Abstract

AIM To determine whether study on the carcinogenic potential of reflux juice from patients with remote gastrectomy could clarify the inherent relationship between duodenal reflux and gastric stump cancer.

METHODS A total of 37 reflux juice samples (13 BillrothI, 24 BillrothII) were employed in the present study. A two-stage transformation assay using BALB/c 3T3 cells was carried out to test the initiating or promoting activity of these samples.

RESULTS Two of 18 (11.1%) reflux samples exerted initiating activities, whereas 9/19 (47. 4%) samples enhanced the MNNG-initiating cell transformation, suggesting the duodenal reflux juice might more frequently possess the tumor-promoter activity ($P = 0.029$). In addition, there was no difference in initiating activities of the samples irrespective of surgical procedures ($P = 0.488$), while Billroth II samples exhibited stronger tumor-promoter activity than Billroth I samples ($P = 0.027$). Furthermore, the promoter activities were well correlated with the histological changes of the stomas ($r_s = 0.625$, $P = 0.004$), but neither their cytotoxicities nor initiating activities had this correlation (Probabilities were 0.523 and 0.085, respectively).

CONCLUSION The duodenal reflux juice from patients with remote postgastrectomy did have carcinogenic potential, and suggested that tumor-promoting activity should principally account for the high incidence of gastric cancer in gastrectomy patients. In contrast, it is difficult to explain the high stump-cancer incidence with the "N-nitroso compounds" theory-a popular theory for the intact stomach carcinogenesis, and it seemed to be justified to focus chemoprevention of this cancer on the tumor-promoting potential of reflux juice.

INTRODUCTION

Since gastric stump cancer was first described in 1922[1], it has been well established that the incidence of gastric carcinoma is increased in patients who have undergone a partial gastrectomy for peptic ulcer disease[2-6]. But the etiology and exact mechanism of gastric stump carcinogenesis are unclear. Decreased sensitivity of chief cells and parietal cells[7], alteration in gastrin level[8], hypoxia and hemodynamic changes[9], bacterial proliferation[10], and reflux[11,12] are the putative contributing factors. Among these, the excessive duodenal reflux induced by surgery seems to be the main risk factor, because the incidence of stump carcinomas is higher in Billroth II than in Billroth I[13,14], and most of the stump carcinomas are located near the stoma[15-17]. Nevertheless, what is the inherent association between the duodenal reflux and stump cancer To answer the question, a cell transformation assay was employed in our study to examine the carcinogenic potential, initiating and promoting activity, of reflux juices from patients with remote postgastrectomy, in terms of the common theory carcinogenesis is analytically considered to relate to the two stages, initiation and promotion[18-23].

MATERIALS AND METHODS

Sampling

Thirty-seven patients (10 women and 27 men; aged, 42-77 years) who underwent partial gastrectomy at least 10 years previously for benign ulcer disease received endoscopy. Each patient experienced either BillrothI or BillrothII procedures (Table 1). Endoscopy was carried out after 8 to 12 hours of fasting. The bile stained reflux fluid was aspirated in a sterile syringe, then sterilized by passing through a 0.22 μm Millipore filter and stored at -70℃ until analysis. The thirty seven patients were all eligible for this study (patients with histories of smoking were excluded from the study), and informed consent was obtained from each patient.

For the sake of enough reflux juice, samples from BillrothI or Billroth II patients were randomly extracted to make two almost equal sized groups to evaluate the initiating and promoting activity, respectively. At the end of the endoscopy, at least five biopsies in a circle around stoma were taken for histological assessment. Three grades were used which were, in ascending order of significance: chronic superficial gastritis (± minimal atrophic gastritis); atrophic gastritis/intestinal metaplasia; dysplasia[24].

Cytotoxicity assay

BALB/c 3T3 A31-1-1 cells 1×10^4 (one of three standardized cell lines generally recommended for the cell transformation assay)[25] were plated in each well of a 96-well plate covered with 100 μL DMEM (Dulbecco's modification of Eagle's medium, Gibco) supplemented with 10% FCS (fetal calf serum, Gibco) at 37℃ in a humidified incubator containing 5% CO_2 in air for 24 hours. The medium was then replaced by 100 μL medium containing reflux juice (15-20 doses designed serially per sample by a concentration gradient of 1.25% reflux juice), and further incubated for 24 hours. The culture was used as a negative control; 3-(4,5,dimethylthiazol-2yl)2,5-diphenyl tetrazolium bromide (MTT; Promega) was added (5 g/L) and the plates were incubated for a further 4 hours. The dye/medium in each well was carefully removed and 100 μL solubilization solution (Promega) was placed in each well for 1 hour. The plates were read at 570 nm in a microplate reader (Biorad 550). The mean absorbance was calculated and cell survival was expressed as the percentage absorbance of that in wells incubated with the negative control.

Transformation assay

Two-stage transformation was assayed by the protocol described by Hirakawa *et al*[26]. Only the volume of culture medium was changed from 5 mL to 4 mL. In the initial assay, actively growing cells (10^4 cells per 60 mm-diameter plastic dish) were plated. Cultures were incubated for 24 hours, reflux samples with graded concentrations (80% and 40% critical toxicity) were added for 72 hours (initiating phase), and 0.3 mg/L TPA (12-O-tetradecanoylphorbol 13-acetate) were present in the medium for 2 weeks 4 days after reflux juice was removed (promoting phase). The medium was then replaced with fresh, promoter-free medium and the culture was incubated for another 2 weeks. The culture medium was changed twice a week. Ten dishes were used for each sample in 2 independent tests. MNNG (N-methyl-N'-nitro-N-nitro-soguanidine) 0.5 mg/L and culture medium were used as positive and negative control, respectively. Finally, the culture cells were fixed and stained with Giemsa 5 weeks after plating. Type III transformed cell foci (deeply basophilic, criss-crossing, a dense layer formation and a random orientation of cells at the edges of foci[25] were counted. As for the transformation frequency (TF), the percentage of dishes with foci was calculated. In the promoting assay, 0.5 mg/L MNNG (dissolved in DMSO)was employed in the intiating phase, and reflux samples (25% toxicity) were added into the medium during the promoting phase. Twelve dishes were used for each sample in 2 independent tests. TPA 0.3 mg/L and culture medium were taken as positive and negative control, respectively. Other procedures of this assay were the same as described above.

Statistical analysis

One-way ANOVA was used to search for differences in the average TF values between BillrothI or Billroth II groups. In other sections, two-tailed Fisher's exact test was performed. A probability of $P<0.05$ was considered statistically significant and we used Bonferroni's method to get the nominal level for each comparison of TF between a sample and the culture control.

RESULTS

In the 2-stage transformation assay, without a known promoter TPA, a 3-day initiating treatment with a potent carcinogen MNNG at 0.5 mg/L had not significantly yielded an increasing number of transformed foci. While MNNG caused a very remarkable transformation with subsequent TPA (0.3 mg/L) promoting treatment (data not shown). The results suggested that the present assay system work well enough to examine whether an agent could exert an initiating or promoting activity. In addition, the doses of bile samples used in the cell transformation assay were selected based on the results of MTT (toxicity) assay. A small concentration gradient (1.25% reflux juice, v:v) was used in MTT assay to obtain the critical cytotoxicity more accurately. Because the toxicity of the samples were different (ranging from 75 to 250 μL aspirate/mL medium), a unified criterion (the same percent of each sample's own toxicity) was used to compare TF values among various samples effectively. In the initiating assay, the aspirate concentration was extended to a high dose, 80% critical toxicity, to ensure that our conclusions are free from false negative results. A low dose, 25% toxicity, was used in the promoting assay for the sake of the culture cells having to survive a long-term exposure to reflux juice (2 weeks). In addition, this dose-design method makes it feasible to study on the carcinogenic potential independent of the cytotoxicity of reflux juice.

Carcinogenic potential in the transformation assay

Six Billroth I and I2 Billroth II samples were randomly distributed into the initiating group. Two of 18 samples exerted significantly initiating activity compared with negative control group in the TPA-promoting cell transformation assay (Figure 1a). As

analysed by subsite, 1/6 Billroth I and 1/I1 BillrothII samples were positive. There was no marked difference in the average TF values between the two groups (Figure 1b) either at the high or low doses (data not shown for the low dose, 40% toxicity).

The residual samples, 7 Billroth I and 12 Billroth II, made up the promoting group. As shown in Figure 2a, there was an increased number of transformed foci in the MNNG-initiated target cells followed by applications of 9 of 19 samples. The nine positive samples included 2 BillrothI and 7 BillrothII aspirate. A significant difference in the average TF values was observed between the two groups ($P<0.05$, Figure 2b).

In comparison of the results between the initiating and promoting assay, the promoting positive rate (9/19, 47.4%) was statistically higher than initiating positive rate (2/18, 11.1%) ($P = 0.029$). Therefore, the reflux juice might usually exhibit the promoting activity and sparsely possess the promoting potential.

Histological grades with carcinogenic potential and cytotoxicity of reflux juice

A stronger correlation (Spearman's rank correlation coefficient = 0.625, $P = 0.004$) was found between the histological grades of stoma and the promoting activity, but not between histological grades and the initiating activity (Table 2). In addition, with the upward shift of histological grades, a small decrease in the toxic concentrations of reflux juice was observed in Table 1, which did not reach statistical significance.

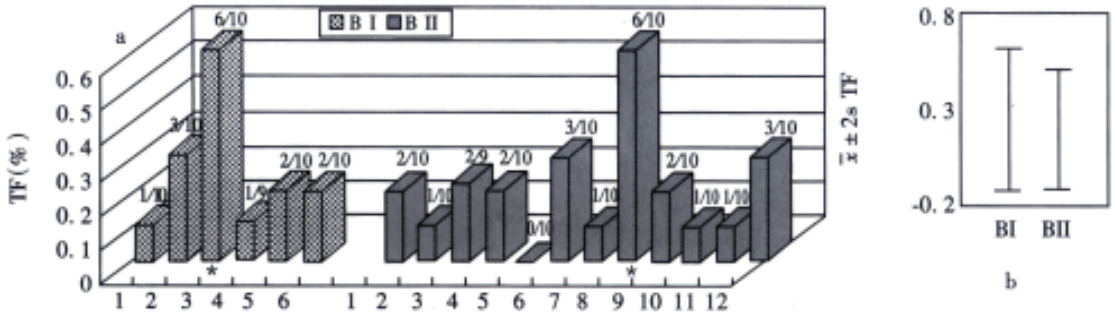

Figure 1 The intiating activity of reflux juice in tranformation assay. *Positive cases. TF of culture control was 7% (4/57). The average TF of BillrothI (BI) and Billroth II (BII) groups shown in Figure 1b.

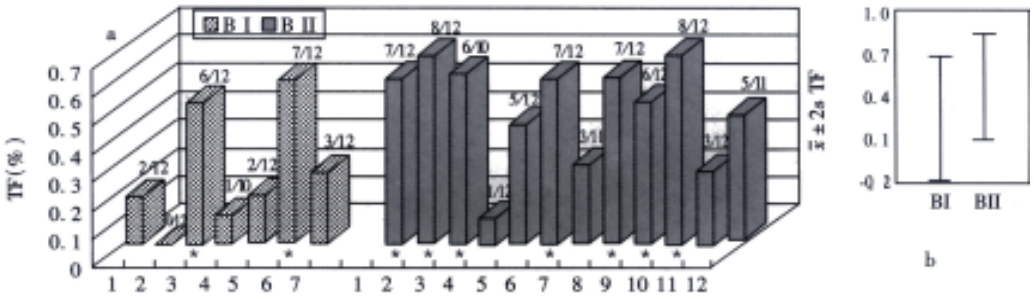

Figure 2 The promoting activity of reflux juice in tranformation assay. *Positive cases. TF of culture control was 7% (4/59). The average TF of BillrothI (BI) and Billroth II (BII) groups shown in Figure 2b.

Table 1 Operation types and critical toxicity of reflux juice in each histological grade

Histological grades	Billroth I	Billroth II	Critical toxic concentrations (%, v:v)	Correlation between histological grades and toxicity[a]
1 Chronic superficial gastritis	7	10	16.4±4.0	
2 Atrophic gastritis/intestinal metaplasia	4	7	15.8±5.0	
3 Dysplasia	2	7	12.9±4.6	r_s = -0.287, P = 0.085

[a]Two tailed spearman's rank correlation.

Table 2 Histological grades of stoma and carcinogenic potential of reflux juice in the cell transformation assay

Histological grades	TF (%)		Correlation coefficient[a]	
	Initiating	Promoting	Initiating	Promoting
1 Chronic superficial gastritis	20.1±18.4 (8)	25.3±18.7 (9)		
2 Atrophic gastritis/intestinal metaplasia	26.0±20.7 (5)	48.1±20.1 (6)	r_s = 0.161	r_s = 0.625
3 Dysplasia	20.4±7.10 (5)	56.7±10.6 (4)	P = 0.523	P = 0.004

[a]Two tailed Spearman's rank correlation. The number of the patients for each histological grade is inside the parentheses.

DISCUSSION

In present study, the duodenal reflux juice from patients with remote postgastrectomy exerted more frequently tumor-promoter activity compared to the initiating (mutagenic) activity. In addition, there was no difference in the initiating activity of reflux samples irrespective of surgical procedures. While the BillrothII aspirates exhibited a stronger tumor-promoter activity than BillrothI, in accordance with many epidemical findings, stump cancer preferred to the BillrothII procedure. All these results strongly suggested that partial gastrectomy - perse- should be responsible for the reflux promoting activity, implying an etiological role for the promoting activity of duodenal reflux juice in the pathogenesis of gastric stump cancer. It is just the tumor-promoter activity, a characteristic beyond what an intact stomach usually possesses, that may elucidate the high incidence of gastric cancer in postgastrectomy patients than in general population.

As for the etiology of gastric cancer, dietary factor has been emphasized principally since some procarcinogens, such as nitrates, can often enter the diet by vegetables, preservatives of food, even drinking water. Nitrite may derive from nitrate by the flora of the mouth or stomach (human saliva typically contains 6-10 mg/L nitrite and 15-35 mg/L nitrate[27], and further react with secondary amines to give rise to N-nitroso compounds which are strong carcinogens suspected of playing a role in upper gastrointestinal carcinogenesis[28] because of their spontaneous synthesis from dietary components and their ability to alkylate nucleic acids. This "N-nitroso compounds" theory has provided a potential explanation for some geographic regions at a very high risk for gastric cancer[29]. But whether this theory can work as well to interpret the high incidence of gastric cancer in the postgastrectomy patients is still a matter of dispute[30-34]. Although we did not measure the concentrations of N-nitroso compounds directly, the initiating assay can effectively detect the mutagenicity of the whole human reflux juice that may contain various mutagenic or carcinogenic substances inclusive of the N-nitroso compounds. When analysing our data from another angle, the initiating or mutagenic activity of reflux samples did not correlate to the histological grades of anastomotic area (Table 2), whereas the promoting activity significantly augmented with the progression of histological abnormalities. Thus, a causal role for the promoting activity of reflux juice in the pathogenesis of stump cancer was further suggested, implying that the tumor-promoter activity might principally account for the high incidence of gastric cancer in the long-standing postgastrectomy patients relative to the initiating activity. While this did not, of course, exclude that the initiating activity or mutagenic activity was indispensable to the stump carcinogenesis. But a perfect explanation for the high stump-cancer incidence seemed to be not available by the "N-nitroso compounds" theory, as it is different from the setting of intact stomach carcinoma. Rising gastric pH in the presence of bacteria after gastrectomy might not favor the formation of the mutagenic or carcinogenic compounds (e.g., N-nitroso compounds)[14,35], and those with a high concentration enough to take an initiating or mutagenic effect were seldom present in the reflux juice of postgastrectomy patients. In addition, as shown in Table 1, with the histological manifestations of the stoma, a slight increase in the non-specific cytotoxicity of reflux juice was observed. Although it did not reach the statistical significance, whether the result alluded to a synergic effect for the reflux toxicity in the gastric stump carcinogenesis deserved further studies.

What is the exact nature of the tumor-promoting species in the reflux juice Some substances exerting a persistent action (e.g., cell differentiating or proliferating[36-39]) must exist in the reflux juice. Unconjugated and secondary bile acids might be first candidates, which have been suggested to take a part in the colon cancer[40-46]. These bacteria-degraded bile acids also present in the gastric aspirate from remote postgastrectomy patients though consisting of a small portion of the whole reflux bile acids. Secondly, lysophosphatidylcholine (lysoPC), the product of phosphatidylcholine hydrolysis by phospholipase A2, has been suggested to play a role in the pathogenesis of gallbaldder cancer in the APBDJ (Anomalous Pancreaticobiliary Ductal Junction) patients[47]. LysoPC might also be produced in the stump stomach due to the reflux juice containing aberrant pancreatic juice and bile. It has been reported that lysoPC at much lower concentrations significantly enhanced the activation of protein kinase C (PKC)[48-50] and regulated cell differentiation[51] if diacylglycerol (DAG) was available. And the unconjugated bile acids happened to remarkably generate DAG[52]. Therefore, whether the above two factors could cooperate to make the reflux juice exhibit tumor-promoter activity This issue also warrants further investigations.

For the first time, we confirmed that the duodenal reflux juice from the long-standing postgastrectomy patients did exert the tumor-promoting activity and initiating activity, and further suggested that tumor-promoting potential should be mainly responsible for the high stump-cancer incidence. Simultaneously, our results demonstrated that a close relationship between the histological changes of anastomotic site and the reflux tumor-promoting activity, thus directly supporting to conduct endoscopic surveillance for postgastrectomy patients with precancerous lesions

(e.g., moderate and severe dysplasia) in stoma. In addition, to decrease the incidence of stump cancer effectively, it seems reasonable not only to perform reconstruction procedures (e.g., Roux en Yanastomosis) for those with severe duodenal reflux, but also to focus the chemoprevention of this cancer on tumor-promoting potential of the reflux juice.

Abstract

AIM To establish a relevant animal model of human gastrointestinal cancer, which can be used for repetitive investigations, so as to improve our understanding and management of carcinogenesis and cancer metastasis.

METHODS Intact tissues of human colorectal and pancreatic cancers were transplanted in nude mice. The biological characteristics of the original and the corresponding transplanted tumors were investigated by HE staining, PAS staining and immunostaining. The metastases in the livers and lungs of nude mice were investigated by immunostaining with biotinylated mab KL-1 and by RT-PCR using CK20 specific primers.

RESULTS There were totally 9 of 16 surgical specimens growing in nude mice subcutaneously and/or orthotopically (4 of 6 colorectal and 5 of 10 pancreatic cancer). Tumor cell content of the specimens and freezing of tissue specimens are important factors influencing the growth of transplanted tumor. In the group of fresh tumor tissues with greater than 50% tumor cell content, the success rate of the transplantation was 100% (3 cases of pancreatic cancer and 3 cases of colorectal cancer). The orthotopically transplanted tumors resemble the original tumor morphologically and biologically, including TAA expression such as CEA by immunohistochemistry, and CEA level in the serum of mice. Ki-67 labeling index and the expression of TAA especially K-ras, 17-1A and RA-96, are associated with the potential of tumor growth in nude mice. Micrometastases in the lungs and livers of tumor bearing mice can be detected by immunostaining with biotinylated mab KL-1 and CK20-specific RT-PCR.

CONCLUSION An orthotopic transplantation model for human colon and pancreatic cancer in nude mice has been set up. We have also established sensitive detection methods with CK-immunohistochemistry and CK20-RT-PCR to study xenotransplanted human cancer and its metastatic cancer cells in the liver and lung of nude mice. This study may be helpful in understanding the mechanism of cancer metastasis and in developing new diagnostic methods and therapeutic strategies for metastases including micrometastases.

INTRODUCTION

Despite significant improvement in surgical techniques and apparently curative resection, recurrence and metastasis still occur and is the leading cause of solid malignant tumors[1-7]. Current standard diagnostic techniques are not able to detect early dissemination of cancer cells (micrometastases)[8-10], and conventional classification of tumor stages cannot account for the presence or absence of distant micrometastasis in the patients with small primary tumors. Thus, one of the most critical prognostic determinants for the subsequent clinical course is neglected in many patients[9,11-16]. Specimens from individual patients are often difficult to obtain for detailed analyses, but it will be much easier to investigate materials in animal models, for studying the various aspects of tumorigenesis, especially metastasis because any part of the tissues from the model can be taken for

detailed investigation.

Most models based on athymic nude mice have been playing an important role in evaluating many anti-cancer drugs. However, human tumors were transplanted subcutaneously and not at an orthotopically relevant organ site. The major problem of this model is that the transplanted tumors are located in an environment quite different from where most human tumors locate. Most subcutaneously transplanted tumors are surrounded by a pseudocapsule, and have little chance to invade and disseminate to the surrounding tissues and rarely metastasize, even when highly aggressive tumors have served as the source of the xenograft[17]. However, human tumor cells implanted orthotopically in the corresponding organs of nude mice can increase the metastatic capability of human tumor cells in nude mice[17-23]. As a relevant model of human gastrointestinal cancer, orthotopically transplanted tumors in nude mice can improve our knowledge about invasive growth and metastasis. Such tumor model would be available for repeated investigation of experimental diagnosis and treatment of early metastasis. It may help design more effective therapeutic strategies[6,19,22-24].

MATERIALS AND METHODS

Specimens and animals

Tumor specimens for transplantation were taken from primary lesions in pancreas, colon and rectum. Surgical tumor specimens which were directly taken from patients were aseptically removed during surgery and immediately transported and processed. Each specimen was separated into three parts: one part for transplantation of fresh specimen, one part for subsequent transplantation of DMSO-frozen specimen (mostly in 1d to 3d), and another part was stored at-80℃ for morphological, immunohistochemistry analyses and for RTPCR. Eight to twelve week old male or female athymic NMRI nude mice, which were obtained from the University Clinic Eppendorf, Hamburg, Germany, were kept in laminar-flow cabinets.

Surgical procedures of tumor transplantation

Each cancerous tissue (fresh or frozen tissue) was divided into small pieces about 2 mm in diameter. Mice were anesthetized with a mixture of 12 $g \cdot L^{-1}$ ketamin Curamed Phama GmbH) and 1.6 $g \cdot L^{-1}$ xylazin solution (Parke-Davis GmbH), The colon or pancreas was then carefully exposed and a tumor piece was then attached on the serosal surface of the colon or the wall of the pancreas, with 6-0 absorbable transmural suture. The colon or pancreas was then returned to the peritoneal cavity and the abdominal wall and the skin was closed with 6-0 absorbable suture. Immediately thereafter, another piece of the tissue was transplanted subcutaneously into the left frank of the respective mouse. For the purpose of convenience, the DMSO-frozen tissues were also transplanted into another 2-3 mice. Tumor pieces from each patient were transplanted into 2-3 mice in general.

Immunohistochemistry

A modified immunoperoxidase procedure, which was introduced in 1981 by Hsu *et al*, was used as follows. Tumor sections were air dried, fixed with acetone for 10 minutes prior to staining, transferred into PBS, blocked for 20 minutes with diluted normal horse serum, incubated for 30 minutes with primary antibody diluted in 10 $g \cdot L^{-1}$ BSA/PBS, washed for 5 minutes in PBS (if quenching of endogenous peroxidase was required, the sections were incubated for 30 minutes in methanol with 3 $mL \cdot L^{-1}$ H_2O_2), incubated for 30 min with a diluted biotinylated secondary antibody solution (biotinylated horse anti-mouse IgG 1:200 in 15 $mL \cdot L^{-1}$ horse serum/PBS). If the primary antibody was C-T84.66, biotinylated goat anti-human IgA+IgG+IgM (Jackson Inco. 1:1000) was used, washed for 5 min in PBS, incubated for 30 min with "VECTORSTAIN ELITE ABC Reagent", washed for 5 min in PBS, incubated for about 5 min in DAB solution, rinsed in tap water, counterstained and cleared, airdried and mounted. Positive and negative controls were included as mentioned above.

Monoclonal antibodies

mAb KL-1 and Biotinilated KL-1 anti-cytokeratin (IgG 1, kappa, 4 $mg \cdot L^{-1}$, Immunotech, Hamburg, Germany); CIP83 (5 $mg \cdot L^{-1}$, Kalthoff, Kiel, Germany) and chimeric-T84.66 (1:100, Neumaier, Hamburg, Germany) anti-CEA (IgG1, kappa); and MIB1 (2.5 $mg \cdot L^{-1}$) and Biotinilated MIB1(10 $mg \cdot L^{-1}$) anti-ki-67 (IgG 1, Dianova, Hamburg, Germany) were used both for investigating original and transplanted tumors. mAb CA-199, Ra-96 and 17. 1A (all 5 $mg \cdot L^{-1}$, Kalthoff, kiel, Germany) were used for investigating human original tumor only, Biotinilated KL-1 was also used for detecting micrometastatic cells in the livers and lungs of mice.

Detection of CEA level in mice serum

Serum from nude mice were measured using a Microparticle Enzyme Immunoassay (MEIA) for the quantitative measurement of CEA with the "IMx" immunoassay analyzer (Abbott Laboratories).

Micrometastases detected by CK20-specific RT-PCR

Livers and lungs of nude mice were cut into 10-20 μm slides with cryosection machine, then RNA was extracted using modified single-step RNA isolation

method with TRIzol (Gibco BRL, Eggenstein, Germany). The integrity of RNA was checked by gel-electrophoresis. RNA extracted from a pancreatic carcinoma cell line A818.4 was used as positive control, GAPDH (glycerdehyde-3-phosphate dehydrogenase) -RT-PCR was used to monitor cDNA synthesis. The detailed protocol of ck20-specific RT-PCR was described previously[25,26].

RESULTS

Mice were killed when transplanted tumors reached 1 cm or larger. There were 4 (67%) out of 6 colon cancer, 5 (50%) of 10 pancreatic cancer, totally 9 (56%) of 16 surgical specimens growing in nude mice sc and/or orthotopically. Tumor growth was observed in 0% of frozen tissues and in 63% of fresh tissues with paired samples of original tumors. When retransplanted with xeno-transplanted tumors, 39% of transplants of frozen tissues and 100% of fresh tissues grew in the mice (Table 1). In the group of fresh tumor samples with a tumor cell content ⩾50%, the success rate was 100% (6/6). While in the group with a cell content of <50%, the success rate was 40% (2/5), (Table 2). The expression of Ki-67, K-ras, 17.1A and Ra-96 antigens in human colorectal and pancreatic cancer with tumor growth in nude mice was higher than in those without tumor growth (Figures 1, 2). Almost the same morphology and CEA expressions were observed between original human tumors and corresponding xenotransplanted tumors of colon and pancreatic cancer (Figures 3-8). The serum CEA levels of mice are closely associated with the existence of tumors in nude mice (Table 3). Micrometastases in lungs and livers of tumor-bearing mice: 16 mice transplanted with colorectal, and pancreatic carcinomas from 7 cases of original tumors (5 of the 7 cases had corresponding orthotopic tumors) were investigated for liver and lung micrometastases. In the 16 mice, which were sacrificed around 13-14 weeks after transplantation, macroscopically invisible metastases were found in the lungs of 3 mice by KL-1 immunostaining and CK20-RT-PCR (2 colorectal and 1 pancreatic cancer). Additionally 2 liver metastases from colorectal cancer were detected by CK-20 specific RT-PCR only (Figures 9-11).

Table 1 Tumor growth of paired fresh (F) and DMSO-frozen (D) tissue: transplanted with original tumors and xenotransplanted tumors[a]

Type	TG / total (*n*)		Success rate (%)	
	F	D	F	D
Colon	3 / 3 (12 / 12)	0 / 3 (6 / 10)[b]	100 (100)	0 (60)
Pancreas	2 / 5 (8 / 8)	0 / 5 (1 / 8)	40 (100)	0 (13)
Total	5 / 8 (20 / 20)	0 / 8 (7 / 18)	63 (100)	0 (39)

[a]Figures in ( ) is the results of transplantation with xenotransplanted tumors; b1 mouse died after transplantation.

Table 2 Influence of tumor cell content on tumor growth of fresh surgical specimens

Tumor	TG / total (*n*)		Success rate	
	⩾50%	<50%	⩾50%	<50%
Colon	3 / 3	1 / 1	100	100
Pancreas	3 / 3	1 / 4	100	25
Total	6 / 6	2 / 5	100	40

DISCUSSION

Developing a relevant animal model of xenotransplantation of human tumors in nude mice could improve our understanding of the biological properties of human gastrointestinal cancer and lead to the development of new effective therapeutic concepts. Human tumor xenografts transplanted SC in athymic nude mice rarely give rise to metastases [24]. However, human tumor cells implanted orthotopically in the corresponding organs of nude mice can increase the metastatic capability of human tumor cells in nude mice[18,24]. Data have shown that desegregated tumor cell suspensions may not always express their fully malignant biological behavior[17,27]. Cell suspensions may have the possibility of seeding tumor cells "artificial" metastases in the surrounding tissues (i.e. peritoneal cavity) during the process of inoculation. Moreover, inoculation of desegregated tumor cell suspensions does not reflect the situation when metastatic cells spread from intact tissue growing in the human body.

Therefore, we have established an orthotopic transplantation tumor model for human tumors in nude mice with intact tissues of pancreatic, and colorectal cancer. The results showed similar morphology and biological behavior before and after transplantation in this model. Orthotopical transplanted tumors present many of the clinical manifestations of the biological behavior of gastrointestinal cancer in humans, including invasion, metastasis, and antigen expressions of CEA, CK, Ki-67, etc. CEA is a most commonly used tumor marker for gastrointestinal cancers. Recent studies showed that CEAmRNA RT-PCR or CEA immunostaining is frequently used in detection of micrometastases of gastrointestinal tract cancers [1,12,28,29]. CEA levels in serum play an important role in monitoring patients with gastrointestinal cancer [30-34]. We found that serum CEA level is obviously elevated in tumor bearing mice, suggesting that serum CEA level is a very useful marker in this model. KL-1 reacts with cytokeratins (CK), components of intracytoplasmic network of intermediate filaments (Ifs)[4,8,35], specifically reacts with epithelial tumors. Anti-CK mABs using immunocytochemistry or CK RT-PCR have been widely used for the detection of micrometastases in lymph nodes, venous blood and bone marrow[1,4,12,28,36-42]. It is satisfactory using KL-1 monoclonal antibody to detect micrometastasis in the lungs and livers of the mice in this study. Ki-67, aproliferation-associated antigen [43-46], is expressed in all phases of the cell cycle (G1, S, G2, and M) except for G0[47]. It is thought to be a useful predictor of aggressive tumor behavior and an indicator of patient survival[43]. Mib-1 is raised against recombinant parts of the Ki-67 antigen[48-52]. Our results showed that the original tumors with higher Mib-1 (Ki-67) labeling index had an increased tendency to grow in the nude mice.

Meanwhile, we established the sensitive method to detect disseminated tumor cells (micrometastasis). Sixteen tumor-bearing mice (with 5 orthotopic transplanted tumors) were used for investigating the metastasis of livers and lungs. There was no obvious metastases with naked eye and HE staining but 3 lung micrometastases with KL-1 immunostaining and CK20 RT-PCR, additionally 2 liver metastases with CK20 RT-PCR, suggesting that RT-PCR may be more sensitive than immunostaining. Many factors influence tumor growth in nude mice. On the one hand, tumor tissues are composed of cells with different biological characteristics[7]. On the other hand, different mice may have various reactions to transplantation.

Our data includes the frozen tumor tissue implantation, because the procedure is more flexible and convenient. Unfortunately, freezing of tissue specimens obviously reduced the success rate. However, for tumors with a good cellularity, freezing is a possible procedure. When xenograft tumor tissues were retransplanted (xenografts were taken from mice and frozen, then thawed and transplanted again), the tumor growth rate of pancreatic and colorectal frozen tumor tissues, was nearly 40% and only the colorectal tumors was 60%. This is likely due to the fact that xenograft tumor tissues contain more tumor cells and less damaged cells due to shorter storage time and better preservation. Tumor cell content is an important factor in our study. In the specimens with a tumor cell content greater than 50% (tumor cells vs stroma over 1:1), the success rate of fresh tumor tissues impliantation reached 100% (Table 3).

In this study, we found that TAAs, including C1P83, RA-96, 17.1A, K-ras and Ki-67 expression, were important indicators of tumor growing potential in nude mice.

ACKNOWLEDGEMENT The authors thank Dr. J. Luettges, Department of Pathology, Kiel University, for investigating the pathological characteristics of the specimens; Dr. N. Zawazawa, for the quantitative measurement of serum of CEA, Institute of Immunology, Kiel University.

Subject headings ulcerative colitis; Crohn disease; incidence

Salupere R. Inflammatory bowel disease in Estonia: a prospective epidemiologic study 1993-1998. ***World J Gastroenterol***, 2001;7(3):387-388

INTRODUCTION

The incidence of ulcerative colitis (UC) and Crohn's disease (CD) in Estonia in 1993-1998 was investigated prospectively. The mean annual incidence of UC was 1.7 per 100 000, and that of CD 1.4 per 100 000. This population-based study showed much lower incidence of UC and CD than those reported for western and northern Europe.

The incidence of ulcerative colitis (UC) and Crohn's disease (CD) have been studied by many doctors and every year new data[1,2] and reviews[3] published. A retrospective study of 1973-1992 revealed that UC (mean annual incidence 1.5 per 100 000) and CD (mean annual incidence 0.27 per 100 000) were not so common in Estonia as it is in other countries[4]. Estonia is a small country in northern Europe close to Scandinavian countries with the highest incidence rates of UC and CD[3]. And, therefore the aim of the present study was to prospectively estimate the incidence of UC and CD for 1993-1998.

MATERIALS AND METHODS

The population-based study included the total population within Tartu County and was based on both ambulatory and hospitalized patients at Tartu University Hospital: Department of Internal Medicine, Department of Pediatrics and Department of Surgery. Tartu County provided excellent conditions for the epidemiologic research as the advantages of small geographic size, a state-controlled health care delivery system, and universal accessibility to health care, also the accessibility of individual data and confidence in data quality. A rather stable population of Estonian origin (caucasian racial group) of the area consisted of 158516 inhabitants in 1993 and 151301 in 1998, i.e. approximately 10% of the population of Estonia. The diagnosis of UC or CD was based on endoscopic, radiological evidence or both, supported by histology from mucosal biopsies or surgical specimens using Lennard-Jones criteria. Only the patients with definite UC and CD in accordance with well-defined diagnostic criteria were included in the study. A thorough registration of the previously diagnosed UC and CD cases in 1973-1992 facilitated the confirmation of the new cases. The presence of antineutrophil cytoplasmic antibodies (ANCA) by indirect immunofluorescence was analyzed.

RESULTS

In 1993-1998 a total of 16 patients with UC and 13 patients with CD were diagnosed. The mean annual incidence of UC was 1.7 per 100 000. The mean age at the diagnosis was 41.2 years (range 16-68 years). The male to female ratio was 1.0. At the time of diagnosis 9 patients had proctosigmoiditis, 5 left-sided colitis and 2 pancolitis. Colonoscopy was done on 14 patients, barium enema on 2 patients.

The mean annual incidence of CD was 1.4 per 100 000. The mean age at the diagnosis was 36.0 years (range 5-69 years). The male to female ratio was 2.3. At the time of diagnosis 6 patients had colitis, 3 ileitis and 4 ileocolitis. Five patients were operated on due to CD. Colonoscopy was done on all patients.

IgG ANCA were detected in 7 of the 14 patients with UC and in 3 of the 11 patients with CD. The predominant ANCA staining pattern was perinuclear.

DISCUSSION

In this paper, the prospective study of 1993-1998 showed much lower incidence of UC and CD than those reported for western and northern Europe. At the same time, there seem to be no significant differences in the prevalence of ANCA compared with the data observed in different countries or in our earlier study. In our earlier study ANCA were detected in 49% patients with UC and 24% patients with CD[4]. Change over time in the incidence of CD (for 1973-1992 0.27 and for 1993-1998 1.4) may

suggest the bias in disease definition and case ascertainment or diagnostic access bias in the previous retrospective study or time trend in incidence.

The reasons for such a low incidence of UC and CD are not known. Therefore, several causes should be taken into account. For instance, altered concentrations of colonic microflora have been demonstrated in inflammatory bowel disease patients. It was hypothesized that this altered concentrations have been reported in association with a decrease in the potentially protective lactobacilli and bifidobacteria[5]. And, there are geographic variations in human gastrointestinal microflora, too. The intestinal microflora was compared in one-year-old Estonian and Swedish infants by quantitative culture of faecal samples[6]. The major differences in the composition of the microflora were high counts of lactobacilli and eubacteria in the Estonian and increased numbers of clostridia in the Swedish infants[6]. The causes for the differences in microflora of the Estonian and Swedish children remain unexplained. The current microflora of the Estonian infants appears to be similar to the prevailing microflora in infants of western Europa in the 1960s and 1970s[6]. Interestingly, epidemiological data generally do support steady and widespread increase in the incidence of CD during 1950-1990 in western Europa while the pattern for UC was stable[3]. Changes over time in the incidence of Crohn disease may suggest many possible factors including gastrointestinal microflora.

INTRODUCTION

Helicobacter pylori (H. pylori) is associated with the development of chronic gastritis, peptic ulcer and gastric cancer and gastric MALT lymphoma[1-9]. *H. pylori* has many antigens, including urease, heat shock protein and vacuolating cytotoxin and so on, and urease is an important factor in the colonization of the gastric mucosa and suspected to cause damage to the gastric mucosa[10-14]. At the same time, urease is also one of the important protective antigens. It consists of two distict subunits with apparent molecular mass of 29.5 ku (UreA) and 66 ku (UreB), and urease B subunit is nontoxic, highly immunogenic, and an effective component of protective antigens[15-18]. In our study, Hp ureB gene was cloned in the fusion expression vector and expressed in *Escherichia coli*. We described the immunological characteristics of purified recombination UreB protein.

MATERIALS AND METHODS

Materials

pHp-UreB, plasmid that contains *H. pylori* urease B gene was constructed by Wu[19] (Third Military Medical University, Chongqing); plasmid PinPoint^{TM} Xa-3 (Promega, USA); *E.coli* JM109 (*SupE44endA*1 *hsdR*17*gyrA*96 *relA1thi* △ (*lac-proAB*)F'[*traD*36 *proAB*$^{+}$ *laclg lacz* △ M15]) was used as a host for analysis of urease B subunit expression; DNA Purification Kits (Sangon, Shanghai); a polyclonal antibody of rabbit directed against *H. pylori* was prepared by ourselves. Sera from *H. pylori* infected patients and sera from healthy people (Southwest Hospital, Chongqing); six-week-old female Balb/C mice were obtained from Laboratory Animal Centre, Third Military Medical University, Chongqing); mini-cycle^{TM}- PCR amplicon (PE Company, USA); UVP nucleic acid and protein analyser (UVP Company, USA); Bio-Rad mini-protein electrophoresis (Bio-Rad Company).

Construction of the expression vector

A 5' primer (CGTCAAGCTTATGAAA-AAGATTAGCAG) and a 3' primer (CGTCGATA-TCATCCTAGAAAATGCTAA) were used in a PCR with *Taq* polymerase to amplify the 1.7-kb fragment containing the sequences of ureB flanked by *Hin*d III and *Eco*R V restriction enzyme digestion sites. The amplification cycles were an initial denaturation step of 94℃ for 5 min, followed by 35 cycles of annealing at 55℃ for 2 min, extension at 72℃ for 2 min, and denaturation at 94 ℃ for 1 min, then extension at 72℃ for 2 min. PCR products were run on 10 g·L^{-1} agarose gels (containing 0.5 mg·L^{-1} ethidium bromide). The amplified product purified with DNA purification kits was digested with *Hin*d III and *Eco*R V, and ligated into the corresponding sites of PinPoint^{TM}Xa-3. The recombination plasmid named pPin-UreB was introduced into *E. coli* JM109 by $CaCl_2$ perforation.

Expression of the ureB gene

E.coli JM109 containing the expression plasmid pPin-UreB was grown in Luria-Bertani broth containing ampicillin(100 mg·L^{-1}) and biotin (2 μmol·L^{-1} final concentration). The culture was incubated at 37℃ and shaked at 200 r·min^{-1}, until the A600 was 0.8. Prior to adding 1 mmol·L^{-1} IPTG to cultures, a 1mL sample was taken (noninduced cell). Cultures were incubated for a further 5 h, at which time another 1 mL sample (induced cell) was taken. The noninduced and induced cell samples were later analyzed by sodium

dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE). Following electrophoresis, the proteins were transferred onto a nitrocellulose membrane by electroblotting. The membrane was incubated in TBST buffer for 60 min firstly, then in 15 mL TBST buffer containing 3 μL streeptavidin-alkaline phosphatase for 30 min at room temperature with gentle agitation. After washed with TBST for 5 min, the membrane was incubated with Promega's Western Blue R stabilized substrate for alkaline phosphatase at room temperature until the bands appear. Dark purple bands will indicate the location of the biotinylated protein species in the lanes containing cellular extracts.

Purification of the recombinant fusion protein

IPTG-induced cultures were spun at 8000 $r \cdot min^{-1}$ for 10 min at 4℃. Pellets were resuspended in cell lysis buffer (50 $mmol \cdot L^{-1}$ Tris-HCl pH 7.5, 50 $mmol \cdot L^{-1}$NaCl,50 $g \cdot L^{-1}$ glycerol) and sonicated on ice. Cellular debris were removed by centrifugation (10 000 $r \cdot min^{-1}$, 4℃, 15 min). The supernatant was added into the column containing SoftLink™- Resin, and the cell extract was captured efficiently. To elute the protein, adding a stabilizing buffer containing 50 $mmol \cdot L^{-1}$ biotin, when a volume of elution buffer equal to one-half the volume of resin in the column had been applied, stop the flow from the column. Wait 15min to allow for release of the fusion protein. The fractions containing higher concentration fusion protein were collected in the eluate. The purified fusion protein was cleaved by factor Xa protease at 37℃. The reaction products were added into SoftLink™- Resin Column again. In the process of elution, the purified UreB protein was collected.

Immunogenicity of recombinant UreB

Two groups of 10 Balb/C female mice (six week old) including controls were used as follows: ① NS control group was non-immunized mice that received NS; ② UreB group was the mice immunized with 200 μL NS containing purification rUreB protein (50 $g \cdot L^{-1}$) each time and once a week for 4 weeks under the skin of the back, and added in Freunds incomplete adjuvant for the first time. Thirty-five days after the immunization, blood was collected from the retro-orbital sinus and the antibody titer was measured with enzyme-linked immunosorbent assay (ELISA). The purified recombination UreB protein was used to coat 96-well microtiter plates (Corning-Coster Company, USA) and sheep anti-mouse IgG antibody conjugated with horseradish peroxidase (HRP) was used in the assay.

Immunoreactivity of recombinant UreB

Microtiter ELISA plates were coated by incubating the plates with 5 $mg \cdot L^{-1}$ recombination UreB 0.1 mL diluted in phosphate-buffered saline (PBS) at 37℃ for 4 h. After washing plates twice with PBS, the remaining binding sites were blocked by incubating the plates with 10 $g \cdot L^{-1}$ bovine serum albumin (BSA) at 37℃ for 30 min (200 $mL \cdot well^{-1}$). The human antisera against Hp and control sera from healthy people were added to the coated well and incubated for 2 h at 37℃. After another washing procedure, HRP-conjugated sheep anti-human IgG antibody 100 μL diluted in PBS (working dilution, 1:5000) was added to each well and incubated for 1h at 37℃ and σ-phenylenediamine in PBS was used as the substrate. The enzyme substrate reaction was read with Spectra Classic spectrophotometer (Tecan, Austria) at 492 nm.

RESULTS

Construction of the expression vector

The PCR product amplified from plasmid pHp-UreB was analyzed under ultraviolet light after 10 $g \cdot L^{-1}$ agarose gel electrophoresis (Figure 1). The 1. 7kbPCR product was digested with *Hin*d III and *Eco*R V restriction enzyme and ligated into the corresponding sites of PinPoint™ Xa-3. The recombinant expression plasmid was named pPin-UreB. pPin-UreB was identified by digesting with *Hin*d III and *Eco*R V, and the 1.7kb ureB fragment was separated by electrophoresis in 10 $g \cdot L^{-1}$ agarose gel (Figure 2). Analysis of DNA sequencing, showed that the nucleotide sequence of ureB gene in plasmid pPin-UreB was the same as reported in the reference[19].

Expression of UreB gene and detection of the fusion protein

The plasmid pPin-UreB was induced to express *H. pylori* UreB protein by IPTG in *E.coli* JM109, and produced the fusion protein with predicted molecular masses of 79ku (Figure 3). The fusion protein on 100 $g \cdot L^{-1}$ polyacrylamide gel was transferred by electroblotting onto an NC membrane and was detected with Streeptavidin-Alkaline Phosphatase Detection System. The result showed that there was a positive band on the site of the fusion protein in pPin-UreB strain but not in control strains (Figure 4). Measured by UVP Protein Analyser, the biotinylated fusion protein was 150 $g \cdot kg^{-1}$ in the total bacterium protein.

Purification of recombinant UreB protein

The recombinant fusion protein expressed in *E. coli* was separated and purified by affinity chromatography with the SoftLink™- Soft Release Avidin Resin. The biotinylated fusion protein was cleaved into two parts with Factor Xa proteinase: UreB protein (66ku) and biotin tag protein (13ku).

With purification of column chromatography, the recombinant UreB protein was obtained and analyzed by SDS-PAGE and Western blotting. The purified UreB protein had predicted molecular masses of approximately 66ku and its purity was more than 95% (Figure 5).

Immunology character of recombinant UreB protein

Balb/C mice, immunized with recombinant UreB, generated anti-UreB antibody and the titer was detected to be 1:3000 with ELISA. However, in the mice of the control group no antibody was found. Fourty antisera against *H. pylori*and 20 control sera from healthy people were detected by ELISA with recombinant UreB protein, the coincidence ratio being 100%.

DISCUSSION

H. pylori urease is a nickel metalloenzyme, which hydrolyzes urea and is 50-100 g·kg^{-1} in total protein of the cell.*H. pylori* urease is a 550ku enzyme, consisting of two distinct subunits: UreA (29.5ku) and UreB (66ku). The ratio of subunits is approximately 1:1, suggesting a stoichiometry of

(29.5ku-66ku)6 for the native enzyme. The research of *H. pylori* urease genes suggest that ureA and ureB are structural genes, which are required for the synthesis and assembly of the 550ku apoenzyme [13], and these additional genes (ureC, ureD, ureE, ureF, ureG and ureH) are required for the expression of urease activity[13,20,21]. To express recombinant UreB protein (rUreB), we cloned *H. pylori* ureB gene by PCR and constructed the expression plasmid pPin-UreB containing *H. pylori* ureB gene. The purified rUreB was absent of urease activity in our study, which is different from what Li *et al*[22] reported. At the same time, the cloned ureB gene was sequenced and the sequence homology of nucleotide and predicted amino acid were 96.44% and 99.65% with those reported by Labigne *et al*[23]. The difference of nucleotide was due to the difference strains and gene diversity, but the obvious DNA homology suggested that the main antigenic determinants which encode *H. pylori* UreB protein were similar in difference strains[13,24,25].

Urease is the important antigen of *H. pylori*, which can stimulate significant immune response. These results suggested that the significant immunoprotection against *H. pylori* infection was induced after the purified native urease from *H. pylori* and recombinant urease were used to immune mice, and that the recombinant UreB but not rUreA protein produced immunoprotective response against *H. pylori* infection in mice after immunization separately[26-30]. In our study, the purified rUreB protein was used to immune Balb/C mice under the skin, and the antibody against rUreB was produced successfully. These demonstrated that the rUreB protein had obvious immunogenicity, and could be used in *H. pylori* vaccine research[31-33].

Individuals infected with *H. pylori* produce vast quantities of specific immunoglobulin G (IgG) antibodies in the serum[34-36]. Serum antibodies against *H. pylori* can be detected by a variety of methods including complement fixation, bacterial agglutination and immunofluorescence but enzyme-linked immunosorbent assay (ELISA) is usually used due to speed, simplicity and reproducibility [37-41]. *H. pylori* urease is a key protein used for detection of the organism by measuring serum antibody against the protein[13]. We discovered that the purified rUreB protein had a positive reaction with specific antibodies against *H. pylori* in sera of patients and negative reaction with the control sera from healthy people. The specificity and sensitivity of rUreB to *H. pylori* antisera of patients will be used in the diagnosis, assessment of curative effect and epidemiological investigation of *H. pylori*.

INTRODUCTION

Gastric epithelial dysplasia (GED) hypothetically is a straight-forward concept: dysplastic epithelium replacing the normal gastric epithelium of the stomach[1]. In the stomach, like any other segment of the gut, it is defined as an unequivocal non-invasive epithelial change[2,3]. The observation of gastric dysplasia as a cancerous lesion was recognized over a century ago, but it is only after the advent of gastroscopy that its clinical significance has been stressed[4-7].

All-trans retinoic acid can effectively reverse dysplasia in gastric epithelial cells, thereby inhibiting its progression to gastric cancer[8-10]. However, its mechanism is not yet clear. We used N-methyl-N-nitro-N-nitrosoguanidine (MNNG) to establish a rat model of gastric epithelial cell dysplasia, and to study the influence of all-trans retinoic acid. Changes in apoptosis and expression of Bcl-2, Fas and ICE were observed to investigate into insight of its mechanism.

MATERIALS AND METHODS

Induction of gastric epithelial cell dysplasia and treatment with all-trans retinoic acid

Forty-five 8-week-old male Wistar rats weighing 120 g-140 g were housed in individual cages at a controlled temperature of 22℃, and a relative humidity of 50%. These animals were randomly divided into three groups each 15 rats. Group 1 served as blank control. Groups 2 and 3 were fed with MNNG to induce gastric epithelial cell dysplasia. Two grams MNNG (Fluka Co.) was dissolved in 2000 mL distilled water, placed in a brown bottle and kept at 4℃. The preserved MNNG solution was further diluted to the concentration of 1 g/mL for use as drinking water ad lib[11,12]. In addition, at one, three, five and seven weeks, 2 mL absolute alcohol was infused into the stomach of each animal. After 24 weeks, when gastric epithelial cell dysplasia had been induced, animals in group 2 were given 40 μg/kg all-trans retinoic acid (Shanghai No.6 Pharmaceutical Co.) through infusion into the stomach every day. Group 3 served as treatment controls and a placebo (distilled water) was given instead of all-trans retinoic acid. The animals were killed at 36 weeks.

The stomachs of the rats were cut along the greater curvature. Specimens were taken from the pyloric area and five paraffin sections were made for each rat following the conventional method. These sections were used for routine pathological examinations, apoptosis determination and measurements for the expression of Bcl-2, Fas and ICE. Pathological diagnoses and gradings were carried out according to the criteria set by the National Gastric Cancer Research Group[13,14].

Determination of apoptosis by TUNEL method

After dewaxing a 4 μm thick section, the fundamental steps of the procedure were: addition of proteinase K (20 μL/mL); incubated at 37℃; addition of Triton x-100 in 0.1% sodium citrate on ice, stood up; addition of 50 g TUNEL (Boehringer Co., Cat. no. 1684817); incubated at 37℃ in a humidified chamber; staining with diaminobenzidine (DAB); sealing the slide; and

examined under a light microscope. Apoptotic cells presented as brownish staining in the nucleus, although part of the cytoplasm also can be stained because of leakage of some nuclear DNA fragments. At least 500 cells were examined and the number of apoptotic cells per 100 cells calculated to arrive at the apoptosis index (AI)[15,16].

Expression of Bcl-2, Fas and ICE measured by immunohistochemical staining

Bcl-2 After dewaxing, the 4 μm thick section was stained using the Avidin-Biotion Complex (ABC) method[16]. The primary antibody used was 2 mg/L rabbit antirat Bcl-2 polyclonal antibody (Santa Cruz Co. USA, Cat. No. Sc-578) diluted 1:50.

Fas To detect Fas activity, sections were stained by ABC method. The primary antibody used was 2 mg/L rabbit antirat Fas polyclonal antibody (Santa Cruz Co. USA, Cat. No. sc-716G) diluted 1:50.

ICE To detect ICE activity, sections were stained by the ABC method. The primary antibody used was 2 mg/L rabbit antirat ICE polyclonal antibody (Santa Cruz Co. USA, Cat. No. sc-514) diluted 1:50.

Positivity control Slides of multiple gene-protein-positive gastric cancer specimens were used as positivite controls. If brown granules appeared on the nuclear membrane and in the cytoplasm of gastric epithelial cells, the specimen was considered to be Bcl-2 positive. If brown granules appeared on the cell membrane, the specimen was considered to be Fas positive; and if brown granules appeared in the cytoplasm, the specimen was considered to be ICE positive. The expression was graded according to the degree of staining: strongly positive (+++), moderately positive (++) and weakly positive (+). If more than 30% of cells in a slide were also considered positive. Those with strongly and moderately positive responses were considered to be overexposing the protein in question[17-20].

Probes

The following oligonucleotide probes were used in this study. Bcl-2, TGATACCAGCACTGGAGCAG, was synthesized by Shanghai Shenggong Company. Fas, CAGCCAGGAAAGATCAAACAGAGAGC, was bought from Fuzuo Company.

Northern-blot analysis

Total RNA was isolated from the gastric epithelial tissue by extraction of guanidine isothiocyanate and centrifugation in cesium chloride[21,22]. Poly(A) +RNA was selected by oligo(dt)-cellular chromatography[23]. Six micograms of poly(A) +RNA from each sample was electophoresed in 1% agarose gel containing 0.66 mol/L formaldehyde and ethidium bromide (0.66 mg/L).

After electrophoresis, the gels were photographed under UV light to confirm that approximately equal amounts of RNA were loaded. The gels were pretreated with 0.05N NaOH for 30 minutes at room temperature[24,25] and RNA was transferred onto nitrocellulose. Then, appropriate probes were labled with 32P deoxycytidine triphosphate using a Random Prime DNA labeling kit (Boehringer Mannheim, Indianapolis, IN). The blots were hybridized overnight at 62℃ (bcl-2) or 52℃ (Fas) in 59% formamide, 10% dextran sulfate, 1% sodium dodecyl sulfate, 1 mol/L NaCl, and 100 g/L of sonicated salmon sperm. Then the blots were washed in 2 × standard saline citrate (1×SSC is 150 mmol/L NaCl, 15 mmol/L sodium citrate, pH 7.4), and 0.5% sodium dodecyl sulfate four times at room temperature for 5 minutes and also washed (3 × 10 minutes) in 0.2 × SSC and 0.5% sodium dodecyl sulfate at 60℃. The blots were then exposed to Kodak XAR film (Eastman Kodak, Rochester, NY) at -70℃. The nitrocellulose filter was boiled in 0.1% SSC and 0.1% SDS for 30 minutes to strip off the radioactivity probes and rehybridized with another ^{32}P labelled Cdna prob in a similar manner[26]. The quantity of specificy transcripts in different lanes was determined by densitometric analysis of autoradiographs.

RESULTS

Histopathological changes of the gastric mucosa

The incidence of dysplasia in group 3 was significantly higher than that in group 2 (73.3% *vs* 26.7%, $P = 0.05$, Table 1).

Table 1 Histopathological changes and apoptosis of the gastric mucosa

Group	*n*	Modest dysplasia (*n*)	Modest and severe dysplasia (*n*)	Percentage (%)	Apoptotic index
Normal	15	0	0	0	8.3±3.1
DIM	15	3	11	73.3%	2.2±0.4[a]
DIMTR	15	4	4	26.7%[ab]	7.8±2.6[bc]

[a]$P<0.05$ *vs* normal; [b]$P>0.05$ *vs* normal; [c]$P>0.05$ *vs* DIM group.

Apoptosis

The apoptosis index was not significantly different in groups 1 and 2 ($P>0.05$), but there was a significant difference between groups 1 and 3 ($P<0.05$) and also between groups 2 and 3 ($P<0.05$).

Expression of apoptosis-associated proteins

Bcl-2 In group 1, two rats (13.3%) expressed Bcl-2 and one rat (6.7%) overexpressed Bcl-2. Expression of Bcl-2 was found in 10 rats (66.7%) and overexpression of Bcl-2 in five rats (33.3%) in group 3. Both the expression and overexpression

were significantly higher than that in group 1 ($P<0.05$). Group 2 had five rats (33.3%) expressing Bcl-2 and one rat (6.7%) overexpressing Bcl-2. Neither expression nor overexpression was significantly different from that of group 1 rats ($P>0.05$) but was significantly different from that of group 3 ($P<0.05$).

Fas In group 1, seven rats (46.7%) expressed Fas and two rats (13.3%) overexpressed of Fas. Group 3 had two rats (13.3%) with expression of Fas and two rats (13.3%) with overexpression of Fas. Expression of Fas was significantly different from that of group 1 ($P<0.05$), but overexpression was not ($P>0.05$). In group 2, six rats (40%) expressed Fas and four rats (26.7%) overexpressed Fas. Neither expression nor overexpression were significantly different from that of group 1 ($P>0.05$), but when compared with group 3, a significant difference was seen in the expression of Fas ($P<0.05$), yet not in overexpression ($P>0.05$).

ICE In group 1, three rats (20%) expressed ICE and no rats were found to be overexpressing this protein. Group 3 had two rats (13.3%) with expressing ICE and one rat (6.7%) with overexpressing ICE. Neither expression nor overexpression were significantly different from that in group 1 ($P>0.05$). In group 2, expression of ICE was seen in nine rats (60%) and overexpression was found in two rats (13.3%). Expression of ICE was significantly different from that in group 1 ($P<0.05$) but overexpression was not ($P>0.05$), and when compared with that of group 3, expression of ICE was significantly different ($P<0.05$) while overexpression was not ($P>0.05$).

Bcl-2 and Fas mRNA expression

The expression of bcl-2 mRNA increased and Fas mRNA was decreased in comparison of group 2 with group 1. The expression of bcl-2 mRNA was decreased and Fas mRNA was increased in comparison of group 2 with group 3 (Figure 1).

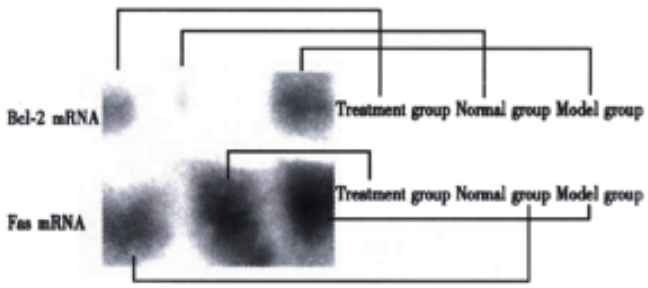

Figure 1 Bcl-2 and Fas mRNA expression.

DISCUSSION

With the introduction of fiberoptic endoscopy in the late 1960s and early 1970s, Nakamura and Nagayo in Japan were among the first to identify possible precancerous lesion on biopsical material and develop several categories for dysplasia[27,28]. In the West, Grundmann in 1975 quote for the first time the word dysplasia to describe exclusively precancerous gastric lesions[29]. Shortly after the WHO committee sanctioned this usage and detailed general diagnostic principles based on cellular atypia, abnormal differentiation and disorganised architecture[30,31]. There are differences between the Japanese and the Western criteria. A multicenter study is now under way to unify the diagnostic criteria[32-34]. So far there has been no unifed criteria of dysplasia among Chinese. We used the Japanese criteria in this study.

Is dysplasia reversible Several investigators have addressed the issue, but the cumulative results remain inconclusive. There are still coutroversies in the interpretation of atrophic changes and intestinal metaplasia resulting in wide discrepancy in the conclusions reached by different authors. Controlled, long-term prospective studies conducted in different ethnic and geographic settings are needed to provide sound evidence-based answers to the question of reversibility of atrophy, intestinal metaplasia, and epithelial dysplasia[6,35], trying to look for new drugs to reverse the dysplasia of great importance.

Normal gastric mucosal epithelial cells undergo apoptosis to clear up the senile cells and maintain the physiological balance of mucosal epithelial cells[36]. The homeostasis of gastric epithelial cells is maintained by the balance between cell proliferation and apoptosis. Alterations of these physiological cellular events in chronic pathological conditions of the stomach, as far as the proliferative pattern is concerned, an increase in the total number of epithelial proliferating cells and an abnormal distribution of the latter are frequently observed in chronic gastritis, gastric atrophy, intestinal metaplasia, gastric dysplasia and gastric cancer. Conversely, apoptosis has been found to be impaired in intestinal metaplasia, gastric dysplasia and cancer[37,38]. We consider the development of gastric cancer as a simple problem of balance, which is explained in the following formula: cumulative rate of epithelial cells' proliferation rate of epithelial cells' apoptotic rate of epithelial cells. When overaccumulation of gastric mucosal epithelial cells due to any reason, there is the possibility of development of gastric cancer. Thus, abnormal apoptosis might be one of the causes of gastric cancer development.

Apoptosis is modulated by regulatory genes. Bcl-2, Fas and ICE are the regulatory genes that have been predominantly studied. The statement of Bcl-2 can inhibit apoptosis, allowing the

proliferating cells to accumulate and inhibiting the removal of the malignant potential cells, thereby facilitating the development of cancerous change. Several scientists have studied the relation among bcl-2, gastric epithelial dysplasia and apoptosis and found that the expression abnormality leads to the apoptosis changed, the result in dysplasia and carcinoma[19,39-42]. The statement of Fas promotes apoptosis and his abnormality has relation with dysplasia too[43]. Interleukin-1-coverzyme can induce apoptosis in certain types of cells[44-46].

A few investigation of bcl-2 expression and dysplasia found that bcl-2 expression did not correlate with the presence or degree of dysplasia in either benign gastric mucosa or gastric carcinoma (GC) patients. bcl-2 protein is frequently expressed in GC[39,47]. The reason perhaps is the difference of rat's model and human gastric epithelial dysplasia, model induced by MNNG caused mainly by chemistrial carcinogenese, is not all the same with human.

Retinoic acid and its analog retinoid has a reverse effect on experimentally induced gastric mucosal precancerous lesions in rats[8-10,48]. The results of the present study further confirmed this. The results of the present study also revealed that retinoic acid can inhibit the overstatement of the Bcl-2 protein, promote the normal statement of the Fas protein and enhance the overstatement of the ICE protein, thereby promoting the apoptosis of gastric mucosal dysplastic epithelial cells. This may be one of the mechanisms by which retinoic acid reverses gastric mucosal precancerous lesions and the high statement of ICE may partly explain the side effects of retinoic acid.

The results of the present study reveal that in moderate and severe gastric mucosal dysplasia precancerous lesions, there is already abnormality in apoptosis and changes in associated genes. The increase in Bcl-2 statement, decrease in Fas statement and inhibition of apoptosis may be an important mechanisms in the progression of dysplasia to cancer.

INTRODUCTION

The field of gastrointestinal hormones has expanded at a dizzying rate[1-4]. Gastrointestinal hormones as regulatory peptides that appear to be major components of bodily integration and have important regulatory actions on physiological function of the gastrointestinal tract. The successful isolation of some gastrointestinal hormones and the development of sensitive methods for their detection have led to the unexpected finding that they also exist in the brain. Recent studies[5-8] have indicated that some disorders of gastrointestinal tract are related to gastrointestinal hormones. We explored this relationship by measuring concentrations of gastrin, somatostatin, G cell and D cell.

MATERIALS AND METHODS

We used healthy adult male Sprague Dawley rats weighing 220 g ± 30 g. The rats were housed in individual cages in a temperature-controlled room (23℃ ± 2℃) with a 12 h light dark cycle. The rats were fed standard rat chow (provided by Experimental Animal Center, First Military Medical University) and water ad labium. Rats were acclimatized to the environment for 7 days prior to the experiments.

Reserpine was obtained from the Hongqi Pharmaceutical Factory (lot No.960313). Si Junzi Tang, composed of ginseng, bighead, Fuling and Zhi Gancao, was prepared by routine method.

Fifty rats were randomly divided into five groups of ten rats each. Group A, the negative control group was injected with physiological saline, 0.5 mL·kg^{-1}·d^{-1},ip and distilled water, 2 mL, twice daily,ig, for 14 days. Group B was injected with reserpine, 0.5 mL·kg^{-1}·d^{-1},ip and distilled water, 2 mL, twice daily,ig, for 14 days. Group C was reserpine (0.5 mL·kg^{-1}·d^{-1}, ip) and Si Junzi Tang (2 mL, twice daily,ig), for 14 days. Group D was first injected with reserpine and distilled water for 14 days (similar to Group B). Group D was then injected with distilled water (2mL twice daily, ig) for 6 days. Group E was first injected with reserpine and water for 14 days (similar to Group B). Group E was then injected with Si Junzi Tang (2 mL, twice daily, ig) for 6 days.

We collected samples of body fluids (intestinal juice[9], gastric juice[10], plasma) and tissues (gastric antrum, jejunum, hypothalamus[11]) after treatment was finished for each group. All samples were stored at -70 ℃ until analysis. All gastroduodenal sections collected were fixed with neutral-buffered 10% formalin and embedded in paraffin.

Gastrin levels in samples were measured with radioimmunoassay kits from the Chinese Atomic Energy Research Institute of Immunotechnology. Somatostatin levels were measured with radioimmunoassay kits from Dong-Ya Research Institute of Immunotechnology. G cells and D cells of gastroduodenal mucosa were analyzed with immunohistochemical technique (using polyclonal antibody to gastrin and somatostatin) and the Quantimet 500 image analysis system (Leica, USA). Staining was performed using a streptavidin/peroxidase kit (SP™, ZYMED, USA). Immunostaining by replacing primary antibody with PBS was also conducted as a negative control. G cells and D cells of gastroduodenal mucosa were stained in continuous sections. Under magnification ×400, five randomly-selected cyclograms of each section were entered into the main computer of Quantimet 500 image analysis system from the photograph system. The main computer system analyzed graphs with corresponding software and obtained data of cell number, even square and even grey. The ratio of the cell number to square of G/D cells was calculated in continuous sections of G cells and D cells stained as follows: ratio of number of G/D cells = G cells number / D cells number; ratio of square on G/D cells = G cells square / D cells square.

Statistical analysis

Data were expressed as mean ± standard error of the mean. Experimental results were analyzed by analysis of variance and *t* tests for multiple comparisons. Statistical significance was determined at $P<0.05$.

RESULTS

Levels of gastrin and somatostatin in body fluids and tissues

The levels of gastrin in all samples tested from Group B (treated with reserpine alone) were 20%-60% less than Group A (controls). Levels of gastrin in Group D (treated with reserpine, the water) were also less than in Group A, though higher than in Group B. Levels of somatostatin were 50%-200% higher the Group B than in Group A. Levels of somatostatin were also higher than in Group A, though not as high as in Group B (Tables 1-4).

Table 1 Gastrin in body fluids (n = 10, $\bar{x} \pm s$, ng/L)

Group	Plasma	Gastric juice	Intestinal juice

[a]$P<0.05$ *vs* A,[b]$P<0.05$ *vs* B, [c]$P<0.05$ *vs* C, [d]$P<0.05$ *vs* D.

Levels of both gastrin and somatostatin in Groups C (treated concurrently with reserpine Si Junzi Tang) and E (treated first with reserpine then Si Junzi Tang) were similar to those in Group A, indicating that Si Junzi Tang may provide a protective effect against the functional disturbance caused by reserpine.

Expression of G cells and D cells in gastroduodenal mucosa

G cells of gastric antrum were mainly located in the lower 2/3 of the mucosa and rarely in the upper 1/3. G cells appeared round, elliptical, fusiform, triangular or irregular. They differed from the typical endocrine cells of gastroduodenum in that they produced long cytoplasmic and processed the end with small bulbous expansions on the putative effector cells. G cells gave off long cytoplasmic and processed terminate on D cells and also on enterochromaffin cells (Figures 1 and 3). D cells of gastric antrum were mainly located in the lower 1/3 of the mucosa and rarely in the upper 2/3 (Figure 2). Appearance of D cells was similar to that of G cells. G cells and D cells of the duodenum were mainly distributed in the intestinal glands and their appearances were similar to those of the gastric antrum. The number and even square of G cells and D cells declined, whereas the even grey of G cells and the ratio of the number and square on G/D increased in functional disturbance of gastrointestinal tract (Tables 5-7).

DISCUSSION

Gastrin and somatostatin are both important gut hormones [12-21]. Edkins first discovered gastrin in 1905. However, the existence of gastrin was questioned until the middle of the 19th century. Gastrin is mostly distributed in the mucosa of gastric antrum, the mucosa of the jejunum, and the central nervous system. Gastrin has a wide range of biological actions[22-25]. The most potent actions of gastrin are stimulation of gastric acid secretion[26-29]and antral smooth muscle activity.

Somatostatin was originally isolated from extracts of sheep hypothalamus as a growth hormone inhibiting factor. In addition to its marked effect on GH secretion, the peptide[30-33] possesses a surprising range of biological effects paralleled by an equally wide but characteristic anatomical distribution. Somatostatin also appears to inhibit the secretion of many gastrointestinal hormones and may be an important regulator for gastrointestinal functions[34-37].

Upon functional disturbance of the gastrointestinal tract, we inferred[22-25] that the inhibition of the release of gastrin might lead to a decrease of basal and maximal gastric acid secretion and inhibition of the secretion of gastric proteinase and inner factor. We further anticipated a decrease in blood flow to the upper digestive tract mucosa, which would lead to a reduction in nutrition and proliferation of gastric mucosal cells. Somatostatin[30-33] inhibited not only secretion of basal gastric acid and gastric proteinase, but also the effect of gastrin on gastric acid secretion. Some studies have demonstrated that motilin[34] had a potent actions on the smooth muscle of the stomach, the duodenum, and the colon, which could enhance gastric emptying rate, colonic motility and nutrition absorption. We observed that

somatostatin inhibited the gastric emptying rate, colonic motility and nutritional absorption by inhibiting motlin secretion following administration of reserpine. We inferred that decrease of gastrin release, increase of somatostatin release, and mutual regulatory disturbance can lead to a functional disturbance of gastrointestinal tract. Treatment with Si Junzi Tang, appeared to regulate the levels of gastrin and somatostatin in body fluids and tissues. Following administration of Si Junzi Tang, both gastrin and somatostatin remained or returned to normal level in the experimental functional disturbance of gastrointestinal tract model. This result indicates that Si Junzi Tang may be used to treat disorders of gastrointestinal hormones secretion.

Somatostatin[38] is also produced by endocrine-like (D) cells of the gut and pancreas and by peripheral nerve cells. Its actions are not restricted to the hypothalamo-hypophyseal system, somatostatin may also inhibit the release of several gastrointestinal and pancreatic hormones and affect on gastric HCl and pancreatic enzyme secretion. The bulk of evidence[38-40] suggests that somatostatin is delivered directly onto the membranes of G cells and parietal cells. In agreement with the cytochemical observations of D cells processing termination on G cells. Studies on the isolated perfused stomach have shown that infusion of somatostatin antiserum results in a brisk increase of gastrin release to up to 70 per cent of maximally stimulated levels. These data suggest that G cells may be under tonic inhibitory control by somatostatin.

The reserpine induced functional disturbance caused the number of G cells, D cells, and the even square of D cells to decline, whereas the even grey of G cells evaluated and ratio of the number and square on G/D increased[39-40]. These data suggest that high levels of somatostatin detected in body fluids and tissues were partly due to the release of somatostatin by D cells. High levels of somatostatin resulted in a decrease of gastrin release. This might explain the changes observed in G cells and D cells.

The study confirmed that changes of gastrin and somatostatin are associated with gastrointestinal disorder, which is one of the important causes for pathogenesis of the gastrointestinal tract.

Xu AG, Li SG, Liu JH, Gan AH. Function of apoptosis and expression of the proteins *Bcl*-2, *p*53 and C-*myc* in the development of gastric cancer. ***World J Gastroenterol***, 2001;7(3):403-406

INTRODUCTION

In China, the incidence and mortality of gastric cancer rank the second among all cancers. Recent studies indicate apoptosis could play a role in the development of cancer[1-20]. The aim of this study was investigat the insight of apoptosis and *bcl*-2, *p*53 and C-*myc* protein expression in the development of gastric cancer.

MATERIALS AND METHODS

Materials

All 122 specimens were collected by gastroscopy or surgical resection. Among these, 32 were chronic active gastritis, 29 were gastric ulcer, 17 were mild non-classic proliferation, 8 were severe non-classic proliferation, 6 were early gastric cancer, and 30 were progressive gastric cancer. The average age among those types of samples were 49.2, 46.3, 45.8, 50.3, 49.3 and 51.0, while the ratio of men to women was 20/12, 21/8, 11/6, 5/3, 5/1 and 21/9, respectively. There was no significant regularity among those samples after analyzed by statistics.

Reagents and methods

Apoptosis was detected using the TUNEL technique as reported by Ishida[1]. Cells in which the nuclear or cytoplasm was dyed brown were identified to be undergoing apoptosis. We observed five visual fields for each spechmen, and 100 nuclei were observed in each visual field. The average ratio of apoptosis cell was apoptosis index. Proteins *bcl*-2, *p*53, and C-*myc* were dyed by the ABC immunohistochemical method. Cells with obvious brown or deep brown after dying were defined to be positive.

RESULTS

The apoptosis index increased stepwise from chronic active gastritis to gastric ulcer and decreased from non-classic proliferation to early gastric cancer and progressive gastric cancer (Table 1). The expression of protein *bcl*-2 and C-*myc* increased progressively as follows: chronic active gastritis, gastric ulcer, mild non-classic proliferation, severe non-classic proliferation, and early gastric cancer. The expression of protein *bcl*-2 decreased when it developed into progressive gastric cancer while that of C-*myc* increased continually. Protein *p*53 was expressed only in severe non-classic proliferation gastric mucosa and gastric cancer.

The apoptosis index, C-*myc* and *p*53 expression of intestinal type were higher than that of diffuse type ($P<0.05$), while the *bcl*-2 expression was lower ($P<0.05$). The two types had the opposite outcomes (Table 2).

DISSCUSION

Apoptosis, programmed cell death, was first described by Kerr *et al*[21]. It is the programmed death of cells by fragmentation of DNA, cell shrinkage, and dilation of endoplasmic reticulum, followed by cell fragmentation and formation of membrane vesicles called apoptosis bodies[21-24]. Recent investigations have demonstrated that apoptosis plays a significiant role in the pathogenesis of tumors[25-30]. Screnhst have began to have realize that apoptosis, in concert with cell proliferation, is an important mechanism towards healthy tissues. Abnormal apoptosis contirbutes to the onset, development, and progression of cancer[2,31]. Stomach carcinoma is estimated to be one of the most frequent cancers worldwide[32-34].

According to Lauren, stomach cancer can be divided into adenocarcinomas of diffuse and intestinal types[35]. Ishida *et al*[1] reported the presence of apoptosis in gastric cancer tissue by using terminal deoxynucleotidyl transferase-mediated dUTP-biotin nick end labeling. They pointed out that apoptosis played a decisive function in pre-cancer changes and participated in the

development of cancer, including epithelial hyperplasia which occurrs in the gastric mucosa. The apoptosis action in sick gastric mucosa cells decreased, cell life was prolonged, and cells were piled up. This may be the reason why gastric cancer developes, infiltrates and transfers. Kasagi *et al*[10] studied the apoptosis indexes of various levels of differentiation. There was some difference between tumor tissue of high and low differentiations (apoptosis indexes were 10.9% and 4.0%, respectively, $P<0.01$). The difference indicated gastric cancer which had a low differentiation was less likely to undergo apoptosis. Non-classic proliferation of gastric mucosa was considered to be a precancerous change. Mijic *et al* [36] reported that numeric densities of apoptosis cell are associated with tumor progression in human gastric carcinogenesis. We found that the apoptosis index decreased from mild non-proliferation to severe non-proliferation, early gastric cancer, and progressive gastric cancer. This indicated that during the development of gastric cancer, apoptosis was inhibited.

The mechanism of apoptosis modulation of gastric-intestinal epithelia is very complicated. Many genes and factors are involved. Various proteins or oncogenes and suppressor gene are involved in the process of apoptosis, including *p*53, *bcl*-2, *myc*, *ras*, Bax and the Fas/Fas system[37-41]. Bax protein expression has been identified in various human malignant tissues[7,15,42,43]. Research has indicated that *bcl*-2 is an inhibitor of apoptosis. Li *et al*[44] reported that abnormal *c-myc* and *bcl*-2 expression is an important factor in biological behavior of gastric carcinoma and can regulate apoptosis. Sundblad *et al*[8] found that the expression of *bcl*-2 increased in cells of gastric cancer. *Bcl*-2 appears to not only inhibit apoptosis, but the protein be an antagonist of apoptosis mediated by oncogenesis suppressor genes. When the expression of *bcl*-2 increased, cancer cells would resist the apoptosis induced by chemical drugs or γ-radiation during therapy. Our results indicates that when non-classic proliferation occurrs in gastric mucosa, the expression of *bcl*-2 increases significantly. Expression of *bcl*-2 reached the top at the early stage of gastric cancer and decreased in the progressive gastric cancer. *bcl*-2 might do some work both in the triggering of gastric cancer and developing of early gastric cancer. Although *bcl*-2 was a strong inhibitor to apoptosis, it could not induce the cancer alone. However, cancer has been associated with *bcl*-2 in combination with C-*myc*[45].

Gastric carcinogenesis is a gradually developed process which result from the sequential alteration of multigenes[1,46-48]. Gene *p*53 is an oncogenetic repressor. Its anti-cancer function has been realized by triggering apoptosis. If gene *p*53 is inhibited, apoptosis can not be induced. Ikeda *et al*[49] observed that the progression of gastric cancer is defined by a gradual increase of proliferation activity and constant occurrence of apoptosis. Furthermore, Ikeda reported that the naturally occurring apoptosis is induced predominantly via a *p*53-gene-independent pathway. The half life of the mutant protein *p*53 is prolonged when gene *p*53 is mutated. It is easy to detect by immunohistochemical methods. We observed that expression of *p*53 was mainly in progressive gastric cancer tissue. No *p*53 was observed in the tissue of benign stomach diseases and mild non-classic proliferation. This indicated that the mutation of *p*53 might be an event in the late gastric cancer. The cooperation of *bcl*-2 and C-*myc* could inhibit the biological function of *p*53 to suppress cell growth by keeping it in the cytoplasm. Meanwhile, the co-expression of *p*53 and C-*myc* would lead to cell apoptosis and inhibit oncogenesis[50,51]. The co-expression of *bcl*-2 and C-*myc* in the same carcinoma tissue indicates a higher level of malignancy and a lack of sensitivity to chemical therapy and radiotherapy. The prognosis is not favorable. On the other hand, the co-expression of *C-myc* and *p*53 indicates a low level of malignancy, less sensitivity to chemical therapy and radiotherapy, and a favorable prognosis. Therefore *p*53 status and the expression of *bcl*-2 by tumor cells might be good indicators of sensitivity to chemotherapy for patients with gastric cancer[52].

Table 1 Relationship between apoptosis, protein expression of *bcl*-2, *p*53,C-*myc* and each kind of gastric diseases

	Chronic active gastritis	Gastric ulcer	Non-classic proliferation		Gastric cancer

*Compared with left itim: [a]$P<0.05$, gastric ulcer *vs* chronic active gastritis; [b]$P<0.05$, mild non-classic proliferation *vs* gastric ulcer; [c]$P<0.05$, severe non-classic proliferation *vs* mild non-classic proliferation; [d]$P<0.05$, early gastric cancer *vs* severe non-classic proliferation; [e]$P<0.05$, early gastric cancer *vs* progressive gastric cancer.

Table 2 Relationship between apoptosis, protein expression of *Bcl*-2, *P*53, *C-myc* and Lauren typing of gastric cancer

Lauren typing	Sample numbers	Apoptosis index %	Bcl-2 positive numbers(%)	C-myc positive numbers(%)	P53 positive numbers(%)
Intestinal	18	8.3±7.2	7(38.9)	13(77.7)	15(83.3)
Diffuse	12	5.1±4.9[a]	7(58.3)[a]	6(50.0)[a]	4(33.3)[b]

[a]$P<0.05$, Diffuse *vs* Intestinal; [b]$P<0.01$, Diffuse *vs* Intestinal.

Different pathological types of gastric cancer are associated with different physiological mechanisms. Intestinal gastric cancer had a higher level of differentiation and a closer relationship with gastric epithelial metaplasia as compared with diffuse type of gastric cancer. We observed intestinal type cancer more frequently among men and among older patients. Intestinal type cancer had a more favorable prognosis than diffuse type cancer. Also, the index of intestinal type of gastric cancer was higher than that of diffuse type ($P<0.05$), with lower expression of *bcl*-2 and higher expression of *C-myc* and *p*53. These results indicate that the pathogenic mechanism might be different between those two types of gastric cancer. Vollmers *et al*[53] had similar results, reporting that the gene expression modulation of apoptosis and the apoptosis indexes were different between type intestinal and diffuse gastric cancer. The apoptosis mechanism was different between those two types of gastric cancer.

INTRODUCTION

Chronic hepatitis B virus (HBV) infection is a serious problem because of its worldwide distribution and possible adverse sequelae, such as cirrhosis and hepatocellular carcinoma. The World Health Organization estimates that HBV has infected more than 350 million people worldwide, and up to 20% of them will become chronic carriers and will be at significant risk for cirrhosis and HCC. The ultimate goal of the therapy for chronic hepatitis B is to prevent progression to cirrhosis and to prevent development of HCC. Various subgroups of hepatitis B surface antigen (HBsAg) positive patients with chronic hepatitis have been identified. Typical patients have hepatitis B e antigen (HBeAg) and HBV DNA in serum during the active phase of the disease and usually show remission if they seroconvert to antibody to HBeAg (anti-HBe). However, a subset of patients has been found to be HBeAg negative but instead to have anti-HBe and HBV DNA in serum. This form of hepatitis is characterized by a progressive and relapsing course with fluctuations of viral replication[1,2] and a poor response to interferon α (IFN-α) therapy[3-11].

Thymosin a1 (T-a1) is an immune modifier that has been shown to trigger maturational events in lymphocytes, to augment T-cell function, and to promote reconstitution of immune defects[12]. T-a1 has been shown to promote disease remission and cessation of HBV replication in patients with HBeAg-positive chronic hepatitis B without significant side effects[13,14]. Moreover, clinical trials using T-a1 in the treatment of patients with immunodeficiency or cancer indicate that this agent is nontoxic, enhances immune responsiveness and augments specific lymphocyte functions, including lymphoproliferative responses to mitogens, maturation of T-cells, antibody production, and T-cell mediated cytotoxicity[15,16]. Based on these observations, we conducted a randomized, controlled trial to compare the efficacy and the safety of T-a1 versus IFN-α therapy in anti-HBe and HBV DNA positive chronic hepatitis B.

MATERIALS AND METHODS

Materials

Forty-eight Chinese patients were enrolled in the study. All patients met the following criteria for entry: age between 18 and 60 years; presence of HBsAg in serum for at least 12 months; positive serum tests for anti-HBe and HBV DNA, documented on at least two occasions and at least 3 months apart during the 12 months before entry; aminotransferase levels higher than 1.5 times that the upper normal limit for at least 12 months; and liver biopsy taken within 3 months before enrollment showing chronic hepatitis. Eligible patients with evidence of cirrhosis were also included. Patients treated with immunosuppressive or antiviral therapy within 1 year before entry, and those with concurrent hepatitis C virus, hepatitis delta virus, and human immunodeficiency virus infections, causes of liver disease other than HBV, intravenous drug abuse, pregnancy, malignancy, decompensated liver disease, chronic renal failure, or other serious medical illness that might interfere with this trial were excluded.

Thirty patients with the same virological and clinical characteristics, who were never treated with IFN-α and followed up for at least 12 months, were used as a historical control (HC) group to evaluate the efficacy of the therapies.

Methods

Forty-eight patients were randomly divided into two groups to receive either a 6-month course of T-a1 (Zasaxin, supplied by SciClone Pharmaceuticals Inc., San Mateo, CA) at a dose of 1.6 mg

subcutaneous injection twice a week or a 6-month course of IFN-α at a dose of 3-5 MU subcutaneous injection daily for fifteen days, then three times weekly. The patients assigned as a historical control group were followed up without specific treatment. All patients were assessed biweekly for the first 2 months of study, and then monthly for a total study duration of 12 months. Clinical and laboratory assessments consisted of a detailed history, including postinjection symptoms and physical examination; routine serum biochemical tests (serum alanine transaminase (ALT), aspartate transaminase (AST), r-glutamine transpeptidase (r-GT), alkaline phosphatase (AKP), albumin, globulin, bilirubin, etc.); complete cell count; markers of HBV replication and urine analysis. All biochemical and hematological tests were performed with routine automated techniques. HBV-markers (HBsAg, HBsAb, HBeAg, HBeAb, HBcAb and lgm HBcAb) were detected by enzymelinked immunosorbent assay (ELISA) method. Serum HBV DNA was detected by polymerase chain reaction (PCR) method.

Responses were evaluated both at the end of the therapy and at the end of follow-up. A virological response was defined as sustained disappearance of serum HBV DNA, and a biochemical response as sustained normalization of serum ALT. At the end of the treatment and follow-up, a complete response was defined as HBV DNA clearance from the serum and normalization of ALT activity. Relapse was assessed on the basis of ALT flare and/or HBV DNA reappearance during the follow-up period.

Statistical analysis

Analysis of data was accomplished using Chi-square test. *P* values less than 0.05 were considered to be statistically significant.

RESULTS

Of the 48 patients enrolled in the study, 18 were randomized to receive T-a1 and 30 to receive IFN-α and all were followed up for 6- months. The three groups were not significantly different in age, sex, biochemical, histological, serological parameters and number of patients with histological evidence of cirrhosis.

The biochemical and virological modifications at the end of treatment and follow-up period in the two treated groups and the biochemical and virological events in the HC group are illustrated in Table 1. In the group receiving T-a1, serum HBV DNA was negative in 9 of 18 patients at the end of treatment. During the follow-up period, five other patients showed HBV DNA loss at the 2nd, 3rd, 5th (in 2 patients) and 6th month, respectively, whereas HBV DNA reappeared in two at the 2nd and 3rd month, respectively. In the group receiving IFN-α, 18 of 30 patients showed HBV DNA loss at the end of treatment. However, during the 6-month follow up, HBV DNA reappeared in 9 patients (in 2 patients at the 1st month, in 5 at the 2nd and in 2 at the 3rd month), while no one lost HBV DNA. In the HC group, HBV DNA became negative in 3 of 30 patients at the 6th (in 2 patients) and 12th month, respectively, whereas HBV DNA reappeared in one at the 8th month. HBV DNA loss was significantly higher in the T-a1 and IFN-α groups compared with the HC group both at the end of therapy (χ^2=11.98, P<0.01 and χ^2=19.21, P<0.01, respectively) and follow-up period (χ^2=19.58, P<0.01 and χ^2=5.46, P<0.05, respectively).

Table 1 Responses to treatment in patients with chronic hepatitis B

	T-a1 (n = 18)	IFN-α (n = 30)	HC (n = 30)
	After 6 mo of treatment		After 6 mo of follow-up
ALT normalization	7 (38.9%)	15 (50%)	3 (10%)
HBV DNA-negative	9 (50%)[b]	18 (60%)[b]	2 (6.7%)
ALT normal / HBV DNA-negative	6 (33.3%)	14 (46.7%)[b]	1 (3.3%)
	After 6 mo of follow-up		After 12 mo of follow-up
ALT normalization	12 (66.7%)[ab]	10 (33.3%)	2 (6.7%)
HBV DNA-negative	12 (66.7%)[ab]	9 (30%)	2 (6.7%)
ALT normal / HBV DNA-negative	10 (55.6%)[ab]	7 (23.3%)	1 (3.3%)

[a]P<0.05, *vs* IFN-α; [b]P<0.01, *vs* HC.

Serum ALT levels fell within the normal range in 7 of 18 patients given T-a1, in 15 of 30 patients in IFN-α group at the end of treatment and in 3 of 30 of the HC group after 6 months of follow-up. During the follow-up, ALT became normal in six patients receiving T-a1 and ALT flare occurred in one patient, whereas five patients of the IFN-α group showed ALT flare, and no one had normal ALT. In the HC group, ALT was normal in two patients between the 6th and 12th month of follow-up and ALT flare was seen in the three patients who had normal ALT during the first 6 months of follow-up. At the end of the study period, a complete response (ALT normalization and HBV DNA loss) was observed in 10 (55.6%) of 18 patients treated with T-a1, in 7 (23.3%) of 30 receiving IFN-α, and in 1 (3.3%) of 30 in HC patients (T-a1 *vs* IFN-α, P<0.05 and T-a1 *vs* HC, P<0.01).

Typical side effects of IFN-α treatment, such as flu-like syndrome, fatigue, irritability, and headache, were seen in most of the patients treated with IFN-α. However, no serious or long-term side effects were noted and no patients discontinued the treatment. Therapy with T-a1 was not associated with significant side effects. Only one patient reported local discomfort at injection sites. No systemic or constitutional symptoms were observed with T-a1 administrations.

DISCUSSION

Anti-HBe and HBV DNA-positive chronic hepatitis B is a clinical entity distinct from classical HbeAg positive chronic hepatitis B. This peculiar form of hepatitis B is usually characterized by a severe progressive outcome often leading to cirrhosis and only occasionally shows spontaneous remission. These patients present fluctuations of viral replication in which relapses of hepatitis and periods of biochemical remission and HBV DNA negativity may occur. IFN-α treatment does not appear to be as successful as in HBeAg positive disease[3-11]. Clinical studies suggested that IFN-α at the dosage ranging from 3MU to 9MU three times a week for 6months is able to suppress HBV replication in more than 50% of treated patients, but the relapse rate after treatment withdrawal is high[3-11]. In our study, a complete response was seen in 46.7% of the patients at the end of treatment and in 23.3% at the end of follow-up. Our results are similar to those previously reported, and the response rate is far from satisfactory.

The results of the present randomized, controlled trial have shown that T-a1 therapy at a dose of 1.6 mg via subcutaneous injection twice a week for 6 months is effective and safe in anti-HBe and HBV DNA-positive chronic hepatitis B, because nearly 60% of the treated patients became HBV DNA-seronegative 6 months after the end of therapy. This response rate is not only significantly higher than that of the spontaneous seroconversion rate (3.3% in this study), but also obviously higher than the response to IFN-α therapy alone (23.3%) assessed 6 months after the end of therapy. The study showed that, at the dose tested, T-a1 has the same efficacy as IFN-α in inducing clinical and virological remission. The response rate in terms of ALT normalization and/or HBV DNA loss was not significantly different in the T-a1 group as compared with the IFN-α group at the end of the treatment ($P>0.05$). But there was significantly difference in the response rate between the two groups at the end of the follow-up ($P<0.05$). The normalization of serum ALT and loss of HBV DNA were observed more frequently in the IFN-α group at the end of therapy and in the T-a1 group at the end of follow-up. Furthermore, in the T-a1 group, the response to the treatment was also observed during the follow-up period, but not in the IFN-α group. On the basis of these results and considering that ALT normalization and HBV DNA negativization may spontaneously occur in the untreated patients infected by the precore mutant virus, we retrospectively compared the two treated groups with a group of untreated patients followed for at least 12 months. The results showed that a significant higher rate of complete response occurred in the IFN-α group at the end of therapy and in the T-a1 group at the end of follow-up compared with the HC group.

It is noted that the benefit of T-a1 was not immediately apparent at the end of therapy. There was a trend for complete virological response to increase or accumulate gradually after the end of thymosin therapy. This trend was also reported in a multicenter American trial in which 5 of the 12 responders to T-a1 therapy showed a delayed response [17]. This is in contrast to therapy with IFN-α, in which responses usually occur during the first 4 months of treatment. These contrasting patterns of response were best demonstrated in a recent Italian study involving HbeAg negative, HBV DNA-positive, interferon naive patients with higher ALT level (181 ± 159U/L), in which the complete response (ALT normalization and HBV DNA loss) rate increased gradually from 29.4% at the end of therapy to 41.2% 6 months after the end of T-a1 therapy. In that study, the response to interferon therapy decreased from 43. 8% at the end of therapy to 25% 6 months after the end of therapy[18]. This trend of delayed effect of T-a1 was also reported by Chien *et al*. in patients with chronic hepatitis B recently[14]. The reasons for this delayed effect of T-a1 are not clear. The delayed response is not likely a result of direct antiviram effects similar to those of interferons. T-a1 may exert an immunoregulatory function that promotes the endogenous antiviral immune response, as previously suggested, improving the effectiveness and coordination of the host cellular immune mechanisms in clearing HBV infected hepatocytes.

It has been shown that patients treated with T-a1 have a higher peripheral blood helper T cell count (CD4) and IFN-α production by peripheral blood mononuclear cells during and after the end of T-a1 therapy[13]. In view of the immune mechanisms involved in the pathogenesis of liver injuries in chronic HBV infection, it is possible that T-a1 may activate viral-specific helper T cells and result in the amplification of the humoral immune response to viral proteins and the induction of viral antigen-specific cytotoxic T lymphocytes through secreting endogenous IFN-α, IFN-γ, interleukin-2, and tumor necrosis factor, and increase lymphocyte interleukin-2 receptor expression[19-28]. Moreover, T-a1 is able to act synergistically with endogenous IFN-α and IFN-β in stimulating natural killer activity[29]. Although T-a1 is not known to possess antiviral properties, a preliminary report showed that this agent is able to inhibit woodchuck hepatitis virus replication[30]. Hence, the delayed effect after the end of T-a1 therapy in the present study was possibly caused by the immunomodulating effect of T-a1 that induced persistently higher helper T-cell function. Because noncytolytic inhibition of HBV RNA, nucleocapsid particles, and replicative DNA intermediates by cytotoxic T lymphocytes has been described in the transgenic mouse model[31,32], it is also possible the viral clearance after T-a1 therapy,

particularly those without preceeding ALT flaring, may be mediated by noncytolytic antiviral effects of cytotoxic T lymphocytes. Clearly, further studies are needed to elucidate the possible mechanisms.

The tolerability of T-a1 was excellent and without side effects. This finding together with a lower number of weekly injections could favor better patient compliance.

In conclusion, the results of this trial indicate that, at the dosage tested, T-a1 is of potential interest in patients with anti-HBe and HBV DNA-positive chronic hepatitis B. Furthermore, compared with IFN-α, T-a1 is better tolerated and seems to induce a gradual and more sustained ALT normalization and HBV DNA negativization, so it might represent an alternative to IFN-α therapy. However, a response rate of 55.6% is still less than ideal. A more effective therapeutic approach, such as combination therapy using the immunomodulating effect of T-a1 and antiviral effect of interferon or nucleoside analogues (such as lamivudine, famciclovir, etc.), warrants further studies.

INTRODUCTION

Chronic hepatitis B virus (HBV) infection is a serious problem because of its worldwide distribution and possible adverse sequelae, such as cirrhosis and hepatocellular carcinoma (HCC)[1,2]. The World Health Organization estimates that HBV has infected more than 350 million people worldwide, and up to 20% of those infected with HBV will go on to become chronic carriers and be at significant risk for cirrhosis and HCC. The ultimate goals of therapy for chronic hepatitis B are to prevent progression to cirrhosis and to prevent development of HCC. Over the past 20 years, many antiviral or immunomodulatory agents, or both, have been used in patients with chronic HBV infection[3-9]. Among them, interferon alfa (IFN-α), the standard treatment for chronic HBV infection, has been shown to be effective, which induces an apparent initial response in approximately 40% of treated patients[10,11]. However, the response rate is far from satisfactory, particularly in Asian patients, the relapse rate after treatment withdrawal is high[12].

Thymosin-a1 (T-a1) is an immune modifier that has been shown to trigger maturational events in lymphocytes, to augment T-cell function, and to promote reconstitution of immune defects[13]. T-a1 has been shown to promote disease remission and cessation of HBV replication in patients with HBeAg-positive chronic hepatitis B without significant side effects[14]. Moreover, clinical trials using T-a1 in the treatment of patients with immunodeficiency or cancer indicate that this agent is nontoxic, enhances immune responsiveness and augments specific lymphocyte functions, including lymphoproliferative responses to mitogens, maturation of T-cells, antibody production, and T-cell-mediated cytotoxicity[15,16]. On the basis of these observations, we conducted a randomized, controlled trial to compare the efficacy and the safety of T-a1 versus INF-α therapy in patients with chronic hepatitis B.

MATERIALS AND METHODS

Materials

Fifty-one Chinese patients were enrolled in the study. All patients met the following criteria for entry: age between 18 and 60 years; presence of hepatitis B surface antigen (HBsAg) and hepatitis B e antigen (HBeAg) in the serum for at least 12 months; positive serum tests for HBV DNA, documented on at least two occasions, at least 3 months apart, during the 12 months before entry; aminotransferase levels higher than 1.5 times the upper normal limit for at least 12 months; and liver biopsy taken within 3 months before enrollment showing chronic hepatitis. Eligible patients with evidence of cirrhosis and severe hepatitis B were also included. Patients treated with immunosuppressive or antiviral therapy within 1 year before entry, and those with concurrent hepatitis C virus, hepatitis delta virus, and human immunodeficiency virus infections, causes of liver disease other than HBV, intravenous drug abuse, pregnancy, malignancy, chronic renal failure, or other serious medical illness that might interfere with this trial were excluded.

Thirty patients with the same virological and clinical characteristics, never treated with IFN-α and followed up for at least 12 months were used as a historical control (HC) group to evaluate the efficacy of the therapies.

Methods

Fifty-one patients were randomly divided into two groups to receive either a 6-month course of T-a1 (Zadaxin, supplied by SciClone Pharmaceuticals Inc., San Mateo, CA) at a dose of 1.6 mg

subcutaneous injection twice a week or a 6-month course of IFN-α at a dose of 3-5 MU subcutaneous injection each day for 15 days, then three times weekly. The patients assigned as a historical control group, were followed up without specific treatment. All patients were assessed biweekly for the first 2 months of study, and then monthly for a total study duration of 12 months. Clinical and laboratory assessments consisted of a detailed history, including postinjection symptoms and physical examination; routine serum biochemical tests (serum alanine transaminase (ALT), aspartate transaminase (AST), r-glutamine transpeptidase (r-GT), alkaline phosphatase (AKP), albumin, globulin, bilirubin, ets.); complete cell count; markers of HBV replication and urine analysis. All biochemical and hematological tests were performed with routine automated techniques. HBV-markers (HBsAg, HBsAb, HBeAg, HBeAb, HBcAb, and Igm HBcAb) were detected by enzyme-linked immunosorbent assay (ELISA) method. Serum HBV DNA was detected by polymerase chain reaction (PCR) method.

Responses were evaluated both at the end of therapy and at the end of follow-up. A complete virological response was defined as a sustained loss of serum HBeAg in association with the disappearance of serum HBV DNA during the 12 months study. A biochemical response was defined as sustained normalization of serum ALT. At the end of treatment and follow-up, a complete response was defined as HBV DNA and HBeAg clearance from the serum and normalization of ALT activity. Relapse was assessed on the basis of ALT flare and/or HBV DNA/HBeAg reappearance during the follow-up period.

Statistical analysis

Analysis of data was accomplished using Chi-square test. *P* values less than 0.05 were considered to be statistically significant.

RESULTS

Of the 81 patients enrolled in the study, 30 had never been treated for HBV with IFN-α, and 2 were non-responders to earlier IFN-α therapy who received T-a1 in the study. Eighteen patients were randomized to receive T-a1 and 33 to receive IFN-α. All patients completed the 6-month follow-up. The three groups were not significantly different in age, sex, biochemical, histological, serological parameters and number of patients with histological evidence of cirrhosis.

The biochemical and virological modifications at the end of treatment and follow-up period in the two treated groups and the biochemical and virological events in the HC group are illustrated in Tables 1 and 2. In the group receiving T-a1, serum HBV DNA was negative in 10 of 18 patients at the end of treatment. During the follow-up period, five other patients showed HBV DNA loss at the 2nd, 3rd, 4th (in 2 patients) and 6th month, respectively, whereas HBV DNA reappeared in two (at the 3rd and 5th month, respectively). In the group receiving IFN-α, 22 of 33 patients showed HBV DNA loss at the end of treatment. However, during the 6 months of follow-up, HBV DNA reappeared in 9 patients (in 3 patients at the 1st month, in 4 at the 2nd and in 2 at the 3rd month), while no one lost HBV DNA. In the HC group, HBV DNA became negative in 3 of 30 patients (at the 5th, 6th, and 11th month, respectively), whereas HBV DNA reappeared in one (at the 7th month). HBV DNA loss was significantly higher in the T-al and IFN-α groups compared with the HC group both at the end of therapy (χ^2=28.97, P<0.01 and χ^2=23.99, P<0.01, respectively) and follow-up period (χ^2=22.49, P<0.01 and χ^2=9.27, P<0.01, respectively). The rates of seroconvertion of HBVe antigen antibody in the T-al, IFN-α and HC groups at the end of treatment were 33.3% (6/18), 45.5% (15/33) and 3.3% (1/30), respectively; and at the end of follow-up 55.6% (10/18), 27.3% (9/33) and 3.3% (1/30),respectively. Serum ALT levels fell within the normal range in 7 of 18 patients given T-al, in 16 of 33 patients in IFN-α group at the end of treatment and in 5 of 30 of the HC group after 6 months of follow-up. During the follow-up, five patients receiving T-al normalized ALT and one patient showed ALT flare, whereas six patients of the IFN-α group showed ALT flare, and no one normalized ALT. In the HC group, two patients normalized ALT between the 6th and 12th month of follow-up and an ALT flare was seen in the four patients who normalized ALT during the first 6 months of follow-up. At the end of the study period a complete response (ALT normalization and HBV DNA/HBeAg loss) was observed in 10 of 18 (55.6%) patients treated with T-al, in 9 of 33 (27.3%) receiving IFN-α, and in 1 of 30 (3.3%) in HC patients (T-al *vs* IFN-α, HC,P<0.01).

Table 1 Responses to treatment at the end of therapy *n*(%)

	T-a1 (n = 18)	IFN-α (n = 33)	HC (n = 30)
	(after 6 mo of follow-up)		
ALT normalization	7 (38.9)	16 (48.5)	5 (16.7)
HBV DNA-negative	10 (55.6)[b]	22 (66.7)[b]	2 (6.7)
ALT normal / HBV DNA and HBeAg-negative	6 (33.3)	15 (45.5)[b]	1 (3.3)

[b]P<0.01, *vs* HC.

Table 2 Responses to treatment at the end of follow-up *n*(%)

	T-a1 (n = 18)	IFN-α (n = 33)	HC (n = 30)
	(after 12 mo of follow-up)		
ALT normalization	11 (61.1)[a]	10 (30.3)	3 (10)
HBV DNA-negative	13 (72.2)[ab]	13 (39.4)[b]	2 (6.7)
ALT normal / HBV DNA and HBeAg-negative	10 (55.6)[ab]	9 (27.3)	1 (3.3)

[a]P<0.05, *vs* IFN-α; [b]P<0.01, *vs* HC.

Typical side effects of IFN-α treatment, such as flu-like syndrome, fatigue, irritability, and headache, were seen in most of the patients treated with IFN-α. However, no serious or long-term side effects were noted and no patients discontinued the treatment. Therapy with T-al was not associated with significant side effects. Three patients reported local discomfort at injection sites. No systemic or constitutional symptoms were observed with T-al administrations.

DISCUSSION

The results of the present randomized, controlled trial have shown that T-a1 therapy at a dose of 1.6 mgvia subcutaneous injection twice a week for 6 months is effective and safe in patients with chronic hepatitis B, because nearly 60% of the treated patients became HBeAg- and HBV DNA-seronegative 6 months after the end of therapy. This response rate was not only significantly higher than that of the spontaneous seroconversion rate (3.3% in this study), but also obviously higher than the response to IFN-α therapy alone (27.3%) assessed 6 months after the end of therapy. The study showed that, at the dose tested, T-a1 has the same efficacy as IFN-α in inducing clinical and virological remission. The rate of response in terms of ALT normalization and/or HBV DNA and/or HBeAg loss was not significantly different in the T-a1 group compared with the IFN-α group at the end of the treatment (P>0.05). But there was significantly difference on the rate of response between the two groups at the end of the follow-up periods (P<0.05). The normalization of serum ALT and loss of HBV DNA and HBeAg were observed more frequently in the IFN-α group at the end of therapy and in the T-a1 group at the end of the follow-up. Furthermore, in the T-a1 group the response to the treatment was observed also during the follow-up period, but not in the IFN-α group. On the basis of these results and considering that ALT normalization and HBV DNA/HBeAg negativization may spontaneously occur in untreated patients, we retrospectively compared the two treated groups with a group of untreated patients followed for at least 12 months. The results showed that a significant higher rate of complete response occurred in the IFN-α group at the end of therapy and in the T-a1 group at the end of follow-up compared with the HC group.

It is noted that the benefit of T-a1 was not immediately apparent at the end of therapy. There was a trend for complete virological response to increase or accumulate gradually after the end of thymosin therapy. This trend was also reported in a multicenter American trial in which 5 of the 12 responders to T-a1 therapy showed a delayed response[17]. This is in contrast to therapy with IFN-α, in which responses usually occur during the first 4 months of treatment. These contrasting patterns of response were best demonstrated in a recent Italian study involving HbeAg negative, HBV DNA-positive, Interferon-naive patients with higher ALT level (181 ± 159 U/L), in which the complete response (ALT normalization and HBV DNA loss) rate increased gradually from 29.4% at the end of therapy to 41.2% 6 months after the end of T-a1 therapy. In that study, the response to interferon therapy decreased from 43.8% at the end of therapy to 25% 6 months after the end of therapy[18]. This trend of delayed effect of T-a1 was also reported by Chien *et al*. in patients with chronic hepatitis B recently[19]. The reasons for this delayed effect of T-a1 are not clear. The delayed response is not likely a result of direct antiviral effects similar to those of interferons. On speculating, T-a1 may exert an immunoregulatory function that promotes the endogenous antiviral immune response, as previously suggested, improving the effectiveness and coordination of the host cellular immune mechanisms in clearing HBV infected hepatocytes.

It has been shown that patients treated with T-a1 have a higher peripheral blood helper T cell count (CD4) and IFN-γ production by peripheral blood mononuclear cells during and after the end of T-a1 therapy[14]. In view of the immune mechanisms involved in the pathogenesis of liver injuries in chronic HBV infection, it is possible that T-a1 may activate viral-specific helper T cells and result in the amplification of the humoral immune response to viral proteins and the induction of viral antigen-specific cytotoxic T-ymphocytes through secreting endogenous IFN-α, IFN-γ, interleukin-2, and tumor necrosis factor, and increase lymphocyte interleukin-2 receptor expression[20-29]. Moreover, T-a1 is able to act synergistically with endogenous IFN-α and IFN-β in stimulating natural killer activity[30]. Although T-a1 is not known to possess antiviral properties, a preliminary report showed that this agent is able to inhibit woodchuck hepatitis virus replication[31]. Hence, the delayed effect after the end of T-a1 therapy in the present study was possibly caused by the immunomodulating effect of T-a1 that induced persistently higher helper T-cell function. Because noncytolytic inhibition of HBV RNA, nucleocapsid particles, and replicative DNA intermediates by cytotoxic T lymphocytes has been described in the transgenic mouse model[32,33], it is also possible that viral clearance after T-a1 therapy, particularly those without preceeding ALT flaring, may be mediated by noncytolytic antiviral effects of cytotoxic T lymphocytes. Clearly, further studies are needed to elucidate the possible mechanisms.

The tolerability of T-a1 was excellent and without side effects. This finding together with a lower number of weekly injections could favor better patient compliance.

In conclusion, the results of this trial indicate that, at the dosage tested, a 6-month T-a1 therapy is safe and effective in arresting HBV replication and

reducing lobular activity in patients with chronic hepatitis B. Furthermore, compared with IFN-α, T-a1 is better tolerated and seems to induce a gradual and more sustained ALT normalization and HBV DNA/HBeAg loss, so it might represent an alternative to IFN-α therapy. However, a response rate of 50% is still not sastifactory. A more effective therapeutic approach, such as combination therapy using the immunomodulating effect of T-a1 and antiviral effect of interferon or nucleoside analogues (such as lamivudine, famciclovir, etc.), warrants further studies.

INTRODUCTION

From the technical aspect of liver surgery, control of bleeding during hepatic parenchymal resection is one of the most important procedures in hepatectomy. Pringle's maneuver, a temporary cross-clamping of the hepatoduodenal ligament, has often been used for this purpose[1]. This is the simplest and useful technique to reduce intraoperative blood loss. Unfortunately, this method has resulted in normothermic ischemiareperfusion injury of the liver. Many clinical observations indicate that prolonged intraoperative normothermic ischemia and succeeding reperfusion of the liver are the most significant disadvantages of Pringle's manever, and may cause postoperative functional disorder of the liver[2-6].

Although the process of ischemia reperfusion injury of the liver is complicated, it consists of three pathologic components: hepatic ischemia, portal congestion, and reinflow of arterial and congested portal blood. Ischemia-reperfusion injury is not merely an ischemic injury but is also related to reperfusion of blood. Moreover, it has been revealed that reactive oxygen radicals and some chemical mediators activated during recirculation play an important role in the development of liver injury after ischemia[7-11]. Because portal congestion is an extremely harmful factor that can induce bacterial translocation, generation of chemical mediators, and reactive oxygen radicals in the portal flow, it is conceivable that reinflow of congested portal blood containing activated pathogens may play a role in the development of ischemia-reperfusion injury of the liver. However, the influence of portal congestion on the development of liver injury during ischemia-reperfusion injury has not been well researched. Only a few authors have described the significance of the reperfusion of congested portal blood[12].

Heat shock protein 72 (HSP72) is produced in the liver after normothermic ischemia and reperfusion [13-15]. HSP72 is now being intensively investigated as one of the most fundamental stress proteins. The protein is produced in response to a variety of stress-induced stimuli and is considered to be an important factor which helps to maintain cellular homeostasis and increase the chance of pateint survival[16-23].

In the present study, we investigated the induction of HSP72 in the liver tissue after 15-minute Pringle's maneuver with or without portosystemic shunt in the rat model, to determine the influence of congested portal blood on the development of ischemia-reperfusion injury in liver.

MATERIALS AND METHODS

Male Wistar rats weighing 200 g to 300 g were housed in chip-bedded cages in a climate-controlled room (24℃ ± 1℃) under a 12-hour light-dark cycle. The rats were provided with ordinary rat chow and water *ad libitum*- according to the animal protection guidelines of Kyoto University. Rats were premedicated with an intramuscular injection of atropine sulfate (0.05 mg) and anesthetized with an intraperitoneal injection of pentobarbital sodium (40 mg/kg rats weight) before all operative procedures. They were divided into two groups. In the first group (Group P), the abdomen was opened through a median laparotomy and the liver was detached from its ligaments. Total hepatic ischemia with portal congestion was produced by clamping

the hepatoduodenal ligament for 15 minutes with a microvascular clamp. In the second group (Group S), the abdomen was opened in the same way and the liver was also detached from its ligaments. Extracorporeal portosystemic shunt was achieved from the cecal branch of the superior mesenteric vein to the right external jugular vein, using a polyethylene tube (0.58 mm inner diameter×200 mm long, Dural Plastics Co., Australia) filled with 0.04 mL heparinized saline solution (250U/mL). The liver was subjected to warm ischemia by cross-clamping the hepatoduodenal ligament for 15 minutes with a microvascular clamp. However, portal congestion was prevented by the extracorporeal shunt. During these interventions, the abdomen was temporarily closed and an electric heater was placed under the animal to keep the rectal temperature at 36℃ ± 1℃. Then, declamping allowed reperfusion until sampling after specified periods.

Liver tissue was removed at 48 hours after each intervention and Western blot analysis was performed to detect HSP72 (monoclonal SPA-810, StressGen Biotechnologies Corp., Canada)[13]. To measure adenosine nucleotide concentration, liver tissue was sampled by freeze-clamping at 1 (n = 6), 3 (n = 6) and 48 hours (n = 6) after reperfusion. Enzymatic assay was performed to measure the concentration of adenine nucleotides in the liver tissue [24,25]. The energy charge potential (EC) was calculated according to the formula proposed by Atkinson: (ATP+0.5 ADP)/(ATP+ADP+AMP)[26], where ATP, ADP and AMP are adenosine tri, *di*, and monophosphate, respectively. Blood samples were taken from the aorta at 1 (n = 6), 3 (n = 6), and 48 hours (n = 6) after the end of each intervention. The serum concentration of aspartate aminotransferase (AST), alanine aminotransferase (ALT) and lactic dehydrogenase (LDH) were measured at a biochemical laboratory. After sampling, rats were killed.

The values were expressed as mean ± standard deviation (SD). For the statistical analysis, Student's *t* test was performed for the biochemical parameters. A P value <0.05 was considered to be significant.

RESULTS

Comparing these two groups, HSP72 was markedly overexpressed in group P but its accumulation in group S was very slight (Figure 1).

In the comparison between AST, ALT and LDH levels in group P and group S (Table 1). There was a trend towards higher transaminase levels in group P, but the difference was not statistically significant (P>0.05).

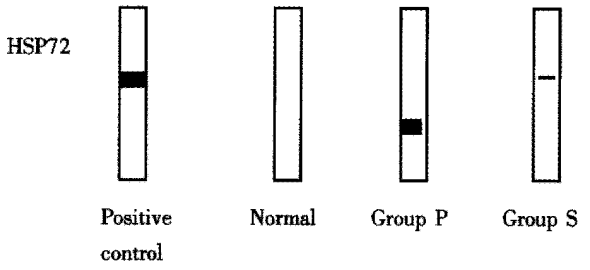

Figure 1 Heat shock protein (HSP) production in the rat liver after 48 hours of reperfusion in each group compared with that in normal liver (5 μg protein per lane). HSC70, which contains inducible HSP72 in approximately 10 per cent, was used as a positive control (0.2 μg protein per lane).

Table 1 Changes in AST, ALT and LDH (IU/L) in serum after reperfusion (n = 6)

Parameter	1 h	3 h	48 h
Group *P*			
AST	4832±1589	4896±3270	199±93
ALT	4860±2015	5218±3230	266±155
LDH	45235±21748	44619±29975	588±265
Group S			
AST	4147±1069	2731±1282	204±72
ALT	4230±1460	2689±1459	181±103
LDH	35752±15954	26327±21973	476±248

Results are expressed as means ± SD.
There was no statistically significant difference in AST, ALT and LDH at any time point examined between two groups.

There were no significant differences between the two groups at any time point examined (P>0.05, Table 2).

Table 2 Change in ATP levels (mmol/g wet wt tissue) and EC in liver tissue (n = 6)

Parameter	1 h	3 h	48 h
Group *P*			
ATP	1.49±0.69	1.91±0.42	3.08±0.42
EC	0.67±0.11	0.62±0.07	0.83±0.03
Group S			
ATP	1.60±0.55	2.22±0.81	3.00±0.22
EC	0.64±0.14	0.68±0.12	0.80±0.05

EC, energy charge. Results are expressed as means ± SD.
There were no significant differences in ATP concentration and EC level at 1 h, 3 h, and 48 h between two groups (P>0.05).

DISCUSSION

Heat shock proteins are intracellular proteins that have been well conserved during evolution. They are present in small amounts in normal cells and larger amounts in cells subjected to a variety of stressful stimuli. Heat shock stress, which induces the synthesis of HSPs, is closely related to the physiologic body temperature of the organism[16,27]. This is the reason by which special attention was paid to control the body temperature of the animals

during operations in this study to obviate the possible effects of body temperature changes. The rectal temperature of the animals was strictly controlled in the range of 36℃ ± 1℃ using an electric heating pad.

Schoeniger *et al*[14] reported that prolonged ischemia induced by Pringle's maneuver did not activate the HSP72 gene in the porcine liver until restoration of blood flow. They concluded that transcription of HSP72 mRNA was highly dependent on the generation of superoxide anions. This participation of superoxide anions in the activation of HSP72 gene partly suggests a contribution by the reinflow of portal blood, but the role of portal blood pooling was not a focus of their report. We observed that the reinflow of congested portal blood into ischemic liver after a shortterm Pringle's maneuver contributed to the production of HSP72 in the liver tissue. However, the liver subjected to the same period of ischemia produced less HSP72 when reperfusion was performed with non-congested portal blood. This observation suggests an adverse impact of congested portal blood on liver function after ischemia and reperfusion. In contrast, Tacchini *et al*[28] reported that inflow occlusion to the partial liver for a longer period (up to 60 minutes) also induced expression of HSP72 mRNA in the ischemic lobe in rat liver. In their experiment, portal congestion did not occur because of hemi-occlusion of the hepatic inflow. The discrepancy in the influence of congested portal blood in the production of HSP72 between their results and ours may be due to the difference in ischemic periods. When the ischemic stress is sufficient due to a longer insult, even non-congested blood may cause oxidative stress sufficient to provoke the activation of heat shock genes. However, when the ischemic derangement of hepatic parenchyma is not so severe, the nature of the blood used for reperfusion may have a marked impact on the results. These findings imply that portal pooling would act appreciably as a key stress factor to increase the production of HSP72, but it would not be an essential factor when the degree of pre-existing ischemia is already high.

Although the mechanism by which the reflow of congested portal blood induces HSP72 production is still unclear, the process seems to be complex. The mechanism most likely involves factors that operate in the ischemic reperfused liver. Active oxygen species and free radicals are known to activate heat shock genes[29,30]. It is likely that free radicals generated in the small bowel during portal congestion play a role in the development of liver tissue injury during reperfusion[31-38]. Kawamoto *et al*[7] reported that the temporary occlusion of the portal vein and hepatic artery both increased xanthine oxidase activity in portal plasma and increased the permeability of the intestine during reperfusion. Both of these were prevented when a portosystemic shunt was performed and splanchnic vascular congestion was prevented. Other potential causative factors in the production of HSP72 include endotoxin and various cytokines translocated from the intestines during portal congestion. Recently, participation of both endotoxin and bacteria in the production of HSP72 has been reported[17,27,39-41]. Pringle's maneuver for 15 minutes was observed to have significantly increased plasma endotoxin levels in the portal blood and enhanced bacterial translocation into the portal blood from the gut[9].

Our results also suggest that HSP72 might prove useful in evaluating the degree of hepatic ischemia-reperfusion injury. Levels of enzymes in serum (including AST, ALT, and LDH), ATP and EC in liver tissue have been commonly used to assess hepatocellular injury. In the present study, no significant difference was observed between the congested and non-congested groups at any time point examined. Thus, even the ATP concentration and EC cannot differentiate these two groups. Animals could fully recover from liver injury as long as the Pringle's maneuver lasted only 15 minutes, and no animals died as a result of it. However, the fact that the stress brought on by the reperfusion of congested portal blood was clearly greater than that produced by the reperfusion of non-congested blood, as demonstrated by the production of HSP72, implies that the accumulation of stress under a repeated or prolonged Pringle's maneuver would likely result in irreversible liver damage. This concept is also consistent with the report of Nitta *et al*[12]. They reported that conventional parameters or arterial ketone body ratio could be used to detect the ill-effect of congested portal blood during reperfusion when Pringle's maneuver was repeated four times, although they failed to detect it after a single 30-minute Pringle's maneuver in dogs. In this sense, the production of HSP72 seems to be more sensitive than conventional parameters to detect the given stress during ischemiareperfusion injury.

In conclusion, HSP72 induced in the liver tissue by a shortterm Pringle's maneuver was associated with the reinflow of congested portal blood into ischemic tissue. The influence of this congested portal blood upon reperfusion of ischemic tissue was detected by HSP72, but not by conventional biochemical parameters. HSP72 is suggested to be useful for determination of the degree of hepatic ischemia-reperfusion injury.

INTRODUCTION

Kupffer cells are residential macrophages in the liver, which play a critical role in the maintenance of normal liver function and in immunal surveilance of hepatocellular carcinoma (HCC) and other cancers[1]. The biological immune modulants have been used for treating patients with HCC and other cancers[2]. In our previous studies, the combined use of biological immune modulants showed better effects. The normal rats and hepatoma rats induced by DEN (Diethylnitrosamine) were treated by either IFNα-2b or BCG or both, the number of KCs and the amount of H_2O_2 released increased obviously, while the combined use of IFNα-2b and BCG showed the best results[3,4]. This study was focused on the influence of biological immune modulants on the release of TNF and IL-1 by KCs in rats with hepatoma.

MATERIALS AND METHODS

Animals

Male Wistar rats weighing 150 g-200 g, were provided by the Experimental Animal Center of the Chinese Academy of Medical Sciences. The rats were given drinking water containing 0.008% DEN for 12 weeks, then randomly divided into four groups, they were given IFNα-2b (Schering Plough Co. USA) at a dose of 16U/kg, BCG (Biological Product's Research Institute, Shanghai) at a dose of 0.1 mg/kg, and combination of the two intraperitoneally, the controls were given the same volume of normal saline at various survival periods (12th week, 16th week).

Isolation of KCs

Under anesthesia, the rats were exsanguinated and the livers were perfused *in situ* via the portal vein with Hank's balanced salt solution (HBSS). The livers were dissected free and passed through 60 μm brass screens into HBSS. Following centrifugation at 500 × *g* for 10 min (4℃), the pellet was resuspended in 30 mL HBSS containing 0.05% collagenase (TYPE I, Sigma) and 0.1% pronase (TYPE E, Sigma), and incubated for 30 min in a 37℃ agitating water bath, following centrifugation at 500 × *g* for 2 min to sediment the hepatocytes,an enriched nonparenchymal cell pellet was obtained by centrifugation of the supernatant at 500 × *g* for 35 min. Erythrocytes were lysed by incubation for 3-5 min with ammonium chloride (0.83%). The cells were washed twice with HBSS and resuspended in standard RPMI-1640. After 4 h incubation at 37℃ in 100 mm plastic petridishes, the nonadherent cells were removed by three successive wash with warm HBSS. The adherent cells, phagocytosing latex beads (Sigma) were designated as Kupffer cells. After 10 min incubation at 37℃ in Trypsin-EDTA (0.05%/0.02%), KCs were liberated from the plastic dishes by vigorous pipetting, washing, and counted. The purity of KC was >95% by latex bead ingestion and viability was >90% as indicated by trypan blue exclusion (0.4% trypan blue stain in 0.85% salin). The KCs of control hepatoma rats (at the 18th week) were isolated and treated with IFNα-2b (2500 U/mL), BCG (2 mg/L) or both respectively. The human hepatoma cell line SMMC-7721 cells and KCs were cocultured in the RPMI-1640 medium supplemented with 10% fetal bovine serum at 37℃ in a humidified atmosphere containing 5% CO_2 for4 h. Supernatants were collected, and stored at -20℃ until use.

IL-1 activity assay

IL-1 activity in the culture supernatants was assayed by the enhancement of thymocyte proliferation to concanavalin A (ConA). Briefly, thymocytes were obtained from female C57BL/6N mice at 5-7 weeks of age, cell suspensions of thymocytes were prepared by pressing the thymus tissue through a 50 μm wire mesh, then filtering the tissue fragments through a 30 μm nylon mesh into RPMI-1640 medium supplemented with 2.4 g/L ConA. The

cells were resuspended to 1.5×10^6 cells/mL, and 100 μL of cell suspensions were placed in each well of 96-well microtiter plates, 100 μL of supernatants were added to each well and the plates were incubated for 72 h. Each cell culture well was plused 3.7×10^{10} μBq ^{3}H-thymidine during the final 8 h of incubation and harvested onto glass fibers, using an automatic cell harvester, ^{3}H-thymidine incorporation was determined by a liquid scintillation spectrometer, the enhancement of thymocyte proliferation of the unknown supernatant IL-1 levels was determined by the ratio of radioactivity incorporated in the experimental and control groups (SI).

TNF assay

The levels of TNF in culture supernatants were determined by a TNF specific ELISA obtained from Institute of Military Medical Sciences. The kit was composed of 96 determinations and the assays were performed exactly as recommended by the manufacturer. All samples were assayed in triplicate.

Statistical analysis

The results were presented as the mean of triplicates ± SEM, and statistical significance was assessed by Student's *t* test.

RESULTS

The influence of biological immune modulants on the release of TNF by KCs of normal rats *in vivo* (Table 1). The KCs of normal rats could release a little TNF and IL-1 when cocultured with human SMMC-7721 hepatoma cells, the TNF and IL-1 released by KCs of normal rats treated with biological immune modulants *in vivo* increased obviously. The effect of combined use of IFNα-2b and BCG exhibited the best effects, the combination of IFNα-2b and BCG increased the production of TNF by 3.5 times and the activity of IL-1 by 80%. BCG was better than IFNα-2b in increasing the release of IL-1, and IFNα-2b was better in increasing the production of TNF.

Table 1 The influence of biological immunal modulants on the release of TNF and IL-1 by KCs of normal rat *in vivo*

Groups	TNF (ng/L)	IL-1 (SI)
Control	56.2±10.5	1.40
BCG	79.4±17.6[a]	2.27[b]
IFNα-2b	134.9±51.4[b]	1.84[a]
IFNα-2b+BCG	199.5±71.5[b]	2.54[b]

n = 18, [a]P<0.05, [b]P<0.01 *vs* control.

The influence of biological immune modulants on the release of TNF and IL-1 by KCs of rat with hepatoma *in vivo* is shown in Table 2. The influence of biological stimulants on the release of TNF and IL-1 by KCs of rats with hepatoma *in vivo* was similar to those of normal rats. The combined use of IFNα-2b and BCG exhibited the best effect, the amount of TNF released by KCs treated with IFNα-2b and BCG increased by 5.6 times (12th week) and by 4. 5 times (16th week), the activity of IL-1 increased by KCs treated with IFNα-2b and BCG increased by 48% (12th week) and 78% (16th week).

Table 2 The influence of biological immunal modulants on the release of TNF and IL-1 by KCs of rats with hepatoma *in vivo*

Groups	2nd week		16th week	
	TNF (ng/L)	IL-1 (SI)	TNF (ng/L)	IL-1 (SI)
Control	50.1±9.4	1.57	79.4±10.6	1.58
BCG	234.4±63.1[b]	2.58[b]	148.5±47.2[a]	2.74[b]
IFNα-2b	251.2±82.1[b]	2.33[b]	166.0±30.5[a]	2.42[b]
IFN-2b+BCG	281.8±63.3[b]	2.80[b]	354.8±96.4[b]	4.08[b]

n = 18,[a]P<0.05, [b]P<0.01 *vs* control.

The influence of biological immune modulants on the release of TNF and IL-1 by KCs of rat with hepatoma *in vitro* is shown in Table 3. The influence of biological stimulants on the release of TNF and IL-1 by KCs of rats with hepatoma *in vitro* was similar to the result *in vivo*. IFNα-2b was better than BCG in increase of release of TNF by KCs, BCG gave better results than IFNα-2b in increasing the activity of IL-1 released by KCs. The combined IFNα-2b and BCG exhibited the best effects, the amount of TNF released by KCs treated with IFNα-2b and BCG increased by 123.8%, the activity of IL-1 released by KCs treated with IFNα-2b and BCG increased by 58%.

Table 3 The influence of biological immune modulants on the release of TNF and IL-1 by KCs of rats with hepatoma *in vitro*

Groups	TNF (ng/L)	IL-1 (SI)
Control	100.0±20.6	1.42
BCG	141.3±31.7[b]	1.80[a]
IFNα-2b	199.5±61.2[b]	1.64[a]
IFNα-2b+BCG	223.8±42.4[b]	2.24[b]

n = 18, [a]P<0.05, [b]P<0.01 *vs* control.

DISCUSSION

TNF and IL-1 are macrophage-derived cytokines, TNF is known to have cytotoxic and cytostatic effects on certain tumor cells, and with a pivotal role in inflammatory reactions and regulation of immunological response[5,6]. The actions of IL-1 have been elucidated in recent years, it is directly cytotoxic for some human tumor cells, and stimulates T cell proliferation by inducing production of interleukin 2 (IL-2) as well as increasing the number of IL-2 receptors on the T cell, and directly stimulate NK cell activity[7].

Kupffer cells are residential macrophages in the liver, and play an important role as scavenger cells in nonspecific elimination of gut endotoxins, immune complexes and viruses[8], especially the important role in immunal surveillance on HCC[9,10]. Kupffer cells have also been reported to release some cytokines when activated by biologically reactive substances, several reports have suggested that IFNγ regulates monocytic function, especially in the production of TNF and IL-1. Kawada had shown that IFNγ enhanced TNF production in the presence or absence of lipopolysaccharide (LPS), but suppressed IL-1 production by KCs[11]. Brandwein showed that IFNγ markedly inhibits LPS-stimulated IL-1 production by mouse peritoneal macrophages[12], but differed from the observations of Boraschi and Hart[13,14]. Amento *et al* have also observed that IFNγ did not stimulate IL-1 production by macrophages from the human monocyte cell line U937[15], and many reports had suggested that IFNγ augments both TNF and IL-1 production by macrophages only in the presence of LPS[12], this variable responses are undoubtedly related to the difference in both the interferon preparations and the responder cell types. Our study showed that IFNα-2b stimulated and enhanced TNF and IL-1 production by KCs in the absence of LPS, the difference may have resulted from the cell types and condition of macrophages, since KCs may always be exposed to endotoxins and activated to some degree [16]. In our previous studies, anti-tumor effects of KCs activated by various biological immunal modulants were different, but the combined use of various biological immunal stimulants showed the best effect [2]. Our previous studies of the mechanism of KCs function also showed that the combination of IFNα-2b and BCG exhibited the best results, the increase of the number and volume of KCs, the increase of the amount of H_2O_2 released by KCs[3,4]. The systematic study mentioned above, regardless of normal or hepatoma rats and both *in vivo* and *vitro* consistently confirmed the combined use of IFNα-2b and BCG was better than either one used alone in enhancing the activity of immune cells. These results suggested that the combined use of IFNα-2b and BCG to HCC patients should be advocated.

INTRODUCTION

Inflammatory pseudotumor of the liver, a rare benign lesion, is often confused with the malignant tumors. Until 1998, less than 80 cases had been reported in the world[1,2]. The accuracy of the pre-surgical diagnosis was low[3,4], and very few materials on the diagnosis using dynamic MRI were reported[5-7]. We collected thirteen cases of inflammatory pseudotumor of the liver were collected and proved by pathology with MRI studies. Our purpose is to describe and analyze the MRI findings of this lesion and find out the valuable signs suggesting the diagnosis so as to avoid unnecessary operations.

MATERIALS AND METHODS

Thirteen cases collected from September 1995 to December 2000 in our hospital (9 men and 4 women aged from 31-58 years, 41 years in average). More than half of the cases had no symptoms, and the others complained of upper abdominal discomfort, only three cases had fever of unknown causes. AFP and other liver lab testing were normal.

All of 13 cases underwent MR examinations with 1-5T Signa scanner (GE Medical Systems Milwaukee, WI), including T_1WI (TR/TE = 500-700 ms/14-16 ms), T_2WI SE sequence (TR/TE = 2000-4000 ms/60-90 ms) and FMPSPGR dynamic enhanced MRI(Matrix 256 × 128, thickness 7 mm, gap 3 mm, TR/TE Flip Angle = 100-150 ms/1.5-4.5 ms/60-90°). Four repeated acquisitions were obtained at 25-30, 60, 90 and 180s respectively following power injection of 15 mL-20 mL (0.15 $mmol \cdot kg^{-1}$) of Gd-DTPA (gadopentetic dimeglumine, Magnevist, Shering Pharmaceutical Ltd.) via an antecubital vein.

The MRI imagings of all cases were read and analyzed by two experienced doctors. Comparisons were made between preoperative diagnosis and results of surgical pathology.

RESULTS

A total of 16 lesions were identified by surgical pathology in the 13 cases, including three lesions in 1 case and single one in 12 cases. The size of the lesions was 0.8 cm-3 cm in diameter (2.1 cm in average). The shape of the lesions was also variable, being round, ovoid, lobular (seen in coalescence of small focus) and irregular.

On SE sequence T_1WI, 6 of 16 lesions were isointense (Figure 1A), the other 10 lesions were slightly hypointense (Figure 2A). On SE sequence T_2WI, 6 of 16 lesions were slightly hyperintense (Figure 2B), the other 10 lesions were nearly equal intensity of signal to that of normal parenchyma (Figure 1B). The lesions discovered on SE sequence MRI were not well defined and the conspicuity between the lesions and the parenchyma were much less than that seen on dynamic MRI imaging of portal venous and delayed phases.

On dynamic enhanced MRI, none of the lesions showed enhancement in the dominant arterial phase (Figure 1C, Figure 2C). Therefore, the lesions were not seen clearly in this phase. On the contrary, all the lesions were well defined in the portal venous phase or/and the delayed phase. In these phases, the following appearances could be found: ① peripheral enhancement of the lesion (12/16, 75%) (Figure 2D). ② Small nodular enhancement (6/16, 37.50%), located in the central area of the lesions like core (Figure 2D), or near the marginal area of the lesions which we described as stalactite. ③ Septum within the lesions which could be linear or thick and irregular in appearance were seen in 8 (50%) of 16 lesions, and enhanced in the portal venous phase or/and delayed phase (Figure 1D). ④ All findings on dynamic MR imaging were seen overlapped.

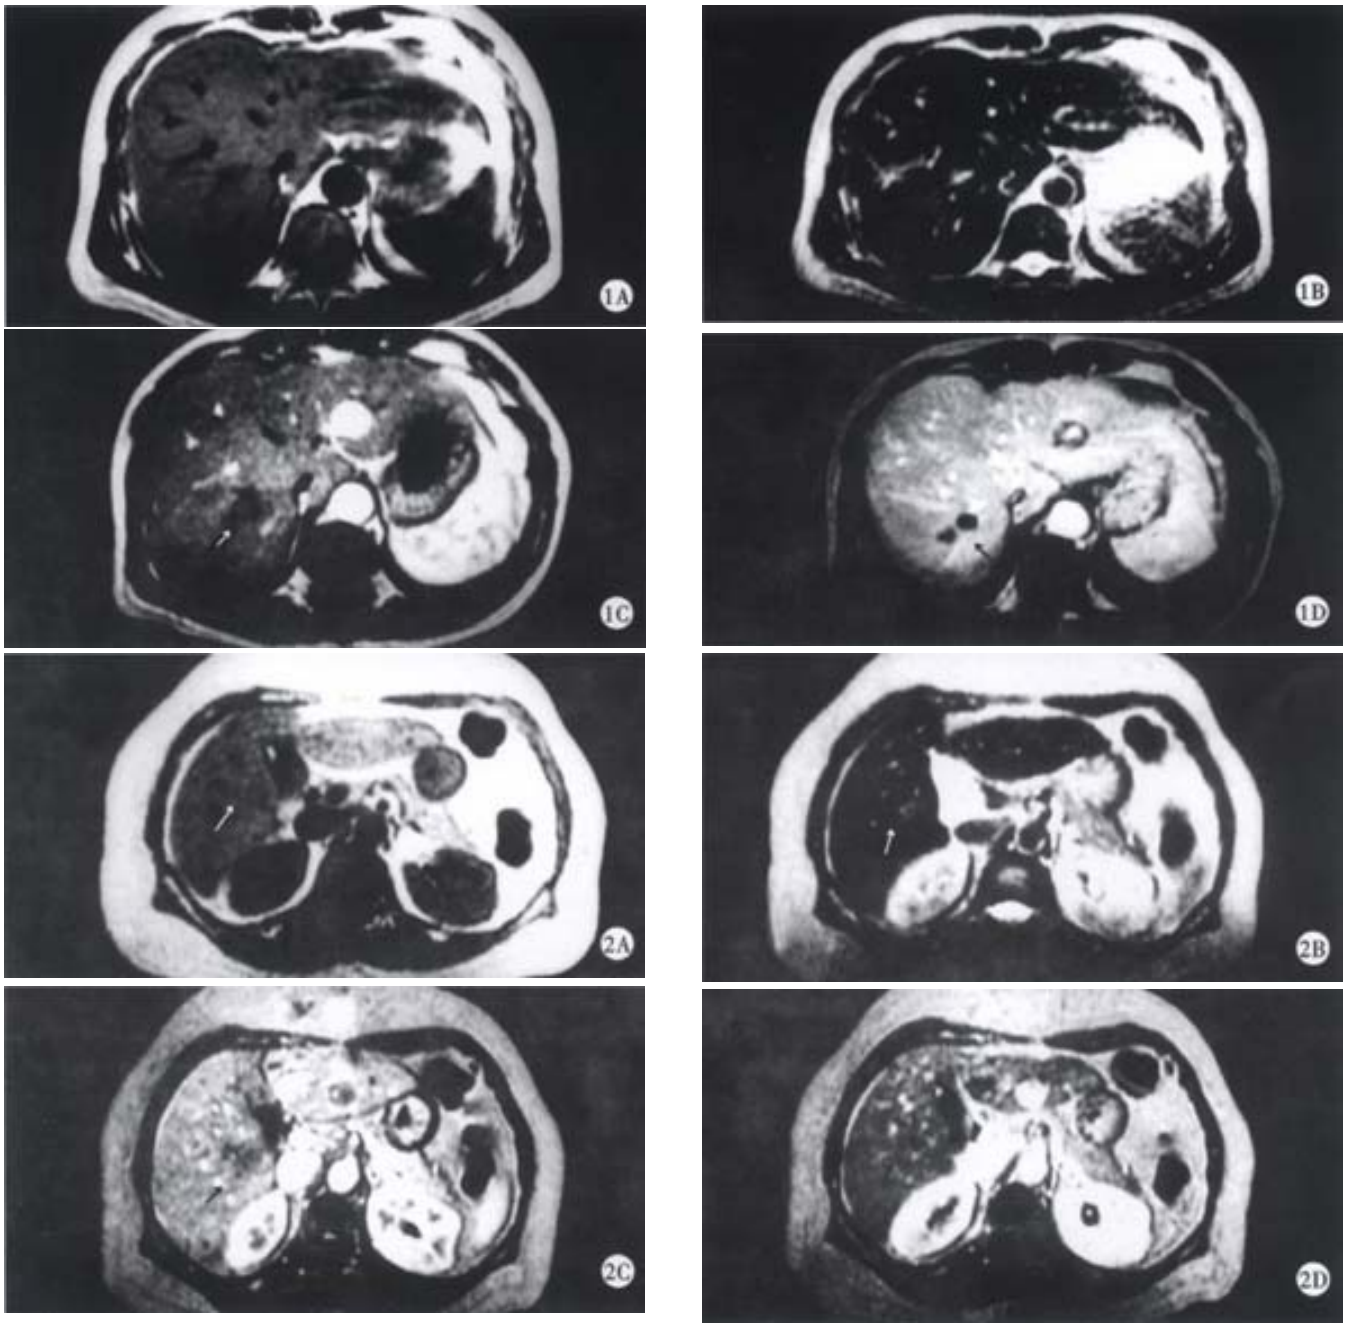

Figure 1 Inflammatory pseudotumor of the liver in the right posterior lobe. A SE T_1WI and B SE T_2WI could not show any lesions. C A hypointense lesion could be found in the right lobe (arrow), there is no enhancement in early arterial phase of dynamic contrast MRI. D portal venous phase of dynamic contrast MRI showed the enhanced septum (arrow).

Figure 2 Inflammatory pseudotumor of the liver in the right posterior lobe. A SE T_1WI showed a hypointense lesion(arrow). B SE T_2WI showed the lesion was slightly and inhomogeneously hyperintense(arrow) . C There is no enhancement in early arterial phase of dynamic contrast MRI, the edge of the lesion was not clear(arrow). D portal venous phase of dynamic contrast MRI showed the punctual core in the center and peripheral enhancement (arrow).

DISCUSSION

Correlation of pathology with MR imaging findings

Inflammatory pseudotumor of the liver is a rare benign disease, occasionally discovered by US, CT and MRI[5-9]. The etiology has not yet been very clear, and may be related to infection and immunogical compromise. Fibroblastic proliferation and chronic inflammatory cell infiltration constitute the characteristic features of the disease[3,10]. The mass is surrounded by the fibrocollageous stroma rich with capillary vessels, which may explain the peripheral enhancement in portal and delayed phases scans in the majority of cases due to the extravascular accumulation of contrast medium. Within the mass, there are less inflammatory cell components and more coagulative necrosis, so on SE T_2WI, most of the lesions were nearly equal

intensity of signal to that of normal parenchyma because of coagulative necrosis containing less free water. These are the characteristics of inflammatory pseudotumor of the liver. Six lesions showed slightly hyperintense on SE T_2WI, because of more inflammatory cell infiltration within the lesions. The larger area consisted of coagulative necrosis and cell components in the central region does not enhance as fibrosis in later phase and appears heterogeneous. It was not enhanced in early arterial phase since the lesion had no direct hepatic arterial blood supply.

Detection and differential diagnosis

Most of the lesions could be detected by sonography in our group, but as it was hard to be characterized, color Doppler ultrasound became mandatory supplementary modality, which could recognize the presence or absence of arterial blood flow to help determine the nature of the lesions.

SE sequence of MRI had more limitations in detection of the lesions since the difference of signal intensity was not conspicuous between the lesion and parenchyma on T_1WI as well as on T_2WI. Six of 16 lesions in this group were isointense on T_1WI and 10 of 16 lesions were also isointense on T_2WI, and the others had only slight or moderate difference with the normal hepatic parenchyma. So, contrast enhanced MRI was very important to avoid potentially missing detection of small lesions and it is very important to recognize the nature of the lesion and not to confuse with the malignant tumors, mainly hepatocellular carcinoma and metastases of the liver.

The key point to differentiate it from hypervascular HCC is the absence of enhancement in arterial phase. Attention should be paid to the differentiation from hypovascular HCC. The following findings on MRI might be helpful: ① peripheral enhancement of lesions on the later phase; ② the presentation of septum and core, which has never been seen in HCC; ③ variable or irregular shape of the lesions, coalescence of several small lesions in one case; ④ most of the lesions were isointense on T_2WI, but more than 90% lesions of HCC were hyperintense on T_2WI[11]. MRI with mangafodipir trisodium might help distinguish inflammatory pseudotumor of the liver from hepatocellular carcinoma[12]. But peripheral ring-like enhancement may mimic the metastatic lesions. The history of primary malignant tumors and the absence of fibrotic septum or linear appearance within the mass and the most of lesions were hyperintense on T_2WI could help the differentiation.

In summary, in view of rare occurrence, few cases of inflammatory pseudotumor of the liver have been accurately diagnosed preoperatively in the past. Since MRI was put into clinical application and with experiences accumulated, the accuracy of diagnosing this disease has been greatly improved.

In conclusion, MRI is very imperative to reveal the features of the lesions, such as no early arterial enhancement, peripheral enhancement, septum and small nodular enhancement occurred in portal venous and delayed phases.

INTRODUCTION

Sialyl Lewis-X antigen, correlated with carcinoma, is a group of carbohydrate antigen containing oligosaccharide expressed both on glycolipids and glycoproteins on cell surface of embryonic tissue and tumor tissue[1]. The SLeX antigen located on cell surface is synthesized principally by two enzymes, αl, 3fucosyltransfrease and α2, 3sialyctransferase. In adults, SLeX antigen is expressed principally on the surfaces of granulocytic cells and some tumor cells. It is a ligand of endothelial leucocyte adhesion molecules (ELAM-1, or E-Selectin) [2,3] and plays an important role in the adhesion of leucocyte to the vascular wall in inflammation and adhesion between tumor cells and blood endothelial cells in tumor metastases[4,5]. This study intends to observe the expression of SleX antigen and analyzes the correlation between the expression and metastatic potential by using cell lines of both Lovo[6] and HT29 [7] of human colon carcinoma. Our experiments have confirmed that both cell lines possess the capability of forming tumor and having the metastatic potential. Lovo cells obviously showed a greater hepatic metastatic potential in experimental nude mice than HT29 cells[8,9]. We employed *in situ* hybridization technique to detect the expression of SLeX antigen synthatase at mRNA level in both low and high metastatic potential of colon carcinoma cells. Meanwhile we used immunohistochemistry and flow cytometry to directly detect the expression of SLeX antigen at intracellular protein level within Lovo and HT29 cells. We observed morphologic features of interaction between tumor cells and blood vessel endothelial cells as well as the linkage of both cells in interaction by means of scanning and transmission electronmicroscope. We used a method of sealed colon carcinoma cells with SLeX monoclonal antibody to observe the adhesive potential between human colon carcinoma cells and umbilical vein endothelial cells and to observe the effects of this method on hepatic metastases of experimental nude mice. We expect to find out the mechanism of how SLeX antigen functions in human colon carcinoma hepatic metastases.

MATERIALS AND METHODS

Materials

Cell lines, both Lovo and HT29 were provided by our laboratory. Endothelial cells were obtained by the perfusing and digesting human umbilical vein. Umbilical cord was provided by the Department of Gynecology and Obstetrics in Nanfang Hospital. BALB/C nude mice were provided by the Experimental Animal Center of the First Military Medical University.

Methods

Lovo, HT29 cells α1, 3Fuc-Toligonucleotide probe was detected by *in situ* hybridization ① Cell culture and manufacture of cell patch:Lovo and HT29 cells (using RPMI-1640 complete medium) were placed in an incubate trunk that contained 5% CO_2 at 37℃. The cells grown well and were digested by pancreatin to make up a 1×10^7/mL cell suspension, and then inoculated a drop of the cell suspension on cover slip of sterilized petridish and the complete medium was cultivated for 48 h, then removed the cover slip, washed thrice with 0.0l M, pH 7.2 PBS, fixed with acetone for 10min and finally washed with PBS for use. ② *In situ* hybridization: The cell patches were digested by 10 μg/mL protease K at 37℃ for 10 min and then washed with PBS buffer. 200 μL prehybri dization buffer was degenerated at 95℃ for 10 min, put into ice cubes to quench, then placed flat into a sealed moist case and incubated at 42℃ for 3 h. Five mL of α1, 3Fuc-T oligonucleotide probe of coragoxin with a density of 39.65pmol/μL was added into 200 μL pre hybridization liquid to form a hybridization liquid. The hybridization liquid was degenerated at 95℃ for 10 min. After being quenched in ice cubes, it was added into the cell sample, placed flat in a sealed moist case, and kept at 42℃ overnight. It was washed with 6 × SSC 45% aminic acid amine, and 2 × SSC and 0.2 × SSC

for 10 min respectively. It was added coragoxin Fab piece labeled alkaline phosphatase (1:125 dilute concentration) at 37℃ for 4 h, and then was washed by buffer. NBT/BCIP was added for coloration for 2 h. It was treated with 100% alcohol and xylene and sealed by neutral gum for later use. The control was done without oligonucleotide probe. Areas that showed positive α1, 3Fuc-T mRNA were dyed royal blue with royal blue grains. The deeper the color, the higher the positive degree. ③ Quantitative analysis and statistics: The quantitative analysis was done with Shen Hong's[10] aw and Leica-Q500M image analysis system. After 10 positive cells were taken randomly, we surveyed the gray degrees (Gα) and the gray degrees of their background (Gβ) in the positive areas. The positive units (PU = 100|Gα-Gβ|/256) were calculated with origin 50 software. Data were analyzed statistically with the *t* test of SPSS.

Immunohistochemistry

① Cell culture and manufacture of cell pieces: The procedure was identical to that of *in situ* hybridization. ② Immunohistochemistry LSAB: The approaches (omitted). The negative control was incubated with PBS on the cell piece without primary antibody. The SLeX protein expression areas were dyed brown. Deep brown was defined as strongly positive, while light brown as weakly positive. ③ Quantitative analysis and statistical method were the same as those in *in situ* hybridization.

Flow cytometry

① Cell culture was identical to that of *in situ* hybridization. ② Flow cytometry measure: The Lovo and HT29 cells digested with 0.25% panceatin, washed with PBS and centrifugated at 1000 rpm × 5 min were made into 1 × 10^7/mL cell suspension and then added SLeX monoclonal antibody (mouse anti-human IgM) (1:100 dilution). The negative control was processed with PBS instead of the primary antibody. Then the goat anti-mouse IgM labled FITC second antibody (1:60 dilution) was added at 4℃ for 30 min. All the suspensions were washed with PBS at 1000 rpm × 5 min, fixed with 1% polymeresatum at room temperature for 30 min, then re-washed with PBS and finally centrifugated at1000 rpm × 5 min for detection with EPICSEMTE model flow cytometry.

Adhesive test of tumor cells to human umbilical vein endothelium

① Tumor cell suspension preparation: The well-grown Lovo and HT29 cells were prepared into 1 × 10^7/mL cell suspension with complete culture medium. The suspension was divided into 4 groups: Lovo cell experimental group and its control group, HT29 cell experimental group and its control group. The experimental groups were added SLeX monoclonal antibody 10 μL (5 μg/mL) and the control groups PBS instead of SleX. They were pre-incubated at 37℃ for 30 min. ② Adhesive test of tumor cells to umbilical vein endothelium: The umbilical vein was cut open under sterile condition and was washed off red blood cells with PBS and then cut into 1 cm × 1 cm pieces, 0.5 cm thick paraffin was put onto the bottom of the 16-well culture plate which was to be rinsed 3 times with PBS after the paraffin congealed. The plate was exposed under ultraviolet light for 30 min, added a suitable amount of culture medium for immersion for 15 min. The luminal surface of blood vessel was put upwards and fixed with stainless needles on paraffin on the bottom of wells. The TNF-α (end density 1:500U/mL) was added at 37℃ for 4 h. After the culture was taken out, the prepared Lovo and HT29 cell suspensions were added into each well and incubated at 37℃ for 4 h in atmosphere 5% CO_2. The umbilical vein taken out was washed with PBS and fixed with 2.5% glutaraldehyde for 30 min and then washed again, dehydrated, dried at critical point, puffed gold and detected under a S-450 scanning electronic microscope. ③ Criteria of results and statistical method: During the adhesive test between tumor cells and umbilical vein endothelium, the tumor cells, which adhered to vascular endothelium in every vision field were counted by 500 × scanning electronmicroscope. Ten vision fields of each group were chosen randomly and their average values were calculated and statistically analyzed with *t* test.

Adhesive test between tumor cells and human umbilical vein endothelial cells

① Preparation of tumor cell suspension: as described above. ② Endothelial cell culture: 15 cm of fresh umbilical core from a healthy puerperal was washed off red blood cells with PBS. One end of the core was cramped and the 0.25% pancreatin was filled into the core from the other end. It was digested at 37℃ for 15 min. The digested fluid that contained the endothelial cells was drawn out and put into a centrifugal tube and centrifugated at 1000 rpm for 15 min and processed into the cell suspension with RPMI-1640 culture medium containing 20% calf serum. The suspension was inoculated onto a plastic cell petridish, and incubated with 100 μg/mL ECG at the atmosphere of 5% CO_2 at 37℃. The liquid was exchanged every 24 h-36 h. ③ Adhesive test of tumor cells to human umbilical vein endothelial cells: the well grown endothelial cells were digested with 0.25% panceatin, prepared into 1 × 10^3/mL cell suspension with complete culture medium, put onto 6 well petridish, added 100 μg/mL ECG, and kept at 37℃ for 20 h. After the 500U/mL TNF-α was added, it was kept at 37℃ for 4 h. One mL of Lovo cells and HT29 cells processed in experimental and control groups, was added respectively into each well. The petri dish was placed into an oscillator of 120 rmp,at room temperature for 30 min and washed twice with PBS. The cells were scraped and collected into the centrifugal tubes for centrifugation of 500 rmp × 10 min. After the upper clear liquid was removed, the cells were fixed with 2.5% glutaraldehyde

buffered, washed, fixed, dehydrated, embedded with gum, made into ultra-thin sections, colored with electronic stain for observation under a JEM1200-EX transmission electronmicroscope.

Effects of SLeX monoclonal antibody on liver metastases of experimental nude mouse

① Preparation of tumor cell suspension: The well-grown Lovo cells and HT29 cells were digested with 0.25% pancreatin, washed twice and diluted into the cell suspension with PBS after 1000 rpm × 5 min. The cell suspension concentration was regulated to 1×10^7/mL. The cell suspension was divided into 4 groups: Lovo cell, HT29 cell and their corresponding control groups. The experimental groups were added 10 μL SLeX monoclonal antibody while the control groups were added the same volume of PBS instead of SLeX. The cell suspensions were incubated at room temperature for 30 min. ② Influences of SLeX monoclonal antibody on liver metastases of experimental nude mouse: 365-week-old BALB/C healthy male nude mice were divided into 4 groups as described above. After the nude mice were anesthetized with 4% amine ketone intraperitoneal injection, their abdominal cavities were opened at 0.5 cm below left rib edge under sterile condition to expose their spleens. The cell suspension (0.3 mL) prepared was injected to the capsule below in the spleen and the abdominal cavity was closed. The mice were fed under SPF condition and killed after 4 weeks. Their spleens, livers, hearts, kidneys and lungs were taken out, dehydrated, transparented and paraffin-embedded. The tumor tissues visible were sliced while the tissues of which tumors were not found with naked eyes made serial sections before being HE dyed and observed under a light microscope. ③ Criterion of results and statistical methods: The liver metastases in each group was observed with naked eyes and under light microscope. The data obtained from the observation were tested with χ^2-test with SPSS software, with $P<0.05$ being significant.

RESULTS

In situ hybridization

αl, 3Fuc-T mRNA expressions in Lovo and HT29 cells showed negative results in the control groups while those were positive in the experimental groups. In the experimental groups, αl, 3Fuc-T mRNA in the Lovo cells were strongly positive, and their cytoplasm showed deep blue with visible royal blue fine particles (Figure 1), while αl, 3Fuc-T mRNA in the HT29 cells were weakly positive, and their cytoplasm showed light blue with visible royal blue fine particles (Figure 2). αl, 3Fuc-T mRNA expressions in Lovo cells were stronger than those HT29 cell, and their difference was significant ($P = 0.002$, Table 1).

Table 1 Expressions of αl, 3Fuc-TmRNA in two cell lines

	n	$\bar{x} \pm s$	*t*	*P*
Lovo cells	10	21.2055±7.7472	3.537	0.002
HT29 cells	10	10.7922±5.1653		

Immunohistochemistry

The SLeX expressions in Lovo cells and HT 29 cells were negative in the control groups but positive in experiment groups. The SLeX antigen expressions in Lovo cells were strongly positive, and their cytoplasm showed brown or deep brown (Figure 3); The SLeX antigen expressions in HT29 cells were weakly positive, and their membranes were brown (Figure 4). There was a significant difference between the expressions of the two ($P = 0.025$, Table 2).

HT29 cells	10	21.9188±8.8016		

Flow cytometry quantitative detection

The Lovo cell and HT29 cell SLeX antigen expressions were positive. The ratio of positive SLeX antigen expressions in the Lovo experimental groups was 42. 9% while that in the control groups was 2.3%. The positive rates in the HT29 cell line were 23.3% and 2. 1% respectively in the experimental groups and their control groups. The percentage was greater in the experiment groups of Lovo cell line than that in the experiment groups of the HT29 cell line (Figures 5,6).

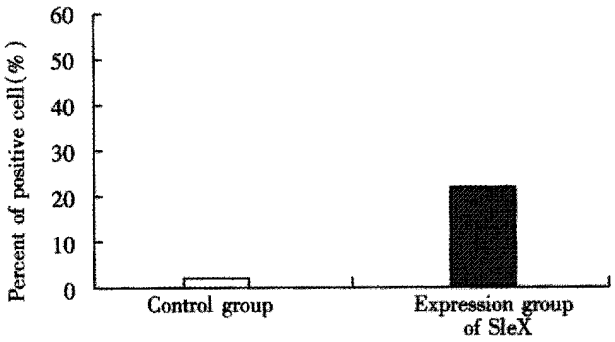

Figure 6 The detective result of HT29 cells. flow cytometry

Observation of the adhesion of tumor cells to umbilical vein endothelial cells under scanning electronmicroscope

Both Lovo cell and HT29 cell line had adhesive potential to umbilical vein endothelial cells in the control groups. The Lovo cell line showed greater adhesive potential to umbilical vein endothelial cells than the HT29 cell line. It could be observed under a 500 × scanning electronmicroscope after co-incubation for4h, a great deal of Lovo cells adhered to umbilical vein endothelial cells, and majority of them were clustered (Figure 7); and some of the HT29 cells adhered only to the surface of the umbilical vein endothelial cells, and only a part of them clustered (Figure 8). The adhesive potential was obviously even lower in the experiment groups. Under a 500 × scanning electronmicroscope after co-incubation for 4 h, the Lovo cells adhered to the umbilical vein endothelial cells were scattered and no clustering could be observed (Figure 9). The adhesive potential of the HT29 cells was weaker than that of the Lovo cells. Only a small amount of the HT29 cells adhered to the endothelial cells, and did not cluster (Figure 10). The cells adhered to the surface of the umbilical vein endothelial cells were fewer in the experiment groups than in the control groups. There was a significant difference between them ($P = 0.0001$, Table 3).

Table 3 The different adhesive potentials of tumor cells to umbilical vein endothelial cells with the tumor cells sealed

	n	Control groups $\bar{x} \pm s$	Experimental groups $\bar{x} \pm s$	*t*	*P*
Lovo cells	10	213±15.6702	124±16.7319	12.167	0.0001
HT29 cells	10	147±4.5522	69±7.3786	28.632	0.0001

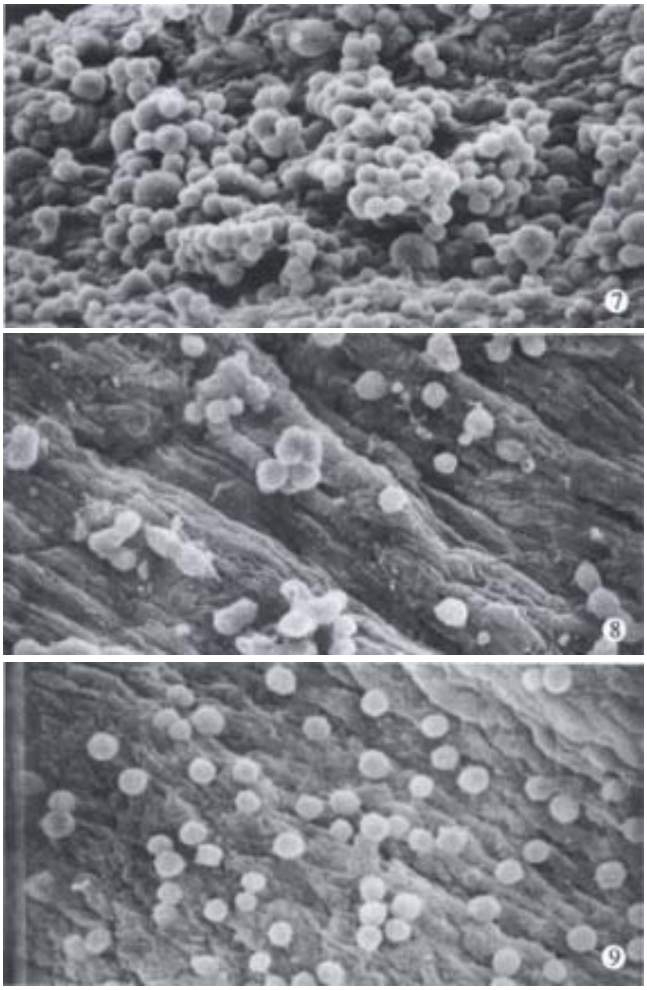

Figure 7 In control groups, a lot of Lovo cells adhered to the surface of umbilical vein endothelium, and tumor cells clustered. SEM, ×500

Figure 8 In control groups, The HT29 cells adhered to the surface of umbilical vein endothelium, a part of them clustered. SEM, ×500

Figure 9 In experimental groups, a small amount of the Lovo cells adhered to the umbilical vein endothelium, no clustering. SEM, ×500

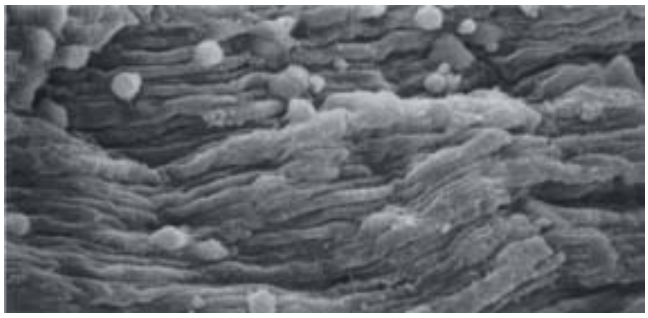

Figure 10 In experimental groups, a small amount of the HT29 cells adhered to the umbilical vein endothelium, no clustering. SEM, ×500

Observation of adhesive potential of tumor cells to umbilical vein endothelial cells under transmission electronmicroscope

In the control groups, there were a great deal of microvilli or interdigitations on the Lovo cell membrane, but few interdigitations on the HT29 cell membrane. The Lovo cells were linked to umbilical vein endothelium via interdigitations on the cell membrane (Figure 11). Some of the apophyses stretched into endothelial cell membrane; but the HT29 cells connected endothelial cell membrane directly via the cell membrane (Figure 12). No significant difference in the way of linking between the experimental groups and the control groups was observed.

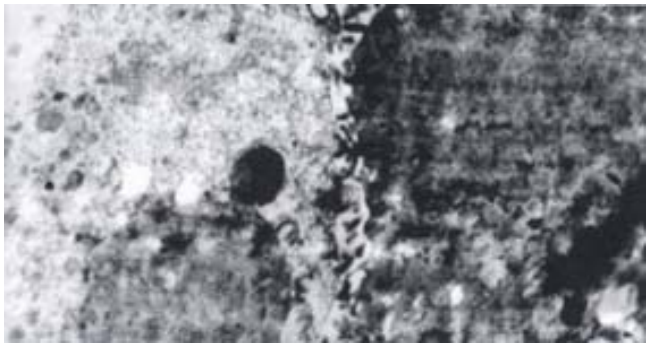

Figure 11 The Lovo cells were linked to umbilical vein endothelium via interdigitations on the cell membrane. TEM ×20K

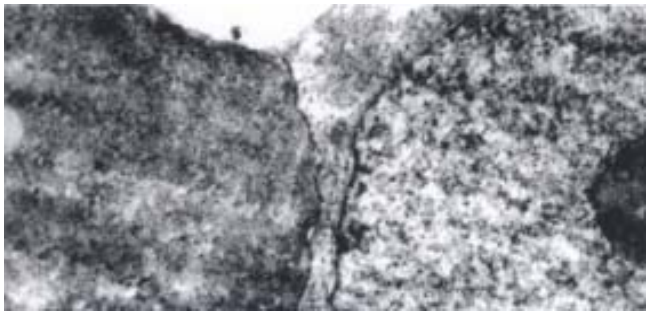

Figure 12 The HT29 cells connected endothelial cell membrane directly via the cell membrane. TEM ×24K

Effects of SLex monoclonal antibody on the liver metastases model of experimental nude mice

The ratio of liver metastases was 9/9 (100%) in the control groups of Lovo cells, while it was 2/9 (22%) in the experimental groups. The ratio of liver metastases in the experimental groups was less than that in the control groups with a significant difference between the two groups (P<0.001). The ratio of liver metastases was 4/9 (44.4%) in the control groups of HT29 cells, but 1/9 (11.1%) in the experimental groups. The ratio of liver metastases in the experimental groups was less than that in the control groups with significant difference between the two groups (P<0.002,Table 4).

Table 4 Effects of SLex monoclonal antibody on the liver metastases model of experimental nude mice

	Lovo cells		HT29 cells	
	Metastases	No metastases	Metastases	No metastases
Control groups	9	0	4	5
Experimental groups	2	7	1	8

Lovo cell groups χ^2 = 11.45, P<0.001; HT29 cell groups χ^2 = 2.498, P<0.002.

DISCUSSION

SLeX antigens are mostly expressed on the cell surface of epithelial tumors such as lung cancer, gastric cancer, colon cancer, ovary cancer[11,12]. The positive ratio in carcinoma of colon is 76%-90%[1,13]. The expression of SLeX antigen is mostly determined by two kinds of enzyme, αl, 3Fuc-T and α2, 3ST. The successive activities of the two enzymes existing in N-acethllactosamine synthesize the SLeX antigens. αl, 3Fuc-T is an important material to produce SLex antigens as well as to adjust and control the expression of SLeX antigens[14]. The increase of αl, 3Fuc-T in matrix plasma results in the increase of SLeX antigens on the cell surface[15]. The αl, 3Fuc-T and α2, 3ST synthesize the SLeX antigens which possess a strong affinity to Lectin in E-selectin and epidermal growth factor resulted with adhesion of tumor cells to the endothelial cells[3]. The SLex antigens on the cell surface in the colon carcinoma as a kind of ligands, their identification from and adhesion to E-selectin recipients on the endothelial cell surface of liver vascularitve are considered as the molecular basis of liver metastatic of colon carcinoma, and as a critical step in the liver metastatic process of colon carcinoma[5]. Modification of carbohydrate antigens on the tumor cell surface, such as SLeX antigen, will affect the ways of tumor cell metastases[4,5,16], such as adhesive potential[17], mobility[18,19], invasion[20], immunogenicity and other immune identification process[21,22] or other unknown cell behaviors which will affect the

metastasis potential of tumor cells. In other words, the structural changes of carbohydrates on tumor cell surface play a key role in the metastases of tumor cells[23]. The well known metastatic steps of tumor cells are: proliferation of tumor cells accompanied by angiogenesis of tumor → intrusion of tumor cells into basement membrane and then into blood vessels and lymphatic vessels → into blood circulation → detection in the target organ and adhesion to the capillaries → breaking through the capillaries and formation of minute metastatic spots → formation of new blood vessels and proliferation of metastatic spots[24]. There are different metastasis potential tumor cells in the primary area, for example, in colon carcinoma, SLeX antigens with high expression in tumor cells show high metastatic potential while the antigens with low expression in tumor cells show weak metastatic potential. The tumor cells with strong metastatic potential are more likely to fall off from the primary area and enter blood vessels and thus adhere to hepatic vascular endothelial cells so as to grow and form liver metastasis[25]. The reason is that SLeX antigens on the tumor cell surface as ligands of E-selectin on the endothelial cell surface of the capillaries induce adhesion between tumor cells and blood vessel endothelial cells of the target organ[26] and promote orientating tendency in motion and result in metastasis.

Our study demonstrated that the Lovo cell line with strong metastatic potential has high expression of SLeX antigen and high expression of SLeX antigen synthase, αl, 3Fuc-TmRNA while the HT29 cells line with weak metastatic potential has low expression of SLeX antigen and low expression of SLeX antigen synthase αl, 3Fuc-T. Our finding that SLeX antigen expression is closely correlated with colon carcinoma metastatic potential.

Our study also showed that Lovo cells with high expression of SLeX antigen had strong adhesive ability to vascular endothelial cells while the HT29 cell with low expression of SLeX antigen had weak adhesive potential. The connecting way to vascular endothelial cells of the Lovo cells with high expression of SLeX antigen was quite different from that of the HT29 cells with low expression of SLeX antigen. The SLeX monoclonal antibodies could effectively restrain the adhesion of tumor cells to vascular endothelial cells and well reduce the formation of liver metastases of experimental nude mice. We speculate that the reason for the decrease of adhesion is that SLeX monoclonal antibodies may have sealed carbohydrate antigens on the tumor cell membrane → site of SLex ligand and result in lower adhesive potential of tumor cells to vascular endothelial cells[27]. The results suggest that SLeX antigens play an important role in liver metastases of colon carcinoma. SLeX monoclonal antibody or its analogs may prevent the formation of liver metastases of colon carcinoma.

INTRODUCTION

Carcinoembryonic antigen (CEA), originally described by Gold and Freedman[1] in 1965, is now an acknowledged member of immunoglobulin superfamily[2], with a role as an intracellular adhesion molecule[3]. Carbohydrate antigen 19-9 (CA19-9), obtained with a monoclonal antibody produced by immunizing a mouse with a colonic cancer cell line in 1979[4], is a ligand for E-selectin that plays an important role in the adhesion of cancer cells to endothelial cells[5,6]. More recently, tumor-associated glycoprotein 72 (TAG-72), has been identified with the monoclonal antibody B72.3[7]. This antigen has been found in a variety of human adenocarcinomas (colorectal, gastric, ovarian, breast, and lung), but rarely expressed in benign and normal adult tissue[8,9]. The CA72-4 antigen is an antigenic determinant of TAG-72 which is recognized by B72.3 and CC-49 monoclonal antibodies[10]. CEA, CA19-9 and CA72-4 represent the currently most useful tumor markers for gastrointestinal malignancies. Elevated serum levels of CEA, CA19-9 and CA72-4 have been found in many patients with colorectal, gastric, biliary tract, and pancreatic carcinoma[11-17]. Today, these tumor markers are primarily used in early diagnosis and monitoring of therapeutics[18,19], and determining the prognosis of patients who have undergone tumor resection. Since April 1996, these three tumor markers have been used as routine in our hospital for detecting colorectal cancer. The aim of this study was to assess their correlations with the tumor pathology and their prognostic value.

MATERIALS AND MEHTODS

Patients'

A total of 107 patients with histologically diagnosed colorectal carcinoma were included in the study group. All had been treated surgically between April 1996 and March 1997. There were 74 men and 33 women. The mean age of the patients was 56.1 years (range: 26-81 years). The pathological findings (types and size of tumor, morphology, depth of invasion and number of positive lymph nodes) of the patients were reviewed. The patients were staged in accordance with Dukes classification. Ninety seven patients (90.7%) were followed up for at least 36 months or till death. Ten patients lost to follow up were excluded from the final assessment.

The control group included 155 healthy adults who received routine physical examination between December 1995 and July 1996 in our hospital, among whom, 72 were men and 83 were women. The mean age was 47.5 years (range: 20-89 years).

Serum assays for CEA, CA19-9 and CA72-4

Peripheral blood samples were obtained from the patients preoperatively and those from healthy subjects in the control group after fasted overnight. Sera were promptly separated and stored at -80℃ for use. Serum CEA was measured with a one-step, solid-phase enzyme immunoassay commercial kit (CEA EIA Kit, General Biologicals Inc., Taiwan). Serum CA19-9 was determined with a two-step, solid-phase enzyme immunoassay commercial kit (CA19-9 EIA Kit, Maxim Biotech Inc., USA). A solid-phase two-site radioimmunometric assay kit, CA72-4 RIA kit (Centocor Inc., USA), was used for determination of serum levels of CA72-4. The upper limit and cut off values of serum CEA, CA19-9 and CA72-4 in the control group 99% confidence interval were 5.0 μg/L, 31.0KU/L and

5 .0KU/L, respectively.

Statistical analysis

Statistical analysis was carried out using the SPSS 8.0 FOR WINDOWS statistical software package (SPSS Inc., USA). Chi-square test was used for univariate analysis between positive rates of serum levels of tumor markers and the pathological findings. The relation between recurrence rates and serum levels of these tumor markers was also evaluated by Chi-square test. The Kaplan-Meier method was used to calculate the cumulate survival rates and plot survival curves, and Log Rank test was used for the evaluation of statistical differences between the curves. *P* values of less than 0.05 were considered to be statistically significant.

RESULTS

The mean serum levels of CEA, CA19-9 and CA72-4 in 107 patients with colorectal cancer were 5.9 ± 10.1 μg/L (range: 0.1 - 70.0 μg/L), 61.5 ± 302.1KU/L (range: 0.1 - 5105.0 KU/L) and 8.4 ± 19.5 KU/L (range: 1.1-188.2 KU/L), respectively. The positive rates of serum CEA, CA19-9 and CA72-4 in these patients were 29. 9%, 25.2% and 32.7%, respectively.

Relationship between serum levels of tumor markers and pathological findings

The correlation between positive rates of serum tumor markers and the pathological variables is shown in Table 1. Positive rate of serum CA72-4 was significantly higher in poorly-differentiated colorectal cancer than in well and moderately-differentiated types ($P = 0.031$). There was no statistical significance between the positive serum tumor markers and the size and morphology of the colorectal cancer, but were well correlated with the depth of invasion. Both serum CA19-9 and CA72-4 were influenced by the number of metastatic lymph nodes. The results also suggested the more advanced the Dukes stage, the higher the positive rates of all these tumor markers.

Preoperative serum levels of CEA, CA19-9 and CA72-4 as prognostic indexes

Of the 97 followed up patients, 86 were classified as Dukes A, B and C stage according to the pathological findings. All underwent curative resection. The overall recurrence rate was 32.6%. In the serum CA19-9 or CA72-4 positive patients, the recurrence rates were significantly higher than that in patients with negative result (Table 2), while serum level of CEA did not correlate well with the recurrence rate ($P = 0.102$).

Among these 97 patients, positive serum CEA, CA19-9 and CA72-4 were found in 30, 25 and 31 cases, respectively. The overall 3-year survival rate was 67.0%. Survival curves of the patients according to positive and negative serum CEA, CA19-9 and CA72-4 are shown in Figures 1-3, respectively. Significant differences in survival curve were found between the positive and negative ones. The 3-year survival rate was 53.3% in serum CEA-positive patients and 73.1% in CEA-negative patients ($P = 0.042$, Figure 1); 48.0% in CA19-9 positive patients and 73.6% in CA19-9 negative patients ($P = 0.011$, Figure 2); 48.4% in CA72-4 positive patients, and 75.8% in CA72-4 negative patients ($P = 0.003$, Figure 3).

DISCUSSION

Ideal tumor markers would be inexpensive screening and deliver early diagnosis in a large population at risk for cancer. Unfortunately, currently available serological tumor markers for gastrointestinal cancers have not been proven to be ideal. Although CEA, CA19-9 and CA72-4 are the tumor markers commonly used currently in colorectal cancer, all of them have low diagnostic sensitivity[11-13,17,20,21]. In this study, the overall positive rates of serum CEA, CA19-9 and CA72-4 were 29.2%, 25.2% and 32. 7%, respectively. For early (Dukes A and B) colorectal carcinoma, the positive rates of the above tumor markers were significantly lower than those with Dukes C and D (Table 1). The lack of sufficient sensitivity of serum tumor markers strongly restrict their applications as appropriate tools for screening and diagnosis[22,23]. Nevertheless, measurement of these tumor markers is still of importance in early detection of recurrence[24-26]. Careful examinations of abdominal-pelvic CT scan, abdominal ultrasonography, colonscopy and endoscopic ultrasonography can be complementary[27].

In this study, we investigated the correlation between preoperative serum revels of tumor markers and pathological following. The main aim was to reveal whether the following pathologic lesions as histological type, depth of invasion, lymph node metastion and staging of lesions, were related to the preoperative serum levels of tumor markers. Our data showed that the positive rate of serum CA72-4 was related to the histological type which was comparable with those reported by Ikeguchi *et al*[28], in which there was a close relationship between CA72-4 and proliferative activity of cancer cells. Although there was no significant correlation between these tumor markers and the size of the tumor or the morphology, serum CEA and CA19-9 correlated well with the depth of invasion and Dukes staging. In contrast to the study carried out by Sato *et al*[29], we found that serum CA19-9 was also influenced by the number of metastatic lymph nodes, whereas serum CA72-4 was related to the depth of invasion, lymph node metastasis and staging of the lesions.

An important consideration in assessing the clinical value of tumor markers is to find whether tumor marker assay can provide useful information on clinical outcome of the patients, in addition to the common prognostic factors. Previous reports demonstrated that elevated preoperative serum levels of CEA and CA19-9 were predictive of increased mortality in colorectal cancer[30]. Increased levels of CEA and CA19-9 were also associated with venous and lymphatic spread[31, 32]. As shown in our study and the reports of Forones and Tanaka[30], preoperative serum level of CEA was not a perfect predictor for recurrence in patients undergoing curative resection, but CA19-9 was proven to be a better indicator for recurrence. Positive CA19-9 expression on tumor tissue, and its positive pre and post-operative serum level, were associated with poor survival rates[33,34]. Our study showed that there was significant difference in 3-year survival curves between serum CEA-positive and CEA-negative patients, and also significant difference was found in serum CA19-9 positive and CA19-9 negative patients, which was similar to that reported by Sato *et al*[29]. CA72-4 was confirmed to have better sensitivity and specificity than CEA and CA19-9[35,36]. However, very few studies on the prognostic value of CA72-4 in colorectal cancer have been reported in the literature, except some concerning gastric cancer[16,28,37]. In the current study, in addition to CEA and CA19-9, we also investigated the prognostic value of serum level of CA72-4 in preoperative patients with colorectal cancer. We found that patients with positive serum CA72-4 had higher recurrence rate than those with negative CA72-4 (P = 0.008), and the 3-year survival rate much lower than that in CA72-4 negative patients (P = 0.003). High serum levels of tumor markers are often associated with more aggressive cancer, which usually has short disease free interval and short survival period. Both CEA and CA19-9 are molecules involved in intercellular

adhesion[3,5], hence, the cells expressing these molecules on their surfaces would possess a greater metastatic potential[38]. It was shown that in experimental metastasis model of colorectal carcinoma in nude mice, a systemic injection of recombinant CEA enhanced hepatic colonization of tumor cell *in vivo*[39], presumably by their increased hepatic retention[40]. Other authors reported that CA19-9 serves as a specific ligand for ELAM-1 and plays a significant role in the ELAM-1mediated binding of human cancer cells to activated endothelial cells, which indicates CA19-9 expressed on the surface of cancer cells may involve in the process of vascular invasion and metastasis[41]. Meanwhile, the function of TAG-72 (CA72-4) in the process of tumor progression remains unclear.

In conclusion, the measurement of preoperative serum levels of CEA, CA19-9 and CA72-4 will aid in predicting the prognosis of patients with colorectal cancer who have been treated surgically. Elevated serum levels of tumor markers indicate high risk of cancer recurrence and poor survival. Such patients should receive adjuvant therapy, at the earlier stages of this disease.

INTRODUCTION

To date, the major therapy for rectal carcinoma is extensive abdomino-perineal resection[1]. Unfortunately, after resection of rectal carcinoma, many patients still die of blood-borne metastases, usually in the liver or lungs, or local pelvic recurrence [2,3], which is the major cause of morbidity and mortality in patients with rectal carcinoma. Pre-or postoperative radiotherapy can reduce the incidence of local recurrence[4-7], but even with moderately high radiation doses, many patients are not locally controlled and have distant metastases[8,9]. The reason for this may be low intrinsic radiotherapy in at least some of the tumors.

Fast neutrons were introduced for cancer therapy in the 1970s. It has been reported that fast neutron therapy is effective for some carcinomas[10,11]. In addition, apoptosis induced by X-rays has been reported[12,13], but apoptosis induced by fast neutron rarely reported. Therefore, in the present study fluorescent staining of DNA is used to detect not only whether irradiation with fast neutron induces apoptosis, but also whether the difference in the level of apoptosis exists between X-rays and neutron induced Chinese rectal carcinoma cell lines. Furthermore, *p*53 and Bcl-2 gene expression were detected by immunohistochemical methods for Chinese human rectal carcinoma cell line with various doses of X-rays and neutrons, we could thereby compare the level of *p*53 and *Bcl*-2 gene expression induced by X-rays and neutrons.

MATERIALS AND METHODS

HR8348 cells taken from poorly differentiated adenocarcinoma of the rectum were grown as a monolayer in Dulbecco's Modified Eagle Medium supplemented with 100 mL·L^{-1} heat-inactivated fetal bovine serum and subcultured every other day. Culture conditions were 37℃ in a humidified atmosphere buffered by 50 mL·L^{-1} CO_2 in air and 56 g·L^{-1} sodium hydrogen carbonate, pH 7.4. Twenty-four hours after passaging, exponential cell cultures were irradiated at room temperature with a single dose of 6-Mv X-rays from Varian linear accelerator (Cancer Institute & Hospital, Chinese Academy of Medical Sciences, Peking Union Medical College). The dose rate was about 250cGy·min^{-1}. The SSD (source-surface distance) was 100 cm. The PDD (percentage of depth dose) was 100%. The field of radiation was about 32. 6 cm × 30.5 cm. Cells were radiated with 0, 2, 4, 6, 8, 10Gy.

Fast-neutron-rays radiation conditions

The conditions of cells culture while cells were radiated by fast-neutron rays from electron cyclotron (High Energy Physics Institute, Chinese Academy of Sciences) were the same as by X-rays. The SSD was about was about 150 cm. The PDD was 93.68%.The field of radiation was about 18.0 cm × 18.0 cm. Cells were irradiated with 0, 0.67, 1.34, 2.01, 2.68, 3.34Gy (the same effects of radiobiology as one-third of the equivalent dose of X-rays).

Apoptosis assay

Cells were plated in 100 mm^2 tissue culture flask (10^6 cells/flask) for determination of apoptotic fraction. The cells were irradiated by various dosages of X-rays (0, 2, 4, 6, 8, 10Gy respectively) and fast-neutron-rays (0, 0. 67, 1.34, 2.01, 2.68, 3.34Gy respectively) in exponential phase, approximately24 h later. After replacement with fresh culture medium, the cell samples were exposed at room temperature to graded doses of X-rays or fast-neutron-rays. After radiation, the tissue culture flasks were incubated at 37℃ for 6, 24, 48 and 72 h respectively prior to the assessment of apoptosis. The cells (detached cells and attached cells) trypsiniszed were collected together, spread on glass slides and fixed with 900 mL·L^{-1} methonal and 100 mL·L^{-1} glacial acetic acid. Then, the slides were stained with 1 g·L^{-1} Hoechest 33 342 in PBS for 10 min, and rinsed briefly in water. The nuclear morphology was then examined by fluorescence microscopy.

Apoptotic cells were counted microscopically, according to published criteria[14-18]. The frequency was expressed as the number of apoptotic cells per 100 cells (apoptotic index). 1500 cells per data point were counted. Additionally, apoptosis was evaluated by gel electrophresis. Cells were washed once with PBS and digested overnight at 37℃ with 100 ug/mL proteinase K in20 mmol·L^{-1} TRIS-HCl (pH 8.0), 10 mmol·L^{-1} NaCl, 1 mmol·L^{-1} EDTA and 10 g·L^{-1} SDS. DNA was extracted with phenol and chloroform, then precipitated with 1/10 volumes of 3 mol·L^{-1} sodium acetate and 4 volumes of ethanol, dissolved in TE buffer (pH 8.0) and digested with RNAase. DNA samples were electrophoresed on a 15 g·L^{-1} agrose gel, stained with ethidium bromide, and visualized with an UV illuminator. Moreover, the method of TdT (terminal deoxynucleotidyl transferase)-mediated dUTP-biotin nick end labeling (TUNEL), was performed according to the instructions *in situ* cell death detection kit (Boehringer Mannheim, Germany).

Immunohistochemistry

The glass slides with cells were immersed in 3 mL·L^{-1} hydrogen peroxidase in phosphate buffered saline (PBS) for 5 minutes to block endogenus peroxidase activity. After washing with PBS, the slides were treated with 100 mL·L^{-1} normal goat serum to reduce nonspecific antibody binding. For antigen retrievals the slides were placed in an antigen retrieval solution (10 mmol·L^{-1} citric acid monohydrate pH 6.0) and heated in a microwave oven for 10 min. After washing with PBS the slides were incubated for 1h with anti-*p*53 and Bcl-2 monoclonal antibody. After further washing with PBS, slides were incubated with biotinylated rabbit anti-mouse second-stage antibody. After washing further with PBS, peroxidase-conjugated streptavidin was applied. Peroxidase activity was demonstrated by adding diaminobenzidine as a chromogen. The slides were counter-stained with hemotoxylin. Negative control slides were processed without the primary antibody. Positive control slides were processed from a nasopharyngeal squamous low-differentiated carcinoma previously shown to express high levels of p53 protein and Bcl-2 protein. Immunostained slides of both test and control slides were independently scored by two of the authors. In rare cases of disagreement, consensus was reached after discussion. For p53 protein, only nuclear staining was considered significant. For Bcl-2 protein, only cytoplasm staining was considered significant. A semiquantitative scale was used for grading of positive immunostaining, depending on the intensity of nuclear staining and the percentage of the stained nuclei.

RESULTS

Apoptosis in relation to time and dose

Increase of apoptotic cells above the spontaneous level (4.1%) was detected up to 2Gy (or 0.67Gy). Apoptotic index (percentage of apoptotic cells) increased with the increase of radiation dose and time after irradiation by X-rays and fast-neutron-rays. No cell apoptosis plateau level 72 h after radiation was observed. At the same point of time, the AI of cells induced by fast-neutron-rays was higher than AI of cells induced by X-rays. (Figure 1A, 1B,1C). Figure 2 represents the features of cell shrinkage, chromatin condensation and margination of cell apoptosis induced by X-rays and fast-neutron-rays respectively in Chinese rectal carcinoma cell line. We were able to visualize the characteristic DNA ladder pattern induced by X-rays and fast-neutron-rays (Figure 3). TUNEL clearly revealed a distinct pattern of nuclear staining (Figure 4).

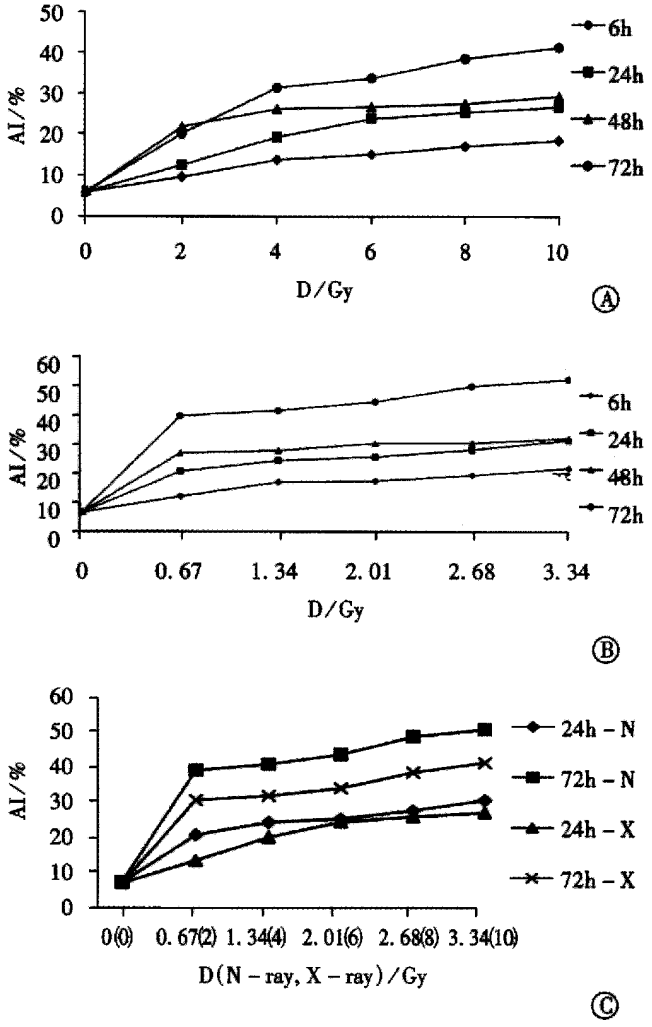

Figure 1 (A) AI at different time intervals after radiation of various doses of X-rays and (B) fast-neutron-rays. AI of cells induced by X-rays and fast-neutron-rays of various doses gradually increased with the increase of dose and time. (C) Comparison of AI between X-rays and N-rays. At the same point of time, AI of cells induced by fast-neutron-rays was higher than that induced by X-rays.

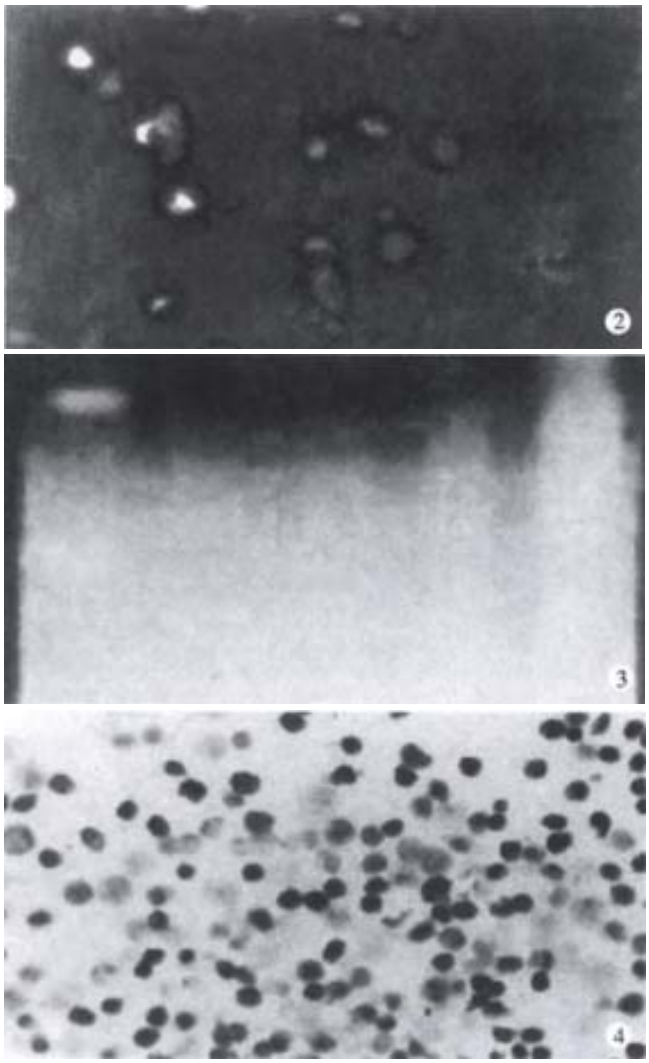

Figure 2 Hoechest 33 342 fluorescence staining of cells radiated by fast-neutron-rays shows the special morphological features of apoptotic cells: cell shrinkage, chromatin condensation, lunated margination.

Figure 3 Effect of X-rays on DNA fragmentation in HR 8348 cells. Cells were incubated for 6 h after radiation by X-rays. DNA fragmentation was examined by agrose gel analysis, as described in Materials and methods. A, 885 bp and 585 bp DNA marker; B, Control; C, 2Gy ; D, 8Gy; E, 10Gy.

Figure 4 Positive nuclear staining of cells irradiated by 8Gy X-rays with TUNEL was observed.

P53 and Bcl-2 immunostaining related to irradiation dose

High expression of p53 protein and Bcl-2 protein were observed in cells without radiation, and the percentage of positive cells was about 90%. After radiation with various dosages of X-rays, no apparent decrease in percentage of p53 positive cells (about 80%) was observed. However, the of p53 positive cells changed from deep yellow to light yellow. While the percentage and degree of Bcl-2 positive cells showed no apparent decrease when compared with p53 protein. As for fast-neutron-rays, it didn't lower the percentage or the degree of p53 and Bcl-2 positive cells significantly (Figure 5).

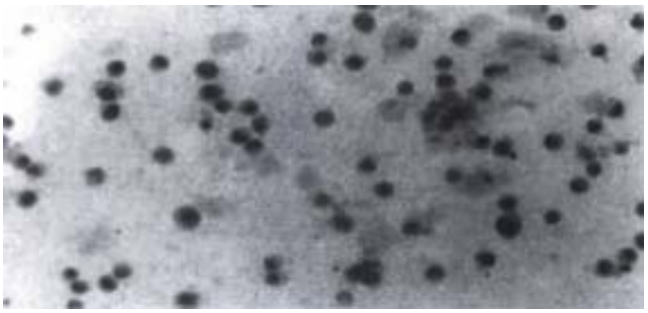

Figure 5 P53 positive nuclear staining of cells irradiated by 8Gy X-rays with immunohistochemistry staining was seen. Nuclei of cells appeared in light yellow.

DISCUSSION

Our results indicate that apoptosis induced by X-rays and fast-neutron-rays in Chinese rectal carcinoma cell line is time-dose dependent. Moreover, the level of apoptosis induced by fast-neutron-rays is higher than by X-rays, which suggests rectal cancer cells are more radiosensitive to fast-neutron-rays than to X-rays. Fast-neutron-rays is particulate radiation and high linear energy transfer (LET) radiation, with no charged particles. X-ray is electromagnetic radiation and low linear energy transfer radiation. These exists difference in radiosensitivity of cells between fast-neutron-rays and X-rays, because: ① anoxic cells exist in most tumor cells [19,20], and ionizing density causes the oxygen enhancement ratio (OER) of high LET radiation to be lower than that of low LET radiation, that is, the radiosensitivity of high LET radiation is less dependent on oxygen in cells than low LET radiation; ② fast neutrons are densely ionizing particles, with a high relative biological effectiveness relative to X-rays (RBE); and ③ sublethal damage repair produced by high LET radiation is lower than that by low LET radiation. So far, the molecular basis of their properties is not yet entirely understood. The term apoptosis was first used by Kerr, Wyllie and co-workers to describe a particular form of cell death, different from necrosis[21-23]. Much evidence has shown that apoptosis is an active process regulated by a series of proto-oncogenes and tumor suppressor genes associated with proliferation and differentiation, such as p53, Bcl-2, c-myc, ICE, Fas/APO-1 etc[24-27].

Of particulate interest is the Bcl-2 gene, which was discovered in 1984 through the cloning of the translocation breakpoint in nodular B cell lymphoma and located at 18q21. Later, the product of Bcl-2 was shown to be a mitochondrial internal membrane protein which had the unique property of blocking apoptosis induced in cultured immature B cells[28-30]. To date, the mechanisms of apoptosis blocking of Bcl-2 has been shown to be a complicated process, involving the regulation of a

growing list of proteins, which share sequence homology with Bcl-2, and the relevant genes[31,32]. One of these proteins, Bax, opposes the action of Bcl-2 and promotes apoptosis. It has been proved that apoptosis has been regulated by the proportion of Bcl-2 and Bax. The Bax's homologous dimer can induce apoptosis, but the rising Bcl-2 protein combining with Bax will form Bax-Bcl-2 heterogenous dimer that is more stable than "Bax-Bax". This will neutralize the Bax function of inducing apoptosis[33,34]. Therefore, only high expression of Bcl-2 protein is not sure to inhibit apoptosis. Our results indicate that downregulation of Bcl-2 protein expression did not appear with the increase in apoptotic index for cells irradiated by X-rays and fast-neutron-rays.

The tumor suppressor gene p53 is indispensable for normal development. It plays a central role in the cellular response to DNA damage from both endogenous and exogenous sources, providing a protection against tumorigenesis. Activation of p53 may result in a cell cycle delay, presumably to allow an opportunity for DNA repair to occur before replication or mitosis[35,36]. In some cell types, however, p53 activation results in apoptotic cell death as a means of eliminating irreparably damaged cells. The final outcome of p53 activation depends on many factors, and is mediated largely through the action of downstream effector gene transactivated by p53[37]. In our experiment, high expression of mt p53 protein appeared in cells without radiation. After being radiated with various doses of X-rays, downregulation of mt p53 protein occurred. In contrast, downregulation of mt p53 protein has not appeared in cells irradiated by various doses of fast-neutron-rays. Some evidence has shown that the difference of DNA dsb (double strand break) repair area exist[38], which suggests basic differences in the nature of the lesions induced by high and low LET ionizing radiations. Other data has provided clear experimental evidence for the existence of clustered DNA double-strand breaks and demonstrate that short DNA fragments may be produced by neutron radiation, an observation not made for damage by low-LET radiation[39]. Additionally, It has been reported that the DNA damage by fast neutrons was shown to be significantly greater than for the same absorbed dose of X-rays[40]. On these grounds, we infer that X-rays and fast-neutron-rays may lead to the different DNA damage, e.g. a single or double strand break in DNA, nuclear supercoils, or the differences in the nature of dsb (double-strand break) induced and the way they are repaired. The difference of DNA damage may lead to different pathway of apoptosis involved in the different regulation of relevant apoptotic genes. Fast-neutron-rays may induce the involvement of apoptotic gene other than p53.

INTRODUCTION

Bifidobacteria are physiologically beneficial bacteria which are predominant in human intestine, and possess the most important functions. They play an important role in maintaining microbial balance of the intestine. Furthermore, their presence is thought to be an important indication of health of the body[1-4]. Whole peptidoglycan (WPG) is the major component in the cell wall of bifidobacterium, which is also a biological response modifier with nontoxic side effects. At present, many scholars have demonstrated that bifidobacteria can activate macrophages, T lymphocytes and natural killer cells to secrete many kinds of cytokines and important mediators[5-8]. In our report, the level of IL-6, IL-12 and TNF-α produced by macrophages is detected by employing laser scanning confocal microscopy, when these cells are stimulated by WPG of bifidobacteria bifidum. Simultaneously, the content of nitric oxide (NO) secreted from the macrophages is investigated by utilizing Griess reagent. Our goal is to explore the roles of these cytotoxic effector molecules on adjusting immune reaction of bifidobacterial WPG.

MATERIALS AND METHODS

Materials

Whole peptidoglycan It was extracted from the cell wall of bifidobacteria bifidum according to the method described by Sekine and his colleagues,donated by Dr. Hu, who worked at department of examination of Zhongjing Medical University. Simultaneously, it had been evaluated[9].

Experimental animals BALB/c nude mice were purchased from the Experimental Animal Center of the First Military Medical University, 6-8 weeks in age, 18 g-22 g in weight, and housed in the SPF animal room.

Methods

Division of the experimental group and management of WPG The experimental animals were divided into two groups: the WPG injection group: 10 nude mice, 2 mL of 100 $g \cdot L^{-1}$ thioglycollate was injected into the nude mice intraperitoneally on d1, 0. 25 mg WPG (equivalent to 1×10^9 bifidobacteria) was injected intraperitoneally from d 2-6 continuously; and the control group: the number of animals and procedures were similar to the WPG injection group on d1, 0.2 mL of PBS was injected intraperitoneally from d 2-6 continuously.

Collection and culture of peritoneal macrophages of nude mice All animals were killed on d7. Abdomen skin of the nude mice was sterilized routinely. Cells were obtained by sterile lavage of the peritoneal cavity with cold D-hanks balanced salt solution. The lavage fluid was centrifuged at 1000 rpm for 10 min. The supernatant was decanted. The cells thus obtained were twice washed, resuspended in RPMI 1640 culture medium containing free fetal calf serum, then adjusted to be $1 \times 10^9 \cdot L^{-1}$, and plated ($2 \times 10^5$ cells/well) in 96-well tissue culture plates. Nonadherent cells were removed by repeated washing after 2 h incubation at 37℃ in 50 $mL \cdot L^{-1}$ CO_2 in air. Adherent cells were macrophages. These cells were stimulated with 10 $\mu g \cdot L^{-1}$ LPS in RPMI 1640 containing 100 $mL \cdot L^{-1}$ FCS for 24 h. Supernatant was stored at -30℃ until assayed.

Detection of IL-6, IL-12 and TNF-α contents of peritoneal macrophages of nude mice Laser scanning

confocal microscopy was utilized to detect the content of IL-6, IL-12 and TNF-α. The concrete protocol was as follows: ① The peritoneal cell suspension of nude mice was harvested and added to the modified Petri plate, and the desired peritoneal exudate cells were adjusted to 1×10^5 in 100 μL·plate^{-1}. After incubated in a 50 mL·L^{-1} CO_2 incubator at 37℃ for 2 h, these plates were washed vigorously to eliminate nonadherent cells, and macrophages were obtained. Then 500 μLof RPMI 1640 medium containing 10 μg·L^{-1} LPS was added to each plate. After 24 h, the supernatants were discarded, and the macrophages were washed with phosphate buffered saline (PBS) 3 times for 5 min; ② 100 g·L^{-1} non-specific bovine serum album was added to the plates which were incubated for 10 min at room temperature; ③ The plates were rinsed with PBS 3 times for 5 min;④ 100 μL of rabbit anti-mouse IL-6, IL-12 and TNF-α monoclonal antibody (Genda Technology Corp. Canada) was added to the plates which were incubated for 60 min at 37℃ respectively; ⑤ The plates were rinsed with PBS 3 times for 5 min; ⑥ 100 μL of FITC labeled goat anti-rabbit IgG (Santa Cruz) was added to the plates which were incubated for 30 min at 37℃. The antibody was used at a dilution of 1 in 100. ⑦ The plates were rinsed with PBS 3 times for 5 min; ⑧ The fluorescent intensity of macrophages was detected by employing laser scanning confocal microscopy with an arousement wavelength of 488 nm and a radiation wavelength of 475 nm. For each plate, average fluorescent value from beyond 100 macrophages in different fields was investigated, which was chosen to be quantitative parameter.

Griess reagent Naphthylethylenediamine hydrochloride (0.1%) (Sigma) was prepared with distilled water, and 1% sulfanilamide (Sigma) was prepared with 5% H_3PO_4. The two reagents were mixed equally before utilization.

Detection of the level of NO After 1 mmol·L^{-1} sodium nitrite ($NaNO_2$) was diluted by means of doubling series, it was mixed with equal Griess reagent, then shaken for 10 min lightly at room temperature. At last, absorbance value (A) of triplicate samples was read on Bio-Rad 550 type microelisa reader using a test wavelength of 550 nm. One hundred microliter of each supernatant which was to be determining was mixed with 5 μL of 300 g·L^{-1} $ZnSO_4$ to remove protein, then centrifuged at 5000 rpm for 10 min. The supernatant was collected, and mixed with equal Griess reagent, then shaken lightly for 10 minutes at room temperature. Absorbance value (A) was read on Bio Rad 550 type Microelisa Reader using a test wavelength of 550 nm.

Statistic analysis

The statistical analysis between WPG injection group and control group was made by means of Student's *t* test.

RESULTS

NO content of produced by peritoneal macrophages of nude mice stimulated by WPG

A standard curve was made by analyzing the relationship between different concentrations of standard $NaNO_2$ and the corresponding A value assayed. Simultaneously, linear correlation and regression analysis was performed, and the linear regression equation was as follows: Y = 0.013 + 0.022X, r = 0.999. It suggested that there existed a fine correlation between the content of standard $NaNO_2$ and the corresponding A value. The content of NO was obtained correspondingly when the A value of different samples substituted the linear regression equation. By means of the statistical analysis,we found that the content of NO produced by peritoneal macrophages of nude mice in WPG injection group was significantly higher than in the control group (P<0.01, Table 1).

WPG influence on IL-6, IL-12 and TNF-α production of peritoneal macrophages of nude mice

The content of IL-6, IL-12 and TNF-α produced by peritoneal macrophages of nude mice was detected by employing laser scanning confocal microscopy, when WPG of bifidobacteria bifidum was injected into nude mice intraperitoneally. The results suggested that the macrophages present different color. The macrophages in WPG injection group appeared white, red, yellow and blue which was narrow in area relatively, while, the macrophages in control group were mainly blue and less yellow. Different color reflected different fluorescent intensities. Analyzing with the ACAS software of laser scanning confocal microscopy, showed that the fluorescent intensity, which reflected the content of IL-6, IL-12 and TNF-α emitting from peritoneal macrophages of nude mice in WPG injection group, was markedly higher that in control group (P<0.01, Table 1 and Figures 1,2).

Table 1 Influence of WPG on IL-6, IL-12, TNF-α and NO production by peritoneal macrophages of nude mice ($\bar{x} \pm s$, n = 10)

Groups	IL-6 / A	IL-12 / A	TNF-α / A	NO (μmol·L^{-1})
WPG	1956.48±265.32[b]	2603.24±395.72[b]	813.42±106.77[b]	53.21±6.40[b]

DISCUSSION

WPG of bifidobacteria bifidum is a bag-form structure which consists of polysaccharides and peptidoglycans. It preserved the integral structure of whole cells, and possessed some important biological characteristics, such as relaxation of senescence, antitumor, control of infection, antimutation, etc[10-14]. Furthermore, it could also activate macrophages of immune system of the body. Tejada-Simon and his colleagues demonstrated that WPG of bifidobacteria infantis could activate RAW 264.7 macrophage cell line to produce a lot of TNF-α and NO *in vitro*[8]. In our report, the fluorescence intensity of IL-1, IL-6 and TNF-α and the content of NO derived from the peritoneal macrophages of nude mice was significantly elevated when WPG of bifidobacteria bifidum was injected into nude mice intraperitoneally. It was indicated that WPG of bifidobacteria bifidum could activate macrophages to secrete a large amount of cytotoxic effector molecules.

IL-1, IL-6 and TNF-α was the important cytokines produced by activated macrophages. They could act many aspects of immune system. IL-6 could promote the differentiation and maturation of B lymphocytes, and stimulate these cells to secrete antibodies. Furthermore, it also could induce proliferation and activation of resting T lymphocytes directly[15,16]. IL-12 could induce the production of IFN-γ by resting and activated T lymphocytes and natural killer (NK) cells, and possess the ability to act as a LAK cell growth factor[17-20]. TNF-α could augment the antitumor ability of NK, CTL and LAK cells, and play an important role in adjusting the activation of T lymphocytes[21,22]. These cytokines had broard antitumor and antimetastatic activities *in vivo* and *in vitro* markedly[23-35]. NO was the signal molecules and effector molecules which had broard biological activities. It was also the important effector molecules that activated macrophages killing tumor cells and pathogenic micro-organisms[36-41]. The induction of these cytotoxic effector molecules may play an important role in antitumor immune reaction of WPG. It was widely acknowledged that WPG could obviously inhibit the growth of many kinds of tumors *in vivo*. Rhee and his colleagues demonstrated that WPG of bifidobacteria spp. Exhibited markedly antitumor activity against subcutaneously transplanted sarcoma 180 in mice [42]. Ishihara, *et al* reported that the volume of metastatic skin melanoma obviously decreased, when intralesional administration of WPG of bifidobacteria infantis was prepared. We had also found that WPG of bifidobacterium bifidum could induce apoptosis of the colorectal carcinoma transplantation neoplasms of nude mice, and inhibit its proliferation simultaneously[43]. In our report, WPG could activate macrophages to secrete a lot of IL-6, IL-12, TNF-α and NO. Because these important mediators present obvious antitumor activity, the cytotoxic effector molecules produced by activated macrophages may mediate the effect on antitumor of WPG.

Abstract

In the recent decades, the incidence of hepatocellular carcinoma (HCC) has been found to be increasing in males in some countries. In China, HCC ranked second of cancer mortality since 1990s. Hepatitis B and C viruses (HBV and HCV) and dietary aflatoxin intake remain the major causative factors of HCC. Surgery plays a major role in the treatment of HCC, particularly for small HCC. Down-staging unresectable huge HCC to smaller HCC and followed by resection will probably be a new approach for further study. Liver transplantation is indicated for small HCC, however, some issues remain to be solved. Different modes of "regional cancer therapy for HCC" have been tried. Systemic chemotherapy has been disappointing in the past but the future can be promising. Biotherapy, such as cytokines, differentiation inducers, anti-angiogenic agents, gene therapy and tumor vaccine will probably play a role, particularly in the prevention of tumor recurrence. HCC invasiveness is currently the major target of study. Tremendous works have been done at the molecular level, which will provide clues for biomarker of HCC progression as well as targets for intervention.

INTRODUCTION

Liver cancer is the 4th most common cause of death from cancer, the highest age-standardised mortality rate is in China ($34.7/10^5$, the 2nd cancer killer since 1990s), which alone accounts for 53% of all liver cancer deaths worldwide[1]. Recently, the incidence of HCC has been found to be increasing particularly in males in countries such as Japan, Italy, France, Switzerland, United Kingdom and the United States[2-4]. Clinical advances have mainly been made in the fields of medical imaging, surgery, regional cancer therapy and biotherapy. Rapidly growing knowledge in basic science appears at the molecular level, particularly in the study of HCC invasiveness. Although a lot of news from bench to bedside on the advances made in HCC has appeared, the overall dismal outcome of patients with HCC changed very little. In the United States, the relative 5 -year survival for liver cancer only increased from 4% (1974-76) to 6% (1986 -93) in white, and from 1% to 4% in black[5]. In Shanghai, the relative 5-year survival of liver cancer in 1988-91 was 4. 4%[6]. These indicate that there is still a long way to go in conquering HCC.

CAUSE AND PREVENTION

Viral hepatitis B (HBV) and/or C (HCV), aflatoxin and alcohol are major risk factors of HCC

However, the importance of these different factors varies in different geographic areas. HBV is more predominant in Chinese, Southeast Asian and African patients with HCC, whereas HCV is common in HCC patients in developed countries (Japan, France, Italy and others). The prevalence of hepatitis B surface antigen (HBsAg) and antibody to HCV (anti-HCV) in HCC patients were reported to be 63.2% and 11.2% respectively in China[7], which was similar to that reported in the past.Prospective studies showed that there is an additive effect of HCV and HBV infection on HCC development[8]. Cirrhotic patients infected with HCV type 1b carry a significantly higher risk of developing HCC than patients infected by other HCV types[9-11]. An association was found between high serum alanine aminotransferase levels and more rapid development and high incidence rate of HCC in patients with HCV-associated cirrhosis[12]. In a transgenic mice, it was found that the core protein of HCV induces HCC[13].

Hepatitis G virus (HGV) and transfusion-transmitted virus (TTV) infection might not play an important role

Based on the data from China, Japan, Africa, United Kingdom and others, HGV might not play an important role in the development of HCC[14-18]. A case-control study also failed to support the hypothesis of an association between transfusion-transmitted virus (TTV) infection and HCC[19]. However, some authors claimed that HGV and TTV could not be completely excluded as causative agents[20-22].

In China, HBV and HCV (mainly HBV), aflatoxin and contamination of drinking water (such as microcystin, a promoter of hepatocarcinogenesis) remain as major risk factors of HCC, and alcohol should be added in northern China

A study showed that exposure to aflatoxin metabolite M1 (AFM1) can account for a substantial part of the risk of HCC[23].

Other risk factors have also been reported

In Japan, alcohol consumption and cigarette smoking were also risk factors of HCC, and synergism between them was observed[24,25]. In Italy, for attributable risk (AR) of HCC, heavy alcohol intake ranked first (45%), HCV second (36%) and HBV third (22%)[26]. The risk of dietary iron overload was 4.1 for HCC in black Africans[27], which is similar to that of haemochromatosis in Caucasians. A role of family history independent from and interacting with known risk factors for HCC was also reported, the odds ratio was reported to be 2.4[28].

HCC risk is high in individuals with both aflatoxin B1 (AFB1)-DNA adducts and HBsAg, suggesting a viral-chemical interaction

Furthermore, AFB1 exposure correlates with a specific mutation at codon 249 of the p53 tumor suppressor gene in HCC, indicating a molecular pathogenesis[29]. How the four major risk factors (HBV, AFB1, p53 mutation and male gender) for HCC interact to produce malignant liver tumors were also demonstrated in transgenic mouse models[30].

X protein of HBV is one of the target of how HBV induces HCC

The incidence of HCC was as high as 86% in a HBV-X transgenic mice[31]. It was also found that the structure of the X gene is modified in the majority of tumorous livers, suggesting a potential role of mutated X proteins in HBV-related liver oncogenesis[32]. Moreover, HBV-X might play a role in hepatic inflammation by up-regulating interleukin-6 production, which can eventually lead to HCC[33]. Transactivation of transforming growth factor alpha (TGF-alpha) gene by HBV preS1 was observed which provides a clue for understanding viral hepatocarcinogenesis[34]. Synergy between TGF-alpha and HBsAg in hepatocellular proliferation and carcinogenesis was also reported[35].

All of these indicate a multifactorial and multistep development of HCC. Interaction among HBV/HCV, aflatoxin, alcohol, and genetic susceptibility might be important.

The dawn of HCC prevention has been shown

Few approaches of HCC prevention have been emerged, namely: prevention of HBV infection using vaccine, avoid exposure to carcinogens and promoters by changing drinking water, and to prevent viral hepatitis B or C progressing to cirrhosis and HCC by interferon (IFN) therapy. Result from a universal hepatitis B vaccination program indicated that the incidence of HCC in children has declined[36]. A significant declining trend of HCC mortality rate ratios was observed in the vaccination group, but not in the reference group[37]. In Qidong County of China, after people changed their source of drinking water from pond-ditch water (microcystin was found) to deep-well water, the mortality rate of HCC stabilized and even decreased slowly[38]. An analysis of patients with chronic hepatitis, liver cirrhosis, chronic hepatitis bearing HCC and liver cirrhosis bearing HCC, found that the incidence of HCC in the control group was 10.4/100 person-year, while that in the IFN treated group was 1.2/100 person-year[39]. IFN decreased HCC incidence in patients with HBV related cirrhosis. The cumulative occurrence rates of HCC in the treated group and the untreated group were 17.0% and 30.8%, respectively, at the end of 10 years[40]. IFN therapy also decreased the development of HCV related HCC. HCC rates in the IFN treated and untreated groups were 7.6% and 12.4% at the 10th year respectively[41]. Patients with HCV-related cirrhosis also benefit from IFN treatment[42]. IFN therapy significantly reduces the risk for HCC, especially among virologic or biochemical responders of patients with chronic hepatitis C[43]. For those nonresponder, retreatment with IFN-alpha appeared to have the additional effect of suppressing the development of HCC in patients who had incomplete responses to the initial treatment, even when the HCV was not cleared with retreatment[44]. Currently, lamivudine or ribavirin, antiviral agent, is added to the treatment of HBV or HCV, however, long-term follow-up study is needed to evaluated whether this additional treatment will increase the efficacy of HCC prevention.

SURGERY OF HCC

Small HCC resection plays an important role to improve HCC prognosis

Small HCC resection has resulted in marked increase in 5-year survival rate from 20%-30% to 40%-60%. At the author's institution, the 5-year survival rate of 963 patients with small HCC ($\leqslant$5cm) resection was 65.1%, whereas it was only 36.1% for large HCC resection (n=1308); of the 368 HCC patients with 5-year survival, 198 (53.8%) patients received small HCC resection[45,46]. Early HCC with well differentiated cancer containing Glisson's triad has been recognized as an entity with a high rate of surgical cure, the 5-year survival was as high as 93%[47]. A comparison between subclinical HCC and symptomatic HCC revealed that operability was higher (26.8% versus 7.9%), and cumulative survival rate was also higher[48].

Makuuchi *et al* (1998) have performed 367 hepatectomies on 352 patients since 1990, the 5-year survival rate was 47.4%[49]. At the author's institution, HCC resection has been performed on 2119 patients between 1979-1998, the 5-year survival rate was 51.5%[50]. Recently, perioperative blood transfusion and diabetes mellitus were found to be prognostic factors after HCC resection[51,52]. An experimental study indicated that partial hepatectomy was associated with increased levels of TGF-alpha, TGF-beta, and basic fibroblast growth factor (bFGF) in the liver and accelerates local tumor growth[53].

Down-staging of unresectable huge HCC to smaller HCC followed by resection will probably be a new approach for further study

At the author's institution, the 5-year survival of 108 patients with this approach (down-staging by hepatic artery ligation, cannulation, cryosurgery, etc.) was 64.7%[45]. Another 65 patients with unresectable HCC down-staged by transcatheter arterial chemoembolization (TACE) followed by resection, the 5-year survival was 56.0%[54]. The 5-year survival rates

were similar to that of small HCC resection, which coincided with a reduction of median tumor size from 10.0cm to 5.0cm during the resection of this approach[55]. However, a well designed randomized trial is needed for a final evaluation.

Orthotopic liver transplantation (OLT) is a reasonable treatment for small HCC if partial hepatectomy (PH) is impossible

For decades, the role of OLT in the treatment of HCC has been unclear. In the early 1990s, it was accepted that small HCC was indicated for OLT. However, only retrospective data were available for the comparison between OLT and PH in the treatment of HCC. The 5-year survival rate of 422 HCC patients with OLT was 44.4%, and tumor histologic grade and tumor size (>5cm) were linked to recurrence-free patient survival[56]. A comparison between PH (n = 294) and OLT (n = 270) showed that survival was comparable, but operative mortality was lower in PH group, and concluded that HCC developing in a well compensated cirrhotic liver initially may be treated with PH, and OLT should be applied selectively to those patients with tumor recurrence and/or progressive hepatic failure[57]. A proper selection of candidates for PH gives better results than OLT, because of the increasing waiting time for OLT[58]. OLT is a reasonable treatment for patients with early stage tumors if PH is impossible. The oncological advantage of OLT compared with PH, however, is questionable[59]. As survival after PH and OLT for early stage HCC does not reveal a significant difference, resection of these tumors is still justifiable[60]. When compared with PH, OLT for resectable HCC offers substantial survival benefit among well-targeted subgroups of patients as long as an organ donor is available within 6 to 10 months time delay. However, the marginal cost-effectiveness ratios incurred by this strategy are higher than that of many other current medical interventions[61]. This might be of particular impact for developing countries where HCC is endemic.

NONSURGICAL THERAPIES FOR HCC

There is still a long way to go of nonsurgical therapies for HCC

Nonsurgical therapies for HCC generally include regional cancer therapies, radiotherapy, chemotherapy and biotherapy. Unfortunately, a systemic review of 37 RCTs to examine the effect of different treatments for non resectable patients indicated that only 3 modalities were minimally and uncertainly effective (embolization, tamoxifen and IFN)[62]. Another overview of 30 RCTs for unresectable HCC found that no treatment has clearly proven efficacy in survival. 5-Fluorouracil, adriamycin and transarterial chemotherapy were not associated with survival benefit at 1 year. The number of RCTs was insufficient to enable a conclusion to be reached for IFN and PEI (percutaneous ethanol injection). Controversy persists concerning tamoxifen efficacy[63].

Regional cancer therapy for HCC is one of the nonsurgical therapies that develops recently

Based on the advances of early detection and medical imaging, more HCCs can be diagnosed with small and localized lesions. As a result, regional cancer therapies have developed in the recent decades. Unfortunately, the number of RCTs was insufficient to make any conclusion as yet.

Transcatheter chemoembolization (TACE) is one choice of the treatment for unresectable but not far advanced HCC, particularly for patients with multifocal HCCs and with acceptable liver functions. However, some RCTs failed to demonstrate that TACE improve the survival with unresectable or advanced HCC[64,65]. A RCT found that the 4-year survival of intrahepatic-arterial ^{131}I-labeled lipiodol (2.2 GBq) was 10% when compared with 0% in TACE group (70mg cisplatin)[66]. Another RCT indicated that styrene maleic acid neocarzinostatin in Lipiodol was better than epirubicin in Lipiodol[67]. A comparison of planned periodic TACE and TACE based on tumor response found that the 3-year survival rates were 0% and 15% respectively in Okuda 2 stage, the mean time between the first and the third courses of TACE was 4 months and 14 months respectively, indicating the efficacy of TACE increased when it was used selectively and was repeated only when necessary[68]. The overall 5-year survival rate after TACE treatment is around 6%-8%. TACE resulted in prolongation of survival in patients with tumor volumes of less than 200mL, tumor-to-liver volume ratios of less than 5%, and iodized oil retention greater than or equal to 75%[69]. Complications of TACE were encountered in 4.4% of cases, of which, hepatic failure and down-staging of cirrhosis remain a problem[70].

Percutaneous ethanol injection (PEI) is a treatment choice of unresectable small HCC. The 4-year survival rate was 39% in 47 small HCC patients with cirrhosis, however, the 4-year recurrence rate was as high as 79%[71]. Local recurrence depends predominantly on the biologic characteristics of the tumor (histologic grade and intrahepatic recurrence), regardless of the efficacy of PEI[72]. For large (>5cm) HCC, PEI performed in a single session under general anesthesia was an alternative. In a series of 108 patients, the 4-year survival rates were 44% for single encapsulated HCC (5 cm - 8.5 cm), 18% for single infiltrating HCC (5cm-10cm) or multiple HCC and 0% for advanced disease, the mortality was 0.7% and major complications 4.6%[73]. A RCT study comparing 50% acetic acid and PEI indicated that local recurrence rate was lower and 2-year survival rates higher with acetic acid[74].

Percutaneous microwave coagulation therapy (PMCT) is an extension of PEI, the 5-year survival for patients with well-differentiated HCC treated with PMCT and PEI were comparable, however, among the patients with moderately or poorly differentiated HCC, 5-year survival with PMCT (78%) was better than with PEI (35%)[75]. PEI is difficult for small HCC on the surface of liver, however, PMCT can be performed safely in such patients[76]. After PMCT, a second biopsy on 19 patients showed complete destruction of tumor in 18 patients[77].

Radiofrequency (RF) hyperthermia is another mode of regional cancer therapy. Of the 73 HCC patients treated with RF and evaluated by CT, complete response rate was 10%, partial response rate 21%, and 5-year survival 17.5%[78]. A comparison was made between RF and PEI in the treatment of small HCCs. It was found that RF ablation resulted in a higher rate of complete necrosis (90% versus 80%) and requires fewer treatment sessions than PEI. However, the complication rate was higher with RF ablation than with PEI[79].

The inadequacy for complete control of cancer nodule is one of the major problems of regional cancer therapies. Therefore, surgery remains the choice of treatment for curatively resectable HCC with Child A cirrhosis until a RCT clarifies the situation. In general, TACE is a treatment choice

for multinodular and large unresectable HCC (a part of TNM Stage II, IIIA, IIIB and IVA; with Child A or Child B cirrhosis). The other regional therapies may be used on unresectable small HCC which is not multinodular.

Three-dimensional conformal radiotherapy will probably play a role for HCC treatment in the future

A pilot study indicated that three-dimensional conformal radiotherapy helped to avoid excessive exposure of the liver and adjacent organs and made it a safer treatment modality for unresectable HCC[80]. Selective internal radiation therapy using 90Y microspheres (median 3.0 GBq) was effective for selected cases of nonresectable HCC. There was a 50% reduction in tumor volume in 26.7% of patients after the first treatment, the nontumorous liver appeared more tolerant to internal radiation than external beam radiation. This treatment may help to convert nonresectable tumors to resectable ones[81]. At the author's institution, long-term follow-up study indicated that a combination of surgery and intrahepatic arterial infusion of ^{131}I-anti-HCC mAb improved survival of unresectable HCC[82].

Systemic chemotherapy for HCC has been disappointing in the past, but in the future can be promising

Neither complete response nor partial response was observed using paclitaxel (175mg/m^2 q3w) for unresectable HCC[83]. However, a phase II study with cisplatin, doxorubicin, 5-fluorouracil, and IFN-alpha in advanced unresectable HCC demonstrated that complete pathological remission was possible, partial response rate was 26%, no viable tumor cells were found in four out of nine resected specimens[84]. Based on the study of the expression of drug resistance-related genes in three human hepatoma cell lines, it was demonstrated that IFN-alpha modulated the mechanism of resistance to cisplatin in liver cancer[85]. Individual patient with complete remission of multiple HCC associated with HCV-related decompensated liver cirrhosis by oral administration of enteric-coated tegafur/uracil has been reported[86].

Biotherapy will play a role in the treatment of HCC in the future

However, the results were still controversial. Many RCTs of tamoxifen for advanced HCC were negative[87-90]. A lack of efficacy of antiandrogen treatment was found for unresectable HCC in a RCT[91]. Oral beta all transretinoic acid (50mg/m^2 t.i.d.) was also ineffective against HCC[92]. Interestingly, Octreotide, a somatostatin analogue, improves survival of inoperable HCC in another RCT[93]. Randomized controlled trial of interferon treatment for advanced HCC indicated that its administration prompts no benefit in terms of tumor progression rate and survival[94].

Gene therapy-"progress but many stone yet unturned[95]"

Gene therapy for HCC remains an attractive field. Experimental studies using cytokine genes (tumor necrosis factor, interleukin-2, interferon), suicide and *p*53 genes; using retrovirus, adenovirus and Epstein-barr virus as vectors; using AFP enhancer; using intraarterial administration, etc. have been reported[96-108]. Data from both the literature[109-112] and from the author's institution[113] demonstrated that human malenoma antigen (MAGE) gene expression is frequent in HCC, suggesting that HCC patients may be good candidates for specific immunotherapy (tumor vaccine) using MAGE encoded antigen. Dendrite cells are good candidates for this particular purpose[114].

METASTASIS OF HCC

Invasiveness of HCC has become a major target of recent research

The high recurrent rate in the liver with mainly intrahepatic metastatic spread remains a major obstacle to further improvement on the long-term survival after curative HCC resection. Therefore, research on the invasiveness of HCC has become a major target. Clinically, targets include prediction, treatment and prevention; in the laboratory, investigations include metastatic model, molecular events, angiogenesis, intervention, etc.

A routine biomarker for prediction of metastasis and recurrence is not yet available

Although many biomarkers have been tried, such as AFPmRNA, circulating VEGF and PD-ECGF[115,116], human macrophage metalloelastase gene[117], p27[118], p53 mutation[119], expression of p73[120], telomerase activity[121], etc.

Both pre- and postoperative chemotherapy or chemoembolization have not adequately proved to be effective for prevention of metastatic recurrence

Convincing evidence is lacking to support systemic preoperative chemoembolization in patients with initially resectable HCC[122]. Although many authors supported the strategy of postoperative chemoembolization, its effectiveness might be due to suppression of intrahepatic micrometastases rather than multicentric carcinogenesis[123]. Postoperative intraarterial chemotherapy has also been claimed to improve survival[124,125]. Recently, a RCT showed that postoperative adjuvant systemic chemotherapy using epirubicin and mitomycin C has a tendency to reduce recurrence rate[126]. However, two RCTs failed to demonstrate the effectiveness of postoperative adjuvant therapy. The adjuvant chemotherapy with epirubicin and carmofur after radical resection of HCC was not effective[127]. Postoperative chemotherapy using intravenous epirubicin and intraarterial iodized oil and cisplatin was associated with more frequent extrahepatic recurrences and a worse outcome[128]. Interestingly, a RCT revealed that oral polyprenoic acid prevents second primary HCC after surgical resection, and reconfirmed after longer follow-up study[129,130]. Recently, a RCT study indicated that a single 1850 MBq dose of intra-arterial ^{131}I-lipiodol increased the 3-year overall survival from 46.3% in the control to 86.4% in the treatment group[131].

The molecular basis of "HCC invasiveness" is similar to that of other solid cancers, its complexity represents as multi-genes involvement and multi-step process

Numerous papers have been published concerning the molecular basis of "HCC invasiveness" in the literature[132-150]. At the author's institution, studies concerning HCC invasiveness could be summarized into the followings: a Factors that positively related to invasiveness included: p16 and p53 mutation, H-ras, c-erbB-2, mdm2, TGFα, epidermal growth factor receptor (EGF-R), matrix metalloproteinase-2 (MMP-2), urokinase-type plasminogen activator (uPA), its receptor (uPA-R) and inhibitor (PAI-1),

intercellular adhesion molecule-1 (ICAM-1), vascular endothelial growth factor (VEGF), platelet-derived endothelial cell growth factor (PD-ECGF), basic fibroblast growth factor (bFGF), etc. On the other hand, factors that negatively related to HCC invasiveness included: nm23-H1, Kai-1, tissue inhibitor of metalloproteinase-2 (TIMP-2), integrin α5, E-cadherin, etc. b The biological characteristics of small HCC was slightly better than that of large HCC c The following blood test have been tried with potential clinical implication: thrombomodulin, ICAM-1, PAI-1, VEGF, bFGF, etc. Serum ICAM-1 content was higher in patients with metastasis than those without metastasis. Loss of heterozygosity (LOH) at D14S62 and D14S51 (on chromosome 14q) in plasma DNA were also related to metastatic recurrence. The combination of several items that mentioned above increased sensitivity[151-164].

Comparison between primary HCC tumors and their metastatic lesions using comparative genomic hybridization (CGH) indicated that chromosome 8p deletion might contribute to HCC metastasis[165]. The presence of at least three novel tumor suppressor loci on 8p in HCC was reported[166], and DLC-1 might be one of the related tumor suppressor gene[167].

Metastatic human HCC model in nude mice (LCI-D20) and HCC cell line with metastatic potential (MHCC97) have been established[168,169]

Using corneal micropocket model in nude mice, the difference of angiogenesis induced by LCI-D20 and LCI-D35 (a low metastatic model) was also demonstrated[170]. Highly metastatic HCCs induced in male F344 rats and a transplantable lymph node metastatic mouse model of HCC were also reported[171,172]. These will provide a tool for the study of the mechanism and the intervention of metastasis.

Angiogenesis is closely related to HCC invasiveness

Vascular endothelial growth factor (VEGF) gene and protein expression are involved in the progression of HCC[173-175], and that VEGF 121 and 165 isoforms play a critical role in angiogenesis of HCC[176]. However, some author reported that VEGF might be associated with the angiogenic process of the cirrhotic liver, but not with the angiogenesis of HCC[177]. VEGF level increased after TACE, indicating that VEGF may be a marker for tumor ischemia[178]. Angiogenesis in HCC depends on the net balance between human macrophage metalloelastase (a potent angiogenesis inhibitor) and VEGF gene expressions[179]. Platelet-derived endothelial cell growth factor (PD-ECGF), another angiogenic factor, is also involved in HCC progression[180]. The enhanced gene expression of angiopoietin-2 may also contribute to the hypervascular phenotype[181]. Angiogenesis in HCC can be evaluated by CD34 immunohistochemistry[182,183]. At author's institution, using CD34 staining to measure microvessel density (MVD), we found that MVD was only useful for small HCC resection, the 5-year survival after resection of hypovascular type small HCC was double to that of hypervascular type, being 74.6% versus 34.7%[184]. As small HCCs increase in size and become increasingly dedifferentiated, the number of portal tracts apparently decreases and intratumoral arterioles develop. These findings may reflect changes in the hemodynamics as the HCC develops[185].

Experimental intervention of HCC metastases is progressing

Many approaches have been tried in preventing metastases, and anti-angiogenesis is one of the major target. For example, anti-angiogenic agent TNP-470, a derivative of fumagillin, was found to inhibited tumor growth and metastasis in nude mice bearing human HCC and suppressed the progression of experimentally-induced HCC in rats[186,187]. High-dose and long-term therapy with IFN-alpha inhibited tumor growth and recurrence in nude mice bearing human HCC xenografts with high metastatic potential in a dose-dependent manner, and the preventive effect was mediated by anti-angiogenesis[188]. However, its clinical significance has to be assessed by a RCT. Other experimental interventions for metastasis were also reported, such as matrix metalloproteinase inhibitor BB-94[189], 4-[3,5- Bis (trimethylsilyl) benzamido] benzoic acid (TAC-101)[190], antisense H-ras oligodeoxynucleotides[191], synthetic β peptide[192], etc.

In short, much has been done and much remains to be done. Well designed RCTs are needed for a more clear conclusion in many treatment modalities that are in debate. Some agents that have not been effective for advanced HCC may still be tried in the prevention of metastases and recurrence with a much smaller tumor burden. In the 21st century, prevention is doubtlessly of prime importance, however, detection of small HCC and studies on HCC invasiveness remain critical issues for further improvement of prognosis of HCC.

ACKNOWLEDGEMENT The author express sincere gratitude to Professor W. Y. Lau, Department of Surgery, The Chinese University of Hong Kong, for his kind assistance in preparing this manuscript.

Alstead E. Fertility and pregnancy in inflammatory bowel disease. *World J Gastroenterol*, 2001;7(4):455-459

INTRODUCTION

Inflammatory bowel disease (IBD) is a chronic disorder affecting young adults in the reproductive years. It is common for both female and male patients with IBD to ask questions about IBD's effect on their relationships, sexual and reproductive function, in particular fertility, the outcome of pregnancy and its possible effects on the disease. An open discussion of the social situation and education targeted at these issues therefore forms an essential part of the management of any young person with IBD. The questions that are most commonly asked are summarised in Table 1. In order to answer these questions we need evidence. There are few large prospective case controlled studies to provide the information which is required but the available data, some of it from small observational studies, will be summarised in this chapter.

Table 1 Questions commonly asked by IBD patients

Sexual health	Will I be able to have normal relationships and a family?
Inheritance	Will my children inherit IBD?
Fertility	Will my fertility be impaired by IBD or its treatment?
Outcome of pregnancy	Will I have a normal, healthy baby?
Disease activity in pregnancy	Will my IBD flare up in pregnancy?
Drug and other treatments	I don't want to take any drugs during pregnancy?
Breast feeding	Is breast feeding advisable and safe

SEXUAL HEALTH

It is well established that general measures of quality of life are impaired in patients with IBD[1]. Sexual health is an important aspect of quality of life which is often overlooked in a routine gastroenterological consultation. Sexual problems in IBD often seem to be focused around three major factors: body image problems, difficulties with social relationships and impaired sexual function[2]. Crohn's disease (CD), in particular has been shown to have an impact on self-image, social relationships and sexual function[1]. Body image concerns are frequently found in IBD patients relating either to the direct physical effects of their disease such as weight loss, growth retardation as a result of chronically active disease in childhood, fistulae or perianal disease. The effect of surgery especially when a stoma is involved is associated with low self-esteem and poor body image. The side effects of steroids and other medications may lead to weight gain, hirsutism, skin changes and other features which promote feelings of unattractiveness. There is some evidence that psycho-social effects of stoma surgery performed in childhood, before puberty may be less severe than if such surgery is performed during the teenage and early adult years[3]. Partners of IBD patients with stomas have been found to be more likely to be able to accept the stoma than the patient themselves[4]. Psychological fears of loss of control of bodily functions and the fear of rejection by new or established partners in an intimate relationship all contribute to difficulties in social and sexual relationships. Counselling and practical advice and support is frequently helpful, but the need for it is not always identified in general gastroenterological practice.

Some studies have reported an increase in sexual difficulties including dyspareunia in women who have had surgery for IBD and there is some evidence that patients with IBD may delay or even defer pregnancy because of their disease[4,5]. Most of the reports of sexual dysfunction are in women with Crohn's disease. There are no specific reports of sexual dysfunction in women with ulcerative colitis (UC) who have not had previous surgery.

In men with IBD the risk of impotence after proctocolectomy is the main concern[4]. Advances in surgical technique have decreased although not eliminated post-operative sexual dysfunction, and this seems to apply to both conventional proctocolectomy and pouch surgery with a reported incidence of impotence of around 4%-8%[6]. It is important to remember that patients are often quite reluctant to discuss such delicate matters and tactful prompting and adequate time during the consultation is the key to their detection.

CONTRACEPTION

As there is clear evidence that the outcome of pregnancy is better in women with IBD who have quiescent disease at the time of conception, advice about contraception is keenly sought and opinions have differed over the years. In women who do not smoke and who have quiescent or mildly active Crohn's disease (CD), the use of a low dose combined oral contraceptive is not associated with increased disease activity compared with non-users[9,10]. There are no data about the thrombo-embolic complications of the oral contraceptive pill in IBD but this should be considered especially in patients with active UC.

INHERITANCE OF IBD

Individuals with IBD are often concerned that their children may inherit the illness. There is a familial increased risk in IBD which is stronger if the parent has CD. This risk also appears to be greater in Jewish families. The life-time risk factor for a child of a parent with CD is around 7%-9% of developing CD and about 10% for the development of IBD[11]. If both parents are affected the risk for any children may be up to 35%.

FERTILITY

Women with UC generally appear to have normal fertility, although one retrospective study from Scotland reported that women who had had surgery for IBD had increased infertility compared to the general population (25% *vs* 7%)[12]. Voluntary childlessness in people with IBD is still probably greater than in the general population however, possibly relating to fear of pregnancy or even inappropriate professional advice suggesting that pregnancy might be dangerous. In CD, fertility is probably normal in individuals with inactive disease[13,14]; however, fertility is impaired in women with active Crohn's disease. This relates directly to disease activity and fertility appears to revert to normal with the induction of remission. Women whose IBD develops before their first pregnancy have been shown to have fewer pregnancies than population controls. In women who had had a pregnancy prior to the onset of IBD, however, they seem to have a similar reproductive history to a control population[13].

Increasingly, men are concerned about fertility and other issues of reproductive health. Sulphasalazine has been known for many years to cause reversible semen abnormalities with impairment of fertility in up to 60% of men on the drug. This effect is reversed two months after withdrawing sulphasalazine. Men express concerns about the safety of immunosuppressive agents in terms of fertility and the risk of congenital abnormality, but there are no reliable data at all for guidance in this area[15].

PREGNANCY OUTCOME IN IBD

In recent years there has been an increased interest in the outcome of pregnancy in IBD and a number of epidemiological surveys and case controlled studies have been published. In UC, there is a large body of evidence suggesting that the frequency of spontaneous abortion, still birth and congenital abnormality are no different to that in the general population[16-19]. In quiescent Crohn's disease, pregnancy outcome, in terms of spontaneous abortion, still birth and congenital abnormality, is also no different from the general population[14,17]. Active Crohn's disease at the time of conception or during pregnancy significantly increases foetal loss and pre-term delivery and it appears that disease activity rather than medical treatment accounts for the adverse outcomes[20,21].

A large prospective population-based study looked at adverse pregnancy outcomes in 239773 single pregnancies in Sweden over a two year period. This included 756 pregnancies in women with IBD. This is the expected number of IBD pregnancies for this population[22]. No significant increase in the most serious adverse outcomes of still birth or infant death in the first year of life was found in the IBD mothers. There was also no significant increase in babies which were small for gestational age. There was however, a significantly increased risk of pre-term birth (odds ratio 1.81, 95% confidence intervals 1.06-3.07) at less than 33 weeks and for 33-36 weeks (odds ratio 1.48, confidence intervals 1.0-1.19), and of low birth weight (less than 1500g, odds ratio 2.15 confidence intervals 1.11-4.15). IBD patients also had an increased caesarean section rate (15% *vs* 10%). These estimates were not affected by adjustments for maternal age, parity and smoking. There was, however, not any information about whether the mothers experiencing pre-term delivery and low-birth weight babies had UC or CD, or whether these were women with active disease during their pregnancies. More recent studies from France and Denmark have confirmed this small increase in pre-term birth and low birth weight, particularly in CD[23,24].

INFLUENCE OF PREGNANCY ON IBD ACTIVITY

In any woman with quiescent IBD at the time of conception, the likelihood of a flare-up of IBD during pregnancy or the puerperium is no greater than in any other year of her life. Active UC at the time of conception is associated with continuing disease activity in about two thirds of pregnant women. Chronic activity will continue throughout pregnancy in about a quarter of these patients and in about 45% the activity may actually worsen[14]. This therefore constitutes a strong indication for aggressive medical treatment, since if remission can be induced by medical therapy, the course of pregnancy is similar to that in patients with quiescent disease at conception. About two thirds of women with active Crohn's disease at the time of conception will continue to have disease activity throughout the pregnancy and in about half of these there will be a deterioration during the pregnancy (Table 2). Therefore it is inadvisable to conceive when CD is active, but if conception occurs, an aggressive therapeutic strategy is indicated as there is clear evidence in Crohn's disease that disease activity is associated with pre-term birth and low-birth weight and some suggestion that early miscarriage may be increased.

MANAGEMENT OF IBD IN PREGNANCY

All the evidence suggests that maintenance treatment, certainly with aminosalicylates, should be continued throughout pregnancy and flare-ups of disease activity should be investigated and treated appropriately as in a non-pregnant patient. All pregnant women are very concerned about taking medication during gestation and it is essential if at all possible that these issues are broached and discussed well in advance of a planned pregnancy enabling informed discussion with the patient and her partner once she becomes pregnant.

Nutrition is extremely important in pregnancy, the average weight gain during a normal pregnancy being between 11 and 16kg. Folic acid supplementation is recommended for all pregnant women but in IBD, patients who may have folic acid deficiency or be taking drugs which interfere with folic acid metabolism, a dose of 5mg daily should be recommended rather than the usually advised dose of 400μg daily. It is extremely important to remember that early nutritional intervention is indicated in a woman with active disease who may not be gaining weight. Women with active CD in pregnancy have received an elemental diet as primary therapy with rapid resolution of symptoms[25] and supplemental feeding may be required in sick IBD patients who are failing to achieve the expected weight gain during pregnancy.

Proper investigation of gastrointestinal symptoms is not contraindicated during pregnancy and indeed it is important in order to ensure that appropriate treatment is advised. Blood

investigations are often difficult to interpret in pregnancy due to haemodilution, and therefore sigmoidoscopy and indeed colonoscopy may be indicated in some circumstances. Both these investigations have been shown to be safe in a small study[26]. Monitoring foetal heart rate during endoscopy has not shown any adverse effects and there has been no evidence of increased premature labour or foetal abnormalities following endoscopy in pregnancy. Radiographic imaging should obviously be avoided unless obstruction, perforation or toxic megacolon are suspected and if possible in this situation, plain abdominal films should be used rather than CT or barium studies which involve much higher radiation exposure. Ultrasound may be useful, for example to identify an intra-abdominal collection in patients with Crohn's disease.

Table 2 Influence of pregnancy on IBD activity
Meta-analysis data from Reference 17

INACTIVE disease at conception. Likelihood of relapse during pregnancy

	Ulcerative colitis	Crohn's disease
Number of pregnancies	528	186
Relapse	34%	27%

ACTIVE disease at conception. Pattern of disease activity in pregnancy

	Ulcerative colitis	Crohn's disease
Number of pregnancies	227	93
Better	27%	34%
No change	24%	32%
Worse	45%	33%

TREATMENT OF IBD IN PREGNANCY

Drug treatment

The safety (or risk) of drug therapy during pregnancy is of prime concern to any pregnant woman. In women with IBD, the most important factors in relation to treatment are to emphasise the importance of planned pregnancy when the disease is quiescent and the fact that, if conception occurs with active IBD, inducing remission with medical therapy carries less risk than continuing a pregnancy without treatment[26].

First line agents

Aminosalicylates and sulphasalazine have been widely used in pregnancy in IBD. They are safe in conventional doses and should be used for maintenance or induction of remission in the same way as in a non-pregnant individual. Both aminosalicylates and sulphasalazine are poorly systemically absorbed and there is little placental transfer from mother to foetus[27-29]. No evidence of teratogenicity has been demonstrated and the outcome of pregnancy has been shown to be similar to that in healthy women. There have however, been reports of nephrotoxicity in the foetus of a woman taking a high dose of mesalazine[30]. High dose aminosalicylates are not therefore advisable during pregnancy.

Corticosteroids are well tolerated in human pregnancy. They cross the placental barrier but there has been no convincing evidence of teratogenesis despite reports of cleft lip and palate in the past. Immune deficiency in the new-born infant is theoretically possible, but is very rarely reported in clinical practice. In IBD patients taking corticosteroids during pregnancy, no increase in foetal complications have been found compared to the general population[29]. It is, therefore, important to use corticosteroids in women with moderate to severe disease activity in pregnancy in the same way as in a non-pregnant patient.

Second line agents

Azathioprine and 6-mercaptupurine have never been demonstrated to be teratogenic in humans and do not have any effects on human interstitial cell function or gametogenesis in the doses used in clinical practice[31,32]. There is extensive experience of the use of these drugs in pregnancy in renal transplant recipients and in patients with systemic lupus erythematosus who are unable to discontinue immunosuppressive treatment, with very little evidence of adverse effect[33,34]. However, because of the theoretical possibility of teratogenesis in animals, gastroenterologists have been very cautious in advising discontinuation of azathioprine prior to pregnancy or even termination of pregnancy in women conceiving on azathioprine. In a small retrospective study on the use of azathioprine in pregnancy and IBD there were no serious adverse outcomes. All the women conceived while taking the drug and half of them continued to take it throughout gestation[35]. In a larger study, looking at pregnant women with IBD on 6-mercaptupurine, there were also no adverse outcomes of pregnancy[36], although in this study only a small number of patients actually continued to take the drug throughout their pregnancy.

In general therefore, if a patient is established and well on azathioprine or 6-mercaptupruine and it is felt to be essential to continue this drug to retain remission, after full discussion with the patient and her partner, it is reasonable to decide to continue treatment during pregnancy. It is essential that this decision is made by the patient who has been presented with the evidence. In view of the complications which may arise at the start of treatment with these agents, it is not advisable to commence treatment for the first time during pregnancy.

Cyclosporine has been used in patients with severe UC which has not responded to steroids in an attempt to avoid surgery which is said to carry a high risk of foetal mortality[37]. Cyclosporine is not teratogenic and has been extensively used in transplant recipients and lupus patients without increased adverse effects[38-41]. Cyclosporine is a highly toxic drug however, carrying the risk to the mother of hypertension, nephrotoxicity and hepatotoxicity and it would therefore appear to be undesirable in almost all circumstances except the avoidance of urgent colectomy in a patient with fulminant UC.

Methotrexate is mutagenic and teratogenic and is therefore contraindicated in pregnancy or immediately prior to conception. There are reports of women with IBD who have conceived while taking methotrexate, who had a high incidence of severe congenital abnormalities in the babies born from these pregnancies, with neural tube defects and other severe deformities[42,43]. In a woman who conceives on methotrexate and will not agree to a therapeutic abortion, however, the methotrexate must obviously be stopped immediately and high dose folic acid replacement is indicated.

Anti-TNF antibodies There are currently no data about pregnancy in patients receiving therapy. By definition this therapy is used for people with severe active CD, and for the present pregnancy should be discouraged during this treatment.There is no evidence that it is safe to continue with the pregnancy if conception occurs during treatment with anti-TNF antibody.

Antibiotics: Metronidazole has not been shown to have

adverse effects and has been used extensively in pregnancy by gynaecologists to treat bacterial vagionosis. There is not any evidence of increased risk of spontaneous abortion or congenital abnormality in humans[44,45]. Ciprofloxacin and other quinolone antibiotics have been suggested to be associated with musculoskeletal problems in foetuses in animal studies but this has not been substantiated in humans. Ciprofloxacin has been used during pregnancy with no increased incidence of spontaneous abortion or congenital abnormality and follow-up of the children born from these pregnancies is ongoing[46].

Surgery

Patients who have undergone previous surgical intervention for UC or CD do not appear to have any increase in problems during pregnancy compared to the general population. Patients who have undergone colectomy and ileostomy or ileal pouch operations can expect a normal outcome of pregnancy. In women with an ileostomy, stomal prolapse has been reported following hyperemesis. This can cause discomfort and require revision of the ileostomy post-partum. Opinions vary about the need for delivery by caesarean section following pouch surgery. Some centres have published data suggesting that vaginal delivery is appropriate. There are no published long-term studies of the effect of vaginal delivery on pouch function although one study demonstrated no short-term deterioration of pouch function[7,8]. Some surgeons advise elective caesarian section to avoid risk of sphincter damage.

Surgery for acute indications during pregnancy has been reported to carry a high risk of foetal loss and is generally felt to be inadvisable. Reports of a 60% risk of foetal loss for urgent colectomy in UC may be an overestimate in the 21st century. A small case report from Manchester recently reported six women who had surgery for intraperitoneal sepsis in Crohn's disease during pregnancy. Five healthy babies resulted from these pregnancies although one miscarriage occurred in a patient with a surgical complication[47].

Breast-feeding

Breast-feeding is the best option for mother and baby in most circumstances. Concerns about breast-feeding are related to worries about the secretion of drugs in breast milk. Sulphasalazine and the aminosalicylates are poorly absorbed from the bowel and very small amounts are excreted in breast milk. It is safe to breast-feed while taking these medications with the small reservation that it is inadvisable to take high doses of amino-salicylates as there is one report of renal impairment in a child of a mother on a high dose of mesalazine[37].

Prednisolone is also concentrated poorly in breast milk and the amount received by the infant is minimal[48]. If breast-feeding is deferred until 4 hours after taking steroids, this further decreases the dose to the infant. It is therefore considered safe to breast-feed while taking these first-line agents.

There are almost no data on the safety of breast-feeding while taking other agents used to treat IBD. Breast-feeding is not recommended by the manufacturers of azathioprine or 6-mercaptopurine. Many transplant recipients and patients who take these drugs for rheumatological disorders and who must remain on azathioprine have breast-fed without reports of ill effect to the baby. This is another situation where full discussion with the mother and her partner may allow them to make an informed decision on the basis of what little evidence is available.

CONCLUSION

The key to the management of the pregnant IBD patient is to have discussed the issues relating to reproductive health prior to conception. Counselling from teenage years in young patients with IBD will help them to understand the importance of planned pregnancy. Fertility can be expected to be normal except in women with active Crohn's disease. The outcome of pregnancy is usually normal but the risks are associated with active disease and more strongly with Crohn's disease. Disease activity is definitely associated with premature delivery and low birth weight. Drug treatment should be discussed in advance of pregnancy and it would seem logical that women should be encouraged to continue maintenance treatment with aminosalicylates or sulphasalazine during pregnancy. If an attack occurs it should be investigated and treated as in a non-pregnant patient, except that use of x-rays should be minimised. Patients maintained on azathioprine may wish to continue with the drug if it is important to retain remission after full discussion. A patient with quiescent IBD can expect normal fertility, normal outcome of pregnancy and there is no contraindication to breast-feeding. The management of IBD in pregnancy is a good example of the therapeutic partnership between patient and doctor. Education and communication are key, active disease is the greatest risk to the outcome of pregnancy and drug therapy may be necessary and if so is safe.

Abstract

The assessment of inflammatory activity in intestinal disease in man can be done using a variety of different techniques. These range from the use of non-invasive acute phase inflammatory markers measured in plasma such as C reactive protein (CRP) and the erythrocyte sedimentation rate (ESR) (both of which give an indirect assessment of disease activity) to the direct assessment of disease activity by intestinal biopsy performed during endoscopy in association with endoscopic scoring systems. Both radiology and endoscopy are conventional for the diagnosis of inflammatory bowel disease (IBD). However these techniques have severe limitations when it comes to assessing functional components of the disease such as activity and prognosis. Here we briefly review the value of two emerging intestinal function tests. Intestinal permeability, although ideally suited for diagnostic screening for small bowel Crohn's disease, appears to give reliable predictive data for imminent relapse of small bowel Crohn's disease and it can be used to assess responses to treatment. More significantly it is now clear that single stool assay of neutrophil specific proteins (calprotectin, lactoferrin) give the same quantitative data on intestinal inflammation as the 4-day faecal excretion of 111Indium labelled white cells. Faecal calprotectin is shown to be increased in over 95% of patients with IBD and correlates with clinical disease activity. It reliably differentiates between patients with IBD and irritable bowel syndrome. More importantly, at a given faecal calprotectin concentration in patients with quiescent IBD, the test has a specificity and sensitivity in excess of 85% in predicting clinical relapse of disease. This suggests that relapse of IBD is closely related to the degree of intestinal inflammation and suggests that targeted treatment at an asymptomatic stage of the disease may be indicated.

INTRODUCTION

Distinguishing irritable bowel syndrome from inflammatory bowel disease

Gastroenterologists are often faced with the diagnostic difficulty of differentiating patients with the irritable bowel syndrome (IBS) from those with organic intestinal pathology, in particular inflammatory bowel disease (IBD). Many symptoms are common to both conditions including abdominal pain, bloating, excessive flatus and altered bowel habit while other clinical features such as a predominance of diarrhoea and rectal bleeding will increase the likelihood of organic disease. Although symptoms are a surprisingly good guide to a diagnosis, most clinicians proceed to and rely on laboratory tests to aid in the differential diagnosis. Certainly, fulfilling the ROME criteria[1,2] and having a normal full blood count, routine biochemical screening, ESR and CRP are reassuring indicators pointing to IBS. As a result a number of investigators[1,3,4] have recommended a straightforward approach to evaluation and treatment of patients with IBS based on the use of the Rome criteria as a means of cost effective management. Despite this the use of the Rome criteria has not been universal and is largely confined to use as entry criteria into research studies of patients with IBS. The concern for gastroenterologists is that some patients with organic intestinal disease will be incorrectly diagnosed if excess reliance is placed upon these criteria. They may therefore feel compelled to exclude all organic disease using invasive diagnostic investigations as objective evidence for there being no other significant pathology. This has significant implications for health care costs as well as exposing patients to the inherent risks associated with invasive procedures.

Managing inflammatory bowel disease

Once IBD is diagnosed the treatment involves induction and subsequently maintenance of remission based largely on clinical disease activity indices[5,6] and the physicians global assessment of well-being. The problem with the use of clinical disease activity scores is that they are a composite of quantitative subjective symptoms that are affected by non inflammatory processes such as fibrous strictures, fistulas and previous surgical intervention. As a guide to clinical decision making, many clinicians therefore use nonspecific laboratory tests to document relapse of disease and radiology and radio isotopic techniques to distinguish between actively inflamed disease and fibrotic strictures. In addition a number of blood tests (erythrocyte sedimentation rate (ESR), orosomucoid, C -reactive protein (CRP), platelet, and white cell counts, IL-6, TNF-α, IL-1β)[7-11] which reflect the systemic consequences of inflammation, have been proposed as predictors and/or markers of clinical relapse of IBD with varying degrees of success. However, the overall predictive values of these different variables in identifying patients at risk of relapse have in general been disappointing. This is possibly due to the fact that these measures are non-specific, affected by a variety of non-intestinal diseases[12] and most importantly do not measure the intestinal inflammation directly. Patients with clinically active IBD can have normal serological inflammatory indices while clinically quiescent disease may be associated with abnormal blood tests. In particular, there is a major discrepancy between severity of

symptoms and macroscopic evaluation of disease activity in patients with Crohn's disease limited to the colon.

Intestinal function tests

Although imperfect the above approach to diagnosis and management of patients with IBD remains the norm and in general it works well for the vast majority of patients. However, few would argue with the notion that there is scope for improvement. Where is such improvement to come from? Recently, investigators have turned to direct tests of intestinal function. Such tests provide new, direct and different information. They have the potential to be used as a diagnostic screen for intestinal disorders as well as providing prognostic information for the behaviour of the disease. At present there are three kinds of intestinal function tests that could fulfill the above promise, two of which (intestinal permeability and white cell scans) have a 20 year history. The third, namely direct assay of faeces for inflammatory markers, we suspect has the greatest potential. There follows a brief outline of how these tests can provide information that is not obtainable by other methods and their possible use in the day-to-day management of patients with IBD.

INTESTINAL PERMEABILITY

Permeability refers to that property of a membrane that enables passage of a solute by unmediated diffusion. The diffusion of a solute across a simple membrane is determined by the structure of the membrane (in terms of its composition, charge, thickness, etc.), the physicochemical properties of the solute (like molecular size, shape, charge and solubility) and its interaction with the media or solvent. Intestinal permeability is assessed non-invasively *in vivo* by measuring urinary excretion of orally administered substances. The ideal permeability probe is water-soluble, non-toxic, non-degradable and not metabolised before, during or after permeating the intestine[13]. The probes should preferably not be naturally present in urine, be completely excreted in the urine following intravenous administration and be easily and accurately measurable. Fordtran *et al*[14] were instrumental in the development of ideas for assessing intestinal permeability in man but it was Menzies who introduced oligosaccharides as test substances for the non-invasive assessment of intestinal permeability[15] in 1974, and later formulated the principle of differential urinary excretion of orally administered test substances[16]. The importance of the differential urinary excretion principle is that it overcomes most if not all the problems associated with the use of a single test substance, where urinary excretion is dependent on a number of pre- and post-mucosal factors as well as intestinal permeability. The differential principle advocates that a nonhydrolyzed disaccharide (i.e. lactulose) and a monosaccharide (L-rhamnose or mannitol) are ingested together. As the pre- and post-mucosal determinants of their excretion affects the two test substances equally and the differential 5 hour urinary excretion ratio (ratio of lactulose/L-rhamnose) is not affected by these variables the urinary excretion ratio becomes a specific measure of intestinal permeability.

Tests of intestinal permeability were initially designed to allow reliable non-invasive detection of patients with untreated coeliac disease[16]. The tests have since come to be viewed as synonymous with assessing intestinal barrier function. In clinically active small bowel Crohn's disease the vast majority of patients (>95%) have an increase in the differential urinary excretion of ingested di-/mono-saccharides (lactulose/L rhamnose or mannitol) and half of those with Crohn's colitis are abnormal[13]. These figures are marginally improved with the use of 51CrEDTA, which requires a 24-hour, as opposed to a 5-hour urinary collection. The vast majority of patients with ulcerative colitis have normal small intestinal permeability when assessed by these methods. However, tests of intestinal permeability have not found widespread application as screening tests to discriminate between patients with Crohn's disease and IBS. The reason for this is probably that the urinary sugar analysis is time consuming and demanding, and there may be some concern that the tests lack specificity being abnormal in a variety of small intestinal diseases (Table 1). At first sight the test appears to identify a number of "clinically irrelevant" diseases, which usually translates into disease for which no treatment is available, but in practice the tests seem often to identify small intestinal pathology where none was previously expected, thus expanding the number of identifiable small bowel pathologies.

There have been attempts to use intestinal permeability as an index of disease activity in Crohn's disease. In general these have been disappointing because the degree of increase in the differential urinary excretion of lactulose/L-rhamnose or the excretion of ^{51}CrEDTA is dependent on localisation and extent of disease within the small bowel as well as activity of the inflammation[13]. Abnormalities in intestinal permeability may, however, be used as a predictor of imminent relapse of quiescent Crohn's disease. Three studies have now shown that, in patients with Crohn's disease in clinical remission, an increased intestinal permeability can predict those at significant risk of relapse of disease in the next few months[17-19]. The strength of this association is difficult to assess from the published studies. Nevertheless, less than 20% of those with normal intestinal permeability appear to relapse over the ensuing 6 months. Interestingly, elevated levels of IL-6 in serum, which can be viewed as a surrogate marker of intestinal inflammation, also has a predictive value for relapse of Crohn's disease[8], but receiver operating curve (ROC) analysis shows relatively low sensitivity and specificity (70 and 50%, respectively). The permeability ratio differs from such indices in that it is not based on concentrations of plasma proteins but rather represents functional changes in the intestinal mucosa, a direct consequence of intestinal inflammation.

The clinical implications of these findings are discussed later.

WHITE CELL SCANS AND FAECAL EXCRETION

Intense neutrophil recruitment to the intestinal mucosa is a feature common to inflammatory bowel diseases[20]. When a patient's own radiolabelled neutrophils are re-injected they migrate to sites of acute inflammation as well as to the liver, spleen and bone marrow[21]. Segal, Saverymuttu and Chadwick were instrumental in the introduction, validation and application of the 111Indium white cell technique for use in gastroenterology[20,22]. The technique visualises inflamed segments of bowel and quantitates the degree of inflammatory activity[20,23-26].

A number of studies have established that abdominal scans are abnormal in virtually all patients with active IBD; their accuracy in localisation of disease and distinguishing between actively inflamed and fibrous stricturing disease has implications for treatment. It was suggested that the technique could be used to discriminate, with an accuracy approaching 100%, between patients with IBD and IBS at the first outpatient visit. In practice this suggestion was not followed up with relevant research.

When combined with measurement of the 4 day faecal

excretion of labelled white cells for quantitation of the inflammatory activity the technique becomes a formidable tool for research and investigation. The faecal excretion of the labelled white cells quantitate inflammation accurately and can be used to document therapeutic efficacy of various treatments in IBD[25,27]. It has also been used to define a number of enteropathies (NSAIDs, alcohol, chronic renal failure, hypogammaglobulinaemia, HIV-AIDS, etc.) where none were suspected or impossible to demonstrate by techniques other than perhaps the intestinal permeability tests (Table 1)[28]. The method is not disease specific, resembling that of the permeability tests, but it is specific for intestinal inflammation. This is not a drawback as it is a simple matter to distinguish between the inflammatory activity in patients with IBD and the above enteropathies, colonic cancer, diverticulitis, etc., since patients with active IBD have excretion values often an order of magnitude higher than the others.

Table 1 Some conditions reported to be associated with increased intestinal permeability

Nonsteroidal anti-inflammatory drugs	Inflammatory bowel disease
Alcohol	Ankylosing spondylitis
Renal failure	Coeliac disease
Abdominal radiation	Intestinal ischaemia
Cytotoxic drug treatment	Hypogammaglobulinaemia
Abdominal surgery	HIV infection
Fasting	Endotoxinaemia
Total parenteral nutrition	Multiorgan failure
Food allergy	Diabetic diarrhoea
Multiple sclerosis	Scleroderma
Cystic fibrosis	Reactive arthritis
Recurrent abdominal pain of childhood	Intestinal infections / bacterial overgrowth
Neomycin	Whipples disease
Acute and chronic liver disease	Sarcoidosis

Why has the white cell technique not been universally adapted for use as a diagnostic screen in IBD, and to assess disease activity? It requires expensive labeling facilities including labelling cabinets. The labeling procedure is time consuming, taking over 2 hours. The cost of isotope and material is in excess of £200 (US $300) and the radiation dose is not trivial if abdominal scans are carried out, being equivalent to that of a barium enema[29,30]. A complete 4-day faecal collection is also demanding and unpleasant for patients, occasionally requiring hospital admission.

Other methods have attempted to build on this success. One such is 99mTc labeling of white cells[31]. This is purported to give superior quality abdominal scintigraphy (which is not clinically important), but does not allow late (>4 hours) scanning, because the label comes off and is excreted into the bowel independent of white cell excretion. Furthermore a faecal collection provides no quantitative information on intestinal inflammation (as the Technetium comes off the white cells and is excreted in faeces) and the labeling requires the same facilities as the white cells.

Newer techniques include E-selectin scanning[32]. This method is derived from the more conventional labelled white cell scintigraphy, but uses a labelled antibody to E-selectin, which is over-expressed in endothelial cells at sites of inflammation. It has the advantage of studying a more fixed entity that (unlike white cells) will not be shed at a variable rate into the bowel lumen and is applicable to the occasional patient with intestinal inflammation who is neutropenic.

In our opinion, the greatest impact that the white cell technique has had is that it ① emphasised that if a sensitive method is to be established for assessing intestinal function there are no shortcuts. Neurologists assess spinal fluid, respiratory physicians assess sputum, urologists urine and the gastroenterologist needs to come terms with the fact that faecal analysis is essential to obtain maximal information about the state of the intestine. ② emphasised that there is life beyond morphological assessment of the gut (x-ray and colonoscopic studies). ③ raised the possibility of dramatically changing our views on the treatment of IBD. Many patients with IBD in full clinical remission are shown to have significant intestinal inflammation[27,33]. At present treatment is non-specifically directed at maintaining remission (5-ASA, azathioprine, etc.). It seems highly probable that those patients with substantial inflammatory activity should be targeted for more aggressive therapy, in particular if they can be shown to be at significant risk of clinical relapse of disease. The analogy with the treatment of rheumatoid arthritis springs to mind. Here, first line treatment is directed to wards reducing the acute inflammatory component of the disease followed by a number of second line agents that can alter the natural history of the disease, reduce the frequency, duration and severity of relapses as well as reducing the joint damage.

FAECAL MARKERS

Faecal analysis is unpleasant but has been with us for a long time. Measure of electrolytes and osmolality helped in the differential diagnosis of diarrhoea in children. Faecal fats were a widespread screening test for steatorrhoea for a while and faecal occult bloods have become the yardstick for colorectal screening with which other methods need to be compared. An improvement on these techniques was the introduction of radioisotopically labelled compounds (labelled red blood cells, proteins, white cells) which provided quantitative and functional data and which was event specific (blood loss, inflammation, protein losing enteropathy, etc.) but non-specific for disease.

The inflamed hyperpermeable mucosa of patients with inflammatory bowel disease is associated with increased protein loss into the bowel lumen[34]. Studies using radiolabelled proteins have demonstrated that there is faecal protein loss in patients with active Crohn's disease and it may therefore be a useful marker of disease activity. Other studies have shown faecal α1 antitrypsin clearance to be a useful indicator of protein losing enteropathy[35] and that in patients with inflammatory bowel disease, 72 hour faecal clearance of α1 antitrypsin is a useful method for quantitating intestinal protein loss[36,37]. Faecal clearance of α1 antitrypsin correlates with that of ^{51}Cr-albumin, and moderate rectal bleeding does not affect the α1 antitrypsin determination[36]. Random faecal α1 antitrypsin levels have been shown to be as useful as more prolonged collection in measuring Crohn's disease activity[38] and correlated with several other laboratory measures that have been proposed as indicators of Crohn's disease activity[39].

Concerns about costs, radiation, and the need for prolonged faecal collections all worked against these techniques for routine use, although many remain very important for research studies. The idea then emerged that it might be possible to assay for cell proteins or substances that are specifically associated with a certain cell type and which would then provide information on a specific component of the inflammatory cascade. Ferguson's Edinburgh group was instrumental in expanding this idea[40]. Concerned about bacterial degradation of markers they used a whole gut lavage method involving ingestion of polyethylene-based purgatives

(Kleenprep or GoLitely) for obtaining clear liquid faecal samples for analysis. The analysis took to various markers, such as immunoglobulins, neutrophils-specific elastase, andhaemoglobin. Separate studies showed that Crohn's disease could be identified with ease, and that the method had a greater sensitivity for colorectal cancer than the conventional faecal occult blood technique. Ideally suited for research, the method has as yet not found wide application for routine screening purposes, possibly because of the drawback of patients needing to ingest large volumes of liquid.

Direct analysis of markers in faeces would be a major advance on this method. Here the problem is initially the bacterial degradation of the marker necessitating swift sample handling. One such marker, TNF, has been successfully used in children and in HIV infection in adults[41,42]. However, it is now clear that it is not necessary for the marker to be completely non-degraded, provided that the antibody (most of these assays are ELISA's or radio immunoassay) is directed at an epitope of the molecule which resists degradation. One such assay is that for lactoferrin[43]. Lactoferrin is a relatively specific marker for neutrophils, in which it is present in cytoplasmic granules.

Faecal calprotectin

The greatest experience with analysis of faecal proteins is with calprotectin[44-48]. It accounts for up to 50% of the neutrophilic cytosolic protein while being resistant to colonic bacterial degradation. It is easily measured in faeces by a commercially available ELISA.

Calprotectin was first isolated from granulocytes by Fagerhol *et al*[49] and named L1 protein, but was later named calprotectin upon identification of its calcium binding and antimicrobial properties[50]. The protein is a heterocomplex protein consisting of two heavy (L1H) chains and one light (L1L) chain[51] which are non-covalently linked[52]. Calprotectin appears to play a regulatory role in the inflammatory process[53] and functions in both an antimicrobial[50,54] and antiproliferative capacity[55-57]. It has both bactericidal and fungicidal properties with minimal inhibitory concentrations comparable to those of many antibiotics[50]. It is released from the cells during cell activation or cell death. The C-terminal sequence of the L1H chain has been shown to be identical to the N-terminus of peptides known as neutrophil immobilising factors (NIF)[58]. It has been suggested that NIF activity of the L1H chain depends upon its phosphorylation[59] and that such an activity of calprotectin could be important for the accumulation of granulocytes, while calprotectin released from dead neutrophils, macrophages and epithelial cells might exert antimicrobial activity, possibly by depriving microorganisms of zinc[60,61]. Calprotectin may inhibit metalloproteinases[62] which may also involve the deprivation of zinc suggesting that it may limit their participation as enzymatic cofactors for invading organisms. Interest in calprotectin as a marker for inflammation in the gut followed the realisation that 111 Indium labelled granulocyte scans could be used to both visualise and quantitate the acute inflammation in the gut of patients with inflammatory bowel disease[20,23]. These findings led to the idea that an increased influx of granulocytes into the intestinal mucosa in conditions of inflammation might give increased levels of proteins from such cells in faeces.

Others[63] have demonstrated that eosinophilic granulocytes are the main cellular source of calprotectin in the normal gut mucosa. However, relatively high levels of calprotectin are found in the stools of normal individuals- about six times the plasma levels (which are about 0. 5mg/L) . This is compatible with data suggesting that in normal individuals most circulating neutrophils migrate through the mucosal membrane of the gut wall and thereby terminate their circulating life[64]. Subsequent lysis within the gut lumen and release of cytosolic calprotectin thereby accounts for the median faecal levels of 2.0mg/L seen in healthy controls[46,65]. The diagnostic use of faecal calprotectin in a broad spectrum of intestinal diseases has been studied by a number of groups with remarkable agreement between the results to date.

Inflammatory bowel disease

It is almost possible to extrapolate all the findings obtained with the white cell faecal excretion technique to the calprotectin method. Both techniques correlate with histopathological assessment of disease activity in ulcerative colitis and there is a very good correlation between the 4-day faecal excretion of white cells and faecal calprotectin concentrations[33,45], a correlation which is maintained when single stool calprotectin concentrations are used as opposed to 1 or 4 day collections. The faecal calprotectin concentration has a narrow normal range with an upper limit of 10mg/L. As with the white cells, faecal calprotectin has potential as a screening procedure to differentiate between patients with IBD and IBS and it may be useful for documenting a fall in intestinal inflammation in response to successful treatment of disease. Calprotectin concentration is rarely within the normal range in patients with IBD despite full clinical remission and is therefore a highly sensitive method for detecting such patients irrespective of disease activity. In over 100 patients with Crohn's disease of varying severity and activity only 4 had normal calprotectin concentrations[33].

Since the method is so much simpler than the white cell technique, requiring only a single stool sample, extraction and an ELISA, it has potential as a screening test to distinguish between patients with IBD and IBS in an outpatient setting. One study in over 225 patients showed that a cut off of 30mg/L had a 100% sensitivity and 94% specificity for this purpose[33]. Another showed that this was also the case when over 600 unselected consecutive patients were studied. Indeed a patient presenting with positive ROME criteria and a normal faecal calprotectin has virtually no chance of having IBD[66]. As a result of these studies it is now our practice not to investigate such patients by radiology or colonoscopy with considerable cost saving implications. The white radiolabelled cell technique demonstrated reduced intestinal inflammation in response to 5-ASA treatment and elemental diets. We have shown (unpublished) that improvement in calprotectin parallels the improvement in the excretion of labelled white cells in response to treatment with elemental diets. These techniques prove to be much more reliable and reproducible than the changes in clinical disease indices. It seems likely that the assay of faecal calprotectin will become an integral part of the assessment of therapeutic efficacy of the acute inflammation in future treatment trials in patients with IBD.

Apart from screening and assessing response to treatment, the faecal calprotectin has a further major advantage over the white cell labeling technique in predicting relapse of IBD. It has been shown that, in patients with clinically quiescent IBD (ulcerative colitis and Crohn's disease), faecal calprotectin values above 50mg/L may be used to predict clinical relapse of disease within a few months with over 80% sensitivity[67]. Symptoms of inflammatory bowel disease often appear to be the direct consequence of the inflammatory process itself and often vary dependent upon

the location of the inflammation. Most patients with quiescent IBD have low-grade inflammation[27] and it is possible that symptomatic relapse occurs only when the inflammatory process reaches a critical intensity. Furthermore, as inflammation is a continuous process it may be that direct assessment of the level of inflammatory activity may provide a quantitative pre-symptomatic measure of imminent clinical relapse of the disease.

The clinical implications of this, if substantiated, are considerable as it might offer targeted treatment at an earlier stage, with less side effects, to avert the relapse, as well as assessment of new therapeutic strategies to maintain symptomatic remission[68]. At present this is done with some degree of success with the rather indiscriminate use of sulphasalazine, 5-ASA and azathioprine, all of which are associated with side effects. However the calprotectin method offers guidance as to whom to treat at this stage and with what kind of vigour. Theoretically such treatment should lead to a dramatic reduction in the frequency and severity of clinical relapses with an improvement in the patient's quality of life.

In addition, the identification of patients at high risk of relapse will improve the design of clinical trials to assess the efficacy of therapeutic regimes designed to maintain patients in remission. In most such trials, patients studied tend to be a heterogeneous mix of those with high and low risk of relapse. This introduces possible bias when assessing the response to a particular treatment regime due to the imbalance of high risk patients in each treatment arm. Stratification by risk group using faecal calprotectin would reduce the possibility of such a bias. It is also possible that a lack of power in detecting a response to treatment may be due to the study of a large number of patients at low/intermediate risk of relapse, in whom all treatments may show the same efficacy, and therefore clinical trials studying a homogenous high risk group may be more powerful in detecting a difference in treatment efficacy.

Much work remains to be done, some is already on its way, but what is clear is that gastroenterologists need to move with the times and start thinking along the lines that rheumatologists do, that is, to implement treatments that alter the natural history of the disease. We are now in possession of tests that have the potential to revolutionise our approach to treatment of patients with IBD. There are some hurdles to overcome. The most frequent criticism of the "faecal" tests is that they are unacceptable to patients and unpleasant to work with.

The faecal calprotectin and lactoferrin methods are the first wave of techniques that allow non-invasive assessment of specific and selective cellular components of the intestinal inflammatory cascade. At present these are useful for a variety of purposes, outlined above, but it is likely that it will be possible to estimate the participation of other cells. Many other cells of the inflammatory cascade are numerically increased in biopsy specimens from patients with a variety of gastroenterological conditions. Some, such as mast cells and eosinophils, are thought to play a central role in mediating intestinal allergic reactions[69]. However, both types of cell are found to be activated in a number of other gastrointestinal inflammatory diseases such as inflammatory bowel disease, coeliac disease, eosinophilic gastroenteritis[69] and collagenous colitis[70], suggesting that both cell types may be involved in the pathogenesis of chronic intestinal inflammation. It may therefore be possible, as for neutrophils and calprotectin, to identify mast cell granule proteins, such as tryptase and chymase, in faecal samples and use them as markers of a specific component of the intestinal inflammatory response. The long-term objective might be to fully automate a faecal sample assay method that provides specific information on the activity of acute inflammation (neutrophils), chronic inflammation (T-cells) and allergy (mast cells).

TREATMENT STRATEGIES FOR ACUTE VARICEAL BLEEDING

Background

Acute variceal bleeding has a significant mortality which ranges from 5% to 50% in patients with cirrhosis[1]. Overall survival is probably improving, because of new therapeutic approaches, and improved medical care. However, mortality is still closely related to failure to control haemorrhage or early rebleeding, which is a distinct characteristic of portal hypertensive bleeding and occurs in as many as 50% of patients in the first days to 6 weeks after admission *et al*[2]. Severity of liver disease is recognised as a risk factor for both early rebleeding and short-term mortality after an episode of variceal bleeding[3]. Active bleeding during emergency endoscopy (e.g. oozing or spurting from the ruptured varix) has been found to be a significant indicator of the risk of early rebleeding[4,5]. Increased portal pressure (HVPG>16mmHg) has been proposed as a prognostic factor of early rebleeding in a study of continuous portal pressure measurement immediately after the bleeding episode[6], and recently Moitinho *et al*[7] have shown a failure to reduce portal pressure more than 20% from baseline is associated with a worse prognosis as well as early rebleeding.

Effective resuscitation, accurate diagnosis and early treatment are key to reducing mortality in variceal bleeding. The aims are not only to stop bleeding as soon as possible but also to prevent early re-bleeding. Early rebleeding, as with the peptic ulcer disease, is significantly associated with worsening mortality[5]. Thus treatments regime should be evaluated not only in terms of immediate cessation of haemorrhage, but also in terms of providing a bleed free interval of at least 5 days. This allows some recovery of the patient, and provides an opportunity for secondary preventative therapy to be instituted.

Diagnosis

Upper gastrointestinal endoscopy is essential to establish an accurate diagnosis, as 26%-56% of patients with portal hypertension and GI bleeding will have a non-variceal source[8], particularly from peptic ulcers and portal hypertensive gastropathy. Endoscopy should be performed as soon as resuscitation is adequate, and preferably with 6 hours of admission. This may need to be done with prior endotracheal intubation if there is exsanguinating haemorrhage or if the patient is too encephalopatic because of the substantial risk of aspiration.

Despite many authors and junior doctors proclaiming endoscopic prowess, it is the authors opinion that a definitive endoscopic diagnosis during or shortly after upper GI bleeding can be difficult, because the view can be obscured by blood. A diagnosis of bleeding varices is accepted either when a venous (non pulsatile) spurt is seen, or when there is fresh bleeding from the O-G junction in the presence of varices, or fresh blood in the fundus when gastric varices are present. In the absence of active bleeding (approximately 50%-70% of cases) either the presence of varices in the absence of other lesions, or a "white nipple sign" - a platelet plug on the surface of a varix[9,10], suggests varices as the source of haemorrhage.

When the diagnosis is in doubt, repeat endoscopy during re-bleeding is mandatory as it will show a variceal source in over 75% of patients[8]. Gastric varices are particularly difficult to diagnose, because of pooling of blood in the fundus. Endoscoping the patient on the right side, with the head up may help. If the diagnosis is still not made, splanchnic angiography will establish the presence of varices, and may display the bleeding site if the patient is actively haemorrhaging.

In the true emergency situation in which the patient is exsanguinating and varices are suspected on the basis of history and examination, a Sengstaken Blakemore tube (SBT) should be passed[11]. If control of bleeding is obtained, varices are likely to be the source of haemorrhage. If blood is still coming up the gastric aspiration port, then varices are less likely to be the cause of blood loss (although fundal varices are not always controlled by tamponade). In practice the position of the SBT has to be re checked and adequate traction applied. If there is still continued bleeding the diagnosis of variceal bleeding should be questioned or fundal bleeding suspected, and emergency angiography performed.

Therapeutic aims in acute variceal bleeding

The important point is to treat the patient and not just the source of bleeding (Figure 1). The specific aims are: ① Correct hypovolaemia; ② Stop bleeding as soon as possible; ③ Prevent early rebleeding; ④ Prevent complications associated with bleeding; ⑤ Prevent deterioration in liver function.

It is important to identify those at high risk of dying during the initial assessment. Individuals in this category should have early definitive therapy, the precise treatment regimen depending on availability Predictive factors for early deaths are: Severity of bleeding[12], Severity of liver disease[13], Presence of infection[14], Presence of renal dysfunction[15], Active bleeding[4,5], Early

rebleeding[5,6,10,16,17], Presence of cardiorespiratory disease, and Portal pressure[7].

Early rebleeding is also associated with many of the same factors associated with mortality including infections[18] and is a strong indication of increased mortality.

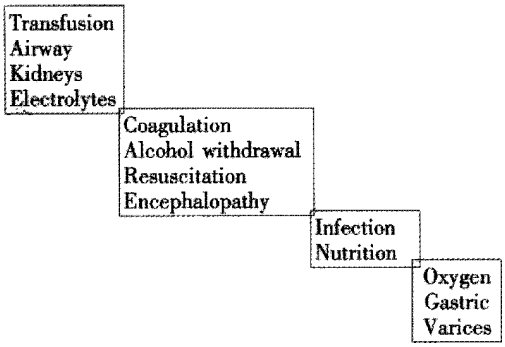

Figure 1 Take care in OGV.

Transfusion

Optimal volume replacement remains controversial. Following variceal bleeding in portal hypertensive animal models, return of arterial pressure to normal with immediate transfusion results in overshoot in portal venous pressure, with an associated risk of further bleeding[19]. This effect may not be relevant in clinical practice as volume replacement is always delayed with respect to the start of bleeding. Over-transfusion should certainly be avoided, and it is usual to aim for an Hb between 9-10g/dL, and right atrial pressure at 4 to 8mmHg, but fluid replacement may need to be greater in the presence of oliguria to be sure that the circulation is filled.

Large volume transfusion may worsen the haemorrhagic state, as well as lead to thrombocytopenia so that fresh frozen plasma and platelets need to be replaced. Optimal regimens for this are not known. It is reasonable to give 2 units of FFP after every 4 units of blood, and when the PT is >20 seconds. Cryoprecipitate is indicated when the fibrinogen level is less than 0.2g/L.

Platelet transfusions are necessary to improve primary haemostasis and should be used if the baseline count is 50×10^9/L or less. Platelet count may show little change following platelet transfusion in patients with splenomegaly. It is also routine to give intravenous vitamin K to cirrhotics, but no more than three doses of 10mg are required. Many cirrhotics have a background tendency of fibrinolysis. Transfusion of more than 15 units of blood results in prolongation of the prothrombin and partial thromboplastin time[20] in normal individuals, and occurs with smaller volumes of blood transfusion in cirrhosis.

Massive transfusion may cause pulmonary microembolism, and the use of filters is recommended for transfusions of 5L or more in normal humans[21]. Therefore, the routine use of filters in variceal haemorrhage could be considered, but rapid transfusions cannot be administered with these, limiting their application.

Further measures in patients who continue to bleed despite balloon tamponade include the use of desmopressin (DDAVP)[22] and antifibrinolytic factors. In stable cirrhotics the former produces a 2-4 fold increase in factors VIII and VWF, presumably by release from storage sites and may shorten or normalize the bleeding time[23]. However, in one study of variceal bleeding DDAVP in association with terlipressin was shown to be detrimental compared to terlipressin alone[24].

The use of antifibrinolytics has not been studied in variceal bleeding, although their role has been established in liver transplantation in our unit as well as others[25]. Their clinical utility should be established in clinical trials, and preferably when increased fibrinolysis has been documented. Recombinant factor VIII may be useful in variceal bleeding as it has been shown to normalize prothrombin time and bleeding times in cirrhotics[26].

PREVENTION OF COMPLICATIONS AND DETERIORATION IN LIVER FUNCTION

Infection control and treatment

Bacterial infections have been documented in 35%-66% of patients with cirrhosis who have variceal bleeding, with a incidence of SBP ranging from 7%-15%. However if only patients with ascites and gastrointestinal bleeding are considered, the incidence of SBP is very high. A recent meta-analysis has demonstrated that antibiotic prophylaxis significantly increased the mean survival rate (9.1% mean improvement rate, 95% CI: 2.9-15.3, P = 0.004) and also increased the mean percentage of patients free of infection (32% mean improvement rate, 95% confidence interval: 22 -42, $P<0.001$)[27](Figures 2,3). Finally our group has recently shown that bacterial infection, diagnosed on admission, is an independent prognostic factor of failure to control bleeding or early rebleeding[4]. These data may support a role of bacterial infection in the initiation of variceal bleeding[28]. All cirrhotics with upper gastrointestinal bleeding should receive prophylactic antibiotics whether sepsis is suspected or not. The optimal regimen is yet to be decided but oral or intravenous quinolones have been used.

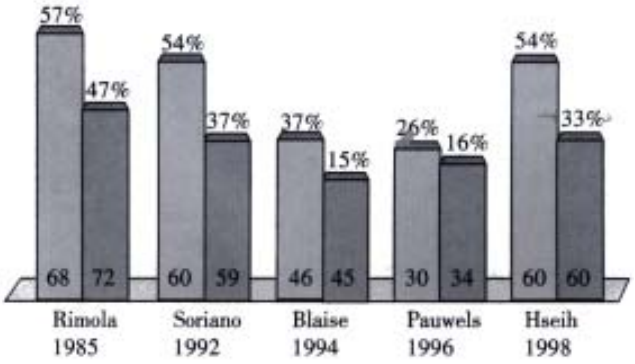

Figure 2 Antibiotics in GI bleeding in cirrhotics (Bernard 1999). Free of infection-mean improvement 32% ($P<0.001$).

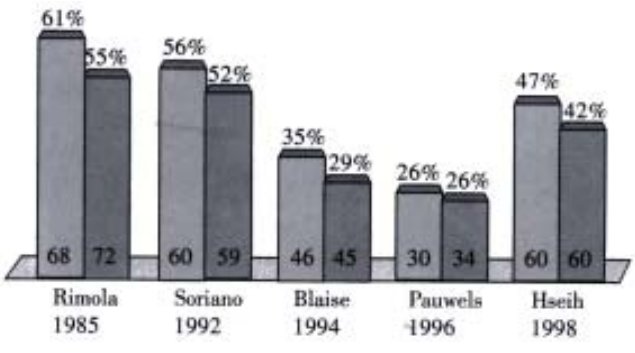

Figure 3 Antibiotics in GI bleeding in cirrhotics (Bernard 1999). Survival-mean improvement 9% (P = 0.0042).

Ascites and renal function

Renal failure may be precipitated by a variceal bleed, usually due to a combination of acute tubular necrosis, and hepatorenal syndrome (HRS) associated with deterioration in liver function and sepsis. HRS is associated with an over 95% mortality. Thus any iatrogenic precipitants must be avoided. The intravascular volume should be maintained preferably with Human Albumin Solution or blood initially. Normal saline should be avoided as it may cause further ascites formation. Catheterisation of the bladder and hourly urine output measurement is mandatory and nephrotoxic drugs should be avoided, especially aminoglycosides and non-steroidal drugs.

Dopamine was the first drug used due its vasodilator effect when given in subpressor doses. Dopamine is frequently prescribed to patients with renal impairment, and yet no studies have ever shown any convincing benefit[29,30]. It is our impression that occasionally a patient responds with an increase in urine output. It is therefore our practice to give a 12-hour trial of dopamine, and stop treatment if there has been no improvement of urine output.

Increasing ascites may occur shortly after bleeding, but should not be the main focus of fluid and electrolyte management until bleeding has stopped and the intravascular volume is stable. If there is a rising urea and creatinine, all diuretics should be stopped, and paracentesis performed if the abdomen becomes uncomfortable, re-infusing 8 gr. of albumin for every litre removed.

When the patient has stopped bleeding for 24 hours, nasogastric feeding can be commenced with low sodium feed. This avoids the need for maintenance fluid, and removes the risk of line sepsis. An unexplained rise in creatinine and urea may indicate sepsis. Evidence of sepsis should be sought by blood, ascitic, cannulae, and urine culture, and non-nephrotoxic broad-spectrum antibiotics commenced, regardless of evidence of sepsis. An undiagnosed delay in effective treatment of infection may increase mortality. In advanced cirrhosis, endotoxins and cytokines play an increasingly important role in advancing the hyperdynamic circulation and worsening renal function[31].

There is now increasing evidence for the use of vasopressin analogues in patients who develop renal impairment during the variceal bleeding episode, probably through maintenance of renal perfusion. Indeed, the beneficial effect of terlipressin with respect to bleeding and survival in trials to date may be through the prevention of this catastrophic complication[32-34].

Porto systemic encephalopathy

The precipitant factors include: haemorrhage, sepsis, sedative drugs, constipation, dehydration, and electrolyte imbalance. These should be evaluated and corrected. Hypokalaemia, hypomagnesaemia and hypoglycaemia may precipitate encephalopathy and should be aggressively corrected (e.g. a patient with ascites and a serum potassium of 3.0mmol/L is likely to require in excess of 100mmol over 24 hours).

As soon as the patient is taking oral fluid, lactulose 5mL -10mL QDS can be started. Phosphate enemas are also useful.

Alcohol withdrawal

It is important to be alert to the possibility of withdrawal from the patient's history. Encephalopathy and withdrawal may co-exist, and careful use of benzodiazepines may be required. Short acting benzodiazepines or oral chlormethiazole can be used. Intravenous preparations should be avoided, particularly of chlormethiazole, because of the risk of oversedation and aspiration.

Nutrition

Only a few cirrhotics are not malnourished[35], particularly with severe liver disease. This may be exacerbated in hospital, as often they do not want to eat, are "nil by mouth" because of investigations, and the food itself may be "unappealing".

A fine bore nasogastric tube should be passed 24 hours after cessation of bleeding to commence feeding. There is no evidence that this may precipitate a variceal bleed, and it allows treatment of encephalopathy in comatose patients and makes fluid management easier. It is extremely rare that parental nutrition is required.

Vitamin replacement: All patients with a significant alcoholic history should be assumed to be folate and thiamine deficient, and be given at least three doses of the latter intravenously. It is easier and more practical to assume all such patients are vitamin deficient rather than delay treatment whilst awaiting red cell transketolase activity levels.

Transfer of the patient with bleeding varices and use of balloon tamponade

Inter-hospital transfer should not be attempted unless the bleeding has been controlled, either with vasopressor agents/ endoscopic therapy or tamponade. If there is any suggestion of continued blood loss, and the source is known to be variceal, then a modified Sengstaken tube must be inserted prior to transfer.(i.e. with an oesophageal aspiration channel such as the Minnesota Tube).

DRUG THERAPY IN ACUTE VARICEAL BLEEDING

Pharmacological agents

The number of placebo controlled trials is relatively small, whilst in the case of octreotide there have been a large number of trials comparing with another form of therapy another drug, or sclerotherapy.

Vasopressin

Only 4 trials compared the efficacy of vasopressin with a placebo[36-39], and two of these studies used an intrarterial route of administration[38,39]. Using meta-analysis, there was a significant reduction in failure to control bleeding (Pooled Odds Ratio 0.22, 95%CI 0.12-0.43), but no benefit in terms of mortality.

Glypressin

The 3 trials are shown in Table 1. There has been criticism of these studies. The trial by Walker *et al* included other therapies, the timing of which is unclear, and the other two trials are hampered by insufficient patient numbers to avoid a type 2 error. These issues will be addressed in forthcoming trials.

A recent study in which terlipressin together with a nitrate patch or placebo was administered before arriving at hospital, based on reasonable evidence of bleeding varices, also showed a reduced mortality of glypressin in grade C patients. How this may have occurred deserves further examination, as there was no difference in blood pressure or early blood product requirements between the drug and placebo arms of the trial, and only three doses of the drug were given. Nonetheless, Terlipressin is a powerful splanchnic

vasoconstrictor, and may be preserving renal blood flow and hence preventing the development of hepatorenal syndrome, in a situation similar to the use of vasopressin anolgues in established hepatorenal failure.

It remains to be seen whether these data can be reproduced. Terlipressin is not licensed in the USA.

Table 1 Randomized studies of terlipressin

POR (95% CI)			0.33 (0.19-0.57)	0.38 (0.22-0.69)
P value			0.0001	0.001

Somatostatin/Octreotide

The first 2 placebo controlled trials came to opposite conclusions. The trial by Valenzuela *et al* suggested that somatostatin is no more effective than placebo, when the end point was a bleed-free period of 4 hours[44]. Furthermore, the 83% placebo rate is the highest reported in the literature. In contrast, the trial by Burroughs *et al* reported a statistically significant benefit for somatostatin in controlling variceal bleeding over a 5 day treatment period, with failure to control bleeding seen in 36% of patients receiving somatostatin, compared with 59% of patients receiving placebo[45]. This emphasizes the problem of differences in end point selection, making meaningful comparisons difficult. The third study[46] also showed no effect of somatostatin, but it took 5 years to recruit 86 patients.

There has been only one randomised placebo controlled trial examining the efficacy of octreotide, and this has only been published in abstract. 383 patient admissions were randomised to 5 days octreotide or placebo. 58% of bleeding episodes in the drug arm were controlled compared with 60% in the placebo arm[45].

Trials comparing drug with drug have shown little statistical difference, though the side effect profile has generally favoured somatostatin/octreotide[47]. Trials in which drugs are examined in association with sclerotherapy are reviewed below.

Randomised controlled trials of emergency sclerotherapy in the management of acute variceal bleeding

Injection sclerotherapy, first introduced in 1939 and "rediscovered" in the late 1970's, rapidly became the endoscopic treatment of choice for the control of acute variceal bleeding. Paradoxically the best evidence for the value of sclerotherapy in the management of acute variceal bleeding has come from a comparatively recent published study by the Veterans Affairs Cooperative Variceal Sclerotherapy Group[48]. In this study sclerotherapy, compared to sham sclerotherapy, stopped haemorrhage from actively bleeding esophageal varices (91% in sclerotherapy arm compared to 60% in sham sclerotherappy, $P<0.001$) and significantly increased hospital survival (75% *vs* 51%, $P = 0.04$).

Today it is generally accepted that sclerotherapy should be performed at the diagnostic endoscopy, which should take place as soon as possible, because there is evidence that this is beneficial compared with delayed injection. Volumes of sclerosant should be small, 1-2 mls in each varix and should be applied in the distal 5cm of the oesophagus. More than two injection sessions are unlikely to arrest variceal bleeding within a 5-day period and are associated with significant complications rate including ulceration and aspiration[2]. Several sclerosing agents have been used for injection ie. polidocanol 1%-3%, ethanolamine oleate 5%, sodium tetradecyl sulfate 1%-2% and sodium morrhuate 5%. There is no evidence that any one sclerosant can be considered the optimal sclerosant for acute injection. As it has been shown that a substantial proportion of intravariceal sclerosant ends up in the paravariceal tissue and vice-versa there is no evidence that one technique is better than the other. One of the main shortcomings of sclerotherapy is the risk of local and systemic complications-although this varies greatly between trials and may be related to the experience of the operator.

Sclerotherapy vs drugs

There are 10 studies, including 921 patients: vasopressin was used in 1[49] terlipressin in 1[50], somatostatin in 3[51-53], and octreotide in 5[54-58], involving 921 patients. The evaluation of the treatment effect was performed at the end of the infusion of the drug (from 48hrs to 120hrs). The overall efficacy of sclerotherapy was 85% (range 73%-94%) in studies of 12 to 48h drug infusion[49,52-56,58] and 74% (68% -84%) in studies of 120hrs drug infusion[49,51,57]. There was significant heterogeneity ($P<0.05$) in the evaluation of failure to control bleeding in these studies was, which was mainly due to the different extent of benefit from sclerotherapy rather than different outcomes in individual studies: only two of the ten studies[55,56], reported that drugs were better than sclerotherapy but in neither did this reach statistical significance. Failure to control bleeding was statistically significantly less frequent in patients randomized to sclerotherapy (Der Simonian and Laird method: POR, 1.68 [95%CI, 1.07-2.63]). The NNT to avoid one rebleeding episode is 11 (95%CI, 6-113). Publication bias assessment showed that 9 null or negative studies would be needed to render the results of this meta analysis non-significant.

There was no significant heterogeneity in the evaluation of mortality in these studies: only two studies[54,56] reported a lower mortality in the drug arm but in neither was this statistically significant. Overall there were statistically significantly fewer deaths in patients randomized to sclerotherapy (POR, 1.43 [95% CI, 1.05-1.95]). The NNT to avoid one death is 15 (NNT, 15 [95% CI, 8-69]).

Finally the type of complications recorded in 8 studies[50-57] differed considerably, resulting in a significant heterogeneity ($P=0.04$). Four studies reported more complications in the sclerotherapy arm[51-54] while 3 reported more complications[50,55,57] in the drug arm and one found equal numbers in both arms[56]. The meta analysis showed a trend in favour of drug treatment but the result was not statistically significant (Der Simonian and Laird method:

POR, 0.71 [95% CI, 0.41-1.2]).

Sclerotherapy plus drugs vs sclerotherapy alone

This group comprised 5 studies[59-64] including 610 patients which compared sclerotherapy plus somatostatin, octreotide, or terlipress in with scleotherapy alone. Only three studies were placebo controlled[59,60,62]. Combination therapy was more effective (POR 0.42; 95%CI 0.29-0.6; failure to control bleeding sclerotherapy + drugs 22%, sclerotherapy alone 38% ARR 16, NNT=6, 95%CI 4-10). No effect on mortality was demonstrated. Only two studies provided data on complication[59,60]. There were no significant differences between arms.

Sclerotherapy vs variceal ligation

There are only two studies specifically designed to compare sclerotherapy with variceal ligation for the management of the acute bleeding episode[65,66]. Other data come from 10 studies of long term sclerotherapy versus variceal ligation[67-76]. There was no statistical heterogeneity (P=0.21) in the analysis of failure to control bleeding from the twelve studies[66-77], including a total of 419 patients. There was no difference between the two treatment modalities, although there was a trend in favour of variceal ligation (POR, 0.66 [95% CI, 0.36-1.18]). Short-term mortality was reported only in two studies[66,77] in both there was a trend in favour of variceal ligation but the result was not statistically significant. Finally only the two studies specifically designed to compare emergency sclerotherapy with variceal ligation[66,77] reported incidence of complications. Complications were less frequent in the variceal ligation arm in both studies and the result reached statistical significance in one[66].

Randomised controlled trials of emergency surgery in the management of acute variceal bleeding

Four randomised trials, performed during the previous decade, compared sclerotherapy to emergency staple transection[78-81]. Failure to control bleeding was reported only in two of these studies, with divergent results. Teres *et al*[80] reported that efficacy of transection in their study was only 71%, the lowest in the literature, compared to 83% in the sclerotherapy arm. In contrast in the largest study performed by Burroughs *et al*[81], a 5 day bleeding free interval was achieved in 90% of the transected patients (none rebled from varices) compared to 80% in those who had 2 emergency injection sessions. There was no difference in mortality between the two treatment modalities. Cello *et al* showed that emergency porta-caval shunt was more effective than emergency sclerotherapy (followed by elective sclerotherapy) in preventing early rebleeding (19% *vs* 50%)[78]. Hospital and 30 day mortality was not significantly different. Finally Orloff *et al* reported, in a small study[82], that portacaval shunt, performed in less than 8 hours from admission, was significantly better than medical treatment (vasopressin/balloon tamponade) in the control of acute variceal bleeding. Survival was also better in the shunted patients but the difference was not statistically significant.

Randomized controlled trials of tissue adhesives in the management of acute variceal bleeding

Two types of tissue adhesives (n-butyl-2-cyanoacrylate [Histoacryl] and isobutyl-2-cyanoacrylate [Bucrylate]) have been used for the control of variceal bleeding[83]. The adhesives could offer better immediate control of bleeding because they harden within seconds upon contact with blood[84]. However extra care must be taken to ensure that the adhesive does not come into contact with the endoscope and blocks the channels of the instrument. This can be prevented if the adhesive is mixed with lipiodol to delay hardening. Ideally, the sclerotherapy needle should be carefully placed within the varix prior to injection, to avoid leak of the adhesive[84]. Two randomised controlled trials compared sclerotherapy alone with the combination of sclerotherapy and Histoacryl for the control of active variceal bleeding[85,86]. The combined treatment was more effective than sclerotherapy alone in both studies. Two further studies compared Histoacryl to variceal ligation for the control of bleeding from oesophageal[87] or oesophagogastric varices[88]. The overall success rate for initial haemostasis of both treatment modalities was similar in these studies. However Histoacryl was superior to variceal ligation for the control of fundic variceal bleeding, but it was less effective for the prevention of rebleeding (67% *vs* 28%). Finally, in a recent small study[89], a biological fibrin glue (Tissucol) was more effective than sclerotherapy with polidocanol in the prevention of early rebleeding and had significantly lower incidence of complications. More studies are necessary to confirm these data and examine the potential risks of activation of coagulation, systemic embolism and transmission of infections with the human plasma derived fibrin glue.

Emergency transhepatic porto-systemic stent shunt

The first reports of TIPS used clinically were in patients with uncontrolled variceal bleeding. In this very ill group of patients TIPS was found to have a life saving role, stopping bleeding in over 90% of patients; over half of these were leaving hospital alive, figures that were unachievable before. Prolonged expensive postoperative ventilation on intensive care was avoided, a situation with a well-defined high mortality[90]. Perhaps as a consequence of this apparent efficacy, there have been no controlled trials of emergency TIPS against other forms of salvage therapy.

One of the biggest problems in discussing uncontrolled variceal bleeding is that there is no accepted definition for this clinical situation. At Baveno 2[91], the panel was unable to reach a consensus as to what this term meant and what its defining parameters were. A re-evaluation of this was recommended at Baveno 3[92] and justified by a prospective evaluation in France[93]. However the reduced efficacy of repeated sclerotherapy is well established, with bleeding control achieved in 70% after the first session and 90% after two sessions. Risk of aspiration, complications of sclerotherapy itself and the general deterioration of the patient render further endoscopy potentially hazardous, as established by Bornman *et al*[94] and at our unit[95] with no improvement in the control of bleeding. Thus with respect to esophageal varices, many use the definition of continued bleeding despite two sessions of therapeutic endoscopy within 5-day period of the index bleed. To this group of patients one

can add those who continue to bleed despite a correctly positioned Sengstaken Blakemore tube (approximately 10% of patients with Sengstaken tube[96], and those patients who continue to bleed from gastric or ectopic varices despite vasoconstrictor therapy.

The results of emergency TIPS are shown in Table 2. There is a predictable proportion of patients with Pugh's C cirrhosis and patients with bleeding gastric varices. In the largest series of salvage TIPS, gastric varices were shown to be no different in terms of bleeding characteristics and portal haemodynamics when compared with oesophageal varices[97].

Patients with bleeding varices that are inaccessible to an endoscope or respond poorly to sclerotherapy are well suited to TIPS. Typical cases include fundal varices, small bowel varices (classically around anastomotic or surgical resection sites[98,99] intraabdominal varices (punctured during large volume paracentesis[100], stomal varices[101,102] (usually in patients with inflammatory bowel disease and sclerosing cholangitis), and bleeding rectal varices[103]. These sites are also amenable to embolization via shunt. TIPS have been successfully placed in infants[104,105], and children[106-108] with similar efficacy.

The results of emergency TIPS are good, especially when compared historically with surgery[109], but the mortality in these series of patients with uncontrolled bleeding is high. There is a need to try to improve patient selection. A number of markers of outcome have been identified. Including the APACHE score[110], presence of hyponatremia and child C liver disease[111], hepatic encephalopathy before TIPS, presence of ascites and serum albumin[112]. Artificial neural network have been developed and validated[113], though many of these series have mixed patients having elective TIPS and those having the procedure as an emergency. The authors feel that this latter group of patients is likely to be different from patients having an elective procedure, with characteristics of haemodynamic instability, worse liver function, lower platelets counts, and higher serum urea concentrations.

At Royal Free Hospital a score system was developed on 54 patients undergoing emergency TIPS as salvage therapy[115]. A prognostic index was developed, based on six factors independently predicted death on multivariate analysis: presence of moderate/severe ascites, requirement for ventilation, white blood cell count, platelet count, serum creatinine and partial tromboplastine time. The score was validated in a further 31 patients and shown to be accurate in predicting mortality. The use of TIPS as a salvage therapy in patients who have uncontrolled variceal bleeding is likely to remain the most established indication for TIPS, and clinical experience to date suggest that this procedure will be required in 10%-20% of patients presenting portal hypertension related bleeding.

CONCLUSION

Today the therapeutic approach in cirrhotic patients with bleeding varices must include the prophylactic use of antibiotics, early endoscopic diagnosis and endoscopic therapy, probably combined use of vasoactive agents. The best evidence for an improvement in mortality is for terlipressin, but only data for 48-hour treatment exists; for somatostatin, which is an alternative, there is data for 5-days use. However mortality is unchanged in trials of endoscopic therapy versus endoscopic therapy combined with vasoactive agents. Further trials are indicated in this area. Although no randomized trials on emergency TIPS exist, this procedure is very effective in stopping bleeding and has virtually eliminated the need for emergency surgery, and reduced ITU stays. If new trials are to be done, comparison with glues or thrombin may be justified.

All studies should now adhere to consensus definition[92] so that the field can accumulate evidence for optimal treatment strategies.

Table 2 Reports of TIPS for acute variceal bleeding

Authors	Patients	Child score A / B	Source of bleeding, Gastric / Oesophageal / 42 days (%)	Immediate control of bleeding (in completed TIPS)	Early rebleeding (within 1mo)	Mortality
Other						
McCormick (1994)[116]	20	1 / 7 / 12	3 / 17 / -	20 / 20	6	11(55)
Jalan (1995)[109]	19	3 / 3 / 13	- / 19	17 / 17	3	8(42)
Sanyal (1996)[117]	30	1 / 7 / 22	4 / 26 / -	29 / 29	2	12(40)
Chau (1998)[97]	112	5 / 27 / 80	28 / 84 / -	110	15	41(37)
Gerbes (1998)[114]	11	1 / 3 / 7	8 / 11	10	3	3(27)
Banares (1998)[112]	56	11 / 22 / 23	19 / 37 / -	53 / 55	8	15(28)

Key Concepts:

- Aim is not only stop bleeding but prevent early rebleeding as this significantly impairs survival
- Prophylactic use of antibiotics is manadatory
- Vasoactive drugs administered before diagnostic endoscopy for at least 48 hours, and perhaps 5 days
- No more than 2 sessions of endoscopic therapy during the first 5 days of admission
- TIPS as salvage therapy for continued bleeding

Abstract

Infection complicating pancreatic necrosis leads to persisting sepsis, multiple organ dysfunction syndrome and accounts for about half the deaths that occur following acute pancreatitis. Severe cases due to gallstones require urgent endoscopic sphincterotomy. Patients with pancreatic necrosis should be followed with serial contrast enhanced computed tomography (CE-CT) and if infection is suspected fine needle aspiration of the necrotic area for bacteriology (FNAB) should be undertaken. Treatment of sterile necrosis should initially be non-operative. In the presence of infection necrosectomy is indicated. Although traditionally this has been by open surgery, minimally invasive procedures are a promising new alternative. There are many unresolved issues in the management of pancreatic necrosis. These include, the use of antibiotic prophylaxis, the precise indications for and frequency of repeat CE-CT and FNAB, and the role of enteral feeding.

INTRODUCTION

Acute pancreatitis is common, the incidence in recent European studies varying between 20 and 70 cases per 100 000 population with an overall mortality of between 3% and 8%[1-6]. Most cases are secondary to gallstones or excess alcohol consumption. Activation of trypsinogen within pancreatic acinar cells is the critical initiating event[7]. This leads to autodigestion of the pancreas, with a localised and then systemic inflammatory response, which if marked leads to the development of multiple organ dysfunction syndrome (MODS) and death[8,9]. Approximately half of deaths from acute pancreatitis occur in the first week following an attack. In patients who survive the initial attack a proportion develop areas of pancreatic and peripancreatic necrosis. Secondary infection then leads to persisting sepsis, MODS, and accounts for the majority of the remaining late deaths[1,10].

IDENTIFYING PATIENTS WITH NECROSIS

Nearly all patients who suffer a mild attack of acute pancreatitis make a complete recovery[11]. About one third of patients with a severe attack, who develop organ failure during the first week, will however, subsequently develop pancreatic necrosis involving more than 30% of the gland. There are several methods that are routinely used to identify early those patients who are likely to develop organ failure and those who will be at risk of pancreatic necrosis. Specific clinico pathological scoring systems include those described by Imrie[12] and Ranson[13]. These, however, are only accurate 48 hours after hospital admission, when they correctly categorise around 80% of patients into mild and severe. An APACHE II score $\geqslant$9 on hospital admission correctly identifies around 85% patients who will suffer a severe attack[14]. Unfortunately the relative complexity of the APACHE II system limits its clinical use.

Plasma C reactive protein levels (CRP), greater than 150mg/L 48 hours after admission, are widely used to predict a severe attack of pancreatitis[15,16]. CRP levels do not however peak until seventy-two hours after onset of symptoms thus CRP levels, like the Imrie and Ranson scores are limited in predicting a severe attack during the first few hours following admission (Table 1). Plasma levels of other direct inflammatory mediators, such as interleukin-8 and interleukin-6 are elevated earlier in the course of an attack of acute pancreatitis and relate to the severity of the systemic inflammatory response[17]. Although the levels of these mediators are as accurate at the time of admission as the APACHE II score, the assay systems are not suitable for widespread clinical use. Urinary levels of trypsin activation peptide (TAP), the cleavage peptide released following the activation of trypsinogen, become significantly elevated with the onset of an attack and measuring TAP has been shown to be a valuable predictor of severe disease[18] and urinary TAP levels may ultimately form the basis of a simple bedside urine test (Table 1).

Intravenous contrast-enhanced computerised tomography (CE-CT) has also been used to predict the severity of an attack of acute pancreatitis[19]. Balthazar described a CT severity index, based on a combination of peripancreatic inflammation and degree of pancreatic necrosis as seen at initial CT study. Patients with a high CT severity index had 92% morbidity and 17% mortality; patients with a low CT severity index had 2% morbidity, and none died[20]. This type of scoring system using CT offers no advantages as compared to clinico-biochemical scoring systems for the prediction of severe disease[21]. Rather the value of CE-CT is in the detection of pancreatic necrosis and definition of its extent and distribution (Figure 1A)[22-25] as well as in helping to delineate any associated collections[26]. Serial CT scans also allow the progression of the disease to be followed and are an essential adjunct when surgical intervention is required.

Table 1 Prognostic accuracy of the APACHE II, the Imrie and Ranson scores, plasma CRP and urinary TAP levels[18]

Scoring System	Sensitivity %	Specificity %	PPV %	NPV %	Accuracy %
Post-symptom 24 hrs					
Urinary TAP >35nmol/L	58	73	39	86	70
Plasma CRP >150mg/L	0	90	0	75	69
Plasma CRP >150mg/L or urinary TAP >35nmol/L	58	72	37	86	69
Plasma CRP >150mg/L and urinary TAP >35nmol/L	0	92	0	74	70
Post-symptom 48 hrs					
Urinary TAP >35nmol/L	81	71	42	94	73
Plasma CRP >150mg/L	65	73	37	90	72
Plasma CRP >150mg/L or urinary TAP >35nmol/L	86	60	35	94	65
Plasma CRP >150mg/L and urinary TAP >35nmol/L	60	85	50	90	80
Post-hospitalisation 24 hrs					
Urinary TAP >35nmol/L	68	74	44	89	73
Plasma CRP >150mg/L	47	82	42	84	74
Plasma CRP >150mg/L or urinary TAP >35nmol/L	74	66	38	90	68
Plasma CRP >150mg/L and urinary TAP >35nmol/L	40	91	57	83	79
APACHE II ⩾8	63	73	38	88	71
Post-hospitalisation 48 hrs					
Urinary TAP >35nmol/L	83	72	44	94	74
Plasma CRP >150mg/L	86	61	37	94	66
Plasma CRP >150mg/L or urinary TAP >35nmol/L	94	49	32	97	58
Plasma CRP >150mg/L and urinary TAP >35nmol/L	74	85	58	92	83
APACHE II ⩾8	56	64	30	85	63
Imrie Score ⩾3	77	75	44	93	76
Ranson Score ⩾3	89	64	38	96	69

PPV=positive predictive value; NPV=negative predictive value.

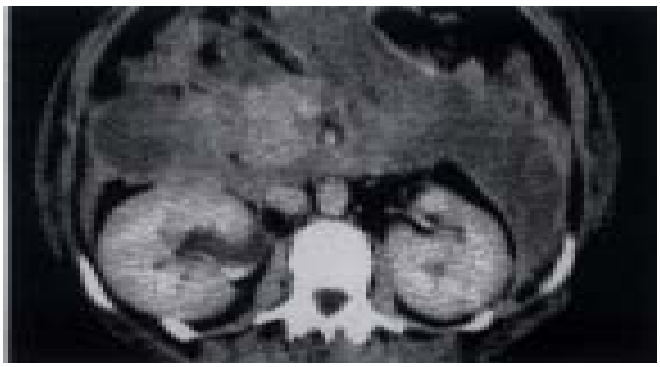

Figure 1A Extensive retroperitoneal pancreatic necrosis.

DETECTION OF INFECTION

In addition to the amount of pancreatic necrosis the outcome in severe pancreatitis is also determined by the presence or absence of infection within the necrotic tissue[27]. Clinical indicators that suggest the presence of infection include pyrexia, hypotension, continuing tachycardia, and a leukocytosis, but these features of sepsis syndrome are identical to those in patients with severe pancreatitis irrespective of the presence of pancreatic infection[28]. Beger *et al* studied 144 patients who underwent open necrosectomy. The proportion of patients who had demonstrable bacterial contamination at the time of necrosectomy increased from 24% during the first week to 36% in the second and peaked at 72% during the third week suggesting that infection is not immediate but that its frequency increases with time[29]. Table 2 shows organisms found within infected necrotic pancreas in their study, which was conducted prior to the routine use of prophylactic antibiotics. The profile of infecting organisms suggests origin from the gastrointestinal tract.

Table 2 Bacteria isolated from operative specimens taken at necrosectomy prior to the introduction of routine antibiotic prophylaxis, Beger *et al*, 1986[29]

Bacteria isolated	No. of patients
Gram - ve aerobic	
Escherichia coli	24
Enterobacter aerogenes	16
Pseudomonas aeruginosa	5
Proteus species	5
Klebsiella pneumonia	3
Citrobacter freundi	1
Gram - ve anaerobic	
Bacteroides species	5
Gram + ve aerobic	
Streptococcus faecalis	6
Staphlococcus aureus	4
Streptococcus viridans	1
Staplococcis epidermidis	1
Others	
Mycobacterium tuberculosis	1
Candida species	3

Several studies have shown that persistently elevated CRP is associated with infected pancreatic necrosis[30]. The presence of gas within an area of necrosis shown by CE-CT is highly suggestive of infection (Figure 1B), although it is desirable to detect the presence of infection before this becomes apparent. CE-CT guided fine needle aspiration, however, allows direct sampling of the necrotic tissue and subsequent microscopy and bacteriology (FNAB) will confirm the presence of infecting organisms (Figure 1C)[31,32].

Figure 1B Infection of pancreatic necrosis with gas forming organisms.

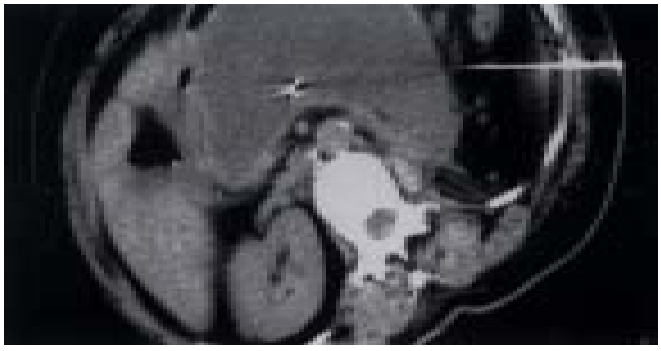

Figure 1C CE-CT guided fine needle aspiration for bacteriology.

The nature of the inflammatory response may also be modified by the presence of infection and recent studies have attempted to identify circulating factors that might confirm this. Serum procalcitonin is a potential marker for non-invasive prediction of infected necrosis[33]. Rau *et al* studied 50 patients with acute pancreatitis, 18 patients with oedematous pancreatitis, 14 patients with sterile necrosis, and 18 patients with infected necrosis. Levels of procalcitonin were measured in plasma during the first two weeks of admission. If levels reached 1.8ng/mL on at least two days during this time, sensitivity, specificity, and accuracy for the prediction of infected necrosis were 94%, 91%, and 92% respectively. This was not confirmed however in a more recent study[34].

PREVENTION OF PANCREATIC NECROSIS

Reducing the severity of the initial attack of acute pancreatitis might reduce the incidence and magnitude of pancreatic necrosis. Unfortunately at the present time, in the absence of effective intervention, management of the acute attack is predominantly supportive. One exception is the use of endoscopic retrograde cholangio-pancreatography and sphincterotomy in patients with predicted severe gallstone pancreatitis, which reduces the severity of an attack. Patients with severe acute pancreatitis due to gallstones need to undergo endoscopic sphincterotomy during ERCP, irrespective of the presence of acute cholangitis and ERCP should be undertaken within forty-eight hours of diagnosis[35-37].

ANTIBIOTIC PROPHYLAXIS

Prophylactic antibiotic use may reduce the incidence of septic complications particularly infection involving areas of pancreatic necrosis. In the 1970s three randomised placebo controlled studies assessed the role of prophylactic antibiotics in acute pancreatitis and found no effect on mortality or morbidity[38-40]. These studies, which were small, consisted almost entirely of patients with mild disease and without necrosis and thus no conclusions can be drawn.

In 1993 Pederzoli *et al* reported a multi-centre randomised study in which 74 patients with pancreatitis from all causes and with confirmed necrosis on CT at the time of admission were randomly assigned to imipenem or to no antibiotic[41]. The incidence of pancreatic sepsis, which was determined by fine needle aspiration or culture of intra-operative specimens, decreased from 30% in those untreated with antibiotics to 12% in the antibiotic treated group. There was, however, no significant difference in the rate of surgical intervention or mortality.

In a subsequent study from Finland, 60 patients with severe alcohol-induced necrotising pancreatitis as determined by CT and CRP estimation were randomly assigned to treatment with cefuroxime or to no antibiotic. One (3%) patient in the antibiotic treated group died compared to seven (23%) patients in the untreated group, ($P<0.05$)[42]. Surprisingly given the large difference in mortality there was no significant difference in the overall incidence of sepsis or the number of patients requiring surgery. Further, given the relatively small size of the study it is probable that there was heterogeneity in the randomisation as shown by the greater number of patients with fulminant pancreatitis on admission in the control group.

More recently, 60 patients with severe acute pancreatitis and necrosis affecting at least 50% of the pancreas, were randomly allocated to receive intravenous treatment for 2 weeks with pefloxacin, (30 patients), or imipenem, (30 patients), within 120 hours of onset of symptoms. The incidence of infected necrosis and extra-pancreatic infections was 34% and 44% respectively in the pefloxacin group and 10% and 20% in the imipenem group. Although imipenem proved significantly more effective in preventing pancreatic infections ($P<0.05$), there was no significant difference in mortality nor in the number of patients requiring surgery between the two treatments[43]. A feature of this last study and of other recent series[44,45] in which prophylactic antibiotics have been used is the increasing incidence of drug resistant or unusual organisms, including fungi, cultured from pancreatic tissue removed at necrosectomy. When such organisms are present the mortality following necrosectomy may be increased[46,47]. Thus the data imply that the use of prophylactic antibiotics promotes drug-resistant organisms and the growth of fungi. In the absence of further studies routine antibiotic prophylaxis in patients with acute pancreatitis cannot be recommended at present.

TRANSLOCATION OF GUT ORGANISMS

The gastrointestinal tract is thought to be the major source of organisms infecting necrotic pancreatic tissue. Increased translocation of bacteria and toxins is known to occur in acute pancreatitis[48,49]. Anaerobic bacteria are less likely to translocate from the gut lumen. Thus selective digestive decontamination (SDD) with appropriate antibiotics may change the intestinal flora to one that is less invasive. Between 1990 and 1993, 102 patients with severe pancreatitis from 16 centres in the Netherlands were randomized to selective digestive decontamination plus standard treatment or standard treatment alone[50]. There was a significant reduction in the incidence of gram-negative pancreatic infection in treated patients. Although deaths were reduced from 35% in the control group to 22% in the treatment group this difference was not significant. A short course of systemic antibiotics (cefotaxime) was used in the SDD group so that interpretation of the data with regard to the specific effects of gut decontamination as opposed to antibiotic prophylaxis is difficult[50].

Early re-introduction of nutrition via the gastrointestinal tract may also help to restore mucosal integrity and reduce translocation. A number of studies in patients with major trauma, surgery and burns showed that enteral nutrition significantly decreased the acute phase response and incidence of septic complications when compared with total parenteral nutrition[51,52]. In acute pancreatitis therefore early reintroduction of feeding via the gastro intestinal tract might also reduce the incidence of pancreatic infection.

Two randomized studies have compared enteral and parenteral nutrition in patients with severe acute pancreatitis. In the first study, 38 patients received enteral nutrition through a nasoenteric tube with a semi-elemental diet or parenteral nutrition through a central venous catheter. Patients who received enteral feeding experienced fewer total complications ($P<0.05$) and were at lower risk of developing septic complications ($P<0.01$) than those receiving parenteral nutrition. The cost of nutritional support was three times higher in patients who received parenteral nutrition[53].

In a second study from Leeds, 34 patients with acute pancreatitis received either parenteral or enteral nutrition for seven days and were then re-evaluated. The frequency of SIRS, sepsis, organ failure and the need for ITU admission was reduced in the enterally fed patients[54].

In a third study from Edinburgh, 27 patients with predicted severe acute pancreatitis were randomised to early introduction of enteral nutrition via a nasojejunal tube or conventional therapy, i.e. nil by mouth with re-introduction of oral intake with return of gut function. There were no significant complications as a consequence of enteral nutrition. The introduction of enteral nutrition did not affect the serum concentrations of IL-6 (P=0.28), soluble tumour necrosis factor-α receptor (P=0.53) or CRP (P=0.62) over the first 4 days of the study. Although there were no significant differences in intestinal permeability between the two patient groups at admission, by day four abnormal intestinal permeability occurred more frequently in patients receiving enteral nutrition (P=0.03).

Thus it can be concluded that enteral nutrition is safe in patients with severe acute pancreatitis and there is some evidence that it may be preferable to parenteral nutrition. The power of these three studies was too low to show any differences with respect to surgical intervention, incidence of pancreatic infection or mortality and the effect of nutrition route and timing on these outcomes requires further study.

NON-OPERATIVE TREATMENT OF PANCREATIC NECROSIS

Although there are isolated case reports of patients with pancreatic infection surviving with medical treatment alone[55] and limited success using percutaneous drainage[56,57], the presence of infection in necrotic pancreatic tissue is accepted to be an absolute indication for surgical intervention (Table 3). The situation in patients with extensive areas of sterile necrosis is less clear. Bradley *et al* reported on 38 patients with necrosis on CT who were initially treated medically and underwent FNAB if they remained persistently febrile. Infected pancreatic necrosis was demonstrated in 27 (71%) of the 38 patients with pancreatic necrosis who were treated by open drainage, with a mortality rate of 15%. All 11 patients with sterile pancreatic necrosis, including six with pulmonary and renal insufficiency, were successfully treated without surgery[58]. On the basis of this and subsequent studies sterile necrosis, should initially be managed non-operatively[59].

Table 3 Indications for surgical intervention

Absolute	• Presence of infected pancreatic necrosis shown by CE-CT or FNAB.
Relative	• In a patient with >50% pancreatic necrosis, failure to improve appreciably after 2 - 3 weeks, unexplained deterioration, or a suspicion of infected pancreatic necrosis even in the absence of firm evidence on CE-CT and FNAB. In a patient with >50% pancreatic necrosis, • prolonged illness with an unacceptably slow recovery

The optimal frequency of CE-CT imaging and FNAB has not been clearly established. In the recent study from Bern, all patients underwent contrast-enhanced CT within 24 to 48 hours of admission and this was repeated weekly in those patients whose clinical condition did not improve[45]. Fine needle aspiration under CT guidance with subsequent microscopy and bacteriological culture was undertaken to rule out infection in patients who developed signs of metabolic disorders, those with deteriorating function of lung, kidney or the cardio circulatory systems and those with persistent leukocytosis or fever (>38.5℃).

A second issue is the treatment of patients with sterile necrosis who remain unwell. In this group surgical intervention has been suggested for patients with persisting or advancing organ complications despite intensive care therapy[59]. In contrast in a recently published single-centre study, pancreatic infection, if confirmed by fine-needle aspiration, was considered an indication for surgery, whereas patients without signs of pancreatic infection were treated medically[45]. Eighty-six (42%) of the patients in this study had necrotizing disease, of which two thirds had sterile necrosis. The death rate was 1.8% (1/56) in patients with sterile necrosis managed without surgery versus 24% (7/29) in patients with infected necrosis (P<0.01). Two patients whose infected necrosis was not diagnosed in time died whilst receiving medical treatment. Thus, an intent to treat analysis (non-surgical *vs.* surgical treatment) produced a death rate of 5% (3/58) with conservative management versus 21% (6/28) with surgery. The authors concluded that non-surgical management, including early antibiotic treatment, should be used in all patients with sterile pancreatic necrosis[45]. In contrast other authors have observed a similar mortality in patients undergoing necrosectomy between those with sterile and those with infected necrosis[60].

TIMING OF SURGERY

Timing of surgery is critical. Necrosectomy is technically difficult during the first week but becomes progressively easier with time. One controlled trial has addressed the role of early surgery. Forty-one patients with pancreatic necrosis on CT were randomized to early necrosectomy (within 48 to 72 hours of onset) or late necrosectomy (at least 12 days after onset). Both groups continued with open packing and staged necrosectomies. Although the mortality rate (58% versus 27%) did not reach statistical significance, the odds ratio for mortality was 3.4 times higher in the early group and for this reason the study was terminated early[61]. Thus the contemporary management of patients with extensive necrosis involves repeated imaging using contrast-enhanced CT in association with fine needle aspiration for microscopy and bacteriology with immediate surgery if infection is detected.

OPEN NECROSECTOMY

Necrosectomy has traditionally been undertaken by an open route. Following laparotomy the lesser sac is opened if possible, the colon is mobilised downwards and the pancreas identified. Necrotic pancreas is debrided by blunt finger dissection and wide bore suction drainage. If opening of the lesser sac is not possible, direct access from the infracolic compartment via the left transverse mesocolon (space of Riolan) is an alternative. Adequate debridement is usually achieved with a single visit to theatre. Any associated fluid collections are drained by the most direct route. Large drains and irrigating catheters are left within the retroperitoneal area and continuous irrigation is continued post surgery[62]. The use of open packing with multiple visits to theatre prior to secondary closure over drains has been described but hospitalisation can be significantly reduced by using prolonged lavage rather than pre-planned multiple laparotomies. Mortality rates in recent series are generally between 20%-40%[45,58,60-67], but may be higher even in specialised centres[33].

Several developments have led to a reassessment of the role and the extent of surgery in acute pancreatitis. Percutaneous drainage has been advocated as a means of

treating pancreatic necrosis[56,57,68]. Unfortunately it is impossible to achieve adequate debridement of solid pancreatic debris by this route except in a minority of cases and it may lead to secondary infection in pancreatic necrosis that is initially sterile. Aggressive percutaneous drainage has been proposed as a means of treating infected pancreatic necrosis. A major reason for failure however is the variable amounts of infected solid material that cannot be removed. Indeed Paye *et al* [69] found percutaneous drainage to be largely inadequate requiring surgical intervention in the majority of cases.

In an attempt to reduce the high mortality from surgical necrosectomy less traumatic approaches than open laparotomy have been advocated. Fagniez *et al*[70] described a retroperitoneal approach for pancreatic necrosectomy through the left flank just anterior to the 12th rib. There was an overall mortality of 33% in 40 patients with severe pancreatic necrosis and 18% in the 22 patients in whom this was the only abdominal procedure performed. Similarly good results have been reported in three other small series[71-73]. Morbidity rates, including colonic fistulae and haemorrhage were, however, high.

Another factor that has led to the re-evaluation of the extent of surgery has been the concept of the two-hit response. This hypothesis states that many patients with a severe attack of acute pancreatitis are primed to mount an inappropriate and exaggerated inflammatory response to a second traumatic challenge[8,9]. Thus a subsequent hit, for example from an open procedure to debride the infected necrotic pancreas, may lead to an overwhelming systemic inflammatory response and death. This would account in part for the continuing high mortality that follows open surgical necrosectomy. Unfortunately patients liable to have such an abnormal response cannot be identified at present although markers of genetic susceptibility are being sought.

A new technique of minimally invasive pancreatic necrosectomy via a left loin approach, analogous to the open technique of Fagniez *et al*[70] was recently pioneered in Glasgow[74]. The advantages of this technique are two-fold. First the peritoneal cavity is not transgressed, and second, tissue damage is limited-thus reducing the magnitude of the systemic inflammatory response of the second hit. Mortality in the 10 patients treated by this technique was only 20%. We have used this technique in a further 14 patients with 3 (21%) deaths[75]. We believe that these results are encouraging and that in the future a significant proportion of patients with infected pancreatic necrosis may be managed by this technique.

Abstract

The outlook for patients with pancreatic cancer has been grim. There have been major advances in the surgical treatment of pancreatic cancer, leading to a dramatic reduction in post-operative mortality from the development of high volume specialized centres. This stimulated the study of adjuvant and neoadjuvant treatments in pancreatic cancer including chemoradiotherapy and chemotherapy. Initial protocols have been based on the original but rather small GITSG study first reported in 1985**. There have been two large European trials totalling over 600 patients (EORTC and ESPAC-**1**) that do not support the use of chemoradiation as adjuvant therapy. A second major finding from the ESPAC-**1 **trial (**541 **patients randomized) was some but not conclusive evidence for a survival benefit associated with chemotherapy. A third major finding from the ESPAC-**1 **trial was that the quality of life was not affected by the use of adjuvant treatments compared to surgery alone. The ESPAC-**3 **trial aims to assess the definitive use of adjuvant chemotherapy in a randomized controlled trial of** 990 **patients.**

INTRODUCTION

Pancreatic cancer is the 5th most common site of deaths due to cancer among all cancer sites in the Western world. Low cure rates ensure that the mortality is nearly as high as the incidence. It is responsible for 7 000 deaths per year in the UK[1], 40 000 per year in Europe and 28 000 in the USA[2]. The peak mortality ages are estimated to be between 65 and 72 years in Europe and 55 and 75 years in the USA[2]. The incidence of this deadly disease has been rising during the last century. In the past 20 years however, there have been vast improvements in the surgical management of patients with pancreatic cancer. The surgical procedures have been improved and become more standardized between centres and countries. The level of pre- and post-operative support for these patients has been optimized, particularly in established centres with a high throughput[3]. These measures have ensured that the outlook for patients with resectable disease has certainly improved, particularly in the short term. Extending patient survival still remains a problem. The overall five-year survival for all patents with pancreatic cancer is only 0.4%[4]. Patients who are suitable for resection have five-year survival rates of between 10% and 24%[5-8] and are virtually never cured. Therefore, even for the 10% to 15% of patients who undergo surgery, there appears to be no guarantee of cure or indeed long-term survival. These outcomes would suggest a role for the use of additional or adjuvant therapy to attempt to improve patient survival and quality of life.

RADICAL SURGERY

Japanese groups amongst others have been enthusiastic in pursuing radical resection as means of increasing disease free margins and thus hopefully improving patient survival. Radical surgery includes extensive lymph node dissection and retroperitoneal connective tissue clearance as well as pancreatic resection. The Japanese groups have suggested that these approaches are superior to conventional Kausch-Whipple resection but several studies have not shown significant survival advantages when compared with conventional resection[9-13]. Kayahara *et al* found that radical resection in patients with Stage I and II disease (Japanese classification) and clear margins (R0) resulted in a reduction of local recurrence but did not translate into improved survival because of hepatic metastases[14]. Interestingly highly detailed serial section analysis of presumed R0 specimens has revealed microscopic margin disease (R1) in up to 38% of specimens[14].

Difficulties are encountered when comparing survival figures of Western and Japanese studies because of the different staging systems used (UICC *vs* JPS respectively). This is because of the phenomenon of 'staging system migration' that may give apparently better survival for each stage in one system compared to the other even though there is no overall difference in survival. Satake *et al*[15] compared the Japanese and UICC staging systems in a large cohort of patients. Stage for stage the Japanese system revealed a better survival from Stage I to IV compared with UICC system. The overall five-year survival however, was the same (11%) because the systems had been analysed in identical patients.

The majority of radical resection studies have been non-randomized and performed in single institutions. The radical lymph node dissection allows more accurate staging of disease and these tumours will tend to be upstaged because of this. Thus it is necessary to examine overall group survival within the context of randomized studies by an intention to treat analysis. There has been one multicentre prospective randomized trial comparing traditional partial pancreatoduodenectomy with and without a more extensive lymph node dissection[16]. Eighty-one patients were randomized to receive a standard (n=40) or extended (n= 41) lymphadenectomy and retroperitoneal soft tissue clearance. The standard lymphadenectomy included removal of lymph nodes situated at the anterior and posterior

pancreatoduodenal, pyloric, main bile duct, superior and inferior pancreatic head and pancreatic body stations. The extended lymphadenectomy also included the removal of lymph nodes from the hepatic hilum, along the aorta from the diaphragmatic hiatus to the inferior mesenteric artery, laterally to both renal hila and clearance of the coeliac trunk and superior mesenteric artery. There was no significant difference of overall survival between the two groups. Patients who had lymph node positive disease demonstrated better survival following an extended resection compared to those who did not have an extended lymphadenectomy but must be regarded as a statistically invalid manoeuvre as this was a post-hoc subgroup analysis. In light of these findings the ultimate benefit of extended lymphadenectomy surgery still needs to be proven with further critical evaluation.

There appears to be no additional survival benefit associated with total pancreatectomy compared to Kausch-Whipple pancreatoduodenectomy and at the present time the pylorus preserving pancreatoduodenectomy has been shown to produce similar results to the more traditional Kausch Whipple procedure[17,18]. The latter approach is now the procedure of choice in most centres.

The lack of survival benefit associated with radical resection may be due in part to the pattern of disease recurrence in resected pancreatic cancer. Most tumour recurrences are local, peritoneal and hepatic[19-24]. The early appearance of hepatic metastases following resection almost certainly indicates the presence of hepatic micrometastases at the time of surgery. Microscopic peritoneal disease also tends to occur early in contrast to the relatively later presentation of local recurrence. Pancreatic cancer cells tend to spread within a range of peripancreatic tissues. Lymphatic infiltration and perineural invasion may be found in 90%-100% of resected specimens[25]. Reasons for recurrence following an apparently curative resection include residual retroperitoneal disease, perineural invasion, hepatic micrometastases and lymph node involvement. The pattern of relapse after surgery reflects the natural course of the disease without resection. The most commonly affected organs include abdominal lymph nodes (72%-83%), liver (64%-80%), peritoneum (40%-53%) and lung (27%-50%)[14]. An R0 resection in patients with no lymph node metastases cannot be achieved in more than about half of the patients undergoing resection. Kayahara *et al*[14] at post mortem examined 15 patients who had undergone radical resection. The local recurrence rate in this group of patients was 80%. The local recurrences were associated with perineural invasion, lymphatic invasion and soft tissue infiltration. High rates of local recurrence have been confirmed in numerous studies of patients who have undergone pancreatoduodenectomy and the majority occur within 1 to 2 years of surgery[23,24].

Identification of extrapancreatic disease at the pre-operative stage has improved due to accurate imaging techniques[26] and laparoscopy[27]. Peritoneal cytology has been shown to be positive in 58% of patients who may have unresectable tumours or have a limited postoperative survival[27]. The best predictors of outcome following surgery also reflect the causes of disease relapse. These include tumour stage (which also includes the lymph node status), grade of primary tumour and resection margin status[28-32]. Not surprisingly patients with stage I or II disease and negative resection margins tend to demonstrate the best survival.

The poor overall survival of patients with pancreatic cancer, even following optimal surgical intervention, and the pattern of disease progression and recurrence are clear indications for the use of additional treatment modalities.

CHEMOTHERAPY

Advanced pancreatic cancer

There have been many studies of chemotherapy in patients with advanced pancreatic cancer. Single agents and combination regimens have been used. At the present time there is no accepted standard chemotherapeutic agent for the treatment of pancreatic cancer. 5-fluorouracil (5-FU) remains the most effective and most frequently used single chemotherapy agent. 5-FU works partly by interference with enzymes such as thymidylate synthase and partly by incorporation of 5-FU metabolites into DNA and RNA. The response rates of -15% with a median survival of 3-5 months[33]. The addition of the modulator folinic acid has produced marginal survival benefit over 5-FU alone but this has not been a significant increase[33]. The addition of other modulators such as phosphonacetyl-L-aspartate (PALA), and interferon has also not produced significant improvements in survival[34,35]. Comparisons of 5-FU alone and 5-FU with a combination of other agents have not shown any advantage for the combination groups in randomized trials[33].

A new agent, gemcitabine has been compared to 5-FU in a randomized multi-centre phase III clinical trial[36]. Gemcitabine is a deoxycytidine analogue that is phosphorylated to an active form and competes with dCTP for incorporation into DNA. The study, in which over 70% of patients had stage IV disease, randomized 63 patients to receive gemcitabine and 63 patients to receive 5-FU. Median survival in the gemcitabine group was 5.7 months compared to 4.4 months in the 5-FU group but no patient survived beyond 19 months. The clinical benefit response was also significantly higher in the gemcitabine group[36]. Despite the fact that this is the only trial with a straight comparison between the two agents gemcitabine has been recommended as the drug of choice in the USA. Gemcitabine has also been combined with 5-FU in several phase II studies. It is generally well tolerated but can have unpredictable side effects such as neutropaenia, abnormal liver function tests and nausea and vomiting. In patients who have had previous radiotherapy to the mediastinum there have been unpredictable reactions[37].

There is good evidence from several randomized controlled trials comparing chemotherapy with a no treatment group that chemotherapy is of benefit in patients with advanced pancreatic cancer. Mallinson *et al*[38] demonstrated a median survival of 11 months for patients treated with 5-FU, cyclophosphamide, methotrexate, vincristine and mitomycin C compared to 2.2 months for the untreated control group. This regimen did not produce a significantly greater survival when compared to 5-FU alone in a much larger randomized control trial[39]. Another rather poorly controlled study compared 5-FU and carmustine to untreated controls[40]. There was no significant survival benefit associated with this regimen but the majority of patients in this study received only a single treatment and did not finish the course. A further trial of the combination of 5-FU, doxorubicin and mitomycin C (FAM) resulted in median survival of 33 weeks compared with median survival of 15 weeks in untreated control patients[41]. A recent study compared the use of 5-FU + folinic acid (+/- etoposide) with best supportive care and showed that the median survival in the treated group was 6 months compared to 2.5 months in the control group[42]. Moreover there was better overall

quality of life score for the treated patients.

Adjuvant chemotherapy

There have been only a few studies of adjuvant chemotherapy in pancreatic cancer and (up until the ESPAC-1 trial) there was only one randomized controlled trial comparing surgery and chemotherapy with surgery alone (Table 1)[43-46]. Splinter *et al* [43] reported no evidence of improvement or survival using a FAM regimen in 16 patients who had undergone pancreatoduodenectomy with a three year survival of 24% compared to a three year survival of 28% in 36 patients who had undergone surgery only. Patients from different time periods were included in the two groups and there were only nine patients with pancreatic ductal adenocarcinoma in the adjuvant group and 18 in the surgery only group. Baumel *et al*[46] reported adjuvant chemotherapy in 43 selected patients with a median survival of 12 months but there was no difference in median survival from those patients who underwent surgery only (12 months). Bakkevold *et al*[45] randomized 61 patients who had undergone pancreatoduodenectomy for pancreatic cancer or ampullary cancer to receive either six courses of FAM or no chemotherapy. There was a significant difference in the median survival rates between the two groups: 23 months. Unfortunately this did not translate into a significantly improved long-term survival however: the 5-year survival rates were 4% for the treatment arm versus 8% for the surgery only arm. There was also considerable toxicity encountered with the FAM regimen. Only 24 out of 30 patients randomized to treatment actually started therapy. Sixteen patients needed hospitalization after the first chemotherapy course and a total of 13 patients managed to complete all six cycles of FAM.

The European Study Group for Pancreatic Cancer (ESPAC) has commenced the ESPAC-3 trial with the objective of definitively defining the role of adjuvant chemotherapy following curative resection for pancreatic ductal adenocarcinoma. Two adjuvant regimens are being studied against a no chemotherapy control: ① 5-FU + folinic acid for 24 weeks versus ② gemcitabine for 24 weeks versus ③ observation. All patients will have undergone potentially curative resection for pancreatic ductal adenocarcinoma. A total of 990 patients (330 in each arm) will be recruited over the next few years and survival analysis will be completed after two years of follow-up. At the present time recruitment is underway from centres across Europe with further centres in Canada, Australia and New Zealand due to join.

RADIOTHERAPY (CHEMORADIOTHERAPY)

Advanced pancreatic cancer

External beam radiotherapy (EBRT) although used in the treatment of advanced pancreatic cancer, has never been compared with an untreated control arm in any randomized controlled trial. The most commonly used and probably the best radiosensitizer used with EBRT for advanced pancreatic cancer is 5-FU. Many retrospective studies of EBRT, usually in relatively small groups of selected patients report median survival times of 10 - 15 months with good palliation of symptoms[47,48].

The improved local control of disease achieved with EBRT has not translated into significantly longer survival times, so there have been various refinements in an attempt to enhance the effectiveness of radiotherapy. Wide field irradiation has been used to address the problem of hepatic micrometastases. A Radiation Therapy Oncology Group (RTOG) study of 79 patients who received pancreatic and hepatic irradiation resulted in a median survival of 8.4 months but at the expense of considerable toxicity[49]. Intraoperative radiation therapy (IORT) aims to deliver higher doses of radiation with greater precision and thus reducing the exposure of neighbouring organs. Experimentally, its effectiveness may be as high as five times the equivalent dose given by EBRT. In advanced pancreatic cancer the survival times achieved using IORT have not been encouraging (median survival -6 months) and it has been mainly used to boost EBRT[50,51]. A study comparing EBRT + IORT + 5-FU with EBRT +5-FU demonstrated no significant survival difference (12 and 13 months respectively)[50,51]. Complications encountered during IORT include, duodenal and gastric ulceration, vascular sclerosis and pancreatic abscess[52]. IORT offers good local control and pain relief but cannot be recommended as a standard treatment as it has not been possible to demonstrate any advantages over conventional therapy.

Adjuvant radiotherapy (chemoradiotherapy)

Adjuvant EBRT and IORT have been used alone and in combination in the adjuvant setting (Table 2)[21,32,53-60]. The majority of studies indicate that EBRT alone or in combination with IORT has a significant survival advantage over the use of IORT alone. In a randomized trial IORT was observed to reduce the local recurrence rate by 50% following surgery, but this did not translate into a significant survival advantage (3-year survival with IORT=7% *vs* no IORT 3%)[21]. In selected patients IORT and resection produced 3 and 5-year survival rates of 53% and 29%[61,62]. The use of IORT however requires specialised facilities and can be associated with severe complications.

EBRT (with concomitant chemotherapy) following resection is generally well tolerated but the degree of survival advantage, if any, is uncertain. To address this issue a multicentre Phase III trial organized by the European Organisation for Research and Treatment of Cancer (EORTC) compared chemoradiotherapy in patients following potentially curative surgery for pancreatic cancer with surgery alone[58]. Between 1987 and 1995, 218 patients were randomized to receive either chemoradiotherapy or no chemoradiotherapy following curative surgery for pancreatic or ampullary cancer. Ninety-three out of 110 patients randomized to treatment received a total of 40 Gy with concomitant continuous infusion of 5-FU. There were a total of 54 patients in the observation group and 60 patients in the treatment group with pancreatic ductal adenocarcinoma. There was no significant difference in median survival (with treatment 17.1 months *vs* 12.6 months with observation) and in five year survival [with treatment 20 (95% CI, 5-35)% *vs* 10 (0-20)% with observation]. Similarly there was no significant difference in survival between the treatment and observation groups in patients with ampullary cancer. This study showed that there was no survival advantage for adjuvant chemoradiotherapy for pancreatic and ampullary cancer but has been criticized because it was almost certainly underpowered.

REGIONAL THERAPY

Advanced pancreatic cancer

Regional therapy has been developed with the objective of

delivering high doses of cytotoxic drug to the tumour. The systemic side effects should be reduced with this approach. The coeliac and hepatic arteries and portal vein have all been used to deliver chemotherapeutic drugs to the tumour bed. Good control of hepatic metastases has been reported, with disease progression mainly due to local progression or peritoneal deposits. The combination of 5-FU, folinic acid and cisplatin produced median survival times of 9-14 months in selected patients[63,64]. It has also been reported that some apparently irresectable tumours have become resectable following regional therapy[64].

Adjuvant regional therapy

There have been several studies which have demonstrated improved survival in patients receiving regional chemotherapy following pancreatic resection largely in comparison with historical controls (Table 3)[65-68]. Link *et al*[69] found a median survival of 21 months in 18 patients who had undergone pancreatoduodenectomy for pancreatic ductal adenocarcinoma and then coeliac artery infusion of 5-FU, folinic acid, mitoxantrone and cisplatin compared to 9.3 months for historical controls. Disease progression occurred principally locally or in the peritoneum and was rarely detected in the liver. The rate of hepatic recurrence was greatly reduced using a combination of hepatic artery and portal vein infusion in patients with resected pancreatic, which in one study cancer produced a 54% three-year survival compared to 34% in historical controls[65]. Ozaki *et al*[66] found a 5-year survival rate of 32% patients treated with extended resection, IORT and hepatic artery and portal vein. The encouraging results of these small studies have prompted the ESPAC-2 trial, which is a multicentre, prospective randomized controlled Phase III trial. This study will compare adjuvant intra-arterial chemotherapy (cisplatin, 5-FU, folinic acid and mitoxantrone) and radiotherapy (Arm A) with surgery alone (Arm B) in patients who have undergone potentially curative resection for pancreatic ductal adenocarcinoma or ampullary carcinoma. The trial will recruit 110 patients into each arm and will be completed by 2007 aiming to provide a definitive answer to the role of adjuvant regional therapy for pancreatic cancer.

Table 1 Survival following surgery and adjuvant chemotherapy for pancreatic cancer

Series	Period	Number		Regimen	Median survival (months)	Actuarial survival (%)

NEOADJUVANT THERAPY

The rationale for pre-operative therapy includes (a) the avoidance of long delays following surgery before starting adjuvant therapy and (b) an attempt to downstage the tumour and thereby increase the prospect of resection (Table 4)[70-77]. Pre-operative radiotherapy produced only modest increases in resectability and so chemotherapy was added in an attempt to improve the efficacy of this approach. Recent studies have reported resection rates as high as 60%[70-77] but not surprisingly those tumours >4cm-cm, encase the superior mesenteric artery or obstruct the superior mesenteric/ hepatic portal vein are less likely to be resected[71,73]. Pre-operative chemoradiotherapy may also increase the incidence of clear resection margins to as high as 90%, compared to the accepted norm of 60%-80%.

The effect of any long-term survival benefit from neoadjuvant treatment, if any, is not known due to the lack of randomized controlled studies. Twenty- four out of 53 patients with pancreatic ductal adenocarcinoma initially treated with 5-FU, mitomycin C and 50.4 Gy were able to undergo resection with a medi an survival of 15.7 months[74]. There was a significant level of toxicity associated with this regimen with two treatment related deaths. Another recent non-randomized study found a median survival of 19.2 months for patients with pancreatic cancer treated by pre-operative chemoradiation compared to 22 months for those treated by post-operative chemoradiation. Neither survival nor the pattern disease of recurrence was significantly different between the two groups[73].

COMBINATION THERAPY

Advanced pancreatic cancer

The combination of chemoradiation and follow-on chemotherapy may enable good local control with systemic destruction of the disease. The Gastrointestinal-Tumour Study Group (GITSG) randomized patients with advanced pancreatic cancer to receive either 60Gy EBRT (with radiosensitizing 5-FU) with or without follow-on 5-FU versus 40Gy EBRT with radiosensitizing 5-FU and follow-on 5-FU. The median survival times were 40, 23 and 42 weeks respectively, indicating a- likely valuable role for radiosensitizing (± follow-on)chemotherapy but not for increased radiotherapy[78]. Other combinations have been evaluated in the palliative setting[79]. A randomized trial of IORT versus IORT and methotrexate/5-FU produced a median survival of 4.8 and 8.5 months respectively[80].

Adjuvant combination therapy

The regimen originally adopted by the GITSG for patients with advanced pancreatic cancer was used in the adjuvant setting for a randomized trial in the 1970's . Forty-three patients were randomized to receive either 40Gy (with radiosensitizing 5-FU) then weekly 5-FU or surgery alone. The median survival in the treated group was 20 months compared to 11 months in the surgery only group and the two year survival rates were 42% and 15% respectively[81]. To increase numbers in the treatment group a further 30 patients received adjuvant therapy. The median survival was 18 months with a two year survival of 46%[82]. The number of patients that received treatment as part of the randomized study however was far too small for convincing conclusions to be drawn. The results were encouraging enough for other studies to adopt this protocol and investigate its role in the treatment of pancreatic cancer (Table 5)[81-88]. Yeo *et al*[84]compared three different regimens in selected patients who had undergone pancrea toduodenectomy: ① 40-45Gy EBRT plus follow-on 5-FU for 4 months (standard); ② 50-57Gy EBRT plus hepatic radiation plus 5-FU + folinic acid for 4 months (intensive); ③ no adjuvant treatment. The median survival was 21 months and the two-year survival was 44% for the group given standard adjuvant treatment, significantly better compared to 13.5 months and 30%, respectively in the no treatment group. There was no significant survival difference however between patients that had received the intensive treatment and those that had received no treatment. The main drawbacks to this study are the retrospective data that suffer from patient selection bias and no specification of patient performance status, which is an extremely important independent prognostic factor.

A phase III randomized controlled study organised by the Radiation Therapy Oncology Group (RTOG) in the USA is currently recruiting patients who have undergone resection for pancreatic adenocarcinoma. This study aims to compare 5-FU versus gemcitabine pre- and post- chemoradiotherapy all following surgery. The trial has already accrued the original 330 patient target but is still recruiting, presumably because of a lack of a significant therapeutic effect so far.

The UK Pancreatic Cancer Trials Group (UKPACA)[85] utilized the GITSG protocol for an open phase II study of 40 patients (34 with pancreatic ductal adenocarcinoma and 6 with ampullary tumour) who had undergone-pancreatoduodenectomy between 1987 and 1993 were recruited. Patients received 40Gy (with 5-FU as a radiosensitizer) plus 5-FU weekly for a maximum of 24 weeks. After a median of eight treatments there were no treatment related deaths and no hospitalizations even with a prolonged course of post-operative chemotherapy. The median survival for patients with pancreatic ductal adenocarcinoma was 13.2 months and the five-year survival rate was 15%.

The findings of these studies were instrumental in the design of the ESPAC-1 trial, which commenced in 1994. This trial was established to compare the effects of three adjuvant treatments with a control group. The four groups were: ① chemoradiotherapy (40Gy with radiosensitizing 5-FU); ② chemotherapy (5-FU plus folinic acid for six months); ③ combination chemoradiotherapy followed by chemotherapy; and ④ best supportive care. Patients were eligible following potentially curative resection for pancreatic ductal adenocarcinoma. Between February 1994 and April 2000 a total of 591 patients were randomized of which 541 had pancreatic ductal adenocarcinoma. A total of 61 centres recruited patients from UK, Ireland, France, Sweden, Spain, Italy, Germany, Switzerland, Greece, Hungary, Belgium and Austria. Randomization was stratified by resection margin status. Clinicians could randomize patients into a 2×2 factorial design (obse rvation, chemoradiation, chemotherapy or combination) or into one of the main treatment comparisons (i.e. chemoradiation *vs* control or chemotherapy *vs* control). Two-hundred and eighty five patients were randomized to the 2×2 factorial design, a further 68 patients were randomized to chemoradiation *vs* no chemoradiation and 188 patients were randomized to chemotherapy *vs* no chemotherapy. Tumour grade, size, nodal status and resection margin status were all significantly associated with survival. The overall results showed no benefit for chemoradiation *vs* no chemoradiation (median survival 15.5 months *vs* 16.2 months respectively). There was evidence of a survival benef it for

chemotherapy (median survival 19.7 months) compared to those patients who did not receive chemotherapy (median survival 14 months). The effect was reduced when taking into account whether patients had also received chemoradiation suggesting that chemoradiation may decrease the benefit of chemotherapy[89]. Moreover quality of life analysis showed no significant difference between any of the groups indicating that adjuvant therapy in pancreatic cancer is worthwhile, provided there is a significant prolongation of life[90].

The results of ESPAC-1 have provided for the first time a clear indication of a potential benefit for the use of chemotherapy in the treatment of pancreatic cancer. Even more importantly both ESPAC-1 and the EORTC trials have rejected the use of chemoradiation as adjuvant therapy in pancreatic cancer. Thus the focus of future studies such as ESPAC-3 will be on new and efficacious chemothe rapy regimens. This study is randomizing patients to three arms: 5-FU+folinic acid, gemcitabine and observation. The power of the study is such to detect a 10% difference in 2-year survival between any of the groups. Thus ESPAC-3 will establish (a) the benefit of adjuvant chemotherapy for pancreatic cancer and (b) if such, then the best form of chemotherapy.

Table 4 Neoadjuvant therapy for pancreatic cancer

Series	Year	Number	Regimen	Resection rate		Positive resection margin (*n*)	Median survival (months)	Actuarial survival (%)

EBRT = external bean radiotherapy; 5-FU = 5-fluorouracil; FA = folinic acid; CPP = cisplatin

CONCLUSION

This is a very encouraging time for the treatment of pancreatic cancer. The results of these large European trials have at last given clear indications for future therapies of pancreatic cancer. By using this information, reasoned approaches are being developed to improve the treatment of patients with pancreatic cancer without sacrificing quality of life.

AKNOWLEDGEMENTS We are grateful to the Cancer Research campaign, UK for funding the ESPAC-1 and ESPAC-3 trials of adjuvant treatments in pancreatic cancer.

Abstract

AIM **To observe the growth suppression effect of exogenous introduction of early growth response gene-1 (Egr-1 gene) on esophageal carcinoma tissue as well as on esophageal carcinoma cell line Eca109 and to explore the potential application of Egr-1 gene in gene therapy of tumor.**

METHODS **Eukaryotic expression vector of PCMV-Egr-1 plasmid was introduced into Eca109 cell line which expressed no Egr-1 protein originally with lipofectamine transfection method. The introduction and expression of PCMV-Egr-1 plasmid into Eca109 cell line was confirmed by G418 selection culture, PCR amplification of neogene contained in the vector, Western blot analysis and immunocytochemical analysis. The cell growth curve, soft agar colony formation rate and tumorigenicity in SCID mice were examined to demonstrate the growth suppression effect of exogenous Egr-1 gene on Eca109 cell line. The Egr-1 mRNA and Egr-1 protein were also detected in 50 surgical specimens of esophageal carcinoma by *in situ* hybridization and immunohistochemistry.**

RESULTS **Exogenous Egr-1 gene was introduced successfully into Eca109 cell line and expressed Egr-1 protein stably. The transfected Eca109 cell line grew more slowly than control Eca109 as shown by cell growth curves, the soft agar colony formation rate (4.0% *vs* 6.9%, *P*<0.01) and the average growth rate of tumor in SCID mice (35.5±7.6 *vs* 65.8±7.6, *P*<0.05). The expression level of Egr-1 mRNA and protein significantly increased in dysplastic epithelia adjacent to cancer rather than in cancer tissues (65.8% *vs* 20.0% by ISH and 57.9% *vs* 14.0% by IHC, *P*<0.01).**

CONCLUSION **Exogenous Egr-1 gene shows the strong effect of growth inhibition in Eca109 cell line. Egr-1 in the cancer tissue shows down-regulated expression that supports the inhibited function of Egr-1 in cancer growth and suggests Egr-1 may have an important role in gene therapy of esophageal carcinoma.**

INTRODUCTION

Esophageal carcinoma is one of the most common malignant tumors in China[1-5]. Its pathogenesis and development are closely related with some of proto-oncogenes and their products[6-17]. Early growth response gene-1 (Egr-1 gene) is known as a member of immediate early gene (IEG) family characterized by rapid and transient expression in response to stimulation, modulating gene transcription positively or negatively depending on the cell types and playing an important role in the early cell growth. But its relationship with esophageal carcinoma is not well understood so far. In order to evaluate the growth inhibition in the cell line of esophageal carcinoma (Eca109) and analyze the expression of Egr-1 in the cancer tissue of esophageal carcinoma, the relationship between Egr-1 and esophageal carcinoma is explored by the methods of gene transfection, tumorigenicity in severe combined immunodeficient (SCID) mice and *in situ* hybridization.

MATERIALS AND METHODS

Human esophageal carcinoma cell line Eca109

Eca109 cell line from Chinese Academy of Medical Sciences was cultured in Dulbecco's modified Eagle medium (DMEM) supplemented with 100mL·L^{-1} fetal bovine at 37℃ and 50mL·L^{-1} CO_2 incubator. The cancer tissue with adjacent mucosa and the esophageal mucosa in the upper surgical margin was from the same surgical specimen of 50 patients with esophageal carcinomas who had received neither chemotherapy nor radiotherapy before surgery. These were fixed in 40mL·L^{-1} neutral formalin with 1/1000 diethyl pyrocarbonate (DEPC, Sigma Chemical Co, USA) and embedded in paraffin, the sections were cut in 5μm.

Eukaryotic expression vector of PCMV-Egr-1 plasmid

The plasmid was donated by Dr RP Huang (Molecular Medicine, Northwest Hospital, WA, USA). The final construct contains the neogene (5.5kb fragment) driven by the respiratory syncytial virus (RSV) promoter and the Egr-1 gene (2.1kb fragment) driven by the human cytomegalovirus (CMV) promoter. The plasmid was confirmed by amplification, purification and tested by cutting endonuclease.

Gene transfection

The eukaryotic expression vector of PCMV-Egr-1 plasmid was transfected to human esophageal carcinoma cell line Eca109 by the lipofectamine (Gibcobrl Company, USA) according to the manufacturer's instructions. After transfection, the cells were trypsinized and reseeded at 1:2 ratio for selection culture with G418 at 600mg·L^{-1}. Four weeks later, the resistant colonies were formed.

Detection of transfected cell neogene with polymerase chain reaction

Extracting the cell DNA followed by performing polymerase chain reaction (PCR) to amplify 327bp of neogene with primer 1 (5'ACAAGATGGATTGCACGC AGG3') and primer 2 (5'TTCTCGGCAGGAGCAAGGTGAG3'). The cycling procedure was: denatured at 95℃ for 1 min, annealed at 55℃ for 1.5 min, extended at 72℃ for 1 min, and after 30 cycles, lengthened at 72℃ for 5 min. The untransfected Eca 109 cell line was used as a negative control.

Western blot and immunocytocheimstry

Cells (3×10^5) were harvested and dissolved by the addition of sodium dodecyl sulfate (SDS)-containing lysis buffer. The lysate was used for SDS-polyacrylamide gel electrophoresis on a 75g·L^{-1} gel. The proteins were electrophoretically transferred from the gel to NC membrane. The transferred membrane was treated with polycolonal antiserum against Egr-1 protein (1:200, Santa Cruz Biot Co, USA) followed by detection with peroxidase-labeled goat anti-rabbit (1:1000, Dako, USA). The resulting complexes were detected with the ECL reagent (Amersham Company, UK) according to the manufacturer's instructions. The Egr-1 protein was detected by immunocytochemistry.The untransfected Eca 109 cell line was used as a negative control.

Detection of biological feactures in transfected cells

Growth curve assays Cells (1×10^4) were seeded in each well of a 24-well plate and were allowed to grow for varying periods. The trypsinized cells were counted by cell counter plate. The growth assays were made by counting in triplicate on every other day of culture for up to 7d followed by constructing the cell growth curves.

Soft agar culture The anchorage independent growth was examined by seeding 1000 cells in 3g·L^{-1} agar medium into 60mm plates previously lined with 5g·L^{-1} agar medium. The plates (in triplicate and repeated twice) were cultured at 37℃, 50mL·L^{-1} CO_2 incubator for 14d. The average number of colony formation (any colony containing >50 cells was counted as a colony) and the colony formation rate (the number of colonies/the number of seeded cells) were calculated.

Tumorigenicity in SCID mice Two groups were divided randomly. The experimental group that consisted of 6 mice was used for Eca 109 cells with transfected Egr-1 injection. The control group of 4 mice was used for Eca 109 cells without transfected Egr-1 injection. Trypsinized cells (5×10^6) were injected into the subcutaneous sites on the shoulders of SCID mice. Animals were inspected at regular intervals for the appearance of visible tumors to measure the time of first appearance. Thirty days later, the mice were sacrificed and the tumors were carefully removed by blunt dissection. The tumors were weighed and their average growth rates were measured as mg·d^{-1}.

Egr-1 in situ hybridization

The expression of Egr-1 was detected by digoxigenin-labeled gene probe from a commercial kit (Boster Company, China) according to the manufacturer's instructions. The human breast tissue and the mouse brain tissue were used as the positive control. Either the sections detected with incubation solution instead of the probe or the sections digested with ribonucleases (RNase) (10mg·L^{-1}) before Egr-1 detection was designed for the negative control. The positive expression showed the brown staining signal in the cytoplasm.

Immunohistochemistry

Egr-1 was analyzed by using Egr-1 rabbit polyclonal antiserum with the SABC method according to the manufacturer's instructions (Boster Company, China) following treatment with 3.3'-diaminobenzidine (DAB) staining. The human breast tissue and the mouse brain tissue were used as the positive control. Negative control was designed using phosphate-buffered saline (PBS) instead of Egr-1 rabbit polyclonal antiserum in detection. The positive expression showed the brown staining signal in nuclei.

Statistical analysis

The data were statistically analyzed using Student's *t* test and the difference of results was analyzed by *U* test and χ^2 test.

RESULTS

Identification of plasmid

The eukaryotic expression vector of PCMV-Egr-1 plasmid was tested by PCR amplification, purification and restriction endonuclease and confirmed to be consistent with the plasmid map. With single digestion of *Sac* II, a 7.6kb band was obtained which represents the whole lengh of the plasmid DNA. With double digestion of *Sac* II combining with *Sma* I, both 5.5kb and 2.1kb bands were obtained which represented the fragment of the vector and Egr-1 gene fragment respectively (Figure 1).

Gene transfection

Eca109 was transfected with PCMV-Egr-1 plasmid by lipofectamine transfection method. Four weeks after G418 selection culture, the resistant colonies were formed. PCR

indicated that 327bp of neogene was shown in transfected Eca109 compared to the negative band in control Eca109 (Figure 2), demonstrating that PCMV-Egr-1 plasmid had been introduced into Eca109 cell and integrated into the genomic DNA.

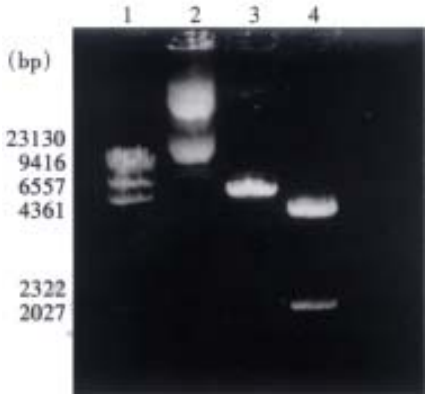

Figure 1 Identification of PCMV-Egr-1 plasmid.
1. Marker; 2. Uncut plasmid; 3. Cut with *Sac* II, showing 7.6kp fragment of whole plasmid; 4. Cut with *Sac* II and Sma I, showing 5.5kp fragment of vector and 2.1kp fragment of Egr-1 gene.

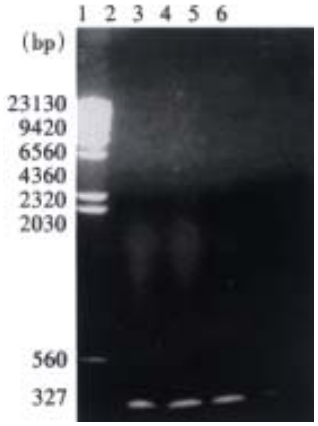

Figure 2 PCR amplification of neogene.
1. Marker; 2-5. For transfected Eca109, showing 327bp of neogene; 6. Negative control Eca109, no band was shown.

Detection of Egr-1 protein in transfected Eca109

Western blot The 80kd of Egr-1 protein was shown for transfected Eca109 compared to the negative band of the control Eca109.

Immunocytochemistry The transfected Eca109 was positively brown stained in the nucleus compared to the negative staining for control Eca109 (Figure 3). The results demonstrated that exogenous Egr-1 gene introduced into Eca109 expressed high level of Egr-1 protein.

Growth feature of transfected Eca109

Growth curves The transfected Eca109 grew much more slowly in DMEM medium than the control Eca109 cell (Figure 4).

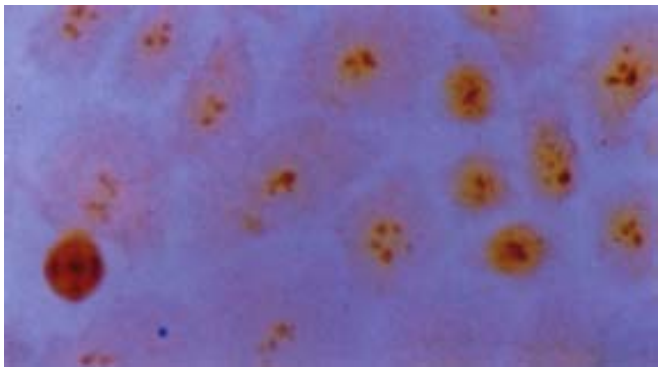

Figure 3 Positive Egr-1 protein in nuclei of transfected Eca109 cells. ICC ×400

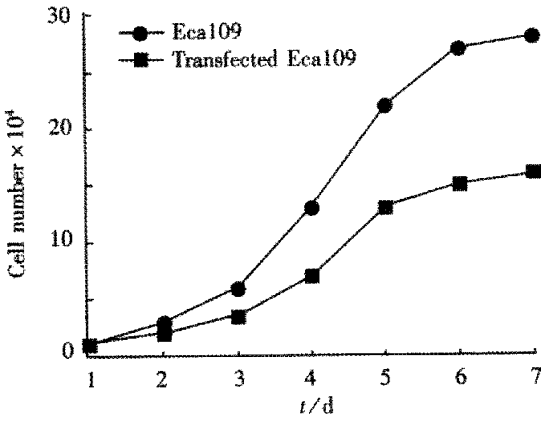

Figure 4 Cell growth curves showing lower growth rate in transfected Eca109 cell than in the control Eca109 cell.

Soft agar growth assay Small and few colonies were formed slowly in transfected Eca109 compared to large and numerous colonies formed quickly in control Eca109. The colony formation rates were 4.0% and 6.9% in transfected Eca109 and in control Eca109 respectively (Table 1) which demonstrated that the anchorage independent growth ability of Egr-1 expressing Eca109 was reduced.

Table 1 Soft agar assays in Eca109 cell line

Cell line	No. of seeded cell	No. of colonies				CFR
		1	2	3	Mean	
Eca109	1000	65	71	73	69±2.4	6.9%
Egr-1-Eca109	1000	40	43	39	40±1.2	4.0%[b]

[b]$P<0.01$, *vs* Eca109, *U* test.

Tumorigenicity in SCID mice The tumorigenicity test showed that the tumors started to appear on the 21st day after injection in the six SCID mice injected with transfected Eca109, and on the 14th day in four SCID mice injected with control Eca109. The tumors of Egr-1 expressing Eca109 grew slowly with an average growth rate of 35.5mg·d^{-1}, and the tumors of control Eca109 grew fast with an average growth rate of 65.8mg·d^{-1} (Figure 5, Table 2). The results demonstrated that the tumorigenicity in SCID mice of Egr-1 transfected Eca109 was inhibited.

Table 2 Tumorigenicity assays in Eca109 cell line

Cell line	Tumorigenicity rate	Growth rate of tumors(mg·d^{-1})						
		1	2	3	4	5	6	Mean
Eca109	4/4	83.3	70.0	46.6	63.3			65.8±7.6
Egr-1-Eca109	6/6	20.0	13.3	33.3	66.6	43.0	36.7	35.5±7.6[a]

[a]P<0.05, *vs* Eca109, Student's t test.

Egr-1 expression on esophageal tissues

In simple hyperplastic epithelia of esophageal mucosa, the expression of Egr-1 was found in the basal layer of the mucosa (Figure 6). In dysplastic epithelia, the expression of Egr-1 increased but significantly decreased in cancer tissues in which only a few cases of well-differentiated squamous cell carcinoma had the Egr-1 expression (Figure 7). The expression of Egr-1mRNA and proteins in the various pathological changes of esophagus are shown in Table 3.

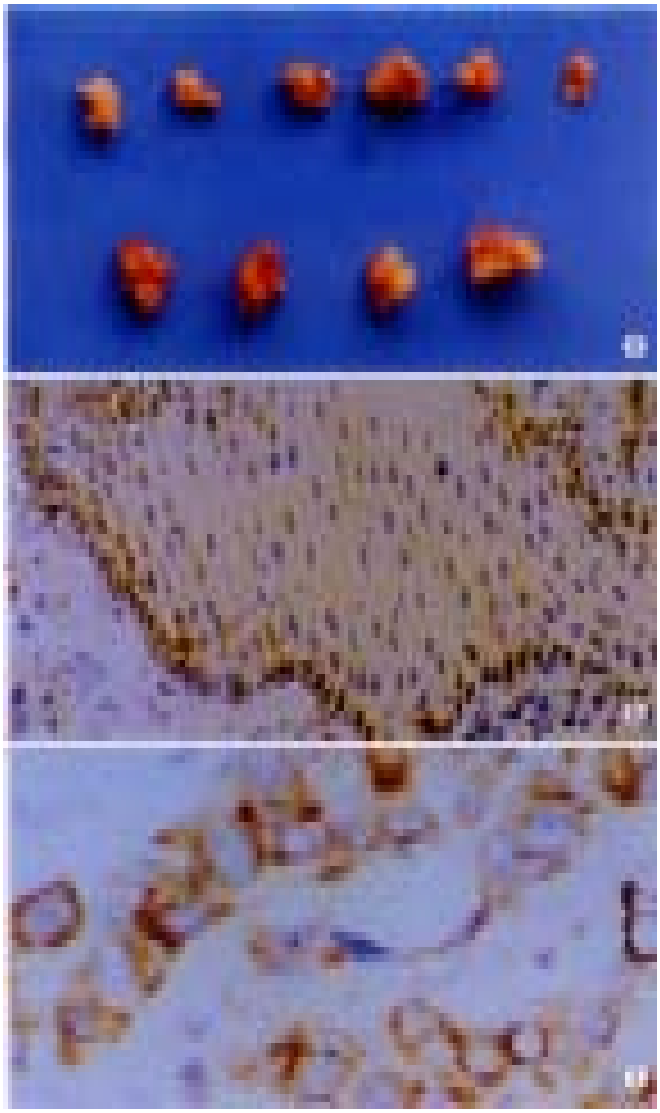

Figure 5 The tumors of transfected Eca109 are smaller than that of control Eca109, *in vitro*, 30 d after injection in tumorigenicity test in SCID mice.

Figure 6 Egr-1 protein expression in basal mucosal layer in simple hyperplastic epithelia of esophagus. IHC ×200

Figure 7 Positive Egr-1 mRNA in cytoplasm of esophageal squamous cell carcinoma. ISH ×400

Table 3 Expression of Egr-1mRNA and proteins in various pathological changes of esophagus, n(%)

Group	n	ISH	IHC

[a]P<0.05, *vs* simple hyperplasia, χ^2 test; [b]P<0.01, *vs* dysplasia,χ^2 test.

DISCUSSION

As we know, the oncogenes and tumor suppressor genes are involved in the pathogenesis and development of esophageal carcinoma[18-32]. Recent studies in dicate that Egr-1 gene as a tumor related-gene is correlated with the tumor development. It was reported that Egr-1 proteins were decreased and even disappeared in several kinds of cancer tissues. Furthermore, the Egr-1 mRNA expression was consistent with the expression level of Egr-1 protein which had been verified in the down-regulation of Egr-1 occurred at the transcription level in cancer cells[33]. Southern blot analysis indicated no deletion, no rearrangement or mutation of Egr-1 on DNA level. The exogenous introduction of Egr-1 could inhibit the growth of tumor cells accompanied in a dose-dependent manner, for example, the ability of anchorage independent growth and tumorigenicity in SCID mice of human HT1080 fibrosarcoma without original Egr-1 was significantly inhibited after the exogenous introduction of Egr-1. If the antisense Egr-1 was introduced to the cells, it would inhibit the endogenous Egr-1 expression and promote the malignant transformation of the cells. In the present study, eukaryotic expression vector of PCMV-Egr-1 plasmid was introduced into Eca109 cell line that expressed no Egr-1 protein originally with Lipofectamine transfection method. The introduction and expression of PCMV-Egr-1 plasmid into Eca109 cell line was confirmed by G418 selection culture by which colony formation persisted in next generations and by PCR amplification of neogene contained in the vector. Furthermore, the strong expression of Egr-1 protein in transfected Eca109 was detected by Western blot and immunocytochemistry, which verified the success of gene transfection. Growth inhibition of the transfected cells shown by the growth curves, the colony formation rates in the soft agar and tumorigenicity in SCID mice demonstrated that exogenous Egr-1 gene inhibited the growth of Eca109.

Recent studies suggest that the mechanism of suppression of tumor growth by Egr-1 is the Egr-1 protein with a zinc-finger domain which regulates the transcription of many downstream genes by binding to the GC rich element in the promoter region and modulates genes transcription and various biological effects[34-45]. Egr-1 can compete with transcription activator SP1 in binding to an overlapping consensus binding motif in the promoter region of GCE which commonly exists in oncogene and tumor suppressor gene and abolishes the function of SP1, leading to the transcription inhibition of downstream genes and growth inhibition of tumor cells[46,47]. In addition, the exogenous Egr-1 may inhibit the growth by binding to the GEE of TGF-β1 and activating the transcription of TGF-β1 and subsequently activating p21 gene or by down-regulating Bcl-2 gene to influence the tumor cells[48,49]. Some

studies indicated that the activation of some oncogenes e.g. wild type *p*53 gene, cell apoptosis, the TNF-α and the concentration of calcium may be involved in the mechanism of growth inhibition property of Egr-1[50,51]. On the whole, various and complicated mechanisms may be involved in the suppressive property of Egr-1 for tumor growth.

Egr-1 is one of the immediate early gene family which regulates the cellular growth and differentiation by activating Cyclin D1 to promote the cells from the G_0/G_1 phase into the G2/M phase[52]. The mechanism of down-expression of Egr-1 in cancer tissues is not clear up to now. It was hypothesized that the high concentration of Egr-1 proteins produced by overstimulation of Egr-1 interacted with the promoter region of EBS and subsequently the gene transcription was inhibited, which was concordant with the present results that showed strong expression of Egr-1 in dysplastic cells adjacent to esophageal carcinoma and weekly expression in cancer cells.

Since only downregulation expression without gene mutation occurred in Egr-1 DNA level, it was different from some tumor suppressor genes such as *p*3, *p*16 and Rb with mutation gene on DNA level. It is more convenient to introduce normal exogenous gene into the tumor cells than to repair mutation gene in gene therapy. The present study substantiates that exogenous Egr-1 as a target gene has a potential application in gene therapy of esophageal carcinoma.

Abstract

AIM **To investigate if sleep deprivation is able to increase the expression of inducible heat shock protein 70 in gastric mucosa and its possible role in mucosal defense.**

METHODS **Rats for sleep disruption were placed inside a computerized rotating drum, gastric mucosa was taken from rats with 1, 3 and 7d sleep deprivation. RT-PCR, immunohistochemistry and Western blotting were used to determine the expression of heat shock protein 70. Ethanol (500mL·L^{-1}, i.g.) was used to induce gastric mucosa damage.**

RESULTS **RT-PCR, Western blotting and immunostaining confirmed that the sleep deprivation as a stress resulted in significantly greater expression of inducible heat shock protein 70 in gastric mucosa of rats. After the 500mL·L^{-1} ethanol challenge, the ulcer area found in the rats with 7d sleep deprivation (19.15±4.2)mm^2 was significantly lower (P<0.01) than the corresponding control (53.7± 8.1) mm$_2$.**

CONCLUSION **Sleep deprivation as a stress, in addition to lowering the gastric mucosal barrier, is able to stimulate the expression of inducible heat shock protein 70 in gastric mucosa of rats, the heat shock protein 70 may play an important role in gastric mucosal protection.**

INTRODUCTION

Stress has been shown to induce gastric mucosal lesions and lower the effectiveness of the mucosa as a barrier[1-6]. In rats, gastric ulcers can be produced by cold-restraint stress[7-9] and it is frequently employed as a model for the study of the mechanisms of stress on ulcer formation. Cold-restraint stress, however, is not normally encountered in human subjects while sleep deprivation is a common experience among city dwellers. swift workers and medical professionals. It imposes stress on the body, and produces a variety of health problems[10-14]. Sleep deprivation is associated with poor congitive ability, and shortening of longevity[15]. Studies have found that the cognitive function of doctors after a night shift was considerably decreased. Sleep deprivation is also a major problem in the intensive care units and it has been suggested to affect the healing process of patients thus contributing to an increase in morbidity and mortality[16]. Sleep deprivation has been shown to induce typical dermatitis in experimental animals. Severe ulcerative and hyperkeratotic skin lesions localized to the paws and tails developed in rats deprived of sleep[17]. This effect of sleep deprivation may affect the epithelial linings of the gastrointestinal tract, because stress has been demonstrated to produce gastric mucosal lesions in rats[18,19]. Our previous works showed that the food and water consumption in sleep disturbed rats were not affected but they had a smaller percentage gain in body weight. The locomotion activities of sleep disturbed rats were similar to the controls, however, their adrenal weights were increased[20]. The mucosal epithelial cell proliferation rate was also suppressed by sleep disturbance. Although various factors have been proposed to account for this process, the precise mechanism of how sleep deprivation affects the gastric mucosa barrier, especially at the molecular level, still remains unclear. Previously, we used cDNA expression arrays to identify genes that abnormal expressed in gastric mucosa of sleep deprivation rats[20]. In this project, inducible heat shock protein 70, one candidate gene emerging from cDNA array for its potential significance was further analyzed.

MATERIALS AND METHODS

Rats and reagents

Male Sprague Dawley rats weighing 180g-200g were used in the experiments. They were housed in a temperature 22℃ ± 1℃ and humidity 65% - 70% controlled room with a day night cycle of 12h. The rats were given standard laboratory diet (Ralston Purina Co., Chicago, IL) and tap water *ad libitum*. Rats were starved for 24h and water withdrawn 1 hour prior to any oral or intragastric administration of agents in order to obtain a uniform distribution of those agents onto the gastric mucosa. All chemicals used in this study were purchased from Sigma Chemical Co. (St. Louis, USA) unless specified otherwise. The present study has been examined and approved by the Committee on the Use of Live Rats for Teaching and Research of the University of Hong Kong.

Sleep disturbance

Rats for sleep disruption were placed inside a computerized rotating drum while the control animals were left undisturbed in a stationary drum. The drum was rotated 180° in 30s at 5 minutes intervals and was programed to switch off for 1h

every day at 13:00 to allow for an hour of undisturbed sleep. Sleep disturbance was continued for 1wk before the animals were killed.

Collection of gastric mucosa

Rats were killed by ether anesthesia followed by cutting off the abdominal aortic artery. The stomachs were removed rapidly, opened along the greater curvature, and rinsed with cooled normal saline thoroughly. A longitudinal section of gastric tissue was taken from the anterior part of the stomach and then fixed in 100mL·L^{-1} buffered formalin for 24h. It was cut into sections of 5μm and then used in immunostaining. Gastric mucosa was taken from the remaining part of the stomach by scraping with a glass slide on a glass dish on ice. They were wrapped by a piece of aluminum foil, immediately froze in liquid nitrogen and stored at -70℃ until assayed.

Detection of inducible heat shock protein 70 *mRNA expression by RT-PCR*[21-23]

Total RNA was extracted from gastric mucosa of rats by using Trizol reagent (Gibco BRL, Gaitherburg, MD). First-strand complementary DNAs were synthesized from 5μg RNA by using oligo dt primer and Thermoscript RT-PCR system (Gibco BRL, Gaithersburg, MD). The PCR cycle was performed for in ducible heat shock protein 70 and β-actin from the same complementary DNA sample using a PCR Thermal Cycler (Gene Amp PCR System 9700, The Perkin-Elmer Corporation, Norwalk, CT). The sequence of the oligonucleotide primers are as follows: sense inducible heat shock protein 70, 5'-TGCTGACCAAGATGAAG-3'; antisense inducible heat shock protein 70, 5'-AGAGTCGATCTCCAGGC-3'[24] and sense β-actin, 5'-GTGGGGCGCCCCAGGCACCA-3'; antisense β-actin, 5'-CTCCTTAATGTCACGCACGATTTC-3'[25]. After-denaturation for 10 min at 95℃, 30 cycles of amplification were carried out followed by final extension of 10 min at 72℃, each step for 1 min. After amplification, 10μL of PCR products were electrophoresed in a 1% agarose gels containing 0.5μg/mL ethidium bromide.

Immunohistochemical detection of inducible heat shock protein 70 in gastric mucosa[26-30]

Fixed tissue sections (5μm) were mounted on Vectabond Reagent-coated slides, deparaffinized and rehydrated through xyline, graded ethanol to distilled water. After blocking endogenous peroxidase with 3mL·L^{-1} hydrogen peroxide in methanol for 30 min, sections were treated with 0.05mol·L^{-1} phosphate-buffered saline containing 30mL·L^{-1} normal horse serum and 3g·L^{-1} Triton X-100 for 30min, then the sections were rinsed with PBS, incubated with mouse anti-rat monoclonal antibody (StressGen Biotechnologies Corp. Victoria, Canada, Cat# SPA-810) at dilution of 1:200 overnight at 4℃ in a humidity chamber. The secondary, biotinylated antibody (LSAB kit, Dako, Denmark) was then applied for 30 min followed by rinsing with PBS. Staining was performed by the addition of streptavidin (LSAB kit, Dako, Denmark) for 30 min, rinsed in PBS and developed in 3, 3'-diaminobendine tetrahydrochloride for about 3 min. Sections were counterstained with Mayer's hematoxylin, dehydrated, cleared and mounted.

Detection of inducible heat shock protein 70 *proteins expression by Western blotting*

The gastric mucosa were homogenized at 4℃ in RIPA buffer (50 mmol·L^{-1} Tris-HCl, pH 7.5, 150 mmol·L^{-1} NaCl, 1g·L^{-1} sodium dodecyl sulfate, 5g·L^{-1} a-cholate, 2 mmol·L^{-1} EDTA, 10 g·L^{-1} Triton X-100, 100 mL·L^{-1} glycerol) containing 1 mmol·L^{-1} PMSF and 10 mg·L^{-1} aprotinin. After centrifuged at 10000×*g* at 4℃ for 20 min, the supernatant (50μg of total protein) were denatured and separated on 75g·L^{-1} sodium dodecyl sulfate-polyacrylamide gel electrophoresis, and then transferred to nitrocellulose membrane (Bio-Rad, Hercules, CA)[31,32]. The membranes were blocked with blocking buffer (50mL·L^{-1}) nonfat milk in wash buffer (20 mmol·L^{-1} PBS, pH 7.5 containing 100mmol·L^{-1} NaCl and 1g·L^{-1} Tween 20) for 1h at room temperature, and subsequently incubated at 4℃ with mouse monoclonal antibody against rat inducible heat shock protein 70 (StressGen Biotechnologies Gorp. Victoria, Canada, Cat # SPA-810) diluted in blocking buffer (1:1000). Membranes were washed 6 times and incubated with a rabbit-anti-mouse immunoglobulin G conjugated with the horseradish peroxidase (1:4000) (Bio-Rad Laboratories) for 1h . After six times additional washes, membranes were developed by a commercial chemiluminescence system (Amersham, Arlington Heights, IL) and exposed to X-ray film. Protein determinations were made with Bio-Rad protein assay kit with bovine serum albumin as a standard. Prestained molecular-weight standards (Bio-Rad) were used as markers.

Ethanol-induced gastric mucosal damage

Rats were starved for 24h before 1mL of 500mL·L^{-1} ethanol was administered orally to induce acute gastric mucosal damage[33]. Rats were killed 2h later by a sharp blow on the heads followed by cervical dislocation. The stomach was removed and opened along the greater curvature. The gastric lesion area (mm^2) was traced onto a glass plate and subsequently measured on a graph paper with 1mm^2 division[34]. The lesion index was calculated by dividing the total lesion area with the number of rats in each group.

Statistics

The data were statistically analyzed with the unpaired two-tailed Student's *t* test.

RESULTS

Sleep deprivation increase the expression of inducible heat shock protein 70

Total RNA and protein were isolated from rats' gastric mucosa at various times of sleep deprivation. As shown in Figure 1, RT-PCR results indicated that the expression of inducible heat shock protein 70 mRNA was low in normal gastric mucosa. Following the sleep deprivation, inducible heat shock protein 70 mRNA expression was elevated. The pattern of inducible heat shock protein 70 protein accumulation showed a similar trend to mRNA expression (Figure 2).

Inducible heat shock protein 70 immunohistochemistry in gastric mucosa

To further prove that inducible heat shock protein 70 is increased in gastric mucosa of sleep deprived rats, confirm their expression at protein level, and determine their cellular sources, immunostaining for iHsp 70 was performed on gastric mucosa of sleep deprived rats and normal rats. The results showed that inducible heat shock protein 70 staining was nearly absent in normal mucosa but in mucosa of sleep deprived rats was detected in epithelium (Figure 3).

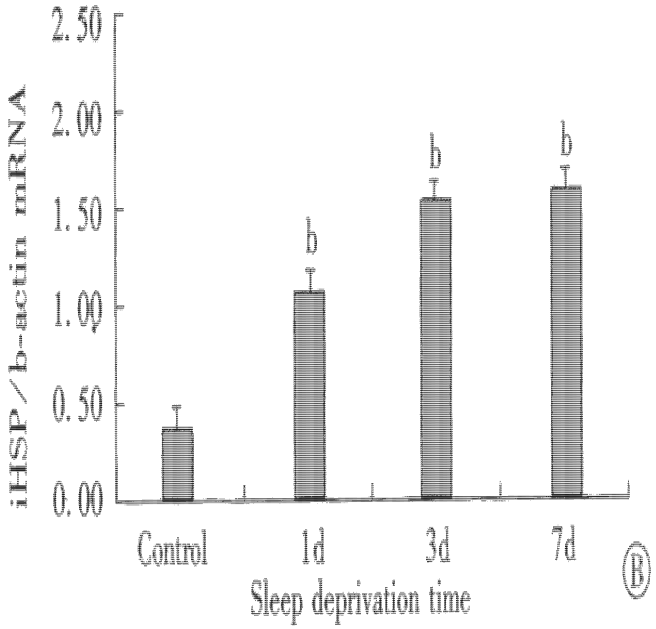

Figure 1 Effect of sleep deprivation in inducible heat shock protein 70 mRNA expression in gastric mucosa of rats. Inducible heat shock protein 70 mRNA was determined by RT-PCR.

Sleep deprivation decrease ethanol induced gastric ulceration

After the 500mL·L^{-1} ethanol challenge, the ulcer area found in the rats with 7d sleep deprivation (19.2±4.2) mm^2 was significantly lower (P<0.01) then the corresponding control (53.7±8.1) mm^2, as shown in Figure 4.

DISCUSSION

In our previously experiment, cDNA arrays were used to search for genes that were differentially expressed in gastric mucosa of sleep deprivation rats compared to gastric mucosa of control rats. More than 10 differentially expressed genes were found in total 588 genes, most of these were digestive enzyme related genes, one of the overexpression gene was inducible heat shock protein 70 gene[20]. A variety of chemicals, viruses, and noxious stimuli such as trauma, hypoxia, or ischemia trigger the heat shock response and the subsequent synthesis of heat shock proteins[35-43]. The results of our experiment indicated that sleep deprivation as a stress resulted in significantly greater expression of inducible heat shock protein 70 in gastric mucosa of rats, which was confirmed by RT-PCR, Western blotting and immunostaining. Substantial evidence showed that heat shock is capable of protecting cells, tissues and organs, and animals from a subsequent, normally lethal heating, as well as from other types of noxious condition[44]. The protective effect of heat shock is likely mediated by overexpressed heat shock protein 70, because there is a lag between heat shock and the development of protection correlated with the production of heat shock protein 70, and protection is affected when heat shock protein 70 production is inhibited by treatment with inhibitors[45-47]. Microinjection of anti-heat shock protein 70 antibody into fibroblasts to neutralize heat shock protein 70 increases the vulnerability of the cells to sublethal temperatures[48]. Furthermore, heat shock protein 70 also provides protection when induced by methods other than heat shock, such as rats that overexpress heat shock protein 70 induced by methods other than heat shock display protection of the lungs from sepsis-induced injury[49] and a reduction in hepatocyte apoptosis induced by tumor necrosis factor-α[40]. Transgenic mice that overexpress heat shock protein 70 demonstrate resistance to adverse effects of lethal heat or ischemia[41]. Similar evidence has been derived from the study of cultured cells after heat shock or heat shock protein 70 gene transfection to promote overexpression of heat shock protein 70[50,51]. Our results showed that sleep deprivation was able to decrease the gastric mucosa damage caused by 50% ethanol. Although we cannot completely preclude the possibility that the vascular, neural, and hormonal factors may be involved in this mucosa protective effect, our previous work showed that sleep deprivation decreased the gastric mucosal blood flow, hampered the ability of the gastric mucosa to repair itself by slowing down its cellular replication rate, and depressed gastric potential difference. In conclusion, our results lead us

to speculate that the heat shock protein 70 may play an important role in gastric mucosal protection.

ACKNOWLEDGEMENTS We would like to thank Mr. Leung for his technical assistance in constructing the rotating drum.

Abstract

AIM **To establish the role of vascular endothelial growth factor (VEGF) in the oncogenesis of human gastric carcinoma more directly.**

METHODS **The expression of VEGF and its receptor kinase-domain insert containing receptor (KDR) in human gastric cancer tissue were observed by immunohistochemical staining. VEGF levels were manipulated in human gastric cancer cell using eukaryotic expression constructs designed to express the complete $VEGF_{165}$ complimentary DNA in either the sense or antisense orientation. The biological changes of the cells were observed in which VEGF was up-regulated or down-regulated.**

RESULTS **VEGF-positive rate was 50%, and VEGF was mainly localized in the cytoplasm and membrane of the tumor cells, while KDR was mainly located in the membrane of vascular endothelial cells in gastric cancer tissues and peri-cancerous tissue. In 2 cases of 50 specimens, the gastric cancer cells expressed KDR, localized in both the cytoplasm and membrane. Introduction of $VEGF_{165}$ antisense into human gastric cancer cells (SGC-7901, immunofluorescence intensity, 31.6%)) resulted in a significant reduction in VEGF-specific messenger RNA and total and cell surface VEGF protein (immunofluorescence intensity, 8.9%) (P<0.05). Conversely, stable integration of $VEGF_{165}$ in the sense orientation resulted in an increase in cellular and cell surface VEGF (immunofluorescence intensity, 75.4%) (P<0.05). Lowered VEGF levels were associated with a marked decrease in the growth of nude mouse xenografted tumor (at 33 days postimplantation, tomor volume:** 345.40±136.31 **mm^3) (P<0.05 *vs* control SGC-7901 group:** 1534.40±362.88 **mm^3), whereas up regulation of VEGF resulted in increased xenografted tumor size (at 33 days postimplantation, tomor volume:** 2350.50±637.70 **mm^3) (P<0.05 *vs* control SGC-7901 group).**

CONCLUSION **This study provides direct evidence that VEGF plays an important role in the oncogenesis of human gastric cancer.**

INTRODUCTION

It is known that malignant tumors depend on neovascularization for their growth and metastasis[1,2]. Recently, many studies have shown that the secretion and activation of various endothelial growth factors, called angiogenic factors, by tumor cells plays a crucial role in the formation of neovasculature[3-8]. VEGF is a powerful mitogen for vascular endothelial cells, both *in vitro* and *in vivo*. In addition, VEGF has the property of inducing vascular permeability *in vivo*. Three evidences for the central role played by VEGF in tumor angiogenesis were: ① the detection of high levels of VEGF expression in palisading cells around regions of necrosis in a number of solid tumor systems, coupled with the rapid induction of VEGF when tumor cells are grown under hypoxic conditions[9,10]; ② injection of antibodies against VEGF markedly reduced the *in vivo* growth of s.c. injected tumor cells, which are known to produce robust tumor angiogenesis[11]; and ③ introduction into tumor endothelial cells of a dominant-negative version of VEGF-R_2 by means of retroviral transfer markedly reduced tumor size[12]. The current study was designed to establish the role of VEGF in the oncogenesis of human gastric cancer more directly.

SUBJECTS AND METHODS

Immunohistochemistry

Resected specimens from 50 patients with gastric carcinoma who underwent gastrectomy at our institute were studied. The patients ranged in age from 27 to 76 years (average 56.3 years); 40 were men, and 10 were women. No patient had received chemotherapy or radiation therapy before surgery. Specimens were fixed in a 40g·L^{-1} formaldehyde solution and embedded in paraffin. Five μm thick sections were cut and mounted on glass slides. Immunohistochemistry was performed using the avidin-biotin complex method. Sections were dewaxed in xylene, taken through ethanol, and then incubated with 30mL·L^{-1} hydrogen peroxide in methanol for 30 minutes to block endogenous peroxidase activity. Sections were then washed in phosphate-buffered saline and incubated in 20mL·L^{-1} normal goat serum for 30 minutes to reduce nonspecific antibody binding. The antibody for VEGF and

KDR (Santa Cruz Biotechnology, Inc, Santa Cruz, CA) were used respectively. Specimens were then incubated with a 1:500 dilution of anti-VEGF antibody overnight at 4℃, followed by three washes with PBS. Sections were then incubated with biotinylated goat antirabbit immunoglobulin G (Sino-American Biotechnology Co.) at a dilution of 1:100 for 2 hours followed by 3 washes. Slides were then treated with the complex of Reagent A and Reagent B (ABC kit, Sino-American Biotechnology Co.) for 2 hours at a dilution of 1:100 and were washed with phosphate-buffered saline 3 times. Finally, slides were incubated in phosphate-buffered saline containing diaminobenzidine and 300 $mL \cdot L^{-1}$ hydrogen peroxide for 10 minutes. Normal rabbit immunoglobulin-G was substituted for primary antibody as the negative control.

Plasmid constructs

pGEM-hVEGF is pGEM-3Zf(+) derivative Promega cloning vector plasmid containing the complete complementary DNA (cDNA) sequence of human $VEGF_{165}$ (this plasmid was generous gifts from Judith Abraham, Scios Nova, Inc.)[13]. The $VEGF_{165}$ cDNA was subcloned into the $pCDNA_3$ eukaryotic expression vector using the Eco-RI and *Xba* I or *Eco*R I and *Hin*d III restriction enzyme sites in sense or antisense orientation respectively. Restriction enzyme analysis (*Eco*R I, *Xba* I and *Hin*d III) and dideoxy sequencing method were used to confirm the orientation and quality of the VEGF cDNA in the $pCDNA_3$ vector, respectively.

Gastric cancer cell line culture conditions

Cell line SGC-7901 was derived from a moderately-differentiated gastric adenocarcinoma and has been characterized extensively[14]. The cells were routinely cultured in RPMI 1640 / 100 $mL \cdot L^{-1}$ NCS (heat-inactivated) and 2 $mmol \cdot L^{-1}$ L-glutamine in a humidified atmosphere of 50 $mL \cdot L^{-1}$ CO_2 at 37℃, supplemented with penicillin (100 $KU \cdot L^{-1}$) and streptomycin (100$mg \cdot L^{-1}$).

Liposome-mediated transfection

Human SGC-7901 cells were grown in RPMI 1640 / 100$mL \cdot L^{-1}$ NCS in 6-well tissue culture dishes to 50% confluence. The lipofect Amine-mediated transfection (Gibco/BRL) was performed as described previously using 2μg of recombinant constructs DNA (or $pCDNA_3$ vector alone)[15]. After 48h, they were trypsinized from the plates and dilute cells into selective medium containing Geneticin G_{418} (350$mg \cdot L^{-1}$). Cell death was observed after 3 days in culture, and discrete colonies were apparent by 10 days post-selection. Individual colonies were then isolated and grown in 24-well culture plates. Genomic DNA and total RNA were then isolated from these colonies, and PCR analysis and RNA dot blotting were performed. Clones demonstrated to express the sense and antisense-VEGF constructs were then recloned by growing single cell in 96-well plates.

Detection of expression constructs in genomic DNA by PCR

PCR was used to determine which human gastric cancer cell clones were successfully transfected with the sense or antisense-VEGF construct. PCR was performed on genomic DNA isolated from human SGC-7901 gastric cancer cells and individual clones of transfected cells using a sense primer(a) that corresponds to the 5' initial sequence of VEGF cDNA insert (5'GCACCCATGGCAGAAGGAGGAG 3') or an antisense primer (b) that corresponds to the 3' terminal sequence (5'TCACCGCCTCGGCTTGTCACATC 3') and a primer that corresponds to the SP_6 transcription start of the $pCDNA_3$ expression vector (5'GATTTAGGTGACACTATAG 3'). The PCR reaction was performed using standard protocols with 30 cycles of 50s at 94℃, 50s at 55℃ and 60s at 72℃. Appropriately sized amplification products were verified by agarose gel electrophoresis. Negative controls lacking target DNA or containing a nonhomologous plasmid routinely did not show amplification.

RNA dot blotting

Total RNA was isolated from parental and derivative cell lines using the Trizol reagent (GIBCO/BRL). The samples were serially diluted in diethyl pyrocarbonate-treated water containing placental RNase inhibitor (Boehringer Mannheim) to produce working stocks with a final concentration of 10$mg \cdot L^{-1}$ as spectrophotometrically. Denatured RNA was immobilized on nitrocellulose membranes (Boehringer Mannheim). "Run-off" digoxigenin (DIG) labeled riboprobes specific for the sense or antisense strands of VEGF was synthesized from appropriately linearized plasmid stocks using the DIG-RNA labeling kit (Boehinger Mannheim) and appropriate RNA polymerase (Promega) plus 10U placental RNase inhibitor. The specificity of each probe stock was verified by hybridization to originating plasmids and negative controls. The blots were prehybridized in DIG easy Hyb buffer (Boehringer Mannheim), then hybridized for 18 hours at 60℃ in buffer containing 100$\mu g \cdot L^{-1}$ of sense or antisense-specific DIG-labeled probe. After hybridization, the blots were washed extensively and the extent of hybridization was visualized colorimetrically using reagents from the DIG nucleic acid detection kit, Boehringer Mannheim).

Immunofluorescence staining

Confluent monolayers of parental and derivative cell lines were harvested in calcium and magnesium free Dulbeco's phosphate-buffered saline (CMF) supplemented with 2$mmol \cdot L^{-1}$ EDTA. These stocks were pelleted by centrifugation, resuspended in ice cold CMF with 10$g \cdot L^{-1}$ bovine serum albumin and 0.2$g \cdot L^{-1}$ sodium azide, quantitated for viability by trypan blue dye exclusion, and then diluted to a final total viable cells concentration of $1 \times 10^9 \cdot L^{-1}$. Each stock was then exposed to anti-VEGF for 1 hour at 4℃. The cells were washed three times with ice-cold CMF with 10$g \cdot L^{-1}$ bovine serum albumin, then exposed to a 1:20 dilution of fluorescein isothiocyanate- conjugated goat anti-rabbit IgG (Boehringer Mannheim) for 30 minutes at 4℃. The cells were washed twice in CMF, and extent of surface fluorescence for equal number subpopulations of cells was analyzed by fluorescence-activated cell-sorting (FACSTAR; Becton Dickinson) analysis.

In vitro growth rate

Human gastric cancer cells SGC-7901 and its transfected ones with sense or antisense VEGF were cultured at 4×10^4 cells and grown under standard culture conditions. Cell counts were performed on a hemocytometer, initially at 12h time points, and then every 24h for a total of at least 140h. The total number of cells from duplicate experiments was determined as a function of time (h), and the rate of division was calculated from the exponential phase of growth.

In vivo tumor analysis

Adult male or female (nu/nu) mice (5 - 8 weeks of age) received s.c. injections of SGC-7901 gastric cancer cells or SGC-7901 gastric cancer cells transfected with the sense-VEGF or antisense-VEGF constructs. Approximately 10^6 cells

resuspended in a volume of 100μL of serum free cell culture medium were s.c. injected into the dorsa of mice. The mice were monitored daily, and tumor sizes were determined by tridimensional calliper measurements. Tumor volume was calculated as 1/2×length×width 2 (mm^3). Mean tumor volumes were calculated from measurements performed on five mice in each of two individual experiments. The animals were killed 33 days later. s.c. tumors were removed from mice, formaldehyde fixed, and paraffin-embedded. Five μm thick sections were cut and mounted on glass slides. The sections were stained with hematoxylin and eosin[16-18].

RESULTS

VEGF and KDR expressions in human gastric cancer tissues

Among 50 formalin-fixed, paraffin-embedded surgically resected tissue specimens of gastric carcinoma, 10 specimens were composed of two different histological type cancer cells, most of which were poorly differentiated adenocarcinoma and mucinous cell carcinoma. Normal gastric mucosa was not immunoreactive with an anti-VEGF antibody. VEGF was mainly localized to the cytoplasm or the membrane of the carcinoma (Figure 1). Tumor cells that stained strongly for VEGF were observed more often in the invasive front than in the tumor center. Weakly positive VEGF staining was seen on some endothelial cells. VEGF expression was detected in 25 (50%) tumors. KDR was mainly localized in the cytoplasm or the membrane of vascular endothelial cells in gastric cancer tissue and peri-cancerous tissue (Figure 2). In 2 cases of 50 specimens, the gastric cancer cells expressed KDR, localized in the cytoplasm and membrane (Figure 3).

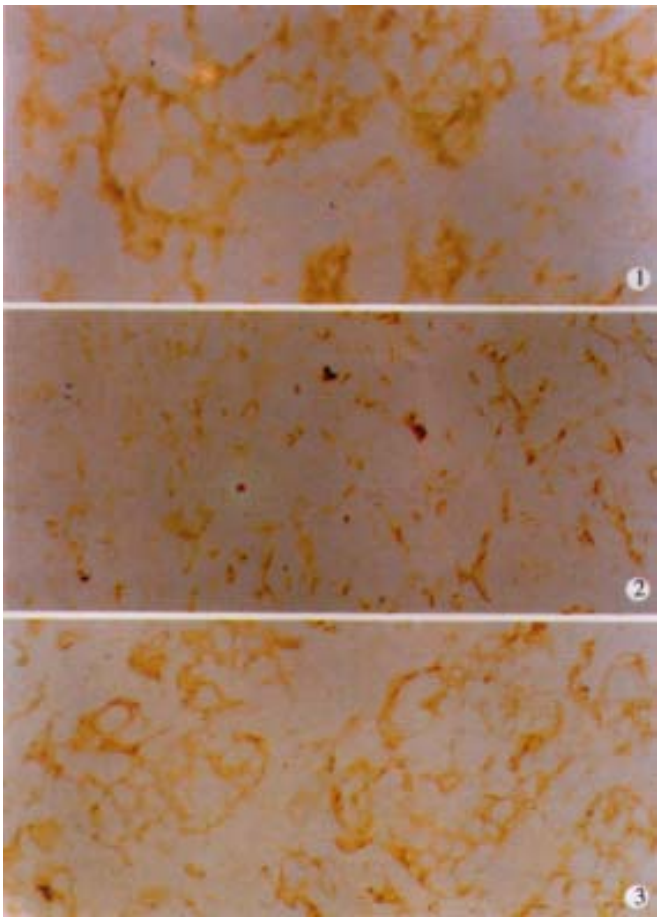

Figure 1 Immunohistochemical staining for VEGF in adenocarcinoma tissues of the stomach. The positive signal was found mainly on the surface and in the cytoplasm of gastric cancer cells. ×400

Figure 2 Immunohistochemical staining for flk-1/ KDR in undifferentiated cancer tissues of the stomach. The positive signal was found on the surface of endothelial cells. ×100

Figure 3 Immunohistochemical staining for flk-1/ KDR in adenocarcinoma tissues of the stomach. It was found mainly on the surface and in the cytoplasm of gastric cancer cells. ×200

Cloning of the sense and antisense VEGF Cdna

The $VEGF_{165}$ insert was cleaved from pGEM-3Zf(+) by restriction enzymes digestion and cloned into the same restriction sites of the eukaryotic expression vector, $pCDNA_3$. Restriction enzyme mapping and dideoxy sequencing assay performed on DNA from transformed clones demonstrated the presence of the $VEGF_{165}$ cDNA insert cloned in the sense and antisense orientation in the $pCDNA_3$ vector (Figure 4).

SGC-7901 gastric cancer cells expressing sense or antisense VEGF

Following transfection of human SGC-7901 gastric cancer cells with the sense or antisense VEGF construct (or vector alone control) and subsequent antibiotic selection, individual clones were isolated and grown in 24-well culture plates. Polymerase chain reaction (PCR) analysis of DNA isolated from these clones revealed that the positive clones had the sense or antisense VEGF construct. A selection of these clones were then re-cloned at the level of one cell/well, and the PCR analysis was repeated to confirm expression of the cDNA.

VEGF levels in SGC-7901 cells by stable transfection with sense and antisense VEGF constructs

To better determine whether VEGF plays a functional role in the oncogenesis of gastric cancer, gastric cancer cells were transfected with sense or antisense VEGF expression vector, and the effect on the growth of tumor was evaluated. Stable integration of expression constructs into G_{418}-resistant subclones was shown by PCR-based approach that utilized SP6 and VEGF-specific primer pairs and genomic DNA (see Methods). Introduction of the VEGF antisense construct into SGC-7901 cells resulted in a markedly reduction in the expression of VEGF-specific mRNA by dot blot analysis in SGC-7901/as hVEGF compared with the parental cell line.

Conversely, the expression of VEGF in mRNA level was enhanced in SGC-7901 cells transfected with the sense-VEGF construct. Alterations in total cellular VEGF after transfection with sense or antisense constructs were accompanied by similar changes in cell surface VEGF protein as determined by flow cytometer analysis (Figure 5).

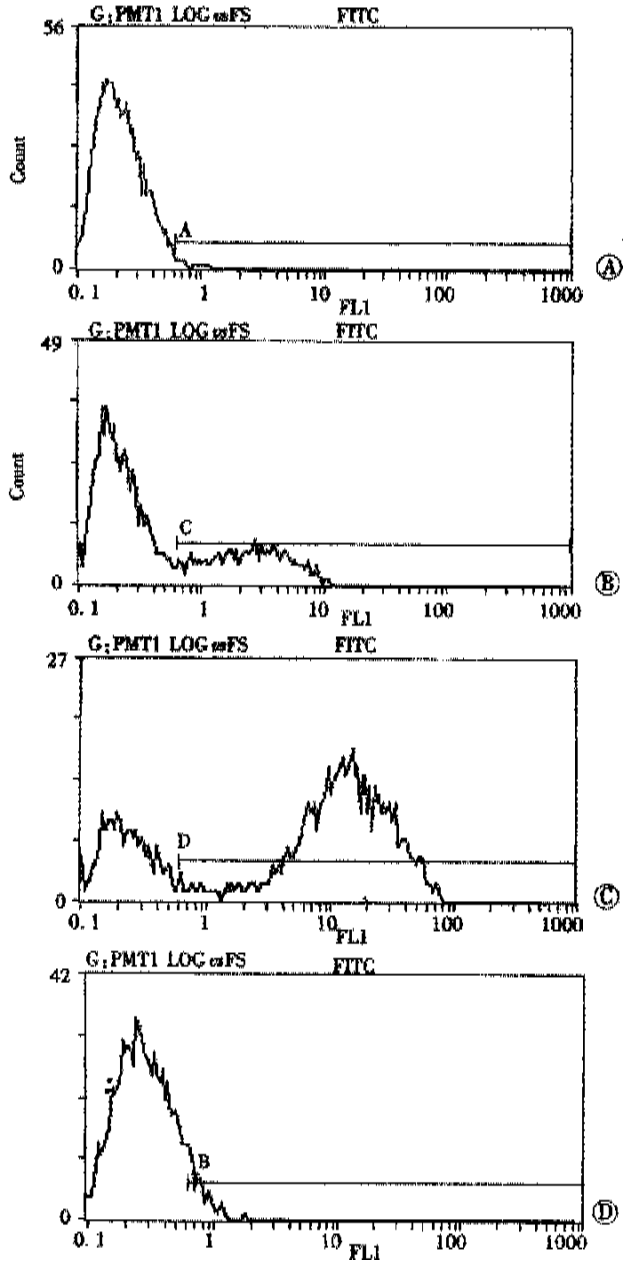

Figure 5 Changes in cell surface VEGF protein as deter mined by flow cytometer immunofluorescence staining analysis.
(A) Flow cytometric detection of VEGF changes of control. (B) Flow cytometric detection of VEGF changes of SGC-7901. (C) Flow cytometric detection of VEGF changes of SGC / s-hVEGF. (D) Flow cytometric detection of VEGF changes of SGC / as-hVEGF.

In vitro growth properties of parental and derivative cell lines

The sense-VEGF cell lines and antisense-VEGF cell lines appeared phenotypically indistinguishable from normal SGC-7901 gastric cancer cells and SGC-7901 transfected vector alone cells, and the growth rates of the derivative cell lines were identical to that of normal SGC-7901 cells (Figure 6).

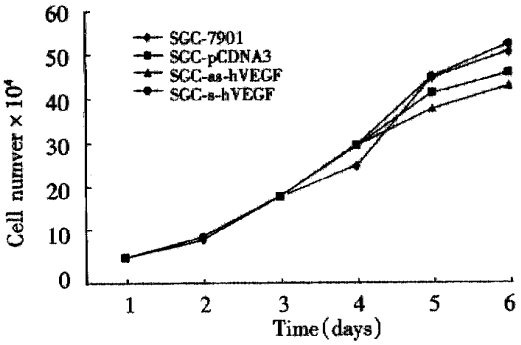

Figure 6 The growth curve of different transfectant.

In vivo growth of parental and derivative cell lines

Control human SGC-7901 gastric cancer cell, sense and antisense-VEGF cell lines were s.c. injected into nude mice, and tumor volumes were measured daily for the duration of the experiments. Tumor growth was detectable and measurable by 8 days postimplantation. At this time point, the parental cells, sense-VEGF cells, and antisense-VEGF cells had produced tumors of 13.25 ± 3.58 mm^3, 13.46±6.04 mm^3 and 12.46 ± 3.01 mm^3. There were no significant differences between their volumes(P>0.05). After 18 days postimplantation, however, the tumors from the sense-VEGF cell lines begun to grow more quickly than that from the parental cells, but the growth rate of tumors from the antisense-VEGF cell lines become slow. At 33 days postimplantation, sense-VEGF, SGC-7901, and antisense-VEGF cell lines produced tumors of 2350.50 ± 637.70 mm^3, 1534.40 ± 362.88 mm^3, and 345.40 ± 136.31 mm^3, respectively (Figure 7). At this time point, the tumor inhibiting rate was 77% through antisense inhibition. Sections of tumors were observed for their degree of tissue necrosis and vascularization. The results demonstrated that there was higher degree of necrosis in the tumors of the antisense-VEGF cell lines in comparison to tumors produced by control SGC-7901 cells, and the number of blood vessels observed in the tumors derived from the sense VEGF cell lines was higher.

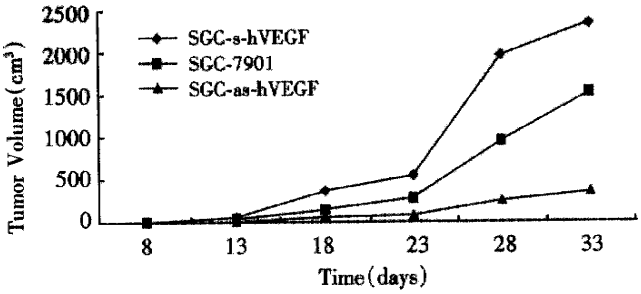

Figure 7 The volume of tumors in nude mice (n=5/ group) s.c. developing from s.c. injection totaling 1.4×10^6 cells / animal of the different transfectants.

DISCUSSION

Chemotherapy is the main treatment for patients with malignant tumor not to be resected, however, acquired resistance to chemotherapy is a major problem during cancer treatment. One mechanism for drug resistance is overexpression of the MDR (multidrug resistance)1 gene encoding the transmembrane efflux pump, P-glycoprotein (P-gp). In recent years, it has attracted much attention and has

been studied as a mechanism of multidrug resistance of tumors to anticancer drugs, however, the application of most agents with the capacity to reverse multidrug resistance (MDR) via modulation of the multidrug transporter P-glycoprotein (Pgp) was shown to be associated with toxic side-effects[19-21]. In addition to it, the heterogenerous of tumor may caused some trouble for choosing sensitive agents. Take altogether, many attempt were made to search for notoxic agents aiming at a common target. Neovascularization is critical for supporting the rapid growth of solid tumors. Tumor angiogenesis appears to be achieved by the expression of angiogenic agents within solid tumors that stimulate host vascular endothelial cell mitogenesis and possibly chemotaxis[22-25]. One such protein, vascular endothelial growth factor, or vascular permeability factor, is a selective endothelial cell mitogen and angiogenic agent induced by several growth factors and cytokines, and elevated expression of either the Ras[26,27], Raf[28], Src[29], or mutant P53[30] oncogenes and hypoxia[31-33] characteristic of rapidly growing solid tumors. VEGF was over expressed in many solid tumors, including breast[34], ovarian[35], lung[36], esophageal[37], and colon[38] cancer. These data suggest a potential role for VEGF in the oncogenesis of solid tumor.

VEGF-positive rate was 50% in human gastric cancer tissues, and it was mainly localized to the cytoplasm and membrane of the tumor cells, while KDR was mainly localized in the endothelial cells. This finding indicated that VEGF might have paracrine effect upon the endothelial cells to promote angiogenesis. In 50 specimens, of 2 cases in which the gastric cancer cells expressed VEGF and its receptor KDR, suggesting that VEGF might have an autocrine effect upon the gastric cancer cells themselves. Analysis of human gastric cancer tissue sections has shown that they are highly heterogeneous[39-41]. The cellular profile of each individual is also heterogeneous in that they contain cells at varying stages of malignancy and have growth factor/receptor expression profile that differ markedly[42-48].

The current study provides a more direct evidence that VEGF plays a role in the growth of gastric cancer. Reduction of VEGF mRNA and protein levels through antisense inhibition significantly lowered the growth rate of the tumors from antisense-VEGF cell lines. Conversely, elevation of VEGF levels after sense transfection resulted in a significant increase of the growth rate of the tumors from sense VEGF cell lines. These results provide strong evidence that VEGF plays an important role in the oncogenesis of the gastric cancer.

A potential therapy based on the interruption of paracrine and/or autocrine growth factor pathways that impinge upon the tumor cells themselves might well prove to be a successful antitumor approach[49-53]. Exploiting the ubiquity of tumor angiogenesis as a suitable target for therapy has been proposed previously to be an important concept for antitumor therapy[54]. This concept has recently been the subject of renewed interest in the development of new therapeutic strategies. Significant evidences are accumulating in favor of the notion that VEGF and its receptor play important roles in the development of solid tumors, such as those derived from gastric cancer origin.

Much indirect evidences indicate that VEGF is an important participant in tumor biology[11,12,55,56]. We now provide direct evidence that VEGF plays an important role in the growth of gastric cancer. VEGF might have mainly paracrine effect upon the endothelial cells to promote angiogenesis[57-62], and it might have an autocrine effect upon the gastric cancer cells themselves. The inhibition of VEGF is sufficient to control tumor growth *in vivo* by the suppression of tumor neovascularization[63-69]. The antisense VEGF strategy offers a new avenue of gene therapy development as an adjuvant treatment for human gastric cancer[70-76].

Abstract

AIM **Glutathione S-transferases (GSTs) are involved in the detoxification of many potential carcinogens and appear to play a critical role in the protection from the effects of carcinogens. The contribution of glutathione S-transferases M1 and T1 genotypes to susceptibility to the risk of gastric cancer and their interaction with cigarette smoking are still unclear. The aim of this study was to determine whether there was any relationship between genetic polymorphisms of GSTM1 and GSTT1 and gastric cancer.**

METHODS **A population based case-control study was carried out in a high-risk area, Changle County, Fujian Province, China. The epidemiological data were collected by a standard questionnaire and blood samples were obtained from 95 incidence gastric cancer cases and 94 healthy controls. A polymerase chain reaction method was used to detect the presence or absence of the *GSTM1* and *GSTT1* genes in genomic DNA. Logistic regression model was employed in the data analysis.**

RESULTS **An increase in risk for gastric cancer was found among carriers of *GSTM1* null genotype. The adjusted odds ratio (OR) was 2.63 [95% Confidence Interval (95% CI) 1.17-5.88], after controlling for age, gender, cigarette smoking, alcohol drinking, and fish sauce intake. The frequency of *GSTT1* null genotype in cancer cases (43.16%) was not significantly different from that in controls (50.00%). However, the risk for gastric cancer in those with *GSTM1* null and *GSTT1* non-null genotype was significantly higher than in those with both *GSTM1* and *GSTT1* non-null genotype (OR = 2.77, 95% CI 1.15-6.77). Compared with those subjects who never smoked and had normal GSTM1 genotype, ORs were 1.60 (95% CI: 0.62-4.19) for never smokers with *GSTM1* null type, 2.33 (95% CI 0.88-6.28) for smokers with normal *GSTM1*, and 8.06 (95% CI 2.83-23.67) for smokers with *GSTM1* null type.**

CONCLUSIONS ***GSTM1* gene polymorphisms may be associated with genetic susceptibility of stomach cancer and may modulate tobacco-related carcinogenesis of gastric cancer.**

INTRODUCTION

Glutathione S-transferases (*GSTs*), a supergene family of detoxification enzymes, appear to form a protection mechanism against chemical carcinogenesis. In human tissues this family consists of four multigene classes, referred to as alpha, mu, pi, and theta. The *GSTM1* gene is classified into the mu class and the *GSTT1* gene belongs to the theta class. They detoxify reactive chemical species, such as polycyclic aromatic hydrocarbon epoxides by catalyzing their conjugation to glutathione. Genes coding for *GSTM1* and *GSTT1* proteins are polymorphic in humans and these genes are absent in 10% -60% of different ethnic populations[1,2]. Accumulating evidence indicates that susceptibility to cancer is mediated by genetically determined differences in the effectiveness of detoxification of potential carcinogens. Genetic differences are likely to be a major source of interindividual variation in susceptibility to cancer[3].

Gastric cancer is the most common cancer in whole China[4-8], especially in Changle County, Fujian Province, China[9,10]. Previous studies have shown that a number of environmental risk factors may play a role in a multistep and multifactorial process[11-13]. Tobacco smoking has been considered a potential risk factor for gastric cancer[14]. Few data have so far been reported on the risk of gastric cancer associated with genetic and environmental exposures. To evaluate the relationships between *GSTM1/GSTT1* and gastric cancer, a molecular epidemiological study was conducted in Changle County.

MATERIALS AND METHODS

Study subjects

Cases and controls were all residents in Changle County, China, which is one of areas with the highest rates of gastric cancer in the world. All primary gastric cancers (n=95) were histologically confirmed or diagnosed by operation between January 1996 to March 1998. Population controls (n = 94) were randomly selected from the same geographical region, and matched to cases by their gender and age. The field staff conducted face-to-face interviews. Cases and controls were interviewed in the same manner using a standard epidemiological questionnaire. Blood samples (5mL) were collected.

GSTM1 and GSTT1 Assay

DNA was isolated from peripheral white blood cells by proteinase K (Huamei Biotechnology, Inc.) digestion and phenol / chloroform extractions. The PCR reactions were performed in 50μL of a solution containing PCR buffer (1.5 mmol·L^{-1} $MgCl_2$, 50 mmol·L^{-1} KCl, 10 mmol·L^{-1} Tris-HCl, pH 8.3), 200 μmol·L^{-1} of each dNTP, 1 μmol·L^{-1} of each primer, 200ng of template DNA, and 2.5 unit of TAQ DNA polymerase (Promega). Primer sequences for *GSTM1* were 5'-GCTTCACGTGTTATGGAGGTTC-3' and 5'-GAGATGAAGTCCTCCAGATTT-3', which produced a 157 base pair band. The *GSTT1* primers were 5'-TTCCTTACTGGTCCTCACATCTC-3' and 5'-TCACCGGATCATGGCCAGCA-3'-3, which produced a 480-base pair band. β-globin was used as an internal positive control, which was amplified with the following primers: 5'-CAACTTCATCCACGTTCACC-3' and 5'-GAAGAGCCAAGGACAGGTAC-3' and produced a 268-base pair band. The primers were synthesized by Sangon and PCR amplifications were carried out in a Thermal Cycler (Perkin Elmer 4800). Main cycling parameters were 94℃ for 8 min, followed by 35 cycles of 94℃ for 30s, 60℃ for 40s and 72℃ for 1 min with a final extension at 72℃ for 10 min. PCR products were detected by electrophoresis in agarose gels (2g·L^{-1} for *GSTM1* and 12g·L^{-1} for *GSTT1*).

Statistical analysis

The Chi-square method was used to test the frequencies of *GSTM1* and *GSTT1* genotypes. ORs and 95% CIs were calculated by logistic regression analysis controlling for possible confounding factors.

RESULTS

GSTM1 and *GSTT1* null genotypes are indicated by the absence of a 157bp band and 480 bp band, respectively. β-globin (268bp) indicating the presence of DNA is co-amplified in all the samples (Figures 1, 2).

Main characteristics of subjects

The main characteristics of cases and controls are presented in Table 1, the distribution of sex and age among cases and controls were not statistically significant (P>0.05).

Table 1 Main characteristics of cases and controls

	Cases (n=95)		Controls (n=94)	
	n	(%)	n	(%)
Age groups / yr				
<50	21	(22.1)	22	(23.4)
50 - 59	23	(24.2)	22	(23.4)
60 - 69	33	(34.7)	34	(36.2)
⩾70	18	(19.0)	16	(17.0)
Mean age	59 ± 11		58 ± 11	
Age range	32 - 78		34 - 79	
Gender				
Male	81	(85.3)	82	(87.2)
Female	14	(14.7)	12	(12.8)
Education				
College	1	(1.1)	1	(1.1)
High school	15	(15.8)	63	(67.0)
Elementary school	61	(64.2)	22	(23.4)
Illiterate	18	(19.0)	8	(8.5)

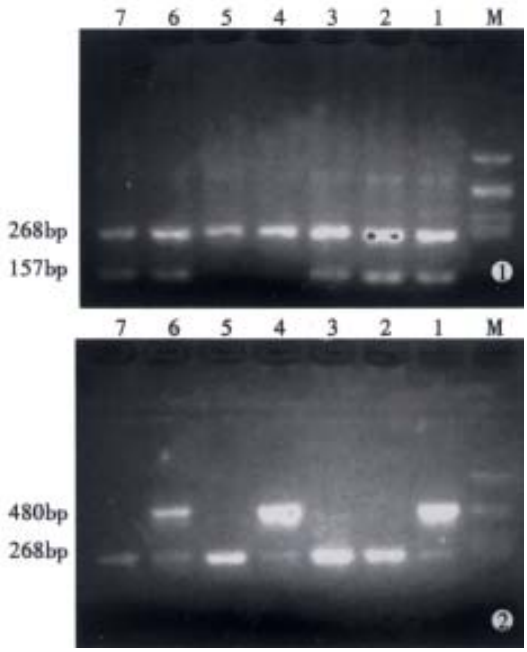

Figure 1 Agarose gel electrophoresis of PCR products. 157bp fragment: *GSTM1*; 268bp fragment: β-globin. Lane M: marker; Lanes 4 and 5:*GSTM1* null; Lanes 1, 2, 3, 6 and 7: *GSTM1* non null.

Figure 2 Agarose gel electrophoresis of PCR products. 480bp fragment: *GSTT1*; 268bp fragment: β-globin. Lane M: marker; Lanes 1, 4, and 6: nun-null; Lanes 2, 3, 5 and 7: *GSTT1* null.

GSTM1 and GSTT1 genotype frequencies in cases and controls

The results showed that GSTM1 null genotype distributed unevenly between gastric cancer cases and controls. The frequency of *GSTM1* null was significantly increased in gastric cancer cases compared with the general controls (χ^2 = 5.75, P=0.0165, Table 2).

Fifty percent (47/94) of individual in the controls exhibited the *GSTT*1 null genotype, and 43.2% (41/95) in gastric cancer cases. The frequencies of *GSTT*1 genotypes in cases and population controls were not significantly different (OR = 0.76, 95% CI 0.1 ~ 1.4). The odds ratio of gastric cancer associated with the combined genotypes of the polymorphisms of *GSTM*1 and *GSTT*1 are shown in Table 3. Persons who carried the *GSTM*1 null genotype and *GSTT*1 non-null had a higher risk of gastric cancer. The odds ratio was 2.77.

Table 2 Association between *GSTM1* and gastric cancer risk

	*GSTM*1 genotype				
	Nonnull	n	(%)	null	n	(%)
Contr		51	54.3		43	45.7
Case		35	36.8		60	63.2
Crude OR (95% CI)		2.03 (1.13-3.65)				
Adjusted OR[a] (95% CI)		2.03 (1.13-3.68)				
Adjusted OR[b] (95% CI)		2.47 (1.21-5.03)				
Adjusted OR[c] (95% CI)		2.63 (1.17-5.88)				

a: Logistic regression adjusted for age and sex; b: Adjusted for age, sex, cigarette smoking and alcohol drinking (yes / no); c: Adjusted for age, sex, cigarette smoking, alcohol drinking (yes / no), and fish sauce intake (continuous).

Table 3 Association between gastric cancer and combinations of *GSTM*1 and *GSTT*1 genotypes

*GSTM*1	*GSTT*1	Case		Contr		OR(95% CI)
		n	%	*n*	%	
Non-null	Non-null	21	22.1	30	31.9	1.00
Non-null	Null	14	14.7	21	22.3	0.95 (0.36~2.50)

GSTM1 null genotype and smoking

Because *GSTM*1 may play an important role in the metabolism of tobacco smoke-derived carcinogens, the risk of gastric cancer associated with the polymophisms of metabolic enzymes may depend on the individuals' smoking status. We compared smokers with and without gastric cancer and found that the increased susceptibility to gastric cancer in smokers with *GSTM*1 null phenotype. The subjects which have been exposed to cigarette smoking and *GSTM*1 null genotypes had 8.06 fold risk to develop gastric cancer (Table 4).

Table 4 Risk of gastric cancer in relation to *GSTM1* genotypes by e smoking

Genotype	Smoke	Contr		Case		OR (95% CI)
		n	%	*n*	%	
Nonnull	No	28	29.8	12	12.6	1.00
Null	No	32	34.0	22	23.2	1.60 (0.62-4.19)
Nonnull	Yes	23	24.5	23	24.2	2.33 (0.88-6.28)
Null	Yes	11	11.7	38	40.0	8.06 (2.83-23.9)

DISCUSSION

Changle County is a hyperendemic area of gastric cancer. Familial aggregation of gastric cancer in this area has been reported in previous studies[15,16]. This familial tendency toward gastric cancer may result from a common environment shared by familial members of inherited genetic susceptibility[17]. Gastric cancer is a multistage process[18]. each caused by numbers of factors[19-31]. Environmental and host factors may all contribute to the etiology of gastric cancer[32]. The relationship between polymorphisms of genes involved in carcinogen metabolism and individual susceptibility to the mutagenic and carcinogenic actions of specific chemical exposure is a new field of research[33-35].

Recent studies reported genes that on code enzymes involved in the metabolism of carcioogens or environmental toxins may be related to an increased risk of cancer in some individuals[36,37]. GSTs are multifunctional proteins that catalyze many reactions between glutathione (GSH) and lipophilic compounds with electrophilic centers, including cytotoxic and genotoxic reactions[38]. Polycyclic aromatic hydrocarbons, N-nitrosomines, found in cigarette smoke and food, are potential human carcinogens[39,40]. Deficiency of detoxifying enzymes may affect the metabolic fates of these chemicals and raise cancer risks in exposed individuals[41]. The *GSTM*1 enzyme is involved in detoxifying a number of carcinogenic electrophiles, such as the epoxides of polycyclic aromatic hydrocarbons. Individuals with the homozygous *GSTM*1 null genotypes express no protein and are expected to have reduced abilities of detoxification of hazardous compounds, particularly epoxides.

In this study, *GSTT*1 gene deletion was not associated with gastric cancer. We observed evidence of a relationship between null genotype of *GSTM*1 and risk of gastric cancer. The *GSTM*1 genotype exhibited a higher frequency of gene deletions in cases than in controls. The finding suggests that *GSTM*1 may play a role in gastric cancer susceptibility. Gastric cancer, which is associated with exposure to smoking, may be more striking in individuals who carrying the null genotype *GSTM*1. This result suggests that intervention against smoking may be important for the prevention of gastric cancer in high incidence area because the *GSTM*1 is present in a majority of persons and the potential population impact may be important. However, these results should be considered preliminary. Larger studies will be needed to confirm potential gene-environment interactions.

Abstract

AIM **To develop the single chain variable fragment of MG_7 murine anti-human gastric cancer monoclonal antibody using the phage display technology for obtaining a tumor-targeting mediator.**

METHODS **mRNA was isolated from MG_7 producing murine hybridoma cell line and converted into cDNA. The variable fragments of heavy and light chain were amplified separately and assembled into ScFv with a specially constructed DNA linker by PCR. The ScFvs DNA was ligated into the phagmid vector pCANTAB5E and the ligated sample was transformed into competent *E. Coli* TG1. The transformed cells were infected with M13K07 helper phage to form MG_7 recombinant phage antibody library. The volume and recombinant rate of the library were evaluated by means of bacterial colony count and restriction analysis. After two rounds of panning with gastric cancer cell line KATOIII of highly expressing MG_7-binding antigen, the phage clones displaying ScFv of the antibody were selected by ELISA from the enriched phage clones. The antigen binding affinity of the positive clone was detected by competition ELISA. HB2151 *E.coli* was transfected with the positive phage clone demonstrated by competition ELISA for production of a soluble form of the MG_7 ScFv. ELISA assay was used to detect the antigen-binding affinity of the soluble MG_7 ScFv. Finally, the relative molecular mass of soluble MG_7 ScFv was measured by SDS-PAGE.**

RESULTS **The V-H, V-L and ScFv DNAs were about 340bp, 320bp and 750bp, respectively. The volume of the library was up to 2×10^6 and 8 of 11 random clones were recombinants. Two phage clones could strongly compete with the original MG_7 antibody for binding to the antigen expressed on KATOIII cells. Within 2 strong positive phage clones, the soluble MG_7 ScFv from one clone was found to have the binding activity with KATOIII cells. SDS-PAGE showed that the relative molecular weight of soluble MG_7 ScFv was 32.**

CONCLUSION **The MG_7 ScFv was successfully produced by phage antibody technology, which may be useful for broadening the scope of application of the antibody.**

INTRODUCTION

In our previous studies, MG_7 hybridoma cell line had been successfully prepared by immunization of mouse with KATOIII gastric cancer cells and hybridization of the B cells from the spleen of the immunized mouse with the murine myeloma cell line SP 2/0. This hybridoma cell line generates a kind of monoclonal antibody against gastric cancer which can specifically recognize an ascertained gastric cancer associated antigen[1]. MG_7 antibody was confirmed to be of great value and good potency in the targeting gene therapy of gastric cancer due to the overexpression of its corresponding antigen in a large proportion of patients with gastric cancer. But owing to its murine origin, like many other similar antibodies, MG_7 antibody can elicit human anti-mouse immunoreaction and thus its use in clinical practice is restricted[2,3]. One of the efficient solutions to this problem is to remove the constant region of antibody which makes main contribution to the immunogenicity of the murine antibody to human being. It has been proved that antibody devoid of constant region still maintains its capacity of specific antigen-binding affinity[4-10]. Additionally, antibody without constant region, termed ScFv, is a small molecule and comprises 1/6 of its original antibody in molecular mass. Therefore, ScFv can more readily penetrate into the solid tumor *in vivo* and be easily cleared up from the normal tissue. In the early 90's, the emergence of recombinant phage library represented a great breakthrough in the antibody technology which provides an economical means to prepare the ScFv/Fab of any desired antibody[11-19]. In the present study, the MG_7 recombinant phage antibody derived from MG_7 hybridoma was constructed and screened to prepare the MG_7 ScFv which might help establish an efficient strategy of targeting gene therapy in gastric cancer.

MATERIALS AND METHODS

Detection of antigen-binding affinity of MG_7 antibody

MG_7 hybridoma cells and KATOIII cells were cultured with RPMI 1640 (purchased from Gibco) supplemented with heat-inactivated $100mL\cdot L^{-1}$ fetal bovine serum at 37℃ under $50mL\cdot L^{-1}$ CO_2. MG_7 hybridoma cells were harvested at log phase and stored at -70℃ with aliquot of 10^6 for RNA isolation. Supernatant was collected for detection of antigen-binding affinity of MG_7 antibody by ELISA. KATOIII cells in log phase were transferred into a 96 wellplate and immobilized on the wall by centrifiguation at $1\,000\times g$ for 10 min, finally

fixed by 0.25mL·L^{-1} glutaraldehyde. Supernatant of 0.2mL was applied to each well and incubated at 4℃ overnight, and 0.1mL HRP-labeled goat anti-mouse (HRP-GAM) Ig was added into each well. The absorbance value (*A*) at 492nm of reactant in each well was measured after incubation for 1 hour at 37℃ and staining with OPD.

Construction of MG_7 recombinant phage antibody library

According to the protocol of svtotal RNA isolation system and polyAT tract mRNA isolation system (purchased from Promega), mRNA was isolated from MG_7 hybridoma cells and quantified by gel electrophoresis for following reverse transcription reaction. Subsequently, reverse transcription reaction was performed with 0.3μg mRNA, 2U reverse transcripase (purchased from Promega) mixed together for incubation of 1 hour under 37℃. PCR was conducted with a mixture of 10μg product of reverse transcription, 2U *Taq* DNA polymerase and 2μL V H/V_L primers mix (purchased from Promega) in a total volume of 50μL. The procedure of PCR was arranged in the following order: 95℃×5min; 94℃ ×1min, 55℃×2min, 72℃×2min and 30 cycles; 72℃×10min. After precise quantification of PCR product by gel electrophoresis, 50ng of V_H and V_L product was respectively mixed with 50ng linker primer and 1μL *Taq* DNA polymerase to perform PCR (94℃×1min, 63℃×4min, 7 cycles). Subsequently,50ng RS primers (purchased from Promega) underwent another PCR (94℃×1min, 55℃×2min, 72℃×2min and 30 cycles; 72℃×10min). Two μL *Sfi* I and 0.5μg ScFv product were added into a sterile 0.5mL microtube and incubated at 50℃ for 4 hours. After being purified by PCR purification kit, 0.5μg *Sfi* I digested ScFv product mixed with 2μL *Not* I was incubated at 37℃ for 4 hours and purified again for later use. ScFv (150ng) and pCANTAB5E (250ng) mixed with 2μL T_4 DNA ligase was incubated at 16℃ for 16 hours. Ligated product was transformed into TG1 cell. Transformed product with aliquot of 100μL was placed onto SOBAG plates and incubated overnight at 37℃ to form bacterial clones.

Evaluation of volume and recombinant rate of phage antibody library

Colony count was adopted to exhibit the total number of clones formed on the SOBAG plates. Eleven clones were randomly singled out from the SOBAG plates and passaged into 5mL 2×YT-AG medium for an incubation of 12 hours at 37℃. Plasmid from each clone was respectively isolated and digested by *Eco* RI and *Hin* dIII. Gel electrophoresis was conducted with restriction digested product to examine the recombinant phagmid.

Panning and enrichment of MG_7 recombinant phage antibody

The initial recombinant phage antibody library was incubated for 1 hour at 37℃ with shaking at 250r·min^{-1}, and helper phage M13KO7 was added and incubated for another hour at 37℃ with shaking at 250 r·min^{-1}[20]. The culturing product was spinned at 1000×*g* for 10 min to precipiate the cells. Then the entire sample was gently resuspended in 10 mL 2× YT-AK medium. After an overnight incubation at 37℃ with shaking at 250r·min^{-1}, the culturing product was spinned at 1 000×*g* for 20 min and the supernatant which contained the recombinant phages was collected. Then, 2mL PEG/NaCl was added and placed on ice for 45 min for precipitation of recombinant phage clones. It was spinned at 10000×*g* for 20 min at 4℃ and the pellet was resuspended in 16mL 2×YT medium diluted with 14 mL blocking buffer containing 0.1g·L^{-1} sodium azide and incubated at room temperature for 15 min. Twenty mL of the diluted recombinant phage was then added to the flask which was coated with KATOIII cells and well blocked. The flask was incubated for 2 hours at 37℃, washed 10 times with PBS plus another 10 times with PBS containing 1mL·L^{-1} Tween20. Ten mL log-phase TG1 cells were added to the flask and incubated with shaking at 37℃ for 1 hour for reinfection. After two rounds of panning, reinfected TG1 cells with bound phages directly in the panning flask were plated for colony isolation.

Screening for MG_7 recombinant phages

Recombinant phages were rescued from individual clones and screened for MG_7 binding by ELISA. Microtiter wells were coated with KATOIII cells. Bound phages were detected by incubation with a 1:5000 dilution of conjugate (Pharmacia Biotech). And the detection was achieved by addition of TMB substrate. Clones reacted to KATOIII cells were referred to as positives.

Competitive test of positive selected MG_7 recombinant phages

Microtiter wells were coated with KATOIII cells as mentioned above. The supernatant of the selected positive MG_7 recombinant phages was applied into each well (100mL·well^{-1}) and then incubated for 1 hour at 37℃. After disposing of the supernatant, MG_7 antibody (100mg·L^{-1}, 50μL·well^{-1}) was added and incubated for 1 hour at 37℃. PBST was used to wash 5 times, and HRP-GAM Ig (1:1000 diluted, 50μL·well^{-1}) was added and developed by TMB to measure the absorbance value at 450nm. The inhibiting ratio of selected positive MG_7 recombinant phages with MG_7 antibody for binding of KATOIII cells was calculated by the following formula: Inhibiting ratio = 1- (value of sample/value of control)×100%

Detection of antigen-binding affinity of the soluble MG_7 ScFv

The positive phages were transfected into *E.coli* HB2151 cells for the production of a soluble form of the MG_7 ScFv. Five mL culturing product of transfected *E.coli* HB2151 cells with overnight induction of 1mmol·L^{-1} isopropyl β-D-thiogalactopyanoside (IPTG) was centrifugated at 1000×*g* to collect the sediment and the supernatant (containing extracellular soluble ScFvs). The sediment was given osmotic shock to prepare periplasmic extracts. Microtiter wells were coated with KATOIII cells, and ELISA test was made twice to detect the antigen-binding affinity of soluble MG_7 ScFv.

Measurement of the relative molecular weight of soluble MG_7 ScFv

Periplasmic extracts from transfected *E.coli* HB2151 cells induced by IPTG was adopted to measure the relative molecular weight of soluble MG_7 ScFv by SDS-PAGE.

RESULTS

Antigen-binding affinity of MG_7 antibody

The ELISA showed that the A_{492} absorbance of reactant with presence of MG_7 antibody was up to 0.65 (0.208 in control).

Amplification of V_H, V_L and ScFv gene

On electrophoresis, V_H product formed a band at 350bp and V_L at 320bp, and ScFv was successfully spliced together to form a fragment of 750bp, as shown in Figure 1.

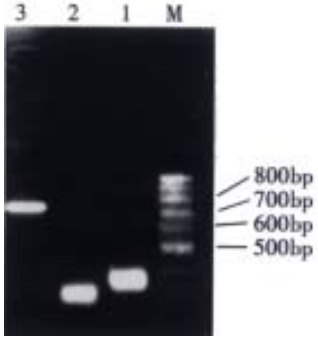

Figure 1 RT-PCR of V_H, V_L and ScFv fragment of MG_7 antibody. 1: V_H; 2: V_L; 3: ScFv; M: 100bp ladder

Volume of MG_7 phage antibody library

Colony counts showed that MG_7 phage antibody library consisted of 2×10^6 clones.

Recombinant rate of MG_7 recombinant phage antibody library

Eight of 11 random clones were found to release a 2.1 kb DNA fragment and confirmed to be recombinant phagmid by restriction analysis and gel electophoresis (Figure 2). The recombinant rate was 72.7%.

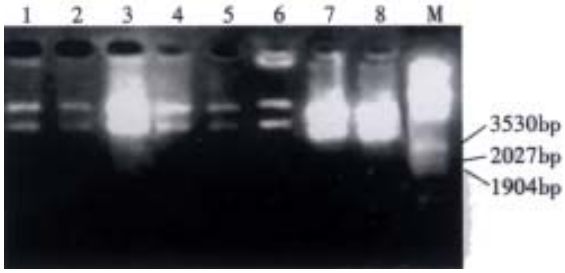

Figure 2 Enzymatic analysis of MG_7 recombinant phage antibody library with *Eco* RI and *Hin* dIII. 1-8: Recombinant clones from library; M: λ / *Eco* RI and *Hin* d III

Screening of MG_7 positive recombinant phages

Using ELISA assay, we yielded six strains of positive clones which had a good reaction with KATOIII cells (Table 1).

Table 1 ELISA results of screening from enriched phage displayed antibody library

Screening	Number of positive clones (A- value)						Neg. ctrl
	1	2	3	4	5	6	
First round	0.495	0.508	0.488	0.805	0.845	0.580	0.157
Second round	0.543	0.606	0.560	0.840	0.796	0.758	0.185

Results of competitive ELISA

Two strong positive clones were found to inhibit the binding of MG_7 antibody and KATOIII cells with the inhibiting ratio of 26.1% and 30%, respectively.

Antigen-binding affinity of soluble MG_7 ScFv

By means of ELISA assay, one of the strong positive clones exhibited the capacity of binding with KATOIII cells (Table 2).

Table 2 ELISA results of the soluble MG_7 ScFv for binding with KATOIII cells

ELISA	Number of strong positive clones (*A* value)		Neg. ctrl
	1	2	
First round	0.776	0.287	0.201
Second round	0.802	0.346	0.223

The relative molecular weight of soluble MG_7 ScFv

From Figure 3, an extra band on the lane of sample was visualized at M_r 32, as compared with the negative control. The relative molecular weight of soluble MG_7 ScFv was 31.

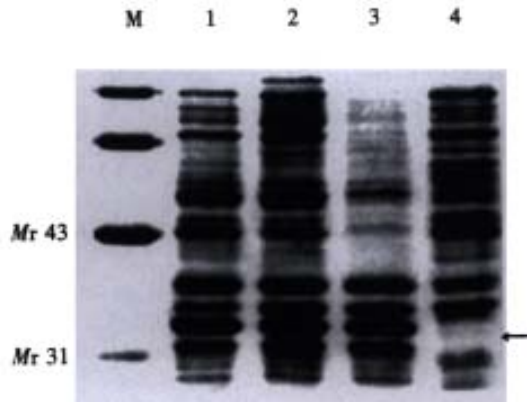

Figure 3 Measurement of the relative molecular weight of soluble MG_7 ScFv. 1-3: Periplasmic extracts; 4: Neg. ctrl; M: Low molecular mass protein marker

DISCUSSION

The phage antibody technique is one of the most remarkable achievements in antibody technology. With this technique, the repertoire of V_H and V_L genes are amplified and joined together by PCR and finally inserted into phagmid[20]. After transformation into *E.coli*, phage with the fusion of exogenous ScFv and pIII protein exposed on the surface was released from *E.coli* with the aid of the helper phage M13KO7. This technique uniforms the phenotype of ScFv to its genotype. By immunosorbance of the immobilized antigen, phage with functional ScFv can be bound and enriched. Subsequently, the desired phage harboring functional ScFv gene can be selected from the enriched phage antibody library by ELISA. The resultant ScFv can be solubly expressed in *E. coli* HB2151. The primary structural information of ScFv of antibody is accessible by DNA sequence of phagmid from the bound phage. Therefore, phage antibody has become an optimal measure to develop the ScFv of desired antibody[21-26].

It is well known that the immune system will be triggered and activated in response to the presence of certain antigens in patients with some kinds of diseases, such as tumor, infective diseases and autoimmune diseases[27-32]. The immune system will produce abundant B lymphocyte clones which can yield and secrete antibody directed against the disease associated antigens in these patients. Therefore, the B lymphocyte

population isolated from PBMC of these patients can be used as an ideal material source for construction of the recombinant phage antibody library[29-31]. Additionally, the B lymphocyte isolated from PBMC of immunized animals with given antigen is an alternative material source[20]. Besides the B lymphocyte population from patients or immunized animals, many kinds of antibody-producing hybridomas are also suitable as a kind of material source for construction of the recombinant phage antibody library[6,19]. Owing to the unraveling of biological functions over many antigen recognized by antibody from hybridomas, hybridomas are more favorable as material source for construction of recombinant phage antibody library.

In order to understand the quality of MG_7 hybridoma as a material source for construction of MG_7 recombinant phage antibody library, we detected the antigen-binding activity of MG_7 antibody in present study. ELISA assay showed that the *A* 492nm value of reactant with presence of MG_7 antibody was 0.65 which was over twice higher than that with absence of MG_7 antibody (0.208 only). It demonstrated that MG_7 hybridoma could secrete functional antibody and could be used as the source of mRNA to amplify the V_H and V_L genes of MG_7 antibody. Colony count and restriction analysis were conducted for evaluating the volume and quality of MG_7 recombinant antibody library. The large volume of MG_7 recombinant antibody library (2×10^6) and high recombinant rate (72.7%) confirmed that MG_7 phage antibody library comprised sufficient repertoire of recombinant clones for further research. ELISA assay and SDS-PAGE showed that the soluble MG_7 ScFv had antigen-binding activity and was M_r 31. Taken together, we have successfully constructed the MG_7 recombinant phage antibody library and prepared the phage-displayed/soluble MG_7 ScFv.

Gastric cancer is a highly prevalent neoplasm and is the first killer among various malignancies. In advanced cases, many current therapeutic approaches, including surgery combined with chemotherapy, appear to be palliative. These therapeutic approaches can not be targeted to and completely annihilate individual tumor cells, which leads to the failure of preventing metastasis and recurrence of many tumors. Besides, some kinds of therapeutic approaches, such as chemotherapy, can cause damage to both the tumor cells and normal tissue cells. Thus, introduction of a new way of targeting therapy for tumor is desperately needed to overcome these obstacles with the conventional approaches, such as surgery and chemotherapy[33-44]. Targeting therapy for tumors in the last decade has become a highlight in the field of tumor therapy. This therapy mediated by antibody still remains as a promising curative modality among the ways of tumor therapy and attracts worldwide attention[45-50].

Developing ScFv of the MG_7 is of great significance in both early diagnosis and treatment of gastric cancer. For instance, MG_7 ScFv fused with avidin can be used as a reagent in immuno-PCR for early diagnosis of gastric cancer. Additionally, a new immunotoxin with curative effect on gastric cancer can be developed by fusing the MG_7 ScFv and A subunit of ricin. MG_7 ScFv can direct the A subunit of ricin to MG_7 positive gastric cancer cells. Thus, the construction of MG_7 phage antibody library and subsequent preparation of MG_7 ScFv may be a step forward in seeking an efficient way for targeting therapy for gastric cancer.

Abstract

AIM **To investigate the relationship between the expression of *p*16 gene and the gastric carcinogenesis, depth of invasion and lymph node metastases, and to evaluate the deletion and mutation of exon** 2 **in *p*16 gene in gastric carcinoma.**

METHODS **The expression of P**16 **protein was examined by streptavidin-peroxidase conjugated method** (**S-P**)**; the deletion and mutation of p16 gene were respectively examined by polymerase chain reaction** (**PCR**) **and polymerase chain reaction single strand conformation polymorphism analysis** (**PCR-SSCP**) **in gastric carcinoma.**

RESULTS **Expression of P**16 **protein was detected in** 96.25**%** (77/80) **of the normal gastric mucosa, in** 92.00**%** (45/50) **of the dysplastic gastric mucosa and in** 47.54**%** (58/122) **of the gastric carcinoma. The positive rate of P**16 **protein expression in gastric carcinoma was significantly lower than that in normal gastric mucosa and dysplastic gastric mucosa** (***P***<0.05)**. The positive rate of P**16 **protein expression in mucoid carcinoma** 10.00**%** (1/10) **was significantly lower than that in poorly differentiated carcinoma** 51.22**%** (21/41)**, undifferentiated carcinoma** 57.69**%** (15/26) **and signet ring cell carcinoma** 62.50**%** (10/16) (***P***<0.05)**. The positive rate of p16 protein in 30 cases paired primary and lymph node metastatic gastric carcinoma: There was** 46.67**%** (14/30) **in primary gastric carcinoma,** 16.67**%** (5/30) **in lymph node metastatic gastric carcinoma. The positive rate of lymph node metastatic carcinoma was significantly lower than that of primary carcinoma** (***P***<0.05)**. There was of *p*16 gene mutation in exon** 2**, but** 5 **cases displayed deletion of *p*16 gene in exon** 2 **in the** 25 **primary gastric carcinomas.**

CONCLUSIONS **The expression loss of P**16 **protein related to the gastric carcinogenesis, gastric carcinoma histopathological subtypes and lymph merastasis. The mutation of *p*16 gene in exon** 2 **may not be involved in gastric carcinogenesis. But the deletion of *p*16 gene in exon** 2 **may be involved in gastric carcinogenesis.**

He XS, Su Q, Chen ZC, He XT, Long ZF, Ling H, Zhang LR. Expression, deleton and mutation of p16 gene in human gastric cancer. *World J Gastroenterol*, 2001;7(4):515-521

INTRODUCTION

Carcinogenesis and progression of human gastric cancer are related to the activation of proto-oncogenes and/or the inactivation of anti-oncogenes and they are the results of genetic alteration accumulated. A recently cloned new tumor suppressor *p*16 gene is located in 9p21, with the full-length of 8.5 kb. It consists of 2 introns and 3 exons, encoding P16 protein-whose molecular mass is 15840 M_r, a single strain peptide comprising 148 amino acid, participating in regulating the proliferation of normal cell growth negatively[1,2]. There was a high frequent loss of homozygosis of *p*16 gene in a variety of cancer cell lines such as gliocytoma, melanoma, breast cancer cell lines[2] and in certain primary cancer, for example, leukemia[3], gliomas[4], astrocytomas[5], bladder cancer[6], melanoma[7], oral squamous cell carcinomas[8], squamous cell carcinoma of head and neck neoplasm[9,10]. The frequency of *p*16 gene deletion and mutation is up to 75% in all kinds of human neoplasm, higher than that of the well-known p53 gene. Gastric cancer is common in China[11-30]. In this paper, S-P immunohistochemical staining was used to detect the expression of P16 protein in gastric cancer and precancerous lesions. PCR and PCR-SSCP methods were used to analyse the deletion and mutation of *p*16 gene exon 2. This study aims to evaluate the relationship between P16 protein and the carcinogenesis, progression, histological types as well as biologic behaviors in human gastric cancer, to find a new marker in early diagnosis and to discover the role of deletion and mutation of *p*16 gene in exon 2 in the carcinogenesis and progression of human gastric cancer.

MATERIAL AND METHODS

Specimens and treatment

All specimens were confirmed by pathology. Paraffin-embedded tissue were collected from the department of pathology and fresh resected specimens were from the First Affiliated Hospital of the Nanhua University, among which there were 50 cases of dysplasia of gastric mucosa and 122 cases of gastric cancer (25 cases were resected freshly from September 1995 to December 1996). In the 122 cases of gastric cancer, 29 were well-differentiated adenocarcinoma, 41 were poorly-differentiated adenocarcinoma, 26 were undifferentiated carcinoma, 16 were signet ring cell carcinoma and the other 10 were mucoid carcinoma. There were 81 men

and 41 women, 22 aged below 40 years, 69 aged from 41 to 59 years, and 31 were older than 60 years. The youngest was 15 years and the oldest 79 years (mean 56 years). Superficial muscles, were invated in 50 cases and deep muscles and the full layer in 72. Sixty-nine cases had lymph node metastasis, 53 had no lymph node metastasis. Thirty cases primary and lymph node metastasis cancer selected randomly were paired and compared. According to Borrmann's classification, 15 were type I, 43 were type II, 47 were type III and 17 were type IV. The 25 cases of fresh resected specimens included cancer, cancer-surroundings and normal mucosa selected far from cancer, were cut into 2 - 4 blocks under sterile conditions. Each block was 2-3 mm^3 and stored in -70℃ refrigerator for PCR and PCR-SSCP analysis. The rest tissues were fixed in 100 $mL \cdot L^{-1}$ neutral formalin, resected, dehydrated, cleaned and paraffin-embedded. All paraffin-embedded tissues were cut into sequential slices for 5μm and adhered to the glass which was processed by poly-lys previously.

Reagents and instruments

Rabbit-anti-human P16 protein multiple clonal antibody, streptavidin-peroxidase immunozator kit (S-P kit), and DAB were all bought from Maxim Company, USA. Protase K (Merk, USA), *Sma* I, agar gel, propylene acrylamide, N-N-sulmethyl bipropylene acrylamide, ammonium persulfate, xylene nitrile, bromophenol blue were bought from Shanghai Sangon Company. PCR primer synthesized by Shanghai Sangon, primer sequences of p16 gene exon 2[4].

Sense: 5'-TCT GAC CAT TCT GTT CTC TC-3'

Antisense: 5'-CTC AGC TTT GGA AGC TCT CA-3'

The fragment length of amplification was 384 bp. Primer sequences of β-active served as an internal control.

Sense: 5'-GCG GGG CGC CCC AGG CAC CA-3'

antisense: 5'-CTC CTT AAT GTC ACG CAC GAT TTC-3'

The fragment length of amplification was 548bp.

Instrument Ultra low refrigerator (Japan) of -70℃, rotary sector (Germany), microscope (Japan), type 480 DNA amplificatory (PE,USA), type 901 ultraviolet spectrophometer (PE,USA), type DY-IIIB vertical eletrophores and all kinds of centrifuges(Beijing Liuyi).

METHODS

S-P immunohistochemical staining

Operated as the specification of sp kit, that was: paraffin-embedded tissue slices deparaffined hydrated→endogenous peroxidase blocked→added first antibody→then bridge antibody→added enzyme labeled S-P reagents→DAB colorized →hematoxylin stained→dehydrated→cleaned and paraffin-embedded→observed by microscope.

Genomic DNA extraction[31]

Frozen tissue of 0.5g was put into liquid nitrogen and powdered immediately, 10× buffer (10$mmol \cdot L^{-1}$ Tris-HCl pH 8.0, 0.1$mol \cdot L^{-1}$ EDTA pH 8.0, 5$g \cdot L^{-1}$ SDS) was added and span in 37℃ water for 1h at the same time, added protase K to the mixture at a final concentration of 100$mg \cdot L^{-1}$ in 50℃ water for 3h and readjusted the protase K as possible reaction. After the mixture lysed completely, 20$mg \cdot L^{-1}$ Rnase reacted in 37℃ water for 1h, saturated phony was put together and bugged slightly for 10 min, centrifuged and extracted up clean liquid transfer to a cleaned plastic tube, saturated phony processed repeatedly 3 times, added 1/10 volume 3$mol \cdot L^{-1}$ NaAc and 2-2.5 times cold ethyl, DNA precipitated by centrifugation, removed ethyl, DNA washed by 700$mL \cdot L^{-1}$ ethyl land centrifuged 3 times, dried, resolved with TE, A260/A280:1.8-1.9, stored at 0℃ for use.

PCR amplification

PCR was performed according to the reference[31] in 50μL reactive volume containing 0.1μg gDNA template, 200$\mu mol \cdot L^{-1}$ each of dCTP, DATP, dGTP, dTTP, 0.25$\mu mol \cdot L^{-1}$ primer, PCR buffer (Tris-HCl 10$mmol \cdot L^{-1}$, pH 8.3, $MgCl_2$ 1.5$\mu mol \cdot L^{-1}$, KCl 50$mmol \cdot L^{-1}$, gelatin 100$mg \cdot L^{-1}$) pre-denatured at 95℃ for 5 min and added 1.5μL of Taq DNA polymerase, 75μL of mineral oil. These samples were subjected to 30 cycles, including: 95℃ 1 min, 60℃ 1 min, 72℃ 1 min, and extended at 72℃ 5 min. Five μL of PCR product and appropriate bromophenol blue was added to the sample point container and electrophoresed at 20$g \cdot L^{-1}$ agarose gel containing 0.5$mg \cdot L^{-1}$ ethidium bromide at tank with 0.5×TBE liquid of electrophoresis, then observed and photographed with ultraviolet radiography.

PCR-SSCP analysis [31]

Five μL digested PCR product mixed with 5μL denatured dissolution (950$mL \cdot L^{-1}$ forman mide, 20$mmol \cdot L^{-1}$ EDTA, 0.05% bromophenol blue, 0.5$g \cdot L^{-1}$ xylene nitrile) denatured at 95℃ 5 min and colded on ice. Solution processed as above was added to the gel containing 80$g \cdot L^{-1}$ polypropylene acrylamide, vertical electrophoresed at 100 V for 4h and gel stained with silver: fixed in 100$mL \cdot L^{-1}$ alcohol for 10 min→oxidized in 100$g \cdot L^{-1}$ nitric acid for 3 min→drip washed for 1 min with double distilled water→stained in 12$mmol \cdot L^{-1}$ silver nitric acid for 20 min→drip washed for 1 min with double distilled water→showed appropriate color in 0.028 mol anhydrous sodium carbonate and 0.19$mL \cdot L^{-1}$ formalin→ended reducing response by 100$mL \cdot L^{-1}$ glacial acetic acid→drip washed with double distilled water→analysis results and photographed. P16 protein expression of confirmed positively cervix carcinoma served as positive control. PBS substituted with first antibody served as negative control.

Immunohistochemical determination

According to Gevadts' standard modefied slightly[32,33], nuclear or plasma stained brown-yellow as positive, (-) indicated no cell stained positive or only plasma stained or the number of nuclear stained positive less than 1 cell, (+) indicated the cells stained weakly or the number of stained cells less than 25%, (++) indicated the cells stained moderately or the stained cells covering about 26%-50%, (+++) indicated cells stained strongly or the number of stained cell more than 50%. The number of nuclear stained positively more than 2 cells per high time sight was considered to be positive. No folding, and no edging-effect fields were chosen to calculate 100 cells per 5 sights and evaluate the average number of positive cells. Positive cells discerned by two

researchers alone and decided on the disagreements together. No products of PCR amplification were loss of homozygosis of *p*16 gene, and abnormal traces found in PCR-SSCP were considered gene mutation.

Statistical analysis

Chiq-square test was used *P* value less than 0.05 was considered to be statistically significant.

RESULTS

P16 protein expression in gastric cancer

The positive rate of P16 protein expression in 80 cases of normal gastric mucosa was 96% (Figure 1), and in 50 cases of dysplasia mucosa was 90% (Figure 2). In these mucosa P16 protein expression could only be seen in partical adenoepithelial cells. We did not find staining in mucosal epithelial cells, matrix fibrocytes, lymphocytes and smooth myocytes. But in gastric cancer, the ratio was 48% (Figure 3). The positive rate of P16 protein expression in gastric cancer was lower than that in normal and dysplasia mucosa ($P<0.05$). There was no significant difference between the normal gastric mucosa and dysplasia mucosa ($P>0.05$, Table 1).

In the 122 gastric cancer, the positive rate of P16 protein expression was 38%, 51%, 58%, 62% and 10% in well-differentiated adenocarcinoma, poorly-differentiated adenocarcinoma, undifferentiated carcinoma, signet ring cell carcinoma and mucoid carcinoma, respectively. The P16 protein expression in mucoid carcinoma was lower than that in signet ring cell carcinoma, undifferentiated carcinoma and poorly-differentiated adenocarcinoma ($P<0.05$). The positive rate of P16 protein expression was 48% (24/50) in gastric cancer invaded superficial muscle layer and 47% (34/72) in gastric cancer invaded deep muscle and full layer. There was no apparent relevance between P16 protein expression and the depth of invasion ($P>0.05$). In 30 cases of paired primary cancer and lymph node metastasis cancer, the rate of P16 protein expression of the lymph node metastasis cancer was 17%(5/30), significantly lower than that of primary cancer, 47% (14/30), ($P<0.05$).

Deletion and mutation of p16 gene exon 2 in gastric cancer

In 25 fresh resected gastric cancer, there were 7 well-differentiated adenocarcinoma, 13 poorly-differentiated adenocarcinoma, 3 undif ferentiated carcinoma, 1 signet ring cell carcinoma and 1 mucoid carcinoma, cancer-arrounding and normal mucosa were taken at the same time. The PCR amplification showed no product in 1 case of well-differentiated adenocarcinoma, 1 case of poorly-differentiated adenocarcinoma and 1 case of mucoid carcinoma; little product found in 1 case of well-differentiated adenocarcinoma and 1 case of poorly-differentiated adenocarcinoma. There were products of PCR amplification in the rest 20 cases of gastric cancer, tumor adjacent tissue and normal mucosa. All experiments were repeated three times. The result was identical. No product of PCR amplification might indicate the loss of homozygosis of *p*16 gene, little product of PCR amplification was possibly loss of heterozygosis of *p*16 gene or loss of homozygosis of *p*16 gene, but contaminated with normal mucosa (Figure 4). Four of these 5 cases were P16 protein negative expression and 1 case expressed weekly by immunohistochemical staining. No gene mutation was observed in PCR-SSCP analysis after the PCR amplification products cut with *Sam* I (Figure 5, Table 1) (the location of restriction site, and the length of fragment are shown in Figure 6).

DISCUSSION

The *p*16 gene is a tumor suppressor gene that participates in the negative regulation of the cell growth and proliferation, and a hot spot in the molecular biological research of neoplasm since its discovery in 1993. The product of p16 gene-P16 protein is the inhibitor of CDK4. Its function is to default the activity of CDK4 by binding with CDK4 against Cyclin D_1 competitively, then inhibits the phosphation of Rb protein, transcription factor such as E2F when combined with the dephosphated Rb protein can not be released and activated, thus cells arrest in G_0/G_1 phase, resulting in cell dividing and proliferation suppressed. If p16 gene was abnormal, its function of negative regulation of cell growth would be lost. CDK4 combines to cyclin D_1 and PRb phosphates, lots of transcription factors would be released. The cell from G_1 phase enters into S phase rapidly, cell proliferates excessively and results in carcinogenesis and progression[1,2,34-36]. A lot of investigations show that there were P16 protein deletion and *p*16 gene abnormality in various primary cancers and cancer cell lines. The alteration forms of *p*16 gene were deletion, mutation[2,9,37-43], rearrangement, insertion[44-48], translocation[49-51]and hyper methylation of CpG islands presented in promotor sequence[52-58]. Such alterations consequently change the gene activity, cause abnormality, structure change of the product of *p*16 gene expression and the loss of its physiological functions. Recently, it has been reported that the exoteric *p*16 gene was transfected into the cancer cell which *p*16 gene deletes. The cancer cell restored *p*16 gene expression and cell growth was remarkably inhibited[59-67]. It has also been documented that the CpG island methylated of *p*16 gene cancer cell line was treated with 5-aza-2'-deoxycytidin. Cancer cell restored *p*16 gene expression and showed growth inhibition[68-71]. All these indicated that *p*16 gene and its product played important roles in the carcinogenesis.

This investigation showed that the positive rate of P16 protein expression in gastric cancer was remarkably lower than that in dysplasia and that in normal gastric mucosa ($P<0.05$). The result indicated that gastric carcinogenesis was probably related to the loss of P16 protein expression. But there was no significant difference between the normal mucosa and the dysplasia mucosa of the stomach ($P>0.05$). The positive rate of P16 protein expression in gastric cancer was not identical with other reports[72£¬73]. The cause was not clear. It was possibly related to the different standards of determination, reagents and some uncertain factors. However, the quantity of P16 protein expression increased from normal mucosa to precancerous lesions and gastric cancer ($P<0.05$). Following pathological lesions, P16 protein expression increased. This change may inhibit cell proliferation. The positive rate of P16 protein expression in mucoid carcinoma was significantly lower than in poorly-differentiated adenocarcinoma, undifferentiated carcinoma and signet cell carcinoma ($P<0.05$). The result suggested that the alteration of *p*16 gene was different in various histological types gastric cancer. The discrepancy of P16 protein expression exists in various histological types of lung and esophageal cancer[33,74]. There was difference of P16 protein expression and deletion of *p*16 gene in various differentiation types of gliomas. But the deletion of *p*16 gene concurred with the expression of P16 protein[4]. In 30 cases of primary gastric cancer paired with lymph node metastasis cancer, the positive expression rate of P16 protein in metastasis cancer was lower than in primary gastric cancer

($P<0.05$), which was in agreement with the reported results[75]. The result convincingly suggested that the P16 protein deletion might be related to gastric cancer metastasis and indicate P16 protein expression heterogentity in gastric cancer[76]. What was more intriguing that 2 neighboring lymph nodes metastasis cancer migrated from primary cancer had positive expression P16 protein. Expression of P16 protein is not only related to neoplasms metastasis but also related to prognosis and progression. Expression of P16 protein is low, clinical prognosis is bad[77-81]. We also investigated the relevance between various factors such as age, sex, the depth of invasion and Borrman classification and P16 protein expression in gastric cancer. There was no significant difference ($P>0.05$). The positive expression of P16 protein could merely be observed in partial adeno-epithelial cells of normal and dysplasia gastric mucosa, and weakly positive expression or undetectable in gastric mucosa epithelium cells, interstitial lymphocytes, fibroblasts and smooth muscle cells, which is contrary to some published files[82]. Nevertheless, others confer that the undetectability of P16 protein expression in neoplasm interstice[32], normal lung tissue[83] and normal urinoepithelial cells[82] might attribute to a paucity of P16 molecule in G_0/G_1[84] phase cells or short halftime of P16 protein[85].

Among some human neoplasms, *p*16 gene alterations always resided in exon 2[5]. There was no product of PCR amplification in 3 of 25 cases possibly due to the loss of homozygosis. Little product of PCR in 2 of 25 cases amplification might be the loss of heterozygosis or loss of homozygosis but normal mucosa contaminated. In the 5 cases, the expression of P16 protein was negative in 4 cases and weekly positive in one. The results manifested that 4 cases might be the loss of homozygosis and 1 case might be the loss of heterozygosis among the 5 cases of gastric cancer and the deletion of *p*16 gene is possibly related to the carcinogenesis and progression of gastric carcinoma. The rate of deletion in this study was slightly lower than that reported by others[74]. It was likely that only exon 2 was examined or inadequate for specimens or other unknown factors. Nevertheless, PCR amplification products were found in the rest 20 cases of gastric cancer, normal gastric mucosa and cancer-surrounding mucosa. No abnormal PAGE band and mutation of *p*16 gene was found by SSCP analysis digestion product of PCR amplification. We suggested that *p*16 gene was not involved in the carcinogenesis of gastric cancer, which coincided with other authors[86,87]. We also found that the frequency of *p*16 gene deletion was lower than that of deletion P16 protein expression. P16 protein was undetectable in normal and dysplasia gastric mucosa epithelial cells but in partial adenoepithelium. Some other uncertain mechanisms might exist in the regulation of *p*16 gene and the expression level of P16 protein[88-90], which require further studies.

Abstract

AIM **To correlate the length of the telomere to microsatellite instability (MSI) and loss of heterozygosity (LOH) of APC, MCC and DCC genes in gastric carcinomas.**

METHODS **Telomeric restriction fragment (TRF) length of gastric cancer was measured with Southern blot. LOH of APC, MCC and DCC genes, microsatellite instability (MSI) and frameshift mutation of hMSH6, TGF-βRII and BAX genes were analyzed by PCR-based methods.**

RESULTS **Sixty-eight cases of sporadic gastric carcinoma were studied for MSI using five microsatellite markers. MSI in at least one locus was detected in** 17 (25%) **of** 68 **tumors analyzed. Frameshift mutations of hMSH6, TGF-βRII and BAX were detected in** 2,6 **and 3 of gastric carcinomas respectively showing high MSI (**≥2 **loci, *n* =** 8**), but none was found in those showing low MSI (only one locus, *n*=**9**) or MSS (tumor lacking MSI or stable, *n*=**51**). Thirty-five cases, including all high MSI and low MSI, were studied for TRF. The mean TRF length was not correlated with clinicopathological parameters. No association was observed between TRF length and MSI or frameshift mutation. On the contrary, LOH at the DCC locus was related to telomere shortening (*P*<**0.01**). This tendency was also observed in APC and MCC genes, although there was no statistical significance.**

CONCLUSION **The development of gastric cancer can arise through two different genetic pathways. In high MSI gastric cancers, defective mismatch repair allows mutations to accumulate and generate the high MSI phenotype. In gastric cancers showing either low MSI or MSS, multiple deletions may represent the LOH pathway. Telomere erosion is independent of high MSI phenotype but related to the LOH pathway in gastric cancer.**

INTRODUCTION

Eukaryotic linear chromosomes are capped by a special structure known as the telomere. In vertebrates, telomeres consist of several kilobases of tandem TTAGGG repeats bound by the related telomere-specific proteins, TRF1 and TRF2[1,2]. TRF1 regulates telomere length[3] and TRF2 maintains telomere integrity[4]. In most human cells, telomeres shorten with each cell division due to the incomplete replication of linear DNA molecules and the absence of telomere-elongating mechanisms[5]. It has been reported that telomeric repeats are often reduced in various human tumors as a consequence of many cell divisions of tumor cells, and the loss of telomeric repeats would cause additional senetic changes as a consequence of chromosomal instability.

The presence of telomeric DNA at the chromosomal termini is essential for genetic stability. Genetic instability may be classified into two different forms in which hypermutability occurs either by means of chromosomal instability or microsatellite instability (MSI)[6-10]. There is now increasing evidence that telomere shortening is involved in chromosomal instability. Indeed telomeres are thought to maintain the chromosome integrity during the cell cycle by allowing a proper segregation during cell division. Broken chromosomes that are uncapped become hotspots for different types of recombination. They may therefore undergo aberrant recombination, end-to-end fusions and bridge-fusion-breakage mechanisms. Being unprotected, the chromosomes are also susceptible to exonucleolytic degradation[11]. Telomeres would also prevent the activation of DNA-damage check-points[12]. Thus, without these essential structures, the chromosome is unstable.

MSI represents an important new form of genetic alteration characterized by widespread instability in repetitive nucleotide sequences. MSI has been found in the majority of tumors associated with hereditary non-polyposis colorectal cancer (HNPCC)[13,14] in which germ-line mutation occurs within the mismatch repair genes hMSH2, hMLH1, hPMS2 or hMSH6[15-17]. Mutations of the transforming growth factor type II receptor gene (TGF-βR II), and BAX gene are strongly correlated with MSI[18-20]. MSI is also a distinctive feature in about 10%-15% of sporadic colorectal tumors and to a varying degree in tumors of other organs, including the stomach[7,21-24]. Although alterations of telomerase activity have been reported in MSI and microsatellite stable (MSS) tumors[25,26], less clear, however, the relevance of progressive telomere shortening as a potential factor in MSI is less clear. The aim of the present study is to correlate telomere status with MSI and loss of heterozygosity (LOH) of APC, MCC and DCC genes in gastric carcinomas.

MATERIAL AND METHOD

Sixty-eight cancer and corresponding normal tissues were obtained from surgically resected gastric carcinoma patients in our hospital. Each specimen was frozen immediately and

stored at -80℃ until analyzed. A 5μm section was cut from each tissue and stained with hematoxylin /eosin in order to ascertain whether the cancer cells in tissues were predominant or not. Genomic DNA was isolated by standard proteinase-K digestion and phenol-chloroform extraction protocols. Of the 68 patients with gastric cancer, 45 were men and 23 were women with an age range of 30-76 years (mean age of 56.2 years at diagnosis). None of the patients included in the present series had a family history suggestive of HNPCC and had received chemotherapy or radiation therapy.

MSI analyses included five microsatellite markers: BAT25, BAT26, BAT40, D2S123, and D5S346. PCR was performed in 15μL of reaction mixture containing 10mmol·L^{-1} Tris-HCl (pH 8.3), 50mmol·L^{-1} KCl, 1.5mmol·L^{-1} $MgCl_2$, 200μmol·L^{-1} each deoxynucleotide triphoshate, 0.5μmol·L^{-1} of each primer, 0.75unit Ampli Taq polymerase (Perkin-Elmer, Norwalk, CT, USA), and 100ng genomic DNA. The reaction was carried out in a thermal cycler at 94℃ for 1min, 55℃-62℃ for 1min, and 72℃ for 1min, for 35 cycles with an initial denaturation step of 94℃ for 5min and a final extension step of 72℃ for 10min. The PCR products were then separated on 5% polyacrylamide, 7M urea denaturing gel, and visualized by autoradiography. MSI was defined as the presence of band shift in the tumor DNA that was not present in the corresponding normal DNA. Based on the number of mutated MSI markers in each tumor, carcinomas were characterized as high MSI if they manifested instability at two or more markers, low MSI if unstable at only one marker, and MSS if they showed no instability at any markers (microsatellite stable)[27-29].

To detect frameshift mutations in coding regions, repetitive mononucleotide sequences, the (A)10 tract of TGF-βRII, the (G)8 tract of BAX and the (C)8 tract of mismatch repair gene MSH6 were amplified using published primers, respectively[30-32]. The reaction condition consisted of 35 cycles at 94℃ for 1min, 55℃ or 56℃ for 1min and 72℃ for 1min using 0.5μCi[33p] dATP into 15μL reaction mixture. DNA denaturation, electrophoresis and autoradiographic procedure were done likewise with MSI analysis, except for TGF-βRII where 8% denaturing gel was used.

Southern blot analysis to estimate telomeric restriction fragment (TRF) length was based on previously reported methods[33]. High molecular weight DNA was prepared from each sample, followed by extraction with phenol chloroform isoamyl alcohol and precipitation with 3M sodium acetate and ethanol. Genomic DNA was digested with *Hin* fI (Promega, USA)at 37℃ for 6 hours and then 10μg of digested DNA was subject to electrophoresis on 1% agarose gels. After electrophoresis, the gel was denatured in 0.5M NaOH and 1.5M NaCl for 30 minutes and neutralized in 0.5M Tris (pH 8.0) and 1.5M NaCl for 30 minutes. The DNA was then transferred onto a nitrocellulose membrane (Promega, USA) overnight. The membrane was dried at 80℃ for 1 hour and subsequently hybridized to α-^{32} P-ATP end- labeled $(TTAGGG)_4$ probe. The membranes were autoradiographed on X-ray films for 24 hours. Each lane was scanned with a densitometer and the data was used to determine the mean TRF length as previously described[34].

The APC, MCC and DCC genes were investigated for LOH and PCR was carried out as described[35,36]. The priming regions were located within specific tumor suppressor genes at sequence, either a restriction fragment length polymorphism (RFLP) or a variable mumber of tandem repeats-type polymorphism (VNTR)[37]. Annealing temperature, extension time and the number of amplification cycles were optimized for each primer set. After amplification, PCR products were digested with appropriate restriction enzymes (for RFLPs) or not digested (for VNTRs) and electrophoresed on 1.5% agarose gels or 8% polyacrylamide gels, which were stained with ethidium bromide and photographed under UV light. When the intensity of one allele in cancerous tissue was less than 50% of the other allele in comparison with the ratio of intensity of the allele in the corresponding normal tissue, it was judged as LOH.

One factor analysis of variance, and Chi-square test with Yates' correction were used. A P value <0.05 was considered significant.

RESUTS

Alterations of electrophoretic patterns of PCR products of five microsatellite markers, TGF-βRII, BAX, and MSH3 genes were compared between tumor and normal DNA in each patient (Figures 1,2). MSI affecting at least one locus was observed in 17 (25%) of 68 tumors, among which eight (11.8%) had high MSI and nine (13.2%) had low MIS. A comparison of MSI status with frameshift mutation is shown in Table 1. The (A)10 frameshift mutation in TGF-βRII gene was detected in 6 of 8 gastric cancers with high MSI, whereas none of the low MSI or MSS tumors showed such a mutation. The mutation in the BAX (G)8 repeat site and hMSH6 (C)8 tracts was detected in 3 of 8 and 2 of 8 gastric cancers with high MSI, respectively, and no mutation was found in tumors with low MSI and MSS.

Table 1 Relationship between MSI status and frameshift mutation

MSI status	No. of cases	Frameshift mutations		
		MSH6	TGF β RII	BAX
MSI-H	8	2	6	3
MSI-L	9	0	0	0
MSS	51	0	0	0

Thirty-five gastric cancers, including all 8 with high MSI and 9 with low MSI, were examined for alteration in TRF length using the Southern blot technique. Since the signal of telomeric repeats is detected as a smear (Figure 3), we visually determined the peak of signal, which was confirmed using a densitometer. When the TRF length in the tumor was more than 20% shorter or longer than that in corresponding normal tissues, we classified the TRFs as shortened or elongated, as previously described[38]. Compared with the corresponding normal mucosa, 20 (57.1%) had considerable shortening (<80% of corresponding normal tissues), 12 (34.3%) had approximately the same length (between 80%-120%), and 3(8.6%) showed elongation (>120%). No correlation was found between mean TRF length and clinicopathological parameters in gastric carcinomas. However, a decrease of the mean TRF length with the age was observed except for the group aged from 50 to 59 years. The mean TRF length in the age group of 30 to 39 years was significantly longer than that in the group aged from 60 to 69 years or 70 to 79 years (P <0.05) (Table 2).

We compared the TRF length with MSI and frameshift mutation status. Table 3 shows the association of MSI and frameshift status to the TRF length of 35 gastric cancers. No relationship was observed between TRF length and MSI or frameshift mutation in gastric cancer.

Tissues from 35 patients were also studied for LOH of APC, MCC and DCC. In order to increase the assay sensitivity, three different sites, i.e., M2, M3 and VNTR were used for analysis of LOH at DCC genetic locus. LOH of APC, MCC and DCC were observed in 6 (27.3%) of 22, 7 (36.8%) of 19 and 18(56.3%) of 32 of informative cases, respectively (Figure 4). The relationship between LOH at various loci and the alteration in TRF length in primary tumors is shown in Table 4. LOH at the DCC locus were associated with telomere shortening (P<0.01). This tendency was also observed in APC and MCC genes, although there was no statistical significance.

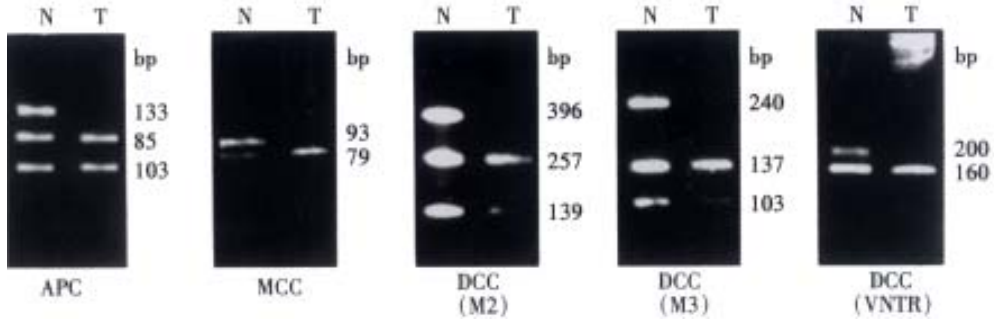

Figure 4 Representative LOH analysis of APC, MCC and DCC genes. (APC: Rsa1 RFLP in APC exon 11, loss of 133bp allele is seen in tumor DNA, MCC: A 14bp insertion / deletion polymorphism in MCC exon 10 gives rise to a 93 or 79 allele. Loss of the 93bp allele is seen in the tumor. DCC: Losses of 396bp, 240bp and 200bp alleles are seen at M2, M3 and VNTR polymorphic sequences in the tumor DNA)

DISCUSSION

In this study, 17(25%) of 68 sporadic gastric cancers had MSI in at least one locus. This finding is similar to previous studies[23,39]. There is now evidence that MSI cancer comprises distinctive high MSI and low MSI categories[40,41]. High MSI cancers are distinguished clinicopathologically and in their spectrum of genetic alterations from cancers showing low MSI and MSS cancers[40,41]. Our previous studies indicated that high MSI gastric cancers often show lower frequency of LOH of APC, MCC and DCC genes than low MSI and MSS cancers[41]. In our series of 68 gastric cancers, 8 were classified as high MSI, 9 as low MSI and 51 as MSS. Frameshift mutations of hMSH6, TGF-β RII and BAX were detected in gastric carcinomas with high MSI, but no mutation of these genes was found in those showing low MSI or MSS. These results indicate that these genes are mutational targets in high MSI tumor cells and support the notion that high MIS tumors identify an alterative pathway of tumorigenesis that has been proposed by Vogelstein and co-workers[42].

In the present study, 35 gastric carcinomas were examined for TRF length using the Southern blot. Telomere shortening was detected in 57.1% of the gastric carcinomas, indicating that telomere erosion may play a role in the gastric carcinoma development. It has been reported that telomere shortening was associated with a short survival and disease recurrent in prostate cancer[43]. In the current study, subdivision of the tumors according to telomere length did not reveal an obvious relationship between the shortening of telomere and tumor size, depth of invasion, node metastasis or clinical stages, indicating a limited role of the telomere shortening in predicting prognosis of gastric carcinomas. This finding is in agreement with the recently published data on renal cell carcinoma and colorectal carcinomas[44,45].

TRF reduction was demonstrated in various human malignant tumors[38,45-47]. In contrast to these results, it was also found that telomeres in some tumors are similar to, even elongated, as compared with normal tissues[36,48]. In this study, the mean TRF length was reduced in 20 of 35 tumors, similar in 12 cases and elongated in 3 cases, as compared with the corresponding normal mucosa. The discrepancy in TRF length may be related for several reasons. For tumor samples with TRF of normal length, there are at least three possibilities: ① The majority of cells in such tumors have not experienced many cell divisions nor experienced critical shortening of telomeric repeats; ② In most tumor cells, telomerase already activated, elongated the once shortened telomeric repeats back to normal length, as observed in HPV-immortalized epithelial cells *in vitro*[49]; and ③ The amount of tumor cells also affects TRF analysis. Therefore, with the predominance of normal cells in tumor specimens, telomere loss may be underestimated[48]. We found that the TRF length in tumors was progressively reduced with age, suggesting that patients' age should be considered in evaluating the TRF lengths of tumor. Finally, end-to-end chromosome fusion observed in some tumors could lead to telomere elongation[50].

It has been reported that telomerase activity and microsatellite instability are independent events in colorectal carcinogenesis[25]. To our knowledge, this is the first report on the relationship between MSI and telomere length. We did not find any correlation between telomere erosion and MSI, suggesting that the MSI pathway is independent of telomere erosion.

It has been found that chromosomal instability is correlated with telomere erosion and inactivation of G2 checkpoint function in human fibroblasts[12]. Alterations in the TRF length were often associated with LOH of the p53 gene and Rb gene, but less often with mutation of k-ras and p53 genes in lung cancer[38]. We found that LOH at the DCC locus was associated with telomere shortening. Although not statistically significant, LOH at the APC and MCC genetic loci tends to occur in telomere shortened gastric cancers, indicating that telomere erosion may be involved in the LOH pathway.

In summary, our data indicate that telomere shortening may play a role in gastric carcinogenesis. There are at least two distinct genetic instabilities in gastric tumorigenesis: one is the chromosomal instability (or suppressor pathway) and the other is microsatellite instability (or MSI pathway). The former, may include tumors with low MIS as well as MSS and accumulation of loss of tumor suppressor genes such as p53, Rb, APC, MCC and DCC plays an important role in their carcinogenesis; whereas the latter consists of a small subset of gastric cancer with high MSI, defective repair of mismatched bases results in an increased mutation rate at the nucleotide level, and consequent widespread MSI. Telomere shortening may be involved in the LOH pathway but independent of the MSI pathway. Our analysis of TRFs should further provide some clues to the molecular mechanisms underlying the profound genomic instability in the MSI and LOH pathway for gastric carcinoma.

Abstract

AIM **To extract and purify the transforming growth factor β (TGF β), and to demonstrate its biological activity *in vivo* and induction of apoptosis of hepatocytes *in vitro*.**

METHODS **TGF β was isolated from fresh bovine platelets by acid/ethanol extraction method and purified with ion exchange and gel chromatography. The extracted TGF β as injected subcutaneously to mice, and its biological activity *in vivo* was observed** 72 **hrs post-injection by HE staining. The morphological changes were observed by HE staining and the occurrence of apoptosis was detected by TUNEL method after the human normal hepatic cell line QZG was treated with** 8μg·L^{-1}**TGFβ for** 12 **hrs *in vitro*.**

RESULTS **The molecular mass** 25 **ku TGF β protein was successfully extracted. It was able to induce localized granulation tissue formation *in vivo*. TGF β-treated hepatocytes showed obvious apoptotic morphological changes, including the pyknosis and dense-stained nuclei and cytoplasm, the fragmentary, annular or crescent nuclei, and the "bubbling" cytoplasm. Moreover, its apoptotic rate was significantly higher than that of the control group** (***P***<0.05)**.**

CONCLUSION **Biological active TGF β protein is extracted and purified successfully from bovine platelets, and it is able to induce the apoptosis of hepatocytes.**

INTRODUCTION

Liver diseases are very common in China[1-10], and apoptosis is the research focus in recent years[11-20]. Transforming growth factor β (TGFβ) is a kind of polypeptide growth factors that is extensively present in most tissues and cells. A variety of cell types, both nonneoplastic and neoplastic, synthesize TGF β and most of these cells have specific high-affinity receptors for TGF β[21-24]. It is a multifunctional molecule which is known to play an important regulatory role in cell growth, migration and differentiation[25], embryogenesis[26,27], tumorigenesis[28], wound healing[29-31], bone formation[32-35] and immunomodulation[36], acting by both autocrine and paracrine mechanisms. It is also suggested that TGF β may be responsible for some pathological process, such as scarring and fibrosis, renal diseases and immunosuppressant[37-39]. Furthermore, TGF β is able to induce many kinds of cells, including hepatic and hepatoma cells to undergo apoptosis[40,41]. The molecular mechanisms underlying TGF β induction of the apoptosis of hepatocytes is still unclear. In this study, TGF β was extracted from the fresh bovine platelets by acid/ethanol procedure and purified by ion exchange and gel chromatography, then its biological activity was detected *in vivo* and its induction of apoptosis of cultured hepatocytes was observed *in vitro*, and to provide the basis for the study of the relationship between TGFβ and the signal transduction of hepatocellular-apoptosis.

MATERIALS AND METHODS

Isolation of platelets

The fresh anticoagulant bovine blood was collected in bags containing 0.1 volume of 8.78g·L^{-1} NaCl and 22.50g·L^{-1} EDTA (pH 7.4). The blood was centrifuged at 2000r·min^{-1} for 15 min and the supernatant was recentrifuged at 4000r·min^{-1} for 15 min. Then the supernatant was discarded and the precipitated platelets was washed twice with PBS (pH 7.4) by centrifugation at 5000r·min^{-1} for 30 min[42,43]. All the centrifugations were carried out at 0℃.

Extraction procedure

TGF β was extracted by a modified acid/ethanol procedure of Roberts and others[44,45]. The platelets were suspended in acid/ethanol extraction solution containing 375mL of 950mL·L^{-1} ethanol and 7.5mL of concentrated HCl, plus 33mg phenylmethylsulfonyl fluoride(PMSF) and 1.9mg pepstatin A as protease inhibitors. The mixture was sonicated in ice-bath, extracted overnight at 4℃, and centrifuged at 15000r·min^{-1} for 40 min at 0℃. The supernatant was adjusted to pH 3.0 with concentrated ammonium hydroxide. Then 2 volumes of cold anhydrous ethanol (-20℃) and 4 volumes of cold anhydrous ether (-20℃) were immediately added. After the mixture stood at -20℃ for 48 hrs, the resulting precipitate was collected by centrifugation at 20000r·min^{-1} for 30 min at 0℃ and redissolved in 1mol·L^{-1} acetic acid. After extensive dialysis at 4℃ against 0.17mol·L^{-1} acetic acid in a dialyzing tube (molecular mass cutoff, 10000ku), the sample was then subjected to the next purification.

Ion-exchange chromatography

The above crude sample was centrifuged at 20000r·min^{-1} for 40 min at 0℃ to remove the small precipitate and the supernatant was then applied to a CM-Sepharose column

(1.6cm×11cm, Phamacia Biotech, Uppsala, Sweden) equilibrated with 0.17mol·L^{-1} acetic acid. The column was eluted successively with 0.17 mol·L^{-1} acetic acid, 41.02g·L^{-1} NaOAc, 82.04g·L^{-1} NaOAc and 4g·L^{-1} NaOH at a flow rate of 90mL·h^{-1} at room temperature. The fraction that eluted by 4g·L^{-1} NaOH was immediately neutralized by adding 100mL·L^{-1} acetic acid. The eluted fractions were collected respectively and subjected to sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS PAGE).

Gel chromatography

The above fractions containing 25ku component were collected, concentrated with glycol polyethylene and extensive dialyzed at 4℃ against tridistilled water and then 1 mol·L^{-1} acetic acid. After being centrifuged at 20000r·min^{-1} for 10 min, the supernatant was applied to a Superdex 75 column (1.6cm×70cm, Phamacia Biotech, Uppsala, Sweden) equilibrated with 1mol·L^{-1} acetic acid. The elution was carried out at a flow rate of 36mL·h^{-1} with 1mol·L^{-1} acetic acid containing 11.69g·L^{-1} NaCl at room temperature. The eluted fractions were collected and analyzed by SDS-PAGE. The fraction containing the 25ku component was concentrated using glycol polyethylene. After extensive dialysis at 4℃ against tridistilled water and 0.17mol·L^{-1} acetic acid, the samples were stored at -20℃ for the following assays. The protein content was determined by Coomassie brilliant blue G-250 method and bovine serum albumin (BSA) was used as control.

Detection of TGF β activity in vivo[46]

Nine male Balb/c mice (10 days old) were injected subcutaneously each day in the back with the purified TGF β (0.5g·L^{-1}). After 72 hrs, the tissues at the injection sites were removed and fixed in 100mL·L^{-1} formalin and paraffin sections were then subjected to the routine HE staining. The other 3 mice were injected with equivalent BSA as controls.

TGF β induction of hepatocellular apoptosis

Human normal hepatic cell line QZG (purchased from the Institute of Cell Biology, Chinese Academy of Sciences, Shanghai, China) were cultured routinely on cover slides. After having grown to logarithmic phase, 8μg·L^{-1} of TGF β was added and then for a further 12 hrs culture. BSA (8μg·L^{-1}) was added as control. The cells were subjected to HE staining. In addition, the cells were stained by terminal deoxynucleotidyl transferase (TdT) mediated dUTP nick end labeling (TUNEL) method to detect apoptosis[47]. A random field of cells was chosen with a magnification of ×400, and adjacent non overlapping fields were counted until the minimum 500 limits for each slide was obtained. TUNEL index was expressed as the number of positive cells/the total number of cells.

RESULTS

Purification of TGF β

The crude TGFβ was purified by ion exchange chromatography on a CM-Sepharose column, as shown in Figure 1. SDS-PAGE analysis showed that peaks 2 and 3 contained the 25ku component. The peaks 2 and 3 fractions were collected and then purified by gel chromatography on a Superdex-75 column (Figure 2). SDS PAGE analysis showed that peak 2 predominantly contained 25ku component (Figure 3) . The protein content was 1.1g·L^{-1}.

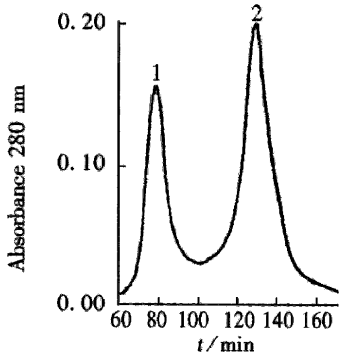

Figure 2 Gel chromatography of the CM-Sepharose peak 2 and peak 3 fractions on a Superdex-75 column.

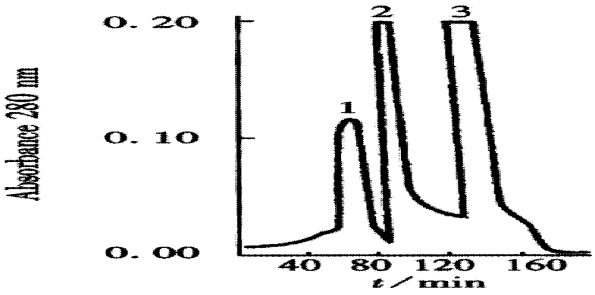

Figure 3 Molecular mass analysis of the extracted TGF β (SDS PAGE). Right Lane: marker proteins.

TGFβ activity in vivo

Seventy-two hrs after subcutaneous injection of TGF β, there was evident proliferation of fibroblasts and a few infiltration of inflammatory cells at the injection sites. The newly formed blood capillaries were also seen at the injection sites (Figure 4). The granulation tissue was confined at the injection sites. No obvious tissue change was observed in the control group.

Detection of apoptosis of hepatocytes

HE staining revealed that apoptotic hepatocytes exhibited the pyknosis and dense-stained nuclei and cytoplasm. Moreover, the nuclei demonstrated fragment, annular or crescent body, and the cytoplasm showed "bubbling" (Figure 5). TUNEL positive signals were olivine or yellow florescence in the nuclei. The TUNEL index of the TGF β treated group was 0.31 and distinctly higher than that of control group (0.09), (P<0.05)

DISCUSSION

TGF β is a disulfide-linked homodimeric 25ku protein that consists of two identical 112 amino acid subunits, and only the dimer is biologically active. It is acid and heat stable and the presence of 18 half cystine residues in each dimeric molecular contributes to this stability[48-50]. There are at least five described subtypes of TGF β, encoded by distinct but closely related genes. TGF β 1, 2 and 3 have been found in many species, including humans; TGF β 4 has been found in chickens and TGF β 5 in amphibians[51] . Bone is the richest source of TGF β in the body, as it contains more than 200μg per kg of wet weight, whereas blood platelets represent the most concentrated source of TGF β (up to 20mg per kg of wet weight) and is released from β granules of platelets when blood clots[52,53]. Therefore, TGF β is generally extracted from the fresh platelets. It is suggested that TGF β is highly stable under acidic condition and can be activated by heating in boiling water for 5 min, or treatment with 1N acetic acid or 6M urea. The acid/ ethanol procedure is a practical way and previously used to extract biologically active polypeptides such as insulin, insulin like growth factor and platelet-derived growth factor[54,55]. Some other studies verify the effectiveness of this extraction procedure for isolation of TGF β from many tissues, including platelets, placenta and kidney[53,56,57]. Isolation of TGF β from platelets includes five steps: collection and washing of platelets, acid/ethanol extraction, ethanol/ether precipitation, ion exchange chromatography and gel chromatography. In the present study, crude TGF β was isolated from the fresh bovine platelets and then purified by ion exchange and gel chromatography. The SDS-PAGE analysis showed that the molecular weight of its main component was 25ku,which corresponded to that of standard TGF β protein.

Wound healing and tissue repair involve a complex series of biological events which include inflammation, cellular migration, fibroblasts proliferation, production of collagen and tissue remodeling. Growth factors have been reported to enhance the repair process in animal models by increasing the degree of cellularity, the rate of angiogenesis, and the amount of collagen accumulated[58,59]. TGF β has been studied in association with wound healing and the ability of TGF β to initiate a cascade of events leading to enhanced wound healing has been clearly demonstrated by many reports. Pierce and co-workers[60-65] have reported that TGF β significantly accelerate soft tissue repair by attracting fibroblasts into the wound and stimulating rapid synthesis, deposition and maturation of collagen *in vitro* and *in vivo*. Other major activities of TGF β are its abilities to promote the synthesis and deposition of various extracellular matrix (ECM) proteins and increase the expression of integrins and fibronectin, receptors that mediate cellular interactions with ECM proteins[66,67]. Different assay systems have been developed to measure the TGF β activities, including cell proliferation and inhibition assays, radio receptor assays, immunoassays and matrix formation or cell surface antigens expression assays[68,69]. In the present study, the analysis of activity *in vivo* demonstrated that there were fibroblast proliferation and blood capillaries formation after subcutaneous injection of the extracted TGF β. Moreover, the granulation tissue was only located in the injection sites and had no tendency to diffuse. That the action of the extracted TGF β *in vivo* led to granulation tissue formation suggested the successful extraction of TGF β and its participation in repair of tissue injury.

TGF β has been shown to either stimulate or inhibit proliferation in different cell types, and within same cell types, depending upon the stage of cell differentiation, *in vitro* condition and the presence of other growth factors. TGF β has a stimulatory effect on the proliferation of cells of mesenchymal origin, such as fibroblasts, osteoblasts and Schwann cells, yet is a growth inhibitor for cells of epithelial or neuroectodermal origin, including epithelial cells, osteoclasts, keratinocytes, T and B lymphocytes, endothelial cells and hepatocytes[70-72].

Apoptosis is a genetically and highly conserved process. Regulation of the balance between cell proliferation and apoptosis is essential for development and maintenance of multicellular organisms[73-77]. Previous studies suggest that TGF β is able to induce evidently apoptosis of hepatocytes and hepatoma cells *in vitro*. The animal experiments *in vivo* also manifest that the hepatocytes undergoing apoptosis have obviously elevated level of TGF β expression[78,79]. Furthermore, hepatoma cells which have a high apoptotic incidence rate, simultaneously demonstrate a high level of TGF β expression[80]. These studies suggest an involvement of TGF β in the initiation of apoptosis of hepatocytes. In our HE staining, normal hepatic cell line QZG showed remarkable morphological changes of apoptosis, including the pyknotic and hyperchromic cytoplasm and nuclei, and the fragmentary, crescent form or annular nuclei, and the “bubbling” cytoplasm, after being treated with exogenous TGF β. TUNEL staining also showed that the incidence rate of apoptosis was distincly higher in the TGF β treated group than that of the control group. The present study further supported the apoptotic induction of hepatocytes by TGF β, and verified the good biological activity of the extracted TGF β as well. Better understanding of the relationship between TGF β and the signal transduction of hepatocellular apoptosis requires further investigations.

Abstract

AIM **To investigate the correlation between lymphogenous metastasis and matrix metalloproteinases (MMPs) activity and the expression of Fas ligand of tumor cells in lymph nodes.**

METHODES **Fifty-six inbred 615-mice were equally divided into 2 groups and inoculated with Hca-F and Hca-P cells. Their lymph node metastatic rates were examined. Growth fraction of lymphocytes in host lymph nodes was detected by flow cytometry. The Hca-F and Hca-P cells were cultured with extract of lymph node, liver or spleen. The quantity of MMPs in these supernatants was examined by zymographic analysis. The expression of Fas ligand, PCNA, Bcl-2 protein of Hca-F and Hca-P cells in the mice were examined by immunohistochemistry. The apoptosis signals of macrophages in lymph nodes were observed with *in situ* DNA fragmentation.**

RESULTS **On the 28th day post-inoculation, the lymph node metastatic rate of Hca-F was 80%(16/20), whereas that of Hca-P was 25%(5/20). The growth fraction of lymphocytes was as follows: in the Hca-F cells, the proliferating peak of lymphocytes appeared on the 14th day post-inoculation and then decreased rapidly, while in Hca-P cells, the peak appeared on the 7th day post inoculation and then kept at a high level. With the extract of lymph node, the quantity of the MMP-9 activity increased (P<0.01) and active MMP-9 and MMP-2 were produced by both Hca-F and Hca-P tumor cells, which did not produce MMPs without the extract of lymph node or with the extracts of the liver and spleen. The expression of Fas Ligand of Hca-F cells was stronger than that of Hca-P cells (P<0.01). The expressions of PCNA and Bcl-2 protein of Hca-F cells in the tumors of inoculated area were the same as that of Hca-P cells. *In situ* DNA fragmentation showed that the positive signals of macrophages were around Hca-F cells.**

CONCLUSION **Secretion of MMPs which was associated with metastatic ability of Hca-F and Hca-P tumor cells depends on the environment of lymph nodes. The increased expression of Fas ligand protein of Hca-F tumor cells with high lymphogenous metastatic potential in lymph nodes may help tumor cells escape from being killed by host lymphocytes.**

INTRODUCTION

Metastasis is the most lethal attribute of a cancer[1,2]. Metastasis is a complex process which is made up of several steps[3]. Lymph nodes are often the first organ to develop metastasis[4,5]. Whether lymph nodes or other sites first develop metastases remain poorly understood. Lymph node metastases form a bridgehead for further metastatic spread. But its molecular mechanism is still unclear because of its complicated course. Anchorage on lymph node and escape from being killed by host immune cells in lymph node were two important steps. A mouse hepatocarcinoma cell line (Hca-F) with high lymphogenous metastatic potential and its syngeneic cell line (Hca-P) with low one were separated from hepatocarcinoma (HCC)[6] in mice. Matrix metalloproteinases (MMPs)[7] are a class of proteinases with variable substrate such as collagen, fibronectin and are related to the invasion-metastasis of hepatocellular cancer (HCC)[8]. Therefore, MMPs can be used as a marker of tumor cell infiltration in lymph node. The potential of tumor cells to induce apoptosis of host immune cells is to escape from being killed by immune cells. In this study, we detected the differences in the MMPs productions of Hca-F from Hca-P cells under various conditions, and different potentials of the carcinoma cells with different lymphogenous potentials to inhibit host immune reaction.

MATERIALS AND METHODS

Animals, cell lines and flow cytometry

Fifty-six inbred 615-mice maintained in our laboratory were equally divided into two groups. The Hca-F and Hca-P tumor cell lines preserved in our laboratory were inoculated at 2×10^6 in 28 mice subcutaneously in each group. On the 7th, 14th, 21st, and 28th day post-inoculation, two mice from each group were killed, and their lymphocytes were collected and detected for growth fraction with flow cytometry. The process of flow cytometry is as follows[9]: the lymph nodes were minced and centrifuged at 3000×g, and the supernatant was discarded. After repeated washing, cells were suspended in PBS. The lymphocytes at 10^5/100μL suspension were stained for 30 minutes by Propidum Iodide. Flow cytometry

was performed on a FACScan cytometer with LYSYII software. The fluorescence of 10^4 cells was analyzed for each sample. The other 40 mice were terminated on the 28th day post-inoculation, and their lymph nodes were H.E. stained and examined under microscope by paraffin sections. Therefore, the lymph node metastatic rates of Hca-F and Hca-P tumor cells were calculated.

Cell culture and zymographic analysis

The Hca-F and Hca-P cells cultured were put into different wells at 5×10^5, and then added 50mg extract of lymph node, liver or spleen respectively. The RPMI 1640 medium without fetal calf serum was placed into each well up to 1mL. The wells containing only Hca-F or Hca-P cells, and RPMI 1640 medium added only extracts of lymph node, liver or spleen up to 1mL served as controls. These cells were cultured at 37℃ for 24h. The supernatant of cultured cells was collected by centrifugation at 3000×*g*. MMP-2 and MMP-9 and their active type, and MMP-8 contained in supernatants of Hca-F and Hca-P with or without extracts of lymph node, liver or spleen were detected by zymographic analysis, according to the method described by Fridman *et al*[10]. The density and area of each band were measured using QuantiScan Software (Biosoft, USA).

Immunohistochemistry

The expressions of Fas-L (Santa Cruz, USA), proliferating cell nuclear antigen (Santa Cruz, USA, PCNA) and Bcl-2 (Santa Cruz, USA) protein in the tumor cells of inoculated area of Hca-F and Hca-P tumor cells, and metastatic tumor cells of lymph nodes of Hca-F were detected by standard immunohistochemistry[11]. The semiquantitative estimation of cancer cells stained was classified into 4 categories by assessing the percentage of stained tumor cells: 0, <2%; 1, 2%-25%; 2, 26%-50%; 3, 51%-75%; and 4, >75% cells.

In situ DNA fragmentation

We examined DNA fragmentation of the tumor cells of inoculated area of Hca-F and Hca-P cells, and metastatic tumor cells of Hca-F cells in lymph node, by the method of Zhu *et al*[12]. After desparaffin, these slides were pre-treated with $20mg\cdot L^{-1}$ proteinase K for 30 minutes, and then incubated with terminal deoxynucleotidy transferase and fluorescein labeled dUTP containing nucleotide mixture (TUNEL reaction mixture, *in situ* Cell Death Detection Kit/ POD, Boehringer Mannheim, Germany) in a humid atmosphere at 37℃ for 30 minutes. Each experiment set up by TUNEL reaction mixture without terminal transferase served as negative control.

RESULTS

Lymph node metastatic rate and flow cytometry

On the 28th day post-inoculation, the lymph node metastatic rate of Hca-F was 80%(16/20), whereas that of Hca-P was 25%(5/20). The growth fraction of lymphocytes from lymph nodes of mice transplanted with Hca-F and Hca-P tumor cells was examined using flow cytometry (Figure 1). For the Hca-F cells, the proliferating peak of lymphocytes appeared on the 14th day post-inoculation and then decreased rapidly, and for the Hca-P cells, the peak appeared on the 7th day post-inoculation and then kept at the high level.

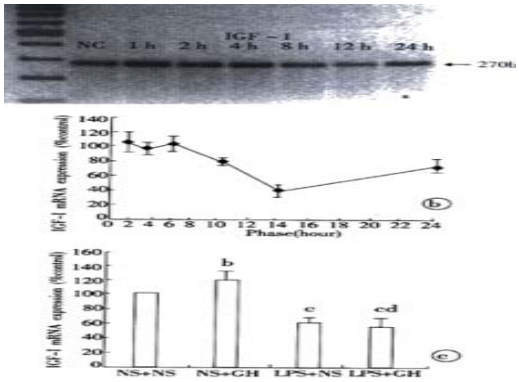

Figure 1 Changes of growth fraction of lmphocytes (G_2+S/G_1+G_2 +S+M) in draining lymph nodes of Hca-F/Hca-P burden mice.

Zymographic analysis

Both Hca-F and Hca-P cells produced a small account of MMP-9, but did not produce MMP-2 and MMP-8 (Table 1, Figure 2). Both Hca-F and Hca-P cells with extract of lymph node produced higher amounts of MMP-9 than Hca-F and Hca-P cells without extract of lymph node ($P<0.01$), and produced active MMP-9 and MMP-2. However, the Hca-F cells produce much greater quantities of activity of MMP-9, active MMP-9 and MMP-2 than Hca-P cells ($P<0.05$). The extract of lymph node did not contain any MMPs (Table 1, Figure 2). There was activity of MMP-8 in both Hca-F and Hca-P cells with extract of liver (Hca-F: 1767, Hca-P: 1564). The extract of liver contained activity of MMP-8 (1837). There was activity of MMP-8 in both Hca-F and Hca-P cells with extract of spleen (Hca-F: 2036, Hca-P: 1993). The extract of spleen contained the same quantity of activity of MMP-8 (1784). Therefore, we think that both Hca-F and Hca-P cells in the environment of liver and spleen did not produce activity of MMP-8 (Figures 3, 4).

Table 1 Activities of MMPs secreted from Hca-F and Hca-P cells under different conditions ($\bar{x}\pm s$)

Condition	MMP-2	Active MMP-2	MMP-9	Active MMP-9
Hca-F				
RPMI1640 medium	0	0	1256±157	0
Medium with lymph node extract	7364±2001	2009±901	12403±894	7297±1657
Hca-P				
RPMI1640 medium	0	0	2642±385	0
Medium with lymph node extract	2997±1990	1237±905	9086±686	3914±1253
Lmyph node extract	0	0	0	0

3. Hca-P cells in liver extract; 4. Liver extract.

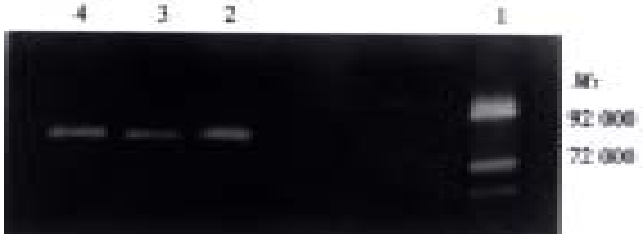

Figure 4 MMPs activity of Hca-F and Hca-P cells in spleen extract by using zymographic analysis.
1. Type-four collagenase; 2. Hca-F cells in spleen extract;
3. Hca-P cells in spleen extract; 4. Spleen extract.

Table 2 Analysis of Fas-L expression in Hca-F and Hca-P cells

Tumor	Grade				
	0	1	2	3	4
Primary tumor of Hca-F	0	0	0	8	12
Primary tumor of Hca-P	2	10	8	0	0
Metastatic tumor of Hca-F	0	5	9	6	0

Immunohistochemistry

The expression of Fas ligand protein of Hca-F cells was significantly higher than that of Hca-P cells ($P<0.01$, Table 2, Figure 5). The expressions of PCNA and Bcl-2 protein of Hca-F cells were as strong as those of Hca-P cells.

In situ DNA fragmentation

Few positive Hca-F and Hca-P cells were observed. Positive signals appeared in the macrophages around Hca-F cells (Figure 6).

DISCUSSION

As early as a hundred years ago, the fact that tumor cells had organ-specific metastasis had attracted scientists' attention. Recent major discoveries concerning invasion and metastasis are identification of certain molecular mechanisms leading to organ-selective metastatization[13]. Cancer cell gene expression is regulated by interactions of tumor cells with host microenvironment, both in primary and secondary

lesions[14,15]. Whether the anchorage of carcinoma cells in lymph nodes is influenced by the specific environment of the lymph nodes remains unclear. Hca-F and Hca-P tumor cells have the potentials of specific lymphogenous metastasis. The matrix metalloproteinases[16] (MMPs) are a family of proteolytic enzymes, and the importance of MMPs in the processes of tumor invasion is now widely acknowledged in gastrointestinal cancer[17], breast cancer[18], colorectal cancer[19], and melanoma[20]. Inhibit the activity of MMPs can reduce the metastatic potential of cancer cells[21]. MMps digest collagen-containing structural barriers that cancer cells must pass in the step of cancer cell's anchoring to lymph node[22]. In this paper when the extract of lymph node was added, the quantity of the MMP-9 activity increased and active MMP-9 and MMP-2 were produced by both Hca-F and Hca-P tumor cells, which did not produce MMPs without the extract of lymph node or with extracts of liver and spleen. These results indicated that the secretion of MMPs of these tumor cells depend on the lymph node environment. In the environment with extract of lymph node, Hca-F cells with high lymphogenous metastatic potential produced much more MMPs than Hca-P cells with low one. So we can conjecture that Hca-F cells with high lymphogenous metastatic potential can easily receive the signal from lymph node and then start to infiltrate in lymph node to form metastatic focus.

The macrometastases were more proliferative than dormant micrometastases[23]. PCNA[24] functions as a cofactor of DNA-polymerase and is an important mark for evaluating the proliferation of colon cancer[25,26], gastric adenocarcinoma[27], lung cancer[28], ovarian cancer[29], thyroid carcinoma[30], and large intestine polyps[31]. We can use PCNA as an index of cellular proliferative status[32]. Bcl-2 proteins can extend cell survival by suppressing apoptosis[33] and are up-regulated in squamous cell carcinoma[34], breast cancer[35], lung cancer[36]. Bcl-2 proteins may promote metastasis in breast cancer[37] and melanoma[38]. The expressions of PCNA and Bcl-2 proteins could reflect accurately the status of cancer cells's growth. The expressions of PCNA and Bcl-2 protein of Hca-F cells in the tumors of inoculated area are the same as those of Hca-P cells. Therefore, the proliferating ability of Hca-F was equal to Hca-P, although their lymph node metastatic potentials were different.

A metastatic tumor in lymph node may form as long as the tumor cells escape the killing of lymphocytes. Fas/Apo-1, together with its protein-binding partner (Fas ligand), is a key regulator of programmed cell death and induces apoptosis when it binds FasL[39-42]. In this study, we found that growth fraction of lymphocytes in host lymph nodes was lower with Hca-F cells stimulation than with Hca-P cells. The result suggests that Hca-F cells may inhibit the growth and function of lymphocytes in lymph nodes. Tumor cell survives only by evasion of the immune system[43]. The Fas/FasL system is involved in the induction of apoptosis and mediates T-cell cytotoxicyty[44]. The expression of Fas ligand in many cancers plays an important role in establishing immunologically privileged environments that allow tumors to escape the host's immune surveillance, such as in esophageal carcinomas[45,46], lung cancer[47], melanoma[48], gastric carcinoma[49], intrahepatic cholangiocellular carcinoma[50] and promotes these cancers' metastasis. The expression of Fas ligand protein of Hca-F cells was stronger than that of Hca-P cells. Hca-F cells also produced Fos ligand in lymph node. Macrophages in lymph node are one of important antigen-presenting cells, and Fas ligand in tumor cells can combine with Fas in the membrane of macrophages to induce apoptosis and decrease their function. Because lymphocytes can not receive the signals from the macrophages, tumor cells in lymph nodes can escape the suppression of lymphocytes, then accomplish the metastatic process in the lymph node.

In a word, secretion of MMPs, which was associated with metastatic ability, of Hca-F and Hca-P tumor cells depend on the environment of lymph nodes. The increased expression of Fas ligand protein of Hca-F tumor cells with a high lymphogenous metastatic potential in lymph nodes may help tumor cells escape from the killing of host lymphocytes and shape up metastatic focus in lymph nodes.

Abstract

AIM **To identify the property of dendritic cells (DCs) of peripheral blood monocytes (PBMC) in patients with chronic HBV infection.**

METHODS **Twenty patients with persistent HBV infection were included in this study,** 10 **healthy subjects being used as a control group. The peripheral blood mononuclear cells (PBMC) of T cell-depleted populations were incubated and induced into mature dendritic cells in the RPMI-**1640 **medium in the presence of cytokines GM-CSF, IL-**4**, FLt-**3**, TNF-α and** 100**mL·L^{-1} of fetal calf serum for a total of** 10-12 **days. The expressions of surface markers on DCs were evaluated using flow cytometric analysis. ELISA method was used to determine the cytokine levels of interleukin-**12 **(IL-**12**) and IL-**10 **in the supernatant produced by DCs. For detection of the stimulatory capacity of DCs to T cell proliferation, mytomycin C-treated DC were incubated with allogenic T cells.**

RESULTS **A typical morphology of mature DCs from healthy subjects and HBV-infected patients was induced in *in vitro* incubation, but the proliferation ability and cellular number of DCs from HBV-infected patients significantly decreased compared with healthy individuals. In particular, the expression levels of HLA-DR, CD**80 **(B**7-1**) and CD**86 **(B**7-2**) on DC surface from patients were also lower than that from healthy individuals** (0.46 ***vs*** 0.92 **for HLA-DR,** 0.44 ***vs*** 0.88 **for CD**80 **and** 0.44 ***vs*** 0.84 **for CD**86**, *P*<**0.05**). The stimulatory capacity and production of IL-**12 **of DCs from patients in allogenic mixed lymphocyte reaction (AMLR) significantly decreased, but the production level of nitric oxide (NO) by DCs simultaneously increased compared with healthy subjects** (86±15 ***vs*** 170±22 **μmol·L^{-1}, *P*<**0.05**).

CONCLUSION **The patients with chronic HBV infection have the defective function and immature phenotype of dendritic cells, which may be associated with the inability of efficient presentation of HBV antigens to host immune system for the clearance of HBV.**

INTRODUCTION

The infection of hepatitis B virus (HBV) causes 130 million HBV carriers, of them 23 million were patients with chronic hepatitis B in mainland China. As a result, a considerable number of the patients are developing progressive liver diseases such as liver cirrhosis and hepatocellular carcinoma (HCC) each year[1]. The pathogenesis of developing chronic HBV infection is complex and unclear[2]. The dominant reason responsible for viral persistence within host is mainly lack of efficient antiviral immune response to the viral antigens, in particular, inability to produce specific CTL response, which is critical for complete elimination of virus within hepatocytes[3,4]. The mechanism for weak antiviral immune reaction in patients is not well understood. Dendritic cells (DCs) are one of the most potent antigen-presenting cells (APC) and play crucial roles in the enhancement or regulation of antiviral immune reactions. The previous reports showed the defects of DCs function in HBV-transgenic mice and in patients with HCC and chronic HCV infections[5-13], but there is little evidence of defect DCs function in chronic HBV-infected patients. In order to have more insights in this regard, we induced peripheral blood monocytes (PBMC) from HBV-infected patients and uninfected healthy donors into maturation of DCs, compared their morphologic characterization, expression of surface antigens, and their proliferation capability to stimulate AMLR for evaluation of the functions of DCs.

MATERIALS AND METHODS

Patients

Blood was obtained from each of the twenty patients who were positive for HBV antigens and serum HBV-DNA in this study after written consent had been obtained from them. All patients were negative for HCV infection and had no histories of other types of liver diseases. The diagnosis of chronic HBV infection is made in accordance with the standards for chronic viral hepatitis issued in the Fifth National Conference on Infectious Diseases and Parasitosis in China (Beijing, China, 1995)[14]. Ten age-matched healthy donors from the Blood Center of Chinese PLA 307 Hospital were assigned as controls. The clinical background of patients and donors are shown in Table 1.

Table 1 Clinical background of HBV-infected patients and healthy donors

Group	*n*	Gender M/F	Age (years)	ALT (nkat·L^{-1})	AST (nkat·L^{-1})	HBV DNA	HBsAg	Anti-HBs	HBeAg	Anti-HBe	Anti-HBc
Patients	20	17/3	29.5(12-47)	215±218	186±172	19	18	—	16	4	20
Donors	10	8/2	27.5(20-35)	20-40	20-40	—	—	6	—	—	—

—: Nagative results

Reagents

RPMI1640 medium, recombinant human IL-4, GM-CSF, fetal calf serum and TNF-α were all purchased from Gibco Co. (Jingmei Biological Co, Beijing). The Flt-3 ligand, mouse anti-human FITC-conjugated HLA-DR-FITC, CD-86-FITC, PE-conjugated CD80-PE, CD1α-PE monoclonal antibodies were obtained from BD-Pharmingen (Jingmei Biological Co, Beijing).

Culture of DCs

Fifteen milliliters of peripheral blood was drawn from each study subject in heparin-coated tube, PBMC were obtained by Ficoll Hypaque separation, washed twice, resuspended in RPMI1640 medium and incubated in 6-well culture plates at the concentration of 3×10^9 cells·L^{-1} in medium at 37℃ in 50mL·L^{-1} CO_2 atmosphere for 2h. Non-adherent lymphocytes were collected by careful rinsing in 37℃ warm and cryopreserved for their future use in antigen presentation assays. The adherent aggregates were kept for incubation in complete medium with 100mL·L^{-1} fetal calf serum (FCS) in the presence of 1×10^6 IU·L^{-1} GM-CSF, 1×10^6 IU·L^{-1} IL-4, and 50μg·L^{-1} Flt3-L respectively, and expanded over the next 7. At d7, 1×10^6 IU·L^{-1} TNF-α cytokine was added into the medium for 10-12 days incubation. The wells were fed every other day by aspirating 0.3mL medium and adding back 0.5mL fresh medium with cytokines. The protocol has been proven reproducible in 20 HBV-infected patients and 10 healthy donors[15].

AMLR stimulated by DCs

To evaluate the allo-stimulatory activity of DC, AMLR (allogeneic-mixed lymphocyte reaction) was performed[16]. After DCs had been treated with 50μg mytomycin C for 45 min at 37℃ and washed three times with 37℃ warm PBS (pH 7.0). The DCs were placed at 0.5×10^4, 1.0×10^4, 1.5×10^4 and 5.0×10^4 per well on 96-well flat-bottom culture plates, incubated in complete medium. T-cells were from the PBMC of a healthy donor by removing the CD8-positive cells, monocytes, B cells and NK cells with magnetic bead-tagged mouse monoclonal anti-human CD8, CD14, CD19, and CD56 Abs (BD-PharMingen). After the separation, the degrees of positivity of these cells in the samples were all less than 5% and those of CD4-positive cells were more than 95%, respectively. CD4 T cells at 2×10^5/well were mixed with DC and cultured for 4d at 37℃, 50mL·L^{-1} CO_2 atmosphere. The MTT method was used according to the manufacturer instructions.

Detection of NO IL-10 and IL-12

The levels of nitric oxide (NO) and cytokine production by DCs were determined according to a previous report with slight modification (Kakumu *et al*, 2000). In short, DC (1×10^9·L^{-1}), enriched from HBV-infected patients and uninfected healthy donors by cytokines, were cultured in RPMI1640 plus 100mL·L^{-1} FCS for 48h in the presence of *Staphylococcus aureus Cowan* I strain (SAC). After the end of the culture, supernatant was collected and centrifuged. The production of NO and cytokines in the culture supernatants was determined[16,17]. The levels of NO production in the sample was determined by assaying the stable end product NO^{2-} by Greiss reaction using a commercial kit (Griess Assay Kit NO kit-C; Wako), as described by Lu[18]. Aliquots of culture supernatants were incubated with Griess reagent (10g·L^{-1} sulfanilamide, 1g·L^{-1} nephthylethlenediamine, dihydrochloride, and 25g·L^{-1} H_3PO_4) 100 μL at room temperature for 10min. The color developed due to enzymatic reaction was determined with an ELISA reader at 540nm. Concentrations of NO in the sample were caliberated with a reference standard of sodium nitrite supplied with the kit and the levels of NO were expressed as μmol·L^{-1}.

IL-10 and IL-12 in the supernatants were estimated by an ELISA method using commercial kit (PharMingen, San Diego, CA) according to the instructions of the manufacturer. Samples were incubated on microtitre plates coated with the respective monoclonal antibodies (mAbs), followed by addition of a biotinylated second antibody. After removal of excess antibody, color development was finished by enzymatic reaction of strepavidin peroxidase, the intensity of which was directly proportional to the concentration of the respective cytokines in the samples. The amounts of cytokines in the samples were estimated by caliberating the absorbance (optical density, OD) values of the samples with A values of the standards, supplied with kits using an ELISA reader (Labsystems Multiskan MS, USA). The lowest levels of cytokines detectable by these kits were IL-10>15.0ng·L^{-1}, and IL-12>7.8ng·L^{-1}.

Flow cytometry

After 12d incubation, the mature DCs from patients and healthy donors were washed in PBS and directly stained with an optimum dilution of FITC conjugated specific antibody (PharMingen, San Diego, CA) or stained with an optimum dilution of primary antibody followed by FITC-conjugated antibody against HLA-DR, CD86 and PE-labelled antibody against CD80 and CD1a. Finally, FITC+ and PE-cells were counted in an FACScaliber (Becton Dickinson)[19,20].Subclass matched FITC-conjugated mouse IgG and FITC-conjugated secondary antibody alone served as controls.

Statistical analysis

The Student's *t* test was used to determine significant differences in mean values between two groups. Statistical significance was established at the $P<0.05$ level.

RESULTS

Proliferation and Morphology of DCs

The adherent cells, the progenitor cells of DCs were incubated in complete medium containing 100mL·L^{-1} FCS, Flt-3-L, GM-CSF and IL-4 at 37℃ in 50mL·L^{-1} CO_2 atmosphere. The proliferation of DCs could be observed from the third day

incubation. The number of proliferative DCs increased following the extension of incubation time, and reached top value at the 12th day, then gradually went down as shown in Figure 1. Under phase-contrast microscopy, the DCs display a typical morphology with many fine dendrites. These cells extend large, delicate processes or veils in many directions from the body, and display typical morphology of DCs. The yield of proliferation of DC populations increased around 45 times for the healthy donors and 30 times for HBV-infected patients after 12d incubation.

Surface markers on DC

Mature DCs 1×10^6 after 12d incubation were defined by the expression of dendritic cell-restricted markers. The analyses of flow cytometry showed that positive cells constituted between 56% and 80% of all cells recovered at the end of the culture; the purity was not different between patients and controls. The frequencies of $CD86^+$ cells in the dendritic cell population were 84%±10% for control donors (n = 10) and 44% ± 8% for patients with chronic HBV infection (n = 20), respectively, indicating a significant difference between the groups. In addition, the average ratio of $HLA\text{-}DR^+$, and $CD80^+$ surface molecules expressed in the dendritic cell population are shown in detail in Table 2. Figure 2 shows the fluorescence intensity of representative DCs from one patient and one healthy donor, and there was a high expression of surface markers on DCs from healthy donors, reflecting a significant statistical difference from the patient group.

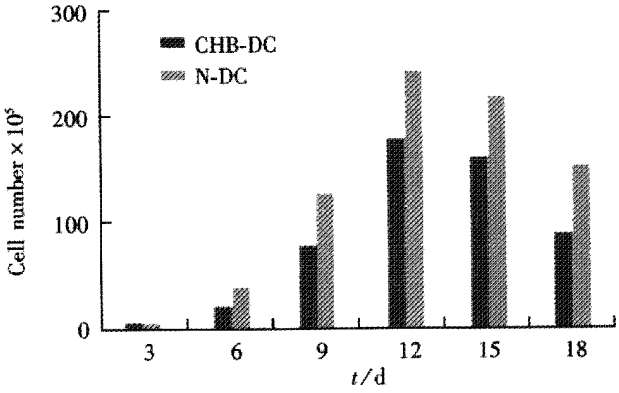

Figure 1 Proliferation of dendritic cell population in *in vitro* culture.

Table 2 Comparison of expression of DC surface markers from CHB patients and healthy donors (number fraction, $\bar{x}\pm s$)

Group	*n*	B7-1(CD80)	B7-2(CD86)	CD1[a]	HLA-DR
CHB-DC	20	0.44±0.08	0.44±0.08	0.25±0.07	0.46±0.09
Normal-DC	10	0.88±0.10[b]	0.84±0.09[b]	0.89±0.09[b]	0.92±0.09[b]

[b]P<0.001 *vs* CHB-DC.

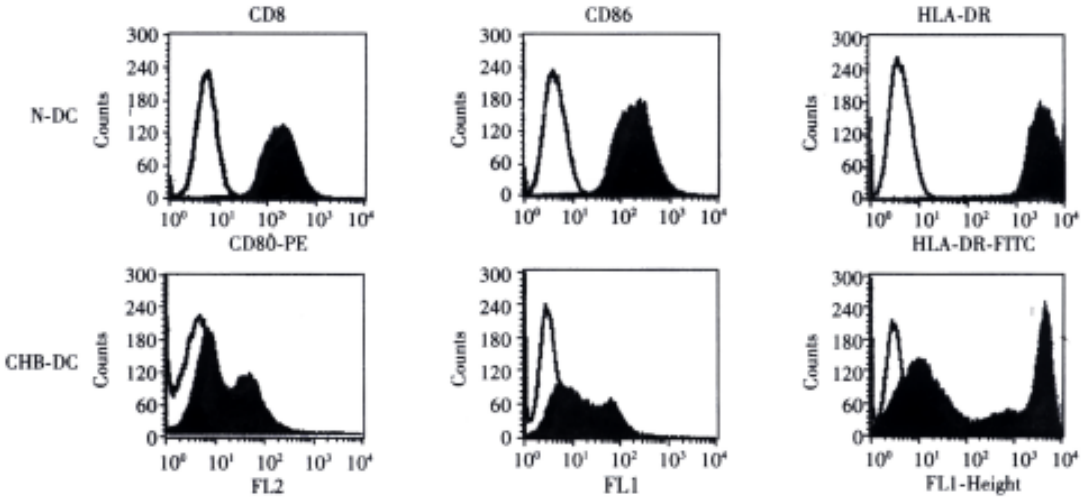

Figure 2 Comparison of fluorescent intensities of flow cytometric analyses on surface of dendritic cells (DCs) from a representative of HBV-infected patients (HB-DC) and a representative of uninfected healthy donors (N-DC). The green line is for signals from controls (DCs stained with mouse IgG_2 instead of specific antibody against surface marker of DCs). The green line with purple color represents the signals obtained from surface of DCs stained with corresponding specific antibody. Note the shift to the left in the peak with increasing expression of surface markers on DCs. Two other independent experiments gave similar results.

AMLR from HBV-infected patients

The T-cell stimulatory activity of DC populations in AMLR was expressed as stimulation index (SI) value, which is the ratio between the proliferative response (optical absorbance, OD) of T cells in the presence and the absence of DCs in the cultures at a T cell:DC ratio of 100:2.5, 100:5, and 100:25, respectively. Although the number of T cells was the same (2×10^5 cells/well) in all AMLR cultures, the SI went up significantly according to the increase of DCs number in AMLR. The SI values were between 2.1 and 4.8 for HBV-infected patients as compared with the values between 6.8 and 12.8 for healthy donors. The SI for HBV-infected patients was the lowest (SI=2.1) when the AMLR system contained 0.5×10^4 $well^{-1}$ of DCs. The results showed that HBV-infected patients tended to have significantly decreased T cell-stimulatory activity (P<0.01) as compared with the values for healthy donors.

Cytokine production by DC in AMLR

IL-12 is known to induce T cell proliferation and is the only

vital cytokine produced by DCs. Spontaneous IL-12 production of dendritic cells in the supernatants of dendritic cell population and AMLR are shown in Table 3. IL-12 produced by DC from patients (27±4ng·L^{-1}) was significantly lower than that from healthy donors (86±32ng·L^{-1}), indicating the statistical difference. Although the IL-12 in this AMLR was most likely produced entirely by the DCs, we decided to confirm this by culturing DCs for 48h and measuring the spontaneous production of IL-12 in culture by pure populations of DCs. Pure DCs from patients produced significantly lower amounts of IL-12 as against healthy donors. In addition, there was no statistical difference in IL-10 levels in AMLR supernatants of DCs from HBV-infected patients (18 ± 7 ng·L^{-1}) (Table 3) and normal controls (25±9ng·L^{-1}).

Table 3 Spontaneous cytokine production in pure DCs population and AMLR ($\bar{x}$±s, ng·L^{-1})

Dendritic cell	Supernatant from MLR culture		Supernatant from pure DCs population(ng·L^{-1})
	IL-12(ng·L^{-1})	IL-10(ng·L^{-1})	
CH-B	27±4	18±7	99±51
Normal	86±32[b]	25±9	218±104[b]

[b]P<0.01, *vs* Normal.

Increased NO production by DC from HBV-infected patients

As shown in Figure 3, the levels of NO in the AMLR supernatant of DCs from HBV-infected patients (168±35 μmol·L^{-1}) were significantly higher than that produced in AMLR of DCs from normal controls (90 ± 43 μmol·L^{-1}) (P<0.05). There was no correlation between the level of NO and the levels of transaminase (data not shown). NO produced by DCs is supposed to be one of the main products in AMLR supernatant. To have direct evidence of increased NO production by DCs, we cultured DC with SAC, a known inducer of NO. Pure DCs from HBV-infected patients produced significantly higher amounts of NO (170 ± 22 μmol·L^{-1}) than the normal controls (86 ± 15 μmol·L^{-1}, P<0.05, Figure 3). The significance of increased production of NO by DC in HBV infection might find the clinical implications of these observations.

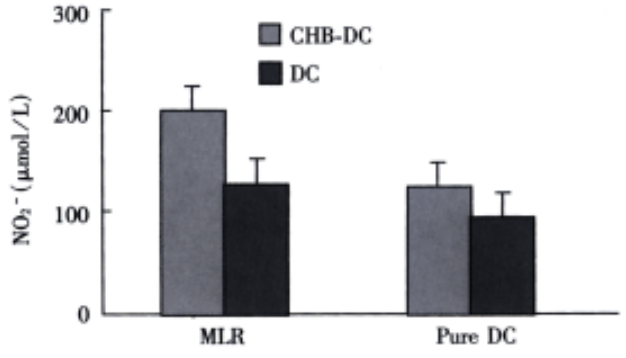

Figure 3 Increased NO production by DCs from HBV-infected patients. All the T cells (2×10^5/ well) were donated from a healthy volunteer in AMLR DC (1×10^4 well^{-1}) from patients with chronic hepatitis type B (CHB) and healthy donors were cultured for 5d. Pure population of DCs (1×10^9·L^{-1}) isolated by the cytokine enrichment method were cultured with SAC I strain 75mg·L^{-1} for 48h.

DISCUSSION

Though B and T lymphocytes are the main mediators of immunity, their function is under the control of DCs which is the sentinels of host immune system[21]. In this way, the property and its implications of DCs have become the focus of immunity against tumor and infectious diseases. Interestingly, the present culture techniques allowing the generation of large numbers of immunostimulatory DCs *in vitro* from human peripheral blood have made it possible to analyse the DC function in human diseases[7,10]. Though depletion and dysfunction of DCs were reported in some infectious diseases induced by HCV, HIV-1 and measles virus[6,20,22], dendritic cell function still remains uncertain in chronically HBV-infected patients. In particular, there appears to have few reports in the published literature about the effects of chronic HBV infection on DC function. These make us attempt to compare the stimulatory potential against allogenic CD4 T cells, levels of surface antigens, levels of interleukin-12, and degree of maturation of DCs from HBV-infected individuals with uninfected healthy donors in this study.

Flow cytometry showed that the expressions of cellular surface markers such as the co-stimulatory factors B7-1, B7-2 and CD1a and MHC II molecules HLA-DR on DCs significantly decreased in chronic HBV-infected patients compared to those in healthy donors. Furthermore, the T-cell stimulatory activities of DCs from patients were much lower than the DCs from uninfected healthy donors in AMLR.Simultaneously, there were notably low levels of cytokine IL-12 and high levels of NO produced by DCs from patients, in particular, NO was considered to have the suppressive activity on cellular enzymes and produce damage to normal cells. Taken together, our present study indicated that there is an immature phenotype and dysfunction of DC population in chronic HBV-infected patients in comparison with uninfected controls. It is necessary to study whether the dysfunction of DC population in patients is associated with the failure to mount an effective immune response for clearance of HBV.

Since IL-12 is an important cytokine to stimulate the proliferation of T lymphocytes, the decrease of IL-12 production was directly attributed to the low T-cell stimulatory of DCs from HBV-infected patients in AMLR[23]. The following reasons probably resulted in the low level of IL-12 production: ① IL-10 could inhibit the expression of class II and B7 molecules and suppress the IL-12 production of DCs[8]; ② there is a high level type I interferon in patients with HBV infection, which induces the down-regulation of IL-12 secretion of DCs[24]; ③ the previous study reported that the HBV itself and some cytokines induced by HBV infection may produce direct or indirect influences on transcriptions of IL-12 gene[25,26]; and ④ host genetic factors, such as the polymorphisms of both antigen-capturing receptor alleles and cytokine genes in DCs might explain HBV-infected patients mount dysfunction of DCs[27].

The maturation and efficient antigen-presentation of DCs are crucial for the initiation of immunity against viral infection[4]. The impairment of dendritic cell function suggested a role in the pathogenesis of chronic HBV infection, which has been probably attributed to the inability of the host to eradicate viruses[1]. It is unknown whether the HBV-infected DCs were eliminated by specific cytotoxic T lymphocytes (CTLs) if the DC is infected itself, which induced the dysfunction of DCs in these patients with chronic HBV infection or the HBV-infected DCs directly induce the T cell tolerance to HBV infection[27].

Decreased function of DC may allow the development of HBV infection, so that modulating the function of dendritic cells is considered to be beneficial to the production of

efficient immunity against viruses[28], but it must be made clear whether the dysfunction of DCs in patients is the result of direct injury of DCs from chronic HBV infection, or a protection from host itself to avoid the destruction of a large amount of HBV-infected hepatocytes induced by itself-inducing immune reaction, and or both In the early stage of HBV-infected patients, efficient antigen-presentation of DCs help the host to clear the virus[29], but in the late stage of chronic HBV-infected patients, induction of dysfunction of DCs or immune tolerance to HBV infection might also be helpful to host survival. Further studies are needed to clarify the mechanisms of depression of DCs function in HBV-infected patients[30,31].

The development of methods to generate a large number of DCs has facilitated their application for immunotherapy. Recent studies have demonstrated the safety and immunogenicity of DCs in humans and have begun to outline the durability, kinetics, and nature of the elicited T-cell responses. However, DC-based immunotherapy remains a challenge and several parameters need to be examined to optimize immune responses, in order to maximize the clinical efficacy against cancer and infectious diseases.

Abstract

AIM **To study the abnormal expression of β-catenin gene and its relationship with invasiveness of primary hepatocellular carcinoma among Chinese people.**

METHODS **Thirty-four hepatocellular carcinoma (HCC) specimens and adjacent paracancerous tissues,** 4 **normal liver tissues were immunohistochemically stained to study subcellular distribution of β-catenin. Semiquantitive analysis of expression of β-catenin gene exon** 3 **mRNA was examined by RT-PCR and *in situ* hybridization. The relationship between expressions of both β-catenin protein, mRNA and clinicopathological characteristics of HCC was also analyzed.**

RESULTS **Immunohistochemistry showed that all normal liver tissues and para-cancerous tissues examined displayed membranous type staining for β-catenin protein, occasionally with weak expression in the cytoplasm. While** 21 **cases** (61.8**%**) **of HCC examined showed accumulated type in cytoplasms or nuclei. The accumuled type Labling Index** (**LI**) **of cancer tissue and para-cancarous tissue was** (59.9±26.3) **and** (18.3±9.7) **respectively** (***P***<0.01)**. Higher accumulated type LI was closely related with invasiveness of HCC. Results of RT-PCR showed the β-catenin gene exon** 3 **mRNA Expression Index** (**EI**) **of** 34 **HCCs was higher than that of para-cancerous tissue and normal liver tissue. Using *in situ* hybridization, the signal corresponding to β catenin gene exon** 3 **mRNA was particularly strong in cytoplasm of HCC when compared with those of para-cancerous and normal liver tissues. Over expression of β-catenin exon** 3 **was also found to be correlated with high metastatic potential of HCC.**

CONCLUSION **Abnormal expression of β-catenin gene may contribute importantly to the invasiveness of HCC among Chinese people.**

INTRODUCTION

Hepatocellular carcinoma (HCC) is quite common in China. In recent years, great progresses have been made in the treatment of HCC, but the major problem is the high malignancy of HCC, that is, more than 50% of the patients receiving grossly radical treatment will suffer from recurrence within two years. So much effort has been put to investigate the molecular biological characteristics of HCC in order to lower the recurrence rate[1-20]. β-catenin is a ubiquitous intracellular protein which is important in both intercellular adhesion and Wingless/Wnt developmental signaling transduction pathway[21]. β-catenin plays an important role in the interactions between cadherins and other transmembrane receptor proteins, such as the epidermal growth factor receptor. In addition, it is also a signaling molecule and can activate gene transcription by forming a heterodimer with the T-cell factor/lymphoid enhancer-binding factor family of DNA binging proteins[22]. Previous studies have shown that β-catenin is involved in pathways that regulate cellular differentiation and proliferation. In the absence of growth or differentiation signals, cytoplasm β-catenin is rapidly turned over under the control of the APC protein and the GSK-3β, resulting in low level of cytoplasm β-catenin level in normal cells[23,24]. The presence of a wingless-Wnt signal in normal embryonic cells stabilizes β-catenin, which accumulates in the cytoplasm, where it binds to Tcf-lymphoid enhancer factor and triggers gene transcription. Abnormal expression and/or structural abnormalities of catenins are closely associated with tumor development for human esophageal, gastric and colon cancers[25,26]. Previous study has shown that E-cadherin expression was significantly lowed and is closely related with the metastatic potential of HCC[27], and abnormal β-catenin expression has been observed by immunohistochemistry in many malignant human tumors including HCC[28], so it is our logical thoughts whether abnormality of β-catenin gene existed and what its relationship with malignancy in HCC among Chinese people is because of the close relationship between E-cadherin and β-catenin.

MATERIALS AND METHODS

Tissue

Thirty-four HCC specimens and adjacent para-cancerous tissues, four normal liver tissues obtained from patients who underwent surgery in Liver Cancer Institute, Zhongshan Hospital, Shanghai Medical University were analyzed. The tissues were each cut into three parts: one was fixed in formalin, and then embedded in paraffin. Paraffin sections were stained with HE for histological examination of HCC and were also used for immunohistochemistry. One was immediately frozen by liquid nitrogen and stored at -80℃, which was to be used for DNA and RNA extraction. Genomic DNA was purified from all samples using standard proteinase K digestion and phenol/chloroform extraction. Total RNA was extracted using a Trizol reagent (Promega) according to

the protocol recommended by the manufacturer. And the last was rinsed in cold PBS, placed in OCT compound, and immediately frozen in liquid nitrogen, which was to be used for *in situ* hybridization.

Immunohistochemical staining

Immunohistochemical analysis was carried out with the avidin-biotin complex immunoperoxidase technique as described previously[29]. As the primary antibody, polyclonal human anti-β-catenin antibody (Sigma) was used at 500×dilution. As the secondary antibody, biotinylated anti-rabbit IgG (Dako) was used at 100× dilution. Staining was performed using avidin-biotin reagents, 3, 3'-diaminobenzidine, and hydrogen peroxide. As a negative control, duplicate sections were immunostained without exposure to the primary antibodies. All cases were divided into two groups according to immunostaining pattern. Cases with a membrancous staining pattern similar to that in normal hepatic cell were classified as membraneous or normal and cases with marked cytoplasmic and nuclear staining in addition to the membranous staining were defined as accumulated or abnormal. Cells from five randomized views were counted and the cell labeling index (LI) was arbitrarily defined as: (positive cells counted/all cells counted)×100.

RT-PCR

Primers for PCR were designed to amplify the consensus sequence for GSK-3 β phosphorylation in exon 3 of β-catenin gene, based on the published cDNA sequence of human β-catenin gene. To verify the validity of amplification, the primers were designed within the region of exon 3 of β-catenin gene, and the amplification was performed by direct PCR and RT-PCR respectively. Primers, F: AAAGCGGCTGTTA-GTCACTGG R: GACTTGGGAGGTATCCACATCC. PCR: PCR mixture, containing 100pM of primer A and B each, deoxyribonucleotide triphosphates at 200μmol·L^{-1} each, 1.5mmol·L^{-1} $MgCl_2$, 2U *Taq* polymerase (Promega) and 2μL DNA template was adjusted to 50μL by adding double distilled water. Then the mixture was overlaid with 50μL mineral oil and subjected to amplification for 40 cycles. Each cycle consisted of 95℃ for 60s, 55℃ for 45s, 72℃ for 45s. RT-PCR: Total RNAs were reverse-transcribed to obtain the cDNA that was going to be amplified. PCR was also performed under the above same condition except for adding 1μL cDNA to the PCR mixture. A 450bp fragment of β-actin mRNA was also amplified by RT-PCR as the internal control. The PCR products were identified first onto 20g·L^{-1} agrose gel and photographed. The photos of RT-PCR were scanned by optical density scanner (Shimadzu C-9000) and the gene expression index (EI) was arbitrarily defined as density Lum of β-catenin/density Lum of β-actin.

In situ hybridization

Cryostat sections (6μm) were obtained, dried for 2h at RT, and delipidated in chloroform for 5min. Sections were fixed in 40g·L^{-1} paraformaldehyde/PBS for 7min, rinsed in PBS for 3min, rinsed twice in 2× SSC for 5min, and prehybridized at 42℃ for 60min in 4× SSC/100g·L^{-1} dextran sulfate/1× Denhardt's solution/2mM EDTA/500g·L^{-1} deionized formamide/ 500mg·L^{-1} salmon sperm DNA. Hybridization was for 16h in 100μL of prehybridization solution and 20μg·L^{-1} digoxin labeled oligonucleotides (TGTTCC-CACTCATACAGGACTTGGGAGGTATCCACATCCTCTT CCTCAGGA). After hybridization, sections were rinsed twice in 2×SSC for 5min at 37℃, 3 times for 5min each in 60g·L^{-1} formamide and 0.2×SSC at 37℃ and twice for 5min each in 2×SSC at RT. Sections were then rinsed in 100 mol·L^{-1} Tris · HCl, pH 7.5/150 mol·L^{-1} NaCl for 5min, and treated with the same solution saturated with blocking mix for 30min, and then reacted with a 1:2000 dilution of alkaline phosphatase-conjugated sheep antidigoxigenin Fab fragments (750×10^3·L^{-1}) in the same solution. They were rinsed twice in 100mol·L^{-1} Tris · HCl, pH 7.5 and 150mol·L^{-1} NaCl for 5min each, then in 100 mol·L^{-1} Tris · HCl, pH 9.5/100 mol·L^{-1} NaCl/ 50mol·L^{-1} $MgCl_2$ for 10 min, and then reacted with 0.18g·L^{-1} 5-bromo-4-chloro-3-indolyl phosphate, 0.34g·L^{-1} nitroblue tetrazolium, and 240mg·L^{-1} levamisole (Sigma) in the same solution for 6h in the dark at RT. The reaction was stopped with 10mol·L^{-1} Tris · HCl (pH 8.0) and 1mol·L^{-1} EDTA. Sections were counterstained in nuclear methyl green, mounted with aqueous solution, and the final results of average density area and density lum of 500 signal positive cells were analyzed by a multifunctional true digital system (MTDS) using a computer. Albumin oligonucleotide probe and hybridization solution without probe were used as positive and negative control respectively.

RESULT

Immunohistochemical analysis

Immunostaining with polyclonal antibody was performed to evaluate the significance of β-catenin accumulation in HCC. Immunohistochemistry showed that all normal liver tissues and para-cancerous tissues examined showed membranous type, occasionally with weak expression of β-catenin in the cytoplasm, but no β-catenin accumulation in nuclei was found. While for HCC, 21 cases (61.8%) showed accumulated type (Figure 1). The LI of accumulated type for tumor tissue and paracancerous tissue were 59.9±26.3 and 18.3±9.7 respectively (P<0.01), while the LI of membraneous type for tumor tissue and paracancerous tissue were 24.6±8.5 and 91.8±10.6 respectively (P<0.01, Table 1). When LI of accumulated type was analyzed according to the clinicopathological characteristics of HCC, close relationship could be seen with capsule, portal vein tumor thrombus, pathological grade, intrahepatic metastasis (Table 2) and postoperative recurrence (Figure 2).

β-catenin exon 3 mRNA expression

Since the primers were designed in such a way that the product was within β-catenin gene exon 3, direct PCR and RT-PCR were used separately to verify the amplification. Agrose gel electrophoresis showed that PCR and RT-PCR amplification products were both 132bp, which were the same as those of normal liver tissues, para-cancerous tissues and HCC tissues. None of amplification products showed fragment that was shorter. RT-PCR results showed the β-catenin exon 3 mRNA EI were (0.77±0.16) and (0.50±0.05) for HCC tissues and para-cancerous tissues respectively (P<0.05, Figure 3). In HCC, higher EI of β-catenin mRNA attempted to be seen in cancer with incomplete capsule, intrahepatic metastasis and portal vein thrombus (Table 2). Using *in situ* hybridization, we also found the signal corresponding to β-catenin exon 3 mRNA was particularly strong in cytoplasm of HCC when compared with those of para-cancerous tissues and normal liver tissues (Figure 4) and stronger signal of β-catenin mRNA was also closely related to incomplete capsule, intrahepatic metastasis and portal vein thrombus.

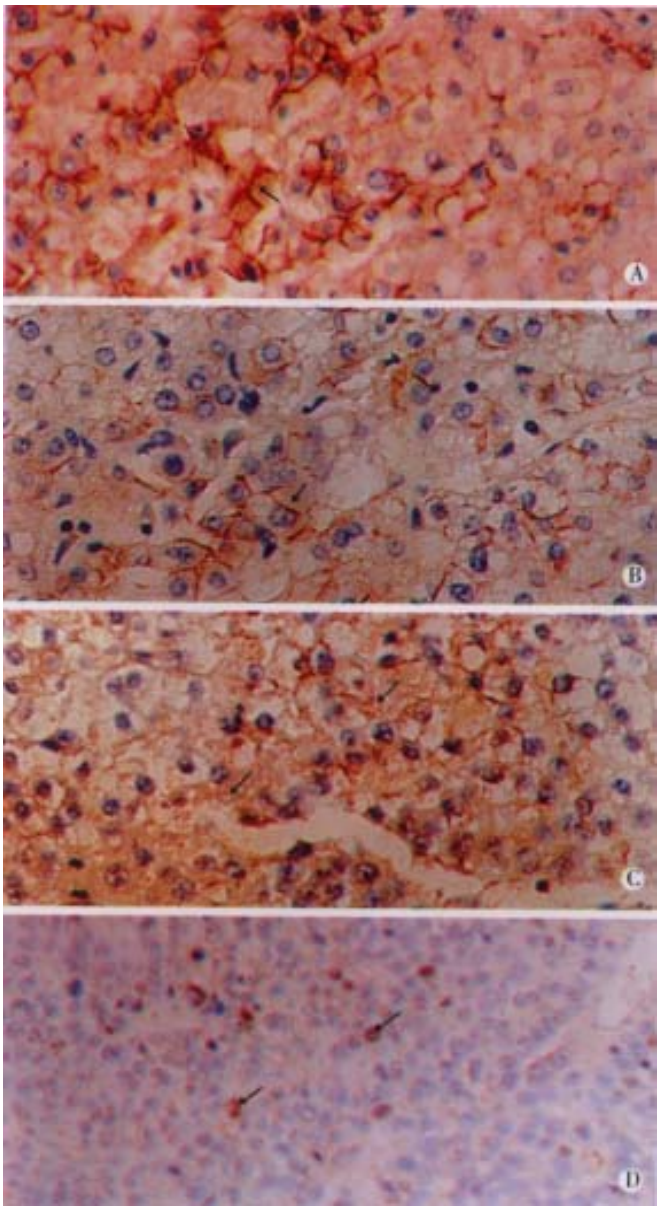

Figure 1 Immunohistochemistry of β-catenin.
A: In normal liver tissue, the staining was mainly positive on the cellular membrane (arrowpoint), with very weak cytoplasmic staining. ×200 B: Para-cancerous cirrhotic liver tissue showed membrane staining (arrowpoint) like normal liver tissue. C,D: For HCC, cytoplasmic and nuclear staining was dominant (arrowpoints), whereas membrane staining was rare. ×200

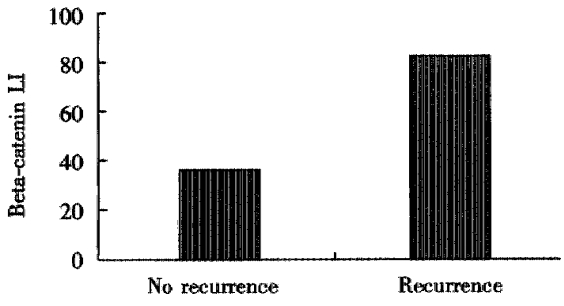

Figure 2 Labeling index (LI) of β-catenin.
Recurrent patient (n = 15) was much higher than that of non-recurrent patient (n=19) (84.9±17.4) *vs* (39.1±14.3).

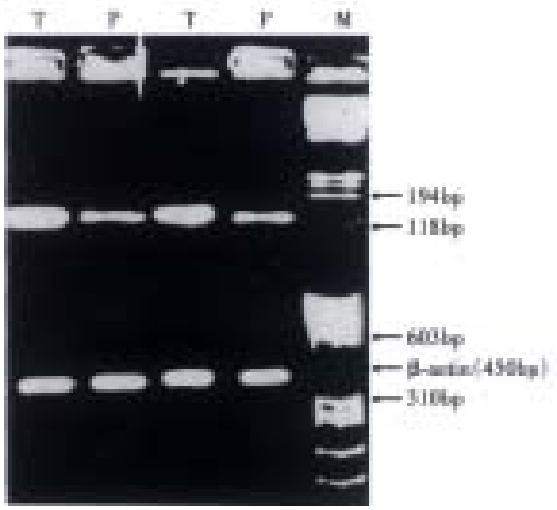

Figure 3 β-catenin mRNA expression index (EI).
HCC was higher *vs* para-cancerous tissue (P<0.05). P: para-cancerous tissue; T: HCC; M: nucleic acid molecular mass marker.

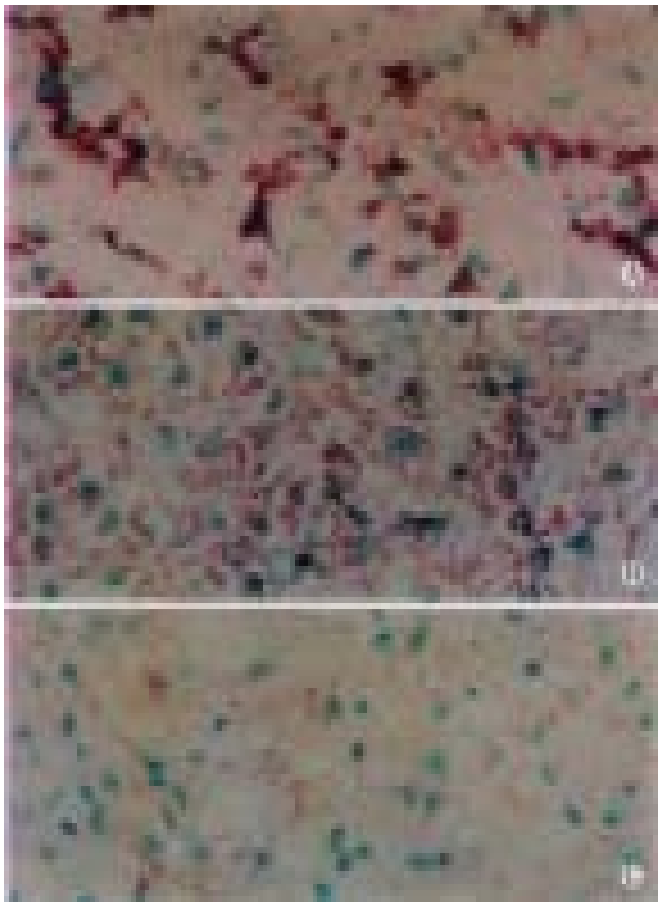

Figure 4 *In situ* hybridization of β-catenin gene mRNA. Stronger in HCC (A) *vs* para-cancerous cirrhotic liver tissue and (B) normal liver tissue (C).

Table 1 Labeling index for β-catenin accumulated type and membraneous type in HCC and para-cancerous tissues (n=34, $\bar{x}$±s)

Tissue	Membraneous	Accumulated
HCC	59.9±26.3	24.6±8.5
Para-cancerous tissue	18.3±9.7[b]	91.8±10.6[b]

[b]P<0.01 *vs* HCC.

Table 2 Relationship between labeling index of β-catenin accumulated type, expression index of β-catenin mRNA and clinicopathological characteristics of HCC

	n	LI of β-catenin accumulated type	EI of β-catenin mRNA

DISCUSSION

Previous studies have shown that activation of the wnt pathway results in up-regulation of cytoplasmic β-catenin and its translocation to the nucleus, presumably via the binding of β-catenin to T-cell factor/lymphoid-enhancing factor family members[25,26,30]. Thus, as a first assessment, we examined the subcellular localization of β-catenin in 34 HCC specimens with the result that 61.8% of HCC specimens showed to be accumulated type, suggesting cytoplasmic stabilization of the protein. This showed that activation of Wnt pathway maybe of importance in the carcinogenesis of HCC among Chinese people. Although either β-catenin mutations involving the GSK-3 β phophorylation sites or inactivation of APC and some other factors are related to activation of the Wnt pathway in colon cancer and melanomas[31,32], loss of heterozygosity at the APC locus on chromosome 5 has been detected only at low frequency in human HCC, indicating that inactivation of APC may be infrequent[33]. So mutation of exon 3 of β-catenin gene is probably one of the most important factors activating Wnt pathway and thus causing β-catenin protein accumulated in the cytoplasms in HCC.

Although some studies have been made to investigate β-catenin mutation and abnormal Wnt pathway in HCC[34-41], no previous results have been reported concerning about the relationship between expression abnormality of β-catenin and clinocopathological features of HCC. Furthermore, research reports about the relationship between β-catenin abnormal expression and clinicopathological features of tumors such as colon cancer[42,43], melanoma[44,45], breast carcinoma[46,47], gastric carcinoma[48,49], and lung carcinoma[50,51] are rather various and some of the results were even totally contradictory. That is partly due to most of the previous immunohistochemical studies on β-catenin did not differentiate between membrane-associated type and intracellular accumulated type. Most tumors showed reduced β-catenin in the cytoskeletal fraction but increased β-catenin in the cytosolic fraction and truncated β-catenin protein which was encoded by mutational β-catenin gene was found bound weakly to β-catenin monoclonal antibody when compared with non-truncated β-catenin[52]. This is the reason why we chose polyclonal antibody instead of monoclonal antibody in our study. In this study we aimed to determine which type of expression abnormalities for β-catenin correlate with clinicopathological features and postoperative recurrence in HCC. Our results demonstrated that although great difference existed between cancer tissue and non-cancer tissue, we failed to show the LI of membraneous type to be correlated with the invasiveness of HCC (data not shown here). But, the LI of accumulated type was discovered closely related with the invasive characteristics of HCC, higher EI would predict high ability of invasiveness of HCC and thus a worse prognosis. This was different from another article about gastric carcinoma, which showed that membraneous type, instead of accumulated type, was related to the invasiveness and prognosis of the tumor[47].

Since abnormal expression of β-catenin protein can be caused by both β-catenin gene mutation and over expression, and in some HCCs, both strong membraneous type and accumulated type of staining could be observed, it is our logical thoughts to figure out whether over expression of β-catenin gene existed and what its relationship with the invasiveness of HCC was. This article is the first one to study the β-catenin gene expression in HCC at mRNA level. First we used RT-PCR to examine the expression of β-catenin gene exon 3 mRNA. Since RT-PCR was not very accurate in semi-quantitive analysis of gene expression, we chose *in situ* hybridization to reconfirm the results of RT-PCR. The results of them are the same, that is over expression did exist in HCC and it showed relationship with the invasiveness of HCC (data of relationship between *in situ* hybridization and HCC clinicopathological characteristics not shown). This could give some explanation why strong membranous and cytoplasmic distribution of β-catenin was observed on immunohistochemistry in some HCC while β-catenin gene exon 3 mutation was not observed. It was the accumulation of β-catenin, though apparently normal, that exceeded the capacity of E-cadherin combination and GSK-3 βdegradation, resulting in increase and stabilization of this protein in the cytoplasm.

Although we found that LI of β-catenin accumulated type was related with HCC recurrence, we were unable to find there was such relationship between β-catenin gene EI and HCC recurrence, either by RT-PCR or *in situ* hybridization. This implies that the LI of β-catenin accumulated type would be of greater value in predicting recurrence of HCC. From above we can see that abnormal expression of β-catenin protein, especially the accumulated type, which is closely related to the invasiveness of HCC among Chinese people. Further study should be carried out to confirm this and investigate what the other mechanism causing abnormal expression of β-catenin gene is.

ACKNOWLEDGEMENTS The authors are grateful to assistant professor Teng-Fang Zhu, Department of Pathology, Medical Center of Fudan University, for his technical support on *in situ* hybridization.

Abstract

AIM **To study the pathogenicity of hepatitis G virus (HGV) and observe the genesis and pathological process of hepatitis G.**

METHODS **HGV-RNA in serum was detected by RT-PCR assay. The immunohistochemical assays of liver tissue were performed with HGV monocoloned antibody (McAb) expressed from the region of HGV NS5 nucleic acid sequence. The clinical and pathological data of 52 patients with hepatitis G were discussed. In animal experiment, the Chinese Rhesus monkeys were infected with the serum of a patient with HGV infection. And the dynamic changes in serology and liver histology of animals were observed.**

RESULTS **One hundred and fifty-four patients with HGV-RNA positive were selected from 1552 patients with various kinds of hepatitis. Of 154 patients with HGV infection, 52 were infected with HGV only, which accounted for 33.8% (52/154) and 102 with positive HGV-RNA were super-infected with other hepatitis viruses, which accounted for 66.2% (102/154). The clinical and pathological observation showed that the acute and chronic hepatitis could be induced by HGV. The slight abnormality of transaminases ALT and AST in serum of monkeys lasted nearly 12 months and histological results showed a series of pathological changes.**

CONCLUSION **HGV is a hepatotropic virus and has pathogenicty.**

INTRODUCTION

Hepatitis G virus (HGV/GBV) is a new type of hepatitis virus which was first identified by Simons and Linnen between 1995 and 1996[1,2]. It has been shown that HGV is a single-stranded, positive chain DNA virus which has world-wide distribution, and spread by blood circulation. HGV infection is mostly mixed with infections caused by other types of hepatitis viruses. The patients with single hepatitis G infection were rare. It makes the investigation difficult. Currently, the pathogenicity of hepatitis G virus is controversial. We report the results of our study below.

MATERIALS AND METHODS

Patients

One hundred and fifty-four patients with hepatitis G infection were collected from 1552 patients with different types of hepatitis admitted consecutively to our hospital during recent 4 years. The serum level of alanine trasaminase (ALT) in all investigated patients was twice that of the normal subjects. Fifty-two of these cases were simply HGV infected and 102 were super-infected with other types of hepatitis virus. The liver biopsies were performed in 42 of the 52 patients with single HGV infection.

Etiological assays for serum specimens

Serum specimens were tested for HGV-RNA by retro-polymerase chain reaction (RT-PCR), for HBV-M, anti-HAV IgM, anti-HEV IgG, anti-HCV IgG by enzyme-linked immunosorbent assay (ELISA), for HBV-DNA by PCR, and for HCV-RNA by RT-PCR. Reagents were obtained from Shanghai Meihua Company, DA-AN Genotype-Diagnostic Center of Zhongshan Medical University, Medical Institute of Nanjing Military Area, respectively. The primers of HGV were obtained from the Institute of Microbiology and Epidemiology of Chinese Military Academy of Medical Sciences.

Histological and immunohistochemical assays

The biopsied liver tissues from the patients were sent to 3 pathologists for histological examinations under light and electron microscopy to determine the degree of necrosis of the liver cells, inflammatory cellular infiltration and fibroplastic proliferation. As for immunohistological examinations, monoclonal antibodies (McAb) were obtained from HGV NS5 gene antigen, the labeled antigen and antibody were presented by the Institute of Microbiology and Epidemiology of Chinese Military Academy of Medical Sciences. The histochemical reagents with HCVAg (NS3) and HBsAg were obtained from Beijing Zhongshan Biotechnical Limited Company and Fuzhou Maixin Biotechnical Company Limited, respectively. The technical procedures were followed according to the requirements for use.

RESULTS

The relationship between HG and the other different types of viral hepatitis

One hundred and fifty-four cases of HG in our study were collected from 1552 cases of different types of viral hepatitis

and evidence of an HGV infection were confirmed by positive HGV-RNA twice in all 154 cases. The relationship between them is shown Table 1.

There were 52 patients with the simple HG infection (33.8%), and 103 of HG super-infected with other type of HV. Most of the cases were complicated with HCV and/or HBV infection (66.2%).

The clinical and pathological features of HGV infection

Of 52 cases of HG, the biopsies were performed in 42. The clinical and/or pathological diagnosis of 154 cases is shown in Table 2.

Table 1 The relationship between HG and the other viral hepatitis

Group	No. of cases	No. of positive HGV-RNA	%
HNA-E	583	52	8.9
HA	38	2	5.3
HB	713	69	9.1
HC	125	18	14.4
HB+HC	17	5	29.4
HA+HB	22	2	13.6
HB+HE	20	1	5.0
The others *	7	0	0
Total	1552	154	9.9

*The others include: HA+HC 2, HA+HE 1, HC+HE 3 and HA+HB+HE 1.

Group	No.of cases	Acute hepatitis	Chronic hepatitis	Severe	Cirrhosis hepatitis
Sigle HG	52	2	49		1
Super-infected HG	102	80	4		18

It is difficult to identify what damages of the liver are predominant clinically and pathologically in the patients with HG super-infected with other HV infection. We had intensively observed the clinical manifestations and pathological lesions in single-infected cases of HG so as to better clarify the pathogenicity of HGV. Of the 52 cases, only 2 cases were acute hepatitis (confirmed by clinical and pathological evidence). Most of single-infected patients with HG had chronic hepatitis.

Case 1 A 46-year-old female with a history of surgery in 1988 was hospitalized with endometriosis. During the operation, blood transfusion was taken. Fifty days after transfusion, she felt weak and had a poor appetite, abnormal liver functions with ALT 180U/L. After treatment with biphenyl dimethyl dicaboxylate, the ALT level was lowered. But her liver function was continued to be abnormal (ALT: 66-120, AST: 57-108U/L) for 9 years. Serum examinations of pathogens performed in many large hospitals were negative. She was admitted to our hospital on Sept. 27, 1997. Laboratory examinations showed ALT 106U/L, AST-192U/L, normal level of TSB, A/G 1.17, and r- GP 22%. Serum tests for HA -E were negative. The test for HGV-RNA was positive. Liver biopsy was taken on October 18. Histological examinations showed hepatocyte swelling, acidophilic degeneration, piecemeal necrosis, obvious fibroplastic proliferation in the portal area and P-P bridging hepatic necrosis. The pathologic diagnosis showed chronic hepatitis: G 2-3, S 1-2. CT-displayed splenomegaly and occupied lesions in the liver. The patient was treated with α-Interferon at a dose of 3 million IU three times per week, for 6 months. Thirty days later, HGV-RNA became negative. Two months after cessation of the treatment, the HGV-RNA again became positive. The ALT continued to be abnormal. The patient had faint jaundice and symptoms of liver cirrhosis (Figure 1).

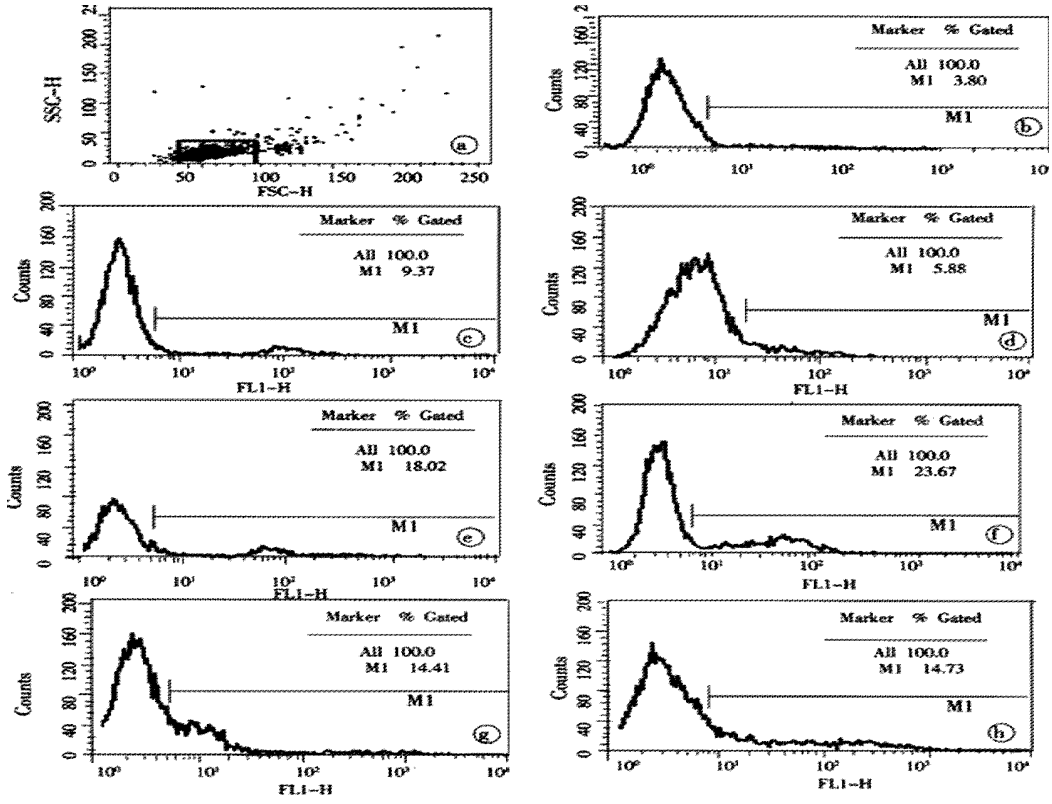

Figure 1 Dynamic changes of serum ALT, AST and HGV-RNA in patient Hu.

Case 2 An 8-year-old girl was admitted on July 9,1998 because of abdominal distension. Splenomegaly and a small amount of ascites were displayed by B super-sound examination. Repeated examinations showed positive HGV-RNA, ALT 60U, AST 120U/L, A/G 0.98, and r-GP 28%. CT showed uneven liver density with small nodular lesions, splenomegaly extended in an area of 8 costae. The clinical diagnosis was chronic hepatitis G infected from liver cirrhosis (Figure 2).

In our group, there were 2 patients with acute hepatitis G having following histological findings: cloudy hepatocyte swelling, partial vacuolation (Figure 3), punctate necrosis of liver cells, focal lymphocyte infiltration, and accidophilic degeneration of partial liver cells. In patients with chronic hepatitis G, the histological examinations of the liver tissue showed extended portal area, a moderate degree of lymphocyte infiltration, and piecemeal necrosis (Figure 4). A tendency of P-P bridge necrosis in the portal area could be found. In a case of acute hepatitits G, the electron micrographs showed shrinkage of liver cells with zigzag edges, extension of rough surfaced endoplasmic reticulum in hepatocytes, and proliferation of collagen fibrils extended into the cytoplasm in the damaged hepatocytes (Figure 5). In immunohistochemical assays, brown-yellow granules were found in the cytoplasm of hepatocytes stained by specific HGV McAb in either acute hepatitis G or chronic hepatitis G patients. The positive-stained granules were also seen in the nuclei of a few hepatocytes (Figure 6). Negative results were obtained by histochemical analysis with anti-HBs McAb and anti-HCV (McAb) expressed from HCV N3. All these results suggested that HGV could cause a series of histological damages of the liver.

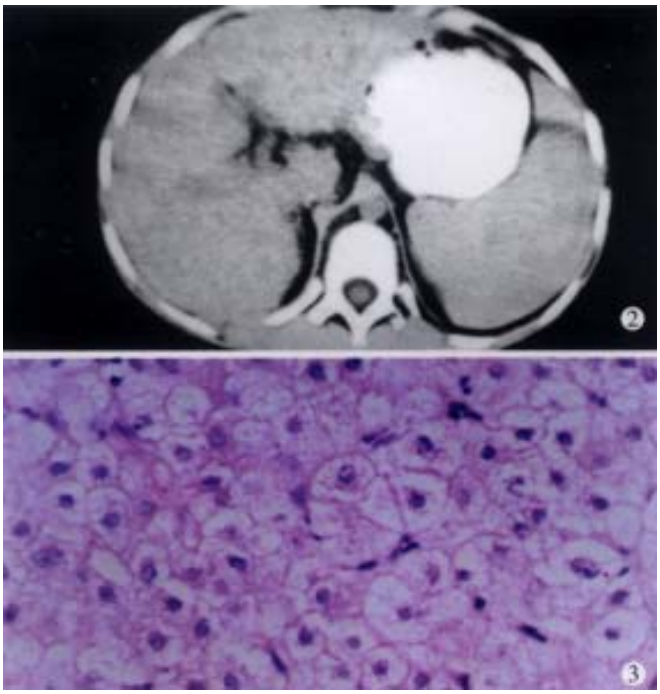

Figure 2 CT picture displays uneven liver density, small nodular changes and splenomegaly extended in an area of eight costae. EM× 15000

Figure 3 Histological changes of the liver showing cloudy swelling of hepatocytes.

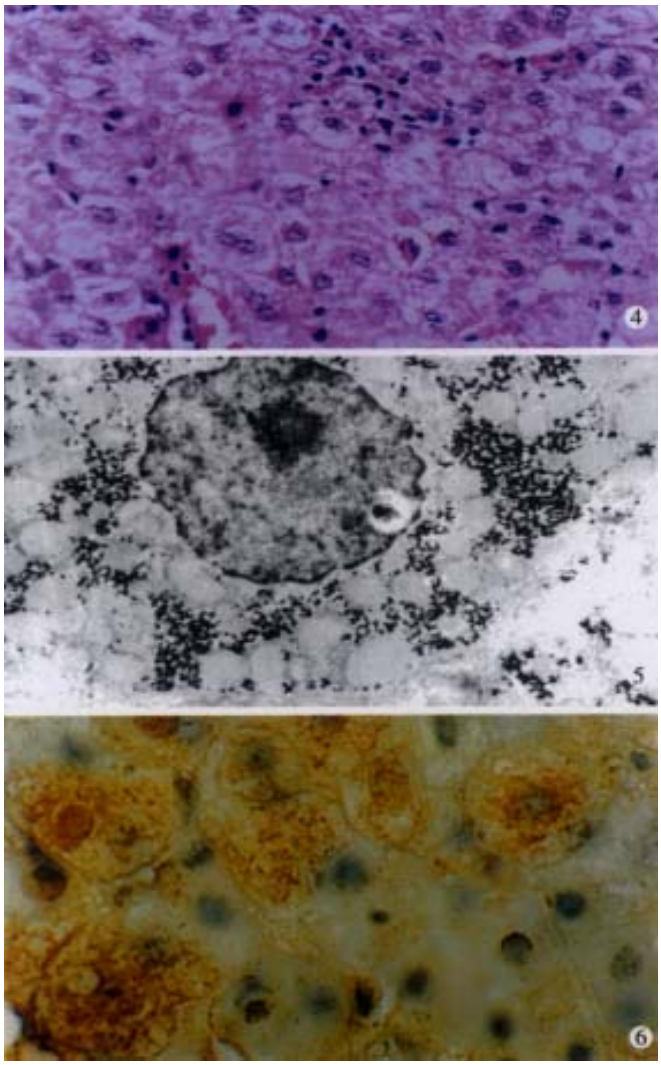

Figure 4 Histological changes of the liver in a patient with acute single-infected hepatitis G showing punctate necrosis, focal lymphocyte infiltration, and acidophilic degeneration of hepatocytes.

Figure 5 Ultrastructure of the liver tissues in a patient with acute simple HGV infection showing shirinkage of liver cells with zigzag edges, extension of rough surfaced endoplastic reticulum of hepatocytes, proliferation of collagen fibrils extended into the cytoplasm of hepatocytes. EM×15000

Figure 6 Immunohistochemical preperation stained by specific HGV McAb for HGVNS5 in a patient with single HG infection showing brown-yellow granules presented mostly in cytoplasm of hepatocytes, and partially in the nuclei. DAB staining, hematoxylin staining, BA staining. (oil)×1000

DISCUSSION

In recent years, the pathogenicity of hepatitis G virus has caused much controversies, because of the following aspects. ① HGV infection is usually mixed with the infections caused by other hepatitis viruses. The patient with single hepatitis G infection are rare; ② A body of evidence has been limited to serologic studies without sufficient histological evidence; ③ Lack of animal modes for the study of hepatitis G. A study on hepatitis G in our hospital was started earliest in China. In 1994, at "World Chinese Symposium on Hepatopathy" our report on clinical and pathological study in chronic hepatitis produced by "non-A, non-B and non-C agents" aroused great interests[3]. In 1996, we reported the paper "Clone of partial

HGV genes in Nanjing, China and analysis of its cDNA sequence", and established the method for determination of HGV-RNA by RT-PCR. The clinical and pathological characteristics of viral hepatitis G were described[4,5]. Of the 154 cases of HG collected from 1552 cases of different kinds of hepatitis in this paper, 52 were single HGV infection and 102 were super-infected with other hepatitis viruses, which accounted for 33.8% (52/154) and 66.2% (102/154) respectively. The clinical and pathological data from the simple HG patients in this study showed that: ① the clinical symptoms of HG patients vary in degree. It was mostly- sub-clinical; ② majority of patients had no jaundice, less hepatic damage than HB and a mild to moderate elevated ALT and AST level; ③ most of the patients were chronic. Of 52 patients with HG, there were 49 chronic cases, 1 cirrhosis and only 2 acute cases in our study. One of the two patients with acute HG had jaundice (TSB 106.7μmol/L) 30 days after blood transfusion, with the ALT level 535U/L and AST 116U/L; ④ histological changes were local necrosis and piecemeal necrosis in most patients, P-P bridge necrosis and a tendency of cirrhosis in a few patients. Electron micrographs of the two acute patients displayed proliferation of collagen fibrils extended into the cytoplasm of hepatocytes; ⑤ HGV antigen was generally present in cytoplasm and sometimes in the nuclei of the hepatocytes by immuohistochemical assay. We studied a Chinese Rhesus monkey intravenously attacked with the serum from a chronic hepatitis G patient only with positive HGV-RNA for one year. The dynamic changes of the serology and histology of the liver in the animal were observed before and after infection. It was found that the serological and histological changes of the animal were similar to that of the patients in our study[6]. Eighteen months after the infection, the monkey was dissected and its internal organs were taken for histological examination. The internal organs were normal except the liver tissue in which there were focal necrosis and slight piecemeal necrosis. The pathological diagnosis was confirmed to be chronic hepatitis. It is suggested that HGV would be a hepatotropic virus and had the pathogenicity to human.

ACKNOWLEGEMENTS We would like to thank Prof. T. H. Zhang, the General Hospital of Nanjing Military Area, for his guidance in this study.

Abstract

AIM **To investigate SBA2 expression in CRC cell lines and surgical specimens of CRC and autologous healthy mucosa.**

METHODS **Reverse transcription-polymerase chain reaction (RT-PCR) was used for relative quantification of SBA2 mRNA levels in 4 human CRC cell lines with different grades of differentiation and 30 clinical samples. Normalization of the results was achieved by simultaneous amplification of** β-actin as an internal control.

RESULTS **In the exponential range of amplification, fairly good linearity demonstrated identical amplification efficiency for SBA2 and β-actin (82%). Markedly lower levels of SBA2 mRNA were detectable in tumors, as compared with the coupled normal counterparts ($P<0.01$). SBA2 expression was significantly ($0.01<P<0.05$) correlated with the grade of differentiation in CRC, with relatively higher levels in well-differentiated samples and lower in poorly-differentiated cases. Of the 9 cases with lymph nodes affected, 78% (7/9) had reduced SBA2 mRNA expression in contrast to 24% (5/21) in non-metastasis samples ($0.01<P<0.05$).**

CONCLUSION **SBA2 gene might be a promising novel biomarker of cell differentiation in colorectal cancer and its biological features need further studies.**

INTRODUCTION

Colorectal cancer (CRC) is increasing in China[1-10], and the treatment is still difficult in advanced stage[11-20]. Butyrate is an important colonic fuel and induces differentiation in colonic cell lines[21]. cDNA for a novel CRC differentiation-related gene, designated SBA2 (GenBank accession No: AF229181), has been identified in human CRC cell line CloneA after modulation by sodium butyrate. We investigated the use of reverse transcription-polymerase chain reaction (RT-PCR) for the relative quantification of SBA2 expression in 4 human CRC cell lines with different grades of differentiation and in 30 surgical specimens of CRC and autologous healthy mucosa.

MATERIALS AND METHODS

Materials

The poorly-differentiated human CRC cell line CloneA, moderately-differentiated human CRC cell line CX1, and well-differentiated human CRC cell line CCL187 were obtained from Dana-Farber Cancer Institute, Harvard Medical School. The moderately-differentiated human CRC cell line LS174T was bought from the Shanghai Institute of Cell Biology, Chinese Academy of Sciences. These cells were cultured in Dulbecco's modified Eagle's medium containing $50mL \cdot L^{-1}$ calf serum at 37℃ with 100% humidity and $50mL \cdot L^{-1}$ CO_2. Tumor tissues were obtained from 30 patients (15 men and 15 women) at the time of surgery for removal of CRC. All cases were assessed by histopathology. Both tumor tissues and autologous healthy mucosa (at the distance >5cm from the neoplastic focus) were sampled. All specimens were snap frozen and stored in liquid nitrogen. Total cellular RNA was isolated with the TRIzol reagents (Gibco-BRL). The yield and quality of RNA preparation were determined by spectrophotometry.

Quantification of gene expression by semi-quantitative RT-PCR

Reverse transcription of 2μg of total RNA using 0.5μg oligo (dT)-15 primer was performed for 1h at 42℃ in 20μL of a reaction mixture containing 15U AMV reverse transcriptase (Promega), 5 mmol/L $MgCl_2$, 1 × RT buffer (10 mmol/L Tris-HCl, pH 9.0 at 25℃, 50 mmol/L KCl, 1 g/L Triton X 100), 1mmol/L dNTP mixture and 25U of recombinant RNasin ribonuclease inhibitor. The samples were then heated at 99℃ for 5 min to terminate the reverse transcription.

Primers used for amplification of β-actin specific sequence were residues 2217-2238 (TGTATGCCTCTG-GTCGTACCAC; sense-strand) and residues 2009-2030 (ACAGAGTACTTGCGCTCAGGAG; antisense-strand). PCR using these primers yields a 592 bp product. SBA2-specific sequence was amplified by the sense-strand primer (residues 51 - 72: GCTTGTCACGGCTTCTTACGAT) and the antisense-strand primer (residues 390 - 411: GCATAAGTGCTTCAGTGAGGAC), which yield a 361bp product.

Unless otherwise specified, 2.5μL of the reversely-

transcribed mixture was used as template DNA and amplified in a reaction volume of 25 μL containing 1 mmol/L $MgCl_2$, 1 ×RT buffer (10mmol/L Tris-HCl, pH 9.0 at 25℃, 50mmol/L KCl,1g/L Triton X100), 0.2μmo/L each of 5' and 3'primers for β-actin, 0.5μmol/L each of 5' and 3' primers for SBA2. After heat denaturation at 95℃ for 5min, 1.25U of thermus aquaticus DNA polymerase (Promega) was added to the mixture. Amplification was performed in a DNA thermal cycler (Perkin-Elmer Cetus) in sequential cycles at 94℃ 30s; 68℃ 45s and 72℃ 1 min. After the last cycle, all samples were incubated for an additional 10 min at 72℃. Ten μL of PCR product were separated on 15g/L agarose gels, stained with ethidium bromide, and loaded onto 80g/L polyacrylamide gels, stained with DNA silver staining system (Promega). The gel was analyzed with the Electrophoresis Documentation and Analysis System 120 (Kodak 1D).

RESULTS

Linearity of PCR amplification

The yield of PCR product is proportional to the starting amount of the template only under conditions in which PCR amplification proceeds exponentially at a constant efficiency. To establish the optimal conditions for detection and quantification of SBA2 expression, the relative yield of PCR products was determined by terminating aliquots of starting reaction solution at sequential PCR cycles as shown in Figure 1. The resultant amplified sequences were analyzed and the signal intensities of the bands were plotted on a semilogarithmic scale against the cycle number to obtain amplification curves. Figure 1 shows that at higher cycle numbers (>28), the yield of the SBA2-specific product approaches the plateau while β-actin shows a tendency of saturation beyond 26 cycles. Before saturation at the plateau, however, good linearity is observed for both SBA2 and β-actin amplification over the range of cycles examined. Figure 2 compares the results obtained with successive dilutions of cDNA. The serial 1:2 dilutions were performed beginning with 5μL of reversely-transcribed mixture, as shown in the graph, and amplified 24 cycles. Thus the number of 24 cycles and the volume of 2.5μL of cDNA were chosen as the optimal parameters for the semi-quantitative RT-PCR.

If the efficiency of amplification is the same for each cycle (as indicated by the good linearity of the curves), the amount of cDNA produced can be predicted from the equation $cDNAn = (cDNA_0) \times (1+R)^n$, where cDNAn stands for the amount of product after n cycles, $cDNA_0$ is the initial amount of cDNA, and R is the efficiency of amplification. The efficiency of the amplification can be assessed from the following equation: $\log cDNAn = \log cDNA_0 + n \times \log (1+R)$. Within the exponential range, the linear regress equation for SBA2 is $y = 0.2612 \times x - 0.6179$ ($r = 0.9496$), for β-actin: $y = 0.2594 \times x - 0.4468$ ($r = 0.9754$), where y is the logarithm of cDNAn, x is the number of PCR cycles (n), r is correlation coeficient. The slope of the curve should be $\log (1+R)$ in the semi-logarithmic plot. Thus an R- value of 82% and 82% can be determined for SBA2 and β-actin respectively. Since the same amplification efficiency is observed for both the target and the internal control within the exponential range, the relative amounts of SBA2 mRNA can be determined by comparison with β-actin.

Patterns of SBA2 expression

In cultured cell lines and clinical specimens of CRC, the assay described above was used to investigate the levels of SBA2 mRNA in 4 human CRC cell lines and in 30 surgical samples of CRC and autologous healthy colonic mucosa. In the 30 samples analyzed, significantly lower levels of SBA2 mRNA were detectable in tumors, as compared with the coupled normal counterparts (Wilcoxon test, $T = 6$, $P<0.01$).

Differential expression of SBA2 in clinical samples of CRC with different grades of differentiation was similar to that observed in 4 cell lines of CRC, as shown in Figures 3 and 4, respectively. Thirty clinical samples were assigned into 3 groups, depending on the grade of differentiation. The levels of SBA2 mRNA were significantly (q test, $0.01<P<0.05$) correlated with the degree of differentiation in CRC, with relatively higher levels in well-differentiated samples and lower in poorly-differentiated ones. Mean levels of SBA2 mRNA was calculated for each group. There was a significant difference between well-differentiated group (0.384 ± 0.024) and poorly-differentiated group (0.158 ± 0.014) ($q = 3.9564$, $0.01<P<0.05$), between moderately-differentiated (0.297

±0.015) and poorly-differentiated ($q = 3.2767$, $0.01<P<0.05$), in spite of no significant difference ($q = 0.0798$, $P>0.05$) between well-differentiated and moderately-differentiated.

We also analyzed the relationship between SBA2 expression and lymph nodes metastasis. Of the 9 patients with lymph nodes affected, 78% (7/9) had reduced SBA2 mRNA expression in contrast to 24% (5/21) in non-metastasis samples ($\chi^2=5.5622$, $0.01<P<0.05$).

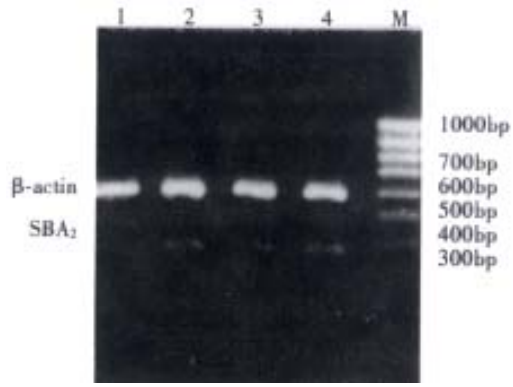

Figure 4 Relative quantification of SBA2 mRNA in cell lines of CRC. 1-4: Human CRC cell line CloneA, CX1, CCL187, and LS174T, respectively. M: Marker (100 bp DNA ladder).

DISCUSSION

We have developed an efficient protocol for relative quantification of gene expression in both clinical samples and cell lines of CRC by semi-quantitative RT-PCR. Linear evaluation of gene expression over a wide range was achieved by plotting the amplification curves of the sequence of interest and the β-actin sequence that served as an internal control. Determination of the optimal parameters of an exponential range was carried out by terminating the PCR at sequential cycles and by serially diluting the amount of cDNA. The amplification efficiency of PCR and the amount of sample cDNA have been verified by the simultaneous amplification of a sequence of a gene that serves as an internal control, such as, aldolaseA, β2-microglobulin, glyceraldehyde-3-phosphate dehydrogenase (G_3PD), dihydrofolate reductase[22]. However, the simultaneous amplification of a large amount of a sequence of an internal control can affect the efficiency of amplification of the sequence of interest[23]. A possible explanation of the competition is that the effect of an internal control sequence on amplification efficiency may depend on the gene sequences amplified[24]. For instance, the simultaneous amplification of a β2-microglobulin mRNA sequence suppressed the amplification efficiency of an *mdr* mRNA sequence, while amplification of β-actin sequence did not affect the amplification efficiency of a tax/rex sequence[25]. In our study, in the exponential range of amplification, fairly good linearity demonstrated identical amplification efficiency for SBA2 and β-actin (82% for both). Thus β-ctin can be used as an internal control to normalize the relative levels of SBA2 mRNA in this experiment.

Histologic types reflect the biologic nature of the cancer, exercising the most decisive influence upon the diagnosis and prognosis. A variety of pathologic changes are all closely associated with the cellular differentiation in CRC, including gross typing, growth pattern, depth of infiltration and metastasis into lymph nodes[26,27]. Classic grading categorized CRC into three discrete classes: well, moderately and poorly differentiated. Such grading, however, is largely dependent on the subjective assessment of the histopathologist. Heterogeneity of differentiation in the same cancer specimen often leads to considerable inter-and intra-observer variation in grading[28]. Colorectal neoplasia develops in a mucosa that has alterations in proliferation, maturation, and differentiation[29]. Normally, the major zone of cell proliferation is at the base of the crypts (the lowest one third) with little extension to the surface of proliferating cells. As cells migrate from the crypts to the luminal surface, they become increasingly differentiated and mature so that by the time they have reached the surface they have lost their proliferative capabilities, finally leading to apoptosis (i.e. programmed cell death)[30].

Butyrate is an important colonic fuel and induces differentiation in colonic cell lines[21]. cDNA for a novel colorectal cancer (CRC) differentiation-related gene, designated SBA2 (GenBank accession No: AF229181), has been identified in human colorectal cancer cell line CloneA after modulation by sodium butyrate. It consisted of 2470 nucleotides and an open reading frame (ORF) encoded 404 amino acid residues with a M_r of 44400. The deduced amino acid sequences showed significant homology to mouse SWiP-2 (96%), mouse WSB-2 (95%) and human WSB-1 (52%), which belong to a new family of the suppressor of cytokine signaling (SOCS). The SBA2 protein product may be a new member of SOCS protein family negatively regulating cytokine signal transduction. We have used RT-PCR for relative quantification of SBA2 mRNA levels in 4 CRC cell lines with different grades of differentiation and 30 surgical specimens of CRC and autologous healthy mucosa. Our assay showed significantly lower levels of SBA2 mRNA in tumors, as compared with coupled normal counterparts. Furthermore, differential expression of SBA2 in CRC with different grades of differentiation was observed both in clinical tissues and in cell lines SBA2 mRNA levels were correlated with the degree of differentiation in CRC, being relatively higher in well-differentiated samples and lower in poorly-differentiated ones. There was also a significant difference in the frequency of lower-level SBA2-expressing samples between patients with lymph nodes metastasis and those without metastasis. It was indicative of the close association of SBA2 with metastasis in CRC. The reduced levels of SBA2 mRNA in CRC and the correlation between SBA2 mRNA expression and the grade of differentiation in CRC suggest that SBA2 might be a

promising novel biomarker of cell differentiation of CRC, and that the biological features of SBA2 and its product in CRC and other tumors need further studies.

Abstract

AIM **To explore the kinetic changes in plasma D(-)-lactate and lipopolysaccharide (LPS) levels, and investigate whether D(-)-lactate could be used as a marker of intestinal injury in rats following gut ischemia/reperfusion, burn, and acute necrotizing pancreatitis (ANP).**

METHODS **Three models were developed in rats: ① gut ischemia/reperfusion obtained by one hour of superior mesenteric artery occlusion followed by reperfusion; ② severe burn injury created by 30% of total body surface area (TBSA) full-thickness scald burn; and ③ ANP induced by continuous inverse infusion of sodium taurocholate and trypsin into main pancreatic duct. Plasma levels of D(-)-lactate in systemic circulation and LPS in portal circulation were measured by enzymatic-spectrophotometric method and limulus amebocyte lysate (LAL) test kit, respectively. Tissue samples of intestine were taken for histological analysis.**

RESULTS **One hour gut ischemia followed by reperfusion injuries resulted in a significant elevation in plasma D(-)-lactate and LPS levels, and there was a significant correlation between the plasma D(-)-lactate and LPS (r = 0.719, P<0.05). The plasma concentrations of D(-)-lactate and LPS increased significantly at 6h postburn, and there was also a remarkable correlation between them (r = 0.877, P<0.01). D(-)-lactate and LPS levels elevated significantly at 2h after ANP, with a similar significant correlation between the two levels (r =0.798, P<0.01). The desquamation of intestine villi and infiltration of inflammatory cells in the lamina propria were observed in all groups.**

CONCLUSION **The changes of plasma D(-)-lactate levels in systemic blood paralleled with LPS levels in the portal vein blood. The measurement of plasma D(-)-lactate level may be a useful marker to assess the intestinal injury and to monitor an increase of intestinal permeability and endotoxemia following severe injuries in early stage.**

INTRODUCTION

Apart from their major functions of digestion and absorption of nutrients, the intestines also act as a barrier to prevent micro-organisms and toxins contained within the lumen from spreading to distant tissues and organs[1-7]. Failure of intestinal barrier function often occurs in many clinical conditions, including hemorrhage shock, severe burn injury, and the surgically critical illness, resulting in the increased intestinal permeability and subsequent translocation of bacteria or/and endotoxin from gut[8-12]. It is clear that increased gut permeability and bacteria with or without endotoxin translocation play a key role in the development of severe complications such as systemic inflammatory response syndrome (SIRS), sepsis, multiple organ dysfunction syndrome (MODS) and multiple organ failure (MOF)[13-20]. Therefore, it is important to know the intestinal injuries following a variety of insults (shock, burn injury, sepsis, and some critically surgical illness)[21,22]. D(-)-lactate is a product of bacterial fermentation. It is produced by many of the bacteria found in the human gastrointestinal tract[23]. Tissues in mammalian do not produce it and its metabolism is very slow[24]. In this study, we investigated the changes of plasma D(-)-lactate and lipopolysaccharide (LPS) levels and their correlation in gut ischemia/reperfusion, burn injury and acute necrotizing pancreatitis (ANP); and explored whether the changes of D(-)-lactate levels could be used as a predictor of increased intestinal permeability and endotoxemia following severe injuries.

MATERIALS AND METHODS

Animals

Male Wistar rats were used in this serial studies. They were housed in individual cages. The room temperature was maintained at 22℃ - 24℃ with a 12h light-dark cycle, and free access to a commercial laboratory rodent chow and fresh water were allowed. Twelve hours prior to experiment, the rats were fasted, but allowed free access to water.

Rat models of gut ischemia/reperfusion

Rats weighing 190g - 250g were divided into three groups. Gut ischemic group (n = 20): Animals were anesthetized with an intraperitoneal injection of 0.3mL 30g·L^{-1} pentobarbital sodium. Through a middle abdominal incision, intestinal

ischemia was produced by occluding the superior mesenteric artery for 1 and 1.5h with an automatic microvascular clamp. Animals were sacrificed at the end of gut is chemia. Gut ischemia/reperfusion group (n=50): superior mesenteric artery was occluded for 1h and then the vascular clamp was removed to produce gut reperfusion. Animals were sacrificed at 0.5, 1, 2, 6 and 24h after gut reperfusion. Sham-operated control (n=10): animals were treated identically omitting the superior mesenteric artery occlusion. Blood samples were collected aseptically from cervical artery and portal vein for D (-)-lactate and LPS assay before animals were killed at each time point.

Rat models of burn

Male Wistar rats weighing 190g - 250g were used. Animals were divided into two groups. In thermal group, they were subjected to a 30% total body surface area (TBSA) full-thickness scald burn injury (n=40). They were anesthetized with an intraperitoneal injection of 30g·L^{-1} pentobarbital sodium (60mg·kg^{-1}) and then the dorsal hair was shaved. A 30% TBSA full-thickness burn was created on the back of the rats in boiling water at 98℃-100℃ for 12s. Rats were resuscitated immediately after thermal injury with 50g·L^{-1} glucose saline solution (50mL·kg^{-1}) intraperitoneally. In the control group (n=10), rats were exposed to the room-temperature water. Animals in thermal group were killed at 3, 6 12 and 24h after burn. Blood samples were collected aseptically from cervical artery and portal vein before the rats were killed at each time point.

Rat models of acute necrotizing pancretitis (ANP)

Male Wistar rats weighing 270g-330g were randomly divided into two groups. In the ANP group (n=27), animals were anesthetized with 30g·L^{-1} pentobarbital sodium (60mg·kg^{-1}, ip). After medium laparotomy, the duodenum was mobilized and the pancreatic duct was identified at its duodenal junction. ANP was induced by a continuous inverse infusion of sodium taurocholate (50g·L^{-1}, 1mL·kg^{-1}) and trypsin (1.67×10^{5}U·kg^{-1}) into the main pancreatic duct. Animals were immediately given saline (50mL·kg^{-1}) subcutaneously after injury. In control group (n=6), animals were treated identically with infusion saline. Blood samples were taken aseptically from cervical artery and portal vein at 2, 8, 24 and 48h after injury.

D(-)-lactate determination

The plasma from systemic blood samples was obtained and subjected to a deproteination and neutralization process by acid/base precipitation using perchloric acid and potassium hydroxide. The protein-free plasma was then assayed for D (-)-lactate concentration by enzymatic-spectrophotometric method with minor modification[25].

Lipopolysaccharide (LPS) determination

The plasma from portal vein blood was also obtained and subjected to a deproteination and neutralization process by acid/base precipitation using perchloric acid and sodium hydroxide. The LPS levels of portal vein blood were assayed by the chromogenic limulus amebocyte lysate (LAL) test with a kinetic modification according to the test kit procedure[26].

Morphologic studies

Tissue samples of intestines were taken for morphologic study. Biospies were fixed in 100mL·L^{-1} neutral buffered formalin, embedded in paraffin, microtome sectioned at 4μm-6μm thickness, and stained with hematoxylin and eosin. Sections were examined under light microscope.

Statistical analysis

Data were expressed as means ± SD. The statistical significance of mean values between groups was evaluated by the Student's t test. The relationship between circulating systemic D(-)-lactate and portal vein LPS concentrations was determined by the calculation of Pearson correlation coefficient. P<0.05 was considered to be significant.

RESULTS

Kinetics of D(-)-lactate and lipopolysaccharide concentrations in plasma after gut ischemia/reperfusion in rats

One hour of gut ischemia alone induced a slight increase in systemic blood D(-)-lactate and portal vein blood LPS concentrations (Table 1). Either D(-)-lactate or LPS concentrations had a further significant increase at 0.5h-2h after gut reperfusion (P<0.05-0.01), and decreased to normal at 6h. Meanwhile, correlation analysis revealed a significant correlation between systemic blood D(-)-lactate levels and portal vein blood LPS concentrations (r = 0.719, P<0.05).

Table 1 The plasma contents of D(-)-lactate and lipopolysac charide in rats after gut ischemia / reperfusion insults (mean±SD)

Groups	Time (h)	No.	D(-)-lactate (mmol/L)	LPS(EU/L)
Sham-operated control		10	0.234±0.072	380±84
Gut ischemia	1	10	0.260±0.086	407±41
	1.5	10	0.269±0.092	453±129
Gut ischemia / reperfusion	0.5	10	0.489±0.179[b]	576±244[a]
	1	10	0.373±0.179[a]	611±278[a]
	2	10	0.253±0.062	562±167[a]
	6	10	0.237±0.044	335±73
	24	10	0.228±0.025	283±81

Compared with sham-operated control, respectively: [a]P<0.05; [b]P<0.01.

Alterations in plasma D(-)-lactate and LPS levels in thermal rats

Results presented in Table 2 indicated that there was a significant increase both in circulating blood D(-)-lactate and portal vein blood LPS concentrations at 6h after injury, and kept significantly increasing to the end of our observation period (72h, P<0.01). In addition, correlation analysis revealed that there was a strong positive correlation between plasma levels of D(-)-lactate and LPS after injury (r = 0.877, P<0.01).

Table 2 Changes in systemic blood D(-)-lactate levels and portal blood LPS content in thermal rats (mean±SD)

Groups	Time(h)	No.	D(-)-lactate (mmol/L)	LPS (EU/L)
Control group		10	0.275±0.175	118±37
Thermal group	3	10	0.371±0.123	159±83
	6	10	0.517±0.162[a]	347±111[a]
	12	10	0.619±0.208[a]	670±139[a]
	24	10	0.638±0.198[a]	396±57[a]

Compared with control group, respectively: [a]P<0.01.

Changes in plasma D(-)-lactate and LPS levels in ANP rats

In rats subjected to ANP, the levels of D(-)-lactate in systemic blood and LPS in portal vein blood began to increase at 2h after ANP (P<0.01) (Table 3), and peaked at 24h after injury. Furthermore, a marked correlation was noted between the changes in contents of plasma D(-)-lactate and LPS (r=0.798, P<0.01).

Table 3 Alterations in systemic blood D(-)-lactate levels and portal blood LPS content in ANP rats (mean±SD)

Groups	Time(h)	No.	D(-)-lactate (mmol/L)	LPS (EU/L)
Control group		6	0.157±0.044	105±7
ANP group	2	6	0.328±0.063[a]	301±131[a]
	8	7	0.507±0.157[a]	449±164[a]
	24	7	0.653±0.216[a]	611±210[a]
	48	7	0.448±0.112[a]	422±136[a]

Compared with control group, respectively:[a]P<0.01.

Gut pathology

Mucosal edema, necrosis, and the loss of the epithelium in mucosa, as well as vascular dilution, congestion, edema and inflammatory cell infiltration in the lamina propria were observed in small intestinal biopsies in three groups. The intestinal injury paralleled with the changes of plasma D(-)-lactate levels.

DISCUSSION

The present study showed that the intestinal damage caused by gut ischemia caused a slight increase in plasma concentrations of D(-)-lactate in systemic blood and LPS in portal vein blood. After gut ischemia followed by reperfusion, the plasma levels of D(-)-lactate and LPS significantly elevated, but declined to normal rapidly at 6h after reperfusion[27-29]. The intestinal damage mediated by burn injury or ANP displayed a more severe damage than that in gut ischemia/reperfusion. A remarked increase of plasma D(-)-lactate and LPS concentrations occurred at 6h, and 3h after insult, respectively, and persisting to the end of our observation. Moreover, the elevation of plasma D(-)-lactate levels in systemic blood was associated with increased plasma LPS contents in portal vein blood, and histological examination also exhibited intestinal injury in those three rodent models.

D(-)-lactate is produced by some bacteria including *Klebsilla*, *Escherichia coli*, *Lactobacillus species*, and *Bacteroides species*. It is an indigenous products in gut[24]. Normally, serum levels of D(-)-lactate in mammals are quite low. During the event that an ischemia/reperfusion insults, the mucosa is injured and intestinal permeability is increased, leading to an efflux of bacteria and the products of their metabolism[30-33], including D (-)-lactate into the circulation. Otherwise, the gut ischemic insult leads to a loss in normal host defenses against bacterial overgrowth, resulting in increased numbers of bacteria within the lumen of the infected intestine[34-36]. This bacterial proliferation would be expected to cause an increased bacterial metabolism with increased production of D(-)-lactate. Mammals do not possess the enzyme system to rapidly metabolize D (-)-lactate, thus, it passes through the liver with unchanged way and enters the peripheral blood early in the disease process. Thus, D(-)-lactate accumulation in the systemic circulation can generally be considered as a result of bacterial over growth and increase in gut permeability induced by some gastrointestinal disorders. Therefore, D(-)-lactate levels could be used as a predictor of intestinal injury. In fact, the elevation of plasma D(-)-lactate levels has been used as the predictor of bacterial infection in patients with short-bowel syndrome[37]. In rat model of acute mesenteric ischemia, D (-)-lactate was significantly elevated after gut ischemia, and the histopathological evaluation scores of intestinal injury were remarkably correlated to the plasma D(-)-lactate levels[38,39]. Recently, in clinical study, it has also been demonstrated that patients with mesenteric ischemia at laparotomy had significantly elevated D(-)-lactate levels in systemic circulation as compared with patients operated on for an acute abdomen or normal abdomen[40].

In conclusion, our data in these rat models suggest that the changes in D(-)-lactate concentrations paralleled with LPS concentrations, and correlated similarly with the intestinal histopathological alterations as well. Therefore, plasma D(-)-lactate in systemic circulation measurement would be a useful marker to evaluate intestinal injury and endoxemia following severe injuries.

Abstract

AIM **To clone the cDNA fragment of human TRAIL (TNF-related apoptosis inducing ligand) into a tetracycline-regulated gene expression system, the RevTet-On system, transduce expression vectors into a gastric carcinoma cell line-NCI-N87 and examine the effects of controlled expression of TRAIL *in vitro* on the gastric carcinoma cells.**

METHODS **The full-length cDNA of TRAIL was inserted into a vector under the control of the tetracycline-responsive element (TRE) to obtain the plasmid pRevTRE-TRAIL, which was transfected into a packaging cell line PT67. In addition, vector pRev-Tet On and pRevTRE were also transfected into PT67 separately. After hygromycin and G418 selection, the viral titer was determined. The medium containing retroviral vectors was collected and used to transduce a gastric carcinoma cell line NCI-N87. The resulting cell line NCI-N87-Tet On TRE-TRAIL and a control cell line, NCI-N87 Tet On-TRE, were established. TRAIL expression in the cell line was induced by incubating cells with doxycycline (Dox), which is a tetracycline analogue. The killing effect on gastric carcinoma cells was analyzed after induction.**

RESULTS **The recombinant plasmid pRev-TRE-TRAIL was constructed. After hygromycin or G418 selection, the producer cell lines PT67-TRE, PT67-TRE-TRAIL and PT67-Tet On were obtained, with titers of about 10^8 CFU·L^{-1}. By transducing NCI-N87 cells with retroviral vectors from these cell lines, stable cell lines NCI-N87-Tet On TRE-TRAIL (NN3T) and control cell line NCI-N87-Tet On TRE (NN2T) were established. The growth curves of the selected cell lines were the same with the wild type NCI-N87. When Dox was added, cell death was obvious in the test groups (29%-77%), whereas no difference was observed in control and wild type cell lines. With the addition of a medium from the test group, human leukemia cell line Jurkat was activated till death (83%), indicating the secretion of active TRAIL proteins from the test cells to the medium.**

CONCLUSION **With the use of the RevTet-On system, a regulated expression system for TRAIL was constructed. Using this system, the selected killing effect of TRAIL on gastric carcinoma cell line NCI-N87 could be observed.**

INTRODUCTION

TRAIL (TNF-related apoptosis inducing ligand, Apo2 ligand, Apo 2L), which belongs to the tumor necrosis factor (TNF) cytokine family, can induce rapid apoptosis in a wide variety of tumor cell lines[1-3]. TRAIL protein consists of 281 (human TRAIL) or 291 (mouse TRAIL) amino acids.The human TRAIL gene is located in chromosome 3(3q26). The mRNA distribution of TRAIL is broad[1,4-8]. Although the *in vivo* role of the TRAIL is not currently known, *in vitro* studies have found that TRAIL is capable of inducing apoptosis in a wide range of human tumor cells, but generally not normal cells[9-16]. TRAIL induces apoptosis by binding and cross-linking death-domain containing receptors[17-21], TRAIL-R1[22,23] (also known as DR4) and TRAIL-R2[24-26] (DR5). Apoptotic signaling occurs via recruitment of adapter proteins, which results in the activation of caspases[24,27]. Because of its selective killing effect on tumor, TRAIL is likely to be a drug in cancer treatment[28-30]. Therefore, we tested the effect of TRAIL expression in human gastric carcinoma cells, most commonly found in oriental population. In addition, the study may form a basis for the safety and effectiveness of TRAIL expression in gene therapy of cancer.

In gene therapy, it is important to regulate gene expression effectively. The tetracycline-controlled gene expression system (Tet system) is a tight control system[31]. It is based on the Tn10 specified tetracycline resistance operon of *E. coli*. In the Tet-Off system, the regulator unit, encodes a hybrid tTA (tetracycline-controlled transactivator) protein composed of the tetracycline repressor (tetR) fused to the herpes simplex virus (HSV) transactivator protein, VP16. The response unit, tetracycline-responsive element (TRE), is composed of the tetracycline resistance operon regulatory elements (tetO) embedded within a minimal cytomegalovirus (CMV) promoter. The expression of a gene inserted downstream of the promoter is highly dependent on tTA, which binds tetO sequences. With the addition of tetracycline, tTA protein dissociates from the TRE and the gene expression is inhibited. Conversely, the Tet-On system allows gene expression to be activated by the addition of

tetracycline. It is based on the reverse tTA (rtTA) in the regulator unit.

The RevTet-Off/On system uses the retroviral vectors. They have the characteristic of Tet system, and their gene transfer is more rapid and efficient, which can be used in gene therapy. In this study, TRAIL gene was cloned into the RevTet-On system, to achieve tight control of the expression of TRAIL protein in mammalian cells. The gene expression system on gastric carcinoma cell line NCI-N87 was constructed, and the killing effect of controlled-gene expression in the resulting cells was observed.

MATERIALS AND METHODS

Construction of retroviral plasmids

The RevTet-On System, which include pRevTet-On and pRev-TRE vectors and the RetroPack PT67 cell line, were purchased from Clontech, Palo Alto, California, USA. TRAIL gene was obtained by using PCR method from a human placenta cDNA library (Clontech). The PCR primers are: 5'-AAGCTTATGGCTATGATGGAGGTCCAGGGGGG-AC-3'and 5'-AAGCTTTTAGCCAACTAAAAAGGCCCCG-AAAAAACTGGC-3'. The resulting PCR product was cloned into an intermediate vector PCR-2 (Invitrogen, Carlsbad, California, USA) and then cut with *Hin* dIII, which was cloned into the same site in vector pLNCX, resulting in vector pLNCX-TRAIL. The Tet-regulated vector pRev-TRE-TRAIL was cloned in the same manner.

Cell culture

The retroviral packaging cell line PT67 and the murine fibroblast cell line NIH3T3 were maintained in Dulbecco's modified essential medium (DMEM) containing 100mL·L^{-1} fetal bovine serum. The human gastric carcinoma cell line, NCI-N87, and the human leukemia cell line, Jurkat, were maintained in RPMI 1640 medium containing 100mL·L^{-1} or 150mL·L^{-1} fetal bovine serum respectively.

Transfections, infections and determination of viral titer

The packaging cells PT67 were plated in a 60 mm plate at a density of 50%-80% 24h before transfection. Cells were washed with DMEM twice and incubated with 2mL DMEM before transfected with 10μg of plasmid DNA by lipofectin method (Life Technology, Gibco BRL). Four h-6h after transfection, 2mL DMEM (containing 200mL·L^{-1} FBS) was added. To obtain stable virus-producing cell lines, the packaging cells transfected with retroviral plasmids were plated in selection medium 48h later. The regulatory vector Tet-On carries the neomycin gene as a selectable marker. For G418 selection, cells were cultured in the presence of G418 (0.4g·L^{-1}, Gibco) for two- weeks. The vectors pRev-TRE and pRev-TRE-TRAIL carry the gene for hygromycin selection. These cells were selected in the presence of hygromycin B (0.06g·L^{-1}, Sigma) for two weeks. For transduction, NCI-N87 cells were plated 24h before infection. The medium from packaging cells containing virus were collected, filtered through a 0.45μm filter, and added to the NCI-N87 cells in the presence of Polybrene (4g·L^{-1}, Sigma). The medium was replaced 4h later. Three to six serial infections were performed to increase the efficiency of infection. Forty-eight hours after infection, the cells were subjected to G418 or hygromycin selection. For determination of viral titer, NIH3T3 cells were plated 24h before transduction in 6-well plates (2×10^5 cells per well). The cells were infected with filtered virus-containing medium (six 10-fold serial dilutions, 1 - 10^5). The cells were then incubated in G418 or Hygromycin 48h later, and the selection lasted about weeks until clear colonies appears.

Growth curve

The cells were plated in 96-well plates (5×10^4 cells per well), and counted by Typan blue dye exclusion method over a 24h period.

Induction of gene expression

The cells were added with the medium containing Dox (0.01 -10mg·L^{-1}, Sigma). After a period of time, the fraction of dead cell was calculated by Typan blue dye counting. The medium after induction was added in Jurkat cells (100mL·L^{-1}), the fraction of dead cell was calculated by Trypan blue dye.

RESULTS

Construction of retroviral vectors

To clone the TRAIL gene into the Tet system, we inserted the cDNA of TRAIL into the Tet response vector pRev-TRE, which was named pRevTRE-TRAIL. The desired recombinant plasmid orientation was confirmed by Hin dIII and *Ssp* I digestion. In this plasmid, the TRAIL gene is the downstream of the TRE, which can bind rtTA expressed by pRevTet-On. So, in combination with the pRevTet-On regulatory vector, the TRAIL gene can be inductively expressed at high levels in response to varying concentrations of tetracycline or doxycycline. Because of their retrovirus-mediated gene transfer, we can incorporate the Tet-controlled TRAIL protein expression system into mammalian cells.

Establishment of Tet-controlled TRAIL system

We transfected vectors into packaging cells PT67. Using G418 (pRevTet-On) and hygromycin selection (pRev-TRE and pRevTRE-TRAIL), we obtained the stable virus-producing cell lines, PT67-TetOn, PT67-TRE and PT67-TRE-TRAIL. Viral titers were 1-2×10^{8}CFU·L^{-1}, determined by titering NIH3T3 cells. After serial infections of NCI-N87 cells with viral-containing supernatants and antibiotic selections, two kinds of cell lines were established. One is the test group NCI-N87-TetOn-TRE-TRAIL (NN3T, Figure 1A), which is a Tet-controlled TRAIL expression cell line. The second is the control cell line NCI-N87-TetOn-TRE (NN2T, Figure 1B), which is the same with NN3T but without TRAIL expression.

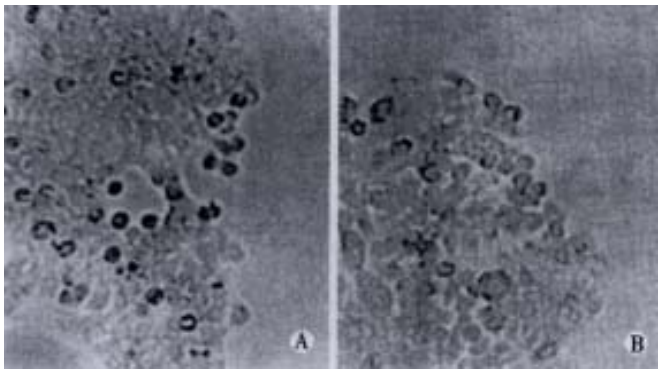

Figure 1 Morphology of cells. A: NN3T; B: NN2T

Killing effect of TRAIL induced by doxycycline

When we added doxcycline to cells, some cells died in the test group NN3T 48h later (Figure 2), whereas no clear death effect can be detected in cells in the control group (NN2T)

and wild type NCI-N87. Under normal conditions without Dox, the growth curves of these three types of cells showed no obvious differences (Figure 3). In order to test the possible secretion of TRAIL protein into the medium, the media from the test group and control group were removed and inoculated into the human leukemia cells Jurkat (sensitive to TRAIL-induced apoptosis). Obvious cell death was observed after one day culturing in the test group as compared with the control and the normal groups. From these results, we concluded that the regulated expression of TRAIL in the Tet system has killing effect on the gastric carcinoma cell NCI-N87.

DISCUSSION

Tumor necrosis factor (TNF) is a prototypic member of the family of cytokines that interact with a corresponding set of receptors that form the TNF receptor (TNFR) family. Three of these ligands, CD95L, TNF and LTα, have received particular attention because they can induce apoptosis in transformed cells and activated lymphocytes[32-34]. The potential utility of systemically administered ligands is limited by their acute toxic effects on normal tissues *in vivo*, thereby limiting their potential widespread use in the treatment of cancer[35]. Previous studies have shown that TRAIL can induce apoptosis in a variety of tumor cell lines. In contrast to other members of TNF family, TRAIL mRNA is expressed constitutively in many tissues including peripheral blood lymphocytes, spleen, thymus, prostate, ovary, small intestine, colon and placenta[1,7,17,36-38], which suggests the existence of physiological mechanisms that can protect many normal cell types from induction of apoptosis specifically by TRAIL. A relatively high proportion (approximately two-thirds) of tumor cell lines tested so far are sensitive to the cytotoxic effects of TRAIL *in vitro*[1,7,11,39], indicating that TRAIL may prove to be a powerful cancer therapeutic factor.

Although TRAIL potently induces apoptosis in tumor cells and some virally infected cells, it has little or no detectable cytotoxic effects on normal cells, whereas this was first thought to be due to regulated expression of the TRAIL receptors[3,24,40-42], the fact that mRNA for both TRAIL and TRAIL receptors is often expressed in the same cells makes this explanation untenable[17,43]. Indeed, the identification of four distinct TRAIL receptors (TRAIL-R1, R2, R3, R4) has significantly increased the potential complexity of this receptor/ligand system[17,43,44]. Based on current information it seems mikely that multiple factors, both intra and extra-cellular, may function together to protect normal cells from the cytotoxic effects of TRAIL[17,43,45-48], but many questions remain unexplained.

Although the reason for determining the sensitivity of cells to TRAIL-induced apoptosis has not been understood, we still try to use TRAIL in cancer treatment to achieve the effectiveness and the safety of the therapy. In our laboratory, the cDNA sequence of TRAIL has been cloned from human placenta cDNA library. We have expressed the TRAIL in the *E. coli* by the pET system[49], after purification and refolding the antitumor activity of the protein has been examined[50]. On the other hand, a chief concern with the potential use of TRAIL protein in the treatment of tumors *in vivo* is the potential undesirable toxicities. Because of the recent report that some normal human cells were sensitive for the apoptosis induced by TRAIL[51], we inserted the gene into a mammalian expression vector to study its effect further in this experiment.

In most inducible mammalian gene expression systems (heavy metals, steroid hormones, or heat shock), induction is nonspecific and expression levels cannot be precisely regulated. In addition, these systems are generally leaky in the "off" state, and the inducing agent itself may be cytotoxic or have pleiotropic effects. In contrast, regulation of gene expression by the Tet system is very specific[31]. Furthermore, the levels of tetracycline or doxycycline required for the full range of gene expression are not cytotoxic and have no significant effect on cell proliferation or animal growth. Using retroviral vectors instead of DNA transfection to transduce the complete inducible system greatly expands the target cell types in which gene functions can be studied. This strategy may be useful for clinical applications in human gene therapy trials.

In this study, the effectiveness of TRAIL in killing human gastric cells was evident. It showed that the gastric carcinoma cell line was sensitized to TRAIL-induced cell death. In addition, the concentrations of doxycyline that constituted the effect were within a range of clinical security. We can believe that this effect will be safe to normal tissues with the specificity of TRAIL and regulation of the Tet system.

At the moment, malignant gastric carcinoma remains one of the difficult types of cancer to treat successfully, and with the incidence of gastric carcinoma increasing at China, it continues to be a leading cause of death in Japan and other countries of Asia. In our experiment, the expression system of TRAIL gene controlled by tetracycline was established in gastric carcinoma cell line NCI-N87, and its killing effect to the tumor cell was observed. This study clearly demonstrates the possible usefulness of Tet-controlled TRAIL expression system in gastric cancer gene therapy, and further studies of the mechanisms of TRAIL-mediated cytotoxicity are required to assess the potential use of TRAIL as an anti-cancer therapeutic *in vivo*.

Abstract

The incidence of Barrett's metaplasia (BM) as well as Barrett's adenocarcinoma (BA) has been increasing in western populations. The prognosis of BA is worse because individuals present at a late stage. Attempts have been made to intervene at early stage using surveillance programmes, although proof of efficacy of endoscopic surveillance is lacking, particularly outside the specialist centres. The management of BM needs to be evidence-based as there is a lack clarity about how best to treat this condition. The role of proton pump inhibitors and antireflux surgery to control reflux symptoms is justified. Whether adequate control of gastroesophageal reflux early in the disease alters the natural history of Barrett's change once it has developed and or prevents it in patients with gastroesophageal reflux disease but with no Barrett's change remains unanswered. There is much to be learned about BM. Thus there is great need for carefully designed large randomised controlled trials to address these issues in order to determine how best to manage patients with BM.

INTRODUCTION

The recent rise in the incidence of esophageal adenocarcinoma in parallel with an increased incidence of Barrett's metaplasia (BM) favours the theory that BM is a pre-cancerous lesion for adenocarcinoma. This BM is thought to occur as a result of prolonged and severe gastroesophageal reflux that can lead to chronic inflammation resulting in replacement of normal squamous epithelium in the distal oesophagus with specialised intestinal-type columnar epithelium containing goblet cells. Attempts have been made to treat acid reflux with medical treatment as well as anti-reflux surgery in the hope that it might prevent progression of BM. Surveillance strategies for established BM to detect early cancer have not been proven cost effective[1,2], although lesions identified during surveillance program have better prognosis. Despite extensive research, the natural history of BM is poorly understood. Many questions remain regarding the diagnosis of BM, its treatment, and the impact of surveillance strategies on early detection of cancer. It is important to realise the sheer scale of the problem as oesophagitis secondary to gastroesophageal reflux disease is one of most common conditions in the western world with up to 30% of adults complaining of heartburn at least once per month, a third of whom will develop oesophagitis. About 10% of patients with oesophagitis will progress to BM, of whom up to 5% will progress to cancer.

Using pooled data, the cancer risk in BM is about 1% (range 0.5% - 2%)[3]. Proposed clinical risk factors for cancer progression including chronicity of symptoms, length of Barrett's segment, gastroesophageal reflux and mucosal damage. For example gastroesophageal reflux symptoms are considered an independent risk predictor for cancer risk but may not discriminate low from high risk BM. Molecular changes in p53, p16, and *cyclin* D1 overexpression, decreased E-cadherin expression, and loss of heterozygosity of the adenomatosis polyposis coli (APC) gene have been detected[3]. These molecular changes have been evaluated in a clinical research setting but are not routinely used in clinical practice, although such genetic changes may become useful screening markers to monitor progression of BM and to identify individuals at risk of developing malignant transformation in the future. Thus, there is a pressing need for better understanding of BM and to develop strategies not only to prevent this pre-cancerous condition but also to identify high-risk individuals with this condition who are at risk of developing Barrett's adenocarcinoma. This article discusses issues that concern clinicians in the management of BM including definition, diagnosis, screening and surveillance of BM, as well as management of uncomplicated BM.

DEFINITION AND DIAGNOSIS OF BM

BM may be defined as visible columnar-lined oesophagus of any length above the esophago-gastric junction (OGJ) confirmed on biopsies with the presence of specialised intestinal-type columnar epithelium containing goblet cells. However, there is considerable disagreement in defining BM. One technical problem in this regard is the precise identification of the OGJ. Suggested endoscopic criteria for identifying OGJ include the point of flaring of the stomach from the tubular oesophagus[4] and confluence of the proximal margin of longitudinal gastric folds[5]. One has to realise that this location point of flare can shift during breathing as well as peristaltic activity in the oesophagus and prolapse of the gastric folds into the oesophagus could further confuse the situation. Distinction between long and short Barrett's segment is irrelevant as the tendency to develop high-grade dysplasia may be similar in short and long segment Barrett's[6].

To avoid confusion endoscopists should avoid such terminology and instead describe only what they see i.e. if columnar-lined oesophagus is present or not and if present whether it is continuous or tongues and islands are observed. The histopathologist often finds it difficult to differentiate between intestinal metaplasia occurring in the distal oesophagus and in the cardia, and thus should avoid the term Barrett's and instead report whether columnar epithelium is present and the presence or absence of intestinal metaplasia

and identification of squamo-columnar junction. It is essential that precise site of biopsies with reference to OGJ should be documented to help the histopathologist make an accurate diagnosis. Thus the diagnosis of BM becomes clinicopathological integrating both endoscopic and histopathological information to increase diagnostic accuracy. Occasionally (1% - 5% of cases), however, the pathologists see esophageal glands submerged under columnar-lined tissue corroborating the biopsy as being esophageal in origin (personal correspondence Prof N Shepherd, Gloucester Royal Hospital, UK) (Figure 1).

EPIDEMIOLOGY OF BM

The true prevalence of BM in the general public is unknown. Reported lifetime risk in adult general populations in western countries is 1%[7] based on post-mortem studies. In addition, the incidence of new cases is about 0.5%-2.0%/year[3] and increasing[8]. It mainly occurs in white people, with a male predominance (male: female 2.3:1)[9]. Recently its prevalence has been shown to be rising all over the world, including in the Far East[10]. There is no significant relationship between smoking, alcohol consumption and high body mass index in the genesis of this metaplastic change.

SCREENING AND SURVEILLANCE OF BM

It is not clear why only 10% of patients with oesophagitis progress to BM and why only a tiny fraction of these patients will go on to develop adenocarcinoma. In view of the low prevalence of BM in patients with gastroesophageal reflux as well as uncertainties regarding diagnosis and treatment, it is difficult to justify screening for Barrett's in patients with gastroesophageal reflux, although patients aged >45 with longstanding severe reflux symptoms (5 - 10 years) should have a one off screening endoscopy.Barrett's adenocarcinoma develops through stages of increasing dysplasia (Sandic 1998). If this theory is correct, then surveillance endoscopies biopsies of BM should permit early cancer detection and reduce mortality from Barrett's adenocarcinoma[11], as prognosis in early Barrett's adenocarcinoma is more favourable as compared to advanced disease[12]. Attempts to identify tumours at early stage with surveillance programmes has not been cost effective in few studies[1,2]. Surveillance of BM with no dysplasia at 2.5 years has been recommended, although its usefulness has never been validated in a randomised study. Using the Markov model based on UK NHS cost per life saved if the surveillance programme is based on two yearly endoscopy, surveillance is comparable to other health disciplines in terms of cost per cancer detected and cost per life saved. It is fair to say that for an expense of this order we should first have some convincing evidence of effectiveness of surveillance programmes. Until results of such studies are available we face the dilemma of telling patients that they have a pre-cancerous condition with 5% life-time risk of cancer and that we could offer lifelong surveillance endoscopy programme that cannot guarantee to detect every cancer that may develop.

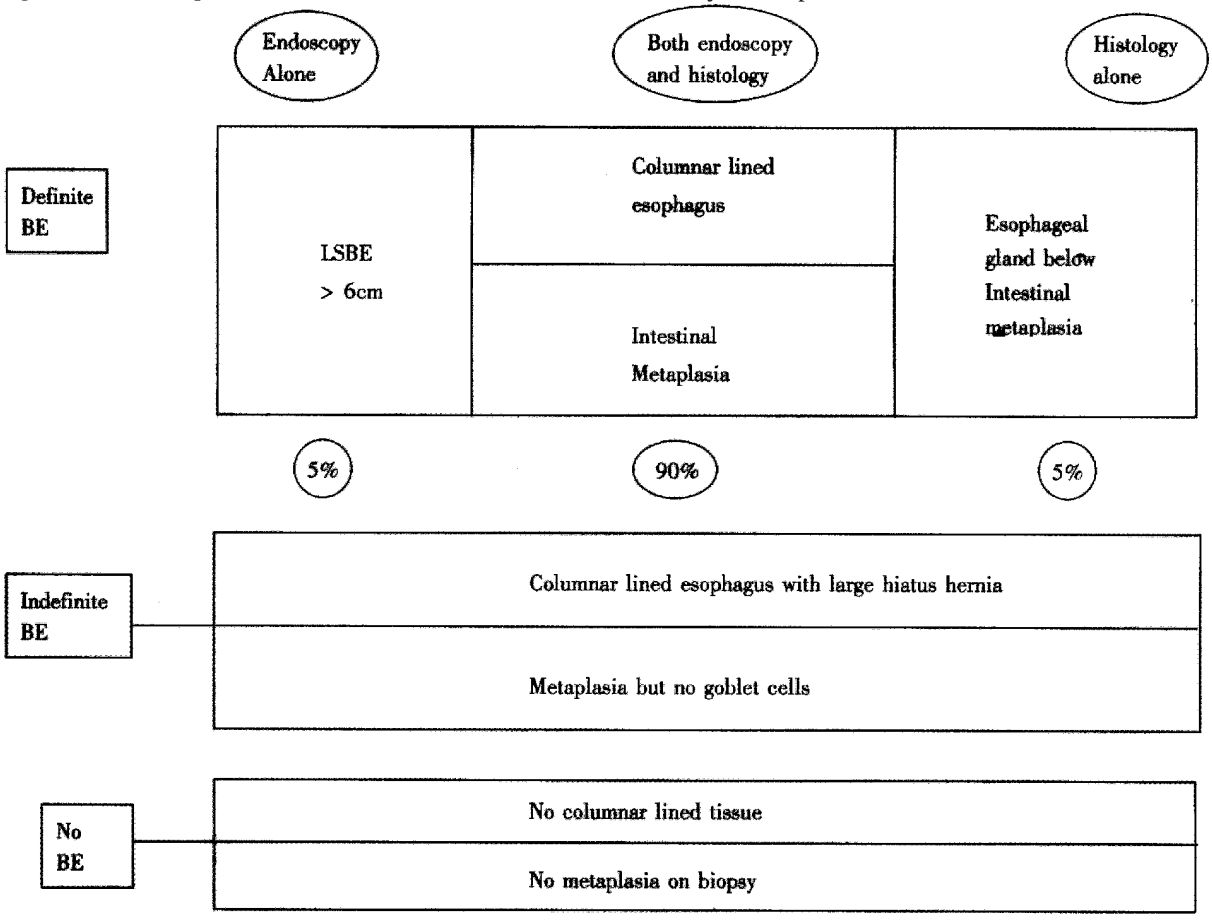

Figure 1 Diagnostic criteria for Barrett's esophagus (BE), based on endoscopic, histological criteria or both. LSBE (long segment Barrett's esophagus). Definite diagnosis can be made with endoscopy in 5%, histology alone in 5%, but in about 90% both endoscopy and histology is required.

MANAGEMENT OF UNCOMPLICATED BM (NO DYSPLASIA)

The symptoms of GORD, a presumed cause of BM, can be effectively eliminated with medical treatment or with anti-reflux surgery; however, regression of established BM does not occur with either intervention. On the other hand, many patients with BM will either have reduced or absent symptoms due to reduced sensation of Barrett's epithelium. The role of PPI's in BM is unclear. High dose PPI's are still proposed regardless of symptoms by many who justify that such an approach may be necessary to achieve regression of BM[13]. Opponents of this approach advocate no treatment of asymptomatic BM and are less convinced that acid suppression prevents complications. Until there is more clarity in the scientific evidence, PPI's remain an attractive treatment for the BM, especially if there is endoscopic evidence of esophagitis above the BM segment as is the case in about 40% -60% cases.

Competent fundoplication for BM has been advocated in patients with complications or intractable symptoms unresponsive to conservative medical treatment. If performed early, before the development of Barrett's changes, fundoplication is slightly more effective than medical treatment to prevent this metaplastic change. The effect of this anti-reflux surgery on the natural history of BM once it has developed is less clear. Until we have more data to determine the role of anti-reflux surgery in the setting of BM or GORD, it would be sensible to perform these procedures once medical treatment fails or on patients fully informed of the choice. In addition, because there is a 0.1%-0.2% mortality rate for fundoplication surgery, this detracts from its efficacy. In particular, if there is an estimated 5% lifetime risk of cancer in BM, only half will die of the cancer because co-morbidity such as cardiac diseases will usually kill them. Secondly, no treatment is ever 100% effective in preventing cancer, so if 50% of individuals could be prevented from getting cancer only 1.25% of the 5% at risk population would benefit from surgery. Therefore for every 9 patients benefiting from long term advantages of surgery, 1 or perhaps even 2 would die prematurely from the surgery itself.

Because of the inability to effect regression of Barrett's mucosa with medical or anti-reflux surgery, there has been renewed interest in the development of new modalities to eliminate this metaplastic change and hence reduce the cancer risk by destruction of Barrett's mucosa by endoscopic ablation with thermal (Laser, Argon Plasma Coagulator), chemical (photodynamic) or mechanical (surgical ultrasound) in a reflux free environment to prevent further damage. These techniques have shown healing by squamous epithelium regeneration in 66% - 100% patients[14], although nests of glandular epithelium may remain beneath the neo-squamous epithelium in up to 60% of patients that may progress to cancerous change. In view of this and high complication rates[14], many authors have debated the usefulness of these potentially hazardous therapies. Using NNT calculations, a reduction of absolute risk has not been established for any of these therapies. Efficacy of such treatment should thus be verified in controlled trials before their widespread use.

CONCLUSIONS

In spite of extensive research in this area it appears that we have more questions than answers. Our understanding of the natural history of BM is limited, as available data is not only insufficient but also either contradictory or subject to variable interpretation. Longstanding gastroesophageal reflux has been proposed to contribute towards BM. Whether adequate control of gastroesophageal reflux early in the disease alters the natural history of Barrett's change once it has developed, or prevents it in patients with GORD, remains unanswered. To date, we simply cannot estimate or eliminate either the cancer risk or BM itself. On the basis of evidence available, it is difficult to promote or reject Barrett's surveillance programmes on economic grounds alone. We must not forget that only 25% Barrett's adenocarcinoma patients are known to have BM before they develop cancer and that 75% of cancer patients present for the first time with this disease without any prior knowledge of GORD or BM. Thus there is a pressing need for more work to be done, in large randomised controlled trials, to unravel these issues before we will be able to treat this condition effectively.

ACKNOWLEDGEMENTS This paper was formulated at a time when the British Society of Gastroenterology guidelines were being written. We have tried to avoid any conflict of opinion and are grateful to Prof Hugh Barr, Prof Neil Shepherd, Department of Pathology of the Gloucester Royal Hospital (Gloucester, UK), Prof Tony Watson Department of Surgery of the Royal Free Hospital (London, UK) and Dr Paul Moayyedi of the Department of Gastroenterology General Infirmary (Leeds, UK).

INTRODUCTION

Fulminant hepatic failure (FHF) is a severe disease with devastating consequences; the incidence is high in China. Before the availability of liver transplantation, the mortality rate was more than 80%[1,2]. The advent of liver transplantation revolutionized the outcome of FHF[3,4]. However, many patients were unwilling to accept liver transplantation until very late, hence most of them died because of donor shortage and urgency of the disease[5-7]. To overcome the problems, we performed orthotopic liver transplantation (OLT) in combination with artificial liver support (ALS) in the treatment of FHF in the past 2 years with satisfactory results. Our experience was reported below.

PATIENTS AND METHODS

Patients

All eight patients were male with a mean age of 40 (range 32 -49) all had hepatitis B with acute absolute liver failure on admission. These patients had a history of hepatitis for 7 days to 12 weeks, with acute onset of severe hepatic disfunction, rapidly progressive jaundice, abdominal distention, asthenia, ascites, coagulopathy and encephalopathy. Two of them were complicated with acute hepatorenal syndrome and acute necrotizing pancreatitis respectively. Seven patients had stage II-IV coma. All 8 patients received artificial liver support for 2-20 times before transplantation.

Artificial liver support therapy

All patients received artificial liver support treatment with Plasmaflo KM8800 (Kuraray Co. Japan). Plasma exchange (PE), hemodiafiltration (HDF) or bilirubin absorption were singly or jointly selected to treat the patients respectively[8]. On the first treatment, anconeus venous or femorali catheterization was established. Plasma exchange given was 2000mL - 4000mL, plasma transfusion or plasma substitute of 2500 mL - 4500 mL and albumin infusion of 20 g - 40 g each time. The rate of plasma seperation and the flow rate of plasma exchange were controlled at the speed of 20-30mL/ min and 60 - 100mL/min, respectively. The whole course took 3-5 hours.

Procedure of liver transplantation

The 8 patients underwent orthotopic liver transplantation under veno-venous bypass[9,10], of whom 7 underwent standard orthotopic liver transplantation[11] and 1 modified Piggyback liver transplantation[12]. The transplantation was successfully performed with a median anhepatic phase of 78 minutes and operation lasted averagely 5 hours and 30 minutes, but the 2 patients with preoperative renal failure had oliguria during operation. An average bleeding of 5600mL (2000mL-10000mL) was recorded during the operation and the blood lost was collected with Cellsaver.

RESULT

Recipient's survival

All patients became conscious soon after liver transplantation and one in stage IV coma also awoke 2 hours postoperatively. Six of 8 recipients have survived for 2-20 months with good hepatic function, of whom 3 had returned to normal work for more than 18 months. Three days after transplantation, 2 patients died of multi-organ failure (MOF), one with acute necrotic pancreatitis that was unnoticed. Acute rejection occurred in one patient who recovered after anti-rejection treatment of methylprednisolone.

Effect of artificial liver support on FHF

After treatment with artificial liver support the ascites and coagulopathy, decreased serum bilirubin declined, encephalopathy relieved and hepatic function improved (Table 1).

Table 1 Changes of hepatic function before and after ALS

Treatment	N	ALT(U/L)	AST(U/L)	TBil(μmol/L)	IBil(μmol/L)	PT(second)
Before	8	125.4+55.9	132.0+42.9	559.2+209.3	310.8+151.8	40.9+6.7
After	8	120.3+35.5	119.0+29.6	423.7+157.0	252.3+118.5	36.7+6.2
t		0.574	1.336	6.187	4.206	1.959
P		>0.50	>0.20	<0.001	<0.005	>0.05

DISCUSSION

Fulminant hepatic failure progresses rapidly with high mortality and liver transplantation has emerged as an effective therapy for whom do not responded to the standard treatment[13-16]. All patients with FHF must be considered as potential transplantation candidates[17,18]. At King's College Hospital in England, the criteria used for liver transplantation are dependent on the cause of FHF[19,20]. In patients with paracetamol-induced FHF, a pH of less than 7.3 at 24 hours or more after overdose, with concurrent presence of a serum creatinine level greater than 300 μmol/L (>3.4 mg/dL), hepatic encephalopathy of grade III or IV, and a prothrombin time greater than 100 seconds are considered indications for liver transplantation. In non-paracetamol-induced FHF, the decision is based on the occurrence of three of the following: a prothrombin time greater than 50 seconds; jaundice proceeding to encephalopathy more than 7 days; non-A, non-B hepatitis or drug-induced hepatitis; age younger than 10 years or older than 40 years; bilirubin level greater than 300 μmol/L (>17.5 mg/dL); or an isolated finding of prothrombin time of greater than 100 seconds. The indications of 8 patients in our group met with the criteria of King's College Hospital. But in China, where brain death has not been accepted as a criterion for human death, most of the patients with FHF died before the organ became available because not only of the organ donor shortage but also of the rapidity of the course. Thus, it is necessary to develop artificial liver support system as a bridge to cross over to liver transplantation[21,22]. In our study, 8 patients with FHF underwent artificial liver support, then 6 of them survived the most critical period and returned to normal life. Liver transplantation plus artificial liver support creates a new avenue for treatment of FHF.

Artificial liver support system can remove the toxic substances by way of plasma exchange[23], hemodialysis[24], hemo-infiltration[25] and absorption[26], in order to substitute the hepatic function of detoxication[27-31]. Perhaps ALS can remove the toxic substances causing encephalopathy, improve the patients' consciousness, prevent and treat multi-organ failure[32,33]. Why ALS is effective in preventing brain edema is also unelucidated, perhaps by change in permeability of the blood-brain barrier and by raising the osmolality of neural cells[34-36]. ALS, particular the hemodialysis, may prevent the brain edema[37-41]. Our experience showed that pretransplant ALS may not only help the patients to tide over critical period but also increase the chance for liver the transplantation

INTRODUCTION

The T-cell dependent specific liver injury in mice induced by concanavalin A (ConA) is a newly established experimental liver injury model, which is considered more eligible for the study of pathophysiology of several human liver diseases, such as viral hepatitis and autoimmune hepatitis[1-9]. T cell activation and several cytokines release had been proven to play a critical role in ConA-induced liver injury[10-19]. Cyclosprine A (CsA), an effective in hibitor of activation of T lymphocyte, has been used widely in clinical treatment, especially in autoimmune diseases and organ transplantation[20-25]. In this study, we investigated the possible effect of CsA on ConA-induced liver injury in Kunming mice.

MATERIALS AND METHODS

Materials

Male Kunming mice were purchased from the animal experimental center of the Second Military Medical University, weight range 17g-21g, free access to water and food prior to the experiment. ConA and CsA were purchased from Dongfeng Ltd Shanghai and Sandoz Ltd respectively.

Methods

All the fifteen Kunming mice were divided into three groups randomly. ConA at a dose of 40mg·kg^{-1} was administered through the tail vein as a solution in pyrogen-free PBS at a volume of 300μL, which was the ConA group. CsA was injected subcutaneously twice at a dose of 130mg·kg^{-1} 15 and 1h before ConA challenge, which was used as the CsA group. PBS only in the corresponding volume served as controls.

Eight hours after ConA administration, the Kunming mice were sacrificed by cervical dislocation. Blood samples were obtained by puncture of heart with 25g·L^{-1} heparin. Liver specimen was fixed immediately in 100 mL·L^{-1} formalin/PBS for histological examination with HE stain. The degree of liver injury was assessed by determination of serum alanine aminotransferase (ALT) activity, serum TNF-α was determined by radioimmunoassay.

Statistics

The results were analyzed by Student's *t* test. The data were expressed as $\bar{x} \pm s$, and $P<0.05$ was considered to be significant.

RESULTS

ConA-induced liver injury in Kunming mice

Eight hours after ConA administration, two out of the five experimental mice were found dead in ConA only group, with elevated serum ALT 22 261 ± 2 523 nkat·L^{-1}. The concentration of serum TNF-α also increased significantly in ConA only group, increased more significantly than that of PBS only group 647±183ng·L^{-1} (Table 1).

Histological examination of liver specimen from ConA-treated mice showed diffuse cloudy swelling of the cytoplasm, spotty and necrotic foci were frequently present, severe agglutination of erythrocytes in the sinusoids of the liver were also observed. Lots of infiltrated lymphocytes in the portal area were the characteristic of this new liver injury model (Figure 1), indicating that lymphocyte may play an important role in the pathogenesis of ConA-induced liver injury, whereas no obvious tissue damage was found in the lung or kidney.

CsA protection

When pretreated with CsA (CsA group), serum ALT activity declined significantly (730 ± 266) nkat·L^{-1}, and the serum TNF-α was below the detective level (Table 1). No obvious hepatic necrosis or lymphocytes infiltration in the portal area was observed under light microscopy in the CsA group (Figure 2).

Table 1 ConA-induced liver injury in Kunming mice (n=5, $\bar{x}$±s)

	ALT- nkat·L^{-1}	TNF-α ng·L^{-1}	Dead
Con A only	22 261±2 523[b]	1230±240[b]	2
PBS only	647±183		0
CsA	730±266		0

[b]$P<0.05$, *vs* PBS only or CsA.

Figure 2 CsA pretreated, no obvious hepatocyte necrosis or infiltration of lymphocytes was observed. HE×66

DISCUSSION

ConA-induced specific liver injury in mice is a newly developed experimental animal model, which has been closely studied in the pathogenesis of the liver injury in recent years. T lymphocyte activation, cytokines release such as TNF-α, interferon-γ, and interleukines have been discovered to be involved in the pathogenesis of this liver injury model, especially the activation of T lymphocyte and the subsequent release of TNF-α are considered to play a much more important role in this experimental liver injury. The pathological process of ConA-induced liver injury was similar to what seen in several human liver diseases, such as viral hepatitis, and at least three types of autoimmune hepatitis. CsA is a specific inhibitor of T lymphocyte by inhibiting the transcription[21,23], and whether CsA has any protective effect on ConA-induced Kunming mice liver injury by inactivation of T lymphocytes has to be studied In our experiment, the ConA-induced specific liver injury was successfully duplicated in Kunming mice. The results (Table 1) showed that eight hours after ConA administration, the serum ALT activity was significantly increased compared with that in the control group (PBS only group). At the same time, two mice (2/5) died within eight hours. When pretreated with CsA, no death occurred, and the serum ALT level also declined significantly as compared with that of ConA group 730 ± 266 *vs* 22 261± 2 523 nkat·L^{-1}, P<0.01. The experimental results showed that CsA had potential protective effect on the ConA-induced liver injury in Kunming mice.

TNF-α has been proven to be the key cytokine in the destruction of hepatocyte in human liver diseases or liver injury animal model, such as acute and chronic viral hepatitis, especially in fulminant liver failure[26-41]. Anti-TNF antibody resulted in complete protection of ConA-induced liver injury in Balb/C mice[13]. We found that TNF-α increased significantly within eight hours when treated with ConA, but when pretreated with CsA before ConA administration, serum TNF-α became undetectable, hence the reduction of TNF-α might be due to the partial protective effects of CsA. Besides destruction of hepatocytes seen in the liver specimen of ConA group, lots of infiltrating lymphocytes in the portal area were also observed (Figure 1). When pretreated with CsA (CsA group), there was absence of lymphocytes infiltration in the portal area (Figure 2). The histological results gave a direct evidence that the protective effect of CsA in ConA-induced Kunming mice liver injury is through abrogating the activation of the T lymphocytes. The decline of serum TNF-α in CsA group may be a subsequent to T lymphocyte inactivation. $CD4^+$ lymphocyte was identified as the effector cells in the ConA-induced liver injury[3], however, in view of the fact that TNF-α synthesis is substantially higher in macrophages than in T lymphocytes, it seems likely that activated T lymphocytes might stimulate the macrophages to release TNF-α[15], but details of the concrete process worth further studies.

INTRODUCTION

The incidence of primary non-function (PNF) of grafted liver in the early postoperative stage is 2% - 23%[1-4], its main cause is the ischemic-reperfusive injury[5,6]. In this experiment, anisodamine was added into the preserving fluid and the grafted liver was rewarmed at different temperatures to protect the cell membrane and prevent ischemic-reperfusive injury.

METERIALS AND METHODS

Selection and grouping

Twenty male Wistar rats (270g - 330g in weight, 10 - 12 weeks in age) were used in the experiment. The rats were divided into 2 groups, 10 in each group, and the action of anisodamine was studied. In the experimental group, 40mg anisodamine was added into 1 liter of preserving fluid, no anisodamine was used in the control group. The rats were divided into 4 groups, 5 in each group, and the action of rewarming was studied. Before reperfusion, the 12℃, 20℃, 28℃ and 36℃ of gelofusine were injected into the portal vein respectively to rewarm the grafted liver.

Establishment of animal model[7-9]

Make a midline epigastric incision, dissociate the liver fully, incise the infrahepatic inferior vana cava (IVC), input a shaped three way stopcock, make its upper end 5mm higher than liver, ligate the both ends of IVC incision, and obstruct hepatic artery[10]. Cut off the portal vein, connect its distal end with one opening of the three-way stopcock, shunt the portal-cava vein provisionally, and reverse the blood of IVC and portal vein to the heart through the duct. Inject proximately 5 mL saline mixed with 1 mL heparin. Ligate the suprahepatic inferior vana cava provisionally, release the ligature above the IVC incision, wash the liver through portal vein, make the preserving fluid flow outside the duct. Wash the liver at low temperature for 4 hours within the body, maintain the pressure at 90 - 100 cm H_2O, and velocity at 8-12mL/min. The preserving fluid was the lactic Linger's fluid composed of 10mL dethomaxone, 100mg ATP and 100U/L insulin. After managing the experimental factors, take out the three-way stopcock, connect with the portal vein, release the occlusion of hepatic artery, repair the IVC incision, and restore the hepatic reperfusion[11].

Collection and test of samples

Liver tissue of 500mg was resected before the obstruction of blood and reperfusion, and 30min and 60min after reperfusion respectively. Superoxide dismutase (SOD)[12,13] and lipid peroxidase (LPO) were tested[14], and the morphologic changes were observed under microscopy and electric microscopy synchronically[15,16].

Statistical analysis

Data were presented as the mean ± SE. The *t* test was applied between two groups and variance analysis between multi-groups. $P<0.05$ values were regarded as significant.

RESULTS

Effect of anisodamine on the changes of oxygen-derived radicals (Table 1)

Table 1 Effect of anisodamine on change of oxygen-derived radicals

Groups	LPO(nmol/100mg)		SOD(nu/mg pr)	
	EG(10)	CG(10)	EG(10)	CG(10)
Pre-obstruction of blood	48.50±2.53	53.80±2.19	109.70±4.23	105.00±7.33
Pre-reperfusion	61.10±5.12	72.30±2.44	100.20±5.66	97.60±6.35
30' post-reperfusion	164.40±10.55	273.30±14.61[b]	72.50±5.60	55.10±6.47[b]
60' post-reperfusion	142.40±11.35[b]	242.40±11.92[b]	61.50±6.99[b]	43.10±6.61[b]

[a]$P<0.05$ *vs* the other groups; [b]$P<0.01$ *vs* the post-rewarming group.

Morphologic change of liver cells

Observation under microscopy No obvious changes in HE stain between the post-rewarming groups, the hepatic tissue swelled when rewarmed at 4℃ at 30min and 60min post-reperfusion. Light red granules could be seen in the cellular plasm, no obvious changes after the rewarming at 28℃ and 36℃. At 60min post-reperfusion, the effect was better in anisodamine group than in the other groups.

Observation under electric microscopy The chrodrosome of hepatic cells swelled slightly after rewarming and the structure was roughly normal. At 30min post-reperfusion, the chrodrosomes of hepatic cells swelled, being destroyed partially and impaired in structure and the endoplasmic reticulums dilated in the 4℃, 12℃ and 20℃ rewarming groups. The injury was more serious at 60min post-reperfusion. Accasionally, the chrodrosomes swelled slightly and the ridges decreased. At 60min post-reperfusion, the chrodrosomes of hepatic cells swelled, and were impaired obviously, and the endoplasmic reticulums dilated in the non-anisodamine group. The results of anisodamine group were better evidently than the other groups. The injury of hepatic cells was the most slight in the 36℃ rewarming group.

DISCUSSION

Oxygen-derived radical and malmicrocirculation were the main causes of postoperative primary nonfunction of grafted liver[15,17]. Resent studies found that anisodamine can stabilize cell membrane and resist oxygen-derived radical[18-21], thus protecting cells from injury. Up to now, there has been no report about application of anisodamine in liver transplantation. This study deals with the protective action of anisodamine during the low temperature preserving period. The results showed that anisodamine had no obvious influence on LPO and SOD during the low temperature preserving period, yet it may reduce the production of LPO and stop the decrease of SOD after reperfusion[22]. At the time of ischemia-reperfusion, the increase of intracellular Ca^{2+} activates Ca^{2+} dependent proteinase, which can change xanthine dehydrogenase into xanthine oxidase (XOD). Rich oxygen supply accompanying with reperfusion oxidates xanthine and hypoxanthine into uric acid under the action of XOD, meanwhile produces- lots of oxygen-derived radicals[23,24]. Anisodamine is the antagonist of Ca^{2+}, it may inhibit the change of xanthine dehydrogenase into xanthine oxidase, thereby the anti-oxygen-derived radical action of anisodamine may reduce the peroxide injury of lipid of cell membrane, and relieve the reperfusive injury of grafted liver[25].

The study found that the production of LPO and decrease of SOD occurred chiefly after reperfusion. With the increase of LPO, SOD decreased gradually, indicating that SOD may antagonize LPO[26]. Pathologic observation verified that the injury of hepatic cells became more serious with the lasting of reperfusion, indicating that peroxide action of lipid caused by oxygen-derived radicals mainly occurred after reperfusion. Oxygen-derived radicals may lead to peroxide reaction of lipid, and the lipid radicals cava cause further decrease of mobility and increase of the permeability of cell membrane, swelling of the chrodrosome, release of lysosome, and serious injury of tissues[27]. We reckoned that the oxygen-derived radicals after reperfusion may damage the grafted liver, which is a chief cause of post-operative primary non-function of grafted liver.

In 36℃ rewarming group, the level of LPO was obviously lower and the activity of SOD higher than that in other groups. There was no evident morphologic change under microscopy in the 28℃ and 36℃ rewarming groups, and the change under electric microscopy was slight. It indicated that rewarming to grafted liver preserved in the low temperature fluid reduced the production of oxygen-derived radicals, and relieved the injury of grafted liver. Low temperature may decrease the activity of ATPase and the function of K^+ Na^+ and Ca^{2+} pumps in cell membrane, impair the electrolytes[28,29]. Reperfusion may lead to anomaly of Ca^{2+} and production of oxygen-derived radicals. Rewarming may improve the activity of ATPase and restore the function of pumps, therefore decreasing the intracellular concentration of Ca^{2+} and inhibiting the production of oxygen-derived radicals[30], and protecting the cells of grafted liver[31]. This study showed that morphologic change of hepatic cells was slighter in the 28℃ and 36℃ rewarming groups than in other groups. There was no significant difference between the 28℃ and 36℃ groups. Less oxygen-derived radical was produced in the 36℃ group than in other groups. Therefore, we think that it is a favorable choice for liver transplantation to apply anisodamine during the low temperature preserving period and

rewarm the grafted liver before reperfusion at 36℃[32].

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the major causes of death in the world. The mechanism of carcinogenesis is unknown, although it is widely accepted that HBV and HCV are closely related to liver cancer[1-5]. Previously, a variety of studies have described the differences in gene expression which distinguished tumor from nontumor[6-11]. Cloning of the genes, especially the genes associated with HBV and HCV, is still very important to account for the development of liver cancer.

Traditionally, several methods were used to clone the new genes, which means to compare two population of mRNA and obtain clones of genes that expressed in one population but not in the other. Although these methods have been successful in some cases, they require many rounds of hybridization and are not well suited for the identification of rare messages. The suppression subtractive hybridization is a latest method employed in the gene cloning, which is a unique method based on selective amplification of differentially expressed sequences and overcomes technical limitation of traditional subtraction methods[12-14]. Hence, the purpose of our study is to find the differentially expressed genes in liver tumor and nontumor tissues induced by woodchuck hepatitis B virus using suppression subtractive hybridization.

MATERIALS AND METHODS

Patient samples

The tumor and nontumor tissues induced by woodchuck hepatitis B virus were obtained from Department of Pathology & Cell Biology, Thomas Jefferson University, Philadelphia, USA. The other HCC and surrounding nontumor liver tissues used for analysis were obtained from the patients who had undergone surgery for the removal of their tumors in Xijing Hospital. Fresh frozen blocks and -80℃ snap frozen paired liver and tumor samples from individual patients were collected, and were then made available for RNA extraction and *in situ* hybridization.

Total RNA and mRNA extraction

Total RNA and mRNA were extracted separately from tumor and nontumor tissues by using the Qiagen RNeasy Kit (Qiagen, Inc. Valencea, CA, USA) and the quality of extraction was determined by assaying 18S and 28S rRNA with agarose gel electrophoresis and ethidium bromide staining.

RT-PCR and adaptor ligation

The reverse transcriptase PCR was started with 2μg poly-(A) + RNA isolated from tumor and nontumor tissues. Two adaptors were ligated to the fraction of *Rsa* I digested cDNA generated by RT-PCR. The sequence of two adaptors is as follows:

Ad1: 5'-CTAATACGACTCAC-TATAGGGCTCGAGCGGCC-GCCCGGGCAGGT-3'
Ad2: 5'-TGTAGCGTGAAGACGACAGAAAGGGCGTGG-TGCGGAGGGCGGT-3'

cDNA subtraction and suppression PCR

The cDNA from tumor was referred to as tester, and the reference cDNA from nontumor as driver. The tester and driver cDNA were digested with *Rsa* I to obtain shorter, blunt-ended moleclules. The tester cDNA was then subdivided into two portions and each ligated with different cDNA adaptors. The driver cDNA had no adaptor. Two hybridizations were then performed. In the first hybridization, an excess of driver cDNA was added to each sample of tester for equalization and enrichment of differentially expressed gene. During the second hybridization, templates for PCR amplification were generated from differentially expressed sequence. The entire population of molecules was then subjected into PCR to amplify the desired differentially expressed genes. In the first PCR, only differentially expressed genes were amplified exponentially because of using suppression PCR. The second PCR was performed using nested primer which matched the sequence of adaptors to reduce the background and further enrich the differentially expressed genes.

Sequencing and GeneBank search of cloned genes

Following agarose gel electrophoresis, the unique fragments were eluted from the gels (using Qiagen gel extraction kit,

Qiagen, Inc. Valencea, CA, USA) and cloned into pT7Blue (R) T vector (Novagen, Medison, WI, USA). Positive clones were selected by blue-white phenotype. Recombinant DNAs were isolated from minipreps of individual clones, and digested by *Rsa* I to check insert size, and then both strands were individually analysed by sequence analysis in the DNA sequence facility at the Kimmel Cancer Institute of Thomas Jefferson University in USA. The sequences obtained were compared with those in GeneBank using the FASTA command in the GCG software package for homology to known genes.

In situ hybridization (ISH)

The gene fragments obtained from PCR select cDNA subtraction were used as probes for *in situ* hybridization (ISH). ISH was conducted to verify that the subtraction hybridization procedure yielded probes whose expression was different between tumor and normal tissues. ISH was carried out using the Oncor ISH and digoxigenenin/biotin detection kits according the instruction provided by the manufacturer (Oncor, Gaithersburg, MD, USA).

RESULTS

PCR selected cDNA subtraction, cloning, sequencing and GeneBank search

PCR select cDNA subtraction generated totally 14 differentially expressed genes in tumors as compared with nontumors. Among them, 8 cDNA fragments from both tumor and nontumors had considerable homology with known genes in GeneBank (Table 1). Five genes from tumor and one gene from normal liver tissues had no homology as compared to those in the GeneBank, which implied that these may be new genes. PCR select cDNA subtraction was also performed with HBV virus X gene transfected HepG2 cells and control HepG2 cells. Ten genes were differentially expressed in HepG2X compared with HepG2 cells(data not shown). Interestingly, three genes cloned from the tumor tissue of woodchuck mouse liver shared considerable homology with sequences independently found to be upregulated in HBV-X [+] cells, suggesting that the different expressions of HBxAg effector can be independently observed in the tumor and nontumor tissues induced by woodchuck hepatitis B virus.

Table 1 Differentially expressed genes in tumor and nontumor liver induced by woodchuck hepatitis B virus

Clone	GeneBank search	
	Match	% homology
Tumor[a]		
T8[b]	Human chromosome 1(UT751,L1637).	54% in 280bp overlap
T18	Unknown protein, uterine endometrium(x7723)	60% in 151bp overlap
T19	Ribosomal protein L35A(x03475)	88% in 91bp overlap
T22	Human T cell receptor beta chain(L166059)	61% in 97 bp overlap
T6	None	
T7[b]	None	
T11[b]	None	
T24	None	
T25	None	
Nontumor[a]		
N7	Human aminopeptidase N(x13276)	93% in 54 bp overlap
N10	Human IFN receptor gene (U10360)	79% in 271 bp overlap
N11	Human glutathione S-transferase(L02321)	75% in 248 bp overlap
N13	Beta-2 glycoprotein 1 from HepG2(S80305)	79% in 159bp overlap
N8	None	

[a]The clones represent fragments of genes whose expression is activated (T6,T7, T11, T18, T19, T22, T24, T25) or suppressed (N7, N8, N10, N11, N13) in HCC compared to nontumor cells.
[b]Probes whose sequences share considerable homology with sequences independently found to be upregulated in HbxAg[+] cells.

Validation and in vivo expression patterns of these genes

The cDNA fragments obtained from subtraction hybridization of tumor and nontumor tissue were then used as probes for *in situ* hybridization.In all cases, the probes from tumor showed transcripts that were preferentially expressed in tumor tissue compared with nontumor tissues. In contrast, the genes from nontumor tissue demonstrated strong hybridization in normal tissues, but little or no signal in tumor tissues.

DISCUSSION

Hepatocellular carcinoma is one of the major causes of the death in the world[15-20]. Although many researchers worked on HCC, the mechanism is still unclear[21-46]. It is widely accepted that HBV is closely associated with HCC, especially HBxAg. A common feature of HBV infection is the integration of HBV DNA, in whole or in part, into host chromatin[47-49]. The site of HBV integration is scattered throughout the host genome[50], making it unlikely that HBV brings about hepatocellular transformation by cis acting mechanisms in most cases. With regard to virus sequences, integration commonly occurs within a small region near the end of the virus genome[51], which is consistent with the hypothesis that transformation may be associated with the expression of one or more virus proteins from the integrated templates acting in trans. Integrated fragments of HBV DNA have been shown to make a truncated preS/S and or HBX polypeptides, both of which have trans-activting activities[52-56]. However only HBxAg transforms a mouse hepatocyte cell line in culture[57,58], and gives rise to liver tumors in at least one strain of transgenic mice[59-61]. Independent work has also shown that HBxAg stimulates the cell cycle, perhaps by the activation of a number of signal transduction pathways[62-66]. HBxAg is more consistently expressed than preS in the liver of infected patients. In addition, the findings that HBxAg binds to and inactivates the tumor suppressor p53 both *in vitro* and *in vivo*[67-69], and that it may bind to and alter the function of other transcriptional factors in the cells[70], implied that HBxAg

function is important to the pathogenesis of HCC. There is some evidence that HBxAg naturally trans activates the insulin-like growth factor-1 (IGF-1) receptor[71], and may also stimulate the production of IGF-11[72], both of which may help sustain the survival and/or growth of tumor cells.

Because lots of factors are involved in the development of HCC induced by HBV and the mechanism need to be further elucidated, the new genes, especially the functional genes directly related with tumor are still worth being found in the liver tissues infected by HBV. Using the newly created method, which is the suppression subtractive hybridization, we identified the difference in gene expression which distinguished tumor from nontumor induced by woodchuck hepatitis B virus. The use of these fragments as probes for *in situ* hybridization of tumor and nontumor tissues verified that the PCR-selected cDNA subtraction actually yielded differences in the gene expression that distinguished tumor from nontumor, and that its differential expression may be relevant to the pathogenesis of HCC. Because of hepatitis B virus is closely associated with the development of chronic liver diseases, such as hepatitis and cirrhosis, as well as with the development of HCC, it is not known whether these differences are associated with HBxAg associated trans-activation[73-77], its inhibition of protesome function[60], its ribo/deoxy APTase[78], or AMP kinase activation[79], and/or its ability to alter signal transduction pathways[80]. However, experiments are in progress to firmly address these issues.

The results of this study showed that the up-regulation of multiple genes in tumor had considerable homology with known products from GeneBank, suggesting that the function of these genes is likely to positively regulate cell growth, while several genes generated from normal tissues suggests that these genes may be the negative regulators for cell growth. In addition, five genes from tumor and one gene from normal liver tissues had no homology as compared with entries in GeneBank, which implied that these may be new genes, and that it is very important to clone the full-length genes of these cDNA fragments to do the functional analysis. This kind of experiments are already on the way.

ACKNOWLEDGEMENTS Prof. Bo Rong Pan in Oncology Center, Xijing Hospital has made great contributions to this article.

INTRODUCTION

The mechanism of hepatocellular carcinoma (HCC) is still unclear, although some genes have been found to play a role in the transformation of liver cells, and a variety of studies have described differences in gene expression which distinguished tumor from nontumor[1-6]. The new genes, especially the functional genes directly related with tumor are still worth being found.

The purpose of our study is to find the different genes between human liver tumor and normal tissues using suppression subtractive hybridization.

MATERIALS AND METHODS

Patients samples

HCC and surrounding nontumor liver tissues used for analysis were obtained from the patients who had undergone surgery for the removal of their tumors in Xijing Hospital. Fresh frozen blocks and -80℃ snap frozen paired liver and tumor samples from individual patients were collected, and were then made available for RNA extraction and *in situ* hybridization.

PCR selected cDNA subtraction, cloning, sequencing and identification of cloned gene fragments

The difference in gene expression between human tumor and nontumor tissues were evaluated by a commercially available subtraction hybridization approach (the PCR selected cDNA subtraction kit from Clontech, Palo Alto, CA, USA) according to the instruction provided by the manufacturer. Briefly, we got total RNA and mRNA from tumor and nontumor tissues using the Qiagen RNeasy Kit (Qiagen, Inc. Valencea, CA, USA), and then both mRNA (2 μg each) were converted into cDNA. We refer to the cDNA from tumor as tester, and the reference cDNA from nontumor as driver. The tester and driver cDNA were digested with *Rsa* I to obtain shorter, blunt-ended moleclule. The tester cDNA was then subdivided into two portions and each ligated with different cDNA adapters. The driver cDNA had no adaptor. Two hybridization was then performed. In the first hybridization, an excess of driver cDNA was added to each sample of tester for equalization and enrichment of differentially expressed gene. During the second hybridization, templates for PCR amplification were generated from differentially expressed sequence. The entire population of molecules was then subjected into PCR to amplify the desired differentially expressed genes. In the first PCR, only differentially expressed genes were amplified exponentially because of using suppression PCR. The second PCR was performed using nested primer to reduce any background and to further enrich differentially expressed genes. The cDNA fragments were directly inserted into a T/A cloning vector(Novagen, Medison, WI, USA), and homology analysis was undertaken within GeneBank. On the other hand, we used normal tissues as the tester and tumor as the driver to do PCR select cDNA hybridization. The procedure was as above.

In situ hybridization (ISH)

The gene fragments obtained from PCR select cDNA subtraction were used as probes for *in situ* hybridization (ISH). ISH was conducted to verify that the subtraction hybridization procedure yielded probes whose expression differed in tumor compared to normal tissue. ISH was carried out using the Oncor ISH and digoxigenenin/biotin detection kits according to the instruction provided by the manufacturer (Oncor, Gaithersburg, MD, USA).

RESULTS

PCR selected cDNA subtraction, cloning, sequencing and GeneBank search

PCR select cDNA subtraction generated totally 19 differentially expressed genes in tumors and nontumors. Among them, 14 cDNA fragments had considerable homology with known genes in GeneBank (Table 1). For example, T2 and T3 had homology with ribosomal protein and elongation factor EF-1α, suggesting that these genes may stimulate cell growth. N1 from normal tissues had homology with interferon gamma gene, suggesting that this gene may be a negative regulator for cell growth. Interestingly, one gene from tumor

and three genes from normal liver tissues had no homology as compared with those in GeneBank, which implied that these may be new genes.

Validation and in vivo expression patterns of these genes

The cDNA fragments obtained from subtraction hybridization of tumor and nontumor tissues were then used as probes for *in situ* hybridization. In all cases, the probes from tumor showed transcripts that were preferentially expressed in tumor tissues as compared with nontumors. In contrast, the genes from nontumor tissues demonstrated strong hybridization in normal tissues, but little or no signal in tumor tissues.

Table 1 Differentially expressed genes in human tumor and nontumor liver

Clone	GeneBank search	
	Match	% homology
Tumor		
T1	Retinoblastoma gene (L11910)	75% in 193 bp overlap
T2	Ribosomal protein L7(L16588)	87% in 209 bp overlap
T3	Elongation factor EF-1α (J04617)	85 % in 157 bp overlap
T4	2-oxoglutarate dehydrogenase (D10525)	89% in 258 bp overlap
T5	Proteasome activator HPA28 subunit β (D45348)	93% in 204 bp overlap
T6	Ribosomal protein S2 (X57432)	89% in 195bp overlap
T7	Rab geramylgeranyl transferase-α Subunit(Y08200)	90% in 110 bp overlap
T8	Nuclear-encoded mitochondrial NADH-ubiquitinone reductase	93% in 197 bp overlap
T9	None	
Nontumor		
N1	Interferon gamma gene (L07633)	88% in 308bp overlap
N2	None	
N3	V-fos transformation effector protein	92% in 200bp overlap
N4	Sigma-1 receptor (266537)	75% in 123bp overlap
N5	Glycoprotein gll gene (D00464)- 3'flanking region	62% in 549bp overlap
N6	None	
N7	RABAPTIN-5 protein(X91141)	86% in 110bp overlap
N8	Dishevelled-3 (DUL3) protein	89% in 72bp overlap
N9	None	
N10	None	

DISCUSSION

Hepatocellular carcinoma is one of the major causes of death in the world[7-10]. The mechanism of carcinogenesis is unknown, although it is widely accepted that hepatitis B virus (HBV) and hepatitis C virus (HCV) are closely related to liver cancer, especially hepatitis B virus X antigen[11-14]. A common feature of HBV infection is the integration of HBV DNA, in whole or in part, into host chromatin[15-17]. The sites of HBV integration are scattered throughout the host genome[18], making it unlikely that HBV brings about hepatocellular transformation by cis-acting mechanisms in most cases. With regard to virus sequences, integration commonly occurs within a small region near the end of the virus genome[19], which is consistent with the hypothesis that transformation may be associated with the expression of one or more virus proteins from the integrated templates acting in *trans*. Integrated fragments of HBV DNA have been shown to make a truncated preS/S and or HBX polypeptides, both of which have trans-activting activities[20-24]. However, only HBxAg transforms a mouse hepatocyte cell line in culture[25,26], and gives rise to liver tumors in at least one strain of transgenic mice[27-29]. Independent work has also shown that HBxAg stimulates the cell cycle, perhaps by the activation of a number of signal transduction pathways[30-34]. The expression of HBxAg is more consistent than that of preS in the liver of infected patients. In addition, the findings that HBxAg binds to and inactivates the tumor suppressor p53 both *in vitro* and *in vivo*[35-37], and that it may bind to and alter the function of other transcriptional factors in the cells[38], implied that HBxAg function is important to the pathogenesis of HCC. There is some evidence that HBxAg naturally trans-activates the insulin-like growth factor-1 (IGF-1) receptor[39], and may also stimulate the production of IGF-11[40], both of which may help sustain the survival and/or growth of tumor cells.

Because the mechanism of HCC induced by HBV still need to be elucidated, cloning of the genes, especially the genes associated with HBV and HCV, is still very important to account for the development of liver cancer. By the newly created method, which is the suppression subtractive hybridization, we identified the difference in gene expression which distinguished tumor from nontumor. The use of these fragments as probes for *in situ* hybridization of tumor and nontumor tissues verified that the PCR-selected cDNA subtraction actually yielded differences in the gene expression that distinguished tumor from nontumor, and that its differential expression may be relevant to the pathogenesis of HCC. It is not known whether these differences are associated with HBxAg associated trans-activation[41,42], its inhibition of protesome function[43] its ribo/deoxy APTase[44], or AMP kinase activation[45], and/or its ability to alter signal transduction pathways[46], because hepatitis B virus is closely associated with the development of chronic liver diseases, such as hepatitis and cirrhosis, as well as with the development of hepatocellular carcinoma (HCC)[47-60]. However, experiments are in progress to firmly address these issues.

The results of this study showed that the up-regulation of multiple genes in tumor which have considerable homology with known products from GeneBank, for example, ribasomal protein and elongation factor EF-12, suggesting that the

function of these genes is likely to positively regulate cell growth. Several genes are generated from normal tissues and one has >88% homology with interferon gamma gene, suggesting that these genes may be the negative regulators for cell growth. In addition, one gene from tumor and three genes from normal liver tissues had no homology, as compared with entries in GeneBank, which implied that these may be new genes, and that it is very important to clone the full-length genes of these cDNA fragments to do the functional analysis. This kind of experiments are already on the way.

ACKNOWLEDGEMENTS Prof. Bo Rong Pan in Oncology Center, Xijing Hospital has made great contribution to this article.

Abstract

AIM **To identify hepatitis C virus(HCV) core protein epitopes recognized by HLA-A2 restricted cytotoxic T lymphocyte (CTL).**

METHODS **Utilizing the method of computer prediction followed by a 4h ^{51}Cr release assay confirmation.**

RESULTS **The results showed that peripheral blood mononuclear cells (PBMC) obtained from two HLA-A2 positive donors who were infected with HCV could lyse autologous target cells labeled with peptide "ALAHGVRAL (core 150-158)". The rates of specific lysis of the cells from the two donors were 37.5% and 15.8%, respectively. Blocking of the CTL response with anti-CD4 mAb caused no significant decrease of the specific lysis. But blocking of CTL response with anti-CD8 mAb could abolish the lysis.**

CONCLUSION **The peptide (core 150-158) is the candidate epitope recognized by HLA- A2 restricted CTL.**

INTRODUCTION

Hepatitis C virus (HCV) is a single-stranded RNA virus responsible for the majority non-A non-B hepatitis[1,2]. More than 50% - 60% of acute infection lead to chronic disease, and once chronicity is established, spontaneous recovery is exceptional. The related mechanism is still unknown[3-5]. Recent studies demonstrate that major histocompatibility complex (MHC) class I-restricted cytotoxic T lymphocytes (CTL) of patients with chronic hepatitis C recognize epitopes from different regions of both structural and nonstructural HCV proteins[6-12]. Some scholars speculate that CTL-mediated cellular immune response probably plays an important role in viral clearance[13,14].

$CD8^+$ CTL interact through their polymorphic T cell receptor with HLA class I molecules containing endogenously synthesized peptides of 9-11 on the surface of infected cells. The presence of allele-specific amino acid motifs has been demonstrated by sequencing of peptides eluted from MHC molecules. Among the best studied motifs is that of HLA-A2, which is prevalent in a high percentage of population. Several reports[7,8,15-20] described the method of using HCV derived synthetic peptides containing the HLA-A2.1 binding motif to identify and characterize the HLA-A2 restricted CTL in the peripheral blood of patients with chronic HCV infection. We[21] have designed a computer programme to score the reported HCV peptides. Our results revealed that all the reported peptides were with a relative high score of 144 points or higher. Based on the previous study, we attempted to identify the epitopes recognized by the HLA-A2 restricted CTL on HCV core protein utilizing the method of computer prediction followed by 4h ^{51}Cr release assay.

MATERIALS AND METHODS

Materials

Subjects Six patients with chronic hepatitis C and 2 healthy controls were selected from among those monitored at Xijing blood center. Table 1 summarizes patient characteristics and history of treatment. All subjects had not received any antiviral treatment for at least one year.

Table 1 HLA-A and serology of patients studied for CTL response to HCV epitopes

Subjects	HLA-A	Anti-HCV	HCV-RNA
Experiment

Note: All subjects received no treatment and had been followed-up for one year.

HLA typing HLA typing of PBMC from patients and from normal donors was determined by microcytotoxicity, using trays (One lamda, Canoga Park, CA). The HLA haplotypes of subjects participating in this study are shown in Table 1.

Merthods

Prediction of candidate HLA-A2 restricted CTL epitopes Based on previous study, we use our computer programme to predict HLA-A2 restricted CTL on HCV C protein. In brief, a

computer programme with the function of finding peptides containing HLA-A2 allele-specific peptide motif was written in C language. The HCV cDNA is translated into HCV amino acid sequence from which the peptides was chosen, and the selected peptides include those with a length of 9-11 amino acids, a leucine (L), isoleucine (I) or methionine (M) at position 2 and a leucine (L) or Valine (V) at the last position. According to Nijiman's score system, we scored six points for an anchor residue, four points for a strong and two points for a weak residue. The score for a given peptide is obtained by multiplication of the scores for each amino acid position. Predicted candidate CTL epitopes with scores of 144 or higher.

Synthetic peptides Peptides YLLPRRGPRL (core35-44), NLGKVIDTL (core 118 - 126), DLMGYIPLV (core 132 - 140) and ALAHGVRAL (core 150 - 158) were selected from the predicted results and synthesized in automated multiple peptide synthesizer (American Research Genetics, Inc). All peptides were >90% pure and diluted to $1g \cdot L^{-1}$ with RPMI1640 medium before use (Gibco, Grand Ialand, N.Y.).

CTL generation PBMC from donors were separated on Ficoll-Hypaque density gradients (Shanghai Huajing, Inc), washed three times in phosphate-buffered saline (PBS), resuspended in RPMI1640 medium (Gibco, BRL.) supplemented with L-glutamine ($10g \cdot L^{-1}$), penicillin ($5 \times 10^4 U \cdot L^{-1}$), streptomycin ($50mg \cdot L^{-1}$) and Hepes ($5mol \cdot L^{-1}$) containing $100mL \cdot L^{-1}$ fetal calf serum (FCS) and plated in 24-well plates at 4×10^6 cells per well. PBMC were stimulated with concanavalin A (ConA, 20μg per well) during the first week. On d3, 1mL of complete medium supplemented with rIL-2 at 2×10^3 $U \cdot L^{-1}$ final concentration was added into each well. On d7, the cultures were restimulated with the peptides plus rIL-2 and irradiated (30Gy) autologous PBMC feeder cells, and the cultured PBMC were restimulated five days later with the original peptides plus rIL-2. On d16, the stimulated cells were used as effectors in CTL assay.

Preparation of autoguous B lymphoblastoid cell line After Ficoll-Hypaque separation, PBMC were suspended in the RPMI1640 medium containing $200 mL \cdot L^{-1}$ FCS and then plated in 24-well culture plate at a concentration of 2×10^6 cells per well. EBV-transfected B cell lines were established by culturing 2×10^6 PBMC with $100g \cdot L^{-1}$ of cyclosporin A and 1 mL B95-8 EBV culture supernatant (provided by Dr. Jin, the Fourth Military Medical University, Xi'an). After transformation, the lymphoblastoid cell lines (B-LCL) were maintained in RPMI1640 medium with $200 mL \cdot L^{-1}$ FCS, with media change twice each week. The cell lines were maintained at 37℃ in a humidified chamber with $50 mL \cdot L^{-1}$ CO_2 and used as targets.

CTL assay Target cells were incubated overnight with synthetic peptides at $200 mg \cdot L^{-1}$, and then were labeled with 3.7MBq 1-Cr for 1h and washed three times with PBS. Cytotoxity activity was determined in a standard 4h Cr release assay using U -bottom 96 welL plates containing 5000 autogenous targets per well. All assays were performed in triplicate with effector target cell (E/T) ratios of 100:1, 50: 1, and 1:1. Maximum release was determined on the basis of lysis of labeled target cells with $50g \cdot L^{-1}$ Triton X-100. We examined spontaneous release by incubating target cells in the absence of effector cells. It was less than 25% of the maximum release. Percent cytotoixity was determined by the formula: 100×[(experiment release-spontaneous release)/ (maximum release-spontaneous release)].

Blocking of CTL response by antibodies CTL responses were tested in the presence of anti-CD8 or anti-CD4 monoclonal antibody added to the 96-well plates at the indicated concentrations used for the CTL assay.

RESULTS

Prediction of HLA-A2 restricted CTL epitopes on HCV protein

Seven high-scoring peptides (≥144 points) were selected from HCV C protein using our computer programme. Among them, peptide ① and peptide ④, namely peptide YLLPRRGPRL and peptide DLMGYIPLV, have been reported to be epitopes recognized by HLA-A2.1 restricted CTL. Predicted peptide ⑦, namely FLLALLSCL (core 177-185) was almost the same as the reported peptide LLALLSCLTV (core 178-187). The rest predicted peptides have not been proved to be epitopes recognized by HLA-A2 restricted CTL. Four peptides (peptide ①,②,④,⑤), were selected randomly from the seven predicted peptides to be used in CTL assay (Table 2).

Table 2 Predicted results of epitopes recognized by HLA-A2 restricted CTL on HCV C protein

No	Peptide sequence	Peptide site	Score
①	YLLPRRGPRL	35-44	144
②	NLGKVIDTL	118-126	576
③	TLTCGFADL	125-133	144
④	DLMGYIPLV	132-140	576
⑤	ALAHGVRAL	150-158	576
⑥	NLPGCSFSIFL	168-176	288
⑦	FLLALLSCL	177-185	144

A: Reported epitopes recognized by HLA-A2.1 restricted CTL; B: Almost consistent with the reported epitope LLALLSCLTV (core 178 -187)

Screen of HCV peptide-specific response

In this experiment PBMC from 8 subjects were stimulated individually with the four peptides from HCV C protein, and cultures were tested after 16d of expansion for peptide-specific CTL activity. Two of the four donors of HLA-A2 and HCV RNA positive responded to peptide ⑤. After induced by peptide ⑤, the two donors' PBMC can lyse autologous target cells pulsed with peptide ⑤ and the specific lysis was 37.5% and 15.8%, respectively (Table 3). Treatment of the CTL specific for peptide ⑤ with anti-CD8 mAb, but not anti-CD4 mAb, plue complement markedly reduced cytotoxic activity on target cells (Figure 1).

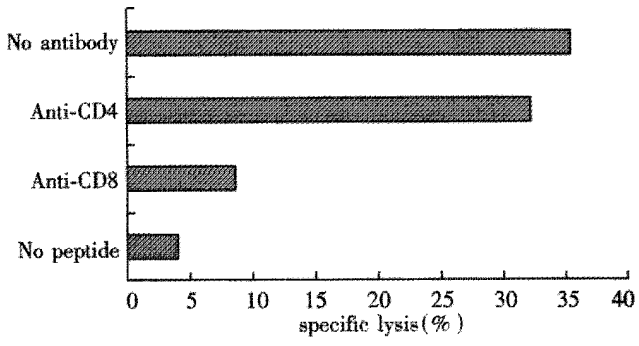

Figure 1 Blocking of CTL activity of Mr.Tang with mAb.

CTL activity induced by peptides at E/T ratio of 50:1; NT: No test; ①, ②, ④ and ⑤ represent YLLPRRGPRL (core35 - 44), NLGKVIDTL (core118-126), DLMGYIPLV (core132-140) and ALAHGVRAL (core150-158), respectively.

DISCUSSION

CTL mediated cellular immune response probably plays an important role in anti HCV infection. Many researchers reported[22-30] that CTL specific for HCV were discovered in PBMC and liver infiltrated lymphocytes of patients infected with HCV, and that the epitopes recognized by CTL were identified. Owing to the fact that HLA-A2 exhibits a high gene frequency in populations, Cerny *et al*[7] focused their study on the epitopes recognized by HLA-A3 restricted CTL and have determined several epitopes on every protein region recognized by CTL. However, because of the great work and high cost, it is quite difficult to manipulate in general laboratory. In this study, we attempted to identify the HCV peptides containing HLA-A2 binding motifs, and to confirm the prediction via 4h ^{51}Cr release assay.

Prediction of candidate epitopes recognized by HLA-A2 restricted CTL

According to the reference[31-32], determining epitopes recognized by CTL included two steps: synthesis of many peptides with multi-peptide overlapping method, and identification of the peptides with experimental means. Up till now, peptides YLLPRRGPRLL (core35 - 44), DLMGYIPLV (core132 - 140), and LLALLSCLTV (core178 -187) were determined by using this method. The method is direct and reliable, but difficult to manipulate. We analyzed HCV core protein using computer programme. The results demonstrated that there were only 7 peptides with scores of 144 or higher. Of those[21], two peptides, YLLPRRGPRL (core35 - 44), DLMGYIPLV (core132 - 140) were ever reported in other studies, which could be recognized by HLA-A2 restricted CTL. Another peptide, FLLALLSCL (core177 -185) was in agreement with the reported peptide LLALLSCLTV (core178 - 187). Purposeful study of the 7 peptides would simplify experimental processes and save cost. Of those, 4 peptides (Nos ①,②,④,⑤), were synthesized and applied in CTL assay.

Activation of CTL in peripheral blood of donors by synthsized peptides

Four synthesized peptides of the HCV core protein were tested using CTL assay. Four donors were positive for HLA-A2. Among donors positive for HCV RNA, 2 donors' PBMC were found to have lysed autologous target cell-labeled with peptide ⑤. The specific lysis rate was 37.5% and 15.8% respectively. The other 3 peptides didn't show obvious CTL induction action. CTL response was very weak in two healthy and HLA-A2 positive donors, and also in two HCV RNA+ HLA-A2- donors.

According to the reference[33], the lysis might be considered specific with the lysis rate $\geqslant$15%. The specific lysis rate was up to 37.5% in Tang with effector / target cell (E/T) ratio of 50:1, and 15.8% in Zhang with E/T ratio of 100:1. Blocking of the CTL response with anti-CD4 mAb did not decrease the specific lysis significantly. But blocking of the CTL response with anti-CD8 mAb could abolish the lysis. It indicated that[34-40] the lysis was mediated by CD8$^+$ T cells rather than CD4$^+$ T cells, and that the epitope ⑤ was probably the candidate epitope recognized by HLA-A2 restricted CTL.

Although 3 peptides, including 2 reported in other studies, YLLPRRGPRL (core35 - 44), DLMGYIPLV (core132-140), didn't demonstrate obvious CTL induced activity, we could not draw a conclusion that they were not HLA-A2 restricted CTL recognized epitopes. The two reported epitopes were recognized by HLA-A2.1 restricted CTL, but in this study, we did not determine the HLA-A2 subtypes. Various subtypes of HLA-A2 restricted CTL probably recognized different epitopes[41-50]. Another pssible reason is that HCV protein sequence of HCV-infected patients might not be in complete accordance with the synthesized peptides. To clarify the reasons, further study is still necessary.

Abstract

AIM **To study the palliative treatment of malignant obstrution of digestive tract with placement of intraluminal stent combined with intra-arterial infusion of chemotherapeutic drugs.**

METHODS **A total of** 281 **cases of digestive tract malignant obstruction were given per oral** (**esophagus, stomach, duodenum and jejunum**), **per anal** (**colon and rectum**) **and percutaneous transhepatic** (**biliary**) **installation of metallic stent. Among them,** 203 **cases received drug infusion by cannulation of tumor supplying artery with Seldinger's technique.**

RESULTS **Altogether** 350 **stents were installed in** 281 **cases, obstructive symptoms were relieved or ameliorated after installation. Occurrence of restenotic obstruction was** 8-43 **weeks among those with intra-arterial drug infusion, which was later than** 4-26 **weeks in the group with only stent installation. The average survival time of the former group was** 43 (3-105) **weeks, which was significantly longer than** 13 (3-24) **weeks of the latter group.**

CONCLUSION **Intraluminal placement of stent combined with intra-arterial infusion chemotherapy is one of the effective palliative therapies for malignant obstruction of the digestive tract with symptomatic as well as etiological treatment.**

Subject headings digestive tract disease; treatment; stent; therapeutic embolization chemotherapy; infusion, local

Mao AW, Gao ZD, Xu JY, Yang RJ, Xiao XS, Jiang TH, Jiang WJ. Treatment of malignant digestive tract obstruction by combined intraluminal stent installation and intraarterial drug infusion. *World J Gastroenterol*, 2001;7(4):587-592

INTRODUCTION

Intraluminal installation of stent in digestive tract is being more and more widely used[1-31]. Drug infusion via supplying artery and embolization therapy have been used in clinical practice as an effective way of suppressing the growth of malignant tumors[32-43] But up to now there have been few reports of the combined use of the two in the treatment of malignant stenotic lesions[44,45]. We have used the combined therapy in cases of malignant stenosis of digestive tract and have obtained good results in relieving symptoms, improving quality of life and prolongation of survival time. We managed 281 cases from October 1996 to May 2000 and the therapeutic results are reported below.

MATERIAL AND METHODS

Patients

A total of 281 patients with malignant obstruction of digestive tract were treated. Among them, 182 were males and 99 females, age ranged from 20 to 93 years, with an average of 65 years. The cause of obstruction was stenosis or obstruction of the digestive tract by infiltration or pressure of the malignant tumor. All cases belonged to late stages of tumor, impossible for surgical resection. One hundred and seventy-seven cases had operative histories of primary tumor resection, with reconstruction of digestive tract, biliary endostomy, bypass drainage or laparatomy, etc, 6 had histories of four operations, 83 cases of one operation . The primary disease included carcinoma of esophagus, 79 cases; stomach cancer 55 cases; carcinoma of liver, 25 cases; carcinoma of pancreas, 53 cases; colorectal cancer, 39 cases; cholangiocarcinoma, 10 cases; and other carcinomas, 20 cases. Pathological types: adenocarcinoma, 96 cases; squamous cell carcinoma, 74 cases; and others, 111 cases. Among the 281 cases, site of stenosis and obstruction at esophagus, 119 cases; at stomach (including gastrointestinal stoma), duodenum and jejunum, 76 cases; colorectal segment, 28 cases; and biliary tract, 58 cases. Some cases had more than two sites of stenosis or obstruction. They were divided in to groups A and B by patient or close relative's choice. Group A (203 cases) received treatment by installation of intraluminal stent combined with intra-arterial cannulation for drug infusion via supplying artery. Group B (78 cases) received only installation of intraluminal stent and again according to their choice supplemented with intravenous chemotherapy, radiotherapy or traditional Chinese medicinal treatment. Those with impaired liver and /or kidney function due to the cancer, or very poor general condition not suitable for intravenous chemotherapy and radiotherapy were advised to join group A. In group A, there were 132 males and 71 females, aged 20 - 93 years, averaging 61 years. Of them, 82 cases could not meet the requirements of routine radiotherapy and chemotherapy such as blood routine, liver and kidney

function or abnormalities of some other tests. In group B, there were 50 males and 28 females, age ranged from 28 - 87 years, averaging 58 years. Fourteen cases could not meet the requirements of routine radiotherapy and chemotherapy. Karnofsky quality of life evaluation in group A was 10-80 (average 36.2) score and 20 - 80 (average 40.2) score in group B.

Metallic intraluminal stent

Woven type nickel-titanium alloy stent was mainly used. The tubular meshwork, the whole some structure somewhat like wallstent was woven by single fine threads of nickel-titanium alloy of 0.20mm-0.32mm in diameter. Membranous stent was coated with polyurethane or silica gel on the mesh of the stent main body. For biliary tract, straight-neted duct stent was used without trumpet ends. The diameter of the tube is 0.8cm - 1.6cm, and the length 6cm - 10cm. The stent used for esophagus, stomach, duodenum and jejunum is of the type with trumpet opening on one end or both ends. The proximal end is basin-trumpet in shape, and the distal end cup or mushroom in shape. The tubular diameter of the stent main body is 1.1 cm - 1.5 cm at cervical segment, 1.8 cm - 2.8 cm at thoracic and abdominal segment of the esophagus. At stomach body, it is 2.0cm-2.5cm, and at duodenum and jejunum 1.8 cm - 2.0 cm; the length of the stent is 3.5 cm - 14cm. The stent for the use of colon and rectum has both ends of ball or mushroom shape trumpet opening. The tubular diameter of the stent main body is 2.0cm - 2.2cm at transverse colon, 2.5cm - 2.8cm at descending colon, and 2.5cm - 3.2cm at sigmoid colon and rectum; the length of the stent is 8cm-14cm. The width of the trumpet opening of all stents is 0.4cm-0.7cm. Some stents are specially made for specific requirements. Other stents we have used are home made"Z" shape esophageal stent, Wallstent for biliary and esophageal use (Schineder) and Memotherm biliary stent (Agmidel).

Transporter and auxilliary instruments

Wallstent and Memotherm stents were provided with a disposable coaxial two duct type transporter. Home-made "Z" shape stent was fixed with a sheath tube type pusher. Home made biliary and esophageal stents for cervical segment were used together with a sheath tube type pusher of Cook Company. For other stents we used self-made posterior positioned coaxial three ducts type transporter. Other auxilliary instruments included 6F Corber transmitting catheter, 2600mm long Torumo Radifocus guide wire, 2600mm-3000mm long soft head super-hard guide wire, 1300mm long exchange catheter, bulb dilating catheter of 25mm in diameter and double-channel imaging catheter made from used bulb catheters. Gastroscope, colonoscope, microwave or diathermic apparatus were also available.

Treatment modalities

Installation of intraluminal stent. Stent was placed perorally to esophagus, stomach, duodenum and jejunum. Radiopaque guide wire was inserted via gastroscope or perorally. The pusher attached with the stent was introduced by the guide wire so that the stent could be slowly released after passing through the stenosed segment. For the installation of stent in duodenum and jejunum, super-hard guide wire was introduced via exchange catheter, and the stent was put by the pusher introduced by the hard guide wire. Biliary stent was installed by percutaneous puncture and insertion method. The puncture needle was inserted percutaneously and transhepatically into biliary tract. Radifocus guide wire was introduced through the puncture needle along the intrahepatic biliary tract into the common bile duct, and then through the stenosed segment deep into the small intestine. Through exchange soft head hard guide wire, sheath tube or coaxial two ducts type transporter put the stent into the stenosed segment. Colonic and rectal stent was inserted through anus. Radifocus guide wire was inserted through the stenosed segment by the catheter or via colonoscope. Exchange catheter was introduced and replaced the super-hard guide wire. The hard guide wire introduced the coaxial two ducts type transporter that releases the stent.

Intra-arterial drug infusion

Two to eight days before the installation of the stent or 0d-4d after it, chemotherapeutic infusion via cannulation of the supplying artery of the tumor was given. The Seldinger's technique was used. According to the primary lesion or the infiltration field of the metastatic site, the supplying artery of the tumor was chosen as the target artery. Generally, the main trunk of the supplying artery was chosen for cannulation or multiple target points were chosen for cannulation at one time. The target arteries chosen for cannulation are: external jugular artery, inferior thyroid artery, or subclavicular artery bronchial artery, esophageal propriae artery, intercostal artery, hepatic artery (or coeliac artery trunk), superior mesenteric artery, inferior mesenteric artery, internal iliac artery, etc. The perfusing drugs used with dosage calculated according to surface area of the body were epirubicin 25mg·m^2, carboplatin 200mg·m^2, 5-Fu 500mg·m^2 forming triad drug group for use. For patients with abnormal liver and /or kidney functions (all caused by the malignant factors), dosage will be decreased accordingly. For those patients having normal routine profiles with better general condition, VM26 50-100mg·m^2 was added. For those with impaired cardiac function, adriamycin was substituted by pirarubicin 300mg·m^2. For some suitable patients emulsified 40% lipiodol and chemotherapeutics were given for superselective emolization. Patients with arterial venous fistula were first given gelfoam strips to block the fistular tract and then drug infusion. The second treatment was administered three weeks afterwards, and the third treatment was given after another 3 -5 weeks. From then on, the interval could be prolonged to 1.5-5 months.

RESULTS

Installation of stent (Table 1)

A total of 350 stents were installed in 281cases. Among them 144 were esophageal stents (23 in cervical segment, 69 in thoracic segment and 52 in abdominal segment of esophagus). Ninety-eight stents were put in stomach duodenum and jejunum (21 in gastric body and pyloric region, 22 in gastrointestinal anastomotic oriface, 49 in descending and horizontal part of duodenum and 6 in proximal jejunum); 30 in colon and rectum (9 in transverse colon, 5 in descending and 16 in sigmoid colon and rectum). Seventy-eight were biliary stents. Among the 144 esophageal stents, 142 were home-made woven type tubular mesh stents (127 with attached membrane and 15 without membrane), one was home-made "Z" type stent with attached membrane. There

was one wallstent without membrane. Among 98 stents used in stomach, duodenum and jejunum, 97 were home made (35 with attached membrane, 62 without). One Wallstent without membrane was used. Thirty stents used in colon and rectom (20 with membrane and 10 without) and 71 of 78 biliary stents were all home made. There were 4 Wallstents and 3 Memotherm stents. Biliary stents were all without membrane. The distribution of stents installed in groups A and B are shown in Table 1.

Drug infusion (Table 2)

Group A (203 cases) had received cannulation of supplying artery with infusion of chemotherapeutics (a total of 708 times). The minimum was one time (9 cases) and maximum was 14 times (one case). The average time was 3.49. Table 2 shows different patients undergoing drug infusion. Among the nine cases receiving treatment only once, which was refused by their relatives in 5 cases, and discontinued due to deterioration of their general condition in 2 cases, and the remaining 2 cases died. Three out of the 203 cases had received lipiodol emulsion embolization for 7 times, 11 cases had gelfoam embolization for 18 times. Besides occational hematoma at the puncture site, few cases complained of pain at the site of drug infusion and embolization treatment and 37% of cases had reversible lowering of blood counts, and no other arterial interventional procedure related complication was noted.

Clinical symptomatic impro ement

Among 119 cases with installation of esophageal stent, 18 had stent in the cervical segment and they all could take low residue regular diet. In 101 cases with stent in the thoracicor abdominal segment, those with simple stenosis basically restored to normal meals. Among 13 patients with esophagotracheal or esophagothoracic fistula, 11 could take normal meals after complete obliteration of the fistular tract, one still had some irritating cough while eating. Another case was a patient who developed esophageal stenosis with esophagothoracic fistula after unilateral pneumonectomy. Four days after installation of stent and obliteration of the fistula, the patient developed obvious irritating cough during eating. Imaging demonstrated proximal orifice of the stent protruded into the thoracic cavity forming another fistular tract. Among 76 patients with stent in stomach, duodenum or jejunum, 71 restored to normal meals and 5 had the obstructive symptoms improved, but could only take liquid diet. Twenty-eight cases with stent in colon or rectum had immediate relief of intestinal obstructive symptoms after installation, one of them who had colonic pelvic fistula had no more exudative leakage from the fistula tract after the installation. A case of rectal vaginal fistula had much less fecal exudation from vagina after installation. In 58 cases with installation of stent into the biliary tract, jaundice was significantly decreased, 39 cases had serum bilirubin returned to normal within a week. Nineteen cases had serum bilirubin dropped below 70mmol/L. Clinical symptomatic improvement were similar between groups A and B shortly after treatment. Among 82 cases in group A whose conditions could not reach the requirements of laboratory profiles for routine radiotherapy or chemotherapy, 46 cases fulfilled the requirements after two drug infusions. Among 14 cases of group B, only 3 cases approached the requirements after 1-2 months. As the disease progressed, the number of patients whose original profiles were normal but became abnormal when the disease got worse, was significantly larger in group B than in group A. Comparison of Karnofsky life quality evaluation between the two groups at 4 - 6 week after installation of stent showed that the average score in group A increased from 36.2 to 53.2, while in group B, from 40.2 to 46.2. There was significant difference between the two groups.

Maintenance of efficacy and survival time

In group B, 23 restenotic obstructions occurred 4-26 weeks after treatment in 15 (23.1%) cases. In group A, 29 (14.3%) had 38 restenotic obstructions 8-43 weeks after treatment (Table 3). The survival time in group A was 3-105 weeks, averaging 43 weeks, while 3-24 weeks in group B averaging only 13 weeks. The survival time of group A was more significantly prolonged than group B (Table 4).

Table 1 Installation of stents

Site	Group A		Group B		Total	
	No.of cases	No.of stents	No.of cases	No.of stents	No.of cases	No.of stents

DISCUSSION

Significance and technical difficulties

Digestive tract is the necessary passage of alimentation digestion, absorption and excretion of waste metabolites. Obstruction of digestive tract interferes with food intake, bowel movement, or causes obstructive jaundice. All these seriously affect the quality of life of the patients and even accelerate death. In 1983, Frimberger first reported the use of metallic stent to treat esophageal stenosis[46]. Domschke in 1990 successfully used self-expansible woven mesh type metallic stent to treat a case of esophageal malignant obstruction[47]. Thus it was made possible the relief of obstruction of digestive tract by non-surgical procedures. Karnel *et al*[48], Goldrn *et al*[49], Keymling *et al*[50] and others had respectively tried to use metallic intraluminal stent in treating colonic, biliary and duodenal obstruction. Their success had laid the basis of the expanded use of digestive tract intraluminal stent. As intraluminal installation of stent in digestive tract is a non-surgical method with mini-invasive technique to render the stenosed digestive tract becoming patent again, thus providing a new approach in the palliative treatment of digestive tract malignant obstruction. Comparing with the conventional surgical operation, treatment by intraluminal installation of stent has the characteristics of mini-invasion, fast, effect, good clinical sutclins and repeatablity of the procedure. This avoids the damage caused by surgical operation. For those with no indication for operation or too weak to stand the operation, treatment with intraluminal installation of stent can provide palliation to the patients with symptomatic relief and improved quality of life.

Compared with vascular lumen and other non-vascular lumens, the various lumens at different parts of the digestive tract have special histologic structures and functional characteristics. For example, the cervical segment of esophagus has strong contractive force and is very sensitive to foreign body. Duodenum and jejunum are quite distant from mouth, their lumens are tortuous with frequent peristalsis. Colon has a haustral structure with a strong group contractile force. The peculiar tissue structure and functional characteristics make the procedure of installation of intraluminal stent somewhat difficult. So, up to now, the clinical use of installation of digestive tract intraluminal stent is still limitted to esophagus and biliary tract. We have chosen nickel-titanium alloy in the form of single fine threads woven longitudinally and transversely into a flexible mesh tabular stent according to the common feature of digestive tract structure and function. For the installation of stent in the high position cervical segment of esophagus, we made tolerance dilatation test and used small caliber so as to ameliorate foreign body or pain sensation, thus succeeding in putting the stent in the cervical segment of esophagus. We used high hardness, small friction and elongation coefficient, not easily restored once deformed material, polytetrafluroethylene, to make coaxial duct and put it in between the external and internal ducts made of polyethylene, which is soft, easily to be restored with big friction force. The coaxial duct type transporter was made in this way that can be introduced into tortuous intestinal tube to release the coaxial duct type transporter of the stent. We also used endoscope to help the insertion of the guide wire. Super-hard guide wire helps enlarge the turning angle of the colonic loops. All these measures solve the difficulty encounted in the remote release of the stent. This not only increased the success rate of installation of duodenal and proximal jejunal intraluminal stent orally[11], but also facilitated the installation of stent at high level transverse colon via anal route[17]. At the same time, we selected big caliber with high degree hardness double bulb shaped or mush room shaped trumpet orifice stent. This not only increased the expanding force but also increased the compliance of the connecting segment between the terminal opening of the sent and the normal intestinal tract. The therapeutic effect of colonic and rectal stent installation was thus elevated and its complication reduced.

Drug infusion via supplying artery of tumor

Intraluminal stent treatment can build up the basis for the patients for further treatment by the relief of digestive tract obstructive symptoms and improvement of life quality of late tumor cases. The advanced patients with tumor can rarely tolerate the toxic or side effect of traditional radio-and/or chemotherapy. In fact, the sensitivity toward traditional radio- and chemotherapy in absolute majority of patients with solid tumor of digestive tract is rather poor. As

chemotherapeutics have killing and injurious effect to most tumor cells, the difference of therapeutic effect is mainly determined by whether the drug in the target organ can reach effective antitumor blood drug concentration or not. The general effect of traditional chemotherapy makes it difficult to reach an effective blood drug concentration in the target organ of gastrointestinal tract at safe dosage. As a result, clinical efficacy is low, while toxic and side effects are severe. Interventional chemotherapy by drug infusion of supplying artery can make the blood drug concentration in the vascular network of the tumor area reach an effective antitumor level by relative safe dosage, thus decreasing toxic and side reactions and increasing therapeutic efficacy. Intraluminal installation of stent in combination with drug infusion of supplying artery can release obstruction, improve life quality and at the same time inhibit growth of the malignant tumor. In the present study, the average survival time of our group B patients was 13 weeks, close to that reported by Turegano-Fuentes *et al*[51], Cwikiel *et al*[52] and P Scott Mackie *et al*[53]. The average survival time was 44 weeks in group A, significantly longer than the former. The restenosis was also more significantly prolonged in group A than in group B. This showed that interventional chemotherapy by arterial cannulation can produce in certain extent inhibition of the malignant tumor growth by its therapeutic effect. In conclusion, intraluminal stent therapy in combination with intra-arterial cannulation of interventional chemotherapy can be considered as an effective therapy with regard to symptomatic and etiological treatment and should be used more widely in the near future.

INTRODUCTION

Gallstone is one of the common primary diseases of bile system. Chinese researchers have done comprehensive and thorough studies on it, but there are still some problems we have not solved. It is necessary to review the achievements we have made in this field recently, to summarize the experiences and find the tendency so as to provide a sound foundation for the researches in the new century. Due to the popularization of molecular biological research methods, a rapid development of modern imaging techniques and medical equipment, the basic and clinical studies of cholelithiasis have set foot on the fast lane. Studies on the cause of cholelithiasis formation and its prevention have covered areas from epidemio logical investigation at macroscopical level to molecular biological researches at microcosmic level. Clinical studies include prevention and treatment of cholelithiasis with traditional Chinese medicine, popularization of micro-injury surgery, treatment of complicated calculus of bile duct, and other aspects.

PRESENT SITUATION

Studies on pathogenesis of gallstone

Study on the cause of cholelithiasis formation is an important field of studies on gallstone over a long period of time in China, and it will hold a very import ant position in the future. Formation of gallstone is a complicated pathologic process, which involves many factors. Researches in this field consist of epidemi ological investigation, studies on components of gallstone, biliary elements which cause stone formation, anatomy and physiology of bile system, etc.

Han *et al*[1]found that formation of gallbladder stones is related to age, metabolic disturbance of fat and damage of gallbladder emptying function in a case-control study on 66 cases of asymptomatic gallbladder stones. To know the morbidity of gallbladder stone in the young is essential to the study of the pathogenecity and prevention of cholelithiasis. Shi *et al*[2] found a morbidity of gallstone of 0.94% in 522 young students by an epidemiological investigation, which is significantly lower than in adults. By ultrasound scanning study, we also found that the gallbladder volume of young female is smaller than that of male (P<0.01), and the rate of cystic contraction 1 hour after meal is also lower than in male. The result supports that the gallbladder contractility of female and fatty is weakened significantly, which is one of the key factors of accumulation of bile and inducement of gallstone. Kuang *et al*[3] studied the relation between asymptom HBV carrier and gallstone, and found that serum HBV-M positive detectable rate in patients with gallbladder stone is higher than normal control group. He thinks that infection of HBV could be an inducer of gallstone formation. Zhu *et al*[4] investigated the incidence of gallstone in 672 fatty liver patients diagnosed by B-ultrasonography and 14610 non-fatty-liver subjects simultaneously, and found that the incidence increases in fatty liver patients obviously because of metabolic disturbance.

Wu *et al*[5] used X-ray diffraction analysis to measure human gallbl adder bile stone. The results are as follows: particulate gallbladder bile stone is chiefly composed of crystalline material containing cholesterol; sandy bile stone is mainly made up of noncrystalline material containing bile pigment or porphobilinogen. They compared the results with those in the early 1980's and found that the proportional number presented a rise in cholesterol bile stone. They thought that the main reason is the increase of cholesterol intake, metabolic disturbance of cholesterol, and descending incidence of biliary ascariasis and bacterial infection. They also determined bilirubin level by spectrophotometry and determined cholesterol contents by TLc scanning in 31 cases of human biliary calculus, and found that 31 cases of gallstone were all mixed bilestones primarily containing pure cholesterol or cholesterol bilestones[6,7]. Shi *et al*[8,9] studied black bilestones by Fourier Transform Infrared Spectroscopy and found that known organic constituent and inorganic constituents of black stones were the same, but their contents are varied. They think that black stone contains quite a few of protein, and that might be the key constituent to form black stone.

The study on the relationship between metabolism of bile acid and formation of gallstone[10-12] is the subject causing great attention of scholars all the time. It had been shown that the ability of diffluence was determined by the ratio of choleserol, bile acid and lecithin. In the bile of patients who suffered from cholesterol calculus, bile salts, total bile acid pool, and contents of chenodeoxycholic acid decreased. At the same time, contents of cholyglycine rose while cholyltaurine reduced, and proportion of conjugated deoxy-cholanic acid increased. All above factors promote cholesterol crystal nucleation and gallstone formation. Uniform recognition about the mechanism of bile acid dissolving bilirubin has not been obtained, but most of scholars believe that reduced bile acid is one of the key factors in gallstone formation. These results provide a solid theoretical basis to study the cause of cholelithiasis formation, prevention of gallstone and litholytic therapy. However, because some mechanisms have not been pinpointed, the effects of clinical application are not satisfactory. Lu *et al*[13] found that fever had obvious influence on biliary elements in a study on guinea pigs. All the animals in fever group had significantly higher concentrations of total bile protein and bilirubin than that of the control groups, which is prone to gallstone formation.

Bacterial infection is very important in the forming of the gallstone. Recently, there are many research reports[14-17]

about the function in the for ming of the gallbladder stone. The content of aerobe, anaerobe, L-bacterium, and *Helicobacter pylori* of the gallbladder tissue, bile, gallstone and portal vein have been tested through the use of the immunohistochemistry and the proliferation of PCR-DNA. These results indicated that bacterial infection and the formation of gallbladder stone and the chronic inflammation of bile duct system are closely related. According to the bacterial enzymology, the formation of bilirubin gallstone is related to the content of exterior β-glucuronidas -G, which result from the proliferation of bile duct bacterial infection, the interior environment (the best pH is 7.0), and the content of inhibitor. But according to the research of Yang *et al*[18], the interior β-glucuronidas-G, as a kind of active enzyme in human body, is one of the related factors of bilirubin gallstone.

The research of the relation between the contracting function of gallbladder and incidence of gallstone is a very important content of the study on cause of gallstone formation. Ma *et al*[19] found that the gallbladder emptying rate is not normal in half of the gallstone patients through the observati on of 100 cases of gallbladder stone patients. He considers that the function of gallbladder is mainly affected by its thickness, the location of the gallstone and the shape of the gallstone. Zhao *et al*[20] also holds the vie w that gallbladder emptying rate in gallstone patients' is below the normal, and especially in the pregnant women it is lower than in the men of the same age. Xu *et al*[21] have done a research on the change of the contractive function of gallbladder after gastrectomy, and the result showed that and incidence of cholestasis, and gallstone rose because of cut of liver rami of nervus vagus, gastrointestinal reconstruction and decrease of secretion of cholecystokinin.

In recent years, many researchers have done experiments to explore the relation between the disease of gallbladder stone and human gene group with molecular biological technology, and that made the study enter into gene level. Jiang *et al*[22] used PCR-RFLP to analyse the relation between variety of *Xba* I in Apo B Gene and blood fat. The research shows that the X^+ allele of Apo B gene is associated with high serum cholesterol and it may be regarded as a high-risk gene of cholesterol gallstone formation. Shuai *et al*[23] explored the relation between the expression of CCK-A receptor of gallbladder and gallbladder hypomotility in patients with gallstone. He thought that the down-regulation of gene expression of CCK-A receptor plays an important role in gallbladder hypomotility in patients with gallstone.

The relation between the change of interior or exterior hormone level and the formation of gallstone attracts the attention of scholars. Through case-control study, Luo *et al*[24] concluded that the use of steroid contraceptives in gallbladder stone women patients aged 20-44 years and the absorpt ion quantity of heat are the main factors of the formation of gallbladder stone. Steroid contraceptives containing estrogen and progesterone, are the reflection of the effect of exterior hormone on gallstone formation. With the help of radioimmunology, Wang *et al*[25] have experimented on the alteration of ATCH, Cor and thyroxine of the gallbladder stone. The results showed that the formation of cholecystolithiasis was related to the increase of Cor, and the decrease of T3 in serum. They[26] also proved that the cholelithiasis patients have an obvious increase in level of tyrosine peptide and cholecystokinin in serum in another experiment. Han *et al*[1] found that the content of the insulin in gallstone patients was much higher than in non-gallstone patients, showing that the level of insulin was related with formation of gallstone.

Research on prevention and treatment of gallstones

Research on prevention and treatment of gallstones can be divided into combined treatment by traditional Chinese medicine and modern medicine, surgery, litholytic and lithotriptic therapy. An important part of non-surgical treatments of gallstones is litholytic and lithagogue one. Great achievements have been made in extrinsic experiments of dissolving gallstones with different solvents for different components of gallstones. However, the outcome of clinical applications is not satisfactory as far as cholesterol or bile pigmental stone, litholytic treatment by oral drug in particular is concerned. Another important cause of the limited clinical application is the toxic and side effects of the litholytic. Many scholars put much emphasis on studying extrinsic lithodialysis and direct perfusion of litholytic into the biliary tract[27-30]. The application of traditional Chinese medicine is given much attention in China. Litholytic and lithagogue treatment with Chinese herbs in clinical application is the most vigorous research field in gallstone research in China besides the researches on gallstone formation. The drugs selected can change the components of stone-forming bile, dissolve the gallstones formed, improve contractility of the gallb ladder, relax sphincter of the bile duct and exert anti-inflammatory and antibacterial functions. Several medical institutions of our country[31-37] have carried out basic and clinical experimental researches on their prepared patent Chinese drugs with litholytic and lithagogue functions. They proved that some formulae can relieve the depressed liver, normalize the function of the gallbladder, promote blood circulation to remove stagnancy, heat and dampness, and achieve purgation. Many clinicians[38-43] have made inductions of indications and specific methods for treating cholelithiasis with Chinese herbal drugs and combined traditional Chinese and modern medicine, making its application more rational and effective. Zhou *et al*[44] made extrinsic CT scan of cholelithiasis cases, compared the results with the chemical components of the stone, and proved that CT imaging and value can demonstrate the chemical type of gallstones. He suggested that 40HU, the critical value of judging cholesterol calculus can provide a valuable basis for non-surgical treatment, especially litholytic method.

With the popularization of laparoscopy, the age of micro-traumatic surgery has come and great changes have taken place in surgical operation and surgical ideology. Cholecystectomy has entered the stage of laparoscopy in developed countries. This tendency is becoming obvious in China. The surgical treatment of gallstones with clinical application of celioscope[45-53] consists of peritoneoscopic cholecystectomy, peritoneoscopic choledocholithotomy, endosco pic papillectomy, and application of choledochoscopy. Indications of laparoscopy for gallstone treatment are not limited to pure gallbladder stone now. Choledoc holith, acute cholecystitis, and acute pancreatitis are no longer the contraindications of laparoscopic cholecystectomy (LC). Among them, choledocholith could be treated by two methods at least. One is sphincterotomy of Oddi before LC, The other is laparoscopic choledochotomy. Sphincterotomy performed with endoscope is a simple therapy for calculus of common bile duct with a diameter smaller than 3 cm and strictur e of terminal common bile duct shorter than 3 cm. Undoubtedly, application of all kinds of choledochoscopy has improved the rate of pre- and intra-operative diagnoses of biliary diseases, reduced the rate of residual bile stone, and could help patients avoid a second operation. Therefore, their application is welcome by clinicians increasingly.

Much concern is being taken in research on surgical treatment of hepatic calculus[54-56]. As Huang pointed out, 'early-stage systemic lobectomy of liver or segmental hepatectomy' is drawing a highly

increasing attention in treating hepatic calculus, especially in early stage cases that are diagnosed by CT scanning. It is thought that the treatment procedure could achieve the aim of maximal clearance of lesions and reservation of functional liver tissues. Furthermore, most scholars[57] think that irritating of hepatic calcul us and secondary infection could result in mucosal ulcer of bile duct, or even metaplasia leading to the development of hepatic cholangiocarcinoma finally, although there are disputes about question. Therefore, the reports of present clinical studies make lobectomy of liver the key point in surgical treatment of hepatic calculus although removing obstruction, getting rid of calculus and making drainage are the principles that should be followed. Introperative choledochoscopy, intraoperative ultrasound, intraoperative fast pathological examination and other imaging and diagnostic metho ds are key measures in treating hepatic calculus.

Operations of biliary tract, especially cholecystectomy, have been widely perfor med in grass-root-level medical institutions, but many complications and seque lae have resulted from inappropriate handling of indications, inappropriate choice of operative methods, and malpractice during operation, even making another operation necessary. With aging of the population, more and more studies[12,49] have been conducted on prevention and treatment of gallstones of elderly people. As to the chemical cholecystotomy started in the 1980s, Sun Shuming[58] concluded that chemical excision is very safe after uhe experiment performed on pigs. The clinical study of lithotriptic therapy[53,59,60] shows that extracorporeal shock wave lithotomy or lithotomy through sinus tract of skin after operation is effective to cure gallstone. However, these techniques and their values still need further improvement.

COMMENT AND PROSPECTIVES

Researches on causes of gallstone have been carried out for a long time with many conclusions drawn about cholesterol lithiasis and bilirubin lithiasis. Take the former as an example, almost all the cases experience three courses: cholesterol saturating, unbalance between causing and anti-causing factors; and dynamic disfunction of bile duct. Experts have worked over all aspects of that and obtained valuable findings. New research trend in this field is to discover its molecular biological and genetic nature with sophisticated research approaches. And we can expect that research in this field will become a hotspot in the up coming years, with the deepening of human genome Project. According to the status in quo, many risk factors causing the formation of gallstone have already been discovered, but in our opinion, emphasis must be laid on nation-wide big sample clinical epidemiological surveys so as to find effective measures to prevent gallstone occurrence based on integrating the basic research with clinical practice.

There is a close relationship between the research on prevention of gallstone and litholytic therapy and study on the cause of cholelithiasis formation. An effective litholytic therapy using traditional Chinese medicine could be expected if we take good advantage of the dissolving measures used abroad. But more precise basic studies on this issue are needed in China. We anticipate that, just like what has happened to other traditional Chinese medicine, researches focusing on traditional medicine curing gallstone will shift from simple summarization of clinical cases to strict double-blind case-control study using monomer components purified from raw Chinese medicine through high-tech settings.

Surgical treatment still is a consequence in gallstone treatment. As far as gall stone is concerned, laparoscopic cholecystectomy will play a major role in the treatment of the disease for a relatively long time. At the same time, more reports on the issue will appear. Consequently, laparoscopy will be widely utilized in all branches of surgery. Basic and clinical researches on complications of this therapy, such as bile duct injury, will be further strengthened. As to the therapies for hepatic calculus, early-stage systemic lobectomy of liver or segmental hepatectomy will be commonly recognized, and the idea about curing the cases of this type will shift from treating the complications to radical surgical treatment. Furthermore, choledochoscopy, which belongs to micro-injury surgery, will play an more important role. Nevertheless, effect of lithotriptic therapy and chemical cholecystotomy in curing lithiasis should be further evaluated.

The present faults of some gallstone studies in China are the echo at low level and the lack of innovation. Therefore, revolutional progresses are difficult to achieve. The key to better the current situation in a short time is to put more stress on prevention and treatment of gallstone, especially on issues about the integration of theory and application of basic findings to clinical practice.

SUGGESTIONS

To summarize, through the application of molecular biological techniques, studies on causes of gallstone and their mechanism at molecular and genetic level should be enhanced. A good theoratic basis for prevention of gallstone could be anti cipated. In the research on prevention of gallstone and litholytic therapy, especially the application of traditional Chinese medicine, more emphasis should be laid on the basic researches of mechanism and strict double blind case-control studies. Micro-injury surgery should be especially stressed. At the same time, clinical case-control studies with vast specimens are expected to guide the gal lstone therapy. As it is known that improved health situation and changing the diet structure will make the incidence of cholesterol lithiasis in gallstone increase in the coming years, researches on this issue will be strengthened. In regard to prevention of hepatic bile duct stone, more importance should be attached to researches on indication and complications of early stage systemic lobectomy of liver or segmental hepatectomy and prevention of the recrudescence of gallstone after surgery.

Abstract

Metastatic human HCC model is needed for the studies on mechanism and intervention of metastatic recurrence. By using orthotopic implantation of histologically intact tissues of 30 surgical specimens, a patient-like metastatic model of human HCC in nude mice (LCI-D20) and a low metastatic model of human HCC in nude mice (LCI-D35) have been established. All mice with transplanted LCI-D20 tumors exhibited extremely high metastatic ability including spontaneous metastasis to liver, lungs, lymph nodes and peritoneal seeding. Remarkable difference was also found in expression of some of the invasiveness related genes and growth factors between the LCI-D20 and LCI-D35 tumors. PAI-1 increased gradually following tumor progression in LCI-D20 model, and correlated with tumor size and AFP level. Phasic expression of tissue intercellular adhesion molecule-1 in this model was also observed. Using corneal micropocket model, it was demonstrated that the vascular response induced by LCI-D20 tumor was stronger than that induced by LCI-D35 tumor. Similar report on metastatic human HCC model in nude mice and human HCC cell line with metastatic potential was rarely found in the literature. This LCI-D20 model has been widely used for the studies on intervention of metastasis, including anti-angiogenesis, antisense approach, metallopro teinase inhibitor, differentiation inducer, etc. It is concluded that the establishment of metastatic human HCC model in nude mice and human HCC cell line with metastatic potential will provide important models for the *in vivo* and *in vitro* study of HCC invasiveness, angiogenesis as well as intervention of HCC recurrence.

INTRODUCTION

Liver cancer is the 4th most common cause of death from cancer and the 3rd most common in men. The highest age-standardised mortality rate was in China (34.7/100000), which alone accounts for 53% of all liver cancer deaths worldwide[1]. Surgical resection has been accepted the best treatment forhepatocellular carcinoma (HCC), the most common type of primary liver cancer in China. However, recurrence and metastasis remain the major obstacles for further prolonging survival after resection. Even after curative resection of small HCC, the recurrent rate remained high[2,3]. Therefore, studies on metastasis and recurrence will be an important issue in the 21st century. To this end, metastatic human HCC mod el in nude mice and cell line with metastatic potential are needed for the studies on mechanism, angiogenesis and intervention of metastatic recurrence.

Brief review of literature

In 1963, the first human HCC cell line (BEL-16) was established by Chen[4]. At the authors' institution, the human HCC model in nude mice (LTNM) was established in 1982, but metastasis was not found in this model[5]. Human HCC nude mice model and human HCC cell line with metastatic potential were rarely reported in the literature.

Hepatocellular carcinoma cell line

In the recent three decades, a good number of human HCC cell lines have been established. Shen *et al*[6], after the establishment of the first human HCC cell line in 1963, reported a series of human HCC cell line (BEL-7402, BEL-7404, BEL-7405) in the ensuing years. In 1973, Alexander *et al*[7] established the famous human HCC cell line (PLC/PRF/5) which produces HBsAg. Dong[8] established the human HCC cell line (SMMC-7721) in 1977, which remains one of the human HCC cell line that currently used in China.

Many human HCC cell lines have been established for the studies on etiological factors of HCC, such as hepatitis B virus (HBV)[9-14], hepatitis C virus (HCV)[15], hemochromatosis[16] , thorotrast[17], for the study of alpha fetoprotein (AFP)[18,19], and for other studies[20-30]. Unfortunately, of the above human HCC cell lines, metastatic potential was rarely mentioned or demonstrated.For animal HCC cell lines, the establishment of such cell lines in rat[31], in woodchuck[32-34], and in chicken[35] have been reported.

Hepatocellular carcinoma cell line with metastatic potential

Human HCC cell line with metastatic potential was rarely reported in the literature. Besides Tian *et al*[36,37] at the authors' institution reported two paper in 1998 and 1999, only one paper has yet been reported. Seki *et al*[38] (1999) established a human hepatocellular carcinoma cells with metastasis to lymph nodes.

Again, very few papers have been reported concerning animal HCC with metastati c behavior. Ogawa *et al*[39] (2001) reported the establishment of rat HCC cell lines with differing metastatic potential in nude mice. Reichner *et al*[40] (1996) reported that interleukin-6 production by rat hepatocellular carcinoma cells is associated with metastatic potential.

Hepatocellular carcinoma model in animal

In 1976. Shimosato *et al*[41] reported the establishment of a series of human tumors in nude mice including HCC. The same group has used the human HCC nude mice model for the study of alpha fetoprotein in relation to tumor growth [42]. As had mentioned, at the authors' institution, a human HCC model in nude mice has been reported in 1982[5]. In 1995, Liu *et al*[43] established a nude mice xenograft model from human HCC. In 1996, Leveille-Webster *et al*[44] established an intrahepatic xenografts of human HCC in severe combined immunodeficiency mice for the study of multidrug resistance.

For animal HCC model, Qian *et al*[45] (1987) established a transplan table HCC model in 615-strain mice (H 615).

Hepatocellular carcinoma model in animal with metastatic behavior

In this paper, we need to focus to human HCC model in nude mice with metastati c behavior. In 1993, Aruga *et al*[46] reported the establishment and characterization of liver metastatic model of human hepatoma in nude mice, metastasis was mainly found in the liver of this subcutaneous tumor model. Sun *et al*[47,48] (1995 and 1996) at the authors' institution reported the first patient-like metastatic human HCC model in nude mice with 100% of spontaneous metastasis to lung, lymph node and liver. Peng *et al*[49] (1996) established a human HCC model in nude mice using orthotopic transplantation, and malignant behavior (invasion of abdominal cavity) was observed. Tao *et al*[50] (1998) established a human HCC nude mice model using SMMC-LTNM tumor transplanted into abdominal cavity and liver, the lung metastatic rate was 59%. Genda *et al*[51] (1999) reported the construction of metastatic models using orthotopic implantation of human HCC cell lines into the livers of SCID mice, two of the 5 cell lines injected showed vascular tumor thrombi and intrahepatic metastasis. Zheng *et al*[52] (2000) establ ished an orthotopic transplantation tumor model from the subcutaneous model of human HCC in nude mice, the spontaneous metastatic rate was 57.8%. Shi *et al*[53] (2001) established a human HCC model in nude mice with high metastatic rate in lymph node.

For animal HCC, Masui *et al*[54] (1997) reported a highly metastat ic HCC in male F344 rats induced by chemical carcinogens. Li *et al*[55] (1998) established a lymph node metastatic model of mouse HCC Hca-F cells in C3H/Hej mice.

A synopsis of related studies at Liver Cancer Institute of Fudan University

At the authors' institution, studies on recurrence and metastasis of HCC have been conducted since 1993[56-60]. Because either metastatic human HCC model in nude mice or human HCC cell line with metastatic potential was not availuable at that time, therefore, efforts have been made for the establishment of such model and cell line. At the authors' institution, the establishment of metastatic human HCC model in nude mice was reported in 1995 (in Chinese) and 1996 (in English)[47,48] and human HCC cell line with high metastatic potential was reported in 1998 (in Chinese) and 1999 (in English)[36,37]. These might probably be the first metastatic human HCC model in nude mice and cell line with metastatic potential. A Synopsis on the establishment and studies of these models at the Liver Cancer Institute of Fudan University is reported herein.

Establishment of metastatic human HCC in nude mice

In 1988, development of *in vivo* models for studies of brain metastasis has been reported in Fidler's group[61]. In early 1990s, "metastatic models constructed in nude mice by orthotopic transplantation of histologically inta ct patient specimens" has been used in Hoffman's group, and several such models including lung cancer, pancreatic cancer, ovarian cancer, etc have been reported[62-64]. However, patient-like human HCC model in nude mice with metastatic behavior was not found.

At the authors' institution, by using orthotopic implantation of histologically preserved metastatic tumor tissues of 30 surgical specimens, a highly metastatic model of human HCC in nude mice (LCI-D20) has been established. This model was obtained through *in vivo* clonal selection by repeated "lung foci to liver". All mice with transplanted LCI-D20 tumors in the liver exhibited 100% transplantability and metastatic ability as well as various manifestations of tumor behaviour in HCC patients. These included: local growth, regional invasion , spontaneous metastasis to liver, lungs, lymph nodes and peritoneal seeding. The high metastatic ability maintained up to 120 passages. Histological characte ristics of LCI-D20 tumor were similar to those of the original tumor. Karyotype analysis revealed heteroploid cells. Expression of AFP and HBxAg was shown using immunohistochemistry. The duration between two passages was around 20 d. At the same period, using orthotopic implantation of histologically preserved metastatic tumor tissues, a low metastatic model of human HCC in nude mice (LCI-D35) has also been established as a control. Invasion to the liver and peripheral organs was not found. Pathological findings revealed no metastasis in the liver, lung and lymph node. The duration between the two passages was around 35d. The biological characteristics of this LCI-D35 model remained unchanged up to 59 passages. Karyotype analysis revealed diploid cells[47,48].

Biological characteristics of LCI-D20 and LCI-D35 models

Remarkable difference was found between the LCI-D20 and LCI-D35 tumors: ① High expression of some of the invasiveness related genes, such as c-*fos*, c-*jun*, N-ras, H-ras and P53 mutation was found in LCI-D20 tumor but not in LCI-D35 tumor[65]. ② Using comparative genomic hybridization (CGH) technique, we have demonstrated that chromosome 8p deletion was associated with HCC metastasis[66]. When comparison was made between LCI-D20 and LCI-D35 using CGH, it was shown that 8p deletion remains one of the important alterations[67]. ③ Corneal micropocket model has been employed to investigate angiogensis, it was found that the vascular response induced by high metastatic model LCI-D20 was stronger than in low metastatic model LCI-D35[68]. ④ N-Acetylglucosaminyltra nsferase V (GnT V) activity was much higher in LCI-D20 model when compared with LCI-D35, indicating the close relation between GnT V activity and HCC metastas is[69].

It was observed that both serum and tissue PAI-1 content increased gradually following tumor progression in LCI-D20 model, PAI-1 correlated with tumor size and AFP level and provided potential clinical impact as prognostic marker[70]. Phasic expression of tissue intercellular adhesion molecule-1 (ICAM-1) in this model was also observed, ICAM-1 increased

with the progressio n of LCI-D20 tumor, and markedly increased when metastasis occurrs[71].

Establishment of human HCC cell line with high metastatic potential

Metastatic behavior was not reported in human HCC cell lines that commonly use d in China when inoculated into nude mice, such as BEL-7402[6], PLC/PRF/5[7] and SMMC-7721[8].

In order to conduct in vitro study for metastatic recurrence, a human HCC cell line with metastatic potential (MHCC97) was established from a subcutaneous xenograft of the above LCI-D20 tumor using alternating *in vivo* and *in vitro* cultivation. The MHCC97 cells appear as polygonal epithelial cells. The doubling time was 31 h. Karyotype analysis revealed that the number of chromosome was 59-65, the median range of chromosome number was 60-61, which accounted for 73%. Aberrant chromosomes i(1)(q) and der(4) (pter→q35::?) were its chromo some markers, which might be related to carcinogenesis and progression of HCC. Secretion of AFP was demonstrated in MHCC97 cells. HBsAg and HBxAg were detected using PCR. Upon intrahepatic inoculation in nude mice, the xenograft grew and metastasized to the lungs, with metastatic rate up to 100% at 5th week. The cancer cells of lung foci were AFP positive. The latency period of tumor nodule formation after inoculation was 15d-20d. Invasion to the liver, diaphragm an d abdominal wall was observed after intrahepatic inoculation. The biological cha racteristics remained stable after in vitro passages for 2 years. The MHCC97 cell line was preserved in liquid nitrogen at the 120 passages. RT-PCR products for integrin α5 and β1, uPA-R, VEGF and nm23-H1 mRNA from MHCC97 cell line were positive. Immunostaining showed strongly positive for c-Met, uPA-R in both of xenografts and lung me tastatic lesions. However, integrin α5 and β1 were positive only in xenograft but not in lung metastatic lesions. E-cadherin was not expressed either in xenograft or in the metastatic lesions. Mutation of p53 at codon 249 was also observed in MHCC9 7 cells, but not in LCI-D35 cells (low metastatic model), indicating p53 mutati on might relate to HCC metastasis[36,37,72].

Experimental intervention for metastasis using LCI-D20 model

The LCI-D20 model, a patient-like metastatic human HCC model, is a useful model for the studies of experimental intervention. Two kinds of approach have been used: ① Studies on a well established model to observe the tumor inhibition rate and lung metastatic rate. ② Studies on intervention after curative resection of the established liver xenograft, which mimicked to that of curativ e resection of HCC in patient, to observe the recurrent rate and lung metastatic rate.

Several anti-angiogenic agents have been studied in nude mice bearing LCI-D20 tumor. ① Suramin was shown to inhibit tumor growth and metastasis of human HCC in nude mice, when compared with control, the tumor volume (cm^3) was 7.5 *vs* 10.8, and lung metastasis found in 62.5% and 100% respectively[73]. ② Inhibitory effect of the angiogenesis inhibitor TNP-470 on tumor growth (tumor weight being 0.97 g *vs* 2.04 g) and lung metastasis (being 8% *vs* 50%) was also demonstrated in LCI-D20 nude mice model[74]. ③ Gene transfer of dominant-negative flk-1 mutant has been studied and showed inhibition of angiogenesis, growth and metastases in LCI-D20 model, the tumor was 10 folds smaller than the control, lung metasta sis being 20% *vs* 100%, and vessels were hardly visible as compared with rich neovascularization in the control[75]. ④ Endostatin, a potent anti-angiogenic agent, has been shown to inhibit tumor growth in LCI-D20 model, and the combination with cisplatin enhanced the response, the mean tumor volume (mm^3) was 8376 for control, 3777 for endostatin, 1629 for cisplatin, and 463 for endostatin + cisplatin[76]. ⑤ Cytostatic calcium influx inhibitor carboxyamido- triazole (CAI) was also proved of effect for anti-angiogenesis[77]. ⑥ Recently, interferon (1b was proved effective to prevent the recu rrence in the liver and inhibit lung metastasis after resection of liver tumor in a dose-dependent manner. The mechanism was mediated by anti-angiogenesis[78].

The following approaches have also been tried for the intervention of metastas is in the LCI-D20 model. ① Antisense H-ras: When antisense H-ras oligodeoxyn ucleotides (ODNs) was used, specific inhibition of H-ras expression observed. Antisense H-ras ODNs induced apoptotic cell death, inhibited the growth rate of LCI-D20 cells in vitro and *in vivo*, and alter *in vivo* tumorigenesity (being 50% *vs* 100%) and metastatic potential (lung metastases being 0% *vs* 100%)[79]. ② Heparin is structurally and functionally similar to that of heparan sulfate, metabolite of suramin, therefore the role of heparin on metastasis was studied in LCI-D20 model. It has been demonstrated that hepa rin inhibited tumor growth (tumor size being 1.50±0.61 cm *vs* 2.98±0.50 cm in the control), inhibited lung metastas is (being 20% *vs* 60%) and prolonged survival (50 days survival being 60% *vs* 0)[80]. ③ Metalloproteinase inhibitor-BB94: Effect of BB-94 on tumor growth and metastasis in the LCI-D20 model was also observed, the tumor weight being 2.27g *vs* 3.13 g, lung metastasis being 44% *vs* 100%, and survival on day 45 being 100% and 56%[81]. ④ PD-ECGF that expressed in HCC, and particularly in tumor thrombus, is able to convert more prodrug (such as Furtulon and Xeloda-Capecitabine) into 5-Fu. Using capecitabine, prevention of lung metastasis as well as inhibition of tumor growth was observed in nude mice model of LCI-D20, thus will of potential as "targeting chemotherapy"[82]. ⑤ ICAM-1 is closely related to HCC metastasis. It was demonstrated that β peptide (a polypeptide designed by authors' institution, which is able to block ICAM-1) can inhibit recurrence in the liver and lung metastasis in LCI-D20 model after resection of tumor at early stage and advanced stage. However, the metastatic recurrent rate in the liver after resection in the early stage was lower than that after resection in the advanced stage, being 0%(0/5) versus 60%(3/5), and 100%(5/5) in the control[83]. ⑥ Retinoid acid was not effective in controlling tumor growth and metastasis in this particular LCI-D20 model.

The conclusion is that the establishment of metastatic human HCC model in nude mice and human HCC cell line with metastatic potential will provide an importan t model for the *in vivo* and *in vitro* study of mechanism of HCC metastasi s, angiogenesis as well as intervention of HCC recurrence after resection.

Abstract

Introduction: **This paper provides a review of the practice of liver transplantation with the main emphasis on UK practice and indications for transplantation.**
Referral and Assessment: **This section reviews the process of referral and assessment of patients with liver disease with reference to UK practice.**
Donor Organs: **The practice of brainstem death and cadaveric organ donation is peculiar to individual countries and rates of donation and potential areas of improvement are addressed.**
Operative Technique: **The technical innovations that have led to liver transplantation becoming a semi-elective procedure are reviewed. Specific emphasis is made to the role of liver reduction and splitting and living related liver transplantation and how this impacts on UK practice are reviewed. The complications of liver transplantation are also reviewed with reference to our own unit.** ***Immunosuppression:*** **The evolution of immunosuppression and its impact on liver transplantation are reviewed with some reference to future protocols. Retransplantation: The role of retransplantation is reviewed.**
Outcome and Survival: **The results of liver transplantation are reviewed with specific emphasis on our own experience.**
Future: **The future of liver transplantation is addressed.**

Subject headings liver transplantation; review; Great Britain; human

INTRODUCTION

Recent years have seen dramatic changes in the practice of liver transplantation. In 1980 in Europe fewer than 30 liver grafts were performed compared to over 3000 in 1995 (Figure 1). During this period liver transplantation has evolved from a rare procedure in patients with end-stage liver disease, to a semi-elective operation with current predictable success rates of approximately 90% in patients with chronic disease.

In the early period of liver transplantation it was reserved for patients with end stage chronic liver disease or unresectable primary liver malignancy, but in recent years there has been a considerable broadening of the accepted indications. Improving results have led to liver transplantation becoming a semi-elective procedure with both quantity and quality of life being of major concern. Patients who may not be in immediate risk of death from liver decompensation but have significantly impaired quality of life are now considered as candidates.

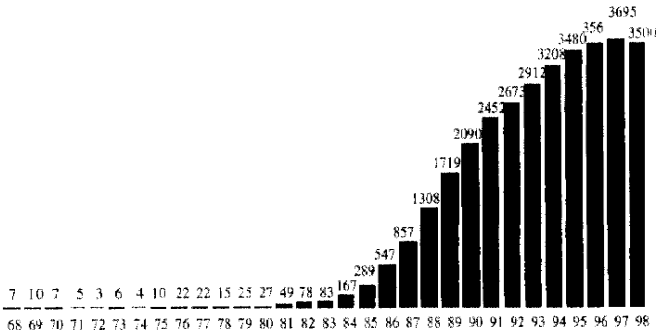

Figure 1 Evolution of european liver transplantation.

The current indications can be classified into four broad groups; chronic liver failure, acute liver failure, primary hepatic malignancy not treatable by conventional resection and inborn errors of metabolism due to a liver based enzyme defect but without parenchymal liver disease (Table 1).

Chronic liver failure is the most common indication for liver replacement and can be caused by a wide variety of diseases including autoimmune, viral, congenital and alcohol induced liver disease. Primary biliary cirrhosis (PBC) is the commonest indication for liver transplantation in the UK. Several studies on survival in PBC have led to the development of a prognostic index that is helpful in planning the timing of liver replacement[1]. Primary sclerosing cholangitis (PSC) is a condition that is usually found in patients with inflammatory bowel disease. Progression of PSC is less predictable than PBC but approximately 30% of patients with PSC will develop cholangiocarcinoma that is usually incurable at diagnosis. Autoimmune hepatitis (AIH) is less common than PBC and PSC but immunosuppressive therapy can delay progression. Excess immunosuppression prior to transplantation however, may increase the morbidity and mortality associated with liver replacement and the optimal timing of liver replacement is a finely balanced decision.

An estimated 300 million people worldwide carry the hepatitis B virus (HBV). In Western Europe and North America the carrier rate is low (0.5%) and is mainly confined to high-risk groups including intravenous drug users, homosexuals and immigrants from high prevalence areas. HBV is a significant problem however, because of the risks of early recurrence after liver replacement. Patients who are HBV-DNA positive at time of transplant develop rapid recurrence with early death. The results of trials of antiviral therapy using agents such as lamivudine and HBV specific immunoglobulins prior to transplantation suggest that viral replication can be suppressed prior to and post liver replacement with encouraging early results[2-5]. Hepatitis C

virus (HCV) is an increasing public health problem. Most patients seen in the UK have become infected following transfusion of blood products or from intravenous drug abuse. The development of cirrhosis following HCV infection is slow but with a significant risk of subsequent hepatocellular carcinoma development[6]. Recurrence of HCV after transplantation is common but not usually problematic in the early years[7,8]. The evolving strategies for anti-viral therapy in this group of patients are likely to have a significant impact on survival in this group of patients[9-11].

Alcoholic liver disease (ALD) is the commonest cause of cirrhosis in many parts of the western world although during the evolution of liver transplantation very few cases were accepted. Many transplant physicians were initially reluctant to consider liver replacement in these patients because of the risks of returning to alcohol and public attitudes[12]. The alcoholic who can prove abstinence prior to grafting has an equivalent survival to those transplanted for other chronic liver disease and recidivism is surprisingly uncommon[13]. There has therefore been an increasing pressure to acceptre formed alcoholics and an increasing proportion are now being grafted[14].

The commonest cause of chronic liver failure in children is biliaryatresia. If diagnosed early and treated surgically with a portoenterostomy (Kasai operation), the progression of liver disease is delayed and up to 40% of children will survive long term[15]. Many children however, will develop end stage liver disease and die within the first few years of life if not transplanted. Failure to thrive is a common sequelae of chronic liver disease in children and should be considered an indication for grafting.

The development of hepatic encephalopathy within eight weeks of onset of symptom s in a patient without previous liver disease is defined as acute fulminant hepa tic failure (AFHF)[16]. Sub-acute or late onset hepatic failure has al so been recognised with encephalopathy developing between eight weeks and six months of onset of symptoms. The commonest causes of AFHF in the UK include drugs and toxins[17-20], viral hepatitis (Hepatitis A, B, and non-A non-B)[21,22] and miscellaneous causes including Wilson's disease, fatty liver of pregnancy and Budd-Chiari syndrome[23-26]. Specific prognostic factors for spontaneous recovery from AFHF have been published and are helpful in decision making about transplantation[27].

An increasing number of inborn errors of metabolism with a deficiency of a single hepatic enzyme are being treated by liver transplantation, even though the liver is otherwise structurally and functionally normal (Table 1). Timing is important and transplantation should be performed before irretrievable damage is don e to other organs e.g. renal failure in primary oxalosis or cerebral damage in Crigler-Najjar syndrome[28,29].

Hepatocellular carcinoma (HCC) is the commonest primary liver malignancy and although it is rare in the UK it is one of the commonest cancers worldwide[30]. The majority of cases occur in the background of liver cirrhosis with the presence of HCV and HBV being additional risk factors (Figure 2). It has been recommended that transplantation be restricted to patients with HCC who have lesions up to 3 cm and up to three in number[31-33]. There are other rare unresectable hepatic tumours that are occasionally conside red for transplantation. These include epithelioid haemangioendothelioma, sarcomata, cholangiocarcinoma and secondary neuroendocrine tumours[34-36]. Hilar cholangiocarcinomas almost invariably recur early after grafting and are no longer considered appropriate candidates[37].

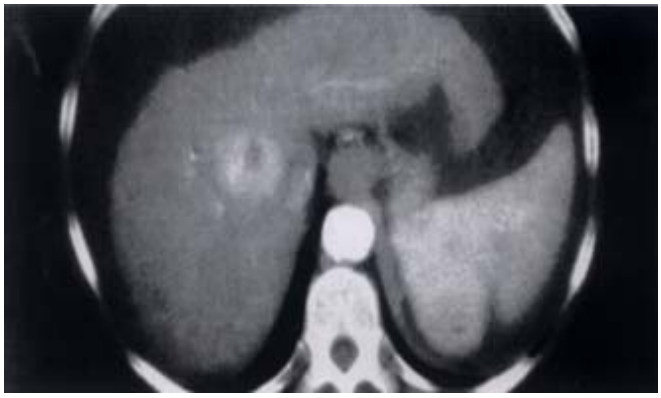

Figure 2 CT Scan showing HCC in cirrhotic liver with ascites and splenomegaly.

Table 1 Common indications for liver transplantation

		Birmingham series	
		n	%
Chronic liver failure	Primary biliary cirrhosis	434	24.7
	Primary sclerosing cholangitis	158	9
	Autoimmune chronic active hepatitis	96	5.5
	Alcoholic cirrhosis	122	6.9
	Cryptogenic cirrhosis	92	5.2
	HBV or HBC cirrhosis	165	9.4
	Biliary atresia	142	8
	Alpha-1 anti-trypsin deficiency	65	3.7
	Budd-Chiari syndrome	8	0.1
Acute liver failure	Viral hepatitis (non-A, non B, HBV, HAV)	10	8
	Drugs (Paracetamol, anti-tuberculosis therapy, halothane)	66	3.8
	Toxins and solvents	0	
Primary hepatic malignancy	Unresectable HCC	20	0.4
	Small HCC in cirrhotic liver	78	10.2
Inborn errors of metabolism	Crigler-Najjar type 1	1	0.05
	Proprionic acidaemia	6	0.08
	Primary oxalosis	8	0.1
	Urea cycle defects	0	

REFERRAL AND ASSESSMENT

In patients with acute or chronic liver failure timely referral is necessary if a successful outcome is to be achieved[38-40]. Many patients with chronic liver disease can remain stable for long periods and decompensation may occur secondary to a complication such as variceal bleeding, portal vein thrombosis, development of hepatic malignancy or spontaneous bacterial peritonitis. The ability to intervene before any major deterioration is dependent on the recognitio n of early indicators of disease progression; in cholestatic conditions (PBC and PSC) the level of bilirubin is an obvious indicator of the underlying disease severity and is likely to lead to an early referral for specialist opinion but for many liver conditions the appearance of jaundice is a late feature and other signs of a deterioration in liver synthetic function, such as a falling albumin or rising prothrombin time are a better indicator of the need for referral.

A multi-disciplinary team including hepatologists and transplant surgeons usually assess patients in the UK. A careful review is required to determine the diagnosis of the liver disease and this will include a specialist pathologist at the transplant centre reporting on the liver histology. Often patients who drink moderate amounts of alcohol are labelled as having alcoholic liver disease but an open mind for these cases is encouraged because modest alcohol intake may unmask an underlying liver condition such as alpha-1 anti-trypsin deficiency or haemochromatosis[41,42].

Assessment for transplantation includes both physical fitness for major surgery as well as psychological evaluation and counselling. A detailed evaluation of the cardio-respiratory system is often indicated and this may require ECG, echocardiogram, exercise ECG, coronary angiography and pulmonary artery catheter isation in those with evidence of ischaemic heart disease, pulmonary hypertension or suspected major pulmonary shunts as seen in the hepatopulmonary syndrome[43].

Technical considerations such as patency of the portal vein are also required an d this can be determined by Doppler ultrasound, angiography, spiral computerised tomography (CT) or magnetic resonance imaging (MRI). An absent portal vein is not a contraindication to transplantation if a patent superior mesenteric vein or large coronary vein can be identified which would be suitable for anastomosis to the donor portal vein[44]. Patients with primary HCC require detail ed investigation for evidence of disease outside the liver and this should include laparoscopy to detect peritoneal disease or transcapsular spread[45], isotope bone scanning and computerised tomographic studies of the abdomen and chest. Difficulty may occur in patients with PSC in trying to differentiate between malignant and benign hilar strictures (Figure 3). In our series malignancy was present in 25% of the patients with significant biliary dilatation but that pre-transplant diagnosis was difficult (unpublished data).

Figure 3 Cholangiogram showing dominant hilar stricture in a patient with PSC.

DONOR ORGANS

The number of liver transplants performed annually in the UK has remained largely stable over the last five years and this has been despite a slight fall in the number of cadaveric organ donors. The total number of liver transplants has been maintained in the UK by an increase in the number of split liver grafts perfor med and a wider use of more marginal liver donors. Over the last ten years the introduction of seatbelt laws and stricter drink driving legislation has reduced the number of cadaveric donors being derived from road traffic accident victims. Donor numbers have been largely maintained by utilising older donors who have usually died from cerebro-vascular disease and have concomitant co-morbidity. The use of such marginal donors does not seem to have been at the expense of worse outcomes. Successful outcome from liver transplantation is possible even in haemodynamically unstable donors and in those with abnormal liver function tests[46].

Assessment of the liver by an experienced transplant surgeon at time of retrieval is a useful guide to subsequent function but if there is evidence of fatty change, a frozen section histological assessment prior to implantation can be helpful[47-49]. A fit recipient can often cope with a marginal graft but a poor recipient will need a graft which functions well immediately for the best chance for survival.

Size matching of donor and recipient is attempted when selecting a patient for a particular liver. Attempting to place a large graft in a small recipient can cause major technical problems. Patients with cholestatic diseases such as PSC and particularly PBC often have large livers and will accept grafts from significantly larger donors, as can patients with marked ascites.

Approximately 60% of potentially suitable organ donors (approximately 1000 per year) are missed each year in the UK[50]. UK organ donation rates remain some of the lowest in Europe but a more aggressive approach to the identification and confirmation of brainstem death and improved family requesting could achieve significant improvements in organ donation in the UK[51]. A number of initiatives such as presumed donor consent and elective ventilation are currently being considered[50].

OPERATIVE TECHNIQUE

Many factors can be identified which have contributed to the improved early outcome after liver replacement. Semi-elective daytime operating ensures that the surgical and anaesthetic team produce the best technical results. The ability to store livers long enough to allow this came from the development of University of Wisconsin preservation fluid which allows satisfactory immediate graft function for storage periods of eighteen hours or more[52].

Meticulous attention to haemostasis has been aided by developments in surgical techniques and instruments (conventional diathermy, argon beam coagulator, fibrin glue, etc.). The monitoring of coagulation parameters in the operating room with the help of the thromboelastogram (TEG) means that blood coagulation is optimised and that predictable deteriorations in clotting which often occur on reperfusion can be anticipated and minimised[53]. The role of anti-fibrinolytic agents such as aprotinin (Trasyslol) and human recombinant factors (Novoseven) remains unclear but are the subject of clinical study[54,55].

Technical innovations

The introduction of venovenous bypass for the anhepatic phase

produced a significant stabilisation of haemodynamic parameters during portal vein and caval clamping with a clear reduction in transfusion requirements and an improvement in renal function[56]. The alternative to venovenous bypass is to preserve the vena cava at the time of hepatectomy and anastomose the back of the donor vena cava to the front of the recipient cava (piggyback technique)[57]. Several techniques have been described but the piggyback technique is not without its complications[58-62]. Most units currently utilise a combination of techniques and a minority of units still perform liver replacement without either bypass or the piggyback technique.

Early techniques of biliary reconstruction involved utilising the donor gall bladder as a conduit between the donor and recipient duct. This technique has been abandoned because of the almost universal development of stones in the conduit. An end-to-end duct anastomosis is now the routine but this has been followed by stricture formation in up to 13% of cases[63-65] and techniques of anastomosing the ducts obliquely with the ends spatulated or by utilising a side-to-side anastomosis are gaining wider acceptance[66,67]. The use of a T-tube has been abandoned by most units[63-65,68].

Liver reduction and splitting

The shortfall in size matched grafts for small children led to the development o f reduced grafts in the mid 1980's[69-71]. The most commonly used technique is to transplant the left lateral lobe segments II and III with venous outflow based on the left hepatic vein which is anastomosed to the retained recipient vena cava[72]. Weight ratios as high as ten-to-one between donor and recipient have been reported[73] the ideal weight ratio however, is four, five or six to one. Reduced liver grafts are not without their comp lications[74] but there appears to be a low incidence of hepatic artery thrombosis[75,76]. The introduction of this technique has led to a significant reduction in mortality from liver disease in children[77]. The techniques of graft reduction have led to the development of splitting livers where the left lobe (or left lateral segments) is transplanted into a paediatric recipient and the right lobe is grafted usually into an adult recipient (split-liver)[78-80]. This technique was developed on the backbench following removal of the cadaveric donor organ. The pro cedure can take approximately two hours and during this time the donor organ is subject to some re-warming that might be detrimental to its initial function. Recently the technique of *in situ* splitting of cadaveric donor organs has been developed as an extension of the development of living related liver transplantation. The advant age of this technique is that the splitting of the liver is performed during the warm phase dissection prior to organ perfusion and cooling and the organ is then not subject to re-warming during a subsequent splitting procedure. The results of this technique appear to result in better initial graft function[81-83].

Living related liver transplantation

In countries that do not have legal recognition of brainstem death and therefore have no access to cadaveric organs, solid organ transplantation has been limited to living related organ donation and this has led to the development of living related liver transplantation[84]. The increasing donor organ shortfall with the increasing number of potential recipients; despite the option of organ splitting, has meant that even in countries that do recognise brainstem death living related liver transplantation has had to be undertaken[85-88]. The organ shortfall in the UK for patients with liver disease is less than in other countries and the number of units performing this procedure is small with only 12 being performed in 1999[89,90]. The greatest experience with this technique has been with adult-to-child left lateral lobe because of the obvious size discrepancy and donor to recipient weight ratios[91] but increasing experience of the technique has led to the expansion of the technique to include adult-to-adult donation[92-96]. The increasing demand for liver transplantation in the UK and the reduction in cadaveric donor organs[90] suggest that this technique is likely to become established practice but careful preoperative evaluation of the donor is needed[97-100].

Complications

The one-year survival following liver transplantation has improved from approx imately 30% in the 1960s and 1970s to more than 80% in the 1990s[14,101,102].

The immediate complications following liver transplantation include primary non -function, haemorrhage and acute renal failure. The incidence of these is sign ificantly influenced by the quality of the donor liver and technical aspects of the transplant operation itself. Over the last 10 years in the UK there has been an increase in the use of marginal organs[46] but this has been offset by improvements in technical aspects of the surgical procedure, per-operative anaesthetic management and post-operative intensive care management. In our own unit the incidence of these complications between 1985 to 1989 and 1995 to 1999 was; primary non-function 1.9% and 1.7%, return to theatre for pack removal or haemorrhage 8.4% and 2. 4% and post-operative renal failure 18.6% and 16.4% respectively (unpublished data). Despite the use of an increasingly marginal donor pool the incidence of these complications hastherefore reduced.

Primary non-function may be due to pre-existing but occult problems in the donor, poor retrieval or preservation, or injury caused by reperfusion (post-reperfusion syndrome). The clinical picture mimics acute fulminant hepatic failure and death rapidly follow unless urgent regrafting can be undertaken. Fortunately primary non-function is rare although primary dysfunction occurs in 5% to 10% of cases and is associated with a worse long-term outcome[103,104].

The majority of routine liver transplants require minimal or no transfused blood . In our own series 47% of liver transplants required four units or less of blood per-operatively (unpublished data). Patients with severe portal hypertension and previous major upper abdominal operations can pose a major surgical challenge, meticulous haemostasis, venovenous bypass, warming of blood and blood products and strict control of coagulation parameters will usually be effective.

A significant number of transplant candidates already have impaired renal function and a combination of factors lead to a rise in the serum creatinine after surgery[105-107]. This will usually respond to optimisation of hydration and pharmacological manipulation but a proportion of patients will develop anuria and require renal replacement therapy at least in the short term[108].

Histological evidence of acute rejection can be documented in approximately 80% of liver grafts at the end of the first week but many of these do not require ad ditional immunosuppression if other parameters of graft function are improving[109]. Histological evidence of severe cellular rejection and less severe histological forms associated with significant biochemical abnormalities (approximately 30% of liver grafts) are usually

treated with high dose steroids[110,111]. Steroid resistant rejection may respond to other agents including monoclonal (OKT3) and polyclonal antibodies (ATG) or by switching immunosuppression regimes[112,113]. Chronic or irreversible rejection in the liver is a biliary rather than a vascular phenomenon in which the small bile radicals are destroyed[114,115]. This can occur very early on after grafting and if progressive leads to loss of the graft although predicting which patients might require regrafting can be difficult[116,117]. Chronic rejection accounts for approximately 5% of graft loss within the first three to five years following transplantation[118]. Lower rates of chronic rejection and graft salvage in early chronic rejection may occur with newer immunosuppressive regimes[119-121]. Histological examination of the transplanted liver in stable long-term patients often shows evidence of chronic post-transplant hepatitis[122]. The causes of the histological changes are unknown although unrecognised viral infections may be responsible for some cases and the steroid sparing immunosuppression regimes may also be partly responsible.

Serious cytomegalovirus (CMV) infections tend to be primary (transmitted by the donor liver) rather than reactivation infections and should be avoidable if CMV-matched donors are used. Clinical infection usually presents between four and eight weeks with fever and leucopenia but asymptomatic sero-conversion does not require treatment. This will respond well to a combination of reduction in base line immunosuppression and ganciclovir therapy[123]. The traditional se rological tests vary between centres, take time and are less sensitive than PCR tests[124]. In patients with symptoms specific to an organ histologi cal analysis should be used in conjunction with PCR tests[125,126].Significant CMV infection is associated with acute rejection and may result in a worse long-term outcome[127]. The routine use of prophylactic ganciclovir reduces the incidence of clinical CMV infection although a high index of suspicion and prompt treatment will also result in negligible mortality[128-132].

Biliary complications are a significant problem in most units undertaking liver transplantation and these include bile leaks, anastomotic strictures, non-anast omotic strictures of the donor bile duct and sludge formation. The overall incidence in adults is approximately 10% but is higher in children[74,133]. In our own series the overall incidence of biliary complications requiring inte rvention is 12%, this rises to 27% in those patients undergoing re-transplantation (unpublished data). The ability to image the biliary tree effectively using ultrasound, MRI cholangiography, endoscopic retrograde cholangiography (ERCP) or percutaneous transhepatic cholangiography (PTC) has led to most biliary complications being managed without reoperation[134]. The presence of a major biliary disruption or an associated biliary obstruction is an indication for urgent biliary reconstruction[135]. Biliary obstruction without leakage will usually be evident from simple ultrasound, can be confirmed by ERCP or PTC and can usually be managed without recourse to open surgery[136-138]. Non-anastomotic biliary strictures involving the confluence or intra -hepatic bile ducts are a rare but serious complication that were once attributed to prolonged preservation times[139]. These strictures are complicated but a proportion can be resolved using a PTC approach by a skilled radiologist although a number of cases will require regrafting. In any patient with a biliary complication patency of the hepatic artery should be confirmed, as hepatic artery thrombosis will cause ischaemia and necrosis of the biliary tree[140]. The late biliary complications seen after transplantation are usually obstruction with possible secondary sepsis and cholangitis. The commonest cause is an anastomotic stricture, with or without stone or sludge formation in the proximal dilated biliary tree. An ERCP may enable duct clearance, dilatation of any stricture and stent insertion. Most strictures will recur and therefore formal biliary reconstruction is usually required.

Hepatic arterial thrombosis (HAT) after liver transplantation occurs most frequently in the first postoperative month and leads to graft necrosis, intra-hepatic abscess or biliary necrosis and bile leakage. In all suspected cases patency of the artery should be checked with Doppler ultrasound and confirmed with spiral CT or angiography[141-143]. Per-cutaneous attempts at revascularizati on of stenosed or thrombosed hepatic arteries can be attempted and urgent thromb ectomy has been successful in some cases but the majority of cases of early HAT will need regrafting[144-148]. Late arterial thrombosis may be occult an d if asymptomatic can probably be ignored. In our own series HAT has occurred in 4.6% of adult grafts and 9.1% of paediatric grafts (unpublished data). Technical problems account for the majority of cases but over transfusion at the time of surgery, producing a high a haematocrit, has been reported as a risk factor[149,150].

Malignancy is well recognised as a potential complication of long term immunosup pression. Longer survival is seen with the liver compared to other solid organ transplants and therefore the time exposed to the risk of malignancy is greater. The most common malignancies seen secondary to prolonged immunosuppression are the lymphoproliferative diseases and lymphoma and skin malignancy[151,1 52]. Reduction in the level of immunosuppression is often enough to treat lymphoproliferative disease[153]. A proportion of liver transplants are performed for primary hepatic malignancy and paradoxically the donor liver (free from malignancy at the time of transplant) is the commonest site of recurrence. The predilection for circulating malignant cells to return and then grow in the liver is well recognised.

IMMUNOSUPPRESSION

The widespread introduction of cylosporine A in the early 1980s was responsible for the improvement in liver graft survival from 35% to 70% survival at one-year[154]. Immunosuppression with cylosporine, azathioprine and steroids remained the main immunosuppressive regimen until the development of tacrolimus in 1989[155]. Tacrolimus was initially used to salvage grafts failing from rejection on cylosporine based regimens[156] but has subsequently been increasingly used as first line immunosuppression by many units. Although structurally different to cylosporine, it also acts by inhibiting calcineurin and subsequent interleukin (IL) 2 production and therefore prevents T cell proli feration[157]. Three prospective randomised trials have compared the ef ficacy of tacrolimus and cylosporine in liver transplant recipients[158-160]. The incidence of rejection was significantly lower with tacrolimus in all studies but there was no difference in one-year patient and graft survival. Long-term follow up has shown a trend towards en hanced survival in patients treated with tacrolimus[161]. The toxicity profile of tacrolimus is similar to that of cylosporine (nephrotoxicity, neurotoxicity, hypertension and diabetogenic potential) but without the gingival hyperplasia and hirsutism commonly seen with cylosporine[162].

Mycophenolate mofetil (MMF) is another new agent that

blocks purine metabolism by inhibiting inosine monophosphate dehydrogenase in T and B lymphocytes[163]. The role of MMF in liver transplant recipients remains to be fully defined but initial reports suggest that when combined with tacrolimus the incidence of acute rejection is reduced[164,165]. MMF has haematological and gastrointestinal side effects but is not nephrotoxic and may be useful in patients with compromised renal function so that the dose of tacrolimus can be reduced[166]. New immunosuppressants continue to be developed and some are currently under eva luation including sirolimus (inhibits action of IL2), basiliximab (chimeric IL2 receptor monoclonal antibody) and daclizumab (humanised IL2 receptor monclonal antibody)[167,168]. Polyclonal antibody therapy that has previously b een used to treat steroid resistant rejection has however, been rendered almost obsolete by current immunosuppressant protocols. In our own centre the current immunosuppression regimen is tacrolimus combined with azathioprine and prednisolone, with steroid taper and withdrawal over three months. MMF is used in place of azathioprine to allow low dose tacrolimus regime ns in those patients with renal impairment prior to transplantation and is also used in place of azathioprine in those patients undergoing retransplantation for chronic rejection.

The available immunosuppressive options will continue to increase and with it the permutations of immunosuppressive regimens. This may make it difficult to effectively evaluate individual regimens. Immunosuppression will however, continue to be a balancing act, with over immunosuppression culminating in toxicity, life threatening infections and malignancy and under immunosuppression leading to rejection and graft loss.

RETRANSPLANTATION

In our own series 10% of nearly 2000 liver transplants were regrafts, although the proportion of patients requiring a regraft is decreasing[169]. HAT accounts for 30% of regrafts, primary non-function for 16%, chronic rejection for 31% and recurrent disease for 6%, although the incidence of HAT and primary non-function is decreasing and the incidence of recurrent disease (PSC and HCV) is increasing[169]. Early re-transplantation is technically straightforward and usually performed for HAT or primary non-function. In an era of donor shortage and donor/ recipient number mismatch the role of re-transplantation has been questioned but the outcome of re- transplantation is good with survival rates only slightly worse than those achieved for the first graft[170].

SURVIVAL

One-year survival rates for elective liver transplant in patients with benign disease now exceed 90% in many centres, with predicted 10 year survival rates expected to exceed 70%[102,171]. Patients transplanted for AFHF have a worse one-year survival with higher post-operative death rates usually related to cerebral complications and multi-organ failure. Experienced centres have however, obtained one-year survival rates of approximately 70%[172-174]. The long-term outcome for patients undergoing liver transplant for AFHF is as good as those transplanted for chronic disease. The increasing interest in living related transplantation offers a new opportunity for those patients with AFHF who cannot wait for a cadaveric organ[175]. The outcome in children undergoing liver transplantation is equally good, even in high-risk groups such as children age under 1 year in whom donor organ shortage might prevent grafting at the optimal time[75].

Survival rates for patients grafted for primary liver cancer (HCC) are less good however, patients transplanted for asymptomatic lesions up to 3 cm in diameter have survival rates close to those seen in patients grafted for benign disease[32]. In our own unit overall survival (including fulminant hepatic failure) at one-year is 81% for adults and 86% for children with different long-term survival depending on disease type (Figure 4).

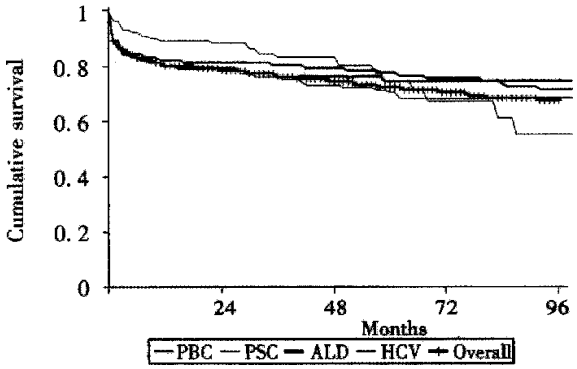

Figure 4 Survival following liver transplantation by disease type: birmingham series 1988-2000.

THE FUTURE

The most serious issue currently facing liver transplant physicians is the short fall in donor organs needed to meet demand. This deficit is greater in the US than in the UK. If the UK could increase its rates of organ donation to levels seen in other European centres and split all livers that meet appropriate criteria (approximately 25% of UK cadaveric organs) then current organ demand could be met. Patient demand will however, mean that increasingly transplant physicians will be asked to justify why certain categories of patient are not considered suitable for transplantation. The limited supply of cadaveric organs allows these physicians to justify transplantation criteria on the basis of the scarcity of this resource. The continued success of living related liver transplant programmes around the world is likely to lead to increasing pressure to relax the criteria for liver transplantation for those patients able to provide their 'own' source of suitable transplant organs. This will require strict control and the application of new National guidelines if the UK is to avoid an expensive and potentially dangerous situation in the application of universal standards of care. A successful UK living related programme would certainly help to ease the deficit in urgent organs for those with AFHF and could address the deficit that currently exists for liver transplantation in chronic liver disease but we believe that this should only occur after the UK has exhausted the potential that is currently un tapped in potential cadaveric organs.

The use of genetically modified xenografts could be potential major breakthrough for organ recipients but is not easily applicable to liver failure patients and there remain many biological and ethical obstacles before these organs become a sustainable source[176].

Abstract

Advances in technology continue at a rapid pace and affect all aspects of life, including surgery. We have reviewed some of these advances and the impact they are having on the investigation and management of colorectal cancer. Modern endoscopes, with magnifying, variable stiffness and localisation capabilities are making the primary investigation of colonic cancer easier and more acceptable for patients. Imaging investigations looking at primary, metastatic and recurrent disease are shifting to digital data sets, which can be stored, reviewed remotely, potentially fused with other modalities and reconstructed as 3 dimensional (3D) images for the purposes of advanced diagnostic interpretation and computer assisted surgery. They include virtual colonoscopy, trans-rectal ultrasound, magnetic resonance imaging, positron emission tomography and radioimmunoscintigraphy. Once a colorectal carcinoma is diagnosed, the treatment options available are expanding. Colonic stents are being used to relieve large bowel obstruction, either as a palliative measure or to improve the patient's overall condition before definitive surgery. Transanal endoscopic microsurgery and minimally invasive techniques are being used with similar outcomes and a lower mortality, morbidity and hospital stay than open trans-abdominal surgery. Transanal endoscopic microsurgery allows precise excision of both benign and early malignant lesions in the mid and upper rectum. Survival of patients with inoperable hepatic metastases following radiofrequency ablation is encouraging. Robotics and telemedicine are taking surgery well into the 21st century. Artificial neural networks are being developed to enable us to predict the outcome for individual patients. New technology has a major impact on the way we practice surgery for colorectal cancer.

INTRODUCTION

Advances in technology continue at a rapid pace and affect all aspects of life. Medicine is no exception. Colorectal carcinoma (CRC) is the third most commonly diagnosed cancer in the western world[1]. There have been considerable steps forward in the survival and outcome of CRC in recent years. New technology has in no small way contributed to this improvement. One of the major advances in surgery in the 20th century was the development of circular stapling devices in Russia in 1967[2]. These instruments have revolutionized the colorectal anastomosis, particularly deep in the pelvis and almost certainly contributed to the increase in sphincter preserving operations. Another was the introduction of minimally invasive techniques, which has altered the approach to many surgical procedures. Imaging investigations are shifting from analogue film storage to digital data sets. Once acquired this imaging data can be stored, reviewed remotely, potentially fused with other modalities and reconstructed as 3 dimensional images for the purposes of advanced diagnostic interpretation and computer assisted surgery. There will be an increased reliance on 3D-imaging in all aspects of patient care[3]. Now that we have entered the 21st century, how will these and other new technologies affect the practice of coloproctology The AIM of these advances is to continue to improve the outcome of patients with CRC, by altering the way physicians diagnose and treat their diseases. We discuss a number of new technological advances and their impact on surgery for CRC (Table 1).

Table 1 New technology available for colorectal surgeons

INVESTIGATION

Virtual colonoscopy
Trans-rectal ultrasound
Magnetic resonance imaging
Positron emission tomography
Radioimmunoscintigraphy
INTERVENTION
Colonic stents
Transanal endoscopic microsurgery
Minimally invasive surgery
Radiofrequency ablation
Robotics
OUTCOME
Artificial neural networks

INVESTIGATION OF COLORECTAL CANCER

The management of CRC relies on its early detection and characterization. Improving the outcome of CRC depends not only on sensitive investigations but also the encouragement of early presentation by symptomatic patients and population screening. Currently, fibre optic endoscopy is the investigation of choice for the diagnosis of CRC. New colonoscopes are being developed with improved optics, magnifying and localisation capabilities and dual channels allowing endoscopic resection and endoscopic assisted surgery. Endoscopy though, is invasive and carries a small risk of perforation of around 0.2%[4]. Virtual colonoscopy is being

developed which will alleviate this risk and still examine the entire colon in 3-dimensions. There are many treatment modalities available once CRC has been diagnosed. The best option for an individual patient depends on the stage of the disease and the surgeon's expertise. Ultrasound, computed tomography (CT), magnetic resonance imaging (MRI), positron emission tomography (PET) and radioimmunoscintigraphy can all be used to diagnose tumours, provide staging information pre operatively and detect recurrence. Improvements in the sensitivity of these investigations will result in a better outcome for patients.

Modern endoscopes

Fibre optic endoscopy and biopsy remains the investigation of choice for examining the colon and diagnosing CRC. Unfortunately in the United Kingdom a complete colonoscopic examination to the caecum is achieved in only 70% of cases[5]. This results in the patient having to make another visit to the hospital for either a repeat colonoscopy or a completion barium enema. Incomplete colonoscopy is usually due to a combination of looping of the scope, redundant or angulated sigmoid colon and patient intolerance. Several different configurations of looping are possible in the colon, including alpha, gamma, and N loops. Many of these require a different manoeuvre to un-loop the scope. Magnetic imaging localisation and variable stiffness endoscopes are being developed to reduce these loops forming and aid in their reduction, making the procedure more comfortable for the patient and improving the success rate of a complete examination of the colon. Magnifying endoscopes can help differentiate between neoplastic and non-neoplastic lesions without the need for histologic examination. As a result, the overall efficiency of colonoscopy should improve.

The position of the colonoscope within the colon and presence of any looping can be demonstrated using real time 3-dimensional magnetic imaging, which is built into the scope. Shah[6] has shown that even in the hands of expert endoscopists, correct identification of loop configuration occurred only 31% of the time. As the image generated is in real time, loops can be detected and straightened as soon as they form, resulting in shorter intubation time and higher completion rates[7]. Appropriate position change of the patient or a bdominal pressure can be used to correct to loop, if it's configuration is known. The magnetic imaging endoscope can also be used to indicate the extent of the examination. It has the advantage over fluoroscopic screening of having no radiation exposure to either the patient or endoscopy staff. However, identification of the ileocaecal valve, appendix orifice or ilealmucosa remains the gold standard of assuring complete examinati on of the colon. Not only are these new scopes good for patient care, but they are a useful tool for teaching as it shows the trainee exactly what is happening to the scope inside the colon. This feedback gives the operator a better understanding of how loops form, how this changes the resistance of scope insertion and how to prevent and straighten these loops. Shah[7] has shown that trainees using the MR imaging colonoscope have a higher completion rate and spend less time looping the instrument. As a result we should have more proficient endoscopists in the future.

Another new development is a variable stiffness colonoscope. The endoscopist can increase the stiffness of the scope, which reduces looping. Brooker[8] in a randomised control trial has found significantly quicker caecum intubation time (7 *vs* 11 minutes) and less patient discomfort (median pain scores 7 *vs* 24) when using this scope compared with a conventional colonoscope. As a result the rate of incomplete examinations should decrease and patient satisfaction increase.

Currently colonic polyps are biopsied or removed for histological diagnosis to determine if they are neoplastic. Patients with neoplastic lesions require ongoing surveillance, while those with non-neoplastic lesions can be reassured of their low risk of CRC and discharged. The complication rate with colonic biopsy is around 0.5% and includes bleeding, perforation and trans-mural thermal injury[9]. The crypt pattern of polyps has been shown to predict their underlying histology[10]. Magnifying endoscopes are being used to examine t he crypt patterns of polyps. Togashi[11] used a 100 times magnifying scope to examine the crypt pattern of 923 polyps following dye spray. The crypt or ifices were classified into 6 categories: medium round, asteroid, elliptical, small round, cerebriform and no apparent pattern. The first 2 were considered to be a non-neoplastic lesion, while the remainder was neoplastic. Neoplastic and non-neoplastic lesions could be distinguished by the crypt pattern in 88%, when compared to their histological diagnosis. With the use of the magnifying scope in the future, non-neoplastic lesions may not need to be biopsied. Advances in endoscopes will enable more complete and less painful examination of the colonic mucosa, with more accurate evaluation of polyps and a lower overall morbidity, making colonoscopy an even more valuable investigation.

Virtual colonoscopy

Virtual colonoscopy, CT colography CT colonography and CT pneumocolography are all terms which have been used to describe essentially similar investigations. It was first reported by Vining in 1994. Advances in CT software and hardware, particularly the advent of helical data acquisition, have enabled rapid high resolution 2 and 3-dimensional images of the colon to be created. The majority of colonic lesions can be detected on the standard 2-dimensional data set, while the 3-dimensional data is used for problem solving by simulation of an endolu minal image. However, Hara[12] reported that the accuracy of this test is superior when both the 2-D and 3-D images are reviewed, compared to the 2-D images alone. After the patient has taken mechanical bowel preparation, the clean colon is distended with 1.5 L-2 L of air or carbon dioxide, via a rectal catheter. This technique has several advantages. Firstly it is a rapid examination, with the volumetric CT data acquisition taking only a few minutes. It is non-invasive (apart from the introduction of a rectal catheter) and is performed without the need for sedation or abdominal compression. Virtual colonoscopy can examine other abdominal organs, avoids the 1 in 1000 risk of perforation by colonoscopy and is well tolerated by patients. Hara[12] reported that patients were more comfortable during virtual colonoscopy than with barium enema or colonoscopy. The imaging data can then be viewed and manipulated at a remote works station at a convenient time. The disadvantages of virtual colonoscopy are that histological specimens cannot be taken and at present, mucosal detail is poor, relying mostly on polypoidal morphology for lesion detection. Data interpretation can be time consuming, particularly if 3-D reconstruction is required.

Initially the main limitation of this investigation was a difficulty in distinguishing small polyps from faecal residue and examining collapsed segments of colon. The addition of prone imaging to the routine supine imaging has largely overc ome this problem, with improvement in the detection of polyps 5 mm in size or greater, from 75% to 88%[13]. Recent years have seen developments in spatial resolution and image manipulation such as colon mapping. The colon is "digitally

straightened" and opened for purposes of analysis of the colonic mucosal surface. In addition bowel preparation which permits the tagging of faecal residue and subsequent digital subtraction of these artifacts should lead to enhanced polyp detection. Currently the accuracy of polyp detection by virtual colonoscopy is superior to barium enema and is approaching conventional colonoscopy. Results are dependent on polyp size. A large randomised control trial of 180 patients, with 420 colonoscopically proven polyps, showed virtual colonoscopy to have a sensitivity and specificity of 85% and 93% respectively of detecting polyps 1 cm or more in size and 88% and 72% of detecting polyp s 5 mm or greater[13]. Fenlon reported that both virtual and conventional colonoscopy had a similar rate of complete examination of the colon (87% and 89% respectively). The former detected 89% of polyps greater than 6 mm[14].

The problem with conventional endoscopy remains incomplete examination of the pr oximal colon, either due to an occlusive lesion or patient intolerance. Virtual colonoscopy has the ability to examine the proximal colon above an obstructing o r impassable lesion. Morrin[15] compared virtual colonoscopy with bariu m enema in 40 patients who had a failed endoscopy. Virtual colonoscopy had significantly better views of all colonic segments and was better tolerated by the patient. The right colon is easier to evaluate than the sigmoid colon because a greater degree of distension is achievable and it lacks muscle spasm and hypertr ophy. Endoscopic blind spots behind mucosal folds are eliminated by virtual colonoscopy as the 3-D "fly through" can be done in both directions.

Virtual colonoscopy has the advantage of being able to examine the other organs in the abdomen and pelvis at the same time as the colon. Cross sectional views of the colon can show the wall thickness. Evidence of enlarged lymph nodes and liver involvement can be obtained. Morrin[16] correctly staged 13 out of 16 CRC's. Imaging of the liver makes it an efficient use of resources as many patients with a carcinoma have hepatic imaging to stage their disease. Much of the necessary pre operative data can be obtained in one visit with virtual colonoscopy. The uncovering of unrelated asymptomatic pathology has evoked some controversy. Hara[12] found highly clinically important secondary pathology in 11% of patients, including asymptomatic aortic aneurysms. The detection of other potentially life threatening diseases, which are common in this age group, can only be beneficial.

Virtual colonoscopy may revolutionise population screening for CRC as it is edging towards most of the factors needed for a screening tool. It is quick, non invasive, has a high patient acceptance, minimal morbidity, increasing sensitivity and can screen for several diseases at once. At present though, there are no reports in the literature on its use as a screening modality.

Trans-rectal ultrasound and magnetic resonance imaging

The importance of accurate pre operative staging of rectal cancer has grown with the increasing number of treatment options available. These include, local resection, trans abdominal resection, pre operative down staging and palliative radiotherapy. Benign or early malignant (pT1) rectal lesions can be excised locally. Patients with stage pT3 and pT4 tumours benefit from pre operative radiotherapy[17]. Asymptomatic or elderly patients with distant metastases may be given palliative chemoradiotherapy. Accurate pre operative staging of rectal cancer is thus essential in the planning of optimal therapy. Clinical examination, trans abdominal and trans-rectal ultrasound (TRUS), CT, phased-array pelvic body coil and endo-rectal MRI scanning are all used in some combination to assess the depth of rectal wall tumour invasion, and the presence of lymph no de and distant metastases. Despite these modern investigations, the "educated" digital rectal examination remains an important part of the assessment of recta l lesions, particularly in assessing tumour fixity and the need for down staging pre operative radiotherapy[18].

TRUS and MRI are currently both being used clinically in the pre operative assessment of rectal lesions. Both modalities can assess the depth of rectal wall invasion by the primary tumour and detect enlarged lymph nodes, suggesting tumour involvement. MRI has an advantage that it can simultaneously examine the liver for distant metastases. Unlike CT, there is no radiation risk to the patient with either modality. Many studies have shown that TRUS and MRI are more sensitive than CT in staging rectal lesions[19,20]. However, there are conflicting reports as to which of these 2 former investigations is the most accurate in determining the depth of invasion. This in part depends on the MRI technique, whether a surface (phased-array) or an endo-rectal coil is used and is operator dependent. Satoh[21] found TRUS more accurate than MRI, while Thaler[22] and Waizer[23] found no difference between the two. In two recent prospective comparative studies there was no significant difference between TRUS and endo-rectal MRI in both T and N[24] (Tables 2 and 3). Drew[25] highlighted the problem of inter-observer variation with only 31% accuracy in assessing depth of invasion. The accuracy of pre operative staging continues to improve as refinement and understanding of the MRI technique improves. Brown[26] has achieved a 100% T-staging accuracy, predicting depth of extramural tumour invasion to within 5 mm, with the use of high resolution phased-array pelvic coil MRI.

Results of lymph node staging are also conflicting,with neither investigation consistently showing a high level of accuracy. Thaler[22] found TRUS mo re accurate than MRI (80% versus 60%). Using MRI, McNicolas[27] reported a 95% accuracy, where as Drew[25] reported only a 58% positive predictive value. While TRUS and MRI are both reasonably sensitive at staging the depth of tumour, MRI is better at assessing tumour extension into adjacent organs. Both MRI and TRUS rely on highly skilled interpretation of the images, with the former being more expensive and the latter user dependent.

Hepatic metastases can be detected either by ultrasound, CT or MRI. Although ultrasound is quick and easy, MRI is the most sensitive by virtue of enhanced contrast resolution, with an accuracy of 81% in detecting liver[28]. The time has passed when the only pre operative staging of a rectal lesion was with the educated digital rectal examination. Pre-operative staging continues to improve with Brown[26] achieving a 100% T-staging accuracy with the use of high resolution phased-array pelvic coil MRI. Such technological developments will continue to slowly enhance patient outcome, as accurate pre operative staging will triage patients to the appropriate treatment.

The usefulness of intense follow up programs after curative CRC resection remain s controversial. Survival benefits have not been shown in a randomised control trials comparing intensive follow up to no follow[29]. Tumour recurrence is often diagnosed late, with less than 30% amenable to further curative surgery[30]. This recurrence is usually a marker of advanced disease. Radiologic pelvic surveillance is hindered by its inability to distinguish tumour recurrence from post operative fibrosis. Dynamic contrast enhanced MRI is still clAIMed to be the most accurate means of detecting early recurrent disease in the pelvis[21,23].

Table 2 Rectal cancer staging by TRUS and MRI[24]

	TRUS (%)	MRI (%)
T stage accuracy	80	85
N stage sensitivity	72	81
N stage specificity	80	66

Table 3 Rectal cancer staging by TRUS, MRI and CT[20]

Accuracy of detection	TRUS (%)	MRI (%)	CT (%)
Depth of invasion	81	81	65
Lymph node metastases	63	63	56

Positron emission tomography

Positron emission tomography (PET) was first applied to CRC in 1982. PET detects abnormal cellular metabolic activity. PET utilises a number of radiolabelled an alogues, including F-18-FDG, which are preferentially concentrated in malignant cells due to their accelerated glycolysis. F-18-FDG decays by positron emiss ion, which releases 2 protons, which are detected by the imager. Ultrasound, CT and MRI rely largely upon morphologic changes to detect tumour recurrence. The a dvantage of PET is that these cellular changes precede any structural abnormality. There have been 2 large studies showing PET to be more sensitive in detecting recurrent CRC than conventional imaging. Valk[31]reported a sensitivity of 93% *vs* 69% and a specificity of 98% *vs* 96% of PET versus CT respec tively. Whiteford[32] found similar results when comparing PET with CT and colonoscopy combined (sensitivity 90% *vs* 71% and specificity 92% *vs* 85% respectively). PET has detected unsuspected metastases in up to 32% of patients with normal[33,34]. The sensitivity and specificity of PET versus CT in detecting extrahepatic metastases is 94% *vs* 67% and 98% *vs* 96% respectively. As a result there should be a reduction in the number of unnecessary laparotomies, which should help to offset the high purchase cost of the PET hardware. In the future PET may also have a role in evaluating tumour response to chemotherapy and radiotherapy. Findlay[35] reported that the rate of uptake of F-18-FDG in CRC liver metastases compared to normal liver could discriminate tumour response from non-response to fluorouracil.

The main disadvantage of PET is its inability to distinguish between tumour and inflammation. PET has increased uptake in the setting of acute inflammation. This may be the reason for the high false positive rate reported by Schiepers[36], who had 11 false positive results in the chest out of 25 positive tests. Likewise, assessing the response of CRC to radiotherapy is limited by the inflammatory response it produces. This may decrease as experience with this modality increases.

The current role of PET in the management of CRC remains unclear. Early benefits have been shown in detecting recurrent and metastatic disease. Fusing the information it yields with CT and MRI images is enhancing its diagnostic interpretation. There are few reports of its use in screening and detection of primary lesions. Other disadvantages of PET include its limited availability and high cost (around 1.5 million capital cost) and tracer production and distribution.

Radioimmunoscintigraphy

Radioactive labelled antibody scans are being used in many aspects of medicine today. Like PET it detects cellular abnormalities prior to any structural change s in the tissues. There have been many monoclonal antibodies developed to detect CRC antigens, with sensitivity ranging from 74% to 92%. These antigens include B72.3, carcinoembryonic antigen (CEA), BW431/21 and PR1A3[37-40]. CEA molecules break off the colonic columnar cell membrane and circulate in the blood stream. This shed antigen significantly reduces the accuracy of CEA scanning. In contrast, PR1A3 is an anti-CEA monoclonal antibody that binds preferentially to columnar cell surface bound CEA rather than soluble CEA found in circulating[41]. Technetium labelled PR1A3 has been shown to detect 100% of primary CRC's. At present however, colonoscopy remains the investigation of choice for detecting primary lesions, although 99m-Tc PR1A3 is being used clinically to detect recurrent CRC, with a sensitivity and specificity of 96% and 50% respectively[42]. Despite the realization that it is difficult to detect recurrence early enough to be curable, in this study 25% had a beneficial alteration in their management plan.

Despite modern radiology and endoscopy, the aetiology of a recto-sigmoid mass or stricture may remain undiagnosed. Every surgeon has been in the dilemma of whether the lesion is malignant or diverticular in origin. The timing and extent of the resection is determined by the underlying aetiology. Malignant lesions require early surgery with radical en-bloc resection, while diverticular disease should have an initial conservative approach, followed by a limited resection when the inflammation has resolved. Ongoing efforts are concentrating on whether PR1A3 can differentiate between malignancy and inflammatory conditions and early results are encouraging[43]. Overall therefore, the role of radio immunoscintigraphy in the management of CRC seems likely to continue to expand as new, more specific antibodies are developed.

MANAGEMENT OF COLORECTAL CANCER

Colonic stents

The management of a malignant large bowel obstruction in the acute setting, in t he elderly with co-morbidity and those with unresectable disease remains problematic. A new treatment option, the expanding metallic stent, was first reported by Itabashi[44] in 1993. They can be used to relieve obstruction prior to surgery or as palliation and are inserted either with fluoroscopic or endosc opic guidance. Preoperative stenting of large bowel obstructions relieves sympto ms in 87%-100% within 96 hours[45-47]. Stenting AIMs to allow time for the patient's overall medical condition to improve. This reduces the complexity and number of stages of the surgery, with 90% of patients able to undergo an elective single stage procedure[47,48]. The short-term benefits of stenting are obvious, but we do not know of any long-term risks, such as tumour fracture and dissemination. If the procedure can be shown to be safe, then all patients should have a stent placed to improve their nutritional status, electrolyte balance and permit bowel preparation prior to surgery. All these factors will reduce mortality and morbidity and the number of defunctioning stomas required. The main risk of the procedure is perforation of the colon, but this is usually recognised early and patients can proceed to surgery, reverting to a conventional treatment plan. Law[46] reported a series of 24 malignant large bowel obstructions, with 1 perforation requiring a Hartmann's procedure and 3 patients later requiring a stoma. Turegano-Fuentes[49] reports severe tenesmus in 2 patients where the stent was placed low in the rectum.

Palliative stenting of advanced colorectal carcinoma is a quick, effective and non-invasive way of relieving symptoms. It avoids both a laparotomy and a stoma in a patient with a life expectancy of less than 12 months. At present the role of

stents in the management of resectable colon cancer remains uncertain. Stent design and technology and appropriate patient selection is continually evolving, making this a rapidly changing field. Overall results in the literatur e are variable and have mostly been confined to palliation. A prospective randomized trial comparing stenting with primary surgery in resectable disease is clearly required. Further studies need to be done into patient selection for stenting and timing of subsequent resection.

Minimally invasive surgery

Minimally invasive techniques have gained popularity over the past two decades, especially for upper gastrointestinal and biliary pathology. Laparoscopic cholec ystectomy has revolutionised biliary surgery and it is regarded as the procedure of choice for gallstones. Schlinkert[50] performed the first laparosco pically a ssisted hemicolectomy in 1991. Colorectal surgeons have been more cautious in ad opting laparoscopic techniques, particularly for malignant disease. Concern over the ability to perform safe dissection with adequate oncologic tumour and lymph node resection, intracorporeal anastomosis and port site recurrences has led regulating bodies in both the United Kingdom (National Institute for Clinical Exce llence) and United States of America (National Cancer Institute) to recommend that laparoscopic resections for CRC be restricted to clinical trials only. The advantages of minimally invasive surgery are well documented and include statistically significant less post operative pain, a reduced post operative ileus, a shorter hospital stay, better cosmesis and an earlier return to normal activity (Table 4)[51-53]. There is no difference in the cancer related outcome in experienced hands. In randomized control trials comparing laparoscopic and open colectomy, there was no difference in the length of colon, margin distance, length of mesentery and number of lymph nodes excised[54]. There is also no difference in 2 year recurrence free and crude survival rates[55]. Concern over the initially high rate of port site recurrences of up to 26% has not been sustained[56]. Since 1993, fifteen papers on port site recurrences have been published. Rates range from 0% to 1.7%, with a mean of only 0.65%. The threelargest series have a rate between 0.65% and 1.1%[57-59]. This is similar to the reported wound recurrence rates of 0.6% and 0.8% after open resection[60,61]. The cause of port site recurrence is still unknown, although Whelan[62] has suggested that they may be related to the "learning curve" phenomenon. Many patients, in both the laparoscopic and open groups however, had signs of disseminated intra abdominal disease. This fact is believed to be a more signifi cant risk factor for wound recurrence rather than the method of access. Over the years a number of preventative measures have been put forward to reduce recurrence, including the use of wound protectors, gasless laparoscopy, wound excision and peritoneal irrigation.

The advantages of laparoscopic resection for CRC is more pronounced in procedure s which do not require an incision to remove the specimen and perform the anasto mosis. An abdomino-perineal resection is an ideal laparoscopic case as the specimen is removed through the perineal wound and an end colostomy is created through a port hole. Darzi[63] suggests that better views of the mesorectal plane can be obtained using the laparoscope, allowing more precise dissection.

There is no doubt that minimally invasive surgery for CRC is safe, feasible and beneficial for the patient. It should however be limited to experienced laparoscopic and colorectal surgeons, with a low threshold for conversion to an open procedure. Patience is required as it usually takes longer to perform the procedure laparoscopically, especially in the beginning. Surgical principles of oncologic resection must not be compromised by the laparoscopic approach.

Table 4 Advantages of laparoscopic colectomy compared to open colectomy

Mean	Laparoscopic colectomy	Open colectomy
Narcotic use (days)	2.7	4.8
Ileus (days)	3.9	5.9
Hospital stay (days)	6.5	10.2

Transanal endoscopic microsurgery

Transanal endoscopic microsurgery (TEMS) was first performed by Buess[64] in 1983 in Germany. It has revolutionised local resection of rectal lesions, particularly malignant and those in the upper rectum. Traditionally, trans anal resection was limited to benign disease in the low and mid rectum. Many surgeons find this surgery cumbersome, with difficult access and poor views of the operating field. This usually limits its use to small lesions, usually less than 4cm diameter, within 6 cm-8 cm from the anus[65]. Surgery, with a curative intent, for malignant or upper rectal lesions, previously required trans-abdominal resection if endoscopic resection was not feasible. Mortality following trans-abdominal resection is around 5%-8%, but increases to 20% in patients over the age of 80[66]. Operative morbidity is around 25%[67].

There are two main advantages of TEMS in benign rectal disease. Firstly it allow s access to lesions in the mid and upper rectum. In two series of TEMS resection s most of the lesions would have been too high for a trans anal approach without TEMS, as the mean distance of the lesions from the dentate line was greater than 7 cm (Table 5)[68,69]. Secondly the local recurrence rate after TEMS (5%-9%), is much lower than traditional trans-anal resection (12%-25%)[70]. We feel that this low recurrence rate is due to the technique, as the rectum is constantly dilated by insufflation of CO_2 gas, enabling more precise surgery.

Table 5 TEMS excision of benign lesions[68,69]

	Lev-Chelouche	Neary
Number	46	21
Distance from dentate line (cm)	3-18 (mean 7)	5-17 (mean 10)
Size (cm)	1- 7 (mean 2.5)	2-12 (mean 3.9)
Recurrence	4 (9%)	1 (5%)

The use of local excision for malignant rectal lesions remains controversial. Willett[71] reported no difference in the outcome of pT1 and pT2 carcinomas, having favourable histologic features, resected trans-anally or trans-abdominally. The 5 year recurrence free rates were 87% and 91% respectively. Mellgren[72], on the other hand, reports a worse outcome with local resection when compared with trans abdominal resection. Overall 5 year survival rates were 69% and 82% respectively and local recurrence rates were 28% and 4% respectively. Mellgren however, did not exclude poorly differentiated lesions from trans anal excision, nor analyse the results of histological grade subgroup s. Also, these resections were performed using the less precise traditional trans-anal approach. The disadvantage of TEMS in malignant disease is the lack of lymph node sampling and clearance. The incidence of nodal involvement in pT1 tumours with a favourable

histological grade is only 3%, compared to 12% in pT1 lesions with poor prognostic grade[73,74] advocated TEMS for pT1 lesions due to lower morbidity, similar local recurrence rates and similar survival benefit to that of a major resection . We feel that TEMS is a suitable alternative treatment option for pT1 and pT2 lesions with favourable histology. It can also be used in more advanced lesions and those with unfavorable histology in the elderly or those unfit for major surgery[69]. Results of TEMS for rectal malignancy are shown in Table 6. By carefully selecting the patients who undergo local excision for a malignant rectal lesion, acceptable results in overall survival and local control can be achieved. Neary[69] reports no recurrence after a mean follow up of 20 months, which is better than 3% local recurrence after total mesorectal excision[75].

Table 6 TEMS excision of malignant lesions[68,69]

	Lev-Chelouche	Neary
Number	29	19
Distance from dentate line (cm)	3-15 (mean 8)	4-14 (mean 10)
Size (cm)	2-5 (mean 3.2)	1-6 (mean 3.2)
Recurrence	4 (18%)	0 (0%)

Mortality and morbidity rates of TEMS are less than 1.3% and 20% respectively. This extremely low mortality makes it a very valuable alternative to a trans-abdominal approach, provided the cancer related outcomes remain equal. Most of the morbidity is minor and include urinary retention and haemorrhage managed conservatively. Intra-peritoneal perforation is the major complication of this procedure, which can be sutured locally or treated by reverting to the original operative choice of an anterior resection. The hospital stay is only 3 days on average, which is much shorter than a trans abdominal resection[69]. The saving in bed costs more than offsets the initial outlay to purchase the reusable equipment. The advantages of TEMS are listed in Table 7.

Table 7 TEMS excision of benign and malignant lesions[68,69]

	Lev-Chelouche	Neary
Number	75	40
Mortality	1 (1.3%)	0 (0%)
Morbidity	10 (13%)	8 (20%)
Hospital stay (days)	2-13 (mean 5.5)	1-6 (mean 3.2)

TEMS will continue to play an increasing role in the management of rectal lesion s. It has the advantage of allowing precise surgery in the mid and upper rectum on both benign and early malignant lesions. Advanced cancers are still better de alt with by trans-abdominal resection, unless the patient is elderly or unfit for major surgery. In these two groups the risk of major surgery out weighs the benefits.

Radiofrequency ablation

Liver metastases ultimately develop in 50% of patients with colorectal cancer[76]. Surgical resection offers the only potential for cure and long term survival, with 5 year survival rates up to 46% after "curative surgery"[76,77]. However, less than 25% of patients with colorectal liver metastases are considered suitable for hepatic resection[78]. In those patients where their tumour load, tumour distribution or co-morbidity prevents attempte d curative resection or they have recurrent disease, there are other therapeutic options. Palliation can be achieved with systemic or hepatic arterial chemotherapy, cryotherapy, and radioactive yttrium-90 microspheres, although cure is ext remely unlikely[79]. The mean survival of patients undergoing the different treatments for CRC liver metastases is listed in Table 8.

Table 8 Median Survival following treatment for CRC liver metastases

Treatment	Median survival
Supportive care[91]	7-11 months
IV Fluoruoracil chemotherapy[91]	11-14 months
Hepatic artery chemotherapy[91]	15-17 months
Radiofrequency ablation[84]	27 months

Radiofrequency ablation (RFA) by applying an alternating current at 300-500 kHz causes frictional heating of tissues to between 50-85 degrees Celsius. This thermal injury results in coagulative necrosis of spheres of tissue usually between 3 cm-5 cm in diameter[80,81]. It is safe and effective, with up to 98% of lesions showing persistent complete necrosis at 15 months[82-84]. Gillams[84] has shown RFA improves survival of patients with CRC liver metastases unsuitable for resection. RFA was performed in 69 patients, with an average number of metastases of 2.9 (range 1-16) and a mean maximum diameter of 3.9 cm (range 1-8). 26% had undergone previous hepatic resection and 93% received chemotherapy. The 3 year survival rate and mean survival time from diagnosis was 34% and 27 months respectively. 58% developed new hepatic metastases and 33% new extrahepatic disease. A subgroup of 24 patients, with less than 4 metastases, with a maximum diameter of 5cm, performed better, with a median survival of 33 months. Bilchik[85] recommends RFA for un-resectable primary or secondary malignant liver lesions up to 3 cm in size. Mortality and major morbidity occurred in 1.4% and 3.2% respectively, the latter being needle tract seeding. Minor morbidity, including pain and sepsis, occurred in 12%. RFA has the advantages of being safe, well tolerated and can be applied percutaneously, laparoscopically or at laparotomy. Lesions close to the diaphragm and colon are best accessed under direct vision by either of the latter 2 approaches. Percutaneous application has the added advantage of a shorter hospital stay of less than 24 hours. The role of RFA should continue to expand, as it is beginning to be applied to small lesions in the remaining liver segments during resection. In turn, this will broaden the horizon of hepatic resection.

Robotics

Robotics is at the forefront of the technological advances in medicine. Many innovations are being developed to aid laparoscopic surgery. Robotic arms has enabled solo laparoscopic surgery, which abolishes the need for an assistant, has greater stability of views and does not fatigue[86]. Voice activated robotic arms are being produced, which further enhances their ease of use. One of the drawbacks of laparoscopic surgery is the lack of depth perception. Robots (Davinci from Intuitive Surgical Ltd) and stereoscopic glasses (Optimize Interna tional) are being developed with 3-dimensional tactile and visual capabilities. Computer assisted colonoscopy, using a miniature self propelled robotic probe, is being developed to reduce the discomfort and increase patient acceptance of colonoscopy[87]. Tele-medicine will have an increasing role as we shift to digital data based investigations. Expert opinions can be given over the telephone, thus improving patient care.

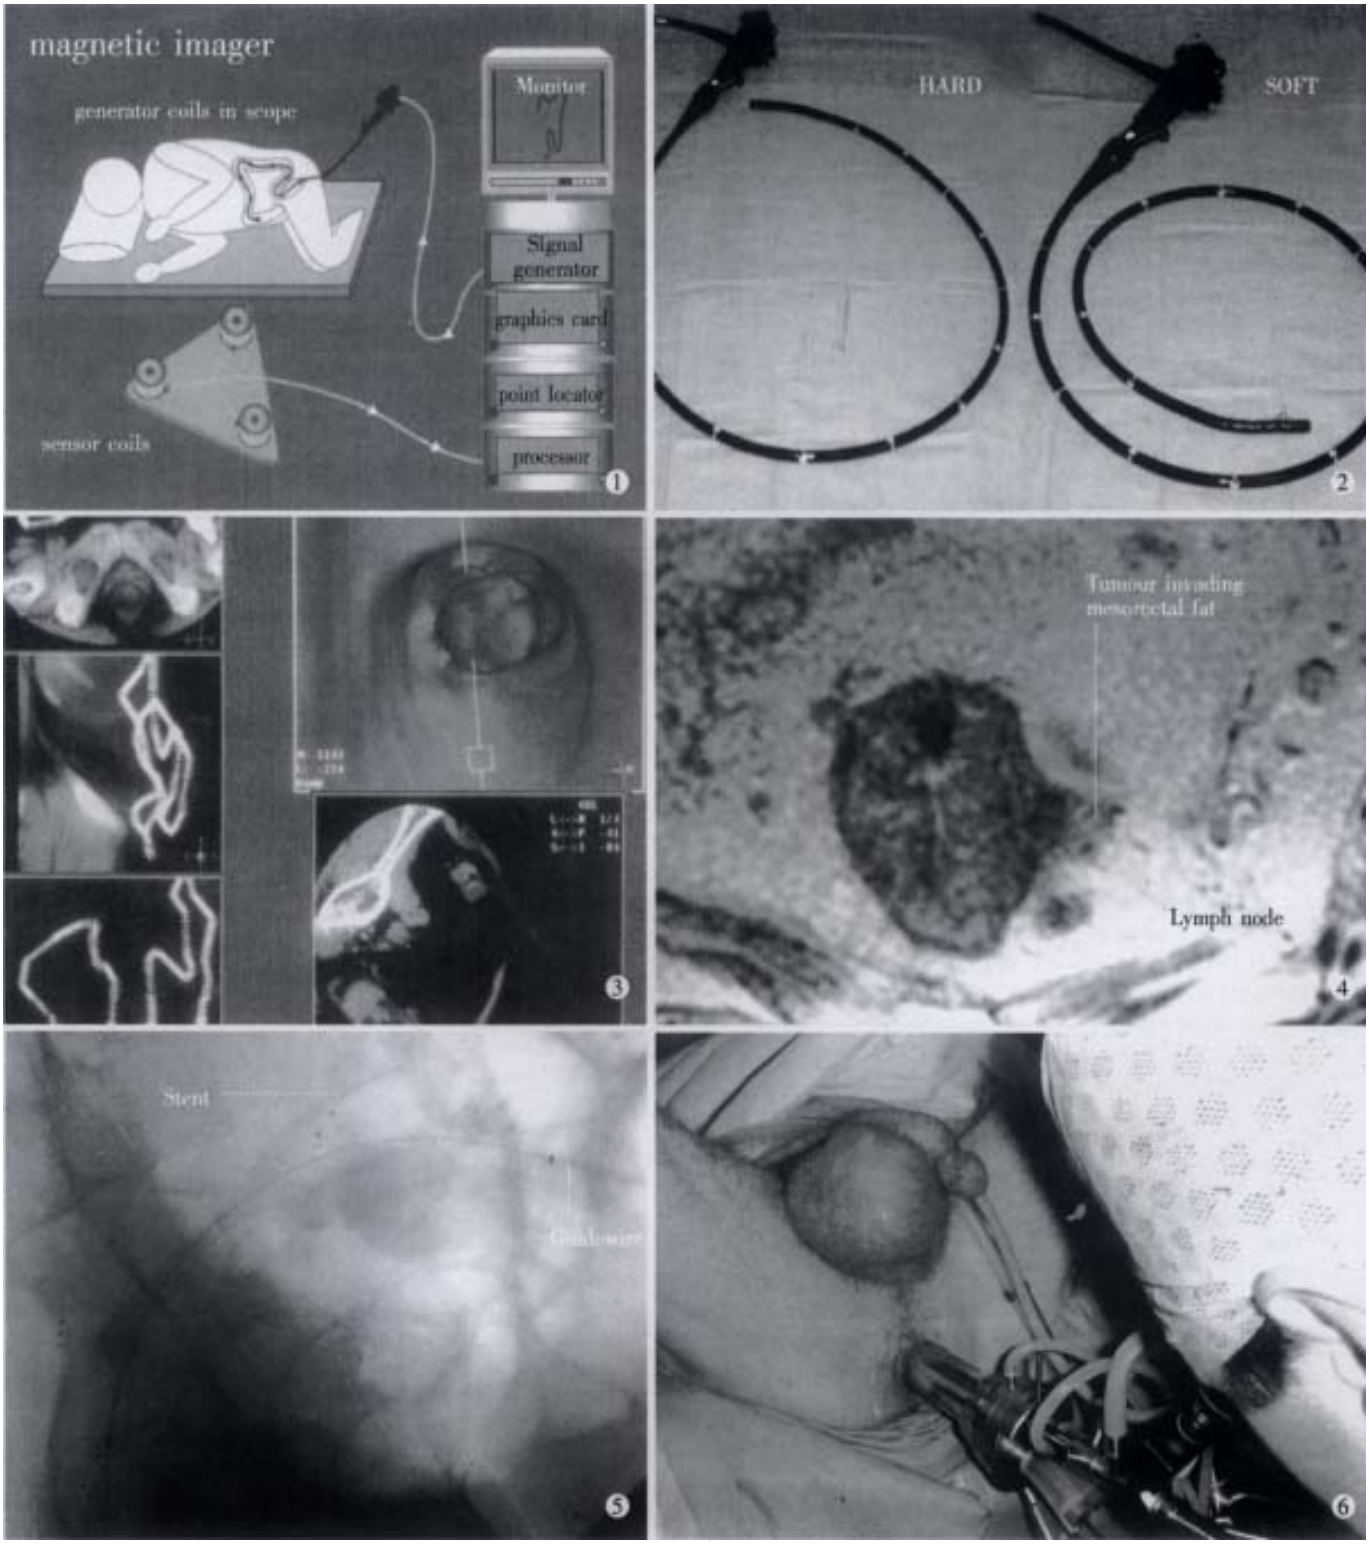

Figure 1 Magnetic imager colonoscope: magnetic generator coils built into the endoscope enable its position and presence of looping in the colon to be identified on the monitor.

OUTCOME OF COLORECTAL CANCER

Artificial neural networks

Analysis of the treatments available to patients with CRC traditionally relied on population statistics. These predictions have little meaning for individual patients. Artificial neural networks (ANN) are particularly suited for the analysis of complex databases and the relations within these data sets[88]. They allow recognition of patterns in complex biological data sets, which cannot be detected in conventional linear statistical analysis. The advant age of ANN's is that once the network is established, it can be used to predict outcome for individual patients. Imputation of data is the first step in setting up and training a network, and the more data entered the better. Outcome is entered at the same time. Once the network is validated using a second set of data and outcome, data from an individual can be entered and a prediction of outcome for that individual calculated.

Neural networks have been applied to several aspects of CRC. Bottaci[89] analysed pre operative, operative and follow up data on 334 patients treated for CRC. ANN's were used to predict the death of an individual patient and compared to a surgeon's opinion. In the first institution where the initial data to train the network was collected, the network was marginally more accurate (80% *vs* 75%). When this ANN was used on data from a second institution, its accuracy increased to 90%, compared to the surgeon's prediction of death of 79%. Neural networks have also been used to accurately predict the lymph node status and tumour stage of a resected colonic malignancy, based on the patient's age and tumour biopsy grade and immunohistochemistry[90]. Data from 75 patients were used to train the network. The ANN correctly predicted the lymph node status of 20 of 24 test cases (sensitivity 85%, specificity 80%) and the tumour stage of 21 of 24 test cases (sensitivity 92%, specificity 82%). The application of neural networks in coloproctology is endless. Once a network is established from a data set, the outcome for each individual patient on any aspect of CRC can be predicted.

Shankar A, Russell RCG. Recent advances in the surgical treatment of pancreatic cancer. *World J Gastroenterol*, 2001;7(5):622-626

INTRODUCTION

Pancreatic cancer remains the fourth commonest cause of cancer related death in the western world[1]. The prognosis remains dismal due partly to late presentation, with associated low resectability rates, and the aggressive biological nature of these tumors. The median survival time from diagnosis in unresectable tumors remains only 4-6 months.

For those patients amenable to surgical resection over the last 20 years have seen marked improvements in postoperative mortality and morbidity, especially in specialist pancreatic centres[2,3]. Despite these changes long-term survival remains low, with a total 5-year survival rate remaining less than 5%. Patients with ampullary cancer have a better 5-year survival of 40%-60%.

Resection, however, remains the only chance of long term survival with adjuvant therapies providing disappointing results. Operability remains low due to the local and distant extent of the disease. Assessment of this extent has been greatly advanced by modern radiological techniques.

PREOPERATIVE ASSESSMENT

Once distant disease has been excluded, selection of patients for resection is crucial if the rate of irresectability discovered at operation is to be kept to a minimum.

Angiography

Once considered crucial in the assessment of operability, angiography is now virtually unnecessary. It was argued that the venous phase of the arteriogram was fundamental if invasion of the superior mesenteric and portal vein were to be excluded. This has now been superseded by improvements in helical CT scanning, which is able to accurately determine venous involvement. The issue of preoperative detection of vascular anomalies should not be an indication for routine angiography in the hands of experienced pancreatic surgeons.

Computerised tomography (CT)

CT is still the traditional imaging modality for staging pancreatic cancer, although it lacks specificity and sensitivity. Spiral CT with intravenous contrast offers higher resolution than conventional CT and improves diagnostic and staging accuracy[4]. Unfortunately CT is still limited by its ability to differentiate between benign and malignant lesions and also may miss subcentimetre hepatic deposits and peritoneal seedlings. The impact of helical CT scanning using defined pancreatic protocols with multiplanar reconstruction has yet to be assessed, but the extent of local disease, involvement of arteries and veins and lymphatic spread can be assessed with improved accuracy (as illustrated in the following CT images).

Magnetic resonance imaging (MRI/MRCP)

Although a relatively new technique for assessing pancreatic lesions, MRI is particularly useful at differentiating inflammatory from neoplastic pancreatic lesions. Pancreatic adenocarcinomas are usually low signal on T1 and T2 weighted images[5], although it has as yet not been shown to be superior to CT in assessing operability. The use of magnetic resonance endoscopy may in the future improve the accuracy of MRI. At present, both MRI and CT scanning give additional information such that both techniques are of value in assessment.

Laparoscopy and laparoscopic ultrasound

Laparoscopy has the advantage of being able to detect small (<10 mm) hepatic deposits (with and without laparoscopic ultrasound), assess degree of lymph node involvement and identify peritoneal disease over that detected by conventional imaging. The position of the pancreas in the retroperitoneal area does, however, limit its ease of application.

When combined with laparoscopic ultrasound, a sensitivity up to 90% for predicting operability have been suggested[6,7] which may be further improved with the addition of peritoneal lavage cytology[8]. Positive lavage cytology for tumor cells is associated with lower resectability and lower survival rates[9].

Determination of irresectability by laparoscopy in patients deemed operable by CT is usually due to the detection of occult liver metastases and peritoneal seedlings. Laparoscopic ultrasound allows direct placement of the probe onto the pancreas providing views of the tumor in relation to the superior mesenteric and portal veins. Such reports have led to the routine use of staging laparoscopy in some units prior to resection, although laparoscopic ultrasound is still relatively uncommon.

The issue of port site metastases is a risk in this technique, although the mechanism is not completely understood.

Endoscopic ultrasound (EUS)

This technique involves real time ultrasound scanning from within the lumen of the stomach and duodenum. Initial reports suggested highly reproducible results in expert hands in relation to staging of pancreatic cancer, especially in regard to vascular invasion, providing more accurate results than conventional CT[10]. It is less useful at demonstrating malignant lymph node involvement due to confounding factors such as nodal reactivity and inability to differentiate nodal micrometastases[11]. EUS is also used to obtain fine needle

aspiration cytology of pancreatic masses and has yielded almost 80% diagnostic sensitivity[12]. One of the main drawbacks to this technique is that it is highly user dependent.

Positron emission tomography (PET)

PET involves the injection of radiolabelled glucose which is preferentially picked up by malignant cells and metabolised. PET scanning has found increasing applications throughout oncological assessment and when combined with CT scanning provides both anatomical and functional information. The most commonly used agent is 2-Fluoro-2-deoxy-D-glucose (FDG), which when taken up by cells and metabolised emits positrons that collide with electrons creating gamma rays, which are then picked up by a ring detector.

PET aids diagnosis of adenocarcinoma of the pancreas and also improves the sensitivity of conventional imaging in the detection of peritoneal and hepatic disease, enabling correlation between CT detected abnormalities and PET findings. Initial studies suggest that when PET is combined with EUS it may be more accurate than CT in detecting metastatic disease[13].

In addition to aiding diagnosis and staging, the extent of uptake of the radiola belled substrate may correlate with the aggressiveness of the tumor, with a higher uptake predicting shorter survival[14,15]. This extent of expression may also help differentiate benign from malignant lesions[16] .

SURGICAL APPROACH TO RESECTABLE PANCREATIC CANCER

Ninety percent of all malignant pancreatic exocrine tumors are accounted for by pancreatic duct cell cancer, with about two thirds occurring in the head of the gland. Convention states that tumors arising from the left side of the gland have a worse prognosis due to later presentation. Whilst it is true that tumors arising in the head may be detected at an earlier stage due to the associated jaundice, more recent data suggests that resectable tumors in the head, uncinate process and neck have a similar survival to those in the body and tail[3].

A number of issues arise in relation to the surgical approach to pancreatic cancer and include: preoperative biliary drainage, extent of lymphadenectomy, vascular resection and pylorus-preserving versus standard Whipple.

Preoperative biliary drainage

The issue of preoperative biliary drainage either endoscopically or transhep atically remains controversial. Trede and Schwall, in a large retrospective study, demonstrated that patients who underwent preoperative endoscopic stenting had a reduced incidence of postoperative infective complications[17]. Other studies failed to show any benefit and suggested an increased postoperative risk associated with stenting in relation to sepsis introduced with instrumentation. Povoski et al demonstrated that the primary predictor of postoperative complications was the preoperative placement of biliary stents[18].

For patients in whom the date for resection is to be delayed, or in those undergoing palliation of jaundice, biliary stenting is usually recommended.

Extent of lymphadenectomy

A wide variety of opinion exists regarding the extent of lymphatic dissection for both tumors on the right and left side of the pancreas. Results vary depending upon the institution / country of origin and is partly due to the disparity that exists in the definitions used. Recent standardisation of terminology in this regard may clarify future studies, with precise definitions of 'standard', 'radical' and 'extended radical' lymphadenectomy.

Although extended surgical procedures popularised in Japan may increase the resectability rate up to 50%, this does not necessarily translate into improved survival. The retrospective nature of much of this data renders interpretation difficult and requires validation. Node positivity in many series is a strong negative predictor for survival with a 5-year survival stated to be less than 5%[19,20] whilst others using radical lymphadenectomy demonstrate a 5-y ear survival of up to 70% for node negative patients[21], results not reproduced elsewhere. These results are supported by the finding of metastatic disease in lymph nodes removed during extended lymphadenectomies for early disease[22].

Extended lymphatic resection when performed by exponents of this technique report equivalent rates for morbidity and mortality to those found in standard resections[23]. Hirata et al reported a retrospective series of 1001 resected pancreatic cancers from 77 centres in Japan[24]. The majority of these were stage IV according to the standard of Japanese Pancreatic Society (JPS). One hundred and thirty-one patients had a D0 resection (no lymph nodes), 365 a D1, and a D2 in 505 (422 of whom also underwent a further resectional procedure such as IV C reconstruction). The mortality rate was 2.5%. Improved survival was only found in those patients with N1 nodes positive who had a D1 resection.

In a retrospective series, Naganuma *et al* demonstrated a significant improment in survival for patients who underwent extended resections compared to earlier more 'standard' procedures[25]. This study has several failings, one of which is its retrospective nature, and another is the highly selective process of determining which patients underwent a extended resection in the second group.

A relatively small (n = 81) randomised, multicentre, prospective study of standard versus extended lymphadenectomy was reported by Pedrazzoli *et al*[23]. There was a significant improvement in survival for the node positive patients in the extended lymphadenectomy group, although when the whole group was analysed there was no difference. The survival curve of node positive patients undergoing extended lymphadenectomy could be superimposed on that for node negative patients. There was no difference in postoperative morbidity and mortality between the two groups. Multivariate analysis of all the patients demonstrated that long-term survival was significantly affected by tumor differentiation, tumor size, nodal involvement and more than a four unit blood transfusion.

Vascular resection

Whilst technically feasible in some patients *en bloc* resection of infiltrated peripancreatic vessels does not appear to improve survival, with vessel involvement a strong negative predictor of outcome[26,27]. There are few groups reporting worthwhile survival figures for patients undergoing vascular resection and again in a retrospective format[28]. Morbidity is high due to the extensive autonomic neurectomy causing diarrhoea.

Some groups have advocated a more widespread use of venous resection in view of the high rate of vessel involvement by tumor in some patients thought to be macroscopically clear, although the relevance of such findings to survival is hard to quantify[29].

Pylorus-preserving versus standard Whipple

Traditional teaching had been that proximal pancreatic resection should be combined with distal gastrectomy to reduce

gastric acid production and hence minimise the risk of postoperative stress ulceration and also to improve oncological clearance. This approach has now been modified with preservation of the en tire stomach and proximal duodenum. This reduces the complications associated with gastrectomy and does not appear to increase the risk of marginal ulceration. Apart from dorsally placed tumors abutting the duodenum oncological clearance does not appear to be affected although there is a higher incidence of postoperative delayed gastric emptying[30].

COMPLICATIONS OF PANCREATIC RESECTION

In specialist centres perioperative mortality should be less than 5% and in some are less than 1%, although the incidence of postoperative complications is still 30%-40%[2,3,34]. The complications most commonly found are leakage of the pancreatic anastomosis, haemorrhage, abdominal abscess and delayed gastric emptying.

Pancreatic fistulae occur with a reported frequency of 4%-24%[3,35] and may progress to a full leak with associated sepsis and haemorrhage. Such serious leaks occur in less than 5% in specialist units and may carry a mortality of up to 40%. Clearly, access to experienced interventional radiology is crucial in these cases to deal with associated intra-abdominal collections. There is a correlation between the frequency of leaks and the pancreatic consistency, duct diameter and extent of residual exocrine function.

Although some groups routinely stent the pancreatic duct there is currently no randomised data to substantiate this practice, which also applies to the practice of creating separate Roux loops for high risk cases. The method of reconstruction is also debatable, *i.e.* end-to-side or end-to-end, or invagination versus mucosa to mucosa, but again lacks randomised data. The experience of the surgeon is probably the most crucial factor in determining leak rates[36]. Inhibition of pancreatic exocrine function using the somatostatin analogue octreotide prophylactically in the perioperative period has been shown to reduce postoperative morbidity associated with pancreatic fistulae in a number of randomised studies in Europe[37,38].

SURVIVAL POST RESECTION

According to the review on the resection of pancreatic cancer published in 1996 by Sperti *et al*[39], the rate of resection was approximately 20% with a mean operative mortality of 9% and a 5-year survival rate of 12%.

Tumor biology appears to be the most important predictor of survival, with multivariate analysis demonstrating that aneuploidy, tumor size and nodal status are all independent predictors of outcome[40].

Clear resection margins is a crucial measure of long-term survival, especially in relation to the posterior aspect of the tumor[41]. This mode of spread occurs predominantly along the perineural sheath and lymphatics.

Extended resections, whilst improving resectability rates, do not appear to improve survival but await results of randomised studies.

The largest single institution series to date reported by Sohn *et al* has an overall 5-year survival rate of 17% for the 208 patients followed for at least five years (of a total of 616 patients included in the series)[42]. Improved survival was found in those with less than 750 mL intra-operative blood loss, no transfusions, negative nodes, clear margins and tumors less than 3 cm. In addition, there was a demonstrable survival advantage for those patients receiving adjuvant chemoradiotherapy. For those patients with tumors less than 3 cm, node negative with clear margins, the 5-year survival rate was 31% in this series. The issue of blood loss has been noted previously to be a predictor of survival[40] and should be minimised in all cases.

Two other large retrospective series from France[43] and USA[44] of 555 and 327 resections demonstrated 5-year survival rates of 15% and 12% respectively for the groups as a whole.

The use of postoperative chemoradiotherapy has been the subject of much debate. After an apparently curative resection a large number of patients will subsequen tly develop liver and/or peritoneal metastases. The North American Gastrointestinal Tumor Study Group (GITSG) randomised patients to receive radiotherapy and 5-fluorouracil or supportive therapy only, with treatment continuing for two years. Patients receiving adjuvant therapy had a significant survival advantage[45].

These results were contradicted by the results of two European studies-ESPAC-1[46] and The EORTC gastrointestinal study group[47]. The EORTC study randomised 218 patients with T1-2 N0-1a M0 pancreatic head or T1-3 N0-1a M0 periampullary cancer to receive post resection either 5FU and external beam radiotherapy or observation alone between 1987 and 1995. There was no significant improvement in either survival or local recurrence rates in all groups studied. The only difference in treatment protocol between this study and the GITSG trial[45] was a reduced dose of 5FU, 5FU was only given in the first week of chemotherapy. Currently adjuvant therapy cannot be recommended in the context of a randomized control trial.

Some success has been reported in the use of neoadjuvant therapy to down-stage tumors to an operable state, although these are all small, non-randomised studies. Snady *et al* looked at two groups of patients over an 8-year period[48]. Those with initially diagnosed locally invasive but regional tumors were given a combination of 5FU, streptozocin, cisplatin and radiotherapy. The others were patients who underwent resection without preoperative treatment (the majority of whom underwent postoperative adjuvant chemotherapy with or without radiotherapy). Those patients who became down-staged and underwent subsequent resection had significantly better survival than those in the non-pr e treated group.

QUALITY OF LIFE (QOL) AFTER PANCREATICODUODENECTOMY

Few studies have addressed the issues about quality of life after pancreaticoduo denectomy, concentrating rather on morbidity, mortality and survival. McLeod et al compared 25 age- and sex-matched controls undergoing cholecys tectomy with an equivalent number undergoing pancreaticoduodenectomy[31], measuring 6 quality of life assessments. This study demonstrated no difference between the two groups in terms of the quality of life measures and also showed a return to normal preoperative body weight and nutritional status in the pancreaticoduodenectomy patients. Melvin et al compared the quality of life in patients undergoing a standard Whipple with those undergoing a pylorus-preserving procedure[32]. Mental health was the same but physical health quality of life was lower in the Whipple group, with no association noted with the pathology found, *i.e.* benign or malignant. Huang et al assessed 192 patients undergoing pancreaticoduodenect omy using the three domains of quality of life, physical, psychological and social and compared these to healthy patients and those undergoing laparoscopic cholecystectomy[33]. The pancreatectomy patients manifested

similar quality of life profiles to the control groups, but did experience problems related to weight loss, abdominal pain, steatorrhoea and diabetes. When a subgroup analysis was performed, the patients undergoing surgery for chronic pancreatitis scored significantly lower in all three parameters when compared to the control group, presumably secondary to the chronicity of their disease.

SURGICAL PALLIATION OF ADVANCED PANCREATIC CANCER

Given the low rate of resectability for patients with pancreatic cancer, the issue of palliation of symptoms becomes of paramount importance. Surgery may play a part in the management of jaundice, duodenal obstruction and pain.Relief of jaundice plays a key role in improving quality of life and survival in patients with advanced pancreatic and periampullary cancer. The two options are endoscopic/percutaneous stenting (either metal or plastic) and open/laparoscopic surgical drainage. Endoscopic drainage has a success rate of 85%-90% with a relatively low complication rate. Stent occlusion may be a problem and in an effort to overcome this metal stents are now commonly utilize d for proven inoperable malignant tumors. Their greater patency rates compared to plastic stents have been demonstrated in randomized controlled trials. Even if occlusion does occur, tumor ingrowth can be ablated using laser/thermal techniques, otherwise further stents can be placed through the middle, beyond the site of occlusion. For those patients in whom endoscopic access has failed, percutaneous transhepatic stents can be used, although with a higher risk of complications[49].

For those patients who at the time of surgery are found to be inoperable and who have biliary obstruction, surgical biliary drainage is necessary. A variety of techniques are available, although the original cholecystjejunostomy has now been superseded due to the low long-term patency rates. The preferred method of bypass in this institution is choledochoduodenostomy, as this is relatively simple to perform with minimal morbidity and long-term patency. Other groups used choledochojejunostomy, which is suggested by some to have longer patency rates[50].

Operative drainage has a higher morbidity and mortality than stenting[51] and should be reserved for those patients found to be inoperable at surgery and the rare instance in which stenting by either route has failed, bearing in mind the mortality rates of open drainage of 19%-24%.

The issue of duodenal obstruction is controversial, with debate over whether or not routine gastric bypass should be performed at the same time as surgical biliary bypass. Approximately 5% of patients with pancreatic cancer will have actual mechanical obstruction and 17% of patients undergoing biliary bypass alone will develop subsequent duodenal obstruction. A proportion of patients undergoing gastric bypass procedures will develop delayed gastric emptying, with significant morbidity attached to this procedure. Therefore, it seems sensible to reserve gastric bypass for those with definite obstruction or evidence of impending problems, especially given the availability of endoscopically placed metal duodenal stents.

Pain is a major problem in the management of patients with pancreatic cancer and aside from standard analgesic regimens a variety of nerve ablative technique s are available. Coeliac plexus blockade, either at the time of surgery or percu taneously, has been reported as having significant success rates[52]. More recently thoracoscopic division of the splanchnic nerves has reported variable success rates and the results of large randomised studies are underway. Initial enthusiasm was tempered by high complication rates which have now drastically reduced. Unilateral versus bilateral approaches have been assessed and the left side appears to be the most important for its analgesic effect in pancreatic cancer.

CONCLUSION

Pancreatic cancer remains a disease with a dismal prognosis despite improvements in surgical technique. Accurate staging of disease is crucial if inappropriate surgery is avoided, with the choice of technique depending upon available facilities and expertise.

Modifications in surgical approach are unlikely to modify the outcome, and only improvements in adjuvant treatments, coupled with a greater understanding of the biological nature of the disease process, will the survival be improved. Meanwhile, patients with pancreatic cancer should be managed by multidisciplinary teams in specialist centres, if morbidity and mortality associated with the management of this disease are to be minimized.

INTRODUCTION

Tetrandrine (Tet) is a dibenzylisoquinoline alkaloid isolated from Stephania tetrandra S. Moore, a Chinese herbal medicine. In the past decade, lots of studies demonstrated that Tet has multiple bioactivities. It is promising to use Tet as an antifibrogenetic in liver or lung fibrosis with or without portal or pulmonary hypertension, as well as an immunomodulating and anticarcinoma drug.

PHARMACOLOGY

Ca^{2+} channel blocking activity

Abnormal Ca^{2+} signaling and elevated concentration of intracellular free Ca^{2+} are the basic pathophysiological events involved in various diseases. As a Ca^{2+} antagonist, Tet can inhibit extracellular Ca^{2+} entry, int ervene in the distribution of intracellular Ca^{2+}, maintain intracellular Ca^{2+} homeostasis, and then disrupt the pathological processes. As shown in whole cell patch-clamp recordings, Tet blocked bovine chromaffin cells voltage-operated Ca^{2+} channel current in a time- and concentration-dependently manner. In rat phaeochromocytoma PC 12 cells, 100 μmol·L^{-1} Tet abolished high K^+ (30 mmol·L^{-1}) - induced sustained increase in cytoplasmic Ca^{2+} concentration, inhibit bombesin-induced inositol triphosphate accumulation in NIH/3T3 fibroblast and abolish Ca^{2+} entry[1]. In rat glioma C6 cells, studied with fluorometric ratio method, Tet did not affect the resting cytoplasmic Ca^{2+} concentration, but it inhibited IP3 accumulation and the sustained and peak elevation of cytoplasmic Ca^{2+} concentration induced by bombesin and thapsigargin, a microsomal Ca^{2+}-ATPase inhibitor, in a dose-dependent manner. The dose of Tet needed to abolish the sustained and peak elevation of cytoplasmic Ca^{2+} concentration induced by bombesin and thapsigargin was 30 μmol·L^{-1}[2]. Bickmeyer *et al*[3] demonstrated that NG108-15 cells treated with 100 μM Tet for seven minutes could block voltage-dependent Ca2+ entry induced by depolarization with 50 mM KCl. Tet could block non-voltage-operated Ca^{2+} entry activated by intracellular Ca^{2+} store depletion induced by thapsigargin and could release intracellular Ca^{2+} in HL-60 cells, and could therefore increase concentration of intracellular free Ca^{2+}, elicit therapeutic effects. We have previ ously demonstrated that Tet could concentration-dependently block extracellular Ca^{2+} entry into hepatocytes, promote mitochondria Ca^{2+}-uptake, and inhibit Ca^{2+}-mobilizing from mitochondria. However, the blockade of Ca^{2+} channel played the most important role in maintaining Ca^{2+} homeostasis, but not intracellular Ca^{2+} distribution.

In the presence of extracellular Ca^{2+} (1.3 μmol·L^{-1}), glutamate, serotonin and histamine significantly increased the intracellular Ca^{2+} concentration in a dose-dependent manner. 30ìmol·L^{-1} Tet significantly inhibited the increase in intra cellular Ca^{2+} concentration induced by glutamate, serotonin and histamine by 28.0%, 46.8% and 29.0%. In Ca^{2+} free Hanks' solution, Tet did not produce a significant inhibitory effect on the increase in intracellular Ca^{2+} concentration caused by serotonin and histamine. These results indica ted that Tet conducted blocking of Ca^{2+} influx from the extracellular site via NMDA, 5-HT_2 and histamine type I receptor-operated Ca^{2+} channels and has no obvious effect on the Ca^{2+} release from intracellular Ca^{2+} stores[4]. In addition, Tet also inhibited extracellular Ca^{2+} entry and intracellular Ca^{2+} mobilization induced by norepinhprine and angiotonin II via corresponding receptor respectively[3,5]. Taking together, in different tissues and different kinds of cells, Tet may block the Ca^{2+} channel through different mechanisms. It can block the voltage- and/or receptor-operated Ca^{2+} channel. Nevertheless, in some kind of carcinoma cells, Tet does not affect Ca^{2+} channel, but promote Ca^{2+} release from intracellular stores and elevate the cytosolic free Ca^{2+} concentration.

Immunomodulating activity

Clinically, Stephania tetrandra S. Moore has been thought to be effective in treating autoimmune diseases such as rheumatoid arthritis and systemic lupus erythe matosus. Tet, the active ingredient isolated from *Stephania tetrandra* S. Moore, has potential immunomodul ating and anti-inflammatory effects. T-lymphocytesplay a critical role as autoactive and pathogenic population in autoimmune and inflammatory diseases. Some experimental data showed that, through down-regulating the protein kinase C (PKC) signaling, interleukin-2 secretion and the expression of the T cell activation antigen (CD71), Tet inhibited phobol 12-myristate 13-acetate (PMA)+ionomycin-induced T cell proliferation dependent on interleukin-2 receptor alpha chain and CD69, such an action was unrelated to Ca^{2+} channel blockade[6]. Tet (0.1-10 μmol·L^{-1}) significantly inhibited neutrophil-monocyte chemotactic factor-1 upregulation and adhesion to fibrinogen induced by N-formyl-methionyl-leucyl-phenylalanimne and PMA. Tet at 0.1-100 μmol·L^{-1} caused dose- and time-dependent loss of cell viability of mouse peritoneal macrophages, guinea-pig alveolar macrophages and mouse macrophage-like J774 cells, reduced production of oxygen free radical oxygen, down-regulated synthesis and

release of some pro-inflammatory cytokines[7,8].

Nuclear transcription factor kappa B (NF-kappa B) is a multiprotein complex which regulates a variety of genes concerned with immunity and inflammation. For the alveolar macrophages, Tet could inhibit the activation of their NF-kappa B and NF-kappa B-dependent reporter gene expression induced by endotoxin , PMA, and silica in a dose-dependent manner. Western blot analysis suggested that the inhibitory effects of tetrandrine on NF-kappa B activation could be attributed to its ability to suppress signal-induced degradation of I kappa B alpha, a cytoplasmic inhibitor of the NF-kappa B transcription factor[7,9].

Conducting tumor cell apoptosis

To induce tumor cell apoptosis is one of the important chemotherapeutic strategies for malignent tumors. Tet inhibited both proliferation and clonogenicity of human leukemic U937 cells at an optimal concentration of 2.5 $mg \cdot L^{-1}$. The characteristic morphological changes of apoptosis were observed under light microscopy and DNA fragmentation was noted by gel electrophoresis in these cells. Moreover, flow-cytometric detection of surface phosphatidyl serine expression of cells after treatment with Tet confirmed the induction of apoptosis in these cells[10]. Tet concentration-dependently inhibited the proli feration of human leukemic HL-60 cells. Morphological observation and DNA analysis revealed that Tet caused cell shrinkage with the formation of apoptotic bodies, and showed clear evidence of DNA fragmentation[11]. Tet was found to induce pronounced morphological changes characteristic of apoptosis and extensive DNA fragmentation in the human BM13674 cell line 8 h after treatment[12]. The induction of apoptosis by Tet was much more rapid in CEM-C7 cells (4 h) than in the same cells treated with glucocort icoids (40 h), and did not require de novo protein synthesis[13]. These results indicate that Tet may have value as an anti-neoplastic agent.

Reversing multidrug resistance (MDR)

The occurrence of MDR to chemotherapeutic drugs is a major problem for successful cancer treatment. The overexpression of cell membrane P-glycoprotein (P-gp) is one of the major mechanisms of MDR. P-gp pumps antitumor drugs out of tumor cells, causing drug resistance.

Tet (3 $\mu mol \cdot L^{-1}$) reduced the paclitaxel concentration required to achieve 50% inhibition of cell growth (EC50) of HCT15 (P-gp-positive) cells about 3100-fold, and also reduced the EC50 value of actinomycin D about 36.0-fold in the cells. Meanwhile, Tet had no effect on the cytotoxicity of the drugs to SK-OV-3 (P-gp-negative) cells[14]. The non-cytotoxic concentrations of Tet potentiated the growth-inhibitory actions of doxorubicin (Dox) in the Har-resistant HL60 cells. The colony formation efficencies were reduced from 60% by Dox to 0.2% by Tet + Dox. Retardation of the G2M phase cells was increased. But Tet did not potentiate Dox cytotoxity in the sensitive HL60 cells. Dox accumulation in the harringtonine-resistant HL60 cells treated by with was increased. These results indicated that Tet enhanced the cytotoxicity of MDR-related drugs via modulation of P-gp[15]. In addition, Tet could also inhibit platelet- activating factor-induced human platelet aggregation and decrease thromboxane B2 production and thrombus formation[16].

THERAPEUTIC USE IN DIGESTIVE SYSTEM DISEASES

Protective effects on hepatocyte injury

Hepatocyte lesions are common and very important clinically[A17-A21]. Chen *et al*[22] observed the effects of Tet on hepatocytic injury ind uced by CCl_4. The result showed that, compared with control group, Tet (1-1000 $nmol \cdot L^{-1}$) increased viability of liver cell (from 71% to 72%-89%), reduced lactate dehydrogenase release, and malondialdehyde (MDA) formation. Tet prevented the increase of the intracellular Ca^{2+} concentration and the attenuation of the membrane microflow of liver cells. Tet (30 $mg \cdot kg^{-1} \cdot d^{-1}$ via gavage for two wk) could markedly reduce the elevation of serum alanine aminotransferase, alkaline phosphatatase and MDA induced by azathioprine. The level of reductive glutathione and SOD were not different from the normal control group. Histological changes in the Tet-treated group were slight[23]. The protective effect on CCl_4- or azathioprine-injured hepatocytes may be elicited by inhibiting the lipid peroxidation, improving the membrane microflow, and lessening the Ca^{2+} concentration. With flow-cytometric technique, we demonstrated that 10-60 $mg \cdot L^{-1}$ Tet could concentration-dependently accelerate the G1 phase cells transforming to S phase cells, and increase the level of DNA in the S phase and protein in the G1, G2 phase cells significantly. Further stu dies indicated that the effect of Tet in promoting hepatocytes proliferation was not related to blockade of Ca^{2+} influx[24].

Anti-hepatofibrogenetic activity

Tet could significantly reduce the degree of experimental hepatic fibrogenesis induced by CCl_4 in rats; the levels of serum hyaluronic acid and procollagen peptide were decreased, and the liver dysfunction was ameliorated, Tet could also obviously inhibit extracellular matrix formation and collagen deposition. In the liver tissue of rats treated with Tet, hepatic stellate cell (HSC) activation, proliferation, and transformation were down-regulated; the number of desmin-positive cells were reduced significantly. The anti-fibrotic effect of Tet had no significant difference from that of colchicine[25]. HSC activation, proliferation, and transforming into fibroblast are the putative events in hepatic fibrogenesis. Tet could significantly inhibit conventional cultured HSC activation and type I and type III collagen mRNA expressions and protein synthesis were down-regulated. Tet could block HSC proliferation colla gen synthesis induced by platelet-derived growth factor (PDGF), reduce the level of PDGF, PDGF receptor (PDGF-R beta1), transforming growth factor beta1 (TGF beta1) and alpha-smooth muscle actin mRNA, and also down-regulate the au tocrine of PDGF, PDGF-R beta1, TGF beta1. These data suggest that Tet may block hepatic fibrogenesis directly and/or through inhibiting cytokine express ions[26,27]. After taking Tet orally for three months, liver functions of the patients with cirrhosis were obviously improved. Administrat ion Tet for six to eighteen months, serum levels of PIIIP and HA of the patients were markedly reduced. Histological examination showed that, compared with pretreatment or placebo, inflammatory cell infiltration was reduced, and even abolished, and that the deposition of ECM, type I and type III collagen were decreased significantly[28].

Anti-portal hypertension

Portal hypertension is one of important manifestations of the patients with cirrhosis. Upper gastrointestinal hemorrhage caused by portal hypertension commonly led to the patient's death. After injecting Tet intravenously (2.0, 6.0 and 20.0 $mg \cdot kg^{-1}$), portal venous pressure and mean arterial pressure were assessed in cirrhotic rats induced by CCl_4. The results

demonstrated that Tet induced dose-dependent decreases in portal venous pressure and mean arterial pressure. The maximum percentage reductions of portal venous pressure after Tet in the three different dosages were 5.4%±1.0%, 9.2%±0.8%, and 23.7%±1.2% of baseline, respectively. Total peripheral resistance was also reduced by Tet[29,30]. In portal hypertensive rats induced by partial portal vein ligation, Tet (4, 8, 16 and 24 mg·kg^{-1}) induced dose-dependent decreases of portal venous pressure and mean arterial pressure after intravenous infusion. Tet (16 mg·kg^{-1}) caused the portal venous pressure decreasing from a baseline of 12.5 mmHg to 10.0 mmHg, and the mean arterial pressure from a baseline of 90 mmHg to 80 mmHg. At 24 mg·kg^{-1}, Tet reduced portal venous pressure and mean arterial pressure to 20.3%±2.4% and 28.4%±1.4% of baseline, respectively[31]. The effects of Tet on portal hypotension may be attributed to its actions of blocking voltage- and receptor-operated Ca^{2+} channels in vascular smooth muscle cells, inhibiting intracellular Ca^{2+} mobilization and dilating peripheral blood vessels. We had previously observed its clinical therapeutic effects on portal hypertension. Taking Tet orally for 2 consecutive years, the esophageal variceal pressure and the portal blood flow in cirrhotic patients with portal hypertension were significantly reduced. The proportion of patients with no recurrent gastrointestinal bleeding during 2 years' medication of tetrandrine was 87.9%. It is suggested that Tet would be effective for cirrhotic patients with portal hypertension in preventing recur rent variceal bleeding[32].

Therapeutic effect on portal hypertensive gastropathy

Portal hypertensive gastropathy is caused by dysfunction of submucosal circulation and gastric mucosal barrier damage. Recent studies found that Tet increased prostgalandin E2, GMBE and GAM secretion, reduced the degree of gastric mucosa injury, and lowered the portal pressure. This result indicates that Tet may be useful in portal hypertensive gastropathy.

Preventing pancreatic islet beta cells from toxic injury

Pancreatic islet beta cells could be damaged by alloxan (50 mg·k g^{-1} i.v.)[aa] in rats, and diabetic animal models were thus prepared. Pancreatic islet beta cells density in experimental groups pretreated with Tet (100 mg·kg^{-1} via gavage) at 1.5 hours and 5 hours prior to alloxan injection increased from the control value of 13±4 to 62±9 and 65±7 (P<0.001). When the doses of Tet decreased from 100 mg·kg^{-1} to 50 mg·kg^{-1} and 25 mg·kg^{-1}, the pancreatic islet beta cell density were 45±5 and 38±4 (P<0.01 and P<0.001)[33].

Abstract

AIM **To establish clone cells with different metastatic potential for the study of metastasis-related mechanisms.**

METHODS **Cloning procedure was performed on parental hepatocellular carcinoma (HCC) cell line MHCC97, and biological characteristics of the target clones selected by *in vivo* screening were studied.**

RESULTS **Two clones with high (MHCC97-H) and low (MHCC97-L) metastatic potential were isolated from the parent cell line. Compared with MHCC97-L, MHCC97-H had smaller cell size (average cell diameter 43 μm *vs* 50 μm) and faster *in vitro* and *in vivo* growth rate (tumor cell doubling time was 34.2 h *vs* 60.0 h). The main range s of chromosomes were 55-58 in MHCC97-H and 57-62 in MHCC97-L. Boyden chamber *in vitro* invasion assay demonstrated that the number of penetrating cells through the artificial basement membrane was (37.5±11.0) cells/field for MHCC97-H *vs* (17.7±6.3)/field for MHCC97-L. The proportions of cells in G0-G1 phase, S phase, and G2-M phase for MHCC97-H/MHCC97-L were 0.56/0.65, 0.28/0.25 and 0.16/0.10, respectively, as measured by flow cytometry. The serum AFP levels in nude mice 5wk after orthotopic implanta tion of tumor tissue were (246±66) μg·L^{-1} for MHCC97-H and (91±66) μg·L^{-1} for MHCC97-L. The pulmonary metastatic rate was 100% (10/10) *vs* 40% (4/10).**

CONCLUSION **Two clones of the same genetic background but with different biological behaviors were established, which could be valuable models for investigation on HCC metastasis.**

INTRODUCTION

Cancer cell population, either as a solid tumor mass *in vivo* or as a continuous cell line *in vitro*, is an ever-changing entity due to their geneticins tability and selective environmental pressure. A tumor mass consists of different cell clones, a phenomenon known as tumor heterogeneity[1,2]. Based on this phenomenon, tumor cell clones of different biological properties have been isolated from a number of human and animal tumor cell lines. These differences include a variety of biological characteristics such as tumor cell morphology, karyotypes, *in vitro* and *in vivo* growth patterns[3-7], DNA ploidy[8,9] tumorigenicity and drug sensitivity[5], metastatic patterns[4] and metastatic potentials[10-12], albumin secretion[13] and hyaluronan production[14].

Liver cancer is the 4th most common cause of death from cancer and China alone accounts for 53% of all liver cancer death worldwide[15], and the incidence is on slow but steady rise in both developing and the developed countries[16-20] Primary liver cancer in China, of which more than 90% is hepatocellular carcinoma (HCC), remains the second leading cancer killer that mainly affects middle-aged people-those in the prime of their most productive years[21]. Although gratifying progress has been achieved in clinical treatment at some centers, the overall survival for the whole HCC population at large is still very poor. Another dismal problem is that HCC is more prone to recurrence and metastasis even after curative resection[16,22-24]. Therefore researches in the mechanism and intervention of liver cancer recurrence and metastasis have special priority in China's anti-cancer campaign. For a better insight into the mechanisms of HCC metastasis and for the development of new treatment strategies, an ideal HCC model system is essential. To serve this purpose, animal model of metastatic human HCC LCI-D20[25] and metastatic human HCC cell line MHCC97[26] have been established at the authors' institute.

Although several human and animal liver tumor cell clones[13,27-37] have been established, few of these were suitable for the study of human HCC metastasis-the most fundamental characteristics of cancer and the ultimate cause of most cancer mortality. Recently, we isolated two human HCC clones with different metastatic potential from the parent cell line MHCC97, and explored some of their differences.

MATERIALS AND METHODS

Animals

Male athymic BALB/c nu/nu mice, 4 - 6 wk old, were obtained from Shanghai Institute of Materia Medica, Chinese Academy of Science, and housed in laminar- flow cabinets under specific pathogen-free (SPF) condition. All studies on mice were conducted in accordance with the National Institutes of Health "Guide for the Care and Use of Laboratory Animals". The study protocol was approved by Shanghai Medical Experimental Animal Care Committee.

Parent Cell Line

The parent cell line MHCC97[26] is a human HCC cell line established from the animal model of human HCC LCI-D20[25].

Cloning Procedure

Cells of the 25th passage of the parent cell line were used for the current work. The cells were cultured at 37 ℃ in a humidified atmosphere of 50 mL·L^{-1} CO_2 and 950 mL·L^{-1} air. The culture medium was high glucose Dulbecco's modified Eagle medium (DMEM) (GibcoBRL, Grand Island, NY, USA) suppl emented with 100 mL·L^{-1} fetal bovine serum (Hyclone, Utah, USA). Two days after cell passage, the medium was transferred into a sterile tube (Corning Incorporated, Corning, NY, USA), centrifuged at 2000 r·min^{-1} for 10 min, and the supernatant was stored at -20 ℃ as conditioned medium. When the cells grew to approximately 80% confluence, the culture flask was placed in 4 ℃ refrigerator for 4 h to synchronize the cells, followed by incubation overnight at 37 ℃ as usual. In the following morning, single cell suspension was prepared after trypsinization (2.5 g·L^{-1} trypsin, Difco, prepared in Ca^{2+} and Mg^{2+} free Hanks solution d-Hanks), cell viability was confirmed by trypan blue exclusion, and cloning procedure was performed using the limited dilution method[6]. The cloned cells were preserved in culture medium containing 100 g·L^{-1} dimethyl sulfoxide (DMSO, Sigma Chemical Co, St Louis, MO, USA), and stored frozen in liquid nitrogen till used for *in vivo* screening.

In vivo Screening

In vivo screening was conducted in nude mice, when the cloning process was complete. The stored cells were thawed and propagated. Approximately 1×10^7 cells in 0.2 mL culture medium were injected sc into the right flank of the mice, which were then observed daily for signs of tumor development. Once the subcutaneous tumor reached 1-1.5 cm in diameter, it was removed and cut into pieces about 2 mm×2 mm×2 mm which were implanted into the liver of each of 6 nude mice, using the method as described previously[25]. Five weeks later, the animals were sacrificed and autopsied. Lungs and other organs suspected of tumor involvement were sampled for histopathological studies. This was the first round of *in vivo* selection. In order to identify clones with maximal and minimal metastatic potential, all the recovered clones still viable after thawing were tested for initial screening. The parent cell line was used as controls.

Confirmation Test

Once the clones with maximal and minimal metastatic potential were targeted. They were subjected to the second round of confirmation test, which was performe d essentially in the same way as the first round of selection, but more animals were used. Target clone cells were propagated and 5×10^6 cells in 0.2 mL culture medium were injected into the left lower flank region of each of 5 nude mice (4 wk-old, 13 g-17 g). The animals were observed for latency period, defined in this study as the time interval from the day of injection till the day of definite tumor mass about 5 mm in diameter at the injection site. The growth of subcutaneous tumor was recorded for 30 d, then fresh tumor tissues were implanted into the liver exactly the same manner as the first round of selection, 10 mice for each clone. Animal care and pathological studies were the same.

The confirmed clones were subjected to the following studies.

Morphological Observations

The cells were cultured on culture chambers (Lab-Tek) Chamber Slide, Nunc Inc. Naperville, III, USA) for 2 d and stained in Giemsa solution. Cell morphology was viewed under light microscope and representative pictures were taken. Transmission electron microscopy was conducted as described previously[11]. For scanning electron microscopy, cells grown on cover slips were fixed with 25 g·L^{-1} glutaraldehyde fixative (pH 7.2), and observed directly under scanning electron microscope (HITACHI S-520, Japan).

Chromosome analysis

Chromosome preparation was performed with the method described by Seabright[38], with slight modification. Briefly, cells after 60 h of subculture were used. Colchicine (Shanghai Chemical Reagents Co. Shanghai, China) was added to the culture flasks to yield the final concentration of 0.04mg·L^{-1}, and the flasks were incubated for 4h before the cells were harvested. The cells were treated in hypotonic solution consisting of 1:1 mixture (in volume) of 4 g·L^{-1} potassium chloride and of 4 g·L^{-1} sodium citrate, and then fixed in ice-cold methanol: glacial a cetic acid (2:1, volume ratio). The slides stained in Giemsa solution (1:10 dilution in pH 6.8 PBS). Metaphase chromosome spreads were analyzed with Cytovision Chromosome analysis system (CytoVision™ Image Analysis Workstations, USA).

Cell Growth Curves

Cells in exponential growth phase were trypsinized to give single-cell suspensi on. 4×10^4 viable cells in 1mL of medium were added to every well of the 24-well tissue culture plates, which were incubated at 37 ℃ with 50 mL·L^{-1} CO_2. Cell numbers in two wells were counted in a hemocytometer every 24 h for 7 consecutive days, and cell growth curves were plotted based on these results. The tumor cell doubling time was calculated according to the following formula: TD = Tlg2/lg (N/N_0) (TD: doubling time, T: time interval, N_0: initial cell number, N: end-point cell number)[39].

Plate Efficiency (PE)

1×10^7 cells·L^{-1} of single-cell suspension were made from cells of exponential growth phase. 0.2 mL of cell suspension (containing 2000 viable cells) and 4 mL of culture medium were added to each well (3.5 cm in diameter) of 6-well culture plate, which was incubated at 37 ℃ with 50 mL ·L^{-1} CO_2 for 12 d, washed twice with warm PBS, and stained with Giemsa solution. The number of colonies was counted under microscope (40×). PE was calculated using the following formula: PE = (number of colonies/ number of cells inoculated)×100%.

In vitro invasion assay

Matrigel invasion assay was performed using the method by Albini *et al*[40], with modification. Boyden chamber inserts (Nunclon™, Denmark) with filter membrane pore size of 8 μm were used in the assay. 50 μg matrigel (from the Department of Biology, Medical Center of Beijing University, Beijing, China) was coated to each filter and the chamber was incubated at 37 ℃ for 2 h to produce the artificial basement membrane. Tumor cells in serum-free DMEM (200 μL containing 1×10^5 cells) were added to the upper compartment of the chamber, and 800 μL of conditioned medium was added to the lower compartment. After 24 h incubation, the matrigel was removed, the filter was washed, fixed and

stained in Giemsa solution. Cells that had migrated to the under side of the filter were counted under a light microscope (200×). The results were expressed as the number of migrated cells per field and presented as the [AKx-D]±s of three assays.

Flow cytometry

Cells at exponential growth phase were harvested and single-cell suspensions containing 1×10^6 cells were made. The cells were treated following the standa rdized protocol and cell cycle analyses were performed by flow cytometry as described previously[41].

Immunocytochemistry

Cells directly cultured on slides were washed two times with PBS and then fixed in acetone for 5 min at room temperature. Albumin, alpha-fetoprotein (AFP), cytokeratin 8 and hepatitis B surface antigen (HBsAg) were detected by immunocyt ochemistry using a two-step labeled avidin-biotin immunoperoxidase method, as recommended by the supplier. Primary detection was by either rabbit polyclonal or murine monoclonal antibodies. Biotinylated secondary envision antibodies were goat anti-rabbit IgG and rabbit anti-mouse IgG (Dako, Denmark). Negative controls consisted of omission of the primary antibody, and all cells were counterstained with hematoxylin. The slides were viewed under microscope and the degree of staining was recorded.

Detection of hepatitis B virus DNA

Cells were harvested by trypsinization when they were at 90% confluence, and was hed twice in PBS. Total cellular genomic DNA was extracted using the Qiangen DNA extraction kit (Qiagen GmbH, Germany). Hepatitis B virus (HBV) DNA was exami ned by fluorescent primer polymerase chain reaction (PCR) (LightCycler, Roche, USA) using 2 μg cellular DNA, according to the instruction of the HBV DNA detection kit (Shenzhen Piji Biotechnology Development Co. Shenzhen, China). Positive and negative standards were tested at thesame time.

Alpha-fetoprotein determination

At the end of the second test, when the mice were sacrificed, blood was taken from each animal, and the serum AFP levels were determined automatically (ACS: 180 Automated Chemiluminescence System, Bayer Corporation, USA).

Statistical analysis

Fisher's exact test and student's *t* test were used, respectively, for comp arisons of enumeration data (number of mice with lung metastases) and measuremen t data. The statistical analysis software package Stata 5.0 was used for the tests, and $P<0.05$ was considered as statistically significant.

RESULTS

Identification of Clones with Different Metastatic Potential

A total of 28 clones were isolated from the single-cell culturing of four 96-well plates. Among them, clones 2, 3, 12, 14 and 15 were discarded because of suspected microbial contamination; clones 5, 9, 16, 17, 18, 19, 20, 21, 22, 23, 26, 27, 28 were not viable when the cells in the first few passages were thawed from liquid nitrogen. The remaining ten clones (clones 1, 4, 6, 7, 8, 10, 11, 13, 24, and 25) were propagated for *in vivo* screening. The cells of each clone were first injected into the subcutis of nude mice. Then the subcutaneous tumors were implanted into nude mice liver, for evaluation of spontaneous pulmonary metastasis after 5 wk. The results were summarized in Table 1. It was found that most of these clones had similar metastatic potential. Lung metastases were 6/6 for clones 1, 7, 8, 10, 11 and 13, 5/6 for clone 4, 4/6 for clones 6 and 24, and 2/6 for clone 25.

Table 1 Lung metastases of 10 clones

Clone number	*n* Tumor implanted	*n* Lung metastases after 5 wk
1, 7, 8, 10, 11, 13	6	6
4	6	5
6, 24	6	4
25	6	2
MHCC97	6	6

NOTE. Each clone was first sc inoculated into nude mice. Then small pieces of subcutaneous tumor were implanted into the liver of 6 nude mice for every clone. The number of mice with lung metastases was determined by histopathology 5 wk after orthotopic tumor implantation (see the *in vivo* screening for detail.).

Among the clones with greatest metastatic potential, clone 8 produced the most numerous lung metastases (median number of lung colonies 12/mouse). Therefore, clone 8 and clone 25 were selected as target clones and used for the second round *in vivo* confirmation test. For evaluation of subcutaneous tumor development, 5 nude mice for each clone were used, and every mouse wasinjected with 0.2 mL of cell suspensions containing 5×10^6 cells. For evaluation of spontaneous metastasis after orthotopic implantation, 10 animals were used for each clone. The results were shown in Table 2 and Figures 1, 2.

Table 2 Abdominal events and pulmonary metastases after liver implantation of subcutaneous tumor tissue

	Clone number	
	No. 8 (MHCC97-H)	No. 25 (HMCC97-L)
No of mice with tumor implantation	10	10
Tumor size by d 35/cm	1.42±0.11	0.90 ±0.26[a]
Abdominal events		
Abdominal wall invasion	40% (4/10)	20% (2/10)
Bloody ascites	10% (1/10)	0% (0/10)
Intrahepatic metastases	80% (8/10)	0% (0/10)
Diaphragm invasion	10% (1/10)	0% (0/10)
Hepato-splenic/hepato-gastric ligament invasion	10% (1/10)	0% (0/10)
Loco-regional lymph node enlargement	0% (0/10)	0% (0/10)
Pulmonary metastases	100% (10/10)	40% (4/10)[b]

NOTE. [a]$P<0.01$, *t* test. The length (L), width (W) and height (H) of liver tumor was measured at autopsy using a caliper, and the tumor size was expressed as the geometric mean diameter (GMD) GMD = (L×W×H) 1/3; [b]$P<0.05$ Fisher's exact test.

Although both clones were tumorigenic, the latency period differed considerably between them, being (5-10) (6.4±2.2) d for clone 8 and (20-25) (21.3±2.5) d for clone 25. By d 30, the subcutaneous tumor sizes were (1.94±0.36) cm for clone 8 and (0.84±0.47) cm for clone 25 ($P<0.01$, *t* test). Both clones mainly exhibited expansive growth pattern, although clone 8 showed some tumor invasion in 2 of the 5 animals tested, one invading the hipbone and another invading the lumbar spine. The most obvious difference between the two clones regarding the subcutaneous tumor development was the growth rate.

Their differences became even more apparent after small

bits of subcutaneous tumor tissues were implanted into the liver of nude mice for 5 wk, when it was found that clone 8 produced notable intrahepatic metastases in 8 of the 10 recipients examined, whereas clone 25 did not produce any observable nodules. Apart from intrahepatic metastases, clone 8 also caused abdominal wall invasion in 4/10 (40%), diaphragm invasion in 1/10 (10%), hepato-splenic and hepato-gastric ligaments invasion in 1/10 (10%), and bloody ascites in 1/10 (10%). These changes were not observed for clone 25, except 2/10 (20%) animals showed abdominal wall invasion. No enlargement of lymph nodes was observed for either clone.

Pathological studies of liver tumors from the two clones showed similar histology. The tumor cells were polygonal epithelial-like cells forming large tumor nests surrounded by thin fibroconnective tissues. Tumor necroses were prominent at the center of large tumor nests. Anaplastic tumor spindles aggressively infil trating the adjacent tissues and tumor cells invading blood vessels were observe d in clone 8, but not in clone 25. Moreover, the lung metastatic lesions formed by these two clones were also different. The lungmetastases by clone 25 were usually small and located near the surface of the lung, while those formed by clone 8 were large and usually located in the lung parenchyma, pressing blood vessels and the bronchioles (Figures 3A, B).

Thus it was established from these selections and observations that clone 8 was the most metastatic and clone 25 the least metastatic. They were designated as MHCC97-H and MHCC97-L, respectively.

Cell Morphology

Both clones showed polygonal epithelial-like morphology, with firm attachment to the culture flask. However, they were different in cell size (average cell diameter (50±5) μm in MHCC97-L *vs* 43±2 μm in MHCC97-H) and cell morphology (multiform in MHCC97-L *vs* uniform in MHCC97-H). Both cells had large conspicuous nucleus, with 1-3 big nucleoli scattered in the nucleus of MHCC97-L and 3-7 smaller nucleoli in MHCC97-H (Figure 4A, B). Electron microscopy revealed abundant microvilli and projections on the cell surface. Some of the projections on MHCC97-H extended far and formed bulges at the end, while those on MHCC97-L were short and compact. Both cells had many lysosomes in the cytoplasm, which were usually concentrated on one side of the cell in MHCC97-H and scattered around the cytoplasm in MHCC97-L. No obvious desmosomes, tight conjunction or other cell junction structures were observed, nor were virus particles or other particular particles.

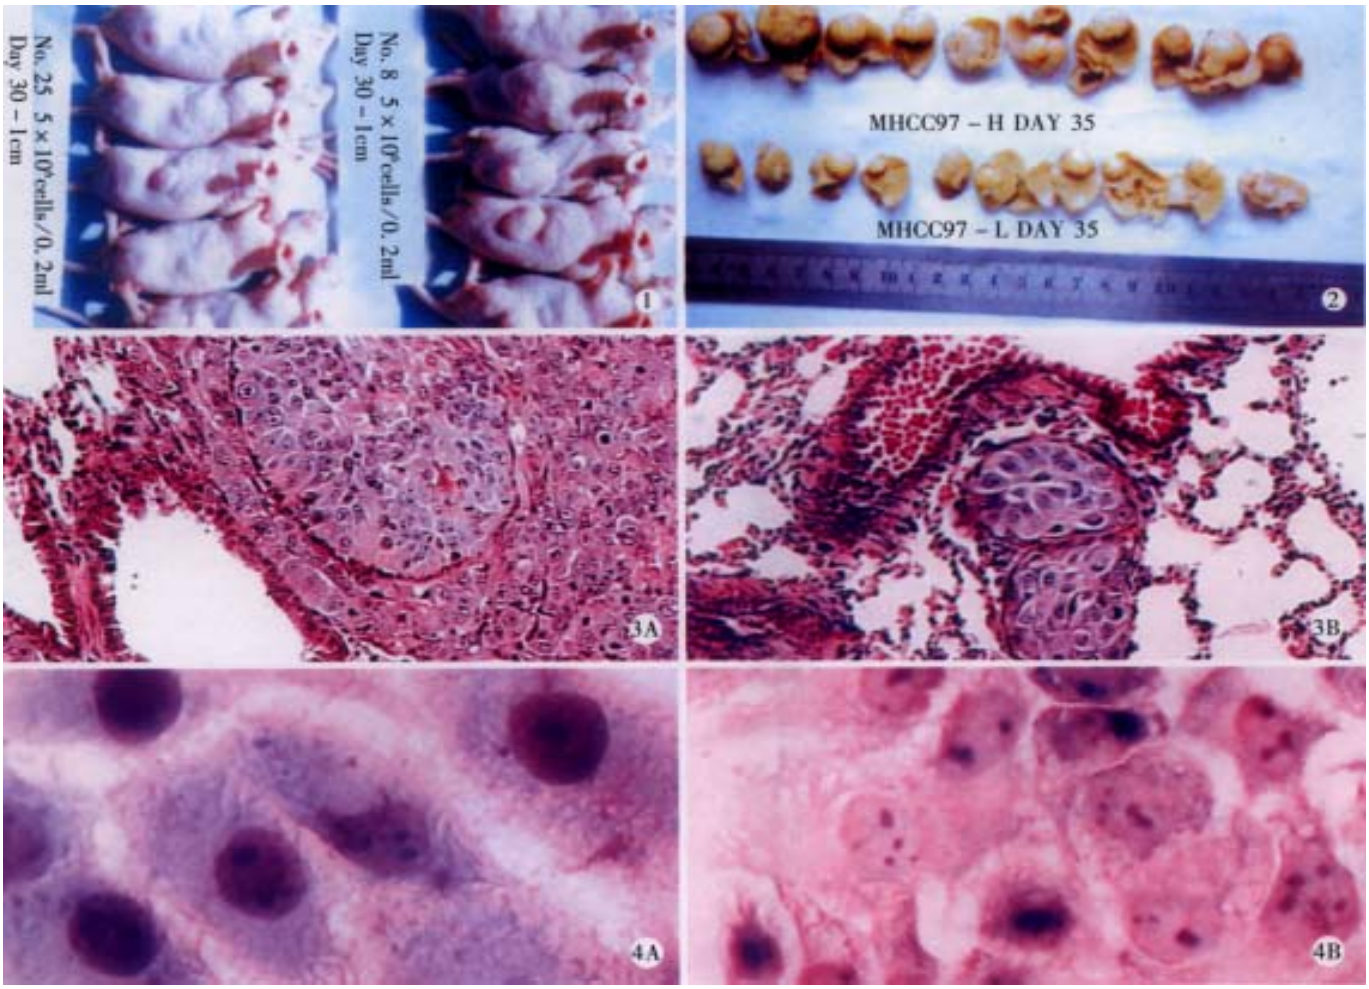

Figure 1 Subcutaneous tumor formation of the two clones. 30d after sc injection of 5×10^6 tumor cells for each nude mouse, the average s.c tumor diameter was (1.94±0.36) cm for MHCC97-H as against (0.84±0.47) cm for MHCC97-L.
Figure 2 The liver tumor size of the two clones 5wk after orthotopic inoculation. The tumor geometric mean diameter (GMD) for MHCC97 -H was (1.42±0.11) cm as against (0.90±0.26) cm for MHCC97-L.
Figure 3 Photomicroscopy of lung metastases of the two clones. MHCC97-H (3A) produced large metastatic lesion pressing the bronchioles while MHCC97-L (3B) only formed small metastasis. HE ×100.
Figure 4 Photomicroscopy of MHCC97-L (4A) and MHCC97-H (4B) illustrating the clear differences in the number of nucleoli. Giemsa×400.

Chromosome analysis

Both clones were heteroploid. The chromosome number in MHCC97-H ranged from 37 to 68, with 68% of cells in the main range of 55-58 chromosomes. The range of ch romosomes for MHCC97-L was from 44 to 105, and 58% in the main range of 57-62 c hromosomes.

Cell growth curve

As shown in Figure 5, MHCC97-H grew much faster than MHCC97-L, their populatio n doubling time being 34.2 h and 60.0 h, respectively.

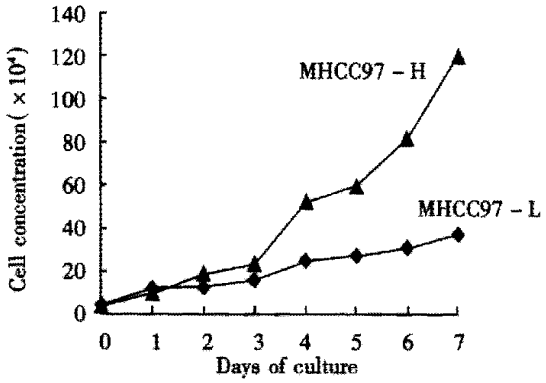

Figure 5 Cell growth curve of two clones. 4×10^4 viable cell s were cultured in each well of the 24 well culture plate. Cell numbers were determined for 7 consecutive days. Each time point represents the mean of duplicate cell counts.

Plate efficiency

Colony formation rates were (22.2±3.7)% in MHCC97-H and (18.6±4.7)% in MHCC97-L, the difference being of no statistical significance ($P>0.05$, *t* test). However, the number of cells in each colony did differ between the two cell clones, with 8-15 cells in each colony of MHCC97-H and 3-5 cells in each colony of MHCC97-L.

In vitro invasion assay

The numbers of cells that penetrated the artificial basement membrane were (37.5±11.0) cells per high power field in MHCC97-H and (17.7±6.3)/ HP field in MHCC 97-L ($P<0.05$, *t* test).

Flow cytometry

Cell cycle analysis by flow cytometry revealed that the proportion of cells in G0-G1 phase, S phase, and G2-M phase for MHCC97-H/MHCC97-L were 0.56/0.65, 0.28%/0.25 and 0.16/0.10, respectively. MHCC97-H had more cells in S phase, and G2-M phase than MHCC97-L.

Immunocytochemistry

Both clones were positive for albumin, AFP and cytokeratin 8, attesting that they were indeed liver cancer cells. However, neither of the two had any positive stain for HBsAg.

Detection of HBV DNA Integration

Both clones were positive for HBV DNA.

AFP Production

Five weeks after orthotopic implantation of the tumor from MHCC97-H and MHCC97-L, AFP levels in nude mice serum were (246±66) $\mu g\cdot L^{-1}$ and 91±66 $\mu g\cdot L^{-1}$, respectively ($P<0.01$, *t* test).

DISCUSSION

Heterogeneous nature of tumor in terms of its *in vitro* and *in vivo* characteristics has been well recognized. Populations of human and animal tumors frequently demonstrate a great variation in a number of cellular and functional properties. Our study reported here confirmed that the metastatic human HCC cell line MHCC97 was also a heterogeneous population, consisting of subpopulations with different metastatic potentials. Immunocytochemical studies demonstrated that these two clones were positive for albumin, AFP and cytokeratin 8, demonstrating they were still HCC cells. HBV DNA integration into the cell genome also confirmed that they were related to their parent cell line MHCC97, which was HBV positive[26].

Systemic comparisons of these two clones revealed many differences between them. Heterogeneity of cell morphology is the most easily observed feature among different clones of the same origin, and it is usually the beginning of the study of tumor heterogeneity. This phenomenon has been well documented in various tumors , including lung cancer[10], colon cancer[42,43], breast cancer[6,44], squamous cell carcinoma of the skin[3] and the tongue[7,11]. In our study, the two clones identified here also showed differences in cell morphology. The highly metastatic variant MHCC97-H was small (average diameter 43 μm) and more uniform than the clone with low metastatic potential MHCC97-L (average diameter 50 μm). Cell size itself may be a mechanical factor influencing metastasis. The small size may facilitate cells to traverse through the blood vessels, evade the immune attacks in the circulation during tumor cell transport, and come up with less mechanical resistance during tumor cell penetration in the target tissue. Since our study was a spontaneous metastasis model, this difference in cell size between the two clones may have some impact on the ability to overcome host barriers. This is in keeping with a earlier finding by Suzuki *et al*[45], who used a mouse fibrosarcoma system to study the experimental metastasic ability (via tumor cell injection into the tail vein to observe the lung colony formation abilities) of various clones, and found that the clone with nearly 10-fold higher lung colony-forming ability was much smaller in cell volume than the low metastatic clone.

Another prominent difference in cell morphology is that MHCC97-H had more nucleoli (3-7 per cell) than MHCC97-L (1-3 per cell). More nucleoli are a marker of active cell proliferation. Derenzini *et al*[46] suggested that nucleoli perse could tell the metatatic potential of tumor cells. Their study indicated that larger nucleoli predicted more rapid tumor cell proliferation. However, our results seem to suggest that nucleolar number rather than the size is an indicator of fast tumor proliferation. Indeed, in our model system, the highly meta static variant with more nucleoli grew much faster than the one with few nucleol i and low metastasis. This could be reflected in cell growth rate curve (tumor c ell doubling time was 34.2 h in MHCC97-H and 60.0 h in MHCC97-L), fraction of cells in S phase and G2-M phase of the cell cycle, latency period in subcutaneous tumor development and liver tumor size at the endpoint of the study. Whether or not tumor cell growth rate is directly related to metastasis is not clear yet. Yasoshima *et al*[47] using metastatic gastric cancer cell line, and Samiei *et al*[48] using metastatic mammary clones found, that metastasis was independent of tumor cell growth; while other works[49,50] showed close association between tumor cell growth rate and metastasis. Our results suggest fast growing tumor is more prone to metastasis.

Cytogenetic studies also revealed the differences in the chromosome number between the two clones. This is in

keeping with a recent findings by Takeuchi *et al*[11], who used similar method to have isolated cloned cancer cells with different metastatic potentials, and found marked difference in modal chromosome number between the highly metastatic clone and the non-metastatic clone.

As HCC is a special health issue in China, basic and clinical researches in this field have been intensive. As early as in the 1960s, Chen[51] establish ed the first human HCC cell line in the world. Later on several HCC cell lines were established[52-58]. Although most of these showed tumorigenicity when inoculated into experimental animals, rarely did they demonstrate the full potential for loco-regional and distant metastases, as seen so frequently in clinical patients. The metastatic HCC cell line MHCC97 was established in order to meet the urgent need for suitable models to study the mechanisms of and interventions on HCC metastasis. And now we took one step further to have isolated clones of different metastatic potential from the same cell line. These new models could be valuable for the study of HCC metastasis.

Cancer metastasis is the ultimate display of complex interactions between the ma lignant cells and the host defense mechanism. The process of metastasis consists of selection and sequential steps that include angiogenesis, detachment, motility, invasion of the extracellular matrix, intravasation, circulation, adhesion, extravasation into the organ parenchyma and growth[2]. The ability of cancer cells to form metastasis depends on a set of unique biological properties that enable the malignant cells to complete all those steps of metastatic cascade. For HCC invasion and metastasis, extensive studies have unveiled many molecular mechanisms involved in these processes, including P53[59,60]/CDKN$_2$ mutation, overexpression of H-ras/EGFR, nm23/TIMP[60], over-expression of CD44v6 and under-expression of nm23-H1[61], over-expression of metalloproteinase-9 and CD34[62], high level of laminin in the blood and tumor[63], intercellular adhesion molecule-1 (ICAM-1)[64], N-Actylglucosaminyltransferase V (GnTV) activity[65], high expression of urokinase-type plasminogen activator (uPA), its receptor (uPAR) and inhibitor (PAI-1)[66], chromosome 8p deletion[67,68]. But it is likely that other genes or gene locus in addition to these genes are also involved in the process of meta stasis in HCC, since most of these studies were focused only on a few genes or their products. It is reasonable to assume that there could be a group of relevant genes rather than a single or a few genes to account for tumor metastasis. The identification of those unknown genes related to metastasis is important in order to gain a complete picture of the molecular biology of HCC metastasis. For this end, a dependable model system that consists clones with high and low metastatic potential from the same origin should be the ideal study material. It is based on this rationale that some recent works seeking metastasis-related genes were conducted on the cloned cells from the same biological background. Reichner *et al*[35] isolated two clonal cell lines with different metastatic potentials from a rat hepatocellular carcinoma model induced by chemical carcinogens, and studied the differences in metastasis related mechanisms. They found no differences in the expression of several antigens noted to correlate with metastatic potential, including CD44 variant glycoprotein, p53, transferrin receptor, and E-cadherin. The only notable difference in the parameters studied was the level of IL-6. The highly metastatic clone released much more IL-6 than the low metastatic clone. Other studies use metastatic and non-metastatic human mammary carcinoma clone lines as comparing materials to seek metastasis-associated genes, and provided a vast amount of information on gene expression and metastatic phenotype[69].

In summary, our study confirmed that the metastatic HCC cell line MHCC97 is a he terogeneous population, consisting of cells with divergent biological properties. The two clones isolated from the parent cell line differed not only in *in vitro* characteristics like cell morphology and growth kinetics, but also in the most fundamental biological behavior-tumor metastasis. Since these two clones are from the same parent cell line, thus having the same genetic background, the differences in their phenotypes must have some underlying molecular mechanisms. In-depth study on their differences might help us gain new insight into the mechanisms of liver cancer metastasis.

AKNOWLEDGEMENTS The authors thank Professor Jin Gao, Ph.D. Chair of Pathology, Institute of Basic Medicine, Chinese Academy of Medical Science, for his help to this work. We also thank Dr. Xiaowu Huang for his help in immunocytochemical analysis and professor. Lun Xiu Qin for his critical reading of the manuscript.

Abstract

AIM **To determine the frequencies of HGV and TTV infections in blood donors in Hangzhou.**

METHODS **RT-nested PCR for HGV RNA detection and semi-nested PCR for TTV DNA detection in the sera from 203 blood donors, and nucleotide sequence analysis were performed.**

RESULTS **Thirty-two (15.8%) and 30 (14.8%) of the 203 serum samples were positive for HGV RNA and TTV DNA, respectively. And 5 (2.5%) of the 203 serum samples were detectable for both HGV RNA and TTV DNA. Homology of the nucleotide sequences of HGV RT-nested PCR products and TTV semi-nested PCR products from 3 serum samples compared with the reported HGV and TTV sequences was 89.36%, 87.94%, 88.65% and 63.51%, 65.77% and 67.12%, respectively.**

CONCLUSION **The infection rates of HGV and/or TTV in blood donors are relatively high, and to establish HGV and TTV examinations to screen blood donors is needed for transfusion security. The genomic heterogeneity of TTV or HGV is present in the isolates from different areas.**

INTRODUCTION

Viral hepatitis is relatively common in China[1-12]. Among them hepatit is G virus (HGV) and hepatitis GB virus (GBV-C) were recently identified as the two isolates of a novel positive-stranded RNA virus belonging to *Flaviviridae* family associated with human non-A-E hepatitis[13,14]. In 1997, a negatively stranded DNA virus, named transfusion transmitted virus (TTV), was isolated from a patient suffering from non-A-G hepatitis. At present TTV was proposed to be a member of a new virus family temporarily named *Circinoviridae*[15,16]. HGV RNA could be detected in patients with non-A-E hepatitis or fulminant hepatic failure (FHF) at relatively high percentages[17-22] and the coinfection of HGV and HCV may accelerate the progression of chronic liver disease[23-25]. However, many investigation data revealed that HGV was able to establish a long-term asymptomatic viremia in non A-E hepatitis patients and only a few of the patients had biochemical evidence of liver damage[26-30]. TTV DNA was frequently found in n on-A-G hepatitis patients with a single elevation of alanine aminotransferase (ALT) and the persistence of TTV infection might be a causative factor of human FHF[31-33]. A high frequency of TTV virus infection among patients with non-B, non-C hepatocellular carcinoma was also reported by Nakagawa *et al*[34]. However, some literatures reported that clinical implication of TTV infection was insignificant because of minimal role of liver injury in non-A-G hepatitis patients[35-37]. The clinical importance of HGV and TTV infections in human hepatic diseases is still present even though the real pathogenic potentials of the two viruses have remained unanswered. Therefore, the prevalence of HGV and TTV infections in blood donors is a significant subject for investigation.

In the present study, HGV RNA and TTV DNA in the serum samples of 203 blood donors in Hangzhou, eastern China, were detected using RT-nested PCR and semi-nested PCR, respectively. The HGV RNA or TTV DNA positive amplification products from part of the serum samples were cloned and sequenced. The results of this study may help determine the frequencies of HGV and TTV infections in blood donors in the local area and provide the basis for screening blood donors to control transmission of the two viruses.

MATERIALS AND METHODS

Materials

A total of 203 serum samples of healthy blood donors were obtained from four hospitals in Hongzhou, Zhejiang Province of China. The blood donors were confirm ed to have neither clinical signals of hepatitis and nor elevation of ALT by conventional hepatic examinations, and the serum samples were negative for hepatitis A-C viruses by EIA and PCR. The reagents used in reverse transcription (RT) and PCR were purchased from Sangon and the other reagents used in this study from Sigma.

Methods

Isolation of serum RNA and DNA Total RNA in 200 μL of each serum samples was prepared by Trizol method according to the manufacturer's instruction and then dissolved in 50 μL

of DEPC treated water. Total DNA in 200 μL of each serum samples was extracted by phenol-chloroform method[38], and then dissolved in 50 μL TE buffer (pH 8.0).

RT-nested PCR for HGV RNA detection Ten microliters of total RNA preparation was mixed with 10 μL RT master mixture containing 1 μmol·L^{-1} of random hexanucleotide as primer, 2 mol·L^{-1} each of dNTP, 20U M-MuLV-reverse transcrip tase, 20U RNase inhibitor and 4 μL of 5× RT buffer (pH 8.3). The steps of RT were described as follows: at 70 ℃×5 min for denaturation, at 42 ℃×60 min for cDNA synthesis, and at 70 ℃×10 min to stop the reaction.

Primers derived from HGV 5'-NCR were used in the RT-nested PCR[39]. External primers: 5'-ATGACAGGGTTG-GTAGGTCGT AAATC-3' (sense), 5'-CCCCACTGGTC-CTTGTCAACTCGCCG-3' (antisense). Internal primers: 5'-TGGTAGCCACTATAGGTGG GTCTTAA-3' (sense), 5'-ACATTGAAGGGCGACGTGGACCGTAC-3' (antisense). For the first round PCR, 10 μL of RT product was mixed with 90 μL PCR master mixture containing 250 nmol·L^{-1} each of the primers, 2 mol·L^{-1} each of dNTP, 25 mol·L^{-1} $MgCl_2$, 2.5 U of Taq DNA polymerase and 10 μL of 10×PCR buffer (pH 9.1). For the second round PCR, 5 μL product from the first round PCR was used as template, and the other reaction reagents were the same as that in the first round PCR except for the primers. The parameters for each of the PCR rounds were: 94 ℃ 5 min (×1); 94 ℃ 1 min, 56 ℃ 1 min, 72 ℃ 1.5 min (×35) and 72 ℃ 7 min (×1). The expected size of target fragments amplified from HGV RNA was 193 bp.

Semi-nested PCR for TTV DNA detection The primers used in the semi-nested PCR for TTV DNA detection were the same des cribed by Okamoto *et al*[40]. External primers: 5'-ACAGACAGAGGAGA AGGCAACATG-3' (sense), 5'-CTGGCATTTTACCATTTCCAAAGTT-3' (antisense). Inte rnal primers: 5'-GGCAACATGTTATGATAGACTGG-3' (sense), 5'-CTGGCATTTTACCATT TCCAAAGTT-3' (antisense). Except for specific primers, $MgCl_2$ concentration (15mol·L-1), total reaction volume (50 μL) and annealing temperature (60 ℃), the compositions and concentrations of other reaction agents and the parameters for semi-nested PCR was the same as that of the RT-nested PCR for HGV detection. The expected size of target fragment s amplified from TTV DNA was 271 bp.

Examination of amplification products The results of amplificat ion reactions were observed on UV light after 20 g·L^{-1} ethidium bromide stained agarose electrophoresis, and 100 bp DNA ladder was used as a size marker to estimate the length of products.

Analysis of nucleotide sequences of amplification products The target DNA fragments from HGV or TTV amplification products by PCR were cloned into plasmid pUCm-T-vector using T-A cloning kit according to the manufa cturer's instruction. The recombinant plasmid was amplified in *E.coli* strain DH 5α and then recovered by Sambrook's method[38]. The nucleotide sequence of inserted fragment was analyzed by Sangon. Homology of the nucleotide sequences was compared with those of reported[13,40].

RESULTS

Positive rates of HGV RNA and TTV DNA in the serum samples The respective target fagments respectively amplified from HGV RNA and TTV DNA are shown in Figure 1. Thirty-two (15.8%) 30 (14.8%) and 5 (2.5%) of the 203 serum samples were positive for HGV RNA, TTV DNA and both of the two respectively (Table 1).

Table 1 Positive rates of HGV RNA and TTV DNA in the 203 blood donors

Virus	Tested (*n*)	Positive (*n*)	%
HGV	203	32	15.8
TTV	203	30	14.8
HGV and TTV	203	5	2.5

Nucleotide sequence analysis and homology comparison Homology of the nucleotide sequences of HGV RT-nested PCR products from 3 serum samples compared with the reported HGV sequence[13] was 89.36%, 87.94% and 88.65% respectively (Figure 2). Homology of the nucleotide sequences of TTV semi-nested PCR products from 3 serum samples compared with the reported TTV TA278 genotype-1a sequence[40] was 63.51%, 65.77% and 67.12% (Figure 3). The homology in comparison of these sequences mentioned above did not contain the primer sequences.

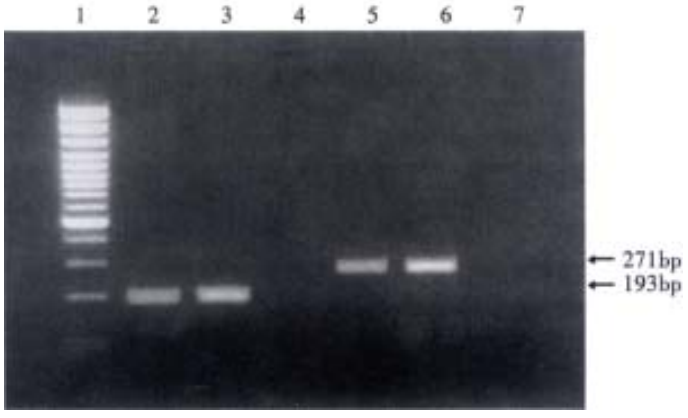

Figure 1 Target amplification fragments from HGV RNA and TTV DNA. (1: marker; 2 and 3: HGV positive serum samples; 4: blank for HGV detection; 5 and 6: TTV positive serum samples; 7: blank for TTV detection)

Figure 2 Homology of the nucleotide sequences from HGV RT-nested PCR products from 3 serum samples as compared with the reported sequence. (1. The reported HGV sequence[13]; 2-4. The sequences of HG V RT-nested PCR products from 3 serum samples. Underlined areas indicate the primer positions.)

Figure 3 Homology of the nucleotide sequences from T TV semi-nested PCR products from 3 serum samples as compared with the reported sequence.
1. The reported TTV sequence[40]; 2-4. The sequences of TTV semi-nested PCR products from 3 serum samples. Underlined areas indicate the primer positions.

DISCUSSION

Viral hepatitis is a common infectious disease in the world and causes a serious healthy problem. Although hepatitis viruses A-E have been demonstrated to be responsible for human hepatitis A-E, approximately 20% of acute and 15% of chronic hepatitis were associated with unknown aetiology[41]. HGV and TTV were recently identified as the transfusion-transmitted viruses and the causative agents of human non-A-E hepatitis[13-15]. However, many investigation data revealed that the patients infected with HGV or TTV were usually asymp tomatic and only a few of them showed mild liver injury[42-44]. Therefore, a wide variety of questions about the potential pathogenicity of HGV and TTV infection remain unanswered[31,45-47].

Since HGV and TTV are generally transmitted by transfusion, high infection frequencies of the two viruses in blood recipients and in hemodialyzed patients have been demonstrated[31,43,48-50]. Many investigations demonstrated that HGV RNA was detectable in 1.3%-10.6% of blood donors in different areas abroad[51-55]. Blood donors were also frequently infected with TTV but the infection rates abroad were usually lower than 5%[56,57]. In China, HGV and TTV infection rates in blood donors were reported to be approximately 8% and 15%, respectively[46,58]. In the present study, HGV infection rat e in the 203 blood donors was as high as 15.8%, which seems obviously higher than the reported HGV infection rates in the blood donors from other areas of China and abroad. Such high HGV infection rate in the blood donors in Hangzhou is probably due to the geographic difference. In this study, TTV viremia was found in 14.8% of the same 203 blood donors, which is higher than that of the reported abroad but similar to the reported in Chinese blood donors from other areas. In addition, 5 (2.5%) serum samples from the 203 blood donors were positive for both HGV RNA and TTV DNA, indicating the existence of coinfection of the two viruses. However, we can not exactly evaluate the significance of the co-infection because of being unable to get the detailed information of the five co-infection blood donors.

None of the blood donors tested in this study showed clinical symptoms and laboratory markers for hepatitis, which suggested that most of blood donors infected with HGV and/or TTV are usually latent. These asymptomatic blood donors carrying HGV and/or TTV may be more risky and important for the source of infection. Since HGV and TTV at least cause mild hepatitis in human[15,41] and high frequency of HGV and/or TTV infections in blood donors, it is necessary to establish HGV and TTV examination items to screenblood donors for transfusion security.

The nucleotide sequences of HGV RT-nested PCR products from 3 serum samples¡¡are highly homologous (87.94%-89.36%) to the HGV sequence reported by Linnen *et al*[13]. This result of sequence analysis indicates that the RT-nested PCR used in this study is reliable for HGV RNA detection. To analyze the details of the nucleotide sequencing data, it seems to show an HGV genotype different from the literature[59-62]. Lower homology (63.51%-67.12%) of the nucleotide sequences of TTV semi-nested PCR products from 3 serum samples compared with the reported TTV sequence[40] reveals the genomic heterogeneity of TTV in the isolates from different areas, and this founding accords with the conclusions of previously published reports[37,40].

Abstract

AIM **To study the epitope distribution of hepatitis G virus (HGV) and to seek for the potential recombinant antigens for the development of HGV diagnositic reagents.**

METHODS **Fourteen clones encompassing HGV gene fragments from core to NS3 and NS5 were constructed using prokaryotic expression vector pRSET and (or) pGEX, and expressed in E.coli. Western blotting and ELISA were used to detect the immunoreactivity of these recombinant proteins.**

RESULTS **One clone with HGV fragment from core to E1 (G1), one from E2 (G31), three from NS3 (G6, G61, G7), one from NS5B (G821) and one chimeric fragment from NS3 and NS5B (G61-821) could be expressed well and showed obvious immunoreactivity by Western blotting. One clone with HGV framment from NS5B (G82) was also well expressed, but could not show immunoreactivity by Western blotting. No obvious expression was found in the other six clones. All the expressed recombinant proteins were in inclusion body form, except the protein G61 which could be expressed in soluble form. Further purified recombinant proteins G1, G31, G61, G821 and G61-821 were detected in indirected ELISA as coating antigen respectively. Only recombinant G1 could still show immunoreactivity, and the other four recombinant proteins failed to react to the HGV antibody positive sera. Western blotting results indicated that the immunoactivity of these four recombinant proteins were lost during purification.**

CONCLUSION **Core to E1, E2, NS3 and NS5 fragment of HGV contain antigenic epitopes, which could be produced in prokaryotically expressed recombinant proteins. A high-yield recombinant protein (G1) located in HGV core to E1 could remain its epitope after purification, which showed the potenti al that G1 could be used as a coating antigen to develop an ELISA kit for HGV specific antibody diagnosis.**

INTRODUCTION

Hepatitis G virus (HGV), also known as GBV-C, is a novel human virus, which can cause acute and persistent infection in humans[1-4]. The clinical significance of HGV infection is still controversial[5-10]. Some studies have reported the seroprevalence of HGV RNA in general population as well as voluntary blood donors between 0.3% and 6%, but the frequency is always significantly higher in high risk groups such as intravenous drug users (IVDU), patients with acute and chronic hepatitis B and C, patients with blood transfusion and hemodialysis, and patients with cryptogenic hepatitis[11-22]. HGV is a member of flaviviridae[3,4,19]. The genome organization of HGV resembles that of hepatitis C virus (HCV). Its positive- stranded RNA genome is about 9.4 kb in length that contains a single open reading frame (ORF), which encodes a polyprotein of about 2900 amino acids. The polyprotein is cleaved by viral and host proteases into structural proteins (Core, E1 and E2) and non-structural proteins (NS2, NS3, NS4, NS5a and NS5b)[1,2,23,24].

Up to now, RT-PCR is the most commonly used method for the diagnosis of HGV infection. It is necessary to develop a convenient antibody detection assay. In this study, we had serial fragments selected from core to NS3 and NS5 region of HGV Chinese strain expressed in *E.coli*, and detected their immunoreactivity by Western blotting and ELISA.

MATERIALS AND METHODS

Bacterial strains and plasmids

E.coli strain DH5α and BL21(DE3) were stored in our laboratory. Serial expression vectors pRSET and pGEX were purchased respectively from Invitrogen Co. and Pharmacia Co.. Clones include gene fragments of Chinese HGV strain (HGVch, Genbank Accession Number U94695) constructed in our laboratory before[25].

Enzymes and other biochemical reagents

Restriction endoenzymes, T4 DNA ligase and DNA polymerase Taq were purchased from Promega. Sepharose 4B GST matrix, His Trap™ and isopropyl- β-D-thiogalactopyranoside (IPTG) were purchased from Pharmacia. Goat anti-human IgG-alkaline phosphatase conjugate and substrates BCIP, NBT were purchased from Boehinger Mannheim.

Serum samples

Three HGV positive serum samples were kindly provided by Dr. Qiu (Beijing Wantai Biological Medicine Co.). Two of them

were HGV RNA positive by RT-PCR, the other one was positive in the synthetic peptides based HGV ELISA kits and with high titer anti-HGV antibodies. These three serum samples mixed in equal ratio and were used in Western blotting.

Construction of recombinant plasmids

By the regular molecule biological METHODS, pRSET and pGEX were digested with single endoenzyme or two endoenzymes, gene fragments of HGV in pGEM T-Easy were digested with the same restriction enzyme (s), and they were ligated by T4 DNA ligase, and the expression clones of HGV gene fragments were constructed.

Expression of HGV gene fragments in E.coli

Two mL fresh overnight cultured BL21(DE3) carrying HGV gene fragment expression plasmids were diluted with 200 mL fresh LB medium in the presence of 100 mg·L^{-1} ampicilin and grew to A_{600} = 0.8 at 37 ℃ at a shaki ng speed of 210 r·min^{-1}. The culture was induced by adding IPTG to a final concentration of 0.2 mmol·L^{-1} at 37 ℃ for 3 h. One mL culture was harvested by centrifugation, cell pellets were resuspended in 400 μL SDS/PAGE loading buffer, and aliquots were run on 120 g·L^{-1} SDS-PAGE gels. In order to obtain soluble recombinant proteins, induction expression was carried out at 20 ℃ for 3 h.

Western blot analysis of recombinant proteins

Total cell lysates were run on SDS-PAGE gels and transferred electrophoretically to nitrocellulose membrane for 1 h under the voltage of 100 V. The membrane was then incubated in blocking solution (50 g·L^{-1} nonfat milk in Tris-buffered saline, TBS) for 1 hour at room temperature followed by incubation at room temperature for 2 h in the sera that prediluted to 1:200 with blocking solution. The membrane was washed three times with TTBS (0.5 g·L^{-1} Tween-20 in TBS) for 10 min, and alkaline phosphatase-labeled goat anti-human IgG antibodies diluted in TTBS (1:2000) were exposed to the membrane at room temperature for 1h. The membrane was visualized with a substrate solution of BCIP and NBT after another washing for 3 times for 10 minutes with TTBS.

Purification of recombinant proteins of HGV

For soluble recombinant proteins, the harvested bacterial pellets were resuspend ed in PBS, after ultrasonification and high speed centrifugation, supernatants were collected and used for purification. Purification of expressed proteins in pRSET was carried out according to the manual of His Trap™ (Pharmacia Co.), and that in pGEX was done following the manual of GST purification modules (Pharmacia Co.).

For insoluble recombinant proteins, the harvested bacterial pellets were resuspended in PBS, and collected after ultrasonification and high speed centrifugation, and then resuspended in washing buffer (50 mmol·L^{-1} Tris-Cl pH 7.2, 5 mmol·L^{-1} EDTA, 150 mmol·L^{-1} NaCl, 5 g·L^{-1} Triton-x 100). Following washing with 2 mol·L^{-1} and 4 mol·L^{-1} urea, the recombinant proteins in pellets were dissolved in 8 mol·L^{-1} urea, which were run on SDS-PAGE gels and stained with 0.3 mol·L^{-1} $CuCl_2$ solution for 5 minutes. The bands of the recombinant proteins could be seen clearly (background was light blue, and the bands of proteins were blank fielded), they were cut carefully and sealed into dialyzer in elution buffer (250 mmol·L^{-1} EDTA, 250 mmol ·L-1 Tris-Cl pH 9.5) to elute target proteins with electrophoresis.

Enzyme linked immunoadsorbent assay (ELISA)

Purified recombinant antigens were coated to microplate in a amount of 100 ng each well in 0.05 mol·L^{-1} CB (pH 9.6) buffer for 2 h at 37 ℃ and overnight at 4 ℃. Plates were washed with PBS containing 0.5 g·L^{-1} Tween 20 and blocked with blocking buffer (0.5 g·L^{-1} Tween 20 and 10 g·L^{-1} bovine serum albumin in PBS)for 2 hours at 37 ℃. Sera (1:1000) were applied for 30 min at 37 ℃. A peroxidase-conjugated goat anti-human IgG used as secondary antibody was incubated for 30 min at 37 ℃ and visualized with o-phenyl-diamine-2HCl (10 g·L^{-1} in 5 mmol·L^{-1} Tris-HCl, pH 7.0). Wells were washed five times with PBST (0.5 g·L^{-1} Tween 20 in PBS) between each step. The reaction was stopped with 50 μL of 2 mol·L^{-1} H_2SO_4. Absorption was measured at A_{495}.

RESULTS

Construction and identification of recombinant plasmids

The recombinant plasmids were digested with proper restriction endoenzymes. Agarose gel electrophoresis showed that all HGV gene fragments were cloned into the vectors with correct orientation and size. The recombinant protein expressed by pGEX vector had a GST fusion protein in N-terminal, while that by pRSET vector had a hexahistidine in N-terminal. The locations of corresponding fragments in HGV genome of these plasmids are listed in Table 1.

Table 1 Amino acid location of constructed expression vector in HGV CH strain, yields in E.coli and immunoreactivity in Western blotting

Clone	Vector	Target fragments	Amino acid location in ORF	Molecular mass of recombinant protein (ku)	Yield in *E.coli*	Immuno-reactivity
G1	pGEX	Core to E1	1- 144	42	High	+
G2	pRSET	E1 to E2	101- 284	23	No	
G3	pGEX	E2	247- 578	62	No	
G31	pGEX	E2	491- 578	36	High	+
G4	pRSET	E2 to NS2	542- 876	40	No	
G5	pRSET	NS2 to NS3	854-1078	28	No	
G6	pGEX	NS3	1073-1345	56	High	+
G61	pRSET	NS3	1160-1345	24	High	+

G61-821	pRSET	NS3+NS5	1160-1345+2357-2524	44	High	+

Expression of recombinant proteins in E.coli

Fourteen clones were constructed, covering the core, E1, E2, NS2, NS3 and NS5 region of HGV (Figure 1). The virus fragment in G1 covered a region from the beginning of the core to the aa144, which was located in the middle of E1. The yield of G1 was about 20% in total bacterial proteins (Figure 2, lane B). No visible expression was found in G2 (covering a region from E1 to E2) and G3 (including almost entire E2). But when the C-terminal 88 residues of G3, named G31, were expressed, a yield of about 30% was obtained (Figure 2, lane C). Both of the clones included NS2 fragment, G4 and G5, and could not produce obvious recombinant proteins. G6 and G7, both located in NS3, were expressed well (Figure 2, lane D and G). To obtain a soluble form of NS3 antigen, a fragment from aa1160 to aa1345 was subcloned from G6 to vector pRSET, the result ed clone G61 was expressed much better than G6 and G7, and the soluble form recombinant protein could be found in the supernatant after centrifugating the ultrasonificated bacteria (Figure 2, lane E and F). The NS5 fragment G8 was not expressed, so did the N-terminal two-three (G81) when G8 was spliced into two parts and subcloned, but the C-terminal one-three (G82) was expressed quite well (Figure 2, lane H). Better expression was found in the yield of G821, resulting from the 78 residues extended from G82 to N-terminal, (Figure 2, lane I), so did the chimerical clone, G61-821 (Figure 2, lane J).

Western blotting analysis

Eight well-expressed recombinant proteins were separated by SDS-PAGE and transferred electrophoretically to nitrocellulose for immumoblotting. As shown in Figure 3, except for fragment G82, all the other seven proteins showed immunoreactivity. G1 and G82 had strong reactivity with HGV positive sera, and reactivity of G31 was relatively weaker.

Purification and ELISA assay of recombinant proteins of HGV

Four immunoreactive antigens, G1, G31, G61 and G821, which were located in the core, E2, NS3 and NS5 respectively, and a chimerical antigen G61-821 was selected for further purification. After electrophoretical elution, the purity of these five proteins was higher than 90% (Figure 4). These antigens were coated respectively to microplate in a amount of 100ng each well. Three HGV antibody positive sera and five negative sera were used in ELISA. The results showed that only G1 could detected all positive sera effectively (Figure 5).

DISCUSSION

We have obtained full-length sequence of a Chinese HGV strain (HGVch) through overlapping RT-PCR[25]. Seven overlapping clones covering from the beginning of core to the end of NS3, were named G1 to G7, and one clone (G8) was located in NS5. They were subcloned to prokaryotic expression vectors pRSET or pGEX and expressed in E.coli in this study. The SDS-PAGE results showed that only fragments within C-E1 (G1) and NS3 (G6 and G7) could be expressed efficiently, but the clones located in E2 (G2 and G3), NS2 (G4 and G5) and NS5 (G8) could not. To improve the yield, one subclone (G31) for E2 and two subclone s (G81 and G82) for NS5 were constructed. The G31 was located in the C-part of G3, the G81 located in the N-terminal two-three of G8, and the G82 in the C-terminal one-three of G8. The results showed that G31 and G82 expressed well, but not G81.

In order to detect the immunoreactivity of different proteins at the same time, it is important to choose serum containing multiclonal antibodies against different epitopes. Due to the lack of reliable METHODS to detect anti-HGV, in this study, we chose a mixed serum as first antibodies in the immunoblotting assay. The Western blotting showed that G1, G6 and G7 had strong immunoreactivit y, the immunoreactivity of G3 could be identified too, but no reactivity could be found with G82. Then we constructed another clone G821, which resulted from the 78 residues, and extended to N-terminal from G82, its immunoreactivity in Western blotting was quite strong, indicating that this 78 residues played an important role in the epitopes of NS5. Both G6 and G7 showed a strong immunoreactivity, suggesting that the epitopic might cluster in NS3 region. We had a truncated fragment of G6 named G61 expressed as an endeavor to obtain the soluble NS3 antigen, because a soluble antigen usually displays more natural epitopic conformation. But we could not see a stronger reactivity in the soluble form of G61 than the insoluble form of G61 in Western blotting. Chimerical gene G61-821 was expressed as an endeavor for making a better diagnostic antigen, and it showed a strong immunoreactivity in Western blotting.

Among the four immunoreactive antigens, G1, G31, G61 and G821, which were locate d in the core, E2, NS3 and NS5 respectively, the chimerical antigen G61-821 was selected for further purification and coating respectively to microplate to make an ELISA kit. The results showed that only G1 could detect HGV positive sera effectively, the other four recombinant proteins could react with none of the three tested HGV positive sera, which may suggest that the immunodominant epitopes in these four antigens were conformationally depended, and were destructed during our purifying procedure, as sustained by the Western blotting results for these five purified proteins, which showed only the reactivity of G1.

Epidemiological studies of HGV have been hampered by the lack of convenience serologic assays. The virus has not been successfully grown in culture, thus no native antigen is available for serologic detections. Many authors had reported the expression of HGV proteins in prokaryotic systems or eukaryotic systems[26-28]. The recombinant proteins of the core, NS3, NS4 and NS5 gene of HGV expressed in E.coli showed immunoreactivity in Western blot assays, but none of them could be used in ELISA. It may be due to the loss of antigenicity during the purification procedure as shown in this study. Dille *et al*[29] successfully established an ELISA for anti-HGV E2 using CHO expressed E2 antigen, however, the presence of anti-E2 and HGV RNA was almost mutually exclusive: few were positive for both markers at the same time, and the utility of this ELISA in epidemiological studies was very limited[30,31]. Two HGV RNA positive sera were positive in ELISA based on the core-E1 antigen G1 obtained in this study. Although the serum samples in this study are very limited, they suggested the potential utility of this ELISA in epidemiological studies.

Although the prevalence of HGV infection is higher than that of HCV infection in the general population, there is absence of an obvious relationship between elevated level of alanine aminotransferase (ALT) and presence of HGV infection. Besides, whether the liver is the replication site of HGV has remained unclear. Saito *et al*[32] had detected both positive and negative stranded HGV RNA by HGV RT-PCR in the liver tissues of all the six tested HGV infected patients, which indicated that liver might be the primary site of HGV replicatio n, but many other scientists could not repeat these findings in their HGV infected patients by the same METHODS[33-36]. Recently, Reshetnyak et al reported that patients with HGV monoinfection had demonstrated the increase of the DNA single-stranded breaks peripheral blood lymphocytes (PBL) quantity[37]. Whether HGV is pathogenic to the liver or not, we should remain open to the possibility that its major pathological consequences, if any, may lie outside of the liver. A convenient serologic assay is undoubtedly crucial for the clarification of these unclear points.

Abstract

AIM **To study the effects of hypoxia, hyperoxia on the regulation of expression and activity of matrix metalloproteinase-2 (MMP-2) in hepatic stellate cells (HSC).**

METHODS **The expressions of MMP-2, tissue inhibitor of matrix metalloproteinase-2 (TIMP-2) and membrane type matrix metalloproteinase-1 (MT1-MMP) in cultured rat HSC were detected by immunocytochemistry (ICC) and *in situ* hybridization (ISH). The contents of MMP-2 and TIMP-2 in culture supernatant were detected with ELISA and the activity of MMP-2 in supernatant was revealed by zymography.**

RESULTS **In the situation of hypoxia for 12 h, the expression of MMP-2 protein was enhanced (hypoxia group positive indexes: 5.7±2.0, n = 10; control: 3.2±1.0, n = 7; P<0.05), while TIMP-2 protein was decreased in HSC (hypoxia group positive indexes: 2.5±0.7, n = 10; control: 3.6±1.0, n = 7; P<0.05), and the activity (total A) of MMP-2 in supernatant declined obviously (hypoxia group: 7.334±1.922, n = 9; control: 17.277±7.424, n = 11; P<0.01). Compared the varied duration of hypoxia, the changes of expressions including mRNA and protein level as well as activity of MMP-2 were most notable in 6 h group. The highest value (A hypoxia-Acontrol) of the protein and the most intense signal of mRNA were in the period of hypoxia for 6 h, along with the lowest activity of MMP-2. In the situation of hyperoxia for 12 h, the contents (A_{450}) of MMP-2 and TIMP-2 in supernatant were both higher than those in the control, especially the TIMP-2 (hyperoxia group: 0.0499±0.0144, n = 16; control: 0.0219±0.0098, n = 14; P<0.01), and so was the activity of MMP-2 (hyperoxia group: 5.252±0.771, n = 14; control: 4.304±1.083, n = 12; P<0.05), and the expression of MT1-MMP was increased.**

CONCLUSION **HSC is sensitive to the oxygen, hypoxia enhances the expression of MMP-2 and the effect is more marked at the early stage; hyperoxia mainly raises the activity of MMP-2.**

INTRODUCTION

It is well known that the key event in the hepatic fibrogenesis is the activation of hepatic stellate cells (HSC) due to the altered circumstances and the activated cells are the main source of MMP-2 which may promote the activation of HSC owing to degradation of the basement membrane matrix rich in collagen type IV around the cells[1-23]. We also know that liver fibrosis may be induced or worsened by hypoxia and reperfusion[24-27]. However, it has not been reported that the effects of oxygen on the expression and the activity regulation of MMP-2 in HSC. In this paper, the regulation of the expression and the activity of MMP-2 in rat HSC was investigated *in vitro* under the conditions of hypoxia or hyperoxia.

MATERIALS AND METHODS

Isolation and culture of HSC

HSC were isolated from adult Sprague Dawley rats weighing 380 g to 420 g (bought from the Experimental Animals Center of Shanghai Medical University, China) according to the method of Di Sario *et al*[28,29]. The cells ($10^5 \cdot mL^{-1}$) were inoculated in culture flasks and dishes with cover-glasses, and then cultured at 37 ℃ in a humidified atmosphere with 5% CO_2. The medium (DMEM, Sigma Co.) was changed 24 h later and thereafter every 2 d to 3 d. After 7 d culturing, the medium was replaced with serum-free medium (DMEM/F12, V/V = 1:1). Meanwhile, some of the dishes were cultured under the condition of hypoxia or hyperoxia, as previously described[30]. Briefly, the dishes were put in a sealed container with two holes (for the gas in and out), through which 100% N_2 or O_2 (Shanghai Biouxi Gas Co. Ltd, China) was inflated for 30 min, and then with the holes shut the dishes were incubated in hypoxia or hyperoxia continually for 12 h. The culture supernatant was collected and centrifuged, and preserved at -20 ℃. The cells on the cover-glasses were

rinsed in phosphate-buffered saline (PBS) for three times, fixed in 40 g·L^{-1} paraformaldehyde/PBS, and preserved in 700 mL·L^{-1} ethanol at 4 ℃[31]. In another experiment for observing the differences among the varied durations of hypoxia, the dishes were cultured with hypoxia for 6 h, 12 h and 24 h, 12 dishes for each group, along with three dishes as parallel controls for each group.

ELISA

Sandwich technique was used to detect the relative contents of MMP-2, TIMP-2 in the culture supernatant with polyclonal antibody against human MMP-2 (present of Dr. Stetler-Stevenson; 1:20 00), polyclonal antibody against human TIMP-2 (1:800), goat anti rabbit IgG-HRP (Huamei Co. Shanghai, China. 1:1 000) and the colorific tetramethyl benzidine (TMB) (Huamei Co. Shanghai, China). Fresh serum-free medium served as negative control. The O.D.values(A_{450} values) measured with the Vmax Kinetic Microplate Reader (Molecular Devices Corporation, Sunnyvale, California, USA) at 450 nm represented the relative contents of the protein.

Detection of the MMP-2 activity with zymography[10]

The activity of MMP-2 was detected by gelatin zymography using 80 g·L^{-1} polyacrylamide gels co-polymerized with 1 g·L^{-1} gelatin which served as the substrate of MMP-2. Culture supernatant (15 μL) was mixed with 2×sample buffer (1:1) and electrophor ised (80V-150V) for 4 h-5 h. Subsequently, SDS was extracted with Triton X-100 from the gels, which were then incubated for 48 h at 37 ℃ in 50 mmol·L^{-1} Tris/HCl, pH 7.4, containing 5 mmol·L^{-1}$CaCl_2$ and 5 mmol·L^{-1} $ZnCl_2$. Gels were stained in 300 mL·L^{-1} methanol/100 mL·L^{-1} acetic acid containing 5 g·L^{-1} Coomassie brilliant blue G250 and decolorized. The clear band against a blue background representing the activity of MMP-2 was measured by using Gel Image System (Image master 1D analysis software, Pharmacia)and recorded with the total *A* (area of clear band times mean *A*).

Immunocytochemistry (ICC)

Labeled streptavidin biotin method with HRP/DAB (Dako Co.) was used in ICC for detecting the expression of MMP-2, TIMP-2, MT1-MMP and desmin in the cells on the cover-glasses. The specific antibodies were: monoclonal antibody against the human MMP-2 (CalBiochem; 1:100), polyclonal antibody against human TIMP -2 (present of Dr. Stetler-Stevenson; 1:300), monoclonal antibody against the human MT1-MMP (CalBiochem; 1:10), polyclonal antibody against chicken desmin (made by the Department of Pathology, Shanghai Medical University; 1:200). According to the stain intensity, the positive result was recorded as the value of 1 (mild), 2 (middle), 3 (intense), and the positive indexes were given by the average values of the positive cells in 9 HP (×400) fields per slide.

In situ hybridization (ISH)

Recombinant plasmids of human MMP-2, TIMP-2 cDNA were gifts from professor Marmer (Medical Center of Washington University, USA). And that of MT1-MMP was presented by Dr. Xiao. Expansion, extraction and purification of the recombinant plasmids were performed as routine. Three cRNA probes were transcripted in vitro according to the protocol of the kit (Boehringer Mannheim Co., Germany). ISH was performed as previuosly described[32,33] with immuno histochemical detection using an alkaline phosphatase (AKP)-conjugated anti-digoxigenin monoclonal antibody (Boehringer Mannheim Co., Germany). Hybridization signal was visualized through the substrate of AKP (NBT and BCIP).

Statistical methods

t or *t'*test was used for statistical analysis.

RESULTS

Morphology and growing state of HSC

The HSC isolated freshly appeared round in shape and rich in cytoplasmic lipid droplets. The cells stretched the cytoplasmic processes and numerous lipid droplets were still seen around nuclei on the third day after seeding. Thereafter the cells became stellate with several long processes, grew in clumps, and took about 7 d to 10 d to cover all over the flasks or dishes. More than 95% of the cells showed expression of desmin. It was noticed that the morp hology and the number of HSC did not change obviously after treated with hypoxia or hyperoxia, as compared with control.

Relative content of MMP-2, TIMP-2 proteins in supernatant

Relative contents of MMP-2 protein in each of three hypoxia periods were higher than those in the control. The highest increase in the value ($A_{hypoxia}$- $A_{control}$) of the protein was in the period of hypoxia for 6 h, and the lowest was in 12 h. The relative content of TIMP-2 was higher in 12 h, while it lowered in both 6 h and 24 h, compared with the control; but there were no significant differences among them (Table 1). The contents of both MMP-2 and TIMP-2 in supernatants of the hyperoxia group (12 h) were higher than those of the control, especially the TIMP-2 (P<0.01, Table 2).

Activity of MMP-2 in supernatant

Activity of MMP-2 in hypoxia group (7.334±1.922, n = 9) was lower than that in control (17.277±7.424, n = 11; P<0.01, Figure 1). Compared the varied periods of hypoxia, the activity came down obviously in 6 h and 24 h, but slightly in 12 h (Table 1). On the contrary, the activity of MMP-2 in supernatant rose remarkably as the cells were cultured in hyperoxia for 12 h (P<0.05,Figure 1, Table 2).

Expression of MMP-2, TIMP-2, MT1-MMP proteins In cell situ

The positive stain of MMP-2, TIMP-2 and MT1-MMP appeared brown and yellow and located in cytoplasm. The expression of MMP-2 in hypoxia was more intense (positive indexes: 5.7±2.0, n = 10) than that in control (3.2±1.0, n = 7, P<0.05, Figures 2,3). The expression of TIMP-2 in hypoxia(positive indexes: 2.5±0.7, n = 10) was weaker (control, 3.6±1.0, n = 7, P<0.05, Figures 4,5). No significant statistical difference was found between hyperoxia and control for the expression of MMP-2. The expression of MT1-MMP was slightly more intense in hyperoxia than that in control (Figures 6,7).

Expression of MMP-2, TIMP-2 and MT1-MMP mRNA

The hybridization signal of MMP-2 in HSC was found in each of three periods of hypoxia. It was most intense in the 6 h group, milder in the 24 h group (Figures 8-10). The signal of TIMP-2 was weak and there was no difference among three periods. The expression of MT1-MMP mRNA was up regulated (Figure 11), TIMP-2 and MMP-2 were slightly elevated in HSC cultured in hyperoxia for 12 h.

DISCUSSION

It is known to all that oxygen is essential for cell living, and hypoxia will lead to cell dysfunction, or even death. Unfortunately, hypoxia always happens during the liver damage or inflammation, in which swelling of the hepatocytes, constriction of vessels, capillarization of sinusoids, increasing of ECMs in Space of Disse, construction of hepatocytes regenerating nodules and fibrotic septa, abnormal vessels network, increasing endothelin promoted by enterogenous endotoxin, and others may result in liver cell hypoxia[34-37]. In other words, tissue hypoxia occurs in the whole course of the liver fibrogenesis including the initiation and development. Meanwhile, ischemia-reperfusion is not rare in liver injury, and counterpulsation and hyperbaric oxygen therapy are suggested to treat some chronic liver diseases recently[38]. However, there are only a few reports about the effects of hypoxia or hyperoxia in liver fibrogenesis. Avila *et al* reported that methionine adenosyltransferase (MAT) mRNA level was down-regulated by hypoxia, the synthes is of glutathione (GSH) decreased because of a drop of MAT, the free radicals could not be eliminated timely, and the antioxidation ability of the liver came down[39]. Blanc et al found that hypoxia-reoxygenation had direct toxic effects on sinusoidal endothelial cells with an increase in xanthine oxidase activity and lipid peroxidation[40]. Up to now, apart from our work[11,14], we have not found any report about the effects of hypoxia or hyperoxia on the expression and the activity regulation of MMP-2 in HSC.

In our *in vitro* experiments, the expression of MMP-2 in HSC in hypoxia was increased, among the three different hypoxia periods, the changes of expression and activity of MMP-2 were most remarkable in the 6h group, suggesting that the harmful effects of the hypoxia were more serious at the early stage of the liver damage. In the meanwhile, the activity of the enzyme went down, this might be related to the regulation of the enzyme activity[41-46]. As we know, the activation of MMP-2 from HSC not only requires interactions with hepatocytes[47], but also is regulated by MT1-MMP and TIMP-2 which directly mediates the binding of pro-MMP-2 to the cell surface. The cell surface-localized complex is then promoted by MT1-MMP to generate a cell surface-bound active MMP-2: TIMP-2 complex. Upon dissociation of the complex, the active site is exposed, and TIMP-2 binds MMP-2, thereby suppressing its activity[48-54]. Apparently a lack of cooperation with hepatocytes and low expression of TIMP-2 in this experiment may contribute to a drop in the enzyme activity. The change of MMP-2 was opposite to that of TIMP-2 in the different hypoxia periods, suggesting that the former might induce the expression of the latter in the negative direction. It is clear that cell function in vitro is not all the same as it is *in vivo*, so the activity of MMP-2 in the liver tissue under hypoxia is worthy of further study. The mechanism in detail of the MMP-2 and TIMP-2 expression variations induced by hypoxia remains to be clarified. It may be the reason why HSC under hypoxia produced transcription factors, such as nuclear factor kappa B (NF-κB) and activator protein 1 (AP-1) which up-regulate the level of transforming growth factor beta 1 (TGF-β1) gene expression. TGF-β1 promotes the production of MMP-2 and inhibits that of TIMP-2[55].

The expression of MMP-2 and its regulation in HSC in the state of hyperoxia have not been reported. We found that the content of MMP-2 in supernatant was increased, and the activity of MMP-2 rose obviously in hyperoxia group. This suggests that the regulation of MMP-2 activation is stronger than that of the enzyme expression in hyperoxia. As hyperoxia promotes the expression of MT1-MMP in HSC and also that of TIMP-2, the elevated activity of MMP-2 in hyperoxia may be related to a combined action of MT1-MMP and TIMP-2.

Abstract

AIM **To observe the gene expression change of eNOSmRNA and iNOSmRNA in the small and large intestines with acute liver failure (ALF), and to reveal the biological function of NO on the pathogenesis of ALF and multiple organs dysfunction at the molecular level.**

METHODS **Sixty male Wistar rats were selected, weighing from 250 g to 350 g, and divided into 5 groups randomly: SO, ALF (6h, 12h), L-Arg, L-NAME, L-Arg and L-NAME, each group with 10 rats. The dose of L-Arg was 300 mg·kg^{-1}, and L-NAME was 30 mg·kg^{-1}, the reagents diluted by normal saline were injected through tail vein 30 minutes pre- and post-operation. The rats in the ALF group were respectively sacrificed postoperatively at 6 h, 12 h, and the rats in the other groups were sacrificed postoperatively at 6 h. The tissues of small and large intestines were harvested in 4% paraforaldehyde containing the reagent of DEPC and fixed at 6 h, embedded in paraffin, and 4 μm section was cut. The expression of eNOSmRNA and iNOSmRNA in these tissues was determined with in situ hybridization, and analyzed with the imaging analysis system of CMM-3 and SPSS statistical software.**

RESULTS **The expression of eNOSmRNA in the large intestine and iNOSmRNA in the small and large intestines increased significantly at 6 h after ALF, but the expression of iNOSmRNA in the small and large intestines reduced notably at 12 h after ALF ($P<0.05$); the expression of eNOSmRNA in the large intestine and iNOSmRNA in the small and large intestines decreased significantly with the reagents of L-Arg at 6 h ALF, but the expression of eNOSmRNA and iNOSmRNA in the small and large intestines decreased totally with the reagents of L-NAME or association with L-Arg 6 h ALF.**

CONCLUSION **The expression of eNOSmRNA in the large intestine increased notably at the early stage of ALF, NO induced by the enzyme of eNOS from the transplantation of eNOSmRNA can protect the function of the large intestine, the high expression of iNOSmRNA is involved in the damaged function of the small and large intestines. NO precursor can reduce the expression of iNOSmRNA in the small and large intestines and the damage to intestines; NOS inhibitor or association with NO precursor can totally lower the expression of eNOSmRNA and iNOSmRNA in the small and large intestines, it cannot notably influence the NOS inhibitor in the gene expression of eNOSmRNA and iNOSmRNA to supply the additional NO precursor.**

Qin JM, Zhang YD. Intestinal expressions of eNOSmRNA and iNOSmRNA in rats with acute liver failure. *World J Gastroenterol*, 2001;7(5):652-656

INTRODUCTION

Acute liver failure (ALF) can severely influence the metabolism, secretion, synthesis and biological transformation, resulting in multiple organs dysfunction (MOD). The effect of gastrointestinal ischemiaon the whole body is extensive and profound, which not only causes the increase of intestinal permeability and the movement of bacteria and toxin in the intestinal cavity, but also release a large quantity of inflammatory media; neuroendocrine element after ALF is closely related to intestinal damage. nitric oxide (NO) is a gaseous molecule with multiple biological function and "two sword" characters, and nitric oxide synthase (NOS) is a key enzyme that can synthesize NO and there are three subtypes including endothelial nitric oxide synthase (eNOS), inducible nitric oxide synthase (iNOS) and neural nitric oxide synthase (nNOS). Abundant nitric NOS is distributed in gastrointestinal tract, NO induced to produce by NOS is a nonadrenergic and noncholinergic (NANC) active media, it participates extensively in various physiological and pathological functions in the intestinal tract. eNOS is Ca^{2+} type and mainly distributed in endothelium, regulated and con trolled by Ca^{2+}/CaM, activated by bradykinin, histamine, PAF, P substance and blood flow shear energy, and catalyzes to produce a little amount of NO that regulates vascular dilation and protects adhesive to vascular wall from platelets and neutrophils. iNOS is a non-Ca^{2+} type and mainly distri buted in macrophages and endothelium, not regulated and controlled by Ca^{2+} /CaM, activated by endotoxin as well as several cytokines (such as IFN-γ, TNF-β, IL-1β), and catalyzes continuously to produce a large amount of NO that has cytotoxic effect. NO induced to produce by iNOS down-regulates the gene expression of iNOS. The negative feedback is conducted by mainly inhibiting DNA binding activity of NF-êB, it may restrict excessive production of NO under the pathophysiological conditions. The physiological and pathological effect of NO to the body depends chiefly on the quality and strength of stimulative elements, the dosage and reactive sites[1-4]. Few reports about the effects on intestinal eNOS and iNOS after ALF are available, and the gene expression of eNOS and iNOS in the intestinal tract. The

study intends to disclose the biological function of NO in ALF and MOD by establishing an ALF rat model and determining the expression of eNOSmRNA and iNOSmRNA in small and large intestines so as to provide a theoretical basis for clinical treatment in ALF.

MATERIALS AND METHODS

Experimental animal

Sixty male wistar rats were obtained from the Experimental Animal Center of Hunan Medical University, weighing from 250 g to 350 g, and divided into 5 groups randomly: sham operation, ALF (6 h, 12 h), L-Arg, L-NAME, L-Arg and L-NAME group. Each group had 10 rats.

Drug and reagents

L-arginine (L-Arg) NO precusor, 300 mg·kg^{-1} , obtained from Shanghai Chemical Reagent Company.

N-nitric -L-arginine methyl ester (L-NAME) NOS inhibitor, 30 mg·kg^{-1}, obtained from Sigma Chemical Company.

eNOSmRNA and iNOSmRNA *in situ* hybridization kit

Obtained from Wuhan Boster Biological Company. Oligoneucleotide probe sequences deriving from human gene: AI925269 GI5661233--① 121---155 (probe sequence --GAGGA CTTTC TCCGT TCTCC TTAGA TTGTA AGCTG---); ② 661---695(probe sequence---ACGTG CCAGA CGTCC TGCAA CAACC GTACC ATTTA---), rat gene AJ011116 GI3676237 -- and 216---250 (probe sequence---CCTAA GACCG TTCTG GCTAA TGTGC TGTAA CTCTA---).

METHODS

The ALF rat model was established by 90% hepatectomy according to Lu *et al*'s method[5]. L-Arg or L-NAME diluted with normal saline was preoperatively and postoperatively injected into the tail vein 30 min after operation in the L-Arg group or L-NAME group; L-Arg was injected preoperatively, L-NAME was preoperatively injected at a 30 min interval, normal saline was injected 30 min preoperatively and postoperatively to SO group and ALF group. The animals were sacrificed at 6 h and 12 h in ALF group after operation, the animals of the other groups were sacrificed at 6 h after operation. The tissues of small and large intestines were fixed in 4% paraformaldehyde containing the reagent of DEPC for 6 hours, dehydra ted gradually, embedded in paraffin, and cut into 4 μm sections.

Determining the expression of eNOSmRNA and iNOSmRNA

The detailed manipulations were conducted according to INTRODUCTION of reagent kits, phosphate buffered saline was used as the negative control in stead of oligoneucleotide probe, and the tissue of breast cancer as positive control. Five views were randomly selected in each tissue sections, measured under the 10×20 fold statistics microscope and analyzed with the imaging analysis system of CMM-3. The mean absorbance optical density (OD) was measured, *P* value less than 0.05 was regarded as having significant difference.

RESULTS

The expressions of eNOSmRNA in large intestine and iNOSmRNA in small and large intestines in ALF increased significantly at 6h (Figures 1-3), and the expressions of iNOSmRNA in small and large intestines in ALF decreased significantly at 12 h ($P < 0.05$). The expressions of eNOSmRNA in large intestine and iNOSmRNA in small and large intestines in ALF decreased significantly at 6 h using L-Arg, but the expressions of eNOSmRNA and iNOSmRNA in small and large intestines in ALF decreased significantly at 6 h using L-NAME or combined with L-Arg (Figure 4, $P<0.05$). The expression of eNOSmRNA and iNOSmRNA in bowel tissues are compared among all groups in Table 1.

DISCUSSION

ALF is a cooperative consequence of endotoxicemia, microcirculation dysfunction as well as inflammatory cells (such as macrophage, lymphocyte, etc) that release inflammatory mediators and cytokines (such as TNF, IFN, IL-1, etc) when stimulated, but definite mechanism remains unclear. The damage and decrease of phagocytosis in the liver result in enteral endotoxicemia and decrease in Na^+/K^+-ATP enzyme activity of liver cellular membrane, it causes intrahe patic cholestatic jaundice, dramatical decrease in glomerular filterable rate (GFR), increase in serum Cr, BUN and decrease in urine narium. Collection of glutamine in cerebral cells results in hepatic coma because of tyrosine, tryptophane and phenylalanine in brain, it suggests that enteral endotoxicemia is common substantial basis causing liver function failure syndrome, important pathophysiological stage of liver function failure, and mutual cause and result with liver function failure. It produces poison to hepatocytes, results in microcirculation dysfunction, aggravates liver damage and inhibits liver regeneration. Irreversible liver damage is also an initiate factor of subsequent multiple organs function failure because of liver function failure, it causes not only jaundice, haemorrhage but also renal function failure and hepatic coma[6,7]. Deficient L-arginine inhibits intrahepatic L-Arg/NO pathway and influences systematic blood flow when liver ischemia-reperfusion, L-arginine injected by portal vein inhibits arginase release in liver, reverses L-Arg/NO pathway, and mitigates liver injury[8,9]. Administration of arginine into intestinal tract can mitigate liver function impairment by acute liver injury,activate immune system of intestinal mucosa and regulate and decrease bacterial translocation[10]. GSH can participate in the regulation of iNOS activity, up-regulate the expression of iNOSmRNA, aggravate liver injury under stress condition[11]. Deficient TNF-α and IL-6 caused hepatic steatosis and high mortality, replenishment of TNF-α and IL-6 restored the hepatocyte regeneration[12]. NO can prevent cell apoptosis induced by TNF, and activate extra endothelial regulating kinase 1 and 2, inhibit NF-κB activation in cell[2,13-16]. Furthermore, NO inhibits Caspase-3-like proteinase and cell apoptosis, iNOS gene transfection mediated by adenovirus into hepatocytes can produce NO, which efficiently inhibits Caspase- 3-like proteinase activity, and local apoptosis in hepatocyte[17-20]. IL-1β can induce iNOS expression in hepatocyte by activating iNOS primer by IFN-γ, and produce a large amount of extra cellular matrix (ECM) such as hyaluronan, which induced iNOS to produce NO and form $ONOO^-$, and aggravate tissue injury by NF-κB signal transduction when liver is damaged, moreover, stabilize microcirculation and protect against liver injury. The effect of protection or impairment on the liver mainly depends on the NO concentration and cell derivation[21-23]. NO induced by iNOS in endotoxemia is closely related to liver function impairment, but NO induced early by hepatocyte cNOS can protect liver tissue[24,25]. The dual stimulation of endotoxemia and ischemia-reperfusion influenced microvascular blood flow and impaired liver tissue by selectively inhibiting eNOS or/and iNOS[26,27]. Enterogenous endotoxin permeated blood circulation and stimulated the expression of iNOS in intestinal tissues by portal-cavity lateral circulation. NO participates in hyperdynamic circulation of portal hypertension and general hyperdynamic circulation in cirrhosis[28,29]. Selectively inhibiting eNOS can cause vascular constriction and thrombosis and lower liver perfusion pressure, but had no influence on portal pressure; the difference may be related to different time interval of endotoxin and NOS inhibitor[30]. The expression of NOSmRNA decreased remarkably in the kidney of endotoxemia of cirrhosis, deficient NO or low sensitivity to NO in renal vessels can aggravate renal damage, and promote hepato-renal syndrome (HRS)[31]. Endogenous NO has anti-inflammatory function and inhibits neutrophiles to adhere to vascular endothelial cells and translocate from vessels. NO deriving from aminoformylp enicillamine can alleviate small intestine impairment induced by endotoxin and plasma leakage, suggesting that endogenous NO can maintain intestinal mucosal microvascular integrity, dilate intestinal vessel and improve gut microvasculation, react with superoxide (O_2^-) to be antioxidation, contribute to recovery of impaired enteric function. L-arginine and solution nitric prusside caused absorption of water and ions, but NOS inhibitor (L-NAMA) caused secretion of water and ions in the ileum, synchronous infusion of L-arginine and L-NAME cause absorption of water and ions in the ileum, indicating that endogenous NO can mediate absorption of water and ions in the ileum, maintain homeostasis of water and electrolytes. Neutrophil activation in circulation has been implicated in the capillary leakage during ischemia-reperfusion. It suggests that endogenous NO can maintain the capillary integrity and prevent macromolecular leakage. Capillary permeability and macromolecular leakage are critical factors causing ARDS during intestinal ischemia-reperfusion, and increased endogenous NO can maintain normal capillary function. It is very important to prevent systemic response such as ARDS caused by intestinal ischemia-reperfusion[32-36]. Endotoxemia results in increased cons titutive NOS and inducible NOS enzyme activities in the jejunum and ilem. LPS can upregulate constitutive NOS and inducible NOS in jejunal and ileal smooth muscle oxyhemoglobin increased intestinal transit in nonendotoxemia. NO may play a major role in mediating the rapid intestinal transit induced by endotoxemia. Hemoglobin attenuated the effect of endotoxin on intestinal motor function. Synthetic hemoglobins currently being a test as blood substitutes may be of therapeutic value in treating intestinal dysfunction complicated with sepsis [37-41]. However, the gene expression increase of iNOAmRNA in the intest inal tract produced a large amount of NO, slowed intestinal transit, promoted intestinal bacteria overgrowth during endotoxemia, and reacted with superoide (O_2^-) to form peroxynitrite anion ($ONOO^-$), causing inactivation of mitochondrial aconitase in entercytes and activation of poly-adenosine diphosphate ribosyl polymerase, leads to depletion of intracellular ATP stores by interfering with mitochondrial

respiration and intestinal mucosal barrier dysfunction, prolonged the exposure of cells to large amounts of NO may inhibit cell respiration, cause maldistribution of regional blood flow and cell damage, increase gut permeability; but inhibition of cNOS can decrease dramatically the blood flow of intestine, increase the damage of enteric hemorrhage by induction of LPS, even small dosage of LPS could cause enteric hemorrhage. LPS can inhibit cNOS,decreasing NO and increasing active oxidizing free radicals . L-Arg can protected the enteric hemorrhage from LPS or LPS associated with L-NAME. Inhibiting NO release can increase active oxygen production, and contribute to acute enteric damage by LPS[42-46]. Mishima *et al*[47] found that the iNOS-deficient mice could resist enterocyte apoptosis induced by LPS, and attenuate intestinal mucosal injury. Bacterial translocation induced by LPS was not found, suggesting that LPS could induce iNOS activation and increase NO production, resulting in intestinal mucosal injury and bacterial translocation, inhibiting iNOS can decrease NO production and prevent intestinal mucosal injury and bacterial translocation. Fruchterman *et al* observed that decrease of activity of cNOS and NO production in the small intestinal endothelial cell resulted in intestinal microvascular dysfunction such as low perfusion, platlets and neutrophils converged into postcapillary venule when hemorrhage shock and resuscitation occurred. $ONOO^-$ deriving from NO connection with O_2^- could decrease NO production, inhibit the synthesis of prostaglandin I_2 (PGI_2), impaie endothelial cell mitochondrial and lead to endothelial cell dysfunction and intestinal nucosal impairment[1,48-50]. NOSmRNA expression in colonic mucosa increased remarkably, especially iNOSmRNA, suggesting that vasodilation and blood flow increase because of increased NO production in colonic tissues, mucosal congestion was active not passive, inhibtion of iNOS and NO production may protect or mitigate the pathogenesis of portal hypertensive enteropathy (PHE). NO plays an important role in maintaining gastrointestinal vascular integrity and gastrointestinal motility under physiological and pathophysiological circumstances, it can relax vascular and gastrointestinal tract smooth muscle and contributes to LPS-induced intussusception pathogenesis by activating soluble guanylate cyclase (sGC) to increase intracellular cGMP, inhibiting NOS worsens the intestinal injury induced by ischemia-reperfusion and endotoxin, decreases the incidence of intussusception, but L-Arg can increase the incidence of intussusception, suggesting that endogenous NO plays an important in regulating normal and pathop hysiological circumstance by activating sGC and altering intracellular level of cGMP[51,52]. our study indicated that the expression of eNOSmRNA increased dramatically at early stage of ALF, NO produced by eNOS can keep the integrity of enteral microvascular mucosa, expand blood vessel in enteral mucosa, improve microcirculation, and has antioxidant function by connecting with superoxide anion and protects enteral function from damage. but the high expression of iNOSmRNA in large intestine can induce iNOS synthesis constantly and produce a large amount of NO, slow enteric peristalsis, promote bacterial outgrowth, increase calcium ion concentration, result in protective barrier dysfunction in enteral epithelium, penetration and bacterial translocation increase. The low expression of eNOSmRNA in small and large intestines might be related to consumable increase of eNOS, furthermore, the low expression of iNOSmRNA in small and large intestines might be related to producing excessive NO locally can and feedbackly inhibiting the expression of iNOSmRNA after replenishing exogenous larginine. L-Arg contributes to water and electrolyte absorption in small intestine and plays an important role in keeping microcirculatory stability, suggesting that replenishing exogenous NO precursor can reduce the enteral expression of iNOSmRNA and beneficial to organism, NOS inhibitor can significantly influence the gene expression of both enzymes in large intestine, especially reducing the eNOSmRNA expression more significantly. NO produced by high expression of iNOSmRNA may influence local microcirculation and integrity in enteral mucosa, and contribute to enteral bacterial transl ocation in ALF. It is similar to influence to eNOSmRNA and iNOSmRNA expression using NO precusor connecting with NOS inhibitor or only using NOS inhibitor, and indicating that replenishing exogenous NO precusor can not significantly influence the effect of NOS inhibitor on both gene expression of eNOS and iNOS. It is necessary to further on the mechanism of mutual interaction with them.

Abstract

AIM **To study the relationship between ABO blood groups and carcinoma of esophagus and cardia in Chaoshan inhabitants of China, which is a unique Littoral high-risk area of esophageal carcinoma in China. The poor communication and transportation in the past has made Chaoshan a relatively closed area and kept its culture and custure of old China thousand years ago.**

METHODS **Data on age, sex, ABO blood type and X-ray or patholog ical diagnose of the patients with carcinoma of esophagus or cardia were collected from the Tumor Hospital. First Affiliated Hospital, Second Affiliated Hospital of Shantou University Medical College; and the Central Hospital of Shantou and the Central Hospital of Jieyang. A total of 6685 patients with esophageal carcinoma (EC) and 2955 patients with cardiac cancer (CC) in Chaoshan district were retrospectively assessed for their association with ABO blood groups.**

RESULTS **The distribution of ABO blood groups in patients with EC or CC was similar to the normal local population in Chaoshan. However, blood group B in male patients with CC and in the patients with carcinoma in the upper third esophagus was 2.3% and 4.7% higher than the corresponding controls. The relative risk B:O was 1.1415 ($P<0.05$) and 1.2696 ($P<0.05$), respectively. No relationship was found between ABO blood groups and tumor differentiation.**

CONCLUSION **ABO blood group B is associated with the incidence of CC in male individuals and carcinoma in the upper third esophagus. The distri bution of ABO blood groups varies in the different geographical and ethnic groups. As a result, proper controls are very important for such studies.**

INTRODUCTION

Chaoshan is an enclosed littoral region surrounded by mountains located at the boundary between Guangdong Province and Fujian Province of China. Chaoshan residents mostly came from Henan, Shanxi, and Changan thousands years ago, and are a relatively isolated population with a high risk of esophageal carcinoma (EC) and cardiac carcinoma (CC). Within Chaoshan, the Nanao Island has the highest risk[1,2]. According to the report from the Department of Public Health. Guangdong Province in 1993, the mortalities of esophageal carcinoma in the Nana o Island were: 108.68±7.88/100 000 standardized population of China and 145.44±10.49/100 000 standardized world population and 261.16±25.01/100 000 standardized world population aged 35-64 years. The annual average incidence rates of male and female were 132.19/100 000 and 69.20/100 000 in the Nanao Island from 1987 to 1992[3,4]. It has been noticed that EC is a race-related disease. People of Chinese origin living in foreign countries have higher EC frequency than those of non-Chinese origin, and in comparison with the frequency in the people with Chaoshan origin is even higher. The mortality of EC within immigrants of the Nanao Island origin in Meixian County, Guangdong Province is 1.7 times that of the local residents[5]. The poor communication and transportation in the past has made Chaoshan a relatively closed society and formed its unique culture, customs and habits. A preliminary study showed that Chaoshan residents were migrants from central China, and their traditional culture, custom and habits were well kept. This unique society provides us an unparalleled base to study cultural and genetic factors and their interaction in the study of EC.

Since the association between blood group A and gastric cancer was reported in 1953, the relationship with blood groups and incidence[6-16], clinicopathologic parameter[17,18] and prognosis[19-21] had been studied in many cancer and other disease[22,23]. However, there is no consistent result[24-27]. Additionally, ABO genes are distributed differently among socioeconomic groups[28] and we know that socioeconomi c status is one of the risk factors for diseases. Thus, a retrospective assessment of the relation between blood groups and EC, CC was performed with a view to start the study of the genetics of these cancers in Chaoshan district.

MATERIAL AND METHODS

Clinical data

Data about age, sex, ABO blood type and X-ray or pathological diagnosis of the patients with EC and CC were collected from the Tumor Hospital (1978-1998). The First Affiliated Hospital (1989-1998), the Second Affiliated Hospital (1983 - 1998) of Shantou University Medical

College; the Central Hospital of Shantou and the Central Hospital of Jieyang. A total of 6685 patients with EC and 2955 patients with CC in Chaoshan district were retrospectively assessed for the association with ABO blood groups. In these series, histopathological diagnoses were available in 4719 patients with EC and 2120 patients with CC. The differe ntiation of the carcinomas was categorized as grade 1 (well-differentiated tumors) to grade 3 (poorly-differentiated tumors). The remaining cancers were diagnosed by X-ray. In 5638 patients with EC, there is definite information on tumor sites within the esophagus. All patients' medical records, including operative notes and histopathological reports, were reviewed.

Normal control

The ABO blood group distribution of the blood donors from the Central Blood Bank in Shantou city was used as control groups 7276 donors were sampled, of the same ethnic group and from the same native place as the patients.

Statistical analysis

Data were stored in a computer data base (FoxPro, version 2.5b) and analyzed using a computer spread sheet (Microsoft Excel 97) and professional statistical computer software (SPSS, version 6.12 and SAS, version 6.08). The differences of ABO blood group distribution in patient groups and controls were assessed using Chi-square test. The gene frequencies of blood group antigen were calculated by the method of Bernstein and the relative risks were estimated using Woolf's methods. P values <0.05 were regarded as statistically significant.

RESULTS

The distribution of ABO blood groups in the EC group was similar to that of a normal population (Table 1) and so was the gene frequencies (Table 2). Although blood group B in total patients with CC and female patients with CC were 2.3% and 1.5% higher than the corresponding controls, the difference was not significant. In male patients with CC, there was a 1.6% deficiency of blood group A and a 2.3% excess of blood group B as compared with the male controls, and the two groups differ significantly in their ABO distribution ($\chi^2 = 8.518$, $P<0.05$). The gene frequencies of blood group B were 0.196 in male patients with CC, which was higher than that of the male controls (0.175), and the relative risk B:O was 1.14 (95% confidenc e interval 1.01-1.29) with statistical significance (Table 2). This suggests that male individuals with blood group B are more susceptible to CC. With respect to the site of EC, carcinoma in the middle third esophagus is most common (73%), but the prevalence of blood groups in this group and the lower third group were identical to the controls. The blood group B patients with carcinoma in the upper third esophagus was 4.7% higher than the controls, with a higher gene frequency (0.2072), and the difference of the blood group distribution between the two groups was of statistical significance. When blood group B was compared with blood group O, the relative risk was 1.27 (95% confidence interval 1.05-1.54), which was statistically significant by Chi-square test. Although the prevalence of blood group B was a little lower in the poorly differentiated squamous cell carcinoma of the esophagus (ESCC) than expected, the deficiency did not reach significance. No relationship between the tumor differentiation and ABO blood group distribution was found.

Table 1 ABO blood group distribution in EC patients (n, %)

DISCUSSION

There seemed to be no association between ABO blood groups and the incidence of EC or CC when the studied patients were not grouped by sex and tumor site. This result is consistent with previous reports. However, in the present study, male individuals with blood group B were more susceptible to CC than those with other blood types, and blood group B was associated with carcinoma of the upper third of the esophagus. It suggested that the susceptibility of male to certain cancer was not the same as female. Thus, further classification by sex may be needed when studying the relation between ABO blood groups and cancer. No relation was found in the current study between blood groups and the histological differentiation of EC or CC. The relationship between ABO blood groups and carcinoma of esophagus and cardia has been controversial[29,30]. Mourant and his colleagues reported that blood groups A and B were both associated with EC and no relation was found between blood groups and CC, based on the data from 31 districts in 13 countries and 7 districts of 6 countries, respectively[31]. But some authors have reported different associations according to geographical locations. Thus, blood group A was associated with EC in the British population of Belfast and blood group B individuals were susceptible to EC in British in Bristol, Bantu in South Africa and Iowa in America. But ABO blood groups have shown no correlation with EC in other districts in these countries[29]. These inconsistent results reflect two fundamental methodological problems with such association studies, the statistical methods and the selection of controls. Since the association between ABO blood groups and different cancers is not the same, associations may be observed if several kinds of carcinoma are analysed together. Small sample size is another possible inconsistency.

The importance of careful selection of controls is illustrated by the comparison of populations from different districts whthin China (Table 3). The distribution of ABO blood groups in different districts differs significantly (χ^2 = 0.141, P<0.01). For instance, there was a 10% excess of blood group A individuals in the population of Wuhan, compared with that of Shanxi, a 13.7% excess of blood group B individuals in Linxian compared with Wuhan, and a difference in the frequency of blood group O in Chaoshan compared to Shanxi, even though Chaoshan residents came from Henan, Shanxi, a thousand years or more ago. This suggests that the frequency of different alleles in immigrants to Chaoshan from Shanxi has drifted, compared with their originating population. The best control is, therefore, the ABO blood group distribution of the healthy population of the same ethnic group and sex and from the same native place as the patients[32]. It is possible that blood group B is just a marker of the ancestral population from Shanxi which is now mixed into the Chaoshan region, Shanxi people are also the population at high risk of EC/CC.

The explanation for the association between ABO blood groups and some special diseases was still unclear. Many reports have shown that blood group antigen expression in tumor is correlated with metastasis[33,34] and prognosis[35,36]. The loss or presence of blood group antigens can increase cellular motility or facilitate the interaction between tumor cells and the endothelium of distant organs[37,38]. ABO(H) blood group genes are map at 9q in which the genetic alteration is common in many cancers[39-44]. Thus, ABO(H) blood group antigen expression may be affected by the genetic change of tumors. On the other hand, it is possible that the observe d associations are not due to the blood group antigens themselves, but to the effects of genes closely associated with them. Additionally, it might have nothing to do with molecular mechanisms or genetics. It is merely the result of population history[45-47], environment[45,48,49], diet[50] and customs[51-55].

In conclusion, the current study shows no association of ABO blood groups with EC and CC, when the patients are not separated by sex and tumor site. If they are so grouped, male individuals with blood group B are found to have increased risk for the development of CC, and blood group B individuals are more likely to get carcinoma in the upper third of the esophagus. These findings may contribute to the genetic or custom study of EC and CC.

Abstract

AIM **To evaluate the role of RARα gene in mediating the growth inhibitory effect of all-trans retinoic acid (ATRA) on gastric cancer cells.**

METHODS **The expression levels of retinoic acid receptors (RARs) in gastric cancer cells were detected by Northern blot. Transient transfection and chlorophenicol acetyl transferase (CAT) assay were used to show the transcr iptional activity of β retinoic acid response element (βRARE) and AP-1 activity. Cell growth inhibition was determined by MTT assay and anchorage-independent growth assay, respectively. Stable transfection was performed by the method of Lipofectamine, and the cells were screened by G418.**

RESULTS **ATRA could induce expression level of RARα in MGC80-3, BGC-823 and SGC-7901 cells obviously, resulting in growth inhibition of these cell lines. After sense RARα gene was transfected into MKN-45 cells that expressed rather low level of RARα and could not be induced by ATRA, the cell growth was in hibited by ATRA markedly. In contrast, when antisense RARá gene was transfected into BGC-823 cells, a little inhibitory effect by ATRA was seen, compared with the parallel BGC-823 cells. In transient transfection assay, ATRA effectively induced transcriptional activity of βRARE in MGC80-3, BGC-823, SGC-7902 and MKN/RARα cell lines, but not in MKN-45 and BGC/aRARα cell lines. Similar results were observed in measuring anti-AP-1 activity by ATRA in these cancer cell lines.**

CONCLUSION **ATRA inhibits the growth of gastric cancer cells by up-regulating the level of RARα; RARα is the major mediator of ATRA action in gastric cancer cells; and adequate level of RARα is required for ATRA effect on gastric cancer cells.**

INTRODUCTION

Retinoic acid (RA) exerts profound effects on the growth, differentiation and apoptosis of normal, premalignant and malignant epithelial cells *in vivo* and *in vitro*[1-7]. The effects of retinoic acid are mainly mediated by two classes of nuclear receptors, retinoic acid receptors (RARs) and retinoid X receptors (RXRs)[8-13], which belong to steroid/thyroid receptor superfamily, and are encoded by three distinct genes, α, β and γ. RXRs form homodimers (RXR/RXR) and heterodimers (RAR/RXR) with RARs receptively, then bind to specific RA response elements (RARE), and regulate positively and negatively their transcriptional activities of target genes[9,13-17]. These receptors, thus, display distinct patterns and exert specific functions on anti-cancer effects in various cancer cell lines.

There have been sufficient evidences showing a link between the alteration of RARs activity and some diseases[18-22]. t (15;17) chromosomal translocation leads to the forming of PML-RARα fusion and abnormal RARα transcription in acute promyelocytic leukemia[23-26] . High frequency of the deletion next to RARα gene in chromosome 3P is observed in human lung cancer. Lack of RARα expression is responsible for the resistance of RA in breast cancer cells[1,20,21,27- 29]. Investigation the functions of retinoic acid receptors, therefore, is essential to elucidate their anticancer effects of RA. In the present study, we evaluate the role of RARα gene in mediating the effect of all-trans retinoic acid (ATRA) in gastric cancer cells. The results indicated that RARá is required for ATRA to exert its growth inhibition on gastric cancer cells.

MATERIALS AND METHODS

Cell lines and culture conditions

The human gastric cancer cell lines, BGC-823, SGC-7901 and MKN-45, were purchased from Institute of Cell Biology, Shanghai, China. MGC80-3 cell line was established by Cancer Research Center in Xiamen University. All of four cell lines were maintained in RPMI1640 medium, supplemented with 100 mL·L^{-1} FCS, 1 mmol·L^{-1} glutamine, and 100×10^3 U·L^{-1} penicillin.

RNA preparation and Northern blot

Total RNA was prepared by guanidine hydrochloride/ultracentrifugation method. About 30 μg total RNA was fractionated on 10 g·L^{-1} agarose, then transferred to nylon, and probed with ^{32}P-labeled probe as previously described[30]. The probes of RARα, RARβ, RARγ and RXRα were provided

by Dr. Zhang (The Burnham Institute, CA, USA). 28S and 18S were shown in quantitation of RNA.

Transient transfection and CAT assay

Cells were seeded in six-well plates with approximately 70% confluent at the time of transfection. Cells were transient transfected by Lipofectamine™ (Gibco/BRL). Transient transfection was performed utilizing βRARE-tk-CAT reporter gene plasmid, containing the βRARE linked with tk-CAT promoter[29], or -73col-tk-CAT receptor gene plasmid, containing an AP-1 binding site located between residues -73 and -63 in collagenase promoter[31,32]. Transfection condition was as follows: 6 μL Lipofectamine™ in 1.0 mL standard medium was added to each well, togelher with 1.0 mL of standard medium containing 400 ng reporter gene plasmid, 400 ng β-galactosidase expression vector (pCH110, Pharmacia), and carrier DNA (pBluescript) added up to 1000 ng total DNA. CAT activity was normalized for transfection efficiency to the corresponding β-galactosidase activity as described elsewhere[1,30-32].

Stable transfection

Sense RARα- and antisense RARα expression vectors (provided by Dr. Zhang) were stably transfected into gastric cancer cells, MKN-45 and BGC-823, respectively, by Lipofectamine™ (Gibco/BRL) as described above, and then screened with 600 μg of G418. Expression of endogenous RARá was determined by Northern blot.

MTT assay

Cells were seeded at 1000 cells per well in 96-well plates, and treated with ATRA (Sigma) at various concentrations. Medium was changed and ATRA was added every other day. After treatment for one week, cells were stained with 3-[4,5-Dimethylthiazol-2-yl]-2, 5-diphenyltetrazolium bromide (MTT, Sigma) for 3 h-4 h. Cell viability was determined by the MTT assay[1,30,32]. An underlayer of 5 $g \cdot L^{-1}$ agar in medium supplemented with 100 mL $\cdot L^{-1}$ FCS was first prepared and hardened in 6-well plate. Cells $1\times10^{8} \cdot L^{-1}$, in culture medium containing 100 $mL \cdot L^{-1}$ FCS, 5 $g \cdot L^{-1}$ agar, and 10^{-6} $mol \cdot L^{-1}$ ATRA (only for experimental groups), were seeded onto the underlayer. The plate was incubated for three weeks in CO_2 incubator. Number of colonies with diameter >80 μm was counted under microscope[5].

RESULTS

Expressions of RARα, RARβ, RARγ and RXRα in gastric cancer cells

Northern blot analysis showed that the level of RARα expression was high in MGC80-3, BGC-823 and SGC-7901 cells, while rather low level in MKN-45 cells. After treated with ATRA, MGC80-3, BGC-823, and SGC-7901, cells exhibited a marked increase in RARα expression, whereas MKN-45 cells had no change in RARα expression. RARβ expressed in MGC80-3, BGC-823, and SGC7901 cells, but not in MKN-45 cells. As for RARγ, none of the four cell lines expressed RARγ (data not shown). All cell lines showed a relatively low-level expression of RXRα. However, the expressions of RARβ, RARγ and RXRα could not be induced by ATRA in these four cell lines (Figure 1).

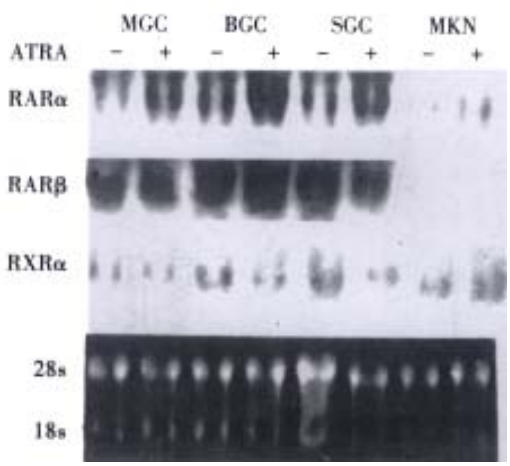

Figure 1 Expressions of RARα, RARβ and RXRα in gastric cancer cell lines detected by Northern blot. Cells were treated with 10^{-6} $mol \cdot L^{-1}$ ATRA.

Transfection and expression of RARα gene in gastric cancer cells

Based on these results mentioned above, we transfected antisense RARα gene and sense RARα gene into BGC-823 and MKN-45 cells, respectively. It was demonstrated by Northern blot that when antisense RARα gene was transfected into BGC-823 cells, RARα expression was repressed, and could not be induced by ATRA, compared with parallel cells BGC-823 (Figure 2A). On the contrary, MKN/RARα cells that transfected with sense RARα gene had a higher expression of RARα than parallel MKN-45 cells, and the expression of RARα could be induced by ATRA (Figure 2B).

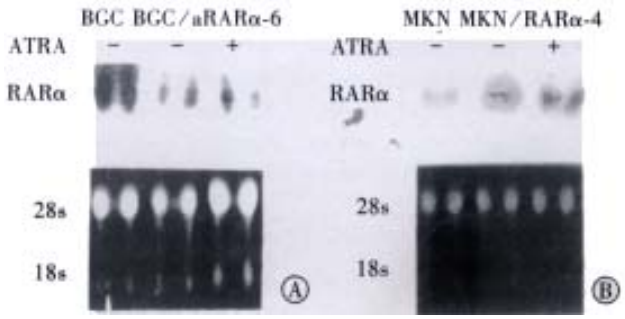

Figure 2 A. Expression of RARα mRNA in BGC-823 cells transfected with antisense RARα gene. B. Expression of RARα mRNA in MKN-45 cells transfected with sense RARα gene.

Effect of ATRA on the growth inhibition of gastric cancer cells

ATRA could effectively inhibit the growth of MGC80-3, BGC-823 and SGC-7901 cells, but had a rather weak effect on MKN-45 cells (Figure 3A). As for the transfected cells, BGC/aRARα, the inhibition rate by ATRA dropped obviously from 61.0% to 18.4%. The opposite result was seen in another transfected cell, MKN/RARα, in which ATRA could effectively suppress the growth of MKN/RARα cells, with an enhanced inhibition rate from 3.9% to 31.7% (Figure 3B).

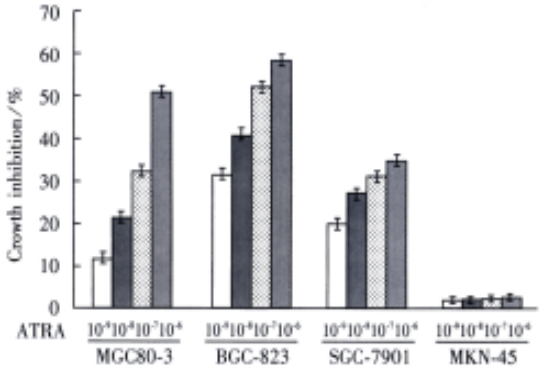

Figure 3A Growth inhibitory effect of ATRA on gastric cancer cell lines measured by the method of MTT. Cells were treated with various concentrations of ATRA indicated.

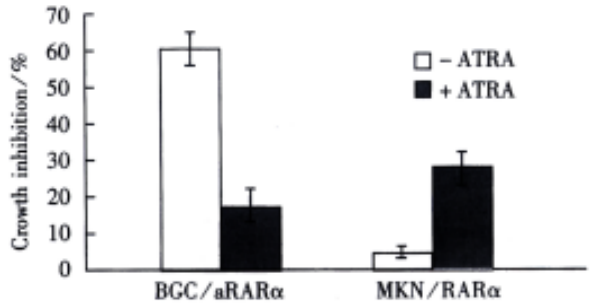

Figure 3B Growth inhibitory effect of ATRA on BGC-823 cells transfected with antisense RARα gene and on MKN-45 cells transfected with sense RARα gene, respectively.

Effect of ATRA on cell clone formation in soft agar

ATRA could inhibit the ability of clone formation in four cell lines and the inhibition for MKN-45 cells was lowest among four cell lines (Table 1). In contrast, in the transfected cells, the highest inhibition on MKN/RARα cells transfected with sense RARα gene was observed, compared with BGC/aRARα cells transfected with antisense RARα gene (Table 1).

Table 1 Inhibitory rate of clone formation of cells treated with 10^{-6} mol·L^{-1} ATRA in soft agar

Cell lines	MGC	BGC	SGC	MKN RARα	MKN / aRARα	BGC / aRARα
Inhibitory rate (%)	48.8[b]	45.2[b]	65.3[b]	14.3[b]	56.1[b]	15.2[b]

[b]$P<0.01$, *vs* control.

Regulation of ATRA on αRARE transcriptional activity

When transient transfection was performed with reporter gene, βRARE-tk-CAT, MGC80-3, BGC-823 and SGC-7901 cells exhibited a stronger induction of CAT activity by ATRA than MKN-45 cells, with an increased induction (CAT activity induced by ATRA deletes CAT activity in control) by 3.67, 3.44 and 2.25 fold, respectively, compared with that of MKN-45 cells by 1.04 (Figure 4A). However, ATRA could not significantly induce CAT activity in BGC/aRARα cells, and the induction was 1.76 fold, compared with 3.40 fold in MKN/RARα cells whose CAT activity was induced by ATRA obviously (Figure 4B).

Inhibitory effect of ATRA on AP-1 activity

AP-1 (activator protein-1) activity is associated with proliferation and trans fomation of tumor cells, and can be induced by some agents for mitogen, such as TPA (12-O-tetradecanoylphorbol-13-acetate)[31-33]. Detection of AP-1 activity by transient transfection and CAT assay was carried out in gastric cancer cells. As shown in Figure 5, the AP-1 activity (CAT activity) induced by TPA was suppressed by ATRA in MGC80-3, BGC-823 and SGC-7901 cells, with an ATRA-dose dependent manner. However, the suppressive effect of ATRA could not be observed in MKN-45 cells (Figure 5A). In the transfected cells, ATRA treatment resulted in a decrease of AP-1 activity induced by TPA in MKN/RARα cells transfected with sense RARα gene, but with a little effect in BGC/aRARα cells transfected with antisense RARα gene (Figure 5B).

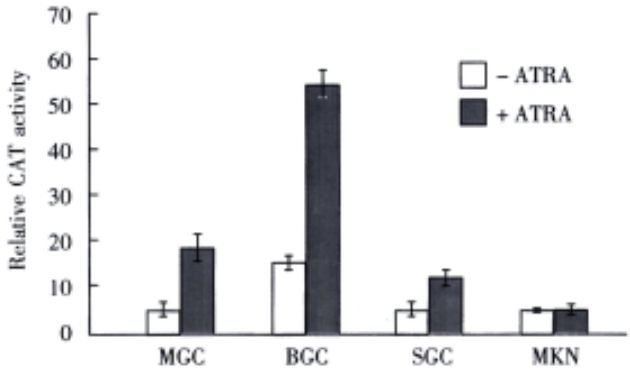

Figure 4A Regulation of ATRA on βRARE transcriptional activity in gastric cancer cell lines detected by CAT assay.

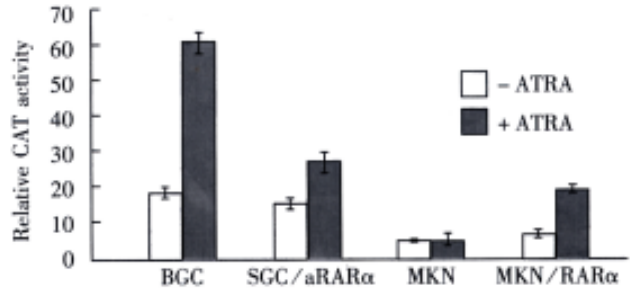

Figure 4B Regulation of ATRA on βRARE transcriptional activity in BGC-823 cells transfected with antisense RARα gene and in MKN-45 cells transfected with sense RARα gene, respectively.

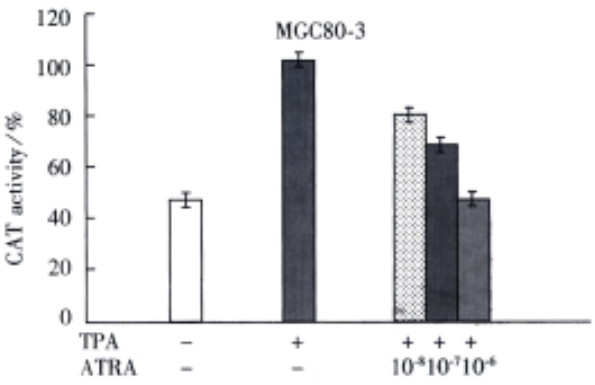

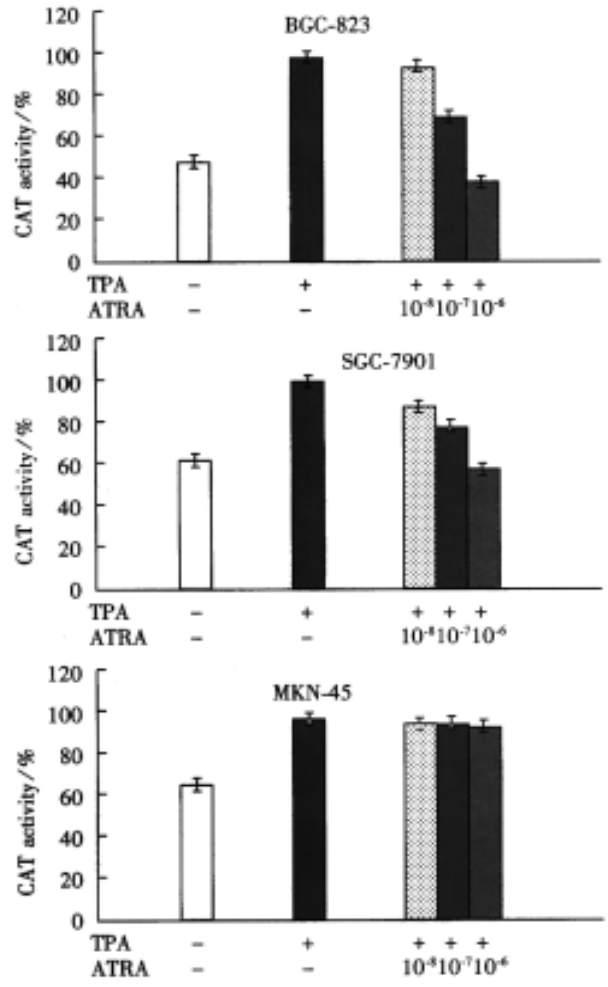

Figure 5A Inhibitory effect of ATRA on AP-1 activity in gastric cancer cell lines at various concentrations of ATRA shown by CAT assay.

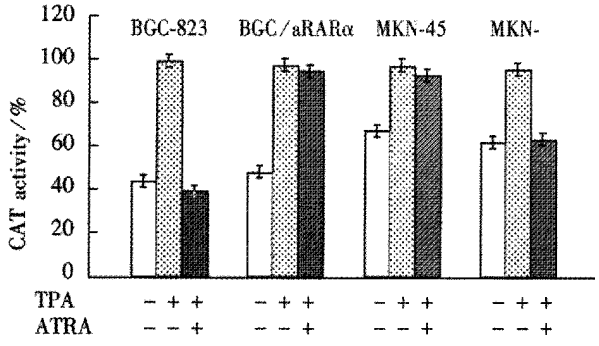

Figure 5B Effect of ATRA on AP-1 activity in BGC-823 cells transfected with antisense RARα gene and in MKN-45 cells transfected with sense RARα gene, respectively.

DISCUSSION

Retinoicacid (RA) is known to inhibit the growth of cancer cells *in vitro*, including cells of breast cancer, lung cancer, gastric cancer and liver cancer[1,15,30,34-36]. Effects of retinoic acid are mediate d by its receptors RARs and RXRs[8-13]. In the present study, we demons trated that the molecular mechanism by which RA inhibited the growth of gastric cancer cells was involved in RARα-mediated signal transduction pathway. Although ATRA did not show any inhibitory effects on MKN-45 cells (Figure 3A, Table 1), the expression of exogenously transfected sense RARα gene at elevated level in MKN-45 cells resulted in acquisition of sensitivity to growth inhibition by ATRA (Figures 2B, 3B, Table 1). In contrast, exogenous transfection of antisense RARα gene into BGC-823 cells, which expressed RARα, and RARα could be induced by ATRA (Figure 1, 2A), failed in growth inhibition by ATRA (Figure 3B, Table 1). These data suggested that the growth inhibitory effect of ATRA is due to the presence of RARα. In addition, we noted that although RARα mRNA was detected in MKN-45 cells, its mRNA level was rather low, compared with that in MGC80-3, BGC-823 and SGC-7901 cells (Figure 1). This may be the reason why ATRA could not exert its anti-proliferation effect on MKN-45 cells. RARα, thus, plays a major role in mediating growth inhibition of ATRA on gastric cancer cells, and adequate level of RARα is required for such action.

AP-1 is a transcriptional factor mainly composed of the products of cJun and cFos[31,37,38], which relate with proliferation and transformation of tumor cells. Our observation that ATRA could effectively inhibit AP-1 activity induced by TPA in MGC80-3, BGC-823 and SGC-7901 cells, but not in MKN-45 cells (Figure 5A) indicated that the suppression of AP-1 activity might contribute to cell growth inhibition by ATRA in gastric cancer cells. The anti-AP-1 effect of ATRA was mediated by the activation of RARα. When transfecting sense RARα gene into MKN-45 cells, a clear inhibition of AP-1 activity was seen (Figure 5B), thus leading to growth inhibition of MKN-45 cells (Figure 3B, Table 1). However, a little effect by ATRA in BGC/ aRARα cells observed in this study (Figure 5B) was associated with a weakened inhibition in BGC/aRARα cell proliferation (Figure 3B, Table 1). Thus, anti-AP-1 activity is one of the mechanisms for ATRA to inhibit growth of gastric cancer cells, and RARα does play a critical role.

RARα, once activated by RA, forms a heterodimer with RXR, then bind to retinoic acid response element (such as βRARE), and regulates transcription and expression of target genes[13-17]. In acute promyelocytic leukemia cells and RA-resistant breast cancer cells, RA could up-regulate the expression of RARα via modulation of RARE motif located in RARα promoter[39-41]. The fact that when the reporter gene βRARE-tk-CAT was transfected into MGC80-3, BGC-823 and SGC-7901 cells, a marked increase in βRARE transcriptional activity induced by ATRA was observed (Figure 4A) suggested that RARs are functional in these cell lines, i.e., to activate βRARE transcriptional activity in the presence of ATRA, and then to stimulate cell growth inhibitory signals to repress the growth of cancer cells. However, when the same reporter gene was transfected into MKN-54 cells, the âRARE transcriptional activity induced by ATRA was relatively low (Figure 4A), indicating the abnormality of βRARE transcriptional regulation or functional loss of RARα in MKN-45 cells, which caused the failure of growth inhibition of MKN-45 cells by ATRA. The similar results were further confirmed by transient transfection assay in transfected gene cell lines, BGC/aRARα and MKN/ RARα, respectively (Figure 4B). All these data are consistent with those observed in breast cancer cells and lung cancer cells[1,42], and imply that low-level expression of retinoic acid receptors in cancer cells is closely associated with the development of malignant tumor. RARα might serve as a candidate marker to determine which gastric cancer patient would respond to and benefit from the retinoid therapy, and this is also useful for the synthesis of RARα-selective retinoids. Of course, some further experiments to verify this issue are needed.

Abstract

AIM **To study the effect of cholecystokinin-octapeptide (CCK-8) on systemic hypotension and cytokine production in lipopolysaccharide (LPS)-induced endotoxic shock (ES) rats.**

METHODS **The changes of blood pressure were observed using physiological record instrument in four groups of rats: LPS (8 mg·kg^{-1}, iv) induced ES; CCK-8 (40 μg·kg^{-1}, iv) pretreatment 10 min before LPS (8 mg·kg^{-1}); CCK-8 (40 μg·kg^{-1}, iv) or normal saline (control) groups. Differences in tissue and circulating specificity of the proinflammatory cytokines (TNF-α, IL-1β and IL-6) were assayed with ELISA kits.**

RESULTS **CCK-8 reversed LPS-induced decrease of mean artery blood pressure (MABP) in rats. Compared with control, LPS elevated the serum level of IL-6 significantly (3567±687) ng·L^{-1} *vs* 128±22 ng·L^{-1}, *P*<0.01), while contents of TNF-α and IL-1β elevated significantly (277±86 ng·L^{-1} *vs* not detectable and 43±9 ng·L^{-1} *vs* not detectable, *P*<0.01) but less extent than IL-6. CCK-8 significantly inhibited the LPS-induced increase in serum TNF-α, IL-1β and IL-6. LPS elevated spleen and lung content of IL-1β significantly (5184±85 ng·L^{-1} *vs* 1047±21 ng·L^{-1} and 4050±614 ng·L^{-1} *vs* not detectable, *P*<0.01), while levels of TNF-α and IL-6 also rose significantly but in less extent than IL-1β. CCK-8 inhibited the LPS-induced increase of the cytokines in spleen and lung. In the heart, CCK-8 significantly inhibited LPS-induced increase of TNF-α (864±123 ng·L^{-1} in CCK-8+LPS group *vs* 1599±227 ng·L^{-1} in LPS group, *P*<0.01), and IL-1β (282±93 ng·L^{-1} in CCK-8+LPS group *vs* 621±145 ng·L^{-1} in LPS group, *P*<0.01).**

CONCLUSION **CCK-8 reverses ES, which may be related to its inhibitory effect on the overproduction of cytokines.**

INTRODUCTION

Lipopolysaccharide (LPS), a main component of gram-negative bacterial endotoxin[1], is the leading cause of sepsis or endotoxic shock (ES), and when administered experimentally to animals, mimics the same inflammatory response. The pathophysiological changes seen in sepsis are often not due to the infectious organism itself but to the uncontrolled production of proinflammatory cytokines, including tumor necrosis factor (TNF)-α and interleukin (IL)-1β. Accumulation of these mediators leads to tissue damage, ultimately producing the lethality of sepsis[2]. Studies suggest that alterations in their circulating levels do not always reflect changes at the tissue level and this has led to the reassessment of tissue cytokine content as a more accurate reflection of the host response to stress[3]. Cholecystokinin (CCK), a component of the gastrin-CCK family and first isolate d from hog intestine, shows a widespread distribution in different organs and tissues. The sulfated carboxy-terminal octapeptide (CCK-8), which has been isolated from the central nervous system and digestive tract, is the predominant active form. CCK-8 possessed both excitatory and inhibitory action on contractile activity of different regions of stomach in guinea pigs[4]. CCK-8 could antagonize the elimination of morphine on the potentiations of ACh to duodenal activities, and these effects were mediated by CCK-A receptor[5]. Besides the effects of CCK-8 on the digestive tract, other biological actions of this peptide have been observed, such as appetite inhibition[6,7]. In the spleen, CCK-8 is formed in high abundance in the white pulp where it appears to surround cell clusters. It seems that CCK -8 increases in vivo the secretion of immunoglobulins[8,9], while it causes *in vitro* an inhibition of Molt-4 lymphoblast proliferation[10] and modulates mitogen-induced lymphoproliferation and intracellular calcium mobilization[11-13]. CCK-8 is a chemoattractant for human monocytes and rat macrophages[14], enhances human eosinophil chemotaxis induced by PAF and LTB4 in allergic patients[15] and is a negative modulator of several murine macrophage and human neutrophil functions[16-18]. It was reported that CCK-8 reversed hemorrhagic shock[19,20]. Our previous studies demonstrated for the first time that CCK-8 could protect animals from LPS-induced ES[21]. However, whether this protecting effect of CCK-8 is related to its modulation of cytokines is still not clear. The AIM of this work is to study the effect of CCK-8 pretreatment on systemic hypotension and on production of cytokines such as TNF-α, IL- 1β and IL-6 in spleen, lung, heart and serum of ES rats.

MATERIALS AND METHODS

Materials

CCK-8 (sulfated), LPS (E.coli LPS, serotype 0111:B4), leupeptin, pepstatin A and Triton X-100 were all purchased from Sigma and aprotinin from Boehringer. ELISA kits were purchased from Endogen (USA) and Medsystem (Austria). All other reagents used were of analytic grade.

Methods

Animal preparation Specific pathogen-free male Sprague-Daw ley rats (n = 48, weighing 150 g-200 g, obtained from Experimental Animal Center of Hebei) were housed in a controlled environment, exposed to 12 h:12 h light-dark cycle and fed standard rat diet. On the day of experiment, animals were randomly assigned to four groups injected different agents via tail vein. For group receiving LPS, a bolus dose (8 mg·kg^{-1}, 5 g·L^{-1}) of LPS was injected into the tail vein. For group of CCK-8+LPS, a bolus dose (40 μg·kg^{-1}, 0.05 g·L^{-1}) of CCK-8 was administered 10 min before injection of LPS. Negative control animals received saline, CCK-8 (40 μg·kg^{-1}) was also administe red alone in the other group.

Mean arterial blood pressure (MABP) detection Catheter was inserted into arteriae femoralis before agents administration and MABP was detected using physiology record instrument (RM-6000, Japan). ES model was made by LPS administration, the effect of CCK-8 on MABP of ES rats was observed.

Enzyme linked immunoabsorbant assay (ELISA) Animals were sacrificed at 2 h or 6 h after treated with LPS, spleen, lung and hear t were rapidly excised, rinsed of blood, and the blood was centrifuged for collection of serum. The samples were stored at -80 ℃. The samples collected at 2 h were for the assay of TNF-α and at 6 h for the assay of IL-1β and IL-6. Serum TNF-α was measured using an ELISA kit (Bender MedSystem, Austria) specific for rat TNF-α with an inter-assay coefficient of variation to be <10% and intra-assay coefficient of variation to be <5%; the lowest limit of detection was 17 ng·L-1. Serum IL-1β was determined with a rat ELISA (Endogen Inc, USA). Intra- and inter-assay coefficients of variation were 5.3%-6.1% and 6.8%-8.8%, respectively. The limit of detection for this assay was <12 ng·L^{-1}. Serum IL-6 was determined with a rat ELISA (Endogen Inc, USA). The intra and inter-assay coefficients of variation were 8.3%-9.2% and 6.9%-7.8%, respectively. The lowest limit of detection was 16 ng·L^{-1}.

Forzen tissue samples were weighed and placed in homogenization buffer (4 ℃) at a ratio of 100 mg per milliliter of buffer. Buffer contained a protease-inhibitor cocktail including 1 mmol·L^{-1} phenylmethylsulfon glfluoride (PMSF), 1 mg·L^{-1} pepstatin A, 1 mg·L^{-1} aprotinin, and 1 mg·L^{-1} leupeptin in phosphate-buffered saline solution, pH 7.2, containing 5 g·L^{-1} Triton X-100. Samples were homogenized and centrifuged at 18000 r·min^{-1}. Tissue supernatants were analyzed for TNF-α, IL-1β and IL-6 using the above described ELISAs.

Statistical analysis

Data were reported as x±s. Statistical differences between values from different groups were determined by one way ANOVA. Significance was set at P<0.05.

RESULTS

Changes of MABP

There was no significant difference among groups before treatment. LPS administr ation resulted in a significant sustained decrease in MABP during the period of 2 h, decreased to 7.82±0.43 kPa 30 min after LPS administration and restored to 9.33±0.63 kPa by pretreatment with CCK-8 (Figure 1).

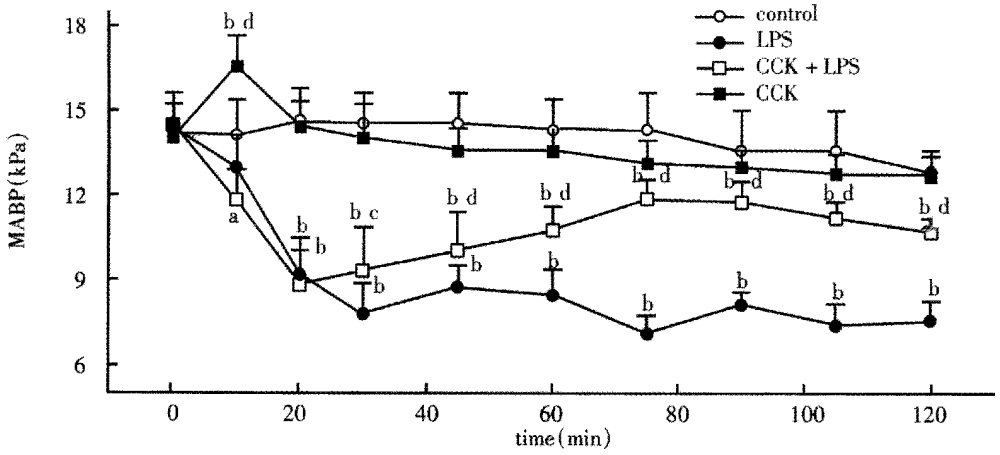

Figure 1 Mean arterial blood pressure (MABP) of animals injected normal saline, LPS, CCK+LPS and CCK. n = 6, ^aP<0.05, ^bP<0.01, *vs* Control; ^cP<0.05, ^dP<0.01, *vs* LPS.

Serum cytokine levels

TNF-α and IL-1β were not detectable in the serum of saline or CCK-8 treated rats, while IL-6 concentration in serum of saline or CCK-8 treated rats were 128±22 ng·L^{-1} and 84±78 ng·L^{-1}, respectively. Significant increase in serum level of TNF-α was observed in LPS group at 2 h to an average of 277±86 ng·L^{-1}, which was inhibited by CCK-8 to 12±21 ng·L^{-1}. Serum levels of IL-1β and IL-6 increased to 43±9 ng·L^{-1} and 3567±687 ng·L^{-1}, respectively, 6 h after administration of LPS, while administration of CCK-8 prior to LPS significantly inhibited this LPS induced increase in IL-1β and IL-6 concentration (not detectable and to 1797±69 ng·L^{-1}, respectively. LPS elevated the serum level of IL-6 significantly, while serum levels of TNF-α and IL-1β rose significantly but less than IL-6 (Figure 2).

Tissue cytokine contents

Spleen TNF-α content was significantly higher 2 h after administration of LPS than in control animals 941±149 ng·L^{-1} *vs* 282±30 ng·L^{-1}, P<0.01, while CCK-8 significantly inhibited the LPS induced increase of TNF-α 462±87 ng·L^{-1}, P<0.01. Similar results of TNF-α were noted in the lung and heart following 2 h post-LPS administration. CCK-8 pretreatment attenuated LPS-

induced increases of IL-1β and IL-6 contents in spleen and lung 6 h after LPS administration. LPS elevated content of IL-1β in the spleen and lung significantly 5184±85 ng·L^{-1} *vs* 1047±21 ng·L^{-1} and 4050±614 ng·L^{-1} *vs* not detectable, respectively (Figure 2), while the levels of TNF-α and IL-6 rose but in less extent than IL-1β. CCK-8 pretreatment attenuated LPS-induced increases of IL-1β content in the heart 6 h after LPS administration from 621±145 ng·L^{-1} to 282±93 ng·L^{-1}, P<0.01. No significant changes were noted in contents of cytokines following CCK-8 administration compared with normal saline administration.

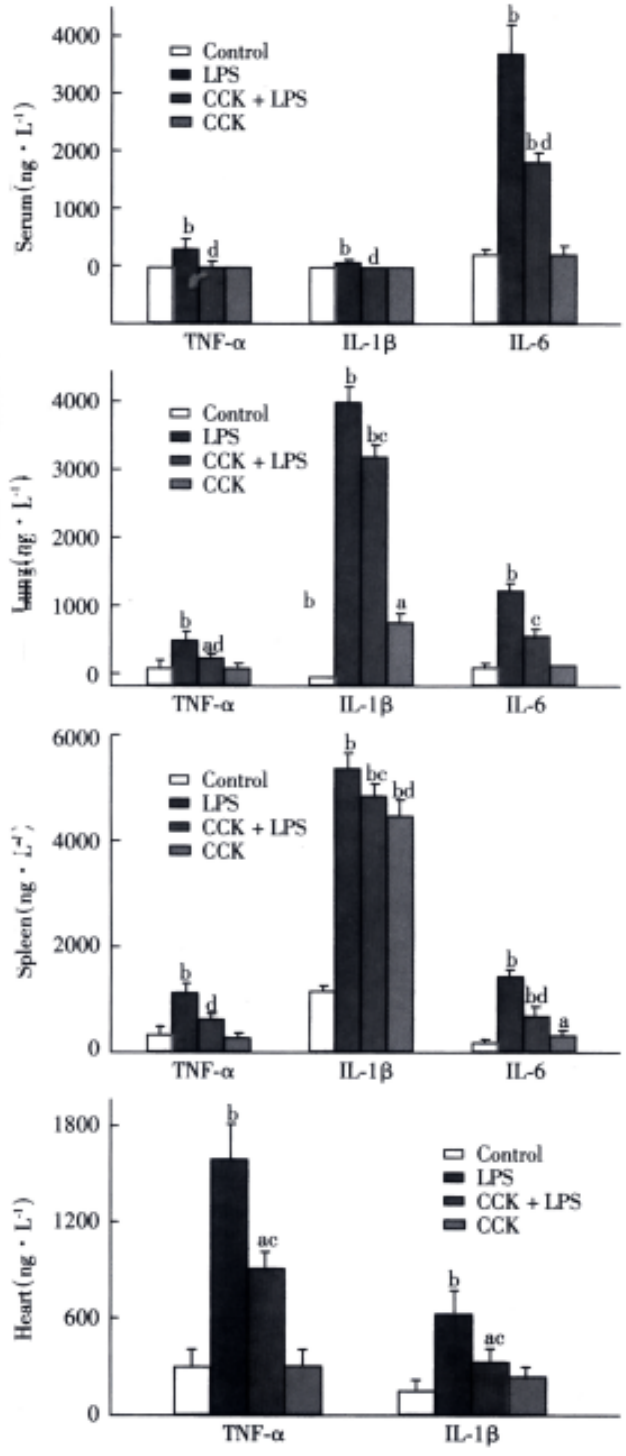

Figure 2 Effects of CCK on TNF-α, IL-1β and IL-6 2 h (TNF-α) or 6 h (IL-1β and IL-6) following LPS administration. n = 6. [a]P<0.05, [b]P<0.01, *vs* Control; [c]P<0.05, [d]P<0.01, *vs* LPS.

DISCUSSION

Interaction of the central nervous system (CNS) with immune system can occur via several endocrine pathways, the presence of various neuropeptide receptors on cells of the immune system suggests more direct communication pathways. Moreover, immune cells release cytokines, which can influence neuronal activity. Thus direct communication between the CNS and the immune system may well be bi-directional[22]. The present study show that administration of brain- gut peptide, CCK-8, prevents the LPS-induced decrease of MABP and attenuates LPS-induced increase of proinflammatory cytokines (TNF-α, IL-1β and IL-6) *in vivo*. Inhibition of these cytokines by CCK-8 may have contributed to the prevention of ES, such as restoring the blood pressure. The macrophages are the sources of proinflammatory cytokines (TNF-α, IL-1 and IL-6)[23]. These three important proinflammatory cytokines respond to the initial stimulation[24] and play predominant roles in the normal inflammatory response. Exaggerated endogenous production is likely responsible for the complications associated with sepsis such as tissue injury and ultimate organ failure[25-28], induce a wide range of pathophysiologic changes in LPS-induced ES. TNF is known to have cytotoxic and cytostatic effects on certain tumor cells, and with a pivotal role in inflammatory reactions and regulation of immunologic al response[29,30]. TNF can enhance the adhesion of PMN to endothelium[31]. Although the migration of leukocytes to and accumulation at the site of inflammation are important for killing micro-organisms, activation of recruited neutrophils coupled with excessive release of oxygen metabolites and proinflammatory mediators may induce tissue injury which can lead to organ dysfunction[32]. TNF-α was mainly produced in the early stage of endotoxemia, and decreased obviously from 6 h to 9 h after challenge[33]. The effect of TNF-α is influenced by other cytokines[34]. IL-1β and IL-6, produced mainly by activated phagocytes and lymphocytes, show a wide variety of biological functions. They can influence secretion of other cytokines and inflammatory mediators in an autocrine or paracrine fashion, induce expression of surface immune molecules of antigen-presenting cells to serve as an activation factor and differentiation factor on T cells and B cells, mediate immunoglobulin secretion, activate the complements, killer cells and phagocytes, and enhance tissue injury mediated by cellular and humoral immune reactions[35]. Most of our knowledge concerning the induction of these cytokines in response to LPS or gram-negative bacteria comes from studies performed either in vitro or in fluids obtained from animal models or patients with sepsis, whereas the major site of action of the cytokines are probably at the tissue and cell level[36]. Our study show that the increase in spleen and lung content of IL-6 following LPS administration was lesser than in serum. In contrast, the increase in spleen and lung content of IL-1β following LPS administration was more than in serum, while the content of IL-1β in heart was more than in serum and less than in spleen and lung. The results demonstrated a dissociation or poor correlation between intra-splenic, intra-pulmonic or intra-cardiac abundance of TNF-α, IL-1β and IL-6 and the magnitude of the increase in circulating cytokine levels. The production of cytokines varies from organ to organ in response to systemic administration of LPS. Activated macrophages in spleen and lung are known to be active producers of pro-inflammatory cytokines. This has led to the suggestion that spleen, lung and heart are important organs in the production of TNF-α

and IL-1β following LPS administration, releasing the cytokines produced into the circulation, thereby contributing to the elevated serum levels of the cytokines. We found that CCK-8 significantly inhibits LPS-induced increase of pro-inflammatory cytokines in vivo. While Cunningham *et al*[37] reported that CCK-8 stimulated production of TNF-α, IL-1β and IL-6 by monocytes, but was considerably less than LPS response. Later studies[38]suggest that the increase of cytokines induced by CCK-8 may be due to the detection of endotoxin/LPS in medium.

Despite convincing data indicating the protective function of CCK-8 to organism in ES, the precise mechanism remains elusive. Our previous study demons trated that exogenous or endogenous CCK reversed pulmonary arterial hypertension (PAH) during endotoxic shock[39]. In vitro studies showed CCK can protect pulmonary artery endothelium against detrimental effects by LPS or TNF-α[40,41]. The anti-inflammatory effect of CCK- showed in this study may mediate the cell protective function of CCK-8 in ES. CCK-8 dose dependently attenuated gastric lesions induced by 75% ethanol, blockade of CCKA receptor with loxiglumide abolished the protective effects of CCK[42]. The effect of CCK may depend on its modulation of immunocyte function, which could occur through CCK receptors. There exists CCKB receptor in human lymphoid cells[43]. It was demonstrated recently that wild-type transcripts of both CCK receptor subtypes and splice variants of the CCK-B/gastrin receptor are expressed in nontransformed human mononuclear cells[44]. Endogenous opioids, such as β-endorphin, are produced within the immune system and are active regulators of the immune response. There were elevations in the circulating levels of β-end orphin in LPS-treated animals, which indicated the potential contribution to modulating the tissue cytokine response to LPS[45]. The hypotensive response was related to release of endorphin, while the mechanism of CCK-8 anti-ES may be related to its anti-endorphin effect[3]. CCK-8 decreased heart rate via CCK-A receptors located in the atrium of the rats[46] . Intravenous administration of CCK-8 to guinea pigs inhibited the motility of the left ventricle of heart[47]. CCK had hypertensive effect on rats and increased the cardiac contraction amplitude, decreased coronary outflow, while it had no effect on heart rate[48]. CCK-B agonist pentagastrin induced significant and very rapid, dose-dependent elevations in adrenocorticotropin and cortisol levels, and significant elevations in heart rate and blood pressure were seen[49]. The different effect of CCK-8 on cardiovascular system may due to the different doses and animals. However, additional mechanisms may be present in mediating the cytokine responses to LPS and CCK. Our study shows for the first time a previously unknown physiological function for CCK- 8 in a model of LPS-induced ES. CCK-8 may have modulatory effects on the immune functions of ES rats. CCK-8, therefore, might be used therapeutically to treat septic shock syndrome and other inflammatory disease states.

Abstract

AIM **To compare the effects of extract F of red-rooted Salvia (EFRRS) on mucosal lesions of gastric corpus and antrum induced by hemorrhagic shock and reperfusion in rats.**

METHODS **The rats were subject to hemorrhagic shock and followed by reperfusion, and were divided randomly into two groups. Group 1 received saline, and group 2 received EFRRS intravenously. The index of gastric mucosal lesions (IGML) was expressed as the percentage of lesional area in the corpus or antrum. The degree of gastric mucosal lesions (DGML) was catalogued grade 0, 1, 2 and 3. The concentrations of prostaglandins (PGs) were measured by radioimmunoassay. The concentration of MDA was measured according to the procedures of Asakawa. The activity of SOD was measured by the biochemical way. The growth rates or inhibitory rates of above-mentioned parametes were calculated.**

RESULTS **As compared with IGML (%), grade 3 damage (%) and MDA content (nmol/g tissue) of gastric antrum which were respectively 7.96±0.59 , 34.86±4.96 and 156.98±16.12, those of gastric corpus which were respectively 23.18±6.82, 58.44±9.07 and 230.56±19.37 increased markedly ($P<0.01$), whereas the grade 0 damage, grade 1 damage, the concentrat ions of PGE_2 and PGI_2 (pg/mg tissue), the ratio of PGI_2/TXA_2 and the activity of SOD (U/g tissue) of corpus which were respectively 3.01±1.01, 8.35±1.95, 540.48±182.78, 714.38±123.74, 17.38±5.93 and 134.29±13.35 were markedly lower than those of antrum which were respectively 13.92±2.25, 26.78±6.06, 2218.56±433.12, 2531.76±492.35, 43.46±8.51 and 187.45±17.67 ($P<0.01$) after hemorrhagic shock and reperfusion. After intravenous EFRRS, the growth rates (%) of grade 0 damage, grade 1 damage, the concentrations of PGE_2 and PGI_2, the ratio of PGI_2/TXA_2 and the activity of SOD of corpus which were respectively 632.56, 308.62, 40.75, 74.75, 92.29 and 122.25 were higher than those in antrum which were respectively 104.89, 58.40, 11.12, 56.58, 30.65 and 82.64, whereas the inhibitory rates (%) of IGML, grade 3 damage and MDA content of gastric corpus were 82.93, 65.32 and 59.09, being higher than those of gastric antrum which were 76.64, 53.18 and 42.37.**

CONCLUSION **After hemorrhagic shock-reperfusion, the gastric mucosal lesions in the corpus were more severe than those in the antrum, which were related not only to the different distribution of endogenous PGs in the mucosa, but also to the different ability of anti-oxidation of the mucosa. The protective effect of EFRRS on the gastric mucosa in the corpus was more evident than that in the antrum, which was related to higher growth degree of PGs contents and anti-oxitative ability in gastric corpus after administratio n of EFRRS.**

Zhang LH, Yao CB, Li HQ. Effects of extract F of red-rooted Salvia on mucosal lesions of gastric corpus and antrum induced by hemorrhagic shock-reperfusion in rats. *World J Gastroenterol*, 2001; 7(4):672-677

INTRODUCTION

More and more stress has been put on gastric mucosal reperfusional injury. Though scholars both at home and abroad have performed plenty of researches on it, there has been no satisfying method or drug yet[1-5]. Red-rooted Salvia is the traditional Chinese medicine for accelerating blood circulation and ameliorating congestion, and its pharmacological effect is very extensive. Resources of red-rooted Salvia in China is sufficient. It has been evidenced that the proportion of red-rooted Salvia dissolving in water can treat acute or chronic gastric mucosal lesions, and has protective effect on gastric mucosa. Extract F of red-rooted Salvia (EFRRS) is extracted from the proportion of red-rooted Salvia dissolving in water[6-11]. Because Prostaglandins (PGs) and oxygen free radical (OFR) play important roles in reper fusional injury[12-18], the present experiment was AIMed at studying the endogen ous PGs and the anti-oxidation of the gastric corpus and the antrum, and comparing their ability to resist the lesions induced by hemorrhagic shock-reperfusi on in rats and the protective effect of EFRRS on the gastric corpus and the antrum.

METERIALS AND METHODS

Drug

EFRRS was extracted from red-rooted Salvia solution provided by Chemical Assay Center of China Medical University using column chromatography.

Animal models

Male Wistar rats, weighing 260 g-300 g, were fasted overnight. The rats were anesthetized intraperitoneally with 5 mg·100g^{-1} of 20% Urethane. Tracheostomy was performed and PE-250 tubing was inserted into the trachea to maintain an open airway. Then open the abdomen and lavage the gastric lumen gently with warm saline. The right carotid artery was cannulated using a polyethylene tube to monitor the blood pressure. The femoral artery was canulated for withdrawing the blood and reinfused the shed blood. After the blood pressure was stabilized, normal saline or EFRRS (1 g·100gw·t^{-1}) was administered for 25 min via a tail vein (0.03 mL·min^{-1}). 1 mL of 0.1 mol/L HCl per 100 g body wt was then instilled into the stomach via the gastric tube, five min after the intragastric instillation of HCL, blood was withdrawn from the femoral artery. The mean arterial blood pressure fell to 2.67 kPa-4.0 kPa and was maintained at that level for 20 min. The shed blood was then reinfused, and 20 min later the rats were sacrificed[19]. Rats were allocated into two groups. Group 1 (n = 9) received NS via the tail vein, and group 2 (n = 7) received EFRRS (1 g·100gwt^{-1}) via the tail vein.

Index of gastric mucosal lesions (IGML) and inhibitory rate (IR) of IGML

The corpus and antrum lesional areas were measured in square millimeters. IGML was expressed as the percentage of lesional area in the corpus or antrum[20]. IR was calculated by the following formula.

$$IR=\frac{\text{Difference of mean value of lesional areas between the two groups}}{\text{Mean value of lesional area in group 1}}\times 100\%$$

Depth of gastric mucosal lesions (DGML) , growth rate(GR) and IR of DGML

After meaursing the lesional areas, the samples for light microscopy (LM) and scanning electron microscopy (SEM) were taken from the proximal anterior wall of the corpus or the middle of the antrum. The samples analyzed by LM were evaluated as follows[21]. The damage was graded as 0, 1, 2 and 3. Grade 0 was defined as normal intact surface mucous cells with intact gastric pits and glands. Grade 1: Surface mucous cells were vacuolated with pyknotic nuclei. Some exfoliation was present. Grade 2: In addition to the above changes, the cells lining the gastric pits were also disrupted and exfoliated. Grade 3: Cell destruction extended into the gastric glands (Figures 1-6). Samples analyzed by SEM were evaluated as follows[22]. Grade 0: The mucosa showed closely packed, polygonal surface mucous cells and narrow openings to the gastric pits. Grade 1: Surface cells were flattened with irregular shape, and gaps between individual cells. Grade 2: The basal lamina was exposed and was largely devoid of surface mucous cells, but still showed continuity, wide openings to the gastric pits were visible. The picture resembled that of a honeycomb. Grade 3: Most of the basal lamina were disrupted, and only a portion being still intact. Regular surface cells were no longer present (Figures 7-12). A close correlation between LM and SEM grading was found (r = 0.846, P<0.01). The percentage of damage of each grade was calculated in each group. The METHODS to calculate the GR or IR of DGML were the same as that of IR of the lesional area.

PGs contents and GRs of PGs

Prostaglandin E_2 (PGE_2), 6-keto-$PGF_{1\alpha}$ (6-keto-$PGF_{1\alpha}$: 6-keto is the metabolite of PGI_2), and TXB_2 (metabolite of TXA_2) boxes were provided by Biochemistry Laboratory of Liberal Army General Hospital, and their concentrations were assayed by using radiommunoassay. GRs of PGs were calculated in the same way as that of IR of the lesional area.

MDA content and IR of MDA

Malondialdehyde (MDA) is the final metabolism product of OFR. It can be measured by the way of Asakawa[23]. IR of MDA was calculated in the same way as that of IR of lesional area.

SOD activity and GR of SOD

Superoxide dimutase (SOD) was measured according to the biochemical method[24]. GR of SOD was calculated in the same way as that of IR of lesional area.

In all experiments, the date was represented by the mean value ± standard error, and analyzed by paired t test. P value of <0.05 was considered significant.

RESULTS

Comparison of IGML and its IRs between the gastric corpus and antrum

The results are shown in Table 1. After hemorrhagic shock-reperfusion, IGML in the corpus was much higher than that in the antrum (P<0.01). As compared with that in the corpus, IR in the antrum was lower after administratio n of EFRRS.

Table 1 IGML and its IR in gastric corpus and antrum (%, $\bar{x}\pm s$)

	IGML	IR
Group 1 (n = 9)		
Corpus	23.18±6.82	
Antrum	7.96±0.59[b]	
Group 2 (n = 7)		
Corpus	4.42±1.39[a]	82.93
Antrum	1.62±0.37[a]	76.64

[b]P<0.01, *vs* corpus; [a]P<0.01, *vs* group 1.

Comparison of DGML, and its IRs and GRs between the gastric corpus and antrum

The results are shown in Table 2. As compared with those in the corpus, grade 0 and 1 damages in the antrum were much increased (P<0.01), and grade 3 damage markedly decreased (P<0.01) after hemorrhagic shock-reperfusion. After administration of EFRRS, the GR of grade 0 and 1 damage and the IR of grade 3 damage in the antrum were much less than those in the corpus.

Comparison of the concentrations of PGE_2, 6-keto and TXB_2, the ratio of 6-keto/TXB_2 and their GRs between the gastric corpus and antrum

In Table 3, higher PGE_2 and 6-keto levels and 6-keto/TXB_2 ratio were found in the antrum compared with those in the corpus after hemorrhagic shock-reperfusion (P<0.01), and the GRs of PGE_2, 6-keto and 6-keto/TXB_2 in the corpus were higher than those in the antrum after administration of EFRRS.

Table 2 DGML and its IR or GR in the gastric corpus and antrum (%, $\bar{x}\pm s$)

	DGML							
	0	GR	1	GR	2	IR	3	IR
Group 1 (n = 7)								
Corpus	3.01±1.01		8.35±1.95		31.32±4.49		58.44±9.07	
Antrum	13.92±2.25[b]		26.78±6.06[b]		25.98±8.32		34.86±4.96[b]

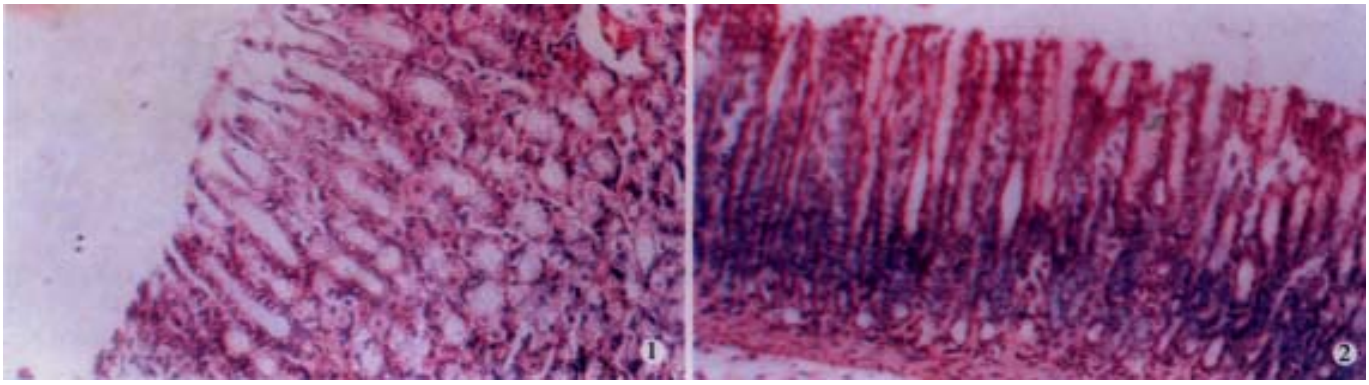
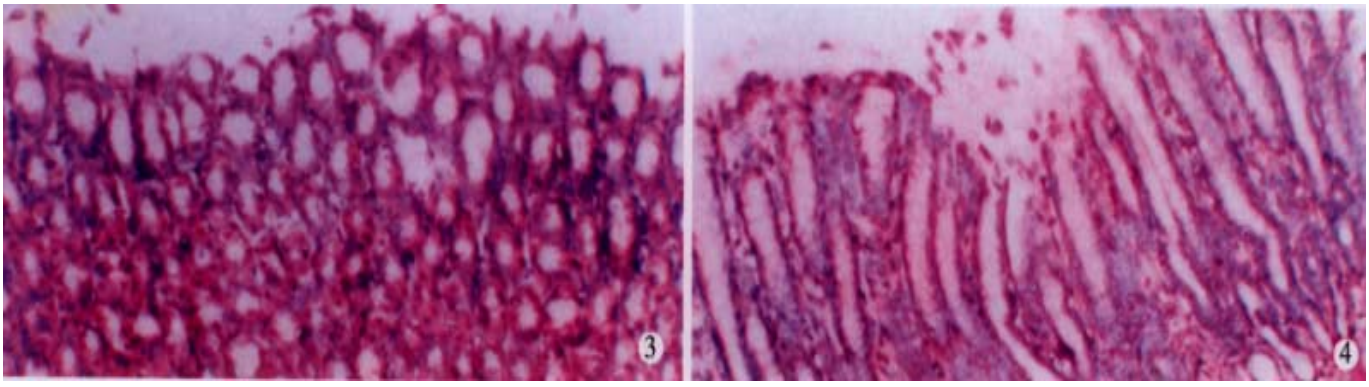
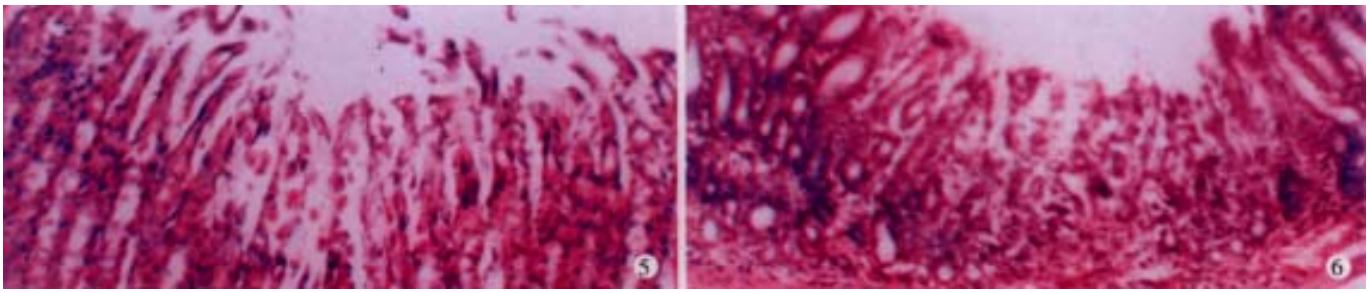


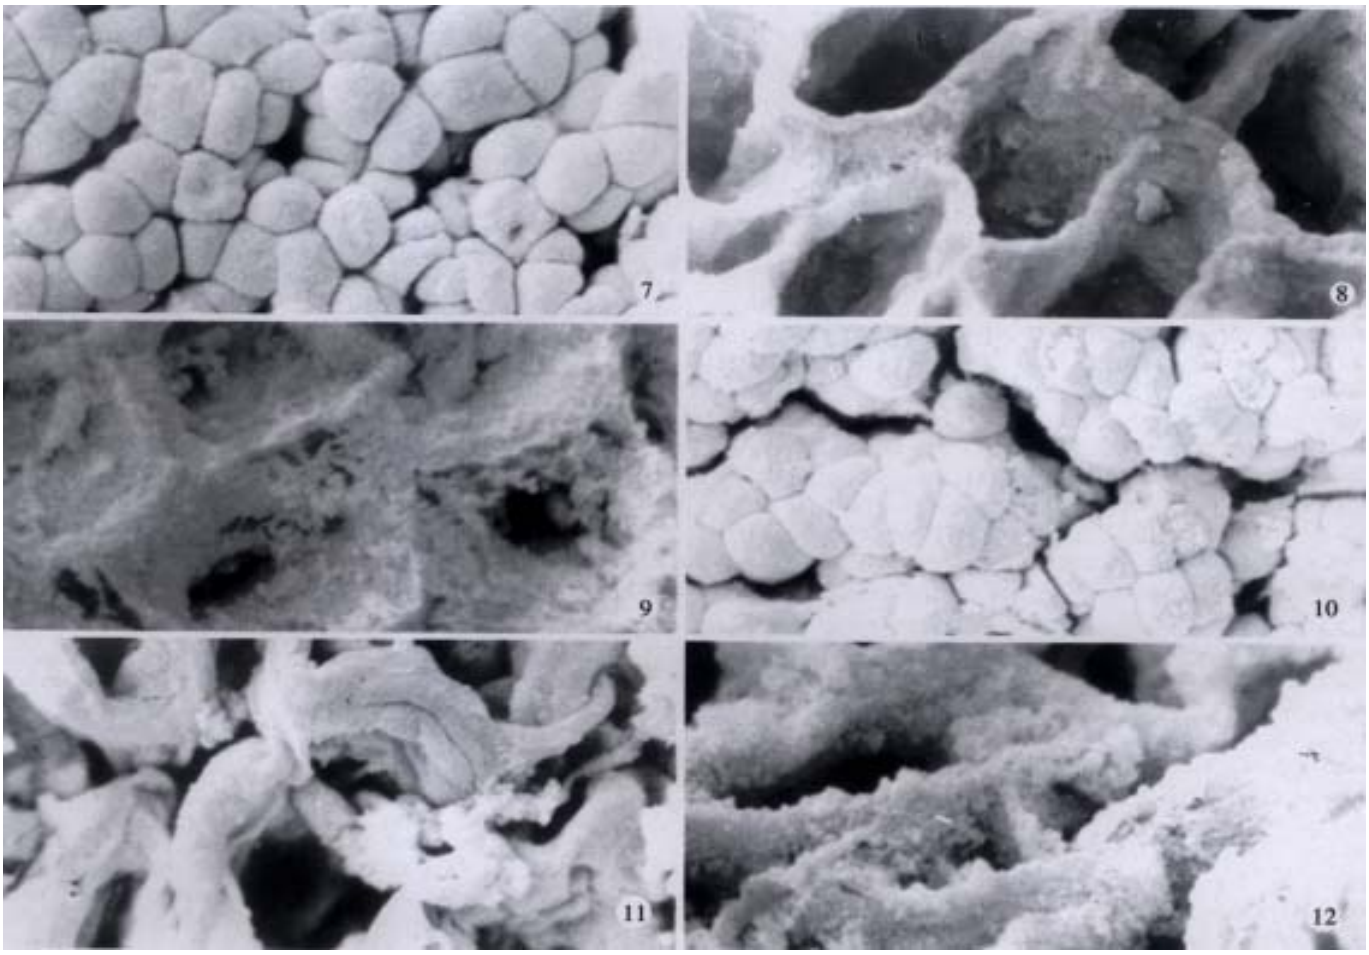
Figures 1, 2 Grade 1 damage in gastric corpus and antr um. LM×330.
In grade 1 damage, surface mucous cells were damaged.



Figures 3, 4 Grade 2 damage in gastric corpus and antrum. LM×330
In grade 2 damage, the cells kining the gastric pits were also disrupted.



Figures 5, 6 Grade 3 damage in gastric corpus and antrum. LM×330
In grade 3 damage, cell destruction extended into the gastric glands.



Figures 7, 8, 9 Grade 1, 2 and 3 damage in gastric corpus. SEM×1500
Figures 10, 11, 12 Grade 1, 2 and 3 damage in gastric antrum. SEM×1500
In grade 1 damage, surface cells were of irregular shape, and gaps between individual cells were present. In grade 2 damage, the basal lamina was exposed, but still showed continuity. Wide openings to the gastric pits were visible. In grade 3 damage, most of the basal lamina was disrupted, Regular surface cells were no longer present.

DISCUSSION

Reperfusion after hemorrhagic shock can lead to multiple organ damage, *i.e.* reperfusional injury. The gastric lesions include stress ulcer, hemorrhage, necrosis, or perforation[25-28]. The present study showed that the area and depth of gastric mucosal lesions caused by hemorrhagic shock-reperfusion in the gastric corpus of rats were more severe than those in the antrum. This indicated that there were differences in resistance in gastric mucosa of the corpus and the antrum, which was probably related to differences in gastric mucosal blood flow, energy metabolism and the capacity to dispose the influxing hydrogen ion, but most propably was related with the different distribution of endogenous PGs and the different ability of anti-oxidation[29-33]. The present study also showed that the protective role of EFRRS was different in the gastric corpus and the antrum, EFRRS possessed more powerful capability to reduce the area of lesions and to lighten the extent of lesions in corpus than those in the antrum, indicating EFRRS had potential protective effect on the corpus mucosa, which was related to the higher changes of PGs and OFR in the corpus caused by EFRRS.

It was generally thought that gastric mucosa was affected by both injury factors as gastric acid and pepsin and protective factors as PGs and gastric mucus. Large quantities of PGs were

found in the gastric mucosa. Numerous studies have doc umented that PGs possessed potent cytoprotective action. PGE_2 could obviously inhibit the secretion of basal gastric acid and acid stimulated by histamine, p entagastrin and food in dogs and humans. In addition, PGE_2 could increase the gastric mucus layer. PGE_2 and PGI_2 could dilate the blood vessel, increase the blood flow and carbohydrate secretion, and enhance the resistibility of gastric mucosa to injury. PGs could also lengthen the life span of epithelia and thick en the mucosa layer[34-37]. In many physiological and pathophysiological conditions, PGI_2 has protective effect on gastric mucosa. On the contrary, TXA_2 may aggravate the gastric mucosal injury[38,39]. The present findings showed the PGE_2 and PGI_2 contents and PGI_2/TXA_2 ratio in the antrum were markedly higher than those in the corpus after hemorrhagic shock-reperfusion, showing gastric antrum was more resistant than gastric corpus. Arakawa[40] found PGE_2 levels in the gastric corpus were significantly lower than that in the antrum, and drug like indomethacin could easily damage the mucosa of gastric corpus. He thought that the concentration of endogenous PGE_2 decided the defensive ability of gastric mucosa. The present study also showed that PGE_2 and 6-keto levels and 6-keto/TXB_2 ratio in the antrum and the corpus both increased after administration of EFRRS, but the GRs of PGE_2, 6-keto and 6-keto/TXB_2 in corpus were higher than t hose in antrum, demonstrating the reinforcement of defensive ability of gastric corpus was more powerful after administration of EFRRS.

OFR played an important role in reperfusional injury. OFR caused lipid peroxid ation (LPO) of polyunsaturated fatty acid of biomembrane, which resulted in the impairment of metabolism and function of cells, even the death of cells. Plenty of OFRs could lead to irreversible damage of gastric mucosa, because they could cause intracellular calcium overload besides of extensive LPO of tissues and cells[41-47]. OFR was produced by the system of enzyme and no-enzyme. Malondialdehyde (MDA) is the metabolite of LPO of OFR, and may reflect the degree of cells attacked by OFR, therefore MDA is usually an marker to monitor OFR. Superoxide dismutase (SOD) can clear superoxide anion,and may reflect the ability of scavenging system of free radical. Under normal conditions, OFR could be promptly cleared by the body. Only when the production of OFR markedly increased, or the ability of scavenging OFR much decreased, tissues were injured[48,49]. The study showed that there were higher SOD activity and lower MDA level in the antrum compared with those in corpus after hemorrhagic shock-reperfusion, so that the ability of anti-oxidation was more powerful in gastric antrum, and the reperfusional injury was easier in gastric corpus. This study also showed that the activity of SOD and the concentration of MDA decreased in the antrum and the corpus after administration of EFRRS, but the GR of SOD and IR of MDA in corpus were higher than those in antrum, demonstrating reinforcement of anti-oxidation of gastric corpus was more powerful after administration of EFRRS. The increase of SOD could accelerate the clearance of OFR to protect cell from the attact of OFR, while the decrease of OFR made cells produce more SOD, and clear more OFRs to form good cycle possessing the role of protective gastric mucosa.

It had been demonstrated in our previous studies[50-54], that EFRRS could increase the PGs contents, decrease the production of OFRs, and had calcium block effect, which resulted in some effects against gastric mucosal lesions induced by hemorrhagic shock-reperfusion. The present study discussed the mechanisms that the gastric injury in the corpus was easier after hemorrhagic shock-reperfusion, and the causes that the protective effects of EFRRS against gastric mucosal injury was moer powerful in the corpus through both PGs contents and OFR system. This made the researches of reperfusional injury of gastric mucosa and the protective effects of EFRRS perform more profoundly and detailedly.

Abstract

AIM **To study the purifying method and characteristics of new gosling viral enteritis virus (NGVEV), the etiological agent of new gosling viral enteritis (NGVE) which was first recognized in China, as well as the pathomorphological development in goslings infected artificially with NGVEV.**

METHODS **① NGVEV virions were purified by the procedure of treatment with chloroform and ammonium sulfate precipitation, dialysis to remove the sulfate radical and ammonium ion and separation by gel filtration chromatog raphy, and SDS-PAGE. ② Forty 2-day-old White Sichuan goslings were orally administered with NGVEV and 24 hr later 2 birds were randomly selected and killed at 24 hr intervals until death occurred. Specimens(duodenum, ileum, liver, heart, kidney, spleen, lung, proventriculus, pancreas, esophagus, and the intestinal embolus) were taken until all birds in this group died and were sectioned and stained with hemotoxylin and eosin and studied by light microscope.**

RESULTS **NGVEV shared the typical characteristics of Adenovirus and which structural proteins consisted of 15 polypeptides. Necrosis and sloughing of the epithelial cells covering the villus tips of the duodenum were first observed in goslings 2 days postinfection artificially with NGVEV. With the progress of infection, this lesion rapidly occurred in the epithelium at the base of the villus and with infiltration of the inflammatory cells, the jejunum tended to be involved. With the intensification of mucosa necrosis and inflammatory exudation of the small intestine, fibrinonecrotic enteritis was further developed and embolus composed of either intestinal contents wrapped by pseudomembrane or of the mixture of fibrous exudate and necrotic intestinal mucosa were observed in the middle-lower part of the small intestine. This structure occluded the intestinal tract and made the intestine dilated in appearance. The intestinal glandular cells underwent degeneration, necrosis and might be found sloughed into the lumen. Hemorrhage and hyperemia could be observed on the lung and kidney. Epithelial cells of the renal tubular underwent degeneration. In some cases, granular degeneration and fatty degeneration could be found in the liver and in some cases at a later stage of this disease the epithelial cells of trachea and proventriculus might be found sloughed. In some cases at an early stage of this disease, cardiac hyperemia and hemorrhage could be observed. Esophagus, pancreas and brain were found normal. Analyses and comparisons between the pathologic lesions of NGVE and Gosling Plague (GP) were available in this paper as well.**

CONCLUSION **① NGVEV is adenovirus. ② Pathological characteristic could be as the data for NGVE diagnosis.**

INTRODUCTION

Cheng *et al*[1] reported that a disease which extremely resembled Gosling Plague (GP)[2-5] in aspects of epizootiology, clinical signs and pathologic lesions was observed in goslings less than 30 days of age in a variety of areas in Sichuan province and that the sausagelike lesion found in birds which died at a later stage of the acute case was almost identical to that observed in the case of GP in terms of gross and histopathological changes. This disease with the name of NGVE was regarded as a new one caused by Adenovirus through preliminary epizootiological investigation, clinical signs, histopathological examination, causal agent isolation and the experiment of artificial infection[1,7-9]. The isolated virus of NGVEV was capable of reproducing the disease identical to natural infection in aspects of clinical signs and histopathological lesions by a variety of routes and the oral route was considered to be the best one. Goslings infected with duck plague virus (DPV) or gosling plague virus (GPV) could be observed enteritis[2,3,5,10-16], but the 36 strains of NGVEV isolated from a variety of areas were antigenically identical and no antigenic relationships with DPV and GPV was demonstrated[1,2,6-9]. The characteristics, purifying method, structural proteins of the representative causal agent of NGVEV-CN as well as the histopathologic developments observed in goslings infected with NGVEV are reported as follows:

MATERIALS AND METHOD

Virus strain

The strain of NGVEV with its minimum lethal dose being 10^{-6}/0.5 mL to 1-day-old goslings by oral administration was isolated from the natural cases of NGVE[1].

Characteristics of NGVEV-CN

According to directions presented in referencer[17], experiments were performed to identify the following properties of NGVEV-CN: hemagglutination, buoyant density, sensitivity to temperature, pH, chloroform and trypsin, type of the nucleic acid and type of the nucleic acid strand.

Virus purification and viral structural polypeptide analysis by SDS-PAGE

Experiments were performed according to directions presented in referencer[18-21].

Virus purification The virus strain of NGVEV-CN inoculated on the primary duck fibroblasts was harvested when 75% of the cells showed cytopathic effect and were centrifugated at 4000 rpm for 10 min after treated with chloroform for 5 times. The supernatant was collected and with stir was slowly added the same volume of saturated ammonium sulfate. After placed overnight at 4 ℃ statically, it was subjected to centrifugation at 10 000 rpm for 1 hr. The precipitate was dissolved in small volume of sterile distilled water and then underwent dialysis to remove sulfate radical and ammoniumion. Sephadex G200 chromatography was performed to elute the solution with phosphate buffered saline solution (PBS) of 0.15 M and pH 7.2 as buffer. Nucleic acid-protein detector was employed to determine the absorbancy at 280 nm of the separately collected eluates. Cellulose acetate electrophoresis and disc polyacrylamide gel electrophoresis (PAGE) were performed to examine the purification of the isolated virus after the virus containing eluates sharing the same absorption peak were mixed. Transmission electronic microscope type H-600 was employed to examine the negatively stained virions.

Viral structural polypeptide analysis by SDS-PAGE 20 μL of the purified virus was boiled for 5 min after mixed with the same volume of buffer whose concentration was 2 times of that used for electroph oreses and the virus lysate underwent PAGE, with the discontinuous gradient gel containing 0.4% SDS. The gel was 1.5 mm, 11cm, 12 cm in depth, width, length respectively and the concentration of the stacking gel and the separating gel was 3% and 12.5% respectively. A solution of Tris-Gly with a pH of 6.8 was used as buffer and electric current was raised from 160 v to 200 v when the sample moved from the stacking gel to the concentrating gel. Electrophoresis was performed at 4 ℃ for 4 hr and six proteins were employed as molecular mass references. These proteins and their molecular masses (Daltons) were: chicken albumen lysozyme (14 400), trypsin inhibitor (20 100), bovine carbonic anhydrase (31 000), rabbit actin (43 000), bovine serum album in (66 200) and rabbit phosphorylase (97 400). The gel was then removed and stained with 0.25% Coomassie brilliant blue for 12 hr. After that, it was decolored with a solution containing methanol and glacial acetic acid until the proteins were visible as discrete blue bands and their background was hyaline, which took about 48 hr. The gel was then photoed by camera and scanned by automa tic gel image-forming and analysis system. After analyzed and processed by the software of Gel, molecular masses and relative percentages of each structural polypeptides were obtained.

The pathomorphological development observed in goslings artificially infected with NGVEV

Eighty 2-day-old White Sichuan geese whose mother birds were all vaccinated twice with attenuated GPV vaccine just before egg production were employed and each one was inoculated subcutaneously with 1mL anti-GPV hyperimmune serum and after observed for one day these birds were divided randomly into 2 groups with each containing 40. Each of the first group was administered orally with 0.5 mL NGVEV which was diluted 1:10 and 24 hr later 2 birds were randomly selected and killed at 24 hr intervals until death occurred in this group. Specimens were taken until all birds in this group died. Each of the second group was administered orally with 0.5 mL sterile physiological saline solution and was kept as control. One bird was killed each day and specimens were taken until all the birds in the first group died. The specimens included the duodenum, ileum, liver, heart, kidney, spleen, lung, proventriculus, pancreas, esophagus, and the intestinal embolus. These specimens were sectioned and stained with hemotoxylin and eosin and studied by light microscope. Special staining method of Maun methylene blue and eosin was also employed for detecting inclusion bodys.

RESULTS AND DISCUSSION

Characteristics of NGVEV-CN

Hemagglutination Under the temperature of 4℃, 25℃, 30℃, 37℃, 42℃, or with the pH of 6.6, 6.8, 7.0, 7.2, 7.4, or with either physio logical saline solution or phosphate buffered saline employed, the isolated virus of NGVEV did not agglutinate the newly prepared erythrocytes of chicken, duck, goose, pigeon, yellow cattle, buffalo or pig. This indicated that NGVEV did not have the property of hemagglutination and this agreed with the conclusion that "The majority of fowl adenovirus serotypes (group 1) do not hemagglutinate"[17].

Buoyant density The buoyant density of NGVEV in cesium chlorid e was 1.32 g/mL.

Sensitivity to temperature The ability of NGVEV to cause primary duck embryo fibroblasts CPE and to cause goslings mortality was unaffected by storage for 36 months at -15℃, for 20 months at 0℃, or for 45 days at 37℃. Ability to cause primary duck embryo fibroblasts CPE and infectivity to goslings were not destroyed by heating at 45℃ for 48 hr, at 56℃ for 5 hr, or at 60℃ for 1 hr. Heating for 5 min at 80℃ or for 10 sec at 96℃ (boiled water) could make the virus lose infectivity to goslings and make the virus lose the ability to cause primary duck embryo fibroblasts CPE, which was revealed by the phenomenon that no CPE was observed when even seven blind passages were performed. All these indicated that the virus of NGVEV was very resistant to heating.

Sensitivity to pH The pathogenicity and infectivity of NGVEV was stable at pH ranging from 3.0 to 8.0 and the titre of NGVEV dropped to certain extent at pH 2.0 or 9.0, which was indicated by the fact that more time was needed for CPE to appear. NGVEV was inactivated at pH 3 or at pH 10. All these suggested that the isolated virus of NGVEV was adaptable to a comparatively wide range of pH.

Sensitivity to Chloroform Typical CPE could be observed in primary duck embryo fibroblasts inoculated with NGVEV that had been treated with chloroform for either 1 or 2 or 3 times and no differences was observed between the experiment group and the control group. This revealed that NGVEV was not sensitive to chloroform and this corresponded with the fact observed by electronic microscopy that the virions had no envelope.

Sensitivity to trypsin Whether NGVEV was treated with trypsin or not, the same CPE occurred. This suggested that NGVEV was insensitive to chloroform and was able to resist the gastroenteric proteases and gastric acid, therefore could penetrate the intestine easily[1]. NGVEV could result in the intestinal exudative or necrotic inflammation and could cause necrosis and sloughing of the intestinal epithelial cells.

Type of the nucleic acid

Drug inhibition It is well known that 5-iodedeoxyuridine (5-IudR) is similar to thymidine (T) in structure and can supersede T in DNA replication. Therefore DNA with no normal function is synthesized and virus propagation is prevented therefore make

DNA virus that is capable of resulting in CPE lose this ability. Five dilutions of NGVEV, 10^0, 10^{-1}, 10^{-2}, 10^{-3}, 10^{-4}, were prepared and 40 bottles of primary duck embryo fibroblasts were randomly divided into 2 groups with each containing 20. Each dilution of NGVEV was inoculated to 4 bottles of primary duck embryo fibroblasts of each group and cultivated at 37℃ for 1 hr for attachment of NGVEV to the cells before the virus containing media was removed. Then maintenance media containing 50 μg/mL 5-IudR was added to the experiment group and that containing no 5-IudR was added to the control group and observation was maintained for 14 days. It suggested that NGVEV was a DNA virus by the experimental result that no CPE was observed in the experiment group.

Enzymatic digestion The purified virus containing suspension was adjusted to a final concentration of 0.5% by adding 10% SDS and then under went extraction by saturated phenol which was dissolved in the solvent of Tris-HCl. The liquid phase was extracted by ether for 4 times and after the ether removed was precipitated by sodium acetate of pH 5.2 and dehydrated alcohol. Then it was placed overnight at -20℃. Then centrifugation at 16 500 rpm for 30 min was employed. After dried, the precipitate was dissolved in the buffer of Tris-EDTA with a pH of 7.3 and then was divided into 3 parts. The second part and the third part were added DNase and RNase respectively and the first part was added with no enzyme. λ DNA as well as DNA of Egg drop Syndrome Virus (EDSV-DNA) were employed as controls. It proved that the nucleic acid of NGVEV could be degenerated by DNase but could not by Rnase and the result suggested that NGVEV was a DNA virus with a nucleic acid of approximately 32 kb.

Nucleic acid strand type of NGVEV

Egg drop syndrome viruses(EDSV) DNA[20] and λ DNA were used as controls of double-stranded nucleic acid and Gosling Plague Virus (GPV)[17] was used as control of single-stranded nucleic acid.

Acridine orange staining It is known that the mechanism of acridine orange staining is based on the stain concentration and the nucleic acid space configuration, not on the type of nucleic acid (DNA or RNA). Under ultraviolet light the single-stranded nucleic acid of GPV was brilliant flame red and the nucleic acid of NGVEV and EDSV, along with ë DNA, was apple green. This suggested that the NGVEV nucleic acid was double stranded.

Nuclease digestion It is known that nuclease S1 usually degrade s the single-stranded nucleic acid, and is capable of, only at a higher concent ration, degrading double-stranded nucleic acid. The result that under the same condition NGVEV-DNA,¡¡along with the controls of EDSV-DNA and ë DNA, could not but GPV-DNA could be digested by nuclease S1, confirmed the double stranded nucleic acid type of NGVEV[21-25].

Virus purification and viral structural polypeptide analysis by SDS-PAGE

Virus purification It proved, by cellulose acetate electr ophoresis and electronic microscopy examination, that purified virions were obtained and could serve as a qualified material for the viral fine structure observation, the nucleic acid extraction and the viral structural protein analysis. Electronic microscopy of the virus revealed NGVEV virion, spherical or slightly elliptical in shape, was an unenveloped icosahedral structure 60-80 nm in diameter, with an average of 70-90 nm. And by morphological analysis, the virus appeared to fulfill the criteria of adenovirus.

Viral structural polypeptide analysis by SDS-PAGE SDS-PAGE of the disrupted purified virus particles revealed 15 discrete bands (Figure 1). After scanned and analyzed by automatic gel image-forming and analyzing system, the molecular mass and relative percentage of each structural polypept ide were obtained (Table 1). The fact that VP_4, VP_7, VP_8, VP_9 and VP_{14} were the main structural polypeptides and made up about 90.2622% of the gross protein revealed that NGVEV fulfilled the criteria of adenovirus to great extent[17,26-28]. From the relationship between DNA base number and the molecular mass of the encoded protein, it is known that NGVEV structural protein with an overall molecular weight of 71 300 D needed DNA of approximately 19.3 kb to code for. But the viral genome of DNA was about 32 kb. This suggested that NGVEV DNA codes not only for the viral structural protein. This property is shared by other adenoviruses as well[17].

From data above we have got, we know that NGVEV is adenovirus[29-45].

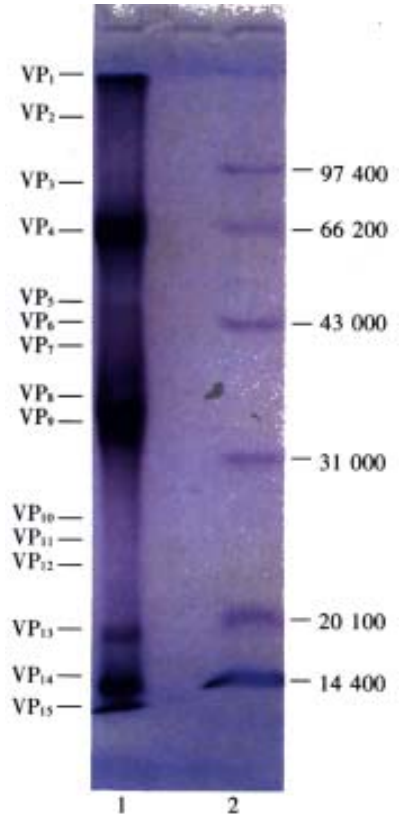

Figure 1 Protein polypetide map of NGVEV-CN virus.
1. Polypetide of NGVEV-CN virus;
2. Low MW. standard protein

Table 1 Molecular weights and relative percentages of NGVEV structural polypeptides

Polypeptides	VP1	VP2	VP3	VP4	VP5	VP6	VP7	VP8	VP9	VP10	VP11	VP12	VP13	VP14	VP15

The pathomorphological development observed in goslings artificia lly infected with NGVEV-CN

Signs

The incubation period of the experimental infection mainly varied from 2 to 3 days (36/40 or 85%) and only a few varied from 4 to 5 days; The early signs were: inactivity of the brood, reduced appetite, listlessness, somnolence, loose drooping, ruffled feathers accompanied by drooping of wings. Besides, the voice of the birds was not sonorous as before; At a later stage of this disease, wet vent feathers, soiled vents, inappetence, watery drooping with yellow or whitish yellow mucoid contained could be seen. Brown drooping might be observed in some individuals and the affected birds could not keep balance in walking and standi ng. Spasmodic prostration and convulsions, kicking spasmodically upwards with both legs might be observed in some affected goslings and opisthotonus might be found in most of the birds which died of this disease. The affected birds usually died of emaciation, extreme weakness, and somnolence. Retarded growth was observed in the affected birds and the body weight might be reduced by one fold compared with the control group. In the experiment group, mortality occurred 4 days postinfection and peaked 10-18 days postinfection and all the birds died at the 25th day postinfection. In the experiment group, altogether 8 birds were killed and 32 died.

Pathological changes

Gross changes

Small intestine In each small intestinal part, no gross lesions was demonstrated one day postinfection and only mild hyperemia could be seen 2 days postinfection; in each part of the small intestine, pronounced hyperemia, mild hemorrhage, obvious mucosa swelling as well as excess mucus production might be observed 3 days postinfection. In addition to pronounced hyperemia as well as excess mucus production, mucosa swelling and serious hemorrhage could be found in each small intestinal part of birds killed 4 days postinfection; severe hemorrhage might be found in each small intestinal part of birds that died of this disease. Besides, swollen intestinal mucosa which appeared bright and contained plenty of mucous secretory products might be observed as well; in addition to the severe hemorrhage which might be demonstrated in each part of the small intestine, a little whitish yellow coagulated fibrous exudate as well as a few pieces of necrotic intestinal epithelia might be found on the intestinal mucosa of birds that died 7-12 days postinfection; coagulative embolus wrapped by yellowish pseudomembrane was first found in birds that died 14 days postinfectio n and was about 0.2 cm in diameter and over 10 cm in length when first observed. This structure found in birds that died at a later time, which was between 0.5 and 0.7 cm in diameter and over 10 cm in length and whose length might reach 30 cm or more, was bigger than that observed previously and the small intestinal part containing it was 1-2 times distended than the control in appearance (Figure 2). The small intestinal part containing this embolus was much thin in its wall and that without this structure underwent severe hemorrhage with, its mucosa reddened. This structure of embolus was mainly observed in the middle-lower part of the small intestine before the bifurcation of the ceca and most of which was in the form of one section. There were emboluses in the form of two sections, but the number was greatly reduced. The intestinal coagulative embolus observed at necropsy could roughly be classified into 2 types. The first with a diameter of over 0.5 cm and a length of approximately 20 cm was big in size and dense in texture. And this embolus occupying the whole intestinal lumen, whether sectioned transversely or long itudinally, was found to be a two-layed structure. The outer layer, which was a pseudomembrane 0.5 mm-1 mm in depth was dry and brownish in appearance and was composed of the mixture of necrotic tissue and fibrous exudate. The inner layer was the intestinal contents which was dry and dense. The second kind of embolus with the appearance of thin rod and with a diameter of 30cm or more was obviously thinner but longer than the first and was composed of the coagulative mixture of necrotic intestinal tissue and fibrous exudate. Both kinds of emboluses did not adhere to, and were easily to be separated from the intestinal wall. The wall of the embolus containing part of the intestine was very thin and its transparency was greatly enhanced. The intestinal lesions observed in this disease, especially the coagulative embolus in the middle-lower part of the intestine that occluded the intestinal tract, resembled that observed in the case of gosling plague (GP)[46] to a great extent.

Rectum and the cecum Swelling, hyperemia and mild hemorrhage might be observed in birds that died at an early stage of this disease; much mucus was observed and the cloaca was filled with yellowish loose contents in cases that died at a later stage.

Other tissues or organs No gross lesions was found in killed birds. Birds that died at an early stage, usually less than 10 days postinfection, of this disease might show subcutaneous hyperemia or hemorrhage; epcardial mural hyperemia or small punctuate hemorrhages might be observed in a few of the m. The pectoral muscle and the leg muscle underwent hemorrhage and presented themselves dark red in appearance; the liver on which petechial or ecchymotic hemorrhages might be presented underwent venous congestion and was dark red in appearance. The swollen gall bladder which was dilated in appearance and 3-5 times larger than the control was dark greenish red and was full of bile; the kidney underwent hyperemia and mild hemorrhage and presented itself dark red in appearance; no obvious lesions was found in other tissues or organs. In birds that died at a later stage (more than 11 days postinfection), no obvious lesion was found except the liver which appeared dark red and the kidney which underwent mild hyperemia and hemorrhage.

Histopathological lesions

Duodenum In birds killed 1 day postinfection, no lesion was found different from the controls. In birds killed 2-4 days postinfection, some of the epithelial cells covering the villustips were found sloughed and some of the lamina propria cells underwent coagulative necrosis and presented themselves to be a sheet of red-stained granules among which fibrinoid necrotic interstitial tissue might be detected. In addition, hyperemia of the villi and necrosis of some of the intes tinal villus tips were observed (Figure 3). In birds that died 4 days postinfect ion, epithelium of the mucosa was found denuded and some of the villi might be completely denuded, with the lamina propria exposed. The lamina propria underwent edema. The intestinal glandular cells underwent vacuolar degeneration and were loosely packed. In birds that died 5-10 days postinfection, intestinal epithelial cells were found completely sloughed, parts of the mucosal axletree of lamina propria were found remained, in which large number of erythrocytes were detected . As the infection advanced, a large number of lymphocytes were observed in the swollen lamina propria and in some parts of it much fibrin was found. Most of the intestinal glandular cells underwent vacuolar degeneration, necrosis and were loosely packed; during the course of this disease, the duodenal fibrinonecrotic enteritis was developed and most of the intestinal villi were completely denuded , with the neat separation surface formed (Figure 4). Abundant fibrin, blood cells and bacteria filled the lumen; in birds that died 11 days postinfection, epithelial cells was completely sloughed from the mucosa and the mucosal axletree of lamina propria was exposed. As for the lamina propria, some was infiltrated with abundant lymphocytes and some underwent necrosis and sloughing. Some intestinal glandular cells

were contracted and were detached from their surrounding connective tissue, with a space around them formed. The intestinal glandular underwent necrosis, sloughing and a small number of intestinal glandular cells underwent vacuolar degeneration and were loosely packed. The blood vessels in the muscle lays were congested and abundant fibrin as well as sloughed or necrotic cells filled the lumen.

Ileum No differences was found between the birds killed 1-4 days postinfection and the controls; in birds that died 4 days postinfection , epithelial cells covering the villus tips underwent necrosis and sloughing. The glandular cells underwent swelling and vacuolar degeneration and were loosely packed, some of which were represented by their outlines, another part of which might be replaced by abundant proliferated connective tissues and lost their outlines. Some of the intestinal villi were observed completely sloughed from the mucosa and with the prolonged course of this disease, the intestinal villi were observed completely sloughed and the typical fibrinonecrotic enteritis was eventually developed. The pseudomembrane covering the embolus in the intestinal tract was mainly composed of necrotic mucosa, droppings, inflammatory cells, bac terium and the exudate of fibrin (Figure 5).

Liver No differences was found between the birds killed 1-4 days postinfection and the controls; in some cases that died of this disease , local congestion, mild granular degeneration and fatty degeneration (7/32) (Figure 6) was observed. As for the pathological changes in the case of gosling plague (GP)[46], pronounced inflammatory lesion and focal necrosis of the liver were successively observed 24-48 hours postinfection and granular degeneration as well as vacuolar degeneration were observed successively. With the prolonged course of GP, the hepatic cells underwent severe vacuolar degeneration and progressive necrosis, which were most evident in birds that died of this disease. The hepatic cells were swollen and their shape changed from polygonal to round. Many vesicles appeared in the hepatic cytoplasm and thus made it appeared loosely foamy. Cytoplasm dissolution, ballooning degeneration, together with the marked vacuolation of the hepatocytes were observed in more serious cases and the Sudan III staining for fat was negative. With the further development of this disease, hepatocytes underwent rupture, necrosis and dissolution and the necrosis-dissolution foci were developed, in which were light red -stained oedematous fluid as well as a small number of monocytes and lymphocytes. Dehydration, condensation and enhanced cytoplasmic acidophilia occurred in a few hepatocyte cytoplasm, in which round eosinophilic droplets were formed and shared great similarity to that structure observed in the case of human viral hepatitis.The hepatic cords were disorganized in structure and some of the hepatic sinusoid,with the necrosis and dissolution of the hepatocyte,were disrupted and erythrocytes were released.The hepatic interstitial blood vessels and the hepatic sinusoids were congested and loose and lost their normal structure and underwent fibrinoid necrosis. The interlobular monocytes and lymphocytes underwent diffuse proliferation and showed diffuse infiltration.Nodular proliferative foci were formed in some parts of the interlobular tissue.

Kidney In birds killed 1-4 days postinfection, the main lesions were: the renal tubular tract was not clear in structure, mild grandular degeneration could be seen in the epithelial cells of the renal tubular; in birds that died of this disease 4 days postinfection, hemorrhage focus and granular degeneration of the epithelium of the renal tubular might be found in some cases (19/32); vacuolar degeneration (Figure 7) and abundant sloughed epithelial cells in the ureter tract might be observed in some cases (9/32), Some cases (5/32) were found normal.

Spleen Mild hyperemia might be observed in some (4/8) of the birds killed 1-4 days postinfection; Mild hyperemia, hemorrhage might be observed in a few (5/32) of the cases that died of this disease and the lymphoid follide of these cases were found equivocal in structure. As for the case of gosling plague[46], no obvious lesions was found during the early stage of this disease and during the later stage, splenic sinusoid might be found congested and contained a large number of monocytes and a small number of heterophiles. Besides, the splenic corpuscles underwent atrophy and was equivocal in structure; lymphocytes underwent necrosis and karyorrhexis; small necrotic foci might be found in the lymphoid nodule; proliferation of monocytes or reticular cells might be observed in the parenchyma of the spleen.

Lung In cases 1 day postinfection, the blood vessels were congested; in cases 2 days postinfection, tertiary bronchuses underwent hyperemia and hemorrhage; in cases 3-4 days postinfection, hyperemia, hemorrhage was found and the vein was congested. The tertiary bronchus and the atrium contained a lot of erythrocytes and the secondary bronchus contained quantities of blood; most of the cases that died 4 days postinfection showed pulmonary congestion and hemorrhage, caseation necrosis foci could only be observed in a few cases (2/32).

Proventriculus No lesions were observed in birds killed 1-4 days postinfection or birds that died less than 5 days postinfection; sloughing of the epithelium from the mucosa was observed in most (30/32) of the birds that died more than 5 days postinfection and there were abundant sloughed cells in the cavity. Besides, sloughed glandular cells might be found in parts of the glandlobular cavities. As for the cases of GP[46], 48 hour s until death, degeneration, necrosis and sloughing of the epithelial cells of the mucosa might be observed. The lamina propria underwent hyperemia and was infiltrated with inflammatory cells. Compound tubular glandular cells might be observed sloughed; many inflammatory cells and sloughed glandular cells filled the collecting sinusoid.

Heart Most (27/32) of the killed birds were found to be normal and only a few (5/32) that died at an early stage of this disease showed mild hyperemia and hemorrhage in their hearts. But in the case of gosling plague[46], the following might occur 12-36 days postinfection: granular degeneration of the myocardium, Cross striations of the myocardium got dim or disappeared; the myocardium underwent karyorrhexis and karyolysis; small necrotic foci and inflammatory cell infiltration might be observed; Focal pericardit is might developed.

Pancreas, brain and esophagus These organs were found normal. But in the case of GP[46] 72 hr postinfection, the following was observed: Interstitial blood vessels were congested, the glandular cells underwent degeneration and was separated from the basal membrane. In birds that died of GP, the acinuses were found disorganized in structure and the glandular cells were necrosed, sloughed, dissolved and finally the necrosis-dissolution focus was formed; the interstitial tissues were infiltrated with inflammatory cells. In the case of GP[46], basically the same lesion, which was not obvious at an early stage, was shown in the cerebrum and the cerebellum; at a later stage, the following might occur: nenix underwent swelling and hyperemia, blood vessels in the cerebral parenchyma were dilated and congested with the perivascular space enlarged, foci formed by the perivacular proliferation of a small number of lymphocyte and monocytes could be seen, matrix of the cerebrum was swollen, the neuron underwent degeneration and vesicles might be observed in its cytoplasm, pykosis was observed and the nucleus was equivocal in structure, the neurogliocytes underwent diffuse proliferation and glial nodules might be formed in some areas within it.

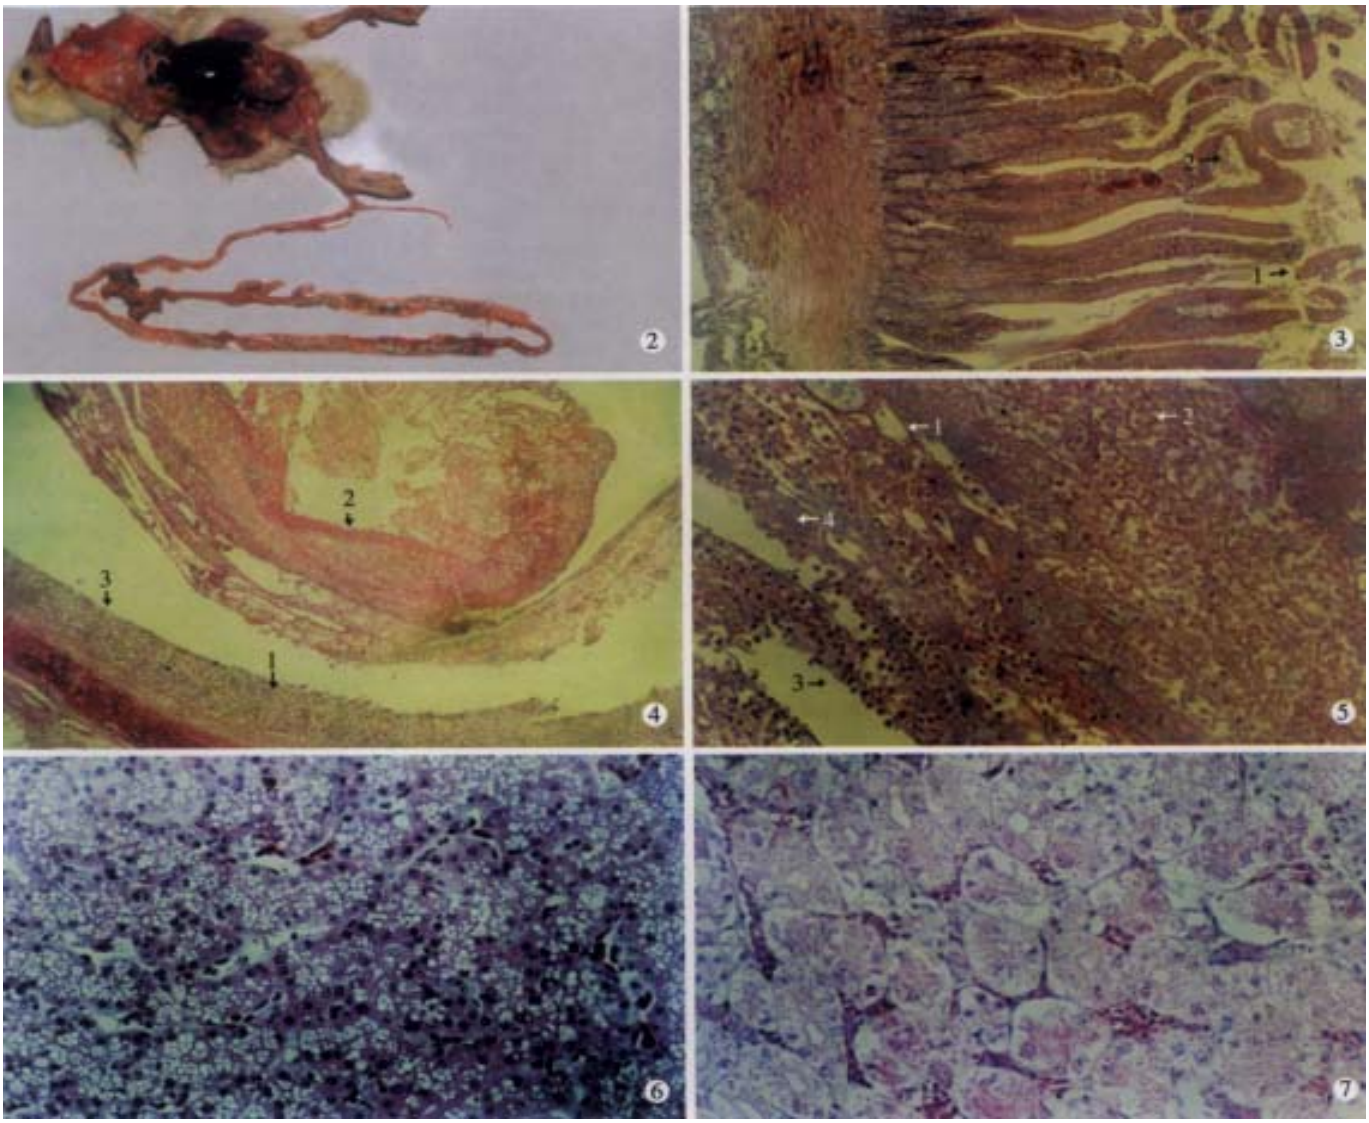

Figure 2 Particular coagulative embolus was formed in small in testine of death gosling (13 days postinfection), the length is over 40 cm. Haemorrhage was occured in small intestine wall and be dyed red.
Figure 3 Many pieces of falled epidermal cells in duodenum cavity (arrow 1), coagulative necroses was occured in some villus top (arrow 2). (150×, H.E)
Figure 4 Particular fibrinous and necrosed enteritis of ileum: necrosed mucosae (arrow 1) and fibrinous edudate coagulated into artificial me mbrane and dropped into the cavity (arrow 2), and surface of separation boundry was smooth (arrow 3). (100×,H.E)
Figure 5 Particular fibrinous and necrosed enteritis of ileum: the embo lus consisted of the necrosed mucosal tissue coagulated and dropped materials, it include fibrinous edudate which like thread and inflammatory cells. Fibrin (arrow 1), necrosed cells (arrow2), inflammatory cells (arrow 3) and bacteria (arrow 4). (400×,H.E)
Figure 6 Fatty degeneration were occured in liver cells. (500×,H.E)
Figure 7 Kidney: Hyperaemia. Granular degeneration was occured seriously in kidney small vessles (arrow 1), or even vacuolar degeneration (arrow 2). (500×,H.E)

About the structure of inclusion body According to the related reports[17,18,46], intranuclear or intracytoplasmic inclusions might be observed in myocardium, hepatocytes, and epithelial cells of the intestine in the case of GP. Wang[46] reported that eosinophilic granules were found in the hepatocytes. In many cases of poultry infected with adenovirus, inclusion body could be observed[47-52]. But none of these mentioned above was observed in the case of NGVE.

Histopathological and ultrastructure analysis is the key method to understand mechanism of human ang animal disease[53-64]. The histopathological change of Goslings be infected with NGVEV can help us to understand mechanism of NGVE, Pathological characteristic could be provide helpful materials for the NGVE diagnosis and differential diagnosis from GP.

ACKNOWLEDGEMENTS We would like to thanks associated professor Fang Jing for making, reading the pathological slides and taking the pathological photos. We also grateful to technician Zhou Yi for his work about transmission electronic microscope.

Abstract

AIM **To establish a cell culture system with long-term replication of hepatitis C virus *in vitro*.**

METHODS **Human hepatoma cell line 7721 was tested for its susceptibility to HCV by incubating with a serum from a patient with chronic hepatitis C. Cells and supernatant were harvested at various phases during the culturing periods. The presence of HCV RNA, the expression of HCV antigens in cells and/or supernatant were examined by RT-PCR, in situ hybridization and immunohisto-chemistry respectively.**

RESULTS **The intracellular HCV RNA was first detected on d2 after infection and then could be intermittently detected in both cells and supernatant over a period of at least three months. The expression of HCV NS_3, CP_{10} antigens could be observed in cells. The fresh cells could be infected by supernatant from cultured infected cells and the transmission of viral genome from HCV-infected 7721 cells to PBMCs was also observed.**

CONCLUSION **The hepatoma line 7721 is not only susceptible to HCV but also supports its long-term replication *in vitro*.**

INTRODUCTION

Hepatitis C virus (HCV) is the major cause of transfusion-associated non-A, non-B hepatitis[1]. Acute HCV infection leads, in more than 70% of the patients, to the development of chronic hepatitis[2], and then cirrhosis and hepatocellular carcinoma[3,4]. HCV is an enveloped positive-stranded RNA virus which contains a genome of about 9500 nts encoding a polyprotein by host and viral proteases results in the production of structural and nonstructual (NS) protein[5-8]. Despite increasing knowledge of genome structure and individual viral proteins, studies on virus replication and pathogenesis have been hampered by the lack of reliable and efficient cell culture systems. To identify critical epitopes that elicit a neutralizing antibody response and to understand the pathogenesis of persistent infection, efficient infection cell models for HCV are needed[8-10]. Many cell lines has been sought to support HCV infection and replication *in vitro*. Human T-lymphocyte cell lines[11-18], human fibroblast cells[19] (VH3), peripheral blood mononuclear cells[20,21] (PBMCs) and hepatocytes[22-28] have been shown to support HCV replication *in vitro*. These cell models have been proved to be useful for the study of HCV. To be mentioned, hepatocytes are the main target cells for HCV replication *in vivo*. Whether the replication of HCV in non-hepatocytes entirely mimics the behavior of human hepatocytes and whether the molecular characterization of growing HCV in these cell models has changed are still poorly understood[28].

In this study, we employed a human hepatoma cell line 7721 to test its susceptibility to HCV and established an infection cell model that can support HCV long-term replication *in vitro*. The presence of both plus- and minus- strand of HCV RNA and the expression of viral antigens in infected cells were demonstrated.

MATERIALS AND METHODS

Inoculum

The principal inoculum was a serum obtained from a 45 year old female chronic patient, who was positive for anti-HCV antibody (Abbott) and HCV-RNA (1b genotype). Sera from patients without any evidence of HCV infection or chronic liver diseases were also used as controls.

Cell line

The hepatoma cell line 7721 was obtained from Lab. of Gastroenterology in Third Military Medical University. Cells were maintained in PRMI1640 medium supplement ed with non-essential amino acids and 100 mL·L^{-1} fetal bovine serum . The cells were fed fresh medium every 3 d to 5 d, and were subcultured at the ratio of 1:2 to 1:4.

Viral inoculation and sample collection

The HCV-positive serum (inoculum) was diluted at the ratio of 1:5. 7721 cells maintained in 25 cm 2 polystyrene flasks and 6-well dishes were incubated with the inoculum at 37 ℃ for 8 hr. Then all medium was removed and cells were washed 6 times with phosphate buffered saline (PBS). Cultures were refed with medium with 100 mL·L^{-1} fetal bovine serum and the media were changed every 4 d-5 d.

Cells and supernatants were harvested according to the method introduced by Iacovacci *et al*[27], with slight modification. Briefly, cells (approximately 2×10^6 cells) and 1 mL aliquots of cell supernatants from infected and uninfected cell cultures were harvested at different periods after infection for up to 70 d, and slices grown with cells were also collected accordingly (for study of the localization of different HCV antigens and minus- strand of HCV RNA),

replacing the medium removed at each collection. Supernatants were centrifuged at 10 000×g to remove cellular debris, and the ultracentrifuged pellets were stored at -20℃ until detection of HCV RNA. Cells were harvested for RNA extraction after 6 washes with phosphate buffered saline (PBS).

Detection of HCV RNA by RT-PCR

For detection of HCV RNA, total RNA was extracted from 1mL of the ultracen trifuged supernatants and approximately 2×10^6 cells by using a nucleotide and protein extraction kit (Tripure, Roche). 10 μL of the RNA solution was denatured at 72℃ for 4 min and incubated at 37℃ for 1 h with 200 U of murine moloney leukaemia virus reverse transcriptase (MMLV-RT, Promega) and 50 pmol of the outer antisense oligonucleotide primer (antisense, CACTCGCAAGCACCCTATCA-; nucleotides 302-285). Synthesis of cDNA was stopped by heating the samples at 95℃ for 10 min. Amplification of the cDNA was performed by using 15 μL cDNA solution and 50 pmol of one of the outer primers (sense,-GGCGACACTCCACCATA GAT-: nucleotides 9-28). Thirty cycles of DNA amplification were carried out followed by and extension step for 10 min at 72℃. Each cycle of PCR consisted of 94℃ for 60 s, 55℃ for 90 s and 72℃ for 120 s. The second PCR was carried out in the same way with 10 μL of the first PCR mixture and 50pmol of each inner prime (sense, -CTGTGAGCAACTACTGTCT-; nucleotides36-55 and antisense, -CGGTGTACTCACCGGT TCC-; nucleotides 161-143). The amplified DNA was visualized by 20 $g\cdot L^{-1}$ agarose gel electrphoresis and ethidium bromide staining.

Detection of HCV antigens by immunohistochemistry

A modification of immunohistochemical staining of viral antigens by streptavidin peroxidase (SP) method was performed. Monolayers of infected and uninfected cells grown on slides were fixed for 15 min in 40 $g\cdot L^{-1}$ formaldehyde pH (7.3) in PBS solution. After washing, endogenous peroxidase was blocked by a 10-minute incubation with 3 $mL\cdot L^{-1}$ H_2O_2 in methanol. Sections were washed in PBS, 15 min at 37℃. Sections were washed in PBS (pH 7.4); then 200 $mL\cdot L^{-1}$ normal goat serum was used for 15 minutes.

The sections were incubated with 1:200 dilution of the primary antibody (anti- NS3) or with 1:60 dilution of primary antibody (anti-CP_{10}) for 16 h at 4℃ in a moisture chamber. The immunostaining was also done without the primary antibodies. These reagents and all subsequent reagents were diluted in PBS with 1 $g\cdot L^{-1}$ bovine serum albumin (BSA) and used at a volume of 100 mL per slide. After a PBS rinse, biotinylated second antibody was applied for 30 min at room temperature. After another PBS rinse, streptavidin peroxidase was applied for 30 min. After a final PBS rinse, the cell sections were incubated with 0.6 $g\cdot L^{-1}$ diaminobenzidine (Sigma) and 0.1 $mL\cdot L^{-1}$ H_2O_2. The sections were then conterstained with hematoxylin, dehydrated with graded alcohols and xylene, and observed under coveslips.

In situ hybridization

The localization of intracellular minus-strand of HCV RNA by in situ hybridization was done according to the METHODS by Cribier *et al*[20] and Nouri-Aria *et al*[29] with modifications. The slides were rehydrated through an ethanol series (1000-500 $mL\cdot L^{-1}$) and rinsed in PBS for 5 min, and then the cells were digested with 1mg $\cdot L^{-1}$ proteinase K (Roche) for 30 min at 37℃. The slides were rinsed twice in PBS containing 2 $g\cdot L^{-1}$ glycine (10 min each), refixed in 40 $g\cdot L^{-1}$ PFA for 5 min at room temperature, then rinsed three times for 10 min in 2×SSC buffer, and finally 10 $mmol\cdot L^{-1}$ DDT was then added to the slides. Dehydration in an ethanol series (500-1000 $mL\cdot L^{-1}$) was followed. The probe was denatured for 15 min at 85℃ and added to hyridization solution (500 g $\cdot L^{-1}$ formamide, 100 $g\cdot L^{-1}$ dextran sulphate, 2×SSC, 2×Denhardt's solution, 1 $g\cdot L^{-1}$ Triton X-100, 0.01 $mol\cdot L^{-1}$ DDT, 200 $mg\cdot L^{-1}$ herring sperm DNA). The final concentration of the probe was 1 $mg\cdot L^{-1}$. The slides were denatured for 2 min at 95℃, and various amounts of probe, depending on the area, were added on the cell section. Samples were covered with siliconized coverslips, sealed with paraffin, and incubated in a humidified chamber at 37℃ for 10 h-20 h. The coverslips were removed and the slides were rinsed three times in 1×SSC buffer and washed twice in 500 $g\cdot L^{-1}$ formamide, 1×SSC for 15 min at 42℃. After two washes at 42℃ in 1×SSC and another wash in 0.1×SSC (10 min each), the slides were dehydrated through an ethanol series and dried under vacuum. The sections were incubated with a streptavidin-biotin alkaline phosphatase complex and successively developed with nitroblue-tetrazolium and bromo-chloro-indolyl phosphate (NBT/BCIP), according to the manufacturer's instructions. After being rinsed in water, the slides usually were stained briefly with eosin. Uninfected cells were hybridized with the HCV probes and served as a first negative control. The Dig-labeled genomic strand RNA transcript was 41mer and its sequences is 5'-CTGCTAGCCGACT AGTGTTGGGTCCGCGAAACC-GCTTGTGG-3'.

RESULTS

Detection of HCV RNA in the infected cells

The intracellular RNA was determined by RT-PCR in infected cells at various times during culture, ranging from d 2 to d 95, as shown in Table 1. Plus- strand of HCV RNA was intermittently detectable after infection, but not detectable on d 25, d 30, d 52 and d 75 after infection. Minus-strand RNA was detectable from d 3 after infection, and still detect able at d 95 after infection.

Table 1 Detection of HCV RNA in 7721 cells and supernatant

Day p.i.	Cells		Supernatant	
	Plus-strand RNA	Minus-strand RNA	Plus-strand RNA	Minus-strand RNA
2	+	-	+	-
3	++	++	+	-
10	+	+	+	ND
20	++	+	-	-
25	-	-	-	ND

60	+	-	-	-
75	-	+	-	-
82	++	++	++	-
90	++	-	+	-
95	+	+	-	-

*+, Weakly positive; ++,Positive; -,Negative; ND, Not detection.

Detection of HCV RNA in the culture medium

The presence of HCV RNA in culture supernatant was also determined by RT-PCR. Plus-strand of HCV RNA in

supernatant was less often than that in cells. The HCV negative-strand could not be detected in the supernatants and inoculum, as shown in Table 1. Immediately after incubation and six washes of the uninfected 7721 cells, the RT-PCR were negative on the buffer used in the final wash of the cells.

These results were confirmed by three other repeated experiments.

The expression of HCV antigens in infected cells

7721 cells were tested for the expression of virus-encoded proteins by SP method using mouse monoclonal antibodies directed against NS_3 and CP_{10}. Figure 1A, B show that infected 7721 cells were positive for different viral antigens. The positive cells were scattered and displayed diffuse cytoplasmic yellow staining similar to that reported in other cell culture systems and naturally infected liver cells[30-34]. Moreover, uninfected cells and cells incubated with normal serum were tested negative using these same antibodies (Figure 1C).

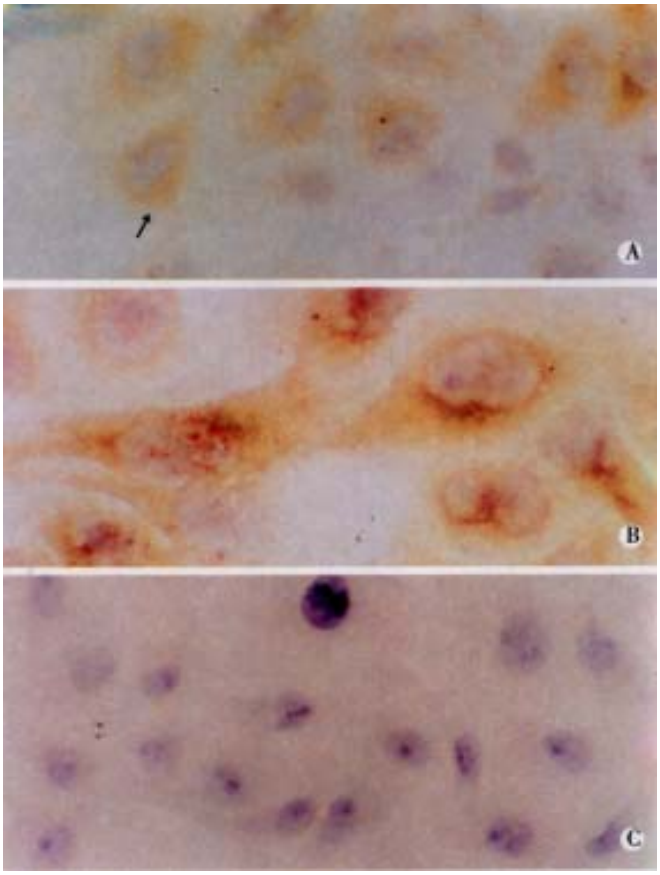

Figure 1 Immunohistochemical detection of HCV-encoded protein in infected 7721 cells. Positive reaction (yellow) with anti-NS_3 (A) and anti-CP_{10} (B) in 7721 cells, were scattered in the lobules (SP method, original magnification, A×200, B×400). Lack of staining with the same antibody in uninfected 7721 cells processed at the same times and 7721 incubated with oormal serum (C).

In situ hybridization

Using the HCV positive-strand probe, positively labeled cells could be observed at various time after infection. The positive signals (blue) also mainly localized in cytoplasm, and were similar to that reported in other cell culture systems and naturally infected liver cells[35-40], as shown in Figure 2A, B. Uninfected 7721 as controls showed no labeling with the same probe (Figure 2C).

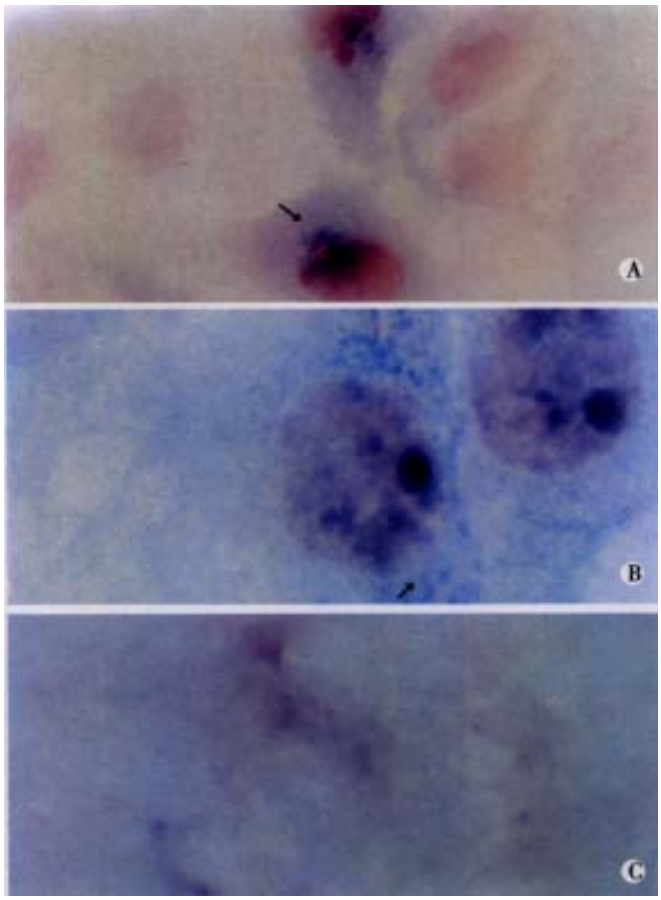

Figure 2 Detection of minus-strand of HCV RNA in cells using in situ hybridization. Positive reaction (blue) was mainly present with cytoplasm (A, original magnification, ×400). Higher magnification showed the positive cells looked morhologically normal (B, original magnification, ×1000). No signal in uninfected cells (C).

Infectivity of the released HCV in the culture supernatant

To determine the infectivity of HCV particles released into the culture supernatant, we harvested cell-free culture supernatant from primary infected-7721 culture on d6 after infection, as described by Mizutani *et al*[14-16]. Fresh (uninfected) 7721 cells were incubated with the culture supernatant containing HCV for 8 h at 37℃ and then the medium was washed.On d 4 and d 8 after initiating the culture, we harvested the medium and cells for the presence of HCV RNA and HCV antigens as above described. Figure 3A shows that minus- strand RNA could be detected in fresh 7721 cells on d 4 and d 8. HCV NS_3 antigen could also be detected in cells on day 8 (Figure 3B).

Transmission of HCV in cell culture

In order to demonstrate whether this system is abortive or productive of infectious HCV, the transmission of the viral genome in HCV-infected 7721 cells to new cells was tested by coculture. For this purpose, we separated the PBMCs from healthy man as described[20]. PBMCs (2×10^5) were mixed with an equal number of HCV-infected 7721 cells. The presence of HCV NS_3 antigen and minus-strand RNA in PBMCs were tested on day 4 and 10 after coculture. The result showed that minus-strand RNA and NS_3 antigen of HCV could be detected by *in situ* hybridization and immunohistochemistry, indicating that the genome was successfully transmitted to PBMCs.

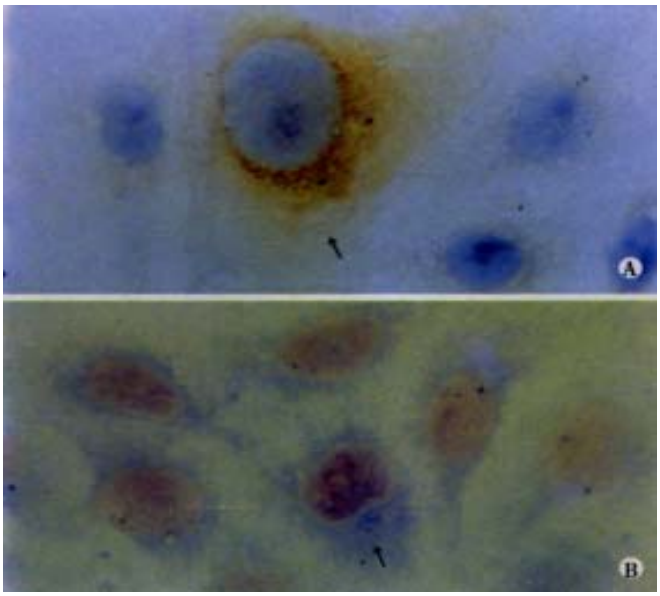

Figure 3 Cell-free transmission of HCV in cell culture. HCV transmission to fresh/uninfected 77 21 was carried out by using the supernatant of culture medium derived from HCV-infected cell culture. The presence of minus-strand of HCV RNA and NS 3 antigen in cells was detected by in situ hybridization (A, original magnification, ×400) and immunohistochemistry (B, original magnification, ×400), respectively.

Cell growth and phenotyic change

7721 cells presented a spindle or round shape in culture and grew in a monolayer. Untreated cells and cells incubated with negative or positive serum, prolifer ated at the same rate with no visible phenotypic changes. Cell growth was not affected by incubation with the HCV-positive serum.

DISCUSSION

Although the knowledge of the molecular biology of HCV has progressed rapidly, our understanding of viral replication and pathogenicity is still hampered by the lack of reliable and efficient cell culture systems. Development of an efficient *in vitro* culture system for HCV will faeilitate the study of HCV. We have demonstrated the susceptibility of a hepatoma cell line 7721 to HCV and established a stable cell model that may support HCV long-term replication *in vitro*. Because HCV RNA in both cells and supernatant after infection may be the residue of the inoculated virus attached to the cell surface, it is necessary to identify that HCV sequences detected in the infected cultures are not from inoculum but newly produced.

We tested both plus-and minus-strands of HCV RNA, the expression of HCV antigens, the localization of minus-strand of HCV RNA, separately, and could show that HCV replication in the cultured cells was not the residue of inoculum. The data presented here indicate that the 7721 cells support HCV infection for at least 3 months. The infected 7721 cultures released detectable levels of HCV into the medium as early as d 2 after infection. Reduction of adsorption time (from 8 h to 2 h) did not significantly reduce the efficiency o f viral replication (not shown), suggesting that binding to cell receptors occurs in a relatively short time[14,28].

We found that both plus- and minus- strands were not often but intermittently detectable in cells and supernatant. Such intermittent detection of the HCV RNA was also reported in other culture systems[20,27,28] and the infection *in vivo*[41-45]. Interestingly, in our study, we showed that the fresh 7721 cells could be infected by the supernatant from cultured infected cells, and that the HCV-infected cells were able to transmit the virus to new cells (PBMCs) after coculture. These results suggested that HCV-infected 7721 cells could deliver infectious and mature virus as others cell models[11,28].

Our findings are consistent with a productive *in vitro* infection of 7721 cells by HCV and are in agreement with the results of Tagawa *et al*[26-28]. However, these authors did not study the expression of viral antigens in hepatoma cell lines after infection. Detection of the HCV protein in cultured 7721 cells by immunohistochemistry indicated that HCV RNA was translated and HCV proteins were produced in cultured cells. The frequency of antigen-positive was less than 30%. The expression of different viral antigens and the localization of minus-strand of HCV RNA were similar to the naturally infected liver cells[30-34]. The results of this study correlates well with experiments as shown in naturally infected hepatocyes, suggesting that the HCV infection and replication occurring in 7721 cultures closely mimic the infection occurring *in vivo*[46-50]. Blocking of viral attachment by a hyperimmune rabbit serum against hypervariable region 1 has been demonstrated on the basis of this model[51]. The mechanisms of HCV infection, replication, assembly, and neutralization can now be studied in detail *in vitro*. This system should also be useful for analysis of antigen epitopes and the evaluation of vaccine candidates, which is especially important because of the limited availability of chimpanzees for vaccine studies and the high degree of variability in the HCV glycoprotein domains.

Abstract

AIM **To prepare a cancer vaccine (H_{22}-DC) expressing high levels of costimulatory molecules based on fusions of hepatocarcinoma cells (H_{22}) with dendritic cells (DC) of mice and to analyze the biological characteristics and induction of specific CTL activity of H_{22}-DC.**

METHODS **DCs were isolated from murine spleen by metrizamide density gradient centrifugation, purified based on its characteristics of semi-adhesion to culture plates and FcR^-, and were cultured in the medium containing GM-CSF and IL-4. A large number of DC were harvested. DCs were then fused with H_{22} cells by PEG and the fusion cells were marked with CD11c MicroBeads. The H_{22}-DC was sorted with Mimi MACS sorter. The techniques of cell culture, immunocytochemistry and light microscopy were also used to test the characteristics of growth and morphology of H_{22}-DC *in vitro*. As the immunogen, H_{22}-DC was inoculated subcutaneously into the right armpit of BALB/C mice, and their tumorigenicity *in vivo* was observed. MTT was used to test the CTL activity of murine spleen *in vitro*.**

RESULTS **DC cells isolated and generated were CD11c+ cells with irregular shape, and highly expressed CD80, CD86 and CD54 molecules. H_{22} cells were $CD11c^-$ cells with spherical shape and bigger volume, and did not express CD80, CD86 and CD54 molecules. H_{22}-DC was $CD11c^+$ cells with bigger volume, being spherical, flat or irregular in shape, and highly expressed CD80, CD86 and CD54 molecules, too. H_{22}-DC was able to divide and proliferate in vitro, but its activity of proliferation was significantly decreased as compared with H_{22} cells and its growth curve was flatter than H_{22} cells. After subcutaneous inoculation over 60 days, H_{22}-DC showed no tumorigenecity in mice, which was significantly different from control groups (P<0.01). The spleen CTL activity against H_{22} cells in mice implanted with fresh H_{22}-DC was significantly higher than control groups (P<0.01).**

CONCLUSION **H_{22}-DC could significantly stimulate the specific CTL activity of murine spleen, which suggests that the fusion cells have already obtained the function of antigen presenting of parental DC and could present H_{22} specific antigen which has not been identified yet, and H_{22}-DC could induce antitumor immune response; although simply mixed H_{22} cells with DC could stimulate the specific CTL activity which could inhibit the growth of tumor in some degree, it could not prevent the generation of tumor. It shows that the DC vaccine is likely to become a helpful approach in immunotherapy of hepatocarcinoma.**

INTRODUCTION

T lymphocyte-mediated immunoresponse plays an important role in the antitumor immune response. The sensibilization, activation and proliferation of T lymph ocytes depend on antigen presenting cells (APC) which was able to present corres ponding antigen peptides and to provide costimulatory signals[1]. However, many tumor cells have weak immunogenicity which expressed low levels or no MHC and costimulatory molecules, so that tumor antigen can not be effectively presented. Therefore, they cannot induce effective antitumor immune response in host, and can not effectively activate specific killing mechanism. APC cancer vaccines are expected to enhance the immunogenicity of tumor cells and increase the presenting ability of antigen presenting cells as well as induce effective specific T lymphocyte mediated antitumor immune response. Dendritic cells (DC) are a kind of the most potential and professional antigen presenting cells *in vivo*[2-8]. DC can catch, process and present antigens, and enhance the killing activity of lymphokine[9-11], especially it can powerfully stimulate the primary immune response[12-16]. So more and more attention has been paid to the function of tumor immunotherapy of DC[17-19]. In this experiment, in order to effectively strengthen the function of antigen presenting of DC, to enhance the immunogenicity of tumor cells and to stimulate the specific CTL activity of host, dendritic cells derived from murine spleen were fused with hepatocarcinoma cells.

MATERIALS AND METHODS

Materials

Male BALB/C mice, 6-8 weeks old, weighing 15 g-20 g, purchased from Shanghai SIPPR/BK Experimental Animal Limited, were randomly divided into test group and control group. Mouse monoclonal antibody CD80, CD86, CD54 were purchased from Coulter Co. rmGM-CSF and rmIL-4 were obtained from R&D Co. Mini MACS (magnetic cell seperation) and CD11c (N418) microBeads were bought from Miltenyi GmbH Biotec. Metrizamide was obtained from

Amresco Co. and PEG was from Sigma Co. Mouse hepatocarcinoma cell line (H_{22}) was obtained from the Cancer Research Institute of Dalian Medical University.

Methods

Isolation of DC According to the previous METHODS[20-24] with minor modefications, DCs were isolated from murine spleen by metrizam ide (145 g·L^{-1}) density gradient centrifugation, purified based on its characteristics of semi-adhesion to culture plates and FcR$^-$, and cultured in the medium containing GM-CSF and IL-4 (500 ng·L^{-1}), and a large number of DC were harvested.

Cell fusion and selecting[25,26] DCs were fused with H_{22} cells by PEG and the fusion cells were marked with CD11c MicroBeads. The H_{22}-DCs were sorted with Mimi MACS sorter. Fused cells were cultured in RPMI 1640 medium containing 20 mL·L^{-1} fetal bovine serum, rmGM-CSF and rmIL-4 (500 ng·L^{-1}) for 2-3 wks.

Cellular morphological analysis Light microscopy and phase contrast microscopy were used to identify the morphological characteristics of H_{22}-DC, H_{22} and DC.

Immunocytochemical staining for CD80, CD86 and CD54 Cells were incubated with antibodies against CD80, CD86 and CD54. Membrane proteins were detected by ABC reagen and DAB staining, and photomicrographs were taken with an Olympus microphoto-microscope.

Cell proliferation analysis *in vitro* DCs were added into 24-well plates at 1.25×10^4 cells per well and three wells were randomly seclected to be counted every 24 h. Then, growth curve of H_{22}-DC was drawn accoding to their average value, using H_{22} as control group at the same time.

Tumorigenecity assays This experiment was conducted in 3 groups. Each group included four experimental subgroups (H_{22}-DC, H_{22}+DC, H_{22} and PBS). Immunogen (0.1 mL 1×10^{10}-2×10^{10} ·L^{-1}) of H_{22}-DC was inoculated subcutaneously into the right armpit of H_{22}-DC subgroup mice of each group and the same amount of H_{22}, H_{22}+DC and PBS were inoculated into the mice in each corresponding subgrou p in the same way. The growth of tumors was observed every day and the survival time of mice was calculated. Meanwhile, mice in the second group were killed on the 14th day after implantation, and tumors were isolated and tumor weight was compared.

CTL activity assays The third group mice were killed for examination at the 10th day after implantation, and the spleen was separated to prepare cell suspension, then the cells were cultured in 100 mL·L^{-1} FCS-RPMI1640 medium containing the final concentration of 100 KU·L^{-1} rhIL-2 by genetic recombination at 37℃ in a saturated humidified 50 m L·L^{-1} CO_2 atmosphere for 3 days. The anti-tumor experiment was conducted in four subgroups. Two ratios of effect (CTL) to target (H_{22}) (5:1 and 10:1) were used in all groups. ① Group A: CTL (H_{22}-DC subgroup) + H_{22}; ② group B: CTL (H_{22}+DC subgroup) + H_{22}; ③ group C: CTL (H_{22} subgroup) + H_{22}; ④ group D: CTL (PBS subgroup) + H_{22}. In addition, T groups were only consisted of CTL as the corresponding control groups and group E was H_{22} control group. Culture medium of the control group only contained 100 mL·L^{-1} FCS-RPMI1640. All of these groups were cultured in 96-well culture plates and each group had 3 wells at 37℃ in a saturated humidified 50 mL·L^{-1} CO_2 atmosphere for 48 h. Cytotoxity activity was determined by MTT assay as previously described[27,28]. Briefly, freshly prepared and filtered 20 μL MTT (5 g·L^{-1} in PBS) were added to each well, and the cells were continuously cultured for 4 h. Then the supernatant was removed and 150 μL DMSO was added to each well and agitated for 10 min to fully liquefy crystals, followed by reading on BIO-RAD 3550-UV type automatic ELSIA reader at 570 nm wavelength.

Statistical analysis

Statistical analysis was made using analysis of variance, if $P<0.05$, the result was considered statistically significant.

RESULTS

DC morphology

DCs are irregular shaped cells with many surface membrane processes, including spiky or spherical pseudopod-like processes. They have oval or irregular-shaped nucleus with wavy movement. The cytoplasm contains rich spherical mitocho ndrias. Determined by immunocytochemical staining, DCs were CD80 and CD86 and CD54 positive cells with irregular shape and brown-yellow fine granules in cytoplasm (Figures 5-7).

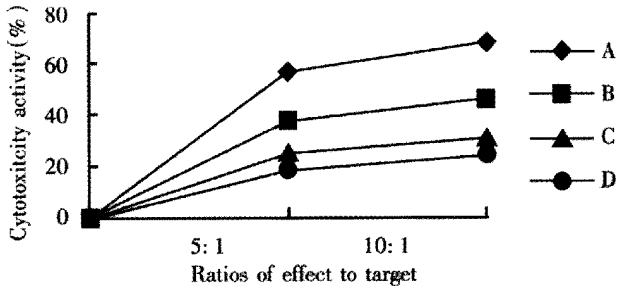

Figure 3 Influence on CTL cells of kill activity in vitro on d10 after inoculation.

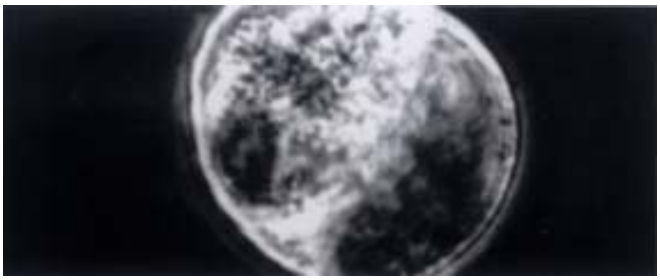

Figure 4 H_{22}-DC fusion cells under phase microscope. 5×40

Characteristics of H_{22}-DC and H_{22} and sorting of fusion cells

Marked with CD11c MicroBeads and sorted with Mini MACs, H_{22}-DCs were $CD11c^+$ cells (Figures 8-10), but H_{22} was $CD11c^-$ cells. By immunocytochemical staining, H_{22}-DCs were CD80, CD86 and CD54 positive cells and H_{22} was negative cells. Cytokine of rmGM-CSF and rmIL-4 was able to induce proliferation of fusion cells and prolong their survival time. The fusion cells which were marked with CD11c MicroBeads and sorted with Mini MACs were mixed with unfused DC. If there were no rmGM-CSF and rmIL-4 in the medium, natural apoptosis would occur in DC after 10-14 days, but H_{22}-DC would be still alive.

Identification and analysis of characteristics of fusion cells

H_{22}-DCs have some characteristics of both of their parental cells such as suspended growth, oval, flat and irregular in shape, they also have irregular shape nucleus and rich mitochondrias (Figure 4). Proliferation of H_{22}-DC in incubation without rmGM-CSF and rmIL-4 showed slow growth and low activity. However, H_{22}-DC incubation with rmGM-CSF and rmIL-4 was able to divide and proliferate, but compared with H_{22}, its activity of division and proliferation was significantly decreased and their growth curve was flatter. After subcutaneous implantation over 60 days, no tumorigenesis was induced in H_{22}-DC of mice, but induced tumorigenesis (100%) was observed in control subgroups (iH_{22}+DC and H_{22} subgroup) (Figure 1). The tumor weight of H_{22}+DC subgroup mice implanted on day 14 was significantly different from that of H_{22} subgroup ($P<0.01$, Figures 2, 11-13).

CTL activity assays

MTT assays showed that CTL activity of spleen in H_{22}-DC group was significantly higher than that in H_{22}+DC, H_{22} or PBS group ($P<0.01$, Figure 3).

DISCUSSION

Steinman and Cohn first isolated DC from the spleen of mice in 1973[20]. Since then, scholars have successfully isolated DC from thymus, aggregated lymphoid follicle, tracheas of mice, livers of rats and human peripheral blood. In recent years, mature DC was considered able to effectively present tumor-peptide epitopes and induce cytotoxic T lymphocytes (CTL) to produce strong specific antitumor immune response[29-32]. Wu and Kufe *et al* prepared DC vaccine using activated B cells and DC fused with tumor cells by traditional fusion METHODS in 1994 and 1997, respectively. This experiment was based on the established METHODS of isolation and generation of DC[20-24] by chemical fusion with PEG and techniques of immunomagnetic beads, it not only apparently simplifies the complicated sorting process of traditional fusion methods, but also effectively increase the purity of cell sorting. It is simple and feasible. The CD11c monoclonal antibody N418 is specific for the integrin αx subunit of αxb2 which was the leukocytic integrin expressed on mouse splenic DC[33,34]. The principle of MACS CD11c+ cell sorting is that the cells are labelled by MicroBeads coupled with CD11c antibodies and passed through a sorting column which is placed in the magnetic field of a MACS sorter. The magnetically labelled $CD11c^+$ DC are retained in the column while the unlabeled $CD11c^-$ cells passed away. After getting the column from the magnetic field, the magnetically retained $CD11c^+$ DC can be eluted as the fraction of positively sorting cells. The effect of MACS sorter is confirmed by fluoroimmunoassay, PCR, FISH and FACS. The advantages of MACS are: it can process numerous cells, its sorting purity is very high, and it can be operated easily.

Much data in recent years show that DC played a very important role in the tumor immune response[35-39], especially with the develpment of gene therapy against tumor specific antigen. But at present, T cells epitopes of tumor specific antigens in most of the human cancers besides melanoma, breast cancer and ovarian cancer are not very clear[40]. Thus, cancer vaccine directly fused DC with tumor cells has become an important way in active immunotherapy of tumors[41-45]. It is simple and reliable and of practical value. At the same time, a tumor immunotherapy approach of specificly distinguishing and killing tumor cells but normal cells of host *in vivo* has developed[45-50].

By sorting with Mini MACS marked with mouse CD11c MicroBeads, H_{22}-DCs have some characteristics of two parental cells, being irregular in shape. Apoptosis occurred in DC-DC and DC mixed with H_{22}-DC respectively after 7-10 d and 10-14 d in the medium with no rmGM-CSF and rmIL-4, but H_{22}-DCs were still alive. H_{22}-DC could divide and proliferate quickly in the initial stage but soon their growth slowed down and their activity of dividing and proliferating reduced. We failed to establish the cell line in vitro, possibly due to the growth nature of the parental cells in vitro and loss of chromosome with the time of incubation.

After subcutaneous implantation over 60 days, H_{22}-DC showed no induced tumorigenesis in BALB/C mice, but did it in H_{22} control group (100%). It suggested that H_{22}-DC has lost its tumorigenecity in vivo. The tumor weight in H_{22}+DC control group was significantly different from that of H_{22} control group when it had been implanted for 14 days ($P<0.01$). It shows that DC simply mixed with tumor cells could obviously inhibit the development of tumor in the early stage, but could not prevent the generation of tumor, which means that DC played a positive role in the course of presenting tumor antigen and inducing sepecific antitumor immune response in the early stage of tumorigenicity. By selecting the spleen of mice in H_{22}-DC, H_{22}+DC and H_{22} group on d10 after implantation spleen CTL activity in vitro was induced in our experiment, and the results showed that the spleen CTL activity of H_{22}-DC inoculated group was significantly higher than H_{22} inoculated group ($P<0.01$), which suggests that the active immunity of cancer vaccine can produce specific antitumorimmune protection in mice. DC and H_{22}-DC could induce specific antitumorimmune response and stimulate production of effective T lymphocytes in mice, and H_{22}-DC induced no tumorigenesis. It indicates that DC directly fused with hepatocarcinomar cells is likely to become a helpful appreach in immunotherapy for hepatocarcinoma.

INTRODUCTION

Birth asphyxia may lead to disturbances of gastroenteric motility of newborn infants[1,2]. The change of gut pressure and reflux are the major manife stations of the motor disturbance[3-9]. To evaluate the effects of perinatal asphyxia on the gastroenteric motility, gastric and esophageal pressure and double pH were measured in a group of asphyxiated newborns. And, their pathophysiological and anatomical effects on gastroenteric function were discussed.

MATERIALS AND METHODS

Subjects

The neonates admitted to our neonatal intension care unit of the Second Affiliated Hospital, China Medical University from August 1995 to March 1996 were studied. The criterion for asphyxia: Apgar score at birth (1 min) $\leqslant$7, accompanied with hypoxia, acidosis and other organ damage caused by asphyxia[10]. The asphyxia group consisted of 35 asphyxia neonates with a mean age of 3.3 d, gestational age 40 wk, and mean body weight of 3189 g. In the asphyxia group, there were 7 infants with severe asphyxia (1 min Apgar score$\leqslant$3). The control group included 17 normal infants, who were admitted for intensive care. These infants showed no symptoms of gastroenteric, neurological and respiratory diseases, with a mean age of 5.2 d, mean gestation age of 39.6 wk, and mean body weight of 3371 g. Two groups were fed with same formula. No prokinetic agent was administrated.

Gastric and esophageal manometry

Multiple channel physiological recorder (RMP-6018, Japan), TP-400 pressure transmitter and Au-601G automatic drawing device were used in this study. The manometry was performed after 3h fasting. By the fluid transformation and synchronous device, the pressure within the stomach, lower esophageal sphincter (LESP), body of esophagus and upper esophageal sphincter were measured respectively and the difference between LESP and gastric pressure was calculated. The distance between the nasal cavity and the LES was calculated as well.

Double pH monitoring technique

Crystal antimony double pH microelectrode (diameter 2.1 mm, type 90-0011, Synectics Medical, Sweden) was used in this study. Before each monitoring, pH calibration was performed. The esophageal electrode was introduced to 2 cm above LES and the distal electrode was advanced 15 cm apart. The infants' diet and activity were not limited during the test. The beginning and ending of each feeding, occurrence of vomiting and crying were written down. The pH signals were recorded during 24 h in a pocket pH meter. After that, the meter was connected with computer and the results were analyzed with a pH analysis software system (Esophogram 5.550 B3 improved edition, Gastrosoft Inc.).

Monitoring index

The indexes of acid gastroesophageal reflux (GER) (esophageal pH<4): acid reflux index (RI) (percentage of total time pH<4); number of reflux episodes; number of reflux episode >5 min; duration of longest episode pH<4 in minutes; total time of pH <4 in minutes; the area under pH<4 curve (pH×min); and esophageal clearance time (min/reflux). The indexes of alkaline duodenogastric reflux (gastric pH>4): gastric alkaline index (AI): percentage of total time pH>4; number of gastric alkaline episodes; number of gastric alkaline episode >5 min; duration of longest episode pH>4 in minutes; total time of pH>4 in minutes; and the area under pH>4 curve (pH×min).

Statistics

The data were expressed as $\bar{x}\pm S_{\bar{x}}$. Inter-group comparison was performed with *t* test. The results were considered statistically significant if *P* value <0.05.

RESULTS

Esophageal and gastric pressure

The gastric pressure of the study group was higher than that of control group (Table 1). The LESP, difference between LESP and gastric pressure, esophageal body pressure and UESP were lower than those of control group, but the differences were not significant (P>0.05). The gastric pressure of severe asphyxia group was significantly lower than that of mild asphyxia group (P<0.01).

24-h esophageal pH monitoring

The GER parameters of asphyxia group were all higher than those of control group (Table 2). The parameters were also higher than the consulting pathological GER diagnosis standard for the age group of <12 mo, i.e. reflux index > 5%, number of reflux episodes >132, number of episodes over 5 min >1, duration of longest episode of pH<4 >13 minutes, the area under pH<4 curve >51. This pH analysis

system recommended a Boix-Ochoa value reflecting infant acid gastroesophageal reflux and a value less than 11.99 was considered normal statistically[11]. In our current study, the asphyxia group had an average value of 37.1 whereas 6.4 in the control group.

24-h gastric pH monitoring

The difference in the parameters between the asphyxia and control groups was not statistically significant ($P>0.05$, Table 3) and with no sensible tendency.

Double pH monitoring in infants with asphyxia of different degree

The acid GER in mild asphyxia group was more severe than that in severe asphyxia group (Tables 2,3). The gastric alkaline parameter was not significantly different between the asphyxia groups of different degree.

DISCUSSION

The pressure measurement of inside gut is a major index reflecting gastroenterol motility. LESP and UESP are important elements to resist GER[12]. Our results showed that gastric pressure in asphyxia group was higher than that of control, LESP, esophageal body pressure and UESP were all lower than those of control group. Though the differences were not significant, it does partly contribute the pathophysiological and anatomical bases for GER[13-16].

GER is a disorder of gastroenterol motility malfunction. Among many inspecting METHODS, continuous 24 h esophageal pH monitoring is regarded as "golden standard" to diagnose and manage GER[17-22]. This study introduced this technique to the digestive tract motility research of asphyxia newborn babies. The acid GER parameters derived from the normal control group were similar with a large sample study (92 cases of same age) done by Vandenplas *et al*[23] with the same technique, which suggests that this method has good stability, reliability and repetition[24].

In children with impaired central nervous system, there is a tendency of more occurrence of GER[25-29]. This is associated with the long-term supine position, uncoordinated or lack swallow movement, impaired function of esophageal movement, abnormal motility of gastric sinus or pylorus duodenum, increased abdominal pressure caused by swallowing too much air, convulsion and effects of some medicine. It has been observed in animal that slight increase of intracranial pressure can cause obvious decrease of LESP[26,27]. Prenatal asphyxia can easily cause temperate or permanent injury of central nervous system, it should be noted that prenatal asphyxia may play an important role in the mechanism of GER.

GER is not all pathological, so it has no feature of all-or-no. There are large laps between physiological and pathological GER[30]. Normal physiological GER occurs when a baby is in a standing position, or in a state of wakening and post meal, whereas the pathological GER occurs when the baby is in supine position, or during sleep and before meal[31]. In our study,the GER in asphyxia patients obviously belong to the pathological GER no matter using Boix-Ochoa Index or other diagnostic standards. So these patients can easily suffer from reflux, vomiting even without feeding, and complications[32-35] such as problems of nutrition and respiratory system.

There is few research of alkaline GER in neonates[36-39]. It is generally regarded that esophageal pH>7 can be called alkaline GER. Because this value is near to the normal esophageal pH (5.0-6.8), the single esophageal pH monitoring can not give an accurate judgment about alkaline GER. But the gastroesophageal continuous double pH monitoring has resolved this problem[39]. It can help analyze the relevance of the changes of gastroesophageal pH and in the meantime it helps understand the pathological bases of the alkaline duodenal GER. However, the gastric alkaline parameter showed

nosignificant difference between the asphyxia group and normal control, mild and severe asphyxia infants. Furthermore, there was no relevance with the esophageal alkaline reflux.

To our surprise, severe asphyxiated infants showed obviously decreased gastric pressure, slighter acid GER and lower gastric alkaline than that of their mild asphyxia cohort. Combining with the clinical symptoms of feeding difficulty, gastric retention, abdominal distension, and constipation in severe asphyxiated infants, this result suggested that after severe asphyxia, a phenomenon similar with "gastropa resis" in adults, developed in newborn infants due to the multiple factors such as inhibition of central nervous system[40,41] and ischemia-refilling injury.

Abstract

AIM **To investigate the influence of L-methionine-deprived total parenteral nutrition with 5-FU on gastric cancer and host metabolism.**

METHODS **N-methyl-N'-nitro-nitrosoguanidine (MNNG) induced gastric cancer rats were randomly divided into four groups: Met-containing TPN group (*n* = 11), Met-deprived TPN group (*n* = 12), Met-containing TPN+5-FU group (*n* = 11) and Met-deprived TPN+5-FU group (*n* = 12). Five rats in each group were sacrificed after 7 days of treatment and the samples were taken for examination. The remaining rats in each group were then fed separately with normal diet after the treatment until death, the life span was noted.**

RESULTS **The tumors were enlarged in Met-containing group and shrank in Met-deprived group markedly after the treatment. The DNA index (DI) of tumor cells and the body weight (BW) of rats had no significant change in the two groups, however, the ratio of tumor cells' S phase was increased. The ratio of G2M phase went up in Met-containing group, but down in Met-deprived group. In the other two groups that 5-FU was added, the BW of rats, and the diameter of tumors, the DI of tumor cells, the S and G2M phase ratio of tumor cells were all decreased, particularly in Met-deprived plus 5-FU group. Pathological examination revealed that the necrotic foci of the tumor tissue increased after Met-deprived TPN treatment, and the nucleoli of tumor cells enlarged. In -MetTPN+5-FU group, severe nuclear damage was also found by karyopyknosis and karyorrhexis, meanwhile there was slight degeneration in some liver and kidney cells. The serum free Met and Cysteine decreased markedly (*P*<0.001), while other amino acids, such as serum free serine and glutamine increased significantly (*P*<0.005). All the rats died of multiple organ failure caused by cancer metastasis. The average survival time was 18.6 days in Met-containing TPN group, 31 days in Met-deprived TPN group, 27.5 days in Met-containing TPN+5-FU group, and 43 days in Met-deprived TPN+5-FU group (*P*<0.05).**

CONCLUSION **Met-deprived TPN causes methionine starvation of tumor cells, and can enhance the anti-tumor effect of 5-FU and prolong the life span of gastric cancer-bearing rats.**

INTRODUCTION

Many tumor cells can not grow in the medium replaced L-methionine (Met) with its direct precursor L-homocyateine. However, normal cells can grow well in that medium. It means that the growth of tumor cell is Met-dependent[1-9]. In this study, we prepared a Met-free amino acid solution and used it as the sole nitrogen source of total parental nutrition (TPN), to investigate the influence of Met-deprived TPN on the gastric cancer and host metabolism.

MATERIALS AND METHODS

Animal grouping and treatment

Male Wistar rats, with N-methyl-N'-nitro-nitrosoguanidine (MNNG) induced gastric cancer (*n* = 46), were verified to have tumor diameter larger than 8 mm in laparotomy and confirmed pathologically. The 46 rats were randomly divided into four groups: Met-containing TPN group (*n* = 11), Met-deprived TPN group (*n* = 12), Met-containing TPN+5-FU group (*n* = 11) and Met-deprived TPN+5-FU group (*n* = 12). Five rats in each group were sacrificed after 7 d of treatment and the specimens were taken for examination and the other rats were then fed with normal diet separately after the treatment until death for noting the life span. After 24 h fasting, the rats were cannulated to the vena cava immediately after peritoneal cavity anesthesia with 25 $g \cdot L^{-1}$ barbital and placed in metabolic cage respectively and infused with different TPN solution after fixing the TPN tube at the back of rats with a plate and tension spring.

Composition and infusion of TPN solution

The rats were infused with 50 $g \cdot L^{-1}$ glucose normal saline 200 mL $\cdot kg^{-1}$ on the cannulation day. Different TPN solutions were infused continously 24 h a day on the next 7 d. During the experiment, the rats were housed individually in metabolic cages. The composition and usage of TPN solutions are shown in Table 1.

Specimen sampling and detection

Pre- and post- TPN, the rats' body mass (BM) and the tumor

diameter were measured, the tumor tissues were sampled for flow cytometry (FCM) tumor cell cycle analysis and DNA index calculation. Blood samples were taken for serum amino acid profile test. Tissues of the rats' gastric cancer, heart, lung, liver and kidney were sampled and fixed with 100 mL·L^{-1} formalin, enbedded with paraffin, sliced in 5 μm, and HE stained for pathohistologic examination.

Table 1 Composition and dosage of TPN solution (kg^{-1}·d^{-1})

Composition	+MetTPN	-MetTPN
250 g·L^{-1} Glucose / mL	100	100
200 g·L^{-1} Intralipid / mL	35	35
+Met amino acid solution / mL	100	0
-Met amino acid solution / mL	0	100
Non-protein energy / J	710	710
Total nitrogen / g	1.30	1.03
Total volume / mL	235	235

Usage and dose of 5-FU

5-FU was added to the TPN solution and infused for 6 d (from d 2 to d 7, 15 mg·kg^{-1}·d^{-1}).

Observation of survival time

The other rats in each group not sacrificed were moved to common cage after withdrawing TPN tube and fed with normal diet until death. The survival time was noted.

Statistical analysis

Student t test was used to examine the data. Survival time was examined with time sequence examination. The difference was considered significant when the *P* value was less than 0.05.

RESULTS

Alteration of the rats' BM, tumor size and DI

The BM and DI had no significant change in both +MetTPN and -MetTPN groups after treatment. The tumor size was markedly enlarged in +MetTPN group and shrank in -MetTPN group. All of the BM and the DI as well as the tumor size were decreased in both groups of +MetTPN+5-FU and -MetTPN+5-FU, and the change was more significant in the -MetTPN+5-FU group (Table 2).

Change of tumor cell cycles

The S phase percentage of tumor cells was increased in both +MetTPN and -MetTPN groups, and it is higher in the other groups. However, the change of G2M phase ratio was different. It was increased in +MetTPN group and decreased in -MetTPN group. The S and G2M phases were lowered in the other groups with 5-FU. The change was more significant in -MetTPN+5-FU group (Table 3).

Table 2 Body mass, tumor diameter and DNA index of tumor cells after TPN ($\bar{x}$±s)

TPN solution	mb / g		dt / mm		DNA index	
	Pre-TPN	Post-TPN	Pre-TPN	Post-TPN	Pre-TPN	Post-TPN
+MetTPN	242±20	243±20	11.2±1.0	14.7±0.7^{b}	1.13±0.24	1.21±0.26
-MetTPN	248±20	245±18	11.5±1.2	6.9±0.8^{ad}	1.15±0.21	1.12±0.23

-MetTPN+5-FU	6.5±0.7	4.5±0.3^{a}	12.4±0.9	6.2±0.5^{bc}	80.1±0.5	89.3±0.7^{b}

^{a}P<0.05, ^{b}P<0.01, *vs* preTPN; ^{c}P<0.05, ^{d}P<0.01, *vs* +MetTPN.

Serum amino acid profile

The serum L-methionine and L-systein were markedly decreased in the -MetTPN rats. However, the other amino acids such as asprine and glutamine as well as serine were significantly increased after treatment (Table 4).

Pathohistological findings

The number of tumor necrotic foci were increased after -MetTPN and -MetTPN+5-FU treatment. Nuclei was enlarged in tumor cells and liver cells.

Survival time

All the gastric cancer bearing rats died of cancer metastasis and cachexia. The mean survival time was 18.6 d in +MetTPN group, 31 d in -Me tTPN, 27.5 d in +MetTPN+5-FU and 43 d in -MetTPN+5-FU (P<0.05).

DISCUSSION

Patients with malignant tumors often show severe protein-amino acid metabolism disorder and uncorrectable negative nitrogen balance as well as low immune function caused by malnutrition[10-21]. TPN support is considered beneficial to improve the patients' nutritional status and immune function, and to lower the surgical complications, and to improve the quality of life[22-28]. But, TPN can also stimulate proliferation of the tumor cells[29,30]. So, there is much concern to study the special feature of tumor cells' metabolism and to find a regimen of TPN that is beneficial to the host, but pernicious to the tumor cells, particularly through the regulation of tumor cells' metabolism[31-52].

In this study, a special regimen of TPN deprived of Met was used in MNNG induced gastric cancer rats. The results showed that the TPN, containing Met or not, has regulative effects on the tumor cells' dynamics. The effects were different between Met-containing TPN and Met-deprived one. Met-containing TPN stimulated tumor cells' proliferation and promoted the tumor cells from G0/G1 phase into S and G2M phase, and made the ratio of S phase to G2M phase increased simultaneously. However, the Met-deprived TPN disturbed the metaboli sm of DNA, especially DNA methylation through Met starvation and inhibited the tumor proliferation by blunting S phase into G2M phase, resulting in increase of S phase ratio and decrease of G2M phase ratio. The inhibitory effect of tumor growth of the Met-deprived TPN was enhanced by simultaneous use of 5-FU, and it was manifested by a longer life span in the rats treated. Pathohistological examination found that the necrotic foci were increased in the tumor tissue and the nuclei of the tumor cells were enlarged. The pathohistologic findings were concordant with FCM analysis of cell cycles, meaning that the metabolism of DNA was blunted. One must be careful when using -MetTPN, particularly -MetTPN+5-FU, as some adverse effects may occur. In this practice, we noticed that the host liver and kidney cells had light degeneration. Hoffman *et al*[53] studied the growth of SV-40 fibroblast cells in the medium deprived of Met and found that the cell proliferation was blunted in S/G2 phase reversibly. Further studies[54] found that in the Met-free environment, the intracellular free Met of tumor was extremely decreased and it lowered greatly the S-Adeosylmethionine (S-AdoMet) which had decreased because of the tumor cell's over active transmethylation, and resulted in a low ratio of S-AdoMet to S-AdoHcy. This directly inhibited the activity of transmethylase and suppressed the transmethylation reaction, including the DNA methylation. When the tumor cells were returned to the Met-containing environme nt, DNA methylation recovered and the cell cycle circulated. This reversible block of tumor cell cycle at S/G2 phase enhanced the anti-cancer effect of 5-FU and hinted the combined and sequenced use of other cycle specific chemotherapy agents with Met-deprived TPN.

By autopsy, we found that the liver and peritoneum metastasis of gastric cancer were much less in the group using Met-deprived TPN and the group using Met-deprived TPN plus 5-FU. It suggests that not only the primary tumor proliferation was inhibited, but also the invasive ability for metastasis was suppressed. Breillout *et al*[55] reported that Met-deprived TPN suppressed the metastasis potential of Lewis lung cancer and rhabdomyosarcoma in experimental animals. They considered that it was Met-starvation which disturbed the methylation of DNA and membrane lipids of the tumor cells, inhibiting their metastastic ability. Some authors even suggested that the inhibitory effect of -MetTPN against metastasis is more powerful than in proliferation of primary tumors. However, this still needs further studies.

INTRODUCTION

The main component of a traditional Chinese drug "Pishuang", arsenic trioxide (As_2O_3), has obviously selective anti-tumor effect on human hepatocellular carcinoma (HCC) in both *in vitro* and *in vivo* studies[1-5]. Due to limited effectiveness when any anti-carcinogen is used alone and obviously increased toxicity when the dose is raised, there is no exception for As_2O_3. Furthermore, combined chemotherapy contributes to improve therapeutic effectiveness, disperse toxicity and surmount drug-resistance, in which the combination of traditional Chinese and modern medicine has more advantages and characteristics. As a result, we made an experimental study on anti-tumor effect of As_2O_3 in combination with cisplantin (PDD) or doxorubicin (ADM) on HCC, to investigate the possibility of As_2O_3 in combination with PDD or ADM and nature of interaction between them, and to provide experimental basis for clinical application.

MATERIALS AND METHODS

Materials

Drugs and reagents As_2O_3 for injection (5 mg per am poul, Lot No. 998068, provided by Professor Ma Jun of Harbin Hamaeotoloy and Oncolony Institute), PDD for injection (20 mg per vial, Lot No. 990618, Shandong Qilu Pharmaceutical Factory) or ADM hydrochloride for injection (10 mg per vial, Lot 990406, Shanxi Mlarmaceutical Co. LTD).

Cell lines Human hepatoma Bel-7402 cells were obtained from the Shanghai Cell Bank of Chinese Academy of Sciences and maintained in our laboratory. Bel-7402 cells were routinely cultured in RPMI1640 medium (Gibco) containing 100 mL·L^{-1} fetal calf (FCS) serum at 37℃ in humidified incubator with 50 mL·L^{-1} CO_2/95 mL·L^{-1} air.

Animals Mice with hepatoma HepA were obtained from the Shanghai Institute of Materia Medica of Chinese Academy of Sciences and Kunming mice (famale and male weighing, 18 g-22 g) from the Experimental Animal Center of Southerneast University Medical College.

methods

Measurement of anticancer activity *in vitro* The exponent growing Bel-7402 cells in culture flasks were harvested by 2.5 g· L^{-1} EDTA, suspended in RPMI1640 medium with 100 mL·L^{-1} FCS, adjusted to the concentration of 3×10^4 cells·L^{-1}, plated into 40-well plates (100 μL cells·well-1) and incubated at 37℃ in 50 mL·L^{-1} CO_2/95 mL·L^{-1} air until the cells were stuck with the plates. The cells were then exposed to 100 μL of various concentrations of a drug alone or combination for 48 h, and the controls to 100 μL of RPMI1640 medium with no FCS. After that, the absorption was detected by adding 20 μL tetrazolium (MTT) to each well, incubating for 4 h, sucking out the media, adding 150 μL dimethylsul foxide (DMSO) to dissolve the violet-crystal and measuring at 570 nm. Double wells were used for each drug concentration. Experiments were triplicated. The inhibitory rate was calculated as follows:

IR(%)=(1-mean absorption in experiments/mean absorption in controls)×100%

Measurement of anticancer activity *in vivo* The mice with hepatocarcinoma HepA were killed and their ascites Abstracted, adjusted to 2×10^7·mL^{-1} and implanted by subcutaneous injection 200 μL to each mouse. Sixty mice with implanted HepA tumor were randomly divided into control group (saline), and groups of As_2O_3 alone (2 mg·kg^{-1}·d^{1}), PDD alone (1 mg·kg^{-1}·d^{1}), As_2O_3 combin ed with PDD (As_2O_3 2 mg·kg^{-1}·d^{1} + PDD 1 mg·kg^{-1}·d^{1}), ADM alone (1 mg·kg^{-1}·d^{1}), and As_2O_3 combined with ADM (As_2O_3 2 mg·kg^{-1}·d^{1} +ADM 1 mg·kg^{-1} ·d^{-1}). Each group was injected intraveously 24 h after transplatation once a day for 7 days continuously. The mice were killed on the 8th day after the treatment and the tumors isolated and weighed. The inhibitory rate of tumor was calculated as follows:

Inhibitory rate of tumor (%)=(1-mean tumor weight in experiments/mean tumor weight in controls)×100%

Statistical method Analysis of variance of two-factor factoria l experiment was applied to evaluate anti-cancer activity *in vitro* and analysis of variance of random experiment was used to evaluate anti-cancer activity *in vivo*.

Evaluation of interaction of drug combination *In vitro* experiment: the interaction between As_2O_3 and PDD or ADM was evaluted by coefficient of drug in interaction (CDI), which was calculated as follows: CDI = AB/(A×B). AB is the absorption ratio between a drug combination group and controls and A or B is that between a drug alone and controls. When CDI value was equal to 1.0, or more than 1.0 or less than 1.0, the nature of the interaction between A and B was considered to be additive or antagonistic or synergistic[6]. *In vivo* experiment: the interaction between As_2O_3 and PDD or ADM was evaluated by Q value, which was calculated as follows: Q=E(AB)/[EA+(1-EA)×EB]. E(AB) is the inhibiting tumor rate and EA or EB is that of a drug alone. When Q value was equal to 0.85-1.15, or less than 0.85 or more than 1.15, additive or antagonistic or synergistic interaction was thought to occur[7].

RESULTS

The effect of As_2O_3 and/or PDD on HCC

The inhibition rates of As_2O_3 *in vitro*, in combination with PDD at various concentrations were more than that of As_2O_3 or PDD alone ($^aP<0.01$, F = 58.96), in which the inhibition rates increased more evidently at low concentrations (Figure 1). CDI values of As_2O_3 and PDD in combination at low concentration were less than 1.0 (Table 1).

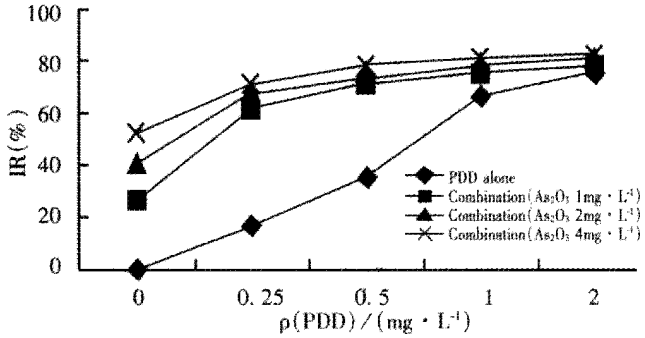

Figure 1 The effect of As_2O_3 and/or PDD on the growth of Bel-7402 cells *in vitro.*

Table 1 CDI value of As_2O_3 in combination with PDD against Bel-7402 cells

Cell line	As_2O_3 (mg·L-1)	PDD (mg·L-1)			
		0.25	0.5	1	2
Bel-7	1	0.60	0.60	1.00	1.22
	2	0.62	0.70	1.03	1.38
	4	0.60	0.65	1.13	1.50

The effect of As_2O_3 and/or ADM on HCC

In vitro the inhibition rates of As_2O_3 in combination with ADM in various concentrations were more than those of As_2O_3 or ADM alone ($^aP<0.01$, F = 64.77), in which the inhibition rates increased more evidently in low concentrations (Figure 2). CDI values of As_2O_3 and ADM in combination in low concentrations were almost equal to 1.0 (Table 2).

The effect of As_2O_3 and/or PDD on HepA implanted tumor

The inhibiting tumor rate of As_2O_3 in combination with PDD was more than that of As_2O_3 or PDD alone and *Q* value was more than 1.15 (Table 3).

[a]$P<0.05$, F = 24.40, *vs* As_2O_3 or ADM alone.

DISCUSSION

As_2O_3, the main component of traditional Chinese drug "Pishuang", has been applied to treat acute promyelocytic leukemia and yielded notable results. Complete remission rate and long-term survival rate are high and the relapse rate is low in APL patients treated with As_2O_3[8-10]. The main mechanism of As_2O_3 is to induce apoptosis of leukemia cells, which is different from all-trans retinoic acid (ATRA)[11-23]. Based on the achievements, the experimental studies on anti-tumor effect of As_2O_3 in such hematopathy as malignant lymphoma[24] and myeloma[25,26] and solide tumors such as cancers of lung[27],

esophagus[28], stomach[29-32], colone[33-35] pancreas[36], mamma[37], cervix[38] and neuroblastoma[39] are in the ascendant.

The morbidity and mortality of hepatocarcinoma is high in China, which is the first cause of death among all kinds of cancers in Jiangshu Province. Due to the hidden onset, low rates of early diagnosis and rapid progression, most patients with hepatocarcinoma cannot be operated on and have to depend on chemotherapy, but the therapeutic effect of the present agents is unsatisfactory. So it is urgent and necessary to go on seeking new drugs and the improving therapeutic METHODS. Our group has taken the lead in conducting the study of As_2O_3 against liver cancer and found that As_2O_3 had obviously selective anti-tumor effect on hepatocarcinoma both *in vitro* and *in vivo*[1-5]: *in vitro* As_2O_3 inhibited the proliferation of several hepatocarcinoma cell lines but not normal human liver cells and *in vivo* inhibited implanted hepatocarcinoma in mice and prolonged the survival phase of mice with hepatocarcinoma but produced no obvious toxicity. The main mechanism is to induce apoptosis of hepatocarcinoma cells, which also has been proved by other reports[40-46].

To further investigate the best therapeutic way of As_2O_3 and raise the effect on hepatocarcinoma, we studied As_2O_3 and PDD or ADM in combination. The experiments *in vitro* showed that As_2O_3 in combination with PDD or ADM can increase the effect on HCC Bel-7402 and the increase extent varies at different concentrations, which was greater at lower concentrations. The possibl e reason is that the anti-tumor activity of an individual drug is saturated at high concentrations and difficult to increase after combination or there was antagonistic action to some extent between two drugs in combination and counteracted part of anti-tumor activity of a drug. CDI values showed that *in vitro* the nature of interaction is markedly synergistic between As_2O_3 and PDD and addictive between As_2O_3 and ADM in low concentrations. On the basis of the experiments *in vitro*, low-dose PDD or ADM combined with As_2O_3 was applied to treat HepA tumor implanted in mice, and inhibitory rate of tumor evidently increased as compared with that of a drug alone. Q value showed that *in vivo* synergistic interaction between As_2O_3 and PDD and addictive between As_2O_3 and ADM were thought to occur, which agreed with the results *in vitro*. These results suggested that low-dose PDD or ADM and As_2O_3 in combination could increase evidently anti-hepatocarcinoma effect. PDD and ADM are the main anti-hepatocarcinoma agents, but their toxicities in kidney, liver or heart restrict their clinical application, as a result patients cannot tolerate the high-dose agents whereas low dose is difficult to achieve satisfactory results. Considering selectively inhibitory effect of As_2O_3 on HCC *in vitro* and unobvious toxicity *in vivo*, the effect may be improved evidently without increased toxicities or keep satisfactory in poorly-tolerated patients with low dose of PDD or ADM when As_2O_3 and PDD or ADM in combination are applied to treat hepatocarcinoma.

Abstract

AIM **To evaluate the efficacy and safety of the TECA-I bioartificial liver support system (BALSS) in treating canines with acute liver failure (ALF).**

METHODS **Ten canines with ALF induced by 80% liver resection received BALSS treatment (BALSS group). Blood was perfused through a hollow fiber tube containing 1×10^{10} porcine hepatocytes. Four canines with ALF were treated with BALSS without porcine hepatocytes (control group), and five canines with ALF received drug treatment (drug group). Each treatment lasted 6 hours.**

RESULTS **BALSS treatment yielded beneficial effects for partial liver resection-induced ALF canines with survival and decreased plasma ammonia, ALT, AST and BIL. There was an obvious decrease in PT level and increase in PA level, and there were no changes in the count of lymphocytes, immunoglobulins (IgA, IgG and IgM) and complement (C3 and C4) levels after BALSS treatment. In contrast, for the canines with ALF in non-hepatocyte BALSS group (control group) and drug group, there were no significant changes in ammonia, ALT, AST, BIL, PT and PA levels. ALF canines in BALSS group, control group and drug group lived respectively an average time of 108.0 h±12.0 h, 24.0 h ±6.0 h and 20.4 h ±6.4 h, and three canines with ALF survived in BALSS group.**

CONCLUSION **TECA-I BALSS is efficacious and safe for ALF canines induced by parcial liver resection.**

Chen XP, Xue YL, Li XJ, Zhang ZY, Li YL, Huang ZQ. Experimental research on TECA-I bioartificial liver support system to treat canines with acute liver failure. *World J Gastroenterol*, 2001;7(5):706-709

INTRODUCTION

The incidence of acute liver failure (ALF) is high, and the survival rate of ALF patients is only 10%-15%[1,2].The current comprehensive treatment for ALF is not satisfactory. Orthotopic liver transplantation (OLT) is an effective therapy for patients with ALF. However, because of the shortage of donor organs, many patients died before they could receive OLT. The recently developed bioartificial liver support system can temporarily replace the complex functions of liver such as synthesis, detoxication and "bridge" the patients with ALF to liver transplantation. To what extent can TECA-I BALSS replace normal liver functions In order to answer the question, we have introduced the basic techniques of a hollow fiber bioartificial liver system, used Chinese experimental miniature swines as the donor of xenogeneic hepatocytes, improved the culturing conditions of porcine hepatocytes in the BALSS, and identified the efficacy and safety of TECA-I BALSS in treating drug-induced ALF canines[3,4]. In the present study, we developed a partial liver resection-induced ALF canine model to assess the efficacy and feasibility of the TECA-I BALSS in treating ALF canines.

MATERIALS AND METHODS

Animal

Nineteen healthy adult hybrid canines weighing 18 kg-22 kg were obtained from the Experimental Center of General Hospital of PLA, and fourteen adult Chinese experimental miniature swines weighing 8 kg-10 kg from the Breed Center of Chinese Agricultural University.

Reagents

All chemicals were provided by Hong Kong TECA Ltd Co. and Sigma Chemical Co.

Development of a canine model of ALF

The canines received eighty percent liver resection. Left lateral, left anterior , right lateral and caudate lobe were removed.

Isolation and culturing of porcine hepatocytes

Hepatocytes were isolated from Chinese experimental miniature swines by collagen ase digestion. Viability of the cells was assayed by trypan blue exclusion and AO/PI fluorescence staining.

BALSS treatment

Freshly isolated hepatocytes were cultured in the TECA-I BALSS provided by Hong Kong Ltd Co. The porcine hepatocytes circulated through the exterior space of capillary hollow fiber in the BALSS. Blood from femoral artery and vein on one side of the ALF canine circulated through the inner space of capillary hollow fiber and the substances exchanged through the membrane of hollow fibers between porcine hepatocytes and ALF blood.

Experimental groups

Nineteen ALF canines were randomly divided into three groups: ① BALSS group (n = 10): perfused with hollow fiber

tube of BALSS containing 1×10^{10} porcine hepatocytes. ② non-hepatocyte BALSS group (control group, $n = 4$): perfused with hollow fiber tube without porcine hepatocytes. ③ drug group ($n = 5$): intravenous injection with arginine, sodium glutamate and branch amino acid. Each treatment lasted six hours.

Biochemical assays

The plasma levels of ammonia, ALT, AST, bilirubin, PT and PA were measured before and 2, 4, 6 hours, 1, 3, 5, 7, 14 and 30 days after treatment.

Immunological assays

The count of lymphocytes, immunoglobulins (IgA, IgG, IgM) and complement (C3, C4)levels were measured before and 7, 14 and 30 days after BALSS treatment.

Morphological observation

The volume of the remnant liver was observed, and the remnant liver, kidneys, heart and lungs were taken out when the canines died or survived for 30 days for paraffin section, and HE stained and examined under light microscope.

Statistical analyses

The values of blood biochemical and immunological parameters were expressed as means±SD. Data of pre- and post-treatment among the three groups were compared using the Chi square test. The differences were considered significant at $P<0.05$.

RESULTS

Development of ALF canine models induced by eighty percent liver resection (Figures 1-6)

The canines demonstrated a significant increase in plasma ammonia, ALT, AST, bilirubin and PT levels, and decrease in PA level 24 hours after oper ation: ammonia (64.52±10.07 μmol/L-128.33±17.32 μmol/L, Figure 1), ALT (14.33±5.12 IU/L-277.04±53 .35 IU/L, Figure 2), AST (16.56±8.91 IU/L-236.06±75.68 IU/L, Figure 3), BIL (5.07±1.56 mmol/L-21.20±3.22 mmol/L, Figure 4), PT (9.68±0.76 s-19.91±1.87 s, Figure 5) and PA (79.16±4.31%-54.66±4.84%, Figure 6). ICG excretion rate of post-operation was lower than that of pre-operation respectively at 5, 10 and 15 minutes (15%, 23% and 30% *vs* 20%, 55% and 76%).

Porcine hepatocytes

Using the modified enzymatic digestive method, each liver yielded approximately $1\text{-}3\times10^{10}$ hepatocytes. Viability of the final suspensions averaged 75%-90% by typan blue exclusion and AO/PI fluorescence staining.

Liver and clotting function recovery of ALF canines after treatment with BALSS

BALSS treatment yielded beneficial effects with decreased plasma ammonia, bilirubin at 2 hours of the treatment, and then returned to normal from 4-6 hours of the treatment. There was an obvious decrease in PT, ALT and AST level and increase in PA level at 7 days after BALSS treatment. In contrast, there were no changes in ammonia, ALT, AST, bilirubin, PT and PA levels for the ALF canines in the control group and drug group. Among seven of ten canines in BALSS group which received one BALSS treatment, only one survived, and six lived an average time of 108.0 h±12.0 h (96 h-120 h). Three often canines received two BALSS treatments, two canines survived, and one died of lung infarction. There was no evidence that BALSS treatment had adverse effects on the morphology of kidneys, lungs and heart. In contrast, four ALF canines in the control group lived an average time of 24.0 h±6.0 h (18 h-50 h). Five ALF canines in the drug group lived an average time of 20.4 h±6.4 h (12 h-28 h).

Immunological changes of ALF canines after BALSS treatment

There were no changes in count of lymphocytes, immunoglobulins (IgA, IgG, IgM) and complement (C3, C4) levels for 3 survived canines.

Morphological changes of remnant liver, kidneys, lungs and heart of ALF canines after treatment with BALSS

The volume of the remnant liver at 30 days after treatment became larger than that of ALF canines before treatment. BALSS treatment had no adverse effects on the morphology of kidneys, lungs and heart.

DISCUSSION

Acute liver failure is a kind of severe disease, and no effective clinical therapy is available currently. Since the liver has many complex physiological functions, such as synthesis, detoxication and biotransformation. The current non-bioartificial liver, for example, activated charcoal hemoperfusion and plasma exchange can not replace the liver function completely. It only can clear some middle and small molecule weight substance in circulation. Fortunately, encouraging success of currently developed bioartificial liver support system has been made in the experimental and clinical research. In BALSS, xenogeneic hepatocytes were used to exchange the substance with ALF blood so that it can temporarily replace the complex liver functions.

BALSS is made of biological and synthetic materials. The main biological material is hepatocytes which include human liver tumor cell lines[5,6], human embryo[7] and porcine hepatocytes[8]. There are possible dangers of the tumor cells to receptors and the scarce of the embryonic liver cells which hinders the application of BALSS, we therefore selected the pure strain Chinese experimental miniature swine as the source of hepatocytes in our experiment. Using modified enzymatic digesting and culturing method, we acquired a large quantity of porcine hepatocytes to meet the needs of BALSS. Porcine hepatocytes 1-3×10^{10} could be acquired from one swine liver, and the viability of hepatocytes reached 75%-90%. Hollow fiber tube is the main synthetic material in which hepatocytes are cultured and exchange substance with ALF blood through semipermeable membrane. A surgical model of acute liver failure is preferred to a toxic model, because it is more reprodu cible and induces only liver damage. In our study, we developed a subtotal hepatectomy induced ALF canine model. Twenty-four hours after operation, the blood hepatic biochemiscal parameters had obvious changes. The ALF canines died within 36-52 hours without treatment. The ALF canine model had a good reproductivity and could suit the studies of BALSS.

One of the most striking observations from the present work is that the ammonia l levels of the ALF canines in BALSS group were lowered dramatically at 2 hours of the treatment, and then returned to normal from 4-6 hours of the treatment. In contrast, there were no changes in the ammonial level for the ALF canines in the control group and drug group. The result indicated that ammonia could move through the semipermeable membrane of hollow fiber tube and was metabolized by porcine hepatocytes through urea cycle enzymes and glutamine synthetase. Significant decreases in plasma bilirubin levels after BALSS treatment were observed and demonstrated that porcine hepatocytes cultured in BALSS could accelerate metabolism of bilirubin in ALF blood. It was reported that hyperbilir ubinemia in animals had been corrected by microencapsulated hepatocyte transplantation.

Results of a phase I clinical trial of BALSS treatment showed that more than two BALSS treatments could clear the toxins in ALF blood completely and provide sufficient metabolic, liver functional support[9,10]. Our experiment indicated that the survival rate of ALF canines that received two BALSS treatments was higher than that of ALF canines that received only one BALSS treatment. Certainly the ultimate goal of a liver support treatment is to treat patients early enough and repeatedly to allow them to regenerate their livers and recover normal liver function.

Although in the development of a bioartificial liver, the use of hepatocytes from xenogeneic origin is the most promising alternative for human hepatocytes due to the shortage of human donor material, potential immunological problems may arise. The central unit of TECA-I BALSS is the so-called bioreactor (hollow fiber tube) which is divided into two sets of compartment by semipermeable membrane: extracapillary and intracapillary compartment. The semipermeable membrane is set such that those substances which are metabolized, detoxified, or synthesized can readily cross the membrane. However, blood cells and hepatocytes should not cross the reactor membrane. In our experiment, in the 3 survived canines, there was neither change in the count of lymphocytes, immune proteins (IgA, IgG, IgM) and supplementary (C3, C4) levels and nor pathological change in kidneys, remnant liver, lungs and heart after BALSS treatment.

On one hand, porcine hepatocytes cultured in BALSS can provide directly liver functional support, and on the other hand, hepatocytes can produce some proteins such as growth factors, and stimulate liver regeneration. Hepatocytes transpla nted into the spleen of rats could reverse the neurologic disorders associated with hepatic encephalopathy[11]. Thus, it is likely that both mechanisms direct action of hepatocytes cultured in BALSS and indirection stimulation of native liver are

involved[12].
