It is suggested that the TECA-I BALSS could temporarily replace the hepatic function of ALF canines effectively and safely, and it may provide a new approach for the treatment of ALF.

Fan JG, Chen LH, Xu ZJ, Zeng MD. Overexpression of hepatic plasminogen activator inhibitor type 1 mRNA in rabbits with fatty liver. *World J Gastroenterol*, 2001;7(5):710-712

INTRODUCTION

Plasminogen activator inhibitor type 1 (PAI-1), an approximately M_r50000 glycoprotein, is the major physiological inhibitor of plasminogen activators. It is not only the priming factor for atherosclerosis and coronary thrombosis[1-3], but also participates in the genesis of chronic hepatitis and liver fibrosis[4-11]. However, there has been no available report yet about the research of hepatic PAI-1 gene expression in hyperlipidemia and fatty liver. The present study AIMed to explore the change of hepatic PAI-1 mRNA and its plasma activity by means of animal model.

MATERIALS AND METHODS

Animal model

Seventeen male New Zealand white rabbits weighing 2 200 g-2 500 g were randomly divided into two groups. The seven rabbits of control group were fed with normal rabbit diet. The ten rabbits of model group were fed with a fat-rich diet, which was prepared by addition of 10 g·kg^{-1} cholesterol and 100 g·kg^{1} lard oil to the normal diet. Vein blood samples of rabbits were collected before the beginning of study and at the 6th week and 12th week of the study respectively. Then the plasma samples were obtained and maintained at -70℃ until assayed. When the rabbits were sacrificed at the 12th week, their body mass and wet liver mass were measured. And two small samples of liver tissue were obtained from the right hepatic lobe. One sample was fixed in formalin, embedded in paraffin and stained with H&E. The other sample was stored in liquid nitrogen for detection of PAI-1 mRNA.

Measurement of plasma biochemistry

Plasma levels of alanine aminotransferase (ALT), aspartate aminotransferase (AST), triglycerides (TG) and total cholesterol (TCH) were determined by automatic biochemical analysis instrument (Olympus AU 1000, made in Japan). Plasma PAI-1 activity was determined by a chromogenic activity kit purchased from Biotechnology Co., Ltd. of the former Shanghai Medical University.

Detection of hepatic PAI-1 Mrna

The primer for rabbit PAI-1 was designed based on its complement DNA (cDNA) sequence published previously[6,12,13] and synthesized by DNA synthesis instrument. The sequence is 5' ATG GAA TTC CCG TGG AAC AAG AAT GAG ATC AG 3'and 5' TGA GCC ATC ATG GGC ACA GAG. The primer for β-actin was given by Shanghai Institute of Cell Biology of the Chinese Academy of Sciences, and the sequence is 5' ATC TGG CAC CAC ACC TTC TAC AAT GAG CTGC 3' and 5' CGT CAT ACT CCT GCT TGC TGA TCC ACA TCT GC 3'. The samples of liver tissues were cut into pieces quickly and the total RNAs were extracted with Trizol Reagent (Gibco BRL Co., Ltd.). Reverse transcription-polymerase chain reaction (RT-PCR) was carried out to amplificate the mRNA of PAI-1 and β-actin, and followed by electrophoresis of the products, photography and computer image scan. And the results were validated by the OD value of β-actin because of its equal expression in various tissues.

Statistical analysis

All results were expressed as $\bar{x}\pm s$. Statistical differences between means were determined by Student *t* test. $P<0.05$ was selected to reflect significance.

RESULTS

General condition

During the experiment, no animal death occurred in both groups. The body mass of rabbits in the model group increased more rapidly than in the control group. The model group had significantly greater body mass and liver index (wet liver mass per body mass) than the control group ($P<0.05$ respectively, Table 1). Compared with the control group, the plasma TCh and TG levels in the model group already increased significantly at the 6th week ($P<0.05$ *vs* controls) and increased more significantly at the 12th week ($P<0.01$ *vs* controls). However, the plasma levels of ALT and AST in the model group only had a tendency to increase as compared with those of control group (Table 2).

Table 1 The changes of body mass and liver index

Groups	*n*	m (body)/(kg)		Liver index/(g·kg^{-1})
		Start	End	End
Control	7	2.4±0.3	3.1±0.2	26±3
Model	10	2.3±0.6	3.4±0.1[a]	31±2[a]

[a]$P<0.05$ *vs* control.

Table 2 Plasma biochemical test at the 12th week

Groups	*n*	c(TG)/(mmol·L^{-1})	c(TCh)/(mmol·L^{-1})	b(ALT)/(nkat·L^{-1})	b(AST)/(nkat·L^{-1})
Control	7	0.34±0.11	0.76±0.17	372±130	215±45
Model	10	0.54±0.17[b]	26.40±3.89[b]	505±215	263±127

[b]$P<0.01$ *vs* control.

Changes of plasma PAI-1 activity

In the model group, the plasma PAI-1 activity of rabbits already increased significantly at the 6th week ($P<0.05$) and increased more significantly at the 12th week ($P<0.01$, Table 3) compared with those at the beginning of the experiment. Moreover, the difference in plasma PAI-1 activity between the two groups at the same period also had highly statistical significance ($P<0.05$ and $P<0.01$, respectively).

Table 3 The changes of plasma PAI-1 activity ($\times 10^3 AU \cdot L^{-1}$)

Groups	*n*	0 wk	6 wk	12 wk
Control	7	5.6±2.6	6.8±1.4	4.8±2.2
Model	10	4.9±3.1	7.7±1.1[a]	14.0±2.5[b]

[a]$P<0.05$, [b]$P<0.01$ *vs* control.

Changes of liver pathology

In the gross, the livers of the model group enlarged markedly as compared with those of control group. Under the light microscope, all the liver tissue sections stained with H&E of the model group showed diffuse and severe foamy steatosis of hepatocyte with mild necrosis and inflammatory cell infiltration, among which monocytes were dominant. And these lesions were located mainly in portal areas.

Expression of hepatic PAI-1 mRNA

The mRNA fragments of PAI-1 and β-actin were 360 bp and 828 bp respectively (Figures 1, 2). The lanes (No.3,4,5) of hepatic PAI-1 mRNA of the model group were markedly more intense than those of control group (No.1,2). The ratio of hepatic PAI-1 mRNA to β-actin mRNA of model group was significantly greater than that of the control group (3.474±0.051 *vs* 1.210±0.031, $P<0.01$).

DISCUSSION

Fibrinolysis system has an inactive zymogen that is called plasminogen. It can be activated by plasminogen activators and be converted to plasmin[11]. Plasmin can not only degrade the fibrin and remove it from the blood circulation, but also degrade extracellular matrix (ECM) directly and protect the tissues from fibrosis[1-11]. Among all fibrinolysis components, PAI-1 plays a central role in the pathophysiology of cardioangiological diseases. It is the major physiological inhibitor of urokinase plasminogen activator (uPA) and tissue plasminogen activator (tPA). The plasma PAI-1 regulates the plasmin cascade by its interaction with the tPA[1,2]. The increased activity of plasma PAI-1 could inactive the tPA in circulation, and the PAI-1 depositing in ECM could accelerate the clearance of tPA in tissues. PAI-1 exists in all of human tissues. Analysis of human tissues for PAI-1 antigen and activity has shown that the greatest quantity and highest specific activity were found in the liver. In plasma and ECM, the free PAI-1 produced by hepatocytes, endothelial cells and smooth muscle cells binds vitronectin (VN) to maintain the stable activity. The binding PAI-1 which increases the anti-fibrinolysis activity of blood vessels and accelerates the deposition of ECM can induce the genesis of atherosclerosis, coronary heart disease, pulmonary fibrosis and kidney fibrosis[1-3]. Recent studies have shown that the activity of PAI-1 is also associated with the occurrence and progression of chronic viral hepatitis and liver fibrosis. With the progression of chronic liver disease, the plasma PAI-1 antigen level and expression of PAI-1 in the liver increased gradually and culminated in the stage of liver cirrhosis, then decreased with the deterioration of liver function (Child-Pugh classification A to C)[4-8]. In vitro, hepatic stellate cells (HSC), also known as hepatic lipocytes, fat-storing cells, or Ito cells, could express PAI-1 when activated[12-15]. And previous studies have already demonstrated that HSC played a critical role in the genesis and development of liver fibrosis[16,17]. However, there has been no report yet about the effect of PAI-1 on the pathogenesis of fatty liver.

The present study established a rabbit model with overweight, hyperlipidemia and fatty liver via a fat-and-cholesterol-rich diet. The rabbits of this model had significantly greater body weight and higher plasma lipid levels than the normal control rabbits and their serum levels of ALT and AST had a tendency to increase. In hepatic histopathology, this model showed severe hepatocyte steatosis with mild hepatocyte necrosis and inflammatory cell infiltration. These characteristics resemble the presentation of human fatty liver associated with obesity and hyperlipidemia[18]. So this model can be used to explore the pathogenesis of nonalcoholic fatty liver. In the present study, while hyperlipidemia occurred in the model rabbits after 6 weeks of the fatty-rich diets, the plasma PAI-1 activity also increased. Then the plasma lipid and the plasma PAI-1 activity increased more significantly at the 12th week. Moreover, it was shown in the RT-PCR that PAI-1 mRNA was markedly intense in the liver with steatosis.

It is known that various factors could influence the expression and translation of hepatic PAI-1 gene. In the non-alcoholic fatty liver with obesity and hyperlipidemia, many accompanying factors such as lipoprotein (VLDL, LDL), hyperinsulinemia or gut-derived endotoxemia can stimulate hepatic PAI-1 production[19-22]. When the cytokines such as IL-1, TNF, PDGF, TGF-β or IGF-1 exist simultaneously, hepatic PAI-1 production will be further increased[23-28]. Besides, other factors such as dexamethasone, prothrombin, or angiotensin II (Ang II) can also accelerate the secretion of

PAI-1[29-32]. Subsequently, the increase in PAI-1 caused the imbalance of tPA and PAI-1, which leads to the decrease in fibrinolysis activity of hepatic microcirculation and degrading of hepatic ECM. Then the dysfunction of hepatic microcirculation, even the microthrombosis could be induced and the occurrence and progression of liver fibrosis promoted[5-11]. However, some studies have indicated that PAI-1 can inhibit the conversion of inactive TGF-β (transforming growth factor-β) into active TGF-β, so that PAI-1 might inhibit liver fibrogenesis since TGF-β can promote the production of ECM and inhibit its degrading[4]. It is therefore, necessary to reinforce the study of the relationship between PAI-1 and fibrosis in fatty liver in order to find an effective method for the prevention and treatment of liver fibrosis.

Abstract

AIM **To evaluate the effects of varying ischemic durations on cirrhotic liver and to determine the safe upper limit of repeated intermitten t hepatic inflow occlusion.**

METHODS **Hepatic ischemia in cirrhotic rats was induced by clamping the common pedicle of left and median lobes after non-ischemic lobes resection. The cirrhotic rats were divided into six groups according to the duration and form of vascular clamping: sham occlusion (SO), intermittent occlus ion for 10 (IO-10), 15 (IO-15), 20 (IO-20) and 30 (IO-30) minutes with 5 minutes of reflow and continuous occlusion for 60 minutes (CO-60). All animals received a total duration of 60 minutes of hepatic inflow occlusion. Liver viability was investigated in relation of hepatic adenylate energy charge (EC). Triphenyltetrazollum chloride (TTC) reduction activities were assayed to qualitatively evaluate the degree of irreversible hepatocellular injury. The biochemical and morphological changes were also assessed and a 7-day mortality was observed.**

RESULTS **At 60 minutes after reperfusion following a total of 60 minutes of hepatic inflow occlusion, EC values in IO-10 (0.749±0.012) and IO-15 (0.699±0.002) groups were rapidly restored to that in SO group (0.748±0.016), TTC reduction activities remained in high levels (0.144±0.002 mg/mg protein, 0.139±0.003 mg/mg protein and 0.121±0.003 mg/mg protein in SO, IO-10 and IO-15 groups, respectively). But in IO-20 and IO-30 groups, EC levels were partly restored (0.457±0.023 and 0.534±0.027) accompanying with a significantly decreased TTC reduction activities (0. 070±0.005 mg/mg protein and 0.061±0.003 mg/mg protein). No recovery in EC values (0.228±0.004) and a progressive decrease in TTC reduction activities (0.033±0.002 mg/mg protein) were shown in CO-60 group. Although not significantly different, the activities of the serum aspartate aminotransferase (AST) on the third postoperative day (POD_3) and P OD_7 and of the serum alanine aminotransferase (ALT) on POD_3 in CO-60 group remained higher than that in intermittent occlusion groups. Moreover, a 60% animal mortality rate and more severe morphological alterations were also shown in CO-60 group.**

CONCLUSION **Hepatic inflow occlusion during 60 minutes for liver resection in cirrhotic rats resulted in less hepatocellular injury when occlusion was intermittent rather than continuous. Each period of 15 minutes was the safe upper limit of repeated intermittent vascular occlusion that the cirrhotic liver could tolerate without undergoing irreversible hepatocellular injury.**

INTRODUCTION

The effective control of intraoperative bleeding is one of the most important measures for successful hepatectomy[1]. Up to now, temporary portal triad clamping (Pringle maneuver) has been used widely as a means of reducing blood loss. In China, hepatocellular carcinoma (HCC) is commonly associated with cirrhosis[2-6], bleeding during hepatic resection is a major factor in determining the severity of postoperative liver damage and the prognosis[7-9]. The safe time limit of hepatic vascular occlusion during the cirrhoti c liver resection remains the major concern of liver surgeons[10,11]. Intermittent occlusion may not only reduce intraoperative bleeding but also increase the total duration of ischemia for hepatectomy[7,12,13]. Thus it is important for the improvement of the safety of the cirrhotic liver resection that how long each time is suitable for the intermittent occlusion[14,15]. The purpose of this experiment is to study the effects of various ischemic durations on cirrhotic liver and determine the safe upper limit of intermittent hepatic inflow occlusion without irreversible damage in rats with cirrhotic liver.

MATERIALS AND METHODS

Male Sprague-Dawley rats weighing 200 g±30 g were allocated randomly into six experimental groups of 20 animals, depending on the duration and form of ischemia: Sham occlusion (SO group), intermittent occlusion for 10 min (IO-10 group), 15 min (IO-15 group), 20 min (IO-20 group) and 30 min (IO-30 group) with 5 min of reperfusion between each period, continuous occlusion for 60 min (CO-60 group). The rat cirrhosis was induced by injecting 600 $g \cdot L^{-1}$ CCl_4 oil subcutaneously twice weekly at a dose of 4 $mL \cdot kg^{-1}$ bw and drinking 50 $mL \cdot L^{-1}$ ethanol. A validated model[16] used by clamping the common pedicle of left and median lobes after

non-ischemia lobes resection did not require splanchnic decompressing. All animals received a total duration of 60 min of hepatic inflow occlusion.

Operative procedure

Rats were anesthetized with intraperitoneal pentobarbital 0.2 mg·kg^{1}. A midline laparotomy was performed. Ligamentous attachments around the liver were divided and the total liver hilum of right and left portal vein, hepatic artery, bile duct as well as the right hepatic vein were also dissected. Ischemia was induced in the median and left hepatic lobes by clamping the corresponding arterial and portal venous branches en masse. This allowed an uninterrupted blood supply to the right lobe and caudate lobe, avoiding congestion of alimentary tract and consequent haemodynamic instability. When the assigned total ischemic duration of 60 min was completed, the clamp was removed and the non-ischemic right lobe and caudate lobe were resected (30% hepatectomy) after ligation of the corresponding pedicles en masse. This technique abrogates the effect of splanchnic congestion caused by total occlusion of the portal hilum during hepatic ischemia.

Assessment of liver viability[17]

A small portion of excised liver (about 30 mg) was immediately frozen by freeze -clamp precooled with liquid nitrogen, lyophilized overnight, and further kept at -80℃ until analysis. The dry tissue was then weighed and homogenized in 1 mL ice-cold 0.6 mol·L^{-1} $HClO_4$. Thirty minutes later, the homogenate was centrifuged for 20 min at -4℃, 20 000×g and the supernatant with 0.3 mL was neutralized with 1 mol·L^{-1} potassium carbonate 0.2 mL and centrifuged in the same manner. The final supernatant was filtered through a filter of 0.45 μm and used as a sample with 20 μL for determining the liver tissue concentration of ATP, ADP and AMP by high-performance liquid chromatography (Shim-pacr CLC-ODS analytical column, 150 mm×6.0 mm i.d, λ=254 nm) at a flow rate of 0.1 mL·min^{-1}. The results were calculated as micromoles of nucleotide per gram of dry tissue. Energy charge was calculated as follows: EC = (ATP+1/2ADP)/(ATP+ADP+AMP).

Quantitation of the extent of irreversible hepatocellular injury

The degree of irreversible cellular injury was assessed by a modified technique described by Rodriguez *et al*[18]. A portion of each liver tissue specimen was rinsed in ice-cold Ringer's lactate solution, and then placed on ice, weighed, and homogenized in 0.25 mol·L^{-1} sucrose to make an 8% homogenate by weight. The homogenate was filtered through a fine stainless steel mesh to remove the remaining fragments. Protein content of the homogenate was determined by the method of Lowry. A 1 mL aliquot of homogenate was then mixed with 1 mL of 10 g·L^{-1} TTC (Sigma) in 0.033 mol·L^{-1} phosphate buffer (pH 7.4). The reaction was made in triplicate. The reactive mixture was incubated at 37℃ in an agitating water bath for 30 min and added with an equal volume of acetone to each reaction tube and then vortexes. The extracted mixture was centrifuged for 15 min at 2 000 r·min^{-1} and the absorbance of the clear red supernatants was measured at 485 nm in a spectrophotometer. The absorbances of the reaction triplicates were averaged and unreacted reagent blanks were subtracted to arrive at a final absor ption. Comparison of these absorption values to a standard curve of known reduce d TTC concentrations to determine the micrograms of TTC reduced per 30 min per milligram of the liver tissue protein.

Serum AST, ALT, lactic dehydrogenase (LDH), alkaline phosphatase (AKP) and total bile acid (TBA) contents were measured at 4℃ using the available kits. Animals of each group were treated as scheduled. The excised median lobe liver was fixed in 100 mL·L-1 formalin and embedded in paraffin. Sections 3 μm thick were stained with hematoxylin and eosin for light microscopy. A segment of the liver tissue of the median lobe, 2 mm×2 mm×2 mm in size, was taken and fixed in 40 g·$^{-1}$ glutaraldehyde-phosphate buffer (0.1 mol·L^{-1}, pH: 7.3) for 24 h and then post-fixed in 10 ·L^{-1} osmian tetroxide for two hours, dehydrated with a descending series of alcohol, and embedded with epoxied resin. The specimens were cut into ultrathin slices pigmented double with uranium acetate and lead citrate before being observed under the HITACHI-600 transmission electron microscope. Ten animals in each group were considered to have survived the procedure if they remained alive on the seventh day after operation.

Statistical analyses

Values were expressed as x±s. Differences among groups were analyzed using one-way analysis of variance (ANOVA). A post hoc analysis using Fisher's PLSD test was used to account for multiple comparisons. Differences in survival were determined using the Kaplan-Meier test. *P* values less than 0.05 were considered significant. All the statistical analyses were made using SPSS software package.

RESULTS

At a total of 60 min of hepatic inflow occlusion, the liver tissue levels of ATP in each ischemia group were significantly decreased, the extent of ATP restoration at 60 min after reperfusion was markedly related with the METHODS of hepatic inflow occlusion. The ATP levels in IO-10 and IO-15 groups were rapidly restored to that in SO group, but there was a progressive decrease in IO-20 and IO-30 groups, the recovery was significantly suppressed in CO-60 group, to only 5.8% of ATP levels in SO group (Table 1). There was significant difference among IO-10, IO-15, IO-20, IO-30 and CO-60 groups.

Table 1 Adenine nucleotide concentrations in the dry cirrhotic livers (x±s, μmol·g^{-1}, n = 6)

Groups	Ischemia 60 min			Reperfusion 60 min		
	ATP	ADP	AMP	ATP	ADP	AMP

^{a}P<0.05, ^{b}P<0.01 *vs* SO; ^{c}P<0.05, ^{d}P<0.01 *vs* IO-10; ^{e}P<0.05, ^{f}P<0.01 *vs* IO-15; ^{g}P<0.01 *vs* IO-20; ^{h}P<0.01 *vs* IO-30.

The EC levels at a total ischemic duration of 60 min significantly and immediately decreased in each ischemia group. At 60 min after reperfusion, there was a rapid restoration in IO-10 and IO-15 groups (0.748±0.016 in SO group, 0.749±0.012 in IO-10 group, 0.699±0.002 in IO-15 group). The EC levels were restored partly in IO-20 and IO-30 groups (0.457±0.023 and 0.534±0.027) and no recovery in CO-60 group (0.228±0.004) (Figure 1). A significant difference was shown among IO-10, IO-15, IO-20, IO-30 and CO-60 groups.

At a total ischemic period of 60 min, TTC reduction activities in IO-20, IO-30 and CO-60 groups (0.098±0.007 mg/mg protein, 0.099±0.005 mg/mg protein and 0.068±0.007mg/mg protein, respectively) markedly declined to 66.7%, 67.3% and 46.3% of SO group (0.147±0.004 mg/mg protein), respectively. At 60 min after reperfusion, TTC reduction activities remained high in IO-10 and IO-15 groups (0.139±0.003 mg/mg protein and 0.121±0.003 mg/mg protein) and significantly decreased in IO-20 and IO-30 groups (0.070±0.005 mg/mg protein and 0.061±0.003 mg/mg protein), there was a progressive decrease in CO-60 group (0.033±0.002 mg/mg protein) in comparison with that in each intermittent occlusion group (P<0.01) (Figure 2).

Although serum AST and ALT activities on POD_1 markedly increased in IO-10 (986±49 μkat·L^{-1} and 1356±221μkat·L^{-1}), IO-15 (1431±116μkat·L^{-1} and 1611±149μkat·L^{-1}), IO-20 (1558±78 μkat·L^{-1} and 1186±187 μkat·L^{-1}), IO-30 (1743±96 μkat·L^{-1} and 2466±489 μkat·L^{-1}) and CO-60 (1773±181 μkat·L^{-1} and 2190±397 μkat·L^{-1}) groups as compared with SO group (294±16 μkat·L^{-1} and 669±26 μkat·L^{-1}), there was no difference among five ischemia groups. However, serum AST activities in CO-60 group on POD_3 and POD_7 (203±14 μkat·L-1, n = 5 and 183±6 μkat·L-1, n = 4) and ALT activities on POD_3 (484±38 μkat·L^{-1}, n = 5) remained to be higher than that in intermittent ischemia groups (P<0.05). In addition, no significant difference was found in postoperative serum LDH, AKP and TBA levels among ischemia groups. All animals in SO and IO-10 groups survived during the 7 d period. The mortality rates in IO-15, IO-20 and IO-30 groups were 10%, 30% and 40%, respectively. In contrast, the mortality rate in CO-60 group increased to 60%, with a significant difference between IO-10 and CO-60 groups (P<0.05).

The morphologic findings revealed that hepatic cells slightly swollen in IO-10 and IO-15 groups, but the dilatation of the rough-surfaced endoplasmic reticulum (RER) and the degeneration changes in mitochondria within cytoplasm were mild, the shape of nucleus was regular. In IO-20 and IO-30 groups, hepatic cells had a moderate swelling with cytoplasmic microvacuolisation, predominantly in the midzonal areas. Ultrastructural changes were shown with a gross dilatati on of RER and mitochondria, an irregular nucleus and an aggregation of the heterochromatins within the nucleus. In CO-60 group, the hepatocytes had vacuolar degeneration accompanied with infiltration of polymorphonuclear leucocytes in the sinusoids. RER and mitochondria were severely dilated, the heterochromati ns within the nucleus markedly increased and nucleus concentration occurred (Figure 3).

DISCUSSION

In China,the incidence of HCC is high and almost 85% of HCC were accompanied with liver cirrhosis[4,19].Bleeding during liver resection is known to be an important prognostic indicator of both morbidity and mortality, particularly for the cirrhotic patients[14,20,21]. Generally, blood loss has been controlled by the Pringle maneuver, which is one of the simplest and most commonly used METHODS and attention has focused on the

length of time for which such ischemia to the liver can be safely tolerated[20,22-26]. Although the healthy human liver could tolerate a major hepatectomy with ischemia of more than 60 min under normothermic condition[24,25], in their studies, there were complications in 18 of 34 patients and a thirteen-fold increase in the activities of plasma transaminase on the first postoperative day. Moreover, the cirrhotic liver would be much more vulnerable to ischemia, Therefore, intermittent portal triad clamping for the control of bleeding during cirrhotic liver resection has been advocated that this would be less detrimental to the liver than continuous clamping[7,12,13,20,21] . How long the cirrhotic liver could tolerate intermittent hepatic inflow occlusion each time remains to be determined.

EC, which expressed the balance between ATP-consuming and -producing reactions and was of central importance in the regulation of metabolic sequences, had bee n used to assess liver viability[17]. These studies had suggested that enhanced ATP synthesis and prompt recovery of EC after revascularization were prerequisites for maintaining the liver viability. In the present study, althoug h ATP content and EC at a total ischemic duration of 60 min were retarded during the ischemic period, a significant difference was shown at 60 min after reperfusion. Because the ability of the liver to restore EC after reperfusion played a decisive role in determining hepatic viability[19], the prompt restoration of the EC levels in IO-10 and IO-15 groups reflected the maintenance of liver viability. However, EC had only partial recovery in IO-20 and IO-30 groups, could not be restored after reperfusion in CO-60 group, indicating the irreversible mitochondrial dysfunction, subsequent ATP depletion and loss of liver viability in IO-20 and IO-30 groups, which were more severe in CO-60 group. These findings were further supported by the morphological results.

Of the variety of cell types in the liver, the hepatocytes were the most sensitive to normotheric ischemia. The liver could tolerate a temporary ischemia of short duration but prolonged ischemia caused irreversible hepatocellular injury and led to liver function failure even if the liver was reperfused. The TTC reduction activity assay reflected the ability of the intact mitochondrial reduction-oxidation enzyme systems to convert the colorless TTC to a red formazan dye. This indicator had been validated to quantitate the extent of irreversible cell damage in the study of the hepatic and cardiac ischemic injury[18].The inability to reduce TTC indicated the irreversible loss of mitochondrial function. In the present study, the TTC reduction activities had no changes during ischemia of 60 min and remained at higher levels at 60 min after reperfusion in IO-10 and IO-15 groups, but had an aggressive decrease in IO-20, IO-30 and CO-60 groups at 60 min of ischemia or reperfusion. These results demonstrated that the irreversible hepatocellular injury firstly occurred in IO-20 group, significantly greater injury occurred in CO-60 group.

As mentioned above, when changes in EC levels were examined in conjunction with changes in TTC reduction activities and morphological features, it was possible to identify a significant injury that was completely reversible when the intermittent occlusion duration was limited to 15 min. However, the intermittent occlus ion of prolonged 20 or 30 min would produce irreversible hepatocellular damage, the extent of damage became greater in continuous occlusion group.

In addition, it has been emphasized in the previous literature that uncontrollab le massive hemorrhage during hepatic resection would lead to a deterioration of liver function and increased postoperative morbidity and mortality, particularly in the patients with liver cirrhosis[7-9,14,20,21]. These patients could tolerate liver ischemia within certain limits better than they do the consequ ences of massive bleeding and blood transfusion. Wu *et al*[20] showed that a cirrhotic liver could tolerate intermittent ischemia for up to 200 minutes without increased postoperative complications and mortality. In another report, immediate postoperative liver function was better preserved in the intermittent occlusion group than in those patients who were operated on without using the intermittent occlusion[15]. This may be due to less hemodynamic disturbance induced by the bleeding as well as hepatovenous retrograde perfusion during the liver transection to maintain the liver viability[21]. However, the preoperative status of liver function should still be taken into account. An improved prognosis appeared to be related to a suitable selection of cirrhotic patients with well-compensated liver function and an increased proportion of limited resections of cirrhotic livers[14,27-29].

In the clinical practice, an intermittent rather than a continuous hepatic vascular occlusion was advocated during limited resection of the cirrhotic live r because it could increase the ability of the liver to tolerate the consequences of prolonged ischemia and splanchnic venous stasis[20,21]. However, the relation between the selected duration of intermittent vascular occlusion and the risk of bleeding from esophageal varices in the cirrhotic patients during the liver resection remains to be determined.

It is concluded from this experiment that intermittent hepatic inflow occlusion to the liver resulted in less hepatocellular damage when compared with continuous occlusion and suggested that intermittent occlusion of the hepatic pedicle was the preferred method to control the intraoperative hemorrhage during cirrhotic liver resections. Furthermore, each period of 15 min was the safe upper limit of repeated intermittent hepatic inflow occlusion that the cirrhotic liver could tolerate without irreversible liver damage.

Abstract

AIM **To analyze the association of HLA-DRB1 with autoimmune hepatitis (AIH) in patients from China.**

METHODS **In 32 patients and 48 healthy controls, polymerase chain reaction amplification with sequence-specific primers (PCR-SSP) was performed to examine the association of certain alleles or polymorphic sequences of HLA-DRB1 with AIH.**

RESULTS **HLA-DRB1 typing by PCR-SSP showed that DR4 had a significantly increased frequency among patients with AIH versus healthy control (46.9% versus 20.8%; relative risk = 3.35, *P* = 0.014). In subtypes of DR4, there was a trend of increase in the gene frequency of DRB1 *0405 in patients with AIH versus healthy controls (21.9% *vs* 6.3%, *P* = 0.04, but P_c = 0.08). In addition, a significant increase was found in the alleles frequency encoding QRRAA from the third hyperpolymorphic region of DR4 in the patients with AIH (86.7% of DR4 positive patients *vs* 40.0% in DR4 positive controls, *P* = 0.016, P_c = 0.028, RR = 9.75).**

CONCLUSION **AIH in Chinese is associated with HLA-DR4. There is a relationship between QRRAA sequence within the third hyperpolymorphic region of the DRB allele and AIH in Chinese.**

INTRODUCTION

Autoimmune hepatitis (AIH) is an inflammation of the liver characterized by the presence of periportal hepatitis in microscopic examination (piecemeal necrosis or interface hepatitis), hypergammaglobulinemia, and serum autoantibodies[1-5]. Infiltration of the liver by T lymphocytes and a peripheral defect in T-suppressor cell function suggest an immune basis for the pathogenesis and liver injury in AIH[6-9]. Among northern European and North American white populations, various studies have shown that the serologically defined HLA-DR3 and DR4 antigen are the primary determinants of HLA-encoded susceptibility to AIH[10]. The principal susceptibility allele for type 1 autoimmune hepatitis among white northern Europeans and Americans is HLA-DRB1 *0301, and a second, independent risk factor is HLA-DRB1*0401, which encodes DR3 and DR4 respectively[11-13]. In Japan, where DR3 is very rare in the normal population, the primary HLA associated with DR4 and almost all patients are in the older age groups, with a peak onset at 50-60 years of age[14-16]. Patients from Argentina[17], Brazil[18], and Mexico[19] have susceptibility alleles for type 1 autoimmune hepatitis that are different from those in white northern European and American patients. These discrepant observations emphasize the importance of studying ethnically homogeneous populations[20]. In present study, we performed HLA genotyping with respect to DRB1 in Chinese patients with AIH using PCR amplification by the sequence-specific primers (PCR-SSP) method to investigate the relationship between the distribution of the HLA-DRB1 allele and the susceptibility to autoimmune hepatitis.

MATERIALS AND METHODS

Subjects

A total of 32 patients, all female, who satisfied the diagnostic criteria for AIH[1,2,21-23], were enrolled in this study. They were followed up at Shanghai Institute of Digestive Disease, Shanghai Renji Hospital from 1996 to December 2000. Each patient denied illicit drug use, contact with jaundiced individuals, family history of liver disease, alcohol abuse, and exposure to hepatotoxic medication or chemicals. Each lacked evidence of infection with hepatitis B and C virus. All patients were seropositive at a titer of at least 1:40 by indirect immunofluorescence for antinuclear antibodies or smooth muscle antibodies. The control population comprised 48 healthy female Chinese who were unrelated to the patients.

Methods

DNA extraction High molecular weight DNA was isolated from peripheral blood leukocytes by phenol/chloroform extractions.

Amplification primers Primer pairs used for HLA-DRB1 and subtypes of HLA-DR4 were synthesized by the Shanghai Branch, Canadian Sangon Bioengineer Company, according to REFERENCES[24,25]. In each PCR reaction a primer pair was included that amplified the third intron of DRB1 genes. These two primers matched non-allelic sequences and thus functioned as an internal positive amplification control. 5'-prime C5 $^{5'}$-TGCCAAGTGGAGCACCCAA$^{3'}$ (Tm 60℃, complementary to codons 173-179 in the 3'end of exon 3) and 3'-primer

C3 5' GCATCTTGCTCTGTGCAGAT3' (Tm 60℃, complementary to codons 193-200 in the 5'end of exon 4) gave rise to a 796 base pair (bp) fragment.

PCR-SSP[24,25] Each PCR reaction mixture contained 2-4 allele- or group-specific DRB1 primers and the internal positive control primer pair in a 5-fold lower concentration. The PCR reaction mixtures (13 μL) consisted of 100 ng genomic DNA in 2 μL, PCR buffer [50 mmol·L^{-1} KCl/1.5 mmol·L-1 $MgCl_2$/10 mmol·L^{-1} Tris-Cl, pH 8.3/0.001% (w/v) gelatin], 200 μmol·L-1 of each dATP, dCTP, dGTP and dTTP, 1 μmol·L^{-1} of the allele- and group-specific DRB primers, 0.2 μmol·L^{-1} of Ampli Taq (diluted 1 to 10 in 1×PCR buffer, Shanghai Branch, Canadian Sangon Bioengineer Co.). PCR amplifications were carried out in a GeneAmp PCR System 9600 (Perkin-Elmer Cetus Instruments). DNAs were amplified by 30 three-temperature cycles in 1 h and 20 min. Each cycle consisted of denaturation at 94℃ for 20 s, annealing at 65℃ for 50 s and extension at 72℃ for 20 s.

Visualization of amplification Absence or presence of PCR products was visualized by agarose gel electrophoresis. After addition of 2.5μL loading buffer [300 mL·L^{-1}% (v/v) gllycerol stained with bromophenol blue and xylene cyanol], the PCR reaction mixtures were loaded in 3 mm wide slost in 10 g·L^{-1} ME agarose gels pre-stained with ethidium bromide (0.5 mg·L^{-1} gel). Gels were run for 25-30 min at 7-8 V·cm^{-1}, then were examined under UV illumination and documented by photography.

Statistical analysis

Data were analyzed by the standard statistical procedure of χ^2 contingency table analysis with Yates' correction. Corrected *P* values were calculated using the Bonferroni inequality method. Relative risk was obtained by the cross-product ratio of the entries in the 2×2 table. A level of $P<0.05$ was considered as statistically significant.

RESULTS

Allelic frequencies of HLA-DRB1 are shown in Table 1. HLA-DRB1 typing by PCR-SSP showed that DRB1 *04, which encodes DR4 antigen, had a significantly increased frequency among patients with AIH versus healthy control (46.9% *vs* 20.8%; relative risk = 3.35, $P = 0.014$). No other allele was significantly associated with autoimmune hepatiti s. DRB1 *04 has 11 subtypes officially assigned as DRB1 *0401-0411. As shown in Table 2, there was a trend of an increase in gene frequency of DRB1 *0405 in patients with AIH versus healthy controls (21.9% *vs* 6.3%, $P = 0.04$, $P_c = 0.08$).

The "shared motif hypothesis" suggests that many susceptibility-associated alleles encode a conserved epitope spanning the third allelic hypervariable region of the DRâ molecule, which may form the molecular basis of susceptibility to autoimmune diseases such as rheumatoid arthritis. The sequence over this third allelic hypervariable region, which spans amino acid 70-74 of the DRβ chain, are QKRAA and QRRAA. QKRAA is encoded by allele DRB1 *0401, QRRAA by DRB1 *0404, DRB1 *0405, DRB1 *0408 and DRB1 *0410. Our analysis indicates a significant increase in the alleles encoding QRRAA from the third hyperpolymorphic region of DR4 in the patients with AIH (13 cases or 86.7% of 15 DRB1 *04 positive patients *vs* 4 cases or 40.0% of 10 DRB1 *04 positive controls, $P = 0.016$, $P_c = 0.028$, RR = 9.75).

Table 1 Allelic frequencies of DRB1 in autoimmune hepatitis

DRB1 allele	DR Ag	Autoimmune hepatitis % (n = 32)	Healthy control % (n = 48)	RR	P value	Corrected P value
DRB1*01	DR1	0.0	4.2			
DRB1*15,*16	DR2	37.5	35.4			
DRB1*03	DR3	15.6	14.6			
DRB1*04	DR4	46.9	20.8	3.35	0.014	0.026
DRB1*11,*12	DR5	12.5	29.2			
DRB1*13,*14	DR6	9.4	12.5			
DRB1*07	DR7	3.1	4.2			
DRB1*08	DR8	9.4	10.4			
DRB1*09	DR9	34.4	37.5			
DRB1*10	DR10	0	2.1

DRB1*0406	3.1 (1)	4.2 (2)			
DRB1*0407	0	0			
DRB1*0408	0	0			
DRB1*0409	0	0			
DRB1*0410	6.2 (2)	0			
DRB1*0411	0	0			

P values are given only where significant at <0.05 level.

DISCUSSION

Autoimmune hepatitis (AIH) is a disease of unknown etiology but is presumed to have a basis in aberrant autoreactivity[26,27]. It is characterized by hypergammaglobulinaemia due mainly to selective elevation of serum IgG, a wide range of circulating tissue autoant ibodies, a picture of periportal (interface) hepatitis on liver biopsy with a predominantly lymphoplasmacytic necroinflammatory infiltrate without cholangiolitic or other changes normally associated with liver diseases of other aetiologies, and usually a notable response to immunosuppressive therapy[1,23,28,29]. Diagnosis is based on the combination of these features together with careful exclusion of all other possible causes of liver disease. Corticosteriods remain as the standard therapy for patients with severe autoimmune hepatitis but the treatment is not universally effective[30]. Novel drugs with potent immunosuppressive and cytoprotetive functions must be evaluated[31,32]. Liver transplanta tion has been an extremely successful treatment option for the decompensated patients[33], but better drug regimens are needed to conserve this limited resource.

The association of AIH with inheritance of the HLA-DR3 allotype in Caucasians has long been recognized. The secondary association with DR4 (in DR3 negative patients) has been more recently defined[34-39]. DR3 tends to occur more frequently in younger patients with severe disease whereas DR4 is mostly associated with an older age at presentation and with generally milder disease that is easier to control[11-15].Using HLA-DR typing by PCR-SSP, we found that DRB1*04 (encoding DR4) was presented in 46.9% of the AIH group versus 20.8% of healthy control individuals,

giving a relative risk of 3.35. No other allele was significantly associated with autoimmune hepatitis in Chinese. In white patients, a dual association of HLA-DR3 and -DR4 has been found in patients with autoimmune hepatitis. The discrepancy in HLA association between Chinese and white patients with AIH is probably caused by the racial or disease differences in the distribution of HLA alleles. Other genetic predispositions or environmental factor responsible for the pathogenesis of these autoimmune diseases may vary among ethnic groups. Our results are similar to the reports from Japan, where relationship between the susceptibility of AIH and the presence of HLA-DR4 had been firmly demonstrated[14-16]. In our study, there was a trend of an increase in gene frequency of DRB1*0405 increased in patients with AIH versus healthy controls, but the difference between patients and controls was not statistically significant, probably due to the small number of patients. "The shared epitope hypothesis" suggests that many alleles encode a similar amino acid sequence in the critical portion of the antigen-binding groove of the HLA DR molecule. The presence of shared third allelic hypervariable region epitopes QKRAA and QRRAA at position 70-74 of the HLA-DRâ chain was analyzed in our study. Unlike in the Caucasian population, the DRB1*0401 allele, which possesses the QKRAA sequence, was very uncommon in the Chinese subjects. There was a significant increase in the percentage of patients who possess the QRRAA sequence. This was accounted for mainly by the DRB1*0405 allele, with the rest being DRB1*0404 allele.

Autoimmune hepatitis is thought to be triggered by various environmental factors in individuals rendered susceptibility by a distinct and genetic background[40]. The immune response is initiated in human when the T-cell receptor recognizes foreign or self-peptide fragments that can be bound to self-HLA molecules encoded by the major histocompatibility complex genes on the short arm of the sixth chromosome. Differences in immune responsiveness among individuals are considered to be caused by allelic variations in HLA antigens with autoimmune diseases associated with specific HLA antigens. DR4 may regulate immune responsiveness to some autoimmune hepatitis, but not all. Other genetic polymorphism of HLA, such as HLA-DR6, -DQ, -C4[41-45], may also play an important role in the pathogenesis of AIH in the white patients, but there has been no data in Chinese yet. Autoimmune promoter genes outside the HLA, such as CTLA-4 (cytotoxic T-lymphocyte antigen-4)[46], T cell repertoire[47,48], cytokine gene[49,50], were investigated in white patients with AIH. So the genetic background of AIH may be very complex, but the clarity of this genetic predisposition and its clinical consequences will render defining susceptible populations and seeking novel therapeutic interventions.

Abstract

AIM **To explore the association of methylation of the CpG island in the promotor of the P16 tumor suppressor gene with the clinicopath ological characteristics of the colorectal cancers.**

METHODS **Methylation-specific PCR (MSP) was used to detect P16 methylation of 62 sporadic colorectal cancer specimens.**

RESULTS **P16 methylation was detected in 42% of the tumors. Dukes' staging was associated with P16 methylation status. p16 methylation occurred more frequently in Dukes' C and D patients (75.9%) than in Dukes' A and B patients (12.1%).**

CONCLUSION **P16 methylation plays a role in the carcinogenes is of a subset of colorectal cancer, and it might be linked to poor prognosis.**

INTRODUCTION

The alterations of p16 gene, i.e. homozygous deletion, point mutation and promoter methylation, and their consequence, P16 gene inactivation, were frequently observed in many human tumors. In colorectal cancers (CRC), since the first two mechanisms have never been demonstrated[1], the role of P16 gene methylation in carcinogenesis has attracted considerable attention recently[2-4]. Whether P16 methylation is associated with clinicopat hological characteristics has not been clear[4,5]. In the present study, we detected the occurrence of p16 methylation in primary CRC using a recently developed methylation specific PCR method (MSP) and explored the relationship between methylated p16 and Dukes' staging and other clinicopathological characteristics of the patients.

MATERIALS AND METHODS

Tumor specimens

Fresh specimens (n = 62) of surgically resected CRC were collected from Rui Jin Hospital and were immediately frozen at -80℃ after rinsed with phosphate buffered saline.

DNA isolation

Tumor DNA was isolated and purified with Trizol reagent (GIBCO Life Technologies) according to the manufacturer's instruction.

Bisulfite conversion of DNA samples

Bisulfite conversion of DNA samples for methylation detection was carried out based on the principle that treatment of DNA with bisulfite would result in the conversion of unmethylated cytosine residues into uracil, while methylated cytosine residues remain unchanged. Thus, the DNA sequences of methylated and unmethylated genomic regions following bisulfite conversion would be different and distinguishable by sequence specific PCR primers. CpGenome DNA modification kit (Intergen, New York, NY) was used. One microgram of DNA was treated with sodium bisulfite and the bisulfite-converted DNA was resuspended in a total volume of 30 μL of TE.

Methylation-specific PCR (MSP)

MSP was performed using CpG p16 WIZ amplification kit (Intergen). With a complete chemical modification reaction, U primers amplified only unmethylated DNA, and M primers amplified only methylated DNA in the region of P16 gene promoter. W primers amplified unmodified DNA no matter they were methylated or not. Each chemically modified experimental DNA sample was amplified with primers U, M and W respectively. The PCR mixture contained 1×PCR buffer (500 mmol·L^{-1} KCl, 100 mmol·L^{-1} Tris-HCl, 10 g·L^{-1} Triton-100, 15 mmol·L^{-1} $MgCl_2$), dNTPs (each at 0.25 mmol·L^{-1}), U or M primers 1.0 μL, Ampli Taq Gold polymerase (Perkin-Elmer, Foster city, CA) 1 U, bisulfite-modified DNA 0.1 μg in a final volume of 30 μL. Reactions were started at 95℃ for 12 min. Amplification was carried out in a thermal cycler (Hybaid, Teddington, England) for 35 cycles (45 s at 95℃, 45 s at 60℃, and 60 s at 72℃), followed by a final 10 min extension at 72℃. U, M and W controls provided by the kit served as validation of the reagents and PCR conditions. PCR products were analyzed by agarose gel electrophoresis and ethidium bromide staining.

The expected PCR products visualized on the gel should be an 154 bp nucleotide for unmethylated P16 and 145 bp nucleotide for methylated p16. If the sample contains unmethylated DNA, Uprimer will produce an 154 bp products (band U), and if it contains methylated DNA, M primer will produce 145 bp products (band M). The appearance of band W from the sample indicated an incomplete bisulfite conversion, and was considered a sign of unqualified chemical modification of the sample.

Clinicopathological data

Clinicopathological data were collected after MSP for p16 methylation was accomp lished. The clinicopathological data

included age, gender of the patients, anatomical location[2] and Dukes stage of CRC.

Statistical analysis

The χ^2 test was performed to analyze the relationship between p16 methylation status and each of the clinicopathologic parameters.

RESULTS

MSP analysis of p16 methylation

Of 62 CRC specimens, 26 displayed bands M, 154 bp products, signifying that 42% of the tumors had detectable p16 methylation. Band U, 154 bp product, was visible in all specimens with varied intensity, indicating the existence of unmethylated DNA in these specimens. No band W appeared in all specimens (Figure 1).

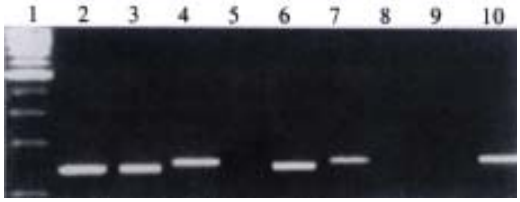

Figure 1 Electrophoresis of MSP products of p16 CpG region. 1. 100 bp marker, 2. W control (142 bp), 3. M control (145 bp), 4. U control (154 bp), 5,6,7. The same sample (from patient No.9) reactive with W, M,U primers respec tively, 6. 145 bp product, 7. 154 bp product, indicating p16 was methylated in this sample, 8,9,10. Same sample (from patient No.34) reactive with W, M, U primers respectively, 10. 154 bp product, indicating that p16 was unmethylated in this sample.

Clinicopathological correlations with p16 methylation

No correlation was found between p16 methylation and some of clinical factors, including age, gender, tumor location, etc. However, P16 methylation was signif icantly associated with Dukes' staging. Dukes' C, D patients were more likely to contain methylated p16 compared with Dukes' A, B patients (Table 1).

Table 1 Clinicopathological correlations with p16 methylation

	n	Methylated	Unmethylated
Male	35	18 (51.4)	17 (48.6)
Female	27	8 (29.6)	19 (70.4)
Age (yrs)			
<50	15	7 (46.7)	8 (53.3)
>50	47	19 (40.4)	28 (59.6)
Tumor location[2]			
Proximal	21	12 (57.1)	9 (42.9)
Distal	41	14 (34.1)	27 (65.9)
Dukes' staging			
A, B	33	4 (12.1)	29 (87.9)
C, D	29	22 (75.9)	7 (24.1)[b]

[b]$P<0.01$, *vs* A, B.

DISCUSSION

DNA methylation involves addition of a methyl group to the carbon 5 position of the cytosine ring. This reaction is catalyzed by DNA methyltransferase in the context of the sequence 5'-CG-3', which is also referred to as a CpG dinucleotide[6,7]. The potential contribution of DNA methylation to oncogenesis is mediated by one or more of mechanisms that include DNA hypomethylation, hyper methylation of tumor suppressor gene and chromosomal instability in cancers[8-13]. The methylation of gene, particularly the methylation of CpG-rich promoters, could block transcriptional activation[6]. P16 tumor suppressor gene plays a monitor role in the passage of cells through the G1 to S phase of the cell cycle by binding to cyclin-dependent kinase 4 and inhibiting its effect on cyclin D1[14-16]. Methylation of cytosine residues at CpG sites in p16 gene promotor, resulting in a silenced p16 expression, has been reported in many cell lines, including CRC, and some primary carcinomas in varied origins, such as colon, brain, breast, bladder, ovary, lung, and myeloma and so on[17-30].

In the previous studies on p16 methylation, most researchers used Southern analysis and digestion of methylation-sensitive enzymes to detect methylation[15,31]. We used MSP, in the present study, for analysis of the methylat ion status of p16. This method provided significant advantages over previous ones used for assaying methylation. MSP is much more sensitive than Southern analysis, facilitating the detection of low numbers of methylated alleles and the study of DNA from small samples. MSP allows examination of all CpG sites, not just those within sequences recognized by methylation sensitive restriction enzymes. In summary, MSP is a simple, sensitive and specific method for determining the methylation status of CpG rich region[32]. This might account for that the occurrence of p16 methylation detected by MSP (20%-50%)[4,5,33] was usually higher than those by Southern analysis and other METHODS (10%-20%)[15,31]. In our study, methylated p16 in primary CRC was found in a frequency as high as 42%, probably revealing a number more precise than those detected not by MSP.

Though p16 methylation is common in CRC cell lines[4,34,35] and has been suggested to involve also in the primary CRC[2,4,5,33,36-38], the association of p16 methylation with the clinicopathological characteristics of primary CRC has rarely been investigated and concluded with conflicts[2,5,37-39]. The role of p16 methylation in the development and progress of the primary CRC therefore awaits to be elucidated. Wiencke *et al* found that women were much more likely than men to have p16-methylated tumors and that proximal tumors were more likely to contain methylated p16. They reported that p16 methylation was also associated with poorly differentiated tumors[2]. Liang *et al* reported that the presence of p16 methylation predicted shorter survivals in colorectal cancer patients[5]. Zhang et al found that p16 methylation in CRC was not associated with clinicopathologic data[37,38]. In our study, no correlation was found between p16 methylation and various clinicopathologic factors including age, gender or tumor location. However, p16 methylation was significantly associated with Dukes' staging. Dukes C, D patients were more likely (75.9%) to contain methylated p16 as compared with Dukes' A, B patients (12.1%). Dukes' staging is a clinical classification for colorectal cancers based on the tumor size, local extent, metastatic status, i.e. lymph node involvement. Hence, Dukes' staging has been considered a most important prognostic determinant. In the present study, p16 methylation was more likely to occur in Dukes' C, D patients. This result suggested that p16 methylation might link to a more malignant outcome of CRC.

How does the existence of methylated p16 promoter affect the expression pattern of p16 protein in primary tumors Controversy has emerged over recent years on the

relationship of p16 promoter methylation and its gene expression in whole tumors. Although most of authors hold the traditional viewpoint that detectable p16 methylation necessarily link to the inactivation of p16 protein, or transcriptional silencing of p16 gene[3,10,19,31,40], coexistence of p16 methylation and p16 expression in one specimen has been frequently described[2,41-44]. It was noticeable that, in our study, band U, i.e. PCR products amplified by primer U, was visible in each specim en. Similar results were also reported by other investigators[2]. This might first be attributed to the contamination of non-neoplastic cells that naturally harbored unmethylated DNA. However, Guan *et al* demonstrated that band U appeared even in the samples acquired by microdissection which got rid of the non-neoplastic cells[4] . This indicated the possibility that tumor cells in one sample were virtually the mixture of those contained methylated and unmethylated DNA. In fact, the cell line in which p16 methylation was detected could still express p16 protein, due to a partial methylation[45]. In summary, coexistence of p16 methylation and p16 expression in one sample might reflect the cell heterogeneity, in which, as we speculated, a part of cells contained methylated p16 and loss of p16 expression whereas another part of cells kept expressing or even overexpressing p16 protein. We found that, in a previous immunohistochemical study on 71 archival specimens of CRC, p16 expression-positive tumor cells were seen in roughly 50% specimens, and these p16 expressive specimens were coincident with those with a poorer differentiation grade[46]. Other investigators have also proposed that activation but not inactivation of p16 gene was associated with primary CRC[47]. We will continue our effects to explore the correspondent relation of p16 methylation and p16 expression in the identical CRC specimen, so as to determine how the seemly paradoxical events might unite in one tumor. The elucidation of the relationship between p16 expression and p16 gene methylation in primary tumors will certainly help better understand the role of methylation of tumor suppressor genes in carcinogenesis.

Abstract

AIM **To construct subtracted cDNA libraries and further identify differentially expressed genes that are related to the development of colorectal carcinoma (CRC).**

METHODS **Suppression subtractive hybridization(SSH) was done on cDNAs of normal mucosa, adenoma and adenocarcinoma tissues from the same patient . Three subtracted cDNA libraries were constructed and then hybridized with forward and backward subtracted probes for differential screening. Positive clones from each subtracted cDNA library were selected for sequencing and BLAST analysis. Finally, virtual Northern Blot confirmed such differential expression.**

RESULTS **By this way, there were about 3-4×102 clones identified in each subtracted cDNA library, in which about 85% positive clones were differentially screened. Sequencing and BLAST homology search revealed some clones containing sequences of known gene fragments and several possibly novel genes showing few or no sequence homologies with any known sequences in the database.**

CONCLUSION **All results confirmed the effectiveness and sensitivity of SSH. The differentially expressed genes during the development of CRC can be used to shed light on the pathogenesis of CRC and be useful genetic markers for early diagnosis and therapy.**

INTRODUCTION

Colorectal carcinoma (CRC) is one of the most common forms of malignancy and the major cause of mortality in the population. The adenoma-carcinoma sequence has been accepted as the main pathway involving a series of molecular changes, which include activation of oncogenes, inactivation of tumor suppressor genes, etc. in colorectal carcinogenesis for several years[1]. However, due to the complexity of carcinogenesis, there are still many problems unsolved for the model of CRC. Not only are all the known genetic alterations not enough to explain fully the progression toward malignancy, but also there is no one genetic marker which is entirely tissue and / or cancer specific. Hence, an attempt was made to find new genes that are related to the development of CRC. Our goal was to clone and identify new cancer-predisposing genes.

In almost any area of biology or medicine, questions arise from the differential gene expression. Transformations in the normal mucosa-adenoma-carcinoma sequence result from the expression changes of specific gene(s) too. The identification and characterization of human genes expressed exclusively or preferentially in tumor tissue will hopefully shed light on the mechanisms of CRC development and provide useful genetic markers for screening, diagnosis, prognosis, therapeutic monitoring and even follow-up development of therapeutic vaccines.

There are many techniques that AIM at producing an inventory of differential transcripts between two populations of mRNAs. Although all these methods have proven successfully isolating differentially expressed genes, they all had some intrinsic drawbacks: need for plenty of initiating materials, difficulty in obtaining rare transcripts, significant incidence of false positives, labor intensive, etc. Suppression subtractive hybridization (SSH), a PCR-based cDNA subtracted method[2], combines normalization and subtraction in a single procedure and generates subtracted cDNA libraries. This method overcomes many drawbacks mentioned above.

In this research, we conducted SSH to identify genes differentially expressed am ong cDNAs of normal mucosa, adenoma and adenocarcinoma tissues from the same patient. Three subtracted cDNA libraries were constructed and numerous sequences were isolated.

MATERIALS AND METHODS

Tissue sample preparation

All normal (N), adenoma (A) and adenocarcinoma (T) tissue samples obtained from the same patient were histologically confirmed by a pathologist. The tissues were frozen in liquid nitrogen and homogenized with mortar. Total RNA was prepared using Trizol reagent (Gibco BRL, USA). RNA integrity was checked on 1% formaldehyde agarose gel. Poly (A)+ RNA was then purified using PolyATract mRNA cDNA system kit (Promega, USA) as per manufacturer's instructions.

SMART cDNA synthesis

0.5 μg mRNAs from each sample were reversely transcribed using MuLV SuperScript II reverse transcriptase (Gibco BRL, USA), SMART II oligonucleotides and CDS primers from SMART cDNA synthesis kit (Clontech, USA). The first strand cDNA mixtures were amplified by LD PCR. Before amplification, the number of PCR cycles was optimized (19 for N, 17 for both A and T) to ensure that cDNA products remain in the exponential phase of amplification to reduce nonspecific amplification.

SSH

After cDNAs were produced, they were purified by passing through Chroma spin-400 columns (Clontech, USA). Each purified tester cDNA was digested with RsaI to give an average insert length approximately longer than that of 600 base pairs. Then they were phenol chloroform-extracted, ethanol-precipitated, and dissolved in 6 μL ddH_2O. The tester cDNAs were subdivided into two equal groups and then ligated to adaptor 1 and 2R in separate ligation reactions. Ligation efficiency was tested. Subtractive hybridi zation was performed by annealing an excess of driver cDNAs with each sample of adaptor-ligated tester cDNAs. The cDNAs were heat-denatured and incubated in 68℃ for 8 h. After the first hybridization, the two samples were mixed together and hybridized again with freshly heat-denatured driver cDNAs for 20 h at 68℃. Two rounds of hybridization would generate a normalized population of tester-specific cDNAs with different adaptors on each end.

After filling in the ends, two rounds of PCR amplification were performed to enrich desired cDNAs containing both adaptors by exponential amplification of these products. The optimized cycles for the first and second PCR were 26 and 12 respectively to increase representation and reduce redundancy of subtracted cDNA libraries.

Secondary PCR products were used as templates for PCR amplification of human G3PDH at 18, 23, 28 and 33 cycles to assure subtraction efficiency. PCR products were run on 1.8% agarose gel.

Both forward and backward SSH were performed. The difference between them was that the tester sample in forward SSH was used as driver sample in backward SSH.

Cloning and differentially screening of subtracted cDNA libraries

Products from the secondary PCR were T-A cloned into pGEM-T Easy Vector using pGEM-T Easy Vector System II kit (Promega, USA). The ligation products were transformed into DH5α competent cells. The transformed cells were plated on 2-YT agar plates containing ampicilin, X-Gal and IPTG allowed for color selection of colonies. Transformation efficiency was calculated and white clones were selected for further characterization.

Randomly selected individual clones were grown for 8 h in 96-well culture plates and then used for clone PCR amplification. The primers used were nested Primer1 and 2R of adaptors. After 27 cycles amplification, the PCR products were subjected to a differential screening process. Briefly, 3 μL of amplified products of each candidate gene was mixed with DNA dilution buffer (50 μg/mL herring sperm DNA, 10 mM Tris. Cl, pH 8.0, 1 mM EDTA), spotted onto duplicate Hybond N+ Membranes (Boeheringer Mannheim, Germany) and UV cross-linked for 1 min. The forward and backward subtracted cDNAs were used as probes. These cDNAs were DIG-labeled by PCR amplification using PCR DIG probe synthesis kit (Boeheringer Mannheim, Germany), digested with *Rsa*I, *Eag*I and *Sma*lI to remove the adaptors and purified with column. After prehybridization, the duplicate membranes were hybridized with forward and backward subtracted cDNA libraries probes respectively at 42℃ for 16 h-20 h in hybridization solution with 50% deionized formamide, 0.1% (w/v)-Lauroylsarcosinee, 2% blocking reagent, 0.02% (w/v) SDS, 2 μg/mL NP1, NP2R and CDS primer sequences. The membranes were then washed for 2×5 min with 2×SSC, 0.1% SDS at room temperature and for 2×15 min in 0.5×SSC, 0.1% SDS at 68℃. Then, they were blocked by gently agitating in blocking solution at 37℃ for 1 h, incubated in buffer I with Anti-DIG (1:4 000) at 37℃ for 30 min, washed in buffer I for 2×15 min and equilibrated in buffer III for 5 min. Finally, the membranes were incubated in mixture of NBT and BCIP for about 15 min. The clones giving at least 5-fold higher hybridization signals with the forward probes were selected for further analysis.

Sequencing and BLAST homology search

Candidate positive clones from each subtracted cDNA library were selected for sequencing. Cycle sequencing reactions were conducted with Thermo Sequenase cycle sequencing core kit (Amersham Life Science, USA). Each clone was sequenced on both 5' and 3' end. The BLASTN program was used to search for the DNA sequence homology of the isolated clones in the database of Genbank.

Virtual Northern blot

High yields of full-length cDNAs were generated from 1ìg total RNA of normal mucosa, adenoma and adenocarcinoma using SMART PCR cDNA Synthesis kit (Clontech, USA). 0.2 μg cDNAs were electrop hosed on a 1.0% agarosegel, transferred onto Hybond N+Membrane (Boeheringer Mannheim, Germany) and hybridized with DIG-labeled clone probes. These probes were generated by PCR amplification of the relevant inserts, adaptor-cutting and column-purification. Hybridization and washing conditions were the same as described above in screening of cDNA libraries. DIG-labeled G3PDH probes were used as control.

RESULTS

Subtracted cDNA library construction by SSH

In this research, SSH was done to identify differentially expressed genes among cDNAs of normal mucosa, adenoma and adenocarcinoma tissues from the same patient. Three subtracted cDNA libraries were constructed. The subtracted A-N cDNA library used normal mucosa as tester cDNA and adenoma tissue as driver cDNA; the subtracted T-N cDNA library used adenocarcinoma tissue as tester cDNA and normal mucosa as driver cDNA; the subtracted T-A cDNA library used adenocarcinoma tissue as tester cDNA and adenoma tissue as driver cDNA. Figure 1 shows subtractedcDNA libraries after secondary PCR amplification. They usually looked like smears with or without several discrete bands. However, the patterns among them were different.

Subtraction efficiency analysis showed the effectively reduced abundance of non -differentially expressed genes. In nonsubtracted cDNA libraries, housekeeping gene G3PDH PCR products were visible after 18 cycles of amplification and became saturated after 23-28 cycles. However, subtracted libraries required a higher number of amplification cycles for G3PDH to be detected. Depletion of G3PDH was more significant in the subtracted A-N and T-A cDNA libraries, suggesting that these two subtractions were more complete.

Differential screening of subtracted cDNA libraries

About 4×10^2,3×10^2 and 3.5×10^2 clones were respectively identified in subtracted A-N, T-N and T-A cDNA libraries with average insert size of 0.2-1 kb. These clones were

screened by hybridization with both forward and backward subtracted cDNA library probes. Clones corresponding to truly differentially expressed genes would mainly hybridize with the forward subtracted cDNA probe, but not, or only faintly, with the backward subtracted cDNA probe, asshown by signal comparison between two blots. By this way, more than 85% positive clones in three subtracted cDNA libraries were differentially screened.

Sequencing and homology search

Automated sequencing proved that most clones were isolated no more than two times. BLASTN homology search revealed that some clones contained substantial sequence homologies with known gene fragments and several possibly novel genes, showed few sequence homologies with any known sequences in the GenBank database. The results of homology search are shown in Table 1.

Virtual Northern Blot

The cDNAs of selected clones were mainly expressed in tester tissue but not, or to a lesser extent, in driver tissue as Figure 4 shows. Virtual Northern Blot showed such differential expression in most clones. These results were also confirmed by RNA Dot blot (data not shown).

Table 1 Characteristion of randomly selected differentially expressed clones from the three subtracted cDNA libraries screening of forwar subtraction. Clone name, insert size, sequence identity and redundancy are shown

Clone	Insert(bp)	Sequenceidentity	Redundancy
Subtracted A-N cDNA library			
a1	850	DNA sequence from clone RP5-991C6 on chromosome 6q14	1
a2	850	Mitochondrion genome	1
a3	850	DNA sequence from clone 75K24 on chromosome 6q13-1	1
a4	550	No match	1
a5	500	No match	1
a6	550	No match	1
a7	500	Guanylin mRNA, complete cds	1
a8	500	DNA sequence from clone GS1-279B7 on chromosome 1q25.1-31.1	1
a9	700	beta 2-syntrophin mRNA	1
a10	450	mRNA fragment coding for HLA-1	1
a11	500	mRNA for KIAA0212 gene	1
a12	650	No match	1
a13	800	PAC clone RP5-1131G17 from 7p15.1-p14	1
a14	600	BRX mRNA	1
Subtracted T-N cDNA library			
b1	480	mRNA fragment coding for HLA DR	2
b2	750	Insulin-like growth factor binding protein 7	1
b3	750	mRNA for KIAA0494 protein	1
b4	760	mRNA for immunoglobulin kappa light chain	1
b5	500	Complement component 3 gene, exons 1-30	1
b6	620	mRNA for anti-HbsAg immunoglobulin	1
b7	600	mRNA for fibronectin	2
b8	770	BAC clone RG158017 from 7q22-q31.1	1
b9	620	Ribosomal S25(RPS25) mRNA	1
b10	650	No match	1
b11	400	Mitochondrion, cytochrome oxidase subunit II	1
b12	450	Eukaryotic translation elongation factor1 gamma	1
b13	400	No match	1
b14	350	Ribosomal SII(RPSII)	1
Subtracted T-A cDNA librar			
r1	700	Ribosomal S12(RPS12) mRNA	2
r2	520	No match	1
r3	550	Clone P13 anti-phospholipid immunoglobulin 1	1
r4	500	mRNA for heat shock protein 90	2
r5	700	Chromosome 14 DNA sequence	1
r6	450	Chromosome 18, clone hRPK	1
r7	350	HLA-DR alpha-chain mRNA	2

Species is human.

DISCUSSION

It was learned in the last two decades that genetic changes lie at the root of all cancers. In response, the Cancer Genome Anatomy Project (CGAP) will unite the newest technologies to identify all the genes responsible for the initiation and growth of cancer. In this research, we used SSH to identify candidate genes that were differentially expressed during CRC development.

The novel technique called SSH is an ideal subtractive system that combines high subtraction efficiency with normalized representation of differentially expressed genes, and is based on suppression PCR that permits exponential amplification of genes differing in abundance, at the same time that amplification of sequences of identical abundance genes in two populations is suppressed. Therefore, differentially expressed genes of low abundance can be cloned, while differentially expressed genes of high abundance are not

excessively isolated[3,4]. It was reported that SSH achieved more than 1000-fold enrichment of low-abundance genes but only required 2 μg mRNA instead of the 10-20 μg required in other methods. This method has been successfully used to isolate significant genes in many rese arches. Here we report the efficiency of SSH technique in identifying differenti ally expressed genes in normal mucosa, adenoma and adenocarcinoma from the same patient. All of the results confirmed the effectiveness and sensitivity of this method.

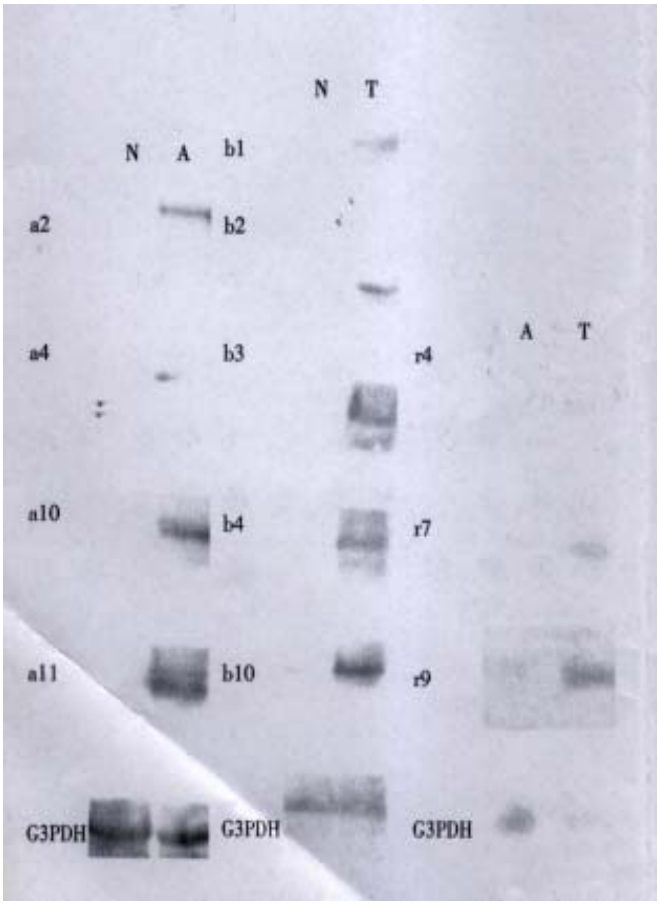

Figure 5 Virtual Northern Blot analysis of several differentially expressed cDNA: N: normal mucosa; A: adenoma; T: adenocarcinoma.

PCR analysis of the subtraction efficiency after subtractive hybridization was showed that the abundance of the non-differentially expressed gene G3PDH was effectively reduced. The difference of subtraction efficiency among the three subtracted libraries might be due to the diversity of starting materials for comparison. As we know, no subtraction technique is 100% effective. Although SSH greatly improved the subtraction efficiency, some false positive clones were still present in the studied material. Therefore, non-radioactive hybridization with forward and backward subtracted cDNA library probes was used to differentially screen these subtracted libraries before Virtual Northern blot confirmation[5]. About more than 85% positive clones in each subtracted cDNA library were differentially screened. von Stein OD *et al*[3] found about 94% positive rate in their research, so they considered confirmation of differential expression by Northern blot analysis for each clone obtained was probably unnecessary. In our research, Virtual Northern Blot and RNA Dot Blot were still performed to con firm such differential expression before further analysis of the clones.

By this way, we constructed three subtracted cDNA libraries, A-N, T-N and T-A , as mentioned above. About 3-4×10^2 clones were identified in each subtracted cDNA library through differential screening. After sequencing and BLASTN homology search, these clones could be divided into three groups: known genes preciously described as differentially expressed genes in cancer and closely related with carcinogenesis of CRC; known genes never before associated with carcinogenesis; and unknown genes that remain to be fully characterized. The identification of the first group of known genes attested to the validity of this method. In addition, no more than only two times isolation of most clones also proved the high efficiency of SSH.

HLA-DR, identified in both subtracted T-N and T-A cDNA libraries, was reported to be abundantly expressed in CRC but less so in adenoma and normal mucosa[6,7]. However, the relationship of HLA-DR expression with prognosis is still disputed[6,8]. Other molecules such as invariant chain may take part in this mechanism. So it is very important to conduct comprehensive research on the role of these molecules.

Heat shock protein (Hsps) is thought to play an important role in the cell cycle s and various processes of carcinogenesis. It can be divided into two types: Hsp90α and Hsp90β[9]. The former may play a role in cell proliferation; the later is inversely related to differentiation. Both of them are present in normal tissue but are more highly expressed in neoplasm. More important, Hsp90 was recently reported to interact with HLA-DR. In this study, Hsp90 was screened in the subtracted T-A cDNA library two times, which showed its high expression in carcinoma.

IGFBP-rp1 belongs to the IGFBP family with low affinity with IGFs. It had been shown to decrease expression with disease progression in breast carcinomas[10] and in the worsening from the benign to malignant prostate epithelial cells[11,12]. Methylation with down-regulated expression was found to be associated with liver tumorigenesis[13]. So it is inferred that IGFBP-rp1 may have a suppressive effect on cancer development. Surprisingly, in this study, IGFBP-rp1 was overexpressed in CRC in contrast to their down-regulation in carcinoma, which was also shown in prostate cancer tissue[14]. It remains to be further investigated what the role of IGFBP-rp1 is and whether such different expression is individual- specific, tissue- specific or even cell-specific.

Two cDNA clones were shown to have more than 90% homology with Ig κ gene, one screened in the subtracted T-N

cDNA library and the other in T-A. Hu *et al*[15] reported a new transforming gene Tx showed very high (99.5%) homology with the C region of Ig κ. A literature survey revealed Ig or Ig-like materials expression in carcinoma[16]. It is generally considered that Ig is mainly secreted by B-lympho cytes, so the relationship between Ig κ and carcinogenesis of CRC should be further confirmed.

Guanylin (GN) is the endogenous peptide ligand for guanylyl cyclase C (GCC) and can regulate intestinal Cl- secretion. It is robustly expressed in normal intestinal epithelium of colon but is absent in CRC[17]. So, it is possible that loss of GN activity leads to or is a result of adenocarcinoma formation. In this study, GN was expressed at higher levels in adenoma than in normal mucos a but not in CRC. It is uncertain if such increase of GN activity in adenoma means a kind of reaction to carcinogen stimulation.

Several genes shown to be dysregulated in neoplasm cells such as EF1-r[18], mitochondrion, RPS12, RPS 22/25, RPSII[19] were also identified. All of them were increased in cancer cells, as previously reported and some of them were related to the robust growth characteristics.

Besides the known genes, a very important finding in this study was the identification of several new genes that were previously undescribed in Genbank. Both Virtual Northern blot and RNA dot blot hybridization has showed such different expression. Among three subtracted cDNA libraries, A-N showed the highest rate of novel genes isolation. Although it remains to be explored the full-length sequence of these new genes by RACE or other methods and their function in carcinogenesis of CRC, these results really provide clues for us to understand newly proposed mechanisms of cancer formation.

In the past years, much of cancer research laid particular stress on analysis of single gene expressed differentially in tumor cells as compared with their normal counterparts, but little stress on comprehensive study of gene expression in cancer. It was interesting that in this study several genes including anti-HbsAg and IGFBP-rp1 were also differentially expressed in carcinoma. Based on available reports, anti-HbsAg gene was mainly related with the individual character, while IGFBP-rp1 was even supposed to be an anti-oncogene. So we propose that such diversity and specificity of gene expression may contribute to the heterogeneity in biological properties of cancer, which may be individual-specific, tumor-specific, process-specific or even cell-specific. Literature also indicated that there were differences of gene expression among cancers. Therefore, two novel concepts can be brought forward on carcinigenesis: one is the model formed by a total of individual gene expression in cancer, the other is the module formed by interaction among molecules[20]. Cellular functions, such as signal transduction, are carried out by modules. Connecting different levels of analysis from molecules, through modules, to models is essential for an understanding of carcinogenesis. Differentially expressed genes between tissues comprise the molecular basis for understanding model and module. So, despite the limitations of tissue from the same patient, this approach has provided interesting results for further research.

This is the first time that differentially expressed genes in colorectal adenoma and adenocarcinoma were isolated by the new technique SSH. Now, microarray detection of these differentially expressed genes as model and module to hybridize with other tumor samples is being investigated[21]. Comprehensive study of these genes will be helpful for us to create theoretical models of some systems and verify that such predictions match reality, which, in turn, will be useful for screening, detecting, classifying and therapy of CRC.

Abstract

AIM **To summarize the experience of diagnosis and treatment of congenital choledochal cyst in the past 20 years (1980-2000).**

METHODS **The clinical data of 108 patients admitted from 1980 to 2000 were analyzed retrospectively.**

RESULTS **Abdominal pain, jaundice and abdominal mass were presented in most child cases. Clinical symptoms in adult cases were non-specific, resulting in delayed diagnosis frequently. Fifty-seven patients (52.7%) had coexistent pancreatiobiliary disease. Carcinoma of the biliary duct occurred in 18 patients (16.6%). Ultrasonic examination was undertaken in 94 cases, ERCP performed in 46 cases and CT in 71 cases. All of the cases were correctly diagnosed before operation. Abnormal pancreatobiliary duct junction was found in 39 patients. Before 1985 the diagnosis and classification of congenital choledochal cyst were established by ultrasonography preoperatively and confirmed during operation, the main procedures were internal drainage by cyst enterostomy. After 1985, the diagnosis was established by ERCP and CT, and cystectomy with Roux-en-Y hepaticojejunostomy was the conventional procedures. In 1994, we reported a new and simplified operative procedure in order to reduce the risk of choledochal cyst malignancy. Postoperative complication was mainly retrograde infection of biliary tract, which could be controlled by the administration of antibiotics, there was no perioperative mortality.**

CONCLUSION **The concept in diagnosis and treatment of congenital choledochal cyst has obviously been changed greatly. CT and ERCP were of great help in the classification of the disease. Currently, cystectomy with Roux-en-Y hepaticojejunostomy is strongly recommended as the choice for patients with type I and type IV cysts. Piggyback orthotopic liver transplantation is indicated in type V cysts (Caroli's disease) with frequently recurrent cholangitis.**

Subject headings choledochal cyst/surgery; choledochal cyst/radiography; choledochal cyst/diagnosis; biliary tract/abnormalities; choledochal cyst/therapy; Caroli's disease/diagnosis; Caroli's/surgery

INTRODUCTION

Choledochal cyst, or congenital cystic dilatation of the common bile duct, is a rare entity in western countries. Most of reported cases in the world come from Asia, about two-thirds of cases reported from Japan[1]. In recent years, cases of choledochal cyst are reported increasingly in China[2-5].We analyzed retrospectively the clinical data of 108 patients admitted from 1980 to 2000 in our two hospitals in order to summarize the Chinese experience of diagnosis and treatment of this congenital choledochal cyst.

MATERIAL AND METHODS

Patients

From October 1980 to February 2001, a total of 108 patients with choledochal cyst were treated In the Department of Surgery, the Second Affiliated Hospital of Zhejiang University School of Medicine and Zhongda Hospital of Southeast University. There were a total of 85 females and 23 males. The mean age was 27.8 years, with a range from 3 to 68 years. Among them, 91 cases were adults. According to Todani and colleagues' classification of congenital choledochal cyst[1]. Seventy-five patients belonged to type I (solitary extrahepatic cyst), 19 type IV A (extrahepatic and intrahepatic cysts), 5 type IV_B (multiple extrahepatic cysts), 1 type III (choledochocele) and 6 type V (only intrahepatic segmental ductal dilatation, also known as Caroli's disease); two cases were unclassifiable. In 23 patients their condition was associated with biliary tract stones. Abdominal pain, jaundice and abdominal mass were presented in most child cases, and clinical symptoms in adult cases were non-specific, resulting in delayed diagnosis frequently. Fifty-seven patients (52.7%) had coexistent pancreatiobiliary disease, 7 patients had synchronous and 11 had metachronous carcinoma lesions arising from the biliary duct cyst. Three patients appeared in pregnant period. Among complications at the time of admission for care there were jaundice in 77 patients, cholangitis in 61 patients. Ultrasonic examination was undertaken in 94 cases, ERCP performed in 46 cases and CT in 71 cases.

Surgical procedures

From 1980 to 1985, Roux-en-Y cystojejunostomy was performed in 19 patients, side to side cystoduodenostomy in 15 patients and exploratory laparotomy in 4 patients. From 1986 to 1994, 24 cases underwent cystectomy plus cholecystectomy with Roux-en-Y hepatoenterostomy, 6 underwent partial cystectomy plus cholecystectomy with Roux-en-Y hepatoenterostomy, 4 underwent cystectomy or cyst transection plus duodenocholedochotomy by jejunal

interposition, and 3 underwent left hepatectomy. After 1995, we also performed cyst excision plus cholecystectomy with Roux-en-Y hepatoenterostomy in 19 cases. Meanwhile, we reported a new and simplified operative procedure (cyst wall resection plus Roux-en-Y hepatoduodenostomy and doudenojejunuostomy) in order to reduce the risk of choledochal cyst malignancy. This procedure was performed in 9 patients. Two cases underwent piggyback orthotopic liver transplantation.

RESULTS

There was no operative death in this series. Twenty-eight patients developed early postoperative complications including cholangitis, bile leakage and wound infection. All of them recovered with conservative therapy. Late complications occurred in twenty-three patients, who suffered from ascending cholangitis, hepatolithiasis, pancreatitis and adhesive intestinal obstruction six months to five years after operation. Twenty-two cases underwent reoperation. Among them, 11 cases owing to bile duct malignant change resulting from previous internal drainage procedures (including cystoduodenostomy and cystojejunostomy); 6 cases owing to suppurative cholangitis or pancreatitis; 3 cases owing to postoperative biliary stricture accompanied stones; and 2 cases owing to calculus of bile duct. The reoperative procedures included resection of tumoror plastic repair of stricture. Sixty-two patients were under follow-up for an average period of ten years (6 months to 18 years).

DISCUSSION

Diagnosis

Choledochal cysts are recognized as a disease of childhood[1,6,7], but in our study, 91 (84.2%) of 108 patients were older than 14 years at the time of operation. Thereafter, the surgeon should be aware of choledochal cysts even in the adult patients. Abdominal pain, jaundice and abdominal mass were presente d in most child cases. In this series, 12 patients(70.5%) had these symptoms . Clinical symptoms in adult cases were non-specific, 57 patients (52.7%) had coexistent pancreatiobiliary disease. In addition, the increased likelihood of associated hepatobiliary disease, as well as previous surgery makes management in adults more complex[8]. Although the classical clinical triad of abdominal pain, jaundice and right hypochondriac mass has been reported in children, most patients (71 cases) described here had symptoms that were chronic and intermittent, often resulting in delayed diagnosis[9]. Furthermore, secondary hepatobiliary disease in adults may obscure the primary problem and compound the complexities of subsequent surgery[10-13]. Twenty-three patients with intra- or extra hepatic stones were found in this series, it deserved attention. In 1959, Alonso-Lej[1] and in 1977, Todani[1] classified choledochal cysts based on the location of the cyst. From that time, they were diagnosed more frequently with the aid of improved diagnostic technique, for example, Ultrasound, CT and direct cholangiography such as PTC and ERCP. US is the first imaging modality of choice in the evaluation of patients suspected to have extrahepatic bile duct dilatation[14]. With a new ultrasound technology, the normal common bile duct is easily identifi able, and recognition of localized or generalized dilatation is facilitated. In our case, the specific ultrasound diagnosis of a choledochal cyst was made by identifying two bile ducts entering into a large cystic mass which was separate from the gallbladder and extended deeply into the portahepatis. Biliary ductal obstruction or other cystic lesion, such as pancreatic pseudo-cyst, was excluded by detection of a normal-sized gallbladder and nondistended intrahepatic bile ducts[14]. We demonstrated the entrance of extrahepatic bile ducts into the choledochal cyst in 91 of 108 patients by US. After 1985, we considered that PTC and ERCP were the most useful and direct METHODS in establishing the diagnosis of choledochal cyst, but the former may result in some trauma and complication[15]. At present, we advocate performing ERCP at the time of US and CT examination in order to classify the type of cyst and to recognize the presence of an anomalous pancreaticobiliary duct junction (APBDJ)[16]. In our series, of 46 patiens examined with ERCP, 39 patients (93.4%) had APBDJ. Komi[1] also reported a 92.2% association between choledochal cysts and APBDJ in 645 cases, which is similar to our results. There were many theories about the etiology of the choledochal cysts[1]. Babbit suggested that in these patients there is an abnormal pancreaticobiliary duct junction that allows reflux of pancreatic secretions into the biliary system during a critical stage of its development. Consequent chemical and enzymatic destruction of the duct wall leads to cystic dilation[17,18]. Iwai[19] and other authors[16,18] found that the choledochal dilation has a close association with abnormal choledochopancreaticoductal junction, whether direct or indirect. CT can clearly visualize cyst location, number, scope, stone and relationships with surrounding structures. After 1994, 71 cases were routinely performed with CT examination, all of them were diagnose d definitely. In recent 5 years, CT cholangiography and MR cholangiography have been used in most advanced countries[20]. Our center also want to practice this new METHODS in the future.

Operative procedure

Choledochal cyst is a congenital abnormality that requires surgical intervention to prevent hepatobiliary and pancreatic complication[21-23]. A lot of reports have demonstrated that cystenterostomy, an internal drainage procedure without resection, carries a high morbidity rate and often requires subsequent reparative operation[24]. Todani[25] analyzed carcinoma arising from retained cysts with internal drainage procedures, and suggested that enteric drainage tend to creat a cul-de-sac in the choledochal cyst and to activate pancreatic juice when intestinal juice with enterokinase refluxes into the cyst through an anastomotic stoma. As a result, inflammation of the bile duct wall is accelerated, possibly resulting in carcinoma because of the long-standing irritation of the biliary epithelium. Kobayashi[26] points out that the incidence of bile duct carcinoma is still high, even after excision of extrahepatic bile ducts in APBDJ patients with choledochal dilatation. For these patients, careful long-term follow-up is necessary, especially after operations. In the present series, 11 of 108 patients who had previous cyst enterostomy developed carcinoma. However, all cases who developed carcinoma in our study were over 30 years of age, which supports the previous report that the risk of carcinoma increases with age[25,27-29]. After 1985, cyst internal drainage was abandoned and total excision of the cyst and Roux-en-Y hepatojejunostomy had been recommended as the first choice by us. In 1994, we reported a new and simplified operative procedure to separate the biliary and pancreatic flow so as to reduce the risk of malignancy of choledocha l cyst, which was clinically applied in 9 cases, and proved effective[30].

Total excision of type I and type IV choledochal cyst and Roux-en-Y hepatoj ejunostomy has been recommended by many investigators because of the lower incidence of postoperative complications, especially in Japan, and has been

increasingly popularized worldwide[24,31,32], we agree with their opinions. Treatment for type V cysts is still controversial. At present, hepatic resection is safe and effective for some of type V cysts (Caroli's disease)[33]. In our series, three left lobectomy and four nonanatomical hepatic resections were performed and symptomatic relief was obtained completely and permanently. About type V cysts with frequently recurrent cholangitis, resulting in biliary liver cirrhosis, liver resection is seldom feasible because of associated congenital hepatic fibrosis.

In this setting, liver transplantation may represent the only effective and durable form of treatment and offers the only hope for such patients. In this study, nearly two years ago we performed piggyback orthotopic liver transplantation for two cases of Caroli's disease and both patients recovered smoothly with satisfactory results after operation and are healthily surviving[34]. In conclusion, the surgical strategy should be selected based on the type of cyst. For those who had internal drainage operation before, careful long-term follow-up is required. We recommended total excision of type I and type IV choledochal cyst and Roux-en-Y hepaticojejunostomy. It is an important topic to actively explore new procedure in preventing malignancy of congenital cyst of common bile duct, and it deserves paying attention to. About type V cysts with frequently recurrent cholangitis resulting biliary liver cirrhosis, liver transplantation should be considered.

Abstract

AIM **To observe the effects of Qiwei Baizhu Powder (QWBZP) on rotaviral gastroenteritis in children and in animal models.**

METHODS **Enrolled patients were divided into two groups, and one group was treated with oral rehydration solution (ORS) and the other treat ed with oral liquid of QWBZP. Neonate mice were orally infected with 50 μL rotavirus suspension (4×10^8 PFU/mL) and treated with ORS or oral liquid of QWBZP, respectively.**

RESULTS **Eighty-three cases of rotaviral gastroenteritis treated with QWBZP revealed a better efficacy than that treated with ORS ($\chi^2 = 10.87$, $P<0.05$). The contents of sodium and glucose as well as number of patients with positive human rotavirus antigen in stool in QWBZP group were all less than that in ORS group. In a nimal models, QWBZP was found effective in treating rotavirus gastroenteritis in neonate NIH mice, as compared with control groups. In QWBZP group, the mortality of infected mice was decreased by 73.3%, the body weight of infected mice was increased, the contents of sodium and glucose as well as number of mice with positive rotavirus antigen in feces were significantly reduced, and the pathological changes such as damage of small intestinal mucosa and villi were also obviously alleviated.**

CONCLUSION **QWBZP has effects on improving the absorptive function of small intestine, shortening the duration of diarrhea and rotavirus shedding from stool and alleviating the pathological changes of small intestine induced by rotavirus.**

INTRODUCTION

Rotavirus is the most common cause of acute gastroenteritis in infants and young children all over the world[1-4]. Although rotaviral diarrhea is a self -limited disease, it caused 870 000 deaths per year in developing countries[5], even a small part of patients were involved in encephalopathy[6,7]. The primary treatment of this illness is oral or intravenous rehydration to modulate dehydration and electrolyte disturbances due to vomiting and wat ery diarrhea[8,9]. Based on the oral rehydration solution (ORS) recommen ded by World Health Organization (WHO)[10,11], reduced osmolarity ORS[8], addition of Lactobacillus GG to ORS[12,13], and rice-based solution[14] have been used to treat this disease. Also, oral immunoglobulins was used as antiviral therapy[15,16], and rotavirus candidate vaccines are developing[17], in which a oral tetravalant, rhesus rotavirus-based, human reassortant vaccine has been licensed in USA[18].

To seek more effective and cheaper drugs to treat rotaviral diarrhea from Chinese medicinal herbs, we found that a Chinese traditional medical prescription named Qiwei Baizhu Powder (QWBZP) had been employed to treat acute diarrhea in infants and children for nearly one thousand years in Traditional Chinese Medicine (TCM). QWBZP was written by a famous ancient Chinese pediatrician who named ZhongYang Qian and lived from 1035 to 1117. After Mr. Qian, many other ancient Chinese pediatricians demonstrated that QWBZP had good effects in shorting diarrhea and improving the symptom of thirst in their pediatric works. According to their description and our clinical experiences, we prepared oral liquid from QWBZP[19], and tested the effects of the oral liquid in treating rotaviral infection in clinical and experimental studies. This traditional Chinese prescription was shown to be effective in inhibiting replication of human rotavirus at monolayer of MA104 cells[20]. In the present study, we investigate the effects of QWBZP in treating rotaviral gastroenteritis in both clinic and animal models.

PATIENTS AND METHODS

Study population

All patients aged from 3 to 24 months (mean age 13.5±3.2 months) were observed at pediatric wards or out-patients service in both the hospital affiliated to Hunan Province Academy of Traditional Chinese Medicine and the Second Hospital of Shuangfeng County at Hunan Province in China from October 1993 to March 1996. Patients enrolled into the study were diagnosed based on clinical symptoms and laboratory tests in accordance with the diagnostic standard worked out by the Chinese Ministry of Health[21]. That was: the age of patients was less than 24 months, history of acute watery diarrhea less than 72 hours with or without upper respiratory symptoms, negative pathogenic bacteria in stool culture, positive of rotaviral antigen in stool samples. Any patient with negative rotaviral antigen or positive pathogenic

germs was excluded.

Preparation of oral liquid from QWBZP and oral rehydration solution

The oral liquid prepared from QWBZP was described as previously[19]. The prescription of Qiwei Baizhu Powder was composed of seven kinds plants or herbs as listed below: Panax ginseng C. A. May, 7.5 gm; Poriacocos (Schw.) Wolf, 15 gm; Atractylodes macrocephala Koidz, 15 gm; Glycyrrhiza uralensis Fisch, 3 gm; Pogostemon cablin (Blanco) Benth, 15 gm; Pueraria lobata (Willd.) Ohwi, 30 gm; and Viadimiria souliei (Franch.) Ling, 6 gm.Briefly, the seven medicinal materials were washed and dried. Among them, Glycyrrhiza was fried with a little honey. These medicinal materials were carefully weighed and grounded into powder. The seven kinds of powder were mixed together and decocted with eight-fold of water (w/w) until half the water was evaporated off. The volatile oil evaporated from these herbs was collected at the same time. The decoction was extracted and filtered through 50 μM hole of sieves, then clarified at 4℃ overnight. The supernatant was collected and mixed with the volatile oil, bottled in 200 mL per glass flask, sealed and sterilized. The bottled decoction were stored at 4℃ and used as oral liquid of QWBZP. Detected by high performance liquid chromatography (HPLC) or automatic analyzer (7170A type, Hitachi, Japan), the oral liquid contained 12.6mg/L gensenoside Rg^1, 95.3 mmol/L K^+, 50.6 mmol/L Cl^-, 37.4 mmol/L Na^+, 2.01 mmol/L Ca^{2+}, with pH 6.1. The oral rehydration solution was prepared according to the formulae recommended by WHO, and contained in mMol per liter, Na^+90, K^+20, HCO^3-30, Cl^-80 , glucose 110 with pH 7.5[2,10,11].

Treatment protocol

The enrolled patients were divided into two groups at random, one was ORS group, and the other was QWBZP group. There were 83 patients in QWBZP group, aged 3-24 months (mean age 13.6±3.5 months), with histories of watery diarrhea for 21 to 72 hours (mean history of diarrhea 53.5±12.4 hours), 50 boys and 33 girls, 65 moderate cases, and severe 18. And 72 cases in ORS group, aged 3-24 months (mean age 14.1±4.1 months), with histories of diarrhea for 19-72 hours (mean history 56.2±13.7 hours), 41 boys, 31 girls, 56 moderate cases, and 16 severe cases. Patients in QWBZP group were fed with the oral liquid of QWBZP, and ORS group were fed with oral rehydration solution for three days. Children aged less than 12 months were fed 5 mL of ORS or QWBZP each time, children aged 12-24 months were fed 10mL ORS or QWBZP each time. The total dose per day was 10-15 $mL \cdot kg^{-1} \cdot d^{-1}$. During the treatment, the children continued to have their mother's breast-milk or milk or their usual food, other treatment including antibiotics, and antimobility drugs were not used[2,21]. Their stool frequency was recorded. The children were observed until the cessation of diarrhea. If their symptoms such as diarrhea, vomiting, and dehydration became more severe after 24 hours of treatment in both groups, these patients would receive intravenous rehydration and other treatments, who were considered as inefficient cases statistically.

Laboratory tests

Before and during the observation, blood and stool samples of patients were collected for detection of glucose, electrolytes, hematocrit, antigen of rotavirus, and pathogenic bacteria including Salmonella, Shigella, Vibrio cholerae, and enteropathogenic Escherichia coli. Stool was placed in Eagle's medium complemented with 5% bovine serum, 5 U/mL penicillin and 5 μg/mL streptomycin, and frozen until examined for rotavirus antigen by enzyme-linked immunosorbbent assay (ELISA). The monoclonal antibody against human rotavirus was supplied by Dr. Zhu SH, Laboratory of Immunology at Medical College of Zhejiang University, Hangzhou)[22-24] or under direct electron microscopy[25]. Concentration of glucose in stool, and contents of electrolytes in serum and stool were measured by automatic analyzer. hematocrit was tested by microtube method.

Evaluation of curative effect

The curative effect was classified into three categories: ① cured: all of symptoms disappeared, normal appetite and stool, negative rotaviral antigen in stool, normal value of laboratory tests; ② efficient: stool output and frequency were obviously decreased, appetite improved, index of laboratory tests improved; and ③ inefficient: stool output and frequency as that before treatment, dehydration was not improved or even worse, rotavirus antigen was positive or negative.

METHODS IN ANIMAL MODELS

Cells and virus

MA_{104} cells, a cell line derived from fetal rhesus monkey kidney, were obtained from Prof. Hong T, Institute of Virology, Chinese Academy of Preventive Medicine. The cells were cultured in Dulbecco's Modified Eagle's Medium (DMEM , Gibco Inc., USA) complemented with 10% fetal bovine serum, 5U/mL penicillin, 5ìg/mL streptomycin, and 10mmol/L HEPES. Human rotavirus (HRV) Wa strain was kindly granted by Dr. Qian Y, Laboratory of Virology at Capital Pediatric Institute of China through the authority of Dr. Kapikian AZ, National Institute of Allergy and Infectious Diseases, NIH of USA. The virus was replicated at the monolayer of MA_{104} cells[26-29]. When the viral titer was raised to 10^8 PFU/mL after several passages, the viral suspension was stored at -80℃ and employed to inoculate animals.

Animal infection

Pregnant dam mice (NIH strain, supplied by Experimental Animal Department at Hunan Institute of Medicinal Industry) were fed in sterile cages. The new born pups were maintained in germfree isolators at 20℃ room temperature and fed with sterilized milk in germfree conditions. The neonate mice were divided into 4 group at 2 days of age. The four groups were normal group, infected group, ORS group, and QWBZP group. Pups in the later three groups were orally inoculated with 50 μL of cold viral suspension of 4×10^8 PFU/mL human rotavirus according to the METHODS as described for mice[30-34]. Neonate mice in normal group were not inoculated. Pups in each group were maintained in isolated room after division.

Treatment

After 24 hours of inoculation, the pups in ORS group and in QWBZP group were fed with 0.1 mL of ORS or 0.1 mL oral liquid of QWBZP each time, respectively, 4 times per day for

three days. The total dose was 0.5 mL, or about 150 mL·kg^{-1}·d^{-1}. Pups in normal group and infected group were fed with sterilized distilled water at the same dose as other two groups. Aside the oraltherapy, all pups in the four groups were fed with 0.1 mL sterilized milk, three times per day.

Observation and laboratory tests

After inoculation, the intake of food, body weight, activity, and number of death of the pups in all four groups were carefully recorded daily until 10 days after inoculation. For the observation of the intake of food, when fed with 0.1 mL milk, there was a white round lump in the stomach of pup to be seen through the transparent skin. If the digestive function and absorptive function of neonate mouse were normal, the white lump in the stomach of pup gradually became smaller and smaller after feeding. If the digestive and absorptive functions were decreased, the white lump in stomach did not become smaller, in contrast, the a bdomen of the pup became distended. In this condition, the next feed of milk was not needed. For assessment of diarrhea, when the abdomen of pup was gently pressed[35,36], the watery stool or loose yellow stool was shedding fro m the anus of the pup. The blood samples and stool specimen were collected before the treatment and at day 4 and 7 after infection for the analysis of serous electrolytes, glucose, and hematocrit, and rotaviral antigen, electrolyte, and glucose in stool. The METHODS of analysis was described in clinical study.

METHODS of statistics

All quantitative data in the study were presented as $\bar{x}\pm s$, and compared by Student's *t* test between two group or by analysis of variance (ANOV) among three groups or more than three groups. The dichotomous data were compared with Chi-square test.

RESULTS

Effects of antidiarrhea

After treatment for 3 days, 71 cases in QWBZP group and 45 cases in ORS group had formed stool, and their symptoms of vomiting, diarrhea, dehydration, and fever disappeared. As seen in Table 1, the cured cases in QWBZP group we re more than that in ORS group ($\chi^2 = 10.87$, $P<0.01$) , while the inefficient cases in QWBZP group were less than that in ORS group ($\chi^2 = 5.85$, $P<0.05$). From these cured cases, the duration from beginning of treatment to stop of diarrhea was 25.9±13.5 hours in QWBZP group, and 41.8±19.3 hours in ORS group. The duration of cessation of diarrhea in QWBZP group was shortened as compared with ORS group (t = 5.86, $P<0.01$). The results showed that the curative effect of QWBZP in treating rotaviral diarrhea was better than that of ORS.

Table 1 The curative effect of QWBZP and ORS

Group	Total cases	Cured cases	Efficient cases	Inefficient cases
ORS	72	45	15	12
QWBZP	83	71	8	4

Changes of electrolytes in serum and sodium and glucose in stool

Hematocrit and serum electrolytes of patients were all improved in the two groups after treatment, but as seen in Table 2, more improvedment were shown in QWBZP group. Contents of sodium and in stool samples of patients were not changed in ORS group, but remarkably reduced in QWBZP group as seen in Table 3. The results showed that QWBZP had the effects in reducing the contents of sodium and glucose in stool and promoting the absorptive function of small intestine to intake sodium and glucose from intestinal cavity.

Table 2 Changes of electrolytes in serum and hematocrit after treatment ($\bar{x}\pm s$)

Treatment	Cases	Time point	Na^+ (mmol/L)	K^+ (mmol/L)	Cl^- (mmol/L)	Hematocrit (%)
ORS	72	Before treatment	146.4±9.4	3.9±0.2	98.5±5.0	50.6±4.6
		After treatment	140.6±7.3[a]	4.1±0.3	102.4±6.7	45.7±3.8[a]
QWBZP	83	Before treatment	145.7±8.6	3.8±0.2	101.0±5.4	51.2±4.4
		After treatment	141.2±8.1[a]	3.9±0.3	103.5±4.8	46.1±5.8[a]

[a]$P<0.05$ *vs* the same group before treatment.

Table 3 Changes of sodium and glucose in stool after treatment (mmol/L, $\bar{x}\pm s$)

Treatment	Cases	Time point	Sodium	Potassium	Chloride	glucose
ORS	72	Before treatment	25.3±4.1	18.5±3.4	11.7±2.6	0.9±0.2
		After treatment	26.8±4.7	11.7±4.1	13.0±3.1	1.0±0.4
QWBZP	83	Before treatment	26.2±4.3	17.3±3.5	12.4±2.5	0.9±0.3
		After treatment	11.5±3.6[a,b]	10.4±2.8[a,b]	6.8±2.7[a,b]	0.2±0.1[a,b]

[a]$P<0.05$ *vs* the same group before treatment; [b]$P<0.05$ *vs* ORS group.

The clearance of rotaviral antigen in stool

There were positive rotaviral antigen or rotaviral particals in stool samples of all patients in two groups. After 3 days of treatment, 13 cases became positive for rotavirus in QWBZP group, 45 cases in ORS group. Significant difference was seen between the two groups ($\chi^2 = 30.47$, $P<0.01$). The result indicted that treatment with QWBZP can shorten the duration of rotavirus excretion from stool.

The taste of the oral liquid QWBZP

Compared with ORS, the oral liquid of QWBZP tastes slightly sweat and free from bitterness. So the oral liquid was easy to be drunk for infants and young children. In contrast, ORS was so bitter, which often induced vomiting maleings the patients refus to drink. Furthermore, the appetite, the intake of food, the activities, and nutrition of patients in QWBAZ group were considerably improved. No side-effect was presented during

the treatment with QWBZP.

The endpoint of diarrhea and mortality of mice

The neonate mice were ill with decreased digestive function (the white lump in stomach was not decreased after 4-8 hours of feeding with milk), abdominal distension, and watery diarrhea at 48 hours of rotaviral inoculation. Dehydration occurred after 3 days of rotavirus infection with the presence of dry, loose, and wrinkly skin, in activities. Symptoms of prostration, cyanosis, and weight loss appeared at day 4 after inoculation. All of the pups in infected group (15/15), 10 mice in ORS group (10/15), 4 mice in QWBZP group (4/15) died during the observation. But still 1 mouse died in the normal group. The surv ivals in QWBZP group were more than that in the infected group ($\chi^2 = 17.37$, $P<0.01$) and in ORS group ($\chi^2 = 4.82$, $P<0.05$). The diarrhea in survived mice stopped at day 6-12 after inoculation. The diarrhea in QWBZS group stopped at day 5-10 (7.4±1.3 days), and in ORS group at day 8-12 (9.9±1.8 days) after infection. There was significant difference between the two groups (t = 2.79, $P<0.05$).

Changes of body weight

The body weight of mice in all four groups are shown in Table 4. The body weight of mice in infected group was not increased, but that in QWBZP group was increased after three days of treatment. The result indicated that treatment with QWBZP could rectify dehydration and improve nutrition of mice infected with rotavirus.

Table 4 Changes of body weight of mice after inoculation (g, $\bar{x}$±s)

QWBZP	6	2.1±0.3	2.7±0.4[a]	4.8±0.5[b]

[a]$P<0.05$, [b]$P<0.01$ *vs* infected group.

Changes of laboratory value

As shown in Tables 5-9, contents of sodium and glucose in stool samples from the mice in QWBZP group were both decreased in comparison of infected group and ORS group at day 4 and 7 after inoculation. Hematocrit of mice in QWBZP and ORS groups were also improved. Content of sodium and glucose in blood were not changed in all four groups after treatment. These results suggested that QWBZP had effects in promoting the absorption of sodium and glucose after rotavirus infection.

Reduction of rotavirus shedding from stool

There were 2 mice with positive rotaviral antigen in stool in QWBZP group (2/1 5), 9 mice with positive rotaviral antigen in infected group (9/15), and 10 mice with positive rotaviral antigen in ORS group (10/15) at day 4 after inoculation. No mouse with positive rotaviral antigen was seen in the normal group. The mice with rotaviral antigen positive in QWBZP group were less than that in infected group ($\chi^2 = 8.1$, $P<0.01$) and in ORS group ($\chi^2 = 13.3$, $P<0.01$).

Histological changes of intestine

Main morphological changes seen at day 4 after rotavirus infection were villous shorting and exfoliation, irregular construction of small intestinal mucosa with infiltration of lymphocytes, thinned intestinal wall. At day 7 after inoculation, the villi of small intestine became rarer and the intestinal wall became thinner. The pathological changes in ORS group were the same as that in infected group at day 4 after inoculation, and at day 7, the pathological changes were obviously moderated in comparison with that in infected group, but more severe than that in QWBZP group. Compared with control groups, the villi and mucosa construction of small intestine were alleviated at day 4 after in oculation, and were nearly normal at day 7 after rotaviral infection. These results suggested that QWBZP had the effect in protecting intestinal

mucosa against the damage induced by rotavirus infection.

DISCUSSION

The results of this study clearly indicated that treatment with the oral liquid of QWBZP significantly shortened the duration of diarrhea and rotavirus shedding from stool, reduced the contents of sodium and glucose in stool samples as compared with ORS treatment in clinic. In animal models, treatment with QWBZP remark ably reduced rotavirus antigen in feces, decreased the mortality of infected mice, reduced the contents of sodium and glucose in stool, and alleviated the damage of small intestinal mucosa and villi. These results suggested that QWBZP had the effects in improving in absorptive function, protecting intestinal mucosa against in jury induced by rotavirus infection, and enhancing the clearance of rotavirus from stool. Another noteworthy finding in this study during clinical observation w as that the less bitter taste of the liquid of QWBZP was easily accepted by children as compared with ORS.

According to the epidemiology, only 0% to 20 % of summer diarrhea cases were rot avirus associated, while 70% to 80% of winter diarrhea cases were due to rotavirus[11,37], and 55.9% of all hospitalized diarrheal children were associated with rotavirus and significantly clustered during winter months in China[38]. Resides vomiting, watery diarrhea, and dehydration, most patients with rotaviral diarrhea had upper respiratory symptoms such as fever, cough, and sneeze[39]. These clinical manifestations of rotavirus diarrhea were similar to one type of acute diarrhea named “cold diarrhea” in TCM. The “cold diarrhea” is thought to be caused by cold weather, cold wind, or cold food, which mostly occurred in winter or cold climates. The “cold diarrhea” was first described by Mr. Qian ZY. Qian said in his pediatric work: “If their diarrhea is caused by cold and wind , the children will have vomiting, fever, cough, sleepiness, thirst, and diarrhea with yellow watery stool. The patients need to drink decoction of Qiwei Baizhu Powder for quenching their thirst”. Following Mr. Qian, many other ancient Chinese pediatricians treated acute diarrhea in children with QWBZP. They recorded the effects of QWBZP in anti-diarrhea, quenching thirst, and improvement of appetite in detail. In our clinical practice, we observed that treatment wit h QWBZP not only shortened the duration of diarrhea and rotavirus shedding, but also improved the condition of nutrition and appetite of the ill patients. Therefore treating rotaviral diarrhea with QWBZP yielded better results than with ORS. The theory of TCM considered that the digestive and absorptive function in young children was immature, so children were susceptible to diarrhea. Treatment for acute diarrhea in childhood with QWBZP can improve the digestive and absorptive function and quench thirst induced by vomiting and diarrhea through the effect of “Bupi” of this prescription.

Following infection of rotavirus, the duodenal biopsies showed a patchy irrgulalarity of mucosal surface, shorting and bunting of the villi, distorting microvilli of absorptive cell[40]. As a consequence of virus replication in the cytoplasm and viral shedding, the infected cell at the surface of villilysed and the villious tip became atrophic[2,11,41], and the villious surface was replaced by immature cells migrating from the crypts[42]. The destruction of mature enterocytes and replacement of immature crypt cells result in reduced levels of disaccharidase and xylose absorption[43], and decrease in the absorptive surface of the small bowel. So diarrhea caused by rotavirus is mainly due to decreased absorption[11,44]. Clinical studies demonstrated that the stools of rotavirus diarrhea contained higher contents of sodium and glucose than normal[45]. In our observation in both clinic and animal models, we found that the contents of sodium and glucose in feces in ORS group or infected group were higher than that in QWBZP group. The result indicated that treatment with QWBZP could promote the absorption of sodium and glucose. The mechanism of ORS on rehydration was based on glucose-facilitated sodium transport[46], while the mechanism of QWBZP on treating rotavirus diarrhea would be more complex and involved in improving the digestive and absorptive function, protecting intestinal mucosa cells from damage induced by rotavirus, and clearance of rotavirus.

More recently, some studies identified that the non-structural protein 4 (NSP4) of rotavirus is a viral enterotoxin, which induced diarrhea by stimulating chloride secretion through a calcium-depedent signaling pathway after binding to the pulative receptor on the intestinal epithelium[34,44,47-50]. So the rotavirus diarrhea is caused by reduction of absorption as well as secretory hyperactivity[2,44,48]. The therapeutical method to improve the absorptive function to enhance the intake of sodium and glucose, therefore, plays an important role in cessation of diarrhea. That may be the reason why the efficacy of QWBZP is better than ORS. Indeed, a lot of studies in TCM in recent years demonstrated that some of medicinal herbs contained in QWBZP have effects of enhancing absorption of D-xylose.

As rotavirus diarrhea in children, rotavirus infection in animal models is also a self-limited disease[36,51]. But in our study, most of infected mice died of severe diarrhea and dehydration without treatment of QWBZP. This result might be due to different METHODS of feeding. In our study, we fed neonate mice with sterilized milk orally, Guerin-Danan, *et al* let the infected pups return to their dams and allowed to suckle[36]. Because breast milk contains IgA antibodies against rotavirus and trypsin inhibitors, which will provide protection to breast-fed infants[52]. Furthermore, it is well known that nutrition in breast milk was more easily absorbed than that in other milk. Treatment with QWBZP can promote the intake of nutrition through improvement of digestive and absorptive function. Therefore, the body weight was increased and most infected mice survived in the QWBZP group as compared with the infected group as well as ORS group.

Abstract

There are two common types of adult patient with a short bowel, those with jejunum in continuity with a functioning colon and those with a jejunostomy. Both groups have potential problems of undernutrition, but this is a greater problem in those without a colon, as they do not derive energy from anaerobic bacterial fermentation of carbohydrate to short chain fatty acids in the colon. Patients with a jejunostomy have major problems of dehydration, sodium and magnesium depletion all due to a large volume of stomal output. Both types of patient have lost at least 60 cm of terminal ileum and so will become deficient of vitamin B_{12}. Both groups have a high prevalence of gallstones (45%) resulting from periods of biliary stasis. Patients with a retained colon have a 25% chance of developing calcium oxalate renal stones and they may have problems with D (-) lactic acidosis. The survival of patients with a short bowel, even if they need long-term parenteral nutrition, is good.

INTRODUCTION

A patient has a short bowel when there is an insufficient length of functioning gut to allow adequate absorption, so macronutrient and/or water and electrolyte supplements are needed to maintain health and/or growth. If untreated or without compensatory mechanisms undernutrition and/or dehydration result[1]. This is likely to be the case if less than 200 cm small bowel remains. The problems experienced by patients with a short bowel depend upon the type and length of remaining small bowel and the presence or absence of a functioning colon. Patients traditionally described as having the short bowel syndrome were those with a retained colon who had intractable diarrhoea with malabsorption of fat, vitamin, and other nutrients so leading to undernutrition, with continuing weight loss and anaemia[2]. The normal adult human small intestinal length varies from about 275-850 cm as measured from the duodeno-jejunal flexure at autopsy or surgery and tends to be shorter in women[3-6]. Congenital cases of a short bowel have been reported and are usually associated with malrotation of the gut[7]. Patients who start with a small intestinal length at or below the lower end of the normal range may develop the problems associated with having a short bowel after relatively little small intestine has been removed[8]. It is important to refer to the remaining length of small intestine rather than to the amount resected.

REMAINING BOWEL

Ileum or jejunum

Ileal mucosa, in contrast to the jejunal mucosa, has "tight" intercellular junctions and thus can concentrate its contents. However, jejunal mucosa has "leaky" intercellular junctions and so the osmolality of the luminal contents is similar to that of plasma. Gastrointestinal transit is naturally slower in the ileum than jejunum so allowing more time for absorption[9,10]. The terminal ileum has the specific functions of absorbing vitamin B_{12}[11,12] and bile salts. Any ileum remaining, after a small bowel resection, can structurally and functionally adapt so increasing absorption[13-16], while remaining jejunum can only functionally adapt if some ileum or colon also remains[16-19]. Thus the outcome is more favourable after a jejunal than an ileal resection.

Ileocaecal valve

Preservation of the ileocaecal valve has traditionally been thought to slow transit and prevent the reflux of colonic contents into the small bowel. However, resection of the ileocaecal valve in adults does not affect these functions[9,20].

Colon

Conservation of the colon is advantageous as it absorbs water, sodium[21-25], magnesium[25,26], calcium[27], short and medium chain fatty acids[28-30], slows gastro-intestinal transit[31] and stimulates small intestinal hyperplasia[32]. Patients with a preserved colon after a small bowel resection may survive without parenteral support with a very short[33,34] or even no remaining jejunum[35].

TYPES AND CAUSES OF A SHORT BOWEL

There are three types of patient with a short bowel. Patients in whom the ileum, often with the ileocaecal valve has been removed leaving a jejuno-colic anastomosis (jejunum-colon); patients in whom some jejunum, the ileum and colon have been removed, so they have an end jejunostomy and patients who have had a predominantly jejunal resection, and have more than 10 cm of terminal ileum and the colon remaining (jejuno-ileal)[25,36,37]. Jejuno-ileal anastomosis patients are not common and as their management is broadly similar to those with a jejuno-colic anastomosis, they are not specifically discussed. Patients with a jejunostomy can be classified as net "absorbers" or net "secretors". The net "absorbers" absorb more water and sodium from their diet than they take orally (usual stomal output about 2 kg/24), thus they can be managed with oral sodium and water supplements and parenteral fluids are not needed. They usually have more than 100 cm residual jejunum. The net "secretors" usually have less than 100 cm residual jejunum and lose more water and sodium from their stoma than they take by mouth (usual stomal output may be 4-8 kg/24). The jejunostomy output from a net "secretor" increases markedly in the daytime in response to food and is minimal at night[38] (Figure 1). The three most common reasons for patients having less than 200 cm of small bowel are superior mesenteric artery thrombosis, Crohn's disease and irradiation damage[25,36,37,39] (Table 1). A short bowel more commonly arises in women (67%) thao men[25], this may be because women start with a shorter length of small intestine than men.

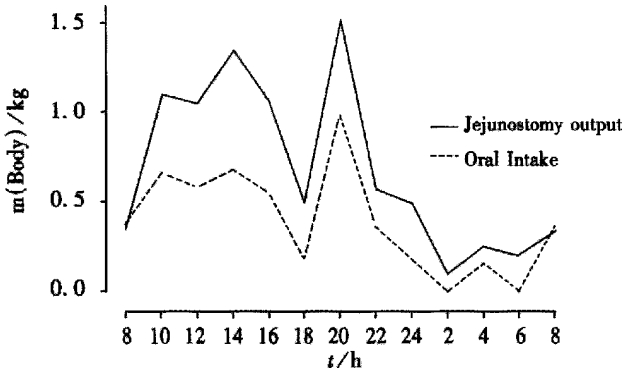

Figure 1 Oral intake (kg) and stomal output measured every 2 hours in a patient who has 30 cm of residual jejunum. There is a marked net "secretory" output in response to food and drink (38).

Table 1 Reasons for a short bowel (less than 200 cm small bowel) (25)

	Jejunum-colon	Jejunostomy
Total (sex)	38 (26F)*	46 (31F)
Age	46 (7-70)	42 (16-68)
Median jejunal length (cm)	90 (0-190)	115 (20-190)
Diagnosis		
Crohn's disease	16	33
Ischaemia	6	2
Irradiation	5	3
Ulcerative colitis	-	5
Volvulus	5	-
Adhesions	4	1
Diverticular disease	1	1
Desmoid tumour	1	1

*:7 had an ileocaecal valve and 31 a jejuno-colic anastomosis.

PHYSIOLOGICAL CHANGES

The problems that arise after a major intestinal resection reflect both normal and altered physiology. Most experimental work in animals involves a predominantly jejunal resection (jejuno-ileal anastomosis), which is not the common situation in man.

Gastro-intestinal motility

Gastric emptying and small bowel transit of liquid is fast in patients with a jejunostomy and normal in patients with a retained colon, probably due to circulating plasma levels of peptide YY being low and high respectively[40] (Figure 2). Peptide YY is an enteric hormone produced by the L cells in the terminal ileum and colon upon exposure to luminal nutrients, it slows gastric emptying and gastrointestinal transit[41].

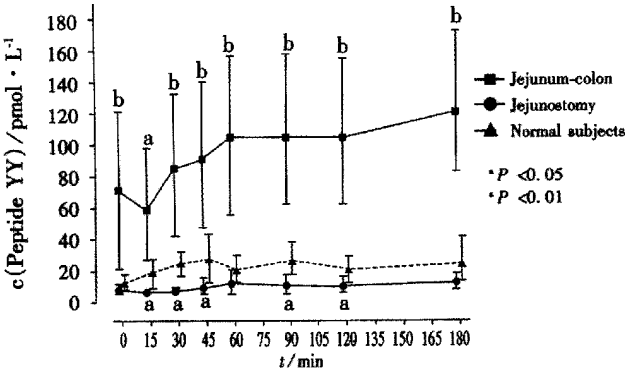

Figure 2 Median peptide YY levels with interquartile range for 6 jejunum-colon patients, 7 jejunostomy patients and 12 normal subjects after a pancake and orange juice meal (40). GLP-2 levels mirror this pattern (65,69).

Gastrointestinal secretions

Salivary secretion is reduced in patients with a jejunostomy[42]. Gastric acid secretion is increased in dogs with denervated gastric pouches. In man some cases of long-term survival in patients with a short bowel has been attributed to their previous gastric surgery[43-45]. High circulating gastrin levels are observed[40,46,47] and may be due to less small bowel being available to catabolizegastrin[48,49]. Gastric acid hypersecretion could increase the incidence of peptic ulceration[50]; impair nutrient absorption by causing bile salt precipitation[51]; reduced pancreatic enzyme function and increased jejunal motility. However although there may be an increase in gastric acid secretion in the first 2 wk after a small bowel resection[52], there is no good evidence for gastric acid hypersecretion in man in the long-term, especially in those with a jejunostomy[53]. Pancreatic function is reduced by undernutrition[54] and if there is no oral intake[55], but not after a small bowel resection leaving the colon[56].

Absorptive functions

The ileum absorbs vitamin B_{12} and bile salts. If more than 60 cm of terminal ileum is resected vitamin B_{12} deficiency is likely to occur[11,12,57]. Fat is absorbed over a longer length of the intestine than carbohydrate or protein and this distance increases as oral intake rises[58]. When more than 100 cm terminal ileum has been resected the increased hepatic synthesis of bile salts is not enough to keep up with the stool or stomal losses and a degree of fat malabsorption results[59].

Adaptation

Intestinal adaptation is the process that attempts to restore the total gut absorption of macronutrients, macrominerals and water, to that of before the intestinal resection[60]. This may occur by the patient eating more food than normal (hyperphagia)[61]. The remaining bowel may increase its absorptive area (structural adaptation) and/or gastrointestinal transit may slow (functional adaptation). After a jejunal resection in animals the ileal remnant undergoes structural changes, which include elongation of villi, deepening of the crypts and an increase in the number of enterocytes along a given length of villus. This structural adaptation may relate to circulating plasma levels of glucagon-like peptide-2 (GLP-2). GLP-2 is an enterocyte specific peptide growth hormone produced by the L cells in the terminal ileum and colon and it causes small and large bowel villus and crypt growth[62].

Jejunum-colon In patients with a jejuno-colic anastomosis, no structural adaptation has been demonstrated[17,63,64] even though high GLP-2 levels are observed[65]. Functional adaptation with slowing of gastric emptying and small bowel transit may occur[31] and may be due to high circulating peptide YY levels[40]. In these patients there is a small reduction in faecal weight in the 3 months following the small bowel resection[16]. There is increased jejunal absorption of macronutrients (e.g. glucose), water, sodium and calcium with time[15,18,19,66], and an increased chance of the patient being able to stop parenteral nutrition[25,36,37,67]. The intestinal calcium absorption may continue to increase for more than two years after a resection[66].

Jejunostomy Although adaptation occurs in the months after the creation of an ileostomy, there is no evidence for any structural[53] or functional[25,68,] adaptation at any time in patients with a jejunostomy. This may be because patients with a jejunostomy have low circulating plasma levels of GLP-2 and peptide YY[40,69,70].

PRESENTATION AND CLINICAL ASSESSMENT

Jejunum-colon patients often appear well after their resection except for diarrhoea/steatorrhoea, but in the following months may lose weight and become severely undernourished. Patients with a jejunostomy have problems of dehydration immediately after surgery due to large stomal water and sodium losses. This jejunal output is greatest after food and drink have been consumed.

The clinical assessment of a patient with a short bowel includes a measurement of residual small bowel length and an assessment of water, sodium, magnesium and nutritional status. The state of hydration and magnesium balance is of immediate importance to those with a jejunostomy.

Assessment of residual small intestine

From knowledge of residual bowel length predictions about the long-term need for fluid/nutrition can be made (Table 2).

Table 2 Guide to bowel length and long-term fluid/nutritional support needed by patients with a short bowel (5,37,38,74)

Jejunal length (cm)	Jejunum-colon	Jejunostomy
0-50	PN	PN+PS
51-100	ON	PN+PS*
101-150	None	ON+OGS
151-200	None	OGS

*:at 85-100 cm may need PS only
PN:Parenteral nutrition
PS:Parenteral saline (+/-magnesium)
ON:Oral (or enteral) nutritinon
OGS:Oral (or enteral) glucose/saline solution

Anatomical length The remaining small bowel length can be measured at surgery (10-30 cm segments are measured along the anti-mesenteric border with great care being taken not to over-stretch the bowel). If not measured at surgery, an opisometer, a device used for measuring distances on maps can be used to trace the long axis of the small bowel on a small bowel meal radiograph. This technique is relatively accurate if the total small intestinal length is less than 200 cm and if the entire small bowel is shown on one film[36,71].

Functional length Citrulline is a non-essential amino acid synthesised from glutamine and all the citrulline in the systemic circulation is derived from the enterocytes. Post absorptive plasma levels of citrulline relate to the length of remaining functional small bowel[72].

Hydration (water and sodium status)

Water and sodium deficiency (most common in jejunostomy patients) may result in hypotension and pre-renal failure. Daily body weight and accurate fluid balance (including stomal output) are the most important measurements. The serum creatinine, potassium and magnesium, and urinary sodium may be measured every 1-2 d initially, then once or twice a week and if long-term at home every 2-3 mo. Water and sodium deficiencies are detected by an abrupt fall in body weight, postural systolic hypotension (1.33 kPa), low urine volume and, if severe, by a rising serum creatinine and urea. The most helpful early measure of sodium depletion is the sodium concentration in a random urine sample. A concentration of 0-5 mmol·L^{-1} suggests sodium depletion. The aims are to maintain hydration/body mass and a daily urine volume of at least 801 ml with a sodium concentration greater than 20 mmol·L^{-1}.

Magnesium

Magnesium depletion is common especially in patients with a high stomal output. A serum value of less than 0.6 mmol·L^{-1} may give rise to symptoms.

Nutritional status

A patient may be assessed as undernourished if the body mass index is less than 18.5 kg·m^{-2}, if there is a recent weight loss of more than 10% or if the mid-arm muscle circumference is less than 19 cm in a woman or 22 cm in a man[73]. The degree of malabsorption and thus oral enteral nutrition requirements can be predicted from knowledge of the residual length of small bowel (Table 2). In terms of energy absorption parenteral nutrition is needed if a patient absorbs less than one-third of the oral energy intake[38,74]; though in people with high energy needs parenteral nutrition may be needed at a higher percentage energy absorption.

CLINICAL PROBLEMS AND TREATMENT

Salt and water depletion

Jejunum-colon The colon has a large capacity to absorb sodium and water; thus patients with a short bowel and a preserved colon are rarely in negative water and sodium balance and rarely need water or sodium supplements[23-25]. Although the colon secretes potassium, a low serum potassium level rarely occurs[25]. If sodium depleted, a glucose-saline drink can be sipped during the day as for patients with a jejunostomy. There is an exchange mechanism of chloride for bicarbonate in the colon; thus if much sodium chloride is consumed, bicarbonate may be lost in the stools, giving rise to a metabolic acidosis.

Jejunostomy Patients with a jejunostomy have a large volume of stomal output, which is greater after eating or drinking. Each litre of jejunostomy fluid contains about 100 mmol·L^{-1} of sodium[38]. This high volume output is mainly due to a loss of the normal daily secretions (0.5 L saliva, 2.0 L gastric juice and 1.5 L pancreatico-biliary) produced in responseto food and drink. Each day about 6 litres of chyme pass the duodeno-jejunal flexure, but by 100 cm distal to the duodeno-jejunal flexure the chyme volume is about the same as that of the oral intake[75,76]. If a jejunostomy is at a small bowel length of less than this more emerges from the stoma than is taken in by mouth ("secretors"). Even in the fasting state there is an obligatory loss of intestinal secretions produced with the migrating myoelectric complex (MMC)[77]. The effluent from a jejunostomy or ileostomy contains relatively little potassium (about 15 mmol·L^{-1})[23,24,38]. Potassium balance is not often a problem and net loss through the stoma occurs only when less than 50 cm jejunum remains[38]. A low serum potassium level is most commonly due to sodium depletion with secondary hyperaldosteronism and thus greater than normal urinary losses of potassium[23]. Hypokalaemia can also be due to hypomagnesaemia, which causes dysfunction of potassium transport systems and increases renal potassium excretion; this hypokalaemia is resistant to potassium treatment but responds to magnesium replacement[78,79]

Management of a high output stoma (jejunostomy/ileostomy) or enterocutaneous fistula

It is helpful both in predicting outcome and in choosing the type of nutritional support if the length of bowel above the stoma/fistula is known. Contrast studies (small bowel meal, fistulogram or stoma enema) may help with this. An examination of the output (colour/consistency/24 hr volume) gives an indication of the internal origin of the fistula.

Exclude other causes of a high output

A stoma may produce a high output if there is intra-abdominal sepsis, enteritis (e.g. clostridium or salmonella), partial/intermittent bowel obstruction, recurrent disease in the remaining bowel (e.g. Crohn's disease or irradiation) or sudden stopping of drugs (steroids or opiates).

Treatment of a high output jejunostomy

The concentration of sodium in the output remains constant (about 100 mmol·L^{-1}) whatever treatment is given. While there is a small stomal loss when fasting, the greatest increase in stomal output is after food or drink (Figure 2)[38]. Even in patients with a jejunostomy and receiving parenteral nutrition, the stomal output should be reduced, as this may reduce the amount or frequency of parenteral fluid required and the social problems of managing a high output stoma. If there is marked sodium and water depletion and severe thirst, it is often necessary to establish equilibrium by giving intravenous normal saline (2-4 L·d^{-1}) keeping the patient 'nil by mouth', which will also demonstrate that the output is driven by their oral intake. Over 2-3 d intravenous fluids are gradually withdrawn while food and restricted oral fluids are reintroduced. Great care must be taken not to administer too much fluid, which will readily cause oedema (partly due to the high circulating aldosterone levels[23,24,80,81]. To correct hypokalaemia in patients with a high output stoma, sodium/water depletion must be corrected and the serum magnesium brought into the

normal range. It is uncommon for potassium supplements to be needed.

Restrict oral fluids Jejunal mucosa is 'leaky' and rapid sodium fluxes occur across it. If water or any solution with a sodium concentration of less than 90 mmol/l is drunk there is a net efflux of sodium from the plasma into the bowel lumen[82], until a luminal sodium concentration of about 100 mmol/l is reached. In a patient with a jejunostomy this fluid is then lost in the stomal output. It is a common mistake for patients to be encouraged to drink oral hypotonic solutions to quench their thirst, but this causes large stomal sodium losses[80,82-85]. Treatment for the high output from a jejunostomy, ileostomy or high fistula begins with the patient restricting the total amount of oral hypotonic fluid (water, tea, coffee, fruit juices, alcohol or dilute salt solutions) to less than 500 $mL \cdot d^{-1}$. To make up the rest of the fluid requirement the patient is encouraged to drink a glucose-saline replacement solution. Many patients at home with marginally high stoma outputs (1.0-1.5 L) will be helped by a combination of oral fluid restriction (less than 1.0 $L \cdot d^{-1}$) and the addition of salt to their diet. Often patients are advised to take liquids and solids at different times (no liquid for half an hour before and after food) however there is no published evidence that this reduces stomal output or increases macro or micronutrient absorption[86].

Drink oral glucose-saline solution Patients with stomal losses of less than 1200 $mL \cdot d^{-1}$ can usually maintain sodium balance by adding extra salt to the limit of palatability at the table and when cooking. When stoma losses are in the range 1200 - 2000 mL, or sometimes more, it is possible for a patient to maintain sodium balance by taking a glucose-saline solution or salt capsules[84]. In hot weather, due to water and sodium loss in sweat, patients with a stoma are more likely to have problems of dehydration. As the sodium content of jejunostomy (or ileostomy) effluent is relatively constant at about 90 $mmol \cdot L^{-1}$ and as there is coupled absorption of sodium and glucose in the jejunum[87-89]; patients are advised to sip a glucose-saline solution with a sodium concentration of at least 90 $mmol \cdot L^{-1}$ throughout the day. The World Health Organization (WHO) cholera solution has a sodium concentration of 90 $mmol \cdot L^{-1}$[90] and is commonly used (without the potassium chloride) (Table 3). The concentration of sodium in this solution is much higher than many commercial preparations used to treat infective or traveller's diarrhoeas. There is no evidence that the sodium bicarbonate adds to the effectiveness of this solution[89] and it may be more palatable if the sodium bicarbonate is replaced by sodium citrate. If the sodium concentration is increased further (e.g. to 136 $mmol \cdot L^{-1}$) absorption of sodium and water is improved[91]. However even though taste perception is different in patients who are salt and water depleted, they may find a more concentrated salt solution too salty to drink. The patient should be encouraged to sip a total of one litre or more of one of these solutions in small quantities at intervals throughout the day. As compliance is often a major problem, patients need to understand the need for the solution. To improve palatability the solution may be chilled or flavoured with fruit juice.

Table 3 The modified WHO cholera rehydration solution

Sodium chloride	60 mmol (3.5 gm)
Sodium bicarbonate (or citrate)	30 mmol (2.5 gm) (2.9 gm)
Glucose	110 mmol (20 gm)
Tap water	one litre
Alternative rehydration solution	
Sodium chloride	120 mmol (7 gm)
Glucose	44 mmol (8 gm)
Tap water	one litre

A glucose-polymer (55 gm Maxijul) may be substituted for glucose to increase the energy intake by a mean of 648.8$kJ \cdot d^{-1}$ (115 kcal/day)[84]. A rice powder based oral rehydration solution can further increase the amount of energy absorbed, and if there is a functioning terminal ileum one study has shown that the sodium concentration in this solution can be reduced to 60 $mmol \cdot L^{-1}$[92]. The glucose-polymer/rice based solution can be especially useful in diabetic patients as it causes less extreme changes in blood glucose than glucose based solutions. Sodium chloride capsules (500 mg each) are effective when taken in large amounts (14/24 h), but can cause some patients to feel sick and even vomit[84]. If an enteral feed is given, sodium chloride needs to be added to make the total sodium concentration of the feed 100 $mmol \cdot L^{-1}$ while keeping the osmolality near to 300 $mmol \cdot L^{-1}$.

Drug therapy If restricting oral fluids and giving a glucose-saline solution to drink are not adequate, drugs may be needed. As the intestinal output, especially in net "secretors" rises after meals, it is important to give the drugs before food. Drugs used to reduce jejunostomy output actto reduce either intestinal motility or secretions. If any tablets/capsules emerge unchanged in stool/stomal output, they can be crushed, opened and/or mixed with water or put on food.

Antimotility (antidiarrhoeal) drugs Loperamide and codeine phosphate reduce intestinal motility and thus decrease water and sodium output from an ileostomy by about 20%-30%[93-95]. Loperamide is preferred to opiate drugs (e.g. codeine phosphate) as it is not sedative, addictive and does not cause fat malabsorption[94,96]. However loperamide does reduce postprandial pancreaticobiliary secretion of trypsin and bilirubin in patients with a short bowel and preserved colon[97]. They are usually taken half an hour before food. Oral loperamide 4 mg taken four times a day was more effective in reducing the weight and sodium content of ileostomy fluid than codeine phosphate 60 mg taken four times a day (94) but the effect of both together may be greater[98]. Loperamide circulates through the enterohepatic circulation, which is severely disrupted in patients with a short bowel and small bowel transit may be very rapid. Thus high doses of loperamide (e.g. 12-24 mg at a time) may be needed, as following a vagotomy and pyloroplasty[99]. These drugs are effective in most patients with a jejunostomy[38,100] particularly net "absorbers".

Antisecretory drugs Food and drink are diluted by digestive juices, thus the volume of stomal effluent can be reduced in 'secretors' by drugs that reduce the secretions from the stomach, liver and pancreas. Drugs that reduce gastric acid secretion (e.g. the H_2 antagonists or proton pump inhibitors or the somatostatin analogue octreotide) are most commonly used. There is one report of a patient with a jejunostomy for Crohn's disease having gastric irradiation to successfully reduce their stomal output[101].

H_2 antagonists/proton pump inhibitors Cimetidine (400 mg orally or intravenously four times a day)[102,103], ranitidine (300 mg orally twice daily)[38] and omeprazole (40 mg orally once a day or intravenously twice a day)[104,105] reduce jejunostomy output particularly in net secretors and generally in those with an output exceeding 2 litres daily. Omeprazole is readily absorbed in the duodenum and upper small bowel, but if less than 50 cm jejunum remains it may need to be given intravenously. The effect of these drugs is as good as octreotide (50 ìg subcutaneously twice daily) in terms of the reduction in stomal volume[38,104]. They do not change the absorption of energy, carbohydrate, lipid, nitrogen and divalent cations[102-105] and do not reduce jejunostomy output enough to prevent the need for parenteral fluid and electrolyte replacement.

Somatostatin/octreotide Somatostatin/octreotide reduce salivary, gastric and pancreatico-biliary secretions, slow small bowel transit and may delay gastric emptying. Somatostatin has a serum half-life of 3 min so is given by continuous infusion and does reduce stomal output[106]. Octreotide has a serum half-life of 90 minutes so is given as regular (two or three time's daily) subcutaneous injections before food. Several studies in adults have shown octreotide to reduce ileostomy diarrhoea and large volume jejunostomy outputs [100,107-114]. The greatest reductions in intestinal output have occurred in net

"secretors", and many patients have been able to reduce the volume of parenteral supplements needed[110,114]. All studies have shown a reduction in sodium output, which parallels that of the intestinal output[100,107-114]. Magnesium balance has not been changed by octreotide[107,112]. Octreotide does not significantly change total energy[110,113,114] or nitrogen absorption[107,109,112-114]. Fat absorption may be unchanged[112-114] or reduced[107] as might be predicted from a reduction in pancreaticobiliary secretion. The effect of octreotide is maintained in the long-term[107,109,110,112,114]. Somatostatin and octreotide both reduce the output from a high fistula and appear to accelerate the rate of spontaneous closure[115,116].

Steroids/fludrocortisone/desmopressin Mineralocorticoids (e.g. 2 mg oral fludrocortisone or 2 mg intravenous d-aldosterone)[117-119] or high dose hydrocortisone[120] can occasionally reduce the stomal output in patients with a retained ileum. Desmopressin (an analogue of antidiuretic hormone) has no effect upon ileal fluid or electrolyte loss in man[121]. Some patients cannot be maintained with any oral regimens (usually if jejunal length is less than 100 cm) and need regular parenteral saline supplements. Most such patients also need oral or parenteral nutritional supplements, but a few need only one or two litres of parenteral (or subcutaneous) saline daily, often with added magnesium sulphate (4-12 mmol).

Magnesium depletion

Magnesium deficiency occurs partly because its main absorptive sites have been removed (distal small bowel and colon)[122]. However the degree of malabsorption of magnesium does not correlate with the residual length of jejunum[42,123]. Fatty acids derived either from digestion of dietary fat or from bacterial fermentation of malabsorbed carbohydrate, combine with magnesium, calcium and zinc so preventing absorption and increasing faecal or stomal losses[124]. Another reason particularly in patients with a jejunostomy is that salt and water depletion causes secondary hyperaldosteronism, which increases renal magnesium excretion[125,126].

The clinical syndrome of magnesium deficiency in man includes fatigue, depression, jerky and weak muscles, ataxia, athetoid movements, cardiac arrhythmia's and, if severe, convulsions[127-130]. The occurrence of carpopedal spasm, positive Chvostek and Trousseau's signs generally occur if there is a concomitant hypocalcaemia[128,129,131]. Low serum magnesium levels are more common in patients with a jejunostomy (70%) than patients with a retained colon (40%)[25]. Hypomagnesaemia can perpetuate itself as it reduces both the secretion and function of parathormone[132]. Thus parathormone cannot promote magnesium absorption in the ascending limb of the loop of Henle or activate renal 1 alpha-hydroxylase, which catalyses the formation of 1,25 hydroxy-vitamin D. The failure to make 1,25 hydroxy-vitamin D results in reduced intestinal magnesium and calcium absorption[133].

Treatment of hypomagnesaemia

Dehydration and sodium depletion, which will cause secondary hyperaldosteronism (which leads to renal magnesium loss), must first be treated. A diet relatively low in fat reduces stool/stomal magnesium losses especially in patients with a retained colon[124,134]. Various magnesium salts have been given as a treatment orally: magnesium sulphate, chloride, hydroxide, acetate, carbonate, gluconate, lactate, citrate, aspartate, pyroglutamate, oxide (magnesia) and diglycinate. Most magnesium salts are poorly absorbed and may worsen diarrhoea/stomal output. Magnesium acetate has been shown to cause less diarrhoea than magnesium gluconate[135]. Magnesium oxide is commonly given and contains more elemental magnesium than the other salts, is insoluble in water and alcohol but soluble in dilute acid. In the stomach it is converted to magnesium chloride. It is given as gelatine capsules of 4 mmol magnesium oxide (160 mg of MgO) to a total of 12-24 mmol·d^{-1}. Magnesium oxide is usually given at night when intestinal transit is assumed to be slowest and hence there is more time for absorption. Magnesium diglycinate (chelate) is absorbed as well as magnesium oxide as an intact dipeptide in the proximal jejunum and it results in the passage of fewer stools, after an ileal resection, than magnesium oxide[136].

As hypomagnesaemia will have caused both a failure of parathormone release and a resistance to its action, 1-alpha hydroxy-cholecalciferol cannot be made in the kidney in adequate amounts. Thus if oral magnesium supplements do not bring the magnesium level into the normal range, oral 1-alpha hydroxy-cholecalciferol in a gradually increasing dose (every 2-4 wk) of 1-9 μg·d^{-1} will improve magnesium balance in patients, at least in those with a retained colon[137,138]. This action is by increasing both intestinal and renal magnesium absorption[138]. Occasionally magnesium is given as an intravenous or subcutaneous infusion.

Undernutrition - protein-energy malnutrition

Undernutrition only becomes apparent slowly and should be prevented from occurring by predicting its likelihood and from knowledge of the residual length of bowel remaining (Table 4). All patients who can be maintained on an oral diet need to consume more energy than normal subjects because 50% or more of the energy from the diet may be malabsorbed. Patients can achieve this by eating more high-energy food, having oral sip-feeds, or high energy enteral feeds given at night through a nasogastric or gastrostomy tube. There are rarely any problems inserting a percutaneous endoscopic gastrostomy (PEG) into patients with Crohn's disease providing that there is no distal obstruction[136]. Once weight is regained, a nocturnal feed can be reduced or stopped and sip-feeds during the day may be adequate. Only if these measures fail and the patient continues to lose weight, or fails to regain lost weight, is parenteral nutrition given. Parenteral nutrition may only be needed for a few weeks or months before oral supplements are adequate.

In the long-term parenteral nutrition is needed if a patient absorbs less than one-third of the oral energy intake[38,74], if there are high-energy requirements and absorption is 30-60% or if increasing the oral/enteral nutrient intake causes a socially unacceptably large volume of stomal output or diarrhoea. In addition to consuming a high energy diet the dietary advice given to the two types of patient is different.

Table 4 Summary of the problems of a short bowel

	Jejunum-colon	Jejunostomy
Presentation	gradual, diarrhoea and undernutrition	acute fluid losses
Water, sodium and magnesium depletion	uncommon in the long-term	common
Nutrient malabsorption	Common*	very common
D(-)lactic acidosis	occasionally	none
Renal stones (calcium oxalate)	25%	none
Gallstones (pigment)	45%	45%
Adaptation	functional adaptation	no evidence
Social problems	diarrhoea dehydration dependency on treatment	high stomal output

*:bacterial fermentation of carbohydrate salvages some energy, but D (-) lactic acidosis can occur if the diet is high in mono and oligosaccharides.

Jejunum-colon Unabsorbed long chain fatty acids in the colon reduce the transit time[139] and reduce water and sodium absorption[140] somaking diarrhoea worse. In addition they are toxic to bacteria so reduce carbohydrate fermentation[141]. They bind to calcium and magnesium increasing stool losses, and they increase oxalate absorption so predisposing to the formation of renal stones (see below). Theoretically, a low fat diet is ideal for patients after a small bowel resection[142], however in practice it is hard to implement. Fat yields twice as much energy as a comparable weight of carbohydrate or protein and makes food palatable. A high carbohydrate/low fat diet involves eating a large volume of food. A low fat diet may increase calcium, magnesium and zinc absorption[124] but makes essential fatty acid deficiency more likely[143]. Sunflower oil may be rubbed onto the

skin to ensure adequate amounts of essential fatty acids enter the body[144]. If a diet is high in monosaccharides D (-) lactic acidosis may occur (see below). Medium chain triglycerides are an alternative source of energy and are absorbed from the small and large bowel[145-148]. In order to increase the energy absorption, reduce the risk of renal stones and D (-) lactic acidosis, patients with a retained colon need a large totalenergy intake with a diet high in carbohydrate (polysaccharides)[29], but not increased in fat (long chain triglycerides) and low in oxalate.

Jejunostomy Patients with a jejunostomy absorb a constant proportion of the nitrogen, energy and fat from their diet[29,134,149]. Increasing fat in the diet, increases energy density, keeps the diet osmolality low, increases palatability and provides essential fatty acids[143]. It does raise fat excretion but does not usually increase stomal output, nor make the output offensive[29,134,149]. Two studies have shown fatty acids to increase the stomal output of divalent cations[124,150] and two others found no such effect [134,149]. There is no advantage in giving a diet of small molecules (e.g. an elemental diet), which causes a feed to be hyper-osmolar[149] and usually contains little sodium, so stomal losses of water and sodium from the stoma increase. A peptide diet has a relatively high osmolality and thus can increase stomal output[151]. Little advantage comes from taking a diet of water-soluble medium chain triglycerides in place of normal fat[148]. The addition of glutamine (15 gm) to a litre of rehydration solution in patients with jejunostomy resulted in no additional benefit in terms of water or sodium absorption[152]. The fibre content of the diet plays only a minor role in determining jejunal output[93]. As the stomal sodium losses are about 100 mmol·L^{-1} any diet will need added sodium chloride. These patients need a diet of high energy (carbohydrate or lipid) in which the osmolality is kept low by using large molecules (polysaccharides, protein and triglycerides)[149,150] and to which sodium chloride is added to give the meal/liquid feed a total sodium concentration of 90-120 mmol·L^{-1} and an osmolality of about 300 mmol·L^{-1}.

Conjugated bile acid treatment As fat malabsorption in both types of patient with a short bowel may partly be due to bile acid depletion, bile salts have been tried as a treatment. Cholylsarcosine, a synthetic bile acid resistant to bacterial deconjugation and dehydroxylation and which does not itself cause colonic secretion so does not cause diarrhoea. When 4 grams are taken three times a day, there is a variable improvement in fat and calcium absorption in patients with and without a retained functioning colon; however it may cause nausea[153-154].

Other vitamin and mineral deficiencies

Both groups of patient have had more than 60 cm of their terminal ileum removed, and need long-term hydroxycobalamin injections[11,12,57]. Patients receiving parenteral nutrition are commonly selenium deficient[155-157] and need larger amounts of selenium than are required in the diet of normal subjects[157] this suggests a loss of selenium from the gastrointestinal secretions. In patients with a jejunostomy there is a reduction in selenium absorption, which relates to the length of remaining jejunum[158]. The kidney can conserve selenium but this may not be adequate and selenium deficiency is common. This causes weak muscles and a dilated cardiomyopathy[159]. Zinc deficiency is not common unless stool volumes are large[160]. There may be impairment of absorption of the fat-soluble vitamins A D E K and essential fatty acids. Essential fatty acid deficiency can be treated by rubbing sunflower oil into the skin[144].

Diarrhoea (Jejunum-colon patients)

The oral intake determines the amount of stool passed. Diarrhoea, which may severely restrict a patient's life style, can be reduced by limiting food intake, but this may increase the problems of undernutrition. Rarely a patient needs parenteral nutrition to allow them to eat less and so reduce the diarrhoea.

Diarrhoea may be treated with loperamide 2-8 mg given half an hour before food in the same way as for patients with a jejunostomy and occasionally codeine phosphate is also added (30-60 mg half an hour before food). If less than 100 cm terminal ileum has been resected bile salt malabsorption may contribute to the diarrhoea and may be helped by cholestyramine, which has the additional advantage of reducing oxalate absorption, but may be detrimental by reducing fat absorption and by further reducing the bile salt pool[58]. Although a gastric anti-secretory drug may reduce diarrhoea shortly after surgery, they are not usually effective in the long-term.

Confusion

In addition to the many common general medical causes of confusion (e.g. hypoxia, hepatic, renal or cardiac failure, sepsis, hypoglycaemia, alcohol or other drugs) other specific causes should be sought in a patient with a short bowel. Hypomagnesaemia may cause mild confusion when the serum magnesium level is very low (less than 0.2 mmol·L^{-1}). Thiamine deficiency can cause a Wernicke/Korsikoff psychosis, which responds rapidly to large regular doses of thiamine. Two other specific causes in patients with a short bowel are D (-) lactic acidosis and hyperammonaemia. D (-) lactic acidosis is only seen in patients with a short bowel and a preserved colon. Lactic acid produced and utilized by mammalian cells is the L (+) isomer but colonic bacteria produce both the L (+) and the D (-) isomers. In rare circumstances the colonic flora may rapidly degrade a surplus of easily fermentable carbohydrate (mono and oligosaccharides and rapidly digestible starch[161] to D (-) lactate. A reduction in colonic gram-negative anaerobes and a predominance of gram-positive anaerobes, especially Lactobacillus, Eubacterium, and Bifidobacterium has been found[162]. D (-) lactate is absorbed and cannot be easily metabosised. It causes ataxia, blurred vision, ophthalmoplegia and nystagmus, slurred speech, aggressiveness, inappropriate behaviour, and stupor, which may progress to coma[163]. It is suspected when a patient is found to have a metabolic acidosis with a large anion gap, and confirmed by increased concentrations of D (-) lactate in blood and urine. The diet is changed so that simplecarbohydrates (mono and oligosaccharides)[164] are restricted and more slowly digestible polysaccharides (starch) encouraged and thiamine may be given. Broad-spectrum antibiotics (neomycin or vancomycin) can be given to reduce the bacterial production of lactate. Medium chain triglycerides may be omitted[165]. If very severe the patient may need to fast and be given parenteral nutrition.

Confusion may occur in both types of patients with a short bowel due to hyperammonaemia, this results because ammonia cannot be detoxified. The small amount of intestine remaining cannot manufacture adequate citrulline to detoxify ammonia in the urea cycle. The increase in blood ammonia is a problem if there is concomitant renal impairment, as the excess ammonia cannot be excreted. By giving arginine (an intermediary in the urea cycle) the hyperammonaemia can be corrected[166,167].

Drug absorption

Omeprazole can be absorbed in the duodenum/ upper jejunum and only if less than 50 cm jejunum remains are problems likely to occur. Many drugs will be incompletely absorbed by patients with a short bowel and may be needed in much higher amounts than usual (e.g. thyroxine, warfarin[168], and digoxin[169]) or may need to be given intravenously. As the enterohepatic circulation, round which loperamide circulates, is disrupted, higher doses than usual may need to be given.

Gallstones

Gallstones are common (45%) in both types of patient and are more common in men[25]. It was originally thought that gallstones in this circumstance were due to deposition of cholesterol because of a depleted bile-salt pool. However, the gallstones tend to contain calcium bilirubinate and these probably result from gallbladder stasis with the consequent formation of biliary sludge. These stones may

appear calcified on an abdominal radiograph[170]. Calcium bilirubinate crystals, within biliary sludge, are more commonly found in men than women[171]. The reasons for the formation of biliary sludge include, abdominal surgery, ileal resection, Crohn's disease, rapid weight loss, drug therapy (e.g. octreotide) and altered gastrointestinal transit and flora. Disturbed cholesterol or bilirubin metabolism, and changes in nucleation may also be important[172]. There are many therapies proposed to prevent the formation of gallstones. Cholecystokinin (CCK) injections have been successful[173]. Periodic pulsed infusions of amino acids or small amounts of enteral feed stimulate endogenous CCK release, cause gallbladder contraction and thus prevent gallbladder stasis[174]. Non-steroidal anti-inflammatory drugs may prevent gallstones by decreasing the mucin glycoprotein involved in nucleation[175], or by a prokinetic effect (via leukotrienes) on the gallbladder[176]. Ursodeoxycholic acid (UDCA) causes bile to become richer in glycine or taurine conjugates of UDCA and this results in a marked reduction in cholesterol crystallisation. This may be due to a reduction in some crystallisation promoting factors (e.g. aminopeptidase N, haptoglobin and some immunoglobulins)[177,178]. Reducing the amount of the more lithogenic secondary bile acids could be achieved by either increasing intestinal transit (e.g. cisapride[179]) or by inhibiting bowel bacteria (e.g. metronidazole)[180]). Some units advocate prophylactic cholecystectomy whenever a large intestinal resection is performed[181].

Renal stones

Patients with a retained colon have a 25% chance of developing symptomatic calcium oxalate renal stones[25]. Oxalate is a metabolic end product that cannot be metabolised in man. Under normal circumstances, most urinary oxalate derives from the metabolism of amino acids (mainly glycine) and of ascorbic acid. Less than 10% is derived from dietary oxalate[182]. However after an ileal resection there is increased colonic absorption of dietary oxalate especially by the distal colon[183].

There are many factors contributing to calcium oxalate renal stone formation[184].

Fat malabsorption Increasing the dietary intake of lipid results in increasing enteric hyperoxaluria[185]. Fat malabsorption leads to calcium soap formation and calcium malabsorption and to oxalate being unbound and thus easily absorbable. Colonic oxalate absorption is increased by low dietary calcium, hyperparathyroidism, and vitamin D administration, all of which reduce calcium concentrations in the colon and thus the extent to which oxalate is bound to calcium in the gut lumen.

Increased colonic permeability Unabsorbed bile acids increase colonic permeability to oxalate. Chenodeoxycholate, infused into the colon, increased oxalate absorption five-fold[186]. Cholestyramine taken orally decreased oxalate absorption[187,188].

Reduced bacterial breakdown of oxalate An anaerobic bacteria (Oxalobacter formigenes) within the colon degrades oxalate to carbon dioxide and formate[189]. A reduction in its amount could contribute to increased oxalate absorption. It is cultured less frequently from the stools of patients with Crohn's disease or steatorrhoea[190]. Its growth is inhibited by low bile acid concentrations as occur in patients with a short bowel and retained colon[191].

Vitamin deficiency Pyridoxine deficiency may increase the metabolic formation of oxalate and/or the ileal absorption[192,193]. Thiamine deficiency may increase oxalate production. In contrast ascorbic acid deficiency decreases oxalate absorption[194].

Hypocitraturia Citrate prevents nucleation, the first step in stone formation. Hypocitraturia is common in patients with malabsorption or jejunoileal bypass[195-197]. Citrate excretion and urine pH are reduced by systemic acidosis, including that caused by gastrointestinal bicarbonate wastage, and by hypomagnesaemia. Hypocitraturia in patients with malabsorption can be corrected by oral citrate supplementation and magnesium injections[196].

Type of oxalate ingested Sodium oxalate as found in tea is more readily absorbed that calcium oxalate in most foods.

To prevent calcium oxalate renal stone formation, patients should avoid dehydration and take a diet low in oxalate. A low oxalate diet means avoiding foods such as spinach, rhubarb, beetroot, nuts, chocolate, tea, wheat bran, and strawberries[184]. Fat restriction is theoretically good but may not be desirable for nutritional reasons. Substitution of medium chain triglycerides may be effective in reducing oxalate absorption[198]. Restriction of dietary oxalate and fat intake reduce urinary oxalate excretion[188,199-201]. Dietary calcium must not be restricted but must be increased. Calcium salts reduce absorption of dietary oxalate in patients with ileal resection or jejunoileal bypass[202-209]. Calcium-containing organic marine hydrocolloid decreases oxalate absorption without increasing calcium absorption[206]. Binding bile salts with cholestyramine has variable effects. It binds oxalate *in vitro*[210] and some studies showed it to decrease urinary oxalate excretion[187,210], however, other studies have shown no benefit[195,202] or even increased urinary oxalate excretion[211].

Aluminium salts can bind oxalate *in vitro*[205]. There was a halving of urinary oxalate excretion after oral aluminium hydroxide had been given to 4 patients with enteric hyperoxaluria[212], but no such reduction was observed in another study[211].

Social problems

Most long-term patients with a short bowel have a body mass index within the normal range and most are at full time work or looking after the home and family unaided[25]. Both groups may have diarrhoea and in those with a colon the diarrhoea is malodorous and bulky due to steatorrhoea.

The effluent from a small-bowel stoma, unlike from a colostomy, is not offensive but sometimes is a large volume (e. g. 3 or more litres/24 h). The bag then has to be emptied frequently and, if it becomes overfull, the adhesive flange may separate from the skin with embarrassing leakage of fluid, and with the likelihood of skin soreness. A patient with no remaining jejunum and a preserved colon can survive without parenteral nutrition but their quality of life is poor[35].

New and future treatments

New treatments aim to increase the absorptive function of the remaining gut. As plasma levels of GLP-2, which causes villus growth, and peptide YY, which slows upper gastrointestinal transit, are low in patients with a jejunostomy, treatments to correct these are being tried. GLP-2 gave a small increase in nutrient absorption[213]. Peptide YY agonists are available but have not yet been tried[214]. Other treatments that may increase structural adaptation include epidermal growth factor[215,216], colostrums and aminoguanidine[217]). Studies using growth hormone, glutamine and fibre have been disappointing[218,219]. Attempts are being made to replace colonic mucosa with small intestinal mucosa to increase absorption[220]. Other areas of importance are in the prevention of gallstones after an intestinal resection and randomised placebo controlled trials using prophylactic antibiotics, ursodeoxycholic acid and cholecystokinin are awaited. An oral nutrient solution containing 100 mmol/litre sodium and having an osmolality of 300 $mmol \cdot L^{-1}$ has yet to be commercially manufactured as an ideal nutrient solution to give to patients with a jejunostomy or high output ileostomy.

Small bowel transplantation is becoming a more successful operation, however few patients are suitable for this (no venous access or parenteral nutrition induced severe liver disease) and even when tacrolimus is used for immunosuppression only 40%-47% of patients will be alive 3 years later and 29%-38% will have a functioning

graft[221,222]. 78% of those who survive with the transplant are able to stop parenteral nutrition. These figures contrast to those for patients on home parenteral nutrition for non-neoplastic reasons who can expect to have a relatively good quality of life good and a survival rate of 70% at 3 years[223,224].

INTRODUCTION

Gastric cancer is common in China[1-42], and its early diagnosis and treatment in advanced stage are difficult[31-50]. In recent years, gene study in cancer is a hotspot, and great progress has been achieved[41-80]. Cancer gene therapy has shifted from the imagination into the laboratory and clinical trials. The "logic of how genes function" coupled with the connections of cell cycle processes to specific gene actions is creating a promise of treating tumors by gene therapy. There have been significant advances against both local and metastatic growths. The potential role of gene intervention extends from diseases caused by single gene defects, through severe viral infections, to polygenic disorders, such as diabetes mellitus and arteriosclerosis. However, gene therapy can be defined as the introduction and expression of an exogenous gene into human cells for therapeutic benefit, and is conventionally restricted to human diseases associated with single gene defects. The rapid progress in our understanding of some of the molecular mechanisms involved in the pathogenesis of cancer and metabolic disorders, with the development of gene delivery vector technology, has urged us to consider novel gene approaches to digestive diseases. There is no shortage of ideas and applications for gene intervention in human diseases, but there are great limitations not only with the efficiency and targeting of the present generation of gene transfer vectors but also with our incomplete understanding of transcription control[1,2].

The graduation of gene therapy from unfulfilled dreams to conventional therapy for gene and acquired disorders will require a mastery of multiple disparate components including gene delivery vectors, regulated tissue-specific gene expression, control of immunity and manipulation of cell viability. Improvement in suicide genes has opened up a whole new treatment modality for treating hyperproliferative disorders and for designing animal models for disease[3]. Along with herpes simplex virus-1 thymidine kinase, a host of additional suicide gene has been developed. A critical comparison of these will follow along with progress in utilizing these reagents for therapeutic benefits[81-90].

The current delineation of the molecular basis of cancer provides a strong rationale to consider gene therapy approaches for cancer as a complement to other cancer therapies. Phase III trials focused on adenoviral vector-mediated delivery of wild-type *p*53 to compliment *p*53 mutations were recently initiated for head and neck cancer and ovarian cancer. Clinical testing of the tumor inhibitory gene E1A, delivered by synthetic vectors is ongoing. Positive clinical data from these clinical studies will establish the use of gene therapy as a component of the multimodal treatment for certain cancers[4-6].

Although the rapid technological advances continue to sustain the field of cancer gene therapy, few individual patients have benefited from the revolution so far. The plethora of clinical trials described confirms that each malignancy has its own ideal strategy based on the associated molecular defects, and there has been rapid progress in this viewpoint. At the same time, there has been a renewed appreciation for the limitations to gene therapy, which include low efficiency of gene transfer, poor specificity of response and methods to accurately evaluate responses, and lack of truly tumor-specific targets at which to aim. With all new therapies, we are climbing a steep learning curve in encountering treatment-related toxicities, as well as profound ethical and regulatory issues[5-9].

GENE THERAPY THEORY

Recent advances in understanding and manipulating genes—the biological units of heredity—have set the stage for scientists to alter patients' genetic material to fight or prevent diseases. One major goal of gene therapy is to supply cells with healthy copies of missing or flawed genes. This approach is revolutionary. Instead of giving a patient a drug to treat or control the symptoms of a gene disorder, physicians attempt to correct the basic problem by altering the gene makeup of some of the patient's cells(www.chgb.org.cn/spec-topics/therapy/text00.htm). Hundreds of major health problems are influenced by gene functions. In the future, gene therapy could be used to treat many of these conditions. Theoretically, it could also be used to alter germ cells (egg or sperm) in order to prevent a gene defect from being transmitted to future generations. However, difficult ethical and social questions as well as technical obstacles will be set in the possibility of germ-line gene therapy (Figure 1, www.chgb.org.cn/spec-topics/hgp/medicine/med03.htm). Gene therapy could also be used as a drug delivery system. To accomplish this, a gene that produces a useful product would be inserted into the DNA of the patient's cells[10-14]. For example, during blood vessel surgery, a gene that makes an ant-clotting factor could be inserted into the DNA of cells lining blood vessels to prevent dangerous blood clots from forming. Many other conditions might also lead themselves to treatment by using this general approach. As medicine operates increasingly at the molecular level, gene therapy for drug delivery could save much effort and expense. It could shortcut the lengthy and complicated process of collecting large amounts of a gene's protein product, purifying the product, formulating it as a drug, and administering it to the patient. However, gene therapy is still extremely new and highly experimental. The number of approved trials is small, and relatively few patients have been treated to date[8,11-13].

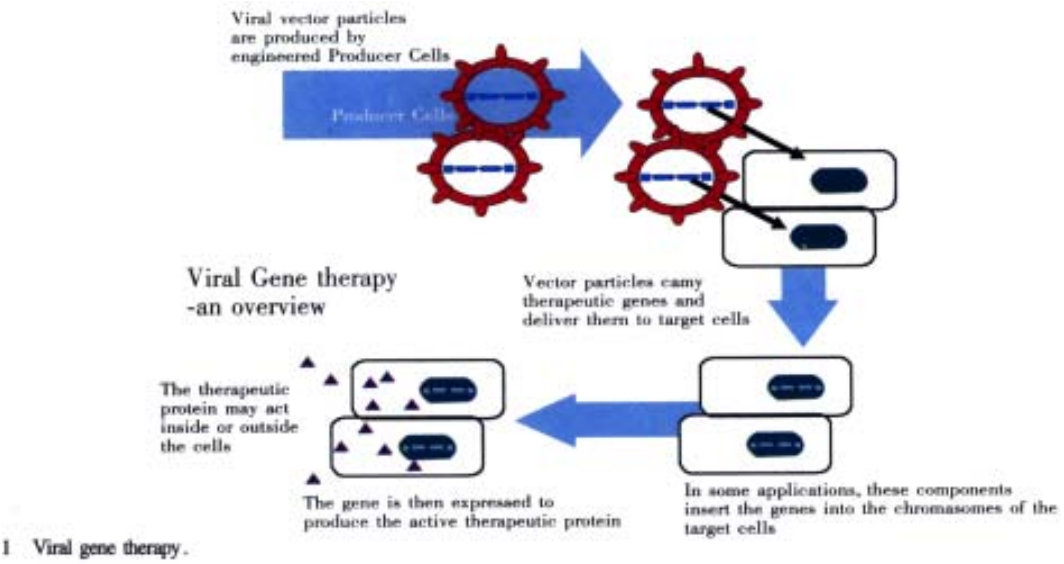

Figure 1 Viral gene therapy.

BASIC STEPS INVOLVED IN CURRENT GENE THERAPY EXPERIMENTS

In some current experiments, cells from the blood or bone marrow are removed from the patient and grown in the laboratory under conditions that encourage them to multiply. Then the desired gene is inserted into the cells with the help of a disabled virus, and the successfully altered cells are selected out, encouraged to multiply, and returned to the patient's body. In other cases, liposomes (lipid particles) or disabled viruses may be used to deliver the gene directly to cells within the patient's body. Basic requirements for gene therapy are as follows[91-110].

Potential of gene therapy

Gene therapy offers a new treatment paradigm for curing human disease. Rather than altering the disease phenotype by using agents that interact with gene products, or are themselves gene products, gene therapy can theoretically modify specific genes resulting in disease cure following a single administration. Initially gene therapy was envisioned for the treatment of gene disorders, but is currently being studied in a wide range of diseases, including cancer, peripheral vascular disease, arthritis, neurodegenerative disorders and other acquired diseases[15-20].

Gene identification and cloning

Even though the range of gene therapy strategies is quite diverse, certain key elements are required for a successful gene therapy strategy. The most elementary of these is that the relevant gene must be identified and cloned. Upon completion of the Human Genome Project, gene availability will be unlimited, but until then the starting point for any gene therapy strategy remains gene identification and cloning for relevant genes related to the disease[3,16].

Gene transfer and expression

Once the gene has been identified and cloned, the next consideration must be expression. Questions pertaining to the efficiency of gene transfer and gene expression remain at the forefront of gene therapy research. Currently much debate in the field of gene therapy revolves around the transfer of desired genes to appropriate cells, and then obtaining sufficient levels of expression for disease treatment. Hopefully, future research on gene transfer and tissue-specific gene expression will resolve these issues in the majority of gene therapy protocols[21-23]. Other important considerations for a gene therapy strategy include: a sufficient understanding of the pathogenesis of the targeted disorder, potential side effects of the gene therapy treatment, and understanding of the target cells to receive the gene therapy[22].

Terminology

Like most fields, gene therapy has unique terminology. The list provided below will clarify the meaning of some of the most common terms[1-3,6,9,22-26].

Ex vivo In gene transfer, transfer of gene material to cells located outside the host. Following transfer of the gene material, the cells are then implanted back into the host. This term has also been called the indirect method of gene transfer.

In vivo In gene transfer, transfer of gene material to cells located within the host. This has also been termed the direct method of gene transfer.

Gene therapy The transfer of selected genes into a host with the hope of ameliorating or curing a disease state.

Cell therapy (genome therapy) The transfer of entire cells, that have not been genetically modified, into a host with the hope that the transferred cells will engraft into and improve host function.

Somatic gene transfer Transfer of genes to non-germline tissues in the hope of correcting the disease state of a patient.

Germline gene Transfer of genes to germline (eggs or sperm) tissues in the hope of altering the genome of future generations.

Transgene The selected gene tested in a gene transfer experiment. For example, if you wished to treat a patient for phenylketonuria, you might plan to transfer a corrected version of the phenylalanine hydroxylase gene into the liver cells. In this example, the corrected version of the phenylalanine hydroxylase gene would be the transgene.

Reporter gene Genes that are used to test the efficiency of gene transfer. Examples include genes encoding luciferase, -galactosidase, and chloramphenicol acetyltransferase.

Gene transfer vector The mechanism by which the gene is transferred into a cell.

Transfer efficiency The percentage of cells that are expressing the desired transgene.

APPROACHES TO CANCER THERAPY

The idealized approach to gene therapy is the replacement of a mutated gene with a correct copy that restores normal functioning and therapeutically alters the malignant phenotype. One meaning of the

word "vector" is "carrier". In the field of infectious diseases, the term has been used to describe an agent, such as an insect, that carries an infectious organism from one individual to another. By analogy, the genetically disabled viruses used in gene therapy are referred to as vectors because they carry genes to cells. Most often, these vectors are derived from mouse retroviruses.

Scientists are working on ways to genetically alter immune cells that are naturally or deliberately targeted to cancers. They are interested in arming such cells with cancer-fighting genes and returning them to the body, where they could more forcefully attack the cancer. Clinical trials along these lines are in progress for the treatment of melanoma. Alternatively, cancer cells can be taken from the body and altered genetically so that they elicit a strong immune response. These cells can then be returned to the body in the hope that they will act as a cancer vaccine. A variety of clinical trials using this approach are now under way. It is also possible to inject a tumor with a gene that renders the tumor cells vulnerable to an antibiotic or other drug. Subsequent treatment with the drug should kill only the cells that contain the foreign gene. Since other cells would be spared, the treatment should have few side effects. Two trials using this approach are in progress for treatment of brain tumors[17-19,24].

Tumor-suppressor gene therapy

Goals of tumor suppressor gene therapy are: cell death and changes in growth of the cell, behavior of the cell, invasiveness of the cell, and metastatic ability of the cell.

Because *p*53 is the most common mutated in cancer and influences transcription, cell cycle movement, apoptosis, and angiogenesis, it is a prime target for gene replacement. In model systems, transduction of cancer cells with *p*53 has been demonstrated to inhibit growth, inhibit angiogenesis, and induce apoptosis.

Early clinical trials using a *p*53 retrovirus have also been encouraging. Current limitations of tumor-suppressor gene therapy are: limited number of target genes known to induce or maintain malignancy; and difficulty of transducing enough cancer cells to result in a cure.

A bystander effect—the death of more cells than are actually transduced—has been proposed although how it occurs has not been yet understood. This effect may result from cell-cell contact, immune mediated responses, *and/or* other local actions.

Other therapeutic possibilities are: combining *p*53 transduction with radiation or apoptosis-inducing chemotherapy, systemic delivery of *p*53 using liposomes, systemic delivery of *p*53 using hepatic artery infusion, use of an adenovirus that replicates only in *p*53 mutant cells and results in cell death through lysis of the cell.

Suicide gene therapy

Suicide gene therapy is the transduction of a gene that transforms a non-toxic "pro-drug" into a toxic substance. Systems under investigation are as follows[22-26]:

Escherichia coli cytosine deaminase (CD) gene + 5-fluorocytosine (5-FC). CD converts 5-FC to 5-fluorouracil (5-FU), a chemotherapeutic agent. This combination produces a bystander effect and has been demonstrated to have some success in animals with hepatic metastasis of gastrointestinal tumors. Delivery of CD to specific sites and the use of tissue specific promotors are a focus of work with this strategy.

Herpes simplex virus thymidine kinase gene (HSV-tk) + ganciclovir (GCV). HSV-tk phosphorylates GCV causing it to inhibit the synthesis of DNA. Like the first system, this also causes a bystander effect. This strategy has been looked at for treatment of localized brain tumors, liver metastases, peritoneal-based metastases, and mesotheliomas. Thus far, the unpredictability of the bystander effect and difficulties in transduction has kept cure rates low. The use of tissue-specific vectors to deliver the genes and the combination of the strategy with radiation may improve the efficacy of the approach in time.

Immunomodulatory gene therapy

Immunomodulatory gene therapy is a method to induce cellular immune responses to metastatic lesions. The strategy involves injecting into the skin of a patient a suspension of irradiated tumor cells that have been transduced with a cytokine gene to stimulate a systemic immune response against tumor-specific antigens[1-4,27-29]. In preclinical cancer models vaccination with tumor cells have been demonstrated to generate a cellular immunological response against "challenge" tumors. There are several problems that still need to be addressed to make this strategy successful[20,30-32]: ① there are only a few tumor-specific antigens that act as recognition targets; ② antitumor activity has been active against a relatively low tumor burden in several studies; and ¢Û the financial and labor costs are high and efficiencies will need to be developed.

Future modifications to the basic strategy may include: a combination of cytokine and costimulatory molecule vaccination to increase tumor vaccine efficiency; the use of *in situ* strategies to invoke immunologic responses, including direct injection into a tumor, as has been done with an adenoviral vector containing the IL-2 gene; combining a suicide gene therapy approach (eg, HSV-tk + GCV) with IL-2 transgene therapy or, more generally, using combinations of cytokines to induce antitumor activity both *in situ* within a tumor and systemically.

The future of cancer gene therapy appears to rest on increased competence with *in situ* transduction; further advances in techniques to induce expression of transduced genes; and further advances in inducing significant antitumor responses at the systemic level. These, in turn, will probably rest on advancing our understanding of tumor immunology, strategies to limit angiogenesis, and continued development of safe and effective vectors to carry genes to directed sites[27-31].

GENE TRANSFER TECHNOLOGY

The gene delivery technology is developing rapidly and there have been specific developments that could be translated into gene-based therapies for gastroenterological diseases. For example, *ex vivo* transfer methods are being studied extensively by using hepatocytes obtained through liver biopsy, partial hepatectomy, and from specimens harvested for liver transplantation. Adult liver cells transiently undergo active proliferation permitting *in vitro* gene transfer even with vectors that require active cell division for entry and expression. Gene transfer may then be facilitated by a number of methods, including viruses, liposome, calcium phosphate coprecipitation, particle bombardment, naked DNA injection, and electroporation. The transfected cells are reintroduced into the host by using, for example, a microcarrier system into the peritoneum, gel beads, hepatocyte coated cell support matrix implanted next to liver tissue, or into the spleen or portal circulation through direct injection[2-5,32-40].

The spectrum of delivery systems for *ex vivo* gene transfer is broadly applied also to the *in vivo* model. Although the transfer efficiency of liposomes is low, these lipids can be made comparatively easily to high chemical purity and have low immunogenicity, which may permit repeated administrations. They have been used successfully in an *in vivo* model, by topical administration to epithelial cells both in the airways and the intestinal tract and also by the intravascular route. A recent study showed high efficiency transfer of the APC tumor suppresser gene in liposome complexes delivered to normal mouse colonic epithelium by rectal catheter infusion. Almost 100% of epithelial cells expressed the gene for up to four days, which

is consistent with the known rate of turnover of this tissue[41]. Intravenous injection of a rat insulin gene expression vector in liposome complexes results in uptake primarily by the liver and spleen. Improvement in hepatocyte uptake can be achieved by incorporating lactosyl ceramide into the phospholipid bilayer; this galactosyl terminal asialoganglioside is specifically recognized by a receptor highly selective for hepatocytes. Many different lipid agents are now being explored for efficacy of DNA transfer and it seems likely that the composition of the complex will have to be optimized for different targets and different routes of administration.

Of the available methods of gene delivery, viruses have been proved the most efficient so far. Achieving viral gene transfer to specific organs for clinical application will be difficult, however, particularly as viral titres 10 to 1000 times higher than those usually attained (typically 106 infectious units per milliliter) will be necessary for *in vivo* strategies. There is now extensive experience with retroviruses whose main advantages include their small size and easy manipulation, and with stable colinear integration with host genome. They are comparatively non-toxic and are efficient for gene transfer. Retroviruses persist in up to 5% of hepatocytes three months after injection of an infected hepatocyte cell suspension into the portal vein after partial hepatectomy. The small intestinal epithelium is an attractive target for gene therapy because of its large surface area, easy accessibility, and the presence of stem cells with known locations. Although few studies have yet targeted the intestinal system *in vivo*, marker genes have been transferred to the epithelial surface with retroviral vectors in animal models. Clearly, unless the therapeutic or marker gene is transferred to the stem cells, the rapid turn-over of this specialized epithelium would seriously limit potential benefits of delivered genes. Retroviruses have a number of disadvantages, notably the requirement for cells that are actively dividing to permit viral DNA integration, the ability to carry only small DNA sequences, and a small but finite risk of causing insertional mutagenesis as a result of random integration[42-47].

Currently alternative viral vectors with potential advantages over retroviruses in specific applications are under development. Adenoviruses can infect non-dividing cells, can be concentrated to high titres, and are comparatively highly efficient vectors. Adeno-associated viruses are ubiquitous and non-pathogenic in humans and can also infect non-replicating cells, but, like retroviruses and adenoviruses, are limited in the size of the foreign gene that can be inserted. This problem may be overcome by the use of herpes simplex group viruses and possibly even vectors based on hepatitis B virus, which has potential additional advantages of hepatotropism and an ability to integrate with host genome *in vivo*.

GENE THERAPY FOR GASTRIC CANCER

The generation of retroviral vectors that infect specific cell types through recognition of cell surface antigens is a promising and effective approach to targeted gene therapy of cancer. Carcinoembryonic antigen (CEA), a highly characterized, cell surface glycoprotein overexpressed by various tumor cells, provides a specific tool for tumor tissue-specific targeting by retroviral vectors. The conventional suicidal gene delivery systems need additional drugs other than their gene products. The inducible nitric oxide synthase (iNOS) gene product yields nitric oxide (NO), which directly induces autocytotoxicity and cytolysis of bystander cells. In the present study, we have developed a novel bifunctional Moloney murine leukemia virus-based recombinant retroviral vector that displays a chimeric envelope protein containing a single-chain variable fragmented (scFv) antibody to CEA and carries the iNOS gene in the genome. The resultant bifunctional retroviral vector showed a specific delivery of the iNOS gene to human CEA-expressing carcinoma cells, resulting in the direct and efficient killing of CEA-expressing carcinoma cells by induction of apoptosis. This is the first report of successful killing of CEA-expressing cells by specific targeting of the iNOS gene. This approach may offer a one-step procedure for effective gene therapy of CEA-expressing tumors[44,48].

This study used a recombinant antisense c-myc adenovirus (Ad-ASc-myc) to evaluate how alterations of c-myc expression in the SGC7901 human gastric carcinoma cells could influence the proliferation, apoptosis and the growth of human gastric tumors in nude mice[42,49]. The human gastric carcinoma cell line, SGC7901 cells, treated with Ad-ASc-myc or adenovirus recombinants carrying LacZ gene (Ad-LacZ) were analyzed by using X-gal stain, MTT, DNA ladder, TUNEL assay, flow cytometric analysis, polymerase chain reaction and western blot *in vitro*. The tumorigenicity and experimental therapy in nude mice models were assessed *in vivo*. The Ad-ASc-myc could strongly inhibit cell growth and induce apoptosis in SGC7901 cells. The proliferation of the Ad-ASc-myc-infected SGC7901 cells was reduced by 44.1%. The mechanism of killing gastric carcinoma cells by Ad-ASc-myc was found to be apoptosis, which was detected by the use of a DNA ladder, TUNEL and flow cytometric analysis. Infection of Ad-ASc-myc in nude mice showed that all three mice failed to form tumors from a 7-30 day period, as compared with injection of Ad-LacZ and parent SGC7901 cells. Experimental therapy on the nude mice bearing subcutaneous tumors of SGC7901 cells showed that intratumor instillation of Ad-ASc-myc inhibited the growth of the tumors. Recombinant antisense c-myc adenovirus-treated tumors were inhibited by 68.9%, as compared with tumors injected with Ad-LacZ and control (LacZ and phosphate-buffered saline). The expression of Ad-ASc-myc can inhibit growth and induce apoptosis of gastric cancer cells *in vitro* and *in vivo*, thus it is a potential clinical utility in gene therapy for the treatment of gastric carcinoma.

The oncofoetal antigen 5T4 is a 72 ku glycoprotein expressed at the cell surface. It is defined by a monoclonal antibody, mAb5T4, which recognises a conformational extracellular epitope in the molecule. Overexpression of 5T4 antigen by tumors of several types has been linked with disease progression and poor clinical outcome. Its restricted expression in non-malignant tissues makes 5T4 antigen a suitable target for the development of antibody directed therapies. The use of murine monoclonal antibodies for targeted therapy allows the tumor specific delivery of therapeutic agents. However, their use has several drawbacks, including a strong human anti-mouse immune (HAMA) response and limited tumor penetration due to the size of the molecules. The use of antibody fragments leads to improved targeting, pharmacokinetics and a reduced HAMA. A single chain antibody (scFv) comprising the variable regions of the mAb5T4 heavy and light a chain has been expressed in *Escherichia coli*. The addition of a eukaryotic leader sequence allowed production in mammalian cells. The two 5T4 single chain antibodies, scFv5T4WT19 and LscFv5T4, described the same pattern of 5T4 antigen expression as mAb5T4 in normal human placenta and by FACS. Construction of a 5T4 extracellular domain-IgGFc fusion protein and its expression in COS-7 cells allowed the relative affinities of the antibodies to be compared by ELISA and measured in real time using a biosensor based assay. The small size of this 5T4 specific scFv should allow construction of fusion proteins with a range of biological response modifiers to be prepared whilst retaining the improved pharmacokinetic properties of scFvs[50].

The assessment of the angiogenic profile of tumors may become an important tool as a guide for the inclusion of novel drugs and molecular therapies into the standard chemoradiotherapy policy. Several studies have shown the prognostic importance of microvessel density (MVD) and of angiogenic factor expression in operable gastric cancer. In the present study we investigated the MVD, with immunohistochemistry the expression of vascular endothelial growth factor (VEGF) and of thymidine phosphorylase (TP) expression as

well as the nuclear expression of p53 protein, in a series of patients with locally advanced inoperable gastric cancer. A strong association of VEGF with TP expression was noted ($P<0.01$), and tumors coexpressing these factors had a statistically higher MVD ($P<0.01$). Nuclear *p*53 accumulation was also related to a high MVD ($P<0.01$), and this was independent of VEGF or TP expression. Microvessel density showed a bell-shaped association with prognosis; cases with an intermediate MVD exhibit a favorable outcome ($P<0.05$). A trend of nuclear TP expression to define a group of patients with poorer prognosis was noted ($P>0.05$), while none of the remaining variables showed any significant association. The immunostaining results allowed the grouping of the angiogenic profile in four major categories: ① highly vascularized tumors with VEGF *and/or* TP expression (about 36%); ② highly angiogenic tumors with p53 nuclear accumulation and low VEGF/TP expression (7%); ③ poorly vascularized tumor with low VEGF/TP and negative nuclear p53 staining (32%) and poorly vascularized tumors with TP expression (7%). Specific therapies targeting hypoxia, VEGF, or TP expression as well as p53 gene therapy have entered clinical experimentation or are already available for clinical use. Using the suggested markers, more than 80% of locally advanced gastric carcinomas can be grouped in different categories according to their angiogenic profile. Such a categorization may be useful for phase III trials on novel therapies targeting the major angiogenesis-related features studied here[51].

Mammalian degenerin (MDEG) is a member of the amiloride-sensitive sodium ion channel family, and its site-directed active mutant (MDEG-G430F) induces massive Na+ influx into cells, leading to cell ballooning and cell bursting. We attempted a novel therapeutic approach for gastric cancers by transferring MDEG-G430F into cancer cells using tumor-specific promoters[52]. In carcinoembryonic antigen (CEA)-producing gastric cancer cells, the level of cell death observed when MDEG-G430F was used with a CEA promoter was similar to that observed when using a potent nonspecific promoter such as the cytomegalovirus promoter. In an *in vivo* study, fusogenic liposome complexes containing MDEG-G430F driven by the CEA promoter were injected intraperitoneally into CEA-producing gastric cancer cells in a mouse peritoneal dissemination model. Although all 15 of the control mice were dead by 50 days postinoculation, 13 of the 15 mice treated with MDEG-G430F survived. These results indicate that transferring MDEG-G430F into cancer tissues using tumor-specific promoters can achieve striking and selective cancer cell death irrespective of the transcriptional efficiency of the promoters used *in vivo*, and suggest that this approach is a promising new strategy for cancer gene therapy[38,41].

Lymph node metastasis is one of the prognostic factors in gastric cancer. Sunami *et al*[63] have previously reported that decreased intercellular adhesion molecule-1 (ICAM-1) expression on cancer cells is associated with lymph node metastasis using a gastric cancer cell. In this study, ICAM-1 gene into a gastric cancer cell line was transected, 2MLN, and analyzed the effect on lymph node metastasis *in vitro* and *in vivo*. A significantly greater amount of peripheral blood mononuclear cells (PBMC) adhered to ICAM-1 transfected 2MLN cells, 2MLN/ICAM cells, than to 2MLN/vector cells. The lysis of 2MLN/ICAM cells by PBMC was significantly increased as compared with that of 2MLN/vector cells. The tumor growth rate of 2MLN/ICAM cells was significantly decreased *in vivo*. Lymph node metastases caused by 2MLN/ ICAM cells were found fewer in number and smaller in size, while many lymph node metastases were caused by 2MLN cells. Histologic findings showed that leukocytes were heavily infiltrated in both the 2MLN/ICAM tumors and metastasis lesions, while only a few leukocytes were observed in the lesions associated with 2MLN cells. The above findings indicate that ICAM-1 gene transduction could prove to be an effective gene therapy for lymph node metastasis of gastric cancer.

The elderly population has much to gain from the advances of molecular medicine, although at present genetic pharmacology remains mostly at the conceptual level. Cancer, in particular, is an increasing health burden and the majority (over 70%) of gene therapy trials aimed at tackling this problem. Available strategies employ both viral and synthetic vectors with the selective delivery and expression of therapeutic genes a pivotal requirement. Clinical trials are now in progress with a view to modulating disease at many different levels, including the direct replacement of abnormal genes. Suicide-gene formulations, and the delivery of "gain of function" genes, which seek to alter the malignant phenotype by indirect means, such as, immunopotentiation and stromal reorganisation. Early data from these studies is tantalising and we must remain optimistic that gene therapy will benefit the patients with cancer by both reducing morbidity and extending life[64].

The antitumoral effects of antisense RNA to K-ras were investigated in gastric cancer cell lines by examining the level of K-ras expression and the tumorigenicity *in vitro* and *in vivo*. Polymerase chain reaction-single strand conformation polymorphism (PCR-SSCP), DNA sequencing, and immunoblotting analysis revealed that YCC-1 gastric cancer cells overexpressed wild type K-ras, whereas YCC-2 cells had a homozygous mutation in codon 12 from GGT (glycine) to AGT (serine), while SNU-1 cells had a heterozygous mutation to GAT (asparagine) in the identical position. Both YCC-1 and YCC-2 cells were transduced by LNC-AS/K-ras containing the antisense 2.2 kb genomic K-ras DNA fragment covering exon 2 and exon 3 specific for K-ras. The application of antisense K-ras significantly downregulated the expression of K-ras and had no influence on the expression of either H-ras or N-ras. The antisense-transduced YCC-2 cells grew considerably slower than the control group transduced by LNCX, whereas the growth inhibition of antisense-transduced YCC-1 cells was less prominent than that of transduced YCC-2 cells. In addition, the tumorigenicity of YCC-2 cells transduced by LNC-AS/K-ras was totally lost. Therefore, our results imply that the specific inhibition of K-ras p21 protein can be accomplished by introducing the antisense covering the K-ras-specific region to gastric cancer cells with aberrant K-ras expression, resulting in a reduction of the growth rate and suppression of tumorigenicity[65]. Dysregulation of apoptosis may be closely related to the development of cancer and its chemoresistance. Overexpression of Bax, an inducer of apoptosis, has led to increased cell death in a variety of cancer cell lines. In this study, we investigated the effect of Bax overexpression in two gastric cancer cell lines, MKN-28 and MKN-45, using a Cre-loxP-mediated inducible expression system. After induction of bax, both cell lines showed decreased proliferation, partially due to increased cell death. Furthermore, Bax-expressing MKN-28 cells were more sensitive to cisplatin. These results indicate that up-regulation of the bax gene may provide a novel strategy for the treatment of gastric cancer[66].

In an attempt to obtain suitable *in vivo* models for optimizing new tumor therapy strategies for intestinal adenocarcinomas, carcinoembryonic antigen (CEA) promoter/SV40 T antigen gene constructs have been used to generate transgenic mice[67]. One transgenic line (L5496), which contains a 424-bp CEA promoter/SV40 T antigen transgene, exclusively developed multi-focal carcinomas in the pyloric region of the stomach in 100% of the offspring. Tumors were already observable in 37-day-old animals as dysplastic cell foci within the mucosal layer. In 50-day-old mice, the tumor mass was mainly restricted to the mucosa with invasive growth into the submucosal tissue. The animals became moribund at 100-130 days of age due to blockage of the pylorus. At this time, the tumor had penetrated into the duodenum and had invaded all tissue layers within the stomach. In contrast to most other stomach tumor

models, this one perfectly matches the development of the most common stomach cancers found in humans. Furthermore, after crossing these mice with mice that are transgenic for the human CEA gene, the double transgenic offspring revealed expression of CEA in the resulting tumors. Thus, being a model for studying gastric carcinoma development and prevention, this system should provide a useful preclinical model for CEA-targeted gastric tumor therapy[31,37].

PROSPECT IN THE FUTURE

Recent scientific breakthroughs in the genomic field and our understanding of the important role of genes in disease has made gene therapy one of the most rapidly advancing fields of biotechnology with great promise for treating inherited and acquired diseases. Many human diseases are caused by the absence or inappropriate presence of a protein. The first promise of biotechnology was to isolate and produce these natural proteins through genetic engineering and recombinant technology. The protein could then be administered to patients in order to compensate for its absence. Because proteins are not orally available, biotech companies focused on innovative methods of protein delivery and sustained drug delivery. Today, gene therapy is the ultimate method of protein delivery, in which the delivered gene enters the *body's* cells and turns them into small "factories" that produce a therapeutic protein for a specific disease over a prolonged period[82-93].

As gene therapy has shifted from the laboratory into the clinic, several issues have emerged as central to the development of this technology: gene identification, gene expression and gene delivery. Academic researchers supported by the *government's* Human Genome Project and more recently through genomics companies originally tackled gene identification. A number of disease-related genes with direct clinical have already been identified, and this number is growing as the field rapidly advances. Some of these genes are in the public domain and some are proprietary. Genes with broader clinical application are also being utilized to make cells express immune activating agents locally at the disease site or to become susceptible to further drug treatment or to immune response recognition[76-84,100-112].

The control of gene transcription is extremely complicated. For the most intensely investigated systems such as the globin genes, our understanding is still fragmental. While most protocols presently use strong viral promoters to drive expression of recombinant cDNA copies of therapeutic genes, future work must be directed to defining the genomic elements that enable temporal and spatial control of expression through a lifetime. The identification of locus control regions that can insulate gene clusters from interference by surrounding genetic influences has been an important step, and many investigators are now working to understand how the promoter and enhancer/silencer elements of a gene interact with structures within the nucleus. Advances in this area will require parallel developments in the sophistication of vector design before they can be transferred into practice[95-104].

INTRODUCTION

The origins of oesophageal surgery, like most surgical treatments, are based in the treatment of traumatic injury. The *Smith Surgical* Papyrus describes the examination, diagnosis and treatment of "a gaping wound of throat, penetrating the gullet"[1]. This article focuses on the important conditions facing the oesophageal surgeon today, with an emphasis on those where there have been significant changes in our understanding of disease or approaches to treatment.

BENIGN OESOPHAGEAL DISEASE: SURGICAL PRINCIPLES AND PRACTICE

Oesophageal motility disorders: Achalasia

Pathogenesis While the exact cause remains obscure, achalasia is clinically characterized by a triad of findings: oesophageal aperistalsis usually with atony, varying degrees of oesophageal dilatation, and failure of normal lower oesophageal sphin cter (LOS) relaxation in response to deglutition. It has been recognized recently that symptoms (particularly pain) can occur when the oesophagus remains undil ated and still exhibits contractions which are frequently of high amplitude, although it should be stressed, non-peristaltic. This is called vigorous achalasia. Most theories surround the concept of a neurogenic origin for achalasia, due to a loss of ganglion cells in Auerbach's plexus[2]. The cause remains obscure. Recent evidence suggests that achalasia may be part of a spectrum of oesophageal motility disorders with potentially common or similar aetiologies including diffuse oesophageal spasm (DOS) and nutcracker oesophagus[3].

Diagnosis The onset of symptoms is typically insidious and diagnosis is commonly made months to years later. Dysphagia is the most common presenting symptom, occurring in over 80% of patients. As the disease progresses, oesophageal dilatation occurs, which may lead to regurgitation and aspiration, resulting in pulmonary complications.

A clear diagnosis of achalasia can rarely be made on clinical grounds alone, and this usually relies on a combination of contrast radiography, motility studies, and endoscopy. Contrast oesophagography characteristically demonstrates a dila ted, possibly tortuous oesophagus, with smoothly tapered "birds beak" narrowing at the OGJ. Endoscopy may be indicated to ensure that no mucosal lesion is present and rule out the presence of a neoplasm in the lower oesophagus which can lead to a manometric pattern indistinguishable from achalasia (pseudoachalasia[4]). Manometry demonstrates absent relaxation of the LOS during wet and dry swallows, as well as usually simultaneous, low amplitude contractions in the body of the oesophagus. Although multiple medications have been tried for achalasia, including calcium channel blockers, nitrates, anticholinergics, prostaglandins, aminophylline and beta-agonists, none provide long-term symptomatic improvement. The intramuscular injection of botulinum toxin into the LOS was popularized in 1994. The toxin directly inhibits the release of acetylcholine from nerve terminals, causing the sphincter fibers to relax. Long term results have been disappointing. Of 28 patients enrolled in one study[5], only 20 experienced a remission lasting longer than 3 months, with most requiring additional treatments. Various strategies to improve results have not led to sustained relief of symptoms. Botulinum toxin injection is probably best regarded as an alternative to pneumatic dilatation in those who are not candidates for surgery.

The use of rigid mechanical dilators has given way to hydrostatic and pneumatic balloon dilators. Sanderson reported improved results in a cohort of 457 patients when successive dilatations were used[6]. Perforation occurs in 1%-5%, leading to a mortality rate of about 0.3%[7]. Balloon dilatation has compared favorably to oesophagomyotomy in some reviews[8], although in the only prospective, randomized trial to date, conducted by Csendes *et al*, oesophagomyotomy achieved 98% good to excellent results compared to just 68% good to excellent results after balloon dilatation[9]. Many authors have, however, considered that this was optimal surgery versus sub-optimal endoscopic therapy due to the nature of the "bag" used for dilatation. Since Heller described oesophagomyotomy, surgery has remained the standard against which all other methods are compared. The myotomy extends for approximately 5 cm to 6 cm above the oesophagogastric junction. It does not need to extend for any great length on to the stomach[10,11]. Intraoperative oesophagoscopy is helpful in assessing the proper proximal and distal extent of the myotomy, allowing the surgeon to accurately visualize the level of the squamocolumnar junction, and test the myotomy by air insufflation.

When performed through the abdomen, there seems to be a higher incidence of pathological gastroesophageal reflux than seen after a thoracic approach. DeMeester and colleagues reported an approximately 12% incidence of pathologic reflux after successful myotomy, reduced to 4% with the addition of fundoplication[12]. Surgeons who advocate the use of a Toupet fundoplication, argue that as it lies posterior and is sewn to the leading edges of the myotomy it allows the mucosa to bulge, keeping the myotomy pulled open so that it is less likely to scar. While reasonable arguments exist for the application of the Dor, Toupet, or Belsey partial fundoplications, none has been shown to have a clear advantage over the others. With the advent of minimally invasive surgery, thoracoscopic and laparoscopic approaches have become popular. Advocates of a thoracoscopic approach have propos ed that the chest offers a better view of the oesophagus in order to achieve a long myotomy[13], although difficulties extending the myotomy onto the anterior wall of the stomach may leave the muscular sling at the gastric cardia intact resulting in an ineffective myotomy and a higher incidence of post operative dysphagia[14]. Most early advocates of the thoracoscopic

approach have converted to laparoscopy.

In any event, the limited surgical morbidity afforded with a minimally invasive approach to oesophagomyotomy and the excellent results achieved have led to a change in the clinical decision making regarding the management of the patient with achalasia. Patients and physicians who once shunned the morbidity and time of recovery from open surgical treatment may consider a laparoscopic procedure to avoid the long term complications of achalasia.

Diffuse oesophageal spasm (DOS) The hallmarks of DOS are intermittent and unpredictable chest pain and non -progressive dysphagia. Dysphagia may be associated with chest pain, which is spontaneous, reproducible, retrosternal in location and may radiate to the left arm or neck. The dysphagia and chest pain may be triggered by certain hot or cold foods, carbonated beverages, or stress. Before the development of manometry, contrast oesophagography was the meth od of choice in making the diagnosis of DOS. A barium swallow may demonstrate s imultaneous, nonperistaltic contractions, with segmentation of the barium column, giving the characteristic "corkscrew" appearance to the oesophageal body, but is unreliable as these abnormalities exist in only a minority of patients[15]. While manometry remains the preferred method of establishing the diagnosis of DOS, disagreement exists over a precise definition. The most widely accepted manometric definition of DOS is two or more swallows resulting in simultaneous contractions in a series of ten wet swallows (the rest being peristaltic). Neither amplitudes, nor duration considered [16]. Recent authors have advocated the use of 24 hr ambulatory manometry, as DOS commonly produces intermittent symptoms that can be correlated with abnormal motility findings during a 24 hour study. An alternative and perhaps more acceptable definition of DOS is "the presence of multi-peaked contractions over at least 10cm of the oesophageal body lasting longer than 15 seconds and with maximum amplitudes of greater than 200 mmHg. Some of these spasm contractions should produce symptoms of ches t pain and/or dysphagia"[17]. Management of DOS is directed at symptom relief. Medical management has included the use of sublingual or oral long acting nitrates, calcium channel blo ckers, and hydralazine, all of which can provide some symptomatic and manometric improvement. Balloon dilatation has been shown to significantly relieve the severity of DOS symptoms in 70% of patients in whom initial medical management proved unsuccessful[18]. The surgical management of DOS is based on oesophagomyotomy, its length being de termined by the extent of manometric abnormalities. Most authors recommend carrying the myotomy through the LOS onto the gastric cardia. In carefully selected patients, the results have been excellent, with significant improvements (P<0.01) in symptoms, and a 93% effective palliation of dysphagia[19]. With the advent of minimally invasive surgery in the last several years, more surgeons are approaching DOS with a thoracoscopic long oesophageal myotomy, although there are no long-term results as yet.

Nutcracker oesophagus High amplitude peristaltic contractions were first described by Brand and collea gues in patients with noncardiac chest pain and dysphagia, and were confirmed by Benjamin and associates in 1979, who coined the term "nutcracker esophagus"[20], on the assumption that these contractions were the cause of symptoms. The manometric definition states that average peristaltic pressures are at least two standard deviations above the normal value, usually defined as 180mmHg[18]. The aetiology of nutcracker oesophagus is unclear. A psychological component has been implicated, and it has been reported to evolve eventually into diffuse oesophageal spasm or achalasia. It is the most common motor disorder diagnosed in patients with noncardiac chest pain.

Management focuses on symptom relief, and like DOS, many patients obtain relief with nitrates and calcium channel blockers, although dilatation seems ineffective. A few case reports have shown positive results after myotomy whose symptoms were not relieved with medical management, although there are no long-term results.

Gastroesophageal reflux disease and hiatus hernia

Gastroesophageal reflux disease (GORD) has become the most prevalent upper gastrointestinal disorder in the west. In 1946, Allison coined the term "ref lux oesophagitis" after identifying the fundamental pathophysiologic process resulting in the inflammation found at the gastroesophageal junction[21]. Since then, it has become clear that injury due to reflux may extend beyond the oesophagus to the larynx and lungs, and heartburn can occur without the changes in the oesophageal mucosa that define reflux oesophagitis. Thus, the broader term GORD was coined to describe any symptomatic condition or pathologic alterat ion that occurred as a result of reflux[22]. Although GORD is thought to account for approximately 75% of oesophageal disease in clinical practice, the epidemiology is not well defined, as no precise definition exists, nor is there a gold standard diagnostic procedure. Heartburn is experienced by approximately 20% to 40% of the western population[23], although the true prevalence is almost certainly higher than reported, as many sufferers treat themselves. Incidence increases with age in both sexes. Many foods exacerbate symptoms including coffee, chocolate, peppermint, and dairy products. Tobacco use and obesity are also related to increased incidence of GORD[24].

Symptoms are not reliable predictors of the presence of GORD. Only 60% of patients with "heartburn" have abnormal 24 hr pH and manometry testing, while chronic heartburn and regurgitation can be present without evidence of mucosal damage on upper endoscopy[25]. Complications develop in approximately 50% of patients with abnormal gastroesophageal reflux by pH testing including oesophagitis, oesophageal stricture, Barrett's metaplasia, and pulmonary disease[26].

Pathogenesis The anatomic and physiologic barriers to the development of GORD involve a lower oesophageal high pressure zone/sphincter (LOS), a gastroesophageal junction that is located intrabdominally, an anatomically intact gastroesophageal flap valve, an intact esophageal clearance mechanism that efficiently evacuates refluxed gastric contents from the oesophageal lumen, and a stomach that empties properly. The role of hiatus hernia in GORD has been controversial, although it clearly alters the anatomic relationship between the OGJ and diaphragmatic crura, and may contribute to LOS incompetence. Patients with large hiatus herni as have been demonstrated to have lower LOS pressures, be exposed to more reflux than patients with no or smaller hiatus hernias, and have prolonged acid exposure in t he oesophageal lumen, which may be secondary to impaired oesophageal clearance, rather than an increased number of reflux episodes[27]. Impaired oesophageal clearance has been demonstrated to correlate with inc reasing severity of inflammation[28]. As oesophageal clearance becomes increasingly impaired, even effective acid suppression may not be enough to reverse the mucosal injury in some patients, and for this reason it has been argued that surgical correction of a dysfunctional LOS should be considered before peristaltic function becomes impaired[29].

Diagnosis and treatment Oesophagoscopy provides the opportunity for the diagnosis of complications of GORD, including the identification of the presence of Barrett's metaplasia. Further

evaluation may involve 24 hour pH and manometry testing, to confirm the diagnosis of GORD and identify motility abnormalities.

The indications for surgery vary, but most recommend antireflux surgery in patients with symptoms refractory to medical management, and when complications exist such as stricture formation, bleeding, or pulmonary manifestations due to regurgitation and aspiration. It is important to recognize that most of the conditio ns which complicate gastroesophageal reflux disease are of a benign nature.

Many operations have been devised to treat GORD. While no single technique can guarantee excellent results under all circumstances, all involve reduction of any hiatus hernia and crural repair. The Nissen fundoplication is undoubtedly the most commonly employee and widely known antireflux procedure in the world. Multiple modifications to the original operation have been made since its original description by Nissen in 1956[30].

The Nissen-Rosetti operation incorporates a 360° fundic wrap without ligation of the short gastric vessels for simplicity and ease of dissection. The Rosett imodification proved quite effective, although postoperative morbidity with regard to dysphagia, gas bloat, and inability to belch are higher (8%) than the later "floppy" Nissen (3%), potentially reflecting the difference when a lower part of the fundus/ greater curve must be used in the wrap and the short gastric vessels not divided[31]. When performed correctly and for the right indications, long term outcomes with the "floppy" Nissen fundoplication have been excellent, with the alleviation of reflux and its symptoms in approximately 85%-90% of patients at 10 years, with morbidity including dysphagia, gas bloat, and inability to belch in the range of 3%-10%[32].

A variety of incomplete (<360°) wraps have been described (Toupet, Lind, Wats on). Historically, the most widely used was the 240° vertical fundoplication developed by Belsey and performed via a left thoracotomy. All produce excellent results in the hands of experienced surgeons with similar results to total fundiplication[33-35]. Hill championed the importance of the gastroesophageal flap valve as one of the chief natural barriers to reflux. He described a musculomucosal valve created by the angle of His, acting to prevent reflux by closing against the lesser curve with increased gastric pressure. The original Hill repair reconstructed the oe sophagogastric junction by posteriorly fixing it to the median arcuate ligament and accentuating the angle of His, thereby reestablishing the gastroesophageal flap valve apparatus[36].

The Hill operation has not enjoyed the popularity of the Nissen, probably as a result of the perceived difficulty in defining the median arcuate ligament. Vansant simplified the dissection in 1976[37], while further modifications have adopted the use of the preaortic fascia and condensation of the crus as the anchor for the repair. Long-term results with the modern Hill antireflux operation have been excellent, in one of the longest postoperative follow-up studies in antireflux surgery, after 15 to 20 years, 88% of patients had good to excellent outcomes[38].

With the development of minimally invasive techniques, it became possible to perform antireflux operations laparoscopically. Isolauri and associates demonstra ted that ten years worth of a proton pump inhibitor will cost 10 times more than a laparoscopic Nissen fundoplication, including the preoperative evaluation and postoperative care[39]. An initial report by Dallemagne[40] led to the rapid popularization of laparoscopic Nissen fundoplication throughout the world. Hinder reported on 198 patients who underwent laparoscopic Nissen fundoplication from 1991 to 1994, the main indication for surgery being symptom s refractory to medical management. The outcome for most patients was excellent , although nearly a third had problems with postoperative dysphagia or gas bloat[41]. Watson reported on 230 laparoscopic Nissen fundoplications, with a median follow-up of 16 months with symptom relief in 88%[42]. Whether the long term results of laparoscopic fundoplication will match those of open surgery remain to be seen, but initial results appear favourable when the surgery is performed at high volume centres.

Although laparoscopic antireflux surgery has proved successful for patients with small hiatus hernias, larger hiatus and paraesophageal hernias pose additional problems. The technical imperatives, as outlined by Horgan for open surgical technique, apply equally well to laparoscopic repair and include transhiatal oesophageal mobilization with reduction of the oesophagogastric junction into the abdomen, complete reduction of the hernia sac, effective crural closure, attention to the geometry of the fundoplication, and an anchored repair[43].

Although most series have demonstrated good to excellent results[44-46] they have been criticized for their short follow-up periods and lack of objectivity. Hashemi and associates demonstrated a concerningly high recurrence rate in patients who underwent laparoscopic repair of paraesophageal hernias. Routine postoperative contrast oesophagography demonstrated a 43% recurrence rate, compared to 15% following open surgery at 5 years[47], prompting many surgeons to discontinue the laparoscopic approach to large hiatus and paraesophageal hernias. While the presence of a large hiatus or paraesopha geal hernia is not a contraindication to laparoscopic repair, the high recurrence rate reported in the recent literat ure should prompt responsible surgeons to follow patients objectively while more data are obtained, preferably through prospective trials.

OESOPHAGEAL CANCER

The German-born surgeon, Dr. Franz Torek, working in New York in 1913, performe d the first successful transthoracic resection of the oesophagus for carcinoma[48]. In 1933 Grey Turner successfully resected an intra-thoracic oesophageal tumor by the trans-hiatal route, and in the same year Ohsa wa reported success in eight patients undergoing transthoracic oesophageal resec tion with intrathoracic oesophagogastrostomy for carcinoma of the lower oesophagus[49]. While refinements in techniques reduced morbidity and improved outcomes in the latter part of the 20th century, surgical treatment continues to be viewed unfavorably, mostly due to high operative mortality and poor survival statistics as documented by Earlam[50] and Muller[51]. Recent advances in perioperative care, more accurate staging techniques, better patient selection and the addition of chemo-radiotherapy have led to decreased perioperative mortality and improved survival rates, which has challenged the pessimistic attitudes toward oesophageal resection.

Pathogenesis Oesophageal carcinoma has a unique and changing epidemiologic pattern. Ge ographic variation is remarkable with 5 cases per 100 000 population in the United States, 7-10 cases per 100 000 in the United Kingdom, to over 500 cases per 100 000 population in parts of Iran, China, and Russia, leading most to believe that environmental causes play a large role in the development of oesophageal carcinoma[52]. Factors associated with an increased risk of oesophageal cancer include age, gender, race, excessive tobacco and alcohol use, diet and a variety of nutritional deficiencies including retinoic and ascorbic acids, riboflavin, and zinc. In areas where oesophageal carcinoma is endemic, diets appear to be low in fruit, vegetables, minerals, and vitamins A, C, and riboflavin[53].

Another remarkable feature of oesophageal cancer is the recent change in histologic pattern. While 20 years ago adenocarcinoma made up just 10% of oesophageal cancers, it now represents approximately 50% to 70% in the western world, virtually all due to a marked increase in the incidence of adenocarcinoma. While the exact reason for this is unknown, it has something to do with the rising incidence of Barrett's metaplasia, a condition which occurs as a response of the lower oesophageal epithelium to chronic

gastroesophageal reflux. The associ ation of specialized Barrett's oesophagus with an increased risk of developing oesophageal adenocarcinoma is well documented. Further understanding of the biology of oesophageal cancer, coupled with the identification of significant risk factors, such as Barrett's oesophagus, have permitted the surveillance of high-risk patients and the identification of early stage disease. The impact of this on future survival remains to be seen.

Diagnosis and staging The decision to consider a patient for curative therapy is essentially influence d by fitness to withstand treatment aimed at cure and accurate staging. At presentation, a careful history and physical exam may immediately reveal that the disease is beyond cure. Severe weight loss, spinal pain, recurrent laryngeal nerve palsy, or lymphadenopathy all indicate advanced disease. A chest x-ray may demonstrate mediastinal enlargement, tracheal deviation, a dilated fluid filled oesophagus, pleural effusions, or nodular lung involvement; all indicating advanced disease. Flexible endoscopic examination permits tumour visualization and biopsy. Contrast oesophagography can be used to confirm tumour location and length, and may be particularly useful in the detection of fistula formation or in clarifying anatomy in patients who have undergone previous gastric surgery.

Although computed tomography is not useful in staging early carcinomas of the oe sophagus[54], it can define the extent of more locally advanced disease as well as identify distant metastases. Patients with haematogenous metastases are incurable. With the advent of endoscopic ultrasound, the ability to more accurately define the locoregional extent of oesophageal carcinoma has improved significantly. Endoscopic ultrasound provides an accurate assessment of oesophageal wall p enetration (T-stage), as well as peri-tumoral and regional lymph node status (N-stage). Nodal positivity is the single factor which correlates most with the chance for cure[55], and the detection of contiguous organ invasion has made "open and close" or by-pass surgery virtually obsolete. Multiple reports have demonstrated an overall accuracy of approximately 90% for T-staging and approximately 80% to 85% accuracy for N-staging[56-58]. In addition, thoracoscopic and laparoscopic techniques are being more widely used to exclude pleural or peritoneal metastases again with accuracy approaching 90%[59].

Surgical treatment and results Exactly what constitutes an adequate resection margin or extent of lymph node dissection is widely debated, but it is evident that prolonged survival in oesopha geal carcinoma depends principally on the completeness of surgical resection as well as the pathologic stage of disease. Most surgeons recommend removing at least a 5 cm margin of normal oesophagus proximal to the lesion with surrounding pleura and fibro-areolar tissue along with the entire distal oesophagus and cardia. More proximal oesophageal tumors require a total thoracic oesophagecto my and cervical anastomosis for adequate resection margins, while more distal oesophagogastric junction tumors require removal of more stomach, especially along the lesser curve. A number of techniques have been developed for oesophageal resection, and while there does not appear to be a substantial difference in the overall mortality be tween procedures, the type and degree of morbidity does vary. The most popular approach in the west is the two-phase (abdomen, right chest) operation popularized by Lewis[60]. While devised principally for mid-oesophageal tumors, it is equally useful for distal tumors as well in providing adequate resection margins. A three-phase oesophagectomy combines a cervical incision for total thoracic oesophagectomy and cervical oesophagogastric anastomosis[61].

Transhiatal oesophagectomy involves the resection of the intrathoracic oesophagus through the oesophageal hiatus and the thoracic inlet with a cervical oesopha gogastric anastomosis. Most of the operation can be done under direct vision through the diaphragmatic hiatus, although the mid and upper thoracic dissection is done bluntly, with risk of tracheobronchial or great vessel injury. Many surgeons believe transhiatal oesophagectomy to be an appropriate choice only for distally located tumours due to the risk of radial margin positivity and the inability to perform an adequate intrathoracic lymph node dissection with mid-oesophageal tumours.

A left thoracoabdominal oesophagectomy is also widely used for lower oesophageal tumors. Anastomosis may be performed in the left chest or after further mobilization of the upper oesophagus a cervical oesophagogastric anastomosis can be fashioned. The incidence of symptomatic reflux is highest following 'low' anastomosis in the left chest and diminishes with higher anastomoses. There are relatively few series that have compared right and left thoracotomies for oesophageal resection, although Launois and associates demonstrated similar operative mortality and survival rates for both approaches[62]. The choice of conduit for reconstitution of gastrointestinal continuity is largely based on surgical preference, as there have been no controlled clinical trial s comparing techniques. Stomach, colon and jejunum have all been used successfully. The easily mobilized stomach has been found by many surgeons to be the best functional replacement for the resectedoesophagus. There is no standard for performance of the oesophagogastric anastomosis; the advent of circular stapling devices may have resulted in a decrease in anastomotic leak rates. Stricture rates of approximately 5% to 10% are seen with handsewn anastomotic techniques and medium sized stapling devices, although this can be as high as 30%-40% with smaller stapling anvils[63]. Stricturing occurs more commonly with cervical than intra-thoracic anastomoses irrespective of technique[64].

Emptying of the gastric conduit, occurs mainly as a gravity dependent mechanism with very little propulsive action in the gastric tube[65]. While there is continued debate regarding the need for a gastric emptying procedure, randomized studies do not support the use of pyloroplasty or pyloromyotomy to improve postoperative function. Gastric outlet obstruction after gastric pull-up may be due to axial rotation of the gastric tube and not pyloric function, thus, close attention should be paid intraoperatively to maintaining the correct anatomic orientation of the conduit. The extent of lymphadenectomy performed during oesophageal resection for carcinoma is highly variable. While no prospective trial has been performed in the was tern hemisphere demonstrating improved survival with more extended lymphadenecto my, the "three field" lymph node dissection has been claimed by Japanese autho rs to contribute to their improved survival statistics. Advocates of standard oesophagectomy argue that once an oesophageal carcinoma has penetrated the oesophageal wall and involved peritumoral lymph nodes, surgical cure is unlikely. Skinner, however, demonstrated that the removal of involved regional lymph nodes will improve survival rates[66], while Sasaki and colleagues showed that patients who underwent extended lymphadenectomy with oesophageal resection had significantly improved survival compared to patients who underwent more limited node dissection[67].

A standard lymphadenectomy in oesophageal cancer should include all paraesophageal, subcarinal, left gastric, common hepatic, proximal splenic, and crural nodes . A proper oncologic resection with adequate lymphadenectomy might improve survival, but it will certainly lead to more accurate staging and avoid the error of "improved" survival figures which reflect the stage migration inherent in a more accurate nodal assessment. Extended lymphadenectomy, however, does potenti ally increased morbidity, particularly when applied to nodes along the recurrent laryngeal nerve chains[68].

Postoperative mortality in oesophageal resection has decreased from approximatel y 25% to less than 8% in the past two decades. While complications have also decreased, a third of patients can be expected to have a major complication after surgery, including arrythmias, pulmonary embolus, pneumonia, or anastomotic leak . Most patients resume a normal diet within three to six months following surgery and maintain their weight at approximately 90% of normal. While surgery remains the mainstay of therapy for oesophageal carcinoma, there is considerable cur rent interest in combined modality approaches.

Loco-regional disease is a significant cause of morbidity and mortality, but even when this is controlled, most patients eventually die of metastatic disease. Combined modality therapy aims to improve local control, eliminate micrometas tatic disease and improve cure rates. Adjuvant systemic chemotherapy has not been shown to reduce the risk of metastases in randomized studies[69,70]. While some studies have shown a statistically significant reduction in loco -regional recurrence with the use of post-operative radiation, this also has not translated into a survival advantage[71].

Most enthusiasm now focuses on the use of neo-adjuvant multimodal therapy designed to reduce the size of the primary tumor to potentially improve the curative resection rate, and expose micrometastases to systemic chemotherapy at an early stage. Randomized trials comparing preoperative chemoradiation plus surgery to surgery alone vary considerably with regard to chemotherapy regimens, radiation doses, histologic type of cancer, and numbers of patients accrued making conclus ions difficult. Trials conducted by Walsh *et al*[72] and Forastiere *et al*[73] have demonstrated either a statistically significant survival advantage or trend toward improved survival with preoperative chemoradiation, while others have not[74]. While it is clear that some oesophageal carcinomas respond dramatically to preoperative chemoradiation, further prospective randomized trials are needed to see if this will translate into a clear survival advantage.

Parks RW, Garden OJ. Liver resection for cancer. *World J Gastroenterol*, 2001;7(6):766-771

HISTORY OF HEPATIC RESECTION

The earliest hepatic surgery was almost exclusively performed for trauma with records from as far back as 1870[1,2]. Among the earliest liver resections performed for tumor were those of Langenbuch in 1888[3], Tiffany in 1890[4], and Lucke in 1891[5]. By 1899, 76 cases of liver resection had been reported with a mortality rate of 14.9%[6], a remarkably low figure for operations of this magnitude, all performed at the end of the 19th century. Wendel undertook the first anatomical resection for liver cancer in 1911 when he performed a right lobectomy. The patient who had a primary hepatocellular carcinoma survived for 9 years following the resection[7]. The earliest methods of achieving haemostasis were by electrocautery, elastic tourniquet, and suturing with flexible blunt needles. In 1902, Pringle described compression of the portal triad as a technique to reduce bleeding. A year later Anschutz described finger fracture although this was popularized much late r by Lin[8]. Over the past 50 years, the basic techniques of liver surgery have been refined and developed. Improved survival and reduced mortality rates associated with hepatic resection have resulted in a broader application of these operations, nonetheless, the majority of procedures are performed with a curative intent, although occasionally a palliative procedure may be considered.

BASIC HEPATIC ANATOMY

Precise knowledge of the surgical anatomy of the liver is essential before embar king on hepatic resection. The liver is supported beneath the diaphragm by the reflections of its visceral peritoneum, namely the right and left coronary ligaments, the left triangular ligament and the falciform ligament. There have been many descriptions of the internal architecture of the liver, but that reported by Couinard in 1957[9] is the most widely recognized and remain s the most clinically useful description for the hepatic surgeon.

The anatomical divide between the right and left liver is not at the falciform ligament but in a plane which runs from the gallbladder fossa to the inferior vena cava and is known as the midplane of the liver (the principal plane or Cantlie's line). Within this imaginary plane runs the middle hepatic vein which drains into the vena cava at a common confluence with the left hepatic vein. The right and left hemilivers are themselves further divided by the right and left hepatic vein and the right and left branches of the portal vein. Couinaud identified eight segments in the liver, each supplied by its own portal venous and hepatic arterial pedicle and each drained by a single bile duct. Terminology for various anatomical portions of the liver and the surgical removal of these portions continues to evolve. The Terminology Committee of the Intern ational Hepato-Pancreato-Biliary Association recently published a description of the newest terminology of hepatic anatomy and liver resections[10]. It had no responsibility to investigate anatomy per se and based its report on accepted internal liver anatomy. Right hepatectomy (or hemihepatectomy) and left hepatectomy (or hemihepatectomy) are the appropriate terms for removal of the right and left sides of the liver respectively. Any individual anatomical segment of the liver can be removed, the procedure being referred to as a segmentectomy. Groupings of segments can also be removed and these procedures may be referred to as sectionectomies (or sectorectomies) (Figure 1 a,b).

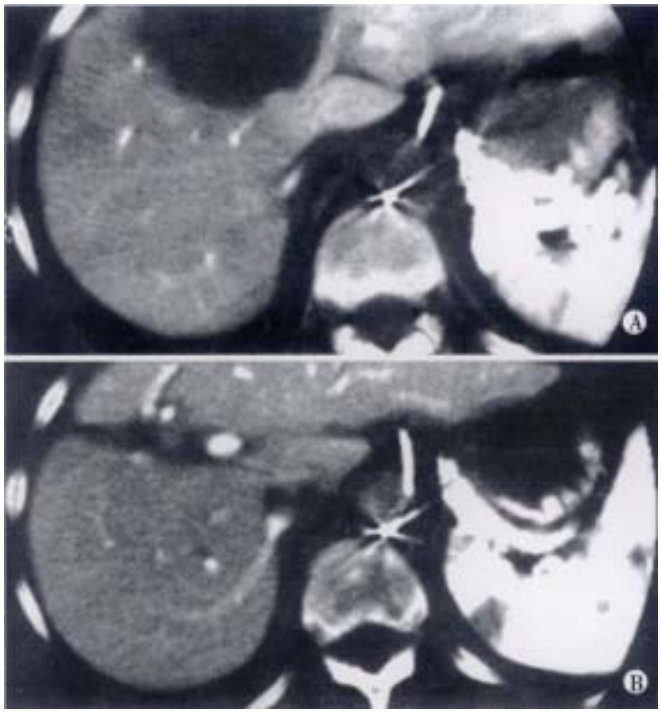

Figure 1 (a) Solitary hepatic metastasis occupying segment 4, 5 and 8, managed by trisegmental resection. (b) CT scan at one year showing hypertrophy of residual left lobe and segments 6/7.

PREOPERATIVE ASSESSMENT

The aim of preoperative investigations should be to determine the nature of the lesion and assess whether it is resectable. Furthermore, the relationship of the tumour to the hepatic vasculature will aid a decision as to the probable surgical procedure.

Liver function tests are frequently abnormal in patients with malignant liver disease and particular attention should be paid to the coagulation profile. Hepatitis B and C antigen screening should be undertaken in view of the associat ion between primary hepatocellular carcinoma and hepatitis. Elevation in tumour markers such as carcinoembryonic antigen (CEA) or alphafetoprotein (AFP) may point towards a diagnosis of colorectal liver metastasis or primary

hepatocellular carcinoma and will serve as a useful baseline for further follow-up.

Characterisation of hepatic lesions is provided by radiological imaging of the liver. Ultrasonography (US) and computed tomography (CT) are the cornerstone of diagnosis and often complement one another. However, magnetic resonance imaging (MRI) is becoming more widely available and may supersede these imaging techniques as the principal radiological investigation. A particular advantage of MRI is its ability to show major blood vessels accurately and demonstrate their relationship to tumour masses. Abdominal ultrasonography gives information regarding the number and size of hepatic lesions and will distinguish liver cysts from solid tumours. If ultrasonography shows multiple solid lesions suggesting incurable malignancy, a biopsy may be performed during the same session to obtain a pathological diagnosis. Duplex ultrasonography may provide additional information regarding involvement of majo r blood vessels and may be particularly useful in the preoperative evaluation of hilar cholangiocarcinoma[11].

Computed tomography may provide more detailed information on the number and size of liver lesions. Most metastases are hypovascular and appear as low attenuation lesions on contrast-enhanced CT scanning. Tumours that may be hypervascular i n relation to normal hepatic parenchyma (e.g. primary hepatocellular carcinoma and metastases from pancreatic islet cell tumour, carcinoid and renal cell carcinoma) may become isodense on a contrast-enhanced CT scan and therefore these patients should undergo both a non-contrast and dynamic contrast study. Dynamic CT scanning ensures enhancement of branches of the portal vein and the hepatic veins so that the relationship of the lesion can be assessed with regard to the hepatic vasculature. This enables determination of resectability and planning of surgical resection. CT arterioportography (CTAP) is a technique whereby the contrast medium is delivered into the portal venous system without prior systemic distribution and dilution. This is achieved by selective catheterisation of the superior mesenteric artery and results in greater hepatic parenchymal enhancement.

Technology now allows three-dimensional modelling of the liver based on spiral computed tomography images[12-14]. Such techniques not only permit detailed reconstruction of the vascular and biliary anatomy of the liver but also offer the potential to measure liver volume before surgery which could be useful in determining the extent and nature of hepatic resection. Accurate assessment of liver volume and an estimate of liver function may also allow prediction of postoperative liver failure in patients undergoing resection, assist in volume- enhancing embolisation procedures, help with planning of staged hepatic resection for bilobar disease and aid in selection of living-related liver donors. Wigmore *et al* have recently demonstrated that virtual hepatectomy of 3-D CTAP reconstructed images provides an accurate prediction of liver mass removed during subsequent hepatic resection[15].

Several techniques have been described for functional assessment of liver capaci ty. These measure drug excretion (e.g. lidocaine clearance[16] or its metabolite monoethylglycinexylidine[17]) or dye excretion (indocy anine green[18,19]). In the future, in patients with impaired hepatic function for whom liver resection is being contemplated, it may be advantageous to combine a functional assessment with an estimation of liver volume to be resected by virtual hepatectomy as described above.

Hepatic angiography is not employed routinely in modern clinical practice to pro vide a specific diagnosis or aid in the planning of surgical intervention, although it may facilitate infusion of lipiodol which may demonstrate “occult” hepatoma in cirrhotic patients being considered for curative resection of primary hepatic malignancy. Laparoscopy is increasingly used to allow direct visualisation of liver lesions and can be combined with laparoscopic ultrasonogr aphy to provide high resolution images[20].

Liver lesions amenable to resection in patients who are fit for surgical intervention should not be biopsied as this may be associated with haemorrhage, sampling error, misdiagnosis and needle-tract tumour seeding. Percutaneous biopsy should only be performed in those patients who are not considered candidates for surgical intervention and only where the results of biopsy might influence further management. In patients with primary hepatocellular carcinoma, it may be valuable to take a biopsy of the uninvolved liver to detect and determine the severity of parenchymal liver disease such as chronic hepatitis or cirrhosis.

Extrahepatic metastases should be sought by means of a chest CT scan before major resection is undertaken, although it is accepted that pulmonary nodules may not always represent metastatic deposits. Upper and lower gastrointestinal endoscopy or barium studies, intravenous urography and mammography (in female patients) may be valuable in patients with a solitary liver metastasis of unknown origin. More recently, positron emission tomography (PET) and isotope scanning using CEA antibodies have been investigated and have shown promising results in demonstration of the hepatic lesions and in determining the extent of extrahepatic disease[21].

Portal vein embolisation (PVE) of the hemiliver to be resected has been proposed to induce homolateral atrophy and contralateral compensatory hypertrophy of the remnant liver and thereby reduce the risk of postoperative liver failure[22]. The concept of PVE appears to be well accepted when performed on healthy liver when extensive resections are being considered[23,24], however, its use in injured liver is also becoming more widely accepted[23,25,26].

PREOPERATIVE PREPARATION

Anaemia and coagulation disturbances should be corrected preoperatively. Administration of vitamin K will improve coagulation disorders secondary to poor nutrition and absence of luminal bile salts in patients with biliary obstruction, but will not reverse coagulopathy secondary to hepatocellular dysfunction. Fresh frozen plasma should be administered to correct the prothrombin time to within 2 seconds of control before surgery if possible.

Patients with obstructive jaundice and portal hypertension have a higher risk of bleeding complications and hepatic decompensation in the postoperative period. Preoperative biliary drainage may improve some of the pathophysiological disturbances associated with obstructive jaundice[27], however placement of biliary endoprostheses may introduce infection and exacerbate subsequent complications[28,29]. The role of preoperative biliary decompression prior to definitive hepatic resection remains unclear.

Surgery in patients with active alcoholic hepatitis carries a substantial risk and abstinence for as little as 3 months will reduce this risk. Patients with active hepatitis who are on long-term steroid therapy may require an increase in steroid cover during the perioperative period. Ascites should be controlled preoperatively by salt restriction and diuretic therapy as ascites increases the risk of impaired wound healing.

Assessment of underlying liver disease is vitally important because, although ex tensive hepatic resection may be well tolerated when the remaining liver has nor mal function, even minor resections in cirrhotic patients may be poorly tolerate d. The use of clinical and biochemical parameters (using the modified Child-Pugh classification) in the assessment of surgical risk in cirrhotic patients is well established and correlates well with surgical risk.

OPERATIVE TECHNIQUES

Hepatic resection is performed under general anaesthetic with a controlled central venous pressure of less than 5 mmHg. For the majority of hepatic resections, the initial incision should be a bilateral

subcostal incision. Exposure may be further improved in some patients with a narrow costal margin by extending the incision in the midline upwards to the xiphoid process.

In patients with hepatic malignancy, a thorough search is made of the peritoneum and regional lymph nodes to exclude extrahepatic dissemination of malignancy. The liver is carefully palpated and intraoperative ultrasound is undertaken to confirm the position of the tumour and its relationship to the hepatic vasculature.

All major hepatic resections mandate control of the inflow vasculature and hepatic venous outflow to and from the portion of the liver to be resected with maint enance of good hepatic arterial and portal venous blood supply to the remnant. This may be done by dissection of the relevant portal pedicle at the hilus and outside the liver substance as is the authors' preference, or alternatively, the major branches may be secured within the liver following division of liver tissue. We have not found it necessary to consider the use of total vascular exclusion[30] in the last 10 years and have favoured "classical" hepatic resection in preference to segmental resections particularly for metastatic tumours[31]. Detailed descriptions of these various techniques are outwith the scope of this article but can be referred to in many major texts[32,33]. The liver parenchyma can be transected in a number of ways, but it is the authors' preference to employ a Cavitron ultrasonic surgical aspirator (CUSA) which skeletonises the vessels within the hepatic parenchyma, allowing their identification before they are damaged. Small vessels (<2 mm) can be secured by diathermy before division, although larger vessels and branches of the hepatic veins are best secured by ligation or application of clips. The relevant hepatic vein(s) may be divided using a vascular stapler or clamped, divided and oversewn with a continuous non-absorbable suture.

The exposed raw surface of the transected liver, vena cava and retroperitoneum are carefully inspected for any bleeding which should be controlled with diathermy or suture. An argon beam coagulator can be applied to the raw surface to ensure haemostasis. Thrombin glue can also be sprayed on these areas to minimize the risk of postoperative bile leakage. It is the authors' preference to place routinely a large tube drain connected to a closed drainage system before wound closure.

POST-OPERATIVE MANAGEMENT

High dependency nursing care is required to provide adequate observation of vital signs and conscious level in the postoperative period. Monitoring includes regular measurement of heart rate, blood pressure, central venous pressure, oxygen saturation, urine output and drain losses.

Patients undergoing major hepatic resection and those with poor preoperative liver function are at particular risk of developing postoperative hepatic decompensation. Maintenance of adequate liver function can be judged by regular assessment of conscious level, acid base status, blood glucose levels, blood lactate levels and prothrombin time.

COMPLICATIONS

Despite improvements in surgical technique and perioperative care, major complications and death may occur following major hepatic resection and the risks to the patient should not be underestimated. In a series of 133 hepatic resections in 129 patients published from our own unit[34], the overall operative mortality was 4.7%. Major early morbidity occurred in 20% of patients and resulted in unplanned radiological or repeat operative intervention, transfer to the intensive care unit in some patients and prolongation of hospital stay. Other major series report similar morbidity and mortality rates[35,36].

Postoperative liver failure from inadequate functional residual liver tissue is the leading cause of death after hepatectomy[37,38]. It has been previously reported that patients with a postoperative residual volume of 35% with good function are at low risk of developing liver failure[39]. However, in patients with impaired liver function, smaller resections may be hazardous.

INDICATIONS FOR HEPATIC RESECTION

The main indication for hepatic resection is primary or secondary hepatic malign ancy. (Figure 2 a,b). Primary malignant hepatic lesions include hepatocellular carcinoma, and less common tumours such as cholangiocellular carcinoma and haem angiosarcoma. Liver resection for metastatic disease is predominantly undertaken for patients with colorectal metastases, however, resection has been performed for non-colorectal liver metastases. Hepatic resection is also undertaken for contiguous tumours involving the liver, such as in selected patients with gallbladder carcinoma or cholangiocarcinoma involving the extrahepatic biliary tree. The indication for hepatic resection for malignancy in our own unit is shown in Table 1.

Hepatocellular carcinoma (HCC) is one of the world's most common malignancies and is particularly challenging because it usually develops on a background of chronic inflammatory liver disease[40]. The mean overall survival of patients with untreated HCC is generally reported to be 3 to 4 months after symptom s appear, however, in Japan and other parts of the world where HCC is being detected earlier, median survival times are nearly 6 months. Surgical resection is the treatment of choice for HCC if the resection can be performed safely and will not leave gross residual disease, however, unfortunately only a small proportion of HCC's are amenable to surgical removal. In non-cirrhotic patients, the tumour has often reached a substantial size by the time of presentation, whereas cirrhotic patients frequently have compromised liver function sufficient to preclude even segmental resection. The average survival time of patients who have undergone resection is about 3 years. Five year actuarial survival rates of 60%-70% have been reported in patients with Stage I/II disease compared with corresponding survival rates of 20%-30% in patients with more advanced disease (stage III/IV)[41,42]. Although the operative mortality rate from liver failure after hepatectomy for patients with HCC has decreased with experience[43], it still ranges from 0%[44,45] to 32%[46-48].

Table 1 Indication for hepatic resection for malignancy in Edinburgh (1988-2001)

Indication	Number
Primary liver tumor	
Hepatocellular carcinoma	30
Intrahepatic cholangiocarcinoma	8
Angiosarcoma	1
Clear cell carcinoma	1
Metastatic liver tumor	
Colorectal adenocarcinoma	131
Stromal tumor	8
Carcinoid tumor	7
Breast metastases	2
Appendiceal metastases	2
Metastatic melanoma	2
Contiguous tumor involving liver	
Hilar cholangiocarcinoma	29
Gallbladder carcinoma	7
Adrenocortical tumor	1
Total	230

Figure 2 (a) Large solitary metastasis resected by extended right hepatectomy. (b) CT scan showing hypertrophied left and caudate lobes with no evidence of recurrence at one year.

Resection if possible is the treatment of choice for colorectal metastases and offers the only potential for cure[35,49]. Several studies have document ed the unfavourable prognosis of untreated hepatic metastases from colorectal cancer. Without treatment, 60%-75% of patients are dead at 1 year and the mortality rate at 3 years is almost 100%[50,51]. Five year survival rates in patients undergoing hepatic resection for colorectal metastases range between 25%-40% in most major centres[35,52,53]. Figures from the authors' unit demonstrate a 3-year survival rate of 65% in patients who underwent resection of colorectal liver metastases[34]. The number of metastases is no longer considered to be as important a predictor of long-term survival as previously[53,54]. Complete excision of all demonstrable tumour with clear resection margins has been shown to be of much greater importance[35]. Segmental-based resection allows excision of bilateral or multiple liver lesions that previously might have been deemed irresectable. Staged resection is another technique whereby large volumes of liver parenchyma may be resected without inducing hepatic insufficiency. There is increasing evidence that selected patients who develop recurrent hepatic tumour following previous resection of colorectal liver metastases will benefit from re-resection[55,56].

Surgical resection of hepatic metastases from neuroendocrine tumours is curative in some cases and is usually effective in relieving symptoms[57]. Palliative debulking or cytoreductive surgery is often worthwhile as it offers a chance of prolonged survival and may cause complete or partial relief of the incapacitating symptoms related to hormone production. McEntee *et al* reported the outcome of 37 patients (24 carcinoids and 13 islet cell tumours) who unde rwent hepatic resection for metastatic neuroendocrine tumours[58]. Seventeen resections were considered curative and in this group, results were encouraging in terms of survival and symptom relief, however in patients undergoing palliative resection the mean duration of symptom relief was only 6 months. Thompson *et al*, however, reported that half their patients with islet cell tumours had symptomatic improvement with a mean duration of 39 months after noncurative resection[59].

The role of hepatic resection for non-colorectal non-neuroendocrine metastases is less well defined. Most studies report small numbers of patients and must be regarded as anecdotal. Schwartz' review of the literature concluded that little improvement could be anticipated for resection of metastases from tumours of the oesophagus, stomach, small intestine or pancreas[60]. Similarly, there was little evidence to support routine resection of metastases from gynaecological or breast carcinomas, however, resection of metastases from primary renal cell carcinoma, Wilms' tumour, and adrenocortical carcinoma was indicated. Harrison *et al* reported a single centre experience of 96 patients who underwent liver resection for non-colorectal, non-neuroendocrine metastas es with no perioperative deaths[61]. The overall survival rate at 1, 3 and 5 years was 80%, 45% and 37% respectively (median survival, 32 months), with 12 actual 5 year survivors. Patients with genitourinary primary tumours exhibited the best outcome followed by patients with primary soft tissue tumours (breast, melanoma and sarcoma). Hepatic resection for non-colorectal gastrointestinal primary tumours was generally associated with a poor survival. Similar results have been reported from other centres where long-term survival was only seen in patients with non-GI-origin metastases[62].

Contiguous cancer arising from the extrahepatic biliary tree or gallbladder may also be amenable to hepatic resection. A more aggressive approach to the management of hilar cholangiocarcinoma in recent years has been associated with improve d long-term survival and quality of life[63-65]. In a recently reported series of 114 patients who presented with hilar cholangiocarcinoma, 98 patients had a radical resection, three underwent palliative resection and only 13 were not treated surgically[66]. The operative mortality rate was 4% and the 5-year survival rate was 28%. This report supports the widely held view that radical resection provides the best prognosis for selected patients with hilar cholangiocarcinoma. A number of recent studies have reported long-term survival after radical surgery for gallbladder cancer[67,68]. Radical regional lymphadenopathy may have survival benefits for patients with node-positive disease[69,70]. Aggressive reresection has been shown to be beneficial for patients with gallbladder cancer discovered during or after laparoscopic cholecystectomy for patients other than those with T1 tumours[71].

SUMMARY

Recent reports have highlighted consistently improved perioperative morbidity and mortality rates following hepatic resection. Operative mortality rates, even in cirrhotic patients, are less than 5% in most recent series. The commonest indication for hepatic resection is primary or secondary hepatic malignancy and therefore appropriate preoperative assessment of such tumours is vitally important. Accurate radiological imaging, including the use of three-dimensional reconstruction, will indicate if lesions are resectable and will aid the decision regarding the likely surgical procedure. Portal vein embolisati on is becoming a more widely accepted technique to induce contralateral hypertrophy reducing the risk of postoperative hepatic impairment and therefore increasing the indications for liver resection. The selection and subsequent management of patients with primary and secondary hepatic malignancy requires a multidisciplinary team approach invo lving hepatologists, radiologists, anaesthetists and surgeons and therefore the care of such patients should be undertaken in specialist hepatobiliary centres. Whilst accepting that hepatic resection offers the only prospect of cure for many patients, it is evident that future efforts will also be focused on determining the role of adjuvant treatments to reduce the inevitable recurrence of tumour which occurs in the majority of patients.

INTRODUCTION

Coeliac disease (CD) is an enteropathy, characterised by villous atrophy, which occurs in genetically susceptible individuals. It affects mainly the proximal small intestine, and is caused by an intolerance to cereal storage proteins found in wheat, barley and rye. Due to earlier diagnosis, and the recognition of 'silent' or 'latent' forms of the disease, the very severe symptoms that were seen previously are not very common now[1]. Malabsorption, with steator rhoea and weight loss, occur less frequently. Anaemia, vitamin deficiencies, complications of pregnancy and associated autoimmune diseases, such as insulin dependent diabetes mellitus or thyroid disease are often the clues which lead to the diagnosis of coeliac disease. Coeliac disease affects people from all ethnic groups, though it is most common in people originating in Europe, including people in North America and Australia. It is rarely seen in people from an Afro-Caribbean background[2].

In the past, the prevalence of coeliac disease has been thought to be 1 in 1 500 of the population in Western countries, based on the number of identified cases. However, recent screening studies of blood donors has shown a far higher prevalence of 1 in 250 in Sweden[3] and the United States[4]. In Italy, a population screening study of 17 000 school children between the ages of 6 and 15 revealed a prevalence rate of 1 in 184[5]. This appears to be uniform throughout most of Europe, with some areas of higher incidence, such as the west coast of Ireland. It affects males and females equally.

The reason for this discrepancy between clinically apparent cases, and the number of individuals with positive screening results, lies in the concept of the 'coeliac iceberg'[2]. The majority of people with coeliac disease are symptom-free, or have only mild symptoms, and do not approach a health care professional for a diagnosis. These individuals have 'silent' coeliac disease, if they have abnormal screening antibodies and an abnormal small bowel biopsy, but no symptoms. Individuals with abnormal screening antibody tests, but a normal small bowel biopsy and no symptoms, have 'latent' coeliac disease[6]. Thus, there are large numbers of people who are undiagnosed, in the 'coeliac iceberg' analogy this would be the vast portion of the iceberg which is not visible, whereas the diagnosed individuals with symptoms form the tip of the iceberg (Figure 1).

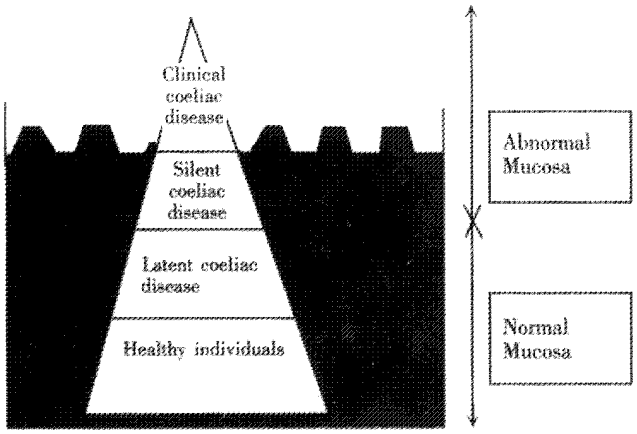

Figure 1 The coeliac iceberg. After A Ferguson[2]

HISTOPATHOLOGY

In the small intestine, the abnormalities are most marked proximally and decrease in severity with distal progression through the small intestine. In severe cases, the lesion may affect the ileum and even the stomach and rectum[7].

Flattening of the mucosa can vary from mild, through partial villous atrophy, to a total absence of villi. Classically, in untreated celiac disease, there is a flat mucosa with no villi (total villous atrophy), but more usually there is a reduction in the normal villous height, resulting in the villous height: crypt depth ratio being reduced from its normal value of between 3-5:1. The thickness of the mucosa is usually increased because of crypt hyperplasia.

The surface epithelial cells become pseudostratified compared to their normal tall columnar shape with resultant fall in enterocyte height. Crypt mitotic activity is no longer confined to the base and, although the histological appearance is usually normal, crypt abscesses have been described. Cell migration from the crypt base to the villous tip is reduced in untreated coeliac disease to 12-24 hours compared with the normal 3-5 days.

There is a chronic inflammatory cell infiltrate in the mucosa of the small intes tine in untreated coeliac disease with a rise in the number of plasma cells in the lamina propria. There is an increase in the ratio of intra-epithelial lymphocytes to surface enterocytes in active disease. Most of the intra-epithelial lymphocytes express the common leucocyte antigen CD3, 70% express the suppressor/ cytotoxic leucocyte antigen CD8, 5% express the helper/inducer CD4 phenocyte, whereas 20% of the cells are CD3+ve, CD4-ve and CD8-ve. Most of these cells express the more primitive γ/δ rather than the more usual α/β T-cell receptor. This results in a significant increase in the number of γ/δ T-cell receptor +ve lymphocytes in the surface epithelium of the small intestin e, both in treated and untreated coeliac disease[7].

CEREAL CHEMISTRY

Cereal storage proteins fall into four groups, the minor albumins, the globulins, the ethanol-insoluble glutenins, and the ethanol-soluble fraction termed prolamins.

Initial separation of wheat proteins depends on their relative solubility charac teristics. Gliadins are soluble in 40%-90% ethanol and high molecular weight glutenins are insoluble in neutral aqueous solution, saline or ethanol, although low molecular weight glutenins are ethanol soluble. The gliadins may be subdivided according to their relative electrophoretic mobility into α, β, γ and ω subfractions or according to their N-terminal amino acid sequence into α, β or ω subfractions, the previously described β-subfraction being reclassified as a type of α gliadin[8]. The molecular weight of these proteins rises from 32K to 58K daltons through α to ω gliadins.

Prolamins, the alcohol-soluble fraction of storage proteins are responsible for triggering the disease[9]. Wheat, barley and rye, being closely related, all contain prolamins (known respectively as gliadins, hordeins and secalins) with a high composition of glutamine and proline, whereas the prolamins of oats and more distantly related cereals, contain less glutamine and proline and more alanine and leucine[10]. The glutamine-rich peptide sequences appear to be responsible for the toxicity of wheat, barley and rye in coeliac disease.

Immune activation occurs after ingestion of these cereals, when these peptides a re presented, in conjunction with MHC class II molecules, to activate CD4+ T helper lymphocytes, causing release of Th_1 and Th_2 cytokines, which encourag e expansion of autoreactive B cell clones, and mucosal destruction. Much recent research has provided an insight into the mechanisms of pathogenesis by which this occurs.

Once the diagnosis of coeliac disease has been made, the patient needs to be established on a gluten free diet. All foods which contain wheat or wheat flour, as well as barley and rye must be avoided. There are a number of foods which contain hidden gluten, including soy sauce, mustard, mayonnaise and beer, which contains the barley prolamin, hordein. Gluten-free flour, bread, biscuits, pasta and snacks are available from a variety of companies.

An average Western diet contains 13 g of gluten, a "Codex-Alimentarius" gluten free diet contains <0.3% gluten from grains, and is sufficiently gluten free for the majority of coeliac patients, however, some patients continue to have symptoms, and improve only when gluten is completely removed from the diet. This was shown in a study by Faulkner-Hogg[11], where 15 out of 22 patients with symptoms on a Codex-Alimentarius gluten free diet improved after removal of all detectable gluten.

In the past, it was assumed that the small bowel mucosa returns to normal after introduction of a gluten-free diet, however, despite improvement of symptoms, persistent small bowel mucosal abnormalities may occur, and are not necessarily an indication of poor dietary compliance[12].

Oats are a member of the avena tribe of the gramineae, or grass family, of plant s, whereas wheat, barley and rye belong to the triticeae tribe, both tribes belonging to the pooideae sub-family. Thus avenin, the prolamin of oats, is genetically less like gliadin than secalin and hordein (Figure 2).

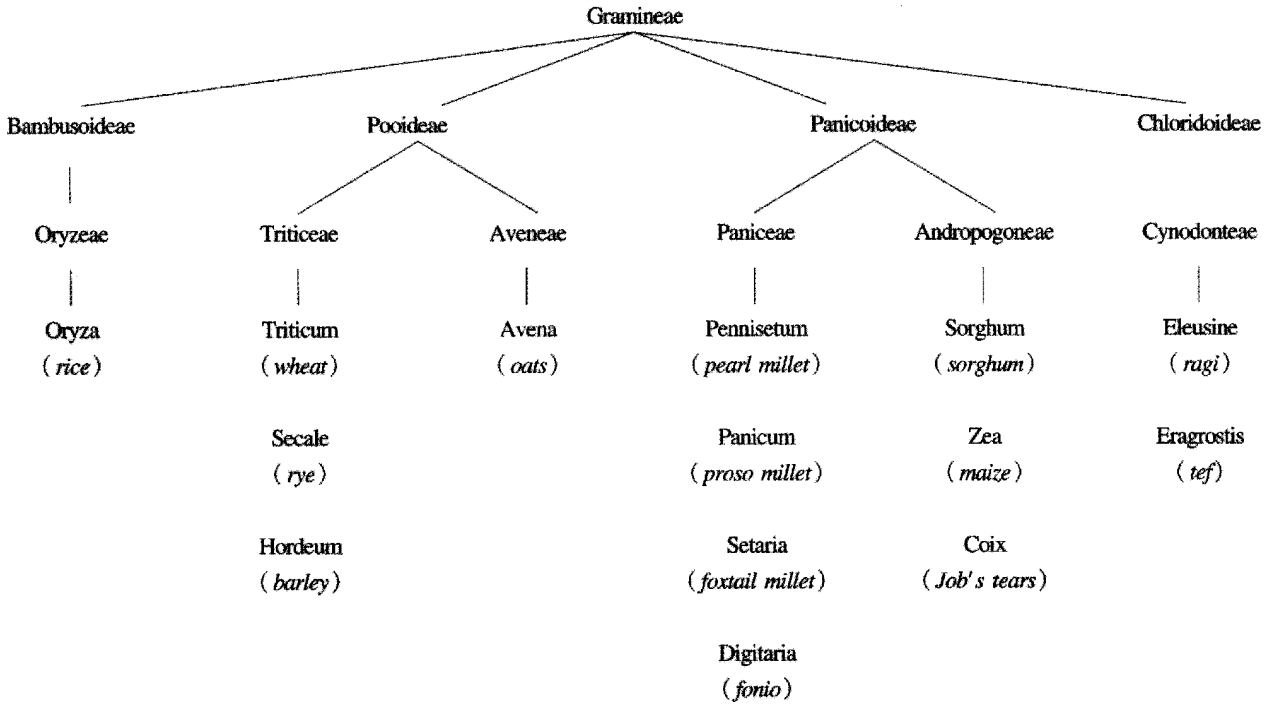

Figure 2 The taxonomic relationships of cereals. After P Shewr y, A Tatham and D Kasarda[10]

The toxicity of oats to patients with coeliac disease has been a controversial issue, as early studies have shown conflicting results. Harmful effects were observed by some workers[9,13], but not by others[14,15], and some investigators found variable results[16,17]. However, a recent Finnish study[18] on newly diagnosed patients, as well as coeliac patients in remission on a gluten-free diet, have shown that moderate amounts (up to 60 g/day) of oats are not detrimental, as witnessed by no significant differences in gliadin and reticulin antibodies, as well as numbers of intra-epithelial lymphocytes before and after introduction of oats into the diet.

Sequence homologies, and weak immunological cross reactivity, have been found between avenin and the prolamins of wheat, barley

and rye[10,19,20]. Additionally, only 5% to 15% of the total protein in oats is avenin, whereas 40% to 50% of the total protein in wheat, barley and rye are made up of their respective prolamins[21]. Thus, there is a smaller amount of avenin per gram if oat seed, and there are fewer toxic epitopes per gram of avenin. This suggests that a small amount of oats can be consumed by patients with coeliac disease, as long as the oats are not contaminated by wheat flour. In many mills however, the same equipment is used to grind wheat, as that used to grind oats, causing enough contamination to have a detrimental effect on the health of sensitive coeliac patients.

THE IMMUNODOMINANT PEPTIDE

The precise structure of the gluten proteins that exacerbate coeliac disease remains unknown, although there have been considerable recent advances in this area. Peptides from the fully sequenced α-gliadin, A-gliadin, have been used in a number of studies to try to identify the toxic epitope, which induces intestinal inflammation. A peptide corresponding to amino acids 31 to 49 of A gliadin was found to cause significant histological changes in small bowel biopsy specimens after *in vivo* challenge by intraduodenal infusion[22]. Anderson et al used 51 overlapping synthetic 15-amino acid peptides, spanning the complete sequence of the A-gliadin. They assessed optimal peripheral blood mononuclear cell (PBMC) secretion of the Th_1 cytokine gamma interferon (IFN-γ) in response to incubation with each of the peptides and demonstrated a transient, disease-specific, DQ2 restricted, CD4 T-cell response to a single dominant epitope. This peptide corresponded to amino acids 57-73 of A-gliadin, which had been partially deamidated by tissue transglutaminse at position 65 (Q65E)[23].

Arentz-Hansen *et al* produced eleven different recombinant antigens from α-gliadin, to demonstrate that the intestinal T cell response to α-gliadin in adult coeliac disease patients is focused on two immunodominant, DQ2 restricted peptides that overlap by a seven residue fragment. Gluten-specific T cell lines from small intestinal biopsies of 16 different patients all responded to one or both of the deamidated peptides, indicating that these epitopes are highly relevant to disease pathology. The peptides correspond to amino acids 62-75 (α2) and 57-68 (α9) with Q65E[24].

The identification of these peptide sequences, which act as potent T cell epitopes, may lead to the development of antigen specific therapy for coeliac disease. Once a target has been defined for immunomodulation, it may be possible to create non-toxic cereal based wheat, by removal or modification of the antigeni c sequence in gliadin proteins.

TISSUE TRANSGLUTAMINASE

Tissue transglutaminase (tTG) is a ubiquitous cytoplasmic enzyme, which is found mainly in respiratory and gut epithelial cells. It is important in prevention of tissue damage, by catalysing protein cross-linkage, causing formation of isopeptide bonds between glutamine and lysine residues. tTG also deaminates glutamine residues to glutamic acid.

Native gluten proteins have very few negatively charged residues, as they contai n approximately 40% glutamine and 20% proline, however, several of these glutamines are converted to glutamic acid in the presence of tTG. Deamidation of glutam ine residues to glutamic acid was found to strongly enhance T cell reactivity, due to the formation of negatively charged amino acids needed for efficient binding to DQ molecules, thus inducing maximal T cell proliferation[25].

Virtually all patients with CD have been found to express either HLA-DQ2 or -DQ8 class II molecules. HLA class II molecules are responsible for binding exogenous protein antigens and presenting them to CD^{4+} T cells. These molecules have a characteristic binding groove, which differ in size, shape and position between class II alleles, and which can be used to predict the sequence of pep tides needed to fit into it. Both DQ2 and DQ8 require negatively charged amino acids at certain positions for effective binding. Gluten specific HLA-DQ2 and -DQ8 restricted T cell clones can be isolated from small intestinal biopsy samples of patients with CD, and have been used to characterise gluten derived peptides capable of stimulating T cells[26].

Arentz-Hansen proposes that conditions may exist in the gut where T cell epitopes are both created and trapped locally by tTG, prohibiting their presentation by tolerogenic APCs in the gut. Alternatively, tTG may prevent these epitopes from spreading systemically as soluble antigen, a factor thought to be important in oral tolerance. Thus, it may be possible to administer soluble deamidated gliadin peptide to patients with coeliac disease, to induce tolerance to gliadin[24].

IMMUNOGENETICS

The precise mode of inheritance of coeliac disease is unknown, although l0%-15% of first degree relatives of probands are similarly affected[27,28]. There is 70%-100% concordance in affected monozygotic twins and 30%-50% concordance in human leukocyte antigen[29] (HLA)-identical siblings. Efforts to understand the mechanisms and genetics of polygenic human diseases have focused on the identification of DNA or protein products and protein molecules that segregate in both populations and families.

The most significant observation was the increased frequency of specific serologically defined lymphoid cell surface proteins, termed HLA class II molecules, in people with coeliac disease. These are glycosylated transmembrane heterodimer s comprising both α and β-chains, the genes for which are organised into three related subregions DR, DP and DQ. The genes are encoded within the HLA-class II region of the major histocompatibility complex on the short arm of chromosome 6. The association of particular HLA-DR and DQ types with coeliac disease is well established[30]. Associations with the HLA-DP region and the TNF-α genes have been reported but are thought to be secondary to linkage disequilibrium with HLA-DR and DQ haplotypes[31,32]. The genes most strongly associated with coeliac disease are DQAl *0501, DQB1 *0201[33,34]. 98% of northern Europeans with coeliac disease have these alleles in cis (DQ2) whereas in Southern Europe a third of the population with the condition express the same class II molecule from these alleles in trans (DR5,7)[30]. Italian and Argentinian coeliac disease populations are also reported to have a increased frequency of the DR5,7 haplotype[35]. In Israel there is also an association with the haplotype HLA-DR4, DQ8[36]. This genotype encodes a class II molecule with considerable similarity in the peptide binding groove configuration to that produced by the DQ2 genes, supporting a central role for the class II molecule in an immune mediated model of coeliac disease.

Twenty-five percent of people in the general population of Northern Europe have HLA-DQ2. It has been shown in epidemiological studies that only 30% of the genetic susceptibility to coeliac disease lies in the HLA region[37], the remaining 70% being elsewhere in the human genome. Two genome-wide linkage studies to identify these remaining susceptibility alleles have been undertaken using sibling pair analysis and have produced conflicting results. The first group from Ireland performed an autosomal screen using 40 affected sibling pairs, and identified five areas of interest at the following locations: 6p23, 7q31.3, 11p11, 15q26 and 22cen[38]. The second group from Italy using 110 sibling pairs, failed to confirm linkage in the areas identified in the previous study, but proposed to further areas of interest, at 5qter, and in a subgroup of patients at 11qter[39].

Our group, employing analysis of multi-generation families,

identified two new potential susceptibility loci at 10q23.1 and 16q23.3, and found evidence of linkage on chromosome 7, close to the γ T-cell receptor gene and on chromosome 2, near the CTLA4 gene[40].

The CTLA4/CD28 region, on chromosome 2q33, has been independently implicated in an association study from France[41] and a linkage study from Finland[42]. These genes control T cell proliferation, and play a part in other autoimmune dieases, such as type I insulin dependent diabetes mellitus and Graves' disease.

IMMUNE RESPONSE

It has been suggested that in coeliac disease there is a primary abnormal immune response of the small intestine to gluten proteins that produces an allergic phenomenon. There is considerable evidence to support this hypothesis, although the observed aberrant immune response may be secondary to an unrecognised alternative aetiopathology. There is a dense infiltration of the small intestinal lamina propria with lympho cytes and plasma cells in patients with untreated coeliac disease. There is also an increased ratio of intra-epithelial lymphocytes to surface enterocytes with the majority of these cells expressing the suppresser/cytotoxic phenotype and having the appearance of immunoblasts[43], and there is a strong assoc iation with the histocompatibility antigen HLA-DQ2 which is also associated with other auto-immune disorders.

High titres of antibodies to gliadin occur in coeliac disease as well as antibodies to reticulin and endomysium, which also implies an immune mediated mechanism[44]. The role of these antibodies in the disease pathogenesis is unknown. However, it has recently been shown that the antigen for anti-endomysial antibodies is the enzyme tissue transglutaminase, which is present in the small intestine and causes selective partial deamidation of gluten molecules.

There are an increased number of cells that express the cytokines IL-2, interferon-γ (IFN-γ) tumour necrosis factor-α (TNF-α) and tumour necrosis factor-β (TNF-β), IL-10, IL-1β and transforming growth factor-β (TGF-β). The expression of both Th1 (IFN-γ and IL-2) and Th2 (IL-4 and IL-10) associated cytokine transcripts in the same biopsies indicate the activation of Th0 cells. The expression of IL-2 and IL-4 mRNA was not observed in the peripheral blood samples of patients with inactive coeliac disease, implying that they are associated with disease activity[45]. This also supports the immune-mediated hypothesis. The isolation of gluten-sensitive T-cells both from both the peripheral blood and small intestinal biopsies from coeliac patients[34,46], the HLA-DQ2 restriction of the majority of these cells and their production of pro-inflammatory cytokines when stimulated with wheat gliadin[47], provide further evidence that these represent an hyperimmune sensitivity to certain cereal peptides.

"Gliadin (or gluten) shock", is a rare condition which affects treated coeliac patients. In this condition a gluten challenge is followed by collapse with vomiting and tachycardia. The condition responds to treatment with corticosteroids.

In patients who do not respond to a strict gluten free diet, or who relapse on a gluten free diet, steroids can be used, such as prednisolone 20 mg/day, with a reducing course over the next 6 weeks. Azathioprine can also be used as a steroid-sparing agent[48]. Cyclosporine does not appear to be useful[49], indeed, some patients' symptoms increase, and budesonide, despite reducing the risk of osteoporosis, is not useful, as it is formulated to be slowly released in the terminal ileum, usually beyond the coeliac small bowel lesion, and is absorbed only in very small amounts.

INTRODUCTION

Clinical factors contributing to the therapeutic challenge of hepatocellular carcinoma (HCC) are manifold: tumors arise often in patients with compromised liver function, therefore limiting therapeutic options; symptoms develop only at later stages of tumor progression, and tumors tend to invade normal structures or occur in multiple locations simultaneously. Ninety percent of patients with tumors larger than 5 cm will have synchronous intrahepatic metastases at the time of presentation. In the majority of patients undergoing partial hepatectomy for HCC, intra-hepatic or distant metastases will occur[1]. Likewise, in about fifty percent of the patients who die within five years after liver transplantation for HCC, intra- and extrahepatic recurrences are the cause of death[2]. Tumor characteristics predicting recurrence of HCC following resection include portal vein invasion, intrahepatic metastasis, extratumoral spread, high mitotic index[3-5], and a sarcomatous phenotype[6]. Such observations demonstrate t hat tumor cells that are easily invading normal tissues and achieve access to the circulation harbor the greatest risk of tumor recurrence. The molecular events promoting invasiveness of HCC cells are still widely unknown. Further understanding of the se processes is urgently needed for the development of rational strategies for prevention and treatment of metastatic disease in HCC.

Investigations in different tumor types and murine models of cancer depict a characteristic cascade of events necessary for a tumor to achieve successful dissemination of met astases from a primary tumor. After malignant transformation and initial tumor growth, the first step towards metastasis formation is the initiation of vascularization of the tumor, a process known as the angiogenic switch. While the tumor progresses, new genetic changes occur leading to ① a reduced cell-cell adhesion, and, ② alterations in the interaction of the tumor cell with the extracellular matrix, allowing invasion into surrounding tissues including blood vessels (which are mediated by changes in integrin expression and activation of proteolytic enzymes). Tumor cells reaching the circulation must have developed mechanisms to suppress anoikis, which is programmed cell death caused by disruption of cell-substrate adhesion. At distant sites, tumor cells need to leave the circulation and migrate to sites with favorable conditions. Here, angiogenesis is again in itiated and cell progression of the metastasis continues. It is obvious that this sequence of events will be dependent on multiple molecular factors in malignant and normal (e.g. stroma and immune competent) cells. Some of these factors have been characterized in HCC. So far, and in agreement with data from other tumor types, there is evidence that a high proliferative index (as measured by PCNA or Ki-67 expression) is associated with reduced tumor differentiation and might b e predictive of recurrence after tumor resection[7-9]. In HCC, several signaling pathways are candidates for driving this proliferation, mainly those related to growth factor receptors, including Met, the receptor for the hepatocyte growth factor/scatter facter (HGF/SF) and epidermal growth factor receptor (EGFR)[10,11]. While enhanced proliferation is an important step during tumorigenesis, in creases in invasiveness and cell mobility are necessary for the generation of metastases. It has been demonstrated that signaling through the Ras/MAPK pathway (which confers signals from growth factor receptors, including EGFR and Met), could cooperate with the TGF-β signal transduction pathway in promoting the switch from a epithelial to mesenchymal phenotype in cancer cells, rendering them significantly more mobile and invasive[12]. *In vitro* data from HCC cell lines support this possibility, as it has been demonstrated that TGF-â signaling enhances prol if eration of HCC cell lines[13]. Disassembly of protein complexes involved in cell -cell adhesion has been demonstrated as a consequence of TGF-β and Ras/MAPK signaling[14]. Accordingly, loss of expression of the cell-adhesion molecul e E-cadherin and nuclear expression of its binding partner β-catenin, occurs frequently in high-grade HCC and correlates with a poor prognosis[15]. There is also strong evidence that HCC indeed activates angiogenesis. For example, vascular endothelial growth factor (VEGF), a promoter of angiogenesis, was found to be upregulated in HCC[16]. A recent prospective study in 100 patients undergoing resection of HCC demonstrated a strong correlation between serum concentration of vascular endothelial growth factor (VEGF) and microscopic vascular invasion[17]. In the same study, high serum levels were associated also with the presence of intrahepatic metastases and reduced disease-free survival. As indicated, successful invasion into surrounding tissues can also be facilitated by proteases that allow malignant cells to migrate through physiologic barriers, e.g. basement membranes. Indeed, experiments using HCC cell lines revealed that membrane-type 1 matrix metal loproteinase confer invasiveness and promote intrahepatic metastases[18]. In addition, expression of urokinase-type plasminogen activator (uPA), uPA receptor (u PAR) and plasminogen activator inhibitor type-1 (PAI-1) was found to be associated with tumor invasiveness in a mouse model of HCC and human HCC[19]. Overall, these data suggest that mechanisms of metastasis in HCC that are consistent with data in other types of solid tumors. However, most of

the evidence is circumstantial and correlative, reflecting a lack of appropriate model systems.

As Li *et al*. describe in this issue of the World Journal of Gastroenterology, new model systems might be available that could lend insight into the mechanisms underlying the metastatic process in HCC. The authors generated two clonally related cell line derivatives from human HCC cell line MHCC97 that show dramatic differences in their metastatic potential. Notably, the authors used an *in vivo* selecti on process that included the orthotopic transplantation of xenografts into the livers of mice, thus simulating the clinical situation as closely as possible. The differences in metastatic potential were mirrored by significant phenotypical differences. These included morphologic differences as well as faster proliferation, enhanced in vitro invasiveness, and increased alpha-fetoprotein (AFP) production of the highly malignant derivative compared to its less metastatic counter part. These findings are consistent with the expected metastatic phenotype of H CC and it will be most exciting to see results from molecular analyses of these cells. Particularly, analyses of differential gene expression, e.g. using cDNA expression arrays, will be revealing and could be compared to results from the an alysis expression profiles in human tumors[20].

Identification of differentially expressed genes represents an important step toward understanding metastasis in this disease. However, genetic evidence will be necessary to pinpoint the culprits in this process. So far, transgenic mouse models of HCC have bee n created in which liver-specific expression of potential oncogenes, including C yclin D1, c-myc, TGF-a, and Met leads consistently to the development of HCC- like tumors[21,11,22]. Interestingly, tumors occurring in these models lack a highly invasive or metastatic phenotype. A next step is to rebuild the full phenotype of HCC in mice using modified transgenic models that include combinations of growth and metastasis promoting genes. Based on these models, rational therapeutic approaches could be developed and tested.

Abstract

AIM: **To study the relationship between *Helicobacter pylori* (*H.pylori*) and gastric carcinoma and its possible pathogenesis by *H.pylori*.**

METHODS: **DNEL technique and immunohistochemical technique were used to study the state of apoptosis, proliferation and *p*53 gene expression. A total of 100 gastric mucosal biopsy specimens, including 20 normal mucosa, 30 *H.pylori*-negative and 30 *H.pylori*-positive gastric precancerous lesions along with 20 gastric carcinomas were studied.**

RESULTS: **There were several apoptotic cells in the superficiale pithelium and a few proliferative cells within the neck of gastric glands, and n o *p*53 protein expression in normal mucosa. In gastric carcinoma, there were few apoptotic cells, while there were a large number of proliferative cells, and expression of *p*53 protein significantly was increased. In the phase of metaplasia, the apoptotic index (AI, 4.36%±1.95%), proliferative index (PI, 19.11%±6. 79%) and positivity of *p*53 expression (46.7%) in *H.pylori*-positive group were higher than those in normal mucosa (*P*<0.01). AI in *H.pylori*-positive group w as higher than that in *H.pylori*-negative group (3.81%±1.76%), PI in *H.pylori*-positive group was higher than that in *H.pylori*-negative group (12.25%±5.63%, *P*<0.01). In the phase of dysplasia, AI (2.31%±1.10%) in *H. pylori*-positive group was lower (3.05%±1.29%) than that in *H.pylori*-negative group, but PI (33.89%± 11.6 5%) was significantly higher (22.09±8018%, *P*<0.01). In phases of metaplasia, dysplasia and gastric cancer in the *H.pylori*-positive group, AIs had an evidently gradu all decreasing trend (*P*<0.01), while PIs had an evidently gradual increasing trend (*P*<0.05 or *P*<0.01), and there was also a trend of gradual increase in the expression of *p*53 gene.**

CONCLUSION: **In the course of the formation of gastric carcinoma, proliferation of gastric mucosa can be greatly increased by *H. pylori*, and *H. pylori* can induce apoptosis in the phase of metaplasia, but in the phase of dysplasia *H. pylori* can inhibit cellular apoptosis. And *H. pylori* infection can strengthen the expression of mutated *p*53 gene.**

Subject headings *Helicobacter pylori*; gastric precancerous lesion; apoptosis; proliferation; *p*53 gene

Zhang Z, Yuan Y, Gao H, Dong M, Wang L, Gong YH. Apoptosis, proliferation and *p*53 gene expression of *H. pylori* associated gastric epithelial lesions. *World J Gastroenterol*, 2001;7(6):779-782

INTRODUCTION

H. pylori infection is epidemiologically associated with the development of gastric cancer[1-7], but it is unknown how *H. pylori* does so . In this study, DNEL technique[8]and immunohistochemical staining were used to dynamically observe and compare the state of apoptosis, proliferation and *p*53 gene expression in *H.pylori*-negative or *H.pylori*-positive gastric precan cerous lesion as well as gastric carcinomas. The purpose is to probe into the effect of *H.pylori* on apoptosis, proliferation and *p*53 gene expression in gastric epithelium and to find out the relationship between *H.pylori* and gastric carcinog enesis, and the possible mechanism.

MATERIALS AND METHODS

Subjects

All samples were selected from people screened by endoscopy in a high risk area of gastric carcinoma in Zhuanghe, Liaoning Province. A total of 100 gastric mucosal biopsy specimens, including 20 normal mucosa, 30 metaplasia, 30 dysplasia and 20 gastric carcinoma cases. *H.pylori* infecti on was assessed by hematoxylin-eosin staining[9-11] and PCR[12]. If both results of the tests in a patient were positive, the patient was considered to be infected by *H.pylori*; if neither was positive, the patient was considered negative.

Terminal deoxynucleotidyl transferase-mediated dUTP nick-end la belling method

Using the kit (Oncor, San Diego, USA), the staining steps are as follows: ① the sections were deparaffinised through xylem and alcohol, and washed; ② diges ted for 15 min with proteinase K (20 mg·L^{-1}); ③ quenched with 30 ML·L^{-1} H_2O_2 for 20 min ; ④ applied with equilibration buffer for 15 s at room temperature ; ⑤ added with terminal deoxynucleotidyl transferase (TdT) and incubated at 37℃ for 60 min; ⑥ added with STOP/WASF buffer at 37℃ for 10 min ; ⑦ dropped with hydrogen peroxidase for 30 min at room temperature; and ⑧ visualized by immersi on in 3,3'-diaminobenzidine (DAB) solution, restained with methyl-green, and deh yd rated, transparency, mounted . PBS was substituted for TdT as negative control.

Immunohistochemical staining

SP kit was used (Zymed, USA).The primary a ntibodies were PCNA monoclonal antibody(diluted 1:50) and *p*53 monoclonal anti body (ready to use, Maixin, Fijian), respectively. Before staining, the sections were microwave heated in 0.05 mol·L^{-1} citric acid solution for antigen retrieval. PBS was substituted for primary antibodies as negative control.

Observed parameters

Two samples were stained by DNEL and immunohistochemical staining, then the DNEL-positive cells (apoptotic cell) and PCNA-positive cells (proliferative cell) were observed. Apoptotic index (AI) and proliferative index (PI) were obtained by calculating the percentage of positively stained cells evaluated for each tissue section after counting 1000 cells at more than 5 high power fields.

Statistical analysis

t test was used to compare the means. The positivity of *p*53 protein was analyzed by X^2 test

RESULTS

Charateristics of DNEL-positive, PCNA-positive and p53 protein-positive cells under microscopy

DNEL-positive cells (apoptotic cell) appeared brown corpuscular or diffuse in cell nuclei, and individual thickening nuclear membrane appeared brown. PCNA-positive cells (proliferative cell) appeared brown corpuscular in cell nuclei. Positive pro duct of *p*53 expression was restricted in cell nuclei. In normal mucosa, apoptotic cells sporadically scattered on the epithelium, a few proliferative cells scattered on the glandular neck and expression of *p*53 protein was not seen. But in the tissue of gastric carcinoma, apoptotic cells accounted for 1.62%; prolifer a tive cells for 41.99% and a cluster was formed all over the lesions; and there was a significant increase in the expression of p53 protein. Effect of *H. pylori* infection on apoptosis in gastric epithelium In the metaplasia mucosa, the apoptotic index in *H. pylori*-positive group was higher than that in normal mucosa ($P<0.01$), and it was also higher than that in *H. pylori*-negative group; while in the dysplasia mucosa, AI in *H. pylori*-positive group was lower than that in *H. pylori*-negative group. In the metaplasia, dysplasia mucosa and gastric carcinoma AI presented with an evidently gradual decrease trend ($P<0.05$ or $P<0.01$ Table 1) in *H. pylori*-positive group.

Table 1 Effect of *H. pylori* infection on AI in gastric epithelium (%, $\bar{x}\pm s$)

DISCUSSION

Gastric mucosa consists of continuously renewed cells and cell proliferation an d apoptosis maintain their balance[13]. This study shows that the apoptotic cells were identified in gastric surface epithelium and formed “an apoptotic zone”; proliferative cells were seen in the neck region of the mucosal glands and formed “a prolife rating zone”. This distribution shows the proliferating zone gradually maturation, aging and death to the surface in the gastric mucosal epithelium. However in gastric carcinoma, apoptotic cells amount to 1.62%, proliferative cells amount t o 41.99%, which clustered all over the tumor tissue. This change obviously lost the distribution characteristics of apoptotic zone and proliferating zone which elucidates that the regulation of apoptosis and proliferation have already been beyond the normal mucosa and appear significantly disordered in gastric carcinoma.

Human gastric carcinogenesis is a multistep and multifactorial process[14-17]. In this process, the state of apoptosis and proliferation of gastric epithelium will change[18,19]. In this study, *H.pylori* infection was found to affect the cell apoptosis and proliferation. In the metaplasia mucosa, AI was higher than that in normal mucosa in *H.pylori*-positive group, and higher than that in *H.pylori*-negative one; however, in the dysphasia mucosa, AI in *H.pylori*-positive group is lower than that in *H.pylori*-negative group. In the process of gastric carcinogenesis[14,15], from the phase of metaplasia, dysplasia to gastric carcinoma, AI gradually decreased in *H.pylori*-positive group. This shows that from normal mucosa to gastric carcinoma, *H.pylori* may induce cell apoptosis in the phase of metaplasia; but it inhibits cell apoptosis in the phase of dysplasia, this is familiar with gastric carcinoma. Several reports suggest that *H.pylori* produces cytotixic protein (CagA and VacA)[20-28], and gastric mucosa can increasex some cytokines, nitrous oxide sythetase and oxygen radicals released after *H.pylori* infection[29-35]. At the same time, *H.pylori* infection can lower the gastric antioxidant ability. All those factors make DNA dam age or enhance the susceptibility of DNA-damage, and those DNA-damaged cells can be

cleared away by apoptosis[36],and this may be the mechanism that *H. pylori* in duces apoptosis. It has been proved that wild type *p*53 protein can induce cell apoptosis but the intracellular accumulation of mutant *p*53 protein can inhibit cell apoptosis and promote cell transformation and proliferation, resulting in carcinogenesis[37-41]. In this study, in the phae of metaplasia, positivity of *p*53 protein expression in *H.pylori*-positive group was higher than that in nor malmucosa. From the phase of metaplasia to gastric carcinoma, the positivity of *p*53 protein expression increased in *H. pylori*-positive group. As positive *p*53 protein confirmed by immunohistochemical staining was considered as mutation type[42]. It suggests that beginning with metaplasia, *H.pylori* infect ion can strengthen the expression of mutant *p*53 gene. With the accumulation of mutant and expression of *p*53, its inhibiting effect on apoptosis[43-45] will overpass the indution effect of *H. pylori*. Therefore in the *H.pylori*-positive dyspl asiamucosa, there was a decrease in apoptosis. In this study, in the *H. pylori*-positive gastric precancerous lesions-metaplasia and dysplasia, PI was significantly higher than that in normal mucosa, and higher than those in the c orresponding negative lesions. In the progress from normal mucosa to the malignant phenotype, PI gradually increased in *H.pylori*-positive group. T here sult shows that *H.pylori* apparently improves gastric epithelium proliferation which is very similar with the proliferating characteristics of gastric carcinoma. The mechanism may be that urease enzyme produced by *H. pylori* hydrolyses urea into carbon dioxide and ammonia, the latter can promote mitosis[46]; *H. pylori* infection will increase mucosal content and expression of EGF and TGF-α[47-52] and the effect of mutant *p*53 on proliferation, will result in rapid proliferation of epithelium.

In the phase of metaplasia, *H.pylori* can induce apoptosis, stimulate hyperproliferation and result in the regulation disorder of apoptosis and proliferation in the gastric epithelial cells, which increase the instability of gastric mucosa and carcinoma variability. Accompanied with the progress of lesions and the accumulation of *p*53 protein, *H. pylori* induce s gastric epithelial cell hyperproliferation and apoptosis reduction or even imb alance of the apoptotic and proliferative process, and accumul at ion of DNA-damaged cells, ultimately resulting in gastric carcinogenesis.This makes it clear that *H. pylori* infection may be an important factor of gastric car cinogenesis. Thus, it is significant to prevent *H. pylori* infection, eradicate *H. pylori* in early stage and study the relationship between *H. pylori* infection and gastric carcinoma in order to decrease the incidence rate and prevent gastric carcinoma.

Abstract

AIM: **To study the polymorphism of flagellin A genotype and its significance in *Helicobacter pylori* (*H. pylori*).**

METHODS: **As the template, genome DNA was purified from six clinical isolates of *H. pylori* from outpatients, and the corresponding flag ellin A fragments were amplified by polymerase chain reaction. All these products were sequenced. These sequences were compared with each other, and analyzed by software of FASTA program.**

RESULTS: **Specific PCR products were amplified from all of these *H. pylori* isolates and no length divergence was found a mong them. Compared with each other, the highest ungapped identity is 99.10%, while the lowest is 94.65%. Using FASTA program, the alignments between query and library sequences derived from different *H. pylori* strains were higher than 90%.**

CONCLUSION: **The nucleotide sequence of flagellin A in *H. pylori* is highly conservative with incident divergence. This information may be useful for gene diagnosis and further study on flagellar antigen phenotype.**

INTRODUCTION

Helicobacter pylori (*H. pylori*) is widely distributed among humans. It is the major pathogen for most of the gastric diseases. Several potential virulence factors have been suggested to play a role in Helicobacter pathogenesis, those studied in most details including the production of abundant amounts of urease, motility, the expression of cytotoxins and other extracellular enzyme, liposaccharides and adhesion to tissue-specific receptors[1-12].

Even in the viscous environment, a high degree of motility is is conferred by three to six flagellas that extends from one pole of the bacterium. The flagella consist of a basal body that contains the motor and the hook structure, the central filament and a membranous sheath enveloping each filament. Flagellin A is the major molecule of filament and responsible for bacterial motility to most degree in *H. pylori*[13-15].

According to the data reported previously, the sequence of flagellin A is highly conservative in both amino acid and nucleotide level; flagellin A is one of the major antigens to induce the production of antibody in serum[16-20]. Based on these points, flagellin A may be one of the best alternatives for gene diagnosis and designs of vaccine against *H. pylori*.

MATERIAL AND METHODS

H. pylori strains

Six *H. pylori* isolates were offered by the Department of Bacteriology, Xijing Hospital, the Fourth Military Medical University.

Amplification of flagellin A fragment in H. pylori

Genome DNA as template was purified from *H. pylori* isolates by using genome DNA purification kits (Shanghai Watson Biotech. LTD). Referring to the complete sequence of flagellin A gene in Genbank (X60746), primers were designed by primer3 program as follows[21]. Forward primer: 5'GCGGATAAGGCTATGGATGA 3'; reverse primer: 5'GATCGCTGCGACTAACCTTC 3'. Amplification was proceeded by two-step polymerase chain reaction; that is: 94℃ for 5 min, 94℃ for 45 s, 68℃ for 1 min, 30 cycles, and then 72℃ for 10 min.

Comparison of PCR products and alignment analysis by FASTA program

Sequences of PCR products amplified from six *H. pylori* isolates were compare d with each other. One of these sequences was presented and analyzed by FASTA program (version 3.3t07).

RESULTS

Any other sequences were compared with sequence A, the numbers of divergent nucleotides were eighteen, ten, twenty-one, thirteen, and twenty-eight between sequence A and B, A and C, A and D, A and E, and between sequence A and F, respectively (Figure 1).

PCR products including 561 nucleotides each were compared mutually and the identity was calculated as follows. Identity (%) =1-[100% × number of divergent nucleotides / 561nucleotides]. By comparison, it is found that sequence F has much more divergence from any other sequences, while sequence Ehas higher alignment with other sequences except sequence F (Table 1).

Figure 1 Comparison of PCR products between sequence A and other sequences. Note: Divergent nucleotides were thickened and shadowed.

Table 1 Comparison of identity and divergent numbers among different PCR products

Identity (%)	Number of divergent nucleotides (base pairs)					
	A	B	C	D	E	F
A	-	18	10	21	13	28
B	96.79	-	16	18	4	29
C	98.21	97.15	-	18	13	30
D	96.25	96.79	96.79	-	17	22
E	97.68	99.29	97.68	96.97	-	30
F	95.01	94.83	94.65	96.08	94.65	-

Data of identity (%) were under dashed line.

Sequence A was forwarded to EMBL server, and fifty library sequences were searched and analyzed by FAS TA program. Ten library sequences with highest Z-score were shown here. All these sequences were derived from *H. pylori* strains and had identity with Sequence A higher than ninety-five percent (Table 2).

Table 2 Identity analysis of sequence A in DNA data base using FASTA program

Source of nucleotide sequence in Genbank	Z-score	Identity (%)	Length of compared sequences (base pairs)
X60746	2736.1	96.4	561
AE001487	2694.1	95.9	561
AE000574	2692.0	95.9	560

U63253	2082.9	96.7	424

DISCUSSION

Flagella are well-controlled organelle and essential for microbial motility in many bacterial genera[22-28]. Though much effort has been made to study the polymorphism of flagella in other genera like Salmonella, relatively little was known about that in *Helicobacter pylori*[29-34]. Recently, genome DNA of several isolates was sequenced, which offered the first structural information and made it possible to do further work. Flagellin A is unique in the known *H. pylori* database, which means that it has sequence quite different from analogs in other bacteria but high conservative within genus.

H. pylori are genetically highly diverse, the intraspecific free recombination of flagellin A is a frequent incident just as occurred in VacA and CagA[35-43]. Not like the diversity of serotypes in Salmonella or other bacteria, few of specific flagellar serotypes have been found in *H. pylori* so far[44-47]. The reported sequences of flagellin A were highly conservative and some difference may be caused by different methods. This fact was accordant to the results presented here. In this experiment, a fragment of about four hundred nucleotides in *H. pylori* flagellin A gene was found highly conservative between the oriental and the occidental.

As the unique pathogen, *H. pylori* are correlated with almost all of the gastric diseases[48-58]. Therefore, development of new methods to detect and eradicate *H. pylori* infection has become one of the central tasks to treat most of gastric diseases. The conservatism of flagellin A discovered in this experiment may be very helpful for PCR-based gene diagnosis.

Though the polymorphism of Flagellin in *H. pylori* was reported previously in some labs, it has not determined whether there are specific flagellar serotypes that may be relevant to the clinical symptoms[59-66]. In this experiment, one of the PCR products was found more divergent than that caused by geographical or ethnic fact ors. It is still not known whether the polymorphism shown here has influence on the flagellar serotype, motility, virulence or its colonization to gastric mucosa. To be one of the vaccine candidates against *H. pylori*, more work should be done on epitope mapping, analysis of molecular structure, and determination of antigen determinant region as well.

As one of the major known pathogenic factors, much research has been done on *H. pylori*. In one hand, much work was focused on its influence on gastric physiology, pathogenesis, carcinogenesis, and mutual reaction between host and pathogen; on the other hand, more attention was paid on its clinical aspect involving treatment, detection and prevention[67-84]. Though there have already been some methods to detect and treat *H. pylori* infection so far, much effort must be made to develop more effective w ay to deal with these worms.

In summary, the nucleotide sequence of flagellin A in *H. pylori* is highly conservative with incident divergence. This character is favorable for PCR-based diagnosis. The significance of the polymorphism in nucleo tide level has not well understood. Further study on the divergent isolate that discovered in this experiment might be helpful to interpret this phenomenon.

Abstract

AIM: **To explore the etiologic role of HPV infection in esophageal carcinoma, and the association of HPV-16 E6 with the nuclear matrix of carcinoma cells.**

METHODS: **Two esophageal carcinoma cell lines, EC/CUHK1 and EC/CUHK2, were tested for HPV-16 E6 subgenetic fragment by polymerase chain reaction amplification of virus DNA associated nuclear matrix. RT-PCR and immunocytochemistry were also used to visualize the expression of E6 subgene in the cells.**

RESULTS: **The HPV-16 E6 subgenetic fragment was found to be present in nuclear matrix-associated DNA, E6 oncoprotein localized in the nucleus where it is tightly associated with nuclear matrix after sequential extraction in EC/CUHK2 cells. It was not detected, however, in EC/CUHK1 cells.**

CONCLUSION: **The interaction between HPV-16 E6 and nuclear matrix may contribute to the virus induced carcinogenesis in esophageal carcinoma.**

Chen HB, Chen L, Zhang JK, Shen ZY, Su ZJ, Cheng SB, Chew EC. Human papillomavirus 16 E6 is associated with the nuclear matrix of esophageal carcinoma cells. *World J Gastroenterol*, 2001;7(6): 788-791

INTRODUCTION

Esophageal carcinoma is the most common malignant epithelial neoplasm of the esophagus worldwide. The incidence of esophageal carcinoma reported by WHO has increased many folds in the past 20 years and is apparently still rising. However, the incidence of this disease varies widely among different geographic regions, being remarkably high in certain regions, including the northern parts of China, Iran and South Africa, whereas being remarkably low in Western Europe and North America. The wide geographic variation in incidence of esophageal carcinoma implies a causal role of environmental factors in the pathogenesis of esophageal carcinoma. Epidemio logical studies have shown that environmental factors, including tobacco, alcohol, certain dietary products, nutritional deficiency, and other chemical agents are associated with the development of esophageal carcinoma in both high and low risk regions[1,2].

Human papillomavirus (HPV) has recently been implicated as an important etiological factor in the development of esophageal carcinoma in high incidence areas[3-6]. HPV DNA sequences were detected in 24% to 60 % of esophageal squamous cell carcinoma in high risk regions. HPVs are small DNA viruses that can be classified as either high risk or low risk group. HPV-16 and 18 is most common in high risk group. In most HPV infected cells, E6E7 subgenetic fragments of viral genome are retained and integrated in host cell chromosomes[7,8]. The *in vivo* and *in vitro* transforming properties of the virus reside in these two genes. E6 interacts with a tumor suppressor protein P53 and has been shown to target the P53 protein for rapid degradation[9,10]. E6 expressing cells are the refore unable to express effective levels of P53 protein, resulting in the loss of normal P53 functions within these cells. The ability of the high risk HPV types to interfere with normal P53 function is particularly significant for oncogenetic activity since alterations of the p53 gene are the most common genetic event detected so far in almost all types of human cancers[11-14]. E6 also targets other proteins: the focal adhesion protein paxillin[15] and the interferon regulatory factor 3[16]. These data indicate the multifunctions of viral oncop roteins, modifying a multitude of cellular functions.

Nuclear matrix is operationally defined as the nonchromatin component of the nucleus after sequential extraction with non-ionic detergents, nucleases and high salt buffers. It consists of nuclear envelope and inner- fibrous web forming a scaffold for attachment of DNA[17]. Nuclear matrix has been shown to play a fundamental role in nuclei c acid m etabolism[18-21]. It has been found to harbor sites for DNA replication[22,23], transcription[24,25], RNA processing[26,27] and steroid hormone action[28-30]. In addition, proto-oncogene products and several viral oncoproteins such as the E B virus nuclear antigen leader protein[31],adenovirus E1A protein, the simian virus 40 large tumor antigen and HPV E7 protein[32,33] associate with the nuclear matrix. The involvement of nuclear matrix and its proteins in various nuclear a ctivities has also provided a potential target for anticancer agents[33-36] and toxicant[37].

In this study, the association of both HPV-16 E6 gene and E6 protein with nuclear matrix in HPV-16-containing esophageal carcinoma cell line was investigated by PCR, RT-PCR and immunocytochemistry.

MATERIALS AND METHODS

Cell culture

Two human esophageal carcinoma cell lines, EC/CUHK1 and EC/CUH K2, were used. EC/CUHK1[38] was established from a well-differentiated human esophageal carcinoma and it is HPV negative.

EC/CUHK2[39] was established from a Chinese male patient with a poorly differentiated squamous carcinoma of the esophagus, the cells contain HPV-16 DNA. The cell lines were cultured in DMEM (Gibco) supplemented with 50 mL/L fetal bovine serum (Gibco), 10^5 units/L penicillin an d 100 mg/L streptomycin (Sigma) at 37℃ in humidified 50 mL/L CO_2 incubator.

Nuclear matrix-associated DNA extraction

The method developed by Fey *et al* was modified[40]. Briefly, culture cells were trypsinized and resuspended in cytoske leton buffer (100 mmol/L KCl, 3 mmol/L $MgCl_2$, 1 mmol/L EGTA, 1 mmol/L PMSF, 10 mmol/L PIPES pH 6.8, 300 mmol/L sucrose and 5 ml/L Triton X-100) for 15 min at 4℃. Chromatin was removed by incubation of the pellet with different concentrat ions (50 and 100 mg/L) of DNase I and RNase A (100 mg/L) in digestion buffer (same as CSK except with 50 mmol/L NaCl instead of KCl) for 30 min at room temperature. The digestion was terminated by addition of cold ammonium sulfate to a final concentration of 0.25 mol/L. After centrifugation, the resulting pellet containing nuclear matrix was digested overnight by proteinase K at 55℃ for DNA ext raction. The DNA was extracted by phenol-chloroform method and RNA was removed by DNase-free RNase treatment at 37℃ for 1 h. After re-extraction with phenol -chloroform, DNA was precipitated with ethanol in the presence of ammonium acetate and stored in Tris-EDTA buffer at 4℃.

Polymerase chain reaction

Purified primers specifying HPV-16 E6 sequences were designed, forming the viral sequence at position nucleotide 82-559 amplifying 477 bp fragments. The primer sequences are 5'-ATGCACCAAAAGAGAACTGC-3' and 5'-TTACAGCTGCGTTTCTCTAC-3'. PCR was performed in a 25 μl volume of PCR buffer with 1.0 mmol/L MgCl 2, 4×dNTPs, primers and sample DNA. The mixture was hot-started to reduce non-specificity. The amplificati on reaction was conducted with 30 cycles: 95℃ for 1 min; 55℃ for 1 min; and 72℃ for 1.5 min. HPV-16 plasmid DNA was employed as positive control. The PCR products were finally electrophoresed in 10 g/L agarose gel after ethidium bromide staining.

Total RNA extraction and RT-PCR

Total RNA was extracted by Trizol-chloroform method and precipitated with isopropanol. The RNA pellet was washed with ice-cold 750 ml/L ethanol, dried and resuspended in DEPC-treated water. The RNA quantity was determined with OD 260 and OD 280. Reverse transcription was performed with random hexamers, reverse transcriptase, RNase inhibitor, dNTPs and 1. 5 mmol/L $MgCl_2$ (Perkin Elmer) at 42℃ for 45 min. cDNA samples were then sub jected to PCR with HPV-16 E6 primer. The amplification condition was the same as the PCR.

Nuclear matrix preparations in situ and immunocytochemistry

To obtain whole mount nuclear matrix *in situ*, the method described by Staufenbiel *et al*[41] was followed with modifications. The monolayer of culture cells were grown on coverslips for 2 days. After three rinses with PBS at 4℃, the cells were incubated in cytoskeleton buffer, added 4 mmol/L ribonucleoside vanadyl complexes for 15 min at 4℃. Following the removal of supernatant, the cells were incubate d in reticulocyte standard buffer (42.5 mmol/L Tris-HCl pH 7.4, 8.5 mmol/L NaCl , 2.6 mmol/L $MgCl_2$, 1.2 mmol/L PMSF, 10 ml/L Tween 40, 12 mmol/L sodium deoxycholate, 2 mmol/L ribonucleoside vanadyl complexes) for 10 min at 4℃. Chromatin was removed by incubation of the cells in DNase I (100 mg/L) in digestion buffer f or 20 min at room temperature and terminated by addition of cold ammonium sulfate to a final concentration of 0.25 mol/L. The nuclear matrix on coverslips were fixed in PBS buffered 100 mL/L formalin for 10 min. After blocking the non-specificity, the cells were incubated with anti-HPV-16 E6 (Santa Cruz) antibody. The labeling was then detected by ABC method (Dako) and the result was visualized with DAB substrate. Negative controls were incubated in the absence of primary antibody.

RESULTS

PCR

A specific 477 bp PCR product was amplified by HPV-16 E6 primer in nuclear matrix associated DNA from EC/CUHK2 cell line, whereas DNA from nuclear matrix of EC/CUHK1 cell line showed negative reaction. Positive control using HPV-16 plasmid DNA confirmed the specificity and performance of PCR system. (Figure 1). Different concentrations (50 mg/L and 100 mg/L) of DNase I were employed to elute DNA during nuclear matrix preparation of EC/CUHK2. The residual nuclear matrix associated DNA was subjected to PCR. As shown in Figure 1, 477 bp PCR signal was detected in nuclear matrix associated DNA after 50 mg/L DNase and signal was found weakened in stronger DNase (100 mg/L) digestion groups.

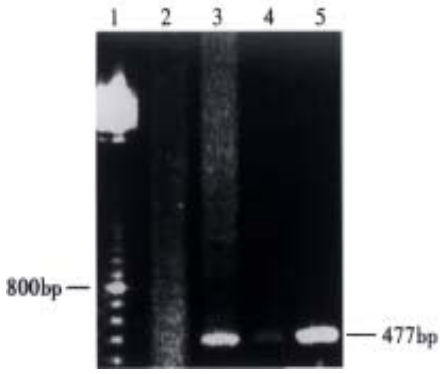

Figure 1 Results of PCR amplication with HPV-16 E6 primers. 1:100 bp DNA ladder marker. 2: nuclear matrix associated DNA of EC/CUHK1 cells, with 50 mg/L DNase digestion. 3: nuclear matrix associated DNA of EC/CUHK2 cells, with 50 mg/L DNase digestion. 4: nuclear matrix associated DNA of EC/CUHK2 cells, with 100 mg/L DNase digestion. 5: HPV-16 plasmid DNA.

RT-PCR

The expression of HPV-16 E6 in EC/CUHK1 and EC/CUHK2 cell lines were detected in the total RNA level. RT-PCR was conducted using specific HPV-16 E6 primer to detect HPV-16 E6 with 477 bp in length. The samples extracted from EC/C U HK2 showed specific amplification of 477 bp product, but negative results were observed in EC/CUHK1 (Figure 2).

Immunocytochemistry

HPV activity was assayed by anti-HPV-16 E6 oncoprotein antibody. EC/CUHK2 cells were immunolabelled wit h the antibody. The staining was found concentrated inside the nucleus. E6 oncoprotein distributed diffusely both in the nuclear filamentous structures and in the periphery of the nuclear lamin (Figure 3). In EC/CUHK1 cells, E6 protein immuno staining was negative (results not shown).

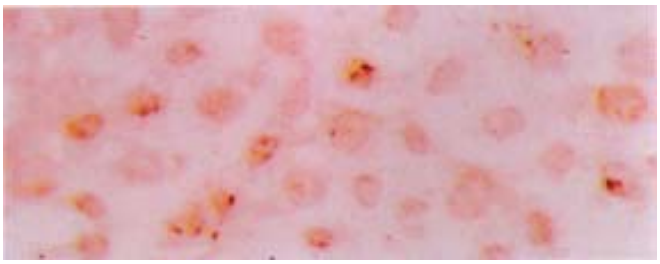

Figure 3 Immunocytochemical staining of anti-HPV-16 E6 protein in nuclear matrix of EC/CUHK2 cells.

DISCUSSION

HPV infections have been suspected to play a role in development of esophageal carcinoma. The prevalence of HPV varies among laboratories and different geographic regions from 0% to 67%. Recent reports found a relatively high rate (27.3% and 34.9%) of HPV positive biopsies in samples obtained from China and in 26.4% of samples obtained from cancer cases in South Africa[5,6]. In particular, HPV types of 16 and 18 are believed to play an important role in esophageal carcinogenesis in those areas with a high incidence of esophageal carcinoma[5,42]. Early observation and analysis of HPV genomes and the viral transcription pattern revealed frequent integration of viral DNA and the consistent expression of the early viral genes E6 and E 7. The same genes have subsequently been shown to be necessary for immortalizati on of various types of human cells[9,43,44]. The integration and retention of viral E6 and E7 fragments within the host cell genome is crucial in the initiation and promotion of virus induced carcinogenesis. The nuclear matrix has been repeatedly shown to be a site for DNA replication and transcription. The active genes are tightly bound to the nuclear matrix while the untranscribed genes are not[18,21]. Nuclear matrix is also an important site of viral host cell interactions[45-50]. The viral activities, such as viral replication and encapsulation were found highly associated with nuclear matrix of host cells. In our previous studies, we have demonstrated that the HPV-16 gene is associated with the nuclear matrix of cervical carcinoma cells[33,51-53]. The role of nuclear matrix in organizing HPV integration is also substantiated by our result. HPV-16 E6 DNA fragment was positively detected in the DNA pieces isolated from nuclear matrix after the treatment by a low or moderate concentration of DNase I. This suggests that so me of the nuclear matrix DNA or matrix attachment region may associate with HPV - 16 E6 DNA. It shows not only the integration of the E6 DNA fragment inside the genome of EC/CUHK2 cells but also a close relationship between the E6 fragment an d the site of active replication and transcription which is one of the proposed functions of nuclear matrix.

In this study, the results of RT-PCR and immunocy tochemistry after nuclear matrix preparation *in situ* show the expression of HPV-16 E6 gene and E6 oncoprotein in EC/CUHK2 cells to be localized in the cell nucleus where it is tightly associated with the nuclear matrix. The role of high risk HPV E6 oncoproteins in malignant transformation is supported by their immortalizing and transforming activities in cells in culture. Our findings provided evidence that the viral E6 protein is expressed inside EC/CUHK2 cells after persistent infection and helps efficient immortalization and survival of the infected cells. The interaction of E6 oncoprotein with P53 has been investigated extensively using *in vitro* systems and in cells[54-57]. The binding of E6 and P53 caused rapid ubiquitin-dependent proteolytic degradation of P53[9,10,58,59]. Cells expressing E6 therefore, have significantly depleted endogenous p53 expression, fail ed to show P53 accumulation following DNA damage and lost normal P53-mediatednegative cell growth control. The E6 targeting of P53 for degradation depends on the ability of the proteins to bind, but not the ability of P53 to form homo-oligomeric complexes. The subsequent degradation of P53 following the interaction with E6 is dependent on another cell protein, named E6-associated protein (E6-AP).

The E6/E6AP complex functions as a ubiquitin-protein ligase, equivalent to E3 in general ubiquitination pathways, allowing E2 catalysed conjugation of ubiquitin groups to lysine residues on P53[60-62]. The linkage of ubiquitin to P53 in this way serves as a recognition signal for specific protease targeting. In view o f the binding of E6 protein and nuclear matrix, we speculate that the E6-AP may be a nuclear matrix protein. It need to be further elucidated.

Since HPV-16 E6 subgenic fragments and oncoprotein are associated with nuclear matrix in esophageal carcinoma cell lines, further studies on the structure and function of these nuclear matrix proteins may provide more information on the relationship between HPV and esophageal carcinoma. It is of great importance to understand the car cinogenesis, and improve the diagnosis and treatment of esophageal carcinoma.

Abstract

AIM: **Genetic polymorphism in enzymes of carcinogen metabolism has been found to have the influence on the susceptibility to cancer. Cytochrome P450 2E1 (CYP2E1) is considered to play an important role in the metabolic a ctivation of procarcinogens such as N-nitrosoamines and low molecular weight organi c compounds. The purpose of this study is to determine whether CYP450 2E1 polymorphisms are associated with risks of gastric cancer.**

METHODS: **We conducted a population based case-control study in C hanglecounty, Fujian Province, a high-risk region of gastric cancer in China. Ninety-one incident gastric cancer patients and ninety-four healthy controls were included in our study. Datas including demographic characteristcs, diet intake, and alcohol and tobacco consumption of indivduals in our study were completed by a standardized questionnaire. PCR-R FLP revealed three genotypes:heterozygote (C1/C2) and two homozygotes (C1/C1 and C2/C2) in CYP2E1.**

RESULTS: **The frequency of variant genotypes (C1/C2 and C2/C2) in gastric cancer cases and controls was 36.3% and 24.5%, respectively. The rare homozygous C2/C2 genotype was found in 6 indivduals in gastric cancer group (6.6%), whereas there was only one in the control group (1.1%). However, the re was no statistically significan difference between the two groups (two-tailed Fisher's exact test, $P = 0.066$). Indivduals in gastric cancer group were m ore likely to carry genotype C1/C2 (odds ratio, OR = 1.50) and C2/C2 (OR = 7.34) than indivduals in control group ($\chi^2 = 4.597$, for trend $P = 0.032$). The frequencies of genotypes with the C2 allele (C1/C2 and C2/C2 genotypes) were compared with those of genotypes without C2 allele (C1/C1 genotype) among indivduals in gastric cancer group and control group according to the pattern of gastric cancer risk factors. The results show that indivduals who exposed to these gastric cancer risk factors and carry the C2 allele seemed to have a higher risk of developing gastric cancer.**

CONCLUSION: **Polymorphism of CYP2E1 gene may have some effct in the development of gastric cancer in Changle county, Fujian Province.**

Cai L, Yu SZ, Zhang ZF. Cytochrome P450 2E1 genetic polymorphism and gastric cancer in Changle, Fujian Province. *World J Gastroenterol*, 2001;7(6):792-795

INTRODUCTION

Fujian Province is one of the highest risk areas of gastric cancer in China[1,2]. Gastric cancer is the major cause of cancer mortality in Changle County,Fujian Province[3-5]. Epidemio logical studies have shown that an increased risk of developing gastric cancer is associated with diet and tobacco smoking[6-8]. One particular hypothesis, which has been paid more attention, is that N-nitroso compounds from dietary sources are involved in carcinogenesis of gastric cancer[9-10]. Recent advances in cancer research have revealed that the main etiology of human cancers are genetic changes in cancer related genes caused by carcinogens in the environment[11-14]. It is known that most of exogenous (xenobiotics) and endogenous chemical car cinogens require biotransformation to activated forms to be carcinogenic[15,16]. Most of the human metabolizing enzymes are genetically polymorphic, and those polymorphisms may affect the enzyme activity or inducibility[17-20]. The sensibitity to procarcinogen differs among individuals, which may have substantial importance in carcinogenesis[21-24]. Cytochromes P450 (CYPs) play an important role on metablism of several aspects of cancer. Cytochrome P450 2E1 (CYP2E1) is primarily responsible for the bioactivation of many low molecular weight carcinogens, and is involved in the metabolic oxidation of carcinogenic nitroso compounds, including N-nitrosoamines[25-26]. This study was designed to in vestigate the relationship between polymorphism of CYP 2E1 and gastric cancer.

MATERIALS AND METHODS

Subjects

All indivduals in our study are the residents of Changle county, Fujian Province of China. Ninety-one patients with pathologic diagnosis as primary gastric cancer between January 1996 to March 1998 and 94 age-and sex matched healthy controls were included in this study. Each indivdual was personally interviewed to obtain information on demographic characteristics, habits of cigarette smoking, alcohol drinking, and dietary consumption frequency. Blood specimens from them were also obtained.

DNA isolation and PCR-RFLP analysis

Genomic DNA was isolated from white blood cells by extraction u sing phenol/chloroform and precipitation using ethanol. PCR was performed using the primers 5'-CCAGTCGAGTCTACATTGTCA-3 (1370-1349) and 5'TTCATTCTGTCTTCTAACTGG-3 (999-978). The amplification reaction was conducted in a 50 (L solution

containing PCR buffer (1.5 mmol·L^{-1} $MgCl_2$, 50 mmol·L^{-1} KCl, 10 mmol· L^{-1} Tris-HCl, pH 8.3), 200 μmol·L^{-1} dNTP, 1ìmol·L^{-1} primer, 200 ng template DNA, and 2.5 μ Taq DNA polymerase (Promega Corp). Those reactions were performed about 35 cycle s at conditions following as denaturation for 1 min at 95℃, annealing for 1 min at 55℃, extension for 1 min at 72℃ and a final extension for 10 min at 72℃. T he PCR products were digested with PstI or RsaI (Fermantas-MBI. Vilnius, Lithuania) for 18 h at 37℃. The restriction sites was identified by 2.2% agarose gel electrophoresis. The genotypes of CYP2E1 were classified as following: a predominant homozygote (C1/C1), a heterozygote (C1/C2) and a rare homozygote (C2/C2). Figure 1, 2.

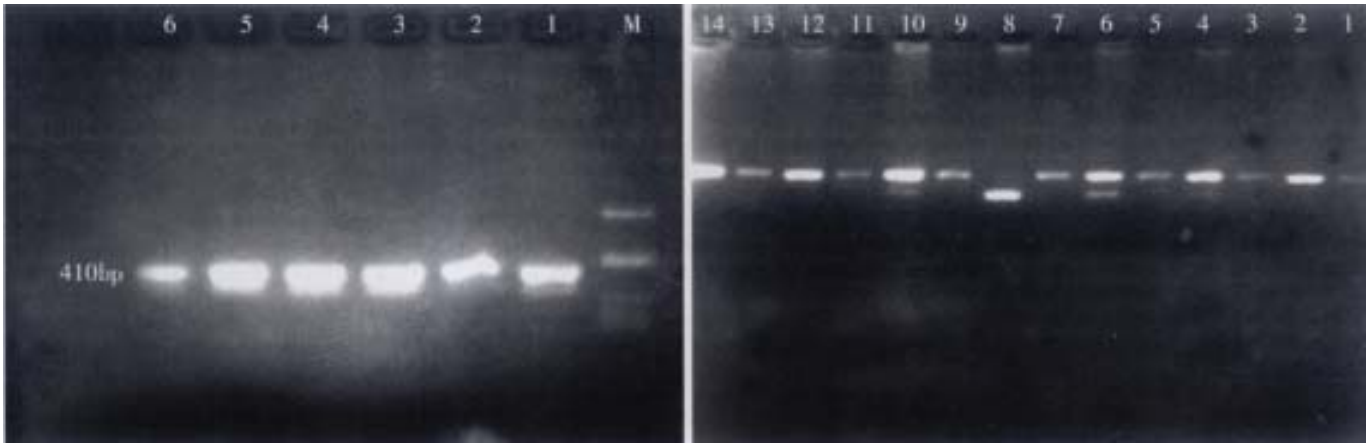

Figure 1 The PCR products of CYP2E1 gene. M: markers.
Figure 2 PCR-RFLP with Pst1.
Lanes 2, 12, 14: C1/C1; Lanes 4, 6, 10: C1/ C2; Lane 8: C2/C2; Lanes 1, 3, 5, 7, 9, 11, 13: Sample controls.

Statistical analysis

Fisher's exact tests were determined by standard methods. The relationships between CYP 2E1 genotypes and putative risk factors were measured using the odds ratios (ORs) and their 95% confidence intervals (95%CIs).

RESULTS

The age (x±s) of indivduals in gastric cancer group and control group were 58.4±11 years and 58.2±11 years, respectively. The distributions of age and sex were similar in cases and controls. The risks of gastric cancer were related to smoking, alcohol drinking, and fish sauce intake (a condiment commonly used by local residents), Table 1.

Table 1 Distribution of selected variables in gastric cancer group and group

	Gastric cancer (*n* = 91)	Control (*n* = 94)	*P* value

Alcohol drinking/y			
0	40 (44.0)	66 (70.2)	
<10	3 (3.3)	13 (13.8)	
10-	14 (15.4)	8 (8.5)	
20-	34 (37.4)	7 (7.5)	0.0000
Fish sauce intake			
Low (<3 times/w)	17 (18.68)	69 (73.40)	
High (≥ 3 times/w)	76 (81.32)	25 (26.60)	0.0000

The frequency of variant genotypes (C1/C2 and C2/C2) in gastric cancer group and control group was 36.3% and 24.5%, respectively. The rare homozygous C2/C2 genotype was found in 6 of gastric cancer group (6.6%), but in 1 of the controls (1.1 %). However, the result showed no statistical difference. Fisher's exact test $P = 0.066$ (Table 2). The allele frequencies of CYP2E1 fit with Hardy-Weinberg equilibrium ($\chi^2 = 0.242$, $P>0.05$).

Table 2 Cytochrome P450 2E1 genotype and risks of gastric cancer

CYP2E1	Gastric cancer		Control (n = 94)		OR (95%CI)
	n	(%)	n	(%)	
C1/C1	58	(63.7)	71	(75.5)	1.00
C1/C2	27	(29.7)	22	(23.4)	1 .50 (0.74-3.07)
C2/C2	6	(6.6)	1	(1.1)	7.34 (0. 84-166.60)

Fisher's test $P = 0.066$ *vs* controls χ^2 trend = 4.597 $P = 0.032$ *vs* controls

Gastric cancer indivduals were more likely to carry genotype C1/C2 and C2/C2 than indivduals in control group. Individuals carried at least one C2 allele (genotypes C1/C2 or C2/C2) seemed to have an increased risk of gastric cancer (OR = 1.86, 95%CI 1.07-3.25), Table 3.

Table 3 The allele frequencies of CYP2E1 in gastric cancer group and control group

	C1		C2	
	n	Frequencies	n	Frequencies
Gastric cancer	143	0.7857	39	0.2143
Controls	164	0.8723	24	0.1276

$\chi^2 = 4.91$ $P<0.05$ *vs* controls; OR = 1.86 95%CI 1.07-3.25.

The frequencies of genotypes with the C2 allele (C1/C2 and C2/C2) were compared with those of genotypes without C2 allele (C1/C1) among indivduals in gastric cancer and control group according to the pattern of gastric cancer risk factors of smoking, alcohol drinking and fish sauce intake. Indivduals who have been exposed to those risk factors of gastric cancer and carried the C2 allele seemed to have a higher risk of developing gastric cancer (Table 4).

Table 4 Relationships between CYP2E1 together with selected variables and risk of gastric cancer

CYP2E1	Variables	Gastric cancer	Controls	OR (95%CI)
	Smoking			
C1/C1	No	21	48	1.00
C1/C1	Yes	37	23	3.68 (1.67-8.19)
C1/C2 or C2/C2	No	10	12	1.90 (0.64-5.69)
C1/C2 or C2/ C2	Yes	23	11	4.78 (1.82-12.78)
	Alcohol drinking

C1/C1	High	47	18	12.58 (5.40-29.34)
C1/C2 or C2/C2	Low	6	16	1.81 (0.58-5.66)
C1/C2 or C2/C2	High	27	7	18.58 (6.47-53.37)

[a]High ⩾3 times/w; Low<3 times/w

DISCUSSION

Epidemiological studies have shown that up to 90% of all cancers are related to environmental factors. Most of the environmental carcinogens need to be metabolically activated to exert their carcinogenic effects[27-30]. Genetic polymorphisms in enzymes involved in carcinogen metabolism has shown to influence the susceptibility to cancer[31-33]. Cytochrome P4502E1 (CYP2E1) plays an important role in this process. It participates in the metabolic activation of carcinogenic nitrosamines. Several recent studies show that the genetic polymorphisms of metabolizing enzymes are associated with some cancers such as lung cancer[34-36], esophageal cancer[37-40] and colorectal cancer[41]. But the results of those studies of the relation between CYP2E1 and cancer susceptibility are inconsistent[42].

The possibility that N-nitrosated compounds are involved in gastric cancer has been an issue for many years. Nitrosamines occur in tobacco smoke and in some kinds of food, which are also formed endogenously in the stomach. In this study, fish sauce intake, cigarette smoke, and alcohol drinking were positively associated with gastric cancer. Fish sauce is a condiment that is particularly favored by the local residents in Fujian Province[43-45]. Many N-nitro compound precursors have been found in fish sauce[46,47]. Tobacco smoke contains many potential carcinogens, also including nitroso compounds[48]. CYP2E1 are known to vary and are induced by ethanol consumption. Several studies reported that the variant C2 was associated with enhanced enzyme activity. Hayashi *et al*[49] reported that enhanced activity of C2/C2 DNA was about 10 times than that of C1/C1 DNA. This difference in the transcriptional activities might associate with the susceptibility in human carcinogenesis. There is evidence suggesting that there may be a gene-environment interaction in the development of cancer so that cancer risk associated with a given exposure is modified by the genotype of the host[50]. In this study, a much higher risk was observed from those who exposed to the risk factors of gastric cancer and carried the C1/C2 or C2/C2 genotypes. The results suggest that polymorphic genes that code for tobacco carcinogen and alcohol metabolizing enzymes may play a role in susceptibility of gastric cancer. The intervention against cigarette smoking, alcohol drinking, bad eating habits may be important for the prevention of gastric cancer in high-incidence areas.

Because of the limited number of samples in this study, determination of precise dose-response relations with respect to a sufficient number of dose level for each of genotype groups may not be able to be conducted. Further studies with a larger number of samples are needed to confirm the role of genetic polymorphism of human CYP2E1 in gastric cacinogenesis.

Abstract

AIM: **To evaluate the effects of sulindac in inducing growth inhibition and apoptosis of human gastric cancer cells in comparison with human hepatocellular carcinoma (HCC) cells.**

METHODS: **The human gastric cancer cell lines MKN45 and MKN28 and human hepatocellular carcinoma cell lines HepG$_2$ and SMMC7721 were used for the study. Anti-prolife rative effect was measured by MTT assay, and apoptosis was determined by Hoechst-33258 staining, electronography and DNA fragmentation. The protein of cyclooxygen ase-2 (COX-2) and Bcl-2 were detected by Western dot blotting.**

RESULTS: **Sulindac could initiate growth inhibition and apoptosis of MKN45, MKN28, HepG$_2$ and SMMC7721 cells in a dose-and time-depen dent manner. Growth inhibitory activity and apoptosis were more sensitive in HepG$_2$ cells than in SMMC7721 cells, MKN45 and MKN28 cells. After 24 hours incubation with sulindac at 2 mmol·L^{-1} and 4 mmol·L^{-1}, the level of COX-2 and Bcl-2 prote in were lowered in MKN45, SMMC7721 and HepG$_2$ cells but not in MKN28 cells.**

CONCLUSION: **Sulindac could inhibit the growth of gastric cancer cells and HCC cells effectively *in vitro* by apoptosis induction, which was associated with regression of COX-2 and Bcl-2 expression. The growth inhibition and apoptosis of HCC cells were greater than that of human gastric cancer cells. The different effects of apoptosis in gastric cancer cells may be related to the differentiation of the cells.**

INTRODUCTION

Nonsteroidal anti-inflammatory drugs (NSAIDs) such as aspirin and indomethacin were widely used for the treatment of inflammatory joint and muscle pain. The stuidies of past two decades indicated that NSAID could prevent colorectal cancer[1-3]. As a member of NSAID, sulindac has been shown to induce regression of adenomas in familial adenomatous polyposis (FAP) patients, prevent recurrence of adenomas[4-5] and reduce the risk of colon cancer[6]. Rahman *et al*[7] demonstrated that sulindac and its irreversible oxidized derivative, sulindac sulfone exhibited a growth inhibitory effect on human hepatocellular carcinoma (HCC) cell lines, indicating that sulindac has chemopreventive effect on colon cancer as well as on other types of cancer in GI tract. Gastric cancer is one of the most common causes of malignancy-related death in China[8-11]. It is imperative to find effective chemopreventive methods to reduce the morbidity and mortality of gastric cancer. Lots of chemical agents have been proved having the chara cter of inducing apoptosis in human gastric cancer cells[12-13]. Recent studies gave the concept that overexpression of cyclooxygenase-2 (COX-2) was the early event in carcinogenesis of gastric cancer[13] and made it the target of chem oprevention against gastric cancer[14]. The present study was undertaken to analyze the effect of sulindac in two gastric cancer cell lines as compared with two HCC cell lines.

MATERIALS AND METHODS

Cell lines and culture

The huamn gastric cancer cell lines MKN45 and MKN28 were obtained from the Japanese Cancer Res earch Resources Bank (Tokyo, Japan). HepG$_2$ and SMMC7721 cells were available commercially from the Institute of Biochemistry and Cell Biology, Shanghai Institute for Biological Sciences, Chinese Academy of Sciences. Cells were grown in RP M I 1640 (Gibco) supplemented with 100 mL·L^{-1} fetal bovine serum (Sijiqing, HangZhou , China), penicilin (100 mg·L^{-1}) and streptomycin (100 mg·L^{-1}) in a humidified atmosphere of 50 mL·L^{-1} CO_2 at 37℃. Sulindac purchased from Sigma Chemical Co. (St Louis, MO, USA) was freshly prepared in DMSO (less than 5 g·L^{-1} in w hole medium) before use. Vehicle controls of DMSO was included in the studies.

MTT assay

Antiproliferative effects were measured by MTT assay. About 10 000 cells per well were plated in 96-well microtitre plates and incubated overnight in 100 μL of culture media. Then cells were treated with various concentrations of sulindac for 24 h and 48 h (0, 0.25, 0.5, 1, 2 and 4 mmol·L^{-1} for MKN45, MKN28 and SMMC77 21 cells, 0, 25, 50, 100, 200 and 400 μmol·L^{-1} for HepG$_2$ cells); 100 μL MTT (1 g·L^{-1}) was then added to each well, and the cells were further incubated for 4 h. The supernatant was removed and 100 μLDMSO was added to each well, and then incu bated for 30 min. The absorbance at wavelength of 570 nm was measured by a micro - ELISA reader. The negative control well has no cells and used as zero point of a bsorbance. Each assay was performed three times in triplicate.

Morphological measurement of apoptosis

The morphological change of apoptosis was assayed under fluorescence microscope following staining with Hoechst33258. The cells were fixed in 200 mL·L^{-1} ethanol/PBS, stained with 5 mg·L^{-1} Hoechst33258 (CNI) for 30 min at 37℃, then visualized under UV fluorescence microscope. Apoptotis cells were de fined as cells

showing nuclear and cytoplasmic shrinkage, chromatin condensation and apoptosis body. At least 300 cells were counted and the percentage of apoptotic cells (Apoptotic Index) was calculated.

DNA fragmentation analysis

Following sulindac treatment, cells were washed by PBS, and fixed in ice-c old 700 mL·L^{-1} ethanol for 24 h. After the ethanol was removed, cells were rinsed in 40 μL 0.2 mol·L^{-1} Na_2HPO_4/0.1 mol·L^{-1} citric acid (192:8, pH7.8) for 60 min at room temperature. After being centrifuged 5 min (1000G), the supernatant was c ollected in Eppendorf tubes, 4 μL 2.5 g ·L^{-1} NP-40 and 4 μL 10 g ·L^{-1} RNase A were added at 37℃ for 30 min, then 4 μL Protein K (1 mg/mL, Promega) were added at 50 ℃ for 30 min. Equal amount of DNA (15 μL) was electrophoresed in 10 g·L^{-1} a garose gels impregnated with ethidium bromide (5 mL·L^{-1}) for 2 h at 80 V. DNA fragments were visualized by ultraviolet transillumination.

Western Dot blot analysis of COX-2 and Bcl-2

Cells incubated with various concentrations of sulindac for 24 h (0, 2 and 4 mmol·L^{-1} for MKN28, MKN45 and SMMC7721 cells, 0, 400 and 800 μmol ·L^{-1} for $HepG_2$ cells). These cells were washed by PBS and dissolve d in 100iL extraction buffer (50 mmol·L^{-1} Tris-HCL (pH 8.0), 150 mmol·L^{-1} NaCl, 10 g·L^{-1} Triton-X-100 and 1mg·L^{-1} Aprotinine). Equal amounts of cell lysates (100 μg) were dotted on nitrocellulose membrane (Amersham). The membrane was incubated first with a primary antibody overnight at 4℃ and then with peroxidase- conjugated anti-rabbit or anti-mouse IgG antibody for 2 h. Protein was detected by chemilu minescence (ECL) system. The membranes were washed and added by equal amounts of luminal reagent A and B (Santa Cruz) for 2 min and exposed to film. Rabbit anti-h u man polyclonal antibody COX-2(H-62, sc-7951), goat anti-mouse IgG conjugate d with HRP(Cat#sc-2005) , Goat anti-rabbit IgG conjugated with HRP(Cat#sc-2004) we re purchased from Santa Cruz Co. Mouse anti-human bcl-2 monoclonal antibody (Cat.No.M-0025) was purchased from Antibody Diagnostica Inc(USA).

Statistical analysis

Student's *t* test was used for results comparison among different groups. The presented data were mean values of at least three different experiments and expressed as $\bar{x}\pm s$. A *P* value of less than 0.05 is considered statistically significant.

RESULTS

Effects of sulindac on cell growth

Various concentrations of sulindac were incubated with cells for 24 h and 48 h. Cell growth was determined by MTT assay. As shown in Figure 1, sulindac could inhibit the growth of gastric cancer cells and HCC cells in a dose-and time-dependent manner. Sulindac showed a more potent effect in reducing $HepG_2$ cells' growth as compared with SMM C77 21, MKN45 and MKN28 cells. The cell death rate was more obvious in MKN45 cells than in MKN28 cells (Figure 1).

Apoptosis of cells induced by sulindac

To evaluate the apoptosis of cells, Hoechst-33258 staining and agarouse gel electrophoresis of genomic DNA were used. The Hoechst-33258 staining showed apoptosis in all four types of cells, which was characterized by cytoplasmic and nuclear shrinkage, chromatin condensation and apoptosis body (Figure 2). The apoptosis was mo re evident in $HepG_2$ cells than in SMMC7721 and gastric cancer cells and the AI of MKN45 cells were higher than that of MKN28 cells (Figure 3). DNA fragmentation was shown as a ladder pattern on agarose gel.

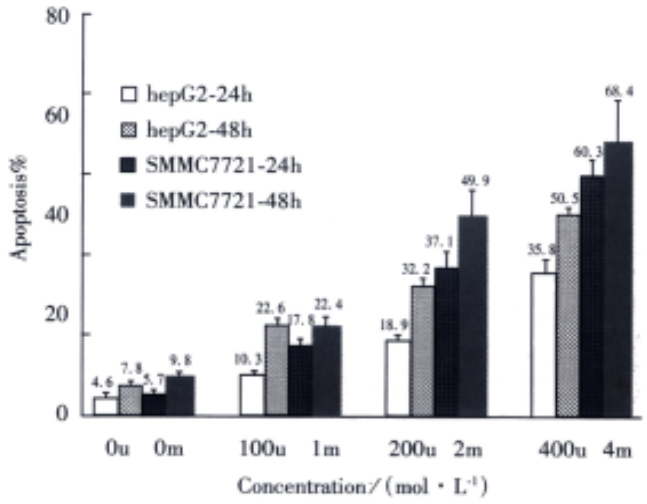

Figure 3B The apoptosis of 2 HCC cells induced by sulindac by Hoechst 33258 staining. (N = 3)

Differential expression of COX-2 and Bcl-2 protein in sulindac-treated cells

The protein levels of COX-2 and Bcl-2 were determined by Western dot blotting. After treatment with 2 mmoL ·L^{-1} and 4 mmoL·L^{-1} of sulindac for 24 h, the protein level of COX-2 and Bcl-2 showed marked decrease in MKN45, HepG$_2$ and SMMC7721 cells, whereas the protein level remained unchanged in MKN28 cells (Figure 4).

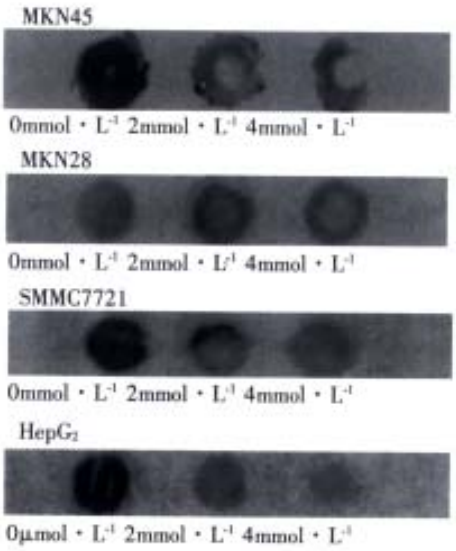

Figure 4A COX-2 protein levels in human gastric cancer and HCC cells with sulindac for 24 h.

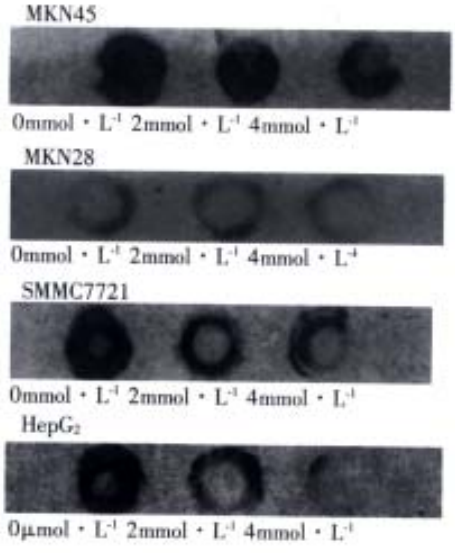

Figure 4B Bcl-2 protein levels in human gastric cancer cells and HCC cells with sulindac for 24 h.

DISCUSSION

Since Adolphie *et al* reported that certain NSAIDs were capable of inhibiting proliferation of Hela cells in 1972, the chemopreventive effect of NSAIDs has been widely studied *in vivo* and *in vitro* in recent years[15-16]. Most results indicated that the mechanism related to this capability was by the inhibition of cyclooxygenase-2 (COX-2) which was not found in most normal tissues and could be induced by cytokines and growth factors[17-19]. Elevated level of COX-2 suggested the existance of inflammation or carcinoma[20-25]. Lim *et al* found that all 104 gastric cancer tissues showed positive expression of COX-2 but not in normol gastric mucosa. Ratnasinghe *et al*[26] found that gastric cancer tissues could produce more prostagland in than normal gastric mucosa. COX-2 was also found to be related to tumor angiogenesis[27-28] and metastasis[29-31]. In this study, we confirmed the results of other studies that COX-2 was positive in MKN45, MKN28 and HepG$_2$ cell lines as well as in SMMC7721 cells and the level of COX-2 protein was much lower in MKN 2 8 cells. The results also confirmed that COX-2 was correlative with carcinogenesis in GI tract.

One of the strongest evidence that NSAID has the capability of chemoprevention and treatment of colorectal cancer was the obvious effect of sulindac in treatment of FAP[32-33]. Pasricha *et al* reported that the number and size of polyps were reduced in 24 FAP patients after treatment with sulindac and induction of apoptosis was regarded

as the main mechanism. However, there we re no studies about growth inhibition and apoptosis induction of sulindac in gastric cancer. In this study, two gastric cancer cell lines with different status of differentiation were used. The growth inhibition and apoptosis of $HepG_2$ cells were more obvious as compared with MKN45 and MKN28 cells. Since sulindac is a pro-drug and is metabolized to sulindac sulfide and sulfone by the gut flora and in the liver[34], HCC cells might be able to convert sulindac to its metabolic derivative and increase its capability of growth inhibition and apoptosis inducti on. We suggested that the effects of growth inhibition of sulindac on gastric cancer might be increased *in vivo* than *in vitro*. We also concluded that sulindac could induce apoptosis in gastric cancer cells and HCC cells, which may account for its growth inhibitory effects.

Bcl-2 is one of the most important factors in apoptosis process[35]. The elevated expression of COX-2 could increase the level of Bcl-2 in the epithelial cells of rat colon and decrease the apoptotic rate of colonic cells[36]. Prostaglandin E_2, mediated by COX-2 from a rachidonic acid, could inhibit apoptosis of human colon cancer cells *in vitro* and increase expression of Bcl-2 in cancer cells[37]. Liu *et al*[38] also confirmed the relationship between COX-2 and Bcl-2 in prostate cancer. We found that the levels o f COX-2 in MKN45, SMMC7721 and HepG 2 cells as well as Bcl-2 were decreased after treatment with sulindac, whereas both COX-2 and Bcl-2 were unchanged in MKN28 cells. Apoptosis was also more evident in MKN45, SMMC7721 and $HepG_2$ than in MKN28 cells. It was suggested that COX-2 and Bcl-2 were involved in apoptosis of gastric cancer cells and HCC cells induced by sulindac.

Several mechanisms have been proposed affecting the pathways regulating cellular proliferation and apoptosis by NSAIDs. Although parts of the mechanisms were related to COX-2 inhibition, most of them were COX independent[39-44]. Sulindac and its derivatives have different mechanism in inducing apoptosis of cancer cells. Sulfone neither inhibits COX nor has anti-inflammatory properties, but can produce chemopreventive effect similar to that of sulindac[45-46]. The death rate of MKN28 cells was higher than its apoptotic rate in our study, which might be caused by the COX-2 in dependent way.

As COX-2 specific inhibitors, Celecoxib and Rofecoxib have been used clinically with few side effects[47]. The chemopreventive eff ect of COX-2 specific inhibitor has not yet been well studied as compared with COX-2 nonsp ecific inhibitors[48-49]. As one of COX-2 nonspecific inhibitors, sulindac had little effect in renal prostanoid synthesis and provides addtional advantage for its use in clinical trials[50]. The concentration and time course of sulindac in inhibiting growth and inducing apoptosis of gastric cancer cells *in vivo* need further investigations. Other possible mechanisms of action of sulindac need to be further studied.

Abstract

AIM: **To follow the principles of evidence based medicine to reach the integrated results of these studies.**

METHODS: **Twenty-one papers of case-control studies were selected, including 11 on gastric cancer, 7 on precancerous lesion of stomach and 3 on lymphoma of stomach. Meta analysis was used to sum up the odds ratios (OR) of these studies.**

RESULTS: ***H. pylori* vsgastric cancer (intestinal and diffuse type): the odds ratio from the fixed effect model is 3.0 016 (95% CI: 2.4197-3.7234, *P*<0.001). *H. pylori vs* precancerous lesion of stomach: a random effect model was used to calculate the summary odds ratio and its value is 2.5635 (95% CI: 1.8477-3.5566, *P*< 0.01). *H. pylori vs* lymphoma of stomach: though the quantity of literature is too small to make Meta analysis, the data of these 3 studies show that lymphoma of stomach is highly associated with *H. pylori* infections.**

CONCLUSION: **Since it had been revealed that *H. pylori* infection pre-exists in gastric carcinoma and precancerous lesions, the results of Meta analysis present a strong evidence to support the conclusion that *H. pylori* infection is a risk factor for gastric carcinoma.**

INTRODUCTION

Since *H. pylori* was founded in 1983, the association of *H. pylori* with *H. pylori* related diseases has become the hot spot of gastroenterological studies. Gastric carcinoma is the most important disease among *H. pylori* related diseases. It is believed that *H. pylori* is one of the important causes of gastric carcinoma. But there is still lack of the final conclusion and the definite mechanisms of their association.

In China, malignant tumor is the second death cause of men and the third death cause of women according to the investigation of death cause in 29 provinces, municipalities and autonomous regions conducted from 1 973 to 1975. The annual average mortality rate of gastric carcinoma is as high as 16 per 100 thousand, which is the leading death cause among malignant tumors, and the rates of *H. pylori* infection are higher than 50 percent in the mainland of China[1]. In t he past two decades, Chinese medical researchers and clinical workers have done much a great amount of studies to reveal the relationship and the mechanisms of the association of *H. pylori* with gastric carcinoma. Most of them agree to the opinion that *H. pylori* is a risk factor for gastric carcinoma, but a certain number of them hold different points of view[2-19].

Eslick *et al*[20] have workedout the summary odds ratio of 2.04 of those same studies made in Western countries. In this paper, we reviewed all the literatures of studies in China on the relationship between *H. pylori* and gastric carcinoma as well as precancerous lesions of stomach published from 1995 in order to reach a summary conclusion using statistical methods.

MATERIALS AND METHODS

Literature

A CBM (Chinese Biomedical Database) search for articles published from 1995 was performed with the MeSH headings "*Helicobacter pylori*," "gastric carcinoma (cancer),""precancerous lesion of stomach" and "lymphoma of stomach." More than 100 papers were retrieved. Since most of them had no appropriate controls or their data did not meet the requirements of Meta analysis, only 21 papers of case-control studies were selected, including 11 about gastric cancer (Table 1), 7 on precancerous lesions of stomach (Table 2) and 3 on lymphoma of stomach (Table 3).

Data

Eleven case-control studies on the relationship between *H. pylori* infection and gastric cancer (intestinal and diffuse type) included totally 820 patients and 11-647 controls. Among them, 7 attained significant results, and 4 did not (Table 1).

Seven case-control studies on the relationship between *H. pylori* infection and precancerous lesions of stomach included totally 1978 patients and 6076 controls. All of them had significant results (Table 2).

Three case-control studies on the relationship between *H. pylori* infection and lymphoma of the stomach included totally 83 patients and 143 controls. All of them had significant results (Table 3).

Methods

In the statistical analysis, Meta analysis method with fixed effect model and random effect model was used to reach the integrated conclusion[42].

RESULTS

H. pylori infection vs gastric cancer

All 11 odds ratios were statistically homogenous ($P>0.05$). Summary odds ratio for gastric cancer related to *H. pylori* infection was 3.0016 using fixed effect model (95% CI 2.41 97-3.7234, Table 1). Figure 1 shows the summary odds ratio and odds ratios and their 95%CI of 11 case-control studies on the relationship between *H. pylori* infection and gastric cancer.

H. pylori infection vs precancerous lesion of stomach

Since 7 odds ratios were not statistically homogenous ($P<0.05$), random effect model was used to calculate the summary odds ratio. The summary odds ratio for precancerous lesions of stomach related to *H. pylori* infection was 2.5635 (95% CI 1.8477-3.5566, Table 2). Figure 2 shows the summary odds ratio and odds ratios and their 95%CI of 7 case-control studies on the relationship between *H. pylori* and precancerous lesions of the stomach.

H. pylori vs lymphoma of stomach

Though the quantity of literature is too small to make Meta analysis, the data of these 3 studies show that lymphoma of the stomach was highly associated with *H. pylori* infections. Figure 3 shows the odds ratios and their 95%CI of 3 case-control studies on the relationship between *H. pylori* infection and lymphoma of the stomach.

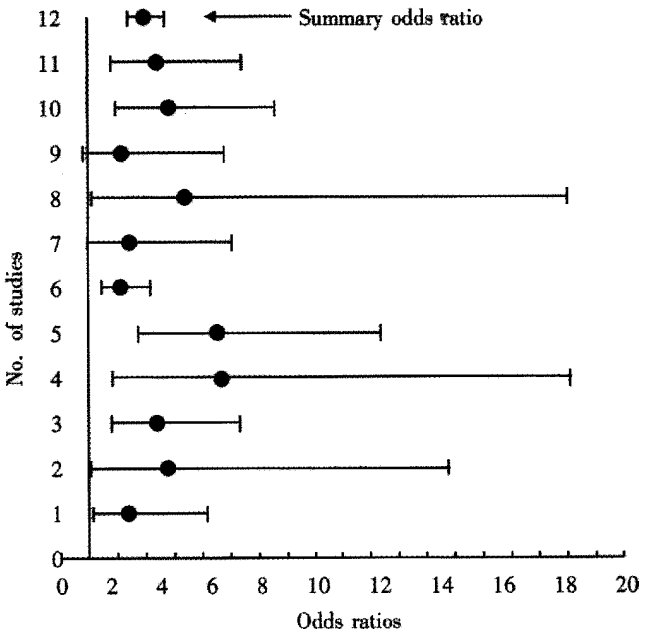

Figure 1 Odds ratios and summary odds ratio with 95%CI of 11 case-control studies.

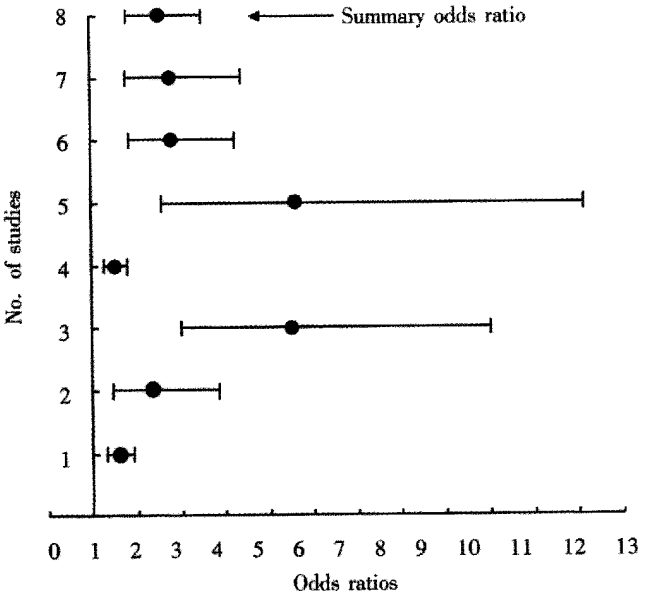

Figure 2 Odds ratios and summary odds ratio with 95%CI of 7 case-control studies.

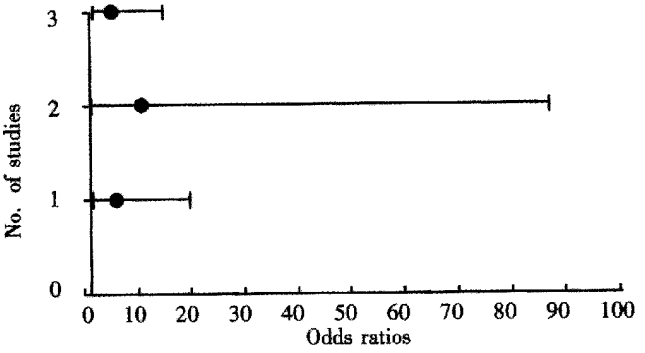

Figure 3 Odds ratios with 95%CI of 3 case-control studies.

DISCUSSION

Since it had been revealed that *H. pylori* infection pre-exists in gastric carcinoma and precancerous lesions, the result of the Meta analysis present a strong evidence to support the conclusion that *H. pylori* infection is a risk factor for gastric carcinoma.

The following statements might explain the association of *H. pylori* infection with gastric carcinoma: ① gastric carcinoma is caused by *H. pylori* infection; ② *H. pylori* infection is caused by gastric carcinoma; ③ there are some certain factors for *H. pylori* infection and gastric carcinoma[9]. As we all know that *H. pylori* infections also exist in the gastric mucosa of nearly normal persons, it is impossible that *H. pylori* infection is caused by gastric carcinoma. Numerous studies support the point that *H. pylori* infection exist before the occurrence of gastric carcinoma[43-48], indicating that *H. pylori* infection is not a secondary infection but a primary infection. It was reported that. Mongolia gerbils have been infected with *H. pylori* through mouth route, which is implanted in their stomach for a long time. Twenty-six weeks after the infection, severe chronic active gastritis, ulcer and intestinal metaplasia occurred in the stomachs of the gerbils. And 37% of the gerbils involved in the study were attacked with gastric adenocarcinoma 62 weeks after the infection[10].

The development and occurrence of gastric carcinoma is a long-lasting process and the effect of multiple factors. It is accepted by numerous scholars that *H. pylori* is an important risk factor for gastric carcinoma. In addition to the studies that support the association of *H. pylori* with gastric carcinoma, some researchers investigated the relationship between *H. pylori* and other kinds of carcinoma such as cancer of the colon, rectum, esophagus etc. and they made a negative conclusion, which proved the effect of *H. pylori* in gastric carcinoma in the other directions. However, *H. pylori* is not the unique etiological factor for gastric carcinoma. The association of the occurrence of gastric carcinoma with *H. pylori* infection should be considered from the angle of the multi-agent compound etiological theory[49-62].

According to the studies that support the opinion of association of *H. pylori* with gastric carcinoma, It can be assumed that t he canceration of gastric mucosa took place under the action of *H. pylori* in the following process: *H. pylori* related gastritis of antrum→ atrophic gastritis→intestinal metaplasia→gastric carcinoma.

There are many problems we are going to face. The infection rate of *H. pylori* is very high in the pop ulation surveys. But why most of those with *H. pylori* infection were not atta cked wit h gastric carcinoma. What are the other factors acting together with *H. pylori* to cause gastric carcinoma? How do they act? We must do more prospective interventional trial to answer these questions. It will be more helpful to do random interventional trial of eradication of *H. pylori* infection among the high-risk groups of gastric carcinoma and precancerous lesions to observe if their incidence rate of gastric carcinoma will decrease. In China, though very few of this kind of prospective studies have been made, an interventional trial of eradication of *H. pylori* is being made in Shandong and Fujian provinces. It will be of great help in revealing the exact mechanism of *H. pylori* in the process of gastric mucosa canceration.

Abstract

AIM: **To study the clinicopathological and mole cular genetic characteristics of typical Chinese hereditary nonpolyposis cotorectal cancer (HNPCC) families.**

METHODS: **Four typical Chinese HNPCC families were analyzed using microdissection, microsatellite instability analysis, immunostaining of hMSH2 and hMLH1 proteins and direct DN A sequencing of hMSH2 and hMLH1 genes.**

RESULTS: **All five tumor tissues of 4 prob ands from the 4 typical Chinese HNPCC families showed microsatellite instability at more than two loci (MSI-H or RER+phenotype). Three out of the 4 cases losthMSH2 protein expression and the other case showed no hMLH1 protein expression. Three pathological germline mutations (2 in hMSH2 and 1 in hMLH1), which had not been reported previously, were identified. The same mutations were also found in other affected members of two HNPCC families,respectively.**

CONCLUSION: **Typical Chinese HNPCC families showed relatively frequent germline mutation of mismatch repair genes. High-level microsatellite instability and loss of expression of mismatch repair genes correlated closely with germline mutation of mismatch repair genes. Microsatellite instability analysis and immunostaining of mismatch repair gene might serve as effective screening methods before direct DNA sequencing. It is necessary to establish clinical criteria and molecular diagnostic strategies more suitable for Chinese HNPCC families.**

Cai Q, Sun MH, Lu HF, Zhang TM, Mo SJ, Xu Y, Cai SJ, Zhu XZ, Shi DR. Clinicopathological and molecular genetic analysis of 4 typical Chinese HNPCC families. *World J Gastroenterol*, 2001;7(6):805-810

INTRODUCTION

Hereditary nonpolyposis colorectal cancer (HNPCC), also called Lynch syndrome, is the most common human hereditary cancer predisposition and accounts for 5%-10% of total colorectal carcinomas (CRCs). Tumors in HNPCC families are characterized by an early age (before the age of 50) of onset, an excess of syn-and meta-chronous colore ctal cancers, nigh occurrence in the proximal colon and an increased risk of neoplasms of other organs including endometrium, ovary, stomach, small intestine , pancreas, biliary tract, bladder and ureter[1-5]. The lack of characteristic diagnostic features has prompted the establishment of the so-called Amsterdam criteria for diagnosis: the histologically verified colorectal cancer must occur in at least three relatives (one of whom is a first-degree relative of the other two); the cancer must occur in at least two successive generations; and at least one case must occur at an onset age of less than 50. In addition, familial adenoma touspolyposis (FAP) must be ruled out[6].

Germline mutations of six genes in volved in DNA mismatch repair (MMR), i.e. hMSH2, hMLH1, PMS1, PMS2, MSH6 (also known as GTBP) and MLH3, have been identified in patients with the disease, and t he former two genes account for the large majority of mutations found in families with HNPCC. hMSH2 is localized to chromosome 2p21-22, contains 16 exons, and is predicted to encode a 935 amino acid protein, whereas hMLH1 is localized to chromosome 3p21 and contains 19 exons encoding a 756 amino acid protein[3,7-12]. These genes are required for the correction of DNA mismatches that occur during replication. Defective DNA mismatch repair genes result in microsatellite instability (or called replication errors, RER+). It has been suggested that the presence of replication errors can be a useful marker for HNPCC[13-25]. More recent studies indicate that immunohistochemistry may be a useful alternative strategy for identifying tumors with mismatch repair deficiency. Additionally, immunohisto chemistry provides information on the specific defective gene involved and may, therefore, be cost-effective by limiting the numbers of genes to be sequenced[26-30]. MSI and immunohistochemical analysis may be useful screening methods before MMR gene mutation analysis[22-23,31-34]. Until now there have only be en some case reports of HNPCC in China and no systemic study of molecular genetic aspects of HNPCC had been presented. We have collected 61 Chinese HNPCC families (reported elsewhere) and conducted clinicopathological and molecular genetic analyses of 4 HNPCC families fulfilling the Amsterdam criteria (referred to as typical H NPCC families).

MATERIAL AND METHODS

Patients

Four typical Chinese HNPCC families were taken into the study after informed consent (Figure 1) was made. One proband was female and the other three were male. The onset age was 38, 29, 58 and 67 years respectively, with a mean age of 48. Metachronous and synchronous tumors and their locations are listed in Table 1. Tumor tissues and peripheral white blood cells were collected for the study.

Table 1 Clinicopathological charcateristics, MSI status, immun ostaining and the affected MMR genes

Family	Onsetage	Number of CRC	Tumor site	MSI status	Immunostaining		Gene
					hMSH2	hMLH1	
H2	29	4	RightColonX2; rectum X2	4/5	—	+	hMSH2
H9	67	2	Hepatic flexure; transverse colon	4/5; 5/5	+	—	hMLH1
H11	58	2	Rectum X2	4/5	—	+	hMSH2?
H27	38	2	Cecum; transversecolon	3/5	—	+	hMSH2

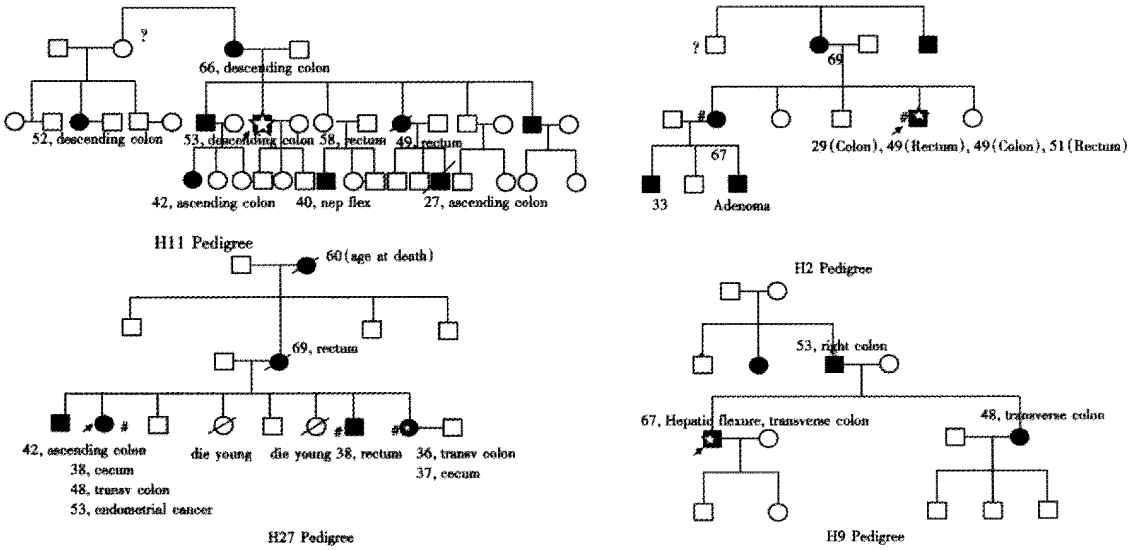

Figure 1 Four typical Chinese HNPCC pedigrees.

Microdissection and minimal amount of DNA extraction

One 5 μm and four 7 μm paraffin-embedded sections were deparaf finized. The 5 μm slide stained with HE served as control. The 7 μm ones were lightly stained with hematoxylin for microdissection. The microdissection was performed under the dissection microscope with a scalpel. Tumor cells should account for at least 80% of the total cells isolated. The microdissected tissues were transferred directly into a centrifugation tube with 150 μL cell lysis buffer (0.5 mol·L^{-1} Tris, 20 mmol·L^{-1} EDTA, 10 mmol·L^{-1} NaCl, 10 g·L^{-1} SDS, 0.5 g·L^{-1} Proteinase K). The subsequent DNA extraction was performed according to the protocol of the DNA extraction kit (Daxia Biotech Ltd, Shanghai). Genomic DNA from per ipheral white blood cells was also extracted with a large volume.

Microsatellite instability analysis

Matched normal and tumor DNA were investigated with a panel of 5 microsatellite markers (mononucleotide repeats BAT26 and BAT25, dinucleotide repeats D5S346, D2S123 and mfd15)[31]. The primer sequences have been published elsewhere[35]. The primer pairs were synthesized by Shenyou Biot ech Ltd. Each forward primer was labeled with a fluorescent dye at 5' end (Fam, Tamara or Joe) to enable the PCR products detectable by an ABI automated DNA sequencer. After successful amplification, the 2 μL PCR product was mixed with 12.5 μL dei one d formamide and 2 μL 350 Rox Sizer. The mixture was denatured, snap cooled and electropheresed on ABI 310 automated DNA sequencer according to the manufacturer' s recommendation. The electrophoresis results were analyzed by GeneScan Software (Applied Biosystems, Incorporated, Foster City, CA). MSI was determined according to Gebert *et al* [36]. Additional peaks (bands) at a microsatellite locus in the tumor compared with the normal tissue from the same patient were interpreted as microsatellite instability (MSI). Cases with MSI in more than 2 of the 5 loci were interpreted as exhibiting high microsatellite instability (MSI-H).

Immunostaining for hMSH2 and hMLH1

Sections of 4 μm were prepared from 100 mL·L^{-1} neutral buffered formalin-fixed and paraffin-embedded tumor tissue. After deparaff inization and rehydration, the sections were pretreated with microwave (4 min×4 at 900 W) in 0.1 mol·L^{-1} citrate buffer and were then incubated overnight at 4℃ with a monoclonal antibody against the hMSH2 prepared with the carboxy-terminal fragment (FE11, Oncogene Research Products, Cambridge, MA) and a monoclonal antibody against the hMLH1 prepared with full-length protein (G168-728, PharMingen, S an Diego, CA) at 1:40 dilutions. The antibodies were detected by the Envison two-step method (Dako, Denmark) using diaminobenzidine as the chromagen. The slides were counterstained with hematoxylin. Diminished expression of hMSH2 or hMLH1 in cancer tissues were demonstrated when there was complete absence of detectable nuclear staining of neoplastic cells. Infiltrating lymphocytes as well as normal colonic crypt epithelium next to the tumor area served as internal positive controls. Two pathologists assessed all cases without any knowledge of microsatellite instability or germline mutation status.

Sequencing analysis

All 19 exons of hMLH1 gene and all 16 exons of hMSH2 gene (including all intron - exon borders) from proband's genomic DNA were individually amplified in a thermocycler (Perkin-Elmer 9700, Applied Biosystems.). All the primers were kindly provided by Prof. von Knebel in the Division of Molecular Diagnostics and Therapy, Department of Surg ery, University of Heidelberg. Either sense or antisense was anchored with a M13 primer that benefits the subsequent

sequencing. PCR reaction was set in 25 μL volume containing 100 ng genomic DNA. The PCR products were purified using the Q IAquick-spin PCR purification kits (Qiagen Inc., Chatsworth, CA) and were subjected to direct sequencing with M13 forward primers using the ABI PRISM dye terminator cycle sequencing kit (Applied Biosystems) according to the manufacturer's instructions. The electrophoresis was performed on an ABI 310 automated sequencer. Search of the same mutation in additional family members was performed in the family with a detected mutation.

RESULTS

Clinicopathological characteristics are shown in Table 2.

Microsatellite instability

All 5 tumors of the 4 HN PCC probands showed microsatellite instability at more than two loci (MSI-H, or called RER+ phenotype) (Table 1, Figure 2). One tumor displayed MSI in 5/5 loci, three tumors showed MSI in 4/5 loci and the others had MSI in 3/5 loci.

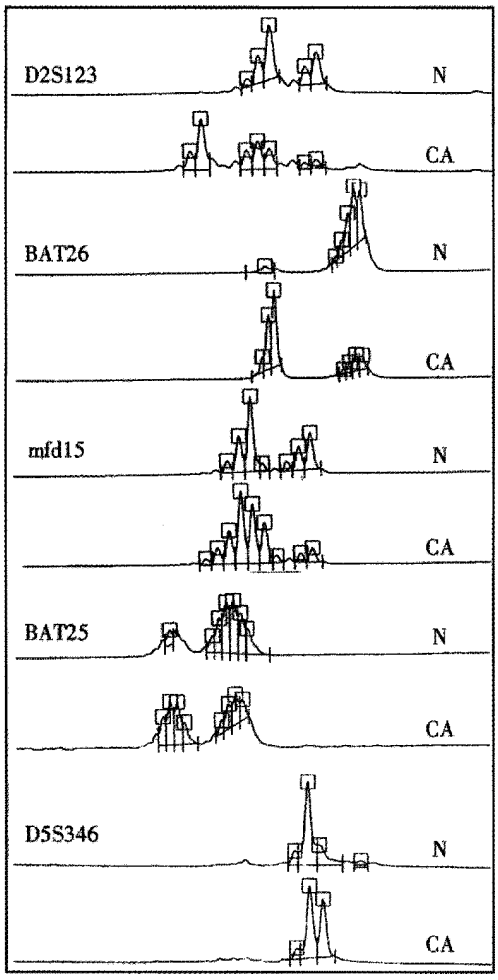

Figure 2 MSI status of H2 proband. Microsatellite analysis of H2 proband with five microsatellite markers, MSI in 4/5 loci

Loss of expression of hMSH2 and hMLH1 protein

Lack of hMLH1 immunostaining was observe d in tumors from H9 proband. Tumors from probands of H2, H11 and H27 were negative for hMSH2 immunostaining (Table 1, Figures 3 and 4).

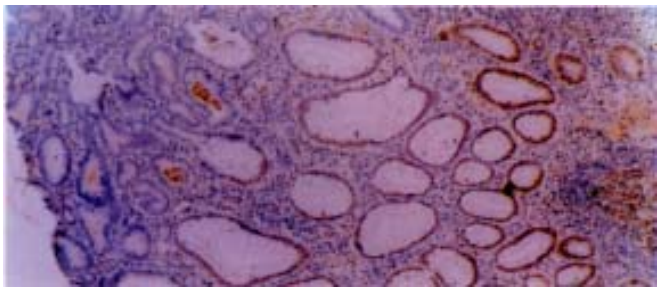

Figure 3 Immunohistochemical staining. No hMSH2 protein expression in adenoma and carcinoma areas of H11 proband tumor section, infiltrating lymphocytes as well as normal colonic crypt epithelium next to the tumor showed nuclear staining of the hMSH2 protein. ×100

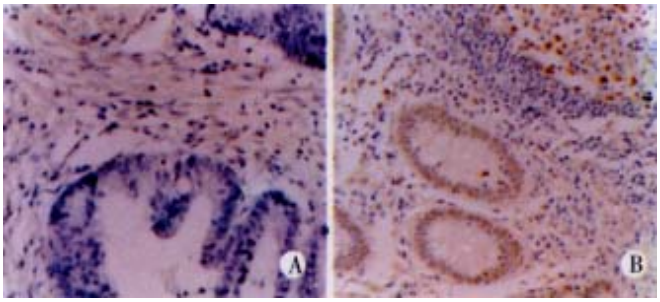

Figure 4 Immunohistochemical staining. A: No hMLH1 protein expression in carcinoma area of H9 proband tumor section. ×400
B: Infiltrating lymphocytes as well as normal colonic crypt epithelium next to the tumor showed nuclear staining of the hMLH1 protein.×200

Germline mutation of hMSH2 and hMLH1 gene

Germline mutations were found in all four probands. Three of four were definitely pathological mutations that had not been reported previously (family H2, H9, H27). The first pathological mutation was a transition of C to T in exon 13 (codon 680) of hMSH2, which leads to a stop codon (CGA-TGA) (family H2)(Figure 5). The second mutation was a 24 bp deletion in exon 11 (codon 305) of hMLH1 (family H9) (Figure 6). The third mutation was one "A" insertion at codon 206 of exon 3 of hMSH2 leading to a stop codon 73 bp downstream (family H27) (Figure 7). All 3 mutations give rise to protein truncation or protein structure alteration. In addition, the affected sister of H2 proband also carried t he same mutation in exon 13 of hMSH2. One sister and one brother of H27 porband also suffered from colorectal cancer at young age (her sister at 36 in transvers al colon and at 47 in cecum; her brother at 38 in rectum), both carrying the sam e germline mutation as their proband does. In H11 proband, a missense mutation in exon 1 of hMSH2 was identified. In order to determine whether this alteration represents a neutral polymorphism or a disease causing mutation, we assessed all possible family members and found no definite relationship between the base change and the disease. So it could not be demonstrated to be pathological and might be a single nucleotide polymorphism (SNP).

Table 2 Pathological germ-line mutations in the hMLH1and hMSH 2 genes

Family	Gene	Exon	Codon	Mutation	Nucleotide Change
H2	hMSH2	13	680	Nonsense	CGA-TGA(stop codon)
H9	hMLH1	11	305	In-frame deletion	24 bp deletion
H27	hMSH2	3	206	Frame shift	1 bp(A) insertion; stop at 73 bp downstream of the mutation

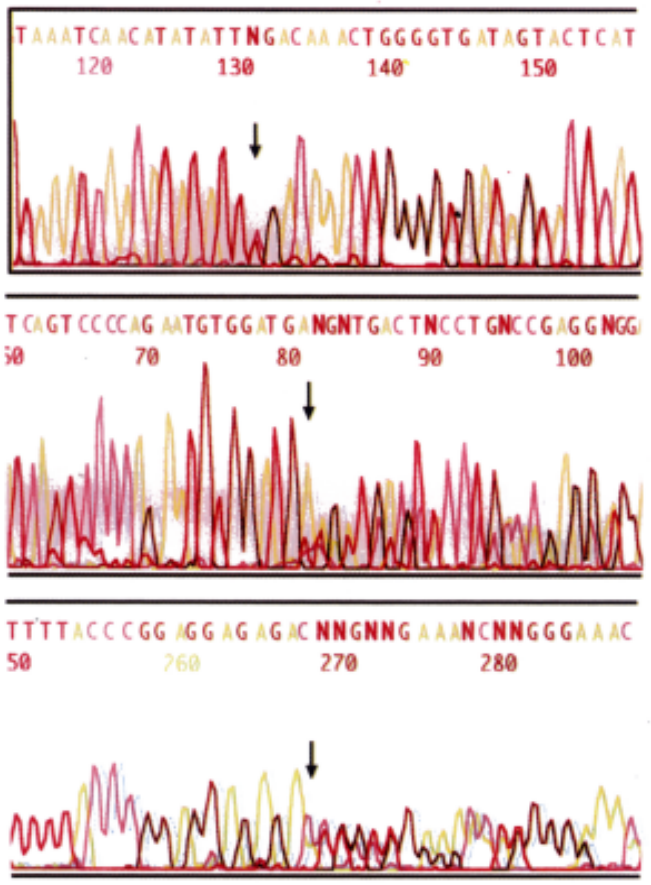

Figure 5 C-T transition (CGA-TGA) at codon 680 in exon 13 of hMSH2 gene in H2 proband, resulting in a stop codon.
Figure 6 A 24 bp deletion at codon 305 in exon 11 of hMLH1 gene in H9 proband.
Figure 7 A 1 bp insertion at codon 206 in exon 3 of hMSH2 gene in H27 proband, resulting in a stop codon 73 bp downstream of the mutation.

DISCUSSION

In China, the first clinical report of HNPCC cases was published by Mo *et al*[37] in 1996. Attention has been paid to this kind of hereditary tumor syndrome thereafter by Chinese sc holars[38-39]. Our study is a postlude of Mo's report. Three male prob ands and one female proband out of the 4 typical Chinese families had a mean onset age of 48 years. Three displayed proximal CRCs and one had a rectum cancer, all showed synch ronous and/or metachronous tumors, with one having metachronous endometrial cancer. These families fulfilled the strict HNPCC criteria. The four probands mentioned above had altogether 10 tumors. The current study is the first report with comprehensive microsatellite analysis, immunohistochemistry and direct mutation a nalysis of mismatch repair genes in Chinese HNPCC study.

Microsatellite is highly polymorphical, thus it has been widely considered as an ideal genetic marker. Microsatellite instability reveals loss of the function of mismatch repair gene s. It can serve as a reliable preliminary screening strategy of HNPCC family as several studies have shown that microsatellite instability occurs in about 80%-90% of HNPCC tumors[13-25]. Microsatellite instability was also found in 15%-20% of sporadic colorectal carcinomas[36,40]. In the current study, we adopted a panel of five sensitive microsatellite markers accepted by the International Collaborative Group for HNPCC and the National Cancer Institute to detect the MSI status[35]. One hundred percent (5/5) of the five tumors displayed high-level microsatellite instability, which suggests that Typical Chinese HNPCC families show high level defection of mismatch repair function in the affected patients.

The majority of HNPCC cases are associated with the mutation of hMSH2 and hMLH1 genes. Recent studies showed that the immunostaining of proteins produced by these two genes could serve as a convenient, rapid and cheap approach in screening HNPCC families[26-30]. In our study, the tumors from H2, H11 and H27 probands lost the expression of hMSH2 protein, while germline mutation of hMSH2 gene was only detect ed in H2 and H27 probands. The tumor of H9 proband showed no hMLH1 protein expression and a germline mutation of hMLH1 gene was identified. Although H11 proband had a tumor displaying no expression of hMSH2 protein, no pathological germline mutation had been detected. In general, microsatellite instability status and immunohistochemical alteration of hMSH2 and hMLH1 proteins correlated closely with each other. Immunohistochemistry is also very useful in screening HNPCC families.

Direct gene sequencing remains the most reliable method for HNPCC diagnosis. Mutations of hMSH2 and hMLH1 accounted for 25%-86% of the total cases[41-46]. Two main reasons were suggested for the discrepancies of mutation detection rate: firstly, different clinical criteria for selecting HNPCC families were adopted in various studies; secondly, the methods used by individual investigators varied. Till now more than three hundred different predisposing mutations have been reported, mainly affecting the MMR genes hMLH1 (about half), hMSH2 (about 40%) and MSH6 (about 10%)[7]. There appeared no hot spot mutations among those found in these mutations. The three pathological mutations (two in hMSH2 and one in hMLH1) found in our collectives are all novel mutations that had not been reported before (http:/ www.nfdht.nl/database/mdbchoice). The rate of mutation is 75% (3/4). The one A-insertion frame shift mutation in H27 proband gave rise to stop codon 73 bp downstream. H9 proband showed 24 bp deletion mutation in exon 11 of hMLH1 gene. The third mutation was a base substitution resulting in a stop codon. All of the detected mutations resulted in the truncation or structure alteration of the proteins. The mutations existed also in genomic DNA from other affected family members. That all mutations in our study appear new demonstrates the wide spectrum of the mutation responsible for HNPCC. The mutation may be different in a variety of races and geographical regions. It is therefore very important to develop HNPCC screening and genetic analysis strategies in China. The remaining family proband (H11) possessed a missense mutation (CCG-CAG, Pro-Glu). Its pathological meaning could not be demonstrated, because the presence and absence of cancer in this family showed no relation with the base change, suggesting that this may be only a polymorphism, i.e., SNP. This result could not explain the phenomenon of the lost of hMSH2 protein in the tumor of H11 proband. Curia et al con sidered that the possible germline mutation of such cases was located outside the coding region and intron-exon borders. Such mutations have the potential to affect the transcription, processing, and/or stability of mRNA encoded by the corresponding allele, resulting in germ-line transcript imbalance that should be detectable in normal tissues or PBLs. Such imbalance could be investigated by primer extension assays[47]. This kind of screening is necessary for the family like this, so as to discover the abnormality not detectable by sequencing.

Since HNPCC has many characteristics different from those of sporadic colorectal cancer, it is necessary to distinguish between them. HNPCC has better prognosis and shows more resistance to the chemotherapeutic drugs (for example, 5-FU, cisplatinum, etc). MMR gene mutation analysis will give both HNPCC proband and his family members better management and surveillance, and it will also support genetic counseling as well as gene therapy in the future. To the proband himself, it is helpful for us to conduct positive and

effective therapy to reduce the occurrence of possible me tachronous multiple colorectal cancer. To the mutation carriers in his family who have not yet suffered from colorectal cancer, close follow-up and early diagnosis are more likely to be performed. Colonoscopy every 1 to 3 years starting at age of 25 is recommended. To the non-mutation carriers, we should free them from unnecessary psychological and economical burden[48-50].

The current report is only a first description of our study at the initial stage. We hope that it could provide a guidance to the surgeons and pathologists in China who are closest to the patients. A wider survey with more kindreds in detail and a deeper analys is of the tumor spectrum of Chinese HNPCC kindreds remain a heavy assignment for us.

Abstract

AIM: **To construct the natural immune Fab antibody phage display libraries of colorectal cancer and to select antibodies related with colorectal cancer.**

METHODS: **Extract total RNA from tissue of local cancer metastasis lymph nodes of patients with colorectal cancer. RT-PCR was used to amplify the heavy chain Fd and light chain κ and the amplification products were inserted successively into the vector pComb3 to construct the human libraries of Fab antibodies. They were then panned by phage display technology. By means of Dot immunoblotting and ELISA, the libraries were identified and the Fab phage antibodies binding with antigens of colorectal cancer were selected.**

RESULTS: **The amplified fragments of Fd and κ gained by RT-PCR were about 650 bp. Fd and κ PCR products were subsequently inserted into the vector pComb3, resulting in a recombination rate of 40% and the volume of Fab phage display library reached 1.48×10^6. The libraries were enriched about 120-fold by 3 cycles of adsorption-elution-multiplication (panning). Dot immunoblotting showed Fab expressions on the phage libraries and ELISA showed 5 clones of Fab phage anti bodies which had binding activities with antigens of colorectal cancer.**

CONCLUSION: **The natural immune Fab antibody phage display libraries of colorectal cancer were constructed. They could be used to select the relative antibodies of colorectal cancer.**

INTRODUCTION

The incidence of colorectal cancer is growing in China. It has been clear that the prognosis of colorectal cancer is related to early diagnosis and treatment[1-15]. Since the development and evolution of the colorectal cancer is one kind of complicated pr ocedures involving multi-genes, multi-factors and multi-steps, there have been no highly peculiar molecular pathologic changes and tumor[16-39]. A major focus of cancer immunology is on the isolationof antibodies that react selectively with human tumor cells[40,41], because the antibodies could have important applications for targeting diagnostic and therapeutic agents to tumors and for identifying tumorigenic antigens[42-47]. The established approach has been to generate large panels of monoclonal antibodies (mAb) from mice immunized with human tumor cells and to screen the antibodies for reactivity against the tumor[48-50]. Despite the enormous efforts put on this approach, few antibodies that react preferentially with human tumors, and none that react specifically with one type of tumor (such as colorectal cancer), have been reported. Further attempts to isolate more specific and high affinity antibodies will require improved methods of generating and selecting antibodies against human tumors[51]. One is the introduction of method for synthesizing virtually the entire repertoire of a person's antibody genes of variable regions by PCR technique and for expressing the encoded antibodies on the surface of a phage vector[52]. The resulting phage antibody library can be panned to select and clone rare antibodies on the basis of their binding specificities[53,54]. It can resolve the problems of generating humanization mAb by hybridoma approach. Humans can be immunized or are immune to many antigens (including tumor antigens) but only local lymph nodes, a productive source of antibody-producing cells, is readily available. Here we describe the construction of the natural immune phage display libraries expressing Fab antibodies derived from local cancer metastasis lymph nodes of co lorectal cancer patients and report the initial results of panning the libraries for anti-colorectal cancer antibodies.

MATERIALS AND METHODS

Vector, E.coli and helper phage

The vector (pComb3), about 4894 base pairs, contains ampicillin resistance (Ampr) gene, start sites of plasmid CO1E1 and f1 phage replication. The expression of inserting fragments is control led by the same LacZ promoter on its upstream sequence. *E.coli* XL1-Blue contains tetracycline re sistance (Tetr) gene on its gene type of Tn10. Helper phage (VCSM13) contains kanamycin resistance (Kanar) gene with valency of 10^{15} pfu·L^{-1}. It is amplified in SOC culture medium and preserved in 4℃.

Lymph nodes total RNA preparation

Lymph nodes in mesenterium were resected during surgical operation on patients with colorectal cancer and preserved in liquid nitrogen immediately. The nodes of patients (case number 260280, 260583 and 260476) were defined as tumor metastatic lymph nodes by pathological examination. One hundred mg of each node was used to

extract total RNA by the standard method of guanidinium isothiocyanate.

Amplifying Fd and κ chain genes of antibodies by RT-PCR

Total RNA (20-50 μg) was added to 60pmol primer of *Oligo(dt)* and heated at 65℃ for 10 min. The mixture was then used in a 20 μl reverse transcription reaction containing 200 μmol·L^{-1} each dNTPs and 20 U of reverse transcriptase (Promega), which was incubated at 37℃ for Ih. The RNA-cDNA mixture (5 μL) was then used in 50 μL PCR reaction mixture containing all four dNTPs at 60 μmol·L^{-1}, 5 U of Taq polymerase (Promega), and 50 pmol·L^{-1} of appropriate 5' and 3' primers[55,56]. VK1a and VK3a are 5' primers for amplification of the κ chain with the Sac I site f or cloning into the vector pComb3. CK1a is a 3' primer corresponding to the 3' end of the light chain κ, *Xba* I site. VH1a and VH3a are 5' primers for the heavy chain (Fd), *Xho* I site. CG1z is the 3' primer for the Fd and corresponds to part of the hinge region, *Spe*I site.

$V_κ$5' primers: VK1a, 5'-GACATCGAGCTCACCCAGTCTCCA -3';
$V_κ$3a, 5'-GAAATTGAGCTCACGCAGTCTCCA-3';
$V_κ$3' primers: CK1a,
5'-GCGCCGTCTAGAACTAACACTCTCCCCTGTTGAAGCTCTTTG-TGACGGGCAAG-3';
V_H (Fd) 5' primers: VH1a, 5'-CAGGTGCAGCTCGAGCAGTCTGGG-3';
V_H3a, 5'-GAGGTGCAGCTCGAGGAGTCTGGG-3';
V_H (Fd) 3' primers: CG1z, 5'-GCATGTACTAGTTTTGTCACAAGATTTGGG -3'.

The reaction mixtures were then subjected to 35 rounds of amplification (PE/Cetus thermal cycler) at 94℃ for 1 min, 52℃ for 1.5 min and 72℃ for 2 min followed by a final incubation at 72℃ for 10 min. An aliquot of the reaction mixture (5 μL) was run on a 10 g·L^{-1} agarosegel.

Cloning heavy chain Fd into pComb3

The Fd fragment product of PCR (isolated by agarose gel electrophoresis) was cut with an excess of the restriction enzymes *Xho* I and *Spe* I and typically about 350 ng was ligated with 2 μg of *Xho/Spe* I -linearized pComb3 vector (isolated by agarose gel electro phoresis) in a total volume of 150 μL with 10 U of ligase (Promega) at 16℃ for 15 h. Following ligation, DNA was precipitated at -20℃ for 2 h by the addition of 15 μL of 3 mol·L^{-1} sodium acetate (pH 5.2), and 330 μL of ethanol. DNA was pelleted by microcentrifugation at 4℃ for 15 min. The DNA pellet was resuspended in 20 μL of water and transformed into 150 μL XL1-blue (porated by calcium chloride). After transformation, XL1-blue samples (10, 1, 0.1 μL) were withdrawn for plating to determine the rate of transformation. The insertion of target Fd fragments were detected by PC R from the plasmids extracted from several random XL1-blue monoclones. The plasmids with Fd insertion were named p+Fd.

Cloning light chain κ into p+Fd and antibodies Fab libraries construction

The κ fragment product of PCR and recombined p+Fd (isolated by agarose gel electrophoresis) were cut with an excess of the restriction enzymes *Sac* I and *Xba* I. The ligation, transformation, *E.coli* amplification and determination of the transformation rate were same as described above. The insertion of target κ fragments was detected by digestion with *Sac* I / *Xba* I from the plasmids extracted from several random XL1-blue monoclones. The Fab fragments' insertion was detected by digestion with *Xho* I and *Xba* I. The plasmids with Fd together with κ insertion were named Fd+κ. Helper phage VCSM13 (10^{12} pfu) was added to XL1-blue samples contained Fab gene libraries. Following the superinfection, the primer Fab phage display libraries of two patients were constructed, named K1 and K2, and preserved at 4℃.

Panning of the primer Fab phage display libraries

The colorectal cancer antigens were derived from fresh cancer tissues of patients 1, 2, and 3 by sonicating the tissues (each mass 500 mg). The supernatants were named Ag1, Ag2 and Ag3. Colon cancer cell line of Lovo (10^9 ·L^{-1}) was sonicated also, and its supernatants were named Lovo. The wells of a microtiter plate were coated overnight at 4℃ with the antigen supernatants above respectively (antigens were diluted with 0.1 mol·L^{-1} bicarbonate buffer, pH9.6). Cancer tissue antigens coated the microtiter plate wells in mixture of Ag1 and Ag2. Lovo cells of 200 μL(0.5×10^8·L^{-1}) were attached to the wall of the microtiter plat e wells, and 50 μL mixture of K1 and K2 was added to the wells coated with antigens respectively. The panning procedure is a modification[57] of that originally described by Parmley and Smith. The phage binding with antigens re-infected the XL1-Blue by eluting from the wells. A round of panning was finished after superinfection by VCSM13. Following 3 rounds of panning, the percent yield of phage was determined as (no. of phage eluted / no. of phage applied) ×100.

Dot immunoblotting analysis of Fab displaying[58]

Five μL library of each round of panning was added to nitrocellulose (NC) filter (with diameter of 0.5 cm). After being dried at room temperature, the NC filters were blocked in 50 mL·L^{-1} de-lipid milk and then react with the biotinylated anti-human IgG (1:100 dilution) and alkaline phosphatase (AP)-avidin at room tempe rature successively. Finally the NBT+BCIP was added and color developed. The control unit was the suspension of the phage contained vacant vector pComb3.

ELISA analysis of Fab displaying[59]

The wells of a microtiter plate were coated overnight at 4℃ with the antigen supernatants Ag1, Ag2, Ag3 and Lovo respectively (antigens were diluted in 1:100 with 0.1 mol·L^{-1} bicarbonate buffer, pH9.6). The suspension of K1 and K2 (50 μL each) was added to the wells respectively, and cultivated at 37℃. Following 3 washes with TBS buffer, 25 μL of a 1:100 dilution of biotinylated goat anti-human IgG and HP-conjugated biotin were added succes sively and incubated at 37℃. Finally 50 μL of TMB was added and color development was moni tored at 490 nm. The A490 values of positive clones were higher than that of neg ative clones at least two folds. After 3 rounds of panning, 5 clones of positive XL1-blue were superinfected with VCSM13 and the supernatants of Fab displaying were prepared. FiftyìL of the Fab display supern atants were added to the wells (coated with antigens of Ag1, Ag2, Ag3 and Lovo) respectively, and ELI SA analysis was applied by the method described above.

RESULTS

Amplifying the fragments of Fd and κ chain genes of antibodies by RT-PCR

The total RNAs of the lymph nodes defined as tumor metastasis in mesenterium of patients with colorectal cancer were isolated. The integrity of RNAs was shown by alkaline denaturing agarose gel. Their purity (A_{260}/A_{280}) reached 2.04. Fd and κ immunoglobulin chains were PCR-amplified after reverse transcription from this RNA. For amplifying Fd and κ, two 5'primers and one 3'primer were used respectively which contained some sites of the restriction enzymes corresponding to the vector pCom b3. The PCR amplification of Fd and κ was about 650 bp (Figure 1).

Figure 1 PCR products of Fd and κ.

Construction and identification of recombinant p+Fd

The recombinants of p+Fd were constructed by cloning Fd fragments into pComb3. After transforming XL1-blue, the Fd gene libraries were formed. And the quantity of the transformants reached 5.53×10^6. After extracting the plasmids from eight random XL1-blue monoclones, the insertion of target Fd fragments was detected by PCR with the primers same as that in amplifying Fd described above. Four of eight PCR could amplify the fragments of 650 bp (Figure 2). This meant that the recombination frequency was 50%, so the practical volume of Fd library was 2.77×10^6.

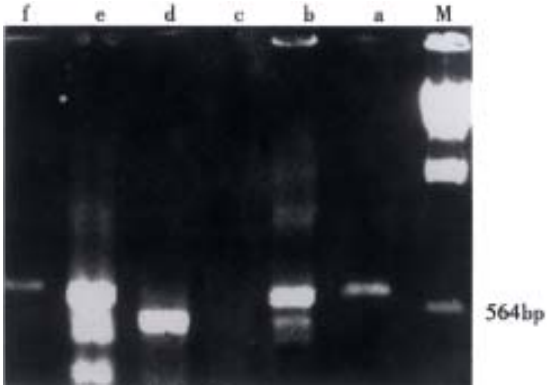

Figure 2 Fd insertion by PCR identification.

Construction and identification of Fab gene recombinant

The recombinants of Fd+κ were constructed by cloning ê fragments into p+Fd. After transforming XL1-blue, the Fab gene libraries were formed and the quantity of the transformants reached 7.4×10^6. Following extracting the plasmids from ten random XL1-blue monoclones, the insertion of target κ fragments was detected by digestion with *Sac* I and *Xba* I, and five of these plasmids discharged the fragments of 650bp (Figure 3). By digesting with *Xho* I and Xba I, four of these plasmids discharged the fragments about 2.4 kb (Figure 4). The recombination frequency of fragments Fd together with κ insertion was 40%, so the practical volume of Fab library was $7.4\times10^6\times50\%\times40\% = 1.48\times10^6$.

ELISA of binding activity of colorectal cancer antigens and Fab displaying on primer phage libraries

The activity of colorectal cancer antigens binding with K1 (or K2) was identified by ways of ELISA with control unit of wash buffer. The primer phage display libraries integrated with the colorectal cancer antigens of not only its immune derivation, but also other immune derivation (Table 1).

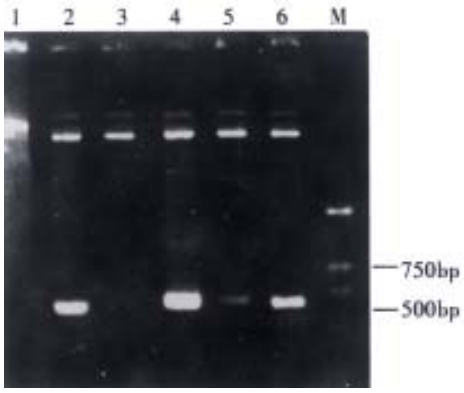

Figure 3 Identification of κ insertion by *Sac* I/*Xba* I digestion.

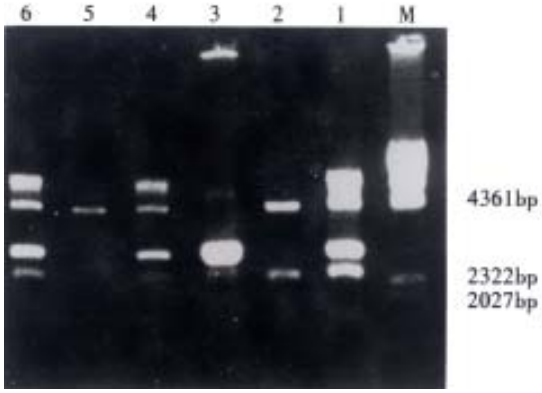

Figure 4 Identification of κ and Fd insertion by *Xho* I/ *Xba* I digestion.

Table 1 Binding of Fab displayed by prime phage display libraries with colorectal cancer antigens (A_{490})

	Ag1	Ag2	Ag3	Lovo	Wash buffer
K1	1.285	1.496	1.332	0.326	0.105
K2	1.324	1.552	1.352	0.322	0.122
BC	0.115	0.105	0.110	0.092	0.087

Panning and identification of the Fab phage display libraries

After 3 rounds of panning, the libraries were enriched about 120-fold. Dot immunoblotting applied by the system of AP-goat anti-human IgG showed that there were Fab expressions on the phage lib raries of each panning round (Figure 5). There was no obvious color development in the control units (C). The supernatants of Fab displaying prepared from 5 clones of positive XL1-Blue after 3 rounds of panning showed the significant binding activity with the antigens related with c olorectal cancer by ELISA analysis (Table 2). The control units were the rat colon antigens and wash buffer.

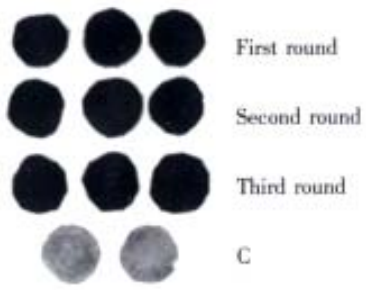

Figure 5 Dot immunoblotting analysis.

Table 2 Binding activity of phage antibodies with antigens (A_{490})

Phage antibodies	Ag1, Ag2 and Ag3	Lovo	Rat colon antigens	Wash buffer
Clone 1	1.236	1.042	0.121	0.096
Clone 2	1.117	0.873	0.110	0.100
Clone 3	1.450	1.329	0.182	0.121
Clone 4	1.106	0.912	0.106	0.087
Clone 5	1.345	1.024	0.090	0.083

DISCUSSION

Fd parts and κ immunoglobulin chains (650 bp) were PCR-amplified after reverse transcription from the RNAs, which were isolated from the lymph nodes de fined as tumor metastasis in mesenterium of patients with colorectal cancer. For mimicking the diversity of the antibody genes, we used 5' primers based on the leader exon and the N terminus of first framework (FR1) sequences according to their relatively constant regions, and 3' primers within the constant regions during amplifying the V genes of immunoglobulin Fab. To maximize complementarity, degeneracy was incorporated into the primers, or different primers were designed for different families of antibody V genes. For cloning of the amplified DNA into expression vectors, rare restriction sites were introduced within the PCR primers. Following mixing the 2-group of Fd PCR products, we cloned them into the vector pComb3. Then the 2-group of κPCR products were inserted into the recombinants of p+Fd. Therefore the gene libraries of humanization antibody were constructed, which contained parts of 2 -subgroup of heavy chains and 2-subgroup of κ chains. Previously reports had shown that the volume of the phage display libraries was 1.0×10^7 at most constructed by this vectors and ways[57]. In review, the volume was 10^6-10^7 according to the reports abroad, and about 10^6 according to the domestic reports[60,61]. We reported the volume being 1.48×10^6.

By antibody technology, the mAbs can be prepared by-passing hybridoma approach. Construction of the natural immune antibody library is the method of by-passing unnatural immunization. The natural immune antibody library is constructed from the natural donors, such as lymphocyte B and plasma cell. In our present study, the natural immune Fab antibody phage display libraries were constructed from the lymphocytes in the lymph nodes of 2 patients with colorectal cancer. There have been several studies on the library of immunity antibody in recent years[60-62], but no reports on construction of the natural immune antibody library of human colorectal cancer. Theoretically the humanization antibody library constructed from the lymphocytes B in lymph nodes defined as tumor metastasis of patients with tumor can aim at screening the antibodies, because the genes of heavy and light chains have been rearranged and ligated *Spe* cifically due to immunizing of tumor antigens. By this way the promiscuous work of preparation of antigens by immunizing rats was relieved and the problems of weak antigens, heterologica l antibodies, low fusion, instability and low antibodies products of hybridoma were resolved. From the natural immune antibody library, a few of phage antibodies immunized by some foreign antigens (such as bovine serum album, lysozyme, bovine thyroid globulin, etc.) were screened, and some self-antigens (such as tumor necrosis factor-α, carcinoembryonic antigen, CD4, thyroid globulin, etc.). Many of these phage antibodies showed high affinity and specificity, and the potential value for application.

It is important to assemble antibody molecules that have correctly folded heavy and light chains and thus retain antigen-recognition capabilities. Previously it had been demonstrated that Fd chains (comprising V_H and C_{H1}, the variable region and constant domain 1 of the immunoglobulin heavy chain) and κ chains targeted to the periplasm of *E.coli* assemble to form functional Fab molecules. If the Fd chain was anchored in the membrane and concomitantly provided with secreted κ chain, functional Fab molecules could form on the membrane surface facing the periplasm. The coexpression behind the PelB leader sequence of Fd fused to cpIII (the major coat protein of M13 phage) and ê chains lead to membrane anchoring of the Fdc hain and compartmentalization of the κ chains in the periplasm. These two chains could a ssemble *in situ* to allow accumulation of functional Fab on the membrane surface, which, by virtu e of the cpIIIsequences, would be incorporated along the entire length of the filamentous ph age particles on subsequent infection with helper phage. These phages displaying Fab could inf ect *E.coli* again. Following rounds of panning by adsorption-wash-amplification, the phages comprising specific antibody molecules could be enriched[63]. Our study showed that the phage Fab libraries were enriched about 120-fold after 3 rounds of panning. It suggested that the colorectal cancer antigens had selected the phages in the libraries displaying Fab. Dot immunoblotting showed that there were Fab expressions on the phage libraries of each panning round. ELISA analysis showed that the phage displaying Fab had the significant binding activity with the antigens related with colorectal cancer. Considering that nowadays there are few and hypo-specific antibodies related with colorectal cancer, the natural immune Fab antibody phage display libraries of colorectal can be used to select the affinity and specificity antibodies related to colorectal cancer. It is important to diagnose and treat colorectal cancer using these antibodies.

Abstract

AIM: **To explore the role of SF/HGF-Met autocrine and paracrine in metastasis of hepatocellular carcinoma (HCC).**

METHODS: **SF/HGF and c-met transcription and protein expression in HCC were examined by RT-PCR and Western Blot in 4 HCC cell lines, including HepG2, Hep3B, SMMC7721 and MHCC-1, the last cell line had a higher potential of metastasis. sf/hgf cDNA was transfected by the method of Lipofectin into SMMC7721. SF/HGF and c-met antibody were used to stimulate and block SF/HGF-c-met signal transduction. Cell morphology, mobility, and proliferation were respectively compared by microscopic observation, wound healing assay and cell growth curve.**

RESULTS: **HCC malignancy appeared to be relative to its met-SF/HGF expression. In MHCC-1, c-met expression was much stronger than that in other cell lines with lower potential of metastasis and only SF/HGF autocrine existed in MHCC-1. After sf/hgf cDNA transfection or conditioned medium of MHCC-1 stimulation, SMMC7721 changed into elongated morphology, and the a bilities of proliferation ($P<0.05$) and mobility increased. Such bio-activity could be blocked by c-met antibody ($P< 0.05$).**

CONCLUSION: **The system of SF/HGF-c-met autocrine and paracrine played an important role in development and metastas is potential of HCC. Inhibition of SF/HGF-c-met signal transduction system may reduce the growth and metastasis of HCC.**

INTRODUCTION

The human proto-oncogene c-met encodes a Mr. 190, 000 heterodimeric transmembrane protein with structural features of a tyrosine kinase receptor and is expressed predominantly on epithelial cells. Its ligand HGF is a mesenchymal protein which is identical to Scatter factor (SF), a factor secreted by fibroblasts. It is well known that SF/HGF has a special binding with c-met, mainly attending mitogenic, motogenic and morphogenic effects on normal targeted cells[1-4]. Recently, its signal pathway has been explored a lot, including STAT in tubulogenesis[5], Gab-1 in cell growth[6,7], MAPK in morph ogenesis[8,9], and PI-3K in cell mitogenesis[10,11]. Its relationship with ad hesive factors[12-16] and apoptotic factors[17,18] and the cross-talk between HGF/SF-c-Met and other growth factors[19] and proto-oncogenes[20] have also bee n discussed. However, in cancer research, controversial results have been found in various tumors. Some reports suggested that HGF/SF was potent stimulator for tumor proliferation and motility[21-29], some reports made exactly opposite conclusions[30-33]. Among all the tissues, situation in liver becomes the most complicated, since SF/HGF attends all the stages of liver growth, regeneration, cirrhosis and carcinoma. SF/HGF was first found as a serum derived factor that stimulated proliferation of primary liver cells, acted as one of the initial factors in liver regeneration[34-35] and reversed cirrhosis by suppressing the increased TGF betal, fibrogenesis and hepatocyte apoptosis[36]. It ha s been unexpectedly reported to inhibit the growth of hepatoma cell in many reports[31]. Little has been known about the mechanism.

We studied a HGF/SF autocrine hepatocellular carcinoma (HCC) cell line which has a high potential of metastasis and compared its characteristic with several other HCC cell lines which do not have these features. Gene transfection and other interfering methods were used to further demonstrate the SF/HGF autocrine and paracrine on malignant capability of HCC.

MATERIALS AND METHODS

Cells

SMMC7721, HepG2, and Hep3B human HCC cell lines were purchased from Shanghai Institute of Cell Biology, Chinese Acadamy of Science (Shanghai, China). MHCC-1 was a cell line with high potential of metastasis from a resected lesion of a HCC patient. Cells were cultured in DMEM supplemented with 100 $mL \cdot L^{-1}$ fetal calf serum or AB serum (MHCC-1), penicillin (100 $kU \cdot L^{-1}$), streptomycin (100 $kU \cdot L^{-1}$).

Collection of MHCC-1 conditioned medium (MHCC-1-CM)

Cells were planted in 100 ml culture bottles. When 80% cells were subconfluent, they were washed and replaced with serum free DMEM (0.1 $mL \cdot cm^{-2}$). Three to five days later, conditioned medium was collected, centrifuged under 2000 $r \cdot min^{-1}$ for 20 minutes and stored at -20℃ until use.

Plasmid and DNA transfection

The plasmid pBS7.3 containing human full-length sf/hgf(kindly provided by Dr. George Vande Woode) was cloned into the BamHI-ApaI site of the p cDNA3.0(+) mammalian expression vector. SMMC7721 HCC cell line was transfected overnight with the constructed plasmid, using lipofectamine (Gibco). Cells were selected by G418. Colonies of cells were trypsinized within cloning rings, then they were transferred to 24-well dishes, and grown to confluency. After conditioned medium was changed to serum free DMEM for 3 d, both supertenant and whole lysised cells were screened for SF expression (ELISA, R&D). The highest expressing

clone (SF7721) was selected for further research.

RT-PCR

Total RNA was extracted (QIAGEN) and 1 μg was reversing transcribed in a 25 μL volume using Super rScriptII™ (Gibco), according to the manufacturer's instructions. Five μL reverse transcription product was used for amplification with the following primers: SF: 5'-CAG CGT TGG ATT CTC AGT AT-3', 5'-CCT ATG TTT GTT CGT GT T GGA-3'. c-met: 5'-ACA GTG GCA TGT CAA CAT CGC T-3', 5'-GCT CGG TAC TC T ACA GAT TC-3'. Forty cycles were performed, each consisting of 95℃, 45 s; 60℃, 1 min. There was a time delay for 7 min at 72℃.The reaction products were visualized by 15 g·L^{-1} agarose gel electrophoresis.

Western blotting

Goat anti-human HGF antibody was purchased from R&D. Rabbit anti-human c-met anti body, anti-rabbit IgG-AP and anti goat IgG-AP were purchased from Santa Crus. Cells were washed with PBS, and lysed at 0℃ for 30 min in lysis buffer (TrisCl 50 mmol·L^{-1} pH8.0, NaCl 150 mmol·L^{-1}, NaN_3 0.2 g·L^{-1}, PMSF 100 mg·L^{-1}, Aprotinin 2 g·L^{-1} , TritonX-100 10 g·L^{-1}). In c-met detection, protein content was examined using BCA™ Protein Assay (Pierce), and 20 μg protein per lane was electrophoreses on 80 g·L^{-1} SDS polyacrylamide gels after boiling for 5 min in 2X loading buffer. As to SF/HGF, conditioned medium was mixed with 2X loading buffer and added to 100 g ·L^{-1} SDS polyacrymide gels. Protein was blotted onto nitrocellulose membranes. After electrobloting, the membranes were blocked in PBS-50 mg·L^{-1} non-fat dry milk, washed with PBS-Tween buffer, and incubated with the primary antibody (1:500) diluted in blocking buffer for 2 h. Membranes were then washed, incubated with the appropriate second antibody (1:500) in blocking buffer for 2 h, and re-was hed. Blotted proteins were stained with BICP-DAB (Huamei).

Cell scatter and morphology

5×10^3 cells of SMMC7721 and SF7721 were planted into the wells of 96-wells plates. Three replicated wells. Twenty-four hours later, wells were washed with PBS and fixed with ethanol and stained with Giemsa and examined under an inverted microscope. To explore the role of SF/HGF-c-met paracrine, 5×10^3 cells of SMMC7721 were planted into the wells of 96-wells plates. And 200 μL MHCC-1-CM was added into each well within diluted range 1:2, 1:4, 1:8, 0, respectively. Three replicated wells. Twenty-four hours later, cells were fixed and observed as above.

Cell migration assay

The 'wound assay' of Birch was used to determine the migratory capacity. 5×10^4 SMMC7721 or SF7721 cells were planted into the wells of 24-well plates and cultured 24-48 h until the cultures were subconfluent. A wound track was scored in each well. In paracrine system detection, 5×10^4 SMMC7721 were planted into the wells of 24-well plates and cultured 24-48 h until the cultures were subconfluent. A wound track was scored in each well. Conditioned medium was replaced in the experimental group with 1 mL MHCC-1 - CM and 1 mL control medium, control group with 1 mL surum free DMEM and 1 mL control medium. Replicated wells were terminated at 16, 24 and 48 h after wounding and examined under inverted microscope.

Cell growth curve

5×10^4 SMMC7721 or SF7721 were planted into 24-well plates, respectively. From the next day, cells of triplicate wells were digested by typsin and counted under microscope for 8 d. The average was recorded as cell number of the day. In addition, 2×10^4 SMMC 7721 cells were planted into the wells of 96-wells plates. Twenty-four hlater, 200 μL MH CC-1-CM was added into each well within diluted range 1:2, 1:4, 1:8, 0, respectively. Three replicated wells. The effects of MHCC-1-CM on SMMC7721 were also contrasted using SMMC7721-CM. After 72 h incubation, 20 μL MTT (Methabenzthiazuron, Serva Co, USA) was added into each well to a final concentration at 50 g·L-1. Four hours later, the medium with 100 μL DMSO was replaced, and asorbance (OD) was read under 540 nm (Bio-rad).

Inhibition assay by c-met antibody

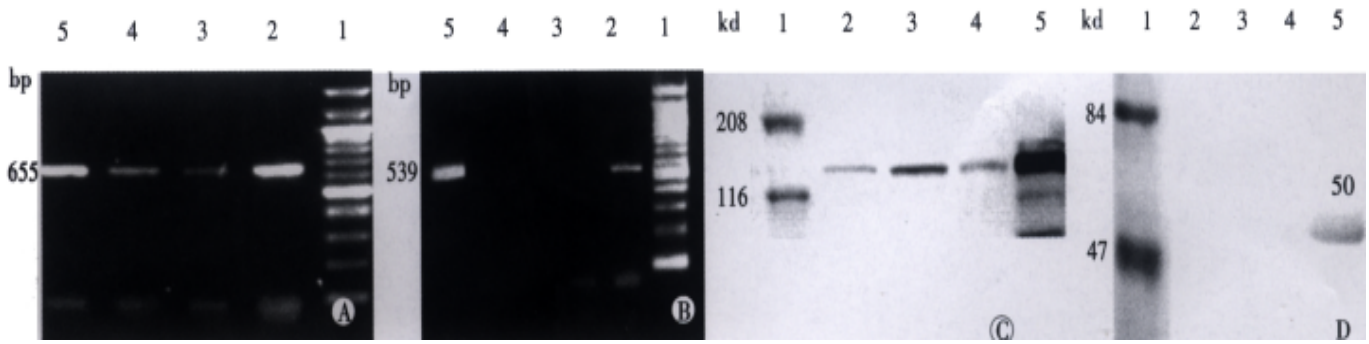
2×10^4 MHCC-1 or S F7721 were planted in 96-well plates, 3 replicated wells. After 24 h incubation, cells were washed by free DMEM, and incubated in 50 μL c-met polyantibody within a concentration range of 20, 10, 5, 2.5, 0 mg·L^{-1}. Rabbit IgG was used as control. Two hours later, 150 ìL control medium was added into each well and 72 h later, cells were examined by MTT. As to SMMC7721, 10^4 cells incubated with 2 μg c-met antibody for 2 h. Afterward, cells were washed by D-Hanks and added into wells of 96-well plates within 100 μL conditioned medium and 100 μL MHCC-1-CM or SM MC7721-CM, respectively. Twenty-four h later, cells were observed under micros cope. Rabbit IgG was used as negative control.

Statistical analysis

In SMMC7721 cell proliferation experiments, Student's *t* test was used to compare the difference of each corresponding dosage groups. Values were expressed as means ± standard. The cell growth curve and c-met blocking assay were tested by two-way anova.

RESULTS

SF and c-met expression in HCC cell lines (Figure 1)



A:c-met transcription B: SF/HGF transcription
1: Mark; 2: MHCC-1; 3: HepG2; 4: Hep3B; 5: SMMC7721; 6: pBS7.3

C: c-met protein expression D: SF/HGF protein expression
1: Mark; 2: SMMC7721; 3: Hep3B; 4: HepG2; 5: MHCC-1

Figure 1 SF/HGF and c-met expression in HCC cell lines.

RT-PCR showed that all the cell lines had the transcription and protein expression of c-met, in which MHCC-1 most actively expressed. Only MHCC-1 had the transcription and protein expression of SF/HGF to the medium.

SF/HGF expression in SF7721

After sf/hgf transfection, in SF7721 cell extracts, the highest expression of SF/HGF reached 692 $\mu g \cdot L^{-1}$, compared with 0.026 $\mu g \cdot L^{-1}$ in control cells. However, no SF/HGF was detected in conditioned medium.

SF/HGF-c-met autocrine stimulate HCC malignancy

After gene transfection, SF7721 cells displayed scattered distribution and elongated morphology (Figure 2A) together with increased ability of proliferation. The cell growth curve showed that after 8 days, cell number of SF7721 reached almost double of that of SMMC7721 (Figure 2C, $P<0.05$). Also, the transfected SF7721 acquired stronger mobility. In "wound healing assay", SF7721 moved faster than SMMC7721 cells into cell free area (Figure 2B). However, the c-met expression in SF7721 and SMMC7721 did not show great difference.

Figure 2 B Cell morphology comparison ×400

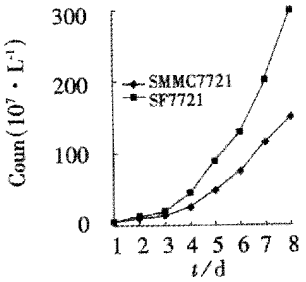

Figure 2 C Cell growth curve before and after gene transfection

Role of SF/HGF-c-met paracrine

The paracrine system of SF/HGF-c-met was examined by stimulating SMMC7721 with MHCC-1-CM. Results were consistent with that in autocrine. The proliferation of SMMC7721 was stimulated by MHCC-1-CM at 1:2 dilution (Table 1, $P<0.01$). In addition, MHCC-1- CM increased the mobility of SMMC7721 cells in wound healing assay and induced the elongated morphology displayed in SF7721 cells. (Data not shown).

Table 1 MHCC-1-CM stimulated proliferation of SMMC7721 (contrasted by SMMC7721-CM, $\bar{x}\pm S_{\bar{x}}$)

Group	Conditioned medium/culture medium (volume ratio) 0	1:16	1:8	1:4	1:2[b]
SMMC7721-CM	0.596±0.090	0.535±0.315	0.568±0.099	0.524±0.053	0.541±0.377
MHCC-1-CM	0.513±0.043	0.581±0.080	0.570±0.061	0.620±0.033	0.853±0.031

[b]$P<0.01$, 0.541±0.377 *vs* 0.853±0.031.

Assay of C-met antibody blocking

Both cell proliferation and motility could be blocked by c-met antibody. After 3-day's incubation with c-met antibody, either MHCC- 1 or SF7721 showed inhibition of growth, and was correlative with antibody concentration (Figure 3, $P<0.05$). As to SMMC7721, the effect of inhibition could be seen under microscope, their shape turned round, and became shrank.

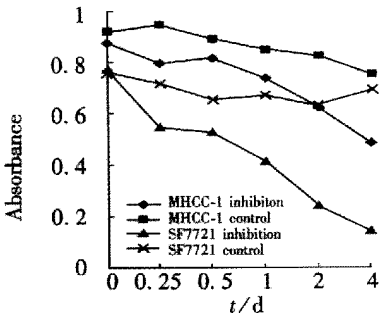

Figure 3 C-met inhibition assay.

DISCUSSION

Metastatic dissemination of solid tumors is a complex patho-physiological process including various factors. When we started to research on a HCC cell line (M HCC-1) with high potential of metastasis, we found that it had a high expression of c-met and with SF/HGF autocrine, which did not exist in other cell lines without or with low potential of metastasis. Thus, it became a promising approach to discuss c-met-HGF/SF signal transduction and tumor metastasis. Our result showed that cell malignancy of HCC is relative to its SF/HGF-c-met expression. The c-met expression of cell line with a higher potential of metastasis is much stronger than those with lower potential of metastasis and appeared with SF/HGF autocrine. Previous studies reported that many cancer cells expressed HGF/SF and c-met *in vivo*, but few of carcinoma cell lines produced HGF/SF *in vitro*, indicating that SF/HGF is a negative regulator in tumor progression. To further eluciate the phenomena, we transfected SF/HGF cDNA into S MMC7 721 cell line, trying to demonstrate that acquired SF/HGF autocrine may increase the malignancy and improve the metastatic potential in less metastatic cells. Our results showed that the proliferation, mobility and cell morphology had greatly changed in

SF7721 cells. Although the c-met expression in SF7721 cell did not increase significantly, it did improved greatly in SF7721 tumors in nude mice assay, later in the *in vivo* research. (Data not shown) When SF/HGF-c-met system was blocked by c-met antibldy, both MHCC-1 and SF7721 were blocked, demonstrating that SF/HGF-c-met was a positive regulator in HCC progression. Thus, we postulated that carcinoma cells may lose the ability to produce HGF/SF during *in vitro* passage, or the expression of HGF/SF need an activation from matrix. The high potential of metastasis of MHCC-1 may, to a great extent, contribute to its preservation of HGF/SF expression and keep the c-met activated all the way. *In vivo*, fibroblasts can produce HGF/SF, which may induce the expression of HGF/SF and c- met in cancer cells, thus establishing an autocrine and paracrine system and promoting cell scatter, proliferation and invasion[37-39]. We also studied the paracrine role of HGF/SF by stimulating SMMC7721 with MHCC-1-CM. Results were cons is tent with that from experiment of autocrine. Cell scatter, proliferation and mobility in SMMC7721 increased after they were stimulated by conditioned medium of M HCC-1. Such biological activities can be blocked by anti c-met polyclonal anti body. However, the influence of SMMC-7721 proliferation by the conditioned medium of MHCC-1 happened only when the medium was in 1:2 dilution, suggesting that the c-met receptor needs a certain amount of SF/HGF to activate. Once activated, the biological activity may depend on the quantity of c-met expression and the ex tent of receptor phosphorylation, thereby initiating downstream regulations. There were two reasons why we choose c-met rather than SF/HGF to be blocked. One was the conflicting reports of SF/HGF. Up to now, various of SF/HGF variants have been found, each having different structure and bioactivity *in vitro* and/or *in vivo*. This could be another reason why different results of SF/HGF are reported[40-47]. Compared with HGF/SF, c-met introduces many biological functions, but all the signal transductions start from a same 'multifunctional docking site'[4,5,48]. The different biological functions come from different signal messages, thus making it a better choice compared with HGF/SF and other members of tyrosine kinase family. Recently, c-met inhibition has become a hot spot in anticancer research[1,2,49-51]. In our research, the tumor cells blocked by c-met antibody shrank in morphology and decreased in cell proliferation. Results suggested that the inhibition of met-SF/HGF could become one of the potential approaches to reduce tumor growth and metastasis. In conclusion, our experiment showed that the system of SF/HGF-c-met autocrine and paracrine play an important role in invasion and metastasis of hepatocellular carcinoma. Inhibition of c-met-H GF/SF system may reduce the proliferation and metastasis of hepatocellular carcino ma by lowering the expression of c-met or its downst ream signal transduction.

ACKNOWLEDGEMENTS Dr. George Vande Woude providing us PBS7.3 and Dr. Bo-Heng Zhang performing stastical analysis.

Abstract

AIM: **To study and clone a novel liver cancer related gene, and to explore the molecular basis of liver cancer genesis.**

METHODS: **Using mRNA differential display polymerase chain reaction (DDPCR), we investigated the difference of mRNA in human hepatocellular carcinoma (HCC) and paired surrounding liver tissues, and got a gene probe. By screening a human placenta cDNA library and genomic homologous extend, we obtained a full-length cDNA named HCCA3. We analyzed the expression of this novel gene in 42 pairs of HCC and the surrounding liver tissues, and distribution in human normal tissues by means of Northern blot assay.**

RESULTS: **A full-length cDNA of liver cancer associated gene HCCA3 has been submitted to the GeneBank nucleotide sequence databases (Accession No. AF276707). The positive expression rate of this gene was 78.6% (33/42) in HCC tissues, and the clinical pathological data showed that the HCCA3 was closely associated with the invasion of tumor capsule ($P = 0.023$) and adjacant small metastasis satellite nodules lesions ($P = 0.041$). The HCCA3 was widely distributed in the human normal tissues, which was intensively expressed in lungs, brain and colon tissues, while lowly expressed in the liver tissues.**

CONCLUSION: **A novel full-length cDNA was cloned and differentiated, which was highly expressed in liver cancer tissues. The high expression was closely related to the tumor invasiveness and metastasis, that may be the late heredited change in HCC genesis.**

INTRODUCTION

Primary hepatocellular carcinoma (HCC) is one of the most common fatal malignant tumors in China[1-26]. According to the statistics of our country, primary liver cancer claims 20.40 lives per 100 000 people annually, with 19.98 per 100 000 in cities and 23.59 per 100 000 in rural areas, ranking as the 2nd and the 1st leading cause of cancer death, respectively. Of all the newly enrolled cases in the world each year, 45% are found in the mainland of China. In the southeast areas of high incidence, the situation is even worse with tumors tending to occur in a younger age group. The molecular events for HCC development are very complex, and HCC has proved to be genetically heterogenous neoplasm[27-30]. But to date, the identified genes have not yet fully disclosed the mechanisms of HCC[31-38]. In an attempt to identify HCC susceptible genes, differential display method was employed in this study. In the analysis of altered expression genes between HCC tissues and their nontumor counterparts, we isolated a novel gene named HCCA3 with a full length of cDNA.

MATERIALS AND METHODS

Materials

PCR polymerase is a product of Promega (Madison, USA); isotope α-^{32}P-dATP was purchased from Amersham Pharmacia Biotech (Arlington Heights, IL); Qiaex II gel extraction kit were from Qiagen (Hilden, Germany); pGEM-T vector were from Promega; human placental cDNA library were from Clontech (USA); nitrocellulose were from Amersham Pharmacia Biotech; Prime-a-Gene Labeling System were from Promega; 14-mer anchored oligo (dT) primer (dT_{12}CA) and an arbitrary 10-base olignucleotide A2 (5'-AATCGGGCTG-3') were donated by Professor Pei.

Patients and specimens

Primary HCC and their surrounding liver tissues were obtained from 42 patients who received surgical resection at the Eastern Hepatobilliary Surgical Hospital of the Second Military Medical University, Shanghai, China. These included 41 male and 1 female patients with a median age of 49 years (range 24-72 years, mean age of 49.8 years). Thirty-five (83.3%) patients had serological evidence of hepatitis B virus infection. The serum AFP level was above 25 $\mu g \cdot L^{-1}$ in 23 cases (54.8%). The tumor size was smaller than 5cm (small HCC) in 13 patients and larger than 5 cm in 29. Histologically, 40 patients (95.2%) were complicated with cirrhosis. There were 7 well differentiated (Edmondson's grades I and II) and 35 poorly differentiated (Edmondson's grades III and IV) HCCs. Macroscopic portal vein tumor spread was found in 3 patients, and microscopic surrounding liver vascular cancer thrombi were found in 26. Gross and microscopic intrahepatic adjacent small satellite nodules lesions were found in 28, and tumor capsule invasion of liver cancer in 32. Adult normal tissues were obtained from a healthy young man who died of a traffic accident.

Methods

RNA extraction and differential display Total cytoplasmatic RNA was extracted by the acid guanidinium thiocyanate-phenol - chloroform extraction methods[39, 40]. The differential display method

was perf ormed as described previously[39-41,42]. Amplification consisted of initial den aturation at 94℃ for 4 min, followed by 40 reaction cycles (60 s at 93℃, 2 min at 40℃, and 90 s at 70℃) and a final cycle at 72℃ for 10 min. PCR fragments were then reamplified by the same primer, separated on a 16 g·L^{-1} agarose gel, purified by Qiaex II gel extraction kit, and subcloned into the pGEM -T vector using standard molecular cloning techniques.

Library screening and DNA sequencing Fragment contained in the PCR clone (length in 350 base pairs) from DDPCR served as probe to screen placental cDNA library, using the standard filter hybridization techniques described[43,44]. At the end of the third screening, we got several plagues containing the target DNA sequence and sequenced them by DNA automated sequencing system. To obtain the cDNA in a full length, genomic homologous screening was used through comparing the cDNA sequence obtained by screening the library with the NCBI GeneBank EST database. We used the PCR assay and sequencing to confirm the correct ness of the cDNA sequence.

Northern blot assay For Northern blot analysis[37,40,44], 40 μg of total RNA was denatured, loaded on a 15 g·L^{-1} agarose gel and ran at 5 V·cm^{-1} for about 3 h. The collected gels were then transferred to nitrocellulose. Hybridization of the filters was performed using specific probe of HCCA3 cDNA fragment (length in 1125 bp) obtained from screening the library. The probe was labeled with 50 μCi A-^{32}P-dATP using Prime-a-Gene labeling kit according to the given protocol. After prehybridization at 42℃ for 3 h, the membranes were hybridized in the same solution containing the labeled probe for 6 h at the same temperature, and exposed to X-ray film for 10 d at-70℃. In order to calibrate relative quantities of loaded RNAs, the blot was rehybridized with a cDNA probe of the â-Actin gene.

Statistical analysis

χ^2 test or Fisher's exact test was used to examine the differences and relationship among groups of patients classified by HCCA3 expression. Differences at $P<0.05$ were judged to be statistically significant.

RESULTS

Differential display analysis and library screening

By DDPCR, we found a differentially expressed gene fragment that exclusively present in the liver cancer lane. This fragment (length in 350 bp) was then subcloned into pGEM-T vector and served as specific probe to screen human placental cDNA library. We have o btained the gene fragment of 1125 bp in length, which shortened nearly 600 bp according to the location of Northern hybridization by screening the library. We also obtained the full-length cDNA of 1706 bp, which was in good agreement with the size of the mRNA species observed by Northern blotting through genomic h omologous extend, along with the EST sequence (GeneBank Accession No. AP001077, length in 197663 bp) of NCBI GeneBank EST databases. The sequence of 1706 bp in length was corrected by PCR assay and sequencing. It was named HCCA3 (HCC associated gene 3, also named STW-2) and submitted to EMBL/GenBank/DDBJ nucleotide sequence databases (Accession No. AF27 6707).

Sequence characteristics of the full-length HCCA3

HCCA3 contains a consensus initiation codon[45,46] at position 681 followed by a single open reading frame of 792 bp encoding 264 amino acids. The 3' untranslated region of 230 bp had a consensus polyadenylation signal (AATAAA) beginning 16 bases upstream the poly (A) tail. Alignment at nucleotide and amino acid level showed no significant homologues with known genes. The deduced protein was estimated to be 29 396 dalton and has a pI of 6.93. Amino acid sequence analysis by GCG sequence analysis software package (version 9.1, Genetics Computer Group, Madison, Wisconsin) and PC/GENE (Version 5.03, Geneva University, Switzerland) showed that there were several putative modification sites. These include two N-glycosylation sites at amino acid of 40 and 67, three N-myristoylation sites at amino acid of 183, 185 and 258, five phosphorylation sites for protein kinase: two protein kinase C (PKC) phosphorylation sites at 82 and 250, three cases in kinase II phosphorylation sites at 8, 189 and 209. No transmembrane domain and signal peptide was found. Further·more, there was no nuclear targeting sequence. The schematic presentation of HCCA3 cDNA is shown in Figure 1.

Normal tissue distribution of HCCA3 Mrna

Northern blot analysis showed that HCCA3 mRNA appears to be widely expressed in human normal tissues (Figure 2). The HCCA3 gene was particularly highly expressed in human lungs, brain and colon, moderately expressed in muscle, stomach, spleen and heart tissues, weakly expressed in small intestines, pancreas, and liver tissues. Among the tissues with positive signals, HCCA3 mRNA was observed in a transcript of approximately 1.7 kb which well corresponded to the size of the cloned cDNA.

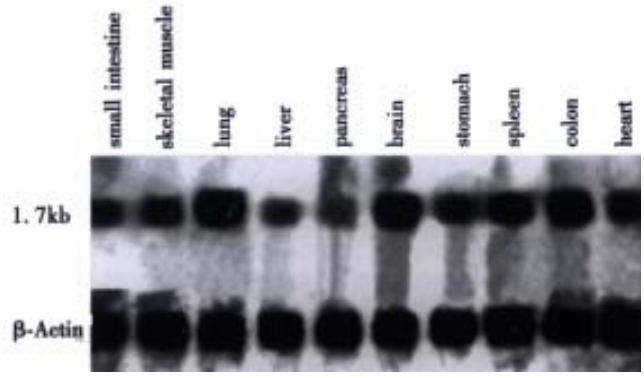

Figure 2 Northern blot analysis of HCCA3 mRNA in human adult normal tissues. Upper panel showed HCCA3 mRNA was highly expressed in human lungs, brain and colon, moderately expressed in muscle, stomach, spleen and heart tissues, weakly expressed in small intestines, pancreas, and liver tissues. Equal a mounts of total RNA loading as indicated by rehybridizing with (-actin cDNA probe (lower panel).

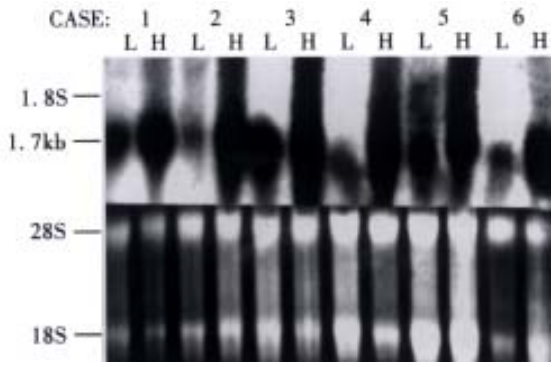

Figure 3 Differential expression of HCCA3 analyzed by Northern b lot. Upper panel shows that HCCA3 mRNA was highly expressed in HCC tissues (H), and lowly in paired surrounding liver tissues (L). A signal transcript of 1.7 kb is shown in six tumors. 28S and 18S rRNAs were used for evaluating the quality and quantity of RNA loading (lower panel).

HCCA3 mRNA expression in HCC and its clinical significance

HCCA3 mRNA expression was noticed in 78.6% (33/42) patients, which was intensively expressed in HCC tissues (Figure 3), while lowly expressed in the surrounding liver tissues. To investigate the potential biological role of HCCA3 in the development of HCC, we further investigated its expression in HCC with extensive samples and compared with the clinically pathological parameters. The mRNA expression level of HCCA3 was associated with the invasion of liver cancer capsule and the adjacant small satellite nodules lesions ($P< 0.05$), but not with tumor size, tumor differentiation, serum AFP, hepatitis B vrius (HBV) infection and microscopic vascular cancer cell thrombi ($P>0.05$). The results are listed in Table 1.

Figure 1 Nucleotide sequence and predicted amino acid sequence of HCCA3. HCCA3 nucleotide sequence (1706 bp) and deduced amino acid sequence (264 amino acid). The franking sequence of the predicted initiating methionine which satisfied the Kozak criterion is shown in the box. A consensus polyadenylation signal sequence (AATAAA) be ginning 16 bases upstreams the poly(A) tail shown in black line. The asterisk indicates the stop codon. EMBL / GenBank™ / DDBJ accession number is AF276707.

DISCUSSION

Differential display polymerase chain reaction (DDPCR) method is a useful tool for detecting and characterizing altered gene expression in eukaryotic cells[39,41,47,48]. Using this technique, we have successfully isolated a gene named HCCA3 with a transcript of 1706 bp. A consensus initia tion coden is at 681 bp and the franking sequence of the predicted initiating me thionine coincides with Kozak[45,46,49] criterion because the nucleot ides at -3, +4 site of start codon are purine, and there is one stop codon at the upstream sequence. The length of HCCA3 cDNA agrees with the size of mRNA by Northern b lot analysis. No significant homologues with known genes at nucleotide and amino acid levels were found[47-50]. No signal peptides searched by GCG and PC/GENE software were found, suggesting that HCCA3 was not a secretive protein[51,52]. This protein also has no transmembrane domain and nuclear targeting sequence indicating that it may not be located on cell member or within nucleus. The putative protein of HCCA3 revealed several phosphorylation sites for protein kinase C and casein kinase II. It is generally accepted that protein phosphorylation-deph osphorylation plays a role in the regulation of essentially all cellular functions, and there is evidence that deregulation of protein phosphorylation is involved in several human cancers[22,53,54]. HCCA2 as a possible oncoprotein may be functionally abnormal, and phosphorylative deregulation may be a mechanism. The function of HCCA3 protein may also largely depend on its phosphorylation status[22,54]. However, this needs further studies.

Studies on the expression of HCCA3 can reveal its potential biological significance[22,36,37,55]. By Northern blot analysis, we noted that HCCA3 mRNA was expressed widely in normal human tissues, indicating that HCCA3 is a normal cellular gene which may be involved in the physical process of the distributed tissues. Although HCCA3 mRNA was lowly expressed in normal liver tissues, it was significantly expressed in HCC tissues, showing that the high expression of HCCA3 might participate in the process of liver on cogenesis[36,37]. Because HCCA3 is a normal cellular gene, increased expression of HCCA3 in HCC implys the genetic abnormality and acts as an oncogene in the dev elopment of HCC. In 42 patients with HCC, HCCA3 mRNA was detected in 33 (78.6%), which was highly expressed in HCC tissues, suggesting that HCCA3 is a very common molecular event involved in the pathogenesis of HCC. These findings indicate that HCCA3 mRNA is overexpressed preferentially in HCC and can serve as a tumor biomarker for HCC[7,18,23,36,37]. The three patients with macroscopic portal vein tumor thrombi all had significantly high expression of HCCA3 mRNA, implying that HCCA3 is a late incidence in HCC carcinogenesis. Compared with pathological features,HCCA3 mRNA expression was associated with the invasion of tumor capsule and the adjacant small satellite nodules lesions ($P<0.0$ 5), indicating that HCCA3 mRNA expression is a factor of HCC invasiveness and metastasis[37,38]. Although the function of HCCA3 is still unknown, our results suggest that the up-regulation of expression of HCCA3 mRNA may play an important role in the development and/or progression of hepatocellular carcinoma[36-38,42,45]. This finding demonstrated that it is possible to identify the pr eviously unknown, differential gene expression from a small amount of clinical samples[39-42,56]. Information about such alteration of HCCA3 in gene expression could be useful in elucidating the genetic events in HCC pathogenesis, developing new diagnostic markers, or determining novel therapeutic targets.

Abstract

AIM: **To assess the efficacy and safety of TECA type hybrid artificial liver support system (TECA-HALSS) in providing liver function of detoxification, metabolism and physiology by treating the patients with acute liver failure (ALF).**

METHODS: **The porcine liver cells (1-2)×10¹⁰ were separate d from the Chinese small swine and cultured in the bioreactor of TECA-BALSS at 37.0℃ and circulated through the outer space of the hollow fiber tubes in BALSS. The six liver failure patients with various degree of hepatic coma were treated by TECA-HALSS and with conventional medicines. The venous plasma of the patients was separated by a plasma separator and treated by charcoal adsorbent or plasma exchange. The plasma circulated through the inner space of the hollow fiber tubes of BALSS and mixed with the patients' blood cells and flew back to their blood circulation. Some small molecular weight substances were exchanged between the plasma and porcine liver cells. Each treatment lasted 6.0-7.0 h. Physiological and biochemical parameters were measured before, during and after t he treatment.**

RESULTS: **The average of porcine liver cells was (1.0-3.0) ×10¹⁰ obtained from each swine liver using our modified enzymatic digestion method. The survival rate of the cells was 85%-93% by trypan blue stain and AO/PI fluorescent stain. After cultured in TECA-BALSS bioreactor for 6 h, the survival rate of cells still remained 70%-85%. At the end of TECA-HALSS treatment, the levels of plasma NH_3, ALT, TB and DB were significantly decreased. The patients who were in the state of drowsiness or coma before the treatment improved their appetite significantly and regained consciousness, some patients resumed light physical work on a short period after the treatment. One to two days after the treatment, the ratio of PTA increased warkedly. During the treatment, the heart rates, blood pressure, respiration condition and serum electrolytes (K^+, Na^+ and Cl^-) were stable without thrombosis and bleeding in all the six patients.**

CONCLUSION: **TECA-HALSS treatment could be a rapid, safe and efficacious method to provide temporary liver support for patients with ALF.**

INTRODUCTION

Liver diseases are common in China[1-8]. The treatment for acute liver failure (ALF) is still a focus of research[9-15]. Some clinical reports have shown that non-biological-artificial liver support system with charcoal adsorbent or plasma exchange could improve the rehabilitation process in the patients with acute and chronic liver failure[16-25]. Our previous experiments have demonstrated that as a temporary alternative treatment, TECA type bioartificial liver support system (TECA-BALSS) using the swine liver cells was safe and effective in treating the ALF dogs induced by acetaminophen, with the injured liver cells regenerated and repaired, and a long-term survival[26-30]. In order to reduce the damage to the swine liver cells caused by the toxic substances in the ALF patients' blood and improve the efficacy of the treatment, we treated 6 patients with acute and chronic liver failure by our newly developed TECA type hybrid artificial liver support system (TECA-HALSS) using swine liver cells combined with charcoal adsorbent or plasma exchange.

MATERIALS AND METHODS

TECA-BALSS

The swines were purchased from the small swine breeding laboratory of Beijing Agricultural University. The porcine liver cells were separated by the enzyme method from Chinese experimental small swine and the survival rate of the cells was determined by trypan blue stain and AO/PI fluorescent stain. Porcine liver cells (1-2)×10¹⁰ were cultured in the T ECA-BALSS bioreactor at 37.0℃ and circulated through the outer space of the hollow fiber tubes in BALSS[31-32]. One of the femoral veins or subclavian veins of the patient was cut and a tube was inserted to establish the blood circulation pathway. The venous plasma of the patient was separated by a plasma separator and through the inner space of the hollow fiber tubes of BALSS and mixed with the patient's blood cells and flew back to their circulation.

Non-bioartificial liver support system

The plasma was treated by carbon absorption with Gambro Adsorda 300C and mixed with the patient's blood cells and flew back to their venous sys tem for 2-3 h in cases 1, 2 and 3. The patient's plasma was separated and exchanged for 2 to 3 L by PLASAUTO-IQ Plasma Exchanger (Japan) in cases 4, 5 and 6[33,34]. The heparin was administered to all the patients for anticoagulation.

TECA-HALSS

After the treatment with the non-bioartificial liver support system, the

patient's plasma was circulated through the inner space of the hollow fiber tubes in TECA-BALSS for 4-5 h.

Examination indexes

Before, during and after the treatment with BALSS, the porcine liver cells' survival rate in the cell suspension was examined by trypan blue stain and AO/PI fluorescent stain once an hour and the patient's heart rate, blood pressure and respiration condition were measured with multi-functional monitor and the blood biochemical indexes for liver function, kidney function and blood coagulation function were analyzed.

Clinical data

The general condition and the therapeutio methods for the six patients with live r failure are shown in Table 1. Among these patients, cases 1, 3 and 5 were chronic viral hepatitis, their liver function decompensated and developed liver failure; cases 2, 4 and 6 were ALF caused by partialliver excision after surgery, viral hepatitis or drug toxication, respectively. Before the treatment of TECA-HALSS, all the patients suffered from various degree of hepatic coma. They were treated by TECA-HALSS for 6-7 h, and with conventional medicines as well.

Table 1 Clinical data of six patients with liver failure

No	M/F	Age	Diagnosis	General condition	Program of treatment	*t* (treatment)/h

RESULTS

The swine liver cells obtained and cultured

The obtained average of porcine liver cells was (1.0-3.0)×10^{10} from each swine liver by our modified enzymatic separation method. The survival rate of the cells was 85%-93% by trypan blue stain and AO/PI fluorescent stain. After cultured in TECA-BALSS bioreactor for 6 h, the survival rate of cells still remained 70%-85%.

Changes in basic physiological indexes

During the TECA-HALSS treatment, heart rates, blood pressure and respiration condition in all the six patients remained stable without thrombosis and bleeding. Those who were in the state of drowsiness or coma before the treatment improved their appetite significantly and regained consciousness, some patients resumed light physical work in a short period after the treatment.

Changes in biochemical indexes of blood

At the end of the treatment with HALSS, the patients' liver function related biochemical indexes, such as the levels of NH 3, ALT, TB and DB were significantly decreased. Blood coagulation was improved, the PT was shortened and PTA was raised. There were no significant changes in the levels of the patients' main serum electrolytes (K^+, Na^+ and Cl^-) during the treatment.

Typical cases

Case 2 was a patient with ALF complicated with acute kidney failure after left half liver excision. After twice blood dialysis, the patient's renal function was improved temporarily, but she was in the state of hepatic coma with drowsiness. At the 7th day after operation, she received the treatment of TECA-HALSS with plasma-carbon absorption for 2h and plasma-BALSS treatment for 4h. The patient's blood ammonia level was returned to normal and she regained consciousness (Table 2). Two days after the treatment of HALSS, she had normal liver function and receive d blood dialysis for the renal disfunction. Because of economic reasons, she was discharged from the hospital voluntarily.

Table 2 Changes of pre- and post-treatment by TECA-HALSS in case 2

Parameters	Pre-HALSS	Post CA	4 h post-BALSS	2 d post-HALSS
NH_3(μg/L)	134	93	30	53
ALT (IU/L)	64	27	29	53
AST (IU/L)	69	47	269	97
TB (μmol/L)	495	423	400	405
DB (μmol/L)	240	204	198	350
UN (mmol/L)	41	35.7	36.6	37
Cr (μmol/L)	651	121	407	
K^+(mmol/L)	4.99	4.66	4.47	4.9
Na^+(mmol/L)	132	131	133	131
Cl^-(mmol/L)	99.6	104	104	96
Mentality	Lethargy	Lethargy	Consciousness	Consciousness

Case 4 was a patient with acute severe viral hepatitis complicated with fulminant liver failure and stage IV hepatic coma and PTA 13%. The liver was found shrink and diffused liver damage by ultrasound B examination. After coma for three days, she received T ECA-HALSS with 2.5 L plasma exchanged and 4 h of BALSS treatment. After the treatment, the levels of ALT, TB, DB and ALP were significantly decreased and PTA value increased rapidly (Table 3). The patient experienced superficial coma one day and regained consciousness and could eat food two days after treatment. Five days later, her abilities of calculation and orientation became normal and eight days later, she was discharged from the hospital. Two months' follow up showed that her general condition was good and she could do some light physical work, his liver function parameters were within normal range.

Table 3 Changes pre- and post-treatment by TECA-HALSS in case 4

Pre-HALSS		HALSS			Post-HALSS			
		Post-PE	BALSS 2 h	BALSS 4 h	d 1	d 2	d 4	d 7
NH3 (μg/L)	78	114	101	108				
ALT (IU/L)	1352	408	390	336			225	146
AST (IU/L)	142	45	629	751			45	63
TB (μmol/L)	17.11	7.23	9.99	9.22			16.95	29.18

TP (g/L)	69.8	54.5	48.1	43.5			48	56.2
ALB (g/L)	34.29	31.8	28.5	25.6			23.3	24.6
ALP (IU/L)	297	144	140	115			176	213
PTA (%)	13.15				21.6	29.6		48.8
Mentality	Deep coma	Deep coma	Deep coma	Deep coma	Superficial coma	Consciousness		

DISCUSSION

It is well known that ALF has a very high morbidity and mortality rate. The conventional medical treatment was hard to achieve satisfied outcomes since liver cells possess the strong ability of regeneration. Therefore, if a full liver support therapy can be provided to keep the patients alive and avoid severe complications to occur, the patients' liver function can recover spontaneously or win the time for liver transplantation. The research about using artificial means to temporarily support the liver function has attracted worldwide attention. Many years of research has been carried out on non-bioartificial liver support systems, which detoxicate nonspecifically or specifically by using absorption, plasma dialysis, blood or plasma exchange and so on. In this way, it can eliminate the possible toxic substances in the blood so as to provide a chance for liver cells to regenerate and repair. But some reports indicated that these methods did not work well in treating liver failure. For example, carbon absorption can only nonspecifically detoxicate part of the toxic substances in the blood and can not greatly increase the survival rate of patients with liver failure. Although replacing a large quantity of patients' plasma (3-4L) within a short time can correct one third of the biochemical indexes related to liver function, this effect can only last 1-3 days and the patients' mental malfunction can not be improved significantly[35-37]. Case 3, received 8 times of plasma exchange. Each time after plasma exchange, the patient was still listless and drowsy, his biochemical indexes of liver function were corrected by only one third to one fourth, and deteriorated again within 1-3 days. At the end of TECA-HALSS treatment, the patient turned from drowsy to conscious, he also asked for food and walked out of the treatment room without help. The patient's blood parameters of liver function remained normal for almost 20 days. Therefore, it is believed that non-bioartificial liver support system could not be enough for substituting the complicated function of liver. In recent years, newly developed bioartificial liver support systems use exnogenous liver cells to provide the functions of biosynthesis, detoxication and biotransformation. Our previously developed TECA-BALSS has been proved to be safe and effective as a temporary replacement of liver function in the treatment of ALF in dogs caused by acetaminophen[26]. The porcine liver cells cultured in TECA-BALSS possess liver cell functions, such as biosynthesis, detoxication and biotransformation. The ALF patient's blood circulated through BALSS and reacted with the porcine liver cells through the semipermeable membrane of the hollow fiber tubes in BALSS[31,38-39]. Our and other studies showed that porcine liver cells in BALSS, functioning as a temporary replacement of liver, could win a period of time for the patients or animals with liver failure to regenerate and repair their liver[29,40]. Our research found that t he toxic substances of the ALF patients' blood can damage the porcine liver cells[41]. In this experiment, we used non-bioartificial liver methods (carbon absorption and plasma exchange) for reducing the toxic substances first and later used BALSS to exert biological function of liver cells, i.e., TECA-HALSS. The results from 6 cases of acute and chronic liver failure showed that TECA-HALSS could significantly improve the liver function by lowering the levels of blood NH 3, ALT, TB and DB and increasing PTA. Our preliminary result indicated that BALSS could significantly improve the patient's consciousness and the effect persisted longer than by plasma exchange.

According to the reports both domestic and overseas, the major use of HALSS is for the patients with ALF caused by various reasons, such as viruses, drugs and ischemia[42-45]. Through temporary liver function substitution, HALSS treatment wins the time for liver cells to regenerate and repair and compensatie liver function. However, for the patients with chronic liver failure, the main propose of HALSS treatment is to provide the bridge to liver transplantation, especially for the patients with hepatic coma staged III-IV[30,46-47]. BALSS treatment can be carried out in two ways: blood perfusion and plasma perfusion. Our results suggested that it preventing thrombosis by the way of plasma infusion is favored in HALSS. This can also reduce the dosage of heparin, which is very important to the patients with liver failure complicated with coagulation malfunction. The times and duration of HALSS treatment depend on the patients' biochemical indexes of liver function, mental consciousness and so on. It was reported that some patients received HALSS treatment as many as over 10 times[48-50]. The results from our experiment and others indicated that HALSS treatment is safe and practical. During the treatment, to monitor the basic physiological indexes of the patients and supplement blood instantly are suggested. Other authors found that after the treatment with HALSS, there were no significant immune reactions and no negative effect on the following liver transplantation. No immune factors directly influence the patients' prognoses. The results suggested that TECA-HALSS could be a rapid, safe and efficacious method to provide temporary liver support for the patients with ALF.

Abstract

AIM: **To study the influence of inducers of drug metabolism enzyme, β-naphthoflavone (BNF) and dexamethasone (DEX), on the stereoselective metabolism of propafenone in the rat hepatic microsomes.**

METHODS: **Phase I metabolism of propafenone was studied using the microsomes induced by BNF and DEX and the non-induced microsome was used as the control. The enzymatic kinetics parameters of propafenone enantiomers were calculated by regress analysis of Eadie-Hofstee Plots. Propafenone enantiomer concentrations were assayed by a chiral HPLC.**

RESULTS: **The metabolite of propafenone, N-desalkylpropafenone, was found after incubation of propafenone with the rat hepatic microsomes induced by BNF and DEX. In these two groups, the stereoselectivity favoring R(-) isomer was observed in metabolism at low substrate concentrations of racemic propafenone, but lost the stereoselectivity at high substrate concentrations. However, in control group, no stereoselectivity was observed. The enzyme kinetic parameters were: ①K_m. Control group: R(-) 83±6, S (+) 94±7; BNF group: R(-) 105±6, S(+)128±14; DEX group: R(-) 86±11, S(+) 118±16; ② υ_{max}. Control group: R(-) 0.75±0.16, S(+) 0.72±0.07; BNF group: R (-)1.04±0.15, S (+)1.0 7±14; DEX group: R(-) 0.93± 0.06, S(+) 1.04±0.09; ③ Cl_{int}. Control group: R(-) 8.9± 1.1, S(+) 7.6±0.7; BNF group: R(-)9.9±0.9, S(+)8.3± 0.7; DEX group: R(-) 10.9±0.8, S(+) 8.9±0.9. The enantiomeric differences in K_m and Cl_{int} were both significant, but not in υ_{max}, in BNF and DEX group. Whereas enanti omeric differences in three parameters were all insignificant in control group. Furthermore, K_m and υ_{max} were both significantly less than those in BNF or DEX group. In the rat liver microsome in duced by DEX, nimodipine (NDP) decreased the stereoselectivity in propafenone metabolism at low substrate concentration. The inhibition of NDP on the metabolism of propafenone was stereo selective with R(-)-isomer being impaired more than S(+)-isomer. The inhibition constant (Ki) of S(+)- and R(-)-propafenone, calculated from Dixon plots, was 15.4 and 8.6 mg·L^{-1}, respectively.**

CONCLUSION: ***CYP*1A subfamily (induced by BNF) and CYP3A4 (induced by DEX) have pronounced contribution to propafenone N-desalkylation which exhibited stereose lectivity depending on substrate concentration. The molecular base for this phenomenon is the stereo selectivity in affinity of substrate to the enzyme activity centers instead of at the catalyzing sites.**

INTRODUCTION

Propafenone, is a widely used antiarrhythmic agent administered as the racemic mixture of R(-) and S(+) enantiomers. The two enantiomers are equipotent in terms of sodium channel-blocking activity, but the main side effect, ie., β-adrenoreceptor-blocking action resides in the S (+)-isomer[1], and, therefore, information on stereoselective disposition of the racemate is of clinical relevance.

The main metabolic pathways of propafenone in vivo and *in vitro* involve CYP1A2 and CYP3A4 mediated N-desalkylation, CYP2D6 mediated 5-hydro xylation and UDPGT mediated glucuronidation[2-6]. N-desalkylpropafenone has the same electrophysi ological potency as 5-hydroxypropafenone and propafenone, and the plasma concentrations of N-desalkyl propafenone are similar to those of 5-hydroxypropafenone during chronic administration in human, therefore, N-desalkylpropafenone contributes to the antiarrhythmic effects of propafenone, especially in patients with poor metabolizer phenotype of CYP2D6[7-8]. Although stereoselectivities in 5-hydroxylation and glucuronidation *in vitro* have been reported[9-11], whether N-desalkylation exhibits stereoselectivity has not been addressed. Meanwhile, rat liver microsomes pretreated by specific inducers provide sound models to study metabolism *in vitro*[12-16]. Considering that β-nap hthoflavone (BNF) was a typical inducer of CYP1A subfamily and dexamethasone (DEX) was a typical inducer of CYP3A4[17-21], this experiment studied the stereoselective propafenone N-desalkylation in rat hepatic microsomes induced by BNF and DEX.

Material AND METHODS

Chemicals and solutions

Dexamethasone (DEX), β-naphthoflavone (BNF), 7-ethoxyresorufin (ER), triacety loleandomycin (TAO), NADPH, 2,3,4,6-tetra-*O*-acetyl-β-D-glucopyranosyl isothiocynate (GITC), (R,S)-propafenone, R(-) and S(+)-propafenone were supplied by Sigma Chemical Co (St. Louis, MO, US A). N-desalkylpropafenone was a generous gift from Prof. Tang YN (Xinhua Hospital, Shanghai). All other chemicals were obtained from the common commercial sources. Stock buffer (pH7.4): 1 mol·L^{-1} pH7.4 Tris-HCl buffer 25 mL, 1 mol·L^{-1} KCl 75 mL and 1 mol·L^{-1} $MgCl_2$ 5 mL were mixed and diluted with water to 500 mL. NADPH solution: dissolve NADPH in ice-cold 10 g·L^{-1} NaH CO_3

solution to the desired concentration of 25 mmol·L^{-1}. The solution should be freshly prepared just before the incubation.

Preparation of hepatic microsomes

Sprague-Dawley rats (male, 170-210 g) were divided into three groups. One group received three daily intraperitoned injection of 80 mg·kg^{-1} BNF (dissolved in oil); the second group received three daily DEX (132 mg·kg^{-1}·d^{-1}, ig) and the third group was used as the non-treated control. About 24 h after the last treatment and with no food supplied for 16 h before taking the livers, the rats were sacrificed by decapitation. Liver samples were excised and perfused by the ice-cold physiological saline to remove blood and homogenized in ice-cold Tris buffer. Hepatic microsomes were prepared with the ultracentrifugation methods[22,23]. All manipulations were carried out in cold bath. Pellets were re-suspended in sucrose-Tris buffer (pH 7.4)(95:5, mass to volume ratio) and immediately stored at -30℃. Protein and cy tochrome P450 contents were estimated according to the methods of Zeng *et al*[24]and Omura *et al*[25],respectively. Enzymatic activity of CYP1A was measured according to the method of Klotz *et al*[26], and expressed as initial velocity of O-deethylation of 7-ethoxyresorufin (activity of EROD). Enzymatic activity of CYP3A4 was determined according to the method of Wrighton *et al*[27], and expressed as the extent of P450-MI complex (absorbance difference per gram of protein between 456 nm and 510 nm) using triacetyloleandomycin as substrate. Incubation of propafenone with rat hepatic microsomes The incubation mixture contained microsomal protein (1.6 g·L^{-1}), stock buffer (pH 7.4) bubbled with oxygen for 1 min and racemic propafenone as substrate. After 5 min preincubation, reaction was started by adding 10 μL NADPH solution. The final volume was 250 μL. For kinetic experiments, racemic propafenone was used at concentrations of 10, 20, 40, 80, 160, and 320 mg·L^{-1} and the incubation time was 30 min. For the time dependent experiments, the substrate concentration used was 10 mg·L^{-1}. For inhibition experiments, nimodipine was used as inhibitors (at 0, 8, 16, 32 mg·L^{-1}) and incubated simultaneously with racemic propafenone (50, 100 mg·L^{-1}). After the indicated time, the reaction was terminated by adding 750 μL chlorform. The mixture was votexed for 3 min, then centrifuged at 2 000 g for 10 min. The organic layer was transferred to a clean tube and evaporated to dryness under a gentle stream of air. GITC solution (in acetonitrile) and methanol containing 14 g·L^{-1} triethamine were added and the tube was capped and allowed to react for 30 min a t 35℃. After evaporation of organic solvents, the residues were reconstutited with 100 μL methanol, and 20 μL was injected into HPLC system.

HPLC procedure for determining propafenone enantiomer in the rat hepatic incubates

Enantiomers of propafenone were quantitated with an HPLC system with UV detection (λ = 254 nm)[28]. A 5-ìm reverse phase column (Shimpack CLC- ODS 15 cm×4.6 mm) was used with a flow rate of 0.8 mL/min. The mobile phase was a mixture of methanol -water-glacial acetic acid (67:33:0.05).

Statistical analysis

The maximum velocity (υ_{max}) and Michaelis-Menten constant (K_m) values for propafenone enantiomer were determi ned by regress analysis of Edie-Hofstee plots. The $\bar{x}\pm s$ of three determinations of υ_{max} and K_m was calculated for each substrate and metabolic reaction. Intrinsic clearance was calculated by the ratio of υ_{max}/K_m. All statistical difference was tested by unpaired *t* test.

RESULTS

A baseline separation between the diastereomers of S(+) and R(-)-propafenone was achieved, with the retention time being 23 min and 28 min, respectively. The HPLC system also allowed monitoring the formation of N-desalkylpropafenone. The retention time was 8 min and 10 min for diastereomer of N-desalkylpropafenone, respectively. The amount of diastereomers of N-desalkylpropafenone were increasing while those of propafenone were decreasing during 30 min incubation with the rat hepatic microsomes induced by DEX and BNF. Typical chromatograms were showed in Figure 1. Quantitation was performed by external standardization. Calibration curves were linear at a range of 0.5 to 320 mg·L^{-1} for each enantiomer of propapfenone. The LOQ was 0.5 mg·L^{-1} (S/N = 10, *n* = 5) for each enantiomer. The inter-assay and intra-assay variability averaged 8.5% for both enantiomers. The method recovery averaged 77.1% for both enantiomers.

Induction of rat hepatic metabolizingenzymes

In DEX group, the extent of P450-MI complex (an indicator of activity of CYP3A4) was significantly more than the control or BNF group (P<0.001, Table 1). In BNF group, the initial velocity of deethylation of 7-ethoxyresorufin (an indicator of activity of CY P1A) was significantly more than in the control or DEX group (about 20-fold, P<0.001). Therefore, CYP1A subfamily was successful inducted by BNF and CYP3A4 by DEX, which provided sound enzymatic sources for getting information on CYP1A and CYP3A4 mediated N-desalkylation of propafenone.

Impact of substrate concentration on stereoselective metabolism of propafenone

At 10 mg·L^{-1} concentration of racemic propafenone, stereoselectivity was observed in DEX and BNF group, but not in control group (Table 2). The depletion of R(-)-isomer was faster than that of S(+)-isomer. However, with the substrate concentration increasing, S/R ratios of prop afenone were not altered in control group (P>0.05), but in DEX and BNF group S/R ratios were decreasing from 1.18 to 1.00 (P <0.01), and 1.10 to 1.00 (P<0 .01), respectively.

Table 2 Ratio of S(+)/R(-) propafenone at different concentrations in rat liver microsomal incubates ($\bar{x}$±s, n = 3)

Enantiomer / mg·L^{-1}	Pretreat

Concentration-time curves and ratio of S(+)/R(-) propafenone concentration

The ratio of S/R was in unity in control group from the incubation time of 0 to 30 min, whereas in DEX or BNF group, the ratio of S/R increased and was significantly different with the corresponding ratio in control group at 8 and 30 min (P<0.01, 0.05, Table 3). Moreover, the ratio of S/R in DEX group at incubation time of 30 min was significantly higher than that in BNF.

Table 3 Ratio of S(+)/R(-) propafenone concentration in rat liver microsomal incubates ($\bar{x}$±s, n = 3)

Group	t (incubation)/min

Enzymatic kinetic parameters for propafenone metabolism in hepatic microsomes

Depletion of propafenone could be described by Michaelic-Menten kinetics. K_m had no statistical difference between the two enantiomers in control microsomes, whereas the enantiomeric difference in K_m was significant in the microsomes induced with DEX or BNF (S>R, P< 0.05, Table 4). There was signific ant difference for Clint between the two enantiomers (S<R, P<0.05, Table 4) in DEX or BNF group,

but not in control group. The K_m of S(+)-isomer in DEX, or S(+)- or R(-)-isomer in BNF group was significantly higher than the corresponding enantiomer in control group (P<0.05, 0.01, Table 4). The υ_{max} of S(+)-isomer in DEX group, or S(+)- or R(-)-isomer in BNF group, was significantly higher than the corresponding enantiomers in the control group (P<0.05, 0.01, Table 4). Difference for Clint between the two enantiomers in DEX or BNF group and the corresponding enantiomer in control group was insignificant. Moreover, the K_m of R(-)-propafenone in DEX group was significantly lower than that in BNF group (P <0.05, Table 4).

Stereoselective inhibition of propafenone metabolism by nimodipine

*K*i for S(+)- and R(-)-propafenone was 15.4 and 8.6 mg·L^{-1}, respectively, which suggested that nimodipine (specific substrate of C YP3A4) inhibited metabolism of propafenone enantiomer stereoselectively (Figure 3). With nimodipine amount increasing, the depletion of propafenone enantiomers and the S/R ratio of the remaining amount o f propafenone enantiomer were decreasing (Table 5).

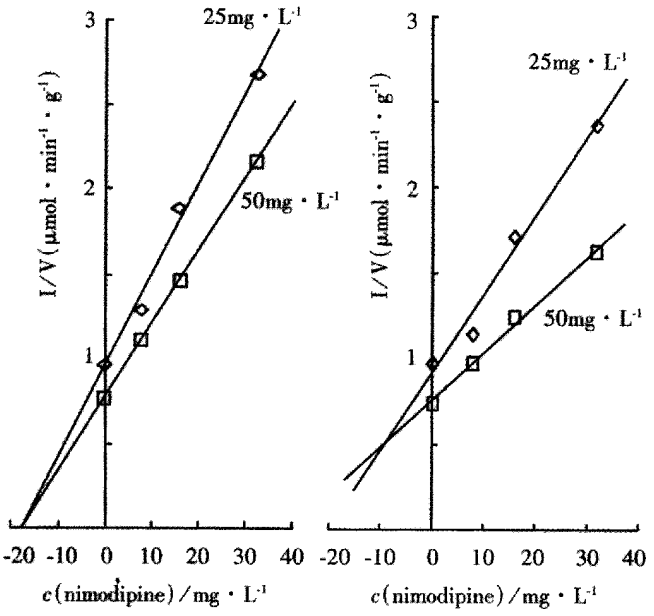

Figure 3 Dixon plot for S(+)-propafenone (Left) and R(-)-pro pa fenone (Right) wit nimodipine as inhibitor at three concentration. Ki for S(+)-and R(-)-PPF was 15.4, 8 mg·L^{-1}, respectively. Each data point represents the mean of duplicate determinations.

Table 5 The stereoselective effects of nimodipine on metabolic depletion of propafenone ($\bar{x}$±s, n = 3)

Group	Nimodipine /mg·L^{-1}	S(+)-propafenone	R(-)-propafenone /mg·L^{-1}	S/R
DEX	0	2.10±0.04	1.75±0.14[a]	1.20

DISSCUSSION

Due to the capabilities of highly efficient separation and sensitive determination of enantiomers in microsome incubates, chiral chromatography is extremely valuable to study stereoselectivity of racemate met abolism[29-34]. So far as we are aware, we took the lead in acquiring the information on stereoc hemistry of propafenone metabolism by chiral HPLC method.

Previously, we observed that the glucuronidation of propranolol in rat hepatic microsome has stereoselectivity of S(-)-propranolol, and that the induction of phenobarbital reduced this stereoselectivity[35]. The phase I metabolic stereoselectivity of propranolol was reversed by the induction of BNF and increased by the induction of phenobarbital[36]. Phenobarbital instead of BNF inducted the stereoselective difference of Cl_{int} in glucuroniodation of ofloxacin[37]. However, the induction of DEX or BNF in this study vested propafenone metabolism with stereoselectivity in rat hepatic microsomes. It is thus clear that different inducers may have different impacts on some racemate metabolism.

The enantiomers of a racemic drug may differ in metabolic behavior as a consequence of stereoselective interaction with hepatic microsomes[38-42]. The underlying mechanism of stereoselectivity in metabolism, as many studies have shown, was enantiomeric difference in υ_{max} (an indice of enzymatic catalyzing ability) and/or in K_m (an index of enzyme affinity to the substrate). For example, the stereoselective N-demethylation of chlorpheniramine was due to enantiomeric differences in K_m[43]. Whereas there were little or no difference in K_m of the enantiomers of ofloxacin, the stereoselectivities in glucuronidation were caused by enantiomeric differences in υ_{max}[44]. The υ_{max} of the O-demethylation of (-)-tramadol was 1.6 times that of (+)-isomer, but the Km for both enantiomers was same, thus resulted in its stereos elective O-demethylation[45]. Recently, we have also proved that stereoselectivity of propranolol cytochrome P450 metabolism in the rat hepatic microsomes was due to the stereoselectivity of the catalyzing function in enzyme[35]. In this *in vitro* study, stereoselectivity of propafenone occurred in K_m and Clint in the rat hepatic microsomes induced by DEX or BNF, but not in υ_{max}. Combining with the interesting results of Table 2 that stereoselectivity depends on substrate conce ntration, we suppose that stereoselectivity at low substrate concentration was mainly due to the enantiomeric difference of the enzyme affinity to the substrate, and that insignificant enantiomeric difference in catalyzing abilities resulted in the abolished stereoselectivity at high subs trate concentration. Fujita *et al*[46] also reported that stereoselectivity of propranolol in rat liver microsomes was sometimes altered when the substrate concentration was varied. Augustijns *et al*[38] observed that the enantiomeric ratio (R/S) of desethylchloroquine was dependent on concentrati on, and ranged from 8 at 1 microM to 1 at 300 microM. Mutual enantiomer-enantiomer interacti on studies at low concentration (1-5 microM) revealed that the formation of (R)-desethylchlor oquine was strongly inhibited by (S)-chloroquine. In this *in vitro* metabolism,

enantiomer-enantiomer interaction at enzyme activity centers may also exist at low concentration, resulting in enantiomeric difference of the enzyme affinity to the substrate. This needs to be addressed by additional experiments.

Table 3 indicated that the stereoselectivity in DEX was stronger than in BNF. It maybe explained by the difference in K_m of R(-)-propafenone between DEX and BNF group and that the affinity of R (-)-PPF with CYP3A4 was higher than that with CYP1A, and that of S(+)-PPF with CYP3A4 was similar with CYP1A. Table 1 showed that CYP1A and CYP3A4 were significantly inducted by BNF and DEX, respectively, and this agreed with the well known documents. In BNF or DEX group, the υ_{max} was also significantly higher than that in the control group (about 1.5-fold), which indicated that CY P1A and CYP3A4 contributed to the metabolism of propafenone. This substantiated the methods used by Botsch *et al*[47]. In their study, CYP1A2 and CYP3A4 were identified involved in N-desalkylation using specific antibodies and inhibitors and stably expressed cytochrome P450. K_m in the control group was significantly lower than that in DEX or BNF group, which indicated that other enzyme with high affinity to substrate involved in metabolism of propafenone. CYP2D6 which had very low value of K_m might be one of such enzymes. Due to the lower value of both K_m and υ_{max} in control group, the Clint of propafenone enantiomer was not different from that in DEX or BNF group.

The competitive inhibition model (propafenone/nimodipine) suggested that propafenone and nimodipine were both substrates of the same coenzyme. Because nimodipine was as pecific substrate of CYP3A4[48,49], the results of inhibition experiment also proved that CYP3A4 contributed to propafenone metabolism. Drug interaction of enantiomer with specific inhibitor of P450 is an important tool in the search for detailed information on the stereoselective metabolism of xenobiotics[1]. Because fluoxetine impeded in vivo met abolism of R-methadone more than that of S-methadone, Eap *et al*[50] conclud ed that CYP2D6-mediated methadone metabolism exhibited stereoselectivity. The fact that the AUC ratio for the two enantiomers of reboxetine was minimally affected by ketoconazole treatment indicates similar affinities of the enantiomers for CYP3A4[51]. In the present study, the phenomenon that nimodipine in hibited S(+)-propafenone more than R(-)-isomer also implies that CYP3A4-mediated propafenone metabolism existed stereoselectivity.

Abstract

AIM: **To evaluate the relationship between the expression of lipopolysaccharides (LPS) binding protein (LBP) and CD14 mRNA and the severity of liver injury in alcohol-fed rats.**

METHODS: **Twenty Wistar rats were divided into two groups: ethanol-fed group (group E) and control group (group C). Group E was fed with ethanol (5-12 g·kg^{-1}·d^{-1}) and group C received d extrose instead of ethanol. Rats of the two groups were sacrificed at 4 weeks and 8 weeks. Levels of endotoxin and alanine transaminase (ALT) in blood were measured, and liver pathology was observed under light and electronic microscopy. Expressions of LBP and CD14 mRNA in liver tissues were determined by RT-PCR analysis.**

RESULTS: **Plasma endotoxin levels were increased more significantly in group E (129±21) ng·L^{-1} and (187±35) ng·L^{-1} at 4 and 8 wk than in control rats (48±9) ng·L^{-1} and (53±11) ng·L^{-1}, respectively (P<0.05). Mean values of plasma ALT levels were (1867±250) nkat·L^{-1} and (2450±367) nkat·L^{-1} in Group E. The values were increased more dramatically in ethanol-fed rats than in Group C after 4 and 8 weeks. In liver section from ethanol-fed rats, there were marked pathological changes (steatosis, cell infiltration and necrosis). In ethanol-fed rats, ethanol administration led to a significant increase in LBP and CD14 mRNA levels compared with the control group (P<0.05).**

CONCLUSION: **Ethanol administration led to a significant increase in endotoxin levels in serum and LBP and CD14 mRNA expressions in liver tissues. The increase of LBP and CD14 mRNA expression might wake the liver more sensitive to endotoxin and liver injury.**

INTRODUCTION

There is an accumulating evidence suggesting a role for endotoxin or lipopoly-sac charide(LPS) in the cause of alcohol-induced liver disease (ALD)[1-5]. Circulating LPS consists of several compounds including its specific carrier, the LPS binding protein (LBP)[6-8]. The LPS-LBP complex has high affinity to the LPS receptor CD14 located on monocytes/macrophages. CD14 is a 55-kD myeloid membrane glycoprotein, expressed mainly by monocytes and macrophages[7,9-11]. Attachment of LPS-LBP complex to the CD14 initiates a process lead in g to the release of cytokines and liver injury[13-17]. Although indirect evidence cited previously suggested an interaction among LPS, LBP and CD14 during ALD[18-20], a direct link is lacking. To evaluate the role of LBP and CD14 in ALD, the intragastric ethanol porat model for ALD was used to study the relationship between the expression of LBP and CD14 genes and the severity of liver injury in ALD rats.

MATERIALS AND METHODS

Animals and treatments

Twenty adult female Wistar rats weighing 180 and 220 g were fed ad libitum a liquid diet. They were divided into two groups (ten rats/group): et hanol liquid diet group (group E) and control liquid diet group (group C). Group E were fed ethanol, and group C received the same diet but with isocaloric amounts of dextrose instead of ethanol. In the ethanol-fed rats, an initial dose of 5 g·kg^{-1}·d^{-1}. The ethanol concentration within the diet was gradually increased up to 12 g·kg^{-1}·d^{-1} in 8 wk. All diets were kept fresh daily. They were anesthetized with sodium pentobarbital (30 mg kg^{-1} intraperitoneally) and sacrificed at different time points (4 wk and 8 wk). Blood was withdrawn from the tail vein and liver samples were frozen in liquid nitrogen and stored at -70℃ before use.

Blood endotoxin and ALT

For determination of endotoxin, blood was collected into pyrogen-free tubes containing heparin. Plasma was immediately separated at 4℃ by centrifugation at 200 g for 8 minutes and stored in pyrogen-free tubes at -70℃. Plasma en dotoxin levels were measured within a week using the Limulus Amebocyte Lysate assay. Levels of endotoxin in plasma from normal rats were below the limits of detection. Serum alanine transaminase (ALT) was measured by standard enzymatic procedures.

Liver pathology

Liver samples from different liver lobes were fixed with 100 ml·L^{-1} buffered formalin or 25 g·L^{-1} glutaraldehyde immediately. For optical microscopy, the tissue blocks were embedded in paraffin, and stained with hematoxylin and eosin (HE). For electronic microscopy, the tissue blocks were embedded in Epon 618 resin and ultrathin sections

were stained with urany acetate and lead citrate. A H-2000 transmission electron microscope was used.

RNA isolation and complementary DNA synthesis

Total RNA was isolated from rat liver tissue using the TRIZOL Reagent (Life Technologies, USA). The quality of RNA was controlled by the intactness of ribosomal RNA bands. A total of 0.5 mg of each intact total RNA samples was reverse-transcribed to complementary DNA (cDNA) using the reverse transcription polymerase chain reaction (RT-PCR) kit (Roche, USA). cDNA was stored at -70¡æ until polymerase chain reaction (PCR) analysis.

Determination of LBP and CD14 mRNA by RT-PCR

The PCR primers used were LBP: sense (5'-GAGGCCTGAGTCTCTCCATCT-3'), antisense (5'-TCTGAGATGGCAAAGTAGACC -3'); CD14: sense (5'-CTCAACCTAGAGCCGTTTCT-3'), anti-sense (5'-CAGGATTGTCAGACAGGTCT-3'); β-actin: sense (5'-ACCACAGCTGAGAGGGA-A ATCG-3'), antisense (5'-AGAGGTCTTTACGGATGTC-AACG-3'). The sizes of the amplified PCR products were 552 bp for LBP, 267 bp for CD14, and 281 bp for β-actin. The conditions for amplification were as follows: denaturation at 94℃ for 1 min, annealing at 58℃ for 2 min, and extension at 71℃ for 2 min for 28 cycles. The PCR products were electrophoresed in 20 g·L^{-1} agarose gels, and the gels were ethidium bromide stained and videophotographed on an ultraviolet transilluminator.

Statistical analysis

All results were expressed as $X \pm S_x$. Statistical difference between means were determined using two-way ANOVA or Student's *t* test. A *P* value of ≤0.05 was considered significant.

RESULTS

Blood endotoxin and ALT levels

Plasma endotoxin levels in control rats were (48±9) ng·L^{-1} and (53±11) ng·L^{-1} at 4 wk and 8 wk, respectively. Plasma endotoxin levels in ethanol -fed rats were increased significantly by ethanol to values of (129±21) ng·L^{-1} at 4 wk and (187±35) ng·L^{-1} at 8 wk. The Levels of endotoxin were about 2-and 3-fold higher than the values from control rats (Figure 1). Me an values for ALT in the control animals were (517±200) nkat·L^{-1} and (550±150) nkat·L^{-1} at 4 wk and 8 wk, respectively. Plasma ALT levels were increased dramatically to (1867±250) nkat·L^{-1} and (2450±367) nkat ·L^{-1} in ethanol-fed rats after 4 wk and 8 wk, respectively (Figure 2).

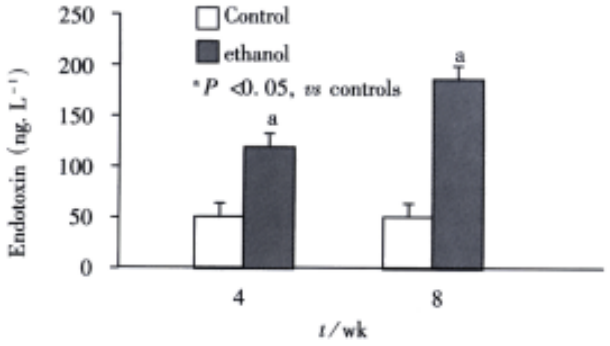

Figure 1 Chenges of endotoxin levels in two groups at different time points.

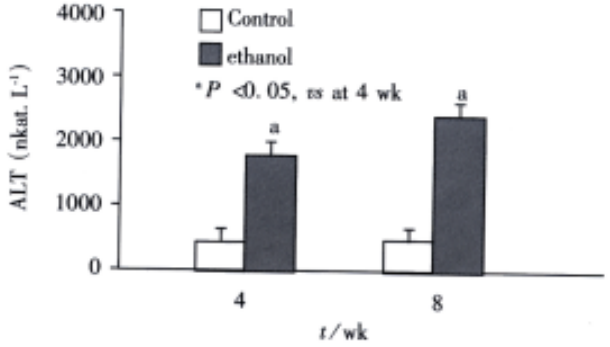

Figure 2 Changes of serum transaminase levels in two groups at different time points.

Pathological changes

Rats in the two groups, increased their body weight. Although the average weight gain was lower in ethanol-fed rats than the control rats, the differences between the two groups were not significant. Histopathological changes of the liver tissues were depicted in rep resentative photomicrographs in Figure 3A and 3B. None of the rats in the control group deve loped pathological changes in the liver at 4 wk or 8 wk. But, in liver section from rats after 4 wk on ethanol liquid diet, steatosis which was both microvesicular and macrovesi cular and few in flammation but accumulation of blood cells in the sinusoidal lining can be seen. In liver section from rats after 8 wk on ethanol diet, there was marked pathological changes (steatosis, cell infiltration and necrosis). Under electron microscopy, focal cytoplasmic degeneration and necrosis could be seen in hepatocytes of ethanol-fed rats(Figure 4A and B).

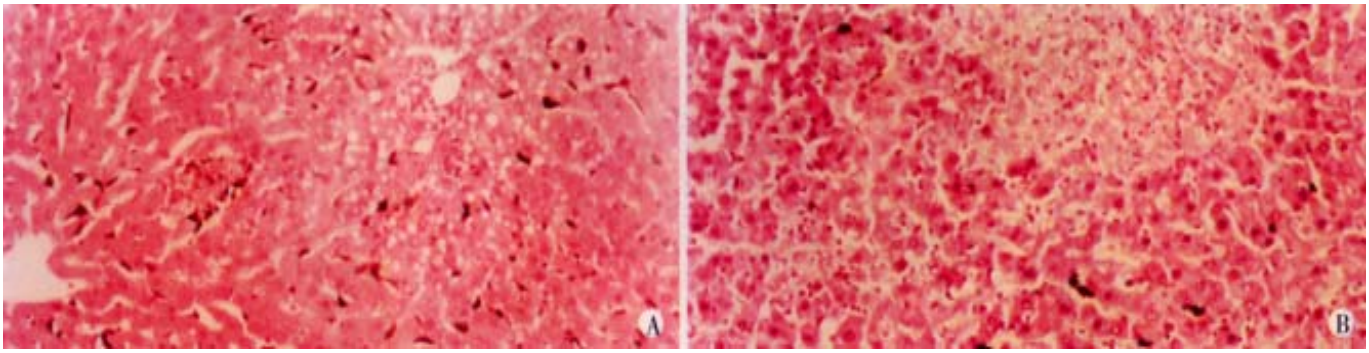

Figure 3 Liver section from rats (HE×200) A: 4 wk after ethanol liquid diet, steatosis and accumulation of blood cells in the sinusoidal lining; B: 8 wk after ethanol diet, steatosis, cell infiltration and necrosis.

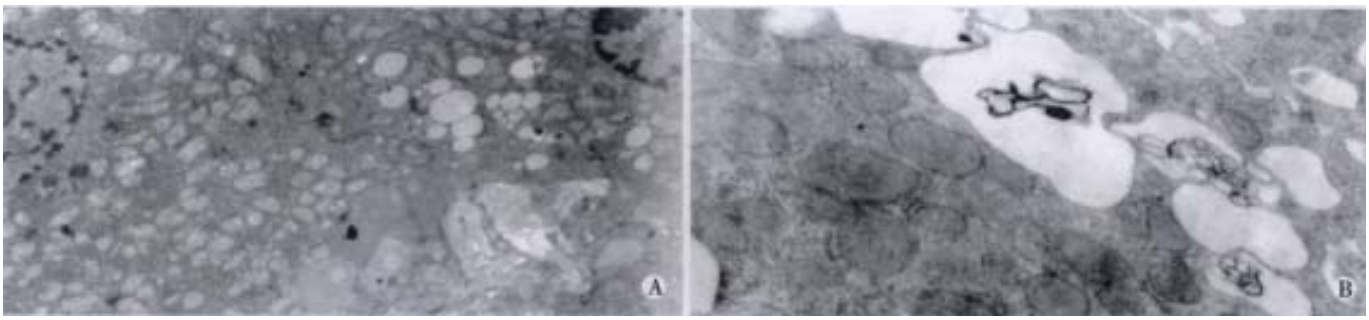

Figure 4 Ethanol-fed rats. A: Steatosis degeneration and necrosis in hepatocytes TEM×5000 B: Focal cytoplasmic degeneration and many myelin figures (TEM×20 000).

Expression of LBP and CD14 mRNA in the liver

The livers of rats in the individual group were examined for LBP and CD14 mRNA expression by RT-PCR (Figure 5). In the control rats, there was no significant difference in the levels of LBP and C D14 at 4 wk and 8 wk. Ethanol administration led to a significant increase in LBP and CD14 mRNA levels compared with the control group ($P<$ 0.05). The levels of LBP and CD14 mRNA in ethanol-fed rats were significantly higher in 8 wk than in 4 wk ($P<0.05$). The highest levels of CD14 mRNA were seen in ethanol-fed rats after 8 wk (Figure 6).

DISCUSSION

It is well documented that liver disease can result from the dose- and time-dependent consumption of alcohol[23-25] , female rats exhibit greater susceptibity to early alcohol-induced injury than males[26-28], Glycine prevents alcohol-induced liver injury by decreasing alcohol in the stomach[29]. However, mechanisms re main unclear. There appears to be increasing evidences that ethanol toxicity is associated with increased level of endotoxin in plasma[1,2,31]. Endotoxin or LPS is believed to exert many of its effects on the liver injury via interaction with LBP and CD14[11-18]. LBP and CD14 are clearly implicated in the mo lecular and cellular basis of the interaction between endotoxin and monocytes/ macrophages. LBP in serum can recognize and bind LPS to form LPS-LBP complexes and activate cells through the CD14 receptor on membrane of these cells, initiate a process leading to the release of cytokines (e.g. tumor necrosis factor a and interleukines), prostanoids, and other soluble mediators[24,31-34].The release of these mediators is considered to be an early key step in the pathogenesis of liver disease because they trigger inflammatory events in the liver and alter the parenchymal homeostasis, ultimately initiating liver injury[35-38].

A major goal of this study was to observe the expression of LBP and CD14 mRNA in ethanol-fed rats an d evaluate the in role in ALD. It was found that endotoxin levels in the plasma of rats treated with ethanol were increased significantly when compared with control animals and fatty liver, necrosis, and inflammation were developed in the ethanol treated rat. Control rats showed no liver pathology. In the present study, we found the severity of pathological changes in ethanol-fed rats were accompanied by an increase in intrahepatic LBP and CD14 mRNA levels and serum ALT levels. The increase in LBP and CD14 mRNA levels in the ethanol-fed rats is correlated with the degree of inflammation and necrosis in the livers of these animals. A similar pattern of changes was observed by Yin, *et al*[39]. They found that blood end otoxin and hepatic levels of CD14 messenger RNA and protein were increased by ethanol. Therefore, the sensitivity of rat liver to alcohol-induced injury is directly related to CD14 expression in the liver that lead to increasing the production of TNF-á, free radicals, interleukins and other cytokines[40-44]. The marked increase in CD14 expression suggests a new mechanism by which alcohol increases the LPS-mediated cytokine signaling by the liver macrophages, thus promoting the interaction between alcohol and endoto xins in the development of liver damage[45-50].

It has been well established that the role of LBP is to augment the response of monocytes/macrophages to low levels of endotoxin via interaction with CD14 protein and play an important role in alcoholic liver injury[36,]. The increase in intrahepatic CD14 m RNA expression may represent either an increase in the expression of CD14 within cells that reside in the liver or may represent recruitment of inflammatory cells(e.g., infiltrating mononuclear cells or macrophages) that have high expression of CD14 gene and CD14 protein[39,51-53]. In either case, an increase of C D14 may result in greater sensitivity to

endotoxin and NF-kB activation and production of pro-inflammatory cytokines which mediate liver injury[54-57].

In summary, our results show that ethanol administ ration led to a significant increase in LBP and CD14 mRNA levels in ethanol-fed rats when compared with the control rats. Increase of LBP and CD14 mRNA expression may result in greater sensitivity to endotoxin and liver injury. However, the mechanism of LBP increase and CD14 mRNA express ion is thus as yet unclear and needs further studies.

Abstract

AIM: **To clone the cDNA of UGT1A9 from a Chinese human liver and establish the Chinese hamster lung (CHL) cell line expressing human UGT1A9.**

METHODS: **cDNA of UGT1A9 was transcripted from mRNA by reverse transcriptase-ploymerase chain reaction, and was cloned into the pGEM-T vector which was amplified in the host bacteric *E. Coli* DH5α. The inserted fragment, verified by DNA sequencing, was subcloned into the *Hind* III/*Not* I site of a mammalian expression vector pREP9 to construct the plasmid termed pREP9-UGT1A9. CHL cells were transfected with the resultant recombinants, pREP9-UGT1A9, and selected by G418 (400 mg·L^{-1}) for one mo nth. The surviving clone (CHL-UGT1A9) was harvested as a pool and sub-cultured in medium containing G418 to obtain samples for UGT1A9 assays. The enzyme activity of CHL-UGT1A9 towards propranolol in S9 protein of the cell was determined by HPLC.**

RESULTS: **The sequence of the cDNA segment cloned, which was 1666 bp in length, was identical to that released by Gene Bank (GenBank accession number: AF056188) in coding region. The recombinant constructed, pREP9-UGT1A9, contains the entire coding region, along with 18 bp of the 5′ and 55 bp of the 3′ untranslated region of the UGT1A9 cDNA, respectively. The cell lines established expressed the pro tein of UGT1A9, and the enzyme activity towards propranolol in S9 protein was found to be 101±24 pmol·min^{-1}·mg^{-1} protein (n = 3), but was *Not* detectable in parental CHL cells.**

CONCLUSION: **The cDNA of UGT1A9 was successfully cloned from a Chinese human liver and transfected into CHL cells. The CHL-UGT1A9 cell lines established efficiently expressed the protein of UGT1A9 for the further enzyme study of drug glucuronidation.**

INTRODUCTION

Most organisms are exposed to a range of lipophilic compounds and converted them into excretable hydrophilic compounds. This metabolism of foreign compounds (xenobiotics) can be divided into two phases. For phase I metabolism, a reactive group is mostly introduced into the xenobiotic molecule. These reactions are mainly catalyzed by the cytochrome P450 monooxygenase system which consists of cytochrome P450s (CYPs) and cytochrome P450 reductase (CPR). For phase II metabolism, the reactive metabolite is conjugated to small, hydrophilic endogenous molecules such as glucuronic acid. The conjugation of this cofactor to xenobiotics is catalyzed by UDP-glucuronosyltransferases (UGTs). Since xenobiotic metabolizing enzymes have to catalyze the metabolism of structurally very divers e substrates, the various enzyme systems (e.g. CYPs and UGTs) comprise several isozymes that differ in their catalytic properties. The members of a given enzyme system have been grouped into families and subfamilies based on sequence homologies. In UGTs, two enzyme families termed UGT1 and UGT2 have been described.

The UGT1 locus is highly conserved between species[1]. UGT1A is a subfamily of UGT1 gene complex that is located at chromosome 2q37. UGT1A subfamily is encoded by tandem individual promoters and their first exons are linked by differential splicing to four common exons. As one of the isoforms, UGT1A9, is mainly expressed in liver. UGT1A9 can be induced by polycyclic aromatic hydrocarbons (PAHs), and therefore the drug glucuronidation catalyzed by UGT1A9 will be increased in cigarette smokers who inhale PAHs[2].

Human hepatic UDP-glucuronosyltransferases (UGT) is a family of microsomal enzymes that catalyze the glucuronidation of many important drugs, xenobiotics and endogenous compounds. Attempts to characterize the microsomal enzymes by conventional purification technique are often frustrated due to its instability. UGT isoenzyme expressed by cells is a useful tool for characterizing UGT's function. The cDNA cloning of UGTs from various sources (rabbit, rat, monkey, human beings, etc.) and their expression in cell lines were widely used for the gene characterization and function study of UGT isoforms[3-9]. In order to study tie drug metabolisms by UGTs, the cDNA encoding UGT1A9 was cloned from human liver and expressed in Chinese hamster lung (CHL) cell line in this study. The enzyme expressed was extracted and its activity was assayed with a substrate of propranolol which is a nonselective β-adrenergic blocking agent and can be used widely clinically[10].

MATERIALS AND METHODS

Isolation of RNA from human liver tissue

Human liver tissue was obtained from a surgical specimen of Chinese and stored at -80℃ until use. The total RNA was isolated with TRIzol reagent (Gibco Corp, USA)

UGT1A9 cDNA transcription

cDNA was transcr ipted from mRNA by revere transcriptase polymerase chain reaction (RT-PCR). Five μg of the total RNA and 2 μg of random primer (SANGON, Shanghai) in deionized water containing

DEPC (1 g·L^{-1}) were denatured at 65℃ for 15 min, then 4 μL 5 ×reverse transcriptase buffer, 3 μL10 mmol·L^{-1} dNTP, 1 μL M-MuLV reverse transcriptase (200 U) (Fermentas) and essential deionized water containing DEPC (1 g·L^{-1}) were added to have the total volume of 20 μL. The reaction was performed at 25℃ for 10 min, then 42℃ for 1 hour, and 70℃ for 10 min to inactivate the reverse transcriptase. The product was finally held at 4℃. Two μL of the reactant was mixed with 2 μL of 10 mmol·L^{-1} dNTP, 30 pmol of PCR primers and 3.5 U of DNA ploym erase (Perkin-Elmer Corp). The total volume of 100 μL was reached by adding deionized water. Two 26 meroligonucleotides as PCR primers were designed according to the DN A sequence of UGT1A9 (GenBank accession no. AF056188). The sense oligonucleo tides corresponding to base positions 1 to 26 was 5'-CTAAGCTTCAGTTCTCTGATGGCTTG-3 'with a restriction site of *Hind* III, and the anti-sense one, corresponding t o the bases position from 1641 to 1666, was 5'-GTTGGAAATG CCTAGGGAATGGTTC-3'. The poly merase chain reaction (PCR) was performed at 94℃ 2 min, then 94℃ 15 s, 60.1℃ 30 s and 72℃ 2 min for 31 cycles, and 72℃ for 10 min. The product was finally held at 4℃. An agrose gel electrophoresis was carried out with 10 μL of the PCR solution to check the 1666 bp DNA amplified.

Construction of recombinant pGEM-UGT1A9 and sequencing of UGT1A9

The PCR product of about 1.5 kb was isolated and ligated with pGEM-T (Promega) vector by T4 DNA ligase (Fermentas). *E. Coli* DH5α was transformed with the resulted recombinants pGEM-UGT1A9[11] and the positive bacteria colonies were screened by ampicillin resistant and blue-white screening with X-gal and IPTG. The cDNA of UGT1A9 subcloned in pGEM-T was sequenced on both strands by dideoxy chain-termination method marked with BigDye with primers of T7 and SP6 promoters and a specific primer of 5'-CAAGTATCGT GTTGTTCGC-3'. The termination products were resolved and detected using an automated DNA sequencer (Perkin-Elmer-ABI Prism 310, Foster City, CA).

Construction of the pREP9 based expression plasmid for UGT1A9

The *Hind* III-*Not* I fragment of the human UGT1A9 cDNA cleaved from the selected and amplified recombinant pGEM-UGT1A9 by *Hind* III and *Not* I digestion was purified by agarose electrophoresis and cloned directly into a unique *Hind* III-*Not* I site within the multicloning site of the mammalian expression vector pREP9 (Invitrogen, San Diego, CA) with T4 ligase.

Transfection and selection

Chinese hamster lung (CHL) cells were transfected with the resultant recombinants, pREP9-UGT1A9, using a calcium phosphate method[12]. After 24 h incubation at 37℃, the culture was rinsed and re-fed with fresh growth medium. Seventy-two h after transfection, the culture was split and then selected in the culture medium containing the neomycin analogue G418 (Gibco BRL, MD) (400 mg ·L^{-1}). The selective medium was changed every 3-4 d to remove dead cells and allow the growth of resistant colonies. After 1 mon, surviving clonies (termed C HL-UGT1A9) were harvested as a pool and propagated in medium containing G41 8.

Preparation of S9 of CHL-UGT1A9

CHL-UGT1A9 cells grown in the culture medium containing G418 (400 mg·L^{-1}) were rinsed with phosphate balanced solution (PBS), scraped and collected from the bottle with 11.5 g·L^{-1} KCl in aqua solution and t hen sonicated 3 s for 5 times with 5 s of interval break. The resulted homogenate was centrifuged at 9000×*g* for 20 min and the supernatant (S9) was transferred carefully to a clean tube for assay or storage under -70℃. The protein in S9 was determined by the same method that was used in our previous paper[13].

UGT assay

The UGT1A9 activities of S9 fraction were determined by the gl ucuronidation of propranolol. The assay was performed in a total volume of 100 μl containing final concentrations of 0.2 mmol·L^{-1} propranolol, 1 mmol · L^{-1} UDPGA, 1g ·L^{-1} Triton X-100, 50 μg of S9 protein in 50 mmol· L^{-1} Tris-HCl, 10 mmol·L^{-1} $MgCl_2$ buffer, pH 7.8 at 37℃. The mixtures were pre-incubated and the glucuronidation was started by the addition of UDPGA and stopped after 2 h by the addition of 100 μL of methanol. The mixtures were stirred thoroughly and centrifuged at 10 000 r·min^{-1} for 10 min. Un-reacted propranolol in the layer of reactant was d etermined by HPLC and the enzyme activity was calculated according to the amount of propranolol declined after incubation.

HPLC analysis of propranolol metabolized by S9 of CHL-UGT1A9

The concentration of propranolol metabolized by S9 of CHL-UGT1A9 was assayed by the HPLC procedure[13] with modification to the mobile phase. Twenty mL of the sample was applied to a reversed phase column (Shim-pack CLC-ODS15 cm×0.6 cm id, 10 μm particle size). Propranolol was monitored with a UV detector at 290 nm. The mobile phase is made up with ammonium acetate buffer (4.0 g ammonium acetate, 10 mL acetate acid and de-ionized water in 1 L)-methanol-acetonitrile (2:1:1), and to 500 mL mobile phase add 0.7 mL triethylamine as the elution modifier. The flow rate is 1.0 mL·min^{-1}.

RESULTS

Construction of recombinants

The recombinant of pGEM-UGT1A9 (Figure 1) was const ructed with the human UGT1A9 inserted into the cloning site of vector pGEM- T between the promoters of T7 and SP6. Selection and identification of the recombinant was carried out by *Hind* III / *Not* I endonuclease digestion and agarose elector phoresis (Figure 3). The cloned DNA segments in selected recombinants were sequenced completely. According to the results of DNA sequencing, the cDNA in a selected recombinant was identical to the DNA sequence of UGT1A9 reported by Ciotti-M *et al* (GenBank accession no. AF056188) in the reading frame. The restriction sites of *Hind* III and *Not* I in the recombinant were used for the subcloning of insertion fragment into an expression vector.

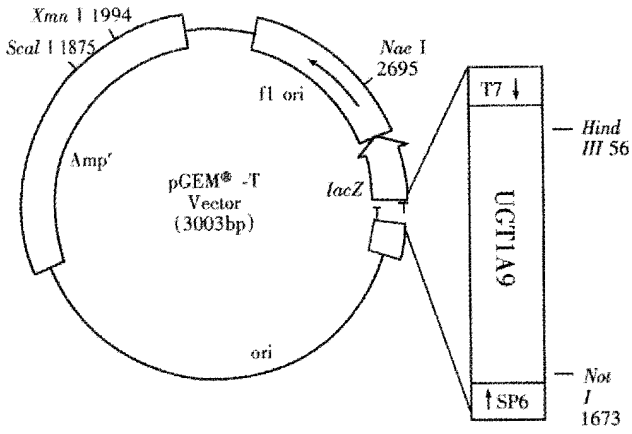

Figure 1 Scheme of pGEM-UGT1A9.

The *Hind* III/*Not* I fragment (1.5 kb) containing the complete *UGT*1A9 cDNA was subcloned into the *Hind* III/*Not* I site of mammalian expression vector pRE P9 (Figure 2). Selection and identification of the recombinants were carried out by *Hind* III/*Not* I endonuclease digestion and agarose electrophoresis (Figure 3). The re sulting plasmid was designated as pREP9-*UGT*1A9 which contained the entire coding region, along with 18 bp of the 5' and 55 bp of the 3' untranslated region of the *UGT*1A9 cDNA, respectively. In addition, the neo gene of the plasmid confers the G418 resistant phe*Not*ype to CHL cells for the selection of transfected cells.

Establishment of recombinant cell lines with UGT1A9 enzyme activity

CHL cells were transfected with pREP9-UGT1A9, and selected with G418 (400 mg·L^{-1}). The surviving clone was propagated and the cell line termed CHL-UGT1A9 was established. The preparation S9 was prepare d from CHL-UGT1A9 cells harvested for UGT1A9 activity assay by HPLC. Figure 4 shows t he typical elution of propranolol in incubation solution. The UGT enzyme activity towards propranolol in S9 protein was found to be 101±24 pmol·min^{-1}·mg^{-1} (n = 3), but was *Not* detectable in parental CHL cells.

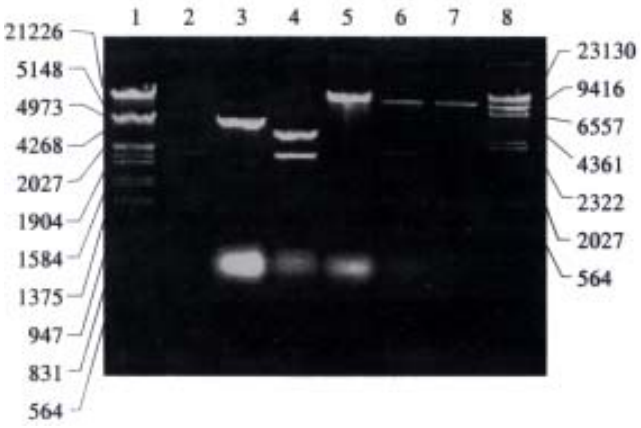

Figure 4 Chromatogram of propranolol after incubation with S9 prepared from CHL-UGT1A9 cell. A Shi m-pack CLC-ODS column (15 cm×0.6 cm i.d.) was used. The mobile phase was constituted with ammonium acetate buffer-methanol-acetonitrile (2:2:1) and 1.4mL·L^{-1} triethy lamine with the flow rate at 1.0 mL·min^{-1}. Propranolol was monitored at 290 nm. propranolol: t_R = 9.065 min.

DISCUSSION

UGTs are involved in the conjugation of UDP-glucuronic acid (UDPGA) to a variety of chemicals, drugs, and endogenous compounds. The elimination of hydrophobic chemicals from cells is aided by their conversion to water-soluble glucuronides. UGTs are closely relatied to the system of cytochrome P450 monooxygenase, and involved in the transportation of carrier and the passage of drugs through cell phospholipid bilayer. In most cases, the lipophilic compounds are converted by phase I metabolism to the substrate f or glucuronidation by obtaining an essential function (such as carbon, nitrogen, sulfur and oxygen), but in many cases xenobiotics and endogenous substances canalso be glucuronidated by UGTs without the phase I metabolism. The xenobiotic metabolizing cytochrome P450 monooxygenase system and the UGTs reside mainly in the endoplasmic reticulum. However, CYPs and the CPR are localized on the cytosolic side of the endoplasmic reticulum, which the UGTs are localized on its luminal side[14]. UGTs are latent enzymes, needing activation (in general by detergents) to express its maximal activity.

Numerous reports revealed that glucuronidation is a major pathway involved in the metabolism of drugs, exogeno us, and numerous endogenous compounds such as bile acids and steroid hormones. E ach UGTs family or subfamily has its own substrates but the substrate spectrum a re partly overlapped. UGT1 has substrates such as thyroid hormone[15], SN-38[16], bilirubin[17,18], opioids, bile acids, fatty acids, retinoids, c iprofibrate , furosemide, dilunisa, catechol estrogens, coumarins, flavonoids, anthraquinone s, EM-652 (an active antiestrogen)[19] and phenolic compounds[20]. UGT2 catalyzes substrates such as estrogens, androgens, morphine, AZT, and retinoicacid, epirubicin[16,21,22,23], etc. UGT1A9 is a member of UGT1A subfamily. The endogenous substrates for UGT1A9 are estrone, 4-hydroxyestrone, ethinylestradiol, retinoic acids, etc, and exogenous substrates include propofol, propranolol, paracetamol, S-naproxen, ketoprofen, ibuprofen, entacapone, some mutagenic arylamines, etc[2,24-26]. UGT1A9 was found to have regioselectivity on the glucuronidation of hydroxyl group of carbohydrate-containing drugs[27].

UGTs are expressed extensively in organs and tissues, and they may play a key role in the regulation of the level and action of steroid hormones in steroid target tissues. Organs that express UGTs include liver, kidney, gastrointestinal tract[28-29], olfactory[30], jejunum,

ileum[31], prostate[32-33], colon[34]. UGT1A9 is mainly expressed in liver, and also expressed in steroid targets[35] and colon[34].

UGTs are inducible enzymes. In most cases this induction is due to increased transcription of the corresponding genes but sometimes it is also due to an improved stability of proteins. The pattern of enzymes affected is dependent on the inducing agent. Usually, phenobarbital induces mainly enzymes within UGT2 family, and methylcholanthrene induces enzymes belonging to the UGT1 family[28]. Other chemicals that induce UGTs include aryl hydrocarbon receptor ligands or oltip raz[36], flavonoid chrysin[37], and t-butylhydroquinone and 2,3,7,8-tetrachloro dibenzo-p-dioxin[38], etc. UGT1A9 can be induced by polycyclic aromatic hydro carbons (PAHs)[39]. On the other hand, UGTs can also be inhibited, for example by uridine diphosphate[40], and N-glycosylation is involved in the functional properties of UDP-glucuronosyltransferase enzymes[41].

To clone and express UGTs in cells can help screen substrates that an isoenz yme is responsible. The prod uction of a UGT enzyme protein using transgenic cell lines is a practical manner to study its function[42-43]. We report here the cloning of UGT1A9 cDNA and establishment of a CHL cell line expressing UGT1A9 from a Chinese human liver. The full-length cDNA, UGT1A9, that encodes for a human UDP-glucuronosyltransf erase protein, was isolated from a Chinese human liver total RNA. To achieve high expression levels of UGT1A9, the UGT1A9 cDNA was cloned into the eukaryotic expressi on vector pREP9, which we had previously used in this laboratory for the express ion of human CYP450 1A1, 2B6, 3A4, etc in CHL cells[44-45]. The salient feature of this vector has an EBV origin of replication and nuclear antigen (EBNA-1) to allow high-copy episomal replication in mammal cell lines. The Rous sarcoma virus long terminal repeat (RSV LTR) early promoter controls the expression of the U GT1A9 cDNA. As *Not*ed under "Results", the isolated clone contains a 1592-nuc leoti de open reading frame flanked by 18 and 55 base pairs of 5' and 3' noncoding sequences, respectively. The DNA sequence in the reading code frame is identical to that reported (GenBank accession no. AF056188). The expression of a protein that catalyzed the glucuronidation of propranolol was proven in the Chinese hamster lung cells transfected with the recombinant plasmid pREP9-*UGT*1A9.

Conjugation with glucuronic acid is an important biotransformation pathway for a large number of clinically used drugs. In human intestinal, UGTs play an important role in the detoxification of xenobiotics compounds and, in some cases, may limit the bioavailability of therapeutic agents[20]. The deficient of a UGTs isoenzyme, may cause disease and clinical incident[46-47], the typical example was serious adverse events associated with chloramphenicol toxicity in neonates. Human UGTs are regulated in cases of healthy condition and exposure of harmful environmenta l carcinogens[48-50]. Moreover, UGT was identified as an antigenic tar get in a subgroup of liver- kidney microsomal auto-antibodies[51]. Hence, it is very necessary to undertake the study of functions and characteristics of UGTs. Over the last decade, some research papers were published about the usage of cloned and expressed human UGTs for the assessment of human drug conjugations and identification potential drug interactions[6-8]. However, the information gap still exists regarding the enzymatic aspects of UGTs to drugs elimination and its potenti al impact on therapy. More researches on the drug metabolism by UGTs are necessary for effective translation of scientific information into clinically applicable knowledge. As has been shown with the CYPs, coupling of basic and clinical science is needed to continually improve our understanding of the UGTs. Many factors are known to influence the activities of UGTs involved in drug metabolism, hence plasma clearances of glucuronidated drugs. Such factors include age (especially neonatal period), cigarette smoking, diet, certain disease states, drug therapy, ethnicity, genetics and hormonal effects. Knowledge of the profile, substrate specificities and regulation of human UGTs remains limited and cons equently it is still generally *Not* possible to predict the effects of specifice nvironmental and genetic factors on the metabolism and pharmacokinetics of individual glucuronidated drugs. Future investigations must define the substrate spec ificities of the various UGTs and investigate mechanisms by which the separate isozymes are regulated. Only then will it become possible to rationalize (and predict) the alterations in pharmacokinetics and response to glucuronidated drugs in specific patient groups.

Abstract

AIM: **To study the effect of copper transporting P-type ATPase in copper metabolism of hepatocyte and pathogenesis of Wilson disease (WD).**

METHODS: **WD copper trans porting properties in some organelles of the cultured hepatocytes were studied from WD patients and normal controls. These cultured hepatocytes were incubated in the media of copper 15 mg·L^{-1} only, copper 15 mg·L^{-1} with vincris tine (agonist of P-type ATPase) 0.5 mg·L^{-1}, or copper 15 mg·L^{-1} with vanadate (antagonist of P-type ATPase) 18.39 mg·L^{-1} separately. Microsome (endoplasmic reticulum and Golgi apparatus), lysosome, mitochondria, and cytosol were isolated by differential centrifugation. Copper contents in these organelles were measured with atomic absorption spectrophotometer, and the influence in copper transportion of these organelles by vanadate and vincristine were comparatively analyzed between WD patients and controls. WD copper transporting P-type ATPase was detected by SDS-PAGE in conj unction with Western blot in liver samples of WD patients and controls.**

RESULTS: **The specific WD proteins (Mr155 000 lanes) were expressed in human hepatocytes, including the control and WD patients. After incubation with medium containing copper for 2 h or 24 h, the microsome copper concentration in WD patients was obviously lower than that of controls, and the addtion of vanadate or vincristine would change the copper transporting of microsomes obviously. When incubated with vincri stine, levels of copper in microsome were significantly increased, while incubated with vanadate, the copper concentrations in microsome were obviously decreased. The results indicated that there were WD proteins, the copper transportion P-type ATPase in the microsome of hepatocytes. WD patients possessed abnormal copper transporting function of WD protein in the microsome, and the agonist might correct the defect of copper transportion by promoting the activity of copper transportion P-type ATPase.**

CONCLUSION: **Copper transportion P-type ATPase plays an important role in hepatocytic copper metabolism. Dysfunction of hepatocytic WD protein copper transportion might be one of the most important factors for WD.**

INTRODUCTION

Hepatolenticular degeneration (Wilson disease, WD) is an autosomal recessive disorder first described in detail by Wilson in 1912, which is characterized by excessive accumulation of copper in the liver, brain, cornea an d subsequently in kidneys and other organs. The disease has a world prevalence of 5-50 per million and a birth incidence from 17-29 per million[1-6]. In China, WD is one of the most common neurogenetic diseases. According to a survey reported in 1995, WD patients accouted for about 10.14% of the total 957 neurogenetic patients first visiting the Neurogenetic Clinic of the First Hospital affiliated to Sun Yat-Sen University of Medical Sciences, and ranked as the second on the list[7]. The principle of copper metabolic disturbance in WD includes low serum cerulopl a smin levels and low serum copper levels, as well as increased copper excretion in urine. By means of removing the excessive copper, the disease development will be inhibited, and if treatment started before the appearance of neurological manif estations, the latter can be prevented to a large extent[2-3,8]. However, why does the abnormal copper metabolism happen in WD? It has been shown that more than 95% of circulating plasma copper were bound to a blue-copper oxidize cerulopl smin (CP), while the levels of CP was magnificently reduced in the majority of WD patients[1,9]. But no relationship was found between the concentration of cellular copper and the CP gene expression or CP protein with rodent mod el of WD and patients' cultured fibroblasts[10-13]. Therefore, it was suggested that the genetic defect of copper transportation did not alter biosynthetic and secretary of CP. Seemingly, neither the theory of MT (metallothionein) nor lysoso me abnormality could well explain the pathogenesis of WD[14-16]. Recently more concerns were focused on ATP7B, the gene of WD, which was just found in 1993 and has been mapped to chromosome 13q14.3 by three different genetic techniques[17-19]. Many researchers are trying to search for clues to the copper metabolic abnormality from the mutations of this gene, and the latter was predicted to en cod e a putative protein product, the WD copper-transporting P-type ATPase (WD protein), which has 1411 amino acids and a calculated molecular mass of about 159ku[20-28]. But up to now, the cellular localization of WD protein apparently has not yet been documented. There were reports that canalicular membranes, mitochondri a, microsome, or Golgi apparatus had WD

proteins[29-34]. However, all these researches were carried out in animal livers or in abnormal/immortal cell lines, which h ad much more different cell structures and biochemical metabolisms from human beings. We now set up a cultured hepatocyte model for studying WD copper transporting properties in such suborganelles as microsomes, lysosomes, cytosol, and mitochondria of the cultured hepatocytes from WD patients and normal controls under different incubative conditions with copper, ATP or the adjusting agents of WD proteins, and analyzed the cellular localization of WD proteins in hepatocytes.

MATERIALS AND METHODS

Subjects

Five (male 3, female 2) patients, aged 13-31 years, were diagnosed as having Wilson disease patients according to clinical symptoms, signs and copper biochemical laboratory assay by our Neurohereditary Clinic from 1998 to 1999. They had lower levels of serum ceruloplasmin and high levels of urinary copper. They all had liver cirrhosis accompanied by splenomegaly, and intended to receive splenectomy and liver biopsy. Five (male 4, female 1) controls, aged 28-49 years, were patients with hepatolith, cholith, or liver a ngioma, or healthy liver grantors, with normal neurological examinations and nor mal copper chemical tests, and were to receive hepatolobectomy. Immediately after operation, liver samples were rinsed and preserved in 4℃ F12/DMEM culture medium.

Hepatocyte culture and protein blotting

Hepatocytes were separated by 0. 5 $g \cdot L^{-1}$ type IV collagenase digested and cultured according to the methods introd uced by literatures[35-40]. The isolated hepatocytes were seeded and cultured in flasks pre-coated with rat tail collagen at 37℃ 50 $mM \cdot L^{-1}$ CO_2 with F12/DMEM supplemented with 200 $mM \cdot L^{-1}$ fetal bovine serum, 10 $mmol \cdot L^{-1}$ nicotinamide, 5 $mg \cdot L^{-1}$ a mphotericin B, 0.5 $mg \cdot L^{-1}$ glucagon,10 ìg·L^{-1} EGF(epidermal growth factor), 10 $\mu g \cdot L^{-1}$ insulin-transferrin-sodium selenite media supplement, and other growth factors. The cultured cells were observed and photographed and the media were partly changed every day. When they grew to contact with each other, discard the culture media, and cultured the hepatocytes further for 2 or 24 h in all WD patients and controls with culture media containing: copper 15 $mg \cdot L^{-1}$ only; copper 15 $mg \cdot L^{-1}$, ATP 30 $mmol \cdot L^{-1}$ and vanadate 18.39 $mg \cdot L^{-1}$; copper 15 $mg \cdot L^{-1}$, ATP 30 $mmol \cdot L^{-1}$ and vincristihe 0.5 $mg \cdot L^{-1}$; and copper 15 $mg \cdot L^{-1}$ and ATP 30 $mmol \cdot L^{-1}$, respectively. After reincubation, cells were rinsed with D-Hanks solution atroom temperature, harvested by rubber policeman after adding 1 mL of 0.05 $mol \cdot L^{-1}$ Tris-HCl (2.5 $g \cdot L^{-1}$ Nonidet P-40, 0.5 $mmol \cdot L^{-1}$ PMSF, 0.1 $g \cdot L^{-1}$ aprotinin, 1 $mg \cdot L^{-1}$ leupeptin, 1 $\mu mol \cdot L^{-1}$ pepstantin, pH8.6), dissolved for 15 min at 4℃ and disintegrated under ultrasonic (80 W×90 s), and then centrifuged at 16 000× *g* for 20 min. Finally, the protein rich supernatants were transferred to separate vials for testing or preservation at-700℃.

Fifty μg proteins of the supernatants were first separated by SDS-PAGE on 200 volts in 60 $g \cdot L^{-1}$ gels for 45 min, followed by 90 min of electrophoretic transfer to nitrocellulose membranes on 120 volts[31,41] according to the instructions of the Bio-Lab kit (New England Bio-Lab Co.). Transferred membranes were incubated with the primary antibodies and goat anti -rabbit antibodies with HRP (Bio-Lab Co.), respectively. After rinsed with the buffer thoroughly, the membranes were reacted with enhanced chemiluminescence. The primary antibody was a rabbit anti-human WD protein antibody (anti-WD), a gift from Dr. Gitlin and Dr. Lutsenko. The band number, density and molecular weight of specific bands were observed and analyzed by Bio-Rad Gel 2000 Imaging System.

Isolation of organelles

Total homogenates of cytosol, lysosome, microsome and mitochondria were isolated at 4℃ by differential centrifugation (8 000×g, 10 min; 9 000×g, 10 min; 30 000×g, 15 min; 108 000×g, 60 min) using super-high speed centrifuge (Beckman L8-55M, USA). Degree of contamination of cytosol, lysosome and microsome were estimated by measuring the lactate dehydrogenase a ctivities, acid-phosphatase activity and glucose-6-phosphatase activityies, respectively.

Content of copper and protein assay

All samples were assayed for protein concentration by the methods described by Bradford[4], using the bovine serum albumin as a standard. Copper contents were measured with atomic absorption spectrophot ometer, and expressed as copper/protein ratios (Cu/Pr):

$$\text{Cu/Pr } (\mu g \cdot g^{-1}) = \frac{\text{Copper contents } (\mu g \cdot L^{-1})}{\text{Protein contents } (g \cdot L^{-1})}$$

Statistical analysis

Results were given as the mean with the corresponding standard deviation ($\bar{x} \pm s$). Statistical analysis was performed with SPSS/8.0. F test and Student's t test were used to determine the differences between the means of different groups. Statistical significance was considered at the level of $P<0.05$.

RESULTS

Hepatocyte morphology

After the first 24 h culture, viable hepatocytes changed their shape from spherical to flat on the substrate and displayed one or two long cytoplasmic projections onto the substrate, and a ppeared three to six sided in shape. After 4 d, a widespread and a monolayer of hepatocytes could be found. After 7 d, they became smaller and with more granules. After 21 d culture, hepatocytes began to fall from the flasks and died.

Protein blotting

Western blotting analysis of WD protein separated from cultured human hepatocytes two main lanes with molecular mass of M_r 155 000, 90 000 and 80 000 were found in normal human and WD patient hepatocytes, but non could be seen in the blood vessel endotheliocytes of human liver (Figure 1).

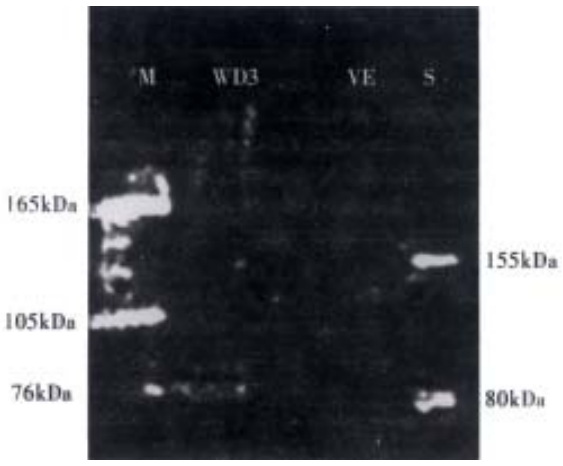

Figure 1 Western blotting analysis of WD protein separated from cultured human hepatocytes. M: Protein molecular mass markers; WD3: The hepatocytes of one WD patient; VE: Blood vessel endotheliocyte; S: Normal human hepatocytes.

Copper transportion of hepatocytes

Normal subjects After 2 h incubation with 15 mg·L^{-1} copper, the copper levels of all organelles increased significantly. When adding 30 mmol ·L^{-1} ATP to the culture media, there were different changes of copper concentrati ons in different organelles. Lysosome and microsome copper contents were much higher with ATP than without ATP, and the cytoplasmic copper level with ATP was lower than that of without ATP, and the differences between each group were not significant by Student's *t* test. The copper level of mitochondria showed no significant change. After 24 h copper incubation, the copper contents of microsome, mitochondria and cytoplasm with ATP became much lower than that without ATP, while the copper contents in lysosome showed no changes (Table 1).

Table 1 Concentrations of copper in organelles of nor mal hepatocytes after 2 h or 24 h culture ($\bar{x}\pm s$, μg·g^{-1})

t (culture) /h	ATP / (30 mmol·L^{-1})	Microsomes	Lysosomes	Cytoplasm	Mitochondria
0		74±13	70±10	526±63	85±11

WD patients

Copper contents of cytoplasm after incubation with medium containing 15 mg·L^{-1} copper for 2 h, cytoplasmic copper concentration in WD patients became obviously higher than that of controls under all incubative conditions (*P*<0.05 *vs* control). When co-incubated with 0.5 mg·L^{-1} vincristine, there was no significant change of copper concentration in WD patients, while it decreased in the controls; when adding 18.39 mg·L^{-1} vanadate, there was no significant change of copper concentration in WD patients, while it inicreased in the controls (*P*<0.05). After 24 h culture with copper, cytoplasm copper levels of WD patients were higher than the controls (*P*<0. 01 *vs* control). The adding of 0.5 mg·L^{-1} vincristine decreased its cop per level (*P*<0.01 *vs* no vincrinstine), but there was no difference between the WD group and the controls. When adding 18.39 mg·L^{-1} vanadate, the copper level in WD group increased (*P*<0.05 *vs* no vanadate), while that of the controls did not change, and that of WD group was higher than the controls (*P*<0.01 *vs* control, Figure 2).

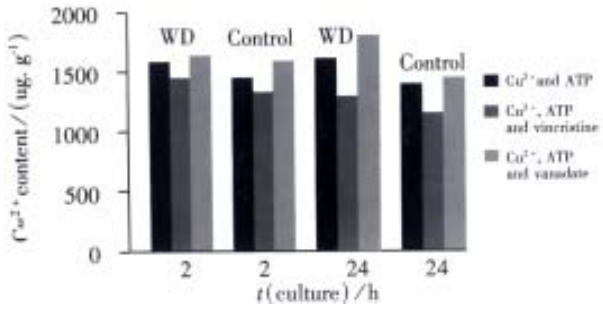

Figure 2 Cu^{2+} levels in hepatic cytosol at different culturing conditions.

Copper contents of microsome Copper concentrations of microsome in WD patients were obviously lower than that of controls after incubation for 2 h under each incubative condition (*P*<0.05 *vs* control). After incubation of copper and 0.5mg·L^{-1} vincristine, copper levels in the microsome were significantly increased (*P*<0.05 *vs* no vincrinstine). And after incubation with copper and 18.39 mg·L^{-1} vanadate, the copper concentrations of microsome in WD patients were obviously decreased (*P*<0.05 *vs* 2 h of no vanadate).

After 24 h incubation with 15 mg·L^{-1} copper and 30 mmol·L^{-1} ATP, copper contents in WD group were lower than the controls (*P* <0.05 *vs* control). When adding 0.5 mg·L^{-1} vincristine, there was no change in the WD group, and when adding 18.39 mg·L^{-1} vanadate, the copper contents increased (*P*<0.05 *vs* 24 h of no vanadate, Figure 3).

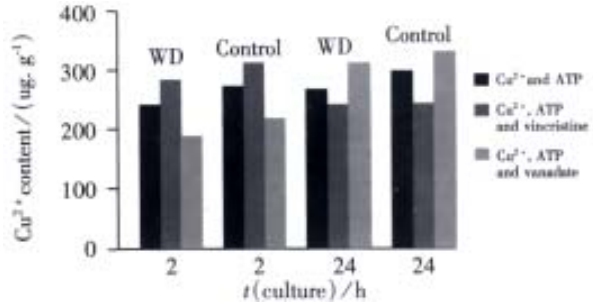

Figure 3 Cu^{2+} levels in hepatic microsome under different culturing conditions

Copper contents of lysosome After incubation with medium containing 15mg·L^{-1} copper and ATP for 2 h, lysosomal copper concentrations in WD patients were lower than that of controls (*P*< 0.05 *vs* control), and when adding vanadate, there was significant decrease of copper concentration in the controls (*P*<0.05 *vs* no vanadate). With incubation up to 24 h, the WD patients' lysosome copper concentrations rose to the same level as the controls. When co-incubated with vincristine or vanadate, there was no change in the copper concentration of WD patients (Figure 4) .

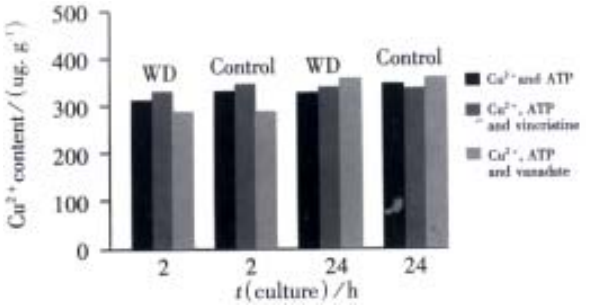

Figure 4 Cu^{2+} levels in hepatic lysosome under different culturing conditions.

Copper contents of mitochondria The copper content in mitochond ria was significantly lower than the controls when cultured 2 h or 24 h with 15 mg ·L^{-1} copper and 30 mmol·L^{-1} ATP. But when adding 0.5 mg·L^{-1} vincristine or 18.39 mg·L^{-1} vanadate, there was no significant change in the copper level of mi tochondria (Figure 5).

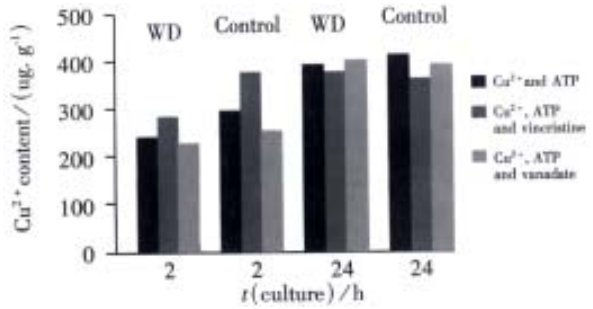

Figure 5 Cu^{2+} levels in hepatic mitochondria under different culturing conditions.

DISCUSSION

Copper is a trace element required by most organisms and is indispensable as a cofactor in a number of proteins, including cytochrome-c-oxidase, superoxide dismutase (SOD), dopamine o-hydroxylase, lysyl oxidase and ceruloplasmin. Both of lack and accumulation of copper may cause diseases[13,20]. One of the most important copper pumps in human body is considered as the copper transporting P-type ATPase, which is considered to play an essential role in cellular copper homeostasis[17-19,42]. In order to study the copper metabolism disorder of WD, Chan *et al* [43] ha d first applied the technique of skin fibroblast culture *in vitro* 20 years a go. Because it is easy to get the skin specimen, skin fibroblasts can be cultured and pass generations successfully, and its culture *in vitro* can be controlled and repeated steadily, this model had been widely used by researchers from all over the world[4,12,44]. In China, Liang and Chen *et al*[4,44] improved the fib roblast culturing model to study the copper metabolism of WD in 1992, and found that incubation with high contents of copper could promote the expression of hereditary abnormalities of copper metabolism in cultured skin fibroblasts of WD patients. They had studied the characteristics of copper uptake and excretion, analyzed the copper transporting manner of suborganelles, probed the actions of zinc on WD, and investigated the possible mechanisms of vanadate and vincristine to regulate the copper metabolism of WD cultured cells. However, as the copper metabolism disorders originated from the liver, and the main lesions were also localized in the liver, the study on the hepatocytes of WD patients can more directly reveal the possible mechanism of abnormal copper metabolism in WD.

Hepatocyte is one of the high-differentiated cells in human body[36-39,45]. Under normal biological conditions, hepatocytes of adult human body remain still and do not divide until stimulated by lesion, inflammation or other pathological factors. Cultured with common medium *in vitro*, hepatocytes can not multiply and divide. The rough endoplasmic recticulums disappear rapidly, cell appearance changed early, and its biochemical functions attenuated simultaneously. The cultured hepatocytes lost their tissue specific functions within 3 d to 5 d[35,36]. So it is important to improve the skills of hepatocyte separation and culture.

We had used thin biopsy liver pieces to culture rat hepatocytes by the method for skin fibroblasts culture[43,45,46]. In the first 3 days culture, there were round cells removing from the liver slices, and the cell number increased gradually. One week later, most of the cells grew to triangles or multipleangles in shape which were hepatocytes, and less cells showed shuttle-shaped, which were fibroblasts or other fibroblastoid. Up to 2-3 weeks, cells spread over the bottom of the flasks, but most of them were fusiform shaped and were fibroblastoid, and the hepatocytes were very rare then. This indicated that hepatocytes needed much higher culture condition than fibroblasts. When we cultured hepatocytes from embryo rats, the hepatocytes could be divided rapidly even if common culture media PMP L 1640 were used. And when various growth factors and mineral metals were added into the media, the embryo hepatocytes could maintain strong capacities of albumin synthesis and secretion up to one month or more. Most researchers agreed that embryo hepatocytes remained immature, so they could divide and be cultured easily[36].

WD patients we studied in this series, all had liver cirrhosis, and their hepatocytes were more difficult to culture. We mimicked the normal natural growth conditions of human liver and supplemented the culture media with fetal bovine serum, nicotinamide, amphotericin B, glucagon, EGF (epidermal growth factor), insulin-transferrin-sodium selenite media supplement. The hepatocytes in WD were then growing as the normal ones except that fewer fibroblasts speckled. We could erase the fibroblasts easily with rubble policeman under microscope or only by prolonging the collagenase digesting period to 60-90 minutes.

We observed that copper uptake by normal hepatocytes, and found that the copper contents in microsomes (endoplasmic reticulum and Go lgi apparatus) and lysosome all increased significantly, while the copper contents in cytoplasm decreased markedly after 2 h of culture with 15 $mg \cdot L^{-1}$ copper and 30 $mmol \cdot L^{-1}$ ATP in the culture media. This indicated that there existed ATP de pendent copper uptake in these organelles of hepatocyte. We could not determine w here the concrete copper absorption took place at that time, because there is a variety of types of ATP-dependent copper transporters in hepatocytes, such as A TP-dependent glutathion coupling copper transporter, canalicular CMOT transporter and copper transporting P-type ATPase. When the culture medium was absent of magnesium, which was a necessary catalyzer to ATPase for the hydrolysis of its terminal phosphate, the copper accumulation in these organelles could not happen. And more importantly, after adding sodium vanadate, the specific antagonist sensitive to copper transporting P-type ATPase, the copper transporting in micro some and lysosome were inhibited markedly (Figures 3, 4). This proved that the A T P-dependent copper transporter was right the copper transporting P-type ATPase and suggested that it is located in both of the above two organelles, and our immunologic al blotting results with specific antibody against WD protein also proved that W D proteins were existing in hepatocytes. These were identical to the results of that of Bingham[48,49], Dijkstra[29], Shah[24] *et al* .

Liver plasma membranes in canalicular and basolateral fractions from Wistar rats were fractionated on discontinuous sucrose gradients by Dijkstra *et al*[29] and Usta *et al*[32], and it was found that there was ATP-stimulated uptake of radiolabeled copper in canalicular membranes, which was consistent with Adachi *et al*' studies[47] about the biochemistry of copper transporting in LEC rat, an animal model of Wilson disease. If this copper transporter functioned abnormally, it would lead to copper acc umulation in the liver as a result of deficient biliary copper excretion. This w ell explained the mechanism of copper excretion disorder of WD, but it could not answer the question of the deficiency of ceruloplasmin (CP), since CP is formed in endoplasmic reticulum where copper was transported to apo-ceruloplasmin. The research of Bingham *et al* (1995)[49] on rat hepatocytes indicated that copper transporting P-type ATPase might exist in endoplasmic reticulum. Furthermore, Shah[24] and other researchers did immunohistochemical studies using antibodies against the cation combining sites or other function domains and also found the specific reaction in endoplasmic reticulum in the transferred cell strains[33,41]. These results all suggested that copper transporting P-type ATPase should be in endoplasmic reticulum.

Several groups had provided evidence which suggested that the copper transporting ATPase transport copper with the oxidation equivalence (I), that is Cu^+ ion. One key evidence is the six conserved metal binding motifs Gly-Met-X-Cys-X-Ser-Cys in the amino terminal of each copper transporting P-type ATPase, where the cysteine residues only bind copper as Cu^+. Other reports an d our study did not support this hypothesis. It was shown that Cu^+ transportion in microsomes was not dependent on ATP, but our data indicated that the copper accumulation in microsomes was ATP-dependent. Moreover, when we detected the concent rations of Cu^+ in each organelles, we did not find any significant changes under different incubation conditions (data not shown), so all the copper contents provided in this paper were the results of Cu^{2+} detected by atomic absorption spectrophotometer. Finally, many papers have shown that the most common gene mutation of WD patients in Western Europe and Northern America is the His1069Glu in the conserved sequence Ser-Glu-His- Pro-Leu of copper transporting P-type ATPase[5,21,32], and we know histidyl residues bind copper as Cu^{2+}[48,49]. All this argued that copper transporting P-type AT Pase might transport copper as Cu^{2+}.

Microsome consists of endoplasmic reticulum and Golgi apparatus. The former mainly functions to synthesize proteins (including ceruloplasmin), and the latter works to process these proteins and make them glycosylated, while the function of lysosome is to digest the endogenous and exogenous fractions of cells, and to join the renewal of cells and tissues of the hepatocytes[48]. Harada *et al*[50] used colchicine to destroy microtubules in lysosome vesicles, and found that the secretion of bile copper was inhibited, therefore indicated that lysosome could work to transport cellular copper. We found that the copper levels in hepat ocyte lysosome of controls could be regulated by the antagonist of copper transporting P-type ATPase (vanadate) after incubation for 2 h, the agonist (vincristine) was not found in stimulating lysosome's copper transportion, and when incubated longer, vanadate did not show the inhibition to copper uptake. It remains unclear whether the copper transportion of lysosome is reached by WD proteins. Yin *et al*[46] regarded that copper transporting P-type ATPase was in both microsome and lysosomes of the cultured fibroblasts of WD patients. Our data showed that lysosome had copper transporting function too, but it did not belong to WD protein, because of its absence of the permanent inhibition by vanadate, the specific inhibitant to WD protein. This disagreement suggested that more evidences are needed to solve the problem.

In cultured hepatocytes of WD patients, the microsome copper contents after being co-cultured with copper and vanadate were significantly lower than that co-cultured with copper only, while being co-cultu re d with copper and vinscrtine, the copper contents in microsome and cytoplasm were significantly higher than that with copper only. This suggested that the agonists and antagonist of P-type ATPase affected the uptake and excretion of copper in microsome by inhibiting or increasing the activation of P-type ATPase. After 24 h of culture with copper and vanadate, the copper contents of microsome and cytoplasm were significantly higher than that with copper only, which indicated that the agonist and antagonist affected the secretion of copper significantly, which further suggested that there was copper transporting P-type ATPase in the microsome of human hepatocytes. Our data showed the significantly different copper levels of microsomes in WD patients' hepatocytes after co-cultured with copper as compared with the controls, which indicated that there were abnormalities of copper transportion in microsomes, that is the disturbance of WD proteins in view of the above results.

WD is one of the rare neurogenetic diseases that can be curable. Because of the frequent side effects (the most often applied medicine), there are about 10 to 30 percent of WD patients who could not tolerate the long-term use of the drug[2,4,51-53]. Much more adverse effects had also been found on the use of DMS, trientene or all other therapeutic drugs. These made it necessary to find new safe and effective alternation to D-Penicillamine to treat WD. When we added agonist (vincristine) to the culture media, the copper levels microsomes in WD patients' hepatocytes in c reased significantly, and showed no difference with the controls. This indicated that the function of the copper transporting ATPase in WD patients' hepatocytes could be promoted by vincristine's activation, and recover to the normal levels. Yin *et al*[46] also found that the agonist of copper transporting AT Pase could modify the impairment of copper excretion from the microsome of WD cultured cells . All the data suggested that it might be a new clinical approach for WD to useagonists of copper transporting ATPase by regulating this enzyme's activity of WD patients. Furthermore, cultured hepatocyte model using high content copper for copper transportion will provide a useful cytological tool for probing the mechanism and therapeutic methods of WD.

In conclusion, this paper used cultured hepatocyte model for WD copper studies, and the data indicated that there is copper transporting P-type ATPase in the microsomes; WD patients had abnormal functions of copper transportion P-type ATPase in the microsomes, and the agonist might correct the defect of copper transporting by increasing P-type ATPase activity.

ACKNOWLEDGEMENT Anti-WD antibodies were generous gifts from Dr. JD Gitlin and Dr. S Lutsenko. We thank Prof. Xue-Fen Lu, Director of Guangdong Provincial Neurological Division of the Chinese Medical Association and Guangzhou Medial College, for her valuable discussion and comments.

Abstract

AIM: **To study the distribution of nitric oxide synthase (NOS) in rat stomach myenteric plexus.**

METHODS: **The distribution of NOS in gastric wall was studied in quantity and location by the NADPH-diaphorase (NDP) histochemical staining method and whole mount preparation technique.**

RESULTS: **NOS was distributed in whole stomach wall, most of them were located in myenteric plexus, and distributed in submucosal plexus. The shape of NOS positive neurons was basically similar, most of them being round and oval in shape. But their density, size and staining intensity varied greatly in the different parts of stomach. The density was 62±38 cells/mm² (antrum), 43±32 cells/mm² (body), and 32±28 cells/mm² (fundus), respectively. The size and staining intensity of NOS positive neurons in the fundus were basically the same, the neurons being large and dark stained, while they were obviously different in antrum. In the body of the stomach, the NOS positive neurons were in an intermediate state from funds to antrum. There were some beadlike structures which were strung together by NOS positive varicosities in nerve fibers, some were closely adherent to the outer walls of blood vessels.**

CONCLUSION: **Nitric oxide might be involved in the modulation of motility, secretion and blood circulation of the stomach, and the significant difference of NOS positive neurons in different parts of stomach myenteric plexus may be related to the physiologic function of stomach.**

INTRODUCTION

Recent pharmacological and physiological studies indicated that nitric oxide (NO) is a neurotransmitter in the non-adrenergic non-cholinergic (NANC) inhibitory nerves in the mammalian gastrointestinal tract[1-15]. It may play a very important role in the neuronal regulation of gut. Previous studies have revealed the distribution, morphological features and projections of nitric oxide synthase (NOS) activity neurons and fibers in the enteric nervous system in intestine[16-25]. However, there have been much fewer studies of NOS activity in stomach wall since it is very difficult to make whole mount preparations of stomach. If NO is a transmitter of NANC inhibitory nerves, it should be present in neurons innervating the muscularis in stomach. What are the regularity of distribution of NOS in rat gastric wall, and the pat tern of innervation of these neurons? To answer these questions, we examined the distribution and morphological feature of NOS positive neurons in the stomach wall using improved whole mount preparation technique.

MATERIALS AND METHODS

Whole mount preparations production

Adult male or female Wistar strain rats (210 g-250 g in body weight) were provided by the Center of Laboratory Animals of the Third Military Medical University. The rats were fasted overnight prior to the experiment, and anaesthetized with sodium pentobarbitone (50 mg·kg^{-1}, ip). Stomach was rinsed with 0.01 mol·L^{-1} phosphate buffered saline (PBS, pH 7.4) and poured into gastric cavity with 40 g.L^{-1} paraformaldehyde (until 3-4 times of normal stomach volume), put in the same fixed liquid for 4 h-6 h (4℃), and soaked in 300 g·L^{-1} sucrose liquid for 24 h (4℃). Thereafter, wash away with PBS, wrap stomach up with bandage, rub gently for 2-3 min, stuff tightly with cotton, then demarcate trace along greater curvature of stomach toward lesser curvature with an extremely thin piece of bamboo, and strip slightly. Finally, trim the longitudinal muscular layer and dip in PBS for staining.

NADPH-diaphorase staining

Whole mount preparations were rinsed with PBS three times, and incubated in a solution of 0.1 mol·L^{-1} PBS (pH 8.0) containing 0.5 g·L^{-1} β-NADPH, 0.2 g·L^{-1} nitroblue tetrazolium (NBT), 2.0 g·L^{-1} L-malic acid, 3g·L^{-1} Triton X-100, hatched at 37℃ for 45 min, and rinsed three times with PBS, then mounted on glass slide, paved nicely (drug ratio less than 1:1.1), dehydrated through graded alcohol, cleared in xylene, and coverslipped with DPX. Incubative solution without adding β-NADPH served as negative control.

Statistical analysis

All results were expressed as the x±s, data were analyzed by Student *t* test. *P* values <0.05 were considered statistically significant.

RESULTS

Our study showed that NOS was widely distributed in rat stomach wall, most of them being localized in myenteric plexus, and distributed in submucosal plexus, gastric mucosal epithelium and gastric gland as well. In the myenteric plexus, NOS positive neurons were clearly identified by their sharply defined dark blue cytoplasmic stain with almost no background, the nuclei appeared as colorless "holes" (Figure 1). The shape of neurons was basically similar, most of them varied from round, oval to fusiform, while their density, size and staining intensity varied greatly in the different parts of stomach.

The density was 62±38 cells/mm^2, 43±32 cells/mm^2 and 32±28 cells/mm^2, respectively in antrum, body and fundus. Two subtypes of NOS positive neurons could be distinguished on the basis of size, staining intensity and progress in number. In fundus, about 75% neurons were large, dark stained and had some long progresses (Figure 2). Neurons of the second subtype were slightly smaller, with some short processes and mainly located in antrum (approximately 65%) (Figure 3). In the body of stomach, the NOS positive neurons were in an intermediate state from fundus to antrum. Moreover, some beadlike structure was strung together by NOS positive varicosities in nerve fibers, and some were colsely adherent to the outer walls of blood vessels (Figure 4).

DISCUSSION

Since the early 1960s, it has been known that discrete populations of nerve cells can be labeled by an obscure, but simple, histochemical reaction involving the reduction of tetrazolium salts to form dark formazan products. This reaction is catalyzed by an unidentified enzyme contained in these cells and requires NADPH. The enzyme, called NADPH diaphorase, has been identified as being identical to NOS[26-39]. It has been demonstrated that NADPH diaphorase reacticity and NOS immunoreactivity coexist in enteric neurons. The simple histochemical procedure to visualize NADPH diaphorase may be useful to localize NOS in other tissues in view of the currently limited availability of antisera to NOS[40-50]. Therefore, the NADPH-d is now wildly used as a marker for neuronal structures in the CNS and ENS which contain the enzyme NOS.

The result showed that NOS was widely distributed in the gastric wall. Briefly, many NOS positive neurons were present in the myenteric plexus but relatively few in the submucous plexus. The majority of the NOS positive neurons in stomach could be classified as either Dogiel type 1 or type 2 neurons,although they were not as typical as the Dogiel neurons in small intestine, suggesting that NOS is both in the circular muscle motor neurons and in some interneurons. Some NOS positive nerve fibers formed a dense network in the circular muscle and in myenteric ganglia, and few nerve fibers in the mucosa. Based on this evidence, it is clear that the distribution of NOS in the enteric nervous system is compatible with a transmitter role of NO in stomach.

The significant difference of NOS positive neurons in different parts of the stomach myenteric may be related to the physiologic function of stomach. The density of NOS positive neurons was scarce in fundus, it is advantageous to keep tonic contraction at fundus and maintain foundation tension, but the activity of NOS was more powerful than that in antram. It benefits gastric lumen relaxation for food store after diet. Teng *et al*[6] found that involvement of NO in the reflex relaxation of the stomach to accommodate food or fluid, and the NO released from fundus plays a principal role in adjusting, gastric lumen volume and press. We also found that the density of NOS in pyloric part was intensive, it is possibly related to stomach peristalsis since there were not only NOS neurons, but also other types, especially cholinergic neurons[7]. They released transmitters to coordinate each other, adjust stomach smooth muscle to shrink, thus producing peristalsis as a mechanical pump pushing food to duodenum. Meanwhile, the results show that staining intensity of NOS neurons was different in pylorus, hinting that some NOS neurons may be in a reserving condition, once required NOS will be activated and NO sythesized to regulate stomach movement and the tension of pyloric sphincter. But the detailed mechanism is far from clear. We also found that there were many NOS positive varicosities, and bead-

like structure strung together in nerve fibers. Some of them were closely adherent to the outer walls of blood vessels and smooth muscle fibers. This finding has provided morphological evidence of NO involved in the modulation of motility and blood circulation of gastrointestinal tract.

Abstract

AIM: **To investigate the specific mechanisms of intrinsic and acquired resistance to taxotere (TXT) in pancreatic adenocarcinoma (PAC).**

METHODS: **MTT assay was used to detect the sensitivity of PAC cell line SUIT-2 and its sublines (S-007, S-013, S-020, S-028 and TXT selected SUIT-2 cell line, S2/TXT) to TXT. Mdr1 (P-gp), multidrug resistance associated protein (MRP), lung resistance protein (LRP) and β-tubulin isotype gene expressions were detected by RT-PCR. The functionality of P-gp and MRP was tested using their specific blocker verapamil (Ver) and indomethacin (IMC), respectively. The transporter activity of P-gp was also confirmed by Rhodamine 123 accumulation assay.**

RESULTS: **S-020 and S2/TXT were found to be significantly resistant to TXT(19 and 9.5-fold to their parental cell line SUIT-2, respectively). RT-PCR demonstrated strong expression of Mdr1 in these two cell lines, but weaker expression or no expression in other cells lines. MRP and LRP expressions were found in most of these cell lines. The TXT-resistance in S2-020 and S2/TXT could be reversed almost completely by Ver, but not by IMC. Flow cytometry showed that Ver increased the a ccumulation of Rhodamine-123 in these two cell lines. Compared with S-020 and SUIT-2, the levels of β-tubulin isotype II, III expressions in S-2/TXT were increased remarkably.**

CONCLUSION: **The both intrinsic and acquired TXT-related drug resistance in these PAC cell lines is mainly mediated by P-gp, but had no relationship to MRP and LRP express ions. The increases of β-tubulin isotype II, III might be collateral changes that occur when the SUIT-2 cells are treated with TXT.**

INTRODUCTION

Up to now, pancreatic adenocarcinoma (PAC) is still one of the leading causes of cancer death in the world, although meat progress has been made in the treatment of this disease[1,2]. Most patients with PAC are in its advanced stages and surgically unresectable at the time of diagnosis, and for those who are resected, the risk of recurrence is very high[3,4]. Consequently chemotherapy still is an alternative strategy for patients with non-resectable PAC[5-8]. However, the response to most forms of chemotherapy achieved so far is generally quite limited, and is related in part to the resistance to these chemical agents[1,5,9]. To date, some specific mechanisms of drug resistance have been elucidated, among which the best understood are increased expressions of mdr1-encoded p-glycoprotein (P-gp)[10-14], multidrug resistance protein (MRP)[15-17] and lung resistance protein (LRP)[18-20]. These membrane transporter proteins play important roles in multiple drug resistance (MDR) involving increased drug efflux and intracellular drug entrapment and/or redistribution.

Taxotere (TXT) is a member of the family of taxanes and is more potent than paclitaxel with regard to the promotion of the polymerization of tubulin, inhibition of depolymerization, and it inhibits cell replication and has greater antitumor activity in many *in vitro* and *in vivo* tumor model systems[21-24]. The drug has displayed significant antitumor efficacy against breast, lung and ovarian cancer s in clinical trials[25-28], but some clinical studies do not support the use of Taxane in advanced PAC[29,30]. The studies on mechanisms by which cells acquire resistance to Taxane demonstrated that the drug is a substrate for the P170 multidrug resistance pump that is able to confer resistance to a wide variety of naturally derived hydrophobic substances[16,29,31]. Therefore, the cells selected with Taxane were found to exhibit cross-resistance to a variety of other hydrophobic drugs and have elevated levels of P-gp[32]. Other possible mechanisms of resistance to TXT the include the alteration in microtubulin composition and/or dynamics[33,34] increased protein kinase C-α and -γ expression[35] and overexpression of Bc1-2[36], and SP-gp[37]. But the exact mechanism of TXT- resistance in PAC is still not clear[32,38]. The specific mechanisms in different tumors might be different.

The mechanisms of refractoriness to chemotherapy of PAC are not fully understood. Published reports provide confl icting information regarding the expression of this MDR phonotype in human PAC[16,39]. Whether t he intrinsic and acquired TXT-resistance share the same MDR mechanism is unclear, which might be important for designing a chemotherapeutic regiment and investigating appropriate reversal agents. This study was designed to investigate the mechanisms of intrinsic and acquired resistance to T XT in PAC cell line SUIT-2 and its sublines.

MATERIALS AND METHODS

Chemical reagents

Taxotere (Rh0ne-Poulenc Rorer Pharmaceuticals Inc.) was stored as 10 mmol·L^{-1} stock solution in absolute ethanol at -20℃. These solutions were further diluted in the mediu m used in the cell culture immediately before each experiment. Final dilutions of 0.5-3.5 nmol·L^{-1} TXT were used for the experiments to detect the sensitivity of SUIT-2 and its sublines. Verapamil (Ver) was purchased from

American Reagent Laboratory, Inc. and Trypsin, EDTA was purchased from Gibco. MTT (3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyltetrazolium bromide), rhodamine (Rho) 123 (2-[6-Amino-3-imino-3H-xanthen-9-yl] benzoic acid methyl ester), indomethacin (IMC) (1-[P-chl orobenzoyl]-5-methoxy-2-methylindole-3-acetic acid), McCoy's 5A Medium [modified], DMEM (phenol free) medium, Fetal calf serum (FCS), sodium pyruvate, MEM amino acids (50X), MEM amino acids (100X), MEM Vitamins, L-glutamine (200 mmol·L^{-1}) penicillin-streptomycin, serine, a sparagine sodium bicarbonate were purchased from Sigma.

Cell cultures

Human pancreatic cancer cell line SUIT-2 was established and supplied by Iwamura. Its sublines, including S2-007, S2-013, S2-020, S2-028, were cloned by soft agar culture and shown to have different metastatic potential[40]. These cell lines were cultured and the TXT resistant SUIT-2 cell line (S2/TXT) was develop ed as described previously[41].

MTT colorimetric assay

The MTT colorimetric assay was performed as described previously[41]. Briefly, when the cells of SUIT-2 and its sublines reached 85%-90% confluency, they were detached from the flasks with 0.25% trypsin and resuspended in the culture medium. Cells were grown within 9 6-well microtitre plates (Costar) in 2×10^{10} cells·L^{-1} of culture medium each well and acclimated for 6 h, and 100 μL of various concentrations of drugs diluted in culture medium was added. To study the effect of Ver and IMC on TXT cytotoxicity, 1 μmol·L^{-1} Ver or 10 μmol·L^{-1} IMC was added with this drug. Five duplicate wells were used for each determination. The plates were incubated for 72 h when the control cells reached 90% confluency, and 30 μL of MTT in PBS solution was then added to each well and the plates were incubated for another 4 h. The medium and MTT solution were then aspirated and 150 μL of dimethyl sulfoxide (DM SO) (Sigma) was added. The plates were read on Bio-Tek Microplate reader EL 800 (Bio-Tek Instruments, Inc). Fractioo of cell proliferation was defined as the ratio of optical density volume to that of controls. The IC_{50} was defined as the concentration of the drugs required to reduce the absorbance by 50% in treated cells as compared to that of the controls.

Rho-123 accumulation assay

Rho-123 accumulation was determined by flow cytometry. Briefly, SUI T -2, S-020 and S2/TXT cells in logarithmic growth phase were harvested with trypsin and resuspended in phenol red-free DMEM medium at 1×10^{9} cells·L^{-1}. Aliquots of 1 ml cell suspension were preincubated with or without Verapamil for 45 min and then 200 μg·L^{-1} Rho-123 dissolved in DMEM was added and incubated for 40 min. After incubation, cells were washed and resuspended in ice-cold Rho-free DMEM with 5 μmol·L^{-1} Ver. The accumulation of Rho-123 in cells was analyzed with flow cytometry. Ten thousand cells per sample were analyzed. Cells of these cell lines, which had not been exposed to Rho-123, were used to determine the background of autofluorescence.

RT-PCR

The isolation of total RNA was based on the method of Chomczynski *et al*[40]. Equal amounts of RNA were reversed transcribed using SuperScript™ O ne-step™ RT-PCR System (Life Technologies). Twenty-five μL PCR mixed in each tube containing: 0.5 μL RT/Tag Mix, 3 μL of 5 mmol·L^{-1} $MgSO_4$, 5 μL diethy pyrocarbonate (DEPC, Sigma)-treated distilled water, 3 μL mixed primer pairs, 12.5 μL 2X Reaction Mix and 1 μg Template RNA in DEPC water. After an initial denaturation in a programmable thermocycler at 94℃ for 2 min, PCR was carried out for 30 cycles with the thermal profile: denaturing at 94℃ for 30s, annealing at 55℃ for 30 s and extension at 72℃ for 1 min with an extra-10 min extension for the last cycle. After completion of the amplification cycles, 5 μL of each PCR product was electrophoresed at 60 V for 1.5 hrs on a 1.2% agarose gel (GIBCOBRL) in Trizma base and Glacial acetic acid EDTA buffer. Both target and control (β-actin) gene sequen ces were coamplified in the same tube. Gene expression was normalized to β-actin transcript; this was noted for REL for relative expression levelg(REL=densitometric value of studied gene/densitometric value of â-actin). The specific primers for mdr1, MRP and LRP used in this study were as described as before [41]. The beta-tubulin isotype sequences were designed as follows: The sense primer sequence was 5'-CAA CAG CAC GGC CAT CCA GG-3'. The antisense primer sequences were M40 (Cla ss I): 5'-AAG GGG CAG TTG AGT AAG ACG G-3', β9 (Class II): 5'-GTA GAA AG A CCA TGC TTG GG-3', β4 (Class III): 5'- CTT GGG GCC CTG GGC CTC CGA-3', 5β (C lass I Va): 5'-AAG TAG CCA GAG GTA AAG CGA G-3', β2 (Class IVb): 5'-CTT TCC CCA GTG AC T GAA GG-3'. β-actin was used as control. Its sense primer was: 5'- TGA CG G GGT CAC CCA CAC TGT GCC CAT CTA-3'; and antisense primer was: 5'- CTA GAA GCA T TT GCG GTG GAC GAT GGA GGG-3'.

RESULTS

Sensitivity of SUIT-2 and its sublines to TXT

To identify for intrinsic TXT-resistant PAC cell lines, SUIT-2 and its sublines (S2-007, S2-013, S2-0 20 and S2-028)) were investigated as to their sensitivity to TXT as by MTT assay. The in nate sensitivity of SUIT-2 and its sublines to TXT were found. S2-020 cells we re most resistante to TXT compared with its parental cell line SUIT-2 (IC_{50} 0.85 nmol·L^{-1}), and other cell lines. IC_{50} of S2-020 (16.2 nmol ·L^{-1}) was 19-fold to that of SUIT-2. The second most resistant cell line was found to be S2-007 (IC_{50}: 1.82 nmol·L^{-1}). The other cell lines had no significant resistance to TXT. The IC_{50} of S2-013 and S2-028 were 0.75 and 1.2 nmol·L^{-1}, respectively. IC_{50} of the acquired TXT resistant cell line established from SUIT-2 was 8.1 nmol·L^{-1}, 9.5- fold to its parental cell line SUIT-2 (Figure 1).

Reversal effects of Ver and IMC on the resistance to TXT

In order to elucidate the function of drug transporter pump P-gp and MRP expressed in the cell line S2-020 and S2/TXT, their corresponding blockers Ver and IMC were used respectively. Figure 2A shows that Ver at a concentration of 1ìmol·L^{-1} can almost completely reverse the resistance of S2-020 and S 2/T XT to TXT, but the same concentration of Ver had no sensitizing effect to SUIT- 2, which did not express P-gp. IMC, a specific modulator of MRP, had no reversal effect on the TXT-resistance found in these cell lines, although they all expressed MRP (Figure 2B).

Rho 123 accumulation and efflux

Accumulation and efflux of Rho-123, which is related to the transporter activity of P-gp, from SUIT-2, S2/TXT and S-020 cells as tested by flow cytometry. The accumulation of Rho-123 in SUIT-2 cells is much higher than that of S-020 and S2/TXT cells. The addition of 5 μmol·L^{-1} Ver led to significantly increased intracellular Rho 123 levels in the TXT-resistant S2-020 and S2/TXT cells but not in the TXT-sensitive SUIT-2 cells and its other cell sublines.

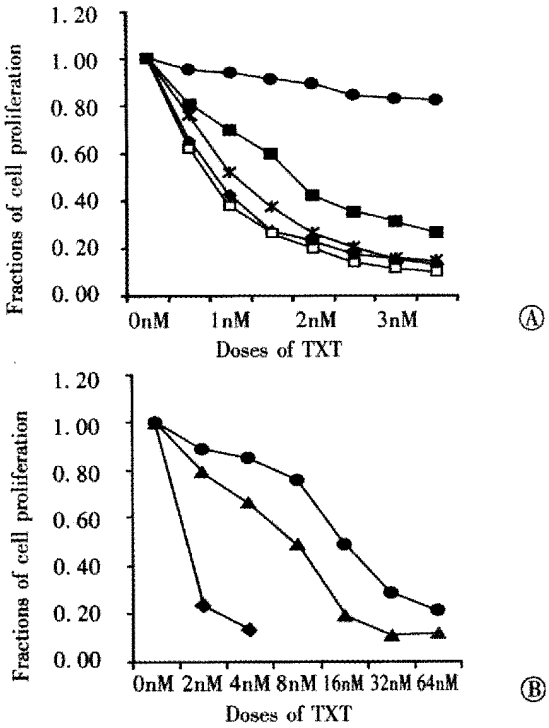

Figure 1 Dose-response curves of SUIT-2 and its subl ines for taxotere. ◆: SUIT-2, ■: S2-007,: S2-013, ●: S2-020, : S2-028, △: S2 /TXT.

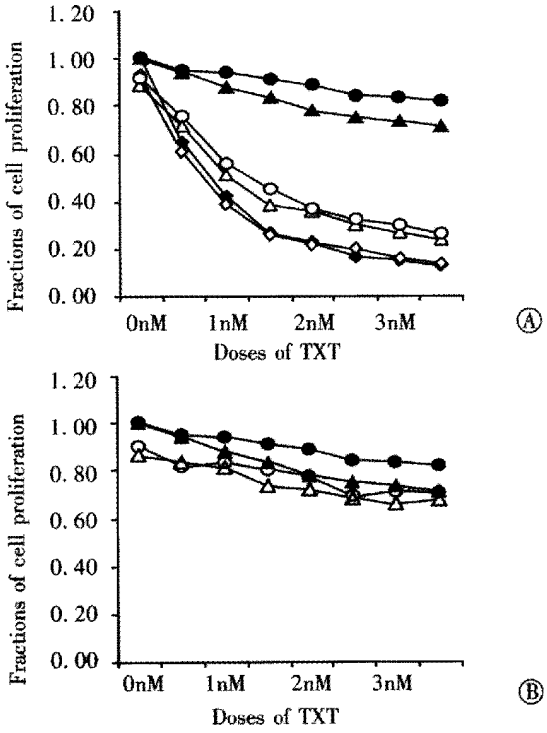

Figure 2 Reversal effects of Verapamil and Indomethacin on TXT -resistance. S2/TXT (▲), and S2-020 cell lines (●) were compared to SUIT- 2 (◆). Ver (Figure 2A) and IMC (Figure 2B) have been shown different sensitizing effects of TXT-resistance in S2/TXT and S2-020 (open symbols).

Expressions of mdr1, MRP, and LRP

The expressions of three major drug transporter pump genes mdr1, MRP, L RP were studied by RT-PCR. Figure 3 shows that there is a strong expression of mdr1 in both TXT-resistant cell line S2-020 and S2/TXT, no expressions in their parental cell line SUIT-2 and other two subline S2-013 and S2-028, which are most sensitive to TXT. MRP and LRP expressed in most of these cell lines, but no relationship was found between their expression and TXT-resistance.

Expressions of β-tubulin isotypes

β-tubulin isotype transcript analysis was performed by using isotype-specific primers and the RNA from SUIT-2 and its two TXT-resist ant cell line S2-020 and S2/TXT. Densitometric analysis of expression levels of each isotype was quantitated relative to the expression of the control gene β actin by calculating the ratio of the target gene to the control gene PCR product. As shown in Figure 4, the βI and β I Vb were the predominant transcript in all the three cell lines. A 2.4-fold increase of β II and a 2.3-fold increase of β III compared to SUIT-2 cell line were seen in S2/TXT cell line.

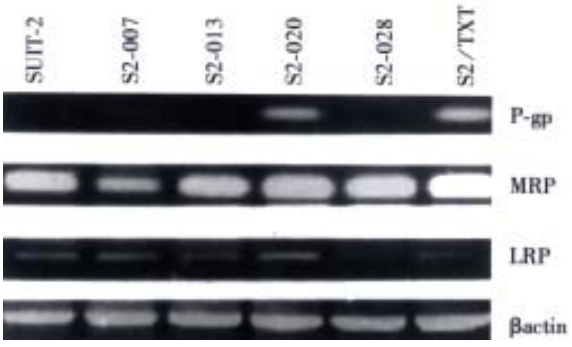

Figure 3 Expressions of mdr1, MRP, LRP in SUIT-2 and its sublines by RT-PCR analysis.

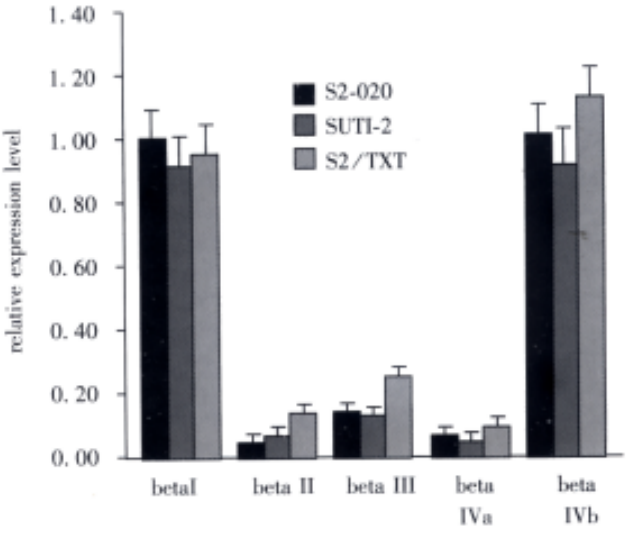

Figure 4 The RT-PCR analysis of the β tubulin isotype transcripts for the SUIT-2 and its two TXT- resistant cell lines. The relative expression levels of transcripts were expressed as a ratio of denitomet ric value of studied gene to that of β actin.

DISCUSSION

An increasing use of Taxanes in the treatment of variety of cancer including advanced PAC, has highlighted the need to elucidate the mechanism responsible for the development of resistance to this kind of drugs. Multidrug resistance may develop through a variety of mechanisms, which may include the alterations of extracellular drug efflux, intracellular extrapment or redistribution, drug detoxification, nuclear target and apoptotic response[42]. With respect to taxane-related resistance, many studies have shown that it is often associated with the expression of mdr1[29,32], but the expression of the mdr1 gene only accounts for part of the resistance mechanisms to taxanes. In

a study by Dumontet *et al*, only 44% of resistant clones were found to express the mdr1 gene, and accumulation studies with labeled PTX did not show altered accumulation in mdr1 negative clones[33]. Such observations indicate that there must be other mechanisms involved in taxanes resistance. Whether or not other drug transporters including MRP and LRP are also involved in this mechanism is not clear. There are reports that cell lines with MRP or LRP phenotype also confer a low level of resistance to taxane[43], though most findings showed that taxane-resistance is independent of MRP expression[44,45].

In this study, both intrinsic and acquired TXT resistant cell lines, which were derived from the same parental cell line, have expression of mdr1 gene, and also these resistances can be reversed almost completely by a P-gp blocker Verapamil. Active drug transporter pump in these TXT-resistant cells was also shown by Rho-123 accumulation assay. Though most of cell lines expressed MRP and LRP as show n by RT-PCR, they had no relationship with the TXT-resistance in these cell lines. To confirm that no MRP mediated TXT resistance exists in these cell lines, we used Indomethacin, a specific inhibitor of MRP[46] and found no sensitizing effect to TXT cytotoxity. LRP positive cell line SUIT-2 had the same sensitivity as LRP negative S2-028 cell lines, showing that there is n o active LRP mediated TXT-resistance. These data indicated that the TXT-related drug resistance in these cell lines is mainly mediated by P-gp. The high incidence of MRP and LRP expressions in these PAC cell lines might be involved in other kinds of intrinsic drugs resistance. Recently, other studies on the mechanisms involve d in taxane-resistance have been focused on the composition and the mutations in â-tubulin isotypes[32,33,47-49]. The possible mechanisms involved in the induction of resistance to taxanes may include altered metabolism and/or subcellular distribution, altered interaction between the tubulin-binding agents and microtubules, and altered response to cell cycle arrest by mitotic blockage.

The taxanes are unique among tubulin-targeted cytotoxins so far as they bind to polymerized tubulin only[24,50]. Direct photoaffinity labeling has demonstrated that taxane binds preferentially to the β subunit of the microtubule[51]. Sequence analysis identified the photoaffinity labeled amino acid residues β270 and β364 as important modulators of paclitaxel's interaction with the tubulin molecule[47]. The direct proofs that altering the isotype composition of a cell affects its sensitivity to any antimitotic drug have been reported, but the results were conflicting[32,33,47,48,52]. Virtually all major β-tubulin isotypes have been reported to be changed in various drug resistant mutants[32-34,4 7-49,52], and this runs counter to the idea that specific isotype of β-tubulin confers altered sensitivity to these drugs. Currently, more direct evidences t hat altered expressions of β-tubulin isotype in taxane-resistance cells contribute to their resistance phenotype have been demonstrated. Blade *et al* [32] by transfecting Chinese hamster ovary cells with cDNA encoding epitopetagged class I,II, and IV b â tubulins found that the production of βI, βII, or βIVb tubulin had no effect on the sensiti vity of the cells to PTX. However, Kavallaris *et al*[53] designed antisense phosphrothioate oligode oxynucleotides targeted against resistant lung cancer cells, and demonstrated that a decrease in class IIIβ tubulin mRNA and protein expression which corresponded to a 39% decrease sensitivity to PTX.

Different mechanism of taxane-related drug resistance may be tumor (or cell line)-dependent or even cell-dependent. Tumor histologic origination and heterogeneity of tumor cells may be responsible for this difference[33]. Since P-gp was often expressed in normal pancreatic tissue[54], P-gp mediated TXT resistance can be found natively in PAC or be readily induced by their subst rates. This study showed the changes of â-tubulin isotype not only in the P-gp-negative taxanes-resistance cells as in other studies[47,48], but also in P-gp-positive cells. However, the S2-020/TXT cells with both P-gp expression and changes of tubulin isotype profile did not show an additive or synergetic effects on TXT-resistance resistant to TXT compared with only P-gp-positive cell line S2-020. On the other hand, this resistance can be fully reversed by P-gp reversal agent Verapamil, suggesting that the change of β-tubulin isotypes might be a collateral change and not necessarily responsible for TXT-resistance in this cell line. Since many critical cellular functions, such as cell movement, mitosis, and maintenance of cell structure are associated with cytoskeletal elements in which the microtubular system plays a major role, it is not clear whether the changes of tubulin in this TXT selected cell line are involved in other biologic behavior of cells, such as cell mobility and inva siveness[55-58], which need to be further investigated.

The different expression of P-gp or tubulin mutation may also be related to the means by which the resistant cells were selected. Multiple step selected cells often present high levels of taxane-resistance mediated by P-gp, while single -step selection yields low level taxane-resistance cells with tubulin mutations[59], since severe tubulin mutations are very likely to affect cell survival and will be lost during the selection. The cells with di fferent mechanisms of taxane-resistance may have different characteristic. TXT-related drug resistan ce mediated by P-gp often presents a cross-resistance to other natural chemical agents, which is different from the taxane-resistance induced by the changes of â-tubulin isotype profile, the latter was often only cross-resistant to other kinds of anti-microtubule agents, such as Vinca alkaloids[33]. However, additive and synergetic effects between Vinorelbine and TXT on human lung cancer[60] seems that their combinations are not contraindicated. Another study has shown that resistance to taxanes can be reduced by increasing the duration of exposure in P-gp expressing cells, but no t in the taxane-resistance cell line which does not express P-gp[61]. Since the resistance was highly drug specific and none of the cell lines was resistant to all drugs, identifying specific mechanism of drug resistance phenotype in certain tumor is helpful in selecting non-cross-resistant regiments and appropriate reversal agents.

Abstract

AIM: **To investigate FasL expression in hilar cholangiocarcinoma tissues and cultured cholangiocarcinoma cells, and to assess its ability to induce apoptosis.**

METHODS: **We studied the expression of FasL by human hilar cholangiocaroinomas tissues by immunohistochemistry, and the QBC939 cholangiocarcinoma cell line by RT-PCR, immunohistochemistry, and Western Blot. TUNEL and flow cytometry were used to detect apoptotic cells.**

RESULTS: **Prevalent expression of FasL was detected in 39 resected hilar cholangiocarcinoma tissues. TUNEL staining disclosed a high level of cell death among lymphocytes infiltrating FasL positive areas of tumor. FasL mRNA and protein expressions in cholangiocarcinoma cells could induce Jurkat cells.**

CONCLUSION: **Hilar cholangiocarcinomas may elude immunological surveillance by inducing, via Fas/FasL system, the apoptosis of activated lymphocytes.**

Li ZY, Zou SQ. Fas counterattack in cholangiocarcinoma: a mechanism for immune evasion in human hilar cholangiocarcinomas. *World J Gastroenterol*, 2001;7(6):860-863

INTRODUCTION

The evasion, also called 'tumor escape', has been suggested to result from the inability of the immune system to react to the tumor, because of either non-recognition of tumor antigens or non-reactivity secondary to insufficient co-stimulation, anergy, tolerance, or immunosuppression. Recent reports showing the expression of FasL in Sertoli cells of the testis and ocular tissues[1,2], have provided new insights into the concepts of tolerance and immune-privilege. FasL triggers apoptotic cell death of sensitive lymphoid cells which express its cell surface receptor (Apo-1/CD95)[3-5]. FasL has been shown to confer immunological privilege in tissue transplantation experiments[6]. In rodents, successful allograft survival was obtained from FasL expressing tissues[2,7]. Moreover, FasL has been found to be expressed by non-lymphoid tumors as a mediator of immune evasion, which was initially raised by the finding that colon cancer cell lines express functional FasL[8]. Despite being immunogenic, cholangiocarcinoma overcomes antitumor immune responses by the mechanism that has not yet to be fully elucidated. The fact that many diverse tumors have been found to express FasL, suggests that a 'Fas counterattack' against antitumor immune effector cells may contribute to tumor immune escape[9-15]. We studied the expression of FasL on human hilar cholangiocarcinomas and the QBC939 cholangiocarcinoma cell line. We also studied apoptosis of lymphocytes (TILs) in filtrating into tumors. Jurkat cells were cocultured with cholangiocarcinoma cells.

MATERIAL AND METHODS

Human hilar cholangiocarcinoma tissue and cell

Thirty-nine human hilar cholangiocarcinomas of disparate pathological stages were collected from surgical resections performed at Qingdao municipal hospital. The patients were diagnosed as having hilar cholangiocarcinoma by histologic examination, and consisted of 17 males and 22 females. None of the patients have received chemo-, radio- or immuno-therapy before resection. The differentiati on of tumors were moderate (n = 12), poor (n = 18), or high (n = 9). The QBC939 cells (a human hilarcholangiocarcinoma cell line) were a generous gift from Professor Wang (Third Military Medical University, China)[16]. The human T cell line Jurkat was purchased from the American Type Culture Collection (Rockville, MD). QBC939 cells were cultured in DMEM supplemented with 100 mL·L^{-1} FBS. Jurkat cells were maintained in RPMI1640 nutrient medium supplemented with 100 mL·L^{-1} FBS, penicillin (100 KLI·L^{-1}) and streptomycin (100 mg·L^{-1}), and incubated at 37℃ in a 50 mL·L^{-1} CO_2 atmosphere.

Immunohistochemistry for FasL and CD45

Detection of FasL expression and CD45 positive cells was performed using a rabbit polyclonal anti-human FasL specific IgG and a mouse anti-human monoclonal antibody on paraffin sections of human cholangiocarcinoma respectively (Boster Biological Technology Company, Wuhan, China). Five μm thick sections on the slides were deparaffinized, rehydrated and blocked for removing endogenous peroxides activity with 3 mL·L^{-1} H_2O_2 in methanol. Then the sections were washed in PBS and pre-incubated with 50 mL·L^{-1} normal goat serum for 30 min. The slides were incubated with antibodies against FasL and CD45 for 1h at room temperature respectively. After washing, antibody binding was localized using a biotinylated secondary antibody with the ABC detection kit. The slides were counterstained with haematoxylin.

RT-PCR for FasL Mrna

Total RNA was prepared from the QBC 939 cell line with Trizol reagent (Gibco) according to the manufacturer's instructions. RT-

PCR was performed using RT-PCR kit (Promega) according to the manufacturer's protocol. cDNA synthesis was carried out with 2 μg of total RNA. The primers for PCR were 5'-TCCAACTCAAGGTCCATGCC-3' (forward) and 5'-CAGAGAGAGCTCAGATACGTTT-3'(reverse). PCR reactions mith total volume of 50 μL were processed in a MJ. PTC 100 Thermocycler under the following conditions: 94℃ for 2 min; 94℃ for 30 s, 57℃ for 45 s, and 72℃ for 1 min for 35 cycles; and 72℃ at 5 min. The RT-PCR products (342 bp fragments) were analyzed on 20 g·L^{-1} agarose gels. Amplication of human β-actin served as control for sample loading and integrity.

Western blotting

Immunoblotting was performed for detection of FasL. Cells (1×10^6) were scraped, centrifuged briefly, and lysed for 30 min on ice in 50 mmol ·L^{-1} Tris-HCl buffer (pH 8), containing 120 mmol·L^{-1} NaCl and 10 g·L^{-1} lyepal supplemented with the complete-TM mixture of proteinase inhibitors. T h e total protein was collected by centrifugation (14,000 r·min^{-1}, 30 min, 4℃) and assessed for protein concentration. SDS-PAGE (120 g·L^{-1}) was performed, an d the proteins were electroblotted onto nitrocellulose membranes. After 1h incubation in blocking solution (200 mL·L^{-1} IgG-free normal horse serum in PBS), the membrane was exposed to the primary antibody overnight at 4℃. After washing in PBS, the secondary peroxidase-labeled antibody was added at a 1:10 000 dilution for 40 min at room temperature. The proteins were visualized with the enhanced chemiluminescence technique.The primary anti-FasL antibody was the clone 33 (Jingmei Biotech Co. Ltd. China) mAb (1:1 000 dilution). The secondary antibody was peroxidase-labeled anti-mouse IgG antibody.

Cell death detection in situ by TUNEL

Cell death was detected *in situ* in resected tissues by enzymic labelling of DNA strand breaks using a TUNEL assay (Boehringer Mannheim GmbH, Germany) according to the manufacturer's instructions. Only those cells with positive TUNEL staining and of apoptotic morphology were considered apoptotic.

T-cell apoptosis analysis

Cholangiocarcinoma cells were seeded in 6-well tissue culture plates and allowed to grow to 90% confluence. The cells were then washed twice with PBS and fixed with 20 g·L^{-1} paraformaldeyhde at 4℃ for 1 h. After the cells were washed 3 times with PBS, they were layered with 2 mL of Jurkat cell suspension (5×10^8 T cells·L^{-1}) in serum-containing media. After 48 h of coculture, Jurkat cells were collected from the 6-well plates, centrifuged, fixed in 700 mL·L^{-1} ethanol, and stored at -20℃ prior to analysis. Apoptotic cells were detected as a sub-G_1 fraction after propidium iodide staining and analysis using a FACScan.

RESULTS

Immunohistochemical localization of FasL

Paraffin sections from hilar cholangicarcinomas (n = 39) were stained for FasL. Positive staining for FasL was seen in the tissue of all 39 patients with hilar cholangiocarcinomas assessed (Figure 1). Positive staining of neoplastic tissue varied in both intensity and extent from individual tumor cell to cell, region to region in tumor and among tumors. Intensity of staining varied from weakly positive neoplastic areas to in tense regions and was stronger than that observed in local FasL positive TILs staining areas where staining was locally uniform with nests of tumor cells. All tumors examined were predominantly FasL positive (>70% of tumor area). To generate further evidence that FasL is expressed by human hilar cholangiocarcinoma cells, we also identified the protein expression of FasL in QBC939 cholangiocarcinoma cell line (Figure 2).

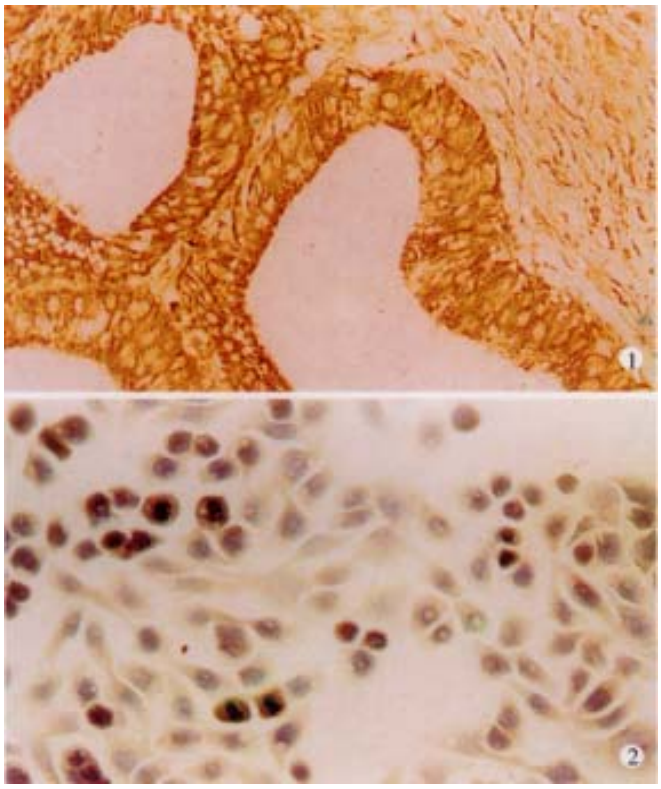

Figure 1 FasL positive in human hilar cholangiocarcinom as (brown). SABC×200
Figure 2 Expression of FasL in cholangiocarcinoma cell line. QBC939×200

Expression of FasL mRNA

To confirm the results obtained from the immunohistochemical studies, we evaluated the expression of FasL mRNA in the QBC939 human cholangiocarcinoma cell line. Total RNA was extracted and tested using RT-PCR. FasL mRNA was identified in QBC939 cells (Figure 3).

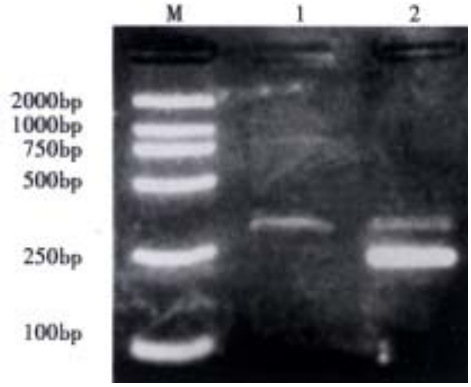

Figure 3 Expression of FasL mRNA in human cholangiocarcinoma cells QBC939. M: DL 2000 Marker; 1: FasL; 2: FasL+β-actin

Apoptosis of TILs

CD45 immunohistochemistry showed immunocyte infiltration in all 39 carcinomas (Figure 4). Most of the CD45 positive cells were of lymphoid morphology. Apoptosis was detected by TUNEL among TILs adjacent to FasL positive areas of the hilar cholangiocarcinomas. These

TUNEL positive TILs exhibited morphological features of apoptosis, including nuclear condensation and fragmentation (Figure 5). This was a consistent finding in all the tumors examined (n = 15).

Figure 5 Positive apoptotic TUNEL stainig *in situ* (brown) with apoptotic morphology.

FasL by Western blot

Whole cell lysates from QBC939 cell cultures were electrophoresed in a polyacry lamide gel. We had previously obtained mRNA from the same samples, Mr 37 000 protein was recognized on line 06 clone 33 (Figure 6).

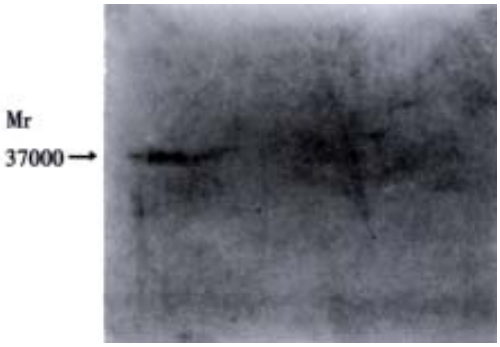

Figure 6 Western blotting of FasL protein with mAb from QBC939 cell cultures clone 33 from QBC939 cell cultures

Is functional FasL expression

To determine if FasL expressed by cholangiocytes in culture was capable of inducing cell death, we cocultured fixed cholangiocacinoma cells with FasL-sensitive (Jurkat) thymocytes. The QBC939 cholangiocarcinoma cell line induced cell death in FasL-sensitive T cells. At 48 h of coincubation, the cellline induced cell death in 50% of FasL-sensitive cells. These data show that the FasL expressed by the cholangiocarcinoma cells is capable of inducing T-cell apoptosis and therefore is functional.

DISCUSSION

It has been shown that hilar cholangiocarcinomas could express FasL, an inducer of immunocyte apoptosis in our study. The expression of FasL potentially enables hilar cholangiocarcinomas to counterattack and kill antitumor immune effector cells that seem Fas sensitive. As an established mediator of immune privilege and immunological tolerance in the eye and testis, functional FasL expressed in hilar cholangiocarcinomas was recognized as a contributor to the im mune evasion of hilar cholangiocarcinoma. Expression of FasL in human hilar cholangiocarcinomas was prevalent; all 39 samples resected from hilar cholangiocarcinomas were found to express FasL protein. FasL staining was variable in both intensity and extent within tumors. The fact that extensive expression (>70% of the tumor area) occurred in all tumors irrespective of tumor stage or degree of differentiation suggest that FasL may be expressed throughout hilar cholangiocarcinoma progression. In contrast with the extensive expression detected in the hilar cholangiocarcinomas, FasL expression was consistently restricted to only those epithelial cells at the luminal surface in control normal biliary epithelial sections (n = 6).It was estimated that a down-regulation and upregulation of FasL expression occurs during the transformation process. Using well-characterized, stable primary culture system of human cholangiocarcinoma cells, we found that cholangiocarcinomas in culture could express mRNA and protein of FasL and induce cell death in T cells. Apoptosis of TILs is an evidence *in vivo* which indicated that FasL expressed by the tumor is functional and can kill Fas sensitive anti tumor immune effector cells.

Several cancers have been reported to express FasL. The tumor derived cell lines in all of the cases could induce apoptosis in Fas sensitive, but not Fas resistant lymphoid target cells *in vitro*[17-30]. Tumors and cell lines themselves usually exhibit resistance to FasL mediated apoptosis because of various defects acquired in Fas signal transduction[31-37,44-48]. Immunogenic tumor cells are probably subjected to a barrage of c ell mediated cytotoxic antitumor immune assaults[38-43,49-52]. The fact that most tumor cells are efficiently killed by LAK cells *in vitro* suggests that cancer cells probably exhibit some degree of susceptibility to cell mediated cytotoxic mechanisms. Expression of a molecule to defuse antitumor immune challenge clearly offers a protective advantage to tumor growth and development. As an established mediator of immunological tolerance and privilege, FasL is such a molecule. Our findings have conclusively show that human hilar cholangiocarcinomas express functional FasL. Hilar cholangiocarcinoma may therefore be added to the growing list of malignancies that appear to be immunologically privileged through FasL expression. The high prevalence of FasL expression in the tumors suggests that this molecule may be critical to tumor immune privilege. In conclusion, the Fas counterattack appears to prevail as a potentially critical mechanism of immune privilege in human hilar cholangiocarcinoma.

Abstract

AIM: **To discover the relationship between the genotype and antigen serotype of flagellin C among Salmonella strains.**

METHODS: **Fragment of Salmonella flagellin C in plasmid pLS408 was cloned, sequenced and compared with the corresponding sequence in other strains. Salmonella strains including two typhi strains, one paratyphoid strain, one enteritidis and one typhimurium strain were isolated from outpatients. Genome DNA was purified respectively from these clinical isolates, then the corresponding flagellin C fragment was amplified by polymerase chain reaction, and the amplification products were analyzed by agarose gel electrophoresis.**

RESULTS: **The cloned fragment includes 582 nucleotides encoding the variable region and partial conservative region of Salmonella flagellin C in plasmid pLS408. With comparison to the corresponding sequences reported previously, there is only a little difference from other strains with the same flagellar serotype in both nucleotide and amino acid level. Specific PCR products were amplified in Salmonella strains with flagellar serotype H-1-d including *S. muenchen*, typhi and typhimurium, but not in *S. paratyphoid* C or S. enteritidis strains.**

CONCLUSION: **In this experiment, the specificity of nucleotide sequence could be found in flagellin C central variable regions as it exists in flagellar serotypes in Salmonella. It may be helpful to developing a rapid, sensitive, accurate and PCR-based method to detect Salmonella strains with serotype H-1-d.**

INTRODUCTION

Bacteria of genus Salmonella are both major and minor pathogens that cause disease outbreaks that arise from single incidents of breakdown in food hygiene. Much effort has been devoted to methods that differentiate these organisms in order that a given outbreak may be traced to its source and breakdown. Serological analysis of the surface antigens, such as flagellar antigen, has been proven to be the most suitable approach and has resulted in the recognition of a large number of serotypes.

In the past decade, the nucleotide sequences of flagellin in several Salmonella strains were published, the information of secondary and tertiary structure of flagella was discovered by chemical methods and X-ray crystallogram, and the antigen variable region was also determined roughly. These results indicate that serotype of flagella is determined by the linear primary structure of flagellin and the strain with different serotypes has different amino acid sequence in the central region of flagellin.

According to the standpoint that phenotype is determined by corresponding genotype, it is reasonable to think that the differentiation in the variable region of flagellin may be reflected by the nucleotide sequence. Detection of nucleotide difference by specific amplification may be helpful for the diagnosis and typing of Salmonella.

MATERIAL AND METHODS

Strains and plasmid

Salmonella 5930, which contains plasmid pLS408, was offered by Professor Stocker (Stanford University School of Medicine). Plasmid pUC18 and Eschrichiacoli. DH-5á was stored in our laboratory. Salmonella strains including two typhi strains, one paratyphoid strain, one enteritidis and one typhimurium strain were isolated from outpatients, and samples were stored in Department of Bacteriology, Xijing Hospital.

Cloning of partial flagellin C gene fragment

Plasmid pLS408, in serted with the complete sequence of flagellin C from *S. muenchen*[1], was prepa red as template by plasmid purification kit (Shanghai Watson Biotech. LTD). Primers, including EcoRV and *KpnI* sites for convenient cloning, were designed referring to the complete sequence of flagellin C in *S. muenchen* and *S. typhi*. Forward primer: 5' GCAGGATATCTTCCTCGAGACCACAGTTGCGGCTC 3'; reverse primer: 5' TGCGCC AGAACGGAGGTACC 3'. PCR product was digested by EcoRV and *KpnI*, ligated to pUC18 digested by *HinCII* and *KpnI* and sequenced in Sangon.

Amplification of flagellar serotype specific fragment in Salmonella strains

Genome DNA was prepared by genome purification kit according to the Watson's Handbook for DNA Isolation an d Purification. Amplification was performed by two-step polymerase chain reaction, i.e. preheating at 94℃ for 5 min, then denaturing at 94℃ for 45 s and an nealing at 68℃ for 1 min, 30 cycles with a final extension at 72℃ for 10 min. Amplification products were analyzed by 1.5 $g \cdot L^{-1}$ agarose gel electrophoresis.

RESULTS

The map of plasmid pLS408 and the result of agarose gel electrophoresis of fliC PCR product were demonstrated (Figure 1).

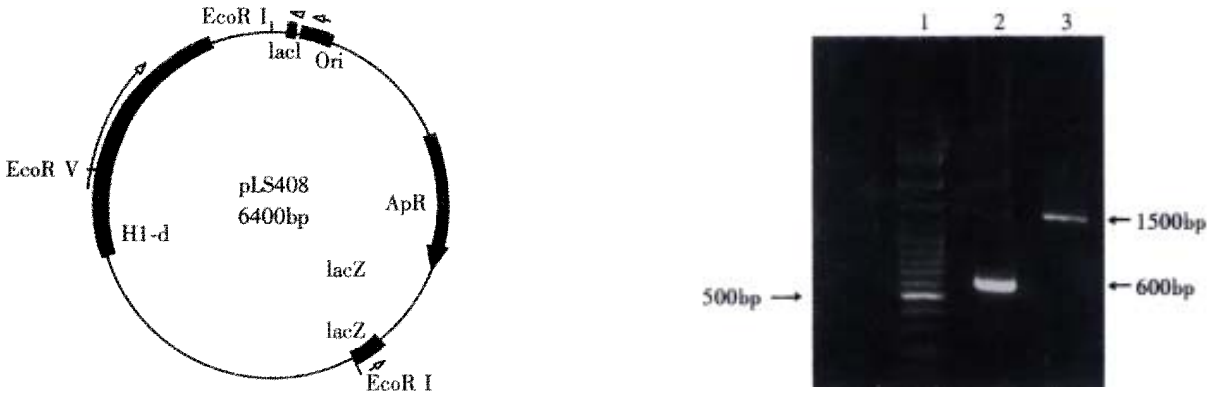

Figure 1 Map of pLS408 (left) and gel electrophoresis of PCR p roduct (right).
Lane 1: 100 bp DNA ladder, lane 2: PCR product of partial flagellin C gene, lane 3: PCR product of flagellin C gene.

The amplification product includes 582 nucleotides encoding variable region and partial conservative region of flagellin C. In comparison with the corresponding sequences reported before, there is only a little difference from other strains with the same flagellar serotype in both nucleotide and amino acid level (Figures 2 and 3). Compared with the known *S. muenchen* sequence, there are three single-nucleotide insertions, which cause frame shift and ten amino acid changes (166-195). T here are three single-nucleotide mutations, which cause two missenses (23:C to T, 136:G to A) and one silent mutation (216: G to T), and a double-nucleotide mutation (281, 282:TA to AT) and a three-nucleotide short fragment mutation (217, 218, 219: CTC to GCT), which causes one missense mutation, respectively. Though t here are some differences between the sequence here and that derived from the other *S. muenchen* strain, it is conservative highly with the corresponding sequence in Salmonella strains with the same flagellar serotype.

DISCUSSION

Flagella is a necessary organelle for bacterial motility and its biological behavior is well controlled[2-23]. The flagellar filament is composed of a single protein, flagellin. Serological analysis has proved that diverse types exist among different Salmonella strains[24-26]. The a minoacid sequence of flagellin has been assigned to four domains of flagellin subunit structurally identified in the filament structure, based on biochemical, immunological and structural information[27,32]. The terminal regions form the c ore of t he filament and the central regions form the outer part. Despite the high conservatism in terminal regions, the great divergence in central regions was discovered in both amino acid and nucleotide sequence among the different Salmonella strains. This point was also strongly supported by our experiments.

By comparison with other sequences in Genbank, we found the conservatism of flagellin C central regions among the different strains with the same flagellar antigen type. It is the foundation for the design of primers. In this experiment, primers were designed by software (primer 3 on the Internet) to amplify the flagellin C gene with specific antigen type H-1-d. The sequence of flagellin C variable region in *S. muenchen* was sequenced and compared with other sequence. The cloned fragment was highly aligned with other strains. In fact, the specific amplification occurred in all isolates with H-1-d serotype like *S. muenchen*, typhi or typhimurium, but not in other serotypes like *S. enteritidis* or typhoid C strain and the negative amplification was found in other bacteria like *Helicobacter pylori* is olates or *Eschrichia Coli.* strains (data not shown).

As a developed tool, PCR-bas ed technique has been widely used in both basic and clinical research[33-58]. In bacterial taxonomy, PCR-based genotype typing is complementary to serological typing[59-61]. Furthermore, as a rapid and convenient method, polymerase chain reaction is very helpful to the detection of many microbes like *H. pylori*, Salmonella, crypt ococcal neoformans and many other microbes [62-66]. In this experiment, the specificity of nucleotide sequence could be found in central variable regions of flagellin C as it exists in flagellar serotypes in Salmonella.

In summary, the specificity of nucleotide sequence was found in central variable regions of flagellin C as it exists in flagellar serotypes in Salmonella in this experiment. It may be helpful in the develop ment of a rapid, sensitive and accurate method to detect Salmonella strains with serotype H-1-d.

Abstract

AIM: **To study preliminarily the properties of myosin light chain kin ase (MLCK) in rabbit liver.**

METHODS: **The expression of MLCK was detected by reverse transcription-polymerase chain reaction (RT-PCR); the MLCK was obtained from rabbit liver, and its activity was analyzed by γ-^{32}P incorporation technique to detect the phosphorylation of myosin light chain.**

RESULTS: **MLCK was expressed in rabbit liver, and the activity of the enzyme was similar to rabbit smooth muscle MLCK, and calmodulin- dependent. When the concentration was 0.65 mg·L^{-1}, the activity was at the highest level.**

CONCLUSION: **MLCK expressed in rabbit liver may catalyze the phosphorylation of myosin light chain, which may play important roles in the regulation of hepatic cell functions.**

Subject headings myosin light chain kinase; liver, rabbit; enzyme activity; reverse transcription-polymerase chain reaction

INTRODUCTION

Protein kinases perform important regulatory roles in response to both intra cellular and extracellular signals. Specific protein kinases are thought to control various cellular functions including glycogen metabolism, muscle contraction , and growth. Myosin light chain kinase (MLCK) is an enzyme of the kinase family, which phosphorylates the light chain of smooth muscle, skeletal muscle and no n-muscle myosin in the presence of Ca^{2+} and CaM, id it requires the C a^{2+} and the Ca^{2+} binding protein CaM for the activity. Phosphorylation of the light chain in skeletal muscle is involved in modulating the tension produced during contract ion, whereas in smooth muscle it appears to be required for initiation of contraction. Phosphorylation of myosin regulatory light chain (RLC) by smooth muscle myosin light chain kinase is a key event initiating smooth muscle contraction. However, the roles of myosin phosphorylation in non-muscle function is not well understood. However, present researches show that a variety of non-muscle processes are associated with MLCK, including endothelial cell retraction, fibroblast con traction, mast cell secretion, receptor capping in lymphocytes, and platelet aggregation, contraction, etc. That MLCK controls endothelial Ca^{2+} entry in endothelial cells not through myosin light chain phosphorylation suggests its role in vasodilation through its action in endothelial cells[1]. The activation of volume-regulated anion channels in macrovascular endothelium is modulated by myosin light chain phosphorylation through the action of MLCK or myosin light chain ph osphatase[2].

Ma *et al*[3] incubated the filter-grown Caco-2 intestinal monola yers in Ca^{2+} free solution (CFS) and found an increase in tight junction p ermeability of the monolayer. The CFS-induced modulation of tight junction barrier was related with the activation of MLCK activity and centripetal retraction of peri-junctional actin and myosin filaments. Ueno *et al* reported that a Ca^{2+}-CaM- dependent protein kinase purified from rabbit liver phosphorylated the regulator y light chain of hepatocyte myosin. The kinase catalyzed the incorporation of ph osphate into the 22 ku light chains of hepatocyte myosin, which resulted in a 7 - fold activation of the Mg (2+)-ATPase activity by F-actin. MLCK is possibly involved in many Ca^{2+}-dependent activities of monocytes or macrophages[4]. It is found that there are at least two different stress fiber systems in human foreskin fibroblasts including central stress fiber system and peripheral stress fiber system, and the latter system depends on MLCK[5]. MLCK plays an important role in the development of neuron. Preventing calcium influx through blocking of MLCK activity selectively decreased dendritic branching[6]. A novel MLCK cDNA was isolated from a HeLa cell cDNA library. The deduced amino acid sequence was identical to that of a zipper-interacting protein kinase, which mediates apoptosis. With the fragment of the bovine stomach MLCK gene including kinase and calmodulin regulatory domains as a probe. Murata-Hori *et al*. screened a HeLa cell cDNA library. They found that one serine/threonine kinase, HeLa zipper-interacting protein kinase, from non-muscle cells phosphorylated regulatory chain of myosin II[7]. Is there any novel MLCK in hepatocytes? How is MLCK involved in cellular functions of hepatocytes? In order to investigate the roles of MLCK in the maintenance of liver functions and its association with some liver diseases in the future study, we preliminarily studied the expression of the enzyme in the rabbit liver by reverse transcription polymerase chain re action (RT-PCR) and observed some of its properties preliminarily through assaying its catalytic activity of the phosphorylation of myosin light chain by γ-^{32}P incorporation method. Our preliminary research provides basis for our further investigation of functions of MLCK in the liver and its relation with the pathology of some hepatic diseases.

MATERIALS AND METHODS

Reagents and instruments

CaM, rabbit smooth muscle MLCK positive control and myosin

regulatory light chain were the gifts from Dr. Zhi at University of Texas Southwestern Medical Center, USA. EGTA and MOPS were purchased from Sigma Chemical Company, and DTT, phenylmethy sulfonylflouride (PMSF) and proteinase inhibitors from Sino-America n Biotechnological Corp, Shanghai. HEPES was produced by MERCK; EDTA was obtained from Life Technology, GibicoBRL. [γ-^{32}P]ATP (radio activity > 185 PBq ·mol-1·L^{-1}) was purchased from Yahui Biomedical Engineering Corp of Beijing. Other reagents were made in China and they were of analytical purity. Backman LS1701, Liquid Scintillation System was made in USA and DYY-III type-2 electrophoresis and transfer system were made in June 1 Instrument Factory of Beijing and idEA Ideal Sci Co. UV-754 Spectrophometer was made by The Third Factory of Analytical Inst ruments of Shanghai.

Tissue samples and hepatocyte isolation

Fresh liver tissues were obtained from New Zealand white rabbits and hepatocytes were isolated in reference as described elsewhere[8]. For liver tissues they were rinsed with cold Hanks solution (NaCl 137; KCl 5.0; $CaCl_2$ 1.3; $MgSO_4 \cdot 7H_2O$ 0.8; Na_2HPO_4 0.6; KH_2PO_4 0.4; $NaHCO_3$ 3.0; glucose 5.6 mmol·L^{-1}; pH7. 4). Blood vessels and other tissues were removed carefully. After washing with Hanks solution, the liver was cut into about 1 mm^3 slices and homogenized or stored at -80℃ for further processing.

RT-PCR of MLCK fragments[9,10]

For RT-PCR, hepatocytes were directly lysed with TRIZOL Reagents (GibcoBRL), and total cellular RNA was isolated according to the manufacturer's instructions. First-strand cDNA was generated in the presence of 0.5 μg·L^{-1} Oligo (dT) 12-18 from 5 μg total RN A with reverse transcriptase (Superscript™ Preamplification System, GibcoBRL). The paired primers to detect endogenous MLCK fragments were designed according to the r eported MLCK sequence, and they are paired primer one: 5'> AAGAATTCGATGTCAGCTGAAC <3' and 5' CTTCTCCAGAAGCTTATAGGA <3', and paired primer two: 5'> CCACTGGTG AAGCTTAAAATC<3' and 5'> TGGAATTCCATGGGGGACGTGAA <3'. The PCR was performed in reference as described elsewhere[9]. The PCR products were examined by 20 g·L^{-1} agarose gel and ethidium bromide staining. The photos were taken for the analysis of the PCR products.

Preparation of MLCK from rabbit liver

Using metho d described by Ramji *et al* and Tang *et al*[11], the liver tissues were obtained. Briefly, the liver slices removed blood vessels and other tissues were put into glass homogenizer with addition of suit amount of tissue buffer for homogenizat ion on the ice block, and the homogenized tissues were thawed for three times (5 min once) after homogenizing. 16 000 r·min^{-1} centrifugation for 30 min at 4℃, and MLCK was prepared by the method described by Wang *et al* and Bartelt *et al*. The purified MLCK was used for activity assay

Assay of calmodulin- and calcium-dependent MLCK activity

Ca^{2+}/CaM-dependent activity of MLCK was measured by rates of [γ-^{32}P]ATP incorporation into myosin light chain as substrate referring to Wang *et al* and Blumenthal *et al*. Briefly, the relation of MLCK activity with time, regulatory light chain and CaM concentrations as well as with MLCK concentrations were analyzed. Maximal activity was determined in the reaction buffer containing 50 mmol·L^{-1} MOPS in mmol·L^{-1} at pH 7.0: magnesium acetate 10, dithiothereitol 1, $CaCl_2$ 0.3; 1 mmol·L^{-1} [γ-^{32}P] ATP (200-300 cpm·pmol^{-1}) ; 1.2 μmol·L^{-1} CaM, 25 μmol·L^{-1} regulatory light chain of myosin, and diluted MLCK at room temperature. MLCK was freshly diluted in 10 mmol·L^{-1} MOPS (pH 7.0), 1mmol·L^{-1} dithiothreitol, and 1 g·L^{-1} bovine serum albumin and a dded to the reaction mixture. Final MLCK concentrations used in kinetic measurements showed linear phosphorylation rates with respect to time and enzyme concentration in a certain range.

Protein contents determination

Lowry's method was used for the determination of contents of various proteins, in which bovine serum albumin was used as the standard.

Statistical analysis

Data of MLCK activity were collected and processed through analysis of difference of MLCK activity by Student's *t* test with SPSS 8.0 Windows software. $P<0.05$ or $P<0.01$ was considered as statistically significant in the difference of MLCK activity.

RESULTS

Confirmation of MLCK expression in rabbit hepatocytes by RT-PCR

Two pairs of specific primers were used to detect the expression of MLCK in freshly is olated hepatocytes. The total cellular RNA was isolated and first-strand cDNA was generated. The results showed that the RT-PCR products were 400 bp and 450 bp respectively, confirming with the expected molecular size (Figure 1), which suggests that there is expression of MLCK in rabbit liver.

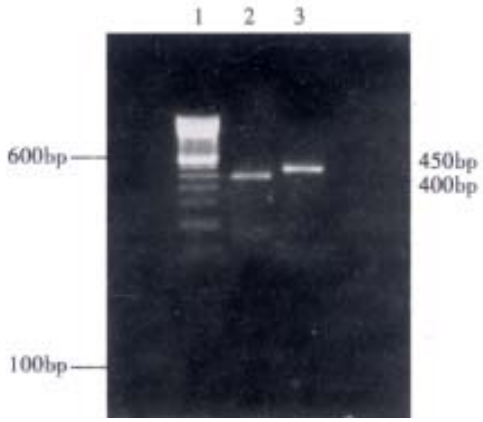

Figure 1 Reverse transcription polymerase chain reaction of cellular total RNA from hepatocytes in New Zealand rabbit. 1.100 bp DNA ladder; 2-3, PCR products: amplified MLCK DNA fragments.

Features of rabbit liver MLCK activity analysis

Comparison of activity of rabbit liver MLCK with that of smooth muscle MLCK To observe the activity level of our isolated MLCK in rabbit liver, we assayed the activity of the MLCK and smooth muscle MLCK. I t was found that both kinds of MLCK had similar catalytic activity, there is no statistically significant difference between two kinds of enzymes ($P<0.01$ £½ by Student's t test (Figure 2 A).

MLCK from rabbit liver was CaM-dependent To confirm the MLCK isolated from the rabbit liver is dependent on CaM, we assayed the effect of phosphorylation of MLC K on regulatory light chain of myosin. It was found that the light chain was obv iously phosphorated when CaM was added into the reaction buffer at the suitable concentration of Ca^{2+}. The MLCK activity increased markedly with CaM added. Ther e is significantly statistical difference when compared with the activity of the MLCK without adding CaM ($P<0.01$) through Student's t test analysis with SPSS 8.0 Windows software. See Figure 2 (B).

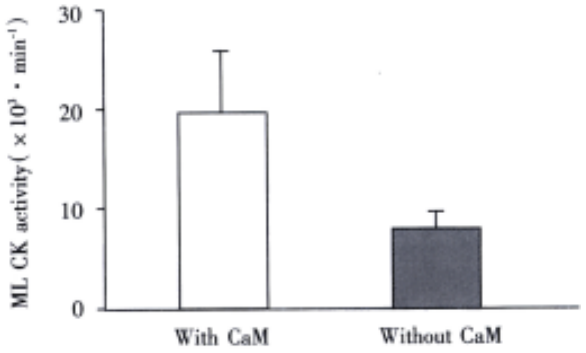

Figure 2 (A) Comparison of enzymatic activity between smMLCK and rabbit liver MLCK (P>0.05)

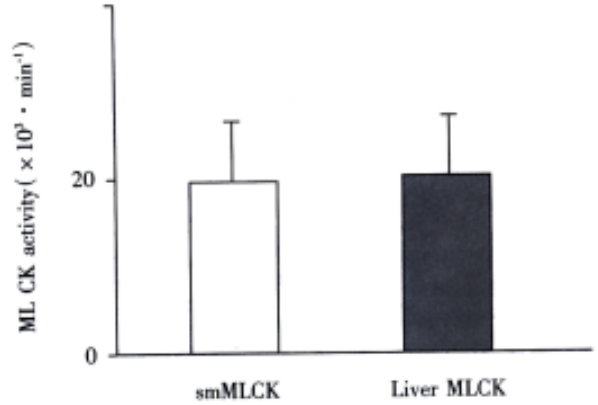

Figure 2 (B) Effect of CaM on MLCK in rabbit liver activity (P<0.01)

Action characteristics of MLCK of rabbit liver In the reaction system, enzymatic catalytic action of the MLCK increased gradually at first three min and the extent of phosphorylation of the regulatory light chain of myosin was at the highest level at about three min on the suitable concentrations of substrate, Ca^{2+} and CaM. In addition, the activity of MLCK of rabbit liver changed with the changes of the substrate concentrati on or the concentration of light chain of myosin. When the concentration was 0.65 mg·L^{-1}, the activity of MLCK was at the highest level, the most amount of light chain was phosphorated at this time. Finally, MLCK concentration influenced t he activity of the enzyme itself. On the suitable substrate, CaM and calcium ion concentrations, the activity of MLCK from the rabbit liver was basically at the higher level when MLCK ranged from 15 mg·L^{-1} to 25 mg·L^{-1}.

DISCUSSION

MLCK is the key regulator of cell motility and smooth muscle contraction in higher vertebrates. MLCK expression shows a complex pattern. In undifferentiated myoblasts, 220-kulong or non-muscle form of MLCK is expressed during differ entiation of skeletal muscle. During myoblast differentiation, expression of the 220-ku MLCK declines and expression of this long-form is replaced by 130 ku smooth muscle MLCK and a skeletal muscle-specific MLCK. In fact, 130 ku smooth muscle MLCK is not a smooth muscle-specific protein, it is ubiquitous in all adult tissues[12]. A prerequisite for vertebrate smooth muscle contraction, potentiation of skeletal and cardiac muscle contraction and various non-muscle motile events in response to intracellular Ca^{2+} signaling is the phosphorylation of myosin II RLC at Ser-19 by MLCK. The phosphorylation of RLC increases the Mg^{2+}-ATP activity of myosin, which catalyses cyclic conversion of ATP chemical energy into mechanical work through the reversible actomyosin interactions. Ca^{2+}-calmodulin -dependent phosphorylation of RLC of myosin by the catalytic COOH-terminal half of MLC K activates myosin II in smooth and non-muscle cells. Three-dimensional reconst ructions showed MLCK density on the extreme periphery of subdomain-1 of each actin monomer forming a bridge to the periphery of subdomain-4 of the azimuthally adjacent actin. There is interaction of MLCK-147 close to the COOH terminus of the first actin and near residues 228-232 of the second. The unique location ensure that MLCK binds to actin without interfering with the binding of any other key actin-binding proteins, including myosin, tropomyosin, caldesmon, and calponin[13]. In addition, the unique sequence of MLCK-210 is involved in its interacti on with the microfilaments and contributes to its tighter association with the actin cytoskeleton[14]. Non-muscle cells may use different mechanisms for targe ting the long-form MLCK to actomyosin structures during interphase and mitosis. MLCK and myosin II phosphatase act cooperatively to regulate the level of Ser 19 -phosphorylated myosin II during mitosis and initiate cytokinesis through the a ctivation of myosin II motor activity[15].

Ca^{2+}/CaM forms a ternary complex with MLCK, facilitating in activation of the kinase and phosphorylation of RLC. Ph osphorylation induces a conformational change, which allows myosin crossbridges to along actin filaments. Some non-muscle processes are also regulated by RLC phosphorylation of the myosin, while smooth muscle MLCK plays important roles in contractile-motile processes of a variety of cells[16]. MLCK has an actin-binding activity in addition to its kinase activity, which assembles actin filaments in to bundles morphologically and biochemically. There are two actin-binding sites on MLCK, including calcium- and calmodulin-sensitive site and insensitive site . The cross-linking between this two sites assembles actin into bundles[17]. Recently, it is found that a novel approximately 60 ku MLCK immunogen contributes to the aberrant contractility associated with preterm labour[18], while Sohn *et al* reported that calmodulin and MLCK play a role in Ach-induced lower esophageal sphincter contraction, whereas the classical MLCK may not be the major kinase responsible for contraction and phosphorylation of myosin light chain in esophagus. Esophagus contraction is protein kinase C dependent contraction[19]. Various new functions of MLCK have been found recently, activation of myosin II by MLCK produces force for many cellular processes including mitosis, migration, and other cellular shape changes. Inhibition or potentiation of myosin II activation via over-expression of a dominant negative or wild type MLCK can delay or accelerate tumor necrosis factor-á induced apoptotic cell death in cells [20]. MLCK specific ally mediates agonist-induced sarcomere organization during early hypertrophic response[21]. During vascular injury, the expression of MLCK decreased[22]. In rabbit portal vein myocytes, MLCK mediates noradrenaline-evoked non-selective cation current[23]. In the liver, agents that elevate intracellular free Ca^{2+} concen tration increase tight junctional permeability and stimulate bile canalicular contraction. Myosin phosphorylation is probably responsible for the tight junction al permeabilization caused by elevation of intracellular Ca^{2+} in hepatocytes. Moreover, the integrity of the phosphorylation system of myosin is essential for normal bile flow. In addition, hepatic sinusoidal Ito cells (fat storing cells) play a regulatory role on hepatic sinusoidal blood flow through their contraction, while the integrity of myosin light chain kinase is essential for Ito cell con traction and normal sinusoidal blood flow. However, the roles of myosin phosphor ylation by MLCK in non-muscle tissues is not well characterized but correlates with important activities such as cell division, receptor capping, etc. Recently, the study showed the existence of a 208 ku protein, named embryonic MLCK because its expression can be detected in early embryonic

tissues, stem cells, and in proliferating cultured cells. In the liver, down-regulation of this 208 ku embryonic MLCK is not so dramatic, and the less dramatic decline in the expression of embryonic MLCK may possibly reflect the high regenerative capacity of liver tissue. It is now found that MLCK is associated with non-muscle cells closely[1,2,4-7]. MLCK activation is also a critical step in the cytoskeletal changes causing pseudopod formation during polymorphonuclear leukocyte phagocytosis[24]. MLC K immunoreactivity was found to be colocalized with the insulin granules which suggests that it increases insulin granules in the ready-releasable pool by acting on different steps in the secretory cascade[25]. In 3T3 fibroblasts, MLCK is responsible for phosphorylation of MLC at the cell periphery, showing its unique spatial regulation of myosin RLC[26]. From the gene of vertebrate smooth muscle and non-muscle MLCK there are at least four proteins expressed. Two high molecular weight MLCK splice variants, EC MLCK-1 and EC MLCK-2 (210-214 ku) in human en dothelium are identical except for a deleted single exon in MLCK-2 encoding a 69 - amino acid stretch that contains potentially important consensus sites for phosphorylation by p60 (Src) kinase, while p60 (Src)-mediated tyrosine phosphorylation represents an important mechanism for splice variant-specific regulation of n on-muscle and cascular cell function[27]. MLCK is also associated with the gap fomation and endothelial hyperpermeability of coronary venular endothelial cell monolayers[28]. Our preliminary study revealed that MLCK in the rabbit liver could phosphorate myosin light chain obviously, and was calmodulin-dependent, which may play an important role in maintaining the normal functions of the tissue. Bu t in the liver, what form of MLCK expressed more, long form MLCK (embryonic MLCK) or short form MLCK with the molecular weight about 130-150 ku? What are their exact roles in the liver? What roles it will play in liver regeneration, in liver injury or in hepatic carcinoma? And what are the action mechanisms? These remain to be elucidated in our further study.

Abstract

AIM: **To study the anti-hepatofibrosis mechanism of Bie Jia Jian oral liquid (BOL).**

METHODS: **The model was induced by subcutaneous injection of CCl_4. BOL was administered and the change of serum hyaluronic acid (HA) and lamin in (LN) was observed and the degeneration of liver cells and the degree of fibre hyperplasia analyzed. Changes of ultra micro-structure in liver cells were observed in some samples.**

RESULTS: **HA was reduced in both the groups with low and high dosage of BOL, which showed a remarkable difference as compared with that of the model group (low dosage group: 376.15 μg/L±35.48 μg/L *vs* 806.07 μg/L±98.49 μg/L, *P*<0.05; high dosage group: 340.14 μg/L±30.18 μg/L *vs* 806.07 μg/L±98.49 μg/L, *P*<0.05). The LN content of low and high dosage group of BOL was lower than that of model group (low dosage group: 71.99 μg/L±8.15 μg/L *vs* 133.94 μg/L±14.45 μg/L, *P*<0.01; high dosage group: 71.68 μg/L±11.62 μg/L *vs* 133.94 μg/L±14.45 μg/L, *P*<0.01) and colchicine group (low dosage group: 71.99 μg/L±8.15 μg/L *vs* 118.28 μg/L±16.13 μg/L, *P*<0.05; high dosage group: 71.68 μg/L±11.62 μg/L *vs* 118.28 μg/L±16.13 μg/L, *P*<0.05). Examined by Ridit, BOL could reduce the degeneration and necrosis of liver cells (χ^2 = 11. 99 *P*<0.05), the degree of fibre hyperplasia (χ^2 = 13.24 *P*<0.05) and the pathological change of ultra micro-structure as well.**

CONCLUSION: **The BOL has certain therapeutic effect on the exp eriment hepatofibrosis. Its mechanisms might include: protecting the function of liver cells, inhibiting excessive synthesis and secretion of extracelluar matrix from hepatic stellate cells, relieving the capillarization of hepatic sinusoid, improving liver micro-circulation, and regulating immune function.**

INTRODUCTION

Since 1994, our research group has studied on anti-hepatofibrotic effect of the Biejiajian pill and Biejiajian oral liquid (BOL) in rats. It verified that both of them had fair effect on anti-hepatofibrosis[1-3]. Supported by the Natural Scientce Foundation of Zhejiang Province in 1999, we studied the anti-hepatofibrotic mechanism of BOL in rats again. Now we report the results below.

MATERIALS AND METHODS

Materials

Eighty SD rats, weighing (180±20) g, offered by Animal Centre of the Academy of Medical Sciences of Zhejiang Province. Fodder: maize powder (produced by Hangzhou Sijiqing Feed Factory); Lard (commercially supplied); Cholesterol (produced by Chemical Branch of Guangzhou Medicinal Company, batch number: 980503). Ethanol (A.R) (produced by Changyuan Chemical Plant of Changshu City, batch number: 980630). Medicines: All of the 23 ingredients of BOL are purchased from the Out patient Department of Zhejiang College of TCM, such as Biejia, Danpi, etc. appraised by the Department of Pharmacy. Colchicine (produced by Kunming Pharmacy Company, Limited. batch number: 980536). Reagents: CCl_4(A.R) (produced by Fenshui Synthesis Chemical Plant of Yixing City, batch number: 1995122). Liquid paraffin (C.P) (produced by Hangzhou Chemical Reagents Factory , batch number: 971020). HA and LN radioimmunoassay kits (afforded from Shanghai Navy Institute of Medical Science); main instruments: SN-688γ -counter (Shanghai Atomic Energy Institute); UV-754 ultraviolet-visible spectrophotometer (Shanghai 3rd Analytic Instrument Factory); MR4100 enzyme mar ker (American Dynatach Company); H-500 transmission electricmicroscope (Japanese Hitachi, Co).

METHODS

Animal model

All groups but the normal group received sc CCl_4 (A.R) 5 mL·kg^{-1} in the first day of experiment, afterwards sc 400 mL·L^{-1} CCl_4-liquid paraffin mixture 3 mL·kg^{-1} every 3 days; the normal group sc equal amount of 9 g·L^{-1} NaCl (NS), lasted 6 weeks. Except the normal group, every group was fed with mixed fodder (maize powder with 5 g·L^{-1} cholesterol and 200 g·L^{-1} lard) and drank 200 g·L^{-1} ethanol only. The normal group was fed with general fodder and water. The time required to complete the induction of model is 6 weeks.

Grouping

Thirty-seven established rat models were grouped into II-V groups randomly i.e. group II model control (n = 10), group III colchicine (n = 9), group IV low dosage of BOL (n = 9) and group V high dosage of BOL (n = 9). Another 11 normal rats served as normal control in group I.

Therapy

The BOL afforded by Zhejiang College of TCM, according to the ingredient of Jingui Biejiajian pill, which is recorded in an ancient medical book of TCM (Jinkui Yaolue). It contains crude Chinese

medicine 0.92 g per millilitre (that is 20 times the dosage used in adults). I, II group ig NS 10 mL/kg, III group ig 0.001% colchicine in distilled water of the dosage of 0.1 mg·kg^{-1}, IV group ig BOL 4.6 g·kg^{-1} and V group ig BOL 9.2 g·kg^{-1}. All groups had been treated once a day for 5 weeks and took water and fodder ad lib. For maintaining pathological attack, 400 mL·L^{-1} CCl_4-liquid paraffin mixture 3 mL·kg^{-1} once a week until the end of treatment was injected subcutaneously to the models of II-V groups. After the treatment, venous blood was collected from retrobulbar vein, serum was separated and preserved under -70℃ for test. HA and LN were examined by radioimmunoassay. The left liver lobe was dessected and fixated by 100 mL·L^{-1} formalin and embedded in paraffin, serially sectionalize d and then stained with HE observed under optical microscope. In case of observing the collagenous fiber hyperplasia Masson staining was employed. The standards for interpreting the degree of hyperplasia under microscope are in accordance to the criteria of the 5th National Academic Conference of Infection and parasitosis[4], and the degree of degeneration refers to the standard of reference[5].

Statistical analysis

Data described as $\bar{x}\pm s$ and analysed by F test, and *q* test was used to compare the data between 2 groups of multiple groups. The semiquantitative data was analysed by Ridit test. $P<0.05$ regarded as significant.

RESULTS

During the period of treatment, in gruop II2 rats died, 1 rat each died in group I, IV and V, and in group III no rat died.

Influence of BOL on serum HA and LN

Compared with model group, the serum HA of each treated group was lowered significantly ($P<0.05$). There was no significant difference between each treated group ($P>0.05$). This is in accordance with the results of other article[6]. Results of the serum LN: the difference between the colchicine group and the model group was not significant ($P>0.05$). Compared with the normal group, the LN of each treated group was raised signific antly ($P<0.01$). The LN in both low-and high-dose BOL groups were higher significantly than that of normal group ($P<0.01$) and colchicine group ($P<0.05$, Table 1). The difference between high-and low-dose BOL groups was not significant.

Table 1 Serum HA and LN in BOL treated SD rats ($\bar{x}\pm s$, μg·L^{-1})

Groups	*n*	HA	LN
Normal	10	197.77±26.02	42.78±10.05
Model	8	806.07±98.49^{b}	133.94±14.45^{b}
Colchicine	9	402.53±50.78^{a}	118.28±16.13^{b}
Low-dose BOL	8	376.15±35.48^{a}	71.99±8.15^{bdc}
High-dose BOL	8	340.14±30.18^{a}	71.68±11.62^{bdc}

$^{b}P<0.01$ *vs* normal group; $^{a}P<0.05$ *vs* model group, $^{d}P<0.01$ *vs* model group; $^{c}P<0.05$ *vs* colchicine.

Influence of BOL on liver hyperplasia and degeneration

Being analysed by Ridit ($\chi^2 = 13.24$, $P<0.05$, Table 2), we found that the treatment was relevant with the extent of liver hyperplasia. According to the average Ridit, the high-dose BOL group did the best in improving liver hyperplasia.

According to the results of statistical analysis ($\chi^2 = 11.99$, $P<0.05$, Table 3), we considered that the extent of liver cell degeneration was related to the treatment. Referring to the average Ridit, the effectiveness of improving the degeneration in high dosed BOL group was best, and model group had the worst result.

Table 2 Extent of liver hyperplasia in each treated group

Groups	*n*	Degree of liver fibrosis					Average of Ridit
		-	+	++	+++	++++	
Model	8	0	0	1	4	3	0.7247
Colchicine	9	0	1	2	4	2	0.5894
Low-dose BOL	8	0	2	1	4	1	0.5176
High-dose BOL	8	0	5	2	1	0	0.2364

$\chi^2 = 13.24$, $\chi^2_{(4)} = 9.49$.

Table 3 Liver cell degeneration in each treated group

Groups	*n*	Extent of hyperplasia					Average of Ridit
		-	+	++	+++	++++	
Model	8	0	0	2	3	3	0.7408
Colchicine	9	0	1	4	3	1	0.5584
Low-dose BOL	8	0	1	2	4	1	0.5599
High-dose BOL	8	0	4	3	1	0	0.2576

$\chi^2 = 11.99$, $\chi^2_{(4)} = 9.49$.

Electron microscopy

The nucleuses in liver cell of normal SD rats were circular or elliptic and located in the center of cell, the mito chondria were circular or elliptic, the ridges were clear, the Ito cell could be found in Disse's spaces, its cytoplasm contained plenty of fat droplets. Howeic, the nucleoluses disappeared, rough endoplasmic reticulums expanded obviously, the mitochondria were tumid, the ridges were broken or lacked, there were a great deal of fat droplets in the cytoplasm. Many collagenous fibers accumulated in Disse's spaces. The number of stellate cells and rough endoplasmic reticulum increased and surrounded by a large number of collagenous fibers. Compared with the model group, the fat droplets in liver cell of the high-dose BOL group decreased, the structure of nucleus was clear and the mitochondria were tumid lightly. Being observed under the electronic microscope the results of low dosed BOL group were similar to those of colchicine group. Their damage as lighter and more serious than that in model group and high-dose BOL group respectively (Figures 1-5).

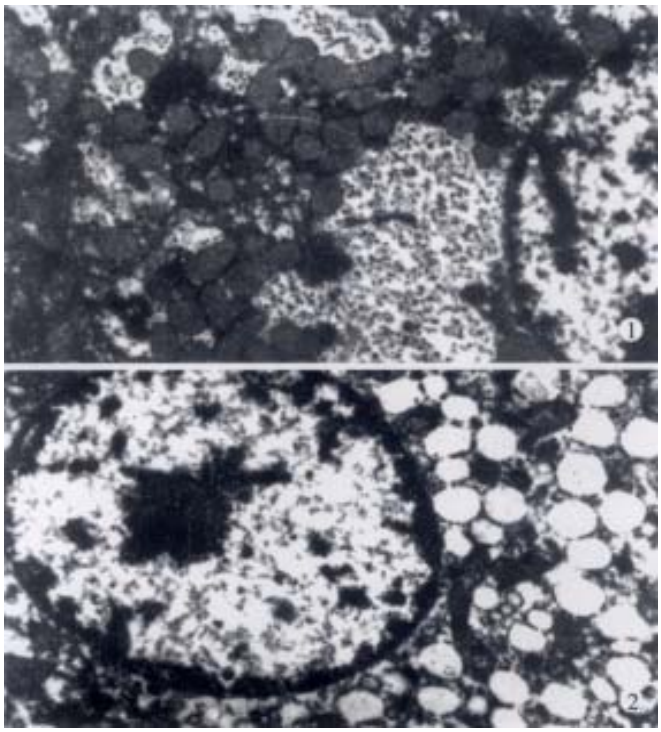

Figure 1 Normal group Showing clear liver cell structure with plenty of mitochondria and clear ridges, no fat droplets in cytoplasm. EM×6 000

Figure 2 Model group Showing few mitochondria without nucleolus, cell structure is not clear, a lot of fat droplets in cytoplasm. EM×4 000

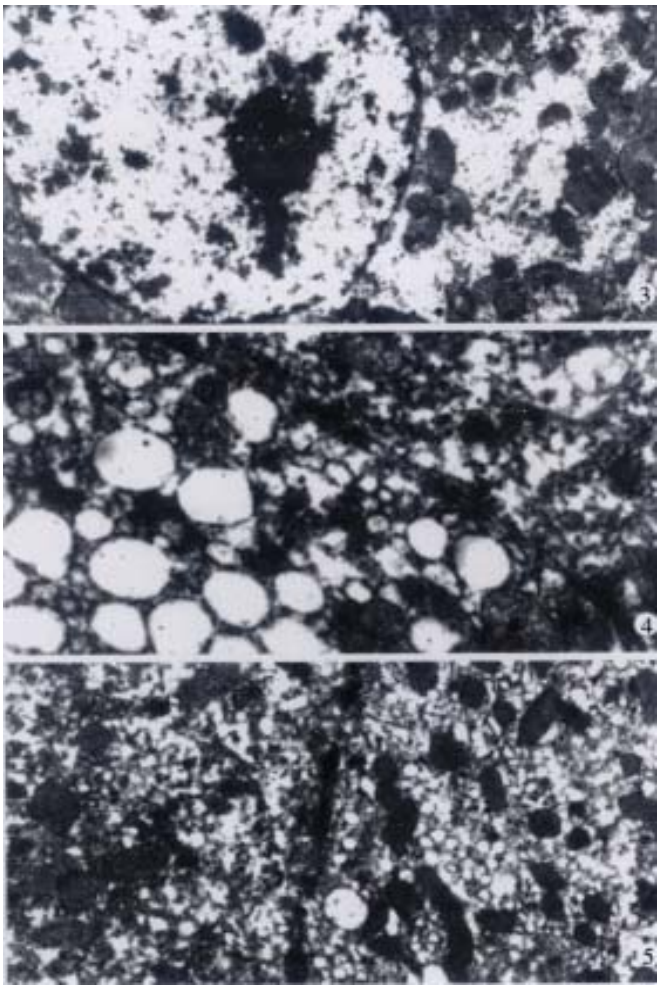

Figure 3 High dosed BOL group Showing clear nucleus structure, lightly tumid mitochondria and few fat droplets in cytoplasm. EM×4 000
Figure 4 Model group Showing many deposited fibers. EM×8 000
Figure 5 High dosed BOL group Showing few deposited fibers. EM×5000

DISCUSSION

Recently, studies on the prevention and treatment of liver fibrosis are very popular in China. Besides western medicine[7-11], single Chinese drug and its effective ingredients[12-19], anti-hepatofibrotic effect of Chinese complex formula[20-27] are also the main project in researches. These studies illustrate the mechanism and clinical effectiviness[28-32] in anti-hepatofibrosis from different point of view. Now, we will especially discuss the anti-hepatofibrotic mechanism of BOL.

The knowledge of liver fibrosis in TCM

Though the term, liver fibrosis, is not mentioned in the ancient medical documents of TCM, the corresponding clinical symptoms of this disease in TCM terms such as abdominal mass, costal pain, flatulence, jaundice, blood stasis, etc. are commonly noted. The clinical symptom of liver fibrosis is intricate. According to the theory of TCM, its basic pathogenesis is that: the condition is manifested as body resistance weakened while pathogenic factors prevailed, damp-heat and blood stasis coexisted, liver depressed and deficiency of *qi* and blood in spleen and kidney. Liver depression and *qi* stagnation can result in blood stasis, blood fails to nourish liver, and the key pathogenetic mechanism is blood stasis[33]. At the beginning, the pathogenetic mechanism is qi stagnation and blood stasis. If being treated unproperly, the disease will evolve into blood stasis mainly, then into a condition which manifests as blood stasis, body resistance weakened and excess in superficiality. The therapy is promoting the circulation and relieving the stasis, strengthening the body resistance to eliminate pathogenic factors, resolving and softening hard mass.

BOL is an improved preparation from Biejiajian Pill which is recorded in an ancient medical book (Jinkui Yaolue). Its ingredients include twenty-three herbs, such as biejia, taoren, danpi, shaoyao, dahuang, caihu, guizhi, banxia, houpu, renshen, e-jiao, huangqin etc. The combination of ingredients has the effect on promoting circulation and relieving stasis, strengthening body resistance and eliminating pathogenic factors simultaneously, resolving and softening the hard mass, which is conformable with the principle of treating liver fibrosis. The therapy of promoting blood circulation and cleminishing stasis has been adopted in clinic[34].

Inquiring into the anti-hepatofibrotic mechanism of BOL

At present, the mechanism of liver fibrosis is inferred that the pathogenic factors injure the liver cell and activate Kupffer's cells to secrete certain kinds of cytokines, which act jointly with other cytokines secreted by the platelets, hepatic sinusoid endotheliocytes, hepatocytes and some chemical intermediates to activate stellate cells, converting them into myofibroblasts, secreting a great deal of extracellular matrix(ECM). The increase of secretion and decrease o f degradation result in accumulation of ECM in liver, forming liver fibrosis gradually[35-39]. According to this experimental result, we suggest the main effect of BOL on treating liver fibrosis in four aspects as follows. ① Preventing the hepatocyte from degeneration and necrosis. The degeneration and necrosis of liver cell are the factors inducing excessive deposition of ECM, which takes an important role in the progression of liver fibrosis[40,41]. So, preventing the degeneration and necrosis of liver cell after being hurt can eliminate the promoting factor of liver fibrosis, preventing Kupffer's cells and stellate cells from being activated, inhibiting the progression of liver fibrosis. This experimental result shows that BOL can protect the liver cells from being harmed, reduce their d egeneration and necrosis, clean or partly clean the inflammatory reaction (also a promoting factor of liver fibrosis), all these demonstrate the good effect on treating liver fibrosis. ② Inhibiting the liver stellate cells to synthesize and secrete ECM. It is well known that liver stellate cells are the interstitial cells served as the main source of ECM. As the liver cells are injured, they will be activated, and increased, and then convert into the transitive type and myofib roblast which synthesize and secrete the ECM excessivly[40,42-44]. The collagens are the main elements of ECM. They are formed in rough endoplasmic reticulums of fibroblasts and are secreted as collagenous fibrils[45]. Both the number of stellate cells and rough endoplasmic reticulums of high dosed BOL group are less than those of model group, which indicates that inhibiting the activation and hyperplasia of the liver stellate cells maybe one of the effects of BOL to prevent and treat liver fibrosis. ③ Relieving the capillarization of hepatic sinusoid, improving the microcirculation of liver. The fenestrate on the hepatic sinusoid endotheliocyte is the site for exchanging materials between the liver cells and plasma. When liver fibrosis developed, ECM synthesized profoundly, deposited in Disse's spaces, forming the membranous spiral lamina under the hepatic sinusoid endothelium, fenestrate of hepatic sinusoid decreased or vanished and then forming capillarization, resulting in impairment of microcirculation, subsequently, affecting the exchange of the oxygen and substance of the liver cell seriously, thus bringing out or aggravating the damage of liver cell[45-48]. LN is the main glycoprotein of the membranous spiral lamina and distributes together with the IV type collagen in the liver. So its serum content is considered as a renewal index of membranous spiral lamina[49-51]. This experimental result indicated that: BOL can decrease the LN content in liver fibrosis, thus relieving the capillarization of hepatic sinusoid, improve the microcirculation of liver, reducing the damage of liver cell and accelerating the repairment of liver. This may be an

important effect of BOL on promo ting the circulation and transforming stasis. ④ Regulating the immune function, reducing the immuno-damage of liver cell. Some researchers[52] complain that the liver cirrhosis is the result of the immune function disturbance. According to our previous report[2], we suggest that BOL can adjust humoral immunity, reduce the immuno-damage of liver cell, improve the substance metabolism and protect the liver tissue from being injured.

Abstract

AIM: **To evaluate the clinical application of serial operations with preservation of spleen.**

METHODS: **Serial operations with preserving spleen were performed on 211 cases in our hospital from 1980 to 2000. The patient's age ranged from 13 to 56 years, averaging 38 years. Diseases included splenic injury in 171 cases, portal hypertension in 9 cases, splenic cyst in 10 cases, and the lesion of pancreatic body and tail in 21 cases.**

RESULTS: **All the cases were cured, and 129 patients were followe dup from 3 months to 3 years with the leukocyte phagocytosis test, detection of immunoglubin, CT, ^{99m}Tc scanning and ultrasonography. The results were satisfactory.**

CONCLUSION: **The operations with preserving spleen were safe, feasible, and worth of clinical application.**

INTRODUCTION

Serial operations with preservation of spleen, which are mainly performed to treat splenic injury, in addition to portal hypertension, splenic cyst and lesion of body and tail of pancreas, were performed in our hospital on 211 cases from the early 80s to January 2000. The clinical application study on preserving spleen is reported below.

CLINICAL MATERIALS

Among the 211 patients, including 165 males and 46 females, with average age of 38 years (range 13-56 years), 171 had splenic injuries complicated with hepatic lacerations in 9 and 18 hemorrhagic shock in 17 and mesentery lacerations in 21, portal hypertensions in 9, 10 splenic cysts in 10 and lesions of body and tail of pancreas in 21 which included 8 pancreatic cyst adenom as and 3 pancreatic pseudocysts and 3 insulinomas and 7 pancreatic injuries. All the injuries were abdominal closed injuries. All the patients were cured, and 129 patients were followed up from 3 months to 3 years with the leukocyte phagocytosis test, detection of immunoglubin, splenic CT scan, ultrasonography and Technetium ^{99m}sp lenic scan. The results of following up were satisfactory (Table 1).

Table 1 Operative procedures of preserving spleen

Diagnosis	Operative procedures	*N*	Rate (%)
Splenic injury	Arresting bleeding by adhesion	9	4.3
	Suture and repair	19	9.0
	Ligation of splenic artery	7	3.3
	Partial splenectomy	27	12.8
	Ligation of splenic artery plus Suture and repair	23	10.9
	Suture and repair or adhesives plus partial splenectomy	28	13.3
	Autosplenosis after splenectomy	58	27.5
Splenic cyst	Partial splenectomy	5	2.4
	Autosplenosis after splenectomy	2	1.0
	Paracentesis under BUS	3	1.4
Portal hypertension	Subtotal splenectomy and splenorenal venous shunt	9	4.3
Lesions of body and tail of the pancreas	Resection of the body and tail of the pancreas with preservation of spleen	21	10.0
Total		221	100

METHODS, RESULTS and DISCUSSION

Spleen is not an essential organ to life, though it has many important functions[1,2]. Tempestuous bleeding and h emorrhagic shock are the most commont manifestation of splenic laceration, which are often complicated with other organ injuries and need to be rescued rapidly and decisively following the fundamental treatment principle (or golden standard) of splenic injury-saving life first, preserving spleen second. It is the modern viewpoint that we should do our best to preserve the spleen (tissue) if it permits. In this study, 58% of the cases with splenic injury underwent total splenectomy, which was nearly 61% reported by Livingston, and 63% of the m underwent autosplenosis after splenectomy when the patients' vital signs were permitted. We realized that in treating splenic injury, the fundamental principle is "saving life first, preserving spleen second"; the younger the patient is, the more precedent the spleen-preserved operation is chosen; choose the best operative procedure according to the degree and type of splenic injury; and it is more safe and practical to combine with several operative procedures in preserving spleen.

It is controversy whether the spleen of the patient with portal hypertension should be preserved[3-8]. It was reported that 31% of patients with portal hypertension had immunologic function[9-12]. It has more practical significance for patients with portal hypertension to undergo the operation that can not only protect the immunologic function of spleen but also eliminate the hypersplenism, which is the source of Warren's operation[13-16]. The effect of Warren's operation is not satisfactory in China because post-hepatitis cirrhosis is more

frequently encountered and splenomegalia and hypersplenism are more severe[17-20]. It is difficult to improve the hypersplenism if the spleen has been preserved[21-26]. According to this point of view, we designed the subtotal splenectomy and splenoren al venous shunt by artificial vessel bypass to treat portal hypertension. In all the 9 cases, 1-3 years' postoperative follow-up gave no evidence of recurrent bleeding. It also showed that the hypersplenism relieved and the residual spleen had immunologic function. The significance of this operative procedure is: This operative procedure of preserving spleen is also fit for portal hypertensio n provided we follow the principle of partialsplenectomy, This method does not only eliminate hypersplenism but also preserve the spleen and its immunologic function; and this gives a new way to treat portal hypertension.

Spleen is located near the body and tail of pancreas. When we dealt with the lesion of the body and tail of pancreas previously, we always resected the spleen, though the spleen was healthy, which is called "innocent splenectomy". In fact, the blood supply and function of spleen can b e preserved even if splenic artery is ligated or resected. In this study, 21 cases of distal pancr eatectomy with preservation of spleen were performed. This operative procedure can be classified into two types, one is conservation of splenic vessels (14 cases), the other is conservation of short gastric vessels and left gastropepipolic vessels (7 cases). The former operative procedure is the first choice, because the original blood supply and anatomy of spleen are intact. The latter is the second choice, because the splenic blood supply is influenced and the splenic clearance ability to bacteria is decreased.

Splenic cyst is a benign lesion of spleen, so we should try our best to preserve the spleen and its function[27-30]. If the congenital or acquired splenic cyst is small or symptomless, usually no treatment is needed. If the splenic cyst is big or located at the hilus of spleen or complicated with secondary infection or might autorupture or causes symptoms, it should be treated with cystectomy which mainly includes partial splenectomy (5 cases in our group) and autosplenosis in omental bursa after splenectomy (2 cases). The former operative procedure can preserve the splenic function better. If the patient does not accept the operation or cannot tolerate the operation, we can use the method of splenopuncture drainage under BUS guide (3 cases), its therapeutic effect is definite and can be performed repeatedly. But splenic cyst is liable to relapse (2 cases) and to be infected secondarily, which influences the late results. This method is the second choice and it is especially prohibited when applied for parasitic splenic cyst[31-36].

We should master the types of spleen-preserving operation and choose suitable operative procedures according to splenic injury degree correctly[37-39].The degree of splenic injury is the pathological foundation of spleen -preserving operative procedure[40]. Classification and standard for splenic injury[41-44] varied among different countries. We should set up a new classification of splenic injury degree based on our national conditions and the development of splenic surgery soas to facilitate the academic exchange and the statistics and analysis of document. By synthesizing 121 cases of splenic injury treated in our hospital, we put forward the IV degree clinical classification of splenic injury and corresponding spleen-preserving operative procedures (Table 2). Degree I:rupture of splenic capsule or solitary and multiple splenic laceration , length<5.0 cm, depth<1.0 cm; Degree II: solitary or multiple splenic lacerat ion with intact splenic hilus, length >5.0 cm, depth>1.0 cm; Degree III: irregular laceration, with destroyed splenichilus or a part of spleen broken; Degree IV: spleen is widely broken, capsule is widely peeled, the trunk of splenic vessels are destroyed or broken. The characters of this classification are: simple, convenient and practical; including all the injury types from capsule to parenchyma, from branch to trunk of splenic vessels; the splenic injury degree is classified by quantified index and can be judged promptly; it meets with the common mechanism of splenic injury in our country to date; it stems from practice and can help choose treatment principle and spleen-preserving operative procedures clinically. In clinical practice, the degree of splenic injury can not be as classical as the standard of splenic injury classification. No operative procedure can fit all the patients with splenic injury. We should flexibly choose and use several operative procedures jointly based on the indication and basic skill of the operative procedure. And we should not use some spleen-preserving operative procedure mechanically. Among all the 211 cases of spleen-preserving operations performed in our hospital, 171 cases (81.0%) were splenic injuries, including 9 cases by arresting bleeding by adhesion, 19 cases by suture and repair, 7 cases by ligating splenic artery, 23 by ligating splenic artery and suture and rep air, 28 by suture and repair and arresting bleeding by adhesion plus partial splenectomy, 27 by partial splenectomy, and 58 cases by autosplenosis after total splenectomy.

Table 2 The degree of splenic injury and the choice of therape utic method

I	Nonsurgical treatment
	Arresting bleeding by adhesion
	Suture and repair
II	Partial splenectomy
	Binding the rupture of spleen
III	Ligation of splenic artery
IV	Splenectomy plus autosplenosis

Grasping the main technical points of spleen-preserving operation is the most important factor in the serial operations with preserving spleen.

Suture and repair of the rupture of spleen

The parenchyma of spleen is fragile like bean curd so that suturing and knotting often tear it open, which is liable to cause bleeding or impediment of blood supply[38,39]. We met two cases. One bled to bleed more and more seriously during suturing, so we had to perform total splenectomy because of the turbulent life sign. The other case had to undergo upper-half splenectomy because of the impediment of blood supply res ulting from wide and deep suturing. The width and depth of the suture should be proper, the strength knotted should be well distributed, drawing dexterously and knotting slowly. In order to prevent the second knot from cutting the spleen tissue, or the first knot sliding and loosing while making the second knot, the first knot must be pressed with forceps. To prevent the thread cutting the spleen tissue, a pad of galform or with a piece of omentum beneath the rupture should be used for the knotting. If the suture and repair of the spleen failed or new rupture and bleeding occurred, we should change the operative procedure decisively instead of sticking to suturing and repairing.

Partial splenectomy

Partial splenectomy means less than half of splenectomy, half splenectomy and subtotal splenectomy. We should handle the corresponding blood vessels near the rupture of spleen with each bundle, and observe the boundary of blood supply of spleen, which is the relative avascular plane[40,41]. The "U" shaped interlock suture was performed withdrawing 0.5cm from the boundary to blood supply side. The spleen was excised with forcipressi on. If blood still oozes from the splenic cross-section, wet gauze was used to hemostasis by compression, or "8" shaped suture was made. We covered the cross-section with the capsule pealed off from the cut spleen, and immobilized the capsule on the cross-section with round needle and 1# thread. The advantages of this method are: transplanting splenic capsule can prevent bleeding or liquefaction and necrosis of the cross-

section; the transplanted capsule made the cross-section peritoneal metasplasia, which can decrease the chance of abdominal adhesion; omentum was not used to cover the cross-section rountinely, which reduced the interruption of the abdominal cavity, pre serving the function of the omentum. The splenic capsule is a tissue containing serous coat of its off, so transplanting splenic capsule has a high success rate; the collagen of the transplanted capsule is exposed, which facilitate activating coagulation system to hemostasis effectively and eliminate the dead space. This method has been used in handling the cross-section of partial spleen transplantation. The cross-section is still in good condition after rejection occurred several times. In this group, 41 cases underwent partial splenectomy, including 27 cases with splenic injury, 5 cases with splenic cyst and 9 cases with portal hypertension.

Autosplenosis

After the spleen is excised, it is washed with cold normal saline and put into the 4℃ Hartmann solution[45]. The abdominal cavity was washed and the splenic capsule pealed off and the slice of spleen tissue prepared. The spleen slices of 2.0 cm×2.0 cm×0.4 cm made from 1/3 of the spleen were put into the space between the anterior and posterior lobe of great omentum rich in blood supply. We found that peeling off the capsule facilitates the establishment of blood supply between the graft and the transplantion space, making the hormone from the spleen come into blood cir culation easily. We suggest that autosplenosis should be performed in the omental bursa by transplanting the little splenic cubes peeled off the capsule. In our study, 60 cases of autosplenosis after splenectomy were performed, including 58 cases with splenic injury and 2 cases with splenic cyst .

Resection of the body and tail of the pancreas with preservation of spleen

Dissociating the posterior pancreas space: Dissect the gastrocolic ligment out of the gastro epiploic vessels, then come into the lesser omental bursa, and expose the body and tail of pancre as and the pedicle of spleen[46-49], and protect the short gastric vessels extremely[50,51]. In the avascular area between the upper and lower edge of the body and tail of the pancreas, incise the posterior peritoneum along the pancreas longitudinally, an d dissociate the soft tissue behind the pancreas bluntly to join together with right index finger[52-55]. And then the body and tail of the pancreas and the splenic vessels are dissociated completely with the tissue around them[56-58]; Exsecting the pancreas: Exsect the pa ncreas at the proximal end of the pancreas where you want to cut, and ligate the pancreatic duct, then suture the proximal end of the pancreas with silk thread interruptedly; Dissociating splenic vessels: Clamp the distal end of the pancreas with Kocher's forceps, dissociate the splenic vessels from the pancreas tissues towards the tails of pancreas and protect the splenic vessels, which is called antidromic dissociated method (10 cases)[59-62], on the cont rary, dissociate the splenic vessels from the tail to the proximal end of pancreas, which is called anterograde dissociated method (4 cases). The former method is more commonly used in clinic, because it is difficult to recognize the tail of the pancreas from the fat tissue around t he pedicle of spleen, and the vessels of the tail of the pancreas remified to many thin branches. The resection of the body and tail of the pancreas comes to an end when the splenic vessels are dissociated from the pancreas tissues completely. When the adhesion between the splenic vessels and the pancreas tissue is wide and inseparable and it is too difficult to preserve the spleen vessels, the trunk of splenic vessels far away from the splenichilus and near the tail of the pancreas (1.0 cm from the branch of splenic vessels at least) should be ligated. At this moment, the preserved short gastric vessels and left gastroepiploic vessels supply the blood of spleen (7 cases). To the resectied body and tail of the pancreas with preservati on of spleen and its vessels, the splenic vessels should be immobilized properly because the ve ssels losing the support of the pancreas are easy to twist and bend. For those with preserved short gastvic vessels and left blood vessel of gastric omentum for the blood supply of pancreas, the breaking end of splenic vessels should be ligated exactly. Finally, check the colour and activity of spleen before close the abdomen[63,64].

Abstract

AIM: **Clinical application and potential complication of percutaneous transsplenic varices embolization (PTSVE) of esophageal or gastrio-fundal varices in patients with hepatocellular carcinoma (HCC) complicated with portal vein cancerous thrombosis (PVCT).**

METHODS: **18 patients with HCC complicated with PVCT and esophageal or gastrio-fundal varices who underwent PTSVE were collected. The rate of success, complication, mortality of the procedure and postoperative complication were recorded and analyzed.**

RESULTS: **PTSVE were successfully performed in 16 of 18 cases, and the rate of success was 89%. After therapy erythrocyte counts decreased in all of the natunts. 5 of patients needed blood transfusion, 2 patients requiredsurgical intervention because of and 11 patients with ascites were alleviated by diuresis. Among these 18 patients, the procedure-related mortality was 11% (2/18), one died of acute hepatic failure on the forth day after procedure, another died of acute renal failure on the fifth day. The patients were follow up for 1-12 mon exceptone. 13 of them died of their tumors but none of them experienced variceal bleeding.**

CONCLUSION: **PTSVE is a relatively safe and effective method to treat esophageal or gastrio-fundal varices in HCC patients with PVCT when percutaneous transhepatic varices embolization (PTHVE) of varices is impossible.**

INTRODUCTION

Hepatocellular carcinoma (HCC) is common in china[1-8] and many complica tions occur[9-13] including ascites, portal hypertension and splenomegaly. Reviewed literatures, we found there are many articles about treatment of HCC[2,4,11,14-32] or varices[33-38], but few relering the treatment of HCC complicated varices[39-41]. The percutaneous transhepatic variceal embolization (PT HVE) of gastroesophageal varices is a highly promising procedure for controlling acute variceal hemorrhage and decreasing the mortality in patients with portal hypertension. However there are limitations of PTHVE application, because the natench of the main trunk of portal vein is reauired, which was limited its use. Thus, it is very important to find another route to catheterize into portal vein in patients whose portal vein were invaded by HCC. In order to control variceal hemorrhage in these patients it is very important to find another approach for catheterizing into their portal vein. From 1999-08 to 2001-01, 18 HCC patients with portal vein cancerous thrombosis (PVCT) underwent percu taneous transsplenic embolization (PTSVE) of esophageal or gastrio-fundal varices in our institution as reported here.

MATERIALS AND METHODS

Patients

18 patients (17 male, 1 female, mean age 48 yr, aged from 29-72 yr) of HCC with PVCT enrolled in to this study. The diagnosis of HCC with esophageal or gastrio-fundal varices was made by clinical history, alpha-fetoprotein (AFP), ultrasound, CT or MRI. 4 of the patients experienced variceal hemorrhage in different degree and 1 patient had seven episodes of serious variceal bleeding before therapy.

Varices classification

According to Burcharth *et al*, varices were classified into 4 grades: 0 means no varices were visible; 1 grade: only tiny va rices were visible; 2 grade: varices were distinctly visible, and 3 grade: severe varices were seen.

Clinical data

According to the Child-Pugh scores, 10 patients were Child A and 8 patient s were Child B. Patients' average platelet counts were 83. 2×10^9, ranged from (11 to 195)$\times1\ 0^9\cdot L^{-1}$, and 3 patients had accepted 4 units blood transfusion due to decreased erythrocyte before thera py. The slight or moderate ascites were observed in 10 patients.

Pre-operative preparation

The patients with ascites were given albumin and diuretics. The patients have not underwent PTSVE until the ascites were alleviated. CT angiography (CTA) or MR angi ography (MRA) of portal venous system was necessary to show patients' splenic vein and its tributary[42], main trunk of portal vein and esophageal or gastrio-fundal varices in order to obtain the inlormations of the site, direction, and depth of puncture before therapy (Figure 1).

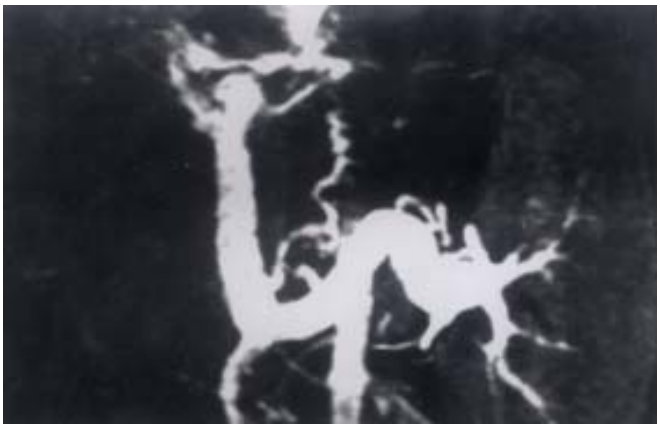

Figure 1 CTA of portal vein that show tributary of splenicve in clearly.

Procedure

For clearly visualization of portal venous system and varices, indirect or direct portography was performed on Natie nt them.

Indirect portography

The indirect portography was performed after 5F RH catheter was catheterized into patient's splenic artery via left or right femoral artery approach. 40 mL cont rast medium (Ultravist 300, Schering AG or Omnipaque 300, Nyegarrd) were injected into the splenic artery at a speed of 7 mL·s^{-1}. The film were exposed 1 picture·s^{-1} for 10 s until the main stem of patients' splenic vein and portal vein were clearly displayed. The tip of catheter was to be kept in the site for localization of the puncture.

Direct portography

The puncture site was determined on the basis of CTA or MRA images of portal vein s. Usually the seventh to ninth intercostal space on the left midaxillary line was selected as the puncture site. Local anaesthesia was followed by percutaneous transsplenic puncture using a 21 G Chiba needle. The core of needle was removed and the needle was pulled back slowly with intermittent aspiration. When blood can be freely aspirated, 5 ml diluted contrast medium (1:3) was injected as test. If patient's splenic vein was displayed clearly, a 0.018" (0.457 mm) guidewire was introduce d and manipulated into the main stem of portal vein through the needle. Then the needle was withdr awn and replaced by a COPE puncture cannula system. A 5F catheter's sheath was pushed into patient's splenic vein through the exchanged 0.038" (0.968 mm) guidewire. After a 5F pigtail catheter was put in patient's superior mesenteric vein (SMV), the direct portography was performed with 40 ml contrast medium injected into patient's SMV at a ratio of 7 mL·s^{-1}.

Variceal embolization

A 5F Cobra or Simmons I catheter was catheterized into patient's varices. Abs olute alcohol, gelfoam and steel coils were used as embolizational material. When the variceal vessels were occluded or the blood flow in varices was very slow, the varices were considered completely embolized. Then, the catheter was removed and the sheath was pulled back to the edge of the parenchyma of spleen. The duct of puncture was embolized by gelfoam and steel coil till the main stem of splenic vein was not displayed when the contrast medium was injected.

Post-operative management

Routine post-operative management included hematischesis, hepatic function protection and anti-infection. Hepatic function and hematocyte were examined d 2 and d 5 after procedure. Abdominal symptom and body temperature were recorded too. B ultrasound, CT or MRI was followed in 9 patients 1 wk after operation. It was considered the proof of infection that high body temperature (> 38.5℃) and high leucocytic counts (>10×10^{9}·L^{-1}), persisted longer than 7 d.

Follow-up

Survival time and post-operative bleeding rate were recorded in 15 patients in whom the follow up was done.

RESULTS

Rate of success

The branches of splenic vein have been successfully punctured in 16 of 18 patients and esophageal or gastrio-fundal varices were embolized in the patients except 1 one patient with slight varices. The success rate of PTSVE was 89% (16/18). The other 2 patients whose PTSVE was unsuccessful didn't undertake the CTA or MRA examination before treatment.

Portography

Hepatofugal blood flow in portal vein was observed in 16 patients. The main stem of portal vein obstructed and collateral circulation occurred in 14 patient s. Grade 1 varices in 1 patient, Grade 2 in 4 patients, and grade 3 in 11 patients were observed (Figure 2-4). Among 3 patients whose varices fallen in grade 2, 2 patients had spontaneous splenorenal shunt and another one had spontaneous portacaval shunt.

Complication and mortality

All patients' erythrocyte counts were decreased after the procedure and 5 of them needed blood transfusion. 2 patients experienced hemoperitoneum and 1 patient had mild reactive pleural effusion. All of these counlications were alleviated by conservative treatment. 11 patients had mild or moderate ascites because of severe hypoproteinemia which was controlled by supplying albumin and diuresis (Table 1). Hepatic functions didn't deteriorate in the patientexcept one who had thrombosis in the main stem of his portal vein and died on the forth day after therapy. Another patient died of acute renal failure on the fifth day after therapy. The procedure-related mortality was 11%(2/18). No severe infection was observed. 9 patients undertook B ultrasound, CT or MRI 1 wk after procedure and no hamatoma in spleen surrounding area was displayed.

Figure 2 indirect portography via transsplenic artery show splenicvein and its tributary.

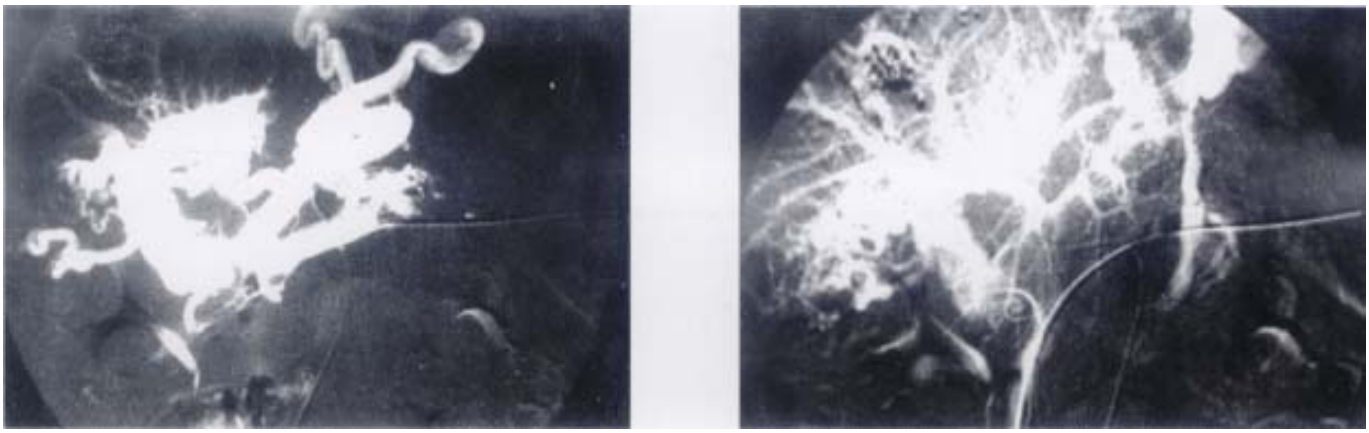

Figure 3 direct portography show main portal vein obstruction and the varices.

Figure 4 the same patient as figure 3, the variceal blood flow was turned slowly after embolization.

Table 1 Postoperative data of 18 HCC patients received PTSVE

Code/Survival	Reconstitu-tion of the portal vein	Operative Success	Blood infusion (Unit)	Ascites	Post-operative bleeding	Other complications

*Patient with slight varices which needn't to be embolized.

Follow up

15 of 16 patients whose varices were successfully embolized had been followed up 1 to 12 mo. During the follow-up 13 of these 15 patients died. The cause of death was hepatic failure in 7 patients (1 in 4 d after procedure, 1 in 1 mo, 2 in 3 mo, 2 in 6 months, 1 in 8 mo). One died of acute renal failure in the fifth day after therapy, 2 died of metastasis, 2 died of ulcer bleeding which were conformed by gastroscope, 1 committed suicide. In the 2 failed cases, one was dead, the other was beyond follow up.

7 of the Nationls was died of hepatis failure which was the main ocuse of the do nth the causes of the ather 6 Natient were different. They night died of acute read failuisinth fifth day after the rany (Icase), of metastasis (2 case), of wher bleading (2 case) and committted suiside (1 case).

DISCUSSION

Interventional treatments include two different way, one is shunt (for example: transjugular intra-he patic portosystemic shunt, TIPSS), and the other is varices embolization[33-36]. There are some defects of TIPSS: proximal shunt can decrease hepatic blood flow in portal vein, which makes hepatic function deteriorated and restenosis rate high. Traditional embol ization route includes transhepatic and transumbilical vein and celiotomy incision to puncture branches of SMV. The latter two have been abandoned because of difficult operation and traumatic problem.

Percutaneous transhepatic variceal embolization (PTHVE) may be useful to control acute variceal bleeding and decreasing mortality. Since PTHVE is less traumatic and it s success rate is high, some authors apply PTHVE as a prophylactic management for the patients wit h severe varices in whom the rate of bleeding is high. However, the premise to perform PTHVE is that main portal vein must be patent and there is no tumor on the route of puncture. HCC has a high in cidence in our country. Advanced HCC usually complicated with portal vein cancerous thrombosis (PVCT) which deteriorated the previous portal hypertension. In such patient there was a high incidence of esophageal or gastrio-fundal variceal bleeding. Since main portal vein is invaded and obstructed by HCC and the tumor always impedes the puncture route, the utility of PTHVE is limited. Basing on PTHVE and percutanous transsplenic portography[43], we designed PTVSE to avoid puncturing obstructed main stem of portal vein and to treat embolus in portal vein in addition.

In 16 of 18 patients, the splenic vein was punctured, and superselective catheterization into varices was done successfully. In order to determine the puncture site, most of the patients undertook pre-operative CTA or MRA of portal vein and indirect portography via splenic artery. The rate of success of PTSVE in this group was 89%

(16/18), similar to PTHVE and Liang's report in which 16 of 17 transsplenic portography were done susccsshully under B ultrasound guidance[43]. We find that only Rasinska has reported one case treated by PTVSE in 1987 through our review.

It is suggested that transsplenic puncture might lead to hamorrhage because of d ecrease of erythrocyte counts after procedure in all patients. But in most of cases, it didn't need blood transfusion except 5 patients who accepted 2 to 4 units of blood transfusion. Hemoperitoneum occurred in two cases and slight reactive pleural effusion occurred in one. Both of the complications could be alleviated by conservative treatment. Portal vein thrombosis developed in 1 case within 4 d and led to acute hepatic failure. 1 case experienced acute renal failure within 5 d. Both of them died. Procedure- related mortality was 11% (2/18). Examination in 9 patients by imaging modalities 1 wk after procedure, no hamatoma was found around spleen. In addition, 11patients developed slight or moderate ascites after procedures that were alleviated by heteropathy. No severe infection occurred in all 18 patients. It is suggested that PTSVE be a safe technique relatily[43]. However PTSVE is not the first choice of treatment when PTHVE can be performed because its mortality was higher and may lead to hamorrhage compared with.

No esophageal or gastrio-fundal variceal bleeding occurred in the 15 patients during follow-up. Only two cases had bleeding due to gastric ulcer verified by gastroscope. It is also suggested that PTSVE be relatively effective in short term and similar to PTHVE. Since the life expectancy of patients of HCC complicated with PVCT is short, the long-term follow up seems to be unnecessary.

Abstract

ATM: **To describe a rapid technique for procurement of donor liver with aortic perfusion only (APO).**

METHODS: **Only the aorta is cannulated and perfused with chilled preservation solution.**

RESULTS: **The quality of donor liver can ensure the grafted liver functions.**

CONCLUSION: **The method of APO can simplify the operative procedure, compared with the dual cannulation. It also can minimize the danger of injuring vascular structures and involve less dissection.**

INTRODUCTION

A rapid technique of harvesting the donor liver helps to ensure the quality of the grafted liver. The aim of this report is to describe a simple and rapid method for procurement of the donor liver using aortic perfusion only.

Operative procedures

Organ preparation

At induction of anaesthesia, cefuroxime and methyprednisolone are given intravenously to the donor. A midline incision is made with electrocautery from the suprasternal notch to pubis. The sternum is spilt with a sternal saw, and hemostasis is obtained. Self-retaining retractors for the sternum and the abdominal wall provided excellent exposure. At this point the liver is evaluated, with particular attention paid to its consistency, color, and size. The liver is mobilized first by dividing the falciform ligament down to the suprahepatic vena cava. The left lateral section of the liver is mobilized by dividing the left triangular ligament and lesser omentum. At this stage it is important to check for a accessory left hepatic artery (HA) coming off the left gastric artery (LGA). The right colon and the caecum are mobilized together with the mesentery of the intestine to expose the aorta, superior menteric artery (SMA), inferior vena cava (IVC), left renal vein and inferior mesenteric vein (IMV). The IMV is ligated and divided. Both ureters are identified and slung with vascular loops. The first step is the dissection of the IVC from above its bifurcation to the left renal vein level, with a No. 1 silk encircled above the bifucation. A small segment of the aorta just above the bifurcation is cleared, and the No. 1 silk ties are looped at two sites above the bifurcation. The aorta is dissected to view the SM A. The inferior mesenteric artery (IMA) may be ligated and divided with 3-0 vicryl sutures to prevent loss of cold perfusion. The fundus of the gallbldder is incised and the bile is washed out with saline using a 50-mL bladder syringe. The duodenum is Kocherised then a search is made for an anomalous right hepatic artery arising from the SMA, which occasionally can be the only artery to the liver[1-3]. This is found by palpating for a pulse behind the portalvein. If the arterial anatomy is normal, the gastroduodenal artery is then ligated and divided, thereby bringing into view the portal vein. The oesophagus is taped with a red rubber for retraction t o facilitate the dissection of the supracoeliac aorta, which is mobilized by incising the right d iaphragmaticcrus between the oesophagus and the inferior vena cava. The SMA is dissected to its origin from the aorta. It is essential to examine again for an abnormal left hepatic artery arising from left gastric artery[2] before dissecting the tissues around the oesophagus. A tape is then passed around infradiaphragmatic aorta. 3 bowls with ice slush are prepared on the bench table, two containing one sponge and the other containing four sponges. If cardiac transplantation is also occurring, the heart teams come in at this stage and prepare their organ for retrieval.

Cannulation

The donor is systemically heparinised at a dose of 300 U/kgbody weight, lasting about 3 minutes. A large cannula (Wire Reinforced Venous Return Catheter with TF 28 diameter and 35 cm in length) previously flushed with preservation solution is p laced in the distal aorta and fixed; care should be taken not to insert the tip of the cannul a beyond the origins of the renal arteries. The lower end of the IVC is tied off with the silk tie in place, and a large aortic clamp is simultaneously used above supraceliac artery to cross clamp. The aorta line clamp is then opened to flush the liver with 4 liters Ross solution. The suprahe patic inferior vena cava is opened at its entrance to the heart and blood is vented into the pericardium and pleural space. Cold packs are put over and under the liver and also over the kidneys and slush are poured into the abdominal cavity to facilitate rapid cooling of the viscera. Four litres of Ross solution and two litres of UW solution (each liter of UW solution containing 15mg of dexa methasone and 40 units of insulin) are used for the perfusion.

Organ retrieval

When the effluent clears and the liver is cold, in the bloodless field, the infr ahepatic IVC is opened and transected above the renal veins. The diaphragm is divided on the left side down to the aorta avoiding the oesophagus. The pericardium and the posterior wall of the suprahepatic IVC are divided. The hepatic hilar dissection commences with dissection of the common bile duct (CBD) inferiorly. It is divided low behind the head of the pancreas, the stump being marked with a 5-0-prolene stitch. The SMV is followed behind the head of

pancreas tow ards the portal vein. The branches of SMV are dissected and ligated. The lower part of SMV is divided, and the origin of spleen vein is ligated and dissected. The PV and SMV are harvested tog ether. The aorta is opened from the bifurcation to the origin of SMA. The LGA and the splenic artery are ligated and divided close to the stomach and the splenichilum, respectively. The possible existence of an abnormal right hepatic artery from the SMA still needs to be ruled out by careful examination. The duodenum is then dissected off the pancreas. The origin of the coeliac artery is identified within the opened aorta and cannulated with an infant feeding tube probe to ensure the supply to the liver. The presence of any accessory hepatic arteries from either the SMA or the aorta must be excluded again[3]. If no abnormal arterial anatomy is found, a patch of aorta and SMA combining the coeliac artery and the common hepatic artery with a part of pancre as are completely retained until the next step that is to remove en bloc. The right diaphragm is incised from anterior to posterior down towards the upper pole of the right kidney, a generous patch of diaphragm left attached to the liver. The right side is protected by gentle down ward traction, with careful division of the hepatorenal ligament. When the diaphragmatic attachment of the liver freed, the liver vasculature is delineated; the remaining diaphragamatic and peritoneal attachments are divided. The liver is removed and put into an ice bowel over a cold abdominal pack containing cold normal saline solution. The portal vein is cannulated and perfused with some UW solution, and the liver is put into a bag and packed for transport in this UW solution. Both iliac arteries and veins are routinely removed from the donor for possible use in artery or portal vein reconstruction in the recipient. These vessels can be preserved in specimen bottles containing UW solution and transported in the same ice chest as the liver.

Table work and liver storage

Trimming of the liver is carried out under in a sterile operating theatre, the liver being kept in the same basin containing cold UW solution. The aorta is first divided and infant-feeding tube 5F is used to delineate arterial anatomy from the aortic patch towards the liver. The tissue around the vessels is excised, and all of the major arterial branches are ligated except for one or two, which may be left to check after the anastomosis. The divided common bile duct is flushed with cold saline using the larger infant feeding tube until the effluent clear. The biliary tract is not usually dissected to prevent devascularisation of the bile duct. Further preparation of the common bile duct is left until biliary reconstruction is being performed in the recipient. The inferior vena cava is prepared by excising the patch of diaphragm around the suprahepatic vein lumen. Excising the adrenal tissue and carefully ligating the right adrenal veins similarly cleans the infrahepatic ven a cava. Sometimes it is helpful for the operator to insert their finger into the lumen of inferior vena cava to provide guidance to the dissection. All of the redundant tissues attaching the liver should be cleaned up, and the opening of the vessels should be sutured with 5-0 prolene sutures. Liver biopsy is routinely done. The Donor liver is also weighed and recorded. The first bag containing the donor liver is tied and put into another bag containing cold saline and the 2nd bag is tied again and put into the 3rd bag and tied. The bags are placed in a box containing ice with the lid tightly seale d and the bag placed into a large box containing ice.

DISCUSSION

Since the earliest description of a standardized technique for multiple organ procured by Starzl *et al*[4], modifications have been suggested to simplify the operative methods and minimize the risk of damage to the graft[5-7]. Ville de Goyet[8] *et al* have previously reported that APO has no detrimental affect on the graft liver function in either adult or pediatric transplant patients. Effective liver perfusion occurs in the APO via the aorta and hepatic artery, but also via the portal vein after the fluid has traversed the intestinal circulatory bed (Figure 1). The donor liver is in fact perfused with the cold solution from both of HA and PV, thereby rende ring the liver with APO safe for grafting as shown in our previous report[9].

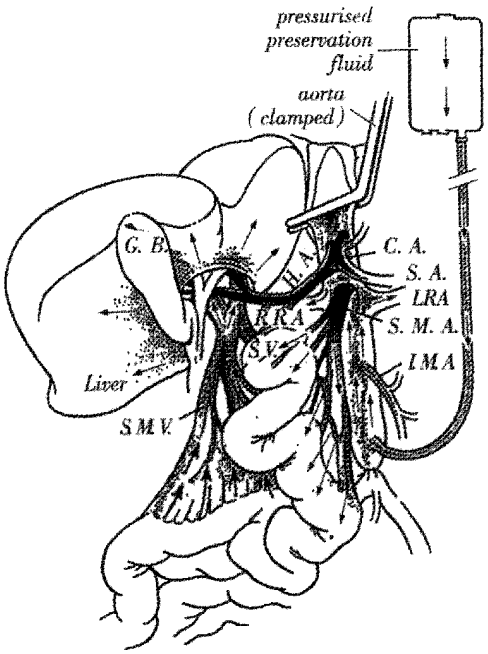

Figure 1 Effective liver perfusion occurs in the APO via the aorta and hepatic artery

The advantage of the technique of aortic perfusion only is the avoidance of the need to undertake the additional dissection and vessel cannulation required for a technique involving portal vein perfusion. The method has simplified the operative procedure, as it involves flushing through an aortic cannula only, instead of having the two cannulae and perfusion sets needed for the portal vein perfusion technique. In the critically unstable donors these methods have been shown to be beneficial.

The APO method can minimize the risk of damage to the graft. The conventional portal vein perfusion technique requires dissection especially around the SMA prior to its ligation. Such dissection may result in a higher incidence of hepatic arterial injury[1-3,10]. The risk of surgical error is especially significant when the right hepatic artery arises from the SMA. This vascular anomaly occurs in about 9%-15% of the population[1,6]. With regard to the other abdominal organs retrieved during multiorgan procurement, the vascular anatomy can be defined on a side table allowing the best setting for the most appropriate division of common vascular supplies, which reduce the danger of injured vessels as well. Another advantage of the APO method is to decrease the risk of manipulative arterial spasm with resulting ischaemic damage to the organs.

The method also allows the other organs of donor to be utilized. The procedure of perfusing the liver allows the other abdominal viscera, including the pancreas, intestine and kidneys, to be flushed with a perfusion solution at the same time. The procurement of abdominal multiorganen bloc combined liver; pancreas, kidneys and intestine can be performed in a single donor.

The presence of a normal blood supply is very important for a liver following transplantation. Any procedure resulting in damage to the arterial sup ply should be avoided at all costs. Special attention should be paid to the possible presence of accessory hepatic arteries from the SMA, LGA and aorta. During prolonged back-table

procedures involving arterial reconstructions, hypothermia should be also strictly maintained.

CA	-	celiac artery	SA	-	splenic artery
HA	-	common hepatic artery	SMA	-	superior mesenteric artery
SMV	-	superior mesenteric vein	IMA	-	inferior me senteric artery
LRA	-	left renal artery	RRA	-	right renal artery
SV	-	splenic vein	GB	-	gall bladder
