed incurable<sup>[2,3]</sup>. Two European groups investigated the efficacy of NRM in these hard-to-treat conditions in small samples. Both studies reported PNE to be effective in improving continence in approximately half of those treated, but the efficacy of permanent implantation was not reported<sup>[20,21]</sup>. Atrophy of the anal sphincter is an additional hard-to-treat FI disease for which NRM has been associated with clinical benefit in open trials. Santoro *et al*<sup>[31]</sup> have reported a single-center study of 28 patients with magnetic-resonance-imaging-documented external anal sphincter atrophy of different severity undergoing permanent implantation for FI. A significant improvement in both FI and QOL scores was reported regardless of severity of sphincter atrophy<sup>[31]</sup>. This study provided indirect evidence of improvement in anal sphincter function as the mechanism of action of NRM<sup>[31]</sup>. Finally, a few studies have evaluated the efficacy of NRM for loss of normal bowel function due to nerve injury, neurological disease, or congenital defects of the nervous system - so-called neurogenic bowel. Holzer *et al*<sup>[32]</sup> assessed clinical outcome in a cohort of 29 patients undergoing permanent implantation for FI of mixed neurological etiology, including diabetes. The authors claimed that most patients were symptomatically improved, but outcome parameters were ill defined<sup>[32]</sup>. Recently, an Italian group reported on the efficacy of NRM in improving symptoms of pelvic floor dysfunction in 23 patients with incomplete spinal cord damage<sup>[33]</sup>. A significant improvement in FI was found in the majority of patients, but the grouping of patients with both constipation and FI made it hard to interpret the results<sup>[33]</sup>.

## COST

The cost of NRM is high when compared to conserva-

tive medical management, pelvic floor exercises and biofeedback therapy. Actual cost of NRM varies widely among countries as well as health insurance conditions. However, studies from three different countries have concluded that NRM is cost-effective when offset by the quality-adjusted life-years gained, and that it is likely to be reimbursed by government health programs<sup>[22,24,34,35]</sup>.

## CONCLUSION

In conclusion, NRM is effective for FI of diverse etiology. Encouraging results have also been reported for FI therapy in distinct and rare conditions, but RCTs are lacking and no firm conclusion can be actually drawn. NRM is reported to have long-term benefit in more than two-thirds of patients with FI undergoing permanent implantation, by some as-yet-unknown mechanism. However, when analyzed by ITT analysis, the median responder rate drops to 59% of those treated. NRM is a minimally invasive procedure. The most common serious adverse event is infection at the site of implantation, which occurs in about 3% of cases and requires device explantation in about 3% of all patients receiving permanent implants. Cost of treatment is high relative to that of conservative treatment and biofeedback but there are studies from different countries suggesting that NRM is cost-effective when offset by gains in quality-adjusted life years. However, RCTs comparing NRM to biofeedback therapy for FI are required to resolve this issue.

### Abstract

Metabolic changes are inextricably linked to chronic hepatitis C (CHC). Recently polymorphisms in the IFNL3 (IL28B) region have been shown to be strongly associated with spontaneous and treatment induced recovery from hepatitis C virus (HCV) infection. Further, circumstantial evidence suggests a link between IFNL3 single nucleotide polymorphisms and lipid metabolism, steatosis and insulin resistance in CHC. The emerging picture suggests that the responder genotypes of IFNL3 polymorphisms are associated with a higher serum lipid profile, and less frequent steatosis and insulin resistance. This review analyzes the current data regarding this interaction and its meaning for HCV pathogenesis and disease progression.

### INTRODUCTION

Hepatitis C virus (HCV) infection affects about 170 million people worldwide. It leads to slow but progressive hepatic inflammation and fibrosis in as many as 70% of infected individuals. Over time, 20% will develop cirrhosis and its related complications, and about 1%-2% of subjects may develop hepatocellular carcinoma after 2-3 decades of infection<sup>[1]</sup>. The natural history of HCV infection in terms of chronicity and disease progression seems to be largely determined by the host immune response to

virus-infected hepatocytes. The interplay between many viral, host, genetic and environmental factors modifies the course of HCV infection and the degree of hepatic inflammation. In this context, the discovery of the association between IFNL3 polymorphisms and spontaneous or treatment induced clearance of HCV presented a major milestone in the study of chronic hepatitis C (CHC)<sup>[2-5]</sup>.

Metabolic syndrome is a constellation of problems that includes obesity, dyslipidemia, diabetes, and insulin resistance<sup>[6]</sup>. The prevalence of metabolic syndrome is increasing, paralleling the obesity epidemic worldwide and in the United States and European countries especially<sup>[7]</sup>. Multiple levels of interaction between HCV, metabolic syndrome and genetics have been recently postulated, including a molecular interaction between IFNL3 polymorphisms and HCV associated glucose and lipid metabolism. In this review we summarize the current clinical evidence for an interaction between IFNL3 polymorphisms and metabolic syndrome, and its clinical implications.

## IFNS LAMBDA AND HCV

The type III interferon (IFN) or IFN- $\lambda$  (IFNL) family consists of three members: IFN- $\lambda$ 1, IFN- $\lambda$ 2 and IFN- $\lambda$ 3 (formerly known as IL-29, IL-28A and IL-28B), which were discovered in 2003 by computational prediction and are genetically distinct from type I IFNs<sup>[8,9]</sup>, and a fourth, IFN- $\lambda$ 4, recently described from primary human hepatocytes<sup>[10]</sup>. Another recent study identified a novel TT/-G polymorphism in the CpG region upstream of IL28B, which is a better predictor of HCV clearance than rs12979860<sup>[11]</sup>. Whereas IFN- $\alpha$  binds to the constitutively expressed type I IFN receptor in almost all nucleated cells, IFN- $\lambda$  cytokines bind to a heterodimer of part of the IL-10 receptor and the IFNL receptor (IL10RA and IL28R, respectively)<sup>[12]</sup>, the latter of which is only expressed in restricted cell types, including epithelial cells, plasmacytoid dendritic cells and hepatocytes<sup>[13]</sup>. IFNL stimulation results in the upregulation of interferon stimulated genes (ISGs) *via* the Jak-STAT (Janus kinase-signal transducer and activator of transcription) pathway similar to type I IFNs<sup>[12,14]</sup>.

In an attempt to identify host genetic markers for IFN responsiveness to predict treatment outcome in CHC, genome-wide association studies identified single nucleotide polymorphisms (SNPs) in the IFNL3 (IL28B) region to be strongly associated not only with response to treatment with pegylated IFN- $\alpha$  (Peg-IFN- $\alpha$ ) with ribavirin (RBV) in HCV genotype 1 infection<sup>[2-5]</sup>, but also spontaneous recovery<sup>[15]</sup> (Table 1). This association has been validated in different ethnic populations and for various HCV genotypes<sup>[16,17]</sup>. In a recent meta-analysis, IFNL3 polymorphisms seem to be clinically useful even in the era of new direct acting antiviral drugs<sup>[18]</sup>. Moreover, the responder genotypes of the IFNL3 polymorphisms have been reported to be associated with increased hepatic inflammation in CHC patients<sup>[2,19]</sup>.

**Table 1 Summary of the IFNL3 polymorphisms identified by genome-wide association studies**

GWAS	Total population	IFNL3 SNP	Wild (responder) type/non-responder allele

<sup>1</sup>rs12979860 and <sup>2</sup>rs8099917 single nucleotide polymorphisms (SNPs) are strongly associated with clearance and commonly used in clinical practice. GWAS: Genome-wide association studies.

## HCV-ASSOCIATED METABOLIC CHANGES

CHC can be considered not only a viral disease, but also a metabolic disease. HCV interacts with lipid metabolism leading to steatosis, it impairs glucose metabolism leading to insulin resistance (IR) and diabetes mellitus type II and is associated with an increased risk of carotid atherosclerosis<sup>[20,21]</sup>.

The prevalence of steatosis in patients with CHC is reported to be between 40% and 80% depending on the features of the population studied in terms of alcohol consumption, prevalence of overweight/obesity, diabetes and other risk factors for fatty liver<sup>[22,23]</sup>. However, when all common contributing factors to steatosis have been excluded, the prevalence of steatosis in CHC still remains about 40%. This figure represents an approximately 2-fold increase compared to the prevalence of steatosis in other common chronic liver diseases such as chronic hepatitis B virus infection (20%)<sup>[24]</sup>.

Various studies have shown that both host and viral factors may contribute to the development of steatosis, with the relative importance of each varying with HCV genotype. In particular, in patients infected with HCV genotype 3, steatosis seems to be mostly virus-induced and often severe<sup>[2,25]</sup>. In contrast, in patients infected with non-genotype 3, steatosis seems to be mainly associated with host metabolic factors and correlates with body mass index (BMI) and central adiposity<sup>[3,26,27]</sup>.

Steatosis is known to have deleterious clinical consequences in CHC, as it is associated with accelerated progression of liver fibrosis<sup>[28]</sup> and probably HCC<sup>[29]</sup>. It has also been shown in large clinical trials that steatosis impairs the response to antiviral therapy<sup>[30]</sup>. However, the effect is more prominent in patients with non-3a genotype<sup>[30]</sup>, likely due to IR as the underlying mechanism affecting the response to standard dual therapy with Peg-IFN- $\alpha$ /RBV, and suggesting that the viral steatosis does not impair response to treatment<sup>[25]</sup>. Increasing levels of IR are associated with reduced rates of rapid virological response (RVR) as well as sustained virological response (SVR) in patients with HCV genotype 1, 2, 3 and 4 infections when treated with dual therapy comprising Peg-IFN- $\alpha$  and RBV<sup>[31-33]</sup>. This observation has been confirmed in two meta-anal-

yses<sup>[34,35]</sup>. A direct correlation between lipid profiles and the virologic response to Peg-IFN- $\alpha$  and RBV was also reported in some recent studies<sup>[36,37]</sup>.

## IFNL3 POLYMORPHISM AND LIPID METABOLISM

Since the discovery of the correlation of IFNL3 polymorphisms with HCV clearance, there is an accumulating body of evidence about an association between these polymorphisms and metabolic changes in CHC.

The IFNL3 responder genotype is associated with less pronounced disturbances of lipid metabolism in CHC, as reflected by higher serum cholesterol and lipoprotein levels: CHC genotype 1 individuals with IFNL3 rs12979860 CC genotype have significantly higher apolipoprotein B and low-density lipoprotein cholesterol (LDL-C) levels<sup>[38]</sup>, and lower serum apolipoprotein E levels<sup>[39]</sup>, compared to those with the non-responder CT and TT genotypes. In accordance with these findings, another study from Japan showed that the responder genotype of rs8099917 TT was associated with high LDL-C levels and high SVR<sup>[40]</sup>. This association may result from suppression of hepatic lipase and lipoprotein lipase by endogenous interferon, which in turn decreases serum LDL-C, implying a stronger endogenous interferon response to HCV in those subjects<sup>[36]</sup>.

In a small cohort (55 patients), Sheridan *et al.*<sup>[39]</sup> showed that although HCV RNA was significantly higher in those with rs12979860 CC genotype, this difference was mainly accounted for by a higher non-lipoviral particles (LVP) fraction. It is known that LVPs are low-density HCV particles that have high infectivity<sup>[41]</sup>. This may partially explain the paradox that the IFNL3 responder genotypes have higher HCVRNA total viral load, despite high viral load being a negative predictor of SVR<sup>[42]</sup>. However, further confirmation of this data in larger cohorts is required before any final conclusion can be extracted.

Chiba-Falek *et al.*<sup>[43]</sup> investigated the genetic basis for the variance of LDL-C and apolipoprotein B levels in CHC patients and their potential interaction with IFNL3 genotype: Their data show that two of the APOE genomic region polymorphisms, rs7412 and rs429358 (which defines the  $\epsilon$ 4 isoform), appear to be associated with serum lipoprotein levels in HCV patients. Polymorphisms in  $\epsilon$ 4, however, were not associated with apolipoprotein E levels in HCV-infected Caucasians patients (in contrast to a healthy control cohort), and the overall amount of variance in serum apolipoprotein E levels explained by APOE genotype was much lower in the HCV cohort (7% *vs* 20%). A recent genome-wide association studies in non-HCV-infected cohorts suggested associations of polymorphisms at the TOMM40-APOE genomic region with multiple lipid traits (LDL-C, triglycerides)<sup>[44]</sup>. In particular, two nonsynonymous SNPs in exon 4 of the APOE gene, rs429358 and rs7412 have been associated with lipid levels<sup>[44]</sup>. Further this study also refers

to a potential interaction between TOMM40-APOE and IFNL3 polymorphisms, as rs429358 was associated with apolipoprotein B levels in a IFNL3 genotype dependent manner, *i.e.*, the effect was more profound in patients carrying rs12979860 CC, than those carrying rs12979860 CT/TT. These results together suggest that HCV-associated dyslipidemia may not be controlled to the same extent by the same genes that affect lipids/lipoproteins in healthy (non-HCV infected) cohorts<sup>[43]</sup>.

There is increasing evidence that the life cycle of HCV is directly linked to host lipoproteins: (1) HCV circulates in plasma with lipoprotein as an infectious complex; (2) Hepatocyte lipoprotein receptors are involved in HCV entry; (3) Replication of HCV RNA in hepatic cells is inhibited by inhibitors of lipid metabolism; (4) HCV particles released from hepatocytes are attached to lipoproteins; and (5) Serum lipid profiles (LDL-C, HDL-C and triglycerides) are associated with higher rates of spontaneous or treatment-induced HCV clearance<sup>[45]</sup>. At least, the latter is also affected by IFNL3 polymorphisms, opening up the possibility of interaction in mediating this effect. Thus, better understanding of the interaction between lipids, IFNL3 polymorphisms and the HCV life cycle will improve our understanding of HCV pathogenesis and open new avenues in treating HCV infection.

## IFNL3 POLYMORPHISM AND STEATOSIS

The relationship between steatosis and IFNL3 genotype is still subject to debate, as the current literature demonstrates conflicting results (see Table 2). A retrospective analysis of 1604 patients enrolled in the IDEAL trial (Individualized Dosing Efficacy Versus Flat Dosing to Assess Optimal Pegylated Interferon Therapy) of HCV genotype 1 patients showed that the IFNL3 rs12979860 CC responder genotype was significantly associated with higher pretreatment LDL-C levels and less frequent hepatic steatosis<sup>[46]</sup>. In keeping with this, other recent studies show the same association between the IFNL3 rs12979860 CC genotype and less frequent steatosis in CHC genotype 1<sup>[47-49]</sup>. This observation also extends to two other IFNL3 polymorphisms, rs8099917<sup>[50]</sup> and rs12980275, which were associated with steatosis in genotypes non-3<sup>[51]</sup>. In contrast, a study from Japan failed to find a significant association between rs8099917 and hepatic steatosis in 122 Japanese Mongolian patients infected with HCV genotype 1b<sup>[52]</sup>, and another study from Spain failed to confirm an association between rs12979860 and steatosis in 445 Caucasian patients<sup>[53]</sup>. These conflicting results may be owing to the relatively small sample size of these cohorts, differences in ethnicity, population characteristics and local other risk factors for steatosis, different IFNL3 SNPs being investigated, which may exhibit different features, and the respective assessments of individual pathologists.

In the setting of liver transplantation for CHC, a recent abstract presented at the European Association for the Study of the Liver (EASL) meeting 2013 suggested

**Table 2** *IFNL3* polymorphisms and steatosis in chronic hepatitis C

No. of patients	Study design	HCV genotype	<i>IFNL3</i> SNP	Results	Ethnicity	Ref.
1604	Retrospective	HCV-1	<i>rs12979860</i>	CC genotype associated with higher pretreatment LDL-C levels and less frequent hepatic steatosis	Caucasians	46
145 180	Retrospective analysis of two Independent cohorts: (1) (antifibrotic) Study cohort; (2) Duke cohort	HCV-1	<i>rs12979860</i>	CC genotype associated with less hepatic steatosis	122 (84.1%) Caucasians 130 (72.2%) Caucasians	47
434	multi-center, Retrospective	HCV-1	<i>rs12979860</i>	CC genotype associated with less frequent hepatic steatosis	Caucasians	48
202	Prospective	HCV-1: 181 (89.6%) HCV-4: 21 (10.4%)	<i>rs12979860</i>	CC genotype associated with less frequent hepatic steatosis	Caucasians	49

240	Retrospective	HCV-1 ( <i>n</i> = 188) HCV-2 ( <i>n</i> = 3) HCV- (n = 30) HCV-4 ( <i>n</i> = 19)	<i>rs12979860</i>	46% (89/193)	≥ 2	No differences in HOMA-IR levels according to <i>IFNL3</i> genotypes	Caucasians	59

HCV: Hepatitis C virus; IR: Insulin resistance.

that *IFNL3* rs12979860 TT nonresponder genotypes had an increased incidence of graft steatosis over time, while recipient *IFNL3* was not associated with steatosis<sup>[54]</sup>.

In an attempt to better understand the interaction of *IFNL3* polymorphisms with other polymorphisms in influencing steatosis, a recent study investigated the interaction between *IFNL3* rs12979860 and the Patatin like phospholipase domain-containing 3 (PNPLA3) rs738409 polymorphism, a strong determinant of hepatic fat accumulation and steatohepatitis<sup>[55]</sup>. Albeit, the association between rs12979860 genotype and steatosis was independent of PNPLA3 GG genotype, the rs12979860 CC genotype protected from steatosis only in patients positive for the PNPLA3 G variant, a genetic risk factor for severe steatosis<sup>[56]</sup>. In another study, the PNPLA3 G variant showed a close association with steatosis in patients with

rs12979860 CT/TT, but not rs12979860 CC genotype<sup>[53]</sup>. These findings suggest a potential interaction between *IFNL3* and PNPLA3 polymorphisms on the risk for steatosis in non-genotype 3 CHC patients, though further analysis is required to better understand the nature of this interaction.

Finally, an interaction between *IFNL3* genotype and an amino acid substitution at residue 70 (aa70) of the HCV core region has been suggested<sup>[52]</sup>. Although these authors failed to find a direct association between rs8099917 and hepatic steatosis, they found significant associations between rs8099917 and aa70 and between aa70 and hepatic steatosis<sup>[52]</sup>. This suggests that the amino acid at residue 70 of the HCV core region should be considered as a parameter for adjustment in any future studies of the correlation between *IFNL3* genotype and steatosis.

## IFNL3 POLYMORPHISM AND INSULIN RESISTANCE

The relationship between IR measured by HOMA and IFNL3 genotype is still subject to debate (see Table 3). Two recent reports showed that the responder IFNL3 rs12979860 CC genotype was associated with reduced IR in HCV genotype 1 patients<sup>[48,49]</sup>, while other reports failed to find this association<sup>[57-59]</sup> with either rs8099917<sup>[57]</sup> or rs12979860<sup>[57-59]</sup>. Interestingly, a recent study from Spain shows that IR can predict SVR in CHC patients independently of the IFNL3 rs12979860 polymorphism<sup>[59]</sup>. This is quite intriguing as it sheds new light on the clinical observations linking higher LDL, less steatosis and lower insulin resistance with SVR.

## CONCLUSION

In conclusion, the discovery of IFNL3 polymorphisms and their impact on CHC presents a major breakthrough in HCV research. The association of IFNL3 responder genotypes with higher LDL, less steatosis, less insulin resistance and SVR suggests a mechanistic link between IFNL3 and the metabolic syndrome in CHC. This sheds new light on the pathogenesis of CHC and opens exciting avenues to explore. Further work is needed to better understand the mechanistic explanation of these inter-related associations, and its potential implications in improving the current management of CHC patients.

**Key words:** Systemic sclerosis; Gastrointestinal tract; Manometry; Endoscopy; Diagnosis; Treatment

**Core tip:** Although often overlooked by clinicians, the gastrointestinal tract is the most commonly damaged system in patients with progressive systemic sclerosis. Virtually all parts of the gastrointestinal tract can be involved, although the esophagus is the most frequently reported. The mechanisms of gastrointestinal tract involvement have not been clarified; however, vascular damage, excessive accumulation of collagen, and immunological abnormalities may play a role because they are the most frequent histological findings in biopsies and autopsies. Non-specific symptoms, including dyspepsia, nausea, vomiting, and abdominal distension are common complaints. Although supportive and symptomatic treatment is the main therapeutic strategy for systemic sclerosis, early diagnosis is critical for improving patient prognosis.

### Abstract

Systemic sclerosis is an autoimmune disease characterized by progressive skin thickening and tightness. Pulmonary interstitial fibrosis and kidney damage are the most important indicators for mortality; however, the gastrointestinal tract is the most commonly damaged system. Virtually all parts of the gastrointestinal (GI) tract can be involved, although the esophagus is the most frequently reported. The mechanisms that cause such extensive damage are generally unclear, but vascular changes, immunological abnormalities, excessive accumulation of collagen in the submucosa, smooth muscle atrophy and neuropathy may participate because these are the most common histological findings in biopsies and autopsies. Most patients with GI tract involvement complain about dyspepsia, nausea, vomiting, abdominal bloating/distension, and fecal incontinence. These symptoms are generally mild during the early stage of the disease and are likely ignored by physicians. As the disease becomes more advanced, however, patient quality of life is markedly influenced, whereby malnutrition and shortened survival are the usual consequences. The diagnosis for systemic sclerosis is based on manometry measurements and an endoscopy examination. Supportive and symptomatic treatment is the main therapeutic strategy; however, an early diagnosis is critical for successful management.

### INTRODUCTION

Systemic sclerosis (SSc) is a chronic autoimmune disease with an unknown etiology. The most common clinical presentations include: Raynaud's phenomenon, skin thickening and tightness caused by widespread vasculopathy and excessive fibrosis. The gastrointestinal (GI) tract is the most commonly involved internal organ in SSc. It is estimated that GI involvement occurs in approximately 70%-90% of SSc patients<sup>[1-3]</sup>; however, a recent study by Schmeiser *et al*<sup>[4]</sup> has shown that 98.9% of SSc patients

suffered from GI symptoms. Additionally, the symptoms of GI manifestation can be mild to severe, including pain, dysphagia, vomiting, diarrhea, constipation and fecal incontinence<sup>[5]</sup>. Anatomically, GI involvement can affect the whole length of the GI, starting from the mouth to the anus. In this review, we have highlighted the clinical features of each anatomical GI region believed to be involved in SSc, as well as the possible treatment approaches.

## **PATHOLOGY AND PATHOGENESIS OF THE GI INVOLVEMENT IN SSc**

Although the entire GI tract can be affected, the underlying pathological changes and symptoms are similar in all parts of the GI, from the esophagus to the rectum. Additionally, vascular changes, immunological abnormalities, excessive accumulation of collagen in the submucosa and smooth muscle atrophy are histological hallmarks of SSc found in the digestive tract walls from patient biopsies and autopsies<sup>[1]</sup>. The progression of the GI involvement in SSc patients ranges from a grade of 0-2. These scores were based on the following parameters: (1) Vascular damage to the vasa nervorum (grade 0), which is a part of the characteristic SSc vasculopathy that can lead to ischemia; (2) Neurogenic impairment (grade 1), which is secondary to ischemia but causes damage to neurons of the intestinal wall; and (3) Myogenic dysfunction (grade 2), whereby normal smooth muscle is replaced by collagenous fibrosis and may cause atrophy<sup>[2,4]</sup>. This progression may explain the characteristic pathological changes observed in SSc patients.

The pathogenesis of the GI complications that occur during SSc is generally unknown. Vascular and auto-immune hypotheses have been proposed to explain the GI histopathological changes observed in SSc<sup>[5]</sup>. The vascular change hypothesis suggests that the initial GI lesions occur because of a neural dysfunction caused by arteriolar changes in the vasa nervorum or by increased collagen deposition. Moreover, studies have shown that mucosal blood flow to the stomach and duodenum are reduced and that vascular insufficiency occurs before smooth muscle atrophy develops. Additionally, increased proliferation and fibrosis of the adventitia may also occur. All these vascular changes can lead to ischemia, which in turn may cause neuron damage and collagen tissue compression of nerves. Vascular ectasia with focal intra-vascular thrombi and antrum fibromuscular hyperplasia also can occur with SSc, providing additional evidence for the vascular change hypothesis.

It is generally accepted that the immune system participates in SSc pathogenesis. One study has shown that damaged stomach endothelial cells express high levels of the cell adhesion molecules including vascular cell adhesion molecule-1 and intercellular adhesion molecule-1 and can attract activated lymphocytes that move into the damaged sites. The increased CD4<sup>+</sup>/CD8<sup>+</sup> ratio in the gastric mucosa T cell infiltrate suggests that the acquired immune response is a trigger of GI damage during the

early stage of SSc<sup>[1]</sup>. Additionally, weak expression of vascular endothelial growth factor in the gastric submucosa suggests angiogenesis impairment, which then causes nerve plexuses dysfunction and smooth muscle atrophy. Antibodies to the M3 muscarinic receptor, which can block binding of the enteric cholinergic neurotransmission, have also been detected in SSc patients<sup>[6]</sup>. As GI damage advances during SSc, severe fibrosis, with abundant type I and III collagen deposition in the lamina propria and muscularis mucosa, can be observed, and these changes are associated with smooth muscle atrophy and fibrosis. Furthermore, a prominent T-cell infiltration, with a significantly elevated CD4<sup>+</sup>/CD8<sup>+</sup> ratio, has been detected in SSc patients with GI involvement. Moreover, over-expression of fibrogenic cytokines, such as transformation growth factor  $\beta$ , connective tissue growth factor, endothelin-1 and  $\alpha$ -smooth muscle actin have been observed around intestinal glands and blood vessels<sup>[7,8]</sup>.

The association between autoantibodies and SSc GI damage has also attracted great interest. Howe *et al.*<sup>[9]</sup> reported the presence of anti-myenteric neuron antibodies in some SSc patients, suggesting that this autoantibody may be associated with the GI symptoms that occur in some SSc patients. Nishimagi *et al.* had found that the presence of anti-centromere antibodies (ACA) or Scl-70 antibodies were less frequent in patients with severe GI damage; however, there was an increased frequency of anti-U3RNP (ribonucleoprotein) and anti-U1RNP antibodies as well as an increased ratio of Th/To cells<sup>[10,11]</sup>. Additionally, there was a higher incidence of severe diarrhea in patients with anti-U3RNP antibodies but not in patients with anti-U1RNP antibodies. Thoma *et al.* found that there was a negative association between diarrhea and pulmonary fibrosis, although this association was not statistically significant. In general, however, there is no reported SSc GI involvement between localized and diffuse SSc subtypes<sup>[12]</sup>.

## **CLINICAL FEATURES**

The symptoms of GI damage in SSc patients, including pain, dysphagia, vomiting, diarrhea, constipation, fecal incontinence, and weight loss vary in severity. Even in patients without GI symptoms, up to 77% of them had reflux-esophagitis, 85% had distal esophagus dysmotility, and 92% had gastritis when evaluated by oesophago-gastro-duodenoscopy<sup>[13]</sup>. In fact, the whole GI tract may be involved and contribute to the symptoms listed above; however, different GI regions also have their own specific symptom presentations.

### **Oral cavity**

Facial skin tightness and thickening limits the opening of the mouth and interferes with oral intake and mastication. Approximately 20% of patients develop secondary Sjögren's syndrome, which may cause dysphagia, difficulty in swallowing, and periodontal disease and may further impair a patient's ability to maintain a good quality of life

and nutritional status<sup>[9]</sup>.

### Esophagus

The esophagus is the most commonly involved and most intensively studied GI complication in SSc patients. Up to 96% of SSc patients have esophageal complications, including esophageal motility abnormalities, lower esophageal sphincter (LES) abnormalities, gastroesophageal reflux disease (GERD) and Barrett's esophagus. A recent study has shown that esophageal involvement is more pronounced in SSc patients with positive anti-centromere antibodies compared with patients with increased levels of anti-topoisomerase I (Scl-70) or anti-nuclear antibodies<sup>[14]</sup>.

**Esophageal dysmotility and GERD:** Esophageal dysmotility is the most common GI manifestation in SSc patients. Damage to the distal two-thirds of the esophagus smooth muscle during SSc causes decreased or even complete loss of peristalsis in the smooth muscle and distal portion of the esophagus, delaying food bolus transportation and clearance of refluxed materials from the stomach<sup>[15]</sup>. Dysphagia and difficulty in swallowing are common complaints.

**GERD:** The damage to the lower two-thirds of the esophagus caused by SSc often leads to a weakened LES. LES abnormalities, which presents as a low baseline pressure, results in the sphincter neither opening normally when swallowing nor closing completely afterwards. Such abnormalities allow for a pathological gastric acid reflux to the esophagus, which causes further damage to the LES. This condition is known as GERD. Initially esophageal damage caused by GERD manifests as simple peptic esophagitis, but it can progress to erosive esophagitis, bleeding and frank ulceration. If left untreated, esophageal stricture, fistulas and achalasia-like syndrome may occur<sup>[2]</sup>. Patients with GERD usually have heartburn, dysphagia, substernal chest pain, nausea and vomiting after eating; however, the intensity of the symptoms is not related to the severity of GERD. It is reported that GERD severity is associated with pulmonary interstitial fibrosis<sup>[1]</sup>.

**Barrett's esophagus:** Chronic GERD can lead to Barrett's esophagus. The estimated prevalence of Barrett's esophagus in SSc patients is 6.8%-12.7%<sup>[16]</sup>. Additionally, Barrett's esophagus in SSc patients is associated with an increased risk of esophageal carcinoma<sup>[1,2,5]</sup>.

### Stomach

It is reported that stomach involvement occurs in 10%-75% of SSc patients<sup>[17]</sup>. The gastric manifestations of SSc include gastric antral vascular ectasia (GAVE), which is typically presented as "watermelon stomach" during gastro-endoscopy examinations. Additionally, GAVE can cause gastric dysmotility, which leads to delayed gastric emptying or gastroparesis. Moreover, these SSc patients may have GI bleeding, early satiety, bloating,

dyspepsia, nausea and vomiting.

**GAVE:** The appearance of GAVE under gastroendoscopy observation is unique and is characterized by multiple, parallel longitudinal columns of red vessels within the gastric antrum radiating to the pylorus, resembling the stripes on a watermelon. This condition, therefore, is also known as "watermelon stomach". GAVE can precede an SSc diagnosis<sup>[18]</sup>. It is estimated that the prevalence of GAVE ranges from 5.7% to 14% of SSc patients<sup>[1,5]</sup>. GAVE can sometimes manifest itself as severe GI bleeding, although achlorhydria, with or without pernicious anemia, is more common. Furthermore, the pernicious anemia is usually microcytic.

**Gastroparesis:** This condition is the result of chronic gastric motility alternations. These patients may experience delayed gastric emptying or complete gastric paralysis. Delayed emptying can result in early satiety, bloating, dyspepsia, nausea and vomiting. Succussion splashing during examinations often suggests gastroparesis. Delayed emptying occurs equally with solid and liquid meals and can make GERD even worse.

### Small bowel

The small intestine is the second most commonly involved portion of GI tract during SSc, following the esophagus. It is suspected that the small intestine function is compromised in 40% of SSc patients<sup>[19]</sup>. Although most mild cases have no symptoms, bloating, vomiting, abdominal pain, diarrhea, pseudo-obstruction, malabsorption and weight loss may occur in severely affected patients. Small intestine hypomotility is the primary abnormality and may lead to pseudo-obstruction and bacterial overgrowth, which is the major cause of malnutrition in SSc patients. Additionally, pneumatosis cystoides intestinalis (PCI) may occur but is a rare condition.

### Intestinal hypomotility and secondary bacterial overgrowth

Intestinal dysmotility has been reported in 40%-88% of SSc patients<sup>[5]</sup>. Manometric and electrophysiological studies have revealed neuropathy of the enteric nervous system in SSc patients with intestinal dysmotility. Additionally, the autoantibody that inhibits M3-muscarinic receptor-mediated enteric cholinergic neurotransmission was also detected in these patients<sup>[20,21]</sup>. Intestinal hypomotility can result in nausea, vomiting, bloating, distension, anorexia and abdominal pain. Because decreased motility of the small intestine can result in intestine contents stasis, it is believed that stasis of intestinal contents can cause small intestinal bacterial overgrowth (SIBO). SIBO is defined as the presence of more than  $1 \times 10^5$  organisms per millimeter of duodenal aspirate fluid. It is not a rare disorder and has been detected in up to 55.5% of SSc patients<sup>[22,23]</sup>. Additionally, it has been observed that SIBO is more prevalent in patients with limited SSc. Bacteria overgrowth competes with the host for nutrition and causes malabsorption of fat, proteins, carbohy-

drates and vitamins<sup>[5]</sup>. SSc patients with SIBO, therefore, have lower levels of serum albumin and total protein, as well as vitamin B<sub>12</sub> and ferritin. The symptoms caused by SIBO are similar to those caused by small intestinal hypomotility; however, steatorrhea, multiple nutritional deficiencies and weight loss can occur when the flora overgrowth is severe enough to cause prominent malabsorption.

**Small intestine pseudo-obstruction:** This complication is secondary to small intestinal hypomotility because decreased peristalsis, or even aperistalsis, may provoke luminal dilatation and overt pseudo-obstructions. There is no difference in the clinical and radiographic features of the pseudo-obstructions caused by SSc or by other reasons. Abnormal collagen deposition in the small intestinal wall, which can occur during SSc, is irreversible, resulting in recurrence of pseudo-obstructions.

**PCI:** PCI is characterized by the presence of intramural gas in the gastrointestinal tract<sup>[24]</sup>. It is a rare SSc GI complication. Like small intestinal pseudo-obstructions, it is secondary to small intestine dysmotility. It is basically a radiological diagnosis and usually has no consequences. Rarely, however, intestinal ischemia can occur and surgical intervention is needed. Occasionally, the air-filled cysts in the bowel may rupture, leading to benign pneumoperitoneums<sup>[5,25]</sup>. Generally, the prognosis of PCI is good.

### Colon

Colon involvement is observed in 10%-50% of SSc patients<sup>[1,5]</sup>. Colon hypomotility is the most common colonic complication during SSc and can cause delayed colon transit. As a result, constipation and evacuation difficulty may occur. Constipation, however, does not often persist for long because of intestinal bacterial overgrowth-induced diarrhea. Therefore, constipation and diarrhea are the most common clinical symptoms of SSc patients. Although wide-mouth diverticula in the colon may occur in SSc patients, it is rarely symptomatic. Colonic telangiectasias are common during SSc and may cause overt bleeding, which can result in anemia.

### Anorectal SSc

The reported anorectal involvement in SSc is 50%-70%<sup>[5]</sup>. Patients may present with chronic diarrhea, fecal incontinence and rectal prolapses. Fecal incontinence is the most frustrating symptom and seriously impairs patient's quality of life. It is reported that 37.1% to 70% of SSc patients develop incontinence<sup>[2,5]</sup>; however, the prevalence of fecal incontinence is likely under-estimated because most patients are reluctant to report the symptoms. Neuropathy plays a key role in the development of SSc fecal incontinence.

Defecation requires the collaboration of the internal and external sphincter as well as intact rectoanal inhibitory reflex (RAIR). RAIR consists of relaxation of the smooth muscle internal anal sphincter (IAS) and contrac-

tion of the striated muscle external anal sphincter (EAS), which makes it possible to maintain anal continence. The IAS is primarily responsible for the anal resting tone and the EAS is primarily responsible for the voluntary contraction of the anal sphincter. IAS weakness leads to passive fecal incontinence, while EAS weakness leads to urge fecal incontinence. As smooth muscle is more likely to be damaged because of SSc, the IAS is more likely to be affected in the anorectum. IAS atrophy may be secondary to vascular or neurological dysfunction. Heyt *et al*<sup>[26]</sup> demonstrated that SSc patients had a thinned IAS. Additionally, the circular and longitudinal IAS smooth muscle layers were replaced with fibrous tissue. A lower IAS resting pressure is also common in SSc patients with anorectal involvement; however, the squeeze pressure is usually normal, as the EAS is generally not affected. Because there is a decrease in the rectal resting tone in these patients (due to smooth muscle cell atrophy that results from ischemia); rarefaction of innervations and neurogenic dysfunction often occur as well, consequently impairing the RAIR. Thoua *et al*<sup>[27]</sup> demonstrated that the RAIR was compromised in 46% of SSc patients with incontinence and provided evidence that neuropathy played a key role in the development of fecal incontinence in these observed patients. Furthermore, Malandrini *et al*<sup>[28]</sup> observed nerve degeneration in the rectal mucosa of SSc patients with fecal incontinence. Most studies have shown that the resting anal pressure is also reduced in fecal-incontinent SSc patients, resulting in an absent or impaired RAIR; however, their maximal squeeze pressures are normal. Additionally, inappropriate collagen and connective tissue deposition often occurs in SSc patients, which disrupts neural fiber connections and insults neural tissue, usually resulting in neuropathy. Interestingly, however, although the IAS response is diminished or absent and the EAS response is normal or increased in rectal-incontinent SSc patients, no correlation between disease duration, ACA status or SSc subtype has been observed<sup>[25]</sup>.

### Liver and biliary tract

Liver and biliary involvement in SSc is relatively rare; however, primary biliary cirrhosis (PBC) is the most common hepatobiliary manifestation in SSc patients, with an estimated prevalence of 2.5%<sup>[29]</sup>. Eight percent of SSc patients have positive anti-mitochondrial antibodies, while anti-glycoprotein and anti-sp100 antibodies have been detected in up to 15% of SSc patients<sup>[29-31]</sup>. The onset of PBC may precede, occur concomitantly with, or more commonly, follow SSc onset. Patients with a concomitant SSc and PBC disease occurrence have a higher prevalence of calcinosis and telangiectasia than patient with only SSc<sup>[32]</sup>.

## DIAGNOSIS

The diagnosis of SSc related GI disorders generally depends on the location of the involvement. Oral cavity

problems can be diagnosed by routine oral examination. Esophageal motility disorders, such as GERD, can be diagnosed by the combination of upper GI endoscopy and esophageal manometry procedures, together with ambulatory PH studies. Esophageal biopsies can confirm the diagnosis of Barrett's esophagus. Electrogastrographic recordings and scintigraphic evaluations following a radiolabeled meal are both useful for the diagnosis of delayed stomach emptying. A typical endoscopic procedure, whereby "watermelon stomach" is obvious, is diagnostic for GAVE. Small bowel manometry is helpful not only in the screening for SSc patients who have small intestine involvement but also in identifying symptomatic patients with intestinal pseudo-obstructions who may benefit from octreotide. Additionally, low resting anal canal pressure and impaired or absent RAIP observations are helpful in diagnosing anorectal disorders.

## TREATMENT

Treatments for SSc-induced GI impairment are generally symptomatic and supportive. Nutrition status assessment should be a routine component of clinical care for SSc patients<sup>[33]</sup>. Moreover, a multi-disciplinary approach is important for the optimal care of SSc patients with GI involvement.

### Oral cavity

For patients with decreased oral aperture, techniques such as facial grimacing exercises, mouth stretching exercises and oral opening augmentations with tongue depressors are recommended. Bilateral commissurotomy may also be performed to increase mouth opening. For patients with dry mouth, attention should be paid to oral hygiene to prevent caries.

### Esophagus

For patients with esophageal dysmotility, modified lifestyle measures should be initiated and have proven to be helpful. These measures include frequent small meals, sitting up during and after meals, elevating the heads of patients' beds, and avoiding known irritants and bedtime meals or snacks. Patients with endoscopically documented GERD require chronic treatment with proton-pump inhibitors. Use of prokinetic drugs that increase gastric emptying, such as metoclopramide, may help reduce reflux. Additionally, esophageal strictures can also be dilated under endoscopic guidance. Patients not responding to medication therapy can be treated with anti-reflux surgery. The outcomes of anti-reflux surgeries, however, are variable, and careful pre-operative evaluations are warranted. Partial funduplications (Toupet procedure) may also be helpful in some patients<sup>[32]</sup>.

### Stomach

Bipolar cautery, heat probe, sclerotherapy and laser ablation are available for the treatment of GAVE. Prokinetic drugs, such as metoclopramide, domperidone, pruc-

lopride and tegaserod, are helpful in patients with early stage stomach disease, but become less effective as the disease progresses. Macrolide antibiotics are believed to have motilin agonist properties and have been evaluated in delayed stomach emptying patients. Erythromycin, however, is the most widely studied drug. It has been shown to stimulate intestinal motility even with low dosages; however, its effectiveness may decrease with time<sup>[34]</sup>.

### Small intestine

Bacterial overgrowth is the major cause of symptoms in patients with small intestinal involvement. Antibiotics, such as metronidazole (500 mg BID) and ciprofloxacin (500 mg BID), administered for 14 to 28 d can be helpful for these patients. An alternative antibiotic regimen includes oral intake of chloramphenicol and the third generation cephalosporins. Rotating antibiotics monthly is suggested to circumvent bacterial resistance. Probiotics have been proven to be effective and safe for patients with bloating caused by bacterial overgrowth<sup>[35]</sup>. Lactobacillus can be used to treat this condition because it can competitively inhibit the attachment and growth of pathogenic organisms and restore the microbial balance in the GI tract. Additionally, lactobacillus may also enhance the immune-modulating effects in patients by increasing the IgA response or by modifying mucosal IL-10 and Th1/Th2 lymphocyte levels. Studies have shown that lactobacillus can also produce proteinaceous factors that alter epithelial permeability, inhibit bacterial translocation, and influence the level of gut mucin glycoprotein<sup>[5]</sup>.

Small intestine pseudo-obstructions are common in SSc patients. The initial treatment for this condition should include bowel rest, intravenous fluid infusion and electrolyte correction. Octreotide has also been shown to be effective<sup>[36]</sup>. The starting dosage is usually 50 µg *bid* (given subcutaneously) during acute onsets; however, the dosage can be increased up to 200 µg if a satisfactory response is not observed. For patients with recurrent pseudo-obstruction episodes, 50 µg of octreotide at bedtime is usually effective and depot octreotide can be prescribed on a monthly basis. Neostigmine can lead to prompt colon decompression; therefore, it can be used for this condition. If octreotide and neostigmine treatments are not effective, however, colonoscopic decompression is normally the treatment of choice. Surgery procedures are reserved for cases of peritonitis and perforation.

### Colon and anorectal disorders

Constipation, diarrhea and fecal incontinence are the major symptoms in patients with colon and anorectal involvement. High-fiber diets and bulk-forming laxatives should be avoided in constipated patients because these can worsen constipation. Fluid ingestion and osmotic laxatives, such as senna, lactulose, bisacodyl and polyethylene glycol, are recommended because these medications can alter intestinal mucosa electrolyte transportation and also increase intestinal motor activity. Antibiotics can be given to patients with diarrhea caused by bacteria

overgrowth syndrome. For patients with incontinence, sacral nerve stimulation has been shown to be successful in most patients and may also abolish incontinence in some patients<sup>[5]</sup>. Posterior anal repair may be considered when sacral nerve stimulation fails. Rectal and vaginal prolapses should be detected and surgically repaired, as these two conditions can contribute to incontinence. Additionally, biofeedback may be helpful in improving rectal continence. Surgical procedures such as dynamic graciloplasties or the installation of artificial bowel sphincters should be considered in patients with resistant and severe incontinence.

### Liver and biliary disorders

PBC in SSc patients can be treated with ursodeoxycholic acid, which delays the histological progression rate. Patients with severe liver disorders, however, may need liver transplantation.

In summary, GI involvement in SSc patients is common and sometimes troublesome. An early diagnosis is crucial for improving patient prognosis due to the insidious progressive nature of the disease. Symptomatic and supportive treatments, as well as modified life style measures are the management mainstays for this disease.

### Abstract

Acute liver failure (ALF) is an uncommon but dramatic clinical syndrome characterized by hepatic encephalopathy and a bleeding tendency due to abrupt loss of liver function caused by massive or submassive liver necrosis in a patient with a previously healthy liver. The causes of ALF encompass a wide variety of toxic, viral, metabolic, vascular and autoimmune insults to the liver, and identifying the correct cause can be difficult or even impossible. Many patients with ALF develop a cascade of serious complications involving almost every organ system, and death is mostly due to multi-organ failure, hemorrhage, infection, and intracranial hypertension. Fortunately, the outcome of ALF has been improved in the last 3 decades through the specific treatment for the disease of certain etiology, and the advanced intensive care management. For most severely affected patients who fail to recover after treatment, rapid evaluation for transfer to a transplantation center and consideration for liver transplantation is mandatory so that transplantation can be applied before contraindications

develop. This review focuses on the recent advances in the understanding of various contributing etiologies, the administration of etiology-specific treatment to alleviate the liver injury, and the management of complications (*e.g.*, encephalopathy, coagulopathy, cardiovascular instability, respiratory failure, renal failure, sepsis and metabolic disturbance) in patients with ALF. Assessment of the need for liver transplantation is also presented.

**Key words:** Acute liver failure; Cerebral edema; Liver transplantation

**Core tip:** Acute liver failure (ALF) is a dramatic clinical syndrome of abrupt loss of liver function in a patient with a previously healthy liver. The causes of ALF encompass a wide variety of toxic, viral, metabolic, vascular and autoimmune insults to the liver. ALF patients develop serious complications, and death is mostly due to sepsis, followed by multiple organ failure, and intracranial hypertension. However, disease outcome has been improved through etiological treatment and advanced intensive care management. For most severely affected patients who fail to recover after treatment, liver transplantation may be life-saving.

### INTRODUCTION

Acute liver failure (ALF) is an uncommon but dramatic clinical syndrome characterized by sudden and massive hepatic necrosis that results in jaundice, coagulopathy [international normalized ratio (INR)  $\geq 1.5$ ], and hepatic

encephalopathy (any degree of altered mentation) in the absence of pre-existing liver disease<sup>[1]</sup>. A timely diagnosis of ALF is critical because of its feature of rapid deterioration, and delayed diagnosis can be disastrous. The most prominent causes include drug-induced liver injury, viral hepatitis, autoimmune liver disease and shock or hypoperfusion; many cases have no discernible cause<sup>[2]</sup>. The mortality rate of ALF is as high as 40%-50%, depending on the cause and improper therapeutic management. The immediate cause of death in 35% of ALF patients is brain herniation due to elevated intracranial pressure (ICP), and most other deaths are the result of severe refractory hypotension resulting from supervening sepsis culminating in multiorgan failure<sup>[3]</sup>. Orthotopic liver transplantation (OLT) has emerged as the only therapeutic intervention with proven benefit for patients with advanced ALF<sup>[4]</sup>.

## ETIOLOGY AND SPECIFIC THERAPIES

The causes of ALF encompass a wide variety of toxic, viral, metabolic, and vascular insults to the liver, and the etiology of ALF varies with geography. In Africa and Asia, viral hepatitis dominates the causes of ALF<sup>[5]</sup>. By contrast, in Europe and North America, toxic etiologies predominate<sup>[6]</sup>. In many cases, the cause of ALF cannot be established and remains indeterminate. Determination of etiology is important because specific therapies can be given once the diagnosis is established. In addition, knowing the cause could provide a reasonably valid guide to predicting outcome<sup>[7]</sup>.

### Toxins

Acetaminophen (APAP) overdose accounts for 46% of ALF cases in some areas, and APAP-induced ALF is currently more commonly seen after unintentional than intentional overdose<sup>[8]</sup>. The development of liver failure from APAP is dose dependent; hepatic failure is more likely with ingested dosages > 150 mg/kg. Various risk factors increase the probability of acute liver damage even at therapeutic doses of APAP. The factors include alcoholic addiction, malnutrition (resulting in glutathione depletion), and concurrent use of narcotic analgesics compounded with APAP. The liver damage leads to a characteristic pattern of pericentral necrosis due to cytochrome P450-mediated oxidative metabolism of APAP to the highly reactive, intermediate metabolite, *N*-acetyl-p-benzoquinone imine (NAPQI)<sup>[9]</sup>. Accumulation of NAPQI leads to cell death and hence hepatocellular necrosis. *N*-Acetylcysteine (NAC) is established as a proven beneficial agent for APAP-induced hepatotoxicity<sup>[10]</sup>. It acts by replenishing glutathione that detoxifies NAPQI. In addition, excessive NAC also provides substrates for hepatic ATP synthesis, thus supporting mitochondrial energy metabolism. The latter pathway may be particularly important in delayed administration of NAC.

Mushroom poisoning, most commonly from *Amanita* genus mushrooms, should be suspected in patients with

a history of severe gastrointestinal symptoms (nausea, vomiting, diarrhea and abdominal cramping), which occur within hours to a day after mushroom ingestion<sup>[11]</sup>. Amanitin toxin, recycled *via* the enterohepatic circulation, interrupts hepatocyte mRNA synthesis resulting in dose-dependent hepatotoxicity. The mortality of ALF secondary to mushroom poisoning approaches 10%-30%. Penicillin G and silybinin may ameliorate the hepatic injury, however, patients should be listed for hepatic transplantation, because this procedure is often the only life-saving option<sup>[12]</sup>.

Drugs other than APAP rarely cause dose-related liver injury<sup>[13]</sup>. Many of these injuries are idiosyncratic, and they often occur within the first 6 mo after intake of the drug. In this setting, it is necessary to discontinue all but the most essential medications. Medications commonly associated with acute liver injury include antimicrobials, neurological and psychiatric drugs, and nonsteroidal anti-inflammatory drugs (Table 1)<sup>[14]</sup>.

### Virus

Patients with viral hepatitis that develop hepatic failure are largely suffering from hepatitis B, and less frequently hepatitis A. Hepatitis B carriers undergoing immunosuppressive or cancer chemotherapy may experience reactivation of hepatitis B virus (HBV) replication, which may lead to ALF. Prophylactic antiviral therapy is recommended for HBV carriers at the onset of cancer chemotherapy or of a finite course of immunosuppressive therapy<sup>[15-17]</sup>. High viral load at baseline is the most important risk factor for HBV reactivation. Patients with baseline HBV DNA < 2000 IU/mL level should continue treatment for 6 mo after completion of chemotherapy or immunosuppressive therapy. Patients with a high baseline HBV DNA (> 2000 IU/mL) level should continue treatment until they reach treatment endpoints as in immunocompetent patients. Lamivudine or telbivudine can be used if the anticipated duration of treatment is short (< 12 mo) and baseline serum HBV DNA is not detectable. Tenofovir or entecavir is preferred if longer duration of treatment is anticipated<sup>[17]</sup>. In addition, all transplant recipients positive for hepatitis B surface antigen should receive antiviral therapy, preferably using tenofovir or entecavir<sup>[15]</sup>.

In an endemic area such as Russia, Pakistan, Mexico, or India, hepatitis E remains an important cause of hepatic failure, particularly in the context of pregnancy, and it carries a high mortality in this setting<sup>[18]</sup>. Moreover, vertical transmission of hepatitis E from women with acute infection results in ALF in more than half of neonates. So far, ALF due to acute hepatitis C infection is uncommon and occurs in < 1% of patients. Few data suggest that hepatitis G virus plays a major pathogenic role in ALF<sup>[19]</sup>. Herpes viruses occasionally cause ALF, usually among immunosuppressed and pregnant patients<sup>[20]</sup>. Epstein-Barr virus, adenoviruses, cytomegalovirus, varicella zoster virus, parvovirus B19, yellow fever virus and hemorrhagic fever virus are also implicated as causes of ALF. For ALF caused by herpes viruses or varicella zoster,

**Table 1** Drugs which may cause idiosyncratic liver injury leading to acute liver failure

Classification	Drugs
Anti-infective agents	Amoxicillin/clavulanate erythromycin, roxithromycin, telithromycin, doxycycline, minocycline nitrofurantoin, ciprofloxacin, levofloxacin, moxifloxacin trimethoprim-sulfamethoxazole, sulfasalazine, isoniazid, rifampin, pyrazinamide, ethambutol, dapsone, fluconazole, itraconazole, terbinafine, ketoconazole, chloroquine Didanosine, fialuridine, efavirenz, abacavir, nevirapine-lamivudine
Cardiovascular agents	Amiodarone, labetalol, diltiazem, methyldopa, valsartan, lisinopril, angiotensin converting enzyme inhibitor Asparaginase, flutamide
Hypolipidemic agents	Atorvastatin, cerivastatin, simvastatin, pravastatin, fluvastatin, ezetimibe
Hypoglycemic Agents	Metformin, troglitazone
Anti-allergic agents	Zafirlukast, loratadine, diphenhydramine
Herbal products/dietary supplements	Kava, Herbalife, Comfrey, Senecio, Greater Celandine, Polygonum multiflorum, ginseng, Teucrium polium, usnic acid, ma huang, Chaso, Onshido, Hydroxycut, LipoKinetix
Neurological and psychiatric drugs	Halothane, isoflurane, butorphanol opiates, amphetamines, marijuana, cocaine Phenytoin, valproic acid, carbamazepine, felbamate, lamotrigine, vigabatrin amitriptyline, imipramine, sertraline, paroxetine, venlafaxine, pemoline, bupropion Chlorpromazine, quetiapine, clonazepam tolcapone
Nonsteroidal anti-inflammatory drugs	Diclofenac, bromfenac, etodolac, naproxen, ibuprofen, indometacin
Miscellaneous	Propylthiouracil, retinol, infliximab, allopurinol, cyclosporine, disulfiram, iron sulfate, anabolic steroids, carbon tetrachloride, phenprocoumon, nicotinic acid
Antineoplastic agents	Methotrexate, cytoxan, etoposide, dactinomycin, azathioprine, tamoxifen

acyclovir (5-10 mg/kg *iv* every 8 h) is the recommended treatment<sup>[21]</sup>.

### Metabolic causes

Metabolic disorders like Wilson disease (WD), HELLP (hemolysis, elevated liver enzymes, low platelets) syndrome, acute fatty liver of pregnancy, Reye's syndrome, galactosemia, hereditary fructose intolerance, hemochromatosis,  $\alpha$ 1-antitrypsin deficiency and tyrosinemia may also cause ALF.

WD accounts for 6%-12% of all patients with ALF who are referred for emergency liver transplantation. ALF due to WD occurs predominantly in young women (female:male ratio 4:1)<sup>[22]</sup>. Diagnostic tests for WD should include ceruloplasmin, serum and urinary copper levels, total bilirubin/alkaline phosphatase ratio, slit lamp examination for Kayser-Fleischer rings, and hepatic copper levels when liver biopsy is feasible<sup>[23]</sup>. High bilirubin (> 20 mg/dL) and low alkaline phosphatase levels (including

undetectable levels) due to profound hemolytic anemia help with its rapid recognition. Liver transplantation is the only effective option for those with WD who present with ALF. One-year survival following liver transplantation ranges from 79% to 87%, and those who survive this early period continue to survive in the long term<sup>[23]</sup>.

The hepatic damage of HELLP syndrome is proposed to result from disordered placentation, leading to either the circulation of antiangiogenic factors and endothelial dysfunction, or cytokine production causing the characteristic periportal hemorrhage and fibrin deposition observed by Sánchez-Bueno *et al.*<sup>[24]</sup>. Acute fatty liver degeneration of pregnancy is a sudden catastrophic illness occurring most frequently in the third trimester, when mitochondrial dysfunction due to maternal and fetal fatty acid  $\beta$ -oxidation defects resulting in microvesicular fatty acid accumulation in hepatocytes<sup>[25]</sup>. There is an overlap of these two clinical syndromes, and they play a major role in the pathogenesis of pre-eclampsia, with hypertension, and proteinuria. Early recognition of these syndromes and prompt delivery are critical in achieving good outcomes. Failure to recover from the illness should be promptly listed for liver transplantation<sup>[26]</sup>.

### Vascular causes

The Budd-Chiari syndrome (acute hepatic vein thrombosis) is an uncommon cause of ALF<sup>[27]</sup>. Right upper quadrant pain, striking hepatomegaly, and fluid retention characterize the initial clinical picture and may help distinguish this syndrome from other forms of ALF in which the liver is small and not tender. Therapeutic strategies have included anticoagulation, use of transjugular intrahepatic portocaval shunting, or transplantation. It is important to rule out underlying cancer prior to transplantation for these patients. Liver ischemic injury can also cause ALF and could be seen in the setting of sepsis, cardiac arrest, heart failure, or hypotension induced by long-acting niacin or cocaine<sup>[28]</sup>. Aminotransferase levels will be markedly elevated and respond rapidly to stabilization of the circulatory problem. Cardiovascular support is the treatment of choice in this setting.

### Miscellaneous causes

Some rare causes of ALF include heat shock, protracted seizures, autoimmune hepatitis, and malignant infiltration<sup>[29,30]</sup>. ALF occurs in a small fraction of autoimmune hepatitis patients-probably < 20%. These cases are usually recognized prior to hospitalization as having autoimmune disease that proceeds to rapid deterioration. The clinical picture is in the form of a subacute presentation, with intermediate elevation of enzyme levels and high bilirubin concentrations. Presence of autoantibodies and a compatible picture on biopsy help to confirm the diagnosis, but they may not be notable. Some autoimmune hepatitis patients may respond well to steroid therapy, and others may still require transplantation. The most common forms of malignant infiltration implicated in ALF are lymphoma, breast cancer, and melanoma<sup>[31]</sup>.

Others include small cell lung cancer and prostate cancer. Diagnosis should be made by imaging and biopsy, and treatment appropriate for the underlying malignant condition is indicated.

### Indeterminate causes

About 15%-20% of ALF occurs with an indeterminate cause, which includes unrecognized idiosyncratic drug toxicity, non-A-E viral hepatitis, and possibly unrecognized metabolic and genetic diseases. The reasons for this misdiagnosis may include failure to obtain an adequate history as mentioned, failure to perform the definitive diagnostic tests, or simply due to some other elusive diagnoses. As has been noted, about 20% of ALF of indeterminate cause is related to obscure APAP toxicity through detection of APAP-protein adducts, the byproducts of the toxic reaction<sup>[32]</sup>. However, the adduct assay is not available for routine use at this time.

## CLINICAL MANIFESTATIONS

The clinical presentation of ALF is multifaceted, ranging from slightly altered conscious level with profound coagulopathy to a catastrophic failure of multiple organs. The initial clinical features of ALF may be nonspecific and may include anorexia, fatigue, abdominal pain and fever. As the metabolic and detoxification function of liver becomes impaired, the signs of ALF emerge, including jaundice, encephalopathy, coagulopathy, haemodynamic instability, acute lung injury/acute respiratory distress syndrome (ARDS), renal failure, sepsis, and metabolic disturbance.

Depending on the interval between development of jaundice and onset of encephalopathy, clinical manifestation could be stratified into three groups such as hyperacute (< 7 d), acute (7-28 d) and subacute (4-26 wk)<sup>[33]</sup>. This classification is popular but not particularly helpful because it does not have prognostic significance that is distinct for identifying the cause of the illness. Hyperacute failure, most commonly caused by APAP hepatotoxicity, is characterized by high aminotransferase level and low bilirubin level<sup>[34]</sup>. Hepatic encephalopathy develops rapidly in this setting, sometimes preceding jaundice. Subacute liver failure due to idiosyncratic drug toxicity presents as minimal encephalopathy with no cerebral edema<sup>[35]</sup>. This condition is usually associated with severe jaundice, renal dysfunction, and moderate coagulopathy.

## ICU TREATMENT

NAC is a proven effective therapy for APAP hepatotoxicity. It is also beneficial in non-APAP ALF patients showing early (grades I / II) hepatic encephalopathy<sup>[36]</sup>. NAC can increase non-transplant survival among these patients. Thus, administration of NAC should be initiated immediately when ALF is established. Except for NAC, there is no other proven therapy for ALF. Management consisting of intensive care support should be initiated to address

the various organ dysfunctions associated with ALF.

### Cerebral edema and intracranial hypertension

Cerebral edema leading to intracranial hypertension (ICH) is one of the major causes of morbidity and mortality in patients with ALF. The pathogenesis of cerebral edema and ICH in ALF appears to be multifactorial. Ammonia is converted in the astrocytes to osmotically active glutamine, producing osmotic cerebral edema<sup>[37]</sup>. Other factors such as impaired cerebral blood flow (CBF) autoregulation, systemic inflammatory response and ischemic injury have also been proposed as the cause of ICH. Some risk factors for the development of cerebral edema in patients with ALF include high-grade encephalopathy (grade III or IV), high serum ammonia concentrations (> 200  $\mu\text{mol/L}$ ), and requirement for vasopressor support or renal replacement therapy.

Cerebral edema presents clinically as hepatic encephalopathy due to ICH. Basic interventions for the management of cerebral edema should be applied universally in patients with high-grade hepatic encephalopathy. These interventions include elevation of the head of the bed to 30°, maintenance of a neutral neck position, endotracheal intubation, minimizing painful stimuli, and control of arterial hypertension<sup>[38]</sup>. Propofol is a reasonable choice for adequate sedation because it may protect from ICH. For treatment of pain, fentanyl is preferred as the first-line agent. Factors that increase ICP need to be avoided and include hypercapnia, hyponatremia, frequent movements, neck vein compression, fluid overload, fever, hypoxia, coughing, sneezing, seizures, and endotracheal suctioning.

ICP monitoring is recommended in ALF patients with high-grade hepatic encephalopathy, in centers with expertise in ICP monitoring as well as in patients awaiting and undergoing liver transplantation<sup>[39]</sup>. ICP monitoring can detect elevations in ICP to direct interventions, which may preserve brain perfusion and prevent cranial herniation. Generally, the goal of therapy in ALF is to maintain ICP < 20 mmHg and cerebral perfusion pressure (CPP) > 60 mmHg. Prolonged ICP > 40 mmHg and CPP < 50 mmHg are associated with a poor outcome. CPP < 40 mmHg for > 2 h indicates reduced neurological blood flow to maintain intact brain function and should contraindicate liver transplantation because of poor post-transplantation prognosis. However, patients with refractory ICP elevation > 35 mmHg and CPP < 50 mmHg who made a full neurological recovery contradicted previous findings.

In patients with persistently elevated ICP, osmotic therapy can be considered. Mannitol reduces ICP by osmotically drawing water from the brain parenchyma into the intravascular space<sup>[40]</sup>. ICP > 20 mmHg necessitates intravenous administration of mannitol (0.5-1 g/kg) provided serum osmolality is < 320 mOsm/L. However, mannitol fails to normalize ICP once a level > 60 mmHg is reached. Thus, its best use is for mild to moderate ICH. Alternately, hypertonic saline mitigates ICH through both osmotic and nonosmotic effects<sup>[41]</sup>. Hypertonic saline to

target serum sodium levels 145-155 mmol/L are suggested to avoid complications associated with extreme hyponatremia, such as seizure and changes in mentation.

Hypothermia also has some benefit in reducing ICP, because it lowers brain energy metabolism, reduces arterial ammonia concentration and extraction of ammonia by the brain, normalizes CBF autoregulation, and reverses systemic inflammatory reactions<sup>[42]</sup>. In addition to its neurological effect, hypothermia results in significant improvement of cardiovascular hemodynamics, as manifested by increased mean arterial pressure (MAP) and systemic vascular resistance, and reduction in noradrenaline requirements. Therapeutic hypothermia (cooling to a core temperature of 34 °C-35 °C) is probably well tolerated and effective, but randomized, controlled trials are needed to confirm the benefits of hypothermia before it is applied routinely.

Barbiturates are centrally acting hypnotics that reduce brain oxygen utilization and are effective in lowering ICP<sup>[43]</sup>. However, untoward side effects such as arterial hypotension, negative inotropic effects, and immunosuppressant effects make barbiturates a poor first-choice treatment for ICH. Hyperventilation can induce hypocapnia that causes cerebral vasoconstriction, which in turn reduces CBF, thus leading to a decrease in ICP<sup>[44]</sup>. Although hyperventilation effectively reduces ICP, there is a concern that the resultant vasoconstriction could exacerbate cerebral ischemia and even cause hypoxia. It is believed that hyperventilation to maintain PaCO<sub>2</sub> between 30 and 35 mmHg may reduce ICP acutely, but it should not be used over a prolonged period.

The use of hepatectomy in patients awaiting liver transplantation is based upon the concept that the necrotic liver is the source of unknown humoral substances that contribute to increased ICP<sup>[45]</sup>. Removal of the liver in an ALF patient resulted in improved ICP possibly through a reduction in CBF, nitric oxide (NO) and liver-derived proinflammatory cytokines.

### **Hemodynamic failure**

ALF is characterized by a hyperdynamic circulation with high cardiac output, low MAP, and low systemic vascular resistance<sup>[46]</sup>. Increased NO production and cyclic GMP may be involved in these hemodynamic disturbances. Because the patients have such markedly deranged circulation, it is important to use monitoring devices that are able to provide information about changes in MAP, filling status, cardiac output, and oxygenation status. Due to poor oral intake, transudation of fluid into the extravascular space, and possibly gastrointestinal bleeding, most patients are volume depleted and require initial fluid resuscitation. The initial treatment of hypotension should involve intravenous infusion of normal saline and a volume challenge is recommended<sup>[47]</sup>.

After adequate fluid replacement and treatment of infection and sepsis, vasopressors may also be required to maintain adequate MAP and CPP. ALF patients have lost CBF autoregulation and an increase in MAP results in an

increase in CPP. The MAP should be maintained in a narrow range to achieve a CPP of 60-80 mmHg to prevent cerebral hypoperfusion on the one hand and further cerebral hyperemia on the other hand. Noradrenaline, with fewer  $\beta$ -adrenergic side effects, could increase hepatic blood flow in parallel with minimizing tachycardia and is often the preferred vasopressor<sup>[48]</sup>. In patients who do not respond to a volume challenge and norepinephrine, vasopressin or terlipressin may potentiate the effects of norepinephrine. Patients with uncorrectable hypotension after volume repletion and vasopressor administration should be evaluated for adrenal insufficiency, which occurs frequently in this setting<sup>[49]</sup>. Adrenal insufficiency could be corrected with a stress dose of hydrocortisone 200-300 mg/d in divided doses.

### **Respiratory failure**

Acute lung injury/ARDS is not uncommon in patients who have ALF and severe multiple organ dysfunction; particularly a requirement for vasopressors and concurrent ICH<sup>[50]</sup>. The hypoxemia caused by acute lung injury and ARDS should be managed with low tidal volume ventilation to minimize risks of pulmonary volume trauma and barotrauma. Upregulation of respiratory rate is needed to ensure adequate minute ventilation, avoiding marked hypercapnia. It is desirable to maintain the lowest level of positive end-expiratory pressure that achieves adequate oxygenation because high levels may exacerbate cerebral edema and hepatic congestion. Recruitment, a transient increase in mean airway pressure to expand the lungs, is also beneficial in improving oxygenation.

### **Acute renal failure**

The incidence of acute renal failure in ALF is as high as 50%-80%. Acute renal failure resembling hepatorenal syndrome is multifactorial in the setting of ALF<sup>[51]</sup>. Direct drug nephrotoxicity and acute tubular necrosis due to ischemia from hypotension are among the most important associated disease entities. In addition, development of abdominal compartment syndrome, due to ascites, intra-abdominal hemorrhage or severe abdominal and gut wall edema, is a common cause of renal impairment in ALF. Management includes avoidance of nephrotoxic agents, treatment of infection, maintenance of adequate renal perfusion, and renal replacement therapy. Early targeted volume replacement and vasoactive agent administration are essential to avoid arterial hypotension and ensure adequate renal perfusion. Worsening renal failure needs to be addressed with renal replacement therapy. Continuous renal replacement therapy is recommended, because most patients with ALF tolerate intermittent hemodialysis poorly because of circulatory instability, precipitous fluid shifts, and a rise in ICP<sup>[52]</sup>.

### **Infection**

ALF patients have enhanced susceptibility to infection because of the presence of indwelling lines and catheters, dysfunction of monocytes, and impaired complement

system and neutrophil and Kupffer cell function<sup>[53]</sup>. Bacterial infections have been documented in 80% of cases; most commonly pneumonia, urinary tract infections, intravenous catheter-induced bacteremia, and spontaneous bacteremia. Infectious organisms are mainly Gram-negative enteric bacilli, Gram-positive cocci and *Candida* species. Infection inhibits hepatic regeneration, and it is associated with progression of hepatic encephalopathy and renal failure, reduces successful rate of transplantation, and increases mortality in ALF. Thus, close surveillance for infection should be maintained in all ALF patients, with frequent chest radiographs and cultures of blood, urine and sputum. Empirical antibiotics should be administered when surveillance cultures are positive. To patients who develop progression to grade 3 or 4 hepatic encephalopathy and elements of systemic inflammatory response syndrome, antibiotic treatment is also recommended<sup>[54]</sup>.

### Bleeding

Deficiencies of fibrinolytic proteins, anticoagulant proteins (protein C/S or antithrombin III) and procoagulation factors (II, V, VII, IX and X) are often present in ALF; in part due to failure of synthesis as well as consumption of these factors. Data have also shown quantitative and qualitative platelet dysfunction in ALF. Hemostatic changes thus incorporate coagulopathy [confirmed with prolonged prothrombin time (PT) and partial thromboplastin time] as well as a tendency to develop thrombotic events such as disseminated intravascular coagulation. However, there are abnormalities in both the coagulation and the fibrinolytic pathways, and data suggest that the defects are balanced; that is, there is a relative preservation of hemostasis<sup>[55]</sup>. Clinically significant bleeding occurs rarely (about 5% of cases) and the perceived bleeding risk based upon INR may be overstated.

Bleeding generally occurs from superficial mucosal lesions, especially gastric erosions. Administration of histamine-2 receptor antagonists or proton pump inhibitors has been shown to decrease the risk of gastric mucosal bleeding in patients with ALF. In general, infusion of fresh frozen plasma is indicated only for control of active bleeding or during invasive procedures such as insertion of ICP monitor, to maintain an INR  $< 1.5$ <sup>[56]</sup>. When fresh frozen plasma fails to normalize PT/INR adequately, the use of recombinant factor VIIa can be considered. Cryoprecipitate is recommended in patients who have significant hypofibrinogenemia ( $< 1$  g/L). Platelet transfusion is indicated only to aid in controlling active bleeding or during invasive procedures if the count is  $< 50 \times 10^9$ /L or prophylactically if  $< 15 \times 10^9$ /L<sup>[57]</sup>. Finally, vitamin K (5-10 mg subcutaneously) should be considered in all patients with ALF, because its deficiency can occur in  $> 25\%$  of patients.

### Metabolic concerns

Patients are prone to develop hypoglycemia because hepatocyte necrosis causes glycogen depletion and defective

glycogenolysis and gluconeogenesis. Rapid development of hypoglycemia, which can confound the hepatic encephalopathy, should be managed with continuous intravenous glucose infusion<sup>[58]</sup>. Hyperglycemia should also be avoided because it may contribute to poor ICP control. Low systemic blood pressure and poor systemic microcirculation result in a build-up of lactate; a complication that may be accentuated by the lack of the lactate metabolism in the failing liver. Correction of hyperlactatemia is important because it can affect circulatory function and aggravate cerebral hyperemia. Serum phosphate, potassium and magnesium are frequently low, requiring repeated supplementation. Severe restrictions of protein should be avoided; normal protein intake of about 1 g/kg per day is reasonable in most cases<sup>[59]</sup>. Owing to the hypercatabolic state of ALF, nutrition is vital and enteral feedings should be initiated early. If enteral feeding is contraindicated, parenteral nutrition is a reasonable alternative.

## LIVER SUPPORT DEVICES

Extracorporeal supportive devices have been advocated to replace the liver function in ALF patients; however, the complexity of liver metabolic, synthetic, detoxifying, and excretory functions makes the extracorporeal hepatic support extremely difficult. Currently available liver support systems comprise nonbiological systems and bioartificial systems. As the most common techniques of nonbiological systems, molecular adsorbent recirculatory system and Prometheus therapy are useful methods of detoxification for patients with ALF<sup>[60]</sup>. Unfortunately, no survival benefit could be demonstrated compared with standard medical therapy.

Bioartificial liver (BAL) systems rely on the use of liver cells (human or nonhuman) to perform detoxification and secretion of hepatocyte-derived factors. The selection of the ideal cell source and the design of more sophisticated bioreactors are the main issues in this field of research. Preliminary data on the use of BAL devices suggest some improvement in encephalopathy, but no real improvement could be demonstrated in overall survival.

## LIVER TRANSPLANTATION

OLT remains the only definitive treatment for patients with ALF proven to have irreversible liver injury. Rapid evaluation for transfer to a transplantation center and consideration for liver transplantation is mandatory so that transplantation can be applied before contraindications develop. Towards this end, multiple prognostic indicators and scoring systems have been devised to predict outcome in ALF. The King's College criteria are widely used to assess of the severity of ALF and the potential variability of the prognosis, with a sensitivity of 68%-69% and a specificity of 82%-92% (Table 2). Recently, the addition of arterial lactate levels in patients with APAP-induced ALF has been proposed to improve sensitivity of the criteria and identifies patients in need

**Table 2 King's College criteria for selecting recipients of emergency liver transplants**

Acetaminophen-induced ALF	Non-acetaminophen-induced ALF
Strongly recommended list for OLT if: Arterial lactate > 3.5 mmol/L after early fluid resuscitation	List for transplantation if: INR > 6.5 and encephalopathy present irrespective of grade
List for transplantation if: Arterial pH < 7.3 or arterial lactate > 3.0 mmol/L after adequate fluid resuscitation	Or if any 3 of the following features (encephalopathy irrespective of grade) are present: Age < 10 yr or > 40 yr <sup>1</sup> Interval from jaundice to encephalopathy > 7 d <sup>1</sup>
List for transplantation if all 3 of the following occur within a 24-h period: Grade 3 or 4 hepatic encephalopathy INR > 6.5 Creatinine > 300 µmol/L	INR ≥ 3.5 Serum bilirubin ≥ 300 µmol/L Unfavorable etiology, such as seronegative hepatitis, idiosyncratic drug reaction or Wilson disease

<sup>1</sup>These criteria have not been found to be predictive of outcome in recent analyses. ALF: Acute liver failure; OLT: Orthotopic liver transplantation; INR: International normalized ratio.

for OLT earlier<sup>[61]</sup>. The Clichy/Villejuif criteria are widely used in Northern Europe for ALF patients with severe encephalopathy, and assess outlook with consideration of coagulation factor V concentrations and patient age. The criteria include grade 3 and 4 hepatic encephalopathy and factor V levels < 20% in patients < 30 years of age or < 30% in patients aged > 30 years. Other systems such as Acute Physiology and Chronic Health Evaluation (APACHE) II score and the Model for End-Stage Liver Disease (MELD) score have also been used to determine the prognosis in ALF. The MELD score is calculated by the formula: MELD = 3.8 [Ln serum bilirubin (mg/dL)] + 11.2 (Ln INR) + 9.6 [Ln serum creatinine (mg/dL) + 6.4]. The sensitivity of APACHE II score and MELD score is too low to determine outcome, but the specificity is acceptable. This means that they are more applicable for predicting death rather than spontaneous survival.

In general, key factors involved in determining outcome of ALF are the etiology, degree of encephalopathy, degree of hepatocyte damage, and risk of extrahepatic complications. First, the etiologic diagnosis *per se* appears to be the strongest driver of outcome. ALF cases due to APAP toxicity, hepatitis A, ischemia, and pregnancy may have a better prognosis<sup>[62]</sup>. Approximately 90% of APAP-induced ALF cases recover with supportive measures, whereas ALF cases due to idiosyncratic drug injury, acute hepatitis B, autoimmune hepatitis, mushroom poisoning, WD, Budd-Chiari syndrome and indeterminate causes carry a much poorer prognosis in the absence of OLT. Up to 80% of patients who develop liver failure due to idiosyncratic drug injury might die without transplantation. Second, grade 3 or 4 encephalopathy is considered to show irreversible liver damage; spontaneous recovery is rare, and in most cases the patient is transferred to a transplantation centre and undergoes OLT as soon as possible<sup>[63]</sup>. Moreover, the degree of hepatocyte damage,

reflected as coagulopathy or jaundice, is viewed as inverse correlation with survival. Finally, extrahepatic complications, such as comorbid cardiovascular, respiratory and systemic conditions have a negative affect on patient outcomes. In addition, studies have also identified serum phosphate, blood NH<sub>3</sub> levels, high body mass index, genetic polymorphism, and surrogate markers of cell death as additional predictive or diagnostic factors<sup>[64]</sup>. Hypophosphatemia is an indication of increased hepatic ATP production during liver regeneration and serve as a good prognostic indicator especially in APAP-induced ALF. Genetic polymorphisms in keratins 8 and 18, the sole keratins expressed by hepatocytes, confer susceptibility to ALF and are also prognostic.

Before OLT, contraindications to transplantation such as substance abuse, suicidal predilection, psychiatric disorders, uncontrollable sepsis and other organ system involvement (irreversible brain damage, extrahepatic malignancy, cardiovascular failure requiring > 1 µg/kg per minute norepinephrine infusion, and ARDS requiring FiO<sub>2</sub> > 60% and PEEP > 12 cm H<sub>2</sub>O) must be excluded. Once listed for OLT, patients waited an average of 3.5 d. However, 66% of patients were transplanted, and of the remainder, 22% died prior to transplantation and 12% recovered spontaneously. The 1-year survival of cadaveric liver transplant in ALF patients is lower than that in chronic liver failure patients; in part because of the extreme emergency conditions often encountered. After the first year, this trend has reversed and ALF patients have a better long-term survival. In addition to whole-organ deceased donor liver transplantation, live donor and auxiliary liver transplantation have been attempted but still remain controversial<sup>[65]</sup>.

## CONCLUSION

The management of ALF challenges our best skills because of its rapid progression and frequently poor outcomes. Early identification of ALF and the administration of etiology-specific treatment are crucial to improve the outcome. Extrahepatic organ failure should be well managed with advanced intensive care management. Better-targeted use of OLT techniques becomes important to save the patients who fail to recover spontaneously. A better understanding of the pathophysiology of ALF will probably lead to further improvement in survival rates.

### Abstract

**AIM:** To identify molecular biologic differences between two gastric adenocarcinoma subgroups presenting different prognoses through the analysis of microRNA and protein expression.

**METHODS:** Array technologies were used to generate 1146 microRNAs and 124 proteins expression profiles of samples from 60 patients with gastric cancer. For the

integrative analysis, we used established mRNA expression data published in our previous study. Whole mRNA expression levels were acquired from microarray data for 60 identical gastric cancer patients. Two gastric adenocarcinoma subgroups with distinct mRNA expression profiles presented distinctly different prognoses. MicroRNA and protein expression patterns were compared between gastric cancer tissue and normal gastric tissue and between two different prognostic groups. Aberrantly expressed microRNA, associated mRNA, and protein in patients with poor-prognosis gastric cancer were validated by quantitative reverse transcription polymerase chain reaction and immunochemistry in independent patients.

**RESULTS:** We obtained the expression data of 1146 microRNAs and 124 cancer-related proteins. Four microRNAs were aberrantly expressed in the two prognostic groups and in cancer *vs* non-cancer tissues ( $P < 0.05$ ). In the poor-prognosis group, miR-196b, miR-135b, and miR-93 were up-regulated and miR-29c\* was down-regulated. miR-196b expression positively correlated with Homeobox A10 (HOXA10) expression ( $r = 0.726$ ,  $P < 0.001$ ), which was significantly increased in poor-prognosis patients ( $P < 0.001$ ). Comparing gastric cancer with non-cancer tissues, 46/124 proteins showed differential expression ( $P < 0.05$ ); COX2 ( $P < 0.001$ ) and cyclin B1 ( $P = 0.017$ ) were clearly over-expressed in the poor-prognosis group.

**CONCLUSION:** Co-activation of miR-196b and HOXA10 characterized a poor-prognosis subgroup of patients with gastric cancer. Elucidation of the biologic function of miR-196b and HOXA10 is warranted.

**Key words:** Gastric cancer; Gene expression; Microarray; MicroRNA; miR-196b; Homeobox A10

**Core tip:** Using an integrative analysis of the tumor transcriptome and protein expression profiles obtained by microarray techniques, we have elucidated the molecular biologic characteristics of a poor prognosis gastric cancer subgroup. Overexpression of miR196b and Homeobox A10 are implicated in gastric cancer, particularly in tumors with poor prognosis features. We anticipate this integrative approach will contribute to the characterization of cancer heterogeneity and the development of personalized therapy through the identification of cancer targets.

Overexpression of miR-196b and HOXA10 characterize a poor-prognosis gastric cancer subtype. *World J Gastroenterol* 2013; 19(41): 7078-7088 Available from: URL: <http://www.wjg-net.com/1007-9327/full/v19/i41/7078.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i41.7078>

## INTRODUCTION

Gastric cancer is the second leading cause of cancer-related deaths worldwide<sup>[1]</sup>. Surgery is the only curative treatment strategy and conventional chemotherapy has shown limited efficacy for the treatment of patients with advanced disease. Understanding the molecular mechanisms governing carcinogenesis, progression, and prognosis in gastric cancer is a prerequisite for the construction of a convincing management strategy. It is widely acknowledged that there are favorable and poor-prognosis subtypes of cancer, although the treatment strategy is generally determined by clinical and histopathologic stage rather than disease type. Patients with gastric cancer are also clinically heterogeneous, which suggests an underlying molecular diversity<sup>[2,3]</sup>. Molecular subtypes of gastric cancer have been suggested through analysis of gene or protein expression profiles and oncogenic signaling pathways<sup>[4-9]</sup>. In a previous study, we identified distinct gastric cancer subclasses by analyzing gene expression profiles and we described two gastric cancer subtypes that were strongly associated with prognosis<sup>[10]</sup>.

MicroRNAs play a role in the pathogenesis of various human cancers<sup>[11]</sup>. Some microRNAs function as oncogenes and others as tumor suppressors, although their mechanisms remain to be elucidated<sup>[12,13]</sup>. The relationship between microRNA expression profile and gastric cancer prognosis has been actively explored<sup>[14,15]</sup>, as has the pathogenesis of gastric cancer<sup>[16,17]</sup>. Overexpression of miR-196b has been linked to leukemia and several solid cancers including gastric cancer and may represent a useful gastric cancer marker<sup>[18,19]</sup>. A role for miR-196b as an oncogene or tumor suppressor has not yet been confirmed<sup>[20]</sup>, nor has its role in gastric carcinogenesis and progression.

Homeobox A10 (HOXA10) is transcription factor involved in the proliferation of hematopoietic stem cells

and progenitor cells. Its over-expression is associated with cancer development and poor prognosis in patients with acute myeloid leukemia and solid cancers<sup>[21-23]</sup>. HOXA10 is a neighboring gene of miR-196b but these genes have no known function in gastric cancer pathogenesis.

In this study, we generated microRNA and protein expression profiles using samples from 60 patients with gastric cancer to identify molecular biologic differences between previously identified good- and poor-prognosis patient subgroups.

## MATERIALS AND METHODS

### Patients and samples

Tumor specimens and clinical data were obtained from patients with primary gastric adenocarcinoma who underwent curative gastrectomy as the primary treatment between 1999 and 2007 at Severance Hospital and Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, South Korea. Three independent patient cohorts were used for each experiment: Group 1 (frozen tissue samples from 60 patients, each of whom provided a cancer sample and 8 of whom provided a non-cancer sample) for microRNA, and protein microarray analysis (Table 1); Group 2 (12 paired cancer and non-cancer frozen tissue samples from 12 patients) for validation tests using quantitative reverse transcription polymerase chain reaction (qRT-PCR); and Group 3 (paraffin-embedded samples from 368 patients with gastric cancer) for tissue microarray immunohistochemistry (IHC). Frozen tissue samples were examined by pathologists at the time of collection and were stored below -80 °C at a tissue bank until the analysis. Samples were collected after obtaining written informed consent from the patients. The study was approved by the institutional review board of Yonsei University Health System.

### MicroRNA microarray

Total RNA was extracted from fresh frozen tissues using a mirVana<sup>TM</sup> miRNA isolation kit (Ambion, Austin, TX, United States). Microarray experiments were performed according to the manufacturer's protocols (Illumina microRNA Expression Profiling Assay; Illumina, San Diego, CA, United States). The panel contained 1146 miRNA assays described in the Sanger Institute miRBase Release 12.0 (from miR-1 to miR-1827)<sup>[24]</sup>; 200 ng RNA was used for labeling and hybridization. Chips were scanned with an Illumina BeadArray Reader (Illumina, San Diego, CA, United States) and intensity values were analyzed using BeadStudio version 3.1.3. A cut-off detection *P* value of 0.01 was used to determine whether a microRNA probe was significantly detected. Microarray data were normalized using the quantile normalization method. MicroRNA microarray data is available in the National Center for Biotechnology Information (NCBI) Gene Expression Omnibus (GEO) public database (accession number GSE26595).

### Protein expression assay

Reverse-phase protein array (RPPA) was performed according to the manufacturer's protocol and the data were analyzed as previously described<sup>[25]</sup>. Frozen tissues were lysed in RPPA lysis buffer and complete protease inhibitor cocktail (Roche Diagnostics, Mannheim, Germany). Protein-containing samples were diluted to a uniform protein concentration and transferred into 384-well plates. The lysate was printed onto nitrocellulose-coated glass slides and probed using 124 antibodies. Signal intensity was measured by scanning the slides: slides were scanned, analyzed, and quantified using the customized Microvigene software (VigeneTech, Inc., Carlisle, MA, United States) to measure spot intensity.

### Analysis of microarray data

The microarray expression level was transformed into a log 2 base before further analysis. Cluster analysis was performed after median centering using the Cluster 3.0 program and visualized in Treeview (Eisen Lab. CA, United States). BRB-ArrayTools (version 3.6; Biometrics Research Branch, National Cancer Institute, MD, United States) were used for microarray data analysis<sup>[26]</sup>. The previously generated gene expression data from the poor-prognosis group<sup>[10]</sup> were obtained from the NCBI GEO public database (accession number GSE13861).

### Quantitative RT-PCR and analysis

Quantitative RT-PCR was carried out according to the manufacturer's protocols (miRURY LNA microRNA PCR System, Exiqon, Vedbaek, Denmark) and was performed in duplicate. The RT reactions were incubated for 30 min at 50 °C followed by heat inactivation at 85 °C for 5-10 min. cDNA templates were diluted and added to the PCR master mix. Cycling conditions were as follows: 37 °C for 10 min, 95 °C for 10 min, followed by 40

cycles of 95 °C for 20 s and 60 °C for 60 s. RT-PCR was performed on a 7900HT Fast Real-Time PCR System (Applied Biosystems, Foster City, CA, United States) with a 96-well block module. Relative amounts of microRNA were calculated from the threshold cycle (C<sub>T</sub>) number using the expression of U6 snRNA for normalization.

### Tissue microarray construction and IHC staining

Paraffin-embedded tissue microarray blocks were created using gastric cancer tissue specimens obtained from 368 patients. A tissue microarray set contained 14 slides with 30 tissue cores per slide. Sections 4 µm thick were deparaffinized and treated to block endogenous peroxidase activity. After antigen retrieval, the primary antibody - anti-HOXA10 antibody (polyclonal, dilution 1:75; Santa Cruz Biotechnology, Santa Cruz, CA, United States) - was applied to the sections. The sections were incubated with a secondary antibody (horse radish peroxidase-rabbit/mouse), developed using a NovaRED substrate kit (VECTOR Laboratory, Burlingame, CA, United States) and counterstained with Harris hematoxylin. Stained slides were examined with a Zeiss Axio Imager M2 microscope with an AxioCam HRc camera and photographed using AxioVision 4.8.2 software (Zeiss, Jena, Germany). Strong cytoplasmic staining was considered as positive expression. Positive expression was defined as staining stronger compared to smooth muscle. Negative expression was defined as staining positivity lower than or similar to smooth muscle.

### Statistical analysis

Statistical analysis was performed with PASW Statistics 18 (SPSS Inc., San Diego, United States) and graphical interpretations were generated with GraphPad Prism 5 (GraphPad Software, San Diego, CA, United States). The Kaplan-Meier method was used to estimate patient

prognosis; differences between genotypes were compared using the log-rank test. Differences between groups were analyzed using the two-tailed Student's *t* test and the  $\chi^2$  test. Associations between the expression levels of the two targets were analyzed using the Pearson correlation coefficient. Generally, differences were considered statistically significant at  $P < 0.05$ .

## RESULTS

### Gene expression microarray-established gastric cancer subgroups C1 and C2

In our previous study<sup>[10]</sup>, two gastric cancer subgroups [a poor-prognosis group C1 ( $n = 32$ ) and a good-prognosis group C2 ( $n = 28$ )] were established through unsupervised hierarchical clustering of gene expression data from the 60 patients with gastric cancer in Group 1. Genes with expression levels that were at least 2-fold different in at least 15 tissues, relative to the median value across tissues, were selected for hierarchical clustering analysis (2077 gene features) (Figure 1A). Following comparison of gene expression profiles of samples from C1, C2, and non-cancer patients, unique gene sets were identified for the C1 and C2 groups that contained 2755 and 1437 genes, respectively ( $P < 0.001$ ). C1 patients had significantly poorer relapse-free survival than C2 patients ( $P = 0.0019$ ; log-rank test). This was independent of disease stage, indicating that the molecular features reflected in gene expression patterns might be strong independent predictors of clinical outcome (Figure 1B). Gene expression data for 5922 transcription factor (TF) genes were selected and C1-specific TF genes were extracted (Figure 1C). A total of 413 up-regulated and 326 down-regulated TF genes are shown in Figure 1D; the top 20 up- and down-regulated TF genes are listed in Figure 1E.

### microRNA expression profile of gastric cancer

A total of 410 out of 1146 probes in the microRNA expression assay were significantly detected ( $P < 0.01$ ) and further processed (Figure 2A). Though unsupervised clustering analysis revealed two major subtypes, these did not appear to have any prognostic or clinico-pathologic value. Subsequently, 164 microRNAs significantly ( $P < 0.05$  in the *t* test) aberrantly expressed in gastric cancer tissue were identified (Figure 2A). Non-cancer tissue showed relatively homogenous microRNA expression patterns, in contrast to the highly heterogeneous expression patterns observed in cancer tissues.

### Aberrant microRNA expression in C1 and C2 patients

MicroRNA expression data were compared between non-cancer and cancer tissues and between C1 and C2 samples. Four microRNAs were uniquely dysregulated ( $P < 0.05$ ) among non-cancer, C1, and C2 samples (Figure 2A). miR-196b, miR-135b, and miR-93 were up-regulated and miR-29c\* was down-regulated in the C1, poor-prognosis group (Figure 2B). Log-transformed expression lev-

els are shown in Figure 3A. miR-196b showed the most significantly different expression patterns between cancer and non-cancer samples ( $P < 0.001$ ), and between the C1 and C2 groups ( $P < 0.001$ ).

### Validation of microRNA expression by quantitative RT-PCR

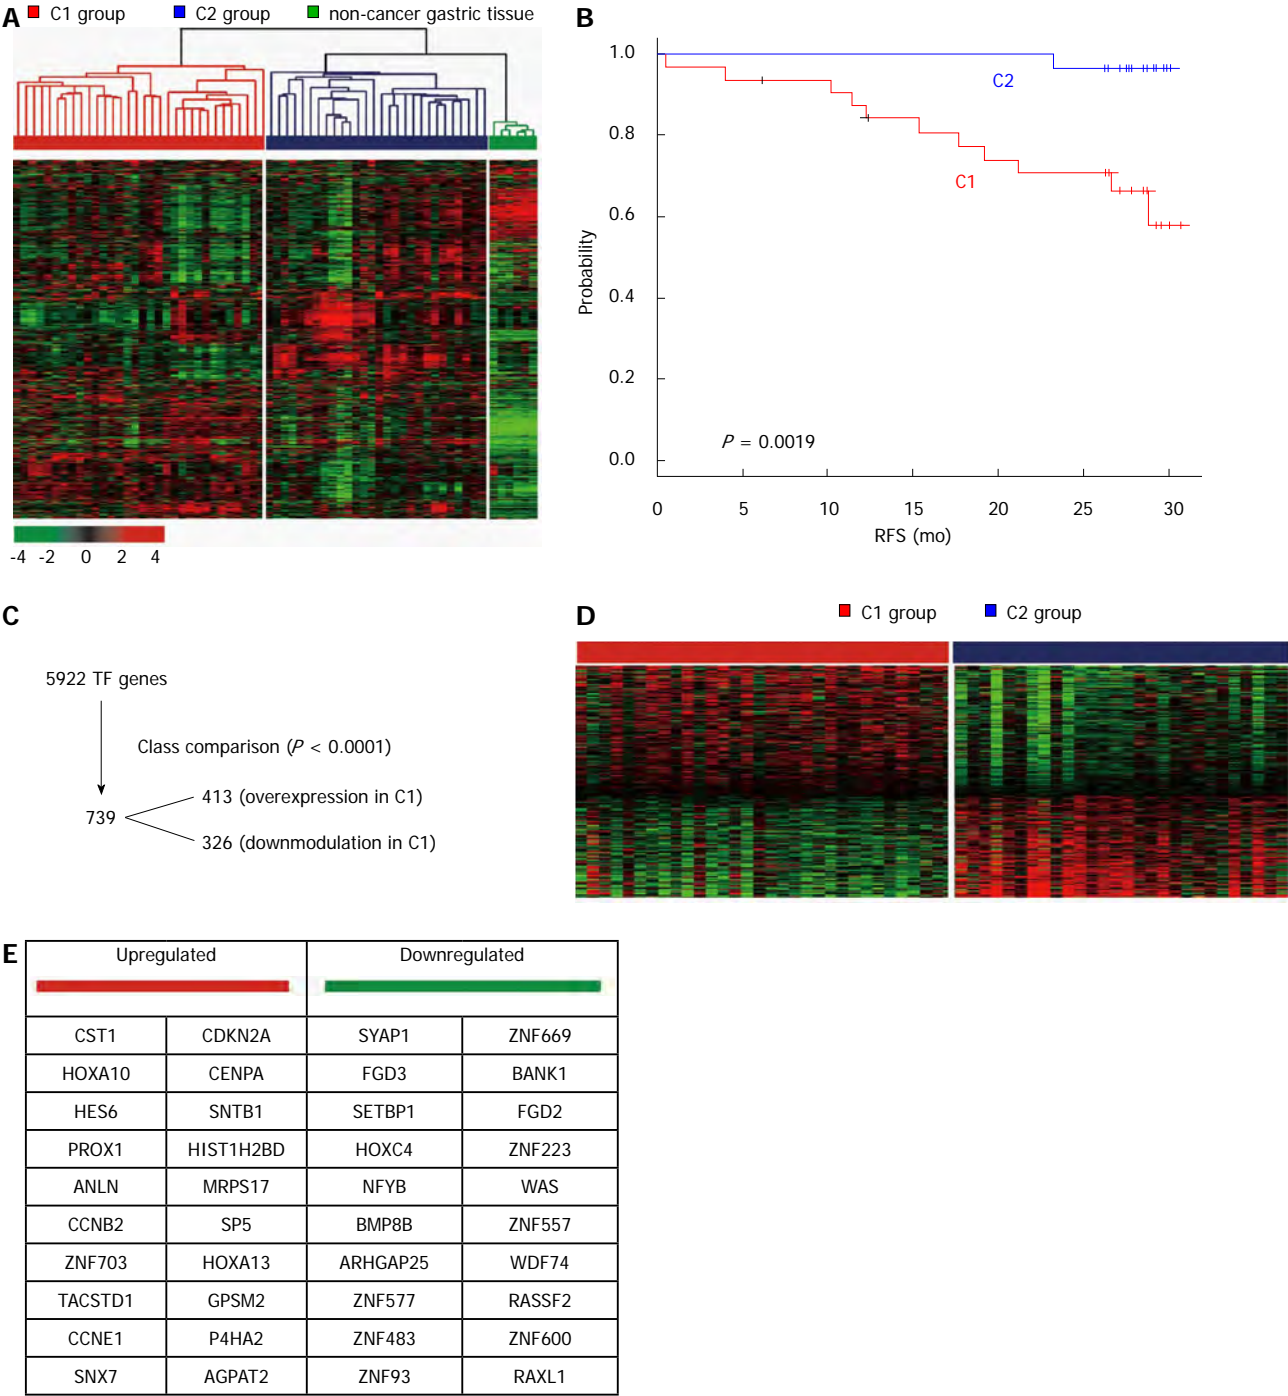

To validate the microRNA expression microarray data, qRT-PCR was performed using RNA from the 12 patients in Group 2. Using Ct numbers, miR-196b was determined to be up-regulated in gastric cancer tissue compared with non-cancer tissue ( $P = 0.007$ ; two-sample paired *t* test; Figure 3B). The up-regulation of miR-135b in gastric cancer samples was not statistically significant ( $P = 0.118$ ).

### Correlation between HOXA10 and miR-196b expression

HOXA9 and HOXA10 are neighboring genes to miR-196b (Figure 4A) and are regarded as miR-196b-associated genes. Therefore, the expression level of HOXA9 and HOXA10 and their correlation with miR-196b expression were evaluated. Analysis of microRNA and mRNA expression data from gastric cancer tissue samples obtained from patients in Group 1 showed that HOXA10 mRNA expression was positively correlated with miR-196b expression (Figure 4B;  $r = 0.726$ ,  $P < 0.001$ ). HOXA10 expression was up-regulated in gastric cancer compared with non-cancer tissue and was higher in C1 compared with C2 patients (Figure 4C). Overexpression of miR-196b was significantly associated with shorter overall survival (OS;  $P = 0.022$ ; Figure 4D). Overexpression of HOXA10 exhibited a tendency to poor OS ( $P = 0.202$ ; Figure 4D) but HOXA9 did not exhibit any significant association with miR-196b or prognosis (Figure 4B and D). HOXA10 protein-positive expression was identified in 56 of 368 gastric cancer tissue samples (15.2%) from patients in Group 3 (Figure 5A and B). In non-cancer gastric tissue, body glands were stained variably. In contrast to well and moderately differentiated adenocarcinoma, poorly differentiated adenocarcinoma and signet ring cell carcinoma showed less positive staining for HOXA10 (29.4% vs 8.4%,  $P < 0.001$ ).

### Protein expression profile of gastric cancer

The unsupervised clustering analysis revealed that protein expression was highly variable compared with mRNA and microRNA expression in non-cancer and cancer tissues. Two-group two-sample *t* tests comparisons were performed using cancer and non-cancer samples to identify gastric cancer-specific proteins. Univariate analyses revealed 48 out of 124 proteins with significantly different levels ( $P < 0.05$ ) between cancer and non-cancer tissues (Figure 5B). Among these 48 proteins, the expression of COX2 and cyclin B1 was significantly increased in gastric cancer vs non-cancer tissue (both  $P < 0.001$ ), and up-regulated in the C1 compared with C2 groups ( $P < 0.001$  for COX2 and  $P = 0.016$  for cyclin B1).

**Figure 1** Two prognostic groups of patients with gastric cancer, C1 and C2, have distinct mRNA expression patterns. A: mRNA expression patterns of gastric cancer and non-cancer gastric tissue are depicted in a heat map. Hierarchical clustering revealed two subtypes of gastric cancer, C1 and C2. The data are presented as a matrix in which rows represent individual mRNAs and columns represent each tissue. The color red represents relatively high expression levels and green reflects lower expression levels; B: Kaplan-Meier plot of relapse-free survival (RFS) revealed C1 and C2 represented poor- and good-prognosis gastric cancer tissues, respectively; C: Workflow of C1-specific 739 transcription factors (TFs) selected from a total 5,922 TFs; D: Hierarchical clustering of gene expression for 739 TF genes; E: List of top 20 up- and down-regulated TF genes in the C1 group.

## DISCUSSION

We previously identified two prognostic subgroups of patients with gastric cancer through gene expression microarray technology<sup>[10]</sup>. Our findings suggested that their gene expression signatures reflected clinical differences between good- and poor-prognosis patients independent

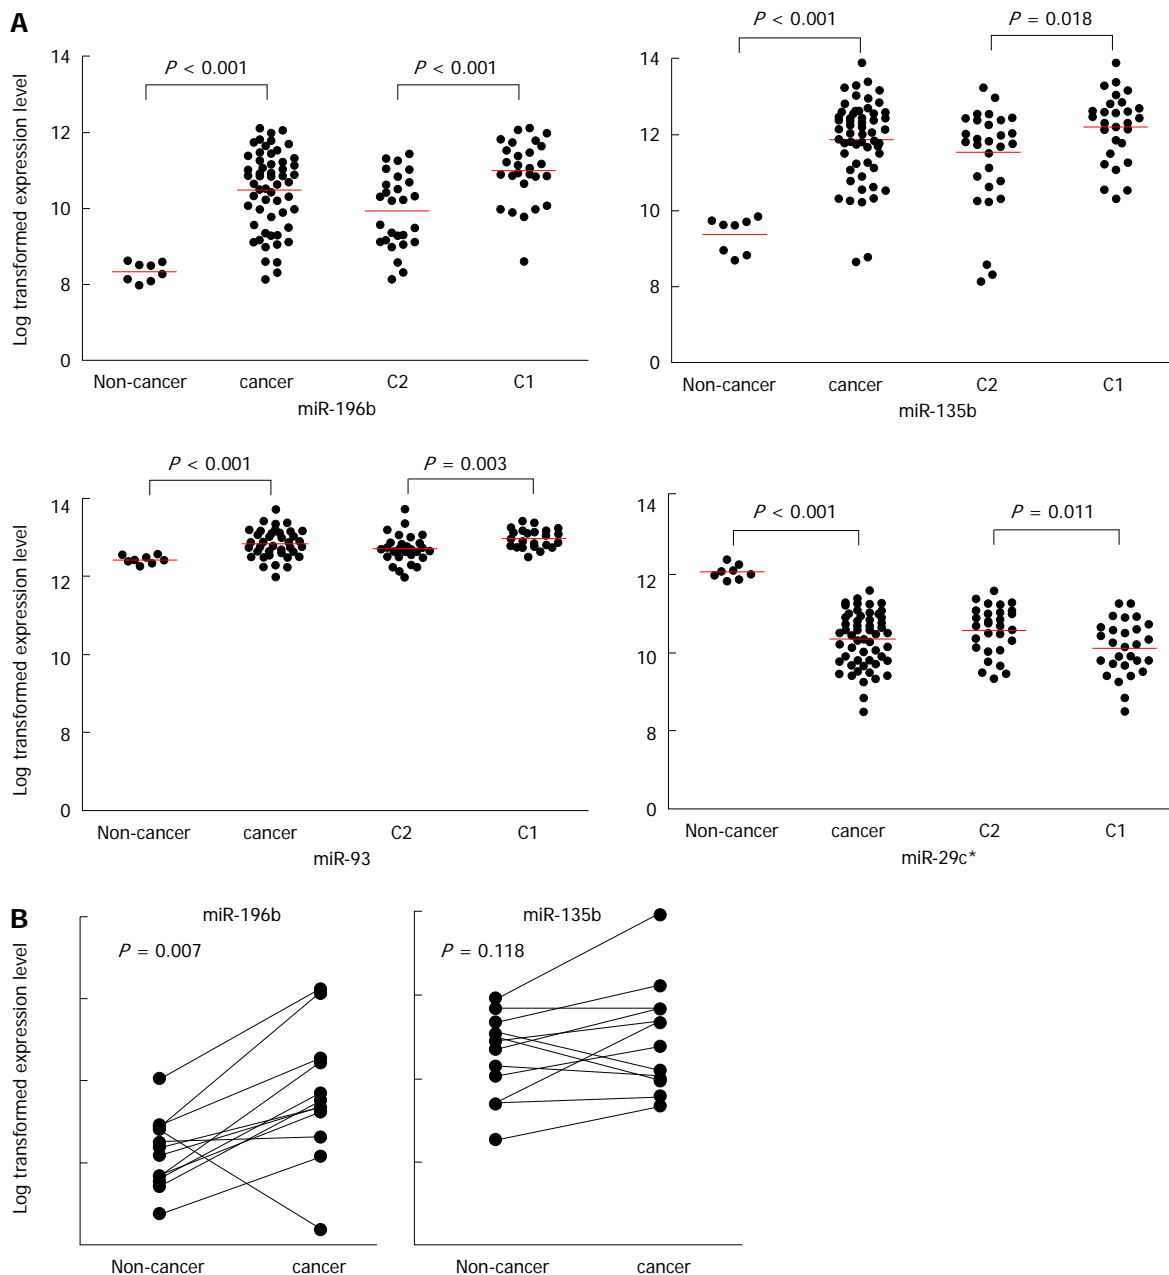

of tumor-node-metastasis stage and histology. The molecular biologic mechanisms responsible for these clinical differences were unknown. In an effort to understand these molecular mechanisms, we obtained microRNA and protein expression data from tumor tissue samples using high-throughput microarray techniques.

First, two-group comparison analysis revealed 164 mi-

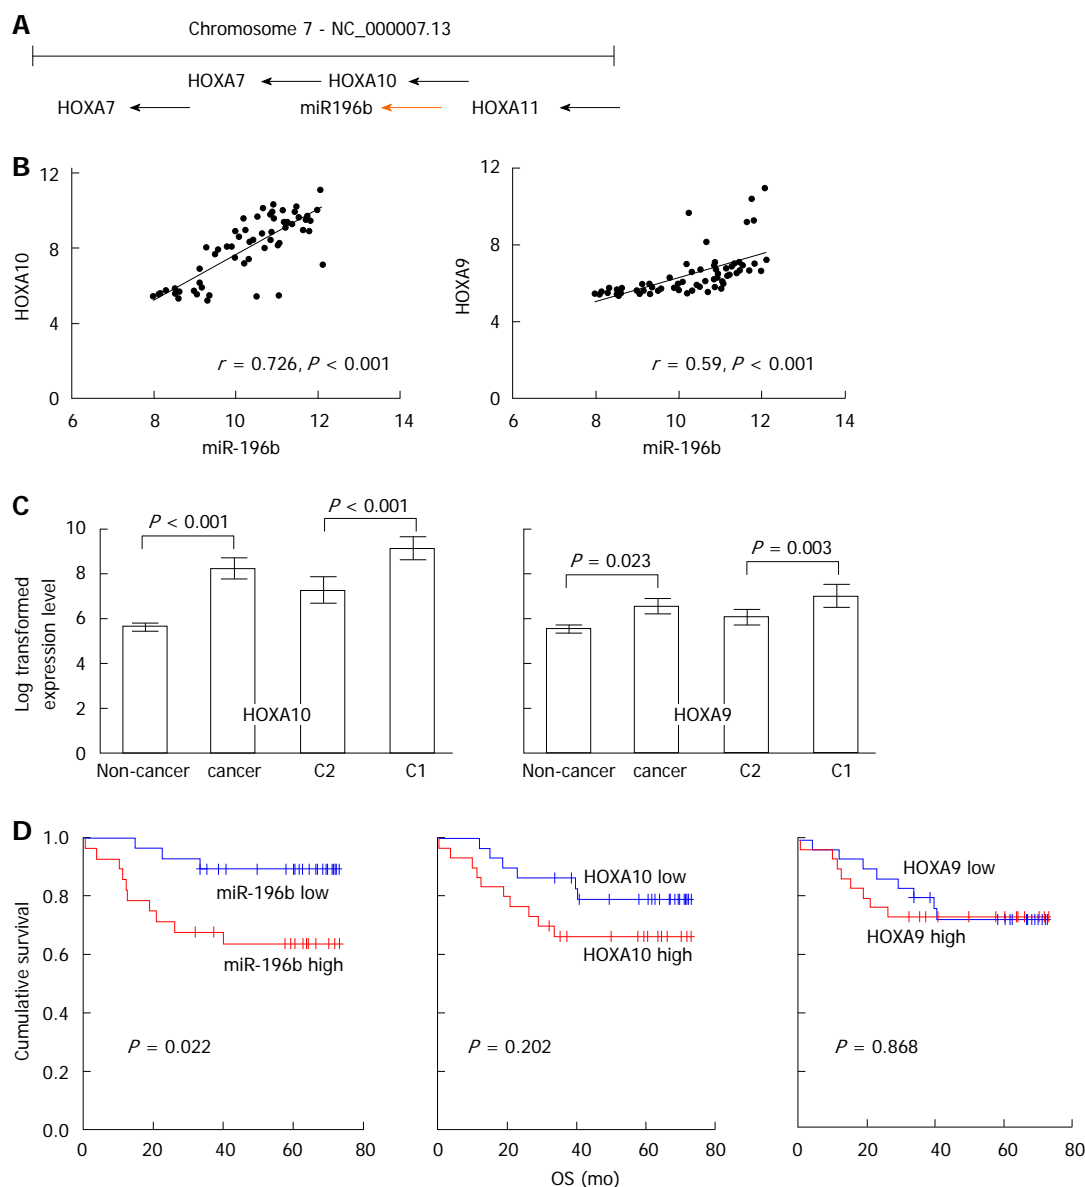

**Figure 2** Aberrant microRNA expression in gastric cancer. A: Flowchart of the data analysis to identify poor-prognosis C1-specific microRNAs. Four microRNAs (miR-196b, miR-135b, miR-93, and miR-29c\*) were selected; B: Expression patterns of the four microRNAs are shown in a heat map for C1, C2, and non-cancer gastric tissues. The color yellow represents relatively high expression levels and blue reflects relatively low levels.

**Figure 3** The expression levels of four microRNAs. A: Four microRNAs expressed differentially in gastric tissues. Scatter plots of gene expression levels with a bar indicating the mean; B: The expression level of miR-196b and miR-135b were validated in a quantitative reverse transcription polymerase chain reaction study of 12 patients samples.

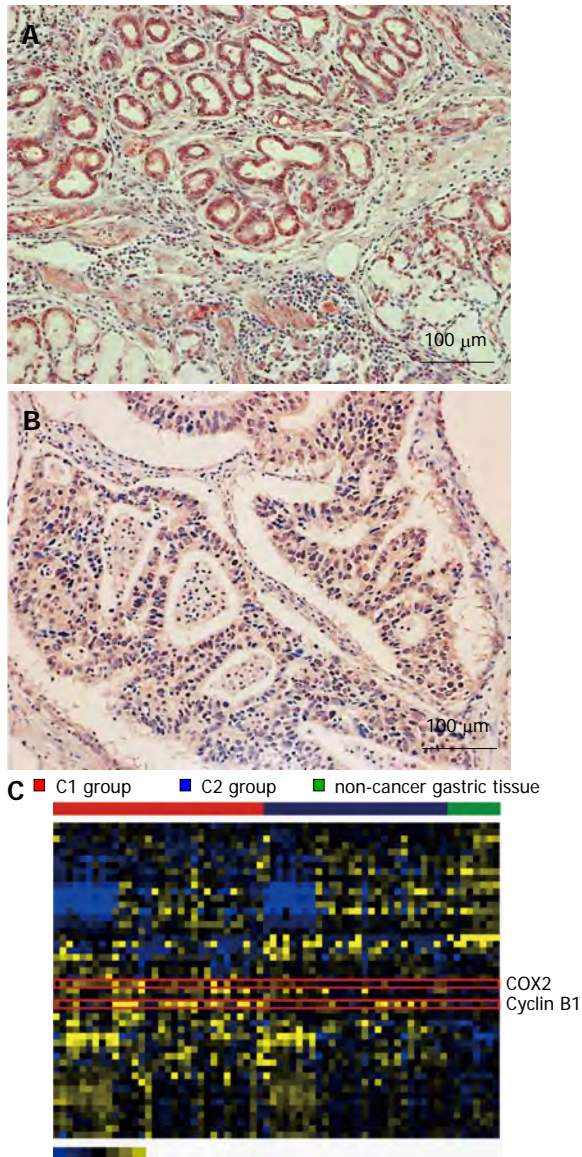

**Figure 4** The correlation between miR-196b and homeobox A10 expression in gastric cancer. **A:** miR-196b, homeobox A10 (HOXA10), and HOXA9 are neighbor genes and located on chromosome 7p15.2; **B:** Expression of miR-196b and HOXA10 were positively correlated ( $r = 0.726$ ;  $P < 0.001$ ). The correlation between miR-196b and HOXA9 expression was less significant; **C:** HOXA10 and HOXA9 expression level in gastric cancer vs non-cancer tissues and in the C1 vs the C2 group. Results are presented as means with 95%CI; **D:** Kaplan–Meier plot of overall survival according to the expression level of miR-196b, HOXA10, and HOXA9.

croRNAs that showed different expression profiles in the cancer and non-cancer tissue samples. Supervised clustering (C1 vs C2 vs non-cancer) using these 164 microRNAs revealed that non-cancer tissues manifested relatively homogenous microRNA expression. A comparison of the microRNA expression revealed that three microRNAs (miR-196b, miR-135b, and miR-93) were up-regulated in C1 vs C2 and in cancer vs non-cancer tissues. Conversely, miR-29c\* was down-regulated in C1 samples. We suggest, therefore, that dysregulation of those four microRNAs might characterize C1, our previously identified poor-prognosis gastric cancer subgroup. The accumulated knowledge about microRNA-associated genes and cancers is summarized in Table 2.

The overexpression of miR-196b has previously been linked to leukemia and several solid cancers<sup>[18,19]</sup>. The

increased expression of miR-196b contributes to the development of leukemia and the relationship between differential miR-196b expression and clinical and biologic features has been studied in leukemia<sup>[18,39–41]</sup>. miR-196b expression is also increased in pancreatic ductal adenocarcinoma and bronchial squamous cell carcinoma, although its role in these cancers has not been established<sup>[27,28]</sup>. Tsai *et al*<sup>[19]</sup> reported that a lack of promoter methylation in miR-196b resulted in its overexpression in gastric cancer cell lines and patient samples, and they proposed that miR-196b overexpression might provide a useful tumor marker. However, it has not yet been determined whether miR-196b functions as an oncogene or a tumor suppressor<sup>[20]</sup>, and its role in gastric carcinogenesis and progression has not yet been identified.

In recent *in vitro* study, a leukemia oncogene was found

**Figure 5** Aberrant protein expression in gastric cancer. A: Representative image from the homeobox A10 (HOXA10) immunohistochemical assay ( $\times 200$ ) of gastric cancer tissue. The moderately differentiated adenocarcinoma shows positive for HOXA10 expression. A strong cytoplasmic immunoreaction was noted; B: Negative for HOXA10 expression; C: The expression pattern of 48 proteins from Reverse-phase protein array (RPPA) was depicted using a heat map. The color yellow represents relatively high expression levels and blue reflects relatively low levels.

to promote the expression of miR-135b, with elevated miR-135b expression decreasing chemosensitivity, suggesting the contribution of miR-135b to the oncogenic activity of the leukemia oncogene<sup>[29]</sup>. It has been suggested that oncogenic kinase-linked miR-135b contributes to tumorigenesis through modulation of the tumor-immune phenotype and microenvironment<sup>[29]</sup>. Others have identified miR-135b as a novel biomarker for pancreatic ductal adenocarcinoma<sup>[30]</sup>. In chronically inflamed or genetic models of colon cancer, miR-135b was suggested along with other microRNAs, to regulate signaling pathways related to mitogen-activated protein kinase, phosphoinositide 3-kinase, WNT, and transforming growth factor

(TGF)- $\beta$ , all of which are known to be involved in cell transformation<sup>[31]</sup>. However, there are as of yet no data relating to the pathogenesis of gastric cancer.

miR-93 is a well-known constituent of the miR-106b approximately 25 cluster, paralogs of which have oncogenic activity in several cancers, including gastric cancer. Up-regulated miR-93 in gastric cancer leads to cell cycle activation and impaired apoptosis<sup>[17,32]</sup>. miR-29c\* is, however, poorly understood with no known target and it has only been shown to be an independent favorable prognostic factor in malignant pleural mesothelioma<sup>[38]</sup>.

Information about each of these microRNAs provides support for the proposal that our poor-prognosis microRNA signature - up-regulation of miR-196b, miR-135b, and miR-93 and down-regulation of miR-29c\* - is relevant. As miR-93 has largely been investigated in gastric cancer and miR-29c\* is poorly understood, we focused our attention on miR-196b and miR-135b. The qRT-PCR assay demonstrated that miR-196b was significantly overexpressed in cancer *vs* non-cancer tissue while miR-135b was not (Figure 3B). Therefore, the role of miR-196b in gastric cancer was further investigated.

Using correlation analysis, we identified that HOXA10 levels were also elevated in gastric cancer. The expression of miR-196b appears to be most positively associated with HOXA10 expression. Our previous gene expression microarray data indicated that HOXA10 was ranked as the second most up-regulated TF in gastric cancer (Figure 1E), as it was significantly elevated in gastric cancer *vs* non-cancer and in poor-prognosis C1 *vs* good-prognosis C2. Evidence is accumulating that HOXA10 is involved in the proliferation of hematopoietic stem cells and progenitor cells, leading to cancer development through activating the target genes coding for TGF $\beta$ 2, dual-specificity protein phosphatase 4, and integrin- $\beta$ 3<sup>[21,42,43]</sup>. Up-regulation of HOX genes is associated with a tumor stem-like cell phenotype of glioblastoma, and high HOXA10 protein expression has been associated with resistance to chemotherapy<sup>[44]</sup>. HOXA10 is also over-expressed in a poor-prognosis subset of patients with acute myeloid leukemia and in several solid cancers<sup>[21-23]</sup>. On the basis of these findings, we postulate that HOXA10 may induce gastric carcinogenesis and function as a marker of poor prognosis. Recently, it was reported that upregulation of HOXA10 was correlated with favorable prognosis and inversely correlated with the depth of invasion in gastric cancer<sup>[45]</sup>. Different patient populations and detection methods for HOXA10 seems to be responsible for inconsistent results. More reliable evidences should be accumulated to elucidate the role of HOXA10 in gastric cancer.

miR-196b is located in the HOXA cluster on chromosome 9 and expression levels of pri-miR-196b are highly correlated with its neighboring gene HOXA10<sup>[18]</sup>. A previous study showed that expression patterns of miR-196b were inversely correlated with the methylation status of promoter CpG-rich regions in gastric cancer cell lines and primary gastric cancer samples<sup>[19]</sup>. Suzuki

*et al.*<sup>[46]</sup> analyzed genome-wide profiling of chromatin signatures combining microRNA expression and suggested that DNA demethylation can alter the chromatin signatures of numerous microRNAs in cancer. Elevated expression of miR-196b in gastric cancer cells may result from the preferential unmethylated status of CpG islands and from other TFs. We suggest that HOXA10 expression might also be governed by miR-196b modulation; however, the exact mechanism of miR-196b promoter activity modulation by TFs remains to be elucidated.

In the present study, miR-196b and HOXA10 were co-activated in gastric cancer samples, especially in the poor-prognosis group. miR-196b and HOXA10 are also closely related to the development and progression of hematopoietic stem cells. This suggests that gastric cancer co-activated by miR-196b and HOXA10 might share the same pathogenesis as leukemia. Chronic inflammation caused by *Helicobacter pylori* (*H. pylori*) is associated with gastric carcinogenesis and there is recent evidence that *H. pylori* infection recruits bone marrow-derived cells (BMDCs) in the gastric epithelial mucosa that participate in gastric preneoplasia<sup>[47,48]</sup>. Over-expression of miR-196b and HOXA10 may mediate the development of hematopoietic progenitor cells and gastric cancer; thus, it is necessary to elucidate the mechanism and function of the co-activation of miR-196b and HOXA10 in gastric cancer.

RPPA is a quantitative assay that analyzes large samples for known proteins and their active forms. We evaluated the expression of 124 proteins to understand the physiology and pathogenesis of gastric cancer at the protein level. The limitations of this platform, measuring only small numbers of known antibodies, were taken into consideration when interpreting the data. As shown in Figure 5B, protein expression patterns are highly heterogeneous, even between gastric cancers, indicating that a few tumor targets will apply to almost all patients with gastric cancer and that most markers are likely to only apply to selected patients. In the present study, COX2 and cyclin B1 were significantly elevated in the C1 group compared with the C2 group. In combination with gene expression array data, the HOXA10 promoter has a nuclear factor- $\kappa$ B (NF $\kappa$ B) binding site, and NF $\kappa$ B controls COX2 expression, leading to inflammation and

carcinogenesis. The elucidation of this relationship might explain the mechanism of HOXA10 over-expression in gastric cancer.

In conclusion, using an integrative analysis of tumor transcriptome and protein expression data by microarray techniques, we have elucidated the molecular biologic characteristics of a poor-prognosis gastric cancer subgroup. We postulate that the overexpression of miR-196b and HOXA10 are implicated in gastric cancer, particularly in tumors with poor-prognosis features. The personalized cancer therapy targets aberrations that drive tumor growth and survival. Administering the right drug for the right person consequently improves clinical outcomes and decreases toxicity. We anticipate that this approach will contribute to the characterization of cancer heterogeneity and the development of personalized therapy through the identification of cancer targets.

## ACKNOWLEDGMENTS

The authors would like to acknowledge Yiling Lu, Department of Systems Biology, University of Texas MD Anderson Cancer Center, for performing the RPPA experiment.

## COMMENTS

### Background

Gastric cancer is clinically heterogeneous, which suggest underlying molecular diversity. Advances in high-throughput technologies such as microarray for gene or protein expression profiles have reinforced the identification of molecular biologic characteristics of cancer. It is of great clinical value to perform integrative analysis of data from diverse high-throughput technologies simultaneously, to elucidate gastric cancer subtype harboring poor prognosis.

### Research frontiers

MicroRNAs play a role in the pathogenesis of various human cancers by regulating the expression of target gene post transcriptionally. Microarray and bioinformatic technologies enable the investigation of the trans-correlation of hundreds of microRNAs and tens of thousands of genes.

### Innovations and breakthroughs

MiR-196b was the most significantly up-regulated microRNA in gastric cancer and was significantly correlated with poor prognosis. The expression of miR-196b appeared to be most positively associated with homeobox A10 (HOXA10) expression. The expression of miR-196b and HOXA10 seems to be regulated by identical biologic mechanism and characterize a poor-prognosis gastric cancer subtype.

## Applications

An integrative approach that simultaneously evaluates the expression profiles of mRNA, microRNA, and protein in cancer tissue will contribute to characterizing cancer heterogeneity and developing personalized therapy through the identification of cancer targets.

## Terminology

A microarray is a multiplex lab-on-a-chip and assays large amounts of biological material using high-throughput screening methods. The types of microarrays include DNA microarray, microRNA microarray, protein microarray, and tissue microarray. Bioinformatics is the analysis of biological data including gene and protein expression and regulation data.

## Peer review

This study generated and analyzed gene, microRNA, and protein expression profiles from 60 patients with gastric cancer and identified the overexpression of miR-196b and HOXA10 as a characteristic of a poor-prognosis gastric cancer subtype. Further investigation to elucidate the molecular biologic function of miR-196b and HOXA10 in gastric cancer is necessary.

III (long oval), IV (tubular), V (villous)] by Endo's classification. Then, a 0.5% solution of methylene blue (MB) was sprayed over columnar mucosa. The patterns of the magnified image and MB staining were analyzed. Biopsies were obtained from the regions previously observed by magnifying endoscopy and MB chromoendoscopy.

**RESULTS:** Three of five patients with a type V (villous) epithelial pattern had SIM, whereas 21 patients with a non-type V epithelial patterns did not have SIM. The sensitivity, specificity, accuracy, positive predictive value, and negative predictive value of pit-patterns in detecting SIM were 100%, 91.3%, 92.3%, 60% and 100%, respectively ( $P = 0.004$ ). Three of the 12 patients with positive MB staining had SIM, whereas 14 patients with negative MB staining did not have SIM. The sensitivity, specificity, accuracy, positive predictive value, and negative predictive value of MB staining in detecting SIM were 100%, 60.9%, 65.4%, 25% and 100%, respectively ( $P = 0.085$ ). The specificity and accuracy of pit-pattern evaluation were significantly superior compared with MB staining for detecting SIM by comparison with the exact McNemar's test ( $P = 0.0391$ ).

**CONCLUSION:** The magnified observation of a short-segment BE according to the mucosal pattern and its classification can be predictive of SIM.

### Abstract

**AIM:** To determine whether magnified observation of short-segment Barrett's esophagus (BE) is useful for the detection of specialized intestinal metaplasia (SIM).

**METHODS:** Thirty patients with suspected short-segment BE underwent magnifying endoscopy up to  $\times 80$ . The magnified images were analyzed with respect to their pit-patterns, which were simultaneously classified into five epithelial types [I (small round), II (straight),

opsy still represent the standard for the surveillance of Barrett's esophagus (BE). In our study, we investigated the usefulness of magnifying endoscopy for the diagnosis of specialized intestinal metaplasia (SIM) in patients with short-segment BE compared with methylene blue chromoendoscopy. We found that the magnified observation of a short-segment BE according to its mucosal pattern and classification can be predictive of SIM.

## INTRODUCTION

Barrett's esophagus (BE) is important clinically as the link between one of the most common gastrointestinal diseases, gastroesophageal reflux disease (GERD), and the most rapidly increasing cancer of the gastrointestinal (GI) tract, esophageal adenocarcinoma (EAC). For an adenocarcinoma to develop in the esophagus, the squamous epithelium must transition to columnar epithelium and subsequently become dysplastic. This metaplasia-dysplasia-carcinoma sequence is attributed to the repeated injury of the esophagus by gastroesophageal reflux<sup>[1-3]</sup>. According to the Montreal consensus from 2006, BE is characterized by the replacement of the squamous epithelia in the distal esophagus by columnar epithelia (gastric metaplasia), irrespective of the presence of specialized intestinal metaplasia (SIM)<sup>[4]</sup>. Controversy exists regarding the absolute requirement of intestinal metaplasia to define BE, primarily because long-term follow-up studies are not available to assess the risk of progression for each histologic subtype. However, cross-sectional and descriptive studies suggest that SIM either coexists with or precedes a significant majority of EAC cases and is likely the precursor lesion<sup>[5,6]</sup>. Therefore, histologic confirmation of SIM in BE is required. Because of the latent period of transition to high grade dysplasia, EAC is significantly shorter for patients with low grade dysplasia (median of 2.75 years) than for patients without low grade dysplasia (median of 9.88 years)<sup>[1]</sup>.

Patients with SIM are currently recommended to undergo periodic endoscopic surveillance to determine the progression to dysplasia at an early, potentially curable stage<sup>[5,7]</sup>.

Discerning SIM and obtaining satisfactory target biopsies at the region of interest by standard endoscopic observation is difficult<sup>[8,9]</sup>. Thus, to identify the presence of SIM and dysplasia according to the Seattle protocol, specimens are obtained using a predefined four-quadrant sampling technique<sup>[10]</sup>. The major disadvantages of this method are the need for multiple biopsies, random choice

of biopsy places, and the high cost.

Chromoendoscopy and magnifying endoscopy have been improving mucosal visualization to allow for better differentiation of the SIM and dysplasia from the columnar epithelium during endoscopy<sup>[11,12]</sup>. These techniques provide more accurate biopsies as well as reduce the number of biopsies<sup>[13,14]</sup>. Chromoendoscopy involves the use of dyes sprayed over the mucosa. Methylene blue (MB) stains actively absorbing cells, such as the intestinal epithelium and intestinal metaplasia<sup>[11]</sup>. The sensitivity and specificity of MB staining for SIM detection in BE is still under discussion<sup>[15,16]</sup>. Magnifying endoscopy, which provides images of fine mucosal detail that correspond to histologic structure, is now widely accepted for the study of GI disorders. After magnification, a characteristic relief called a pit-pattern is visible on the surface of the esophageal epithelium. The most widely known classification of esophageal pit-patterns in relation to histology were described by Endo *et al*<sup>[17]</sup>. The usefulness of this classification is its ability to predict the presence of SIM based on the structure of the mucosal surfaces.

BE can be subdivided into long-segment BE ( $\geq 3$  cm) and short-segment BE ( $< 3$  cm)<sup>[18]</sup>. Just as for long-segment BE, histologic confirmation of SIM in short-segment BE is also needed; not only long-segment BE but also short-segment BE, have been known as major risk factors for the development of EAC<sup>[19,20]</sup>. Furthermore, small areas of dysplasia can be difficult to diagnose.

The aim of this study was to determine whether the magnified observation of short-segment BE is useful for the detection of SIM and for the prediction of histological diagnosis compared with MB chromoendoscopy.

## MATERIALS AND METHODS

Patients with short-segment BE were prospectively enrolled into this study at Soonchunhyang University Hospital in South Korea between March 2002 and June 2002 (Figure 1). Patients underwent magnifying endoscopy, which could enhance the image up to  $\times 80$  (Olympus GIF-Q240Z, Japan) (Figure 2). Mucus was removed by a 10% solution of acetylcysteine instillation. The magnified images were analyzed with respect to pit-patterns, which were simultaneously classified into five epithelial types [I (small round), II (straight), III (long oval), IV (tubular), V (villous)] by Endo's classification (Figure 3). Then, a 0.5% solution of methylene blue was sprayed over the columnar mucosa. The excess of dye was flushed away with 50 mL of water after 2 min. The patterns of the magnified image and MB staining were analyzed. Biopsies were obtained from the regions previously observed by magnifying endoscopy and MB chromoendoscopy (Figure 4). If the biopsies were unsatisfactory or inaccurately targeted, other biopsies were performed. Every biopsy was classified into three types of epithelium by a pathologist: the fundic type, cardiac type and SIM (Figure 5). The study was performed after receiving approval from the Institutional Review Board of the Soonchunhyang University in Seoul, South Korea.

Figure 2 Magnifying endoscopy. A: Magnifying endoscopy up to  $\times 80$  (Olympus GIF-Q240Z,  $\times 80$ ); B: Magnified image of the short-segment Barrett's esophagus.

Figure 3 Classification of pit-pattern of Barrett's esophagus by Magnifying endoscopy (Endo's classification). A: I (small round); B: II (straight); C: III (long oval); D: IV (tubular); E: V (villous).

### Statistical analysis

To analyze the relationships among the variables, Fisher's exact test was used. We performed an exact McNemar's test to compare the diagnostic value of MB chromoendoscopy and magnifying endoscopy for detection of SIM. Data analysis was performed using SPSS 14.0. All statistical hypotheses were verified at a significance level of  $P < 0.05$ .

## RESULTS

### Patient characteristics

Thirty patients, 16 men and 14 women, with an average age of 44.8 years (range 17-75 years), were enrolled into this study. All of the patients had tongue-like columnar epithelium in the tubular esophagus within 3 cm from the

**Figure 4 Methylene blue chromoendoscopy.** A: 0.5% solution of methylene blue (MB) was sprayed over the columnar mucosa; B: Biopsies were obtained from the regions previously observed by magnifying endoscopy and MB chromoendoscopy.

Esophagogastric junction, as identified by previous standard endoscopy. No patient had previous histologically proven SIM in the columnar lined epithelium.

The results for individual patients, including the pit-

pattern, MB staining, histologic diagnosis and reflux esophagitis, are listed in Table 1. Distributions of the types of pit-pattern, MB staining, and histologic diagnosis are shown in Figure 6.

<sup>1</sup>Fisher's exact test:  $P = 0.538$ ; <sup>2</sup>Sensitivity = 100%, specificity = 91.3%, accuracy = 92.3%, PPV = 60%, NPV = 100%, Fisher's exact test:  $P = 0.004$ ; <sup>3</sup>Sensitivity = 100%, specificity = 60.9%, accuracy = 65.4%, PPV = 25%, NPV = 100%, Fisher's exact test:  $P = 0.085$ . SIM: Specialized intestinal metaplasia; PPV: Positive predictive value; NPV: Negative predictive value; MB: Methylene blue.

Histologic examination revealed SIM in 3 of 26 patients (11.5%). The remaining four patients could not be diagnosed due to the insufficiency of the specimens for histologic examination. Reflux esophagitis was diagnosed by histologic examination in 11 of 26 patients (42.3%). The patients without RE did not have a history of GERD. SIM in BE was not more common in patients with reflux esophagitis (2 patients, 18.1%) than in those without it (1 patient, 5.2%;  $P = 0.538$ , Table 2).

#### Relationship between type of pit-pattern and SIM

The fine mucosal patterns (pit-pattern) of 30 patients were recorded and classified according to Endo's classification. The specimens obtained previously from the regions observed by magnification without MB staining underwent histologic examinations to determine the relationship between the type of pit-pattern and SIM by magnifying endoscopy.

Of the 30 patients, one case was type I (small round);

four cases were type II (straight); eight cases were type III (long oval); 12 cases were type IV (tubular); and five cases were type V (villous). Type IV (tubular) was the most common epithelial type. As shown in Table 1 and Figure 6, three of five patients with a type V (villous) epithelial pattern had SIM. Twenty-one patients without type V epithelial patterns did not have SIM ( $P = 0.004$ ). These results suggest that a type V (villous) epithelial pattern is compatible with SIM, and the sensitivity, specificity, accuracy, positive predictive value, and negative predictive value of type V pit-pattern in detecting SIM were 100%, 91.3%, 92.3%, 60% and 100%, respectively (Table 2).

#### Relationship between MB staining and SIM

Out of 30 patients, 13 patients (43.3%) had positive MB staining, and 17 patients (56.7%) had negative MB staining. One of the 13 patients with positive MB staining and three of the 17 patients with negative MB staining did not receive a histological diagnosis due to insufficient specimens. As shown in Table 1 and Figure 6, three of 12 patients with positive MB staining had SIM, whereas 14 patients with negative MB staining did not have SIM ( $P = 0.085$ ). The sensitivity, specificity, accuracy, positive predictive value, and negative predictive value of MB staining in detecting SIM were 100%, 60.9%, 65.4%, 25% and 100%, respectively (Table 2).

#### Diagnostic value of pit-pattern evaluation and MB staining for detecting SIM

In comparison with MB staining, pit-pattern evaluation according to Endo's classification had much higher specificity (91.3% *vs* 60.9%), accuracy (92.3% *vs* 65.4%), and positive predictive value (60% *vs* 20%) for the detection of SIM in BE; however, it had a similar sensitivity (both 100%) and negative predictive value (both 100%). The exact McNemar's test revealed that the specificity and accuracy of pit-pattern evaluation was significantly superior to that of MB staining for detecting SIM by ( $P = 0.0391$ ;

**Table 3** Diagnostic value of pit-pattern evaluation and metaplasia staining for detection of specialized intestinal metaplasia ( $n = 3$ )

	TP	TN	P value
Pit-pattern	3	21	
MB stain	3	14	
	Pit-pattern	MB stain

## DISCUSSION

SIM in BE is a risk factor for EAC. A strong relationship has been established between the presence of SIM and the subsequent development of adenocarcinoma<sup>[5,6]</sup>.

Detecting esophageal neoplasias at an earlier stages will allow for the possibility of intervening more quickly and lowering the mortality from EAC. However, the effectiveness of the screening and surveillance of BE has not been studied in randomized, controlled trials. For example, various endoscopic approaches and advancements have shown great promise, yet the confirmation of their utility in high-quality clinical trials has yet to occur<sup>[21,22]</sup>.

Canto *et al.*<sup>[11]</sup> found that the overall accuracy of MB staining for detecting SIM was 95%. However, the same level of accuracy was not achieved in other studies. Dave *et al.*<sup>[16]</sup> reported that MB staining was associated with prolonged endoscopy, increased patient discomfort, and potentially serious adverse events; furthermore, it was neither very sensitive nor specific for SIM. According to Horwhat *et al.*<sup>[13]</sup>, chromoendoscopy might decrease the number of biopsies without an improving the overall detection rate of dysplasia compared with a conventional four-quadrant biopsy. Wasielica-Berger *et al.*<sup>[14]</sup> and Ferguson *et al.*<sup>[23]</sup> found no convincing data indicating that pit-pattern evaluations may replace multiple biopsies, according to the Seattle recommendations for the detection of SIM in BE. Therefore, the aim of this study was to determine whether the magnified observation of short-segment BE is useful for the detection of SIM or for the prediction of histological diagnosis, compared with MB chromoendoscopy.

Oberg *et al.*<sup>[3]</sup> showed that a long duration of reflux symptoms (RR = 1.3; 95%CI: 1.2-1.7) were independently associated with an increased risk of developing high-grade dysplasia or esophageal adenocarcinoma. However, SIM in BE was not more common in patients with reflux esophagitis who had a history of GERD compared with those without such a history ( $P = 0.538$ ).

Endo's study found that the type IV (tubular) and type V (villous) classifications were characteristic of

SIM. Similarly, we found a significant correlation between pit-patterns evaluated according to Endo's classifications and histology. The differences in the frequency of SIM were related to the particular mucosal pit-pattern types. We frequently found SIM in places with a type V (villous) epithelial pattern (3 of 5 patients). SIM did not coexist in any case with a non-type V epithelial pattern. Therefore, the surface structure of type V (villous) epithelial pattern is compatible with SIM ( $P = 0.004$ ).

MB is a vital stain that is taken up by actively absorbing tissues, such as the small intestinal and colonic epithelium. In BE, areas of intestinal metaplasia are positively stained, whereas non-absorptive epithelia, such as those found in squamous or gastric mucosa, remain unstained. We found SIM in places with MB-positive stained epithelium (3 of 12 patients). No case of SIM was associated with MB-negative stained epithelium. However, MB-positive staining cannot be considered characteristic of SIM, as the difference was not significant ( $P = 0.085$ ).

Compared with MB staining, the pit-pattern evaluation by magnifying endoscopy according to Endo's classification had much higher specificity (91.3% *vs* 60.9%) and positive predictive value (60% *vs* 20%) for the detection of SIM in BE, despite similar sensitivity (100% *vs* 100%) and negative predictive values (100% *vs* 100%). The specificity and accuracy of pit-pattern evaluations were significantly superior, according to McNemar's exact test, to those of MB staining for the detection of SIM ( $P = 0.0391$ ).

There were some limitations to our study. First, we found no sites with dysplasia or cancer cells, which may be attributed to the relatively small number of patients. In addition, the present study enrolled too few patients (3 out of 5 patients with type V pit-pattern). However, this study was very difficult regarding the recruitment of patients due to the refusal of many of the patients and the quite rare prevalence of this condition in Korea<sup>[24,25]</sup>. Second, long-segment BEs were excluded in our study. The risk of progression to malignancy appears to increase significantly with increasing lengths of BE<sup>[26,27]</sup>. It would be worth knowing about pit-patterns in long-segment, salmon-colored mucosa and also pit-pattern correlation with histological diagnosis of BE. However, there is conflicting evidence in the literature<sup>[28]</sup>. Short-segment and long-segment BE are biologically identical and have significant if not equivalent malignant potential. In addition, Kim *et al.*<sup>[29]</sup> showed that patients with long-segment BE are very rare in South Korea. So, we focused on short-segment BE in this study. Third, we did not address whether the simultaneous use of magnifying endoscopy and MB staining might improve the diagnostic yield. Sharma *et al.*<sup>[12]</sup> reported that high magnification chromoendoscopy might be a useful clinical tool for the increased detection of patients with intestinal metaplasia. Statistically, there is no doubt that the results are improved when magnifying endoscopy is performed with MB staining simultaneously, if both are characteristics of SIM. In our study, MB-positive staining could not be considered a characteristic of SIM. Therefore, we did not

try to demonstrate that the simultaneous performance of magnifying endoscopy and MB staining could improve the results. Fourth, we did not count the total number of biopsies. Thus, we could not show that the magnifying endoscopy might decrease the number of biopsies, generating an overall improvement in the detection rate of dysplasia compared with a conventional, four-quadrant biopsy.

In summary, we identified the usefulness of magnifying endoscopy for the diagnosis of SIM in patients with short-segment BE from preceding studies. However, we were still unable to demonstrate the usefulness of MB chromoendoscopy. Because we did not count the total number of biopsies, we could not confirm that both of the endoscopic examinations decreased the number of biopsies, costs and inspection time. We found that both methods were time-consuming and caused patient discomfort. These are among the disadvantages of the other studies.

Various endoscopic approaches and advancements have shown great promise. Still, careful endoscopic observation and stepwise four quadrant biopsy still represent the standard for the surveillance of BE<sup>[21,30]</sup>. In our study, the evaluation of mucosal surfaces under magnification has potential to allow the selection of the biopsy site according to the pit-pattern. In conclusion, the magnified observation of short-segment BE according to the mucosal pattern and its classification can be predictive for SIM.

## COMMENTS

### Background

Crosssectional and descriptive studies suggest that specialized intestinal metaplasia (SIM) either coexists with or precedes a significant majority of esophageal adenocarcinoma (EAC) cases and is the likely precursor lesion.

### Research frontiers

Detecting esophageal neoplasia at an earlier stage will allow for the possibility of intervening more quickly and the lowering mortality due to EAC. However, the effectiveness of screening and surveillance of Barrett's esophagus (BE) has not been studied in randomized controlled trials. In addition, discerning SIM and obtaining satisfactory target biopsies at the region of interest by standard endoscopic observation is difficult.

### Innovations and breakthroughs

The sensitivity, specificity, accuracy, positive predictive value, and negative predictive value of pit pattern in detecting SIM were 100%, 91.3%, 92.3%, 60% and 100%, respectively ( $P = 0.004$ ). The sensitivity, specificity, accuracy, positive predictive value, and negative predictive value of methylene blue (MB) staining in detecting SIM were 100%, 60.9%, 65.4%, 25% and 100%, respectively ( $P = 0.085$ ). The specificity and accuracy of the pit-pattern evaluation were significantly superior compared with MB staining for detecting SIM by comparison of exact McNemar's test ( $P = 0.0391$ ).

### Applications

The study results suggests that the magnified observation of short-segment BE according to the mucosal pattern and its classification can be predictive for SIM.

### Terminology

BE is characterized by the replacement of the squamous epithelia in the distal esophagus by columnar epithelia (gastric metaplasia), irrespective of the presence of specialized intestinal metaplasia.

### Peer review

The paper found that the magnified observation of a short-segment BE according to its mucosal pattern and classification can be predictive of SIM. It's an

informative manuscript, nicely written.

induced with 6 injections of cerulein (Cn, 50  $\mu$ g/kg) at 1-h intervals, then intraperitoneal injection of lipopolysaccharide (LPS, 7.5 mg/kg) in CHOP-deficient (*Chop*<sup>-/-</sup>) mice and wild-type (WT) mice. Animals were sacrificed under anesthesia, 3 h or 18 h after LPS injection. Serum amylase, lipase, and cytokines [interleukin (IL)-6 and tumor necrosis factor (TNF)- $\alpha$ ], pathological changes, acute lung injury, and apoptosis in the pancreas were evaluated. Serum amylase and lipase activities were detected using a medical automatic chemical analyzer. Enzyme-linked immunosorbent assay kits were used to evaluate TNF- $\alpha$  and IL-6 levels in mouse serum and lung tissue homogenates. Apoptotic cells in sections of pancreatic tissues were determined by terminal deoxynucleotidyl transferase-mediated dUTP-biotin nick-end labeling (TUNEL) analysis. The mouse carotid arteries were cannulated and arterial blood samples were collected for PaO<sub>2</sub> analysis. The oxygenation index was expressed as PaO<sub>2</sub>/FiO<sub>2</sub>.

**RESULTS:** Administration of Cn and LPS for 9 and 24 h induced severe acute pancreatitis in *Chop*<sup>-/-</sup> and WT mice. When comparing *Chop*<sup>-/-</sup> mice and WT mice, we observed that CHOP-deficient mice had greater increases in serum TNF- $\alpha$  (214.40  $\pm$  19.52 pg/mL vs 150.40  $\pm$  16.70 pg/mL;  $P$  = 0.037), amylase (4236.40  $\pm$  646.32 U/L vs 2535.30  $\pm$  81.83 U/L;  $P$  = 0.041), lipase (1678.20  $\pm$  170.57 U/L vs 1046.21  $\pm$  35.37 U/L;  $P$  = 0.008), and IL-6 (2054.44  $\pm$  293.81 pg/mL vs 1316.10  $\pm$  108.74 pg/mL;  $P$  = 0.046) than WT mice. The histopathological changes in the pancreases and lungs, decreased PaO<sub>2</sub>/FiO<sub>2</sub> ratio, and increased TNF- $\alpha$  and IL-6 levels in the lungs were greater in *Chop*<sup>-/-</sup> mice than in WT mice (pancreas: *Chop*<sup>-/-</sup> vs WT mice, hemorrhage,  $P$  = 0.005; edema,  $P$  = 0.005; inflammatory cells infiltration,  $P$  = 0.005; total scores,  $P$  = 0.006; lung: hemorrhage,  $P$  = 0.017; edema,  $P$  = 0.017; congestion,  $P$  = 0.017; neutrophil infiltration,  $P$  = 0.005, total scores,  $P$  = 0.001; PaO<sub>2</sub>/FiO<sub>2</sub> ratio: 393  $\pm$  17.65 vs 453.8,  $P$  = 0.041; TNF- $\alpha$ :  $P$  = 0.043; IL-6,  $P$  = 0.040). Results from TUNEL analysis indicated increased acinar cell apoptosis in

### Abstract

**AIM:** To investigate the pathophysiological role of C/EBP homologous protein (CHOP) in severe acute pancreatitis and associated lung injury.

**METHODS:** A severe acute pancreatitis model was

mice following the induction of acute pancreatitis. However, *Chop*<sup>-/-</sup> mice displayed significantly reduced pancreatic apoptosis compared with the WT mice (201.50 ± 31.43 vs 367.00 ± 47.88, *P* = 0.016).

**CONCLUSION:** These results suggest that CHOP can exert protective effects against acute pancreatitis and limit the spread of inflammatory damage to the lungs.

**Key words:** C/EBP homologous protein; Acute pancreatitis; Lung injury; Cytokines; Apoptosis

**Core tip:** We found that mice lacking C/EBP homologous protein (CHOP) had aggravated acute pancreatitis-induced increases in the severity of pancreatic pathology, pancreatitis-associated lung injury, and cytokines interleukin-6 and tumor necrosis factor- $\alpha$  levels compared with wild-type (WT) mice. Pancreatic apoptosis was also lower in *Chop*<sup>-/-</sup> mice than in WT mice during acute pancreatitis. These results suggest that CHOP exerts protective effects against acute pancreatitis and limits the spread of inflammatory damage to the lungs.

## INTRODUCTION

Acute pancreatitis is an acute inflammatory process of sudden onset, and occurs in the peripheral and internal areas of the pancreas. At an early stage of the disease, acute pancreatitis induces multiple organ system dysfunction syndromes in the lung, kidney, liver, and other organs. These are major contributory factors to the high mortality rate of severe acute pancreatitis<sup>[1,2]</sup>. Acute pancreatitis can spread systemically through systemic inflammatory responses<sup>[3]</sup>. Acute lung injury occurs frequently in acute pancreatitis and is a major component of acute pancreatitis-associated multiple organ dysfunction<sup>[4]</sup>. The overproduction of several cytokines and non-cytokine inflammatory mediators may account for the systemic manifestations of acute pancreatitis<sup>[5-7]</sup>.

Acinar cell damage initiates acute pancreatitis, resulting in local activation of the immune system and local inflammation of the pancreas<sup>[5]</sup>. The local pro-inflammatory response to acinar cell damage is counteracted by an anti-inflammatory response; however, uncontrolled local inflammation can lead to generalized inflammation and systemic inflammatory response syndrome<sup>[8]</sup>. Pancreatic acinar cell damage during acute pancreatitis generally oc-

curs through a combination of apoptosis and necrosis<sup>[9]</sup>. Recent studies have shown that mild acute pancreatitis is associated with extensive apoptotic acinar cell death, whereas severe acute pancreatitis involves acinar cell necrosis with minimal apoptosis<sup>[10,11]</sup>. Acinar necrosis-induced inflammation can progress systemically, causing multiple organ failure and death. Studies have proposed that acinar apoptosis might protect the pancreas from local and systemic cytokine release<sup>[10,11]</sup>.

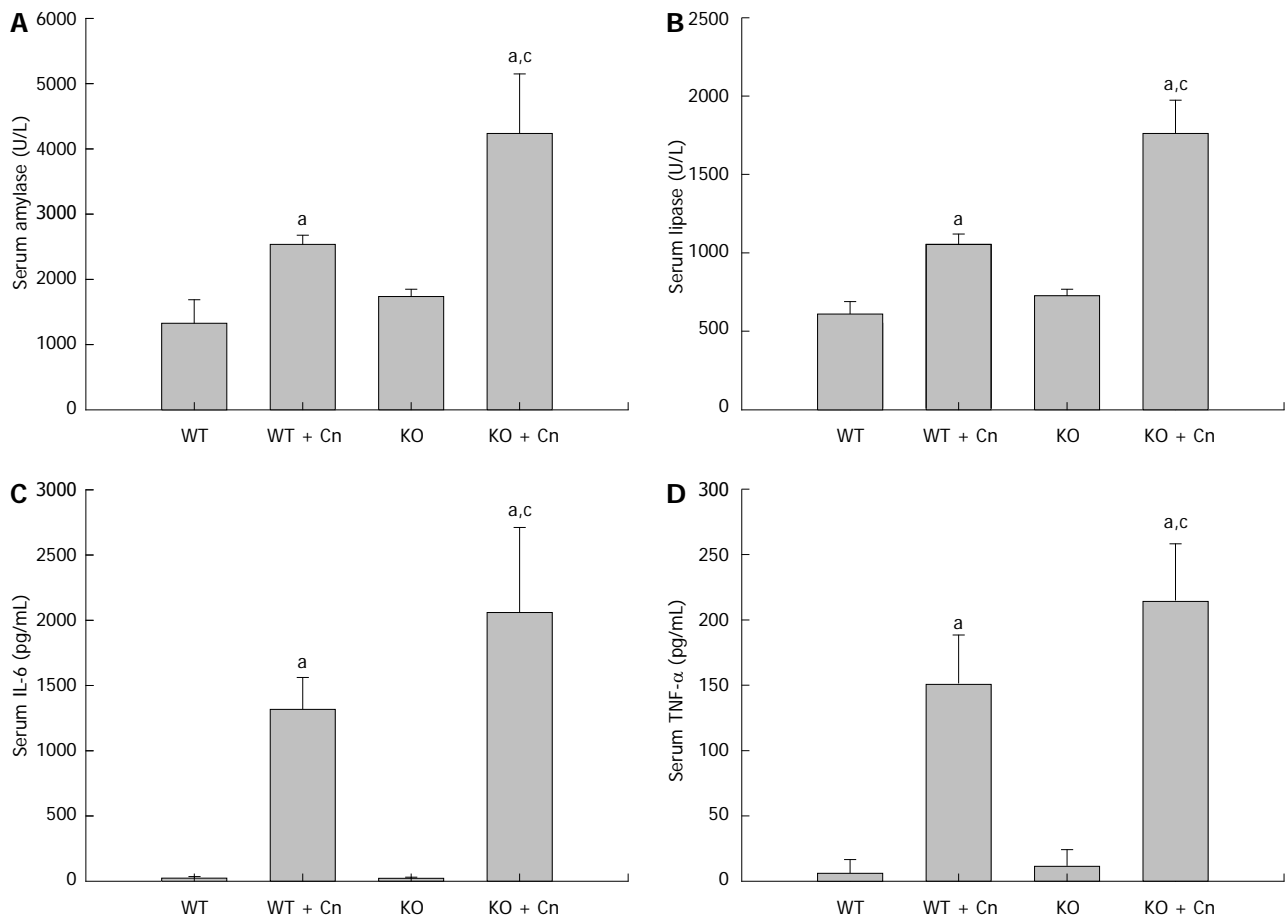

C/EBP homologous protein (CHOP), also known as G1 arrest and DNA damage 153 (Gadd153), is the 19.2-kDa protein product of DNA damage-induced transcript 3 (Ddit3) and a key regulator of stress responses. CHOP is known to play an important role in the induction of apoptosis. Overexpression of CHOP promotes apoptosis in several cell lines, whereas CHOP-deficient (*Chop*<sup>-/-</sup>) cells are resistant to endoplasmic reticulum (ER) stress-induced apoptosis<sup>[12]</sup>. Experiments using *Chop*<sup>-/-</sup> mice revealed that CHOP-mediated apoptosis contributes to the pathogenesis of a number of ER stress-related diseases<sup>[13]</sup>. ER stress is the most potent inducer of CHOP expression and CHOP is known as a pro-apoptotic factor<sup>[14,15]</sup>. It is also involved in several physiological adaptive processes<sup>[15,16]</sup>, including mitochondrial<sup>[17]</sup> and oxidative stress<sup>[18]</sup>, amino acid starvation<sup>[19]</sup>, and differentiation of keratinocytes<sup>[20]</sup> and osteoblasts<sup>[21]</sup>. Studies have reported CHOP upregulation in a murine model of acute pancreatitis<sup>[8,22]</sup>; however, the mechanism(s) and functional consequences of acute pancreatitis-induced CHOP expression are not well-understood. We hypothesized that CHOP plays an important role in acute pancreatitis and influences acute pancreatitis-induced systemic inflammation and acute lung injury. In this study, we used *Chop*<sup>-/-</sup> mice to investigate the pathogenesis of acute pancreatitis.

## MATERIALS AND METHODS

### Animal experiments

All animal care and experimental procedures were approved by the Animal Care Committee of the College of Medicine, National Taiwan University. Mice deficient in CHOP (*Chop*<sup>-/-</sup>) on a C57BL/6 background were purchased from Jackson Laboratories (Bar Harbor, ME, United States). Adult male *Chop*<sup>-/-</sup> mice and wild-type (WT) C57BL/6 mice weighing 18-25 g were used in this study. Mice were housed at a constant temperature of 20 °C-22 °C with a 12 h:12 h light-dark cycle.

A mouse model of severe acute pancreatitis induced by cerulein (Cn) and lipopolysaccharide (LPS) has been well-established<sup>[20,21]</sup>. The *Chop*<sup>-/-</sup> and WT mice were injected with 6 doses of Cn (50  $\mu$ g/kg; Sigma, St Louis, MI, United States) at 1-h intervals, and then intraperitoneal injection with LPS (7.5 mg/kg; derived from *Escherichia coli* 0111:B4, Sigma), to induce severe acute pancreatitis. Animals were sacrificed under anesthesia (tribromoethanol, 250 mg/kg, dissolved in 2-methyl-2-butanol) by intraperitoneal injection at 3 h or 18 h after LPS injection, and their pancreases and lungs were dis-

**Figure 1** Mice deficient in C/EBP homologous protein displayed increased serum amylase, lipase, interleukin-6, and tumor necrosis factor- $\alpha$ . Acute pancreatitis was induced using cerulein (Cn) and lipopolysaccharide (LPS) in Chop<sup>-/-</sup> (KO) and wild-type (WT) mice. Serum levels of amylase (A), lipase (B), interleukin (IL)-6 (C), and tumor necrosis factor (TNF)- $\alpha$  (D), were detected 24 h (A-C) and 9 h (D) after induction of acute pancreatitis. Data are presented as mean  $\pm$  SEM ( $n = 6$ ). The data are normally distributed. <sup>a</sup> $P < 0.05$  compared with WT mice without pancreatitis; <sup>c</sup> $P < 0.05$  vs WT mice with pancreatitis.

sected immediately<sup>[23,24]</sup>. Blood samples were collected for amylase, lipase, and cytokine assays. After rinsing with saline and blotting on paper, segments of the tissues were fixed and embedded in paraffin wax for histological analysis. Other tissue parts were fully homogenized. The lung tissue homogenates were stored in liquid nitrogen before use to evaluate tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) and interleukin-6 (IL-6) levels.

#### Histological examination

To evaluate the morphological severity of acute pancreatitis, the pancreas was fixed in 10% formaldehyde for 24 h, embedded in paraffin, and stained with hematoxylin and eosin. A pathologist who was blinded to the treatment protocol scored the tissues for edema, inflammatory infiltration, and hemorrhage in 10 fields, each on a scale of 0-3. Grades of edema were 0, absent or rare; 1, edema in the interlobular space; 2, edema in the intralobular space; 3, isolated island shape of pancreatic acinus. Inflammation was graded as 0, absent; 1, mild; 2, moderate; 3, severe. Parenchymal hemorrhage was graded as 0, absent; 1, mild; 2, moderate; 3, severe. To evaluate the morphological severity of acute pancreatitis-associated lung injury, lung tissue was rapidly removed and

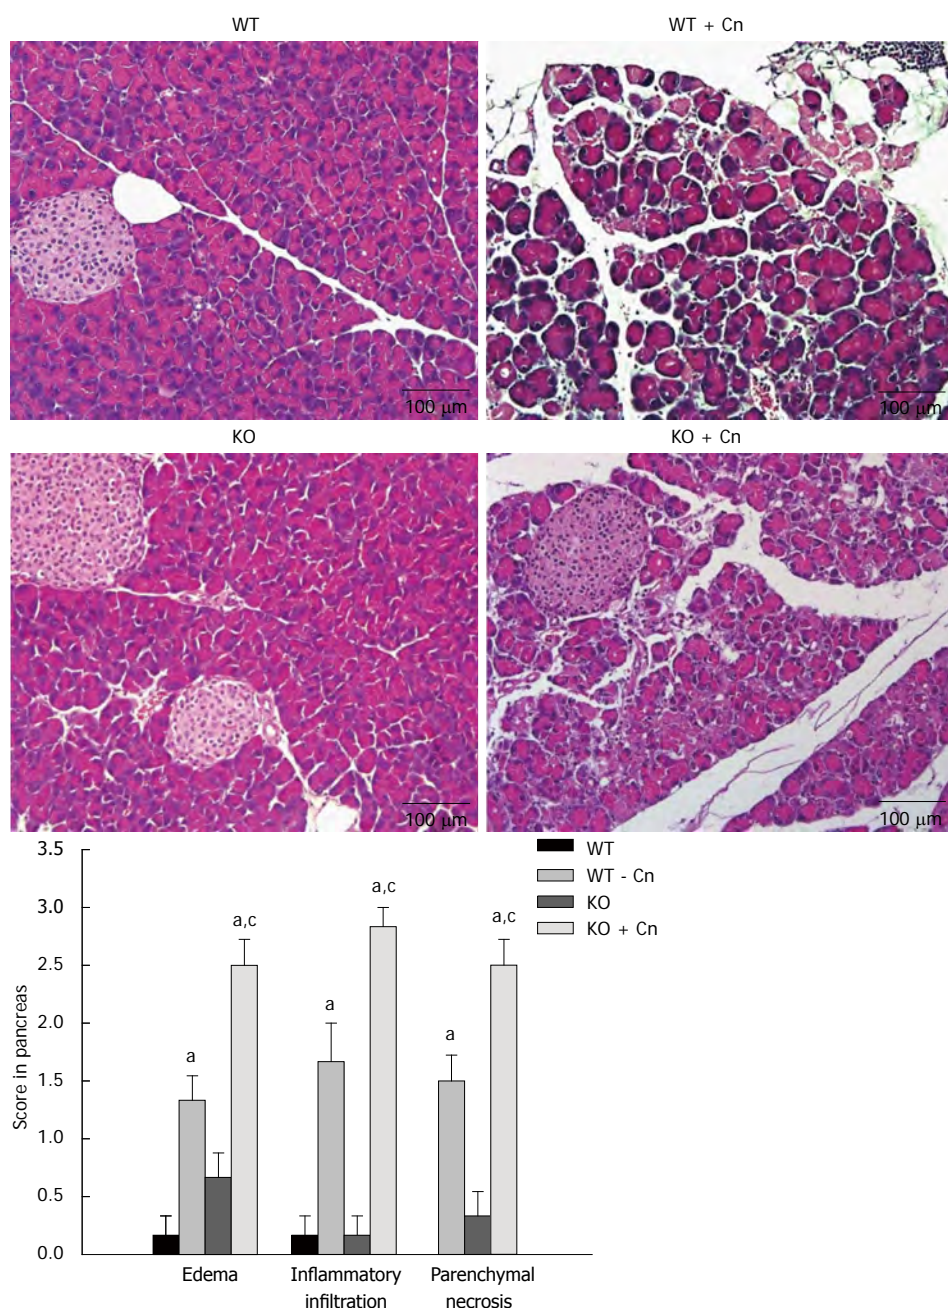

immersed in 10% formalin. Two areas of the lung, one central and one peripheral, were embedded in paraffin. Histological sections were stained with hematoxylin and eosin. Pulmonary alterations were scored by an experienced pathologist in a blind manner. Polymorphonuclear cellularity, pulmonary edema, congestion, necrosis, and hemorrhage were graded, each on a scale of 0-3.

#### Measurement of PaO<sub>2</sub>/FiO<sub>2</sub> ratio

Twenty-four hours after LPS injection, mice were anesthetized with tribromoethanol (250 mg/kg) dissolved in 2-methyl-2-butanol by intraperitoneal injection. The mouse carotid arteries were cannulated and arterial blood samples were collected for PaO<sub>2</sub> analysis. The oxygenation index was expressed as PaO<sub>2</sub>/FiO<sub>2</sub>.

#### Analysis of cell apoptosis

Apoptotic cells in sections of pancreatic tissues were determined using a TdT-Frag ELTM DNA fragmentation detection kit (Oncogene Research Products, Boston, MA, United States) according to the manufacturer's instruction. Terminal deoxynucleotidyl transferase-mediated dUTP-biotin nick-end labeling (TUNEL) analysis was conducted to detect cells containing labeled DNA frag-

**Figure 2** Experimental acute pancreatitis in *Chop*<sup>-/-</sup> mice. Acute pancreatitis was induced using cerulein (Cn) and lipopolysaccharide (LPS) in *Chop*<sup>-/-</sup> (KO) and wild-type (WT) mice. Histological examination was performed 24 h after induction of acute pancreatitis. Representative histological changes in pancreatic sections stained with hematoxylin and eosin are shown. Scale bar = 100 μm. Pathological changes in the pancreas were scored. Data are presented as mean ± SEM (*n* = 4). The data are normally distributed. <sup>a</sup>*P* < 0.05 vs WT mice without pancreatitis; <sup>c</sup>*P* < 0.050 vs WT mice with pancreatitis.

ments. These were revealed as green staining in cell nuclei, indicating the internucleosomal cleavage of DNA.

#### Measurements of serum amylase, lipase, and cytokines

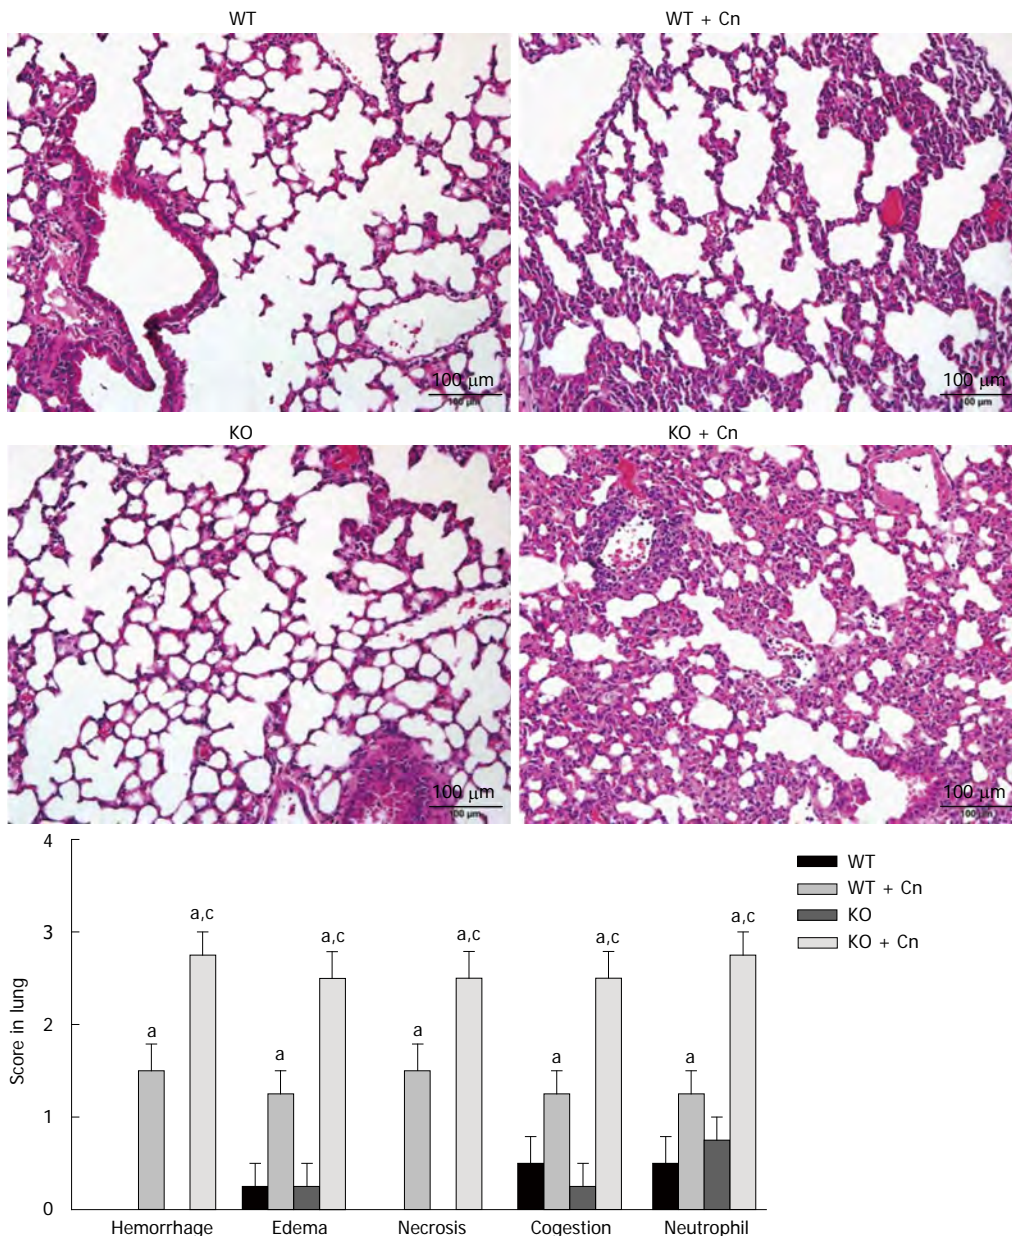

Serum amylase and lipase activities were detected using a medical automatic chemical analyzer. Enzyme-linked immunosorbent assay kits were used to evaluate the levels of TNF-α (R and D Systems) and IL-6 (Assaypro) in

mouse serum and lung tissue homogenates following the induction of acute pancreatitis.

#### Statistical analysis

Data are expressed as mean ± SEM. Statistical comparisons between experimental groups were performed using one-way analysis of variance test followed by the two-tailed Student *t* test. A *P* value < 0.05 was considered significant.

**Figure 3** Experimental acute pancreatitis-associated lung injury in *Chop*<sup>-/-</sup> mice. Acute pancreatitis was induced using cerulein (Cn) and lipopolysaccharide in *Chop*<sup>-/-</sup> (KO) and wild-type (WT) mice. Histological examination was performed 24 h after induction of acute pancreatitis. Representative histological changes in lung sections stained with hematoxylin and eosin are shown. Scale bar = 100 μm. Pathological changes in lungs were scored. Data are presented as mean ± SEM (*n* = 4). The data are normally distributed. <sup>a</sup>*P* < 0.050 vs WT mice without pancreatitis; <sup>c</sup>*P* < 0.05 vs WT mice with pancreatitis.

## RESULTS

### Mice deficient in CHOP displayed acute pancreatitis-induced increases in serum amylase, lipase, IL-6, and TNF-α

Administration of Cn and LPS for 9 and 24 h induced severe acute pancreatitis in *Chop*<sup>-/-</sup> and WT mice. Following induction of acute pancreatitis, mice displayed increased serum amylase and lipase activities and TNF-α and IL-6 levels (Figure 1). When comparing *Chop*<sup>-/-</sup> mice and WT mice, we observed that CHOP-deficient mice demonstrated significantly greater increases in serum TNF-α ( $214.40 \pm 19.52$  pg/mL *vs*  $150.40 \pm 16.70$  pg/mL; *P* = 0.037), amylase ( $4236.40 \pm 646.32$  Units/L *vs*

$2535.30 \pm 81.83$  Units/L; *P* = 0.041), lipase ( $1678.20 \pm 170.57$  Units/L *vs*  $1046.21 \pm 35.37$  Units/L; *P* = 0.008), and IL-6 ( $2054.44 \pm 293.81$  pg/mL *vs*  $1316.10 \pm 108.74$  pg/mL; *P* = 0.046) than WT mice (Figure 1).

### Mice deficient in CHOP displayed increased acute pancreatitis-induced changes in lung histopathology and TNF-α and IL-6 levels

After administration of Cn and LPS for 24 h, mice showed features of typical acute pancreatitis in the pancreas, including the expansion of interlobular and intralobular spaces by moderate to severe interstitial edema, extensive infiltration of inflammatory cells, and pancreatic hemorrhage (Figure 2). They also displayed

**Figure 4** The PaO<sub>2</sub>/FiO<sub>2</sub> ratio in *Chop*<sup>-/-</sup> mice with acute pancreatitis. Acute pancreatitis was induced by using cerulein (Cn) and lipopolysaccharide in *Chop*<sup>-/-</sup> (KO) mice and wild-type (WT) mice. The PaO<sub>2</sub>/FiO<sub>2</sub> ratio was detected 24 h after induction of acute pancreatitis in mice. Data are presented as mean ± SEM (*n* = 6). The data are normally distributed. <sup>a</sup>*P* < 0.05 vs wild type mice without pancreatitis; <sup>c</sup>*P* < 0.05 vs wild type mice with pancreatitis.

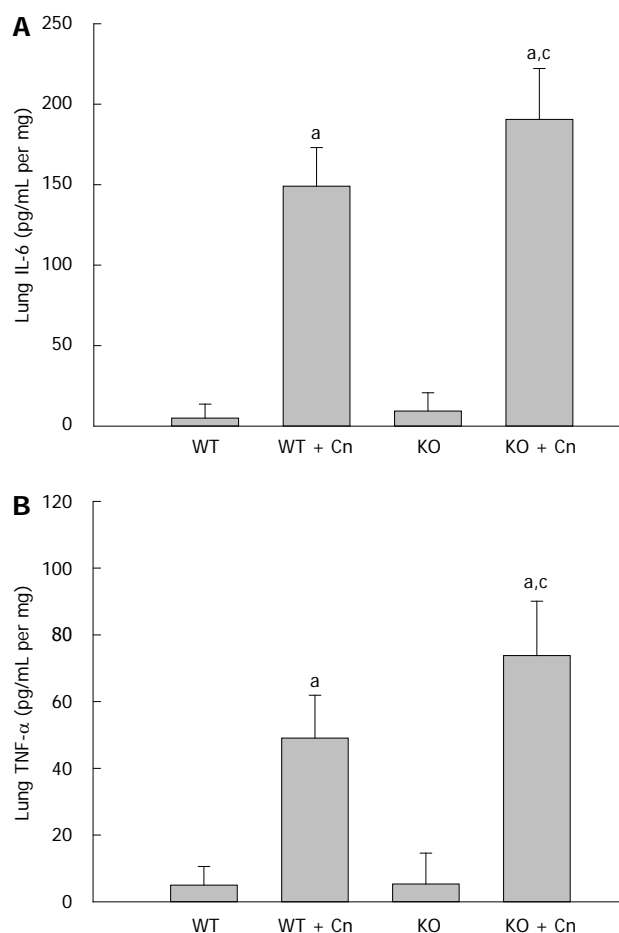

pulmonary changes such as marked pulmonary edema, inflammatory infiltration, and alveolar collapse (Figure 3), and decreased PaO<sub>2</sub>/FiO<sub>2</sub> ratio (an oxygenation index) (Figure 4). The levels of TNF-α and IL-6 in the lungs were markedly increased in mice with acute pancreatitis (Figure 5). Histopathological changes in the pancreases and lungs, decreased PaO<sub>2</sub>/FiO<sub>2</sub> ratio, and the increases of levels of TNF-α and IL-6 in the lungs were greater in *Chop*<sup>-/-</sup> mice than in WT mice (pancreas: *Chop*<sup>-/-</sup> vs WT mice, hemorrhage, *P* = 0.005, edema, *P* = 0.005, inflammatory cells infiltration, *P* = 0.005, total scores, *P* = 0.006; lung: hemorrhage, *P* = 0.017, edema, *P* = 0.017, congestion, *P* = 0.017, neutrophils infiltration, *P* = 0.005, total scores, *P* = 0.001; PaO<sub>2</sub>/FiO<sub>2</sub> ratio: 393 ± 17.65 vs 453.8, *P* = 0.041; TNF-α: *P* = 0.043; IL-6, *P* = 0.040).

#### Mice deficient in CHOP showed reduced acute pancreatic-induced apoptosis in the pancreas

Results from TUNEL analysis indicated increased acinar cell apoptosis (Figure 6) in mice following the induction of acute pancreatitis. However, *Chop*<sup>-/-</sup> mice displayed significantly reduced pancreatic apoptosis vs the WT mice (201.50 ± 31.43 vs 367.00 ± 47.88, *P* = 0.016; Figure 6).

## DISCUSSION

In a murine model, acute pancreatitis and its associated lung injury induced by Cn/LPS injection are compatible with the clinical manifestations of severe acute pancreatitis with lung damage<sup>[25,26]</sup>. In our previous study, we demonstrated the upregulation of pancreatic CHOP expression following Cn/LPS-induced acute pancreatitis. In the present study, we evaluated the pathophysiological role of CHOP in acute pancreatitis and its associated acute lung injury. Mice deficient in CHOP displayed increases in the severity of pancreatic pathology, increased activities of serum amylase and lipase, increased levels of pancreatitis-

**Figure 5** Mice deficient in C/EBP homologous protein displayed increased interleukin-6, and tumor necrosis factor-α in the lungs. Levels of tumor necrosis factor (TNF)-α (A), and interleukin (IL)-6 (B) were detected 9 h (A) and 24 h (B) after induction of acute pancreatitis in *Chop*<sup>-/-</sup> and wild-type (WT) mice. Data are presented as mean ± SEM (*n* = 6). The data are normally distributed. <sup>a</sup>*P* < 0.050 vs WT mice without pancreatitis; <sup>c</sup>*P* < 0.05 vs WT mice with pancreatitis.

induced systemic inflammatory cytokines such as TNF-α and IL-6, and increased acute lung injury compared with WT mice. Moreover, mice with Cn-induced acute pancreatitis displayed low levels of apoptosis and high levels of necrosis<sup>[27]</sup>. It is known that severe acute pancreatitis is primarily associated with necrosis and, to a lesser extent, with apoptosis in acinar cells. Mild acute pancreatitis, however, is primarily associated with apoptotic acinar cell death<sup>[10]</sup>. In this study, we observed higher numbers of TUNEL-positive pancreatic cells in WT mice than in *Chop*<sup>-/-</sup> mice. These results suggest that CHOP mediates the increases in pancreatic cell apoptosis induced by Cn and LPS.

CHOP has been found to be upregulated during ER stress, which is typically associated with cellular death and associated organ dysfunction<sup>[28]</sup>. Recent evidence has shown that CHOP exerts diverse functional effects in addition to regulation of apoptosis. CHOP contributes to inflammation, the generation of reactive oxygen species, and altered cellular interaction within the extracellular matrix<sup>[29]</sup>. Lozon *et al*<sup>[30]</sup> found that *Chop*<sup>-/-</sup> mice displayed

**Figure 6 Mice deficient in C/EBP homologous protein displayed decreased apoptosis in the pancreas after induction of acute pancreatitis.** Acute pancreatitis was induced using cerulein (Cn) and lipopolysaccharide in *Chop*<sup>-/-</sup> (KO) and wild-type (WT) mice. We performed transferase-mediated dUTP-biotin nick-end labeling (TUNEL) analysis 9 h after induction of acute pancreatitis. Results indicated the presence of TUNEL-positive cells (A, B) in the pancreas. Data are presented as mean  $\pm$  SEM ( $n = 6$ ). The data are normally distributed. <sup>a</sup> $P < 0.050$  vs WT mice without pancreatitis; <sup>c</sup> $P = 0.016$  vs WT mice with pancreatitis.

increased lung edema and permeability, indicating that CHOP plays a protective role after prolonged hyperoxia. Here we observed that CHOP exerts protective effects in a murine model of Cn/LPS-induced acute pancreatitis. This finding is in contrast to those of Suyama *et al.*<sup>[31]</sup>, who reported the role of the ER stress-CHOP pathway in the acceleration of pancreatitis. We applied a different protocol from the study by Suyama *et al.*<sup>[31]</sup> to induce severe acute pancreatitis, observing that experimental acute pancreatitis and acute pancreatitis-associated lung injury induced by 6 episodes of Cn injection and one subsequent LPS injection are compatible with the clinical manifestations of severe acute pancreatitis with lung damage<sup>[25,32-34]</sup>. In the study of Suyama *et al.*<sup>[31]</sup>, 12 doses of Cn and 3 doses of LPS were used to induce acute pancreatitis; they did not, however, evaluate the systemic inflammatory cytokines and the severity of lung injury. Acute lung injury is a major component of acute pancreatitis-associated morbidity and mortality<sup>[34]</sup>. Moreover, Kubisch and Logsdon have examined the effects of secretagogues on the function of acinar cells and the unfolded protein response components including CHOP<sup>[35]</sup>. They found that the cholecystokinin analog CCK8 significantly increased amylase secretion and mRNA expression of CHOP; however, the pathophysiological role of CHOP was still unclear. In our study, we observed that pancreatic and systemic inflammatory responses and acute lung injury during Cn/LPS-induced acute pancreatitis were greater in CHOP-deficient mice than in their WT counterparts. Taken together, these findings suggest that endogenous CHOP may play a systemic anti-inflammatory role and reduce the severity of acute lung injury during acute pancreatitis.

In conclusion, the present findings demonstrate for the first time that CHOP plays a significant role in the induction of apoptosis and prevention of systemic inflammation and acute lung injury during severe acute pancreatitis.

## COMMENTS

### Background

Severe acute pancreatitis is a life-threatening disease. Studies have reported C/EBP homologous protein (CHOP) upregulation in a murine model of acute pancreatitis. However, the mechanism(s) and functional consequences of acute pancreatitis-induced CHOP expression are not well-understood.

### Research frontiers

Overexpression of CHOP promotes apoptosis in several cell lines. The authors hypothesized that CHOP plays an important role in acute pancreatitis and influences acute pancreatitis-induced systemic inflammation and acute lung injury.

### Innovations and breakthroughs

The authors found for the first time that mice lacking CHOP have aggravated acute pancreatitis-induced increases in the severity of pancreatic pathology, pancreatitis-associated lung injury, and cytokine interleukin-6 and tumor necrosis factor- $\alpha$  levels compared with wild-type mice. Pancreatic apoptosis was also lower in *Chop*<sup>-/-</sup> mice than in wild-type mice during acute pancreatitis.

### Applications

CHOP exerts protective effects against acute pancreatitis and limits the spread of inflammatory damage to the lungs.

### Terminology

CHOP, C/EBP homologous protein, also known as G1 arrest and DNA damage

153 (Gadd153), is the 19.2-kDa protein product of DNA damage-induced transcript 3 (Ddit3) and a key regulator of stress responses. CHOP is known to play an important role in the induction of apoptosis.

### Peer review

The authors aimed to investigate the pathophysiological role of CHOP in severe acute pancreatitis and associated lung injury. This is a unique study and the acquired data support that CHOP has a protective effect against acute pancreatitis.

### Abstract

**AIM:** To compare effectiveness, safety, and cost of photodynamic therapy (PDT) and radiofrequency ablation (RFA) in treatment of Barrett's dysplasia (BD).

**METHODS:** Consecutive case series of patients undergoing either PDT or RFA treatment at single center by a single investigator were compared. Thirty-three patients with high-grade dysplasia (HGD) had treatment with porfimer sodium photosensitizer and 630 nm laser (130 J/cm), with maximum of 3 treatment sessions. Fifty-three patients with BD (47 with low-grade dysplasia -LGD, 6 with HGD) had step-wise circumferential and focal ablation using the HALO system with maximum

of 4 treatment sessions. Both groups received proton pump inhibitors twice daily. Endoscopic biopsies were acquired at 2 and 12 mo after enrollment, with 4-quadrant biopsies every 1 cm of the original BE extent. A complete histological resolution response of BD (CR-D) was defined as all biopsies at the last endoscopy session negative for BD. Fisher's exact test was used to assess differences between the two study groups for primary outcomes. For all outcomes, a two-sided *P* value of less than 0.05 was considered to indicate statistical significance.

**RESULTS:** Thirty (91%) PDT patients and 39 (74%) RFA were men (*P* = 0.05). The mean age was  $70.7 \pm 12.2$  and  $65.4 \pm 12.7$  (*P* = 0.10) year and mean length of BE was  $5.4 \pm 3.2$  cm and  $5.7 \pm 3.2$  cm (*P* = 0.53) for PDT and RFA patients, respectively. The CR-D was (18/33) 54.5% with PDT vs (47/53) 88.7% with RFA (*P* = 0.001). One patient with PDT had an esophageal perforation and was managed with non-surgical measures and no perforation was seen with RFA. PDT was five times more costly than RFA at our institution. The two groups were not randomized and had different BD grading are the limitations of the study.

**CONCLUSION:** In our experience, RFA had higher rate of CR-D without any serious adverse events and was less costly than PDT for endoscopic treatment of BD.

**Key words:** Barrett's esophagus; Dysplasia; Photodynamic therapy; Radiofrequency ablation; Cost comparison

**Core tip:** Barrett's esophagus containing dysplasia confers an elevated risk for developing esophageal adenocarcinoma. Photodynamic therapy (PDT) and radiofrequency ablation (RFA) have both been shown in randomized controlled trials to eradicate Barrett's dysplasia (BD) and reduce the risk for disease progres-

sion. We compared the effectiveness, safety, and cost of PDT and RFA in managing BD in consecutive case series performed at single center by single endoscopist. We found that RFA had significantly higher rate of complete histological resolution of Barrett's dysplasia and it was five times less costly than PDT at our institute compared to PDT.

## INTRODUCTION

Adenocarcinoma of the esophagus and gastroesophageal junction (GEJ) is a devastating disease with 5-year survival rate of less than 15%<sup>[1]</sup>. Since 1970s, the incidence of this cancer has increased by more than 500% and it is considered one of the most rapidly increasing cancers in western society<sup>[2,3]</sup>. Barrett's esophagus (BE), defined as metaplasia of the esophageal epithelium, in which squamous mucosa is replaced by a specialized columnar epithelium containing goblet cells, is a premalignant condition of the esophagus with increased risk of developing esophageal adenocarcinoma<sup>[4]</sup>. BE is based on the endoscopic findings of columnar epithelium lining the distal esophagus and diagnosis is confirmed by the presence of specialized intestinal metaplasia in esophageal biopsy specimens<sup>[5]</sup>. BE, sometimes also referred as intestinal metaplasia (IM), is caused by chronic inflammation and injury due to gastroesophageal reflux disease (GERD). BE may be present in as many as 10%-15% of patients with GERD and is associated with a significantly elevated risk of esophageal adenocarcinoma<sup>[4,6-9]</sup>.

Barrett's dysplasia (BD) is a histological diagnosis that one or more clones of epithelial cells have acquired genetic alterations rendering them neoplastic and prone to malignancy. Most recent study suggests the annual rate of cancer development for patients with BE is 0.12%<sup>[10]</sup>. While this rate increases to 6% for patients with BE and HGD<sup>[11]</sup>. Even among experienced pathologists, the extent of inter-observer agreement for the diagnosis of BD is a major problem<sup>[12-14]</sup>. Despite several imperfections such as sampling errors and inter-observer variability, pathologic classification of dysplasia on endoscopic biopsy specimens is the single most predictive variable for progression to cancer in patients with BD<sup>[15]</sup>. The degree of dysplasia has been shown to correlate with the risk of development cancer. The optimal care of patients with BD is unclear. In uncontrolled studies, satisfactory results have been noted in BE with HGD who were managed with esophagectomy<sup>[16]</sup>, intensive endoscopic surveillance<sup>[17]</sup> and various endoscopic ablation techniques<sup>[18,19]</sup>. Although current guidelines<sup>[11]</sup> endorse various strate-

gies, the relative efficacy and safety of the promising endoscopic ablation treatment modalities remain unclear. There is no previous head-to-head comparison of photodynamic therapy (PDT) *vs* radiofrequency ablation (RFA) exists. Therefore, we compare efficacy, safety, and cost-effectiveness of PDT *vs* RFA in patients with BD, in IRB-approved, prospectively collected BE outcome database at single center.

## MATERIALS AND METHODS

### Study population

The institutional review board at The Methodist Hospital, Houston, Texas approved this protocol. All patients signed an informed consent form prior to being enrolled in the study. We retrospectively evaluated prospective collected database of all patients with a diagnosis of BE containing dysplasia [low-grade dysplasia (LGD) and high-grade dysplasia (HGD)] between May 2000 and June 2009 to ascertain eligibility for surveillance and therapeutic intervention. Inclusion criteria were: age > 18 years of age and non-nodular BD at enrollment. Exclusion criteria were: active esophagitis, esophageal stricture preventing passage of a therapeutic endoscope, any history of esophageal cancer, esophageal varices, and uncontrolled coagulopathy. All patients with BD were counseled about antireflux measures and received twice daily oral proton pump inhibitors throughout the study. All HGD patients underwent surgical consultation and based on age, performance status and co-morbidities were either ineligible for surgery or were offered surgery and refused after multidisciplinary meeting with gastroenterologist and surgeon regarding the risk and benefits related to endoscopic therapy and surgery.

### Interventions

All endoscopic procedures (biopsy and ablation) were performed on an outpatient basis using intravenous conscious sedation (narcotic and benzodiazepine) or monitored anesthesia care (propofol). Endoscopic biopsies for baseline dysplastic grade confirmation, as well as for surveillance after ablative therapy, were performed using jumbo forceps in at least four quadrants every 1 cm of the BE segment. Post-ablative biopsies always encompassed the entire original extent of BE. Additional directed biopsies were obtained and placed in a separate container if any other visible abnormalities were noted during surveillance. Specimens from each level were fixed in formalin and embedded in paraffin to allow mapping of lesions. The blocks were sectioned, applied to glass slides, and stained with hematoxylin and eosin. All slides were independently evaluated by two gastrointestinal pathologists with expertise in the field of BE. Each specimen was assessed for the presence of BE, and if present, the worst pathologic grade noted per specimen as follows: non-dysplastic BE, LGD, HGD, or cancer. The worst pathologic grade used as the grade for that patient for that biopsy session. In cases of discordance between independent pathology readings, an open consensus di-

agnosis was obtained. Patients with visible nodule(s) who had endoscopic mucosal resection (EMR) were excluded from this study group.

Eligible patients with HGD who were enrolled between May 2000 and late 2007 were offered PDT, consisting of an intravenous photosensitizing agent (2.0 mg/kg, porfimer sodium, Axcan Pharma, Birmingham, AL) 40–50 h prior to endoscopy. During endoscopy, laser light (630 nm) was applied to the BE segment using a laser catheter without centering balloon (dose 130 J/cm<sup>2</sup>). A maximum of 7 cm of BE was treated per session. In longer segments, a second PDT session was performed 3 mo later to treat the remaining segment. PDT patients had upper endoscopy and biopsies at 2 and 12 mo after the primary PDT and then annually thereafter, provided no HGD or adenocarcinoma was found on biopsy. If HGD was detected, PDT was repeated for a maximum of 3 total PDT sessions.

Eligible patients with LGD or HGD who were enrolled between September 2007 and June 2010 were offered RFA, consisting of step-wise treatment with the HALO ablation system (Covidien Inc., Mansfield, MA). In cases where the BE segment was > 3 cm, the primary ablation treatment was performed with the HALO<sup>360</sup> ablation catheter, a balloon-based electrode which creates a circumferential 3-cm long ablation zone (40 W/cm<sup>2</sup>, 12 J/cm<sup>2</sup>). In cases where the BE segment was < 3 cm, the primary ablation treatment was performed with the HALO<sup>90</sup> ablation catheter, an endoscope-mounted electrode which creates a focal 1.3 cm by 2.0 cm ablation zone (40 W/cm<sup>2</sup>, 12 J/cm<sup>2</sup>). After primary ablation, patients had endoscopy every 2 mo with assessment of endoscopic response to therapy. If residual BE was detected visually, RFA touch-up with HALO-90 was performed (maximum 2 additional sessions). Upon achieving a complete visual response or exceeding the maximum allowed sessions, biopsies were performed to confirm a histological complete response. Thereafter, patients were biopsied at two and 12 mo, and then annually provided no BD or BE detected.

### Post-ablation care

After ablation, all patients were provided with double dose proton pump inhibitor medication to enable healing of the ablation zone and ensure long-term control of GERD. Patients were also provided with pain medication and anti-emetics to use as needed for 1–2 wk after therapy. PDT patients were educated to avoid exposure of eyes and skin to direct sunlight and high intensity visible light for at least 30 d or longer in patients with lighter skin color.

### Outcome measures

The primary outcomes for this study were complete histological response of BD (CR-BD), defined as no evidence of dysplasia at last available biopsy session. Detection of cancer during any follow-up was considered a censoring event for the primary outcome. Secondary outcomes include the occurrence of adverse events, occurrence of

**Table 1** Characteristics factors of the patients *n* (%)

subsquamous intestinal metaplasia at the last biopsy visit, and cost calculated per procedure and per patient.

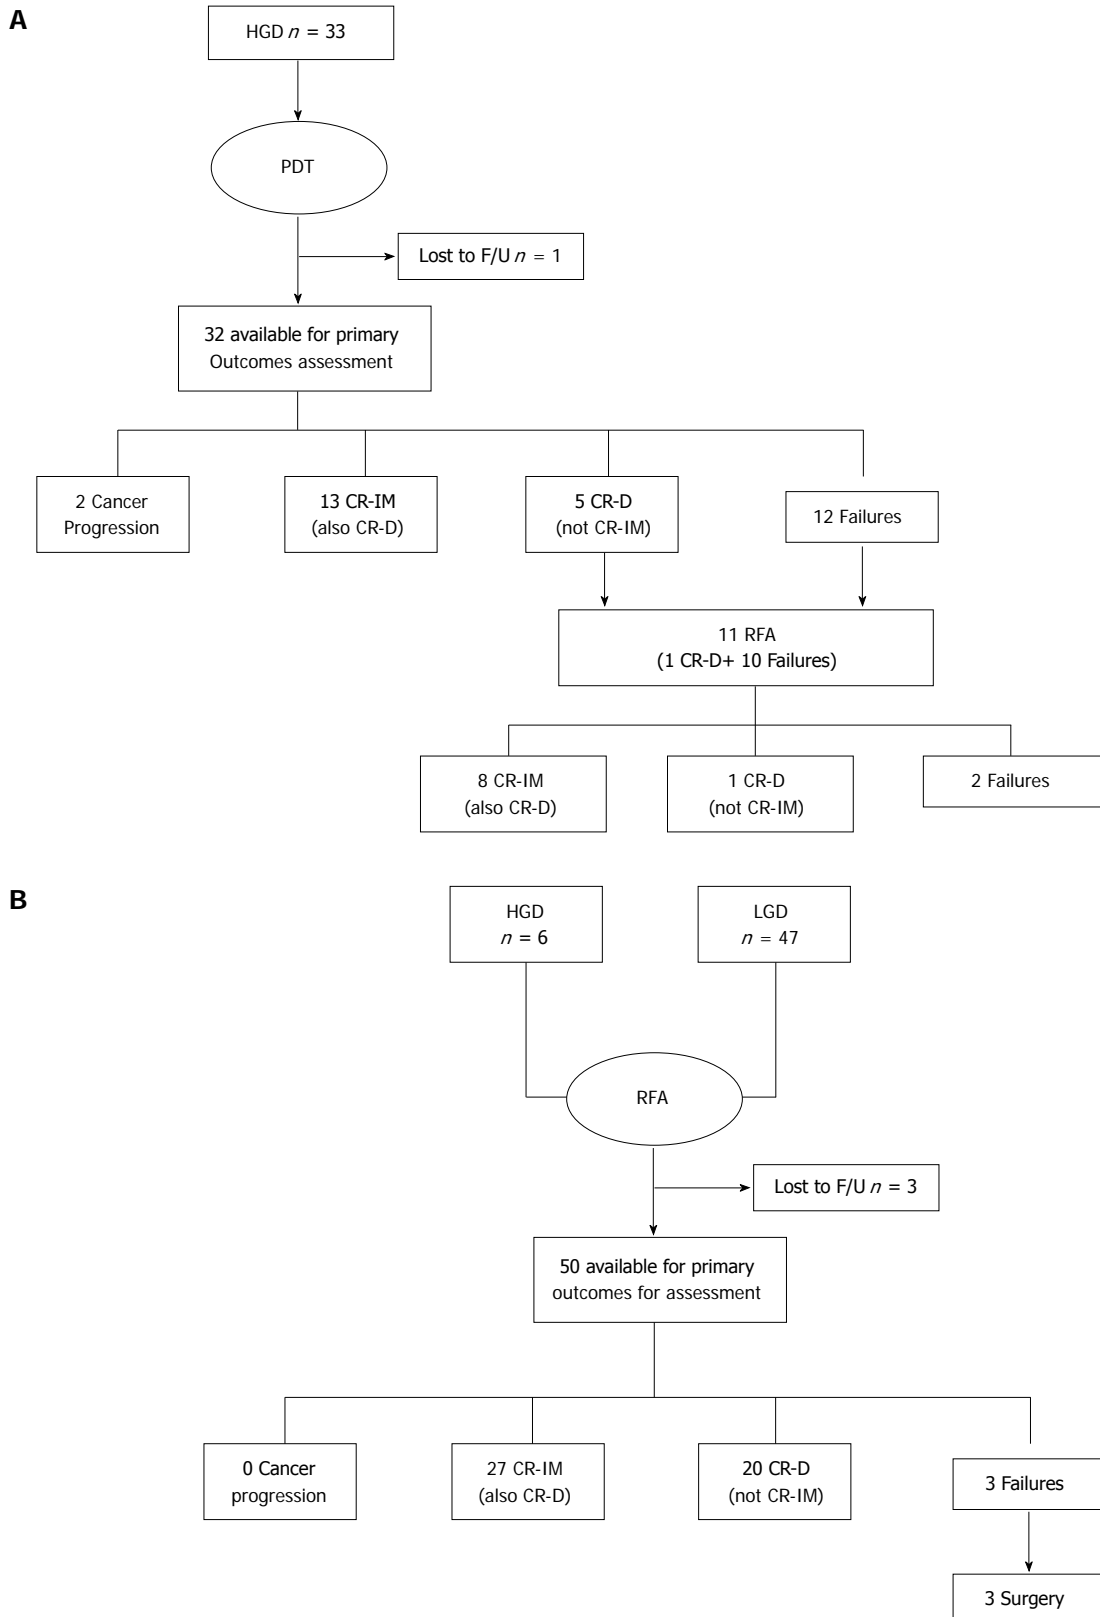

### Statistical analysis

The primary analysis was intention-to-treat (ITT), with all lost-to-follow-up patients being considered failures for the primary outcomes. The secondary analysis was per-protocol (PP), evaluating those patients with data available. Fisher's exact test and Student's *t* test were used to compare baseline variables. Fisher's exact test was used to assess differences between the two study groups for primary outcomes. For all outcomes, a two-sided *P* value of less than 0.05 was considered to indicate statistical significance. The statistical analysis was performed using the SPSS 12.0.1 software for Windows. The costs of the PDT and RFA were calculated with a non-bias formula by the Methodist Hospital Cost Center.

## RESULTS

There were 86 patients who fulfilled the study criteria and signed informed consent. Thirty-three patients underwent primary PDT (all with HGD). Fifty-three patients underwent primary RFA (6 with HGD and 47 with LGD). See Table 1 for baseline patient characteristics and Figure 1 for patient flow. Mean baseline BE length values were similar between groups (PDT: 5.4 ± 3.2, RFA: 5.7 ± 3.2, *P* = 0.53), while PDT patients tended to be older (PDT: 70.7 ± 12.2, RFA: 65.4 ± 12.8, *P* = 0.10) and more likely to have HGD (PDT: 33/33, RFA: 6/53) as entry diagnosis (*P* < 0.0001).

The average length of follow-up from primary ablative therapy to primary outcome biopsy session was 44 mo (range 24–60 mo) for PDT and 33 mo (range 24–48 mo) for RFA. PDT patients had an average of 1.4 PDT sessions, while RFA had an average of 2.6 sessions. CR-D was achieved in 18/33 (54.5%) PDT and 47/53 (88.7%) RFA patients (*P* = 0.0001), Table 2. Eight PDT patients demonstrated an initial complete response, but then recurred (1 HGD, 7 LGD) at later biopsy sessions and were considered failures for the primary outcomes with PDT. After recurrence, these patients could not un-

**Figure 1 Patient flow.** HGD: High-grade dysplasia; PDT: Photodynamic therapy; CR-D: Complete histological resolution of Barrett's dysplasia; IM: Intestinal metaplasia.

dergo further PDT due to exceeding the maximum PDT sessions achieved or intolerance to therapy, therefore all underwent salvage therapy with RFA with 100% CR-BD (post-hoc analysis). Two PDT patients developed cancer during follow-up at 18 and 24 mo. Both were considered

failures for the primary endpoint of this study and both underwent esophagectomy. Surgical pathology showed T1NOMO lesions. No RFA patient developed cancer progression.

In the PDT cohort, two patients reported photo-

**Table 2 Outcomes measures *n* (%)**

	PDT	RFA
<b>Primary outcomes</b>		
Complete Response IM		
ITT	13/33 (39.4)	27/53 (50.9)
PP	13/32 (40.6)	35/61 (57.4)
Complete Response Dysplasia		
ITT	18/33 (54.5)	47/53 (88.7)
PP	18/32 (56.3)	56/61 (91.8)
<b>Secondary outcomes</b>		
Complications		
Perforation	1/32 (3.1)	0/50 (0.00)
Stricture	9/32 (28.1)	2/50 (4.0)
Cost per session	\$9449	\$1888 (HALO-360) \$1486 (HALO-90)

PDT: Photodynamic therapy; RFA: Radiofrequency ablation; ITT: Intention-to-treat; PP: Per-protocol; IM: Intestinal metaplasia.

sensitivity reactions (none required therapy), 9 (28.13%) developed a stricture necessitating serial endoscopic dilations (mean 3 per patient) with two requiring temporary stent placement. One patient developed an esophageal perforation that was managed by nonsurgical measures in the PDT cohort. In the RFA cohort, 2 patients (4.0%) developed a stricture managed with endoscopic dilation (one dilation per patient). No perforation was seen in the RFA patients. Subsquamous intestinal metaplasia (SSIM, "buried glands") was seen in 4/32 (12.5%) of patients treated with PDT and 3/50 (6%) of those treated with RFA ( $P = 0.28$ ).

The facility cost for a HALO-360 RFA session *vs* a PDT session was \$1888 and \$9449, respectively. The facility cost of a HALO-90 RFA was slightly lower at \$1486. Cost per patient was also calculated, including primary ablation, follow-up ablation, and salvage ablation procedures, but excluding surgical salvage. According to a calculated cost analysis in our institution, PDT was approximately five times more costly than RFA per procedure.

## DISCUSSION

Professional guidelines endorse various strategies for management of BE with dysplasia<sup>[11]</sup>. Due to lack of head to head comparison, relative efficacy of interventions like PDT, RFA, and cryotherapy remains unclear. Based on the finding that over 40% of patients with HGD undergoing esophagectomy have invasive cancer in their pathology specimen<sup>[16,20]</sup>, esophagectomy is still been recommended for patients with HGD<sup>[11]</sup>. The prevalence of a missed cancer in patients may be less with recently used aggressive endoscopic biopsy protocols and better endoscopic visualization, however it is not been proven yet. Moreover, even when an esophagectomy is performed by experienced surgeons in high volume centers, it is associated with significant morbidity and mortality<sup>[16,20]</sup>. There are no RCTs comparing esophagectomy and endoscopic therapy for treatment of dysplastic BE<sup>[21]</sup>. Although debatable, intensive endoscopic surveillance

with rigorous biopsy protocol can detect the progression from BD to cancer at the curative stage<sup>[17]</sup>, but is associated with considerable anxiety for these patients with a negative impact to their quality of life. The accumulated evidence suggests that endoscopic resection (ER) therapy like endoscopic mucosal resection (EMR) and endoscopic submucosal dissection (ESD) or endoscopic ablation modalities such as PDT and RFA have become attractive alternatives for the management of patients with BD<sup>[22-25]</sup>. ER of focal lesions can achieve complete eradication of HGD and IMC in 82.5%-95% of patients and also allows detection of occult invasive adenocarcinoma<sup>[21,26-28]</sup>. However, metachronous lesions or disease recurrence is been seen in up to 14% of patients within 12 mo, and 21.5% of patients over 5 years after ER<sup>[21,24,29]</sup>. International consortium of expert clinicians recommends ER for focal lesions followed by ablation of whole Barrett's segment to decrease recurrence rate<sup>[30]</sup>. Endoscopic ablation modalities are based on the hypothesis that injury to the metaplastic and dysplastic epithelium will reverse the pathologic progression of BD to invasive cancer and restore a normal squamous epithelium. Despite the attractiveness of these endoscopic ablation technologies, no previous head-to-head comparison of PDT *vs* RFA exists in patients with BD.

In our study, we compared outcomes in patients treated with PDT and RFA in a single center by a single gastroenterologist in a prospectively collected database. These two modalities were compared with regard to complete eradication of BE and BD, adverse events, and costs. Our data shows that PDT and RFA eradicated dysplasia in 54% and 89%, respectively. Complete reversal of intestinal metaplasia was noted in 39% cases for PDT and 51% cases for RFA.

Overholt *et al*<sup>[31]</sup> compared PDT with Photofrin (PHO) plus omeprazole (PHOPDT) to omeprazole (OM) only to eradicate BE-HGD in a multicenter, randomized (2:1 randomization), pathology-blinded trial. At 5 years PHOPDT was significantly more effective than OM in eliminating HGD [77% (106/138) *vs* 39% (27/70),  $P < 0.0001$ ]. A secondary outcome measure preventing progression to cancer showed a significant difference ( $P = 0.027$ ) with about half the likelihood of cancer occurring in PHOPDT [21/138 (15%)] *vs* OM [20/70 (29%)], with a significantly ( $P = 0.004$ ) longer time to progression to cancer favoring PHOPDT. In our experience, PDT eliminated HGD in 54.5% of patients compared to 77% on Overholt *et al*<sup>[31]</sup> study. In Overholt *et al*<sup>[31]</sup> study 36% of the patients developed stricture, and 69% had a photosensitivity reaction. Similarly, in our study 28% of patients developed strictures requiring serial endoscopic dilation. Shaheen *et al*<sup>[32]</sup> performed a multicenter, sham-controlled trial, and randomly assigned 127 patient with dysplastic BE in a 2:1 ratio to receive either RFA or a sham procedure (control group). In the intention-to-treat analyses, among patients with LGD, complete eradication of dysplasia occurred in 90.5% of those in the ablation group, as compared with 22.7% of those in the

control group ( $P < 0.001$ )<sup>[32]</sup>. Among patients with HGD, complete eradication occurred in 81.0% of those in the ablation group, as compared with 19.0% of those in the control group ( $P < 0.001$ ). Overall, 77.4% of patients in the ablation group had complete eradication of intestinal metaplasia, as compared with 2.3% of those in the control group ( $P < 0.001$ ). Patients in the ablation group had less disease progression (3.6% vs 16.3%,  $P = 0.03$ ) and fewer cancers (1.2% vs 9.3%,  $P = 0.045$ ). We observed similar rates of complete response as illustrated in Table 2.

While making decisions about the management of precancerous conditions, potential benefits, risks and costs associated with different competing strategies are the most important considerations. For less severe disease like BE with LGD compared to BE with HGD, safety and cost of the suggested intervention becomes even more important<sup>[32]</sup>. According to the calculated direct cost comparison analysis, PDT was five times more costly than RFA in our institution. Detail cost effective analysis requires calculation for direct and indirect cost related to each intervention, as well as cost associated with complication and treatment failure. PDT patients are required to avoid sun and high intensity visible light during four weeks after the procedure and this may add significant indirect cost, in addition to high direct cost with PDT therapy. In our experience, side effects and complications of RFA were also less than PDT therapy.

In principle, a head-to-head comparison of PDT and RFA requires a randomized, blinded study design but this is currently impossible given the limited availability of PDT ablation technology for the esophagus. The strengths of our study are the very low drop-out rate, tight control of technique by a single experienced gastroenterologist (AE), and a rigorous biopsy protocol with review of all pathology by two well known gastroenterology pathologists and long follow up duration. Our study also has several limitations including the lack of randomization, the significant disproportion of HGD between the PDT and RFA groups respectively and difference in follow up time for both PDT and RFA group and the results of our study should be interpreted accordingly. PDT therapy was approved for HGD only and till RFA technology became available, only patients with BE-HGD were offered treatment with PDT. The implications of LGD vs HGD in Barrett's patients are markedly different. LGD implies a risk of progression to cancer of less than 1% per patient-year<sup>[33]</sup>, whereas the risk associated with HGD may be as high as 10% per patient-year<sup>[34,35]</sup>.

In conclusion, in our experience both PDT and RFA were successful in eradicating dysplasia in BE. However, overall success rate of RFA was higher than PDT and RFA was very well tolerated without any major complications and fewer side effects. At our center, each session of RFA therapy was five times less costly than PDT therapy. However, for head-to-head comparison of PDT and RFA, prospective, randomized, blinded, multi-center studies are needed.

## ACKNOWLEDGMENTS

The authors would like to thank the contributing GI pathologists, Mamoun Younes, MD, and Mary Schwartz, MD, for their expertise and contributions in reviewing all pathology specimens from this study.

## COMMENTS

### Background

The incidence of esophageal adenocarcinoma has increased by more than 500% since 1970 and it is considered one of the most rapidly increasing cancers in western society. Barrett's esophagus (BE) is a premalignant condition and predisposes to adenocarcinoma of the esophagus and gastro-esophageal junction.

### Research frontiers

Current guidelines endorse various strategies like esophagectomy, intensive endoscopic surveillance and various endoscopic resection and endoscopic ablation techniques for management of dysplastic BE. Significant controversies and disagreement exists in management of BE including the role of Barrett's surveillance, the optimal means of intervention, and the stage at which intervention is indicated.

### Innovations and breakthroughs

Various endoscopic ablation techniques like photodynamic therapy (PDT), radiofrequency ablation (RFA) and cryotherapy are currently available for treatment of dysplastic Barrett's esophagus. Both PDT and RFA have been proven to be superior to eradicate dysplastic Barrett's esophagus compared to routine antireflux measures and pharmacological anti-reflux measures in randomized trials. This study compared relative safety, efficacy and cost related to PDT and RFA therapy for dysplastic BE in a single center consecutive case series and found that RFA was more effective, safe and less costly than PDT therapy.

### Applications

With better understanding of relative efficacy, safety and cost between PDT and RFA, this study will help physicians to determine optimal endoscopic ablation technique for treatment of dysplastic BE.

### Peer review

It is a well written and accurate study. It shows a striking superiority of RFA vs PDT for Barrett esophagus and, even that the study has not been randomized and the number of patients is not very long, the results deserve its publication and must be known by practical endoscopists.

### Abstract

**AIM:** To investigate whether celiac disease (CD) patients with tissue-transglutaminase antibody (tTGA)  $\geq 100$  U/mL are different from patients with lower tTGA levels.

**METHODS:** Biopsy-proven (Marsh III) pediatric CD patients ( $n = 116$ ) were prospectively included between March 2009 and October 2012. The biopsies were evaluated by a single pathologist who was blinded to all of the patients' clinical data. The patients were distributed into 2 groups according to their tTGA level, which was measured using enzyme-linked immunoassay: tTGA  $\geq 100$  U/mL and tTGA  $< 100$  U/mL. The patients' characteristics, symptoms, human leukocyte antigen (HLA) genotype and degree of histological involvement were compared between the 2 groups.

**RESULTS:** A total of 34 (29.3%) children had tTGA values  $< 100$  U/mL and 82 (70.7%) tTGA levels of  $\geq 100$  U/mL. Patients with high tTGA levels had lower average body weight-for-height standard deviation scores (SDS) than did patients with tTGA  $< 100$  U/mL ( $-0.20 \pm 1.19$  SDS vs  $0.23 \pm 1.03$  SDS,  $P = 0.025$ ). In the low tTGA group, gastrointestinal symptoms were more common (97.1% vs 75.6%,  $P = 0.006$ ). More specifically, abdominal pain (76.5% vs 51.2%;  $P = 0.012$ ) and nausea (17.6% vs 3.7%,  $P = 0.018$ ) were more frequent among patients with low tTGA. In contrast, patients with solely extraintestinal manifestations were only present in the high tTGA group (18.3%,  $P = 0.005$ ). These patients more commonly presented with aphthous stomatitis (15.9% vs 0.0%,  $P = 0.010$ ) and anemia (32.9% vs 11.8%,  $P = 0.019$ ). In addition, when evaluating the number of CD-associated HLA-DQ heterodimers (HLA-DQ2.5, HLA-DQ2.2 and HLA-DQ8), patients with low tTGA levels more commonly had only 1 disease-associated heterodimer (61.8% vs 31.7%,  $P = 0.005$ ), while patients with high tTGA more commonly had multiple heterodimers. Finally, patients with tTGA  $\geq 100$  U/mL more often had a Marsh IIIc lesion (73.2% vs 20.6%,  $P \leq 0.001$ ) while in patients with low tTGA patchy lesions were more common (42.4% vs 6.8%,  $P \leq 0.001$ ).

**CONCLUSION:** Patients with tTGA  $\geq 100$  U/mL show several signs of more advanced disease. They also carry a larger number of CD associated HLA-DQ heterodimers.

**Key words:** Celiac disease; Serology; Anti-tissue transglutaminase antibodies; Human leukocyte antigen; Phenotype

**Core tip:** We prospectively investigated the differences between celiac disease (CD) (Marsh III) patients with tissue-transglutaminase antibody (tTGA) levels  $\geq 100$

U/mL and patients with lower tTGA levels. We found that patients with high tTGA more often carried multiple CD-associated heterodimers compared with patients with tTGA < 100 U/mL. In addition, high-tTGA patients have more advanced mucosal lesions that are also less patchy. Phenotypically, high-tTGA patients have a lower body weight and more often present with extraintestinal symptoms compared with patients with lower levels of tTGA, who more often have intestinal symptoms. These results provide further evidence that patients with tTGA  $\geq$  100 U/mL are truly a distinct group with more advanced disease.

Mubarak A, Spierings E, Wolters VM, Otten HG, ten Kate FJW, Houwen RHJ. Children with celiac disease and high tTGA are genetically and phenotypically different. *World J Gastroenterol* 2013; 19(41): 7114-7120 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i41/7114.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i41.7114>

## INTRODUCTION

Celiac disease (CD) is a highly prevalent disorder with a strong genetic component. The disease has a complex and variable clinical presentation: some patients display symptoms ranging from severe malabsorption to vague intestinal or extraintestinal manifestations, while others have no symptoms at all<sup>[1-3]</sup>. The disease is caused by inappropriate immune responses to gluten, a storage protein in wheat and the related grain species barley and rye<sup>[4]</sup>. The immune reaction mainly affects the small intestine, where it typically causes lymphocyte invasion in the epithelium, hyperplasia of the crypts and various grades of villous atrophy<sup>[5,6]</sup>. These histological lesions can be patchily distributed throughout the small intestine and can even occasionally be localized exclusively in the duodenal bulb<sup>[7,8]</sup>. Serologically, signs of inflammation are also evidenced by the presence of disease-associated antibodies, including endomysium antibodies (EMA) and tissue transglutaminase antibodies (tTGA)<sup>[4,9,10]</sup>.

Until recently, these serological and histological manifestations were used in combination to detect CD, with histological evaluation being essential for establishing the diagnosis in all cases<sup>[9,11]</sup>. However, given the excellent sensitivity and specificity of serology, the new ESPGHAN guidelines now indicate that a biopsy can be omitted in symptomatic children with tTGA levels  $\geq$  100 U/mL (> 10 times the upper limit) and positive EMA, provided the patient also carries a disease-associated human leukocyte antigen (HLA) type and responds well to the diet<sup>[12]</sup>. In contrast, in patients with a tTGA < 100 U/mL, a biopsy is always necessary because a significant proportion of patients with these levels do not have CD.

It is unclear why patients with a tTGA  $\geq$  100 U/mL virtually always have CD. These high levels could be a sign of advanced disease. Patients with high serum tTGA may also have a different genetic risk profile. Because

HLA genes make the greatest genetic contribution, the aim of this study was to assess whether patients with a tTGA  $\geq$  100 U/mL have a different HLA distribution compared with patients with lower tTGA levels<sup>[13]</sup>. We also investigated whether more advanced small intestinal histological lesions were present in patients with a tTGA  $\geq$  100 U/mL. In addition, as it remains to be resolved whether patients with tTGA levels  $\geq$  100 U/mL are phenotypically distinct from those with a tTGA < 100 U/mL, we set out to detect differences in clinical presentation between both groups.

## MATERIALS AND METHODS

### Study population

Pediatric patients who had a histologically confirmed diagnosis of CD between March 2009 and October 2012 in the Wilhelmina Children's Hospital in Utrecht, The Netherlands, were prospectively included in the study. Patients were referred to us because of CD-associated symptoms or because they belonged to a group at risk for CD. Biopsies were collected from patients with abnormal serology. Biopsies were also collected from patients with negative serology but a strong clinical suspicion of the disease. Patients with immune globulin A (IgA) deficiency ( $n = 3$ ) were excluded from the study. The clinical symptoms at presentation were collected from the medical records. The study was performed according to the guidelines of the local medical ethics board.

### Histological evaluation

Biopsies were obtained using upper endoscopy. On average, 3.09 biopsies (range 1-5, SD = 0.75) were obtained from the distal duodenum, and 2.41 (range 0-5, SD = 1.03) were obtained from the duodenal bulb. The biopsies were evaluated by a single experienced pathologist who was blinded to all of the patients' clinical data and who used the Marsh classification, as modified by Oberhuber<sup>[5,6]</sup>. The duodenal bulb and the distal duodenum were scored separately, but the final Marsh score for each patient was graded according to the most affected site (highest Marsh score). Only Marsh III lesions (*i.e.*, those characterized by an increased number of intraepithelial lymphocytes, crypt hyperplasia and villous atrophy) were considered diagnostic for CD. Patients with other histological findings were not included. Marsh III lesions were further classified according to the degree of villous atrophy: Marsh IIIa (partial villous atrophy), Marsh IIIb (subtotal villous atrophy) and Marsh IIIc (total villous atrophy).

### Serological assessment

Serum IgA tTGA levels were measured using the ELiA Celikey IgA kit (Phadia AB, Uppsala, Sweden). Serum samples containing an antibody titer of more than 10 U/mL were considered positive, as recommended by the manufacturer. IgA EMA levels were detected *via* indirect immunofluorescence using sections of distal monkey

esophagus mounted on glass slides (IMMCO Diagnostics Inc., Buffalo NY). Total IgA was measured in all patients, and a serum IgA concentration below 0.07 g/L was regarded as IgA deficiency.

### HLA-typing

Genomic DNA was isolated from ethylenediaminetetraacetic acid-anticoagulated blood with a standardized DNAzol-based technique. The HLA-DQA1 and HLA-DQB1 alleles were typed using the sequence-specific oligonucleotide primed polymerase chain reaction technique with the Luminex-based OneLambda LABType SSO Class II DQA1/DQB1 typing kit, following the recommendations of the manufacturer (One Lambda Inc., Canoga Park, CA, United States). Samples were analyzed on a LABScan™ 100 System (Luminex, Austin TX, United States), and data were interpreted using the HLA-Fusion 2.0 Software package (OneLambda).

HLA-DQ2.5 (DQA1\*05:01, -DQB1\*02:01 or DQA1\*05:05, -DQB1\*02:02), HLA-DQ2.2 (DQA1\*02:01, -DQB1\*02:02) and HLA-DQ8 (DQA1\*03:01, -DQB1\*03:02 or DQA1\*03:02, -DQB1\*03:02) were considered CD-associated HLA-types. The patients were scored for the number of CD-associated heterodimers that they could form with their HLA-genotypes. For example, a patient who is homozygous for HLA-DQ2.5 (or HLA-DQ2.2 or HLA-DQ8) can form 4 different heterodimers that are associated with CD. The same is true of patients who are compound heterozygous for HLA-DQ2.5 and HLA-DQ2.2, because these patients can also make 4 different CD-associated heterodimers: HLA-DQA1\*05:01, -DQB1\*02:01; HLA-DQA1\*02:01, -DQB1\*02:02; HLA-DQA1\*05:01, -DQB1\*02:02 and HLA-DQA1\*02:01, -DQB1\*02:01 (the latter 2 of which are molecularly indistinguishable from the first 2). Patients who are heterozygous for HLA-DQ2.5 and HLA-DQ8 or HLA-DQ2.2 and HLA-DQ8 can only form 2 CD-associated heterodimers. Finally, patients with only 1 CD-associated HLA genotype can only generate 1 CD-associated heterodimer.

### Statistical analysis

The patients were divided in 2 groups: those with tTGA  $\geq 100$  U/mL and those with tTGA  $< 100$  U/mL. Subsequently, the differences between the 2 groups in terms of gender, average age at diagnosis, average height and weight, the presence of a CD-associated disease, the presence of a first-degree relative with CD, symptoms, HLA type, Marsh classification and histological differences between the duodenal bulb and the more distal duodenum were calculated using SPSS Version 20.0.

To test for statistical significance, the  $\chi^2$  or Fisher exact test was used for nominal variables. For continuous variables, the independent *t* test or the Mann-Whitney *U* test were used. A *P* value  $< 0.05$  was considered statistically significant.

## RESULTS

### Patient characteristics

A total of 116 patients met the study's inclusion criteria. Of those, 34 (29.3%) patients had tTGA values  $< 100$  U/mL and 82 (70.7%) had a serum tTGA of at least 100 U/mL. Within the low tTGA group, 2 patients, a 10-month-old girl and a 2-year-old boy, had a tTGA level  $< 10$  U/mL and negative EMA, which is not an uncommon finding in very young children<sup>[11,14-18]</sup>. All of the remaining patients had positive EMA levels.

Of the total study population, 32 (27.6%) were male and 84 (72.4%) female, with no difference in gender distribution between the high and low tTGA groups (Table 1). The mean age of the included patients at diagnosis was 6.5 years, ranging from 0.9 to 17.7 years. The average age at diagnosis was slightly higher (7.4 years) in the low tTGA group compared with the high tTGA group (6.1 years), but this was statistically not significant. The patients in the high tTGA group were slightly shorter (-0.83 standard deviation score, SDS) compared with the low tTGA group (-0.60 SDS), but this difference was not significant. In contrast, the average body weight-for-height was significantly lower (-0.20 SDS) in the high tTGA group compared with patients in the low tTGA group, who had an average weight of 0.23 SDS (*P* = 0.025).

Regarding comorbidity, 5 (4.3%) patients had Down syndrome, and 1 (0.86%) of those also had hypothyroidism. Another 4 (3.4%) patients had diabetes mellitus Type I, 1 (0.86%) patient had juvenile rheumatoid arthritis and 1 (0.86%) patient had Graves disease. Remarkably, all but 1 of the patients with comorbidity had tTGA  $\geq 100$  U/mL; however, this finding was not statistically significant. Finally, 9 (26.5%) patients in the low tTGA group had a first-degree relative with CD, compared with 14 (17.1%) patients in the high tTGA group; again, this difference was not statistically significant.

### Symptoms

Only 5 (4.3%) patients were asymptomatic, 4 of which had a tTGA  $\geq 100$  U/mL and 1 of which had a tTGA  $< 100$  U/mL (Table 2). The other 111 (95.7%) patients had various gastrointestinal and extraintestinal symptoms. Interestingly, gastrointestinal symptoms were significantly (*P* = 0.006) more common in the low tTGA group (*n* = 33; 97.1%) compared with the high tTGA group, in which 75.6% (*n* = 62) of the patients suffered from a gastrointestinal symptom. However, although patients with symptoms restricted to the gastrointestinal tract (without any extraintestinal manifestations) were also more common in the low tTGA group (23.5% *vs* 9.8%, respectively), this difference was not statistically significant (*P* = 0.074). In terms of specific gastrointestinal complaints, abdominal pain and nausea were significantly more common in the low tTGA group. Indeed, 76.5% (*n* = 26) of the patients in the low tTGA group had abdominal pain, compared

**Table 1 Characteristics of patients *n* (%)**

Patient characteristic	tTGA < 100 U/mL ( <i>n</i> = 34)	tTGA ≥ 100 U/mL ( <i>n</i> = 82)	<i>P</i> value
Gender (M)	8 (23.5)	24 (29.3)	0.529
Average age (yr)	7.40 ± 4.06	6.10 ± 3.82	0.114
Average height in SDS	-0.60 ± 1.15	-0.83 ± 1.22	0.331
Average weight for height in SDS	0.23 ± 1.03	-0.20 ± 1.19	0.025
CD associated comorbidity	1 (2.9)	10 (12.2)	0.171
First degree relative with CD	9 (26.5)	14 (17.1)	0.248

tTGA: Anti-tissue transglutaminase antibodies; SDS: Standard deviation scores; CD: Celiac disease; M: Male.

with 51.2% (*n* = 42) in the high tTGA group (*P* = 0.012). Similarly, in the low tTGA group, 17.6% (*n* = 6) of the patients suffered from nausea, compared with 3.7% (*n* = 3) in the high tTGA group (*P* = 0.018). Moreover, there was a statistically non-significant trend (*P* = 0.096) towards more constipation in the low tTGA group (*n* = 14; 41.2%) compared with the high tTGA group (*n* = 21; 25.6%). In contrast, diarrhea was more common in the high tTGA group (*n* = 27; 32.9%) compared with the low tTGA group (*n* = 8; 23.5%), but the difference was not significant (*P* = 0.316). Similarly, a comparable trend (*P* = 0.277) was seen for vomiting, which occurred more often in the high tTGA group (11.0% *vs* 2.9%). Finally, the presence of bloating was comparable in both groups with more than 1/3 of the patients suffering from this symptom.

Extraintestinal symptoms occurred in 25 (73.5%) of the patients with low tTGA compared with 70 (85.4%) patients in the high tTGA group, but this difference was not statistically significant (*P* = 0.132). However, patients with solely extraintestinal symptoms (*i.e.*, without gastrointestinal symptoms) were only present in the high tTGA group (*n* = 15; 18.3%), a finding that was statistically significant (*P* = 0.005). Similarly, aphthous stomatitis only occurred in patients with high tTGA (*n* = 13; 15.9%). This was statistically significant, with a *P* value of 0.010. Likewise, anemia was significantly (*P* = 0.019) more common in the high tTGA group: 27 (32.9%) of the patients with high tTGA had anemia, compared with 4 (11.8%) patients with low tTGA. There was also a trend towards more increased appetite (7.3% *vs* 2.9%), joint pain (11.0% *vs* 5.9%) and low weight (8.5% *vs* 5.9%) in the high tTGA group, but these differences were not statistically significant (*P* > 0.05). Tooth enamel defects were more common in the low tTGA group (5.9% *vs* 3.7%), but this was also not statistically significant (*P* = 0.629). Finally, the presence of fatigue, irritability, anorexia and short stature was comparable in both groups.

### HLA-types

All of the patients carried at least one of the CD-associated HLA types. In the high tTGA group, the patients more often carried multiple CD-associated heterodimers (*P* = 0.005; Table 3). Illustratively, in the low tTGA

group, more than half of the patients (*n* = 21; 61.8%) had only one CD-associated heterodimer, compared with 26 (31.7%) in the high tTGA group. Two patients (5.9%) with low tTGA had 2 CD-associated heterodimers, compared with 20 (24.4%) patients in the high tTGA group. Finally, 36 (43.9%) patients in the high tTGA group had 4 CD-associated heterodimers, compared with 11 (32.4%) patients with low tTGA.

### Histology

In the low tTGA group, 5 (14.7%) patients had a Marsh IIIa lesion, 22 (64.7%) had a Marsh IIIb lesion, and only 7 (20.6%) had a Marsh IIIc lesion (Table 3). This was significantly different from the high tTGA group (*P* < 0.001). Illustratively, only 4 (4.9%) patients in the high tTGA group had a Marsh IIIa lesion; 18 (22.0%) had a Marsh IIIb lesion, and the largest proportion of the patients in the high tTGA group (*n* = 60; 73.2%) had flat mucosa (Marsh IIIc).

In 106 patients, both duodenal bulb and distal duodenum biopsies were taken. To assess the presence of patchy lesions, the Marsh classification in both locations was compared. A patchy lesion was defined as the absence of villous atrophy in either the duodenal bulb or the distal duodenum. In 7 (6.6%) patients, a Marsh III lesion was only found in the duodenal bulb, while the distal duodenum was spared. In 12 (11.3%) patients, the distal

Patchy lesions <sup>2</sup>	14 (42.4)	5 (6.8)	

<sup>1</sup>Only 106 patients out of the total study population also underwent duodenal bulb biopsies; <sup>2</sup>Discrepancy in the diagnosis based on histology in the duodenal bulb *vs* in the distal duodenum. HLA: Human leukocyte antigen; tTGA: Anti-tissue transglutaminase antibodies.

duodenum was the only affected site. Interestingly, a discrepancy between the diagnosis in the distal duodenum *vs* the duodenal bulb was more common in patients with low tTGA than in patients with high tTGA (42.4% *vs* 6.8%, *P* < 0.001). In addition, patchy lesions were more common in patients with Marsh IIIa (in 5 of 9 patients, 55.6%) than in patients with Marsh IIIb (in 13 of 35 patients, 37.1%) or IIIc lesions (in 1 of 62 patients; 1.6%, *P* < 0.001).

## DISCUSSION

CD is defined as a chronic small intestinal immune-mediated enteropathy precipitated by exposure to dietary gluten in genetically predisposed individuals<sup>[19]</sup>.

Patients with tTGA levels ≥ 100 U/mL (> 10 times the upper limit) virtually always have CD, whereas the disease can be histologically absent in a significant number of patients with a lower serum tTGA level. In the present study, we show in a pediatric population that patients with a tTGA level ≥ 100 U/mL also have a different HLA-pattern and a more severe histological lesion and seem to be phenotypically different, with more extraintestinal symptoms and a lower body weight.

Patients with high tTGA levels are more likely to have 2 and 4 CD-associated heterodimers compared with patients with lower tTGA levels, who more often only have 1 CD-associated heterodimer (Table 3). This seems pathophysiologically logical. In CD, HLA-molecules on antigen-presenting cells in the lamina propria present gluten peptides to CD4+ T-cells, which in turn further activate the immune system, including B-cells<sup>[20-22]</sup>. Thus, increased cell-surface expression of CD-associated heterodimers will lead to more antigen presentation and therefore more T- and B-cell stimulation, which will eventually generate a stronger antibody response. However, because not all patients with multiple heterodimers had a tTGA ≥ 100 U/mL, and some patients with a single HLA-heterodimer also had tTGA levels ≥ 100

U/mL, other factors, such as non-HLA genes or environmental factors, are likely to contribute to the tTGA-level response. This finding is in line with a previous study showing a correlation between antibody level and HLA-dose; patients homozygous for HLA-DQB1\*02 had significantly higher tTGA levels compared with patients with a single dose of HLA-DQB1\*02 and to patients not carrying any HLA-DQB1\*02<sup>[23]</sup>. In the current study, a comparable HLA-DQB1\*02 correlation was found, but the difference was not significant (*P* = 0.101; data not shown).

The current study also provided evidence that patients with high tTGA levels have more advanced mucosal lesions compared with CD patients with lower tTGA levels. First, patients with tTGA levels ≥ 100 U/mL had a more severe grade of villous atrophy, in line with previous studies showing an increasing tTGA titer with increasing villous atrophy<sup>[24,25]</sup>. However, we also showed that patchy lesions, defined as the absence of villous atrophy in either the duodenal bulb or the distal duodenum, were more common in patients with low tTGA than in patients with high tTGA, suggesting that in patients with high tTGA, the total area of mucosa involved is larger. In addition, patients with a lesser degree of villous atrophy, which is more common in the low tTGA group, also had a higher chance of patchy lesions, providing more evidence that the disease in these patients is truly less advanced.

Interestingly, we also found significant differences in clinical presentation between patients with high tTGA and those with levels < 100 U/mL. The group with high tTGA levels had lower body weight and more extraintestinal complaints than did patients with low tTGA (Table 2). This suggests that patients with high tTGA levels have more advanced or generalized disease. Other studies investigating the relationship between antibody levels and symptoms are rare. Dahlbom and colleagues found that children with an onset of CD in early childhood and/or severe malabsorption had higher tTGA levels than did patients with a late childhood onset of disease and/or moderate symptoms, and also when compared with patients presenting in adulthood<sup>[24]</sup>. Taavela *et al*<sup>[26]</sup> also showed that the serum levels of antibodies associated with CD correlated with gastrointestinal symptoms. None of these two studies specifically investigated the differences in intestinal and extraintestinal symptoms, so their results cannot be directly compared with our study. However, in both studies, a relationship between antibody levels and symptom severity was observed, once again suggesting that patients with a high tTGA have more advanced disease.

Finally, we showed that patients in the low tTGA group more often have a positive family history for CD (26.5% *vs* 17.1%), although this difference was not statistically significant. This difference could have resulted because patients with a positive family history are detected earlier than those without a positive history, before a very high tTGA level is reached. Conversely, patients with

comorbidity were found more frequently (although statistically not significant) in the high tTGA group (12.2% *vs* 2.9%), which might be due to a more advanced disease progression in this group.

Our combined data confirm, in a pediatric population, the hypothesis that patients with tTGA  $\geq 100$  U/mL have more advanced disease, given the more severe histological involvement and the increased incidence of extraintestinal manifestations and lower body weight. Pathophysiologically, these patients also express more CD-associated HLA-heterodimers on their cells. These findings should also be investigated in adults.

## COMMENTS

### Background

Genetically predisposed symptomatic children with positive endomysium antibodies (EMA) and tissue-transglutaminase antibody (tTGA) levels  $\geq 100$  U/mL virtually always have the classical histological triad of an increased number of intraepithelial lymphocytes, crypt hyperplasia and villous atrophy. These features are diagnostic for celiac disease (CD); therefore, in children with these high tTGA values, recent ESPGHAN guidelines have suggested that a biopsy is unnecessary to confirm the disease. In contrast, in patients with lower tTGA levels, a biopsy is still mandatory for histological confirmation because a significant number of these patients appear not to have CD.

### Research frontiers

It is unknown whether CD patients with high tTGA are phenotypically and genotypically different from CD patients with low tTGA.

### Innovations and breakthroughs

Authors prospectively investigated the differences between CD (Marsh III) patients with tTGA levels  $\geq 100$  U/mL and patients with lower levels. They found that patients with tTGA  $\geq 100$  U/mL more often carry multiple CD-associated heterodimers compared with patients with lower levels. In addition, these patients have more advanced mucosal lesions that are also less patchy. Phenotypically, they have a lower body weight and more often present with extraintestinal symptoms compared with patients with lower tTGA levels, who more often have intestinal symptoms.

### Applications

The findings of the current study provide further evidence that patients with high tTGA values are truly a distinct group with more advanced disease. These results therefore support the new European Society for Paediatric Gastroenterology, Hepatology and Nutrition criteria.

### Terminology

tTGA: these antibodies are directed against the enzyme tissue-transglutaminase, which is the auto-antigen in CD. This enzyme plays a key role in eliciting the immune response against gluten. EMA: the endomysium is the intercellular matrix that lies between the smooth muscle cells of the muscularis mucosae throughout the gastrointestinal tract. It is rich in the enzyme tissue-transglutaminase. Antibodies directed against the endomysium are actually directed against tissue-transglutaminase. Human leukocyte antigen (HLA)-DQ2/8: gluten-derived peptides, especially after enzymatic modification by the enzyme tissue-transglutaminase, show a very high affinity for HLA-DQ2/8. In contrast, gluten peptides barely show affinity to other HLA-DQ types. Therefore, having more of these CD-associated heterodimers will result in a stronger T- and B-cell response, while an absence of HLA-DQ2/8 excludes the presence of CD.

### Peer review

The paper by Mubarak *et al* investigated celiac children with high tTGA titres vs low titres. Main findings are a genetic diversity, extra-intestinal pathologies, lower height/weight ratio in high titre group. The paper is interesting and well written.

### Abstract

**AIM:** To evaluate the suitability of reference genes in gastric tissue samples and cell lines.

**METHODS:** The suitability of genes *ACTB*, *B2M*, *GAPDH*, *RPL29*, and *18S rRNA* was assessed in 21 matched pairs of neoplastic and adjacent non-neoplastic gastric tissues from patients with gastric adenocarcinoma, 27 normal gastric tissues from patients without cancer, and 4 cell lines using reverse transcription quantitative real-time polymerase chain reaction (RT-qPCR). The ranking of the best single and combination of reference genes was determined by NormFinder, geNorm™, BestKeeper, and DataAssist™. In addition, GenEx software was used to determine the optimal number of reference genes. To validate the results, the mRNA expression of a target gene, *DNMT1*, was quantified using the different reference gene combinations suggested by the various software packages for normalization.

**RESULTS:** *ACTB* was the best reference gene for all gastric tissues, cell lines and all gastric tissues plus cell lines. *GAPDH* + *B2M* or *ACTB* + *B2M* was the best combination of reference genes for all the gastric tissues. On the other hand, *ACTB* + *B2M* was the best combination for all the cell lines tested and was also the best combination for analyses involving all the gastric tissues plus cell lines. According to the GenEx software, 2 or 3 genes were the optimal number of references genes for all the gastric tissues. The relative quantification of *DNMT1* showed similar patterns when normalized by each combination of reference genes. The level of expression of *DNMT1* in neoplastic,

adjacent non-neoplastic and normal gastric tissues did not differ when these samples were normalized using *GAPDH* + *B2M* ( $P = 0.32$ ), *ACTB* + *B2M* ( $P = 0.61$ ), or *GAPDH* + *B2M* + *ACTB* ( $P = 0.44$ ).

**CONCLUSION:** *GAPDH* + *B2M* or *ACTB* + *B2M* is the best combination of reference gene for all the gastric tissues, and *ACTB* + *B2M* is the best combination for the cell lines tested.

**Key words:** Gastric cancer; Reference gene; Normalization; Gene expression; Quantitative real-time polymerase chain reaction

**Core tip:** Gene expression studies have revealed much about the molecular basis of gastric cancer. However, the normalization of expression data using reference genes without validation may undermine the results. In the present study, we evaluated the suitability of possible reference genes in gastric tissues and cell lines. To our knowledge, our study is the first to determine and validate reference genes for gastric samples in a Western population. In addition, the inclusion of normal gastric tissues from patients without cancer in determining the best reference genes is original in the literature.

## INTRODUCTION

Gastric cancer (GC) is the fourth most common cancer and the second leading cause of cancer-related death<sup>[1]</sup>. Although approximately 90% of gastric tumors are adenocarcinomas, the etiology and disease evolution may vary among populations, primary tumor location, histological subtypes of adenocarcinoma, and other variables. Among these factors, ethnicity can determine different levels of susceptibility and aggressiveness of gastric tumors<sup>[2,3]</sup>. An understanding of GC biology is important to identify cancer biomarkers, which may help in early diagnosis and in the development of new targets therapies and, therefore, contribute to reduce mortality or morbidity rates.

Although gene expression studies have revealed much about the molecular basis of GC, the detailed mechanisms remain unclear. Reverse transcription quantitative polymerase chain reaction (RT-qPCR) is currently considered the gold standard for accurate, sensitive, and rapid measurements of gene expression<sup>[4-6]</sup>. However, to

obtain reliable data, the gene expression levels must be normalized using two or more reference genes<sup>[7-9]</sup>. Ideally, reference genes should be stable, unregulated, and invariable under the conditions of the experiment<sup>[10,11]</sup>; therefore, a validation experiment for the evaluation of reference gene expression stability for each target tissue and disease is recommended<sup>[12,13]</sup>. To our knowledge, only one previous study has aimed to assess the best single and combination of reference genes for gastric adenocarcinoma and non-neoplastic samples in an East Asian population<sup>[14]</sup>. In contrast, there is no information about the stability of candidate reference genes in gastric samples from other populations.

In this study, we assessed the suitability of 5 possible reference genes in 21 matched pairs of neoplastic and non-neoplastic gastric tissues from patients with gastric adenocarcinoma and 27 normal gastric tissues from patients without cancer. We also included 4 cell lines in the analysis. The stability analysis was performed using 4 freely available software packages.

## MATERIALS AND METHODS

### Cell lines

The ACP02 and ACP03 cell lines were established by our research group from primary gastric adenocarcinomas classified as diffuse and intestinal types, respectively<sup>[15]</sup>. The PG100 and MRC-5 cell lines were obtained from Rio de Janeiro Cell Bank, Brazil, and were established from a primary gastric adenocarcinoma and from normal human fibroblasts, respectively. All the cell lines were cultured at 37 °C in RPMI media 1640 (GIBCO®, Grand Island, NY) supplemented with 10% fetal bovine serum (GIBCO®, Grand Island, NY), and 0.02 mg/mL kanamycin (GIBCO®, Grand Island, NY).

### Patients

Twenty-one matched pairs of neoplastic and adjacent non-neoplastic gastric tissues were obtained from patients with gastric adenocarcinoma who were subjected to gastric resection. Twenty-seven normal gastric tissues were obtained from patients subjected to routine endoscopic examination. Table 1 shows the clinicopathological features of the studied patients. All the gastric tissue samples were obtained from João de Barros Barreto University Hospital (HUIBB) in Pará State, Brazil, and were snap-frozen in liquid nitrogen and stored frozen until use. All patients had negative histories of exposure to either chemotherapy or radiotherapy before surgery, and there was no other co-occurrence of diagnosed cancers. Written informed consent with approval of the ethics committee of HUIBB was obtained from all patients prior to sample collection.

### RNA extraction and cDNA synthesis

Total RNA was extracted from the cell lines and tissue samples using the AllPrep DNA/RNA/Protein Kit (Qiagen, Hilden, Germany) according to the manufacturer's

**Figure 1** Expression level of five candidate reference genes detected by quantitative real-time polymerase chain reaction. A lower cycle threshold (Ct) value indicates higher gene expression.

instructions. The concentration and quality of the extracted RNA were measured using a Nanodrop ND-1000 (Thermo Scientific, Wilmington, DE), and the integrity was determined by gel electrophoresis. The complementary DNA was synthesized using High-Capacity<sup>®</sup> cDNA Reverse Transcription (Life Technologies, Foster City, CA) following the manufacturer's protocol.

### RT-qPCR

The reaction to detect the expression range of the 5 candidate reference genes was performed in triplicate using TaqMan<sup>®</sup> inventoried Assays-on-Demand probes (Life

Technologies, Foster City, CA) and the Applied Biosystems 7500 fast real-time PCR system. We also quantified the mRNA expression of a target gene, *DNMT1*, using the possible candidate genes for normalization. For this analysis, we evaluated 18 matched pairs of adjacent non-neoplastic and neoplastic gastric tissues from patients with gastric adenocarcinoma and 19 normal gastric tissues from patients without cancer. The analyzed genes, their respective TaqMan<sup>®</sup> assay identification and efficiencies are provided in Table 2. The relative quantification (RQ) of *DNMT1* expression was calculated according to the Livak method<sup>[16]</sup>. A sample from a patient without cancer was designated as a calibrator.

### Analysis of reference gene stability

We categorized the gastric tissues and cell lines into the following groups: (1) neoplastic tissues; (2) adjacent non-neoplastic tissues; (3) matched pairs of adjacent non-neoplastic and neoplastic gastric tissues; (4) normal tissues; (5) all gastric tissues; (6) cell lines; and (7) all gastric tissues plus cell lines. For the stability comparisons of the candidate reference genes, we used the software NormFinder version 20 (<http://www.mdl.dk/publicationsnormfinder.htm>)<sup>[17]</sup>, geNorm<sup>™</sup> (<http://medgen.ugent.be/~jvdesomp/genorm/>)<sup>[7]</sup>, BestKeeper1 (<http://www.gene-quantification.de/bestkeeper.html>)<sup>[18]</sup>, and DataAssist<sup>™</sup> (<http://www.lifetechnologies.com/us/en/home/technical-resources/software-downloads/dataassist-software.html>) according to the recommendations of the authors. The software GenEx (<http://genex.gene-quantification.info/>) was used to determine the optimal number of reference genes by calculating the Accumulated Standard Deviation (Acc.S.D.).

In the analysis using geNorm, the reference genes were ranked according to the expression stability value M (average pair-wise variation of a gene with all other tested candidate reference genes). Using NormFinder, the set of candidate reference genes was ranked accord-

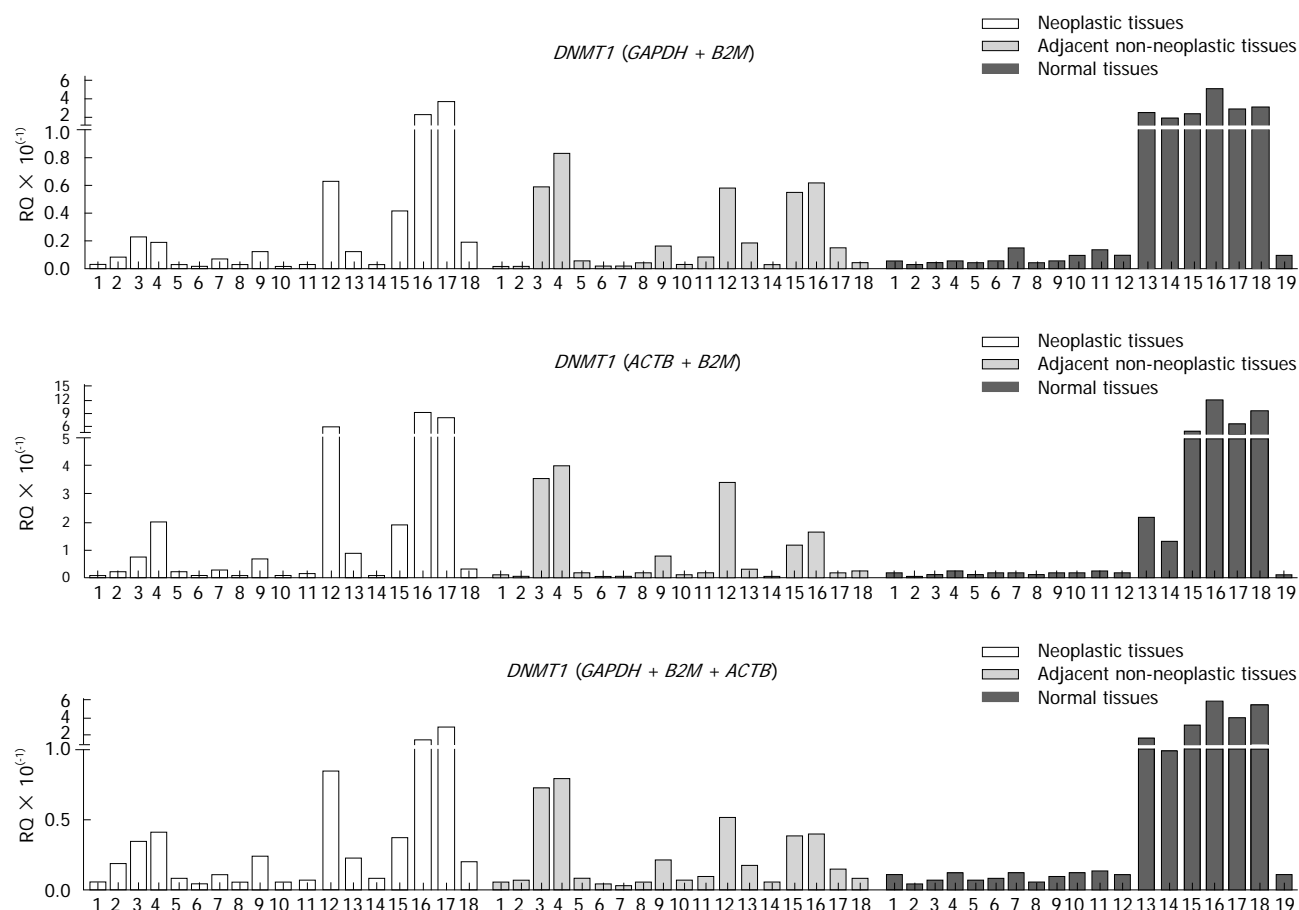

Figure 2 Relative quantification of *DNMT1*, as normalized by *GAPDH + B2M*, *ACTB + B2M*, and *GAPDH + B2M + ACTB* in gastric tissues.

ing to their expression stability (combination of the intra- and intergroup variation). The ranking of the 5 reference genes by Bestkeeper was based on the standard deviation (SD) and coefficient of variance (CV) expressed as a percentage of the cycle threshold (Ct) level. Lastly, DataAssist provides a metric to measure reference gene stability based on the geNorm algorithm. Unlike all the other programs, DataAssist uses RQ to calculate the stability value of individual candidate reference genes. The two genes that showed the highest stability were considered the best combination of reference genes.

## RESULTS

### Expression level of candidate reference genes

The expression levels of 5 candidate reference genes as the Ct value are shown in Figure 1. These genes displayed a wide range of expression levels. *18S rRNA* showed the highest expression level in the gastric tissues and cell lines. In contrast, *RPL29* showed the lowest expression level and did not amplify in 3 samples of neoplastic tissue, 2 samples of adjacent non-neoplastic tissue, and 9 samples of normal tissue. Similarly, *RPL29* and *GAPDH* did not amplify in any of the 4 cell lines studied. Therefore, *RPL29* was excluded from the ensuing analysis, and *GAPDH* was excluded from the set of

candidate reference genes in the cell line analysis.

### Expression stability of candidate reference genes

Table 3 demonstrates the stability value ranking of the single candidate reference genes calculated using the 4 different software packages. Although the various software packages suggested different reference genes, *ACTB* was the gene most cited as the best reference gene in the different gastric tissue categories, followed by *GAPDH* and *B2M*. *ACTB* was also the best reference gene in the cell line and all gastric tissues plus cell line categories.

Table 4 shows the best combination of reference genes suggested by the 4 software packages. Overall, for the different gastric tissue categories, *GAPDH + B2M* were the genes more cited as the best combination of reference gene, followed by *ACTB + B2M* and *GAPDH + ACTB*. *ACTB + B2M* was also the best combination of reference genes suggested for the cell lines and all gastric tissues plus cell line categories.

Although the software indicated up to 2 genes as the best combination of reference genes, we also used GenEx software to determine the optimal number of reference genes. This software revealed that an Acc. S.D. of 0.03 was the lowest when 2 or 3 reference genes were used for both the matched pairs of adjacent non-

**Table 2** Summary of five reference genes and a target gene

Symbol	Gene name (Assay ID <sup>1</sup> )	Location	Description	Efficiency
<i>ACTB</i>	β-Actin (Hs03023943_g1)	7p22	Cytoskeletal structural protein	109%
<i>B2M</i>	β-2-Microglobulin (Hs00984230_m1)	15q21	Beta-chain of major histocompatibility complex class I molecules	104%
<i>GAPDH</i>	Glyceraldehyde-3-phosphate dehydrogenase (Hs99999905_m1)	12p13	Oxidoreductase in glycolysis and gluconeogenesis	102%
<i>RPL29</i>	Ribosomal protein L29 (Hs00426490_g1)	3p21	Structural constituent of the ribosome	100%
<i>18S rRNA</i>	18S ribosomal RNA (Hs99999901_s1)	22p12	Ribosome subunit	110%
<i>DNMT1</i>	DNA (cytosine-5-)-methyltransferase 1 (Hs00945875_m1)	19p13	Regulation of tissue-specific patterns of methylated cytosine residues	98%

<sup>1</sup>TaqMan® probes were purchased as Assays-on-Demand Products for Gene Expression (Life Technologies, Foster City, CA).

<sup>1</sup>A lower value indicates increased stability in gene expression.

neoplastic and neoplastic gastric tissues and all gastric tissues categories.

#### Target gene normalization using different combined reference genes

Because *GAPDH* + *B2M* and *ACTB* + *B2M* or *GAPDH* + *B2M* + *ACTB* were identified as the best combinations of reference genes for gastric tissues, we evalu-

ated the expression of *DNMT1*, as normalized by these combinations of reference genes. The RQ of *DNMT1* normalized by each combination of reference genes showed similar patterns (Figure 2). The level of expression of *DNMT1* in neoplastic, adjacent non-neoplastic and normal gastric tissues did not differ when these samples were normalized using *GAPDH* + *B2M* ( $P = 0.32$ , Kruskal-Wallis test), *ACTB* + *B2M* ( $P = 0.61$ ,

**Table 4** Best reference gene combinations according to each software

Neoplastic tissues	Adjacent non-neoplastic tissues	Normal tissues	Matched pairs of adjacent and neoplastic gastric tissues	nonneoplastic All gastric tissues	Cell lines	All gastric tissues <sup>+</sup> cell lines
<i>ACTB</i> + <i>B2M</i>	<i>GAPDH</i> + <i>B2M</i>	<i>GAPDH</i> + <i>ACTB</i>	<i>ACTB</i> + <i>B2M</i>	<i>ACTB</i> + <i>B2M</i>	<i>ACTB</i> + <i>B2M</i>	<i>ACTB</i> + <i>18S rRNA</i>
<i>GAPDH</i> + <i>B2M</i>	<i>GAPDH</i> + <i>B2M</i>	<i>GAPDH</i> + <i>ACTB</i>	<i>GAPDH</i> + <i>B2M</i>	<i>GAPDH</i> + <i>B2M</i>	<i>ACTB</i> + <i>B2M</i>	<i>ACTB</i> + <i>B2M</i>
<i>GAPDH</i> + <i>B2M</i>	<i>GAPDH</i> + <i>B2M</i>	<i>GAPDH</i> + <i>B2M</i>	<i>GAPDH</i> + <i>B2M</i>	<i>GAPDH</i> + <i>B2M</i>	<i>ACTB</i> + <i>B2M</i>	<i>ACTB</i> + <i>B2M</i>
<i>ACTB</i> + <i>B2M</i>	<i>GAPDH</i> + <i>B2M</i>	<i>GAPDH</i> + <i>B2M</i>	<i>GAPDH</i> + <i>B2M</i>	<i>GAPDH</i> + <i>B2M</i>	<i>ACTB</i> + <i>B2M</i>	<i>ACTB</i> + <i>B2M</i>

Kruskal-Wallis test), or *GAPDH* + *B2M* + *ACTB* ( $P = 0.44$ , Kruskal-Wallis test).

## DISCUSSION

Reference genes have been described for RT-qPCR studies in several diseases and tissues<sup>[19-23]</sup>. However, with regard to gastric adenocarcinoma samples, there is only one previous study that evaluated the best single and combination of reference genes in an East Asian Population<sup>[14]</sup>. Because ethnicity can determine different levels of gene expression, it is important to determine the suitability of reference genes considering the population in addition to the disease type and target tissue. To our knowledge, our study is the first to determine and validate reference genes for gastric samples in a Western Population. The population in Pará State, Brazil, is composed of interethnic crosses between three main groups: European (mainly represented by Portuguese), Africans, and Amerindians<sup>[24]</sup>. In addition, to our knowledge, the study of normal gastric tissue from patients without gastric cancer and its inclusion in determining the best single and combination of reference genes is original in the literature.

The software packages NormFinder, geNorm<sup>TM</sup>, BestKeeper, and DataAssist<sup>TM</sup> are statistical tools that aid in the selection of appropriate reference genes. Although these software packages differed in the suggestion of the best single and combination of reference genes, at least two programs agreed with the results for each group evaluated (Tables 3 and 4), emphasizing the importance of using more than one software to assess the best reference genes among a set of candidate genes. When considering all gastric tissues, our results showed that *ACTB* and *GAPDH* + *B2M* or *ACTB* + *B2M* were the best single and combination of reference genes, respectively. Despite the software packages indicating up to 2 genes as the best combination, the GenEx software revealed that 2 or 3 reference genes were necessary for gene normalization in all gastric tissue. When the expression of the target gene *DNMT1* was evaluated using the 3 different combinations of reference genes for normalization (*GAPDH* + *B2M*, *ACTB* + *B2M*, and *GAPDH* + *B2M* + *ACTB*), no differences in *DNMT1* expression were detected among the neoplastic, adjacent non-neoplastic, and normal tissues. These results validated the combination of reference genes suggested by the software, proving that combinations of 2 genes can be used and that it is not necessary to use 3 or more reference genes for all gastric tissues. *ACTB* and *ACTB* + *B2M*

were the best single and combination of reference genes, respectively, for all the cell lines. Our results showed that *ACTB* + *B2M* was the best option under circumstances that require the use of the same combination of reference genes for all gastric tissues and cell lines. Although the measure of stability for *18S rRNA* was within the range of acceptance when using BestKeeper, it has repeatedly been documented that this is not a good reference gene because the regulation of its synthesis is not representative of mRNA levels<sup>[25-28]</sup>.

Rho *et al.*<sup>[14]</sup> proposed different reference genes for the study of gene expression in gastric tissues and cell lines, suggesting *RPL29* and *RPL29* + *B2M* and *B2M* and *GAPDH* + *B2M* as the best single and combination of reference genes, respectively. Interestingly, the genes suggested by Rho *et al.*<sup>[14]</sup>, *RPL29* and *GAPDH*, did not amplify in our cell lines and in some tissue samples. The different methodologies applied can explain the different results. In the present study, we evaluated gene expression using commercially available TaqMan<sup>®</sup> assays, whereas Rho *et al.*<sup>[14]</sup> evaluated gene expression using SYBR green and primers previously reported in the literature that can detect non-specific reaction products with variable sensitivity. In addition, it should be considered that samples obtained from different ethnicities could contribute to the different results of our group and Rho *et al.*<sup>[14]</sup>.

In conclusion, our suitability analysis suggested *ACTB* and *GAPDH* + *B2M* or *ACTB* + *B2M* as the best single and combination of reference genes for all gastric tissues, with *ACTB* and *ACTB* + *B2M* as the best single and combination of reference genes for all cell lines tested. When circumstances require the use of the same combination of reference genes for all gastric tissues and cell lines, our results showed that *ACTB* + *B2M* was the best option. The use of these genes for RT-qPCR data normalization may enhance the robustness of transcription level determination in gastric samples.

## COMMENTS

### Background

Gastric cancer is the fourth most common cancer worldwide, with high rates of mortality and morbidity. Reverse transcription quantitative polymerase chain reaction is currently considered the gold standard for the accurate, sensitive, and rapid measurement of gene expression. To obtain reliable data, a validation experiment to evaluate the best reference genes for the normalization of gene expression data is recommended for each target tissue and disease.

### Research frontiers

The etiology and disease evolution of gastric adenocarcinomas vary among patients due to several factors. Among them, ethnicity can determine different levels of gastric tumor susceptibility and aggressiveness. The understanding

of gastric cancer biology is important to identify cancer biomarkers, which may help in the early diagnosis and development of new targets therapies and, therefore, contribute to reduce mortality and morbidity rates.

### Innovations and breakthroughs

Only one previous study aimed to evaluate the best reference genes for gastric adenocarcinoma in an East Asian population. To their knowledge, the present study is the first to determine and validate reference genes for gastric samples in a Western population. In addition, the analysis of normal gastric tissue from patients without gastric cancer and its inclusion in determining the best reference genes is original in the literature.

### Applications

The use of the combination of reference genes determined and validated in our study for reverse transcriptional quantitative polymerase chain reaction data normalization may enhance the robustness of transcription level determination in gastric samples.

### Terminology

Reference genes are internal controls used in reverse transcription quantitative polymerase chain reaction analysis to avoid the sample biases related to variability in the total RNA content, RNA stability, and enzymatic efficiency. Ideal reference genes should be stable, unregulated, and invariable under the conditions of the experiment.

### Peer review

The authors evaluated the suitability of five possible reference genes in matched pairs of non-neoplastic and neoplastic gastric tissues from patients with gastric adenocarcinoma and normal gastric tissues from patients without cancer. Four cell lines were also included in this analysis. The stability analysis was performed using four freely available software packages. This study validated *GAPDH* + *B2M* or *ACTB* + *B2M* as the best combination of reference genes for all gastric tissues. In addition, *ACTB* + *B2M* were suggested as the best combination of reference genes for cell lines. When circumstances require the use of the same combination of reference genes for all gastric tissues and cell lines, the *ACTB* + *B2M* combination was found to be the best option.

### Abstract

**AIM:** To elucidate surgical outcomes of pancreaticoduodenectomy (PD) in patients with liver cirrhosis.

**METHODS:** We studied retrospectively all patients who underwent PD in our centre between January 2002 and December 2011. Group A comprised patients with cirrhotic livers, and Group B comprised patients with non-cirrhotic livers. The cirrhotic patients had Child-Pugh classes A and B (patient's score less than 8). Pre-operative demographic data, intra-operative data and postoperative details were collected. The primary outcome measure was hospital mortality rate. Secondary outcomes analysed included duration of the operation, postoperative hospital stay, postoperative morbidity and survival rate.

**RESULTS:** Only 67/442 patients (15.2%) had cirrhotic livers. Intraoperative blood loss and blood transfusion

were significantly higher in group A ( $P = 0.0001$ ). The mean surgical time in group A was significantly longer than that in group B ( $P = 0.0001$ ). Wound complications ( $P = 0.02$ ), internal haemorrhage ( $P = 0.05$ ), pancreatic fistula ( $P = 0.02$ ) and hospital mortality ( $P = 0.0001$ ) were significantly higher in the cirrhotic patients. Postoperative stay was significantly longer in group A ( $P = 0.03$ ). The median survival was 19 mo in group A and 24 mo in group B. Portal hypertension (PHT) was present in 16/67 cases of cirrhosis (23.9%). The intraoperative blood loss and blood transfusion were significantly higher in patients with PHT ( $P = 0.001$ ). Postoperative morbidity (0.07) and hospital mortality ( $P = 0.007$ ) were higher in cirrhotic patients with PHT.

**CONCLUSION:** Patients with periampullary tumours and well-compensated chronic liver disease should be routinely considered for PD at high volume centres with available expertise to manage liver cirrhosis. PD is associated with an increased risk of postoperative morbidity in patients with liver cirrhosis; therefore, it is only recommended in patients with Child A cirrhosis without portal hypertension.

**Key words:** Periampullary tumour; Liver cirrhosis; Portal hypertension; Pancreaticoduodenectomy

**Core tip:** Traditionally, cirrhosis has been considered a contraindication to major gastrointestinal surgery. Hospital mortality rates have been reported to be 17.5 % to 38% for cirrhotic patients undergoing gastrointestinal surgery. Pancreaticoduodenectomy is associated with an increased risk of postoperative morbidity in patients with liver cirrhosis; therefore, it is recommended only in patients with Child A cirrhosis. Cirrhotic patients with portal hypertension were associated with poorer

outcome than cirrhotic patients without portal hypertension. Patients with periampullary tumours and well-compensated chronic liver disease should be routinely considered for radical surgery at high volume centres with available expertise to manage liver cirrhosis.

El Nakeeb A, Sultan AM, Salah T, El Hemaly M, Hamdy E, Salem A, Moneer A, Said R, AbuEleneen A, Abu Zeid M, Abdallah T, Abdel Wahab M. Impact of cirrhosis on surgical outcome after pancreaticoduodenectomy. *World J Gastroenterol* 2013; 19(41): 7129-7137 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i41/7129.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i41.7129>

## INTRODUCTION

Pancreaticoduodenectomy (PD) is a complex procedure; however, it is the only curative procedure for patients with malignant diseases of the pancreas and periampullary region. The procedure is also recommended in some benign pancreatic tumours<sup>[1-3]</sup>. Although PD is performed in many hospitals, its associated morbidity and mortality rates are still high. Recently, the operative mortality rate after PD has dramatically decreased to less than 5%, while the incidence of postoperative complications remains high: from 30% to 60%<sup>[3-7]</sup>. Recent studies have suggested that many factors influence postoperative morbidity and prognosis after PD, including age, sex, preoperative jaundice, operative time, intraoperative blood loss, type of pancreatic reconstruction, anastomotic technique, consistency of pancreatic stump, pancreatic duct diameter, use of somatostatin, mass size, safety margin, lymph node ratio and surgeon experience<sup>[5-9]</sup>.

Cirrhosis represents a common pathological pathway for a wide variety of chronic liver diseases. The progression of liver injury to cirrhosis can occur over weeks to years. Hepatitis C virus (HCV) is the most important cause of liver cirrhosis in Egypt<sup>[10,11]</sup>. Traditionally, cirrhosis has been considered a contraindication to major gastrointestinal surgery. The hospital mortality rates have been reported to be 17.5% to 38% for cirrhotic patients undergoing any gastrointestinal surgery<sup>[12-14]</sup>. Studies from the 1980s reported a mortality rate of approximately 25% and a morbidity rate of 35% for patients with cirrhosis undergoing open cholecystectomy<sup>[15,16]</sup>. Postoperative mortality for cirrhotic patients undergoing cholecystectomy has decreased significantly over the last two decades, partly because of the use of laparoscopy<sup>[17-19]</sup>.

Many studies have observed that patients with cirrhosis tend to have a significant risk of developing postoperative complications after major abdominal operations, frequently leading to their eventual death<sup>[15,16,20]</sup>. Patients with cirrhosis have an increased risk of complications during surgery (bleeding because of portal hypertension and coagulopathy, liver dysfunction, and ascites, which often lead to sepsis), which is related to the severity of

liver disease. It is a challenge to determine which patients are the best candidates for surgery<sup>[20,21]</sup>. Now, major surgical procedures can be safely performed in patients with cirrhosis with intensive preoperative care and with minimised intraoperative blood loss because surgical techniques and medical management have been improved significantly<sup>[16,19,20]</sup>.

The impact of cirrhosis on postoperative morbidity and mortality for gastrointestinal cancer resection has not been well described<sup>[12,22-25]</sup>. The aim of this study was to elucidate surgical outcomes of PD in patients with liver cirrhosis.

## MATERIALS AND METHODS

### Study design

We studied retrospectively all cirrhotic patients who underwent PD for malignant and benign diseases in pancreatic head and periampullary region in our Gastroenterology Surgical Center, Mansoura University, Egypt, from January 2002 to December 2011. The clinical condition of the patients was graded according to the Child-Pugh classification system<sup>[26]</sup>. In our centre, the inclusion criteria for PD included patients with resectable Periampullary tumours with CTP classes A and B (patient's score less than 8), and no other hepatic pathology. Exclusion criteria for surgery included patients with CTP classes B (patient's score > 8), and C, patients with poor liver function, patients with bleeding risky oesophageal varices or gastric varices, and patients with thrombosed portal veins, malnutrition or coagulopathy.

The medical records of patients, including their well-designed pancreatic surgical sheet, were reviewed. Informed consent for the surgical procedures was obtained from each patient. The local ethical committee approved this study.

The patients who underwent PD formed two groups: Group A (PD in patients with cirrhotic livers) and Group B (PD in patients with normal livers).

### Preoperative assessment

Preoperative diagnostic workup for all patients included clinical assessment, laboratory investigations (complete blood count, liver functions, HCV and HBV markers, creatinine, serum amylase and tumour markers, such as CEA and CA19-9) and radiological investigations [abdominal ultrasound, magnetic resonance cholangiopancreatography (MRCP) and abdominal computerised tomography CT].

Preoperative endoscopic retrograde cholangiopancreatography (ERCP) was carried out in selected patients (patients with serum levels of total bilirubin greater than 10 mg/dL or patients with hepatic dysfunction (transaminase: more than threefold the normal *i.e.*, more than 120 IU/mL).

The diagnosis of cirrhosis was proven on ultrasound findings, CT findings and intraoperatively. Liver biopsies were performed in some cases. The presence of preop-

erative portal hypertension was evaluated retrospectively: direct measurement of portal pressure was not performed routinely in this study, and portal hypertension was indirectly defined as oesophageal varices detected by endoscopy, or splenomegaly [major diameter > 12 cm with platelet count less than 100000/mm<sup>3</sup>, according to the Barcelona Clinic Liver Cancer (BCLC) group criteria]<sup>[22-25]</sup>.

### Surgical procedures

PD was carried out under general anaesthesia; hepatotoxic drugs were avoided. Standard Whipple type operation or pylorus preserving PD (PPPD) was performed. All patients underwent standard regional lymphadenectomy, which included resection of nodes within the outlines of the hepatoduodenal ligament, the right side of the superior mesenteric artery and the inferior vena cava. The presence of cirrhosis did not modify the standard procedure; however, we preferred to use suture ligature rather than cauterisation when possible. Pancreatic reconstruction was performed by either pancreaticogastrostomy (PG) or pancreaticojejunostomy (PJ), based on surgeon preference. Biliary drainage was achieved by end-to-side hepaticojejunostomy (retrocolic). However, gastric drainage was achieved by gastrojejunostomy (GJ) (antecolic or retrocolic) (manual or using a stapler) in the standard Whipple operation or duodenojejunostomy in PPPD (end-to-side or end-to-end).

### Postoperative management

All patients were managed in the intensive care unit (ICU) for at least one day before transfer to the ward. All patients received antibiotics intraoperatively and for 4 d postoperatively. Prophylactic sandostatin was given subcutaneously and continued postoperatively for 4 d in risky patients, which included patients with liver cirrhosis. The drain was removed in all enrolled patients if no bile leak, pancreatic leak or pus occurred. Outputs from Ryle tube were recorded daily, and it was removed if the patients passed flatus, had no distension or the daily output was less than 500 mL. The patients resumed oral feeding, started by a fluid diet, followed by a regular diet once the bowel movement restarted and they could tolerate oral feeding.

Liver functions were measured on post-operative day (POD) 1, and POD 6. Abdominal ultrasound was performed routinely for all patients, and repeated if we suspected intraabdominal collection. Ultrasound (US) guided tubal drainage was done if there was abdominal collection.

### Definitions

Postoperative pancreatic fistula was defined as proposed by the International Study Group of Pancreatic Fistula (ISGPF) as any measurable volume of fluid on or after POD 3 with amylase content greater than three times the serum amylase activity, and classified into grades A, B, and C<sup>[7,27,28]</sup>.

Biliary leak was defined as the presence of bile in the

drainage fluid that persisted to POD 4. Delayed gastric emptying was defined as output from a nasogastric tube of greater than 500 mL per day that persisted beyond POD 10, the failure to maintain oral intake by POD 14 or reinsertion of a nasogastric tube<sup>[7,23]</sup>. Postoperative ascites was defined as effusion of more than 400 mL/d through the drain after POD 4.

### Follow up

Patients were followed up after 2 wk, 1 mo, 6 mo, 1 year and then annually. Patients' follow-up was based on medical records, their last hospital visit and personal communication conducted by telephone calls.

### Data collection

Preoperative demographic and clinical data, surgical procedure, intra-operative data, pathologic diagnosis, post-operative course, early and late complications details and survival were collected.

### Statistical analysis

The primary outcome measure was hospital mortality rate. Secondary outcomes analysed included duration of the operation, postoperative hospital stay, postoperative morbidity and survival rate. Statistical analysis of the data in this study was performed using SPSS software, version 17. For continuous variables, descriptive statistics were calculated and were reported as the mean  $\pm$  SD. Categorical variables were described using frequency distributions. Independent sample *t*-test was used to detect differences in the means of continuous variables and  $\chi^2$  test was used in cases with low expected frequencies. Survival was calculated and plots constructed according to the Kaplan-Meier method and life table method. A log-rank test was used for comparison of survival in different subgroups. *P* values < 0.05 were considered to be significant.

## RESULTS

### Characteristics of patients

PD was performed in 442 patients in our Gastroenterology Surgical Center, Mansoura University, Egypt, between January 2002 and December 2011. During this study, only 67 patients (15.2%) had cirrhotic livers [48 (71.6%) men and 19 (28.4%) women, with a mean age  $54.07 \pm 9.43$  years] (group A), and the other 375 patients (84.8%) had non-cirrhotic livers (group B).

In group A, cirrhosis was diagnosed as secondary to hepatitis C in 44 patients (65.7%), hepatitis B in eight patients (11.9%), both hepatitis C and B in five patients (7.5%) and pure bilharzial periportal fibrosis in 10 patients (14.9%, Table 1).

Portal hypertension was present in 16/67 cases (23.9%) and absent in the remaining 51 (76.1%). Of these 16 cases, four patients had Child-Pugh class B (all patients had splenomegaly with platelet count less than 100000/mm<sup>3</sup> and oesophageal varices grade 1) and 12 patients had Child-Pugh class A (all patients had splenomegaly with

**Table 1** Demographic data for cirrhotic patients *n* (%)

platelet count less than 100000/mm<sup>3</sup>, and two patients had oesophageal varices).

There was no statistical difference between patient groups with regard to age, BMI, Preoperative SGPT, bilirubin, haemoglobin, preoperative drainage or preoperative CA19-9. There was statistical difference between patient groups with regard to gender: more male patients were in cirrhotic group ( $P = 0.006$ ). Preoperative albumin values were significantly lower in group A than in group B ( $P = 0.01$ ). The mean preoperative CEA was significantly higher in group A than in group B ( $67.31 \pm 69.78$  *vs*  $30.97 \pm 62.57$  respectively,  $P = 0.0001$ , Table 2).

PD was decided for cirrhotic patients (Child A or B with patient's score less than 8) for whom surgery could be performed (the tumour was not locally advanced, and they had no distant metastases).

### Operative data

There was no statistical difference between the groups in terms of tumour size, pancreatic texture, pancreatic duct diameter and site of the tumour. The median intraoperative blood loss and blood transfusion were significantly different between the groups. Blood loss was 500 mL (100-2500 mL) in the cirrhotic group *vs* 200 mL (50-2000) in the non-cirrhotic group,  $P = 0.0001$  and blood transfusion was 1 (0-4 units) in the cirrhotic group *vs* 0 (0-4 units) in the non-cirrhotic group,  $P = 0.0001$ . Estimated intraoperative bleeding of more than 500 mL occurred in 36 patients (53.7%) in group A and 142 (37.9 %) patients in group B; the difference between the two groups was statistically significant ( $P = 0.015$ ). Thirty eight patients (58.7%) in group A required a blood transfusion, and 145 patients (38.7%) in group B required a blood transfusion intraoperatively. The mean operative time in group A was  $5.81 \pm 0.87$  h, which was significantly longer than that in group B, which was  $5.1 \pm 0.99$  h ( $P = 0.0001$ ) (Table 3).

### Postoperative data

The mean postoperative stay was significantly longer in group A ( $12.97 \pm 11.2$  d *vs*  $10.71 \pm 7.41$  d,  $P = 0.03$ ). In group A, 70 postoperative complications developed in 31 patients (46.26%). While in group B, 188 postoperative complications occurred in 85 patients (22.66%). Patient morbidity was more frequent in group A than in group B. A statistically significant difference was observed in wound complications ( $P = 0.02$ ), occurrence of internal haemorrhage ( $P = 0.05$ ) and development of a postoperative pancreatic fistula (POPF,  $P = 0.02$ ). POPF occurred in 13 patients (19.4%) in group A and in 37 patients (9.9%) in group B. The POPF was grade C in 11 patients, five of them in cirrhotic group who died from sepsis and six in the non cirrhotic group, three of whom died from sepsis (Table 4).

In group A, two patients developed encephalopathy, seven patients developed postoperative ascites that was treated by diuretics and three patients (4.5%) developed liver cell failure. Twelve patients (17.5%) developed intra-abdominal collection, for whom ultrasound guided tubal drainage was performed. Eight patients (11.5%) required re-exploration, four because of internal haemorrhage, one for bleeding gastrojejunostomy, one for bleeding PG and two for debridement and drainage.

In group B, 40 patients (10.7%) developed intra-abdominal collection and were managed by ultrasound guided tubal drainage. Twenty seven patients (7.2%) required re-exploration, seven because of internal haemorrhage, 12 for bleeding gastrojejunostomy, six for bleeding

PG, one for debridement and drainage (one patient) and completion spleno-pancreatectomy was required in one patient who had PF complicated by internal haemorrhage because of erosion of the gastroduodenal artery.

Postoperative complications, including delayed gastric emptying, intra-abdominal collection, biliary leakage, pulmonary complication, bleeding gastrosplenostomy and bleeding PG, were not significantly different between both groups (Table 4).

Cirrhotic patients with portal hypertension were associated with poorer outcome than cirrhotic patients without portal hypertension. The median intraoperative blood loss and blood transfusion were significantly more in cirrhotic patients with portal hypertension than in cirrhotic patients without portal hypertension [blood loss was 1000 mL (200-2500 mL) *vs* 300 mL (100-2500 mL), *P* = 0.001 respectively and blood transfusion was two units (0-4 units) *vs* one unite (0-4 units), *P* = 0.02 respectively]. Twelve (75%) of the cirrhotic patients with portal hypertension required a blood transfusion, while 26 (51%) cirrhotic patients without portal hypertension required a blood transfusion intraoperatively. Patients who had portal hypertension developed 30 postoperative complications in the form of pancreatic leakage in six patients (37.5%), ascites in three patients (18.8%), wound infection in four patients (25%), intra-abdominal collection in four patients (25%), delayed gastric emptying in four patients (25%) and deterioration of liver function in two cases (12.5%, Table 5).

Hospital mortality was significantly higher in group A than in group B [8 (11.9%) *vs* 6 (1.6%), *P* = 0.0001].

Mortality in the cirrhotic group, 6/63 patients died had Child A and 2/4 patients had Child B (Table 4). Hospital mortality in cirrhotic patients with portal hypertension was higher than in cirrhotic patients without hypertension [4/16 (25%) *vs* 4/51 (7.8%), *P* = 0.07, Table 5].

### Long term survival

The median follow up time for this study was 22 mo (range; 1-123 mo).The median survival was 19 mo in group A and 24 mo in group B. The 1, 2, and 3 year survival rates were 42%, 13%, and 3% respectively in group A and 59%, 29%, and 19%, respectively, in group B. There was a statistically significant difference between the two groups (*P* = 0.009, Table 4).

## DISCUSSION

Recently, the operative mortality rate after PD has dramatically decreased to less than 5%, while the incidence

NS: Not significant; PHT: Portal hypertension.

of postoperative complications remains high, from 30% to 60%<sup>[1-4]</sup>. However, PD remains the only curative treatment for periampullary tumours. In the majority of cases, morbidity and mortality after PD are related to surgical management of the pancreatic stump and anatomical feature of the stump<sup>[4-6]</sup>. PD may have a high risk of developing considerable complications, including POPF, intraabdominal bleeding, delayed gastric emptying, or intraabdominal collection<sup>[1-6]</sup>.

The incidence and prevalence of cirrhosis has been increasing in many countries for the past four decades, due to the increase incidence of viral hepatitis, alcoholic intake and non-alcohol related fatty liver disease<sup>[10,11,29,30]</sup>. These individuals are at an increased risk of bleeding, infection, hepatic decompensation, including hepatic coma after a major abdominal operation. Therefore, PD in these patients must be performed in a high volume center<sup>[29-34]</sup>. Indication for cancer treatment in cirrhotic patients has expanded, because surgical techniques and medical management have been improved remarkably. It has been suggested that PD in cirrhotic patient carries a

high risk of morbidity and mortality. Appropriate perioperative evaluation of cirrhotic patients will lead to their safer management<sup>[13,20,31-36]</sup>.

Few studies with small numbers of patients have been published to show the impact of cirrhosis on the surgical outcome after pancreatic resection<sup>[20,31-34,37]</sup>. No evidence-based guidelines were obtained regarding the management of resectable periampullary tumour in cirrhotic patients<sup>[1,35-40]</sup>. Artinyan *et al*<sup>[12]</sup> reported that cirrhosis is a risk factor for postoperative morbidity and mortality after general surgical procedures. However, the impact of cirrhosis on surgical outcome in gastrointestinal malignancies has not been described.

In our study, we decided to perform PD in child A and B patients with periampullary tumours. One way to avoid a high operative mortality in Child B and C is not to operate. The severity of liver disease is the most important factor predicting postoperative surgical outcome. Patients with liver cirrhosis have an inappropriate response to surgical stress secondary to the loss of liver reserve and because of other systemic derangements that

are the result of hepatic dysfunction (such as hemodynamic impairments)<sup>[32]</sup>. A case control study by Warnick *et al*<sup>[31]</sup> compared outcomes in 32 cirrhotic patients (30 Child A and Child B) *vs* matched controls (non cirrhotic) undergoing pancreatic resection surgery, they concluded that the cirrhotic group had a significantly higher rate of complications than the non-cirrhotic group (47% *vs* 22%;  $P = 0.035$ ), and required reoperation (34% *vs* 12%,  $P = 0.039$ ). These patients also had a prolonged hospital stay (27.9 d *vs* 24.3 d), a significantly longer ICU stay (8.6 d *vs* 3.7 d;  $P = 0.033$ ) and required twice as many transfusions. Overall, the hospital mortality was 3 patients, 1 with Child A (3% of all Child A patients) and 2 with Child B cirrhosis. The demanding medical efforts required by these patients demand that they are treated exclusively in high-volume centres<sup>[29]</sup>.

In this study, we found that intraoperative blood loss was significantly higher in cirrhotic patients. Estimated intraoperative bleeding of more than 500 ml occurred in 36 patients (53.7%) in group A and 142 (37.9%) patients in group B, the difference between the two groups was statistically significant ( $P = 0.015$ ). In cirrhotic patients, there are a bleeding tendency and portal hypertension explained the increased intraoperative blood loss. We have overcome this bleeding tendency using vitamin K injection and fresh frozen plasma. We used suture ligation rather than cauterisation when possible. Currently, the ultrasonically activated (Harmonic) scalpel and LigaSure™ have proved to be effective and safe instruments for dissection and haemostasis in both open and laparoscopic surgical procedures<sup>[17,19,38,40]</sup>.

Pancreatic leakage remains the most important cause of morbidity, and also contributes significantly to prolonged hospitalization, increased health care costs and mortality. It remains a challenge at high volume centres for pancreatic surgery<sup>[4,5]</sup>. The incidence of pancreatic anastomotic leakage after PD among different series ranged from 5% to 30%<sup>[2,6]</sup>. Many factors influence PF after PD, including age, sex, preoperative jaundice, operative time, intraoperative blood loss, type of pancreatic reconstruction, anastomotic technique, consistency of pancreatic stump, pancreatic duct diameter, use of somatostatin and surgeon experience<sup>[6-11]</sup>. In our study, POPF occurred in 13 patients (19.4%) in group A and in 37 patients (9.9%) in group B ( $P = 0.02$ ). The POPF was grade C in 11 patients, five in the cirrhotic group who died from sepsis, and six in the non-cirrhotic group, three of whom died from sepsis. This is because the healing power of cirrhotic patients is reduced compared with non-cirrhotic patients.

In this study, two patients developed encephalopathy and seven patients developed postoperative ascites in the cirrhotic group. Encephalopathy may be induced by infection, diuretics, metabolic alkalosis, constipation, hypoxia, sepsis, bleeding and electrolyte imbalance in the perioperative period. Correction of electrolyte imbalance, treatment of infection, branched chain amino acid and restriction of sedatives help to prevent encephalopa-

thy<sup>[32-34]</sup>.

The degree of portal hypertension can be correlated with the severity of cirrhosis, which is estimated by the Child-Pugh score. As a result, an improvement in liver function is associated with decrease in portal hypertension. Cucchetti *et al*<sup>[24]</sup> reported that cirrhotic patients with portal hypertension were associated with poorer outcome. Patients with portal hypertension were often Child-Pugh B and C patients, and when considering only Child-Pugh A class, the results were similar with or without portal hypertension. Some authors concluded that portal hypertension should not be considered as a contraindication for hepatic resection<sup>[24,25]</sup>. In our study, cirrhotic patients with portal hypertension were associated with poorer outcome than cirrhotic patients without portal hypertension. Intraoperative blood loss and blood transfusion were significantly higher in cirrhotic patients with portal hypertension than in cirrhotic patients without portal hypertension. Patients who had portal hypertension developed 30 postoperative complications in the form of pancreatic leakage, ascites, wound infection, intra-abdominal collection, delayed gastric emptying and deterioration of liver function.

The hospital mortality rates after various surgical operations among cirrhotic patients range from 8.3% to 25% (even in well selected cases) compared to 1.1% in non-cirrhotic patients<sup>[34-37]</sup>. Mortality is the consequence of a high rate of postoperative liver cell failure (especially in cases of intra-abdominal surgery) and an increased risk of bacterial infection<sup>[36]</sup>. Warnick *et al*<sup>[31]</sup> reported that, overall, 3 patients died following surgery. In Child A cirrhotic patient, the mortality is, however, comparable to non-cirrhotic patients. Artinyan *et al*<sup>[12]</sup> reported that a query of the National Inpatient Sample Database (2005-2008) identified 106729 patients who underwent resection for GI malignancy; 1479 (1.4%) had cirrhosis. Cirrhotic patients had higher risk of hospital mortality (8.9% *vs* 2.8%,  $P < 0.001$ ) and longer postoperative stay ( $11.5 \pm 0.26$  d *vs*  $10.0 \pm 0.03$  d,  $P < 0.001$ ). Mortality was highest in patients with moderate to severe liver cirrhosis (21.5% *vs* 6.5%,  $P < 0.001$ ). On multivariate analysis, cirrhosis was an independent predictor of hospital mortality. That study also suggested that resection of gastrointestinal malignancy can be performed safely in well-selected cirrhotic patients with mild liver dysfunction. In our study, the hospital mortality was significantly higher in cirrhotic patients than in non-cirrhotic patients [8/67 (11.9%) *vs* 6/375 (1.6%),  $P = 0.0001$ ] and the hospital mortality was higher in Child B patients than Child A. The cause of death in cirrhotic group was liver cell failure in four patients (6%) and sepsis in four patients (6%). Hospital mortality in cirrhotic patients with portal hypertension was higher than in cirrhotic patients without hypertension [4/16 (25%) *vs* 4/51 (7.8%),  $P = 0.07$ ]. In our series, postoperative mortality was low probably because we have experience in pancreatic surgery: in our centre we perform around forty cases per year<sup>[41,42]</sup>.

In this study, the median survival was 19 mo for cir-

rhctic patients, which is comparable to the 15.8 mo reported by Fuks *et al*<sup>[39]</sup> for PD in patients with cirrhosis.

The limitations of this study were the retrospective design and the limited number of cases. Further studies are needed to confirm the impact of cirrhosis and portal hypertension in surgical outcome after PD and to show risk factors.

In a conclusion, PD is associated with an increased risk of postoperative morbidity in patients with liver cirrhosis; therefore, it is recommended only in patients with Child A cirrhosis. Cirrhotic patients with portal hypertension were associated with poorer outcome than cirrhotic patients without portal hypertension. Patients with periampullary tumour and well-compensated chronic liver disease should be routinely considered for radical surgery at high volume centres with available expertise to manage liver cirrhosis.

## COMMENTS

### Background

Indication for cancer treatment in cirrhotic patients has expanded. Patients with periampullary tumours and well-compensated chronic liver disease should be routinely considered for pancreaticoduodenectomy (PD) at high volume centres with available expertise to manage liver cirrhosis. PD is associated with an increased risk of postoperative morbidity in patients with liver cirrhosis; therefore, it is only recommended in patients with Child A cirrhosis without portal hypertension.

### Research frontiers

Intraoperative blood loss and blood transfusion were significantly more in cirrhotic. The mean surgical time in group A was significantly longer than that in group B. Wound complications, internal haemorrhage, pancreatic fistula and hospital mortality were significantly higher in cirrhotic patients. Postoperative stay was significantly longer in cirrhotic. The median survival was in cirrhotic patients after PD. Portal hypertension (PHT) was present in 16/67 cirrhotic patients (23.9%). The intraoperative blood loss and blood transfusion were significantly more in portal hypertension (PHT). Postoperative morbidity and hospital mortality were higher in cirrhotic with PHT.

### Innovations and breakthroughs

Patients with periampullary tumour and well-compensated chronic liver disease should routinely be considered for radical surgery at high volume centres with expertise available to manage liver cirrhosis.

### Applications

PD is associated with an increased risk of postoperative morbidity in patients with liver cirrhosis, and therefore it is recommended only in patients with Child A cirrhosis. Cirrhotic patients with portal hypertension were associated with poorer outcome than cirrhotic patients without portal hypertension. Patients with periampullary tumour and well-compensated chronic liver disease should routinely be considered for radical surgery at high volume centres with expertise available to manage liver cirrhosis.

### Peer review

It is interesting and important to investigate surgical outcomes of PD in patients with liver cirrhosis. PD is recommended only in patients with Child A cirrhosis.

### Abstract

**AIM:** To investigate whether predicting patients that might be at a higher risk for complications might serve to improve the selection of patients undergoing colonic stenting.

**METHODS:** A retrospective review of consecutive patients who underwent an attempted self-expandable metal stent (SEMS) insertion for malignant colonic obstruction between November 2006 and March 2013. All patients were either referred for preoperative colonic decompression with the intent of a single surgical procedure, or for palliation of the malignant colorectal obstruction for unresectable cancer. Fisher's test or  $\chi^2$  test was performed on categorical variables, and the  $t$  test

for continuous variables. Univariable and multivariable logistic regression were used to examine the association between independent variables and the presence of complications from SEMS insertion.

**RESULTS:** SEMS insertion was attempted in 73 patients. Males comprised 55.71% and the mean age was  $67.41 \pm 12.41$  years. Of these, 65.15% underwent subsequent surgery, while 34.85% received SEMS as palliation for advanced disease. Extracolonic tumors were only 4.76%. The majority of patients had stage IV disease (63.83%), while the remainder had stage III (36.17%). SEMS were successfully inserted in 93.85% (95%CI: 87.85%-99.85%). Perforations occurred in 4.10%, SEMS migration in 8.21%, and stent re-occlusion from ingrowth occurred in 2.74% of patients. The mean duration of follow up for the patients was  $13.52 \pm 17.48$  mo (range 0-73 mo). None of the variables: age, sex, time between the onset of symptoms to SEMS insertion, time between SEMS insertion and surgery, length of the stenosis, location of the stenosis, albumin level, or receiving neoadjuvant chemotherapy, could predict the development of complications from either SEMS insertion nor prolonged survival.

**CONCLUSION:** None of the variables could predict the development of complications or survival. Further studies are required to identify patients who would benefit the most from SEMS.

**Key words:** Colonic obstruction; Colorectal cancer; Palliative interventions; Self-expanding metal stent; Colonic stents; Enteric stenting; Emergency surgery; Complications; Endoscopy

**Core tip:** Despite the debate as to whether there is an added benefit from the use of self-expandable metal stents (SEMS), when compared to surgery, as an ini-

tial management strategy in patients with malignant colorectal obstruction, this study found that SEMS insertion for malignant colonic obstruction is a safe option with an acceptable risk profile. We could not identify factors that would predict the development of complications or factors that might impact long-term survival. Nonetheless, based on current guidelines, SEMS insertion for malignant colorectal obstruction is the best option for palliation or as a bridge to surgery when technical skills for such a procedure are available.

Complications and survival in patients undergoing colonic stenting for malignant obstruction. *World J Gastroenterol* 2013; 19(41): 7138-7145 Available from: URL: <http://www.wjg-net.com/1007-9327/full/v19/i41/7138.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i41.7138>

## INTRODUCTION

The use of self-expandable metal stents (SEMS) has increased in recent years, mostly either as a palliative measure or as a bridge to surgery<sup>[1-4]</sup>. There are risks associated with the use of SEMS, such as perforation<sup>[2-6]</sup>, migration<sup>[2-6]</sup> and reobstruction<sup>[2-4]</sup>, as well as a debate as to whether there is an added benefit from the use of SEMS when compared to surgery as an initial management strategy<sup>[7,8]</sup>, and even possibly a negative effect on survival<sup>[8,9]</sup>. However, there are study design considerations that might account for such results<sup>[8,9]</sup>. As a consequence of the variability in individual study designs as well as the lack of standardization in reporting outcomes, results of numerous meta-analyses conducted on this topic have been variable<sup>[10-16]</sup>. SEMS remain an attractive option due to the avoidance of emergency surgeries, the advantage of undergoing a single operation with the avoidance of stomas<sup>[17,18]</sup>, a lower early morbidity, a shorter hospital stay<sup>[11,17,18]</sup>, and decreased cost<sup>[2]</sup>. Attempting to predict patients that might develop complications and identifying factors that might impact long-term survival from the insertion of SEMS for the management of malignant colorectal obstruction might aid in the better selection of patients who undergo this management strategy and who would benefit the most from SEMS.

## MATERIALS AND METHODS

A retrospective review was conducted using an endoscopic reporting database of individuals seen at a major tertiary care university hospital: King Khalid University Hospital in Riyadh, Saudi Arabia. The medical records of consecutive patients who underwent an attempted SEMS insertion between November 2006 and March 2013 were included. All patients were either referred for preoperative colonic decompression with the intent of a single surgical procedure, or for palliation of the malignant colorectal obstruction of unresectable cancer.

Based on a computerized tomography (CT) scan that was performed for the patients, the stage of the tumor was determined, and the SEMS insertion would be either as a bridge to surgery in patients that were deemed resectable or as a palliative procedure in those who had metastatic disease or were poor surgical candidates. All demographic features were collected through a chart review, which included: age, sex, symptoms, comorbidities, indication for SEMS insertion, date of the procedure, date of subsequent surgery (if performed), location, length of stenosis, stage of the tumor, whether the patient received neo-adjuvant chemotherapy, whether the SEMS insertion was successful (as well as the reason if it did not succeed), length of the SEMS used, number of SEMS used (if more than one SEMS was used for a patient), any complications that occurred after the SEMS insertion, duration between the initial symptoms and the SEMS insertion, and the duration between SEMS insertion and last date of follow up. Patients with any of the following were excluded: clinical evidence of bowel perforation or peritonitis, free intraperitoneal air on abdominal imaging, significant coagulopathy, hemodynamic or pulmonary instability, non-malignant strictures (*e.g.*, those with inflammatory strictures due to diverticulitis), those where the endoscopist found a patent lumen not requiring SEMS insertion, or rectal cancer within 5 cm from the anocutaneous line.

### Endoscopic technique

Before insertion of colonic SEMS, the patients underwent a CT scan of the chest, abdomen, and pelvis to evaluate the location and extent of the tumor, and to assess the area of the stenosis. SEMS were inserted by 1 of 3 therapeutic endoscopists. All endoscopies were performed under fluoroscopic guidance and were inserted through the working channel of the endoscope, which was either a therapeutic gastroscope, a colonoscope, or a duodenoscope depending on the location of the tumor and its angulation compared to the lumen of the colon. All the SEMS used were uncovered (WallFlex colonic stent), 22 mm in diameter, and 60 or 90 mm in length. The length of the stent used was dictated by the judgment of the endoscopist. The majority of the procedures were performed with the patient under conscious sedation, with intravenous midazolam and fentanyl administered by the endoscopist. Cleansing enemas were used until the washing water became clear. No oral bowel preparation was given. The endoscope was carefully inserted to the site of obstruction, then a straight tip guidewire (0.035 in diameter and 450 cm long) was inserted through a triple-lumen 5.5 French ERCP cannula through the stricture, and water soluble contrast was injected to delineate the length of the stricture, as well as the anatomy, and to confirm the intraluminal position of the guidewire. After the guidewire was passed through the stricture, a colonic SEMS assembly was advanced over the guidewire through the working channel and inserted through the obstruction site under combined fluoroscopic and endo-

scopic guidance. The stent was deployed at the stricture site while pulling back the outer sheath. If a SEMS did not expand, no dilation was attempted but a second stent inserted co-axially within the initial SEMS might have been used. If there was clinical suspicion of a complication, a plain abdominal radiograph was performed post-procedure. Stool softeners were routinely prescribed to prevent stool impaction in the stent. A plain abdominal radiograph the day after the procedure was performed, to confirm correct positioning and expansion of the SEMS. Successful SEMS insertion was defined as deployment and expansion of the SEMS across the stricture, radiologic and clinical relief of obstruction, and the ability to defecate. After the SEMS insertion, patients were observed for any procedure-related complications. Patients who had SEMS inserted with a palliative intent or as a bridge to surgery were followed until their last visits or death. The ethics committee of King Khalid University Hospital approved the study.

### Statistical analysis

Descriptive statistics were computed for continuous variables including mean  $\pm$  SD, and minimum and maximum values. Frequencies and inter-quintile ranges were used for categorical variables. Fisher's test or  $\chi^2$  test was performed on categorical variables, and the *t* test for continuous variables. Univariable and multivariable logistic regression were used to examine the association between independent variables and the presence of complications from SEMS insertion. OR and 95%CI were estimated. Cox proportional hazard ratio was used for survival analysis. We used the software STATA 11.2 (StataCorp, TX, United States) in our analysis. A *P* value of  $< 0.05$  was considered statistically significant.

## RESULTS

SEMS insertion was attempted in 73 patients. Males comprised 55.71% of the cohort and the mean age was  $67.41 \pm 12.41$  years (95%CI: 63.50-71.33). Clinical and laboratory values for these patients are summarized in Table 1.

Of these, 65.15% (95%CI: 53.35%-76.95%) underwent subsequent surgery while 34.85% (95%CI: 23.05%-46.65%) received SEMS for palliation for advanced disease or were not surgical candidates. The majority of the tumors were adenocarcinomas of the colon or rectum, while extracolonic tumors were only 4.76% (95%CI: 0.01%-14.70%). The obstruction in the sigmoid colon was found in 69.57%, the rectum and splenic flexure each comprising 8.70%, descending colon 7.25%, transverse colon 4.35%, and ascending colon in 1.45% (Table 1). The mean length of the strictures was  $5.16 \pm 0.32$  cm.

Looking at time trends, there was an increased use of SEMS for malignant colorectal obstruction over the duration of the study (Figure 1). The majority (63.83%) of the patients had stage IV disease (95%CI: 49.57%-78.09%), while the remainder (36.17%) had stage III (95%CI:

**Table 1** Description of the study population

ALT: Alanine aminotransferase; AST: Aspartate aminotransferase; ALP: Alkaline phosphatase; INR: International normalized ratio; CEA: Carcino-embryonic antigen; SEMS: Self-expandable metal stents.

21.91%-50.43%). SEMS were successfully inserted in 93.85% (95%CI: 87.85%-99.85%) of patients, while insertion failed in 6.15% (95%CI: 0.15%-12.15%). SEMS technical failure occurred in 4 patients; in 3 the guidewire could not be passed through the stricture, while in the fourth patient the SEMS would not expand. The majority of patients required one SEMS insertion 87.32% (95%CI: 79.39%-95.25%), while two SEMSs inserted in a co-

Figure 1 The number of colonic stents inserted for malignant colonic obstruction over the study period.

axial fashion for long strictures were required in 12.68% (95%CI: 4.75%-20.61%). The mean duration from the onset of symptoms to SEMS insertion was 4.7 d, and from SEMS insertion to surgery was 33.8 d. The mean duration of follow up for the patients was  $13.52 \pm 17.48$  mo (range 0-73 mo). Of the cohort of patients included in the study, 52.38% (95%CI: 29.09%-75.95%) received neo-adjuvant chemotherapy in our institution. Perforations occurred in 4.10%, SEMS migration in 8.21% and stent re-occlusion from ingrowth occurred in 2.74% of patients.

#### Predictors of complications from SEMS insertion:

On hypothesis testing, there was no association between any of the measured variables and the development of complications (Table 2). On univariable analysis, none of the following variables predicted the development of complications (perforation, migration, and stent re-occlusion) from SEMS insertion: patient age (OR = 1.02, 95%CI: 0.95-1.10), patient gender (OR = 2.37, 95%CI: 0.69-8.14), time between the onset of symptoms to SEMS insertion (OR = 1.01, 95%CI: 0.99-1.03), time between SEMS insertion and surgery (OR = 1.02, 95%CI: 0.85-1.22), length of the stenosis (OR = 1.12, 95%CI: 0.70-1.80), location of the stenosis (OR = 1.03, 95%CI: 0.97-1.08), albumin level (OR = 0.98, 95%CI: 0.90-1.06), or receiving neoadjuvant chemotherapy (OR = 1.38, 95%CI: 0.39-4.88). Also, on multivariable analysis, none of the variables were associated with the development of complications from SEMS insertion in malignant colorectal obstruction.

#### Predictors of survival

There was a difference in survival between the patients receiving SEMS as a palliative therapy ( $4.1 \pm 3.08$  mo) and those who had SEMS inserted as a bridge to surgery ( $19.4 \pm 0.83$  mo) (Figure 1). We think that this is a function of the stage of the disease; stage III with a mean duration of  $21.88 \pm 5.98$  mo *vs* stage IV with a mean duration of follow-up of  $7.36 \pm 1.93$  mo (Figure 2A). On univariable analysis, the albumin level was associated

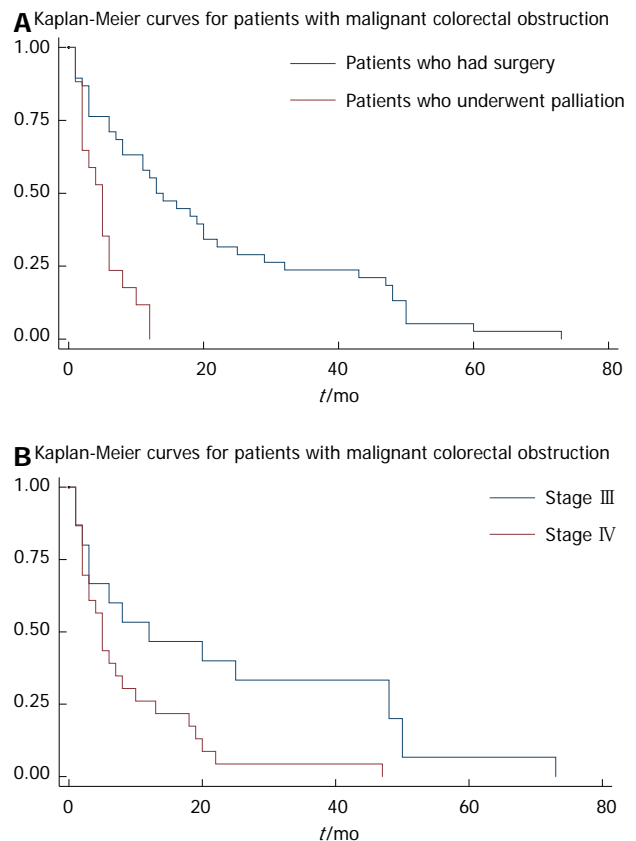

Figure 2 Survival curves. A: Survival curves for patients who received self-expandable metal stents for malignant colorectal obstruction stratified by those who had surgery and those who had palliation; B: Survival curves for patients who received self-expandable metal stents for malignant colorectal obstruction that stratified the stage of their disease.

with a survival advantage ( $P < 0.01$ ). None of the following predicted long term survival: time between the onset of symptoms to SEMS insertion ( $P = 0.91$ ), time between SEMS insertion and surgery ( $P = 0.44$ ), location of the stenosis ( $P = 0.43$ ), length of the stenosis ( $P = 0.95$ ), development of complications from SEMS insertion ( $P = 0.07$ ), carcinoembryonic antigen level ( $P = 0.10$ ), or neoadjuvant chemotherapy ( $P = 0.71$ ). On multivariate analysis, none of the variables were associated with long-term survival.

## DISCUSSION

SEMS are a reasonably safe option for patients with malignant colorectal obstruction<sup>[19]</sup>. The aim for the insertion of SEMS includes decreasing the need for emergency surgeries, reducing the rate of stomas, facilitation of laparoscopic resection when surgery is indicated, decreasing morbidity, shortening the time to chemotherapy, improving the quality of life for patients, and being more cost-effective<sup>[3,15-21]</sup>. Despite these potential and important endpoints and numerous studies addressing the use of SEMS for malignant colorectal obstruction, there still remains considerable controversy concerning their added benefit when compared to surgery as a dominant strategy

**Table 2** Factors associated with the development of complications (perforation, migration, and stent re-occlusion)

Variables	Complication				P value
	Yes		No		
	Mean	95%CI	Mean	95%CI	
Age	70	58.37-81.63	66.97	62.60- 71.34	0.56
Sex					
Male	12.82%	2.00%-23.64%	87.18%	76.36%-98.00%	0.17
Female	25.80%	9.87%-41.74%	74.19%	58.26%-90.13%	
Hemoglobin	106	73-140	102	92-114	0.84

Alkaline phosphatase	439	1-930	144	92-196	0.21
Total bilirubin	37	1-88	13	8-17	0.33
International normalized ratio	1.15	1.06-1.24	1.44	1.19-1.68	0.03
Carcinoembryonic antigen	188	0-439	69	19-148	0.32
Length of stenosis (cm)	5.43	4.75-6.11	5.09	4.24-5.93	0.49
Duration between symptoms and stenting (d)	5	1.62-8.38	4.59	2.94-6.24	0.80
Duration between stenting and surgery (d)	51.33	10.96-91.70	28.34	11.76-44.93	0.26
Neo-adjuvant chemotherapy	17.14%	4.22%-30.07%	22.22%	5.92%-38.53%	0.62
Number of stents	1.15	0.93-1.38	1.1	1.03-1.20	0.66

for managing these patients<sup>[5,7,20,22]</sup>. This is mostly due to methodological issues in these studies that are inherited in their design, as well as the possibility of selection bias, being underpowered in detecting differences between study arms, lack of standardized outcomes (as well as definitions), heterogeneity of the patients included, underlying origin of the tumor, stage of the disease, and the use of covered or uncovered SEMS<sup>[20]</sup>.

In a meta-analysis that included 601 patients, of which 38.6% underwent colonic SEMS insertion compared to emergency surgery, the SEMS group had a reduced risk of requiring intensive care with a risk ratio (RR = 0.42, 95%CI: 0.19-0.93), the need for a stoma (RR = 0.70, 95%CI: 0.50-0.99), reduced anastomotic leakage (RR = 0.31 (95%CI: 0.14-0.69), and reduced complications (RR = 0.42, 95%CI: 0.24-0.71)<sup>[15]</sup>. Furthermore, SEMS insertion prior to surgery did not affect the mortality or long-term survival<sup>[15]</sup>. Although encouraging, the meta-analysis by Zhang *et al*<sup>[15]</sup> had considerable heterogeneity, and included various study designs between observational and randomized studies<sup>[20]</sup>. In an editorial by Dayyeh *et al*<sup>[20]</sup>, a meta-analysis was attempted and included only randomized trials<sup>[23-26]</sup>. It demonstrated that there was a decrease in the rate of stomas with the use of SEMS for malignant colorectal obstruction (RR = 0.68, 95%CI: 0.53-0.89), and no difference in complications when compared to emergent surgery (RR = 0.88, 95%CI: 0.66-1.18)<sup>[20]</sup>. The authors correctly pointed out that when examining studies with a high technical success rate in inserting the SEMS, they had a more favorable complication profile when compared to emergent surgery<sup>[20]</sup>, and that possibly the focus should be on the probability of inserting a SEMS in patients with malignant colorectal obstruction, as a determinant for using it as a management strategy<sup>[4,20]</sup>.

The benefits of SEMS for right-sided malignant colorectal obstruction are less than that of distal lesions, as right hemicolectomy with primary anastomosis is possible even in an unprepared colon, although it avoids emergent surgery and possibly permits preoperative medical optimization of patients<sup>[4]</sup>.

Our cohort had a mean age similar to other studies<sup>[1,3,23,27]</sup>, with about half the study population being female, which is higher than in some series<sup>[1,27]</sup>. Also, in other series, 27%-41% of patients who underwent colonic SEMS insertion with a palliative intent had extracolonic tumor origins<sup>[1,27,28]</sup>, while only 4.8% of our series had extracolonic tumors, which is similar to the cohort by Jiménez-Pérez *et al*<sup>[3]</sup>. These salient differences in patient characteristics can explain some of the variation in study results, as patients who had SEMS inserted for malignant colonic obstruction from extraintestinal tumor origins were more likely to be unsuccessful<sup>[6,29]</sup>, but in those receiving SEMS with a palliative intent there was no difference in the SEMS patency and reobstruction rate (21.9% *vs* 30%, *P* = 0.29)<sup>[28]</sup>.

The location of the obstruction was mostly in the sigmoid colon and the majority was on the left side of the colon, this is also in keeping with the literature<sup>[1,3,27,28]</sup>.

The rate of patients with complete obstruction in this cohort (38.1%) was lower than that by Yoon *et al*<sup>[11]</sup> (73%), but a number of series have included patients with incomplete obstruction, defined as a state with narrow stool caliber or the ability to pass only small amounts of liquid stool or gas. We had a lower rate of patients with stage IV (64%) disease when compared to others (92%)<sup>[27]</sup>, although it was still similar to some series<sup>[30]</sup>. One of the concerns with some of the series, and which limits the generalization of their results, is a lack in reporting the stage of the disease; a known independent factor affect-

ing the overall survival of patients.

The success rate for SEMS insertion in our cohort was 93.85%. This is similar to that reported in the literature (83%-100%)<sup>[27,28,31]</sup>. Our study exclusively used uncovered SEMS, since covered SEMS had no added benefit when compared to uncovered SEMS with regards to technical or clinical success. Covered SEMS had a higher proportion of late migration (40% *vs* 0%) and loss of function during the long-term follow-up (60% *vs* 18.8%)<sup>[32]</sup>. A randomized trial also demonstrated that although there was a higher rate of ingrowth when using uncovered SEMS (14.5% *vs* 3.8%), the rate of migration was higher in the covered SEMS group (21.1% *vs* 1.8%), with no difference in the mean patency rate<sup>[33]</sup>. The migration rate in this study was 8.21%; this is in keeping with that reported by others (1%-6%)<sup>[3,27]</sup>, as well as a pooled analysis that found the migration rate to be 11.81%<sup>[34]</sup>. Kim *et al*<sup>[30]</sup> found that covered SEMS and those with a diameter of less than 24 mm had a higher risk of migration. The perforation rate was 4.1%. A pooled analysis of 2287 patients found the perforation rate to be 4.9%, with no statistical difference between the use of stents as a bridge to surgery or palliation<sup>[34]</sup>. The rate of silent perforations could not be assessed in our study, although it was been reported to be as high as 20% in a randomized trial<sup>[23]</sup>.

In our series, none of the patient or tumor characteristics were a predictor for complications from SEMS insertion. This may well be due to the low number of events in this cohort. A study by Kim *et al*<sup>[28]</sup> did not find any predictors for failed SEMS insertion, while in a series of 412 patients, Yoon *et al*<sup>[11]</sup> described predictors for technical and clinical failure in patients who underwent SEMS insertion. Factors associated with technical failure were: right-sided obstruction (OR = 2.25, 95%CI: 1.06-4.75), extrinsic origin of malignancy (OR = 2.57, 95%CI: 1.25-5.32), and the presence of carcinomatosis (OR = 2.83, 95%CI: 1.19-6.75). Factors associated with long term clinical failure, defined as the recurrence of obstructive symptoms requiring re-intervention after initial relief, were when balloon dilatation was used in combination with SEMS insertion (OR = 3.58, 95%CI: 1.25-5.32), while it was decreased when the patient received additional chemotherapy (OR = 0.52, 95%CI: 0.31-0.88)<sup>[11]</sup>.

Since we did not have the exact mortality data, we conducted the survival analysis until the patients' death, when known, or till the last date of follow up. The mean duration of follow up for the complete cohort was 425 d (95%CI: 297-554). As expected, the patients receiving subsequent surgery after SEMS insertion had a longer survival than those who had SEMS inserted with a palliative intent; 608 d *vs* 137 d respectively (Figure 2A). The authors think this is mainly due to the stage of the disease (Figure 2B), and also probably due to unmeasured factors like the functional status of the patients. On univariable analysis, the albumin level was found to be associated with a better survival, but this probably reflected the overall health of the patient. Thus, on mul-

tivariable analysis, this variable was not associated with a survival advantage. Jung *et al*<sup>[35]</sup> found that the location of the tumor affected the mean event-free survival, with distal obstructions being better than proximal lesions; 122.9 ± 18.6 d *vs* 35.8 ± 12.8 d respectively<sup>[35]</sup>. Additionally, SEMS < 10 cm long had a better mean event-free survival when compared to those > 10 cm; 151.0 ± 24.5 d *vs* 59.5 ± 14.4 d respectively<sup>[35]</sup>. The median duration of stent patency in patients with malignant colorectal obstruction was 193 ± 42 - 200 d<sup>[27,28]</sup>. This was not affected by patient demographics<sup>[27]</sup>, site of obstruction<sup>[27]</sup>, or the administration of palliative chemotherapy<sup>[27,28]</sup>.

We also demonstrated through this study that side-viewing duodenoscopes can be used successfully (as was the case in at least three patients in this series) for better visualizing of the tumor and targeting the insertion of a guidewire in areas where the tumor is situated in a tight angle in the distal colon<sup>[4,36]</sup>.

Guidelines on the management of left-sided colonic obstructions state that, in facilities where SEMS insertion is possible, they should be preferred to colostomy, since SEMS have a similar mortality/morbidity rate and a shorter hospital stay (grade of recommendation 2B)<sup>[37]</sup>. The guidelines also suggested considering alternative treatments to SEMS in patients eligible for further bevacizumab-based therapy, due to the potentially increased perforation rates<sup>[37]</sup>. Furthermore, the guidelines state that SEMS should be used as a bridge to elective surgery in referral centers with specific expertise and in selected patients, as their use seems to be associated with a lower mortality rate, a shorter hospital stay, and a lower colostomy rate (grade of recommendation 1B)<sup>[37]</sup>.

In conclusion, none of the variables in our study could predict the occurrence of complications (perforation, migration, and stent re-occlusion) from the insertion of SEMS or long-term survival in cases with malignant colonic obstruction. This may well be due to the size of the cohort in this study. Based on current guidelines<sup>[37]</sup>, as well as in a technical review<sup>[4]</sup>, SEMS insertion for malignant colorectal obstruction is the best option for palliation or as a bridge to surgery when technical skills for such a procedure are available<sup>[4]</sup>.

## COMMENTS

### Background

In patients presenting with malignant colorectal obstruction there is a debate in the literature about the best management strategy that would translate to decreased morbidity, mortality, and cost to the health care system. Despite some randomized controlled trials on the use of self-expandable metal stents (SEMS) or surgery, the answer is not clear due to the variability in the results, as well as the wide variability in the frequency of adverse events from the use of SEMS.

### Research frontiers

SEMS are an attractive management strategy for the management of malignant colorectal obstruction, as it allows for the avoidance of emergency surgeries as providing a single operation without the need for stomas, lower early morbidity, a shorter hospital stay, and decreased costs when compared to emergency surgery. In this study, the authors have demonstrated that the insertion of SEMS in cases with malignant colorectal obstruction is effective with an acceptable risk profile, but could not find any predictors that could determine the development

of complications or survival.

### Innovations and breakthroughs

Despite the conduction of randomized controlled trials with regards to an emergent surgery strategy compared to the insertion of SEMS as a bridge to surgery, there are considerable arguments with regards to the outcomes and the proportion of complications encountered during the insertion of SEMS. This study, although retrospective, replicates that the insertion of SEMS is relatively safe and the rate of complications is less than that reported in some randomized trials.

### Applications

By identifying factors that might predict complications or a survival advantage from one treatment modality compared to another, the authors could individually tailor the best management strategy for patients who present with malignant colorectal obstruction.

### Terminology

SEMS: tubes that are made of a metallic material and are inserted into the colon through the use of endoscopes. These are usually deployed in individuals who have developed a blockage of the colon, most commonly due to malignancy. Migration: when the stent has moved from its intended position to an area either before or after the area of obstruction. Ingrowth: when the tumor tissue extends through the mesh network of the stent and causes occlusion of the stent.

### Peer review

This is a well-written manuscript on an important topic. The authors aimed to predict complications after stent placement for colonic obstruction either in a palliative or a curative attempt. The purpose of the study is interesting and could help in selecting patients who present with malignant colorectal obstruction and would be good candidates for the insertion of SEMS.

### Abstract

**AIM:** To evaluate the efficacy of computer-assisted color analysis of colorectal lesions using a novel auto-fluorescence imaging (AFI) system to distinguish neoplastic lesions from non-neoplastic lesions and to predict the depth of invasion.

**METHODS:** From January 2013 to April 2013, consecutive patients with known polyps greater than 5 mm in size who were scheduled to undergo endoscopic treatment at The Jikei University Hospital were prospectively recruited for this study. All lesions were evaluated using a novel AFI system, and color-tone sampling was performed in a region of interest determined from narrow band imaging or from chromoendoscopy findings without magnification. The green/red (G/R) ratio for each lesion on the AFI images was calculated automatically using a computer-assisted color analysis system that permits real-time color analysis during endoscopic procedures.

**RESULTS:** A total of 88 patients with 163 lesions were enrolled in this study. There were significant differences in the G/R ratios of hyperplastic polyps (non-neoplastic lesions), adenoma/intramucosal cancer/submucosal (SM) superficial cancer, and SM deep cancer ( $P < 0.0001$ ). The mean  $\pm$  SD G/R ratios were  $0.984 \pm 0.118$  in hyperplastic polyps and  $0.827 \pm 0.081$  in neoplastic lesions. The G/R ratios of hyperplastic polyps were significantly higher than those of neoplastic lesions ( $P < 0.001$ ). When a G/R ratio cut-off value of  $> 0.89$  was applied to determine non-neoplastic lesions, the sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and accuracy were 83.9%, 82.6%, 53.1%, 95.6% and 82.8%, respectively. For neoplastic lesions, the mean G/R ratio was  $0.834 \pm 0.080$  in adenoma/intramucosal cancer/SM superficial cancer and  $0.746 \pm 0.045$  in SM deep cancer. The G/R ratio of adenoma/intramucosal cancer/SM superficial cancer was significantly higher than that of SM deep cancer ( $P < 0.01$ ). When a G/R ratio cut-off value of  $< 0.77$  was applied to distinguish SM deep cancers, the sensitivity, specificity, PPV, NPV, and accuracy were 80.0%, 84.4%, 29.6%, 98.1% and 84.1%, respectively.

**CONCLUSION:** The novel AFI system with color analysis was effective in distinguishing non-neoplastic lesions from neoplastic lesions and might allow determination of the depth of invasion.

**Key words:** Autofluorescence imaging; Computer-aided diagnosis; Colon; Neoplasia; Colonoscopy

**Core tip:** Recently, a novel auto-fluorescence imaging (AFI) system with has higher resolution and higher flame rate than those offered by previously used AFI systems has become commercially available in Japan. We evaluated the efficacy of computer-assisted color

analysis using the novel AFI system for distinguishing colorectal neoplasia and non-neoplasia and for predicting depth of invasion. The green/red ratios, which were obtained by dividing green color intensity by red color intensity, were significantly different between hyperplastic polyps, adenoma/intramucosal cancer/SM superficial cancer, and SM deep cancer. The novel AFI system was effective in distinguishing non-neoplastic lesions from neoplastic lesions and might have potential to predict the depth of invasion.

Efficacy of a novel auto-fluorescence imaging system with computer-assisted color analysis for assessment of colorectal lesions. *World J Gastroenterol* 2013; 19(41): 7146-7153 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i41/7146.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i41.7146>

## INTRODUCTION

Colonoscopy is the most effective method for the detection of colonic neoplastic lesions in the earlier and more curable stages. According to the National Polyp Study, colorectal cancer incidence was decreased by the endoscopic removal of polyps detected during colonoscopy screenings<sup>[1]</sup>.

Accurate endoscopic determination of the histology of colorectal polyps could prevent unnecessary polypectomies and may allow the proposal of adequate surveillance recommendations. The strategy of “resect and discard” for diminutive colorectal polyps has been suggested by The American Society for Gastrointestinal Endoscopy<sup>[2]</sup>. However, a report evaluating real-time optical biopsy analysis of polyps with narrow band imaging (NBI) concluded that only 25% of community-based gastroenterologists assessed polyps with > 90% accuracy<sup>[3]</sup>. Therefore, easy and objective methods for distinguishing colorectal neoplastic lesions from non-neoplastic lesions are required.

We previously reported the effectiveness of auto-fluorescence imaging (AFI) systems in distinguishing colorectal non-neoplastic lesions from neoplastic lesions<sup>[4,5]</sup>; however, in that study, the number of lesions examined was limited.

In an AFI system, white light is separated into excitation light and green light and used to irradiate onto the colon mucosa. After blocking the reflected light, a false color image is displayed on the monitor based on the balance of autofluorescence intensity and green light intensity. Recently, a novel AFI system composed of light sources (EVIS LUCERA ELITE CLV-290SL; Olympus Medical Systems, Tokyo, Japan) and video processors (EVIS LUCERA ELITE CV-290; Olympus Medical Systems, Tokyo, Japan) was developed. The newer AFI systems feature two major improvements over previously available AFI systems (EVIS LUCERA CLV-260SL, EVIS LUCERA CV-260S; Olympus Medical Systems, Tokyo, Japan). The first improvement is a brighter lamp

that allows a higher frame rate, although the overall brightness of the endoscopic images is the same as that in first-generation AFI systems. The use of a brighter lamp produces less flickering and color splitting in the endoscopic images. The second major improvement is in the image-processing algorithm used, specifically the noise-reduction algorithm, which results in higher resolution images with less noise interference (Figure 1). In addition, software that enables real-time color analysis has been developed and is available.

The aim of this study was to prospectively evaluate the efficacy of computer-assisted color analysis of colorectal lesions by using the novel AFI system to attempt to distinguish non-neoplastic lesions from neoplastic lesions. In addition, if a colorectal neoplasm invades the submucosal layer, which contains where autofluorescent substances such as, collagen, nicotinamide adenine dinucleotide hydrate (NADH), flavin adenine dinucleotide, lysosome granules, and porphyrin<sup>[6-8]</sup>, autofluorescence would be expected to be attenuated. Therefore, we hypothesized that the AFI system would be useful in determining the depth of invasion of colorectal neoplasms. To verify our hypothesis, we evaluated the effectiveness of the novel system in permitting diagnosis of the depth of invasion of colorectal neoplasia.

## MATERIALS AND METHODS

This study was approved by the ethical committee of our institution [registration number 24-188(6954)] and was registered in the University Hospital Medical Information Network (UMIN) in Japan under registration number 24-188(6954): UMIN R000011404. Written informed consent for examination and treatment was obtained from all patients prior to the procedures. From January 2013 to April 2013, consecutive patients with known polyps over 5 mm in size who were scheduled to undergo endoscopic treatment at The Jikei University Hospital were prospectively recruited for this study.

The exclusion criteria were refusal to participate, ages less than 19 or more than 91 years, and the presence of inflammatory bowel disease (IBD), familial adenomatous polyposis, or serrated sessile adenoma/polyp (SSA/P) lesions confirmed by pathological findings after endoscopic resection. Patients with SSA/P lesions were excluded because the histological diagnostic criteria for SSA/P are controversial in Japan at present<sup>[9]</sup>.

### Endoscopic procedure

All patients received total bowel cleansing with polyethylene glycol solutions (Niflec; Ajinomoto Pharmaceuticals Co. Ltd., Tokyo, Japan) after 12 h of nil per os (NPO) status. All colonoscopies were performed using the novel AFI system with a colonoscope designed for AFI observation (CF-FH260AZI; Olympus Medical Systems, Tokyo, Japan) by 5 endoscopists, each of whom possesses more than 5 years of experience in colonoscopy and treats more than 500 cases a year.

**Figure 1** Comparisons of images obtained with the previous autofluorescence imaging system and with the novel autofluorescence imaging system. The major improvement in the novel autofluorescence imaging (AFI) system is in the image-processing algorithm, specifically the noise-reduction algorithm, which results in higher resolution images with less noise interference. An AFI image from the previous AFI system (A) is clearer than an image from the novel AFI system (B).

**Figure 2** A determination of region of interest. A: A white light image of a flat-elevated lesion located in the sigmoid colon; B: A depressed area observed on chromoendoscopy (the area surrounded by yellow arrows). The region of interest for color tone analysis was chosen by the endoscopist based on the findings of non-magnifying narrow-band imaging or chromoendoscopy.

All endoscopic procedures were performed under conditions of CO<sub>2</sub> insufflation<sup>[10]</sup>. First, colonoscopy was performed using the white light imaging (WLI) function of the AFI system. When colorectal lesions were detected, they were observed by switching to the NBI mode using a button on the control head of the endoscope. Subsequently, the lesions were observed by chromoendoscopy (CE) using 0.4% indigo carmine and the WLI mode. The region of interest (ROI) was then determined from the NBI findings without magnification or CE. We determined the placement of the ROI in regions where characteristic endoscopic findings for SM deep invasion, such as expansion appearance, a large nodule equal to or greater than 10 mm in size, redness, or demarcated depressed areas<sup>[11,12]</sup> were found, we determined the placement of the ROI based on the individual characteristics of the lesion (Figure 2). In lesions without these findings, the ROI was placed at the center of the lesion. After washing the indigo carmine with water insufflation, real-time color analysis of the ROI on the AFI images was conducted using a personal computer with software for color analysis connected to the endoscopy system. On

the computer monitor, the ROI was placed using a cursor (10 × 10 pixels). The green/red (G/R) ratio, which is obtained by dividing the green color tone intensity by the red color tone intensity, was calculated automatically during the endoscopic procedures (Figure 3). Finally, magnifying endoscopy with NBI and CE using crystal violet was performed to estimate the depth of invasion of the encountered lesion<sup>[13]</sup>.

If the estimated depth of invasion was limited to the mucosa or superficial SM (less than 1000 μm from the muscularis mucosae), the lesions were endoscopically removed. Lesions diagnosed as SM deep cancer (1000 μm or more from the muscularis mucosae) from magnified endoscopic findings were surgically resected.

### Histological assessment

All tissue specimens were fixed in 10% buffered formalin and cut into 2-mm slices. The specimens were then examined microscopically to determine depth of invasion and histological type. Histological diagnoses were based on the Japanese classification system for cancer of the colon and rectum<sup>[14]</sup> and on the Vienna classification system<sup>[15]</sup>.

**Figure 3** A method for real-time color intensity analysis calculated software. A: A personal computer with software that enables real-time color tone analysis was connected to the endoscopy system. B: The user interface of the personal computer for color tone analysis. The region of interest was chosen using the cursor (yellow square). The color tone intensity (blue square) and the green/red ratio (red square), which is obtained by dividing the green color tone intensity by the red color tone intensity, were calculated automatically.

The final pathological assessments were conducted by a pathologist who was blinded to this study and to the results of the color analyses.

### Endoscopic diagnosis

The endoscopist assessed whether the lesions were neoplastic or non-neoplastic and determined the depth of invasion (SM deep or not) on the basis of the findings of magnified observation using NBI and CE. After completion the color analysis, the diagnoses were related to the study coordinator by the endoscopist.

### Statistical analysis

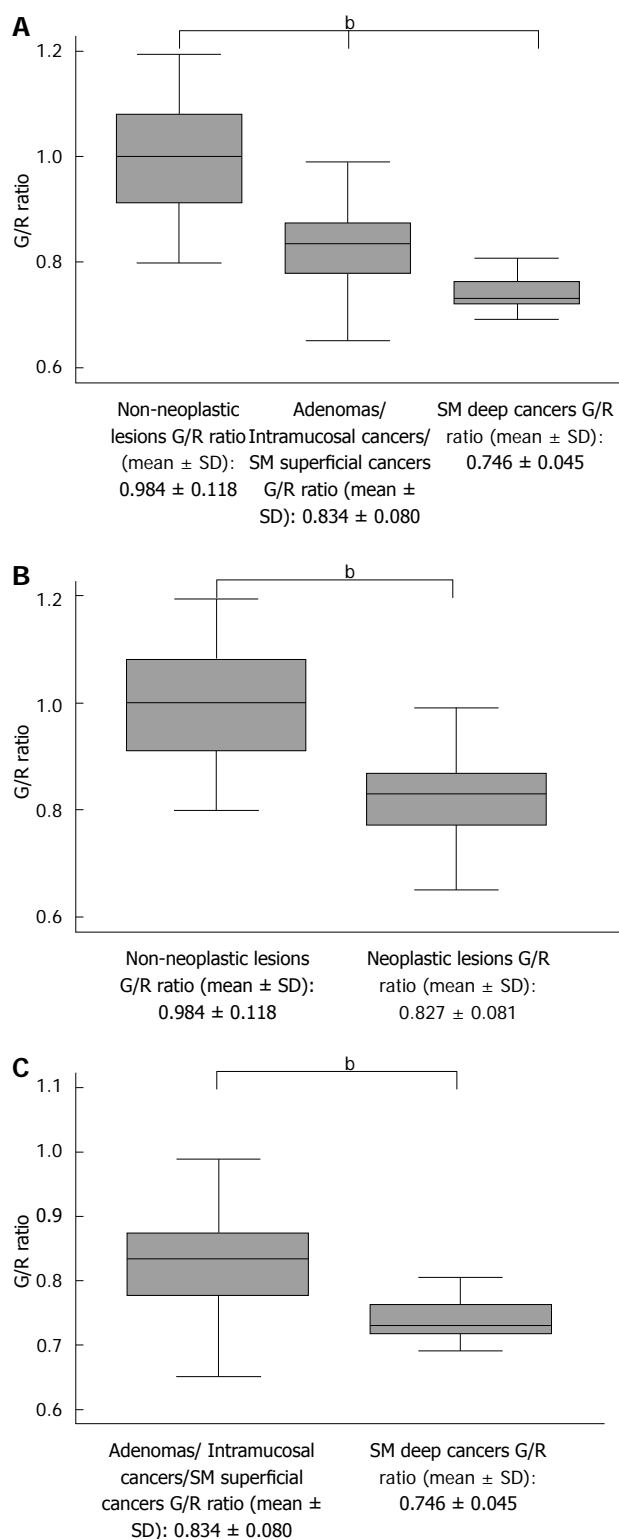

Statistical analysis was performed using SPSS for Windows (SPSS, release 6.0, 1993; SPSS Inc., Chicago, Illinois, United States). Data are expressed as the mean  $\pm$  SD. To determine differences in the mean G/R ratio, comparisons between groups were performed using one-way analysis of variance (ANOVA) followed by multiple comparison testing using the Bonferroni-Dunn method. Continuous variables were analyzed using a *t* test. A *P* value  $< 0.05$  was considered statistically significant.

## RESULTS

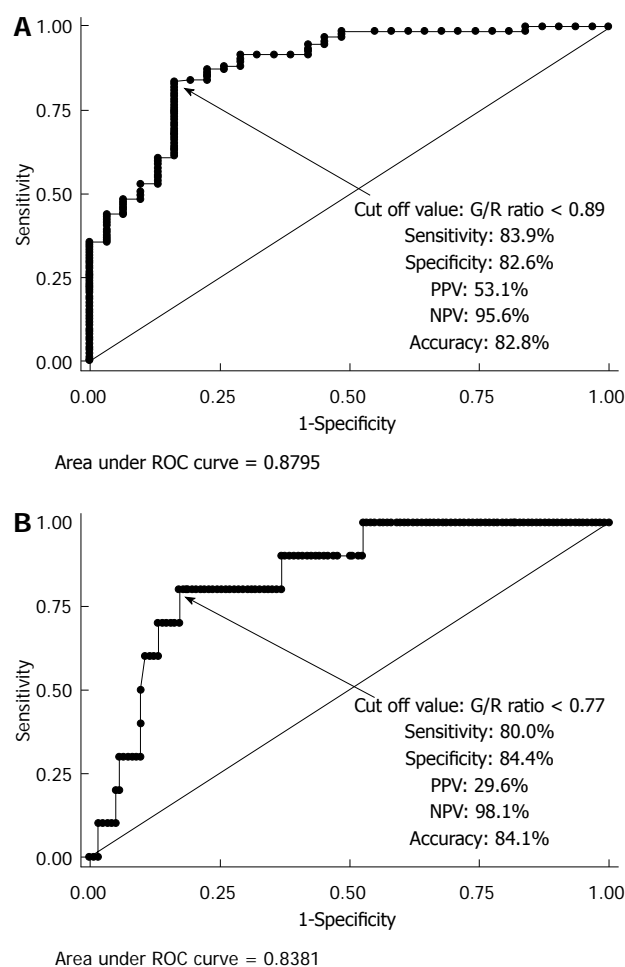

A total of 191 patients were recruited for this study. The following patients were excluded from this study based on the exclusion criteria: 89 patients who refused to participate, 9 patients who had SSA/P lesions, and 5 patients diagnosed with IBD. Finally, 88 patients with 163 lesions were enrolled in this study. The mean patient age was  $63.0 \pm 10.4$  years, the male-to-female ratio was 1:0.51, and the mean lesion size was  $15.0 \pm 12.6$  mm. Histologically, of the 163 lesions, there were 31 hyperplastic polyps (19.0%), 82 tubular/tubulovillous adenomas (50.3%), 40 mucosal or SM superficial cancers (24.5%), and 10 SM deep cancers (6.1%). Macroscopic types included 72 protruded (44.2%) and 91 flat elevated or depressed (55.8%) lesions. Tumor locations included 13 in the cecum (8.0%), 63 in the right colon (38.7%), 64 in the left colon (39.3%), and 23 in the rectum (14.1%). There

were significant differences between the G/R ratios of the hyperplastic polyps (non-neoplastic lesions), adenoma/intramucosal cancer/SM superficial cancer, and SM deep cancer ( $P < 0.0001$ ) (Figure 4A). The mean G/R ratios were  $0.984 \pm 0.118$  in hyperplastic polyps and  $0.827 \pm 0.081$  in neoplastic lesions. The G/R ratios of hyperplastic polyps were significantly higher than those of neoplastic lesions ( $P < 0.001$ ) (Figure 4B), and the area under the receiver operating characteristic (ROC) curve sensitivity and 1-specificity of the G/R ratio in discriminating between hyperplastic polyps and neoplastic lesions was 0.8795. When a G/R ratio cut-off value of  $> 0.89$  was applied to determine non-neoplastic lesions, the sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and accuracy were 83.9%, 82.6%, 53.1%, 95.6%, and 82.8%, respectively (Figure 5A). Regarding the use of endoscopic diagnosis by experienced endoscopists to distinguish neoplastic lesions from non-neoplastic lesions using magnifying endoscopy with NBI and/or CE, the sensitivity, specificity, PPV, NPV, and accuracy were 93.5%, 97.0%, 87.9%, 98.5% and 96.3%, respectively. The accuracy of color analysis for distinguishing neoplastic lesions from non-neoplastic lesions was 90.1% for flat/depressed types and 70.8% for protruded types. The diagnostic accuracy for the flat/depressed type was significantly higher than that for the protruded type (Table 1).

For neoplastic lesions, the mean G/R ratio was  $0.834 \pm 0.080$  in adenoma/intramucosal cancer/SM superficial cancer and  $0.746 \pm 0.045$  in SM deep cancer (Figure 4C). The G/R ratio of adenoma/intramucosal cancer/SM superficial cancer was significantly higher than that of SM deep cancer ( $P < 0.01$ ), and the area under the ROC curve sensitivity and 1-specificity of the G/R ratio in discriminating between adenoma/intramucosal cancer/SM superficial cancer and SM deep cancer was 0.8381. When a G/R ratio cut-off value of  $< 0.77$  was applied to distinguish SM deep cancers, the sensitivity, specificity, PPV, NPV, and accuracy were 80.0%, 84.4%, 29.6%, 98.1% and 84.1%, respectively (Figure 5B). Regarding the endoscopic diagnosis of depth of invasion by experi-

**Figure 4** Distribution of green/red ratios. A: Between non-neoplastic lesions, adenoma/intramucosal cancer/submucosal (SM) superficial cancer, and SM deep cancer, there was a significant difference in the green/red (G/R) ratios of non-neoplastic lesions, adenomas/intramucosal cancer/SM superficial cancer, and SM deep cancer ( $^bP < 0.01$ ); B: Between non-neoplastic lesions and neoplastic lesions, There was a significant difference between non-neoplastic and neoplastic lesions ( $^bP < 0.01$ ); C: Between adenoma/intramucosal cancer/SM superficial cancer, and SM deep cancer, there was a significant difference between the two groups ( $^bP < 0.01$ ). SM superficial cancer: Submucosal invasion was defined as less than 1000  $\mu$ m from the muscularis mucosae; SM deep cancer: Submucosal invasion was defined as 1000  $\mu$ m or more from the muscularis mucosae.

**Figure 5** Receiver operating characteristic curve. A: For discriminating between hyperplastic polyps and neoplastic lesions, the area under the receiver operating characteristic curve (AUC) was 0.8795; B: For discriminating between adenoma/intramucosal cancer/SM superficial cancer and SM deep cancer, the area under AUC was 0.8381. G/R: Green/red.

enced endoscopists using magnifying endoscopy for SM deep cancers, the sensitivity, specificity, PPV, NPV, and accuracy were 60.0%, 100%, 100%, 96.8%, and 84.1%, respectively (Table 2).

## DISCUSSION

The NBI system, which enables precise observation of microvasculature and surface strictures of colorectal lesions<sup>[16-18]</sup>, is considered an effective method for distinguishing non-neoplastic lesions from neoplastic lesions, and an international expert group has proposed the NBI International Colorectal Endoscopic (NICE) classification to distinguish adenomas from hyperplastic polyps<sup>[19]</sup>. However, because diagnosis of colorectal neoplasia using the NBI system is based on the subjective judgment of the endoscopist, the accuracy of diagnosis differs between expert endoscopists and community-based gastroenterologists<sup>[3]</sup>. Therefore, a method that permits objective and real-time diagnosis with respect to for distinguishing colorectal non-neoplastic lesions from neoplastic lesions is needed.

**Table 1 Diagnostic value of colorectal lesions (for distinguishing neoplastic lesions from non-neoplastic lesions)**

	Sensitivity	Specificity	Positive predictive value	Negative predictive value	Accuracy
Diagnosis based on the color analysis	83.9%	82.6%	53.1%	95.6%	82.8%
Flat or depressed type	93.1%	79.0%	94.4%	75.0%	90.1%
Protruded type	66.7%	91.7%	97.6%	35.5%	70.8%
Diagnosis based on the endoscopic findings <sup>1</sup>	93.5%	97.0%	87.9%	98.5%	96.3%

<sup>1</sup>Using magnifying endoscopy with narrow band imaging and chromoendoscopy.

**Table 2 Diagnostic value of colorectal lesions (For distinguishing intramucosal lesions/SM superficial cancer from SM deep cancer)**

	Sensitivity	Specificity	Negative predictive value	Positive predictive value	Accuracy
Diagnosis based on the color analysis	80.00%	84.40%	29.60%	98.10%	84.10%
Diagnosis based on the endoscopic findings <sup>1</sup>	60.00%	100%	100%	96.80%	84.10%

<sup>1</sup>Using magnifying endoscopy with narrow band imaging and/or chromoendoscopy. Submucosal (SM) superficial cancer: Submucosal invasion was defined as less than 1000  $\mu$ m from the muscularis mucosae; SM deep cancer: Submucosal invasion was defined as 1000  $\mu$ m or more from the muscularis mucosae.

The results of the present study indicate that color analysis using the novel AFI system is an effective method for the objective diagnosis of colorectal lesions, although the sensitivity/specificity/PPV/NPV for determining neoplastic lesions obtained in this study were inferior to those previously reported<sup>[5]</sup> using an earlier AFI system. The mean G/R ratios of colorectal lesions (non-neoplastic lesions, 0.984; neoplastic lesions, 0.827) in the present study were lower than the ratios reported in a previous study (non-neoplastic, 1.12; neoplastic, 0.86)<sup>[5]</sup>. The improvements in the novel AFI system, including the noise-reduction algorithm, higher frame rate, and brighter light source, may affect color tone intensity. In addition, in a previous report, color tone sampling was performed in one area of the lesion that was judged to represent a particular AFI color tone<sup>[5]</sup>; however, in the present study, color tone sampling was performed on an ROI, that, was determined using chromoendoscopy under WLI. Moreover, the present study was limited to patients with polyps over 5 mm in size; however, there were no size limitations on polyps in the previous report<sup>[5]</sup>. The use of different methods of color tone sampling and different inclusion criteria are possible reasons for the differences in the results. However, the lower G/R ratios obtained in the present study might indicate that the novel AFI system permits clearer visualization of colorectal lesions than the former AFI system.

The results of the present study also indicate the potential of color tone analysis to predict the depth of invasion of colorectal neoplasia. Standard methods in use for predicting the depth of invasion of colorectal neoplasia for planning treatment strategies are pit pattern classification using magnifying endoscopy and/or endoscopic ultrasonography<sup>[20-22]</sup>, both of which require long procedure times. A color tone analysis that involves a shorter procedure time and that permits objective diagnosis of the depth of invasion of colorectal neoplasia may provide significant benefits, especially to less endoscopists. However, because the number of SM deep lesions exam-

ined in this study was limited, larger studies are needed to further validate this method. The current study has several limitations. First, because it was difficult to estimate the effectiveness of color tone analysis in distinguishing neoplastic lesions from non-neoplastic lesions using the novel AFI system, the sample size was not calculated for this study. Second, the colonoscopies and ROI determinations performed in this study were conducted by experienced endoscopists; therefore, the results of this study might not be reproducible when patients are assessed by non-experienced clinicians. Finally, the lesions included in this study were limited to those over 5 mm in size, and the number of SM deep lesions was limited.

In conclusion, the results of the present study indicate that computer-assisted real-time color analysis using the novel AFI system was effective in distinguishing non-neoplastic lesions from neoplastic lesions. Color tone analysis, which is an objective and time-saving method, may have potential as a methods for predicting the depth of invasion of colorectal neoplasia, although the number of SM deep lesions examined in the present study was limited. Further studies are needed to determine the effectiveness of color tone analysis for predicting the depth of invasion of colorectal neoplasia.

## COMMENTS

### Background

Colonoscopy is the most effective method for the detection of colonic neoplastic lesions in their earlier and more curable stages. Accurate endoscopic determination of the histology of colorectal polyps could prevent unnecessary polypectomies and may allow the proposal of adequate surveillance recommendations. The authors have reported the effectiveness of autofluorescence imaging (AFI) systems in distinguishing colorectal non-neoplastic lesions from neoplastic lesions. Recently, a novel AFI system that employs second-generation light sources (EVIS LUCERA ELITE CLV-290SL; Olympus Medical Systems, Tokyo, Japan) and video processors (EVIS LUCERA ELITE CV-290; Olympus Medical Systems, Tokyo, Japan) was developed. In addition, software that enables real-time color analysis was developed.

### Research frontiers

AFI systems can be used to visualize fluorophores (autofluorescent substanc-

es) in the gastrointestinal (GI) tract. Several studies have demonstrated that the autofluorescence emitted by neoplastic lesions in the colon has a relatively longer wavelength than the autofluorescence emitted by surrounding normal mucosa. The aim of this study was to prospectively evaluate the efficacy of computer-assisted color analysis of colorectal lesions using a novel AFI system to distinguish non-neoplastic lesions from neoplastic lesions. The authors also evaluated the effectiveness of the system in determining the depth of invasion of colorectal neoplasms.

### Innovations and breakthroughs

The results of the present study indicate that color tone analysis using the novel AFI system is an effective method for the objective diagnosis of colorectal lesions. The improvements in the novel AFI system, including the noise reduction algorithm, higher frame rate, and brighter light source may affect color tone intensity. In addition, in the present study, color tone sampling was performed on the region of interest, which was determined using chromoendoscopy under white light imaging. The results of the present study also indicate the potential of color tone analysis for use in predicting the depth of invasion of colorectal neoplasia. A color tone analysis that involves a shorter procedure time and permits objective diagnosis of the depth of invasion of colorectal neoplasia may provide significant benefits to endoscopists, especially to those who are less experienced.

### Applications

The study results suggest that computer-assisted real-time color analysis using the novel AFI system was effective in distinguishing non-neoplastic lesions from neoplastic lesions. In addition, color tone analysis, which allows objective and time-saving prediction of the depth of invasion of colorectal neoplasia, has potential for use in determining appropriate treatment strategies for colorectal neoplasia.

### Terminology

AFI systems can be used to visualize fluorophores (autofluorescent substances) in the GI tract. In an AFI system, a rotation filter divides the light from the xenon light source and permits only blue and green light to pass. The returning reflection from the tissue, including fluorescent light, is captured by the CCD via a special barrier filter. Image processing then generates the AFI image. The novel AFI system has a brighter lamp that permits a higher frame rate, and produces, less flickering and color splitting, resultings in higher-resolution images with less noise interference.

### Peer review

This study prospectively evaluated the efficacy of computer-assisted color analysis of colorectal lesions using a novel AFI system to distinguish non-neoplastic lesions from neoplastic lesions. In addition, the authors also evaluated the effectiveness of the system in diagnosing the depth of invasion of colorectal neoplasia. They found that the novel AFI system with color analysis was effective in distinguishing non-neoplastic lesions from neoplastic lesions and that it may allow determination of the depth of invasion. The study is interesting, and the manuscript is well-written.

### Abstract

**AIM:** To assess the clinicopathologic characteristics, risk factors, and prognosis for synchronous multiple early gastric cancer (SMGC).

**METHODS:** A total of 146 patients with SMGC and 1194 patients with single gastric cancer who had undergone gastrectomy between 1989 and 2008 were retrospectively analyzed to determine their clinicopathologic characteristics and postoperative survival. Tumors were classified into groups on the basis of location and histology. Smoking habits were evaluated using the Brinkman index. Clinical and pathological factors were compared using either Fisher's exact test or Pearson's  $\chi^2$  test. Logistic regression analysis was performed to identify independent risk factors. Survival rate was calculated using the Kaplan-Meier method.

**RESULTS:** SMGCs accounted for 10.9% of gastric cancer cases and occurred predominantly in elderly male patients with a family history of gastric cancer who were both smokers and drinkers. These tumors were typically

macroscopically elevated and histologically differentiated. There were no significant differences between SMGC and single gastric cancer patients with respect to tumor location, tumor size, lymph node metastasis, the number of metastatic lymph nodes, venous invasion, or tumor stage ( $P = 0.052$ ,  $P = 0.347$ ,  $P = 0.595$ ,  $P = 0.805$ ,  $P = 0.559$ , and  $P = 0.408$ , respectively). Further, there was no significant difference in postoperative survival between the patient groups ( $P = 0.200$ ). Of the 146 SMGC patients, a single patient had remnant cancer.

**CONCLUSION:** A careful preoperative endoscopy is necessary for patients who are at high risk of SMGC, and minimally invasive treatment may be indicated in some cases.

**Key words:** Gastric cancer; Synchronous; Multiple; Endoscopy; Prognosis

**Core tip:** This study compares the clinicopathologic characteristics of synchronous multiple gastric cancer (SMGC) and single gastric cancer. Further, we identified risk factors for SMGC and assessed whether they can be treated with a minimally invasive approach. We found that SMGC occurred predominantly in elderly male patients who had a family history of gastric cancer, and who were both smokers and drinkers. The tumors were macroscopically elevated and histologically differentiated. Lymph node metastasis and vascular invasion were equally prevalent, and there was no significant difference in postoperative survival between these patient groups. We suggest minimally invasive approach may be applicable.

synchronous multiple early gastric cancer. *World J Gastroenterol* 2013; 19(41): 7154-7159 Available from: URL: <http://www.wjg-net.com/1007-9327/full/v19/i41/7154.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i41.7154>

## INTRODUCTION

Due to the recent technical advances in endoscopic examinations, the number of patients with synchronous multiple gastric cancer (SMGC) has increased, and SMGC has been reported to account for 6%-14% of all gastric cancer cases<sup>[1-3]</sup>. A previous study reported that multiple gastric cancers have several clinicopathologic features, including incidence in old age, well differentiated tumors, and early stage tumors, and that the prognosis is similar to that of single gastric cancers<sup>[4]</sup>. Minimally invasive resection procedures, such as endoscopic mucosal resection (EMR), endoscopic submucosal dissection (ESD), and laparoscopic surgery, are known to improve the quality of life of early gastric cancer patients<sup>[5,6]</sup>. However, the presence of SMGC may increase the risk of missing a remnant gastric lesion and may make it more difficult to determine the range of gastrectomy required. Furthermore, it is unclear whether the same indication criteria for endoscopic resection can be applied to SMGC because comparative studies on the incidence of recurrence and prognosis between multiple and single gastric cancers are limited. The aim of this study was to compare the clinicopathologic characteristics between SMGC and single gastric cancer, to identify risk factors for SMGC, and to assess whether SMGC can be safely treated with a minimally invasive approach.

## MATERIALS AND METHODS

SMGC was defined in accordance with Moertel's criteria<sup>[7]</sup> as follows: (1) each lesion must have a pathologically proven malignancy; (2) all lesions must be clearly separated by intervals of microscopically normal gastric wall; and (3) the possibility that one of the lesions represents a metastatic tumor must be ruled out beyond any reasonable doubt. Between 1989 and 2008, we identified a total of 1406 patients who underwent gastric resection surgery for early gastric cancer at the Department of Surgery at Kurume University School of Medicine. The patients were excluded from the study if they had undergone gastrectomy after neoadjuvant chemotherapy, if they had surgery after EMR or ESD, or if they had gastric cancer in the remnant stomach after a previous gastrectomy. Therefore, a total cohort of 1340 patients with gastric cancer was analyzed. Microscopic examination of surgically resected specimens revealed SMGC in 146 patients (group A) and a single gastric cancer in the remaining 1194 patients (group B). We retrospectively analyzed the patients' clinicopathologic characteristics, including age, sex, family history, the presence of cancer in other organs (synchronous or metachronous), smoking and drinking

habits, tumor location, tumor size, macroscopic type, histological type, depth of invasion, number of metastatic lymph nodes, lymphovascular invasion, and tumor stage as defined by the Japanese Classification of Gastric Carcinoma (3<sup>rd</sup> English edition)<sup>[8]</sup>. The design of this study and the procedures for obtaining informed consent were based on the principles of the Declaration of Helsinki. Our study was approved by The Ethical Committee of Kurume University (No. 13091).

Tumors were classified into groups based on whether they were located in the upper (U), middle (M), or lower (L) third of the stomach, and the macroscopic type of each cancer was classified as I (protruding), II a (superficial, elevated), II b (flat), II c (superficial, depressed), III (excavated), or a combination of these (I + II a, II a + II c, II c + II a, or II c + III). All cases were regrouped into the elevated, flat, depressed, or mixed type. The histological type was classified as either differentiated (papillary adenocarcinoma, well-differentiated and moderately differentiated adenocarcinomas) or undifferentiated (poorly differentiated adenocarcinoma, signet ring cell carcinoma, and mucinous adenocarcinoma). If the depth of invasion of 2 or more lesions was equal, the largest was regarded as the primary lesion, with all other lesions regarded as accessory lesions.

Smoking habits were evaluated using the Brinkman index (BI)<sup>[9,10]</sup>, which is defined as (number of cigarettes per day) × (number of years for which the patient smoked). Using this index, we divided the patients into 3 groups: nonsmokers, light smokers (BI < 400), and heavy smokers (BI ≥ 400). To assess drinking habits, all patients were asked about their frequency of drinking, the amount (1 go = 22.8 g ethanol) typically consumed on any one occasion, and the type of beverage usually consumed (sake, shochu, beer, whisky, wine, or others). From these data, we calculated the amount of ethanol (in grams) consumed per day, and we classified patients into 3 groups: non-drinkers, occasional drinkers, and daily drinkers (< 22.8, 22.8-45.5, and > 45.5 g of ethanol per day, respectively). For each factor assessed, we used the same questionnaire for all patients when they were admitted.

Clinical and pathological factors were compared using either Fisher's exact test or Pearson's  $\chi^2$  test, as appropriate. Logistic regression analysis was performed to identify independent risk factors with odds ratios and 95%CI. The survival rate was calculated using the Kaplan-Meier method.  $P < 0.05$  was considered statistically significant. Data analysis was performed using the statistical program JMP 8 (SAS Institute, Cary, NC).

## RESULTS

A total of 1340 patients [146 patients with SMGC (group A) and 1194 patients with single gastric cancers (group B)] were included in this study. In group A, 120 patients had 2 lesions each, 22 had 3 lesions, 3 had 4 lesions, and 1 patient had 8 lesions, making a total of 326 lesions (Table 1).

The clinical differences between the groups are sum-

**Table 1** Incidence of multiple lesions in synchronous multiple early gastric cancer patients

marized in Table 2. The patients in group A were older (68.0 years *vs* 64.3 years,  $P < 0.001$ ) and more likely to be male (81.5% *vs* 67.1%,  $P < 0.001$ ) than those in group B. Furthermore, patients in group A had a significantly greater number of family members with gastric cancer compared with those in group B ( $P = 0.046$ ), and SMGC patients also smoked ( $P = 0.020$ ) and drank more ( $P = 0.005$ ). However, there were no significant differences with respect to the presence of synchronous and metachronous cancers in other organs.

The pathological features of each group are listed in Table 3. Macroscopically, more than 50% of the tumors in both groups were of the depressed type, and this type was more common in group B than in group A. Elevated-type tumors were present more often in group A than in group B (68.3% *vs* 55.5% and 26.7% *vs* 18.3%,

**Table 3** Pathological features of lesions observed in groups A and B *n* (%)

Factors	Group A ( <i>n</i> = 146)	Group B ( <i>n</i> = 1194)	<i>P</i> value

respectively). The differentiated type was present more often in group A than in group B (80.8% *vs* 64.6%,  $P < 0.001$ ). Furthermore, the depth of invasion and the rate of lymphatic invasion in group A were both significantly higher than those in group B ( $P = 0.011$ ,  $P = 0.034$ , respectively). There were no significant differences between the groups with respect to tumor location, tumor size, lymph node metastasis, the number of metastatic lymph nodes, venous invasion, or tumor stage ( $P = 0.052$ ,  $P = 0.347$ ,  $P = 0.595$ ,  $P = 0.805$ ,  $P = 0.559$ , and  $P = 0.408$ , respectively). Of the 9 factors that were statistically significant in the univariate analyses, multivariate logistic regression analysis showed that the important risk factors for SMGC were age (OR = 1.93, 95%CI: 1.27-2.99,  $P = 0.002$ ) and sex (OR = 1.86, 95%CI: 1.07-3.32,  $P = 0.028$ , Table 4).

The overall median follow-up period was 78.1 months. Of the 146 patients in group A, a single patient had remnant cancer. This patient was diagnosed 1 year after distal gastrectomy, and the lesion was located in the cardia, necessitating a total gastrectomy. One patient died of the disease (hepatic metastasis), and there were 18 other deaths: 3 from an unknown cause, 14 from other diseases (including 5 deaths from cancer of another organ), and 1 from a traffic accident. The 3-year overall survival rates in group A and group B were 95.8% and 96.6%, respectively, and the 5-year overall survival rates in group A and group B were 90.3 and 93.2%, respectively (Figure 1). There was no significant difference in postoperative survival between the groups ( $P = 0.200$ ).

## DISCUSSION

Although the histogenesis of normal gastric cancer has been addressed in numerous studies, relatively little is known about the development of multiple gastric can-

**Table 4** Multivariate analysis of risk factors for synchronous multiple early gastric cancer

Factor	Odds ratio	95%CI <sup>1</sup>	P value

cers. Recent advances in endoscopy have made it possible to detect early gastric cancer, for which EMR and ESD have become common treatment modalities<sup>[2,11]</sup>. Such therapies conserve function; however, after resection, a large quantity of the gastric mucosa remains, which can give rise to further cancers. Concurrent multiple cancers and the development of post-therapeutic asynchronous multiple cancers represent serious problems. Nasu *et al.*<sup>[12]</sup> followed 143 patients with early gastric cancer who had undergone EMR and found that 16 (11%) patients developed SMGC within 1 year of the initial EMR. It is important to identify patients who are at a high risk of developing multiple gastric lesions due to the complexity involved in fully diagnosing and treating these patients.

Based on previous reports, SMGC accounts for 6%-14% of all early gastric cancers<sup>[1-4]</sup>. The incidence of SMGC among patients in this study was 10.9%, which is within this range. In the present study, we found that patients with SMGC were significantly older than those with single gastric cancer. The predominance of SMGC in elderly patients may be explained by the pathogenetic importance of intestinal metaplasia<sup>[13]</sup>, as gastric glands generally show atrophic change with a concomitant increase in intestinal metaplasia in the stomachs of elderly people.

Patients with a family history of carcinoma were reported to have a high incidence of gastric cancer<sup>[14,15]</sup>. One report reviewed 15 case-control studies of family history and gastric cancer, all of which indicated a positive relationship between these parameters, with risk ratios that ranged from 1.5- to 3.5-fold<sup>[16]</sup>. The relationship between gastric cancer and genetics has been demonstrated by the non-random involvement of certain chromosomes and related oncogenes, especially Ras and p53<sup>[17,18]</sup>. Another study showed that gastric cancer was associated with intestinal metaplasia in 52% of the included

**Figure 1** Survival curve for patients with synchronous multiple early gastric cancer (group A: solid line) and those with single gastric cancer (group B: dotted line). The 3-year survival rates of group A and group B were 95.8% and 96.6%, respectively, and the 5-year survival rates of group A and group B were 90.3% and 93.2%, respectively ( $P = 0.200$ ).

patients<sup>[19]</sup>. In this study, compared with single gastric cancer patients, a significantly greater number of SMGC patients had a family history of gastric cancer based on univariate analysis. Furthermore, the number of family members affected also appears to be significant. This may be attributed to genetic factors, in addition to the environmental conditions presumably shared by members of same family, which result in familial clustering of gastric cancer. However, we cannot determine whether this result is due to environmental or genetic factors.

Smoking and alcohol consumption have been reported to be risk factors for gastric cancer<sup>[20-22]</sup>, although a study by Morita *et al.* found that there was no significant association between the occurrence of multiple gastric cancer and either of these factors<sup>[3]</sup>. In this study, we also examined these factors in patients with SMGC and those with single gastric cancer. We found that there were significant differences in smoking and drinking habits between patients with SMGC and those with single gastric cancer based on univariate analysis. However, none of these habits were found to be independent risk factors in multivariate analysis. Therefore, the effects of smoking and alcohol on the occurrence of multiple gastric cancers remain controversial.

Tumor location is an important determinant of treatment, and a major concern for patients undergoing subtotal gastrectomy or endoscopic resection is the difficulty of detecting a lesion in the remnant portion of the stomach. In this study, 39.0% of patients with SMGC were found to have tumors located in different thirds of the stomach. In a report concerning the localization of SMGCs, Kitamura *et al.* stated that early multiple-tumor cases more frequently involved the upper region of the stomach than early single-tumor cases<sup>[23]</sup>. We also found that SMGC patients were more likely to have a tumor located in the upper third of the stomach compared with single gastric cancer patients. It is difficult to find lesions located in the upper third of the stomach because of

the technical limitations of forward-viewing endoscopy. Therefore, this area should be observed very carefully, and caution should be exercised before performing a proximal gastrectomy for early gastric cancer in the cardia or high body.

Most SMGCs were shown to have a differentiated histological type in previous studies<sup>[2,3,12]</sup>. Correspondingly, we found that, among 326 lesions in the 146 patients with SMGC, 271 (83.1%) lesions were of the differentiated type. Lymphovascular involvement has also been shown to be significantly associated with lymph node metastasis in gastric cancer<sup>[24]</sup>. Although lymphatic invasion occurred more frequently in the SMGC cases in this study, the frequency of lymph node metastasis and venous invasion in these cases did not differ significantly from that in the single gastric cancer group.

The prognosis of early gastric cancer is generally favorable, and a 5-year relative postoperative survival of  $\geq 90\%$  has been reported<sup>[2]</sup>. In this study, there were no significant differences in the 3- and 5-year survival rates between patients with SMGC and those with single gastric cancer, and the 5-year survival rate was  $\geq 90\%$  in both groups.

A total gastrectomy has been recommended for the treatment of multiple gastric cancer because it is believed that the remnant stomach of patients who have undergone a partial gastrectomy is at increased risk for ongoing carcinogenesis<sup>[7]</sup>. However, prophylactic total gastrectomy reportedly did not improve outcome in patients with multiple gastric cancer<sup>[2]</sup>. The cumulative prevalence of gastric remnant cancer after ESD or surgical partial gastrectomy for early gastric cancer is reportedly 2.4%-14% at 5 years<sup>[12,25,26]</sup>. In the present study, 1 patient had remnant cancer, and 2 patients died of gastric cancer after gastrectomy. Early gastric cancer patients treated using EMR or ESD have been identified as a high-risk group for remnant gastric cancer. However, most metachronous lesions were intramucosal tumors with no lymphovascular involvement and no lymph node metastasis, indicating the potential for additional ESD or other local therapies rather than gastrectomy<sup>[5]</sup>. Endoscopists should recognize the characteristics of SMGCs, and special attention should be given to cases of EMR or ESD to avoid missing synchronous lesions, as SMGC patients are at a high risk of developing metachronous cancer in the remnant stomach after treatment<sup>[12,25-27]</sup>. Based on our findings, EMR or ESD may be applicable for SMGC cases if they meet the criteria for endoscopic resection.

The limitations of this study include the small number of patients enrolled, its retrospective design, and the fact that not every patient received total gastrectomy; therefore, whole stomach pathology could not be evaluated.

In conclusion, on the basis of the results from our study, we suggest that elderly male patients with a family history of gastric cancer who also have a history of smoking and alcohol consumption should be carefully examined preoperatively, especially if their tumor is macroscopically elevated and histologically differentiated.

Additionally, a minimally invasive approach may be applicable for cases of SMGC if they meet the criteria.

## COMMENTS

### Background

Due to improved diagnostic procedures, more cases of gastric cancer have been diagnosed. Minimally invasive procedures, such as endoscopic resection and laparoscopic surgery, have also gained worldwide acceptance as they improve the quality of life of early gastric cancer patients. However, the benefits of such procedures have not been demonstrated for synchronous multiple early gastric cancer (SMGC).

### Research frontiers

It is questionable whether the same indication criteria for minimally invasive procedures can be applied to SMGC because comparative studies on the incidence of LN metastasis and prognosis between multiple and single gastric cancers are limited. Here, we compare the clinicopathologic characteristics of SMGC and single gastric cancer to identify risk factors for SMGC and to assess whether SMGC patients can be safely treated with a minimally invasive approach.

### Innovations and breakthroughs

There have been very few studies regarding the risk factors for SMGC. The clinicopathologic characteristics of SMGC and single gastric cancer were addressed in this retrospective study, using a long term follow-up of a large number of patients. Furthermore, this is the first demonstration that there are significant differences in the smoking habits, alcohol consumption, and family history of gastric cancer between patients with SMGC and those with single gastric cancer.

### Applications

The findings of this study may lead to an improvement in the post-surgical prognosis of gastric cancer, especially in older men with a family history of smoking and alcohol consumption. Furthermore, if the tumor is macroscopically elevated and histologically differentiated, a minimally invasive approach may be applicable for SMGC cases, provided the criteria are met.

### Terminology

SMGC was defined as follows: (1) each lesion must have a pathologically proven malignancy; (2) all lesions must be clearly separated by intervals of microscopically normal gastric wall; and (3) the possibility that one of the lesions represents a metastatic tumor must be ruled out beyond any reasonable doubt. Endoscopic mucosal resection is an endoscopic technique of resection of a lesion that requires the separation of the submucosa using normal saline solution. Endoscopic submucosal dissection is a new method of resection, allowing the dissection of the lesion within the thickness of the submucosa or the interface between the submucosa and the muscularis propria.

### Peer review

This is a good retrospective study in which authors analyze the clinicopathologic characteristics and the risks factors of SMGC. The results are interesting and suggest that careful preoperative endoscopy and minimally invasive treatment must be used for patients with high risk of SMGC.

### Abstract

**AIM:** To evaluate the feasibility of diagnostic and therapeutic transgastric (TG) peritoneoscopic interventions with a forward-viewing endoscopic ultrasound (FV-EUS).

**METHODS:** This prospective endoscopic experimental study used an animal model. Combined TG peritoneoscopic interventions and EUS examination of the intra-abdominal organs were performed using an FV-EUS on 10 animal models (1 porcine and 9 canine). The procedures carried out include EUS evaluation and endoscopic biopsy of intraperitoneal organs, EUS-guided fine needle aspiration (EUS-FNA), EUS-guided radiofre-

quency ablation (EUS-RFA), and argon plasma coagulation (APC) for hemostatic control. The animals were kept alive for 7 d, and then necropsy was performed to evaluate results and complications.

**RESULTS:** In all 10 animals, TG peritoneoscopy, followed by endoscopic biopsy for the liver, spleen, abdominal wall, and omentum, was performed successfully. APC helped control minor bleeding. Visualization of intra-abdominal solid organs with real-time EUS was accomplished with ease. Intraperitoneal EUS-FNA was successfully performed on the liver, spleen, and kidney. Similarly, a successful outcome was achieved with EUS-RFA of the hepatic parenchyma. No adverse events were recorded during the study.

**CONCLUSION:** Peritoneoscopic natural orifice trans-luminal endoscopic surgery (NOTES) interventions through FV-EUS were feasible in providing evaluation and performing endoscopic procedures. It promises potential as a platform for future EUS-based NOTES.

**Key words:** Forward-viewing endoscopic ultrasound; Oblique-viewing endoscopic ultrasound; Endoscopic ultrasound guided intervention; Peritoneoscopy; Natural orifice transluminal endoscopic surgery

**Core tip:** Recently, the forward-viewing endoscopic ultrasound (FV-EUS) was developed, however, peritoneoscopic natural orifice transluminal endoscopic surgery (NOTES) interventions with an FV-EUS has never been discussed. In this study, transgastric peritoneoscopy with FV-EUS, real-time EUS, EUS-guided fine needle aspiration, EUS-guided radiofrequency ablation, and bleeding control were successfully undertaken. FV-EUS will broaden the prospects of NOTES interventions to endoscopists, and the NOTES interventions with an FV-

EUS might be performed in the various conditions.

Forward-viewing endoscopic ultrasound-guided NOTES interventions: A study on peritoneoscopic potential. *World J Gastroenterol* 2013; 19(41): 7160-7167 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i41/7160.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i41.7160>

## INTRODUCTION

Natural orifice transluminal endoscopic surgery (NOTES) reaches the target organ by inserting the endoscope through a natural orifice (*e.g.*, mouth, anus, vagina, or urethra) and entering the peritoneal cavity by making an incision on the luminal wall. In the years after the first described NOTES by Kalloo *et al.*<sup>[1]</sup> in 2004, a wide range of NOTES procedures with a transgastric (TG) endoscopic approach to access the peritoneal cavity have been reported. Several studies, mainly performed using animal models, have been feasible for a variety of procedures, including fallopian tube ligation<sup>[2]</sup>, cholecystectomy<sup>[3]</sup>, biliary anastomosis<sup>[4]</sup>, gastrojejunostomy<sup>[5]</sup>, splenectomy<sup>[6]</sup>, and partial hysterectomy<sup>[7]</sup>. NOTES with flexible peritoneoscopy enables the examination of the peritoneal cavity with minimal invasiveness. By avoiding abdominal incisions, these successful NOTES procedures have the potential to offer less postoperative pain and reduced postoperative recovery time while avoiding hernia formation, adhesions, surface incision infection and scarring<sup>[8]</sup>. Primarily confined to the proponents of NOTES in the surgical discipline, these procedures offered a viable alternative to laparoscopic surgery, especially in patients deemed at high risk for complications.

In assessing the peritoneal cavity, the anterior wall of the stomach is usually the ideal incision site while the posterior wall may be selected to explore the retroperitoneum<sup>[9-11]</sup>. However, the TG approach has inherent risks, such as access site bleeding, adjacent organ injury during gastrotomy creation, or gastric content leakage, giving rise to infection in the peritoneal cavity. Apart from infection, bleeding is one of the most common complications. Given these considerations, the endoscopic ultrasound (EUS) has been used to avoid and mitigate the risk of injury to extraluminal structures, as well as to detect neighboring vessels by using color Doppler imaging<sup>[12,13]</sup>. In these studies, an oblique-viewing, curved, linear-array endoscopic ultrasound (OV-EUS) was used to acquire real-time images of the vessels and structures outside the gastrointestinal tract during access into the peritoneal cavity. After making an incision on the gastric wall, the OV-EUS must be exchanged for endoscopy to perform the subsequent NOTES procedures, because it provides oblique-viewing images different from the direction of the echoendoscopic movement.

To overcome several limitations of OV-EUS in EUS-

interventions, a forward-viewing endoscopic ultrasound (FV-EUS) was developed. The FV-EUS simultaneously offers a straight endoscopic view and an ultrasound image. In several studies, FV-EUS was successfully tested in EUS-interventions, such as the drainage of pancreatic pseudocysts<sup>[14,15]</sup>, EUS-guided fine needle aspiration (EUS-FNA)<sup>[16]</sup>, and celiac plexus neurolysis<sup>[17]</sup>. In addition, it is now possible to go beyond the gut wall with the FV-EUS for intraluminal to intraperitoneal EUS evaluation. Although it showed advantages in other EUS-interventions, studies have yet to suggest the possibility of FV-EUS in NOTES procedures. Hence, this study was conducted to evaluate the technical feasibility and safety profile of the FV-EUS in a variety of procedures related to diagnostic and therapeutic TG peritoneoscopic interventions.

## MATERIALS AND METHODS

### Animals

A mini pig (40 kg) and 9 dogs (mean weight, 18 kg; weight range, 15-20 kg) were used. Approval of the Institutional Animal Care and Use Committee was obtained before initiation of the study. All animals were fasted for 24 h but permitted water *ad libitum*. Anesthetic induction was achieved with a drug combination of tiletamine and Zolazepam (7.5 mg/kg) (Zoletil 50, Virbac, South Korea) and Xylazine Hydrochloride (2 mg/kg) (Rompun; Bayer, South Korea) and maintained on 1.5% isoflurane (Forane, JW pharmaceutical, South Korea) following endotracheal intubation. Cardiopulmonary parameters were monitored throughout the procedure.

### FV-EUS-guided transgastric access

Under general anesthesia, an FV-EUS (UCT 160J-AL5, Olympus, Tokyo, Japan) was advanced into the esophagus and stomach. The access site on the anterior gastric wall was first evaluated under real-time image and Doppler guidance to exclude adjacent organs and interfering vessels. A single-lumen microknife needle (Boston Scientific, Natick, MA) was used to create and puncture a small hole in the anterior gastric wall. Through the puncture site, a standard 0.035-guidewire (Jagwire; Boston Scientific, Natick, MA) was advanced through the microknife into the abdominal cavity. The microknife was then withdrawn with the guidewire left *in situ*.

This portal of access was then dilated with a 20-mm controlled radial expansion (CRE) balloon (Boston Scientific, Natick, MA). The balloon was held in place for 1 min. The radially expanded puncture formed a circular gastrotomy that granted passage of the FV-EUS into the peritoneum. The resultant entry allowed air insufflation through the echoendoscope to expand the peritoneal cavity for improved visualization.

### Peritoneoscopic interventions

After access into the peritoneal cavity with the FV-EUS, the following procedures were performed: (1) Peritoneoscopy and endoscopic biopsy of the liver, spleen,

Figure 1 Peritoneoscopy and endoscopic biopsy of the intraperitoneal organs. A: Liver; B: Spleen; C: Abdominal wall; D: Omentum.

Figure 2 Forward-viewing endoscopic ultrasound image of the intraperitoneal organs and endoscopic ultrasound-guided fine needle aspiration using a 19G aspiration needle (white arrow). A: Liver; B: Kidney; C: Spleen.

abdominal wall, and omentum using a rat-tooth biopsy forceps (Olympus, Tokyo, Japan) (Figure 1); (2) Real-time FV-EUS examination of the intraperitoneal solid organs (Figure 2); (3) EUS-FNA with a 19G (Cook Medical Inc., Winston-Salem, NC) aspiration needle on the liver, spleen, and kidney (Figure 2); (4) FV-EUS-guided radio-frequency ablation (EUS-RFA) with the newly developed 18G RFA needle (Starmed, Seoul, South Korea) on the hepatic parenchyma (Figure 3); and (5) Argon plasma coagulation (APC) for hemostatic control of artificially induced bleeding at the liver and spleen (Figure 4).

#### Gastrotomy closure and post-procedure assessment

The gastrotomy site was closed with endoscopic hemoclips. After the procedure, antibiotics and analgesics were

administered and the regular diet was introduced 24 h later. The animals were kept alive for 7 d and then sacrificed. Necropsy was performed to evaluate macroscopically the EUS-FNA and EUS-RFA lesions, as well as any gross anatomical injuries to the intraperitoneal organs and infective complications.

## RESULTS

### Feasibility

This study was performed on 1 pig and 9 dogs. After gastrotomy, the FV-EUS, using forward optic view to enter the peritoneal cavity, and diagnostic TG peritoneoscopy for various intraperitoneal organs was undertaken safely and easily in all animals. Endoscopic biopsies of the liver,

**Figure 3** Endoscopic ultrasound-guided radio frequency ablation using an 18G radiofrequency ablation needle on the hepatic parenchyma. A: Radiofrequency ablation (RFA) needle (white arrow) in the hepatic parenchyma with echogenic ablation zone (red arrow); B: RFA needle tip with ablation zone (red arrow) echogenic marker (white arrow); C: Gross pathology of ablated tissue in the liver parenchyma.

spleen, abdominal wall, and omentum were also completed successfully without complications in all 10 animals.

APC was successfully used to control minor artificial bleeding caused by deliberate multiple-forceps biopsy and

poking on the liver and spleen in 4 animals. Real-time EUS images were acquired with ample clarity and ease while observing the deeper portions of the intra-abdominal organs. When the scope contacted the target organ, the endoscopic view was switched to the sonographic view, and EUS-FNA from the peritoneal cavity was successfully performed on the liver, spleen, and kidney in the 9 dogs.

The EUS-RFA was undertaken when the equipment was made available. In the EUS-RFA, the power was set to 50 watts, and the duration was 1 min. The EUS-RFA of the hepatic parenchyma was equally successful in 6 animals by using the RFA needle (Table 1).

### Evaluation of post-procedure outcomes

All the animals survived for 7 d without any obvious pattern of behavioral distress. Necropsy revealed no apparent or gross anatomical damage to the intraperitoneal organs related to these diagnostic and therapeutic procedures. The closure of the gastrotomy orifice was accomplished using 6 to 7 endoscopic hemoclips. No significant peritoneal adhesions or peritonitis were seen in the necropsies. In addition, neither intraperitoneal infectious complications nor abscesses were detected in the animals.

## DISCUSSION

EUS-guided therapeutic interventions are performed with the OV-EUS. The major disadvantage of the OV-EUS is that the echoendoscope occasionally accesses the targeted area at an acute angle. Because of the acute angle, the force of accessory advancement may cause the scope to push away from the target organ. Another limitation of the OV-EUS is the lack of forward-viewing endoscopy. It requires reorientation in switching from a sonographic to endoscopic view. As a result of technological advances and a surge in new therapeutic modalities for EUS-guided procedures, FV-EUS was developed to overcome the disadvantages of OV-EUS.

The FV-EUS facilitated needle or device insertion and deployment<sup>[18]</sup>. Unlike the OV-EUS an important advantage offered with the FV-EUS is that the axis and optics of the echoendoscope is in line with the accessory channel. This straight alignment not only provides the operator easier deployment and manipulation of needle and devices through the working channel but also renders better transmission of force to the tip of the accessory

device or needle<sup>[17]</sup>. Furthermore, the FV-EUS could be manipulated to secure a perpendicular puncture trajectory instead of the angulated puncture direction in OV-EUS, thereby, preventing the “pushback” phenomenon or moving away from the gut wall<sup>[19]</sup>. This ensures that the echoendoscope could be kept more easily in its intended position during therapeutic interventions.

Of course, the FV-EUS has disadvantages: narrow ultrasound scanning range, absence of an elevator, and incapability of using a balloon at the tip of the echoendoscope. However, these disadvantages of FV-EUS did not affect its maneuverability or outcomes<sup>[15,19,20]</sup>. Overall, the FV-EUS facilitates EUS-guided therapeutic procedures.

With the introduction of the FV-EUS, its use in TG NOTES peritoneoscopy could mark the evolution from mainly a diagnostic modality to the prospect of carrying out a wide range of peritoneoscopic interventional procedures. This is possible because of certain advantages afforded by the FV-EUS, namely, improved maneuverability guided by forward optics, wider distal-end range of angulation, a shorter and smaller distal tip in front of the view, the facility to deploy needles and other accessory devices along the axis of the scope, and the ability to switch readily between sonographic and endoscopic views without the need for frequent echoendoscope re-orientation<sup>[14]</sup>. By using FV-EUS to identify and avoid extraluminal organs and vessels, the gastrotomy site created on the anterior abdominal wall was accomplished without intra- or post-procedural complications. Neither bleeding from the gastric wall during its incision nor injury to the contiguous organs on entry into the peritoneal cavity was observed. FV-EUS enhanced safety by providing real-time images of the anticipated path of the microknife puncture. Hence, with the advantages mentioned earlier, the transmural microknife puncture through the gastric layers, advancement of the guidewire *via* the fistula into the peritoneal cavity, and fistula dilatation with the CRE balloon were successful in all 10 animal cases. In particular, the FV-EUS circumvents the need of a second endoscopic procedure for peritoneal cavity entry and, thereby, reducing overall procedure time<sup>[12]</sup>.

In the current animal study, biopsies were taken from the liver, spleen, anterior abdominal wall, and omentum successfully with the FV-EUS. This was exemplified in the minimal resistance and enhanced facility the operator encountered during the procedure. In the event of

bleeding, APC was used to attain control. Hemostasis was achieved effectively for minor bleeding, which was deliberately induced by the forceps biopsy at the liver and spleen in 4 dogs. Electrocautery could also be used to prevent further bleeding from the biopsy sites<sup>[21]</sup>. These findings suggest that liver and splenic biopsies *via* the TG peritoneoscopic approach could be accomplished uneventfully and without major bleeding complications.

The EUS-FNA and EUS-RFA needles were clearly visualized extruding from the working channel of the FV-EUS and then they were inserted directly into the various organs under real-time EUS imaging. The FV-EUS, with its ability to switch readily between endoscopic and sonographic views, diminished manipulative reorientation of the echoendoscope during EUS-FNA or EUS-RFA, greatly improving technical performance. This translated into successful attempts at EUS-FNA with a 19G needle on the liver, spleen, and kidney in all 9 dogs. Likewise, EUS-RFA with an 18G RFA needle at 50W for 1 min to the hepatic parenchyma was successfully duplicated in 5 dogs and 1 pig.

Necropsy findings revealed a well-demarcated RFA ablation zone in the hepatic parenchyma while FNA needle puncture marks were seen on the intra-abdominal organs. Therefore, the design of the FV-EUS enabled the operator to target lesions within and external to the organs with relative ease, which greatly improved the ability to perform diagnostic and therapeutic procedures. This suggests that the new EUS-RFA method is able to treat the mass of intraperitoneal solid organs by using the newly developed RFA-needle.

The improvement in intraperitoneal maneuverability of the FV-EUS results in adequate visualization of all four abdominal quadrants and intestinal loops<sup>[22]</sup>. As modern imaging techniques tend to understage around 10%-40% of GI malignancies<sup>[23,24]</sup>, peritoneoscopy with intraperitoneal FV-EUS could provide adequate minimally invasive staging of GI malignancies, especially for pancreatic and stomach cancers, prior to surgical resection. Therefore, by providing better diagnostic accuracy, the FV-EUS, with its extra ability to see through solid organs, might be a preferred substitute to staging laparoscopy in detecting peritoneal carcinomatosis and small metastatic tumors. In addition, endoscopic visualization of the anterior abdominal wall could be easily achieved by looking up to the abdominal wall rather than looking back with angled laparoscopes.

Necropsy findings in this study did not reveal any organ injury or infective complications related to the TG peritoneoscopy. Nevertheless, bacterial contamination and infection in the abdomen is a genuine concern for a gastrotomy site. Donatsky *et al.*<sup>[25]</sup> reported that in TG NOTES with over-the-scope-clip closure, intra-abdominal chronic abscesses were discovered in 3 of 10 pigs at necropsy, although all the animals survived during the study period. The study concluded that peritoneal contamination did occur, which warranted implementation other than the use of single-dose prophylactic anti-

biotics to prevent infective complications. In contrast, a study by Narula *et al.*<sup>[26]</sup> revealed that despite the presence of contamination measured by an increase in the bacterial colony-forming units, no clinically significant spillage into the peritoneum that resulted in abscess formation was seen. These conflicting results would require further evaluation to prevent post-gastrotomy septic complications, including peritonitis.

The effectiveness of current suture techniques and the perforation risk following closure of the gastrotomy site remain unsettled issues. Unsatisfactory closure of the transluminal access site has resulted in several animal cases of microabscesses, peritonitis, and death<sup>[27]</sup>. Although the endoclips used in this study did not give rise to any adverse complications, mucosal closure with endoclips has been shown unreliable and it could result in substantial air and gastric fluid leakage<sup>[28]</sup>. The presence of tissue edema and widely opposing incisional edges considerably impede satisfactory tissue approximation. Without achieving full thickness closure, the potential for gastric fluid leakage and spontaneous perforation risk definitely exist. Until now, the unavailability of a simple and safe closure technique continued to impede the progress of NOTES procedure.

This study was limited in its small number of animal cases, as well the substantial difference in porcine and canine abdominal anatomy that may limit the relevance of the study findings in relation to clinical human applicability. Despite the limitation, this animal study is the first report that suggested the possibility of FV-EUS in NOTES procedures and show that the FV-EUS was very efficient as a modality of NOTE interventions. It is possible to go beyond the gut wall with the FV-EUS from intraluminal to intraperitoneal EUS evaluation, enabling freedom to assess many areas within the abdominal cavity, including the pelvic region. Armed with a sonographic window, extraluminal peritoneoscopic evaluation with the FV-EUS would enable assessment beyond visual inspection by providing views and accessibility to lesions within solid intraperitoneal organs and structures, thereby, broadening the appeal of NOTES peritoneoscopic interventional procedures to the endoscopist.

In conclusion, TG NOTES combined with EUS-guided peritoneoscopic interventions and intraperitoneal, as well as intraluminal, EUS could be achieved with the FV-EUS. This study ably demonstrated the utility and success of FV-EUS in both diagnostic and therapeutic peritoneoscopic interventions in animal models, which adds to the growing armamentarium available for NOTES procedures. Even though concerns remain, embracing this strategy is essential for further development of EUS-guided NOTES interventions.

## ACKNOWLEDGMENTS

We wish to thank Olympus Medical Systems, Tokyo, Japan for generous providing the prototype echoendoscope for evaluation.

## COMMENTS

## Background

Natural orifice transluminal endoscopic surgery (NOTES) is a new surgical technique and it has the potential to offer less operation related complications. However, the therapeutic transgastric (TG) approach to access the peritoneal cavity has inherent risks, such as bleeding and adjacent organ injury. The endoscopic ultrasound (EUS) has been used to avoid the risk of injury to extraluminal structures and oblique-viewing, curved, linear-array echoendoscope (OV-EUS) have been used in NOTES interventions. Recently, the forward-viewing endoscopic ultrasound (FV-EUS) was developed and successfully tested in EUS-guided interventions. The FV-EUS is regarded as an ergonomic and viable endoscopic modality to perform TG peritoneoscopic interventions via NOTES. However, peritoneoscopic NOTES interventions through FV-EUS have never been discussed.

## Research frontiers

The FV-EUS was developed to overcome the limitations of OV-EUS which provides oblique-viewing images different from the direction of the echoendoscopic movement. Several experimental studies through FV-EUS have been feasible for a variety of EUS-interventions, such as the drainage of pancreatic pseudocysts, EUS-FNA, and celiac plexus neurolysis.

## Innovations and breakthroughs

FV-EUS has not been used previously for NOTES access. In their animal experiments, the authors aim to investigate the use of the FV-EUS for the performance of standard NOTES interventions. This study ably demonstrates the utility and success of FV-EUS in both diagnostic and therapeutic peritoneoscopic interventions, and it suggests that FV-EUS can improve safety of the NOTES access to the peritoneal cavity. In conclusion, this animal study is the first report that suggested the possibility of FV-EUS in NOTES procedures and show that the FV-EUS was very efficient as a modality of NOTES interventions.

## Applications

Armed with a sonographic window, extraluminal peritoneoscopic evaluation with the FV-EUS would enable assessment beyond visual inspection by providing views and accessibility to lesions within various intraperitoneal structures. Therefore, FV-EUS will broaden the prospects of NOTES interventions to endoscopists and gastroenterologists, and the NOTES interventions through a FV-EUS might be performed in the various conditions.

## Terminology

NOTES: NOTES is an experimental surgical technique. NOTES reaches the target organ by inserting the endoscope through a natural orifice (e.g., mouth, anus, vagina, or urethra) and entering the peritoneal cavity by making an incision on the luminal wall, thus avoiding any external incisions. FV-EUS: FV-EUS has both an forward endoscopic view and a sonographic view, plus a working channel in alignment with the endoscope shaft. It is able to deploy needles and other accessory devices along the axis of the scope, and has a wider angulation range of the tip.

## Peer review

The authors performed the first animal study of NOTES procedures using forward view EUS guidance. The study confirm the feasibility of FV-EUS guided NOTES. It is an interesting study that provide important information on future studies of NOTES under FV-EUS guidance.

### Abstract

**AIM:** To evaluate the safety and effectiveness of endoscopic papillary large balloon dilation (EPLBD) for bile duct stone extraction in patients with periampullary diverticula.

**METHODS:** The records of 223 patients with large common bile duct stones ( $\geq 10$  mm) who underwent EPLBD (12-20 mm balloon diameter) with or without limited endoscopic sphincterotomy (ES) from July 2006 to April 2011 were retrospectively reviewed. Of these patients, 93 (41.7%) had periampullary diverticula (PAD), which was categorized into three types. The clinical variables of EPLBD with limited ES (EPLBD + ES) and EPLBD alone were analyzed according to the presence of PAD.

**RESULTS:** Patients with PAD were significantly older than those without ( $75.2 \pm 8.8$  years *vs*  $69.7 \pm 10.9$  years,  $P = 0.000$ ). The rates of overall stone removal and complete stone removal in the first session were not significantly different between the PAD and non-PAD groups, however, there was significantly less need for mechanical lithotripsy in the PAD group (3.2% *vs*

11.5%,  $P = 0.026$ ). Overall stone removal rates, complete stone removal rates in the first session and the use of mechanical lithotripsy were not significantly different between EPLBD + ES and EPLBD alone in patients with PAD (96.6% *vs* 97.1%; 72.9% *vs* 88.2%; and 5.1% *vs* 0%, respectively). No significant differences with respect to the rates of pancreatitis, perforation, and bleeding were observed between EPLBD + ES and EPLBD alone in the PAD group (3.4% *vs* 14.7%,  $P = 0.095$ ; 0% *vs* 0%; and 3.4% *vs* 8.8%,  $P = 0.351$ , respectively).

**CONCLUSION:** EPLBD with limited ES and EPLBD alone are safe and effective modalities for common bile duct stone removal in patients with PAD, regardless of PAD subtypes.

**Key words:** Endoscopic papillary large balloon dilation; Endoscopic sphincterotomy; Periampullary diverticula

**Core tip:** Endoscopic papillary large balloon dilation (EPLBD) is a highly effective technique for treating difficult bile duct stones. However, the safety of EPLBD is of concern, especially in patients with periampullary diverticula (PAD). In the present study, the clinical outcomes and complications of EPLBD with limited endoscopic sphincterotomy (ES) (EPLBD + ES) and EPLBD alone according to the presence of PAD were not significantly different. We suggest that EPLBD + ES and EPLBD alone are safe and feasible modalities for large bile duct stone removal in patients with PAD. Furthermore, the presence of PAD was not found to affect therapeutic outcomes.

## INTRODUCTION

Although endoscopic sphincterotomy (ES) is the standard therapy for choledocholithiasis, it has been reported to produce several serious complications, such as bleeding and perforation<sup>[1-3]</sup>. Endoscopic papillary balloon dilation (EPBD), which was introduced by Staritz *et al*<sup>[4]</sup>, has been used as an alternative procedure for the removal of common bile duct (CBD) stones. However, several cases of post-procedural pancreatitis and two deaths associated with EPBD have been documented<sup>[5]</sup>. Furthermore, it has been reported that mechanical lithotripsy is more frequently required during EPBD than during ES<sup>[6,7]</sup>.

Some bile duct stones are difficult to remove due to a large size, a rectangular shape, or anatomical difficulties, and these remain challenges for endoscopists despite advancements in expertise and the developments of various accessories. Several recent series have demonstrated that endoscopic papillary large balloon dilation (EPLBD) combined with limited endoscopic sphincterotomy (EPLBD + ES) has a similar therapeutic effect, but a lower complication rate than standard ES for the removal of difficult bile duct stones<sup>[8-12]</sup>. In particular, anatomical variations, such as periampullary diverticula (PAD), which can influence endoscopic outcomes because of the high risk of procedure-associated complications. Duodenal diverticula are outpouchings of mucosa, submucosa, and partially speckled muscle along the intestinal wall. Reported locations and incidences of PAD in the general population vary<sup>[13-18]</sup>. PAD is known to be associated with an increased frequency of pancreatobiliary diseases, and it is widely accepted that the presence of diverticula can be a technical obstacle to cannulation and requires skillful endoscopy manipulation<sup>[13,14]</sup>. However, recent two studies have shown that rates of successful cannulation are not dependent on the presence of diverticula<sup>[17,19]</sup>.

Nevertheless, when EPLBD is performed in patients with PAD, the potential risks of perforation and bleeding are of concern, because the ampullary area in PAD is composed of thin mucosa without sphincter muscle. Recent studies have indicated that EPLBD without ES is as effective and safe as ES for the removal of large bile duct stones, regardless of the presence of PAD<sup>[20-22]</sup>. Accordingly, the aim of this study was to evaluate the technical feasibility and safety of EPLBD with or without ES for the removal of CBD stones in patients with PAD.

## MATERIALS AND METHODS

The records of 223 patients with CBD stones  $\geq 10$  mm in diameter who underwent EPLBD combined with antecedent ES (EPLBD + ES) or EPLBD alone (EPLBD - ES) for the removal of bile duct stones from July 2006 to April 2011 were retrospectively reviewed. Patients with a history of endoscopic sphincterotomy or Roux-

en-Y gastrojejunostomy were excluded. All procedures were performed using side-viewing endoscopes (TJF-240; Olympus Optical Corporation, Tokyo, Japan). Endoscopic retrograde cholangiopancreatography (ERCP) was performed by experienced endoscopists at a single center. Cannulation was attempted using an ERCP catheter or a pull-type sphincterotome. When conventional cannulation failed, a pre-cut technique using a needle knife was applied. EPLBD was performed using a dilating balloon catheter (CRE balloon, Boston Scientific Cork, Ireland) positioned at the center of the balloon across the ampullary orifice (Figure 1). Dilating balloon catheters with a diameter of 12-20 mm were used. Ballooning size was determined based on stone sizes and CBD diameter, but should not exceed 2 mm of the diameter of the distal CBD. Balloons were inflated with caution until balloon notches disappeared. Mechanical lithotripsy was attempted when stones were too difficult to remove intact. When incomplete stone removal was suspected, a nasobiliary tube or a plastic stent was placed to prevent cholangitis. Complete stone removal was confirmed either by cholangiogram at the end of each procedure or by follow-up cholangiogram through a nasobiliary tube. The presence and types of diverticula were documented. Duodenal diverticula were categorized into three subtypes based on the locations of the major papilla with respect to diverticula: (1) type 1, when papilla was located inside the diverticulum; (2) type 2, when papilla was located in the margin of the diverticulum; and (3) type 3, when papilla was located outside the diverticulum (Figure 2). Patients were thoroughly observed for possible complications including bleeding, pancreatitis, and perforation during and after ERCP. Post-ERCP pancreatitis was defined as a serum amylase level exceeding three times the upper normal limit and the development of abdominal pain after ERCP. Hyperamylasemia was defined as a serum amylase level exceeding three times the normal upper limit without any abdominal pain. Post-ERCP bleeding was classified as major or minor based on amounts of hemorrhage. Major bleeding was defined as moderate to severe hemorrhage necessitating transfusion or intervention, and minor bleeding was defined as mild hemorrhage not requiring transfusion. Clinical and endoscopic factors were retrospectively evaluated. The study was approved by the institutional review board of our hospital.

### Statistical analysis

Statistical analysis was carried out using the Student's *t* test, the  $\chi^2$  test, and one-way ANOVA in SPSS version 17.0 (SPSS, Inc., Chicago, IL, United States). A *P* value < 0.05 was considered statistically significant.

## RESULTS

Demographic characteristics of the 223 patients (122 men, 101 women; mean age  $72.0 \pm 10.4$  years) are presented in Table 1. The incidence of PAD was 41.7% (93/223). The mean age was significantly higher in the

Values are presented as mean ± SD (range). PAD: Periampullary diverticula; BMI: Body mass index; ES: Endoscopic sphincterotomy; CBD: Common bile duct.

and in 19 patients (14.6%) in the non-PAD group ( $P = 0.138$ ). The frequencies of EPLBD + ES and EPLBD - ES were not significantly different between the PAD and non-PAD groups (EPLBD + ES, 63.4% *vs* 56.2%; and EPLBD - ES, 36.6% *vs* 43.8%,  $P = 0.334$ , respectively). The mean stone size in the 223 patients was  $15.9 \pm 5.8$  mm (range, 10-40 mm), the mean bile duct diameter was  $19.9 \pm 5.3$  mm (range, 10-37 mm), and the mean dilated balloon size was  $15.6 \pm 2.4$  mm (range, 12-20 mm). The mean stone(s) and CBD diameters were not significantly different between the PAD and non-PAD groups ( $16.4 \pm 6.0$  mm *vs*  $15.5 \pm 5.7$  mm,  $P = 0.252$ ; and  $20.0 \pm 5.0$  mm *vs*  $19.8 \pm 5.4$  mm,  $P = 0.743$ , respectively). Mean balloon diameter for EPLBD was  $15.5 \pm 2.4$  mm in the PAD group and  $15.8 \pm 2.4$  mm in the non-PAD group ( $P = 0.374$ ).

Of the 223 patients, stone removal was completed in 96.9% (216/223). The rates of overall stone removal and stone removal in the first session were not significantly

different between the PAD and non-PAD groups [90/93 (96.8%) *vs* 126/130 (96.9%),  $P = 1.000$ ; and 73/93 (78.5%) *vs* 93/130 (71.5%),  $P = 0.277$ , respectively], but the frequency of mechanical lithotripsy was significantly lower in the PAD group [3/93 (3.2%) *vs* 15/130 (11.5%),  $P = 0.026$ ]. When the PAD and non-PAD groups were further divided by EPLBD + ES or EPLBD - ES, no significant differences with respect to overall stone removal rates, stone removal rates in the first session or needs for mechanical lithotripsy were observed [57/59 (96.6%) *vs* 33/34 (97.1%),  $P = 1.000$ ; 43/59 (72.9%) *vs* 30/34 (88.2%),  $P = 0.016$ ; and 3/59 (5.1%) *vs* 0 (0%),  $P = 0.297$ , respectively, Table 2]. Sub-analysis by PAD type revealed no significant difference with regard to age, stone size, CBD diameter, distal CBD angle, dilated balloon size, or duration of ballooning (Table 3). When comparing types of PAD, overall stone removal rates, complete stone removal rates in the first session, and the use of mechanical lithotripsy were not significantly different (Table 3).

<sup>1</sup>Comparison of the periampullary diverticula (PAD) and non-PAD groups. EPLBD: Endoscopic papillary large balloon dilation; ES: Endoscopic sphincterotomy; EPLBD + ES: Endoscopic papillary large balloon dilation with limited ES; EPLBD - ES: Endoscopic papillary large balloon dilation without ES; NA: Not applicable.

Procedure-related complications are listed in Table 4. The rates of post-ERCP pancreatitis, perforation, and bleeding were not significantly different between the PAD and non-PAD groups [7/93 (7.5%) *vs* 12/130 (9.2%), *P* = 0.809; 0% *vs* 1/130 (0.8%), *P* = 1.000; and 5/93 (5.4%) *vs* 11/130 (8.5%), *P* = 0.548, respectively]. When complications of EPLBD with or without ES were compared in the PAD group, the rates of pancreatitis, perforation, and bleeding did not differ significantly [2/59 (3.4%) *vs* 5/34 (14.7%), *P* = 0.095; 0% *vs* 0%; and 2/59 (3.4%) *vs* 3/34 (8.8%), *P* = 0.351, respectively]. Moreover, complication rates were not significantly different for PAD subtypes (Table 5). All cases of pancreatitis were mild and they

were treated conservatively. There were 16 (7.1%) bleeding cases, including one case (0.4%) of major bleeding and 15 cases (6.7%) of minor bleeding. The one major hemorrhage, which required more than 5 pints of blood, occurred in the non-PAD group. This patient was referred for emergency surgery for bleeding control and was managed effectively, with no further consequence. In addition, there were two in-hospital deaths in the non-PAD group. One in the EPLBD - ES group was caused by retroperitoneal perforation directly attributed to ERCP, and the other occurred in cirrhotic patients with fulminant hepatic failure and multi-organ failure due to sepsis in the EPLBD + ES group.

**Table 5** Complications of endoscopic papillary large balloon dilation by periampullary diverticula subtype *n* (%)

	PAD subtype ( <i>n</i> = 93)			<i>P</i> value

Type 1: When major papilla is located inside the diverticulum; Type 2: In the margin of the diverticulum; and Type 3: Outside the diverticulum. EPLBD: Endoscopic papillary large balloon dilation; PAD: Periampullary diverticula; NA: Not applicable.

## DISCUSSION

Currently, EPLBD combined with limited ES (EPLBD + ES) is regarded as an effective modality for treating difficult common bile duct stones. Complications, such as, hemorrhage and perforation, have been reported to be less frequent in EPLBD + ES than in standard ES<sup>[9-12]</sup>. Furthermore, mechanical lithotripsy is less required during EPLBD + ES, because it provides spacious ampullary opening, and thus, facilitates complete bile duct stone removal. More recently, it has been suggested that EPLBD without ES is as safe and effective as ES for the removal of large bile duct stones<sup>[20-22]</sup>. Nevertheless, the safety of EPLBD with or without antecedent ES is still a matter of concern. In particular, risks of complications might be greater in cases of PAD.

Most periampullary diverticula are asymptomatic and are found incidentally during ERCP<sup>[15]</sup>. Although duodenal diverticula are known to be acquired lesions, the etiology of PAD has not been established<sup>[18]</sup>. Several studies have mentioned that PAD is rarely found in patients younger than 40 years old, and that the incidence of PAD shows an increasing tendency with age<sup>[15,17,18,23]</sup>. In the present study, the mean age of patients in the PAD group was significantly higher than in the non-PAD group ( $75.2 \pm 8.8$  years *vs*  $69.7 \pm 10.9$  years,  $P = 0.000$ ), which concurs with previous reports and supports a substantive relationship between age and the formation of PAD<sup>[15,17,18,23]</sup>. However, previous studies have reported a prevalence of PAD at ERCP ranging from 5% to 32%, whereas the prevalence of PAD in the present study was higher at 41.7%, which might be explained by the relatively high proportion of older individuals in the present study<sup>[13-18]</sup>.

It is known that PAD represents a technical barrier during ERCP, and that the rate of cannulation failure is higher in PAD patients than in non-PAD patients. Several studies have addressed the influence of PAD on the technical difficulties of ERCP and on complications, and it appears that endoscopist skill, diverticula size, the

location of ampulla with respect to the diverticulum, CBD angulation, bowel motility, and patient cooperation contribute to the technical success of cannulation<sup>[16,17]</sup>. In order to facilitate cannulation of the bile duct in patients with PAD, a number of clever techniques, such as precutting with a needle knife and delicate handling of the scope, have been tried. Several series have reported successful cannulation rates ranging from 94.2% to 97.0%, complete stone removal in the first session ranging from 69.9% to 76.2%, and overall stone removal in up to 95.2% of patients with PAD<sup>[15,17,24,25]</sup>. In the present study, the rates of overall CBD stone removal and complete stone removal in the first session did not differ significantly between the PAD and non-PAD groups, which concurs with previous studies<sup>[17,25]</sup>. Moreover, overall stone removal and complete stone removal rates in the first session were not significantly different between PAD subtypes in the present study, which suggests that PAD types do not influence the clinical outcomes of EPLBD.

Mechanical lithotripsy is a rather labor-intensive but necessary technique for removing difficult stones, although EPLBD + ES reportedly reduces the need for mechanical lithotripsy<sup>[25,26]</sup>. Lowering the frequency of mechanical lithotripsy is important to prevent recurrent duct stones because remnant stone fragments following lithotripsy can act as nidi for stone recurrence. Theoretically, if EPLBD with a large-diameter balloon (12-20 mm) is applied, mechanical lithotripsy might be less required than after EPBD with a small-sized balloon ( $\leq 10$  mm). In the present study, mechanical lithotripsy was used significantly less in the PAD group than in the non-PAD group (3.2% *vs* 11.5%,  $P = 0.026$ ). Furthermore, when EPLBD alone was performed, bile duct stones were successfully removed without mechanical lithotripsy in the PAD group. However, when EPLBD + ES was applied, mechanical lithotripsy was required for three patients (5.1%) in the PAD group, although this did not represent a significant difference. One possible explanation of these results is that ampullary enlargement can easily be achieved by EPLBD alone because of the lack of sphincter muscle in patients with PAD, which may explain the reduced need for mechanical lithotripsy after EPLBD without ES. Furthermore, ease of ampullary widening by EPLBD could explain the tendency toward a shorter ballooning time in the PAD group. These findings suggest that EPLBD - ES could be an appropriate technique for CBD stone retrieval in the presence of PAD, as long as safety is guaranteed.

Post ERCP pancreatitis, perforation and bleeding are the most important complications related to EPLBD. According to the present study and previous reports, ERCP-related complication rates are similar in patients with or without PAD and for different PAD types<sup>[16,24,25]</sup>. Pancreatitis is the most concerning complication, and EPBD is not widely recommended for stone removal due to the possibility of severe pancreatitis<sup>[5,7]</sup>. This increased risk of pancreatitis is associated with an im-

pairment of pancreatic duct flow or direct pancreatic damage caused by physical compression during balloon dilation<sup>[3,26]</sup>. Although the pathogenesis of pancreatitis following EPLBD is not clear, it is suggested that ES prior to EPLBD could prevent potential injury of the main pancreatic duct, because ES can steer the direction of balloon dilation toward the CBD and minimize the pressure overload on the pancreatic orifice<sup>[8,20-22]</sup>. However, the recent studies have proposed that EPLBD alone can be an alternative for the removal of large stones<sup>[20-22]</sup>. Repeated cannulation attempts and excessive contrast injection due to anatomical difficulties could be major culprits of post-ERCP pancreatitis in patients with PAD. However, in the present study, no significant difference was observed in rates of post-ERCP pancreatitis between the PAD and non-PAD groups (7.5% *vs* 9.2%,  $P = 0.809$ ) or among types of PAD (5.6% *vs* 9.8% *vs* 5.9% for types 1, 2, and 3, respectively,  $P = 0.913$ ). Furthermore, the rate of post-ERCP pancreatitis in the PAD group (7.5%) was lower in the present study than in previous studies (9.6%-14.5%), which could have been due to cautious and gentle cannulation<sup>[24,25]</sup>. The relatively high percentage of older patients in this study might be associated with the observed lower incidence of pancreatitis<sup>[21]</sup>. In particular, it has been suggested that longstanding CBD stones can cause gradual bile duct dilation, and subsequently, a patulous ampullary orifice<sup>[22]</sup>. In a recent study, a very low incidence of pancreatitis (1.4%) was observed following EPLBD in patients with recurrent CBD stones after ES, which is similar to the pathophysiology of the process of patulous ampulla<sup>[27]</sup>.

Perforation is one of the most serious complications associated with EPLBD. Hypothetically, the risk of perforation should be higher in patients with PAD due to lack of sphincter muscle components around the ampulla. Balloon diameter and duration of ballooning are the important parameters for perforation after EPLBD. In most previous studies, balloon dilators sized from 12 to 20 mm were applied for 10 to 60 seconds, and in the present study, balloon dilators not exceeding CBD diameters were used and balloons were dilated gradually to minimize the risk of perforation<sup>[25-27]</sup>. As a result, the overall incidence of perforation was 0.4% and the risk of perforation was found to be not higher in the presence of PAD. In fact, only one case of perforation occurred in the non-PAD group. The size of sphincterotomy is another issue to consider before EPLBD. In the present study, after deep cannulation, the length of cutting was adjusted according to the locations of the ampulla and the bile duct axis. Ampullary distension without mucosal rupture around the ampulla can be obtained by gradual inflation and ballooning to an appropriate size. Because the weakest point is vulnerable to rupture by the radial forces produced by ballooning, overdilation of the ampulla exceeding CBD diameter should be avoided to prevent perforation, especially in cases of biliary stricture<sup>[27]</sup>.

Bleeding is another complication and is possibly related to excessive ampullary dilation. Theoretically, bleeding

risk can be increased if ES is performed. Previous studies have reported incidences of bleeding after EPLBD + ES ranging from 0% to 9%<sup>[5,8-12,25]</sup>. However, recent studies involving EPLBD without ES have reported lower rates of post-ERCP bleeding (0%-2.4%), which suggests that EPLBD without ES is suitable in patients with coagulopathies<sup>[20,21]</sup>. In the present study, we experienced one episode of major bleeding after sphincterotomy in the non-PAD group. It is presumed that most cases of post-ERCP bleeding are associated with small caliber vessels surrounding ampulla that are liable to be injured by radial pressure caused by balloon dilation, whereas large vessels are so elastic that they tend to be repelled by gradual balloon dilation<sup>[27]</sup>. The rates of adverse events in patients with PAD were acceptable in the present study.

In conclusion, EPLBD combined with limited ES and EPLBD alone appear to be safe and effective modalities for CBD stone removal in patients with PAD. PAD is commonly found in patients undergoing ERCP, and this study shows that the presence of PAD does not affect therapeutic outcome. Furthermore, an incidental finding of PAD presents no additional technical challenge to the achievement of successful EPLBD. This result complements those of previous studies on the management of CBD stones in patients with PAD. Nevertheless, because the present study is limited by its retrospective nature and a relatively small cohort, a large prospective study is needed to analyze the clinical feasibility of EPLBD with or without limited ES in patients with PAD.

## COMMENTS

### Background

Periampullary diverticula (PAD) may influence endoscopic outcomes because of the high risk of complications associated with anatomical variations. Endoscopic papillary large balloon dilation (EPLBD) is a useful method to remove difficult common bile duct (CBD) stones. However, the effectiveness and safety of this procedure in patients with PAD is not fully established. Accordingly, authors conducted this study to investigate the feasibility and safety of EPLBD with or without ES for the removal of CBD stones in patients with PAD.

### Research frontiers

It has been reported that 10%-15% of bile duct stones are difficult to retrieve by conventional techniques. Challenging cases of stone removal are as follows: a rectangular shape, a large size (> 15 mm), Billroth-II gastrectomy, Roux-en-Y gastrojejunostomy, and PAD. PAD can infrequently present a technical barrier during endoscopic retrograde cholangiopancreatography (ERCP). In particular, diverticula size and the location of ampulla may pose technical difficulties associated with ERCP and complications. Much conflicting data regarding the technical success and complications of ERCP have been published, and recently, EPLBD has been introduced for CBD stone removal in patients with PAD.

### Innovations and breakthroughs

Endoscopic papillary large balloon dilation following limited ES (EPLBD+ES) by Ersoz *et al* has been advocated as an alternative to ES for removal of large CBD stones. According to a few recent reports, EPLBD + ES showed a similar therapeutic effect but a lower complication rate than ES. EPLBD + ES requires mechanical lithotripsy less often due to enlargement of the ampullary opening. However, when EPLBD is performed in patients with PAD, the potential risks of perforation and hemorrhage are of particular concern. Nevertheless, several recent studies have suggested that EPLBD without ES is easy to perform for the removal of large bile duct stones, with similar therapeutic outcomes.

### Applications

EPLBD combined with limited ES and without ES were found to be safe and

effective for treating difficult CBD stones in patients with PAD. An incidental finding of PAD presents no additional technical challenge to the achievement of successful EPLBD.

### Terminology

EPLBD + ES is defined as endoscopic papillary balloon dilation (usually  $\geq 12$  mm in diameter) after limited sphincterotomy, using a dilating balloon catheter (CRE Balloon, Boston Scientific Cork, Ireland). The balloon is positioned across the orifice of ampulla, gradually inflated up to an appropriate size. Duodenal diverticula (PAD) are categorized into three subtypes based on the locations of the major papilla: (1) type 1, when papilla was located inside the diverticulum; (2) type 2, in the margin of the diverticulum; and (3) type 3, located outside the diverticulum

### Peer review

This retrospective study was conducted to investigate the technical feasibility and safety of EPLBD for the removal of difficult CBD stones in patients with PAD. The authors conclude that EPLBD + ES and EPLBD alone appear to be safe and effective procedures for CBD stone removal in patients with PAD. This result is encouraging and provides valuable information for other researchers.

### Abstract

**AIM:** To obtain reference values for pancreatic flow output rate (PFR) and peak time (PT) in healthy volunteers and chronic pancreatitis (CP); to correlate quantification of secretin enhanced magnetic resonance cholangiopancreatography (SMRCP) of pancreatic fluid output following secretin with fecal elastase-1 (FE-1) tests.

**METHODS:** The present study includes 53 subjects comprised of 17 healthy individuals and 36 patients with CP from April 2011 to January 2013. The 36 patients with CP were divided into three groups of mild CP ( $n = 14$ ), moderate CP ( $n = 19$ ) and advanced CP ( $n = 3$ ) by M-ANNHEIM classification for CP. Fifty-three cases underwent FE-1 test and magnetic resonance imaging using 3.0 T-device (Signa EXCITE, GE Healthcare). Coronal T<sub>2</sub>-weighted single-shot turbo spin-echo, spiratory triggered, covering the papillae, duodenum and small bowel. MRCP was performed with a heavily T<sub>2</sub>-weighted fat-suppressed long TE HASTE sequence

(thick slab 2D MRCP sequence), repeated every 2 min up to 11 min after 0.1 mL/kg secretin injection (Secrelux, Sanochemia®, Germany). FE-1 test used sandwich enzyme-linked immunosorbent assay (ELISA) test (ScheBo. Tech®, Germany).

**RESULTS:** A good linear correlation showed between the calculated volume and the actual volume by Phantom experiments. Fifty-three paired Quantification of secretin enhanced magnetic resonance cholangiopancreatography (MRCPQ) and FE-1 data sets were analyzed. The mean FE-1 of 53 cases was  $525.41 \pm 94.44$   $\mu\text{g/g}$  for 17 healthy volunteers,  $464.95 \pm 136.13$   $\mu\text{g/g}$  for mild CP,  $301.55 \pm 181.55$   $\mu\text{g/g}$  for moderate CP,  $229.30 \pm 146.60$   $\mu\text{g/g}$  for advanced CP. Also, there was statistically significant difference in FE-1 ( $P = 0.0001$ ) between health and CP. The mean values of PFR and PT were  $8.18 \pm 1.11$  mL/min,  $5.76 \pm 1.71$  min for normal;  $7.27 \pm 2.04$  mL/min,  $7.71 \pm 2.55$  min for mild CP;  $4.98 \pm 2.57$  mL/min,  $9.10 \pm 3.00$  min for moderate CP;  $4.13 \pm 1.83$  mL/min,  $12.33 \pm 1.55$  min for advanced CP. Further, statistically significant difference in PFR ( $P = 0.0001$ ) and PT ( $P = 0.0001$ ) was observed between health and CP. Besides, there was correlation ( $r = 0.79$ ) and consistency ( $K = 0.6$ ) between MRCPQ and ELISA Test. It was related between M-ANNHEIM classification and PFR ( $r = 0.55$ ), FE-1 ( $r = 0.57$ ).

**CONCLUSION:** SMRCP can provide a safe, non-invasive and efficient method to evaluate the exocrine function of the pancreas.

## INTRODUCTION

Pancreatic exocrine function test plays an important role of in the diagnosis of chronic pancreatitis. It can guide the clinical diagnosis and therapy. At present, the "tubed" secretin test is the standard reference method for functional investigations. Unfortunately, this test is hampered by lack of test standardization and is uncomfortable for the patient due to prolonged duodenal intubation<sup>[1,2]</sup>. Indirect pancreatic function test is non-invasive, safe and cost-effective, but it is positive only in a serious shortage of pancreatic exocrine function<sup>[3,4]</sup>. FE-1 (fecal elastase-1) test is one of the indirect pancreatic exocrine tests, and widely used in the clinical. Its role in diagnosing chronic pancreatitis is controversial<sup>[5-7]</sup>. However, previous studies have proven a positive correlation between the secretin test and FE-1, suggesting that it has a possible role in evaluating exocrine pancreatic function<sup>[8-10]</sup>.

Magnetic resonance cholangiopancreatography (MRCP) has been a reliable noninvasive method for the diagnosis of both pancreatic and biliary disease<sup>[11,12]</sup>. Magnetic resonance imaging is a noninvasive diagnostic imaging method without ionizing radiation and provides details of pancreatic parenchymal and ductal morphology with potential relevance for pancreatic exocrine function<sup>[13]</sup>.

Secretin enhanced magnetic resonance cholangiopancreatography (SMRCP) is routinely performed as part of the work up of patients with known or suspected pancreatic disease in many centers. Recently, SMRCP has gained increasing interest as a noninvasive imaging method enabling visualization and quantitative assessment of various aspects of pancreatic exocrine function<sup>[14-19]</sup>.

In this study we propose a similar quantification method using S-MRCP to evaluate pancreatic exocrine function during secretin stimulation by measuring pancreatic flow rate (PFR). Our study has both primary and

secondary purposes: (1) to obtain reference values for PFR in healthy volunteers and CP; and (2) to correlate quantification of secretin enhanced magnetic resonance cholangiopancreatography (MRCPQ) of pancreatic fluid output following secretin with FE-1 tests.

## MATERIALS AND METHODS

### Ethics

This work has been supported by Natural Science Foundation of China. This study was approved ethically by the Second Military Medical University. All patients provided informed written consent.

### Patients

From April 2011 to January 2013, the study included 53 subjects (18 females and 35 males) composed of 17 healthy volunteers and 36 patients with CP. Twelve health were male and five health were female, with a mean age of  $43.71 \pm 14.48$  years (range, 64-24 years) and a mean body mass index (BMI) of  $24.60 \pm 3.45$  kg/m<sup>2</sup> (range, 31.12-24.60 kg/m<sup>2</sup>). Twenty-three patients were male and thirteen patients were female, with a mean age of  $41.73 \pm 14.13$  years (range, 15-78 years) and a mean BMI of  $23.60 \pm 4.42$  kg/m<sup>2</sup> (range, 15.39-34.65 kg/m<sup>2</sup>). Thirty six patients with CP were divided into three groups of mild CP ( $n = 14$ ), moderate CP ( $n = 19$ ) and advanced CP ( $n = 3$ ) by M-ANNHEIM classification for CP<sup>[20-24]</sup>.

### Phantom experiments

Measurement phantoms (MP) had a cylindrical shape and were filled with water. MPs were moved to isocenter. All images were acquired with the same the positions ensuring all imaging volume included matching phantoms. Volumes from 0 mL up to 200 mL water were applied. Put 200 mL of water into MP with different increments (0-50 mL in 5 mL increments, 50-100 mL in 10 mL increments, 100-200 mL in 50 mL increments). Then, the correlation between actual volume and calculated volume was examined.

Voxels containing 100% water were identified from the middle slice of the last volume step, when MP underwent maximal filling<sup>[17]</sup>. Commercially available software provided to measure the mean signal intensity/voxel.

### FE-1 Test

For the FE-1 test, a single random stool sample was required with no need to stop enzyme supplements. Pancreatic exocrine reserve was in all patients using the FE-1 test determined. Results were determined using the sandwich enzyme-linked immunosorbent assay (ELISA) test, with two monoclonal antibodies that only bind to human elastase-1. A commercial kit was used (ScheBo Tech®, Germany) containing a human elastase-specific antibody-sensitized ELISA plate. Elastase concentration was then determined by a photometric method. The FE-1 values were separately scored as 1 for  $FE-1 \geq 200$  µg/g, and 0 for  $FE-1 < 200$  µg/g.

**Figure 1** Images of Phantom experiments. A: Measurement phantoms (MP) images with 5-70 mL of water in the MP; B: Correlation between the calculated and actual volumes of water *in vitro* study.

### MR technique

All examinations were performed using a 3.0-T MR (Signa EXCITE, GE Healthcare) with a phased array body coil. All examinations were fasted for at least 4 h before examination. Immediately, before imaging patients drank 100 mL of water ensuring the presence of a voxel containing 100% water within the imaging volume.

The pancreatic MR examination protocol consisted of: (1) coronal T<sub>2</sub>-weighted single-shot turbo spin-echo, respiratory-triggered, covering the papillae, duodenum and small bowel. The parameters for coronal T<sub>2</sub>-weighted sequences were the following: TR/TE 1375/119 ms, slice thickness 64 mm, no gap, echo time 119 ms, FA 90°, field of view (FOV) 400 × 400, matrix 224 × 288; and (2) MRCP was performed with a heavily T<sub>2</sub>-weighted fat-suppressed long-TE HASTE sequence (thick slab 2D MRCP sequence). Imaging parameters were TR/TE 7000 ms/1270 ms, flip angle 90°, 64 mm slice thickness, FOV 320 mm × 320 mm - 420 mm × 420 mm, matrix 288 × 288, echo time 1274 ms. After the first dynamic acquisition, a bolus of secretin was injected intravenously at a dose of 1 CU/kg body weight. The secretin (Secrelux Sanochemia®, Germany) dose 0.1 mL/kg was administered and the exact same sequence repeated at 1, 3, 5, 7, 9 and 11 min. All positions before and after injection remained unchanged.

### Imaging analysis

Two single radiologists assessed pancreatic imaging without knowledge of clinical and FE-1 data.

A semi-quantitative evaluation of duodenal filling (DF), a function of pancreatic exocrine secretion, was

**Table 1** Results in normal and chronic pancreatitis

	<i>n</i>	FE-1 (μg/g)	PFR (mL/min)	PT (min)
Normal	17	525.41 ± 94.44	8.18 ± 1.11	5.76 ± 1.71
Mild	14	464.95 ± 136.13	7.27 ± 2.04	7.71 ± 2.55
Moderate	19	301.55 ± 181.55	4.98 ± 2.57	9.10 ± 3.00
Advanced	3	229.30 ± 146.60	4.13 ± 1.83	12.33 ± 1.15
<i>F</i> value		9.45	9.59	9.06
<i>P</i> value		0.000	0.000	0.000

FE-1: Fecal elastase-1; PFR: Pancreatic flow output rate; PT: Peak time.

performed on MRCP images obtained 10 min after secretin injection and compared with MRCP images acquired before secretin administration. MRCP images were assessed as follows described by Matos *et al.*<sup>[25]</sup>, grade 0 for absence of DF; grade 1 for fluid limited into the duodenal bulb; grade 2 for DF up to the genu inferius; grade 3 for filling beyond to the genu inferius. In agreement within the literature, pancreatic exocrine function reduced when DF was less than grade 3.

Subsequently, a quantitative analysis of DF was performed by drawing an appropriate region of interest (ROI). Changes in signal intensity in the imaging volume were plotted against time, and the flow rate derived from the gradient. PFR were calculated using the method previously described in<sup>[17,19,25]</sup>. Pancreatic exocrine secretions were quantified by PFR and PT. Then the PFR values were separately scored as 1 for PFR ≥ 5 mL/min, and 0 for PFR < 5 mL/min. The volume of water was calculated with the following formula: Volume = (Mean signal intensity/Voxel × Size of the region of interest)/Signal intensity (100% water).

### Statistical analysis

Statistical analyses were performed in SPSS 20.0 for Windows software. Data are reported as the median or the mean ± one SD. Mean flow rates and FE-1 were compared using the one-way ANOVA LSD test and Student's *t* test. It was statistically significant different at the 0.05 level. Linear regression analysis was used to compare the values between PFR and FE-1. Correlations between DF grades, M-ANNHEIM classifications and PFR, FE-1 were tested using the Spearman's rank correlation coefficients respectively. Correlation was significant at the 0.01 level. The consistency of the two methods was compared with the test where MRCPQ < 5 mL/min, FE-1 < 200 μg/g as abnormal.

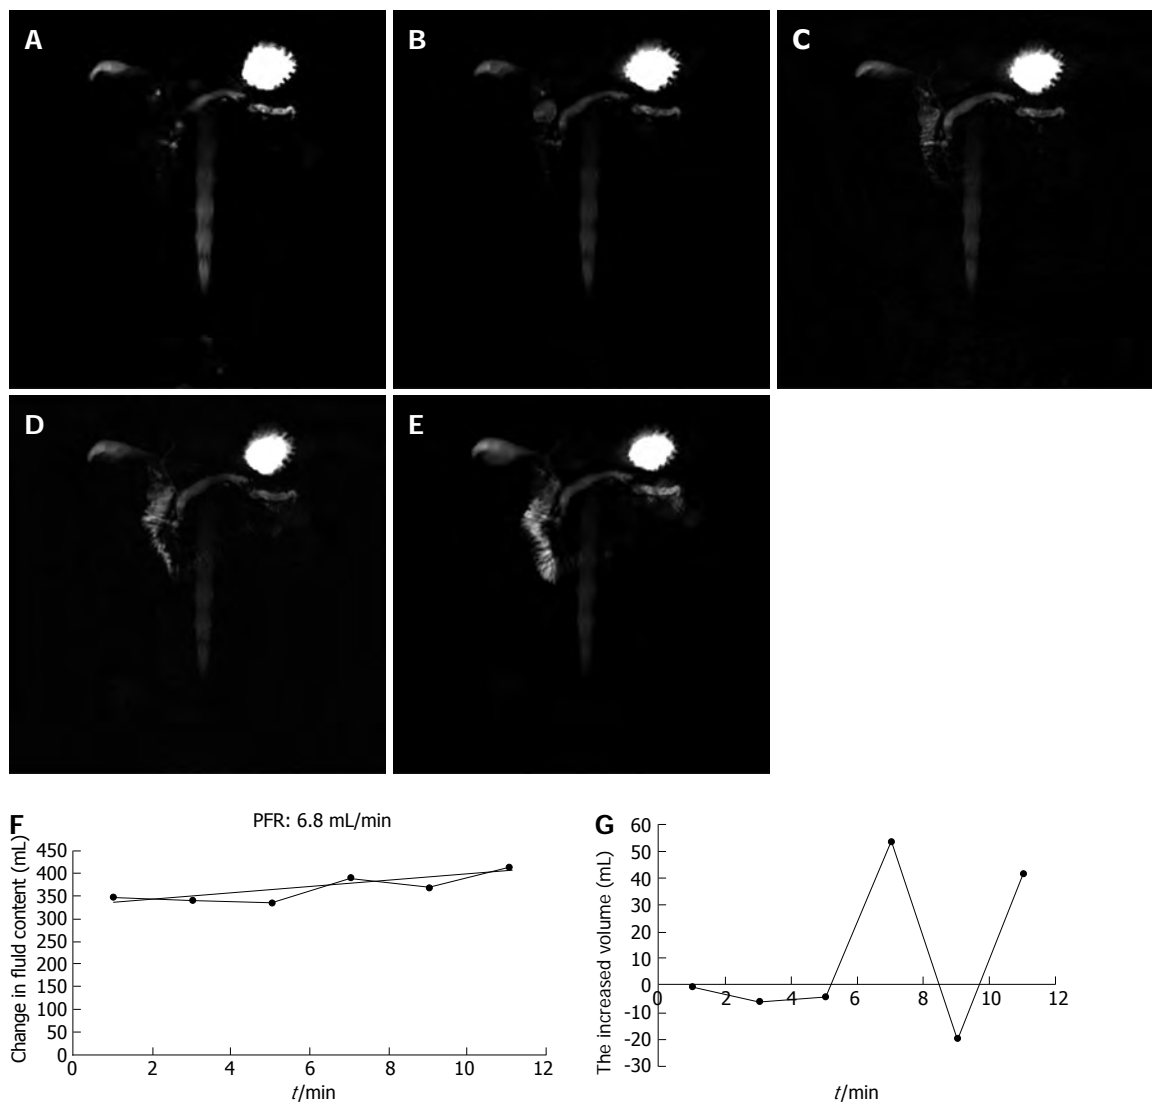

## RESULTS

### The result of phantom experiments

Phantom experiments showed a good correlation between known and calculated volumes of water (Figure 1).

### Semi-quantitative image analysis

Ten minutes after secretin administration, 17 volunteers and 23/33 patients showed a DF beyond the genu inferius (grade 3); whereas 8/36 showed a DF up to the

**Figure 2** An illustration of the secretin effect with the calculated pancreatic flow rate in a 54-year-old man with chronic pancreatitis. A-E: There was a visible increase in DF at 1, 3, 5, 7, 9, 11 min after secretin, grade 3 DF was present on SMRCP at 10 min; F, G: A plot of change in volume over time from patient data, normal response with a flow rate of 6.8 mL/s and PT of 7 min.

Table 2 Results in normal and reduced duodenal filling				
	n	FE-1 (μg/g)	PFR (mL/min)	PT (min)
Normal DF (grade 3)	40	453.64 ± 162.74	7.16 ± 2.34	7.28 ± 2.56
Reduced DF (grade 1, 2)	13	285.59 ± 158.03	4.71 ± 1.92	9.61 ± 3.57
P value		0.002	0.001	0.012

FE-1: Fecal elastase-1; PFR: Pancreatic flow output rate; PT: Peak time; DF: Duodenal filling.

genu inferius (grade 2); 5/36 showed a DF limited to the duodenal bulb (grade 1); None of the patients showed absent filling (grade 0).

**Quantitative image analysis**

Table 1 demonstrated results of the mean FE-1, PFR and PT of volunteers and patients based on M-ANNHEIM classification for CP. Table 2 demonstrated results of the mean FE-1, PFR and PT of volunteers and patients

**Figure 3** Scatter plot of pancreatic flow output rate and fecal elastase-1.

based on DF volume for CP. There was correlation ( $r = 0.79$ ) and consistency ( $K = 0.6$ ) between MRC PQ and FE-1. Also, it was related between M-ANNHEIM classification and PFR ( $r = 0.55$ ), FE-1 ( $r = 0.57$ ). There were correlations between DF grades and PFR ( $r = 0.36$ ), but

**Table 3** Quantification of secretin enhanced magnetic resonance cholangiopancreatography vs Fecal elastase-1 *n* (%)

	Normal FE-1	Abnormal FE-1
Normal MRCPQ	18 (51.4)	3 (8.6)
Abnormal MRCPQ	4 (11.4)	10 (28.6)

MRCPQ (quantification of secretin enhanced magnetic resonance cholangiopancreatography) < 5 mL/min and FE-1 < 200 µg/g are abnormal *K* = 0.6. FE-1: Fecal elastase-1.

**Table 4** Results of correlation

	M-ANNHEIM		DF	
	<i>r</i> value	<i>P</i> value	<i>r</i> value	<i>P</i> value
PFR	0.55	0.000	0.36	0.009
FE-1	0.57	0.000	0.29	0.038

Correlation is significant at the 0.01 level (2-tailed). DF: duodenal filling.

no FE-1 (*r* = 0.29, Figures 2 and 3, Tables 3 and 4).

## DISCUSSION

In this study, we quantified pancreatic exocrine function of CP. Some technical details are worth emphasis. The coil we used was the body coil not torso phased-array coil, because the body receiver coil provided a uniform sensitivity<sup>[26,27]</sup>. Second, Voxels containing 100% water was chosen in order to reduce the impaction of surrounding. If not, it would cause a high PFR<sup>[19,20]</sup>. Third, all cases fasted for at least four hours before examination. Immediately, patients were given 100 mL of water to drink before imaging, to ensure the presence of a voxel containing 100% water within the imaging volume. Keeping positions constant is also critical before and after the injection of secretin. Fourth, the scanning images should be along the long axis of the pancreas<sup>[28-31]</sup>. Lastly, we chose 64 mm slice thickness and large ROI including the papillae, duodenum and small bowel to prevent fluid loss.

There are some limitations in this study. The study sample is relatively small, in particular, the subgroup. Besides, it is distinguishing between water filled in measurement phantoms and pancreatic juice. Additionally, phantom experiments are only valid in vitro. The other data<sup>[15,16,18,29]</sup> show that a thin multilayer coronal T2WI images were obtained after the injection of secretin; based on change of signal, the volume of pancreatic secretion by the equation is calculated. This method needed patients to drink water many times. Finally, what we calculated is PFR, not pancreatic flow volume.

In summary, we have shown a good linear correlation between the calculated volume and the actual volume by Phantom experiments, which also has been reported in the literature<sup>[32-34]</sup>. The data gathered by the phantom studies strongly support the feasibility of this technique. Using the same technique, we have been able to measure pancreatic flow rates in health and CP. Moreover, there are correlation and consistency between MRCPQ and

FE-1. Our study confirmed the capability of MRCP images to quantitatively evaluate the pancreatic exocrine reserve. Nevertheless, considering the limitations of this study, we need to confirm our results with further trials.

## COMMENTS

### Background

Pancreatic exocrine function test plays an important role of in the diagnosis of chronic pancreatitis. It can guide the clinical diagnosis and therapy. At present, the "tubed" secretin test as the standard reference method is hampered by lack of test standardization and is uncomfortable for the patient due to prolonged duodenal intubation. Indirect pancreatic function test is non-invasive, safe and cost-effective, but it is positive only in a serious shortage of pancreatic exocrine function. Recently, secretin enhanced magnetic resonance cholangiopancreatography (SMRCP) has gained increasing interest as a non-invasive imaging method enabling visualization and quantitative assessment of various aspects of pancreatic exocrine function.

### Research frontiers

The authors examined the published literatures on quantification of pancreatic exocrine function and there were no other related or similar studies in China.

### Innovations and breakthroughs

In this study, the authors chose 64 mm slice thickness and large region of interest to quantify pancreatic exocrine function of chronic pancreatitis. This way is non-invasive, safe and effective and above all, directly measure pancreatic fluid output.

### Applications

The results of the present study indicate that SMRCP has been a reliable non-invasive method for the diagnosis of pancreatic exocrine function, whereas it can displace the "tubed" secretin test and other indirect tests.

### Terminology

Quantification of secretin enhanced-MRCPQ was acquired as follows: The secretin dose 0.1 mL/kg was administered and the exact same sequence repeated at 1, 3, 5, 7, 9 and 11 min. All positions before and after injection remained unchanged.

### Peer review

Pancreatic exocrine function test plays an important role of in the diagnosis of chronic pancreatitis. It can guide the clinical diagnosis and therapy. Recent developments in SMRCP techniques have shown the feasibility of a quantitative assessment of the pancreatic exocrine function.

### Abstract

**AIM:** To compare the clinical factors and tumor characteristics that predict survival in colorectal cancer (CRC) patients with different ethnicities in Xin Jiang area.

**METHODS:** A total of 1421 histopathologically confirmed sporadic CRC patients who were either Han/Chinese or Uyghur were identified and enrolled from a database of both diagnoses and operative procedures from Xin Jiang Tumor Hospital, which is affiliated to Xin Jiang Medical University between 2000 and 2007. Patients with family histories of CRC, hereditary nonpolyposis CRC, familial adenomatous polyposis, inflammatory bowel disease, carcinoid, squamous carcinoma or melanoma were excluded. The two ethnic groups were compared with regard to clinical features, tumor characteristics, disease stage, overall survival rate, disease-free survival rate and cancer-specific survival rate. The factors predicting long-term survival were assessed *via*

both univariate and multivariate analysis.

**RESULTS:** Among the 1421 patients with CRC enrolled in this study, 1210 patients were Han/Chinese (mean age,  $62.3 \pm 4.5$  years; range, 19-92 years), while 211 patients were Uyghur (mean age,  $52.4 \pm 15.6$  years; range, 17-87 years). There were significant differences in proportions of gender, age, blood type, occupation and histopathological type between the Han/Chinese and Uyghur patients ( $P < 0.05$ ). The median overall, disease-free and cancer-specific survival time were 45, 62 and 65 mo for the Han/Chinese patients and 42, 49 and 61 mo for the Uyghur patients ( $P = 0.000$ ,  $P = 0.005$ ,  $P = 0.007$ ). The cumulative 5-year survival of the Uyghur patients was significantly worse than that of the Han patients ( $P = 0.000$ ). A multivariate analysis showed that age, ethnicity, histopathological type, differentiation, T (Infiltration depth), N (Lymph node metastasis), staging, postoperative metastasis and metastatic site ( $P < 0.05$ ) were found to be the prognostic factors.

**CONCLUSION:** The Uyghur CRC patients are associated with significantly younger age, more aggressive histopathologic characteristics and have significantly worse prognosis than the Han/Chinese patients.

© 2013 Baishideng Publishing Group Co., Limited. All rights reserved.

**Key words:** Colorectal cancer; Ethnicity; Clinicopathological factor; Survival

**Core tip:** Racial/ethnic differences in colorectal cancer (CRC) survival have been documented in the literatures. However, the reasons for these disparities are difficult to decipher. These disparities may be attributed to many factors, including differences in socioeconomic status, tumor biology, stage at diagnosis, treatment, post-treatment surveillance, physician characteristics and hospital factors. This is the first comparative study on the clinicopathological factors and survival of CRC

patients with different ethnicities in Xin Jiang. We found some marked differences and performed preliminary analysis for possible reasons.

Clinical features and prognosis in colorectal cancer patients with different ethnicities in Northwest China. *World J Gastroenterol* 2013; 19(41): 7183-7188 Available from: URL: <http://www.wjg-net.com/1007-9327/full/v19/i41/7183.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i41.7183>

## INTRODUCTION

The incidence and mortality rates of colorectal cancer (CRC) worldwide are continuously rising. There were approximately 1.2 million new cases and 630000 deaths world-wide in 2007, which is increased compared with that in 2000 (by 27% and 28%, separately). The average increases for these figures are 3.9% and 4.0% annually<sup>[1,2]</sup>. With the development of the economy and the improvement of living conditions and eating habits, the incidence of CRC in China has been increasing continuously and has become the second most common malignancy<sup>[3,4]</sup>. According to WHO reports, the death rate of CRC has increased by 70.7% in 2005 compared with that in 1991, annually increasing by 4.9%<sup>[5]</sup>.

Disproportionately high mortality rates are observed among African Americans for cancers of the lung, breast, prostate, colon and rectum, oral cavity and pharynx, cervix<sup>[6]</sup>, and esophagus<sup>[7]</sup>. In addition, the 5-year survival rates for African Americans are lower than those for whites for all of the major cancer sites. Similarly, mortality rates for cancers of the cervix, liver, and stomach are higher among Asians/Pacific Islanders and Native Americans than among non-Hispanic whites. Overall breast cancer mortality rates for Native Hawaiians are the highest of all racial/ethnic groups<sup>[8]</sup>. Colon cancer incidence and mortality vary markedly by race/ethnicity; specifically, African Americans have a higher incidence and mortality for colon cancer compared with other population groups<sup>[9]</sup>.

The Xinjiang Uyghur Autonomous Region is a part of the People's Republic of China located in the northwest of the country. This region is the home to a number of different ethnic groups, including Uyghur, Han/Chinese, Kazakh, Hui, Kyrgyz, and Mongols, accounting for the a majority of the population. The Uyghurs are a population with Eastern and Western Eurasian anthropometric and genetic traits and one of the many populations of Central Eurasia that can be considered to be genetically related to European and East Asian populations. Uyghur and Han/Chinese people are the two major ethnic groups in this area and have different origins, cultures, religions as well as living and eating habits. The purpose of this study was to determine whether racial disparities in clinicopathological features and survival exist among CRC patients in two ethnic groups in Xin Jiang.

## MATERIALS AND METHODS

The Xin Jiang Tumor hospital is a unique hospital capable of comprehensive treatment for cancers in Xin Jiang that serves the patients from all parts of the Xin jiang Uyghur Autonomous Region and functions as a primary cancer registration unit. Thus, data from this hospital possess relative representativeness and reliability. Between 2000 and 2007, there were 1759 newly diagnosed cases of histopathologically confirmed colorectal malignancies at Xin Jiang Tumor Hospital affiliated to Xin Jiang Medical University. A total of 1421 patients who were either Uyghur or Han/Chinese were identified and enrolled using a computer-generated search from a database with information on both diagnoses and operative procedures. Patients with family histories of CRC, hereditary non-polyposis CRC, familial adenomatous polyposis, inflammatory bowel disease, carcinoid, squamous carcinoma or melanoma were excluded. The clinicopathological characteristics included age, gender, ethnicity, occupation, blood type, onset tumor location, tumor size, histopathological types, gross type, pathological staging, recurrence, metastasis, metastatic site and so on were retrospectively analyzed. The right colon included the cecum, ascending colon, hepatic flexure, and transverse colon, while the left colon included the splenic flexure, descending colon, and sigmoid colon. A surgical metachronous tumor was considered the presence of another tumor found away from the primary tumor, when detected at least 6 mo after the primary operation. Resection was considered radical when there was macroscopic resection of all malignant tissue and no microscopic evidence of surgical margin spread. The tumor, node and metastasis (TNM) staging system<sup>[10]</sup> was used for tumor staging. Postoperatively, all patients were followed up at 3-mo intervals for the first year, 6-mo intervals from years 2 to 5, and annually thereafter. The end of follow-up was December 31, 2010. The two ethnic groups were compared in regard to clinical features, tumor characteristics, disease stage, overall survival rate, disease-free survival rate, and cancer-specific survival rate.

### Statistical analysis

Differences in the distribution of baseline characteristics between ethnic groups were assessed using Students T test or  $\chi^2$  or Fisher's exact tests. The overall survival was calculated as the time from diagnosis to death due to any cause. Colon cancer-specific survival was calculated as the time from diagnosis to death due to colon cancer. Disease-free survival was calculated as the time from surgical resection of the tumor to recurrence due to colon cancer. The cumulative survival rates were calculated using the Kaplan-Meier method and compared with the log rank test. The Cox technique was used for univariate and multivariate survival analyses. Significance was established at  $P < 0.05$ . Statistical calculations were performed using Stata Statistical Software, version 15 (SPSS, Inc., Chicago, IL).

## RESULTS

### Patients and clinical data

A total of 1421 patients with sporadic colorectal adeno-

carcinoma were enrolled, of which 1210 patients were Han/Chinese (mean age,  $62.3 \pm 4.5$  years; range, 19-92 years), while 211 patients were Uyghur (mean age,  $52.4 \pm 15.6$  years; range, 17-87 years, Table 1). There were more patients who were over 50 years of age in the Han/Chinese group (80.2% *vs* 56.3%,  $P = 0.000$ ) and more patients who were under 50 years of age in the Uyghur group (43.6% *vs* 26%,  $P = 0.000$ ). The proportion of male patients in the Han/Chinese group was higher than that of the Uyghur group ( $P < 0.05$ ). There were differences between occupational proportions in the two ethnic groups. Cadre (office workers) and physical workers were the most prevalent in the Han/Chinese group (70.1% *vs* 43.1%) and farmers and herders were more prevalent in the Uyghur group (42.7% *vs* 16.9%). There were more A blood type patients in the Han/Chinese group (31.2% *vs* 20.9%,  $P < 0.05$ ), while there were more B blood type patients in the Uyghur (38.4% *vs* 31.9%,  $P < 0.05$ ) group. Although there was no significant difference in tumor sites between the two ethnic groups, the most common sites for cancer occurrence were the sigmoid colon and the rectum in both groups (73.0% in the Han/Chinese group *vs* 79.1% in the Uyghur group,  $P = 0.196$ ). There was no statistically significant difference in treatment including surgery, post-operative chemotherapy or radiotherapy between the two ethnic groups ( $P > 0.05$ , Table 2).

### Tumor characteristics

The histopathologic differences between the two ethnic groups are summarized in Table 1. Compared with the Han/Chinese group, the Uyghur patients had a greater proportion of suffering from signet-ring cell type (6.6% *vs* 2.7%,  $P < 0.05$ ). A comparison of the Han/Chinese and Uyghur patients revealed that they exhibited almost the same incidence of any stage, presence of metastasis at the initial diagnosis and recurrence rate after resection ( $P > 0.05$ ). There were no significant differences in gross type, tumor size or carcinoembryonic antigen between the two groups, respectively.

### Recurrence and survival

The median follow-up in all patients was 42 mo (range, 7-122 mo; mean, 48.73 mo in the Han/Chinese group and 42.37 mo in the Uyghur group). A total of 175 patients (12.3%) were lost to follow-up; in total, 543 patients (44.9%) in the Han/Chinese group and 104 in the Uyghur group (49.3%) developed either local or distant recurrence ( $P = 0.235$ , Table 2). The Han/Chinese group had respective 1-year, 3-year, and 5-year overall survival rates of 87.2%, 46.8%, and 29.2%, whereas the respective rates were 80.4%, 42.9%, and 10.1% in the Uyghur group. There was significant difference in median survival time between the two groups ( $P = 0.000$ ). As shown in Figure 1, overall survival, disease-free survival and cancer-specific survival in the Uyghur group were significantly lower than the Han/Chinese group ( $P = 0.000$ ,  $P = 0.005$ ,  $P = 0.007$ , respectively). Using univariate Cox proportional-hazards regression analyses, the related factors of age, ethnicity, tumor site, histopathological type,

differentiation, tumor infiltration depth (T), numbers of lymph node metastasis (N), metastasis (M), TNM staging, postoperative metastasis and the metastatic site were found to be the prognostic factors ( $P < 0.05$ ); multivariate analysis showed that age, ethnicity, histopathological type, differentiation, T, N, TNM staging, postoperative metastasis and the metastatic site were the prognostic factors ( $P < 0.05$ , Table 3).

## DISCUSSION

Our results provide the first single center-based comparison of clinicopathological factors and hazard ratios regarding the survival of patients with CRC between the two ethnic groups in Xin Jiang. The ethnic distribution significantly differed in Xin Jiang; the majority of Uyghurs inhabited in the south of Xin Jiang and most of the Han/Chinese population resided in northern Xin Jiang. The economic development of southern and northern Xin Jiang is not consistent and thus is related to level of education. Northern Xin Jiang is undergoing more rapid economic and educational developments, while socioeconomic status and health care knowledge are higher than those in southern Xin Jiang. Additionally, the quality of health care services in northern Xin Jiang is superior to those in southern Xin Jiang. This circumstance may be able to explain the difference between occupational proportions in the two ethnic groups. Our study showed that the proportion of male patients in the Han/Chinese group was higher than that in the Uyghur group ( $P < 0.05$ ). In a study by Brenner *et al.*<sup>[11]</sup>, gender is also shown to be a contributing factor to the development of CRC in young individuals. The risk of CRC in male patients is higher at an earlier age than in women; accordingly, their recommendation is that the optimal age for initiating

**Figure 1** Kaplan-Meier estimates. A: Overall survival for different ethnic patients with colorectal cancer (CRC); B: Disease-free survival for different ethnic patients with CRC; C: Tumor-specific survival for different ethnic patients with CRC.

T: Tumor infiltration depth; N: Number of lymph node; M: Metastasis at diagnosis.

CRC screening in women is approximately 5 years older than that for men<sup>[10,11]</sup>. In terms of dietary habit, Uyghurs primarily consume meats (roasted, fried and boiled) and pastas every day, while Hans (Chinese) primarily consume rice and vegetables. The incidence of CRC is generally higher in populations with a high intake of meat and a low intake of staple plant foods<sup>[12]</sup>. A comprehensive review by the WCRF and the American Institute for Cancer Research concluded that “the evidence that red meat and processed meat are a cause of CRC is convincing”<sup>[13]</sup>. The disparities regarding age, blood type and histological features may also suggest some biological or genetic differences between the two ethnic groups, which is the area of study of our future investigations. Because of this prominent bias, it was particularly important to take regional, social and conventional gaps into consideration during the analysis.

Ethnic disparities have been demonstrated at each step of the cancer care continuum. Although these disparities are multifactorial in nature, they have a profound impact on cancer-related survival. Increased mortality among African American colon cancer patients has been attributed to decreased screening, more advanced stage at diagnosis, the disproportional receipt of standard surgical therapy and the unequal receipt of adjuvant therapy and postoperative surveillance<sup>[14,21]</sup>. Additionally, African American patients present at more advanced disease stages and are more likely to have an undetermined stage at presentation<sup>[22]</sup>. In contrast, East Asian American patients had significantly better 5-year overall and colon cancer-specific survival than non-Hispanic white, Hispanic white, and African American patients, which persisted when separately analyzed in patients with stage II and stage III diseases<sup>[23]</sup>. Several studies have suggested that there may be variations in CRC stage and survival between the Asian/Pacific Islander subgroups<sup>[24]</sup>.

In our study, the Uyghur patients had significantly worse prognosis than Han/Chinese patients given no significant differences in staging, recurrence or treatment. Numerous reports have suggested that socioeconomic status is a important factor in the poor prognosis of African American patients<sup>[25,26]</sup>. However, Wudel *et al.*<sup>[27]</sup> suggested that the marked reductions in survival of African

American patients did not appear to be related to variations in treatment but may have been due to biological factors or non-cancer-related health conditions. Uyghurs are more reluctant to screen with colonoscopy due to their traditional and religious beliefs and are more likely to live in a low-income community with limited access to gastroenterologists. Uyghurs also may have a lower incidence of insurance to cover a colonoscopy. In the present study, a poor prognosis in the Uyghur patients was consistently observed in overall survival, disease free survival and colon cancer-specific survival across nearly all stages. Therefore, it is likely that biological differences, socioeconomic status, disparities in health care service and ideology all contributed to the poor prognosis. A further epidemiological multicenter survey is needed to better quantify and determine whether dietary, regional, educational, socioeconomic status or genetic background could impact the incidence and mortality of CRC patients in these ethnic groups.

In a conclusion, Uyghur CRC patients are associated with a much younger age at disease onset, more aggressive histopathologic characteristics and a significantly worse prognosis than those in the Han/Chinese patients. Therefore, more attention should be paid to enhancing health care education and regular screening for the Uyghur population as well as promoting comprehensive treatment techniques in an effort to improve survival for both ethnic groups.

## COMMENTS

### Background

Cancer disparities between racial and ethnic groups are major public health concerns. It has been well established that the rates of cancer incidence and colorectal cancer (CRC)-related death are variable between patients from different racial and ethnic groups. Despite the great advances in medicine over recent decades, racial disparities in cancer-related mortality remain a challenging problem. The authors attempted to identify whether there are any differences that may contribute to survival between these ethnic groups.

### Research frontiers

The survival of patients with colon cancer reportedly differs according to race/ethnicity in the United States. Several studies have shown that African Americans are more likely to be diagnosed with advanced stage CRC and to have poorer survival rates after diagnosis compared with Caucasians. Several factors

including lack of health insurance, inability to access medical care, poverty, and low education level, are attributable to such findings. There has been no formal research thus far regarding the disparities between CRC patients with different ethnicities in the Xin Jiang area. This is the first report on clinicopathological factors and survival of CRC patients with differing ethnicity in Xin Jiang.

### Innovations and breakthroughs

This study has several strengths. First, the sample size was relatively large and the reliability and representativity of data were strong. Second, when the authors compared the survival rates of two different ethnic groups, the comparability between other confounding factors, such as staging, recurrence and treatment were guaranteed. Third, Uyghur CRC patients were found to be associated with significantly younger age, more aggressive histopathologic characteristics and significantly worse prognosis than Han/Chinese patients. These disparities may suggest that some biological or genetic differences exist between the two ethnic groups or that several factors, including a lack of health insurance, reluctance to access medical care, poverty, and low education level, in Uyghur patients contributed to such findings.

### Applications

This article demonstrated that there were disparities between the two ethnic groups in regard to clinicopathological factors and survival. The possible reasons for poor survival were preliminarily analyzed. These findings are valuable for CRC detection and prevention in the Xin Jiang region.

### Peer review

This is a retrospective study to assess clinical features and prognosis in CRC patients of different ethnicity in a medical center in Xinjiang province. The results provide valuable information for communities and public health programs.

### Abstract

**AIM:** To assess diagnostic accuracy of Ras association domain family 1A (RASSF1A) promoter methylation in body fluids (serum, plasma and whole blood) for hepatocellular carcinoma (HCC).

**METHODS:** Relative information about study characteristics and incidence of RASSF1A methylation was collected. Quality of all included studies was evaluated by Quality Assessment of Diagnostic Accuracy Studies-2. Sensitivity and specificity were pooled using a random-effect model, and a summary receiver operating characteristic curve was used to demonstrate the overall diagnostic performance. Positive likelihood ratio (PLR), negative likelihood ratio (NLR), and diagnostic odds ratio (DOR) with 95%CI were also calculated. Meta-regression was applied to analyze observed heterogeneity, and

Deeks' test was performed to detect publication bias.

**RESULTS:** After a systematic literature review, seven studies with a total of 302 cases of HCC and 250 cases of chronic liver diseases were included in the analysis. The pooled sensitivity and specificity were 0.70 (95%CI: 0.49-0.85) and 0.72 (95%CI: 0.54-0.85), respectively. The PLR was 2.51 (95%CI: 1.64-3.86), NLR was 0.41 (95%CI: 0.25-0.68), and DOR was 6.13 (95%CI: 3.17-11.84). The  $\chi^2$  values of sensitivity, specificity, PLR, NLR and DOR were 59.41 ( $P < 0.001$ ), 50.50 ( $P < 0.001$ ), 17.40 ( $P = 0.010$ ), 31.24 ( $P < 0.001$ ) and 80.51 ( $P < 0.001$ ), respectively. The area under the curve was 0.77 (95%CI: 0.73-0.81). Three factors were analyzed by univariate meta-regression and none was significant to interpret the observed heterogeneity ( $P > 0.05$ ). No significant publication bias was detected by Deeks' test ( $P = 0.346$ ).

**CONCLUSION:** We showed the potential diagnostic value of RASSF1A methylation in body fluids in HCC patients and it may improve diagnostic accuracy combined with the  $\alpha$ -fetoprotein test.

**Key words:** Methylation; Ras association domain family 1A; Hepatocellular carcinoma; Biomarker; Diagnostic sensitivity; Diagnostic specificity

**Core tip:** The published results on the diagnostic potential of Ras association domain family 1A (RASSF1A) promoter methylation for detection of hepatocellular carcinoma (HCC) are not consistent. We performed a comprehensive literature search to assess the diagnostic accuracy of RASSF1A promoter methylation. We rigorously selected patients with chronic liver diseases as controls to mimic clinical practice, and we only included studies that used body fluids as samples for detection

because such an approach is non-invasive and promising for clinical application. Our meta-analysis demonstrated good sensitivity and specificity of RASSF1A methylation and may complement the  $\alpha$ -fetoprotein test to improve HCC detection.

Association between Ras association domain family 1A promoter methylation and hepatocellular carcinoma: A meta-analysis. *World J Gastroenterol* 2013; 19(41): 7189-7196 Available from: URL: <http://www.wjg-net.com/1007-9327/full/v19/i41/7189.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i41.7189>

## INTRODUCTION

Hepatocellular carcinoma (HCC) is the sixth most prevalent cancer and the third most frequent cause of cancer-related death worldwide<sup>[1]</sup>. With a dramatic increase in incidence, HCC has become a major health challenge and has aroused growing concern. Due to the fact that most HCC patients at the advanced stage are prone to present a poor prognosis, early HCC detection is urgently needed. Currently, the serum  $\alpha$ -fetoprotein (AFP) test is widely used, however, with a relatively low sensitivity, the application is barely satisfactory and its function is limited<sup>[2]</sup>.

Recent studies have revealed that inactivation of multiple tumor suppressor genes underlain by hypermethylation of promoter CpG islands can be a critical event in hepatocarcinogenesis<sup>[3,4]</sup>. Thus, DNA methylation may provide an ideal route for screening because methylated DNA can be detected with a high sensitivity and specificity<sup>[5]</sup>. Furthermore, the circulating DNA in cell-free serum/plasma is becoming a new focus. Increasing studies have attempted to identify abnormal methylation pattern in cfDNA of patients with human cancers<sup>[6-10]</sup>. Several tumor-associated alterations including plasma/serum DNA methylation have been well demonstrated in liver cancer<sup>[11]</sup> and such cfDNA is thought to be derived from apoptosis and necrosis of cancer cells in tumor microenvironment<sup>[12]</sup>. Thus, approaches have been developed to analyze promoter methylation using DNA isolated from fluid samples, which makes it possible to perform noninvasively and allows patients to avoid physical discomfort and other complications.

Among the biomarkers studied previously, the Ras association domain family 1A (RASSF1A) gene has been extensively investigated. RASSF1A is located at 3p21.3 and is implicated in the Ras signaling pathway, which plays a pivotal role in cell cycle control, microtubule stabilization, cellular adhesion, cell motility, and apoptosis<sup>[13]</sup>. The tumor suppressor function of RASSF1A has been identified by both *in vivo* and *in vitro* observations in which re-expression of the gene in RASSF1A-negative cancer cells results in reduced colony formation in soft agar and reduced tumorigenicity in nude mice<sup>[14]</sup>. Loss of RASSF1A expression is one of the most common events in human cancer, with aberrant promoter methylation

reported in a variety of tumor types, including HCC<sup>[15]</sup>.

During the past decade, there have been an increasing number of investigations focusing on the diagnostic role of RASSF1A promoter methylation in HCC and many of them utilized body fluids as samples, which can be used for clinical application. Although the results of the studies are encouraging, there was some disagreement in relation to diagnostic accuracy. Therefore, we conducted a meta-analysis on the diagnostic sensitivity and specificity of RASSF1A methylation in body fluids for diagnosis of HCC. The results of this study indicate the potential diagnostic value of RASSF1A methylation and provide evidence for a reliable biomarker to discriminate HCC.

## MATERIALS AND METHODS

### Study selection

We performed a comprehensive literature search of articles through the following databases without date limitation: PubMed, Embase, Web of Science, and the Cochrane Library. The search terms used were: "hepatocellular carcinoma/ HCC/liver cancer", "Ras association domain family protein 1A/RASSF1A", "sensitivity", "specificity" and "diagnosis". The search was updated to May 24, 2013. The reference lists of the publications were also manually searched for additional related studies.

### Inclusion and exclusion criteria

We considered studies eligible for inclusion if they met the following criteria: (1) measurement of DNA methylation in one of the following samples: whole blood, plasma, serum, and buffy coat; (2) designed as a cohort study or a case-control study; (3) published in the English language; and (4) conducted in adults.

We excluded studies that tested RASSF1A methylation in liver tissues and cell lines. We also excluded studies in which body fluid samples were not collected before surgery or other treatment which may have reduced RASSF1A methylation dramatically. In clinical practice, patients who are recommended for advanced imaging examination (such as computed tomography and magnetic resonance imaging) and biopsies typically, have elevated AFP levels, aberrant ultrasonic images, and abnormal liver function or other related symptoms, and can differ from healthy controls<sup>[1]</sup>. Therefore, we rigorously classified the controls into two categories: (1) patients who had negative biopsies but suffered from chronic liver diseases such as liver cirrhosis, chronic hepatitis B, and chronic hepatitis C; and (2) healthy controls. In particular, we excluded healthy controls in order to diminish selection bias and avoid exaggerating diagnostic power. The selection process for studies included in this review is shown in Figure 1.

### Data extraction and quality assessment

For each study included, two reviewers (ZH Zhao and YC Fan) independently extracted the following information: authors' names, year of publication, sample type, detection technique, primer sequence, annealing tempera-

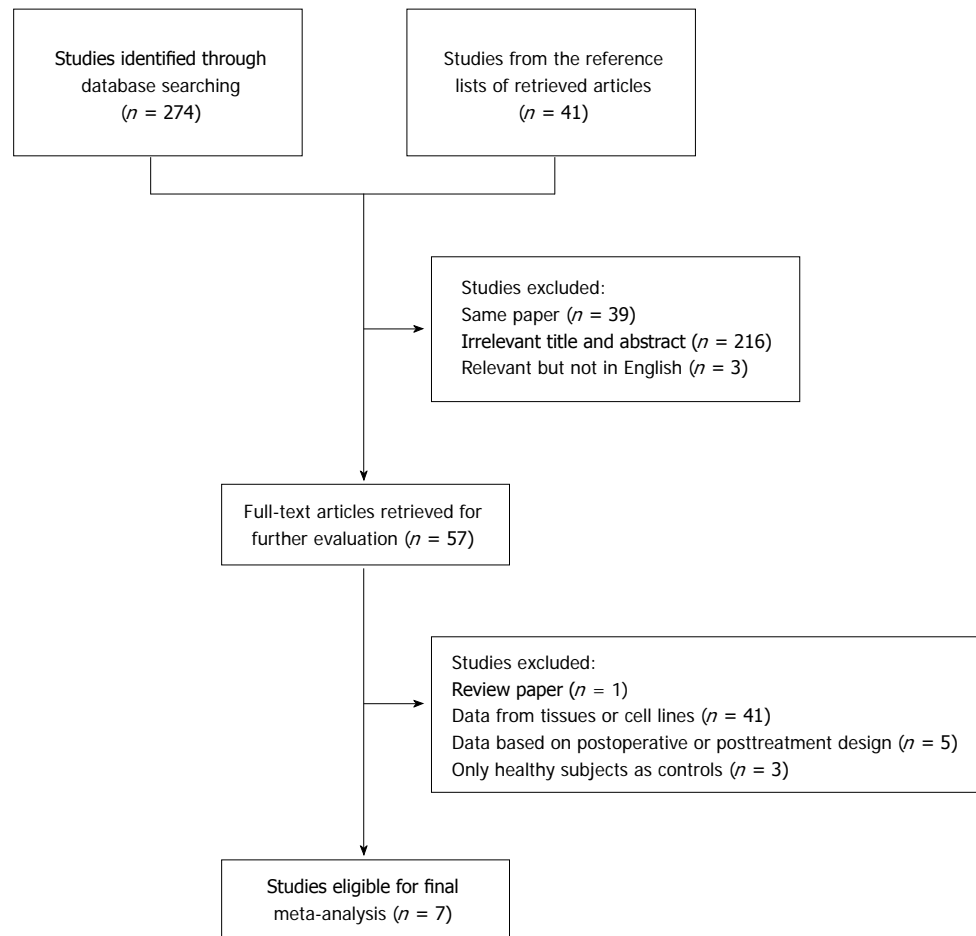

Figure 1 Flowchart of study selection.

ture, country, race, number of positive and negative results among cases and controls, and other characteristics of the study population. All disparities were resolved by discussion.

An updated quality evaluation tool Quality Assessment of Diagnostic Accuracy Studies-2 (QUADAS-2) guideline was consulted to assess the methodological quality of each study. The newly revised tool is reported to perform better because it offers additional and improved features, including distinguishing between bias and applicability, identifying four key domains supported by signaling questions to aid judgment on risk of bias, and rating risk of bias and concerns about applicability as “high” and “low”<sup>[16]</sup>. The results were presented in a recommended way.

### Statistical analysis

We referred to a standard procedure recommended for meta-analysis of diagnostic test accuracy (DTA) studies<sup>[17]</sup>. Before the statistical analysis was conducted, we gathered the number of cases and controls with RASSF1A methylation. The true-positive (TP) ones were indicated to have RASSF1A methylation within cases, and false-negative (FN) ones were without RASSF1A methylation. A similar

definition was given to FP and TN controls. The sensitivity, specificity, positive likelihood ratio (PLR), negative likelihood ratio (NLR), and diagnostic odds ratio (DOR) estimates with 95%CI from each study were analyzed using a random-effect model<sup>[17,18]</sup>. The pooled sensitivity and specificity were illustrated with a coupled forest plot. We also created a summary receiver operation characteristic (SROC) curve that displayed the results of individual studies in ROC space and reflected the discriminating ability<sup>[19]</sup>. The area under the curve (AUC) was calculated to present the general performance of the test and could be interpreted as the probability that the test would correctly rank a randomly chosen case/non-case pair with respect to their test values<sup>[20]</sup>. To assess the heterogeneity between studies, the  $\chi^2$ -based Cochrane  $Q$  test of heterogeneity was performed for each analysis. The  $I^2$  statistic, which measured the extent of inconsistency between studies, was also assessed. For detecting publication bias, Deeks’ test was conducted to examine funnel plot asymmetry, which was reported to be more appropriate for reviews of DTA studies<sup>[21]</sup>. The analysis was conducted using Stata version 12.0 (Stata Corporation, College Station, TX, United States). All  $P$  values were two-tailed and  $P < 0.05$  was considered significant.

## RESULTS

### Study characteristics

According to our search strategy and inclusion and exclusion criteria, seven studies with a total of 302 cases and 250 controls were included in the final meta-analysis (Table 1)<sup>[22-28]</sup>. The eligible studies were published between 2007 and 2012. Among the studies, two used sera, three used plasma, and two used whole blood as samples. Three methods were applied to detect the methylation status of RASSF1A promoter: four studies used methylation-specific polymerase chain reaction (MSP); one study used quantitative MSP (QMSP); and two used methylation-sensitive endonuclease-quantitative polymerase chain reaction (qPCR). The primer sequences used in the studies are summarized in Table 2.

### Quality assessment

Quality assessment results based on the updated QUADAS-2 are shown in Table 3. According to the guidelines, if the case-control design was not avoided, the risk of bias should be considered to be high in the patient selection domain. All seven studies included in our analysis were case-control studies and could have introduced selection bias. For other domains, the studies were basically satisfactory.

### Diagnostic accuracy analysis

The coupled forest plot of sensitivity and specificity for RASSF1A methylation assays in the diagnosis of HCC of the seven studies is shown in Figure 2. The sensitivity ranged from 0.27 to 0.94 (pooled: 0.70; 95%CI: 0.49-0.85) and the specificity ranged from 0.38 to 0.95 (pooled: 0.72; 95%CI: 0.54-0.85). The PLR was 2.51 (95%CI: 1.64-3.86), NLR was 0.41 (95%CI: 0.25-0.68), and DOR was 6.13 (95%CI: 3.17-11.84). The  $\chi^2$  values of sensitivity, specificity, PLR, NLR, and DOR were 59.41 ( $P < 0.001$ ), 50.50 ( $P < 0.001$ ), 17.40 ( $P = 0.010$ ), 31.24 ( $P < 0.001$ ), and 80.51 ( $P < 0.001$ ), respectively, which indicated significant heterogeneity between studies. The graph of the SROC curve is shown in Figure 3. We noted that the curve was positioned near the desirable upper left corner. The AUC was 0.77 (95%CI: 0.73-0.81), which represented a relatively high level of overall accuracy.

### Meta-regression and publication bias

Due to the heterogeneity observed in both analyses, we conducted meta-regression to search the sources<sup>[29]</sup>. The accuracy estimate we used was DOR, because it could demonstrate the diagnostic performance combining both sensitivity and specificity. The assay methods used to detect RASSF1A methylation could have affected the diagnostic accuracy directly for discriminating HCC.

**Table 3** Quality Assessment of Diagnostic Accuracy Studies-2 results of all included studies

Study	Risk of bias				Applicability concerns		
	Patient selection	Index test	Reference standard	Flow and timing	Patient selection	Index test	Reference standard
Chan <i>et al</i> <sup>[22]</sup>	↑	?	↓	↓	↓	?	↓
Chang <i>et al</i> <sup>[23]</sup>	↑	?	↓	↓	↓	?	↓
Maurizio <i>et al</i> <sup>[24]</sup>	↑	?	↓	?	↓	?	↓
Mohamed <i>et al</i> <sup>[25]</sup>	↑	↓	↓	↓	↓	↓	↓
Azab <i>et al</i> <sup>[26]</sup>	↑	↓	↓	↓	↓	↓	↓

**Table 4** Meta-regression results of meta-analysis

Sources	Coefficient (95%CI)	SE	T	P value	$\tau^2$	$I^2$ Res (%)	Adjusted $R^2$ (%)
Method	1.09 (-0.55-2.73)	0.64	1.71	0.148	0.24	37.16	50.47
Race	0.83 (-1.00-2.66)	0.71	1.17	0.294	0.36	46.68	26.54
Sample	0.88 (-1.09-2.85)	0.77	1.87	0.301	0.36	45.96	26.46

**Figure 2** Coupled forest plot showing the sensitivity and specificity of Ras association domain family 1A methylation in diagnosis of hepatocellular carcinoma. Forest plots document estimates of sensitivity and specificity for each study together with 95%CI. The point estimates of sensitivity and specificity from each study are shown as solid squares.

Also, race and sample type may have had an influence to a varying degree. Therefore, we considered the three factors above as covariates and performed univariate meta-regression analysis. However, none of the factors was statistically significant ( $P > 0.05$ , Table 4).

Publication bias was evaluated using Deeks' test (Figure 4). We found no significant publication bias among the studies that detected RASSF1A methylation in body fluids from patients with HCC ( $P = 0.346$ ).

## DISCUSSION

Although there have been many studies about sensitivity and specificity of RASSF1A promoter methylation

in diagnosis of HCC, to the best of our knowledge, no meta-analysis has been reported. For the traditional serum marker AFP, the specificity varied, but the sensitivity was generally low. A large multi-center survey including 1158 patients with HCC reported that the sensitivity for the most used cutoff value (20 ng/mL) was only 0.54<sup>[2]</sup>. Another recent study showed that the sensitivity and specificity of the AFP test was 0.42 and 0.95 when the cutoff value was 20 ng/mL<sup>[30]</sup>. In comparison, our analysis showed a relatively high sensitivity (0.70) of RASSF1A promoter methylation, which, if combined, may complement the AFP test and reduce FNs by performing detection of RASSF1A methylation status and the AFP test simultaneously. Positive results for either of

**Figure 3 Summary receiver operation characteristic curve for Ras association domain family 1A methylation assays.** Hollow numbered circles represent included studies. Summary receiver operation characteristic (SROC) curve summarizes the overall diagnostic accuracy.

the two tests demonstrate a high likelihood of HCC and patients should be recommended for advanced imaging or percutaneous liver biopsies. Nevertheless, more evidence on the correlation between RASSF1A methylation and AFP level should be collected. In our analysis, we observed FPs in some of included studies. *RASSF1A* gene promoter methylation might occur in controls including chronic liver disease and/or in preneoplastic (cirrhotic) liver to hepatocellular nodules to HCC<sup>[25]</sup>.

The *RASSF1A* gene has been long noted and intensively studied for its role in tumor suppression, and aberrant methylation in the promoter region is suspected as the main mechanism of downregulation and silencing that is widely observed in human malignancies<sup>[15]</sup>. However, in this meta-analysis, we aimed to verify the feasibility of body fluid RASSF1A methylation in identifying HCC from high risk population rather than healthy population. So we selected patients with chronic liver diseases which were in high risk of developing HCC as controls. Under this condition, HCC was of greater possibility than other types of cancer. Thus, methylation of RASSF1A is relatively specific to HCC and the detection was still meaningful in distinguishing HCC from benign liver diseases. The potential clinical use of RASSF1A methylation as a biomarker for HCC diagnosis has not been fully exploited, and studies measuring RASSF1A methylation in body fluids are rare. Nevertheless, the non-invasive test possesses considerable advantages. It avoids the risk of complications and sampling error caused by imaging or percutaneous liver biopsies and is more acceptable to patients<sup>[31]</sup>. Although tumor-specific cfDNA is thought to be mainly derive from apoptosis and necrosis of cancer

**Figure 4 Assessment of the potential publication bias in Ras association domain family 1A methylation detection.** We found no significant publication bias ( $P > 0.05$ ). Each spot represents one study and the regression line is shown.

cells in tumor microenvironment, discordance between frequencies of alterations found in DNA extracted from tumor tissue and cfDNA do exist<sup>[12]</sup>. Zhang *et al.*<sup>[32]</sup> showed that the frequency of RASSF1A methylation in 48 HCC tissues was 100%, which was greatly higher than our results.

Moreover, rapidly developed technologies for DNA methylation detection make it easier, faster and cheaper to measure RASSF1A methylation accurately<sup>[5,33-35]</sup>. The technologies applicable to the analysis of the small amounts of DNA present in the body fluids are mainly real-time PCR-based approaches such as MethyLight, HeavyMethyl, methylation-sensitive high-resolution melting analysis, and methylation-sensitive melting analysis after real-time methylation specific PCR<sup>[36]</sup>. However, some methodological issues should be resolved. The primer sequences and PCR procedures are varied in studies applying qualitative MSP. Also, MSP may have difficulties in distinguishing TP from FP due to the methodological limitations. Besides, the different cut-off values chosen could affect judgment of positive or negative results in detection using QMSP. We summarized the primer sequences for RASSF1A methylation detection in all the included studies to facilitate further confirmation. Before the assay can be put into clinical practice, more evidence based on methodological investigations should be collected and a standard protocol developed.

Exploring the sources of heterogeneity is one major purpose of meta-analysis<sup>[37]</sup>. Due to the significant heterogeneity observed in our analysis, we performed meta-regression. However, we failed to figure out the sources as all the covariates we took into consideration could not significantly interpret the heterogeneity. We surmise that the limited number of included studies was the main factor that hampered the analysis of heterogeneity, which also made subgroup analysis not possible.

In addition to the small number of studies, there were

some other limitations. First, the case-control design used in all our included studies was likely to have introduced bias in patient selection<sup>[16]</sup> and more prospective studies are needed. Second, although we classified the controls and excluded healthy controls, the remaining patients still presented a spectrum of diseases. Due to the insufficient detailed information provided by the publications, we failed to subdivide the chronic liver diseases and specific stages of one single disease, which may have introduced considerable heterogeneity. Third, it has been reported that time of sampling influences the level of methylation dramatically<sup>[38,39]</sup>. The studies included in our analysis varied greatly in time of sampling, which may have caused heterogeneity.

In conclusion, RASSF1A promoter methylation is a valuable diagnostic biomarker with a qualified sensitivity, which may complement the AFP test in screening for HCC. More prospective diagnostic trials with strictly defined controls are needed to elucidate further the accuracy of RASSF1A methylation for diagnosis of HCC.

## COMMENTS

### Background

Hepatocellular carcinoma (HCC) is one of the most prevalent human malignancies. HCC patients are prone to present a poor prognosis due to failure of early detection. The currently used serum  $\alpha$ -fetoprotein (AFP) test has a relatively low sensitivity, which limits its application. Ras association domain family 1A (RASSF1A) methylation has been shown to be a diagnostic marker for HCC.

### Research frontiers

Recently, there has been an increasing number of investigations focusing on the diagnostic role of RASSF1A promoter methylation in HCC. However, there is disagreement about the actual diagnostic accuracy. This study was conducted to assess pooled estimates of the diagnostic accuracy of RASSF1A methylation in HCC.

### Innovations and breakthroughs

The authors assessed RASSF1A methylation for HCC diagnosis by meta-analysis. The controls were rigorously defined as patients with chronic liver diseases to mimic clinical practice and only studies that used body fluids as samples for detection were included because they were non-invasive. The results showed a better sensitivity compared to the AFP test. The findings may improve HCC diagnostic accuracy.

### Applications

RASSF1A methylation may have diagnostic potential for HCC and could be a new candidate marker. Furthermore, detection in body fluids makes it possible to be non-invasive and more acceptable to patients.

### Terminology

DNA methylation is a conversion of the cytosine to 5-methylcytosine which typically occurs at CpG islands in the promoter region with the help of DNA methyltransferases. This process may result in gene silencing without changing its coding sequence.

### Peer review

The authors showed that RASSF1A methylation in body fluids in HCC patients can improve HCC diagnostic accuracy using meta-analysis. The idea of this study is novel and important as they continue to evaluate novel potential biomarkers for the early diagnosis of HCC.

### Abstract

**AIM:** To assess the theoretical advantages of magnetic endoscope imaging (MEI) over standard colonoscopies (SCs) and to compare their efficacies.

**METHODS:** Electronic databases, including PubMed, EMBASE, the Cochrane library and the Science Citation Index, were searched to retrieve relevant trials. In addition, abstracts from papers presented at professional meetings and the reference lists of retrieved articles were reviewed to identify additional studies. The meta-analyses were performed using RevMan 5.1. A random effect model with the Mantel-Haenszel method was used for pooling dichotomous and continuous data. A sensitivity analysis was performed by excluding the trials with a small number of patients and by excluding the trials performed by inexperienced providers.

**RESULTS:** Eight randomized controlled trials (RCTs), including 2967 patients, were included in the meta-analysis to compare cecal intubation rates and times, sedation dose, abdominal pain scores and the use of ancillary maneuvers between MEI and SC. The overall OR was 1.92 (95%CI: 1.13-3.27, eight RCTs), as indicated by the cecal intubation rate of MEI compared with SC, but MEI did not have any distinct advantage over SC for cecal intubation time (MD = -0.07, 95%CI: -0.16-0.02; three RCTs). MEI did not generally result in lower pain scores. Outcomes were also analyzed for the two subgroups based on the endoscopists' experience level to evaluate cecal intubation rates. MEI presented better outcomes for non-experienced colonoscopists than experienced colonoscopists.

**CONCLUSION:** The real-time magnetic imaging system is of benefit in training and educating inexperienced endoscopists and improves the cecal intubation rate for experienced and inexperienced endoscopists.

**Key words:** Colonoscope; Magnetic endoscope imaging; Magnetic; Standard colonoscope; Meta-analysis

**Core tip:** This study aimed to assess the theoretical advantages of magnetic endoscopic imaging (MEI) over standard colonoscopy (SC) and to compare the efficacies of MEI and SC. The meta-analyses compared the cecal intubation rate and time, sedation dose used, abdominal pain scores and the use of ancillary maneuvers between MEI and SC. The real-time magnetic imaging system is of benefit in training and educating inexperienced endoscopists, and it improved the cecal intubation rate for both experienced and inexperienced endoscopists.

## INTRODUCTION

Colonoscopy is the gold standard and the most common and accurate tool for detecting important structural lesions of the lower gastrointestinal tract and for diagnosing colonic diseases, such as polyps, colorectal cancer and inflammatory bowel disease<sup>[1-3]</sup>. However, the existence of sharp angulation or looping of the colon increases the difficulty of the procedure and causes distinct discomfort for patients. The failure rate of initially reaching the cecum remains significant at 2%-10%<sup>[4-6]</sup>. In addition, there is still a small but definite risk of procedure-related complications, notably bleeding and perforation<sup>[7,8]</sup>. Thus, technological advances in colonoscopy have continued over the last decade<sup>[9,10]</sup>.

Magnetic endoscopic imaging (MEI) is a non-radiographic imaging technique that has been developed in recent years that is capable of displaying real-time three-dimensional images of the colonoscope shaft within the abdominal cavity<sup>[11-12]</sup>. The MEI system has previously been described in detail<sup>[13]</sup>. A pulsed low-magnetic field is sequentially produced by a series of electromagnetic generator coils spaced 10 cm apart along a catheter inserted through the accessory channel of the endoscope. The imager view is updated every 0.2 s to make the system essentially real time, and the images are subsequently recorded on a computer disk for subsequent replay or analysis<sup>[14]</sup>. The MEI system has been shown to be beneficial in increasing the cecal intubation rate<sup>[15,16]</sup>, reducing the number of attempts to straighten loops<sup>[16,17]</sup>, and in reducing the duration of looping, especially with trainees, when compared with no visualization. To date, a few studies have compared MEI with standard colonoscopy (SC); however, the results have not been uniform.

The aim of the present meta-analysis was to evaluate the effect of the two different methods.

## MATERIALS AND METHODS

### Data sources

First, electronic databases, including PubMed (1966 to June 2012), EMBASE (1980 to June 2012), the Cochrane Central Register of Controlled Trials (CENTRAL, The Cochrane Library, Issue 6 of 12, June 2012), and the Science Citation Index, were searched. The search was performed with the following search terms as free-text terms as well as MeSH terms: colonoscope, colonoscopy, magnetic and magnetic endoscopic imaging. Second, meeting abstracts and the reference lists of the retrieved articles were reviewed for additional relevant studies. No language restrictions were imposed.

### Equipment type

The instruments used in the trials included the Olym-

pus CF-1T200L scope (160 cm)<sup>[16,17]</sup>, the ScopeGuide endoscope insertion tube system<sup>[18-20]</sup>, the Olympus CF-Q160DI with the Olympus ScopeGuide system<sup>[15,21]</sup>, the Olympus CF-Q180AL, the Olympus CF-Q160AL and the CF-Q140DL/I with the Olympus ScopeGuide system.

### Study selection

Randomized controlled trials (RCTs) comparing MEI with SC were included in this analysis. Only the most recent study was included if more than one study was published using the same study population. Thirty-five papers were uncontrolled, observational studies and case reports and were thus excluded from the meta-analysis.

### Data extraction

All the data were tabulated with standard data abstractions sheets. For each study and each type of intervention, the following characteristics were extracted: study design and conduct, numbers of patients, endoscopist characteristics, instrument features and study outcomes. The study outcomes included the cecal intubation rate, cecal intubation time, sedation dose used, abdominal pain score, and ancillary maneuvers during the procedure (manual pressure used and position changes made).

Two investigators (Chen Y and Xie Q) independently extracted details of the study population, interventions and outcomes. A paper was reviewed if either of the two investigators thought its abstract was relevant. If there were any discrepancies in the information provided in a title and the corresponding abstract, the full article was reviewed for clarification. Differences in opinion were resolved by discussion with the third author of this paper (Chen B).

### Assessment of risk of bias in included studies

To avoid the risk of bias in the assessment, two investigators independently used an assessment form recommended by the Cochrane Handbook. Any disagreements were resolved by discussion with a third author until consensus was obtained. We considered the following criteria: (1) Sequence generation: was the allocation sequence adequately generated? (2) Allocation concealment: was the allocation adequately concealed? (3) Blinding: was knowledge of the allocated intervention adequately prevented during the study? (4) Incomplete outcome data: were incomplete outcome data adequately addressed? (5) Selective outcome reporting: were reports of the study free of the suggestion of selective outcome reporting? and (6) Other sources of bias: was the study apparently free of other problems that could place it at a high risk of bias?

Each domain was graded as yes (low risk of bias), no (high risk of bias), or unclear (uncertain risk of bias) according to the criteria.

For rating the strength and quality of the evidence for a given comparison, the Working Group grades of evidence and Summary of Findings tables recommended by the Cochrane Collaboration were used.

### Assessment of reporting biases

For the assessment of publication bias, a funnel plot was

constructed if sufficient data were available.

### Statistical analysis

Meta-analyses were conducted for trials comparing MEI with SC using the statistical tool Revman 5.1. Dichotomous data were expressed as an OR, and continuous outcomes were expressed as the mean difference (MD) with a 95%CI. A random effects model was used for the pooling of data.

We used a random effect model with the Mantel-Haenszel method for pooling dichotomous and continuous data. We assessed the heterogeneity of the trial results by calculating the  $I^2$  measure of inconsistency with a cutoff point of  $I^2 = 50\%$ .

A sensitivity analysis was performed by excluding the trials with small numbers of patients and by excluding the trials performed by inexperienced providers.

## RESULTS

### Search results

Overall, our searches identified 43 articles that compared MEI with SC. After reading the abstracts and full-texts, we excluded 35 of these articles because they were reviews or were not RCTs or case reports. Finally, eight studies met the criteria for inclusion in the review<sup>[9-15,22]</sup>.

### Trial characteristics

The characteristics of these studies are summarized in Table 1. All of these studies were RCTs, containing a total of 2967 participants (1566 male, 1401 female) of 7 to 90 years of age.

The instruments used in the trials included the Olympus CF-1T200L scope (160 cm)<sup>[16,17]</sup>, the ScopeGuide endoscope insertion tube system<sup>[18-20]</sup>, the Olympus CF-Q160DI with the Olympus ScopeGuide system<sup>[15,21]</sup>, the Olympus CF-Q180AL, the Olympus CF-Q160AL and the CF-Q140DL/I with the Olympus ScopeGuide system.

The experience levels of the endoscopists were evaluated either by years of experience (more than six years) or by the number of procedures performed (more than 200 procedures). In the retrieved articles, eight trials evaluated MEI procedures performed by experienced colonoscopists; while four studies evaluated MEI procedures performed by less experienced colonoscopists (four studies included both experienced and less experienced colonoscopists).

### Risk of bias in included studies

Among the eight RCTs that were included in this meta-analysis, an allocation sequence was generated using a computer-generated random number table<sup>[15-17,20,23]</sup>. Four of the eight trials reported adequate allocation concealment<sup>[15,20,21,23]</sup>, while in another four trials, the allocation concealment was unclear. In all eight trials, all patients were blinded, but the endoscopists were not blinded in any of these trials because of the nature of the interventions.

The quality of the evidence for the outcomes in the included studies is shown in the Summary of Findings

tables (Table 2).

### Outcomes

**Cecal intubation rate:** There were eight research papers that reported on this topic. MEI with a colonoscope showed a higher cecal intubation rate compared with SC (OR = 1.92, 95%CI: 1.13-3.27, Figure 1A).

**Cecal intubation time:** Only three studies included the cecal intubation time, and all of these studies were included in the analysis. The meta-analysis of these three trials showed no significant difference in the cecal intubation time between MEI and SC (MD = -0.07, 95%CI: -0.16-0.02; Figure 1B). There was no heterogeneity among these three studies ( $I^2 = 2\%$ ,  $P = 0.36$ ).

**Sedation dosage:** Five studies reported the sedation dose used during the colonoscopic procedure. One trial used a patient-controlled analgesia (PCA) pump consisting of a mixture of midazolam and meperidine<sup>[17]</sup>; another one employed a combination of midazolam and pethidine<sup>[16]</sup>. Franciosi JP *et al*<sup>[19]</sup> reported the use of a mixture of midazolam and fentanyl<sup>[19]</sup>, and Dechène A *et al*<sup>[20]</sup> used midazolam, pethidine and propofol together. The other studies used midazolam, pethidine and diazepam<sup>[21]</sup>.

**Abdominal pain:** Eight studies presented pain scores as the mean and standard deviation or median. However, the scales used for scoring pain were different. In two studies<sup>[18,19]</sup>, a 0 to 10 score scale was used, and the other six studies used a 0 to 100 score scale, a 1 to 7 visual analogue scale, a validated questionnaire or abdominal compression<sup>[15-17,20,23]</sup>. Due to the differences in the scales, we did not pool the data for these studies.

**Ancillary maneuvers:** Four trials reported ancillary maneuvers during colonoscopy. Only two trials listed the amount of abdominal pressure applied, and only two trials reported the position changes made during colonoscopy; therefore, these data were not pooled for analysis.

### Subgroup and sensitivity analysis

A subgroup analysis was performed to evaluate the cecal intubation rate during colonoscopy according to the experience level of the endoscopists. The cecal intubation rate of MEI with experienced endoscopists was similar to that of SC (OR = 1.84, 95%CI: 0.97-3.48, seven trials, Figure 1C), while the chance of achieving cecal intubation was clearly higher with MEI than SC for inexperienced endoscopists (RR = 3.63, 95%CI: 1.96-6.74, three trials, Figure 1D).

The sensitivity analysis that excluded the studies with a small number of patients (less than 100) resulted in insignificant changes to the ORs and Weighted Mean Difference (WMDs). Additionally, we used the fixed-effect model to reanalyze all the data previously analyzed using the random-effect model. There were no significant changes to the ORs or RRs and WMDs when the fixed-effect model was used.

**Table 1** Characteristics of the included studies comparing use of the magnetic endoscopic imaging colonoscope and standard colonoscope

MEI: Magnetic endoscopic imaging; SC: Standard colonoscopy VAS: Visual Analogue Scale.

**Table 2 Summary of findings for the main comparison of magnetic endoscopic imaging colonoscopy and standard colonoscopy**

Outcomes	Illustrative comparative risks <sup>1</sup> (95%CI)		Relative effect (95%CI)	No of Participants (studies)	Quality of the evidence (GRADE)	Comments
	Assumed risk Standard colonoscopy	Corresponding risk Magnetic endoscope imaging colonoscopy				
Cecal intubation rate	Study population 912 per 1000	952 per 1000 (921 to 971)	OR = 1.92 (1.13-3.27)	2945 (8 studies)	+ + + - Moderate <sup>1</sup>	
	Moderate 939 per 1000	967 per 1000 (946 to 981)				
Cecal intubation time		The mean cecal intubation time in the intervention groups was 0.43 lower (0.13 lower to 0.28 higher)		1934 (3 studies)	+ + + + High <sup>1</sup>	

<sup>1</sup>The basis for the assumed risk (e.g., the median control group risk across studies) is provided in the footnotes. The corresponding risk (and its 95%CI) is based on the assumed risk in the comparison group and the relative effect of the intervention (and its 95%CI). GRADE: Working Group grades of evidence. High quality: Further research is very unlikely to change our confidence in the estimate of the effect; Moderate quality: Further research is likely to have an important impact on our confidence in the estimate of the effect and may change the estimate; Low quality: Further research is very likely to have an important impact on our confidence in the estimate of the effect and is likely to change the estimate; Very low quality: We are very uncertain about the estimate.

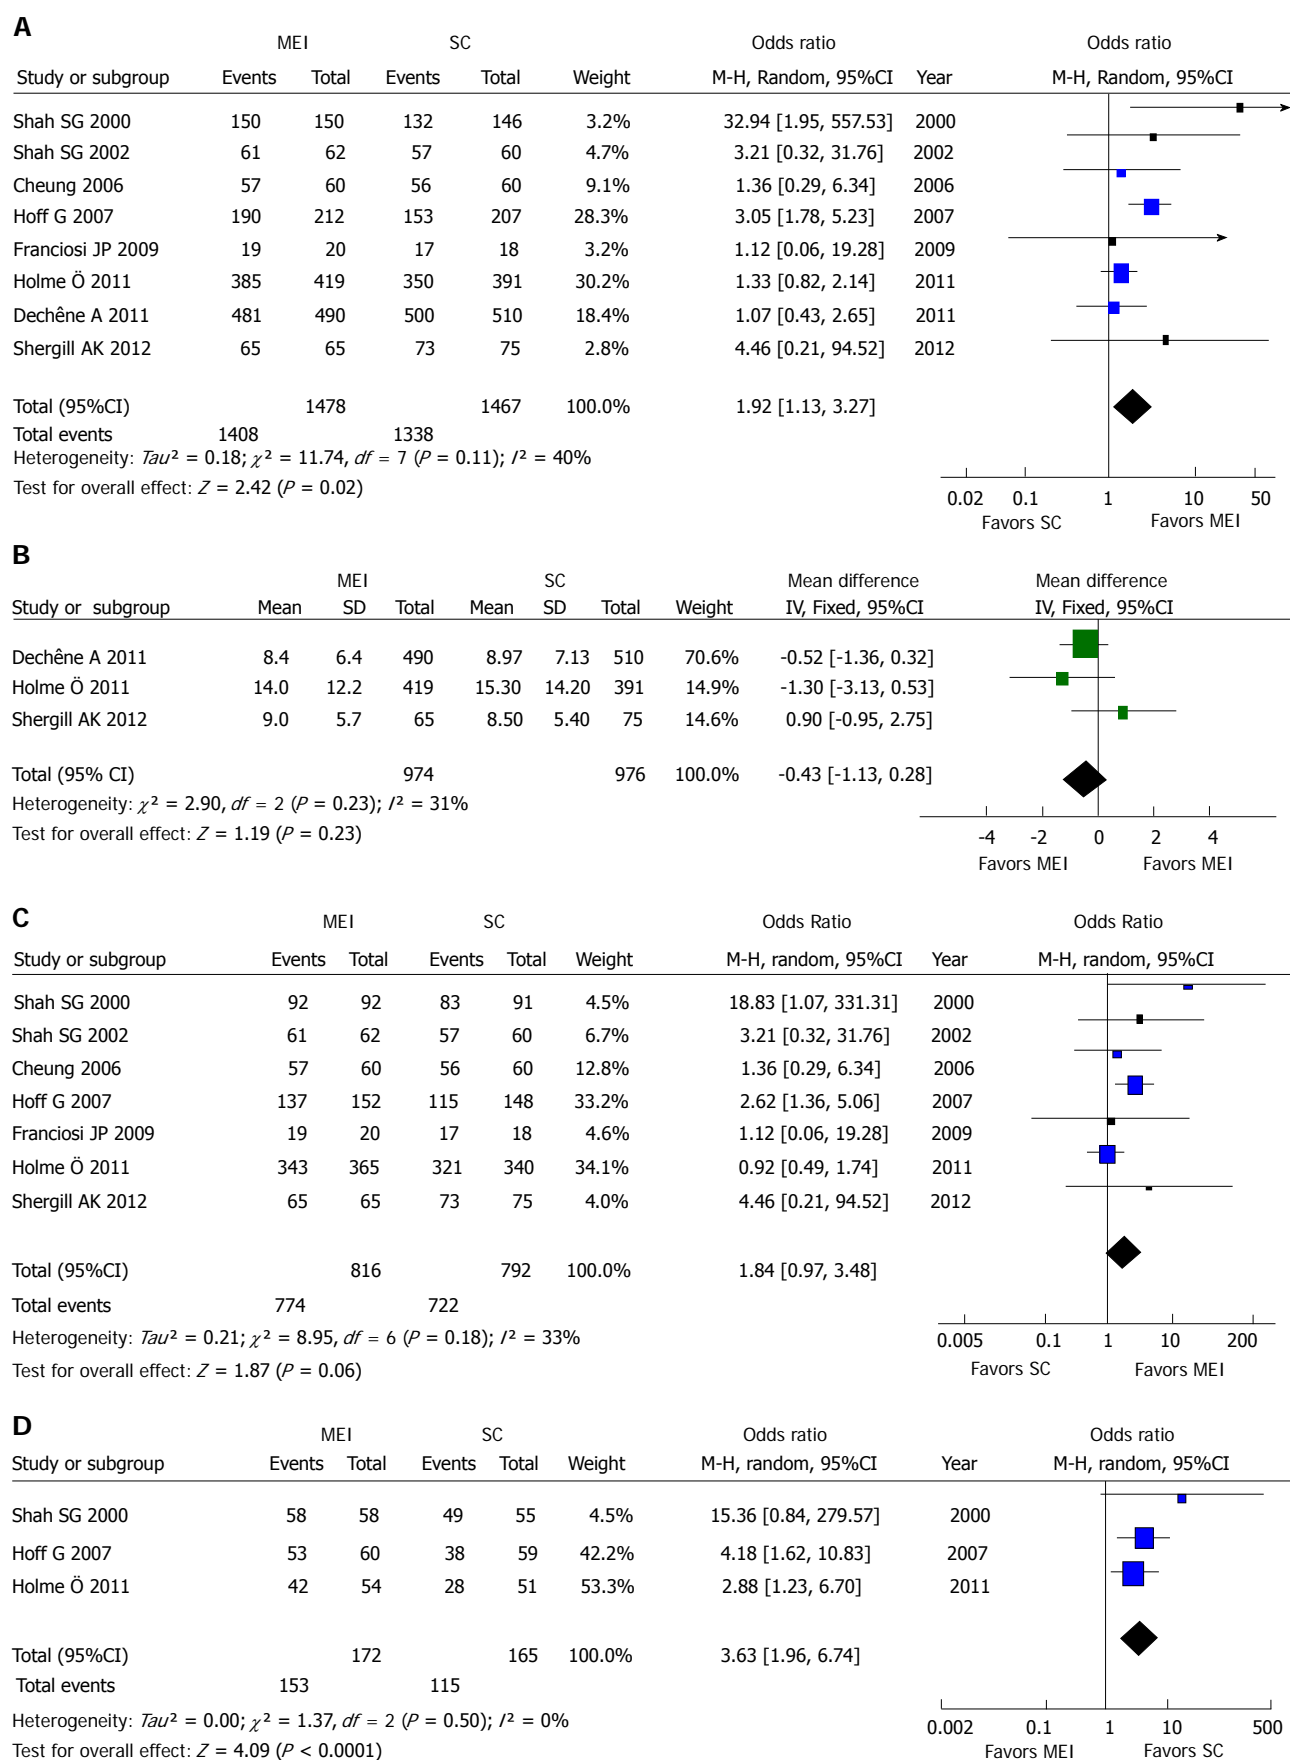

To detect publication bias, asymmetry was explored using a funnel plot. The distribution of the results of each study in the funnel plot excluded any potential publication bias.

## DISCUSSION

The meta-analysis included eight RCTs published up to June 2012, including a total of 2967 participants who received MEI or SC. MEI has replaced X-ray imaging during colonoscopic procedures in many situations and therefore has a proven benefit for patients and staff<sup>[24-26]</sup>. MEI exhibited higher cecal intubation rates compared with standard colonoscopy but did not have any distinct advantage over standard colonoscopy in terms of cecal intubation time. Considering the potential advantage of real-time imaging, we were surprised to find that most of the individual studies showed no difference between the MEI and standard groups in the time required to reach the cecum but that the pooled data favored MEI. The in-

creased sample size is the most likely explanation for the difference in the cecal intubation rate. A larger number of participants reduced the sampling error and directly affected the cecal intubation rate between MEI and SC. These results are meaningful in clinical practice. As is known, the failure rate of cecal intubation remains high in day-to-day SC. This means that part of the colon of some patients is not clearly visualized, which can prevent the early diagnosis and treatment of colonic diseases. MEI has increased the intubation rate and has made the early and accurate diagnosis of colonic issues, such as colorectal cancers, polyps and inflammatory bowel disease, possible.

The cecal intubation rate was also analyzed in two subgroups based on the experience level of the endoscopists (experienced and inexperienced). For inexperienced endoscopists, the MEI system appears to be advantageous. The cecal intubation rate for inexperienced endoscopists was higher in patients randomized to MEI than in the standard group. It is possible that inexperienced

**Figure 1 Meta-analysis.** A: Cecal intubation rate comparison for the magnetic endoscopic imaging (MEI) colonoscopy and standard colonoscopy (SC); OR with 95%CI; B: Cecal intubation time comparison for the MEI colonoscopy and SC; MDs with 95%CI; C: Cecal intubation rate: subgroup analysis of trials comparing the MEI colonoscopy and SC with experienced endoscopists; OR with 95%CI; D: Cecal intubation rate: subgroup analysis of trials comparing the MEI colonoscopy and SC with inexperienced endoscopists; OR with 95%CI.

endoscopists are capable of identifying and minimizing loops with the continuous real-time imaging system. However, experienced endoscopists are likely able to recognize and resolve loops quickly without the need for MEI visualization. Therefore, whether MEI actually makes both inexperienced and experienced physicians better endoscopists remains to be determined.

The individual studies included in this meta-analysis showed concordance in the cecal intubation times between the two groups, and the pooled results for all trials also showed no significance.

There were four complications reported in two studies included in this meta-analysis<sup>[15,21]</sup>, and they all occurred in the standard group. Three patients had a vasovagal reaction with rapid spontaneous recovery, and there was one case of bleeding following a polypectomy. To this point, no safety concerns have been raised with the use of MEI. During the procedure, precise judgment and caution are necessary, especially when advancing through a narrowed colon or pushing through loops.

A potential limitation of the meta-analysis is that these studies could not be performed in a way that would 'blind' the endoscopists to the scope used because of the nature of the interventions. Additionally, different models and manufacturers of MEI equipment were used in the studies included in the analysis. Finally, in several studies, specific patient subsets, such as colonic cancer patients and patients who had undergone prior colonic surgery, were excluded.

In conclusion, the present results indicated that the real-time magnetic imaging system is safe and beneficial in training and educating inexperienced endoscopists, as well as improving the cecal intubation rate for both experienced and inexperienced endoscopists. However, only a few studies have reported the advantages of MEI because it is a new technique, and further studies should be performed to confirm the role of the MEI colonoscope.

## COMMENTS

### Background

Colonoscopy is the gold standard and the most common and accurate tool for detecting important structural lesions of the lower gastrointestinal tract and diagnosing colonic diseases, such as polyps, colorectal cancer and inflammatory bowel disease. Magnetic endoscopic imaging (MEI) is a non-radiographic imaging technique that has been developed in recent years that is capable of displaying real-time three-dimensional images of the colonoscope shaft within the abdominal cavity. A pulsed low-magnetic field is sequentially produced by a series of electromagnetic generator coils spaced 10 cm apart along a catheter inserted through the accessory channel of the endoscope. The imager view is updated every 0.2 s to make the system essentially real-time, and the images are then recorded on a computer disk for subsequent replay or analysis.

### Research frontiers

The MEI system, when compared to standard colonoscopy (SC) with no visualization, has been shown to be beneficial in increasing the cecal intubation rate, reducing the number of attempts to straighten loops, and in reducing the duration of looping, especially with trainees. A few studies have compared MEI with SC; however, the results of these studies have not been uniform.

### Innovations and breakthroughs

A few studies have compared MEI with SC; however, the results of these studies have not been uniform. Thus, this was the first meta-analysis to assess

the theoretical advantages of MEI over SC and to compare the efficacies of MEI and SC. Through this study, we found that the real-time magnetic imaging system is of benefit in training and educating inexperienced endoscopists and improves the cecal intubation rate for experienced and inexperienced endoscopists.

### Applications

The results indicated that the real-time magnetic imaging system is safe and of benefit in training and educating inexperienced endoscopists, as well as improving the cecal intubation rate for both experienced and inexperienced endoscopists.

### Peer review

The authors report a meta-analysis of trials that have compared MEI colonoscopy with standard colonoscopy for cecal intubation rates and cecal intubation times. Although colonoscopy supported by MEI was first reported in 1993, this technique has not been widely adopted either because it is expensive or because gastroenterologists are uncertain of its benefits.

Patient was managed conservatively with bowel rest, continuous nasogastric decompression, total parenteral nutrition, recombinant factor VIII (humateP) and transfusion. Symptoms resolved over the course of the hospitalization. This case highlights an important complication of an inherited coagulopathy.

© 2013 Baishideng Publishing Group Co., Limited. All rights reserved.

**Key words:** Duodenal hematoma; von Willebrand disease

**Core tip:** Spontaneous non-traumatic duodenal hematoma has been linked to coagulopathy, but this case includes a rare form of coagulopathy in von Willebrand type 2B. Early identification with computed tomography imaging and treatment of the coagulopathy aided the usage of conservative therapy which allowed the patient to avoid surgical intervention consistent with prior successful cases of duodenal hematomas.

### Abstract

Intramural duodenal hematoma is a rare cause of a proximal gastrointestinal tract obstruction. Presentation of intramural duodenal hematoma most often occurs following blunt abdominal trauma in children, but spontaneous non-traumatic cases have been linked to anticoagulant therapy, pancreatitis, malignancy, vasculitis and endoscopy. We report an unusual case of spontaneous intramural duodenal hematoma presenting as an intestinal obstruction associated with acute pancreatitis in a patient with established von Willebrand disease, type 2B. The patient presented with abrupt onset of abdominal pain, nausea, and vomiting. Computed tomography imaging identified an intramural duodenal mass consistent with blood measuring 4.7 cm × 8.7 cm in the second portion of the duodenum abutting on the head of the pancreas. Serum lipase was 3828 units/L.

Spontaneous intramural duodenal hematoma in type 2B von Willebrand disease. *World J Gastroenterol* 2013; 19(41): 7205-7208 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i41/7205.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i41.7205>

### INTRODUCTION

Intramural duodenal hematoma is a rare occurrence of proximal gastrointestinal tract obstruction. Presentation of intramural duodenal hematoma most often occurs following blunt abdominal trauma in children, but non-traumatic cases have been linked to anticoagulant therapy, pancreatitis, bleeding disorders, malignancy, vasculitis and upper endoscopy<sup>[1-4]</sup>. We report a unique case of spontaneous intramural duodenal hematoma presenting as an intestinal obstruction associated with acute pancreatitis infection in a

patient with established von Willebrand disease, type 2B.

## CASE REPORT

A 24-year-old male was transferred to our tertiary center with a 10 h history of abrupt onset abdominal pain, nausea, and vomiting. History was notable for type 2B von Willebrand disease initially diagnosed at 12 years of age following recurrent hemorrhagic episodes (epistaxis, gingival bleeding and hemarthrosis) and diagnosis in his dizygotic sibling for a spontaneous bleeding episode. Both dizygotic siblings were genetically tested for mutations and found to have the G3946A genotype. Physical examination on admission revealed heart rate 66 beat/min, blood pressure 115/53 mmHg, temperature 36.7 °C and respiration rate 16. Patient was in moderate amount of pain. There were minor facial petechiae. Oropharynx was pink and moist and no evidence of gingival bleeding or epistaxis. There was no conjunctival injection. Neck was supple without adenopathy or thyromegaly. Heart was regular rate and rhythm without murmur. Respirations were unlabored and auscultation was clear bilaterally. Abdominal exam demonstrated hypoactive bowel sounds, epigastric tenderness, without rebound tenderness or guarding. Testicular exam revealed bilateral ecchymoses without edema or tenderness. The lower extremities noted multiple small ecchymosis in various stages of healing. There was normal range of motion in upper and lower extremities, no focal joint pain or effusions noted. Hemoglobin was 15.0 g/dL, white blood cell count 18.8 cells/mL, segmented neutrophils 85%, bands 6%, platelets were immeasurable due to clumping. Sodium 140 mmol/L, potassium 4.0 mmol/L, chloride 107 mmol/L, bicarbonate 26 mmol/L, BUN 21 mg/dL, creatinine 0.9 mg/dL, total protein 7.1 gm/dL, albumin 4.3 gm/dL, aspartate aminotransferase 33 U/L, alanine aminotransferase 34 U/L, alkaline phosphatase 46 U/L, bilirubin 2.4 mg/dL, Lipase 3828 units/L.

Computed tomography (CT) of the abdomen without contrast revealed a hyperdense mass in the second and third portions of the duodenum measuring 4.7 cm × 8.7 cm with associated retroperitoneal hemorrhage, extending from the right anterior pararenal space to the right pelvic sidewall. The duodenal mass resembled a hematoma and was abutting the pancreatic head to the left. Liver, spleen, adrenal glands and genitourinary organs were normal. The findings led to a diagnosis of intramural duodenal hematoma complicated by acute pancreatitis (Figure 1).

The patient was transfused one unit of single donor platelets and administered human antihemophilic factor/von Willebrand factor complex (Humate P<sup>®</sup>) 80 Units/kg prior to transfer from outside facility. A nasogastric (NG) tube was placed, and intravenous bolus of three liters of normal saline was given. Surgery consultation was obtained. He received factor replacement therapy (Humate P<sup>®</sup> 40 units/kg every 12 h) for the next 72 h, following an initial loading bolus.

Esophagogastroduodenoscopy and endoscopic ultrasound were delayed until day eleven of the hospitalization due to potential risk for hemorrhage from the hematoma during endoscopy. Endoscopy showed a near complete obstruction in the second portion of the duodenum with large amount of gastric fluid (Figures 2 and 3). The patient was discharged to home on day 15 of hospitalization after patient's pain receded, repeat imaging noted unchanged duodenal and retroperitoneal hematoma and resolution of gastric outlet obstruction. The patient was readmitted to the hospital the following day with worsening abdominal pain with development of nausea and vomiting. On readmission a repeat abdominal CT was performed due to concern of enlargement and extravasation of the hematoma. Imaging revealed a minute increase in size of the duodenal hematoma that measured 5.3 cm × 5.8 cm (previously 5.3 cm × 5.2 cm) in the AP and transverse dimensions and persistent retroperitoneal hematoma. After control of the patient's symptoms and his ability to tolerate a modified and limited oral diet the patient was finally discharged home on day 23 of the second hospitalization. Following discharge the patient had not experienced return of abdominal pain, nausea and vomiting. Patient was able to tolerate a full diet and total parenteral nutrition (TPN) was discontinued shortly after discharge. Abdominal CT performed at day 68 from presentation revealed decreased size of the duodenal hematoma with measurements of 2.1 cm × 2.6 cm (initially 4.7 cm × 8.7 cm).

## DISCUSSION

McLachlan described the first published report of duodenal hematoma in 1838 as a false aneurismal tumor<sup>[5]</sup>. Decades later, the first case of a non-traumatic intramural hematoma was reported by Sutherland in a child with Henoch-Schonlein purpura that presented as intussusception.

The most common clinical scenario for presentation of intramural duodenal hematoma is seen in blunt abdominal trauma in children<sup>[3,4]</sup>, but non-traumatic cases have been linked to anticoagulant therapy, pancreatitis, bleeding disorders, malignancy, vasculitis and upper endoscopy<sup>[1,3,4,6]</sup>. In adults the most common risk factor for spontaneous intramural small-bowel hematoma reported is supratherapeutic anticoagulation<sup>[7]</sup>. Other notable risk factors include bleeding disorders (hemophilia, idiopathic thrombocytopenic purpura), malignancies and its therapies (leukemia, lymphoma, myeloma, pancreatic cancer, and chemotherapy), vasculitis and pancreatitis<sup>[7,8]</sup>.

Common signs and symptoms on presentation typically include abdominal pain that ranges from vague abdominal complaints to intestinal tract obstruction with vomiting and tenderness mimicking an acute abdomen<sup>[7]</sup>. Abbas noted that most of the patients presented after having symptoms for several days<sup>[7]</sup>. Other infrequent signs and symptoms include jaundice and right upper quadrant tenderness due to bile duct obstruction second-

Figure 1 Axial image (A) and coronal image (B) from abdominal computed tomography with contrast depicts the intramural hematoma as it compresses the head of the pancreas and its associated hemorrhage as it extends into the retroperitoneum (arrows).

Figure 2 Esophagogastroduodenoscopy showing near complete obstruction of duodenum by intramural hematoma.

Figure 3 Endoscopic ultrasound image of intramural duodenal hematoma.

ary to compression by the hematoma<sup>[8]</sup>. In this case, the patient's elevated lipase identified pancreatitis induced by the hematoma as opposed to the case of Bellens *et al*<sup>[9]</sup> in which pancreatitis was the inciting event.

The location of the hemorrhage in spontaneous non-traumatic intraluminal hematoma is submucosal and originates from a small vessel<sup>[7]</sup>. In our case, based upon the imaging findings, the bleeding originated from the gastroduodenal artery. Extravasation of submucosal hematomas can occur into intraluminal, intra-mesenteric, and retroperitoneal sites<sup>[7]</sup>. Whereas traumatic small-bowel hematomas commonly affect the duodenum, most spontaneous small-bowel hematomas involve the jejunum<sup>[7,10]</sup>. Additionally, Abbas noted that no spontaneous intramural hematoma was less than 8 cm in length, consistent with our findings of an 8.7 cm length<sup>[7]</sup>.

In recent years, there has been an increase in detection of non-traumatic intramural small bowel hematomas in patients that are anti-coagulated. This increase has also coincided with more sensitive imaging modalities that have led to earlier detection. In general, CT is the imaging choice for diagnosis of spontaneous intramural small bowel hematoma, but as a rapid screening modality, ultrasound can be used effectively during the initial evaluation, as it is inexpensive, rapid, noninvasive and readily available in most instances<sup>[5,7]</sup>. Characteristic features

have been described include circumferential bowel wall thickening, intramural hyperdensity with Hounsfield units characteristic for blood (30-80 H), luminal narrowing and intestinal obstruction<sup>[7]</sup>. Reassessment of the status of the hematoma is generally recommended with CT in 2 wk following diagnosis and conservative management<sup>[8]</sup>.

In prior case reports, the initial treatment regimen for IDH favored medical management; if feasible in a stable patient, as spontaneous local absorption of the hematoma occurs in most circumstances<sup>[5-8]</sup>. Conservative management constituted bowel rest, continuous NG decompression, TPN, blood transfusion and correction of coagulopathy. Minimally invasive drainage through image-guided modalities is generally not recommended in consideration to the technical difficulty required to access the precarious location of the pathology as well as the risk for bowel perforation<sup>[8]</sup>. Complete resolution of the hematoma and healing of the intestine usually occurs within 2 mo after diagnosis in cases of non-extensive hematomas<sup>[5,7]</sup>. Surgical intervention is only indicated if there is significant intraluminal hemorrhage, bowel perforation or identifiable risk of ischemia<sup>[4,5,7]</sup>. Surgical evacuation of the hematoma through laparotomy or laparoscopy tends to be the best surgical treatment in these situations, specifically in instances in which the abdominal pain or obstruction did not resolve and objective findings of bowel infarction were present<sup>[11-13]</sup>. Limited case reports have detailed suc-

cessful outcomes with percutaneous aspiration and endoscopic dilation<sup>[4,14,15]</sup>. Finally, bypass surgery is reserved for patients with severe duodenal perforation and multiple comorbidities precluding resectional surgery<sup>[8]</sup>.

Our case highlights a rare but important complication of coagulopathy. Acute abdominal pain with signs and symptoms of obstruction in patients with coagulopathy should raise suspicion for spontaneous intramural small-bowel hematoma. Prompt diagnosis with CT imaging is a crucial contribution to patient treatment, because conservative medical management can be achieved in most patients. Whereas, in cases of failed conservative medical management surgical intervention is performed.

### Abstract

Efferent loop syndrome is a very rare postgastrectomy syndrome that can occur following Billroth-II or Roux-en-Y reconstruction. The most common loop syndrome after gastric surgery is afferent loop syndrome; however, efferent loop syndrome has been reported in rare cases. Here, we report a case of efferent loop obstruction that occurred after postoperative adhesiolysis of a small-bowel obstruction. The patient had undergone a partial gastrectomy with Billroth II anastomosis and gastric ulcer perforation 30 years prior. The efferent loop obstruction was successfully resolved by the insertion of a double pigtail stent. To the best of our knowledge, this is the first case in the literature describing the treatment of efferent loop obstruction.

### INTRODUCTION

Efferent loop syndrome is one of two “loop syndromes” that can occur after certain types of gastric surgery. Afferent loop syndrome is commonly reported, while efferent loop syndrome is very rarely reported. The signs and symptoms of both loop syndromes may be similar and difficult to distinguish, and surgical treatment is usually required to correct these problems. This report provided the first description of the successful treatment of a patient with efferent loop obstruction with the implantation of a double pigtail stent.

### CASE REPORT

A 58-year-old man, who had undergone a previous partial gastrectomy 30 years prior, was admitted to the emergency room with severe abdominal pain and vomiting. He was resuscitated and underwent computed tomography, which revealed different sites of small-bowel obstruction in the left and middle lower abdomen. A

**Figure 1** Endoscopic finding revealed a narrowed and swollen entrance of the efferent loop.

**Figure 2** Gastrograph in study showed nearly complete obstruction of the efferent loop.

laparotomy, showed that the small bowel was markedly distended over adhesion band but not strangulated. Adhesiolysis was performed. Other abdominal findings were nonspecific. During surgery, signs of a partial gastrectomy that included a retrocolic and antiperistaltic gastrojejunostomy. Gross findings were nonspecific.

The patient recovered well and started orally; however, seven days later, he developed abdominal discomfort and experienced episodes of copious bilious vomiting at night. His abdomen remained soft and not distended. Plain abdominal radiography and laboratory tests showed no remarkable findings. The next day, the symptoms persisted, and a gastroendoscopy was performed under the suspicion of afferent loop syndrome. Copious amount of bilious fluid were found in the remnant stomach and dilatation. The lumen of the afferent loop was normal; however, the efferent loop was narrowed and edematous approximately 5 cm below the site of the gastrojejunostomy (Figure 1). The endoscope could be passed into the loop. The narrowed loop did not appear to have any abnormal mucosal lesions. A gastrografen study showed nearly complete obstruction of the efferent loop (Figure 2). The patient was treated with nasogastric tube decompression and total parenteral nutrition, but did not improve. After seven days, a follow-up endoscopy showed that the efferent loop had not changed. Endoscopic pneumatic balloon dilatation (CRE™ Balloon, Boston Scientific Co. Ltd., Ireland; 12 mm; 40 psi for 1 min, 45 psi for 1 min) over the guide-wire and under endoscopic view was immediately performed but was not effective. Subsequently, a double pigtail stent (Zimmon™ Biliary Stent, Cook Co. Ltd., Ireland; 10 Fr; 7 cm) was inserted through the efferent loop stenosis and over the guide wire using a double-channel endoscope (Olympus GIF-Type 2T240) under endoscopic view (Figure 3). Beginning the day after the procedure, the patient did not complain of abdominal discomfort or experience vomiting. The device was monitored by abdominal radiography (Figure 4A). Serial plain abdominal radiographs did not show migration of the stent to the other site. The patient subsequently recovered, and there were no further episodes of abdominal discomfort and vomiting. A repeated gastrograph in study

and gastroscopy showed a good patency and a widened loop (Figure 5). Thirteen days after procedure, the double pigtail stent was expelled with the feces (Figure 4B). The patient eventually recovered and was discharged. At a 3-mo follow-up, the patient did not have any symptoms.

## DISCUSSION

Afferent or efferent loop syndrome is a purely mechanical problem characterized by the obstruction of gastric emptying at or near the site of a gastrojejunostomy<sup>[1]</sup>. Efferent loop syndrome is a rare post gastrectomy syndrome, while afferent loop syndrome is more common<sup>[2]</sup>. The major cause of syndrome is an intestinal hernia. The more minor causes include an adhesive band and kinking because of scarring or poor reconstruction during gastric surgery<sup>[3,4]</sup>. In some cases, intussusception causes efferent loop syndrome<sup>[5]</sup>. Rarely do we experience efferent loop obstruction with mucosal prolapse-like stenosis of efferent loop due to adhesion or bowel edema.

Efferent loop syndrome usually occurs within the first few weeks following a gastric surgery. However, this syndrome can also develop years after gastric surgery<sup>[6]</sup>. The usual causes of this syndrome during the early post-operative period are anastomotic edema and kinking due to poor operative procedure. The later-occurring forms of the syndrome may be caused by anastomotic stricture, ulcer, bowel adhesion, jejuno gastric intussusception, and anastomotic cancer<sup>[7]</sup>. Rarely do we experience efferent loop syndrome caused by the adhesiolysis of a mechanical obstruction from a previous operation.

The clinical symptoms of efferent loop syndrome are characterized by abdominal cramps and copious bilious vomiting. In particular, abdominal discomfort is relieved by vomiting. This symptom is worse when the patient is supine, as in this patient who had vomiting only at nights. Patients may be dehydrated and have metabolic alkalosis if the syndrome occurs over a prolonged period of time, patients may experience paradoxical aciduria.

The treatment of efferent loop syndrome varies depending on the cause of the syndrome. Complete loop obstruction due to a mechanical cause requires surgical

Figure 3 Endoscopic stent procedure was performed that double pigtail stent was inserted through efferent loop stenosis and over the guide wire using double-channel endoscope under endoscopic view.

Figure 4 Plain abdominal radiography revealed double pigtail stent to efferent loop (A) and no double pigtail stent and other specific finding (B).

Figure 5 Follow-up gastrograin and endoscopic study showed free flow of contrast and recovery of narrowed, swollen orifice of the efferent loop.

intervention. Surgical interventions are numerous. However, if the syndrome is caused by an anastomotic ulcer or edema and adhesion, conservative treatment is indicated. Conservative treatments include nasogastric drainage,

keeping non *per os*, prescribing H2 antagonist or proton pump inhibitors, and total parenteral nutrition.

Because of recent advances in endoscopic intervention, various treatment methods have been attempted.

However, treatment has mainly been reported in afferent loop syndrome, very little documentation on the treatment of efferent loop syndrome exists in the literature. In several cases, endoscopic stent insertion was reported for the treatment of an obstruction due to tumor recurrence or peritoneal seeding. An endoscopic stent induced complication generally involve dislocation and clogging with subsequent infection. An endoscopic stent could be used in various types of gastrointestinal (GI) tract diseases, whereas a double pigtail stent is specifically used for managing biliary tract or pancreatic diseases. Pigtail stents may be inferior to straight stents in their drainage capacity, but the risk of migration of pigtail stents is lower<sup>[8]</sup>. In this case, we treated a patient with efferent loop obstruction caused by benign stricture with a double pigtail stent to prevent the dislocation of the GI stent. The patient improved following the clearing of efferent loop obstruction by the treatment. We therefore report that this case was resolved with the use of a double pigtail stent.

In conclusion, efferent loop syndrome following after a gastrectomy can be diagnosed by meticulous history-taking, physical examination, and radiologic modalities. In our opinion, a double pigtail stent should be considered a treatment option for relieving efferent loop obstruction if immediate surgical treatment is not required.

**Key words:** Fecal microbiota transplantation; Crohn's disease; Rescue therapy; Inflammatory bowel disease; Fistula

**Core tip:** We proposed that standardized fecal microbiota transplantation (FMT) might be a promising rescue therapy for refractory inflammatory bowel disease. This case report provided the first description of severe Crohn's disease in sustained clinical remission after FMT, and the brief protocol of patient preparation before and during FMT. Although there was only one case, the present result in our pilot clinical trial strongly supported our initial hypothesis and highlighted the attractive role of the remodeling of gut flora in host diseases.

### Abstract

The concept of fecal microbiota transplantation (FMT) has been used in traditional Chinese medicine at least since the 4<sup>th</sup> century. Evidence from recent human studies strongly supports the link between intestinal bacteria and inflammatory bowel disease. We proposed that standardized FMT might be a promising rescue therapy for refractory inflammatory bowel disease. However, there were no reports of FMT used in patients with severe Crohn's disease (CD). Here, we report the successful treatment of standardized FMT as a rescue therapy for a case of refractory CD complicated with fistula, residual Barium sulfate and formation of intra-peritoneal large inflammatory mass. As far as we know, this is the first case of severe CD treated using FMT through mid-gut.

### INTRODUCTION

The gut microbiota is considered to constitute a "microbial organ" which plays a pivotal role in the intestinal diseases<sup>[1]</sup>. The gut metagenome sequencing showed that over 99% of the genes are bacterial<sup>[2]</sup>. Although fecal microbiota transplantation (FMT) has only recently gained popularity with its success in treating *Clostridium difficile* infection<sup>[3]</sup>, the concept of FMT for treatment of human intestinal diseases has been recorded at least for 1700 years in traditional Chinese medicine<sup>[4]</sup>. Evidence from human studies strongly supports the link between intestinal bacteria and inflammatory bowel diseases (IBD)<sup>[5-7]</sup>. IBD includes ulcerative colitis (UC) and Crohn's disease (CD). However, there have been only four publications on FMT for the treatment of IBD in 18 cases of UC<sup>[8-10]</sup>

and one case of newly diagnosed CD<sup>[10]</sup>. To date, there has been no report of FMT used as a rescue therapy in patients with severe CD. We proposed that standardized FMT might be a useful rescue therapeutic option for refractory inflammatory bowel disease.

## CASE REPORT

A 32-year-old Chinese man with known severe enterocolonic CD presented to our hospital in November 2012 because of progressive abdominal pain, bloody and purulent diarrhea and high fever of 38 °C-39.5 °C for 8 wk. He was diagnosed with CD in May 2010 when he was found three stricturing lesions and a penetrating lesion in ileum. In fact, he had gastrointestinal symptoms such as abdominal pain since 2005 and received enterectomy for presumptive appendicitis in 2007.

He was initially treated with intravenous prednisolone and Pentasa (mesalazine) 4.0 g daily for 6 years with frequent relapses. Colonoscopy in May 2011 revealed severe Crohn colitis with extensive ulcers throughout the entire colon. Therefore, he was treated with intravenous prednisolone and Mycophenolate Mofetil 1.0 g by mouth daily. In September 2012, many large ulcers were found in colon. He refused anti-tumour necrosis factor antibody infusion due to lack of medical insurance. He then received Mycophenolate Mofetil capsules 1.25 g daily and mesalazine 3.0 g daily. He was transferred to our center in November 2012.

On physical examination on admission, the patient showed poor general conditions. A large mass could be seen in the hypogastrium with tenderness. Laboratory tests showed leukocyte count of  $17.5 \times 10^9/L$  with 89.4% of neutrophils, erythrocyte sedimentation rate of 97 mm per hour and C-reactive protein of 141 mg/L. He had normal liver function test except album of 27.4 g/L (normal range, 35-55 g/L) and total cholesterol 2.6 mmol/L (normal range, 3.0-6.0 mmol/L).

CT scan showed an abdominal mass measuring 14 cm  $\times$  8 cm  $\times$  10 cm, enterocolic fistula and residual Barium sulfate in the mass (Figure 1A). The patient underwent barium meal examination in another hospital three months ago. Colonoscope could not pass through the severely inflamed sigmoid colon. He was given antibiotics intravenously for 10 d. However, symptoms of frequent fever, abdominal pain and abdominal mass were still the therapeutic dilemma.

He agreed to participate in a clinical trial with FMT for moderate to severe refractory CD (NCT01793831), approved by the ethics committee of our center. One week prior to FMT, Mycophenolate Mofetil capsules and Etiasa were stopped, and Salofalk (mesalazine) 3.0 g was given daily. His CD Activity Index (CDAI) score was 537.

Based on the patient's desire and the protocol of scanning tests and questionnaires made by our group (not shown in the present article), the donor was his 10-year-old healthy daughter. According to the protocol of standardized preparation, Esomeprazole Magnesium 40 mg

**Figure 1** Abdominal computerized tomography scan. A: Before FMT, formation of an intraperitoneal large inflammatory mass measuring 14 cm  $\times$  8 cm  $\times$  10 cm, arrows showing gas indicating fistula, and the scattered bright image indicating Barium sulfate in fistula; B: Four months after FMT, no mass and gas was present and only a little Barium sulfate in the mass was shown. FMT: Fecal microbiota transplantation.

by intravenous push and metoclopramide 10 mg by intramuscular injection were given one hour before endoscopic procedure. The highly purified gut flora at lab was prepared as 150 mL liquid suspension and was transplanted into mid-gut below Vater papilla<sup>[11]</sup> by a tube within the channel of gastroscope under anesthesia. The time from collection of stool to FMT procedure with endoscopy was 50 min. A week after FMT, his symptoms, such as fever, bloody purulent stool and abdominal pain, were dramatically alleviated, the size of intraperitoneal inflammatory mass became much smaller than that before FMT, and the CDAI score was reduced to 228. He had a severe cold in the whole third week after he was discharged with clinical improvement. At one month of follow-up after FMT, his CDAI score was further reduced to 143, which met the criteria of clinical remission. Three months after FMT, CDAI score was further reduced to 62, suggesting sustained clinical remission. CT scan (Figure 1B) showed resolved mass without exudation and the disappearance of the previous Barium sulfate intraperitoneally. Then, Salofalk 2.0 g daily was given. The patient was followed up for 9 mo and his CDAI score remained at 62, suggesting sustained clinical remission. Of note, he has gained his body weight by 11 kg, compared with the 50 kg as his baseline body weight before FMT. His nutrition status has also improved, evidenced by normalized album and total cholesterol 47.4 g/L (normal range, 35-55) and 4.5 mmol/L (normal range, 3.0-6.0), respectively. The key

**Table 1** Clinical parameter changes of the patient during follow-up

Parameter (normal range)	Before FMT	After FMT			
		1 wk	1 mo	3 mo	9 mo
Body weight (kg)	50	51	52	56	61
CDAI score	537	228	143	62	62
Haemoglobin (110-160, g/L)	97	113	120	142	144
CRP (0-10, mg/mL)	141	8	9	1.7	7
ESR (0-20, mm/h)	97	10	13	10	10
Album (g/L)	27.4	-	35	49.9	47.4
Total cholesterol (3.0-5.7 mmol/L)	2.6	-	2.7	4.2	4.5
Triglycerides (0.4-1.7 mmol/L)	0.5	-	0.6	2.4	2.5
HDL-C (1-2 3.1 mmol/L)	0.6	-	0.7	1.3	1.3
LDL-C (< 3.1 mmol/L)	1.8	-	1.9	2.5	2.6
IgM (6.8-14.5, g/L)	0.5	-	0.7	1.0	0.8

CDAI: Crohn's disease activity index; CRP: C reactive protein; ESR: Erythrocyte sedimentation rate; HDL-C: High density lipoprotein-cholesterol; LDL-C: Low density lipoprotein-cholesterol; FMT: Fecal microbiota transplantation.

clinical parameter changes are shown in Table 1.

## DISCUSSION

CD usually affects the intestine, but may occur anywhere from the mouth to the end of the rectum (anus). CD with fistula and formation of intraperitoneal large inflammatory mass has considerable morbidity associated with this complication and remains an unresolved challenge<sup>[12]</sup>. This case presented CD with fistula, residual Barium sulfate and refractory inflammation in a large mass after enterectomy and long-term use of mesalazine, prednisolone and mycophenolate mofetil. Further medications (aminosalicylic acid preparations, steroids, immunomodulators, antibiotics and biologics such as anti-tumor necrosis factor antibody) not only yielded significant side effects, but also unpredictable outcome. Long-term use of immunomodulators increased the risk of refractory inflammation. Surgery for this case does pose a challenge for a surgeon in the skill and expertise according to the recent consensus<sup>[13]</sup>.

The etiology of CD is unknown, but one dominant hypothesis is that the inflammation might result from altered or pathogenic microbiota in a genetically susceptible host<sup>[14]</sup>. We proposed that FMT might be a promising rescue therapy for refractory CD. Based on the attractive therapeutic effect<sup>[15]</sup> and less concerns in safety<sup>[16]</sup>, as well as the long history of recognition in traditional Chinese medicine<sup>[4]</sup>, standardized FMT is acceptable in treating refractory CD. As a rescue therapy in this severe CD, it is intriguing that standardized FMT was safe. The patient's sustained remission indicated that a single application of standardized FMT *via* mid-gut should be effective.

In order to prove the therapeutic role of FMT, one week before FMT, immunosuppressive agent was stopped and only Salofalk 3.0 g was continued daily. CDAI decreased

dramatically during the first week after FMT. The large mass and inflammation within the fistula subsided in 4-6 wk. The expulsion of residual Barium sulfate within 4 mo actually not only decreased the risk of refractory infection within fistula, but also played a role in improving the internal fistula.

Gut microbial communities represent one source of human genetic and metabolic diversity. Previous studies have shown that relatives of patients with CD bear the risk of this disease and have altered gut microbiome<sup>[17]</sup>. The recent reports also have shown that the gut microbiota composition in healthy persons has the age-associated changes<sup>[18]</sup>. These experimental evidences indicated that the family members of CD patients might not be the best donor of stool for FMT. However, in the present case, the clinical results demonstrated that the patient's 10-year-old daughter under healthy state was his right choice as a donor. Further studies are needed to clarify whether the ideal donor of stool for FMT can be from CD patient's relatives or family members.

We reported here the first case of severe CD using FMT through mid-gut. The single standardized FMT resulted in sustained clinical remission for more than 9 mo and the follow-up is going on. Although there was only one case, the present result in our clinical trial strongly supported our initial hypothesis and highlighted the attractive role of the remodeling of gut flora in host diseases. Our ongoing study will report more evidences of standardized FMT through mid-gut on refractory intestinal diseases in a difficult therapeutic dilemma.

portant issues regarding immunisation in inflammatory bowel disease patients. However, in our opinion, definition of vaccine efficacy is misused. In fact this article is on vaccine immunogenicity. Here, we emphasise the differences between the definitions of efficacy, effectiveness and immunogenicity, differences that are fundamental in vaccinology.

Banaszkiewicz A, Radzikowski A. Efficacy, effectiveness, immunogenicity - are not the same in vaccinology. *World J Gastroenterol* 2013; 19(41): 7217-7218 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i41/7217.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i41.7217>

### Abstract

Manuscript of Carrera *et al* is devoted to immunization in inflammatory bowel disease (IBD) that is very important issue in gastroenterology. However, some specific definitions used in the article need clarification. Efficacy of vaccine is measured in a randomised, placebo-controlled studies, that are expensive and difficult to plan. Moreover, it is unethical to offer a placebo instead of vaccine. For all of these reasons, efficacy of vaccine is measured in IBD patients rarely. Effectiveness of vaccine is measured as an epidemiological affect from observational studies. These studies are also uncommon in IBD because it would be difficult to perform a study that assess the prevalence of one rare disease (vaccine-preventable) in patients with a chronic rare condition, such as IBD. Immunogenicity of vaccine refers to the ability of a vaccine to induce an immune response in a vaccinated individual that is, in fact, the matter of the article.

**Core tip:** The Carrera *et al*'s article presents some im-

### TO THE EDITOR

We read with interest the manuscript of Carrera *et al*<sup>[1]</sup>, devoted to immunisation in inflammatory bowel disease (IBD) patients. However, we would like to clarify the definitions used in the article.

The title of the article suggested that the body of the manuscript is focused on the efficacy of vaccines in IBD. Moreover, the authors defined efficacy as “percent risk reduction for clinically significant infection in a vaccinated group *vs* a control group”, but there is nothing in the article about efficacy. The entire article is about the immunogenicity of vaccines. These two words are not synonyms.

How well a vaccine works can be measured through different types of studies<sup>[2]</sup>. The measurement of a vaccine's effect in a randomised (placebo-controlled) study is referred to as efficacy. Randomised studies are expensive and are not always conducted after a recommendation for vaccination has been issued because withholding the vaccine from people recommended to receive it would place them at risk for infection, illness and possibly serious complications. The measurement of a vaccine's epidemiological effect from observational studies is referred

to as effectiveness. Apart from ethical and economic considerations, it would be difficult to perform a study that assessed the prevalence of one rare disease (vaccine-preventable) in patients with a chronic rare condition, such as IBD. The efficacy of a vaccine may indirectly predict cases of that one rare disease when the protecting level of antibodies is known from previous epidemiological studies. Immunogenicity refers to the ability of a vaccine to induce an immune response (antibody- and/or cell-mediated immunity) in a vaccinated individual. Until now, neither efficacy nor effectiveness has been assessed in IBD patients for any vaccine. All of the vaccine studies in IBD patients have instead assessed the immunogenicity of the vaccines.

Proper use of these terms is not just an academic issue, as the level of antibodies does not always predict real protection against a disease. Immunogenicity can be low, as observed in hepatitis B virus vaccine (*i.e.*, in the

Gisbert *et al*<sup>[3]</sup> study, only 36% of IBD patients on immunosuppressive and biological therapy achieved adequate hepatitis B surface antibody levels), but hepatitis B cases are extremely rare in a vaccinated IBD population.

## GENERAL INFORMATION

*World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a peer-reviewed open access (OA) journal. *WJG* was established on October 1, 1995. It is published weekly on the 7<sup>th</sup>, 14<sup>th</sup>, 21<sup>st</sup>, and 28<sup>th</sup> each month. The *WJG* Editorial Board consists of 1352 experts in gastroenterology and hepatology from 64 countries.

### Aims and scope

The primary task of *WJG* is to rapidly publish high-quality original articles, reviews, and commentaries in the fields of gastroenterology, hepatology, gastrointestinal endoscopy, gastrointestinal surgery, hepatobiliary surgery, gastrointestinal oncology, gastrointestinal radiation oncology, gastrointestinal imaging, gastrointestinal interventional therapy, gastrointestinal infectious diseases, gastrointestinal pharmacology, gastrointestinal pathophysiology, gastrointestinal pathology, evidence-based medicine in gastroenterology, pancreatology, gastrointestinal laboratory medicine, gastrointestinal molecular biology, gastrointestinal immunology, gastrointestinal microbiology, gastrointestinal genetics, gastrointestinal translational medicine, gastrointestinal diagnostics, and gastrointestinal therapeutics. *WJG* is dedicated to become an influential and prestigious journal in gastroenterology and hepatology, to promote the development of above disciplines, and to improve the diagnostic and therapeutic skill and expertise of clinicians.

*WJG* is published by Baishideng Publishing Group (BPG) in both electronic and online forms. All *WJG* articles are published in *WJG* website and PubMed Central. The major advantages of OA journals are faster release and delivery, no page or graph restrictions, and increased visibility, usage and impact. Full-text PDF articles and electronic/online versions are freely available to global readers. After the paper is published, the author(s) can obtain high-quality PDF files, which contain the journal cover, a list of editorial board members, table of contents, text, and back cover of the journal. BPG has a strong professional editorial team composed of editorial board members, editors-in-chief, science editors, language editors, and electronic editors. BPG currently publishes 42 OA clinical medical journals, including 41 in English, has a total of 15471 editorial board members or peer reviewers, and is a world first-class publisher.

### Columns

The columns in the issues of *WJG* will include: (1) Editorial: The editorial board members are invited to make comments on an important topic in their field in terms of its current research status and future directions to lead the development of this discipline; (2) Frontier: The editorial board members are invited to select a highly cited cutting-edge original paper of his/her own to summarize major findings, the problems that have been resolved and remain to be resolved, and future re-

search directions to help readers understand his/her important academic point of view and future research directions in the field; (3) Diagnostic Advances: The editorial board members are invited to write high-quality diagnostic advances in their field to improve the diagnostic skills of readers. The topic covers general clinical diagnosis, differential diagnosis, pathological diagnosis, laboratory diagnosis, imaging diagnosis, endoscopic diagnosis, biotechnological diagnosis, functional diagnosis, and physical diagnosis; (4) Therapeutics Advances: The editorial board members are invited to write high-quality therapeutic advances in their field to help improve the therapeutic skills of readers. The topic covers medication therapy, psychotherapy, physical therapy, replacement therapy, interventional therapy, minimally invasive therapy, endoscopic therapy, transplantation therapy, and surgical therapy; (5) Field of Vision: The editorial board members are invited to write commentaries on classic articles, hot topic articles, or latest articles to keep readers at the forefront of research and increase their levels of clinical research. Classic articles refer to papers that are included in Web of Knowledge and have received a large number of citations (ranking in the top 1%) after being published for more than years, reflecting the quality and impact of papers. Hot topic articles refer to papers that are included in Web of Knowledge and have received a large number of citations after being published for no more than 2 years, reflecting cutting-edge trends in scientific research. Latest articles refer to the latest published high-quality papers that are included in PubMed, reflecting the latest research trends. These commentary articles should focus on the status quo of research, the most important research topics, the problems that have now been resolved and remain to be resolved, and future research directions. Basic information about the article to be commented (including authors, article title, journal name, year, volume, and inclusive page numbers); (6) Minireviews: The editorial board members are invited to write short reviews on recent advances and trends in research of molecular biology, genomics, and related cutting-edge technologies to provide readers with the latest knowledge and help improve their diagnostic and therapeutic skills; (7) Review: To make a systematic review to focus on the status quo of research, the most important research topics, the problems that have now been resolved and remain to be resolved, and future research directions; (8) Topic Highlight: The editorial board members are invited to write a series of articles (7-10 articles) to comment and discuss a hot topic to help improve the diagnostic and therapeutic skills of readers; (9) Medical Ethics: The editorial board members are invited to write articles about medical ethics to increase readers' knowledge of medical ethics. The topic covers international ethics guidelines, animal studies, clinical trials, organ transplantation, etc.; (10) Clinical Case Conference or Clinicopathological Conference: The editorial board members are invited to contribute high-quality clinical case conference; (11) Original Articles: To report innovative and original findings in gastroenterology and hepatology; (12) Brief Articles: To briefly report the novel

## Instructions to authors

and innovative findings in gastroenterology and hepatology; (13) Meta-Analysis: Covers the systematic review, mixed treatment comparison, meta-regression, and overview of reviews, in order to summarize a given quantitative effect, *e.g.*, the clinical effectiveness and safety of clinical treatments by combining data from two or more randomized controlled trials, thereby providing more precise and externally valid estimates than those which would stem from each individual dataset if analyzed separately from the others; (14) Case Report: To report a rare or typical case; (15) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (16) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (17) Autobiography: The editorial board members are invited to write their autobiography to provide readers with stories of success or failure in their scientific research career. The topic covers their basic personal information and information about when they started doing research work, where and how they did research work, what they have achieved, and their lessons from success or failure.

### SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

### Biostatistical editing

Statistical review is performed after peer review. We invite an expert in Biomedical Statistics to evaluate the statistical method used in the paper, including *t* test (group or paired comparisons), chi-squared test, ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc.* The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word “significantly” should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

### Conflict-of-interest statement

In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: [http://www.icmje.org/ethical\\_4conflicts.html](http://www.icmje.org/ethical_4conflicts.html).

### Statement of informed consent

Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

### Statement of human and animal rights

When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/esps/>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS ([http://www.wjgnet.com/1007-9327/g\\_info\\_20100315215714.htm](http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm)) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [wjg@wjgnet.com](mailto:wjg@wjgnet.com), or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Viscer-

## Instructions to authors

al, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039 Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision on acceptance is made only when at least two experts recommend publication of an article. All peer-reviewers are acknowledged on Express Submission and Peer-review System website.

### Abstract

There are unstructured abstracts (no less than 200 words) and structured abstracts. The specific requirements for structured abstracts are as follows:

An informative, structured abstract should accompany each manuscript. Abstracts of original contributions should be structured into the following sections: AIM (no more than 20 words; Only the purpose of the study should be included. Please write the Aim in the form of “To investigate/study/...”), METHODS (no less than 140 words for Original Articles; and no less than 80 words for Brief Articles), RESULTS (no less than 150 words for Original Articles and no less than 120 words for Brief Articles; You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.,  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ), and CONCLUSION (no more than 26 words).

### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

### Core tip

Please write a summary of less than 100 words to outline the most innovative and important arguments and core contents in your paper to attract readers.

### Text

For articles of these sections, original articles and brief articles,

the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both.

### Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: ...etc. It is our principle to publish high resolution-figures for the E-versions.

### Tables

Three-line tables should be numbered 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  should be noted ( $P > 0.05$  should not be noted). If there are other series of *P* values, <sup>c</sup> $P < 0.05$  and <sup>d</sup> $P < 0.01$  are used. A third series of *P* values can be expressed as <sup>e</sup> $P < 0.05$  and <sup>f</sup> $P < 0.01$ . Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, etc., in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, “Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>”. If references are cited directly in the text, they should be put together within the text, for example, “From references<sup>[19,22-24]</sup>, we know that...”.

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

**PMID and DOI**

Pleased provide PubMed citation numbers to the reference list, e.g., PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

**Style for journal references**

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

**Style for book references**

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

**Statistical data**

Write as mean  $\pm$  SD or mean  $\pm$  SE.

**Statistical expression**

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as *v* (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

**Units**

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h; blood glucose concentration, *c* (glucose) 6.4  $\pm$  2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6

## Instructions to authors

24.5 µg/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23243641.

The format for how to accurately write common units and quantums can be found at: [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315223018.htm](http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm).

### Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

### Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gylA*, *arg 1*, *c myc*, *c fos*, *etc.*

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kbo I*, *Kpn I*, *etc.*

Biology: *H. pylori*, *E. coli*, *etc.*

### Examples for paper writing

All types of articles' writing style and requirement will be found in the link: <http://www.wjgnet.com/esps/Navigation-Info.aspx?id=15>.

## RESUBMISSION OF THE REVISED MANUSCRIPTS

Authors must revise their manuscript carefully according to the revision policies of Baishideng Publishing Group Co., Limited. The revised version, along with the signed copyright transfer agreement, responses to the reviewers, and English language Grade A certificate (for non-native speakers of English), should be submitted to the online system *via* the link contained in the e-mail sent by the editor. If you have any questions about the revision, please send e-mail to [esps@wjgnet.com](mailto:esps@wjgnet.com).

### Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A.

### Copyright assignment form

Please download a Copyright assignment form from [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315222818.htm](http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm).

### Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315222607.htm](http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm)

### Proof of financial support

For papers supported by a foundation, authors should provide a copy of the approval document and serial number of the foundation.

## STATEMENT ABOUT ANONYMOUS PUBLICATION OF THE PEER REVIEWERS' COMMENTS

In order to increase the quality of peer review, push authors to carefully revise their manuscripts based on the peer reviewers' comments, and promote academic interactions among peer reviewers, authors and readers, we decide to anonymously publish the reviewers' comments and author's responses at the same time the manuscript is published online.

## PUBLICATION FEE

WJG is an international, peer-reviewed, open access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. Publication fee: 1365 USD per article. All invited articles are published free of charge.

### APPENDIX I-VI Instructions to authors

**ABOUT COVER** Editorial Board Member of *World Journal of Gastroenterology*, Seng-Kee Chuah, MD, Gastrointestinal Motility Unit, Division of Gastroenterology, Kaohsiung Chang Gung Memorial Hospital, College of Medicine, Chang Gung University, Kaohsiung 833, Taiwan

**AIMS AND SCOPE** *World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a peer-reviewed open access journal. *WJG* was established on October 1, 1995. It is published weekly on the 7<sup>th</sup>, 14<sup>th</sup>, 21<sup>st</sup>, and 28<sup>th</sup> each month. The *WJG* Editorial Board consists of 1352 experts in gastroenterology and hepatology from 64 countries.

The primary task of *WJG* is to rapidly publish high-quality original articles, reviews, and commentaries in the fields of gastroenterology, hepatology, gastrointestinal endoscopy, gastrointestinal surgery, hepatobiliary surgery, gastrointestinal oncology, gastrointestinal radiation oncology, gastrointestinal imaging, gastrointestinal interventional therapy, gastrointestinal infectious diseases, gastrointestinal pharmacology, gastrointestinal pathophysiology, gastrointestinal pathology, evidence-based medicine in gastroenterology, pancreatology, gastrointestinal laboratory medicine, gastrointestinal molecular biology, gastrointestinal immunology, gastrointestinal microbiology, gastrointestinal genetics, gastrointestinal translational medicine, gastrointestinal diagnostics, and gastrointestinal therapeutics. *WJG* is dedicated to become an influential and prestigious journal in gastroenterology and hepatology, to promote the development of above disciplines, and to improve the diagnostic and therapeutic skill and expertise of clinicians.

**INDEXING/ABSTRACTING** *World Journal of Gastroenterology* is now indexed in Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®), Journal Citation Reports®, Index Medicus, MEDLINE, PubMed, PubMed Central, Digital Object Identifier, and Directory of Open Access Journals. ISI, Journal Citation Reports®, Gastroenterology and Hepatology, 2012 Impact Factor: 2.547 (34/74); Total Cites: 19145 (6/74); Current Articles: 944 (1/74); and Eigenfactor® Score: 0.06035 (6/74).

### CHRONIC PANCREATITIS

Chronic pancreatitis is characterized by an inflammatory process of the pancreas, which is replaced by fibrosis and progressive destruction. Clinically, the early phase is typically dominated by pain or recurrent episodes of pancreatitis and complications, whereas in the advanced phase symptoms related to exocrine and/or endocrine insufficiency are seen. Hence, the three major clinical features of chronic pancreatitis are pain, maldigestion, and diabetes. The incidence of the disease has been estimated to 2-10/100000 and seems to be increasing<sup>[1]</sup>, but there are major regional differences, and in some countries the disease is much more prevalent. It is also likely that there are many patients with, e.g., abdominal pain, diarrhea and malnutrition - without diagnostic classification - that in reality suffer from chronic pancreatitis. Apart from the illness the economic burden is also of major importance. Chronic pancreatitis has a profound impact on social life and employment patterns<sup>[2]</sup>. For society the disease in year 2000 accounted for 327000 hospitalizations, 200000 emergency room visits and 532000 physician visits costing 2.5 billion \$ in the United States<sup>[3]</sup>. Even though excess alcohol intake still is a major risk factor, recent data suggest that in some series less than half of the patients have alcoholic pathogenesis and much attention has been paid to "new" entities such as autoimmune pancreatitis<sup>[4]</sup>.

In the current issue of *World Journal of Gastroenterology*, different topics highlight experimental models of chronic pancreatitis and bridge findings from recent research to bedside<sup>[5]</sup>. The pathogenesis of pancreatitis is reviewed using the recent "MANNHEIM" classification,

### Abstract

Chronic pancreatitis is characterized by an inflammatory process of the pancreas, which is replaced by fibrosis and progressive destruction. The three major clinical features of chronic pancreatitis are pain, maldigestion, and diabetes. Chronic pancreatitis has a profound impact on social life and employment patterns. In the current issue, different topics highlight experimental models of chronic pancreatitis and bridge findings from recent research to bedside. Although the disease is still difficult to treat the current papers represent useful guidelines on how to approach chronic pancreatitis in the clinical settings with the major aim to improve the patient's suffering and quality of life.

**Key words:** Chronic pancreatitis; Pathogenesis; Diabetes; Treatment

**Core tip:** Chronic pancreatitis has a profound impact on social life and employment patterns. In the current issue of *World Journal of Gastroenterology*, different topics highlight experimental models of chronic pancreatitis and bridge findings from recent research to bedside.

which may help us in correct diagnostics and subsequent treatment<sup>[6]</sup>. Diagnosing of chronic pancreatitis has been challenging and imaging techniques are emerging. The main development has been within magnetic resonance imaging and ultrasonography. Two review papers outlined state-of-the-art as well as arising techniques such as diffusion-weighted imaging to indirectly assess the degree of fibrosis<sup>[7]</sup>. Contrast enhanced ultrasonography and elastography are other examples of new techniques to e.g., differentiate between malignancy and benign lesions<sup>[8]</sup>. As support for imaging in diagnostics it is of major importance to assess the degree of exocrine and endocrine insufficiency. The so-called “direct or invasive methods” for assessment of exocrine insufficiency such as the Lundh test has been replaced by methods that are more suitable for screening, although imaging methods such as estimation of pancreatic juice flow during secretin stimulation may end up being a major supplement to screening methods. The pros and cons for different methods to unravel exocrine insufficiency are also outlined in the current issue<sup>[9]</sup>. Treatment of uncomplicated disease is usually conservative, with the major aim to effectively alleviate pain, maldigestion, and diabetes. Malnutrition due to the lack of enzymes results not only in weight loss, but also in specific deficits in vitamins and nutrients that are essential for normal physiological functioning. Malnutrition as complication to chronic pancreatitis is often overlooked and it is of major importance that gastroenterologists are aware of this in the differential diagnosis of patients with weight loss. The paper about nutrition highlights that depletion of nutrients on the one hand and malabsorption (with potential changes in metabolic activity) on the other shall both be considered to avoid severe complications<sup>[10]</sup>. Another frequent complication is pancreatic pain. The pain is severe and often postprandial resulting in malnutrition despite adequate enzyme replacement therapy. There has been an increasing understanding of the pathogenesis of pain in chronic pancreatitis. Hence, many patients suffering from undiagnosed extrapancreatic causes for the pain should be treated appropriately. Although the pain can be related to strictures and stones in the main pancreatic duct, new research has questioned the importance of the micro- and macrostructural pathological findings. Neurogenic pain due to destruction of the nerves may rather play a role for the pain in the majority of patients - and should be treated accordingly<sup>[11]</sup>. In the paper about pain treatment there is an update on the current treatment options and it is highly recommended that clinicians are aware of the possibilities for optimal pain relief<sup>[12]</sup>. Diabetes complicating chronic pancreatitis (type 3c) is a special entity that differs from type 1 and 2 as a variety of hormones apart from insulin are lacking - and the malabsorption also has to be taken into consideration. Despite the importance of this complication few papers have explored the pathogenesis and treatment of type 3c diabetes and this is also updated in the current issue<sup>[13]</sup>.

Finally, there are many challenges when it comes to pharmacological, endoscopical and surgical treatment of chronic pancreatitis. In the paper about pharmacology it is discussed how the influence of complications to the disease is affecting drug absorption and metabolism<sup>[14]</sup>. Surgical and endoscopic interventions are mainly reserved for complications such as pseudocysts, abscesses, and malignancies. There has been a major development of endoscopy in diagnosing complications and treatment of complications such as endosonographic transmural drainage of pseudocysts and biliary strictures and this is discussed in the paper about endoscopy<sup>[15]</sup>. Finally, surgery still has a place in treatment of chronic pancreatitis and should be considered in selected cases.

In conclusion important advances have been made in recent years with respect to our understanding of the pathogenesis of chronic pancreatitis. Although the disease is still difficult to treat the current papers represent useful guidelines on how to approach chronic pancreatitis in the clinical settings with the major aim to improve the patient's suffering and quality of life.

**Key words:** Animal model; Pancreatitis; Visceral pain; Mechanism

**Core tip:** Choosing the right model of pancreatitis is difficult and the scientific rationale needs to be carefully considered. Furthermore, no model of pancreatitis parallels all classical symptoms and the question under investigation is of importance when choosing a model. One of the main symptoms of chronic pancreatitis is visceral pain and in order to improve the pain treatment and obtain more knowledge about the physiology behind the pancreatitis associated visceral pain, animal models of pancreatitis associated visceral pain are needed.

### Abstract

Chronic pancreatitis affects many individuals around the world, and the study of the underlying mechanisms leading to better treatment possibilities are important tasks. Therefore, animal models are needed to illustrate the basic study of pancreatitis. Recently, animal models of acute and chronic pancreatitis have been thoroughly reviewed, but few reviews address the important aspect on the translation of animal studies to human studies. It is well known that pancreatitis is associated with epigastric pain, but the understanding regarding to mechanisms and appropriate treatment of this pain is still unclear. Using animal models to study pancreatitis associated visceral pain is difficult, however, these types of models are a unique way to reveal the mechanisms behind pancreatitis associated visceral pain. In this review, the animal models of acute, chronic and un-common pancreatitis are briefly outlined and animal models related to pancreatitis associated visceral pain

Zhao JB, Liao DH, Nissen TD. Animal models of pancreatitis: Can it be translated to human pain study? *World J Gastroenterol* 2013; 19(42): 7222-7230 Available from: URL: <http://www.wjg-net.com/1007-9327/full/v19/i42/7222.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i42.7222>

### INTRODUCTION

Pancreatitis represents a common disorder of the gastrointestinal tract. Acute pancreatitis (AP) has an incidence ranged from 4.9 to 35 per 100000 populations<sup>[1]</sup>, whereas chronic pancreatitis (CP) has an incidence from 2.4 to 4.4 per 100000 populations<sup>[2]</sup>. The etiology of this disease is complex and so far a variety of environmental factors including alcohol abuse, nicotine habits, hereditary factors, efferent duct obstructions, immunological factors and rare metabolic factors have all been described. However,

the pathophysiology of AP and CP remains poorly defined<sup>[3]</sup>. As a result appropriate therapies are still limited, and prognosis has not improved to date, which is mainly due to the lack of a satisfactory animal model of pancreatitis<sup>[4,5]</sup>.

It is well known that pancreatitis is associated with visceral pain, however, the understanding of pain signaling related to pancreatitis is poor<sup>[6]</sup>. In order to facilitate the development of new pharmaceutical treatments for AP and CP, characterization of the mediators and receptors or ion channels on the sensory nerve terminals and the pathways of the pain signaling are needed. Therefore, in this aspect, the animal models of pancreatitis are needed in parallel in order to explore the mechanism behind pancreatitis associated visceral pain, as this is difficult to study in humans.

In this review, we briefly outline the animal models of acute, chronic and un-common pancreatitis as well as animal models related to pancreatitis associated visceral pain.

## ANIMAL MODELS OF ACUTE PANCREATITIS

AP is an inflammatory condition of the pancreas characterized clinically by abdominal pain and elevated levels of pancreatic enzymes in the blood<sup>[7]</sup>. Other characteristics of AP include edema, acinar cell necrosis, hemorrhage, and severe inflammation of the pancreas. Severe AP may lead to systemic inflammatory response syndrome and multi-organ dysfunction syndrome, which account for the high mortality rates of AP<sup>[8,9]</sup>. As it is difficult to study AP in the clinic, animal studies are important in order to understand the pathogenesis of AP, however an AP model which is strictly comparable to human AP is still needed. The current animal models of AP have contributed to our knowledge of mechanisms involved in early cellular events, pathogenesis and pathophysiology of AP<sup>[10,11]</sup>. We have illustrated the summary of existing AP animal models in Table 1<sup>[12-59]</sup>. Details of different AP animal models including advantages, disadvantages and clinical relevance can be found in a recently published review<sup>[4]</sup>. From a methodological aspect, selecting the appropriate AP animal model depends on the objectives of each study as different animal models are targeted to different AP features. For developing the effective treatment for AP in the clinic, continued investigation of AP animal models are needed.

## ANIMAL MODELS OF CHRONIC PANCREATITIS

A recently published review<sup>[5]</sup> has described the most frequently used and best established models for CP in animals. The majority of the animal models are rodent models, since mice and rats are easy to handle and there is a steadily increasing number of genetic models ob-

**Table 1 Different animal models of acute pancreatitis**

Methods	Models and examples
Non-invasive	Hormone-induced
	Acute caerulein pancreatitis of rats <sup>[12]</sup> , mice <sup>[13]</sup> , dogs <sup>[14]</sup> , and syrian hamsters <sup>[15]</sup>
	Trinidadian scorpion toxin induced acute pancreatitis in dogs <sup>[16]</sup>
	Alcohol-induced: rats <sup>[17-19]</sup> , cats <sup>[20]</sup> and dogs <sup>[21]</sup>
	Immune-mediated
	Ovalbumin in rabbit <sup>[22]</sup>
	Foreign serum in mice <sup>[23]</sup> and rat <sup>[24]</sup>
	Spontaneous model of autoimmune acute pancreatitis mice <sup>[25]</sup>
	Diet-induced: Fed a choline-deficient diet containing ethionine in mice <sup>[26]</sup>
	Gene knockout: Interleukin (IL)-1 and tumour necrosis factor- $\alpha$ <sup>[27]</sup> , IL-6 <sup>[28]</sup> , IL-10 <sup>[29]</sup> , chemoattractant cytokine receptor-1 <sup>[30]</sup> , neurokinin-1 receptor <sup>[31]</sup> , intercellular adhesion molecule 1 (ICAM-1) <sup>[32]</sup> , metallothionein-1 <sup>[33]</sup> , cathepsin B <sup>[34]</sup> , mouse a2-macroglobulin and murinoglobulin <sup>[35]</sup> , complement factor C5a <sup>[36]</sup> , granulocyte-macrophage colony-stimulating factor <sup>[37]</sup> and phospholipase A2 <sup>[38]</sup>
Invasive	<i>L</i> -arginine-induced: Administration of a large dose of <i>L</i> -arginine in rats <sup>[39,40]</sup>
	Closed duodenal loop (CDL): Dog <sup>[41]</sup> and rat <sup>[42,43]</sup>
	Antegrade pancreatic duct perfusion: Cat <sup>[44]</sup> and rat <sup>[45]</sup>
	Various compounds infusion into the pancreatic duct: Rat <sup>[46]</sup> and dog <sup>[47]</sup>
	Combined intraductal glycodeoxycholic acid with intravenous caerulein: Rat <sup>[48]</sup>
	Vascular-induced
	Impairment of pancreatic circulation in dogs <sup>[49]</sup>
	To occlude pancreatic arteries in rats <sup>[50]</sup>
	Occlusion of pancreatic veins in dogs <sup>[51]</sup> and in rats <sup>[52]</sup>
	Complete but reversible ischaemia of the pancreas by occluding different arteries using microvascular clips: Rats <sup>[53]</sup> and canine <sup>[54]</sup>
	Duct ligation
	Ligating the distal bile duct at the level of the duodenum <sup>[55]</sup>
	Combined pancreatic duct ligation with the secretory stimulation, secretin in dogs <sup>[56]</sup>
	Combining duct ligation with both secretory stimulation and minimal arterial blood <sup>[57]</sup>
	Duct-ligated opossums models <sup>[58]</sup>
	Transient obstruction of the sphincter of Oddi (SO) in Australian brush tailed possums <sup>[59]</sup>

tained by gene deletion or transgenic expression of genetic variants. In the same way for animal models of AP, the models of CP can be classified into noninvasive or nonsurgical models and invasive or surgical models. Table 2 summarizes different animal models of CP<sup>[60-100]</sup>.

In the non-invasive models, repetitive caerulein injections are amongst the most widely used models. Firstly, caerulein injections are relatively easy to perform and show a high reliability and reproducibility. Secondly, other compounds mediating injury such as lipopolysaccharides or cyclosporin A can easily be added to the design. Thirdly, serial caerulein injections can be performed in transgenic or knockout animals. It is likely that there are dose and frequency dependency for caerulein. The most translational models include repetitive injections of *L*-arginine, which appears to produce CP similar to that in humans<sup>[70-72]</sup>. In this model, fibrotic tissues are progressively

Table 2 Different animal models of chronic pancreatitis

Methods	Models and examples
Non-invasive	Caerulein-induced Serial caerulein injections in mice <sup>[60]</sup> and rats <sup>[61]</sup> Combination of repetitive caerulein injections with toxins and other agents such as lipopolysaccharides <sup>[62]</sup> , cyclosporin A <sup>[63]</sup> , dibutyltin dichloride <sup>[64]</sup> and Alcohol <sup>[65-67]</sup> Intraperitoneal caerulein injections are administered in genetically transformed mice such as TRX-1 transgenic mice <sup>[68,69]</sup>
	Arginine-induced A single <i>L</i> -arginine injection in rat <sup>[70]</sup> Serial <i>L</i> -arginine injections <sup>[70-72]</sup> Alcohol feeding-induced: Lieber-DeCarli formula <sup>[73-76]</sup> Genetic models: Wistar Bonn/Kobori (WBN/Kob) rats <sup>[77-79]</sup> ; R122H transgenic mice <sup>[80]</sup> ; SPINK3-deficient (SPINK3-/-) mice <sup>[81]</sup> ; CFTR-deficient (cfrtm1UNC) mice <sup>[82]</sup> and CFTR(-/-) pigs <sup>[83]</sup> ; Kif3a-deficient mice <sup>[84]</sup> ; PERK-deficient (PERK-/-) mice <sup>[85]</sup> ; Interleukin 1-β transgenic mice <sup>[86]</sup>
Invasive	Sodium taurocholate-induced: Retrograde infusion of sodium taurocholate (NaTc) into the pancreatic duct system of the rat <sup>[87]</sup> Oleic acid-induced: Retrograde infusion of oleic acid <sup>[72,88-91]</sup> , viscous solution of zein <sup>[92]</sup> , mixture of zein-oleic acid, or viscous solution consisting of zein-oleic acid-linoleic acid <sup>[93,94]</sup> into rat pancreatic duct Congestion of pancreatic fluid flow: Combination of transient stasis of pancreatic juice flow and mild pancreatic duct injury <sup>[95]</sup> Duct ligation model Ligation of the common bile duct close to the duodenum pancreatic tissue in dogs <sup>[96]</sup> , mouse <sup>[97]</sup> and pigs <sup>[98]</sup> Incomplete pancreatic duct ligation in canine <sup>[99]</sup> Occlusion with two different tissue glues in the rat <sup>[100]</sup>

replaced with adipose tissue. Due to the high impact of alcohol consumption as a risk factor on the pathogenesis in human pancreatic diseases, alcohol has frequently been used to trigger CP in animal models<sup>[73,74]</sup>. However, it is still being considered whether a model for CP induced by alcohol alone is feasible or satisfactory. The combination of alcohol feeding with caerulein injections exacerbates the course of pancreatitis and consequently increases pancreatic fibrosis and the loss of parenchyma.

Genetic animal models of CP are suitable for different studies. It is well known that activation of trypsinogen is one of the key events in the early phase of pancreatitis, and therefore genetic abnormalities found in the trypsinogen gene and in its inhibitors might be of particular importance of which R122H transgenic mice<sup>[80]</sup> are a good example. Transgenic expression of the *R122H* mutation of murine trypsin 4 in the pancreas of mice led to progressive fibrosis and chronic inflammation of the pancreas. Repetitive inductions of experimental pancreatitis with supramaximal doses of cerulein resulted in extensive deposition of collagen in periacinar and perilobular spaces of this transgenic animal. However other genetic models might also help us to understand how CP develops<sup>[77-79,81,83-86,101]</sup>.

Invasive animal models can also be used to induce CP. As an example, retrograde infusion of sodium taurocholate (NaTc) into the pancreatic duct<sup>[46]</sup> or intraductal

infusion of NaTc<sup>[72]</sup> can generate pancreatitis, however the structure of the pancreatic tissue will return to an almost normal state after 14 d. Retrograde infusion of oleic acid<sup>[72,88-91]</sup>, viscous solution of zein<sup>[92]</sup>, a mixture of zein-oleic acid or a viscous solution consisting of zein-oleic acid-linoleic acid<sup>[93,94]</sup> into rat pancreatic duct will cause severe pancreatic atrophy with irregular fibrosis and fat replacement over a period of 6 mo. However, these models of pancreatitis appear quite distinct from CP in humans. As one factor alone is inadequate to cause persistent pancreatic injury, a combination of transient stasis of pancreatic juice flow and mild pancreatic duct injury is a well established and reliable method to generate CP in animal models<sup>[95]</sup>. It is well known that pancreatic ductal hypertension contributes to the pathogenesis of CP; therefore animal models can also be generated by complete obstruction of the pancreatic duct<sup>[96-98]</sup>, incomplete pancreatic duct ligation<sup>[99]</sup> and occlusion with different tissue glues<sup>[100]</sup>. Yamamoto *et al*<sup>[102]</sup> developed an animal model with pancreatic ductal hypertension and demonstrated that this plays an important role in the onset and development of CP in rats. However, models for CP based on duct obstruction are not common and there is only a minority of studies examining the morphological and biochemical changes of the pancreas after duct ligation<sup>[41,103,104]</sup>.

## ANIMAL MODELS OF UN-COMMON PANCREATITIS

Un-common types of pancreatitis can include autoimmune pancreatitis (AIP), hereditary pancreatitis<sup>[105]</sup>, groove pancreatitis<sup>[106]</sup>, tropical pancreatitis, pancreatitis in ectopic or heterotopic pancreatic tissue, ascaris-induced pancreatitis, pancreatitis in cystic fibrosis, pancreas divisum, annular pancreas, pancreatic cancer manifesting as AP, and duodenal villous adenoma with pancreatitis. With exception of AIP and hereditary pancreatitis, no relevant animal models were found for other un-common pancreatitis. Furthermore, hereditary pancreatitis animal models were mentioned in the genetic animal models of CP above. Therefore only animal models of AIP are briefly introduced in this section.

To date, several animal models of AIP have been described. The first model involves the adoptive transfer of amylase-specific (an antigen mainly located in acinar cells) CD4<sup>+</sup> T cells and results in pancreatitis in naive syngenic recipient animals<sup>[107]</sup>. Notably, the histological lesions of this model mimic the lobulocentric inflammatory reaction in type 1 AIP. A model developed by immunization of neonatally thymectomized mice with CA (an antigen mainly located on the pancreatic epithelium) and later transfer of CD4<sup>+</sup> lymphocytes resulted in a duct-centric pattern of pancreatitis resembling type 2 AIP<sup>[108]</sup>. In another model, NTx-NFS/sld mice spontaneously developed sialoadenitis in which α-fodrin was involved as an autoantigen, as reported in some patients with Sjogren syndrome and AIP<sup>[109]</sup>. Transforming growth factor-β

(TGF $\beta$ ) appears to be an important regulatory factor in maintaining immune homeostasis. Loss of TGF $\beta$  signaling contributes to AIP in TGF $\beta$  dominant negative mutant mice<sup>[110]</sup>.

Recently two animal models for AIP were proposed. The WBN/Kob rat model, associated with congenital decreased peripheral Tregs spontaneously develops sialoadenitis, thyroiditis, sclerosing cholangitis and tubulointerstitial nephritis<sup>[111]</sup>. Although the target antigens remain unclear, CD8<sup>+</sup> cells may be the effector cell in this rat model<sup>[112]</sup>. Another recently described animal model of AIP is the Treg-deficient NOD mouse<sup>[113]</sup>. CD28KO mice spontaneously develop AIP that closely resembles the human disease<sup>[113]</sup>. More recently, Haruta *et al.*<sup>[114]</sup> investigated the possible involvement of chronic, persistent exposure to avirulent bacteria in the pathogenesis of AIP using C57BL/6 mice.

Existing animal models for AIP have several limitations. In most models the disease is induced by adoptive transfer of autoreactive cells and/or antibodies rather than spontaneous development of the disease with identical antigen specificity. The distribution of lesions produced in animal models for AIP is also variable. This may be attributed to the diversity of target antigens, different methods of immune staining and different mouse strains. In addition, typical histopathological findings of AIP (*e.g.*, lymphoplasmacytic infiltration with fibrosis, obliterative phlebitis and GELs) are rarely observed in animal models. Thus, there is a need to develop spontaneous animal models with identical autoantigens and typical histopathological findings for AIP.

## VISCERAL PAIN IN ANIMAL MODELS OF CHRONIC PANCREATITIS

One of the main clinical symptoms of CP in humans is pain, occurring either in episodes or as a constant disabling pain<sup>[115,116]</sup>. Hence, an important goal of treatment for CP is to relieve the pain. The analgesic treatment is often inadequate as the pathophysiology behind CP as well as the mechanisms behind the accompanying pain is not yet fully understood<sup>[117]</sup>. As described in the previous sections, no single animal model displays all aspects of CP and each of the different models display histological similarities to the human condition to various degrees. In order to improve the pain treatment and obtain more knowledge about the physiology behind CP associated pain, animal models of CP associated pain are needed.

Rat models of CP where pancreatic nociception was investigated, have been established through invasive, non-invasive and spontaneous models<sup>[118,119]</sup>. In these models pancreatic pain has been shown through both mechanical and thermal stimulation of the abdomen (referred pain<sup>[120]</sup>) as well as direct electrical stimulation of the pancreas<sup>[118,121]</sup>. These models had histopathological similarities to the human disease and had progressive fibrosis and inflammation. Furthermore, the models showed correlation between nociceptive behaviour and increased

expression of nerve growth factor (NGF) in the pancreas and calcitonin gene-related peptide (CGRP), substance P (SP), proteinase-activated receptor 2 (PAR2), and brain-derived neurotrophic factor (BDNF) in thoracic dorsal root ganglion and spinal cord segments<sup>[118,122-124]</sup>. Increased expression of NGF, CGRP, SP and BDNF has also been shown in human patients with CP<sup>[125-127]</sup>.

Several animal models have investigated the mechanisms involved in pain accompanying CP. Takamido *et al.*<sup>[119]</sup> reported morphological changes of the nervous system being involved in development of CP pain. This study suggested that elongation of dorsal root ganglia axons and enlargement of intrapancreatic nerve bundles as being a possible mechanism of pain generation in CP. On a supraspinal level, findings have suggested that descending facilitation from the rostral ventromedial medulla plays an important role in persistent pain associated with CP<sup>[128]</sup>. Furthermore, recent rat experiments have suggested that spinal microglia becomes activated during CP and has an important role in initiating and maintaining chronic pain<sup>[129]</sup>.

## TRANSLATION OF PANCREATITIS-ASSOCIATED VISCERAL PAIN STUDY FROM ANIMAL TO HUMAN

It may be difficult to use animal models to study pancreatitis associated visceral pain as pain is a subjective experience. However animal models are needed to explore the molecular mechanisms behind pancreatitis associated visceral pain as this is difficult to study in humans. The molecular mechanisms behind the chronic pain associated with CP are poorly understood, but within recent years, animal experiments have suggested some mechanisms that might be involved. The transient receptor potential vanilloid 1 (TRPV1) and transient receptor potential ankyrin 1 (TRPA1) have been shown to be contributing factors to pain in CP<sup>[122,130,131]</sup>. It has been shown that CP is accompanied by an increased level of NGF which caused an up-regulation of TRPV1 expression and sensitivity, resulting in hyperalgesia and allodynia<sup>[122,130]</sup>. TRPA1 is important in both inflammation and pain in CP and can be sensitized through activation of PAR2<sup>[131]</sup>.

The mechanisms mentioned above could be used as targets for the development of novel therapeutics, aiming at treating the chronic pain accompanying CP. Neutralizing antibodies against neurotransmitters such as BDNF and NGF<sup>[124,130]</sup> or receptor specific antagonists<sup>[122]</sup> has proven to reverse the characteristic nociceptive behavioral changes induced by CP in several of the experimental models. Furthermore, inhibition of trypsin or inhibition of microglia activation has also abrogated the pain related behavior seen in response to CP<sup>[123,129]</sup>. All these different mechanisms of pain treatment in CP models could have a potential as targets for novel pharmacological treatment of the chronic pain associated with CP in human patients. Also established analgesic drugs such as gaba-

pentin, buprenorphine, and morphine have been tested in animal models of CP<sup>[118,121,132]</sup>, and shown to have analgesic effect. However, many of these therapeutic approaches need to be tested in humans, before their true potential analgesic treatment of CP pain in humans can be established. It is known that some of these analgesic mechanisms are species specific and specific to the different models of induced CP.

## CONCLUSION

Choosing the right model of pancreatitis is difficult and the scientific rationale needs to be carefully considered. Furthermore, no model of pancreatitis parallels all classical symptoms and the question under investigation is of importance when choosing a model. One of the main symptoms of CP is visceral pain and in order to improve the pain treatment and obtain more knowledge about the physiology behind the pancreatitis associated visceral pain, animal models of pancreatitis associated visceral pain are needed.

### Abstract

Chronic pancreatitis (CP) is an inflammatory disease of the pancreas characterized by progressive fibrotic destruction of the pancreatic secretory parenchyma. Despite the heterogeneity in pathogenesis and involved risk factors, processes such as necrosis/apoptosis, inflammation or duct obstruction are involved. This fibrosing process ultimately leads to progressive loss of the lobular morphology and structure of the pancreas, deformation of the large ducts and severe changes in the arrangement and composition of the islets. These conditions lead to irreversible morphological and structural changes resulting in impairment of both exocrine and endocrine functions. The prevalence of the disease is largely dependent on culture and geography. The etiological risk-factors associated with CP are multiple and involve both genetic and environmental factors. Throughout this review the M-ANNHEIM classification system will be used, comprising a detailed description of risk factors such as: alcohol-consumption, nicotine-consumption, nutritional factors, hereditary factors, efferent duct factors, immunological factors and miscella-

neous and rare metabolic factors. Increased knowledge of the different etiological factors may encourage the use of further advanced diagnostic tools, which potentially will help clinicians to diagnose CP at an earlier stage. However, in view of the multi factorial disease and the complex clinical picture, it is not surprising that treatment of patients with CP is challenging and often unsuccessful.

**Key words:** Chronic pancreatitis; Pathogenesis; Risk factors; Etiology

**Core tip:** The reported prevalence of chronic pancreatitis (CP) is approximately 0.5%. Etiological risk-factors associated with CP are multiple and throughout the review the M-ANNHEIM classification is used comprising environmental factors (alcohol consumption, nicotine habits and nutrition), hereditary, well characterized mutations, ductal obstruction and autoimmune factors. CP is characterized by progressive fibrotic destruction of glandular tissue, inflammation or duct obstruction, leading to irreversible functional impairment of both exocrine and endocrine functions. In view of the multi-factorial disease and the complex clinical picture, it is not surprising that treatment of patients with CP is challenging and often unsuccessful.

Brock C, Nielsen LM, Lelic D, Drewes AM. Pathophysiology of chronic pancreatitis. *World J Gastroenterol* 2013; 19(42): 7231-7240 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i42/7231.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i42.7231>

### INTRODUCTION

The reported prevalence of chronic pancreatitis (CP) var-

ies due to differences in study design, diagnostic criteria, culture and geography; however in Europe and United States it is relatively rare varying between 0.2% and 0.6%<sup>[1]</sup>. The annual incidence is estimated to be approximately 7-10 per 100000<sup>[2]</sup>. The etiological risk-factors associated with CP are multiple and involve environmental factors (alcohol consumption, nicotine habits and nutrition), hereditary well characterized mutations, ductal obstruction and autoimmune factors<sup>[3]</sup>. CP is characterized by progressive fibrotic destruction of the glandular tissue. The secretory parenchyma is destroyed by processes such as necrosis/apoptosis, inflammation or duct obstruction. Increasing evidence indicates that pancreatic stellate cells (PSC) are the major mediators of fibrosis, resulting in the formation of extracellular matrix (ECM) in the interstitial spaces and in the areas where acinar cells disappear or duct cells are injured. This process ultimately leads to progressive loss of the lobular morphology and structure of the pancreas, bizarre deformation of the large ducts and severe changes in the arrangement and composition of the islets. The fibrotic destruction of the pancreatic gland is irreversible and the morphological and structural changes lead to functional impairment of both exocrine and endocrine functions, eventually leading to malnutrition and/or diabetes<sup>[3-6]</sup>. In many aspects the PSCs share many similar features to hepatic stellate cells and glomerular mesangial cells. The onset of pancreatic fibrogenesis is caused by injury which may involve interstitial mesenchymal cells, the duct cells and/or the acinar cells. Which of these elements is affected depends on the etiological risk factor. However, destruction to any one of these pancreatic tissue compartments is associated with transformation of resident fibroblasts/pancreatic stellate cells into myofibroblast-like phenotypes; a process called activation. In the activated state PSCs express  $\alpha$ -smooth muscle actin ( $\alpha$ -SMA), proliferate, and secrete fibrillar collagens, including collagen I and III and fibronectin. All together this production and deposition of ECM is characteristic in chronic pancreatic fibrosis, and the PSCs likely represent the wound-healing myofibroblasts of the pancreas<sup>[7,8]</sup>. The exact pathophysiological mechanisms initiating and maintaining the development of fibrosis in the pancreas are poorly understood, but may be viewed as a progression similar to, *e.g.*, liver fibrosis<sup>[9]</sup>. Hence, the initial injury to one or all of the various tissue compartments or cell types of the pancreas, leads to cell necrosis and/or apoptosis and consequently release of cytokines/growth factors (*e.g.*, tumor growth factor b1, interleukin-8, platelet-derived growth factor and CC-chemokines), either from immigrating inflammatory cells, especially macrophages, and/or nearby preexistent epithelial or mesenchymal cells<sup>[10-13]</sup>. Thereafter damaged cells are phagocytosed by macrophages, causing release of cytokines, which in turn causes activation and proliferation of resident fibroblasts/PSC situated in the immediate surroundings of the original site of injury, which accordingly induces transformation into myofibroblast cells<sup>[7,14]</sup>. However, it has also been suggested as an alternative hypothesis, that the abovementioned progression is bypassed,

**Figure 1** The etiological risk-factors associated with chronic pancreatitis are multiple and involve both genetic and environmental factors. According to the M-ANNHEIM classification system, different synergistic risk factors are known such as: alcohol-consumption, nicotine-consumption, nutritional factors, hereditary factors, efferent duct factors, immunological factors and miscellaneous and rare metabolic factors. CP: Chronic pancreatitis.

and the initiating etiological factor (for instance, ethanol consumption) activates resident fibroblasts directly. In the final stage, myofibroblasts produce and extracellular matrix deposits replace the inflammatory infiltrate and affect the architecture and function of the remaining pancreatic tissues<sup>[4]</sup>. Subsequently, a vicious circle has started, because in order to facilitate the deposition of the newly formed ECM, myofibroblasts enhance production of specialized enzymes, such as metalloproteinase matrix metalloproteinase (MMP)-3 and MMP-9, which are able to demolish the normal pericellular ECM. These metalloproteinases are in return regulated by cytokine tumor growth factor (TGF)- $\beta$ 1s, which through autocrine inhibition enhances pancreatic fibrogenesis by reducing collagen degradation<sup>[8]</sup>. As a consequence of declined ECM production (due to withdrawal of the initiating factor), myofibroblasts may disappear either through apoptosis or retransformation into fibroblasts. Furthermore, pancreatic stellate cells express both mediators of matrix remodeling and the regulatory cytokine TGF- $\beta$ 1 that, by autocrine inhibition of MMP-3 and MMP-9, may enhance fibrogenesis by reducing collagen degradation<sup>[8]</sup>. Pancreatic stellate cells express both mediators of matrix remodeling and the regulatory cytokine TGF- $\beta$ 1 that, by autocrine inhibition of MMP-3 and MMP-9, may enhance fibrogenesis by reducing collagen degradation<sup>[8]</sup>.

To describe the heterogeneity of the underlying pathophysiology we have throughout the review used the M-ANNHEIM classification<sup>[3]</sup>, comprising detailed description of Multiple risk factors such as: alcohol-consumption, nicotine-consumption, nutritional factors, hereditary factors, efferent duct factors, immunological factors and miscellaneous including rare metabolic factors (Figure 1). Increased knowledge of the different etiological factors may encourage the use of further advanced diagnostic tools, which potentially will help clinicians to diagnose CP at an earlier stage.

Figure 2 A schematic overview showing the overall hypothesis for the pathogenesis of alcoholic chronic pancreatitis. The effect of ethanol and its metabolites on the subcellular organelles include increased digestive and lysosomal enzyme content [due to increased synthesis (increased mRNA) and impaired secretion (1)] and destabilization of lysosomes (L) (2) and zymogen granules (ZG) [mediated by oxidant stress, cholesteryl esters (CE) and fatty acid ethyl esters (FAEE) (3)]. These changes will make the cell more sensitive to trigger factors and in the presence of appropriate trigger factors, overt acinar cell injury is initiated (alcoholic acute pancreatitis). Pancreatic stellate cells are activated by cytokines during alcohol-induced necroinflammation, or directly by ethanol *via* its metabolism to acetaldehyde and the subsequent generation of oxidant stress (4). Activated pancreatic stellate cell then increases the synthesis of extracellular matrix proteins leading to pancreatic fibrosis. Modified from Vonlaufen *et al*<sup>[84]</sup> (5).

However, in view of the multi-factorial disease and the complex clinical picture, it is not surprising that treatment of patients with CP is challenging and often unsuccessful.

According to the M-ANNHEIM classification, the following etiological risk factors are involved in the pathogenesis of chronic pancreatitis.

## ALCOHOL CONSUMPTION

A relationship between alcohol consumption and pancreatic impairment has been reported as early as 1878<sup>[15]</sup> and hence, alcohol intake has long been regarded as the primary cause of chronic pancreatitis. Nowadays, there is satisfactory indication that the pancreas has the ability to metabolize ethanol *via* both oxidative and the non-oxidative pathways<sup>[16]</sup>. The metabolites and their byproducts injure acinar cells and activate stellate cells to produce and deposit ECM (Figure 2). A study by Dufour *et al*<sup>[17]</sup> suggested that CP development is associated to the dose and duration of alcohol consumption. It was estimated that approximately 80 g of alcohol per day for a minimum of 6-12 years is required to produce symptomatic pancreatitis. However, the consumption of lesser quantities may also lead to pancreatic injury and may have an impact on the progression of the disease<sup>[18]</sup>. In order to consider the risks associated with lower consumption of alcohol, the M-ANNHEIM classification system of CP grouped alcohol consumption into patterns of moderate

(< 20 g pure ethanol per day), increased (20-80 g pure ethanol per day), or excessive (> 80 g pure ethanol per day)<sup>[3]</sup>. While alcohol consumption is doubtlessly a contributing factor in CP, it must be noted, that considerable amount of recent epidemiological studies and animal experiments suggest that alcohol alone is not sufficient to induce CP. An overview of the associations between alcohol consumption and other risk factors are listed in Table 1.

A multi-centre study from Italy reported that excessive alcohol consumption was the principal factor in only 34% of cases of CP<sup>[19]</sup> and an assessment from the United States concluded it was the main factor in 44% of CP cases<sup>[20]</sup>. Moreover, African-Americans are at particular risk of developing alcoholic CP<sup>[21]</sup>. Overall, less than 10% of heavy alcohol consumers develop alcoholic induced CP<sup>[17]</sup>. Hence, several theories have been proposed as to how alcohol might lead to CP, but no clear-cut answer exists as prolonged feeding of ethanol does not trigger the onset of CP in itself. Therefore, there are indications that alcohol sensitizes the pancreas to other external factors which interact to increase ethanol toxicity *in vivo*, such as cigarette smoking and diet<sup>[22]</sup> or genetic predisposition). Interestingly, alteration of pancreatic secretory trypsin inhibitor (*SPINK1*, Figure 3) and *CFTR* genes was present in patients with alcoholic CP and the increase of those genes was moreover associated with higher levels of alcohol consumption<sup>[23]</sup>. In this line, a recent study<sup>[24]</sup> found a genetic variant on chromosome X near the *CLDN2* gene

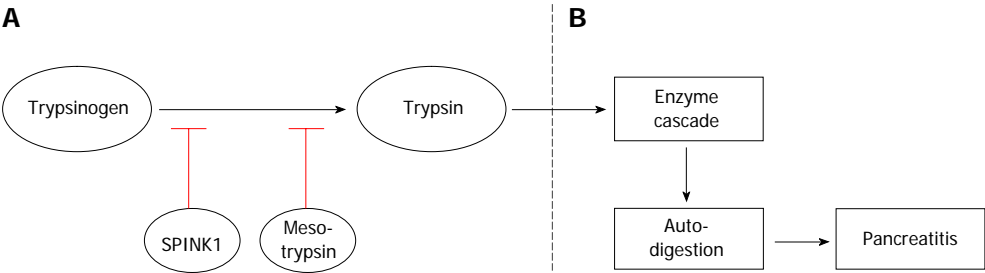

Figure 3 A scheme representing the role of digestive enzymes in normal pancreatic tissue and in the case of pancreatitis. A: In a normal pancreas, SPINK1 (first line of defense) and mesotrypsin (second line of defense) inhibit the generation of trypsin resulting from auto-activation of trypsinogen. These defense mechanisms prevent the pancreas from activating the pancreatic enzyme cascade and auto-digestion; B: If mutations are present in the SPINK1 and/or in the mesotrypsin gene, they losses their ability to inhibit the generation of trypsin resulting in activation of enzyme cascade and subsequent pancreatic auto-digestion leading to pancreatitis. SPINK1: Serine protease inhibitor, kazal type 1, gene (encodes for pancreatic secretory trypsin inhibitor).

Table 1 Association with alcoholic chronic pancreatitis

Factor	Association
Drink type	Yes: Vonlaufen <i>et al</i> <sup>[83]</sup> Nakamura <i>et al</i> <sup>[84]</sup> No: Levy <i>et al</i> <sup>[29]</sup> Wilson <i>et al</i> <sup>[85]</sup>

that predicts which heavy drinking males were in higher risk of developing CP.

### NICOTINE CONSUMPTION

Smoking has been identified as an important risk factor for development of chronic pancreatitis. The effect of tobacco in CP was first described in 1994<sup>[25]</sup>, where heavy smokers had a significantly increased risk of developing pancreatic calcifications but no effects of alcohol were

found. Another study reported that cigarette smoking increased the risk of pancreatic calcifications in late onset idiopathic CP in a population that never drank alcohol<sup>[26]</sup>. Moreover, a study by Maisonneuve *et al*<sup>[27]</sup> showed that smoking accelerated the degenerative alcohol induced pancreatitis quantified by the presence of calcifications and diabetes. Recently, a study reported that tobacco increased the occurrence of all major complications of alcoholic CP depending on the amount of smoking (1 pack-year is calculated as the number of cigarettes per day, multiplied by the number of years of smoking divided by 20 cigarettes/pack)<sup>[28]</sup>. No differences in CP outcome were seen at nicotine consumption corresponding to 10 pack-years. At a threshold of 15 pack-years CP was diagnosed earlier (36 years *vs* 46 years) and at nicotine consumption threshold of 20 pack-years up to 76% of patients were presented with pancreatic calcifications and ductal changes<sup>[28]</sup>. Tobacco effect on CP has long been considered to merely potentiate the main pancreatic toxic role of alcohol. However, although heavy smokers tended to be heavy drinkers, these recent findings indicate that tobacco intake is an independent risk factor in CP and accelerates the course of the disease.

### NUTRITIONAL FACTORS

Only a few studies were conducted to investigate nutritional effect on CP<sup>[29-31]</sup>, finding that diets rich in fat and protein possibly have an impact on the development of CP. However, due to subjective descriptions of daily nutritional customs and determination of the retrospective body mass index make it nearly impossible to deliver a simple report of past daily nutrition in majority of patients with CP. There is a type of CP named tropical CP which has been first described in Indonesia in 1959<sup>[32]</sup>. Tropical CP is a form of non-alcoholic CP existing in tropical developing countries. There is some confusion regarding the nomenclature sine tropical CP previously was hypothesized to be linked to diets high in consumption of cassava<sup>[33]</sup>, which is a root high in carbohydrates but low in proteins and is cultivated in tropical and subtropical regions of the world. However, a study in rats which were fed cassava for up to one year failed to

produce CP<sup>[34]</sup>. Moreover, a study in humans comparing the amount of consumption of cassava did not observe a difference between healthy controls and tropical CP patients<sup>[35]</sup>, and today tropical pancreatitis is - at least partly - linked to genetic mutations<sup>[36]</sup>. Hence, tropical CP is widespread in parts of India and Africa where cassava is not a part of nutrition and tropical CP is not observed in rural West Africa where cassava intake is high<sup>[37]</sup>. Therefore, the cassava theory lacks evidence.

## HEREDITARY FACTORS

Over the last decades an association between different types of chronic pancreatitis and hereditary factors has been reported. Hereditary chronic pancreatitis is a rare form which is characterized by an early onset of recurrent attacks of severe epigastric pain usually before ten years of age<sup>[38]</sup>. Back in 1952, Comfort and Steinberg<sup>[39]</sup> first described hereditary chronic pancreatitis as an autosomal dominant disease. In 1996, the hereditary chronic pancreatitis disease gene was mapped to chromosome 7q35, which encodes the cationic trypsinogen gene (*PRSS1*), and the first mutation, *R122H*, was detected<sup>[40]</sup>. Ever since then, many others mutations have been identified (*A16V*, *D22G*, *K23R*, *N29I*, *N29T*, *R122C* and *R122H*)<sup>[41-46]</sup> and nowadays it is known that approximately 80% of hereditary chronic pancreatitis patients have a *PRSS1* mutation<sup>[47]</sup>. *R122H* is the most frequent mutation causing hereditary chronic pancreatitis, where Arginine (Arg) is substituted with Histidine (His) at residue 117 on codon 122<sup>[5]</sup>.

Trypsinogen is the inactive pro-enzyme for trypsin and cationic trypsinogen is the most abundant isoform in the human pancreatic juice (Figure 3). Trypsin becomes active when an eight-amino acid amino-terminal peptide is removed by an enteropeptidase, and the active trypsin plays a central role in pancreatic exocrine physiology as it initiates the cascade activation of other pancreatic digestive enzymes. Normally minor amounts of trypsin are activated within pancreatic acinar cells. Despite the small amount of active trypsin, an ongoing rapid inactivation takes place in order to prevent the digestion enzymes activation cascade and pancreatic auto digestion. To avoid auto digestion, two inhibitory mechanisms are present. First line of defense is the pancreatic secretory trypsin inhibitor (*PSTI*, gene name: serine protease inhibitor, kazal type 1, *SPINK1*), which inhibits up to 20 % of the trypsin activity<sup>[38,48]</sup>. If *SPINK1* fails to inhibit the trypsin activity, the trypsin-like enzymes (*e.g.*, mesotrypsin) are activated which hydrolyses trypsin and other zymogens (second line of defense)<sup>[49,50]</sup>. Hence, any mutation in *SPINK1* or the mesotrypsin gene will delay the protection, and therefore hereditary chronic pancreatitis patients are only protected against pancreatic auto digestion and progressive pancreatitis as long as the level of trypsin activity is less than *SPINK1* level.

In addition, a diagnosis of familial pancreatitis refers to pancreatitis from any cause that occurs in family with

an incidence greater than expected by chance alone, given the size of the family and incidence of pancreatitis within a defined population<sup>[51]</sup>. Familial pancreatitis may as well be caused by genetic mutations.

As mentioned above *SPINK1* encodes *PSTI* (one of the defensive mechanisms against prematurely trypsin activity within the acinar cells) and *SPINK1* mutations are thought to be a disease modifying factor rather than being disease causing factor in idiopathic chronic pancreatitis<sup>[52,53]</sup>.

Idiopathic chronic pancreatitis is defined as cases of pancreatitis within a family where no associated factor can be identified and represents 20%-30% of cases of chronic pancreatitis<sup>[54,55]</sup>. Most of the idiopathic chronic pancreatitis cases may be due to a variety of processes such as mutations in *SPINK1* and cystic fibrosis transmembrane conductance regulator (*CFTR*) gene<sup>[54-56]</sup>, or Sjögren's syndrome<sup>[57,58]</sup>.

In 1998 a relationship between the *CFTR* gene and idiopathic chronic pancreatitis was described<sup>[59,60]</sup>, but the underlying mechanisms leading to the development of chronic pancreatitis are still poorly understood. *CFTR* is identified as the cystic fibrosis gene and the link between cystic fibrosis and chronic pancreatitis is that both conditions may show abnormal sweat chloride concentrations together with pancreatic ductal obstruction caused by inspissated secretions. Furthermore, 1%-2% of patients with cystic fibrosis may suffer from recurrent pancreatitis<sup>[60,61]</sup>, however up to 85% suffer from exocrine insufficiency and even up to 93% take exogenous pancreatic supplements<sup>[62]</sup>.

There are two forms of idiopathic chronic pancreatitis: early- and late-onset pancreatitis, which both differ from alcoholic pancreatitis. Patients with early-onset develop calcification and exocrine and endocrine insufficiency more slowly than patients with late-onset disease, but they experience more severe pain<sup>[63]</sup>.

## EFFERENT DUCT FACTORS

Anatomically, the main pancreatic duct joins the common bile duct, after which both ducts perforate the medial side of the second portion of the duodenum at the major duodenal papilla. Hence any obstruction (partial or complete), compression or inflammation of the pancreatic tissue will increase the pressure within the pancreatic efferent ducts leading to ductal dilation proximal (upstream) of the stenosis and to atrophy of the acinar cells and replacement by fibrous tissue<sup>[4]</sup>. During embryogenesis, two efferent pancreatic ducts, a ventral and a dorsal duct fuse together to form one main pancreatic duct. When this fusion fails to occur, a pancreas divisum is formed, which is one of the most frequent congenital ductal anomalies. Theoretically this may cause flow problems within the pancreatic duct. However, pancreas divisum is present in up to 9% of autopsy studies and controversies exist whether presence of this abnormality is overrepresented in chronic pancreatitis in comparison to the normal pop-

ulation. Despite the rarity (5-15 cases per 100000), annular pancreas is another congenital disease which may be linked to chronic pancreatitis, as the pancreatic tissue forms a complete or partial ring around the duodenum<sup>[64]</sup>.

There are various other possible causes for a duct obstruction, but the most important and common is the narrowing and eventual occlusion of the main pancreatic duct in the head of the pancreas due to a ductal adenocarcinoma. Other causes for obstruction of the main pancreatic duct include intraductal papillary-mucinous neoplasms, cystic and endocrine neoplasms and acquired fibrous strictures. In the smaller pancreatic ducts, ductal papillary hyperplasia is a common cause of narrowing of the duct lumen. Finally, obstruction caused by a gallstones in the common bile duct (choledocholithiasis) or sphincter of Oddi dysmotility can obstruct flow and therefore cause retention of bile in the biliary tree and pancreatic juice in the pancreatic duct. The former is a frequent and well-known cause for acute pancreatitis.

## IMMUNOLOGICAL RISK FACTORS

Immunological risk factors involved in chronic pancreatitis leading to autoimmune pancreatitis (AIP) deserve increased awareness as the underlying pathogenesis is not fully elucidated. The effort to diagnose autoimmune pancreatitis is mainly focused on the treatment possibilities with *e.g.*, glucocorticosteroids and differentiating the disease from pancreatic cancer. There are several lines of evidence that immunological factors play a key role in CP. Even though lymphoplasmacytic infiltration in AIP is most pronounced in the pancreatic ducts, advanced cases also show intralobular lymphoplasmacytic infiltration, and the inflammation may also specifically attack the acinar cells. IgG antibodies to a plasminogen-binding protein homologous to the human ubiquitin-protein ligase E3 component n-recogin 2, is expressed in pancreatic acinar cells, and have been found in the sera of AIP patients<sup>[65]</sup>. In AIP patients auto-antibodies to trypsinogens are also upregulated, which is not the case in alcohol induced chronic pancreatitis patients, corresponding to loss of trypsinogen-positive acinar cells in AIP tissues<sup>[66]</sup>. Furthermore, basement membrane deposits of complement C3c, IgG4 and IgG not only around pancreatic ducts but also around acini have been demonstrated in AIP<sup>[67]</sup>.

Even though it has not yet been fully proved that there are differences in the pathogenesis, AIP is separated into two distinct types: Type 1 and type 2 AIP.

Type 1 AIP patients (most common type in East Asia) are typically older than type 2 patients, with a mean age at disease onset of 62 years<sup>[68]</sup>. Plasma levels of IgG4 are increased and in approximately 50% of the cases other organs are affected<sup>[68,69]</sup>. The key histological feature that distinguishes type 1 AIP from type 2 AIP is strong infiltration of IgG4-immunopositive plasma cells and lymphoplasmacytic infiltration<sup>[70,71]</sup>. IgG4-positive sclerosing cholangitis represents one of the main extrapancre-

atic manifestations of type 1 AIP, and hence jaundice is a common symptom<sup>[72]</sup>. Due to the multiple extrapancreatic manifestations of type 1 AIP, Kamisawa *et al.*<sup>[73]</sup> promoted the concept of AIP as part of a clinicopathological entity of IgG4-associated systemic disease, together with retroperitoneal fibrosis, sclerosing sialadenitis and sclerosing cholangitis. This systemic fibroinflammatory disease probably also includes lesions in the aorta, breast and prostate<sup>[73-76]</sup>.

Type 2 AIP patients (45% of the cases in United States and Europe) are typically younger than type 1 AIP, with a mean age of 40-48 years<sup>[68,77]</sup>. AIP is often associated with Crohn's disease and ulcerative colitis<sup>[78]</sup>. The most characteristic histological feature which distinguishes type 2 from type 1 AIP is the so-called granulocytic epithelial lesions which are a hallmark of type 2 AIP<sup>[77,79]</sup>. Besides, type 2 AIP is usually not associated with the extrapancreatic manifestations observed in type 1 AIP.

## MISCELLANEOUS

### *Tropical chronic pancreatitis*

Tropical chronic pancreatitis may be referred to an idiopathic, juvenile, non-alcoholic form of chronic pancreatitis widely prevalent in the developing countries of the tropical world. Tropical chronic pancreatitis can be sub-grouped in two entities: Tropical calcific pancreatitis and fibrocalculous pancreatic diabetes. Tropical calcific pancreatitis describes the early pre-diabetic stage of the disease and affects younger people. Tropical calcific pancreatitis is characterized by severe abdominal pain, pancreatic calcification, and signs of pancreatic dysfunction (no diabetes mellitus at the time of diagnosis). Fibrocalculous pancreatic diabetes describes the late diabetic stage of the disease where diabetes mellitus is the first major clinical sign to determine the diagnosis of fibrocalculous pancreatic diabetes. The etiology of tropical calcific pancreatitis and fibrocalculous pancreatic diabetes has shown to be related to genetic mutations in the *SPINK1* gene, but it is still unknown if environmental factors have an influence<sup>[36,80-82]</sup>.

### *Primary hypercalcemia*

It has been suggested that higher serum calcium levels may contribute to pancreatitis, as hypercalcemia may predispose the pancreatic acinar cell to abnormal, sustained calcium levels, which leads to premature pancreatic protease activation, and consequently pancreatitis.

### *Hyperparathyroidism*

Controversies exist regarding associations between primary hyperparathyroidism and acute or chronic pancreatitis. However, most studies show an increased rate of pancreatitis among patients with primary hyperparathyroidism in comparison to general hospitalized patients without the disease.

### *Hyperlipidemia*

Hyperlipidemia covers abnormally elevated levels of any

or all lipids, lipoproteins or both in the blood. Hyperlipidemia can be divided in primary and secondary subtypes. Lipid and lipoprotein abnormalities are relatively common in the general population, and are regarded as a modifiable risk factor associated with acute pancreatitis.

## CONCLUSION

Increased knowledge of different etiological factors and how they interact may encourage the use of further advanced diagnostic tools, which potentially will help clinicians to diagnose and treat CP at an earlier stage. Recent research has increased our understanding of the disease and has changed the approach to CP. However, in view of the multi-factorial disease and the complex clinical picture, it is not surprising that treatment of patients with CP is challenging and often unsuccessful.

### Abstract

Magnetic resonance imaging (MRI) techniques for assessment of morphology and function of the pancreas have been improved dramatically the recent years and MRI is very often used in diagnosing and follow-up of chronic pancreatitis (CP) patients. Standard MRI including fat-suppressed T1-weighted and T2-weighted imaging techniques reveal decreased signal and glandular atrophy of the pancreas in CP. In contrast-enhanced MRI of the pancreas in CP the pancreatic signal is usually reduced and delayed due to decreased perfusion as a result of chronic inflammation and fibrosis. Thus, morphological changes of the ductal system can be assessed by magnetic resonance cholangiopancreatography (MRCP). Furthermore, secretin-stimulated MRCP is a valuable technique to evaluate side branch pathology and the exocrine function of the pancreas and diffusion weighted imaging can be used to quantify both parenchymal fibrotic changes and the exocrine function of the pancreas. These standard and advanced MRI techniques are supplementary techniques to reveal morpho-

logical and functional changes of the pancreas in CP. Recently, spectroscopy has been used for assessment of metabolite concentrations *in-vivo* in different tissues and may have the potential to offer better tissue characterization of the pancreas. Hence, the purpose of the present review is to provide an update on standard and advanced MRI techniques of the pancreas in CP.

### INTRODUCTION

The diagnosis and follow-up of chronic pancreatitis (CP)

patients rely on both clinical and imaging information such as the Mayo Clinic diagnostic criteria<sup>[1]</sup>. Especially, the diagnosis of CP at an early stage is a clinical challenge. The development in imaging techniques, and especially magnetic resonance imaging (MRI), has dramatically improved the information on both morphology and function of the pancreas. In the Mayo diagnostic criteria for CP, MRI is now an accepted method for assessing ductal pathology and concretions<sup>[1]</sup>.

A few decades ago, before the clinical introduction of cross-sectional imaging techniques, the imaging evaluation of CP was limited to plain radiography depicting calcifications. Traditionally, the ductal morphology has been assessed with endoscopic retrograde cholangiopancreatography (ERCP), which is based on intraductal contrast-enhancement with severity assessed using the Cambridge classification<sup>[2]</sup>. Today routine imaging modalities in the evaluation of CP typically include: Computed tomography (CT) with one or more contrast-enhancement phases, MRI with or without magnetic resonance cholangiopancreatography (MRCP) and ultrasound with a transabdominal or endoscopic approach. The advantage of MRI is the superior soft tissue visualization without radiation exposure. The main focus of imaging is typically to describe glandular atrophy and calcifications, duct pathology, pseudocysts and complications such as abscess formation and concomitant acute inflammation.

Recently, more advanced MRI methods have emerged which also provide important information on both tissue characteristics and pancreatic function.

The aim of this review is to provide an update on standard and advanced MRI techniques of the pancreas in CP.

## STANDARD MRI

Parenchymal changes can be assessed in the early stage of CP by standard MRI typically including fat-suppressed T1-weighted images, T2-weighted images and gadolinium-enhanced imaging<sup>[3-6]</sup>.

Fat-suppressed T1-weighted images show high signal intensity in normal pancreas and decreased signal intensity in CP due to loss of aqueous protein in the acini within the glandular elements of the pancreas caused by chronic inflammation and fibrosis<sup>[7-9]</sup>. Fat-suppression of T1-weighted images enhance the signal of the pancreas in relation to the surrounding retroperitoneal fat and the signal intensity can be compared to surrounding organs and tissue such as the spleen or muscles<sup>[9]</sup>. The biliary system and pancreatic ducts are enhanced on fat-suppressed T2-weighted images (Figure 1). The size of pancreas normally decreases with age but as acinar atrophy occurs more rapidly in CP, the pancreas diminishes segmentally or diffusely in the anteroposterior dimensions. The diameter can typically be assessed at the head, body and tail of the pancreas and compared with age-related normal values of the anteroposterior diameter<sup>[10]</sup>.

**Figure 1 Pancreatic morphology.** Axial T2-weighted magnetic resonance imaging views showing glandular atrophy (A), dilated irregular duct (B, arrow) and irregular side-branches (C, arrow heads) in a patient with chronic pancreatitis.

Gadolinium-enhanced imaging is used to investigate the perfusion of the pancreas during a series of contrast-enhanced images with repeated sequential scans. During the arterial phase of gadolinium infusion the normal pancreas shows pronounced enhancement due to high vascular perfusion and decreased signal during the venous phase<sup>[11]</sup>. The perfusion of the pancreas is decreased in patients with CP due to chronic inflammation and fibrosis resulting in reduced and delayed enhancement of the pancreatic signal<sup>[7,12]</sup>.

Standard MRI is often used together with MRCP to assess both parenchymal and ductal changes of the pancreas. One important limitation of MRI lies in its inability to depict small parenchymal calcifications, which can easily be evaluated with CT.

MRI also has a role in diagnosing autoimmune pancreatitis (AIP) which can be a differential diagnosis to CP<sup>[13,14]</sup>. In diffuse AIP, MRCP may show a decreased di-

Figure 2 Magnetic resonance cholangiopancreatography. Upper figure displays a single coronal image and the lower figure a 3D view of the pancreato-biliary tree. In this chronic pancreatitis patient the dilated irregular main duct has irregular side branches (arrow heads) and contains multiple rounded filling defects (arrows).

ameter of the main pancreatic duct and can be accompanied by strictures and an irregular wall. However, in AIP the pancreas is typically with diffuse or localized enlargement with reduced signal on T1 and increased signal on T2-weighted images. A surrounding capsule with reduced signal in T2-weighted images can be seen<sup>[13,14]</sup>.

## MRCP

MRCP was first described in 1991, providing a non-invasive alternative to ERCP, which relies on the endoscopic injection of contrast fluid into the common bile duct<sup>[15]</sup>. By applying either a single-shot breath-hold technique or a free-breathing technique with respiratory triggering, MRCP can provide both 2D and 3D images<sup>[16,17]</sup>. Advances in scanner technology in the recent years allow faster image acquisition and better quality with more detailed images including 3D reconstructions. These advances benefit from a high signal-to-noise ratio. Additionally, the 3D free-breathing protocol makes it superior to 2D imaging in patients who are unable or unwilling to hold their breath for the duration of the scan<sup>[18]</sup>.

MRCP relies on heavily T2-weighted pulse sequences, benefiting from the T2-weighted differences in relaxation time between fluid-filled compartments and adjacent soft tissue. Hence, the pancreato-biliary tree is displayed as high signal intensity and the pancreatic duct is clearly visualized in the normal pancreas. Accordingly, the MRCP technique is relevant in detecting pancreatic ductal dila-

tion, small filling defects (stones and protein plugs), strictures, irregularities of the main pancreatic duct, and irregularity (sacculation and/or ectasia) of side branches<sup>[6]</sup> (Figure 2). Furthermore, pseudocysts and other ductal congenital abnormalities and normal variants (such as pancreas divisum) can be visualized<sup>[19,20]</sup>.

The Cambridge classification system of ductal dimensional changes has been modified for the MRCP technique in the following fashion: Cambridge 1 (normal pancreas): pancreatic ducts are normal; Cambridge 2 (equivocal pancreas): 1-2 side branches and main duct 2-4 mm; Cambridge 3 (mild disease):  $\geq 3$  side branches and main duct 2-4 mm; Cambridge 4 (moderate disease):  $\geq 3$  side branches and main duct  $> 4$  mm; Cambridge 5 (marked disease): as traditional Cambridge classification system<sup>[2,6]</sup>.

The acquisition of MRCP sequences following intravenous administration of secretin hormone allows a better visualization of subtle ductal changes especially in the early stage of CP<sup>[21]</sup>.

## SECRETIN-STIMULATED MRCP

The secretin hormone stimulates pancreatic duct cells to produce a large volume of watery bicarbonate-rich pancreatic juice, which is secreted into the ducts and duodenum. Typically, images are obtained before and frequently after secretin stimulation for a period. In the normal pancreas the effect starts almost immediately and peaks between 2-5 min and by 10 min the caliber of the duct should return to baseline<sup>[21]</sup>. In secretin-stimulated MRCP (s-MRCP) the ductal system including side branch pathology and filling defects are better visualized compared to traditional MRCP, and s-MRCP provides images comparable to ERCP with Cambridge classification<sup>[21-23]</sup>. Furthermore, the exocrine function can be evaluated with assessment of duodenal filling, changes in pancreatic duct caliber, change in anteroposterior diameter of the pancreas, and change in signal intensity ratio between pancreas and spleen on T1-weighted and arterial-venous enhancement ratios<sup>[10,23,24]</sup>. The s-MRCP findings in CP (reduced duodenal filling grade and reduced increase in pancreatic duct caliber) are comparable to the results of endoscopic pancreatic function testing (ePFT)<sup>[23]</sup>. Studies in CP by Manfredi *et al.*<sup>[25]</sup> and Schneider *et al.*<sup>[26]</sup> showed correlation between assessment of the pancreatic exocrine reserve by dynamic s-MRCP and exocrine function assessed by fecal elastase test and <sup>13</sup>C-mixed chain triglyceride breath test. Wathele *et al.*<sup>[27]</sup> found correlation between endoscopic aspiration-based bicarbonate test and s-MRCP findings in healthy controls. However, the use of s-MRCP has not yet been integrated as a part of the Mayo diagnostic criteria for CP and further evaluation of s-MRCP as a test for exocrine function in comparison to traditional tests is needed.

Furthermore, s-MRCP can be combined with diffusion weighted imaging (DWI) of the pancreas.

Figure 3 Diffusion weighted imaging. The apparent diffusion coefficient map of a chronic pancreatitis patient is shown with a measuring region of interest positioned in the pancreatic head to assess the degree of parenchymal fibrosis (red is high and blue low water diffusion).

DWI

DWI is an emerging technology to assess early parenchymal changes associated with CP and has shown results comparable to other existing methods such as MRCP and ePFT<sup>[9,28]</sup>. DWI assesses the random microscopic motion of water protons to obtain the apparent diffusion coefficient (ADC). The flow of water is less restricted in fluid-rich tissues, which will then be represented by a high ADC value. Water molecules interacting with cell membranes and macromolecules will be restricted thereby causing a reduction in the ADC value. A reduced amount of diffusible water is present in fibrotic tissue and in reduced pancreatic exocrine function<sup>[28]</sup>. Hence, presence of parenchymal fibrosis in CP causes diffusion restriction and results in lower ADC values<sup>[29,30]</sup> (Figure 3).

Furthermore, when used in combination with secretin stimulation, the ADC value increases both in normal pancreas and in CP as the secretion stimulation facilitates an increased mobility of water molecules and increased circulation in the pancreatic capillaries. Following secretin stimulation, the diffusion coefficients have either delayed or lower peak values in CP patients, indicating reduced exocrine function<sup>[29,31]</sup>. Also, patients in risk of CP (such as alcohol consumption, nicotine consumption, nutritional factors, hereditary factors, efferent duct obstructions, immunological factors and rare miscellaneous factors) generally exhibit a delayed peak in diffusion coefficients compared to controls<sup>[31]</sup>.

This technique can be particularly useful in patients with early stage CP where atrophy and ductal pathology are subtle. Furthermore, the technique is useful in differentiating between pancreatic cysts, inflammatory cysts and cystic neoplasms and between pancreatic adenocarcinoma and normal pancreas due to different content of cellular elements<sup>[32]</sup>. Inan *et al*<sup>[33]</sup> calculated ADC values and ADC cyst-to-pancreas ratios and found significant lower values for abscesses, hydatid cysts and neoplastic cysts compared to values of simple cysts and pseudocysts. This technique may be useful in the diagnosis of intraductal papillary mucinous neoplasms (IPMN), which

Table 1 Advantages of magnetic resonance imaging techniques

	MRI	MRCP	s-MRCP	DWI
Loss of aqueous protein	Yes	No	No	No
Glandular atrophy	Yes	No	No	No
Perfusion	Yes	No	No	No
Calcification <sup>1</sup>	No	No	No	No
Pancreatic ductal dilation	No	Yes	No	No
Filling defects	No	Yes	Yes	No
Strictures	No	Yes	Yes	No
Irregularities	No	Yes	Yes	No
Pseudocysts	Yes	Yes	Yes	No
Side branch pathology	No	Yes	Yes	No
Exocrine function	No	No	Yes	Yes
Parenchymal fibrosis	No	No	No	Yes

Advantages of the different magnetic resonance imaging (MRI) techniques in diagnosing chronic pancreatitis. <sup>1</sup>A disadvantage of MRI is the inability to detect calcifications. This can be achieved through computed tomography scans. DWI: Diffusion weighted imaging; MRCP: Magnetic resonance cholangiopancreatography; s-MRCP: Secretin-stimulated MRCP.

is often difficult since CP and IPMN may have overlapping imaging findings<sup>[13,34]</sup>. Patients with main duct IPMN can present with ductal dilatation and associated parenchymal atrophy, and patients with side-branch IPMN can present with cystic lesions often confused with pseudocysts. ADC values of the cystic lesions may be helpful in deciding the malignant potential of IPMN<sup>[34,35]</sup>.

NEW TECHNIQUES

Recently, other advanced MRI techniques have become more interesting as the development within the MR hardware and software is expanding and allows increased signal-to-noise ratios, shorter scan time and breath-hold imaging.

MR spectroscopy with non-invasive *in-vivo* assessment of metabolite concentrations has been applied in a variety of different tissues (*e.g.*, brain, prostate, breast and liver). Hence, spectroscopy of the pancreas has the potential to offer a more accurate tissue characterization. Due to methodological challenges, the pancreas has only been studied to a very limited degree with spectroscopy. Despite of this, Su *et al*<sup>[36]</sup> characterized the normal pancreas at 3T and identified metabolites such as lipid, choline and cholesterol. Cho *et al*<sup>[37]</sup> used MR spectroscopy to distinguish between patients with chronic focal pancreatitis and patients with pancreatic carcinoma and found less lipid in pancreatitis than in pancreatic carcinoma. Furthermore, other studies also detected differences between normal pancreatic tissue and carcinoma tissue with alterations in lipid, choline and fatty acids<sup>[38,39]</sup>. However, to the best of our knowledge, this technique has not yet been applied in the characterization of CP patients.

CONCLUSION

This review provides an update on standard and ad-

vanced MRI of the pancreas in CP. Table 1 summarizes the capability of the different MRI techniques to display the different aspects of pancreatic changes and dysfunction in CP. Depending on local practice, scanner configuration and radiological experience, it should be possible to construct or customize individual MR protocols including the (or some of the) techniques reviewed in this paper to get the best possible morphological and functional information in CP.

### Abstract

The course and outcome is poor for most patients with pancreatic diseases. Advances in pancreatic imaging are important in the detection of pancreatic diseases at early stages. Ultrasonography as a diagnostic tool has made, virtually speaking a technical revolution in medical imaging in the new millennium. It has not only become the preferred method for first line imaging, but also, increasingly to clarify the interpretation of other imaging modalities to obtain efficient clinical decision. We review ultrasonography modalities, focusing on advanced pancreatic imaging and its potential to substantially improve diagnosis of pancreatic diseases at earlier stages. In the first section, we describe scanning techniques and examination protocols. Their consequences for image quality and the ability to obtain complete and detailed visualization of the pancreas are discussed. In the second section we outline ultrasonographic char-

acteristics of pancreatic diseases with emphasis on chronic pancreatitis. Finally, new developments in ultrasonography of the pancreas such as contrast enhanced ultrasound and elastography are enlightened.

**Key words:** Ultrasonography; Pancreas; Chronic pancreatitis; Transabdominal ultrasound; Medical imaging technique; Contrast enhanced ultrasonography; Elastography; Strain imaging

**Core tip:** Pancreatic diseases include acute and chronic inflammatory diseases and neoplastic tumors. It is a clinical challenge to diagnose these patients at an early stage because biochemical and imaging signs may be unspecific and are only evident at an advanced stage of the disease. Advances in pancreatic imaging are important for early detection of pancreatic diseases. Ultrasonography, as a diagnostic tool, has undergone major technical improvements over the last decade. It still is the preferred method for first line imaging, as well as it is increasingly used to clarify findings by others imaging modalities to support decision making.

### INTRODUCTION

Transabdominal ultrasonography still is the most used first line imaging modality in the diagnostic workup of abdominal diseases. Ultrasonography is, noninvasive, widely available, inexpensive, without side effects and

easy to perform on a daily basis, if needed. As a “real-time” imaging modality, transabdominal ultrasonography gives first a broad overview and then can localize the “region of interest” to perform detailed evaluation and eventually determine the cause of the disease. It can also reduce the use of computed tomography, magnetic resonance pancreatography, endoscopic ultrasonography or other diagnostic methods, which are personnel-intensive and thereby costly<sup>[1,2]</sup>.

Ultrasonography (US) of the pancreas is challenging, given its retroperitoneal location with overlying structures and relatively small size. The quality and thereby the clinical usefulness of the pancreatic ultrasound imaging has rapidly advanced along with the technological progress. Early works in the seventies and eighties describe evidence of pancreatic structural changes seen by transabdominal ultrasonography of approximately two-thirds in the diagnosed chronic pancreatitis (CP) cases<sup>[3-7]</sup>. Concerning pancreatic malignancy, most early works describe, somewhat surprisingly, pathological findings in the majority of the cases, but the distinction between malignancy and chronic pancreatitis could not be achieved<sup>[3-7]</sup>. With modern, high-end scanners, experienced physicians could achieve complete imaging of the pancreas in 90% in the nineties<sup>[6]</sup>. The current sensitivity and specificity of transabdominal ultrasonography in the diagnosis of pancreatic diseases, the ability to differentiate between acute and chronic inflammation and premalignant or malignant lesions is not yet determined. Today we have real-time, high-resolution imaging, where the spatial resolution is in line with the best image quality computed tomography (CT) or magnet resonance imaging (MRI) can offer. Furthermore, the temporal resolution far exceeds that of CT, positron emission tomography and MRI, which is particularly relevant for contrast-enhanced ultrasonography (CEUS). Moreover, the image quality and especially the amount of information are evolving along with the technological progression and introduction of new modalities such as of CEUS and elastography<sup>[8,9]</sup>.

Figure 1 shows a standard B-mode image of the pancreas, liver and surrounding vessels with a 1-5 and 12-15 MHz transducer. A clear overview of the gland and surrounding structures can be obtained and by changing the frequencies for any depth, focus on a smaller area of interest can be achieved.

We shortly review the current and forthcoming technical modalities and methods in transabdominal ultrasonography and endoscopic ultrasonography (EUS) of the pancreas with emphasis on CP. In our opinion, transabdominal ultrasonography has an important place in imaging of the pancreas, alongside CT, MRI and EUS.

## ULTRASONOGRAPHIC EXAMINATION

Ultrasonographic imaging of the pancreas can be difficult given its retroperitoneal location, variety in appearance among individuals and body habitus. Overlying bowel gas and obesity are the most frequent limitations in trans-

cutaneous scanning of the pancreas<sup>[10-12]</sup>.

Due to the food related production of intestinal gas reflecting the ultrasound beams, every examination should be performed fasting. US examination of the pancreas includes transverse, longitudinal and angled oblique scans. Successful visualization can often be achieved by manipulations with the transducer and is directly linked to the skill and persistence of the examiner. By applying graded compression by the transducer, bowel gas can be moved away, and all the portions of the pancreatic gland; head, neck, body and tail can often be visualized. Further improvement can also be obtained by drinking two glasses of water/juice, thereby using the fluid-filled stomach as an acoustic window. Other manipulations such as; changing the patient's position to stand or sit; let the patient turn from the supine position to oblique position or change/stop the breathing circle; let the patient “blow up the belly”, can also improve visualization of the pancreas<sup>[13]</sup>.

The pancreatic tail can sometimes be difficult to access in transversal scan. Figure 2 shows trans-splenic access, where the tail of the pancreas (cauda pancreatis) is scanned from the left lateral side using the spleen as acoustic window.

In a US examination of the pancreas the echotexture, the size of the gland including the main pancreatic duct (MPD), and anatomical landmarks of the pancreas should be evaluated. The echotexture in a normal pancreas is isoechoic or hyperechoic compared to the healthy liver<sup>[14]</sup>. Frequently, the echogenicity of pancreas is increasing with age. Orientational antero-posterior dimensions of the pancreas are: the head (2.5 cm), body (1.5 cm), tail (3.5 cm) and the pancreatic duct (< 2.5 mm). Fatty replacement (lipomatosis) of the pancreatic gland and decrease in size is common with increasing age but can also be found in patients with cystic fibrosis, CP, some types of diabetes and other diseases<sup>[15-17]</sup>.

The surrounding vascular, ductal and abdominal organ landmarks are the portal vein, splenic vein, confluens with the mesenteric vein, vena cava, aorta, superior mesenteric artery, common hepatic artery, splenic artery, common bile duct, duodenum, stomach and the liver.

## MODALITIES IN ULTRASONOGRAPHY

### Grayscale B-mode ultrasound

Grayscale B-mode ultrasound of the pancreas is the most used imaging modality. Complete evaluation of organ size, borders, echo structure, surrounding vessels, and pancreatic ducts can be obtained swiftly. These parameters are often sufficient to diagnose many diseases of the pancreas and patients can be managed accordingly.

### Tissue harmonic imaging

Tissue harmonic imaging (THI) or second harmonic imaging overcomes several of the B-mode limits. By receiving harmonic overtones instead of the emitted US-frequencies, the lateral delineation is sharpened and

**Figure 1** Pancreas and the surrounding anatomical landmarks. A: B-mode image (1-5 MHz); B: B-mode image with a 12-15 MHz transducer. Details shown with high resolution. **Figure 2** Left lateral side scan shows the pancreatic tail (cauda) using the spleen as acoustic window.

reverberation artifacts are reduced<sup>[18]</sup>. The image quality is improved by better discrimination between liquid and solid structures increasing the spatial and contrast resolution, making millimeter sized structures detectable. Thus, ultrasonography with THI may have better resolution than CT and MRI, in the absence of extreme obesity or a large amount of intestinal gas, which may temporarily mask the pancreas<sup>[19-21]</sup>. There are only a few disadvantages of THI; reduction of frame rate, reduced penetration depth, motion artifacts and only marginal improvement of image quality in the near sound field. This modality is normally used with CEUS, which is probably the most important application of this modality<sup>[22,23]</sup>.

### Doppler imaging

The Doppler effect in ultrasound is the change in US frequency of reflected wave from an object moving relative to the ultrasound probe, adding the option to show and record blood flow direction and velocity from vessels in ultrasound imaging.

Several modalities in conventional Doppler ultrasonography exist<sup>[24]</sup>. Combining B-mode gray scale and color-Doppler ultrasonography, overall accuracy rises substantially. By international convention, Doppler color is coded in such a way that red color expresses flow towards

the ultrasound transducer, while blue color expresses flow away from the transducer. The recent technological progress, in particular increased color-Doppler sensitivity is contributing to diagnosing and staging of pancreatic diseases. Doppler interrogation of the gland may show the outlines of the organ more precisely, since the pancreas is surrounded by vessels. The normal intrapancreatic vessels are small and difficult to show in conventional Doppler imaging. Color-Doppler shows flows in normal surrounding vessels and abnormal vascularity, such as in tumors with high vessel infiltration or tumor infiltration in vessels<sup>[25]</sup>. This method can also discriminate between cystic avascular processes without blood flow and aneurisms. Very small pancreatic calcifications which can be hard to distinguish in the irregular parenchymal pancreatic tissue in CP can be identified by the presence of twinkling artifacts. Modern high-end scanners can distinguish between inflammation (high flow) and infarction without flow<sup>[26]</sup>.

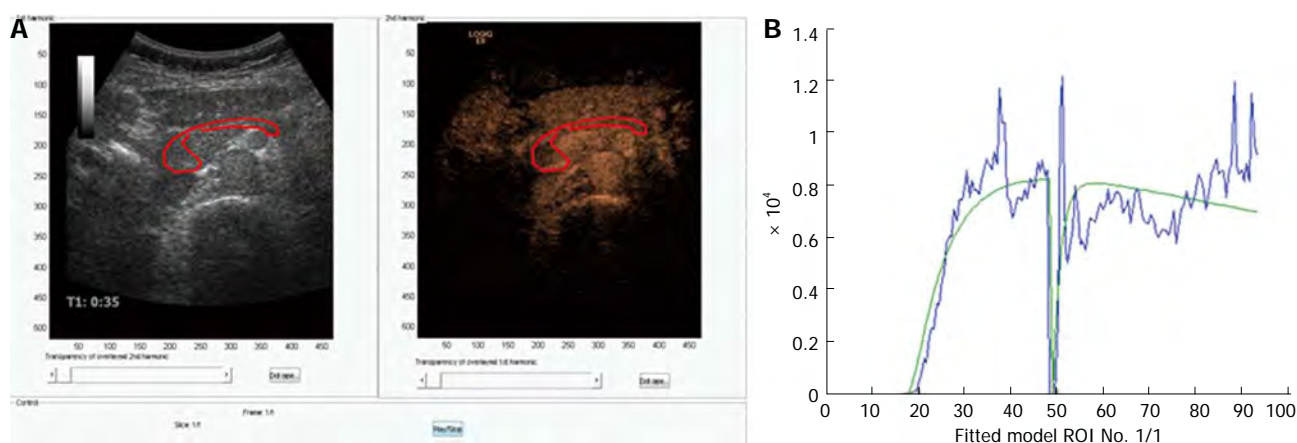

## METHODS IN ULTRASONOGRAPHY

### Panoramic imaging

In a conventional ultrasound field of view, only parts of the pancreas are visible in one image. With the panorama technique, based on real time image reconstruction the whole pancreas can be displayed in one image, allowing the creation of images similar to those in CT and MRI. However, the usefulness of these computed images regarding the evaluation of pancreatic disorders is not well documented.

### Compound imaging

Compound imaging obtains multiple coplanar images from different angles using computed beam steering. Multiple views are integrated into a single compound image with improved tissue definition, where signals from real structures are intensified and the artifacts are suppressed<sup>[14,18,19]</sup>. Organs appear smoother with clear contours. The MPD and vessels are clearly accentuated. As these images are generated from several angles, classi-

**Figure 3** Perfusion analysis of the pancreas. A: Dual view of contrast-enhanced ultrasonography examination of the pancreas in a healthy volunteer. 1.5 mL bolus of Sonovue was given as a bolus and after approximately 45 s the area of interest was exposed to high MI ultrasound bursting the bubbles in the imaging plane; B: A motion correcting analyzing software was used (DCE-US, <http://www.isibrno.cz/perfusion/>). A region of interest have been drawn including the head and body of the pancreas (unpublished data).

cal signs in transabdominal ultrasonography such as cast shadows behind pancreatic calcifications or ultrasound enhancement behind pancreatic cysts are attenuated<sup>[27]</sup>.

### Contrast-enhanced ultrasonography

The development of microbubble contrast agents enables the display of the vasculature, down to parenchymal microvasculature. With this technique enhancement patterns of lesions can be studied in real time in a similar way as contrast-enhanced CT or contrast-enhanced MRI, under full control of the operator<sup>[28-31]</sup>. Ultrasound contrast agents are confined to the blood pool where CT or MRI contrast agents are rapidly cleared into the extravascular space. As the contrast bubbles, approximately the size of a red blood cell, are gas-filled, they create strong acoustic reflectors within the fluid filled blood pool. An advantage of CEUS is the ability to study the dynamics of lesions in real time. The excellent tolerance and safety profiles allow repeated administrations in the same session if needed. The elimination of the contrast agent is by breathing, independent of liver and kidney function. Today, CEUS is increasingly incorporated in clinical use, alongside with traditional US, in liver lesions, which is by the far the most common use, but also in the kidneys, in vesico-ureteric reflux, in trauma and in the cerebral circulation<sup>[28]</sup>.

Transabdominal ultrasonography with CEUS in the pancreas has probably near the same potential, and has in some few centers been established in diagnostic routine<sup>[14,31]</sup>. The most common application is to define pancreatic lesions, in most cases already known lesions, previously seen on CT/MRI or seen in the initial US examination. Several studies show that transabdominal CEUS can be used to differentiate malignancy and CP<sup>[32-36]</sup>. The time window in a pancreatic CEUS examination is notably shorter than in the well-known liver CEUS study. This is due to the entirely arterial blood supply of the pancreas. The enhancement of the pancreas begins almost simultaneously with the aortic en-

hancement and reaches its peak between 15 and 20 s after injection of the ultrasound contrast agent. After a noticeable parenchymal enhancement in the arterial early phase, there is a washout of contrast medium with gradual loss of echogenicity during the late phase for approximately 120 s<sup>[36,37]</sup>.

New technologies may be able to discriminate between normal pancreatic perfusion and pathological in parenchymal pancreatic diseases or different tumor perfusion patterns that can be visualized using the small microbubbles of ultrasound contrast agents<sup>[38]</sup>. Time-intensity curves expressing arrival time of the microbubbles, time to peak or other parameters have so far not been able to show significant difference in focal masses in patients with CP and carcinomas<sup>[34]</sup>. The first generation analyzing software did not incorporate motion correction and that can be one of the reasons for the insensitivity of this method, since the pancreas moves in both planes, thereby moving the region of interest out of plane. New versions of more sophisticated analyzing software are under development. Figure 3 shows an example of a CEUS examination of the pancreas with a motion tracked area of interest.

In the near future, microbubbles may be an important part of the therapeutic armaments<sup>[39]</sup>. Studies have been undertaken to investigate the ability and efficacy of sonoporation in a clinical setting to increase the overall survival in patients with pancreatic adenocarcinoma. In a pilot study, numbers of treatment cycles with gemcitabine were increased from an average of 9 to 16 cycles. In two out of five patients treated, the maximum tumor diameter was temporally decreased to  $80\% \pm 5\%$  and permanently to  $70\% \pm 5\%$  of their original size, whilst the other patients showed reduced growth. This study demonstrated that it is possible to combine ultrasound, microbubbles, and chemotherapy in a clinical setting prolonging the quality of life in patients with pancreatic adenocarcinoma when comparing to chemotherapy alone. Figure 4 shows an experimental microbubble sonopora-

Figure 4 Ultrasound targeted treatment of pancreatic cancer using combined microbubbles and a chemotherapeutic. Left: B-mode frame. Right: The main tumor with spicules, clearly demarked, using the sonoporation settings. Tu: Tumor; Ao: Aorta.

Figure 5 Endoscopic ultrasound with elastography of chronic pancreatitis. Endoscopic ultrasonography B-mode sonogram (right) and an elastogram superimposed a sonogram (left). In this image of the pancreatic head, hyperechoic foci and strands are seen in the parenchyma, as well as inhomogeneous echogenicity, which are signs of chronic pancreatitis. The elastogram shows predominantly a blue, indicating harder tissue, and green representing intermediate hardness in a honeycomb pattern over the pancreatic tissue.

tion therapy setup targeting a pancreatic adenocarcinoma, using a clinical ultrasound scanner<sup>[39]</sup>.

## ENDOSCOPIC ULTRASONOGRAPHY IN THE WORKUP OF CP

Even if transcutaneous US may image the pancreas in many cases, the limitations of obesity, reverberations and bowel gas may not always be eliminated. EUS has the advantage over trans-cutaneous US examinations that the US probe can be placed close to the organ of interest allowing the use of high frequency ultrasound (5-12.5 MHz). This may allow the imaging of small alterations in the pancreatic duct and parenchyma. The findings are usually grouped as ductal changes or parenchymal changes. The classic features include: ductal calcifications, hyperechoic duct walls, duct-caliber dilatation, visible side ducts. Parenchymal changes include: lobulation with or without honeycombing, parenchymal hyperechoic areas with or without shadowing, echogenic strands and cysts.

The problem is that some of these features also are found in healthy subjects, and increasing with age. A study compared EUS and an endoscopic pancreatic function test (ePFT) sampling the peak bicarbonate concentration after secretin stimulation. EUS showed a good correlation with fibrosis. The sensitivity of EUS and ePFT had similar sensitivity for diagnosing CP (0.84%-0.86%), but EUS was more specific (100% *vs* 67%). By combining the two methods, however, the sensitivity reached 100%<sup>[40]</sup>. The Rosemont classification is a set of EUS-based criteria for the diagnosis of CP. These criteria are based on detailed evaluation on pancreatic parenchymal and ducts. Both parenchymal and ductal features are divided in major and minor criteria<sup>[41]</sup>. Major criteria for CP are; hyperechoic foci with shadowing, lobularity with honeycombing and MPD calculi. Minor criteria for CP; cysts, dilated ducts  $\geq 3.5$  mm, irregular pancreatic duct contour, dilated side branches  $\geq 1$  mm, hyperechoic duct wall, strands, non shadowing hyperechoic foci, and lobularity with noncontiguous lobules. The Rosemont criteria, using a combination of major and/or minor criteria, categorize the patient into four groups: consistent, suggestive, indeterminate of CP or normal.

## NEW IMAGING METHODS FOR EUS IN CP-EUS ELASTOGRAPHY

Elasticity imaging of pancreatic tissue may help the examiner distinguish between harder and softer tissue. Elasticity imaging is currently an option in ultrasonography. Two main methodologies are commercially available. Strain imaging provides a qualitative strain map, frequently in a colored pattern superimposed on a B-mode echogram, visualizing the local strain as a result of endogenous movements or by an acoustic pulse. Alternatively, a shear wave method is used, providing quantitative elasticity information based on the travelling speed of shear waves. The energy for these shear waves is deposited in the tissue by an acoustic pulse. In some systems both deformation based images and local shear-wave quantification are combined.

Up to now, only strain based imaging systems have been available in combination with flexible echo-endoscopes. In Figure 5 an EUS image of a pancreas with CP is imaged with Real-Time Elastography. In Figure 6 a reactive hilar lymph node in a patient with CP is imaged as green in the strain map indicating intermediate hardness.

Several studies including two meta-analyses conclude that EUS elastography may help characterize focal pancreatic lesions as benign or malignant based on their imaged strain with an high accuracy<sup>[42-44]</sup>. In CP, the pathology is sometimes more diffusely distributed, and tissue hardness may not be limited to hypoechoic areas. Fibrosis and calcifications, if present, also increase tissue hardness in addition to local edema. In a transcutaneous shear wave study of acute pancreatitis Mateen *et al*<sup>[42]</sup> found that pancreatic tissue undergoes a cycle of increasing tissue hardness, resulting in low strain, in the acute

**Figure 6** Endoscopic ultrasonography B-mode sonogram and elastogram of lymph node in chronic pancreatitis. The sonogram (right) shows a lymph node as a hypoechoic oval shape surrounded by more echogenic tissue in the liver hilum. This lymph node approximately 18 mm × 10 mm, appeared in the liver hilum of a patient with chronic pancreatitis. On the left, the lymph node is not harder than the surrounding tissue as the predominant color hue is green. This finding is frequent in reactive lymph nodes, and may be a sign of benign etiology.

phase of inflammation which subsequently turned softer as the inflammatory reaction resolved. In a study on focal pancreatic lesions we found that hypoechoic lesions that turned out to be inflammatory in origin were significantly softer than the malignant lesions. However, these lesions were imaged at a median of 8 mo after the last inflammatory attack (range: 1.2-12 mo). It is our experience that inflammatory lesions in the pancreas may present with a wide range of tissue strain. If a high-strain area (indicating soft tissue) is found, corresponding to a hypoechoic area in a sonogram, the chance of finding malignancy is however low (abstract Havre, UEGW 2011).

## INFLAMMATORY DISEASES OF THE PANCREAS

In the following morphological and sonographic characteristics of pancreatic diseases with emphasis on CP will be outlined. Pancreatic neoplasms are also shortly described as an important differential diagnosis.

### Acute pancreatitis

Acute pancreatitis is an acute inflammatory process that may include interstitial edema, necrosis, hemorrhage of pancreatic tissue and fluid collections, depending on the severity of the inflammation. The changes can be focal enlargement or diffuse, depending on its distribution and sometimes difficult to differentiate, especially when acute pancreatitis occurs in a patient with CP. Furthermore, focal pancreatitis often occurs in the pancreatic head, as a hypoechoic mass and not easily distinguishable from a tumor or changes seen in CP. The introduction of CEUS and its ability to differentiate between avascular necrotic tissue, cysts, abscesses and normal or hypervascular inflamed tissue equates US with CT<sup>[45]</sup>. CEUS has bedside availability, better cost effectiveness and can also be used in those patients where CT contrast agents are contraindicated.

**Figure 7 Advanced chronic pancreatitis.** Classical signs in advanced chronic pancreatitis: main pancreatic duct dilatation in an atrophic organ with sharp, irregular contours, calcifications and small cysts. The pancreatic head is outlined.

licated. However, visualization of the whole gland can be a problem in very obese patients.

### *Chronic pancreatitis*

Classical diagnostic findings of CP in transabdominal ultrasonography reflects the spectrum of pancreatic disorders in CP. Ranging from progressive and irreversible morphological and functional derangement, inflammatory episodes and obstruction of structures adjacent to the pancreas<sup>[46]</sup>.

Late stage, severe CP is normally easily recognizable due to characteristic morphological changes. The presences of pancreatic or intraductal calcifications presented as hyperechoic foci are pathognomonic<sup>[47]</sup>. Caliber abnormalities such as a dilated and irregular pancreatic duct is seen with a sensitivity of approximately 70%<sup>[48]</sup>. The reported sensitivity is probably due to limited duct changes in early/mild and moderate CP, where the pancreatic duct is less than 3 mm in diameter<sup>[49]</sup>. Pseudocysts may cause benign duct obstruction (stricture) and dilatation upstream<sup>[50]</sup>. Solid or cystic lesions and malignant infiltration, especially if contiguous to the main duct, may also cause duct compression, with progressive development of obstructive CP upstream. A small atrophic gland with focal alterations and parenchymal heterogeneity is easily identified in advanced stages. Figures 7 (B-mode US) and 8 (CEUS image of the pancreas in the early arterial phase) shows typical morphological changes in advanced CP.

In moderate to severe CP, the pancreatic gland echo texture is inhomogeneous and rough due to coexistence of fibrotic hyperechoic and hypoechoic focal inflammation signs<sup>[49,51,52]</sup>. These findings are reported to be observed in approximately 70% of the cases, already in the late eighties<sup>[48,53,54]</sup>. Echogenicity of the pancreas is usually increased in CP due to fibrosis and fatty infiltration. This is not a specific parameter due to presence of adipose tissue in elderly and obese patients<sup>[10,53]</sup>. Increased echogenicity of duct wall can also be detected<sup>[50]</sup>. Figure 9 show an example of elastography in moderate CP.

Early stage CP is normally without or with minimal

**Figure 8** An example of contrast enhanced ultrasound in advanced chronic pancreatitis. The parenchymal enhancement is clearly irregular reflecting the parenchymal heterogeneity, calcifications and focal inflammation.

**Figure 9** Elastography of the pancreas in moderate chronic pancreatitis. The colors show tissue hardness; The scale on the left defines the color code: Blue is hard, red is soft, yellow and green are intermediate. The elastogram shows predominantly soft (red) tissue with parts of green and yellow, indicating harder pancreatic tissue.

**Figure 10** Early chronic pancreatitis. Typical signs in early chronic pancreatitis: lobularity (L), stranding (S), hyperechoic foci (H) and honeycombing (Ho). Pancreatic body (Corpus). This subtle changes are usually only seen in endoscopic ultrasonography.

**Figure 11** Autoimmune pancreatitis. Enlarged pancreas with a tumorous formation in the head. The inflammatory lesion is isoechoic to the rest of the pancreas but still clearly visible.

morphological changes, where imaging modality falls short in diagnosing CP. Late stages signs like calcifications or dilated and irregular main pancreatic duct are diagnostic for CP, but can also be absent in severe exocrine insufficiency, depending on the type of CP<sup>[55,56]</sup>.

Cambridge classification of endoscopic retrograde pancreatography (ERP), US and CT imaging, grades the severity of CP, based on pancreatic structural changes and abnormalities of the main duct and side branches<sup>[52]</sup>. The sensitivity in diagnosing and grading the severity of CP with ultrasound alone, compared to the morphological gold standard ERP, rose to over 80% in the late eighties<sup>[53]</sup>. With the development of endosonographic

ultrasound, subtle early changes in the pancreatic echotexture could be visualized, and a new gold standard, based on morphological criteria correlating with pathologic features emerged<sup>[57,58]</sup>. Current transabdominal high-end ultrasound scanners can visualize some of these criteria, although the Rosemont classification is only for EUS images. Figure 10 shows minimal morphological changes in a patient with early CP, obtained by transabdominal US. Forthcoming studies comparing transabdominal ultrasonography findings with EUS criteria seem to be a logical step forward.

Pancreatic functional tests are still the only option to diagnose an early pancreatitis without morphological changes but with physiological insufficiency. Today, the

**Figure 12 Malignant tumor of the pancreatic body: Ductal adenocarcinoma.** The tumor is clearly visible on B-mode, left upper image. Contrast enhanced ultrasonography: The characteristics are hypoechogenicity and diffuse contours. The plastic biliary stents are clearly noticeable on B-mode, right upper image. Cho: Biliary duct (ductus choledochus); Tu: Tumor; CEUS: Contrast-enhanced ultrasonography.

short endoscopic secretin-based, pancreas function test is reasonably validated and the best available test<sup>[59,60]</sup>. This test can be combined with bedside US, to detect any morphological changes of the pancreas. Using this combined method we observed that the MPD wall had an increased echogenicity, *i.e.*, hyperechoic duct wall and changes in the diameter, short after secretin was given. Data not yet published.

### Autoimmune pancreatitis

Autoimmune pancreatitis is a benign form with autoimmune pathogenesis and a remarkable response to steroid therapy. From an imaging point of view, there are three (focal, diffuse, and combined) types of autoimmune pancreatitis where, especially the focal type can be misinterpreted as cancer<sup>[61,62]</sup>. Figure 11 shows an enlarged pancreas with a round tumorous formation, without cysts and calcification. On CEUS the affected tissue is hyperemic and shows an increased contrast-enhancement, whereas pancreatic cancer lesions are typically hypervascularized<sup>[63]</sup>. The patient avoided excessive abdominal surgery and was successfully treated with corticosteroids.

### Pseudocyst

Pseudocysts can arise as a complication of acute pancreatitis and also often occur in CP. These cysts are well-defined, fibrous-walled anechoic structures without an epithelial lining. Pseudocysts are normally easily differentiated from pancreatic cystic tumors, where especially the

premalignant and malignant forms should be identified. CEUS can classify cystic tumor's or solid nodules through evaluation of the vascularization pattern or absence of vessels in pseudocysts<sup>[36]</sup>.

### Pancreatic solid neoplasm

Differentiation between mass-forming lesions in CP and adenocarcinomas of the pancreas are a daily challenge. The ultrasonographic findings are similar with homogeneous or inhomogeneous poorly defined hypoechoic mass in both cases<sup>[64]</sup>. After the initial detection by ultrasound, the subsequent use of CEUS, with its possibility to visualize the vascular pattern will improve the diagnostic accuracy of the lesion type. A ductal adenocarcinoma is typically hypoechoic in arterial phase without clear-cut margins, with optional central necrotic parts. On the contrary, CP has usually more vascularity, with the same enhancement pattern as the surrounding pancreatic parenchyma<sup>[31,65,66]</sup>. Figure 12 shows a large hypervascularized mass with marked dilatation of the main bile duct. However, in advanced CP, due to fibrosis, inhomogeneous hypervascularization can be present, making the differential diagnosis very difficult<sup>[35,67]</sup>. Differences in vascularity seen on CEUS, often correlate well with histology. Taking in account the higher temporal and spatial resolution of ultrasound into account makes CEUS equal or even superior to CT<sup>[32,34,38]</sup>. The relationship with the surrounding arterial and venous vessels, the presence of thrombosis of the portal or splenic vein are used for local staging and

assessment of tumor resectability. The presence of liver metastases can also be evaluated during the late phase of the CEUS scanning procedure.

## CONCLUSION

Today's modern high end ultrasound scanners are still the first line modality in abdominal and pancreatic imaging. Ultrasonography is highly available, relative cheap and can be repeated on a daily basis, if needed. Ultrasound technology is developing towards smaller and really mobile scanners, implying that ultrasonography can be present in the pockets of the doctors supporting the clinical examination. With the rapid technical development, different modalities and methods, which demands computer processed images can be combined. This means highly improved image quality and diagnostic accuracy. Under good scanning conditions, ultrasonography has higher spatial resolution than CT or MRI. Furthermore, CEUS with its ability to show macro- and micro vascularity is also used as a second line modality to clarify small lesions, previously detected on CT or MRI.

Regarding transabdominal ultrasound of the pancreas, we predict that the resolution and thereby the ability to detect small morphological changes will be approaching the performance of EUS. Elastography in pancreatic imaging is now well known in EUS and studies' regarding the usefulness of this method in transabdominal ultrasonography is warranted. The ability of CEUS to visualize and quantify perfusion and thereby to characterize a given lesion or to differentiate between vascular (solid) and avascular (liquid/necrotic) components of the lesion is one of the most important progresses in pancreatic imaging today. Furthermore, the development of three-dimensional technology offers new clinical possibilities for real-time 3D volume images of the pancreas in the future.

### Abstract

Pancreatic exocrine insufficiency is an important cause of maldigestion and a major complication in chronic pancreatitis. Normal digestion requires adequate stimulation of pancreatic secretion, sufficient production of digestive enzymes by pancreatic acinar cells, a pancreatic duct system without significant outflow obstruction and adequate mixing of the pancreatic juice with ingested food. Failure in any of these steps may result in pancreatic exocrine insufficiency, which leads to steatorrhea, weight loss and malnutrition-related complications, such as osteoporosis. Methods evaluating digestion, such as fecal fat quantification and the  $^{13}\text{C}$ -mixed triglycerides test, are the most accurate tests for pancreatic exocrine insufficiency, but the probability of the diagnosis can also be estimated based on symptoms, signs of malnutrition in blood tests, fecal elastase 1 levels and signs of morphologically severe chronic pancreatitis on imaging. Treatment for pancreatic exocrine insufficiency includes support to stop smoking and alcohol consumption, dietary consultation, enzyme replacement therapy and a structured follow-up of nutritional status and the effect of treatment. Pancreatic enzyme replacement therapy is administered in the form of enteric-coated minimicro-

spheres during meals. The dose should be in proportion to the fat content of the meal, usually 40-50000 lipase units per main meal, and half the dose is required for a snack. In cases that do not respond to initial treatment, the doses can be doubled, and proton inhibitors can be added to the treatment. This review focuses on current concepts of the diagnosis and treatment of pancreatic exocrine insufficiency.

### INTRODUCTION

Pancreatic exocrine insufficiency (PEI) can be defined as a reduction in pancreatic enzyme activity in the intestinal lumen to a level that is below the threshold required to maintain normal digestion. This concept is crucial for the understanding of PEI and has several important consequences for the diagnosis and treatment of this

Figure 1 Different causes of pancreatic exocrine insufficiency.

condition. First, pancreatic exocrine secretion can be significantly reduced without PEI being present. In a landmark paper four decades ago, DiMagno *et al*<sup>[1]</sup> demonstrated that steatorrhea does not occur until pancreatic lipase output is reduced to 5%-10% of normal output. Hence, the demonstration of moderately reduced bicarbonate or enzyme output in sensitive tests of pancreatic secretion, such as the secretin/cholecystokinin-stimulation test, is a reliable indicator of chronic pancreatitis (CP) but does not necessarily indicate PEI. Second, any pathology, including extrapancreatic conditions, that interrupt the chain of events required for the normal digestion of ingested food by pancreatic digestive enzymes may cause PEI. Thus, “pancreatic exocrine insufficiency” is a denomination that, from a semantic point of view, is too narrow for this condition; “pancreatic maldigestion” could be an alternative and probably more correct term. Diseases of the pancreatic parenchyma, such as CP, cystic fibrosis and status post necrotizing acute pancreatitis, are the most common causes of PEI. However, PEI may also be caused by obstruction of the pancreatic duct system due to a tumor or a stricture, by reduced stimulatory capacity in the intestine secondary to untreated celiac disease<sup>[2]</sup> or Crohn’s disease, by increased intraluminal inactivation of pancreatic enzymes in Zollinger-Ellison syndrome<sup>[3]</sup> or by impaired mixing of ingested food and the pancreatic juice after upper gastrointestinal surgery<sup>[4]</sup> (Figure 1).

The pancreatic juice plays a pivotal role in the digestion and absorption of nutrients<sup>[5]</sup>. Pancreatic enzyme secretion is stimulated during the cephalic<sup>[6]</sup> and gastric<sup>[7]</sup> phases to a certain degree, but the most important stimulation occurs during the intestinal phase, when chyme enters the duodenum. The presence of fatty acids, amino acids and gastric acid in the duodenum is the most potent stimulator of exocrine pancreatic secretion<sup>[8]</sup>. Vagal and neural reflexes stimulate pancreatic secretion during the cephalic and gastric phases<sup>[6,7]</sup>. During the intestinal phase, cells in the duodenal mucosa release CCK, which stimulates the secretion of pancreatic enzymes from acinar cells<sup>[9]</sup>, and secretin, which elicits water and bicar-

bonate secretion from ductal cells<sup>[10,11]</sup>.

The pancreatic juice consists of bicarbonate and water secreted by ductal cells and several enzymes, secreted by acinar cells, with the specific capacity to digest proteins, carbohydrates and fat. In situations with reduced exocrine pancreatic function, the ability to digest fat is the determining factor that causes the most important symptoms and clinical complications because lipase, the major lipolytic enzyme of the pancreatic juice, is the pancreatic digestive enzyme with the poorest stability in the gastrointestinal lumen. The destruction of lipase is even more rapid when the pH is below 4, which is often the situation in CP, in which the buffering of gastric acid is insufficient due to low bicarbonate excretion by the pancreas<sup>[12]</sup>. Furthermore, there is minimal extrapancreatic lipolytic enzyme production, as opposed to the extrapancreatic capacity to digest carbohydrates provided by salivary amylase and intestinal oligosaccharidases or the proteolytic capacity provided by gastric pepsinogen.

PEI is one of the major complications in CP and should be considered in all CP patients. The prevalence of PEI in CP increases with disease duration, and approximately half of patients will have developed PEI by 12 years after disease onset<sup>[13]</sup>. There are no reliable estimates of the prevalence of PEI in the general population.

Patients with untreated PEI not only suffer from impaired quality of life due to steatorrhea, weight loss, abdominal discomfort and other PEI-related symptoms but are also highly likely to develop deficiencies of micronutrients and lipid-soluble vitamins<sup>[14]</sup>. These deficiencies in turn place patients at risk of malnutrition-related complications, such as osteoporosis<sup>[15,16]</sup>. Hence, an early and accurate diagnosis of PEI is of high clinical importance.

## DIAGNOSIS OF PANCREATIC EXOCRINE INSUFFICIENCY

The gold standard for the diagnosis of PEI is three-day

fecal fat quantification and determination of the coefficient of fat absorption<sup>[17]</sup>. A major drawback of fecal fat quantification is that the test is cumbersome and unpleasant for both the patient and laboratory personnel. The patient is required to keep a strict diet, with 100 g of fat per day for five days, and to collect the complete volume of feces for three days. Laboratory personnel need to handle large volumes of feces. Therefore, this test is very rarely performed in daily clinical practice and is only available at few specialized centers. Several alternative methods for the diagnosis of PEI have been proposed.

### **Diagnosis based on symptoms, blood tests and imaging**

Symptoms in patients with PEI vary, depending on the degree and etiology of PEI. The classical clinical picture is a patient presenting with foul-smelling, loose stools, weight loss, muscle wasting, and flatulence. Advanced tests of pancreatic exocrine function can usually be avoided in patients with a well-established CP diagnosis based on morphological findings and a clear clinical picture of PEI. A trial of pancreatic enzyme replacement therapy (PERT) based only on the clinical picture is recommended by several national societies when the clinical presentation is strongly suggestive of PEI<sup>[18,19]</sup>. However, only relying on symptoms may lead to both the over- and under-diagnosis of PEI. Diarrhea and weight loss may be due to conditions other than PEI, and PEI can also be present in the absence of overt steatorrhea.

In addition to explaining and treating clinical symptoms, the second rationale for the early diagnosis of PEI is to prevent complications of malnutrition. It is reasonable to assume that such malnutrition-related complications will be preceded by deficiencies of macro- or micronutrients detectable by routine blood tests. Hence, from a theoretical point of view, serum nutritional markers could be used to support the diagnosis of PEI. Deficiencies of several nutrients in blood tests have been demonstrated in CP, including apolipoproteins<sup>[20,21]</sup>, total cholesterol<sup>[22]</sup>, magnesium<sup>[22,23]</sup>, lipid-soluble vitamins<sup>[24-26]</sup>, retinol-binding protein<sup>[26]</sup>, calcium, zinc and selenium<sup>[25]</sup>, but the majority of these studies have not taken the exocrine function status of patients into consideration. Studies investigating the association between nutritional markers and PEI in CP patients have demonstrated that deficiencies of lipid-soluble vitamins are associated with an increased probability of PEI<sup>[15,26]</sup>, as opposed to B12 and folate levels, which are not associated with PEI<sup>[14,27]</sup>. The possibility of diagnosing PEI based on nutritional markers in the blood was recently studied in a cohort of 114 patients with CP, of whom 38 suffered from PEI<sup>[14]</sup>. Hemoglobin, albumin, prealbumin and retinol-binding protein levels below the lower limit of normal magnesium levels below 2.05 mg/dL; and HbA1C levels above the upper limit of normal were all significantly associated with PEI. No PEI patient in this study presented with normal values for all of these parameters. The central conclusion that can be drawn from this study is that

a normal panel of serum nutritional markers can exclude PEI with a high negative predictive value.

The probability of PEI in CP can also be estimated based on pancreatic imaging findings in the absence of more advanced tests of pancreatic function<sup>[28]</sup>. Notably, ductal changes on endoscopic retrograde pancreatography, computerized tomography (CT)<sup>[29]</sup> and endoscopic ultrasound (EUS) have been associated with decreased exocrine pancreatic function. The diagnosis of CP by EUS is based on the demonstration of several different parenchymal (hyperechoic foci, hyperechoic strands, parenchymal lobularity and cysts) and ductal (pancreatic duct dilatation, irregular pancreatic duct contour, hyperechoic pancreatic duct margin, dilated side branches and intraductal calcifications) abnormalities defined in the Rosemont classification<sup>[30]</sup>. A recent study demonstrated a clear correlation between the number of EUS criteria met and the probability of PEI. Calcifications and main pancreatic duct dilatation were independently associated with PEI in a multivariate analysis, and the probability of PEI was > 80% if these features were present<sup>[28]</sup>.

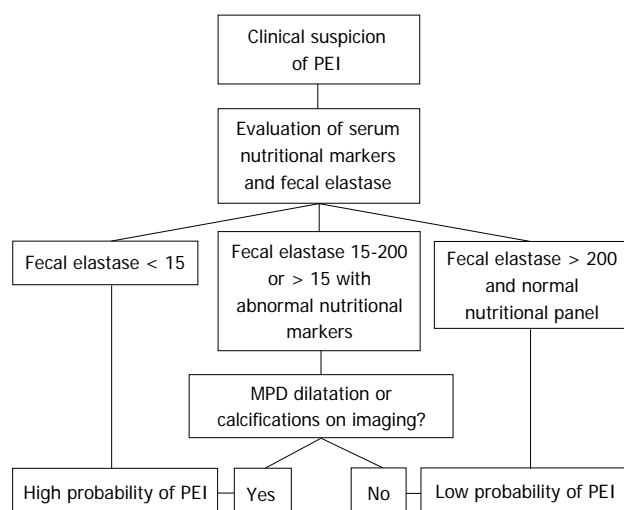

### **Fecal elastase 1**

Pancreatic elastase 1 is an enzyme of the pancreatic juice that is highly stable during passage through the gastrointestinal tract<sup>[31]</sup>. The concentration of elastase 1 can be measured in feces using a simple enzyme-linked immunosorbent assay [fecal elastase 1 (FE-1)] on a spot fecal sample<sup>[32,33]</sup>. FE-1 levels have been demonstrated to correlate with more sensitive tests of pancreatic secretion, such as the secretin test<sup>[32,34]</sup>. Low FE-1 levels have also been demonstrated to correlate with morphological tests for CP, such as endoscopic retrograde pancreatography<sup>[35]</sup> and magnetic resonance cholangiopancreatography<sup>[36]</sup>. However, as opposed to the relatively large number of studies evaluating FE-1 assessment as a test for the diagnosis of CP, studies evaluating the role of FE-1 testing in the detection of PEI in CP are scarce. Recently, Benini *et al*<sup>[37]</sup> investigated FE-1 and fecal fat in patients with CP or pancreatic resection. Three important conclusions can be drawn from this study. First, an FE-1 concentration of < 15 µg/g feces detects PEI with high sensitivity and specificity in patients with CP without prior pancreatic surgery. Second, intermediate FE-1 values (15-200 µg/g feces) are more difficult to interpret and likely warrant testing with more sensitive methods. Third, FE-1 assessment is not a reliable test for PEI in patients post-pancreatic resection. The fecal fat concentration was consistently higher in relation to FE-1 levels in operated compared with non-operated cases<sup>[37]</sup>. This finding was not unexpected; inadequate mixing of food with the pancreatic juice and other factors not related to pancreatic secretory capacity are likely to contribute to the pathogenesis of PEI after pancreatic resections.

### **<sup>13</sup>C-mixed triglycerides breath test**

The <sup>13</sup>C-mixed triglycerides (<sup>13</sup>C-MTG) breath test was introduced by Vantrappen *et al*<sup>[38]</sup>. The test directly mea-

**Figure 2** Evaluation of the probability of pancreatic exocrine insufficiency in the absence of advanced tests for maldigestion, such as fecal fat quantification and the  $^{13}\text{C}$ -mixed triglycerides breath test. PEI: Pancreatic exocrine insufficiency; MPD: Main pancreatic duct.

sure the clinically most relevant end-effect of exocrine pancreatic function: the degradation of triglycerides. This makes this test preferable to tests that measure exocrine pancreatic secretion, such as the secretin test and the FE-1 assay. For the  $^{13}\text{C}$ -MTG test, the patient ingests a small amount of  $^{13}\text{C}$ -marked triglycerides (2-octanoyl (1- $^{13}\text{C}$ )-1,3 distearoyl glycerol), together with butter on a piece of toasted bread, after an overnight fast. In the presence of normal lipase activity,  $^{13}\text{C}$ -triglycerides will be degraded in the intestinal lumen, and  $^{13}\text{C}$ -marked fatty acids will then be absorbed. These fatty acids will in turn be metabolized in the liver, and  $^{13}\text{CO}_2$  can finally be measured in exhaled air. Subjects with PEI have decreased lipase activity, which can be detected as a decreased recovery of  $^{13}\text{CO}_2$  in exhaled air. Currently, there is no general agreement on the optimal design of the test and several different protocols have been proposed<sup>[39-43]</sup>. The protocol developed by Domínguez-Muñoz *et al.*<sup>[44]</sup> has been adopted by several groups, including our institution, and this protocol is described in Table 1<sup>[44]</sup>. Values below 29% are considered as pathological, and the test detects fat maldigestion with a sensitivity of  $> 90\%$ <sup>[40]</sup>.

### Test based on analysis of pancreatic juice after secretin/erulein stimulation

Exocrine pancreatic function can be measured by so-called direct pancreatic function tests. In these tests, pancreatic secretion is stimulated by secretin and/or cerulein<sup>[45]</sup> or by the ingestion of a standard test meal<sup>[46]</sup>. After stimulation, samples of the pancreatic juice are aspirated from a tube that has been placed in the duodenum, and the concentrations of pancreatic digestive enzymes and bicarbonate are measured. A peak bicarbonate concentration in pancreatic secretion significantly

below normal values (a cut-off value of 80 mEq has been advocated by most authorities) in the secretin test has long been considered as the most sensitive test for early CP. A drawback of the direct function tests is that they require the placement of a large-bore tube in the duodenum during the complete duration of the test, which is poorly tolerated by patients. It is also important to keep in mind that a mild reduction in pancreatic exocrine function, occasionally called “exocrine pancreatic dysfunction” or “mild pancreatic exocrine insufficiency”, is not equivalent to clinically significant PEI. PEI, based on its definition, is a reduction in exocrine pancreatic function to a level that results in maldigestion. Since the introduction of highly sensitive pancreatic imaging methods, such as MRI, modern CT and endoscopic ultrasound, the need to rely on pancreatic function testing for the diagnosis of CP has diminished, and most centers have abandoned the classic secretin test.

Recently, an endoscopic direct pancreatic function test was developed, with a simplified protocol for pancreatic fluid collection through an endoscope. A good correlation between the endoscopic pancreatic function test and standard direct tests has been demonstrated<sup>[47,48]</sup>. Exocrine pancreatic secretion can also be evaluated based on the degree of duodenal filling on MRI after secretin stimulation, which has been demonstrated to correlate with a combination of the FE-1 assay, the  $^{13}\text{C}$ -MTG breath test and fecal fat testing<sup>[49]</sup> and the endoscopic pancreatic function test<sup>[50]</sup>. Further studies are needed to evaluate the role of the endoscopic function test and secretin-enhanced MRI in the diagnosis of PEI. It should be noted that all tests of pancreatic secretion share the drawback of ignoring other factors that may alter the effect of pancreatic enzymes in the intestine. Thus, tests of pancreatic secretion are irrelevant in situations in which factors other than the secretory capacity of the pancreas may contribute to PEI.

### Integrated use of methods to diagnose PEI

The optimal test for the diagnosis of PEI is a test that can detect the maldigestion of fat with high sensitivity and specificity. Fecal fat quantification and the  $^{13}\text{C}$ -MTG breath test are recommended for the accurate diagnosis of PEI because these two tests best fit this description. However, due to the limited availability of these tests and the odious nature of fecal fat quantification, there is a need for a simplified way to estimate the probability of PEI based on generally available clinical parameters. In Figure 2, a proposal for a diagnostic algorithm to estimate the probability of PEI based on routine blood tests, FE-1 assessment and standard imaging is presented. The algorithm is designed to have a high negative predictive value for PEI and integrates knowledge from recent studies<sup>[14,28,37]</sup>. However, it should be stressed that this algorithm provides only an estimation of the probability of PEI and that the algorithm has not been scientifically validated.

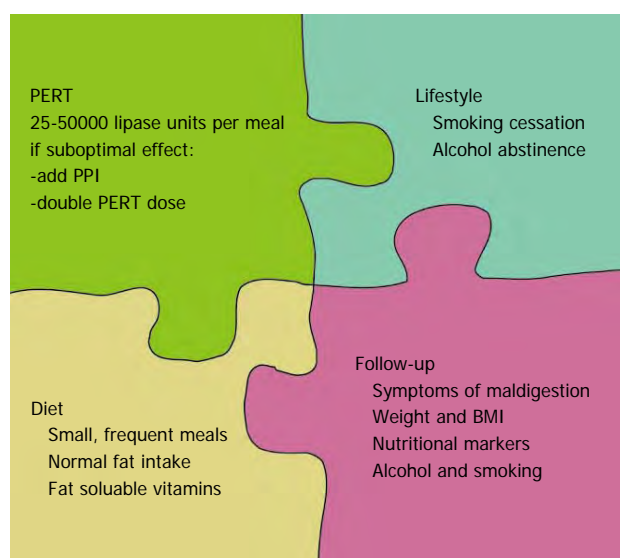

Figure 3 Fundamental aspects in the care of patients with pancreatic exocrine insufficiency. PERT: Pancreatic enzyme replacement therapy; PPI: Proton pump inhibitors.

## TREATMENT OF PANCREATIC EXOCRINE INSUFFICIENCY

Cornerstones in the treatment of PEI are PERT, support to cease smoking and alcohol consumption, consultation with a dietitian and a systematic follow-up to assure optimal treatment effect (Figure 3). The goal of this treatment concept is to normalize digestion, alleviate PEI-related symptoms and prevent malnutrition-related morbidity and mortality and disease progression.

### Diet, smoking and drinking

Historically, a low-fat diet has been recommended in PEI to reduce steatorrhea. This recommendation has been abandoned in modern dietary counseling in PEI due to the risk of aggravating PEI-related weight loss and deficiencies of lipid-soluble vitamins<sup>[18,51]</sup>. By optimization of the PERT dose and supportive treatment with PPI, most PEI patients will tolerate a normal-fat diet. Dietary consultation should include advice for sufficient caloric intake and normal fat content. Small, frequent meals are usually better tolerated than large, high-caloric meals. Deficiencies of fat-soluble vitamins are very common in PEI patients, and vitamin supplementation therapy should be given if necessary<sup>[15]</sup>. Support for alcohol abstinence should be offered to all patients with alcohol-related CP. In addition to the general health benefits of alcohol withdrawal, this withdrawal has also been demonstrated to slow the further deterioration of pancreatic exocrine function<sup>[52]</sup>. Smoking is a risk factor for pancreatic cancer, acute pancreatitis and CP<sup>[53]</sup>, and is also associated with an increased probability of reduced pancreatic exocrine function based on the endoscopic pancreatic function test in cases with CP<sup>[54]</sup>. Continued smoking has been associated with earlier development of calcifications in patients with CP<sup>[55]</sup>. Smoking cessa-

tion should be encouraged in all patients with CP with or without PEI.

### Pancreatic enzyme replacement therapy

Pancreatic digestive enzymes can be administered orally, together with meals, in patients with PEI to compensate for the lack of endogenous enzyme secretion. Modern pancreatic enzyme preparations are extracts from the porcine pancreas (pancrelipase) that are administered as enteric-coated minimicrospheres. Several different preparations are commercially available, with minor differences in particle size and pH-related release kinetics<sup>[56]</sup>. PEI with steatorrhea and/or weight loss is an undisputed indication for PERT. Several studies have demonstrated an improved coefficient of fat absorption<sup>[57-60]</sup>, decreased maldigestion-related symptoms<sup>[57,59-61]</sup> and even improved quality of life<sup>[61,62]</sup>. The need for PERT in PEI without symptoms is a matter of debate, and randomized clinical trials on this issue are lacking. Nevertheless, certain collateral evidence supports PERT, even in the absence of overt steatorrhea and weight loss: (1) A longitudinal study in patients with CP demonstrated that patients with no clinical symptoms of steatorrhea but an abnormal steatocrit who did not receive PERT lost more weight than not only CP patients with a normal steatocrit but also patients with an abnormal steatocrit and symptoms of steatorrhea who were treated with PERT<sup>[63]</sup>; (2) Laboratory signs of malnutrition have been demonstrated in a large proportion of patients with CP and asymptomatic steatorrhea who were not under treatment with PERT<sup>[64]</sup>. The clinical relevance of such deficiencies has not been specifically investigated in CP and PEI, but an increased risk of complications that are generally associated with malnutrition can be assumed<sup>[65]</sup>; and (3) Based on observational studies in CP, it is well known that malnutrition-related diseases and findings, such as osteoporosis-related fractures<sup>[16]</sup>, decreased bone mineral density<sup>[15,66,67]</sup> and deficiencies of fat-soluble vitamins<sup>[15]</sup>, are common in CP.

As evidence for nutritional deficiencies in patients with PEI with and without symptoms has increased in recent years, PERT is now increasingly regarded as a treatment for maldigestion rather than a way to suppress diarrhea in patients with CP<sup>[65]</sup>. The goal of PERT is stated to be the elimination of maldigestion in the Australasian Pancreatic Club recommendations<sup>[18]</sup>. Meanwhile, the Spanish Pancreatic Club regards any clinical or nutritional deficiency in a CP patient as an indication for PERT<sup>[68]</sup>, and the Italian Association for the Study of the Pancreas states in its guidelines that PEI is an indication for PERT<sup>[19]</sup>.

The safety and efficacy of PERT for the treatment of PEI in CP has been investigated in four randomized, double-blinded, placebo-controlled clinical trials including up to 72 patients over study periods of 1-2 wk<sup>[57-60]</sup>. Significant improvements in the coefficient of fat absorption<sup>[57-60]</sup>, the coefficient of nitrogen absorption<sup>[58-60]</sup>, stool fat content<sup>[60]</sup> and stool weight<sup>[60]</sup> have been docu-

**Table 1** The  $^{13}\text{C}$ -mixed triglycerides breath test according to Domínguez-Muñoz *et al*<sup>[44]</sup>

The patient fasts from midnight
Twenty minutes before the test, 10 mg of metoclopramide is ingested
A baseline breath sample is taken
At time 0, 250 mg of $^{13}\text{C}$ -mixed triglycerides mixed with 16 g of fat on a piece of toasted bread is ingested, together with a glass (200 mL) of water
Breath samples are taken every 15 (or 30) min for 6 h
Finally, $^{13}\text{CO}_2/^{12}\text{CO}_2$ is measured in collected breath samples by mass spectrometry or isotope-selective nondispersive infrared spectrometry

**Table 2** Pancreatic enzyme replacement therapy: How we do it

PERT is started at 50000 lipase units per main meal and 25000 lipase units per snack
The basic concepts of the pathophysiology of PEI and how PERT works are explained to the patient. It is emphasized that PERT should be taken with meals and that the dose should be adjusted to the fat content of the meal
If maldigestion persists, proton pump inhibitors can be added, and the dose is increased to 80000 lipase units per main meal and 40000 lipase units per snack
If PERT is still ineffective, despite the optimization described above, small intestinal bacterial overgrowth is considered, and the evidence for a diagnosis of PEI is revised

PEI: Pancreatic exocrine insufficiency; PERT: Pancreatic enzyme replacement therapy.

mented. Two of these trials have also reported results from open-label extension periods of 6 and 12 mo<sup>[62,69]</sup>. Continuous improvement during treatment, with a steady-state reached at week 13, was observed for most symptom variables<sup>[62]</sup>. In these clinical trials, PERT has been well tolerated, and no serious adverse events have been reported. Fibrosing colonopathy is the only serious complication that has been associated with PERT. In the vast majority of reported cases, this rare condition has been observed in patients with cystic fibrosis using high doses of PERT<sup>[70]</sup>. The pathophysiology of this condition is unknown, but factors related to cystic fibrosis disease per se, the dosing of PERT and possibly agents in the enteric coating of the pancrelipase preparations may play a role<sup>[71]</sup>.

There are no studies investigating the long-term effects of PERT on morbidity and mortality from PEI, which should be kept in mind if patients with no or minimal symptoms of PEI are considered for PERT.

### Dosing of pancreatic enzyme replacement therapy

The concept of PERT is to induce a lipolytic capacity that corresponds to the amount of ingested fat at every meal. Therefore, higher doses are necessary for large, high-fat meals, and lower doses are sufficient for snacks and lean meals. The optimal dose of PERT in CP has not been investigated systematically in clinical trials. Recommendations from different national societies range from 20-40000 lipase units per main meal, as recommended by the German Society of Digestive and Metabolic Diseases<sup>[72]</sup>, to 25-40000 lipase units per main meal, as recommended by the Australasian Pancreatic Club<sup>[18]</sup> and the Italian Association for the Study of the Pancreas<sup>[19]</sup>, to 40-50000 lipase units per mail mean, as recommended by The Spanish Pancreatic Club<sup>[68]</sup>. In general, half of the dose is recommended for snacks and minor meals. Recent randomized clinical trials have used higher doses (72000 USP units<sup>[59]</sup> and 80000 Ph.Eur.U

units<sup>[60]</sup> per main meal). It is noteworthy that even in a study using 80000 lipase units per main meal, only 26% of the patients had a normalized coefficient of fat absorption at the end of the 51-wk open-label extension of the study<sup>[62]</sup>.

There is no consensus on the definition of treatment success in PERT. If the elimination of maldigestion is accepted as the aim of the treatment, fecal fat quantification or an indirect test of maldigestion, such as the  $^{13}\text{C}$ -MTG breath test, would be the most appropriate examination for verifying treatment success. However, this approach is rarely feasible in clinical practice. Most guidelines recommend a reevaluation of symptoms and weight and a reevaluation of serum tests of malnutrition.

In fact, it is highly likely that many patients with PEI today are receiving PERT that is suboptimal. A recent study from the Netherlands has indicated that as many as 70% of patients with CP report steatorrhea-related symptoms despite PERT<sup>[73]</sup> and that persistent deficits in blood nutritional parameters despite PERT are common in PEI<sup>[15,64]</sup>. What measures can be taken to optimize the result of PERT? First, it is of utmost importance to ensure that the patient is taking the prescribed dose correctly. Capsules should be administered with meals (as opposed to before or after) for optimal effect<sup>[74]</sup>. If signs or symptoms of maldigestion persist, the PERT dose can be increased, and proton pump inhibitors can be added<sup>[44,75,76]</sup>. The rationale for adjuvant treatment with proton pump inhibitors is that bicarbonate secretion is impaired in CP, resulting in insufficient buffering of the gastric chyme when it enters the small bowel. This phenomenon may in turn compromise the effect of PERT because lipase is rapidly degraded at a low pH and because enzyme release from microspheres is pH dependent. If PERT is ineffective despite an increased dose and adjuvant treatment with PPI, the diagnosis of PEI should be revised, and possible coexisting and/or alter-

native reasons for maldigestion, such as small intestinal bacterial overgrowth, should be considered. A summary of PERT concepts in clinical practice is presented in Table 2.

In conclusion, PEI is a state of maldigestion that is the result of a reduction of pancreatic enzyme activity in the intestinal lumen to a level that is below the threshold required to maintain normal digestion. CP is the most common cause of PEI, but several other pancreatic and extrapancreatic diseases can lead to PEI. The diagnosis of PEI is best established by tests that directly measure digestion, such as fecal fat quantification or the <sup>13</sup>C-MTG breath test. If these tests are not available, clinical and biochemical signs of malnutrition; pancreatic imaging findings; and tests that measure pancreatic secretion, such as the FE-1 assay, can be used to estimate the probability of PEI. The treatment of PEI relies on the elimination of risk factors for disease progression, such as smoking and alcohol consumption; consultation with a dietitian; PERT; and a systematic follow-up of the treatment effect on nutritional status and symptoms. If required, PERT can be optimized by dose augmentation and the addition of proton pump inhibitors.

### Abstract

The pancreas is a major player in nutrient digestion. In chronic pancreatitis both exocrine and endocrine insufficiency may develop leading to malnutrition over time. Maldigestion is often a late complication of chronic pancreatic and depends on the severity of the underlying disease. The severity of malnutrition is correlated with two major factors: (1) malabsorption and depletion of nutrients (*e.g.*, alcoholism and pain) causes impaired nutritional status; and (2) increased metabolic activity due to the severity of the disease. Nutritional deficiencies negatively affect outcome if they are not treated. Nutritional assessment and the clinical severity of the disease are important for planning any nutritional intervention. Good nutritional practice includes screening to identify patients at risk, followed by a thoroughly nutritional assessment and nutrition plan for risk patients. Treatment should be multidisciplinary and the mainstay of treatment is abstinence from alcohol, pain treatment, dietary modifications and pancreatic enzyme supplementation. To achieve energy-end protein requirements, oral supplementation might be beneficial.

Enteral nutrition may be used when patients do not have sufficient calorie intake as in pyloro-duodenal stenosis, inflammation or prior to surgery and can be necessary if weight loss continues. Parenteral nutrition is very seldom used in patients with chronic pancreatitis and should only be used in case of GI-tract obstruction or as a supplement to enteral nutrition.

### INTRODUCTION

Chronic pancreatitis (CP) is an inflammatory disorder that causes irreversible anatomical changes and damage, including infiltration of inflammatory cells, fibrosis and

calcification of the pancreas with destruction of the glandular structure and thereby affects normal digestion and absorption of nutrients.

Maldigestion is often a late complication of CP and depends on the severity of the underlying disease. The medium latency between onset of first symptoms and signs of maldigestion is about 8-9 years in alcoholic CP and more than 15 years in idiopathic non-alcoholic pancreatitis. Nutrient deficiencies are common in CP, driven by many risk factors including malabsorption, diabetes and, in alcoholic CP, alcoholism. However, deficiencies are frequently overlooked, leading to malnutrition<sup>[1,2]</sup>.

The aim of this article is to discuss the definition of malnutrition and good nutritional practice in patients with CP.

## DEFINITION OF MALNUTRITION AND GOOD NUTRITIONAL PRACTICE

Generally about 20%-50% of all patients in hospital are found at risk of undernutrition, dependent on definition, clinical setting and screening tool amended. A large part of these patients are at nutritional risk when admitted to hospital and in the majority of these, undernutrition develops negatively during hospital stay<sup>[3,4]</sup>.

This can be prevented if special attention is paid to nutritional care of patients. Routine identification is paramount as a first stage in a patient's care in order to identify at-risk patients, with a view to providing nutrition support if necessary<sup>[5,6]</sup>.

Good nutritional practice for the patient starts by nutrition screening. The European Society for Clinical Nutrition and Metabolism (ESPEN) Guidelines for Nutrition Screening recommend a continuity of issues to be considered in all patients admitted to hospital (Figure 1)<sup>[6]</sup>. (1) Initially on admission, a simple nutritional screening is to be done, to identify patients at actual nutritional risk; (2) Subsequently for patients at nutritional risk, a thorough nutritional assessment is to be completed; (3) This stage leads to an individual evaluation of nutritional requirements, and a plan for nutrition therapy and care; and (4) Monitoring and defining of targeted outcome should be structured in order to reconsider therapy and care-planning. Finally, communication around results of screening, assessment, plan and monitoring should be communicated to other health care professionals, when the patient is transferred, either back to the community or to another institution<sup>[7-9]</sup>.

In order to give priority to nutritional intervention for relevant patients, nutrition screening methods have been developed and validated. These screening methods regard nutritional status and acute disease. However, there is still no clear consensus agreement on a uniform definition of undernutrition or agreement for a gold standard method of screening and identification of undernutrition<sup>[10]</sup>. This also applies for patients with CP and malnutrition which has been offered numerous definitions. Simply stated, malnutrition is a sub-optimal nutrient status appearing

as a consequence of nutrient deficiencies, which change body composition and functional status. However, this definition neglects the numerous causes of malnutrition. An international guideline committee has recently proposed an aetiology-based approach that incorporates a current understanding of the inflammatory response, as seen in CP and many other patients. The committee proposed the following nomenclature for nutrition diagnosis in adults in the clinical practice setting: "Starvation-related malnutrition", for chronic starvation without inflammation *i.e.*, anorexia nervosa, "chronic disease-related malnutrition", when inflammation is chronic and of mild to moderate degree *i.e.*, CP, and "acute disease or injury-related malnutrition", *i.e.*, CP with a serious complication in the intensive ward, that is, when inflammation is acute and of severe degree<sup>[11,12]</sup>.

The causes of malnutrition in patients are thus included in its definition. As such, screening tools, which neglect to include relevant disease related parameters such as chronic or acute inflammation, may be less efficacious in identifying malnutrition risk.

Nutritional screening should be a simple and rapid process, which can be carried out by busy admitting nursing and medical staff. Most screening tools address four basic questions: recent weight loss, recent food intake, current body mass index and disease severity or some other measure of predicting risk of malnutrition. In 2003, ESPEN published guidelines for nutrition screening in the community, in the hospital and among elderly in institutions. The Nutrition Risk Screening 2002 (NRS 2002) seems to be the best validated screening tool, in terms of predictive validity, *i.e.*, that clinical outcome improves when patients identified to be at risk are treated, however the evidence is sparse<sup>[3,5,6,9]</sup>.

For adult patients in hospital it is thus suggested to use the NRS 2002 (Figure 2)<sup>[9]</sup>. A score equal to or greater than 3 generates a nutrition plan in all cases. If the patient is at risk, but metabolic or functional problems prevent a standard plan being carried out, or if there is doubt as to whether the patient is at risk, a referral should be made to an expert or expert team for a more detailed assessment.

## HOW DOES CP INFLUENCE NUTRITIONAL STATUS AND METABOLISM?

According to the definition, the severity of malnutrition is correlated with two major factors: depletion of nutrients (alcoholism and pain) and malabsorption causes impaired nutritional status and increased metabolic activity due to the inflammatory component of CP (severity of disease). Generally patients at nutritional risk have an increased number of complications and a poorer outcome, but specific studies investigating this issue in CP are however not available<sup>[2,13,14]</sup>.

A persistent alcohol intake, pain after a meal and maldigestion are the main causes of weight loss, and weight loss is strongly associated with maldigestion of fat<sup>[1,14,15]</sup>.

It is widely acknowledged that patients with CP are

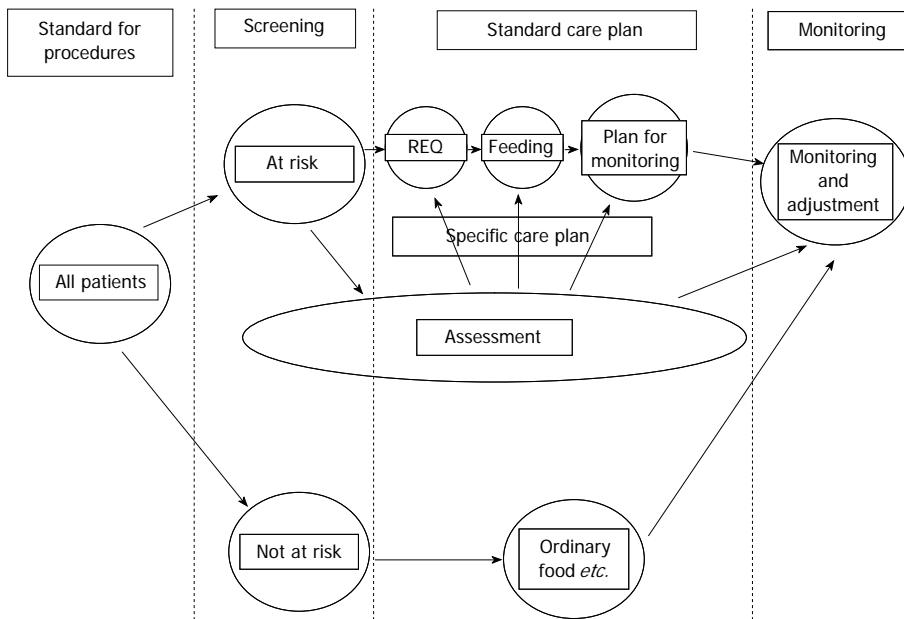

Figure 1 The nutritional care process including screening, plan and monitoring according to the European Society for Clinical Nutrition and Metabolism guideline<sup>[6]</sup>. REQ: Requirement.

often undernourished; however few studies have assessed this. In a medical rehabilitation clinic setting, 32% had a BMI < 20 kg/m<sup>2</sup>; 57% chronic diarrhea and 24% steatorrhea<sup>[2]</sup>.

Others have found that patients are malnourished prior to surgery and that the problem remains after surgery in a substantial proportion of patients with CP<sup>[16]</sup>. Furthermore, lean body mass and fat mass are found to be decreased both in patients with or without residual pancreatic function<sup>[17]</sup>. Decreased lean body mass may lead to decreased functional capacity as found in 34% of patients with moderate to severe weight loss. This also affected quality of life<sup>[18]</sup>. In this study fatigue, found in 46%, also had a major impact on quality of life. In a cohort of ambulatory patients with CP (60 patients), we found 28% at nutritional risk. These patients had a lower fat- and muscle mass and a tendency to lower handgrip strength. Furthermore, handgrip strength was associated with muscle- and fat mass<sup>[19]</sup>.

It has been found that 30%-50% of patients with CP have increased resting energy expenditure<sup>[20]</sup>. We found no difference between estimated (Harris-Benedict) and measured resting energy expenditure (indirect calorimetric) in a cohort of ambulatory CP patients. However, when adjusted for fat free mass and height, we found higher resting energy expenditure (around 20%) in patients with low BMI (< 20 kg/m<sup>2</sup>)<sup>[19]</sup>.

### Substrate metabolism during chronic pancreatitis

Daily intake of carbohydrates is about 300 grams corresponding to about half the caloric intake per day. About half of the caloric intake is carbohydrates and 30% are sucrose. Pancreatic  $\alpha$ -amylase is the only enzyme for carbohydrate digestion that is produced by the pancreas. The final digestion of sugars take place at the brushbor-

der of enterocytes where a range of disaccharidases produce the three sugars glucose, galactose and fructose that can be absorbed. In exocrine pancreatic insufficiency, carbohydrate digestion is maintained for a long time by salivary amylase and brush-border oligosaccharidases. The loss of endocrine function leads to glucose intolerance in 40%-90% of patients with severe CP. Furthermore, in 20%-30% of patients an insulin-dependent diabetes develops associated with impaired glucagon and pancreatic polypeptide regulation (discussed in other article).

Daily protein intake in the Western world lies between 70 and 100 g and gastrointestinal secretions contain further 50-60 g of proteins per day. Protein digestion is initiated by intragastric proteolytic activity and continued by intestinal brush-border peptidases. Luminal proteolytic activity is maintained even in the absence of pancreatic peptidases and azotorrhea is therefore a very late and rare symptom in CP<sup>[21]</sup>. Trypsinogen is the inactive precursor for trypsin, which is the key enzyme for activation of all proteolytic enzymes in the duodenum. Trypsinogen becomes activated by enteropeptidase that is secreted by the brush-border of duodenal enterocytes. Proelastase is produced by the pancreas and belong to the chymotrypsin-like elastase family (elastase-2A, elastase-2B, elastase-3A, and elastase-3B). The elastase-3A isoform can be measured and quantified by the faecal elastase test. About 40% of proteins are digested to free amino acids. Brush border peptidases continue the digestion of peptides longer than three amino acids. Dipeptides, tripeptides, and free amino acids are then absorbed by the enterocytes by different transport mechanisms.

In Western diet up to 40% of the daily caloric intake derives from lipids, although 30% is recommended. Lipids are insoluble in water and need to be transferred to water-soluble micelles formed by bile acids, phospho-

Step 1: Initial screening		Yes	No
1	Is BMI < 20.5 kg/m <sup>2</sup> ?		
2	Has the patient lost weight within the last 3 mo?		
3	Has the patient had a reduced dietary intake in the last week?		
4	Is the patient severely ill? ( <i>e.g.</i> , in intensive therapy)		

Yes: If the answer is 'Yes' to any question, the screening in Step 2 is performed.

No: If the answer is 'No' to all questions, the patient is re-screened at weekly intervals. If the patient *e.g.*, is scheduled for a major operation, a preventive nutritional care plan is considered to avoid the associated risk status.

Step 2: Final screening			
Impaired nutritional status		Severity of disease (approximately increase in requirements)	
Absent Score 0	Normal nutritional status A	Absent Score 0	Normal nutritional requirements
Mild Score 1	Wt loss > 5% in 3 mo or Food intake below 50-75% of normal requirement in preceding week.	Mild Score 1	Hip fracture <sup>1</sup> Chronic patients, in particular with acute complications: cirrhosis <sup>1</sup> , chronic obstructive pulmonary disease <sup>1</sup> . Chronic hemodialysis, diabetes, oncology.
Moderate Score 2	Wt loss > 5% in 2 mo or BMI 18.5-20.5 + impaired gen. condition or Food intake 25%-50% of normal requirement in preceding week	Moderate Score 2	Major abdominal surgery <sup>1</sup> Stroke <sup>1</sup> Severe pneumonia, hematologic malignancy.
Severe Score 3	Wt loss > 5% in 1 month (> 15% in 3 mo) or BMI > 18.5 + impaired general condition or Food intake 0-25% of normal requirement in preceding week	Severe Score 3	Head injury <sup>1</sup> Bone marrow transplantation Intensive care patients (APACHE >10).
Score: _____ +		Score: _____ = Total score:	
Age _____ if ≥ 70 yr: Add 1 to total score above		= Age-adjusted total score:	
Score ≥ 3: The patient is nutritionally at-risk and a nutritional care plan is initiated.			
Score < 3: Weekly rescreening of the patient. If the patient <i>e.g.</i> , is scheduled for a major operation, a preventive nutritional care plan is considered to avoid the associated risk status.			

NRS-2002 is based on an interpretation of available randomized clinical trials.

<sup>1</sup>Indicates that a trial directly supports the categorization of patients with that diagnosis. Diagnoses shown in *italics* are based on the prototypes given below. Nutritional risk is defined by the present nutritional status and risk of impairment of present status, due to increased requirements caused by stress metabolism of the clinical condition.

A nutritional care plan is indicated in all patients who are

- (1) severely undernourished (score = 3)
  - or
  - (2) severely ill (score = 3)
  - or
  - (3) moderately undernourished + mildly ill (score 2 + 1)
  - or
  - (4) mildly undernourished + moderately ill (score 1 + 2)
- Prototypes for severity of disease  
Score = 1: A patient with chronic disease, admitted to hospital due to complications. The patient is weak but out of bed regularly.

Protein requirement is increased, but can be covered by oral or supplement in most cases.

Score = 2: A patient confined to bed due to illness, *e.g.*, following major abdominal surgery. Protein requirement is substantially increased, but can be covered, although artificial feeding is required in many cases.

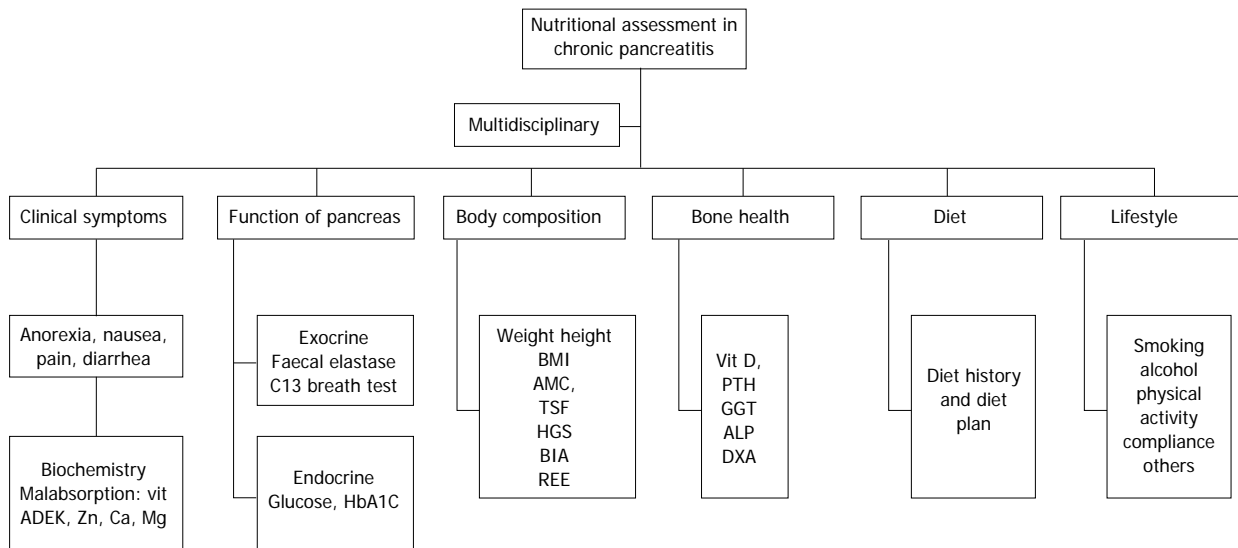

Score = 3: A patient in intensive care with assisted ventilation etc. Protein requirement is increased and cannot be covered even by artificial feeding. Protein breakdown and nitrogen loss can be significantly attenuated.

Figure 2 Nutrition risk screening 2002<sup>[9]</sup>. BMI: Body mass index.

lipids, cholesterol and other products. This facilitates hydrolysis by lipase. In the stomach lingual lipase and gastric lipase hydrolyse triglycerides to glycerol and free fatty acids. Lipases from the gastric and salivary glands have a minor role in digestion of triglycerides and cannot compensate an insufficient pancreatic fat digestion. Thus, luminal lipid digestion within the small intestine depends on the action of pancreatic lipase and cofactors such as colipase and bile acids. There are no triglyceride-digestion enzyme systems within the intestinal brush-border membrane. Consequently, lipid digestion is decreased by insufficient lipase secretion and reduced luminal bile acid concentration. Because bicarbonate secretion is also diminished in CP and postprandial intraduodenal pH may fall < 4, luminal lipase degradation occurs more rapidly than that of other enzymes due to its greater instability. Gastric lipase only partly compensates for the lack of pancreatic lipase (discussed in other article).

### Vitamin deficiency

A deficiency in vitamins A, D, E, K correlates with the severity of steatorrhoea in patients with CP, but may be caused by several different mechanisms including, suboptimal dietary intakes, increased losses, increased requirements, impaired binding of nutrients, antioxidant activity, and fat malabsorption. E vitamin deficiency may be seen more often than deficiencies of vitamin A, D, and K<sup>[22-24]</sup>. However, osteopathy (osteoporosis, osteomalacia, osteopenia) may occur in at least 25% of CP patients<sup>[22]</sup>. The adjusted hazard ratio (HR) for any fracture was 1.7 in patients with CP (95%CI: 1.6-1.8) in a recently Danish study<sup>[25]</sup>. Due to inadequate protease secretion by the pancreas, vitamin B12 deficiency can occur<sup>[26]</sup>. Zinc deficiency may be seen especially in association with diabetes<sup>[27]</sup>. Also, deficiencies in calcium, magnesium, thiamine and folic acids have been reported. The functional meaning of such deficiencies are how-

**Figure 3** Nutritional assessment in patients with chronic pancreatitis. AMC: Arm muscle circumference; TSF: Triceps skin fold; HGS: Hand grip strength; BIA: Bioimpedance; REE: Resting energy expenditure; GGT:  $\gamma$ -glutamyl transferase; ALP: Alkaline phosphatase; PTH: Parathyroid hormone; DXA: Dexa scan.

ever undetermined and in our cohort of ambulatory patients with CP we did not find any correlation between micronutrient deficiencies and handgrip strength as measured by bioimpedance (unpublished data). On the other hand we recently demonstrated that the fibrotic changes as well as atrophy and ductal-related parameters were associated with exocrine insufficiency such as reflected in vitamin D deficiency, and future studies should explore this in further details<sup>[28]</sup>.

## NUTRITIONAL ASSESSMENT

Assessment of nutrition status should include a multidisciplinary approach<sup>[14]</sup>, including assessment of clinical symptoms, exocrine and endocrine pancreatic function, body composition, bone health, dietary evaluation and lifestyle as illustrated in Figure 3.

Clinical symptoms should include routine medical history and psychological examination with special emphasis on nutrition related symptoms and risk factors (nausea, anorexia, pain, alcohol, smoking). Micronutrient status should be measured 1-2 times a year including malabsorption of fat-soluble vitamins, minerals and trace elements. Function of pancreas concerning the exocrine and endocrine part will not be discussed in this article.

Because both weight and BMI do not take body composition into account and may be misinterpreted as a result of fluid changes including ascites and edema, further investigation and assessment may be made with anthropometrics and bioimpedance measurements, both for baseline and follow-up (*i.e.*, every 3-6 mo), because even patients with a normal BMI may have a decreased muscle mass that further might decrease function and lead to a higher morbidity, *i.e.*, higher incidence of postoperative complications after surgery for CP<sup>[16]</sup>.

Anthropometric measurements as mid-arm circum-

ference estimating lean body mass and triceps skinfold estimating subcutaneous fat stores can be compared with age- and gender-specific centiles and are useful especially in patients with edema or ascites and as a long-term follow-up for nutritional status<sup>[14]</sup>.

Bioimpedance is easy, non-invasive, and relatively inexpensive, and can be performed in almost any subject because it is portable. ESPEN guidelines<sup>[29-31]</sup>, report results for fat-free mass body fat, body cell mass total body water, extracellular water and intracellular water from various studies in healthy and ill subjects. The data suggests that bioimpedance works well in healthy subjects and in patients with stable water and electrolytes balance with a validated bioimpedance equation that is appropriate with regard to age, sex and race. Clinical use of bioimpedance in subjects at extremes of BMI ranges or with abnormal hydration cannot be recommended for routine assessment of patients until further validation has proven for bioimpedance algorithm to be accurate in such conditions. Multi-frequency- and segmental-bioimpedance may have advantages over single-frequency bioimpedance in these conditions, but further validation is necessary. Longitudinal follow-up of body composition by bioimpedance is possible in subjects with BMI 16-34 kg/m<sup>2</sup> without abnormal hydration, but must be interpreted with caution.

Since muscle function correlates closely with whole body protein, body cell mass, anthropometrically measured arm muscle mass, and even with BMI, loss of weight or muscle mass invariably results in decreased muscle strength which is reflected in deteriorating function tests as well as in prominently altered muscle morphology<sup>[32]</sup>. Reduced muscle strength is in turn associated with loss of physical functionality and with negative impact on recovery of health after illness or surgery, which partly explains the high predictive power of muscle

function tests<sup>[2]</sup>. Hence, various studies have shown a close correlation between muscle strength and outcome in acute and chronic disease<sup>[32-34]</sup>. Just as measuring body composition offers a qualitative aspect of nutritional status, muscle function represents a dynamic indicator of muscle mass. Measurement of muscle function as indicator of functional as well as nutritional status has therefore gained considerable attention in the past years. Although hand grip strength correlates well with other muscle function tests such as knee extension strength or peak expiratory flow, it cannot be used as surrogate for muscle function of lower extremities when evaluating physical performance. Short term effects of nutritional therapy as *e.g.*, refeeding of acute malnutrition are seen earlier by muscle function than by changes in body composition. Long-term nutritional therapy should result in both changes of body composition and muscle function, which should be paralleled by improvements of physical status<sup>[31,35]</sup>.

Reference values for age- and gender-specific percentiles exist<sup>[36]</sup>.

Resting energy expenditure (REE): Institution of appropriate nutritional therapy necessitates accurate determination of energy requirements. Data on measured REE in CP are very limited, but has shown, that weight loss is accompanied by hypermetabolism, and that between 30% and 50% of patients with CP have increased REE<sup>[20]</sup>. It may help us predict the energy level necessary to promote weight restoration and optimize nutritional rehabilitation preventing severe medical complications such as the refeeding syndrome<sup>[37]</sup>. Unfortunately, this technology is not available in the majority of the hospitals, because it requires skilled technicians and sophisticated methodologies that are costly and difficult to apply in standard clinical settings.

Predictive formulas of REE may be used as an alternative to indirect calorimetric that may be utilized by clinicians. The most cited and used predictive formula is the Harris-Benedict equation, which includes age, stature, and body weight to estimate REE<sup>[38]</sup>. However, studies are needed to validate predictive formulas *vs* measured resting energy expenditure by indirect calorimetric.

Bone health: Despite the reported high incidence of osteopathy in CP, no disease specific guideline exists for CP. However, extrapolating from guidelines for comparable malabsorptive diseases, calcium and vitamin D supplementation as well as regular monitoring of bone health should be an integral part of the nutrition management of CP, hence biochemistry and DXA scan should be performed regularly (*i.e.*, once a year).

Diet: A detailed assessment of current and habitual dietary intakes should be made by a dietician for all patients at nutritional risk as indicated by the NRS 2002 screening tool. Nutrient intake may be measured by a 24-h recall interview or a diet history, and analyzed using specialized software providing detailed information about energy- and protein intake as well as fat and micronutrients intake. For evaluating specific food items a food fre-

quency questionnaire can be used<sup>[39]</sup>. A specific diet plan should be made and follow-up visits evaluating intake compared to recommended energy- and protein intake should be employed according to clinical monitoring practice. It has been shown, that both dietary counseling and oral supplements for CP patients at nutritional risk can improve weight, BMI and decrease fecal fat excretion<sup>[40]</sup>.

Lifestyle: To minimize nutritional risk factors in patients with CP, an effort should be made to investigate and eliminate possible individual barriers such as smoking and alcohol abuse. Furthermore, to assure patient compliance regarding medical treatment (*i.e.*, treatment with enzymes) and to evaluate pain treatment (discussed in another article). Physical activity should be encouraged alongside nutritional therapy for optimal result<sup>[32-34]</sup>.

## NUTRITIONAL MANAGEMENT

### *Nutritional treatment in chronic pancreatitis*

Maldigestion of macronutrients is the major cause of progressive nutritional and metabolic impairment in patients with CP. Nutritional interventions depend on the degree of maldigestion and the nutritional status.

The main goals for nutritional interventions are to ensure sufficient macro- and micronutrients intake, to decrease maldigestion, malabsorption and other risk factors in order to prevent or treat malnutrition.

The treatment of exocrine deficiency begins with dietary recommendations and pancreatic enzyme supplementation. About 80% of patients can be managed by a combination of analgesics, dietary recommendations and pancreatic enzyme supplements, while 10%-15% need oral nutritional supplements, 5% need enteral tube feeding and around 1% require parenteral nutrition<sup>[21,41,42]</sup>.

### *Diet recommendations*

Dietary recommendations begin with total abstinence from alcohol. In addition, an adequate number of calories should be taken. Estimation of REE [or measurement in patients with a low BMI (< 20 kg/m<sup>2</sup>)] is essential in all patients to calculate the adequate caloric intake because of risk of increased resting energy expenditure. Frequent small meals (4-8 times a day) should be given. The carbohydrate intake might be limited when an overt diabetes mellitus is present (described in more detail in other article).

A protein diet of 1.0-1.5 g/kg body weight/d is generally sufficient and well tolerated. Usually, if 30%-40% of the calories are given as fat this is well tolerated, especially when the foods are rich in vegetable fats.

If weight gain is insufficient and/or steatorrhea persists, medium chain triglycerides (MCT) can be tried to increase fat absorption. MCT are absorbed directly across the small bowel into the portal vein, even in the absence of lipase, co-lipase and bile salts. However, MCTs have low energy density and unpalatable taste, and a maximum of about 50 g/d might be given. Higher doses may be

ketogenic and are associated with side effects such as cramps, nausea and diarrhea. Fat soluble vitamins (A, D, E and K), vitamin B12 and other micronutrients should be supplemented if serum levels indicate deficiencies.

In general, a low fibre diet is recommended, because fibre may absorb enzymes and delay the absorption of nutrients. An adequate quantity of exogenous pancreatic enzymes is necessary to correct protein and lipid mal-digestion<sup>[1,43-45]</sup>. In 10%-15% of patients oral supplements can help to attenuate weight loss and delay the use of enteral tube feeding<sup>[42,46]</sup>.

The best clinical follow-up parameters for monitoring therapeutic success of dietary counseling are improvement of the patient's general condition and weight gain.

### Enteral nutrition

The cause of inadequate caloric intake in CP can be anatomical (due to pyloro-duodenal-stenosis or cyst compression) or inflammatory with acute complications (new attack of acute pancreatitis or development of fistulas). Patients suffering from serious insufficient caloric intake may benefit by oral supplements or enteral nutrition. To test if enteral nutrition is tolerated and increases nutritional status it is recommended to give the nutrition via a naso-jejunal tube. However, for long-term therapy feeding (exceeding 2-3 wk) a percutaneous endoscopic gastrostomy with a jejunal tube extension is more convenient. Continuous overnight delivery of the nutrients is suitable and entails more easily the patient's nutritional goal. From a theoretical point of view a semi-elemental diet can be recommended, but there are no studies showing improvement in the nutritional status compared to regular enteral nutritional formulas.

Owing to the fact that CP patients are frequently undernourished, nutritional support before pancreatic surgery may be beneficial. Data from patients undergoing general abdominal surgery have provided evidence that preoperative enteral or oral nutritional support improves outcome compared to undernourished patients by reducing postoperative morbidity and the length of hospital stay<sup>[47]</sup>. Thus, it should be emphasized that nutritional therapy should go alongside surgery, and that surgery for pain or any obstruction in the GI-channel should be a primary indication.

The potential to modulate the activity of the immune system by interventions with specific nutrients is termed immunonutrition. This concept is normally applied to any situation where nutritional formulas are supplemented with specific nutrients such as arginine, glutamine, omega-3 fatty acids, nucleotides and others. Meta-analysis of randomized controlled trials giving a combination of arginine and omega-3 fatty acids at home for 5-7 d before surgery reduced both postoperative infection rate and length of hospital stay in patients who underwent elective major GI surgery<sup>[48,49]</sup>. Specific trials in patients with chronic pancreatitis are not available. A recent RCT giving supplemental immunonutrition preoperatively in well-nourished and mal-nourished gastrointestinal sur-

gery patients showed, that LOS and costs were reduced especially in mal-nourished patients<sup>[50]</sup>.

Another recent study showed that enteral immunonutrition given post-operatively *vs* a standard enteral nutrition showed a reduction of infectious complications, anastomotic leak rate and LOS as well as an improved immunologic outcome<sup>[51]</sup>.

We therefore highly recommend a week with pre-operative immunonutrition to patients going to elective surgery for chronic pancreatitis. Early postoperative enteral nutrition is feasible and may additionally improve outcome after surgery.

### Parenteral nutrition

Parenteral nutrition is infrequently used in patients with chronic pancreatitis. Enteral nutrition preserves immune function and mucosal architecture and decreases the possibility for hyperglycemia while parenteral nutrition also increases the risk of catheter infections and sepsis complications. Parenteral nutrition is therefore only indicated when it is impossible to use enteral nutrition<sup>[52]</sup>. This means if the patients do not reach their requirements because gastric emptying is blocked, the patient needs gastric decompression, it is impossible to introduce a tube into the jejunum, or a complicated fistula is present. Parenteral nutrition is mainly performed over a short term period, *e.g.*, in apparent severe malnutrition prior to pancreatic surgery if enteral feeding is incomplete and may thus be used as a supplement to fulfill their requirements. There are no reported studies of patients with chronic pancreatic insufficiency who have been treated with parenteral nutrition for a long period.

### Future perspectives

Future studies evaluating a systematic approach for assessment and treatment of CP patients at nutritional risk should be made to further elucidate the nutritional course of these patients. Special emphasis should be on body composition, absorption of nutrients and metabolism, as well as measuring micronutrient deficiencies. Furthermore, nutritional interventions should be tested in randomized controlled trials with relevant clinical outcomes, *i.e.*, morbidity, quality of life, physical function and mortality.

### Abstract

Diabetes secondary to pancreatic diseases is commonly referred to as pancreatogenic diabetes or type 3c diabetes mellitus. It is a clinically relevant condition with a prevalence of 5%-10% among all diabetic subjects in Western populations. In nearly 80% of all type 3c diabetes mellitus cases, chronic pancreatitis seems to be the underlying disease. The prevalence and clinical importance of diabetes secondary to chronic pancreatitis has certainly been underestimated and underappreciated so far. In contrast to the management of type 1 or type 2 diabetes mellitus, the endocrinopathy in type 3c is very complex. The course of the disease is complicated by additional present comorbidities such as maldigestion and concomitant qualitative malnutrition. General awareness that patients with known and/or clinically overt chronic pancreatitis will develop type 3c diabetes mellitus (up to 90% of all cases) is rather good. However, in a patient first presenting with diabetes mellitus, chronic pancreatitis as a potential causative condition is seldom considered. Thus many patients are misdiagnosed. The failure to correctly diagnose type 3 diabetes mellitus leads to a failure to implement an appropriate

medical therapy. In patients with type 3c diabetes mellitus treating exocrine pancreatic insufficiency, preventing or treating a lack of fat-soluble vitamins (especially vitamin D) and restoring impaired fat hydrolysis and incretin secretion are key-features of medical therapy.

**Key words:** Diabetes mellitus; Chronic pancreatitis; Type 3c diabetes; Pancreatogenic diabetes; Pancreatitis

**Core tip:** Type 3c diabetes mellitus is more common than generally thought. Its prevalence is supposed to be among 5%-10% among all diabetics. Most patients with type 3c diabetes mellitus suffer from chronic pancreatitis as the underlying disease. Misclassification of these patients is very common, yet identification of these patients is very important due to some special diagnostic and therapeutic considerations in this subset of patients. Among these are *e.g.*, restoring proper fat assimilation, preventing fat-soluble vitamin deficiency and early identification of pancreatic cancer patients. Specific diagnostic criteria for type 3c diabetes mellitus are proposed within this review.

### INTRODUCTION

Chronic pancreatitis is a disease characterized by pancreatic inflammatory and fibrotic injury resulting in irreversible parenchymal damage. Progressive nutrient maldigestion and disturbance of the timing and the interactions

**Table 1** Current classification of diabetes mellitus

I	Type 1 Diabetes Mellitus ( $\beta$ -cell destruction, usually leading to absolute insulin deficiency) A: Immune mediated B: Idiopathic
II	Type 2 Diabetes Mellitus (may range from predominantly insulin resistance with relative insulin deficiency to a predominantly secretory defect with insulin resistance)
III	Other Specific Types Of Diabetes Mellitus A: Genetic defects of $\beta$ -cell function B: Genetic defects in insulin action C: Diseases of the exocrine pancreas 1: Pancreatitis 2: Trauma/pancreatectomy 3: Neoplasia 4: Cystic fibrosis 5: Hemochromatosis 6: Fibrocalculous pancreatopathy 7: Others D: Endocrinopathies E: Drug- or chemical-induced F: Infections G: Uncommon forms of immune-mediated diabetes H: Other genetic syndromes sometimes associated with diabetes
IV	Gestational Diabetes Mellitus

between nutrient digestion and absorption is observed and may lead to severe metabolic derangements. Glucose intolerance and diabetes mellitus are observed quite frequently in the course of the disease<sup>[1,2]</sup>.

Development of diabetes mellitus in chronic pancreatitis mainly occurs due to the destruction of islet cells by pancreatic inflammation. Additionally, nutrient maldigestion leads to an impaired incretin secretion and therefore to a diminished insulin release of the remaining beta-cells<sup>[3]</sup>. In contrast to the autoimmune mediated destruction of the beta-cells in type 1 diabetes mellitus, glucagon secreting alpha-cells and pancreatic polypeptide secreting pancreatic polypeptide-cells are also subject to destruction in chronic pancreatitis leading to a complex deranged metabolic situation.

Diabetes mellitus secondary to pancreatic diseases (such as chronic pancreatitis) is classified as pancreatogenic diabetes or type 3c diabetes mellitus according to the current classification of diabetes mellitus (Table 1)<sup>[4,5]</sup>. Whereas the awareness of type 1 and type 2 diabetes mellitus is rather good, type 3c diabetes mellitus, however, is a condition rarely considered in everyday practice. Yet, recent data on type 3c diabetes mellitus show that it might be more common than generally thought. Studies also suggest that this important condition might be consistently under- and misdiagnosed<sup>[6,7]</sup>.

Due to the complex pathophysiology of type 3c diabetes mellitus it bears clinical and laboratory features which are very distinct from both type 1 and type 2 diabetes mellitus. This review focuses on diagnosis and treatment of diabetes mellitus secondary to chronic pancreatitis.

## PREVALENCE OF DIABETES MELLITUS SECONDARY TO PANCREATIC DISEASES (TYPE 3C)

In contrast to type 1 and type 2 diabetes mellitus, detailed data on the prevalence of type 3c diabetes mellitus hardly exist. Some older studies estimate a rather low prevalence of about 0.5%-1.15% among all cases of diabetes mellitus in North America<sup>[8,9]</sup>. Other studies from, e.g., Southeast Asia where tropical or fibrocalculic pancreatitis is endemic, report a higher prevalence of approximately 15%-20% of all diabetes mellitus cases<sup>[10,11]</sup>.

A recent review of the currently available studies on this topic proposes a prevalence of 5%-10% for type 3c diabetes mellitus among all diabetes mellitus cases in Western populations<sup>[12]</sup>. Data are mainly based on a large retrospective study of 1868 patients at a German University Hospital, where type 3c diabetes mellitus accounted for 9.2% of all diabetics<sup>[7]</sup>. This emphasizes that previous older estimates of the prevalence of type 3c diabetes mellitus must be inaccurately low. In 78.5% of all patients with type 3c diabetes mellitus, chronic pancreatitis was identified as the underlying diseases, therefore resembling the most important causative condition<sup>[7]</sup>.

The previous underestimation of the prevalence of type 3c diabetes mellitus might partly be due to the fact that investigation of the pancreas has meanwhile been facilitated by new diagnostic procedures. Nowadays it has become much easier to detect exocrine pancreatic pathology as imaging methods of the pancreas have clearly improved and noninvasive screening methods to quantify exocrine pancreatic insufficiency are easily available.

If chronic pancreatitis accounts for nearly 80% of all type 3c diabetes mellitus cases, and if the prevalence of type 3c diabetes mellitus is expected to be approximately 5%-10% of all diabetes mellitus cases, the true prevalence of (subclinical) chronic pancreatitis in the general population seems to be far underestimated. This might especially hold true since chronic pancreatitis has previously been considered a disease of alcoholism until the discovery that it is a multifactorial disease with an impact of complex genetic genotypes, smoking, special anatomic conditions, toxic agents and autoimmunity, also<sup>[13]</sup>. Up to date quite a few autopsy studies<sup>[14-16]</sup>, endoscopic ultrasound studies<sup>[17]</sup> and exocrine pancreatic function studies<sup>[18]</sup> report a high frequency of exocrine pancreatic injury suggestive of chronic pancreatitis in the general population. This further supports the view of an underestimation of chronic (subclinical) pancreatitis in the general population.

## DIAGNOSIS OF DIABETES MELLITUS IN CHRONIC PANCREATITIS

As stated above glucose intolerance and diabetes mellitus are common in chronic pancreatitis. Diagnosing diabetes

**Table 2** Proposed diagnostic criteria for type 3c diabetes mellitus

Major criteria (must be present)
Presence of exocrine pancreatic insufficiency (monoclonal fecal elastase-1 test or direct function tests)
Pathological pancreatic imaging (endoscopic ultrasound, MRI, CT)
Absence of type 1 diabetes mellitus associated autoimmune markers
Minor criteria
Absent pancreatic polypeptide secretion
Impaired incretin secretion ( <i>e.g.</i> , GLP-1)
No excessive insulin resistance ( <i>e.g.</i> , HOMA-IR)
Impaired beta cell function ( <i>e.g.</i> , HOMA-B, C-Peptide/glucose-ratio)
Low serum levels of lipid soluble vitamins (A, D, E and K)

MRI: Magnetic resonance imaging; CT: Computed tomography; GLP-1: Glucagon-like peptide-1; HOMA-IR: Homeostasis model assessment of insulin resistance; HOMA-B: Homeostasis model assessment of beta-cell.

mellitus in a patient with known chronic pancreatitis may not be that difficult. Yet, the correct classification of type 3c diabetes mellitus is often missed and patients are commonly misclassified. In a German study only about half of the cases of type 3c diabetes mellitus were classified correctly. Type 3c diabetes mellitus patients were mostly misclassified as type 2 diabetes<sup>[7]</sup>. This might be due to the very poor awareness of this diabetes type.

However, another thing appears even more difficult: do not forget to take into account that a patient first presenting with diabetes mellitus might have a type 3c diabetes mellitus. In any case of a new diabetes mellitus manifestation we should truly use the classification criteria defined by the European Association on the Study of Diabetes (EASD) and the American Diabetes Association (ADA)<sup>[4,5]</sup> and check for type 3c diabetes mellitus. At least if a patient does not fit into the common presentation and complains about gastrointestinal symptoms the physician should be aware of the existence of type 3c and initiate further diagnostics.

### Screening for type 3c diabetes mellitus in chronic pancreatitis

Any patient with chronic pancreatitis should of course be monitored for the development of type 3c diabetes mellitus. The prevalence of diabetes mellitus among patients with an established diagnosis of chronic pancreatitis is reported to be up to 70% (in chronic calcific pancreatitis even up to 90%)<sup>[1,2]</sup>. Patients with long-standing duration of the disease, prior partial pancreatectomy, and early onset of calcific disease seem to be at higher risk for developing type 3c diabetes mellitus. There is a clear increase in the prevalence with the duration of chronic pancreatitis<sup>[19,20]</sup>.

The initial evaluation of patients with chronic pancreatitis should include fasting glucose and HbA<sub>1c</sub>. These tests should be repeated at least annually. Impairment in either one requires further evaluation. If testing suggests an impaired glucose tolerance, further evaluation by a 75 g oral glucose tolerance test is recommended<sup>[21]</sup>. A concomitant analysis of insulin and/or C-peptide levels may be help-

ful in distinguishing between type 2 and type 3c diabetes mellitus<sup>[22]</sup>.

### Distinguishing type 3c diabetes from other types

It is not always easy to diagnose and classify a patient with type 3c diabetes mellitus correctly. Long-standing type 1 and type 2 diabetes mellitus patients are associated with exocrine pancreatic failure<sup>[23]</sup> and patients with diabetes mellitus are at a higher risk for developing acute and/or chronic pancreatitis anyway<sup>[24,25]</sup>. Patients with previous episodes of pancreatitis may also develop type 1 or type 2 diabetes independently of their exocrine pancreatic disease. In order to classify patients with type 3c diabetes mellitus correctly, commonly accepted diagnosis criteria should be established.

In distinguishing between the different diabetes types the presence of islet cell antibodies is consistent with type 1 diabetes mellitus, and the presence of clinical or biochemical evidence of insulin resistance is associated with type 2 diabetes mellitus. Due to the lack of commonly accepted diagnostic criteria up to date, we propose the following criteria for diagnosing type 3c diabetes mellitus (Table 2).

The evaluation of pancreatic polypeptide response to insulin-induced hypoglycemia, secretin-infusion or a mixed nutrient ingestion might be of additional diagnostic interest as discussed elsewhere<sup>[21]</sup>. An absent pancreatic polypeptide response is able to distinguish between type 3c diabetes mellitus from early type 1 and may also distinguish type 3c from type 2, which is characterized by elevated pancreatic polypeptide levels<sup>[26-28]</sup>. Routinely testing of incretin secretion or pancreatic polypeptide response in everyday practice, however, does not seem feasible.

## TREATMENT OF DIABETES MELLITUS SECONDARY TO CHRONIC PANCREATITIS

### Managing hyperglycemia

The derangement in glucose metabolism in type 3c diabetes mellitus ranges from a mild impairment to a severe form characterized by frequent episodes of hypoglycemia, commonly referred to as brittle diabetes<sup>[9]</sup>. In type 3c diabetes mellitus, blood glucose control may be unstable due to the loss of glucagon response to hypoglycemia, carbohydrate malabsorption and/or inconsistent eating patterns due to concomitant pain and/or nausea or chronic alcohol abuse. Thus it is generally reported that type 3c diabetes mellitus is difficult to control, although there are only very few studies in this field<sup>[29,30]</sup>. Astonishingly, all large clinical trials, including Diabetes Control and Complications Trial<sup>[31]</sup> and United Kingdom Prospective Diabetes Study<sup>[32]</sup> specifically excluded patients with type 3c diabetes mellitus.

Currently, there are no generally accepted guidelines

regarding treatment pathways for type 3c diabetes mellitus. Yet, a first step was taken at Pancreas Fest 2012<sup>[21]</sup>. The pharmacological agents typically used for the treatment of type 3c diabetes mellitus are the same as for type 2 diabetes mellitus. The ADA and the EASD recommend metformin as the first-line oral therapy for type 2 diabetes mellitus<sup>[33]</sup>. Therefore many type 3c diabetes mellitus patients are initially treated with metformin as a drug of first choice. If hyperglycemia is rather mild and concomitant insulin resistance is additionally diagnosed or suspected, therapy with metformin may be a good choice in the absence of contraindications. However, metformin treatment might not be tolerated by a majority of patients since its main side effects include nausea, abdominal complaints, diarrhea and weight reduction. A patient with chronic pancreatitis will probably not tolerate these symptoms. Since metformin therapy proves capable of reducing the risk of pancreatic cancer by as much as 70%, however, its anti-diabetic and anti-neoplastic effects may be beneficial in patients with type 3c diabetes mellitus due to chronic pancreatitis<sup>[34]</sup>. This holds especially true since chronic pancreatitis and diabetes mellitus are both well accepted risk factors for the development of pancreatic cancer<sup>[35-37]</sup>.

Incretin based therapies [*e.g.*, glucagon-like peptide-1, (GLP-1)-analogues, dipeptidyl peptidase (DPP)-IV-inhibitors] also enhance insulin secretion. Yet, GLP-1-analogues as well as DPP-IV-inhibitors are both associated with a higher risk of pancreatitis and are reported to have a high frequency of prominent gastrointestinal side effects (*e.g.*, nausea, delayed gastric emptying, weight loss)<sup>[38]</sup>. Therefore their use should best be avoided at present time until their safety is confirmed. A better and probably safer way to positively influence the incretin system might be a proper supplementation with pancreatic enzymes in these patients as discussed below.

In early type 3c diabetes mellitus, oral therapy with insulin segretagogues (sulfonylurea and glinides) may also be considered, thiazolidines should be avoided due to prominent side effects (*e.g.*, bone fractures, fluid retention, congestive heart disease).

Chronic pancreatitis, however, must be seen as a progressive disorder and many patients will eventually require insulin therapy. Patients should then be treated using general insulin dosing guidelines as established for type 1 diabetes mellitus. In patients with severe malnutrition insulin therapy is commonly used as a therapy of first choice. This is due to the desired anabolic effects of insulin in this special subset of patients.

Insulin pump therapy may also be considered for patients who experience a brittle form of diabetes mellitus despite being sufficiently motivated.

As it is in the other diabetes types, initial treatment should include all efforts to correct lifestyle factors which contribute to hyperglycemia and the risk of pancreatic malignancy (*e.g.*, abstinence from alcohol and smoking cessation, weight loss in overweight subjects, physical exercise and dietary modifications).

### Managing exocrine pancreatic insufficiency

Many patients with chronic pancreatitis manifest some degree of fat malabsorption, regardless of the presence of symptoms. In patients with type 3c diabetes mellitus exocrine pancreatic insufficiency is nearly ubiquitous present. Since clinically overt steatorrhea is usually not observed until over 90% of exocrine pancreatic function have vanished, exocrine pancreatic insufficiency and maldigestion might remain undetected. However, the relevant maldigestion, which is present in the majority of patients with chronic pancreatitis, may cause qualitative malnutrition. This is especially important concerning the absorption of fat-soluble vitamins (A, D, E and K).

Very recent studies show a vitamin D deficiency in > 90% of patients with chronic pancreatitis<sup>[39,40]</sup>. Additionally a significant correlation of exocrine pancreatic insufficiency and osteoporosis and/or alterations in bone metabolism can be observed<sup>[41,42]</sup>.

Further considering the possible role of vitamin D deficiency in the pathogenesis of type 1 diabetes mellitus and the association of low vitamin D levels and poor glycemic control in observational studies<sup>[43,44]</sup>, qualitative malnutrition of vitamin D in patients with type 3c diabetes mellitus seems of clinical importance. Measuring serum-25-hydroxyvitamin D levels and supplementing deficient patients might thus be beneficial.

The incretin system may play another crucial role in the metabolic control of type 3c diabetes mellitus. The regulation of the beta-cell mass and the physiological incretin secretion are directly dependent on normal exocrine pancreatic function and fat hydrolysis. Chronic pancreatitis and exocrine dysfunction have been associated with a functional impairment of the incretin system. Impaired GLP-1 secretion, however, can be normalized by pancreatic enzyme supplementation as previously described<sup>[3,45,46]</sup>.

Adequate oral pancreatic enzyme replacement therefore seems very important in type 3c diabetes mellitus. Besides helping to control symptoms of steatorrhea, it also seems capable of preventing qualitative malnutrition and metabolic complications.

### CONCLUSION

Type 3c diabetes mellitus is a clinically important disease with a prevalence of 5%-10% among all patients with diabetes mellitus. The prevalence and clinical importance of this condition has been underestimated and underappreciated in the past.

Most patients with type 3c diabetes mellitus suffer from chronic pancreatitis as the underlying disease. The prevalence of (subclinical) chronic pancreatitis might also been underestimated as some studies suggest. Recognizing a diabetic state in patients with known chronic pancreatitis is obligatory. Patients should undergo screening tests in order to detect hyperglycemia early. Fasting glucose, HbA<sub>1c</sub> and 75 g oral glucose tolerance testing are appropriate diagnostic tools. When diagnosing diabetes

mellitus in patients with chronic pancreatitis, physicians should be aware of the existence of type 3c diabetes mellitus and should classify this condition correctly as pancreatogenic diabetes or type 3c diabetes mellitus.

To identify a (subclinical) chronic pancreatitis as the underlying condition of patients with the established diagnosis of diabetes mellitus certainly is the greater challenge in everyday practice. This is due to the fact that most physicians are not aware of type 3c diabetes mellitus and (subclinical chronic) pancreatitis does not necessarily present in a clinically impressive manner. A patient with unspecific gastrointestinal complaints and diabetes mellitus should therefore always prompt further diagnostics with regard to type 3c diabetes mellitus.

Identifying patients with type 3c diabetes is important since the endocrinopathy in type 3c diabetes is very complex and complicated by additional present comorbidities such as maldigestion and concomitant qualitative malnutrition. Specific diagnostic criteria are proposed above (Table 1). The failure to correctly diagnose type 3c diabetes mellitus leads to failure to implement an appropriate medical therapy. It is mandatory to treat pancreatic exocrine insufficiency in these patients even if clear clinical symptoms such as steatorrhea or gastrointestinal complaints are missing. Adequate pancreatic enzyme supplementation therapy might for once help preventing a lack of fat-soluble vitamins (especially vitamin D). Additionally it might exert beneficial effects on the impaired incretin release in patients with chronic pancreatitis. Furthermore one has to realize that type 3c diabetes mellitus due to chronic pancreatitis might be referred to as a premalignant condition since both diseases are well accepted risk factors for the development of pancreatic cancer.

### Abstract

Despite multiple theories on the pathogenesis of pain in chronic pancreatitis, no uniform and consistently successful treatment strategy exists and abdominal pain still remains the dominating symptom for most patients and a major challenge for clinicians. Traditional theories focussed on a mechanical cause of pain related to anatomical changes and evidence of increased ductal and interstitial pressures. These observations form the basis for surgical and endoscopic drainage procedures, but the outcome is variable and often unsatisfactory. This underscores the fact that other factors must contribute to pathogenesis of pain, and has shifted the focus towards a more complex neurobiological understanding of pain generation. Amongst other explanations for pain, experimental and human studies have provided evidence that pain perception at the peripheral level and central pain processing of the nociceptive information is altered in patients with chronic pancreatitis, and

**Core tip:** Pain management in chronic pancreatitis often remains unsatisfactory. An overview of the current theories on pain generation in chronic pancreatitis is crucial in order to understand the complexity and limitations of current therapeutic approaches. Also, optimal treatment will only be achieved on the basis of a better understanding of these mechanisms. Furthermore, this review may serve as an inspiration for future research and development of methods that can determine the relative contribution of different mechanisms to the "collective" abdominal pain, before patients are subjected to more or less empirical treatment.

Pain and chronic pancreatitis: A complex interplay of multiple mechanisms. *World J Gastroenterol* 2013; 19(42): 7282-7291 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v19/i42/7282.htm> DOI: <http://dx.doi.org/10.3748/wjg.v19.i42.7282>

## INTRODUCTION

Abdominal pain is the most significant symptom and a major clinical challenge in chronic pancreatitis (CP). It is present in up to 90% of the patients and the primary cause of hospitalization<sup>[1]</sup>. Pancreatic pain is characteristically described as a constant, severe, dull, epigastric pain that often radiates to the back and typically worsens after high-fat meals. However, many different pain patterns have been described, ranging from no pain to recurrent episodes of pain and pain free intervals, to constant pain with clusters of severe exacerbations<sup>[2,3]</sup>. In the often cited Zürich series, pain was reported to decrease over time, coinciding with the occurrence of exocrine insufficiency, which led to the “burn-out” hypothesis of pain in CP<sup>[3,4]</sup>. However, evidence against this hypothesis was subsequently provided in two large prospective studies<sup>[5,6]</sup>, where no association between the duration of CP and the quality or frequency of pain was found. Today the “burn-out” hypothesis is regarded obsolete by most clinicians, and even though a few patients may experience spontaneously pain relief, pain in the majority of patients is unpredictable and has a substantial impact on physical and mental quality of life, employment and health care expenses<sup>[6-8]</sup>.

The etiology of pain in CP is increasingly better understood and likely involves multiple mechanisms. Traditional theories focused on the role of local pathology within or in close proximity to the pancreas, as the main generator of pain, but since the late 1990's there has been a shift towards a neurobiological understanding of pain in CP. Accordingly, there is solid histological and neurophysiological evidence for an abnormal pain processing in many of these patients<sup>[1,9]</sup>. Various mechanisms responsible for this altered pain processing have been proposed, among them sensitization of the peripheral and central nerves, reorganization of the cerebral cortex and alterations in pain control systems. In addition, local complications (such as pancreatic pseudocysts and duodenal and/or bile duct obstruction) and adverse effects to treatment also contribute to the complex symptomatology in many patients and is an often a neglected problem in the clinical settings. Also, it has been shown, that the clinical pain pattern varies with the etiology of CP, and hypothesized that different pathogenic mechanisms of pain are associated with or predominates depending on etiology<sup>[2,4]</sup>, but so far it is not possible to correlate pain mechanism and clinical pain pattern to the etiology of CP uniformly.

The aim of this review is to highlight current theories regarding the pain mechanisms in CP. This is important in order to understand the complexity of this debilitating disease and why pain management is often insufficient. Also, optimal treatment will only be achieved on the basis of a better understanding of the mechanisms underlying pain in CP<sup>[10]</sup>. There is a variety of potential pain mechanisms that needs to be taken into consideration (Figure 1), but in this review we present for simplicity

a schematic division of the pain mechanisms into five main categories as an easy-to-remember overview (Table 1).

## “PLUMBING” PROBLEMS

The mainstay of pain treatment in CP has for many years focused on the pancreatic gland based on the assumption, that pain is generated by increased pressure in the pancreatic duct or in the pancreatic parenchyma<sup>[11]</sup>. This mechanistic understanding of pain, termed the “the plumbing theory”, has been the most widely accepted theory regarding the cause of pain and it is the theoretical background of most interventions including surgical and endoscopic drainage procedures<sup>[12]</sup>.

### *Pancreatic duct hypertension and pain*

A direct relationship between pancreatic duct hypertension and pain was reported for the first time in a case report by White *et al.*<sup>[13]</sup>. A patient undergoing open necrosectomy following acute necrotizing pancreatitis had a drainage catheter placed in a fistula tract communicating with the pancreatic duct. He reproducibly developed pain after saline infusion when the ductal pressure exceeded 25 mmHg<sup>[13]</sup>. Inspired by this finding, subsequent studies attempted to compare ductal pressure measurements in CP patients and other patient groups. Many of these studies were flawed by inappropriate comparison of intraoperative pressure measurements in CP patients to endoscopic pressure measurement in controls. Accordingly, only a few studies have compared ductal pressure using the same technique in patients and controls. Based on intraoperative measurement of pancreatic duct pressure, significantly increased pressures were evident in patients with CP undergoing a surgical pancreatic drainage procedure compared to patients undergoing surgery for gastric cancer<sup>[14]</sup>. Moreover, in a study comparing endoscopic manometry of the pancreatic duct, CP patients had evidence of ductal hypertension compared to controls<sup>[15]</sup>. Other studies based on endoscopic manometry have, however, not documented ductal hypertension in CP, and the only study comparing CP patients by the presence or absence of pain demonstrated no difference in pressure levels<sup>[16-20]</sup>. In addition, the pathological mechanism by which increased ductal pressure causes pain in CP is not clear and, taken together, the link between ductal hypertension and pain in CP remains hypothetical.

### *Pancreatic parenchymal hypertension and pain*

Measurement of intrapancreatic pressure was pioneered by Ebbelhøj *et al.*<sup>[21]</sup>, who developed a technique based on a needle probe inserted directly into the pancreatic parenchyma. Measurements were employed directly intraoperatively or by using a percutaneous procedure guided by ultrasonography<sup>[21]</sup>. In 39 patients with CP, they found that the intrapancreatic pressure was higher in patients

Figure 1 Pain mechanisms in chronic pancreatitis. The source of pain in chronic pancreatitis is complex and almost certainly multifactorial, and the relative contribution of different factors can be difficult to determine in the individual patient. See manuscript for further details. Modified from Demir *et al*<sup>[87]</sup>. CCK: Cholecystokinin.

with pain than in patients without pain, and this intrapancreatic hypertension was reversed following surgical drainage<sup>[22]</sup>. At one-year follow-up, patients with recurrent pain had a rebound of intrapancreatic hypertension, while patients who remained pain free continued to have normal intrapancreatic pressures<sup>[23]</sup>. Although intriguing, these findings were not reproduced by a subsequent study in which no relation between intrapancreatic pressure and pain was found<sup>[24]</sup>.

The pathophysiological link between intrapancreatic hypertension and pain has been explained as a “compartment-like syndrome” induced by fibrosis of the pancreatic parenchyma and peripancreatic capsule<sup>[2]</sup>. During secretory stimulation in an animal model of CP, increased interstitial pressures, diminished blood flow and ensuing tissue acidosis were documented<sup>[25]</sup>. The latter was possibly secondary to ischemia, thus mimicking the pathophysiology underlying muscular compartment syndrome. Although no pain data were collected in this experiment, it is plausible that acidosis may have caused pain by activation of the transient receptor potential vanilloid-1, which is a nociceptor found to be up regulated in CP and other conditions characterized by neurogenic inflammation<sup>[26,27]</sup> (described further below). However, it must be highlighted that these findings have never been reproduced in a human study and needs confirmation.

### Pancreas morphology and pain

In clinical practice, measurement of ductal or intrapancreatic pressure is not routinely performed and most

decisions regarding surgery or endotherapy to relieve pain rely on morphological abnormalities of the pancreas<sup>[2,11,28]</sup>. However, the relationship between ductal or intrapancreatic pressure and pancreatic morphology is ambiguous<sup>[29]</sup>. Furthermore, in a very recent study by Frokjaer *et al*<sup>[30]</sup> magnetic resonance cholangiopancreatography including diffusion weighted imaging was obtained in 23 patients with painful CP and 17 controls. Compared to traditional imaging techniques (*i.e.*, endoscopic retrograde cholangiopancreatography, magnetic resonance cholangiopancreatography, computed tomography, and endoscopic ultrasound), which mainly focus on atrophy and ductal pathology, this modality also provides a measure of fibrotic changes in the pancreatic gland<sup>[31]</sup>. Interestingly, the authors found no association between degree of pathological imaging (fibrosis, atrophy, and ductal pathology) and pain. However, pancreatic atrophy and ductal pathology were associated with diabetes (*i.e.*, more severe atrophy in patients with high levels of glycated hemoglobin), and low levels of phosphate and hemoglobin.

Taken together, pathological pancreatic morphology does not necessarily reflect the burden of pain in CP. Nowhere is this observation made more obvious, than by the patient who undergoes total pancreatectomy for painful CP and still continues to suffer from pain<sup>[11]</sup>.

### “WIRING” PROBLEMS

Lesions to intrapancreatic nerves and their impact on the pathogenesis of pain in CP have been the focus of

**Table 1 Pain mechanisms in chronic pancreatitis**

Main category	Proposed mechanism/source	Ref.
Plumbing problems	Pancreatic duct hypertension	[14,16,20]
	Pancreatic parenchymal hypertension	[21-23]
Wiring problems	Pancreas morphology	[29,30]
	Peripheral nociception	[35-37]
	Pancreatic neuropathy	[41,42,44]
	Central mechanisms of pain	[50,52,53,56]
Pancreatic and extrapancreatic complications	Pseudocysts	[62,64]
	Duodenal obstruction	[66]
	Bile duct obstruction	[66,67]

	Splenic vein thrombosis	[75,78]
Adverse effects to treatment	Opioid induced bowel dysfunction	[79]
	Complications to surgery and endoscopic therapy	[12]
	Bacterial overgrowth due to changed bowel motility	[81]
Additional causes	CCK elevation	[82]
	Increased norepinephrine levels	[85]
	Diabetic neuropathy (type 3c diabetes)	[86]
	Mesenteric ischemia <sup>1</sup>	

<sup>1</sup>Complications to and/or possible concomitant diseases. CCK: Cholecystokinin.

a substantial amount of research past 25 years. The International Association for the Study of Pain recently changed its definition of neuropathic pain to “pain caused by a lesion or disease of the somatosensory system”<sup>[32]</sup>. In the context of pain and CP there is emerging histological and neurophysiological evidence of such lesions to peripheral nerves in the pancreatic gland and coincident aberrant central pain processing. Three aspects of the neural basis of pain in CP are usually considered: Peripheral nociception, pancreatic neuropathy and central mechanisms of pain.

### Peripheral nociception

A nociceptor is a sensory nerve cell capable of integrating and transducing nociceptive stimuli into pain signals<sup>[33]</sup>. Nociception begins with the primary afferent nerves, whose cell bodies lies in the dorsal root ganglia next to the spinal cord. They have two branches-one terminating in the target tissue and one that ends in the dorsal horn of the spinal cord. The peripheral nerve endings sense tissue injury or pain stimuli *via* a variety of receptors, which respond to physical or chemical factors in their surroundings<sup>[12]</sup>. Depending on the excitability of the neural membrane, the stimulus leads to an action potential, which travels to the spinal end of the nerves in the dorsal horn. Here it triggers the release of neurotransmitters, which cross the synapse and act on secondary neurons and transmit the stimulus to the brain through diverse pathways, ultimately resulting in the sensation of pain.

Currently, it is unknown what actually activates the intrapancreatic nociceptors in humans. However, increased expression of the transient receptor potential vanilloid-1 has been demonstrated in an animal model of CP<sup>[34]</sup>, as well as in humans, although no correlation to pain was seen<sup>[35]</sup>. Furthermore, studies on nociceptive activation markers, *i.e.*, neurotransmitters secreted by

activated afferents, especially the large family of neurotrophic factors, are gaining increasing attention. Among others, both nerve growth factor and brain-derived neurotrophic factor have been shown to be upregulated in CP patients<sup>[36,37]</sup>, as well as many other proinflammatory cytokines, and in some cases this upregulation has been associated with increased pain intensity and/or frequency (for a review see<sup>[2]</sup>).

These changes render the nociceptors more sensitive to further stimulation, so that there can be a reduction in the threshold for activation, an increase in the response to a given stimulus, or the appearance of spontaneous activity<sup>[38,39]</sup>. This sensitization, called peripheral sensitization, results in an increased barrage of pain signals to the spinal cord<sup>[40]</sup>.

Taken together, several articles have demonstrated upregulation signaling molecules involved in inflammation and pronociceptive mediators, but also neurotrophic factors in CP. The trophic nature of the nociceptive activation markers further suggests a link between this altered nociception and the neuropathy of CP described below.

### Pancreatic neuropathy

Increased neural density and hypertrophy, sprouting and neuritis of the intrapancreatic nerves, as well as activation of glia and immune cells have also been reported in pancreatic tissue from CP patients<sup>[41-43]</sup>. These changes, collectively known as neuropathy, have been strongly associated with clinical pain scores, and thus suggests to be an important factor in the pathogenesis of pain in CP<sup>[41,42,44]</sup>. Autonomic innervation, especially sympathetic, is also decreased<sup>[43]</sup>, and has been correlated with abdominal pain.

Overall, substantial evidence supports the notion that pancreatic neuropathy leads to a remodeling of the intrapancreatic innervation, a concept known as pancreatic

neuroplasticity, which is likely an important factor in the pathogenesis of pain in CP.

### Central mechanisms of pain

A sustained and increased peripheral nociceptive drive may result in an increased responsiveness of central pain transmitting neurons. This phenomenon is known as central sensitization, and refers to an increased synaptic efficiency established in sensory neurons in the dorsal horn of the spinal cord (and/or at supraspinal sites), following intense peripheral noxious stimuli, tissue injury, or nerve damage<sup>[45,46]</sup>. The end result is pain, which is no longer coupled to the presence, intensity, or duration of noxious peripheral stimuli<sup>[47]</sup>. Clinically these changes manifests as allodynia (a painful response to stimuli not normally painful), hyperalgesia (increased sensitivity to painful stimuli) and secondary hyperalgesia (a receptive field expansion that enables input from non-injured tissue to produce pain)<sup>[45]</sup>.

Several studies have reported findings compatible with central sensitization in CP. Patterns of referred pain can be examined to assess central sensitization, as viscera-somatic convergence between peripheral nerves occurs at the spinal cord and higher levels of the central nervous system. Hence, visceral sensitivity of the upper gastrointestinal organs (sharing spinal innervation with the pancreatic gland) serves as a proxy of spinal sensitization<sup>[48,49]</sup>. In one study, increased areas of referred pain to electrical stimulation of the esophagus, stomach, and duodenum was reported in CP patients compared to controls<sup>[50]</sup>. Other studies reported decreased pain thresholds to visceral stimulation of the rectosigmoid as well as somatic stimulation of muscle and bone<sup>[51,52]</sup>. Taken together, these findings characterize a generalized hyperalgesic state of the pain system and likely mirrors widespread sensitization of the central nervous system as seen in many other chronic pain disorders<sup>[45]</sup>.

From the spinal cord, visceral afferents are projected to cortical and subcortical structures of the brain. Experimental pain studies, based on somatic stimulation of the epigastric skin area (sharing spinal segmental innervation with the pancreatic gland) as well as visceral stimulation of the upper and lower gut with concomitant recording of evoked brain potentials and brain source localization, have indicated that chronic pain and hyperalgesia is associated with functional reorganization of the cerebral cortex<sup>[50,53-55]</sup>. Hence, compared to healthy controls CP patients show reorganization of the brain areas involved in visceral pain processing including the insula, secondary somatosensory cortex and cingulate cortex similar to what is seen in phantom pain<sup>[53]</sup>. Interestingly, insular reorganization was associated with clinical pain intensity. In addition to reorganization of the brain areas involved in visceral pain processing, the excitability of these neural networks is abnormal with evidence of impaired habituation to noxious stimuli, possibly reflecting a neuronal hyperexcitability (*i.e.*, cortical sensitization)<sup>[55]</sup>.

The structural correlate of functional cortical reor-

ganization and hyperexcitability is found in studies based on advanced magnetic resonance imaging (MRI). In one study using diffusion weighted MRI, microstructural changes in the insular and frontal brain areas was associated with clinical pain intensity and functional scores<sup>[56]</sup>. Patients with a constant pain pattern demonstrated the most severe microstructural abnormalities compared to patients with an attack-wise pain pattern. This translates well to the clinic where patients with constant pain was recently reported to have the most reduced quality of life and functioning<sup>[6]</sup>. In another MRI study based on cortical volumetry, brain areas involved in visceral pain processing was shown to have a reduced thickness<sup>[57]</sup>. This finding suggests a central neurodegenerative response to severe and sustained pain.

The pain system has several inherent mechanisms whereby inflowing pain signals can be modulated. In particular, modulation of spinal pain transmission from the brainstem and higher cortical areas has been subject to increased interest during the last decades. Descending pain modulation where the brain can exert a downstream gating of the incoming spinal activity can lead to either an increase in the spinal transmission of pain impulses (facilitation) or a decrease in transmission (inhibition). The balance between these states ultimately determines the quality and strength of the pain signals perceived by the brain. Alterations in the state of descending modulation from inhibition towards facilitation have been implicated in the transition of acute into chronic and neuropathic pain. In the context of pain and CP, impaired descending inhibitory pain modulation has been reported in studies based on experimental human pain models<sup>[52,58]</sup>. In addition, brainstem facilitation has been reported to maintain pancreatic pain in an animal model of CP<sup>[59]</sup>.

Taken together, several lines of evidence indicate that central pain processing is abnormal in CP. However, it is difficult to determine whether these central abnormalities are maintained by a sustained nociceptive drive from the pancreatic gland or whether they have become independent of peripheral input. In favor of the latter, a recent pilot project documented generalized hyperalgesia (a clinical measurable proxy of central sensitization) to be associated with failure of thoracoscopic splanchnic denervation<sup>[60]</sup>. The authors concluded that in patients with hyperalgesia and failure to denervation, the disease has advanced and the generation of pain becomes self-perpetuating and independent of the initial peripheral nociceptive drive. However, these findings need confirmation in larger and longitudinal studies.

## PANCREATIC AND EXTRAPANCREATIC COMPLICATIONS

Although questions still remain, “plumbing” and “wiring” problems are probably important generators of pain in CP. Nevertheless, pain due to complications to

the disease is also likely to contribute, and should not be overlooked, when evaluating the origin of abdominal pain in CP patients.

### Pseudocysts

Pancreatic pseudocysts are relatively common in CP with estimated incidence rates of 20%-40%<sup>[61,62]</sup>, however, there is a lack of precise data based on long term follow-up. Yet, due to the chronic nature of the disease, CP patients are at high risk of developing pseudocyst in the course of their disease<sup>[63]</sup>. The exact pathogenesis of pseudocyst formation in CP is not known, but it has been proposed, that blockage of the major branch of the main pancreatic duct, and ongoing pancreatic secretion proximal to the obstruction leads to a saccular dilatation of the duct. This is then filled with pancreatic juice resulting in a pseudocyst<sup>[62]</sup>. The range of symptoms is wide-from asymptomatic to severe abdominal pain dependent on etiology, localization, and size<sup>[64,65]</sup>.

### Duodenal and bile duct obstruction

Advanced CP is characterized by replacement of the pancreatic parenchyma with fibrous tissue. Due to the close anatomical relationship of the common bile duct and the second part of the duodenum with the head of the pancreas, fibrosis can exert extrinsic pressure on these structures. The end result is mechanical obstruction of the common bile duct and duodenum<sup>[66,67]</sup>.

The clinical presentation of duodenal and bile duct obstruction is variable and can be asymptomatic<sup>[66,68]</sup>. Postprandial abdominal pain, early satiety and nausea are the most common symptoms of duodenal obstruction, while pain and abnormal liver function tests are suggestive of bile duct stenosis and cholangitis<sup>[69]</sup>. The mechanisms underlying such "obstructive pain" are unclear and one study concluded that bile duct obstruction without cholangitis is not the cause of pain in patients with CP<sup>[70]</sup>.

### Peptic ulcer

Upper abdominal pain is a prominent symptom in patients with peptic ulcer. Previous studies have demonstrated, that the prevalence of duodenal ulcer is high in patients with CP (ranges from 3.6% to 37.5%)<sup>[5,71,72]</sup>. The reason for the higher prevalence is unclear and many hypotheses have been suggested, including higher prevalence of *Helicobacter pylori* infection<sup>[71]</sup>, increased gastric acid secretion<sup>[73,74]</sup>, and insufficient pancreatic exocrine function which reduces bicarbonate secretion and decreases duodenal pH<sup>[72]</sup>. Furthermore, changes in gastric and intestinal blood flow due to previous acute pancreatitis may also be of importance.

As peptic ulcer can be asymptomatic, the high prevalence may be a result of a "detection bias" due to intensive search for the "origin" of epigastric pain in a selected group of patients. Patients with CP are more likely to undergo an upper gastrointestinal endoscopy, and therefore ulcers with atypical or no symptoms may

be included, causing a higher prevalence than in the background population<sup>[72]</sup>.

Under all circumstances, peptic ulcer may contribute to or be the reason for abdominal pain in CP patients and therefore diagnostic upper gastrointestinal endoscopy should be considered on wide indications.

### Splenic vein thrombosis

The splenic vein runs along the posterior surface of the pancreas and may be affected by inflammation in the pancreatic gland, leading to thrombosis and abdominal pain. Because most patients are asymptomatic the incidence of splenic vein thrombosis in CP is not known<sup>[75]</sup>, but incidence from 4%<sup>[76]</sup> to 45%<sup>[77]</sup> have been reported. Only few studies address the issue, but in one of the largest studies on splenic vein thrombosis in CP, 266 patients were investigated prospectively for a mean time of 8.2 years<sup>[78]</sup>. Splenic vein thrombosis was found in 22 patients (8.3%), but was only symptomatic in two patients. Hence, the role of splenic vein thrombosis in the pathogenesis of pain in CP is still questionable.

## ADVERSE EFFECTS TO TREATMENT

In many CP patients, strong opioids are often necessary to relieve pain. Unfortunately, opioids have the potential to produce substantial gastrointestinal adverse effects, including constipation, reflux, nausea and abdominal pain-a phenomenon known as opioid-induced bowel dysfunction<sup>[79]</sup>. In a study on the prevalence of gastrointestinal symptoms in patients treated with opioids for non-cancerous diseases, chronic abdominal pain was reported in 58% of the patients<sup>[80]</sup>. Hence, opioid consumption may confuse the clinical picture in CP and worsen or contribute significantly to abdominal pain. Medications that change bowel motility may also contribute to the bacterial overgrowth that is reported in up to 40% of the patients<sup>[81]</sup>. This may manifest as abdominal distension and pain.

In addition to side effects to medical therapy, complications to surgical endoscopic therapy may cause pain in a number of patients. These may include post-operative adhesions, ductal and parenchymal trauma, pancreatic and bile duct strictures, and complications to pancreatic stenting-all of which may result in abdominal pain. However, the relative contribution to abdominal pain due to surgical complications in CP is difficult to assess, and as far as the authors are aware of, no studies have examined this.

## ADDITIONAL CAUSES FOR PAIN

The above mentioned theories and mechanisms of pain are considered the most common and well-founded by the authors, but other rarer, less well examined causes, and complications to concomitant and comorbid diseases may also play in role in pain generation. A thorough evaluation of all these plausible causes is beyond the

scope of this review, but the reader is referred Table 1 for an overview.

However, elevated cholecystokinin (CCK) levels and increased sympathetic activity deserves to be mentioned separately as an additional cause of pain in CP. It has been shown, that CCK levels are elevated threefold in some early pancreatitis patients compared to controls<sup>[82]</sup>. This may generate pain by increasing the pressure in the pancreatic duct, but also through direct activation of nociceptive pathways in the central nervous system<sup>[83]</sup>. In one placebo-controlled, multicentre trial including 207 patients with chronic pancreatitis, an oral CCK receptor antagonist significantly decreased pain over placebo, although the placebo response was 30%<sup>[84]</sup>. However, further research into CCK antagonists has been hampered by concerns about induction of exocrine insufficiency and gallstones<sup>[11]</sup>.

Although limited by a small number of patients, Buscher *et al.*<sup>[85]</sup> showed significantly lower pain tolerance thresholds to pressure pain in dermatome T10 (pancreatic dermatome) in CP patients with increased norepinephrine levels compared to CP patients with normal norepinephrine levels, suggesting that sympathetic activity may play a role in these patients pain processing.

## CONCLUSION

Intense abdominal pain is a dominant feature of CP and it is associated with poor mental and physical quality of life. Basic studies of pancreatic nerves and experimental human pain research have provided evidence that pain processing is abnormal in these patients and in many cases resembles that seen in neuropathic and chronic pain disorders. This neurobiological view of pain is somewhat in opposition to the traditional view of pain etiology in CP, where pain was assumed to arise from pathology in or in close proximity to the pancreatic gland. However, these theories are not mutually exclusive, and aspects of both may contribute in the generation and perpetuation of pain. In addition, adverse effects and complications to medical and interventional therapies may account for a substantial morbidity in many patients and should be considered as an additional source of pain. Therefore, it is important to consider the different mechanisms, when evaluating the origin of pain in CP patients (Figure 1), and it is plausible that the “collective” abdominal pain is a result of a complex interplay of several mechanisms. This novel and multifaceted understanding of pain etiology in CP requires a paradigm shift in pain management. Hence, modern mechanism based pain treatments taking into account especially altered pain processing are likely to increasingly replace traditional invasive therapies. In addition, the improved understanding of pain etiology will likely pave the way for new treatment modalities.

### Abstract

Intense abdominal pain is a prominent feature of chronic pancreatitis and its treatment remains a major clinical challenge. Basic studies of pancreatic nerves and experimental human pain research have provided evidence that pain processing is abnormal in these patients and in many cases resembles that seen in neuropathic and chronic pain disorders. An important ultimate outcome of such aberrant pain processing is that once the disease has advanced and the pathophysiological processes are firmly established, the

generation of pain can become self-perpetuating and independent of the initial peripheral nociceptive drive. Consequently, the management of pain by traditional methods based on nociceptive deafferentation (*e.g.*, surgery and visceral nerve blockade) becomes difficult and often ineffective. This novel and improved understanding of pain aetiology requires a paradigm shift in pain management of chronic pancreatitis. Modern mechanism based pain treatments taking into account altered pain processing are likely to increasingly replace invasive therapies targeting the nociceptive source, which should be reserved for special and carefully selected cases. In this review, we offer an overview of the current available pharmacological options for pain management in chronic pancreatitis. In addition, future options for pain management are discussed with special emphasis on personalized pain medicine and multidisciplinary.

**Key words:** Chronic pancreatitis; Pain; Treatment; Pharmacology; Analgesics; Adjuvant analgesics

**Core tip:** Pharmacological pain management in chronic pancreatitis is complicated and requires a multidisciplinary approach. Identification of risk factors associated with disease progression and evaluation of extra pancreatic causes of pain and complications is essential in all patients. Analgesics are typically titrated according to the World Health Organization ladder principle, but in some situations a top-down approach may be useful to control pain and avoid sensitization of central pain pathways. Adjuvant analgesics and combinations of drugs should be considered at an early stage. Non-encapsulated enzyme therapy, somatostatin-analogues and antioxidants can be considered as supplements to conventional analgesics in special situations.

## INTRODUCTION

Chronic pancreatitis (CP) remains a major source of morbidity in the Northern Europe, with an annual incidence of approximately 10/100000 inhabitants<sup>[1]</sup>. It is a disease characterised by progressive destruction of the pancreatic gland and is typically characterised by severe abdominal pain. As the disease evolves, significant impairment of exocrine as well as endocrine functions also become evident<sup>[2,3]</sup>. The aetiological risk-factors associated with CP are multiple and involve both genetic and environmental factors. In the Northern Europe, excessive alcohol consumption is the leading cause of CP, although genetic susceptibility is also recognised as playing an increasing role<sup>[1,4]</sup>.

From the perspective of the patients (and their doctors) pain is the most significant symptom in CP, and most patients develop chronic pain during the course of their disease. The classic description of the pain is that of a constant, severe, dull ache in the mid-epigastrium, which often radiates to the back. It is typically worsened by high-fat foods, and pain attacks may last for days. However, just as the disease has different causes and morphological expressions, this classic pain pattern is not universal, and the location, character and quality of pain can be quite variable<sup>[2]</sup>. Furthermore, pain has been associated with malnutrition, narcotic addiction, physical and emotional disability, and major socioeconomic problems. Consequently, the clinical evaluation of pain is often blurred by addiction to alcohol and narcotic analgesics as well as by the personality disorders underlying these dependencies<sup>[3,5]</sup>. In view of this complex clinical presentation, it is not surprising that treatment of pain in patients with CP is challenging and often unsuccessful<sup>[6]</sup>.

The aim of this review is to summarise current available pharmacological therapies for pain in CP. In addition, future options for pain management are discussed with special emphasis on personalized pain medicine and multidisciplinary.

## OVERVIEW OF PAIN MECHANISMS IN CP

A detailed overview of the complex pain mechanisms underlying pain in CP is beyond the scope of this review and provided elsewhere in this issue of the journal. It is important to emphasise that none of the current acknowledged theories are mutually exclusive, and it is most likely that several pain mechanisms act in concert to cause pain in the individual patient.

Historically, the focus of pain treatment has been on

the pancreatic gland as a nociceptive source, based on the assumption that pain is generated by local pathology within or in close proximity to the pancreas. This mechanistic understanding of pain, has for many years, been the most widely accepted theory regarding the origin of pain in CP<sup>[7]</sup>. However, there is no direct relationship between the presence of pancreatic pathology such as duct dilation, pancreatic duct stones, pancreatic duct strictures, etc. and abdominal pain in CP pain patients<sup>[8-11]</sup>. Furthermore, the experimental evidence supporting this theory is sparse and findings have been conflicting<sup>[12]</sup>.

On the contrary, many current theories of the pathophysiology of CP postulate that in a high number of cases, repeated episodes of inflammation and pancreatic injury drive the process within the gland towards irreversible injury and are associated with damage to the pancreatic nerves<sup>[7,13,14]</sup>. Key in this theory is the recognition that the resulting ongoing and aggressive nociceptive input is likely associated with altered function of the pain processing system, particularly at the central level<sup>[15-18]</sup>. An important ultimate outcome of such aberrant pain processing is that once the disease has advanced and the pathophysiological processes are firmly established, the generation of pain can become self-perpetuating and independent of the initial peripheral nociceptive drive<sup>[19,20]</sup>. Consequently, the management of pain by traditional methods based on nociceptive deafferentation (*e.g.*, surgery and visceral nerve blockade) becomes difficult and ineffective<sup>[20]</sup>. This novel and improved understanding of pain aetiology requires a paradigm shift in pain management of CP. Hence, modern mechanism based pain treatments taking into account altered pain processing are likely to increasingly replace invasive therapies targeting the nociceptive source, which should be reserved for special and carefully selected cases.

## RISK-FACTOR MODIFICATION AND PROPHYLAXIS

The risk-factors associated with CP can be classified according to the MANNHEIM risk-factor classification system<sup>[4]</sup>. In this system, the multiple (M) risk factors underlying CP are categorised into six major subcategories of alcohol consumption (A), nicotine consumption (N), nutritional factors (N), hereditary factors (H), efferent pancreatic duct factors (E), immunological factors (I), and various rare miscellaneous and metabolic (M) factors. The rationale for modifying these risk-factors is to reduce recurrent injury to the pancreas. Hence, with repeated episodes of acute inflammation triggered by one or more risk factors, the inflammatory environment within the pancreas shifts towards chronic inflammation, with subsequent activation of pancreatic stellate cells, fibrinogenesis, and irreversible pancreatic damage<sup>[21]</sup>. Although not well established for all risk-factors (see below), it seems likely that prevention of recurrent pancreatitis attacks, clinical or sub-clinical, by risk-factor modification, will translate into a slowing of disease progression, less exo-

**Table 1 Recommended risk factor modifications in chronic pancreatitis according to the MANNHEIM criteria**

Risk factor	Treatment	Comments
Alcohol	Alcohol cessation	Decrease disease progression and may have beneficial effects on pain
Nicotine	Smoking cessation	Decrease disease progression and may have beneficial effects on pain
Nutritional	No specific recommendations	No prospective data
Hereditary	Endoscopic surveillance	Currently no formal evidence, a prospective trial has been initiated
	Pancreatectomy with autolog stem cell transplantation	Preferred strategy in some United States centers
Efferent duct	Endoscopy or surgical interventions	The benefit of intervention is controversial
Immunological	Steroid treatment	Treatment of autoimmune pancreatitis follows guidelines provided in <i>e.g.</i> , Ref. 32
Metabolic	Lipid lowering therapy, parathyroidectomy, <i>etc.</i>	Consider referral to an endocrinologist

**Table 2 Treatment of extrapancreatic causes of pain in chronic pancreatitis**

	Treatment	Comments
Peptic ulcer	Proton pump inhibitor +/- eradication of <i>H. pylori</i>	Avoid NSAIDs in CP Patients
Pseudocysts	Endoscopic drainage, transcutaneous drainage or surgical drainage	Preferred treatment dependent on pseudocyst localization and morphology
Duodenal obstruction	Endoscopic dilation or surgical therapy	Endoscopic dilation preferred as first line therapy
Bile duct obstruction	Covered metal stent or plastic stent	Controversial, one study found no relationship between bile duct obstruction and pain

NSAID: Nonsteroidal anti-inflammatory drugs; CP: Chronic pancreatitis; *H. pylori*: *Helicobacter pylori*.

crine and endocrine insufficiency and most importantly decreased abdominal pain. In Table 1 recommended risk factor modifications are summarized.

In patients with an alcoholic aetiology of CP, there is evidence to support that cessation of alcohol may have beneficial effects on disease progression and pain<sup>[22,23]</sup>. Furthermore, there is increasing evidence that tobacco use is also an important and independent risk factor for CP and that cigarette smoking accelerates progression of alcoholic CP<sup>[24,25]</sup>. Hence, tobacco cessation is highly recommended in these patients, although the association with pain relief has yet to be determined.

Data on the association between nutritional factors and CP are sparse. The consumption of a diet rich in fat and protein was associated with the development of CP in a case-control study<sup>[26]</sup>. However, retrospective descriptions of daily nutritional habits are difficult and such data may be subject to recall bias. Thus, it is difficult to provide a simple description of past daily nutrition in the majority of patients with CP and these findings needs to be confirmed in a prospective trial before specific recommendations can be made.

In patients with CP following gallstone pancreatitis, prevention of recurrent choledocholithiasis is crucial and reduces further damage to the pancreas<sup>[27]</sup>. In this situation cholecystectomy is recommended for patients suitable for surgery<sup>[28]</sup>. Also, patients with recurrent pancreatitis and efferent duct abnormalities such as pancreas divisum may benefit from endoscopic therapy or surgery to decrease the risk of recurrent pancreatitis and progression to CP<sup>[29]</sup>. However, data on this subject are limited and the optimal treatment of this specific entity is still a subject of controversy.

No specific treatment exists to modify the disease progression in hereditary CP. These patients have a sig-

nificantly increased risk of pancreatic cancer and surveillance or even total pancreatectomy with autologous islet-cell transplantation is recommended in some centers<sup>[30]</sup>. Patients with autoimmune pancreatitis comprise a special subset of patients with a potentially curable form of pancreatitis. Management of these patients is beyond the scope of this review and the reader is referred to reference<sup>[31]</sup>.

In CP due to metabolic abnormalities such as hypertriglyceridaemia, maintenance of triglycerides within the normal range would be expected to reduce the chance of repeated pancreatitis attacks and thus progression to CP<sup>[32]</sup>. Also, patients with hypercalcaemia induced pancreatitis due to hyperparathyroidism should be managed appropriately and - if necessary - referred to an endocrinologist.

## TREATMENT OF EXTRA-PANCREATIC CAUSES OF PAIN

In addition to risk factor modifications, extra-pancreatic causes of pain should be thoroughly investigated and treated (Table 2). Peptic ulcers are reported to have an increased prevalence in CP. This is possibly explained by changes in blood flow to the mucosa following attacks of acute pancreatitis as well as deterioration of pancreatic exocrine function resulting in a reduction of bicarbonate concentration and hence acidification of the milieu in the duodenal lumen. Also, increased gastric acid secretion and an increased prevalence of *Helicobacter pylori* in CP have been associated with the increased prevalence of peptic ulcers<sup>[33]</sup>. Another important source of pain in CP is pseudocysts, which should be investigated by an appropriate radiological work-up and treated accordingly<sup>[34]</sup>. Some patients may have pain as a consequence of obstruction of adjacent viscera (duodenum or common

**Table 3** Current available pharmacological treatments for pain in chronic pancreatitis

Pain mechanism	Treatment option(s)	Comments	Ref.
Raised levels of CCK	Pancreatic enzyme replacement therapy	Only non-enteric coated enzymes have proven effective	[57-65]
	Somatostatin-analogues	Conflicting results, prolonged release formulations may be of value	[67,68]
Pancreatic inflammation and oxidative stress	Antioxidants	Conflicting results, probably most valuable in tropical calcifying CP	[71,72]
Central sensitisation	Antidepressants (TCA, SSRI, SNRI)	Expert opinion, no clinical data (Ref.)	[2]
	Gabapentinoids (Gabapentin/Pregabalin)	Modest effect on pain in a randomised placebo controlled trial (Pregabalin)	[42]
	Ketamine	Reverses hyperalgesia in an experimental pain study	[54]
Analgesics	Tramadol <i>vs</i> morphine	No difference in pain relief in a randomised controlled trial, fewer side effects on tramadol treatment	[35]
	Fentanyl <i>vs</i> Morphine	No difference in pain relief in a randomised controlled trial	[41]
	Oxycodone <i>vs</i> Morphine	Oxycodone superior to morphine on experimental pain measures	[39]
	ADL 10-0101:KOR agonist	KOR agonist superior to morphine on experimental and clinical pain measures. Limited number of patients ( <i>n</i> = 6)	[40]

CCK: Cholecystokinin; CP: Chronic pancreatitis; TCA: Tricyclic antidepressant; SSRI: Selective serotonin reuptake inhibitor; SNRI: Serotonin norepinephrine reuptake inhibitor; KOR: Kappa opioid receptor.

bile duct)<sup>[35]</sup>. However, the mechanisms underlying such “obstructive pain” remain unclear and in the case of bile duct obstruction there is evidence to the contrary<sup>[36]</sup>.

## ANALGESICS

The standard guideline for analgesic therapy in CP patients follows the principles of the “pain relief ladder” provided by the World Health Organization (WHO)<sup>[37]</sup>. This principle is based on the serial introduction of drugs with increasing analgesic potency, titrated until pain relief is obtained. However, in patients with a severe and debilitating pain pattern, a more aggressive approach using opioids combined with adjuvant analgesics as first line therapy (*i.e.*, a top-down approach), is useful to control pain and prevent sensitization of central pain pathways. An overview of the current available pharmacological therapies used to treat pain in CP is reported in Table 3.

Paracetamol is usually the preferred drug in level I analgesia due to its limited side effects. It has analgesic and antipyretic activity that work through central and peripheral non-opioid mechanisms, which have not yet been fully characterised<sup>[38]</sup>. Nonsteroidal anti-inflammatory drugs (NSAIDs) are particularly useful for treating musculoskeletal pain and are in general less favourable for visceral pain because of their toxicity to the GI tract<sup>[39]</sup>. Consequently, we recommend avoiding NSAIDs for painful CP.

Codeine is a weak opioid in level II analgesia, but is still associated with the same spectrum of opioid-related side effects seen for stronger opioids, *e.g.*, constipation, nausea, dyspepsia amongst other symptoms involved in opioid-induced bowel dysfunction<sup>[40]</sup>. Tramadol possesses both a weak opioid agonist activity along with an effect on noradrenaline and serotonin uptake in the spinal cord. It has been shown to be more potent than codeine and may be considered as a halfway house between level II and level III analgesics. Tramadol was also shown to be more efficacious than morphine in patients with CP, with fewer gastrointestinal side effects for the same level of

analgesia<sup>[41]</sup>.

Strong opioids, such as morphine, mainly exert their analgesic effects in the central nervous system, although it is now well known that opioid receptors are synthesised in the dorsal root ganglia and transported towards both central and peripheral nerve terminals<sup>[42]</sup>. Several opioid receptors exist, including the  $\mu$ -receptor,  $\delta$ -receptor and the  $\kappa$ -receptor<sup>[43]</sup>. Most clinically available opioids have their primary activity at the  $\mu$ -receptor and have been used widely to treat pain in CP patients<sup>[6]</sup>. However, animal studies have suggested that activation of the  $\kappa$ -receptor may be more efficacious for attenuation of gastrointestinal pain<sup>[44]</sup>. In keeping with these findings, oxycodone (an opioid targeting the  $\mu$ -,  $\delta$ - and  $\kappa$ -receptor) was shown to attenuate experimental visceral pain better than morphine in CP patients<sup>[45]</sup>. Also, in a pilot study including six CP patients with chronic abdominal pain, infusion of a peripherally restricted  $\kappa$ -receptor agonist (ADL 10-0101) - but not placebo - reduced clinical and experimental pain scores<sup>[46]</sup>. These findings were not replicated in patients with pain due to pancreatic cancer<sup>[47]</sup>, but this may relate to the confounders associated with clinical studies on opioids<sup>[48]</sup>. Taken together, these findings may suggest differentiated effects of opioids for pain management in CP patients. However, it must be emphasized that data from well-designed clinical studies with long-term follow-up are not yet available.

Opioids used in the outpatient clinic can be administered either orally (*i.e.*, tablets) or transdermally (*i.e.*, patch formulation). In an open label randomized crossover trial, transdermal fentanyl plaster was compared to sustained release morphine tablets in an equipotent dosage regime<sup>[49]</sup>. No significant differences were found for pain control, patients' preference or quality of life, while 44% of patients treated with fentanyl plaster reported skin side effects. Taken together with the increased costs of patch formulation, the authors concluded that transdermal administration of opioids cannot be recommended as first line opioid therapy for CP, but should be reserved to patients having trouble with tablet ingestion<sup>[49]</sup>.

As discussed above, CP patients may be suffering from hyperalgesia due to sensitization of the central nervous system<sup>[14,19]</sup>. In general, opioids are not very effective in treating established central sensitization and may even cause hyperalgesia themselves (*i.e.*, opioid induced hyperalgesia)<sup>[50]</sup>. Furthermore, opioid induced bowel dysfunction is a common problem in clinical practice and typically manifests as abdominal discomfort or even diffuse abdominal pain<sup>[40]</sup>. Taken together, opioid based therapies often become ineffective and associated with gastrointestinal side effects in the context of advanced CP and hence other treatments are highly warranted.

### Adjuvant analgesics

Adjuvant analgesics are a heterogeneous group of drugs initially developed for indications other than pain. However, many have proven effective in painful conditions, which has now been widely recognised as a separate therapeutic indication. Adjuvant analgesics modify the nociceptive processes through several modes of action, including anxiolytic effects (benzodiazepines, alpha-2-delta ligands), antidepressive effects (antidepressants), and anti-hyperalgesic effects (antidepressants, alpha-2-delta ligands). Although they have been widely used to treat pain associated with CP, only the alpha-2-delta ligand pregabalin has been studied in the context of painful CP<sup>[2,51]</sup>. Hence, in a placebo controlled double blinded randomized trial, we recently demonstrated the efficacy of pregabalin as an adjuvant analgesic for pain in CP. We found that CP patients treated with pregabalin escalated to a maximal dose of 600 mg *bid* had a significant reduction in self-reported pain scores compared to placebo. Furthermore, the percentage of patients with much or very much improved health status score was higher in the pregabalin group compared to the placebo group. The side effects were relatively few and of mild to moderate severity; with a “drunk feeling” being the most prevalent side effect (35% of patients) and typically showing a ceiling effect after one or two weeks of treatment<sup>[51]</sup>.

The analgesic mechanisms of action underlying pregabalin analgesia are not completely understood, and it probably exerts a range of effects on pain transmission<sup>[52,53]</sup>. *In vitro* studies indicate that pregabalin binds selectively to the alpha-2-delta subunit of voltage-dependent calcium channels, thereby blocking the influx of calcium into pre-synaptic nerve terminals. This reduces release of excitatory neurotransmitters, including glutamate, noradrenalin and substance P, and dampens pain transmission<sup>[54,55]</sup>. These findings translate well to experimental pain studies in CP, where antinociceptive effects of pregabalin on electrical evoked pain from the gut and skin were observed, compatible with a reduction of central sensitization<sup>[56,57]</sup>.

### Ketamine

Introduced in 1965 as an anesthetic, today ketamine is used not only for anesthesia, but also as a potent analgesic in acute and chronic pain as well as an antihyperalgesic

used to reduce central sensitization in various chronic pain conditions. It is a noncompetitive *N*-Methyl-*D*-aspartate (NMDA) receptor antagonist, but it also exerts its analgesic effects through other mechanisms including opioid receptor activation<sup>[58]</sup>. Sensitization of the central nervous system has been documented in several studies of painful CP and is believed to play a prominent role in pain generation in this entity<sup>[15,16]</sup>. One of the best-characterized mechanisms in the early phase of central sensitization is activation of the NMDA receptors<sup>[59]</sup>. Multiple studies have consistently produced positive results regarding the use of ketamine in chronic pain patients with central sensitization and hyperalgesia and it thus comprises an interesting remedy to revert reduce central sensitization and its associated hyperalgesia in CP<sup>[60]</sup>. This was supported by a double-blinded crossover trial designed to evaluate the effect of ketamine infusion on hyperalgesia associated with CP<sup>[61]</sup>. Infusion of ketamine temporarily reversed pressure pain hyperalgesia and the underlying sensitized state of the pain system. However, only short-term effects were evaluated and no effect was seen on clinical endpoints. Hence, the use of ketamine for pain in CP is still in its infancy and prospective clinical trials are warranted to establish its role in the management of painful CP.

## SUPPLEMENTARY THERAPIES

### Pancreatic enzyme therapy

Pancreatic enzyme therapy for pain control in CP has been the subject of several randomized trials and meta-analyses (Table 3). The proposed mechanism of action is the ability to degrade cholecystokinin (CCK) releasing factor in the duodenum and thereby lower CCK<sup>[2]</sup>. An elevated level of CCK have been reported in CP patients and may generate pain by increasing the pressure in the pancreatic duct (CCK-A), but also through direct activation of nociceptive pathways in the central nervous system (CCK-B)<sup>[62,63]</sup>. Only non-enteric coated formulations have duodenal protease activity and studies using this type of enzymes have documented improvement in pain<sup>[64,65]</sup>. In contrast, most studies using enteric coated preparations (which are not active in the duodenum and hence cannot degrade CCK-releasing factor) have not shown any improvement on pain measures<sup>[66-69]</sup>. One study, however, showed pain relief of enteric coated enzymes during acid inhibition, but this study used a measurement of pain that included symptoms of malabsorption (bloating, gas or cramping), rather than more traditional pain measures<sup>[70]</sup>. A meta-analysis combining all studies found no effect of enzymes on pain relief in CP<sup>[71]</sup>. Nevertheless, combining the two types of enzyme formulations in a meta-analysis is probably not appropriate given the proposed mechanism of action<sup>[72]</sup>.

### Somastotatin-analogues

Somastotatin-analogue inhibits pancreatic secretion by blocking CCK and secretin release and also by a direct

inhibitory effect on acinar cells<sup>[73]</sup>. As discussed above, these effects may alleviate pain through reduction of pancreatic ductal pressure and by lowering the central effects of CCK. There are conflicting data about the efficacy of somatostatin-analogues for pain in CP. While early pilot series of octreotide showed an effect on pain control, this effect could not be confirmed in a double-blind cross-over study enrolling 10 CP patients treated with octreotide (100 µg *tid*) or placebo for 3 d<sup>[74]</sup>. Although pancreatic secretion measured by fecal chymotrypsin was reduced by octreotide, no differences were seen in pain control or analgesic use. This study has been criticized for its relatively short follow-up and limited wash out period (48 h). Also, four patients had evidence of concretions in the pancreatic duct, which may have compromised the effect of octreotide. In a later pilot study, a long-acting version of octreotide (Octreotide LAR) administered once monthly, was compared to conventional subcutaneous octreotide treatment administered three times daily. Although not significant, there was a trend toward improved pain control for octreotide LAR<sup>[75]</sup>. These results, however, have never been subject to a formal placebo controlled trial and the role of octreotide treatment for painful CP has so far not been satisfactorily documented. Taken together with the numerous side effects and their cost, a general use of somatostatin-analogues for pain in CP cannot be recommended<sup>[76]</sup>.

### Antioxidants

The use of antioxidants for pain control in CP was presented two decades ago, but never gained widely clinical popularity. The proposed analgesic mechanism of action underlying this therapy is an anti-inflammatory and blocking effect on free radicals<sup>[77]</sup>. Propelled by an Indian randomized placebo controlled trial, antioxidant therapy recently had a rebirth for pain management in CP. In this trial, six months antioxidant therapy was associated with significant and prolonged pain relief compared to placebo<sup>[78]</sup>. However, these findings were not reproduced by a subsequent study from North America<sup>[79]</sup>. A possible explanation for this dichotomy may be that the patients included in the two trials were different. While the Indian study mostly included patients with trophic calcifying pancreatitis and malnutrition (and hence deficiency in antioxidants), the American study included a more elderly population who had alcohol as the leading etiology of CP and a normal nutritional condition. Hence, the efficacy of antioxidant therapy may be related to the etiology of CP and its associated malnutrition<sup>[80]</sup>. This idea was supported by a subgroup analysis of the patients with alcohol etiology in the Indian trial, who, in agreement with the American study, demonstrated no benefit of antioxidants<sup>[78]</sup>. Taken together, the evidence is not sufficient to recommend antioxidant therapy be used routinely for the typical Western CP patient with alcoholic pancreatitis.

### Other treatments

In addition to the abovementioned treatment options, various other pharmacological principles have been used

to treat pain associated with CP, including leukotriene antagonism and stimulation with secretin<sup>[81,82]</sup>. However, none of these treatments have documented any effect on pain and are regarded obsolete by most experts.

## INDIVIDUALISED PAIN THERAPY AND FUTURE ANALGESICS FOR PAIN IN CHRONIC PANCREATITIS

A major problem in pain medicine is the lack of knowledge about which treatment suits a specific patient. In a recent study, we tested the ability of quantitative sensory testing to predict the analgesic effect of pregabalin and placebo in patients with CP<sup>[83]</sup>. Pregabalin effect was associated with pretreatment sensitivity to electric tetanic stimulation of the upper abdominal area (sharing spinal segmental innervation with the pancreatic gland). Hence, patients expressing lower pain thresholds in the “pancreatic viscerotome” were more likely to benefit from pregabalin treatment compared to patients with normal sensitivity<sup>[83]</sup>. These findings suggest sensitization of spinal neurons in the segment innervated by pancreatic visceral afferents to be an important predictor of pregabalin efficacy in patients with painful CP. Interestingly, this method may be used to tailor pain medication based on patient's individual sensory profile and thus comprises a significant step towards personalized pain medicine.

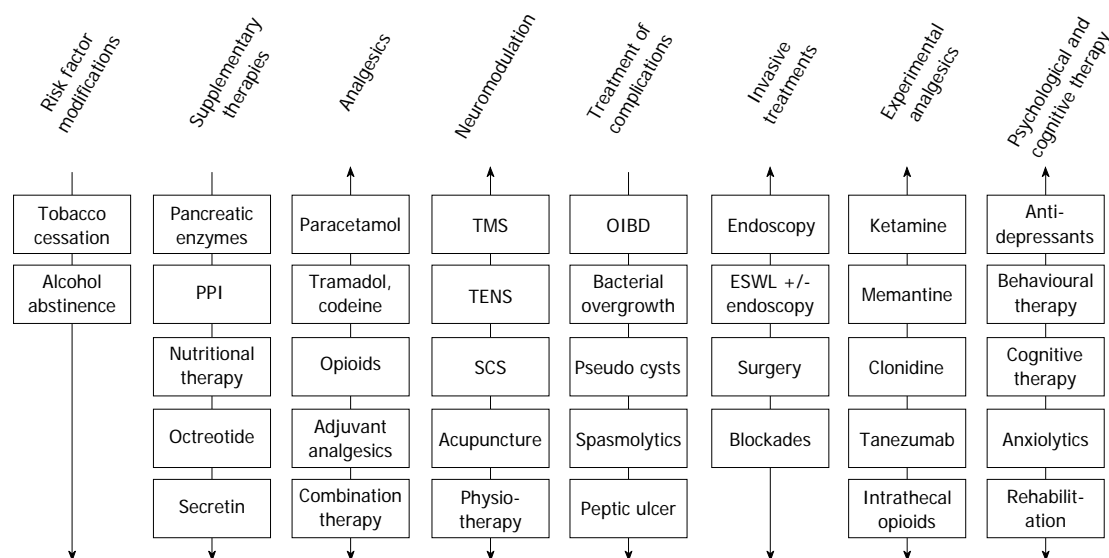

The novel and improved understanding of pain mechanisms in CP may pave the way for new treatments. Analgesics specifically targeting neural or humoral mediators of pain, such as nerve growth factor (NGF) and transient receptor potential vanilloid-1 antagonists, are currently being tested in clinical trials and hold promise for the future, although these drugs have yet to be tested in patients with CP<sup>[84,85]</sup>. Recently, a NGF-antagonist (Tanezumab) was shown to relieve pain in patients with knee pain due to gonarthrosis<sup>[84]</sup>. As NGF has been shown to be up-regulated in CP patients and is known to play a pivotal role in the process of peripheral sensitization, NGF-antagonism may be effective for pain relief in CP patients<sup>[86]</sup>.

### Multidisciplinary pain treatment

As discussed above the mechanisms underlying pain in CP are highly variable in the individual patient. Consequently, there is no single approach that is effective for all patients and choosing the right algorithm for pain treatment is highly depending of the pathogenesis of pain in the individual situation. Hence, a successful management of pain requires a multidisciplinary approach as illustrated in Figure 1. In addition, establishing a stable doctor-patient relationship is an important factor for a successful treatment outcome<sup>[80]</sup>.

## CONCLUSION

Intense abdominal pain is the most prominent feature of CP and its treatment remains a major clinical challenge.

**Figure 1** An illustration of the multidisciplinary approach recommended for managing pain in chronic pancreatitis. The mechanisms underlying pain in chronic pancreatitis (CP) are highly variable in the individual patient and there is no single approach that is effective for all patients. Hence, choosing the right algorithm for the pain treatment is highly depending of the pathogenesis of pain in the individual situation. Some treatments follow a typical step-up approach as indicated by the unidirectional arrows. Other treatments follow either a step-up or a top-down approach depending on the specific situation as illustrated by the bidirectional arrows. The latter is seen for example for analgesic therapies, where weak analgesics may be appropriate to control pain in one situation. On the other hand a more aggressive approach, using opioids combined with adjuvant analgesics as first line therapy (*i.e.*, top-down), is useful in patients with a more aggressive and debilitating pain pattern to control pain and prevent sensitization of central pain pathways. Often combination therapies of *e.g.*, opioids or adjuvant analgesics are used. Surgery, endoscopic therapies *etc.* are included in the figure for completeness, although these therapies are beyond the scope of this review. PPI: Proton pump inhibitor; TENS: Transcutaneous electrical nerve stimulation; SCS: Spinal cord stimulation; OIBD: Opioid-induced bowel dysfunction; TMS: Transcranial magnetic stimulation; ESWL: Extracorporeal shock wave lithotripsy.

Medical management requires a multidisciplinary approach including identification of risk factors associated with disease progression and appropriate modification. A systematic evaluation of extra pancreatic causes of pain and complications followed by appropriate treatments is essential in all patients. Analgesics are typically titrated according to the WHO ladder principle, but in some situations a top-down approach may be useful to control pain and avoid sensitization of central pain pathways. Also, adjuvant analgesics should be considered at an early stage and combinations of drugs are often used. Non-encapsulated enzyme therapy, somatostatin-analogues and antioxidants can be considered as supplements to conventional analgesics in special situations. An improved understanding of pain mechanisms in CP will undoubtedly pave the way for new treatments and future strategies should be based on modern mechanism based and personalized pain treatment.

### Abstract

Drug absorption in patients with chronic pancreatitis might be affected by the pathophysiology of the disease. The exocrine pancreatic insufficiency is associated with changes in gastrointestinal intraluminal pH, motility disorder, bacterial overgrowth and changed pancreatic gland secretion. Together these factors can result in malabsorption and may also affect the efficacy of pharmacological intervention. The lifestyle of chronic pancreatitis patients may also contribute to gastrointestinal changes. Many patients limit their food intake because of the pain caused by eating and in some cases food intake is more or less substituted with alcohol, tobacco and coffee. Alcohol and drug interaction are known to influence the pharmacokinetics by altering either drug absorption or by affecting liver metabolism. Since patients suffering from chronic pancreatitis experience severe pain, opioids are often prescribed as pain treatment. Opioids have intrinsic effects on gastrointestinal motility and hence can modify the absorption

of other drugs taken at the same time. Furthermore, the increased fluid absorption caused by opioids will decrease water available for drug dissolution and may hereby affect absorption of the drug. As stated above many factors can influence drug absorption and metabolism in patients with chronic pancreatitis. The factors may not have clinical relevance, but may explain inter-individual variations in responses to a given drug, in patients with chronic pancreatitis.

**Key words:** Pharmacology; Absorption; Metabolism; Chronic pancreatitis; Treatment

**Core tip:** In patients with chronic pancreatitis several pathophysiological factors can account for malabsorption and may also affect the efficacy of pharmacological intervention by reduced drug absorption. For example it can be speculated that changes in gastrointestinal intraluminal pH, motility disorder, bacterial overgrowth and changed pancreatic gland secretion may contribute. The lifestyle of chronic pancreatitis patients may also be a factor to gastrointestinal changes. The factors may not have clinical relevance, but may explain inter-individual variations in responses to a given drug, in patients with chronic pancreatitis.

### INTRODUCTION

Chronic pancreatitis is a persistent inflammation of the pancreas that results in irreversible morphological

changes and impairment of both exocrine and endocrine functions<sup>[1]</sup>. The etiology of chronic pancreatitis is multifactorial and the risk factors include alcohol and nicotine consumption, hereditary factors, efferent duct obstructions, immunological factors or rare metabolic disorders<sup>[2]</sup>. It is well known that pancreatitis patients suffer from malabsorption<sup>[3-5]</sup> and it could be hypothesized that this would also affect drug absorption.

Drug absorption in patients with gastrointestinal disorders can be influenced by alterations in several factors. For example; gastric and intestinal motility, changes in the mucosal surface area available for drug absorption, and altered physical and chemical properties of the intestinal luminal content. These properties are usually changed in combination and the degree of each factor impact is dependent on the duration and severity of the disease<sup>[6]</sup>. Despite this, most of the data about bioavailability of orally administered drugs are obtained from healthy individuals.

The knowledge about drug absorption in patients with chronic pancreatitis is limited. It has been demonstrated that the pharmacokinetic profile of pregabalin was not extensively affected by chronic pancreatitis<sup>[7]</sup>. However, inter-individual variations were found and several factors affecting drug pharmacokinetic profiles in patients with chronic pancreatitis may be relevant to consider.

This aim of this review was therefore to evaluate different factors which could possibly affect drug absorption in chronic pancreatitis patients leading to pharmacological challenges in this patient group. Moreover, suggestions on how to diminish the impact of these factors will be provided.

## GASTROINTESTINAL PHYSIOLOGICAL CHANGES THAT MAY AFFECT DRUG EFFECTS

Two primary factors influencing bioavailability of orally administered medications is the amount of drug absorbed, and metabolism by the liver. Hence, any factor influencing the gastrointestinal tract can alter drug absorption, such as gastric pH, regional blood flow, mucosal surface area and gut motility<sup>[8]</sup>.

### Drug absorption

Chronic pancreatitis is a clinical condition in which exocrine pancreatic insufficiency occur leading to secondary maldigestion. Several causes of exocrine pancreatic insufficiency may be associated with changes in gastrointestinal physiology such as: (1) changes in gastrointestinal intraluminal pH; (2) motility disorders; (3) bacterial overgrowth; and (4) pancreatic secretion.

Together these factors can result in malabsorption and may also affect the efficacy of pharmacological treatment in exocrine pancreatic insufficiency<sup>[8]</sup>. The main clinical manifestation of exocrine pancreatic insufficiency

is fat malabsorption, identified as steatorrhea<sup>[4]</sup>. Steatorrhea leads to deficit of fat-soluble vitamins (A, D, E and K) with consequent clinical manifestations<sup>[4]</sup>. Moreover, fat malabsorption may affect absorption of lipophilic drug formulations and as such deserves particular attention<sup>[6]</sup>.

Changes in intraluminal pH: Low intraluminal pH in the upper small intestine might be a factor in the pathogenesis of fecal loss of bile acids in pancreatic insufficiency<sup>[4]</sup>. The drug's ability to cross membranes is determined by the environmental pH and the acid dissociation constant (pKa). Therefore, decreased intraluminal pH may affect drug absorption. However, this may be of variable importance, as changes in intraluminal pH might be negligible in some cases and more pronounced in others.

**Motility disorders:** The rate of gastric emptying and intestinal transit is abnormal in patients with chronic pancreatitis and this may affect the efficacy of treatments<sup>[8]</sup>. Gastric emptying can be accelerated due to diarrhea<sup>[4]</sup> or decreased by, *e.g.*, opioids. Because most drugs are absorbed through the small intestines, delayed gastric emptying will prolong the time to peak concentration and delay the onset of the action of a drug<sup>[9]</sup>. Clinicians should be aware that delayed gastric emptying can delay the onset of action of a medication if administered orally<sup>[9]</sup>. On the other hand accelerated gastric emptying will have the opposite effect. Taken together gastric emptying is likely to be a rate limiting step in drug absorption unless normal absorption (prolonged release) is slow<sup>[10]</sup>.

**Bacterial overgrowth:** One mechanism which has been hypothesized between maldigestion and intestinal alterations relates to bacterial overgrowth in the small intestine. It has been speculated that lack of coordination between motor activity and peak of secretory activity in the gastrointestinal tract may reduce the effectiveness of the "housekeeper" function and thereby contribute to the intestinal bacterial overgrowth often observed in patients with chronic pancreatitis<sup>[11]</sup>. Bacterial overgrowth might either contribute to diarrhea or account for the persistence of diarrhea<sup>[4]</sup>. Moreover, bacterial overgrowth might give rise to bile acid malabsorption and changes in intestinal permeability<sup>[4,12]</sup>. Bacterial overgrowth may interfere with the normal intestinal environment and lead to atrophic mucosa with structural abnormalities which can decrease drug absorption<sup>[13]</sup>.

**Pancreatic gland secretion:** The pancreatic gland normally secretes more than 2 L of juice per day (high protein content) with enzymes able to digest lipids, proteins and carbohydrates. Patients with exocrine pancreatic insufficiency exhibit decreased pancreatic bicarbonate secretion resulting in reduction in duodenal pH postprandial, leading to inactivation of orally administered exogenous enzymes<sup>[6]</sup>. In the same line acidic inactivation of pancreatic enzymes is considered a significant reason for

**Figure 1** Absorption of pregabalin in eight female patients with chronic pancreatitis. Curves illustrate the variance in absorption of pregabalin after 75 mg pregabalin (oral capsule). Especially one patient varied from other subjects by having increased plasma concentration of pregabalin. Not a single cause could explain this outlier, but it could be a combination of several factors suggested.

failure of drug therapy<sup>[8]</sup>.

A combination of the above mentioned factors may affect drug absorption in patients with chronic pancreatitis. Figure 1 illustrates the variance in absorption of pregabalin in a group of women with chronic pancreatitis.

### Drug elimination

To our knowledge only one study investigated hepatic drug metabolism in patients with chronic pancreatitis and found reduced drug elimination capacity in this group of patients<sup>[14]</sup>. The results were most probably explained by the patients' general state, with a fairly overt malnutrition, although theoretically, a subclinical, probably alcohol-induced, liver affection could not be ruled out<sup>[14]</sup>. Interestingly, the study results yielded the need for caution upon administration of drugs that are biotransformed in the liver.

Thus, to optimize the efficacy of pharmaceutical treatment, the management of exocrine pancreatic insufficiency should ideally be individually tailored to account for both the underlying cause and any associated disturbance in gastrointestinal physiology.

### Lifestyle

The gastrointestinal physiological changes in chronic pancreatitis can be further affected by patients' lifestyle. Many patients limit their food intake because of the pain caused by eating and in some cases food intake is more or less substituted with tobacco and coffee<sup>[15]</sup>. Due to malabsorption and lifestyle factors, chronic pancreatitis patients are likely to have a lower body mass index than those not suffering from this disease<sup>[15]</sup>. Thus, body mass index is an easy accessible but important factor to consider in dose decision in these patients, as drug disposition might be affected. This is especially important when drugs with a narrow therapeutic index, such as, *e.g.*, warfarin and digoxin are prescribed<sup>[14]</sup>.

Furthermore, decreased food intake, could be an important factor in several cases of chronic pancreatitis as food intake will affect some of the physiological processes, *e.g.*, changes in pH, reduced gastric emptying time, increased gall secretion, increased motility, increased gastrointestinal and liver blood flow. Most of these pro-

cesses are already affected by the pancreatitis and hence these changes could possibly affect drug bioavailability. Consequently, reduced food intake in itself will worsen gastrointestinal physiological processes.

Insufficient food intake due to nausea, anorexia or alcoholism may also be of some significance<sup>[16]</sup>. Alcohol abuse is a well known etiological factor (alcoholic chronic pancreatitis) and the lifestyle of the alcoholic chronic pancreatitis patient group is in general characterized by excessive alcohol consumption and smoking. Together, these factors can be further accompanied by insufficient food intake and will eventually also lead to malnutrition.

Alcohol can be used as a central nervous system depressant to relieve pain and concerns about the disease. Therefore many patients with chronic pancreatitis continue their alcohol consumption throughout disease progression. In relation to alcohol induced chronic pancreatitis it is relevant to consider how the lifestyle with regard to alcohol- and alcohol related dietary habits may provide pharmacologically challenges. The most frequent pharmacological interaction is the combination of alcohol with other depressors of the central nervous system<sup>[17]</sup>. Moreover, alcohol drug interactions can influence the pharmacokinetics of a drug by altering the drug absorption or by affecting the liver metabolism. The effect will vary with, *e.g.*, the amount of alcohol consumed, the nature of the drug, the dosage and how the drug is administered. There are various interactions between alcohol and drugs. Antihistamines, analgesics and antidepressants are examples of drugs which may interact with alcohol.

The liver is the primary site of drug metabolism and the cytochrome P450 mixed-function oxidase enzyme system, is primarily responsible for this process. Alcohol inhibits the oxidation of drugs by cytochrome P450 isoenzyme (CYP2E1). In contrast, chronic alcohol consumption will cause induction of the CYP2E1 leading to increased drug metabolism. Previously, concerns have been raised regarding interactions of paracetamol and alcohol. However, paracetamol interaction is only a problem when ingestion of alcohol is suddenly stopped. Consequently, the hepatic glutathione is unable to detoxify which leads to irreversible hepatic damage. Therefore, in chronic alco-

**Table 1 Pathophysiological and lifestyle related effects on drug absorption**

Pathophysiology	Effect on drug absorption
Low intraluminal pH	The drugs ability to cross the luminal wall
Motility disorder	Delayed drug effect
Bacterial overgrowth	Decreased absorption due to diarrhea or structural abnormalities
Pancreatic secretion	Lack of enzymes leads to inactivation of pro-drugs
Steatorrhea	Problems with absorption of lipophilic drugs
Low body mass index	Increased plasma concentration

holic patients the consumption of alcohol should not be suspended on prescribing paracetamol<sup>[17]</sup>. Additionally, extensive alcohol consumption may result in gastric mucosal injury and hereby further affect drug absorption<sup>[8]</sup>.

Smoking may increase hepatic drug metabolism to a significant extent<sup>[14]</sup> and may in addition result in induction of the cytochrome oxidases<sup>[18]</sup>. It has also been demonstrated that body mass index is associated with cigarette smoking in chronic alcoholic-associated pancreatitis patients; the more cigarettes smoked per day, the lower the mean body mass index<sup>[19]</sup>. This is in line with the hypothesis that alcohol consumption and smoking can cause insufficient food intake and hereby affecting drug absorptions.

Abdominal pain is usually the symptom that causes patients with chronic pancreatitis to seek medical attention. In parallel, they can have a history of alcoholic abuse making opioids, with their associated abuse potential together with other side effects as, for example, bowel dysfunction, less suitable for these patients and other treatment regimens should be considered<sup>[7]</sup>. Recently it was demonstrated that pregabalin was superior to placebo for attenuation of experimental visceral pain in chronic pancreatitis patients<sup>[20]</sup>. Therefore, pregabalin may be used to treat pain in patients with chronic pancreatitis when there is a conflict or concern with abuse.

A summary of pathophysiological effects on drug absorption is given in Table 1.

## MANAGEMENT IN CHRONIC PANCREATITIS

The physiological processes affected by chronic pancreatitis are widespread. This section will focus on how to treat the pathophysiology of chronic pancreatitis in order to reduce the impact of factors possibly affecting drug absorption.

### Pharmacological management

**Enzyme therapy:** The main goal with enzyme treatment is to achieve optimal enzyme activity in the duodenum<sup>[21]</sup> and hereby improve the nutritional status, preventing weight loss, vitamin deficiencies and exocrine pancreatic insufficiency related symptoms, resulting in steatorrhea. The most widely used enzyme preparation is porcine

pancreatin. The preparation contains a mixture of protease, lipase and amylase<sup>[22]</sup>. Löhr *et al.*<sup>[23]</sup> analyzed the effectiveness of different preparations and concluded that overall pancreatin preparation replacements must contain high lipase activity. Lipase of porcine pancreatin is destroyed by protease and acids, thus it is necessary to protect the pancreatin against the influence of gastric acids. Another factor that is of great importance is the particle size and the rate of which the porcine pancreatin is released into the duodenum. The best particle size is assumed to be a diameter of  $\leq 2$  mm, since these particles leaves the stomach at the same time as solid food. The enzymes should be released within 30 min<sup>[24]</sup>. Pancreatic enzyme supplements improve fat absorption<sup>[25]</sup>, and hence reduces steatorrhea<sup>[26]</sup> and this may have beneficial effects on drug absorption. In contrast high-dose enzyme replacement therapy with or without gastric acid suppression may cause additional challenges related to drug absorption and interactions if additional drug therapy is required<sup>[6]</sup>. Thus, enzyme treatment can either enhance or complicate drug absorption in different aspects and this should be considered in the pharmacological management of clinical symptoms.

### Endoscopic therapy or surgical management

More invasive treatment is recommended for patients with pancreatic duct stones and pancreatic obstruction in whom standard medical therapy is not sufficient. The goals of endoscopy and surgery are to decompress ducts, dilate stricture with stent placement and preserve pancreatic tissue and adjacent organs<sup>[27,28]</sup>. Endoscopic therapy should be the first-line option because it is less invasive than surgery<sup>[29]</sup>. Surgery should be the first-line option in patients in whom endoscopic therapy failed or those with pancreatic mass with suspicion of malignancy<sup>[29]</sup>. It has been assumed that invasive procedures designed to improve drainage of the main pancreatic duct, will result in decreased pain. It could therefore be hypothesized that pain attenuation can improve the lifestyle and hereby indirectly affecting drug absorption. There is consensus that endoscopical and surgical management have both benefits and harms<sup>[26]</sup> and it has been suggested that management may include medical, endoscopic and surgical approaches with the interaction between various specialties, calling for a concerted multidisciplinary approach<sup>[28]</sup>. Moreover, as surgery has a low rate of success with attendant morbidity, mortality and slow recovery rates, it is not considered an option for optimizing absorption of drug in the pharmacological management.

### Lifestyle changes

Patients with chronic pancreatitis are often advised to eat small meals with low-fat content ( $< 20$  g of fat) in an attempt to decrease the need of pancreatic secretion<sup>[30]</sup>. Low-fat diets decreases the amount of overall fat presented to the intestine for digestion and absorption, and may be helpful alleviating steatorrhea<sup>[26]</sup> and hereby could lead to better conditions for some drug absorptions.

However, a systematic review of benefits and harms of low-fat diet in chronic pancreatitis found no studies of sufficient quality to confirm the effect of low-fat diet<sup>[31]</sup>. Thus, if people are given pancreatic enzyme supplements, they are usually advised to maintain a normal diet, as there is no need to lower fat intake alongside enzyme supplementation<sup>[31]</sup>.

Overeating is dissuaded, instead smaller meals on a more frequent basis is preferred. Frequent meals will also benefit gastric motility and result in more normal gastrointestinal conditions, and hereby improve drug absorption. The restriction in fat intake should be monitored by a dietitian who follows the total caloric intake and the diet should compensate the loss in caloric intake by carbohydrate-enriched diet. On a carbohydrate-enriched diet 65%-70% of the total daily energy intake should derive from carbohydrate. Hereby, it is possible for the patient to gain weight, which again will be beneficial in several ways, *e.g.*, in relation to drug absorption, where body weight and body composition is directly related to drug distribution volumes.

In general alcohol consumption and smoking should be diminished or avoided to reduce the impact on the pharmacokinetic profiles. Total alcohol abstinence is only recommended for patients whose chronic pancreatitis is derived from alcohol abuse.

## ADDITIONAL GASTROINTESTINAL CHANGES CAUSED BY OPIOIDS

Patients with painful chronic pancreatitis are often treated with opioids which lead to diverse issues and alterations in the gastrointestinal tract. Opioids have intrinsic effects on gastrointestinal motility and can modify the absorption of other drugs taken at the same time<sup>[10]</sup>. It has been demonstrated that, *e.g.*, tramadol is an effective oral opioid analgesic for reducing pain in people with chronic pancreatitis, but it is also associated with gastrointestinal adverse effect<sup>[26]</sup>. Opioids will affect opioid receptors in the enteric nervous system and will cause changes in motility, sphincter function and secretion which affect absorption leading to opioid induced bowel dysfunction<sup>[32]</sup>.

Opioid induced decreased motility occurs throughout the entire gastrointestinal tract. In the circular muscle in the small and large intestine, opioids induce increased resting contractile tone and decreases tonic inhibition of the muscle tone, which leads to increased tone in the circular muscle layer. This is accompanied by occasional occurrence of high-amplitude, non-propulsive phasic contractions enhanced by rhythmic contractions and associated changes in smooth muscle electrical activity. These motility abnormalities result in decreased propulsive forward peristalsis, and increased segmental contraction which in clinical settings manifests as constipation, abdominal cramps and gut spasm<sup>[33-35]</sup>. An additional consequence of this peristaltic disruption is stasis of luminal contents, which leads to increased passive fluid absorption<sup>[36]</sup>. Furthermore, intestinal fluid secretion is inhibited

by opioids directly *via* the enteric nervous system. In the sympathetic nervous system opioids also increase activity and thereby decrease the secretion. Serotonin and nor-adrenaline as terminal transmitters seems to dominate the local effect<sup>[37,38]</sup>. An overall decreased gut secretion of intestinal fluids takes place and together leads to harder and dryer stools<sup>[36-38]</sup>. Therefore, patients treated with opioids might have even more pronounced decreased motility which will complicate drug absorption further. Furthermore, as solid drug forms must dissolve before absorption can occur; dissolution rate determines availability of the drug for absorption. The increased fluid absorption caused by opioid effects will decrease water available for drug dissolution and may hereby affect absorption. If dissolution is slower than absorption it becomes the rate-limiting step.

## CONCLUSION

Several factors might affect drug absorption and metabolism in patients with chronic pancreatitis: gastric pH, regional blood flow, mucosal surface area and gut motility. The impact of these factors on drug absorption may be reduced by treating the pathophysiology of chronic pancreatitis. Treatment can be pharmacological management, enzyme therapy, endoscopic therapy or surgical management. Moreover, as gastrointestinal physiological changes in chronic pancreatitis can be affected by patients' lifestyle, lifestyle changes may lead to more optimal drug absorption. However, issues raised in this review may not have clinical relevance, but could explain part of the variation observed in drug effects in this patient group.
